Background: The finding of hydronephrosis by renal ultrasound has been suggested to predict the presence of Vesicoureteral Reflux (VUR). A review of published data has shown conflicting results. We hypothesized that in patients with VUR grade IV or V, hydronephrosis will be found, if the patient does have a full bladder during the renal ultrasound examination.

Methods: This retrospective study included 837 patients, median age 1.3 years with a range of 0-18.7 year, 569 female and 268 male patients. Each patient underwent at least one voiding cystourethrogram (VCUG) and one renal ultrasound examination. On renal ultrasound, particular attention was paid to the presence of hydronephrosis and bladder filling status in patients with VUR grade IV or V.

Results: Sensitivity and specificity for the renal ultrasound showing hydronephrosis to detect the presence of VUR grades IV and V were 60 % and 92 %, respectively. Positive predictive value (PPV) and negative predictive value (NPV) were 74 % and 87 %, respectively. The Breslow-Day test for the homogeneity of the odds ratios supports the hypothesis that odds ratios differ by VUR grade , with more severe VUR associated with a stronger hydronephrosis/full bladder relationship ($p=0.045$). It also supports the hypothesis that odds ratios differ by bladder status, with a full bladder associated with stronger hydronephrosis and severe VUR relationship ($p=0.046$)

Conclusions: Hydronephrosis will be likely observed on a renal ultrasound examination in the presence of a full bladder, in patient with VUR grade IV or V.

TH-PO371

Inpatient Healthcare Utilization for Hemolytic Uremic Syndrome in the U.S.A. Hyunjung Stella Shin,[1] Brian Becknell,[1] John D. Mahan,[2] David S. Hains.[2] *[1]Pediatrics, Nationwide Children's Hospital, Columbus, OH; [2]Pediatrics, Division of Nephrology, Nationwide Children's Hospital, Columbus, OH.*

Background: Hemolytic uremic syndrome (HUS) is a leading cause of pediatric acute renal failure. In this study, we evaluated the demographics and economic impact of inpatient hospitalizations for HUS in the U.S.A, and determined the specific effect of extrarenal comorbidities and procedures on length of stay (LOS).

Methods: We analyzed 2276 pediatric HUS admissions, using the Kids' Inpatient Database of the Healthcare Cost and Utilization Project, from 1997, 2000, 2003, and 2006. Admissions with a primary diagnosis of HUS were identified by ICD-9 code. Patient sex, age, LOS, hospital charges, comorbidities and procedures were evaluated.

Results: 60.7% (1326) of admissions were for children 1-4 years old, and 56.7% (1284) of admissions were for female patients. Mean LOS was unchanged over the period of study (10 ± 0.7 days), and hospital charges increased 2.1-fold, from $29,605 ± $3,460 to $62,960 ± $5,957. Among extrarenal comorbidities, pancreatitis notably occurred in 10.5% of admissions and was associated with increased LOS (20.4 ± 2.8 days). Increased LOS was also noted with gastrointestinal hemorrhage (15 ± 3.5 days) and respiratory insufficiency (26.1 ± 3.7 days). Among procedures, admissions requiring dialysis (19%) were associated with increased LOS (18.4 ± 1.5 days). Red blood cell (RBC) transfusion was associated with decreased LOS (6.4 ± 0.4 days).

Conclusions: Our results demonstrate multiple novel findings: (1) We identify sex-skewing among pediatric HUS admissions, with a female predominance. (2) There has been no reduction in LOS for HUS over the study period, despite rising hospital charges. (3) Extrarenal comorbidities – particularly pancreatitis and respiratory insufficiency – significantly impact LOS. This highlights the need to aggressively identify and manage extrarenal comorbidities in patients with HUS. (4) The potential association between RBC transfusion and decreased LOS is consistent with studies recommending isotonic fluid resuscitation in HUS patients and merits further evaluation.

TH-PO372

Low Utilization of Growth Hormone Therapy in Children with Short Stature in the CKiD Cohort Amira Al-Uzri,[1] Hilary M. Hotchkiss,[2] Ora Yadin,[2] Michael F. Schneider,[2] Laurence A. Greenbaum,[2] Frederick J. Kaskel,[2] Susan L. Furth,[2] Bradley A. Warady.[2] *[1]Oregon Health & Science University, Portland, OR; [2]CKiD Study Group.*

Background: Growth hormone (GH) improves growth velocity in children with chronic kidney disease (CKD), but multiple studies have demonstrated underutilization of GH in children with CKD and short stature (SS). We describe the rate of utilization of GH and risk factors for underutilization in the multicenter, Chronic Kidney Disease in Children (CKiD) cohort study.

Methods: This is a cross sectional baseline analysis of 135 participants at enrollment. SS was defined as height SDS <-1.88 for age and gender. 63 subjects had SS and were not on GH and 72 were on GH (24 also had SS). Demographic data and iohexol GFR were obtained on all subjects. The two groups were compared using X^2 tests for categorical variables or Wilcoxon rank-sum tests for continuous variables.

Results:

Characteristics *	SS and no GH use (N=63)	GH use (N=72)	p-value
Age, y			0.418
Age1-<6 y	24% (15)	29% (21)	
Age 6- ≤ 10 y	25% (16)	26% (19)	
Age > 10 y	51% (51)	44% (32)	
Male	51% (32)	63% (45)	0.170
White Race	65% (41)	75% (54)	0.208
Age-gender specific Height SDS	-2.31 (-2.85, -2.03)	-1.51 (-2.28, -0.59)	<0.001
Glomerular etiology of CKD	17% (11)	8% (6)	0.111
Tanner Stage II-V	34% (21)	25% (17)	0.221
Iohexol GFR , ml/min/1.73m²	39.6 (30.1 - 50.0)	33.7 (28.3 to 40.3)	0.009
Family income > $75,000/y	27% (16)	28% (19)	0.872
Maternal education, high school or higher	45% (27)	60% (42)	0.088
Private Health Insurance	44% (27)	52% (36)	0.368

* Median (inter-quartile range) or % (n)

Conclusions: SS in children with CKD is frequently not treated with GH. This is not due to advanced pubertal maturation since most untreated children are Tanner stage 1. The association of GH usage with lower GFR and with higher maternal education may reflect an increased focus on growth as GFR declines and an increased access to resources or more concern about SS, respectively. Longitudinal analysis of this cohort may yield better understanding of the risk factors for GH underutilization, and the medical and psychosocial impact of low GH utilization.

TH-PO373

Long-Term Maintenance of Efficacy with Losartan in Children with Proteinuria: Results of a Randomized Controlled Trial Nicholas J. Webb,[1] Shahnaz Shahinfar,[2] Thomas G. Wells,[3] Rachid Massaad,[4] Gilbert Gleim,[5] Emanuela P. Santoro,[5] Christine McCrary Sisk,[5] Chun Lam.[5] *[1]Royal Manchester Children's Hospital, Manchester, United Kingdom; [2]S. Shahinfar Consulting, Inc., Newton Square, PA; [3]University of Arkansas for Medical Sciences, Little Rock, AR; [4]MSD, Brussels, Belgium; [5]Merck, Whitehouse Station, NJ.*

Background: Reducing proteinuria is a key treatment goal in children with CKD. In a 12-week, double-blind, multinational study, losartan significantly lowered proteinuria compared with placebo and amlodipine and was well tolerated in children aged 1-17 y. The aim of the present open-label, extension phase of this study was to assess the long-term efficacy and tolerability of losartan versus enalapril after 3 y of treatment.

Methods: Patients who had completed the 12-week core study were re-randomized to remain on losartan or start enalapril, and followed for proteinuria and renal function. The extension study continued until 100 patients completed 3 y of follow up.

Results: A total of 268 patients were randomized in a 1:1 ratio to losartan (0.30 to 4.42 mg/kg/d) or enalapril (0.02 to 1.13 mg/kg/d). After 3 y of treatment, the LS mean percent reduction from baseline in the urinary protein/creatinine ratio was 30.3% in the losartan group vs. 41.7% in the enalapril group [geometric mean ratio (95% CI) = 1.2 (0.9, 1.6)] and the LS mean change from baseline in GFR was 3.3 ml/min/1.73m² in the losartan group versus 7.0 ml/min/1.73m² in the enalapril group [treatment difference (95% CI) = -3.8 ml/min/1.73m² (-15.2, 7.6)]. The adverse event (AE) incidence was relatively low, including that of hyperkalemia (3.0% on losartan vs. 6.7% on enalapril) and renal dysfunction (8.2% on losartan vs. 6.7% on enalapril), and comparable in both treatment groups. Fewer drug-related AEs occurred in the losartan group than in the enalapril group (6.0% vs. 11.2%, respectively).

Conclusions: In children aged 1-17 y with proteinuria, losartan and enalapril significantly reduced proteinuria, an effect that was maintained for the entire 3-y study period. Both losartan and enalapril were generally well tolerated.

TH-PO374

Vesico-Ureteral Reflux as a Risk Factor for Acute Pyelonephritis and Renal Damage in Children with UTI: Systematic Review and Meta-Analysis

Sandrine Leroy,[1,2] Justine Bacchetta,[3] Pierre Cochat,[3] Reynaldo Espindola.[2] *[1]Centre for Statistics in Medicine, University of Oxford, United Kingdom; [2]Unité de Maladies Infectieuses et Émergentes, Institut Pasteur, Paris, France; [3]Centre de Référence des Maladies Rénales Rares 'Néphrogone', Hôpital Femme Mère Enfant, Lyon, France.*

Background: Urinary tract infection (UTI) is one of the most common bacterial infections in childhood. UTI may result in renal scarring (RS), and vesicoureteral reflux (VUR) may be a risk factor for both acute pyelonephritis (APN) and RS that predisposes to long-term complications. However, which imaging should be performed after UTI is strongly debated, and part of the debate is due to the remained question of the true relationship between VUR, and both APN and RS. Recently, two meta-analyses found conflicting results, because of important missing studies, and pooling together APN and RS. We aim to update the meta-analysis and study if VUR is a risk factor for APN, and RS.

Methods: A systematic review and meta-analysis was performed according to the CDR guidelines. All studies of children with UTI, DMSA scan and cystography, were identified by a systematic electronic search in MedLine, and Embase, until 2011. Pooled estimates were calculated using DerSimonian and Laird random-effects model.

Results: From the 1558 potentially relevant articles, 80 were included, representing 11,410 children; children had a first UTI in 53 (66%) studies; 48 (60%) studies were prospective, and in 15 (19%) children underwent both early and late DMSA scan. At all, 6,681 children with an early scan were included, and 5,879 with a late scan. All-grade VUR was significantly associated to both APN (OR=2.0; 95%CI: 1.8-2.3) and RS (OR=4.8; 95%CI: 4.3-5.5). High-grade (≥3) was also significantly related to APN (2.4; 95%CI: 1.9-3.1) and RS (OR=5.7; 95%CI: 4.5-7.3). Pooled estimates were found with heterogeneity, partly explained by the delay between UTI and late DMSA scan, and by the number of UTI.

Conclusions: Children with VUR had a higher risk of APN and RS. These data suggest that identification of VUR can be a practical method of identifying children who are at risk for renal scarring.

End Stage Renal Disease Health-Related Quality of Life in Korean Children

Min Hyun Cho,[1] IL-Soo Ha,[2] Hee Gyung Kang,[2] Young Seo Park,[3] Yoon Jung Lee.[3] *[1]Pediatrics, Kyungpook National University Hospital, Daegu, Korea; [2]Pediatrics, Seoul National Univerisity Children's Hospital, Seoul, Korea; [3]Pediatrics, Asan Medical Center, Seoul, Korea.*

Background: Health-related quality of life (HRQOL) is very important issue in children with end stage renal disease (ESRD) and their family. Moreover, this problem can maintain all their life long. We performed the cross-sectional investigation of HRQOL in Korean children undergoing renal replacement therapies such as dialysis, renal transplantation due to ESRD.

Methods: We used the Korean version of PedsQL 4.0 Generic Core Scales and PedsQL 3.0 ESRD module simultaneously and compared differences of HRQOL score between various clinical characteristics including gender, age, dialysis modality, socioeconomic status of patient's parents. Ninety two pediatric patients with ESRD aged 2-18 year old were enrolled in four Korean university hospitals.

Results: Male: Female ratio was 44:48 and most common cause of ESRD was chronic glomerulonephritis. Fifth five children have been treated by dialysis (mean age: 12.47 years-old) and thirty seven children received renal transplantation (mean age: 11.57 years-old). On parent proxy-report, three scales including About My Kidney Disease Scale, Treatment Problems Scale, and Perceived Physical Appearance Scale showed significantly higher HRQOL in children with a renal transplant than children receiving dialysis. However, on child self-report, there was no statistically significant difference of HRQOL score between treatment modalities. There was also no significant difference of HRQOL score according to age and gender. Child self-report showed significantly lower HRQOL in three scales including General Fatigue Scale, Family and Peer Interaction Scale, Worry Scale than that of parent proxy-report. Children on peritoneal dialysis self reported significantly higher QOL than children on hemodialysis.

Conclusions: QOL should be evaluated in all children with ESRD to support more favorable growth and development as well as disease problem. The PedsQL 3.0 ESRD Module may be useful as an ESRD-specific instrument to evaluate HRQOL in Korean children and larger, longitudinal prospective study is needed.

TH-PO376

ERA-EDTA Registry and European Alport Registry: Prognosis on Renal Replacement Therapy and Improvement of Life-Expectancy in Alport Patients as Well as in Heterozygous Carriers

Johanna Temme,[1] Anneke Kramer,[2] Kitty J. Jager,[2] Gerhard A. Mueller,[1] Oliver Gross.[1] *[1]Nephrology&Rheumatology, University of Goettingen, Germany; [2]ERA-EDTA Registry, Academic medical center/ERA-EDTA-Registry, Amsterdam, Netherlands.*

Background: The hereditary renal disease Alport Syndrome (AS) is caused by mutations of type IV collagen genes. AS leads to an impaired function of the glomerular basement membrane progressing to end stage renal disease (ESRD). Heterozygous carriers also have a relatively high risk to develop ESRD.

Methods: We used data from 11 European countries providing data to the ERA-EDTA Registry to compare Alport males on renal replacement therapy (RRT, dialysis as well as transplanted patients) with age-matched males with other renal diseases. Furthermore, we used data from the European Alport Registry to analyze the effects of a preemptive RAAS-blockade (ACE-inhibitor or ARB) regarding age at start of RRT and life expectancy in Alport patients and in heterozygous carriers.

Results: ERA-EDTA registry data showed better patient survival for Alport males on RRT when compared to age-matched males with other diseases; furthermore, kidney graft survival was found to be better in transplanted Alport patients . The age at start of RRT of Alport patients tended to increase somewhat sharper after the year 2000 compared with the 1990s. Alport registry data show a better life-expectancy in Alport patients who received RAAS-blockade before onset of RRT. Both results (better life-expectancy and delayed start of dialysis) also apply for heterozygous Alport carriers in the Alport registry.

Conclusions: a. Data from two different independent registries support our hypothesis that pre-emptive RAAS-blockade may delay ESRD in Alport patients . b. Alport carriers also seem to profit from RAAS-blockade. This should increase alertness for oligosymptomatic patients with microhematuria as possible heterozygous carriers for autosomal Alport mutations (1% of total population). c. Life expectancy of Alport patients with ESRD might be better than that of patients with other renal diseases.

TH-PO377

Performance of Two Strategies for Urgent ANCA and Anti-GBM Analysis in the Diagnosis of Suspected Severe Small Vessel Vasculitis

Anoek A.E. Joode,de, Caroline Roozendaal, Marcel Van der Leij, Laura Bungener, Johannes S. Sanders, Coen A. Stegeman. *University Medical Center Groningen, Groningen, Netherlands.*

Background: In acute situations, patients suspected of small vessel vasculitis (SVV) may benefit from rapid and reliable testing for ANCA and anti-GBM antibodies. We analysed the diagnostic performance of two rapid methods for assessing the presence of ANCA and anti-GBM in a cohort of severly ill patients with suspected SVV and compared the results with capture ANCA ELISA

Methods: Between Jan 2003 and Nov 2010, we received 260 requests for urgent analysis of ANCA and anti-GBM. These samples were analyzed by qualitative Dotblot (Biomedical Diagnostics) for PR3-, MPO-ANCA and anti-GBM. Routine IIF and ELISA were performed afterwards. We retrospectively analyzed these samples with the novel high sensitive automated Phadia EliA $PR3^s$ and MPO^s and anti-GBM EliA. Results were related to the final clinical diagnosis and compared with our routine ELISA.

Results: In 74 of 260 patients (28%) a final diagnosis of AAV (n=62) or anti-GBM disease was made (n=12).

Both Dotblot and EliA detected all 12 cases of anti-GBM disease (sensitivity 100%, negative predictive value (NPV) 100%). Both methods found one false positive (specificity 99%) resulting in a positive predictive value (PPV) of 93%.

Dotblot detected anti-PR3 or anti-MPO in 55 of 62 AAV-patients (sens 89%, NPV 96%), but showed 6 false positives (spec 97%, PPV 90%). The Phadia EliA $PR3^s$ or MPO^s was positive in 58 of 62 AAV- patients (sens 94%), and had 9 false positives (spec 95%), resulting in a PPV of 87% and a NPV of 97%. The false positives in the Dotblot or ELIA were diagnosed with f.e TIN, sarcoidosis and IgA-nephropathy. Our standard ELISA was equally accurate as EliA and slightly more accurate than dotblot due to less false positives (sens of 94 %, spec of 97%, PPV of 91%, and NPV of 98%).

Conclusions: The Dotblot and Phadia EliA on GBM^s ,$PR3^s$ and MPO^s performed excellent in our cohort of patients clinically suspected of AAV or anti-GBM disease in whom urgent testing was ordered. As results are almost identical to ELISA, we concluded that both tests are very powerful tools for a rapid serological diagnosis.

TH-PO378

Bleeding Complications of Native Kidney Biopsy: A Systematic Review and Meta-Analysis

Kristin Marie Corapi,[1] Joline L.T. Chen,[2] Craig E. Gordon.[2] *[1]Medicine, Boston University, Boston, MA; [2]Renal Section, Department of Medicine, Boston University, Boston, MA.*

Background: Kidney biopsy provides important information for nephrologists but the risk of complications has not been systematically described. We studied the rate of macroscopic hematuria and erythrocyte transfusion following native kidney biopsy with real-time ultrasound guidance and a spring-loaded biopsy device using meta-analysis.

Methods: A PubMed search was conducted using MeSH terms "biopsy" and "kidney" with subheadings "complications" and "adverse effects" from January, 1980 through December, 2010. Retrieved abstracts were reviewed for inclusion using pre-

specified criteria. Random effects meta-analysis was used to determine the complication rates following kidney biopsy. Subgroup analysis was used to identify predictors of complications.

Results: 2327 studies were reviewed with 32 selected for analysis. The overall rate of macroscopic hematuria was 3.9% (95% CI, 2.8-5.4%) and transfusion was 1.5 % (1.0-2.2%). Significantly higher rates of transfusion were seen with the following factors: 14 gauge needles when compared with smaller needles (3.5% vs. 1.1%, p<0.001), studies with ≥ 50% women (3.4% vs. 1.1%, p=0.003), and with ≥ 10% of biopsies for acute kidney injury (1.5% vs. 0.4%, p=0.005). Higher transfusion rates were also observed in studies with mean creatinine ≥ 2.0 mg/dl (2.4% vs. 0.9%, p=0.054) and mean age ≥ 40 years (1.7% vs. 0.6%, p = 0.067). Similar but non-significant relationships were noted in the macroscopic hematuria rate with the same predictors. Other factors such as number of needle passes and coagulation and platelet parameters were not associated with either outcome.

Conclusions: Native kidney biopsy using spring-loaded device and real-time ultrasound is associated with a small risk of macroscopic hematuria and transfusion requirement. Using a smaller gauge needle may lower complication rates. Patient selection may affect outcome as studies with more women, older patients, higher creatinine, or acute kidney injury had higher complication rates. Future studies are required to further evaluate the risk factors for complications.

TH-PO379

Development of an Outpatient Native Kidney Biopsy Service Gearoid M. McMahon,[1] Molly McGovern,[1] Vanesa Bijol,[2] Julie Lin.[1] *[1]Division of Nephrology, Brigham and Women's Hospital, Boston, MA; [2]Department of Pathology, Brigham and Women's Hospital, Boston, MA.*

Background: In the U.S., native kidney biopsies are usually inpatient procedures. We developed an outpatient biopsy protocol for low-risk pts and assessed its safety and efficacy.

Methods: Pts referred for biopsy were reviewed by the nephrology service director and deferred if they had SBP>140 mmHg, BMI >35 kg/m² or took anticoagulants, ASA or NSAIDS in the preceding 7 days. Under real-time ultrasound guidance, biopsies were performed using a Boston Scientific 16G spring-loaded needle that was changed to a Bard 14G needle in Oct 2009. Vital signs and urine voids were monitored in an outpatient observation unit; CBC was sent 4 hrs after the procedure. Pts were discharged after 5 hrs of strict bedrest if there were no signs of bleeding, and complications were tracked carefully.

Results: Between Nov 2008 and Apr 2011, 105 pts (56 male) underwent outpatient biopsies. Mean age was 49±16 yrs. A 16G needle was used in 43 pts (Group A) and a 14G was used in 62 (Group B). A median of 25 (4-64) glomeruli were obtained in Group A vs. 39 (10-107) in Group B (p<0.001). One pt in each group had insufficient tissue for diagnosis. Complications requiring admission were noted in 7 pts (16%) in Group A vs. 5 pts (8%) in Group B (p=0.22). Most were minor (gross hematuria, perinephric hematoma, fall in Hb) and did not require any intervention. One pt in Group B had clinically significant bleeding in the setting of persistent hypertension that was treated with embolization. Of the 12 pts with procedural complications, 8 experienced these during the 5-hour observation period while 4 pts presented >48 hours after biopsy. The mean fall in Hb was 0.5 g/L in Group A vs. 0.6 g/L in Group B (p=0.29).

Conclusions: In a carefully selected population of pts, outpatient renal biopsy is safe with low complication rates. The majority (75%) of complications occurred during the observation period. The remainder occurred after 48 hours and thus an overnight admission would not have altered management. Importantly, the routine use of a 14G biopsy needle resulted in a greater yield of glomeruli compared to a 16G needle without increased complications.

TH-PO380

Non-Invasive Evaluation of Kidney Hypoxia and Fibrosis Using MRI Tsutomu Inoue,[1] Eito Kozawa,[2] Hirokazu Okada,[1] Tsuneo Takenaka,[1] Hiromichi Suzuki.[1] *[1]Nephrology, Saitama Medical University, Iruma-gun, Saitama, Japan; [2]Diagnostic Radiology, Saitama Medical University International Medical Center, Hidaka, Saitama, Japan.*

Background: Interstitial fibrosis and hypoxia are 2 major complications that accelerate the CKD progression. However, these factors have not been sufficiently evaluated in CKD patients because of the lack of appropriate clinical tools. In this study, we evaluated whether 2 magnetic resonance imaging (MRI) techniques—diffusion-weighted (DW) MRI and blood oxygen level-dependent (BOLD) MRI—could be used to determine kidney fibrosis and hypoxia. Last year, we reported that a decreased eGFR was accompanied by reduced apparent diffusion coefficient (ADC) values, as observed on DW MRI. Additionally, BOLD MRI indicated hypoxia, as determined from the decreased T2* values, in advanced renal dysfunction patients with non-diabetic nephropathy but not in patients with diabetic nephropathy.

Methods: In this study, we examined (1) the reproducibility of DW and BOLD MRI techniques, (2) the effect of kidney size on ADC and T2* values, and (3) the relationship between the ADC values and the degree of interstitial fibrosis in renal biopsy specimens.

Results: We found that (1) the degree of variability for both T2* and ADC values was approximately 4% in the same subject (T2*: 4.08 ± 3.33%, ADC: 4.18 ± 2.75%); (2) the kidney size positively correlated with the eGFR, ADC, and T2* values (r = 0.57, 0.29, and 0.52, respectively) in non-diabetic CKD patients, whereas in patients with diabetic nephropathy, the renal size weakly correlation with the ADC values (r = 0.31), and the T2* values were completely independent of the renal size (r = 0.24); and (3) the percentage of fibrotic area in the renal biopsy specimens significantly correlated with not only the ADC, but also the T2* values (r = 0.69 and 0.48, respectively).

Conclusions: Thus, we conclude that the renal size reflects the degree of interstitial fibrosis, which can be evaluated by measuring the ADC values by using DW MRI. Smaller kidneys have more severe interstitial fibrosis, lower ADC values, and decreased eGFR. The functional MRI values showed a good correlation with the pathological and physiological characteristics of the kidney.

TH-PO381

Reference Ranges and Biological Variability of Kidney Injury Biomarkers Sushrut S. Waikar,[1] Venkata Sabbisetti,[1] Thanh Thu T. Ngo,[1] Julie A. Berkley,[1] Mark Radlinski,[1] Joseph V. Bonventre,[1] Rebecca A. Betensky, Philip L. De Jager. *[1]Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Biostatistics, Harvard School of Public Health, Boston, MA.*

Background: Urinary biomarkers of tubular injury may improve early diagnosis and aid clinical management of individuals with acute and chronic kidney diseases. In order for biomarkers to be used clinically it is important to define normal clinical reference levels and biological variability.

Methods: We collected urine samples from 90 community-dwelling healthy volunteers aged 18 to 52y (median 33.5y, 55% female). Twenty percent were black, 21% Asian or other, and 58% white. Fifty-one of the volunteers provided one or two repeat subsequent urine samples within one year. All urine samples were non-fasting, second-void (or later) morning samples. Urine samples were immediately refrigerated at 4C and then within 4h centrifuged at 3200 rpm for 5 min after which aliquots of the supernatant were stored at -80C and tested within 12 months (mean, 6 months). We measured urinary levels of kidney injury molecule-1 (KIM-1), N-actetyl-β-D-glucosaminidase (NAG), and neutrophil gelatinase-associated lipocalin (NGAL), each normalized to the urinary creatinine concentration. Coefficients of variation were < 15% for each biomarker. We examined associations between biomarkers and age, race, sex, body mass index, and blood pressure. Statistical techniques included random effects models with a random effect for each subject and the Spearman correlation coefficient.

Results: The median (range) concentrations were: KIM-1, 0.23 ng/mg creatinine (0.02 – 0.98); NGAL, 7.5 ng/mg (0.06 – 53.50); NAG, 1.39 U/g (0.45 – 4.90).

KIM-1 levels were lower in blacks by 0.17 ng/mg (P=0.005). NAG levels correlated positively with age (R = 0.41, P < 0.0001) and were higher in Asians by 0.13 U/g. NGAL levels were higher in females by 0.33 ng/mg. The intra-class correlation coefficients were: KIM-1, 0.76; NAG, 0.58; NGAL, 0.19.

Conclusions: The biological and clinical significance of biomarker variability according to age and race merits further study. Intra-individual variability of NGAL was high, which may have implications for epidemiologic studies.

TH-PO382

Diagnostic Value of Serum κ/λ Free Light Chain Assay for Monoclonal Gammopathy in Renal Insufficiency Patients Jeong-Woo Park, Yeo Kyeoung Kim, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Internal Medicine, Chonnam National University Medical School, Gwangju, Korea.*

Background: Patients with plasma cell disorder (PCD) frequently showed reduced renal function, hence, the differential diagnosis should include PCD in these patients. Serum free light chain (sFLC) κ/λ ratio (rFLC, conventional reference range: 0.26-1.65) was generally used as a screening test for the presence of PCD. Recently, an extended renal reference range of rFLC (0.37-3.17) was proposed for renal failure patients, which seems to have more validated in clinical setting.

Methods: Patients who visited the nephrologists due to renal insufficiency were enrolled (n=538). Nephelometric sFLC quantification in combination with serum (s-PEP), urine protein electrophoresis (u-PEP), and pathologic diagnosis were performed to determine the diagnostic usefulness of sFLC testing in these patients.

Results: Median serum Cr and eGFR were 1.9 mg/dL (ranges; 1.4-21.8) and 31 mL/min/1.73 m² (2-60) (56.9% CKD, 43.1% AKI). Of total 538 patients, 23.4% were diagnosed as PCD. The renal range of rFLC increased sensitivity (87.3% vs. 86.5%) and specificity (95.8% vs. 91.4%) for diagnosis of PCD compared to those with conventional one. The area under the ROC curve in renal range increased from 0.89 (conventional range, 95% CI: 0.85-0.93) to 0.92 (0.88-0.95). rFLC results using renal range were more sensitive to find PCD compared to those of PEP (sensitivity: s-PEP 79.7%, u-PEP 67.8%). Combining renal range rFLC and s-PEP resulted in 97.4% of sensitivity for detecting PCD. In twenty-nine patients with light-chain multiple myeloma (LCMM), rFLC assessment (100% positive) showed higher accuracy in diagnosis compared than those of s- and u-PEP (58.6% and 69.0%).

Conclusions: In summary, sFLC immunoassay is sensitive and specific tool to detect PCD in renal failure patients, especially for LCMM. Extended renal reference range is more sensitive and specific than conventional one. For the screening of PCD in patients with renal impairment, physicians should try to integrate the s-PEP and rFLC results to find the underlying cause of renal insufficiency.

TH-PO383

Impact of Multiple Myeloma and Treatment with G-CSF on U and P-HNL/NGAL Jan Melin, Karin Edberg, Kristina E. Carlson, Bengt C. Fellstrom, Per Venge. *Medical Sciences, Uppsala University, Uppsala, Sweden.*

Background: Renal failure is an important complication of multiple myeloma. In myeloma malignant plasma cells produce monoclonal immunoglobulin (M-component). With treatment the M-component can disappear. The M-component can form casts that obstruct tubular flow, be deposited in the renal tissue and cause amyloidosis. Myeloma can also cause renal injury by secondary mechanisms such as hypercalcemia and dehydration. G-CSF is used for autologous stem cell mobilization in myeloma. HNL/NGAL is a promising biomarker of acute kidney injury. The aim of this study was to investigate whether U or P-HNL/NGAL levels were affected by myeloma.

Methods: We examined 50 patients with myeloma who were either on a scheduled visit to the hematology outpatient unit or were admitted to the hospital for treatment. U and P-HNL/NGAL was measured by a sandwich ELISA. Active disease was defined as significantly rising M-component. Comparisons between groups were made by the non-parametric Mann-Whitney U-test.

Results: P-HNL/NGAL, but not U-HNL/NGAL, was significantly increased in patients on treatment with G-CSF. Bence-Jones proteinuria, M-component or active disease were not associated with elevated HNL/NGAL-levels. As expected P-HNL/NGAL correlated with creatinine levels in plasma.

U and P-HNL/NGAL in myeloma patients

	U-HNL/NGALµg/L			P-HNL/NGALµg/L		
	Yes	No	P	Yes	No	P
G-CSF	55.2±35.3 N=6	34.8±10.9 N=44	NS	192.7±54.2 N=6	41.5±3.6 N=44	<0.001
Bence-Jones proteinuria	48.7±29.5 N=14	32.9±9,0 N=36	NS	51.7±8.8 N=14	62.8±13.2 N=36	NS
M-component in serum	39.7±13.7 N=34	32.1±14.9 N=16	NS	53.4±8.3 N=34	73.1±25.2 N=16	NS
Active disease	57.6±26.8 N=17	26.8±7.4 N=33	NS	47.1±7.7 N=17	66.1±14.2 N=33	NS

Values are means±SEM

Conclusions: We did not find any evidence that myeloma per se affects the levels of U and P-HNL/NGAL. However, G-CSF-treatment was associated with a significant increase in P-HNL/NGAL. These findings make it unlikely that the myeloma itself interferes with the interpretation of U and P-HNL/NGAL in patients with multiple myeloma.

TH-PO384

Effect of Pegloticase (PGL) on Renal Function in Patients with Chronic Kidney Disease (CKD) Faith Debra Ottery,[1] Robert A. Yood,[2] Marsha Wolfson.[1] *[1]Savient Pharmaceuticals, Inc., E. Brunswick, NJ; [2]Fallon Clinic, Worcester, MA.*

Background: CKD is common in gout patients. PGL is FDA-approved for refractory chronic gout. In 2 replicate Phase 3 clinical trials (n=212) conducted to assess efficacy and safety of PGL, 49% had stage 3-4 CKD, defined by the National Kidney Foundation. Using pooled data, we evaluated the impact of up to 6 months of PGL on renal function in these patients.

Methods: Data for 103 subjects were available for analysis: PGL 8mg q2wk (n=42) or q4wk (41) or placebo (20). Renal function was assessed by estimated glomerular filtration rate (eGFR, mL/min/1.73^2) using the 4-variable MDRD formula at screening (Week 0) and Wks 7, 13, 19 and 25 post-randomization. Linear mixed effects (random intercept) model was used to analyze eGFR. Treatment, time, treatment X time, age, sex and race were included as fixed effects; subject was included as a random effect. The random intercept model assumes missing data are random for valid treatment inferences. Basis for discontinuation was reviewed to assess bias effects.

Results: Baseline characteristics: mean age 62±12 years, 67% White and 71% males. Table 1 summarizes mean eGFR over time by randomized treatment group and overall. eGFR at Wk 0 was numerically but not statistically higher in the placebo group. Results of the model suggest that change in eGFR was not differentially affected by treatment (treatment X time interaction: p=0.28), independent of age, sex or race. No discontinuation pattern was observed. Absolute and relative changes from baseline in eGFR for individuals were consistent with overall findings. The most common adverse events: gout flare and infusion reaction.

Conclusions: Patients with refractory chronic gout and stage 3-4 CKD had no adverse renal effects with up to 6 months of pegloticase therapy.

Table 1. Mean (±SD) eGFR over time

Time Point	Pegloticase q2wks(n)	Pegloticase q4wks(n)	Placebo (n)	Overall (n)
Wk 0	40±12(42)	40±13(41)	43±13(20)	41±12(103)
Wk 7	43±14(36)	44±19(36)	43±16(20)	44±16(92)
Wk 13	41±13(36)	40±15(33)	46±16(19)	42±14(88)
Wk 19	44±15(33)	41±15(31)	45±15(19)	43±15(83)
Wk 25	42±11(31)	41±15(30)	47±13(18)	43±13(79)

TH-PO385

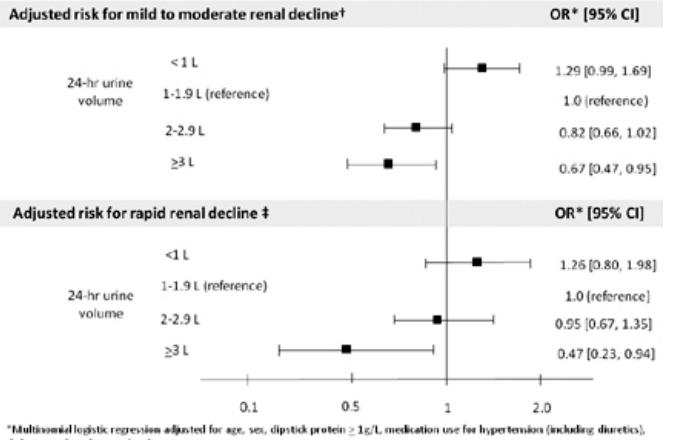
Urine Volume and Renal Decline: Results from a Community-Based Cohort Study William F. Clark,[1,2] Jessica M. Sontrop,[1,2] Jennifer J. Macnab,[1] Rita Suri,[1,2] Louise M. Moist,[1,2] Marina I. Salvadori,[1,2] Amit X. Garg.[1,2] *[1]University of Western Ontario, Canada; [2]London Health Sciences Centre, Canada.*

Background: The effect of increased fluid intake on kidney function is unclear. This study evaluates the relationship between urine volume and change in estimated glomerular filtration rate (eGFR) over six years in a large, community-based cohort.

Methods: Prospective cohort study, Canada (2002-2008). We obtained 24-hr urine samples from adult participants with eGFR≥60 ml/min/1.73m^2 at study entry. Percentage annual change in eGFR from baseline was categorized as average decline <1% per year; between 1% and 4.9% (mild-to-moderate decline) or ≥5% (rapid decline).

Results: A total of 2148 participants provided valid 24-hour urine samples, grouped as <1 L/day (14.5%); 1-1.9 L/day (51.5%); 2-2.9 L/day (26.3%); and ≥3L/day (7.7%). Baseline eGFR for each category of urine volume was 90, 88, 84 and 87 ml/min/1.73m^2, respectively. Overall, eGFR declined by 1% per year, with 10% demonstrating rapid decline and 58% demonstrating mild-to-moderate decline. An inverse, graded relationship was evident between urine volume and renal decline: for each increasing category of 24-hour urine volume, percentage annual eGFR decline was progressively slower from 1.3%, 1.0%, 0.8% to 0.5%, respectively; p=0.02. Compared to those with urine volume 1-1.9 L/day, those with urine volume >3 L/day were significantly less likely to demonstrate mild-to-moderate decline (adjusted odds ratio 0.67; 95% confidence interval: 0.47-0.95) or rapid decline (adjusted odds ratio 0.47; 95% confidence interval: 0.23-0.94); adjusted for age, sex, medication use for hypertension (including diuretics), proteinuria and cardiovascular disease.

Conclusions: In this community-based cohort, decline in kidney function was significantly slower in those with higher vs. lower urine volume.



*Multinomial logistic regression adjusted for age, sex, dipstick protein ≥ 1g/L, medication use for hypertension (including diuretics), diabetes and cardiovascular disease.
†Mild to moderate renal decline: eGFR decline from baseline between 1% and 4.9%.
‡ Rapid renal decline: eGFR decline from baseline ≥5%.

The Effects of Rubber Band Exercise Training with Low Protein Diet on Muscle Mass in Chronic Kidney Disease Patients Burin Laohawatana,[1] Yupa Chanwikrai,[2] Bancha Satirapoj,[1] Ouppatham Supasyndh.[1,2] *[1]Division of Nephrology, Phramongkutkalo Hospital; [2]Biomedical Research and Development Center, Phramongkutklao Hospital, Bangkok, Thailand.*

Background: Chronic kidney disease (CKD) leads to muscle wasting, which may be aggravated by low-protein diets prescribed to delay disease progression. Resistance training is effective to maintain or recover muscle mass and strength. However, it is often difficult to motivate many such patients to undergo exercise training chronically. The objective of the study is to demonstrate the effect of 12 weeks resistance exercise by using rubber band on muscle mass in CKD patients stage 3-5 receiving low-protein diet

Methods: The randomized control trial was conducted in CKD clinic at Phramongkutklao hospital during June to December 2010. The eligible CKD stage 3-5 participants were asked to restrict low protein diet (0.6-0.8 g/kg/day) and randomly assigned to do only gentle exercise (control group) or plus resistance exercise by using rubber band (treatment group) for 12 weeks.The exercise training was supervised and strictly monitored by sport scientist every four weeks. Dual energy absorptiometry was performed to determine lean body mass. The maximum repetition of rubber band exercise was recorded to demonstrate the muscle strength. Daily energy and protein intake were guided using 3-day food record and normalized protein nitrogen appearance.

Results: There were 28 patients (mean age 67.64±9.67 years) in control group and 26 patients (mean age 65.04±12.68 years) in study group. The average dietary protein intake between control and study group was 0.68±0.17 vs. 0.72±0.26 g/kg body weight and daily energy intake was 20.09±5.81 vs. 21.31±6.62 kcal/kg body weight, respectively. There was statistically significant in mean change of total lean body mass in study group (2.45±3.30 vs. 10.79±3.6 g/kg BW, p = 0.006).

Conclusions: Resistance exercise with rubber band is effective in increasing muscle mass in CKD patients with dietary protein restriction.

TH-PO387

Fenoldopam Increases Renal Artery and Parenchimal Blood Flow and Reduces Renal Resistive Index in Hypertensive Patients with Chronic Kidney Disease Roberto Palumbo,[1] Michele Ferrannini,[1] Annalisa Noce,[2] Simone Manca di Villahermosa,[2] Nicola Di Daniele.[2] *[1]Nephrology and Dialysis Department, S.Eugenio Hospital, Rome, Italy; [2]Nephrology and Dialysis Unit, Tor Vergata University, Rome, Italy.*

Background: Fenoldopam mesilate (FM), a short-acting agonist of post-synaptic dopaminergic receptor DA1, is a powerful hypotensive agent reducing systemic arterial resistances at an infusion rate >0.1mcg/kg/min. At infusion rates <0.1mcg/kg/min it seems show renoprotective properties without effect on blood pressure (BP). It could be due to reduced renal vascular resistance (VR) and increased blood flow (BF), as observed in experimental models but not yet in humans. To investigate the effect of <0.1mcg/kg/min FM infusion on renal vascular and parenchimal resistances, renal BF and systemic BP in hypertensive patients with chronic kidney disease.

Methods: Sixty hypertensive patients aged 65,20±14,54 years with CKD (stage I-IV NKDOQI) were enrolled. FM was e.v. infused 0.1mcg/kg/min for 60 minutes. Renal resistive index (RI) and Systolic and Diastolic flow velocity (SF, DF)were recorded by Eco-(color)-Doppler ultrasound, at renal artery origin, mid portion and at renal hylum, before and during FM infusion. BP and heart rate were monitored.

Results: During infusion, both SF and DF were significantly higher than baseline, either at renal artery origin, mid portion and at renal hylum (SF 48,9±11,3 vs. 55,9±15,3cm/sec, p=0,0135; 52,8±9,4 vs. 55,2±12,4cm/sec, p=0,0001; 44,2±9,9 vs. 49,4±10,9cm/sec, p=0,00193; DF 13,84±1,96 vs. 27,69±1,10cm/sec, p<0,001, 14,37±2,67 vs. 27,39±1,53cm/sec, p<0,001, 13,63±… vs. 25,03±5,53cm/sec, p=0,0001, respectively). RI were significantly lower than baseline (0,73±0,05 vs. 0,65±0,06, p<0,0001). BP and heart rate was not significantly affected by infusion. These results were observed in all CKD stages.

Conclusions: Our preliminary data suggest that 0.1mcg/kg/min of FM e.v. infusion increases renal blood flow and reduces RI with no effect on BP and heart rate.

TH-PO388

Long-Term Risks of Hospital Readmission and Death in Patients with Kidney Disease Kenn B. Daratha,[1,2] Robert Short,[2] Katherine R. Tuttle.[2] *[1]College of Nursing, Washington State University, Spokane, WA; [2]Providence Medical Research Center, Spokane, WA.*

Background: Patients with kidney disease are at high risk of hospitalization and death. However, long-term risks of hospital readmission and associated death are unclear. The primary objective of this study was to determine risks of hospital readmission and death in a full-spectrum of patients with early stages of chronic kidney disease (CKD) to end-stage renal disease treated by dialysis or kidney transplant.

Methods: This longitudinal cohort study included persons hospitalized in the State of Washington from Oct 2005 through Dec 2008 (WA-CHARS). Patients who survived their index hospital hospitalization (n=579,381) were classified into 4 cohorts defined by ICD9 diagnostic codes for CKD (n=27,647), dialysis (n=4,884), kidney transplant (n=867), and reference (non-kidney-disease diagnoses, n= 545,983). Primary outcomes were time to hospital readmission and hospital readmission resulting in death. Cox Proportional Hazard models controlling for age, gender, and primary diagnosis were conducted for time-to-event analyses. Analyses were internally validated with bootstrapping techniques.

Results: Risks for hospital readmission significantly increased among patients in the CKD (HR 1.35, 99% CI: 1.32-1.39, p<0.001), dialysis (HR 2.25, 99% CI: 2.15-2.36, p<0.001), and kidney transplant (HR 1.85, 99% CI: 1.65-2.07, p<0.001) cohorts independent of other index hospitalization diagnoses for up to 39 months. Risks for hospital readmission resulting in death were also independently increased for those in the CKD (HR 1.72, 99% CI; 1.63-1.83, p<0.001), dialysis (HR 4.17, 99% CI: 3.80-4.59, p<0.001), and kidney transplant (HR 1.95, 99% CI: 1.37-2.79, p<0.001) cohorts. Risks of readmission and death increased in a graded manner by CKD stage. Internal validation demonstrated ~99 % coverage and unbiased estimates.

Conclusions: Long-term risks of hospital readmission and death for patients with diagnoses of CKD, dialysis, and kidney transplant were among the highest observed in a large, statewide population. Patients with the full-spectrum of kidney disease diagnoses should be a major focus of efforts to reduce hospital readmissions and death.

TH-PO389

Chronic Endothelin-A Receptor Antagonism Modifies Novel Cardiovascular Risk Factors in CKD Neeraj Dhaun. *University of Edinburgh.*

Background: CKD patients have an increased risk of cardiovascular disease (CVD) that is not explained by conventional CVD risk factors alone. Arterial stiffness (AS) and endothelial dysfunction (ED) are features of CKD and may contribute to the CVD with which it is associated. Impairment of the nitric oxide (NO) system may lead to ED/AS. Asymmetric dimethylarginine (ADMA) is an endogenous inhibitor of NO production that promotes vasoconstriction. ADMA concentrations are increased in CKD. Endothelin-1 (ET-1) is a potent endogenous vasoconstrictor that is also upregulated in CKD. Hyperuricemia is another feature of CKD that contributes to ED/AS and so CVD risk. ETA receptor antagonism is a promising novel therapy for proteinuric CKD. Its effects on ADMA, the renal ET system and urate in CKD are not known.

Methods: In a randomized double-blind, 3-way crossover study, 27 subjects with proteinuric CKD received 6 weeks treatment with placebo, sitaxentan 100mg, an ETA antagonist, and nifedipine 30mg. (Dhaun et al Hypertension 2011). Serum urate, ADMA, plasma ET-1 and urine ET-1/creat, as a reflection of renal ET-1 production, were measured at baseline and week 6 of each treatment period alongside the primary endpoints of proteinuria, blood pressure (BP), and AS.

Results: Whereas placebo and nifedipine did not affect urate, ADMA or urine ET-1/creat, sitaxentan reduced all three (baseline vs. week 6 ± SEM – urate: 506±21 vs. 451±22µmol/l, p<0.01; ADMA: 0.52±0.01 vs. 0.48±0.01µmol/l, p<0.0001; urine ET-1/creat: 783±84 vs. 613±81ag/mmol, p<0.01). Plasma ET-1 was unaffected by all treatments. In multivariate analysis, the reduction in proteinuria and BP following sitaxentan treatment was independently predicted by the change in urine ET-1/creat, and the reduction in pulse wave velocity (as a measure of AS) by the change in ADMA.

Conclusions: In addition to currently recognised effects on proteinuria, BP and AS, ETA antagonism may modify novel CVD risk factors and so have broader cardioprotective effects in CKD. Larger and longer-term trials with these specific endpoints are now warranted.

TH-PO390

Effect of Extended-Release Niacin/Laropiprant on Lipid Profiles in Dyslipidemic Stage 3 Chronic Kidney Disease Patients Andrew G. Bostom,[1] Jinyu Zhang,[2] Peter Shorter,[1] Joachim H. Ix,[3] Andrew Tershakovec,[4] Diane Tipping.[5] *[1]Division of Kidney Diseases, Rhode Island Hospital, Providence, RI; [2]Brown Medical School, San Diego, Providence; [3]Division of Nephrology, University of California-San Diego, CA; [4]Merck and Company, Rahway, NJ; [5]; [6]Tipping Consulting LLC, Green Lane, PA.*

Background: Among dyslipidemic patients free of chronic kidney disease (CKD), extended-release niacin (ERN) at 2 g/d causes beneficial lipoprotein-modifying effects. Given the paucity of data regarding niacin's impact on dyslipidemia in CKD, we examined the drug's effect on the standard lipid profiles of patients with stage 3 CKD.

Methods: Subjects (n=261) with a baseline estimated glomerular filtration rate (eGFR) of 30 to < 60 ml/min/1.73 m^2 were drawn from two completed trials of extended-release niacin/laropiprant (ERN-L, laropiprant being an inhibitor of ERN-mediated flushing; ERN-L at 2g/d, n=177; n=84 placebo [P]). Lipid profiles were measured serially over 24-weeks.

Results: The ERN-L and P groups were comparable with respect to baseline mean age, eGFR, total cholesterol (TC), low density lipoprotein-C (LDL), high density lipoprotein-C (HDL), and triglyceride (TG) levels, as well as the distribution of gender, concurrent statin use, and diabetes. Repeated measures analyses revealed that ERN-L, relative to P, caused a decrease (95% CI) of -22.5% (-16.0%, -29.1%) in mean LDL, - 9.1% (-12.7%, -5.5%) in mean TC, and – 28.0% (-43.5%, -21.8%) in median TG, as well as an increase of +28.7% (+23.7%, +33.7%) in mean HDL levels. Stratified analyses revealed that these effects were entirely consistent with what was observed among dyslipidemic patients whose eGFR was ≥ 60 ml/min/1.73 m^2.

Conclusions: ERN-L results in very favorable lipid changes among patients with stage 3 CKD. Till now, stage 3-4 CKD patients have been significantly under-represented in secondary cardiovascular disease prevention trials. We conclude that a niacin treatment arm merits serious consideration within any future clinical trials targeting stage 3-4 CKD patients for the potential reduction of cardiorenal outcomes.

TH-PO391

The Association of Cardiac Concentricity with Kidney Function Decline: Data from the Multi-Ethnic Study of Atherosclerosis (MESA) Meyeon Park,[1] Michael Shlipak,[1,2] Ronit Katz,[3] Subhashish Agarwal,[4] Joachim H. Ix,[5] Chi-Yuan Hsu,[1] Carmen A. Peralta.[1] *[1]UCSF, San Francisco, CA; [2]SF VA Medical Center, CA; [3]Univ. of Washington, Seattle, WA; [4]Oakwood Hospital, Dearborn, MI; [5]UCSD, San Diego, CA.*

Background: Chronic kidney disease (CKD) is strongly associated with heart failure (HF), and HF is associated with faster kidney function decline. Whether subclinical abnormalities of cardiac structure are associated with kidney function decline is not known.

Methods: We included 3866 individuals in MESA (39% white, 25% black, 23% Hispanic, 13% Chinese), free of known cardiac disease, with estimated glomerular filtration rate (eGFR)>60 ml/min/1.73m^2 at baseline and at least 2 measures of kidney function over 5 years of follow-up. Concentricity was assessed by magnetic resonance imaging and calculated as left ventricular (LV) mass over LV end diastolic volume. eGFR was assessed by cystatin C (eGFRcys) and creatinine (eGFRcr). Using multivariate linear mixed models, we investigated the association of concentricity with kidney function decline; covariates included demographics, systolic blood pressure, diabetes, inflammatory markers (HDL, IL-6, CRP), and albuminuria.

Results: Mean (SD) age was 60 (10) years; mean eGFRcys at baseline 97 (16) ml/min/1.73m^2; mean decline per year -1.11 (4.26) by eGFRcys and -1.53 (2.86) by eGFRcr. Higher concentricity was independently associated with faster rates of eGFR decline, based on cystatin C or creatinine.

Decline in eGFR among MESA participants without CKD

Quartiles of Concentricity (g/ml)	N	eGFRcys*	eGFRcr*
		β (95% CI)	β (95%CI)
<0.95(F);<1.06(M)	966	Ref.	Ref.
0.95-1.06(F);1.06-1.17(M)	967	-0.17 (-0.38, 0.05)	-0.19 (-0.33, -0.04)
1.07-1.20(F);1.18-1.35(M)	967	-0.11 (-0.33, 0.11)	-0.22 (-0.37, -0.07)
>1.20(F);>1.35(M)	966	-0.52 (-0.74, -0.29)	-0.57 (-0.73, -0.41)
Per SD change concentricity (SD 0.24)	3866	-0.17 (-0.25, -0.09)	-0.20 (-0.25, -0.14)

*fully adjusted

Conclusions: Subclinical alterations in cardiac structure are associated with kidney function decline independent of the effects of hypertension and other comorbidities. Future studies should focus on elucidating mechanisms to explain these associations.

TH-PO392

Angiopoietin-Like Protein 2 Is Associated with Chronic Kidney Disease in a General Japanese Population: The Hisayama Study Tomoko Usui,[1,2] Toshiharu Ninomiya,[1,2] Masaharu Nagata,[1,2] Takanari Kitazono,[2] Yuichi Oike,[3] Yutaka Kiyohara.[1] *[1]Department of Environmental Medicine, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [3]Department of Molecular Genetics, Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Japan.*

Background: Angiopoietin-like protein 2 (Angptl2) is an adipocytokine which promotes inflammation and endothelial dysfunction of the vessels. People with chronic kidney disease (CKD) have a greater risk of atherosclerotic disease. The aim of this study is to assess the relationship between serum Angptl2 levels and CKD.

Methods: A total of 3,163 community-dwelling subjects (1,368 men, 1,795 women), aged ≥40 years, were divided into quintiles by Angptl2 levels. The estimated filtration rate (eGFR) was calculated using the new Japanese equation for eGFR from serum creatinine. CKD was defined as having either eGFR <60 ml/min/1.73m^2 or urinary albumin to creatinine ratio ≥30 mg/g. The odds ratio for the presence of CKD was calculated using logistic regression model.

Results: The median value (interquartile range) of Angptl2 was 2.72 (2.15-3.47) ng/mL. The prevalence of CKD was 37.4%. The age- and sex-adjusted prevalence of CKD increased linearly for Angptl2 levels of <2.01, 2.01-2.48, 2.49-2.99, 3.00-3.65, and ≥3.66 ng/mL, being 26.0%, 35.4%, 39.4%, 41.3%, and 44.2%, respectively (p for trend <0.001). Every 1 ng/mL increment in Angptl2 levels was associated with 1.09-fold (95% confidence interval 1.01-1.18) greater likelihood of CKD, even after adjusting for age, sex, systolic blood pressure, antihypertensive drug use, hemoglobin A1c, total cholesterol, high-density lipoprotein cholesterol, triglycerides, lipid-modifying drug use, body mass index, high-sensitivity C-reactive protein, electrocardiogram abnormality, history of cardiovascular disease, current smoking, and drinking. In regard to CKD stages, similar associations were observed for stages 1-2 and stages 3-5 with albuminuria, but not for stages 3-5 without albuminuria.

Conclusions: Elevated Angptl2 levels were associated with the likelihood of CKD in the general population.

TH-PO393

Modulation of Erythropoietin by Prolyl Hydroxylase Inhibitor in a Repeat Dose, Randomized Placebo Controlled Trial Richard A. Brigandi,[1] Steven F. Russ,[2] Coreen Oei,[2] Mark E. Westerman,[3] Gordana Olbina,[3] Peter Hodsman,[4] Sanjay Kumar.[1] *[1]GlaxoSmithKline, King of Prussia, PA; [2]GlaxoSmithKline, Research Triangle Park, NC; [3]Intrinsic LifeSciences, La Jolla, CA; [4]Nucleus Network, Melbourne, VIC, Australia.*

Background: Prolyl hydroxylases are enzymes that hydroxylate hypoxia inducible factor (HIF) leading to degradation. GSK1278863A is a novel small molecule that has demonstrated *in vitro* and *in vivo* inhibition of the prolyl hydroxylases resulting in HIF stabilization and HIF-mediated gene expression including erythropoietin (EPO).

Methods: Study PHI112842 was a single-blind, randomized, placebo controlled, dose-rising, 14-day repeat dose, sequential parallel group study to investigate the safety, tolerability, PK and PD of GSK1278863A in healthy adult subjects. Subjects were dosed once daily for 14 days, sequentially, in four ascending cohorts ranging from 15 to 100 mg with randomization to receive GSK1278863A or placebo in a ratio of 2:1. Twice daily dosing for 14 days was also evaluated in one cohort of subjects.

Results: Oral administration of GSK1278863A was generally well tolerated. Drug exposure generally increased with increasing dose up to 75 mg. Exposure was similar between 75 and 100 mg likely due to intersubject variability in absorption. Mean t_{max} ranged from 1.5-2.8 hours post dose, and actual $t_{1/2}$ ranged from 0.8-4.1 hours. There was no drug accumulation and no statistical difference in $AUC_{0\text{-}24h}$ between 25 mg bid and 50 mg daily. Changes were observed across hematologic and iron metabolism biomarkers in a dose dependent manner. Dose-dependent increases in EPO, reticulocyte count, and hemoglobin increases were observed. Subjects receiving greater than 15 mg daily had an average hemoglobin increase of ~1 g/dL by day 14. A decrease from baseline in Hepcidin, a biomarker of iron utilization and inflammation was also observed in a dose dependent manner. Compared to placebo subjects, an increase in VEGF concentration was noted in subjects receiving higher GSK1278863A doses (75 and 100 mg).

Conclusions: These data indicate that GSK1278863A has the potential to induce erythropoiesis in patients with anemia.

Modulation of Erythropoietin by Prolyl Hydroxylase Inhibitor in Renal Impaired Patients in a Single Dose Cross-Over Study Richard A. Brigandi,[1] Steven F. Russ,[2] Coreen Oei,[2] Mark E. Westerman,[3] Gordana Olbina,[3] Richard Austin Robson,[4] Sanjay Kumar.[1] *[1]GlaxoSmithKline, King of Prussia, PA; [2]GlaxoSmithKline, Research Triangle Park, NC; [3]Intrinsic LifeSciences, La Jolla, CA; [4]Christchurch Hospital, Christchurch, New Zealand.*

Background: Prolyl hydroxylases are enzymes that hydroxylate hypoxia inducible factor (HIF) leading to degradation. GSK1278863A is a novel small molecule inhibitor of HIF prolyl hydroxylases resulting in HIF stabilization and HIF-mediated gene expression including erythropoietin (EPO).

Methods: Study PHI112843 was a two part study. Part 1 was a single dose, 2-period crossover, randomized sequence, single blind to sequence and dose study in Stage 3 and 4 CKD patients and matched healthy subjects. Patients were administered a single dose of 50 mg and 150 mg GSK127863A across the two periods. Part 2 was a single dose, 2-period, fixed sequence, open label study in Stage 5 hemodialysis dependent (HDD) patients. Patients were administered a single dose of 150 mg GSK127863A across the two periods. Period 1 dosing was on a hemodialysis (HD) day, 1 hour prior to HD start. Period 2 was on a day without HD.

Results: Oral administration of GSK1278863A was generally well tolerated. There were no marked differences in drug exposure across CKD patients, matched healthy subjects and HDD patients on a non-HD session day. Plasma concentrations were elevated in subjects actively receiving HD. Rapid, dose-dependent increases were observed in mean EPO concentrations in all cohorts following dosing in Period 1, with the greatest increases observed in CKD and HDD patients. Mean reticulocyte and RBC counts also increased. Mean hemoglobin concentrations were observed to increase slightly in healthy subjects in both dosing periods and over time in CKD patients. In HDD patients small increases in mean Hgb concentrations were noted at 24 hours following dosing on an HD day, but returned to baseline at the follow-up assessment. A decrease from baseline in Hepcidin, a biomarker of iron utilization and inflammation, and an increase in VEGF was observed after dosing in all populations.

Conclusions: These data indicate that GSK1278863A has the potential to induce erythropoiesis in patients with anemia.

The Pathogenesis and Clinical Significances of Renal Insulin Resistance Syndrome Hitoshi Minakuchi, Shu Wakino, Koichi Hayashi. *School of Medicine, Keio University, Shinanomachi 35 Shinjuku, Tokyo, Japan.*

Background: The association between chronic kidney disease (CKD) and insulin resistance (IR) has been recognized as "renal insulin resistance syndrome (RIRs)", To delineate the mechanism and significance of RIRs, we conducted a clinical study.

Methods: The cross-sectional study was performed among 186 patients with CKD. Insulin sensitivity was evaluated with the Homeostasis Model Assessment of Insulin Resistance (HOMA-IR). Glomerular filtration rate (GFR) was estimated with modified MDRD-equation adapted for a Japanese population and evaluated in estimated GFR (eGFR). The intervention with mineralocorticoid receptor (MR) antagonist spironolactone was performed with some patients with RIRs. In prospective analysis, we evaluated the 3-year changes in various parameters of renal function and analysed the correlation between HOMA-IR and these parameters.

Results: Of CKD patients, 5 were in stage 1, 89 were in stage 2, 78 were in stage 3, 6 were in stage 4, and 8 were in stage 5. A negative correlation was observed between HOMA-IR and eGFR. Plasma aldosterone level was correlated negatively with eGFR and positively with the levels of fasting blood sugar, insulin and HOMA-IR. By multiple regression analysis, the aldosterone level was identified as an independent risk factor for RIRs. This analysis also revealed that the markers for urinary tubular damages, a1-microglobulin were also correlated with HOMA-IR . The treatment with spironolactone ameliorated the IR status in CKD. In addition, prospective analysis revealed that the decline in eGFR was significantly correlated with HOMA-IR, and multiple regression analysis indicated that HOMA-IR was the independent risk for CKD progression.

Conclusions: These studies demonstrate that plasma aldosterone plays a relevant role in the pathogenesis of RIRs. MR antagonists can be a therapeutic strategy for the prevention against RIRs and its complications including cardiovascular disease. The presence of RIRs have some roles in the progression of CKD probably through the damages of urinary tubular damages. Our study demonstrated for the first time the clinical relevances of RIRs, and RIRs can be the new target for CKD treatment.

The Effects of 1,25-Dihydroxyvitamin D3 on the Risk of Death in a Japanese General Population: The Hisayama Study Toshiharu Ninomiya,[1] Masaharu Nagata,[2] Tomoko Usui,[2] Yutaka Kiyohara,[2] Takanari Kitazono.[1] *[1]Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Japan; [2]Environmental Medicine, Graduate School of Medical Sciences, Kyushu University, Japan.*

Background: Recent evidence emerged to imply that lack of 1,25-dihydroxyvitamin D3 (VD3) increased the risk of death and cardiovascular disease. However, this issue has not been fully evaluated. We assessed whether lower serum VD3 levels were associated with higher risk of death.

Methods: We followed a total of 3,091 community-dwelling Japanese individuals aged 40 years or older, without history of cardiovascular disease and kidney failure, and with available VD3 data, for 7 years, and examined the relationship between serum VD3 levels and the risk of death by using the Cox proportional hazards model.

Results: The mean value of serum VD3 levels in the study population was 66.6 pg/ml (standard deviation 17.4). During the follow-up, 270 subjects died in total. The mortality rate from any causes increased gradually with lower VD3 levels: the risk of death from any causes increased significantly with VD3 levels of <54.8, 54.9-65.8, 65.9-78.5, and ≥78.6 pg/ml, being 18.2, 15.1, 9.9, and 10.3 per 1,000 person-years, respectively (p for trend <0.001). After adjusting for potential confounders: namely, age, sex, systolic blood pressure, use of anti-hypertensive agents, diabetes, total cholesterol, use of lipid-modifying agents, body mass index, estimated glomerular filtration ratio (eGFR), calcium-phosphate product, smoking habits, and alcohol intake, every 10 pg/ml decrement in VD3 levels was associated with a 1.19-fold (95% confidence interval, 1.11-1.28) greater risk of death from any causes. With regard to the causes of death, the risk of death from cardiovascular disease and infectious disease tended toward increasing with lower VD3 levels. There was no evidence of heterogeneity in the association between subjects with eGFR below and above 60 ml/min/1.73 m^2 (p for heterogeneity=0.58).

Conclusions: Our findings suggest that lower serum VD3 level is associated with a greater risk of death in the general Japanese population, regardless of kidney function.

Bone-Specific Alkaline Phosphatase and Coronary Artery Calcification and Mortality in Diabetic Chronic Kidney Disease Magdalena A. Sarna,[1] Sirin Jiwakanon,[2] Rajnish Mehrotra.[2] *[1]Department of Medicine, University of Calgary, Calgary, AB, Canada; [2]Department of Medicine, Los Angeles Biomedical Research Institute, Torrance, CA.*

Background: Higher levels of alkaline phosphatase (ALP) have been previously shown to be associated with increased mortality in patients with chronic kidney disease (CKD) and hemodialysis. However, most studies have used serum ALP rather than bone-specific alkaline phosphatase (BALP), a marker of bone turnover and mineralization. The aim of our study was to evaluate the role of BALP in predicting vascular calcification, using coronary artery calcification (CAC) scores, as well as mortality and progression to end-stage renal disease (ESRD) in type 2 diabetic patients with CKD.

Methods: A total of 166 participants from two prospective cohort studies of CAC in non-dialysis-dependent type 2 diabetics with nephropathy were included. An immunoenzymetric assay was used for quantifying measurement of BALP. Baseline patient characteristics were further stratified according to BALP tertiles. CAC was measured by electron beam computer tomography. Cox regression model was used for mortality and ESRD analysis.

Results: The baseline patient demographics included a mean age of 57 years, estimated glomerular filtration rate (eGFR) of 57 ml/min/1.73 m^2 and a median urine protein-creatinine ratio of 2.6. The median BALP level was 13.8 (10.9–18.2) µg/L. There was no difference in CAC scores according to BALP tertiles (p=0.12). Multivariate analysis for baseline BALP as outcome showed age, parathyroid hormone and triglyceride, but not CAC levels, to be predictors in the model. As expected, a relationship was found between all-cause mortality and higher CAC scores (p= 0.018) but not ESRD (p= 0.99). BALP was not found to be predictive for all-cause mortality (p= 0.69) or ESRD (p= 0.998).

Conclusions: BALP levels do not appear to be correlated with greater vascular calcification. In this study, baseline BALP levels were not predictive of all-cause mortality or progression to ESRD. Further studies are needed to validate whether BALP, a marker of bone turnover, is predictive of cardiovascular risk in patients with CKD.

TH-PO398

Predictive Value of a Multi-Organ Cardiovascular Disease Target Organ Score for Mortality and Cardiovascular Events in a Low Risk Population Branko Braam,[1] Lutgarde Thijs,[2] Tatiana Kouznetsova,[2] Jasjeet K. Minhas Sandhu,[3] Dean Eurich,[3] Jan A. Staessen,[2] Carlo A. Gaillard.[4] *[1]Medicine/Nephrology, University of Alberta, Edmonton, AB, Canada; [2]Department of Molecular and Cardiovascular Research, University of Leuven, Belgium; [3]Department of Public Health Sciences, University of Alberta, Edmonton, AB, Canada; [4]Department of Nephrology, VU University Medical Center, Amsterdam, Netherlands.*

Background: An intrinsic limitation of cardiovascular risk prediction models is that they rely on risk factors, not on individual target organ damage (TOD). The current pilot study tested whether application of a multi-organ TOD scoring system had independent value above standard risk models to predict death and cardiovascular events in a low risk cohort.

Methods: To this purpose, a population-based prospective cohort of subjects age >30 yrs, was analyzed for cardiovascular risk factors to populate the SCORE and Framingham equations and TOD using a new framework, addressing TOD severity in arteries, brain, cardiac and kidney (ABCK).

Results: Of 1970 subjects, sufficient data were available to obtain baseline risk and TOD scores. During a follow up of 10 years, 163 (8%) subjects died, 49 (2%) had an AMI, 45 (2%) had a stroke, 46 (2%)developed end-stage renal disease and 14 (0.7%) developed severe peripheral artery disease. The ABCK TOD score was related to overall and cardiovascular mortality and to cardiovascular events. When compared to the SCORE and Framingham risk models, the ABCK score was independently associated with (fatal and non-fatal) cardiovascular outcome in medium and high-risk individuals over 10 years of follow up. For the intermediate TOD ABCK score the HR were 2.6 and 3.0, for severe TOD ABCK score the HR were 10.7 and 11.4 independent from SCORE and Framingham respectively.

Conclusions: Of interest, scoring renal damage (based on proteinuria and GFR) most strongly added to the prediction by the SCORE and Framingham. This pilot study indicates that addition of a relatively simple to use TOD score can improve the prediction of cardiovascular events.

Comparison of Sexual Dysfunction between Renal Replacement Therapies: A Systematic Review Temitope Olufade, Priscilla Auguste, Deidra C. Crews, Julio Lamprea, Tanjala S. Purnell, Raquel Greer, Patti Ephraim, Johanna Sheu, Neil R. Powe, Hamid Rabb, L. Ebony Boulware. *Johns Hopkins Medical Institutions.*

Background: Sexual dysfunction is common in end stage renal disease (ESRD). However, the strength of evidence regarding differences in sexual dysfunction among patients on different renal replacement therapies (RRTs) is unknown.

Methods: We performed a systematic review to identify published studies describing rates of sexual dysfunction among patients on different RRTs (hemodialysis-HD, peritoneal dialysis-PD and renal transplant- TX). We searched PubMed (English language, after 1987) and hand-searched bibliographies to identify relevant studies. Independent reviewers assessed study quality (internal and external validity). We calculated standardized effect sizes (Cohen's D) to compare the direction and magnitude of associations between RRT and several sexual function outcomes.

Results: Of 130 potentially eligible studies identified, 18 described sexual dysfunction among men (7), women (1), or both genders (10). Studies compared 12 sexual dysfunction outcomes using observational designs (2 longitudinal cohort, 11 cross-sectional, 5 pre-post). Most studies (9 of 10) reported no differences in outcomes among patients on HD versus PD. In 13 studies, transplant was the most consistently favored RRT (no difference to a great amount less sexual dysfunction) compared to other modalities. Study quality varied (low to moderate; no high quality), with few studies adequately accounting for potentially confounding factors such as comorbidity.

Table 1: Comparison of Sexual Dysfunction Outcomes by Renal Replacement Therapy

	HD vs. PD			HD vs. TX			PD vs. TX			Dialysis vs. TX		
Domain (Number of Studies)	Favors HD	Favors Neither	Favors PD	Favors HD	Favors Neither	Favors TX	Favors PD	Favors Neither	Favors TX	Favors Dialysis	Favors Neither	Favors TX
Men												
Sexual Desire (4)		2				3			2		1	
Erectile Function (6)		3			1	3		1	1			1
Premature Ejaculation (2)		2			1	1		2				
Dyspareunia (2)		2				2		2				
Orgasmic Function (2)		2			1	1		2				
Frequency of Intercourse (2)		0				1					1	
Sexual Satisfaction (1)		1				1			1			
Women												
Sexual Desire (2)		2			1	1		1	1			
Sexual Arousal (1)		1				1		1				
Dyspareunia (2)		2			2			1	1		1	
Orgasm Attainment (2)		2			2			2				
Lubrication (1)		1			1			1				
Both Gender												
Frequency of Intercourse (1)		1				1			1			
Sexual Satisfaction (4)	1	2			1	1		1	1			1
Quality of Sex Life (4)		3			1			1				

Conclusions: Limited but variable quality evidence suggests transplant is associated with less sexual dysfunction among patients with ESRD. Rigorously designed prospective studies are needed to better inform patients and providers about the impact of RRTs on this important patient reported outcome.

TH-PO400

Relation between Glomerular Filtration Rate (GFR) and Medical Expense among the Screened Subjects of the Japan Health Insurance Association Kunitoshi Iseki,[1] Tsuyoshi Watanabe.[2] *[1]Dialysis Unit, University Hospital of the Ryukyus, Nishihara, Okinawa, Japan; [2]Division of Nephrology, Fukushima Medical School, Fukushima, Japan.*

Background: Few studies examined the medical expenses according to the baseline GFR.

Methods: We combined registries both health check and report of medical expenses (receipts). The health check was done from April 2008 to March 2009, and all the eligible subjects were covered by the Okinawa Branch of the Japan Health Insurance Association. Every monthly report of medical expense such as physical examination, laboratory tests, surgical procedures and other related expenses were reviewed during April 2008 to March 2010 (24 months). Serum creatinine was measured by the enzymatic method and the estimated GFR (eGFR, ml/min/1.73m^2) was calculated by the Japanese Society of Nephrology. By using the ID number, we could obtain the information of the receipts after the screening. After obtaining written contract with the association, we were provided anonymously coded data.

Results: A total of 74305 subjects, 38.2% females and the mean age of 48.1 years (35 to 74 years) has participated the health check. The total number of receipt was 773,276 during the study period. . The average receipt point per month, 1 point=10 Yen, was extraordinary high as 29700 in subjects with eGFR<15. The relationship between eGFR and medical expense was U-shaped and the expense was lowest at eGFR 90-104. It was 2369 in eGFR 15-29, 2120 in eGFR 30-44, 1022 in 45-59, 689 in eGFR 60-74, 614 in eGFR 75-89, 606 in eGFR 90-104, 622 in eGFR 105-119, 883 in eGFR 120 and over, respectively.Similarly, it was 637 in subjects with proteinuria (-), 695 in proteinuria (+/-), 1001 in proteinuria (1+), 2210 in proteinuria (2+ and over), respectively. Medical cost increased with ageing.

However, in each age-group medical cost was higher in CKD (eGFR<60), in particular younger generation.

Conclusions: The medical expenses increased as lower the eGFR and higher the degree of proteinuria. Reasons for higher cost among subjects with higher eGFR, 120 and over, remained to be investigated.

TH-PO401

Health-Related Quality of Life, Functional Status, and Survival of Poor Prognosis Endstage Renal Disease Patients Ying-Ying Seow,[1] Chung Pheng, Alethea Yee,[2] Limin Qu,[2] Sze Huey Tan,[3] Kok-Seng Wong,[4] Cynthia R. Goh.[5] *[1]Renal Medicine, Khoo Teck Phuat Hospital, Singapore; [2]Palliative Care, National Cancer Centre, Singapore; [3]Clinical Trials and Epidemiological Sciences, National Cancer Centre, Singapore; [4]Renal Medicine, Singapore General Hospital, Singapore; [5]Lien Centre for Palliative Care, Duke - NUS Graduate Medical School, Singapore.*

Background: ESRD patients who are very elderly (≥75 years old) or with high comorbidity burden,have poor survival even on RRT.Symptoms and functional status do not always improve with initiation of RRT in these poor prognosis groups.We studied a group of extremely poor prognosis ESRD patients (median life expectancy <24months) to monitor change in QoL and functional status,whether on RRT or conservatively managed(CM).

Methods: This was a prospective longitudinal study of ESRD patients at the Singapore General Hospital.101 patients with eGFR 8-12ml/min,and either ≥75 years old or with Charlson Comorbidity Index≥8 were followed up for 24months.At enrollment and at fixed time intervals (0,3,6,9,12,18,24months) KDQoL,Karnofsky Performance Score and eGFR were recorded.Baseline demographic data was also recorded.

Results: 38 patients started RRT and 63 were CM.At 24m,33/38(86.8%) RRT and 24/63(38.1%) CM patients were alive.Median survival for CM was 14.6m and GFR at time of death was 6ml/min.GFR at initiation of RRT was 6.3ml/min.For CM,there was a decline over time for Social Support,PF,GH,SF and PCS ($p<0.05$) but an improvement in Burden of Kidney Disease,Work Status and RE.Among RRT,comparing KDQoL and KPS scores closest to initiating RRT and first recorded scores≥3m after initiation,only BKD was improved but symptoms,sleep,overall health,Energy,RP,PCS and MCS were all worse ($p<0.05$).KPS was comparable pre and post-RRT.

Conclusions: Asian RRT populations have been shown to have good survival and QoL.Our study showed that the worst prognosis ESRD patients survived longer on RRT compared to CM.However, their QoL did not improve,on the contrary, this deteriorated on RRT.Functional status remained unchanged.For CM,there was a gradual decline in some HRQoL domains but improvement in others.Scores in general were good.

TH-PO402

Colonic Necrosis Is Not Associated with the Use of Sodium Polystyrene Sulfonate (SPS) Potassium Binding Resins Maura A. Watson, Annie Nguyen, David K. Oliver, Kevin C. Abbott, Christina M. Yuan. *Nephrology, Walter Reed Army Medical Center, Washington, DC.*

Background: The FDA in 2009 recommended against the "concomitant use of sorbitol" with SPS powder due to associated cases of colonic necrosis (CN), a rare (but potentially fatal) event. Little data exists to suggest that oral SPS formulations cause CN.

Methods: This retrospective cohort examined all 121,812 Walter Reed Army Medical Center inpatient subjects between 9/1/2001 and 10/31/2010. Pharmacy data was queried for inpatient SPS/sorbitol (SPS) prescriptions (CHCS/Essentris). CoPath™ anatomic pathology database was used to identify all cases of CN during that time period based on tissue diagnosis. The primary outcome was CN in subjects who were exposed to SPS within one month prior to diagnosis (a plausible temporal association) and associated clinical features in index cases.

Results: SPS was prescribed to 2,195 subjects (0.02%). 83 CN cases were identified (0.07%). Three received oral SPS (1gm/4ml) up to one month prior to CN diagnosis (3.2% of CN cases). Nine-year cumulative CN incidence was 0.14% in those exposed to SPS. SPS exposure was not significantly associated with CN (unadjusted relative risk = 2.08; 95% CI 0.65-6.57; P = 0.20). The number needed to harm was 1411. Exposure to SPS was not significantly associated with CN when adjusted for age>65, eGFR<30, ICU admission, or post surgical status. Sample size analysis showed it would require a population of 4974 patients age>65 treated with SPS and a comparison group ten times as large to perform rigorous multivariate analysis of the risk of SPS for CN.

Conclusions: Inpatient use of SPS was not significantly associated with the development of CN by unadjusted analysis in this cohort of hospitalized subjects at a single tertiary care medical center over 9 years. CN is an extremely rare outcome therefore a single medical center may not have sufficient cases for robust statistical analysis, and analysis of a coordinated national system would be required.

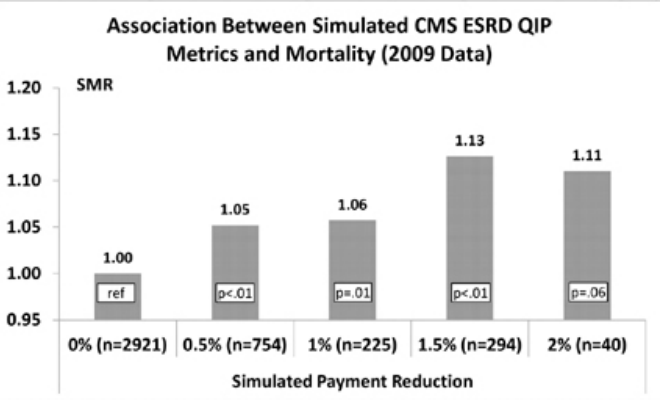
Simulated CMS ESRD Quality Incentive Program and Association with Mortality Robert A. Wolfe,[1] Emily E. Messersmith,[1] Regina S. De los Santos,[1] Erik Roys,[2] Jeffrey Pearson,[1] Alissa Kapke,[1] Matthew Paul,[2] Bruce M. Robinson,[1] Joseph M. Messana.[2] *[1]Arbor Research Collaborative for Health; [2]University of Michigan Kidney Epidemiology and Cost Center.*

Background: As part of the Medicare Improvements for Patients and Providers Act of 2008, the Centers for Medicare & Medicaid Services (CMS) were mandated to implement a Quality Incentive Program (QIP) for payments to dialysis facilities in 2012. The QIP will use 3 measures of dialysis facility performance: the percent of pts with hemoglobin <10 g/dL, hemoglobin >12 g/dL, and urea reduction ratio ≥65%. Each dialysis facility's performance in 2010 will be compared with their facility-specific historical performance in 2007 or national performance in 2008; facilities not meeting one of these standards on any of the 3 measures may face payment reductions of up to 2% in 2012.

Methods: Using CMS data, we simulated the QIP with 2009 facility performance (N=4,718 facilities). After calculating the quality measures, we calculated the total performance score (0-30 points) and categorized facilities by payment reductions (none, 0.5%, 1.0%, 1.5%, or 2%). To assess the validity of the QIP, we related these facility categorizations to a 2009 facility standardized mortality ratio (SMR) using Poisson regression. The SMR accounts for patient case-mix and general population state death rates. Facilities without sufficient data to calculate performance scores were excluded from the analysis.

Results: Facilities receiving payment reductions had higher mortality than facilities with no reductions (see figure).



484 facilities did not have 2007 baseline data; the QIP does not penalize these facilities and we found no evidence for a mortality difference from high performing facilities (p=0.59).

Conclusions: The QIP score categorization has construct validity through its correlation with patient mortality at the facility level.

Human Resource Allocation to Intensive Home Hemodialysis (HHD) Programs in Canada Robert P. Pauly,[1] Deborah Lynn Zimmerman,[2] Paul Komenda.[3] *[1]University of Alberta, Canada; [2]University of Manitoba, Canada; [3]University of Ottawa, Canada.*

Background: There is growing interest in HHD though there are almost no published data on the human resource requirements to maintain a home program. The purpose of this study was to leverage Canadian expertise in HHD delivery and characterize human resource allocation in our programs.

Methods: Between Jul and Dec 2010, 19 dialysis programs (14 university-based centers and 5 community centres known to provide all options of home dialysis therapies) were surveyed to describe their staffing complement and the roles of various disciplines.

Results: Seventeen of 19 (89%) programs responded. The median number (and range) of patients cared for by 1 full-time equivalent (FTE) nurse and dialysis technologist is 14.4 (10.0-24.3) and 22.7 (12.5-42.0) respectively; the median ratio of patients to clerical support FTE is 54:1. Twelve of 17 (71%) units have a dedicated modality educator/coordinator associated with their renal program. Eleven of 17 (65%) programs have a designated dietician, 9/17 (53%) have a social worker, and 7/17 (41%) have a pharmacist; 81% of these positions are part-time FTEs indicating these resources are shared broadly in most renal programs. A single nephrologist cares for all HHD patients in 3/17 (18%) programs, a specialized group of HHD physicians attends in 10/17 (58%) units, and all nephrologists share caring for HHD patients in only 4/17 (24%) units. Technical support for HHD is completely outsourced to a third party vendor in 5/17 (29%) programs, shared with conventional HD in 6/17 (35%) programs and designated solely to HHD in 5/17 (29%) programs. A unique activity in the HHD unit includes the technical assessment of patients' homes which is performed by program technologists (7/17 – 41%), third party vendors (5/17 – 29%), and a combination of a technologist and a vendor (5/17 – 29%).

Conclusions: Significant variability exists in staffing HHD programs in Canada. This may relate to the local practice environment and/or the experience of the centre; this requires further study. Understanding the staffing complement among established HHD programs may be valuable for new programs in considering resource allocation.

TH-PO405

Tacrolimus and Breastfeeding: How Safe Is it? Kate Bramham,[1] Gary Chusney,[2] Janet Lee,[2] Alexander Paul Wardle,[2] Catherine Nelson-Piercy,[3] Liz Lightstone.[2] *[1]Maternal and Fetal Research Unit, King's College London; [2]Renal and Transplant Centre, Imperial College NHS Healthcare Trust; [3]Obstetric Medicine, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom.*

Background: Women have been advised not to breastfeed if taking tacrolimus (Tac), due to theoretical risks of neonatal immunosuppression & assumed secretion into breastmilk. Our aim was to assess neonatal exposure during breastfeeding.

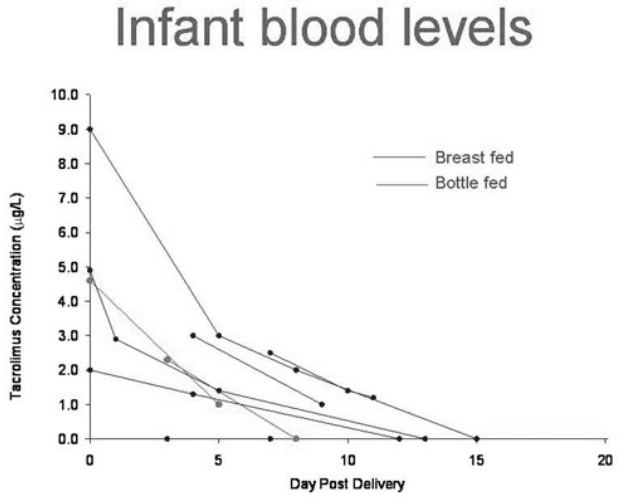
Methods: Maternal, cord & infant blood and breastmilk samples were collected postpartum.Tac levels were analysed by liquid chromatography tandem mass-spectrometry.

Results: Eleven women, taking Tac during pregnancy and lactation, & their 12 infants, 10 of whom were subsequently breastfed, were assessed. Maternal blood (n=12), cord blood (n=6), infant blood (n=21, 1-3/infant), & breastmilk (n=18 samples/8 women, including 1 bottle fed infant) were collected at days 1-72 post delivery. Infant details & breastmilk analysis are shown.

Table

Infant characteristics	
Median Gestation at Delivery (wks)	36, IQR 34.5-36.5
Birth Weight (g)	2432, IQR 1862-2496
Breastmilk Tacrolimus levels	
Median Breastmilk level	0µg/l, IQR 0-0.65
Median Breastmilk : Maternal Blood ratio	0.045, IQR 0-0.13

By 14 days postpartum, Tac levels were undetectable regardless of feeding method.



Estimated infant dose is 0.78µg/day, equivalent to 0.32% of maternal dose (based on highest breastmilk concentration 2.1µg/l, assumed maternal & infant weights 60 & 2.5kg respectively, maternal Tac dose 6mg/day & breastmilk ingestion 0.15l/kg/day).

Conclusions: Ingestion of Tac by infants via breastmilk is negligible. Breastfeeding does not appear to slow the decline of infant Tac levels from high levels present in cord blood. Women taking Tac should not be discouraged from breastfeeding if monitoring of infant Tac levels is available.

Differential Effects of Renal Replacement Therapy on Plasma Inflammatory and Apoptotic Biomarkers in Acute Kidney Injury Xiao-Yan Wen,[1] Raghavan Murugan,[1] Lan Kong,[1,3] Nilesh Shah,[1,3] MinJae Lee,[1,3] Melinda J. Carter,[1] Michele M. Elder,[1] Paul M. Palevsky,[2,4] Mark L. Unruh,[2] John A. Kellum.[1,2] *[1]Critical Care Medicine, Clinical Research, Investigation, and Systems Modeling of Acute Illness (CRISMA), University of Pittsburgh, Pittsburgh, PA; [2]Department of Medicine, University of Pittsburgh, PA; [3]Department of Biostatistics, University of Pittsburgh Graduate School of Public Health, PA; [4]VA Pittsburgh Healthcare System, Pittsburgh, PA.*

Background: Higher concentrations of inflammatory and apoptotic biomarkers are strongly associated with increased risk of death and non-recovery following acute kidney injury (AKI). Whether intensity of renal replacement therapy (RRT) influences circulating biomarker concentrations in patients is unknown.

Methods: Using a subset of 819 patients enrolled in the Acute Renal Failure Trial Network study, we measured 11 circulating inflammatory and apoptotic plasma biomarkers before (day 1) and after (day 8) RRT initiation. We examined whether higher intensity RRT was associated with lower circulating biomarker concentrations.

Results: With the exception of interleukin (IL)-8, we found no differences in any biomarker levels between intensive and less-intensive RRT arms on days 1 and 8. However, compared to less-intensive treatment, intensive treatment was associated with lower day 8 concentrations when day 1 levels were high. In contrast, intensive RRT was associated with higher biomarker concentrations on day 8 when day 1 levels were lower. Differences reached statistical significance for death receptor (DR)-5, IL-6, macrophage migration inhibitory factor (MIF) and tumor necrosis factor receptor (TNFr)-1, but similar trends were seen for all 11 markers.

Conclusions: Intensity of RRT did not impact plasma biomarker concentrations overall. However, higher-intensity RRT had differential effects on day 8 marker concentrations relative to lower-intensity RRT depending on baseline (day 1) levels. Thus, high intensity RRT may be immune modulating in individuals with very high or very low baseline inflammation. Further study is needed to understand the clinical significance of this finding.

TH-PO407

Frequency of Antibiotic Underdosing in Critically Ill Patients Receiving Renal Replacement Therapy Suneel M. Udani, Ling Chen, Mitchell J. Daley, Ishaq Lat, Jay L. Koyner. *Medicine, University of Chicago, IL.*

Background: Achieving target serum antibiotic concentrations in infected ICU patients on renal replacement therapy (RRT) is complex but essential for supportive care. Rates of adherence to antibiotic dosing guidelines for patients receiving RRT is not well studied and given the increased volume of distribution in critically ill patients underdosing antibiotics may have unintended adverse outcomes.

Methods: We conducted a retrospective cohort study evaluating rates of antibiotic underdosing in ICU patients receiving RRT between July 2007 and June 2009 at a single academic medical center. Appropriate dosing was determined by comparison of dose administered with established guidelines and denoted as accurate if adjustment occurred prior to the third administered dose, or, if appropriate dosing is every 12 hours or more, within 24 hours.

Rates of underdosing were compared (to normal and over-dosing) according to modality of RRT (Intermittent Hemodialysis (IHD) vs. Continuous RRT (CRRT)), indication for RRT (Acute Kidney Injury (AKI) vs. End Stage Renal Disease (ESRD)) and the presence of a clinical pharmacist on ICU rounds.

Results: 546 of 723 patients receiving RRT during the study period received antibiotics and had charts available for review. 1761 individual antibiotic administrations were available for analysis. Under-dosing occurred more frequently in antibiotics requiring dose adjustment (22.8% vs. 1.5%, $p<0.001$). Dosing errors were more common in the group receiving CRRT vs. IHD (38.4% vs. 6.5%, $p<0.001$) and in those ICUs without a clinical pharmacist on rounds (31.3% vs. 18.7%, $p<0.001$). Frequency of dosing errors did not differ between those receiving RRT for AKI vs. ESRD (23.4% vs. 21.1%, $p=0.477$). There was no difference of in-hospital mortality in underdosed individuals, (52.3%) compared to those not under-dosed (51.6%), $p=0.92$.

Conclusions: Antibiotic underdosing occurs frequently in ICU patients receiving RRT. Increased awareness of dose adjustment guidelines for CRRT and having a Clinical Pharmacist participate directly in rounds may improve rates of underdosing.

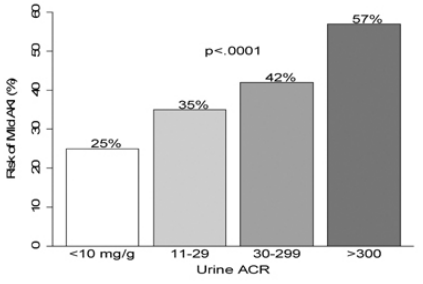
Pre-Operative Proteinuria Predicts Acute Kidney Injury in Patients Undergoing Cardiac Surgery Steven G. Coca, Divakar Jammalamadaka, Kyaw Sint, Heather Thiessen Philbrook, Michael Shlipak, Michael Zappitelli, Prasad Devarajan, Amit X. Garg, Chirag R. Parikh. *TRIBE-AKI Consortium.*

Background: To examine the utility of using proteinuria in pre-operative risk stratification for acute kidney injury (AKI). AKI is a common and important complication for patients undergoing cardiac surgery. Proteinuria, which reflects structural damage to the glomeruli or renal tubules, may aid the prediction of AKI.

Methods: The ratio of urine albumin to creatinine (UACR) and dipstick proteinuria concentration were prospectively measured in 1300 adults and children undergoing cardiac surgery. The cohort was organized into four clinical risk categories based on the pre-operative UACR: UACR ≤ 10 mg/g (≤ 1.1 mg/mmol), 11-29 mg/g (1.2-3.3 mg/mmol), 30-299 mg/g (3.4-33.8 mg/mmol), and ≥ 300 mg/g (≥ 33.9 mg/mmol). The primary outcome was post-operative AKI, defined by the AKIN stage I criterion (serum creatinine rise by ≥50% or ≥ 0.3 mg/dL (26.5 µmol/L)).

Results: An increase in the incidence of AKI was noted across the UACR categories (25%, 35%, 42%, 57%, respectively.

Figure: Incidence of Stage I AKI across the UACR categories



Stage I AKI is defined as serum creatinine rise by 50% or 0.3 mg/dL (26.5 µmol/L). The incidence of AKI increases across the UACR categories in a step-wise manner (p < 0.001 for trend).

Adding UACR to the clinical model to predict AKI improved the AUC from 0.61 to 0.66 ($p < 0.001$) and the continuous net reclassification improvement (NRI) was 32% ($p < 0.001$). UACR categories were also independently associated with risk of in hospital death or dialysis ($p = 0.04$), and ICU and hospital length of stay ($p = 0.005$), ($p = 0.008$), respectively. Surgery status and pre-operative GFR were effect modifiers; the association was stronger amongst those undergoing elective surgery ($p < 0.001$) and those with eGFR 45 mL/min per 1.73 m^2($p = 0.003$).

Conclusions: Pre-operative proteinuria provides graded stratification risk for AKI and is an independent predictor of other outcomes in adults and children undergoing cardiac surgery.

Renal Artery Calcium and Mortality among Community-Living Adults Dena E. Rifkin,[1,2] Joachim H. Ix,[1,2] Christina Wassel,[1] Michael H. Criqui,[1] Matthew Allison.[1] *[1]UC San Diego; [2]VA Healthcare System, San Diego.*

Background: The associations of calcification in the renal vasculature, independent of calcification in other vascular beds, with subsequent mortality risk in the general population are unknown.

Methods: We assessed renal artery calcification (RAC) by abdominal CT scan and used Cox-proportional hazards models to examine the association of RAC with mortality in 4,469 community living adults without known cardiovascular disease (CVD) who presented for preventive screening examinations.

Results: The mean age of the study sample was 56.7, and 42.6% were women. RAC was present in 629 of 4,469 (14%) participants. Over a median follow-up of 8.2 years, 177 individuals died. After adjustment for age, gender, diabetes, smoking, cholesterol and family history of CVD, the presence of RAC conferred a more than 70% increased hazard for all-cause mortality (HR 1.71, 95% CI 1.22-2.39, p = 0.002). Adjustment for calcification in other vascular beds attenuated this effect, although findings remained significant (HR 1.47, 95% CI 1.04-2.06, p= 0.027). Additional adjustment for blood pressure, a potential mediator of the association, did not substantially change the results (HR 1.44, 95% CI, 1.03-2.03, p = 0.036).

Conclusions: We found that RAC is associated with an increased risk of subsequent mortality in individuals without known CVD, independent of traditional CVD risk factors. The risk was attenuated somewhat by adjustment for vascular calcification in other vascular beds, suggesting an effect of systemic calcified atherosclerosis, and was not mediated by hypertension.

Hazard of all-cause mortality at different levels of RAC

	Age-sex adjusted	risk adjusted*	fully adjusted**	putative mediator adjusted***
RAC (any vs. none)	1.86(1.33,2.59)	1.71(1.22,2.39)	1.47(1.04, 2.07)	1.44(1.03,2.03)
p for HR	p < 0.001	p = 0.002	p = 0.027	p = 0.036
RAC (per log change)	1.16 (1.08, 1.25)	1.14 (1.06, 1.23)	1.10 (1.02, 1.19)	1.10 (1.02, 1.19)
p for HR	p < 0.001	p < 0.001	p = 0.01	p = 0.02

* adjusted for smoking, hypercholesterolemia, diabetes, and family history of CVD; ** additionally adjusted for # of other beds with vascular calcification; *** additionally adjusted for hypertension (yes/no)

The Use of Palliative Care Services amongst End Stage Kidney Disease Patients in an Irish Tertiary Referral Centre Lynn Redahan,[1] Bernadette Brady,[2] Andrew Smyth,[1] Stephen Higgins,[2] Catherine A. Wall.[1] *[1]Department of Nephrology, AMNCH Tallaght, Dublin, Ireland; [2]Department of Palliative Medicine, AMNCH Tallaght, Dublin, Ireland.*

Background: It is well accepted that patients with end stage kidney disease (ESKD) have a shortened life expectancy. Despite this, it has been recognised that end of life care is suboptimal in this patient population. The aim of this study was to review the utilisation of palliative care services amongst ESKD patients in a tertiary referral centre.

Methods: We conducted a retrospective chart review of patients with ESKD who died between January 2005 and October 2009. Eligible patients were identified using the renal database. We included patients who had undergone renal replacement therapy for a minimum of 3 months. We recorded palliative care referrals, modality of renal replacement therapy, age at death and place of death.

Results: 128 patients were included in the study. The final modality of renal replacement therapy was haemodialysis in 100 patients (78.1%) and peritoneal dialysis in 28 patients (21.9%). The average age at death was 65 years. Forty five patients (35.2%) were referred to the palliative care services. The palliative care team were involved in the patients' management for a median of 11 days before death. 102 patients (79.7%) died in an acute hospital setting, nine patients (7.0%) died at home, two patients (1.6%) died in an inpatient hospice and the place of death was unknown for fifteen patients (11.7%). Dialysis was withdrawn prior to death in forty eight patients (37.5%).

Conclusions: The palliative care services were involved in the antemortem care of approximately one third of our patients and the majority of referrals were sent at a late stage. A decision to withdraw dialysis was made in a high proportion of cases studied. Given the short timeframe until death once dialysis is withdrawn, it is imperative that appropriate end of life care is instituted for these patients. We have identified an underutilisation of palliative care services for ESKD patients in our hospital. Improved integration of palliative care and nephrology services may allow us to optimise end of life care for these patients.

TH-PO411

Cer1 Is Involved in the Control of Ureteric Bud Branching by Antagonizing Bmp4-Mediated Inhibition of the Gdnf/Wnt11 Positive Feedback Loop during Kidney Development Seppo J. Vainio. *Medical Biochemistry and Molecular Biology, Biomedicine, Oulu, Finland.*

Background: Ureteric bud branching is critical for mammalian kidney development since the process generates the urine transporting collecting duct system and the ureter and the ureteric bud tips trigger also nephrogenesis.

Results: We show here by using gain and loss of function approaches that a secreted Bmp antagonist Cerberus homologue (Cer1) regulates kidney organogenesis. A gain of Cer1 function in the ureteric bud promotes kidney size and enhances formation of trifid and lateral types of ureteric bud branches rather than bifid ones during early stages of organogenesis as revealed by time-lapse image capture in organ culture. These changes are likely behind the Cer1-induced alterations in the 3D structure of the ureteric tree in the advanced kidney and the changes in several 3D ureteric tree parameters as revealed by the optical projection tomography (OPT) in comparison to controls. Cer1 functions by binding and antagonizing signalling of Bmp2/4 that both act as inhibitory signals for ureteric bud development. In specific by binding Bmp4 Cer1 relieves the inhibitory effect of Bmp4 on Gdnf and Wnt11 expression and promotes by this way their co-operated positive influence on ureteric growth control. Consistent with these notions genetic reduction of Wnt11 or excess Bmp4 inhibit the genetically enhanced, Cer1-stimulated ureteric bud branching process.

Conclusions: The results point that Cer1 functions as part of the genetic programme that coordinates ureteric bud branching and Cer1 mediates this by regulating the activity of Wnt11 and Gdnf via the control of availability and out put of Bmp4 signalling.

Kidney Disease Genes in Pre-Diabetics: Epigenomic Approach Vallabh O. Shah,[1] Marilee Morgan,[3] Quynh-Anh Bui,[1] Joan Goldsworthy,[1] Thomas A. Vander Jagt,[1] Julie S. Broyles,[1] Gretchen M. Ray,[1] Donald W. Bowden.[2] *[1]Uni of New Mexico; [2]WFU; [3]MRN.*

Background: T2DM affects more than 27 million in US. About 79 million adults have pre-diabetes (preDM), but only 10% are aware of being preDM. Recent studies suggest that gene-environment interactions relevant for T2DM are at least partly regulated by epigenomic mechanisms.

Methods: We performed DNA methylation study in bisulphite converted DNA from Pre-DM (n=12) at baseline and at their transition to T2DM using Illumina Infinium® HumanMethylation27 BeadChip, that enables the query of 27,578 individual cytosines at CpG loci throughout the genome, which are focused on the promoter regions of 14,495 genes.

Results: Our initial analysis indicated that very significant components of DNA methylation variations (hypo- and hyper-) correlated with PreDM progressing to T2DM. With a false discovery rate of 0.05, we observed about 694 CpG sites hypomethylated and about 174 CpG sites hypermethylated from preDM to T2DM progression representing many genes. Many of the genes identified as hypomethylated have been reported to be involved in glucose, fructose transporter, and inflammation, oxidative and mitochondrial stress and fatty acid metabolism.

Interestingly, CpG loci methylation changes associated with the progression from normal baseline expression patterns to preDM were evident in 21 identified gene loci. These changes in CpG methylation in DNA of preDM remained persistent during the progression to T2DM in these patients. Among the 21 identified genes that were hyper or hypomethylated, the CpG loci associated with carnosinase was hypomethylated in PreDM and remained hypomethylated during the progression to T2DM. This gene has been suggested, from previous GWAS studies, to be involved in genetic disposition to diabetes as well as diabetic nephropathy. SLC22A12, a gene in the family of GLUT9 which is a uric acid and fructose transporter identified in kidney, became hypomethylated after the transition into diabetes.

Conclusions: These data suggest that some epigenomic changes that may be involved in the progression of diabetes and/or the development of complications may be apparent at the preDM state or during the transition to diabetes.

Alterations in Renal MicroRNA Expression in a Mouse Model of Congenital Obstructive Nephropathy Susan E. Ingraham,[1] Kirk M. McHugh.[2] *[1]Division of Nephrology, Nationwide Children's Hospital, Columbus, OH; [2]Center for Molecular and Human Genetics, Nationwide Children's Hospital, Columbus, OH.*

Background: Congenital obstructive nephropathy (CON) is the most common cause of chronic renal failure in children. The megabladder (mgb) mouse, a unique genetic model of CON, allows exploration the molecular changes of CON, potentially facilitating identification of novel biomarkers or therapeutic targets for this devastating condition. MicroRNAs (miRs), a class of small non-coding RNA, are important gene regulators controlling key cellular functions. A number of miRs are highly and differentially expressed in the kidney, and have been implicated in key physiological or pathological renal processes. This project explores changes in miR expression associated with early stages of renal involvement in the mgb mouse.

Methods: Four week old mgb mice were stratified based on general health and ultrasound findings as previously described (Ingraham et al., 2010). Males classified as having moderate renal involvement were selected, along with age- and gender-matched controls. Total kidney RNA was used for comparative miR microarray analysis. miRs that exhibited ≥1.5-fold alteration in expression by microarray were further investigated by quantitative reverse transcription-coupled PCR (RT-qPCR).

Results: Comparative microarray analysis yielded a panel of 22 miRs whose expression levels were altered at least 1.5-fold in mgb kidneys compared to normal controls. RT-qPCR analyses of these miRs confirmed that eight were significantly increased in expression in mgb kidneys ($p<0.05$). Five miRs showed a trend toward increased expression but did not reach statistical significance. Of three miRNAs with decreased expression by microarray, two showed a downward trend by qPCR but did not reach statistical significance. Two miRs showed no difference in expression between mgb and control, and five could not be tested by qPCR due to low sequence complexity.

Conclusions: Alterations in miR expression are associated with early stages of renal involvement in the mgb mouse model of CON. Further characterization of miRs in this animal model may yield new insights into this complex disease process.

TH-PO414

Genome-Wide Association Study (GWAS) of Novel Kidney Function Biomarkers in 6744 European Americans Adrienne Tin,[1] Brad C. Astor,[1] Eric Boerwinkle,[2] Josef Coresh,[1] Wen Hong Linda Kao.[1] *[1]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]Human Genetics Center, University of Texas School of Public Health, Houston, TX.*

Background: Serum beta trace protein (BTP) and beta-2 microglobulin (B2M) have potential as novel biomarkers for renal function. Little is known about the genes influencing either their levels alone or through glomerular filtration rate estimated from serum creatinine ($eGFR_{Cr}$) or cystatin C ($eGFR_{cysC}$).

Methods: We conducted a GWAS of log-transformed serum BTP and B2M levels and further examined their association with known eGFR loci in 6744 European Americans from the Atherosclerosis Risk in Communities (ARIC) study.

Results: The GWAS of BTP identified a genome-wide significant locus upstream of *PTGDS,* the gene that encode BTP (rs7040970, beta=0.04, $p=3.3x10^{-17}$, RSqr=0.8%), which was not associated with either $eGFR_{cr}$ or $eGFR_{cysC}$ ($p>0.05$). The GWAS of B2M identified 2 genome-wide significant loci. One was in the HLA region on chromosome 6 that spans 7 Mb with over 1000 SNPs attaining genome-wide significance (lowest p-value=$1.8x10^{-23}$ for rs9264638, betas=0.02 to 0.07). In this locus, 7 signals with low linkage equilibrium accounted for 3.5% of log(B2M) variance but were not associated with $eGFR_{cr}$ or $eGFR_{cysC}$. The other locus of B2M was on chromosome 12 (rs3184504 in *SH2B3,* beta=0.02, $p=3.1x10^{-8}$, RSqr=0.4%), which was previously implicated as a renal locus. Of the 16 $eGFR_{cr}$ loci previously identified (Kottgen et. al 2010), within our sample $eGFR_{cr}$ was associated with 7, $eGFR_{cysC}$ with 4, BTP with 3, and B2M with 2 (all $p\leq0.05/16$).

Conclusions: Genetic analysis of multiple filtration markers can identify both the genetic effects that influence only one marker (Cr, CysC, BTP, or B2M) and those that influence multiple markers, consistent with an effect on GFR itself. Extending previous work on Cr and CysC to BTP and B2M, we found novel marker-specific loci and confirmed the association of several loci of eGFRcr with BTP and B2M. These findings add to our understanding of the metabolism and future clinical use of BTP and B2M as filtration markers as well as improve genetic research of GFR determinants.

Next Generation Sequencing (NGS) of Targeted Exons in the UK Steroid Resistant Nephrotic Syndrome in Childhood Cohort: A Pilot Study Hugh J. McCarthy, Agnieszka Bierzynska, Matthew Wherlock, Moin Saleem. *Academic Renal Unit, University of Bristol, Bristol, United Kingdom.*

Background: Approximately 350 children in the UK have Steroid Resistant Nephrotic Syndrome (SRNS). This condition displays considerable genetic heterogeneity with an estimated 25% of all patients having a mutation in one of 10 'nephrotic' genes. The prevalence is not known within the UK population where clinical testing for the majority of these genes is not available.

Methods: Utilising the newly formed Rare Renal Disease Registry (renalradar.org), a national cohort of children with SRNS has been developed, with detailed and ongoing clinical phenotyping. This pilot study looked at the effectiveness of undertaking targeted exon capture with sequencing in 12 of these patients for exons in 478 genes. 5 of these patients had previously undergone Sanger sequencing for exons in 3 'nephrotic' genes.

The genes were chosen for reported or potential biological involvement in this condition. Using a Roche Nimblegen Sequence Capture (12x135K) Custom Array, the exons of these genes of interest were targeted. Paired-end sequencing was undertaken using an Illumina GAIIx. Data analysis was performed with CLC Genomics Workbench software.

Results: From all reads 98.2% were mapped uniquely to the reference sequence. 82% of reads were mapped to capture targets. All variants previously detected using Sanger sequencing were identified using NGS. A total of 37511 different variants were identified with 887 causing an amino acid change with an average depth coverage of 31. One homozygous and 2 heterozygous single nucleotide changes were identified in three patients in 'nephrotic' genes which are not previously described in dbSNP (build 132). 13 homozygous and 123 heterozygous variants not described in dbSNP were found in the remaining genes. 27 different deletion - insertion polymorphisms causing an amino acid change were detected, although none in the 10 'nephrotic' genes. (All specific changes described had coverage >10).

Conclusions: This pilot study demonstrated the potential of NGS to provide valid data. In this well phenotyped cohort it allows for exploration of disease modifying variations in a huge number of biologically relevant genes.

TH-PO416

Effects of Lovastatin Treatment on the Metabolic Distributions in the ADPKD Rat Kidney Jelena Klawitter, Jost Klawitter, Uwe Christians, Charles L. Edelstein. *Anesthesiology; Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO.*

Background: We have previously demonstrated that lovastatin decreases kidney and cyst volume and improves kidney function in the Han:SPRD (Cy/+) rat model of PKD. As statins are known to affect energy metabolism, we used NMR-based metabolomic profiling to investigate the metabolic pathways that might be responsible for the protective effect of lovastatin in PKD.

Methods: Cy/+ and normal littermate controls (+/+) were treated with either lovastatin (4mg/kg/day) or vehicle (ethanol) from 3-8 weeks of age. ^{1}H-NMR analysis was performed on water-soluble kidney fractions following a perchloric acid extraction (n=4-5).

Results: PKD in Cy/+ rats was accompanied by changes in several metabolites as compared to the +/+ rats. The concentrations of Krebs cycle intermediates citrate and succinate significantly decreased from 1366.9±296.8 and 3353.4±278.2 nmol/g to 919.3±150.7 ($p<0.05$) and 2219.6±557.0 nmol/g ($p<0.01$), respectively. Their decrease was accompanied by a decrease of kidney glucose concentration. The observed impairment of the glucose import could possibly be a result of a feedback action induced by the decreased Krebs cycle activity. A product of uric acid oxidation and a marker of kidney injury, allantoin, increased almost 3-fold in the Cy/+ rat kidneys ($p<0.001$).

Statin treatment reversed the metabolic changes induced by the PKD in the Cy/+ rats. Citrate concentration increased to 1419.2±92.2 nmol/g ($p<0.005$) and so did the lactate concentration, suggesting a recovery of energy producing Krebs cycle and glycolysis pathways. The increased glucose consumption of the lovastatin treated kidneys further lowered the glucose concentration. Allantoin levels significantly decreased as well, but still remained almost 2-fold higher as in the +/+ controls.

Conclusions: We describe for the first time changes in energy metabolism in PKD kidneys. Lovastatin increased the activity of energy producing metabolic pathways is association with improvement in PKD. NMR-based metabolomics may be a tool to study the relationship between metabolic changes and cellular signaling in PKD and to develop urine biomarkers for the diagnosis of PKD.

TH-PO417

Transcriptome and ChIP-Seq Analyses of JunD Levels Reveal the Basis of *Jund*-Mediated Activation Networks Associated with Crescentic Glomerulonephritis (Crgn) in Rat Macrophages Richard P. Hull,[1] Prashant K. Srivastava,[1] Zelpha D'souza,[1] Santosh S. Atanur,[1] Jennifer Smith,[3] Charles D. Pusey,[3] Jacques Behmoaras,[2,3] H. Terence Cook,[2,3] Timothy J. Aitman.[1] *[1]MRC CSC; [2]CCIR; [3]Renal Medicine, Imperial College, London.*

Background: We previously investigated the genetic basis for the unique susceptibility of the Wistar-Kyoto (WKY) rat to Crgn and identified the AP-1 transcription factor JunD as a primary determinant of macrophage activation. JunD is markedly overexpressed in WKY macrophages compared to the Crgn-resistant Lewis strain and this over-expression, controlled in *cis*, results in increased activity of these cells.

Methods: We studied how differences in *Jund* expression alter the macrophage transcriptome and its cistrome, the genome wide set of JunD-DNA binding sites, following (LPS) stimulation by two approaches: 1. siRNA knockdown of *Jund* in WKY bone marrow derived macrophages (BMDMs) followed by genome-wide expression analysis 2. Genome-wide expression combined with ChIP-Seq analyses in WKY and *Jund* congenic BMDMs where the *Jund* locus from a Lewis rat was introgressed onto a WKY background (WKY.L*Crgn2).*

Results: We identified 1672 genes in basal and 1476 genes in LPS stimulated BMDMs that were differentially expressed following siRNA knockdown of *Jund* and 830 differentially expressed genes between WKY and WKY.L*Crgn2* over a LPS stimulation timecourse. Gene ontology analysis enriched for processes including responses to

stimulation, cell activation and protein kinase cascades in all 3 datasets. Overexpression of JunD in WKY BMDMs results in significantly increased numbers of binding sites in basal (27124 peaks) and LPS stimulated BMDMs (36687 peaks) compared to WKY.L*Crgn2* (16593 peaks basal, 8689 peaks LPS stimulation) which were also associated with genes involved in stimulus responses, protein kinase cascades and cell activation.

Conclusions: This work shows that *Jund* expression levels have modulatory effects on macrophage gene expression as a result of alterations in the JunD cistrome and provides the basis for understanding how JunD mediates macrophage overactivity in the WKY rat enabling the identification of novel targets with which to modulate macrophage function.

Analysis of RNA from Urinary Exosomes/Microvesicles to Non-Invasively Diagnose Renal Cancer and Diabetes Related Renal Dysfunction Leileata M. Russo,[1] Kendall Bate,[1] Neda Sadeghi,[2] Guillermo Salazar,[1] Wayne Comper,[1] Siham Accacha,[3] John K. Maesaka,[3] James McKiernan.[2] *[1]Exosome Diagnostics., Inc., New York, NY; [2]Columbia University Medical Center, New York, NY; [3]Winthrop University Hospital, Mineola, NY.*

Background: Microvesicles, including exosomes, are small lipid bilayer vesicles released from all cells into bodily fluids. These vesicles harbor nucleic acids (in particular RNA) from their parent cell and can be used to interrogate the transcriptional profile of cells in vivo in a non-invasive manner. Using our rapid microvesicle isolation technique we have now demonstrated our ability to non-invasively detect mutational status in a 200 patient prostate cancer cohort demonstrating detection of oncogene fusion status (TMPRSS2:ERG) as well as qPCR analysis of 20 genes previously documented as being associated with prostate cancer progression. Using this experience as a foundation, we now turn our attention to the non-invasive detection of two important renal related diseases i) renal cell carcinoma (RCC) ii) diabetic nephropathy (DN).

Methods: Urine samples were collected from Columbia University (RCC patients) and Winthrop University Hospital (DN patients) under approved IRB. Urinary exosomes/microvesicles were isolated and high integrity RNA was extracted as analyzed via the Agilent Bioanalyzed Pico chip. RNA was subjected to various forms of analysis including array analysis, qPCR and next-generation sequencing (NGS).

Results: We demonstrate that a wide array of genes are detectable within urinary microvesicles using array and NGS analysis. This included CA9 in RCC and various markers of the renin angiotensin system and beyond in the DN patients including angiotensin II receptor, angiotensinogen and angiotensin converting enzyme mRNA expression.

Conclusions: Urinary exosomes/microvesicles offer a novel method to non-invasively monitor renal transcription in various renal related diseases. Array and NGS analysis of urinary exosomes/microvesicles may enable the selection of a diagnostic panel of markers to enable patient stratification and early detection of renal disease.

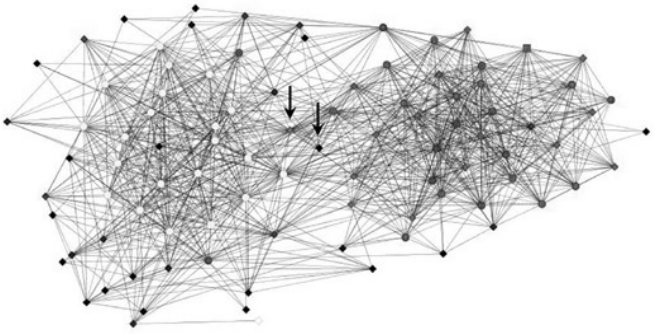
Transcriptional Pathways identified by Genotype-Phenotype Integration in CKD Sebastian Martini,[1] Viji Nair,[1] Felix H. Eichinger,[1] Katherine Gurdziel,[1] Carsten A. Böger,[4] Caroline S. Fox,[3] Clemens D. Cohen,[2] Matthias Kretzler.[1] *[1]University of Michigan; [2]University of Zürich; [3]National Institutes of Health; [4]University of Regensburg.*

Background: Integrating genome-wide association studies (GWAS) with gene expression data sets will help to define interactions of chronic kidney disease (CKD) associated molecular pathways with transcriptional regulators.

Methods: Candidate genes within 60kb of loci associated with CKD in GWAS reported by CKDGen were investigated for correlation of their renal mRNA levels with eGFR in the independent ERCB cohort. Correlated mRNAs were interrogated in genome wide renal gene expression profiles of 177 CKD patients for biological functionality by pathway mapping. An interaction network of individual pathways connected by genes 1) occurring in two or more pathways, and 2) co-regulated with one or more CKD candidate genes, was analyzed.

Results: Renal mRNA levels of 17 out of 29 expressed CKDGen candidate genes correlated with eGFR in an independent cohort. To define functional context of CKDGen associated genes, co-regulated transcripts were identified in the ERCB expression data set. These co-regulated transcripts were significantly enriched in 148 pathways. CKD associated pathways were displayed as pathway network using genes shared between pathways as edges. The network displays two major subclusters: 1. containing metabolism pathways (yellow in Fig. 1, i.e. Fatty acid metabolism, Glycerolipid metabolism) 2. inflammation-related pathways (red in Fig. 1, i.e. NFkappaB-, TNF-signaling). NRF2-mediated Oxidative Stress Response and PPARgamma-signaling (arrows in Fig. 1) are key hubs connecting the two main subclusters.



Conclusions: CKDGen transcripts and their co-regulated mRNAs identify the interplay of inflammation and metabolism pathways in CKD. The CKD pathway network can link specific molecules in their larger context.

TH-PO420

LC-MS/MS and Antibody-Array Based Urinary Proteome Analysis of Obstructive Nephropathy Caubet Cécile,[1] Chrystelle Lacroix,[2] Flavio Bandin,[1,3] Anne Gonzalez de Peredo,[2] Odile Burlet-Schiltz,[2] Jean-Loup Bascands,[1] Stéphane Decramer,[1,3] Joost Schanstra.[1] *[1]Inserm U1048, Toulouse, France; [2]CNRS - IPBS, Toulouse, France; [3]CHU Toulouse, Hôpital des Enfants, Service de Néphrologie, Toulouse, France.*

Background: We have previously shown that urinary peptidome analysis allows early prediction of obstructive nephropathy (ON) in newborns. Although these urinary peptidome biomarkers are of great potential clinical value, they are less informative on the pathophysiology of the disease. Therefore we have focussed on the changes in the urinary proteome of ON patients using label-free LC-MS/MS and antibody–array analyses.

Methods: Urine samples (n=5/group) were divided into 4 groups: bladder urine from controls (healthy), mild ON (NoOp), severe ON (Op) and pelvis urine from severe ON (Pelvis). For antibody array analysis, 90 µg of Cy5-tagged urinary proteins were applied onto antibody arrays (XP725 Sigma). Fluorescence intensity was normalized by the mean intensity of each array. For LC-MS/MS analysis, 30 µg of the protein was digested by trypsin and analysed by online capillary LC-MS/MS. Proteins were identified and quantified as described (Mouton-Barbosa et al., MCP, 2010).

Results: The number of differentially secreted proteins between the different groups (p value <0.05) is shown in the table.

Number of over-secreted proteins
Number of under-secreted proteins

	Healthy/Mild	Healthy/ Bladder-Surgery	Healthy/ Pelvis-Surgery	Mild/ Bladder-Surgery	Mild/ Pelvis-Surgery	Bladder-Surgery/ Pelvis-Surgery
LC MS/MS	23	64	213	13	161	149
	48 pBH<0.05				*1 pBH<0.05*	
	6 | 17	35 | 29	77 | 136	11 | 2	92 | 69	51 | 98
AB ARRAY	22	43	28	7	3	7
	17 | 5	18 | 25	23 | 5	1 | 6	2 | 1	6 | 1

pBH : pvalue after Benjamini-Hochberg adjustment

pBH indicates the number of differentially secreted proteins after Benjamini-Hochberg adjustment. Only the LC-MS/MS comparison of the control group versus pelvic urine yielded 48 proteins that survived correction for multiple testing. Based on these comparisons we established a list of proteins that are specific for the obstructed or controlateral kidney.

Conclusions: We are validating a subset of these proteins on new samples. Two different approaches for validation are used: antibody-based validation and multiple reaction monitoring on small (max 1.5 ml) urine samples.

Alterations in Cellular Proteome of Macrophage Induced by Calcium Oxalate Monohydrate Crystals Are Associated with Phagocytosis Visith Thongboonkerd, Nilubon Singhto, Kitisak Sintiprungrat. *Siriraj Hospital, Mahidol University, Bangkok, Thailand.*

Background: The presence of macrophage in renal tubulointerstitium is the key feature of progressive renal inflammation in kidney stone disease. Macrophage can engulf and eliminate foreign body or microbe, and subsequently produces various inflammatory mediators. However, molecular responses of macrophage to calcium oxalate monohydrate (COM) crystals, the major crystalline composition of kidney stone, remained unclear. Therefore, this study aimed to investigate alterations in cellular proteome of macrophage induced by COM crystals using a proteomics approach.

Methods: Macrophages were derived from U937 human monocytic cells by treatment with 100 ng/ml phorbol myristate acetate for 48 h. Macrophages were then incubated with or without 100 µg/ml COM crystals for 24 h. Thereafter, proteins derived from whole cell lysates of COM-treated and controlled cells were resolved by 2-DE (n=5 gels/group; each was from independent culture) and stained with Deep Purple fluorescent dye. Differentially

expressed protein spots were then identified by Q-TOF MS and MS/MS analyses. Functional significance of these proteins was addressed by global protein network analysis using STRING version 8.3 and double immunofluorescence staining.

Results: Spot matching and quantitative intensity analysis revealed 18 differentially expressed protein spots. These proteins were successfully identified by Q-TOF MS and MS/MS analyses, including those involved in cellular structure, carbohydrate metabolism, DNA/RNA processing, protein metabolism and stress response. The altered levels of α-tubulin, β-actin and ezrin were validated by Western blot analysis. Double immunofluorescence staining revealed a phagosome-like structure outlined with co-localized F-actin and HSP90 and contained COM crystal inside.

Conclusions: Proteomic analysis revealed altered cellular proteome profile of macrophage induced by COM crystals. These findings also showed that the altered proteins were also involved in enhanced phagocytic activity of the COM-exposed macrophage. Our data may help understanding of important role of macrophage in kidney stone disease.

Renal Mendelian Genes Based Pathway Analysis Afshin Parsa, Young J. Kim. *Medicine, University of Maryland School of medicine, Baltimore.*

Background: The development of complex diseases such as chronic kidney disease (CKD) and end-stage renal disease (ESRD) often require the interaction of various genes and environmental factors within individual or interacting pathways. Similarly, injury along multiple points of interacting pathways can results in similar disease phenotypes. As such, we hypothesized that exploring protein to protein interactions (PPI) networks related to Mendelian genes associated with renal phenotypes could help better elucidate pathways critical to the development of renal pathology.

Methods: Starting with over 600 OMIM listings of Mendelian diseases with renal phenotypes, we identified 339 unique entries which were manually curated to 227 unique disease entries with at least one identified autosomal gene and identifiable renal phenotypes. These were classified within 3 broad categories: 1) Developmental and glomerular 2) Tubular, and 3) Secondary renal disease (e.g., deposition of protein within the kidney). Using the Pathway Studio tool, we systematically explored protein interaction network related to our selected Mendelian genes and identified overrepresented biologic pathways within our 3 broad categories of renal disease types.

Results: We identified numerous pathways that were significantly over represented within our Mendelian gene based PPI networks, including FGFR, leptin, PECAM, and guanylate cyclase. These pathways relate, at least in part, to angiogenesis, branching morphogenesis, adipose activation of sympathetic activity, endothelial cell adhesion and nitric oxide signaling. We also found significant overrepresentation of expression targets related to many of our genes, including SHH, PAX2, ACE, LMX1b, ALB, SGK1, AVP, FOXI1, SCNN1G, WNK4, FGF23, PLAU, FOXM1, ERG, RAG2 and PPARG.

Conclusions: By mining genes associated with renal pathology, we have identified numerous first order protein based interactions converging from diverse genetically mediated renal diseases onto definable pathways. These overrepresented pathways provide promising logical targets for further study in both fundamental mechanism and treatment interventions for CKD and ESRD.

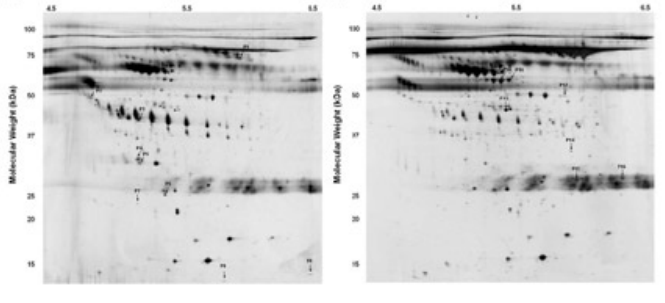
Impact of Uremic Environment on Peritoneum: A Proteomic View Hsien-Yi Wang, Wei-Chih Kan, Chih-Chiang Chien. *Nephrology, Chi-Mei Medical Center, Tainan, Taiwan.*

Background: Morphology and function of peritoneal membrane are abnormal in patients with uremia, but the contributing pathophysiology is unclear. Here we attempted to characterize the differential protein targets that may be related to peritoneal membrane changes in patients with uremic condition and haven't exposed to peritoneal dialysis fluid

Methods: Protein profiles of peritoneal fluids collected from patients with uremia and patients with normal renal function receiving laparoscopic cholecystectomy were displayed by two-dimensional gel electrophoresis (2-DE). Altered protein spots were excised and subjected to in-gel tryptic digestion followed by liquid chromatography- tandem mass spectrometry (LC-MS/MS) analysis

Results: Sixteen 2-DE protein spots were altered between two groups of samples.



Western blots analysis confirmed that kininogen-1, apoptosis inhibitor 2, cat eye syndrome critical region protein 1, and apolipoprotein A-I had higher expression levels in the uremic samples. In contrast, synaptic vesicle 2-related protein, glial fibrillary acidic protein, and envelope glycoprotein (C2-V5 region) showed lower levels [figure2]

Conclusions: The increased expression of differential proteins may result from changes in the permeability of the peritoneal membrane to middle-sized proteins or peritoneal inflammation with proteins sloughing off. All the identified proteins may provide a novel understanding of peritoneal membrane changes injured by uremic toxins and may manifest as predictive biomarkers of peritoneal function or therapeutic targets during the regular peritoneal dialysis in the future

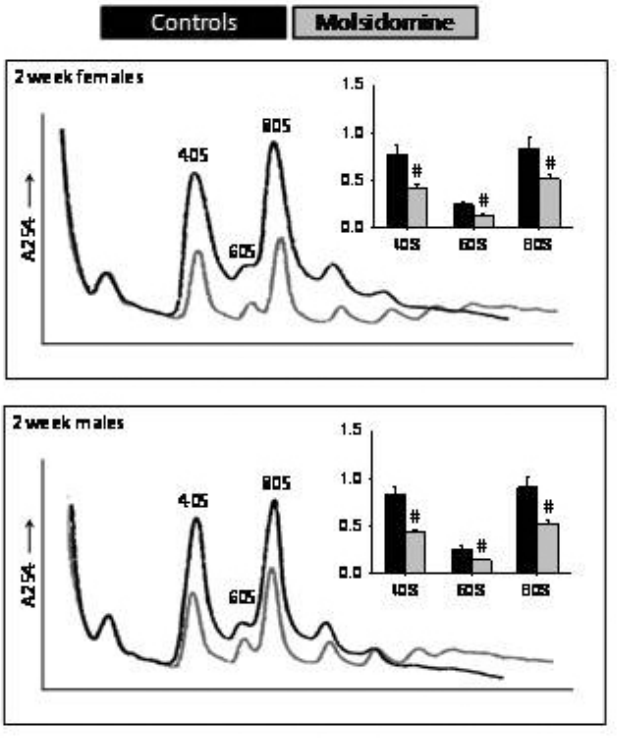
Perinatal Exogenous Nitric Oxide in Fawn-Hooded Hypertensive Rats Reduces Renal Ribosomal Biogenesis in Early Life Sebastiaan Wesseling,[1] Paul B.M. Essers,[4] Maarten P. Koeners,[1] Tamara Pereboom,[4] Branko Braam,[3] Ernst van Faassen,[2] Alyson W. Macinnes,[4] Jaap A. Joles.[1] *[1]Nephrology, UMCU, Utrecht; [2]Nephrology, LUMC, Leiden; [3]Nephrology and Physiology, Univ Alberta, Edmonton; [4]Hubrecht Institute, Utrecht, Netherlands.*

Background: Nitric oxide (NO) is known to depress ribosome biogenesis in vitro. We analyzed the influence of exogenous NO on ribosome biogenesis in vivo using a proven antihypertensive and renoprotective model of perinatal NO administration in genetically hypertensive rats (Am J Physiol 2008;294:R1847-55).

Methods: Fawn-hooded hypertensive rat (FHH) dams were supplied with the NO donor molsidomine in drinking water from 2 weeks before to 4 weeks after birth. Kidneys were collected from 2d, 2wk and adult offspring.

Results: Although the NO donor increased maternal NO metabolite excretion, renal NO status at 2wk was unchanged as assayed by EPR spectroscopy of NO trapped with iron-dithiocarbamate. Nevertheless, microarray analysis revealed marked differential down-regulation of ribosomal protein genes in 2wk old males. These changes in 2wk males were confirmed by polysome profiling, which also showed down-regulation of ribosomes in 2wk females. Polysome profiles were not affected at 2d or in adults.



Kidneys of 2wk old control and molsidomine treated FHH (n=8/group) were profiled to measure assembled ribosome structures. # P<0.01 vs. controls of the same peak.

Conclusions: Marked decreased postnatal expression of renal ribosomal genes and proteins at 2wk of age in the absence of a change in renal NO status suggest that these alterations are epigenetically programmed by NO in the foetus. In conjunction with prolonged antihypertensive and renoprotective effects of perinatal NO administration in FHH, these data provide a salient example of drug-induced reduction of renal ribosome biogenesis accompanied by beneficial long-term effects in both males and females.

Identifying Urinary Peptidomic Biomarkers for Metabolic Syndrome with Early Renal Injury Bixia Gao,[1] Mingxi Li,[1] Xuejiao Liu,[1] Jianfang Cai,[1] Xiaohong Fan,[1] Xiaolin Yang,[2] Xuemei Li,[1] Xue-Wang Li.[1] *[1]Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China; [2]Biomedical Engineering, CAMS, Beijing, China.*

Background: Metabolic syndrome (MS) is associated with chronic kidney disease. Our study aims to establish peptide models and identify urinary biomarkers of MS with early renal injury.

Methods: Samples of overnight (8hr) urine were collected from subjects participating an epidemiologic study of MS with CKD. MS was diagnosed by ATP III criteria, while MS with early renal injury was defined as 20μg/min≤UAE<200μg/min and eGFR≥60ml/min·1.73m^2. Participants were grouped into healthy (G I, n=65), MS with normoalbuminuria(G II, n=54) and MS with MAU(G III, n=46). The urine was fractionated by magnetic bead based weak cation exchange chromatography and subsequently analyzed with MALDI-TOF-MS. The peptide models were respectively established using statistical tests combined GA (ClinProTools2.1) and RF algorithm combined SVM (Matlab7.10.0). The performance of diagnostic models was assessed using 10-fold cross validation and ROC curve. Differential peptide peaks between groups were identified by LC-MS/MS (LTQ Orbitrap Velos).

Results: (1) G I vs G III: GA model showed 100% sensitivity, 92% specificity and 96% accuracy in training set in identifying MS with early renal injury, and it revealed 76% sensitivity, 80% specificity and 78% accuracy in testing set; Correspondingly, SVM model reported 82% sensitivity, 91% specificity and 87% accuracy, AUC value of ROC curve was 0.924. (2)G II vs G III: GA model showed 100% sensitivity, 88% specificity and 93% accuracy in training set, and it revealed 71% sensitivity, 73% specificity and 72% accuracy in testing set; SVM model reported 89% sensitivity, 81% specificity and 86% accuracy, AUC value was 0.911. (3)Three peptide peaks identified were all peptide fragments of fibrinogen α chain (Fgα), m/z 2562.67 was up-regulated in G II and G III, m/z 1884.33 and 2661.41 were up-regulated in G II.

Conclusions: Peptide fragments of Fgα might be urinary peptide biomarkers of MS with early renal injury and Fgα might involve in the pathogenesis of MS and MS with early renal injury.

TH-PO426

CD36 Polymorphisms Associated with Measures of Renal Disease in Zuni Indians Latisha Love-Gregory,[1] Venkata Saroja Voruganti,[2] Sandra L. Laston,[2] Karin Haack,[2] Jean W. Maccluer,[2] Shelley A. Cole,[2] Vallabh O. Shah,[3] Jeanette Bobelu,[3] Arlene Bobelu,[4] Donica M. Ghahate,[3] Antonia M. Harford,[3] S. Paine,[3,4] Philip Zager,[3,4] Anthony Comuzzie,[2] Nada A. Abumrad,[1] Aldi T. Kraja.[1] *[1]Washington University School of Medicine, St. Louis, MO; [2]Texas Biomedical Research Institute, San Antonio, TX; [3]University of New Mexico School of Medicine, Albuquerque, NM; [4]Dialysis Clinic, Inc., Albuquerque, NM.*

Background: The multi-ligand lipid receptor CD36 is implicated in renal pathophysiology in rodents but its potential role in kidney disease (KD) in humans is unknown. We examined whether common (minor allele frequency, maf >0.05) SNPs in the *CD36* gene associate with measures of renal function in the Genetics of Kidney Disease in Zuni Indians study(n=878) who have a disproportionately high prevalence of diabetic and non-diabetic renal disease (RD).

Methods: Linear mixed effect models were applied in a family-based association test to examine the influence of *CD36* SNPs on renal quantitative measures. Minor allele frequencies and linkage disequilibrium structure were determined using 168 *CD36* SNPs and 66 representative tag SNPs (maf >0.05) were selected for association analyses adjusted for age and gender.

Results: Four putative regulatory SNPs (rs3211820, rs3211822, rs3211834, rs3211816) mapping to a region of strong linkage disequilibrium in intron 3 (p=0.006-0.01) and an additional SNP in intron 1 (rs4545029, p=0.02) associated with HDL levels independent of BMI, hypertension and glycated hemoglobin. Two intragenic SNPs inversely associated with MDRD glomerular filtration rate (GFR) (p=0.002-0.017) and one (rs2906199, p=0.007) with KD status (n=202 with KD vs n=662 without KD). Six promoter SNPs and 3 intronic SNPs associated with Cystatin C estimated GFR in a subset of subjects (n=246), (p=0.00068 for SNP rs10249397). Multivariate factor analysis revealed a correlation between urine protein/creatinine and blood pressure at a common promoter variant (rs4545029, p=0.0097).

Conclusions: Our results suggest a potential influence for *CD36* SNPs in RD. In particular the findings regarding Cystatin C will need to be investigated further.

The Updated Database of Glomerulus-Enriched Genes by Combining with the Glomerulus Proteome Database for Novel Biomarker Discovery Hidehiko Fujinaka,[1] Tadashi Yamamoto.[2] *[1]Institute for Clinical Research, NIigata National Hospital, Kashiwazaki, Niigata, Japan; [2]Structural Pathology, Institute of Nephrology, Niigata University, Niigata, Japan.*

Background: A comparative study of the 5 different glomerulus-enriched (Gl-E) gene databases (DBs) using different techniques has revealed only 7 genes, out of 1,407 genes identified by at least one DB, were identified as Gl-E genes in all 5 DBs (He et al., *J Am Soc Nephrol* 2008). We constructed a human glomerular cDNA microarray DB (MAd-761), in which 761 genes of Gl-E (intensity ratio of Cy5 (glomerulus)/Cy3 (cortex) >2.0) were ranked in order of glomerular abundance. The present study aimed to update MAd-761 by comparing it with another Gl-E gene DB from Stanford (StDB) and with human glomerulus proteome DB.

Methods: We constructed a human glomerulus proteome DB by separating glomerular proteins with electrophoresis coupled with the shotgun analysis by LC-MS/MS (2DGE-LS-MS/MS, http://www.hkupp.org/). The 6,686 glomerular proteins (representing 2,966 distinct genes) were ranked in order of glomerular abundance (spectra numbers). Kidney immunohistochemistry of each listed protein was checked in the Human Protein Atlas (HPA, http://www.proteinatlas.org/). Gl-E protein was defined the staining intensity in glomerulus was strong (weak or negative in cortex) or moderate (negative in cortex).

Results: In 761 genes in MAd-761, 203 genes were listed in StDB as Gl-E genes. And among the top 1,000 glomerular proteins in the 2DGE-LC-MS/MS, 83 proteins (31 distinct genes) were shown Gl-E protein by HPA. In 761 genes in MAd-761, 26 genes were shown Gl-E protein. And in 203 Gl-E genes in MAd-761 with StDB, 13 genes were demonstrated Gl-E protein; PODXL, PTPRO, SPARC, NES, PCOLCE2, ARHGDIB, CD34, ANXA1, PDGFRB, WT1, ARRB1, TJP1, ITGA8. The first 10 of 13 were included in the top 200 glomerulus-abundant genes in MAd-761. Among these, increased urinary ARHGDIB was demonstrated only in some patients of glomerulonephritis, but in none of normal humans by real-time PCR.

Conclusions: The Gl-E gene DB has been updated by combining with the glomerulus proteome DB, which can be useful for novel biomarker discovery in human glomerular diseases.

Gene Expression Profiling of Oxalate Nephrotoxicity Hari K. Koul, Sweaty Koul. *Urosciences Program-Urology/Surgery, University of Colorado School of Medicine, Aurora, CO.*

Background: Oxalate interactions with the renal cells results in a plethora of changes, including cell growth, death and altered gene expression as shown in previous studies. This study has been designed to identify specific gene ontology groups and new signaling pathways that undergo changes as a result of oxalate exposure.

Methods: We utilized microarray analysis using Affymetrix HG_U133_plus2 gene chip. Data analysis was performed suing Data Mining Tool (DMT 3.1, Affymetrix) and GeneSpring 7.2 (Silicon Genetics). Differentially expressed genes were classified according to the Gene Ontology functional category (GenMAPP v2) and functional significance of differentially expressed genes was determined using Ingenuity Pathways Analysis Software (Ingenuity® Systems, www.ingenuity.com). Cluster and Heatmap images were generated using BRB-Array tools30. Changes in gene expression were further validated by relative quantitative RTPCR.

Results: Novel signaling pathways and specific genes involved in promoting cell damage and death, nephrosis and tubular damage are highlighted by this study for the first time. We show that CDK2, CDK6 and CDC2 responsible for G1 to S phase transition are highly down-regulated by oxalate. On the other hand,Retinoic acid Receptor and CBX7 that are involved in maintaining the repressive state of many genes involved in cell growth are highly up-regulated. Cluster analysis of genes that are known members of MAPK pathways, identified up-regulation of many genes that are know activators of the p38 MAPK pathway, like Ras oncogene, MKK3 and ASK1 consistent with our previous demonstration of p38 MAP kinase activation. On the other hand Epidermal Growth factor (EGF) signaling is down regulated. We also show that many genes that are potentially involved in nephrosis and injury to the kidney were identified to be differentially expressed in HK-2 cells upon exposure to oxalate for as little as 4 hours.

Conclusions: The results of this study also provide first direct demonstration of activation of distinct pathways in a comprehensive genomic response to oxalate and identifies the potential of gene chip technology in identification of novel targeted pathways in an unbiased fashion.

Metabolomic Profiling of the Autosomal Dominant Polycystic Kidney Disease Rat Model Takafumi Toyohara,[1] Takehiro Suzuki,[1] Yasutoshi Akiyama,[1] Daisuke Yoshihara,[2] Eikan Mishima,[1] Yoichi Takeuchi,[1] Sadayoshi Ito,[1] Shizuko Nagao,[2] Tomoyoshi Soga,[3] Takaaki Abe.[1,4] *[1]Divison of Nephrology, Endocrinology, and Vascular Medicine, Tohoku University, Sendai, Japan; [2]Education and Research Center of Animal Models for Human Diseases, Fujita Health University, Toyoake, Japan; [3]Institute for Advanced Biosciences, Keio University, Tsuruoka, Japan; [4]Department of Clinical Biology and Hormonal Regulation, Division of Medical Science, Tohoku University, Sendai, Japan.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is an inherited systemic disease characterized by renal cyst expansion, resulting in renal failure. With the progression of renal damage, the accumulation of uremic compounds is recently reported to subsequently cause further renal damage and hypertension. The aim of this study was to analyze the profile of uremic retention solutes of ADPKD by capillary electrophoresis–mass spectrometry (CE-MS) using the Han:SPRD rat model.

Methods: Two hundred and ninety-seven cations and 190 anions were comprehensively analyzed by CE-MS in Han:SPRD rats and control rats.

Results: We found 21 cations and 19 anions that accumulated significantly in the heterozygous (Cy/+) ADPKD rat model compared with control rats. Among the compounds, increases in 5-methyl-2'-deoxycytidine, glucosamine,ectoine, allantoate, α-hydroxybenzoate, phenaceturate and 3-phenylpropionate and decreases in 2-deoxycytidine, decanoate and 10-hydroxydecanoate were newly identified in the ADPKD Cy/+ rats. We also compared these compounds with human or rat uremic solutes reported in privious studies. As a results, 3 cations and 4 anions were specific uremic solutes in ADPKD rat and could be a new marker(s) for detecting ADPKD.

Conclusions: We comprehensively identified new uremic solutes in the serum from ADPKD Cy/+ rats and revealed differences in uremic solutes among human CKD patients, the rat renal failure model and Cy/+ rats. We also found new biomarker candidates for detecting renal damage in ADPKD. The results are useful for further studies to elucidate mechanisms accumulating uremic toxins.

TH-PO430

Development of a Scanning Electron Microscopy (SEM) Based Assay for Exosome-Like Vesicle (ELV)-Cilium Interactions Jason L. Bakeberg, Marie C. Hogan, Peter C. Harris, Christopher James Ward. *Mayo Clinic, Rochester, MN.*

Background: Exosome-like vesicles (ELVs) are 50-200nm membrane bound vesicles found in urine and bile that are too small to be resolved by light microscopy. In the kidney, polycystin-1 (PC1) positive ELVs (PKD-ELVs) can interact with primary cilia (Hogan et al 2009). The early assays for this interaction were cumbersome, involving surface biotinylation of human ELVs and multiple purification steps to obtain PC1+ ELVs, and were not suited for high throughput analysis. Furthermore, to visualize the streptavidin gold conjugates on primary cilia we used 22nm carbon to coat the cells, which obscured morphology although it gave good backscatter contrast between the carbon and gold.

Methods: Here we describe a new assay based on the *Pkhd1*$^{Pk(+)/Pk(+)}$ mouse that has an epitope tagged *Pkhd1* gene, with two SV5-Pk tags inserted immediately C-terminal to the signal peptide, so that the tags are at the N-terminus of this large type-1 membrane protein. The *Pkhd1*$^{Pk(+)/Pk(+)}$ mouse is normal and secretes SV5-Pk tagged ELVs in its urine and bile. Wildtype primary mouse kidney epithelial cells were cultured and allowed to polarize and make cilia. *Pkhd1*$^{Pk(+)/Pk(+)}$ urine was then applied for 1-10 mins, the cells are fixed in 4% paraformaldehyde and ELVs detected using the SV5-Pk1 antibody and 15nm anti-mouse IgG gold post-fixed in OsO_4 and critical-point dried. To obtain optimum morphology the cells are then coated with a 1nm layer of osmium metal using plasma deposition. Using this technique we are able to detect ELVs interacting with primary cilia.

Results: Non treated cilia had no gold positive ELVs associated with them. However, cells treated with *Pkhd1*$^{Pk(+)/Pk(+)}$ urine for 1, 2, 5 and 10 minutes have: 1.5, sd+/-1.5; 1.7, sd+/-0.7; 0.55, sd+/-0.68 and 0.36, sd+/-0.67 ELVs with 1 or more gold particles on them, respectively.

Conclusions: The ELV primary cilium assay described above will be used to assess the ability of various recombinant domains derived from the extracellular part of PC1 and fibrocystin to block or stall the interaction and will help define the functional domains required for interaction.

TH-PO431

Podocin a Novel Substrate for Chaperone Mediated Autophagy Substrate Alejandro Quiroga,[1] Ana Maria Cuervo.[2] *[1]Pediatric Nephrology, Montefiore Childrens Hospital, New York, NY; [2]Department of Development and Molecular Biology, Albert Einstein College of Medicine, New York, NY.*

Background: Podocin is a component of the glomerular slit diaphragm and genetic mutations of this protein lead to steroid resistant nephrotic syndrome (SRNS). Altered levels of podocin have been reported in the podocytes of the affected patients, but the contribution of changes in the intracellular turnover of podocin to these altered levels remains unknown. In this study, we have explored the mechanisms that normally contribute to podocin turnover and analyzed changes in this degradation in an experimental model of nephrotic syndrome.

Methods: Endoplasmic reticulum, mitochondria, lysosomes (CMA positive and CMA negative) and cytosol were obtained using whole kidney sub-cellular fractionation from Wistar male rats. Podocin was tagged by green fluorescent protein and transfected into fibroblasts. Lysosome-associated membrane protein 2A (LAMP2A, CMA receptor) was knocked down by shRNA in mouse fibroblasts. Puromycin aminoglicoside (PAN) was used as a model of nephrotic syndrome in cultured human podocytes.

Results: We have found that podocin associates with and is actively degraded in lysosomes. Lysosomal degradation of podocin is maximally activated during nutritional deprivation, however, macroautophagy, one of the starvation-induced forms of lysosomal degradation, does not significantly contribute to the normal turnover of this protein. Instead, we have found that podocin bears in its amino acid sequence a conserved pentapeptide motif used for targeting of proteins for lysosomal degradation via chaperone-mediated autophagy (CMA).

Conclusions: We have confirmed that podocin is preferentially degraded in lysosomes with high CMA activity and that blockage of CMA abrogates this degradation. Lysosomal delivery of podocin via CMA is enhanced in response to PAN treatment, but we have identified a compromise in its degradation in this compartment under these conditions. Our results support that CMA contributes to the normal turnover of podocin in podocytes and that this degradation may be upregulated as a first line of defense in response to damaging agents of the slit diaphragm.

TH-PO432

Gene Screening Identified Early Growth Response 1 as a Regulator of Tubulogenesis in Diabetic Renal Embryopathy Ching-Yuang Lin. *China Medical University and Hospital, Taichung, Taiwan.*

Background: Maternal hyperglycemia can inhibit morphogenesis of ureteric bud branching, with glial cell line-derived neurotrophilic factor (GDNF) as a key regulator of its initiation. Early growth response gene-1 (EGR-1) is one immediate early gene. Our preliminary study found EGR-1 consisting of expression with GDNF in hyperglycemic environment.

Methods: To evaluate the potential relationship of hyperglycemia-GDNF-EGR-1 pathway, *in vitro* human renal proximal tubular epithelial (HRPTE) cells as target and *in vivo* streptozotocin-induced mouse model were used.

Results: *In vivo* microarray, real time-PCR and confocal morphological observation confirmed apoptosis in hyperglycemia-induced fetal nephropathy via activation of the GDNF/MAPK/EGR-1 pathway. *In vitro* evidence indicated high glucose suppressing HRPTE cell migration, and enhanced GDNF-EGR-1 pathway induced apoptosis. Knockdown of EGR-1 by siRNA negated hyperglycemic suppressed GDNF-induced HRPTE cell migration. Also, EGR-1 siRNA alleviated GDNF/EGR-1-induced cRaf/MEK/ERK phosphorylation by 80%.

Conclusions: Our findings demonstrated EGR-1's crucial role in HRPTE cell apoptosis and fetal hyperglycemic nephropathy.

TH-PO433

Stem Cell Microvesicles Rescue Cystinosis In Vitro Diana Iglesias,[1] Reyhan El-Kares,[1] Francesco Emma,[2] Elena N. Levtchenko,[3] Nicoletta Eliopoulos,[4] Paul R. Goodyer.[1] *[1]McGill University, Montreal, Canada; [2]Ospedale Pediatrico Bambino Gesù, Rome, Italy; [3]University Hospital Leuven, Leuven, Belgium; [4]Lady Davis Institute, Montreal, Canada.*

Background: In 2009, Syres *et al* reported that infusion of bone marrow stem cells into a cystinotic mouse dramatically reduces tissue cystine and improves organ function. Since transdifferentiation of stem cells was rare, the benefit seems to involve a paracrine effect. Recent studies suggest that, by shedding microvesicles, cancer stem cells re-program the biology of their neighbors. We hypothesized that normal stem cells release microvesicles (MV) that reduce cystine accumulation in CTNS (-/-) cells.

Methods: Normal bone-marrow (bmMSC) and amniotic fluid (amMSC) mesenchymal stem cells were used as MV donors. Fibroblasts and proximal tubular epithelial cells (PTEC) isolated from cystinotic patients with homozygous CTNS deletions were used as target cells. MV were isolated from culture medium by ultracentrifugation. Cystine was measured by HPLC.

Results: When MSC were co-cultured with cystinotic fibroblasts (1:4), cystine levels decreased by 60%, an effect which could not be explained by cell dilution. We then cultured various donor cells separately and harvested MV shed into the culture medium. When MV (100-300nm) were added to CTNS (-/-) target cell monolayers, cystine content was dramatically reduced in dose-dependent manner after 24 hours. The effect was blocked by MV pre-treatment with annexin V. To address whether MV transfer wildtype CTNS protein to the mutant target cells, we transfected amMSC cells with wildtype CTNS/Red fusion protein. In co-culture, we observed direct transfer of the label to intracellular lysosomes of adjacent mutant fibroblasts. We also identified CTNS mRNA in amMSC MV and demonstrated its transfer to CTNS (-/-) targets. By introducing a CTNS siRNA, we showed that the MV rescue effect is primarily due to transfer of CTNS protein. A rescue effect was not seen when MV were prepared from mutant amMSC or PTEC cells.

Conclusions: We propose a model in which uptake of MV from stem cells containing wildtype CTNS protein can reduce pathologic accumulation of cystine in adjacent mutant cells.

Existence of Neural-Derived Cells in Nephron and Mesangial Cells Akiko Oguchi, Jin Nakamura, Nariaki Asada, Motoko Yanagita. *Graduate School of Medicine, Kyoto University, Kyoto, Japan.*

Background: Recent lineage tracing method demonstrated that almost all cells in the nephron are derived from Six2+ progenitor cell in metanephric mesenchyme during development, and contribution of other cells types is considered less likely, whereas the origin of mesangial cells and glomerular endothelial cells remains controversial. Here we demonstrated the existence of neural-derived cells in the nephron, glomerular endothelial cells and mesangial cells.

Methods: To test the contribution of neural cells in kidney development, we utilized Nestin-CreERT2 mice, in which inducible Cre is expressed under the control of Nestin promoter, and is activated only after the administration of tamoxifen at desired time points. Nestin is a well-known marker for neural stem cells. We bred Nestin-CreERT2 mice to R26ECFP indicator mice, administered tamoxifen at various time points during embryogenesis as well as in adult life, and permanently labeled Nestin+ cells with the expression of ECFP.

Results: When we administered tamoxifen during embryogenesis, ECFP+ cells were detected in tubular epithelial cells, collecting duct, glomerular endothelial cells and mesangial cells, whereas none of Six2+ progenitor cells were positive for ECFP after the administration of tamoxifen. When we administered tamoxifen 1 month after birth, ECFP+ cells were detected only in the inner medulla and papilla.

Conclusions: Taken together, we demonstrated that some cells in the nephron are not derived from Six2+ progenitor cells, but of neural origin. In addition, some mesangial cells and glomerular endothelial cells were derived from Nestin+ cells during embryogenesis. Kidney papilla has attracted attention as a potential niche for kidney stem cells, and lineage tracing of ECFP+ cells in the papilla might give us some insight in the behavior and contribution of these cells during kidney regeneration.

Morphometric Analysis of Urinary Tract Development in Mice Ashley R. Carpenter,[1] Brian Becknell,[2] Carlton M. Bates,[3] David S. Hains,[2] Kirk M. McHugh.[1] *[1]Molecular & Human Genetics, Nationwide Children's Hospital, Columbus, OH; [2]Pediatric Nephrology, Nationwide Children's Hospital, Columbus, OH; [3]Pediatric Nephrology, Chidren's Hospital of Pittsburgh, Pittsburgh, PA.*

Background: Disorders of the urinary tract affect both sexes of all ages and represent a major cause of morbidity and impaired quality of life.

Methods: To understand the morphological events responsible for normal urinary tract development, we performed 3-D reconstructive analysis of the developing mouse urinary tract from embryonic day (E)13 to E17 and postnatal day (P)1. These results were compared to a similar analysis of urinary tract development in the megabladder mouse (mgb-/-) and Fgfr2Mes-/- murine model of vesicoureteral reflux (VUR).

Results: Morphometric analysis showed that detrusor smooth muscle differentiation initiates in the bladder dome and progressively moves caudal, with the leading edge of differentiation extending down the right posterior surface of the bladder. The developing bladder becomes completely invested with smooth muscle by E15, after which it thickens creating a distinct octahedral morphology. Total bladder trigone area and perimeter increased at distinct linear rates during development. From E13 through E16, the bladder trigone progressed from an isosceles triangle with a long base between the ureters to an equilateral triangle due to preferential lengthening of the distance between the ureters and urethra. Morphometric analysis confirmed that the primary defect in mgb-/- bladders was a reduction in the percentage of detrusor smooth muscle throughout development. Morphometric comparison of the developing bladder trigone in Fgfr2Mes-/- mice versus control revealed that deviation from normal bladder trigone patterning was the most consistent predictor of VUR. Direct comparison of the right refluxing versus left non-refluxing ureters indicated that intravesicular tunnel length was a poor predictor of VUR.

Conclusions: In conclusion, our findings have significant implications for bladder morphogenesis as well as the ontogeny of VUR and indicate the 3-D morphometric analysis is a powerful tool to assess both normal and pathologic development of the urinary tract.

Pax2 Maintains Self-Renewing Nephron Progenitors during Mammalian Kidney Development Akio Kobayashi. *Renal Division, Brigham & Women's Hospital, Harvard Medical School, Boston, MA.*

Background: The functional unit of the kidney, the nephron, is repetitively generated during mammalian kidney development. Previously, our fate map analysis revealed that the Six2+ cap mesenchyme represents a multipotent, self-renewing nephron progenitor population throughout kidney development (Kobayashi et al., 2008, Cell Stem Cell). We further found that the nephron and interstitium form distinct compartments with a strict lineage boundary during kidney organogenesis. Currently, it is not well known how the nephron progenitor population is maintained during kidney organogenesis.

Methods: The paired-domain transcription factor Pax2 is expressed in multiple urogenital tissues including the cap mesenchyme. However, Pax2 function in the cap mesenchyme has not been examined in vivo. Therefore, we investigated Pax2 function in the cap mesenchyme using mouse genetic approaches, including tissue-specific inactivation and mosaic analysis.

Results: In this study, we found that the Pax2 mutant mice fail to maintain the cap mesenchyme in the developing kidney. Surprisingly, fate map analysis in the mutants showed that cap mesenchyme-derived cells lacking Pax2 activity are not lost, but persist throughout kidney development. Detailed molecular marker analysis indicated that these cap mesenchyme-derived cells can trans-differentiate into medullary interstitial cells. Our mosaic analysis reveled a cell-autonomous requirement of Pax2 activity for cap mesenchyme cells.

Conclusions: Taken together, our observations suggest that Pax2 maintains a self-renewing nephron progenitor population by repressing interstitial cell fates. Thus, Pax2 activity establishes a lineage boundary between the nephron and non-nephron compartments during kidney organogenesis.

A Novel Iron Transporter Controls Organogenesis Andong Qiu, Jonathan M. Barasch. *Medicine, Columbia.*

Background: It is thought that iron crosses the plasma and endosomal membranes by a Fe^{2+}: H^+ transporter known as the Divalent Metal Transporter 1 (DMT1), but transport is induced by a substantial H^+ gradient that is not typical of the transferrin endosome. In addition, the DMT1 knockout did not inhibit organogenesis. Hence, mechanisms that transfer transferrin-bound iron from circulation to developing organs are currently unknown.

Methods: In order to discover transmembrane transporters of iron we preformed an extensive informatics search of proteins distantly related to yeast and mammalian iron transporters. We performed expression cloning in oocytes and 50 candidate genes were evaluated for their ability of iron transport.

Results: We identified a novel transporter that was specific for Fe^{2+} and active at neutral and mildly acidic pH (7.0-6.5). It had a low micromolar Km for iron conductance.Tagged constructs expressed in cell lines demonstrated that the protein localized in endosomes that contained serum transferrin. There was no overlap in localization with DMT1 which appeared to inhabit a separate endosomal-lysosomal compartment. Application of the transferrin to cells overexpressing the novel gene resulted in increased iron content of the cytosol, and knockdown of the gene had the opposite effect. The knockout of the gene *in vivo* did not inhibit the formation of the embryonic body plan; however, organogenesis throughout the embryo was inhibited including eye, blood, liver, and kidney at E14.5. There was an increase in endosomal oxidized damage induced by accumulated iron in this intracellular compartment of KO cells.

Conclusions: The mechanisms of iron delivery in the embryo are unkown. We have identified a novel transporter sufficient and necessary for iron traffic from the serum iron donor transferrin to developing organs. The is one of the few iron transporters ever identified.

TH-PO438

The Proto-Oncogene, Mdm2, Is Indispensable for Maintenance of the Progenitor Cell Population in the Cap Mesenchyme Sylvia Hilliard, Samir S. El-Dahr. *Pediatrics, Tulane University School of Medicine, New Orleans, LA.*

Background: The cap mesenchyme (CM) can be demarcated by its elevated expression of the transcription factor, Six2, and represents a self-renewing population of cells that provides the kidney with its total endowment of nephron precursors. The dorsally located CM cells with high levels of Six2 respond to canonical Wnt signals to maintain their proliferative status while those ventral to the branching ureteric bud (UB) have lowers levels of Six2 and respond to Wnt signals by committing to a nephron fate. *Mdm2*, a negative regulator of p53 stability and activity, is expressed abundantly in the metanephric mesenchyme. Accordingly, we examined the requirement for Mdm2 in the Six2 population by intercrossing homozygous *Mdm2* floxed mice to *Six2-GFP-Cre* mice.

Results: $CM^{Mdm2-/-}$ mice die at birth and show severely dysplastic kidneys with few isolated glomeruli and depletion of the nephrogenic zone. The proximal tubules that do form are superficially located at the kidney periphery. $CM^{Mdm2+/-}$ kidneys are both intermediate in size and in the degree of renal defects sustained when compared to those of $CM^{Mdm2+/+}$ and $CM^{Mdm2-/-}$ mice. Six2, Pax2 and GFP immunostaining revealed marked thinning of the CM in the kidneys of $CM^{Mdm2-/-}$ mice. Consequently, the Meis1- expressing stroma expands to compensate for the loss of CM cells in $CM^{Mdm2-/-}$ kidneys. TUNEL staining revealed that the apoptotic foci were far more numerous in the CM of the null mutant kidneys. Also the fraction of proliferating cells (pH3-positive) in the Six2 staining CM is much reduced in the $CM^{Mdm2-/-}$ kidneys. The mosaic nature of Six2-GFP-Cre transgene allows the survival of enough wild type CM cells to prevent ectopic/dorsal specification of renal vesicles in these mice. The Lhx1 expressing nephron precursors are identifiable in $CM^{Mdm2-/-}$ kidneys at E14.5 but are largely lost by E16.5. Ex-vivo cultures of $CM^{Mdm2-/-}$ kidneys reveals secondary defects in UB branching characterized by thick trunks with poor bifurcation of the UB tips.

Conclusions: We conclude that Mdm2-p53 signaling is required to strike a balance between progenitor cell expansion and differentiation during normal metanephric development.

TH-PO439

Renal Cystic Hypodysplasia in Mice Lacking HDAC1/HDAC2 Genes in the Ureteric Epithelium Shaowei Chen, Stacy Lyn Rosenberg, Xiao Yao, Samir S. El-Dahr. *Pediatrics, Tulane University School of Medicine, New Orleans, LA.*

Background: HDAC1 and HDAC2, two highly homologous histone deacetylases, have redundant as well as distinct functions in global and tissue-specific gene expression. HDAC1 and HDAC2 are expressed in the nephric epithelial and mesenchyme cell lineages in an overlapping manner, suggesting a potential role in regulation of kidney development. Here, we examined the functional requirement of HDAC1 and HDAC2 in the ureteric bud (UB) lineage.

Methods: To circumvent the early embryonic lethality associated with global gene deletion of *HDAC1* or *HDAC2*, mice bearing conditional null alleles were crossed to Hoxb7-creEGFP transgenic mice to delete *HDAC1* and *HDAC2* genes, singly or in combination, specifically in the UB epithelium

Results: UB-specific deletion of either HDAC1 or HDAC2 led to no overt phenotype, whereas concurrent deletion of both HDAC1 and HDAC2 resulted in early postnatal lethality. At birth, HDAC1 and HDAC2 double knockout (DKO) mice have bilateral renal cystic hypodysplasia, including absent nephrogenic zone, lack of cortico-medullary patterning, decreased nephron number, and multiple cysts in both cortical and medullary zones. Immunostaining of Six2, Pax2, two markers of renal progenitor cells, and phosphorylated histone H3, an indicator of cell proliferation, demonstrated that the DKO mice completely lost renal progenitor cells. The renal cysts originate from glomeruli (WT1), proximal tubules (LTA and angiotensinogen), and collecting ducts (cytokeratin and AQP2). Ex vivo real-time monitoring of GFP fluorescence revealed that DKO mice

exhibited aberrant UB branching pattern as early as E12.5, followed by degeneration of UB tissue over 2-3 days in culture. At E12.5, there was no difference in Six2 and Pax2 expression between DKO and wild type kidneys. By E13.5-14.5, hypoplasia due to defective UB branching was clearly evident and accompanied by reduced number of glomeruli and dysmorphic proximal tubules.

Conclusions: We conclude that HDAC1 and HDAC2 perform redundant yet essential functions in the UB lineage. Double deletion of HDAC1 and HDAC2 disrupts UB branching morphogenesis and differentiation causing a cystic hypodysplastic renal phenotype.

Therapeutic Effects of Mesenchymal Stem Cells in Wistar-Kyoto Rats with Anti-Glomerular Basement Membrane Glomerulonephritis Kei Matsumoto, Masayuki Iyoda, Takanori Shibata, Yuki Hirai, Yoshihiro Kuno, Tadao Akizawa. *Division of Nephrology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan.*

Background: Multipotent mesenchymal stem cells (MSC) have become a popular and promising therapeutic approach in many clinical conditions. In this study, we tested the hypothesis that MSC can provide a potential therapy for human anti-glomerular basement membrane (GBM) glomerulonephritis (GN).

Methods: Nephrotoxic serum nephritis was induced in Wistar-Kyoto (WKY) rats on day 0. Groups of animals were given either human MSC (3 x 106) or vehicle by intravenous injection on day 4; all rats were sacrificed at either day 7 or day 13. Vehicle-treated groups received an equal volume of Hank's balanced salt solution (HBSS). For each group, 10 to 15 rats were analyzed. Proteinuria (U-P), serum creatinine (Cr), and body weight (BW) were measured periodically. Renal morphological investigations were performed at sacrifice.

Results: BW was comparable between the two treatment groups throughout the study. Serum Cr level was significantly lower in the MSC-treated rats than in the HBSS-treated rats on day 13 (WKY-HBSS vs. WKY-MSC, Day 7: NS, Day 13: $p < 0.05$). When compared to vehicle treatment, MSC-treated rats had reduced U-P on day 7 and 13 (Day 7: $p < 0.05$; Day 13: $p < 0.01$). MSC treatment also decreased kidney weight (Day 7: $p < 0.05$; Day 13: $p < 0.01$) and glomerular tuft area (Day 7: $p < 0.05$; Day 13: $p < 0.05$). The percentage of crescentic glomeruli was identical between the two treatment groups. ED1-positive macrophages ($p < 0.05$), CD8-positive cells ($p < 0.05$), and apoptotic cells ($p < 0.001$), assessed by TUNEL staining, in glomeruli were significantly reduced by MSC treatment on day 7. Renal cortical mRNA for TNF-α ($p < 0.0001$), IL-1β ($p < 0.001$), and IL-17 ($p < 0.01$) was decreased, whereas IL-4 ($p < 0.05$) and Foxp3 ($p < 0.01$) was increased in the MSC-treated group on day 7. Collagen type I ($p < 0.01$), type III ($p < 0.01$), and TGF-β ($p < 0.05$) mRNA were significantly decreased by MSC treatment on day 13.

Conclusions: MSC treatment attenuates the progression of renal injury in experimental anti-GBM GN via anti-inflammatory and immunomodulatory effects.

TH-PO441

Critical Role of the Stroma in Mediating Vascular Development of the Kidney Sunder Sims-Lucas, Jose Paredes, George K. Gittes, Carlton M. Bates. *Children's Hospital of Pittsburgh, Pittsburgh, PA.*

Background: Kidney structural abnormalities are the leading cause of pediatric chronic kidney disease, producing significant mortality. Understanding the interactions of different renal lineages is critical for impacting structural renal disease. While many kidney development studies focus on ureteric and nephrogenic lineages, very few examine vascular network formation and patterns of fetal blood flow. The purpose of this study is to elucidate development of the vasculature and blood flow in the kidney and to understand how perturbations in ureteric and stromal lineages affects vascular development.

Methods: Wildtype or *Hoxb7creFgfr2*$^{lox/lox}$ (*Fgfr2*$^{UB-/-}$) mice from Embryonic day (E) 13.5-17.5 were subjected to in utero cardiac microinjection of tomato lectin (which adheres to the endothelial cells) followed by immunostaining and confocal imaging to visualize blood flow through the renal vasculature.

Results: By E13.5, normal kidneys had integrated vascular beds and a moderate number of vessels containing blood flow. Several glomeruli and collecting ducts stained for tomato lectin implying glomerular filtration (challenging current thoughts that GFR begins at E15.5). In older embryos, the amount of perfused vessels and lectin-stained glomeruli increased. Co-labeling of the renal stroma (Foxd1) with vascular markers (PECAM) revealed not only that the vasculature was deeply embedded in the renal stroma but also that stromal-derived cells may be giving rise to some of the renal vascular endothelium. Utilizing a mouse model with defective ureteric branching and cortical stromal thickening (*Fgfr2*$^{UB-/-}$) we visualized regions of significantly thickened blood vessels with aberrant networks.

Conclusions: This study reveals that the robust vascular development, blood flow, and possibly GFR occurs earlier than previously thought. Furthermore, alterations in ureteric and/or stromal lineages had a profound impact on vascular development and blood flow in kidney development. The effects of structural kidney disease on the developing renal vasculature may have a major role in how fetal reprogramming results in postnatal diseases such as hypertension and progressive kidney disease.

TH-PO442

Critical Role of Fgfr2 Adaptor Binding Protein Frs2α in Regulating Ureteric Morphogenesis, Cyst Formation and Cilia Length Valeria E. Di Giovanni,[1] Sunder Sims-Lucas,[1] Caroline Miller,[2] Vincent H. Gattone,[2] V.P. Eswarakumar,[3] Carlton M. Bates.[1] *[1]Div of Nephro, Dept of Peds, University of Pittsburgh, PA; [2]Cell of Anat. and Cell Bio, Indiana University, IN; [3]Dept of Ortho, Yale, CT.*

Background: Renal development is governed by reciprocal signaling between the metanephric mesenchyme (MM) and the epithelial ureteric bud (UB). Abnormal signaling can result in structural urogenital abnormalities, and we have previously demonstrated that conditional deletion of FGF receptors (Fgfrs) 1 and 2 in the MM (*Fgfr1/2*$^{Mes-/-}$)led to severe dysgenesis and blocked UB elongation and branching. Our purpose was to determine whether Fgfr2 signaling mediated by the adaptor Frs2α, was critical for early MM and UB morphogenesis.

Methods: We generated compound mutant mice with *Pax3*cre mediated deletion of *Fgfr1* in renal mesenchyme and point mutations in the Frs2α binding site on Fgfr2 (*Fgfr1*$^{Mes-/-}$*Fgfr2*$^{LR/LR}$). We performed histological staining, 3D reconstructive imaging, real time PCR, immunohistochemistry, and in situ hybridizations against multiple targets in both embryonic and post-natal mice.

Results: Unlike *Fgfr1/2*$^{Mes-/-}$ mice, *Fgfr1*$^{Mes-/-}$*Fgfr2*$^{LR/LR}$ did not develop severe renal dysgenesis. However, E13.5 mutants exhibited non-cell autonomous UB defects, including hyperproliferative, dilated tips and reduced branching, without obvious histological abnormalities in the MM. The dilated mutant UB tips contained extremely long and/or bifurcated renal cilia. By P21, most of the parenchyma of *Fgfr1*$^{Mes-/-}$*Fgfr2*$^{LR/LR}$ kidneys was replaced by cysts. Embryonic analysis showed increased β-catenin expression in UB structures, which increased with age. Mutant UB structures also demonstrated elevated and ectopic expression of c-Ret and its targets Etv4/5 and increased phospho-ERK expression in UB tips and trunks. Mutants had decreased expression of Bmp4 in the MM, which may be driving the UB alterations including changes in Ret expression and signaling.

Conclusions: In conclusion, while Fgfr2 signaling through Frs2α is not required for early renal morphogenesis, it is part of a novel signaling axis which controls UB morphogenesis and cystic disease by regulating cilia morphogenesis and ureteric β-catenin and Ret expression.

TH-PO443

Dynamic Cell Movements in the Morphogenesis of Renal Tubules in Xenopus laevis Soeren S. Lienkamp,[1] John B. Wallingford,[2,3] Gerd Walz.[1,4] *[1]Renal Division, Department of Medicine, University Freiburg Medical Center, Freiburg, Baden Württemberg, Germany; [2]Molecular Cell and Developmental Biology & Institute for Cellular and Molecular Biology, University of Texas, Austin, TX; [3]Howard Hughes Medical Institute, University of Texas, Austin, TX; [4]Center for Biological Signaling Studies (BIOSS), University of Freiburg, Baden-Württemberg, Germany.*

Background: Epithelial tubules are universal building blocks of many organs including the vertebrate kidney. The morphogenetic programs that shape epithelial tubules and renal tubules in particular remain poorly defined. It has been suggested that active cell movement must occur. However, the active movement of renal tubular epithelial cells has not been observed in vivo.

The Xenopus pronephros is a fully functional excretory organ and consists of a single tubule, which is functionally remarkably similar to the mammalian metanephric tubule. Positioned right beneath the epidermis, it is perfectly well suited to study renal development in a living organism.

Methods: We used confocal time-lapse imaging of Xenopus embryos expressing fluorescent proteins within the embryonic kidney. Automated position and focus adjustment algorithms were used to correct for shifts in embryo position or growth. A high degree of spatial and temporal resolution was achieved to resolve movements of cells within a tissue, single cell behaviour, and subcellular protein dynamics in vivo.

Results: We find that tubulogenesis is a highly dynamic process that integrates proliferation, cell shape changes, and complex cellular rearrangements. Classic morphogenetic movements such as convergent-extension and rosette formation occur in the developing tubule. This process depends on myosin II and is disrupted by molecules that interfere with planar cell polarity signalling.

Conclusions: Formation of renal tubules requires active cell movement and dynamic rearrangement within the epithelium. Evolutionary conserved mechanisms of morphogenesis are driving forces. Disruption of morphogenetic cell movements leads to severe defects in tubule formation. This has potential implications for the understanding of hereditary renal malformations.

TH-PO444

Modeling Polycystic Kidney Disease Using Human Induced Pluripotent Stem Cells Benjamin S. Freedman, Albert Q. Lam, Joseph V. Bonventre. *Medicine/Renal, Brigham and Women's Hospital, Boston, MA.*

Background: Induced pluripotent stem (iPS) cells are a powerful new way to model human disease in different cell types and during development.

Methods: We generated iPS cell lines from patients with autosomal dominant and autosomal recessive polycystic kidney disease (PKD-iPS cells) using retroviral transduction of four stem cell transcription factors. These are to our knowledge the first iPS cells from patients with kidney disease.

Results: PKD-iPS cells express pluripotency markers characteristic of embryonic stem cells and differentiate into all three germ layers including somatic cell lineages which are affected by PKD. Undifferentiated iPS cells possess primary cilia and express polycystin-1 and polycystin-2. Compared to control iPS lines from healthy patients, PKD-iPS lines exhibited normal cilia number and morphology but a dramatic reduction in polycystin-2 localization to the cilium. When iPS cells were embedded in three-dimensional extracellular matrix, they formed cysts of OCT4+, ZO-1+ epithelial cells surrounding empty central lumens lined with apical cilia. Differentiated iPS cells showed diverse patterns of polycystin-2 localization to the endoplasmic reticulum, plasma membrane, and primary cilium. In suspension culture, differentiated PKD-iPS cells formed spheroid embryoid bodies featuring sporadic, fluid-filled cysts which increased in the presence of 8-bromo-cAMP. When implanted underneath the kidney capsule of immunodeficient mice, PKD-iPS cells gave rise to large cystic teratomas.

Conclusions: These results establish new experimental models for human PKD and indicate that epithelial phenotypes of iPS cells can be explored to provide insight into underlying PKD pathophysiology.

Low Serum Cultured Adipose-Derived Mesenchymal Stem Cells, but Not Bone-Marrow Derived Mesenchymal Stem Cells, Ameliorate Rat Crescentic Glomerulonephritis by Functional Polarization of Macrophages into Immunoregulatory Phenotype

Kazuhiro Furuhashi, Naotake Tsuboi, Hangsoo Kim, Takayuki Katsuno, Takenori Ozaki, Waichi Sato, Enyu Imai, Seiichi Matsuo, Shoichi Maruyama. *Nagoya Universty Graduate School of Medicine, Nephrology, Nagoya, Aichi, Japan.*

Background: We have reported that adipose tissue-derived stem cells (ASC) promoted regeneration in a rat model of acute kidney injury. More recently, we have shown that ASC more strongly modulate T-cell immune reaction than bone marrow derived mesenchymal stem cells (BM-MSC). In the present study, we examined the renoprotective effects of ASCs focusing on their immunomodulatory properties for macrophages.

Methods: Crescentic glomerulonephritis was induced in WKY rats by intraperitoneal injection of anti-rat GBM IgG. Renal function and histology were assessed in animals treated with ASC or BM-MSC which were intravenously given every day from day 0 through day 5. For evaluation of ASC-driven functional polarization in macrophage, we cultured peritoneal macrophages with ASCs. Specific marker for macrophage phenotype (proinflammatory;M1 and immunoregulatory;M2) and IL-10 in culture supernatant were assessed by FACS and ELISA, respectively.

Results: Intravenous injection of ASC significantly prevented rats from renal dysfunction and proteinuria caused by anti-GBM IgG injection. The number of glomeruli with crescents was significantly decreased in ASC group compared to control group. Interestingly, glomerular infiltrates of M2 macrophages was increased only in ASC group despite comparable number of M1 macrophages to control group. Renal IL-10 concentration in diseased rats was higher in ASC group than in control group. In vitro co-culture system clearly demonstrated that ASC, but not BM-MSC, directly turned macrophage into M2 phenotype. Moreover, these effects of ASC were stronger in low serum culutured ASC than high serum cultured ASC.

Conclusions: ASC exerted profound immunoregulatory properties especially on macrophages and ameliorated glomerular injury in a rat model of anti-GBM glomerulonephritis. Our findings suggest that ASC transfer may provide a novel therapeutic strategy for patients with crescentic glomerulonephritis.

TH-PO446

Amniotic Fluid-Derived Stem Cells Ameliorate Renal Disease in the Remnant Kidney Model

Rita de Cassia Cavaglieri,[1,2] Pamella S.T. Oliveira,[1] Rodrigo J. Ramalho,[1] Marcelo Zugaib,[3] Sergio P. Bydlowski,[2] Irene L. Noronha.[1] *[1]Nephrology, University of Sao Paulo, Brazil; [2]Laboratory of Genetics and Molecular Hematology, Faculty of Medicine, University of São Paulo, Brazil; [3]Obstetrics and Gynecology, Faculty of Medicine, University of São Paulo, Brazil.*

Background: Human amniotic fluid stem cells (hAFSC) are a class of fetal, pluripotent stem cells which exhibit high proliferative capacity, express mesenchymal and embryonic markers but do not undergo neoplastic transformation or induce teratoma transformation. The aim of the present study was to analyze the effects of intravenous injection of hAFSC in an experimental model of chronic renal disease, the 5/6 nephrectomy model (Nx).

Methods: hAFSC derived from second-trimester amniocentesis were isolated by plastic adhesion. After 4-7 passages, hAFSC characteristics were confirmed by flow cytometry and by their ability to differentiate into osteogenic, adipogenic and chondrogenic cells. Male Wistar rats (n=28) were divided into 4 groups: **S**, sham-operated, **S+hAFSCs**, sham rats receiving hAFSC; **Nx**, 5/6 nephrectomy; and **Nx+hAFSCs**, Nx rats receiving hAFSC. $5x10^5$ hAFSC were injected into the tail vein, and rats were followed for 30 days. The following parameters were analyzed: blood pressure, proteinuria, and kidney expression of α-smooth muscle actin (myofibroblasts) and ED1+cells (macrophages), analyzed by immunohistochemistry.

Results:

	BP (mmHg)	$\mathbf{U_{prot}}$ (mg/24h)	$\mathbf{S_{creat}}$ (mg/dL)	**Myofibroblast activation** (%)	**Macrophage infiltration** (cell/mm^2)
Sham (n=5)	123±3	10.9±1	0.5±0.1	0.33±0.08	17±3
Sham+hAFSC (n=5)	105±16	17.7±2	0.5±0.1	0.11±0.01	1±0.2
Nx (n=9)	183±4[a,b]	92.9±14[a,b]	1.1±0.1[a,b]	6.27±0.74[a,b]	50±8[a,b]
Nx+hAFSC (n=5)	132±9[a,b,c]	30.5±9[c]	0.7±0.1	0.44±0.18[c]	3±1[c]

Data are presented as mean±SEM: [a] $p<0.05$ *vs* Sham; [b] $p<0.01$ *vs* Sham+hAFSC; [c] $p<0.01$ *vs* Nx.

Conclusions: These preliminary results suggest that intravenous inoculation of hAFSC ameliorate renal disease in the remnant kidney model and that they may represent an alternative source for stem cell therapy.

Induction and Monitoring of Intermediate Mesoderm from Human iPSCs and ESCs

Shin-Ichi Mae,[1] Fumihiko Shiota,[1] Andrew P. McMahon,[2] Kenji Osafune.[1] *[1]Center for iPS Cell Research and Application (CiRA), Kyoto University; [2]Harvard Stem Cell Institute, Harvard University.*

Background: The differentiation method from pluripotent stem cells, such as embryonic stem cells (ESCs) and induced pluripotent stem cells (iPSCs), into kidney lineage remains to be developed. Kidney is derived from one of early embryonic germ layers, intermediate mesoderm (IM), and directing pluripotent stem cells into IM lineage is a crucial step for kidney regeneration.

Methods: We constructed a targeting vector and transduced it into human iPSCs (hiPSCs) to obtain reporter hiPSC lines for an IM marker gene OSR1 by homologous recombination. To differentiate IM cells from hiPSCs, we examined the combinational treatment of growth factors.

Results: We have efficiently generated hiPSC lines that contain an allele of OSR1 gene into which a green fluorescence protein (GFP) gene was knocked-in by homologous recombination. We have also established an induction protocol using combinational treatment of growth factors, in which differentiation of hiPSCs produced cultures consisting of more than 40 % OSR1+ cells. Furthermore, the cells expressed other IM marker genes, and could differentiate into multiple cell types included in IM derivative organs, such as kidney, gonad and adrenal cortex in vitro.

Conclusions: Our differentiation protocol can induce human pluripotent stem cells into IM cells with similar developmental potential to that in embryos, supplying systems for understanding the developmental mechanisms of IM lineage and cell sources for the regeneration of IM derivative organs.

TH-PO448

Selective Production of Hyaluronan by Epithelial Cells Is Necessary but Not Sufficient To Induce Tubulogenesis

Priscilla Soulie, Alexandra Chassot, Roberto Montesano, Eric Feraille, Patrick Saudan. *Cell Physiology and Metabolism, University of Geneva, Switzerland.*

Background: Branching morphogenesis is a fundamental process in the development of kidney and mammary gland. Extracellular matrix plays an important role in tubulogenesis. We hypothesized that epithelial cells can modify their pericellular matrix to drive tubulogenesis in response to stimuli.

Methods: The role of hyaluronic acid (HA), a key component of the pericellular matrix, in epithelial tubulogenesis, was studied in three different in vitro models of epithelial tubulogenesis in 3D collagen gels: 1) renal MDCK cells in response to hepatocyte growth factor (HGF); 2) renal mCCD-N21 cells (spontaneous) and 3) mammary gland-derived J3B1A cells in response to transforming growth factor β1 (TGF-β1).

Results: Induction of tubulogenesis by either HGF or TGF-β1 strongly induced hyaluronan synthase 2 (HAS2) expression, a key enzyme involved in HA biosynthesis. Immunostaining revealed that HA is preferentially produced at the tips of growing tubes. Reduced HA production, either by pharmacological inhibition (4-MU) or by shRNA-mediated knockdown of HAS2, completely abrogated tube formation in all three cell lines. To assess whether HA production was sufficient by itself (i.e in absence of tubulogenic treatment) to drive the tubulogenic process, we analyzed the effect of inducible HAS2 overexpression in MDCK Tet-off cells. Overexpression of HAS2 in response to doxicyclin removal did not promote tubulogenesis but led to the formation of giant cysts. Similarly, after HGF treatment, HAS2-overexpressing cells did not display enhanced tubulogenesis, but formed enlarged disorganized structures. CD44, the major HA receptor, was expressed at the tips of the tubes formed by MDCK cells. Moreover, addition of CD44 blocking antibody to MDCK and mCCD-N21 cells grown in collagen gels blocked tubule elongation, suggesting that HA-induced tubulogenesis is mediated by CD44.

Conclusions: These results indicate that selective production of HA by epithelial cells is necessary but not sufficient to drive the tubulogenic process, and that non-selective overproduction of HA leads to disorganized cellular outgrowth in response to HGF.

Ectopic Ureteral Budding from the Wolffian Duct Results in Hypoplastic Kidneys but Not in Dysplastic Kidney Masaru Motojima,[1] Fumiyo Komaki,[1] Yoichi Miyazaki,[2] Fumio Niimura,[1] Taiji Matsusaka,[1] Iekuni Ichikawa.[1,3] *[1]Tokai University School of Medicine, Kanagawa, Japan; [2]Jikei University School of Medicine, Tokyo, Japan; [3]Vanderbilt University School of Medicine, Nashville, TN.*

Background: Mice carrying a null mutation of the *Foxc1* gene frequently develop a double collecting system. Since the kidney and urinary tract derived from normal budding can serve as a control within the same tissue specimen, these mice provide an ideal opportunity to ascertain the specific role of ectopic budding in the development of the kidney and ureter anomalies.

Methods: Tissue specimens were collected from *Foxc1*$^{ch/ch}$ mutants at various embryonic stages. The upper and lower pole kidneys were qualitatively and quantitatively examined histologically and by *in situ* hybridization (ISH) and immunohistochemistry.

Results: The upper pole kidneys of newborn *Foxc1*$^{ch/ch}$ mice were significantly more hypoplastic (kidney volume, 81±6% vs. lower pole, p<0.01), and contained significantly fewer glomeruli (68±6%, vs. lower pole, p<0.01). In those mice, the ureter, calyx and tubules in the medulla of the upper pole were abnormally dilated compared with the lower moeities. *In utero,* at E14.5, the stage just before formation of the first urine, the upper kidney was already smaller (43±6% vs. lower kidney p<0.01). At E12.5, the number of condensed mesenchymes assessed by *Pax2* ISH was significantly lower in the lower poles (59±8%, p<0.01). Neither morphological examination by Hematoxylin and Eosin staining nor immunostaining for nephrin, megalin, aquaporin-1 and Tamm-Horsfall protein revealed any dysplastic regions in either pole of newborn *Foxc1*$^{ch/ch}$ mouse kidneys. Of note, at birth, expression of Foxc1 was restricted to maturing podocytes.

Conclusions: Ectopic budding leads to kidney hypoplasia. However, ectopic budding alone does not result in kidney dysplasia unless gene(s) involved in the development of any intermediate structures of the nephron is affected, or ectopic budding occurs at a site substantially distant from normal budding so that adjacent mesenchymal cells are not fully committed to develop into renal parenchyma.

Can Stem Cells Prevent Progression of Kidney Disease? Aleksandra Rak-Raszewska,[1] Bettina Wilm,[1] Simon Kenny,[2] David Edgar,[1] Patricia Murray.[1] *[1]Cellular and Molecular biology, University of Liverpool, United Kingdom; [2]Department of Pediatric Surgery and Urology, Alder Hey Children's NHS Trust, Liverpool, United Kingdom.*

Background: Kidney disease can either be acute or chronic, the latter progressively worsening over time to become end stage renal disease (ESRD) - a stage when kidneys are non-functional. At present, the only treatment options for ESRD are transplantation or dialysis, which both have severe drawbacks. The incidence of ESRD is rising annually, therefore, in order to regenerate kidney tissue or prevent worsening of the kidney condition, a new therapy should be developed. One approach is to use embryonic stem cells (ESC). Therefore, we have first investigated the ability of ESC and their mesodermal derivatives to integrate into mouse embryonic kidney rudiments in an *ex vivo* assay. This study showed that differentiation of ESC into mesoderm promotes integration into ureteric bud, developing glomeruli and functioning proximal tubules. Building on this *ex vivo* study, we have set up an adriamycin nephropathy model to induce acute kidney injury, that with time can progress to chronic disease. This allows us to investigate the ability of ESC and their mesodermal derivatives to prevent the development of acute kidney disease in the short term or prevent progression to chronic disease in the longer term.

Methods: We have differentiated ESC *in vitro* into mesodermal cells. Following differentiation these cells were mixed with freshly dissected E13.5 mouse embryonic kidney rudiments and their nephrogenic potential was investigated in the *ex vivo* assay. For the adriamycin nephropathy *in vivo* model the ESC and their mesodermal derivatives were injected into injured mice. The analysis involved immunohistochemistry, biochemical and molecular analysis.

Results: The *ex vivo* data showed that ESC differentiated into mesoderm integrated into kidney structures more efficiently than undifferentiated ESC. They integrated into glomerular-like and tubular-like structures, and moreover they functioned appropriately to their location, e.g they differentiated into proximal tubular cells with functioning organic anion transporters. The *in vivo* experiments are still ongoing.

TH-PO451

Controlled Tubulogenesis of the Ureteric Bud from Dispersed Ureteric Epithelial Cells Using a Micropatterend Gel Peter V. Hauser,[1,2] Masaki Nishikawa,[1,2] Hiroshi Kimura,[3] Norimoto Yanagawa.[1,2] *[1]Renal Regeneration Laboratory, VAGLAHS at Sepulveda, North Hills, CA; [2]David Geffen School of Medicine, UCLA, Los Angeles, CA; [3]Institute of Industrial Science, University of Tokyo, Japan.*

Background: The initial step in renal development is the interaction of the ureteric bud (UB), an outgrowth of the Wolffian duct, with the metanephric mesenchyme. Our project aims to generate a tubular structure from dispersed renal progenitor cells *in vitro*, using a micropatterned agarose gel to control the growth and define the geometry of the structure.

Methods: A micropatterned agarose gel (3%) was casted from a silicone mask, in which the postive shape of the pattern was etched by photolithography. The pattern in the agarose gel, produced from the mask, contained rectangular cavities (3mm x150µm x150µm), into which dispersed mouse ureteric bud cells (CMUB-1, Probetex) suspended in collagen I (2.5%) were seeded (5.10^{5}cells/mold) by centrifugation (1200rpm,10min). The gel holding the cells was subsequently cultured in DMEM (10%FCS+P/S) at 37°C, 5% CO_2.

Results: After 24h *in vitro* culture, the embedded dispersed ureteric bud cells formed single layered tubular structures that contained a lumen. The tubular structures conformed to the shape and size of the cavities in the gel. Tubular formation was followed by detachment from the mold. The terminal ends of the tubular structure were multilayerd and closed. Laminin staining revealed a closed surface of the tubular structures. Aldosterone (100nM) positively effected tubular formation, while the addition of the factors HGF and EGF, or the matrixprotein fibronectin had no effect.

Conclusions: We conclude that micropatterned gels can be used to control the growth of geometrically defined substructures of the developing kidney from dispersed cells. These structures can be used as building elements for tissue engineering purposes in order to study renal development *in vitro*.

Ongoing studies are underway to examine the expression of ureteric bud markers (c-Ret, Wnt11, Wnt9b, Sox9) along the tubes and the effects of growth factors, such as GDNF on directional growth and branching of the generated tubules.

TH-PO452

Isolation of a Human Nephron Progenitor Population Sally Metsuyanim,[1,3,4] Orit Harari-Steinberg,[1,3] Dorit Omer,[1,3,5] Benjamin Dekel.[1,2,3,5] *[1]Pediatric Stem Cell Research Institute, Sheba Medical Center, Tel Hashomer, Israel; [2]Division of Pediatric Nephrology, Safra Children's Hospital, Sheba Medical Center, Tel Hashomer, Israel; [3]Sheba Center for Regenerative Medicine, Sheba Medical Center, Tel Hashomer, Israel; [4]Mina & Everard Goodman Faculty of Life Sciences, Bar-Ilan University, Ramat Gan, Israel; [5]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.*

Background: A critical step in developing cell based therapies for renal disease is defining a suitable stem/progenitor cell population. Taking into account the bone-marrow derived and blood stem cells lack intrinsic capacities to generate nephron cell types identification of tissue-specific renal stem cells with wide nephrogenic potential has been a long sought after goal. In the mammalian kidney, fresh stem cells are induced into the nephrogenic pathway to form nephrons during development and no equivalent cell types can be traced in the adult kidney. Nevertheless, prospective isolation of such human nephron stem/progenitor cells has yet been accomplished.

Methods: Here we describe the generation of single cell suspensions from mid-gestation human fetal kidneys.

Results: Clonogenic analysis, expansion in serum-free defined conditions and cell sorting with the neural cadherin adhesion molecule 1 (NCAM1) identified a population that is highly clonogenic and specifically enriches for human transcripts of nephron stem/progenitor cells. After transplantation onto the chorio-allantoic membrane of the chick embryo these cells but not differentiated counterparts efficiently formed nephron's proximal, loop of henle and distal tubules. Finally, a single injection of nephron progenitor cells prevented death and renal failure in the SCID – glycerol induced acute kidney injury model.

Conclusions: These cells represent a previously unidentified intrinsic nephron precursor population and are a promising candidate for cell-based therapeutic strategies.

TH-PO453

Fibroblast Growth Factor Receptor Signaling Is Critical for Nephron Differentiation Sunder Sims-Lucas,[1] Caitlin M. Schaefer,[1] Seppo J. Vainio,[2] Carlton M. Bates.[1] *[1]Pediatrics, Children's Hospital of Pittsburgh, Pittsburgh, PA; [2]Department of Medical Biochemistry and Molecular Biology, University of Oulu, Finland.*

Background: Reduced nephron number is one of the leading causes of renal failure in children and is linked with many adult onset diseases. Nephron development requires reciprocal signaling between the ureteric bud and the metanephric mesenchyme (MM). Previously in mice targeted deletion of fibroblast growth factor 8 (Fgf8) in the MM produced renal vesicles (RV) that failed to become mature nephrons. Our laboratory has shown that Pax3cre mediated inactivation of fibroblast growth factor receptor (Fgfr) 1 and 2 in the MM (both cortical stromal and nephrogenic lineages) leads to severe renal dysgenesis. Furthermore, Pax3cre-driven deletion of Fgfr1 and abrogation of the fibroblast growth factor receptor substrate 2α (Frs2α) binding site of Fgfr2 (*Fgfr1*$^{Mes-/-}$*Fgfr2*$^{LR/LR}$) led to cystic kidney disease. The purpose of this study was to determine the role of Fgfr signaling in the nephron lineage using a RV specific cre line.

Methods: Similar to the Pax3cre studies, we used Wnt4cre mice to delete Fgfr1 and 2 in the nephrogenic (RV) lineage (*Fgfr1/2*$^{RV-/-}$) and to delete Fgfr1 in the RV along with abrogation of the Frs2α binding site of Fgfr2 (*Fgfr1*$^{RV-/-}$*Fgfr2*$^{LR/LR}$). Kidneys were harvested from E13.5 to E18.5 and histology and marker analysis performed.

Results: *Fgfr1*$^{RV-/-}$*Fgfr2*$^{LR/LR}$ mice had phenotypically normal kidneys at all ages examined. However, E13.5 *Fgfr1/2*$^{RV-/-}$ mice had defective nephron formation with areas around many ureteric tips devoid of nephron precursors, leading to fewer total nephrons. 3 dimensional reconstructions at E13.5 showed a shift in the nephron distribution toward less mature structures than controls. By E18.5 *Fgfr1/2*$^{RV-/-}$ kidneys were much smaller than controls although they did possess some mature nephrons.

Conclusions: This study reveals that Fgfr signaling through Frs2α in RV is not required for nephron differentiation (and does not mediate the *Fgfr1*$^{Mes-/-}$*Fgfr2*$^{LR/LR}$ renal cystic phenotype). However, Fgfr signaling independent of Frs2α (or requiring multiple adapters) is critical in nephron differentiation and determination of final nephron number.

TH-PO454

Understanding the Mechanisms Downstream of Wnt7b Action in Renal Medulla Formation Latoya Ann Roker, Jing Yu. *Cell Biology, University of Virginia, Charlottesville, VA.*

Background: *Wnt7b* has been shown to mediate renal medulla formation, through canonical signaling to the medullary interstitium. *p57kip2*, a cyclin-dependent kinase inhibitor expressed in both the medullary interstitium and in podocytes, has also been shown to cause a renal medulla defect when ablated in mice, and is probably associated with Beckwith-Wiedemann syndrome including renal medulla anomaly when mutated. However, how *p57Kip2* regulates renal medulla formation, and whether and how it is regulated by *Wnt7b* signaling is unexplored.

Methods: We employed a combination of Luciferase assay in cell culture, Chromatin Immunoprecipitation (ChIP), immunohistochemistry, and mouse genetics to address these questions.

Results: We showed that the *p57kip2* expressing interstitial cells are canonical Wnt signaling responsive cells. A genomic region of *p57kip2* bearing putative Tcf/Lef binding sites responded to canonical Wnt signals in vitro. Furthermore, interstitial cell expression of *p57kip2* is necessary for normal renal medulla formation.

Conclusions: Our data suggest that *p57kip2* is a direct target of Wnt7b/canonical Wnt signaling and *p57Kip2* expressed in the renal interstitium plays a critical role in renal medulla formation.

TH-PO455

p53 in the Cap Mesenchyme Regulates Nephron Endowment Zubaida R. Saifudeen, Yuwen Li, Jiao Liu, Susana Dipp, Samir S. El-Dahr. *Pediatrics, Tulane University School of Medicine, New Orleans, LA.*

Background: The factors which determine nephron endowment or mass are not completely understood, and reduced nephron number is associated with susceptibility to hypertension and progressive renal disease. We recently reported that germ-line deletion of the transcription factor p53 in mice results in renal hypoplasia (50% reduction in nephron mass) (JASN 2009). This study examined the molecular mechanisms whereby p53 regulates nephron endowment.

Results: Confocal microscopy determined that p53 is expressed in the Six2/Pax2-positive cap mesenchyme (CM), suggesting that p53 has the potential to regulate self-renewal, survival, or migration behavior of renal progenitor cells. Genome-wide microarray comparing E15.5 p53$^{-/-}$ and p53$^{+/+}$ kidneys coupled with p53 ChIP-Seq and IPA network analysis revealed that p53 is a direct regulator of 107 CM genes. The top canonical pathways regulated by p53 include VEGF, PI3K/AKT, Myc-mediated apoptosis and DNA methylation and transcriptional repression. Novel p53 targets in the CM encompass developmental regulators - Osr1, Pbx1, Pax2, Cux1, Dach1, Cdh6 and VEGFA; chromatin remodelers - ARID1 and RBBP4; and regulators of cilia formation – IFT172 and KIF24. To determine the functional relevance of p53 in the progenitor cell population, we conditionally deleted *p53* from the CM by crossing Six2-CreGFP to p53-floxed mice (CM$^{\Delta p53}$). CM$^{\Delta p53}$ kidneys are small, exhibit thin, fused caps and reduced number of Six2/Pax2+ cells, and have significantly fewer number of Lhx1+ nascent nephrons. GFP^{+}/CM$^{\Delta p53}$ cells spread dorsally over the flattened ampullae failing to aggregate into discrete caps. Unlike the Six2 domain, the Meis1+ stroma is markedly expanded.

Conclusions: We conclude that p53 performs cell-autonomous functions in the CM progenitor domain via regulation of cell cycle, cell-cell signaling, chromatin remodeling, and cell death.

***Robo1* and *Robo2* Play a Role in Murine Kidney Branching Morphogenesis and Podocyte Foot Process Architecture** Anna Pisarek-Horowitz, Qinggang Li, Xueping Fan, David J. Salant, Weining Lu. *Renal Section, Boston University Medical Center, Boston, MA.*

Background: Robo1 is a homolog of Robo2, both of which are transmembrane proteins involved in the control of axonal guidance and cell migration. *Robo2* is required for normal kidney induction and restricts the ureteric bud to a single site from the nephric duct. The most striking phenotype in homozygous *Robo2* knockout mice is multiple ureters with supernumerary ureteric buds and duplex kidney. Our recent studies show that *Robo2* is also required for normal podocyte structure and function. It is not known, however, if *Robo1* also plays a role in kidney development and acts synergistically with *Robo2*.

Methods: Immunohistochemistry; knockout mice analysis; real time RT-PCR; embryonic kidney organ culture; scanning electron microscopy.

Results: By immunohistochemistry with a specific Robo1 polyclonal antibody, we found that Robo1 was specifically expressed in mouse embryonic kidney, and is significantly downregulated after birth. Robo1 protein is also expressed in mouse developing glomeruli and its mRNA and protein expression are up-regulated in the glomeruli of *Robo2* knockout homozygous newborn kidney. To investigate the compound effect of *Robo1* and *Robo2* on kidney development, we analyzed *Robo1*$^{-/-}$*Robo2*$^{-/-}$ double knockout mice. Compared with *Robo2*$^{-/-}$ single homozygotes, all *Robo1*$^{-/-}$*Robo2*$^{-/-}$ double homozygous mice died within hours after birth. Interestingly, embryonic kidney organ culture and newborn histology analysis revealed that double homozygous mice manifested a severe branching morphogenesis phenotype and reduced glomerular number compared with *Robo2*$^{-/-}$ single homozygotes. The few glomeruli present at birth in a *Robo1*$^{-/-}$*Robo2*$^{-/-}$ double homozygote displayed abnormal podocyte foot process architecture on scanning electron microscopy.

Conclusions: These results indicate that *Robo1* functions synergistically with *Robo2* during kidney branching morphogenesis and podocyte foot process patterning.

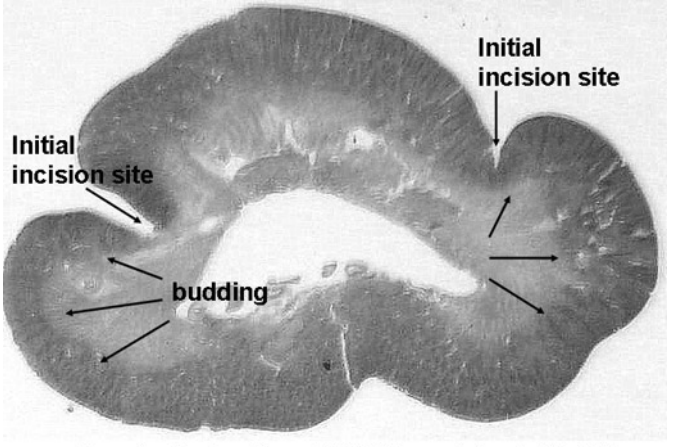
TH-PO457

Compensatory Renal Growth after Unilateral/Subtotal Nephrectomy in the Ovine Fetus Sebastien Sammut,[1] Luc Behr,[1] Mehrak Hekmati,[1] Kathleen Laborde,[3] Martine D. Lelievre-Pegorier.[2] *[1]IMM Research, Paris, France; [2]INSERM U872, Centre de Recherche des Cordeliers, Paris, France; [3]Physiology, Necker Hospital - Paris 5, Paris, France.*

Background: In adult, unilateral and subtotal nephrectomy result in compensatory renal growth but do not involve formation of new nephrons. During the period of active nephrogenesis *in utero*, it is not clear whether compensatory growth can occur and if so, whether more nephrons can be formed.

Methods: Ovine fetuses (n =18) underwent unilateral nephrectomy (1/2Nx, n =5), subtotal nephrectomy (5/6Nx, n =5) or sham nephrectomy (Sham, n=8) at 70 days of gestation. After 134 days, renal functional studies were performed, fetuses were euthanized and kidneys further analyzed.

Results: In 1/2Nx, kidney weight to body weight ratio was greater (5.13 ± 1.09 g/kg vs 2.48 ± 0.20 g/kg in Sham; P<0.05); the nephron number was similar (2658 ± 518 nephrons vs 2467 ± 367 respectively). In 5/6Nx, both catch up in kidney weight (4.62 ± 0.89 g/kg vs 2.48 ± 0.20 g/kg) and nephron number (2560 ± 694 nephrons vs 2467 ± 367) was observed in spite of initial severe 2/3 parenchymal reduction. At incision sites, parenchyma budding was observed, leading to a butterfly-like shape. In all groups, *in utero* glomerular filtration rate was similar. At the molecular level, caspase gene expression was significantly decreased (<0.01) in 5/6Nx. No differences in expression of Bcl2, Pax2, Wt1, VEGF or cRet were observed among the differents groups.



Longitudinal section of 5/6 kidney stained with H.E.

Conclusions: A significant compensatory growth occurs *in utero* after parenchymal reduction. Furthermore, nephron endowment develops after 5/6Nx during the period of active nephrogenesis in sheep. This is the first time such neo-nephrogenesis is described; the morphological pattern observed suggests a stimulation of ureteric bud branching, allowing a compensation of glomeruli number and function, despite 2/3 renal parenchyma reduction.

TH-PO458

Mesenchymal Stem Cells Induce Renoprotection in the Podocyte Injury Model Rodrigo J. Ramalho, Amanda G. Pires, Rita C. Cavaglieri, Denise M. Malheiros, Irene L. Noronha. *Nephrology, Univ Sao Paulo, Brazil.*

Background: Several studies have shown that mesenchymal stem cells (mSC) protects against renal damage. However, the role of mSC in models of podocyte injury is still unclear. The aim of this study was to evaluate the potential effects of mSC in the puromycin model (PAN).

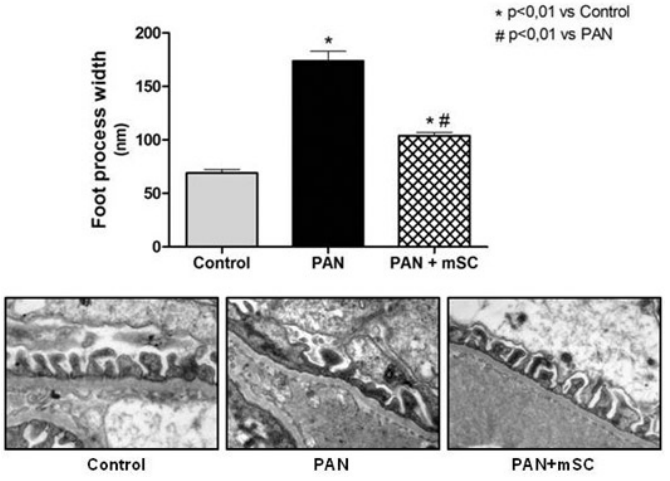
Methods: PAN model (150 mg/kg at day-0 and 5 mg/kg at day-15) was induced in Wistar rats (n=30), aggravated with unilateral nephrectomy. mSC from rat bone marrow were isolated and delivered at the kidney subcapsule. Rats were divided into three groups (Control, PAN, PAN+mSC) and followed for 60 days. The following parameters were analyzed: blood pressure (BP), proteinuria, histological changes, electron microscopy, immunohistochemistry, and real time PCR.

Results: mSC promoted a significant decrease of proteinuria (at 30th and 60th day) and of BP levels (at 60th day). In parallel, a marked proliferative activity was detected in PAN+mSC. Recovery of the podocyte marker WT1 was also observed in PAN rats treated with mSC.

	Proteinuria (mg/24h)		BP (mmHg)		PCNA (cels/mm²)	WT1 (%)
day	30	60	30	60	60	60
CONTROL	12.9±1.0	21.0±3.8	124±2	128±4	2.6±0.7	2.42±0.14
PAN	217.8±16.8#	79.4±6.4#	151±4#	161±5#	6.18±0.6#	1.45±0.12#
PAN + MSC	133.0±24.6#*	44.3±13.7*	154±3#	143±6*	15.0±3.0#*	2.06±0.16*

# p<0,05 vs Control; *p<0,05 vs PAN

There was no significant difference in glomerulosclerosis, interstitial fibrosis, macrophages, lymphocytes, and myofibroblasts. Electron microscopy showed a significant improvement of foot process width associated to mSC administration (figure). Relative mRNA levels of nephrin, podocin, synaptopodin, podocalyxin, WT1 and VEGF recovered partially with mSC.



Conclusions: In the PAN model, mSC induced renal protection characterized by decreased proteinuria and BP levels associated with high proliferative activity, podocyte recovery and improvement of foot process effacement.

TH-PO459

Src Family Kinase Activity Promotes Ureteric Bud Branching While Limiting Ureteric Bud Segment Elongation during Mouse Fetal Kidney Development Alexander E. Davidovich,[1] Josephine Axis,[1] Deborah P. Hyink,[2] Kurt Amsler.[1] *[1]Department of Biomedical Sciences, New York College of Osteopathic Medicine of NYIT, Old Westbury, NY; [2]Division of Nephrology, Baylor University College of Medicine, Houston, TX.*

Background: The activity of Src Family Kinases (SFKs), a family of non-receptor tyrosine kinases, has been implicated in the pathogenesis of both Autosomal Dominant and Autosomal Recessive Polycystic Kidney Disease, disorders characterized by abnormal renal development. The involvement of this kinase family in normal fetal renal development, however, has not been determined.

Methods: Using a mouse fetal kidney organ culture system, we investigated the role of SFK activity in the regulation of fetal renal development. Fetal CD-1 mouse kidney pairs, isolated from gestation day 12 embryos, were separated and cultured on permeable membrane filters in DMEM/Ham's F12 medium containing 5% fetal bovine serum plus insulin/transferrin/selenium in either the absence or presence of 10 μM PP1, a well-characterized SFK inhibitor. Kidneys were imaged daily for three days, beginning from explantation, and parameters of ureteric bud (UB) branching morphogenesis were quantitated.

Results: Kidneys maintained in the presence of PP1 exhibited differences from their control counterparts in several aspects of UB branching. After two days in culture, PP1 produced: 1) a progressive inhibition of UB branch bifurcations (p=5.8 x10-17) reaching approximately 60% inhibition and 2) an inhibition of lateral branching (p=2.9 x10-5). In contrast, UB segment lengthening was not decreased by PP1 treatment. In fact, PP1 produced an increase in the UB primary branch segment length, with the greatest effect being observed on day 1 of treatment (p=0.002). Beginning after the first day of PP1 culturing, fetal kidneys exhibited morphologically abnormal UB tip regions suggesting a disruption of the normal ureteric bud-metanephric mesenchyme interaction.

Conclusions: Our data indicate that: 1) SFKs are activated under standard fetal mouse kidney organ culture conditions, 2) optimal SFK activity is necessary for UB branching, and 3) SFK functional levels may impede UB segment elongation.

TH-PO460

Purification of Differentiated Tubule Cells from Mouse Embryonic Stem Cells Using Flow Cytometry Ryuji Morizane, Toshiaki Monkawa, Hiroshi Itoh. *Internal Medicine, Keio University School of Medicine, Tokyo, Japan.*

Background: Although embryonic stem (ES) cell and induced pluripotent stem (iPS) cell have been utilized to generate various lineage cells *in vitro*, the induction of renal lineage cells from ES and iPS cells have remained to be elucidated. Recently, we found that Activin stimulate the expression of kidney specific protein (KSP) that is exclusively expressed in renal tubule epithelial cells and that it enhances the differentiation of ES and iPS cells to tubule cells.

Methods: In this study, we produced a monoclonal antibody to purify tubule cells differentiated from ES cells by flow cytometry, and we have established a method to generate tubule cells from ES cells *in vitro* by using Activin and flow cytometry with the monoclonal antibody. We designed the monoclonal antibody so that it binds to the extracellular domain of a protein called X which was exclusively expressed in renal epithelial cells, that is, ureteric buds, bowman's capsules, proximal / distal tubules and collecting ducts. We confirmed the specificity of anti-X antibody by flow cytometry, PCR and Western blot using ureteric bud cell line.

Results: We sorted X-positive cells from differentiated ES cells by flow cytometry using anti-X antibody after the induction with Activin. X-positive cells comprised about 1.5% of total differentiated ES cells, and were expressing mRNA of X much more than X-negative cells. X-positive cells also expressed aquaporin 2 (AQP2), aquaporin 3 (AQP3), KSP and E-cadherin, suggesting X-positive cells were similar to tubule cells in gene expression. To observe the formation of tubular structure *in vitro*, we transferred X-positive cells into non-adhesion dish after sorting by flow cytometry, and we found cell aggregates. After 24 hours of formation of cell aggregates, we embedded them in Matrigel ® and cultured with epithelial growth factor (EGF). The cells expanded outward, and formed a ring structure that resembled tubular structure.

Conclusions: In conclusion, we could induce tubule cells from mouse ES cells with Activin stimulation and cell selection using anti-X antibody. Currently, we proceed to characterizing X-positive cells induced by this method.

TH-PO461

Drugs Frequently Used in Premature Neonates Reduce Nephrogenesis in Embryonic Kidney Culture Ruud R.G. Bueters, Lisanne Kusters, Annelies Klaasen, Lambertus V. Heuvel, Michiel F. Schreuder. *Department of Pediatric Nephrology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Background: Nephrogenesis ceases around the 36th week of gestation in man, with no additional nephron formation later in life. A lower number of nephrons leads to glomerular hyperfiltration, hypertension and renal impairment in the long run. Many preterm born children are treated with drugs that may reduce nephron formation. We investigate these drugs for effects on kidney growth and ureteric branching.

Methods: At embryonic day 13 embryo's were delivered from time pregnant mice through Caesarean section and kidneys were dissected. Subsequently embryonic kidneys were cultured on filters in control media. Three different concentrations (including clinical dose) of gentamicin and ceftazidime were added to the media. Starting kidney size was assessed by surface area measurements and kidneys were whole mount stained with anti-calbindin D-28K after 24 hours of culture. Visualization was performed by means of confocal microscopy and ureteric bud branching was evaluated by counting. Additionally, qPCR course experiments were performed with hydrolysis probes to investigate gene expression levels of Wt1, Sox9, Bmp7, Fgf8 and Gdnf. The genes Actb and Hmbs were used for normalization.

Results: Ureteric bud count indicates that 300 μM (high-dose) of gentamicin and 200 or 2000μM (mid- and high dose, respectively) of ceftazidime impair ureteric bud development. Additional qPCR analysis revealed a 2.5 fold down regulation in Fgf8 and a tendency to downregulation in Gdnf for high-dose ceftazidime. No clear changes in gene expression were noted for gentamicin due to lack of a dose response relationship. These results will be verified in additional experiments and at later time-points.

Conclusions: 300μM of gentamicine and 200 or 2000μM of ceftazidime impair ureteric bud formation already after 24 hours of treatment. Additionally, we suggest a role for Fgf8 and Gdnf in the mechanism behind ceftazidime induced bud impairment.

TH-PO462

Notch Signal Is Essential to the Formation of Glomus and Proximal Tubule While It Inhibits the Extension and Differentiation of Distal Tubule in Xenopus Embryos Tomohisa Katada, Hiroyuki Sakurai. *Department of Pharmacology and Toxicology, Kyorin University, School of Medicine, Mitaka, Tokyo, Japan.*

Background: Notch signaling, a highly conserved cell-cell signaling system, has been shown to regulate cell differentiation and/or proliferation at various stages of animal development. This study aimed to elucidate the role of Notch signaling in the development of the pronephros in Xenopus embryos.

Methods: In order to enhance or inhibit Notch signaling, a conditional Notch-activating construct (NICD-hGR) or a conditional Notch-suppressing construct (XSu(H)1DBM-hGR) was injected into the blastomere of Xenopus embryos. These constructs turned on when dexamethasone (DEX) was added to the culture. wt1, XSMP-30 and gremlin were used as gene markers for glomus, proximal tubule and distal tubule, respectively.

Results: Constitutive activation of Notch signaling from late neurula stage on resulted in excessive formation of the glomus and malformation of the proximal tubule. Inhibition of Notch signaling starting at the same stage of development reduced expression of the gene markers for the glomus (wt1) and the proximal tubule (XSMP-30). These results demonstrated important roles of Notch signaling in proximal nephron development, consistent with previous reports by others. In addition, Notch activation at different time points inhibited distal tubule extension to different degrees. These shorter distal tubules, although they were positive for pan distal tubule marker, gremlin, lacked expression of

markers specific for a certain segment of the distal tubule such as claudin 19, claudin 14, or rhcg, suggesting that Notch overactivation inhibited not only extension but also differentiation of the distal tubule.

Conclusions: In summary, activation of Notch signaling defined proximal pronephros while proper inhibition was indispensible for distal tubule development. These results suggest that regulation of Notch activity plays an important role in development of Xenopus pronephros.

TH-PO463

Role of Calcium Oscillations in Metanephric Mesenchyme Cells for Nephron Formation Georgiy R. Khodus,[1] Jacopo Maria Fontana,[1] Hjalmar Brismar,[2] Anita Aperia.[1] *[1]Karolinska Institutet, Sweden; [2]Royal Institute of Technology, Sweden.*

Background: Emerging evidence suggest that many of the processes governing the reciprocal interactions between the metanephric mesenchyme (MM) and ureteric bud (UB) are calcium dependent. Yet little is known about the origin of calcium signals in the metanephric kidney.

Methods: We have used laser scanning confocal microscopy to record calcium activity in explanted kidney rudiments derived from E14.0 rat embryo and cultured for 48 hours. Kidneys were loaded with the calcium sensitive dye "Oregon Green BAPTA-1", placed in a closed chamber at 35°C and slowly perfused with Krebs-Ringer solution. Calcium was recorded in MM cells bordering UB. The intensity of calcium traces was normalized and background was subtracted.

Results: During the recording time of 30 min, spontaneous calcium oscillations, here defined as at least four calcium peaks exceeding more than 10% of baseline, were observed in 34.0 ± 5.8 % of cells (mean ± std.dev.). The calcium oscillations were completely dependent on release of calcium from the intracellular stores and, to a lesser degree, on influx of calcium from the extracellular space.

To examine the functional role of the spontaneous calcium oscillations, the intracellular calcium stores of the kidney rudiments were depleted by partial inhibition of the SERCA pump with cyclopiazonic acid (CPA) during the 2nd day in culture. In kidney rudiments exposed to 5 μ M CPA, the relative number of cells with calcium oscillations was reduced from 35% to 7%. The UB tips were abnormally shaped and appeared swollen and there was a significant, 27 %, decrease in UB branching and formation of glomeruli in CPA treated kidney rudiments compared to non-treated kidney rudiments. GDNF secreted from the MM and acting on UB Ret-receptors, is a key feature of MM and UB interaction. GDNF secretion, which in the brain is known to be a calcium dependent process, was measured in condition media. Twenty four hours of CPA treatment caused a robust decrease of GDNF secretion.

Conclusions: We conclude that spontaneous intracellular calcium oscillations in MM cells, generated by calcium release from intracellular stores, are required for normal nephron development.

Early B Cell Factor 1 (Ebf1): A Novel Regulator of Renal Cortex Maturation and Glomerular Function Jackie A. Fretz,[1] Tracy Nelson,[1] Heino Velazquez,[2] Yougen Xi,[1] Lloyd G. Cantley,[2] Gilbert W. Moeckel,[2] Mark C. Horowitz.[1] *[1]Orthopaedics and Rehabilitation, Yale University School of Medicine, New Haven, CT; [2]Internal Medicine- Nephrology, Yale University School of Medicine, New Haven, CT.*

Background: The maturation of the metanephros occurs via multiple coordinated signaling pathways, cytokines and transcription factors. We report here a previously unrecognized role of the helix-loop-helix protein Early B cell Factor 1 (Ebf1) as a novel transcription factor required for proper glomerular maturation.

Methods: Using the Ebf1-null mouse as a model of Ebf1-deficiency we characterized the biochemical, metabolic, and histological abnormalities in renal development that arise in the absence of this transcription factor.

Results: The expression of Ebf1 is both spatially and temporally regulated within the developing cortex and glomeruli. Initially Ebf1 expression is seen in the early condensed mesenchyme and appears to mediate glomerular maturation. However, Ebf1 expression is less restricted within the mature kidney and appears in both glomeruli and cortical tubular segments, but is excluded from the collecting duct and medulla. In the absence of Ebf1, developing kidneys show thinned cortices, reduced glomerular number, and features of the nephrogenic blastema that persists into adulthood. In the Ebf1-null mice, the glomeruli show abnormal vascularization, crescent-like structures and severely effaced podocytes by TEM. These mice exhibit albuminuria early and show elevated blood urea nitrogen (BUN) levels. Moreover, in glomeruli lacking Ebf1 the GFR is reduced by 66% and the expression of Wt1 as well as VEGF is decreased compared to wild type control animals.

Conclusions: Taken together these results present the first report of a novel and significant role of Ebf1 in glomerular development, maturation and in the maintenance of kidney integrity and function.

Compensatory Growth of the Glomerulus in the Developing Mouse Kidney Ji Ma, Jianyong Zhong, Valentina Kon, Iekuni Ichikawa. *Pediatrics, Vanderbilt University, Nashville, TN.*

Background: Although glomerulogenesis ceases by postnatal day 3 (P3), the glomerular number remains preserved in rodents undergoing reduction in renal mass in the neonatal period. Our recent studies in developing mice reveal a dynamic change in glomerular number which peaks at P7, then decreases and stabilizes after P18. The present study examines the growth pattern of the developing glomeruli following injury of relatively mature glomeruli and the potential modulating effects of podocyte-derived vascular endothelial growth factor-A (VEGF) to promote compensatory recovery of glomerular number.

Methods: Glomerular injury was induced in relatively mature glomeruli within the deep cortex of mice carrying *Nphs1*-hCD25 transgene (NEP25) by a single i.p. injection of LMB2 at P4. Enhanced expression of podocyte VEGF was achieved by administration of doxycycline to *Nphs2*-rtTA/*tetO*-hVEGF (rtTA/VEGF) double transgenic mice starting from birth (P0).

Results: At P21, a time when normal glomerular maturation is nearly complete, there was no significant difference in body weight (BW) and kidney weight among groups. NEP25 transgenic pups showed glomerular destruction and sclerosis in the deep cortex. These glomerular damages were accompanied by significantly decreased glomerular volume especially in superficial glomeruli (Control: 9763±349 μm^3/g BW *vs*. NEP25: 7607±473 μm^3/g BW, $P<0.05$), which was restored by podocyte-specific induction of the VEGF transgene (NEP25/rtTA/VEGF: 10400±778 μm^3/g BW, $P<0.05$ *vs*. NEP25). The total number of glomeruli was not significantly different among groups. The ratio of superficial:deep glomerular number tended to increase in NEP25 *vs*. controls (6.24±0.66 *vs*. 4.29±0.55, $P=0.063$) and was accompanied by significantly decreased medullary thickness, and increased ratio of superficial:deep cortex thickness. Enhanced podocyte VEGF did not change the glomerular number and distribution.

Conclusions: Damage and loss of glomeruli during development can be compensated through activation of glomerulogenesis in the superficial cortex, which contains relatively immature nephrons. The recovery process involves VEGF-mediated angiogenesis that enhances glomerular growth following glomerulogenesis.

TH-PO466

The Identification of MicroRNAs Regulating Gene Expression during the Birth Transition of the Developing Kidney by Next-Generation Sequencing James B. Tee. *University of Calgary.*

Background: The transition from fetal to newborn kidney is associated with several developmental changes that are involved in the maturation of both renal structure and function. Disruptions to the genetic regulation this process can be the contributing source for reduced renal function in children, including low nephron numbers and cystic kidney disease. MicroRNAs (miRNAs) act to reduce the expression of its target genes. Conventional screening of miRNA expression by pre-generated microarrays are typically limited by its older miRNA library source, lacking the evaluation of a growing number of novel miRNAs that would be detected by next-generation sequencing. The potential role of miRNAs in controlling the developmental processes that govern kidney development at birth have not been studied to date.

Methods: To evaluate this process, kidneys were extracted from rats at gestational days 21 and 22, birth, and 1 day of age. A cDNA library of small RNAs was generated from each timepoint and sequenced on the Illumina GA2. Raw data was aligned to the rat genome (rn4), and then manually parsed for the mature sequences of all 408 miRNAs known to date.

Results: Comparing the pre- and postnatal stages revealed 8 miRNAs that exhibited a >= 2-fold increase in expression. Predicted target mRNAs were generated for the top 5 miRNAs (miR-17-2, 30b, 99a, 16, 425) using a combination of miRanda-based algorithms. Correlation with existing gene expression data at these two stages revealed 32 matching target genes that were downregulated >= 2-fold, including those for uromodulin (p = 5.1E-5), annexin A1 (6.7E-6), and solute carrier family 12-1 (7.0E-3). Conversely, 20 miRNAs exhibited a >= 2-fold decrease in expression between the pre- to post-natal kidney. The predicted targets of the top 5 downregulated miRNAs (miR-542, 341, 378, 101a, 10b) correlated with the increased expression observed in 31 genes including polycystic kidney and hepatic disease 1 (p = 7.3E-3), NADPH oxidase 4 (2.5E-2) and solute carrier family 22a1 (6.9E-3).

Conclusions: The presented results provide a first look at miRNAs that may be involved in the regulation of gene expression governing the developmental processes of the kidney at birth transition.

Using the NCAM1 Marker for Prospective Isolation of Highly Clonogenic Human Adult Kidney Epithelial Cells with Unequivocal Tubular Regeneration Capacities Ella Buzhor,[1,3] Orit Harari-Steinberg,[1,3] Dorit Omer,[1,3] Benjamin Dekel.[1,2,3] *[1]Pediatric Stem Cell Research Institute, Sheba Medical Center, Tel Hashomer, Israel; [2]Division of Pediatric Nephrology, Safra Children's Hospital, Sheba Medical Center, Sackler Faculty of Medicine, Israel; [3]Sheba Center for Regenerative Medicine, Sheba Medical Center, Tel Hashomer, Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.*

Background: There is an ongoing debate on existence of genuine epithelial progenitors in the adult kidney. Recent studies have re-assured that dedifferentiation of injured cells and not activation of an intra-tubular progenitors is taking place in regenerating kidneys. NCAM1 expressed only during nephrogenesis, no expression remains in adulthood. Re-expression of NCAM1 has been observed following ischemic injury in S3 proximal tubule cells.

Methods: In this report, surgical human kidney-tissue specimens were studied to prospectively isolate NCAM+ cells, define their phenotype and functional properties in vitro and in vivo.

Results: No in situ expression of NCAM1 was detected in the human nephron compartment. Nevertheless, human kidney epithelial cell (hKEpC) cultures, uniform for the CD24 and CD133 markers, up-regulated NCAM1 expression in 10-15% of the cells. Cell sorting of hKEpCs according to NCAM1, selected a cell subpopulation that overexpressed nephron progenitor (*Six2/Sall1/Pax2/Wt1*) and proximal tubule markers, as well as elevated *Vimentim* and reduced *E-cadherin*. *In vitro* functional assays revealed NCAM1+ cells to be highly clonogenic, slow-cycling and exclusively forming well-defined 'nephrospheres'. *In vitro* depletion of NCAM1+ cells from hKEpCs cultures resulted in loss of clonogenicity and decreased nephrosphere formation. *In vivo*, NCAM1+ cells grafted to the chorioallantoic membrane of the chick embryo generated renal tubules, predominantly of proximal and to a lesser extent of distal origin, while NCAM1- cells, mesenchymal stem cells or HEK293, failed to do so.

Conclusions: Thus, we have isolated a clonogenic, sphere-forming human adult kidney cell population that possess enhanced ability to generate renal tubules. These findings may ultimately pave the way for autologous cell therapy for renal diseases.

CKD Impairs Functionality of Mesenchymal Stem Cells (MSC) in Rats Barbara Mara Klinkhammer, Monika Mallau, Anna Makowska, Rafael Kramann, Claudia R.C. van Roeyen, Eva Bücher, Simon Otten, Esther Stüttgen, Jurgen Floege, Uta Kunter. *Div. of Nephrology, RWTH University Hospital, Aachen, Germany.*

Background: MSC hold promise in many renal diseases, but little is known about the effects of CKD on long term MSC function. We isolated MSC from the bone marrow of CKD rats and tested their functionality in the acute anti-Thy1.1 nephritis model.

Methods: MSC from "healthy" male F344 rats, "CKD" rats 22 weeks after 5/6 Nx, and healthy MSC from transgenic "hPLAP" (*human placental alkaline phosphatase*) rats were analyzed *in vitro* for proliferation capacity, adipogenic differentiation, cellular senescence and growth factor production. To evaluate MSC function *in vivo*, anti-Thy1.1 nephritis was induced in F344 rats. On day 2 after disease induction, 250 000 MSC ("healthy", "CKD", "hPLAP") or DMEM were injected into the left renal artery. Untreated right kidneys served as controls. Rats were sacrificed at days 4 or 6.

Results: *In vitro*, "CKD" MSC exhibited spontaneous adipogenic differentiation, high levels of active SA-β-Gal, and reduced proliferation capacity (cell population doublings: 134±63 h vs. 52±23 h in "healthy" MSC, $p<0.006$). Culture supernatants of "CKD" MSC contained less TGFβ but similar amounts of $VEGF_{164}$ compared to "healthy" MSC. *In vivo*, treatment with "hPLAP" or "healthy" MSC decreased proteinuria on day 6 compared to "CKD" MSC or DMEM ("hPLAP" 9±6 vs. "CKD" 34±16 vs. DMEM 27±4 mg/24h, $p<0,001$ and n.s., respectively). BrdU positive cells and glomerular mitotic figures on day 4 increased in kidneys treated with "healthy" MSC whereas there was no difference between the "CKD" and DMEM group. On day 6 "healthy" or "hPLAP" MSC reduced mesangiolysis scores, while "CKD" MSC or DMEM did not (% damage reduction treated vs. untreated kidney: "healthy" 26±24; "hPLAP" 51±18; "CKD" -3±31; DMEM 2±21 ("hPLAP" vs. DMEM $p<0,001$; "CKD" vs. DMEM n.s.).

Conclusions: CKD induces a sustained loss of *in vivo* functionality in MSC, possibly by reducing cell proliferation, modulating the secretory phenotype and a shift towards adipogenic differentiation, i.e. changes that resemble cellular senescence. Autologous MSC from CKD patients might thus not be a suitable source for regenerative therapies.

The Embryonic Environment of the Metanephric Kidney Promotes p53 Activation Via Post-Translational Modifications and Mdm2 Cleavage Karam S. Aboudehen, Zubaida R. Saifudeen, Samir S. El-Dahr. *Pediatrics, Tulane University School of Medicine, New Orleans, LA.*

Background: In addition to its classical role as a guardian of the genome, p53 functions as a developmental regulator. In the embryonic mouse kidney, p53 prevents ectopic budding from the nephric duct by antagonizing GDNF-Ret signaling. Moreover, p53 regulates expression of a subset of renal function genes (RFG) via direct binding to the target promoters. Cellular p53 levels are normally kept low via proteosomal degradation mediated by interactions with the E3 ubiquitin ligase, Mdm2. In response to cellular stress (e.g., hypoxia, DNA damage) p53 is modified post-translationally, leading to Mdm2 dissociation. p53 also induces caspase-mediated cleavage of 90-kda Mdm2 to 60-kda Mdm2, which acts to stabilize p53. The mechanisms mediating p53 stabilization and activation in the embryonic kidney are unknown.

Results: Using specific antibodies to total and phosphorylated or acetylated p53, we demonstrate that, compared to postnatal and adult kidneys, embryonic and neonatal p53 is hyper-phosphorylated on serines 6, 9, 15, 20 and 392. Embryonic kidney p53 is also hyper-acetylated on lysines 373, 382, and 386, hence exhibits enhanced DNA binding affinity. Site-directed mutagenesis of critical serines and lysines of p53 demonstrated that these modifications exert differential effects on p53 stability and transcriptional activity. In vivo, $p53^{pSer392}$ is enriched in differentiating proximal tubules, whereas $p53^{ace\text{-}373,382}$ is expressed in the metanephric mesenchyme, nephron progenitors and collecting duct cells. Co-immunoprecipitation/Western blotting revealed that embryonic p53 exists mostly in a mono-ubiquitinated form, whereas, in postnatal and adult kidney, p53 is poly-ubiquitinated. This finding correlates well with the temporal switch from cleaved to intact forms of Mdm2 and dramatic reductions in p53 levels.

Conclusions: We conclude that the embryonic environment mimics the stress response pathway leading to enhanced p53 stability and DNA binding activity. Furthermore, the developmental switch in mdm2 protein species likely plays an important role in p53 degradation following the end of nephrogenesis.

Gene-Environment Interactions Cooperate To Repress the Developmental Regulator, Pax2, in Renal Dysgenesis Lei Yan,[1] Nathaniel J.D. McLaughlin,[1] Xiao Yao,[1] Dimcho Bachvarov,[2] Zubaida R. Saifudeen,[1] Samir S. El-Dahr.[1] *[1]Pediatrics, Tulane University School of Medicine, New Orleans, LA; [2]Molecular Medicine, Laval University, Quebec, Canada.*

Background: Gene-environment interactions play an important role in the pathogenesis of human congenital disorders. Bradykinin B2 receptor-null (*Bdkrb2*$^{-/-}$) mice have normal kidney development; however, the *Bdkrb2*$^{-/-}$ progeny develop renal dysgenesis following gestational salt stress via the maternal diet. The transcription factor, Pax2, is significantly downregulated in *BdkrB2*$^{-/-}$ kidneys compared to wild-type pups. Humans with *Pax2* mutations have renal dysgenesis. We tested the hypothesis that embryonic salt stress cooperates with *BdkrB2* inactivation to repress *Pax2* gene transcription.

Results: *Bdkrb2*$^{-/-}$ mice were crossed to *BAC-GFP* transgenic mice carrying 30 kb of *Pax2* upstream elements. GFP protein and mRNA, surrogates of in vivo Pax2 transcriptional activity, from salt-stressed *Bdkrb2*$^{-/-}$;*Pax2-GFP* and wild-type embryonic kidneys were analyzed quantitatively by fluorescent microscopy and real-time PCR, respectively. GFP pixel area/intensity and mRNA levels were lower in E12.5 and E14.5 *Bdkrb2*$^{-/-}$ than *Bdkrb2*$^{+/+}$ kidneys ($p<0.05$). However, when E12.5 *Bdkrb2*$^{-/-}$ kidneys were grown ex vivo for 2 days to remove the embryonic stressor, GFP expression, the number of ureteric bud branching points and tips, and K-cadherin expressing renal vesicles normalized. Microarray analysis in E14.5 salt-stressed *BdkrB2*$^{-/-}$ and *BdkrB2*$^{+/+}$ kidneys revealed significant changes in 1% of probe sets. Upregulated genes (n=202) were linked to extracellular matrix synthesis and muscle development, whereas downregulated genes (n=164) belonged to transcription factors, cell cycle and fate and regulators of nucleic acid metabolism. Importantly, 28 upregulated and 13 downregulated genes have putative Pax2-responsive elements in their promoter regions. Moreover, 8 of these genes have mouse mutant phenotypes consistent with a major role in muscle, kidney, lymphatic and cardiovascular development.

Conclusions: We conclude that *Pax2* transcriptional activity is responsive to gene-environment interactions in vivo, representing a novel mechanism of renal dysgenesis.

Metanephros Transplantation Contributes to Maintaining Blood Pressure in Diltiazem Treated Anephric Rats Shinya Yokote,[1,2] Takashi Yokoo,[1,2] Kei Matsumoto,[1,2] Yasunori Utsunomiya,[1] Tetsuya Kawamura,[1] Tatsuo Hosoya.[1] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, Jikei University School of Medicine, Nishi-Shimbashi, Minato-ku, Tokyo, Japan; [2]Project Laboratory for Kidney Regeneration, Institute of DNA Medicine, Jikei University School of Medicine, Nishi-Shimbashi, Minato-ku, Tokyo, Japan.*

Background: The kidney is an important organ in maintaining blood pressure. We have previously reported that transplanted metanephroi can reproduce some kidney function. The aim of the present study was to determine the metabolic function of transplanted metanephroi with particular reference to maintaining blood pressure during renal failure.

Methods: Ten-week-old male Wistar rats were transplanted with metanephroi in the paraaortic area (PA group; n=5) or in the omentum and epididymis (OE group; n=8), followed by bilateral nephrectomy. For comparison, we performed bilateral nephrectomies without transplantation on fourteen rats (non-transplanted group; n=9 and heminephrectomy control group; n=5). Nephrectomies were performed on the rats in the transplanted and non-transplanted groups two weeks after transplantation. Rats in the control group had sham operations performed. Hypotension was induced by intravenous infusion of diltiazem hydrochloride at a dose of 0.025mg/kg/min for 2 hours and at a dose of 0.05mg/kg/min for further 2 hours using a syringe pump. Mean arterial blood pressure (MAP) was monitored from the left femoral artery. Plasma renin activity (PRA) was analyzed every hour. Renin expression from the transplanted metanephroi was evaluated by RT-PCR and immunopathologically at the time of sacrifice.

Results: RT-PCR showed that metanephroi in the transplanted group expressed renin m-RNA. Metanephros transplantation significantly raised PRA and maintained MAP compared with the non-transplanted, anephric group. No significant differences between the transplanted and control groups were found with respect to PRA and MAP.

Conclusions: The present study has shown that transplantation of metanephroi produces PRA and contributes to maintaining MAP in a rat model of hypotension.

TH-PO472

Branching Tubulogenesis of Renal MDCK Cells Requires HIF-1α and Its Target Gene FSP1 – Implications for a (Patho)Physiological Role in the Human Kidney Bjoern Buchholz, Sven Kroening, Gunnar Schley, Tina Gimm, Wanja M. Bernhardt, Kai-Uwe Eckardt. *Department of Nephrology and Hypertension, University of Erlangen-Nuremberg, Erlangen, Germany.*

Background: During nephrogenesis, outgrowth and branching of the ureteric bud is essential to generate the definitive renal collecting system and to determine the number of nephrons. During kidney development, the hypoxia-inducible transcription factor HIF-1α is expressed in medullary and cortical collecting ducts of various species. In addition, HIF-1α is stabilized in epithelial cells of ischemic and polycystic kidneys. Therefore, we wondered if HIF-1α might play a role in tubulogenesis and tubular repair and which target genes would be involved.

Methods: We studied in vitro branching tubulogenesis of Madin-Darby Canine Kidney (MDCK) cells, which originate from the collecting duct, according to their protein expression of HIF-1α. Therefore, we stabilized HIF-1α by hypoxia or the hypoxia-mimetic DMOG or inhibited HIF-1α with 17 AAG or chetomin. We also established two MDCK cell clones with a stable knockdown of HIF-1α and performed RT-PCR to test for relevant target genes. In addition, we used immunohistochemistry to examine developing kidneys of humans and rats as well as kidneys affected by hypoxia or ischemia.

Results: Both, hypoxia and DMOG enhanced in vitro tubulogenesis. In contrast, 17 AAG, chetomin and knockdown of HIF-1α significantly inhibited branching tubulogenesis. The metastasis-promoting protein FSP1 which has recently been shown to be a HIF-1α target gene was markedly decreased in the HIF-1α knockdown cells. Inhibition of FSP1 by Sulindac as well as knockdown of FSP1 by siRNA diminished in vitro tubulogenesis of MDCK cells. In addition, FSP1 was markedly expressed in tubules of developing human and rat kidneys, as well as in ischemic, hypoxic, and polycystic kidneys.

Conclusions: Branching tubulogenesis of MDCK renal collecting duct cells depends on HIF-1α. In vitro tubulogenesis of MDCK cells also depends on the HIF-1α target gene FSP1. FSP1 is highly expressed in tubular cells of developing kidneys and adult kidneys affected by hypoxia suggesting a physiological and pathophysiological role for FSP1/HIF-1α in vivo.

TH-PO473

An Alternative Splice Product of the HmPKD1 Gene Induces Mesenchyme to Epithelial Transition in COS-1 Cells Robert L. Bacallao, Clifford Babbey, Wei Min Xu. *Medicine, Indiana University and Richard Roudebush VAMC, Indianapolis, IN.*

Background: In a genome wide cDNA library construction using 5' cap probes, additional transcripts from the HmPKD1 locus were identified by Kimura et al, 2006 (Genome Research). We completed the sequence analysis and characterized the biological effects of this cDNA when expressed in COS-1 cells.

Methods: cDNA encoding a splice variant from the HmPKD1 locus was obtained from Dr. Sugano (University of Tokyo) and sequenced at the DNA sequencing facility at Indiana University. The clone was transiently transfected into COS-1 cells. Paired samples of transfected and untransfected were compared for E-cadherin and ZO-1 expression. In addition trans-epithelial resistance (TER) was measured using an Epithelial Volt Ohm meter (EVOM). Finally growth morphology in 3D collagen culture was assessed by multiphoton confocal microscopy.

Results: The cDNA sequence was mapped onto the HmPKD1 genomic sequence database at UC Santa Cruz. The start site of the cDNA maps to intron 40 of HmPKD1. The intron 40 sequence runs into exon 41 with a splice from the 3' end of exon 41 with the 5' end of exon 43. All the rest of the splices are the same as that observed in the full-length PKD1 gene.

Transiently transfected COS-1 cells develop a measurable TER over the course of 3 days post transfection. In contrast untransfected cells fail to develop a TER. Over the same time course, transfected cells homogeneously express ZO-1 and E-cadherin. When plated in 3D collagen culture, transfected COS-1 cells form cysts with a single monolayer of cells surrounding a lumen.

Conclusions: A alternative transcript from the HmPKD1 locus induces expression of epithelial markers in a normally mesenchymal cell line (COS-1). Transient transfected of this cDNA causes mesenchyme to epithelial transition and causes cyst formation in 3D collagen culture.

Low Serum Cultured Adipose Derived Stem Cells Ameliorate Zymosan Induced Severe Rat Peritonitis Model Hangsoo Kim, Masashi Mizuno, Kazuhiro Furuhashi, Takayuki Katsuno, Kaoru Yasuda, Takenori Ozaki, Waichi Sato, Naotake Tsuboi, Yasuhiko Ito, Enyu Imai, Shoichi Maruyama, Seiichi Matsuo. *Nagoya University Graduate School of Medicine, Japan.*

Background: We developed a novel culture system for low serum cultured adipose derived stem cells (LASCs) and have shown the therapeutic potential of LASCs in various animal models.

Methods: In this study, we focused on a fungal peritonitis in peritoneal dialysis(PD),which is a major problem since the fibrosis may progress rapidly and it may evolve into encapsulating peritoneal sclerosis (EPS) even when the peritoneal dialysis catheter is removed.

A rat model of fungal peritonitis was induced by administration zymosan daily for 5 days after scraping peritoneum mechanically. The rats were divided into two groups;LASC(L group) or vehicle(V group) administration intraperitoneally with PD solution(1.5% glucose,neutral liquid) every day.On day 5, thickness of peritoneum, infiltration of inflammatory cells, and deposition of complement etc. were compared between the groups.

Results: On day 5, microscopic findings in L group was less plaques and less edematous. Histologically,the thickness of peritoneum,infiltration of inflammatory cells and deposition of complement both C3 and membrane attack complex(MAC) in L group was significantly reduced than those in V group. In addition, the mesothelial layer on peritoneal surface in L group recovered earlier compared with that in V group.The proliferation of mesothelial cell was confirmed in vitro experiment.

Conclusions: Administration of LASCs into the peritoneal cavity suppressed the inflammation of peritonitis induced by zymosan, and the mesothelial cell layer in L group recovered earlier than that in V group. These data suggest that LASCs have the multiple effects to peritoneal damage.In the future, LASCs therapy may be useful for peritoneal injury during fungal infection of the peritoneum.

Block of Par1 Signaling Inhibits Metanephric Kidney Growth and Differentiation In Vitro Kimberly J. Reidy,[1] Zhongfang Du,[1] David Cohen,[2] Anne Muesch,[2] Jonathan M. Barasch,[3] Katalin Susztak.[4] *[1]Pediatric Nephrology, Children's Hospital at Montefiore, Bronx, NY; [2]Developmental and Molecular Biology, Albert Einstein College of Medicine, Bronx, NY; [3]Nephrology, Columbia University, New York, NY; [4]Nephrology, Albert Einstein College of Medicine, Bronx, NY.*

Background: We have identified expression of Partitioning defective Par1 polarity proteins in developing S-shape nephrons. Par1a/b are serine threonine kinases that are functionally redundant and genetic deletion of both results in embryonic lethality. Par1 and a complex of Par3/Par6/aPKC localize to distinct portions of cell membranes to establish polarity. Podocyte-specific deletion of aPKC induced foot process effacement, proteinuria and glomerulosclerosis. We hypothesized that Par proteins may contribute to nephron differentiation, and sought to define the temporal and spatial expression of Par1a/b during embryonic kidney development, and to examine the effect of Par1 signaling on nephrogenesis in vitro.

Methods: Par mRNA and protein expression of was examined using embryonic kidneys obtained from timed-pregnant Sprague Dawley rats. Localization of Par1a and 1b was examined by immunofluorescence (IF). To examine the effect of Par1 signaling, isolated metanephroi were infected with a GFP tagged dominant negative Adeno-GFP-DNPar1 construct or control Adeno-GFP constructs, induced with LIF, and cultured for 7-14 days.

Results: Par1 mRNA expression correlated with expression of factors involved with nephron segmentation including Notch2 and Lhx1. Par1a, 1b and Par3 proteins are expressed at low levels at E13, and expression increased at E15. Par1b phosphorylation was also regulated during nephrogenesis. In vitro blockade of Par1 signaling with the DNPar1 construct during nephrogenesis resulted in stunted growth. Early mesenchymal to epithelial transition was not inhibited, but expression of podocalyxin was impaired.

Conclusions: These data suggest that Par1a/b may contribute to nephron development, and studies are ongoing to examine their role in cell proliferation, apoptosis and differentiation during nephrogenesis.

Both Excessive and Deficient Maternal Salt Intake Decrease Nephron Number and Cause Delayed Hypertension in the Offspring Grzegorz Piecha,[1] Marie-Luise Gross-Weissmann,[2] Eberhard Ritz,[3] Nadezda Koleganova.[2] *[1]Department of Nephrology, Endocrinology and Metabolic Diseases, Medical University of Silesia, Katowice, Poland; [2]Institute of Pathology, University of Heidelberg, Germany; [3]Department of Internal Medicine, Division Nephrology, University of Heidelberg, Germany.*

Background: An adverse environment during fetal development has life-long consequences: hypertension, increased cardiovascular risk, renal malfunction. Using stereology we studiedwhether high salt intake in pregnancy modifies kidney structure as well as blood pressure in the offspring.

Methods: Sprague-Dawley rats were fed low (0.15% NaCl), medium (1.3%), or high (8.0%) salt diets during pregnancy and weaning. Offspring were weaned at 4 weeks of age and subsequently received a standard rodent diet. Blood pressure was measured by telemetry and albuminuria by a rat specific ELISA up to 52 weeks of age. The nephron number at 12 weeks of age was determined using design-based stereology.

Results: The nephron number was significantly lower in offspring of dams on low (males: 19100±3700 per kidney, females: 19000±2500) and high (m: 12100±600, f: 12800±2800) compared to medium salt intake (m: 32400±2500, f: 28500±6000). In male offspring of dams on both low and high salt intake baseline albumin excretion was higher than in offspring of dams on medium salt intake from 6 months of age. Albumin excretion increased after 1 and 2 weeks of high salt intake. The increase in albuminuria was significantly higher in both male and female offspring of dams on high and low salt diet respectively.

Conclusions: Systolic, diastolic, and mean arterial pressures were not significantly different between the offspring until 6 months of age. Starting at age 7 months systolic blood pressure was higher in offspring of dams on low (123±8 mmHg) and high (124±7) compared to medium (116±5) salt intake and remained higher until 12 months of age.

TH-PO477

The Expression of Prox1 Is Regulated by the Osmolality in Mouse Renal Medulla Yumi Kim, Wan-Young Kim, Sun-Ah Nam, Jin Kim. *Anatomy and MRC for Cell Death Disease Research Center, Catholic University of Korea, Seoul, Republic of Korea.*

Background: Prox1, prospero-related homeobox1 transcription factor, is known to be expressed in various internal organs and is related to those differentiations. We previously reported that Prox1 is expressed in the development of the ascending thin limb (ATL) of Henle's loop by transformation of the thick ascending limb (TAL) in the developing mouse kidney. The maximum urine osmolality develops progressively during postnatal life, while it is about half that of adults in neonates. Prox1 expression areas in the developing region of ATL change according to these osmolality increasing. The purpose of this study was to examine whether the expression and distribution of the Prox1 change with the osmolality in vitro and in vivo condition by immunohistochemistry and Western blot analysis.

Methods: We performed in vitro experiments with MDCK cells under various osmotic culture conditions. And adult male C57BL/6 mice were fed a low-potassium diet for 2 weeks for hypokalemic condition, and control animals received normal diet in vivo experiments.

Results: Prox1 was expressed strongly in nucleus and weakly in cytoplasm of MDCK cells under isotonic medium. In contrast, when MDCK cells were cultured in hypotonic or hypertonic medium, the nuclear immunoreactivity decreased while the cytoplasmic immunoreactivity weakly remained. Furthermore, after 2 wk on a low-potassium diet, urinary osmolality significantly decreased. In the normal adult kidney, the immunoreactivity for Prox1 in ATL was weak in initial part, but not in terminal part of renal papilla. However, Prox1 was expressed not only in initial part of renal papilla but also in terminal part of renal papilla in the potassium depleted mice. And the intensity of Prox1 immunoreactivity was increased in the potassium depleted mice compared to normal mice. Thus as seen both in vitro and in vivo, Prox1 was expressed in the osmotic condition within optimal range.

Conclusions: These results suggested that the expression of Prox1 is regulated by osmolality in the mouse renal medulla.

Diabetes Mellitus and Pup Sex Influence Congenital Kidney Abnormalities in the ACI Rat Pascale H. Lane. *Pediatrics, University of Nebraska Medical Center, Omaha, NE.*

Background: The ACI rat develops congenital abnormalities of the kidney and urinary tract (CAKUT) in 10-15% of offspring via an autosomal dominant mutation with variable penetrance. In humans, maternal diabetes mellitus (MDM) increases the risk of CAKUT by ~15%. We tested the hypothesis that MDM would increase the rate of CAKUT in ACI rats.

Methods: Female ACI rats received streptozocin (MDM) or saline (Control; C) on day 1. Tail-vein blood glucose >300 mg/dL 2-3 days later defined the presence of diabetes. They were then housed with males until signs of pregnancy developed. After spontaneous delivery, pups were weighed and sacrificed on day 3-5 of life. The anterior abdominal wall and peritoneal contents were removed, and the urinary tract photographed with a dissecting microscope. The kidneys were then removed and weighed.

Results: Maternal glucose at the time of pup harvest averaged 173±6 in C and 420±15 in MDM ($p<0.001$). 111 litters (61C and 50MDM) demonstrated no differences in litter size (C 6±0.2 vs MDM 6±0.3) or sex distribution (C 3±0.2 males vs MDM 3±0.2 males).

Pup Characteristics

	Male C	Female C	Male MDM	Female MDM	Significance
PW, g	8.6±0.1	8.3±0.1	6.3±0.1	5.9±0.1	M,S
KW:PW, mg/g	12.6±0.2	13.1±0.2	11.9±0.2	12.7±0.2	M,S
CAKUT, %	13	11	21	14	p=0.08

PW: pup weight; KW:PW: total kidney weight/pup weight; M: maternal metabolic state; S: pup sex

MDM reduced PW ($p<0.001$) and KW:PW ($p=0.007$). Females had lower PW ($p<0.00$) but higher KW:PW ($p<0.002$). No interactions of maternal metabolic state and pup sex were demonstrated. The rate of CAKUT did not differ significantly with maternal metabolic state (C 12% vs. MDM 17%; $p=0.09$), although a strong trend toward increased relative risk was present (RR 1.39; 95% CI 0.97 to 1.99). This trend was most pronounced in male pups (RR 1.55; 95% CI 0.97 to 2.50).

Conclusions: ACI rat offspring from MDM show a strong trend toward increased CAKUT, particularly in male pups. This model may help us understand the mechanism(s) through which MDM increases CAKUT and the particular sex-specific risk of this condition.

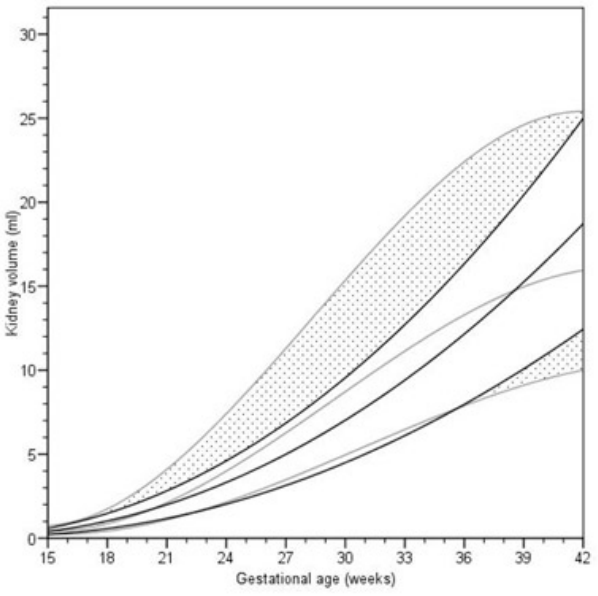
Superior Size and Volume Charts for Fetal Kidney Development Derived from Longitudinal US Measuments Stefan Hendrik Van Vuuren,[1,2] Henny Damen Elias,[3] Robert H. Stigter,[4,3] Robert Van der Doef,[3] Tom P.V.M. De Jong,[2,6] Roel Goldschmeding,[1] Paul Westers,[5] Gerard H.A. Visser,[3] Lou Pistorius.[3] *[1]Pathology, UMCU, Utrecht, Netherlands; [2]Pediatric Renal Centre, UMCU, Utrecht, Netherlands; [3]Obstetrics, UMCU, Utrecht, Netherlands; [4]Obstetrics and Gynaecology, Deventer Hospital, Deventer, Netherlands; [5]Centre for Biostatistics, UU, Utrecht, Netherlands; [6]Pediatric Renal Centre, AMC, Amsterdam, Netherlands.*

Background: Kidney growth continues into puberty but available fetal growth charts suggest it halts soon after birth (Chitty et al, Prenat Diagn 2003;23:891-7). Therefore we established reference curves for sonographic size and volume of the fetal kidney and renal pelvis starting from the 15th week of gestation.

Methods: In a prospective longitudinal study the length and anteroposterior and transverse diameters of both kidneys and the anteroposterior and transverse diameters of the renal pelvises of 102 consecutive fetuses were measured by 4-weekly ultrasound examinations. We carried out multilevel statistical analysis for comparison of kidney dimensions with gestational age and femur length.

Results: Size charts for fetal kidney dimensions, kidney volume and renal pelvis were created and compared with previously published charts. These charts were significantly different from previous published charts by Chitty et al. (see figure).



Comparison of 3rd, 50th and 97th centiles for kidney volume estimation obtained in this study (black lines) and the 3rd, 50th and 97th centiles of Chitty[1] (gray lines).

The shadowed areas represent the potential loss of cases with abnormal growth by using the Charts presented by Chitty[1] in comparison with our data.

[1] Chitty LS, Altman DG: Charts of fetal size: kidney and renal pelvis measurements, Prenat Diagn 2003, 23:891-897

Furthermore, our charts showed a high correlation between kidney and femur length (r = 0.940), and between the kidney volume and the calculated volume based on femur length (r =0.941).

Conclusions: Longitudinal measurements have produced growth charts that differ from previous ones in that renal volume does not level off before birth, which is consistent with continued immediate postnatal growth. The added correlation charts with femur length will be useful to identify deviations in fetuses small or large for gestational age.

The Role of Ubiquitin Specific Protease 40 in the Glomerular Endothelial Cells Hisashi Takagi,[1] Michael P. Madaio,[2] Kunimasa Yan.[1] *[1]Pediatrics, Kyorin University School of Medicine, Mitaka, Tokyo, Japan; [2]Nephrology and Kidney Transplantation Section, Medical College of Georgia, Augusta, GA.*

Background: The vascular endothelium is an essential structure of the glomerular tuft; however, the regulatory mechanism of vascularization in the developing glomerulus remains elusive. The ubiquitination pathway is a highly dynamic and coordinated process that regulates degradation of proteins within a cell, in which ubiquitin specific protease has the ability to remove ubiquitin from a ubiquitylated substrate. Novel glomerulus-enriched transcripts were recently reported, in which ubiquitin specific protease 40 (USP40) was found in mouse glomerulus.

Methods: Mouse USP40 cDNA was cloned from kidney cDNA library and used for generation of recombinant protein and establishment of stably expressing cell line. Polyclonal antibody was generated by using recombinant USP40. RT-PCR was done to determine expression of USP40 mRNA. Immunohistochemistry and immunoelectron microscopy were done to examine localization of USP40 in the mature and fetal kidney. siRNA experiment was done to examine the role of USP40 in podocalyxin biogenesis in the immortalized mouse endothelial cells.

Results: USP40 mRNA was abundantly expressed in the glomerulus compared with the rest of kidney. USP40 was specifically localized at microvascular endothelial cells intensely in the glomerulus, and moderately in the interstitium of mouse, rat, and human mature kidney. The subcellular localization of USP40 in the stable cell line and mouse glomerular endothelial cell line was observed in the cytoplasm, not in the specific organellas. Molecular migration of USP40 of cell lines, isolated glomeruli and the rest of kidney was revealed to be a 150-kDa. In the fetal kidney, USP40 was already recognized in the comma-shaped glomerulus. USP40 siRNA resulted in the drastic decrease of podocalyxin protein of glomerular endothelial cells.

Conclusions: The present data suggest that USP40 may play a crucial role in the glomerular development through interacting with ubiquitin, thereby regulating degradation of specific proteins of the microvascular endothelial cells including podocalyxin.

Gender Differences in Chronic Kidney Disease and Progression in Type 2 Diabetes Margaret K. Yu,[1] Courtney R. Lyles,[2] Bessie A. Young.[1,2,3] *[1]Division of Nephrology, University of Washington, Seattle, WA; [2]Department of Health Services, University of Washington, Seattle, WA; [3]Epidemiology Research and Information Center, VA Puget Sound, Seattle, WA.*

Background: The effect of gender on chronic kidney disease (CKD) and its progression in diabetes is not well defined. The objective of this study is to evaluate gender differences in CKD and CKD risk factors in type 2 diabetes.

Methods: The Pathways Study is a prospective cohort of ambulatory, diabetic patients from a large managed care system in Seattle, WA. Chi-square tests, two-sample t-tests, and logistic regression were used to determine gender differences in baseline CKD stage, risk factors, and progression. Risk of mortality was evaluated by Cox-proportional hazards modeling.

Results: Among 4800 enrollees, 4749 patients met entry criteria (48.6% women, 51.4% men). Women had a higher baseline prevalence of hypertension (45.0% vs 41.0%, p=0.008) and mean LDL (115.9 vs 107.8 mg/dL, p<0.001) than men. Fewer women than men had their LDL checked (60.1% vs 67.5%, p<0.001) or were prescribed a statin (26.5% vs 35.4%, p<0.001). Men had a higher prevalence of baseline microalbuminuria (16.5% vs 14.5%, p=0.032) and number of end organ complications (p<0.001). Women had a higher prevalence of moderate/severe CKD (GFR<60 ml/min, 35.9% vs 31.6%, p<0.001). In logistic regression models, women had a greater odds of progressing to a higher CKD stage (OR=1.34, 95% CI=1.13-1.60) but there was no difference in progression to ESRD at 5 years (p=0.451). Men had greater all-cause mortality at 5 years (HR=1.30, 95% CI=1.05-1.60) but after adjustment for diabetic complications the difference was no longer significant (HR=1.14, 95% CI=0.93-1.41).

Conclusions: Diabetic women had a higher prevalence of hypertension and hyperlipidemia. They were less likely than men to have their cholesterol checked or to have a statin prescribed. Women were more likely to progress to a higher CKD stage but there was no difference in progression to ESRD at 5 years. Men had a higher 5-year mortality which seems related to their higher number of end organ complications. Further studies on the effect of gender on CKD progression in diabetes are warranted.

Investigation of Trajectories of Renal Function Decline in Subjects with Type 1 Diabetes Mellitus and Proteinuria Jan Skupien, Adam Smiles, Marcus G. Pezzolesi, Monika A. Niewczas, Robert C. Stanton, James Warram, Andrzej S. Krolewski. *Joslin Diabetes Center and Harvard Medical School, Boston, MA.*

Background: The modern-day natural history of renal function decline in patients with type 1 diabetes mellitus (T1D) and nephropathy remains unknown.

Methods: We identified 244 patients under care of the Joslin Clinic who had T1D and proteinuria, with normal renal function. These patients were followed for 5 to 18 years (98% until 2008). The multiple measurements of serum creatinine obtained during follow-up and eGFR (estimated glomerular filtration rate) values calculated with CKD-EPI formula were used to determine long-term trajectories of renal function changes.

Results: In one-half of the cohort, renal function was stable or decreased slowly (non-decliners); in the other half, renal function decreased rapidly (-3.5 to -71 ml/min/1.73m2/year) with almost 100% risk of ESRD (decliners). The observed trajectories according to three periods of enrollment into the study are summarized in the Table.

Patterns of trajectories	Calendar year of enrollment			
	1991-1995	1996-2000	2001-2004	Total
	n=74	n=72	n=98	n=244
	Percent			
Non-decliners	35.1	48.6	56.1	47.6
Decliners				
linear slope	23.0	25.0	17.3	21.3
decelerating	13.5	5.5	6.2	8.2
accelerating	18.9	4.2	0.0	6.9
indeterminate	9.5	16.7	20.4	16.0

Most decliners had linear trajectory of eGFR loss. Transitions to slower rate of decline (deceleration) were rare. The risk of development of rapid decline in subjects with stable renal function was 28% in the sub-cohort with the longest follow-up.

Conclusions: Almost half of the patients with proteinuria had stable renal function and minimal risk of ESRD (end-stage renal disease) during their lifetime. The other half of the patients are at risk of ESRD, but time to onset varied between 2 and 20 years due to very variable rate of renal function decline, which was constant in the majority of the decliners. Infrequent decelerating trajectories suggest that the current therapies are ineffective in delaying renal function loss in decliners. It may be hypothesized that the risk of ESRD is primarily determined by currently non-modifiable, early, constitutional (possibly genetic) factors.

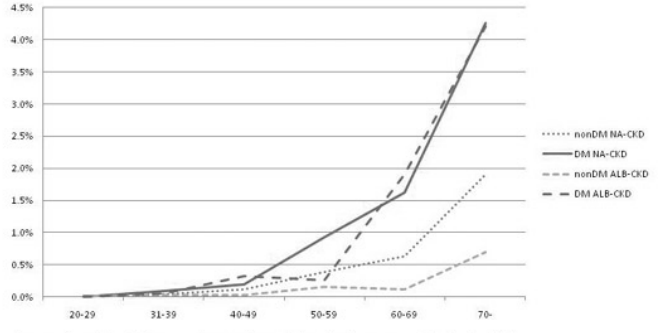
Normoalbuminuric Chronic Kidney Disease in the U.S. Population Amy K. Mottl,[1] Keunsang Kwon,[2] Susan L. Hogan,[1] Abhijit V. Kshirsagar.[1] *[1]University of North Carolina, Chapel Hill, NC; [2]Chonbuk National University, Jeonju, Korea.*

Background: At least one-third of diabetics have decreased estimated glomerular filtration rate (eGFR) < 60ml/min/1.73m^2 in the absence of albuminuria. Our goal was to determine the age-specific prevalence of nonalbuminuric CKD in a sample of the U.S. population and to describe any potential demographic and clinical differences from albuminuric CKD.

Methods: The National Health and Nutrition Examination Survey (NHANES) 2001-2008 cohort included 18,587 participants ≥ 20 years and with both serum creatinine and urine albumin:creatinine ratio (UACR) available for analysis. We determined stratum specific prevalence rates and 95% confidence intervals.

Results: Diabetes was present in 13% of the total population. Nonalbuminuric CKD was prevalent in 7% of diabetic and 3% of nondiabetic participants. Decreased eGFR with albuminuria was prevalent in 7% and 1% of diabetic and nondiabetic participants, respectively. There is a clear relationship between age and the prevalence of decreased eGFR (Figure 1). This relationship is equivalent in diabetics regardless of albuminuric status. In nondiabetics the effect of age is much stronger in the nonalbuminuric stratum. Moreover, in the nondiabetic stratum, nonHispanic Blacks have more albuminuric than nonalbuminuric CKD: 12% (8-17%) versus 3% (2-4%). Nondiabetic women and nonHispanic Whites have a preponderance of nonalbuminuric CKD: 68% (63-73%) versus 53% (45-61%) and 93% (91-95%) versus 78% (73-84%), respectively.

Conclusions: In conclusion, in the U.S. population the prevalence of nonalbuminuric CKD is greater in diabetic than nondiabetic people. Albuminuria is an effect modifier of the relationship between age and decreased eGFR in nondiabetic but not diabetic populations. Nondiabetic, nonalbuminuric CKD is more predominate in women and nonHispanic Whites whereas albuminuric CKD predominates in nonHispanic Blacks.



Age-specific relationship between the prevalence of albuminuric versus nonalbuminuric CKD in diabetic and nondiabetic participants of 2001-2008 NHANES.

TH-PO485

Renal Outcomes after Remission of Albuminuria in Diabetic Patients Nobue Tanaka, Tetsuya Babazono, Ko Hanai, Yasuko Uchigata. *Diabetes Center, Tokyo Women's Medical University, Tokyo, Japan.*

Background: It is known that the reductions of albuminuria are observed in some of diabetic patients. However, the clinical course of albuminuria after the episode of remission has not been well described. We therefore performed this observational cohort study to evaluate the renal outcomes after remission of albuminuria in diabetic patients.

Methods: A total of 1237 albuminuric patients with diabetes were enrolled in this cohort study between 2003 and 2005, and were followed up until 2010. During the observational period, the remissions of albuminuria were found in 310 patients. There were 30 type 1 and 280 type 2 diabetic patients, and the mean (± SD) age at the remission of albuminuria was 58 ± 13 years, including 230 patients with remission from micro- to normoalbuminuria and 80 patients with remission from macro- to microalbuminuria. We assessed the cumulative incidence of re-progression of albuminuria from the onset of remission using the Kaplan-Meier method. The clinical factors associated with the progression of albuminuria were analyzed by the Cox proportional hazard model, adjusting for age, sex, systolic and diastolic blood pressure, estimated glomerular filtration rate (eGFR), urinary albumin-to-creatinine ratio (ACR), hemoglobin and glycated hemoglobin.

Results: The mean follow-up period after remission of albuminuria was 4.9 ± 1.5 years. Five-year cumulative incidences of the progression of albuminuria were 28.7% in normoalbuminuria and 35.0% in microalbuminuria. The clinical factors associated with the progression from normo- to microalbuminuria were higher urinary ACR (hazard ratio [HR] per log10 = 5.92, 95% confidence interval [CI] 1.16-30.3, p = 0.03), lower total cholesterol (HR = 0.99, 95%CI 0.98-1.00, p = 0.03) and higher triglyceride (HR per log10 = 4.11, 95%CI 1.54-10.99, p < 0.01). In microalbuminuric patients, lower eGFR at the remission of albuminuria was related to the progression to macroalbuminuria (HR; 0.97, 95%CI; 0.96-0.99, p < 0.01).

Conclusions: This longitudinal study suggests that the progression of albuminuria occur even after remission of albuminuria in a considerable number of diabetic patients.

TH-PO486

Control of Postprandial Hyperglycemia Is Critical for Renal Preservation in Diabetes Anil K. Mandal,[5812] Linda M. Hiebert.[0980] *[1]Dept of Medicine, Univ of Florida, Gainesville, FL; [2]Veterinary Biomedical Science, Univ of Saskatchewan, Saskatoon, Saskatchewan, Canada.*

Background: We have shown that 2 hour postprandial glucose (2hPPG) and dglucose (2hPPG-Fasting glucose) are significantly related to renal function change (Diab Res Clin Pract 2011; 91: 190 – 194). HbA$_1$c is most commonly used to determine glycemic control in diabetes mellitus (DM). We asked the question: Which glycemic parameters better predict renal function changes in long-term follow up of DM?

Methods: 25 adult patients with established DM were followed in office for an average 8.4 months. DM diagnosis was established by 2 hour postprandial glucose (2hPPG) above 200 mg/dL on two occasions. For brevity, Type I and Type II are not used. Mean age is (mean ± SD) 63.18 ± 11.55 years; males (n=11) and 67.36 ± 8.12 years females; (n=14). They are followed at 6 - 8 weeks with a laboratory of fasting and 2hPP basic metabolic panel consisting of fasting glucose (FG), 2hPPG, and BUN, Serum creatinine (Scr), HbA$_1$c, and average glucose (AVG), prior to office visit. dglucose was calculated. They are treated with a combination of insulin glargine (Lantus®) after breakfast and dinner; and regular insulin based on finger stick glucose 2 hours after each meal and at bed time. Spearman's rank correlation coefficients were obtained; measurements over a mean of 9.5 visits are averaged for each subject.

Results:

(n = 25; mean ± SEM)
FG (mg/dL) 157.5 ± 7.1 (115.3 – 216.3)
2hPPG (mg/dL) 239.9 ± 9.6 (137.6 – 380.4)
dglucose (mg/dL) 87.1 ± 8.9 (0.4 – 205)
HbA1c (%) 8.3 ± 0.3 (6-14)
AVG (mg/dL) 193.4 ± 9.1 (128 – 356)
F Scr (mg/dL) 1.4 ± 0.1 (0.7-2.7)
2hPP Scr (mg/dL) 1.5 ± 0.1 (0.8-3.1)

Correlations between (1) 2hPPG and dglucose and (2) F Scr and 2hPP Scr are statistically significant (-0.49 < r < -0.44; P < 0.03 in every case). Scr levels were at the normal range and decreased with glycemic control. No correlation was found between F Scr and HbA$_1$c (r = 0.099; P = 0.6382), or 2hPP Scr and HbA$_1$c (r = -0.012; P value = 0.9534).

Conclusions: 1) This study reconfirms that treatment of DM with insulin with dglucose of less than 100 mg/dL is a strong predictor of renal preservation in DM.

2) HbA$_1$c is not a dependable predictor of renal function change in DM.

TH-PO487

Prognostic Predictor for Renal Insufficiency and Its Association with Diabetes Mellitus in Patients with Acute Myocardial Infarction Chang Seong Kim, Joon Seok Choi, Jeong-Woo Park, Eun Hui Bae, Seong Kwon Ma, Myung Ho Jeong, Soo Wan Kim. *Department of Internal Medicine, Chonnam National University Medical School, Gwnagju, Korea.*

Background: The existence of diabetes mellitus (DM) and renal dysfunction may individually or simultaneously have a negative prognostic effect on patients with acute myocardial infarction (AMI). However, few studies are assessed the role of renal insufficiency and its association with DM in the context of AMI. The aim of this study was to investigate the interaction between renal dysfunction and DM in patients with AMI.

Methods: We analyzed a total of 9905 patients with AMI were enrolled in a nationwide prospective Korea Acute Myocardial Infarction Registry from November 2005 to August 2008. Patients were categorized into 4 groups using the presence of DM and renal insufficiency (GFR < 60 ml/min/1.73m^2). Group I : no DM and no renal insufficiency (n=5700); Group II : DM and no renal insufficiency (n=1730); Group III : no DM and renal insufficiency (n=1431); Group IV : DM and renal insufficiency (n=1044). The primary end points were major adverse cardiac events including a composite of all cause of death, myocardial infarction, target lesion revascularization and coronary artery bypass graft during a 12-month follow-up.

Results: During 12-month follow-up, the primary end points occurred in 1804 patients (18.2%). There were significant differences on composite MACE in 12-month follow-up among the 4 groups (Group I, 12.5%; Group II, 15.7%; Group III, 30.5%; Group IV, 36.5%; *p* value <0.001). There was stepwise increased in composite MACE with increasing stage of group. In a Cox proportional Hazards model, after adjusting for multiple covariates, going from group II to group IV, the mortality at 12-month was also increasing stepwise compared with Group I (HR 1.96, 95% CI 1.34-2.86, p=0.001; HR 2.42, 95% CI 1.62-3.62, p <0.001, respectively).

Conclusions: Renal insufficiency and its association with DM provide the increment of a composite MACE and the poor prognostic predictor in patients with AMI. Moreover, categorization using presence or absence of DM and renal insufficiency provides valuable information for early risk stratification in patients with AMI.

TH-PO488

Race and Obestity Strengthen the Association of Retinopathy and Low Glomerular Filtration Rate in Type 2 Diabetes Amy K. Mottl,[1] Keunsang Kwon,[2] Seema Garg,[1] Abhijit V. Kshirsagar.[1] *[1]University of North Carolina, Chapel Hill, NC; [2]Chonbuk National University, Jeonju, Korea.*

Background: In type 2 diabetes, decreased estimated glomerular filtration rate (eGFR) may occur in the absence of albuminuria or retinopathy. Determining which characteristics strengthen the relationship of low GFR and retinopathy may provide further insight to the risk and pathogenesis of microvascular complications. NonHispanic Blacks and obese individuals are known to have a greater risk for progression of retinopathy and nephropathy. We hypothesized these two factors may strengthen the association of diabetic eye and kidney disease.

Methods: The National Health and Nutrition Examination Survey (NHANES) 2005-2008 cohort included approximately 1300 participants with older onset diabetes who had retinopathy, serum creatinine and urinary albumin:creatinine ratio (UACR) data. We used multivariate regression analyses to assess the relationship between retinopathy and low eGFR and UACR. Covariates included age, gender, HbA1C, systolic and diastolic blood pressures. Analyses were stratified to evaluate ethnicity/race and body mass index (BMI) as effect modifiers of this relationship.

Results: Of 269 participants with decreased eGFR, 35% had no microalbuminuria and no retinopathy; 16.1% had retinopathy with no microalbuminuria; 27.1% had microalbuminuria and no retinopathy and 22% had both microalbuminuria and retinopathy. Multivariate logistic regression analyses stratified by ethnicity demonstrated retinopathy to be more significantly predictive of decreased eGFR in nonHispanic Blacks than nonHispanic Whites (OR=2.68 ; 95% CI 1.17, 6.14). Multivariate logistic regression analyses stratified by BMI demonstrated retinopathy to be more predictive of decreased eGFR in participants with a BMI ≥ 30 (OR = 2.62; 95% CI 1.26, 5.46). Analyses of albuminuria showed no association with retinopathy and no effect modification by ethnicity or BMI.

Conclusions: In older onset diabetes the absence of albuminuria and retinopathy is common among individuals with reduced eGFR. Retinopathy is predictive of low eGFR but not albuminuria. This relationship appears to be stronger in nonHispanic Blacks and obese individuals.

TH-PO489

Epicardial Fat Volume in Stage 3-5 CKD Patients and Its Associations with Obesity, CKD, and Coronary Artery Calcification Jasmine D. Kerr,[1] Rachel M. Holden,[1] Alexander R. Morton,[1] Robert Louis Nolan,[2] Jocelyn S. Garland.[1] *[1]Department of Medicine, Queen's University, Kingston, ON, Canada; [2]Department of Radiology, Queen's University, Kingston, ON, Canada.*

Background: Epicardial fat volume (EFV) is associated with coronary artery calcification (CAC) and may play a role in the pathogenesis of cardiovascular disease (CVD). It also correlates with the metabolic syndrome, a common co-morbid condition in chronic kidney disease (CKD). Our objectives were to quantify the EFV in stage 3-5 CKD patients and determine its relationship with CKD, metabolic syndrome, and CAC.

Methods: In this cross-sectional study, 95 pre-dialysis patients with stage 3-5 CKD underwent multi-slice cardiac CT for determination of their CAC scores and EFV. EFV was determined as the average volume of two slices at the level of the left main coronary artery.

Results: Mean age was 64 years, 57% were male, 80% had metabolic syndrome, 40% had diabetes, mean BMI was 32kg/m^2, and mean eGFR was 25mL/min/1.73m^2. Mean EFV was 5.01cm^3. Log UACR (r=0.33, P=0.001), abdominal waist circumference, (r=0.5, P=0.0001), HOMA-IR (r=0.4, P=0.001), log CAC score (r=0.29, P=0.006) and log FGF-23 (r=0.23, P=0.03) were significantly associated with EFV. eGFR and serum phosphorus level were not. By linear regression, log UACR (ß=0.60; 95% confidence interval, 0.10 to 1.10; P=0.02), abdominal obesity (ß=2.02; 95% confidence interval, 1.18 to 2.9; P<0.0001) triglycerides (ß=-1.34; 95% confidence interval, -2.64 to -0.03; P=0.045), and log CAC score (ß=0.42; 95% confidence interval, 0.04 to 0.80; P=0.03) were all independent risk factors for increased EFV.

Conclusions: Recognizing the limitation of comparing EFV across different study populations, the burden of EFV appears to be increased in this CKD cohort. EVF was associated with traditional and non-traditional CVD risk factors known to contribute to CAC. The association of FGF-23 and EFV is intriguing and warrants further study, but suggests a potential link between visceral fat, insulin resistance, and CAC in CKD. Studies are needed to clarify the role of epicardial fat in the etiology of CVD and to determine if EFV is a useful measure of cardio-metabolic risk in CKD patients.

TH-PO490

Prevalence of CKD in Type 2 Diabetes – First Results of a Nationwide Study in German Primary Care Physicians Ludwig F. Merker,[1] Baptist Gallwitz,[2] Katja Schoene,[3] Barbara Waldeck.[3] *[1]Diabetes and Kidney Center, Dormagen, NRW, Germany; [2]Med. Klinik 4, Universität Tübingen, Tübingen, Germany; [3]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany.*

Background: No systematic prospective nationwide database on the prevalence of chronic kidney disease (CKD) in type 2 diabetes is available.

Methods: We recruited 2500 consecutive type 2 diabetics from 250 primary care physicians randomized by epidemiologic aspects. The following data was collected by questionnaire: antidiabetic and antihypertensive medication, CKD status, hypertension and comorbidities. On site urinanalysis was carried out by dipstick, the same for microalbuminuria (MAU). Central lab included HbA1c, serum creatinine, ACR and lipid profile; eGFR (ml/min/1,73m²) was estimated using MDRD formula. Pts with signs of UTI were excluded from MAU screening. The study was performed according to GCP standards and approved by German ethics committees. Statistics are descriptive. To ensure data quality 10 % of the PCP's are monitored. Data collection will finish in July 2011. Here we present the first data.

Results: So far, data is available from 373 pts (213 male, 160 female) on average: age 69.9 yrs., BMI 30,4 kg/m2, HbA1c 6,8 %, diabetes duration 8,3 yrs., 79,9 % hypertension, duration 10,9 yrs., 96,3 % were treated, 37,3 % reached < 130/80 mm Hg. 84,5 % patients showed co morbidities, CKD 3 (eGFR 30-60) in 25,7 %; this was recognized in 43,8 % of the PCP. 55 % had MAU, 56,2 % had eGFR estimation and 9,2 % had clearance calculation (Cockr.-Gault) by the PCP. Elevated ACR was seen in 31,2 % (of which 2/3 were male). eGFR >60 without MAU was detected in 54,1 %, isolated MAU in 17,8 %, macroalbuminuria in 2,9 %, macroalbuminuria and eGFR <60 in 2,2 %, isolated eGFR <60 in 14,6 % and MAU as well as eGFR <60 was seen in 8,2 %.

Conclusions: CKD detection by MAU screening only is not sufficient. An eGFR calculation should always be performed when serum creatinine is measured. This should be mandatory in particular in elderly patients. Hypertension is nearly always detected, but treatment goals are not always met. The final study results are pending. These data were first presented at DDG on June 3rd, 2011 as a German language poster (#284).

Mineral Metabolism Disturbances and Atherosclerosis in Type 2 Diabetic CKD Patients Ana Paula Silva, Ana Pinho, Ana Cabrita, André Fragoso, Nelson Almeida Tavares, Nélio Santos, Pedro Neves. *Nefrology, Hospital Faro, Faro, Portugal.*

Background: Epidemiologic studies have demonstrated that the carotid intima-media thickness (CIMT) is a strong and independent predictor of cardiovascular events in both the general population and among those with renal disease.

Methods: In chronic kidney disease (CKD) patients, the disturbances of the mineral metabolism are also related with cardiovascular disease.

The purpose of this study was to evaluate the relationship between the carotid intima media thickness with the mineral metabolism (vitamin D, FGF23, PTH, phosphorus, calcium), inflammation (interleukin 6), oxidative stress (malonaldehyde) and insulin resistance (HOMA-IR) in a group of type 2 CKD diabetic patients.

In this cross-sectional study, we included 50 type 2 diabetic patients (f=18, m=32) with mild and moderate renal disease (mean estimated GFR = 50 ml/min). We measured the CIMT using the high-resolution B-mode ultrasonography.

The population was divided according to the CIMT in 2 groups: G1 (n=25) – CIMT ≥ 0.9 mm and G2 (n=25) - CIMT <0.9 mm. We performed descriptive statistics. Student *t* and Chi-Square tests were used for comparison between groups. We also used a single regression model to evaluate the relation between the CIMT with the FGF-23 and 25(OH) D3 levels.

Results: G1 showed higher malonaldehyde (3.7 *vs* 3.2 mg/dl, p = 0.013), PTH (173.4 *vs* 110.6 µg/ml, p = 0.014), FGF 23 (146.6 *vs* 73.8 ng/mL, p = 0.0001), IL6 (8.6 *vs* 5.8 pg/ml p = 0.008), TNFα (10.4 *vs* 7.5 pg/ml p = 0.001), and lower 25(OH)D3 (10,4 *vs* 24.9 ng/ml p = 0.004) levels. There were no differences regarding the other parameters, such as total cholesterol, phosphorus, HgA1c, HOMA-IR and eGFR. Furthermore, we found in the regression model, that FGF-23 (r=0.785 p=0.0001) and 25(OH)D3 (r= - 0.432 p= 0.002) were significantly related with CIMT.

Conclusions: We concluded that in diabetic patients with early stages of CKD there is a relationship between the mineral abnormalities and the CIMT, a known marker of subclinical atherosclerosis. Further prospective analysis are required to validate the clinical significance role of these new markers of cardiovascular in our renal patients.

ATLANTIC DIP: Extra Counselling Required for Women with Diabetes and Microalbuminuria Embarking on Pregnancy Andrew Smyth,[1,2] Eoin O'Sullivan,[1] Louise A. Carmody,[1] Gloria E. Avalos,[3] Fidelma P. Dunne.[1,3] *[1]Endocrinology, Galway University Hospitals, Galway, Ireland; [2]Nephrology, Galway University Hospitals, Galway, Ireland; [3]School of Medicine, National University of Ireland, Galway, Ireland.*

Background: Pregnancies in patients with pre-existing diabetes are associated with higher rates of morbidity. This study aims to assess the effect of microalbuminuria on pregnancy outcomes in patients with established diabetes pre-pregnancy.

Methods: Pregnancies in patients with established diabetes at five centres between January 2005 and December 2009 were retrospectively reviewed. Outcome measures included birth outcome (live birth, stillbirth, miscarriage and delivery method), maternal complications (hypertension, pre-eclampsia, polyhydramnios, hemorrhage) and neonatal outcomes (gestational age, birth weight, birth height, shoulder dystocia, malformations, jaundice and hypoglycemia). Analysis was performed using PASW for Mac Version 18.0, p<0.05 was considered significant using Chi-square and t-test where appropriate.

Results: 132 pregnancies (81.8% (n=108) type 1 and 18.2% (n=24) type 2 diabetes) were included, with a mean age of 31.9+/-5.6 years and median duration of diabetes prior to pregnancy of 12.6 years (0.4-33.9years). Albumin:creatinine ratio (ACR) pre-pregnancy was available in 100% (n=132) with a mean of 6.55mg/mmol (0-214); 22% (n=29) of these had microalbuminuria. Maternal hypertension occurred in 18.5% (n=20), pre-eclampsia in 13% (n=14), polyhydramnios in 10.4% (n=11) and hemorrhage in 2.8% (n=3). Patients with microalbuminuria had higher rates of polyhdramnios (p=0.04) and hypertension (p=0.05), as well as higher systolic blood pressure early in pregnacy (128.6mmHg versus

119.4mmHg, p=0.01). Patients with microalbuminuria were more likely to have babies who were either large or small for gestational age (p=0.05). There was no association between microalbuminuria and birth or neonatal outcomes.

Conclusions: This study shows that the presence of pre-pregnancy microalbuminuria is associated with higher rates of maternal hypertension, polyhydramnios and larger or small babies. Future studies should explore ways of reducing morbidity within this cohort of pregnant women.

TH-PO493

Recurrence of Diabetic Kidney Disease in Type 1 and Type 2 Diabetic Patients after Kidney Transplantation Izumi Nyumura,[1] Tetsuya Babazono,[1] Kazuho Honda,[2] Yasuko Uchigata.[1] *[1]Department of Diabetes Center, Tokyo Women's Medical University School of Medicine, Tokyo, Japan; [2]Department of Pathology, Tokyo Women's Medical University School of Medicine, Tokyo, Japan.*

Background: Renal lesions are more heterogeneous in type 2 than type 1 diabetic patients due to modification by aging and concomitant obesity, hypertension and lipid disorders. However, information is scarce regarding whether severity of recurrent diabetic kidney disease (DKD) in the renal allograft may differ in type 1 and type 2 diabetic patients. We therefore conducted this study to highlight the relationship between type of diabetes and clinical or histological parameters associated with the recurrence of DKD in renal allograft.

Methods: We studied 34 diabetic renal allograft recipients, 17 with type 1 and 17 with type 2 diabetes who underwent renal biopsy both in the intraoperative period and at 3-16 years after transplantation. Glomerular morphometrical analysis including mesangial area, capillary tuft number and capillary tuft area was performed by a computer-assisted image analyzer. The thickness of glomerular basement membrane (GBM) was evaluated by an electron microscopy. The rate of decline in estimated glomerular filtration rate (eGFR) and albuminuria were evaluated as clinical parameters.

Results: Recipient's age and body mass index (BMI) were significantly higher in type 2 than type 1 diabetes. There were no significant differences in terms of donor's age, posttransplant observational period, blood pressure, HbA1c and lipid parameters. Increase in mesangial glomerular areas and thickness of GBM were significantly greater in type 2 diabetes (p=0.032 and p=0.005), however, after adjustment for covariates including recipient's age, BMI, HbA1c, blood pressure and lipid parameters by covariance analysis, the statistical significance disappeared. Glomerular capillary number and area, the grade of tubulo-interstitial lesions, and vascular lesions, as well as the rate of decline in GFR and albuminuria were not different in the two groups.

Conclusions: Type of diabetes is less likely to be associated with the histological and clinical parameters of the recurrence of DKD in diabetic transplanted patients.

TH-PO494

Predictive Factors for Progression to End-Stage Renal Disease in Diabetic Patients with Chronic Kidney Disease Stage 4-5 Tetsuya Babazono, Izumi Nyumura, Ko Hanai, Nobue Tanaka, Yasuko Uchigata. *Diabetes Center, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Although several factors have been shown to be associated with higher risk of the onset and progression of CKD in diabetic patients; predictive factors for ESRD in diabetic patients with later stages of CKD have never been determined. We therefore conducted this observational cohort study to identify clinical factors associated with higher risk of ESRD in diabetic patients with CKD stage 4-5.

Methods: We studied a total of 131 diabetic patients with CKD stage 4-5, 58 and 73 patients with stage 4 and 5, respectively. There were 39 women and 92 men and the mean age at the start of follow-up was 63 ± 12 years (range: 32-88 years). The primary endpoint was the composite of the start of RRT and death. Patients were observed at least 6 months. Effects of age, sex, urinary albumin-to-creatinine ratio (ACR) and eGFR at baseline, mean values of systolic and diastolic blood pressure, hemoglobin, glycated hemoglobin, serum albumin, uric acid, low- and high-density lipoproteins during the follow-up period on renal outcome were examined using the Cox proportional hazard model.

Results: The median follow-up period was 19 month (range: 6-137 months). Among 131 patients, 88 patients started dialysis and 10 patients died before initiation of dialysis. Five-year cumulative incidence of reaching the endpoint was 83.4% and the median follow-up period was 24.8 months. Among the covariates, higher urinary ACR and diastolic blood pressure, lower eGFR, serum albumin, and hemoglobin levels were significantly associated with higher risk of reaching the endpoints (p<0.05). Higher glycated hemoglobin and lower low-density lipoprotein levels had marginal effects (p<0.2).

Conclusions: Several clinical factors were identified as predictive factors of higher incidence of hard renal outcomes in diabetic patients with CKD stage 4-5. Whether modification of these factors may diminish the risk should be determined.

TH-PO495

Renal Outcome in Biopsy Proven Non Diabetic Renal Disease in a Type 2 Diabetic Multi-Ethnic Asian Population Soumita Bagchi,[1] Thomas Paulraj Thamboo,[2] Vathsala Anantharaman.[1] *[1]Nephrology Division, National University Health System, Singapore; [2]Pathology Department, National University Health System, Singapore.*

Background: Very few studies have investigated the factors affecting the outcome of non-diabetic renal disease (NDRD) in type 2 diabetics (DM). In this study we sought to determine the predictors for NDRD on renal biopsy in DM patients and define the correlates of a favorable renal outcome at 1 year.

Methods: 157 diabetics who had an adequate native kidney biopsy at the National University Hospital, Singapore from 2000 to 2010 were retrospectively reviewed.

Results: 87 (55.4%) patients had NDRD and 70 (44.6%) had diabetic nephropathy (DN). The predominant histopathologic diagnosis involved glomerular abnormalities (71.1%). On multivariate analysis, absence of retinopathy (P<0.001, OR=20.292) and sub-nephrotic proteinuria (P<0.001, OR=5.144) were significant predictors of NDRD.

After excluding 25 with ESRD at presentation and 13 lost to followup, 119 patients were evaluated for 1 year renal outcome. At follow-up, mean MDRD eGFR was higher for NDRD compared to those with DN (46.5±37.4ml/min vs 31.9±24.4ml/min, P<0.005) and proportion with eGFR<15ml/min was lower (8.5% vs 38.7 <0.001). DN on renal biopsy (P=0.001, OR=6.979), baseline serum albumin<35g/l (P=0.023, OR=4.976) and eGFR (P=0.006, OR=1.044) were independently associated with eGFR<15ml/min at 1 year.

34 (48.5%) of the 70 patients with NDRD studied for 1 year renal outcome, had stable or improving eGFR. In these patients, absence of hypertension (P=0.039, OR=5.089), absence of nephrotic range proteinuria (P=0.01, OR=7.183), eGFR<30ml/min at the time of biopsy (P=0.032, OR=4.472) and immunosuppressant use (P=0.003, OR=10.485) were independent predictors of stable or improving eGFR at 1 year.

Conclusions: Possibility of NDRD should be considered in DM patients with kidney disease since they have better renal outcome. Absence of retinopathy and sub-nephrotic proteinuria are independent predictors of NDRD. Absence of an active urinary sediment does not rule out NDRD. Finally, immunosuppressant use should be considered whenever applicable, since it is an independent modifiable predictor of favorable renal outcome in these patients.

TH-PO496

Correlation of Structural and Functional Abnormalities in Type 2 Diabetic Nephropathy with Overt Proteinuria Edmund J. Lewis,[1] Richard D. Rohde,[1] David J. Cimbaluk,[2] The Collaborative Study Group.[3] *[1]Nephrology, Rush University Medical Center, Chicago, IL; [2]Pathology, Rush University Medical Center, Chicago, IL; [3]Collaborative Study Group, Chgo, IL.*

Background: Our objective was to determine structure: function relationships in type 2 diabetic nephropathy (T2DN).

Methods: : Renal biopsies from 27 patients with T2DN were examined. These derived from the Irbesartan Diabetic Nephropathy pilot trial. Mean age 57±8.2 yrs; duration of diabetes: 15±10 yrs; mean BMI 33.5±7.6; mean serum creatinine (SD) (Scr) 1.6±0.5 mg/dl; mean creatinine clearance (Ccr) 63±28 ml/min; mean estimated GFR (eGFR) 52±20 ml/min/1.73m^2; mean proteinuria 4.7±4.2 G/day. Percent global sclerosis (GS) and semiquantitative tubular atrophy (TA) and chronic interstitial fibrosis (CIF) were measured. TA and CIF were scaled: 0 (0%); 1+ (<25%); 2+ (25-50%); 3+ (>50%).

Results: TA correlated with function; Ccr: 0/1+TA = 83.8±20.5 ml/min; 2+TA = 60.8±20.3 ml/min; 3+TA = 35.6±12.2 ml/min, P: 0/1+TA versus 2+TA = 0.04; P: 2+TA vs 3+TA = 0.04; P: 0/1+TA vs 3+TA = 0.00004.

Scr:0/1+TA = 1.3±0.8 mg/dl; 2+TA= 1.6 ±0.2 mg/dl, 3+TA = 2.0±0.2 mg/dl.

eGFR:0/1+TA = 64 ml/min/1.73m^2; 2+TA = 50.6 ml/min/1.73m^2; 3+TA = 35.6 m1/min/1.73m^2

% GS correlated with function:

Tertile 1 (n=9): Scr 1.1±0.2 mg/dl = 14.3% GS

P = 0.0007

Tertile 2 (n=9): Scr 1.6±0.1 mg/dl= 43.2% GS

P = 0.53.0

Tertile 3 (n=9): Scr 2.1±0.3 mg/dl= 50.8% GS

Tertile 1 vs 3: P = 0.0003

Correlation coefficients for % GS:

Scr: R^2 = 0.45; Ccr: R^2 = 0.50; eGFR: R^2 = 0.46

GS and TA were highly correlated: TA 0 = 0% GS; TA 1+ = 21% GS; TA 2+ = 38% GS, TA 3+ = 60% GS. Semiquantitative CIF did not correlate with creatinine parameters. Urine protein excretion did not correlate with TA, GS or CIF.

Conclusions: In this cross-sectional analysis of anatomic changes in the renal biopsy in T2 DN, TA and GS correlated with creatinine parameters of renal function. We found that a 0.5 mg/dl difference in Scr was associated with a mean threefold higher %GS. TA and GS correlated highly. T2 diabetes patients with advanced nephropathy have consistent structure: function relationships. These observations support the use of yearly creatinine parameters as clinical trial endpoints.

TH-PO497

Clinical Indications for Renal Biopsy in Diabetic Glomerulosclerosis with Superimposed Non-Diabetic Renal Disease Jon H. Steuernagle,[1] LaTonya J. Hickson,[2] Axel Pflueger,[2] Ziad El-Zoghby,[2] Sanjeev Sethi,[3] Mary E. Fidler,[3] Samih H. Nasr,[3] Lynn D. Cornell.[3] *[1]Internal Medicine, Mayo Clinic; [2]Nephrology and Hypertension, Mayo Clinic; [3]Anatomic Pathology, Mayo Clinic, Rochester, MN.*

Background: Patients with diabetes have been found to have non-diabetic renal disease (NDRD) on biopsy. The clinical reason for performing such biopsies is not well known from large sample studies.

Objective: To examine clinical indications for renal biopsies having diabetic glomerulosclerosis (DGS) and concomitant NDRD.

Methods: Our renal biopsy database was queried for DGS from 1994 to 2010 followed by review of each DGS report for NDRD. Renal pathologist comments on clinical indications for renal biopsy were recorded.

Results: Of 3575 biopsies with DGS, concomitant NDRD was present in 967 (27%). The most common NDRD was tubulointerstitial (69%), glomerular (29%) and atheroembolic vascular disease (2%). Tubulointerstitial NDRD included acute tubular necrosis (60%), interstitial nephritis (36%), and others (4%). Glomerular-NDRD included IgA (22%), pauci-immune crescentic (17%), membranous glomerulonephritis (16%), post-infectious (16%), membranoproliferative (8%), thrombotic microangiopathy (5%) and others (16%). Mean age was 59±14 years, 54% were male, and creatinine was 4.1±2.5 mg/dL at biopsy. Biopsy reasons included acute renal failure with or without proteinuria (74%), nephrotic range proteinuria (15%), proteinuria (2%), hematuria (1%), rapidly progressive renal failure (1%), and unknown (7%). Acute renal failure (79%) and nephrotic range proteinuria (11%) were primary biopsy reasons in tubulointerstitial NDRD similar to glomerular NDRDs such as IgA (58% and 25%, respectively).

Conclusions: NDRD is common among diabetic patients undergoing renal biopsy. NDRD is often treatable beyond conventional therapies utilized for DGS. Acute renal failure and nephrotic range proteinuria with or without other features help identify a potential need for biopsy in this group.

TH-PO498

Urinary Sulphate Excretion Is a Predictor for Progression of Diabetic Nephropathy Gudbjörg Andrésdóttir,[1] Stephan J.L. Bakker,[2] Henrik Post Hansen,[4] Hans-Henrik Parving,[3] Peter Rossing.[1] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Department of Internal Medicine, University Medical Center Groningen, Groningen, Netherlands; [3]Rigshospitalet, Copenhagen, Denmark; [4]Herlev Hospital, Denmark.*

Background: Hydrogen sulphide (H_2S) mediates smooth muscle relaxation and vasodilatation. Diabetes-related endothelial dysfunction may reduce it's biosynthesis. H_2S is converted to sulfite in the mitochondria, and then oxidized to thiosulphate and sulphate, these are excreted in the urine.

Methods: Urinary excretion of sulphate in type 1 diabetic patients with progressive diabetic nephropathy was measured to evaluate if sulphate excretion can predict progression of nephropathy. It was a post hoc study of a prospective, randomized, unmasked, controlled trial studying the effects of low/high protein diet, following 82 patients for 4 years. 72 patients (49 men) with 3 or more measurements of GFR (^{51}CR EDTA)were included in our study and rate of decline of GFR was determined. Sulphate excretion was measured by ion exchange chromatography in 24h urine at baseline.

Results: At baseline age [mean(SD)] was 40.3(7.9) years and GFR was 70(31) ml/min/1.73m2. Sulphate excretion [median(range)] was 11.1(1.9 - 32.2)mmol/day. During follow-up decline in GFR was 3.9(3.4) ml/min/year. U-sulphate was associated with age (p=0.001, r_s=-0.36) and SBP (p=0.049, r_s=-0.22). U-sulphate excretion showed a significant negative association with the rate of decline of GFR (p=0.016, r_s =-0.28). It was not associated with baseline values of; GFR, HbA1c, AER, cholesterol, assigned diet group, sex, smoking, use of antihypertensive medication or presence of cardiovascular disease. In multible linear regression models, when adjusted for the known progression promotors age, sex, blood pressure, Hba1c, smoking and albuminuria as well as diet group, u-sulphate excretion is highly significant (p=0.0002) and it's inclusion in the model increases adjusted r^2 from 6% in the model without sulphate, to 23% in the model with sulphate.

Conclusions: High urinary sulphate excretion at baseline is associated with slower rate of decline in GFR in diabetic nephropathy during four years of follow up, independent of known progression promoters.

TH-PO499

Close Association of Serum Fibroblast Growth Factor 23 with Diabetic Nephropathy in Type 2 Diabetic Subjects Miho Murata, Atsushi Aoki, San-E Ishikawa. *Department of Medicine, Jichi Medical University Saitama Medical Center, Saitama, Japan.*

Background: The present study was undertaken to determine alterations in serum fibroblast growth factor 23 (FGF-23) and 25(OH)Vitamin D_3 levels in subjects with diabetic nephropathy and atherosclerotic disorders.

Methods: 247 type 2 diabetic patients were enrolled in the present study. They were 149 males and 98 females, with the ages of 64.5±10.2 years. Serum levels of FGF-23 and 25(OH) Vitamin D_3 were measured by methods of ELISA. Serum creatinine, estimated glomerular filtration rate (eGFR) and urinary albumin and/or protein excretion were determined for classification of diabetic nephropathy. Flow-mediated dilatation (FMD), intima-media thickness (IMT) and calcification of carotid artery were examined for atherosclerosis.

Results: Serum FGF-23 levels were 35.7±1.1 pg/ml, ranging from 10.0 to 148.0 pg/ml. Serum 25(OH) Vitamin D_3 levels were 86.1±2.5 nmol/l, ranging from 28.3 to 239.3 nmol/l. We divided the diabetic subjects into two groups by the median level of FGF-23 (31.6 pg/ml). In the subjects of serum FGF-23 level more than 31.6 pg/ml (high FGF-23; n=124), BMI was significantly higher (25.4±3.9 vs. 23.6±3.5, p<0.001) and eGFR was significantly less (72.2±2.2 vs. 82.2±1.7 ml/min/1.73m^2, p<0.001) than those in low FGF-23 group. In single regression analysis, serum FGF-23 levels had a positive correlation with BMI (r=0.25, p<0.001), and a negative correlation with eGFR (r= -0.30, p<0.001). Serum FGF-23 levels were gradually increased according to the progression of diabetic nephropathy (p value in trend test: <0.001). Its elevation was significantly greater in the diabetic subjects with stage 4 than those with stages 1, 2 and 3A. There were no differences in FMD, IMT and vascular calcification between the two groups of high and low FGF-23. Also, we divided the subjects by median of 25(OH)Vitamin D_3 (79.2 nmol/l), and evaluated the differences between the two groups. However, there was no difference in any parameter at all.

Conclusions: These findings indicate that serum FGF-23 levels increase in association with progression of diabetic nephropathy, but not with atherosclerosis, in type 2 diabetic subjects.

TH-PO500

GDF-15 and hs-TnT Predict Progression of Nephropathy in Diabetes and Hypertension Merel E. Hellemons, Stephan J.L. Bakker, Dick de Zeeuw, L.E. Deelman, Hiddo Jan Lambers Heerspink. *Clin. Pharmacology, UMCG, Groningen, Netherlands.*

Background: Increased albuminuria is probably a sign of vascular damage. Biomarkers reflecting endothelial or vascular damage could be eligible to predict progression of albuminuria. We tested this in a prospective case-control study in type 2 diabetes (T2DM) and hypertension (HT).

Methods: We conducted a nested case-control study in the PREVEND-study. Progression of albuminuria (cases) was defined as transition from normo- to micro- or micro- to macro-albuminuria. Controls had non-progressive albuminuria during follow-up and were pair-matched for age, gender, and DM duration. We included 34 case/control pairs with T2DM and 75 pairs with hypertension (HT). The markers growth-differentiating factor-15 (GDF-15) and high-sensitivity Troponin T (hs-TNT) were measured at baseline and their contribution in predicting progression of albuminuria during follow-up (median 2.8 years) was assessed.

Results: GDF-15 was higher in cases than in controls in T2DM (1332±709 vs. 909±381 pg/mL, P<0.001) but not in HT. GDF-15 was independently associated with progression in albuminuria in T2DM (adjusted OR 5.4[1.2-25.0] per doubling of GDF-15) and in HT (2.94[1.20-7.20]) and contributed significantly to prediction of progression of albuminuria with a higher C-statistic and Integrated Discrimination Improvement (IDI) in T2DM and marginally in HT (table 1).

Hs-TnT was higher in T2DM and HT cases (6.8±5.8 vs. 4.0±2.9; P=0.002) and (8.2±5.4; vs. 6.7±4.9; P=0.05) respectively. Hs-TnT was independently associated with progression of albuminuria in HT (OR 2.70[1.13-6.33]) but not in T2DM (3.51[0.62-19.9]) and contributed significantly to prediction of progression of albuminuria in HT [table 1]. Hs-TnT marginally contributed to progression of albuminuria in T2DM.

Conclusions: We identified GDF-15 and hs-TnT as promising markers for progression of albuminuria in T2DM and HT, with GDF-15 superior in T2DM and hs-TnT superior in HT.

TH-PO501

Serum Cystatin C Concentration Reflects the Severity of Carotid Atherosclerosis in Type 2 Diabetes Patients without Chronic Kidney Disease Fang Liu, Ping Fu. *Department of Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan Province, China.*

Background: Atherosclerosis (AS) is the most common arterial complication of diabetes, which reflects the morbidity and mortality of cardiovascular events. This study is to investigate whether serum Cystatin C (Cys C) concentration correlates with the severity of carotid atherosclerosis (CAS) and whether it provides additional information on the risk for cardiovascular disease in patients with type 2 diabetes (T2DM).

Methods: The relationship between serum Cys C and the severity of CAS was investigated in 633 patients met the inclusion/exclusion criteria. Carotid intimal medial thickness (IMT) and the location and size of AS plaque were evaluated by Doppler ultrasound. Based on glomerular filtration rate (GFR) estimated by simplified MDRD

formula, the patients were divided into those with chronic kidney disease (DM-CKD) and without CKD (DM-NCKD). The relationship of serum Cys C with the severity of CAS was examined.

Results: Serum Cys C was closely correlated with GFR in all subjects and in DM-CKD patients, but not in DM-NCKD patients. In 396 DM-NCKD patients (62.5%) with the eGFR ≥60 ml•min–1•1.73 m–2, 210 patients (210/396, 53%) with a significant large number of carotid AS plaques had a higher serum concentration of Cys C than those (186/396, 47%) without AS plaques formation (1.05±0.27mg/L vs 0.89±0.22mg/L). Moreover, the serum concentration of Cys C was closely correlated with the severity of CAS (r=0.338, P<0.001), even after adjustment for confounding factors (r=0.14, P=0.005), such as age and duration of diabetes. Multiple linear regression analysis also showed closely correlation of Cys C with the severity of CAS.

Conclusions: Cys C is more than a sensitive marker of renal function, but a marker of CAS severity in T2DM patients without CKD. Besides DM-CKD, it might serve as an indicator of morbidity and mortality of cardiovascular events.

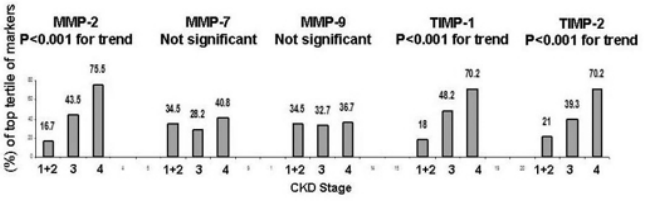
TH-PO502

Urinary Excretion of Markers of Metalloproteinases System and Their Associations with Reduced Renal Function in Subjects with Type 1 Diabetes and Proteinuria Jung Eun Lee, Monika A. Niewczas, William Walker, Adam Smiles, Jan Skupien, James Warram, Andrzej S. Krolewski. *Research Division, Joslin Diabetes Center, Boston, MA.*

Background: Matrix metalloproteinases (MMPs) and their tissue inhibitors (TIMPs) are thought to regulate extracellular matrix turnover contributing to renal fibrosis and to progression of chronic kidney disease (CKD). The aim of this study was to investigate profile of urinary excretion of MMPs/TIMPs system in subjects with type 1 diabetes (T1D), proteinuria and different CKD stages.

Methods: Glomerular filtration rate (GFR) was estimated by the Modification of Diet in Renal Disease study equation. MMPs (MMP1, 2, 7, 9, 12) and TIMPs (TIMP 1-4) were measured on the Luminex platform and adjusted with urinary creatinine for analyses.

Results: This study included 302 patients with T1D and overt proteinuria, 85 (28%) were in CKD stage 3, 49 (16%) were in stage 4, and the others were in stage 1 or 2. The median albumin to creatinine ratio (ACR) was 781 (455-1644) mg/g Cr. Among detectable markers, urinary excretion levels of MMP-2, TIMP-1, and TIMP-2 were increased proportionally with more advanced CKD stages, whereas urinary excretion of MMP-7 and MMP-9 did not differ by CKD stages. The proportions of subjects with the highest tertile of biomarkers distribution stratified by CKD stages are presented in the figure.



Urinary MMPs and TIMPs were closely correlated among each other. In multiple linear regression analysis, urinary excretion of MMP-2 (β = -0.0088, P<0.0001), TIMP-1 (β = -0.0041, P<0.0001), and TIMP-2 (β = -0.0037, P<0.0001), but not of MMP7 and MMP9, were correlated with GFR inversely and independently from ACR.

Conclusions: Urinary excretion of distinct markers of MMPs/TIMPs was associated with more advanced CKD stages in T1D. Longitudinal studies are needed to evaluate the predictive values of the markers.

Urinary Transcriptome Analysis of Diabetic Kidney Disease Sang Youb Han,[1,2] Iram Aqeel,[3] Ae Seo Deok Park,[1] Michele H. Mokrzycki,[1] Vaughn W. Folkert,[1] Katalin Susztak.[1] *[1]Medicine, Albert Einstein College of Medicine, Bronx, NY; [2]Internal Medicine, Inje Univ. Ilsan-Paik Hosp., Goyang, Republic of Korea; [3]Medicine, NY Health and Hospitals Corperation, Bronx, NY.*

Background: Urinary transcript levels has been suggested as a noninvasive marker of renal damage in patients with various renal diseases. However, genome-wide transcriptome analysis of control and DKD urines have not been performed. Here we analyzed mRNA expression profiles of urinary sediments using Affymetrix microarray to determine the feasibility of this approach.

Methods: Random urine were collected from healthy controls and patients with DKD. Patients with DKD had a mean of 1.8 g/day of proteinuria, and significantly decreased GFR (mean 32.8 ml/min). Total RNA was extracted from 30 ml of urine using combination method of Trizol and Qiagen kit after centrifugation with 3000 RPM for 15 min. The quality and integrity of RNA were determined by using the Agilent Bioanalyzer. Total RNA were amplified using the Affymetrix 3' IVT kit and hybridized onto Affymetrix U133 expression arrays. Normalized gene expression data wer analyzed using the Genespring GX and Ingenuity Pathway Analysis Softwares. Transcripts with statistically significant differential expression were determined using the Benjamini-Hochberg corrected p<0.05 and fold changes > 2.0 parameters. In addition, we also examined individual gene expression levels using quantitative RT-PCR with primers specific for different renal cell types.

Results: Using statistical methods we identified 931 probesets with at least 2-fold change in their expression between control and DKD groups. The top 6 transcripts with the highest fold changes were ALB, ALDOB, BBOX1, DDAH1, GATM, and HPD. All these genes showed reduced expression in the DKD group. Network analysis indicated disturbances in protein trafficking, protein synthesis, cellular assembly and organization as the top differentially regulated pathways in DKD urine samples.

Conclusions: The urinary transcriptome analysis may be a useful non-invasive tool to evaluate diabetic nephropathy. Further prospective studies will be needed to elucidate the validity urine transcript levels in diabetes and chronic kidney disease.

Exercise-Induced Increases in Serum Retinol-Binding Protein 4 and Endothelial Progenitor Cells in Diabetic Subjects Atsushi Aoki, Miho Murata, San-E Ishikawa. *Medicine, Jichi Medical University Saitama Medical Center, Saitama, Japan.*

Background: Retinol-binding protein 4 (RBP4) is an adipokine as well as primary carrier for retinol in plasma, and synthesized in liver, adipose tissues and muscular tissues. Endothelial progenitor cells (EPCs) derived from bone marrow are involved in regulating vascular endothelial cells. We determined whether acute exercise load changes serum RBP4 and EPCs in type 2 diabetic subjects.

Methods: 62 type 2 diabetic subjects (65.1±8.1 years) were enrolled. Acute cardio pulmonary exercise (CPX) loaded until maximal oxygen intake was performed, and serum RBP4 and EPCs were determined before and after the CPX. Serum RBP4 was measured by ELISA, and CD34+/133+ cells as EPCs were determined by FACS.

Results: Serum RBP4 levels, but not the numbers of EPCs, were increased according to the progression of diabetic nephropathy (p value in trend=0.043) In the 30 subjects without nephropathy (stage 1), an exercise load promptly increased serum RBP4 from 48.2±23.5 to 54.3±23.1 μg/ml (p=0.0006). In the 32 subjects with nephropathy (stage 2, 3, and 4) the exercise load did not alter serum RBP4. By contrary, an exercise load significantly increased the numbers of EPCs in both the diabetic subjects with stage 1 (88.9±83.3 to 114.9±104.4 cells/100μl , p=0.0003),and stage 2, 3 and 4 (63.0±68.4 to 78.5±68.8 cells/100μl, p=0.005). The alteration in serum RBP4 (ΔRBP4) during the exercise had a positive correlation with eGFR (r=0.30 p=0.018). Also, the numbers of EPCs and the alteration of EPCs (ΔEPCs) during the exercise had positive correlations with serum RBP4 levels (the numbers of EPCs: r=0.402, p=0.006; ΔEPCs: r=0.310, p=0.04).

Conclusions: These findings indicate that acute exercise promptly increases serum RBP4 levels and the number of EPC in diabetic subjects without nephropathy, and that there may be some interaction of RBP4 with the induction of EPCs under acute exercise.

TH-PO505

Association of Serum Leptin Levels with Progression of Diabetic Kidney Disease in Patients with Type 2 Diabetes Ko Hanai, Tetsuya Babazono, Izumi Nyumura, Nobue Tanaka, Yasuko Uchigata. *Diabetes Center, Tokyo Women's Medical University School of Medicine, Tokyo, Japan.*

Background: The association of leptin with diabetic kidney disease (DKD) remains controversial, and furthermore previous reports were limited by cross-sectional design. We therefore conducted this longitudinal study to clarify the association of serum leptin levels with progression of DKD in patients with type 2 diabetes (T2D).

Methods: This was a single-center observational cohort study on Japanese adult patients with T2D. Patients who had malignant diseases, glomerulonephritis diagnosed by biopsy, who had undergone renal replacement therapy or with lower limb amputation were excluded. Patients with an estimated GFR (eGFR) < 60 mL/ min/ 1.73 m^2 were excluded because serum leptin levels are increased due to decreased renal clearance. Then, of 668 patients, 380 and 356 were enrolled as the eGFR and ACR cohorts, respectively. Patients were classified into 3 groups by gender-specific tertile of leptin levels. Outcome measurements were the rate of change in eGFR and progression to a more advanced stage of albuminuria.

Results: During the mean follow-up period of 4.2 ± 1.2 years, the mean rate of change in eGFR was -1.66 ± 3.69 mL/ min/ 1.73 m^2/ year in the eGFR cohort. Patients with low or high leptin levels had a significantly steeper eGFR decline than those with mid-range leptin levels in both the univariate and the multivariate model (all p values < 0.05 vs. patients with mid-range leptin levels). In the ACR cohort, 34 patients showed progression of albuminuria during the mean follow-up period of 3.2 ± 1.6 years. Negative graded relationships between the hazard ratio for progression of albuminuria and 3 groups, based on leptin levels, were recognized in both the univariate and the multivariate model. Patients with the low leptin levels had a significantly elevated risk of progression of albuminuria than those with high leptin levels in both the univariate and the multivariate model (both p values < 0.05).

Conclusions: In this study of patients with T2D, both low and high serum leptin levels were risk factors for kidney function decline. Meanwhile, lower serum leptin levels were associated with progression of albuminuria.

TH-PO506

The Good and the Bad: The Relationships between 25 (OH) D and FGF-23 Levels with Cardiovascular Disease in Type 2 Diabetic CKD Patients Ana Paula Silva, Ana Cabrita, Ana Pinho, Nélio Santos, Pedro Neves. *Serviço de Nefrologia, Hospital de Faro, Faro, Portugal.*

Background: Cardiovascular disease is the main risk factor of morbidity and mortality in chronic kidney disease (CKD) patients and its relevance increases when diabetes is the etiology of the renal disease. Carotid wall thickness, left ventricular hypertrophy and vascular calcification are commonly used surrogates of cardiovascular disease in renal patients. Recently, the disturbances of the mineral metabolism were also related to cardiovascular disease, even in the early stages of CKD.

The aim of this study was to evaluate the relationships between vitamin D and FGF-23 levels with cardiovascular risk factors in a group of diabetic CKD patients.

Methods: In a cross-sectional study, we included 50 type 2 diabetic patients (f=18, m=32) with CKD stages 3 and 4. The mean age was 60.4 years and the mean estimated (MDRD) GFR was 50 ml/min. Exclusion criteria were uncontrolled hypertension, known prior cardiovascular disease, neoplasic or infectious disease, anti-inflammatory, phosphorus binders or vitamin D therapies.

We analyzed several cardiovascular parameters: the left ventricular mass index (LVMI), the carotid intima-media complex thickness (CIMT), the aortic augmentation index (AGI), the aortic pulse pressure (PP) and the difference between the 1st and 2nd peaks of the central pressure waveform in systole (Aix).

Results: Using the Pearson correlation, we found: a *positive* correlation between FGF-23 levels and LVMI (r=0,584 p=0,001), CIMT (r=0,785 p=0,001), AGI (r=0,485 p=0,001), PP (r=0,317 p=0,007) and Aix (r= 0,715 p= 0,001); an *inverse* correlation between 25 (OH) D levels and LVMI (r= - 0,633 p=0,001), CIMT (r= - 0,432 p= 0,002), AGI (r = -0,389 p= 0,004) and Aix (r= - 0,437 p= 0,001).

Conclusions: In our study, we found that the FGF-23 and the 25 (OH)D levels, known risk markers of cardiovascular disease in CKD patients, were related with some of cardiovascular parameters commonly used in the clinical practice.

Further studies are needed to better understand the physiopathology of these relationships and to ascertain if the correction of the FGF-23 and the 25 (OH)D levels improves the outcomes of our patients.

Total Serum Free Light Chains Are an Important Prognostic Marker in Patients with Type II Diabetes

Lakhvir Assi,[1] Philip Young,[1] Richard Hughes,[1] Colin A. Hutchison.[2] *[1]The Binding Site Group Ltd, United Kingdom; [2]Renal Institute of Birmingham, United Kingdom.*

Background: Polyclonal serum free light chains (FLCs) have recently been shown to be prognostic of overall survival and cardiac events in patients with chronic kidney disease (CKD). High FLC levels represent both degree of renal impairment and severity of inflammation. FLCs have also been reported to be elevated in diabetes, which is a major cause of CKD and cardiovascular disease. The purpose of this study was to determine if serum FLCs are associated with a shorter overall survival (OS) in type II diabetic patients.

Methods: A total of 527 patients (280 (53.1%) males; 247 (46.9%) females) were included. Baseline patient characteristics were: median (IQR) - systolic BP: 136 (26), diastolic BP: 82 (14), age: 54 (20), total cholesterol: 4.5 (1), HDL: 1.18 (0), LDL: 2.21 (1), ACR: 1.90 (6), BMI: 28 (7), eGFR: 75.6 (18.7), HBA1C: 6.6 (2), triglycerides: 2.3 (2) and total FLCs: 41.10 (21.6). The prognostic value of each variable was assessed using Kaplan Meier and Cox-regression analysis.

Results: A total of 166 (80 males and 86 females) had elevated FLC levels (normal range: 9-48 mg/L). By 4.5years 17/527 (3.2%) patients had died. Total FLC levels were significantly higher in patients who had died (52.8 mg/L) compared with those who were still alive (20.9 mg/L) (p=0.026). Patients with elevated FLC levels (>50mg/L) had a significantly shorter OS than patients with FLCs <50mg/L (p=0.014). The following variables were included as part of the univariate analysis: systolic BP, diastolic BP, age, gender, creatinine, smoker status, total cholesterol, HDL, LDL, ACR, BMI, eGFR, HBA1C, triglycerides and total FLCs. Only raised FLCs (HR=3.2, p=0.02), age>65 yrs (HR=3.6, p=0.03) and eGFR (HR=0.9, 95% CI=0.93-0.99, p=0.017) were identified to be prognostic of survival. Of these, only FLC>50mg/L were shown to be independently associated with OS in the multivariate analysis (HR=3.8; p=0.029).

Conclusions: To conclude, elevated serum FLCs (>50mg/L) were independently associated with a shorter overall survival in patients with type II diabetes.

Lower Serum Magnesium Level Predicts Adverse Renal Outcome and Mortality in Advanced CKD Patients with Type 2 Diabetes Mellitus

Yusuke Sakaguchi, Akira Suzuki, Tatsuya Shoji, Terumasa Hayashi, Yoshiharu Tsubakihara. *Kidney Disease and Hypertension, Osaka General Medical Center, Osaka, Japan.*

Background: Hypomagnesemia is a common finding among patients with type 2 diabetes mellitus (DM). Magnesium deficiency in type 2 DM is suggested to cause poor glycemic control as well as various micro- and macrovascular complications. However, few studies have focused on the impact of hypomagnesemia on the progression of renal failure and mortality. The aim of this study was to determine whether hypomagnesemia is a risk factor for end-stage renal disease (ESRD) and death among type 2 DM patients with advanced renal failure.

Methods:

Study design: A retrospective cohort study

Settings and participants: CKD stage 3 to 5 patients with type2 DM who were not receiving renal replacement therapy and whose serum magnesium level was measured at least once between January and December 2008.

Outcome: Composite of ESRD and all-cause mortality

Predictor: The participants were stratified into the following 2 groups based on baseline serum magnesium concentration according to the previously published normal lower limit: Lower group (serum magnesium, <1.8 mg/dL) and Higher group (serum magnesium, ≥1.8 mg/dL).

Results: This study included 151 patients (men, 70 %; median age, 69 years; serum creatinine, 2.05 mg/dL; serum magnesium 1.9 mg/dL). At the median follow-up of 29 months, 37 patients had ESRD and 10 died. Unadjusted Kaplan-Meier analysis showed Lower group had significantly worse outcomes than the Higher group (p= 0.01); this persisted after adjustment for age, sex, estimated GFR, serum albumin, hemoglobin A1c, hypertension, angiotensin-converting enzyme inhibitor/angiotensin receptor blocker, diuretics use and history of cardiovascular disease (hazard ratio 2.40; 95% confidence interval 1.14, 4.73; p = 0.02). Although there was no adjustment for proteinuria due to 33% missing data, it must be noted that there was no significant difference in proteinuria between the Lower and Higher group among patients with available data.

Conclusions: Low serum magnesium level independently predicted adverse renal outcome and mortality in advanced CKD patients with type 2 DM.

TH-PO509

Significance of Urinary Full-Length and Ectodomain Forms of Megalin in Patients with Type 2 Diabetes Mellitus

Shinya Ogasawara,[1, 2, 3] Michihiro Hosojima,[1] Ryohei Kaseda,[1] Ichiei Narita,[1] Yoshiaki Hirayama,[2] Sakari Sekine,[2] Akihiko Saito.[3] *[1]Nephrology, Niigata University, Niigata, Japan; [2]Reagent Research and Development Department, Denka Seiken Co., Ltd., Gosen, Japan; [3]Applied Molecular Medicine, Niigata University, Niigata, Japan.*

Background: Megalin mediates endocytic uptake of glomerular-filtered proteins in proximal tubule cells (PTCs). Also, it undergoes regulated intramembrane proteolysis (RIP) by which its extra- and intracellular domains are cleaved for putative signal transduction. To develop efficient novel biomarkers associated with the pathogenesis of PTC injury, particularly in diabetic nephropathy (DN), we investigated urinary megalin excretion in patients with type 2 diabetes mellitus (T2DM).

Methods: Sandwich ELISAs were carried out with monoclonal antibodies against the amino (A-megalin assay) and carboxyl (C-megalin assay) termini of megalin to analyze its urinary forms.

Results: We found that the A-megalin assay detected mainly a megalin ectodomain form, whereas the C-megalin assay identified a full-length form. The A-megalin assay targets were primarily in the soluble fraction, whereas the C-megalin assay targets were in both soluble and insoluble fractions. In 52 T2DM patients, urinary C-megalin levels tended to be elevated in line with increased albuminuria and were associated positively with plasma inorganic phosphate (Pi) and negatively with hemoglobin (Hb) levels, independently of age and sex. Other urinary biomarkers such as albumin, NAG, α_1-microglobulin, β_2-microglobulin, L-FABP, NGAL and type IV collagen did not show such a combined association with Pi and Hb levels. In contrast, urinary A-megalin levels were increased in T2DM patients with normo- and microalbuminuria but not in those with macroalbuminuria. In addition, urinary A-megalin levels were negatively associated with fractional excretion of Na.

Conclusions: Urinary full-length megalin excretion as measured by the C-megalin assay appears to be linked to chronic progression of DN, Pi dysregulation, and anemia, whereas urinary excretion of megalin ectodomain as measured by the A-megalin assay may be associated with RIP-related distinctive mechanisms involved in renal Na handling in T2DM patients.

YKL-40 Levels Are Associated with Coronary Calcium Score in Type 2 Diabetic Patients with Albuminuria but without Known Cardiovascular Disease

Frederik I. Persson,[1] Henrik Reinhard,[1] Henrik Vestergaard,[2] Hans-Henrik Parving,[3] Peter Karl Jacobsen,[1,4] Peter Rossing.[1] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Department of Endocrinology, Herlev University Hospital, Herlev, Denmark; [3]Department of Medical Endocrinology, University Hospital of Copenhagen, Copenhagen, Denmark; [4]Heart Centre, University Hospital of Copenhagen, Copenhagen, Denmark.*

Background: Type 2 diabetic patients (T2D) with albuminuria have a poor prognosis, primarily due to increased morbidity and mortality from cardiovascular disease (CVD). Early detection of asymptomatic CVD is essential to improve treatment and prognosis. In this cross-sectional study we investigated the inflammatory biomarker YKL-40, which seems to reflect early atherosclerosis, in relation to asymptomatic significant coronary artery disease in T2D patients with elevated urinary albumin excretion rate and the association with NT-proBNP and coronary calcium score (CCS).

Methods: A cohort of 200 T2D patients with elevated urinary albumin excretion rate (micro- or macroalbuminuria), but normal plasma creatinine and without a history of CVD were invetigated. Patients with plasma NT-proBNP levels above the median and/or coronary calcium scores (CCS) > 400 (n=133), were examined by myocardial scintigraphy and coronary angiography. YKL-40 levels were measured in all patients with a commercial ELISA assay (Quidel, USA).

Results: Median (IQR) level of YKL-40 was 89 (55-142) ng/mL. YKL-40 was higher in patients with significant CAD (110 ng/mL vs. 82 ng/mL, p= 0.005).YKL-40 was associated with plasma NT-proBNP (R=0.2, p=0.0001) and CCS (R=0.22, p=0.002). Only weak associations (R<0.3) were found between YKL-40 and traditional risk factors as age, known diabetes duration, vibration threshold, BMI and plasma creatinine. In a logistic regression model, YKL-40 in the third tertile was associated with significant CAD, however when adjusting for sex and age these associations were no longer significant

Conclusions: In patients with T2D and albuminuria but without known CVD, YKL-40 levels are associated with CCS, a non invasive marker of coronary calcification, but not independently associated with CAD. This could prove helpful in future risk assessment.

TH-PO511

Phosphorous as an Early Marker of Morbidity and Mortality in Type 2 CKD Diabetic Patients Ana Paula Silva, Ana Cabrita, Ana Pinho, André Fragoso, Marilia Faisca, Nelson Almeida Tavares, Pedro Neves. *Nephrology, Hospital Faro, Faro, Portugal.*

Background: Disturbances of the mineral metabolism, namely the phosphorous (P) level, have been related to increased morbidity and mortality in the general as well in the chronic kidney population.

However, studies conducted to assess the impact of P in stages 3 and 4 of renal disease are scarce. The purpose of this study was to evaluate the impact of P levels in a homogeneous population of type 2 chronic kidney disease (CKD) patients.

Methods: ± 25.1ml/min. Exclusion criteria were: previous cardiovascular disease, uncontrolled hypertension, neoplasic or infectious diseases. The mean follow-up was 47.6 months. We divided the population in 3 groups, according to the P tertiles. GI (n=39) - P <3.60 mg/dl; G2 (n=39) - P > 3.70 and < 4.60 mg/dl; G3 (n=41) P ≥ 4.60 mg /dl

Several laboratory parameters were analyzed: albumin, hemoglobin, estimated glomerular filtration rate (MDRD), markers of inflammation (interleukin 6, TNFa), insulin resistance (HOMA-IR), the left ventricular mass index (LVMI) and the hospitalization days caused by cardiovascular events.

In the analysis we used descriptive statistics, ANOVA for comparison among groups and the Kaplan-Meier method to compare the survival of the 3 groups.

Results: Patients in the higher P tertile (G3), showed lower estimated GFR (p = 0.0001), and hemoglobin (p = 0.030) levels; they also showed higher HOMA-IR (p = 0.0001), LVMI (p=0.0001), IL6 (p = 0.0001), TNF (p = 0.0001) and more hospitalization days (p = 0.0001) when compared with other groups. Using the Kaplan Meier analysis we found that the survival of the G1, G2 and G3 at 24 months was respectively : 93%, 86% and 71% (log-rank = 6.88 p=0.032).

Conclusions: In conclusion, we found in a group of type 2 diabetic CKD patients (stages 3 and 4) that higher P levels, even under the limits of therapeutic intervention, were associated with increased morbidity and mortality. Further studies are needed to verify if an earlier intervention regarding the P metabolism will be associated with improved outcomes in our patients.

TH-PO512

FGF23 and Asymptomatic Coronary Artery Disease in Type 2 Diabetic Patients with Elevated Urinary Albumin Excretion Rate Christel Joergensen,[1] Henrik Reinhard,[1] Orlando M. Gutierrez,[2] Myles S. Wolf,[3] Hans-Henrik Parving,[4] Peter Karl Jacobsen,[1,4] Peter Rossing.[1] *[1]Steno Diabetes Center, Denmark; [2]University of Alabama at Birmingham; [3]University of Miami, Miller School of Medicine; [4]Copenhagen University Hospital, Rigshospitalet, Denmark.*

Background: Coronary artery disease (CAD) is the major cause of morbidity and mortality in type 2 diabetic patients. Elevated FGF23 levels have been associated with surrogate markers (endothelial dysfunction and arterial stiffness) of cardiovascular disease in non diabetic subjects with early chronic kidney disease. We investigated the association between FGF23 and coronary calcium score (CCS) as well as asymptomatic CAD in type 2 diabetic patients with urinary albumin excretion rate > 30mg/24h.

Methods: A cross-sectional study including 200 type 2 diabetic patients without clinical signs of CAD. Patients with p-NT-proBNP>45.2ng/L and/or CCS>400 were stratified as high risk patients of CAD (n=133). High risk patients were examined by myocardial perfusion imaging (MPI; n=109), and/or CT-angiography (CTA; n=20), and/or coronary angiography (CAG; n=86). The patients were divided according to tertiles of FGF23.

Results: Median (range) FGF23 level was 71.3 (18.3- 992.2) RU/ml. All patients had normal creatinine levels. FGF23 was not associated with Agatston CCS intervals 1-5 (p=0.82). In 70(35%) patients, significant CAD was demonstrated by MPI and/or CAG. Compared to patients without significant CAD, FGF23 was not significantly higher in patients with significant CAD, 70.0 (18.3-992.2) RU/ml and 77.0 (36.0-783.0) RU/ml respectively; p=0.14. In a logistic regression model adjusted for conventional cardiovascular risk factors, increasing FGF23 was associated with CAD, OR 1.35 (0.6-3.1); p=0.47 for second vs. first tertile and OR 2.1 (0.9-4.7); p=0.07 for third vs. first tertile; although not statistically significant.

Conclusions: In high risk type 2 diabetic patients with elevated urinary albumin excretion rate, elevated levels of FGF23 are not significantly associated with asymptomatic coronary artery disease.

TH-PO513

Kidney Function and Albuminuria in Patients with Type 2 Diabetes Treated with Exenatide BID vs. Insulin Glargine Pamela W. Anderson,[1] Manjiri Pawaskar,[1] Katherine R. Tuttle,[2] Qian Li,[3] Byron Hoogwerf,[1] Matthew Reynolds.[3] *[1]Eli Lilly and Company, Indianapolis, IN; [2]Sacred Heart Medical Center, Spokane, WA; [3]United BioSource Corporation, Lexington, MA.*

Background: Exenatide twice daily (EXE BID) is a GLP-1 receptor agonist excreted via the kidney indicated to improve glycemic control in adults with type 2 diabetes (T2D). There have been postmarketing reports of decreased kidney function during treatment with EXE BID. This study examined changes in kidney function and incidence of albuminuria over 1-year exposure of EXE BID vs. insulin glargine in patients with T2D treated in usual clinical practice.

Methods: A retrospective analysis was performed using the General Electric (GE) electronic medical record database, comprised of patients who initiated EXE BID (n=4,494) or IG (n=5,424) between 11/1/2006 and 04/30/2009. The 2 groups were 1:1 propensity score matched on baseline demographic, clinical, and resource use variables yielding 2,683 matched pairs. Measures of kidney function or damage included serum creatinine (SCR), urinary albumin/creatinine ratio (UACR), and estimated GFR (eGFR). eGFR was calculated from SCR using the modified MDRD equation.

Results: Both EXE BID and IG groups had less than 1 ml/min/1.73m^2 of change in eGFR from baseline to 1 year, which was not statistically different across groups (IG: 76.6 to 76.7 ml/min/1.73m^2 and EXE BID: 75.7 to 75.8 ml/min/1.73m^2). Also, the number of patients in each stage of chronic kidney disease was not significantly different at baseline and endpoint across the 2 groups. Baseline UACR was significantly higher in the IG group (120 vs. 42 mg/g for EXE BID group, p=0.03) despite propensity score matching. There was no longer a significant difference in UACR after 1 year between the groups (101 vs. 52 mg/g, p=0.51), and there was not a significant change from baseline in either group (11 vs. 8 mg/g, p=0.19 for EXE BID and IG, respectively).

Conclusions: Patients in both IG and EXE BID groups had stable eGFR after 1 year of treatment. Clinical data from a large, diverse patient population in usual care practice did not detect adverse changes in kidney function or damage during treatment with EXE BID.

Renoprotective Efficacy of an L/N-Type Calcium Channel Blocker in Early Diabetic Nephropathy Complicated by Hypertension Shinya Fukumoto, Eiji Ishimura, Yohei Mima, Takaaki Maeno, Eiji Kimoto, Ken Wakikawa, Katsuhito Mori, Tetsuo Shoji, Shigeichi Shoji, Masanori Emoto, Masaaki Inaba. *Metabolism, Endocrinology and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan.*

Background: The renoprotective efficacy of cilnidipine, an L/N-type calcium channel blocker (CCB), in hypertensive patients with chronic kidney disease has been reported, but the efficacy in early diabetic nephropathy has not been studied. We examined differences in efficacy between L/N and L type CCBs for early nephropathy.

Methods: The present study was a multicenter crossover study pre-registered as a CLEARED study. It involved 90 outpatients (57 males and 33 females; age, 65±9 ys) with early nephropathy complicated by hypertension. Their urinary albumin excretion (UAE) was 50±42 mg/gCr, and eGFR was 73±19 ml/min. Forty-nine patients were being treated with inhibitors of the rennin-angiotensin system (RAS). For the group (group A for 69 patients) with switching to cilnidipine after administration of an L-type CCB for more than 6 months and the group with switching from cilnidipine to an L-type CCB (group B for 21 patients), we investigated changes in UAE 6 months before switching, at the time of switching, and 6 months after switching.

Results: Groups A and B each exhibited significant change in neither blood pressure (BP) nor HbA1c level after switching. Group A had a significant increase in UAE during an L-type CCB (52±8 → 92±19 mg/gCr, p<0.01), but a significant decrease in UAE 6 months after switching to cilnidipine (→ 50±10 mg/gCr, p<0.01). Group B exhibited no significant change in UAE during cilnidipine, and no significant change in UAE for 6 months after switching to an L-type CCB. Factors related to increase in UAE in both groups were examined by logistic regression analysis. Cilnidipine was found to be a significant factor reducing the risk (OR: 0.246, 95% CI, 0.074-0.823, p<0.05) independent of age, sex, BP, RAS inhibitors, and HbA1c.

Conclusions: The L/N-type CCB cilnidipine exhibited excellent renoprotective efficacy in patients with early diabetic nephropathy compared with L-type CCBs, and switching from an L-type CCB to cilnidipine had beneficial effects.

TH-PO515

Ameliorating Day- and Night-Time Blood Pressure Control by Combined ECE/NEP Inhibition with Daglutril on Top of Losartan: A Randomized, Cross-Over, Placebo-Controlled Clinical Trial in Patients with Type 2 Diabetes and Albuminuria Irene M. Van Der Meer,[1,3] Aneliya Parvanova Ilieva,[3] Giuseppe Remuzzi,[1,2] Ariela Benigni,[2] Piero Ruggenenti.[1,2] *[1]Unit of Nephrology, Azienda Ospedaliera Ospedali Riuniti di Bergamo, Bergamo, Italy; [2]Mario Negri Institute for Pharmacological Research, Bergamo, Italy; [3]Department of Internal Medicine, HAGA Ziekenhuis, Den Haag, Netherlands.*

Background: Albuminuria reduction and optimal blood pressure (BP) control are of utmost importance for patients with type 2 diabetes (T2DM) and nephropathy. Endothelin-1 receptor antagonism reduces BP and albuminuria, but fluid retention frequently occurs. No study has investigated the antihypertensive and antiproteinuric effects of the combined endothelin-converting enzyme/neutral endopeptidase (ECE/NEP) inhibitor daglutril.

Methods: In a randomized, double-blind, placebo-controlled cross-over trial, 42 micro- or macroalbuminuric patients with T2DM and stable BP control were randomized to treatment with daglutril (300 mg/day) followed by placebo or the reverse. Each treatment lasted 8 weeks and was given on top of losartan (100 mg/day). Change in 24-hour albuminuria was the primary outcome. Secondary outcomes were changes in office and ambulatory BP, renal hemodynamics and glomerular size-selectivity.

Results: Mean±SD 8-week changes for daglutril versus placebo in daytime systolic and diastolic BP were -2.3±8.0 versus 3.2±9.4 mmHg (P=0.03) and 0.3±4.7 versus 1.8±5.5 mmHg (P=0.19), respectively. Corresponding changes in night-time systolic and diastolic

BP were -5.7±10.3 versus 4.0±7.8 mmHg (P<0.001) and -3.3±5.4 versus 2.0±5.9 mmHg (P<0.001), respectively. No significant changes were observed in 24-hour albuminuria. Peripheral edema was observed in four patients, but no heart failure occurred.

Conclusions: Daglutril has no effect on albuminuria, but reduces day- and night-time systolic BP and night-time diastolic BP on top of losartan in T2DM patients. Its safety profile compares favourably to endothelin-1 receptor antagonists. Ameliorating BP control by combined ECE/NEP inhibition provides a new approach to hypertension that may be of value in reducing the incidence of cardiovascular disease in this high-risk population.

Effects of Lipid-Lowering Treatment on Platelet Reactivity and Platelet-Leukocyte Aggregation in Diabetic Patients with Chronic Kidney Disease – A Randomized Trial

Tora C. Almquist,[1,2] Stefan H. Jacobson,[2] Per-Eric Lins,[3] Richard W. Farndale,[4] Paul Hjemdahl.[1] *[1]Karolinska Institutet, Dept. Medicine, Clinical Pharmacology Unit, Karolinska University Hospital, Solna, Stockholm, Sweden; [2]Karolinska Institutet, Dept. Clinical Sciences, Div. Nephrology, Danderyd Hospital, Stockholm, Sweden; [3]Karolinska Institutet, Dept.Clinical Sciences, Div. Diabetology, Danderyd Hospital, Stockholm, Sweden; [4]Dept. Biochemistry, University of Cambridge, United Kingdom.*

Background: Diabetes mellitus (DM) is associated with hyperreactive platelets and increased platelet-leukocyte aggregation (PLA), but the impact of concomitant chronic kidney disease (CKD) has been much less studied. Platelet- and leukocyte activation may contribute to the high incidence of atherosclerotic cardiovascular disease in patients with DM and chronic kidney disease. Lipid-lowering treatment (LLT) with statins may have favorable effects on platelet activation and inflammation, and ezetimibe co-treatment provides additional cholesterol-lowering.

Methods: After a placebo run-in period, the effects of simvastatin alone (S) or simvastatin+ ezetimibe (S+E) were compared in a randomized, double-blind, cross-over study on platelet reactivity, PLA formation, and inflammatory parameters.18 DM patients with estimated glomerular filtration rate (eGFR) 15-59 ml/min x 1.73 m^2 (CKD stages 3-4) (DM-CKD) and 21 DM patients with eGFR >75 ml/min (DM only) were included.

Results: PLAs were elevated at baseline in DM-CKD compared to DM only patients (p<0.001). S+E reduced PLAs among total leukocytes and neutrophils in DM-CKD patients (p=0.01 for both). Platelet reactivity did not differ between patient groups or with LLT. Plasma sCD40L (p<0.001), elastase (p=0.01) and vWf (p<0.01) were elevated in DM-CKD compared to DM only patients. S+E tended to reduce sCD40L in DM-CKD patients, but LLT did not influence vWF or elastase.

Conclusions: In conclusion, DM patients with CKD stages 3-4 had increased platelet-leukocyte aggregation and inflammatory activity compared to DM patients with normal GFR. Simvastatin+ezetimibe decreased PLAs in DM patients with concomitant CKD, but did not influence inflammatory parameters in either patient group.

TH-PO517

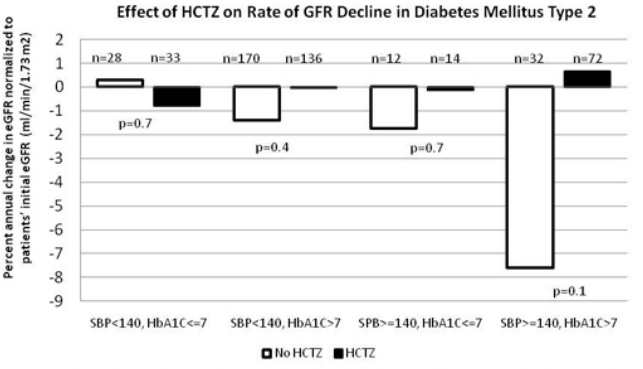
Effect of Thiazides on GFR Decline in Diabetes Mellitus Type 2

D. Vo,[1] P.T. T. Pham,[2] P.C. T. Pham.[1] *[1]Nephrology, UCLA-Olive View Medical Center, Sylmar, CA; [2]Kidney and Pancreas Transplant, UCLA Medical Center, Los Angeles, CA.*

Background: Poor glycemic control and the use of diuretics in DM2 patients can both induce relative volume depletion. The combined effects on volume depletion could potentially induce intermittent acute tubular necrotic episodes and result in acceleration of kidney function decline over time. The current study examines the effect of hydrochlorothiazide (HCTZ), a mild diuretic, on the annual percentage of change in the estimated (MDRD) glomerular filtration rates (eGFR) in DM2 patients stratified by glycemic control and blood pressure.

Methods: This is a retrospective study involving record retrieval of patients with DM2 and hypertension evaluated for any reason at UCLA-OVMC during 2009-2010. Data retrieved include age, gender, use of thiazides and inhibitors of the renin angiotensin system, eGFR, hemoglobin A1C (HbA1C), blood pressure, and albuminuria to creatinine ratio (ACR). Patients were stratified based on systolic blood pressure <= or > 140 mmHg and HbA1C <= or > 7%. Differences in the annual percentage change in eGFR during the duration of follow-up between any 2 groups comparing those receiving thiazides vs. not were based on student's t-test. A p-value <0.05 was considered statistically significant.

Results: 497 patients' records were included. There were 71.8% female, with mean +/- standard deviation age of 57 +/- 9 years, duration of follow-up of 601 +/- 157 days, systolic blood pressure of 134 +/- 14, diastolic blood pressure of 70 +/- 9 mmHg, HbA1C of 8.2 +/- 1.4%, and ACR of 141 +/- 521 mcg/mg. 97.2% of patients were receiving either an angiotensin converting enzyme inhibitor or angiotensin receptor blocker. The percentages of change in the eGFR for the 4 groups are shown.



There is a trend for slower decline in GFR among patients receiving hydrochlorothiazide compared to those who did not across all groups stratified for blood pressure and hemoglobin A1C.

Conclusions: The use of thiazides in DM2 patients with poor glycemic control does not accelerate but appears to be protective against eGFR decline.

TH-PO519

Effect of Atrasentan in Subjects Taking Maximum Doses of Renin Angiotensin-Aldosterone System Inhibitors (max-RAAS) for Diabetic Nephropathy (DN)

Blai Coll,[1] Shihua Wen,[1] Yili Pritchett,[1] Mark E. Molitch,[2] John J. Brennan,[1] Donald E. Kohan,[3] Dennis L. Andress.[1] *[1]Abbott; [2]Northwestern U Feinberg Sch of Med; [3]U of Utah.*

Background: RAAS inhibitors reduce albuminuria in subjects with DN, though >50% taking max-RAAS have residual albuminuria. Low dose atrasentan, a highly selective endothelin A receptor antagonist, reduces residual albuminuria. These analyses evaluated the efficacy and safety of atrasentan + max-RAAS in subjects with DN.

Methods: This was a randomized, double blind trial of subjects with type 2 diabetes and albuminuria on stable doses of RAAS inhibitors, an eGFR >20mL/min/1.73m^2, a UACR of 100-3000mg/g and a NT-pro-BNP level <500pg/ml who were allocated to placebo (PBO), or atrasentan 0.25 mg, 0.75 mg, or 1.25 mg QD for 8 weeks. This abstract is focused on 33 subjects taking max-RAAS out of 89 participating in the trial. Treatment-by-subgroup interaction was tested using ITT population.

Results: The treatment-by-subgroup interaction for change from baseline (BL) to final log UACR was not significant (P=0.816), suggesting subjects taking max-RAAS or taking lower than max-RAAS responded similarly to atrasentan. BL demographics were similar between the groups. Results are shown in the table. The small sample sizes prevented robust statistical comparisons.

		Atrasentan		
Change from BL to Week 8 mean (SE)	PBO (N=9)	0.25 mg (N=5)	0.75 mg (N=8)	1.75 mg (N=11)
UACR (% change)	5%	-27%	-32%[1]	-35%[2]
Systolic Blood Pressure, SBP mm Hg)	0.8 (4.6)	-1.4 (6.4)	-12.2 (5.0)	-6.5 (4.2)
eGFR (mL/min/BSA)	3.2 (2.6)	4.1 (3.9) N=4	-5.3 (2.8)	-0.2 (2.4)
Subjects with a 40% Reduction UACR	11%	40%	63%[3]	36%[4]
Edema (% of subjects)	11%	40%	13%	58%

P-values vs. PBO
1. 0.134
2. 0.087
3. 0.050
4. 0.319

Conclusions: Subjects in the 0.75 mg and 1.75 mg groups had numerically greater % changes in UACR compared with PBO, and subjects in the 0.75 mg group also had a numerically greater reduction in systolic blood pressure (SBP) and eGFR, indicating that atrasentan could be useful for subjects with residual albuminuria while taking max-RAAS. Edema, mostly mild, was higher in subjects taking atrasentan, but was not dose-dependent in those on max-RAAS. With the caveat of small sample size, larger studies are needed to confirm these findings.

Aliskiren Added to Losartan Has Beneficial Effects across Different Levels of Albuminuria in Hypertensive Patients with Type 2 Diabetes and Nephropathy: The AVOID Study Frederik I. Persson,[1] Julia Lewis,[2] Edmund J. Lewis,[3] Peter Rossing,[1] Hans-Henrik Parving.[4,5] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]School of Medicine, Vanderbilt University, Nashville, TN; [3]Rush University Medical Center, Chicago, IL; [4]Dept. of Medical Endocrinology, University Hospital of Copenhagen, Copenhagen, Denmark; [5]Faculty of Health Sciences, Aarhus University, Aarhus, Denmark.*

Background: Aliskiren 300 mg once daily added to standard treatment with losartan 100 mg once daily and optimal antihypertensive therapy has antiproteinuric effect in hypertensive patients with type 2 diabetes and nephropathy. However, the beneficial impact may depend on the level of baseline albuminuria. Consequently we performed a post-hoc analysis of the AVOID study to determine which group of patients benefits the most from the addition of direct renin inhibition.

Methods: In AVOID, 599 patients (eGFR>30 ml/min/1.73m2) with type 2 diabetes, hypertension and nephropathy received 6 months' aliskiren (150 mg titrated to 300 mg after 3 months) or placebo added to losartan 100 mg and optimal antihypertensive therapy. The primary endpoint, changes in early morning urinary albumin creatinine ratio (UACR), was assessed by tertiles of baseline UACR levels.

Results: Patients were divided into tertiles of baseline UACR (<340 mg/g, ≥340 mg/g – 788 mg/g and >788 mg/g respectively). The antiproteinuric effect of aliskiren treatment was consistent across subgroups of baseline UACR with a between-treatment ratio of 0.78 (95% CI 0.62, 0.98) p=0.032 in the lowest tertile; 0.79 (0.63, 0.99) p=0.039 in the middle tertile and 0.84 (0.67, 1.05) p=0.13 in the highest tertile, independent of baseline BP.

Conclusions: This *post hoc* analysis of the AVOID study suggests that renin inhibition with aliskiren 300 mg once daily added to losartan 100 mg once daily plus optimal antihypertensive therapy provides reductions in UACR of equal magnitude across different levels of baseline albuminuria.

Cholecalciferol Reduces Urinary Angiotensinogen in Early Diabetic Kidney Disease Christopher K. Johnson,[1] Alexandra V. Flynn,[1] Hiroyuki Kobori,[2] Bryan R. Kestenbaum,[1] Ian H. de Boer.[1] *[1]University of Washington, Seattle, WA; [2]Tulane University, New Orleans, LA.*

Background: The renin-angiotensin system (RAS) is an important therapeutic target in diabetic kidney disease. Tissue and urinary levels of angiotensinogen (AGT) reflect intrarenal RAS activation and oxidative stress. In animal models, vitamin D receptor agonists downregulate the RAS and reduce tissue and urinary AGT. We investigated whether treatment with cholecalciferol (vitamin D3) decreases urinary AGT in early human diabetic kidney disease.

Methods: In a randomized, double-blind, clinical trial, 22 participants with type 2 diabetes mellitus, albuminuria (urinary albumin-creatinine ratio (ACR) 30-1000mg/g), and estimated glomerular filtration rate >= 60 mL/min/1.73m^2 were assigned to treatment with cholecalciferol 2000 IU daily or matching placebo for one year. All participants were treated with RAS inhibitors. Spot urinary AGT and interleukin-6 (IL-6) concentrations were measured by ELISA at baseline, three months, and one year and indexed to urinary creatinine. We analyzed effects of treatment using linear mixed models.

Results: On treatment, participants in the cholecalciferol group had a 64% decline in urinary AGT (95% CI -83%, -25%; p = 0.006) while patients in the placebo group had a 15% decline (95% CI -51%, +47%); between group difference 58% (95% CI -83%, +6%; p = 0.07). Participants in the cholecalciferol group had a 16% decline in urinary IL-6 (95% CI -39%, 16%), while patients in the placebo group had a 1% decline (95% CI -28%, +36%). Participants in the cholecalciferol group had a 22% decline in urinary ACR (95% CI -50%, 23%), while patients in the placebo group had a 5% decline (95% CI -40%, +50%).

Conclusions: Among individuals with type 2 diabetes and albuminuria on treatment with a RAS blocker, daily cholecalciferol supplementation reduced urinary AGT excretion. This may reflect further downregulation of the intrarenal RAS, possibly due to decreased oxidative stress.

TH-PO522

Analysis of Peripheral Edema in Subjects Taking Atrasentan for Diabetic Nephropathy (DN) Blai Coll,[1] Shihua Wen,[1] Yili Pritchett,[1] Mark E. Molitch,[2] John J. Brennan,[1] Donald E. Kohan,[3] Dennis L. Andress.[1] *[1]Abbott; [2]Northwestern U Feinberg Sch of Med; [3]U of Utah.*

Background: Low dose atrasentan, a highly selective endothelin A receptor antagonist, reduces residual albuminuria in subjects with DN. Peripheral edema is the most frequently reported adverse event (AE) associated with endothelin A receptor blockade. The goal of these analyses was to characterize edema events in subjects taking atrasentan.

Methods: This was a randomized, double blind trial of subjects with type 2 diabetes on stable doses of RAAS inhibitors having an eGFR >20mL/min/1.73m^2 and albuminuria of 100-3000mg/g creatinine (UACR), who were allocated to placebo (PBO), 0.25mg, 0.75mg, or 1.75mg of atrasentan daily for 8 weeks. The protocol was later amended to have serum NT-pro-BNP >500pg/mL as an exclusion.

Results: 89 subjects were randomized: 23 to PBO and 22 to each atrasentan dose group. Baseline (BL) demographics were similar among groups. UACR lowering was different from PBO in the 0.75mg and 1.75mg groups. 21 subjects reported treatment-emergent edema. Of those 21 subjects, 13 were taking diuretics at BL. The incidence of mild/moderate edema was: PBO:2/23, 0.25mg:4/22, 0.75mg:5/22, and 1.75mg:10/22; none reported severe edema. 62% of the treatment-emergent edema were reported in the first 4 weeks. Of the 21 subjects with edema, 6 resolved by treatment end, 9 resolved during the 30 day follow-up after treatment, 5 had continued edema at the end of the study, and 2 subjects were discontinued: 1 in the 1.75mg group from angioedema and 1 in the 0.75mg group from congestive heart failure (BL NT-pro-BNP, 4400 pg/ml). 7 subjects started diuretics during the study. Variables associated with a higher risk of edema by logistic regression were treatment group (1.75mg, OR =17.9, *P*=0.005) and BL UACR (≤300 or >300mg/g, OR=6.1, *P*=0.012).

Conclusions: Edema occurrence with atrasentan therapy was dose-dependent, mostly mild/moderate, and appeared during the first 4 weeks. Less than 1/3 of subjects initiated diuretics during treatment and 71% resolved edema before the end of study. These data suggest that with appropriate patient selection, low dose atrasentan may be safe for long-term clinical trials.

TH-PO523

Determinants of Hyperkalemia in Diabetic (DM) Patients Treated with an ACE Inhibitor (ACEI) and a Mineralocorticoid Receptor Antagonist (MRA): Clinical Implications for Obviating Hyperkalemia Murray Epstein,[1] Bruce Beckerman,[2] John Vincent,[2] Harry Shi.[2] *[1]University of Miami School of Medicine, FL; [2]Pfizer, Inc., New York, NY.*

Background: Although combined RAAS blockade with an MRA and ACEI generally produces a greater reduction in albuminuria/proteinuria than ACEI alone, it tends to cause hyperkalemia. This post hoc analysis of the 067 study (CJASN 1:940-951, 2006) assessed whether estimated baseline GFR (eGFR) predicts hyperkalemia. Sequential measurements of serum potassium (sK) during the study defined its temporal profile.

Methods: 268 patients with type 2 DM, albuminuria, hypertension, eGFR >60 mL/min/1.73m^2 and sK ≤5.0 mmol/L were randomized to receive enalapril 20mg plus either the MRA eplerenone (EPL) 50mg, EPL 100mg, or placebo for 12 weeks. sK was measured at baseline and every 2 weeks during the trial to determine the incidences of sustained hyperkalemia (sK >5.5 mmol/L on two consecutive occasions 1 to 3 d apart) and severe hyperkalemia (sK >6.0 mmol/L on any occasion).

Results: Pertinent data were available for 259 subjects. The Table displays the incidence of sustained and severe hyperkalemia by treatment and GFR quartile (eGFR, MDRD equation). EPL reduced albuminuria in doses as low as 50 mg/day (41% reduction in UACr). Only 6 patients in the EPL groups had severe or sustained hyperkalemia, and hyperkalemia did not correlate with eGFR. Evaluation of time to onset of hyperkalemia failed to confirm a particular time period when enhanced monitoring of sK would be beneficial.

Conclusions: This analysis demonstrates that a dosing regimen of the MRA EPL 50mg with an ACEI or an ARB in type 2 DM patients confers the desired anti-albuminuric benefit with minimal risk of hyperkalemia.

Incidence of hyperkalemia by treatment and eGFR quartile

Baseline eGFR (mL/min/1.73m²)	Hyperkalemia	Placebo/ENAL	EPL50 / ENAL	EPL100 /ENAL

Efficacy and Safety of Dapagliflozin in Patients with Type 2 Diabetes and Moderate Renal Impairment Donald E. Kohan,[1] Paola Fioretto,[2] James List,[3] Weihua Tang.[3] *[1]University of Utah Health Sciences Center, UT; [2]University of Padova Medical School, Italy; [3]Bristol-Myers Squibb, NJ.*

Background: Dapagliflozin (DAPA), a selective SGLT2 inhibitor, promotes urinary glucose excretion (UGE).

Methods: The effects of DAPA on HbA1c, renal function and safety were assessed in patients (pts) with type 2 diabetes (T2D) and moderate renal impairment (eGFR 30–59 mL/min/1.73m^2). Pts (n=252), aged ≥ 18 yrs, HbA1c 7.0–11.0%, were randomized to receive DAPA (5 or 10 mg/d) or placebo (PBO) for 52 wks.

Results: Mean decreases in HbA1c were similar for PBO (-0.32%) and DAPA (-0.41%, -0.44%) at the 24-wk endpoint. At 52 wks, mean UGE with DAPA 5 and 10 mg (27 and 22 g/g creatinine (Cr)) was about half that seen in pts with normal renal function. DAPA 5 and 10 mg decreased PBO-subtracted weight (-2.44 and -2.98 kg) and blood pressure (systolic: -6.22 and -9.14 mm Hg; diastolic: -1.09 and -2.83 mm Hg). DAPA dose-dependently reduced eGFR at wk 1 but then stabilized eGFR vs a continued gradual decline with PBO. Values of urinary albumin:Cr>1800 mg/g were reported in more pts receiving PBO (10.8%) than DAPA (5 mg 7.2%; 10 mg 7.1%). More pts receiving PBO (8%) discontinued due to hyperkalemia vs DAPA 5 (1%) and 10 mg (5%). Renal adverse events, hypotension, fractures, and genital infections were more common on DAPA than PBO. Urinary tract infections were similar among groups. Mean serum phosphorus and

magnesium were slightly increased with DAPA, but remained in the normal range. Serum uric acid decreased and parathyroid hormone increased with DAPA vs PBO.

Conclusions: In summary, DAPA did not improve HbA1c in pts with T2D and moderate renal impairment. Further research is needed to determine if DAPA exerts a renoprotective effect; however potential benefits must be balanced against possible risks in this population.

Influence of Renal Function on Dapagliflozin Pharmacodynamics in Patients with Type 2 Diabetes Mellitus Sreeneeranj Kasichayanula, Xiaoni Liu, Melanie Pe Benito, Frank Lacreta, David W. Boulton. *Bristol-Myers Squibb, NJ.*

Background: Dapagliflozin (DAPA), a selective inhibitor of the renal sodium-glucose cotransporter-2 (SGLT2), is currently in development for the treatment of type 2 diabetes mellitus (T2DM). DAPA reduces hyperglycemia independently of insulin by promoting urinary glucose excretion that is proportional to the filtered load of glucose, the product of plasma glucose and the glomerular filtration rate (GFR).

Methods: This open-label, parallel study was conducted to evaluate the pharmacokinetics/pharmacodynamics (PD), safety and tolerability of DAPA in patients with T2DM and normal renal function or, mild, moderate or severe renal impairment (CLcr of 51–80, 30– 50, and <30 ml/min, respectively, excluding patients on dialysis) and healthy subjects after single (50 mg/d) and subsequent multiple (20 mg/d for 7 days - T2DM patients only) doses of DAPA. Background antihyperglycemic medications, excluding exenatide, were allowed for subjects on stable therapy.

Results: Systemic DAPA exposure (AUC) was higher and urinary glucose clearance and changes in fasting serum glucose were lower with decreasing creatinine clearance. Following a single, 50 mg dose of DAPA, systemic DAPA exposure was 28%, 52% and 75% higher and fasting renal glucose clearance (mL/min) values were 53%, 77%, and 85% lower in T2DM patients with mild, moderate, and severe renal impairment, respectively, in comparison to subjects with normal renal function. The corresponding steady-state glucose clearance values, with DAPA 20 mg/d for 7 days, were 42%, 83%, and 84% lower. Mean 24-h urinary glucose excretion (mg) was similarly reduced with increasing degrees of renal impairment. There were no marked differences in serum electrolytes, including sodium, between groups at baseline or after treatment. DAPA was well-tolerated in all subjects, with no discontinuations due to drug-related adverse events.

Conclusions: The PD effects of DAPA are reduced as renal function decreases, despite higher systemic DAPA exposure, due to a decreased GFR and subsequent decrease in filtered glucose load. These results suggest that DAPA may have reduced efficacy in patients with moderate to severe renal dysfunction.

TH-PO526

Influence of Renal Function on Dapagliflozin Pharmacokinetics in Healthy Subjects and in Patients with Type 2 Diabetes Mellitus Sreeneeranj Kasichayanula, Xiaoni Liu, Melanie Pe Benito, Ming Yao, Frank Lacreta, William Humphreys, David W. Boulton. *Bristol-Myers Squibb, NJ.*

Background: Dapagliflozin (DAPA), a selective inhibitor of the renal sodium-glucose cotransporter-2 (SGLT2), is under development for the treatment of type 2 diabetes mellitus (T2DM). The majority of DAPA is glucuronidated by the enzyme UGT1A9 to the inactive metabolite, DAPA 3-O-glucuronide (D3OG). D3OG is mainly cleared via renal excretion. As the kidney is the primary target of DAPA action, this open-label, parallel study was conducted to assess the pharmacokinetics (C_{max} and AUC of DAPA and D3OG) of single and multiple doses of DAPA in patients with T2DM and normal renal function or, mild, moderate or severe renal impairment and healthy subjects.

Methods: Criteria for mild, moderate and severe renal impairment were CLcr of 51–80, 30– 50, and <30 mL/min, respectively, excluding patients receiving dialysis. Subjects received single (50 mg/d) and subsequent multiple (20 mg/d for 7 days in T2DM patients only) oral doses of DAPA (doses up to 10 mg were studied in phase 3 trials).

Results: Single dose pharmacokinetics of DAPA were similar in healthy subjects and patients with T2DM and normal renal function while exposures to DAPA and D3OG were incrementally higher with decreasing renal function. Compared to patients with T2DM with normal renal function, the steady-state geometric mean C_{max} values for DAPA [D3OG] were 4% [20%], 6% [37%], and 9% [52%] higher in subjects with mild, moderate, and severe renal impairment, respectively, and the corresponding geometric mean values for DAPA AUC0-τ were 32% [54%], 60% [110%], and 87% [169%] higher, respectively. Isolated human kidney microsomes showed a high activity of UGT1A9 and a higher rate of D3OG formation relative to human liver and intestinal microsomes (3- and 109-fold higher, respectively).

Conclusions: These findings indicate that a substantial proportion of DAPA metabolism occurs via UGT1A9 in the kidney. The less than 2-fold increase in D3OG exposure suggests that a dose adjustment of DAPA is likely not needed in patients with renal impairment.

TH-PO527

Nox5-Dependent Reactive Oxygen Species Production in Human Podocytes Exposed to Diabetic Stimuli Chet E. Holterman,[1] Moin Saleem,[3] Chelsea Towaij,[1] Rhian Touyz,[1] Mark E. Cooper,[2] Chris R. Kennedy.[1] *[1]Kidney Research Center, Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]Baker IDI Heart & Diabetes Institute, Melbourne, Victoria, Australia; [3]University of Bristol, Bristol, United Kingdom.*

Background: Reactive oxygen species (ROS) production, via the NADPH oxidase family of enzymes (Noxs), plays a critical role during filtration barrier injury in diabetic nephropathy (DN). While most studies have focused on the role of Nox4 we here examine the role of Nox5 in DN and ROS induced podocyte damage in response to classic diabetic stimuli.

Methods: *In vivo,* Nox5 protein expression was compared by immunofluorescence in human kidney biopsies obtained from non-diabetic and diabetic/albuminuric individuals. *In vitro*, a conditionally immortalized human podocyte line (hPOD) was exposed to various diabetic stimuli including TGF-b (1-10 ng/ml), advanced glycation end-products (AGE), high glucose (25 mM) and equibiaxial mechanical stretch (10% elongation, 0.5 Hz). Nox5 expression was determined by quantitative RT-PCR (qPCR), and western blotting.

Results: Biopsies from diabetic individuals with confirmed albuminuria revealed higher immunodetectable Nox5 expression in glomerular structures vs non-diabetic controls. RT-PCR verified that Nox5β is the predominant isoform present in hPODs while qPCR demonstrated that Nox5 mRNA expression is significantly upregulated in hPODs in response to high-glucose/stretch (>2fold), TGF-b (>2 fold), and AGE (>4fold). As expected Nox5 protein levels are also higher in hPODs in response to diabetic stimuli.

Conclusions: Upregulation of Nox5 in diabetic kidney occurs in response to classic diabetic stimuli. This may in part be responsible for ROS–induced podocyte damage and filtration barrier dysfunction observed in diabetic kidney disease. Mouse models with podocyte targeted Nox5 expression may elucidate the role of Nox5 in the development and progression of DN.

Preservation of Endothelial GTP Cyclohydrolase I Activity by Metformin Prevent the Development of Diabetic Nephropathy Kengo Kidokoro, Minoru Satoh, Naruya Tomita, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: Increased oxidative stress is involved in the pathogenesis of diabetic vascular complications. Uncoupling of endothelial nitric oxide (NO) synthase (eNOS) via oxidation of tetrahydrobiopterin (BH4), a cofactor required for NO production, plays a major role in of oxidative stress generation. GTP cyclohydrolase I (GTPCH I) is the rate-limiting enzyme in BH4 biosynthesis, and hyperglycemia accelerates GTPCH I degradation via inhibition of AMP-activated protein kinase (AMPK) activity. We hypothesized that preservation of GTPCH I activity and improvement of NO availability either pharmacologically or genetically could prevent development of diabetic renal complications.

Methods: We used male C57/BL6 mice (WT) and spontaneously diabetic Ins2Akita mice (AKITA) and treated them with metformin (Met; 300 mg/kg/day), an oral hypoglycemic drug and a potent AMPK activator as well, for 4 weeks. Next, human glomerular endothelial cells (hGECs) were exposed to normal glucose (5 mM), high glucose (30 mM D-glucose), or hyperosmotic control (5 mM D-glucose + 25 mM mannitol) in the presence or absence of Met. We also examined the effect of overexpression of GTPCH I on diabetic renal complications by crossing endothelium-specific GTPCH I transgenic mice with AKITA (GCHtg/AKITA).

Results: Urinary albumin excretion (UAE) was significantly suppressed in AKITA/Met compared with AKITA without any alteration in blood glucose level. Renal BH4 level and GTPCH I expression were increased in AKITA/Met compared with AKITA. Levels of phospho-AMPK, GTPCH I, and eNOS dimer were reduced in hGECs exposed to high glucose, but Met attenuated the alterations. UAE was significantly suppressed in GCHtg/AKITA. Exacerbated superoxide production and diminished bioavailable NO were noed in the glomeruli of AKITA. Biochemical analysis showed eNOS was uncoupled in AKITA. In GCHtg/AKITA, serum levels of BH4 were preserved and glomerular eNOS was re-coupled.

Conclusions: Preservation of endothelial GTPCH I expression by metformin and resultant improvement of BH4 biosynthesis prevented development of renal complications in diabetic milieu.

Fusion of Bone Marrow-Derived Cells with Renal Tubules Contributes to Renal Dysfunction in Diabetic Nephropathy Tomohisa Yamashita,[1] Mineko Fujimiya,[2] Satoshi Yamamoto,[1] Masayuki Koyama,[1] Yusuke Okazaki,[1] Shutaro Ishimura,[1] Marenao Tanaka,[1] Masato Furuhashi,[1] Hideaki Yoshida,[1] Tetsuji Miura.[1] *[1]2nd Department of Internal Medicine, Sapporo Medical University, Sapporo, Hokkaido, Japan; [2]2nd Department of Anatomy, Sapporo Medical University, Sapporo, Hokkaido, Japan.*

Background: We previously reported that in diabetes proinsulin-producing bone marrow-derived cells (BMDCs) appear in various organs and these cells undergo fusion with hepatocytes and neurons in the dorsal root ganglia. Fusion cells are polyploidy and produce tumor necrosis factor (TNF)-alpha, suggesting that diabetes reprograms gene expression in BMDCs by turning on ''inappropriate'' genes, ultimately causing diabetic complications. In this study, we assessed whether the same mechanism is involved in the DN.

Methods: We performed bone marrow transplant (BMT) from green fluorescent protein transgenic mice to C57BL/6J mice and produced diabetes by streptozotocin (STZ) or feeding a high-fat diet. Immunofluorescence staining and fluorescence in situ hybridization for Y-chromosome were performed and observed by confocal laser scanning microscopy.

Results: In the diabetic mice, massive infiltration of BMDCs occurred in the tubular interstitium, and tubular epithelial cell loss and basement membrane abnormality were prominent. The damaged tubular epithelial cells and BMDCs were positively stained with proinsulin and TNF-alpha. Cell fusion between BMDCs and renal tubules is confirmed by the presence of Y chromosome in female mice that received BMT from male mice. 15.4% of tubular epithelial cells contain Y chromosome in STZ-diabetic mice, 8.6% in HFD-diabetic mice, but only 1.5% in nondiabetic mice. In addition, some nuclei contain two Y chromosomes or a large single Y chromosome in STZ-diabetic mice.

Conclusions: This study demonstrated that diabetes causes nuclear fusion between BMDCs and renal tubular epithelial cells at more than 10-fold higher frequency than nondiabetic mice. Chromosomal abnormality induced by the cell fusion may play a crucial role in DN.

TH-PO530

Proximal Tubule Endocytosis by Kidney Injury Molecule-1 Mediates Early Diabetic Nephropathy Takaharu Ichimura,[1] Shan Mou,[2] Huiping Zhao,[1] Sheng Xiao,[2] Heung-Myong Woo,[1] Suetonia Palmer,[1] Craig R. Brooks,[1] Chang Wang,[1] Joel M. Henderson,[3] Vijay K. Kuchroo,[2] Joseph V. Bonventre.[1] *[1]Renal/Medicine, Brigham & Women's Hospital, Harvard Medical School, Boston, MA; [2]Center for Neurologic Disease, Brigham & Womens' Hospital, Boston, MA; [3]Pathology, Boston University Medical Center, Boston, MA.*

Background: Diabetes mellitus is the leading cause of end-stage renal failure. Although diabetic nephropathy (DN) is characterized by glomerulopathy and albuminuria, disease progression best correlates with tubular degeneration and interstitial fibrosis. Kidney Injury Molecule-1 (KIM-1), a scavenger receptor highly expressed by injured proximal tubule cells, is present in the urine of patients with DN and high levels are associated with progression of albuminuria.

Methods: The ability of KIM-1 to mediate uptake of advanced glycosylation end products (AGEs) was determined in kidney epithelial cells in culture. To study the effects of mouse Kim-1-mediated endocytosis on DN disease progression, diabetes was induced in normal mice and mice which contain a targeted mutation of the extracellular mucin domain which prevents endocytosis. DN was induced by combining streptozotocin injection, unilateral nephrectomy and high fat diet.

Results: High glucose levels enhanced Kim-1 expression in cultured kidney epithelial cells via a process that was reactive oxygen species dependent. Kim-1 augmented tubule cell uptake of AGEs and oxidized lipids, two components of the proximal tubular fluid in patients with diabetes mellitus. Mutant mice rendered diabetic developed less albuminuria, brush border loss and fewer interstitial myofibroblasts than normal mice. DN-associated glomerular enlargement, GBM thickening and sclerosis were also diminished by Kim-1 mutation. Kim-1 dependent ingestion of oxidized lipids and AGEs and enhanced caspase-3 activity was inhibited in primary tubule cells from Kim-1 mutant animals.

Conclusions: Kim-1 expression facilitates tubular injury in early DN by endocytic processes which trigger a proinflammatory response leading to interstitial fibrosis. These observations suggest Kim-1 as a novel drug target for prevention and treatment of DN.

TH-PO531

Diabetic Nephropathy (DN) in Insulin-Deficient Mouse Models: Longitudinal Functional & Ultrasonic Dumentation of Progressive Decline in Glomerular Filtration Rate (GFR) & the Role of Reduced Oxidative/ Nitrosative Stress in Metformin Renoprotection Jian Xu,[1] Meghan Pantalia,[1] Alexander Lau,[1] Bonnie Eby,[1] Chris Skaggs,[1] Shujie Yu,[1] Hongtao Liu,[1] Jian-Xing Ma,[2] Kai Lau.[1] *[1]Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]Physiology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Progress in DN research has been hindered by few models with renal failure (RF). In those showing RF, there are concerns of collateral damages or inaccurate GFR estimated by plasma inulin kinetics after bolus injection.

Methods: Here we measured GFR by renal clearance (C) of inulin (in) during steady-state infusion to document RF in male Ove 26 & Akita mice & study the mechanim of renoprotection by metformin. We profiled serial Ccre by HPLC & defined its utility & pitfalls.

Results: At 7 mon, Cin (in µl/min) fell in Ove 26 mice (225 vs. 401/mouse in control, 919 vs 1,319/100g body [B] weight [W], or 332 vs. 813 /g kidney [K]W). Ultrasound showed larger K volume (0.52 vs. 0.23 cc), which correlated (r=0.80) with heavier KW (845 vs. 510 mg). Chronic metformin prevented RF in Ove mice (Cin=404) & blocked the increases in nitrotyrosine-containing proteins in diabetic kidneys. Echogenicity was 24% higher in Akita at 10.5 mon, showing chronic scarring. Ccre (in µl/min), normal at 4 mon (436 vs. 468), showed hyperfiltration at 6 mon (1,477 vs. 581), normalized at 9 mon (672 vs. 717) but finally fell by 13 mon (240 vs. 700). RF was confirmed by reduced Cin (128 vs. 375/ mouse, 591 vs. 1,213/100g BW, or 256 vs. 941/g KW). Ccre correlated with Cin (r=0.8), gave similar estimates of GFR fall, but over-estimated GRF by 80 %.

Conclusions: 1. With chronicity, untreated Ove 26 & Akita diabetics develop renal failure like man, validating their utility in studying DN. 2. Metformin is renoprotective by reducing oxidative/nitrosative stress. 3. Analyzed by HPLC, Ccre separates diabetic from normal but over-estimates GFR by 80%. It defines the evolution from hyper- to hypo-filtration non-invasively & corroborates falls in GFR found by renal Cin. 4. Ultrasound identifies hypertrophy non-invasively & detects chronic scarring with disease progression.

Uremia-Induced Increases in Rodent Hepatic 11bHSD1 and Associated Excessive Gluconeogenesis Contributes to Insulin Resistance in Non-Diabetic Chronic Kidney Disease Ananda Chapagain, Julius Edward Kieswich, Steven Michael Harwood, Martin J. Raftery, Magdi Yaqoob. *Translational Medicine and Therapeutics, WHRI, London, United Kingdom.*

Background: Insulin resistance (IR) is common in chronic kidney disease (CKD). However the mechanism underlying this has yet to be elucidated. Abnormally elevated hepatic gluconeogenesis can cause hyperglycemia and hyperinsulinemia, secondary to upregulation of key gluconeogenic genes in particular phosphoenolpyruvate carboxykinase (PCK1), leading to elevated hepatic glucose production.

Methods: 11b-hydroxysteroid dehydrogenase type I (11bHSDI) catalyses intracellular conversion of the inactive glucocorticoid cortisone to active cortisol and promotes hepatic gluconeogenesis. We investigated the role of elevated hepatic 11bHSD1 in uremia-induced IR.

Rodent models of non-diabetic uremia were created using subtotal nephrectomy and adenine-induced uremia. Sham or uremic animals were gavaged with vehicle or carbenoloxone (CX)50mg/kg for two weeks. In separate experiments,insulin and glucose tolerance tests were perfomed in each of the groups and serum and organs harvested and snap-frozen for analysis.

Results: Uremic rats displayed hyperinsulinemia and abnormal glucose and insulin tolerance. This was associated with upregulation of 11bHSD1 and PCK1. Additionally, levels of the gluconeogenic coactivator PPARg co-activator 1alpha (PGC1a) were increased. Uremia was also associated with increased concentrations of plasma triglycerides, non-esterified fatty acids and cholesterol, alongwith elevated expression of key lipogenic genes; fatty acid synthase (FAS), acetyl CoA carboxylase (ACC), steroid-regulatory element binding protein-1c (SREBP1c), and 3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMGCR).Treatment with CX for two weeks corrected hyperinsulinemia, improved glucose tolerance and insulin sensitivity and reduced expression of PCK1 and PGC1a along with correction of dyslipidemia and expression of FAS, ACC, SREBP1 and HMGCR significantly.

Conclusions: Our results indicate that elevated expression of 11bHSD1 contributes to IR and dyslipidemia in uremia, and confirms 11bHSD1 inhibitors as a novel therapeutic target for management of IR in patients with CKD.

Inhibition of the p66 Longevity Gene Prevents Diabetic Nephropathy in Mutant Akita Diabetic Mice Himanshu Vashistha,[1,4] Pravin C. Singhal,[2] Ashwani Malhotra,[2] Surya V. Seshan,[3] Krzysztof Reiss,[4] Leonard G. Meggs.[1,4] *[1]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA; [2]Division of Nephrology, North Shore LIJ Health System, Great Neck, NY; [3]Department of Surgical Pathology, Weil Cornell Medical School, New York, NY; [4]Department of Medicine, LSUHSC, New Orleans, LA.*

Background: The absence of an experimental model that faithfully mimics diabetic nephropathy (DN) in humans, has been a major limitation in dissecting the pathobiology of DN and in identifying novel molecular targets for therapeutic intervention. The recent development of Akita (Ins2+/C96Y) diabetic mice, lacking the bradykinin 2 receptor (B2R-/-) is a significant advance, in that hyperglycemia (HG) is more durable and sustained , than with inbred strains requiring streptozotocin injection, with a disease phenotype that more closely approximates DN in humans.

Methods: The p66-/- mouse is the unique genetic model of increased resistance to oxidative stress, aging and apoptosis. To test if this loss of function mutation, will delay or prevent DN, p66 was deleted for the genome of mutant Akita diabetic mice, by homologous recombination with the genome of p66-/- mouse. RNAi was used to deliver p66shRNA to human podocytes, which were maintained under HG conditions.

Results: Triple mutant Akita (p66-/-/Ins2+/C96Y/B2R-/-) mice at 11-12 mo of age, show marked attenuation of mesangial sclerosis and tubular injury, with a striking reduction in urinary albumin excretion. Podocytes/glomerulus did not differ from non-diabetic wild type (wt) control mice, with minimum evidence of foot process effacement. In vitro studies, with human podocytes expressing p66shRNA show inhibition of HG-induced ROS production, local angiotensin II generation and apoptosis.

Conclusions: We speculate p66 is a target for therapeutic intervention in glomerular diseases, where ROS have been implicated in metabolic, inflammatory and toxic injury.

TH-PO534

Macrophage Liver X Receptor α Ameliorates Renal Lesions in Hyperlipidemic Diabetic Mice Eva Kiss, Mahnaz Bonrouhi, Katja Wagenblass, Hermann-Josef Groene. *German Cancer Research Center (DKFZ) Heidelberg.*

Background: Abnormal lipid metabolism and renal accumulation of lipids are pathophisiological cofactors of diabetic nephropathy. Liver X receptors (LXR) α and β are nuclear receptors activated by oxidized cholesterols. LXR/RXR heterodimers regulate genes linked to lipid and carbohydrate homeostasis and inhibit inflammatory gene expression in macrophages.

Methods: In this study the effects of systemic and macrophage specific LXR activation were analyzed on renal damage in hyperlipidemic diabetic mice. Diabetes was induced by streptozotozin in LDLR-deficient (LDLR-/-) mice on standard chow or western diet with or without the nonselective synthetic LXR-agonist, GW3965 for 20 weeks. The role of macrophage-LXRα mediated effects were analyzed in mice with macrophage overexpression of LXRa.

Results: Hyperglycemia and hyperlipidemia acted synergistically in inducing renal injury (mesangial matrix increase, podocyte damage, foam cell formation) and altering renal function. LXR activation by GW3965 inhibited significantly impairment of renal function by a 60% higher creatinine clearance, reduced glomerular and interstitial mononuclear cell infiltrate (Mac-2+, F4/80, CD3) and the number of interstitial myofibroblasts (αSMA+) by 40-50%. Renal expression of genes involved in cholesterol efflux (ABCA1, ABCG1) was upregulated concomitant with the downregulation of proinflammatory/ profibrotic cytokines (TNFα, TGFβ) and oxidative enzymes (Nox-2) in GW3965 treated hyperlipidemic diabetic mice. Overexpression of LXRα in macrophages was sufficient to significantly ameliorate hyperglycemia or/ and hyperlipidemia induced renal damage and albuminuria. *In vitro* in macrophages LXR activation by GW3965 or 25-OH-Cholesterol as well as LXRa overexpression significantly reduced the proinflammatory/ profibrotic activity (TNFα, MCP-1, collagen I) induced by glycated LDL.

Conclusions: LXR activation attenuated diabetic and hyperlipidemic renal lesions attesting to the potent regulatory role of these nuclear receptors in metabolic diseases.

Funding: Government Support - Non-U.S.

Renal Effects of Inhibiton of Toll like Receptor Signaling in Type-2 Diabetic Mice Jin Joo Cha,[1] Young Sun Kang,[1] Young Youl Hyun,[1] Mihwa Lee,[1] Jung Eun Kim,[1] Deok Hwa Nam,[1] Hye Kyung Song,[1] Ji Eun Lee,[2] Hyunwook Kim,[2] Sang Youb Han,[3] Kum Hyun Han,[3] Dae R. Cha.[1] *[1]Internal Medicine, Korea University Medical College, Ansan, Kyeonggido, Republic of Korea; [2]Internal medicine, Wonkwang University Medical College, Gunpo, Kyeonggido, Republic of Korea; [3]Internal Medicine, Inje University Medical College, Koyang, Kyeonggido, Republic of Korea.*

Background: Chronic inflammation caused by high concentration of glucose and free fatty acids (FFAs) is one of the major pathogenesis of type2 DM. Recent evidences suggest that the activation of toll-like receptor(TLR) signaling, which is involved in various innate immune responses, induces peripheral insulin resistance and mediates central insulin and leptin resistance. Present study was performed to investigate the renal effects of TLR signaling blockade in the diabetic mouse.

Methods: Eight-week old db/db mice were treated for 12 weeks with intraperitoneal GIT27, which targets the function of macrophages through inhibition of TLR4 and TLR2/6-mediated signaling pathways, at a dose of 20mg/kg/day. Another group of db/db mice were treated with control vehicle.

Results: GIT27 treated db/db mice showed decrease in HbA1c at 3months, improved glucose tolerance, lower lipid profile without impact on body weight and food consumption. GIT27 treatment also markedly decreased urinary albumin excretion(30.24±17.38 vs 6.88±10.50ug/d, p=0.02), decreased pro-inflammatory cytokine synthesis(IL-2, TNF-α, p<0.05), improved tissue lipid metabolism(cholesterol, triglyceride, lipid peroxidase level in the kidney, liver, fat tissue) and improved glomerulosclerosis compared to control db/db group. In cultured podocytes and adipocytes, high glucose with FFAs stimulation increased TLR4 expression and pro-inflammatory cytokines synthesis, which effects were abolished by GIT27 treatment.

Conclusions: In summary, GIT27 treatment improved insulin resistance, dyslipidemia and proteinuria in type 2 diabetic mice. These results suggest TLR pathway inhibition might have a direct protective role in diabetic kidney disease.

TH-PO536

Resveratrol Prevents Diabetic Nephropathy Via Activating the AMPK-SIRT1-PGC-1 Pathway in db/db Mice Sungjin Chung, Min-Young Kim, Ji Hee Lim, Hoon Suk Park, Byung Ha Chung, Hyun Wha Chung, Seok Joon Shin, Hyung Wook Kim, Yong-Soo Kim, Yoon-Sik Chang, Cheol Whee Park. *Division of Nephrology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea.*

Background: AMPK and SIRT1 play key roles in the regulation of lipid and glucose homeostasis and for controlling oxidative stress. Many of resveratrol's effects are consistent with the activation of SIRT1-AMPK-PGC-1α and the modulation of their targets, including PPARs and FoxOs. In this study, we sought to uncover the mechanism by which resveratrol affects diabetic nephroapthy.

Methods: The *db/db* and *db/m* mice were treated with or without resveratrol starting at 8 weeks of age for 12 weeks.

Results: The *db/db* mice treated with resveratrol had decreased albuminuria, and resveratrol ameliorated glomerular matrix expansion compared to the control *db/db* mice even under the same degree of hyperglycemia. Resveratrol decreased inflammatory cell infiltration and the intrarenal free fatty acid and triglyerides contents associated with increased phospho-Thr^{172} AMPK-SIRT1- PGC-1α signaling and activation of its key downstream effecters the PPARα- ERR-1α expressions. Furthermore, resveratrol decreased the activity of PI3K-Akt phosphorylation and FoxO3a phosphorylation, which resulted in a decrease of proapototic Bax and increases in the anti-apoptotic Bcl-2 and anti-oxidant SOD1 and SOD2 expressions in the *db/db* mice. Consequently, resveratrol reversed the diabetes-induced lipid accumulation in the kidney and the increased renal apoptotic cells and oxidative stress that is reflected by the serum 8-hydroxydeoxyguanosine (8-OH-dG) and the urinary 8-OH-dG and isoprostane levels.

Conclusions: Our results suggest that resveratrol prevents diabetic nephropathy in *db/db* mice by activation of AMPK-SIRT1-PGC-1α signaling, which results in prevention of lipotoxicity, apoptosis and oxidative stress in the kidney.

TH-PO537

CCR2 Inhibition in Diabetic Mice Results in a Rapid and Robust Improvement of Renal Function Tim Sullivan, Zhenhua Miao, Bin N. Zhao, Robert D. Berahovich, Lisa C. Seitz, Jay P. Powers, Linda Ertl, Shichang Miao, Ruiping Zhao, Ton Hy Dang, Shirley Liu, Pirow Bekker, Thomas J. Schall, Juan C. Jaen. *ChemoCentryx, Inc., Mountain View, CA.*

Background: Diabetic Nephropathy represents one of the major consequences of uncontrolled diabetes. The chemokine receptor CCR2 has been implicated in the recruitment of blood monocytes into kidney in response to hypertension and hyperglycemia. In addition, parenchymal renal cells are thought to upregulate CCR2 under those pathological conditions. We set out to assess the therapeutic benefit of CCR2 antagonism in a mouse model of diabetic nephropathy.

Methods: CCX417 (a small molecule CCR2 antagonist, analog of the clinical compound CCX140-B) was dosed daily to male db/db mice (age 12-19 weeks). Weekly assessments included body weight, fasting plasma glucose, serum clinical chemistry, and 24 hr urinary volume and output of albumin, creatinine and glucose.

Results: Treatment with CCX417 significantly reduced urinary albumin excretion (UAER) and albumin:creatinine ratio (ACR). Statistically significant improvements in UAER and urinary ACR were noted as early as 48 hours after initiation of CCX417 treatment. Serum markers of renal function were also improved after 14 days of CCX417 treatment: serum creatinine and blood urea nitrogen. The benefits seen on renal function preceded significantly reduced fasting plasma glucose levels. Significant reductions in urinary output were also seen with CCR2 antagonism.

Conclusions: Robust and rapid improvements of albuminuria, serum markers of renal function, and hyperglycemia were seen following pharmacological intervention with a small-molecule CCR2 antagonist in a rodent model of diabetic nephropathy. These results support the clinical evaluation of CCR2 antagonists, such as CCX140-B, for the treatment of diabetic nephropathy.

A Novel Role for Liver X Receptors in Diabetic Nephropathy Xiaoxin Wang,[1] Monika Patel,[2] Hannah Danielle Santamaria,[1] Weidong Wang,[1] Nathaniel L. Solis,[1] Liru Qiu,[1] Carolyn L. Cummins,[2] Moshe Levi.[1] *[1]university of colorado denver; [2]University of Toronto.*

Background: The liver X receptor (LXR) belongs to the nuclear receptor superfamily of ligand-activated transcription factors. Oxysterols and oxidized derivatives of cholesterol are endogenous ligands for LXR. Activation of LXR induces the transcription of genes involved in reverse cholesterol transport and prevents inflammation. We hypothesized that these properties of LXR agonists would make them useful in the modulation of diabetic nephropathy. However, certain LXR agonists also induce de novo fatty acid synthesis which may limit their efficacy. Recently, a novel LXR agonist N,N-dimethyl-3beta-hydroxy-cholenamide (DMHCA) has been developed that does not have undesirable lipogenic effects and therefore facilitates the exploration of LXR function in the diabetic kidney.

Methods: In this study we induced type 1 diabetes in western diet fed DBA/2J mice using multiple low dose streptozotocin injections and treated mice for 10-wk after diabetes was confirmed with the LXR agonist DMHCA at a dose of 80mg/kg body weight/day.

Results: We found that LXR agonist treatment improves proteinuria (DBA/Con: 123±26mg/mg; DBA/STZ: 286±41mg/mg; DBA/STZ/DMHCA: 137±22mg/mg; $p<0.01$), podocyte loss, mesangial expansion, and tubulointerstitial fibrosis. In addition LXR treatment prevented renal lipid accumulation, macrophage infiltration, inflammation, and oxidative stress. In contrast induction of diabetes in the LXR a/b double knockout mice resulted in exaggerated diabetic nephropathy characterized by increased urinary albumin and nephrin excretion, and increased inflammation and lipid accumulation.

Conclusions: These results therefore indicate a novel and an important role for LXR in modulation of diabetic nephropathy.

TH-PO539

Effect of Physical Exercise on Urinary Albumin and N-acetyl-β-glucosaminidase, and Podocyte Numbers in Diabetic KK-A^y Mice Yuji Ishikawa, Tomohito Gohda, Mitsuo Tanimoto, Keisuke Omote, Saori Yamaguchi, Masako Furukawa, Maki Murakoshi, Shinji Hagiwara, Yasuhiko Tomino. *Division of Nephrology, Department of Internal Medicine, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: Exercise is generally recommended for the management of type 2 diabetes, but its effects on diabetic nephropathy are still unknown. We hypothesized that appropriate physical exercise improves early diabetic nephropathy via attenuation of chronic inflammation and oxidative stress.

Methods: Type 2 diabetic KK-A^y mice, a spontaneous diabetic nephropathy model, underwent two different kinds of exercise for one hour five days a week (moderate intensity) and 30 minutes three days a week (low intensity) for 8 weeks. Sedentary mice or those undergoing exercise regimens causing no significant body weight loss were used. We examined the urinary excretion of albumin and N-acetyl-β-glucosaminidase (NAG), number of podocytes in glomeruli, renal expressions of hypoxia inducible factor (HIF)-1α and monocyte chemotactic protein (MCP)-1, and biomarkers of oxidative stress such as urinary 8-hydroxydeoxyguanosine (8-OHdG) and serum superoxide dismutase (SOD).

Results: Exercise reduced urinary albumin excretion and NAG, and also maintained the number of podocytes in the exercised KK-A^y mice independently of improvements of body weight and hyperglycemic status. However, the moderate-intensity exercise increased expression of HIF-1α in the kidneys. Sedentary KK-A^y mice showed increased expression of MCP-1 in the tubules, urinary 8-OHdG levels, and decreased serum SOD levels compared with exercised KK-A^y mice.

Conclusions: On the whole, low-intensity exercise attenuates progression of early diabetic nephropathy without affecting renal ischemia. Reductions in rates of urinary albumin change and urinary NAG, and maintained podocyte numbers, with parallel improvements in oxidative damage and chronic inflammation are related to the beneficial effects of exercise in diabetic kidney disease.

TH-PO540

Fractalkine/CX3CR1 Mediates Extracellular Matrix Accumulation in Diabetic Kidney Kyung Hee Song, Jehyun Park, Hunjoo Ha. *Department of Bioinspired Science, College of Pharmacy, Ewha Womans University, Seoul, Republic of Korea.*

Background: Fractalkine (FKN, CX3CL1) functions not only as a chemokine but also as an adhesion molecule and plays an important role in the recruitment of macrophages into the kidney through binding to its receptor CX3CR1. Previous studies have demonstrated that FKN/CX3CR1 play a role in ischemic and protein-overload renal injury. However, their role in diabetic renal injury and the mechanism involved in have not been clearly understood. This study examined whether FKN/CX3CR1 mediates diabetic stimuli-induced extracellular matrix (ECM) accumulation in the kidney.

Methods: Streptozotocin (STZ; 50 mg/kg/day) was intraperitoneally administered for 5 days in male CX3CR1 wild type (WT) and null C57BL/6J mice. Mouse mesangial cells (MMCs) transfected with siRNA for CX3CR1 were used to further elucidate the direct effect of FKN/CX3CR1 on ECM upregulation.

Results: At 12 weeks after the induction of diabetes, equivalent hyperglycemia was observed in diabetic WT and CX3CR1 null mice. However, parameters of diabetic renal injury including increased plasma creatinine, kidney to body weight ratio, glomerular volume, fractional mesangial area, urinary protein excretion, and accumulation of renal fibronectin, collagen, and macrophage were much less severe in diabetic CX3CR1 null mice than diabetic WT mice. In MMCs, 30 mM high D-glucose, 100 μM oleic acid, 10 ng/ml of transforming growth factor-β1 upregulated FKN and CX3CR1 mRNA and protein expression along with ECM expression, which was significantly attenuated by CX3CR1 siRNA. More importantly, FKN itself increased ECM synthesis in MMCs, and CX3CR1 siRNA abrogated FKN-induced ECM synthesis.

Conclusions: These results demonstrated that FKN/CX3CR1 may play an important role in diabetic renal injury through ECM upregulation, apart from macrophage infiltration, and suggest that FKN/CX3CR1 system may become an effective therapeutic target for the prevention of diabetic renal injury.

TH-PO541

Resveratrol Attenuates Diabetic Nephropathy by Modulating Angiogenic Factors Donghai Wen, Xinzhong Huang, Chuan-Ming Hao. *Division of Nephrology, Huashan Hospital, Fudan University, Shanghai, China.*

Background: Angiogenesis plays an important role in the pathogenesis and progression of diabetic nephropathy(DN). In the present study, we investigated the therapeutic potential of resveratrol, a natural polyphenol with anti-angiogenic activity, in DN.

Results: In a type 1 diabetic rat model induced by streptozocin, urine albumin excretion(13.81±1.25 *vs* 1.53±0.38mg/24h), kidney weight(2.26±0.11 *vs* 1.94±0.04g) and creatinine clearance rate(0.32±0.05 *vs* 0.09±0.02ml/min/100g body weight) were increased, and were suppressed by eight weeks treatment of resveratrol(6.55±0.57mg/24h;1.91±0.07g;0.18±0.03ml/min/100g body weight;respectively). Morphological studies revealed increased glomerular diameter, mesangium expansion, and glomerular basement membrane thickness in diabetic rats(211.67±14.05 *vs* 158.33±6.66nm), which were also reduced by resveratrol treatment(179.67±7.64nm). In addition, treatment of the diabetic rats with resveratrol significantly alleviated renal fibrosis detected by increased expression of fibronectin, PAI-1, CTGF, type IV collagen and TGF-β1. In the diabetic kidney, increased expression of VEGF, Flk-1 and angiopoietin 2, and reduced expression of Tie-2 were observed. Theses changes in angiogenic growth hormones and their associated receptors were attenuated by resveratrol treatment. No change in angiopoietin 1 expression was detected among each group of rats. In vitro, resveratrol significantly down-regulated high glucose-induced VEGF and Flk-1 expression in cultured mouse glomerular podocytes and endothelial cells, respectively. However, these effects of resveratrol were blacked by knocking-down silent information regulator 1(Sirt1) using RNA interference, consistent with a role of Sirt1 in mediating the effect of resveratrol. On the other hand, up-regulation of Sirt1 in cultured endothelial cells by transfecting the cells with Sirt1 plasmid reduced Flk-1 expression. Increased permeability and cellular junction disruption of cultured endothelial cells caused by VEGF were also inhibited by pretreatment with resveratrol.

Conclusions: Resveratrol may attenuate DN via modulating the angiogenesis system.

Funding: Government Support - Non-U.S.

TH-PO542

mTOR Regulates Nox4-Mediated Podocyte Loss in Diabetic Renal Injury Assaad Antoine Eid, Bridget M. Ford, Jeffrey L. Barnes, Yves C. Gorin, Goutam Ghosh-Choudhury, Hanna E. Abboud. *Medicine/Nephrology, University of Texas Health Science Center at San Antonio, TX.*

Background: Glomerular podocyte apoptosis represents a critical mechanism for excessive loss of urinary albumin that eventuates in kidney fibrosis. Pharmacological doses of the mTOR inhibitor rapamycin reduce albuminura in diabetes by unknown mechanism.

Methods: We explored the hypothesis that mTOR mediates podocyte injury in diabetes.

Results: High glucose (HG) induces apoptosis of cultured podocytes and increases the levels of Nox4 and NADPH oxidase activity. HG also inhibits the phosphorylation of AMPK on the activating site Thr^{172}, increases the phosphorylation of tuberin on its inactivating sites Thr^{1462}. HG also activates mTOR and enhances the phosphorylation of its substrate S6 kinase. Inhibition of mTOR by low doses of rapamycin prevents HG–induced expression of Nox4, NADPH oxidase activity and podocyte apoptosis. Inhibition of mTOR had no effect on AMPK or tuberin phosphorylation indicating that mTOR is downstream of these two signaling molecules. In isolated glomeruli of OVE26 type 1 diabetic mice, there is similar decrease in the phosphorylation/activation of AMPK, enhanced phosphorylation of tuberin on the inactivating site Thr^{1462} and activation of mTOR and S6 kinase together with increase in Nox4 and NADPH oxidase activity. Inhibition of mTOR by low and clinically relevant doses of rapamycin reduces podocyte apoptosis, glomerular basement membrane thickening and attenuates albuminuria.

Conclusions: Our data provide evidence for understanding a novel function of mTOR in Nox4-derived ROS generation and podocyte apoptosis that contribute to urinary albumin excretion in type 1 diabetes. Thus mTOR inhibition may represent a therapeutic modality of diabetic kidney disease.

Increased Plasma Glucose and Reduced Albuminuria in AMP-Activated Protein Kinaseβ1 Null Mice with Streptozotocin-Induced Type 1 Diabetes
Suet-Wan Choy,[1,2] Scott Andrew Fraser,[1] Kurt Gleich,[1] Peter F. Mount,[1,2] David A. Power.[1,2] *[1]Nephrology, Austin Health, Heidelberg, Victoria, Australia; [2]Medicine, Austin Health, University of Melbourne, Heidelberg, Victoria, Australia.*

Background: Aim: To determine the effect of type 1 diabetes on glucose metabolism and kidney function in mice lacking the metabolic regulating kinase AMP-activated protein kinase (AMPK).

Methods: Background: AMPK is a master metabolic regulator considered to have an important role in development of insulin resistance. In order to determine whether AMPK might play a role in glucose metabolism in the absence of insulin, we induced diabetes in mice lacking the β1 subunit of AMPK (AMPKB1 -/- mice).

Type 1 diabetes was induced by 5 i.p. injections of streptozotocin (STZ). Mice were sacrificed at 4 weeks post-injection.

Results: There was a significant increase in plasma glucose in AMPKβ1-/- mice at days 28 compared with WT controls (e.g. day 28, 31.1+8.0 vs 20+8.8 mmol/L, $p<0.05$). Insulin concentrations were similar in both groups. Plasma adiponectin was reduced in AMPKβ1-/- mice compared with WT ($p<0.05$), but was similar in the diabetic mice groups. Despite the difference in plasma glucose, diabetic AMPKβ1-/- mice had less albumin excretion than WT at 28 days (ACR 64.7+11.8 vs 34.2+9.5 mg/mmol, $p<0.001$). Creatinine clearance was unchanged. Kidneys from diabetic AMPKβ1-/- mice also had less α-smooth muscle actin accumulation than diabetic wild type controls by Western blot ($p<0.01$) but no difference in TGF-β1 mRNA expression. Administration of the AMPK activator metformin 600 mg/kg to diabetic C57Bl/6 mice for the last 7 days of the STZ model was associated with significantly increased albumin excretion (ACR 63.4±20.6 vs 94.8±26.4 mg/mmol, $p<0.05$) but no change in plasma glucose.

Conclusions: These studies confirm that AMPK contributes to glucose homeostasis independent of any effect on insulin signaling. Within the kidney, reduced AMPK signaling was associated with less albuminuria and markers of fibrosis. The data suggest that anti-diabetic drugs which activate AMPK, such as metformin and the glitazones, may have deleterious effects on kidney survival in diabetes.

Translational Regulation of microRNA-192/194 by Transforming Growth Factor Beta 1 in Chronic Kidney Disease
Robert H. Jenkins, John Martin, Aled O. Phillips, Timothy Bowen, Donald Fraser. *Institute of Nephrology, Cardiff University, Cardiff, Wales, United Kingdom.*

Background: Tubulointerstitial fibrosis is a key determinant of CKD and epithelial-to-mesenchymal transition (EMT) of proximal tubular epithelial cells (PTC) by transforming growth factor beta 1 (TGF) is integral to this process. We have linked changes in expression of microRNAs, notably miR-192, to EMT in diabetic nephropathy. miR-192 is also important in renal electrolyte transport and cell cycle control. The role of miR-192 in kidney disease is complex, with increased and decreased miR-192 expression linked to adverse outcome in various patient groups and animal models. A limitation to our current knowledge is the regulation of miR-192. Previously, we demonstrated the transcriptional co-regulation of miR-194-2/192 and repression by TGF. The purpose of the current study was to identify factors regulating transcription.

Methods: An in vitro study in PTC using RT-qPCR, luciferase reporter constructs, EMSA, and siRNA knockdown.

Results: Analysis of the miR-194-2/192 promoter identified binding sites for hepatocyte nuclear factor 1 (HNF1) and tumor suppressor p53. Analysis of RNA from 20 human tissues detected miR-192/194 expression in a subset of epithelial tissues, including intestine, kidney and liver. HNF1A/B expression was also restricted to the same subset of tissues, while p53 was ubiquitously expressed. RT-qPCR demonstrated decreased HNF1A/B mRNA expression in response to TGF, but there was no change in p53. Transcription factor binding to both HNF1 and p53 sites in the miR-194-2/192 promoter was detected by EMSA. Specificity was confirmed using probes incorporating point mutations to the key residues within each binding site. Supershift analysis confirmed binding of HNF1A/B. Binding to the HNF1 site decreased in response to TGF, while binding to the p53 site remained constant. Reporter constructs with mutations to the HNF1 or p53 binding sites abolished promoter activity. siRNA knock down of HNF1 resulted in decreased miR-192/194 expression.

Conclusions: These data identify a requirement for p53 and HNF1 to enable miR-192/194 expression in PTC. TGF repression is mediated via a decrease in HNF1A/B binding to the promoter.

Physiological Levels of Endostatin Suppress Glomerular Vascular Leak and Inflammation in Diabetic Nephropathy
Yuki Udagawa,[1] Ryota Kimura,[1] Nobunori Satoh,[1] Yoshihiko Ueda,[2] Osamu Yokosuka,[3] Makoto Ogawa,[4] Yuki Hamano.[4] *[1]Clinical Education and Research, Graduate School of Pharmaceutical Sciences, Chiba University; [2]Pathology, Dokkyo Medical University Koshigaya Hospital; [3]Medicine and Clinical Oncology, Graduate School of Medicine, Chiba University; [4]Nephrology, Chiba University Hospital, Japan.*

Background: Disruption of angiogenesis balance to favor enhanced angiogenesis represents a key step in a number of pathological disorders. The potential role of physiological levels of endogenous inhibitors of angiogenesis is poorly understood in diabetic nephropathy. Collagen XVIII (Col18) is a component of highly specialized extracellular matrix associated with basement membranes of epithelia and endothelia. Proteolytic cleavage within its C-terminal domain releases a fragment, endostatin, which has anti-angiogenesis effects. Streptozotocin (STZ) has been commonly used to induce hyperglycemic diabetes and its toxicity leads to vascular injury and inflammation. The aim of this study is to investigate the effect of endogenous endostatin on early vascular leak and inflammation in the kidney of STZ-induced hyperglycemic mice.

Methods: Diabetic nephropathy was induced in Col18/endostatin-null (KO) and wild-type (WT) mice by injection of STZ. Animals injected with citrate buffer only served as controls. At 14 weeks, blood and urine samples were collected and mice were sacrificed to obtain tissues for histological study.

Results: In contrast to animals only injected with citrate buffer, mice that received STZ developed hyperglycemia. No differences in the degree of hyperglycemia and blood pressure were seen between diabetic KO and WT mice. Albuminuria and mean glomerular volume were significantly increased in diabetic KO mice compared to diabetic WT mice. Lack of endostatin led to increased macrophage accumulation, expression of MCP-1 and TNF-α, but not of VEGF, and number of $CD31^+$ blood vessels in the kidney of diabetic mice. $CD31^-CD34^+$ cells were also observed in the glomerulus from diabetic KO mice.

Conclusions: Physiological levels of endostatin, a fragment of collagen XVIII, can serve as a suppressor of renal angiogenesis and inflammation in early stages of diabetic nephropathy.

Angiotensin II Type II Receptor (AT_2R) Deficiency Accelerates the Development of Nephropathy in Type I Diabetes Via Oxidative Stress and ACE2
Shiao-Ying Chang,[1] Yun-Wen Chen,[1] Isabelle Chenier,[1] Julie R. Ingelfinger,[2] Shao-Ling Zhang.[1] *[1]CRCHUM-Hotel Dieu, University of Montreal, QC, Canada; [2]Pediatric Nephrology Unit, Massachusetts General Hospital, Boston, MA.*

Background: Since the functional role(s) of angiotensin II (Ang II) type II receptor (AT_2R) in type I diabetes is unknown, we hypothesized that AT_2R is involved in decreasing the effects of type I diabetes on the kidneys.

Methods: We induced diabetes with low-dose streptozotocin (STZ) in both AT_2R knock-out (AT_2R KO) and wild type (WT) male mice aged 12 weeks and followed them for 4 weeks. Three subgroups [non-diabetic, diabetic and insulin-treated diabetic (Rx insulin implant)] were studied. Systolic blood pressure (SBP), physiological parameters, glomerular filtration rate (GFR), renal morphology, gene expression and apoptosis were assessed.

Results: After 4 weeks of diabetes, compared to WT controls, AT_2RKO mice clearly developed features of early diabetic nephropathy (DN), such as renal hypertrophy, tubular apoptosis, and progressive extracellular matrix (ECM) protein accumulation as well as increased GFR. AT_2RKO mice presented hypertension unaffected by diabetes. Renal oxidative stress (measured as heme oxygenase 1 (HO-1) gene expression and reactive oxygen species (ROS) generation) and intrarenal renin angiotensin system components, such as angiotensinogen (Agt), AT_1R and angiotensin-converting enzyme (ACE) gene expression, were augmented whereas angiotensin-converting enzyme-2 (ACE2) gene expression was decreased in renal proximal tubules (RPTs) of AT2RKO mice. The renal changes noted above were significantly enhanced in diabetic AT_2RKO mice, but attenuated in insulin-treated diabetic WT and AT_2RKO mice. The renal changes noted above were significantly enhanced in diabetic AT_2RKO mice, but partially attenuated in the insulin-treated diabetic WT and AT_2RKO mice.

Conclusions: AT_2R deficiency accelerates the development of DN, which appears to be is mediated, at least in part, via heightened oxidative stress and ACE/ACE2 ratio in RPTs.

The Protective Role of miR-29 in Diabetic Kidney Disease: Mechanism and Therapeutic Potential Haiyong Chen,[1] Xiang Zhong,[2] Xiao Ru Huang,[3] Xiaoming Meng,[1] Hui Y. Lan.[1,3] *[1]Department of Medicine & Therapeutics, Chinese University of Hong Kong, Hong Kong, China; [2]Department of Chemical Pathology, Chinese University of Hong Kong, Hong Kong, China; [3]Li Ka Shing Institute of Health Sciences, Chinese University of Hong Kong, Hong Kong, China.*

Background: TGF-β/Smad signaling plays a vital role in renal fibrosis including diabetic nephropathy (DN). However, general blockade of TGF-β signaling may promote renal inflammation. Thus, identification of TGF-β/Smad3-dependent miRNAs related to fibrosis may be the key step towards to develop specific therapy for DN. We have previously shown that miR-29 is TGF-β/Smad3-dependent miRNA in renal fibrosis, thus, we hypothesized that miR-29 may have therapeutic potential for diabetic kidney.

Methods: miR-29 expression and diabetic kidney injury was examined in db/db mice. The therapeutic effect of miR-29 on diabetic kidney disease was determined by delivering a Dox-inducible miR-29 to 10-week db/db mice using an ultrasound-microbubble-mediated-technique. The regulating mechanisms of miR-29 under diabetic conditions was investigated in tubular cells lacking Smad2 or Smad3 and in a stable mesangial cell line with Dox-inducible miR-29 overexpression and knockdown.

Results: In db/db mice, miR-29 was reduced by 60% over the 20 week time, which was associated with a marked increase in TGF-β/Smad3 signaling, renal fibrosis (collagen I, IV), and microabluminuria (all $p<0.01$). Ultrasound-mediated gene therapy restored normal levels of miR-29 in db/db mice, resulting in inhibition of diabetic kidney injury as described above (all $p<0.01$). In vitro, addition of AGEs induced a loss of miR-29 (60%↓) and increased collagen I & IV(all $p<0.01$), which was further significantly enhanced in miR-29 knockdown mesangial cells, but blocked in cells overexpressing miR-29. Moreover, we found that AGEs-downregulated miR-29 expression was Smad3-depedent, but not Smad2.

Conclusions: miR-29 is lost in the diabetic kidney of db/db mice and is mediated by TGF-β/Smad3. Overexpression of miR-29 is able to attenuate diabetic kidney disease in db/db mice and in vitro under diabetic conditions. Thus, miR-29 may represent a novel therapy for diabetic kidney complication.

Spironolactone Diminishes Urinary Albumin Excretion in Type 1 Diabetic Patients with Microalbuminuria: A Randomized Placebo-Controlled Crossover Study Stine Nielsen,[1] Frederik I. Persson,[1] Erik Frandsen,[4] Takeshi Sugaya,[2] Dietmar Walter Zdunek,[5] Katrine Jordan Pedersen,[1] Hans-Henrik Parving,[3] Peter Rossing.[1] *[1]Steno Diabetes Center; [2]Riken Kobe Institute, Japan; [3]University Hospital of Copenhagen, ; [4]Glostrup Hospital; [5]Roche Diagnostics.*

Background: It has been shown, that adding the aldosterone receptor blocker spironolactone to standard renoprotective treatment, including renin-angiotensin-aldosterone system (RAAS) blockade in diabetic patients, may provide additional renoprotection. These studies have mainly been done in overt diabetic nephropahy. We examined the early renoprotective effect of spironolactone on markers of glomerular and tubular damage in type 1 diabetic patients with microalbuminuria.

Methods: We performed a double-blind, randomized, placebo controlled, crossover study with microalbuminuria using spironolactone 25 mg or placebo once daily for 60 days, added to optimal antihypertensive treatment including RAAS blockade.

After each treatment period, endpoints were evaluated: urinary(u)-albumin excretion/24hour(h), 24h blood pressure, glomerular filtration rate (GFR) and markers of tubular damage: urinary liver-type fatty-acid binding protein (LFABP), neutrophil gelatinase associated lipocalin (NGAL) and kidney injury molecule 1 (KIM1).

Results: All patients completed the study. During spironolactone treatment, u-albumin excretion was reduced with 60% (21-80) from 90 mg/24h to 35mg/24h when compared with placebo ($p=0.01$). Blood pressure (24h) did not change during spironolactone treatment ($p>0.2$ for all comparisons), and GFR decreased from 78(8) to 72(6) mL/min/1.73m^2 ($p=0.003$). The tubular markers u-LFABP, u-NGAL and u-KIM1 did not change during treatment ($p>0.3$ for all comparisons). Treatment was well-tolerated, two patients had severe hyperkaliemia (plasma potassium=5.7 mmol/L), which were treated with diuretics and dietary intervention.

Conclusions: Spironolactone treatment on top of standard renoprotective treatment lowers urinary albumin excretion in microalbuminuric patients with type 1 diabetes, and thus may offer additional renoprotection independent of blood pressure.

TH-PO549

Prostaglandin E2 EP1 Receptor and Its Role in the Development of Diabetic Albuminuria Jean-Francois Thibodeau,[1,2] Anthony Carter,[2] Chris R. Kennedy.[2] *[1]Cellular & Molecular Medicine, University of Ottawa, Canada; [2]Ottawa Hospital Research Institute, Ottawa.*

Background: Inhibition of cyclooxygenase (COX)-derived prostaglandin (PG) synthesis reduces albuminuria in diabetic nephropathy (DN). However the specific PG receptor(s) targeted by such inhibition have not been well defined. We hypothesized that one such receptor-the PGE2 EP1 receptor, contributes to the pathogenesis of albuminuria in DN.

Methods: To test this hypothesis, gene-targeted EP1-null male mice (EP1$^{-/-}$), on an FVB/N background were subjected to a low-dose streptozotocin (stz) model of type 1 diabetes (5 day i.p., 50 mg/kg bw; Na-citrate as vehicle) and studied for 16 weeks. Blood pressures were obtained by tail cuff plethysmography while glomerular filtration rate was measured by FITC-inulin clearance. Albuminuria was determined by ELISA of 24 h urine collections. Kidney fibronectin, megalin and cubilin expression were assessed by immunoblot and immunohistochemistry.

Results: The onset of diabetes had no impact on systolic blood pressure, yet both WT-stz and EP1$^{-/-}$-stz groups became equivalently hyperglycemic (>35 mM) and were hyperfiltering to similar degrees at 16 weeks (WT-stz, 26.1 ± 3.5 vs. WT, 10.3 ± 2.1 µl.min^{-1}.g.bw^{-1}, $p<0.01$; EP1$^{-/-}$-stz, 28.6 ± 3.9 vs. EP1$^{-/-}$, 11.1 ± 2.5 µl.min^{-1}.g.bw^{-1}, $p<0.01$). Renal fibronectin levels increased in WT-stz mice but not in EP1$^{-/-}$-stz mice (WT, 0.809 ± 0.08 vs WTstz, 2.06 ± 0.21; EP1$^{-/-}$ 1.33±0.23 vs. EP1$^{-/-}$stz 1.33 ±0.075 a.u., $p<0.01$). Importantly, albuminuria was significantly reduced in EP1$^{-/-}$-stz mice at 16 weeks (WT-stz, 1546 ± 282 vs EP1$^{-/-}$stz, 526 ± 110 µg/24hours, $p<0.001$, n=7-11). Lastly, immunodetectable megalin but not cubilin expression was decreased significantly in WT-stz mice – while levels were preserved in EP1$^{-/-}$-stz mice (WT, 1250 ± 193 vs WTstz, 769 ± 81; EP1$^{-/-}$, 1242± 209 vs. EP1$^{-/-}$stz, 1416± 252 a.u., $p<0.05$, n=4-6).

Conclusions: These findings suggest that the PGE2 EP1 receptor contributes to early DN-induced albuminuria. Despite similar indices of gross glomerular damage, the mechanisms underlying this effect may be due to subtle injury to the filtration barrier along with altered post-glomerular megalin-mediated albumin processing by the proximal tubule.

TH-PO550

Conditional Ablation of Macrophages Ameliorates Diabetic Nephropathy Alaa S. Awad. *Medicine, Penn State College of Medicine, Hershey, PA.*

Background: Monocyte/macrophage recruitment correlates strongly with the progression of renal impairment in diabetic nephropathy (DN). However, the direct role of macrophages and/or macrophage/podocyte interaction in DN is not known. We hypothesize that macrophages contribute to direct podocyte injury and/or abnormal podocyte niche leading to DN.

Methods: Experiments were conducted in CD11b-DTR mice treated with diphtheria toxin (DT) or vehicle (mutant DT) following streptozotocin (STZ) induced diabetes.

Results: We first established a dose, route and time response curves of DT in CD11b-DTR mice and we were able to chronically deplete kidney macrophages but not B cells, T cells or neutrophils.

We further demonstrated that macrophage depletion using DT in diabetic CD11b-DTR mice significantly attenuated diabetic albuminuria to normal range (5-fold reduction; $p<0.05$) compared to diabetic CD11b-DTR mice treated with vehicle despite comparable blood glucose levels after 6 wks of diabetes.

Vehicle-treated diabetic CD11b-DTR mice showed significant increases in kidney macrophages ($p<0.05$) compared with control mice using Mac-2 staining and flow cytometry and was associated with an early phase of increased M1/M2 macrophages followed by a late phase of increased M2/M1 macrophages. In contrast, kidney macrophages in DT-treated diabetic CD11b-DTR mice were similar to control mice.

In vitro, we demonstrate that podocytes grown on high glucose media are associated with significant increase ($p<0.005$) in macrophage migration from those grown in normal glucose media using transwell migration assay and this effect was completely blocked with the addition of anti-MCP-1 antibody. In addition, classically activated M1 macrophages ($CD11b^+LY6C^+LY6G^-TNF\text{-}^{high}IL\text{-}10^{low}CD206^{low}$); but not alternatively activated M2 macrophages ($CD11b^+LY6C^+LY6G^-TNF\text{-}\alpha^{low}IL\text{-}10^{high}CD206^{high}$) induced podocyte permeability *in vitro*.

Conclusions: These findings provide evidence that macrophages directly induce diabetic renal injury; mainly by altering podocyte permeability through the pro-inflammatory M1 but not the anti-inflammatory M2 subsets.

Attenuating the deleterious effect of macrophages on podocytes could provide a new therapeutic approach to the treatment of DN.

TH-PO551

Fenofibrate Ameliorates Diabetic Nephropathy Via Inhibiting the Canonic Wnt Pathway Rui Cheng, Xuemin He, Ti Zhou, Ying Chen, Jian-Xing Ma. *Department of Physiology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Recent clinical and animal studies have reported that Fenofibrate, a ligand of peroxisome proliferator-activated receptor-α (PPARα), has a protective effect against diabetic nephropathy. However, the underlying mechanism is not clear. Recently, we have demonstrated that aberrant activation of the canonical Wnt pathway plays a pathogenic role in diabetic retinopathy and nephropathy. The objective of the present study is to investigate whether Fenofibrate ameliorates diabetic nephropathy by inhibiting the canonical Wnt pathway.

Methods: Diabetes was induced in rats by one single intraperitoneal injection of Streptozotocin. Diabetic rats were fed with standard chow diet or chow diet containing Fenofibrate. Renal function was evaluated by measuring the urine albumin level and levels of collagenIV, ICAM-1, TNF-α and CTGF. Primary human renal proximal tubular epithelial cells (HRPTCs) were co-treated with high glucose and different concentrations of Fenofibrate. The levels of LRP6, a key co-receptor of Wnt ligands, β-catenin, an essential effector of the Wnt pathway, and CTGF, a target gene of the Wnt pathway, were determined by Western blot analysis.

Results: Fenofibrate treatment reduced albuminuria, decreased collagen IV accumulation and attenuated ICAM-1 and TNF-α expression in the kidneys of diabetic rats, demonstrating protective effects against diabetic nephropathy. Fenofibrate decreased renal levels of LRP6 and β-catenin in the diabetic rats. In HRPTCs, levels of phosphorylated LRP6, β-catenin and CTGF were significantly up-regulated by high glucose, and Fenofibrate attenuated the increases in a concentration- and time- dependent manner.

Conclusions: These results suggest that PPARα has a regulatory role in Wnt signaling, and the protective effect of Fenofibrate against diabetic nephropathy is, at least in part, through inhibiting the canonical Wnt pathway.

TH-PO552

Early Outgrowth Bone Marrow Cells Attenuate Renal Injury and Dysfunction Via a Novel Antioxidant Mechanism in Type 2 Diabetes Yanling Zhang, Darren A. Yuen, Andrew Advani, Kim Connelly, Richard E. Gilbert. *St. Michael's Hospital, Toronto, Canada.*

Background: Despite RAS blockade and antihypertensive therapy, diabetic nephropathy remains the commonest cause of ESRD. While bone marrow derived cells potentially provide a new therapeutic strategy, most experimental studies have been undertaken using healthy donor cells. In the clinical setting, however, the dysfunction of autologous cells from patients with diabetic nephropathy may limit their effectiveness. Accordingly, we assessed the therapeutic efficacy of donor cells derived from both healthy and diabetic animals, delivered to a mouse model of diabetic nephropathy.

Methods: db/db mice were randomized to receive a single intravenous injection of PBS or 0.5 x 10^6 early outgrowth cells (EOCs) cultured from the bone marrow of db/m mice (non-diabetic) or db/db (diabetic) mice. Outcome parameters including mesangial expansion, glomerular hypertrophy, tubular apoptosis and oxidative stress were assessed 4 weeks after cell infusion.

Results: Untreated db/db mice developed mesangial matrix expansion and tubular epithelial cell apoptosis in association with increased reactive oxygen species (ROS) and thioredoxin interacting protein (TxnIP), a negative regulator of the key thiol-reducing enzyme, thioredoxin. EOCs derived from both diabetic and non-diabetic mice were equally effective. Without affecting blood glucose and blood pressure, EOCs not only attenuated both mesangial and peritubular matrix expansion, as well as tubular apoptosis, but also diminished ROS and TxnIP over expression in the kidney of db/db mice (all $p<0.05$). Consistent with a so-called endothelial progenitor type profile, analysis of cell surface markers revealed that EOCs were CD34 and VEGFR2 positive.

Conclusions: This study shows firstly that EOCs from both healthy and diabetic donors preserve kidney structure and function in experimental diabetic nephropathy in association with modulation of oxidative stress. The equally beneficial effects of cells from healthy and diabetic donors highlight the potential of autologous cell therapy in the clinical setting of diabetic nephropathy.

The Role of Growth Differentiation Factor 15 in Streptozotocin Induced Diabetes in Mice Magdalena Mazagova, Maaike Goris, Robert H. Henning, L.E. Deelman. *Clinical Pharmacology, University Medical Center Groningen, Groningen, Netherlands.*

Background: Growth differentiation factor 15 (GDF15), a distant TGF-beta family member, is an early response gene up-regulated after induction of diabetes. Futhermore, GDF15 has recently emerged as an promising biomarker in patients with cardiovascular dysfunction and in patients suffering from type I and II diabetes. In this study, we investigated whether genetic deletion of GDF15 modulates initiation of renal damage in early experimental diabetes.

Methods: The study was performed in wt male mice and male GDF15 knockout mice. Mice were made diabetic by repeated injections with a low dose of streptozotocin (STZ 50mg/kg i.p. for 5 days). A group of healthy mice served as control. Mice were sacrificed, one and two weeks after the last STZ injection. For biochemical analyses, urine and blood samples were collected. Kidney sections were frozen for isolation of mRNA and protein. Remaining kidney sections were fixed in paraformaldehyde and examined by immunohistochemistry.

Results: Injection with 50 mg/kg STZ resulted in similar elevated blood glucose levels in GDF15 ko and wt mice (ko day 7: 21.4+/-2.7mM, ko day 14: 20.5+/-3mM, wt day 7: 19.4+/-2.4mM, wt day 14: 19.9+/-1.3mM,). GDF15 ko mice showed more renal pre-fibrosis (SMA) than wt mice after two weeks of diabetes (GDF15 ko day 14: 292.6+/-22.5%, wt day 14: 184+/-17.3%). GDF15 ko mice demonstrated higher renal expression levels as of day 7 for Collagen1 (5.8+/-1.2, $P<0.05$), KIM-1 (23.1+/-4.3, $P<0.05$), ICAM (3.14+/-0.4, $P<0.05$), compared to wt mice renal expression of Collagen1 (2.1+/-0.4), KIM-1 (6.1+/-1.8), ICAM (1.7+/-0.2). Furthermore, GDF15 ko showed increased urine volume, increased food intake and elevated urinary glucose loss compared to wt.

Conclusions: Our study demonstrates that genetic deletion of GDF15 augments renal damage, indicating that GDF-15 is a protective factor in the early initiation of diabetic kidney disease.

Application of Self-Fabricated mRNA Array To Detect Urinary Gene Expression Profiling in Patients with Diabetic Nephropathy Min Zheng, Linli Lv, Bi-Cheng Liu. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiangsu, China.*

Background: The initiation and progression of diabetic nephropathy (DN) is complex which involves multiple mechanisms. Quantification of mRNA expression in urinary sediment has emerged as a novel strategy for studying renal diseases. It might be a promising approach for searching new biomarkers with DN by screening related gene expression in urine sediment. Considering the numerous molecules involved in DN development, a high-throughput platform with parallel detection of multiple genes is needed. In this study, we applied a high-throughput mRNA array to analyze urinary mRNAs in patients with DN.

Methods: A total of 9 subjects including 6 DN patients and 3 normal controls were studied. These patients with DN were assigned into two groups according to their urinary albumin excretion (UAE): group A (UAE>300 mg/g, n=3) and group B (30≤UAE≤300 mg/g, n=3)Potential molecules which may be involved in the pathogenesis and progression of DN were selected as the target mRNAs. mRNA array containing 88 genes were fabricated. The target mRNAs included tubular injury markers (n=9), epithelial-to-mesenchymal transition markers (n=12), podocyte markers (n=10), cytokines (n=28), extra-cellular matrix (n=6), signal pathway (n=19) and RAS system (n=4). Urinary cell pellet was collected from each study participant. Relative abundance of these target mRNAs from urinary pellet was quantified.

Results: A total of 30 mRNAs were significantly increased in DN patients compared with normal controls ($p<0.05$). Among these genes, α-actin4, CDH2, ACE, FAT1, synaptopodin, COL4α, twist, NOTCH3 mRNA expression were 15-fold higher than those in normal controls. In contrast, urinary TIMP-1 mRNA was significantly decreased in DN patients ($p<0.05$). It was shown that CTGF, MCP-1, PAI-1, ACE, CDH1, CDH2 mRNA varied significantly among the 3 study groups, and their mRNA levels increased with DN progression ($p<0.05$).

Conclusions: Our results suggested that mRNA array could serve as a high-throughput and sensitive tool for detecting mRNA expression in urinary sediment, which might be useful in searching new biomarkers for diabetic nephropathy.

The Effect of Oral Anti-CD3 Antibody on Lipid Metabolism and Diabetic Nephropathy in db/db Mice Hyunwook Kim,[1] Jin Joo Cha,[2] Mihwa Lee,[2] Hye Kyung Song,[2] Deok Hwa Nam,[2] Jung Eun Kim,[2] Young Youl Hyun,[2] Ji Eun Lee,[1] Sang Youb Han,[3] Kum Hyun Han,[3] Young Sun Kang,[2] Dae R. Cha.[2] *[1]Division of Nephrology, Department of Internal Medicine, Wonkwang University College of Medicine Sanbon Hospital, Gunpo-si, Korea; [2]Division of Nephrology, Department of Internal Medicine, Korea University College of Medicine Ansan Hospital, Ansan-si, Korea; [3]Division of Nephrology, Department of Internal Medicine, Inje University College of Medicine Ilsan Baik Hospital, Goyang-si, Korea.*

Background: Recent advances revealed an emerging prominent role of different T lymphocytes from adaptive immunity in obesity-related adipose tissue inflammation. Oral anti-CD3 antibody, as an inducer of regulatory T cell, was recently reported to ameliorate inflammatory milieu in diabetes. Therefore, we asked whether oral anti-CD3 antibody has beneficial effects on progression of kidney disease in diabetic db/db mice.

Methods: Eight-week old db/db mice were divided into control and treatment group administered with 5-consecutive day treatment of oral anti-CD3 antibody. After 12-week study period, mice were killed for analyses.

Results: 2 days after the completion of 5-consecutive day treatment, we found a significant increase both in CD4+CD25-LAP+ and CD4+CD25+FoxP3+ regulatory T cells in spleen of treated animals compared with control. Over 12-week study period, while there were no significant differences in insulin resistance status or blood glucose levels, the treated animals showed significantly improved serum cholesterol and triglyceride levels as well as gained less cholesterol and triglyceride accumulation in both kidney and liver. In addition, lipid hydroperoxide levels in the kidney, adipose tissue, and liver were significantly suppressed and urinary levels of inflammatory cytokines such as IL-2, IL-1β, and TNF-α and 8-isoprostane were also reduced in treated animals. Furthermore, we found a significant decrease in urinary protein excretion and the preservation of renal histologic changes in the treated animals.

Conclusions: Thus, our results suggest that oral anti-CD3 antibody treatment has a protective role in progression of diabetic kidney disease possibly via regulatory T cell modulation.

TH-PO556

Early Kidney Response to Diabetes Mellitus in Mice Lacking Sglt2 Volker Vallon,[1] Maria Gerasimova,[1] Ken Platt,[2] Jean M. Whaley,[3] Scott C. Thomson,[1] Timo M. Rieg.[1] *[1]Depts of Medicine & Pharmacology, UC San Diego & VASDHCS, San Diego, CA; [2]Lexicon Pharmaceuticals, Inc, The Woodlands, TX; [3]Bristol-Myers Squibb R&D, Pennington, NJ.*

Background: The Na-glucose transporter SGLT2 mediates glucose reabsorption in the early proximal tubule and most glucose reabsorption by the kidney, overall. Inhibitors of SGLT2 are developed as new antidiabetic drugs which reduce renal glucose reabsorption

thereby lowering blood glucose levels. We studied gene-targeted mice lacking *Sglt2* (-/-) to elucidate its role in early diabetes where SGLT2 may also contribute to kidney growth and to glomerular hyperfiltration by lowering NaCl delivery to the macula densa.

Methods: Diabetes was induced by low-dose streptozotocin (STZ: 50 mg/kg ip on 5 days). GFR was determined by FITC-inulin kinetics in awake mice.

Results: At 3 and 5 weeks post STZ, hyperglycemia was less in *Sglt2*-/- than wild type (WT) mice (280±13 vs. 434±20 and 290±8 vs. 445±15 mg/dl; n=21-31, P<0.001), while food and fluid intake were increased and body weight modestly reduced to similar levels in both. For a given level of hyperglycemia, urinary glucose to creatinine ratios were greater in *Sglt2*-/- compared with WT mice consistent with lower renal glucose reabsorption in the absence of SGLT2. Induction of STZ-diabetes resulted in similar plasma concentrations of Na^+, K^+, and aldosterone, and a modestly greater hematocrit in *Sglt2*-/- vs. WT (45.5±0.6 vs. 42.3±0.5 %; n=9-10; P<0.05). The STZ-induced increase in GFR observed in WT (291±11 (in non-diabetics) to 383±12 µl/min; n=11/16; P<0.001) was absent in *Sglt2*-/- (292±6 to 308±10 µl/min, n=8/14; NS). However, the STZ-induced increase in kidney weight was similar in *Sglt2*-/- (345±5 (in non-diabetics) to 385±8 mg, n=15/24, P<0.01) and WT (344±6 to 397±15 mg, n=12/19; P<0.01).

Conclusions: We conclude that lack of SGLT2 lowers blood glucose levels in early STZ-diabetes mellitus and prevents glomerular hyperfiltration but not the increase in kidney weight.

The ZDSD Rat, a Translational Model of Obesity, Metabolic Syndrome and Diabetes That Expresses the Characteristics of Human Diabetic Nephropathy Richard G. Peterson,[1] Karen M. Zimmerman,[2] Vincent H. Gattone.[2] *[1]PreClinOmics, Indianapolis, IN; [2]Anatomy, Indiana University School of Medicine, Indianapolis, IN.*

Background: Most previously available rodent models of type II diabetes have leptin/leptin receptor mutations. The ZDSD rat was selectively inbred over a period of 10 years to be a model of type 2 diabetes without these defects. This model is also an excellent model of pre-diabetes/metabolic syndrome.

Methods: The ZDSD rat was developed by crossing lean ZDF rats to polygenic obese CD rats. Selective inbreeding has resulted in a consistent, translational model of metabolic syndrome and type 2 diabetes.

Results: During the pre-diabetic state, ZDSD male rats are obese with: hypertension, glucose intolerance, insulin resistance, hyperlipdemia, hyperglycemia, elevated glycated Hb and increased cardiovascular and inflammatory biomarkers. In the overtly diabetic state, the model exhibits complications very much like the human condition such as delayed wound healing, osteoporosis and nephropathy. Findings include increased kidney biomarkers, urinary: albumin, beta-2 microglobulin, cystatin-C, Kim-1, clusterin, osteopontin, GSTY b-1 and RPA-1; and serum: NGAL, beta-2 microglobulin, GST alpha, and von Willebrand factor. Morphologically, light and electron (transmission and scanning) microscopy revealed mesangial expansion with sclerosis (Kimmelstiel-Wilson-like nodules), thickened glomerular basement membranes, podocyte effacement and glomerulo-sclerosis. These markers and conditions become discernable within reasonable times after diabetes develops. By 8-12 weeks of diabetes there are significant elevations in most of the kidney biomarkers and morphological changes such as mesangial expansion, nodular sclerosis, thickened GBM and podocyte effacement.

Conclusions: As opposed to the ZDF or ZSF1 rat models which have leptin defects, the ZDSD model has a more reproducible nephropathy, exhibiting biomarkers and histopathology more similar to those seen in human diabetic nephropathy. These data indicate that the ZDSD rat model, in the overtly diabetic state, demonstrate that it is potentially the best translational rodent model for diabetic nephropathy available at this time.

ROCK1 Promotes Diabetic Nephropathy by Triggering Mitochondrial Fission through Serine Phosphorylation of Drp1 Jianyin Long, Wenjian Wang, Farhad R. Danesh. *Department of Medicine/Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Mitochondrial dysfunction has been proposed as the underlying molecular mechanism for microvascular complications of diabetes. However, the signaling pathways by which hyperglycemia leads to mitochondrial dysfunction are poorly understood. In this study, we used a genetic approach to determine the role of ROCK1 on mitochondrial dynamics and progression of diabetic nephropathy (DN).

Methods: We generated db/db:ROCK1$^{-/-}$ mice as a model of type 2 diabetes, and a conditionally inducible knock-in mouse expressing a constitutively active (cA) ROCK1 mutant by targeting cA-ROCK1 into ROSA 26 locus. We then crossed Rosa$^{cA\text{-}ROCK1}$ transgenic mice with a tamoxifen- inducible podocyte-specific Cre transgenic line.

Results: We found that targeted deletion of ROCK1 in diabetic db/db mice abrogated albuminuria, while podocin Cre cA-ROCK1 mice developed significant albuminuria. Using electron microscopy, we observed a marked increase in mitochondrial fission in the podocytes of diabetic db/db mice, which was prevented in diabetic db/db:ROCK1$^{-/-}$ mice. Importantly, podocin Cre cA-ROCK1 mice developed significant increase in mitochondrial fission in the glomeruli. We also found that mitochondrial recruitment of dynamin-related protein 1 (Drp1), a major component of the mitochondrial fission machinery, was significantly decreased in the glomeruli of db/db:ROCK1$^{-/-}$ mice, while its mitochondrial recruitment was enhanced in glomeruli from podocin Cre cA-ROCK1 mice. Western blot analysis using phospho Drp1 antibodies indicated that ROCK1 knockdown by dominant negative ROCK1 or siRNA, abrogated high glucose induced phosphorylation of Drp1-Ser^{600}, but not the phosphorylation of Drp1-Ser^{579}. *In vitro* kinase assay indicated that purified ROCK1 kinase phosphorylates bacterially expressed Drp1 at Ser^{600} in the consensus ROCK1 phosphorylation motif. Finally, we found phosphorylation of Drp1 at Ser^{600} promoted its mitochondrial translocation, resulting in enhanced mitochondrial fission and increased mitochondrial apoptosis.

Conclusions: Collectively, we identify a previously unrecognized role of ROCK1 and mitochondrial fission in the pathogenesis of DN.

The Role of Epidermal Growth Factor Receptor in Peroxisome Proliferator Activated Receptor Gamma Mediated Sodium and Water Transport in the Proximal Tubule Sonia Saad,[1] Dania Yaghobian,[1] Rachel Yong,[1] Muh Geot Wong,[1] Xinming Chen,[1] Darren J. Kelly,[2] Carol A. Pollock.[1] *[1]Medicine, Kolling Institute, Sydney, NSW, Australia; [2]Medicine, St Vincent Hospital, Melbourne, Vic, Australia.*

Background: Cellular sodium and water transport are dysregulated in diabetes mellitus. We have demonstrated that EGFr regulates high glucose-induced Na reabsorption via the sodium-hydrogen exchanger-3 (NHE3) in human proximal tubule cells (PTCs). PPARγ agonists, such as Pioglitazone, are used in patients with diabetes, but their use is limited by fluid retention. We have shown that PPARγ agonist induces NHE3 and the water channel AQP1 in PTCs. The role of EGFr in PPARγ agonists mediated increase of sodium and water retention in the proximal tubule are not known.

Methods: PTCs were exposed to 5mM, 25mM glucose (HG) or 3µM Pioglitazone. P-EGFr, NHE3, PPARγ and AQP1 protein expression were measured by Western blot. The role of EGFr was elucidated using the EGFR tyrosine kinase inhibitor PKI166. The specific role of PPARγ in HG mediated increase of P-EGFr, NHE3 and AQP1 was determined by effectively silencing PPARγ using siRNA technique. The expression of PPARγ and P-EGFr was determined in diabetic Ren2 rats with and without pioglitazone. The interaction between PPARγ and EGFr was determined by CHIP assay and the effect of TZDs on EGFr activation by luciferase assay.

Results: Exposure of PTCs to both HG and pioglitazone increased protein expression of P-EGFr, NHE3, AQP1 and PPARγ (P<0.05). EGFr and PPARγ are increased in diabetic rats and further increased in the presence of pioglitazone. Pioglitazone increased expression of NHE3 and AQP1 was abolished with PKI166 (P<0.05). HG induced increase of P-EGFr, NHE3 and AQP1 was significantly decreased with PPARγ siRNA (P<0.05). Pioglitazone induced PPARγ binding to EGFr promoter and subsequent downstream activation.

Conclusions: Our data suggest a role of EGFr in mediating PPARγ induced Na reabsorption via NHE3 and water reabsorption via AQP1 channels in the proximal tubule. This suggest that EGFr inhibition may have the potential to direct future therapeutic targets in DN, as well as limiting salt and water retention which currently restricts the use of PPARγ agonists.

The Effect of Oral Anti-CD3 Antibody Treatment on High Fat Induced Obese Mice Hyunwook Kim,[1] Jin Joo Cha,[2] Young Youl Hyun,[2] Young Sun Kang,[2] Mihwa Lee,[2] Jung Eun Kim,[2] Deok Hwa Nam,[2] Hye Kyung Song,[2] Ji Eun Lee,[1] Sang Youb Han,[3] Kum Hyun Han,[3] Dae R. Cha.[2] *[1]Internal Medicine, Wonkwang University Medical College, Gunpo, Kyeonggido, Republic of Korea; [2]Internal Medicine, Korea University Medical College, Ansan, Kyeonggido, Republic of Korea; [3]Internal Medicine, Inje University Medical College, Koyang, Kyeonggido, Republic of Korea.*

Background: Obesity is considered as a state of chronic inflammation, and it has been shown that pro-inflammatory cytokines expressed in obesity are linked to the development of insulin resistance. Regulatory T-cells(T-regs) have shown to be down-regulated in obese experimental model and recent studies demonstrated the effect of induction of T-regs by oral anti-CD3 antibody in ameliorating insulin resistance and metabolic derangement in ob/ob mice. We investigated the effect of oral anti-CD3 antibody treatment in high fat induced obese mice on diabetic nephropathy, insulin resistance and lipid metabolism.

Methods: C57BL/6(B6) mice, aged 8 weeks, were fed with either normal fat diet(n=3) and high fat diet. After 4 weeks, high fat fed mice were divided into 2 groups. One group(n=8) were fed once a day for 5 consecutive days with anti-CD3 antibody (5ug/feeding).

Results: Although there were no significant differences in glucose tolerance test, insulin and HOMA-IR level, anti-CD3 antibody treatment group showed significantly lower kidney weight, decreased urinary albumin excretion, improved plasma lipid (cholesterol, triglyceride) profile and liver tissue lipid metabolism. Urinary 8-isoprostane level and pro-inflammatory cytokines, glomerulosclerosis index were also decreased in the treatment group. To confirm the effect of anti-CD3 antibody on increased T-regs, $CD4^+LAP^+$ lymphocytes were measured by FACS analysis. There was a trend in increase of spleen $CD4^+LAP^+$ cells after 1 month. However, the level was undetectalbe after 3 months.

Conclusions: Our study suggest that oral anti-CD3 antibody treatment before the disease onset in high-fat induced obesity might have a beneficial effect on lipid metabolism and obesity induced kidney disease. The low percentage of $CD4^+LAP^+$ lymphocytes might be related to the low and chronic inflammatory state of obesity.

TH-PO561

Peroxisomal Dysfunction Mediates Renal Injury in Diabetic Catalase Null Mince Inah Hwang, Jiyoun Lee, Jehyun Park, Hunjoo Ha. *Department of Bioinspired Science, Division of Life & Pharmaceutical Sciences, the Center for Cell Signaling & Drug Discovery Research, and College of Pharmacy, Ewha Womans University, Seoul, Korea.*

Background: Overproduction of reactive oxygen species (ROS) under hyperglycemia plays an important role in diabetic vascular complications, including diabetic nephropathy (DN). Plasma free fatty acid (FFA) as well as glucose is increased under the diabetic milieu and peroxisome and mitochondria participates in cellular FFA oxidation; therefore, we investigated whether deficiency of catalase, a major antioxidant enzyme in peroxisome, determine accelerated diabetic renal injury through peroxisomal dysfunction and abnormal renal FFA metabolism associated with increased ROS.

Methods: Experimental diabetes was induced by multiple injections of low dose streptozotocin into catalase knock-out (CKO) and wild-type (WT) C57BL/6 mice. Mesangial cells transfected with siRNA for catalase were used to further elucidate the role of endogenous catalase in peroxisomal and mitochondrial function regulating FFA oxidation.

Results: At four weeks after the induction of diabetes, equivalent high plasma glucose and FFA levels were observed in diabetic WT and diabetic CKO mice. However, parameters of DN including urinary albumin excretion, glomerular hypertrophy, and accumulation of extracellular matrix (ECM) proteins along with markers of oxidative stress were much more severe in diabetic CKO mice than diabetic WT mice. Catalase deficiency in CKO mice and mesangial cells induced defects in peroxisomal and mitochondrial biogenesis and FFA oxidation leading to renal lipid accumulation. Catalase deficiency in mesangial cells also increased mitochondrial ROS.

Conclusions: The present data provide unprecedented evidence that FFA-induced peroxisomal dysfunction exacerbates diabetic renal injury, and that endogenous catalase is an important antioxidant that protects the kidney through peroxisomal and mitochondrial fitness under diabetic stress.

TH-PO562

Deficiency of Matrix Metalloproteinase-2 Accelerated Renal Injury in Streptozotocin-Induced Diabetic Mice Nana Obara,[1] Kei Fukami,[1] Sho-Ichi Yamagishi,[2] Yoshimi Takamiya,[1] Yusuke Kaida,[1] Seiji Ueda,[1] Seiya Okuda.[1] *[1]Division of Nephrology, Department of Medicine, Kurume University School of Medicine, Kurume, Fukuoka, Japan; [2]Department of Pathophysiology and Therapeutics of Diabetic Vascular Complications, Kurume University School of Medicine, Kurume, Fukuoka, Japan.*

Background: Matrix metalloproteinase-2 (MMP-2) is one of the potent metalloproteinases . Accumulation of ECM in the late stage diabetic kidney are, at least in part, by down-regulation of MMP-2. However, whether MMP-2 could affect in early stage of diabetic nephropathy has not been elucidated. Therefore, we investigated the effects of MMP-2 deficiency on renal injury in early stage of diabetic mice.

Methods: Diabetes was induced by streptozotocin (STZ) (50mg/kg) in male MMP-2 knockout mice (MMP-2 KO) and C57BL/6J mice (Ctrl). After 16 weeks, cortical MMP-2 expression and activity were measured by zymography and real-time PCR. Albuminuria and N-acetyl-β-D-glucosaminidase (NAG) were measured by enzyme-linked immunosorbent assay (ELISA). Alfa-smooth muscle actin (α-SMA) was evaluated by western blots. Glomerular fibrosis and tubulointerstitial injury were evaluated by PAS and Masson-trichrome stain, respectively.

Results: Plasma levels of glucose and HbA1c were increased by about 2-3-folds in 16-week diabetic (DM) mice compared with non-DM Ctrl mice (plasma glucose; 490.3+/-7.5 mg/dl, HbA1c; 9.91+/-0.22 % in 16-week diabetic mice). MMP-2 expression and activity in the kidney cortex of diabetic mice were significantly increased. Serum levels of BUN and creatinine (Cr) and albuminuria were significantly increased in MMP-2 KO DM mice compared with Ctrl DM mice (BUN; 23.2+/-1.7 *vs* 39.8+/-6.0 mg/dl, p<0.01, Cr; 0.07+/-0.01 *vs* 0.17+/-0.04 mg/dl, p<0.01, Albuminuria; 55.9+/-11.9 *vs* 89.3+/-13.8 μg/day, p<0.05). Further, glomernlar and tubulointerstitial injury, and cortical α-SMA expression were enhanced in DM mice, which were further increased in MMP-2 KO DM mice.

Conclusions: Renal MMP-2 is activated in early stage of diabetic nephropathy, and deletion of MMP-2 is further exacerbated. Diabetes-induced overexpression and activation of MMP-2 may be, at least in part, by compensatory action.

TH-PO563

VEGF165b Modifies Glomerular Permeability and Slows Progression of Albuminuria in Animal Models of Diabetic Nephropathy Sebastian Oltean,[1] Joane Ferguson,[1] Amit Kaura,[1] Chris R. Neal,[1] Steve Harper,[1] David O. Bates,[1] Andy Salmon.[1,2] *[1]Microvascular Research Laboratories, University of Bristol, United Kingdom; [2]Academic Renal Unit, University of Bristol, United Kingdom.*

Background: VEGF165b, an alternatively-spliced isoform of VEGF, decreases glomerular permeability to water (LpA/Vi) when directly administered to isolated intact glomeruli ex vivo, or transgenically over-expressed in podocytes in vivo [1].We investigated whether VEGF165b decreases both glomerular permeability to water and albuminuria in animal models of diabetic nephropathy.

Methods: All animals were made diabetic using standard streptozotocin protocols. Glomerular permeability to water (LpA/Vi) was determined as previously described (Salmon et al, J Physiol 2006). uACR ratio was determined from spot urine collection. (*p<0.05 vs control animals; #p<0.05 vs diabetic WT animals; ‡p<0.05 vs sham-treated diabetic animals; all ANOVA)

Results: Sprague-Dawley rats developed proteinuria (2-fold)* six days after diabetes induction with streptozotocin (STZ) (single 45mg/kg injection i.p). Elevated glomerular permeability to water in diabetic glomeruli (1.7-fold vs sham)* was blocked by 1hr incubation in 1nM VEGF165b (0.9-fold vs sham)#.

C57Bl/6 mice expressing human VEGF165b in podocytes (nephrin promoter: nephVEGF165b), or wild-type litter-mates (WT), were injected with 100mg/kg STZ i.p. daily for 3 days to induce diabetes. As compared with diabetic-WT mice, diabetic nephVEGF165b mice had less albuminuria (68% reduction)#, lower LpA/Vi (45% reduction)#, less mesangial matrix expansion (20% reduction)#, and less GBM thickening (15% reduction)#.

DBA2J mice were injected 5 consecutive days with STZ (50mg/kg i.p.). After 2 consecutive weeks of hyperglycemia (>20mmol/L), baseline urinary albumin-creatinine ratio (uACR) was measured, and mice received saline or 1μg VEGF165b injections i.p. twice weekly for 6 weeks. uACR increased progressively to 4.6-fold above baseline at 6 weeks in the sham-treated group, but only to 1.2-fold‡ in the VEGF165b treated group.

Conclusions: Our study suggests the potential of using VEGF165b as a therapeutic agent to slow diabetic nephropathy progression.

TH-PO564

Activation of Renal Genes Encoding Complement Components in Diabetic Nephropathy and Ischemia: Hypothesis Generation by RNAseq Discovery Katherine J. Kelly,[1] Jesus H. Dominguez.[1,2] *[1]Medicine/Nephrology, Indiana University School of Medicine, Indianapolis, IN; [2]Medicine/Nephrology, Roudebush VA Medical Center, Indianapolis, IN.*

Background: We have demonstrated accelerated progression of nephropathy in obese, diabetic ZS (F1 hybrids of Zucker and spontaneously hypertensive heart failure) rats following a single episode of renal ischemia.

Methods: We now examined the nature of renal inflammation in diabetic nephropathy using whole transcriptosome RNA sequencing to evaluate transcript expression in three groups: lean, obese-diabetic/sham surgery, obese-diabetic/postischemia (2 weeks).

Results: The nephropathy in this model is characterized by increased serum creatinine (1.8 ± 0.1 in obese-diabetic/postischemia vs 0.4 ± 0.4 mg/dl in lean rats), proteinuria, marked renal inflammation with fibrosis. An average of 43M (50 nt) reads were detected from each sample and the total number of unique and validated gene transcripts was 16536. Components of the classical (C1q, C2, C3, C4) complement pathway were significantly increased, 1.5 to 2.5 fold, in the obese-diabetic/sham group when compared to the lean group. The alternate complement component 6 was increased 4 fold in the obese-diabetic/sham group. Expression was further increased in the obese-diabetic/postischemia group: 2-5 fold for components of the classical pathway and 8.8 fold for C6. In addition, regulators of the complement system were significantly downregulated in the diabetic kidneys. These include CD55, "decay accelerating factor," and CD59 which inhibits the membrane attack complex. Complement receptors were increased (for example 42 fold increase in CR2 in obese-diabetic/sham group compared to lean) consistent with the inflammatory phenotype observed. Although complement components have long been described in diabetic nephropathy biopsies, this common finding has been viewed as non-specific.

Conclusions: These results support the hypothesis that in diabetes/obesity the kidney is an active participant in complement mediated renal injury by upregulating key complement genes. These critical injury pathways, acting in situ, may amplify inflammation and contribute to chronic renal injury.

TH-PO565

Systems Genomics Studies Implicate Xanthine Oxidase in Diabetes-Induced Podocyte Depletion Haiying Qi, Ilse S. Daehn, Erwin P. Bottinger. *Medicine, Mount Sinai School of Medicine, New York, NY.*

Background: Diabetic nephropathy (DN) risk in diabetics is controlled by genetic susceptibility. Podocyte depletion is a hallmark of experimental murine and human DN. Inbred C57BL/6(B6) are resistant and DBA/2J(D2) are susceptible to diabetes-induced glomerular lesions [Qi, et al. Diabetes,2005],including podocyte depletion [Qi H, et al. ASN 2009].

Methods: BXD recombinant inbred strains and parental B6 and D2 strains were made diabetic using streptozotocin (STZ) low-dose protocol and analyzed for QTL mapping using GeneNetworks tools. In a 2nd experiment, diabetes was induced in 8 wk-old D2 mice in the absence or presence of xanthine oxidase inhibitor(XOI) allopurinol,administered with mouse chow.

Results: The QTL mapping study identified two loci on Chr 13 and Chr 17, respectively, that were significantly associated with diabetes-induced podocyte depletion(DIPL). Xanthine dehydrogenase(Xdh) gene was localized under the peak of Chr 17 QTL, and Xdh gene expression was strongly increased by diabetes in glomeruli of D2, but not B6. Xdh and xanthine oxidase(XO) are interconvertible forms of the same enzyme encoded by the Xdh gene. Circulating XO activities were not different between diabetic B6, and non-diabetic B6 and D2 mice, but significantly(65%) elevated in diabetic D2 mice. Thus, Xdh is a candidate gene for DN susceptibility in D2 mice. Next, we treated non-diabetic and diabetic D2(STZ)with XOI. XOI had no effect on time of onset and levels of hyperglycemia

at 6 or 12 wks of diabetes. XOI mediated significant protection against diabetes-induced albuminuria and DIPL in D2 mice.

podocyte number per glomerular section and ACR ratio

N=5/group	Podocytes/glom. Section	Podocytes/glom. Section	ACR (mg/mg)	ACR (mg/mg)
	6wk	12wk	6wk	12wk
D2 ctr	11.40±0.81	11.49±1.12	28.25±8.51	34.48±7.95
D2 ctr + XOI	11.16±0.67	12.58±0.13	36.69±13.60	27.09±10.72
D2 STZ	9.17±0.77*	8.67±0.48*	358.79±158.06	383.22±193.09
D2 STZ + XOI	11.16±0.53#	10.63±0.26#	190.96±73.97#	143.15±143.27#

*compared with D2 ctr, #compared with D2 STZ , p<0.05

Conclusions: We propose that Xdh/XO may mediate DN susceptibility. Future studies will test XDH locus variants in human DN and evaluate the therapeutic/preventive potential for XOI in human DN.

Funding: NIDDK Support

Metallothionein Overexpression May Underlie Tubular Injury in Type 2 Diabetic Nephropathy

Yumi Takiyama, Manami Kobayashi, Yukihiro Fujita, Yasutaka Takeda, Jun Honjo, Tsuyoshi Yanagimachi, Hiroya Kitsunai, Hidemistu Sakagami, Yuichi Makino, Masakazu Haneda. *Department of Medicine, Asahikawa Medical University, Asahikawa, Hokkaido, Japan.*

Background: Oxidative stress is thought to play an important role in the onset and progression of diabetic nephropathy (DN). On the other hand, chronic hypoxia and TGF-β1 contribute to the development of renal fibrosis in DN.

Methods: For investigation of whether other key factors contribute to the pathogenic mechanism of DN, we analyzed microarray data using Affymetrix GeneChip (Rat Gene 1.0 ST Array) with microdissected juxtamedullary proximal tubules in a rat model of type 2 diabetes, Zucker Diabetic Fatty (ZDF) rats.

Results: A total of 27,342 transcripts were analyzed, among them, 47 were upregulated (>2.0-fold) in the ZDF rat compared with the lean control rat. One of them which were upregulated in diabetic renal tubules was metallothionein(MT)-1. MT is a cysteine-rich protein with low molecular weight, and act as an antioxidant against the toxicity of metals, ischemia, and ROS. By addressing the pathological role of MT, we first studied the regulation of MT expression in human renal proximal tubular epithelial cells (HRPTECs). Hypoxia (1% O_2) slightly increased MT mRNA levels, and insulin (100 nM) markedly enhanced MT mRNA levels up to 2~3 fold. Whereas, TGF-β1 (2.5 ng/ml) decreased MT mRNA levels down to ~50 % of the control in normoxia. Immunofluorescence of the kidney sections of 17 weeks old ZDF rats, showed significantly enhanced MT expression specifically in the tubules, not in the glomeruli, which also demonstrated strong intensity of HIF-1α, hypoxic probe pimonidazole, and oxidative stress marker 8-hydroxy-2'-deoxyguanosine, compared with lean control rats. Intriguingly, MT was faintly expressed in severe fibrotic kidneys in 39 weeks old ZDF rats, as well as control rats.

Conclusions: In conclusion, our data, for the first time, suggest that DN may be associated with the significant serial alterations of renal tubular MT expression in response to hypoxia, insulin or profibrotic TGF-β1, and that enhanced expression of MT may be an early pathogenic event reflecting abnormalities of antioxidant systems in DN.

TH-PO567

SGLT1 Can Reabsorb 70% of the Filtered Glucose Load in Mice Lacking SGLT2

David Powell, Christopher M. Dacosta, Robert Read, Brian Zambrowicz, Melanie K. Shadoan. *Lexicon Pharmaceuticals, Inc, The Woodlands, TX.*

Background: SGLT2 (S2) reportedly reabsorbs 90% of the filtered glucose (G) load. Inhibiting S2 to increase urinary G excretion (UGE) is a promising approach for improving glycemic control in diabetic patients, but clinical trials suggest that SGLT inhibitors highly selective for S2 over SGLT1 (S1) block G reabsorption by only 16-50%. We studied the role of S1 in renal G reabsorption in the absence of S2.

Methods: We generated S1 knockout (KO), S2 KO, S1 & S2 double KO (DKO), and wildtype littermate (WT) mice. Mice fed a high fat diet with fructose as the only carbohydrate (G-free diet) had 24 hr UGE measured; S2 KO and DKO mice were studied with or without a sc dose of 300 mg phlorizin (Ph). Other S2 KO and WT mice were either fed G-free diet and studied with an oral G tolerance test (oGTT), or were fed G-containing diet, exposed to vehicle (Veh) or streptozotocin (STZ, to induce diabetes), and then followed for blood G and HbA1c levels.

Results: All mice appeared healthy on G-free diet. Table 1 shows male UGE data; females showed the same pattern. All data are presented as mean ± SD.

Table 1. 24 hr UGE (mg)

WT (6)	S1 KO (10)	S2 KO (6)	S2 KO+Ph (6)	DKO (6)	DKO+Ph (6)
1 ± 1*	11 ± 4*	184 ± 70*	505 ± 271	681 ± 131	720 ± 106

(N); * different from each other group, p<0.001

G AUC (mg.hr/dl) values during oGTT at 10-12 wks of age were lower for male S2 KO (336 ± 89, n=22) relative to WT (442 ± 112, n=21) mice (p<0.01); females showed the same pattern. 40 wks after STZ or Veh treatment, 50 wk old male WT-STZ mice had HbA1c (%) values (7.7 ± 3.1, n=5) that were higher than values for S2 KO-STZ (5.1 ± 0.5, n=8), WT-Veh (4.9 ± 0.4, n=7) or S2-Veh (4.8 ± 0.6, n=7) mice (p<0.05 for each comparison); blood G values showed the same pattern.

Conclusions: 1) S2 is the major renal G transporter, but S1 can reabsorb 70% of filtered G in the absence of S2. 2) Mice lacking S2 can display improved glucose tolerance despite UGE that is only 30% of maximum. 3) Mice lacking S2 show improved glycemic control after exposure to diabetogenic doses of STZ. 4) S2 KO mice on G-free diet closely model humans receiving highly selective S2 inhibitors in terms of effects on UGE and glucose tolerance.

Intradialytic Parenteral Nutrition (IDPN) Increases Serum Prealbumin (PA) Levels in Malnourished Hemodialysis (HD) Patients – A Prospective, Multicenter, Open, Phase-IV-Study

Tobias A. Marsen, Roman Fiedler, Helmut Mann. *DPN Study Group, Germany.*

Background: Malnutrition (MA) is increasingly becoming a clinical problem in maintenance HD patients. Since PA is a nutritional parameter whose increase was shown to be positively correlated with patient survival and decreased morbidity, it was the goal of this study to assess PA and other nutritional parameters during 16 weeks (w) of IDPN.

Methods: 140 patients on HD with MA (albumin <35 g/l, PA <250 mg/l, phase angle α<4.5°assessed by bioimpedance, subjective global assessment score (SGA)≤grade B) were enrolled and 77 patients were evaluated per protocol. Patients were randomized to receive IDPN 3x/w in the study group (SG, n=34) and compared to the control group (CG, n=43). IDPN was compounded according to guideline recommendations. Oral supplements were allowed in both groups. Endpoints were defined as differences between baseline (BL) and 4 w of treatment (4WT) or BL and end of treatment (ET). Primary endpoint: PA. Secondary endpoints: Early (≥15% at 4WT) rise of PA, phase angle, SGA, albumin, transferrin, quality of life (SF12). Power calculation was established for PA (32 patients per study group) and statistical evaluation was performed according to an adaptive design [Bauer, Köhne: Biometrics 1994]. Statistical calculation: t-test, significance: p<0,05.

Results: There are no significant differences in BL data of both groups. SG shows a significant advantage (p<0,05) in change of PA (mean increase SG: +29,8 mg/l) compared to CG (mean decrease CG: -1,9 mg/l). A relevant early PA increase ≥15% after 4WT is more frequently achieved in SG (44%, n=15). Phase angle, SGA, albumin, transferrin, SF12 show no significance.

Conclusions: IDPN in malnourished HD patients significantly increases PA. It also results in early PA rise. Since increase in PA within 3 months of nutritional support predicts improved survival (Cano: JASN 2007) it is accepted as a positive marker for patient prognosis. Our data demonstrate a positive influence on PA after 16 w IDPN, thus favouring IDPN as a beneficial option of therapy. Due to small patient numbers there is a lack of statistical power to evaluate responsiveness of secondary endpoints in this study.

TH-PO569

A Reduced Appendicular Skeletal Muscle Mass Is Associated with Total Mortality in Male Hemodialysis Patients

Akihiko Kato,[1] Takako Takita,[2] Mitsuyoshi Furuhashi,[2] Hideo Yasuda,[3] Yukitoshi Sakao,[1] Akira Hishida.[3] *[1]Blood Purification Unit, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan; [2]Division of Nephrology, Maruyama Hospital, Hamamatsu, Shizuoka, Japan; [3]First Department of Medicine, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan.*

Background: Decreased skeletal muscle mass and increased abdominal adiposity are often observed in dialysis patients. However, it remains unclear whether either sarcopenia or abdominal adiposity is associated with clinical outcomes.

Methods: We measured appendicular skeletal muscle mass (ASM), a sum of the muscle mass in the four limbs, and trunk fat mass (TFM) from a dual energy X-ray absorptiometry, and determined a skeletal mass index (SMI) as ASM/height^2 and a trunk fat mass index (TFMI) as TFM/height^2 (kg/m^2) in hemodialysis (HD) patients aged from 41 to 75 years old (male/female=165/83, time on HD: 10±7 years). We also followed all patients for the 5 years, and examined the impact of changes of body composition on total mortality.

Results: SMI was positively correlated with serum creatinine (r=0.37, p<0.01) and albumin (r=0.21, p=0.01), while negatively with age (r=-0.25, p<0.01) in male patients. In contrast, no association was found between SMI and clinical parameters in female patients. TFMI was significantly correlated with total cholesterol (p<0.05) and triglyceride (p<0.01) in both sexes. In male patients, there was also a significant association of TFMI with hemoglobin (r=0.23, p<0.01) and carotid artery intima-medial thickness (CA-IMT) (r=0.21, p<0.05). During the follow-up, 27 male and 20 female patients had expired. Cox-hazards analysis after the adjustment for co-morbid risk factors revealed that male patients with the lowest tertile of SMI (≤6.5kg/m^2) (n=48) had a significantly higher risk for total mortality (RR: 8.31 folds [95%CI, 1.45-47.51], p<0.02) when compared with those with the highest tertile of SMI (>8.3 kg/m^2) (n=49). In contrast, SMI did not associate with 5-year mortality in female patients. FMI also did not relate to total death in both sexes.

Conclusions: These findings suggest that SMI less than 6.5kg/m^2 was a significant determinant of total mortality in male HD patients.

TH-PO570

Prognostic Value of Geriatric Nutritional Risk Index for Cardiovascular and All-Cause Mortality in End-Stage Renal Disease Patients on Chronic Hemodialysis

Kaoru Yasuda,[1] Shoichi Maruyama,[1] Hirotake Kasuga,[2] Tomoki Kosugi,[1] Naotake Tsuboi,[1] Waichi Sato,[1] Yasuhiko Ito,[1] Enyu Imai,[1] Seiichi Matsuo.[1] *[1]Department of Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan; [2]Department of Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Aichi, Japan.*

Background: Malnutrition is a prevalent complication in end-stage renal disease (ESRD) patients on hemodialysis (HD), and is associated with cardiovascular (CV) morbidity or poor survival. Geriatric nutritional risk index (GNRI) has been recently developed as a more accurate tool for malnutrition status. We investigated the prognostic value of the GNRI at start of HD therapy for mortality in ESRD patients.

Methods: A total of 1,568 ESRD patients who started HD therapy were examined. The GNRI was calculated as follows; GNRI = (14.89 × albumin) + [41.7 × (body weight / body weight at BMI of 22)] Thereafter, the patients were divided into quartiles according to GNRI levels; quartile 1 (Q1): < 84.9, Q2: 85.0-91.1, Q3: 91.2-97.2 and Q4: > 97.3, and were followed up for up to 10 years.

Results: During follow-up period (mean 63±42 months), 363 patients died including 180 CV deaths. Kaplan-Meier survival rates for 10 years were 57.9, 73.3, 80.8 and 89.2% for CV mortality, and were 32.1, 51.9, 61.3 and 73.8% for all-cause mortality in Q1, Q2, Q3 and Q4, respectively (both p<0.0001). Even after adjustment for other risk factors, GNRI was an independent predictor for both mortality.

GNRI and mortality

	Cardiovascular mortality		All-cause mortality	
	HR (95%CI)	P for trend	HR (95%CI)	P for trend
GNRI > 97.3	Reference	<0.0001	Reference	<0.0001
91.2 - 97.2	1.56 (0.87-2.79)		1.59 (1.09-2.30)	
85.0 - 91.1	1.90 (1.07-3.38)		1.74 (1.20-2.52)	
< 84.9	3.37 (1.96-5.80)		2.92 (2.05-4.15)	

Upon receiver operating characteristic (ROC) analysis, area under curve (AUC) for CV mortality was larger in GNRI (0.71) compared to albumin (0.64) and BMI (0.63) alone. AUC for all-cause mortality was also 0.70, 0.63 and 0.63 in GNRI, albumin and BMI, respectively.

Conclusions: GNRI at starting HD therapy could strongly predict CV and all-cause mortality in ESRD patients. This simple marker might be clinically useful for the assessment of malnutrition status in HD patients.

TH-PO571

Body Composition and Mortality in Prevalent Hemodialysis (HD) Patients: HEMO Study

Rebecca Filipowicz,[2] Tom H. Greene,[1,2] Guo Wei,[1] Srinivasan Beddhu.[1,2] *[1]VA; [2]Univ Utah.*

Background: Both higher body size (as indicated by body mass index- BMI) and higher muscle mass (as indicated by serum creatinine- SCr) are associated with better survival in HD patients (pts) but the relative importance of muscle vs. body size is not established.

Methods: The HEMO Study was a 2 X 2 factorial design study conducted by NIDDK to evaluate the effects of flux and dialysis dose on outcomes in anuric HD pts. Details of HEMO Study have been published elsewhere. In the current study, the associations of SCr, BMI and the ratio of Scr to BMI with time to death were examined in Cox proportional hazards models.

Results: The mean age, SCr, and BMI were 58 ± 14 yrs, 10.2 ± 2.9 mg/dL, 25.5 ± 5.3 kg/m², respectively. 56% were men, 63% black, and 45% had DM. There were 860 (47%) deaths over an average 2.85 years of follow-up.

Associations* of SCr, BMI and SCr/BMI with mortality (n=1,775).

Model 1	HR (95% CI)
For each change in SD of SCr	0.68 (0.63, 0.74)
For each change in SD of BMI	0.86 (0.80, 0.93)
Model 2	
For each change in SD of SCr/BMI	0.82 (0.75, 0.89)

*All models are adjusted for age, gender, race, and HEMO trial interventions

The results indicate that patient differences in Scr level are substantially more strongly predictive of mortality than patient differences in BMI, relative to the SD of each factor. Furthermore, each SD increase in the ratio SCr/BMI was associated with 18% lower risk of death. In subgroup analyses, each SD increase in the SCr/ BMI ratio was associated with lower risk of death in those with BMI< 25 (HR 0.69, 95% CI 0.2-0.78), BMI 25-29.9 (HR 0.72, 95% CI 0.57 -0.90) and BMI 30 (HR 0.53, 95% CI 0.37-0.76).

Conclusions: Both SCr and BMI are associated with lower risk of death in HD pts. However, in the HEMO Study, the magnitude of the association of SCr with mortality was stronger than the magnitude of the association of BMI with mortality, and higher SCr/BMI ratio was also associated with lower risk of death. Interventions targeting muscle mass at any level of BMI may improve survival in HD pts.

TH-PO572

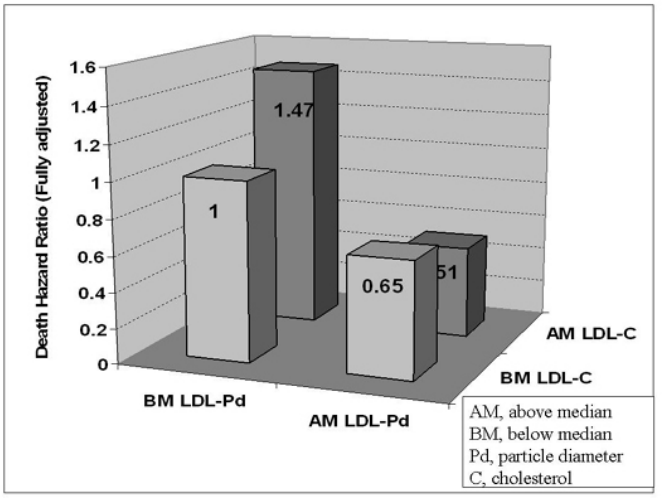
Novel Lipoprotein Subfraction and Size Measurements in Prediction of Mortality in Maintenance Hemodialysis Patients

Nazanin Noori,[1] Michael Caulfield,[2] Susanne B. Nicholas,[3] Miklos Z. Molnar,[1] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh.[1,3] *[1]Harold Simmons Center; [2]Quest Diagnostics Nichols Institute; [3]David Geffen School of Medicine at UCLA; [4]Salem VA Medical Center.*

Background: Studies on CKD patients (pts) are often limited to conventionally measured total cholesterol and LDL-C. What remains to be determined is what measures of lipoprotein help better identify high risk dialysis pts & whether LDL-"altering" strategies are more effective in this population than LDL-lowering medications.

Methods: Mortality-predictability of LDL particle diameter and lipoprotein subfraction concentrations, measured by novel ion mobility, was examined in a cohort of 235 MHD pts who were followed for up to 6 years using Cox models with incremental levels of multivariate adjustment: (A) Case-mix variables. (B) Lipids included LDL and HDL-C and TG concentrations. (C) Malnutrition-inflammation complex syndrome (MICS) variables included serum or blood levels of phosphorus, albumin, creatinine, calcium, ferritin, hemoglobin, nPNA; & BMI. (D) Adjustment for CRP, IL-6, & TNFα.

Results: Over 6 yrs, 71 pts (31%) died. Conventional lipid profile was not associated with mortality. The death hazard ratio (HR, 95% confidence interval) of the highest versus lowest quartiles of very small and large LDL-particle concentrations were 2.14(1.00-4.62) and 0.47(0.20-0.99), respectively. As figure shows, across increasing quartiles of the LDL particle diameter, death HR were 1.0, 0.93(0.46-1.87), 0.43(0.21-0.89), and 0.45(0.31-1.00), respectively.



Conclusions: Whereas conventional lipid profile cannot predict mortality in MHD, novel lipoprotein measures such as larger novel LDL particle diameter or higher large LDL particle concentrations appear predictive of greater survival, while higher very small LDL particle concentration is associated with higher death risk.

TH-PO573

The Predictive Value of the Changes of Nutritional and Anthropometric Parameters for Survival and Hospitalization Outcome in the Hemodialysis (HEMO)Study

Chi-Ting Su,[1,2] Francis Pike,[3] Mark L. Unruh.[4] *[1]Nephrology, National Taiwan University Hospital, Yun-Lin, Taiwan; [2]GSPH, Genetics, U. Pittsburgh; [3]Biostatistics; [4]Renal-Electrolyte Division, University of Pittsburgh Medical Center.*

Background: While previous works have focused on relationships between baseline measures and all-cause mortality in end-stage renal disease, markers of nutrition vary over time and may affect mortality due to either infections or cardiovascular disease. We conducted the study to examine whether changes in nutritional status,anthropometric parameters and Karnofsky performance index would predict cause-specific mortality in hemodialysis patients.

Methods: Anthropometric assessments were measured in HEMO study and functional status was measured by Karnofsky index.Index of coexistent diseases score,baseline demographics,blood studies were covariates.The definition of cause-specific mortality in the HEMO study has been described elsewhere.Cox-regression model was used to examine patient survival along with the decline of anthropometric parameters,and performance status to mortality.

Results: There were 1404 patients,in HEMO study,with at least one follow up anthropometric measurements.The difference of mid-arm muscular circumference(MAMC) between baseline and the data in the first visit was significant(p=0.07).Lower serum albumin and MAMC were associated with increased mortality(p<.0001)and cardiac mortality. Patients with higher Karnofsky index had less all-cause mortality and death from congestive heart failure(p=0.01).The decline of MAMC was associated with all-cause mortality,death from infection(p=0.01)and time to 1st cardiac hospitalization or cardiac death(p=0.03). Adjusted survival analysis revealed declining MAMC is an independent predictor for

all-cause mortality(HR:1.4,p<.0001),death from infection(HR:1.46,p=0.05),and time to 1st cardiac hospitalization(HR:1.25,p=0.0002).

Conclusions: In patients undergoing maintenance hemodialysis,nutritional status and functional performance status are associated to survival.The decline of MAMC is a predictor for patient mortality.Serum albumin,MAMC and Karnofsky index are key modifiable predictors to consider as targets for improving patient outcomes.

TH-PO574

Global Variation of Nutritional Status in Children Undergoing Peritoneal Dialysis Joshua Zaritsky, Dagmara Borzych-Duzalka, Anja K. Büscher, Annabelle N. Chua, Vera Hermina Koch, Maria Lipka, Viola M. Pinto, Lesley Rees, Sara Testa, Patricia G. Vallés, Franz S. Schaefer, Bradley A. Warady. *International Pediatric Peritoneal Dialysis Network.*

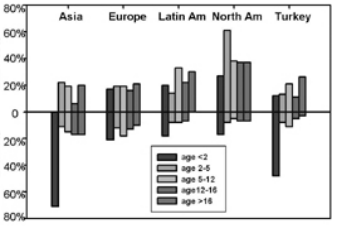
Background: Despite the availability of clinical guidelines, it remains unknown if nutritional practices and outcomes vary globally for children receiving peritoneal dialysis (PD).

Methods: We examined the nutritional status of 1466 children from 78 centers in 30 countries participating in the International Pediatric Peritoneal Dialysis Network (IPPN). Body Mass Index (BMI) and height measurements were normalized to WHO (2006) and CDC (2000) standards for children < and > age 5, respectively (table).

Results: Enteral feeding practices for patients < age 5 varied widely with the highest rate seen in North America. Analysis of BMI distribution by age showed high rates of BMI <5% for ages <2 in Asia and Turkey and BMI >85% (overweight) for ages 2-5 in North America (figure). Height SDS were poor in Asia, Latin American and Turkey. Multivariate analysis identified age (OR 0.94 (0.91-0.97)), residual urine output (OR 0.96 (0.93-0.99)) and residence in India (OR 3.83 (1.41-10.5)) as factors associated with a BMI <5%, while enteral feeding (OR 1.76 (1.1-2.8)) and residence in the USA were associated with a BMI >85%.

Region	BMI SDS (Mean±SE)	BMI <5% (%)	Height SDS (Mean±SE)	Enteral Feeding Age <5 (%)
Asia	-0.2±0.1	18	-2±0.1	4
Europe	-0.2±0.06	15	-1.6±0.07*	46
Latin Am	0.2±0.06*	8	-2.3±0.07	35
North Am	0.5±0.09*	8	-1.6±0.1*	72
Turkey	-0.2±0.08	12	-2.6±0.09	6

*p<0.001 versus other regions



Conclusions: These findings demonstrate considerable global variation in nutritional status and suggest provision of calories alone does not correct growth failure in children receiving chronic PD. Future studies are needed to further examine nutritional practice patterns including underutilization as well as excessive use of enteral feeding in some age groups/regions, and to determine what, if any association exists between a BMI <5% or >85% and unfavorable outcomes in pediatric PD patients.

TH-PO575

Validation of Measurement of Hydration of Fat Free Mass in Volume Expanded Dialysis Patients Alessio Molfino,[1,2,3] Burl R. Don,[1] George A. Kaysen.[1] *[1]Nephrology, UC Davis, Davis, CA; [2]Clinical Nutrition, University of Rome; [3]Clinical Medicine, Sapienza University of Rome, Italy.*

Background: Fat mass (FM) is measured with dual-energy X-ray absorptiometry (DXA), but is expensive and not portable. Multifrequency bioimpedance spectroscopy (BIS) measures total body water (TBW) and intracellular and extracellular water (ICW and ECW). Adiposity is calculated by subtracting Fat Free Mass (FFM) from weight assuming fractional hydration of FFM of 0.73. Hemodialysis patients (HD), however, have non physiologic expansion of ECW.

Methods: We estimated the hydration of FFM in healthy adult subjects (C) and HD with BIS using a formula that allows ECW and ICW to vary (TBW/FFM = (1 +ECW/ICW)/(1.569+1.16*(ECW/ICW)) (Wang Z. et. al. AJP Endo Metab 276:995,1999). We then derived a value for FM accounting for the effects of varying expansion of ECW to be applied to HD and C. FM was measured by DXA in 11 C (6 male and 5 female) median age 32.5 y (23-53 y), weight 76.5 kg (47.9-102.8 kg), body mass index (BMI; kg/m2) 26.5 (17.5-29.8), and in 8 male HD with median (range) age 44.5 y (28-55 y), weight 102.5 kg (73-119.3 kg), BMI of 31.15 (24.7-36.9). We measured TBW, ECW and ICW with BIS and calculated FM using either Weight - TBW/.73 or with the formula to account for variations in ECW/ICW to estimate FM.

Results: ECW/ICW was significantly greater in HD than in C (0.860 vs 0.780; p=0.01) and estimated hydration of FFM by use of the formula significantly greater in HD than in C (0.724 0.004 vs 0.7195 0.003; P=0.048). FM (Kg) estimated by DXA, BIS and the formula were not different in C (20.0 2.7, 20.3 2.9, 19.4 3.0, p=n.s. and correlated r2 p< 0.001) or in HD (27.8 3.2, 28.4 2.9, 27.6 2.9, p=n.s and correlated r2 p< 0.001.). Neither Bland-Altman plot regressed (r2=0.00). Assumption of hydration of FFM of 0.73 provided a measure of FM 0.6 kg > DXA in HD and 0.3 kg > in C. The model provided a measure of FM 0.2 kg < DXA in HD and 0.6 kg < in C.

Conclusions: Expansion of ECW in HD is statistically significant, however the effect on hydration of FFM is insufficient to cause any deviation from values derived using a hydration value of 0.73, validating the use of BIS to estimate adiposity in HD patients.

Funding: Private Foundation Support

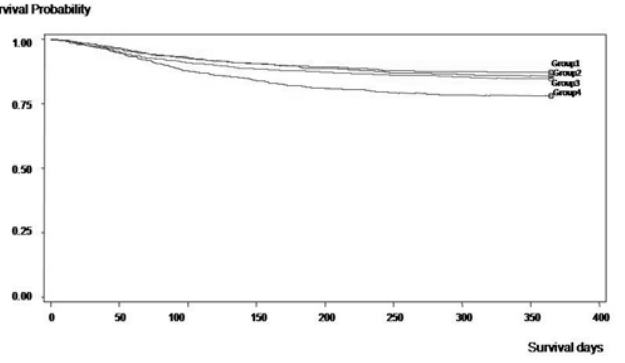
TH-PO576

Nutrition Status Prior to Starting Hemodialysis Is Strongly Associated with One-Year Mortality in Hemodialysis Patients Eiichiro Kanda,[1] Jenna O. Krisher,[2] William M. McClellan.[3] *[1]Tokyo Kyosai Hospital, Japan; [2]ESRD Network 6; [3]Emory University.*

Background: Malnutrition is a common complication in hemodialysis patients. We examined nutritional status prior to starting hemodialysis to determine whether it was independently correlated with one-year mortality among incident hemodialysis patients.

Methods: We enrolled 6304 incident hemodialysis patients in North Carolina, South Carolina and Georgia(ESRD Network 6 area) and followed up these individuals for up to one year. Prehemodialysis nutritional status was assessed using data from the Centers for Medicare & Medicaid Services (CMS) 2728 Form. Nutritional status was evaluated on the basis of body mass index (BMI), serum albumin level, and geriatric nutritional risk index (GNRI) (calculated from height, weight and serum albumin levels). Patients were categorized into quartile groups by GNIR. Mortality was evaluated using a fully adjusted Cox proportional hazard model.

Results: The mean age (SD) was 61.3 (15.0) years old; female 47.9%; diabetes 46.2%; mean BMI 29.1 (9.0) kg/m^2; mean serum albumin 3.02 (0.72) mg/dl; 5.9% under the care of a dietitian prior to dialysis; GNRI median 62.7 (IQR 50.8-90.7). Nutrition status prior to hemodialysis was correlated with mortality: low BMI (less than 23) hazard ratio (HR) 1.32 (95% confidence interval 1.15-1.52); hypoalbuminemia (less than 3.8 g/dl), 2.09 (1.59-2.75). The group with the lowest GNRI, Group 4 (<50.8), had an HR of 1.41 (1.16-1.71) relative to Group 1 (GNRI>90.7)



Patient with higher geriatric nutritional risk index (GNRI) showed lower risk of mortality.
Log-Rank test P<0.0001, Wilcoxon signed rank test P<0.0001
Group 1; 90.7 <= GNRI
Group 2; 62.7 <= GNRI < 90.7
Group 3; 50.8 < GNRI < 62.7
Group 4; GNRI < 50.8

Patients who were under the care of dietitians had higher serum albumin levels (t-test, P<0.0001) and lower mortality, HR 0.74 (0.55-0.99) than patients who were not.

Conclusions: In dialysis patients, nutritional status prior to starting hemodialysis is associated with early mortality risk. Moreover results suggest that the control of nutritional status may decrease the risk.

TH-PO577

Quality of Sleep and Daytime Sleepiness in Chronic Hemodialysis – A Study of 400 Patients Sonia Maria Holanda Almeida Araujo,[1] Andre Pantaroto,[2] Nicole Araujo,[2] Constance Almeida de Alencar Araújo,[1] Gilson Almeida,[3] Elizabeth De Francesco Daher,[1] Pedro Bruin,[1] Veralice Meireles Sales Bruin.[1] *[1]Medicina, Universidade Federal do Ceara, Fortaleza, Ceara, Brazil; [2]Medicina, Faculdade de Medicina de Jundiai, Jundiai, Sao Paulo, Brazil; [3]Medicina, Faculdade Christus, Fortaleza, Ceara, Brazil.*

Background: Impaired sleep has potential health consequences in chronic hemodialysis patients. To date, this issue has not been examined in studies involving a large number of subjects. We aimed to identify factors associated with poor sleep quality and excessive daytime sleepiness (EDS) in dialysis patients.

Methods: This is a cross-sectional observational study, involving 400 patients (59% male) from three hemodialysis centers (SD-HEMOFOR). Quality of sleep was evaluated by the Pittsburgh Sleep Quality Index (PSQI); EDS by the Epworth Sleepiness Scale (ESS); risk of obstructive sleep apnea (OSA) by the Berlin questionnaire and comorbidity severity by the Charlson Comorbidity Index (CCI).

Results: Poor sleep quality (PSQI>5) was found in 227 individuals (57%) and was associated with older age (p=0.001), diabetes (p=0.03), heart failure (p<0.005); hypoalbuminemia (p=0.01), low transferrin saturation (TSAT) (p=0.009), higher CCI score (p=0.01) and depression (p<0.005). Independent factors were older age, heart failure, low TSAT and depressive symptoms. Daytime somnolence was present in 108 patients (27%) and was independently associated with stroke (OR=2.84 CI= 1.03-7.76), lower hemoglobin concentration (OR=2.45 CI= 0.95-3.03) and high risk of OSA (OR=1.65 CI= 1.03-2.63). High risk of OSA (N=120; 30%), was associated with hypertension (p<0.001), overweight/obesity (p=0.001), older age (p=0.003) and symptoms of depression (p=0.01).

Conclusions: Poor sleep quality and EDS are prevalent on chronic hemodialyis. Heart failure, low TSAT and depressive symptoms are independently associated with poor sleep quality. Stroke, anemia and high risk of OSA are independently associated with EDS. These results provide new insight into possible treatment strategies.

TH-PO578

High Dietary Fiber Intake Associates with Lower Indoxyl Sulfate Concentrations in Chronic Kidney Disease Liesbeth Viaene, Bjorn K.I. Meijers, Bert Bammens, Pieter Evenepoel. *Nephrology, University Hospital, Leuven, Belgium.*

Background: Mounting in vitro and clinical evidence indicate that indoxyl sulfate (IndS), a protein-bound uremic toxin originating from bacterial protein fermentation in the colon, is involved in the pathogenesis of accelerated cardiovascular (CV) disease in chronic kidney disease (CKD) patients. High dietary fiber intake suppresses protein fermentation and is associated with decreased CV morbidity and mortality in both CKD and non-CKD populations.

Methods: We performed a cross-sectional observational study to investigate associatons between dietary fiber intake and serum IndS levels. Fasting blood samples were collected and analyzed for routine biochemistry and IndS (HPLC) in 195 stable CKD patients (105 male; age 65±16 year). Dietary intake was estimated through a dietary history and nutrient content was calculated using Becel® Nutritional Software.

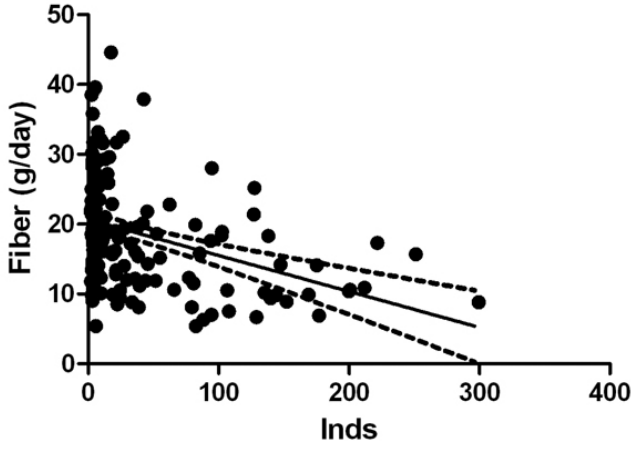
Results: Demographics and biochemistry are summarized in table 1.

Demographics and dietary intake

	CKD1-2	CKD3	CKD4-5	CKD5D	P
Male (%)	28	55	64	62	0.01
Age (y)	44	68	69	70	<0.0001
BMI (kg/m²)	25	28	27	26	0.2
Inds (µM)	4	7	18	88	<0.0001
Total kcal/day	2162	1808	1647	1717	0.0007
Protein (g/d)	84	78	69	71	0.006
Carbohydrate (g/d)	269	209	207	215	0.0002
Fiber (g/d)	24	22	20	13	<0.0001

Median values are shown

Total energy intake, as well as intake of dietary protein, carbohydrate, fat and fiber intake were lower in more advanced CKD stages. Of all macronutrients, only dietary fiber intake was associated with Inds levels (β=-0.06; p<0.0001), independent of eGFR, age, sex and BMI.



Conclusions: Dietary fiber intake is inversely associated with indoxyl sulfate concentrations in CKD patients, independent of eGFR. Suppressing indoxyl sulfate serum levels might be one of the mechanisms through which dietary fiber could decrease CV morbidity and mortality.

TH-PO579

Olfactory Dysfunction of ESRD Patients Was Recovered by Initiation of Dialysis Young-Il Jo,[1] Ju-Young Moon,[2] Sang-Woong Han,[3] Dong Ho Yang,[4] Sang-Ho Lee,[2] Hyeong Cheon Park,[5] Sug Kyun Shin.[6] *[1]Nephrology, Konkuk University Hospital, Seoul, Republic of Korea; [2]Nephrology, Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; [3]Nephrology, Hanyang University Guri Hospital, Guri, Republic of Korea; [4]Nephrology, Bundang CHA Hospital, Sungnam, Republic of Korea; [5]Nephrology, Yonsei University Gangnam Severance Hospital, Seoul, Republic of Korea; [6]Nephrology, NHIC Ilsan Hospital, Goyang, Republic of Korea.*

Background: Olfactory function was impaired in chronic kidney disease patients. Some studies showed that olfactory function of ESRD patients receiving dialysis did not differ from those of healthy controls. However, there was no prospective study following initiation of dialysis on olfactory function in ESRD patients. This prospective study was designed to clarify the effect of dialysis on olfactory function of ESRD patients who initiate hemodialysis (HD) or peritoneal dialysis (PD).

Methods: Fifty-two ESRD patients who initiated maintenance HD (n=16) or PD (n=36) were recruited from 6 hospitals. Olfactory function was tested by using the Cross-Cultural Smell Identification Test (CC-SIT) before the initiation of the first dialysis and then at 3 and 6 months after initiation of dialysis.

Results: There were no differences in mean smell score before initiation of dialysis and baseline characteristics such as age, diabetes, HbA1C or hs-CRP. In ESRD patients not receiving dialysis, the smell score was negatively correlated with ages (*r=-0.179, p=0.02*) and did not differ between DM and non-DM patients and between male and female. The smell scores increased significantly after initiation of HD and PD. In ESRD patients on HD, the smell scores increased from 7.6±2.5 at baseline to 8.4±3.0 at 3 months (*p=0.060* vs. baseline) and to 9.3±2.5 at 6 months (*p=0.014* vs. baseline). PD patients also showed a significant increase of the smell scores after initiation of PD: 8.4±2.2 at baseline, 9.1±1.8 at 3 month (*p=0.034*), 9.2±1.8 at 6 month (*p=0.039*). Improvement of smell scores following HD or PD had no relation to gender, diabetes or age.

Conclusions: These results suggest that smell disturbance in patients with ESRD could be recovered by initiation of HD or PD.

TH-PO580

Increased Levels of Serum Parathyroid Hormone and Fibroblast Growth Factor-23 Are the Main Factors Associated with the Progression of Vascular Calcification in Long-Hemodialysis Patients Guillaume Jean, Charles Chazot. *Hémodialyse, NEPHROCARE, Tassin, France.*

Background: Vascular calcifications (VCs) are frequently observed in hemodialysis (HD) patients and have been associated with poor outcomes. The aim of the present study was to assess the frequency and the factors associated with the progression of VCs using a semi-quantitative X-ray score.

Methods: We included all prevalent HD patients between January 2006 and January 2007, with initial radiological scores ranging from 0 to 3 according to the severity and extent of the VCs (abdominal aorta, iliac, femoral, popliteal, and radial arteries). Patients were classified as non-progressors or progressors according to the change in their VC score after 3 years. We analyzed the values of the means of all biological data and treatment doses.

Results: Among the 85 patients still alive after 3 years, 47 were classified as non-progressors and 38 as progressors (44.7%). No regression in VC score was observed. Among all the studied parameters, only serum PTH and fibroblast growth factor (FGF)-23 levels were increased in the progressor group. On evaluating the association between patients with serum PTH and FGF-23 < or ≥ the median values (190 pg/ml and 3000 RU/ml, respectively), we found that only exhibiting high levels of both parameters is associated with the risk for VC progression (odds ratio, 5.8; 1.7–19.8, $P = 0.004$). Hyperphosphatemia (<10%), and especially, hypercalcemia (1%), and hyperparathyroidism (HPT >; 585 pg/ml = 0%) were infrequently observed. Calcitriol analogs (38%), cinacalcet (15%), dialysate calcium (mean 1.48 mmol/l), and calcium- (10%) and non-calcium based phosphate binders (38%) were prescribed on an individual basis.

Conclusions: After 3 years, VC progression was observed in 44.7% of prevalent HD patients using long-dialysis sessions and an individual therapeutic strategy. The main factor associated with VC progression was the association of higher serum PTH and FGF-23 levels. It remains to be seen whether patients should be treated to lower their PTH value, even in the target range, using calcitriol analogs, calcimimetics, parathyroidectomy, or by modifying the Klotho-FGF-23 axis.

TH-PO581

Greater Reductions in Mortality over Time for Obese and Extremely Obese Patients Compared to Normal or Underweight Patients Who Begin Dialysis Therapy: A Cohort Study from 1995-2005 Austin G. Stack,[1,2] Hoang Thanh Nguyen,[1] Bhamidipati V.R. Murthy,[2] Arif I.F. Mutwali.[1] *[1]Regional Kidney Centre, Letterkenny Genral Hoapital, Letterkenny, Donegal, Ireland; [2]Division of Renal Disease and Hypertension, University of Texas Medical School, Houston, TX.*

Background: Prior studies have identified an inverse correlation between body mass index (BMI) and survival with obese patients experiencing the greatest benefit. The relationship between changing trends in body size and associated mortality risks among new dialysis patients has not been previously explored.

Methods: We compared trends in mortality among underweight, normal, overweight, obese, and extremely obese patients who began dialysis therapy between 1995-2005 using data from the US Renal Data System. National incidence data were available on new patients (N=851,480) between May 1995 and December 2005 and all patients were followed until Oct 2006. Mortality risks were compared across 4 calendar periods (1995-1996, 1997-1999, 2000-2002 and 2003-2005) with the generation of adjusted hazard ratios[1] (HR) 95% Confidence intervals) using multivariable Cox regression analysis. All analyses were conducted using SAS V 9.01.

Results: From 1995-2005 the prevalence of overweight, obesity and extreme obesity increased while the prevalence of normal and underweight decreased. The multivariable relative mortality risks for each weight category by calendar period are illustrated:

Prevalence (%)	1995-96	1997-99	2000-02	2003-05
Underweight (< 18.5)**	10.8	9.0	5.1	4.4
Normal weight (18.5-24.9)**	43.8	41.3	38.5	35.8
Overweight (25-29.9)**	26.7	28.3	30.3	30.8
Obese (30-39.9)**	16.6	18.8	22.6	25.0
Extreme Obese (> 40)**	2.1	2.7	3.5	4.1
Relative Risk Death[1,2]	Referent			
Underweight (< 18.5)	1.00	0.98	1.03	1.01
Normal weight (18.5-24.9)	1.00	0.98*	0.91**	0.88**
Overweight (25-29.9)	1.00	0.97**	0.90**	0.86**
Obese (30-39.9)	1.00	0.95**	0.88**	0.83**
Extreme Obese (> 40)	1.00	0.91*	0.83**	0.78**

[1]Each weight category modeled separately
[2]Adjusted for 17 demographic, clinical and laboratory variables, *P<0.001 **P<0.0001

Conclusions: The increasing prevalence of overweight, obesity and extreme obesity was associated with a trend of falling mortality risks from 1995-2005. The larger the BMI category, the proportionally greater the reduction in relative mortality risks over time with the survival of underweight patients unchanged. Increasing BMI among successive incident dialysis cohorts is associated with temporal improvements in overall survival.

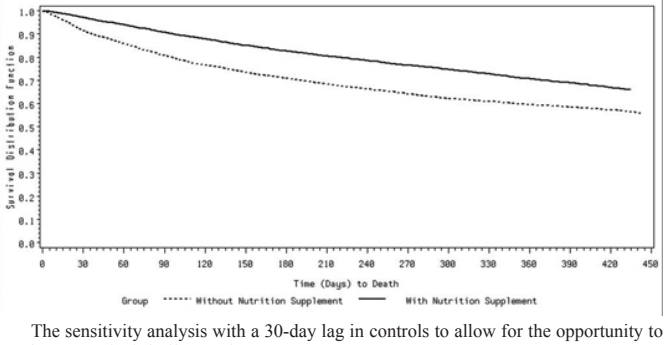
TH-PO582

Effect of Oral Nutritional Supplements on Mortality in Hemodialysis Patients Eduardo K. Lacson, Weiling Wang, Barbara L. Zebrowski, J. Michael Lazarus, Raymond M. Hakim. *Fresenius Medical Care, North America, Waltham, MA.*

Background: We evaluated whether supervised oral nutritional supplement (ONSP) at every treatment impacts survival in hemodialysis (HD) patients.

Methods: All chronic in-center HD patients in Fresenius Medical Care North America facilities, with albumin ≤3.5 g/dL in Q4-2009 without oral supplements in the prior 90-days were eligible for ONSP until albumin was ≥4.0 g/dL. Patients prescribed ONSP in Q4-2009 were study patients (supplement start date defined as Day 1 of follow-up), the rest were controls (date of 1st albumin ≤3.5 g/dL defined as Day 1 of follow-up). Case-mix data as of Day 1 and lab values for hemoglobin, phosphorus and eKt/V from the prior 90-days were recorded. Mortality was tracked for 1 year up to12/31/2010. Cox models were used to compare one-to-one propensity score and geographic region-matched groups. The propensity score used age, gender, race, diabetes, vintage, BMI, cause of ESRD, hospitalization in the prior 30 days, albumin, hemoglobin, phosphorus, eKt/V, access type and an indicator for incident patients (i.e. vintage ≤90 days).

Results: Propensity score plus region matched patients (N=4,354 pairs) had similar mean age of 64.9 years, 49% male, 58% white/38% black, mean vintage of 3.5 years, and mean BMI 30.2. They had 41% fistulas, 21% grafts, 38% catheters, and baseline albumin of 3.27 g/dL. Fewer study patients had diabetes (61.3% vs. 63.4%, p=0.04). The median time to receive supplement was 18 days (mean 23 days). The HR=0.67 (p<0.0001) for ONSP vs. controls. KM survival curves are shown.



The sensitivity analysis with a 30-day lag in controls to allow for the opportunity to receive ONSP had similar results.

Conclusions: Geographic region and propensity score-matched patients with albumin ≤3.5 g/dL who were prescribed and received supervised ONSP exhibited significantly better one-year survival.

TH-PO583

Leptin, NPY and Cortisol Concentration Changes in 4-Hour Hunger Test in Patients with Renal Failure Stanislaw Niemczyk,[1] Katarzyna Romejko-Ciepielewska,[1] Ewa Paklerska,[1] Longin Niemczyk,[2] Katarzyna Szamotulska,[3] Joanna Matuszkiewicz-Rowinska.[2] *[1]Military Institute of Medicine; [2]Medical University of Warsaw; [3]National Research Institute of Mother and Child.*

Background: Malnutrition is a common finding in end-stage renal disease. Weight loss is present in approximately 40% of dialysis patients. Hormone disturbances in end-stage renal disease may be responsible for malnutrition. High leptin concentration in patients with renal failure inhibits food intake and may lead to the loss of weight. Cortisol increases leptin concentration. NPY is an orexigenic peptide. Leptin inhibits NPY synthesis in hypothalamus.

Methods: The study involved 87 pts (37 HD pts and 50 controls). Blood samples for leptin, NPY and cortisol measurement were taken twice (at 8 a.m., after a 12-hour fast, and at noon, after 4 hours of prolonged fasting).

Results: During a 4-hour fast, we observed a decrease in leptin levels in all HD patients, with statistically significant differences in HD patients with normal body weight (p=0,006). We also observed high leptin concentration in fasting state in HD malnourished (0,14-225) and obese (0-275) patients. NPY levels were slightly reduced in undernourished HD patients. We observed a fall of cortisol concentration in 4-hour hunger test in all HD patients, with statistically significant differences in HD obese (p=0,034) and normal weight patients (p=0,013). Cortisol concentration in fasting state were higher in all HD patients in comparison with the control group, we observed the statistically significant differences between malnourished (p=0,010) and obese (p=0,018) pts.

Conclusions: High fasting leptin concentration and no significant reduction in these concentration during prolonged fasting in undernourished HD patients indicate an association between leptin and the development of malnutrition. This association may result from reduced NPY levels. HG fasting leptin concentration in HD obese patients is a result of leptin resistance in this group of patients. High cortisol concentration in HD malnourished patients may be responsible for inhibition of food intake and the loss of weight.

TH-PO584

Site and Size of Vascular Calcifications Are Different in Dialysis Patients with Various Underlying Diseases Hiromichi Suzuki, Tsutomu Inoue, Hirokazu Okada, Tsuneo Takenaka. *Department of Nephrology, Saitama Medical University, Iruma gun, Saitama, Japan.*

Background: It is well known that vascular calcification (VC) contributes to increased cardiovascular disease in dialysis patients and is used as a marker of the severity of vascular disease. However, VC occurs in vessels of various diameters and no definitive studies have determined the significance of VC in different vessels. The aim of this work was to learn if there was any association between the site of VC in the arteries and the underlying disease in dialysis patients.

Methods: This was an observational and cross-sectional study that included 78 dialysis patients. Using computed tomography (CT) scans, the total volume of VC in the thoracic and abdominal aorta and in the arteries of the lower limbs with a density more than 130 Hounsfield Units were semi-quantitatively determined as the sum of all voxels. Clinical characteristics and laboratory variables were determined by cardiac echography, dual-energy x-ray absorptiometry and pulse wave velocity.

Results: The patients (66% men, 40% diabetic) had median age anddialysis period of 62.3 yr and 76.7 months, respectively. VC in the thoracic aorta was present in 92%, in the abdominal aorta in 90% and in the lower limbs in 90% of the patients. All three lesions correlated significantly with each other. Stepwise regression was applied in which the independent variables were identified from the univariate analyses. Significant associations were seen for the following: the prevalence of calcification in the thoracic aorta with age, presence of diabetes, and calcium supplement; the abdominal aorta with period of dialysis, elevations of both systolic and diastolic blood pressure and levels of serum albumin; arteries of the lower limbs with presence of diabetes mellitus, use of sevelamer and cinacalcet and serum levels of intact parathyroid hormone and albumin.

Conclusions: The presence and extension of VC in thoracic and abdominal aortas and in arteries of lower limbs might be regulated in a complex manner and the use of these variables as a marker of the severity of vascular disease should proceed with caution.

TH-PO585

Impact of High Flux Membrane Dialysis on Clearance of Cardiac Troponin T in Asymptomatic Hemodialysis Patients Azharuddin Mohammed, Simon Fletcher, Daniel Zehnder. *Department of Nephrology, University Hospitals Coventry, Coventry, United Kingdom.*

Background: Cardiac troponin T (or I) level at baseline and 6-12 hours later is used to diagnose acute myocardial injury in HD patients. It is not uncommon for the 1st or the 2nd troponin sample collection timing to coincide when the patient is on dialysis. This questions whether collecting a timed troponin sample during dialysis offers reasonable diagnostic accuracy, and if dialysis impacts their clearance significantly.Aim of this study is to assess the impact of dialysis on clearance of troponin T.

Methods: 111 asymptomatic maintenance HD patients using Nipro high flux dialysis membrane and dialysing in-centre had undergone midweek cardiac troponin T testing predialysis. Of these 111 patients, 94 had both pre and post dialysis troponin T checked using Roche E170 immunoassay. Using local troponin T cut off range we divided patients into 3 groups. Troponin T level of <0.01 ug/L are classed as normal(A), 0.01-0.10 ug/L are classed as high(B) and a troponin T of >0.1 ug/L are classed as very high(C).A change in troponin T concentration and a class change post dialysis is then analysed.

Results: Prevalence of troponin T in the 3 groups were 22.5 %(25) in group C, 74.7% (83) in group B and 2.7 %(3) in group A (n=111). We then analysed those who had both pre and post dialysis troponin T checked (n=94). Mean troponin T in group B was 0.045 ug/L (0.1-0.10) and 0.26ug/L (0.11-1.69) in group C. Percentage of patients in the three groups pre and post dialysis were 3.2% Vs 4.25%, 76.5% Vs 80.8% and 20.2% Vs 14.9% respectively for group A, B and C. Mean troponin T change after dialysis in group B was 0.007 ug/L and 0.03 ug/L in group C; p=0.296. A sub analysis of group C (n=19) showed none of the patients changed to group A after dialysis, but 5 patients changed to group B; p=0.318. In group B (n=72), 1 patient changed class to group A.

Conclusions: Dialysis using high flux membrane has shown a minimal clearance of troponin T which is not statistically significant. Scheduled timely serial measurement of troponin T can be undertaken with a reasonable diagnostic accuracy to evaluate for acute myocardial injury in HD patients even if they are on dialysis.

TH-PO586

Prognostic Importance of Serum Magnesium in Peritoneal Dialysis (PD) Patients (pts) Morrell M. Avram, Hitesh Kapupara, William Hartman, Jyotiprakas Chattopadhyay. *Avram Division of Nephrology, SUNY Downstate University Hospital at LICH, Brooklyn, NY.*

Background: Lower serum magnesium is a significant predictor of mortality in hemodialysis pts. We have reported that lower serum magnesium is associated with poorer nutritional status, impaired cellular health and increased inflammation in PD pts. This study was designed to investigate the prognostic value of serum magnesium for mortality in PD pts.

Methods: Sixty two PD pts were enrolled in this study between November 2000 to May 2008. On enrollment, demographic, clinical and biochemical data were recorded. Pts were followed to May, 2011.

Results: Mean age was 54±16 (SD) years, 55% were female, 65% were African American and 24% were diabetic. Mean enrollment serum magnesium was 1.597±0.28 (SD) mEq/L (range:0.8-2.1 mEq/L). Maximum follow-up period was 10.46 years. During the follow-up period, 26 pts (42%) expired. Pts who survived had higher enrollment serum magnesium compared to those who did not survive (1.76 vs. 1.50 mEq/L, p=0.028). Pts were stratified into 2 groups by enrollment serum magnesium. Upon 10.46 years of observation, pts with enrollment magnesium >1.6 mEq/L had significantly better cumulative survival (Kaplan Meier) than that of pts with magnesium<1.6 mEq/L (p=0.02). In Cox's multivariate proportional hazard analysis, after adjusting for age, race, gender, diabetes, months on dialysis at enrollment, serum albumin, creatinine and C-reactive protein, serum magnesium was a significant predictor of mortality (Relative risk: 0.947, p=0.014). Months on dialysis at enrollment (Relative risk:1.022, p=0.002), albumin (Relative risk=0.131, p=0.04) and C-reactive protein (Relative risk=1.055, p=0.04) were also significant predictors of mortality in this model.

Conclusions: In conclusion, enrollment lower serum magnesium level is a strong independent predictor of long-term survival in PD pts. Factors affecting serum magnesium concentration in PD pts should be investigated in more detail. Current dialysate magnesium concentration is 0.5 mEq/L. Higher concentration should be considered in order to prevent magnesium depletion.

TH-PO587

Bone Mineral Density in Patients Receiving Hemodialysis Therapy for More Than 30 Years Shigeru Otsubo,[1] Takashi Akiba,[2] Kosaku Nitta.[3] *[1]Department of Blood Purification, Sangenjaya Hospital, Tokyo, Japan; [2]Department of Blood Purification, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan; [3]Department of Medicine, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Chronic kidney disease-mineral and bone disorder is a regular complication of hemodialysis patients. On the other hand, the number of patients receiving hemodialysis therapy for more than 30 years has been increasing. No information seems to be presently available concerning bone mineral density (BMD) in such patients. We investigated tartrate-resistant acid phosphatase (TRACP) 5b and the BMD, of extremely long-term hemodialysis patients.

Methods: Ninety-three outpatients receiving maintenance hemodialysis at our Hospital were enrolled. TRACP-5b was measured using a novel fragments-absorbed immunocapture enzymatic assay and two monoclonal antibodies. BMD was assessed using dual-energy X-ray absorptiometry scans. The absolute BMD values for the 1/3 distal radius on the side not containing the vascular access were reported. We classified the patients according to the duration of hemodialysis therapy (less than 10 years (n=57), 10-20 years (n=10), 20-30 years (n=8), or more than 30 years (n=18)) and compared them.

Results: The TRACP 5b level was higher in more than 30 years group (1192.4 ± 484.1 mU/dL), compared with each of the other groups (479.6 ± 253.3 mU/dL in less than 10 years group (p<0.0001), 456.7 ± 296.4 mU/dL in 10-20 years group (p<0.0001), 509.6 ± 256.3 mU/dL in 20-30 years group (p<0.0001)).The BMD and Z score was 0.59 ± 0.17 g/cm^2 and -0.26 ± 1.42 in less than 10 years group, 0.59 ± 0.16 g/cm^2 and -1.50 ± 2.33 in 10-20 years group, 0.45 ± 0.12 g/cm^2 and -2.23 ± 1.16 in 20-30 years group and 0.43 ± 0.13 g/cm^2 and -3.21 ± 1.86 in more than 30 years group. The BMD was lower in more than 30 years group than in less than 10 years group (p=0.019) and 10-20 years group (p=0.013). The Z sore was reduced gradually according to the duration of hemodialysis and was significantly lower in more than 30 years group than in less than 10 years group (p<0.0001) and 10-20 years group (p=0.009).

Conclusions: In patients receiving more than 30 years hemodialysis therapy, the BMD was reduced.

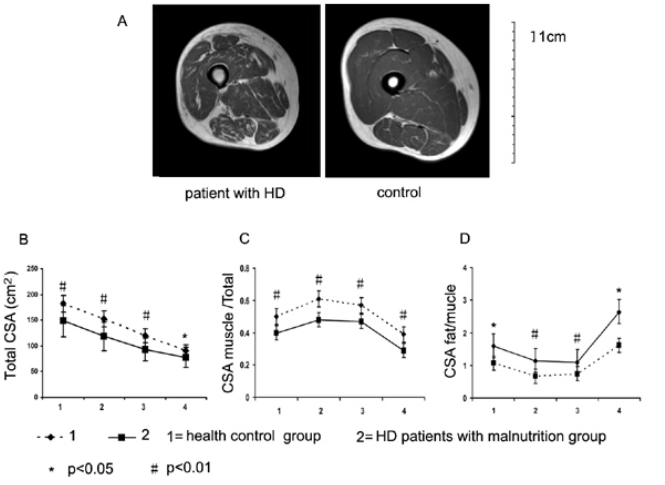
TH-PO588

Endogenous Glucocorticoid and Insulin Resistance Induced Muscle Wasting in Hemodialysis Patients Huiling Wang. *Division of Nephrology, Jimin hospital, Shanghai, China.*

Background: Patients undergoing advanced chronic kidney disease often present muscle wasting, to causes of poor physical function and living quality. The endogenous glucocorticoids (eGC) may trigger skeletal muscle atrophy by interaction with insulin-rsistance. However, the relationship between eGC lever or insulin-resistance and muscle wasting still need systematically addressed in clinic

Methods: We selected 70 patients who undertaken maintenance hemodialysis (MHD) without diabetes, and presenting malnutrition status evaluated by subjective global assessment (SGA); 30 healthy adults as control. Magnetic resonance imaging (MRI) of lower leg was determined the cross-sectional area (CSA) of muscle and fat.The serum corticosterone, fasting insulin and insulin resistance(HOMA-IR) was measured.

Results: The results showed there were no significant differences in gender and blood glucose. The bodyweight and body mass index, serum albumin were decreased in MHD. The serum corticosterone and the fasting insulin increased 4-5 times, the HOMA-IR was increased significantly compared with control. The MRI results showed the length of thighbone was no difference between MHD patients and the control group. The total cross-sectional area (CSA) of leg was significantly reduced in MHD. The morphologic observation showed muscle atrophy in MHD, the muscle CSA/total CSA ratio was lower, but the fat CSA/muscle CSA ratio was higher in MHD. The Spearman correlation analysis showed the eGC, fasting insulin levels and HOMA-IR was positively correlated to the MQSGA and MRI fat CSA; fat /muscle ratio; but negatively correlated with MRI muscle CSA and muscle /total ratio



Conclusions: In summary, dialysis patients with protein energy wasting characterized as decreased BMI and loss muscle mass, but fat content was increased. A high level of endogenous corticosteroids and insulin resistance might be related to muscle wasting

TH-PO589

Effect of Fasting and Refeeding on Global mRNA Expression on Skeletal Muscle of ESKD Patients Manish Suneja, John B. Stokes, Victoria S. Lim. *Internal Medicine, University of Iowa Hospital and Clinics, Iowa City, IA.*

Background: The effects of prolonged fasting (physiological low insulin state) and refeeding (high insulin state) on global mRNA expression in skeletal muscle of End Stage Kidney Disease patients are not known.

Methods: We studied five ESKD (3 male and 2 female) and seven healthy adult human subjects (3 male and 4 female).The subjects fasted for 40 hours, and then were refed with a mixed meal. Muscle biopsies were obtained from vastus lateralis muscle at the end of the 40 hour fast, followed by a second biopsy 6 hours later. Exon expression arrays were used to analyze RNA isolated from the muscle biopsy samples. We studied the differential gene expression in muscle during fasting and refeeding conditions and compared it with control subjects.

Results: Out of > 17,000 mRNAs measured, 344 and 670 genes increased with fasting whereas 349 and 514 genes decreased with fasting in normal controls and ESKD patients respectively ($P \leq 0.05$). There were only 80 genes in common which were regulated by fasting in both the groups ($P \leq 0.05$). Out of these 80 genes, 30 were upregulated; 37 were downregulated; and 13 genes were discordantly regulated . One of the prominent effect of fasting in both the groups was to increase levels mRNAs encoding known mediators of insulin/IGF1 signaling including IGF1 receptor (*IGF1R*), insulin receptor substrate-2 (*IRS2*) and GRB2-associated binding protein 1*(GAB1)*. Interestingly, fasting also induced mRNAs encoding known inhibitors of insulin/IGF1 signaling like thioredoxin-interacting protein (*TXNIP*). There was also a differential gene expression noted in the two groups with regards to insulin/IGF1signaling. Promoters of insulin signaling {insulin receptor (*INSR);* insulin receptor substrate-4(*IRS4)*} and inhibitor of insulin receptor/signaling {PTP1B (*PTPN1*) } were upregulated in the control group but not in the ESKD group.

Conclusions: Fasting and refeeding induces some common set of genes in both groups. Differential gene expression was noted in the two groups with regards to insulin/IGF1signaling. These differential changes in gene expression in the muscle may be responsible for high level of insulin resistance seen in ESKD patients.

TH-PO590

Body Composition Monitoring in Chronic Hemodialysis and Kidney Transplant Patients Sylvie Sulkova, Roman Safranek, Michaela Kubisova, Lydia Habanova, Petr Moucka, Katerina Petranova, Miroslav Merta. *Department of Nephrology, Gerontology and Metabolic Care, Medical Faculty and Teaching Hospital, Hradec Kralove, Czech Republic.*

Background: Chronic hemodialysis (HD) patients are at increased risk of malnutrition. Simple assessment, e.g. BMI calculation are not suitable for HD patients. The aim of our work was to assess one-year monitoring of body composition of HD patients and compare it with kidney transplant patients.

Methods: Body composition was assessed in 63 HD patients (22 females, 64 (54; 71) years) in two-month interval for one year. Bioimpedance spectroscopy (Body Composition Monitor) was used to estimate LTI (lean tissue index, kg/m^2), FTI (fat tissue index, kg/m^2). BMI (body mass index, kg/m^2) was calculated. Body composition of HD patients was compared with 100 kidney transplant patients (40 females, 57 (51; 70) years, 53 (20; 99) months after kidney transplant, serum creatinine 123 (94; 156)µmol/l). Data are given as median (lower; upper quartile).

Results: BMI, LTI, and FTI at the beginning of the study were 28.8 (26.2; 33.8)kg/m^2, 13 (11.4-14.8)kg/m^2, and 15.5 (10.8; 18.3)kg/m^2, in HD patients and 28.3 (25; 31.2) kg/m^2, 14.9 (12; 17.2)kg/m^2, 12.8 (8.7; 16.8)kg/m^2 in kidney transplant patients. Compared to reference range for normal population, we observed low LTI in 44% and 33% of HD and kidney transplant patients and high FTI in 65% and 60% of HD and kidney transplant patients, respectively. We observed no change in BMI during the course of the study in the group of HD patients, but changes in lean and fat tissue index in individual patients.

Conclusions: Bioimpedance spectroscopy shows low lean and high fat tissue index in HD patients. Similar results we obtained in a group of kidney transplant patients, which indicates profound defect in tissue composition regulation both in HD as well as in transplant status. We observed no influence of kidney graft function and time from kidney transplant on body composition. Body composition monitor is a useful tool for monitoring of fat and lean tissue mass in both HD and transplant patients and reveals changes of body composition in individual patients that may help in management of the patients.

Funding: Government Support - Non-U.S.

TH-PO591

Body Composition and Physical Performance in Maintenance Hemodialysis (MHD) Patients Jun Chul Kim,[1,2] Bryan B. Shapiro,[1,2] Kamyar Kalantar-Zadeh,[1,2,3,4] Usama Feroze,[1,2] Janos Porszasz,[1] Rachelle Bross,[1,2] Joel D. Kopple.[1,2,3,4] *[1]Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA; [2]Harold Simmons Center for Chronic Disease Research and Epidemiology, Torrance, CA; [3]David Geffen School of Medicine at UCLA, Los Angeles, CA; [4]UCLA School of Public Health, Los Angeles, CA.*

Background: MHD patients often display protein-energy wasting, sarcopenia and diminished physical performance. This study was undertaken to assess the relationship between body composition and physical performance in MHD patients.

Methods: Body composition, assessed by dual-energy x-ray absorptiometry and body mass index (BMI), were compared to three measures of physical performance: 6-minute walking distance, sit-to-stand testing and stair climbing. At present, 28 patients undergoing MHD for ≥6 months have been examined in this ongoing study.

Results: Patients were 53±13SD years, 36% female; 36% diabetic; dialysis vintage was 53±48 months. Unadjusted analyses indicated that 6-minute walking distance correlated with lean body mass (LBM) (r= 0.358; p= 0.031), LBM index (LBMI) (kg of LBM/m2 height; r= 0.322; p= 0.047) and % body fat (r= 0.435; p= 0.010); stair climb correlated with LBM (r= 0.341; p= 0.038), LBMI (r= 0.366; p= 0.028) and possibly with LBM of both legs combined (r= 0.318; p = 0.050) (Figures A and B). Sit-to-stand did not correlate with any body composition measure. There were no associations between BMI (range, 19.8-44.2 kg/m2) and physical performance.

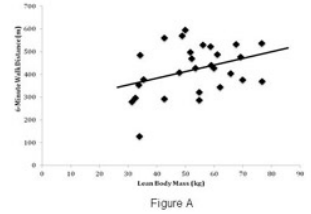

Figure A

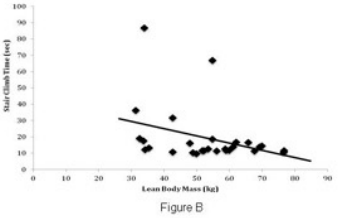

Figure B

Conclusions: These preliminary findings indicate that in MHD patients body composition, and especially LBM, was associated with certain measures of physical performance, and particularly with 6-minute walking distance and stair climbing.

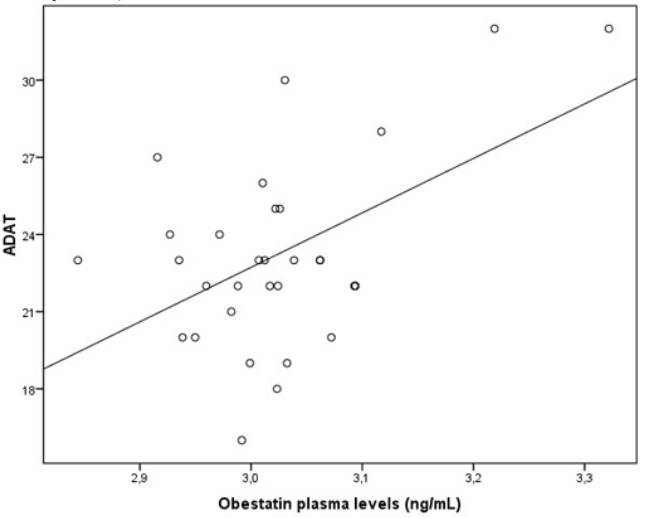
TH-PO592

Plasma Obestatin Levels Are Negatively Correlated with Appetite in Hemodialysis Patients Cristiane Moraes,[1] Julie Lobo,[2] Milena Barcza Stockler-Pinto,[2] Amanda Barros,[1] Denis Fouque,[3] Denise Mafra.[1] *[1]Department of Clinical Nutrition, Nutrition Faculty, Federal University Fluminense, Niterói, Rio de Janeiro, Brazil; [2]Institute of Biophysic Carlos Chagas Filho, Health Sciense Centre, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; [3]Department of Nephrology, Hôpital E.Herriot, Univ Lyon, Lyon, France.*

Background: Obestatin hormone, an appetite suppressant which seems to be up regulated in hemodialysis (HD) patients, appear of interest in chronic kidney disease since the majority of these patients suffer of protein- energy wasting (PEW). The purpose of this study was to analyze plasma obestatin levels in HD patients and its correlation with appetite and biochemical parameters.

Methods: Thirty- four HD patients (64.7% men, 46.6 ± 15.3 yr, BMI, 23.2 ± 4.0 kg/m2, 30.5 ± 6.7% body fat, 57.0 ± 36.0 months on dialysis) were studied. Obestatin levels were measured using the enzyme immunometric assay methods. Anthropometric parameters were recorded and, the appetite was assessed with Appetite and Diet Assessment Tool (ADAT) where the higher score means lower appetite.

Results: Obestatin levels (3.0 ± 0.1pg/mL) and ADAT values did not present differences between gender or BMI groups (cutoff point of BMI 25.0 kg/m2). Obestatin levels were positively correlated with ADAT values (r= 0.5; p= 0.004; Figure 1) and negatively correlated creatinine (r=-0.4; p=0.019). ADAT and creatinine were negatively correlated (r= -0.4; p= 0.019).



Conclusions: Obestatin levels are increased in HD patients with poor appetite and these patients present loss of muscle mass according to creatinine. Therefore high plasma obestatin could be related to PEW.

Association of Adipokines with Cardiovascular Mortality in Patients on Hemodialysis Shoichi Maruyama,[1] Kaoru Yasuda,[1] Hirotake Kasuga,[2] Yoshinari Yasuda,[1] Tomoki Kosugi,[1] Waichi Sato,[1] Naotake Tsuboi,[1] Yasuhiko Ito,[1] Enyu Imai,[1] Seiichi Matsuo.[1] *[1]Department of Nephrology, Nagoya University Graduate School of Medicine, Naogya, Aichi, Japan; [2]Department of Nephrology, Naogya Kyoritsu Hospital, Nagoya, Aichi, Japan.*

Background: The role of adipokines for cardiovascular disease remains controversial in chronic hemodialysis (HD) patients. We prospectively investigated the association of adipokine with cardiovascular mortality in patients on HD.

Methods: Plasma adiponectin, leptin, resistin and tumor necrotic factor-α (TNF-α) were measured in pre-dialysis blood sample in 203 patients on HD (age: 65±11 years, diabetes: 49%, duration of HD: 8.1±7.1 years). Geriatric nutrition risk index (GNRI) as a parameter of nutrition status was also calculated from individual serum albumin levels and body mass index. Patients were followed up for 5 years.

Results: During follow-up period (mean 54±14 months), 27 patients (13.3%) died due to cardiovascular disease. On Cox analysis, only adiponectin (HR: 1.07, 95%CI: 1.02-1.12, P = 0.01) and leptin (HR 0.94, 95%CI 0.88-0.99, P = 0.021) were significantly associated with cardiovascular mortality, respectively. Based on cut-off levels using ROC analysis (11.7µg/ml, AUC=0.72 for adiponectin, and 3.5ng/ml, AUC=0.74 for leptin, respectively), 5-year freedom from cardiovascular mortality was lower in the high adiponectin group than in the low adiponectin group (77.3% vs. 94.1%, P = 0.0006), and was lower in the low leptin group than in the high leptin group (72.3% vs. 93.7%, P = 0.0001), respectively. After adjustment for other risk factors, high adiponectin and low leptin were independent risk factors of cardiovascular mortality (HR: 2.54, 95%CI: 1.01-6.59, P = 0.045, and HR:2.82, 95%CI:1.12-7.14, P = 0.029, respectively). Adiponectin levels were negatively correlated with GNRI levels (r = 0.36, P < 0.0001), and leptin levels were positively correlated with GNRI (r = 0.49, P < 0.0001).

Conclusions: In contrast to general population, high adiponectin and low leptin were associated with an increased risk of cardiovascular mortality in patients on HD. These paradoxical associations were hypothesized to be affected from prevalent malnutrition status in HD patients.

TH-PO594

Phase Angle, a Bioimpedence Analysis (BIA)-Derived Parameter of Body Composition and Cellular Health, Predicts Long-Term Survival in Hemodialysis (HD) Patients (Pts) Neal Mittman, Brinda Desiraju, Jyotiprakas Chattopadhyay, Morrell M. Avram. *Avram Division of Nephrology, SUNY Downstate University Hospital at LICH, Brooklyn, NY.*

Background: BIA has been validated as a useful tool to measure body composition in HD pts. Phase angle (PA), a BIA-derived parameter, has been associated with cellular health in dialysis pts. The objective of this study was to explore the relationship between PA, clinical, and biochemical characteristics in HD pts.

Methods: Fifty-eight HD pts in our urban center were enrolled from 2000, clinical data was recorded, and pts were followed over time.

Results: Mean age was 61 yrs. Fifty-seven percent were women, 37% were diabetic, and 79% were of African descent (79%). Mean dialysis vintage was 81 mo. Mean PA was 5.17 degrees. PA decreases with age, and men had significantly higher PA (6.17 v. 4.42 degrees, p=0.001). Pts with PA≥6 degrees had better cumulative survival compared to those with lower PA (p<0.005). In Cox's multivariate analysis, after adjusting for age, gender, diabetic status and dialysis vintage, PA was an independent predictor of mortality (RR=0.617, p=0.012). Therefore, for each degree higher, the relative mortality decreases by 38%. The correlates of PA are shown below:

Correlations of PA with age and biochemical markers

Variables	Correlation Coefficient	p
Age (years)	-0.35	0.007
Albumin (g/dl)	0.36	0.019
Creatinine (mg/dl)	0.51	0.001
Hematocrit (%)	0.32	0.037
Months on dialysis	-0.24	0.078
Survival period (years)	0.39	0.004

Conclusions: As previously noted, PA is positively correlated with survival, and negatively correlated with age. Higher PA also correlated with arkers of somatic (creatinine) and visceral (albumin) protein stores, serum potassium and hematocrit. In summary, PA is an independent predictor of mortality risk, likely related to its reflection of cellular health and nutritional status in dialysis pts, and therefore may be a useful prognostic tool in this population. The use of serial BIA measurements to assess risk and impact survival, ideally in association with aggressive management of protein calorie malnutrition, should be evaluated in prospective trials.

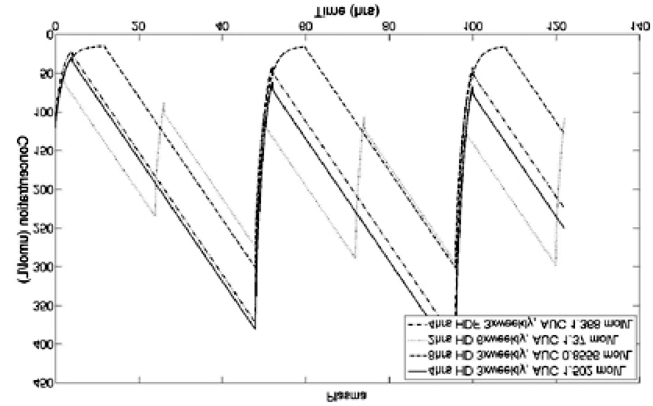
TH-PO595

Optimizing Oxalate Removal in Primary Hyperoxaluria by Hemodialysis Colin A. Hutchison,[1] Richard T. Keir,[2] Anne Bevins,[3] Neil D. Evans,[2] Paul Cockwell.[1] [1]*Renal Unit, University Hospital Birmigham, United Kingdom;* [2]*University of Warwick, United Kingdom;* [3]*The Binding Site Group Ltd, Birmingham, United Kingdom.*

Background: Primary hyperoxalemia is frequently associated with end stage renal disease which in turn is complicated by early cardiovascular disease secondary to oxalosis. It is therefore necessary to optimize the removal of oxalate by hemodialysis to minimize this complication. The purpose of this study was to evaluate the removal of oxalate by different dialysis schedules in a patient recently returned to dialysis following a failed kidney transplant.

Methods: During a three month period the clearance of oxalate was studied with the following dialysis modalities and schedules: high flux hemodialysis (HD), 2 hrs 6x week, and 4 hrs or 8 hrs 3x week; hemodiafiltration (HDF), 4 hrs 3x week; and high cut-off (HCO) hemodialysis, 4 hrs 3x week. A two compartment mathematical model was used to simulate oxalate clearance.

Results: The absolute clearance rate of oxalate with HDF was significantly higher compared with HD alone. However the simulations of the different modalities determined that the greatest reduction in area under the curve (oxalate exposure per week) was achieved with 8 hrs of HD three times per week.



This represented the importance of clearing the extra-vascular compartment by time alone. This was a 43% reduction from the exposure when HD was just 4 hrs three times per week. In comparison there was only a 10% reduction in the area under curve for HDF (4hrs, 3x week). HCO membranes provide clearance rates which were equivalent but not superior to standard HD.

Conclusions: To provide optimal removal of oxalate in a chronic dialysis patient the duration of dialysis was the most significant factor.

TH-PO596

Metabolic Profiling of Frailty in Hemodialysis Patients Quinlyn A. Soltow,[1] Rebecca H. Zhang,[2] Dean P. Jones,[1] Nancy G. Kutner.[2] [1]*Department of Medicine, Emory University;* [2]*Department of Rehabilitation Medicine, Emory University, Atlanta, GA.*

Background: The phenotype of frailty provides criteria that define individuals who lack functional reserve and are at risk for functional decline. An ongoing special USRDS study (ACTIVE/ADIPOSE) is focusing on identifying components and progression of frailty dimensions in prevalent hemodialysis (HD) patients. As an adjunct to this study, our group is using metabolomics to investigate specific metabolites and metabolic patterns unique to frailty.

Methods: A subset (n = 29) of prevalent patients undergoing HD in Atlanta GA dialysis clinics and participating in ACTIVE/ADIPOSE were age- and sex-matched with an equal number of healthy controls. All were assessed for frailty characteristics and supplied plasma samples, which were compared using a dual chromatography-Fourier-transform mass spectrometry (DC-FTMS) method developed at Emory to generate global metabolic profiles.

Results: Mean (sd) age of HD patients = 54.8 (13.1); mean (sd) age of healthy controls = 53.7 (14.7); 62% of each cohort were male. Frailty status was defined by the Fried criteria of recent weight loss, exhaustion, low physical activity, slow walk time, and low grip strength. The DC-FTMS-based metabolomics method detected over 10,000 metabolic features in plasma samples from 58 subjects. Using the following data reduction techniques, Principal Component Analysis separated metabolic patterns unique to HD and frailty status, while False Discovery Rate identified 120 metabolic features that differed significantly by frailty status in HD patients. Among these significant features, many nutritionally relevant metabolites matched to metabolomics databases, including various amino acid dipeptides and tripeptides, lipids, and others.

Conclusions: Metabolic patterns detected by DC-FTMS are altered in HD patients and change according to frailty status, and metabolic features relating to nutritional status and protein metabolism can be identified that change with frailty progression. Metabolic profiling is a useful tool for detection of potential biomarkers or patterns of metabolites to predict frailty in hemodialysis patients and to evaluate interventions that delay functional decline.

TH-PO597

Changes in Pre-Dialysis Weight Relate to Key Laboratory Parameters in Hemodialysis Patients Richard Amerling,[1] Penny Faith Palmiero,[2] James F. Winchester,[1] Len A. Usvyat,[2] Nathan W. Levin,[2] Peter Kotanko.[2] [1]*Division of Nephrology and Hypertension, Beth Israel Medical Center, New York, NY;* [2]*Renal Research Institute, New York, NY.*

Background: Low hemoglobin (Hb) and serum albumin (SA) levels are predictors of poor outcome in hemodialysis (HD) patients (pts). Fluid overload expands intravascular volume and lowers Hgb and SA. Given that these parameters are measured pre-HD, we hypothesized that fluid overload lowers SA and Hgb and confounds their use as prognostic indicators.

Methods: We performed a retrospective record review in 5510 in-center HD pts treated in RRI clinics in February and March 2011. For each pt we identified the first date in February and March 2011 when Hb, SA, and pre-HD weights were recorded. Simple linear regression analysis was used to assess the relationship of Δpre-weight (ΔPW) [March pre-HD weight – February pre-HD weight] versus ΔHb [March Hb – February Hb] and ΔSA [March SA – February SA]. Pts were divided into quintiles of ΔPW.

Results: We found a weak yet significant inverse correlation between ΔPW and ΔHgb (r =-0.15; P<0.001) and ΔPW and ΔSA (r = -0.12; P<0.001). A 1 kg decrease in pre-HD weight was associated with a Hb rise of 0.08 g/dL and an albumin rise of 0.012 g/dL. Dividing patients into quintiles of ΔPW suggests a dose response relationship between ΔPW and ΔSA and Hb (ANOVA with post-hoc Tukey test demonstrated significant differences between Δalbumin and ΔHgb between all quintiles of ΔPW).

Month to month weight change vs. ΔSA and ΔHb

Weight change quintile (range;kg)	Mean ΔSA (g/dL)	Mean ΔHb (g/dL)
1 (<-1.3)	0.043	0.35
2 (-1.3 to -0.4)	0.033	0.144
3 (-0.3 to 0.4)	0.01	-0.02
4 (0.4 to 1.3)	-0.02	-0.048
5 (>1.3)	-0.042	-0.262

ΔPW remained a significant predictor of ΔSA and ΔHgb using simple linear regression models adjusted for Feb pre-HD weight, gender, race, vintage, and age.

Conclusions: We demonstrate that short-term changes in pre-HD weight, which are likely to reflect differences in extracellular volume, are significantly and inversely correlated with changes in Hb and SA. Volume status should be considered when interpreting Hb and SA. Volume overload may partially explain association of low Hb and SA with poor outcomes in HD patients.

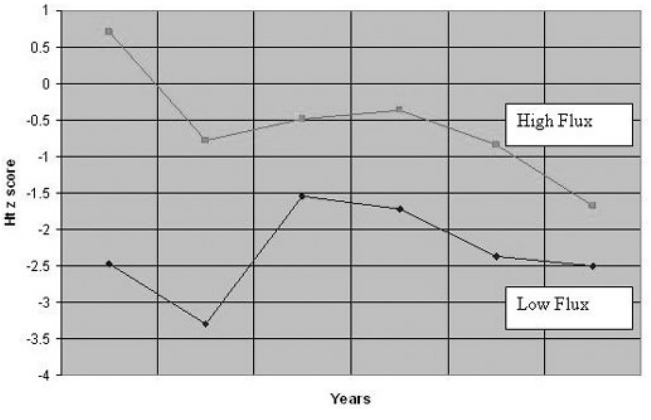
Impact of Membrane Flux on Growth and Mineral Metabolism in Children with End Stage Renal Disease on Hemodialysis Nataliya Chorny,[1] Gail Prado,[1] Sreevidya Kusuma,[1] Amrit Bhangoo,[2] Anil K. Mongia.[1] *[1]Pediatric Nephrology, SUNY Downstate, Brooklyn, NY; [2]Pediatric Endoctrinology, SUNY Downstate Medical Center, Brooklyn, NY.*

Background: Growth retardation in children with ESRD is attributed to various factors including efficacy of hemodialysis, proinflammatory state and bone disease. High flux dialyzers are efficient in removal of both small non-protein bound and middle molecules like β2-microglobulin and may reduce inflammation.

Methods: We hypothesized that children on high flux membranes will show better growth and improved mineral metabolism.

Retrospective review of 21 children on long term hemodialysis from 2006-2011. Patients divided into two group based on high flux (Optiflux and Polyflux) or low flux dialyzers (DZ). One patient in high flux group received rGH, but was discontinued. We measured height, weight, height and weight Z scores, change in height and weight Z scores and laboratory variables including serum albumin, CO2, Hemoglobin, serum ferritin, calcium, phosphorus, PTH, urea reduction rate (URR), kt/V. Statistical analysis was done using t-test

Results: Ages at onset ranged from 2 years to 21 years, 10 were males. 14 were AA, 4 Hispanic. Height and weight Z scores though not statistically significant were better in patient on High flux dialysis compared to patient on Low flux dialyzer (Fig 1)



Mean Predialysis Values

Parametes	Low Flux DZ	High Flux DZ	P-value
Hemoglobin	11±1.34	11 ±5.76	0.875
URR	75±38.8	75±38.2	0.244
Kt/V	1.94 ±1.075	1.72±0.8	0.405
Albumin	4.±0.26	4±1.13	0.453
Ferritin	382.±240	65.2±43.5	0.055
CO2	20 ±7.7	22±7.3	0.07
Phosphorus	4.9±0.69	4.6±1.6	0.576
Calcium	8.9 ±0.55	8.9 ±4.45	0.912
PTH	295±187.5	449±346.	0.204

Conclusions: In children on chronic dialysis, growth may be improved by using High Flux dialysis. This may be related to better uremic toxin removal, acidosis improvement and reduced dialysis induced inflammation.

TH-PO599

The Role of Nutritional Scores for Serial Monitoring of Nutritional Status in Hemodialysis Patients Ilia Beberashvili,[1] Ada Azar,[2] Inna Sinuani,[1] Hadas Kadoshi,[2] Gregory Shapiro,[1] Leonid Feldman,[1] Zhan Averbukh,[1] Joshua Weissgarten.[1] *[1]Nephrology, Assaf Harofeh Medical Center, Zerifin, Israel; [2]Nutrition, Assaf Harofeh Medical Center, Zerifin, Israel.*

Background: Simple prediction scores could help identify hemodialysis patients at high risk for protein-energy wasting (PEW). We compared the longitudinal performance of the malnutrition-inflammation score (MIS) and geriatric nutritional risk index (GNRI) - the two nutritional scores for patients on maintenance hemodialysis.

Methods: Nutritional scores, dietary energy and protein intake, nutritional biomarkers, anthropometry and bioimpedance analysis were performed at baseline and at 6, 12 and 18 months following enrollment in 75 prevalent hemodialysis patients (43% women, mean age 64.8±11.9 years). Additionally the patients underwent simultaneous assessment of MIS and GNRI at baseline, calculated by two independent examiners. The study period encompassed 46.8 ±16.4 months.

Results: GNRI had higher inter-observer agreement (weighted k-score 0.96) than MIS (weighted k-score 0.62). Longitudinally, one-unit increase in MIS over time, controlling for demographic and clinical parameters, was associated with a 0.4089 kcal/kg/day reduction in daily energy intake (P<0.001) and with a 0.0135 g/kg/day reduction in nPNA (P=0.015). GNRI did not correlate with the change over time of dietary intake. Longitudinal changes of both scores were associated with appropriate changes over time in levels of biomarkers of nutrition, inflammation (IL-6) and body composition parameters. Both scores expressed significant associations with prospective hospitalization, whereas only MIS was associated with mortality in our cohort: the Cox proportional hazard-calculated relative risk for death for each one-unit increase in the MIS was 1.15 (95% CI, 1.03 to 1.3; P = 0.015).

Conclusions: Both, MIS and GNRI are valid tools for the longitudinal assessment of nutritional status of hemodialysis patients, whereas the MIS has lower inter-observer reproducibility, but is more comprehensive than GNRI.

TH-PO600

Serum Creatinine to Body Weight Ratio – A Simple Measure of Body Composition? Rebecca Filipowicz,[1] Talat Alp Ikizler,[3] Glen Morrell,[1] Guo Wei,[1] Tom H. Greene,[1,2] Srinivasan Beddhu.[1,2] *[1]VA; [2]Univ Utah; [3]Vanderbilt.*

Background: Body composition is not routinely measured in clinical practice in HD pts. Therefore, we examined whether SCr (a marker of muscle mass in HD pts) to weight (Wt) ratio is associated with measures of body composition, inflammation and functional ability.

Methods: This study is a secondary analysis of an ongoing longitudinal study of nutritional status in HD pts. 116 pts who underwent at least one DEXA scan for measurement of body composition were included. Ht, wt and 6-min walk distance were measured on a non-HD day. Intra-abdominal fat at the L4-L5 level and muscle area at mid thigh level were meausred with MRI. hsCRP was measured using Roche MODULAR P analyzer. hsCRP > 10 mg/L was defined as ↑ CRP. Generalized estimating equations (GEE) were used to fit a pooled cross-sectional regression model relating outcomes to concurrently measured SCr/Wt across 4 study visits.

Results: Baseline characteristics by SCr/wt tertiles

	SCr/wt)0.14	SCr/wt 0.10-0.14	SCr./wt ⟨0.10
SCr, mg/dL	12.0±3.0	9.6 ±1.7	6.9 ±1.9
Wt, kg	65±16	83±15	89 ±18
Age,yr	43± 16	51±14	58±15
Men, %*	58	55	59
DM, %	11	55	62
CHF,%	11	15	33
CVD,%	11	23	26
BMI, kg/m²	23.2± 4.5	29.0±4.7	30.8±5.7
Intra-abdominal fat, cm²	79±43	140±68	167±65
Muscle area, cm²*	109±29	108±28	104±26
DEXA fat mass/wt ,%	25±9	34±9	39±18
6-min walk distance,m	372±109	313±110	244±78

*p=ns As shown in the table, ↓ SCr/wt ratio was associated with ↑ visceral fat and ↑ DEXA fat mass to body wt ratio. In a multivariable GEE regression, adjusted for age, gender, race and DM, compared to the highest tertile of Scr/Wt, the lowest tertile was associated with ↓6 min walk distance (β -61, 95% CI -94 to -29 m). Similarly, compared to the highest tertile, the lowest tertile was associated with ↑odds of CRP (OR 2.91, 95% CI 1.15 to 7.41). Results were similar when these models were further adjusted for wt.

Conclusions: SCr/Wt is associated with direct measures of body composition and correlates with inflammation and physical function. The specific functional form of SCr/Wt which scales optimally with body composition needs to be determined.

TH-PO601

Severity of Glucose Intolerance Is a Morbidity and Long-Term Mortality Risk Factor in Non-Diabetic (NDM) Hemodialysis (HD) Patients (pts) Neal Mittman, Brinda Desiraju, Thomas S. Guagliardo, Jyotiprakas Chattopadhyay, Morrell M. Avram. *Avram Division of Nephrology, S.U.N.Y. Downstate University Hospital at L.I.C.H., Brooklyn, NY.*

Background: Patients with chronic kidney disease have impaired glucose tolerance, a known cardiovascular risk factor, irrespective of etiology. Serum fructosamines (SF), including glycated albumin, have been evaluated as superior markers of glycemic control to HbA1c (A1c) in this population. We have reported that SF, but not A1c, is associated with infection and hospitalization in DM HD pts (KI, 2010). We are unaware of any published work associating degree of glucose intolerance in NDM HD pts with outcomes.

Methods: We enrolled sixty NDM (A1c≤5.6%, no history DM), measured SF (corrected for albumin, AlbSF), and followed them for up to 6 years.

Results: Mean age was 54 yr, and they were evenly divided by gender. The majority (78%) were of African descent. Mean A1c was 5.1% (range, 4.4-5.6). 75% had SF above normal range (normal ≤265µmol/L; mean, 285; range 187-378). There was no association of A1c with morbidity or mortality during 2 and 5 years of observation. AlbSF, on the other hand, was correlated with frequency ($p<0.001$) and duration of hospitalization ($p<.03$) over both periods of observation. In addition, univariate Cox regression analysis revealed that AlbSF was associated with increased mortality risk. In Cox's multivariate analysis, after adjusting for age, gender, and dialysis vintage, AlbSF remained a significant independent mortality predictor (See Table).

Variables	Two years observation	Five years observation
	Relative Risk (p)	Relative Risk (p)
Age (years)	1.025 (p=0.36)	0.99 (p=0.98)
Gender (female vs. male)	0.39 (p=0.23)	0.47 (p=0.17)
Months on dialysis	0.99 (p=0.84)	1.004 (p=0.18)
AlbSF (µmol/g)	1.01 (p=0.003)	1.007 (p=0.004)

Therefore for each µmol/g increase in AlbSF, there was a 1% and 0.7% greater relative mortality risk over 2 and 5 years, respectively.

Conclusions: In conclusion, severity of glucose intolerance in NDM HD pts, as measured by SF, is highly associated with interim and long-term outcomes. These results need to be confirmed in large prospective trials, including therapeutic interventions aiming to normalize or reduce SF levels.

Funding: Private Foundation Support

TH-PO602

Early Time-Dependent Changes in Serum Albumin Predict 2-Year Survival in Maintenance Hemodialysis Jorge P. Strogoff-de-Matos,[1] Giselly R. Pereira,[1] Jorge Reis-Almeida,[1] Adrian Marcos Guinsburg,[2] Cristina Marelli,[2] Ana Beatriz Lesqueves,[3] Marcos Sandro Fernandes de Vasconcelos,[3] Eufronio D'almeida,[3] Frederico Ruzany,[3] Jocemir R. Lugon.[1] *[1]Division of Nephrology, Universidade Federal Fluminense, Niteroi, Brazil; [2]Fresenius Medical Care, Buenos Aires, Argentina; [3]Fresenius Medical Care, Rio de Janeiro, Brazil.*

Background: Our aim was to assess the predictive value of early time-dependent changes in serum albumin (sAlb) on late outcome in hemodialysis (HD) patients.

Methods: In this observational study, 1,775 incident patients on HD from 25 dialysis facilities had the sAlb measured at admission and 3 months later. The time-dependent change in sAlb was calculated as the ratio of 3-month sAlb: initial sAlb, and expressed as percentage. Patients were split into two groups according to initial sAlb (below or above the median) and followed-up for 2 years. The risk of death associated with the early change in sAlb was calculated by a Cox regression model with adjustment by age, gender and diabetes.

Results: Patients were 59% males, 20.7% diabetics, 50±16 years old, and have a median sAlb of 3.8 g/dL. The 2-year survival was significantly higher in the group with initial sAlb above the median (94.3% vs. 85.5%, P< 0.0001). The adjusted hazard ratio (HR) of death was 0.88 (95% confidence interval [CI] 0.78 to 0.99; P=0.04) for each 10% incremental in sAlb among patients in the group with initial sAlb below the median. Conversely, the adjusted HR of death was 1.35 (95% CI 1.21 to 1.50; P=0.0001) for each 10% reduction in the group with initial sAlb above the median.

Conclusions: Early time-dependent sAlb changes have a significant impact on 2-year survival rate. Patients with initial low sAlb can have good outcomes if an early elevation in sAlb is seen, whereas those with initial satisfactory levels can switch to a bad prognosis in case of early reduction in sAlb.

TH-PO603

Risk Factors for Depressive Symptoms in a Large Population on Chronic Hemodialysis Sonia Maria Holanda Almeida Araujo,[1] Nicole Araujo,[2] Andre Pantaroto,[2] Constance Almeida de Alencar Araújo,[1] Gilson Almeida,[3] Pedro Bruin,[1] Veralice Meireles Sales Bruin,[1] Elizabeth De Francesco Daher.[1] *[1]Medicina, Universidade Federal do Ceara, Fortaleza, Ceara, Brazil; [2]Medicina, Faculdade de Medicina de Jundiai, Jundiai, Sao Paulo, Brazil; [3]Medicina, Faculdade de Medicina Christus, Fortaleza, Ceara, Brazil.*

Background: Despite significant effect in quality of life, depressive symptoms have not been sufficiently evaluated as an important parameter in hemodialysis patients. We aimed to identify depressive symptoms, and study risk factors in a large group of individuals with end-stage renal disease (ESRD) on chronic hemodialysis.

Methods: Cases were analyzed according to the presence/absence of depressive symptoms. All individuals were investigated by interview and all variables were measured concurrently. Depressive symptoms were evaluated by the Beck Depression Inventory (BDI-II≥16) and poor sleep quality by the Pittsburgh Sleep Quality Index (PSQI>5).

Results: In 400 patients (59% male), depressive symptoms were present in 77 (19.3%). Depressive symptoms were more common in women and were independently associated with poor quality sleep (P=<0.005), unemployment (P=0.005), diabetes (P=0.005), hypoalbuminemia (P=0.01), heart failure (P=0.01) and pruritus (P=0.03).

Conclusions: Women with ESRD on chronic hemodailysis are at increased risk of depression. Furthermore, unemployment and the presence of diabetes, hypoalbuminemia, heart failure and pruritus should raise suspicion for this diagnosis. Depressive symptoms are also independently associated with poor quality sleep and studies about the effects of sleep hygiene therapy on depressive symptoms are warranted.

TH-PO604

Correlation of Nutritional Status with Depression and Cognitive Function in Hemodialysis Patients Young Rim Song, Jwa-Kyung Kim, Jung-Woo Noh, Ja-Ryong Koo. *Division of Nephrology and Kidney Research Institute, Hallym University Sacred Heart Hospital, Anyang, Kyunggi-do, Korea.*

Background: Malnutrition, depression and cognitive impairment are in themselves challenging problems in hemodialysis patients, but diagnosis and treatment are often suboptimal. Nutritional status and its association with cognitive function and depression remains uncertain

Methods: Seventy seven patients with maintenance hemodialysis were enrolled as part of this cross sectional study. Nutritional assessment was undertaken with a bio-impediance spectroscopy device, the Body Composition Monitoring (BCM), handgrip strength (HGS), a seven-point subjective global assessment (SGA) and serum biomarkers (albumin, prealbumin, cholesterol, CRP). HGS was measured before and after HD sessions on the non-fistula side with dynamometer (Jamar) and the highest value was used for analysis. Muscle function (MF) loss was defined as less than the 10th percentile of population-based reference in Korea. Neuropsychological test was performed by Mini-Mental State Examination in the Korean version of CERAD assessment packer (MMSE-KC) and Beck depression Inventory (BDI) during the 1st hour of dialysis.

Results: The mean age was 59.2 years and the median dialysis duration was 39.5 months. 56.6 % were men, 58 % had diabetes. The Mean MMSE and BDI score were 27.1 ± 3.1 and 20.5 ± 10.8, respectively. 68.9 % had MF loss and 51.3 % had moderate to severe depression. In the multivariate analysis, BDI score correlated with handgrip strength (r=-0.342, p=0.003), SGA score (r=-0.226, p=0.050) and Lean tissue index (r=-0.247,0.035). MMSE score correlated with age (r=-0.337, p=0.003), handgrip strength (r=0.259, p=0.026), lean tissue index (r=0.273, p=0..019), fat tissue index (r=,-0.345, p=0.003), albumin (r=0.283, p=0.013). After adjustment for other clinical variables, Patients with MF loss were more likely to be depressed (adjusted OR=3.78,95% CI 1.2-12.7).

Conclusions: Handgrip strength was associated with depression, independently of age, sex, albumin, proalbumin and CRP levels. MMSE score was not associated with nutritional status.

TH-PO605

Effects of Antioxidants on Postprandial Metabolic Response to a Fat- and Carbohydrate-Rich Meal in Patients with Chronic Kidney Disease Tetsu Miyamoto, Abdul Rashid Tony Qureshi, Björn Anderstam, Tae Yamamoto, Peter Stenvinkel, Bengt Lindholm, Jonas Axelsson. *Renal Medicine and Baxter Novum, Karolinska Institute, Stockholm, Sweden.*

Background: Metabolic and inflammatory pathways are closely interrelated with an impaired sequestration of nutrients. No study has investigated impact of anti-oxidants on the postprandial metabolic and inflammatory response in end-stage renal disease patients (pts).

Methods: A randomized, double-blind study comparing fasting and postprandial circulating biomarkers of glucose and lipid homeostasis and inflammation was conducted in 5 non-diabetic hemodialysis (HD) pts and 9 matched controls assessed at 30, 60, 120, 180 and 240 min after a standardized meal consisting of 75 g of milk fat, 80 g of carbohydrates and 6 g of proteins/m^2. Subjectsts were tested 4 times: at baseline, and after 7 days treatments of anthocyanins (MP865, 240 mg/day), N-acetylcysteine (NAC, 600 mg/day) and placebo (lactose, 200 mg/day) respectively.

Results: NAC resulted in increased plasma NAC levels (17.2±4.1 mmol/L) and decreased circulating homocysteine levels (14.1±3.0 mmol/L after placebo vs 10.3±3.1mmol/L after NAC, p=0.03). Following the meal, glucose increased in a similar manner in the two groups, while insulin and C-peptide increased more in HD-pts. After NAC treatment, a smaller area under the curve of change during the 4 hour postprandial period (ΔAUC_{4hr}) of insulin was observed compared to baseline (p=0.03) and placebo treatment (p=0.08) in controls. However, these effects of NAC on insulin were not observed in HD-pts. HDL- and LDL- cholesterol marginally decreased in both groups with no effects of the treatments. Unexpectedly, IL6 slightly decreased over time in pts (ΔAUC_{4hr} = -3.3±1.2 hr pg/ml) in contrast to controls (ΔAUC_{4hr} = 0.8±1.2 hr pg/ml, $p<0.001$). No effects of the treatments on ΔAUC_{4hr} of IL-6 or TNF-a were detected in pts and control subjects.

Conclusions: The postprandial state in non-diabetic HD-pts is characterized by impaired insulin sensitivity and slight decrease in circulating proinflammatory cytokines. Treatment with anti-oxidants had no impact on selected postprandial metabolic and inflammatory markers in HD-pts.

TH-PO606

Which Frequency for Cobalamin Supplementation in Pre-Dilutional Hemodiafiltration? Carlos Frangié, Thierry Baranger, Frank Bergé, Valerie Drouillat, Emmanuelle Rosier, Piotr Seniuta. *Néphrologie et Dialyse, Polyclinique Bordeaux Nord, Bordeaux, France.*

Background: The technical data of high permeability dialyzers in pre-dilutional hemodiafiltration (HDF)show a high clearance of the cobalamin. The cobalamin is a vitamin not produced by the human body and its serum rate depends on dietary intake. Its was reported that an overdose of cobalamin may increase risk of neoplasia. In chronic HDF, intravenously or orally cobalamin supplementation is common.

Methods: A retrospective study followed by a prospective study, were performed on patients of our HDF centers 1 (C1) and 2 (C2). Retrospective study over a period of one year (June 2009-June 2010), analyzed cobalamin serum level among 50 patients in C1 (28 women, 22 men) and 36 patients in C2 (15 women, 21 men). Patients of C1 had received a weekly injection of cobalamin intravenously; the patients of C2 did not receive supplementation since June 2009. The prospective analysis was conducted over a period of 6 months, using monthly intravenous cobalamin injection for patients of C1, C2 patients constituting the control group without supplementation.

Results: Retrospective analysis shows that C1 patients, all had an overdose of cobalamin. Patients in the C2, initially overdosed in cobalamin, had presented a significant decrease in serum after 6 months ($p = 0{,}0002$) while remaining in the normal range, and this rates remained stable after one year ($p = 0.3$). The prospective analysis showed decreased but remaining high normal serum cobalamin in patients of C1, and stability in normal in patients of C2.

Conclusions: In vitro studies of high permeability dialyzers with pores up to 30 kDa, showed a very high clearance of cobalamin (1,335 KDa). Mean daily intakes of cobalamin (in order of 4 mg) cannot compensate per-dialytic clearance. In this study, serum level of cobalamin may remains normal without supplementation, and cobalamin binding to high molecular weight protein could be an explanation.

In pre-dilutional HDF, quarterly or biannual cobalamin supplementation seems to be sufficient. A prospective study is underway in our centers, using quarterly cobalamin , intravenous (C1, n = 130) or orally (C2, n = 72) supplementation.

TH-PO607

A Pilot Study of Nuclear Magnetic Resonance (NMR) Lipid Profiling in End Stage Renal Disease Hania Kassem, Manish P. Ponda. *Nephrology, New York University School of Medicine, New York, NY.*

Background: Lipoproteins can predict coronary heart disease risk. Hemodialysis (HD) patients suffer from accelerated cardiovascular disease. They also tend to have atherogenic changes in the lipid profile, including hypertriglyceridemia and low HDL. However, conventional therapy has been disappointingly ineffective in lowering cardiovascular risk for this population. Nuclear Magnetic Resonance (NMR) lipid analysis can determine lipoprotein particle size and number, and can complement the standard lipid profile. NMR lipid analysis has been previously studied in the dialysis population, but not in comparison to matched controls.

Methods: We sought to assess, using NMR analysis, lipoprotein particle properties in patients on hemodialysis as compared to matched controls without kidney disease.

After obtaining informed consent, fasting plasma samples were collected from 21 patients undergoing in-center intermittent hemodialysis and from 13 controls (without kidney disease) matched for gender, age and presence of diabetes. Both routine lipid analysis and NMR spectroscopy were performed by Liposcience (Raleigh, NC). Means of different lipoprotein particle numbers and size were compared between both groups.

Results: Both groups were well matched for age, gender and presence of diabetes. There was a statistically non-significant higher frequency in statin use in HD subjects. Subjects on HD had significantly lower total cholesterol, HDL and LDL cholesterol levels. Using NMR analysis, HD subjects had lower numbers of LDL and HDL particles. The percentage of small LDL particles in relation to total LDL particles was not different between groups The mean size of VLDL, LDL and HDL particles was not different between groups.

Conclusions: The dyslipidemia of hemodialysis patients is largely captured by the standard lipid profile. These patients have similar particle profiles as compared to matched controls without kidney disease. Larger studies are required to detect more subtle changes that may impact cardiovascular risk.

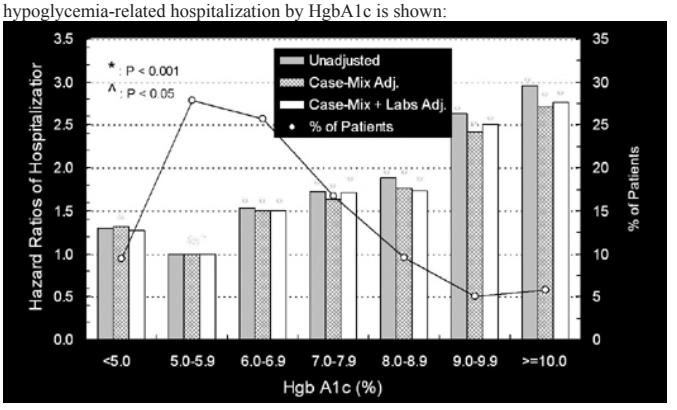
TH-PO608

Hypoglycemia-Related Hospitalization in Diabetic Hemodialysis Patients Eduardo K. Lacson,[1] Weiling Wang,[1] J. Michael Lazarus,[1] Mark E. Williams.[2] *[1]Fresenius Medical Care, North America, Waltham, MA; [2]Joslin Diabetes Center, Boston, MA.*

Background: We evaluated patient characteristics and factors that may associate with hospitalization for hypoglycemia in diabetic maintenance hemodialysis (HD) patients.

Methods: All 24,751 diabetic chronic HD patients in Fresenius Medical Care North America facilities as of 01/01/03, with a hemoglobin-A1c (HgbA1c) in Q4 '02 were included. Baseline characteristics (age, gender, race, BSA, DM Type, vintage, vascular access), insulin use, and labs (eKt/V, albumin, hemoglobin, calcium, phosphorus, creatinine and white cell count) were recorded. Over the next three years, hospital ICD-9 diagnoses for hypoglycemia were found in 4.1% of patients (N=1,017; i.e. "cases"), while the rest (N=23,734) became controls. Stepwise logistic regression (entry: univariate $p \leq 0.1$) and Cox models were used to relate baseline HgbA1c and other variables to hypoglycemia-related hospitalization.

Results: Cases tended to be younger (61.6 vs.63.8 years), but with slightly less BSA (1.81 vs. 1.86 m^2), over-representation of Type 1 DM (10.8% vs. 5.3%) and insulin use (54.3% vs. 46.7%), and higher mean HgbA1c (7.35% vs. 6.75%), all $p<0.0001$. All other case-mix factors and labs were similar, except for calcium (9.21 vs. 9.29, $p<0.001$). The stepwise model indicated that HgbA1c, BSA, DM Type-1, insulin use, male gender and calcium were associated with hypoglycemia-related hospitalization. The hazard ratios for hypoglycemia-related hospitalization by HgbA1c is shown:



Conclusions: Insulin use as well as higher HgbA1c associated with greater risk for hypoglycemia-related hospitalization. The latter finding requires further investigation. We speculate that attempts at glycemic control in high HgbA1c patients may create situations where changes in medications, diet, and clinical conditions lead to hypoglycemia – at times requiring hospitalization.

TH-PO609

New Method To Predict Lean Body Mass Using Estimated Creatinine Excretion in Dialysate and Equilibrated Urea Kt/V in Japanese Maintenance Hemodialysis Patients Tomohito Matsunaga. *Kidney Center, Eijinkai Hospital, Osaki, Miyagi, Japan.*

Background: The assessment of Lean Body Mass (LBM) is quite important to monitor the nutrition status of maintenance hemodialysis patients. Some equations were presented previously. The purpose of this study is to predict LBM using estimated creatinine excretion (CrE) and equilibrated urea Kt/V (eKt/V) in Japanese maintenance hemodialysis patients.

Methods: The 208 patients who have received MHD were analyzed (107 males, 97 females; mean age 61.4±10.5 years; duration of HD treatment 13.7±6.8 years). All patients received four-hour HD session three times per week with ultra-pure dialysate.

The first pre-, post-dialysis levels of BUN and Creatinine (Cr) were measured in the week. LBM and Fat mass were measured using BIA (Inbody 3.0™) after the first post-dialysis. Estimated CrE was calculated the K/DOQI guidelines formula. To avoid the post-dialysis rebound, post-dialysis level of Cr was corrected using single pool Kt/V (spKt/V) and eKt/V. Actual CrE in dialysate were measured by collecting total amount of dialysate during one dialysis session.

Results: The mean levels of LBM, Fat mass, body mass index (BMI) and post-BW were 42.36±7.99 Kg, 13.87±5.36 kg, 22.6±3.13 kg/mand 56.2±9.4 kg and spKt/V, eKt/V, estimate CrE and actual CrE were 1.43±0.25, 1.25±0.21, 1755.4±416.4 mg/session and 2089.7±510.3 mg/session respectively. Estimated CrE was positively correlated with actual CrE ($r=0.8955$ $p<0.001$). Multiple linear regression analysis showed that LBM was significantly correlated with estimated CrE, Body Height (BH), eKt/V and sex ($r=0.9656$, $p<0.001$). The obtained equation of regression was as follows: estimated LBM = 0.005 x estimated CrE + 0.333 x BH (cm) – 11.63 x eKt/V – 1.741 x Sex (male=0, female=1) – 4.486 and estimated Fat mass = post- BW – estimated LBM. Fat mass was correlated with estimated Fat mass ($r=0.9438$, $p<0.001$).

Conclusions: In conclusion, LBM can be predicted using estimated CrE obtained from the first pre-, post-, dialysis levels of Cr and eKt/V in Japanese MHD patients.

TH-PO610

Clinical Correlation of Subclinical Fluid Overload in Peritoneal Dialysis Patients Bonnie Kwan, Cheuk-Chun Szeto, Chi-Bon Leung, Philip K.T. Li. *Dept of Medicine & Therapeutics, Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong.*

Background: Chronic intravascular hypervolaemia may be an important contributing factor of cardiovascular disease in peritoneal dialysis (PD) patients. We explored the relation between body composition parameters, dialysis adequacy, nutritional status, and degree of arterial stiffness in stable chronic PD patients.

Methods: Prevalent chronic PD patients in our dialysis unit underwent clinical assessment. Those with overt fluid overload were excluded. Past medical history of cardiovascular events was noted. Body composition and arterial pulse wave velocity was measured, dialysis adequacy and nutritional status was assessed.

Results: Study included 122 PD patients, 55.7% male, 51.6% diabetic. Within the parameters of body composition, over-hydration (OH) was found to have a significant correlation with total body water ($r = 0.474$, $p < 0.001$) and extracellular water ($r = 0.755$, $p < 0.01$). There was no correlation with intracellular water, lean tissue mass (LTM), fat mass or percentage of fat mass though there was a significantly negative correction with

percentage of LTM (r = -0.241, p = 0.07). OH is common, with 72.1% having OH of >1 litre, while 20.5% had OH >5 litres. OH is more common in male patients, and in diabetic patients.

OH has a significant positive relationship with blood pressure, body mass index, body weight and pulse wave velocity of the carotid-femoral territory. Degree of comorbidity assessed using Charlson's score, and serum albumin, has a significant positive correlation with parameters of OH and a significant inverse correlation with LTM. OH has a modest positive correlation with peritoneal transport characteristics and dialysis adequacy, though not with residual renal function.

After a mean follow-up of 12 months, 7 patients died, 2 were converted to hemodialysis, and 2 had transplants.

Conclusions: Fluid overload is common in PD patients. Markers of fluid overload had good correlation with the degree of comorbidity, systolic BP, serum albumin and pulse wave velocity. Longer follow-up would be useful in assessing the relationship of OH with clinical outcomes.

TH-PO611

Serum Nutritional Markers, Body Composition and Mortality in Peritoneal Dialysis (PD) Patients (pts) Morrell M. Avram, Zoe Hartman, Jyotiprakas Chattopadhyay. *Avram Division of Nephrology, SUNY Downstate University Hospital at LICH, Brooklyn, NY.*

Background: Malnutrition and abnormal levels of some body composition parameters are important predictors of mortality. In this study we have investigated the relationships between visceral and somatic protein stores such as albumin, creatinine and body composition and outcomes in PD pts.

Methods: We enrolled 62 PD pts in this study between November 2000 to May 2008. On enrollment, demographic, clinical and biochemical data were recorded. Pts were followed to May 2011. Body composition was determined by bioelectrical impedance analysis (BIA).

Results: Mean age was 54 years. At enrollment, the mean (±SD) serum albumin and creatinine were 3.71±0.59 g/dL and 11.38±4.2 mg/dL respectively. Mean phase angle (PA) and extracellular mass/body cell mass ratio (ECM/BCM) were 6.06±1.6 degrees and 1.21±0.2 respectively. Correlations of albumin and creatinine with body composition parameters are shown in the Table 1.

Table 1. Correlations of albumin and creatinine with BIA parameters

Variables		Albumin (g/dL)	Creatinine (mg/dL)
BMI(Lbs/in^2)	r	0.28	0.48
	p	0.027	<0.0001
BCM (Lbs)	r	0.31	0.51
	p	0.016	<0.0001
ECM/BCM	r	-0.42	-0.24
	p	0.001	0.07
ECW/ICW	r	-0.44	-0.26
	p	<0.0001	0.049
Reactance (Ohms)	r	0.42	-0.03
	p	0.001	0.82
Phase angle (degrees)	r	0.49	0.28
	p	<0.0001	0.031

BMI: Body mass index; BCM: Body cell mass; ECM/BCM: Extracellular mass/body cell mass ratio; ECW/ICW: Extracellular water/intracellular water ratio;

Albumin and creatinine directly correlated with body mass index (BMI), body cell mass (BCM) and PA. Albumin and creatinine inversely correlated with ECM/BCM ratio and Extracellular water/intracellular water ratio (ECW/ICW). During the study period 26 pts expired. Pts who survived had significantly higher albumin (p=0.005), creatinine (p=0.018), PA (p=0.017) and lower ECM/BCM ratio (p=0.04) compared to those who expired. By univariate Cox's regression analysis, albumin (Relative risk=0.17, p<0.0001), PA (Relative risk=0.58, p<0.0001) and ECM/BCM ratio (Relative risk=1.033, p=0.001) were strongly associated with mortality.

Conclusions: In PD pts there is a strong correlation between serum nutritional markers and BIA derived body composition parameters and their ability to predict survival. It may be useful to incorporate BIA parameters in the management of malnutrition and overall health in these pts.

TH-PO612

The Effects of Different Hemodialysis Modalities on Protein Nutrition: Low-Flux HD, High-Flux HD and Online HDF Tai Yeon Koo, Joon-Sung Park, Chang Hwa Lee, Chong Myung Kang, Gheun-Ho Kim. *Department of Internal Medicine, Hanyang University College of Medicine, Seoul, Republic of Korea.*

Background: Malnutrition is associated with mortality in hemodialysis(HD) patients, and dialysis flux may affect nutrition. Previous studies have reported conflicting results regarding impact of flux intervention on nutrition.This study was performed to compare protein nutrition between patients undergoing three different HD modalities(low-flux HD(LFHD),high-flux HD(HFHD) and online hemodiafiltration(OL-HDF)).

Methods: 13 patients who had maintained LFHD for more than 2 years, were switched to HFHD, and then switched to OL-HDF 2 years later.We longitudinally followed nutritional parameters(dry weight,body mass index(BMI),normalized protein catabolic rate(nPCR),serum albumin,total protein and cholesterol),HD adequacy(Kt/V_{urea},urea reduction ratio(URR) and serum $ß_2$-microglobulin) and inflammatory parameter(hs-CRP).

Results: Dry weight, BMI and serum cholesterol were not changed over three different modalities.nPCR was increased when LFHD was switched into HFHD, and maintained by OL-HDF.When LFHD was switched into HFHD, serum total protein and albumin were initially decreased, but recovered later.With initiation of OL-HDF, serum total protein and albumin were decreased.Compared with LFHD, OL-HDF increased Kt/V_{urea} ,URR and middle molecular clearance.

Comparison of nutritional parameters between LFHD,HFHD and OL-HDF

	Total protein(g/dl)	Albumin(g/dl)	Normalized protein catabolic rate(g/kg/d)	Kt/Vurea	Urea reduction ratio(%)
LFHD baseline	7.1±0.3	4.8±0.3	1.1±0.2	1.6±0.2	70±4.8
HFHD12 mo	7.1±0.4	4.6±0.4	1.3±0.3*	1.6±0.3	72±6.2
HFHD24 mo	7.4±0.3*	4.8±0.3	1.3±0.3*	1.6±0.3	73±6.0
OL-HDF12 mo	7.1±0.3#	4.3±0.3*#	1.3±0.3*	1.8±0.3*	75±4.5*
OL-HDF24 mo	7.1±0.6#	4.2±0.5*#	1.3±0.3*	1.7±0.4*	74±5.5*

Values are described as mean±SD.* p<0.05 vs.LFHD.#p<0.05 vs.HFHD(24 mo).LFHD,low-flux HD;HFHD,high-flux HD;OL-HDF,online HDF

hs-CRP was not affected by three different modalities.

Conclusions: Compared with LFHD, HFHD and OL-HDF may be more efficient in removal of uremic toxins, resulting in improvement of appetite and protein intake. However HFHD and OL-HDF may have negative protein balance probably because of more protein loss during dialysis.

TH-PO613

Association between Metabolic Alkalosis and Malnutrition-Inflammation Complex Syndrome in Maintenance Hemodialysis Patients Kawin Tangdhanakanond, Daranee Chewaproug, Eric J. Bloom, Rasib Raja. *Department of Nephrology, Albert Einstein Medical Center, Philadelphia, PA.*

Background: Metabolic alkalosis is a common finding in maintenance hemodialysis patients partly due to the use of high-bicarbonate dialysate bath and/or malnutrition. Malnutrition-Inflammation Complex Syndrome (MICS) is generally associated with poor dialysis outcomes including increased mortality. However, there is limited and conflicting evidence regarding the association between metabolic alkalosis and MICS in hemodialysis patients.

Methods: We conducted a retrospective analysis on 94 hemodialysis patients at an outpatient hemodialysis unit. All patients received maintenance hemodialysis 3 times per week with 35 mmol/L bicarbonate bath. Demographic and laboratory data including various markers of inflammation and nutritional status were analyzed and compared between 2 stratified groups based on predialysis serum bicarbonate level: the higher bicarbonate group (bicarbonate ≥26 mmol/L, n=51) and the lower bicarbonate group (bicarbonate <26 mmol/L, n=43)

Results: Lower mean predialysis BUN (mg/dL) (53.16 ± 13.38, 60.84 ± 16.20, p=.014), and lower normalized protein nitrogen appearance or nPNA (0.89 ± 0.22, 1.00 ± 0.27, p=.031) were shown in the higher bicarbonate group. However, other markers of nutritional status and inflammation including serum albumin, prealbumin, creatinine, ferritin, as well as lipid profiles were not statistically different between the 2 groups. Urea reduction ratio and Kt/V were also similar between the 2 groups. Even though not significant, mean C-reactive protein (mg/L) was lower in the higher bicarbonate group (21.34 ± 38.05, 30.55 ± 77.36, p=.52).

Conclusions: Our study suggested that metabolic alkalosis in hemodialysis patients might be associated with poor dietary nutrition rather than chronic inflammation. A large prospective study with measurement of various nutritional and inflammatory markers is warranted for further investigation.

TH-PO614

Changes in Plasma Ghrelin Concentrations and Feelings of Hunger or Satiety in Hemodialysis and Continuous Peritoneal Dialysis Patients with Chronic Renal Failure in Post- and Pre-Prandial Periods Yoshitaka Miyaoka, Toshiyuki Nakao. *Nephrology, Tokyo Medical University, Shinjyuku-ku, Tokyo, Japan.*

Background: Ghrelin (G) is known as an appetite-stimulating hormone. However, little is known about the changes in plasma G level and their association with feelings of hunger or satiety in hemodialysis (HD) or continuous peritoneal dialysis (CAPD) patients.

Methods: We measured the plasma concentration of G and assessed the hunger feelings in 51 chronic dialysis patients (36 HD, 15 CAPD), and in 10 healthy controls for comparison. Feeling of hunger or satiety was assessed using a hunger-satiety score (H-S score) which were rated as grade 5. Blood samples and H-S scores were obtained both postprandially (1 hour after breakfast) and preprandially (5 hours after breakfast, just before lunch) on the same day. In the HD patients, 4-hour HD treatment was performed between the postprandial and preprandial periods. In CAPD patients, a 2.5% glucose PD solution was dwelled between the postprandial and preprandial periods.

Results: The mean plasma G levels (fmol/ml) in the postprandial period was no significant differences among the patient groups. In the preprandial period, mean plasma G levels were significantly lower (p<0.05) in the HD patients than in the other patient groups: 12.6±12.2 (HD patients), 24.5±24.5 (CAPD patients), 26.9±13.3 (HD patients on non-HD day), 38.3±22.8 (controls). Compared with the plasma G level in the postprandial period,

that in the preprandial period in the HD patients was significantly lower (p=0.007), while those in the other groups were significantly higher (p<0.05). The mean H-S score (points) in the preprandial period were significantly higher than those in the postprandial period in each patient group, with no significant differences among the patient groups.

Conclusions: Plasma G levels are reduced by HD even in fasting patients. Feelings of hunger or satiety synchronize with plasma G levels excerpt patients receiving HD treatment.

TH-PO615

Nutritional Intervention Strategy in Malnourish Chronic Hemodialysis Patients: Results of a 12-Months Prospective Study Ignace Mpio, Christine Cleaud, Walid Arkouche, Jean-Christophe Szelag, Nouredine Boumendjel, Carlos Cardozo, Alejandra Lenz, Denis Fouque, Maurice Laville. *AURAL, Lyon, France.*

Background: Undernutrition (UN) in chronic hemodialysis (CHD) is a major clinical problem because it affects negatively the survival of patients (pts). Several therapeutic and dietary approaches are described. This work aimed to evaluate the effects of nutritional strategy in our hemofialysis-pts

Methods: The study was conducted during 12 months in 132 CHD (49 women , 83 men, mean age was 66 ± 16 years (median 71 years) dialysis vintage 72 ± 74 months (48 months)). The nutritional care (NC) was based on the action of a multidisciplinary team (nephrologists, dietetican, nurses) in order to improve a better compliance. The protocol consist of an optimization of dietary protein intake and energy with, if required, oral supplementation at home and especially during dialysis session (20 g of protein, 400 Kcal) .

We analyzed serum albumin (ALB), CRP, nPCR, and Kt / V at initiation (D0), at 6 month and at endpoint (M12). Undernutrition was defined as severe with ALB<35g/L, mild with ALB between 35 and 38g/L.

Results: At the end of the study the nutritional status of pts is reversed. The frequency of patients with optimal nutritional status was 68% at month 12 while 59% of subjects were malnourished at D0. A M12 the ALB was > 38 g / L under the effect of 3 potentials factors: the improvement of the inflammatory condition, Kt/V, and a protein intake > 1 g / kg / d. The inflammatory status was determining because ALB was higher in pts with CRP <10mg / L vs CRP ≥ 10 mg / L (40.2 vs. 37.7 g / L, p = 0.002 *), there was an inverse correlation between CRP and ALB (R^2 = 0,080, p = 0.002 **). (*Mann-Whitney test, ** ANOVA test) Five pts (4%) died in 1 year.

Conclusions: Our study showed an improvement of the nutritional status of patients. The success of the NC in HDC malnourished pts can be obtained with a multidisciplinary involvement, under an effective dialysis dose and an absence of inflammatory state.

TH-PO616

Prospective Comparison on the Progression of Abdominal Aortic Calcification According to Dialysis Modality in End-Stage Renal Disease Patients Moon-Jae Kim. *Division of Nephrology & Hypertension, Inha University School of Medicine, Incheon City, Korea.*

Background: In end-stage renal disease patients on dialysis, the prevalence, degree and progression of arterial calcifications are greater than in general population. However, there have been few reports whether the progression of abdominal aortic calcifications (AAC) is different or not according to dialysis modality. The purpose of this study was to compare the incidence of AAC progression between hemodialysis (HD) and peritoneal dialysis (PD) patients.

Methods: HD and PD patients who had been on dialysis for ≥ 3 years were included in this observational, prospective 1-year study. AAC was assessed with plain lateral lumbar spine x-ray using anterior-posterior abdominal aorta calcification score at the baseline and 12 month. AAC progression was defined as the increase in the length of linear calcification or new appearance of calcification.

Results: Thirty one patients were progressed (Group 1) and 68 were unchanged (Group 2) in AAC. In group 1, 11 were HD and 20 were PD patients. In group 1, the AAC scores at baseline were 7.9±5.8 in HD and 8.5±6.0 in PD and, after 1 year, 10.2±5.7 in HD and 10.7±6.5 in PD, respectively. In group 2, AAC scores at baseline and after 1 year were unchanged in HD (6.3±7.0) and PD (6.6±7.2). There were no differences in the mean laboratory values of previous 2 years, the percentages of diabetes (51.6 vs. 38.2%), the presence of residual renal function (32.3 vs. 42.6%) and the presence of coronary artery disease (12.9 vs. 5.9%) between group 1 and 2. However, there was significant difference in the percentages of baseline AAC score of more than 25 percentile (AAC score = 1) (90.3 vs. 55.9%, p<0.001), body mass index (25.1±4.0 vs. 23.2±3.2 kg/m^2, p=0.012), duration of dialysis (6.6±2.8 vs. 5.7±3.0 years, p=0.047), corrected calcium product phosphate (53.5±12.2 vs. 48.5±10.9 mg^2/dL^2, p=0.046), total cholesterol (148±28 vs. 179±37 mg/dL, p<0.001), triglyceride (133±80 vs. 172±101 mg/dL, p=0.038), and LDL-cholesterol (78±24 vs. 100±30 mg/dL, p<0.001) between group 1 and 2.

Conclusions: Dialysis modality seems not to affect differently on the progression of abdominal aortic calcification.

TH-PO617

Enteral Nutrition Is Superior Than Intradialytical Parenteral Nutrition in Hemodialysis Children Yolanda Fuentes, Georgina Toussaint, Saul Valverde, Ana M. Hernández, Maria I. Garcia-Roca, Mara Medeiros. *Hospital Infantil de Mexico Federico Gomez, Mexico, DF, Mexico.*

Background: Protein-energy wasting syndrome is present in 30 to 60% of the patients with chronic kidney disease. The etiology is complex and multifactorial. The intradialytical parenteral nutrition (IDPN) has been used in adults with an improvement of nutritional status, reduction in mortality rates and regression of the net negative whole body muscle protein balance. There is scarce experience regarding IDPN in children; the intervention is expensive with no studies comparing oral supplementation with IDPN.

The aim of this study was to examine the effectiveness of IDPN compared to oral supplementation to improve the nutritional state in children on hemodialysis.

Methods: Prospective, crossover, randomized trial in chidren (6 -1 7 years) on hemodialysis program, with an ABN (anthropometric and bioelectric impedance analysis) score < 10.33. During dialysis procedure they received 3 months the intervention A (oral supplementation) or B (IDPN), designed to provide a third of the required daily caloric intake. Protein RDA for age plus 0.5 mg/kg/day. There was no washout period and patients were switched to the other arm to complete the crossover design. Nutritional status was evaluated monthly using the Anthropometry-Bioimpedance-Nutritional score (ABN Score).

Results: Twenty one patients completed 6 months of treatment. Eleven started with IDPN and 10 with enteral supplementation. The ABN score improved after 6 months of nutritional intervention from 8 ± 1.6 to 9.3 ± 1.7 (p=0.001). After 3 months of enteral supplementation the ABN improved from 8.2 ± 1.8 to 9.04 ± 1.5 p=0.04, and after 3 months of IDPN the ABN score improved from 8.6 ± 1.5 to 9.2 ± 1.8 p=0.17

Conclusions: Nutritional intervention (oral and IDPN) is safe and well tolerated in children with ESRD in hemodialysis. The improvement is significant after enteral intervention but not after IDPN.

TH-PO618

Changes in Concentration of Thyroid Hormones, RT3, Conversion Ratios and Ratios of Thyroid Hormones to Carrier Proteins in a Single Hemodialysis and Hemodiafiltration Longin Niemczyk,[1] Stanislaw Niemczyk,[2] Katarzyna Szamotulska,[3] Wieslaw Klatko,[4] Zbigniew Bartoszewicz,[1] Ivanna Dubchak,[2] Malgorzata Gomolka,[2] Urszula Syta,[2] Janusz Wyzgal,[1] Joanna Matuszkiewicz-Rowinska.[1] *[1]Medical University of Warsaw; [2]Military Institute of Medicine; [3]National Research Institute of Mother and Child; [4]Hospital, Ciechanow, Poland.*

Background: Previous studies have not explained influence of a single HD and HDF on thyroid function.

AIMS: To assess changes in concentration of TSH, thyroid hormones (TH), conversion ratios (CR) and ratios of thyroid hormones to carrier proteins (TH/P) immediately after and 6h after HD and HDF.

Methods: Patients aged 56±15 years, undergoing HD (n=23) or HDF treatment (n=15) were investigated. Concentrations of TSH, TT4, FT4, TT3, fT3, rT3 and TBG were measured before, immediately after and 6 hours after single dialysis. General linear model for repeated measurements was applied in statistical analysis. Non-normally distributed variables were log-transformed.

Results: Concentration of TSH, TH, rT3, CR and TH/P before dialysis (means ± SD) as well as type of observed trend is shown in the table (∪,∩ - quadratic changes, ↑ - increase, ↓ - decrease). There were no significant differences in the shape of the changes between HD and HDF group, except deeper transient reduction in TSH concentration in HDF.

	HD	HDF		
	before dialysis		Trend before-afer-6h after	p-value trend
TSH [µIU/ml]	1,71±1,07	1,87±1,53	∪ - with interaction	<0,001
TT4 [nmol/l]	80,70±22,89	83,50±12,93	↑	<0,001
TT3 [nmol/l]	1,29±0,31	1,28±0,25	↑	<0,001
fT4 [pmol/l]	13,50±2,35	14,61±1,60	↑	<0,001
fT3 [pmol/l]	4,04±0,78	3,80±0,62	↑	<0,001
rT3 [pmol/l]	306,23±219,17	333,28±150,63	↑	<0,001
TT3/TT4	0,017±0,004	0,016± 0,004	∪	<0,001
fT3/fT4	0,304±0,061	0,264±0,060	∪	<0,001
rT3/TT4	3,673±1,620	4,019±1,904	↑	<0,001
rT3/TT3	243,69±160,136	285,836±216,074	↑	<0,001
fT4/TT4	0,173±0,028	0,177±0,023	↓	<0,001
fT3/TT3	3,234±0,723	3,021±0,368	↓	<0,001
TT4/TBG	3,571±0,569	3,483±0,576	∩	<0,001
TT3/TBG	0,058±0,011	0,054±0,016	∩	0,084

Conclusions: Single dialysis causes important temporal changes in concentration of TSH, TH, rT3, TH/P, and CR. The character of these changes is similar in HD and HDF, apart fromTSH concentration.

TH-PO619

Uremic Retention Solutes in Hemodialysis Patients Yoshiharu Itoh,[1] Kaori Kikuchi,[1] Atsuko Ezawa,[1] Toshimitsu Niwa.[2] *[1]Kureha Corp.; [2]Nagoya Univ.*

Background: We found 12 uremic retention solutes such as indoxyl sulfate, p-cresyl sulfate were significantly increased in serum level of chronic kidney disease rats compared to normal rats. These solutes were significantly decreased in serum level after administration of oral charcoal adsorbent, AST-120.

In this research, we checked the presence of these solutes in hemodialysis patients and healthy subjects and measured their protein binding ratios. We also evaluated effects of solutes on ROS production in HUVEC.

Methods: We assayed serum levels of these 12 uremic retention solutes and phenylacetyl glycine and CMPF in 45 hemodialysis (HD) patients before and after HD and in 8 healthy subjects by LC/ESI-MS/MS.

Free fraction of their serum levels in HD patients was measured by ultra-centrifugation method and their protein binding ratios were calculated from free and total fraction of their serum levels.

We evaluated the effect of their solutes on ROS production in HUVEC by using fluorescence probe, CM-H_2DCFDA.

Results: Twelve solutes except indoxylacetyl glycine and phenylacetyl glycine were detected in serum of HD patients and healthy subjects. Serum levels of 11 solutes except 4-ethylphenyl sulfate (4EtPhS) were significantly higher in HD patients than in healthy subjects.

Indoxyl sulfate (IS), p-cresyl sulfate (PCS), phenyl sulfate (PhS), indoleacetic acid, CMPF and 4EtPhS showed protein binding ratios more than 90%. Ratios in serum level of HD patients to healthy subjects were much higher in free fraction than in total fraction in most solutes such as IS, PCS, PhS.

Conclusions: We confirmed serum levels of 11 uremic retention solutes were significantly higher than in HD patients, as well as in CKD rats.

A significant relationship was observed between protein binding ratios and reduction rates by HD. IS, PCS, CMPF, 4EtPhS showed reduction rate less than 30%, with more than 90% protein binding ratios.

TH-PO620

The Effects of On-Line Hemodiafiltration on Inflammatory Markers and other Clinical Findings: Crossover Study Won Min Hwang, Sung Ro Yun. *Department of Nephrology, Konyang University Hospital, Daejon, Republic of Korea.*

Background: On-line hemodiafiltration(HDF) is a method that increase the removal of middle molecules by diffusive and convective solute transport component. The aims of this study are to evaluate the effects of on-line HDF on inflammatory markers and other clinical findings.

Methods: Forty patients on thrice – weekly high flux hemodialysis (HF-HD) were switched to on-line HDF for 1year. We measured intradialytic blood pressure, solute clearance rate(Kt/V, urea reduction ratio (URR, %)), anemia(transferrin saturation(%), ferritin, hemoglobin, hematocrit), nutrition(albumin), bone markers(calcium, phosphate, intact-PHT, alkaline phosphatase), electrolyte (Na, K, Cl), total CO2 and β2-microglobulin at HF-HD, six weeks and one year after switching of on-line HDF. Also, inflammatory markers (hs-CRP, TNF-α), quality of life(SF-36) and itching score(psoriasis area and severity index, PASI) were compared at that times.

Results: The URR (76.68 ± 5.01 vs. 78.31 ± 5.26, %), Kt/V (1.76 ± 0.26 vs. 1.86 ± 0.29) were significantly higher in patients treated with six weeks after on-line HDF compared with those treated with HF-HD. Hb, tCO2, alkaline phosphatase, high density lipoprotein(HDL) level was significantly increased. Itching score (7.5 ± 2.8 vs. 6.1 ± 1.4, p = 0.039) was improved. However, no change of inflammatory markers (hs- CRP, TNF-α) and clinical markers were measured on one year after except the level of β2- macroglobulin(31.19 ± 9.84 vs. 27.88 ± 9.18, p = 0.009)

Conclusions: This study shows that solute clearance rate, itching score, anemia, bone metabolism, and acidosis were improved by the switching from HF-HDF to on-line HDF for 6 weeks (early response). But, these effects of clinical findings and inflammatory markers were not shown between 6 weeks and one year after on-line HDF (late response).

TH-PO621

Epicardial Adipose Tissue as a Marker of Inflammation in Dialysis Luis Gerardo D'Marco,[1] Cristina Karohl,[2] Paolo Raggi.[3] *[1]Ruiz y Paez University Hospital, Bolivar, Venezuela; [2]Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil; [3]Division of Cardiology and Department of Medicine, Emory University, Atlanta, GA.*

Background: Epicardial adipose tissue (EAT) is fat confined within the pericardial sac and it is believed to have a local inflammatory and pro-atherogenic effect. EAT can be measured using Multi Slide Computer Tomography (MSCT). The association of EAT as direct measures of region specific adipose tissue in chronic kidney disease (CKD) has not been shown to date.

Methods: Thirty seven CKD-5D patients (mean dialysis duration 26±30 months, 70% males, 57% African-American, 48% diabetic) underwent MSCT to measure EAT and coronary artery calcium (CAC). CAC distribution in quartiles of EAT was assessed. Finally, we measured patients' body mass index and categorized them as normal (BMI 18.5 - 25 kg/m^2) and abnormal BMI (BMI > 25 kg/m^2).

Results: The mean BMI was 28.6 ± 5.7 kg/m^2, and the mean EAT volume was 66 ± 29 ml and 102 ± 69 ml for normal and abnormal BMI groups. There was a direct correlation between dialysis vintage and EAT while BMI showed an inverse relationship with dialysis vintage (*P=0.05*). In this small sample size, the association of CAC and EAT was only marginally significant (*P=0.7*). EAT was significantly correlated with age (*P=0.02*), history of cardiovascular disease (*P=0.03*) and diabetes (*P=0.001*).

Conclusions: The direct association of EAT with dialysis vintage in the face of an inverse association of BMI with dialysis duration, and the marginally significant association of EAT and CAC appear to support the notion that chronic hemodialysis is a state of chronic inflammation, malnutrition and a proatherogenic condition.

TH-PO622

Effect of Insulin Infusion on Liver Protein Synthesis during Hemodialysis Mark Reinhard,[1] Jan Frystyk,[2] Bente Jespersen,[1] Per R. Ivarsen.[2] *[1]Department of Renal Medicine, Aarhus University Hospital, Aarhus N, Denmark; [2]Aarhus University Hospital, Denmark.*

Background: Hemodialysis (HD) is a catabolic procedure that may contribute to the high frequency of protein-energy wasting among patients on maintenance HD. The aim was to investigate the effect of insulin infusion on liver protein synthesis during HD.

Methods: In a randomized cross-over study 10 non-diabetic, HD patients (M/F:7/3, median age 59 years, range 33-79) received 1) no treatment (NT), 2) glucose infusion (G) (10% glucose, 2.5 mL/kg/h), 3) glucose-insulin infusion (GI) (10% glucose added 30 units of NovoRapid® per liter, 2.5 mL/kg/h) during a standardized 4 h HD. During infusions blood glucose (BG) was maintained at 8.0-10.0 mmol/L by additional glucose infusion. Glucose and glucose-insulin infusions were commenced 2 h prior to HD and continued throughout the dialysis. Fasting blood samples were collected before infusions were started (baseline) and followed by a meal. After HD start, blood samples were collected every hour for hormones and every second hour for inflammatory markers until 2 hours post-HD.

Results: Data presented as mean±SD. BG concentrations were comparable at baseline in the three treatment groups (p=0.37). BG levels from baseline to end of dialysis were significantly different only in the NT group compared with the G group (p=0.008). During all three treatments there was an overall increase in serum albumin (37.3±2.0 to 40.5±2.9 g/L, p<0.001 for each treatment) and fibrinogen (11.3±1.7 to 12.8±2.0 µmol/L, p<0.0001 for each treatment), but no significant differences between treatments over time for either albumin (p= 0.24) or fibrinogen (p=0.14). Preliminary data on 4 patients showed a postprandial increase in bioactive insulin-like growth factor I (IGF-I) 3 h after baseline (from 0.83±0.34 to 1.32±0.51 µg/L) with no difference between treatments (p=0.71) and a corresponding decrease in IGF-binding protein 1 (IGFBP-1) 5 h after baseline (from 348±131 to 157±78µg/L) with no difference between treatments (p=0.58). However after 5 h, IGFBP-1 increased during NT, but remained suppressed following the infusions (p=0.02).

Conclusions: Neither glucose nor glucose-insulin infusion appear to add to the anabolic effects of a meal on liver protein synthesis.

Effects of Six Versus Three Times Per Week Hemodialysis on Depressive Affect and Mental Health: Frequent Hemodialysis Network (FHN) Trials Mark L. Unruh, Brett Larive, Glenn M. Chertow, Paul W. Eggers, Amit X. Garg, Jennifer J. Gassman, Maria E. Tarallo, Fredric O. Finkelstein, Paul L. Kimmel, The FHN Trial Group, Rosio Ramos. *NIDDK, Bethesda, MD.*

Background: Patients undergoing maintenance hemodialysis have a significant burden of poor mental health. More frequent hemodialysis has been associated with gains in general mental health and improved depressive affect in observational studies. We studied the effects of frequent in-center and nocturnal dialysis on depression and mental health in randomized trials.

Methods: A total of 332 patients were randomized to frequent (six times per week) as compared with conventional (three times per week) hemodialysis in the Frequent Hemodialysis Network Daily (n=245) and Nocturnal (n=87) Trials. Adjusted change in scores over 12 months on the Beck Depression Inventory (BDI), RAND Short-form health survey 36-item (SF-36) self-reported mental health composite score (MHC) and emotional subscale.

Results: In the Daily Trial, subjects randomized to frequent as compared with conventional in-center hemodialysis demonstrated no significant change in mean BDI (adjusted mean change of -2.0 ± 0.7 vs. -0.4 ± 0.7; p=0.10), but experienced clinically significant improvements in MHC (3.7 ± 0.9 vs. 0.2 ± 1.0; P<0.01) and emotional subscale (5.1 ± 1.6 vs. -0.6 ± 1.7; p=0.01). The effects of frequent in-center hemodialysis did not appreciably differ according to age, sex, race, or education status. In the Nocturnal Trial, there were no significant changes among subjects randomized to nocturnal as compared with conventional hemodialysis in BDI (adjusted mean change of -2.00 ± 1.2 vs. -0.3 ± 1.2; p=0.30), MHC (3.1 ± 1.6 vs. -0.8 ± 1.7; p=0.08) or emotional subscale (3.5 ± 2.7 vs. -2.2 ± 2.7; p=0.13).

Conclusions: Daily in-center hemodialysis, as compared with conventional in-center hemodialysis, improved general mental health but had no significant effect on depressive affect Increased frequency nocturnal dialysis had no significant effects on depressive affect or mental health, however, the magnitude of the treatment effects were consistent with those observed in frequent in-center dialysis.

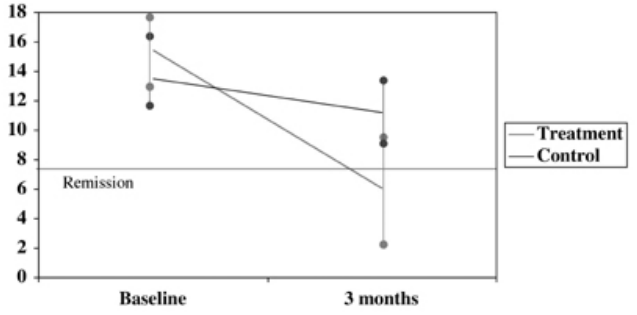
Chairside Cognitive Behavioral Treatment of Depression in Hemodialyzed Patients Is Effective: A Randomized Controlled Trial Daniel Cukor,[1] Nisha Ver Halen,[1] Paul L. Kimmel.[2] *[1]Psychiatry and Behavioral Science, SUNY Downstate Medical Center, Brooklyn, NY; [2]NIDDK, NIH, Bethesda, MD.*

Background: Depression is common, and associated with morbidity and mortality in ESRD patients, but there have been few treatment studies. Non-drug psychotherapeutic treatments, which are effective in the general population, have been under-studied in HD samples.

Methods: We designed an individual standardized intervention for depression in ESRD HD patients. The ten week, once weekly psychosocial intervention (CBT) was administered chairside during dialysis. It taught both cognitive and behavioral skills focused on reducing depressive affect. Subjects randomly assigned to the control group waited for 3 months before getting the intervention. Assessments were at baseline, 3 and 6 months.

Results: The sample included 36 participants (18 cases, 18 controls), 97% African / Caribbean American. 60% were born outside the US. At baseline the population was moderately depressed according to both self-reported (Beck Depression Inventory [BDI] mean = 23.2 ± 8.8) and clinician-administered scales (Hamilton Depression Scale [HAM] mean = 13.5 ± 5.5) Subjects assigned to the treatment condition showed mood improvement (BDI 11.2 ± 7.4, HAM 6.5 ± 6.1) at 3 months when compared to the wait-list controls (BDI 15.6 ± 9.0, HAM 11.2 ± 5.2). There was a significant interaction effect between group and time, indicating the intervention group improved significantly more than controls by both self report (p=.038) and clinician administered (p=.008) depression measures. The intervention group mean HAM scores (<7) reflect remission.

Hamilton-D ratings (M ± SD)pre and post treatment for the treatment (n=18) and control (n=18) groups



Conclusions: A non-drug depression intervention in ethnic minority HD patients is feasible and effective. CBT may be a cost-effective, clinically applicable approach to reducing HD patient depression which has been associated with increased morbidity and mortality.

Neurocognitive Function and the KDQOL Cognitive Function (CF) Subscale Eric P. Sorensen, Mark J. Sarnak, Hocine Tighiouart, Lena M. Giang, Bethany A. Kirkpatrick, Tammy Scott, Daniel E. Weiner. *Tufts Medical Center.*

Background: Cognitive impairment is common and underdiagnosed in ESRD. Prior work suggests that poor performance on the KDQOL cognitive function (CF) subscale can help identify cognitive impairment in ESRD. We tested this hypothesis using a detailed neurocognitive screen assessing multiple cognitive domains.

Methods: The 3-question KDQOL-CF asks patients to quantify on a 6-point scale if they react slowly to things said and done, have difficulty concentrating or thinking, or become confused. KDQOL-CF results were converted to a 100-point scale; a higher score is consistent with better performance. Cognitive tests were administered at the start of a dialysis session. In primary analyses, cognitive outcomes were quantified using principal components analysis as memory and executive function domains. Regression models adjusted for age, sex, race, education and ESRD cause. Consistent with prior work, performance of a KDQOL-CF score ≤60 also was also assessed.

Results: Of 168 patients, 144 had complete data. Age was 62±17 years; 51% were men, 30% black, 90% high school graduates, and 33% had diabetes causing ESRD. KDQOL-CF score was 76±19; 40 (24%) had scores ≤60. In univariate and adjusted analyses, there was no significant association between KDQOL-CF score and memory (p=0.16 and p=0.33) or between KDQOL-CF score and executive function (p=0.13 and p=0.46). CF scores were most highly associated with depression, assessed by CESD>15 (p=0.002 for trend). The KDQOL-CF, using a cutpoint of 60, performed poorly in predicting cognitive function, including lower executive and memory factor scores and impaired performance on individual cognitive tests (figure).

Conclusions: The KDQOL-CF score is a poor determinant of neurocognitive performance in hemodialysis patients.

Test / Factor	Metric	N	Sensitivity	Specificity	PPV	NPV

Cognitive Function in Hemodialysis (HD) Patients Mark J. Sarnak, Hocine Tighiouart, Tammy Scott, Lena M. Giang, Eric P. Sorensen, Bethany A. Kirkpatrick, Daniel E. Weiner. *Tufts Medical Center, Boston, MA.*

Background: There are few large, generalizable studies of detailed cognitive testing in HD patients, and comparisons with the general population. We hypothesized that multiple domains of cognitive function, particularly those relating to vascular disease (sub-cortical function), may be compromised.

Methods: Detailed neurocognitive testing was performed in 324 HD patients from 6 Boston-area HD units. One sample t-tests were used to evaluate differences in cognitive function between HD patients and normative data.

Results: Mean age was 63 years, 78% were white, 54% men, and 17, 48, 35, and 37%, had a history of stroke, diabetes, heart failure, and coronary disease, respectively. Fifty percent were high school graduates. Despite preserved MMSE, HD patients had lower scores on tests of learning and on tests of subcortical function, with 37.5% scoring more than 1.5 SD below the population norm on 2 or more tests of subcortical function.

Cognitive tests in study sample vs reference data

Cognitive Test	Description of Test	HD Patients		Normative Data	Comparisons	
		Mean±SD	Rescaled	Reference ±SD	One-sample t-test P-value	> 1.5 SD below reference
MMSE	Screen	26.7±2.9	NA	Normal ≥ 24	NA	13.7%
NAART	Intelligence	102.3±12.2	NA	100±15	P<0.001	1.6%
Delay Recall	Primary Cortical (Memory)	4.4±2.7	10.5±2.6[a]	10±3	P<0.001	1.3%
Recall Total	Primary Cortical (Learning)	23.8±7.2	7.5±3.2[a]	10±3	P<0.001	29.2%
Recognition	Primary Cortical (Recognition)	20.7±3.0	9.2±3.1[a]	10±3	P<0.001	11.9%
Block Design	Primary Subcortical	26.1±10.6	8.7±2.8[a]	10±3	P<0.001	12.4%
Digit Symbol	Primary Subcortical	40.1±17.0	6.8±2.6[a]	10±3	P<0.001	34.4%
Trials A	Primary Subcortical	61.3±39.6	38.2±9.6[b,c]	50±10	P<0.001	38.2%
Trials B	Primary Subcortical	171.0±88.1	37.1±11.3[b,c]	50±10	P<0.001	39.5%

[a]Normalized for subject age. [b]Normalized for age, gender and education level. [c]T scores for test performance.

Conclusions: There is a high prevalence of cognitive impairment in HD patients, particularly as it relates to subcortical function. We hypothesize that the latter may be due to a higher prevalence of clinical and subclinical cerebrovascular disease in HD patients.

TH-PO627

Comparison of Cognitive Function across ESRD Treatment Modalities: A Systematic Review Deidra C. Crews,[1] Priscilla Auguste,[1] Tanjala S. Purnell,[1] Raquel Greer,[1] Temitope Olufade,[1] Julio Lamprea,[1] Johanna Sheu,[2] Patti Ephraim,[1] Hamid Rabb,[1] Neil R. Powe,[3] L. Ebony Boulware.[1] *[1]Johns Hopkins University; [2]Harvard University; [3]San Francisco General Hospital.*

Background: Patients with ESRD are encouraged to make informed decisions about their choice of renal replacement treatment (RRT). Limitations in cognitive function are common among ESRD patients. However, the quality and quantity of evidence regarding differences in cognitive function among patients treated with different RRTs is unknown.

Methods: We performed a systematic review of published studies describing differences in patients' cognitive function across different RRTs (hemodialysis-HD, peritoneal dialysis-PD, kidney transplant-TX). We identified relevant articles (English, published after 1987) from PubMED and hand-searched bibliographies. We abstracted data on 5 domains of cognitive function. Two independent reviewers assessed studies' quality (e.g. selection bias and validity of outcome assessment). We calculated standardized effect sizes (Cohen's d) of associations between each RRT and outcome.

Results: Of 110 potentially relevant studies, 15 reported RRT comparisons, with 26 comparisons of relevant outcomes (Table). Most studies were from outside the U.S. (80%), and all were observational (11 cross-sectional, 2 cohort and 2 pre-post designs). Studies ranged from very low to moderate quality (only 4 adjusted for important confounders

such as educational level) and suggested better or no different cognitive outcomes among patients on PD and TX compared to patients on HD.

Comparison of Published Studies on Cognitive Function Outcomes by RRT Number of studies favoring each treatment

Study Design (N studies)	HD vs. PD			HD vs. TX			PD vs. TX			*Dialysis vs. TX		
	HD	Neither	PD	HD	Neither	TX	PD	Neither	TX	Dialysis	Neither	TX
Memory												
Cross-sectional (2)		1										1
Pre-Post Transplant (1)												1
Concentration												
Cross-sectional (2)			2									
Pre-Post Transplant (2)					1						1	
Learning												
Cross-sectional (1)			1									
Pre-Post Transplant (1)											1	
Overall Cognition												
Pre-Post Transplant (1)					1							
Self-Reported Cognition												
Cross-sectional (8)		4	2					2			1	
Cohort (2)		2										
Total Study Comparisons	0	7	6	0	2	0	0	2	0	0	3	2

Abbreviations: HD=hemodialysis; PD=peritoneal dialysis; TX=transplant
*Dialysis includes HD and PD patients combined

Conclusions: Current evidence suggests PD and TX patients have better or no different cognitive function than HD patients. However, the quality of evidence is poor. Prospective studies, preferably assessing patients prior to the start of RRT, are needed to better inform patients' choice of RRT.

TH-PO628

High Prevalence of Cognitive Impairment in All Age Groups of Hemodialysis Patients Hristos Karakizlis, Maren Bodden, Christoph Klein, Richard Dodel, Joachim Hoyer. *Dept. of Nephrology and Neurology, Philipps-University, Marburg, Hessen, Germany.*

Background: Cognitive impairment correlate with chronic disease and can cause substantially reduced compliance for therapy. Recently a high prevalence of moderate and even severe cognitive impairment was found in senior patients (pts) from a U.S. hemodialysis patient cohort. We tested cognitive function in a German dialysis cohort and delineated the impairment of specific cognitive function domains by use of an elaborated neuropsychological test battery.

Methods: We performed a population based study in the regional government district Mittelhessen, Germany. All outpatient hemodialysis pts aged ≥18 years were screened for their cognitive function with Mini Mental State Examination (MMSE). Furthermore in pts capable for more intensive testing (MMSE >24) we performed a neuropsychological test battery (CERAD) examining the five cognitive domains verbal and visual memory, constructional praxis, two executive functions.

Results: From a total of 330 patients inclusion criteria were met by 298 patients of whom 200 (67.1%; mean age 68.6 yrs) agreed to take part in the study. 94 pts (47%) scored within normal range (MMSE 30-28), whereas 69 pts (35%) showed mild cognitive impairment (MMSE 27-25) and 36 pts (18%) suffered from moderate to severe cognitive impairment (MMSE ≤24). Cognitive impairment (MMSE <28) was high in senior (≥65 yrs) pts (66%), but was also detected in 30% of younger aged patients (<65 yrs). CERAD testing confirmed the high rate of cognitive impairment in the younger patient group, especially verbal fluency and executive functions were affected.

Conclusions: The results demonstrate an extraordinary high prevalence of cognitive impairment in hemodialysis patients affecting more than half of the patients. In particular almost every fifth patients has moderate or severe cognitive impairment which usually results in a significant reduction of the patients' ability to comply with treatment. The results clearly demonstrate that cognitive impairment is not confined to senior patients but affect the patients younger than 65 yrs. The knowledge of individual cognitive impairment can help to individually adjust therapeutic guidance of hemodialysis patients.

TH-PO629

Development of a Predictive Mortality Risk Score from the ARO European Hemodialysis (HD) Cohort Jurgen Floege,[1] Marc Froissart,[2] Iain A. Gillespie,[3] Daniele Marcelli,[4] Sharon Richards,[3] Kai-Uwe Eckardt.[5] *[1]Nephrology, RWTH University of Aachen, Aachen, Germany; [2]International Development Nephrology, Amgen Europe GmbH, Zug, Switzerland; [3]CfOR, Amgen Ltd, Uxbridge, United Kingdom; [4]Nephrocare, FME, Bad Homburg, Germany; [5]Nephrology, Universitätsklinikum Erlangen, Erlangen, Germany.*

Background: HD patients exhibit a high mortality risk, yet there is no widely accepted predictive mortality risk score for these patients. A large European HD cohort was used to assess predictors of mortality and derive a predictive score.

Methods: We derived and internally validated a mortality risk score in HD patients, using both modifiable and non-modifiable risk factors, in 8132 HD patients (38% incident and 62% prevalent) randomly assigned to either the development or validation dataset. The methodological approach was derived from the predictive model used in the Framingham Heart Study. The risk score was determined using a baseline Cox regression model and derived separately for 1- and 2-year mortality. Continuous variables were introduced as categorical in the model.

Results: Increasing age, history of cancer, diabetes and peripheral vascular disease, as non-modifiable factors, and use of anticoagulant therapy were associated with an increased risk of mortality. Lower BMI was associated with a higher mortality risk, the inverse of the relationship observed in community-based datasets. Mortality risk was higher when Hb was <10 g/dL and lower when Hb was >12 g/dL. PTH values <150 pg/mL indicated higher mortality risk. Use of vitamin D was associated with a slightly lower risk. The magnitude of the difference between the development and the validation datasets was assessed by the c-statistic which reached 0.69 (0.67, 0.70). The resulting clinical additive score [range -9 to +20] conveyed a 2-year mortality risk of 2% to >90%. This allowed building up a simple heat map for risk assessment in an individual patient.

Conclusions: A predictive clinical score for 1- and 2-year mortality risk developed in a large European HD database is now available as a simple clinical tool. An external validation and refinement of the score is currently being conducted in a 12000 incident HD patient database.

Mortality and Race in Pediatric End-Stage Renal Disease: Who Is Dying before Transplant? Sandra Amaral,[1] Rachel E. Patzer,[2] Nancy G. Kutner,[3] William M. McClellan.[2] *[1]Pediatrics, Emory University, Atlanta, GA; [2]Epidemiology, Rollins School of Public Health, Emory University, Atlanta, GA; [3]Rehabilitation Medicine, Emory University, Atlanta, GA.*

Background: Children with End-Stage Renal Disease (ESRD) have increased risk of morbidity and mortality. Kidney transplantation may mitigate these risks and prolong patient survival and quality of life. Yet, some children with ESRD never proceed to transplantation due to premature death. Little is reported about racial differences in mortality risk after incident ESRD.

Methods: We performed a retrospective cohort study of all incident ESRD patients < 21 years of age from January 2000 through Sept. 2008, followed through Sept. 2009. We examined rate of death among dialysis patients by race/ethnicity using multivariable-adjusted Cox models. We censored patients at death or end of follow-up and excluded patients who received a transplant. We considered neighborhood poverty and patient's health insurance at incident ESRD as measures of socioeconomic status.

Results: Among 8, 146 pediatric ESRD patients, 896 (9.7%) deaths occurred. 735 (82%) died before waitlisting and 161 (18%) died on the waiting list. Median time to death after incident ESRD was 463 days; mean age at death was 14.9 yrs. Compared to the incident ESRD population, a greater proportion of patients who died were black (vs. white or Hispanic). In adjusted analyses, the effect of race on death was significantly modified by health insurance, with Hispanics experiencing lower rate of mortality across all levels of insurance status. This was most striking in Hispanics with no health insurance who had 64% lower rate of death (HR=0.36; 95% CI: 0.18-0.71) compared to whites with no insurance, whereas black patients with no health insurance had 59% higher (HR=1.59; 95% CI: 0.95-2.67) rate of death compared to whites.

Conclusions: We found that blacks with no health insurance had a greater rate of death after incident ESRD compared with whites, while Hispanics had significantly lower rate of death after incident ESRD vs. the other racial groups regardless of insurance status. Further studies are needed to elucidate why these racial differences in mortality exist.

TH-PO631

In-Center Daily Hemodialysis and Patient Survival: A Multinational Cohort Study Rita Suri,[1] Robert M. Lindsay,[1] Brian Bieber,[2] Ronald L. Pisoni,[2] Amit X. Garg,[1] Peter Austin,[3] Louise M. Moist,[1] Bruce M. Robinson,[2] Yun Li,[4] Cécile Couchoud,[5] Eduardo K. Lacson,[6] Deborah Lynn Zimmerman,[7] Gihad E. Nesrallah.[1] *[1]U Western Ontario; [2]Arbor Research Collaborative for Health; [3]Institute for Clinical and Evaluative Sciences; [4]U Michigan; [5]Agence de la Biomédecine; [6]Fresenius Medical Care North America; [7]U Ottawa.*

Background: Increasing hemodialysis frequency from 3 to 6 times per week improves left ventricular mass and health-related quality of life. However, the effects of increased frequency on survival remain uncertain.

Methods: We identified 556 patients from France, the United States, and Canada in the International Quotidian Dialysis Registry, who received daily hemodialysis ≥5 times per week from January 2001 to August 2010. Using propensity-score based matching techniques, we matched 318 of these patients to 575 contemporaneous patients receiving conventional, 3 times weekly, hemodialysis in the Dialysis Outcomes and Practice Patterns Study. All patients had session times of less than 5 hours, and received hemodialysis in the clinic or hospital setting. We compared mortality rates between groups using Cox proportional hazards regression.

Results: Mean dialysis frequency in the daily group was 5.8+0.5 sessions/week. Mean weekly treatment time was 15.7+4.3 hours for daily patients and 11.9+1.0 hours for conventional patients. During 1382 patient-years of follow-up, 170/893 patients died. Patients receiving daily hemodialysis had a significantly higher mortality rate than patients receiving conventional hemodialysis (15.6 vs. 10.9 deaths per 100 patient-years: hazard ratio 1.6; 95% CI 1.1-2.3; p=0.023). Similar results were observed in pre-specified subgroup and sensitivity analyses.

Conclusions: In contrast to previous studies, in-center daily hemodialysis was not associated with any appreciable mortality benefit. As we cannot exclude the possibility of residual confounding, these findings require confirmation in an adequately powered randomized trial. Until then, decisions to undertake daily hemodialysis should not be based on assertions of improved survival.

TH-PO632

Relationship of Missed and Shortened Hemodialysis [HD] Treatments to Hospitalization and Mortality Chamberlain I. Obialo,[1] W. Hunt,[2] Khalid Bashir,[1] Philip Zager.[2] *[1]Renal Section, Dept of Medicine, Morehouse School of Medicine, Atlanta, GA; [2]Dialysis Clinic, Inc., Albuquerque, NM.*

Background: Missed and shortened HD treatments are more common in US than in Europe and Japan. The factors that predict these events and their relationships to clinical outcomes have not been previously studied in a nationally representative sample of US HD patients. The present study was conducted to explore: the frequency of missed and shortened treatments by race, treatment schedule, geographic region: and the effect of these events on mortality and hospitalization.

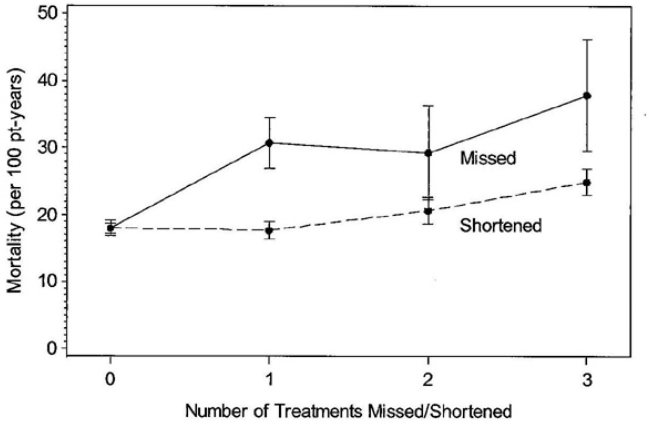
Methods: We studied a prevalent cohort of 15,340 HD patients treated in facilities operated by Dialysis Clinic Inc (DCI) between January 2007 and June 2008. The cohort consisted of 48% non-Hispanic whites [NHW], 41% African Americans [AA], 6% Hispanics, 2% Native Americans [NA], 2% Asians and 1% unknown.

Results: The percent of missed and shortened treatments differed significantly by race.

Race/Ethnicity	AA	NA	Hispanic	NHW	Asian
Missed HD(%)	3.1*	2.9*	2.8*	1.8	0.9*
Shortened HD(%)	18.4*	15.0*	17.0*	12.6	8.9*

* p<0.001 vs. NHW

Missed and shortened treatments were more frequent among patients treated on the Tuesday, Thursday, Saturday vs. the Monday, Wednesday, Friday schedule (2.9% vs. 2.1% missed and 16.4% vs. 14.9% shortened, both p<0.0001). The frequency of missed and shortened treatments differed slightly by geographic region and was lowest in the northeast. Missed and shortened treatments were associated with increased mortality.



Similar associations were also observed for hospitalization (not shown).

Conclusions: The frequency of missed and shortened HD differed by race,dialysis schedule and geographic region and was associated with increased hospitalization and mortality. Increased adherence with prescribed dialysis may decrease morbidity and mortality.

TH-PO633

Declining Mortality in US Dialysis Patients: A General Population Effect-Or More? The United States Renal Data System Robert N. Foley,[1,2] David T. Gilbertson,[1] Areef Ishani,[1,3] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN; [3]Minneapolis VAMC, Minneapolis, MN.*

Background: Substantial reductions in mortality have occurred in US dialysis patients, in spite of increasing burdens of comorbid illness and successive failures of large, multicenter trials to define salutary interventions. Hence, we set out to address the hypothesis that mortality reductions in dialysis populations reflect general-population phenomena.

Methods: Defined as annual mortality rates in prevalent dialysis patients as numerator and mortality rates in the U.S. population as denominator, we compared age-specific mortality ratios for 1998 and 2008.

Results: Dialysis mortality rates fell in all age-groups except 15 to 24 years. In contrast, age-specific dialysis-general population mortality ratios fell in only 3 of the 8 subgroups examined: age 25 to 34 years (ratio 55.6 in 1998/ratio 46.6 in 2008), 35 to 44 years (44.7/37.2) and 45 to 54 years (28.6/23.8). When prior duration of dialysis therapy was taken into consideration declines in mortality ratio were only apparent in dialysis patients with duration ≤ 1 year, among the following subgroups: age 25 to 34 (68.5/50.5), 35 to 44 (48.2/38.9) and 45 to 54 (29.5/23.3).

Conclusions: Mortality reductions in dialysis patients > 55 years reflect general-population trends. Mortality reductions in younger patients, in contrast, may exceed general population expectations.

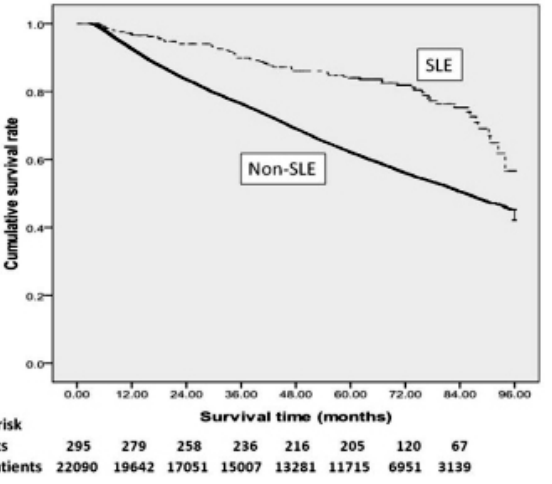
Long-Term Outcomes and Predictors for Mortality among SLE Dialysis Patients: National Cohort Study in Taiwan Chih-Chiang Chien. *Departments of Nephrology, Chi-Mei Medical Center, Tainan, Taiwan.*

Background: To compare the prognosis of patients with systemic lupus erythematosus (SLE) receiving dialysis and non-SLE patients receiving dialysis and determine the factors that affect survival after dialysis.

Methods: We used the National Health Insurance Research Database and collected data on patients who started maintenance dialysis from 2001 to 2003. The patients were followed from initiation of dialysis until death, discontinuing dialysis, or the end of 2008. We performed a Kaplan-Meier analysis of the cohort and used multivariate Cox regression analysis to identify significant predictors of survival.

Results: Of the 22,394 dialysis patients studied, 303 (1.35%) had SLE. Patients with SLE were predominantly women and younger than the other patients (39.4 ± 15.3 years vs. 59.4 ± 14.2 years, p<0.001). The Kaplan-Meier survival curves for dialysis patients with and without SLE are illustrated.



The 1- and 5-year cumulative survival rates were 97.6% and 84.0% in patients with SLE, and 92.7% and 62.2% in patients without SLE. After adjusting for age, gender, dialysis modality, and comorbidities, we did not find a significant survival difference between the two patient groups after 8 years of follow-up. Multivariate analysis showed that older age (≥65), male gender, and the presence of diabetes were independent predictors of mortality (p<0.05) among SLE patients.

Conclusions: The long-term survival outcome was similar between the SLE and non-SLE patients undergoing dialysis. The factors affecting patient mortality were not all identical in these two groups.

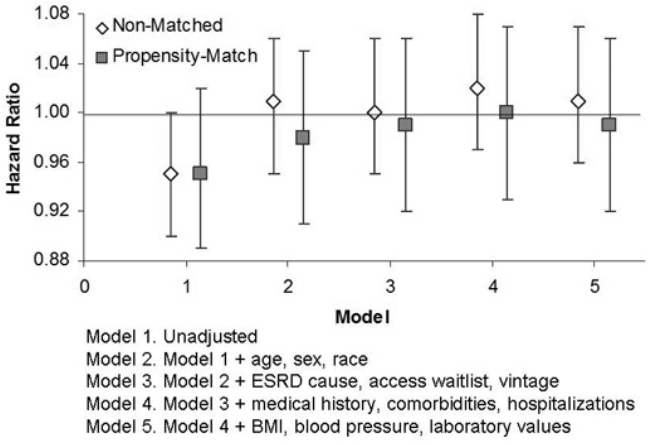
TH-PO635

Single Use Versus Reprocessed Dialyzers and Mortality Daniel E. Weiner, Hocine Tighiouart, Klemens B. Meyer. *Tufts Medical Center, Boston, MA.*

Background: There is limited overall evidence either supporting or discouraging dialyzer reprocessing.

Methods: To explore the long-term medical utility of dialyzer reuse, we compiled patient level data for all prevalent hemodialysis patients with Medicare coverage treated at a DCI facility on January 1, 2005, merging DCI data with USRDS data to better define comorbidity and outcomes based on medical claims. Reuse status was determined by patient dialyzer prescription. The primary outcome was time to all-cause mortality through July 2009, ascertained with both DCI and USRDS data; sensitivity analyses examined transplant and PD-censored mortality. Primary analyses used Cox regression with extensive comorbidity adjustment while secondary analyses matched patients based on their propensity to reuse. A sandwich estimator accounted for center effect.

Results: There were 9,051 Medicare patients included; 5735 were reuse patients in reuse facilities and, of 3316 non-reuse patients, 2641 were in non-reuse facilities. Reuse patients were more likely to be African American, Hepatitis C negative, and had more grafts and fewer catheters. Dialysis vintage was 3 months longer, blood pressure slightly higher and heparin use substantially lower in non-reuse patients. Propensity score matching successfully paired 2533 patients in each groups. Results of primary and propensity matched analyses were similar and revealed no significant difference in outcomes by reuse status (Figure), with a hazard ratio for reuse of 1.01 (0.96, 1.07) and 0.99 (0.92, 1.06) in multivariable adjusted non-matched and propensity-matched analyses, respectively. Analyses censoring at modality change were similar to those in the figure.



Conclusions: Dialyzer reuse is not associated with mortality when compared to single use. The decision to reuse therefore should be based on other factors, including resource utilization and cost and environmental concerns.

TH-PO636

Early Start of Renal Replacement Therapy in Critically Ill Patients Improves Renal Outcome but Not Survival Anne Lerner-Gräber, Timo Speer, Danilo Fliser, Matthias Klingele. *Department of Internal Medicine 4, Saarland University Medical Centre, Homburg / Saar, Germany.*

Background: To assess the relationship between serum creatinine and urea levels at the beginning of renal replacement therapy (RRT) on mortality and need for RRT after discharge in critically ill patients.

Methods: Observational study of all patients requiring RRT in 2 internal medicine and 4 surgical intensive care units (ICUs) of a tertiary hospital between 03/2007 and 08/2009. Patients being on chronic RRT before admission to the hospital were excluded. Serum creatinine and urea levels at the start of RRT, mortality and recovery of kidney function during hospitalization and after discharge (mean follow-up period 511 days) were assessed.

Results: In total, 583 patients and 5694 RRTs were included for analysis. The in-hospital mortality was 68.4 % (n = 399), whereas the mortality rate in survivors after discharge who were not lost to follow-up (n = 140, 24.0 %) was 25.7 %. There was no statistically significant difference of serum creatinine and urea levels at initiation of RRT between those patients who died or who survived. After discharge, in 20 survivors no recovery of renal function after acute kidney injury could be observed and they required RRT due to persistent renal insufficiency. In these patients serum creatinine (261 ± 151 vs. 475 ± 282 µmol/L, p=0.000) as well as serum urea levels (20.8 ± 11 vs. 30.8 ± 16.5 mmol/l, p=0.007) were significantly higher at initiation of RRT compared to those in whom renal function recovered after discharge. Of note, the rise of creatinine or urea levels between admission and start of dialysis treatment are strong predictors of recovery of renal function after discharge (β=0.458, p=0.000; β=0.419, p=0.000).

Conclusions: In critically ill patients with kidney injury requiring RRT on the ICU, lower serum creatinine and urea levels at the start of RRT signalize better renal outcome after hospital discharge, while mortality is not improved.

TH-PO637

Predictors of Hospitalizations in Maintenance Hemodialysis (HD) Patients Jochen G. Raimann,[1,2] Len A. Usvyat,[1] Peter Kotanko,[1,2] Nathan W. Levin.[1,2] *[1]Renal Research Institute; [2]Beth Israel Medical Center.*

Background: Despite technological advances in hemodialysis (HD) technology, mortality and hospitalization (hosp) rates remain high in these patients (pts) (USRDS 2010). This is of substantial clinical and economic impact. This analysis attempts to identify significant predictors of hosp in HD pts.

Methods: Pts receiving HD in RRI clinics for more than 365 days from Jan 1, 2008 to Dec 31, 2010 were included. Clinical parameters, hosp days and admissions during the observation period were averaged per patient for the entire observation period. Two multivariate regression models were developed aiming to predict hosp days (Model 1) and number of admissions (Model 2), respectively, during the observation period. Both models were adjusted for age, gender, race, HD vintage, diabetes (DM), HD access, pre HD systolic and diastolic blood pressure (SBP, DBP), pre HD temperature (temp), interdialytic weight gain (IDWG), post HD weight (wt), difference of post HD wt and prescribed target wt (Δ TW), enPCR, Kt/V, albumin, total calcium, ferritin, hemoglobin (Hgb), potassium, phosphorus, transferrin saturation (TSAT) and treatment time.

Results: 5758 incident and prevalent HD patients (age 60.5±15.4 years, 55% male, 51% blacks, BMI 28.7±12.8 kg/m^2), with an average of 1.74 hosp admissions lasting 11.8 days per year, were studied. Model 1 (adjusted R^2 0.25, P<0.05) significantly predicted hosp days and Model 2 (adjusted R^2 0.25, P<0.05) hosp admissions. **Table 1** shows significant predictors and unstandardized coefficients.

Conclusions: This analysis showed a significant relationship between hosp and potentially modifiable indicators of fluid overload (IDWG, Δ TW), anemia management (Hgb, TSAT) and vascular access (catheter). Knowledge of predictive parameters may aid the the identification of pts at risk and thus help to prevent hosp admissions.

Table 1: Predictors of Hospitalization.

Does Combination Therapy with Peritoneal Dialysis and Hemodialysis from the Initiation of Renal Replacement Therapy Improve the Patients' Prognosis? Atsushi Ueda,[1] Aki Hirayama,[2] Kei Nagai,[1] Kunihiro Yamagata.[3] *[1]Kidney & Dialysis Center, Namegata District General Hospital, Namegata, Ibaraki, Japan; [2]Integrated Medicine, Tsukuba University of Technology, Tsukuba, Ibaraki, Japan; [3]Internal Medicine, University of Tsukuba, Ibaraki, Japan.*

Background: Peritoneal dialysis and hemodialysis (PD+HD) combined therapy is an alternative method to supplement the weak points of PD. Usually this combined therapy is started on the halfway of renal replacement therapy (RRT) and its beneficial effects were already reported. However, the advantage when the combination is carried from the beginning of RRT is little known. The aim of this study is to evaluate the advantages of PD+HD therapy from the initiation of RRT by a retrospective cohort study.

Methods: Ninety-three end-stage renal patients initiated to RRT in our hospital were employed. The patients received an adequate explanation about the three treatment method and selected by own idea. Thus they were divided into three groups: hemodialysis (HD, n=65),peritoneal dialysis (PD, n=18) and HD+PD (n=10). Residual renal function(RRF), peritoneal permeability using peritoneal equilibration test data, serum beta-2-microglobulin (β_2MG) and survivorship curve for three years of every six months were measured.

Results: The RRF rapidly decreased in the HD group compared to PD or PD+HD, and there was no difference between PD and PD+HD group. The peritoneal permeability was not different between PD and the PD+HD group. When the dialysis therapy was introduced, β_2MG did not admit a significant difference in HD and the PD+HD group. However, the value of the β_2MG after 1 year and two years of the HD group increased significantly (HD after 1 year 31.7±9.8 vs. PD+HD 19.4±5.4µg/L and after 2 years 31.4±8.5 vs. 20.6±3.0µg/L, p<0.05). Kaplan-Meier analysis revealed that PD+HD was the most excellent of the prognosis compared other therapies .

Conclusions: PD+HD combination therapy from the initiation of RRT showed advantages in the remaining kidney function, serum β_2MG values and survival rate compared to monotherapy with conventional HD or PD alone. Therefore it was concluded that PD+HD therapy has the possibility of becoming the most excellent selection at the start of RRT.

TH-PO639

Health Literacy and Outcomes in Hemodialysis Patients Jamie Green,[1] Maria K. Mor,[2] Anne-Marie Shields,[2] Mary Ann Sevick,[1,2] Robert M. Arnold,[1] Paul M. Palevsky,[1,2] Michael J. Fine,[1,2] Steven D. Weisbord.[1,2] *[1]Medicine, University of Pittsburgh, PA; [2]VA Pittsburgh Healthcare System, Pittsburgh, PA.*

Background: Although limited health literacy is common among chronic hemodialysis patients, its associations with patient outcomes are not well characterized. We sought to evaluate the associations of limited health literacy with dialysis treatment adherence, hospitalizations, and mortality.

Methods: Using the Rapid Estimate of Adult Literacy in Medicine (REALM), we measured the baseline health literacy of 260 chronic hemodialysis patients enrolled in a randomized clinical trial of symptom management strategies. We used Poisson regression to evaluate the independent associations of limited health literacy (REALM scores <61) with dialysis adherence (abbreviated and missed treatments) and hospitalizations, and Cox regression to characterize the independent association of limited health literacy with mortality over a follow-up period of up to 24 months. The analyses adjusted for potential confounders and used multiple imputation to account for missing data.

Results: Overall, 41 of 260 patients (16%) demonstrated limited health literacy. Limited health literacy was independently associated with a greater number of abbreviated dialysis treatments (9.1% of sessions v. 8.9% of sessions; incident rate ratio = 1.2; 95% CI 1.1-1.3) and missed treatments (3.6% of treatments v. 1.7% of treatments; incident rate ratio = 1.4; 95% CI 1.1-1.7). There was a non-statistically significant trend towards a higher risk of hospitalization among patients with limited health literacy (2.7 hospitalizations per year v. 2.2 hospitalizations per year; incident rate ratio = 1.2; 95% CI 1.0-1.4). Limited health literacy was not associated with a higher risk of mortality (hazard ratio = 1.3; 95% CI 0.6-2.9).

Conclusions: Patients receiving chronic hemodialysis with limited health literacy are more likely to shorten and miss dialysis treatments and may be at greater risk for hospitalization. Interventions to address limited health literacy may increase adherence and reduce health resource utilization in this chronically ill patient population.

TH-PO640

Relationship between Outpatient "AKI", Proteinuria, Diagnosis Diabetes, Race and Rate of Decline in Renal Function, Nine Years Prior to Dialysis Initiation Steven J. Rosansky,[1,2] James W. Hardin,[2] Frankie Richards,[1] Kathlyn Sue Haddock,[1] Ann M. O'Hare,[4] William F. Clark.[3] *[1]Research, Dorn Research Institute, Columbia, SC; [2]Biostatistics, University of SC School of Public Health, Columbia, SC; [3]Nephrology, University of Western Ontario, London, ON, Canada; [4]Nephrology, VA Seattle, Seattle, WA.*

Background: AKI has been examined as a discharge coded, inpatient phenomenon. Predialysis creatinine based e GFR is commonly used in the decision to initiate dialysis,which may not account for AKI episodes and temporarily higher serum creatinine . Proteinuria is a primary determinant of renal function trajectory.

Methods: The current study examines the change in MDRD e GFR (ml/min/1.73m^2/yr) using initial and final serum creatinine, to determine the change of renal function by: AKI; diagnosis diabetes; urine proteinuria and race. Growth curve analysis examined the effect of covariates on renal function decline. We studied 212 chronic dialysis patients with at least: one urinalysis, ≥3 creatinine values over ≥3 years. The method of creatinine determination was the same throughout the study 1989-2008. Diabetics were identified by any HgbA1 C of ≥ 6%. Quarterly "AKI"episodes were defined by sequential serum creatinine values of a 50 percent increase from the prior serum creatinine in a 90-day window.

Results: In the study population:one AKI occurred in 67%, 2 or more in 23%; 50% were diabetic; 9.2 years follow-up:mean of 41 creatinine and 20 urinalysis measures per patient. Patients were divided by : <2plus protein; ≥2plus protein(using all UA data); 3 AKI groups: none, 1, 2 or more episodes; diabetic/non diabetic,white/non white.

Pre-dialysis Change in Renal Function

Co-Variates	N	ml/min/1.73m^2/yr
Urinalysis Results		
< 2+ proteinuria	29	6.0
≥ 2+ proteinuria	183	6.26
AKI Episodes		
None	68	6.27
One	92	6.58
Two or more	52	5.59
Diagnosis Diabetes		
Yes	103	6.0
No	109	6.46
Race		
White	139	6.58
Black	74	5.47

Conclusions: In conclusion, there was no significant difference in predialysis rate of e GFR decline by AKI frequency,proteinuria,race ,diagnosis diabetes.Nevertheless,AKI episodes must be considered in the evaluation of predialysis e GFR data and the decision to initiate dialysis

Funding: Veterans Administration Support

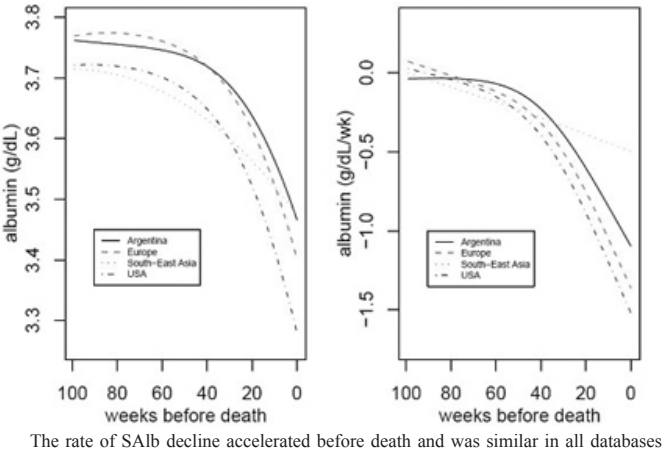
TH-PO641

Serum Albumin Dynamics before Death in Chronic Hemodialysis (HD) Patients – Results of an International Study Michael Etter,[1] Yuedong Wang,[2] Claudia Barth,[3] Mathias Schaller,[7] Adrian Marcos Guinsburg,[4] Daniele Marcelli,[5] Cristina Marelli,[4] Adam Tashman,[2] Len A. Usvyat,[6] Nathan W. Levin,[6] Peter Kotanko.[6] *[1]FMC Asia Pacific, Hong Kong, Hong Kong; [2]University of California - Santa Barbara, Santa Barbara, CA; [3]Kuratorium für Dialyse und Nierentransplantation, Cologne, Germany; [4]FMC Latin America, Buenos Aires, Argentina; [5]FMC Europe, Bad Homburg, Germany; [6]RRI, NY, NY; [7]University of Cologne Medical Center, Germany.*

Background: HD patients (pts) experience mortality rate between 14-20% per year. In a US HD cohort a decline of serum albumin (SAlb) before death was described (Kotanko 2009). Here, we investigate if the SAlb decline holds for a globally diverse HD population.

Methods: HD databases from FMC clinics in Europe, Asia, Latin America, RRI clinics in US, and KfH in Germany were queried. SAlb was standardized to the BCG. Pre-death SAlb dynamics were analyzed by estimating the mean SAlb level before death and its 1st derivative using quintic splines.

Results: 27807 HD pts from 23 countries were studied (Europe 17 [N=12333; age 71.7, 59% males]; South-East Asia 4 [N=1484; age 68; 53% males]; Argentina [N=10517; age 63.1; 58% males]; USA [N=3473; age 69.9; 56% males]). SAlb levels prior to death [mean (SD); g/dL] were 3.53 (0.63); 3.45 (0.59); 3.63 (0.54); 3.3 (0.62); same order as above. In all regions, SAlb levels dropped between 0.24 (South-East Asia) and 0.44 (USA) mg/dL in the 2 years preceding death in female pts (left).



The rate of SAlb decline accelerated before death and was similar in all databases (right).

The results were identical in male pts and in pts from KfH (not shown).

Conclusions: This international study corroborates previous findings in US HD pts. Insights into the pre-death biology are key to the development of alert systems to facilitate timely diagnostic and therapeutic interventions.

TH-PO642

Frequency of Pulmonary Embolism and Associated Mortality in Patients with Chronic Kidney Disease and End Stage Renal Disease Ankit Sakhuja, Gagan Kumar, Puneet Sood, Rahul S. Nanchal, Aaron T. Dall. *Medicine, Medical College of Wisconsin, Milwaukee, WI.*

Background: Chronic Kidney Disease (CKD) and End Stage Renal Disease (ESRD) are growing problems in the United States. Studies are not clear with respect to frequency of Pulmonary Embolism (PE) in these patients.

Methods: We analyzed the data from the Nationwide Inpatient Sample database from the year 2007. Adult patients with ESRD, CKD and PE were identified using appropriate ICD-9-CM codes as previously used. The primary outcomes measured were frequency of PE in patients with CKD and ESRD. Secondary outcome was all cause in-hospital mortality.

Results: Of 32,759,253 estimated adult discharges, 30,119,186 had normal kidney function, 1,799,785 had CKD and 840,282 had a discharge diagnosis of ESRD. The unadjusted frequency of PE was 0.97% in patients with CKD and 0.59% in patients with ESRD in comparison to 0.83% in patients with normal renal function ($p < 0.001$). On multivariate regression analysis, patients with CKD are more likely to have a PE (OR 1.27; 95% CI: 1.14 - 1.42) and those with ESRD are less likely to have a PE (OR 0.69; 95% CI: 0.61 - 0.78) when compared to patients with normal renal function. The all cause in-hospital mortality in patients with PE increased with decline in renal function. 7.2% of patients with normal renal function who had a PE died, this number rose to 12.6% for those with CKD and 17.2% for those with ESRD ($p<0.0001$).

Conclusions: Patients with CKD have a higher frequency of PE whereas patients with ESRD have a lower frequency of PE in comparison to those with normal renal function. The all cause in-hospital mortality in patients with PE is higher in those with CKD in comparison to those with normal renal function and is highest in those with ESRD.

TH-PO643

The Effect of Censoring for Transplantation When Analyzing Survival on Dialysis: Applying Competing Risk Analysis to ERA-EDTA Registry Data
Marlies Noordzij, Karlijn J. Van Stralen, Kitty J. Jager. *ERA-EDTA Registry, Department of Medical Informatics, Academic Medical Center, Amsterdam, Netherlands.*

Background: When studying patient survival on dialysis treatment, kidney transplantation (Tx) is often considered as a censored observation, while it is in fact an event that competes with the occurrence of death. Kaplan-Meier (KM), a conventional method for unadjusted survival analysis, can handle only one outcome and may therefore be inappropriate in the presence of competing risks. We therefore compared the results of KM with those of the Cumulative Incidence Competing Risk (CICR) method; an alternative method specifically designed for analyzing competing risks.

Methods: Based on data of incident dialysis patients from countries participating in the ERA-EDTA Registry we studied 1, 2, and 5 years patient survival of patients starting dialysis between 1999 and 2003. The probabilities of separate events, i.e. death, Tx and event-free survival (EFS) from day 91 after the start of dialysis onwards were calculated using both the standard KM and the CICR methods.

Results: Data analysis was based on 69,081 patients from Europe. When studying 1-year patient survival on dialysis, both methods yielded similar results, i.e. probabilities of death, Tx and EFS of 17%, 7%, and 76%, respectively, with an expected total of 100%. For 2-years survival the KM method yielded probabilities of 31% for death, 16% for Tx and 58% EFS (total 105%). These probabilities were 29%, 13% and 58%, respectively, for the CICR method (total 100%). Finally, after 5-years of follow-up, the difference between the methods was even more pronounced. The probabilities of death (61%) and Tx (34%) were overestimated by KM (EFS 25%) to a total of 120%, while the CICR method yielded lower probabilities of 51%, 24% and 25%, respectively, adding up to 100%.

Conclusions: The KM method overestimates the risk of both mortality and Tx with percentages as high as 10% at 5 years after the start of dialysis Therefore, this method is inappropriate to analyze patient survival in the presence of competing risks and using the CICR method is recommended.

TH-PO644

Time to Death from Cessation of Dialysis in an Elderly Veteran Population
Rizwan Badar,[1,2] Xiao Wan,[1] Seyed-Ali Sadjadi,[1,2] Navin Jaipaul,[1,2] Ruth Peeters.[1] *[1]Nephrology, VA Loma Linda Healthcare System, Loma Linda, CA; [2]Nephrology, Loma Linda University Medical Center, Loma Linda, CA.*

Background: An extensive review shows a paucity of literature on time to death after cessation of dialysis in end stage renal disease (ESRD) patients. A common question nephrologists often face from patients is the length of time before death after dialysis is withdrawn. In a report by Murray et al in 2006 using the United States Renal Data System (USRDS) data from 2001 to 2002, the time to death after stopping dialysis was not looked at.

Methods: We conducted a single center retrospective chart review of 174 adult veteran dialysis patients between January 2002 and May 2011 to determine length of time until death after withdrawal from dialysis. We also looked at DNR status, place of death, and vascular access at death.

Results: The 174 patients had a mean age of 69.0±10.9 years and the following characteristics: 97.1% male, 68.4% diabetic, 93.7% hypertensive, and 59.8% had coronary artery disease. Diabetes and hypertension were the most common cause of renal failure and accounted for 65% of the patients. Mean duration on dialysis was 3.25 years, and vascular access at death was catheter (43.7%) or fistula (48.8%). 74.7% of patients had a DNR, of which only 1.7% did not have it honored. 37.9% of patients withdrew from dialysis. Mean time to death after stopping dialysis was 10.7 days with a standard deviation of 15.5 days. Place of death was 48.3% hospital, 33% hospice, 6.9% nursing home, 5.2% home, 4.6% dialysis unit.

Conclusions: Our results show that withdrawal from dialysis (37.9%) is much more common than that reported by the USRDS. This could be due to the characteristics of our cohort, an elderly veteran population. Mean time to death after cessation of dialysis (10.7 days) is also slightly higher than that reported in the literature. Further studies regarding withdrawal of dialysis as well as patient and family satisfaction with the dying process are needed.

TH-PO645

Cause of Death in a Veteran Dialysis Population: Death Certificate vs. Chart Review
Rizwan Badar,[1,2] Xiao Wan,[1,2] Seyed-Ali Sadjadi,[1,2] Navin Jaipaul,[1,2] Ruth Peeters.[1] *[1]Nephrology, VA Loma Linda Healthcare System, Loma Linda, CA; [2]Nephrology, Loma Linda University Medical Center, Loma Linda, CA.*

Background: According to USRDS, "other" is the most common cause of death (COD) in dialysis patients with ESRD, followed by cardiac death. This information is gathered from the ESRD Death Notification Form 2746, which is completed by nephrologists, other physicians, or non-physicians. Often times the death certificate (DC), which is frequently inaccurate, is used to obtain this information. Determining the COD is difficult due to co-morbidities, low autopsy rate, and lack of physician training.

Methods: We conducted a single center retrospective chart review (CR) of 174 adult veteran dialysis patients between January 2002 and May 2011 to determine the correlation between CR and DC COD. A panel of trained physicians determined the CR COD and extracted the DC COD, and the two were categorized and compared by calculating the Pearson correlation coefficient (r). Statistical analysis was performed using SPSS, version 17.0.

Results: The 174 patients had a mean age of 69.0±10.9 years and the following characteristics: 97.1% male, 68.4% diabetic, 93.7% hypertensive, and 59.8% had coronary artery disease (CAD). Mean duration on dialysis was 3.25 years, and vascular access at death was 43.7% catheter vs. 48.8% arteriovenous. The most common categorized COD by CR and DC are shown in Table 1. The correlation between CR and DC COD was statistically significant ($p<0.001$) but weak ($r= 0.42$).

Table 1. Cause of Death* by Death Certificate vs. Chart Review

	DC COD	CR COD
Cardiac, n(%)	45(37.5)	24(20.0)
Infectious, n(%)	37(30.8)	41(34.2)
Other, n(%)	22(18.3)	35(29.2)
Malignancy, n(%)	11(9.2)	11 (9.2)
Vascular, n(%)	5(4.2)	9(7.5)

*54 patients with missing DC were excluded

Conclusions: Our findings demonstrate poor correlation between COD by CR and DC. In addition, infection and not "other" or CAD, was the leading cause of death in this elderly veteran dialysis population. We speculate that death certificates are often inaccurate due to lack of physician training and bias in coding, and that ESRD death notification form shortcomings limit the ability to properly report the accurate cause of death.

TH-PO646

Health Related Quality of Life and All-Cause Mortality in Patients with Diabetes on Dialysis
Ingrid Os,[1] Tone Brit Hortemo Østhus,[1] Toril Dammen,[2] Lis Ribu,[3] Tone Rustøen.[3] *[1]Department of Nephrology, Oslo University Hospital Ullevål, Oslo, Norway; [2]Department of Psychiatry, Oslo University Hospital Ullevål, Oslo, Norway; [3]School of Nursing, Oslo University College, Oslo, Norway.*

Background: The purpose of the study was to compare HRQOL in dialysis patients with and without diabetes (DM), and assess the mortality risk. Secondly, to assess HRQOL in diabetes patients on dialysis (DDM) with non-dialysis diabetes patients (DM) and patients with diabetic foot ulcers (DFU).

Methods: A 36-item Short-Form Health Survey 36 (SF-36) was used in 301 prevalent dialysis patients of whom 78 had DM, and in 221 nondialysis patients with DM and 127 with DFU, and compared with a general population sample (n=5903). Physical and mental component summary scores (MCS/PCS) were calculated in dialysis patients. Kaplan Meier plot and Cox proportional hazard model were used for mortality analysis in dialysis patients, and data censored for renal transplantation.

Results: DDM had lower HRQOL than other dialysis patients (MSC 46 (IQR 38 -54) vs 50 (40-57), $p=0.04$ and PCS 33 (28-43) vs 37(31-45) $p=0.05$). During follow-up (median 3.6 years), cumulative survival was reduced for DDM (log rank test, $p =0.04$), and DM remained a significant predictor for mortality (hazard ratio 1.59 (95% CI 1.02-2.46) after multiple adjustments. There were significant differences in the eight SF-36 subscales between the DDM, DFU, DM and the general population sample ($p<0.001$ for all, ANOVA), and the differences were most pronounced for physical function, role limitation physical, general health (GH) and vitality (VT). DDM differed significantly from DFU in GH 37 (33-42) vs 46 (41-40) ($p<0.001$) and VT 39 (34-44) vs 47 (43-51) ($p=0.001$)

Conclusions: The very low perceived PCS and MSC in dialysis patients with DM compared to nonddiabetes patients in dialysis and even to non-dialysis patients with DM, and the reduced survival of diabetes patients in dialysis, should lead to increased focus to prevent progression to end stage renal failure, and increased use of preemptive renal transplantation. Physical exercise training should be utilized to overcome or assist in physical function impairment in this patient group.

TH-PO647

Mortality Difference between Older and Younger ESRD Patients Is Smaller 2 Years after Dialysis Initiation Compared to the First 2 Years of RRT
Joachim H. Beige. *Nephrology and KfH Renal Unit, Hospital St. Georg, Leipzig, Saxony, Germany.*

Background: Patients with end.stage renal disease (ESRD) requriring renal replacement therapy (RRT) are subjected to an excess mortality risk compared with general population. In the older ESRD patients, such risk is furtherone exaggerated. That issue impacts on decision-making on the initiation of RRT in the elderly. Data are needed, to estimate mortality in older RRT patients.

Methods: KAPLAN-MEIER survival analyis of all patients of a chronic dialysis unit (hemo- and peritoneal dialysis) affiliated with a nephrological department of an academic teaching hospital from 2000 to 2010 (n=1679). Calculation of time from initiation to death and from initiation plus 2 years to death. Censoring of all non-death dialysis stop events (change to other center, change to transplantation, change to renal function, lost of follow-up).

Results: There was a strong significant overall mortality difference in patients 65 y or younger compared to patients over 65 y (Fig., LogRank $p<0.0001$). However, mortality difference in third, fourth, fifth and sixth year after RRT initiation in younger patients (0.10; 0.11; 0.11; 0.18) compared to older patients (0.24; 0.27; 0.19; 0.35) was not as strong as in the the first 2 years ($p=0.04$).

Conclusions: The excess mortality of ESRD patients >; 65 y in need of RRT compared to younger ESRD patients peaks during the first two years after RRT initiation. After 2 years,

patients in their high seventh or eighth life decade exhibit a yearly mortality of about 20%. From such epidemiological reasoning, stable long-term RRT in the elderly is a satisfying, life-prolonging and adequate treatment modality.

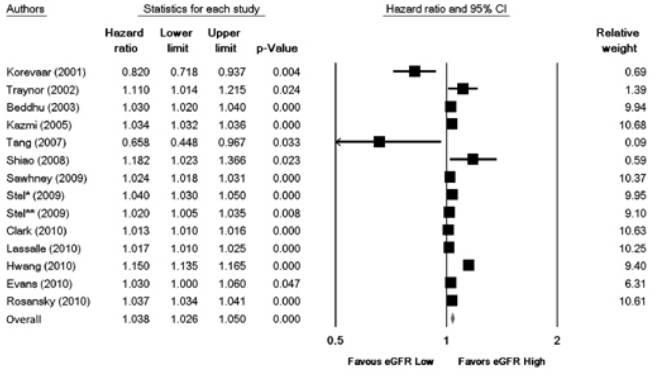
TH-PO648

Estimated Glomerular Filtration Rate (eGFR) at Initiation of Dialysis and Mortality in Patients with Advanced Chronic Kidney Disease (CKD): A Meta-Analysis Paweena Susantitaphong, Sarah Altamimi, Motaz Ashkar, Bertrand L. Jaber. *Medicine, St. Elizabeth's Medical Center, Boston, MA.*

Background: The number of patients with advanced CKD initiating dialysis is on the rise worldwide. Recent data suggest that initiation of dialysis at higher eGFR may be associated with worse clinical outcomes. We conducted a meta-analysis to examine the association of eGFR at initiation of dialysis with mortality in patients with advanced CKD.

Methods: We searched for randomized controlled trials, prospective and retrospective cohort studies in MEDLINE through March 2011. We selected studies that focussed on early versus late initiation of dialysis (defined by eGFR or creatinine clearance) and mortality among patients with advanced CKD. Using random-effects model meta-analysis, we computed the adjusted hazard ratio of eGFR at initiation of dialysis and all-cause mortality.

Results: Sixteen observational studies and one randomized controlled trial were identified (n = 1,365,933). By meta-analysis, which was restricted to the 14 cohort studies with retrievable data (n = 468,188), higher eGFR (per 1 mL/min/1.73 m^2 increase) at initiation of dialysis was associated with a higher pooled adjusted hazard ratio (HR) for all-cause mortality (1.038; 95% CI 1.026, 1.050; P<0.001, Figure). Among the 7 studies that adjusted analytically for nutritional variables, higher eGFR remained associated with all-cause mortality (adjusted HR 1.028; 95% CI 1.013, 1.044; P<0.001) compared to those that did not (adjusted HR 1.053; 95% CI 1.034, 1.072; P<0.001).



*Cohort initiating dialysis in 1999

**Cohort initiating dialysis in 2003

Conclusions: This meta-analysis demonstrates that higher eGFR at initiation of dialysis is associated with a higher mortality risk among patients with advanced CKD, which is independent of nutritional status. This concerning observation requires further study.

TH-PO649

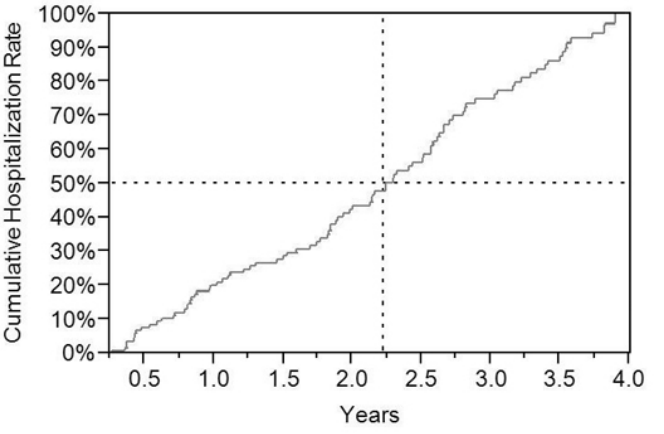
Hospitalizations in Older Incident Hemodialysis Patients Kimberly L. Schoonover,[1] LaTonya J. Hickson,[2] Suzanne M. Norby,[2] Marie C. Hogan,[2] Amy W. Williams.[2] *[1]Internal Medicine, Mayo Clinic; [2]Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Hospitalizations account for high morbidity in older chronic hemodialysis (HD) patients. Better understanding of the cause and predictors of hospitalization may provide a means for intervention.

Objective: To determine rate, cause and predictors of hospitalizations in older incident chronic HD patients.

Methods: Review of hospitalizations in older (age ≥65 years) HD patients initiating therapy from 2007-2009 and remaining on therapy for ≥3 months.

Results: Of 125 patients, mean age was 76±7 years, 72% were male, 52 % were diabetic, and 59% had coronary artery disease. At first HD, 41% had arteriovenous fistula/graft (AVF/G) present. 51% started HD in the hospital. Mean dialysis duration was 1.8±1.0 years. At least one hospitalization occurred in 90 (72%) patients had at least one hospitalization. Mean first hospital stay was 5±5 days. 67 (54%) had two, 46 (37%) had three, and 36 (29%) had four or more hospitalizations. The estimated cumulative hospitalization rate was 50% at 2.2 years (figure). Primary admission diagnoses for the first hospitalization included cardiovascular (32%), infection (17%), gastrointestinal (13%), access (6%), vascular (6%), neurology (4.5%), trauma (4.5%), endocrine (3%), pulmonology (3%), malignancy (2%), and other (9%). The most common cardiovascular diagnoses were acute coronary syndrome, atrial fibrillation, and heart failure exacerbation. Predictors of ≥1 hospitalization included: first dialysis location in hospital (HR 1.8, CI 1.1-3.0, p=0.02) and absence of (AVF/G) at first HD start (HR 1.9, CI 1.2-3.2, p=0.01).



Conclusions: Hospitalizations are common in older incident hemodialysis patients and are often recurrent. Location of dialysis initiation and patient preparedness for therapy may provide insight into degrees of risk for recurrent hospitalizations.

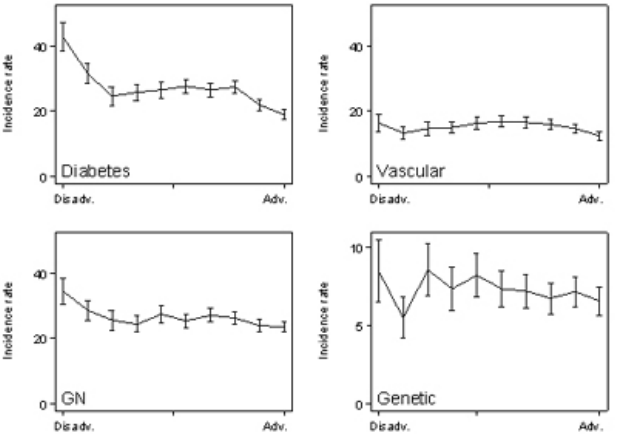
TH-PO650

Socioeconomic Gradients of ESKD Incidence Vary with Age and Primary Renal Disease Stephen P. McDonald, Philip A. Clayton, Blair S. Grace. *ANZDATA Registry, Adelaide, SA, Australia.*

Background: An inverse relationship between socioeconomic status (SES) and the incidence of renal replacement therapy (RRT) has been shown in several settings. In Australia, public hospitals provide access to RRT under a government-funded scheme without a cost barrier. However, previous studies have suggested an inverse relationship exists, not explained by higher RRT among Indigenous people in Australia. We examined relationships between SES and RRT incidence across various groups, including age and primary renal disease.

Methods: Residential postcodes of non-Indigenous people who started RRT in Australia from 1999 to 2009 (N=19,411) were mapped to SES using standard concordance files from the Australian Bureau of Statistics. RRT incidence rates were compared across SES deciles using Poisson regression to adjust for age, gender and year.

Results: The overall incidence rate of RRT decreased with increasing SES advantage (RR per decile 0.96 [95% CI 0.96 – 0.97]). A more marked gradient was noted for ESKD attributed to diabetic nephropathy (in contrast there was lesser or no gradient observed for reno-vascular or genetic diseases).



Trends across the SES spectrum were similar for males and females. However, the SES gradient was more marked among people aged 40-69 years (RR 0.94 [0.94 – 0.95] per decile) than older people (RR per decile 1.00 [1.00–1.01]). The gradient was also more marked among those who lived in major cities (RR per decile 0.90 [0.88–0.92]) compared with more remote locations (RR per decile 0.98 [0.92–1.02]).

Conclusions: A clear, inverse relationship exists in Australia between rates of RRT and SES. The differential is most marked among those with diabetic nephropathy: either the incidence of diabetes is higher among people with lower SES, or diabetic nephropathy progresses more rapidly. The SES effect is most marked among people of working age, and attenuated among older people.

Funding: Government Support - Non-U.S.

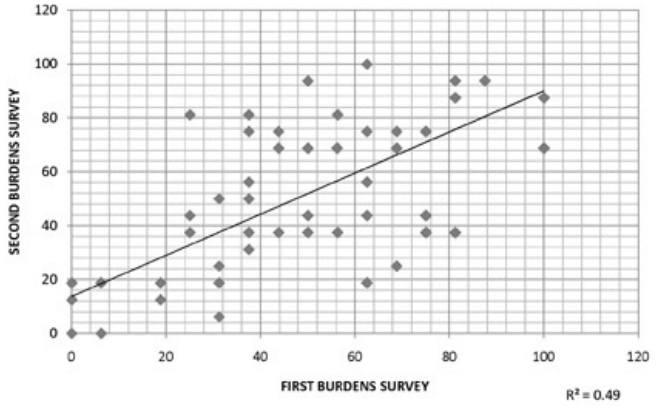
TH-PO651

Lessons Learnt from Consecutive Health-Related Quality of Life (KDQOL-SF) Surveys in a Mayo Clinic Stable Hemodialysis Patient Population Macaulay A. Onuigbo.[1,2] *[1]College of Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, WI.*

Background: The Kidney Disease Quality of Life Short Form (KDQOL-SF), a well validated epidemiological research tool, is a short-form health survey that measures ESRD patients' self-assessment of functioning and well-being as determined by 3 component scores of physical component summary (PCS), mental component summary (MCS) and kidney disease component summary. More recently, there is increasing application of KDQOL-SF scores as a measure of the ESRD patients' health-related quality of life (HRQOL).

Methods: A prospective ongoing administration of KDQOL-SF assessments by certified and trained Dialysis Social Workers as part of ongoing established KDQOL care of HD patients was repeated in 56 patients between October 2008 and September 2010, at least six months between the two consecutive assessments.

Results: A total of 112 administrations of the KDQOL-SF assessments to the 56 HD patients were analyzed; they were administered a mean of 13 (6-22) months apart. PCS mean score increased from 32 to 34 and mean of burden score increased from 47 to 49. Overall, all the indices showed a trend towards improved higher scores at the second testing. When fortuitously, the second testing was administered within days of an acute illness or hospitalization, patient scores were reduced, albeit transiently.



Conclusions: In general, HRQOL scores in stable HD patients tend to get better with more time on dialysis. More of such studies are warranted to enhance the use of this research tool in the improved care of ESRD patients on maintenance HD. Such surveys must be avoided within 30 days of acute illnesses and hospitalizations.

TH-PO652

Usefulness of Assessing Dialysis-Related Symptom by Serum Level of β2-Microglobulin as a New Surrogate Marker Evaluating the Quality of Life among Dialysis Patients Atsuhiro Kanno, Ikuto Masakane, Satoko Ito, Minoru Ito, Kiyotaka Yabuki. *Yabuki Hospital.*

Background: The level of β2-microglobulin [β2-M] is strongly associated with the presence of carpal tunnel syndrome and dialysis-related amyloidosis in chronic dialysis patients. However, it is not fully clarified whether serum level of β2-M is related to the presence of other common problems among dialysis patients, though history of dialsis is not necessarily a long-term.

Methods: A total of 342 patients performed with chronic maintenance hemodialysis [HD] or hemodiafiltration [HDF] in our three facilities were participated and they were evaluated by the self-rating scored questionnaire based on fifth graded face scales from 0 (none) to 4 (very strong) according to the severity of symptoms. They include 20 physical and psychological common dialysis-related symptoms. Odds ratio for each of moderate to severe (score = 2, 3, 4) or severe (score = 3, 4) levels of these complaints were calculated using a multiple logistic regression model adjusted for confounding factors including age, gender, years of dialysis, history of diabetes mellitus, Kt/V, normalized protein catabolic rate, body mass index, predialytic values of hemoglobin, albumin, β2-M, sodium, potassium, phosphate.

Results: Among participants, 146 (42.7%) patients were treated with HDF and the overall mean values were 66.7 years for age and 19.3% of participants had a history of dialysis for more than 10 years (median 5.4 years). There was a significant relationship between β2-M and moderate to severe lethargy (odds ratio [OR] 1.02, P =0.024), loss of interest (OR 1.05, P =0.0028), reduction of blood pressure during dialysis (OR 1.06, P =0.0056) and a sense of thirst (OR 1.06, P =0.0028).

Conclusions: In our study, it was shown that predialytic serum level of β2-M was significantly associated with various dialysis-related symptoms. There is a possibility that β2-M would be a useful clue for the presence of common complaints, though history of dialysis was not necessarily a long-term. It is considered to be verified that an effort to diminish the level of β2-M, as a surrogate marker evaluating the quality of life, would contribute to relieve these symptoms.

TH-PO653

Frailty Is Associated with Earlier Dialysis Initiation in End-Stage Renal Disease Yeran Bao,[1] Lorien S. Dalrymple,[2] Glenn M. Chertow,[3] George A. Kaysen,[2] Kirsten L. Johansen.[1] *[1]Medicine, UCSF, San Francisco, CA; [2]Medicine, UC Davis, Davis, CA; [3]Medicine, Stanford University, Palo Alto, CA.*

Background: Over the last decade, patients have been started on dialysis at progressively higher levels of residual kidney function (early start). Some have suggested higher mortality with early start, while others argue that this could reflect a tendency for sicker patients to start early. We hypothesized that frailty, a predictor of adverse outcomes in end-stage renal disease (ESRD), is associated with dialysis initiation at a higher level of kidney function.

Methods: We undertook a cross-sectional study using data from the Comprehensive Dialysis Study (CDS), a United States Renal Data System (USRDS) special study. We examined the baseline prevalence of frailty, its associated clinical characteristics, and its relationship with early start of dialysis. Frailty was defined using a modification of Fried's criteria. Early start was defined as starting dialysis at an estimated glomerular filtration rate (eGFR)>10 ml/min/1.73 m^2. We used multivariate logistic regression to model the relationship between clinical characteristics and frailty and the association between frailty and early start.

Results: Among a total of 1,576 CDS participants included in the study, the prevalence of frailty was 73.3%. Female gender, being on Medicaid, higher disease burden, and higher eGFR were associated with higher odds of frailty. Each 1 ml/min/1.73m^2 increase in eGFR at dialysis initiation was associated with an 8% higher odds of being frail (OR 1.08, 95% CI 1.05-1.11, p<0.001). When the association between frailty and early start was examined, frail patients were nearly twice as likely to start dialysis at an eGFR>10 ml/min/1.73 m^2 (OR 1.91, 95% CI 1.50-2.44, p<0.001) after adjusting for age, gender, race, Medicaid status, tobacco use, serum albumin, serum hemoglobin, early nephrology referral, erythropoietin use and disease burden.

Conclusions: In light of the recent trend of early start and the lack of evidence to support it, our study highlights that frailty may be an important clinical measure as we assess the timing and effectiveness of renal replacement therapy.

TH-PO654

HIV Infection in ESRD (1995-2007): As Incidence Falls, Prevalence Rises Paul L. Kimmel, Dmitry Vishniakov, Paul W. Eggers. *NIDDK, NIH, Bethesda, MD.*

Background: Access to highly active antiretroviral therapy (HAART) since 1996 has changed HIV infection from a fatal to a chronic illness. Previous ESRD hemodialysis patient studies showed incidence rates plateaued in the 1990's. We report updated trends in incidence, hospitalizations and prevalence of ESRD HD HIV infection.

Methods: A retrospective cohort study of HIV infected ESRD patients was performed, using the CMS Medical Evidence Form where HIV was listed as a primary cause of ESRD and/or Medicare billing data where ESRD HD patients had at least 1 hospitalization or 2 outpatient encounters with an HIV/AIDS diagnosis.

Results: The number of incident cases of ESRD HD HIV infection was relatively stable (mean 816±45 per year), but the incidence rate decreased from 3.0 (1995) to 2.7 per million US population (2007), and from 1.14 to 0.67% of incident ESRD patients (1995 to 2007). Mean incident age increased from 39.0±0.3 to 44.7±0.4 y, black patients decreased from 90.4 to 86.2%, and women increased from 25.3 to 36.0% of the incident population. Median survival tripled from 0.9 (1995) to 2.72 y (2005). In contrast, prevalent HIV ESRD increased linearly from 1,971 to 6,741 cases. Prevalence rate increased from 7 to 12 HIV infected per 1000 ESRD patients from 1995 to 2007 respectively (0.3 to 0.6% of the ESRD HD population). The ESRD program hospitalization rate was 0.218 in 2007, while in HIV infected patients it was 22.4% higher (0.267). There was an approximately 2.5 fold increase in the number of hospitalizations for infection in HIV patients compared to uninfected patients, a disparity not seen in other diagnostic groups.

Conclusions: While the incidence of HIV infection has remained numerically stable, and has decreased in comparison to the increase in the total ESRD incident population, this does not explain the program prevalence of HIV infection. Survival has increased dramatically, leading to doubling in the albeit low prevalence of HIV infection in the ESRD population over the past decade. While access to HAART in the US has resulted in a decrease in incidence, the number and age of HIV infected patients has grown as patient survival improves. HIV infection in HD patients will remain a concern for the foreseeable future.

Risk of Infection-Related Hospitalizations by Dialysis Modality: A Propensity-Score Matched Cohort Jean-Philippe Lafrance,[1,3] Elham Rahme,[2] Sameena Z. Iqbal,[2] Michel Vallee.[1,3] *[1]Université de Montréal, Canada; [2]McGill University, Canada; [3]Centre de Recherche Hôpital Maisonneuve-Rosemont, Canada.*

Background: Infection is the second leading cause of admission after cardiovascular disease among patients receiving maintenance dialysis. How peritoneal dialysis (PD) compare to hemodialysis (HD) in terms of overall infection-related hospitalization risk is not known.

Methods: We conducted a retrospective cohort study using a database linking administrative databases and a dialysis registry in Quebec, Canada, between January

2001 and December 2007. We included all incident adult patients with at least 90 days of dialysis. Patients with a pre-emptive kidney transplant were excluded. A propensity score for dialysis modality was estimated by multivariable logistic regression for each patient using demographics, body mass index, smoking, co-morbidities, and initial laboratory data. PD patients were 1:1 matched to HD patients by this propensity score. Risk of infection-related admissions was estimated using a counting-process survival model by Prentice, Williams and Peterson, which accounts for recurrent outcomes. Missing data was imputed using a multiple imputation technique.

Results: At 90 days after dialysis initiation, we identified 925 patients on PD and 4933 patients on HD. 1830 patients were matched (915 PD and 915 HD). All variables were well balanced in each group including: Mean age (PD: 58.7 vs HD: 58.4 years), male sex (PD: 58.8% vs HD: 59.5%), and diabetes (PD: 40.6% vs HD: 40.0%). During the study period, 338 patients were hospitalized once for an infection, 119 twice, and 101 at least three times. PD was associated with an increased risk of infection-related hospitalizations compared to HD (unadjusted hazard ratio: 1.65, 95% confidence interval: 1.43, 1.89).

Conclusions: PD patients are at higher risk of infection-related hospitalizations than HD patients. Better knowledge of epidemiology of infection-related hospitalizations may help to prevent this high-burden morbidity among chronic dialysis patients.

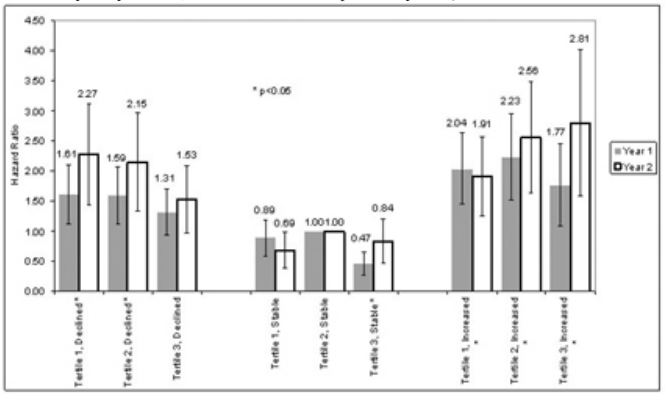
TH-PO656

Body Temperature in Hemodialysis (HD) Patients: A Novel Indicator of Patient Outcomes Len A. Usvyat,[1] Frank Van der Sande,[2] Jeroen Kooman,[2] Jochen G. Raimann,[1] Nathan W. Levin,[1] Peter Kotanko.[1] *[1]Renal Research Institute, NY, NY; [2]University of Maastricht Hospital, Netherlands.*

Background: Pre-HD body temperature (BT) is important routine indicator, however, only BT notably below or above normal range is usually considered relevant. Since little is known about the significance of BT changes over time in HD patients (pts), this study aimed to explore this area.

Methods: Data of all RRI HD pts beginning HD b-n Jan 1, 2000 and Feb 28, 2010 were analyzed. Pts' baseline pre-HD BT (BTBL) was computed as an average of the first 30 days on HD; the slope of BT change (BTSLOPE) was computed by linear regression using all BT in the 1st yr. Pts were stratified according to (a) BTBL tertile: <36.47, 36.47 to 36.71, >36.71 °C, and (b) BTSLOPE: increase: >0.01 °C/month, decrease: <-0.01 °C/month, and stable: BT between -0.01 and +0.01 °C/month. Cox proportional hazards models adjusted for demographics, labs, and multiple comorbids were constructed to assess the relationship b-n BT and BTSLOPE and survival in the 1st and 2nd year on HD.

Results: 7003 pts were studied (avg age 62.1 years; 57% males, 53% white). Cox analysis demonstrated that pts with stable BT have better outcomes, while patients with increasing BT have poorest outcomes in the first year of dialysis. Over all three BTBL tertiles, pts with stable BTSLOPE had the best outcomes (hazard ratios of 0.89, 1.00, and 0.47, respectively). The relationship between BTSLOPE and BTBL groups did not change materially in pts who survived to the second year on HD, using BTBL calculated in the first 30 days of year two, and BTSLOPE computed in year 2).



Conclusions: Increases and to a lesser extent decreases in BT from all BTBL levels are associated with a unfavorable effect on survival. Dynamics of BT in incident HD pts should receive attention as a novel potential indicator of outcomes in HD pts.

TH-PO657

Diabetic End Stage Renal Disease in the Indigenous Population of Guam Saied Safabakhsh, Andrew Charfauros, Joseph Chargualaf, Brittany L. Balajadia, Ali H. Ahangari. *Micronesian Institute for Disease Prevention & Research.*

Background: Diabetic Nephropathy is the most common cause of patients acquiring End Stage Renal Disease (ESRD) in the United States. The purpose of our study was to establish the frequency, familiar patterns, and common complications of diabetic ESRD patients in the indigenous (Chamorro and other Pacific Islanders) population of Guam.

Methods: This retrospective study was conducted at four Hemodialysis (HD) centers on Guam. Relevant information from their medical records were recorded and patients participated in a 5 minute questionnaire. Patients with incomplete data were removed from the study.

Results: The total number of subjects in all four HD centers was 410 and a total of 334 subjects were accounted for during finalization of data. 263 (79%) of all subjects were diabetic and 246 (74%) of all subjects were Pacific Islanders. Of the 246 Pacific Islanders, 208 (84%) were diabetic, 180 (87%) of the diabetic Pacific Islander subjects had a family history of diabetes, while 92 (44%) had a family history of kidney disease in their first degree relatives. 48 (75%) of the Pacific Islanders had peripheral vascular disease (PVD), 158 (68%) had retinopathy and 148 (66%) had coronary artery disease (CAD).

Conclusions: Diabetes is the number one cause of ESRD and has a strong familiar pattern among the indigenous population of Guam. Complication of diabetes including CAD, PVD and retinopathy are highly prevalent among Pacific Islanders in Guam. This may be due to late diagnosis, poor diabetic management and possibly genetic predispositions involved in this population.

TH-PO658

Hemoglobin A1C Levels among Diabetic ESRD Patients with Possible Relationship to a-Erythropoietin Therapy and Inflammation Saied Safabakhsh, Jamie Pangelinan, Josephine Meno, Brittany L. Balajadia, Ali H. Ahangari. *Micronesian Institute for Disease Prevention & Research.*

Background: The objective of this study was to determine if Erythropoietin (a-Erythropoietin) therapy and inflammation affected A1C levels among Diabetic End Stage Renal Disease (ESRD) patients.

Methods: All subjects with ESRD at the three free standing dialysis units on Guam, a U.S. territory in Micronesia, were identified. Data from their medical records were collected and patient questionnaires from all subjects were completed.

Results: Out of 410 total subjects on dialysis, 341 participated in the study. 267 (78%) is caused by diabetes, 43 (13%) is caused by hypertension, 16 (5%) by Glumerolonephritis, 12 (3%) were f other causes. The average A1C level among diabetic subjects was 7.0 (ranging from 2 to 12.7). The average random blood sugar on three different occasions was 189 g/dL (ranging from 60 to 637). Out of 341 subjects, 247 (72%) were on Erythropoietin Therapy (500-20,000 units/treatment). Out of 247, 159 were diabetic subjects. Out of 159 diabetic subjects, 101 (67%) had high Ferratin levels (greater than 500 units). The average Ferratin level was 831 units (ranging from 16 to 1,971). Computed analysis graphs showed that A1C levels did not correlate with average random blood glucose levels with respect to Erythropoietin dosage and inflammatory assays separately.

Conclusions: Our results indicate that A1C levels may be affected by Erythropoietin Therapy and acute or chronic inflammation (established by high Ferratin levels). A1C readings alone may not be a good method for the management of diabetic dialysis patients, nor is it a good indicator of true glucose control among patients who have inflammation or are on Erythropoietin Therapy. We recommend combination of A1C and random blood sugars for better management of diabetes for patients who are on dialysis. Clinicians who care for diabetic dialysis patients should take into consideration the evaluation of patients for Erythropoietin dosage and inflammatory assays for better and more accurate management of their diabetes.

Low Serum Bicarbonate Is Associated with an Increased Risk of Death in the US Population Kalani L. Raphael, Guo Wei, Tom H. Greene, Alfred K. Cheung, Srinivasan Beddhu. *Internal Medicine, University of Utah, Salt Lake City, UT.*

Background: Low serum bicarbonate levels are associated with a higher risk of CKD progression and death in people with CKD, however, the association between low serum bicarbonate levels and death in the general population is unknown.

Methods: Adult NHANES III participants were grouped into one of four serum bicarbonate categories according to the baseline value: ≤20, 21-25, 26-30, and >30mM. The hazard of death for each group, compared to the 26-30mM group, was determined after adjusting for age, gender, race, CKD, albuminuria, CHF, lung disease, and diuretic use.

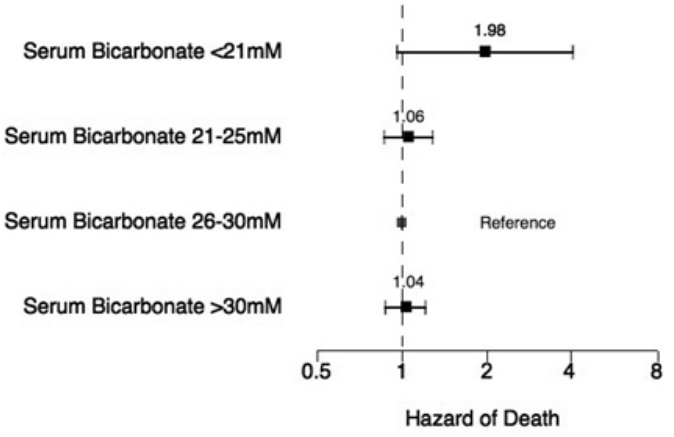
Results: Those with serum bicarbonate ≤20mM were more likely to be female, African-American, and have CHF, CKD, and higher albuminuria.

Characteristics of NHANES III participants by serum bicarbonate

Serum HCO3- (mM)	≤20 (0.7%)	21-25 (23.6%)	26-30 (52.2%)	>30 (23.5%)	p
Age(yrs)	44.7 (20.1)	42.0 (16.7)	45.2 (16.8)	46.6 (17.7)	<0.001
Men(%)	31.3 (21.0, 43.9)	36.9 (34.5, 39.3)	49.6 (47.9, 51.3)	55.4 (53.2, 57.6)	<0.001
African-American Race(%)	15.5 (9.2, 24.9)	12.3 (10.3, 14.6)	10.6 (9.3, 12.0)	9.4 (7.7, 11.5)	0.396
CKD(%)	17.0 (8.6, 30.8)	5.7 (4.6, 7.1)	5.5 (4.8, 6.3)	6.2 (5.4, 7.2)	0.004
Diuretic use(%)	8.5 (3.6, 19.0)	4.3 (3.3, 5.5)	7.2 (6.4, 8.1)	10.5 (9.0, 12.2)	<0.001
Albumin:Cr (mg/gm)	111.4 (690.7)	30.2 (217.3)	23.9 (171.1)	22.9 (172.0)	0.106

Percentages shown as percent (95% C.I.); Continuous measures shown as mean (standard deviation).

Compared to the reference group, those with serum bicarbonate ≤20mM had a two-fold increased hazard of death (HR 1.98, 95%CI 0.97-4.06), whereas no difference was detected in the 21-25mM and >30mM groups.



Conclusions: Serum bicarbonate levels ≤20mM appear to be associated with an increased risk of death in the general population even after adjusting for demographic factors, CKD and other possible confounders.

TH-PO660

Time-Dependent Effects of Dietary Sodium Bicarbonate on Renal Disease Progression in 5/6 Nephrectomized Rats Sejoong Kim,[1] Nam Ju Heo,[2] Yun Kyu Oh,[2] Ki Young Na,[2] Kwon Wook Joo,[2] Jin Suk Han.[2] *[1]Internal Medicine, Gachon University of Medicine and Science, Korea; [2]Internal Medicine, Seoul National University College of Medicine, Korea.*

Background: Sodium bicarbonate therapy ameliorated metabolic acidosis (MA) and the decrease in glomerular filtration rate (GFR) only after the control of blood pressure (BP) in 5/6 nephrectomized rats with casein diet. Recent clinical trials, however, showed beneficial effect of sodium bicarbonate in patients with early and late stage chronic kidney disease. We evaluated time-dependent beneficial effect of sodium bicarbonate to prevent the decline in GFR and correct MA in rats with a remnant kidney.

Methods: Sprague-Dawley rats ate dietary sodium bicarbonate (NaHCO3) or sodium chloride (NaCl) with 20% casein without any antihypertensive medication for 12 weeks after 5/6 nephrectomy.

Results: After treating casein diet, alkali-treated group had higher levels of serum bicarbonate than control group (20.3 ± 0.55 vs. 15.6 ± 0.61 mmol/L at week 4, 25.0 ± 1.73 vs. 13.1 ± 1.29 mmol/L at week 10, and 31.3 ± 3.38 vs. 17.0 ± 0.93 mmol/L at week 12). After week 4, systolic blood pressure in the two groups was over 160 mm Hg, and there was no difference between the groups. At week 4, glomerular filtration rate (GFR) in NaHCO3 group was higher than in NaCl group (0.36 ± 0.09 vs. 0.15 ± 0.01 mL/min/100g BW, p=0.011). After week 10, there were no differences in GFR between the two groups (0.14 ± 0.03 vs. 0.15 ± 0.04 mL/min/100g BW at week 10, and 0.07 ± 0.03 vs. 0.07 ± 0.01 mL/min/100g BW at week 12). At week 4 and week 10, glomerulosclerosis (GS) and tubulointerstitial damage indices (TI) in NaHCO3 group were less severe than in controls. In contrast, at week 12, GS in the alkali-treated group was more profound than in control group, and there was no difference in TI damage between the two groups.

Conclusions: Dietary sodium bicarbonate had short-term beneficial effects in ameliorating metabolic acidosis and preventing the decrease in GFR without correction of blood pressure. However, these effects did not sustain after 10 weeks.

Dietary Determinants of Urinary Citrate Excretion Ernest I. Mandel,[1,2] Eric N. Taylor,[2,3] Gary C. Curhan.[1,2] *[1]Renal Division, Department of Medicine, Brigham and Women's Hospital, Boston, MA; [2]Channing Laboratory, Department of Medicine, Brigham and Women's Hospital, Boston, MA; [3]Division of Nephrology and Transplantation, Maine Medical Center, Portland, ME.*

Background: General strategies for prevention of kidney stones include restricting animal protein intake and increasing fruit and vegetable intake. While these strategies may increase citrate excretion by altering dietary acid-base balance, the independent dietary predictors of urinary citrate excretion have not yet been explored.

Methods: We conducted a cross-sectional study within a sub-cohort of 2612 individuals from the Health Professionals Follow-up Study (older men), Nurses' Health Study I (older women), and Nurses' Health Study II (younger women) who provided two 24-hour urine collections for previous studies of nephrolithiasis. Dietary data were ascertained from the 131-item Willett food frequency questionnaire. Lifestyle and clinical data were culled from responses to biennial questionnaires. Multivariable linear regression was used to quantify the predictors of urinary citrate excretion.

Results: After adjusting for dietary, lifestyle, and clinical factors, those in the highest quintile of non-dairy animal protein intake had urinary citrate excretion 148 mg/d (95% confidence interval, 70.9, 224.5), 76 mg/d (12.3, 139.0), and 57 mg/d (8.3, 122.3) lower than those in the lowest quintile for older men, older women, and younger women respectively. Conversely, those in the highest quintile of dietary potassium intake had citrate excretion 155 mg/d (79.3, 231.4), 121 mg/d (51.7, 189.3), and 56 mg/d (-16.4, 127.7) higher than those in the lowest quintile. Among older men, those with daily vitamin C intake of 1000 mg/d or more had citrate excretion 146 mg/d (47.7, 244.4) lower than those consuming less than 90 mg/d. Both dairy protein intake and urinary sodium excretion, as a marker of sodium intake, were associated with higher citrate excretion.

Conclusions: In addition to non-dairy animal protein and potassium intake, dietary intakes of vitamin C, dairy protein, and sodium are significant independent predictors of urinary citrate excretion in certain populations.

Alkali Therapy from Prenatal Period Is Superior to Postnatal Alkalization in NBC1 W516X Knock-In Mice Featuring Severe Metabolic Acidosis and Early Lethality Yu-Wei Fang,[1,2] Sung-Sen Yang,[3] Min-Hua Tseng,[1] Shih-Hua P. Lin.[1,3] *[1]Graduate Institute of Medical Science, National Defense Medical Center, Taipei, Taiwan; [2]Division of Nephrology, Department of Medicine, Shin-Kong Wu Ho-Su Memorial Hospital, Taipei, Taiwan; [3]Division of Nephrology, Department of Medicine, Tri-Service General Hospital, Taipei, Taiwan.*

Background: We have created the Na^+/HCO_3^- cotransporter 1(NBC1)W516X knock-in mice as model of isolated proximal renal tubular acidosis(KI 2011). These mice had early lethality associated with severe metabolic acidosis and may be used for evaluating the deleterious effects of metabolic acidosis on cell and organ dysfunction.

Methods: $NBC1^{W516X/W516X}$ mice were divided into 3 groups: (1) non-alkali treatment controls, (2) prenatal alkalization since post-coitus by feeding with 280 mM sodium bicarbonate ($NaHCO_3$) in drinking water and 7.5% $NaHCO_3$ 100 µl/7g intraperitoneally since day 6 after birth(PreTx) and (3) The same alkalization since day 6 after birth(PostTx). Blood acid-base status, renal function, organ abnormalities, and survival rate were assessed.

Results: $NBC1^{W516X/W516X}$ mice with severe metabolic acidosis and associated anemia, volume depletion, prerenal azotemia, several organ abnormalities (kidney atrophy, splenomegaly, reduced bone density) exhibited early lethality before weaning (21 days). Both Pre-Tx and Post-Tx alkali administration in NBC1W516X/W516X mice markedly prolonged the survival well beyond weaning, dramatically decreased protein catabolism, and attenuated several organ abnormalities. Pre-Tx group achieved a significantly higher bicarbonate (15.5±1.4 mmol/l in Pre-Tx, n=7 v.s 7.3±1.7 mmol/l in Post-Tx, n=12, $p<0.05$) and pH (7.29±0.03 in Pre-Tx, n=7 v.s 7.14±0.05 in Post-Tx, n=12, $p<0.05$) accompanied by a significantly less splenomegaly and higher body weight than Post-Tx group. On day 60 after birth, the survival rate was significantly higher in Pre-Tx than Post-Tx group (57 % vs 33%, $P<0.05$).

Conclusions: Alkali Therapy from prenatal period is superior to postnatal alkalization in treatment of severe metabolic acidosis in $NBC1^{W516X/W516X}$ mice. Prenatal alkali therapy can also apply to some inherited diseases featuring metabolic acidosis before birth.

TH-PO663

Deletion of Glutamine/Neutral Amino Acid Transporter ASCT2 (ATB0) Does Not Alter Acid-Base Regulation under Baseline Condition or in Response to Acid Loading Faraaz Siddiqui, Manoocher Soleimani, Hassane Amlal. *Internal Medicine, University of Cincinnati, OH.*

Background: Glutamine metabolism through ammoniagenesis plays an important role in the regulation of acid-base homeostasis. Several glutamine/neutral amino acid transporters are expressed in the proximal tubule cells but their role in glutamine transport is not well understood. An amino acid transport system ASCT2 (ATB0) is reported to transport glutamine and is expressed in the brush border membranes (BBM) of kidney proximal tubule and large intestine, however, its role in glutamine metbolism and acid excretion is unknown.

Methods: To understand the role of ASCT2 in glutamine metabolism and acid excretion, mice with genetic deletion of ASCT2 (KO) were generate. KO and wild-type(WT) mice were placed in metabolic cages and subjected to 280 mM NH4Cl loding for 6 days to indcue metabolic acidosis.

Results: he ASCT2 mutant mice (KO) showed complete absence of ASCT2 expression in both kidney and colon. They are fertile, have normal growth and did not exhibit any acid-base abnormalities at steady-state. urinary NH4+ excretion increased from 67 to 753 µmole/day in KO and from 62 to 751 µmole/day in WT mice after 6 days of acid loading, indicating that the capacity of KO mice to excrete daily acid load is not hampered by the deletion of ASCT2. In the cortex of acid-loaded animals, the expression of apical glutamine transporter BoAT1 was not altered in KO vs. WT mice, whereas the expression of BBM gamma glutamyl transferase (GGT), which converts glutamine to glutamate, was significantly increased (+38%, $P<0.02$) in KO vs. WT mice. Interestingly, the expression of basolateral glutamine transporter SN1 was reduced by 46% ($P<0.002$) in KO vs. WT animals.

Conclusions: These studies indicate that the deletion of ASCT2 results in compensatory activation of other mechanisms including GGT, which lead to increased ammoniagenesis and enhanced daily net acid excretion in response to acid loading.

Funding: Clinical Revenue Support

TH-PO664

Angiotensin II-Stimulated Ammonia Production in Cultured Mouse Proximal Tubule Cells Is Modulated by Type 2 Angiotensin II Receptors: Effect of pH Glenn T. Nagami, Alexandria K. Plumer, Evelyn M. Warech. *Nephrology Section, Dept of Medicine, VA Greater Los Angeles Healthcare System & UCLA, Los Angeles, CA.*

Background: We previously found that type 2 angiotensin II (Ang II) receptors (AT2Rs) reduced Ang II-stimulated total ammonia production (TAP) in proximal tubule segments from non-acid loaded control mice but not in segments from 18-h acid-loaded mice and that the greater modulating effect was associated with higher brush border membrane AT2R levels. The purpose of this study was to examine the effects of pre-exposure of cultured S1 proximal tubule cells (derived from an SV40 large T antigen mouse) to normal (7.4) or low (7.0) pH on: a) Ang II-stimulated TAP in the presence or absence of the AT2R antagonist PD123319 (PD) and b) AT2R cell surface expression levels.

Methods: S1 proximal tubule cells were grown to confluence in DMEM: Hams F12 media with 7% fetal bovine serum maintained in 35% O_2 and 5% CO_2. The growth medium was changed to serum-free medium (overnight) and then changed to pH 7.4 or 7.0 medium for specified periods. TAP was measured in the medium using an enzymatic ammonia assay. Cell surface proteins were biotinylated and isolated with streptavidin beads. AT2Rs were detected by immunoblot analysis.

Results: After exposure to pH 7.4, cells acutely treated with Ang II (10^{-9}M) + PD (10^{-6}M) displayed higher TAP compared to cells treated with Ang II alone (7.9±0.2 vs 7.0±0.2 nmol/min/mg prot, N=6, $p<0.05$). After exposure to pH 7.0 for 2h, cells treated with Ang II+PD displayed TAP that was similar to cells exposed to Ang II alone (8.9±0.3 vs 8.7±0.2, N=6, n.s). AT2R cell surface protein expression was 2.2±0.3-fold higher in cells pre-incubated for 2 h at pH 7.4 vs cells incubated at pH 7.0 ($p<0.05$, N=5). The reduction in expression levels with low pH was blocked by colchicine.

Conclusions: Although we previously reported that low pH enhanced the stimulatory effect of Ang II on TAP in proximal tubule cells by increasing AT1R expression, the present results suggest that Ang II-stimulated TAP can be inhibited by AT2R activation and that the colchicine-sensitive reduction in AT2R expression with low pH may also contribute to the enhanced stimulatory effect of Ang II on TAP.

TH-PO665

Rescuing Kidney Anion Exchanger I Trafficking Mutants Emmanuelle Cordat, Carmen Chu, R. Todd Alexander. *Physiology, University of Alberta, Edmonton, AB, Canada.*

Background: The anion exchanger I (AEI) is a membrane glycoprotein that exchanges chloride for bicarbonate. It is found in erythrocytes (eAEI), and in the basolateral membrane of alpha intercalated cells (kAEI). Mutations in the gene encoding the anion exchanger 1 can cause hereditary spherocytosis and/or distal renal tubular acidosis (dRTA). Some dRTA mutants, although functional in red blood cells or when expressed in Xenopus oocytes, are retained intracellularly in tubular epithelial cells. We investigated whether these mutants can be rescued to the cell surface, where they may be functional.

Methods: We tested chemical treatments and lower temperature incubations on two recessive dRTA mutations, G701D and C479W, and a dominant mutation, R589H, of kAEI. We examined the folding, stability, and degradation of wildtype (WT) and rescued trafficking kAE1 mutants.

Results: Our experiments showed that glycerol and DMSO can rescue the trafficking of kAEI mutants G701D and R589H, but not C479W. Incubation at 30C restored trafficking of G701D but not of R589H. Functional studies revealed increased ion exchange activity in some of the rescued G701D and R589H mutants compared to non-treated conditions, although activity remained compromised compared to WT levels. Interestingly, rescued mutant kAE1 proteins are degraded more rapidly than WT kAE1, which could be explained by a limited improvement in the folding of treated mutant kAE1. All three mutant kAE1 proteins are slightly stabilized by proteasome inhibitors but inhibition of the lysosome appears to completely stabilize the G701D mutant, suggesting that G701D is degraded via the proteasomal and lysosomal pathways. Since G701D kAE1 can reach the Golgi even in untreated cells, we hypothesize that in the presence of a lysosomal inhibitor, G701D traffics to the plasma membrane but is endocytosed and degraded more rapidly than WT kAE1.

Conclusions: Our experiments suggest that some trafficking dRTA mutants can be rescued, thus opening the door to alternative treatments for dRTA patients.

The Cytosolic Mutant L522P of NBCe1 Has a Dominant Negative Effec Osamu Yamazaki, Hideomi Yamada, Masashi Suzuki, Shoko Horita, Motonobu Nakamura, George Seki, Toshiro Fujita. *Internal Medicine, Tokyo University, Tokyo, Japan.*

Background: Homozygous mutations in the electrogenic Na-HCO3 cotransporter NBCe1 cause proximal renal tubular acidosis (pRTA) and ocular abnormalities. The defective membrane expression of NBCe1 causes familial migraine (PNAS 107,15963,2010). While the homozygous Δ65bp mutation causes pRTA, the full-brown ocular abnormalities, and hemiplegic migraine, the heterozygous Δ65bp mutation, which forms hetero-oligomer complexes with WT, causes glaucoma and migraine through a dominant negative effect. In this study, we examined whether the L522P mutant of NBCe1, associating with pRTA and hemiplegic migraine, has a similar dominant negative effect.

Methods: Two-electrodes voltage-clamp method in *Xenopus* oocytes and cell pH measurement in HEK293 cells were used to determine the NBCe1 activity.

Results: L522P alone had no electrogenic activity, but decreased the NBCe1 current by 67% when co-expressed with WT in *Xenopus* oocytes. In HEK293 cells, L522P was predominantly expressed in cytoplasmic regions. When co-expressed with WT, L522P and WT showed cytoplasmic overlapping with the diminished membrane expression of WT. Functional analysis confirmed that L522P alone showed no transport activity, but significantly reduced the net NBCe1 activity by 49% when co-expressed with WT. Co-immunoprecipitation analysis using myc- and GFP-tagged constructs confirmed the association between WT and L522P. To examine the role of L522 in more details, we also examined the properties of artificial mutants L522I and L522R in HEK293 cells. L522I was properly expressed in the plasma membrane, showing the transport activity comparable to WT. By contrast, L522R was predominantly expressed in cytoplasmic regions, showing no transport activity. While the co-expression of L522I with WT increased the net NBCe1 activity compared with WT alone, the co-expression of L522R with WT significantly reduced the net NBCe1 activity by42%.

Conclusions: These results indicate that the introduction of either a large structural change (L522P) or a positive charge (L522R) in the critical amino acid L522 impaired the proper trafficking of NBCe1, resulting in the acquirement of dominant negative effect.

TH-PO667

The N-Terminus of NBCe1-A-TM1 Tightly Interacts with the Cytoplasmic Domain Quansheng Zhu, Rustam Azimov, Liyo Kao, Debra Newman, Weixin Liu, Ira Kurtz. *Department of Medicine, UCLA.*

Background: NBCe1-A is expressed on the basolateral membrane of the renal proximal tubule where it plays a critical role in bicarbonate reabsorption. The transporter consists of 1035 amino acids and spans the lipid bilayer 14 times. We have recently determined that the transmembrane segment 1 (TM1) is involved in forming part of the NBCe1-A substrate translocation pathway; however, the actual size of TM1 in the lipid bilayer has remained elusive. The importance of TM1 in NBCe1-A is also exemplified by a TM1-S427L mutation that causes proximal RTA. NBCe1-A-TM1 was previously assumed to have a similar length to that of AE1-TM1 based on the sequence homology, where the N-terminus is connected to the cytoplasmic domain with a highly flexible loop. In this study, we analyzed the folding of the N-terminal cytoplasmic region (Cys389 - Gln424) of NBCe1-A-TM1 using the substituted cysteine accessibility method combined with extensive chemical stripping and functional transport assays. Our findings have uncovered that NBCe1-A-TM1 is structurally unique: 1) TM1 contains 33 residues that starts at amino acid Ala410; 2) the region of Arg394 - Leu406 is inaccessible to aqueous media even after 3 M sodium carbonate stripping; 3) the region prior to Arg394 is increasingly accessible to the aqueous media; 4) substitution of any of the three charged residues, Asp405, Lys409 or Asp416 impairs NBCe1-A membrane processing; 5) surprisingly, cysteine substitution of residues in the Cys389 - Gln424 region affects transporter function only minimally. On the basis of the results, we conclude that the NBCe1-A-TM1 is significantly longer than AE1-TM1 and interacts with the cytoplasmic domain tightly.

TM 5 and 6 Play an Essential Role in Forming the NBCe1-A Dimer Interface Quansheng Zhu, Liyo Kao, Debra Newman, Weixin Liu, Ira Kurtz. *Department of Medicine, UCLA.*

Background: The basolateral electrogenic sodium bicarbonate cotransporter NBCe1-A mediates the absorption of the filtered bicarbonate load in the proximal tubule. We previously determined that NBCe1-A consists of 14 transmembrane (TM) helices and exists as a dimer in the lipid bilayer. The molecular mechanism underlying the formation of the NBCe1-A dimeric interface is currently unknown. To address this question we performed substituted cysteine scanning mutagenesis coupled with disulfide cross-linking studies on NBCe1-A dimers expressed in HEK-293 cells. The results show that: 1) individual cysteine substituted amino acids at the beginning (Tyr567-Ser582) and the end (Gln643-Asp647) of extracellular loops 3 are self cross-linked to form NBCe1-A dimers in the plasma membrane; 2) the cross-linked dimers are sensitive to DTT treatment indicating disulfide bond formation; 3) NBCe1-A dimers are resistant to NEM pre-treatment suggesting the cross-linking is formed during protein synthesis. Biotin maleimide labeling analysis revealed that the extracellular aqueous/lipid interface of TM 5 is at amino acid Tyr566 and TM 6 is at Ile648, indicating that extracellular loop 3 consists of 82 amino acids. Our experiments have demonstrated for the first time that the NBCe1-A dimeric interface is formed by the self-association of TM 5 of each monomer and the self-association of TM 6 of each monomer.

Interplay between Glycosylation and Disulfide Bonding Defines NBCe1-A Extracellular Topography Quansheng Zhu, Liyo Kao, Rustam Azimov, Debra Newman, Weixin Liu, Ira Kurtz. *Department of Medicine, UCLA.*

Background: A common feature among sodium-driven bicarbonate transporters within the SLC4 family is the presence of four cysteines (Cys) in the glycosylated extracellular loop 3 (EC-loop 3). We recently showed that EC-loop 3 is the largest highly exposed surface loop in NBCe1-A and interestingly, resides at the dimer interface. In the present study, we determined the significance of the unique pattern of disulfide bond formation

among the four Cys in the NBCe1-A EC-loop 3. NBCe1-A constructs carrying one to four Cys residues in various combinations in EC-loop 3 were expressed in HEK-293 cells and subjected to an SDS-PAGE gel shift assay, chemical stripping, DTT treatment and chemical probing analysis. The function of each construct was analyzed in the HEK-293 cells. Our results show that: 1) the four cys in EC-loop 3 are in a folded conformation and intra-disulfided; 2) cys 1, 2 and cys 3, 4 form two intra-monomeric disulfide bonds; 3) the first disulfide bond determines the number of glycosylation sites in the loop, and glycosylation guides the disulfide bond formation between cys 3 and 4; 4) in the absence of the four cys residues, NBCe1-A traffics normally to the plasma membrane, however, each monomer becomes triply glycosylated and most of the introduced cys in loop 3 become self cross-linked. The findings indicate that EC-loop 3 in NBCe1-A is highly structured. We predict that the two loops from each of the NBCe1-A monomers interact to form a domain-like structure on the surface of the transporter resembling receptors such as G-protein coupled receptors.

Towards the High-Resolution Structure of hhNBCn1 Natalia Abuladze, Nathaniel Magilnick, Kirill Tsirulnikov, Alexander Pushkin. *Medicine, UCLA, Los Angeles, CA.*

Background: Integral membrane proteins account for ~30% of all proteins, and human membrane proteins are the targets for ~50% of therapeutic drugs. Despite these facts, high resolution three-dimensional (3D) structures of less than 300 unique membrane proteins have been solved at atomic resolution mostly by X-ray crystallography, of which eukaryotic membrane proteins account for less than 10%. Recent advances of cryo-electron microscopy (cryoEM) and single-particle reconstruction have solved the structures of macromolecular complexes at ~4Å providing a new tool that may be used for structural studies of eukaryotic membrane proteins.

Methods: We are using cryoEM for structural study of the human heart electroneutral sodium bicarbonate cotransporter NBC3 (hhNBCn1) that plays an important role in the intracellular pH and sodium regulation. hhNBCn1 fused at the N-terminus with the 6His tag was expressed in Sf9 cells, solubilized in 50 mM Tris-HCl, pH 8.0, containing dodecyl maltoside (DDM), Roche complete protease inhibitor cocktail and pepstatin, and purified in the presence of 0.03% DDM on DEAE-cellulose DE-52 (Whatman) and Ni-IMAC FF (GE HealthCare).

Results: Purified hhNBCn1 was homogeneous by SDS-PAGE and immunoblotting but a mixture of different oligomeric forms was present. hhNBCn1 dimers were further purified by size-exclusion chromatography on Sephacryl S-300 (GE HealthCare). As a preliminary step of structural characterization, hhNBCn1 dimers were negatively stained with 0.5% uranyl acetate and imaged on a FEI Tecnai F20 electron microscope operated at 200 kV and a magnification 50,000X. Analysis of images suggested that the hhNBCn1 dimer consists of a larger and a smaller domain. 3D reconstruction from ~5,000 randomly selected dimer particle images agreed with the proposed 2-doman model but suggested that particles of more than one conformation are present. To separate hhNBCn1 dimers with different conformations, we performed hhNBCn1 crystallization assuming that a certain crystal contains structurally uniform particles. Several similar shape hhNBCn1 microcrystals (<2 μ) were obtained in the presence of MPD. They will be solubilized and used for cryoEM and 3D reconstruction. Supported by AHA.

Structural Study of AE1 Chloride-Bicarbonate Exchanger Kirill Tsirulnikov, Nathaniel Magilnick, Natalia Abuladze, Alexander Pushkin, Ira Kurtz. *Department of Medicine, UCLA.*

Background: In erythrocytes and the collecting duct, AE1 (SLC4A1) mediates 2 major functions: 1) Cl^-/HCO_3^- exchange, and 2) support of the structural integrity of erythrocytes via interaction with cytoskeletal proteins. AE1 (~100 kDa) consists of a ~55 kDa membrane domain responsible for anion-exchange, and a cytoplasmic domain, which functions as an anchoring site for membrane-associated proteins. We have recently generated a 3D model of full-length AE1 using electron tomography of negatively stained AE1 dimers purified from bovine erythrocytes. In the present study the model was refined using single particle 3D reconstruction. Approximately 1,000 images of AE1 dimers negatively stained with uranyl formate were recorded on a FEI Tecnai F20 electron microscope operated at 200 kV and 50,000 magnification with 4kX4k CCD camera. 330,000 particles were automatically picked using Batchboxer (EMAN). 33,000 particles were randomly selected from this data set and used for 3D reconstruction and structure refinement using EMAN. To avoid a model-bias problem in the structure refinement, we used both a ball and a rod as starting models. The independent 3D reconstructions gradually converged into a single model, suggesting that a correct model was generated. The model has a shape like a bottle gourd of 16 nm consisting of larger and smaller domains connected with two narrow pillar-like regions. The reported X-ray structure of the recombinant dimeric cytoplasmic domain of AE1 fits well the smaller domain in our model. Different groups of AE1 dimers were identified that varied only in the size and shape of the connector region between the domains. This flexibility of the connector region accounted for the different orientations of the cytoplasmic domain relative to the membrane domain. We propose that the connector is an important region in AE1 required for the flexibility of the erythrocyte membrane. It is possible that the residues in AE1 deleted in patients with South East Asian Ovalocytosis belong to the connector region, providing a potential explanation for the increased erythrocyte rigidity in this disorder.

CO_2/NH_3 Selectivities and Inhibitor Sensitivities of Mammalian Aquaporins Raif Musa-Aziz,[1,2] R. Ryan Geyer,[1] Xue Qin,[1] Walter F. Boron.[1] *[1]Physiol and Biophys, Case Western Reserve University, Cleveland; [2]Physiol & Biophys, University of Sao Paulo, Brazil.*

Background: The 13 mammalian aquaporins (AQP0-12) have diverse localization patterns and can be divided into 2 major families: orthodox AQPs and aquaglyceroporins. Previously we expressed mammalian AQP1, AQP4-M23 and AQP5 in *Xenopus* oocytes and used video microscopy to compute osmotic water permeability (P_f), and used microelectrodes to record the transient rise in surface pH (ΔpH_S) caused by CO_2 or NH_3 influx. Subtracting the respective values for day-matched, H_2O-injected control oocytes yielded the channel-specific values P_f* and ΔpH_S* (semiquantitative index of gas permeability). We had found that AQP1, 4-M23, and 5 each has a characteristic CO_2/NH_3 and CO_2/H_2O permeability ratio. Also, we had shown that pCMBS (blocks 4 H_2O pores) reduces AQP1's $(\Delta pH_S^*)_{NH3}$ by ~100% and reduces $(\Delta pH_S^*)_{CO2}$ by ~40%. DIDS (does not block H_2O pores) has no effect on $(\Delta pH_S^*)_{NH3}$, but reduces $(\Delta pH_S^*)_{CO2}$ by ~60%.

Methods: Here, we extend our study to determine if other AQPs (0-9) exhibit CO_2/NH_3 selectivity, and use inhibitors to explore the CO_2 and NH_3 pathways through AQP6 and AQP9.

Results: $(\Delta pH_S^*)_{CO2}$ differed significantly from 0 for AQP0, AQP1, AQP4-M23, AQP5, AQP6, and AQP9. $(\Delta pH_S^*)_{NH3}$ differed significantly from 0 for AQP1, AQP3, AQP6, AQP7, AQP8, and AQP9. P_f* differed significantly from 0 for all AQPs tested except AQP6. The ratio $(\Delta pH_S^*)_{CO2}/P_f$* fell in the sequence AQP6 (∞)>AQP5>AQP4-M23>AQP1≅AQP9>AQP0. The ratio $(\Delta pH_S^*)_{CO2}/(-\Delta pH_S^*)_{NH3}$ fell in the sequence AQP4-M23 (∞)=AQP5>AQP6>AQP1>AQP9>AQP4-M1≅AQP2=0. Additionally, for AQP6, pCMBS (1 mM) increased P_f* by 70%, but has no effect on $(DpH_S^*)_{NH3}$ or $(\Delta pH_S^*)_{CO2}$. DIDS (100 mM) has no effect on P_f* or $(\Delta pH_S^*)_{NH3}$, but reduces $(\Delta pH_S^*)_{CO2}$ by 50%. For AQP9, pCMBS reduces P_f* by 60%, $(-\Delta pH_S^*)_{NH3}$ by 100%, and $(\Delta pH_S^*)_{CO2}$ by 50%. DIDS has no effect on P_f* or $(\Delta pH_S^*)_{NH3}$, but reduces $(\Delta pH_S^*)_{CO2}$ by 50%.

Conclusions: In summary, we show that mammalian AQPs exhibit a diverse range of selectivities for CO_2 *vs* NH_3 *vs* H_2O. Also, with AQP9—as with AQP1—H_2O, NH_3, and 50% of CO_2 move through monomeric (pCMBS-sensitive) H_2O pores, whereas 50% of CO_2 takes another (DIDS-sensitive) pathway that is still unidentified.

Anion Exchanger 4 Expression in β-Intercalated Cells Is Characterized by a Unique Subapical:Lateral Pattern and Regulated by Acid:Base Status Jeffrey M. Purkerson, George J. Schwartz. *Pediatrics, University of Rochester Medical Center, NY.*

Background: Adaptation of the rabbit CCD to acidosis is characterized by a reduction in HCO_3 secretion by β-intercalated cells (β-ICs), due in part to down-regulation of apical $Cl:HCO_3$ exchanger (pendrin) activity. Here, we examined expression of AE4 in the CCD to better understand the function of another anion exchanger that may contribute to HCO_3 transport in the collecting duct.

Methods: Immunofluorescence staining of kidney sections showed co-labeling of PNA (peanut agglutinin), and AE4+ cells and failed to demonstrate co-expression of AE4 and AE1 indicating that AE4 is expressed in β-ICs. We performed 3D-reconstructions of images obtained via confocal microscopy of microdissected CCDs and RT-qPCR of kidney cortex.

Results: 3D reconstructions showed that AE4 expression in β-ICs occurs in a hollow barrel-like pattern located underneath the apical PNA cap.

AE4 was localized below the tight junction as defined by ZO-1 staining.We examined regulation of AE4 by acid/base status in normal (urine pH: 8.2±0.22, HCO_3: 26± 3.4 mM), 3 day acid (urine pH: 4.7±0.38, HCO_3: 16±3), and rabbits immediately transitioned from 3 day acid to alkali loading for 16-18 h (recovery: urine pH: 8.0±0.28, HCO_3: 28±4.8). Morphometric analysis of AE4 staining revealed that acidosis reversibly reduced depth and area of the AE4 "barrel" structure in β-ICs by 30±0.1 and 44±0.1%, respectively. Recovery from acidosis restored AE4 "barrel" to near normal size. Similar to pendrin, AE4 mRNA abundance was reduced by acidosis to 36±3% of normal, and was increased to 118±17% of normal upon recovery.

Conclusions: AE4 is expressed in the CCD and may act in conjunction with pendrin to regulate HCO_3 secretion in β-ICs during alkali-loading perhaps via intercellular $Cl:HCO_3$ exchange or by facilitating HCO_3 trafficking from the blood to the urine.

Deletion of the Cl^-/HCO_3^- Exchanger Pendrin Downregulates Calcium-Absorbing Proteins in the Kidney and Causes Calcium Wasting Sharon L. Barone,[1,2] Jie Xu,[1,2] Hassane Amlal,[1] Manoocher Soleimani.[1,2] *[1]Medicine, University of Cincinnati, OH; [2]Research Services, Veterans Administration, Cincinnati, OH.*

Background: The epithelial calcium channel ECaC (TRPV5) and the Cl^-/HCO_3^- exchanger pendrin (SLC26A4) are expressed on the apical membrane of tubular cells in the distal nephron and play essential roles in calcium reabsorption and bicarbonate secretion, respectively. ECaC works in tandem with the basolateral Na/Ca exchange to reabsorb the filtered calcium in the distal nephron. ECaC expression and/or activity is downregulated *in vitro* by extracellular acidic pH. We hypothesized that the acidic urine in pendrin KO mice might affect the expression and or activity of ECaC/calbindin/Na/Ca exchange pathway and alter urine calcium excretion.

Methods: Northern hybridization, immunoblot analysis and immunofluorescent labeling were performed and urine calcium excretion rates were measured.

Results: Immunolocalization studies demonstrate that pendrin and the Na/Ca exchanger are expressed by distinct cell types within the distal convoluted and connecting tubules. In the collecting duct we observe the expression of pendrin but not the Na/Ca exchange. Our results confirm that deletion of pendrin causes acidic urine (urine pH 4.9 in ko Vs. 5.9 in wt mice, $p<0.03$). We further observe that pendrin deletion downregulates the calcium-absorbing molecules ECaC and Na/Ca exchange in the kidney. These changes were associated with a ~100% increase in 24 hr urine calcium excretion in pendrin null mice (~8.1 µmoles/24 hrs in wt Vs. 17.6 in pendrin KO mice, $p<0.01$). Subjecting the wild type and mutant mice to oral bicarbonate loading for 12 days increased the urine pH to ~8 in both genotypes, normalized the expression of ECaC and Na/Ca exchange, and reduced the urine calcium excretion in pendrin null mice to levels in wt mice.

Conclusions: We propose that acidic urine caused by pendrin impairment can play an important role in the pathogenesis of calcium, uric acid and possibly cystine stones. Future studies should investigate whether single nucleotide polymorphisms in pendrin gene are associated with the currently unexplained acidic urine in humans with calcium or uric acid stone.

Acid Decreased the Expression of Ca-Sensing Receptor in Type-B of Mouse Kidney Collecting Duct Intercalated Cells Yukiko Yasuoka,[1] Yuichi Sato,[2] Yuichiro Izumi,[3] Hiroshi Nonoguchi,[4] Katsumasa Kawahara.[1] *[1]Dept of Physiology, Kitasato U. Sch. of Med, Sagamihara, Kanagawa, Japan; [2]Dept of Mol. Diagnostics, Kitasato U. Sch. of Allied Health Sci, Sagamihara, Kanagawa, Japan; [3]Epithelial Systems Biology Labolatory, NHLBI, National Institutes of Health, Bethesda, MD; [4]Division of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.*

Background: The renal collecting duct serves the fine-tuning of renal acid-base homeostasis. Morphological changes, such as hypertrophy and cell height, of intercalated cells (IC) may contribute to the cell function in acid and alkali secretion during metabolic acidosis (Ac) and alkalosis (Al), respectively.

Methods: By using a quantitative *in situ* hybridization technique and immunohistochemistry, in mice (C57B/6J) kidney, we examined changes in the Ca-sensing receptor (CaSR) mRNA and protein expression at each segment of the distal tubules and the cortical collecting duct (CCD) after (1) 6-d $CaCl_2$-loading, (2) Ac or Al induced by NH_4Cl- or $NaHCO_3$-intake (6 d), and (3) furosemide-injection (24-hr).

Results: Moreover, by defining cell types of IC using a double-staining technique with anti-AE1 and AE4 antibodies in the CCD, we determined that CaSR mRNA was expressed not in type-A but in type-B cells of the IC throughout the CCD. The CaSR mRNA expression was moderately high in thick ascending limb of Henle's loop (TAL), macula densa (MD), distal convoluted tubule (DCT), and CCD (TAL, MD > DCT > CCD) in control. Interestingly, although the CaSR mRNA and protein expression was unchanged in all segments examined during Al and furosemide-infusion, it was significantly decreased only in IC-B during Ac and $CaCl_2$-loading. Cell height of IC-A increased during Ac and Ca-loading, whereas cell-height of IC-B increased during Al. No morphological changes occurred after furosemide-injection. All these results indicate that the CaSR expression in IC-B cells was decreased during either acid-loading or secondary acidosis by hypercalcemia and was independent of both hypercalciuria and hypercalcemia.

Conclusions: Unique expression of CaSR in the IC-B suggests that CaSR may be responsible for alkali secretion at least during alkalosis.

Expression of the Ammonia Transporter Family Members, Rh B Glycoprotein and Rh C Glycoprotein, in Foxi1 Null Mice Ki-Hwan Han,[1] Hyun-Wook Lee,[2] Alexandra F. Kovar,[2] Sven Enerback,[3] Jill W. Verlander,[2] David Weiner.[2,4] *[1]Department of Anatomy, Ewha Womans University, Seoul, Korea; [2]Renal Division, University of Florida, Gainesville, FL; [3]Department of Biomedicine, University of Gothenburg, Sweden; [4]Nephrology Section, NF/SGVHS, Gainesville, FL.*

Background: Mice lacking the transcription factor Foxi1 have an intercalated cell-differentiation defect and develop renal tubular acidosis. Rh B glycoprotein (Rhbg) and Rh C glycoprotein (Rhcg) are ammonia transporters critical for renal acid excretion. This study's purpose was to examine Rhbg and Rhcg expression in Foxi1 null mice.

Methods: Kidneys from Foxi1 null and wild-type mice processed for immunohistochemistry. Cell-specific expression was examined using double-immunolabel immunohistochemistry.

Results: In control mice, basolateral Rhbg was heterogeneous, strong in intercalated cells and weak in principal cells. In Foxi1 null mice, in cortical collecting duct (CCD) and outer medullary collecting duct (OMCD) Rhbg immunoreactivity was homogeneous; cells with strong Rhbg label were not present. Rhcg in control mice was apical and basolateral, and greater in intercalated than in principal cells. In Foxi1 null mice, Rhcg was homogeneous and no intensely labeled cells were present in CCD and OMCD. However, Rhbg and Rhcg expression in CCD and OMCD of Foxi1 null mice was similar to or greater than expression in principal cells in wt mice. In connecting segment cells (CNT), both Rhbg and Rhcg expression was intense and unchanged by Foxi deletion. Finally, both AE1-positive and pendrin-positive intercalated cells in Foxi1 null mouse CNT, CCD and OMCD. CA II expression was present in most CCD and OMCD cells in Foxi1 null mouse, consistent with the known CA II expression in mouse principal cells.

Conclusions: Rhbg and Rhcg expression is regulated through two separate pathways; one downstream of Foxi1-dependent stimulation of A-type intercalated cell and non-A, non-B cell development and one independent of Foxi1 and primarily present in CNT cells and principal cells.

Expression and Localization of the Renal Ammonia Transporter, Rhcg, in Male Reproductive Tract Hyun-Wook Lee,[1] Jill W. Verlander,[1] Jesse Bishop,[1] Mary Handlogten,[1] Sijo Parekattil,[1] Ki-Hwan Han,[3] David Weiner.[1,2] *[1]Univ. of Florida, Gainesville, FL; [2]Ewha Womans Univ., Seoul, Korea; [3]NF/SGVHS, Gainesville, FL.*

Background: The Rhesus glycoprotein, Rhcg, is an ammonia transporter that is essential for normal renal ammonia excretion. Global Rhcg deletion decreases renal ammonia excretion and impairs male fertility.

Methods: We performed the first detailed study of Rhcg expression in male reproductive organs using immunoblots, qRT-PCR, and immunolocalization and began to examine functional requirement for Rhcg in male reproduction using cell-specific Rhcg deletion.

Results: Immunoblots and qRT-PCR demonstrated Rhcg protein and mRNA in testis and epididymis, with highest expression in the epididymal head. Rhcg immunolabel was present in testis at the luminal surface in a subset of seminiferous tubules. Immunogold electron microscopy demonstrated Rhcg expression in Sertoli cells, spermatids and sperm. Rhcg immunolabel was present on cilia of ciliated cells in efferent ducts, and was apical in a subset of cells in epididymis. To determine cell-specific expression, we double immunolabeled for H-ATPase. In initial segment and head of epididymis, Rhcg was expressed on principal cell stereocilia. In upper body of epididymis, only principal cell microvilli had Rhcg immunolabel. In middle body, lower body and tail of epididymis, clear cells expressed apical Rhcg. In vas deferens, Rhcg was apical in a subpopulation of epithelial cells. We then identified that Ksp-cadherin-Cre-positive, floxed Rhcg mice had Rhcg deletion from epididymis, but not testis or sperm, as well as the previously reported renal collecting duct Rhcg deletion. Collecting duct and epididymis Rhcg deletion in sires did not alter litter size compared to Cre-, floxed Rhcg control sires.

Conclusions: 1) Rhcg is expressed in sperm and in a heterogeneous pattern in specific cell types in testis and epididymis, suggesting ammonia transport by Rhcg affects one or more components of male fertility; 2) unlike global Rhcg deletion, collecting duct and epididymal Rhcg deletion does not alter male fertility, 3) the complex distribution of Rhcg in male reproductive organs suggests it contributes to multiple components of male fertility.

Renal Rhcg Expression Is Increased during Lithium-Induced Nephrogenic Diabetes Insipidus in Rats Robert J. Walker,[1] Jennifer J. Bedford,[1] Gerard Davis,[1] Frederiek E. Vos,[1] David Weiner,[23] John P. Leader.[1] *[1]University of Otago, New Zealand; [2]University of Florida, Gainsville, FL; [3]Renal Section, NF/SGVHS, Gainesville, FL.*

Background: Lithium is used to treat bipolar disorders but is associated with nephrogenic diabetes insipidus and less commonly an impaired ability to handle an acid load. The role of ammonia via the putative NH3 transporter Rh C Glycoprotein (Rhcg) is unknown.

Methods: 11 participants (8 females) on lithium therapy were matched with 6 healthy volunteers (3 females). They received an acute dose of ammonium chloride (100 mg/kg body weight). Urine and blood samples were taken at the time and 2, 4, and 6 hours later. Rats maintained for 6 months on a lithium diet were also given an acute dose of ammonium chloride (100 mg/kg body weight). Urinary acidification was measured and the kidneys subsequently removed for immunohistochemistry and western blots for Rhcg expression.

Results: At baseline neither the humans nor rats had evidence of a metabolic acidosis. Humans on lithium showed a decreased ability to respond to an acute metabolic acid load and developed a more marked hyperchloremic metabolic acidosis and a less acidic urine. Similarly rats on chronic lithium treatment failed to respond as well to an acute acid load as did control rats. In controls urinary pH fell to 6.5 ± 0.1 and remained low for 6 hours whereas in the lithium rats urinary pH only fell to 6.7± 0.1 and returned to pH 7.0 after 2 hours The ammonia transporter, Rhcg in the outer medulla of rat kidneys showed an increase both with western blots (100 ± 37, control: 154 ± 17, lithium; $p<0.001$) and by immunohistochemistry.

Conclusions: Humans on long-term lithium therapy, demonstrated a reduced ability to excrete an exogenous acid load. This was also evident in our chronic lithium-exposed rat model. Immunohistochemical examination of rat kidneys following long term exposure to lithium revealed a substantially altered and increased expression of Rhcg. This was confirmed with western blots. We presume that this increased expression is a response to prevent the development of lithium-induced metabolic acidosis.

TH-PO679

Specific Firing of Renal Afferent Innervation: Which Role Play Acid-Sensing Ion Channels? Wolfgang Freisinger, Tilmann Ditting, Sonja Heinlein, Johannes Schatz, Roland Veelken. *Medical Clinic 4, Nephrology and Hypertension, Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany.*

Background: Dorsal root ganglion neurons with projections to the kidney exhibit a significantly higher portion of tonically firing neurons (repetitive firing) upon electrical stimulation than neurons with non-renal projections. As renal nerve endings are exposed to pH-changes in e.g. inflammation, we tested the hypothesis that tonically firing renal neurons exhibit currents upon acidic stimulation significantly different from neurons with other firing patterns predominantly linked to non-renal sites.

Methods: Dorsal root ganglion (DRG) neurons from Sprague Dawley Rats (Th11-L2) were characterized according to firing response (tonic – sustained firing vs. phasic – single firing). Furthermore, inward currents due to acid stimulation (pH 5,3) -consisting either of a large transient component and a smaller, sustained component or only sustained component- were measured in voltage clamp recordings and analyzed in terms of the putatively involved channels (ASIC or TRPV1) by adding the respective blockers (Amiloride, Capsazepine).

Results: 40 DRG neurons were examined. Tonic firing pattern was found more frequently in renal DRG neurons than in non-renal neurons (47% vs.10%. $p<0.05$), as shown previously. There was no significant difference in cell size (Ø 40,8 vs. 40,3µm). Tonic cells had higher capacity (120 vs. 70 pF) and lower membrane potential (-49 vs. -53,6 pF). Upon acidic stimulation, only cells with tonic firing exhibited an additional afferent transient current (12750±8750pA vs. 210±390pA), which could be blocked by amiloride (12750±8750pA vs. 710pA±1017pA, $p<0.05$).

Conclusions: For the first time we could show that tonically firing neurons, which are found predominantly in renal afferent innervations, exhibit transient inward currents blocked by the channel blocker amiloride, pointing to the presence of ASIC channels. The expression of these channels in an organ subjected to acid changes appears fascinating. The correlation with a tonic firing pattern as yet unclear, but these channels could influence membrane potential thus leading to higher excitability of these neurons in vivo.

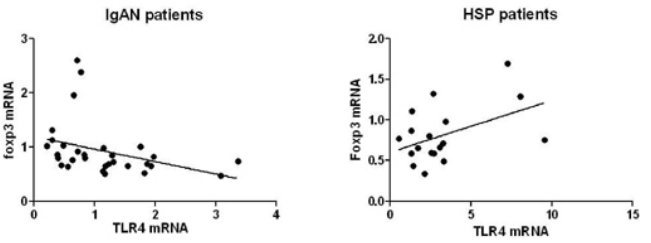
Different Modulation of Regulatory T Cells by Toll like Receptor Activation in Primary IgA Nephropathy and in Henoch-Schoenlein Purpura Nephritis: A Factor Regulating the Different Clinical Outcome? Elisa Loiacono,[1] Roberta Camilla,[1] Valentina Daprà,[1] Laura Morando,[1] Rachele Gallo,[1] Licia Peruzzi,[1] Margherita Conrieri,[2] Manuela Bianciotto,[2] Francesca Maria Bosetti,[2] Rosanna Coppo.[1] *[1]Nephrology, Dialysis, Transplant, R. Margherita Hosp, Turin, Italy; [2]Emergency Pediatrics, R. Margherita Hosp, Turin, Italy.*

Background: Primary IgA Nephropathy (IgAN) and IgAN related to Henoch Schoenlein purpura (HSP) have common histological features but different clinical outcomes. Children mostly show remission in IgAN related to HSP vs progression in primary IgAN. In both cases a dysregulation of innate immunity results in failure of mucosal antigen elimination and/or altered IgA synthesis. Among the innate immunity actors, toll-like receptors (TLR) modulate regulatory T (Treg) cells,that express the transcription factor Forkhead box P3(Foxp3)involved in suppressing pro-inflammatory responses. We had reported increased TLR expression in mononuclear cells(PBMC)of patients with primary IgAN.

Methods: We investigated 21 children with HSP(7.9±2 y.o; 10 with and 11 without urinary abnormalities) and 13 children with primary IgAN(10.7±3 y.o.).

TRL2, TLR4 and TLR9 mRNAs, Foxp3 mRNA (Treg marker) and TGF mRNA (Th17 pro-inflammarory cells marker)were quantified in PBMC of these children and in healthy controls by real time PCR(Taqman), normalizing with Abl mRNA.

Results: We observed a significant inverse correlation between TLR4 and Foxp3 mRNAs in PBMC from children with primary IgAN (r: -0.35, $p < 0.05$) while in cases of HSP TLR4 and Foxp3 mRNAs were directly correlated (r: 0.46, $p< 0.05$).



Conclusions: These data suggest that in primary IgAN TLR4 hyperexpression and dowregulation of anti-inflammatory Tregs may turn into a pro-inflammatory and chronic outcome, while an enhanced Treg activity in front of a similar innate immunity engagement may favor the recovery in children with HSP.

Activation of Innate Immunity in Henoch-Schoenlein Purpura with and without Nephritis: Increased Toll-Like Receptors Expression in Circulating Lymphomononuclear Cells Roberta Camilla,[1] Elisa Loiacono,[1] Valentina Daprà,[1] Laura Morando,[1] Rachele Gallo,[1] Margherita Conrieri,[2] Manuela Bianciotto,[2] Francesca Maria Bosetti,[2] Licia Peruzzi,[1] Alessandro Amore,[1] Rosanna Coppo.[1] *[1]Nephrology Dialysis Transplant, R. Margherita H., Torino, Italy; [2]Pediatric Emergency, R. Margherita H., Torino, Italy.*

Background: Innate immunity is involved in pathogenesis of primary IgA nephropathy (pIgAN).We reported an overexpression of TLR4 in circulating mononucleates(PBMC) from patients with pIgAN. Henoch-Schoenlein purpura (HSP)is a systemic vasculitis with renal features of pIgAN.

We aimed at investigating whether in PBMC from patients with HSP TLRs are upregulated as in pIgAN and the differences in cases with and without renal involvement.

Methods: TLR2, TLR4, and TLR9 expression was detected in BPMC of 28 HSP children (4-13 y.o.,mean age 7.6 ±2y) at clinical onset: 13 had urinary abnormalities(hematuria, proteinuria > 0.250 mg/day in 9/13). Children control groups were 15 pIgAN (5-16 y.o.,mean age 10.9±3y), 27 idiopathic nephrotic and 40 healthy subjects (HC). TRLs were detected by flow cytometry, expressed as MIF and mRNAs were quantified by real time PCR(Taqman).

Results: Patients with HSP showed, in comparison to HC increased expression of TLR2 (4.2±1.5 vs 3.0±0.6 MIF, p=0.02), TLR4 (2.2±0.7 vs 1.7±0.4 MIF, p=0.02), and TLR9 mRNA (2.9±2.0 vs 0.7±0.4, p=0.005). No difference was found in HSP with or without renal involvement. HSP showed, in comparison with pIgAN, higher levels of TLR9 and TLR4 mRNAs (TLR9: 2.9±2.0 vs 0.9±0.6, p=0.01; TLR4: 2.9±2.3 vs 1.6±1.2, p=0.004).

No modification in expression of TLR2,4,9 and corresponding mRNAs was detected in disease control groups in respect to HC.

Conclusions: In conclusion, this study shows for the first time an activation of TLRs during HSP suggesting an activation of innate immunity similar to what found in pIgAN.

The Expression of TLR9 in the Tonsils and Peripheral Blood of IgA Nephropathy Patients and It's Variation after Tonsillectomy Gang Wu,[1] You-Ming Peng,[1] Lin Sun,[1,2] Hong Liu,[1] Fu-You Liu.[1] *[1]Department of Nephrology, Second Xiangya Hospital, Central South University, Changsha, Hunan, China; [2]Departments of Pathology and Medicine, Northwestern University, Chicago, IL.*

Background: TLR9 is a member of the toll-like receptor (TLR) family which plays a fundamental role in pathogen recognition and activation of innate immunity. The expression of TLR9 in the tonsils and peripheral blood in IgAN patients and the changes after tonsillectomy is unclear.

Methods: 55 patients with IgAN (n=28) or chronic tonsillitis (Non-IgAN) (n=27), and 6 normal persons were enrolled into the study. Both the tonsils from chronic tonsillitis patients (n=27) and the peripheral blood from normal persons (n=6) were as control. Pathological changes of tonsillar tissues were observed by immunohistochemistry. The expression of TLR9 in B cells in tonsil was tested by immunohistochemistry and FCM(Flow cytometry), and the expression of TLR9 in peripheral blood from IgAN patients before and after tonsillectomy was tested by FCM as well.

Results: Immunohistochemistry showed that most of TLR9 positive cells were localized at the epithelium of tonsil, and a minor part at germinal centres, follicular and interfollicular area of tonsil. Compared to non-IgAN group,TLR9 positive cells of IgAN were significantly increased ($P<0.05$) showed by FCM. The expression of TLR9 on B cells tested by FCM, both in tonsil and peripheral blood from IgAN , were higher than control groups ($P<0.05$). After tonsillectomy, the expression of TLR9 on B cells of IgAN patients, was significantly decreased showed by FCM, even remain with proteinuria and hematuria; bue it had no obvious effect on the expression of TLR9 on B cells of normal persons.

Conclusions: Our data indicate that IgAN patients have an high expression of TLR9 in tonsils and peripheral blood, which could induce mucosal(innate) immune response.

A Multi-Center Validation Study of the Oxford Classification of IgA Nephropathy in China: ***Working Group on Validation Study of the Oxford Classification of IgA Nephropathy in China*** Cai-Hong Zeng,[1] Wei-Bo Le,[1] Shao-Shan Liang,[1] Hong-Bing Shen,[2] Agnes B. Fogo,[3] Zhi-Hong Liu.[1] *[1]Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China; [2]Department of Epidemiology and Biostatistics & Ministry of Education Key Lab for Modern Toxicology, School of Public Health, Nanjing Medical University, Nanjing, China; [3]Renal/EM Division, Department of Pathology, Vanderbilt University Medical Center, Nashville.*

Background: The Oxford classification of IgA nephropathy (IgAN) identified four pathologic lesions (MEST) for prediction of renal prognosis of IgAN independent of the clinical features. However, the limited number of patients and their heterogeneous origin necessitate validation studies in larger cohorts.

Methods: In this study, we validated the Oxford results using a cohort of 1026 adults with IgAN recruited from 18 centers in China.

Results: 31% of the patients in this cohort received immunosuppression and 27% prednisone, both similar to the Oxford cohort. The mean follow-up was 53 months. Compared with the Oxford cohort, the patients in the current study had slightly milder clinical course, as suggested by lower proteinuria (median, 1.3 vs 1.7 g/24h) at biopsy, and slower decline rate of eGFR (-1.5±10.5 vs -3.5±8.5ml/min per 1.73m^2 per year) during follow-up. In addition, there were lower proportions of patients with endocapillary proliferation(E, 11%) and mesangial hypercellularity (M1, 43%) in our cohort compared with the Oxford cohort, but higher proportions of segmental sclerosis or adhesion (S, 83%) and necrosis lesions (15% vs 2.3% in Oxford). The frequencies of crescents and severity of tubular atrophy/interstitial fibrosis were similar in both cohorts.

Conclusions: Our studies also confirmed a similar predictive value of the MEST lesions for renal outcome in Chinese adults with IgAN. On the other hand, we also reassessed the prognostic value of crescents and necrosis in IgAN, but no conclusive results were obtained.

TH-PO684

The Role of Focal Segmental Glomerulosclerosis in the Progression of IgA Nephropathy Liliany P. Repizo, Elerson Costalonga, Lilian P.F. Carmo, Igor Marques, Leonardo Abreu Testagrossa, Denise Maria Avancini Costa Malheiros, Lectícia Jorge, Rui Toledo Barros, Viktoria Woronik. *Departament of Nephrology, University of Sao Paulo, SP, Brazil.*

Background: Lesions morphologically identical with focal segmental glomerulosclerosis(FSGS) may appear in IgA nephropathy(IgAN). The aim of this study was to evaluate the role of FSGS in IgAN.

Methods: We analyzed 165 patients with biopsy-proven IgAN at our center from 1999 to 2009, 57 patients meet inclusion criteria of age > 18 years, biopsies containing at least 8 glomeruli and follow up longer than 2 years. Biopsies were reviewed and classified according to Columbia classification of FSGS in the context of IgAN. The primary endpoint was reduction of at least 50% of the initial eGFR (estimated by MDRD-simpilfied formula) and/or ESRD.

Results: It was possible to classify 30 of 57(52.7%) cases among the subtypes of FSGS. The FSGS lesions group cases were subdivided as follows: 25 NOS category, 4 tip lesions and 1 collapsing form. Of the remainder, no FSGS lesions group, 8 cases(14%) had glomerular lesions not definably FSGS and 19 cases (33,3%) didn't show lesions on light microscopy aside from mild mesangial prominence in some. The clinical and histological features are summarized in Table 1.

Clinical and histologic Features

N	No FSGS Lesions(27)	FSGS Lesions(30)
AGE(y)	33(25 – 42)	33(25 - 50.2)
Female	15(55,5%)	17(56.6%)
eGFRi(ml/min)*	74(50 - 91)*	34.5(25.5 - 64.7)*
Proteinuriai(g/day)	2.1(0.8-4.4)	2(1 - 4)
Hypertension*	11(40.7%)*	21(70%)*
Follow up	4.5(3 - 6.1)	4.8 (3.2 - 7.4)
eGFRend(ml/min)*	74(53 - 100)*	31.5(16.7 - 63.2)*
Interstitial Fibrosis>25%*	6(22.2%)*	18(60%)*
Crescents	7(25.9%)	13(43.3%)
Endpoint	3(11.1%)	10(33.3%)

Results are shown as median ± IQR * p < 0.05;

Finally, in univariate analysis FSGS lesions group showed a tendency to have a worse renal outcome at the end of follow-up (p0.06; OR 4.0 95% CI 0.9 – 16).We couldn't analyze the impact of FSGS subtypes on outcome because the low number of patients.

Conclusions: Our results underline the usefulness of monitoring all IgAN patients for FSGS, given their potential negative impact on renal outcome.

TH-PO685

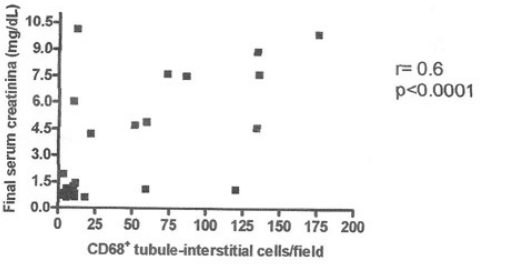
CD68 Positive Cells in Renal Biopsy Predict Long Term Prognosis in Proliferative Lupus Nephritis Cristiane Bitencourt Dias,[1] Patrícia Malafronte,[1] Jin Lee,[2] Aline Lázara Resende,[1] Cilene Carlos Pinheiro,[1] Denise Maria Avancini Costa Malheiros,[2] Rui Toledo Barros,[1] Viktoria Woronik.[1] *[1]Nefrologia, Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil; [2]Patologia, Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.*

Background: No long-term assessment about macrophages in renal histology in lupus nephritis(LN)is known. The aim was to describe relations of renal outcomes with tecidual macrophages (CD68+) expressed in biopsy obtained on the diagnosis.

Methods: Thirty four female patients with proliferative LN were prospectively followed-up. Immunohistochemical was performed with monoclonal antibody anti-CD68 in renal biopsy. Patients were stratified in two groups according to renal outcome: GFR ≤ 60 mL/min/1.73m2 (n=14) and GFR > 60mL/min/1.73m2 (n=20). Patients received prednisone and cyclophosphamide on induction.

Results: The groups with better and worse renal outcome were not diferent between age (25.0±8.3 vs 26.0±11.5 years), activity index(5.0±1.6 vs 4.3±2.5), initial proteinuria (3.8±2.2 vs 5.4±2.7 g/day), systemic sledai (12.0(12.0–16.0)vs 12.0(8.0–12.0), and follow-up (3.6±0.6 vs 3.5 (2.7–4.0)years). The group with better renal outcome showed less chronicity index (1.0(0.0 - 4.0)vs 4.0(2.0–5.0)p=0.04), initial serum creatinine (1.4(1.0–2.1) vs 2.6±1 mg/dL p =0.03) and CD68+ tubule-interstitial (6.1(4.5–10.5)vs 65.8 ± 58.0 cells/field p=0.0006). Tubule-interstitial expression of CD68+ cells showed positive correlation with final serum creatinine (r=0.6, p<0.0001) and patients with CD68+ expression over 50 cells/field showed worse renal outcome p=0.003, with relative risk of 3.2.

Figure 1. Correlation between CD68$^+$ tubule-interstitial and final serum creatinine



Conclusions: CD68+ cells tubule interstitial expression on renal biopsies predict long term GFR. Values more than 50 CD68+ cells/field showed relative risk of 3.2 to develop worse renal outcome.

TH-PO686

Lupus Nephritis Versus "Lupus-Like" Glomerulonephritis: Are the Same Disease? Daniela Loss Mattedi, Roberto Savio Silva Santos, Janaina De Almeida Mota Ramalho, Lectícia Jorge, Rui Toledo Barros, Viktoria Woronik. *Departament of Nephrology, University of São Paulo, São Paulo, SP, Brazil.*

Background: Patients who present with typical histological lesions but do not fulfill the American Rheumatism Association criteria for the diagnosis of systemic lupus erythematosus (SLE) may represent a diagnostic problem. The aim of this study was to compare the clinicopathologic features of patients with SLE and lupus-like GN.

Methods: We performed a retrospective study of 10 patients with lupus-like GN, defined by: (1) immunofluorescence microscopy(IF) staining for granular glomerular IgG, IgM, C3 and C1q ≥ 1+ (0 to 4+ scale); (2) negative antinuclear antibodies (ANA titer ≤ 1:80) and negative anti-dsDNA antibodies; and (3)without extra-renal lupus activity. Cases were randomly matched with 20 patients with classical LN IV, according to baseline clearance (MDRD simplified formula) and time of follow-up. Treatment was decided by the clinical staff based on literature protocols.

Results: The clinical and histological features are summarized in Table 1.

Clinical and Histologic Features

	Lupus-like GN	Class IV LN
n	10	20
Age(yr)	42(35-47)*	27(20-33)*
Female	6(60%)	18(90%)
Serum Creatinine	1.4(0.9-2.3)	1.4(0.7-2.1)
eGFRi	47.5(28-90)	49.5(28-96)
Serum Albumine	2.4(2.0-2.8)	2.6(1.9-3.3)
Proteinuria	5.3(2.9-8.2)	3.9(1.2-7.5)
Hematuria	9(90%)	13(65%)
Hb	10.1(8.2-12)	11.2(10.3-13.1)
C3	72.5(50-99)	72(47-88)
ANA	0*	16(80%)*
anti-dsDNA	0*	12(60%)*
No. Glomerulos	23(12-32)	13(7-21)
Interstitial Fibrosis>10%	9(90%)	19(95%)
Crescents	1(10%)*	19(95%)*
Follow up	24(11.5-72)	24.7(14-76)
eGFRend	75(52-93)	72.6(30-98)
Albumin end	4.2(2.4-4.3)	4.2(4.0-4.6)
C3 end	117(73-145)	91(26-116)
Proteinuriaend(g\day)	0.85(0.3-5.1)	0.9(0.4-4.1)
eGFR\year	0.75(-9.6 - 8.6)	1.9(-23.8 - 45)

Results are shown as median IQR * p < 0.05

The immunosuppressive therapy used did not differ between groups and included prednisone, cyclophosphamide and mycophenolate. At the end of follow-up, one patient progressed to end stage renal disease in "Lupus-like" GN group and 2 patients in class IV LN group.

Conclusions: In our study, "Lupus-like" GN was very similar to LN regarding the clinical features, therapeutic response and outcome.

TH-PO687

Worse Renal Outcome with MPO-ANCA-Associated Nephritis Compared to PR3-ANCA-Associated Nephritis

Marten Segelmark,[1,2] Aladdin Mohammad.[3] *[1]Department of Health and Medicine, Linkoping University, Linkoping, Ostergotland, Sweden; [2]Department of Nephrology, Lund University, Lund, Skane, Sweden; [3]Department of Rheumatology, Lund University, Lund, Skane, Sweden.*

Background: End-stage renal disease is a most debilitating outcome in ANCA associated vasculitis (AAV). Renal involvement and high age at diagnosis have been shown to predict ESRD, however, more prognostic factors are needed.

Methods: In order to analyse the impact of serological specificity on renal outcome clinical and laboratory data at presentation were retrieved from all patients diagnosed during a 13 year-period (1997-2009) within a defined population in southern Sweden. All patients were followed until the end of 2010 and renal survival among proteinase 3 (PR3)-ANCA+ and myeloperoxidase (MPO)-ANCA+ patients were studied by Kaplan-Meier analysis.

Results: A total of 121 patients with AAV, renal involvement and positve ANCA tests (PR3=62; MPO=59) were included in the study. The clinical and laboratory characteristics are listed in the table below. Patients with PR3-ANCA had significantly higher inflammatory activity and larger number of organ involved at diagnosis. Among MPO- ANCA+ patients, 19 (32%) developed end-stage renal disease compared to 10 (16%) of the PR3-ANCA+ patients (p=0.032). These results were consistent after correction for sex, age and creatinine at diagnosis. There was no significant difference in the mortality rate between the two groups.

Demographics, clinical and laboratory features in 121 patients with AAV and renal involvement

	PR3-ANCA	MPO-ANCA	p-value
Number	62	59	
Sex (M/F)	40/32	30/29	0.090
Age, median(range)	69 (19-88)	71 (32-92)	0.304
CRP, median(range)	124 (13-294)	50 (1-295)	<0.001
Hemoglobin,g/l,median(range)	104 (75-155)	103 (72-142)	0.097
>3 organ systems	47 (76 %)	35 (59 %)	0.04
Creatinine, median (range)	237 (53-1214)	259 (44-1369)	0.107
Death during follow-up	22 (35%)	25 (42%)	0.461
ESRD during follow-up	10 (16%)	19 (32%)	0.032

Conclusions: In this population-based cohort of AAV, MPO-ANCA + had a doubled risk of developing ESRD compared with PR3-ANCA + patients, despite similar renal function at diagnosis. These findings should be taken into consideration when prescribing treatment and stratifying patients in therapeutic trails.

TH-PO688

A Multi-Center Study on Renal Transplantation in ANCA-Associated Vasculitis

Arda Goceroglu,[1] Annelies Evaline Berden,[1] Marlies E.J. Reinders,[1] Marcory van Dijk,[2] Anoek A.E. Joode,de,[2] Carine Peutz-Kootstra,[3] Maarten H.L. Christiaans,[3] Frank Smedts,[4] Iris Noorlander,[4] Roel Goldschmeding,[5] Arjan D. Van Zuilen,[5] Eric Steenbergen,[6] Luuk Hilbrands,[6] Lorraine Harper,[7] Mark Little,[8] Ernst C. Hagen,[9] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]LUMC, Leiden, Netherlands; [2]UMCG, Groningen, Netherlands; [3]MUMC, Maastricht, Netherlands; [4]EMC, Rotterdam, Netherlands; [5]UMCU, Utrecht, Netherlands; [6]Radboud Uni Nijmegen MC, Netherlands; [7]University of Birmingham, United Kingdom; [8]UCL Centre for Nephrology Royal Free, London, United Kingdom; [9]Meander MC, Amersfoort, Netherlands.*

Background: Anti-Neutrophil Cytoplasmic Antibody (ANCA)-associated glomerulonephritis (AAGN) can recur in a renal allograft. The aim of this study is to evaluate the outcome of renal transplantation in Dutch patients with AAGN with special focus on disease recurrence and graft survival.

Methods: Patients were retrospectively recruited through the Dutch national pathology database PALGA. The patients had to have 1 of the following diagnoses: Wegener's granulomatosis, microscopic polyangiitis or renal limited vasculitis, AND there had to be at least 1 transplant biopsy. Biopsies and clinical data were available for an interim analysis on 55 patients (median follow-up: 60 months). Biopsies were scored according to Banff '09. Renal recurrence was scored according to the new histopathologic classification of AAGN.

Results: Five years after transplantation, 15 grafts were lost: 4 due to recurrence (1 mixed, 1 focal, 2 crescentic class). In total 8 patients had a recurrence: 5 intra- and extrarenal, 2 intrarenal (2 focal, 2 crescentic and 3 mixed class) and 1 extrarenal. Five years after transplantation, 29 patients had a functioning graft: 20 serum creatinine <200µmol/L, 7 serum creatinine ≥200µmol/L, 2 unknown. There were 23 histologically proven acute rejections in 20 patients.

Conclusions: This is one of the largest studies to date investigating long-term outcome of renal allografts in AAGN patients. The recurrence rate in this cohort was 2.0% per patient year of follow-up. Five years graft-survival is 70.4%. Disease recurrence in the kidney has led to graft loss in most cases (4 out of 7).

TH-PO689

Histopathologic Classification of Glomerular Lesions in ANCA-Associated Glomerulonephritis Does Not Reliably Predict Clinical Outcome

Swarupa R. Eskapalli, Samuel K. Okoh, Martha L. Graber, Thomas M. Kaneko, Alan R. Schned. *Hypertension and Nephrology, and Pathology, Dartmouth Hitchcock Medical Center and Dartmouth Medical School, Lebanon, NH.*

Background: A recently published classification schema identified 4 classes of GN associated with antibodies to neutrophil cytoplasmic antigens (ANCA) based on the appearance of glomeruli; focal (F), crescentic (C), mixed (M) and sclerotic (S) and found class to be an independent predictor of clinical outcomes in a European multicenter cohort of 100 subjects(1). We performed a ten year retrospective analysis of all 21 adults with ANCA-associated GN at a Northern New England center.

Methods: Biopsies were classified according to strict criteria of Berden(1). Statistical analysis was by ANOVA.

Results: Biopsies were readily categorized: 8 as class F; 4 C; 6 M and 3 S. Mean # glomeruli 11.1. Follow up 42.4 (2-122) mo. Mean age 68.1 yr with trend to older age in class S. 3862% were male. Treatment did not differ between groups. Mean entry eGFR 24.4 ml/min. There was a trend to lower entry eGFR in the S class, but no significant difference between groups or in entry eGFR between the non-S classes. Mean changes in eGFR at one yr and follow up were +8.24 and +18.75 ml/min respectively. There was a trend to greater improvement in class C and decline in function in class S, in contrast to the data of Berden(1), which showed greatest improvement in F. 8 reached ESRD: 2 C; 3 F; 2 M and 1 S. 4 died: 1 C; 3 F.

Conclusions: We describe a ten year of ANCA-associated GN in 21 subjects in a population similar to the index study. We did not detect correlation of clinical outcomes with pathologic class. We did not confirm that subjects with F histology had higher eGFR at entry or greater improvement. We conclude that the schema proposed by Berden(1) is not consistently reliable for clinical prognostication in individual patients. Our conclusion is limited by the small number of subjects (n=21) relative to the index study (100), and by wider variation in length of follow up. Our study points to a need for continuing collaborative data collection in this rare but important disease.

TH-PO690

Clinical Implications of the New Pathological Classification of Pauci-Immune Small Vessel Vasculitis of the Kidney

Basu Gopal,[1] Veena Jeyaraj,[2] Nithya Jayaseeli,[3] George T. John,[4] Chakko Korula Jacob,[1] Veerasamy Tamilarasi,[1] Anila Korula.[2] *[1]Nephrology, Christian Medical College, Vellore, Tamil Nadu, India; [2]Pathology, Christian Medical College, Vellore, Tamil Nadu, India; [3]Biostatistics, Christian Medical College, Vellore, Tamil Nadu, India; [4]Renal Medicine, Royal Brisbane and Women's Hospital, Queensland, Australia.*

Background: We aimed to study the clinical correlation of the recent international working of renal pathologists (IWGRP) classification of small vessel renal vasculitis.

Methods: Clinical details and renal biopsy blocks of consecutive patients from 2001 to 2010 diagnosed to have pauci-immune renal vasculitis at our institution were retrieved and histological features re-evaluated by two pathologists to assess the clinicopathologic correlates of eGFR at presentation, follow up and the IWGRP classification.

Results: Of the 12,200 renal biopsies, 107(0.9%) were pauci-immune renal vasculitis (median age 48 (12-82)yrs; M:F = 1.5:1). The mean serum creatinine and proteinuria at presentation were 5.8±4.6mg/dl &1.6±2.1g/d. cANCA was positive in 28% and pANCA in 34.6%. Predictors of eGFR at presentation<30ml/min/1.73sq.m., were glomerular neutrophilic infiltrates(0.005), eosinophilic infiltrates(0.035), karyorrhectic debris(0.020), segmental sclerosis(0.007) and interstitial fibrosis (p<0.001). Based on IWGRP classification of the 9.3% focal , 29.9%crescentic, 55.1% mixed and 5.6% sclerotic lesions, 9.1, 39.0,44.2 and 7.8% respectively had an eGFR≤30ml/min/1.73sq.m. at presentation (p= < 0.001). Among the 28 cases followed up , these groups showed a mean eGFR at 1 year after diagnosis of 49.8±28.2, 46.3±23.4, 71.6±27.9 and 5.3 respectively, with the highest increment in eGFR in the crescentic group. eGFR at 3,6 and 12 months were independently predicted by the IWGRP class (temporally increasing β) and eGFR at presentation (temporally decreasing β).

Conclusions: The IWGRP class and eGFR at presentation are independent predictors of outcome in renal small vessel vasculitis. As interstitial fibrosis is predictive of eGFR at presentation, it could be incorporated into the IWGRP classification.

TH-PO691

Histologic Classification of Pauci-Immune Glomerulonephritis: Outcomes Predictors

Janaina De Almeida Mota Ramalho, Daniela Loss Mattedi, Victor Sato, Denise Maria Avancini Costa Malheiros, Lectícia Jorge, Rui Toledo Barros, Viktoria Woronik. *Departament of Nephrology, University of Sao Paulo, SP, Brazil.*

Background: Although renal biopsy is the gold standard for the diagnosis of pauci-imune glomerulonephritis, its pathologic classification remains a controversial issue. A recently developed classification proposes four general categories of lesions: focal, crescentic, mixed, sclerotic. The aim of our study is to access its prognostic value.

Methods: We analyzed 58 patients with biopsy-proven pauci-imune glomerulonephritis at our center from 2000 to 2010, 51 patients were included in analysis(5 excluded for missing

data and 1 for insufficient number of glomeruli on biopsy) Biopsies were reviewed and classified according to the new classification. X^2, one-way ANOVA, and multiple logistic regression analyses were performed as appropriate. The glomerular filtration rate (GFR) was estimated using modified MDRD simplified equation.

Results: At baseline, the mean age was 45 ± 20 yrs, and 37.2% of the patients were males. ANCA test was positive in 19 (37,3%), negative in 22 (43,1%) and missing in 10 (19,6%). Mean eGFR at entry was 19 ± 24 ml/min/1,73m². Regarding the histological features, cases were subdivided as shown in table.

Renal outcome according to class

	eGFR Entry	n	eGFR 12 Months	n
Focal	110 ± 41	2	129 ± 67	2
Crescentic	8,4 ± 4,1	9	25,8 ± 6,8	4
Mixed	23 ± 19	17	56,7 ± 31,8	9
Sclerotic	12,7 ± 11,4	23	28,7 ± 12,6	4
Total		51		19

Results are shown as mean± SD

As depicted in Table, the renal biopsy categories were correlated to the degree of renal function at presentation(p = 0,02), and showed a tendency at 1 year follow-up(p=0,08). We couldn't analyze the impact of focal subtype on outcome because the low number of patients. Finally, logistic regression analysis showed that sclerotic class was significantly associated with a worse renal outcome after one year of follow-up, even after adjustment initial eGFR (OR 4.7, 95%CI 1.17-19.2 p=0.02).

Conclusions: In our study, the histologic classification was correlated with renal function at baseline and was associated to ESRD at 1 year regardless of eGFR.

Funding: Government Support - Non-U.S.

TH-PO692

Clinical Characteristics of Japanese Patients Having Anti-Neutrophil Cytoplasmic Antigen-Associated Glomerulonephritis with Immune Deposits Yasufumi Takahashi, Makoto Harada, Yuji Kamijo, Makoto Higuchi. *Nephrology, Shinshu University School of Medicine, Matsumoto, Nagano, Japan.*

Background: Anti-neutrophil cytoplasmic antigen-associated glomerulonephritis (ANCA-GN) is pathologically characterized as a pauci-immune type of necrotizing crescentic glomerulonephritis. However, several earlier studies investigating European/American patients reported that ANCA-GN was often accompanied by the glomerular immune deposits. The deposition rate and the clinical significance of the immune deposits were controversial, and there are no data concerning these issues in Japanese patients with ANCA-GN.

Methods: We retrospectively investigated 27 Japanese patients with rapidly progressive kidney impairment who were positive for serum ANCA (MPO-ANCA 24 cases, PR-3 ANCA 3 cases) and exhibited biopsy-proven necrotizing crescentic glomerulonephritis. The immune deposits were confirmed by two methods, immunofluorescence microscopy and electron microscopy. The pathological and clinical data were compared between immune-deposits-positive and negative groups.

Results: Among these 27 cases, 8 cases exhibited the glomerular immune deposits (30%). The clinical parameters at the time of admission, including serum creatinine (2.3 vs 2.5 mg/dl) and ANCA titer (298 vs 556 EU), did not differ between the immune-deposits-positive and negative groups, while massive proteinuria was significantly detected in the immune-deposits-positive groups (2.8 vs 1.1 g/day, P=0.029). However, there was no significant difference in kidney survival rate (75 vs 90%), survival rate (100 vs 84%), or the incidence of extrarenal organ injury (63 vs 53%), between the groups throughout the observation period (26 months).

Conclusions: Glomerular immune deposits were unexpectedly detected at a high rate in Japanese ANCA-GN patients. The clinical course of the ANCA-GN for 2 years after diagnosis was not altered, but the level of proteinuria was markedly enhanced by the glomerular immune deposits, suggesting that they had a potential effect as an aggravation factor of kidney dysfunction. An additional study investigating the long-term effects of the glomerular immune deposits in ANCA-GN is needed in the future.

TH-PO693

Identification of Early Pathologic Features of Focal Segmental Glomerulosclerosis by Repeat Renal Biopsy Cai-Hong Zeng, Hong-Guang He, Feng Xu, Qing-Yan Zhang, Xi Tang, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.*

Background: To explore the early pathologic features of focal segmental glomerulosclerosis (FSGS).

Methods: We analysed 10 patients (8 males and 2 females) whose first renal biopsies showed minimal change lesions while second biopsies indicated FSGS (3 cases classified as NOS, 3 cellular, 2 tip, 1 perihilar, and 1 collapsing)

Results: The mean age at the time of the first biopsy was 22.9±6.7 years. The mean interval time of the two biopsy collections was 22.3±16.6 months. The proportion of segmental glomeruloscleorosis was 11.4±7.2 (3.2~22.2) %. At the first biopsy, there were no global glomerulosclerosis and mesangial proliferation. The splitting of Bowman's basement membrane (BBM) at tubular pole were seen in 7 cases, inflammatory infiltration surrounding glomeruli in 6 cases, and tubular cell refluxing into Bowman's capsule in 6 cases. These numbers increased to 10, 7 and 10, respectively, at the repeat biopsy. The proportions of glomeruli with above lesions in the cases were 69.1±33.6%, 19.7±5.7%, 17.9±6.1% at first biopy, and were 87.4±10.1%, 19.8±10.3%, 23.4±10.9% at second biopsy. Acute tubular-interstitial lesions (ATIL) were observed in both of the biopsies of 9 cases, of which, 4 cases had aggravated ATIL, 4 ameliorated, and 1 unchanged. Chronic tubular-interstitial lesions were present in one case at first biopsy, but in 9 at the repeat biopsy. 7 cases had more severe interstitial inflammatory infiltration at repeat biopsy compared with that at first biopsy. Arteriole hyalinosis was present in 2 cases at the first biopsy and then in 6 cases at the second biopsy. Foot process effacement ≥ 50% of glomeruli, denudation of food process from GBM, and cytoplasm vacuolation were observed in 6, 4, and 5 cases at first biopsy, respectively, and in 9, 6, and 9 cases at second biopsy.

Conclusions: In conclusion, splitting of BBM at tubular pole, inflammatory infiltration surrounding glomeruli, and tubular cell refluxing into Bowman's capsule, ATIL, denudation of foot process from GBM, and cytoplasm vacuolation are the early lesions of FSGS.

TH-PO694

Low Birth Weight-Related Nephropathy Has Similar Pathological Changes Both in Glomeruli and in Tubular Cells with Those of Mitochondrial Cytopathy Toshiyuki Imasawa,[#1] Moritoshi Kadomura,[#1] Takehiko Kawaguchi,[#1] Yutaka Yamaguchi,[#2] Hiroshi Kitamura.[#1] *[1]Division of Nephrology, Chiba-East National Hospital, Chiba-City, Chiba, Japan; [2]Yamaguchi's Pathology Laboratory, Matsudo-city, Chiba, Japan.*

Background: Glomerular involvement in patients with mitochondrial cytopathy is a focal segmental glomerulosclerosis (FSGS). In addition, it was recently reported that granular swollen epithelial cells (GSECs), which include increasing damaged mitochondria, are specific pathological changes in distal tubuli or collecting ducts in patients with mitochondrial cytopathy. On the other hand, adults who were born with low birth weight (LBW) have high risk of kidney damages and sometimes showed FSGS lesions in their glomeruli. Here, we assessed their tubular changes and mitochondrial gene mutations.

Methods: Five adult patients with FSGS lesions who were born under 2500g, two mitochondrial cytopathy patients, and five obesity-related FSGS patients who were born over 2500g, were analyzed in this study.

Results: In all five patients with LBW, glomeruli showed hypertrophy and FSGS perihilar variant lesions. Interestingly, in four of five patients, GSECs, which were previously reported only in patients with mitochondrial cytopathy, were also apparently observed in collecting ducts. A part of these tubular cells were dropping out of tubular arrangement with chromatin condensation. Mitochondrial gene mutations in blood, urine sediments, and kidney specimens were checked by PCR-Luminex assay. Any mitochondrial gene mutations were not detected in these patients with LBW. Two mitochondrial cytopathy patients also had FSGS perihilar variant lesions in glomeruli and had GESCs in their tubuli. PCR-Luminex assay in all blood, urine sediments, and kidney specimens revealed mitochondrial gene mutations (3243 A to G). Although five obesity-related nephropathy patients had FSGS perihilar variant lesions, their tubular cells did never show GSECs. Now, we try to stain kidney specimens for COX IV.

Conclusions: These results suggest that mitochondria should be associated with the etiopathogenesis of LBW-related nephropathy probably by functional defects.

Bilirubin Attenuate Arteriolopathy and Tubular Proteinuria by Inhibition of NADPH Oxidase in Cyclosporine Induced Nephropathy Sewon Oh,[1] Ki Young Na,[1,2] Suhnggwon Kim,[2] Ho Jun Chin.[1,2] *[1]Department of Internal Medicine, Seoul National University Bundang Hospital, Kyeong-Kido, Republic of Korea; [2]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Epidemiological studies have shown that patients with hyperbilirubinemia have a lower incidence of cardiovascular disease and strokes. In addition, bilirubin has been reported as an endogenous antioxidant by inhibition of reactive oxygen stress. We determined whether injection of bilirubin could attenuate vascular or tubular injury though inhibition of nicotinamide adenine inucleotide phosphate (NADPH) oxidase subunits in cyclosporine (CsA) induced nephropathy.

Methods: Male Sprague Dawley rats were administered vehicle, CsA, CsA + bilirubin (BIL), and BIL. Bilirubin was injected intraperitoneally three times for one week (60mg/kg). All groups kept on a 0.05% low salt diet were treated with vehicle (VH) or CsA for 4 week (15mg/kg/day, subcutaneous). Physiologic and histologic changes were studied in addition to the concentration of urine Kidney injury molecule-1 (Kim-1), urine Neutrophil gelatinase associated lipocalin (NGAL) by ELISA, and the protein expression of NADPH oxidase 4 (NOX4) and p22phox NADPH oxidase subunit by western blot. Urine hydrogen peroxide was measured using 2',7'-dichloro-dihydrofluorescein diacetate.

Results: There was no difference on renal function between CsA group and CsA+bilirubin group (1.69 ± 0.93 vs. 1.71 ± 0.35, *P*=0.967). Arteriolopathy was improved in CsA + BIL group compared than CsA group (20.5± 3.4 % vs. 37.3± 9.0 %, *P*=0.004). Also, CsA + BIL group showed lower concentration of urine Kim-1 than CsA group (0.85±0.34 vs. 2.28±1.52 ng/mL, *P*=0.025). Urine NGAL did not show significant difference (0.7± 0.3 vs. 1.5± 1.1 μg/mL, *P*=0.117). CsA + BIL group was found lower expression of NOX4 and p22phox NADPH oxidase subunit than CsA group (*P*=0.011 and *P*=0.028, respectively). Urine hydrogen peroxide was lowered in CsA + BIL group (444.6±74.9 vs. 242.2±140.5, *P*=0.022).

Conclusions: Bilirubin reduced reactive oxygen species by inhibiting NADPH oxidase and attenuate arteriolopathy and tubular proteinuria in CsA induced nephropathy.

TH-PO696

Cyclosporine A Causes Maturation Failure in Embryonic-Type Glomeruli Persisting after Birth Shinsuke Fujita, Keisuke Sugimoto, Kouhei Miyazaki, Mitsuru Okada, Tsukasa Takemura. *Pediatrics, Kinki University School of Medicine, Osakasayama, Osaka, Japan.*

Background: Cyclosporine A (CyA) is administered to patients to enable withdrawal of corticosteroids or to maintain remission in patients with intractable nephrotic syndrome (NS). While, chronic renal injury caused by CyA is a major concern. Early starting CyA treatment in life might be a risk factor for CyA nephropathy, however the cause to develop nephropathy remains unknown.

Methods: We analyzed renal histologic and immunohistologic findings in 22 children with NS who did (n=5) or did not (n=17) develop CyA nephropathy despite appropriately low serum CyA concentrations being maintained over 2 years. We performed staining for type IV collagen α1, laminin β1 and laminin β2 to discriminate embryonic-type from mature glomeruli. Staining patterns were used to semiquantitatively assess glomerular immaturity (glomerular immaturity index; GII).

Results: In follow-up biopsy specimens, residual embryonic-type, collapsed embryonic-type and sclerotic glomeruli that had failed to differentiate were observed. Patients with early-onset CyA nephropathy had a high GII. In patients with a high GII, arteriopathy developed early in CyA treatment. Arteriopathy was observed mostly near embryonic-type glomeruli. Taken together, these glomeruli (surviving embryonic-type, collapsing embryonic-type, and sclerotic glomeruli) essentially equaled the total number of embryonic-type glomeruli in specimens obtained before CyA treatment.

Conclusions: A need for caution in CyA therapy for patients with NS, even for a relatively short course of administration, because some patients may have embryonic-type glomeruli or immature arterioles that predispose them to CyA nephropathy.

TH-PO697

The Mechanism of the Development of Segmental Glomerular Sclerosis in Idiopathic Membranous Nephropathy Megumi Fukui,[1] Akiko Mii,[1] Akira Shimizu.[2] *[1]Internal Medicine (Division of Neurology, Nephrology, and Reumatology), Nippon Medical School, Tokyo, Japan; [2]Pathology, Nippon Medical School, Tokyo, Japan.*

Background: Membranous nephropathy (MN) with focal segmental sclerosis is associated with a poorer prognosis than MN without these lesions. The mechanism of the development of segmental sclerosis in MN is still uncertain.

Methods: We selected renal biopsy cases of idiopathic MN cases with segmental sclerosis (n=26/ total 250), and assessed the development of segmental sclerosis, focusing on the glomerular endothelial cell injuries, organization and thickening of GBM, and VEGF expression in podocytes.

Results: The average age of these cases is 62.4±9.77 years. About 77 % (n = 20) of these cases developed nephrotic syndrome. eGFR (mean 57.36±18.1 mg/dl) was significantly lower compared to MN without segmental sclerosis. In histopathology, the most common pattern of segmental sclerosis in MN was characterized by glomerular capillary collapse with extracellular matrix accumulation. All MN cases with segmental sclerosis showed endothelial cell injuries that characterized by obliteration and loss of glomerular capillaries with disappearance of CD34+ endothelial cells. Interestingly, in all cases with segmental sclerosis, narrowing of glomerular capillaries with endothelial cell injuries was evident even in non-sclerotic areas. In deed, by computer assessed morphometric analysis, MN cases with segmental sclerosis had significantly to smaller glomerular capillaries and larger matrix area in glomeruli than MN cases without sclerotic legion. No difference of VEGF expression on podocytes was detected between MN cases with and without segmental sclerosis (1.20±0.72 /0-4 semiquantitative score in MN with sclerosis vs. 1.35±0.86 /0-4 scores in MN without sclerosis, p=0.64). However, significant difference of the thickness of GBM was evident between MN cases with and without segmental sclerosis (1.48±0.70 μm in MN with sclerosis vs. 1.02±0.48 μm in MN without sclerosis, P<0.05).

Conclusions: The glomerular capillary and endothelial cell injuries may be induced by GBM organization and thickening with subepithelial deposits that contributed to the development of segmental sclerosis in MN.

Differences in Expanded CD8$^+$ T Cell Subsets Indicate Distinct Immune Responses Cause idiopathic and Secondary Membranous Nephropathy Aki Kuroki, Kei Matsumoto, Tadao Akizawa. *Division of Nephrology, Department of Medicine, Showa University, Tokyo, Japan.*

Background: Although idiopathic membranous nephropathy (IMN) and secondary forms of membranous nephropathy (sMN) share similar clinical and histological features, discovery of phospholipase A2 receptor 1, a target antigen in IMN indicates that they are caused by different immunologic processes. In this study, to define whether there are distinct immune responses in IMN and in sMN, we analyzed peripheral lymphocytes subsets.

Methods: We collected peripheral blood samples from patients with IMN, sMN and normal individuals (normal control, NC). sMN group included patients with lupus nephritis, and patients without clinical features of secondary disease, but whose renal tissues were positive for C1q, and/or negative for IgG4 staining, the findings, which were suggestive of sMN. We analyzed peripheral lymphocytes subsets using flow cytometry and analyzed the relationship between clinical parameters. Kruskal-Wallis' test and Spearman's rank correlation were used for statistical analysis.

Results: The most prominent difference between IMN and sMN was subsets of CD8$^+$ T cells. In the IMN group, CD8$^+$ T cells decreased, which was resulted from decrease in CD8$^+$ naïve T cells. However, CD8$^+$effector-memory T cells increased, and level of CD8$^+$effector-memory T cells correlated with the levels of proteinuria. In contrast, in the sMN group, CD 28 null CD8$^+$ T cells increased, although level of those cells was not correlated with any of clinical parameters. Another difference was level of CD25high CD4$^+$ regulatory T cells, which decreased only in the IMN group.

Conclusions: These results indicate that although histological findings are similar, immunologic processes underlying the deposition of immune complex are distinct in idiopathic and in secondary membranous nephropathy, and specific therapeutic approach is required.

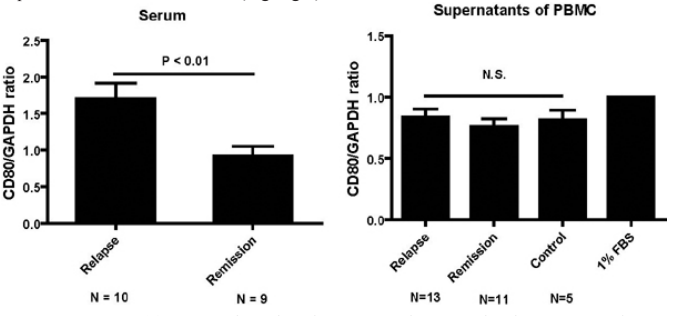
Serum Factor from Minimal Change Nephrotic Syndrome Patients Increases Podocyte CD80 Expression Takuji Ishimoto,[1] Richard J. Johnson,[1] Eduardo H. Garin.[2] *[1]Division of Renal Diseases & Hypertension, University of Colorado Denver, Aurora, CO; [2]Division of Pediatric Nephrology, University of Florida, Gainesville, FL.*

Background: Proteinuria in Minimal Change (MC) patients is thought to be due to a circulating factor released by patients lymphocytes. In MC patients in relapse, glomeruli express CD80 and CD80 urinary excretion is increased. Because CD80 is known to mediate proteinuria, we have evaluated the effect of serum and supernatants of Peripheral Blood Mononuclear Cells (PBMC) cultures from MC patients on CD80 podocyte expression.

Methods: Thirteen MC patients were studied in relapse and 11 in remission. Five normal subjects served as controls. Immortalized human podocytes were incubated with 15% of MC patients serum or with 15% of 4 to 10x concentrated supernatants of PBMC cultures from normal controls and from MC patients. PBMC (1 x 10^6/ml) were incubated with 15% FBS for 72 h prior to obtain the supernatants. RNA was extracted at 6 h, and QPCR for CD80 was done.

Results: Serum albumin was 2.18 +/- 0.53 (g/dl) and urinary protein/creatinine ratio 11.2 +/- 5.12 (mg/mg) in relapse, and 4.1 +/- 0.73 (g/dl) and 0.19 +/- 0.12 (mg/mg) in remission respectively. MC patients in relapse serum significantly increased podocyte CD80 expression when compared to that seen in remission ($p< 0.01$) (Fig. left). No difference in CD80 expression among the groups were seen when podocytes were incubated with supernatants of PBMC cultures (Fig. right)



Conclusions: (1) MC patients in relapse serum increases in vitro CD80 podocyte expression. This finding can explain, at least in part, the mechanism of proteinuria in these patients. (2) The lymphocyte is not involved in the CD80 mediated proteinuria in MCD patients.

TH-PO700

Routine Microscopic Examination of Urine Sediment Can Identify Urinary Podocytes Masanori Hara. *Pediatrics, Yoshida Hospital, Tsubame, Niigata, Japan.*

Background: Podocytopenia is involved in the progression of glomerular sclerosis. One of the causes for podocytopenia is a detachment of podocytes from the glomerular basement membrane into urine. To detect urinary podocytes has a diagnostic value to predict ongoing severe podocyte injury. In this study we evaluated the usefulness of routine microscopic examination of urine as a simple method compared to the previous immunofluorescent (IF) examination.

Methods: Urine samples from patients with various glomerular diseases such as IgA nephropathy, Schoenlein Henoch purpura nephritis, lupus nephritis (N=25) were used. Urine was centrifuged at 1800 rpm for 5 minutes and the sediment was mixed with Sternheimer staining solution and examined carefully for characteristics of the cells appeared in urine sediment using conventional light microscope. For IF study urine sediment was suspended in PBS and then the cells in the sediment were trapped using BD SurePath™ Pap Test on the slide glass. The slide glass was processed to conventional IF procedure using anti-podocalyxin antibody. The cytological characteristics for podocytes was examined on the podocytes isolated from urine sediment using magnetic beads coupled with anti-podocalyxin antibody and then stained by Sternheimer solution.

Results: Cytological characteristics of urinary podocytes was as follow; 1) 15-30 um in diameter, 2) round or oval shape, 3) the margin of cells is mostly smooth, sometimes having processes, 4) the nucleus is located mostly in the center or sometimes deviated slightly, 5) often binucleated, 6) high N/C ratio, 7) large and clear nuclear staining, and 8)

violet (C30M70Y0K0 by CMYK color model) cytoplasmic color. The cells matched for all of the above criteria were regarded as podocytes and the number was counted. The time consumed for whole procedure by routine microscopic examination is within 30 minutes, although that by IF examination is about 3 hours. The number of podocytes by routine microscopic examination was well correlated with that by IF examination (Spearman, N=32, p<0.0001).

Conclusions: Routine microscopic examination of urine sediment by Sternheimer staining is very simple but reliable on identifying urinary podocytes.

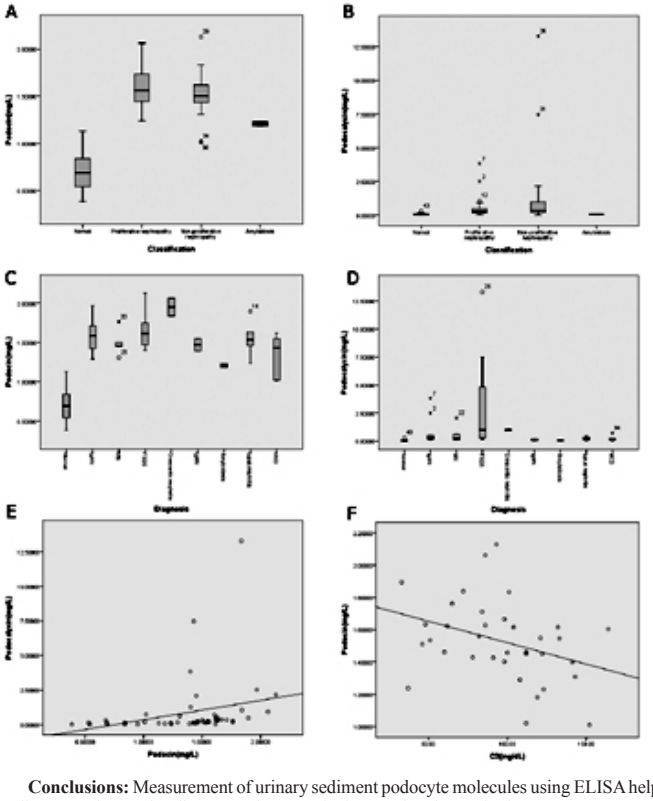
TH-PO701

ELISA Analysis of Urinary Sediment Podocin, Podocalyxin in the Patients with Different Glomerular Diseases Bin Zhu, Yi Lin, Xiaoling Zhu, Sen Zhong, Caifeng Zhu, Ying Lu. *Department of Nephrology, Hangzhou Hospital of Traditional Chinese Medicine, Zhejiang University of Chinese Medicine, Hangzhou, Zhejiang, China.*

Background: To investigate the urinary sediment podocin and podocalyxin in the patients with biopsy proven glomerulonephritis using ELISA method.

Methods: Patients with biopsy proven glomerulonephritis were enrolled for the analysis of urinary sediment podocin and podocalyxin measured using ELISA.

Results: We collected totally 40 patients (15 Males and 25 females). There were 19 proliferative glomerulonephritis cases (IgAN: 10 cases; Crescentic glomerulonephritis: 2 cases; IgMN:2 cases; Lupus nephritis IV(A/G): 5 cases);19 non-proliferative glomerulonephritis cases (MCD: 5 cases; FSGS: 8 cases; MN: 6 cases) and 2 patients with renal amyloidosis. 10 healthy persons were enrolled as the control. Results: Urinary podocin and podocalyxin in the healthy person was the lowest. There was no significant difference in the urinary podocin and podocalyxin between the proliferative glomerulonephritis group and the non-proliferative glomerulonephritis group(P>0.05). The urinary podocin and podocalyxin was increased significantly in the patients with crescentic glomerulonephritis as compared with the patients with other renal disease (podocin: P<0.05; podocalyxin: P>0.05). Then the urinary podocin was gradually decreased in the order as FSGS, IgAN, MN, Lupus nephrits, MCD, IgMN. The urinary podocalyxin was gradually decreased in the order as FSGS, IgAN, Lupus nephrits, MN, IgMN, MCD. The urinary podocin and podocalyxin in the patients with renal amyloidosis was the lowest among the patients. Urinary podocalyxin correlated positively to urinary podocin . Urinary podocin correlated negatively to serum C3.



Conclusions: Measurement of urinary sediment podocyte molecules using ELISA help to diagnose glomerular disease. Urinary podocin correlated negatively to serum C3.

Clinical Implication of Detection of Urinary Podocyte-Associated mRNA Profile in Various Stages of Diabetic Nephropathy Min Zheng, Linli Lv, Jie Ni, Kun Ling Ma, Bi-Cheng Liu. *Institute of Nephrology, Zhongda Hospital, Southeast University School of Medicine, Nanjing, Jiangsu Province, China.*

Background: Podocyte injury and subsequent excretion in urine play a crucial role in the pathogenesis and progression of diabetic nephropathy (DN). Quantification of messenger RNA (mRNA) expression in urinary sediment by real-time PCR is emerging as a noninvasive method of screening DN-associated biomarkers. We hypothesized that the urinary mRNA profile of podocyte-associated molecules may provide important clinical insight into the different stages of diabetic nephropathy.

Methods: DN patients (N=51) and healthy controls (N=13) were enrolled in this study. DN patients were divided into a normoalbuminuria group (UAE<30 mg/g, n=17), a microalbuminuria group (UAE 30~300 mg/g, n=15), and a macroalbuminuria group (UAE>300 mg/g, n=19), according to their urinary albumin excretion (UAE). Urinary cell pellet was collected from each study participant. Total RNA was extracted and cDNA was synthetized. Relative mRNA abundance of synaptopodin, podocalyxin, CD2-AP, α-actin4, and podocin were quantified by real-time PCR technology, and correlations between target mRNAs and clinical parameters were examined.

Results: The urinary mRNA levels of all genes studied were significantly higher in the DN group compared with controls (p<0.05), and mRNA levels increased with DN progression. Urinary mRNA levels of all target genes positively correlated with both UAE and BUN. The expression of podocalyxin, CD2-AP, α-actin4, and podocin mRNA correlated with serum creatinine (r=0.457, p=0.001; r=0.329, p=0.01; r=0.286, p=0.021; r=0.357, p=0.006, respectively). Furthermore, podocalyxin mRNA was found to negatively correlate with eGFR (r=-0.349, p=0.01). The ROC curve analysis shown that all target genes were effectively able to discriminate between DN patients and normal controls, with an AUC above 0.5.

Conclusions: The urinary mRNA profiles of synaptopodin, podocalyxin, CD2-AP, α-actin4, and podocin were found to increase with the progression of DN, which suggested that quantification of podocyte-associated molecules will be useful biomarkers of DN.

Lectin Microarrays of Intact Urinary Exosomes Indicate Distinct Glycosylation Profiles Jared Q. Gerlach,[1] Anja Krüger,[1] Shirley Hanley,[1] Susan Gallogly,[1] Marie C. Hogan,[2] Christopher James Ward,[2] Lokesh Joshi,[1] Matthew D. Griffin.[1] *[1]Regenerative Medicine Institute (REMEDI) and Glycoscience Group, National Centre for Biomedical Engineering Science, National University of Ireland, Galway, Ireland; [2]Dept. of Medicine, Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Urine exosome-like vesicles (ELVs) contain many nephron-derived glycoproteins but characterization of their surface glycosylation is limited and may be compounded by Tamm-Horsfall protein (THP) contamination. Intact ELVs and purified THP were profiled by lectin microarray and flow cytometry (FCM) to compare and contrast their glycosylation profiles.

Methods: 43 lectins were spot-printed on Nexterion® hydrogel slides. ELVs, isolated from healthy adult urine by ultracentrifugation (UC) or ultrafiltration (UF) were labeled with lipophilic dyes (CM-DiI, PKH26), incubated with lectin arrays and laser-scanned at 5μm resolution with fluorescence intensities generated for each lectin. Specificity was determined based on ≥50% inhibition with haptenic sugars. For FCM, ELVs were adsorbed to 4μm latex beads then incubated with biotinylated lectins and fluorochrome-labeled streptavidin prior to analysis on a FACSCanto® cytometer. Identical protocols were applied to AF647®-labeled THP.

Results: *N*-acetyl-glucosamine-binding lectins (LEL, WGA) had the highest fluorescence intensities with ELVs on microarrays and FCM suggesting high *N*-linked surface glycosylation. The α-fucose-specific lectin UEA-I exhibited negative or minimal binding to ELVs in either format. The galactose/*N*-acetyl-galactosamine-binding lectin SNA-II and the sialic acid-binding lectin SNA-I also bound ELVs on arrays, suggesting *O*-linked modifications and α2-6-linked terminal sialic acid, respectively. UC- and UF-prepared ELVs had closely comparable array profiles. THP and ELV profiles were similar but with distinct differences in relative intensities, e.g. β-galactose-binding lectin ABL (THP higher) and SNA-II (ELVs higher).

Conclusions: Microarrays and FCM allow rapid, ELV-specific glycosylation profiling, providing a basis to screen for protein glycosylation abnormalities in kidney disease and to facilitate urine ELV isolation.

TH-PO704

Refinement and Technical Validation of Assay for Urinary microRNAs Taro Horino, Takayuki Tsuji, Robert A. Star, Peter S.T. Yuen. *NIDDK, NIH, Bethesda, MD.*

Background: We previously showed that miRNAs in the urine exosomal fraction are biomarkers for acute and chronic kidney disease, but our assay required large 4 ml samples. Non-exosomal urinary miRNAs from glomerular filtration, tubular secretion, and/or cell death, are also potential biomarkers. Therefore, we developed a more sensitive purification/assay system, then measured and validated the distribution of miR27b in different fractions of normal urine.

Methods: We centrifuged healthy human or rat urine at 17,000 x g for 15 min, retained the 17k pellet, then ultracentrifuged the 17k supernatant at 200,000 x g for 1 h to obtain the exosomal fraction (200k pellet). We purified miRNA by Qiagen miRNeasy kit or TRIzol/miRNeasy. We measured miR27b or miR192 concentration by Taqman (RT-PCR) using synthetic mature miRNA (Dharmacon) standards. We validated assays by the Standard Addition Method (SAM; add 4 known increasing amounts of synthetic miRNA to an unknown sample, then extrapolate back to 0 addition).

Results: We readily detected miR27b in 100 µl of normal rat urine (30 amol/ml, validated by SAM). 20% of miR27b from normal rat urine was in the 17k pellet and 10% in the 200k pellet by direct measurement or SAM. The 200k supernatant contained 70% (direct measurement) or 60% (SAM) of urine miR27b. In contrast, human urine 200k sup (but not the exosomal fraction) contained an endogenous inhibitor which caused the assay to underestimate [miR27b]. Recovery of pure miR27b purified by miRNeasy or TRIzol/miRNeasy was 70% and 80%, respectively; this recovery was inhibited 29% by 5 µl of human urine (n=4 $p<0.05$). EDTA treatment, gel filtration, or dialysis could not remove the endogenous inhibitor.

Conclusions: We developed and validated a sensitive assay for urinary miRNAs that needs only 100 µl of urine. A lower volume requirement will allow miRNA measurements on archived samples. Urinary miR27b was mainly in the 200k supernatant in normal rats. The distribution in normal human urine could not be accurately determined due to endogenous inhibitory activity. Unless the inhibitor(s) can be removed, the Standard Addition Method may be needed to accurately assay miRNAs in unfractionated human urine or non-exosomal human urine fractions.

TH-PO705

Ultrastructural Pathology in IgG4-Related Kidney Disease Shinichi Nishi,[1] Hideki Fujii,[1] Yoko Takeda,[1] Keiji Kono,[1] Kentaro Nakai,[1] Shunsuke Goto,[1] Takako Saeki.[2] *[1]Divsioni of Nephrology and Kidney Center, Kobe University Graduate School of Medicine, Kobe, Hyogo, Japan; [2]Department of Internal Medicine, Nagaoka Red Cross Hospital, Nagaoka, Niigata, Japan.*

Background: Autoimmune or allergic disorders were suspected to be pathogenic mechanisms of IgG4-related kidney disease (IgG4KD) characterized by tubulointerstitial nephritis (TIN). In order to explore pathogenic mechanisms we evaluated the distribution of electron-dense deposits (EDDs) in the interstitium and glomeruli in seven cases with IgG4KD.

Methods: Subjective seven cases were diagnosed according to the criteria of IgG4KD working group in the Japanese Society of Nephrology. Routine light, immunofluorescene and electron microscopy, as well as immunohistochemical and indirect immunofluorescence studies for IgG subclasses were performed. A clinicopathological study was conducted in all the cases.

Results: The distribution of the EDDs was variable, with incidence of deposition being highest in the mesangium (71.4%) and tubular basement membrane (85.7%). EDDs were also observed in the interstitium between collagen fibres, with the deposition rate being 71.4%. Some cases showed no immunological abnormalities, hypocomplementaemia or positive anti-nuclear antibody, but showed EDDs in their kidney. The histochemical and immunohistochemical studies for IgG4 did not indicate that the EDDs were immune complexes containing IgG4.

table1. Distribution of EDDs and serological abnormality

	Subepithelial space	Mesangium	Bwoman's capsule	TBM	Interstitium	Low complement	ANF positive
case 1	0	0	0	0	+	+	+
case 2	2+	0	0	+	+	+	0
case 3	0	+	+	+	+	+	+
case 4	0	+	+	+	+	+	+
case 5	+	+	0	+	0	0	ND
case 6	+	+	0	+	0	+	+
case 7	2+	+	+	+	+	0	0
rate of EDDs	57.1%	71.4%	42.9%	85.7%	71.4%		

ANF: anti-nuclear factor, ND: not detected

Conclusions: Although EDDs were found frequently in the interstitium and glomeruli of cases with IgG4KD, they appear to develop independently of autoimmune or allergic disorders. Further investigation is essential to determine the mechanism responsible for the development of IgG4KD from both immunological and pathological points of view.

TH-PO706

A Novel Case of Nephrotic Syndrome Caused by Immune-Mediated Severe LCAT Deficiency Satoshi Takahashi,[1] Keiju Hiromura,[1] Mayuko Tsukida,[1] Yuko Ohishi,[1] Hiroko Hamatani,[1] Noriyuki Sakurai,[1] Toru Sakairi,[1] Hidekazu Ikeuchi,[1] Akito Maeshima,[1] Takashi Kuroiwa,[1] Michio Nagata,[2] Yoshihisa Nojima.[1] *[1]Department of Medicine and Clinical Science, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan; [2]Department of Pathology, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan.*

Background: Lecithin-cholesterol acyltransferase (LCAT) is a key enzyme in maintaining cholesterol homeostasis. In familial LCAT deficiency (FLD), abnormal lipid deposition causes renal injury and nephrotic syndrome, frequently leading to end-stage renal disease. We found a case of nephrotic syndrome due to acquired LCAT deficiency and examined the mechanism of inhibition of LCAT activity.

Methods: [Case report] A 63-year-old Japanese woman was admitted to our hospital because of edema. Laboratory data revealed U-Pro 4.1 g/day, Alb 2.5 g/dL, S-Cr 0.58 mg/dL, HDL-Chol 2 mg/dL, LDL 51 mg/dL and LCAT activity <50 U. A renal biopsy specimen showed that marked accumulation of foam cells and lipid deposits in most glomeruli, together with depositions of immune complexes along the capillary wall. By the steroid treatment, LCAT activity and urinary protein level returned to normal within 2 month. The re-biopsy specimen at 5 month after the initiation of treatment showed disappearance of foam cells and marked reduction of lipid deposits and immune complexes.

Results: The mixing test with the patient's serum and healthy control serum revealed the existence of an inhibitory factor to LCAT activity in the patient serum. The purified IgG fraction from the patient's serum also suppressed LCAT activity of normal serum. Co-immunoprecipitation study showed that protein G beads preincubated with the patient's serum could capture LCAT of healthy control serum, demonstrating that the patient's serum contained an antibody against LCAT.

Conclusions: This is the first report to describe the patient with an inhibitory anti-LCAT antibody and glomerular lesions comparable to those of FLD. This case would be important in considering the pathogenesis of glomerular lipid depositions and the possibility of treatment of renal injury in FLD with enzyme replacement therapy.

TH-PO707

Renal Monoclonal Immunoglobulin Deposition Disease: A Report of 64 Cases from a Single institution Samih H. Nasr,[1] Anthony M. Valeri,[2] Lynn D. Cornell,[1] Mary E. Fidler,[1] Sanjeev Sethi,[1] Nelson Leung.[3] *[1]Pathology, Mayo Clinic, Rochester, MN; [2]Nephrology, Columbia University, New York, NY; [3]Nephrology, Mayo Clinic, Rochester, MN.*

Background: Monoclonal immunoglobulin deposition disease (MIDD) is a rare dysproteinemia-related renal disease. In order to better define the disease's clinical-pathologic spectrum and prognosis, we report the largest single-center series.

Methods: The characteristics of 64 MIDD patients who were seen at Mayo Clinic, Rochester, between 1992-2011, are provided.

Results: The 64 cases of MIDD included 51 cases of light chain deposition disease (LCDD)(kappa in 84% and lambda in 16%), 7 cases of heavy chain deposition disease (HCDD)(gamma in 6 and alpha in 1), and 6 cases of light and heavy chain deposition disease (LHCDD)(IgG kappa in 4, IgA kappa in 1, IgA lambda in 1). The mean age at diagnosis was 56 yrs and 36% of patients were ≤50 yrs. The M:F ratio was 1.9:1. Clinical evidence of dysproteinemia was present in 97% of patients including overt MM in 59%. M-spike was detected on SPEP in 73% and on UPEP in 81%. Serum free light chain (FLC) ratio was abnormal in all 51 patients (100%) tested. Presentation included renal insufficiency (97%), proteinuria (97%), hematuria (62%), and hypertension (83%). Nephrotic-range proteinuria and nephrotic syndrome (NS) were more common in HCDD than LCDD. By definition, all cases showed diffuse linear monoclonal protein deposition along GBMs and TBMs on IF with corresponding punctate electron dense deposits on EM. Nodular mesangial sclerosis was seen in 61% of cases. During an average of 34 mos of follow-up, 57% had stable/improved renal function, 4% had worsening renal function and 39% progressed to ESRD. The mean renal survival was 64 mos while the mean patient survival was 90 mos. Independent predictors of renal and patient survivals were creatinine at biopsy and the presence of lytic bone lesions, respectively.

Conclusions: Serum FLC ratio is abnormal in all MIDD patients. Nodular sclerosing glomerulopathy is present in most but not all cases. NS is more common in HCDD than LCDD. The prognosis for MIDD is improving. The degree of renal impairment at diagnosis is a predictor of renal survival.

TH-PO708

Myeloproliferative Neoplasm-Related Glomerulopathy Samar M. Said,[1] Nelson Leung,[2] Sandra Herrmann,[2] Sanjeev Sethi,[1] Lynn D. Cornell,[1] Mary E. Fidler,[1] Joseph P. Grande,[1] Vivette D. D'Agati,[3] Samih H. Nasr.[1] *[1]Pathology, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic, Rochester, MN; [3]Pathology, Columbia University, New York, NY.*

Background: Myeloproliferative neoplasms (MPN) are clonal hematopoietic stem cell disorders affecting the erythroid, granulocytic and megakaryocytic lineages. The characteristics of MPN-related glomerulopathy are undefined.

Methods: We evaluated the features of 11 patients with MPN-related glomerulopathy who were identified by searching our nephropathology laboratory archives from 2000-2010.

Results: There were 8 men and 3 women with a mean age of 73 yr (range 60-87 yr) at biopsy. The type of MPN was primary myelofibrosis in 8 patients, chronic myelogenous leukemia in 1, polycythemia vera in 1 and essential thrombocythemia in 1. Indications for biopsy were nephrotic-range proteinuria (mean 6.8 g/day) and chronic renal insufficiency (mean creatinine 2.5 mg/dl). Nephrotic syndrome, hypoalbuminemia, edema, and hematuria were present in 4, 9, 6, and 3 patients, respectively. The mean time from diagnosis of MPN to biopsy was 7.2 yrs (range 1-17 yrs). Histologically, mesangial sclerosis and hypercellularity were seen in all 11 cases, segmental sclerosis in 8, features of chronic thrombotic microangiopathy (TMA) in 9, and intracapillary infiltrating hematopoietic cells in 4. On follow-up, 4 progressed to ESRD and the remaining 7 had persistent renal dysfunction, despite the individualized institution of RAS blockade, immunosuppression and treatment directed to the hematologic disorder.

Conclusions: We describe a novel and under-recognized form of glomerulopathy associated with MPN that enlarges the spectrum of glomerular diseases associated with hematologic neoplasms. MPN-related glomerulopathy appears to be a late complication of MPN, particularly primary myelofibrosis. It is characterized clinically by heavy proteinuria and renal insufficiency and histologically by variable degrees of mesangial sclerosis and hypercellularity, segmental sclerosis, TMA, and intracapillary hematopoietic cells.

Prognosis is guarded. Greater awareness of this entity and larger studies are needed to define the optimal therapy.

TH-PO709

Association of Pathological Features of Renal Biopsies with Clinical Manifestations in Patients with Immunoglobulin Light Chain Amyloidosis – An Analysis of 170 Cases in a Chinese Centre Ying Yao, Su-Xia Wang, Youkang Zhang. *Department of Nephrology, Peking University First Hospital, Beijing, China.*

Background: This study aimed to investigate the association of pathological features of renal biopsies with clinical manifestations in patients with AL.

Methods: All patients with biopsy-proven renal amyloidosis were collected from our institute during 1988 and 2010(n=194). Immunohistochemistry with a panel of antibodies against Ig κ and λ light chains, AA protein, transthyretin, lysozyme, apolipoprotein A-I, and fibrinogen were performed on paraffin sections of renal biopsy. The severity of amyloid deposition in glomeruli, vessels and tubulointerstitium)were scored according to the histopathologic grading system proposed by Sait S(*Arch Pathol Lab Med.* 2010;134:532–544).

Results: AL was diagnosed in 170 cases (accounted for 87.6% of renal amyloidosis), with a ratio of λ light chain in 87%. The others included 1 case of secondary amyloidosis and fibrinogen Aα-chain amyloidosis respectively, 22 cases unclassified. In AL patients, the mean age was 56.8 years (range 26-83 years) with 108(63.5%) males. Multiple myeloma was diagnosed in 12 cases; M protein was detected in 74.3% (55/74) patients by serum or urine IFE. The level of urine protein and incidence of renal insufficiency was significantly higher in patients with diffuse marked glomerular deposition (score 5) than in patients with lesser score(p=0.004, 0.000). Patients with marked vascular amyloid deposition (score 4) or overt interstitial amyloid deposition(score≥2) had a significant higher incidence of liver involvement than that with lesser scores(p=0.048, 0.014). Patients with coexistence of amyloid and immune complexes had a higher level of proteinuria (8.46 vs 5.68 g/24h, P=0.001). Patients with AL-κ showed a higher frequency of liver involvement and marked vascular amyloid deposition than AL-λ(p=0.001, 0.006).

Conclusions: AL is the predominant pattern of renal amyloidosis in China. Diffuse marked glomerular amyloid deposition and coexistence with immune complexes were related with higher degree of proteinuria. Patients with AL-κ were more likely to have liver involvement and pervasive vascular amyloid deposition.

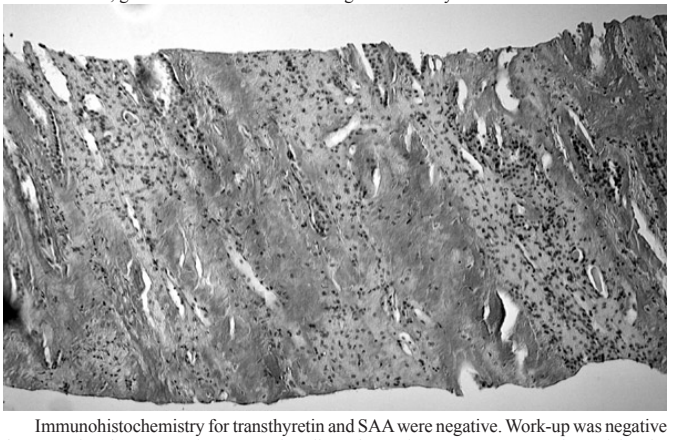
TH-PO710

Medullary Amyloidosis Associated with Apolipoprotein A-IV Sanjeev Sethi,[1] Jason David Theis,[1] Michelle Shiller,[1] Cynthia C. Nast,[2] Julie A. Vrana,[1] Ahmet Dogan.[1] *[1]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; [2]Pathology, Cedars Sinai Hospital, Los Angeles.*

Background: Hereditary and familial forms of amyloidosis include transthyretin, fibrinogen A-a, lysozyme, gelsolin, apolipoprotein A-I and A-II associated amyloidosis. We describe a novel amyloidosis limited to the renal medulla.

Methods: A 52-year old man presented with 10-year history of increased urinary frequency, no significant proteinuria andgradual loss of renal function. There was no family history of renal disease. Serum creatinine had gradually risen to1.97 mg/dL with an eGFR of 33 ml/min.

Results: Renal biopsy showed large amounts of Congo red-positive amyloid restricted to the medulla; glomeruli and vessels were negative for amyloid.



Immunohistochemistry for transthyretin and SAA were negative. Work-up was negative for monoclonal gammopathy. Laser microdissection and mass spectrometry showed that the amyloid was composed of large amounts of apolipoprotein A-IV. MS/MS showed 100, 96 and 73 spectra in 3 microdissected samples that matched to apolipoprotein A-IV.

LC-MS/MS proteomic data by spectra from three samples prepared from 3 separate LMD of Congo red positive medullary tissue

Apolipoprotein A-IV	100	96	73
Apolipoprotein E	61	47	45
Serum Amyloid Protein	16	16	20
Ig gamma 1	11	9	9
Apolipoprotein A- I	4	7	4
Ig gamma 2	9	7	7

Genetic analyses detected 3 sequence variants which appeared to be common polymorphisms in the apolipoprotein A-IV gene. The following three sequence variants of Apolipoprotein A-IV gene were detected: c.548G>A, p.T29T (Thr29Thr); c. 1678G>A, p.S147N (Ser147Asn); and c.2378G>T, p.Q380H (Gln380His).

Conclusions: This is the first report of renal amyloidosis associated with apolipoprotein A-IV deposition, and renal involvement appears to be restricted to the medulla. The diagnosis may be missed if the renal biopsy consists of only renal cortex.

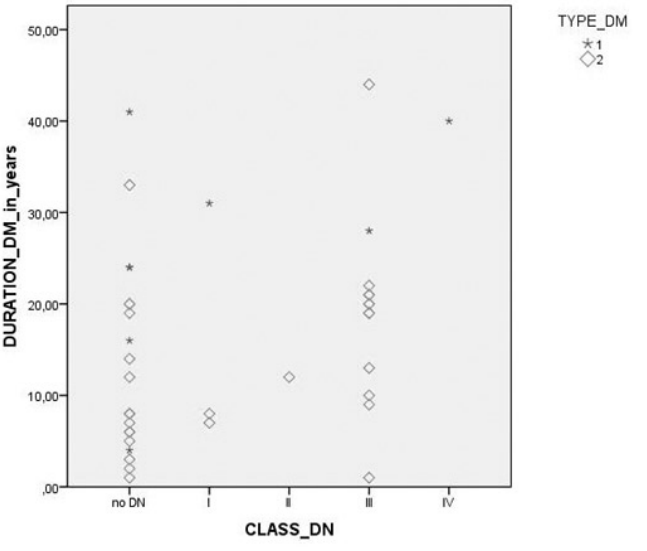
TH-PO711

Duration of Diabetes Mellitus Type 1 and Type 2 Correlates with Succeeding Stages I through IV of Diabetic Nephropathy: An Autopsy Study Elisabeth J. Valk, Hans J. Baelde, Jan A. Bruijn, Ingeborg M. Bajema. *Pathology, Leiden University Medical Center, Leiden, Netherlands.*

Background: The new pathologic classification of diabetic nephropathy (DN) classifies DN into 4 groups, but it is unknown whether these represent progression from group I through IV in the course of the disease. We examined the relationship between duration of diabetes mellitus (DM) type 1 and type 2 and occurrence of DN and its allocation to the classes of the classification of DN (JASN 2010, 21:556-563).

Methods: We retrieved clinical data and paraffin embedded renal slides at autopsy from the archives of the LUMC of 31 patients with DM type 1 and type 2, from 1984 to 2004. Presence of DM was the main inclusion criterion. Patients with more than 15 years DM duration of whom autopsy materials showed no signs of DN were excluded. We also excluded patients with a combined pancreas and renal transplantation. There was 1 patient of whom a previous renal biopsy was available. In case of histologically proven DN, the lesions were scored as consistent with class I through IV.

Results: There were 4 patients with DM type 1 and 27 with DM type 2. 18/31 patients had histologically proven DN (3 patients type 1 DM and 15 patients type 2 DM). Figure 1 shows the distribution among classes according to duration of diabetes. There was a positive significant correlation ($r = 0.688$; $p < 0.001$) between duration of DM and the different groups of DN. Type 2 DM patients contributed mostly to this correlation (for this group, $r = 0.669$; $p < 0.001$). The renal biopsy that was available was performed 5 weeks before death and no transition of classes was shown.



Conclusions: Our preliminary results show that in the combined patient groups of type 1 and type 2 DM, there is a significant association between the duration of diabetes and DN class, which suggests that the histopathological classes indeed represent continuous stages of DN.

TH-PO712

The Pathologic Classification of Diabetic Nephropathy Is Correlated with the Clinical Characteristics of Diabetes Mellitus Fumihiko Yasuda,[1] Emiko Fujita,[1] Akiko Mii,[1] Megumi Fukui,[1] Yukinari Masuda,[2] Akira Shimizu.[2] *[1]Internal Medicine (Division of Neurology, Nephrology, and Rheumatology), Nippon Medical School, Tokyo, Japan; [2]Pathology, Nippon Medical School, Tokyo, Japan.*

Background: Nephrotic syndrome (NS) is a common complication of diabetic nephropathy (DN) . Recently, the renal pathology society (RPS) proposed the pathologic classification of DN (J Am Soc Nephrol 21: 556-563, 2010). In the present study, we examined the pathologic characteristics of DN cases with NS, using the RPS pathologic classification.

Methods: We selected renal biopsy cases of DM (n=62) , and assessed the clinical characteristics, focusing on the proteinuria, clinical stages of DM, and stages of chronic kidney disease (CKD). The renal biopsy was classified using the RPS pathologic classification of DN, and pathologic characteristics were correlated with clinical stages of DM, CKD stages, and proteinuria.

Results: We divided DM cases into 2 groups; DM with NS (n=31) and DM without NS (n=31). In clinical and pathologic characteristics of DM with NS group had tendency of high serum Cr (2.2±1.7 vs 1.5±1.1 mg/dl), low eGFR (36.3±21.9 vs 54.3±27.8 ml/min/1.73m2), high CKD stage, and high grade of pathologic classification than those of DN without NS. In the cases with pathologic class II (mesangial expansion), proteinuria was low levels, but the NS developed, accompanying with the long term DM history or non-DM glomerular disease, including membranous nephropathy. In the cases with pathologic class III (nodular glomerulosclerosis), the NS occurred together with the development of frequent nodular lesions. Importantly, the degree of pathologic classes was significantly correlated with the degree of clinical stages of DM (r=0.308, p<0.05), CKD stages (r=0.306, p<0.05), and levels of proteinuria (r=0.275, p<0.05).

Conclusions: In DM cases with NS, DN was characterized by the development of nodular glomerular sclerosis (Class III) with high clinical stages of DM and CKD stages. The pathologic class II cases with NS had a complication of non-DM glomerular diseases or a long term DM history. Importantly, the RPS pathologic classification of DN was correlated with the clinical characteristics of DM.

Implication of Urinary KIM-1 mRNA Detection in Patients with Diabetic Nephropathy Linli Lv, Min Zheng, Min Wu, Kun Ling Ma, Bi-Cheng Liu. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicime, Nanjing, Jiangsu Province.*

Background: Tubular injury has been found as an important early feature of diabetic nephropathy (DN) in addition to glomerulopathy, while it is still difficult to be early evaluated. The aim of this study was to investigate the role of KIM-1 mRNA expression in the urinary sediment for evaluating the progression of DN.

Methods: A total of 46 patients with DN and 14 healthy controls were studied. To evaluate progression of DN, patients were divided into groups based on the degree of albuminuria: Normoalbuminuria (UAE<30 mg/g, n=20), microalbuminuria (UAE 30~300 mg/g, n=11), and macroalbuminuria group (UAE>300 mg/g, n=15). Clinical data including albuminuria, blood urea nitrogen (BUN), and serum creatinine were recorded at baseline for each of the groups. Urinary KIM-1 mRNA expression was measured, and correlations with renal functional parameters were investigated.

Results: Urinary KIM-1 mRNA was significantly increased in patients with DN compared with healthy controls (p=0.006). Overall comparison showed that KIM-1 mRNA increased with increasing levels of albuminuria. It was the lowest in the control group, increased in the normoalbuminuria, microalbuminuria group, and was the highest in the macroalbuminuria group. KIM-1 mRNA strongly correlated with serum creatinine (r=0.459, P <0.001), BUN(r=0.478, p<0.001), and eGFR (r=-0.433, p=0.001). Moreover, KIM-1 mRNA was significantly higher in microalbuminuria group compared with normal control. Urinary KIM-1 mRNA could separate patients with DN from normal controls with AUC of 0.7430.743(p=0.006, 95% confidence interval (CI), 0.620-0.866). At the threshold that gave the maximal sensitivity and specificity for KIM-1 mRNA was 52.2 percent and the 100 percent (P<0.001) respectively.

Conclusions: The mRNA expression of KIM-1 in urinary sediment may reflect tubular damage in early diabetic nephropathy. KIM-1 mRNA could reflect the disease severity and be a novel biomarker for early detection of DN.

Dysregulated Balance of Th17 and Th1 Cells in Type 2 DM with Diabetic Nephropathy Young-Il Jo,[1] SolAh Park,[2] Eun Hye Seo,[1] Bokung Kim,[3] Seunghyun Lee.[2] *[1]Nephrology, Konkuk University Hospital, Seoul, Republic of Korea; [2]Department of Microbiology, Konkuk University School of Medicine, Seoul, Republic of Korea; [3]Department of Physiology and Biotechnology, Konkuk University School of Medicine, Seoul, Republic of Korea.*

Background: The etiological cause of diabetic nephropathy has yet not to be clarified. Recent evidences indicate that immune related factors may contribute to pathogenesis of type 2 DM (T2DM) with nephropathy and Th17 cells play an important role in the immunopathogenesis of autoimmune tissue inflammation. This research was designed to assess the frequency of Th17 and Th1 cells and the balance between Th17 and Th1 cells in T2DM patients with diabetic chronic kidney disease (CKD).

Methods: Thirty-eight T2DM patients with diabetic CKD, 9 T2DM patients without nephropathy, 11 non-diabetic CKD and 17 healthy controls were recruited. Peripheral blood mononuclear cells were collected and stimulated with phorbol myristate acetate and inomycin. The frequency of Th17 cells producing IL-17 and Th1 cells producing IFN-γ was measured by using flow cytometry. Expression of Th17-associated chemokine receptors CCR4 and CCR6 on $CD4^+$ T cells were assessed.

Results: T2DM patients with diabetic CKD had an increased frequency of Th17 cells compared with other groups, whereas for the frequency of Th1 cells, there was no difference between all groups, indicating an altered balance of Th17 and Th1 cell responses in T2DM with diabetic CKD. In patients with diabetic nephropathy, the frequency of Th17 cell increased only those with eGFR 60-120 ml/min/1.73m^2 but not healthy controls and T2DM patients without nephropathy. In addition, the frequency of Th17 cells in diabetic nephropathy showed a decreasing tendency with decreased eGFR. However, compared to T2DM patients with diabetic CKD, subjects with non-diabetic CKD did not reveal difference according to eGFR. In T2DM with diabetic CKD, the ratio of Th1-to-Th17 cells showed an opposite tendency with the frequency of Th17 cells: the ratio of Th1-to-Th17 cells an increasing tendency with decreased eGFR.

Conclusions: These results suggest that the dysregulated balance of Th17 and Th1 cells may play an role in the pathogenesis of T2DM with nephropathy.

TH-PO715

H,K-ATPases Participate in Mineralocorticoid-Induced Hypertension I. Jeanette Lynch,[1,2] Megan Greenlee,[1,2] Michelle L. Gumz,[1,2] Charles S. Wingo.[1,2] *[1]Division of Nephrology, University of Florida, Gainesville, FL; [2]Nephrology Section, Dept of Veteran Affairs, Gainesville, FL.*

Background: We have previously shown that in response to eight days of desoxycorticosterone pivalate (DOCP) treatment wild type (WT) mice develop a hypochloremic metabolic alkalosis and this response is abolished in $HK\alpha_1$ and $HK\alpha_2$ double null ($HK\alpha_{1,2}^{-/-}$) mice (Greenlee *et al.* JASN 22:49-58, 2011). Additionally, metabolic balance studies showed that this DOCP treatment caused significant Na retention in WT mice, but not in $HK\alpha_{1,2}^{-/-}$ mice. Thus, we hypothesized that renal H,K-ATPases are required for maximal DOCP mediated Na reabsorption and an increase in systemic arterial blood pressure (BP). Furthermore, we asked whether $HK\alpha_{1,2}^{-/-}$ mice had altered protein abundance for the α subunit for the epithelial Na channel (ENaC).

Methods: Age matched WT and $HK\alpha_{1,2}^{-/-}$ male mice were studied in three separate experiments: 1) ENaC subunit mRNA and protein expression levels were evaluated in kidneys from WT and $HK\alpha_{1,2}^{-/-}$ mice; 2) food and water intake, body weight, and urinary aldosterone levels were measured in *ad libitum* or pair fed mice of both genotypes; 3) BP, heart rate (HR) and locomotor activity were measured in WT and $HK\alpha_{1,2}^{-/-}$ mice in control and DOCP-stimulated conditions using radiotelemetry.

Results: We observed that: 1) renal medullary αENaC protein expression was reduced by 45% in $HK\alpha_{1,2}^{-/-}$ mice versus WT; 2) $HK\alpha_{1,2}^{-/-}$ mice consumed more food per body weight and had greater urinary output than WT; 3) pair feeding caused substantial weight loss and increased urinary aldosterone in $HK\alpha_{1,2}^{-/-}$ but not WT mice; 4) whereas two month survival was 100% in DOCP-treated WT mice (N=9/9), it was 43% in DOCP-treated $HK\alpha_{1,2}^{-/-}$ mice (N=3/7); 5) $HK\alpha_{1,2}^{-/-}$ mice had significantly greater (~10%) HR and reduced locomotor activity; 6) DOCP-treatment significantly increased BP in WT mice during the active phase but there was no significant increase in BP in the $HK\alpha_{1,2}^{-/-}$ mice during this time period.

Conclusions: These data strongly support a role for H,K-ATPases in sodium conservation and suggest that the H,K-ATPases are involved in the action of mineralocorticoids to increase systemic arterial blood pressure.

TH-PO716

Dysfunction of Gap Junctions Stimulates COX-2 Expression in Juxtaglomerular Renin-Secreting Cells Jian Yao, Ying Zhu, Masanori Kitamura. *Department of Molecular Signaling, University of Yamanashi, Chuo, Yamanashi, Japan.*

Background: Gap junctions (GJs), formed by the specific proteins called connexin (Cx), play an important role in the control of juxtaglomerular (JG) functions. Mice lacking Cx40 or Cx45 have been shown to have markedly elevated levels of COX-2 in JG cells and develop renin-dependent hypertension. At present, the mechanisms involved are unclear. It is thought to be related to the disruption of GJ-mediated renin-suppressive signals from the neighboring cells. Besides communication-dependent actions, GJs also regulate cell phenotypes through communication-independent way. We, therefore, asked whether COX-2 expression in renin-secreting cells could be directly affected by dysfunction of GJs.

Methods: Renin-secreting As4.1 cells were cultured and assay for GJ protein expression and funciton by immunofluorescent staining, Western blot analysis, and diffusion of Lucifer yellow (LY) after single cell injection. The expression of COX-2 and other related signaling molecules were detected by Western blot analysis.

Results: 1) Renin-secreting As4.1 cells were characterized to express Cx43 and Cx45 and have functional gap junctional intercellular communication (GJIC). 2) Incubation of As4.1 cells with GJ inhibitor α-glycyrrhetinic acid (α-GA) resulted in a time- and concentration-dependent inhibition of GJIC and suppression of phosphorylated levels of Cx43, which was associated with markedly elevated levels of COX-2. 3) This effect of α-GA on COX-2 was mimicked by two active structural analogues carbenoxolone and β-glycyrrhetinic acid that can disrupt GJIC, but not inactive analogue glycyrrhizic acid that cannot disrupt GJIC. In addition, it was also achieved by structurally different GJ inhibitor lindane. 3) α-GA caused a time- and concentration-dependent activation of AKT and MAPK. Suppression of these kinases with specific inhibitors largely abolished its COX-2-elevating effect.

Conclusions: Taken together, our study indicates that dysfunction of GJs in JG renin-secreting cells elevates COX-2 expression. GJs could directly influence renin synthesis and secretion through modulation of COX-2 in a communication-independent way.

TH-PO717

Interleukin-1β Regulates Renin Expression in the Renal Cortex Independently of Cyclo-Oxygenase-2 Erika I. Boesen, David M. Pollock. *Georgia Health Sciences University, Augusta, GA.*

Background: The proinflammatory cytokine interleukin-1β (IL-1β) is produced by a number of cell types within the kidney during health and disease, however its impact on renal function is incompletely understood. Cyclo-oxygenase-2 (COX-2), which is upregulated by IL-1β, is an important regulator of renin production. We therefore hypothesized that IL-1β regulates renin expression in the renal cortex.

Methods: Ren1 and COX-2 gene expression in renal cortical tissue was assessed by quantitative RT-PCR following 14-day treatment of male Sprague-Dawley rats with recombinant human IL-1 receptor antagonist (IL-1Ra; 2 mg/kg/d s.c.) or of male C57BL/6 mice with IL-1β (10 ng/h s.c.) or their respective vehicles. The role of COX-2 in IL-1β-induced Ren1 expression was more directly tested by co-treatment of mice with the selective COX-2 inhibitor celecoxib.

Results: After treatment of rats with IL-1Ra for 14 days s.c. (n = 8), renal cortical Ren1 mRNA expression was significantly reduced by 39% compared to vehicle-treated rats (n = 7; 2-ΔΔCT of 0.63 ± 0.1 vs 1.0 ± 0.1 respectively, $P < 0.01$) and COX-2 mRNA expression was reduced by 52% (2-ΔΔCT of 0.5 ± 0.1 vs 1.2 ± 0.3, $P < 0.05$). There were no significant differences in renal cortical IL-1β protein levels (6.2 ± 2.1 vs 7.0 ± 1.6 pg/mg total protein; ELISA), mean arterial pressure (111 ± 2 vs 114 ± 2 mmHg; telemetry) or sodium intake (2.8 ± 0.2 vs 2.8 ± 1.0 mmol/d) between vehicle and IL-1Ra-treated rats. In mice, infusion of IL-1β (10 ng/h; n = 7) s.c. for 14 days produced significant ($P < 0.05$) increases in both renal cortical Ren1 (2-ΔΔCT of 2.0 ± 0.5) and COX-2 mRNA (3.7 ± 0.5) compared to vehicle-treated mice (n=6; 2-ΔΔCT of 1.0 ± 0.1 and 1.1 ± 0.2 respectively). In separate groups of IL-1β-infused mice, inhibition of COX-2 with celecoxib (30 mg/kg/d p.o.) did not reduce renal cortical Ren1 mRNA levels (2-ΔΔCT of 1.0 ± 0.1 vs 1.0 ± 0.2 in IL-1β-infused mice not receiving celecoxib; n = 3-4).

Conclusions: Our data indicate that IL-1β stimulates renin expression independently of its effects on COX-2 expression.

Effects of Chronic Direct Renin Inhibition on Urine Levels of Renin, Soluble Prorenin Receptor, and Ang II in Cyp1a1-Ren2 Transgenic Rats with Ang II-Dependent Malignant Hypertension Minolfa C. Prieto, Catherine Howard, Gregory Shamitko, Dale M. Seth, Kenneth D. Mitchell. *Physiology and Hypertension and Renal Center of Excellence, School of Medicine, Tulane University Health Sciences Center, New Orleans, LA.*

Background: Cyp1a1Ren2 transgenic rats [TGR(Cyp1a1Ren2)] with malignant hypertension exhibit augmented expression of renin, prorenin receptor (PRR), and the soluble form of this receptor (sPRR) in the renal medulla, suggesting that exacerbation of these RAS components may be a leading mechanism for intrarenal Ang II generation in this model. However, the effects of direct renin inhibition on these RAS components and urinary levels of Ang II have not been established.

Methods: In this study we determined the effects of chronic direct renin inhibition with Aliskiren (60 mg/kg/d for 10 d) on renin, PRR, sPRR, and Ang II content in the urine of Cyp1a1Ren2 rats with inducible Ang II-dependent malignant hypertension.

Results: Compared to control non-induced rats (n=6), Cyp1a1Ren2 rats (n=6) rats exhibited elevated arterial pressures (198±6 vs. 137±7 mm Hg; $p<0.001$), increased protein levels of renin (2.3±0.1 vs. 1.0±0.0 IDU) and even greater of prorenin (4.2±0.3 vs. 1.0±0.1 IDU) in the urine as measured by Western blot. Aliskiren prevented the development of hypertension (141±10 mm Hg; $p<0.01$) and decreased urinary renin/proremin protein levels.. Aliskiren did not alter the PRR and sPRR protein levels in the urine of Cyp1a1Ren2 rats. Urinary excretion of renin increased in the hypertensive rats ($1.3x10^{-6} \pm 2.3x10^{-7}$ vs. $2.0x10^{-7} \pm 2.6x10^{-8}$ Enzyme Units/day; $p<0.001$) and did not change with Aliskiren ($2.8x10^{-6} \pm 2.5x10^{-7}$). However, the urinary excretion of Ang II in Cyp1a1Ren2 rats was increased (6186±1962 vs. 463±89 fmol/d; $p<0.001$) and partially prevented by Aliskiren (3415±424 fmol/day; $p<0.05$).

Conclusions: In Cyp1a1Ren2 rats with malignant hypertension, augmentation of renin/prorenin and sPRR in the urine contributes to increased uAng II content. The Aliskiren-mediated decreased in urinary renin/prorenin protein levels and urinary excretion of Ang II may reflect decreased intrarenal Ang II generation and, thus, the contribution to the antihypertensive effects of Aliskiren in Ang II-dependent malignant hypertension.

Targeted Disruption of Aquaporin-1 Leads to Impaired Recruitment of Juxtaglomerular Cells in Response to Chronic Stimulation of the Renin-Angiotensin System Kirsten Madsen,[1,2] Anne Robdrup Tinning,[1] Armin Kurtz,[3] Boye Jensen.[1] *[1]Department of Cardiovascular and Renal Research, University of Southern Denmark, Denmark; [2]Department of Clinical Pathology, Odense University Hospital, Denmark; [3]Department of Physiology, University of Regensburg, Germany.*

Background: Aquaporin-1 (AQP-1) mRNA is expressed in juxtaglomerular granular (JG) cells that synthesize and release renin. It was hypothesized that AQP-1 is necessary for recruitment of JG cells and contribute in the pathway for renin release.

Methods: AQP-1 knock-out (KO) and wild-type (WT) mice were given a diet with 0.004% NaCl (LS) for 7 days and enalapril (ACEI, 0.1 mg/ml) in the drinking water for 3 days. Plasma renin concentration (PRC) and renal renin mRNA expression was determined. Renal vasculature was dissected from acid-macerated kidneys and afferent arterioles were counted as either 1) JG-cell negative; 2) with JG cells in a juxtaglomerular position or 3) with upstream JG-cell recruitment. Isolated perfused kidneys were used to determine renin release in response to standard stimuli. Perfusion-fixed kidneys from ACEI-treated mice were immunostained for renin and alpha-actin and serial sections were used to 3D-reconstruct the renal vasculature.

Results: At baseline, there were no differences in PRC, renal renin mRNA, renin release from isolated perfused kidneys or tail-cuff blood pressure in AQP-1 KO mice compared to WT mice. PRC was stimulated significantly in response to LS-ACEI treatment in both genotypes but reached a significantly higher level in AQP-1 WT. Renin mRNA level was elevated significantly and to a similar extent in both genotypes by LS-ACEI. In AQP-1 KO mice, the number of afferent arterioles with recruitment was significantly lower after LS-ACEI treatment compared to WT, while the number of arterioles with juxtaglomerular JG-cells was increased in AQP-1 KO mice. 3-D reconstruction of the vascular tree confirmed a predominantly juxtaglomerular position of renin-positive cells after ACEI in AQP-1 KO mice.

Conclusions: AQP-1 is not necessary for baseline regulation of renin secretion or expression but contributes to the recruitment of JG-cells and PRC during chronic stimulation of the renin-angiotensin system.

TH-PO720

Regulation of Renal Renin Release by Proteinase-Activated Receptors Klaus Höcherl, Frank Schweda. *University of Regensburg, Institute of Physiology, Regensburg, Germany.*

Background: Proteinase-activated receptors 1-4 (PAR1-4) are highly expressed in the kidney and are involved in the regulation of renal hemodynamics and tubular function. Since evidence had suggested a role of PARs in the control of the renin system, we investigated the effects of the respective PAR subtypes on renin release.

Methods: In the present study, we evaluated the impact of PAR activation on renin secretion rates (RSR) and kidney perfusate flow using the proteinase thrombin and PAR1-, PAR2-, and PAR4-activating peptides (TFLLR-NH_2, SLIGRL-NH_2 and AYPGKF-NH_2, respectively) in the isolated perfused mouse kidney model.

Results: The proteinase thrombin, that besides its role in the coagulation cascade activates PARs, dose-dependently reduced perfusate flow and inhibited renin secretion rates (RSR) that had been prestimulated by the ß-adrenoreceptor agonist isoproterenol. Direct activation of PAR1 by TFLLR mimicked the effects of thrombin on RSR and vascular tone. The PAR1-activating peptide TFLLR dose-dependently and reversibly decreased isoproterenol-induced RSR and perfusate flow. Moreover, stimulation of RSR by bumetanide, prostaglandin E_2 or by a decrease in renal perfusion pressure was also inhibited by TFLLR. Similarly, TFLLR decreased perfusate flow under these conditions. However, the increase in RSR and perfusate flow induced by a calcium-free perfusate was not influenced by TFLLR. The PAR2-activating peptide SLIGRL concentration-dependently increased basal RSR and perfusate flow. The stimulations of RSR and perfusate flow induced by isoproterenol were further increased by SLIGRL. The stimulatory effects of SLIGRL on RSR were clearly attenuated by L-NAME. In contrast, the PAR4-activating peptide AYPGKF did not modulate RSR or perfusate flow. In addition, PAR1 and PAR2 immunoreactivity were detected in the juxtaglomerular region and were co-localized with renin immunoreactivity.

Conclusions: Our data provide evidence that PAR1 activation inhibits renin secretion and induces renal vasoconstriction likely via a calcium-dependent mechanism, whereas PAR2 activation stimulates renin release and induces vasodilation mainly via the release of nitric oxide.

TH-PO721

Paricalcitol Lowers Plasma Renin Activity and Improve Blood Pressure Control in the 2-Kidney, 1-Clip Hypertensive Rat Model Olivier Phan, Marc P. Maillard, Michel Burnier. *Division of Nephrology, University of Lausanne CHUV, Switzerland.*

Background: Vitamin D has been shown to regulate renin expression in juxtaglomerular cells. The aim of the study was to compare the effects of two vitamine D analogs, paricalcitol and calcitriol on plasma renin activity (PRA), blood pressure (BP) and heart weight (HW) in a high-renin model of hypertension i.e the 2-kidney one-clip rat model.

Methods: Male wistar rats were used at 150 gr. Hypertension was induced by clipping the left renal artery. After 10 days, rats were randomly assigned (based on the normal distribution of baseline body weights) into 3 groups with a standard diet: calcitriol (80 ng/kg), paricalcitol (240 ng/kg), and control (vehicle) with an intraperitoneal injection every 3 days for a total of 4 injections (N=11/group). A sham group was also created as sham control.

Results: 24 h before sacrifice, a catheter was inserted into the right femoral artery to measure BP. The rats were placed in large Plexiglas tubes without noise or visual stimulation for two hours. The catheter was attached to a combination pressure transducer, and arterial blood pressure (BP) was collected using computerized data acquisition software.

	Heart Rate (/mn)	Systolic BP (mmHg)	Diastolic BP (mmHg)	Mean BP (mmHg)	Heart weight (gr)	PRA (ng/ml/h)
Sham control	361±13	142±8*	96±8*	113±9*	1.03±0.1*	1.53±0.38*
Clip control	366±7	193±9	141±7	166±8	1.36±0.06	4.81±1.27
Clip calcitriol	365±8	182±10	129±7	154±8	1.07±0.07*	3.28±0.48
Clip paricalcitol	354±9	163±7*	119±6*	139±7*	1.02±0.06*	1.62±0.3*

* p<0.01 vs clip control

Conclusions: In this model, only paricalcitol is associated with a significant decrease in BP and plasma renin activity. However, both paricalcitol and calcitriol reduce cardiac hypertrophy suggesting a BP-independent effect on cardiac mass.

TH-PO722

Effect of Murine Recombinant ACE2 on Blood Pressure and Serum ACE2 Activity Minghao Ye, Jan A. Wysocki, Daniel Batlle. *Division of Nephrology & Hypertension, Dept. of Medicine, Feinberg School of Medicine, Northwestern University, Chicago, IL.*

Background: There is increasing interest in the potential therapeutic action of Angiotensin-converting enzyme 2 (ACE2), but studies in mouse models have been limited by the lack of tools to amplify ACE2 activity. We developed murine recombinant ACE2 (mrACE2) to circumvent the immunogenicity of human rACE2 when given to mice.

Methods: mrACE2 was purified using Ni-Sepharose followed by size-exclusion chromatography. After 19 hr of incubation in vitro with purified mrACE2 (4ng), Ang II (10-9M) disappeared completely, thereby confirming that mrACE2 effectively cleaves this peptide. Then, Ang II (0.2mg/kg) was given to mice pre-treated with vehicle or mrACE2 (1.0mg/kg IP).

Results: Serum ACE2 activity was markedly increased in mrACE2-pretreated mice (244.2±6.7 vs. vehicle 1.19±1.2, RFU/ul/hr). In vehicle mice, Ang II bolus resulted in a rapid increase in SBP (30 sec) (from 102±3.1 to 173±4.4 mmHg, n=8), which was markedly blunted by mrACE2 (from 109±5.2 to 139±8.3 mmHg, n=7). The SBP recovery was much faster compared with mice pretreated with vehicle (at 5 min, 106±8.2 mmHg vs. 168±3.9 mmHg, respectively, p<0.0001). Whether baseline ACE2 activity plays a role in blood pressure regulation was examined by inhibiting ACE2 pharmacologically. We reasoned that a pharmacologic approach to ACE2 inhibition would be more useful to examine the effect of ACE2 on blood pressure under conditions where Ang II was not infused. Accordingly we administered MLN-4760, a specific ACE2 inhibitor. Acute administration of MLN-4760 (1.0 mg/kg IP) was associated with a rapid but transient increase in SBP as compared to control mice that received vehicle (ΔSBP11.4±2.7 vs.0.1±3.1 mmHg, p< 0.01). This effect of MLN-4760 was associated with a complete inhibition of serum ACE2 activity.

Conclusions: mrACE2 markedly reduces hypertension by increasing serum ACE2 activity. Pharmacological ACE2 inhibition results in an increase in blood pressure showing that baseline ACE2 activity is needed to provide sustained Ang II degradation in the face of continuous Ang II formation. mrACE2 will provide a tool to examine the therapeutic potential of ACE2 amplification in vivo.

Disrupted Angiotensin-Converting Enzyme2 (ACE2) Enhances Angiotensin II Induced Renal Fibrosis Via Smurf2-Mediated Degradation of Renal Smad7 Zhen Liu,[1] Xiao Ru Huang,[2] Haiyong Chen,[1] Hui Y. Lan.[1,2] *[1]Department of Medicine & Therapeutics, Chinese University of Hong Kong, Hong Kong, China; [2]Li Ka Shing Institute of Health Sciences, Chinese University of Hong Kong, Hong Kong, China; [3]Department of Chemical Pathology, Chinese University of Hong Kong, Hong Kong, China.*

Background: ACE2 negatively regulates angiotensin II(Ang II) signaling by cleaving AngII to Ang 1-7, thereby counterbalancing the detrimental effect of Ang II. It is known that Ang II mediates renal fibrosis via TGF-β/Smad-dependent and independent mechanisms. We now hypothesized that ACE2 may interact with Smads to block Ang II-induced renal fibrosis.

Methods: The hypertensive kidney disease was induced in ACE2 knockout (KO) mice via subcutaneous Ang II infusion. Overexpression of renal Smad7 to rescue the loss of ACE2 in Ang II-induced renal fibrosis was examined. Mechanisms of disrupted ACE2 promoted Ang II-mediated renal fibrosis was also studied in vivo and in ACE2 KO mesangial cells.

Results: After Ang II infusion, mice with ACE2 KO developed more severe renal dysfunction (protienuria and serum creatinine, p<0.05), renal fibrosis (30-40%↑ in a-SMA, COL1, COL3), and inflammation (40-45%↑ in T cells, macrophages, IL-1b, and TNFa), which was associated with higher levels of intrarenal Ang II (40%↑), reduced Ang 1-7 (30%↓), and increased Ang II (AT1R and ERK1/2), TGF-β/Smad3, and NF-kB signaling. Enhanced Smad3 and NF.kB activation in ACE2 KO mice was largely due to degradation of renal Smad7(50%↓) mediated by the E3 ligase Smurf2 (40%↑), which was confirmed by the ability of blocking AT1 receptor or knocking down Smurf2 to prevent Ang II-induced degradation of Smad7 in ACE2 KO cells. In contrast, ultrasound-mediated Smad7 gene therapy was able to rescue Ang II-induced progressive renal injury including TGF-b/Smad3-mediated renal fibrosis and NF.kB-driven inflammation in ACE2 KO mice.

Conclusions: Disrupted ACE2 enhances Ang II-induced renal injury which is associated with a loss of renal Smad7. Enhanced AT1-Smurf2-dependent Smad7 ubiquitin degradation may be an essential mechanism by which loss of ACE2 promotes progressive renal injury in Ang II-induced hypertensive nephropathy.

Effects of Renin-Angiotensin System Component Ang-(1-7) on Podocyte Injury In Vitro Induced by Patients' Serum of Preeclampsia Yong Gu,[1,2] Guixiang Chen,[1] Jianying Niu.[1] *[1]Division of Nephrology, Fifth People's Hospital of Shanghai, Fudan University, Shanghai, China; [2]Division of Nephrology, Huashan Hospital, Fudan University, Shanghai, China.*

Background: Renin angiotensin system (RAS) is very complicated and multistrata endocrinium, including various components. Recently a new member of RAS components Ang-(1-7) and its specific receptor Mas were found that they have extensive effects, which could counteract the effects of AngII. The podocyte injury may play a role in the pathogenesis of proteinuria in preeclampsia. Our previous study showed that the decreased serum and urinary Ang-(1-7) may be a cause of podocyte injury in preeclampsia. In order to further study the effect of Ang-(1-7) on podocyte in preeclampsia, we use patients' serum of preeclampsia to preincubate podocyte and then add Ang-(1-7) to observe the change of podocyte specific proteins.

Methods: The podocyte was cultured in vitro and the patients' serum of preeclampsia was collected sterile for preincubating podocyte. They were divided into 4 groups: normal control (NC); normal pregnant serum (NP) group; preeclampsia model (PE) group and Ang-(1-7) + preeclampsia [Ang-(1-7) + PE] group. The morphologic change of podocyte was observed by microscope; the changes of nephrin, CD2AP, F-actin, ZO-1 and Mas receptor were examined by immunofluorescence. Western blot was used to examine the expression of Mas receptor.

Results: 1. The expression of nephrin, F-actin and ZO-1 on podocytes was significantly decreased in PE group than NC and NP group; but their expression in Ang-(1-7) + PE group was significantly increased than in PE group. The expression of CD2AP has no significantly difference among four groups.

2. There exist Mas receptors on podocytes in all groups which was examined by immunofluorescence and Western blot. The expression of Mas receptor on podocytes in PE group was significantly decreased than NC and NP group; but it was increased significantly in Ang-(1-7) + PE group than in PE group.

Conclusions: Ang-(1-7) could protect podocyte from injury in vitro induced by patients' serum of preeclampsia. The effect may be associated with integration of Ang-(1-7) and its specific Mas receptor.

TH-PO725

Identification of Stox1 Transcription Factor as a Specific Repressor of Placental Renin and Its Deficiency Leads to Vascular Defects and Gestational Hypertension Keizo Kanasaki,[#1, #2] Soo Bong Lee,[#1] Daisuke Koya,[#2] Raghu Kalluri.[#1] *[1]Division of Matrix Biology, Beth Israel Deaconess Medical Center, Boston, MA; [2]Division of Diabetes and Endocrinology, Kanazawa Medical University, Uchinada, Kahoku, Ishikawa, Japan.*

Background: Storkhead-box protein 1 (Stox1) was identified as a candidate gene associated families with higher incidence of hypertensive crisis during pregnancies. Stox1 is a putative transcriptional factor with unknown function.

Methods: We generated Stox1 deficient mice (Stox1-/-) and analyzed pregnancy-associated hypertensive phenotype.

Results: Here, we demonstrate that Stox1-/- mice specifically exhibit pregnancy-associated hypertension, vascular defects and basement membrane abnormalities. Pregnant Stox1-/- mice display higher urine albumin excretion when compared to wild-type control pregnant mice. Non-pregnant females and males with deletion of Stox1 are normal despite ubiquitous expression of Stox1 in the control mice. Renin expression is significantly elevated in the placentas of Stox1-/- mice, but not in the kidney. RNA silencing and promoter analysis in the human cytotrophoblasts demonstrate that renin is negatively regulated by transcriptional action of Stox1, via its 3'UTR. Losartan, an angiotensin receptor I antagonist, completely ameliorates all pregnancy associated abnormalities in Stox1-/- mice.

Conclusions: These results indicate that Stox1 is a key regulator of blood pressure during pregnancy, and mice deficient for Stox1 serve as a genetic model for human gestational hypertension, a disease that affects about 8% of all pregnancies, causing significant morbidity.

Funding: NIDDK Support

TH-PO726

Effect of Cyclosporine A Administration in Pregnant Rats on Blood Pressure and Glomeruli Number in Their Offspring Marcin Adamczak,[1] Natalia Slabiak-Blaz,[1] Nadezda Koleganova,[2] Eberhard Ritz,[3] Andrzej Wiecek.[1] *[1]Department of Nephrology, Endocrinology and Metabolic Diseases, Medical University of Silesia, Katowice, Poland; [2]Department of Pathology, University of Heidelberg, Germany; [3]Department of Internal Medicine, University of Heidelberg, Germany.*

Background: Successful kidney transplantation allows women previously suffered from chronic kidney disease stage 5 to get pregnant. However, the immunosuppressive therapy may influence development in the offspring i.e. may cause the hypertension and chronic kidney disease (CKD) in adulthood. The aim of the study was to assess the effect of exposure to cyclosporine A (CsA) during gestation on blood pressure and glomeruli number in the offspring.

Methods: Eight pregnant Sprague-Dawley rats were assigned into two groups (n=4 in each group). In the first group CsA in a dose 3mg/kg/day and in the second group the corresponding volume of solvent were given, respectively. The substances were

administered from the 10th day after the fertilization till the 7th day after the delivery, subcutaneously, once a day. At 7 and 11 weeks of age in the offspring blood pressure was measured. 12 weeks after delivery the experiment was terminated and the number of glomeruli was calculated using unbiased stereological method.

Results: Systolic (SBP) and diastolic blood pressure (DBP) in the offspring of the females treated with CsA during gestation (n=34) was higher compared to the offspring from mothers treated only with solvent (n=31) (7th week - SBP: 125±5 vs. 117±6mmHg, p<0.001; DBP: 82±6 vs. 77±6mmHg p<0.001; 11th week - SBP: 132±9 vs. 126±7mmHg, p<0.05; DBP: 89±8 vs. 83±7mmHg, p<0.001). The number of glomeruli was lower in the kidneys of offspring from mothers treated with CsA compared to the offspring of mothers treated only with the solvent (19553±769 vs 23974±842, p<0.001).

Conclusions: 1. Treatment with CsA during pregnancy may lead to arterial hypertension in the offspring. 2. Exposure on CsA during fetal life influence also on kidney development which results in 18% fewer glomeruli and this may be an important factor participating in the pathogenesis of CKD later in their life.

Funding: Government Support - Non-U.S.

TH-PO727

Offspring of Mother Rats Exposed to Cigarette Smoke Condensate Are Characterized by Elevated Blood Pressure and Reduced Urinary Sodium Excretion

Andrzej Wiecek,[1] Milosz Zarzecki,[1] Marcin Adamczak,[1] Eberhard Ritz.[2] *[1]Department of Nephrology, Endocrinology and Metabolic Diseases, Medical University of Silesia, Katowice, Poland; [2]Department of Internal Medicine, University of Heidelberg, Germany.*

Background: It has been suggested that disturbances of fetal development caused by exposure to cigarette smoke (as a result of maternal smoking) increase the risk of hypertension and chronic kidney disease in the adult life. The aim of the present, experimental study, was to assess the impact of exposure of pregnant rats to cigarette smoke condensate on blood pressure and natriuresis in their offspring.

Methods: Sprague-Dawley rats on day 10 of pregnancy were randomly allocated (5 animals in each group) to twice daily application on oral mucosa cigarette smoke condensate (CSC) containing nicotine or solvent until delivery. Albuminuria, creatinine clearance and urinary sodium, potassium and calcium excretion were measured in 12 weeks old offspring.

Results: At 12 weeks of age significantly elevated systolic blood pressure was found in offspring exposed to CSC during the fetal period (n=54) compared to controls (n=51) (122±7 vs. 116±8 mmHg; respectively, p<0.001). Offspring of mother rats exposed to cigarette smoke condensate did not differ from the control offspring with respect to body weight, albuminuria, creatinine clearance and urinary potassium and calcium excretion, respectively. In contrast, offspring of mother rats exposed to cigarette smoke condensate are characterized by both significantly lower urinary sodium excretion (531±242 vs. 846±384 µmol/24 hours; p=0.004) and urinary sodium/creatinine ratio (8.1±4.1 vs. 9.6±4.2 mmol/mmol; p=0.04).

Conclusions: 1. Exposure of pregnant rats to cigarette smoke condensate causes a blood pressure increase and a reduction of urinary sodium excretion in their offspring. 2. Such effect of cigarette smoke condensate on kidney function may have a consequence on development of arterial hypertension and also chronic kidney disease in the adult life.

Aggravated Phenotypes of Preeclampsia in Mice Bearing 4 Copys of Ace Gene

Feng Li,[1] Oliver Smithies,[1] Nobuyuki Takahashi.[1, 2] *[1]Pathology and Laboratory Medicine, University of North Carolina, Chapel Hill, NC; [2]Clinical Pharmacology and Therapeutics, Tohoku University, Sendai, Miyagi, Japan.*

Background: Preeclampsia is pregnancy-associated hypertension with proteinuria. Excess sFlt-1, an endogenous VEGF inhibitor of placental origin has been implicated to cause hypertension, proteinuria and glomerular endotheliosis, all features of preeclampsia. sFlt-1 antagonizes VEGF and induces endothelial dysfunction . Human *ACE* polymorphisms leading to elevated activity of ACE are associated with preeclampsia.

Methods: We tested whether an increase in ACE aggravation of preeclampsia using mice having 4 copys of *Ace* gene.

Results: Adenoviral mediated sFlt-1 overexpression to the non-pregnant female mice increased BP of both mutant mice and WT mice. All of mutant sFlt-1 mice developed ascites approximately10 days after injection, and body weight (BW) also increased (average gain was 1.7 ± 0.6 g). However, none of WT sFlt-1 mice developed ascites and BW did not increase (average gain was –0.45 ± 0.06 g). Mutant sFlt-1 mice showed higher daily urinary albumin excretion (288 ± 42 mg/day vs. 150 ± 60 in WT sFlt-1) and lower GFR (170 ± 55 ml/min vs. 493 ± 109 in WT sFlt-1). Mutant sFlt-1 mice had less glomerular open capillary volume (20.5 ± 3.8 % vs. 34.7 ± 10.5 % in WT sFlt-1 mice), suggesting mutant sFlt-1 mice have more severe endotheliosis than WT sFlt-1 mice.

Conclusions: We conclude that mice having 4 copies of *Ace* gene develop more sever preeclampsia than WT mice. The mechanism underlying this phenomenon is under studying.

Funding: NIDDK Support, Other NIH Support - MHLBI, Private Foundation Support, Government Support - Non-U.S.

Hydrogen Sulfide: A Protective Gas for Preeclampsia?

Kim M. Holwerda,[1] Eelke M. Bos,[1] Henri G.D. Leuvenink,[2] Albert Timmer,[1] Marijke M. Faas,[1] Harry Van Goor,[1] Titia Lely.[3] *[1]Medical Biology and Pathology, University Medical Centre Groningen, Netherlands; [2]Surgery, University Medical Centre Groningen, Netherlands; [3]Obstetrics and Gynaecology, University Medical Centre Groningen, Netherlands.*

Background: Hydrogen sulfide ($H_{[sup]2[/sup]}S$) is emerging as a regulator of various physiologic functions like blood pressure regulation and neurotransmission. It is protective during renal hypoxia and has strong antioxidant properties. Endogenous $H_{[sup]2[/sup]}S$ is produced from cysteine by the enzymes cystathionine-ß-synthase (CBS) and cystathionine-γ-lyase (CSE). CSE ko mice have increased blood pressure and reduced endothelium-mediated vasorelaxation. CBS ko mice are growth restricted and die within 4 weeks after birth. Preeclampsia (PE) is accompanied by maternal hypertension, placental hypoxia and growth restriction. Therefore, we studied the placental expression profiles of CBS and CSE during PE and healthy pregnancies.

Methods: Placental biopsies were taken from patients with severe early-onset PE (n=10) and healthy pregnant women (n=9) who underwent indicated caesarian. CBS and CSE mRNA was quantified using RT-PCR. Immunohistochemistry (IHC) was performed on frozen tissue with MoABs against CBS and CSE. Colocalizaton studies for CSE/CBS and CD31 (endothelium) were performed using immunofluorescence staining.

Results: Mean time of delivery was 31 (range 27-35) wks in PE and 40 (range 38-42) wks in controls. RT-PCR showed a 3-fold decrease (p<0.05) of CBS mRNA expression in the PE placentae compared to controls. CSE mRNA was unaltered compared to controls. In both groups, IHC showed CBS and CSE-specific endothelial staining of the fetal vessels in both stem- and chorionic villi. CBS was also expressed by placental macrophages, the Hofbauer cells.

Conclusions: As the CBS expression is down regulated in severe early-onset PE, endogenous H2S production is likely to be decreased. We propose that H_2S is an angiogenic mediator during pregnancy and that deficiency of $H_{[sup]2[/sup]}S$ might partly underlie the pathogenesis of PE. This is supported by the endothelial localization of CBS/CSE since PE is accompanied by endothelial dysfunction. Therefore, H_2S may have protective and therapeutic potential in PE.

TH-PO730

Angiotensin II Type 1 Receptors Regulate Renal Medullary Endothelin B Receptor Function in Rats Fed a Low Salt Diet

Wararat Kittikulsuth, Jennifer S. Pollock, David M. Pollock. *Georgia Health Sciences University, Augusta, GA.*

Background: We previously reported that angiotensin (Ang) II hypertensive rats have impaired endothelin B(ETB)receptor-mediated natriuresis. However, the physiological role if Ang II affects ETB receptor function is not known. Thus, we hypothesized that stimulation of endogenous Ang II with a low salt diet attenuates ETB-dependent natriuresis.

Methods: Experiments were designed to determine the diuretic and natriuretic responses to intramedullary infusion of an ETB receptor agonist sarafotoxin 6c (S6c) in rats fed a normal (0.4% NaCl) or low (0.02% NaCl) salt diet for 2 weeks.

Results: In rats on a normal salt, S6c increased urine flow (3.6±0.5 vs. 10.6±1.8 µl/min; p<0.05) and sodium excretion (0.35±0.06 vs. 1.22±0.23 µmol/min; p<0.05). In contrast, rats fed a low salt diet did not display an increase in water (4.3±0.8 vs. 6.2±1.4 µl/min) or sodium (0.26±0.07 vs. 0.34±0.13 µmol/min) excretion during S6c infusion. Moreover, western blotting showed that rats fed a low salt diet expressed less ETB receptors in renal inner medulla compared to a normal salt diet (0.73±0.05 vs. 1.00±0.07 A.U., normalized to actin; p<0.05). We next hypothesized that the reduced ETB receptor function in rats fed a low salt diet is mediated by Ang II type 1 (AT1) receptors. Rats fed a normal or low salt diet were treated with the AT1 antagonist, candesartan (5 mg/kg/d), for 2 weeks. Candesartan restored ETB-induced water (7.5±1.4 vs. 17.7±1.9 µl/min, p<0.05) and sodium (0.46± 0.09 vs. 1.02±0.21 µmol/min, p<0.05) excretion in rats fed a low salt diet. S6c also increased urine flow (4.4±0.6 vs. 10.5±2.6 µl/min, p<0.05) and sodium excretion (0.61±0.09 vs. 1.36±0.42 µmol/min, p<0.05) in candesartan-treated rats fed a normal salt diet.

Conclusions: These findings support the hypothesis that AT1 receptors regulate renal medullary ETB receptor function in a low salt diet model as a means of salt and water retention.

TH-PO731

Localization and Regulation of the Angiotensin II Type 1 Receptor-Associated Protein Arap1 in the Kidney

Elisabeth Doblinger,[1] Klaus Höcherl,[1] Boye Jensen,[2] Hayo Castrop.[1] *[1]Institutes of Physiology, University of Regensburg, Germany; [2]University of Southern Denmark, Odense, Denmark.*

Background: Arap1 is an interacting protein of angiotensin II type 1 (AT1) receptors and it facilitates increased AT1 receptor surface expression in vitro. Here we assessed the tissue localization and regulation of Arap1 in vivo.

Results: Arap1 was found in various organs of the mouse with an order of expression of heart kidney>aorta>adrenal gland≈liver≈testis≈spleen>brain, as determined by RT-PCR. In the kidney, Arap1 was found along a cortical-medullary gradient, with cortical expression levels exceeding those of the inner medulla by 130%. Arap1 protein was localized to the vasculature of the renal cortex including the juxtaglomerular cells; at lower levels, Arap1 was also present in vessels of the medulla. Arap1 furthermore was expressed in glomerular podocytes. Similar like in mice, Arap1 mRNA was detected in all kidney zones of the human kidney. Arap1 expression was regulated by various stimuli. Thus, a

high salt diet (4% NaCl [w/w], 7d, n=5) upregulated renal Arap1 expression in mice by 47% compared to controls (.6% NaCl [w/w], n=5, p=.01). Similarly, AT1 antagonism (losartan, 30 mg/kg/d, 7d), enhanced Arap1 mRNA expression by 52% (n=5 each, p<.01), whereas Ang II infusion (osmotic mini pumps, 7d, 2µg/kg/min Ang II) reduced Arap1 mRNA levels compared to vehicle by 34% (p<.01, n=7 each). Conditions of high Ang II levels, like unilateral kidney artery stenosis (48 hrs, n=5) or water restriction (48 hrs, n=6), all suppressed Arap1 levels compared to controls (-64% and -62% in the clipped and contralateral kidney, respectively, and -28% after water restriction; p<.01 vs. control each). Changes in Arap1 mRNA expression were paralleled by changes in Arap1 protein levels. Similar like in vivo, Arap1 mRNA and protein were suppressed by Ang II in a time- and dose-dependent manner in cultured mesangial cells (down to 32% of control), and this could be blocked by losartan.

Conclusions: In summary, Arap1 is highly expressed in the renal vasculature and its expression appears to be suppressed by AT1 receptor activation. Thus, Arap1 may serve as a local modulator of vascular AT1 receptor function in vivo.

TH-PO732

Candesartan Prevents High-Fat Diet-Induced Hypertension and Renal Injury in Spontaneously Hypertensive Rat Via Angiontensin II Receptor-PI3K/Akt/FoxO Signaling Pathway Sungjin Chung, Ji Hee Lim, Min-Young Kim, Seok Joon Shin, Hyung Wook Kim, Yong-Soo Kim, Yoon-Sik Chang, Cheol Whee Park. *Division of Nephrology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea.*

Background: We have recently demonstrated that intrarenal renin-angiotensin system (RAS) would be involved in high-fat diet-induced renal lipotoxicity. Because the intracellular pathways involved in renal lipotoxicity remain to be determined, we examined the participation of FoxO transcription factors in renoprotective effects of RAS inhibition in spontaneously hypertensive rat (SHR) fed a high-fat diet.

Methods: SHR and WKY were treated with either a normal diet (SHR-C or WKY-C) or a high-fat diet (SHR-HF or WKY-HF) with or without candesartan or hydralazine for 12 weeks.

Results: Intrarenal lipid accumulation were significantly increased in SHR-HF and WKY-HF compared with SHR-C and WKY-C. In SHR-HF, systolic BP was more elevated than those in SHR-C but the increased BP were normalized by treatment with candesartan or hydralazine. Renal morphology showed that mesangial expansion and inflammation were significantly enhanced in SHR-HF. A high-fat feeding resulted in activation of the intrarenal RAS, which findings were shown by immunohistochemical stainings of renin and angiotensin II and Western blot analysis for renin and angiotensin II type 1 (AT1) receptor. These changes were associated with increases in the activity of intrarenal PI3K-Akt phosphorylation and FoxO3a phosphorylation, consequently leading to increases in urinary 8-OH-deoxyguanosine levels and intrarenal active caspase-3 expression, indicating enhanced oxidative stress and apoptosis in the kidney. Treatment with candesartan, but not hydralazine, normalized all of these abnormalities via repression of angiotensin II AT1 receptor and upregulation of FoxO3a.

Conclusions: A high-fat diet resulted in the downregulation of FoxO transcrition factor, and candesartan ameliorated high-fat diet-induced hypertension and renal damage through AT1 receptor-PI3K-Akt-FoxO3a pathway, suggesting that AT1 receptor inhibition and subsequent FoxO activation could provide beneficial effects against renal lipotoxicity.

TH-PO733

ACE Inhibition Attenuates Renal Injury in Mice Lacking Endothelial Nitric Oxide Synthase Wataru Kitagawa,[1,3] Katsuyuki Tanabe,[1] Yoshifuru Tamura,[1] Jelena Klawitter,[2] Christopher J. Rivard,[1] Richard J. Johnson,[1] Takahiko Nakagawa.[1] *[1]Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]Department of Anesthesiology, University of Colorado Denver, Aurora, CO; [3]Division of Nephrology and Rheumatology, Aichi Medical University, Nagakute, Aichi, Japan.*

Background: The renin-angiotensin-aldosterone system (RAAS) plays a pivotal role in the development and progression of renal injury. Non-specific nitric oxide synthase inhibition (by L-NAME) is a known cause for RAAS activation while the specific role of endothelial nitric oxide synthase (eNOS) remains unclear. Our group previously documented that eNOS deficiency accelerated renal injury in the aging mice as well as in the mouse remnant kidney model. However, the role of RAAS has not been studied in these models. Here, we examined if renal injury due to eNOS deficiency depends on RAAS activation.

Methods: 5-month-old C57BL/6 wild type (WT) and Nos3tm1UNC (eNOS-KO) mice were divided into vehicle-treated (each n=10) or enalapril-treated (each n=10) groups. Enalapril was administered in the drinking water at a dose of 20mg/kg/day for 9 months.

Results: Blood pressure was significantly elevated in eNOS-KO mice at 14 months compared with WT mice (118.1±8.4 vs. 101.6±6.1 mmHg, p<0.005). Enalapril treatment significantly lowered the blood pressure in both groups (85.6±5.7 in eNOS-KO vs. 80.7±5.3 mmHg in WT). Urine albumin excretion was increased in eNOS-KO mice (but not in WT mice), whereas it was significantly reduced with enalapril treatment (167.4±64.1 vs. 27.0±9.6 µg/mg creatinine). Histologically, the development of glomerular sclerosis was found only in eNOS-KO mice, and it was significantly prevented with enalapril treatment (5.70±2.26 vs. 2.36±2.21 in % glomerulus, p<0.005). Activation of RAAS in eNOS-KO mice was proven by higher serum aldosterone concentrations compared with WT mice whereas enalapril significantly reduced serum aldosterone levels in eNOS-KO mice (346.3±150.6 vs. 166.8±40.8 pg/ml, p<0.05).

Conclusions: The eNOS deficiency causes RAAS activation in the mouse. Long-term ACE inhibititor treatment effectively prevents renal injury and hypertension in mice lacking eNOS.

TH-PO734

Distinct In Vitro and In Vivo Phenotypes of KCNJ5 Mutations in Hereditary Hypertension Ute I. Scholl,[1] Carol J. Nelson-Williams,[1] Peng Yue,[2] Robert J. Wyatt,[3] Michael J. Dillon,[4] Robert Couch,[5] Lisa Arel Hammer,[6] Anita Farhi,[1] WenHui Wang,[2] Richard P. Lifton.[1] *[1]Yale School of Medicine; [2]New York Medical College; [3]University of Tennessee Memphis; [4]University College London; [5]University of Alberta; [6]University of Michigan.*

Background: We have recently identified mutations in an adrenal potassium channel, KCNJ5, as a cause of primary aldosteronism in humans (Choi et al., Science 2011). Recurrent somatic mutations were found in aldosterone-producing adenomas, and an inherited mutation in a family with massive adrenal hyperplasia. All mutations were located in and near the channel selectivity filter, producing increased Na+ conductance and depolarization, the signal for aldosterone production and cellular proliferation in adrenal glomerulosa.

Methods: We report 9 patients from 4 kindreds with primary aldosteronism, and demonstrate mutations in KCNJ5 in all. Using heterologous expression in 293-T cells, flow cytometry and electrophysiology, we study the impact of these mutations on channel physiology and cell survival.

Results: All families had mutations at G151, different from the T158A mutation in the one family reported to date. Two families had G151R mutations, identical to one of the common mutations in APAs, and the other was G151E, which is never seen in APAs. Patients with G151R mutations developed adrenocortical hyperplasia. Their hypertension was poorly controlled by antihypertensives including spironolactone, leading to bilateral adrenalectomy in childhood. In contrast, G151E subjects treated with spironolactone had excellent control of blood pressure. Imaging, and, where available, histopathology, revealed no evidence of adrenal hyperplasia. Compared with the effect of the G151R mutation, G151E led to a much larger Na+ conductance, and consequently dramatic lethality in 293-T cells.

Conclusions: The absence of hyperplasia in subjects with G151E mutations is likely attributable to increased cell death in vivo, raising the question whether G151E or additional inherited or somatic mutations in KCNJ5 may be present in patients with primary aldosteronism without overt adenoma or hyperplasia.

ROMK Knockout in Rats Is Associated with Decreased Blood Pressure Xiaoyan Zhou, Zuo Zhang, Myung Shin, Sarah Horwitz, John Levorse, Wanda Sharif-Rodriguez, Denis Streltsov, Maya Dajee, Melba Hernandez, Yi Pan, Olga Price, Li Wang, Gail M. Forrest, Daphne Szeto, Yonghua Zhu, Yan Cui, Leslie Balogh, Yan G. Ni, Kathleen A. Sullivan. *Merck Research Laboratories, Merck & CO., Rahway, NJ.*

Background: ROMK channels mediate potassium recycling and facilitate sodium reabsorption through the $Na^+/K^+/2Cl^-$ cotransporter in the loop of Henle and potassium secretion at the cortical collecting duct. Human genetics studies indicate that ROMK homozygous loss-of-function mutations cause type II Barter's syndrome, featuring polyuria, renal salt wasting, and hypotension; Humans heterozygous for ROMK mutations identified in the Framingham Heart Study have reduced blood pressure. ROMK null mice recapitulate many of the features of type II Barter's syndrome. The aim of our study is to investigate the effects of knocking out ROMK on blood pressure in rats.

Methods: Zinc Finger Nuclease (ZFN) technology was used to generate ROMK knockout rats in the Dahl salt sensitive rat background. Rats were fed either a low salt (0.25% NaCl) or a high salt diet (4% NaCl), their blood pressure and renal function were monitored for 8 weeks.

Results: None of ROMK -/- survived beyond 4 weeks. The ROMK +/- rats, in which kidney ROMK mRNA level was decreased by 50% as compared to the wild type littermates, showed decreased systolic blood pressure: ~5 mmHg or ~15 mmHg lower than the wild type littermates while fed the low salt or high salt diet respectively. No significant differences in body weight, food intake, water intake, urine volume, urinary electrolytes and PGE2 excretions, GFR, and plasma electrolyte concentrations, were observed between the ROMK +/- rats and the wild type littermates.

Conclusions: The finding from this study, together with the human and mice genetics evidence, strongly supports the role of ROMK in blood pressure regulation.

Mesenchymal Stem Cells (MSC) Improved Renal Function and Reduced Renovascular Hypertension Elizabeth B. Oliveira-Sales,[1] Edgar Maquigussa,[1] Patricia Semedo,[1] Luciana Guilhermino Pereira,[1] Niels O.S. Camara,[1] Cassia Bergamaschi,[2] Ruy Campos,[2] Mirian A. Boim.[1] *[1]Medicine, Renal Division, UNIFESP, Sao Paulo, Brazil; [2]Physiology, UNIFESP, Sao Paulo, Brazil.*

Background: Renovascular hypertension induced by 2 Kidney-1 Clip (2K-1C), is a renin-angiotensin-system (RAS)-dependent model, leading to vascular rarefaction and renal failure. This work investigated the effects of mesenchymal stem cells (MSC) treatment on the blood pressure, renal function and RAS components in ischemic kidney 2K-1C rats.

Methods: Three weeks after left renal artery occlusion, fluorescently tagged MSC (2x105cells/animal) were weekly injected into the tail vein. Animals were sacrificed 6 weeks after clipping (two cell administration). Animals were divided in the following groups: control (n=5), control MSC-treated (n=2), 2K-1C (n=8) and 2K-1C MSC-treated (n=7).

The systolic blood pressure (SBP) was monitored using tail cuff recording method. Renal function was estimated by plasma and urine creatinine, proteinuria and urinary sodium and potassium. Protein levels of angiotensinogen (AGTN, renin, ACE, Ang II receptors types 1 (AT1) and 2 (AT2) were determined in the renal medulla of clipped kidney by western blot. Tracking assay by flow cytometry showed that labeled MSC were present in the cortex and medulla in the clipped kidney.

Results: MSC had no detectable effects in control animals and significantly reduce the SBP by 22% (from 224 ± 8 to 173 ± 6 mmHg). Proteinuria was increased in 2K-1C compared to control animals (15±3 vs 80±19 mg/24h, p<0.05) and it was significantly reduced after MSC treatment (48±8 mg/24h). Other renal function parameters were unchanged in all groups. AGTN, renin, ACE and AT1 protein expressions were elevated in clipped kidneys (49, 25, 30 and 43%, respectively) and the MSC treatment normalized all these expressions. In contrast, AT2 levels were significantly decreased in clipped kidneys (60%) and it was almost normalized after MSC treatment.

Conclusions: In conclusion MSC therapy suppressed the intrarenal RAS and improved renal function in the 2K-1C model. Whether the improvement of renal function was responsible for the MSC-reducing hypertension effects needs to be investigated.

TH-PO737

MTP-131 Reduces Renal Injury after Percutaneous Transluminal Renal Angioplasty (PTRA) in Swine Atherosclerotic Renal Artery Stenosis (ARAS) Alfonso Eirin, John R. Woollard, Xiang-Yang Zhu, James Krier, Xin Zhang, Stephen C. Textor, Lilach O. Lerman. *Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: MTP-131 (bendavia) is a novel compound that inhibits opening of the mitochondrial permeability transition pore, apoptosis, and cardiac reperfusion injury in animals and humans, but its potential for improving PTRA outcomes in ARAS is unknown.

Methods: Pigs were treated after 6 weeks of ARAS or control with PTRA+stenting (or sham), with adjunct continuous infusion of bendavia (0.05 mg/kg IV, 30 min before to 3 hrs after PTRA) or vehicle (n=7 each). Single-kidney renal blood flow (RBF) and glomerular filtration rate (GFR) were studied 4 weeks later using multi-detector CT, and renal microvascular architecture *ex-vivo* by micro-CT.

Results: Four weeks after successful PTRA blood pressure decreased to normal levels in all PTRA-treated pigs (p>0.05 vs. Normal). Stenotic kidney GFR and RBF remained decreased in ARAS+PTRA+vehicle, but were restored in ARAS+PTRA+bendavia (p<0.05 vs. ARAS+PTRA; p>0.05 vs. normal). Furthermore, spatial density of cortical microvessels was normalized in these pigs (Figure).

Conclusions: Intra-venous infusion of bendavia at the time of PTRA restored renal hemodynamics and function and attenuated microvascular rarefaction in swine ARAS. Bendavia shows a unique therapeutic potential for improving kidney function and outcomes following PTRA in chronic experimental ARAS.

Aggravated Inflammation in Malignant Versus Non-Malignant Course of Experimental Renovascular Hypertension Karl F. Hilgers,[1] Lisa Jagusch,[1] Nada Cordasic,[1] Kerstin U. Amann,[2] Roland Veelken,[1] Andrea Hartner.[3] *[1]Nephrology & Hypertension, University of Erlangen-Nuremberg, Erlangen, Germany; [2]Nephropathology, University of Erlangen-Nuremberg, Erlangen, Germany; [3]Pediatric and Adolescent Medicine, University of Erlangen-Nuremberg, Erlangen, Germany.*

Background: The reason(s) why malignant nephrosclerosis develops in some cases of hypertension but not in others are largely unknown. We hypothesized that malignant nephrosclerosis in experimental renovascular hypertension exhibits a more pronounced macrophage infiltration.

Methods: Two-kidney, one-clip renovascular hypertension was induced in rats; controls (CON) were sham operated. To distinguish malignant hypertension (MH) from non-malignant hypertension (NMH) without using arbitrary definitions, we performed split-half analyses for two factors: weight loss, and the number of characteristic vascular lesions (onion skin lesions and fibrinoid necroses) per kidney section of the nonclipped kidney. Animals in the upper half for both criteria were defined as MH whereas those in the lower half for both criteria were NMH. Macrophage infiltration in the nonclipped kidney was counted (ED-1 stain), and the gene expression of macrophage chemoattractant proteins was measured by real-time RT-PCR.

Results: After 5 weeks, mean arterial pressure was elevated to the same degree in MH (207±10 mmHg, N=13) and NMH (201±4 mmHg, N=15; p=0.4 versus MH) compared to CON (113±3 mmHg, N=25, P<0.001). MH exhibited higher serum aldosterone, left ventricular hypertrophy, and interstitial fibrosis of the nonclipped kidney, compared to NMH and CON (all p<0.05). Macrophage infiltration was present in NMH (8.9±0.8 vs. 5.7±0.5 cells in CON, p=0.009) but more pronounced in MH (14.7±1.4, p<0.001 vs. NMH and CON). Osteopontin expression was increased 29fold in NMH (p=0.03 vs. CON) and 65fold in MH (p<0.01 vs. NMH and CON). MCP-1 expression was not altered in NMH (1.4fold, p=0.447) but increased 2.8fold in MH (p<0.01 vs. NMH and CON).

Conclusions: Macrophage infiltration is much more pronounced in malignant renovascular hypertension than in the non-malignant course of the disease. MCP-1 is induced only in malignant nephrosclerosis and may contribute to its pathogenesis.

TH-PO739

Sestrin2 Regulates Activation of Peroxiredoxin and Mediates Dopamine D2 Receptor/Paraoxonase 2-Induced Decrease in Renal ROS Production Yu Yang, Santiago Cuevas Gonzalez, Yanrong Zhang, Laureano D. Asico, Ines Armando, Pedro A. Jose. *Research for Molecular Physiology, CNMC, George Washington University, Washington, DC.*

Background: We have shown that the D2 dopamine receptor (D2R) decreases renal reactive oxygen species (ROS) production and regulates blood pressure (BP), in part, via positive regulation of paraoxonase 2 (PON2), an enzyme that protects against cellular oxidative stress. Sestrin2 is a conserved antioxidant protein that regulates intracellular ROS level by regenerating over-oxidized peroxiredoxin (Prx-$SO_{2/3}$H). We hypothesized that renal sestrin2 may be involved in counter-regulating renal ROS production via the D2R, contributing to maintain normal BP.

Results: *In vitro* treatment of human renal proximal tubular cells with the D2R agonist, quinpirole (24h, 1μM), decreased ROS production (DCFDA method) by 42% (P<0.05; n=3). This effect was associated with increased protein expression of PON2 (1.3-fold, P<0.05, n=3) and sestrin2 (1.4-fold, P<0.01, n=4), and decreased protein expression of Prx-$SO_{2/3}$H (-55%, P<0.01, n=3). In contrast, silencing D2R (siRNA, 20 nM, 48h) down-regulated PON2 (-25%, P<0.05, n=3) sestrin2 expression (-48%, P<0.05, n=3), and increased Prx-$SO_{2/3}$H protein expression (1.75-fold, P<0.05, n=3) and ROS production (1.4-fold, P<0.01, n=4). Silencing PON2 (siRNA, 10nM, 48h) decreased sestrin2 (-32%, P<0.05, n=3) and increased Prx-$SO_{2/3}$H protein expressions (1.7-fold, P<0.05, n=3) and ROS production (1.4-fold, P<0.01, n=4). Silencing sestrin2 (siRNA, 20 nM, 48h) increased Prx-$SO_{2/3}$H protein expression (2.2-fold, P<0.01, n=3) and ROS production (1.3-fold, P<0.01, n=4). *In vivo* selective renal silencing of sestrin2 by subcapsular infusion of sestrin2 siRNA (3 μg/day, 7 days) in mice increased systolic (117±4 vs. 92±2 [vehicle-treatment] mmHg, P<0.01, n=3) and diastolic BP (86±2 vs. 67±3 [vehicle treatment] mmHg, P<0.01, n=3)

Conclusions: These results suggest that renal sestrin2 is positively regulated by D2R and PON2 and contributes to maintain normal BP. The negative regulation of peroxiredoxin activation by sestrin2 mediates, in part, the inhibitory effect of renal D2R on ROS production.

Aliskiren Ameliorates Insulin Resistance and Aortic Endothelial Dysfunction in Fructose-Fed Rats Te-Chao Fang.[1,2,3] *[1]Internal Medicine, Buddhist Tzu Chi General Hospital, Hualien, Taiwan; [2]Institute of Medical Sciences, Tzu-Chi University, Hualien, Taiwan.*

Background: Renin-angiotensin system plays a major role in the pathogenesis of cardiovascular diseases. The objective of this study was to examine the effects of aliskiren, a direct renin inhibitor, on the aortic endothelial function of fructose-fed hypertensive rats.

Methods: Male Wistar Kyoto rats weighing 200 to 230 g were divided into 4 groups (n=6 for each group). Group Con: rats were fed standard chow diet for 8 weeks; Group Fru: rats were fed high fructose diet (60% fructose) for 8 weeks; Group FruA: rats were fed high fructose and were coinfused with aliskiren (100 mg/kg.day), and Group FruB: rats were treated as Group Fru, but aliskiren was administered 4 weeks later. Isolated vascular ring experiments, systolic blood pressure (SBP), homeostasis model assessment-insulin resistance (HOMA-IR), oral glucose tolerance test (OGTT) and related blood profiles were measured.

Results: By the end of week 4 and 8 of sustaining a high fructose diet, SBP had increased significantly from 110 ± 5 to 143 ± 4 and 140 ± 5 mmHg ($p< 0.05$), respectively. When fructose-induced hypertension had been established (from 112 ± 4 to 140 ± 3 mmHg, $p< 0.05$), subsequent aliskiren treatment for 4 weeks reversed the elevated SBP. Concurrent aliskiren treatment restored the development of hypertension. Additionally, a high fructose diet also had significantly higher HOMA-IR values at week 4 and 8 (21.25 ± 2.08 and 21.28 ± 3.1 from 6.15 ±1.59, respectively; $p< 0.05$), and concurrent or subsequent administration of aliskiren significantly reduced the HOMA-IR values. OGTT showed that fructose feeding resulted in insulin resistance, and co-administration or superimposition of aliskiren significantly ameliorated insulin resistance of fructose-fed rats. The percent of endothelium-dependent aortic relaxation in the Group FruA and Group FruB were significantly higher than that in the Group Fru (63.46 ± 5.50 and 60.10 ± 8.01 than 39.97 ± 7.44 %, respectively; $p<0.05$).

Conclusions: This study demonstrates that aliskiren does not only prevent but also ameliorates hypertension and aortic endothelial dysfunction in fructose-fed rats.

TH-PO741

Vitamin B 6 Prevents the Hypertension Induced by Chronic Fructose Administration & Averts the Cardiovascular Complications in Akita Diabetic Mice: Role of Reduced Oxidative Stress Meghan Pantalia, Uzma Hajiyani, Shuangxi Wang, Bonnie Eby, Alexander Lau, Becky Pennington, Pedro Lozano, Kai Lau. *Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Hyperglycemia is known to stimulate ROS & glycation end-products (AGE). We recently showed benefits of blocking receptors (R) of AGE in preventing diabetic nephropathy & of up-regulating AMPK with metformin in preventing diabetic cardiomyopathy & hypertension. Since vit B6 is known to inhibit AGE, we studied its effects in 2 models.

Methods: Male Akita & controls were randomzied to vit B6 or nothing starting at 7 weeks. We monitored BP by tail-cuffs & heart function by echo. Normal male mice were also randomized to either fructose, fructose + vit B6, or dextrose, adjusted for 1.4 g/d. Endothelial function was studied by aortic relaxation.

Results: Akita mice had significant systolic (S) hypertension (in torr) at 5 mon (119 vs. 111) & 8 mon (127 vs. 109). Diastolic (D) BP (85 vs. 74) & mean arterial BP (MABP) (99 vs. 86) were elevated at 8 mon. In Akita mice, vit B6 normalized SBP at both ages & DBP & MABP at 8 mon. At 5 mon, Akita mice had reduced LV end-diastolic (ED) volume (V), stroke volume (SV) & cardiac output (CO) (7 vs. 13 ml/min). Vit B6 preserved LVEDV, SV & CO (12 ml/min). At 10 mon, LVEDV, SV & CO remained low in Akita, but fully corrected by vit B6. Peripheral vascular resistance was elevated in Akita (15 vs. 8 torr. min/ml) but normalized by vit B 6. Fructose raised fasting insulin (0.58 vs. 0.28 ng/ml) & total cholesterol (131 vs. 95 mg%), but blocked by vit B6. Blood glucose & Hgb A1c were unaltered by fructose/vit B6. Dextrose did not alter BP. Fructose raised SBP (123 vs. 114), DBP (95 vs. 84) & MABP (104 vs. 94), but these elevations were prevented by vit B6. Relaxation of aorta from Akita was reduced but normalized by vit B6. In cultured cells, vit B6 activated AMPK & eNOS.

Conclusions: 1. Vit B6 confers anti-hypertensive benefits to insulin- deficient & resistant states. 2. In fructose-induced metabolic syndrome, it lowers plasma cholesterol & insulin. 3. In Akita diabetics, it prevents cardiomyopathy & endothelial dysfunctions, pututatively, by raising AMPK and eNOS.

Effect of L/N-Type Calcium Channel Blocker Cilnidipine on Adriamycin-Induced Cardiomyopathy and Nephropathy in Spontaneously Hypertensive Rats Shizuka Aritomi, Kazumi Niinuma, Mai Kawakami, Tomoyuki Konda. *Research Center, Ajinomoto Pharmaceuticals Co., Ltd., Kawasaki, Kanagawa, Japan.*

Background: Chronic treatment with adriamycin (ADR) is known to induce cardiomyopathy and nephropathy via activation of sympathetic nervous system (SNS) and renin-angiotensin system (RAS). It has been reported that cilnidipine, L/N-type calcium channel blocker (CCB) suppresses SNS and RAS. In this study, we investigated the effect of cilnidipine on the ADR-induced cardiomyopathy and nephropathy in SHR comparing with that of L-type CCB.

Methods: ADR (1.5 mg/kg) was administered intravenously to SHR rats (12 weeks of age) once a week for 3 weeks. Control rats were administered saline (unaffected group, n=10). One week after the last administration of ADR, rats were divided into 3 groups and administered either the vehicle (untreated group, n=16), cilnidipine (20 mg/kg; cilnidipine group, n=16), or amlodipine (3 mg/kg; amlodipine group, n=16) for 4 weeks.

Results: There was no difference in antihypertensive effect between cilnidipine group and amlodipine group throughout the experimental period. ADR caused an increase in the urinary albumin excretion (UAE), urinary protein excretion (UPE), and N-acetyl-ß-D-glucosaminidase excretion (UNAG), indicating the progression of renal dysfunction in this animal model. Although both cilnidipine and amlodipine suppressed these levels, cilnidipine suppressed the increase of UAE and UPE more effectively than amlodipine. Cardiac contractile function was assessed by echocardiography, and ADR exacerbated its dysfunction. Chronic treatment with cilnidipine also resulted in an improvement of cardiac function, but amlodipine did not. In addition, cilnidipine group showed a lower level of RAS than amlodipine group.

Conclusions: The results of the present study indicate that the L/N-type CCB cilnidipine suppresses the progression of renal and cardiac dysfunction induced by ADR. Since such effect was not observed by L-type CCB amlodipine treatment, blockade of N-type calcium channel might play an important role for protection of both renal and cardiac function. And the mechanism of cilnidipine's action can be partly explained by its suppressive action in RAS.

TH-PO743

A Synthetic Serine Protease Inhibitor Camostat Mesilate Inhibited the Proteolytic Activation of gENaC in the Kidney of the Aldosterone-Infused Rats Kohei Uchimura,[1] Yutaka Kakizoe,[1] Tomoaki Onoue,[1] Manabu Hayata,[1] Jun Morinaga,[1] Teruhiko Mizumoto,[1] Masataka Adachi,[1] Taku Miyoshi,[1] Naoki Shiraishi,[1] Sakai Yoshiki,[2] Kimio Tomita,[1] Kenichiro Kitamura.[1] *[1]Department of Nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [2]Research Headquaters, Ono Pharmaceutical Co., Ltd, Osaka, Japan.*

Background: ENaC plays an important role in the regulation of blood pressure by modulating Na reabsorption in the kidney. ENaC consists of a, b, and g subunits, and the activation of ENaC is mainly regulated by aldosterone in living body. It was reported that aldosterone induced a molecular weight shift of gENaC from 85 to 70 kDa, and recently this shift has been considered as the result of proteolytic cleavages by serine proteases and necessary for the activation of ENaC from the in vitro experiment. But detail mechanisms about the cleavage of gENaC in vivo are still unclear. In order to study the role of serine proteases in this cleavage in vivo, we administrated a synthetic serine protease inhibitor camostat mesilate to aldosterone-infused rats.

Methods: The SD rats (n = 6) were kept for 10 days under the following conditions: (1) Control, (2) aldosterone infusion, (3) aldosterone infusion+camostat treated with free access to water and chow. After 10 days, rats were sacrificed under anesthetic conditions with pentobarbital sodium.

Results: Camostat decreased 70kDa form of gENaC and produced the new about 75kDa form with increase of urinary Na/K ratio, suggesting that camostat inhibited one site of the dual cleavages of gENaC and suppressed the activation of ENaC. Prostasin is one candidate serine protease involved in the cleavage of gENaC in these model rats, because prostasin was shown to cleave this subunit in vitro and its excretion into urine was increased by aldosterone. Camostat inhibited protease activity, activating processing and urinary secretion of prostasin.

Conclusions: These results suggest that prostasin is one important serine protease in the pathogenesis of aldosterone-induced salt sensitive hypertension. A synthetic serine protease inhibitor, camostat mesilate, would be a new strategy in the treatment of salt-sensitive hypertension in human.

TH-PO744

The Sodium Chloride Cotransporter (NCC) and Prostasin, a Regulator of the Epithelial Sodium Channel (ENaC), Are Urinary Biomarkers for Hyperaldosteronism Nils van der Lubbe, Pieter Martijn Jansen, Anton H. Van den Meiracker, Alexander H. Danser, Robert Zietse, Ewout J. Hoorn. *Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands.*

Background: Urinary exosomes are vesicles derived from renal tubule epithelial cells that have been shown to contain many disease-associated proteins. Here, we hypothesize that the aldosterone-sensitive sodium transporters could serve as biomarkers for aldosteronism.

Methods: Urinary exosomes were studied in a rat model of hyperaldosteronism and in patients with essential hypertension or primary aldosteronism (n = 5/group). Rats were adrenalectomized and then received vehicle or aldosterone. Primary aldosteronism was defined as an elevated aldosterone to renin ratio and unsuppressible aldosterone in response to volume expansion. Blood pressure and the number and type of antihypertensive drugs were similar in the two groups of hypertensive patients. Exosomes were isolated from 24h urine using ultracentrifugation. Phosphorylated NCC and prostasin, a protease regulating ENaC, were studied by immunoblotting. Prostasin rather than ENaC was studied, because the latter has not been identified in urinary exosomes.

Results: The animal model was confirmed by finding higher plasma aldosterone and lower urinary sodium in rats treated with aldosterone. In the urinary exosomes of these rats, the abundances of pNCC and prostasin were increased 3.9 and 1.8-fold compared to controls ($p < 0.05$ for both). Patients with primary aldosteronism also had higher pNCC and prostasin abundances compared to patients with essential hypertension (1.4 and 1.9-fold), although this did not reach statistical significance ($p = 0.1$ and $p = 0.2$, respectively).

Conclusions: In animals and patients with hyperaldosteronism, the abundance of pNCC and prostasin in urinary exosomes is increased. These results suggest that these aldosterone-sensitive proteins may be used as urinary biomarkers for primary aldosteronism. To validate these results, we are currently expanding the number of patients tested.

TH-PO745

Fat Distribution and Regulation of the Renin Angiotensin System in Healthy Humans Ann A. Zalucky, David Donald McTavish Nicholl, Michelle C. Mann, Brenda Hemmelgarn, Darlene Y. Sola, Sofia B. Ahmed. *University of Calgary.*

Background: Obesity, a major risk factor for chronic kidney (CKD) and cardiovascular disease (CVD), is associated with up-regulation of the renin angiotensin system (RAS), activity which is deleterious to kidney and CV function. The ideal measure of adiposity associated with increased risk in humans is unclear. We sought to determine the relationship between measures of fat distribution and angiotensin (AngII) dependent-control of blood pressure (BP) in healthy humans.

Methods: Thirty-eight healthy non-obese subjects (15 men, 23 women) were studied in high salt balance. Body mass index (BMI), waist circumference (WC), hip circumference (HC), waist-hip ratio (WHR), body adiposity index, body surface area, fat mass%, and total body water% were measured. BP and circulating components of the RAS were measured at baseline and in response to graded AngII infusion (3ng/kg/min x 30 min followed by 6 ng/kg/min x 30 min). The primary outcome was the association between adiposity measures (BMI, HC and WHR) and the BP response to AngII challenge at 60 minutes.

Results: BMI was associated with baseline BP (SBP: r=0.544, p<0.001; DBP: r=0.324, p=0.047) and HC was associated with baseline SBP in women (r=0.491, p=0.02). However, BMI was not associated with the BP response to AngII (SBP: p=0.8, DBP: p=0.7), overall or when stratified by gender. Conversely, HC was non-significantly associated with both SBP (r=0.3, p=0.076) and DBP (r=0.2, p=0.3) responses to AngII challenge, a relationship that achieved significance in men (SBP: r=0.543, p=0.045; DBP: r=0.58, p=0.03) but not in women (SBP: p=0.3; DBP: p=0.7). While BMI was not associated with any circulating RAS components at baseline or in response to AngII challenge, WHR was a predictor of baseline PRA (r=0.563, p=<0.001), AngII (r=0.468, p=0.006) and aldosterone (r=0.355, p=0.03) as well as the PRA response to AngII infusion (r=0.514, p=0.001). Other anthropometric parameters were not associated with any of the responses to AngII challenge.

Conclusions: Fat distribution, as measured by HC and WHR, is associated with vascular RAS activity in healthy humans and may have implications for assessment and control of obesity-mediated hypertension.

TH-PO746

Underlying Mechanisms of Protection in AngiotensinII (AII)-Induced Salt-Sensitive Hypertension (A-SSHT) by Tubular Overexpression of Liver-Type Fatty Acid-Binding Protein (L-FABP) Ken Osaki,[1] Yusuke Suzuki,[1] Takeshi Sugaya,[2] Akira Nishiyama,[3] Satoshi Horikoshi,[1] Yasuhiko Tomino.[1] *[1]Division of Nephrology, Department of Internal Medicine, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]CMIC Co Ltd., Tokyo, Japan; [3]Department of Pharmacology, Kagawa University Faculty of Medicine, Kagawa, Japan.*

Background: At the last ASN meeting, we reported that overexpression of L-FABP in proximal tubules protects against A-SSHT, which was induced by high salt diet after systemic AII infusion for 4 weeks. The objective of the present study is to examine the underlying mechanisms in L-FABP-mediated protection using transgenic mice which have tubular overexpression of L-FABP in the proximal tubules (L-FABPTg), and the murine proximal tubular cell line transgene with (mProxTg) or without (mProx) L-FABP.

Methods: 1) mProx and mProxTg were subjected to AII-stimulation (10 nmol/L) with or without pretreatment of tempol. mRNA expressions of angiotensinogen (Ag), oxidative stress and inflammatory markers were analyzed.

2) We also examined the expressions of these markers in L-FABPTg and their wild type littermates (WT) with A-SSHT.

Results: 1) AII-stimulation induced mRNA expressions in mProx of HO-1 and MCP-1 peaked at 12 and 36 hr, and Ag peaked at 36 hr. These expressions were significantly attenuated in mProxTg (P<0.05). Tempol pretreatement in mProx also significantly attenuated these expressions at 36 hr (P<0.05).

2) L-FABPTg with A-SSHT showed significant attenuation of renal Ag, 4-HNE, HO-1 and MCP-1 expressions with significant improvement of hypertension and interstitial T-cell infiltration.

Conclusions: It was found that tubular overexpression of L-FABP may protect against A-SSHT through attenuation of AII-induced oxidative stress and exacerbation of intrarenal RAS activation and inflammatory responses.

A Novel Mechanism Explaining Salt Sensitivity: Post-Transcriptional Regulation of 11β-Hydroxysteroid Dehydrogenase Type 2 by miRNA Mina Rezaei,[165875] Thomas Andrieu,[165880] Bernhard Dick,[150254] Brigitte Frey,[150256] Felix J. Frey.[8985] *[1]University of Berne; [2]University of Berne; [3]University of Berne; [4]University of Berne; [5]Nephrology and Hypertension, University of Berne, Switzerland.*

Background: Decreased activity of 11β-hydroxysteroid dehydrogenase (11β-HSD2), protecting the mineralocorticoid receptor from cortisol, induces salt sensitivity in humans and rodents. The mechanisms for tissue specific and inter-personal diverse expression of 11β-HSD2 are unknown. We hypothesized for the first time that miRNAs determine 11β-HSD2 activity.

Methods: The 11β-HSD2 activity in salt sensitive Sprague Dawley (SD) and salt insensitive Wistar (W) rats was investigated, the differences between the target sequence of miRNAs in the HSD11B2-3'UTR were analyzed and the role of dicer to regulate 11β-HSD2, was studied. The urinary ratio of corticosterone/dehydrocorticosterone (B/A) and their metabolites were assessed by gas chromatography/mass spectrometry.

Results: B/A ratio was increased in SD when compared to W rats (0.8±0.2 vs. 0.5±0.1, p<0.05), while (tetrahydrocorticosterone+5α-tetrahydrocorticosterone)/tetradehydrocorticosterone was decreased (0.5±0.1 vs. 1.3±0.3, p<0.001), indicating a diminished 11β-HSD2 activity in SD rats.

To demonstrate whether miRNAs are involved in the diminished 11β-HSD2 activity observed in vivo, the 3'UTR of HSD11B2 of SD and W rats were sequenced and cloned downstream of a reporter gene. Different cell lines (SW620, HT29, HCT116) were transfected with these constructs. The SD 3'UTR construct showed a lower reporter activity than W 3'UTR construct, an effect continuously reversed by cloning various mutated sequences progressively restoring the sequence of the 3'UTR of HSD11B2 found in W rats. These data indicate that the 3'UTR regulates 11β-HSD2 activity. To determine whether miRNAs modulate the expression of 11β-HSD2 we measured the expression of 11β-HDSD2 in HCT116 wild type and HCT116 dicer KO cells. Dicer KO HCT116 cells had an increased expression of 11β-HSD2.

Conclusions: These data indicate for the first time that the 3'UTR and miRNAs determine 11β-HSD2 expression and activity and are of potential relevance for glucocorticoid-mediated increased salt sensitivity.

TH-PO748

Sodium Induced Down Regulation of the Angiotensin II Receptor (AT-1) and CD39 in Endothelial Cells In Vitro Silvana L. Della Penna, Marijke M. Faas, Theo Borghuis, Harry Van Goor, Winston W. Bakker. *Department of Pathology and Medical Biology, University Medical Center Groningen, Groningen, Netherlands.*

Background: High dietary salt intake is associated with hypertension, cardiovascular and renal risk. Endothelial injury leading to endothelial dysfunction plays a major role in these conditions.

To evaluate the mechanism of salt mediated damage, we focused on the endothelium protecting ecto-enzyme CD39 [i.e. ectonucleoside triphosphate diphosphohyrolase-1, (ENTPD-1), or ecto-apyrase] and on the angiotensin II receptor (AT-1). CD39 is sensitive to oxygen free radicals and possibly also to the pro-inflammatory action of angiotensin II.

Methods: Confluent human endothelial cells were co-cultured with human peripheral blood mononuclear cells ($1x10^6$ cells per well) using either medium (RPMI 1640) with a standard amount of NaCl (154.0 mMol/L) (low salt, LS), or with "high" NaCl (155.54 mMol/L) (HS). After 16 hours, cytospins of endothelial cells were prepared for flow cytometry or immunostained for AT-1 and CD39.

In another set of experiments PBMC from HS and LS cultures were isolated after 16 hrs of co-culture with endothelial cells and subsequently labeled with dichlorofluorescein diacetate for detection of O_2^- by flow cytometry.

Results: Endothelial cells cultured in HS medium show a significant decrease of CD39 expression as compared with control cultures, as demonstrated by both immunostaining (P<0.05) and flow cytometry (P<0.05). Endothelial AT-1 receptor expression also showed down regulation in the presence of HS (P<0.01), whereas HS showed enhanced O_2^- production in PBMC as compared with PBMC from LS cultures.(P<0.01)

Conclusions: The present data indicate that a slight increase of salt is able to induce impairment of an important endothelial anti-inflammatory ecto-enzyme (CD39) as well as down regulation of the AT-1 receptor in endothelial cells in vitro. These alterations may be mediated by toxic oxygen radicals produced by PBMC. Down regulation of endothelial AT-1 by salt in vitro may be in line with down regulation of the RAAS, known to occur after salt loading in vivo.

TH-PO749

Salt-Sensitivity of Blood Pressure in Mice with Targeted Knockout of the Insulin Receptor in Thick Ascending Limb through Collecting Duct Lijun Li, Radha Mayuri Garikepati, Karishma Sitapara, Carolyn M. Ecelbarger. *Department of Medicine, Georgetown University, Washington, DC.*

Background: Previously we showed reduced expression and phosphorylation of renal insulin receptors (IRs) in kidneys of insulin-resistant rats. We also demonstrated that targeted knockout of IR from the kidney of mice using Ksp-cadherin-targeted Cre recombinase led to modestly increased systolic blood pressure (BP) and reduced urine nitrates plus nitrites (UNOx) excretion. We hypothesized IR signaling might play a role in BP homeostasis and sensitivity to dietary NaCl.

Methods: To address this, young male KO and wild-type (WT) littermates (~4-months old) were instrumented with radiotransmitters to measure BP and heart rate and transitioned through a 4-week regimen that included 1-week periods on:the following diets: 1) medium-NaCl (MS, 0.5%); 2) low-NaCl (LS, 0.085%); 3) high-salt (HS, 5%) and HS plus the anti-oxidant Tempol (3 mM) in the drinking water. Urine was collected for 24 hours at the end of each week and UNOx measured.

Results: There were no differences in initial or final body weight between genotypes. Under low-NaCl diet (0.085%), there were no significant differences in systolic, diastolic, or MAP. Systolic BPs were as follows (mm Hg): 117 ± 3 (WT) versus 109 ± 7 (KO, p = 0.33, n = 7/genotype). The switch from low- to high-NaCl diet did not affect systolic BP in the WT mice (delta SBP, mm Hg) -2 ± 3, but increased it on average 16 ± 8 in the KO (p < 0.05) in the KO. Tempol led to a small decrease in systolic BP in both genotypes which was not significantly different: -2.7 ± 5.2 (WT) versus -4.4 ± 6.7 (KO, p = 0.84). UNOx

increased approximately 3-fold with HS and was not affected by Tempol. The area under the curve for the rise in UNOx was 20% reduced in the KO mice. Heart rate was slightly reduced in the KO mice, an effect that was significant in the MS period (p= 0.015).

Conclusions: Overall, KO mice show greater BP sensitivity to salt with some blunting of the potentially protective rise in NOx production. The fact that Tempol had little affect on responses to HS diet suggests that factors in addition to oxidative stress, are likely determinant(s) of enhanced salt sensitivity.

TH-PO750

Sodium-Sensitivity Correlates with Differential Regulation of Peripheral Blood MicroRNAs Sophie Domhan,[1] Claudia Sommerer,[1] Felix J. Frey,[3] Martin G. Zeier,[1] Amir Abdollahi.[2] *[1]Nephrology, University of Heidelberg Medical School, Germany; [2]Radiation Oncology, University of Heidelberg Medical School, Germany; [3]Nephrology, Inselspital, University Hospital of Berne, Switzerland.*

Background: Sodium-sensitivity is an important risk factor for cardiovascular events and is associated with increased morbidity and mortality. MicroRNAs (miRs) are considered masterregulators of transcriptome. We aimed to identify the molecular determinants of sodium response and predictors of sodium sensitivity using the blood transcriptome as the sentinel organ.

Methods: Whole blood total RNA including miRs were collected during high (150 mmol/d) and low (30 mmol/d) sodium diet using PAXgene tubes. 24 hour blood pressure monitoring was performed during each diet to assess for changes in blood pressure. MiR isolation was performed using Qiagen's PAXgene Blood miRNA Kit and the QIAcube system. RNA quality control and quantitation was performed using total- and small RNA Agilent Chips (Bioanalyzer, Agilent) and NanoDrop spectrophotometer. Genome-wide miR profiling was performed using Illumina's microRNA DASL assay. Clustering and statistics were performed using SUMO software package.

Results: 53 miRs were differentially regulated ($p<0.02$) after sodium-rich vs. sodium-low diet in n=6 patients. The prevailing effect of sodium rich diet was downregulation of miRs (35 down- vs. 15 upregulated miRs). Given the inhibitory function of miRs on post/transcriptional regulation, our data suggest a global activation of the trancriptome via downregulation of miRs in response to sodium. Of note, the miR200 family, recently attributed to be involved in the EMT process were found to be induced by sodium. Three patients demonstrated increased blood pressure (MAP) of at least 8 mmHg after sodium-rich vs. sodium-low diet and were therefore considered to be sodium-sensitive. We found 105 miRs to be differentially regulated between sodium-sensitive vs. salt-resistant patients ($p<0.05$). The regulation of candidate sodium responsive/sensitivity miRs are confirmed by qRT-PCR.

Conclusions: Our data demonstrate the feasibility of peripheral blood miRNAs as sentinel organ to detect sodium response/sensitivity.

Epigenetic Modulation of Renal b-Adrenergic-WNK4 Pathway in Salt-Sensitive Hypertension Shengyu Mu, Toshiro Fujita. *Department of Nephrology and Endocrinology, University of Tokyo, Japan.*

Background: How high salt intake increases blood pressure is a key question in the study of hypertension. Salt-induced increases in renal sympathetic activity have been shown to induce sodium retention. However, the mechanism underlying the sympathetic control of renal sodium excretion remains unclear. We have reported that β_2 adrenergic receptor (β_2AR) stimulation down-regulated WNK4 transcription (to less than 50%) through epigenetic modulation (Mu S. et al. Nat Med 2011).

Methods: We injected Isoproterenol (ISO) to wild type mice by subcutaneous mini pumps. WNK4 mRNA expression were measured by Realtime-RT-PCR. Then we use the HAT p300 inhibitor curcumin (Cur) to see if reverse of histone acetylation could adjust the WNK4 expression and prevent the sympathetic activity induced salt-sensitive hypertension. Blood pressure were measured by radio-telemetery system.

Results: In former study, we revealed that β_2-AR stimulation suppressed the activity of histone-deacetylase 8 (HDAC8) and recruit glucocorticoid receptor (GR) binding to the negative GR responsive element (nGRE) in WNK4 promoter region, and lead to the transcriptional inhibition of WNK4 gene. And in vivo model, we clarified that suppressed WNK4 leads to activation of the Na^+-Cl^- co-transporter (NCC), which led to the development of salt-induced hypertension (SBP 180mmHg ±10mmHg). In the present study, based upon our finding, we investigated possible therapeutic role of the inhibition of histone acetylase (HAT) in salt-sensitivity by modulating histone acetylation. In isoproterenol infusion mice model, high-salt loading developed obvious salt-sensitive hypertension, as same in our former report, however, the treatment of p300 inhibitor-curcumin to these mice recovered the WNK4 expression in kidney and prevented the development of salt-sensitive hypertension.

Conclusions: Our results illustrate a novel role for another epigenetic modulation – HAT inhibition in the development of salt-induced hypertension and we provided an alternative therapeutic target of salt-sensitive hypertension.

TH-PO752

Renal Afferent Nerves: Key Element of a Tonic Sympatho-Inhibitory System? Tilmann Ditting, Wolfgang Freisinger, Sonja Heinlein, Kirsten Siegel, Christian Fiedler, Roland E. Schmieder, Karl F. Hilgers, Roland Veelken. *Dept. of Nephrology & Hypertension, University of Erlangen Nürnberg, Erlangen, Germany.*

Background: Renal innervation consists of sympathetic efferent and peptidergic afferent nerves. The latter express TRPV1-receptors. We recently found neurophysiological evidence for a functionally relevant intrarenal peptidergic innervation, exhibiting sympatho-inhibitory effects. Hence, we now tested the hypothesis that stimulation of renal afferent nerve activity (ARNA) with the TRPV1-agonist capsaicin inhibits efferent renal sympathetic nerve activity (RSNA).

Methods: Eight methohexital anesthetized male Sprague-Dawley rats were instrumented as follows: arterial and venous catheters for recording of blood pressure (BP) and heart rate (HR) and drug administration; left sided renal arterial catheter for selective intrarenal administration (IRA) of the TRPV1 agonist capsaicin (CAP 3.3, 6.6, and 10*10-7M; 10µl; after 15, 30, 45, and 60 minutes) to stimulate ARNA; right sided bipolar stainless steel electrode for continuous RSNA recording; Before and after IRA CAP increasing intravenous (IV) doses of the NK1-receptor blocker RP67580 was given. The NK2- and CGRP blockers MEN10376 and CGRP8-37 where also tested.

Results: IRA CAP decreased integrated RSNA from 65.4±13.0 µV*sec (baseline) to 12.8±3.2 µV*sec (minimum), $P<0.001$. This sustained RSNA inhibition reached its minimum within 70 minutes, and was not directly linked to the transient electrical ARNA response which is usually seen with IRA CAP. Suppressed RSNA was transiently but completely unmasked by systemic (IV) administration of the NK1-blocker (maximum 120.3±19.4 µV*sec; $P<0.001$). Furthermore NK1-blockade transiently increased baseline RSNA to similar levels in dose dependent manner. NK2- and CGRP blockers had no effect.

Conclusions: Our study provides direct evidence that the afferent renal nerves provide a tonically acting sympatho-inhibitory system which seems to be rather mediated by neurokinin release acting via NK1-receptor pathways, than by electrical ARNA effects on central sympathetic outflow. However, the exact site of NK1-mediated action (central, ganglionic, or other) remains to be further elucidated.

TH-PO753

The Pivotal Role of Midkine on the Development of Hypertension in Endothelial Dysfunction Yuka Sato, Waichi Sato, Tomoki Kosugi, Hiroshi Kojima, Kayaho Maeda, Hiroshi Nagaya, Mayuko Hori, Shoichi Maruyama, Seiichi Matsuo. *Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan.*

Background: The pathophysiology of hypertension includes the complex interaction of vascular effectors such as renin-angiotensin system (RAS), oxidative stress, nitric oxide (NO). The growth factor midkine (MK) is a multi-functional heparin-binding protein, and its biological activity affects in the progress of ischemic renal injury, diabetes and hypertension. We have previously demonstrated that MK induction by oxidative stress regulated the RAS through lung angiotensin converting enzyme (ACE), eventually leading to systemic hypertension and renal dysfunction. However, the regulatory mechanism of hypertension remains unclear. NO regulates intraglomerular pressure, and its reduction causes cadiovascular disease and chronic kidney disease. In the present study, we investigated the role of MK in the development of hypertension in endothelial dysfunction by NO reduction.

Methods: Wild-type mice ($Mdk^{+/+}$) and MK-deficient mice ($Mdk^{-/-}$) are treated with unilateral nephrectomy (UNx) and NO synthase inhibitor, L-NAME administration in a drinking water. They were measured systolic blood pressure (BP) and albuminuria at 1, 2 and 4 months, and sacrificed on 4 months for immunohistochemical and biochemical analyses.

Results: Systolic BP of both $Mdk^{+/+}$ and $Mdk^{-/-}$ were elevated by UNx compared to non-treatment, whereas $Mdk^{+/+}$ with UNx+L-NAME developed marked hypertension compared to $Mdk^{+/+}$ with UNx. Remarkably, $Mdk^{-/-}$ with UNx+L-NAME exhibited normotension. Proteinuria and glomerular sclerosis were also prominent in $Mdk^{+/+}$ mice with UNx+L-NAME. Lowering BP using hydralazine significantly blocked the development of proteinuria and glomerlar sclerosis. However, lung and serum ACE activities were not increased in both groups. Aorta relaxation test by magnus apparatus revealed that MK is markedly associated with endothelial- dependent relaxation.

Conclusions: These data suggest that in endothelial dysfunction, glomerular injury with proteinuria depends on hypertension whereas hypertension by NO blockade might involve MK-NO-cGMP pathway, but not the activation of RAS.

TH-PO754

Genetically Determined Low Nephron Number Is Associated with Hypertension Due to Chloride, but Not Sodium Retention Kerstin Benz,[1] Julia Schlote,[2] Nada Cordasic,[3] Christoph Daniel,[2] Christoph Kopp,[3] Andrea Hartner,[2] Karl F. Hilgers,[3] Jens Titze,[3] Kerstin U. Amann.[2] *[1]Pediatrics, University of Erlangen-Nürnberg, Erlangen, Germany, Erlangen, Germany; [2]Pathology, University of Erlangen- Nürnberg, Erlangen, Germany; [3]Nephrology and Hypertension, University of Erlangen- Nürnberg, Erlangen, Germany.*

Background: An association between low nephron number and development of hypertension in later life has been demonstrated. The underlying pathomechanisms are unknown. Reduced renal Na^+ and water clearance is regarded as one option. We tested the hypothesis that GDNF heterozygous (GDNF+/-) with 30% reduction of nephron number have increased tissue electrolyte and water content compared to wildtype (wt) mice.

Methods: 34 GDNF+/- and 35 wt mice (45-55 wks) received low salt (LSD,0.03%,tap water) or high salt (HSD,4% NaCl,0.9% saline) diet for 4 weeks. Blood pressure (bp) was continuously measured by telemetry (n=4 per group). At the end of the experiment, blood samples were taken, and tissue Na^+,K^+,Cl^- and water content in skin, bone, and total body weight were determined by chemical analysis.

Results: Body weight, dry weight, total body water content, relative skin and body Na^+ and K^+ content were not significantly different between the groups, and no differences in serum concentrations were found. In contrast and independent of the diet, skin and total body Cl^- content of the skin was higher in GDNF+/- than wt mice, resulting in an increased Cl^-space in GDNF+/- mice which is a surrogate parameter for extracellular volume retention. Additionally, GDNF+/- mice under HSD showed significantly higher daily urine excretion and albuminuria compared to wt mice with HSD. In parallel with tissue Cl^- accumulation, bp was higher in GDNF+/- than in wt mice fed LSD. HSD resulted in a more pronounced bp increase in GDNF+/- mice compared to wt mice.

Conclusions: We found that tissue Cl^- accumulation, but no differences in Na^+ and water balance, parallel the development of hypertension in GDNF+/- mice. These findings suggest that reduced renal Cl^- clearance parallels hypertension in mice with reduced nephron number.

TH-PO755

Neutrophil Gelatinase-Associated Lipocalin, a Novel Mineralocorticoid Biotarget in the Cardiovascular System Celine Latouche,[1] Soumaya El Moghrabi,[1] Ivan Hernandez,[2] Diego Alvarez de la Rosa,[2] Natalia Lopez-Andres,[4] Patrick Rossignol,[3] Faiez Zannad,[3] Nicolette E. Farman,[1] Frederic Jaisser.[1] *[1]U872 team 1, INSERM, Paris, France; [2]Department of Physiology and Institute of Biomedical Technologies, University of La Laguna, Tenerife, Spain; [3]Centre d'Investigations Cliniques- 9501, Nancy-Université, France, Nancy, France; [4]U961, INSERM, Nancy, France.*

Background: Mineralocorticoid receptor (MR) activation is deleterious to the cardiovascular system and MR antagonists improve morbidity and mortality of patients with heart failure. However mineralocorticoid signaling in the heart remains largely unkown.

Methods: we used genetically modified mouse models, pharmacological mineralocorticoid stress in rodents and cultured cells to address the implication of Neutrophil Gelatinase-Associated Lipocalin (NGAL also known as Lipocalin2)NGAL as a biomarker of MR activation in the cardiovascular system.

Results: Using a transcriptomic approach, we identified NGAL as the highest upregulated gene in the heart of transgenic mice with conditional MR overexpression targeted to the cardiomyocytes. We show that NGAL expression is directly controlled by mineralocorticoid activation in the cardiovascular system. In addition, using NGAL knock-out mice, we show that NGAL is crucial for the occurrence of extracellular matrix remodeling induced by mineralocorticoid excess in the heart. Moreover, in asymptomatic obese subjects prone to develop heart failure, circulating levels of NGAL-MMP9 complexes are correlated with plasma aldosterone and with serum levels of biomarkers of cardiovascular fibrosis.

Conclusions: CONCLUSION: we suggest that NGAL is potentially a novel MR biotarget and may provide a link between mineralocorticoid stress and cardiovascular remodeling in humans. Whether NGAL is also a biotarget of aldosterone/MR in the kidney is currently under investigation.

TH-PO756

SIRT1 Activation Protects the Endothelial Dysfunction by Inhibiting E-Selectin and VCAM-1 Generation Hideyuki Negoro,[1] Atsuo Goto.[2] *[1]Medicine, Harvard Medical School, Boston, MA; [2]Nephrology, Japanese Red Cross Medical Center Hospital, Tokyo, Japan.*

Background: SIRT1 is a conserved NAD(+)-dependent deacetylase and possesses beneficial effects against aging-related diseases, but little information is available on a putative role of SIRT1 in endothelial and vascular homeostasis. Endothelial senescence causes endothelial dysfunction to promote atherosclerotic change and contribute to age-related vascular diseases. Cellular adhesion molecules, such as endothelial-leukocyte adhesion molecule-1 (E-selectin) and vascular cell adhesion molecule-1 (VCAM-1) play an important part in the progression of age-related vascular diseases.

Methods: We established an in vitro senescence model by prolonged culture of primary endothelial cells isolated from bovine aorta. The freshly isolated young endothelial cells gradually underwent senescence during 1 month of repetitive passages. We knocked down SIRT1 to evaluate the protein levels of LKB1, phosphorylated AMPK, E-selectin and VCAM-1 in the knocked down cells.

Results: It was observed that protein expressions of SIRT1 were decreased time dependently in the senescent endothelial cells. In contrast, the protein levels of LKB1, a serine/threonine kinase, the phosphorylation of its downstream target AMP-activated protein kinase (AMPK), E-selectin and VCAM-1 generation were dramatically increased in the senescent cells. On the other hand, resveratrol activated SIRT1 in the endothelial cells. SIRT1 activation with resveratrol inhibited the increase of LKB1, AMPK. At the same time, SIRT1 activation with resveratrol reduced E-selectin and VCAM-1 generation in the endothelial cells significantly. We knocked down SIRT1 and the protein levels of LKB1, phosphorylated AMPK, E-selectin and VCAM-1 elevated in the knocked down cells. The protein levels of LKB1, phosphorylated AMPK, E-selectin and VCAM-1 generation did not changed in the SIRT1 knocked down cells even if they were stimulated with resveratrol.

Conclusions: These findings indicate that activation of SIRT1 provides beneficial effects against the endothelial dysfunction to promote atherogenesis by inhibiting E-selectin and VCAM-1 generation.

AT1 Antagonism and Renin Inhibition in Mice: Pivotal Role of Targeting Angiotensin II for Nephroprotection Christian Krebs,[1] Christoph Fraune,[1] Alexander H. Danser,[2] Harry Van Goor,[3] Edzard Schwedhelm,[1] Rolf A. Stahl,[1] Ulrich Wenzel.[1] *[1]Medicine, University of Hamburg, Germany; [2]Division of Vascular Medicine and Pharmacology, Erasmus MC, Rotterdam, Netherlands; [3]Pathology and Medical Biology, University Medical Centre Groningen, Netherlands.*

Background: The role of the renin-angiotensin system in hypertensive renal injury involves multiple peptides and receptors. Exerting antipodal pathophysiological mechanisms, renin inhibition and blockade of the Ang II type 1 (AT1) receptor ameliorate renal damage.

Methods: We compared the direct renin inhibitor aliskiren with the AT1 antagonist losartan in mice of the FVB strain with chronic kidney disease (CKD) due to renal ablation. Blockade of the RAS increases renin due to inhibition of the Ang II mediated negative feedback loop. Thus renin expression was used to quantify the extent of RAS blockade. Doses were adjusted to equipotent and maximal inhibition of the RAS.

Results: 6-week treatment with either 500 mg/l drinking water losartan or 50 mg/kg body weight/day aliskiren significantly decreased albuminuria, NGAL excretion, glomerular damage, and transcription rates of markers of fibrosis like PAI-1 and fibronectin to a similar extent. An array analysis comparing renal gene expression of losartan and aliskiren treated mice evaluating >34,000 transcripts demonstrated regulation for 14 genes only, with maximal difference of a signal-log ratio of 2. No superior nehroprotection was found by combining losartan and aliskiren compared to monotherapies. Compared to plasma concentrations, aliskiren accumulated ~7 to 29-fold in heart, liver, lung, and spleen and ~156-fold in the kidney. After withdrawal, plasma concentrations dropped to zero within 24 hrs, whereas renal tissue concentrations declined slowly over several days. Withdrawal of aliskiren in mice with CKD revealed a significantly delayed re-increase in albuminuria compared to withdrawal of losartan.

Conclusions: This study demonstrates equieffective nephroprotection of renin inhibition and AT1 antagonism in mice with CKD without additional benefit of combination therapy. However, aliskiren offers advantages derived by its pharmacokinetics.

Renoprotective Effect of Rosuvastatin in Salt-Sensitive Hypertensive Rats Sun Moon Kim,[1] Seung Hee Yang,[2] Yon Su Kim.[2] *[1]Internal Medicine, Chungbuk National University Hospital, Cheongju, Republic of Korea; [2]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea.*

Background: Hypertension is a significant risk factor for the development and progression of chronic kidney disease. Although recent clinical studies suggested that statins might have pleiotropic effects upon cardiovascular disease, the evidences regarding the benefit of statins in renal injury was not clear. We investigated whether statin treatment would attenuate renal damage in Dahl salt-sensitive (DS) hypertensive rat models which develop hypertension by high salt diet (8.0% NaCl).

Methods: DS rats were fed with high salt diet from 7 weeks and rosuvastatin (20mg/kg/day by gavage, n=6) or vehicle (n=6) was administered from 13 to 21 weeks of age. Body weight, blood pressure, urine protein and creatinine, serum BUN, creatinine, and cholesterol were measured. Glomerulosclerosis index (GSI), tubular lesion index (TLI) and expression of TGF- β1 and ET-1 were assessed from kidney tissue.

Results: DS rat given a high salt diet developed hypertension (systolic blood pressure, 216 ± 42 mmHg) (compared to rat given in normal salt diet; 150 ± 8 mmHg) and showed azotemia and proteinuria. Between rosuvastatin-treated group and vehicle treated group, rosuvastatin treatment had little effect on the blood pressure and the serum level of total, HDL-, LDL-cholesterol, urinary protein/urinary creatinine or serum creatinine compared to vehicle treatment. However, it significantly decreased blood urea nitrogen level (18.0 ± 2.7 in rosuvastatin-treated group vs. 30.5 ± 8.5 mg/dL in vehicle-treated group, p = 0.014) and protected kidney injury assessed by renal histology index (GSI, 1.13 ± 0.27 in rosuvastatin-treated group vs. 1.57 ± 0.33 in vehicle-treated group, p = 0.048; TLI, 0.67 ± 0.08 in rosuvastatin-treated group vs. 1.05 ± 0.15 in vehicle-treated group, p = 0.001). Immunohistochemical analysis showed decreased level of TGF-β1 expression in rosuvastatin-treated rats compared to vehicle-treated rats whereas it showed no difference in the level of ET-1 expression.

Conclusions: Our results suggest that rosuvastatin mitigate hypertensive renal injury independent from lipid lowering effect and its effect may involve TGF- β1.

TH-PO759

Pentoxifylline Inhibits Angiotensin II-Stimulated Proliferation of Rat Vascular Smooth Muscle Cells Sang Youb Han,[1] Kum Hyun Han,[1] Young Sun Kang,[2] Dae R. Cha.[2] *[1]Internal Medicine, Inje-Univ. Ilsan-Paik Hosp., Goyang; [2]Internal Medicine, Korea Univ. Ansan Hosp., Ansan, Republic of Korea.*

Background: Pentoxifylline (PTX) is a non-selective inhibitor of cyclic-3', 5'-phosphodiesterase, which raises intracellular cAMP. PTX has been known to have an effect against cell proliferation, inflammation and fibrosis in some experiments. However, little is known about whether PTX can prevent Ang II-induced proliferation of vascular smooth muscle cell (VSMC) which is an important role in hypertensive vascular damage. To evaluate this, we tested anti-proliferative effect and cell cycle regulation of PTX in the Ang II-stimulated VSMC.

Methods: Rat VSMCs were isolated from the thoracic aortas of male Sprague-Dawley rats. The VSMCs were treated with 1 uM of Ang II and various doses of PTX. The Proliferation was determined by the MTT assay. Cyclic 3',5' –AMP was measured by the cyclic AMP EIA kit. The expressions of mRNA and protein were analyzed using real-time PCR and Western blotting.

Results: 1. Ang II significantly proliferated VSMC (Control: 0.29±0.02 vs. Ang II: 0.40±0.05, p<0.01). PTX dose-dependently suppressed Ang II-induced cell proliferation (PTX 0.1mM: 0.32 ± 0.05; PTX 0.5mM: 0.29 ± 0.03; PTX 1mM: 0.26 ± 0.04; PTX 2mM: 0.25 ± 0.03, p <0.05).

2. Ang II inhibited cAMP generation (Control: 34.62 ± 0.59 vs. Ang II: 17.49 ± 3.30, p <0.05). PTX significantly restored cAMP level in Ang II-stimulated cells (PTX 1mM: 40.68 ± 0.49, PTX 2mM: 41.50 ± 1.78, p<0.05).

3. Ang II significantly upregulated mRNA and protein expression of cyclin D1 by 2 folds, and downregulated mRNA and protein expression of p21 by half. There were no changes of cyclin E, cyclin A, CDK2 and CDK4, and P27. PTX pretreatment prevented the changes of cyclin D1 and p21.

Conclusions: PTX attenuated proliferation in Ang II-stimulated VSMCs. The anti-proliferative effect of PTX was related to the increment of cAMP and partial regulation of cell cycle. Further study will be required to elucidate the role of PTX on hypertensive vessel wall.

Vitronectin-Binding PAI-1 Protects Against Cardiac Fibrosis through Interactions with Fibroblasts Jianyong Zhong,[1] Haichun Yang,[2] Valentina Kon,[1] Iekuni Ichikawa,[1] Agnes B. Fogo,[2] Ji Ma.[1] *[1]Pediatrics, Vanderbilt University; [2]Pathology, Vanderbilt University.*

Background: Plasminogen activator inhibitor-1 (PAI-1) is actively involved in fibrotic processes of multiple organs, with the net effects dependent on the tissue and the cellular composition. Our previous *in vivo* studies indicated that, while PAI-1 deletion or the protease inhibitory PAI-1 variant increased profibrotic responses in the mouse heart exposed to chronic angiotensin II (AII) infusion, the vitronectin (Vn)-binding PAI-1 variant rather decreased expression of cardiac myofibroblast markers. The aim of the present study was to elucidate how Vn-binding and protease inhibitory PAI-1 differentially impact cardiac fibroblast functions.

Methods: Cardiac fibroblasts were stimulated with AII for 48 hours. One of the human PAI-1 variants including, PAI-1AK (AK, retaining protease inhibitory effects, but not binding to Vn), PAI-1RR (RR, binding Vn normally, but no protease inhibitory activity), control PAI-1 (CPAI, retaining all known functions of native PAI-1) was added simultaneously.

Results: Supernatant plasminogen activator and plasmin activities were significantly decreased by AK and CPAI, variants that inhibit protease. These changes were associated with significantly increased supernatant fibronectin (CPAI 1253.4±96.7 and AK 1264.7±2.1 ng/$\times 10^4$ cells *vs.* AII 852.9±45.7 and non-AII control 696.9±78.2 ng/$\times 10^4$ cells; $p<0.05$, respectively). RR did not increase supernatant fibronectin (857.6±47.9 ng/$\times 10^4$ cells). Compared to the AK, cells treated with RR had more TUNEL-positive apoptosis (RR 3.13±0.49% *vs.* AK 1.70±0.35%, $p<0.05$), while there was no difference in cell proliferation among the groups. Among the PAI-1 variants, AK, the non-Vn-binding variant, significantly up-regulated the expression of integrin β3 subunit (AK 0.55±0.02 *vs.* RR 0.36±0.04 and CPAI 0.41±0.03, $p<0.05$).

Conclusions: Protease inhibitory PAI-1 promotes extracellular matrix accumulation, while PAI-1, through its Vn-binding pathway, down-regulates integrin β3 and promotes apoptosis in cardiac fibroblasts. We speculate that preserving the Vn-binding ability of PAI-1 may protect against cardiac fibrosis.

Overexpression of Na+, K+-ATPase and Sodium Sensitive Hypertension Induced by Ovariectomy in Adult Rats Fernando Raul Ibarra,[1] Luis A. Di Ciano,[1] Elisabet Monica Oddo,[1] Pablo J. Azurmendi,[1] Jorge Toledo,[1] Elsa Zotta,[2] Federico Ochoa,[2] Elvira Arrizurieta.[1] *[1]Instituto A Lanari; [2]Faculty of Medicine, Buenos Aires University.*

Background: We have shown that ovariectomy in adult Wistar rats caused an activation of renal kallikrein-kinin system and a decrease in mean blood pressure (MBP) (Kidney Blood Press Res 2009). Now we tested whether Wistar rats ovariectomized (OVX) when 60 days old and studied at 150 days of life could have changes in Na^+ excretion (ENa^+) and in systemic hemodynamic.

Methods: To this purpose, intact (I) and OVX rats consuming either normal sodium diet (NS, 0.24% NaCl) or high sodium (HS, 1% NaCl, in drinking water) for 5 days were studied.

The expression of total Na^+, K^+-ATPase (NKA) alpha1 subunit and its phospho state at Ser 23 (PKC site) was determined by western blot in renal homogenates. Current concepts agree that when dephosphorylated renal NKA is more active. Beta actin served as control. Immunohistochemistry was employed to localise tissue NKA. Glomerular filtration rate (GFR) and renal plasma flow (RPF) were measured by clearance techniques.

Results: On NS diet, expression of total and dephosphorylated NKA was higher in renal medulla from OVX by 10 ± 1% (p <0.05 vs I). The increment was localised in the outer medulla of OVX rats. Under a NS diet, ENa^+, diuresis and MBP did not differ between I and OVX rats, while OVX rats showed a trend to increase RPF (I 3.63±0.29 vs OVX 4.81±0.39 ml/min/g kwt).

When exposed to a HS diet, NKA alpha1 subunit Ser 23 dephospho state decreased in I and OVX rats. But, in OVX rats, Ser 23 remained markedly more dephosphorylated than in I rats (50% higher in renal cortex and medulla, p<0.01, both). Under a HS diet, ENa^+ (mEq/g kwt /day)was lower in OVX than in I rats (3.9±0.1 vs 4.6±0.3, p<0.05) and MBP significantly increased in OVX to 135±9 vs 116±7 mmHg in I rats, p<0.05. Diuresis, GFR and RPF were not different between I and OVX rats under HS diet.

Conclusions: Ovariectomized adult rats have a higher total and dephosphorylated Na^+, K^+-ATPase alpha1 subunit and a lower sodium excretion under HS diet than I rats. Both, together, may contribute to develop sodium sensitive hypertension in rats deprived of ovarian hormones.

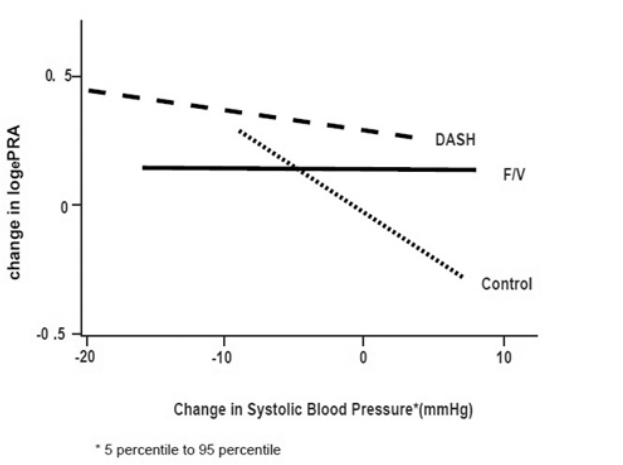
TH-PO762

The Effects of Dietary Patterns on Plasma Renin Activity: Results from the Dietary Approaches To Stop Hypertension (DASH) Trial Qi Chen,[1] Sharon Turban,[2] Edgar R. Miller,[1,3] Lawrence J. Appel.[1,3] *[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]Division of Nephrology, Johns Hopkins University School of Medicine, Baltimore, MD; [3]Welch Center for Prevention, Epidemiology, and Clinical Research, Johns Hopkins University, Baltimore, MD.*

Background: A diet rich in fruits, vegetables, and low-fat dairy products and reduced in saturated fat, total fat, and cholesterol (termed the "DASH" diet) significantly lowers blood pressure (BP). Previous studies have documented that certain therapies that lower BP increase plasma renin activity (PRA).

Methods: Using data from the DASH trial, we assessed the effects of dietary patterns on PRA and determined the relationship of change in PRA with change in BP on each diet. After eating a control diet for three weeks, participants were then randomized to receive for eight weeks: the control diet, a diet rich in fruits and vegetables (F/V), or the DASH diet. Baseline and follow-up levels of PRA were available in 381 participants.

Results: Compared to the control diet, the DASH diet increased PRA by 0.37 ng/mL/h (P=0.01). In multivariable linear regression analyses, there was an inverse association of PRA change with systolic BP change on the control diet (slope=-0.35, p=0.001), but PRA did not differ by BP change on the F/V (slope=-0.002, p=0.98) or DASH diet (slope=-0.08, p=0.32).



Conclusions: These data suggest that a blunted counter-regulatory response of the renin-angiotensin system is associated with the BP lowering effect of the F/V and DASH diets.

TH-PO763

Dietary Salt and Potassium Intake Is Not Associated with Elevated Blood Pressure Levels in US Adults Shailendra Sharma,[1] Kim McFann,[1] Anna Jeanette Jovanovich,[1] Michel B. Chonchol,[1] Jessica B. Kendrick.[1,2] *[1]Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]Denver Health Medical Center, Denver, CO.*

Background: Current guidelines recommend reducing dietary salt intake and increasing dietary potassium intake to reduce blood pressure (BP) levels. The association of dietary salt and potassium intake with increased risk of BP levels is unclear.

Methods: The cross-sectional association between dietary sodium and potassium intake and BP levels was examined in 6985 adults 18 years of age or older with no prior history of hypertension who participated in the National Health and Nutrition Examination Survey (2001-2006). Dietary sodium and potassium intake was calculated from 24-hour dietary recall obtained by trained interviewers. Three BP measurements were collected from each participant. Multivariate logistic regression analysis was performed to evaluate whether high sodium and low potassium intake is independently associated with higher BP levels.

Results: The mean (SE) age of the participants was 45 (0.4) years. The mean (SE) sodium and potassium intake was 3520 ± 26 and 2761 ± 22 mg/day, respectively. In linear regression models there was no association between higher sodium or lower potassium intake with systolic BP (β = -0.000052 ± 0.00012, p = 0.67 and β = 0.000096 ± 0.00018, p = 0.59, respectively). In logistic regression models after adjustment for age, sex, race, diabetes and eGFR, there was no association between higher quartiles of sodium or lower potassium intake with the risk of a BP cutoff of >140/90 mmHg. We also examined the relationship of combinations of potassium and sodium intake with blood pressure cutoff of >140/90 mmHg. Median intake of potassium and sodium were used to determine high and low potassium and sodium intake. High potassium intake combined with low sodium intake was not protective for BP > 140/90 mmHg (p=0.13). Furthermore, high sodium intake combined with low potassium intake was not associated with an increased risk of BP > 140/90 mmHg (p=0.95).

Conclusions: In the US adult population without hypertension, increased dietary sodium or low potassium intake was not associated with elevated BP levels.

TH-PO764

Dietary Salt and Protein Intake and Obesity in Ireland Gemma M. Browne,[1] Joseph A. Eustace,[2] Ivan J. Perry.[1] *[1]Department of Epidemiology and Public Health, University College Cork, Cork, Ireland; [2]Department of Nephrology, Cork University Hospital, Cork, Ireland.*

Background: Obesity is linked to CKD through several established mechanisms including hypertension and salt sensitivity. Ongoing dietary intake of sodium and protein may contribute to progressive renal damage and confound above relationships. This study aims to quantify dietary sodium and protein intake in obese compared to non-obese subjects.

Methods: 599 community dwelling subjects including an occupational group and students, aged 18-81, using random and convenience sampling, participated in a cross-sectional study in Munster, Ireland. Subjects underwent blood pressure (BP) and anthropometric measures using a standardized protocol and performed one 24 hour urine collection. 488 subjects had valid analytes including urinary sodium and urinary urea nitrogen, with a complete collection based on *para*-amino benzoic acid appearance. Protein nitrogen appearance (PNA) was calculated (Maroni B, Mitch WE). The relationship of dietary intake with obesity was examined using multivariate logistic regression (STATA V11.0).

Results: Central obesity was significantly associated with dietary salt intake, urinary PNA, hypertension, age and gender (Table 1) compared to non obese subjects. When dietary associations of central obesity were explored in an adjusted model, salt intake (OR 1.13, p<0.001), urinary PNA (OR1.01, p=0.043), age (OR 1.06, p<0.001) and gender (OR 4.23, p<0.001) continued to be independently significant. Similar independent associations were present comparing subjects with BMI>30kg/m^2 compared to non obese subjects.

Dietary Salt Protein Intake, Hypertension & Central Obesity

Gender (N)	Men N=306		Women N=182	
Waist cm %	>102 (21%)	<102	>88 (31%)	<88
Salt gms/day mean(sd)	12.4 (4.7)	9.9 (4.0)	8.1 (3.1)	7.0 (2.7)
Urinary PNA gms/day mean(sd)	217 (52)	192 (53)	149 (40)	132 (40)
% BP >140/90 / Meds	65%	34.8%	66.7%	33.3%

Conclusions: Using validated methods, obesity is independently related to higher protein and salt intake. In addition to salt sensitivity, obese subjects have higher salt intake in association with higher protein intake. Appropriate dietary advice and salt restriction may be especially important in obese hypertensive subjects.

Association of Sweetened Beverage Intake and Incident Hypertension Is Similar between Sugar-Sweetened and Artificially-Sweetened Beverages Lisa J. Cohen, Gary C. Curhan, John P. Forman. *Renal Division, Brigham and Women's Hospital, Boston, MA.*

Background: Consumption of sugar-sweetened beverages (SSBs) is associated with hypertension in cross-sectional studies. However, prospective data are limited.

Methods: We performed an analysis of originally non-hypertensive individuals in three large, prospective cohorts, the Nurses' Health Studies I (n=88,540) and II (n=97,991) and the Health Professionals' Follow-Up Study (n=37,360), to determine the relation between SSB and artificially sweetened beverage (ASB) consumption and the development of hypertension over time. Cox proportional hazards regression was used to calculate hazard ratios for incident hypertension based on type and quantity of beverage intake, and after adjusting for potential confounders. The association between fructose consumption from SSBs versus fructose from other sources and the risk of incident hypertension was also determined.

Results: Findings were similar across the cohorts. Higher SSB and ASB intake was associated with an increased risk of developing hypertension. In a pooled analysis of all three cohorts, participants who consumed at least one SSB daily had an adjusted HR for incident hypertension of 1.13 (95% CI, 1.09-1.17) compared with those who did not consume SSBs; for persons who drank at least one ASB daily, the adjusted HR was 1.14 (95% CI, 1.09-1.18). There was a significant interaction between carbonation and total beverage intake (p-interaction < 0.001 in NHS I, 0.03 in NHS II, and 0.02 in HPFS). In an analysis of fructose intake as a percentage of daily calories, higher fructose intake from SSBs was associated with increased hypertension risk in the NHS I and NHS II cohorts (p-trend=0.001 in both groups), while higher fructose intake from sources other than SSBs was associated with a decrease in hypertension risk in NHS II participants (p-trend=0.006).

Conclusions: Both SSBs and ASBs are each independently associated with an increased risk of incident hypertension after controlling for multiple potential confounders. The mechanisms that underlie these associations are unclear.

TH-PO766

Uric Acid Is Associated with Systemic Inflammation and Reduced MnSOD Expression in Endothelial Cells of Healthy Adults Diana I. Jalal,[1] Kristen L. Jablonski,[2] Kim McFann,[1] Michel B. Chonchol,[1] Douglas R. Seals.[2] *[1]Internal Medicine/Renal, University of Colorado Denver, Aurora, CO; [2]Department of Integrative Physiology, University of Colorado, Boulder, CO.*

Background: We previously reported that uric acid levels are not related to endothelial function in healthy adults. Yet, experimental data suggests uric acid may induce endothelial dysfunction and vascular inflammation in some clinical settings. To further understand our results, we explored the relation between uric acid and inflammation and oxidative stress systemically and in endothelial cells collected from study participants.

Methods: We examined the relation between uric acid levels and C-reactive protein (CRP) and oxidized- LDL in all participants (n=107) as continuous variables and according to uric acid quartiles (0-5.2, 5.3-6.1, 6.2-7, > 7.0 mg/dL). To evaluate the relation between uric acid and cellular inflammation and oxidative stress, immunostaining of endothelial cells was compared between the highest and the lowest uric acid quartiles (unpaired t-test with Welch correction). Immunofluorescence was performed on endothelial cells collected from the subjects' brachial arteries. The following markers were evaluated: NFκB p65 (n=19), NADPH oxidase p47^{phox} (n=13), nitrotyrosine (n=21), and MnSOD (n=12). To minimize the confounding effect of different staining sessions, values are reported as ratios of endothelial cell protein/human umbilical vein endothelial cell (HUVEC).

Results: CRP increased significantly with increased uric acid quartiles (P<0.005), and P value for the linear regression was 0.015. There was no correlation between uric acid and oxidized- LDL. The endothelial cells of participants with higher uric acid levels expressed 55% less MnSOD than the participants with the lower uric acid levels (intensity/HUVEC was 0.22±0.13 *vs* 0.49±0.12, P= 0.04). NFκB p56, NADPH oxidase p47^{phox}, and nitrotyrosine did not differ between the highest and the lowest uric acid quartiles.

Conclusions: In healthy adults, serum uric acid levels correlate with increased CRP and associate with reduced MnSOD expression in endothelial cells. These findings may have implications on cardiovascular risk for healthy adults.

Combining Uric Acid with Lipoprotein a Could Predict the Atherosclerotic Renal Artery Stenosis in High Risk Patients Peng Xia,[1] Ling Qiu,[2] Limeng Chen,[1] Shuyang Zhang,[3] Xuemei Li,[1] Xuewang Li.[1] *[1]Nephrology Department, Peking Union Medical College Hospital, Beijing, China; [2]Department of Laboratory Medicine, Peking Union Medical College Hospital, Beijing, China; [3]Cardiology Department, Peking Union Medical College Hospital, Beijing, China.*

Background: This study aimed at exploring certain new risk factors of Atherosclerotic renal artery stenosis (ARAS) and establishing a possible tool which might facilitate the clinical decision making in diagnosing ARAS.

Methods: 190 patients highly suspected for ARAS who have received renal artery angiography in Peking Union Medical College Hospital from 2008 to 2011 are selected for analysis. 138 of all 190 patients also received coronary artery angiography and 89 of who

were diagnosed ARAS. The control group is 180 cases who received routine health check. The basic information and lab results such as uric acid (UA), serum lipids (lipoprotein a, total cholesterol, triacylglycerol, HDL and LDL), creatinine (Scr) and hsCRP are collected. Logistic regression analysis is used to identify possible correlations with ARAS and to establish a new tool for predicting ARAS in the high risk population.

Results: The levels of Scr, UA, Lp(a) and hsCRP of ARAS cases are significantly elevated compared to control cases. For high risk population and the patients received coronary artery angiography, there are no significant differences in the levels of Scr, lipids, UA and hsCRP between ARAS cases and non-ARAS cases. Logistic regression analysis shows that uric acid level >344μmol/L correlated to ARAS independently. Using the uric acid level >344μmol/L and lipoprotein a level >242mg/L as a predicting tool for ARAS in high risk population, the specificity is 96.0%, the positive likelihood ratio is 5.45, p=0.001 and the odds ratio is 6.78, 95%CI (1.90, 24.2), p=0.001.

Conclusions: The ARAS cases are experiencing lipids metabolic disorders and inflammatory reactions. In high risk population, the UA might be an independent risk factor of ARAS and combining UA with Lp(a) could predict the ARAS.

Funding: Government Support - Non-U.S.

TH-PO768

Uric Acid Is Not Associated with Blood Pressure in Adolescents with Type 1 Diabetes Jeffrey C. Sirota,[1] Diana I. Jalal,[1] Kim McFann,[1] Franziska K. Bishop,[2] David M. Maahs,[2] R. Paul Wadwa.[2] *[1]Division of Renal Diseases & Hypertension, University of Colorado Denver School of Medicine, Aurora, CO; [2]Barbara Davis Center for Childhood Diabetes, University of Colorado Denver School of Medicine, Aurora, CO.*

Background: Elevated uric acid is associated with increased blood pressure (BP), and treatment of hyperuricemia can improve BP in non-diabetic (non-DM) adolescents. In this study, we hypothesized that uric acid is associated with increased BP in adolescents with type 1 diabetes (T1D).

Methods: Data were collected for 256 youths with T1D (age=15.4±2.2yrs, 50% male, T1D duration 8.7±2.9yrs) and 78 non-DM controls (age=15.5±2.2yrs, 44% male). Cross-sectional association between uric acid and BP was examined by linear regression in unadjusted and adjusted models. Uric acid was log-transformed due to skewed distribution.

Results: T1D youth had higher hemoglobin A1c, waist circumference (WC), BMI-Z, total cholesterol, low density lipoprotein (LDL), & BP (Table 1). Mean uric acid was 4.6±0.8mg/dL in T1D subjects vs. 5.1±1.0mg/dL in controls (p=0.001). In unadjusted analysis, uric acid was significantly correlated with SBP in the entire cohort (R2=0.037, p<0.05), in T1D (R2=0.04, p<0.05), and in non-DM subjects (R2=0.16, p<0.05). After adjusting for age, sex, race, A1c, WC, BMI Z-score, high density lipoprotein (HDL), LDL, triglycerides (TG), creatinine, urinary albumin-creatinine ratio, & smoking status, uric acid was not associated with SBP. There was no correlation between uric acid & DBP.

Table 1

	non-DM (n=78)	T1D (n=256)	p
A1c	5.3±0.3	8.9±1.6	<0.05
WC (cm)	74.6±10.9	77.4±10.6	<0.05
BMI-Z	0.23±1.06	0.62±0.77	<0.01
total cholesterol (mg/dL)	147.2±27.4	158.0±34.7	<0.01
LDL (mg/dL)	81.9±22.4	89.5±27.1	<0.05
HDL (mg/dL)	48.7±9.2	51.2±10.4	0.07
TG (mg/dL)	82.9±40.8	86.3±50.3	0.80
uric acid (mg/dL)	5.1±1.0	4.6±0.8	<0.05
creatinine (mg/dL)	0.7±0.2	0.7±0.1	<0.05
SBP (mmHg)	108.6±8.4	113.2±8.4	<0.05
DBP (mmHg)	64.1±6.0	68.4±6.7	<0.05

Conclusions: Uric acid is weakly associated with SBP in adolescents with and without T1D. However, after adjustment for co-variates, there was no significant association between uric acid and SBP. Further work is needed to clarify the effects of uric acid in young people with T1D.

TH-PO769

Association between Birth Weight and Blood Pressure in 9- to 10-Year Old Children Sandra Dis Steinthorsdottir,[1,2] Sigridur Birna Eliasdottir,[1,2] Olafur S. Indridason,[2] Runolfur Palsson,[1,2] Vidar O. Edvardsson.[1,2] *[1]Landspitali - The National University Hospital of Iceland; [2]University of Iceland.*

Background: Low birth weight has been associated with structural and functional changes in the vasculature, which may increase the risk of hypertension, cardiovascular disease, obesity and type 2 diabetes later in life. The aim of this study was to evaluate the association between birth weight and blood pressure (BP) in a cohort of healthy 9 to 10-year-old Icelandic school children.

Methods: Four seated BP measurements were performed in 1071 Icelandic children, aged 9-10 years. BP percentiles were calculated from an average of the four measurements. Height and weight were measured and information on birth weight was obtained from the Icelandic Birth Registry. Pearson´s correlation coefficient and multivariable linear regression was used for the analysis.

Results: Of 889 children with complete data, 452 were girls (50.8%). The mean BP in girls was 111/63 mm Hg and 112/64 mm Hg in boys (p=0.03). The prevalence of elevated BP was 13.2%. The mean birth weight of boys was 3753 ± 642 g and 3687 ± 588 g for girls (p=0.11). A significant negative correlation between birth weight and systolic BP percentile (r= -0.09, p=0.005) and diastolic BP percentile (r= -0.08, p=0.014) was observed. The relationship was stronger in girls (r= -0.09, p=0.005 vs -0.08, p=0.08). After controlling for body mass index (BMI), there was a significant correlation between birth weight and systolic BP percentile (beta= -0.16, p<0.001) and diastolic BP percentile (beta= -0.14, p=0.003) in girls, and systolic BP percentile (beta= - 0.11, p=0.016) in boys, for whom the association with diastolic BP percentile was of borderline significance (beta= -0.08, p=0.09). There was a direct correlation between birth weight and height (r=0.26, p<0.001), weight (r=0.21, p<0.001), BMI (r=0.14, p<0.001) and BMI percentile (r=0.19, p<0.001).

Conclusions: The results of our study suggest that low birth weight may be an important predictor of hypertension in children. Careful follow-up of BP may be indicated in these children as they may be at increased risk for future cardiovascular complications.

TH-PO770

High Prevalence of Obesity and White-Coat Hypertension in Children Evaluated by Ambulatory Blood Pressure Monitoring (ABPM) Jason M. Kurland,[1] M. Khurram Faizan,[2] Sharon W. Su,[2] Lance D. Dworkin.[1] *[1]Dept. of Medicine, Rhode Island Hospital, Providence, RI; [2]Dept. of Pediatrics, Hasbro Children's Hospital, Providence, RI.*

Background: Pediatric hypertension (HTN) is often secondary (2°) in etiology, as shown by U.S. and European cohorts in the 1980s. ABPM is a useful tool to confirm sustained HTN in children. Prior studies suggest certain ABPM variables- nocturnal dipping and blood pressure (BP) load- may distinguish primary (1°) from 2° HTN. Our study examines the epidemiology of pediatric HTN in an urban referral clinic and seeks ABPM endpoints able to differentiate 1° from 2° HTN in children.

Methods: Retrospective cohort study from 04/1999-09/2010, including ABPM data from all children referred to a pediatric nephrology clinic for evaluation of HTN first seen in a primary-care setting. HTN was defined as mean systolic (SBP) or diastolic BP (DBP) via ABPM as ≥95th percentile for age, sex, and height. All patients were naive to BP medications. 2004 NHBPEP Fourth Report guidelines were used to determine the adequacy of workup for 2° HTN.

Results: 293 patients were included. Mean age was 13.8 years, and 68% were male. Mean BMI was 27.5; 18% were overweight, and 52% obese. 217 patients (74%) were normotensive by ABPM, invoking white-coat HTN. 63 (22%) had 1° HTN, and 13 (4%) had 2° HTN. No significant differences between the 1° HTN and 2° HTN groups were found for the following variables: *(a) age, sex, height, weight, and BMI, (b) mean, SD, and peak for SBP and DBP, (c) nocturnal dip for SBP and DBP, (d) BP load at 90th, 95th, and 99th percentiles, (e) percentage of SBP and DBP values above 95th percentile, and (f) mean, SD, and nocturnal dip for heart rate.*

Conclusions: This study was limited by a small sample size and an unexpectedly low percentage of children with 2° HTN. Differences in ABPM parameters between 1° and 2° HTN may be subtle, requiring larger-scale trials to identify them. Our study demonstrates a strikingly high prevalence of overweight/obesity, which may predispose to 1° HTN. The frequency of white-coat HTN was also markedly higher than that cited from prior studies, reinforcing the value of ABPM as an initial screening tool for suspected HTN in children.

TH-PO771

Long-Term Follow-Up of Children with Essential Hypertension – Are We Minimizing End-Organ Injury? Isabel Roberti, Myriam Jean, Shefali Vyas. *Pediatric Nephrology and Kidney Transplantation, Saint Barnabas Medical Center, Livingston, NJ.*

Background: We have previously shown that essential hypertension (EH) is now the most common cause of HTN in children and it is associated at presentation with obesity in 50 % and end-organ injury in 27% of the cases.

The goal of therapy of children with EH is early lifestyle modification and avoidance of end-organ damage.

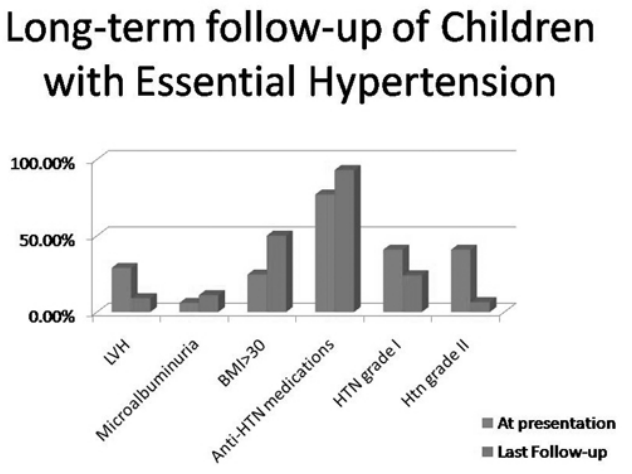
Methods: We reviewed all charts that had the diagnosis of "Essential Hypertension" in children seen at our outpatient office between 2004 and 2010 who had more than 1 year of follow-up. Secondary causes of HTN were excluded in all patients.

We reviewed birth data (gestational age and birth wt), family history (FH), degree of HTN, symptoms, SCr, microalbuminuria (MA), presence of LVH and BMI at presentation and at last follow-up. The impact of routine follow-up and therapy was reviewed including nutritional status change and end-organ involvement. All children received dietary advice regarding salt intake and ideal body weight.

Results: Of the 232 children with EH only 21% (N=49) were followed for at least 1yr (mean f/u = 3.3 yrs).

At presentation: Age: 4-19yrs (mean 13yrs); Ethnicity: 27 AA, 14C, 6 H; 60% male; 76% had + FH for EH; 16% ex-premature/LBW; 49% were symptomatic; 57% had hyperlipidemia.

HTN stages: pre-HTN=9, stage I=20, stage II=20 (41%).



Six of 49 (12%) required more than 1 anti-hypertensive medication. MA was only seen in stage II HTN. Among those with stage I or II HTN 19 (47.5%) were symptomatic. HTN grade significantly declined on f/u: only 3 children had stage II HTN.

Conclusions: The majority of children with EH had significant improvement in the HTN stage and LVH despite worsening BMI. The ability to keep a scheduled appointment and the adherence to life style/dietary changes among our children with EH were dismally poor. More resources are needed to educate these children and families with EH.

TH-PO772

Office Blood Pressure Monitoring (OBPM): A Possible New Tool for Evaluating Blood Pressure in Children and Adolescents Gianluigi Ardissino,[1] Patrizia Salice,[2] Silvia Ghiglia,[2] Pier Paolo Bassareo,[3] Francesca Tel,[1] Sara Testa.[1] *[1]Pediatric Nephrology Unit, Fondazione Ca' Granda Osp Maggiore Policlinico, Milano, Italy; [2]Pediatric Cardiology Unit, Fondazione Ca'Granda Osp Maggiore Policlinico, Milano, Italy; [3]Dpt Scienze Cardiovascolari e Neurologiche, Policlinico Universitario, Cagliari, Italy.*

Background: Recent data suggest that casual office BP measurement (CBP) in children may not be as sensitive as ABPM for detecting hypertensive patients. However ABPM is not feasible in toddlers and it can be difficult and/or misleading in hyperactive children or incompliant adolescents.

Methods: We have developed a method of BP measurement, OBPM: Office BP Measurement, alternative to ABPM for investigating BP in children. The present study compares the results obtained with OBPM and ABPM in 59 children (25F), mean age 11.8 ± 3.5 yrs, referred for suspected or confirmed hypertension to 3 centres.

Results: OBPM utilizes the same recorder and cuff as ABPM (Spacelab 90207) to perform 10 BP measurements in 1 hour just before the ABPM. The readings are introduced in a specific software (developed with FileMaker) that calculates the coefficient of variation (CV) of SBP and DBP, after excluding outlier values (measurements below the 5th and above the 95th of the recorded values). The CV provides an index of reliability of the calculated mean; we suggest to discard OBPMs with a CV >15%. The system finally calculates the mean of the remaining values and the z-score for age, gender and height according to the American Academy Reference values. The correlation between OBPM and ABPM was analyzed as Person's correlation coefficient. The table shows the findings obtained; OBPM and ABPM were performed on the same day.

	OBPM	CV%	24hABPM	r	p
SBP (mmHg)	121.6±14.8	6.3±3.1	120.8±14.3	0.815	<0.0001
DBP (mmHg)	72±11.3	4.4±2.2	71.5 ± 9.4	0.77	<0.0001

Conclusions: Preliminary analysis indicates that OBPM may represent a reliable and promising tool for investigating BP in children as an alternative to ABPM. The software for OBPM is available online at the following website: www.childproject.org

TH-PO773

Assessment of Cardiovascular and Renal Risk Factors in Pediatric Population during World Kidney Day in the Province of Chaco, Argentina Maria Eugenia V. Bianchi,[1] Dario Gomez,[3] Ricardo K. Tannuri,[2] Noelia Alejandra Dellamea,[2] Cecilia Abogado,[2] Ana Cusumano.[4] *[1]Argentina Northeast Kidney Foundation, Resistencia, Chaco, Argentina; [2]National Northeast University, Corrientes, Argentina; [3]Ministry of Health, Resistencia, Chaco, Argentina; [4]CEMIC, Buenos Aires, Argentina.*

Background: Chaco province, Argentina, has one of the highest rates in the nation of teenage pregnancy, low birth weight and infant mortality, with an ethnically diverse population of aboriginal and no aboriginal. Since 2008 and during the WKD celebration, anthropometric measurements and blood pressure (BP) were checked in children. Non aboriginal children were evaluated in the squares of the city and aboriginal ones in a domestic setting. Those with abnormal parameters were referred to medical assistance.

Methods: 18 students of the School of Medicine of the National Northeast University, were trained. Cuffs of different sizes were used with an anaeroid sphigmomanometer to measure BP. Data was analized following the WHO (2006) classification.

Results: 317 children were evaluated. 136 (42.9%) were male, mean age 9.4 yold, mode 13, ranging from 1 to 18 years. 127(47,7%) showed normal BP; 57 (21,4%) High Normal, 57 (21,4%) HT Stage 1, and 25 (9,4%) HT Stage II. The nutritional status of 266 (84%) showed: undernutrition in 13 (4,9%); 26 (9,8%) at risk of undernutrition, 123 (46,2%) normal, 59 (22,2%) at risk of overweight and 45 (16,9 %) with overweight.

Statiscally significant differences between non-Aboriginal and aboriginal children were found: Height: 37.3% of non-Aboriginal were above the 90 percentile, compared with 17.8% of Aboriginal ones.(p <0,005); normal weight was found in 29% versus 60.3%; overweight was detected mainly in the non-Aboriginal (27.4% versus 6.9%)

Conclusions: Cardiovascular and renal risk factors in pediatric population showed a high prevalence and a different pattern in the ethnic frame.

TH-PO774

The Beneficial Effect of Native Nephrectomy on Post-Transplant Hypertension Carrie Diamond, Kathleen M. Waybill, Halie Cook, Harold Yang. *Transplantation, PinnacleHealth, Harrisburg, PA.*

Background: Post-transplant hypertension occurs in >60% of renal transplant recipients, and is associated with cardiovascular complications and decreased allograft survival. While multiple factors may play a role (e.g. immunosuppressive medications, weight gain) the presence of atrophic native kidneys may be a significant contributing factor.

Methods: We performed a retrospective analysis of 16 renal transplant patients (ages 27-72) who underwent a second unilateral native nephrectomy(UNN2)[9 open/7 laparoscopic]. All patients had undergone a prior unilateral native nephrectomy. Five patients underwent UNN2 for severe hypertension; eleven patients required UNN2 for renal masses, polycystic kidney disease or urinary tract infections. We evaluated blood pressure, weight, creatinine, hematocrit, complications, number/dosages of antihypertensive medications at baseline, post-operative (2-6 weeks), and one year. Changes from baseline were evaluated with paired t-tests.

Results:

n=16	Baseline-Mean(SEM)	Post-Op-Mean(SEM)	One Year-Mean (SEM)
SBP(mmHg)	140.4(5.25)	123.6(4.62)*	128.3(4.15)*
DBP(mmHg)	83.1(3.15)	78.2(3.31)	76.7(3.48)*
MAP(mmHg)	102.2(3.24)	93.3(3.47)*	93.9(3.37)*
Weight(kg)	83.5(5.00)	82.0(5.11)	84.6(5.07)
Cr(mg/dl)	1.51(0.10)	1.38(0.10)	1.39(0.11)
Hct	38.7(1.17)	37.9(1.22)	40.7(1.03)
# Meds	3.2(0.37)	2.5(0.35)*	2.5(0.34)*

*p<0.05

In addition to significant reductions in number of medications, 12/16 patients had a >50% dosage reduction of at least one medication. Surgery was well tolerated, with mean length of stay: 5.9±1.63 days after open UNN2 and 2.7±0.29 days after laparoscopic UNN2. One complication occurred (wound infection) in a patient who had undergone open nephrectomy.

Conclusions: Current management of post-transplant hypertension focuses on use of antihypertensive medications. We have previously demonstrated sustained decreases in blood pressure and antihypertensive medications in post-transplant patients who had undergone simultaneous bilateral native nephrectomy. Coupled with similar beneficial results noted in this study,we conclude that surgical removal of native kidneys represents a safe and effective adjunct to medical therapy in the management of post-transplant hypertension.

TH-PO775

Blood Pressure Reduction According to Baseline Systolic BP Value and Diabetes Status in Hypertensive Outpatients: Interim Results of the Canadian ANCHOR Registry Paul Rene De Cotret,[1] Andrew W. Steele,[2] Martine Hubert.[3] *[1]Service de Néphrologie, Centre Hospitalier Universitaire de Quebec, QC, Canada; [2]Lakeridge Health Corporation, Oshawa, ON, Canada; [3]Novartis Pharmaceuticals Canada, Dorval, Canada.*

Background: ANCHOR (AliskireN Canadian HypertensiOn Registry) is a real-life Canadian non-interventional registry of outpatients in which physicians initiated aliskiren, the direct renin inhibitor as monotherapy or add-on, in order to achieve blood pressure control.

Methods: Patients were followed for one year after aliskiren initiation, with 2 visits at 3 months and 12 months. Efficacy and safety were assessed at each visit. An interim analysis was performed at mid-term. The main objective was to assess BP reductions after 3 months of use. One of the secondary objectives, presented in this abstract, was to measure BP changes from baseline to 12 months.

Results: At time of database lock (Aug 2010) for this interim analysis, 9716 patients were enrolled in the study; mean baseline characteristics (± SD) were: 52.1% males, age was 62.6 (12.9), 36.7% had diabetes, BMI was 31.5 (14.8), 76.4% were Caucasians, SBP (mmHg (± SD): 153.6 (15.9) and DBP: 87.6 (11.5). Baseline SBP in 6131 patients without diabetes was 154.7 (15.8) and in 3542 patients with diabetes 151.7 (16.0). At 12 months: mean (mmHg ± SD) systolic BP drop was -18.3 (16.8) in 576 patients with diabetes and -20.5 (18.4) in 830 patients without diabetes.

Table 1 below shows the mean SBP drop (in mmHg) at 12 months with an aliskiren-

based anti-hypertensive therapy according to baseline BP value and diabetes status.

Baseline SBP	N with No Diabetes	Mean SBPdrop	N with Diabetes	Mean SBPdrop
130-139	39	-5.8*	75	-8.9
140-150	213	-14.0	153	-13.2
151-160	250	-19.2	144	-19.1
161-170	166	-26.4	90	-26.0
171-180	75	-32.1	44	-30.3
>180	50	-46.4	33	-41.5

All p values for BP drop were <0.0001 except for *: p<0.004

Conclusions: In this registry, the mean SBP drop with an aliskiren-based anti-hypertensive therapy was comparable in 9716 patients with or without diabetes. In both subgroups the mean BP drop was the highest (> - 41 mmHg) in patients the highest baseline SBP (>180 mmHg). The treatment was generally well tolerated.

TH-PO776

WKD 2011: Cardiovascular and Renal Risk Factors Profile in the General Population in Resistencia, Chaco, Argentina Maria Eugenia V. Bianchi,[2] Shyrley Lorena Basila Cosimi,[1] Facundo Manuel Ferrarini,[1] Dario Gomez,[4] Gabriela Mariel Audisio,[1] Ana M. Cusumano.[3] *[1]School of Medicine, Northeastern National University, Corrientes, Argentina; [2]Argentine Northeastern Kidney Foundation, Resistencia, Chaco, Argentina; [3]CEMIC, Buenos Aires, Argentina; [4]Ministry of Health, Resistencia, Chaco, Argentina.*

Background: Resistencia is the capital of the province of Chaco, Argentina, with an ethnically diverse population that is almost 600 thousand persons, and very few resources to conduct screening programs.

Methods: Last WKD, 431 students from the School of Medicine of Northeast National University were capacitated to obtain anthropometric measurements, glycaemia and blood pressure (BP) control to the citizens in five squares of the city during 8 hours of work. The results were given to the people and those with Stage two of Hypertension were referred to hospital care. VII Joint Comeetee definitions were adopted for hypertension and the ADA to define Diabetes Mellitus. Accucheck Roche was used as glucometer. Central obesity was determined by NIH set points. Data was analyzed by the students with EPI Info Version 3.1®

Results: 3.034 adults were monitored by students. The mean age was 44 (± 17), females 1597 (53%) CI 95% 50.8-54.4%. Normal BP was found in 1619 (53%) CI 95% 50.8-54.4%. BMI normal in 1221 (40%) CI 95% 38.5-42.0%. Central Obesity in 1117 (39,1%) CI 95% 37.3-41.0%. Glycaemia was determined in 1650 (54%).Statistically significant differences were found between sexes in: Height 1,73 m (± 0,07) for men, 1,61 m (± 0,06) for women; Diastolic Blood Pressure (DBP) 81,8 mmHg. (± 12,5) for men, 77,6 mmHg. (± 12) for women; Systolic Blood Pressure (SBP) 126,9 mmHg. (± 14,8) for men, 119,7 mmHg. (± 15,2) for women, BMI 27,2 Kg (± 4,3), for men, 26 Kg (± 5,3) for women, Weight 81,5 Kg (± 14,2) for men, 67,8 Kg (± 14) for women. Central Obesity was more common among females: 46,6%. Eight age groups were defined: glycaemia levels, SBP, DBP, weight, showed statistically significant differences. (p< 0,05)

Conclusions: WKD was a great opportunity to create standardized tables of height, weight, systolic and diastolic blood pressure in this population.

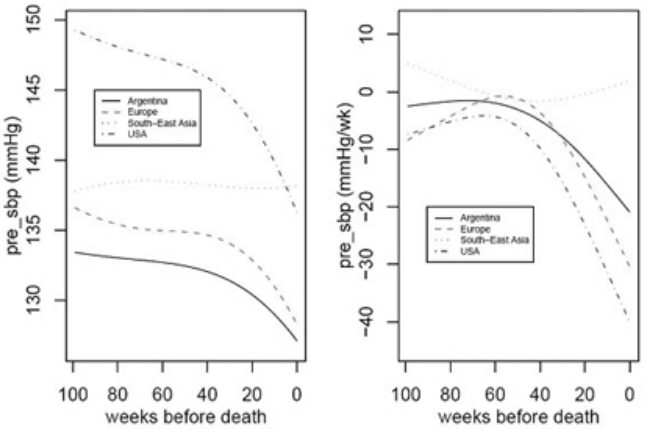
TH-PO777

Systolic Blood Pressure (SBP) Dynamics before Death in Chronic Hemodialysis (HD) Patients – Results of an International Study Daniele Marcelli,[1] Inga Bayh,[1] Aileen Grassmann,[1] Laura Scatizzi,[1] Len A. Usvyat,[2] Michael Etter,[3] Adrian Marcos Guinsburg,[4] Cristina Marelli,[4] Mathias Schaller,[6] Adam Tashman,[5] Yuedong Wang,[5] Nathan W. Levin,[2] Peter Kotanko.[2] *[1]FMC Europe, Bad Homburg, Germany; [2]RRI, NY, NY; [3]FMC Asia Pacific, Hong Kong, Hong Kong; [4]FMC Latin America, Buenos Aires, Argentina; [5]University of California - Santa Barbara, Santa Barbara, CA; [6]University of Cologne Medical Center, Germany.*

Background: Cardiovascular disease is leading cause of death in HD patients (pts). Recent studies in US HD pts showed that decline of SBP is a predictor of death (Li, 2006). We investigate if pattern before death holds for a globally diverse HD population.

Methods: HD data bases from FMC clinics in Europe, Asia, Latin America, RRI clinics in US, and KfH in Germany were queried. Pre-death SBP dynamics were analyzed by estimating the mean SBP level before death and its 1st derivative using quintic splines.

Results: 27807 HD pts from 23 countries were studied (Europe [N=12333; age 71.7, 59% males]; South-East Asia [N=1484; age 68; 53% males]; Argentina [N=10517; age 63.1; 58% males]; USA [N=3473; age 69.9; 56% males]). Pre-HD SBP levels [mean (SD); mmHg] before death were 122 (30); 136 (24); 126 (23); 134 (33); same order as above. In male pts from Europe, Argentina, and US, SBP levels dropped b-n 6 and 13 mmHg in the 2 years preceding death; no SBP change was seen in Asian pts (figure, left). SBP decline accelerated before death and was virtually identical in pts from all databases (figure, right).



The results were materially identical in females and pts from KfH (not shown).

Conclusions: This international study corroborates previous findings in cohorts from Europe and Argentina. Noteworthy, HD patients from South-East Asia show distinctly different SBP dynamics before death. The reasons for this finding are currently unknown.

TH-PO778

APrODiTe (Assessment of Blood Pressure Control and Target Organ Damage in Patients with Chronic Kidney Disease and Hypertension) – Interim Analysis Ran-Hui Cha,[1] Yon Su Kim.[2] *[1]Department of Internal Medicine, National Medical Center, Seoul, Korea; [2]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea.*

Background: The loss of dipping in blood pressure (BP) and masked hypertension are related with target organ damages such as renal dysfunction and cardiovascular diseases.

Methods: APrODiTe is a nationwide multicenter cross-sectional study for Korean CKD stage 2, 3, and 4 patients. The primary aim is to find out the BP control pattern and the secondary aim is to identify the relationship between target organ damages and BP patterns.

Results: We analyzed data from 389 patients out of 1,600. Mean age was 57 year and 59.4% were males. Diabetic nephropathy was 21.1%. The distribution of each BP pattern was as below: sustained uncontrolled, 80.0%; masked, 6.8%; white coat, 10.4%; true controlled, 2.4%; Dipper, 43.6%; non-dipper, 44.1%; reverse dipper, 12.3%. Male gender, current smoking, and spot urine PCR higher than 25percentile (*p*) (100mg/g) were related with masked and sustained uncontrolled hypertension ($p = 0.059$, $p < 0.05$, $p = 0.075$, respectively). In multivariate analysis, female gender (OR = 0.467, p = 0.043) and spot urine PCR less than 25*p* (OR = 0.349, p = 0.007) were related with white coat hypertension, whereas male gender (OR = 2.103, p = 0.009) and spot urine PCR more than 25*p* (OR = 1.908, p = 0.032) with sustained uncontrolled hypertension. Diabetic nephropathy, higher serum creatinine, and lower estimated GFR were related with reverse dipper ($p < 0.05$, $p = 0.002$, and $p = 0.001$, respectively). In multivariate analysis, spot urine PCR less than 50*p* (304 mg/g) was related with dipper (OR = 0.619, p = 0.037), whereas diabetic nephropathy with reverse dipper (OR = 2.457, p = 0.013).

Conclusions: Apparently high proportion of CKD patients were treated inappropriately in Korea. And masked and sustained uncontrolled hypertension and reverse dipper were related with more profound target organ damages. Therefore, appropriate BP control in CKD patients is very important and ambulatory BP monitoring has a significant role to improve physicians' practices. We can understand the real practice in BP control for Korean CKD patients after additional data analysis.

TH-PO779

Clustering of Cardiovascular and Renal Risk Parameters in Non-Hypertensive Individuals George Thomas, Richard A. Fatica, Saul Nurko, Marc A. Pohl, Sankar D. Navaneethan, Titte Srinivas, Martin J. Schreiber, Emilio D. Poggio. *Nephrology & Hypertension, Cleveland Clinic, Cleveland, OH.*

Background: Clinical trial evidence suggests an increase in cardiovascular (CV) events beginning with a systolic blood pressure (SBP) of 115 mmHg and lower levels of GFR. We aimed to study early changes in CV and renal risk profile and their relationship with SBP in living kidney donors with no clinical diagnosis of cardiovascular or chronic kidney disease.

Methods: We studied 394 consecutive living kidney donors between Apr 1997 and Dec 2005 at our institution. Exclusion criteria were BP ≥140/90 mmHg (clinical hypertension), kidney disease, diabetes, CV disease, obesity, and proteinuria. Data collected included age, gender, race, body mass index (BMI), office blood pressure, fasting blood glucose (FBG), uric acid, lipid profile, and iothalamate glomerular filtration rate (iGFR). The study population was stratified into SBP <115 mmHg and SBP 115-139 mmHg. The relationships between risk factors and SBP were studied using regression analysis.

Results: 81% of the study population was Caucasian, with 59% women. Mean age was 41.0 ± 9.9 yrs. Compared to donors with SBP <115 mmHg, those with SBP 115-139 mmHg had significantly abnormal risk factor profile. Interestingly, iGFR was higher in

those with higher SBP. In regression analysis, BMI, FBG, and uric acid, even within the normal range, were independently associated with higher SBP.

Risk factors stratified by SBP < 115 mm Hg (n= 222) and SBP ≥ 115-139 mmHg (n=172)

Variable	SBP < 115 mmHg Mean (SD)	SBP ≥ 115-139 mmHg Mean (SD)	p value
Age	39.3 (8.6)	43.1 (9.7)	<0.001
BMI	25.6 (4.2)	28.0 (3.7)	<0.001
iGFR	104.7 (15.5)	109.3 (17.3)	0.006
eGFR (MDRD)	97.4 (19.5)	95.3 (17.2)	0.25
Total Cholesterol/HDL	3.7 (1.1)	4.0 (1.3)	0.005
LDL/HDL	2.2 (0.9)	2.5 (1.1)	0.008
Fasting blood glucose	84.7 (9.3)	89.2 (9.7)	<0.001
Uric Acid	4.7 (1.2)	5.3 (1.3)	<0.001

Conclusions: Increase in SBP, even in the non-hypertensive range, is associated with early derangement and clustering of risk parameters in otherwise healthy individuals. The higher iGFR observed in those with higher SBP needs further investigation. These results support primary prevention of cardiovascular disease at a much earlier phase.

TH-PO780

Optimal Blood Pressure Control and All Cause Mortality in a Primary Care Setting Zeeshan Khawaja. *Nephrology, Georgetown Univ.*

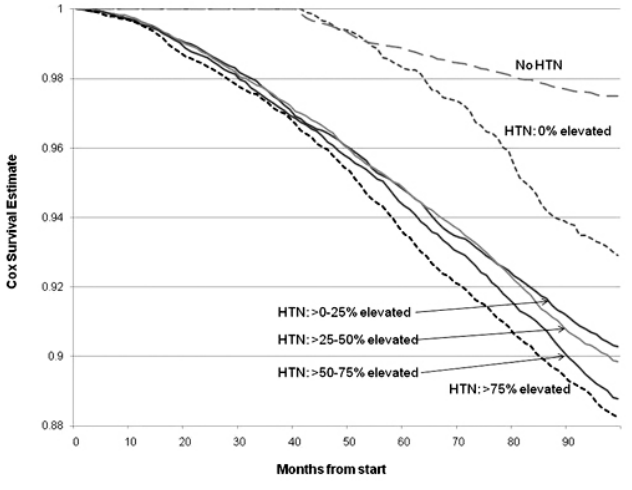
Background: Numerous controlled clinical trials have shown improvement in health outcomes with blood pressure control

Data from a meta-regression analysis of a large population have shown impressive improvement in outcomes for each 20/10 mm Hg reduction in BP for all age groups.

Methods: In the present study we assessed the impact of blood pressure control in 42,346 patients followed at the Washington D.C. VAMC , between January 2000 and December 2007. Electronic Medical Records were used for data gathering and data analysis. A blood pressure control initiative was initiated in 2000 and a battery of recommendations implemented in 2003.

Blood pressure control increased from 44% in the year 2000 to 79% by the end of 2007. In 42,346 patients with multiple BP measurements, systolic and diastolic BPs were averaged for a mean period of 98 months of follow up and accordingly they were allocated to one of 5 groups: G1:never hypertensive (N=4,459), G2: hypertensive always controlled (N=1,305) G3: BP elevated 1-25% of the time(N=8,160), G4: BP elevated 26-50% of the time(N=9,444), G5: BP elevated 51-75% of the time(N=8,045) and G6: BP elevated 76-100% of the time(N=8,045).Results were adjusted for age, sex, heart failure, diabetes mellitus, and BMI.

Results: During the follow up period 6,293 (14.9%) died. Of those 816 patients (10%) died in the Always Controlled group, 2,988 (15.5%) in the partially controlled group and 2,489 (16.7% patients died in the Not Controlled group(p<0.0001 for all comparisons). Cox proportional hazard analysis, adjusted for age, sex, heart failure, diabetes mellitus, and BMI demonstrated a relative risk of 1.24 (CI 1.14 –1.36) for the Partially Controlled group and RR 1.31(CI 1.20 –1.43) for the Not Controlled group compared to the Always Controlled group.



Conclusions: Sustained BP control resulted in the greatest reduction in mortality risk.

TH-PO781

Blood Pressure Measurement in a Peritoneal Dialysis Population. Which Method Is Best? Michelle M. O'Shaughnessy, Martin E. Durcan, Sinead Kinsella, Donal N. Reddan, Matthew D. Griffin, David Lappin. *Department of Nephrology, Galway University Hospitals, Galway, Ireland.*

Background: The optimal method of monitoring blood pressure (BP) in a peritoneal dialysis (PD) population is unclear. Ambulatory BP monitoring (ABPM) can refine cardiovascular prognosis but is inconvenient and costly. Home BP monitoring (HBPM) can be inaccurate in this population. The novel BpTRU device (VSM MedTech Ltd, Coquitlam, Canada) has not been studied.

Methods: A cross-sectional study in a single PD centre. All patients underwent office BP measurement (OBPM), BpTRU BP measurement (BpTRU-BPM), HBPM and ABPM over a 2-week period. Agreement between ABPM and the 3 comparator methods was determined.

Results: 17 patients (54.2±12.0 years, 70.6% male, 94.1% automated PD) were studied. Mean office SBP (126.4±16.9mmHg) and BpTRU SBP (123.8±13.7mmHg) closely approximated mean daytime ambulatory SBP (129.3±14.8mmHg), p=NS. Mean home SBP (143.8±15.0mmHg) over-estimated mean daytime ambulatory SBP by 14.2mmHg (95% CI 4.3 to 24.1mmHg, p=0.008). BpTRU SBP correlated well with daytime ambulatory SBP (r=0.49, p<0.05). Home SBP correlated poorly with daytime ambulatory SBP (r=0.24, p=0.37). Bland Altman plots of office SBP, BpTRU SBP, and home SBP, respectively, against daytime ambulatory SBP demonstrated poorest agreement between HBPM and ABPM. False-resistant hypertension was rare (n=1). Nocturnal non-dipping was prevalent (non-dipping, n=11; reverse-dipping, n=5; normal dipping, n=1).

Conclusions: BpTRU-BPM was more accurate than HBPM, with reference to ABPM, in this PD population. Standard OBPM was also superior to HBPM. We suggest two potential explanations for these findings. Firstly, PD patients are very familiar with medical procedures and may consequently experience minimal white-coat effect. Secondly, patients may not adhere to strict BP measurement technique when monitoring BP at home on a long-term basis. The high prevalence of nocturnal non-dipping observed in this PD population may relate to the predominance of automated PD over ambulatory PD. Larger studies are required to validate these findings. Whether BpTRU-BPM can to lead to improved patient outcomes remains to be determined.

TH-PO782

Hourly Ambulatory Blood Pressure Patterns in Patients with Intradialytic Hypertension Peter N. Van Buren, Bohyun Catherine Kim, Anand Srivastava, Robert D. Toto, Jula K. Inrig. *Nephrology, UT Southwestern Medical Center, Dallas, TX.*

Background: Hemodialysis (HD) patients with intradialytic hypertension (HTN), an increase in blood pressure (BP) from pre to post-HD, have higher average interdialytic BP compared to HD controls. This study's purpose is to compare hourly interdialytic BP slopes in intradialytic HTN patients and HD controls.

Methods: In this case-control study, inclusion criteria were prevalent adult HD patients with HTN (systolic BP [SBP] ≥140 mmHg pre-HD or ≥130 mmHg post-HD) during 6 screening HD treatments. Case subjects had SBP increases ≥10 mmHg from pre to post-HD in ≥4/6 treatments, and controls had decreases ≥10 mmHg in ≥4/6 treatments. A repeated measures mixed linear model analyzed interdialytic ambulatory BP slopes.

Results: Of 50 subjects (25 in each group), average age was 54.5 years, 80% were male, 38% African American, 62% Hispanic, and 86% diabetic. The ambulatory BPs are shown below.

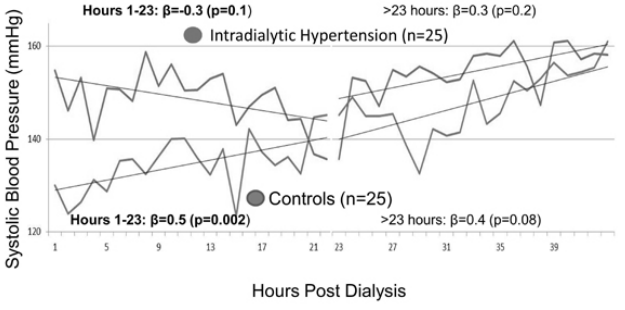
Blood Pressure Comparisons

ASBP (mmHg)	Intradialytic Hypertension	Control	p-value
44-Hr Average	155 (14)	142 (17)	0.005
Hours 1-23	153 (22)	138 (21)	0.0005
Hours > 23	156 (21)	151 (22)	0.2

ASBP=Ambulatory Systolic Blood Pressure

For the initial 23 hours post-HD there was an interaction between group and time (p=0.002). The slope for change in SBP per hour was +0.5 (p=0.002) for controls, but it was a non-signficant decrease in the intradialytic HTN group (β=-0.3, p=0.1).

Figure 1: Mixed Linear Model Analysis of Ambulatory Blood Pressure Slope in Intradialytic Hypertension Patients and Controls During the First 23 Hours Post-Hemodialysis and During the Remaining Interdialytic Time Period



There was a trend towards hourly BP increases in both groups during the remainder of the interdialytic period.

Conclusions: Interdialytic BP slope differs between intradialytic HTN patients and HD controls. The initial post-dialytic BP decrease for 23 hours in intradialytic HTN patients is not consistent with salt sensitive HTN. The increased ambulatory BP burden in intradialytic HTN patients remains to be fully explained, and mechanisms related to increased vasconstriction should be considered.

Blood Volume Monitoring Characteristics during Intradialytic Hypertension Devasmita Choudhury,[1,2] Lynne M. Roetzer.[1] *[1]Medicine, Dallas VA Medical Center, Dallas, TX; [2]Medicine, University of Texas Medical Center, Dallas, TX.*

Background: Inadequate volume removal (VR) during dialysis can lead to elevated blood pressure (BP) and exacerbate volume load. Blood volume monitoring (BVM) can be used to assess rate of volume removal and intravascular volume refill during hemodialysis (HD). These characteristics were examined 71 chronic stable HD patients to determine differences in those with intradialytic normotension, hypertension (HTN), or hypotension.

Methods: Patients were grouped into high (H)BP, normal (N)BP, low (L) BP by changes (Δ) in BP from start to end of dialysis. An increase of ≥ 10mmhg systolic (sys) or diastolic (dias) BP was grouped as HBP. Sys BP changes within 10mmhg were considered NBP. A decrease of ≥ 10mmhg for sys BP during a HD session was grouped as LBP. ANOVA used for continuous variables. BVM was analyzed for vascular refill and drop in BVΔ slope >5%.

Results: Groups were similar in demographics - gender, DM, HTN, and CV disease, Rx time, bath type. Vascular refill rate was similar for HBP and NBP patient however with 20% fewer BVΔ (drops >5%) in HBP compared to LBP, table 1. This was present despite similar volume removal between HBP and LBP, p=.07. Both volume removal and highest ultrafiltration rate (hUFR) was greater for LBP group than NBP p=.002, p=.03 respectively.

Table1: Comparison of volume removal during intradialytic BP changes

	HBP (n=25)	LBP (n=32)	NBP (n=14)
Age (avg± SD)	67±9	65±9	66±15
VR (ml) (avg± SD)	2926±1039	3587±914	2372±1373
Highest UFR (ml) (avg± SD)	892±363	1082±371	757±400
Avg wt gain (kg) (avg± SD)	2.8±1.6	3.2±1.2	1.9±1.3
Refill (%)	84	71	92
slope Δ>5% (%)	52	72	57

Conclusions: These data suggest that patients with intradialytic systolic or diastolic HTN have increased rates of vascular refill with fewer drops in BV slope although they have no clinical evidence for volume retention. This suggests that volume remains an important contributor for intradialytic hypertension and volume removal should be given a trial in those with intradialytic hypertension.

TH-PO784

Should Every Hypertensive Patient Undergo Carotid Ultrasound? A Simple Statistical Method To Target Subgroups Merce Borras,[1] Javier Trujillano,[4] Jorge Roig,[1] Marisa Martin Conde,[1] Angels Betriu,[3] Adriana S. Dusso,[2] Elvira Fernandez.[1] *[1]Nephrology, Arnau de Vilanova Hospital, Lleida, Spain; [2]Experimental Nephrology, IRBLLeida, Lleida, Spain; [3]UDETMA, Arnau de Vilanova Hospital, Lleida, Spain; [4]Statistics, Lleida University, Lleida, Spain.*

Background: To identify the subgroups of hypertensive patients with high likelihood of carotid plaques(CP)

Methods: Hypertensive patients with carotid ultrasound (CU), CP was defined as Intima-media thickness > 1.1 mm. Demographics, blood and pulse pressure, antropometrics, family and smoking background were recorded.Serum glucose, lipids and C reactive protein as well as microalbuminuria and left ventricular hypertrophy (by echocardiography) was considered. Statistics: Classification tree CHAID (Chi-squared Automatic Interaction Detector) for the calculation of probability of developing CP.

Results: 610 hypertensive patients, mean age was 57,6 years, 62% were males, 23 % diabetics and 18,8% current smokers.The prevalence of CP was 54.7%. CHAID identified 10 decission rules.In hypertensive patients age< 64 years active smoking increased the likelihood of CP. In the subgroup of <43 years (11.9% plaque prevalence) (24% vs 2.9% ;p=0.013).In patients between 43 and 55 years (40.7% carotid plaques) (66.7% vs 29,3%; p=0.000); among non smokers those with pulse pressure >48.67 mmHg showed an increased probability of CP (39.5% vs 12.8%;p=0.014).In patients between 55 and 64 years (57.8% CP) (82.6% vs 54.5%;p=0.01); among non smokers, diabetic patients showed higher likelihood of CP (69.4% vs 48.8%;p=0.014).In patients >64 years (79.5% CP) those with a pulse pressure >65.33 mmHg showed an increased likelihood to develop CP (88.9% vs 67.5%;p=0.004).Using CHAID 52.5% of hypertensive patients would be eligible for CU and 80.2% of the patients would be well classified.

Conclusions: 1.The classification tree for the calculation of the probability to develop CP is a simple method to identify, according to age categories and smoking habit, the risk of hypertensive patients of having atheroesclerotic disease. 2.This method would allow us to select target population for CU if these results are confirmed in further studies.

TH-PO785

Gauging Central Hemodynamic Measure and Ambulatory Arterial Stiffness Index (AASI) To Assess the Subsequent Decline in Glomerular Filtration Rate (GFR) in Stage 3 and Stage 4 Chronic Kidney Disease (CKD) Rupesh Raina, George Thomas, Charbel A. Salem, Alaine E. McGarry-Gada, Martin J. Schreiber, Mohammad Rafey. *Dept. Nephrology and Hypertension, GUKI Institute., Cleveland Clinic Foundation, Cleveland, OH.*

Background: Historically, there has been significant emphasis on BP control to prevent progression of underlying CKD.However, the optimal BP target for patients with CKD remains unclear. We conducted this study to assess the association of central hemodynamic measurements with CKD progression.

Methods: We conducted a secondary data analysis using our preexisting CKD registry at Cleveland Clinic. Central hemodynamic assessment data and 24 hr ABPM pressure were obtained from our hypertension database. AASI was calculated as 1 minus the slope of diastolic on systolic BP in individual 24hr ABPM measure.

Results: We identified 62 patients (stage 3 and 4 CKD) from our CKD registry. The mean age of the study cohort was 72 ± 11.9 years with 54% females and 13% African Americans. The impact of central hemodynamic BP measures and 24 hr ABP on change in GFR is delineated in the table.

Central Hemodynamic Measures	Mean Change in eGFR using CKD-EPI equation	P value
Brachial BP >120/80mmHg	-1.4%	P>0.05
Central Systolic BP >125 mmHg	-2.3 %	P>0.05
Augumentation Pressure (AP) >16 mmHg	-4.2%	P=0.03
AASI index (all quartile) >0.5 U	-6.0%	P=0.01
Ambulatory Pulse pressure PP >50 mmHg	-4.1%	P=0.03

These findings persisted after adjustment for age, sex, active smoking, body mass index, race (White vs. African-American), DM, dipping status, hypertension, congestive heart failure, coronary artery disease, metabolic acidosis and alkalosis, hypertriglyceridemia, and HbA1c. A unique composite score consisting of AP, PP and AASI index was developed and demonstrated a mean decline in GFR of 8.1% at 3 years after adjusting for all variables.

Conclusions: Utilizing a hemodynamic composite score (using AP which estimates the effect of reflected wave form of systolic workload, AASI assessing arterial stiffness, and PP reflecting pulse volume and elasticity of vascular wall) may be more comprehensive in determining risk for CKD progression over time as compared to current applied BP targets and warrants further study.

TH-PO786

Does the BpTRU Device Improve the Diagnostic Accuracy of Office Based Blood Pressure Measurements? Cedric A.W. Edwards, Ankur Gupta, Swapnil Hiremath, Marcel Ruzicka. *Renal Hypertension Unit, University of Ottawa, ON, Canada.*

Background: Measurement of blood pressure (BP) in the office setting fails to identify patients with white coat hypertension (WH). 24 hour ambulatory BP monitoring (ABPM) is considered a gold standard to assess daytime BP. 24-hr ABPM has added costs including equipment and labour. BpTRU has shown promise to improve diagnostic accuracy of office BP readings, and hence, minimize the concern of WH.

Methods: In order to assess the diagnostic accuracy of BpTRU device in a tertiary care referral clinic, we conducted a retrospective analysis of adults with either diagnosed or suspected hypertension (HTN). We compared corresponding BP readings a) average of 3 resting readings taken by trained HTN clinic nurse using mercury sphygmomanomentry (RN), b) average of 5 readings obtained by BpTRU and c) average daytime readings from 24-hr ABPM. The clinic readings were obtained on the morning of ABPM recordings. The average Systolic BP (SBP) for each method was compared using Pearson's correlation and performing a Bland-Altman analysis. Amongst patients with WH (RN SBP > 140 mmHg but ABPM ≤ 135), the proportion of patients who were labelled as hypertensive by BpTRU (SBP > 140) were also calculated.

Results: Charts of 2000 consecutive patients from 2004-2010 were reviewed. 329 patients (mean age of 62 years with 49% males) fulfilled above criteria and were analyzed. Each patient data qualified for one entry only. The mean SBP (mmHg) for RN, BpTRU and ABPM was 143.87 ± 19.90, 136.27 ± 21.85, and 139.35 ± 14.24 respectively.

SBP correlations

Variable (SBP mmHg)	Variable(SBP mmHg)	Correlation
BpTRU	RN	0.74(P<0.0001)
ABPM	RN	0.56(P<0.0001)
ABPM	BpTRU	0.61(P<0.0001)

95 % of values of SBP (difference between ABPM and BpTRU) are between -33 to + 31 mmHg. Fifty-two patients (15.81%) had WH. The BpTRU SBP value in 57% of these patients was greater than 140.

Conclusions: Although there is a statistically significant correlation between SBP obtained by BpTRU and ABPM, the clinical utility of this is limited by the poor ability of BpTRU to correctly diagnose WH. Caution is to be used when relying solely on BpTRU readings to eliminate the diagnosis of WH.

TH-PO787

Ambulatory Blood Pressure Monitoring (ABPM) in the CKD Japan Cohort (CKD-JAC) Study Enyu Imai,[1] Satoshi Iimuro,[2] Kosaku Nitta,[3] Tsuyoshi Watanabe,[4] Seiichi Matsuo,[1] Tadao Akizawa,[5] Hirofumi Makino,[6] Yasuo Ohashi,[2] Akira Hishida.[7] *[1]Nagoya University; [2]University of Tokyo; [3]Tokyo Women's Medical University; [4]Fukushima Medical University; [5]Showa University; [6]Okayama University; [7]Yaizu City Hospital.*

Background: The CKD-JAC study was established to prospectively study the renal and cardiovascular outcomes in 2977 Japanese patients with CKD stage 3-5 who are visiting 17 outpatients clinics in Japan. Ambulatory Blood Pressure Monitoring (ABPM) was conducted in 1113 participants to study the impact of 24h BP on outcomes.

Methods: ABPM at 30-min interval was performed from September 2007 to April 2010. Data on medical history, medications, office BP and renal function were used from the data at registration. The following indicators related to BP were calculated from these data: 24h mean BP, daytime BP, nocturnal BP, degree of nocturnal BP fall, early-morning HTN, and morning surge. The criterion for HTN was 140/90mmHg for the office BP and 130/80 mmHg for the 24-hour mean BP.

Results: The data of 1,077 subjects was ultimately analyzed. Based on the 24-hour mean BP and office BP, the HTN patterns were classified as normal BP (37.5%), white-coat HTN (5.6%), masked HTN (30.8%), and persistent HTN (26.1%). Early-morning HTN accounted for 67.6%, and of this group, 41.6% were the morning surge type (with normal 24-hour mean BP). Nocturnal HTN accounted for 33%, and most of it was persistent HTN. Nocturnal BP fall patterns were classified as dipper (36.6%), extreme dipper (9.8%), non-dipper (37.7%), and riser (15.9%). CKD stages 4 and 5 patients had a higher comorbidity of non-dippers and riser. The percentage of non-dippers and risers was the highest (69.4%) in diabetes. Use of RAS inhibitor was associated with decreasing percentage of nocturnal hypertension, while use of diuretics was not.

Conclusions: A significant proportion of CKD population had masked HTN and early-morning HTN. The percentage of patients with non-dipper or riser was increased according to progression of CKD stages. The comorbidity of nocturnal hypertension is remarkable in patients with diabetic nephropathy.

TH-PO788

Comparison of Heart Rate Variability between Patients on Kidney Transplantation, Hemodialysis, Peritoneal Dialysis Due to End Stage Renal Disease and Hypertensives in Korea

Joon Seok Oh, Joong Kyung Kim. *Division of Nephrology, Internal Medicine, Bong Seng Hospital, Dong-gu, Busan, Korea.*

Background: Heart rate variability (HRV) can be used to assess the effects of drug and other interventions including respiration, exercise, metabolic change and psychological or physical stress on cardiac autonomic tone. We investigate the autonomic nerve system activity by HRV in patients with kidney transplantation, hemodialysis, peritoneal dialysis.

Methods: We compared the pattern of cardiac sympathetic and parasympathetic activity through the time- and frequency-domain analysis of HRV with 24-hour Holter monitoring between 30 kidney transplanted subjects, 22 with hemodialysis, 20 with peritoneal dialysis and 34 control patients with hypertension. The subjects have been received renal replacement therapy at the Bongseng hospital between January 2006 and December 2010.

Results: All measures of kidney transplanted gorup were similar to those of control group. In peritoneal dialysis group, HRV index was decreased compared with other groups. In hemodialysis and peritoneal dialysis groups, normalized unit of low-frequency (LFnorm), ratio of low-frequency power to high-frequency power (LF/HF) were increased and normalized unit of high-frequency (HFnorm) was decreased compared with other groups.

The comparison of time-domain and frequency-domain HRV measures between groups

	HD	PD	KTP	Control	p value
HRV index	11.04 ± 5.58	9.21 ± 4.57	16.20 ± 4.57	17.29 ± 6.22	0.002
LF/HF	1.01 ± 1.02	0.85 ± 0.93	2.73 ± 2.48	2.16 ± 2.21	0.001
LF norm, nu	30.38 ± 19.99	25.94 ± 19.85	54.32 ± 19.93	47.46 ± 21.21	0.000
HF norm, nu	41.71 ± 15.71	40.83 ± 11.66	30.26 ± 15.54	33.46 ± 13.82	0.012

HRV index: Integral of the density distribution divided by the maximum of the density distribution, LF norm: LF in normalized units, HF norm: HF in normalized units

Conclusions: Autonomic tones in patients on hemodalysis and peritoneal dialysis are decreased compared with those in patients with kidney transplantation and hypertension. And parasympathetic tones in patients on hemodilaysis and peritoneal dialysis have the preponderance over sympathetic tones. Kidney transplantation may be a modality to improve HRV index in patients with ESRD.

TH-PO789

The Disturbed Circadian BP Rhythm in Chronic Kidney Disease Stage 1-3 Patients

Yan Qin, Lijun Mou, Xuemei Li, Xuewang Li. *Nephrology Department, Peking Union Medical College Hospital, Beijing, China.*

Background: The disturbed circadian rhythm of blood pressure(BP) was independent risk of CKD progression and CVD events. The mechanism of the changing of BP rhythm in CKD is not clear. The present research is to explore the circadian BP rhythm of the youth and middle age patients in CKD stage 1~3 and involved factors.

Methods: The patients underwent 24-hour ambulatory BP monitoring and collected the urine of daytime and nighttime synchronously. The urine was analyzed for Na, K, Cl ,Cr and albumin concentration.

Results: (1)62 patients in CKD stage 1~3 were enrolled,76.6% patients presented as Nondipper BP pattern.The night SBP,DBP and MAP in Nondipper group were higher significantly than the Dipper group.

(2)Both the 24hUP [(1.67±1.73)g/d v.s(3.64±3.00) g/d, P=0.014] and the night RUNa [(4.91±4.18)mmol/h v.s (6.84±3.81) mmol/h,P=0.011] in Nondipper group were significantly higher than those in Dipper group.

(3)Within the Nondipper group, the circadian rhythm of RUNa was reversed. Night RUNa was higher than day RUNa [(6.84±3.81) mmol/h v.s (6.26±3.55) mmol/h].

(4)Night SBP, DBP and MAP increased with the increase of night RUNa and 24hUP from the first to the third tertile significantly(P<0.050), even after adjusted by age, drugs and eGFR.

(5)In the linear regression equations, with the night/day ratio value of RUNa increasing by one, the night SBP, DBP and MAP increased by 2.51 mmHg, 2.54 mmHg and 2.44 mmHg respecitively.

(6)FENa increased significantly from 0.38±0.21 in the first tertile to 1.22±0.57 in the third tertile of night RUNa(P<0.001).

(7)The night RUNa and 24hUP were the risk factors of Nondipper BP pattern, the OR values were 2.37 and 1.42 respectively.

Conclusions: We concluded the disturbed diurnal BP rhythm in the youth and middle age patients in CKD stage 1-3 was common. Both of disturbed circadian rhythms of the RUNa and proteinuria were correlated with the elevation of the night BP and both of them were the risk factors of abnormal circadian BP rhythm. The increase of night RUNa was associated with the decreased ability of tubular sodium reabsorption.

TH-PO790

Low Plasma Renin Activity Levels Are Associated with Lower Mortality in Chronic Kidney Disease Patients

John J. Sim,[1] Jiaxiao Shi,[2] Federico Calara,[3] Simran K. Bhandari,[1] Scott A. Rasgon,[1] Kamyar Kalantar-Zadeh.[4] *[1]Nephrology & Hypertension, KPSC Los Angeles, Los Angeles, CA; [2]Research & Evaluation, KPSC, Pasadena, CA; [3]Novartis Pharmaceuticals, Hanover, NJ; [4]Nephrology, Harbor UCLA, Torrance, CA.*

Background: While the lack of suppression of plasma renin activity (PRA) in poorly controlled hypertension (HTN) has been described to have worse clinical outcomes, no studies to date have evaluated the prognostic implications of PRA in chronic kidney disease (CKD) patients. We sought to determine whether low or suppressed PRA conferred a protective effect on mortality in patients with CKD.

Methods: Longitudinal cohort study within a large ethnically diverse integrated healthsystem during 1/1/1998 thru 12/31/2008 of subjects age ≥ 18 with a minimum of 1 yr followup. Patients with measured PRA and estimated glomerular filtration rate (eGFR) below 60ml/min were included. Primary outcome was mortality rates compared across different levels of PRA. Comparisons were made based on population based quartiles of PRA using cox proportional hazards modeling adjusting for eGFR, age, gender, race, HTN, diabetes (DM), and charlson comorbidity index.

Results: Total of 785 patients were identified for inclusion in the study. Average age 65yrs, 43% men, 41% diabetics, 91% hypertensive, and mean followup was 3.8yrs for the cohort. Compared to the highest PRA quartile, adjusted hazards ratio (HR) for mortality at 2yrs were 1.16 (0.64-2.10 95%CI), 0.94 (0.51-1.76), and 0.55 (0.28-1.11) in the third, second, and lowest quartiles respectively. Linearity was observed where HR for mortality was 1.02 for every 1ng/ml/hr increase in PRA. When lowest PRA quartile (PRA<0.7ng/ml/hr) was compared against the rest of cohort, adjusted HR at 2yrs was 0.59 (0.36-0.96).

Adjusted HR for mortality

PRA quartiles	HR	95% CI
Q3 vs Q4 1yr	1.16	0.64-2.10
Q2 vs Q4 1yr	0.94	0.51-1.76
Q1 vs Q4 1yr	0.55	0.28-1.11
Q3 vs Q4 2yr	1.11	0.67-1.83
Q2 vs Q4 2yr	0.96	0.57-1.62
Q1 vs Q4 2yr	0.60	0.34-1.08

Conclusions: Therapy targeting the renin angiotensin aldosterone system is a cornerstone of CKD management. Our current study suggests that suppressed renin states may confer lower risk for mortality in CKD.

TH-PO791

Antialbuminuric Response to Direct Renin Inhibition in Combination with HCTZ or Amlodipine in Patients with Hypertension

Luis M. Ruilope,[1] Mojdeh Maboudian,[2] Cheraz Cherif-Papst,[3] Dion Zappe.[2] *[1]Unidad de Hipertensión, Hospital 12 de Octubre, Madrid, Spain; [2]Clinical Development & Medical Affairs, Novartis Pharmaceuticals, East Hanover, NJ; [3]Biostatistics, Novartis AG, Basel, Switzerland.*

Background: Microalbuminuria is commonly associated in patients with hypertension and diabetes. Aliskiren, a direct renin inhibitor, like ACEIs and ARBs reduces albuminuria and microalbuminuria in patients with hypertension. The purpose of this pooled analysis was to evaluate the effect of aliskiren in combination with hydrochlorothiazide (HCTZ) or amlodipine (AMLO) in reducing urinary albumin creatinine ratio (UACR) in patients with hypertension who do not have pre-existing renal disease (ie. albuminuria or chronic kidney disease).

Methods: Two separate pooled posthoc analyses were conducted in patients with hypertension (age=54 yrs; 51-56% males; BP=167/96 mmHg; BMI=34-35 kg/m2; 12-19% diabetes; 90-95% eGFR≥60 ml/min; 24-26% microalbuminuria) who were either randomized to aliskiren (300 mg) in combination with hydrochlorothiazide (25 mg; n=316) (pool 1) or amlodipine (10 mg; n=97) (pool 2) for 8-12 weeks of therapy.

Results: The response to aliskiren in combination with HCTZ or amlodipine demonstrated reductions in UACR in hypertensive patients without kidney disease.

	Pool 1		Pool 2	
Geometric means	Aliskiren/HCTZ (n=228)	Amlodipine (n=145)	Aliskiren/AMLO	Amlodipine (n=175)
Baseline (week 0)	1.1 mg/mmol	1.3 mg/mmol	1.36 mg/mmol	1.09 mg/mmol
Week 8/12	0.81 mg/mmol	1.29 mg/mmol	1.11 mg/mmol	1.25 mg/mmol
Δ baseline	-33%	-8%*	-16%	+12%†

*p<0.05 vs. Aliskiren/HCTZ; †p=0.06 vs Aliskiren/AMLO

Conclusions: In hypertensive patients with stage 1-2 kidney disease the treatment with aliskiren in combination with HCTZ or amlodipine reduced UACR. These results confirm the use of HCTZ or amlodipine with aliskiren will not only lead to further lowering of BP in hypertensive patients but will also help reduce urinary protein excretion.

TH-PO792

ACE Inhibitors (ACEI) Are Not More Effective Than Angiotensin Receptor Blockers (ARB) in Suppressing Plasma Aldosterone (pAldo) Levels in Hypertensive Patients (pts) Nabil J. Haddad, Udayan Y. Bhatt, Brad H. Rovin, Lee A. Hebert. *Internal Medicine/Nephrology, Ohio State University Medical Center, Columbus, OH.*

Background: Previous work suggests that ACEI are more effective than ARB in suppressing pAldo. However, those studies involved relatively small numbers of pts and/or used relatively low doses of ACEI or ARB.

Methods: This work involved relatively large numbers of pts who received chronic ACEI or ARB therapy and in usual dose. Although not a randomized comparison, the groups were well matched and we took into account ACEI/ARB dose intensity, co-morbidities, diuretic status, and 24-h intake of sodium and potassium assessed by 24-h urine collection, CKD-EPI eGFR, systolic blood pressure, and ACE genotype. The latter is important because the deletion (D) allele encodes for high ACE level, which might induce resistance to ACEI therapy.

Results: We studied 108 ACEI and 53 ARB treated pts receiving therapy for at least 3 months: Age (54.6 ± 1.4 SD vs 57.7 ± 2.1), percent male (55.6 vs 50.9), Caucasian (80.6 vs 77.4), African American (17.6 vs 17.0), hypertensive (83.3 vs 81.1), with diabetes mellitus, (35.2 vs 32.0), on diuretics (48.2 vs 64.2). eGFR was (53.8 ± 3 vs 51.8 ± 4.). None of the differences between the ACEI and ARB groups was significant, although there was a trend for greater diuretic use in the ARB group (p = 0.056). pAldo was not different between the ACEI and ARB groups by univariate analysis or by bivariate analysis adjusting for ACEI and ARB dose with stratification according to ACE genotype. The multivariate model adjusted for age, race, sex, CHF, diabetes, diuretics, 24-h urine Na and K, eGFR, SBP, and ACE genotype.

Conclusions: Our analysis suggests that ACEI are not better than ARB in suppressing pAldo.

TH-PO793

Serum Potassium Level as a Predictor of Responsiveness to Eplerenone Add-On Therapy in Patients Taking Renin-Angiotensin System Blockers Noritaka Kawada,[1] Toshiki Moriyama,[2] Harumi Kitamura,[1] Tomonori Kimura,[1] Hiroki Omori,[1] Yoshitsugu Takabatake,[1] Masaru Horio,[1] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Div. of Nephrol, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Health Care Center, Osaka university, Suita, Osaka, Japan.*

Background: Renin-angiotensin system blockers are first-line antihypertensive agents, but antihypertensive monotherapy is often not sufficient to achieve appropriate blood pressure (BP) control for organ protection. This study determined whether addition of eplerenone could result in clinical benefits in patients already taking angiotensin-converting enzyme inhibitors (ACEis) or angiotensin receptor blockers (ARBs).

Methods: Twenty-five patients who were already taking ACEis or ARBs due to hypertension or chronic kidney disease were enrolled in this study. During the course of the study, patients were treated with a gradual increase of eplerenone to a final dose of 50 mg/day. BP, serum and urine osmolarity/sodium/potassium/ creatinine, estimated glomerular filtration rate (eGFR), and urinary protein/creatinine ratio were measured before and after the 4-month study period. Baseline plasma renin activity (PRA) and plasma aldosterone concentration (PAC) were also measured in some patients.

Results: At baseline, there was no correlation between PAC and the calculated transtubular potassium (K) gradient (TTKG) or PRA in subjects who were taking ACEis or ARBs. However, PAC was inversely correlated with serum sodium (p=0.02) and osmolarity (p=0.05) and positively correlated with serum potassium level (p=0.008). The administration of 50 mg of eplerenone had no significant effects on BP, TTKG or proteinuria, possibly due to individual variability in the response to eplerenone. When the percent changes in proteinuria between basal levels and those at 4 months were calculated, there was an inverse correlation between the baseline serum potassium level and the percent change in proteinuria after eplerenone (p=0.03).

Conclusions: Serum potassium levels predict responsive to eplerenone add-on therapy in patients already taking renin-angiotensin system blockers.

TH-PO794

Urinary Uromodulin Concentrations and Incident Hypertension: The Framingham Heart Study Conall M. O'Seaghdha, Shih-Jen Hwang, Caroline S. Fox. *NHLBI's Framingham Heart Study.*

Background: A common variant of the UMOD gene has been associated with extreme hypertension, independent of a primary defect in kidney function, in a recent genome-wide association study. The aim of the present study was to determine whether urinary uromodulin concentrations are associated with risk of hypertension in cross-sectional and prospective analyses.

Methods: Participants free of CKD were drawn from exam 6 of the Framingham Offspring Study (1995-1998), with follow-up at exam 8 (2005-2008) for prospective analyses (n=2948). Extreme hypertension was defined as systolic blood pressure ≥ 160 mmHg and/or diastolic blood pressure ≥ 100 mmHg. In prospective analyses, participants with baseline hypertension, defined as systolic blood pressure ≥ 140 mmHg and/or diastolic blood pressure ≥ 90 mmHg were also excluded. Urinary uromodulin concentrations were related to risk of prevalent and incident hypertension and extreme hypertension using logistic regression in unadjusted- and multivariable-adjused analyses adjusted for age, sex and eGFR.

Results: In cross-sectional analyses, urinary uromodulin concentrations were similar between hypertension cases and controls (11.4 vs. 10.6 mg/dL; p=0.9). Similarly, baseline uromodulin concentrations were not statistically different between cases of incident hypertension (11.3 vs. 11.2 mg/dL; p=0.3) and incident extreme hypertension (11.2 vs. 13.9 mg/dL; p=1.0). Results were unchanged after adjustment for urinary creatinine, age, sex, or eGFR.

Conclusions: Although the UMOD gene has been associated with extreme hypertension, its gene product, uromodulin, is not associated with hypertension in the community.

TH-PO795

Effect of Lanosterol Synthase Polymorphisms on Blood Pressure and Endogenous Ouabain Levels in Two Different Clinical Settings Chiara Lanzani, Guido Gatti, Marco Simonini, Simona Pozzoli, Elisabetta Messaggio, Nunzia Casamassima, Simona Delli Carpini, Lorena Citterio, Paolo Manunta. *Chair of Nephrology, San Raffaele Scientific Institute, Milan, Italy.*

Background: Endogenous Ouabain (EO) may affect blood pressure and renal Na excretion through the modulation of the Na pump either as a Na transport system or a signal transduction triggering mechanism in renal tubular cell and in vascular smooth muscle cells. Lanosterol synthase (LSS) regulates the first step in the biosynthesis of cholesterol and steroid hormone, including EO. A polymorphism (rs2254524 V642L) in LSS gene affects mRNA expression in human kidney tissue and in transfected human cells. In this latter setting this polymorphism also affects protein expression, enzymatic activity and EO synthesis.

Methods: To investigate whether the effect of two polymorphism of LSS (rs914247 and rs2254524), on BP and EO levels in mild hypertensive patients in response to two different manouvers: acute Na load with 0.9% NaCl (Na Load) for 2 hrs, and low dietary Na intake (< 100 mEq/day, Low Na diet) for 30 days.

Results: Behaviours of EO plasma levels resulted influenced (p = 0.004) by LSS genotypes: carriers of the wild type variants decreased EO (LSS rs914247 from 259.5±15 to 221.5±19 pmol/L, and LSS rs2254524 from 281.1±16 to 242.2±20 pmol/L). However, mutant variants were associated to slight EO increase (rs914247 265.4±14 to 279.7 pmol/L and LSS rs2254524 269.9±16 to 284.2±20 pmol/L). Furthermore, pressure natriuresis relationship was steeper in those hypertensives carrying the mutated LSS together with ADD2 variants (p epistasis=0.006). Low Na diet: fall in systolic (-8,7±1,7 vs 3,0±1,5 p= 0.013), diastolic (-5,1±0,98 vs -1,4±0,94 mmHg) blood pressure and long term regulation of pressure-natriuresis (0,105±0,02 vs 0,015±0,02 mEq/mmHg/min, p=0.007) were affected by LSS rs2254524 mutated variant.

Conclusions: Our findings suggest that LSS variants regulate plasma EO levels after acute and chronic Na balance variations. Therefore, plasma EO may influence Na-K ATPase activity both at vascular and kidney levels, resulting in modification of blood pressure and urinary Na excretions.

TH-PO796

Increased NO Activity during Statin Treatment in Healthy Humans Frank H. Christensen, Thomas Larsen, Jesper N. Bech, Erling B. Pedersen. *Department of Medical Research and Medicines, Holstebro Hospital, Holstebro, Denmark.*

Background: We investigated the effects of short term atorvastatin treatment on blood pressure (DBP and SBP), GFR and fractional excretion of sodium (FE-Na) during inhibition of nitric oxide synthase (NOS).

Methods: Twenty-six healthy men and women (18-37 years) were included in a randomised, placebo-controlled, double-blinded, cross-over study. All subjects attended 2 study days and were given standardized diet and either atorvastatin 80 mg per day or placebo 4 days prior to each examination day. ^{51}Chrom-EDTA clearance was used for GFR measurements and the NOS inhibitor, L-NMMA, were administered as a 4.5mg/kg bolus injection followed by 3.0 mg/kg/hour IV infusion for one hour. SBP, DBP and heart rate (HR) were repeatedly measured during the study day. Blood and urine samples were collected every 30 minutes during the 90 min baseline period, during L-NMMA infusion and 60 minutes after cessation of L-NMMA infusion. Differences are presented in means with standard deviation. Statistics were performed with t-test and paired t-test.

Results: Atorvastatin caused a significant reduction in total-cholesterol (3.7 vs. 3.1 mmol/l, p<0.001). Baseline levels of DBP (63±5 vs. 63±5 mmHg), SBP (112±8 vs.112±9 mmHg), HR (57±8 vs. 58±9/min), GFR (94±9 vs.96±9 ml/min/m^2) and FE-Na (1.28 vs. 1.35) were not different between groups. IV infusion of L-NMMA increased both DBP and SBP and decreased HR (p<0.001). From 15-60 min a stable blood pressure and HR was observed. There were no differences in change in SBP (4±3 vs. 4±3 mmHg), DBP (8±3 vs. 8±2 mmHg) and HR (-6±3 vs. -7±3/min) between groups. GFR decreased during L-NMMA infusion (p<0.001), but there were no differences between groups (-8±6 vs. -10±7%). FE-Na decreased during L-NMMA infusion (p<0.001) and this decreases was significantly higher during Atorvastatin treatment (-34 vs. -44%, p=0.007). There were no differences in 24 hour urine Na-excretion (106 vs. 114 mmol, p=0.32)

Conclusions: Short term Atorvastatin treatment significantly increased the reduction in FE-Na during NOS inhibition. Our results suggest that atorvastatin increases the bioavailability of renal NO and might be an explanation of the pleiotropic effects of statins.

TH-PO797

Patients Treated with the Angiogenesis Inhibitor Regorafenib Develop Hypertension with Rapidly Reversible Changes in Plasma Nitric Oxide and Endothelin-1 Nilka deJesus-Gonzalez,[1] Emily S. Robinson,[2] Radostin Penchev,[2] George Demetri,[3] Suzanne George,[3] Benjamin D. Humphreys.[2,3] *[1]Children's Hospital Boston; [2]Brigham and Women's Hospital; [3]Dana Farber Cancer Institute.*

Background: Hypertension (HTN) is a common and dose-limiting side effect of therapies that target VEGF signaling such as regorafenib. Understanding the mechanisms leading to HTN is important as such knowledge may lead to clinically useful biomarkers for predicting both toxicity and tumor response. We prospectively tested the hypothesis that regorafenib induces HTN by suppressing nitric oxide (NO) and increasing endothelin-1 (ET-1).

Methods: Plasma was collected from 32 subjects with gastrointestinal stromal tumor at baseline, 2, 4, and 6 weeks of therapy. Regorafenib was given on a 3-week on, 1-week off regimen, and plasma levels of NO, cyclic GMP (cGMP), a downstream effector of NO, and ET-1 were measured. Data analysis was by Wilcoxon and paired t-tests.

Results: The mean age was 55 years, 60% men, 84% white and 65% had prior HTN. At 2 weeks, regorafenib caused a rise in mean arterial pressure (MAP) with increased ET-1 and decreased NO. ET-1 and NO changes normalized after the 1-week washout period. No differences were observed for cGMP. After restarting regorafenib, ET-1 once again rose and NO fell (Table1).

Biomarkers evaluated at baseline and 2, 4, and 6 weeks after starting regorafenib therapy

Biomarker	baseline	2wks	4wks	6wks	*p(to baseline)
MAP,mmHg†	94(9)	97(12)*	94(11)	100(11)*	<0.05
NO,µmol/l††	26(21-35)	21(16-26)*	26(19-40)	13(10-20)*	<0.05
cGMP,pmol/ml††	150(128-172)	151(118-181)	174(73-210)	-	>0.05
ET-1,pg/ml,††	2.4(1.8-3.2)	3.4(2.2-4.7)*	2.8(2.3-3.5)	3.4(2.8-4.6)*	<0.05

†Mean (standard deviation); ††Median (Interquartile range)

Conclusions: These findings indicate the coordinated and reversible downregulation of the NO system and upregulation of ET-1 system by regorafenib, suggesting systemic vasoconstriction as a mechanism of HTN in these patients. This is the first prospective study evaluating both NO and ET-1 pathways as biomarkers of anti-angiogenic therapy-induced HTN in humans. Whether NO and ET-1 might predict the development of HTN or tumor response requires further study.

TH-PO798

Association between Sodium Intake and Hypertension Risk Varies Dependeing upon Levels of Biomarkers Indicating Endothelial Dysfunction John P. Forman,[1] Lieneke Scheven,[2] Paul E. de Jong,[2] Stephan J.L. Bakker,[2] Gary C. Curhan,[1] Ron T. Gansevoort.[2] *[1]Renal Div., Brigham and Women's Hospital, Boston, MA; [2]Dept. Nephrology, UMCG, Groningen, Netherlands.*

Background: The mechanisms underlying chronic sodium loading-related hypertension are unclear. A high sodium diet may first lead to vascular dysfunction, and then to hypertension if the high sodium diet is continued. We hypothesized that a higher sodium intake would be associated with increases in biomarkers of vascular endothelial dysfunction, specifically serum uric acid (SUA) and albuminuria (UAE), and that the association between sodium intake and risk of hypertension would vary according to levels of SUA and UAE.

Methods: We prospectively analyzed the associations of sodium intake with change in SUA, change in UAE, and hypertension incidence (defined by a systolic pressure ≥140 mmHg and/or a diastolic pressure ≥90 mmHg, or use of antihypertensive medications), during a median follow-up of 6.4 yr, among non-hypertensive participants of the PREVEND cohort (N=5571).

Results: After adjusting for multiple potential confounders, a higher sodium intake was significantly associated with increases in SUA and UAE. The relation between sodium intake and risk of incident hypertension varied significantly according to SUA and UAE. For each 1 gram higher sodium intake, the multivariable adjusted hazard ratio for developing hypertension was 0.98 (0.89-1.07) among those whose SUA was in the lowest tertile, and 1.10 (1.03-1.18) among those whose SUA was in the highest tertile. Similar analyses yielded adjusted hazard ratios of 0.99 (0.93-1.06) among participants whose UAE was <10 mg/d, and 1.18 (1.07-1.29) among those whose UAE was >15 mg/d.

Conclusions: Higher sodium intake was associated with increasing SUA and UAE, and was an independent risk factor for developing hypertension only among those with higher levels of SUA or UAE. A high sodium diet may lead to biological changes favoring the development of hypertension if the high sodium diet is continued.

The Effects of Pregnancy, Pregnancy-Associated Hypertension and Gestational Diabetes on the Microvasculature Thao Vi Luong,[1] Alexander James Teare,[1] Tien Y. Wong,[2,3] Ryo Kawasaki,[2,4] Judith A. Savige.[1] *[1]University of Melbourne, Northern Hospital; [2]Centre for Eye Research, Australia; [3]Singapore Eye Institute, National University of Singapore, Singapore; [4]Department of Ophthalmology and Visual Science, Yamagata University, Japan.*

Background: The small vessels of the retina resemble placental vessels in size. This study evaluated the effect of pregnancy, pregnancy-associated hypertension and gestational diabetes on the microvasculature using retinal vessels as a model.

Methods: One hundred and 36 normal pregnant women, 23 with pregnancy-associated hypertension, and 44 with gestational diabetes provided clinical details and underwent retinal photography using a non-mydriatic camera (KOWA or CANON). Retinal vessel diameters were measured from digital fundus images by a trained grader using a computer-assisted method and summarised as the central retinal artery and vein equivalents.

Results: Arteriolar calibre did not change in normal pregnancies between the first trimester and immediately postnatally (138.8 ± 10.3 um, n=29, versus 140.3 ± 12.5 um, n=31 respectively, p=0.62), but was reduced in the third trimester in patients with pregnancy-associated hypertension alone (130.4 ± 6.5 um, n=9 versus 140.3 ± 12.5 um in normals, n=31, p=0.029), and in patients with pregnancy-associated hypertension plus diabetes (127.4 ± 14.7 um, n=6, p=0.031).

Venular calibre increased progressively in normal pregnancies between the first trimester and immediately postnatally (204.9 ± 19.5 um, n=29, versus 218.6 ± 22.0 um, n =33, p=0.012). In diabetic pregnancies, the venular calibre was normal in the first trimester (199.6 ± 10.9 um, n=3, versus 204.9 ± 19.5 um, n=29, p=0.65), but there was a trend to smaller vessels by the third trimester (201.7 ±15.7 um, n=26, versus 211.1 ± 20.4 um, n=31, p=0.06).

Conclusions: Systemic arterioles are narrowed in patients with pregnancy-associated hypertension alone or together with diabetes. Venules normally dilate throughout pregnancy but the dilatation is less in diabetics. The retinal vasculature represents a model to investigate the effect of treatments that improve placental blood flow in pregnancy-associated hypertension and gestational diabetes.

TH-PO800

Obstetrical Thrombotic Thrombocytopenic Purpura. A Retrospective Study Yahsou Delmas,[1] Sebastien Helou,[1] Viviane Guerin,[2] Pierre Chabanier,[3] Christian Combe.[1] *[1]Service de Néphrologie Transplantation Dialyse, CHU Bordeaux, France; [2]Service d'Hémostase Spécialisée, CHU Bordeaux, France; [3]Pôle Gynécologie-Obstétrique-et Biologie de la Reproduction, CHU Bordeaux, France.*

Background: Thrombotic thrombocytopenic purpura (TTP) caused by a deficiency of A-Disintegrin-And Metalloprotease-with-ThromboSpondin-type-1-domain 13 (AD13), is a rare thrombotic microangiopathy (TMA). During pregnancy, clinical and biological presentation can mimic other TMA particularly the HELLP syndrome. AD13 deficiency in pregnancy related TMA has been evaluated in this study.

Methods: We selected all hospitalized pregnant women with platelets count (Plt) <75 G/L in our hospital in 2008. In patients with no identified etiology of low Plt, plasma AD13 activity was measured by the full length method and an AD13 inhibitor was searched for by functional test and ELISA.

Results: There were 4,292 deliveries for 2008, 43 patients (pts) had Plt<75 G/L. 11 pts had a documented cause of low Plt as ITP, MYH9 syndrome. 6 pts were lost to follow-up. AD13 was measured in 26 patients. 4 pts had AD13<5% in peripartum: TTP pts had lowest Plt significantly below non AD13-deficient 22 women (23 vs 53 G/L, p=0,005). 3 primipara pts with initial diagnosis of HELLP had constitutive AD13 deficit (later confirmed on repeated AD13 dosages) and gave birth prematurely. Their children had intrauterine growth retardation and placental pathology showed major lesions of ischemia. The fourth patient had an episode of TTP on the 5th day post partum with significant anti-AD13 antibody and anti-nuclear antibody at 1:500. The 4 pts had spontaneous resolution of their TMA without any plasma therapy. 2 pts with constitutive defect lost their babies in the neonatal period. In subsequent pregnancies they received prophylactic plasma infusion, and gave birth to normal children.

Conclusions: This is the first description of systematic evaluation of AD13 deficiency in pregnant women with low Plt count. Obstetrical TTP incidence is probably underestimated; in our tertiary unit, it can be evaluated to ~1/1000 pregnancies. Identification of AD13 deficiency may be helpful for prophylactic plasma infusion during subsequent pregnancies.

TH-PO801

Acute High-Dose Intravenous Epoetin Does Not Increase Blood Pressure in Critically Ill Patients with Acute Kidney Injury Zoltan H. Endre,[1,2] Azrina Md Ralib,[1] John W. Pickering,[1] Tamas Major,[1] David A. Goodkin,[3] Suetonia Palmer.[1] *[1]Medicine, University of Otago Christchurch, Canterbury, New Zealand; [2]Nephrology, Prince of Wales Clinical School, Sydney, NSW, Australia; [3]Goodkin Biopharma Consulting, LLC, Bellevue, WA.*

Background: Erythropoiesis stimulating agents (ESA) correction of renal anemia increases blood pressure in as many as 35% of patients. It is uncertain whether this phenomenon is due to increased blood viscosity, increased blood volume, reduction of hypoxic vasodilation, and/or ESA-induced vasoconstriction. The Early Intervention in Acute Renal Failure (EARLYARF) trial provided an opportunity to assess whether IV epoetin induces immediate vasoconstriction.

Methods: A post-hoc analysis of blood pressure changes among 163 patients randomized to receive two doses 24 hours apart of IV epoetin (500 U/kg) or placebo. These intensive-care patients were enrolled following identification of acute kidney injury (AKI) by the urinary biomarkers γ-glutamyltranspeptidase and alkaline phosphatase. Mean arterial pressures (MAP) and norepinephrine equivalent dose (NED) were recorded hourly. NED was determined using equipotency conversion factors for doses of epinephrine, vasopressin, phenylephrine, or dopamine. The differences between maximum and baseline (Δ-MAP and Δ-NED) were determined 4, 24, and 72 hours after study drug administration.

Results: At baseline, MAP was 78±14 mmHg in the epoetin group and 81±15 mmHg in the placebo group (p=0.84). At 4-h after the first drug dose, there were no differences

between groups in Δ-MAP (6.5±13 vs 8.4±13 mmHg; p=0.36), in Δ-NED (-0.8±10 vs -0.1±7.7 µg/min; p=0.63), or in Δ-MAP adjusted for Δ-NED (p=0.14). Similarly, there were no differences after 24 or 72-h, or 4 or 24-h after the second dose. Hemoglobin concentration and hematocrit were unchanged. A subgroup analysis of patients with no vasopressor use (n=71) also showed no differences between epoetin and placebo.

Conclusions: Two high doses of epoetin did not increase blood pressure up to 72-h after administration. These data demonstrate that epoetin does not have an acute vasoconstrictor effect among critically ill patients with AKI.

Funding: Government Support - Non-U.S.

TH-PO802

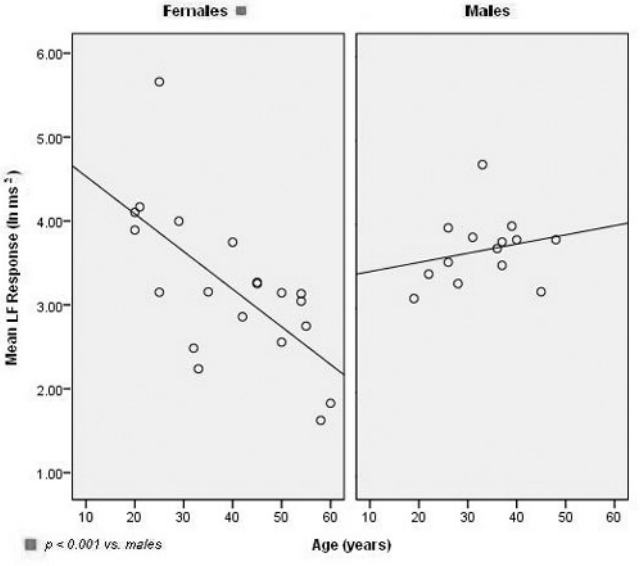
Impact of Gender and Age on the Cardiac Autonomic Response to Angiotensin II in Healthy Humans

Michelle C. Mann,[1] Brenda Hemmelgarn,[1,2] Derek Exner,[1,3] Darlene Y. Sola,[1] Tanvir Chowdhury Turin,[1] Sofia B. Ahmed.[1,2] *[1]Faculty of Medicine, University of Calgary, Calgary, Canada; [2]Alberta Kidney Disease Network, AB, Canada; [3]Libin Cardiovascular Institute, Calgary, Canada.*

Background: Women are protected from cardiovascular disease (CVD) compared to men. Changes in cardiac autonomic tone such as sympathetic overactivity and vagal withdrawal result in altered heart rate variability (HRV), which when coupled with upregulation of the renin-angiotensin system (RAS) are associated with kidney and CVD, though the pathophysiology is unclear.

Methods: 36 healthy subjects (21 women, 15 men, age 38±2 yrs) were studied in high-salt state. HRV, calculated by spectral power analysis [low frequency (LF), sympathetic activity; high frequency (HF), vagal activity; and LF:HF, balance of autonomic tone], was recorded at baseline and during angiotensin II (AngII) infusion (3ng/kg/min x 30min,6ng/kg/min x 30min).

Results: Striking gender differences exist in the HRV response to AngII, with women maintaining overall autonomic tone (LF/HF 2.4±0.3; p=0.36 vs. baseline) while men exhibit increased sympathetic activity and profoundly decreased vagal activity (LF/HF 4.1±0.6; p=0.014 vs. baseline, p=0.018 vs. LF/HF female response). While gender and age remained predictors of HRV response on multivariate analysis (p=0.003 and p=0.042, respectively), LF and HF responses were increasingly sensitive to AngII with age solely in men (LF p<0.001; HF p=0.001 for gender-age interaction).



Conclusions: Women maintain baseline levels of cardiac autonomic tone in response to AngII. In contrast, men exhibit greater cardiac risk with exaggerated cardiac sympathetic activity in response to AngII, a response exacerbated by increasing age. Understanding the roles of gender and age in cardiac autonomic modulation may help guide novel strategies for high-risk populations, such as those with kidney disease.

TH-PO803

Fibroblast Growth Factor 23 Levels Are Elevated in Children and Adults with Autosomal Dominant Polycystic Kidney Disease and Preserved Renal Function

Shailendra Sharma,[1] Michel B. Chonchol,[1] Berenice Y. Gitomer,[1] Wei Wang,[1] Myles S. Wolf,[2] Melissa A. Cadnapaphornchai,[1] Robert W. Schrier.[1] *[1]Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]Nephrology, University of Miami Medical Center, FL.*

Background: Fibroblast growth factor 23 (FGF23) is risk factor for adverse outcomes in chronic kidney disease (CKD). Elevated FGF23 levels weres recently shown in adults with ADPKD and early stages of CKD. Cardiac manifestations of ADPKD, including increased left ventricular mass index, occur as early as childhood. Early intervention early may be more effective to slow progression of cardiac disease in ADPKD. We hypothesized that FGF23 levels are elevated in children and young adults before reduction of kidney function.

Methods: We compared FGF23 levels in 35 children and young adults with ADPKD and normal eGFR (age 17±4 years; mean eGFR 118±23 ml/min/1.73m^2), 33 adults with ADPKD and preserved kidney function (age 37±8 years; mean eGFR 87±18 ml/min/1.73m^2) and 9 adults with more advanced ADPKD (age 51±10 years; mean eGFR 34±7 ml/min/1.73m^2). Serum FGF23 levels were measured by ELISA (Kainos, Tokyo, Japan).

Results: Using the same assay, a previous study reported normal FGF23 level in healthy volunteers aged 20-83 years of 30±21 pg/ml. Mean FGF23 level was 37.3 ± 18.5 pg/ml in the 35 children and young adults with ADPKD , 39.9 ± 21.3 pg/ml in the 33 adults with ADPKD and preserved kidney function and 86.4 ± 61.4 pg/ml in the 9 adults with more advanced ADPKD. Twenty % of children and young adults with ADPKD had an FGF23 >50 pg/ml. In the adults with preserved kidney function, 36% had a level >50 pg/ml. Among adults with more advanced renal dysfunction, only one had an FGF23 level < 50 pg/ml.

Conclusions: FGF23 levels are increased early in ADPKD when kidney function is intact, and abnormally high levels of FGF23 are detectable in many children with ADPKD. Further research is necessary to determine the implications of early increases in FGF23 levels in children and adults with ADPKD and whether these increases contribute to progression of CKD and the developmenmt of cardiovacular disease.

TH-PO804

The Relationship between Renal Volume and Renal Function in Autosomal Dominant Polycystic Kidney Disease

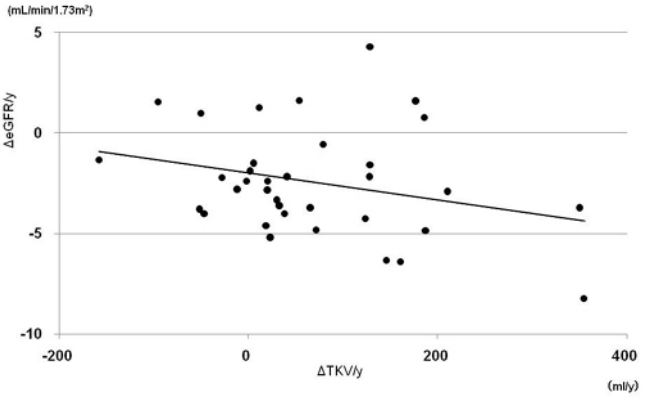
Satoru Muto, Yutaro Ogawa, Toshiyuki China, Hisamitsu Ide, Shigeo Horie. *Urology, Teikyo University, Tokyo, Japan.*

Background: In patients with autosomal dominant polycystic kidney disease (ADPKD), renal cysts grow exponentially. Since remaining renal parenchyma has a capacity to compensate for the loss of glomerular filtration, the glomerular filtration rate (GFR) may be sustained until the disease progresses. The purpose of this study was to determine if renal volumetric indices and clinical parameters are associated with renal function in Japanese patients with ADPKD.

Methods: In 73 ADPKD patients (28 men, 45 women), the associations of mean systolic blood pressure (SBP), mean diastolic blood pressure (DBP), estimated GFR (eGFR), the amount of proteinuria and albuminuria, body mass index (BMI), brachial-ankle pulse wave velocity (baPWV), ankle-brachial Index (ABI), and total kidney volume (TKV) were retrospectively analyzed.

Results: Multivariate linear regression analysis showed that eGFR was significantly and independently inversely correlated with patients' age, and BMI. The median change in eGFR per year (ΔeGFR/y) was -2.8 mL/min/1.73 m2/year. Multiple linear regression analysis showed that ΔeGFR/y was significantly and independently inversely correlated with the change in TKV per year (ΔTKV/y) (Figure1). Multiple linear regression analysis showed that ΔTKV/y was significantly related to initial TKV and the change in albuminuria per year (Δu-alb/y).

Conclusions: This study demonstrated a significant relationship between the change in renal function and the change in renal volume in Japanese ADPKD patients without renal insufficiency. It is possible that the volume measurements can be used as useful markers for disease progression in Japanese ADPKD patients.



TH-PO805

Baseline Renal Cysts Volume Predicts the Recombinant Human Erythropoietin Requirement in Autosomal Dominant Polycistic Disease

Paolo Lentini,[1-5] Luca Zanoli,[2] Antonio Granata,[3] Massimo de Cal,[4-5] Claudio Ronco,[4] Angela D'angelo,[5] Roberto Dell'aquila,[1] Valentina Pellanda.[1] *[1]Nephrology, St. Bassiano Hospital, Bassano del Grappa (vi), Italy; [2]Int. Med, University of Catania, Italy; [3]Nephrology, V.E. Hospital, Catania, Italy; [4]Nephrology, St. Bortolo Hospital, Vicenza, Italy; [5]University of Padua, Italy.*

Background: Prevalence of anaemia in patients with autosomal dominant polycystic kidney disease(ADPKD)increases according to the severity of chronic kidney disease(CKD). However,little is known about the relationship between kidney structure modification and recombinant human erythropoietin(rHu-EPO) requirement in these patients(pts).Aim of

this study was to evaluate the role of renal cysts and kidney size on rHu-EPO requirement in severe CKD and naive chronic hemodialysis(HD)patients.

Methods: A total of 43 pts with ADPKD and anemia treated with alfa-erythropietin (α-EPO)were enrolled(16 pts with CKD Stage 4 and 28 naive chronic HD pts),the total volume of the four largest cysts(cysts-Vol)and the mean antero-posterior renal diameter(AP) were prospectively followed-up for 18months with kidney ultrasound.

Results: Mean age was 65±13yrs.At baseline,AP was 19.4±2.1cm,cysts-Vol 407±369cm3.During the 18months follow-up,haemoglobin(Hb) was 10.8±0.7g/dl,α-EPO dose was 14403±7518UI/week,and α-EPO/Hb ratio was 1379±780.In fully adjusted model,baseline cysts Vol and AP predict EPO dose and EPO/Hb ratio and explain a large amount of variability.

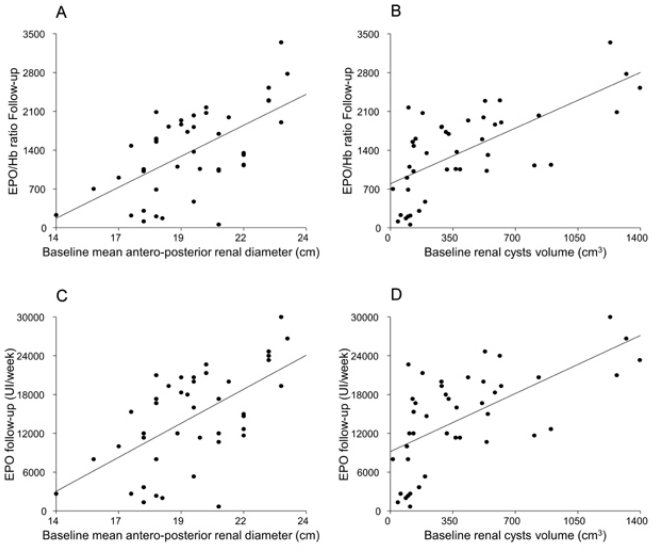


Table 1. Multivariate Analysis.

	Beta (95%CI)	P	R2 incr.
Dependent variable: EPO, UI/Week			
Cysts Vol (100cm3)	870 (250-1480)	<0.05	0.11
AP (cm)	1146 (68-2223)	<0.05	0.06
Model R2=0.46			
Dependent variable: α-EPO/Hb ratio			
Cysts Vol (cm3)	104 (43-165)	<0.05	0.14
AP (cm)	109 (3-215)	<0.05	0.05
Model R2=0.51			

Conclusions: Cysts volume is useful to predict prospectively the rHu-EPO requirement. This assumption is valid even in chronic dialysis patients, where the renal function is completely lost.

TH-PO806

Intravascular Treatment of 1,012 Patients with Symptomatic ADPKD and/or ADPLD Koki Mise, Yoshifumi Ubara, Keiichi Sumida, Rikako Hiramatsu, Tatsuya Suwabe, Kenmei Takaichi. *Nephrology, Toranomon Hospital, Tokyo, Japan.*

Background: Since the kidneys and liver of ADPKD patients are usually supplied by well-developed arteries, we have attempted to reduce the volume of enlarged kidneys and livers in these patients by transcatheter arterial embolization (TAE) using intravascular coils.

Methods: From 1996 to 2011, a total of 1,012 patients with ADPKD were treated for abdominal distension due to nephromegaly and/or hepatomegaly.

Results: Renal TAE was done for 711 patients with intractable enlarged kidneys. After TAE, nephrectomy was performed in 2 patients because of antibiotic-resistant renal cystic infection (unilateral in one patient and bilateral in the other). Nephrectomy was also performed for the affected kidney in 10 patients with renal cell carcinoma. The other patients had no TAE-related or renal complications, but complications of other organs (such as cancer and cardiovascular/cerebrovascular disease) led to death. Hepatic TAE was done in 301 patients with intractable symptomatic polycystic liver. After TAE, antibiotic-resistant hepatic cyst infection relapsed or developed newly in 30 patients. For these infections, cyst drainage was performed in 28 patients and partial hepatectomy was done in 2 patients. The prognosis of 15 patients with severe hepatic failure (total bilirubin >2.0 mg/dL) and intractable massive ascites was poor, but the other patients are doing well.

Conclusions: No major complications of TAE were encountered with treatment of either the kidneys or the liver. So far, it seems that TAE may be less effective in reducing total organ volume than surgical nephrectomy or hepatectomy. However, TAE is an option for patients with symptomatic polycystic liver and/or kidney who are in poor general condition and are not candidates for surgical treatment.

TH-PO807

Renal Denervation for Intractable Autosomal Dominant Polycystic Kidney Disease-Related Pain Marie C. Hogan,[1] Joanne Ryan,[1] James Glockner,[2] Stephen B. Erickson,[1] Dawn S. Milliner,[1] Claude Deschamps,[2] Vicente E. Torres.[1] *[1]Nephrology Div; [2]Radiology Dept; [3]Thoracic Surgery Div, Mayo Clinic, MN.*

Background: Kidney pain can be a severe & debilitating chronic problem in some individuals with ADPKD. Videothoracoscopic splanchnicectomy (VSPL) has anecdotally been used to manage ADPKD patients with intractable kidney pain.

Methods: We have performed VSPL in 15 ADPKD patients(11F, 4M) for chronic kidney pain in 13 [2 unilateral,11 bilateral procedures], a bilateral procedure for pain due to pancreatic cystic disease, & a unilateral procedure for liver pain; 11/15 enrolled in this study to evaluate its effectiveness in alleviating pain, opioid use, QOL, renal blood flow (RBF) [by MRI] & GFR. All had chronic pain >6 mo & were opioid dependent.

Results: All (mean age 38, range 20-51) reported relief of their pain (different/ less intense) immediately post op. Average hospital stay was 4d. Study participants have been followed a mean of 14 mo (range 1-24 mo). One developed severe chest wall pain post-op requiring nerve block & another developed orthostatic hypotension responsive to midodrine.

Improved pain treatment satisfaction occurred at mos 1 (n=9/11; p 0.002), 3 (n=8/10) & 12 (n=5/6) 24 (3/6) respectively compared to baseline. Physical ability improved at mo1(n=6/11; p =0.05), 3 (n=4/9) 12 (4/6) & 24mo(3/6). Depression improved in 5/11& 4/6 patients at 1 mo & 2 yrs. Opiates were discontinued at 1 mo in 4/11 & 3/6 at 2 yrs. Baseline aggregrate RBF (mean± SD) 302 ± 99 increased to 335 ±113 ml/min at 3 mo; (p; NS). Mean SBP (-4mmHg) & DBP (-6mmHg) improved over 2 years. GFR increased from 76 ±37ml/min (baseline) to 96 ±51ml/min/SA (n=7) at 3 mo (p; NS)

One had initial improvemnt at 3 mo but later underwent bilateral nephrectomies for recurrent pain. Another was lost to follow up after mo1. After initial response to VSPL for pancreatic pain that individual had recurrence & underwent pancreatectomy.

Conclusions: VSPL seems to be an effective palliative procedure for intractable visceral pain in some patients with ADPKD & may have a role in the stepwise approach for chronic pain management strategies in selected individuals with relatively preserved renal function.

A Quantitative Proteomic Study of Urinary Exosome Candidate Biomarkers in a Genetically Defined *PKD1* Cohort Marie C. Hogan,[1] Kenneth L. Johnson,[2] Douglas W. Mahoney,[3] Ann L. Oberg,[3] Peter C. Harris,[1] Christopher James Ward.[1] *[1]Nephrology; [2]Proteomics Ctr; [3]Biostatistics, Mayo Clinic, MN.*

Background: We have identified distinct subpopulations of urine exosome-like vesicles (ELVs) reproducibly isolated by gradient centrifugation (5-30% sucrose D_2O). One of these, (PKD-ELVs) is enriched in polycystin-1 (PC1), polycystin-2 (PC2)& fibrocystin/ polyductin (FCP). Analysis may reveal diagnostic PKD biomarkers.

Methods: PKD-ELVs were isolated from ~270mls 1st/ 2nd AM voids [7 controls (28±3 yrs);9 PKD cases (28± 6 yrs)] & proteins fractionated by SDS-PAGE, tryptic peptides id'ed & quantified by label-free LC-MS/MS. Phase 1 examined biomarker variability. Inter-individual variability was corrected by Loess method. Multivariate ANOVA (disease, gender, & interactions) was used to compare proteins between cases & controls. 5% FDR & p< 0.002 were used.

Results: On average we observed ↓of 27% of PC1, ↓27% PC2 & ↓25% FCP compared to controls. Using a p<0.002 cutoff, we identified 21 differentially regulated proteins in the PKD cohort: 9 up & 12 are down-regulated. PC1 peptides were consistently underrepresented in cases. Two Ig heavy chain proteins & haptoglobin were upregulated. SAHH-2 (IRBIT) which is down-regulated, is reported to modulate CFTR & BCe1-B, intracellular Ca by antagonizing IP3 receptor. HOMER1 a known PC1 interactor is consistently upregulated with1c isoform most highly expressed.

Selected Differentially Regulated Proteins in PKD-ELV Proteome

Protein	Uniprot Name	Fold Δ	p-value
Polycystin 1	PKD1_HUMAN	-2.0	0.015
Polycystin 2	PKD2_HUMAN	-1.6	0.086
Fibrocystin	PKHD1_HUMAN	-2.0	0.016
IRBit	SAHH2_HUMAN	-2.1	0.01
Solute Carrier family 12-1	S12A1_HUMAN	-2.8	0.008
Homer 1	HOME1_HUMAN	+3.4	0.002
Ig gamma-1 chain C region	IGHG1_HUMAN	+4.8	0.007
Phospholipid Scramblase 1	PLS1_HUMAN	+2.0	0.012

Conclusions: PC1, PC2 and FCP are ↓ in cases compared with controls, although NS in Phase I of this study. Inflammatory proteins also feature. Homer1 a known PC1 interactor is one of the few proteins that is increased in PKD. We are developing a ratiometric assay using a PC1Mab(7e12) /Homer1cMab to validate these findings if confirmed in our Phase II study (ongoing).

TH-PO809

Modeling Vascular Lesions Associated with Autosomal Dominant Polycystic Kidney Disease Using Patient-Specifick iPSCs Kenji Osafune, Fumihiko Shiota. *Center for iPS Cell Research and Application (CiRA), Kyoto University.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most prevalent, potentially lethal, monogenic disorder, characterized by the development of multiple renal cysts and various extrarenal manifestations. Cardiovascular complications are the main cause of death in patients with ADPKD, including hypertension, intracranial aneurysms and dolichoectasias, thoracic aortic and cervicocephalic artery dissections, coronary artery aneurysms and valvular heart abnormalities. The pathogenesis of cardiovascular lesions as well as renal cyst formation remains largely unknown, and no therapeutic strategies have been established.

Methods: We generated induced pluripotent stem cells (iPSCs) from skin fibroblast samples from seven patients with ADPKD by trasducing four transcription factors, OCT4, SOX2, KLF4 and c-MYC or three factors, OCT4, SOX2 and KLF4. Then we differentiated the ADPKD-iPSCs into vascular endothelia and mural cells.

Results: We have obtained iPSCs from skin fibroblast samples from seven patients with ADPKD. These cells expanded robustly in culture and differentiated into vascular endothelia and mural cells in vitro. Using this differentiation system, we have identified several molecules whose expression levels were upregulated or downregulated in vascular cells differentiated from ADPKD-iPSCs as compared to those from normal Japanese iPSCs.

Conclusions: These results suggest that disease modeling using patient-specific iPSCs can be used for studying the mechanisms of vascular complications associated with ADPKD.

TH-PO810

Cysteamine Causes Angioendotheliomatosis by Stimulating Microvascular Endothelial Cell Proliferation Elena N. Levtchenko,[1] Mieke Dewerchin,[2] Martine T. Besouw.[1] *[1]Dept of Pediatric Nephrology/Laboratory for Pediatrics, KULeuven, Leuven, Belgium; [2]Vesalius Research Centre, KULeuven, Leuven, Belgium.*

Background: Cystinosis is an autosomal recessive disease caused by intralysosomal cystine accumulation. It initially causes renal Fanconi syndrome, progressing to end-stage renal disease by the age of 10 years if left untreated. At this moment, cysteamine is the only available treatment for cystinosis. Recently 8 patients were reported with muscular-skeletal weakness, skin striae and bruising-like lesions on elbows after administration of high doses of cysteamine. One patient died of cerebral ischemia. Skin biopsies of the elbow lesions showed vascular proliferation called angioendotheliomatosis. We aimed to study the mechanism of this severe complication.

Methods: Human dermal microvascular endothelial cells (HDMVEC, the cells involved in angioendotheliomatosis) were incubated with a range of cysteamine concentration (0-10 mM) during 6 or 24 hours in a 96-wells stadium. Cell viability was measured using WST-1, cell proliferation was measured by BrdU incorporation. Growth factors (VEGF: vascular endothelial growth factor, PlGF: placental growth factor, b-FGF: basic fibroblast growth factor, PDGF: platelet derived growth factor) were measured in supernatant medium after 6 and 24 hours of cysteamine exposure. All results represent mean of at least two independent experiments performed in triplicate. The paired student t-test was used for statistical analysis.

Results: HDMVEC viability increased by 135% ($p<0.01$) after 24 hours of cysteamine exposure (0-3.0 mM). Cell proliferation increased by 59% ($p<0.05$) and by 31% ($p<0.05$) after 6 and 24 hours of cysteamine exposure (0.03-1.0 mM) respectively. Cysteamine 0.03-0.3 mM stimulated VEGF production with 54-95% ($p<0.05$) while there was no differences in PlGF, b-FGF and PDGF concentrations.

Conclusions: Cysteamine can cause endothelial proliferation via stimulating VEGF production at concentrations described in patients' plasma (0.03-0.1 mM). We suggest that this mechanism underlies angioendotheliomatosis induced by cysteamine in cystinosis patients.

TH-PO811

Biomarkers of Endothelial Dysfunction and Vascular Inflammation in ADPKD Jelena Klawitter,[1] Jost Klawitter,[1] Kyler Corby,[2] Uwe Christians,[1] Robert W. Schrier,[2] Berenice Y. Gitomer,[2] Michel B. Chonchol.[2] *[1]Anesthesiology, University of Colorado, Aurora, CO; [2]Renal Diseases and Hypertension, University of Colorado, Aurora, CO.*

Background: Cardiovascular disease (CVD) is the leading cause of premature mortality in autosomal dominant polycystic kidney disease (ADPKD). Recent evidence has implicated systemic endothelial dysfunction and vascular inflammation in the pathogenesis of ADPKD even before the loss of renal function.

Methods: Serum and urine samples from 61 ADPKD patients were analyzed. Among these, patients 15 had a total kidney volume (TKV) of < 800mL, 28 a TKV 800-1500mL and 18 a TKV > 1500mL. Multiplexing tandem mass spectrometry assays were used for quantitation of eighteen different lipid signaling molecules (HODEs, HETEs, HEPEs, resolvins) as well as asymmetric (ADMA) and symmetric dimethylarginine (SDMA). All markers were correlated with TKV, glomerular filtration rate (GFR) and cardiac left ventricular (LV) mass.

Results: Patients with higher kidney volume had significantly increased concentrations of pro-inflammatory hydroxyoctadecadienoic acids (HODEs). 9-HODE and 13-HODE increased from 25.3±11.3 and 21.4±9.9 ng/mL in patients with <800mL TKV to 43.1±14.7 and 37.6±13.3 ng/mL ($p<0.001$, respectively) in patients with TKV <1500mL. Urinary ADMA concentration significantly decreased with the higher TKV ($r=-0.378$, $p<0.001$), and also correlated positively with GFR ($r=0.385$, $p<0.001$). a significant 22% increase of ADMA between the patients with TKV <800mL and TKV >1500mL was observed. Its structural isomer SDMA followed the same trend, even showing a more pronounced increase between the two patient groups (1.4±0.3 vs. 2.3±1.1, $p<0.005$).

Conclusions: Increased serum levels of 9-HODE and 13-HODE in ADPKD patients with higher TKV suggest an increase in lipid peroxidation and oxidative stress. With both compounds shown to be implicated in the pathogenesis of atherosclerosis, their monitoring in ADPKD patients could be beneficial to minimize the resulting CVD.A disturbance in the clearance of ADMA and SDMA clearly points towards the role of endothelial dysfunction in ADPKD patients, and makes them to potential strong predictors of cardiovascular events

Methylation Cycle Intermediates in Autosomal Dominant Polycystic Kidney Disease Jelena Klawitter,[1] Jost Klawitter,[1] Kyler Corby,[1] Uwe Christians,[1] Robert W. Schrier,[2] Michel B. Chonchol,[2] Berenice Y. Gitomer.[2] *[1]Anesthesiology, University of Colorado, Aurora, CO; [2]Renal Diseases and Hypertension, University of Colorado, Aurora, CO.*

Background: An elevation of plasma total homocysteine (Hcy) has been identified as an independent risk factor for vascular disease in patients with reduced kidney function. Cardiovascular disease is the leading cause of death in autosomal dominant polycystic kidney disease (ADPKD).

Methods: Serum and urine samples from 61 ADPKD patients were analyzed. Among these, patients 15 had a total kidney volume (TKV) of < 800mL, 28 a TKV 800-1500mL and 18 a TKV > 1500mL. Tandem mass spectrometry assays were used to measure urinary aldosterone, methionine, Hcy, cysteine, adenosine, S-adenosylhomocysteine (SAH) and S-adensylmethionine (SAM). Results were correlated with TKV, glomerular filtration rate (GFR) and left ventricular (LV) mass.

Results: ADPKD patients with TKV > 1500mL had a significantly increased serum concentrations of Hcy (14.9±4.5 vs. 11.4±3.2 μM, $p<0.05$) and SAH (1.7±0.3 vs. 2.0±0.5 μM, $p<0.05$) compared to those with TKV <800mL. In urine the trend was reversed with lower concentrations of homocysteine in the patients with higher TKV (572.0±259.2 nmol/mg creatinine in patients with TKV <800mL vs. 413.4±162.2 nmol/mg creatinine with TKV >1500mL). The reduced excretion of Hcy was accompanied by reduced excretion of the methionine methylation pathways's end product, cysteine. While SAM remained unchanged, the concentration of SAH increased from 1.7±0.3 μM in serum of patients with TKV <800mL to 1.96±0.5 μM in those with TKV <1500mL ($p<0.05$). As a result the SAM:SAH methylation potential ratio decreased. In urine, the excretion of SAH was also significantly increased (17.5±7.6 vs. 22.9±9.3 nmol/mg creatinine, $p<0.05$).

Conclusions: Increased serum Hcy levels in ADPKD associated with increased TKV represents a valuable biomarker in ADPKD which can potentially be used to monitor cardiovascular diseaserisk in these patients. Reduced urinary Hcy suggests a disturbance in the renal excretion, which may account for the accumulation in the blood. No such inhibition was observed for the Hcy precursors, SAM or SAH.

TH-PO813

Renal Phosphate Leak in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Anna Jeanette Jovanovich,[1] Berenice Y. Gitomer,[1] Myles S. Wolf,[2] Xiang-Dong Yan,[1] Robert W. Schrier,[1] Michel B. Chonchol.[1] *[1]Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]Nephrology, University of Miami Medical School, FL.*

Background: In a recent report of 100 ADPKD patients with chronic kidney disease (CKD) stages 1 - 2, serum phosphate levels were significantly lower compared to healthy volunteers and eGFR-matched CKD patients without ADPKD. We hypothesized that a renal phosphate leak is present in ADPKD compared to patients with CKD due to other etiologies and that these differences are detectable across the spectrum of kidney function.

Methods: Biochemical data on 697 ADPKD subjects were extracted from the University of Colorado ADPKD clinical database. Using a t-test we compared serum phosphate levels and 24-hour urinary phosphate excretion across the spectrum of eGFR to literature-reported levels from 3879 non-ADPKD participants in the Chronic Renal Insufficiency Cohort (CRIC) study.

Results: We examined serum phospahte and urinary phosphate excretion accross deciles of eGFR (eGFR 20-29, 30-39, 40 -49, 50 -59 and >60 ml/min/1.73m2). Serum phosphate levels were significantly lower accross the entire spectrum of renal function in the ADPKD participants compared to the eGFR matched CRIC participants. Urinary phosphate excretion levels were significantly higher in ADPKD participants with eGFR < 50 ml/min/1.73m2 (ADPKD vs CRIC) (eGFR 40-49, 800 vs 723 $p=0.0001$; eGFR 30-39, 745 vs 680 $p=0.0006$; eGFR 20-29, 726 vs 632, $p < 0.0001$) compared to eGFR-matched CRIC participants.

Conclusions: These data suggest that a renal phosphate leak occurs in ADPKD and is present across the spectrum of kidney function. Future studies are required to examine whether elevated levels of fibroblast growth factor 23 in ADPKD account for these findings.

Funding: NIDDK Support, Private Foundation Support

TH-PO814

Fractional Excretion of Phosphate Is Independently Associated with Renal Volume and Left Ventricular Mass Index in Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD) Berenice Y. Gitomer,[1] Kim McFann,[1] Myles S. Wolf,[2] Robert W. Schrier,[1] Michel B. Chonchol.[1] *[1]Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]Nephrology, University of Miami Medical School, FL.*

Background: Small increases in serum phosphate within the normal range are associated with greater risk of all-cause mortality, cardiovascular events and kidney disease progression in patients with and without chronic kidney disease (CKD). While the precision for laboratory measurement of serum phosphorus is excellent (CVs < 3%), there is considerable diurnal variability in serum phosphate. This limitation may be overcome by concurrent measurements of serum phosphate and urinary phosphate excretion, to improve insight into phosphorus homeostasis in individual subjects. We hypothesized that higher urinary fractional excretion of phosphate (FEPO4) in patients with ADPKD would be associated with larger renal volume, a validated biomarker of more rapid progression of ADPKD, and increased left ventricular mass index (LVMI), a validated index of cardiovascular disease.

Methods: We measured FEPO4 in 683 adults with ADPKD who had available data on total kidney volume (TKV) measured by ultrasound. LVMI, measured by 2D-echocardiography, was available in 232 of these patients. Linear regression was used to assess the relationship between log transformed FEPO4 with log transformed TKV and LVMI.

Results: The mean (SD) age of the participants was 41(13) years and 61% were female. The mean (SD) estimated GFR, FEPO4, TKV and LVMI were 73 ± 36 ml/min, 26 ± 15%, 1630 ± 1284 ml^3, and 113 ± 37 g/m^2, respectively. Linear regression of lnTKV on lnFEPO4, adjusted for age, height, sex and hypertension, demonstrated a highly significant relationship ($\beta = 0.66 \pm 0.05$, $R^2 = 0.28$, $p < 0.0001$). In addition, FEPO4 was significantly related to lnLVMI ($\beta = 0.11 \pm 0.04$, $R^2 = 0.04$, $p = 0.0021$).

Conclusions: Abnormalities of phosphate homeostasis in ADPKD are associated with increased risk of progression of renal and cardiovascular disease. Future studies are necessary to whether disordered phosphate mechanism is a contributing cause or consequence of progression of renal and cardiac disease in ADPKD.

Funding: NIDDK Support, Private Foundation Support

TH-PO815

Achievement and Maintenance of Blood Pressure Targets in HALT:PKD Vicente E. Torres,[1] Robert W. Schrier,[2] Arlene B. Chapman,[3] Ronald D. Perrone,[4] Dana C. Miskulin,[4] Theodore I. Steinman,[5] Franz Winklhofer,[6] William E. Braun,[7] Marie C. Hogan,[1] Frederic F. Rahbari-Oskoui,[3] Kaleab Z. Abebe,[8] James E. Bost,[8] Michael F. Flessner.[9] *[1]Mayo, Rochester, MN; [2]U CO, Denver, CO; [3]Emory U, Atlanta, GA; [4]Tufts U, Boston, MA; [5]Beth Israel, Boston, MA; [6]UKMC, Kansas City, KS; [7]Cleveland Clinic, Cleveland, OH; [8]U Pittsburgh, Pittsburgh, PA; [9]NIH/NIDDK HALT Study Grp.*

Background: HALT-PKD seeks to determine whether ACEI/ARB is superior to ACEI alone and low BP (<110/75) is superior to standard BP (120-130/70-80) in delaying cystic progression (CKD stage 1 or 2, Study A) and whether ACEI/ARB is superior to ACEI alone (BP target 110-130/70-80 mmHg) in slowing eGFR decline (CKD stage 3, Study B).

Methods: Stepwise dosing of lisinopril (LIS and telmisartan/placebo (P/T) (steps 1-4) followed by stepwise dosing of other agents (steps 5-10) is used to achieve BP targets. During 1/2006-5/2011, 516, 497, 464, 293, 141 A and 458, 446, 430, 253, 111 B patients completed 4, 12, 24, 36, 48-mth follow-up. BP control is assessed by home BP measurements.

Results:

	Mths	Study A Std	Study A Low*	Study B
Mean BP (mmHg)†	4	91.5±5.8	85.0±6.5	91.0±6.9
	12	91.7±6.3	83.7±6.7	91.5±5.8
	24	92.0±6.3	82.9±6.5	91.7±6.3
	36	92.2±6.3	82.2±6.1	91.5±6.2
	48	93.5±6.5	80.7±5.5	91.4±5.3
Step; LIS and P/T dose(mg)†	4	2.2, 15.0, 50.7	3.4, 24.0, 64.3	2.9, 18.2, 55.9
	12	2.2, 15.8, 50.9	3.7, 25.0, 66.2,	3.0, 18.7, 56.3
	24	2.3, 15.1, 51.0	3.9, 26.0, 65.8	3.2, 18.0, 56.1
	36	2.5, 16.1, 52.6	3.9, 26.0, 66.4	3.1, 17.5, 55.6
	48	2.4, 14.0, 51.3	4.2, 27.1, 68.3	3.0, 16.6, 53.8

† mean±SD. *Underlined: P<0.0001 compared to Study A standard.

Based on random regressions, significantly negative BP slopes in Study A low and significantly positive BP slopes in Study A standard result in increasing BP separation over time. Results are similar when only participants with complete data at each timepoint are included.

Conclusions: ACEI alone or ACEI/ARB achieve BP control and MAPs are within target in most subjects at 4-48 months of follow-up. Excellent and increasing separation in BP and doses of LIS and T/P between study A arms is achieved, without detectable differences in heart rate.

Funding: NIDDK Support

TH-PO816

Serum Uric Acid and Renal Disease Progression in Autosomal Dominant Polycystic Kidney Disease Imed Helal, Berenice Y. Gitomer, Kim McFann, Xiang-Dong Yan, Godela M. Brosnahan, Robert W. Schrier. *Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO.*

Background: Higher serum uric acid (SUA) levels are associated with an increased risk for cardiovascular disease. Increased SUA levels are also associated with hypertension, a strong risk factor for ADPKD progression. We examined the hypothesis that SUA levels correlate with progression of ADPKD.

Methods: This retrospective study included 716 ADPKD adults from the University of Colorado ADPKD registry. SUA was examined as gender specific quartiles - quartiles1 - 4 in women: <4.2, 4.3 - 5.1, 5.2-6.5 and >6.5 mg/dL; quartiles 1 - 4 in men :< 5.7, 5.71 - 6.8, 6.9 - 8.2 and >8.2 mg/dL. The study evaluated the association of baseline uric acid levels with ADPKD progression and age at end-stage renal disease (ESRD).

Results: In linear regression, SUA was significantly related to LnTKV (total kidney volume) ($\beta = 0.15 \pm 0.08$, $p < 0.0001$) and Ln TKV/BSA ($\beta = 0.13 \pm 0.01$, $p < 0.0001$). SUA was also significantly related to BMI (body mass index) ($\beta = 0.78 \pm 0.10$, $p < 0.0001$). Those who had SUA in the 3rd and 4th quartile were significantly older, had higher BMI, higher serum creatinine (adjusted for age and sex), lower creatinine clearances (adjusted for age and sex), higher TKV (adjusted for age and sex), higher TKV/BSA, and higher urinary protein than those in the 1st quartile and 2nd quartile. In a sub-group analysis, the 4th quartile had higher microalbumin excretion than those in the 1st quartile. History of hypertension was more prevalent among those ADPKD patients in the 3rd and 4th quartiles of SUA. 503 ADPKD patients had data available on age at ESRD or last known age without ESRD. There was a difference in survival curves among the 4 quartiles of SUA ($p < 0.0001$). Median survival to ESRD was 68 (58-81) years for the 1st Quartile, 70 (64- No Upper) for the 2nd Quartile, 61 (56-65) years for the 3rd Quartile, and 57 (54-60) years for the 4th Quartile. Survival time was shortest for those in the 4th Quartile.

Conclusions: Thus, SUA correlates with age, BMI, impaired kidney function, hypertension, proteinuria, kidney volume and ESRD in ADPKD patients.

The Effect of Everolimus Dose and Schedule on Renal Angiomyolipoma in Patients with Tuberous Sclerosis Complex John J. Bissler,[1] Elizabeth Jo Coombs,[1] Bradley P. Dixon,[1] David N. Franz.[2] *[1]Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Neurology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Inhibition of the mTORC1 pathway in patients with tuberous sclerosis complex leads to a reduction of renal angiomyolipoma volume. The optimal dose and frequency of mTORC1 inhibitor for these patients is unknown. Determining the proper dosing is critical for patient care in order to maximize the angiomyolipoma treatment effect while minimizing patient toxicity. To begin to understand how to treat patients, we undertook a phase two non-randomized open label trial. Thirty patients with tuberous sclerosis or sporadic lymphangioleiomyomatosis and renal angiomyolipoma(s) were evaluated. Renal angiomyolipoma volume was used as the primary endpoint, while safety was included among the secondary outcomes.

Methods: Patients received everolimus (RAD001) for one year, and were observed off drug for an additional year. We examined two different daily doses (5 or 10 mg) and three different weekly dose (30, 50, or 70 mg) regimens. Each treatment group contained a minimum of five patients.

Results: A total of 36 patients enrolled and a total of 30 completed the two-year study. The median age was 32 and there were 10 male and 26 female patients. The average reduction of the angiomyolipoma volume was approximately fifty percent at twelve months. Although once off drug, lesions demonstrated a range of responses from maintaining their reduction in volume to increasing back toward baseline size for both daily and weekly dosing. Grade three adverse events thought to be possibly, probably or definitely related to drug were infrequent, only three in the daily dosing and only one in the weekly dosing cohort.

Conclusions: Both weekly and daily dosing resulted in approximately a fifty percent reduction in angiomyolipoma volume. These results raise the possibility that lower doses, and different dosing schedules may be an option for patients not tolerating higher daily dosing.

Efficacy and Safety of mTOR Inhibitor for Early-Stage Autosomal Dominant Polycystic Kidney Disease Patients: A Meta-Analysis of Randomized Controlled Trials Qiang He, Chiayu Lin, Shunxian Ji, Jianghua Chen. *Kidney Disease Center, First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China.*

Background: The objective of this study is to conduct a meta-analysis of the randomized controlled trials (RCT) to make a profound review and an objective appraisal of the effectiveness and safety of the mammalian target of rapamycin (mTOR) inhibitor therapy in autosomal dominant polycystic kidney disease (ADPKD) patients.

Methods: RCTs regarding the mTOR inhibitor therapy in ADPKD patients are included. The data of studies and major outcomes include the changes of patients' Glomerular Filtration Rate (GFR), urinary protein, total kidney volume (TKV), cyst volume (CV), parenchymal volume (PV), blood pressure, lipid profile and the frequency of adverse events.

Results: Up to January 31st, 2011, 4 RCTs (568 patients) are included in this study. The meta-analysis made in this study indicates that mTOR inhibitor therapy group had smaller TKV than the control group, WMD of TKV after treatment is -302.08 (P=0.04), and also less increasing of TKV (WMD=-70.25, P<0.00001), CV (WMD =-35.91, P<0.00001) and PV (WMD =-34.84, P<0.00001). Also mTOR inhibitor treatment doesn't necessarily slow down the aggravation of renal function. Side effects like hyperlipidemia, myelosuppression, abnormal liver function, diarrhea, rash, aphthous stomatitis could occur during the mTOR inhibitor therapy, but the severities can be controlled by the appropriate use of drug.

Conclusions: Based on the current very limited clinical trials, mTOR inhibitor is a relatively safe drug to slow down the kidney volume growth in ADPKD patients, especially in the parenchymal tissues, but have limited impact on slowing down the decrease of renal function.

TH-PO819

Early Progression Markers in Autosomal Dominant Polycystic Kidney Disease. A Longitudinal Study in Patients with Normal GFR Pablo J. Azurmendi,[1] Adriana R. Fraga,[1] Marta G. Valdez,[3] Elvira Arrizurieta,[1] Rodolfo S. Martin.[1,2] *[1]Experimental Nephrology, Inst. de Invest. Méd. Alfredo Lanari, UBA., Buenos Aires, Argentina; [2]Hospital Universitario, Universidad Austral, Pilar, Buenos Aires, Argentina; [3]Metabolism, Inst. de Invest. Méd. Alfredo Lanari, UBA., Buenos Aires, Argentina.*

Background: It is well known that total renal volume (TRV) is a predictor of ADPKD progression. However, parameters other than TRV are also currently explored in early stages of the disease, when glomerular filtration rate (GFR) is still preserved. We have previously reported that both urinary monocyte chemoattractant protein-1 (MCP-1) and albuminuria, assessed as urinary albumin/creatinine (UACR), are candidates for early markers of progression. High UACR (>6.8 mg/gCr) was associated with both high levels of urine MCP-1 and carotid-intima media thickness as well, as compared with normal UACR (≤6.8).

To investigate whether there is an interaction among TRV, GFR and MCP-1 and a role for UACR as a predictor of disease severity, we performed a longitudinal study of 30±1 months in 32 young ADPKD patients (26±1 years old).

Methods: TRV was measured by ultrasound, urine MCP-1 by ELISA and GFR estimated by MDRD.

Results: TRV, GFR and urine MCP-1 baseline values were 415 ± 52.8 ml, 108 ± 3 ml/min/1.73m^2 and 152 ± 32 ng/gCr, respectively.

An association among the annual change in TRV, GFR and urine MCP-1 was found, independently of their basal values, UACR, age, sex or antihypertensive treatment. The annual change in TRV and urine MCP-1 was increased in high UACR (131 ± 33 ml and 108 ± 49%), as compared with normal UACR patients (48 ± 41 ml and - 5 ± 16 %, p<0.05, respectively). The GFR annual change was not different according to UACR and remained stable in patients treated with angiotensin converting enzyme inhibitors as compared with untreated normotensive subjects (3 ± 5 and -5 ± 2 ml/min/year, p<0.01).

Conclusions: Being MCP-1 and TRV markers of renal inflammatory and cystic component respectively, our results suggest an involvement of both processes in ADPKD progression, even when GFR is within normal limits. Besides this, slight increased rates of albuminuria could be also a predictor of worst prognosis.

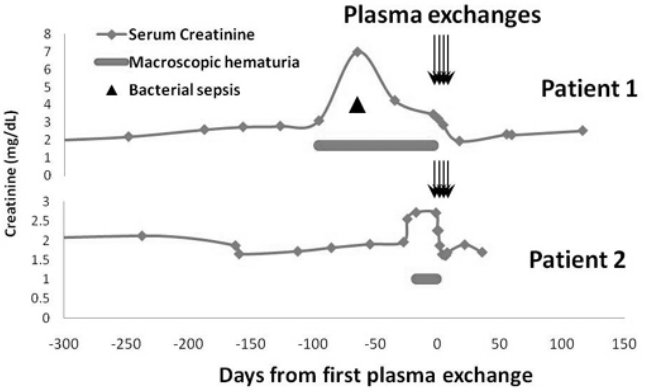
Treatment of Complement Factor H-Related Protein 5 (CFHR5) Nephropathy with Plasma Exchange Daniel P. Gale,[1] Yiannis Athanasiou,[2] Michalis Zavros,[2] Constantinos Deltas,[3] Alkis Mikis Pierides,[2] H. Terence Cook,[1] Patrick Maxwell.[4] *[1]Imperial College Kidney and Transplant Institute, Imperial College, London, United Kingdom; [2]Nephrology Department, Nicosia General Hospital, Nicosia, Cyprus; [3]Biological Sciences Department, University of Cyprus, Nicosia, Cyprus; [4]Division of Medicine, University College, London, United Kingdom.*

Background: CFHR5 nephropathy is a recently recognised autosomal dominant disease which is endemic in Cyprus (1). It is characterised by macroscopic hematuria with stepwise deteriorations in renal function during intercurrent infections and is associated with a heterozygous internal duplication mutation of the CFHR5 gene which results in the production of a larger protein that is detectable in the blood (1). Kidney biopsies show C3 glomerulonephritis, implying that complement alternative pathway dysregulation underlies the disease. Over 80% men (but <20% women) develop renal failure by age 50 (2). Disease can recur following renal transplantation, proving that it results from a defect of a circulating factor (3). This implies that correction of circulating complement regulation during acute flares might be effective.

Methods: 2 patients with CFHR5 nephropathy were treated with 4-7x3 liter plasma exchanges against fresh frozen donor plasma during episodes of macroscopic hematuria with persistently elevated serum creatinine above baseline.

Results: In both patients there was immediate cessation of macroscopic hematuria and rapid return of serum creatinine to the pre-flare baseline.



Conclusions: While further clinical studies are needed to determine if plasma exchange can alter the long term natural history of CFHR5 nephropathy, these cases provide initial evidence that manipulation of circulating complement regulators might be effective in this disease.

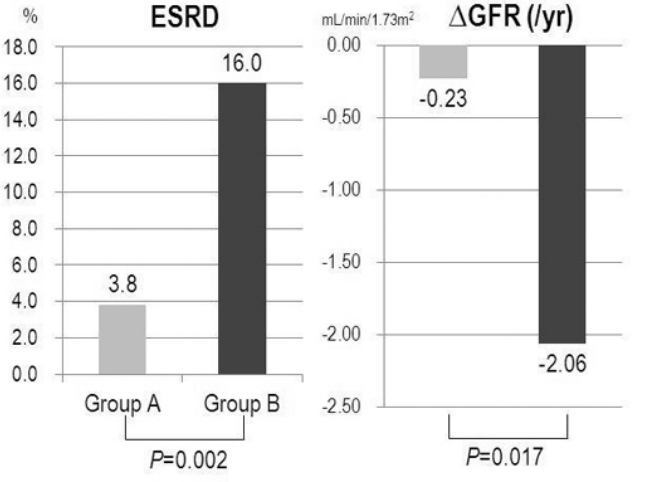
TH-PO821

Chronic Asymptomatic Pyuria Precede Overt Urinary Tract Infection and Renal Function Deterioration in ADPKD Jin Ho Hwang,[1] Young-Hwan Hwang,[2] Hayne C. Park,[1] Yu-Kyoung Yun,[1] Dong Ki Kim,[1] Kook-Hwan Oh,[1] Kwon Wook Joo,[1] Yon Su Kim,[1] Jin Suk Han,[1] Curie Ahn.[1] *[1]Internal Medicine, Seoul National University Hospital, Seoul, Korea; [2]Internal Medicine, Eulji University School of Medicine, Seoul, Korea.*

Background: Urinary tract infection(UTI) is estimated to occur in 30%-50% of individuals with autosomal dominant polycystic kidney disease(ADPKD). However, the clinical manifestation and significance of asymptomatic pyuria(AP) in ADPKD are unknown.

Methods: We reviewed medical records of ADPKD patients who were registered to the ADPKD registry of Seoul National University Hospital from Aug 1999 to Aug 2010. We defined the AP as more than 5-9/HPF of urinary WBCs with no related symptom of overt UTI. AP was categorized into 4 groups depending on its duration and frequency: non-pyuria, transient, recurrent, and persistent pyuria. The former two group were combined into group A, and the latter two groups were combined into group B(chronic pyuria(CP) group). The prevalence of overt UTI and association with renal function decline were examined between these groups.

Results: With a mean follow-up of 66.2 months, 178(70.0%) out of 258 patients showed 688 episodes of AP and 55 episodes of UTI(6.6%). AP showed the incidence of 0.483 episodes/patient/year. Patients in group B showed female predominance, were more hypertensive(93.0% vs. 81.0%, *P*=0.01), and developed more ESRD(16.0% vs. 3.8%, *P*=0.002) compared to group A. Upper UTI occurred more frequently in group B patients(HR 4.5, 95% CI 1.69-12.02; *P*=0.003, when adjusted for gender and hypertension). The rate of decline in GFR(ΔGFR/yr) was significantly faster(-2.06 vs -0.23, *P*=0.017) in group B than group A.



Age and the CP were the independent factors associated with ΔGFR/yr.

Conclusions: CP may increase the risk of developing overt UTI and may be a contributing factor to renal function decline in ADPKD patients.

TH-PO822

Urinary N-Acetyl-β-D-Glucosaminidase as a Surrogate Marker for Renal Function in Autosomal Dominant Polycystic Kidney Disease Hayne C. Park,[1] Jin Ho Hwang,[1] Yu-Kyoung Yun,[2] Myeong-Ok Yoon,[3] Ah-Young Kang,[3] Jaeseok Yang,[1] Kook-Hwan Oh,[1] Jung-Woo Noh,[4] Young-Hwan Hwang,[5] Curie Ahn.[1] *[1]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea; [2]Clinical Trials Center, Seoul National University Hospital, Seoul, Korea; [3]Transplantation Research Institute, Seoul National University Hospital, Seoul, Korea; [4]Department of Internal Medicine, Hallym University College of Medicine, Seoul, Korea; [5]Department of Internal Medicine, Eulji University College of Medicine, Seoul, Korea.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by progressive renal cyst growth leading to end-stage renal disease. Because both serum creatinine (Cr) and total kidney volume (TKV) measurements are considered of limited use to monitor disease progression, we investigated urinary N-acetyl-β-glucosaminidase (NAG) as a useful surrogate marker in this prospective study.

Methods: From Apr 2010 to May 2011, a total of 163 patients were enrolled from SNUH ADPKD registry and 139 patients were followed up for 6months. GFR was estimated using MDRD equation and TKV was measured by modified ellipsoid method. We measured urinary NAG, β2-microglobulin, and neutrophil gelatinase-associated lipocalin (NGAL) and compared their predictive values for renal function.

Results: The mean age of subjects was 47 years. The baseline eGFR and TKV were 69.6 ± 20.0 mL/min/1.73m^2 and 1351.4 ± 977.2 mL, respectively. Log NAG/Cr was negatively correlated with both eGFR (r^2=0.169, p≤0.001) and TKV (r^2=0.043, p=0.01) at baseline. By using ROC curve analysis, AUC of NAG/Cr for decreased eGFR (<60mL/min/1.73m^2) (0.77, 95% CI [0.72-0.81]) was higher than those of NGAL (0.61, 95% CI [0.55-0.66]) and β2-microglobulin/Cr (0.71, 95% CI [0.66-0.76])(p<0.01 and p=0.012, respectively). Log NAG/Cr was also well correlated with the change in eGFR (r^2=0.051, p=0.005). The persistently high NAG/Cr (>4.3 IU/g) group showed renal function decline whereas the persistently low group revealed increased eGFR over 6months (-0.25 ± 17.6 vs. 9.4 ± 16.8 ml/min/1.73m^2 per year, p=0.005).

Conclusions: Urinary NAG may be a good and reliable biomarker to predict renal progression in ADPKD patients.

TH-PO823

Progression of Chronic Kidney Disease in Patients with Autosomal Dominant Polycystic Kidney Disease Nayara Panizo, Marian Goicoechea, Soledad Garcia de Vinuesa, David Arroyo, Claudia Yuste, Abraham Rincón, Caridad Ruiz Caro, Ursula Verdalles, Borja Quiroga, Jose Luno. *Nephrology, Hospital General Universitario Gregorio Marañón, Madrid, Spain.*

Background: The aim of this study was to analyze the factors influencing chronic kidney disease (CKD) progression in patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD).

Methods: We studied 101 patients (mean age 43 ±17.3, 43.56 % male) followed during a mean follow-up time of 77.9 ± 48 months from 1997 to 2010. The primary end point was : time to a 50% decrease of estimated glomerular filtration rate (eGFR) (CKD-EPI) since the first-time visit and/or time to initiation of renal replacement therapy, annual mean change of eGFR was also analysed . Clinical and demographic data, blood pressure, concomitant medications and analytical parameters were collected at each visit.

Kidney size by ultrasound was also recorded at baseline.

Results: Thirty-one patients achieved the primary end point after a mean time of 84.8 ± 39.1 months. Those patients who achieved the primary end point had higher SBP and DBP (p=0.017 and p=0.001), higher LDL-cholesterol (p=0.011), higher creatinine (p=0.006), higher uricemia (p=0.041), more severe proteinuria (p=0.033) and greater kidney size (p=0.05). The mean annual eGFR change was of – 3.52 ± 7.3 ml/min/1.73 m^2. Forty nine patients had a rapid decline renal function: Group A (higher than -3.52 ml/min/1.73 m^2) and 52 patients had a lower renal disease progression: Group B (< -3.2 ml/min/1.73 m^2). Adjusted Cox regression analysis showed that higher SBP and younger age at the first visit were independent variables for poorer renal outcome (p= 0.026).

Conclusions: Initial kidney function, proteinuria, renal size, hypercholesterolemia, hiperuricemia and SBP are the factors that influencing CKD progression in ADPKD. SBP and younger age are the only factors that maintain their independent predictive value in multivariant analysis.

TH-PO824

Progressive Nephromegaly Emerges during Adolescence in Children with ADPKD John F.S. Crocker, Philip D. Acott. *Nephrology, IWK Health Centre, Halifax, NS, Canada.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) has a major impact on the cost of health care. We previously described a clinical phenotype of children with ADPKD including variations of intracranial lesions (MRI angiography) in the subgroup with headaches, stone formation risk factors (i.e. glycinuria), hypertension, proteinuria, and dyslipidemia. This study evaluates serial renal imaging of ADPKD children followed from referral through adolescence.

Methods: We have been referred >300 children over a twenty year period with a family history of ADPKD. Parental and family concerns trigger the referral, especially if a family member with ADPKD had RRT or progressive renal failure.

Results: Sixty-four children of this cohort had radiographic cystic features with ultrasound consistent with ADPKD. Serial ultrasound assessments identified a group of 15 children with evolving significant nephromegaly (kidney size > 95th percentile expected for age, gender, weight and height) during adolescent development. In this sub-group during puberty, six had unilateral (left = 4; right =2) nephromegaly (female = 3; male = 3) and nine patients had symmetrical rapid renal growth (female = 6; male = 3). Many of these children had serial follow up for > 10 years. All children with nephromegaly, whether hypertensive or not, were placed on an ACE inhibitor (ACEi), as we suspect the emergence of nephromegaly during adolescence may influence their risk of renal decline during adulthood. Three of these treated children had reversal of renal size to normal limits. The sub optimal response to ACEi may reflect ACEi dosing, adolescent drug adherence, or ineffective ACEi effect once nephromegaly is present in the ADPKD adolescent population. Many of the children who entered the special program are now young adults and have stable cystic disease.

Conclusions: ADPKD is a disease which may be diagnosed clinically by cyst formation in young children, 15% of which have rapid renal growth and nephromegaly during puberty. It is possible this is a key marker of the cohort at risk of renal decline as adults. Further follow up and evaluation of the adolescent phenotype of ADPKD may sort out which group might benefit from early medical intervention.

TH-PO825

Renal Functional Involvement in Bardet-Biedl Syndrome – Largest Ever National Survey from England and Wales David Goldsmith, Mark Jenkins, Shehla Mohammed, Barbara McGowan. *Renal and Genetics Departments, Guy's and St Thomas' Hospitals, London, United Kingdom.*

Background: Bardet–Biedl syndrome (BBS) is a rare ciliopathic autosomal recessive disorder that affects many body systems. BBS has a prevalence of 1 in 140,000 to 1 in 160,000 newborns It is a pleiotropic disorder with variable expressivity and a wide clinical variability observed within and between families. Renal dysfunction is a major cause of morbidity and mortality. In 2009 the National Commissioning Group for Chronic Conditions set up a national clinical service to provide holistic, organized care for these patients.

Methods: This national service started in 2010, and has two adult centres – in London and Birmingham. There are very few systematic reports of kidney involvement in BBS, so we have compiled data from these centres for all patients seen in 2010-2011 to produce the largest single reported series with special reference to renal functional involvement and urinalysis findings.

Results: 111 subjects (63 men, 48 women) with a mean age of 33 years (range 15 to 56 years) attended the clinics. Three patient were on regular hemodialysis, one on peritoneal dialysis, and five others had functioning renal transplants. Blood samples for renal function were obtained from 98 patients. Plasma creatinine values were 44 to 803 umol/L, and using the 4 variable MDRD formula the eGFR range was 11 to > 90 mls/min. The mean GFR was 83 mls/min with 44 subjects having an MDRD eGFR > 90 mls/min. Significant proteinuria (urinary spot ACR/PCR) was evident in 19.4% of subjects, but only 7 subjects had a PCR > 10 (maximum recorded protein loss was 82 mg/mmoL). Microscopic haematuria was seen in < 10% of subjects. Mean BP was 140/83 mm Hg; 38% of patients had a SBP > 140 mm Hg and 26% had a DBP > 90 mm Hg. Obesity was common with the mean BMI for these subjects was 37 kg/m2.

Conclusions: This is the largest reported series featuring kidney involvement in BBS. About half of the subjects had evidence of kidney disease (within the limitations of single measurements of blood and urine) – around 20% of the patients had significant reduction of GFR, had a transplant, or were on dialysis. Neither heavy proteinuria nor haematuria was a feature of BBS.

TH-PO826

What's Lurking in Autosomal Dominant Polycystic Kidneys below Detection by Current Magnetic Resonance Imaging (MR)? Sumanth Mulamalla,[1] Larry Cook,[2] Connor J. Grantham,[1] Jared J. Grantham.[1] *[1]Kidney Institute, Kansas Univ Medical Center, Kansas City, KS; [2]Radiology, Kansas Univ Medical Center, Kansas City, KS.*

Background: Cyst formation and growth are targets in the development of new drugs for the treatment of ADPKD. The CRISP MR study established that sustained cyst growth accounted for the impressive increase in kidney size and suggested that new cysts appeared in adults. A recent analysis of individual cyst growth rates suggested that exponential cyst growth beginning in the fetus could be the deciding factor leading to renal enlargement and declining GFR.MR scans can detect cysts >2mm in outer diameter (OD) so the appearance of new cysts in sequential exams could be due to small cysts growing above the detection limit rather than due to the formation of new cysts in normal-sized renal tubules.

Methods: To determine the number of cysts below the MR detection limit in ADPKD we measured the mean diameter (um) of cysts in random histologic sections of nephrectomy specimens from 6 adult patients with early (CKD <3; n=4 cases, 278 cysts) and more advanced pre-dialysis stages (CKD >3; n=2 cases, 134 cysts). A cyst had to exhibit an epithelial lining with an OD >200 um to avoid mis-labeling dilated tubules and empty glomerular capsules.

Results: In early stage,cyst OD was <2000 um in 91.4 % and would have gone undetected by MR;OD was <1000 um in 76.2 %. In later stage 87.3 % had OD <2000 um; in 64.9 % OD was <1000 um, similar to the early stage. So when did the invisible cysts develop? Assuming (early stage mean age 37y) that most cysts derived from collecting ducts as large as 100 um OD and grew at 17 %/y (CJASN 5:889,2010), cysts formed a few weeks after birth could have achieved diameters of 200, 400, 800 and 1000 um in 12, 25, 37 and 41 y, respectively; and 12 more y to reach MR detection limit of 2000 um.

Conclusions: 1. More renal cysts develop in ADPKD than meet the eye by conventional imaging; 2. After a period of extraordinary fetal cyst formation and growth, new cysts appear to form in renal tubules for several years thereafter; 3. Drugs targeting post-partum cyst formation may be beneficial if administered early in the course of the disease.

TH-PO827

Magnetic Resonance Imaging (MRI) to Non-Invasively Measure ARPKD Kidney Disease Progression Lan Lu, Christopher A. Flask, Bernadette O. Erokwu, Katherine M. Dell. *Depts of Radiology, Biomedical Engineering, Pediatrics and the CWRU Center for the Study of Kidney Disease and Biology, Case Western Reserve University, Cleveland, OH.*

Background: Autosomal Recessive Polycystic Kidney Disease (ARPKD) results in kidney failure in 40-50% of children. While some therapies have shown promise in animal models, the lack of methods to monitor kidney disease progression in ARPKD patients has limited the development of therapeutic trials. Newer quantitative Diffusion Tensor Imaging Magnetic Resonance Imaging (DTI-MRI) techniques have the potential to provide non-invasive assessments of kidney disease progression, but have not been studied in ARPKD. The objective of this study was to develop DTI-MRI methodologies to measure kidney disease progression in the PCK rat model of ARPKD.

Methods: Kidneys from 4 PCK rats were imaged serially at 2,4 & 6 mos of age using DTI-MRI. Apparent Diffusion Coefficient (ADC) maps were generated, then thresholded to differentiate cystic (higher ADC) from normal tissue. Total cystic area was defined as the cyst pixel number/total kidney pixels. Animals were sacrificed after the last imaging session at 6 mos and histologic scoring for cystic area (%cystic/total parenchyma) of hematoxylin stained paraffin-embedded sections was determined.

Results: Mean cystic area (%) increased at each time point studied (2 mos = 17±11; 4 mos= 36±9; 6 mos= 48±7). Average increase in cystic area over the 4 month study period was 8% per month (range =4-11%), with higher values seen in the 2-4 vs. 4-6 months intervals (10% vs. 6%). There was a strong correlation (r=0.67) between imaged cystic area and cystic area as assessed by histologic scoring at 6 months.

Conclusions: DTI-MRI provided non-invasive, quantitative measures of kidney disease severity in PCK rats at different time points in the disease. Increased cystic area was found at each successive time point, including the 4 to 6 mo interval, for which we have previously shown histologic progression without significant change in clinical parameters (e.g. kidney weight/body weight or serum creatinine). Further studies are necessary to determine if these methods can be used to monitor kidney disease progression in ARPKD patients.

TH-PO828

Cyst Infection in ADPKD: A Critical Analysis of PET-CT Bruno E. Balbo,[1] Marcelo T. Sapienza,[2] Luiz F. Onuchic.[1] *[1]Nephrology, Univ. of Sao Paulo, São Paulo, Brazil; [2]Radiology, Univ. of Sao Paulo, São Paulo, Brazil.*

Background: Cyst infection (CI) remains a complex issue in ADPKD. Positron emission tomography (PET) has emerged as a promising tool for diagnosis.

Methods: A retrospective study was conducted in an ADPKD referral center, including 12 CI episodes in 9 patients (pts) during 12 months. The diagnosis was definite (microbiological) in 4 episodes and likely in 8 (fever, abdominal pain, C-reactive protein >50mg/L, absence of intracystic bleed and exclusion of other causes).

Results: Liver CI (LCI) occurred in 8 episodes (6 pts) and kidney CI (KCI) in 4 (4 pts). Pts with KCI were non-significantly younger and had a trend to lower creatinine clearance compared to LCI pts (21.5 vs 42.0 mL/min/1.73m^2). Four KCI and 2 LCI were associated with positive blood cultures and sepsis, whereas urine culture was positive in 1 KCI. Ciprofloxacin was the first-line antibiotic (ATB) in 8 episodes and association with a third-generation cephalosporin was used in severe presentations (9/12). Initial evaluation included 12 CTs and 1 MRI, suggestive of infection in only 4 cases (3 CTs and 1 MRI). PET-CT was performed in 9 episodes and PET Scan in 2. Total kidney volume (TKV) was non-significantly higher in pts with KCI than LCI while LCI pts showed a trend to higher total liver volume (TLV) than KCI individuals (5516 vs 2043 mL, P=0,063). Seven PET-CT and 2 PET Scan analyses were consistent with CI. Seven cases were submitted to invasive procedures and in 1 a follow-up PET-CT supported a prolonged ATB course. Two deaths occurred in pts with negative PET-CT in whom LCI was diagnosed by autopsy: a kidney Tx and immunosuppressed pt and a cirrhotic and hemodialytic pt. In both cases PET-CT was carried out on the third week of ATB while in the majority of the other cases it was performed within the first two weeks.

Conclusions: In our casuistic LCI included pts in earlier stages of CKD and outnumbered KCI. Our data suggest that increases in TLV and TKV may raise the risk of LCI and KCI, while the observed high reinfection rate supports that anatomical factors may play a role in CI. PET-CT, in turn, was associated with a high CI diagnostic sensitivity which apparently drops over time after initiation of ATB treatment.

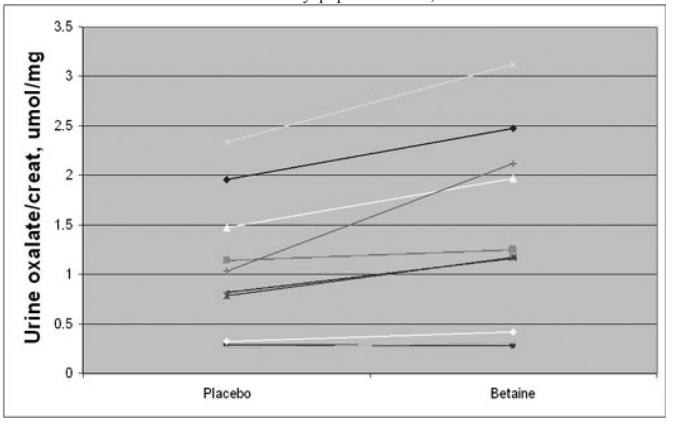
TH-PO829

Effect of Betaine on Urine Oxalate in Primary Hyperoxaluria, Type I Carla G. Monico,[1] Julie B. Olson,[1] Eric J. Bergstralh,[2] Raymond L. Heilman,[3] Dawn S. Milliner.[1] *[1]Division of Nephrology, Mayo Clinic, Rochester, MN; [2]Department of Health Sciences Research, Mayo Clinic, Rochester, MN; [3]Division of Nephrology, Mayo Clinic, Phoenix, AZ.*

Background: In primary hyperoxaluria, type I (PHI) deficiency of hepatic AGT enzyme results in overproduction of oxalate, hyperoxaluria, stones, and kidney failure. Pyridoxine (VB6) treatment reduces urine oxalate in patients (pts) with certain *AGXT* genotypes, suggesting a chaperone effect. Betaine partially corrected enzyme activity of the I244T mutation *in vitro* (Santana 2003). To ascertain effectiveness in PHI patients, we conducted a double blind, placebo controlled trial of betaine in children and adults with PHI who had missense mutations.

Methods: Subjects were randomly assigned oral betaine 10 gm (> 10 yrs old) or 6 gm (< 10 yrs old) or lactose placebo twice daily for 2 months, followed by a 2 month washout. Each then received the alternate study medication for 2 months. Usual medications continued throughout included VB6 (n= 9), neutral phosphate (n= 7), and citrate (n= 3). Two 24 hr urine collections were obtained at baseline, and during the eighth week of each study period. Uox was measured by oxalate oxidase.

Results: 10 of 15 enrolled PHI pts completed the study: 2 withdrew before initiation, 2 were noncompliant, in 1 symptoms led to withdrawal. Mean age was 20.1 yrs (median 18.5, range 6-43 y.o.). GFR was 79 ml/min/1.73m2 (median 92, range 39-134). Uox on betaine was 1.43 ± 0.97 umol/mg creat and differed from placebo 1.04 ± 0.71 by paired t test, p = 0.007. Betaine was well tolerated with dyspepsia in some, but no serious adverse effects.



Conclusions: Uox/creat was higher in pts receiving betaine compared with placebo. The mechanism is unclear and merits further investigation. Results suggest that caution is warranted in interpretation of *in vitro* chaperone effects.

Mutation Screening of the HALT PKD Population Jamie L. Sundsbak,[1] Christina M. Heyer,[1] Sandro Rossetti,[1] Robert W. Schrier,[2] Arlene B. Chapman,[3] Vicente E. Torres,[1] Ronald D. Perrone,[4] Jared J. Grantham,[5] Theodore I. Steinman,[6] William E. Braun,[7] Kyong Tae Bae,[8] Kaleab Z. Abebe,[8] James E. Bost,[8] Peter C. Harris.[1] *[1]Mayo Clinic; [2]U Colorado; [3]Emory U; [4]Tufts U; [5]Kansas U; [6]Beth Israel Deaconess Med Ctr; [7]Cleveland Clinic; [8]U Pittsburgh Med Ctr.*

Background: The genetic characterization of the HALT-PKD population (1044 cases) provides a comprehensive view of the genetics of this disorder and how genotype correlates with phenotype

Methods: PKD1 and PKD2 were analyzed using conventional Sanger sequencing, plus MLPA to assay for large rearrangements.

Results: We have screened 804 families consisting of 916 subjects (73% PKD1, 14% PKD2, 13% No mutation detected). Mutations were identified in 700 families (84% PKD1, 16% PKD2). Truncating changes made up the largest functional mutation group in both PKD1 (68% truncating, 32% non truncating) and in PKD2 (89% truncating, 11% non truncating). Comparison with the ADPKD Mutation Database Version 2.1 showed 70% were novel.

Several patients with interesting mutation combinations were found: two PKD1 truncating (in cis), a PKD2 nonsense and PKD1 in-frame deletion, and combinations of two likely hypomorphic alleles in cis or trans.

As expected in age corrected data, PKD1 cases had more severe disease with lower eGFR ($p<0.001$) and larger total kidney volumes (TKV; $p<0.001$) than PKD2. Looking at extreme deciles for TKV, only 1/43 was PKD1 in the mild group but 45/45 in the severe group. More interestingly, in the PKD1 population, cases with truncating mutations had a lower eGFR than in-frame ones ($p<0.001$). In the smaller PKD1 population with TKV data, cases with truncating mutations tended to have larger kidneys but the difference was not significant ($p=0.161$). However, in the extreme deciles, 33/34 with the most severe disease had truncating mutations compared to 12/29 in the mildest group. This data indicates that a minority of PKD1 mutations are not fully penetrant.

Conclusions: The characterization of the mutations in this clinically well defined population will greatly aid molecular diagnostics of ADPKD and other genetics studies of this disorder

TH-PO831

Autosomal Dominant Polycystic Kidney Disease (ADPKD) Presentation Is Often Influenced by *PKD1* Hypomorphic Alleles Christina M. Heyer, Sandro Rossetti, Katharina Hopp, Jamie L. Sundsbak, Vicente E. Torres, Peter C. Harris. *Mayo Clinic, Rochester, MN.*

Background: ADPKD, a dominantly inherited kidney condition, is typically caused by single inactivating mutations to *PKD1* or *PKD2*, and on average results in end stage renal disease (ESRD) at 54y and 74y, respectively. However, we recently described *PKD1* hypomorphic alleles that modify the disease presentation. Homozygotes or compound heterozygotes had typical to infantile onset disease, while a hypomorph and inactivating mutation caused early onset ADPKD. The role of hypomorphic alleles has been proven by generating a knock-in mouse model of the R3277C variant. Homozygotes are viable with slowly progressive disease (similar to adult onset ADPKD), while compound heterozygotes with a null allele ($Pkd1^{R3277C/-}$) have early onset disease.

Methods: *PKD1* and *PKD2* were sequenced in all probands by direct Sanger sequencing followed by computational analysis and family segregation of potential mutations.

Results: Analysis of ADPKD families with unusually mild or severe disease has yielded further examples where *PKD1* hypomorphic alleles effect the disease presentation. Mild ADPKD, which seldom causes ESRD, was observed in three families where the only detected variant was IVS37-3 C>T. Allele L2816P is also likely incompletely penetrant as it was found to segregate in families with mild disease. Sometimes, more than one allele seems to be required to cause ADPKD. Examples are I3167F inherited in *cis* with R3277H, and N970K in *cis* with V609G. In utero onset ADPKD with enlarged kidneys was observed in three families when a truncating allele was inherited in *trans* with a likely hypomorphic allele. Examples of these hypomorphic alleles are S4189F, R4276W, and a novel splice site in exon 5. A hypomorph in *trans* with an inactivating allele may also result in early ESRD. In one family, the PKD1 variant G2452C was associated with just a few cysts in heterozygosity but ESRD at 25y when found with a truncating mutation.

Conclusions: Together with our previous data, these families illustrate the crucial role hypomorphic alleles play in influencing disease severity in ADPKD.

PKD Mutational Analysis Using Next- Generation Sequencing in Czech Patients Jitka Stekrova,[1] Jana Reiterová,[2] Petr Lnenicka,[1] Vladimir Tesar.[2] *[1]Department of Biology and Human Genetics, 1st Medical Faculty and General Teaching Hospital, Prague, Czech Republic; [2]Department of Nephrology, 1st Medical Faculty and General Teaching Hospital, Prague, Czech Republic.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common form of inherited kidney disease that results in renal failure. ADPKD is a systemic disorder, with cysts and connective tissue abnormalities involving many organs. The disease is caused by mutations of *PKD1* and *PKD2* genes. In the PKD database 846 different variants of the PKD1 gene and 139 different variants of the PKD2 gene have been reported.

Methods: The direct detection of mutations in both *PKD* genes was performed within research projects in our laboratory. Next-generation sequencing method on GS Junior (Roche) analyzer was used. Mutational analysis was performed in relatives in ADPKD families with very-early onset of the disease to detect hypomorphic alleles probably inherited from healthy parents.

Results: The mutation analysis of *PKD1* gene has so far detected probably causal mutations in 57 families.42 mutations are unique for Czech population. Only the described nonsense mutation p.R4021X was detected in three nonrelated families and the described missense mutation p.E2771K was detected in two families; other mutations are unique for individual families; 42 mutations are unique for Czech population.

The mutation analysis of *PKD2* gene has so far detected probably causal mutations in 36 families. The frameshifting mutation c.203_204insC was identified in 9 families, nonsense mutation p.Q160X in 6 families. 14 mutations are unique for Czech population.

Conclusions: 42 new PKD1 mutations and 14 new PKD2 mutations were identified. Next- generation sequencing method is a promising method for mutational analysis of complicated genes.

Next-Generation Sequencing Technology for Research and Diagnosis of Ciliopathies Sophie Saunier,[1] Emilie Filhol,[1] Céline Huber,[2] Cecile Masson,[3] Frederic Tores,[3] Solenn Pruvost,[4] Mohammed Zarhrate,[4] Christine Bole-Feysot,[4] Patrick Nitschke,[3] Cecile Jeanpierre,[1] Isabelle Perrault,[2] Rémi Salomon,[1] Jean-Michel Rozet,[2] Valerie Cormier-Daire,[2] Tania Attié-Bitach,[2] Corinne Antignac.[1] *[1]INSERM U983, Hôpital Necker; [2]INSERM U781, Hôpital Necker; [3]Bioinformatic Platform, Université Paris Descartes; [4]Genomics Platform, Fondation Imagine, Paris, France.*

Background: Ciliopathies are genetically heterogeneous disorders caused by defects of ciliary function sharing a broad phenotypic spectrum: cystic kidney diseases including PKD or nephronophthisis (NPH), Joubert (JBTS), Meckel (MKS) and Bardet-Biel (BBS) syndromes, retinal dystrophies (Senior-Løken syndrome, SLS) and short rib-polydactyly diseases (SRP including asphyxiating thoracic dystrophy, ATD).

Methods: To identify novel disease genes, we performed exon-enriched next-generation sequencing of >1000 candidate genes using a customized Agilent SureSelect Target Enrichment library and the SOLID4 (Lifetech) technologies. Candidate genes were compiled from the Cilia Proteome and Cildb databases and by data mining of published cellular and animal models.

Results: We initially searched for mutations in a set of 25 patients for whom obvious candidate genes had been excluded and mapping data were available: 6 JBTS, 4 NPH, 5 JATD, 1 SRP-II, 5 SLS and 4 MKS. We confirmed the presence of BBS6 and BBS10 mutations in a JBTS case as an internal control. Pathogenic mutations were detected in known genes (TTC21B, NPHP4 and WDR35) in 4 families with NPH and situs inversus or JBTS. In addition, in 3 isolated NPH, JBTS and MKS cases, we found likely pathogenic homozygous or compound heterozygous mutations in 3 genes that have not previously been implicated in any ciliopathy. Functional studies of these mutations are under investigation.

Conclusions: To conclude, this method is a valuable and cost-saving approach to screen a large number of genes in ciliopathies. In addition to provide further insights into disease mechanisms, the analysis of numerous ciliary genes in patients with cystic kidney diseases and various extrarenal disorders will allow to explore the idea of mutational load as a potential predictor of clinical outcome.

TH-PO834

Whole Exome Resequencing Reveals Renal Transporter Mutations May Phenocopy Nephronophthisis-Related Ciliopathies Toby W. Hurd, Andrew Cluckey, Sivakumar Natarajan, Edgar Otto, Friedhelm Hildebrandt. *Pediatrics and Communicable Disease, University of Michigan, Ann Arbor, MI.*

Background: Nephronophthisis-related ciliopathies (NRCs) are the leading genetic cause of end-stage renal failure in the first three decades of life. To date, causative mutations in more than 18 different genes have been identified for NRCs, yet mutations in these genes can only explain approximately 30% of cases. To identify additional causative mutations for NRCs, we performed whole exome resequencing in eight families with apparent NRC phenotypes.

Methods: An Affymetrix Genome-Wide Human SNP Array 6.0 was utilized to identify 8 NRC families that displayed significant homozygosity and hence fit an autosomal recessive hypothesis for disease etiology. Exome capture was performed using the Nimblegen SeqCap EZ Human Exome Library v2.0 followed by resequencing on an Illumina HiSeq2000 platform.

Results: Of the 8 families, we identified mutations in known NRC genes in 3 of the families. These included a novel homozygous truncating mutation in NPHP4 in a patient with nephronophthisis; a previously described homozygous cryptic splice site mutation in BBS1 in a patient with Bardet-Biedl syndrome (BBS); a compound heterozygous mutation in ALMS1, mutations of which give rise to Almström syndrome, in a patient thought to have BBS. In addition, 1 patient who was described as having nephronophthisis based on the observation of renal cysts, was found to have a homozygous deletion in SLC4A1, a causative gene in distal renal tubular acidosis (dRTA). Re-inspection of ultrasound images in this patient revealed cysts surrounded by calcinosis, a hallmark of dRTA. Finally, in a patient with a BBS-like phenotype we found a homozygous missense mutation in the prostaglandin transporter, SLCO2A1, to which no disease has been associated so far.

Conclusions: We successfully identified by whole exome capture the causative mutations in 5 out of 8 patients with NCRs and enabled more accurate disease diagnoses than clinical data alone based on identification of the mutated gene. Moreover, we show that mutations of renal tubular transporter genes may represent phenocopies of NRCs.

TH-PO835

Renal Consequences of Megalin Deficiency in Humans Tina Storm,[1] Lisbeth Tranebjaerg,[4] Carina Anna Frykholm,[3] Tryggve Neveus,[5] Pierre J. Verroust,[2] Henrik Birn,[1] Erik I. Christensen,[1] Rikke Nielsen.[1] *[1]Institute of Biomedicine, Aarhus University, Aarhus, Denmark; [2]Institute de la Vision, INSERM, Paris, France; [3]Department of Audiology/Clinical Genetics, Uppsala University Hospital, Uppsala, Sweden; [4]Department of Audiology, Bispebjerg Hospital, Copenhagen, Denmark; [5]Department of Women´s and Children´s Health, Uppsala University, Uppsala, Sweden.*

Background: Donnai-Barrow (DB)/facio-oculo-acoustico-renal (FOAR) syndrome is caused by mutations in the LRP2 gene encoding megalin. Patients are characterized by a number of abnormalities, including proteinuria. We had the opportunity to investigate a Swedish consanguineous family (Dr. Birgitta Sundelin, Sweden) with three children suspected to suffer from this syndrome. The purpose of the present study was to characterize the mutation and the role of megalin in human kidney function and development.

Methods: To study the renal phenotype of megalin deficieny in humans we used direct sequencing, *in silico* analysis, immnuhitochemestry, ELISA and immunoblotting.

Results: We identified a novel mutation of the donor splice site of *LRP2* exon 18 (c.2639+1G>A). *In silico* analyses predicted a premature termination codon likely to result in nonsense mediated decay of the transcript and immunohistochemistry confirmed the absence of megalin. Light microscopic analyses of two available biopsies revealed no gross alterations in kidney morphology. This included normal distribution and expression of the endocytic receptor cubilin.

Analyses of renal biopsies revealed that megalin ligands including retinol binding protein, albumin and α1-microglobulin were not detectable in proximal tubules. Urinary excretion of both megalin and cubilin ligands were detected. Quantitative measurements of the albumin excretion revealed microalbuminuria.

Conclusions: Our studies demonstrate that abrogation of megalin expression in man results in urinary loss of numerous filtered compounds including vitamin carriersas as observed in megalin knockout mice. Further, normal internalization of cubilin bound ligands is dependent on the presence of megalin, whereas normal kidney development is not. Finally, our study indicates that human filtration of albumin is in the micro-range.

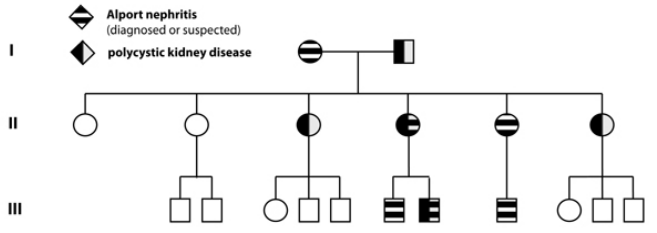
TH-PO836

Co-Occurrence of Alport and ADPKD – Early Progression to Renal Failure Kathy K.Y. Lee-Son,[1] Anna M. Lehman,[1] Mato P. Nagel,[2] Millan Patel,[1] Colin T. White.[1] *[1]BC Children's Hospital, Canada; [2]Nephrologische Praxis, Germany.*

Background: We describe a family with co-inheritance of ADPKD and Alport Syndome.

Methods:



Not all individuals in generation III have been screened for the two disorders.

The mother (II-4) was diagnosed with ESRD from pathology proven ADPKD at age 20 with transplant at 24. Two sons, conceived post-tx, were delivered prematurely. III-6 at 30 wk & 880g; III-7 at 32 wk & 1140g. Both had microscopic hematuria, bilateral echogenic kidneys in childhood & profound sensorineural hearing loss by age 14. III-6 progressed rapidly and was transplanted at age 16. III-7 had bilateral cortical cysts and presumptive diagnoses of PKD1 and Alport based on family history & phenotypic features. At age 18, he has reduced nuclear GFR [83ml/min/1.73m2] & heavy proteinuria on maximal ACE/ARB therapies.

Results: Genetic investigations of mom revealed 2 PKD1 gene variants of unknown significance: R1492H & I1610del. III-7 shared the I1610del, but not R1492H. Sequencing of her COL4A5 gene demonstrated a previously undescribed variant: c4447delG in exon 47, which leads to premature truncation of the protein. Biopsy of (III-6) showed a basket weave & absent IF for collagen α-3 and α-5, consistent with Alport Syndrome.

Conclusions: This family highlights the effects of multiple factors on the progression of renal disease. The mom's progression to ESRD in late adolescence from either Alport or PKD1 in isolation would be rare. We postulate the co-occurrence of both a glomerular and tubulocystic disease accelerated her renal deterioration. Although III-7 has both genetic conditions, his brother (III-6) with only Alport Syndrome progressed to ESRD much earlier than he. Given the similarities between both brothers through childhood, we postulate that the extreme prematurity & low birth wt of III-6 resulted in a diminished nephron endowment and a more rapid progression to ESRD despite his inheritance of only one genetic condition.

TH-PO837

COL4A3 Founder Mutation in a Novel Turkish-Cypriot Kindred Thomas Michael Connor,[1] Duriye Deren Oygar,[2] Daniel P. Gale,[1] Konstantinos Voskarides,[3] Constantinos Deltas,[3] Guy H. Neild,[1] Patrick Maxwell.[1] *[1]Division of Medicine, University College London, London, United Kingdom; [2]Nicosia State Hospital, Nicosia, North Cyprus, Cyprus; [3]Department of Biological Sciences, University of Cyprus, Nicosia, Cyprus.*

Background: Mutations in COL4A3, the gene encoding the α3 chain of type IV collagen, are associated with Alport syndrome and Thin Basement Membrane Nephropathy (TBMN). Recent studies in the Greek-Cypriot population have highlighted a number of mutations in COL4A3. These mutations were associated with both TBMN and FSGS on biopsy, and with a high incidence of end-stage renal disease. These mutations were thought to originate from founder mutations in that population. We investigated a large Turkish-Cypriot pedigree from the Kyrenia district of North Cyprus that segregated microscopic hematuria, mild proteinuria, occasional renal cysts, and variable degrees of renal impairment. There were no extra-renal signs in any of the affected individuals.

Methods: DNA was isolated using the QIAamp DNA blood mini kit. SNP genotyping was performed using the Illumina 300K chip and linkage anlaysis with easyLINKAGE. Tetra-primer PCR was designed to confirm the presence of known mutations. Mutations were confirmed by direct sequencing.

Results: Linkage analysis gave a LOD score of 4.5 in association with a 0.5Mb region at 2q36-7. Testing for known mutations of COL4A3/4 demonstrated co-segregation with the G871C mutation in COL4A3.

Conclusions: This is the first description of familial nephropathy in the Turkish Cypriot population associated with mutations in COL4A3. This demonstrates that this mutation occurs in both Greek and Turkish-Cypriot populations and confirms that it is sufficient to cause end-stage renal disease. Haplotype analysis will allow us to more accurately determine the origin of the mutation.

TH-PO838

Exonic Mutations Associated with Hereditary Renal Diseases Can Result in Major Alterations in the mRNA Felix Claverie-Martin, Marialbert Acosta-Herrera, F. Javier Gonzalez-Paredes, Elena Ramos-Trujillo. *Unidad de Investigacion, Hospital Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain.*

Background: The pathogenicity of missense and synonymous mutations is generally assumed to result from the predicted effect on the reading frame and protein function. However, it is now clear that an unexpectedly large fraction of exonic mutations could be pathogenic by affecting pre-mRNA splicing. The present study investigated the impact on splicing of missense and synonymous mutations previously found in the *CLDN16, SLC12A1, CLCNKB, PKD1* and *PKD2* genes of patients with familial hypomagnesemia with hypercalciuria, Bartter syndrome, and autosomal dominant polycystic kidney disease, respectively.

Methods: Bioinformatics analyses were used to predict the effect of mutations on mRNA splicing. The effect of mutations was tested experimentally by using splicing reporter minigene assays and site-directed mutagenesis. Analysis of RNA from transfected kidney-derived cell lines was performed by RT-PCR.

Results: Several mutations were predicted to disrupt pre-mRNA splicing by abolishing splice sites or creating new ones, or by inactivating or generating exonic splicing enhancers or silencers. We showed that these mutations induce different mRNA defects; *SLC12A1* mutation D648N leads to the incorporation of a truncated exon 14 in the mature mRNA, resulting in frameshift and predicted premature protein termination; *CLDN16* mutation G198A results in an mRNA that lacks exon 4; mutations R149L and L151F cause inclusion of a truncated exon 3 in the *CLDN16* mRNA; mutations D511V and L572L of *PKD2* result in skipping of exons 6 and 7, respectively; and *PKD1* mutation G109G leads to the incorporation of a truncated exon 3 in the mRNA.

Conclusions: Our results demonstrate that some renal disease-causing mutations, initially considered as missense or synonymous, induce splicing defects, resulting in major alterations in the mRNAs. We propose that these mutations are reclassified as splicing mutations. Assays for the effects of the mutation on mRNA splicing should be included in the routine analysis of these pathogenic mutations.

TH-PO839

Structural-Functional Relationships of Fabry Nephropathy Behzad Najafian,[1] Marie-Claire Gubler,[2] Michael Mauer.[3] *[1]Pathology, University of Washington, Seattle; [2]Pathology, Université René Descartes, Paris, France; [3]Pediatrics, University of Minnesota, Minneapolis.*

Background: Renal failure is a major complication of Fabry disease (FD). In order to understand FD nephropathy progression mechanisms, we studied relationships between glomerular structure and renal function in FD patients across wide range of age and renal function.

Methods: Renal biopsies from 25 (male (M)/female (F)=14/11) FD patients were studied using electron microscopy stereology. Results were correlated with proteinuria, GFR and age.

Results: F were 14[8-63], median [range] and M were 19 [4-57] years old. M and F were not different for proteinuria, GFR, volume fraction of GL-3 inclusions per mesangial [Vv(Inc/Mes)], or endothelial cells [Vv(Inc/Endo)]. Volume fraction of GL-3 inclusions per podocytes [Vv(Inc/PC)] was greater in M (0.38±0.11) vs F (0.25±0.13), p=0.01. In all FD patients, there was a direct relationship between age and proteinuria (r=0.5, p=0.008), FPW (r=0.70, p=0.001), Vv(Inc/Mes) (r=0.64, p=0.001) and Vv(Inc/Endo) (r=0.67, p=0.00001). FPW was correlated with Vv(Inc/PC) (r=0.55, p=0.02). Vv(Inc/Mes) and Vv(Inc/Endo) were strongly correlated (r=0.96, p=0.00001). There was negative correlation between age and GFR (r=-0.60, p=0.02). Proteinuria was correlated with FPW (r=0.64, p=0.006), Vv(Inc/PC) (r=0.56, p=0.02), Vv(Inc/Endo) (r=0.57, p=0.01), and Vv(Inc/Mes) (r=0.56, p=0.02). None of the structural parameters were correlated with GFR. While there was no relationship between age and Vv(Inc/PC) (r=0.03, p=0.8) in the entire cohort, in young patients (age<20), Vv(Inc/PC), and not Vv(Inc/Endo) or Vv(Inc/Mes), was strongly correlated with age (r=0.78, p=0.001)

Conclusions: We demonstrated novel relationships between glomerular structure and proteinuria in FD patients across a wide range of age and renal function. Our studies indicate that structural-functional relationships of FD nephropathy may be different in different age groups, perhaps reflecting a difference in progression of various lesions n initial vs late stages of the disease.

TH-PO840

The Frequency of Fabry Disease with the α-Galactosidase A E66Q Variant in Japanese Dialysis Patients Yoko Kikumoto, Hitoshi Sugiyama, Hiroshi Morinaga, Ayu Ogawa, Masashi Kitagawa, Keiichi Takiue, Shinji Kitamura, Shigeru Akagi, Yohei Maeshima, Hirofumi Makino. *Okayama University, Japan.*

Background: Fabry disease (FD) is an X-linked disorder resulting in a deficiency in the α-galactosidase A (α-Gal) enzyme activity. FD is one of the causes of progressive renal dysfunction, but its diagnosis is often either delayed or missed. Its frequency has been reported to be much higher in dialysis patients, and recent newborn screenings have revealed a high incidence of later-onset FD mutations, including renal variants.

Methods: We first screened the α-Gal activity in the plasma of 892 Japanese hemodialysis (HD) patients. When the enzyme activity was below 6.4 nmol/mL/2hr, the test was defined as positive. Next, α-Gal activity was measured from dried blood spots via a fluorescence assay using 4-methylumbellifenyl. Then, online databases were searched to identify any previous screening studies for Japanese FD patients undergoing HD.

Results: One previously undiagnosed 70-year-old male patient was identified by this screening study. He had a low plasma α-Gal activity and was demonstrated to have an E66Q mutation in exon 2 of the α-Gal gene, and one of his daughters had the same mutation. The frequency of FD was 0.11% in all and 0.18% in male HD patients in this study. We further identified 5 previous studies and found a total of 4298 Japanese HD patients screened (2975 males and 1323 females), including those in our present study. Overall, the prevalence of FD was 0.50% in male (6 studies), and 0.23% in female HD patients (4 studies). Notably, the frequency of the E66Q variant was 33.3% (6 of 18 patients) of Japanese FD on HD. The classical manifestations of FD were not observed in any of these patients with E66Q; however, most of them had either cardiac or cerebrovascular involvement. Other mutations included M291I, Y365X, M296I, Q357X, A97V, G373D, Δ288A and Δ254V.

Conclusions: Our results demonstrate that the later-onset disease phenotype with the E66Q variant is more frequent in Japanese FD patients on HD than has been previously reported in other countries. Whether E66Q is a pathogenic mutation, or just a variation will need to be determined in further investigations.

TH-PO841

UMOD Mutations in the Chronic Kidney Disease Population in Taiwan Lim Lee Moay,[1] Chih-Chuan Yu,[3] Daw-Yang Hwang,[1] Chi-Chih Hung,[1] Shang-Jyh Hwang,[1,2] H.C. Chen.[1,2] *[1]Division of Nephrology, Department of Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [2]Faculty of Renal Care, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan; [3]Graduate Institute of Medicine, Collage of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan.*

Background: Taiwan has the highest incidence and prevalence rate of end-stage renal disease (ESRD) and also high incidence and prevalence of chronic kidney disease (CKD) according to the USRDS report. The cause of this high incidence and prevalence are multi-factorials. Genetic factors are believed to be one of them. However, there is no data concerning the prevalence of medullary cystic kidney disease (MCKD) and UMOD gene mutation in CKD population in Taiwan.

Methods: We selected 160 patients, irrespective of family history, from the Kaohsiung Medical University Hospital CKD Care Program based on the criteria with uric acid level in the highest quartile in the CKD stage. For CKD stage 1 and 2, the criteria selected was uric acid higher than 8 mg/dL for male and 7.5 mg/dL for female. Since more than 90 percent of UMOD gene mutation was reported in the exon 4, we amplified this exon by polymerase chain reaction and direct sequencing. HEK293 cells were transient transfected with wild and mutant uromodulin. Immunofluorescence staining was used to study the uromodulin retention in the endoplastic reticulum(ER) and Western blot to study the cytosol cytochrome c expression.

Results: Two novel UMOD mutations, p.C41R and p.R142Q, were found. In vitro analysis showed that these two novel mutations caused retention of mutant uromodulin in the ER compared with wild type. Increased cytosol cytochrome c level in transfected HEK293 cells was also found.

Conclusions: The UMOD mutation contributed a relative small portion for the cause of CKD population in Taiwan. The p.C41R uromodulin caused greater ER retention than R142Q mutant, while the wild type showed the least retention. Both mutants showed increased cytosol cytochrome c, indicated the mutant uromodulin caused cell apoptosis. Our findings are comparable with other UMOD studies showing ER retention, and cell apoptosis may contribute to tubular cell death followed by interstitial fibrosis.

TH-PO842

How Nonsense Mutations in the COL4A4 Gene Cause Autosomal Recessive Alport Syndrome and Thin Basement Membrane Nephropathy Vanessa Sivakumar, Yanyan Wang, Mardhiah Binti Mohammad, Hayat Dagher, Judith A. Savige. *Department of Medicine, University of Melbourne, Melbourne, VIC, Australia.*

Background: Autosomal recessive Alport syndrome results from homozygous or compound heterozygous mutations in the *COL4A3* or *COL4A4* genes. Nonsense changes account for 10% of all mutations. In other collagen diseases, nonsense mutations have their effect through 'nonsense-mediated decay'. The aim of this study was to determine whether mutations in autosomal recessive Alport syndrome and Thin basement membrane nephropathy also resulted in nonsense-mediated decay.

Methods: Peripheral blood lymphocytes from a father and daughter with homozygous and heterozygous copies of S969X in *COL4A4* respectively were EBV-transformed. The resulting cell lines were cultured overnight at 37°C with 5% CO_2, with and without the addition of protein synthesis inhibitors (0.1 mg/ml cycloheximide, 0.1 mg/ml anisomycin). Levels of collagen IV α3, α4 and α5 mRNA were quantitated by real time PCR (7500 Real Time PCR System, Applied Biosystems), and compared with levels in untreated cells after normalisation using *GAPDH*. Levels of mRNA corresponding to pro- and antiapoptotic pathways (Casp 3, Bad and Bcl-2) were also quantitated.

Results: Levels of collagen IV α4 chain mRNA were increased after the addition of cycloheximide (p=0.025, p=0.012) or anisomycin (p=0.03, p=0.009) in both the homozygous and heterozygous cell lines. This is consistent with *COL4A4* nonsense mutations resulting in nonsense-mediated decay. There was no evidence of apoptosis.

Conclusions: Nonsense mutations in autosomal recessive Alport syndrome and Thin basement membrane nephropathy result in nonsense-mediated decay, but not in apoptosis. The use of therapeutic agents that inhibit nonsense-mediated decay in patients with autosomal recessive Alport syndrome may increase collagen IV α3 and α4 chains and ameliorate disease severity.

TH-PO843

Hypermethylation of the Mucin-Like Protocadherin (MUPCDH) Gene Promoter in Autosomal Dominant Polycystic Kidney Disease Jong Hoon Park, Yu Mi Woo, Eunji Lee. *Sookmyung Women's University, Seoul, Korea.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a common human genetic disease and characterized by the formation of multiple fluid-filled cysts, which result in end-stage renal failure. However, cyst mechanism, early diagnosis and treatment for ADPKD are still not clear. Recently, it is reported that the alteration of epigenetic regulation as well as gene mutations may affect on pathogenesis.

Methods: To understand the epigenetic mechanism of pathogenesis of ADPKD, genome-wide methylation profile was compared with expression analysis by Methyl CpG Recovery Assay-Sequencing (MIRA-Seq). Based on this data, to validate the methylation status at CpG dinucleotides, HRM analysis and EpiTYPER was performed following bisulfite treatment. Furthermore, to confirm the effect on recovery of DNA methylation levels in ADPKD, DNMT inhibitors were treated into the immortalized human ADPKD cystic epithelial cells and changed mRNA level of MUPCDH was checked by qRT-PCR.

Results: As a result of genome-wide DNA methylation analysis, overall genome of ADPKD patients was hypermethylated compared with normal samples. Especially, promoter region of MUPCDH gene was significantly hypermethylated in ADPKD kidney tissue. As a result of HRM analysis, hypermethylation patterns was showed in the promoter region of ADPKD kidney tissues compared with normal control, ranging from upstream 1 kb to intron 1 region. As expected, hypermethylation in promoter region of MUPCDH was also observed in cystic patient kidney tissues compared with normal. On the contrary, its expression level was markedly decreased in ADPKD patients. Demethylation of MUPCDH gene promoter by treating DNMT inhibitor such as 5-aza-2'-dexoycytidine induced up-regulation of MUPCDH mRNA level.

Conclusions: In conclusion, MUPCDH promoter CpG islands were significantly hypermethylated in ADPKD patients and it is negatively correlated to its reduced expression level.

TH-PO844

Correlation of Phenotype and *HOGA1* Variants in Obligate Heterozygotes from PHIII Families Carla G. Monico, Andrea G. Cogal, Julie B. Olson, Barbara M. Seide, Dawn S. Milliner. *Division of Nephrology, Mayo Clinic, Rochester, MN.*

Background: Recently, we described primary hyperoxaluria type III (PHIII), due to mutations in *HOGA1*, and identified hypercalciuria and hyperuricosuria in addition to hyperoxaluria in some patients. We also detected heterozygosity for *HOGA1* variants in 2 patients with mild hyperoxaluria and in 3/100 idiopathic calcium oxalate stone formers.

Methods: To further characterize the phenotype in *HOGA1* heterozygotes, we performed segregation analysis in all available first-degree relatives of PHIII probands. Analysis included 1 new and 9 previously ascertained unrelated PHIII families. Hyperoxaluria, hypercalciuria & hyperuricosuria were defined by age-appropriate normal reference ranges, based on 24-hour urine collections, completed on self-selected diets.

Results: Mild hyperoxaluria was observed in only 1 obligate heterozygote harboring 1 of the 2 most common (IVS700+5 G>T and c.944_946 del AGG) mutations. However, both hypercalciuria and hyperuricosuria were detected in some c.944_946 del AGG and IVS700+5 G>T heterozygotes. And both mild hyperoxaluria and hypercalciuria were observed in some R>C missense variant heterozygotes.

Association of mild or intermittent hyperoxaluria, hypercalciuria or hyperuricosuria in obligate heterozygotes with HOGA1 variants.

Family #	HOGA1 allele	↑ Uox	↑Uca	↑Uua	# FDR tested
1	c.944_946 del AGG	0/2	1/2	NA	2
2	c.944_946 del AGG	0/5	0/5	1/5	5

FDR=first-degree relatives. NA=not available, Uox (urine oxalate), Uca (urine calcium), Uua (urine uric acid).

Conclusions: Detection of hyperoxaluria, hypercalciuria or hyperuricosuria in association with *HOGA1* heterozygosity was variable, even among first-degree relatives from the same family, suggesting an influence from other susceptibility factors, genetic or environmental. Diet-controlled studies and further characterization of the metabolic defect in PHIII are needed.

Targeted Exome Sequencing and Homozygosity Mapping Identify Mutation of EMP2 as a Cause of Steroid Sensitive Nephrotic Syndrome Shazia Ashraf,[1] Virginia Vega-Warner,[1] Humphrey Fang,[1] Toby W. Hurd,[1] Sivakumar Natarajan,[1] Fatih Ozaltin,[2] Friedhelm Hildebrandt.[1,3] *[1]Department of Pediatrics and of Human Genetics, University of Michigan, Ann Arbor, MI; [2]Department of Pediatrics, Hacettepe University, Ankara, Turkey; [3]Howard Hughes Medical Institute, University of Michigan, Ann Arbor, MI.*

Background: Idiopathic nephrotic syndrome is a common pediatric kidney disease 80% of all cases are steroid sensitive (SSNS). Whereas gene identification has furthered the understanding of pathomechanisms in steroid-resistant nephrotic syndrome (SRNS), disease mechanisms of SSNS remain unknown. To identify single-gene causes for SSNS, we combined homozygosity mapping, whole human exome capture and consecutive massively parallel re-sequencing.

Methods: In two siblings (of consanguineous parents) with SSNS, homozygosity mapping yielded 4 segments of homozygosity by descent with a cumulative genomic length of ~55 Mb. We performed whole human exome capture in one sibling using NimbleGen SeqCaP EZ Exome with consecutive massively parallel sequencing on an Illumina-Genome Analyzer II platform to identify the underlying disease-causing mutation.

Results: We identified a homozygous truncating mutation (p.Q62X) in the ***epithelial membrane protein 2*** (***EMP2***) gene as the first single-gene cause of SSNS. The mutation segregated with the affected status in this family and was absent from 86 Turkish healthy control individuals. EMP2, a tetraspan protein, has been shown to play a role in trafficking of molecules, which include integrins, major histocompatibility complex (MHC) class I molecules and glycosyl-phosphatidyl inositol (GPI)-anchored proteins. EMP2 is strongly expressed in human glomerular podocytes.

We are now screening ~600 unrelated SSNS patients for all coding exons of the *EMP2* gene to detect additional mutations in this gene.

Conclusions: We identified mutation of *EMP2* as causing SSNS. The identification of the first gene for *SSNS* presented here provides a first step towards our understanding of the pathomechanisms of SSNS.

TH-PO846

Dominant Mutations Cluster in the Signal Peptide of *Renin* and Emphasize a Role for Renin in Erythropoiesis Bodo B. Beck,[1] Howard Trachtman,[2] Friedhelm Hildebrandt,[3] Matthias Tilmann Florian Wolf.[4] *[1]Institute of Human Genetics, University of Cologne, Germany; [2]Department of Pediatrics, Cohen Children's Medical Center, New Hyde Park, NY; [3]Departments of Pediatrics and of Human Genetics, University of Michigan, Ann Arbor, MI; [4]Pediatric Nephrology, University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Renin is an important hormone regulating blood pressure and renal sodium reabsorption via the renin-aldosterone system. Homozygous or compound heterozygous *Renin (REN)* mutations cause renal tubular dysgenesis, which is characterized by death *in utero* due to renal failure and pulmonary hypoplasia. The phenotype resembles the fetopathy caused by angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB) intake during pregnancy. Recently, heterozygous *REN* mutations were shown to result in early-onset hyperuricemia, anemia and chronic kidney failure. So far, only three different heterozygous *REN* mutations have been reported.

Methods: We performed mutation analysis of the *REN* gene in 39 kindreds with hyperuricemia and chronic kidney disease (CKD) previously tested negative for mutations in the *UMOD* and *HNF1*β genes.

Results: We identified a novel c.T28C (p.W10R) *REN* mutation in the signal sequence, affecting individuals over four generations. Patients carrying the novel *REN* mutation were characterized by significant anemia, hyperuricemia and CKD. We report the youngest patient with a heterozygous *REN* mutation so far, showing anemia, hyperuricemia and impaired renal function as early as 11 months of age. Documented anemia is severe in patients with heterozygous *REN* mutations and disproportional to the degree of renal impairment.

Conclusions: We highlight the possible mechanisms of heterozygous *REN* mutations causing anemia. Moreover all heterozygous *REN* mutations are localized in the signal sequence. We conclude that *REN* mutations are rare events in CKD patients and cause a clinical syndrome that resembles Uromodulin associated kidney disease. Screening of the *REN* gene should be considered for CKD patients with hyperuricemia and anemia, focusing on exon 1 sequencing, which encodes the signal peptide.

TH-PO847

Whole Exome Capture Reveals Mutation of *ARHGDIA* as Causing Nephrotic Syndrome Pawaree Saisawat,[1] Virginia Vega-Warner,[1] Shazia Ashraf,[1] Yaacov Frishberg,[2] Toby W. Hurd,[1] Sivakumar Natarajan,[1] Friedhelm Hildebrandt.[1,3] *[1]Pediatrics, University of Michigan, Ann Arbor, MI; [2]Pediatric Nephrology, Shaare Zedek Medical Center, Jerusalem, Israel; [3]Howard Hughes Medical Institute.*

Background: Diffuse mesangial sclerosis (DMS) is a rare histologic variant of early-onset nephrotic syndrome (NS). In our multiethnic cohort of 71 DMS patients, 26 (37%) are caused by mutations in *WT1, NPHS1, NPHS2* or *PLCE1* while the majority of cases are still unsolved. To identify a new causative gene for DMS, we employed homozygosity mapping (Hildebrandt et al. *PLoS Genet* 5: e1000353, 2009) with consecutive whole exome capture (WEC) and massively parallel exon re-sequencing.

Methods: The parents of 3 siblings who were affected with early-onset NS that rapidly progressed to end-stage renal disease were first cousins of Ashkenazi Jewish background. Renal biopsy was carried out in one child and revealed DMS. *WT1, NPHS1, NPHS2* and *PLCE1* were screened and were mutation negative.

Results: Homozygosity mapping showed 5 homozygous candidate regions, confirming the history of consanguinity. We performed whole exome capture using the NimbleGen SeqCaP EZ Exome™ V2 protocol. Sequencing was performed using Illumina Genome Analyzer II. We detected 1 homozygous missense mutation (G173V) in *ARHGDIA* in an amino acid residue, which was consistently conserved to *S. cerevisiae*. G173V was predicted to be 'damaging' by PolyPhen score. The mutation was segregating in the family and was absent from the 1,000 genomes project. *ARHGDIA* encodes a GDP dissociation inhibitor (GDI), which regulates cycling between the GTP- and GDP-bound forms of the Rho family proteins. *Arhgdia*$^{-/-}$ mice develop massive proteinuria at 12 weeks of age and succumb to renal failure at an early age (*Oncogene* 18:5373, 1999). Kidney histology shows mesangial sclerosis and cystic tubular dilatation.

Conclusions: Because the *Arhgdia* loss-of-funcation mouse phenotype recapitulates the human DMS phenotype, our finding of *ARHGDIA* mutation very likely represents a new single-gene cause of early-onset NS.

TH-PO848

INF2 Mutations as a Cause of Familial Versus Sporadic FSGS Elizabeth J. Brown,[1,2] Victoria Charoonratana,[1,2] Giulio Genovese,[2] Andrea Uscinski Knob,[2] Martin R. Pollak.[2] *[1]Medicine, Boston Children's Hospital, Boston, MA; [2]Medicine, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Mutations in INF2, a member of the formin family of actin binding proteins, have been shown to cause autosomal dominant focal segmental glomerulosclerosis (FSGS). We previously described nine missense mutations in exons 2-4 of INF2 in 11/93 families with autosomal dominant inheritance of FSGS. We did not identify any disease-associated mutations outside of this region.

Methods: Genomic DNA was extracted from blood or saliva using standard methods. Using Sanger sequencing, we sequenced PCR amplified segments containing either exons 2-5 or exon 4 alone of INF2 in an additional 294 individuals with familial or sporadic FSGS. We sequenced exons 2-5 in all available family members of an individual in whom we found a variant. Clinical information was obtained from questionnaires and phone discussions with participants and/or their doctors.

Results: We identified 9 missense mutations in INF2 in 10 additional families with autosomal dominant FSGS. We did not find INF2 mutations in individuals with sporadic FSGS. Several of the mutations have been published previously (R214C, R218Q, R218W) while others are novel (H158D, G73S, V181G, R177C, C151R, L81P). All of the mutations are possibly or probably damaging by Polyphen2 analysis. All of the mutations segregate with disease. There are multiple individuals with end-stage renal disease and renal transplants within this new cohort, however, the penetrance is variable. In the H158D family, all 6 individuals in our study carry the mutation and have manifested ESRD. Whereas, in the R214C family, several individuals carrying the mutation are unaffected. Proteinuria was diagnosed in most of this cohort with INF2 mutations in their teens or 20s with ESRD developing in the third or fourth decade of life. No recurrent disease has been noted in renal transplant recipients.

Conclusions: We and others have shown that INF2 mutations are a significant cause of autosomal dominant FSGS. INF2 mutations do not appear to common in individuals with sporadic FSGS suggesting a different pathologic mechanism for the two forms of the disease.

TH-PO849

New *INF2* Mutations in a Large Cohort with Sporadic and Hereditary FSGS and Further Evidence for Variable Expressivity Rasheed A. Gbadegesin,[1] Peter J. Lavin,[2] Gentzon Hall,[2] Alison Homstad,[1] Guanghong Wu,[2] Alison Byrd,[2] Michelle P. Winn.[2] *[1]Pediatrics and Center for Human Genetics, Duke University, Durham, NC; [2]Medicine and Center for Human Genetics, Duke University, Durham, NC.*

Background: Focal and segmental glomeruloscerosis (FSGS) is a major cause of end-stage kidney disease. Recent advances in molecular genetics have provided evidence that defects in the podocyte play a major role in the pathogenesis of FSGS. Mutations in inverted formin 2 (*INF2*) were recently identified as a cause of autosomal dominant (AD) FSGS.

Methods: To define the role of *INF2* mutations in familial and sporadic FSGS, we screened for *INF2* variants in a large cohort with FSGS. The study had a secondary objective of defining a rational approach for genetic screening in families with AD FSGS.

Results: We identified 248 individuals with FSGS. There were 31 (32.6%) individuals with idiopathic disease. The remainder of individuals were from 64 families, 15 (15.8%) individuals from autosomal recessive kindreds and 49 (51.6%) individuals from AD kindreds. We found missense mutations in *INF2* in 8/49 (16%) of families with AD FSGS. Three of the variants detected were novel and all of the mutations were confined to exon 4 of *INF2*. Mutations in exon 4 of *INF2* are responsible for 90% of all mutations reported in FSGS due to *INF2* mutations.

Conclusions: In conclusion, *INF2* mutations are responsible for 16% of all cases of AD FSGS and mutations are clustered in exons 4 and 2, therefore screening for mutations in *INF2* may represent a rapid, non-invasive and cost effective method for the diagnosis of AD FSGS.

TH-PO850

Genetic Backgrounds in Patients with Glomerulopathy with Fibronectin Deposits Hiromi Ohtsubo,[1] Fusako Hashimoto,[1] Shingo Ishimori,[1] Takeshi Ninchoji,[1] Fu XueJun,[1] Yuya Hashimura,[1] Hiroshi Kaito,[1] Naoya Morisada,[1] Noriko Uesugi,[2] Kazumoto Iijima.[1] *[1]Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan; [2]Institute of Basic Medical Sciences, University of Tsukuba, Japan.*

Background: Glomerulopathy with fibronectin deposits (GFND) is a rare autosomal dominant glomerular disease associated with the massive deposition of fibronectin, caused by mutations of fibronectin 1 gene (*FN1*). There are currently few reports about genetic backgrounds in patients with GFND, and little is known about the clinical course. Our purpose in this study is to clarify the genotypes of *FN1* and the clinical features of GFND patients.

Methods: This study was designed for GFND patients and their family members. All patients underwent renal biopsies and were definitely diagnosed as GFND by renal histological findings. Genomic DNA was isolated from peripheral blood leukocytes after informed consent, and *FN1* was analyzed by using PCR and direct sequencing method.

Results: Seven (1 male and 6 females) patients and twelve family members were enrolled in this study. There were 2 cases with clinical renal manifestations in family members; one had persistent proteinuria, and the other was end stage renal failure for unknown reasons. All of the 7 patients had heterozygous mutations of *FN1*; four of them had p.Y973C, which was previously reported located in hepalin-binding domain, and the other three had novel (p.W1925X, p.1472del, p.L1974P). One of the novel mutations, p.1472del, located in integlin-binding domain, which play major roles in assembly of FN as well as hepalin-binding domain. There were six family members with heterozygous mutations of *FN1*; two of them had clinical renal manifestations, and the other four didn't at all.

Conclusions: We could detect heterozygous mutations of *FN1* in all of the patients, including the affected family members. Three novel mutations could be detected in this study, and furthermore this is the first report that demonstrated GFND can develop by *FN1* mutation in integlin-binding domain. It is of much interest that some individuals with the same *FN1* mutations as patients showed no renal manifestations, despite of comparatively late age.

TH-PO851

Two Novel Homozygous SLC2A9 Mutations Cause Renal Hypouricemia Type 2 Dganit Dinour,[1] Nicola K. Gray,[2,3] Liat Ganon,[1] Andrew J.S. Knox,[4] Susan Campbell,[5] Lindsay Sawyer,[6] Daniel Landau,[7] Alan F. Wright,[5] Eliezer J. Holtzman.[1] *[1]Sheba Medical Center and Tel Aviv University, Israel; [2]University of Edinburgh, United Kingdom; [3]Centre for Reproductive Biology, Edinburgh, United Kingdom; [4]Institute for Genetics and Molecular Medicine, Trinity College Dublin, Ireland; [5]MRC Human Genetics Unit, Western General Hospital, Edinburgh, United Kingdom; [6]School of Biological Sciences, University of Edinburg, United Kingdom; [7]Soroka University Medical Center, Israel.*

Background: Elevated serum uric acid is associated with gout, hypertension, cardiovascular and renal disease. Hereditary renal hypouricemia type 1 (RHUC1) is caused by mutations in the renal tubular uric acid transporter URAT1, and can be complicated by nephrolithiasis and exercise-induced acute renal failure. We have recently shown that loss-of-function homozygous mutations of another uric acid transporter, GLUT9, cause a severe type of hereditary renal hypouricemia with similar complications (RHUC1).

Methods: Two unrelated families with renal hypouricemia were clinically characterized. DNA was extracted and *SLC22A12* and *SLC2A9* coding for URAT1 and GLUT9, respectively, were sequenced. Transport studies in *Xenopus laevis* oocytes were utilized to evaluate the function of GLUT9 mutations found. A molecular modeling study was undertaken to structurally characterize the effects of these mutations.

Results: Two novel homozygous GLUT9 missense mutations were identified: R171C and T125M. Mean serum uric acid level of four homozygous subjects was 0.15 ± 0.06mg% and fractional excretion of uric acid was 89-150%. None of the affected subjects had nephrolithiasis, exercise-induced acute renal failure or any other complications. Transport assays revealed that both mutant proteins had a dramatically reduced ability to transport uric acid. Modeling showed that R171C and T125M mutations are located within the inner channel that transports uric acid between the cytoplasmic and extracellular regions.

Conclusions: This is the second report of renal hypouricemia caused by homozygous GLUT9 mutations. Our findings confirm the pivotal role of GLUT9 in uric acid transport and highlight the similarities and differences between RHUC1 and RHUC2.

Funding: Government Support - Non-U.S.

TH-PO852

Evaluation of an Interactive, Visual On-Line Tutorial To Improve Urine Microscopy Teaching Craig E. Gordon,[1] Jessica Gray,[2] John R. Heinrick,[2] Maya Fayfman,[2] Laurence H. Beck.[1] *[1]Renal Section, Department of Medicine, Boston University School of Medicine, Boston, MA; [2]Boston University School of Medicine, Boston, MA.*

Background: The evaluation of urine sediment is one of the oldest non-invasive clinical tools used to diagnose renal and systemic pathology. We developed an online module for urine microscopy training and evaluated its efficacy as a learning tool.

Methods: To evaluate the tutorial, we created a ten-item multiple-choice pre and post-tutorial examination comprising questions focused on image identification, fact, and case-based questions, as well as a curriculum assessment tool using a five-point Likert scale. We hypothesized that post-test results would be higher than pre-test outcomes and that performance on image-based questions would improve more than other item types. Data were analyzed using a two-sample T test.

Results: Second year medical students accessed the tutorial and pre- and post-examinations throughout the renal module of the Disease and Therapy course. Of 183 enrolled students, 30 (16%) completed both pre- and post-tests. Mean score on the pre-test was 47% [95% CI, 41-54%] and 63% [95% CI, 56-70%] on the post-test, p-value < 0.001. Post-tutorial score on image identification items increased by 26% ($p < 0.001$) but did not increase significantly for other question types. Nine students completed the curriculum assessment and reported improved understanding of urine microscopy and that the tutorial was a valuable educational tool which they would recommend to future enrollees.

Conclusions: This novel urine microscopy tutorial is an effective learning tool for second year medical students. Post-tutorial examination scores were higher in general, but significantly for questions requiring image identification. Student evaluations of the tutorial were largely positive. The generalizability of these findings is limited by few students completing the pre- and post-tutorial examinations and curriculum assessment. Despite these limitations, this online educational tool appears valuable for medical student education, and potentially for resident/fellow training, as well as a model tutorial for other image-based medical topics.

TH-PO853

Development of a Validated Nephrology Clinic Letter Fellow Competency Assessment John D. Mahan, David S. Hains, Hiren P. Patel. *Pediatric Nephrology, Nationwide Children's Hospital/OSU, Columbus, OH.*

Background: Competency assessment of nephrology fellows in training should promote acquisition of essential skills, be judged practical by faculty and be relevant to fellows. We developed and tested a Pediatric Nephrology Fellow Clinic Letter Competency Assessment (CLCA) of 8 items deemed essential for an effective clinic letter (by consensus of faculty of the Pediatric Nephrology Division) to address the ACGME competency for Interpersonal and Written Communications. Fellows compose their letters after clinic visits; supervising faculty may provide feedback on the letter before it is finalized. Each starting fellow receives a copy of the CLCA form. 3 letters are randomly chosen and assessed every 6 months/fellow and results discussed at each fellow's semi-annual review.

Methods: For this study, 3 faculty independently evaluated 36 randomly selected letters distributed over 24 months from the entire set of > 1000 letters constructed by the 5 fellows each year. CLCA was completed per letter by each faculty member and data analyzed for 1) inter-rater reliability (IRR) for each item and for the total score for each letter, 2) intra-class correlation (ICC) and 3) class differences by ANOVA and t tests.

Results: Faculty found the CLCA tool easy to use; specific comments were added for 40% of letters. IRR was acceptable for individual elements (0.41) and good for total score (0.58). ICC Coefficient for total score/letter was good at 0.637. CLCA total scores increased per yr of training (ANOVA, $p = 0.057$). Fellows in 3rd yr (mean 7.79+/-0.25) scored better than 1st yr (mean 7.19+/-0.6748), $p = 0.0291$, consistent with increasing competency over time.

Conclusions: The Pediatric Nephrology Fellow Clinic Letter Competency Assessment helped direct and measure increasing competency by fellows. The CLCA tool had strong validity, good inter-rater reliability, and could be used in adult and pediatric programs. Implementation of validated methods for competency assessment can assist fellowship program directors and faculty in developing important skills in trainees. Additional practical and useful competency assessment methods offer the opportunity to more intentionally direct fellow training.

TH-PO854

Case Based Debates- An Innovative Teaching Tool Arun Chawla, Kenar D. Jhaveri. *Nephrology, Hofstra North Shore LIJ School of Medicine, NY.*

Background: There has been a growing concern about the decline in interest in nephrology as a career amongst medical students and residents. At our institution we have continuously worked to develop unique ways of teaching nephrology, which are meant not only to attract medical students and residents to the field of nephrology but also contribute directly to promote learning and training of renal fellows. We hereby present another teaching tool which we have used to teach transplant pathology -"Case Based Debates".

Methods: A faculty member chooses a challenging case (transplant related) and shares brief history and labs with the fellows in advance. Fellows are equally divided into two teams. Each team has a faculty member (gold card/lifeline) who can be used, at the most, twice during the whole debate/game. Fellows sit together to discuss the case and formulate a differential diagnosis and come up with a diagnostic plan involving minimum number of tests leading them to most likely diagnosis. Investigations/questions (like most relevant

history questions, pertinent lab data, donor specific antibodies, viral serologies etc.) are rewarded with points according to their relevance and diagnostic importance. Using the least number and most relevant tests and thereby earning more points, the team that comes closest to correct diagnosis is then asked to predict the biopsy findings. Next, the pathology slides are shown which fetches bonus points to the team who reads them accurately.

Results: The above teaching tool has been an instant hit amongst the fellows and residents. It has also been well received, most participated and the most appreciated teaching tool at the "faculty development workshop" at our institution.

Conclusions: We hope to introduce this tool to teaching of not only transplant pathology but also to discuss and teach challenging cases involving fluid and electrolytes, acid-base imbalance and other aspects of nephrology. It makes learning fun and easy to understand. Also, we learn to use the most cost-effective diagnostic tests, which is an important aspect to understand with increasing economic burden of the healthcare on our economy.

TH-PO855

Paging Doctor Google! Google Searching as a Tool for Diagnosing Renal Disease Peter B. Schrier, Louis R. Spiegel, Kenar D. Jhaveri. *Nephrology, North Shore/LIJ & Hofstra Medical School.*

Background: Patients often approach their doctors with medical information they obtained from the Internet. Increasingly, medical students, residents, and attending physicians have been using the Internet as a tool for diagnosing and treating disease. We asked whether people with basic introductory medical knowledge (i.e. Internal Medicine residents) will be better at diagnosing renal diseases using the internet's most common search engine, Google.com, as an aid.

Methods: We created 100 pairings of common and uncommon renal diseases with keywords related to the features of the disease using a standard renal text as a guide. Nephrology attendings and fellows, and first and second year Internal Medicine Residents were given random selections of keyword parings and asked to identify the associated diseases. The residents were given the aid of the first ten results returned by the Google Search Engine with the input of any or all of the given keywords. The attendings and fellows were not allowed to use google. The diseases were divided in to two groups: common and rare, and the results were analyzed as a whole and separately as divided groups.

Results: Overall, the "Googlers" correctly diagnosed renal diseases less often than the nephrology attendings (72.2% vs. 84.7%, p<.001), but with the same frequency as the nephrology fellows (72.2% vs. 71.5%, p=.795). In a subgroup analysis of common diseases,the "Googlers" correctly diagnosed renal diseases less often than the attendings (76.6% vs. 90.5%, p<.001) and fellows (76.6% vs., 82.3%, p=.031). In a subgroup analysis of rare diseases, the "Googlers" correctly diagnosed renal diseases less often than the attendings (65.2% vs. 76.1%, p=.014), but more often than the fellows (65.2% vs. 56.2%, p=.029).

Conclusions: Google.com is a good tool to help medical residents diagnose renal diseases, but it does not take the place of a trained and experienced clinician. "Googling" a clinical question may be especially useful in the case of rare or "syndromic" diseases, but is likely to be less useful in diagnosing more common renal diseases.

TH-PO856

Further Validation of Peer Chart Audit To Assess Practice-Based Learning and Improvement in a Nephrology Fellow Continuity Clinic Setting Leslie F. Thomas,[1] Suzanne M. Norby.[2] *[1]Nephrology & Hypertension, Mayo Clinic, Phoenix, AZ; [2]Nephrology & Hypertension, Mayo Clinic, Rochester, MN.*

Background: Peer chart audit appears to be a valid method to assess the Practice-Based Learning and Improvement competency in a nephrology fellow continuity clinic setting, with overall data collection accuracy of 91% based on a validation study in our fellowship program in 2010. Accuracy appeared to be associated with the type of data abstracted and was similar for fellows in all 3 years of training. The purpose of this study was to compare accuracy of data collection in 2010 and 2011 and to re-evaluate the validity of peer chart audit in the 2011 fellow cohort.

Methods: Twelve nephrology fellows were instructed to review medical records of 10 consecutive non-dialysis patients with chronic kidney disease (CKD) stage 3, 4, or 5 cared for by another fellow. Five data points were assessed: whether a plan was documented for blood pressure (BP) > 130/80 mmHg; whether hemoglobin (Hgb) and parathyroid hormone (PTH) were measured during the prior 6 months or at the time of the visit; whether iron studies were checked if Hgb < 11 g/dL; and whether a total 25-hydroxyvitamin D2+3 (25[OH]D) level was checked if PTH > normal. Chart audits were then repeated by the program director. Results were compared to those from 2010.

Results: Of 120 patient records reviewed, 7 did not meet inclusion criteria and were excluded prior to analysis. Collections yielded 565 data points from 113 patient records. Overall accuracy did not differ between 2010 and 2011 fellow cohorts (86% vs 91%) nor among 1st year fellows (83% vs 95%), 2nd year fellows (91% vs 88%), and 3rd year fellows (85% vs 89%). Similar to 2010, Hgb data collection was more accurate than iron data collection (98% vs 84%; p=0.05), and PTH data collection was more accurate than 25[OH] D data collection (97% vs 81%; p=0.02). Eight fellows performed the audit in both years; accuracy of individual fellows did not differ significantly from year to year.

Conclusions: Peer chart audit yields valid results overall with 88% mean accuracy for both years combined. Accuracy differed depending on parameters assessed, confirming data from the previous study.

TH-PO857

All Are Not Created Equal: Categorization of Publication Entries on Applications Submitted to a Nephrology Fellowship Program Megan L. Krause,[1] Timothy R. Long,[2] Suzanne M. Norby.[3] *[1]Internal Medicine, Mayo Clinic, Rochester, MN; [2]Anesthesiology, Mayo Clinic, Rochester, MN; [3]Nephrology, Mayo Clinic, Rochester, MN.*

Background: Listing publications in the Electronic Residency Application Service (ERAS) is one way for trainees to distinguish themselves. The ERAS Publications category often includes a wide variety of projects that are not equivalent in academic merit, varying from peer-reviewed journal articles to residency morning report presentations. Since any academic product can be listed at the discretion of the individual applicant, an exaggerated list of total publications may result.

Methods: This study categorizes the type of publications listed by 183 applicants to a single Nephrology fellowship program.

Results: Of these, 155 (84.5%) entered at least one publication on their ERAS application. 64 applicants (41.3%) listed a total of 224 peer-reviewed journal articles (median=2; range 1-22 per applicant), 69 of which (30.8%) were first author. In addition, 13 applicants (8.4%) reported articles accepted but not yet published (range 1-5), and 38 (24.5%) included articles submitted but not yet accepted (median=2; range 1-6). Poster presentations were listed by 115 applicants (74.2%), with the majority (84.6%) presented at regional/national society meetings and the remainder displayed during institutional events. In contrast, oral presentations listed in ERAS were more likely to be delivered in an institutional venue (56.2%) such as journal club or noon conference rather than at regional/national meetings. "Other articles," such as student publications and ongoing projects, were listed by 17 applicants (11%).

Conclusions: The publications category in ERAS allows for heterogenous documentation, and similar number of total "publications" represents different levels of academic success among applicants. By highlighting quantity rather than quality, the current system for categorizing publications in ERAS obscures the ability of program directors to compare applicants based on academic productivity.

TH-PO858

Physician Role in Chronic Kidney Disease Patient Education: Perspectives from Nephrology Trainees Julie A. Wright, Melinda A. Coston, Talat Alp Ikizler, Kerri L. Cavanaugh. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Chronic kidney disease (CKD) education is an important component of patient care, yet little is known about nephrologists' perspectives on their own role in the patient education process. We performed structured interviews of nephrology trainees to gain insight on this topic.

Methods: Interviews of nephrology fellows were performed at one academic institution. Through moderated sessions, participants were asked a series of open ended questions about the role of physicians in patient CKD education. Transcripts were analyzed using content analysis.

Results: Seven out of 16 nephrology fellows (47%) participated. Mean (SD) age was 31 (2) years, 29% were female, 29% were Black, 29% Asian, and 42% White. Participants emphasized disease education as one of the most important roles of the physician. Patient education was viewed as separate from 'taking care of patients' and 'patient management'. 47% (93/196) of all statements focused on barriers to providing education. Limited patient understanding of medical information was perceived as a barrier by every participant. Other barriers included physician time constraints, complexity of CKD diagnoses, and cultural differences, including differing levels of patient formal education attainment. Facilitators included support staff, face-to-face communication, and written materials. Only 8% of statements discussed expectations physicians had of patients to learn more about CKD, and mainly centered on expecting patients to ask questions on topics about which they were unclear. Participants stressed a need for more multi-disciplinary, multi-media approaches using direct (e.g. face-to-face, classroom) and indirect (internet, literacy sensitive handouts) mechanisms of communication, to optimize existing patient education.

Conclusions: Educating patients about CKD is complex and perceived as a very important role by nephrology trainees. Of high importance to trainees was development of concise, clear, and culturally sensitive communication aids for physicians to use during patient encounters to facilitate optimal CKD patient education.

Effect of Multidisciplinary Pre-Dialysis Education in Advanced Chronic Kidney Disease Patients Assessed by Propensity Matched Pair Analysis Eun Jin Cho,[1] Yun Kyu Oh,[2] Ki Young Na,[3] Ho Jun Chin,[3] Curie Ahn,[1] Kook-Hwan Oh.[1] *[1]Internal Medicine, Seoul National University College of Medicine, Seoul, Korea; [2]Internal Medicine, Seoul national University Boramae Hospital; [3]Internal Medicine, Seoul National University Bundang Hospital.*

Background: The mortality and morbidity of end-stage renal failure patients remains high despite recent advances in pre-dialysis care. Previous studies suggested a positive effect on the patient survival and other outcomes for those receiving multidisciplinary pre-dialysis education (MPE). However above studies were limited by unmatched comparisons between the MPE recipients and non-recipients.

Methods: We performed a retrospective single center study, enrolling 1,218 consecutive pre-dialysis chronic kidney disease patients, between July 2007 and Feb 2008, and followed them up to 30 months. By using propensity score matching, we matched 149 recipient- and non-recipient pairs from 1,218 patients. The incidences of renal replacement therapy, mortality, cardiovascular event and infection were compared between MPE recipients and non-recipients.

Results: Renal replacement therapy was initiated in 62 and 64 patients in the recipients and non-recipients, respectively (P>0.05). The MPE reduced unplanned urgent dialysis (8.7% vs 24.2%, P<0.001), and shortened hospital days (2.16 vs 5.05 days/patient/year). MPE recipients had a better metabolic status at the time of initiating renal replacement therapy. Although no significant survival advantage from MPE was exhibited, MPE recipients had lower incidence of cardiovascular event (adjusted hazard ratio, 0.24; 95% CI, 0.08 to 0.78; P=0.017), and a tendency toward a lower infection rate (adjusted hazard ratio, 0.44; 95% CI, 0.17 to 1.11; P=0.083).

Conclusions: MPE was associated with better clinical outcomes in terms of urgent dialysis, cardiovascular events and infection.

TH-PO860

Health Literacy among Patients Referred to a Chronic Kidney Disease Clinic Dana Rizk,[1] Matt J. Glathar,[1] Rosalind M. Peters,[2] Jane S. Davis.[1] *[1]Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Nursing, Wayne State University, Detroit, MI.*

Background: In 2004 the Institute of Medicine Report highlighted that 90 million Americans have suboptimal literacy skills. Despite the high prevalence of chronic kidney disease (CKD) little is known about the health literacy level in that population or its impact on management and outcomes. The goal of our study was to determine the health literacy level among patients referred to the CKD clinic at our institution.

Methods: We recruited 37 consecutive patients on their first visit to the CKD clinic. All patients had prior follow-up by a nephrologist. We collected demographic and clinical data on each subject and administered a 34- item questionnaire assessing the patient's understanding of CKD, its symptoms, causes and risk factors for progression.

Results: The mean patient age was 58.6±15.5 years. Most patients were female (62.2%), white (54.1%), insured (97.3%) and high school graduates (83.7%). At referral 29.7%, 46% and 21.6% had stages III, IV and V CKD, respectively. Although 97.3% of patients acknowledged having CKD, only 43.2% could name its etiology. About 35.2% and 48.7% were unfamiliar with the terms "creatinine" and "glomerular filtration rate" respectively with no difference between those with <6 vs.>= 6 months of nephrology follow up. Although hypertension and diabetes were identified as modifiable risk factors for CKD, only 46% of hypertensives could name their target blood pressure and 40% of diabetics knew their target HgbA1C. Medication intake was significantly lower than prescribed (9.5± 4.8 vs. 12.5±5.6, p<0.0001). Most patients could identify some signs and symptoms of CKD like swelling and anemia, but were less likely to recognize uremic symptoms like anorexia, nausea and vomiting.

Conclusions: Despite a reasonable educational level and access to health care, patients referred to our clinic have a low level of CKD health literacy. Lower literacy has been related to worse outcomes in other chronic conditions. Whether educational interventions in the CKD clinic can improve health literacy remains to be seen.

TH-PO861

Fatal Flaws in Education about Vein Protection for Patients with CKD Marcia R. Silver. *Div of Nephrology, CWRU at MetroHealth Medical Center, Cleveland, OH.*

Background: HD patients using catheters for vascular access (VA) have much higher mortality and costs than those using AVFs. Yet ~80% of CKD patients starting HD in the US use catheters.. Medicare's Fistula First Breakthrough Initiative Change Concept 2 calls for vein protection "at the first sign of kidney disease." The best vascular surgeon can't make a native vein AVF if there is no intact vein to use.

Methods: A large dialysis company provides free classes about RRT options for CKD patients. They invite participants to enroll for follow-up. Some participants provide email addresses. We used these email addresses to query educated CKD patients about their knowledge of vein protection.

Results: Invitations to participate in this research were sent to 1,161 patients by email with a link to the SurveyMonkey survey. Responses came from 182 participants from 34 states. Mean age of respondents was 61 (range 21-96). 53% were male; 12% African-American. 40% had Diabetes. 43% had Stage 4 CKD. 16% reported CKD-1-3. 33% had CKD-5 or RRT. 49% had been advised to protect their non-dominant arm from needle sticks. Only 14% had been advised to use the dorsa of their hands for needle sticks rather than arm veins. Of those protecting veins, almost all understood why. Most who tried to protect their veins found health care personnel honored their requests.

Conclusions: Frequent venipuncture and intravenous catheter use are common in the current practice of medicine in the US. Vein protection is critical to success in creating AVFs in CKD patients. In this large convenience sample of CKD patients who received education about CKD and RRT, we found only ~ half understood the importance of vein protection, and only ~15% were protecting veins in both arms by preferentially using the dorsa of the hands for venipunctures (what we call vein-saving technique.) It is likely that participants in this study were patients with higher socio-economic status and more than average engagement in self care-suggesting average rates of education about vein protection may be lower than those found in our study. This study shows we need improved education of patients and staff to achieve better AVF rates and reduced mortality and costs in ESRD patients.

TH-PO862

Nutritional Intervention Program: An Important Tool for the Control of Hyperkalemia Carmen B. Tzanno-Martins,[1] Camila Machado de Barros,[2] Elzo R. Junior,[2] Bárbara Margareth Menardi Biavo.[2] *[1]Centro Integrado de Nefrologia; [2]Home Dialysis Center; [3]Universidade Federal do Rio Grande do Sul.*

Background: Nutritional intervention can prevent or control most metabolic disorders manifested in chronic kidney disease, including hyperkalemia, which is a risk factor for cardiac arrhythmias and sudden death. The purpose of this study was to evaluate the influence of knowledge about potassium before and after nutritional intervention in hemodialysis patients, four hours/session, three times/week.

Methods: This is a longitudinal, descriptive and primary data collection, which evaluated 61 elderly hemodialysis patients (> 60 years old), with serum potassium above 5.5 mg/dl. The nutritional intervention consisted of a lecture about hyperkalemia, with emphasis on restricting foods rich in potassium, interactive dynamics, games and distribution of educational materials. For assessment, a questionnaire of knowledge about potassium was applied before and after nutritional intervention.

Results: Of the 61 patients, 95% (n = 58) participated in the survey before and after nutritional intervention. Two patients (3.3%) were excluded, because one showed limited level of understanding both questionnaires and the other was absent on the day of sample collection. Of the 58 subjects, mean serum potassium of the last three months before nutritional intervention was 6.2 ± 0.5 mg/dL. After nutritional intervention, 49% of patients showed a decrease of serum potassium. The assessment of knowledge about potassium in the first analysis (pre nutritional intervention) showed that the highest percentage of individuals (55.7%) had less than 90% accuracy. In the second analysis (post nutritional intervention) 93.4% of patients scored higher than 90% of the questions.

Conclusions: The nutritional intervention proposal showed efficacy to increase potassium knowledge and provided benefits in short time. Because of this results we suggest keeping regular educational activities.

TH-PO863

Identifying Educational Needs of Nephrologists in the Management of ANCA-Associated Vasculitides Terry Glauser,[1] Chad Williamson,[1] Jennifer Garick,[1] Stuart M. Levine,[2] Mazi Abdolrasulnia.[1] *[1]CE Outcomes LLC, Birmingham, AL; [2]Department of Rheumatology, Johns Hopkins University, Baltimore, MD.*

Background: Sparse data exists in the current literature regarding practice patterns of physicians in managing patients with ANCA-associated vasculitides (AAV). This study was designed to identify current practice patterns and perceptions of nephrologists in managing these patients.

Methods: A case vignette survey was developed that allowed nephrologists to make diagnostic and treatment decisions for patients with limited and systemic Wegener's granulomatosis (WG) and with microscopic polyangiitis (MPA). The survey was distributed via email to U.S. nephrologists in November 2010, 44 responses were analyzed.

Results: Nephrologists had difficulty distinguishing different forms of AAV. When presented with a patient with clinical indications of MPA, 41% selected WG as the most likely diagnosis. Non-aggressive treatment goals were set, with only 16% considered remission as a goal for a 46-year-old man with limited WG and mild symptoms and likely capable of remission; most (65%) would try to improve symptoms or prevent disease progression. Selection of initial treatment for the patient varied: cyclophosphamide, 36%; nasal saline rinses/trimethoprim-sulfamethoxazole, 21%; nasal rinses/corticosteroids, 11%; oral corticosteroids/methotrexate, 11%. For a patient in remission after 3 months of oral cyclophosphamide, 58% would continue the regimen an additional 3 months before switching to azathioprine for maintenance; only 16% would switch after the initial 3 month regimen.

Regarding perceptions of management, nephrologists are most confident in managing active disease (75% very confident) and least confident in managing relapsed AAV (48% very confident) and differentially diagnosing forms of AAV (50% very confident).

Conclusions: This study identified perception and practice gaps in the management of patients with AAV by nephrologists, including lack of confidence in management, recognition of clinical differentiators, remission rates for therapy, and strategies to minimize cyclophosphamide exposure; all areas that can be addressed and improved through educational initiatives.

Organizational Communication Efforts for the Prevention of Catheter Related Blood Stream Infection from Hemodialysis Catheters Jaswinder S. Rattan,[1] Pavani Rangachari,[1, 2] P. J. Rissing,[1] Donna P. Goins,[1] Wanda Gillespie,[1] Lauren Hall,[1] N. Stanley Nahman.[1,3] *[1]Medicine, Georgia Health Sciences University, Augusta, GA; [2]Health Informatics, Georgia Health Sciences University, Augusta, GA; [3]Medicine, Charlie Norwood VAMC, Augusta, GA.*

Background: Catheter related blood stream infection (CRBSI) is a significant cause of morbidity and mortality (NEJM 355:2725, 2006). Use of CRBSI prevention practices (i.e., the "central line bundle") significantly reduces CRBSI. We previously showed that a lack of an organizational communication network for educating providers about CRBSI was associated with poor compliance with CRBSI prevention practices (CRBSI-PP) in the MICU (Q Manage Health Care, 19:330, 2010). To address these issues, a prospective study examining patterns of communication related to CRBSI-PP was initiated to measure compliance with bedside application of the CRBSI-PP, including the faculty and fellows in the Section of Nephrology. The educational effort included a required one hour didactic session reviewing the CDC recommended CRBSI-PP (the central line bundle) and successful completion of a hands-on session in the simulation center demonstrating application of the bundle.

Methods: The institution initiated the study in January 2011 and the present data reviewed after 15 weeks. Nephrology was educated in the CRBSI-PP in the 11th week.

Results: 100% of faculty (N=8) and fellows (N=6) completed the educational bundle. Compliance with application of the bundle for the 10 weeks prior (PRE) and 5 weeks after (POST) to the educational sessions was 37.5 vs 100 % for PRE vs POST, respectively. In addition, compliance with the 5th point of the bundle (daily documentation for continued use of the device) went from 0 to 100% following the educational intervention. These data indicate that a focused educational effort at improving communication about CRBSI improves compliance with the bundle.

Conclusions: Educational communication efforts result in higher compliance with CRBSI-PP by Nephrology faculty and fellows. We anticipate that this will result in a reduction in CRBSI associated with the placement of temporary hemodialysis catheters.

Nephrology Advanced Practitioner Salary and Benefit Information – A Survey Barbara M. Weis. *Division of Renal Hypertension and Diseases, University of Colorado-Denver, Aurora, CO.*

Background: Nephrology Advanced Practitioner salary and detailed benefit information is limited. NPs and PAs function similarly in Nephrology. The purpose of this study was to compare and contrast the salaries/benefits of NPs and PAs as well as the responsibilities of their positions.

Methods: NKF's Council of Advanced Practitioners (CAP) in conjuction with the American Academy of Nephrology Physician Assistants (AANPA)conducted a salary and benefits survey of NPs, CNSs (clinical nurse specialists), and PAs from January 2010 to June 2010. A Zoomerang link was sent out to CAP and AANPA members via email with directions that this link could be shared with other nephrology APs who were not CAP nor AANPA members. The survey link was sent out monthly for 6 months. There were 276 responses (CAP membership as of 6/1/10 was 240 and was used a denominator since many APs overlapped between CAP and AANPA) for a response rate of 115%.

Results: Over 85% of the respondents were white females, between the age of 31 and 59, who worked full time; 82% held a Master's degree. The top three places that APs work are dialysis unit (71%), office (46%) and hospital (31%). Within the dialysis unit, most APs handled dialysis rounds and primary care issues although close to half (49%) were responsible for call at the dialysis units. Within the office, most APs ran CKD clinics (59%) and did hospital follow-up visits (44%). The average annual salary for all full-time APs was $83,800. There was NO correction between degree and salary. There was a very STRONG correlation between years of experience and salary. Most common benefits were malpractice insurance (93%), health insurance (96%), and paid CME (88%). The most important 'benefit' to APs was to feel valued at work and to have a good working relationship with their physician partners.

Conclusions: In conclusion, the survey showed similar average salary and benefits for APs, with regional variances. Salaries are on the lower end of the spectrum when compared with other specialties, due to one primary payor (Medicare). APs continue provide a cost effective opportunity for the medical community to provide CKD and ESRD patient care.

TH-PO866

A Prospective Multi-Centre Evaluation of Timing of Renal Replacement Therapy for Acute Kidney Injury in Critically Ill Patients in Canada Edward G. Clark,[1] James William Barton,[3] Josee Bouchard,[4] Jan O. Friedrich,[5] Michelle A. Hladunewich,[6] Matthew T. James,[7] Jean-Philippe Lafrance,[8] Adeera Levin,[9] Louise M. Moist,[10] Neesh I. Pannu,[11] D. E. Stollery,[12] Ron Wald,[13] Michael Walsh,[14] Sean M. Bagshaw.[2] *[1]Kidney Research Centre, Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]Faculty of Medicine and Dentistry, University of Alberta, Edmonton, AB, Canada.*

Background: The optimal timing of initiation of renal replacement therapy (RRT) for acute kidney injury (AKI) is unknown. Defining current practice is necessary to properly design interventional trials. We sought to describe the current state of practice in Canada regarding the timing of initiation of RRT for AKI.

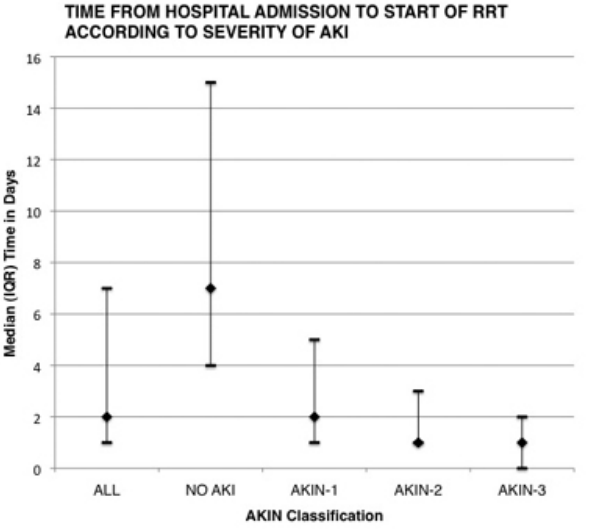
Methods: A prospective, observational study was undertaken at 10 intensive care units across Canada, enrolling 119 consecutive patients starting RRT for AKI. Data was collected regarding demographics, clinical and laboratory findings, as well as indications for, and timing of, RRT initiation.

Results: The mean (SD) age of patients starting RRT was 59 (15) and 34% were female.

Clinical and Laboratory Findings at Time of RRT Initiation

APACHE II Score, mean (SD)	27 (7)
Intubated / Receiving NIPPV, % (n)	83 (99)
Receiving Vasoactive Medication, % (n)	76 (90)
Loop Diuretic (Past 24h), % (n)	28 (33)
Serum Creatinine (umol/L), median (IQR)	322 (221-432)
Serum Urea (mmol/L), median (IQR)	20 (13-27)
Arterial pH, mean (SD)	7.25 (0.15)
Serum Potassium (mmol/L), mean (SD)	4.6 (1.0)

Median (IQR) time from hospital and ICU admission to the start of RRT was 2 days (1-7) and 1 day (0-2), respectively.



Conclusions: The ICU patients started on RRT in our study generally had advanced AKI, high illness severity, and received RRT early after hospital presentation. Our results describe the current state of practice with respect to the timing of initiation of RRT for AKI in Canada and should aid in the design of future interventional trials.

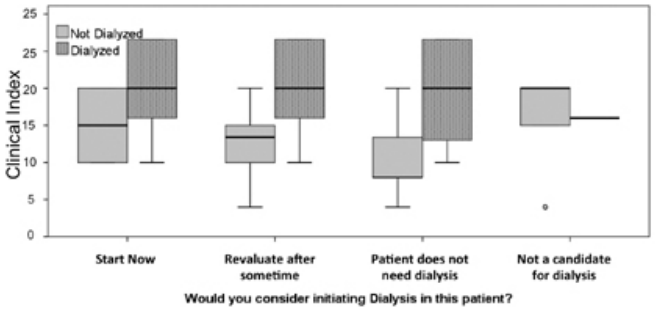
TH-PO867

Can Objective Criteria Improve Decisions for Dialysis Initiation in AKI? Etienne Macedo,[1] Josee Bouchard,[2] Jorge Cerda,[3] Ashita J. Tolwani,[4] Anjali Acharya,[5] Gary R. Cutter,[4] Ravindra L. Mehta.[6] *[1]University of Sao Paulo, Brazil; [2]Hôpital du Sacré-Coeur de Montréal, Canada; [3]Albany Medical College; [4]University of Alabama; [5]Jacobi Medical Center; [6]University of California San Diego.*

Background: Physician decisions vary widely on how criteria to initiate dialysis are applied. We hypothesized that an index based on clinical and lab data could characterize the need to support critically ill patients with renal replacement therapy (RRT) and correlate with physician decisions.

Methods: We utilized a web-based survey to present 12 real cases scenarios with pertinent clinical and lab data from 48 to 72 hs prior and up to the day of dialysis in actually dialyzed patients (n=6) or the day of peak creatinine in those patients that where not dialyzed (n=6). Physicians were asked whether they would dialyze immediately, reevaluate in some time, consider whether the patient does not need dialysis or would not benefit from dialysis. For each patient we calculated a clinical index (CI) each day. We analyzed the relationship of physician decision to start dialysis and the underlying CI on the day of dialysis or peak creatinine.

Results: There were a total of 206 questionnaires; 14 to 31 completed answers for each patient. Physician responses and actual events were frequently discordant (48%). Dialyzed patients had higher values of the CI. Within each category of physician choice, the CI correlated better with actual provision of dialysis than physician response. Among patients with lower CI value, physician choices correlated with the decision that the patient did not need dialysis.



Conclusions: Physicians decisions to initiate dialysis were influenced by the severity of illness, likelihood of benefit and logistic factors. An objective CI may provide further improvement in clinical decisions.

Funding: NIDDK Support

TH-PO868

Creatinine Clearance and Urine Sediment as Predictors of Need of Renal Replacement Therapy in Intensive Care Unit Patients with Acute Kidney Injury Radu R. Raducu,[1] Kolawole Omodayo Atandeyi,[1] Fredric O. Finkelstein.[1,2] *[1]Nephrology, Hospital of Saint Raphael, New Haven, CT; [2]Nephrology, Yale New Haven Hospital, New Haven, CT.*

Background: The patients who are admitted to ICU frequently develop AKI and are consulted by nephrologists. The study is evaluating the role of successive creatinine clearance measurements and urine sediment analysis as predictors of need of RRT during current hospitalization.

Methods: 57 patients were evaluated by nephrology department for AKI. The inclusion criteria were the following: age more 18 years, ICU location, nephrology consultation for AKI, strict monitoring of urine output through Foley catheters. A 2 hour creatinine clearance was measured on day of consult and at 24h and 48 h after nephrology consult. Urine sediment was evaluated on day of consult and an acute tubular necrosis score was devised. The patients were followed for the need of RRT during the entire hospitalization.

Results: 27 % of patients required RRT. In 95% of patients the renal injury was completely established at time of nephrology consult. In the five groups of patients (creatinine clearance at time of consult less than 2.5 mL/min, 2.5 to 5ml/min, 5 to 7.5 ml/min, 7.5 to 10 ml/min and more than 10 mL/min) the risk of requiring HD was 80%, 70%, 30%, 25% and 0%. If we consider the creatinine clearance at 48h the risk of requiring RRT was (in same groups) 100%, 80%, 50%, 0% and respectively 0%. ATN score was 5.5 in patients who didn't require RRT and 1.5 in patients who require HD (p-value= 0.23). The correlation coefficient between ATN score and creatinine clearance at time of consult was 0.135. The correlation coefficient between serum creatinine and need of RRT was 0.213.

Conclusions: At the time of nephrology consult the kidney injury is already completely established in the majority of patients with AKI and serial measurement of creatinine clearance is the best method to quantify the degree of injury, to evaluate the degree of recovery and to predict the need for RRT. Urine microscopy is not useful in predicting need for RRT (in fact kidneys with higher intrinsic function might have higher ATN score on urine analysis).

TH-PO869

Effect of Fluid Removal on Delivered Dose of Intermittent Hemodialysis (IHD) in Acute Kidney Injury (AKI) Rolando Claure-Del Granado,[1] Etienne Macedo,[2] Sharon Soroko,[1] Glenn M. Chertow,[3] Jonathan Himmelfarb,[4] Talat Alp Ikizler,[5] Emil P. Paganini,[6] Ravindra L. Mehta.[1] *[1]University of California San Diego; [2]University of Sao Paulo; [3]Stanford University School of Medicine; [4]Kidney Research Institute, University of Washington; [5]Vanderbilt University; [6]Cleveland Clinic Foundation.*

Background: Standard Kt/V (StdKt/V) is used to measure dialysis efficacy across different types of therapies of variable frequency in patients on chronic dialysis. In AKI, spKt/V or eKt/V is calculated for IHD. Previous equations to estimate StdKt/V were derived using a fixed-volume model. We evaluated the impact of fluid removal on StdKt/V. We hypothesized that not adjusting StdKt/V for fluid removal would underestimate delivered dose of IHD.

Methods: We analyzed data from 599 IHD sessions in 254 critically-ill patients with AKI from 5 centers included in the PICARD study. Delivered dose was calculated using spKt/V (Daugirdas equation), StdKt/V Leypoldt (Leypoldt JK et al. Semin Dial 17: 142-145; 2004) and using StdKt/V proposed by Daugirdas (Daugirdas JT et al. Kidney Int 77: 637-644; 2010) that includes effects of fluid removal. Patients with residual renal function were excluded. We compared the efficacy of 1 – 7 IHD sessions per week.

Results: A good correlation was found between spKt/V and Leypoldt StdKt/V (r^2 = 0.961; p < 0.001). StdKt/V was inversely proportional to the urea volume of distribution (r^2 = 0.017; p = 0.002). Higher frequency of IHD treatments per week was associated with increased delivered StdKt/V (median [IQR]): from 0.58 (0.47 – 0.67) for 1 treatment; 1.26 (0.92 – 1.47) for 2; 1.83 (1.50 – 2.15) for 3; 2.39 (1.91 – 2.84) for 4; 2.67 (2.17 – 3.19) for 5; 3.15 (2.60 – 3.97) for 6; and 3.77 (3.1 – 5.2) for 7 treatments per week respectively. Compared to Leypoldt StdKt/V, values of fluid removal adjusted Daugirdas StdKt/V equation were higher (2.0 IQR [1.5 – 2.7] vs. 1.9 IQR [1.4 – 2.5]; p = 0.001).

Conclusions: The use of StdKt/V Daugirdas et al equation provides an improved assessment of delivered dose of IHD adjusting for fluid removal. These results may inform the design of future studies of dialysis dose in AKI.

Funding: NIDDK Support

TH-PO870

Adverse Effects of Fluid Overload in Patients with Acute Kidney Injury Receiving Continuous Renal Replacement Therapy Min-Jee Han, Youn-Su Park, Jung-Ho Shin, Woojin Nam, Su Hyun Kim, Dong-Jin Oh, Suk-Hee Yu. *Department of Internal Medicine, Chung-Ang University College of Medicine, Seoul, Korea.*

Background: Extensive fluid overload leads to acute physiologic changes such as metabolic imbalance of sodium and water, pulmonary edema and respiratory failure. In critically ill patients with acute kidney injury (AKI), mortality rates range from 50 to 70% and have usually been attributed to multiple complications related to AKI. We thus investigated whether fluid overload is associated with mortality in critically ill patients with AKI receiving continuous renal replacement therapy(CRRT).

Methods: We retrospectively reviewed 100 patients with AKI treated with CRRT at Chung-Ang University Hospital between April 2005 and December 2010. The definition of fluid accumulation is still subject to debate, but we defined fluid accumulation as more than 4L as a sum of daily fluid balance over a period initiating at CRRT.

Results: Of the 100 enrolled patients, 70 were assigned to a fluid overload group and 30 to a fluid restriction group; there were no significant differences between the groups with respect to base-line characteristics. The most common cause of AKI was septic shock (44%), followed by cardiogenic shock (19%). In-hospital mortality was 81.4% in the fluid overload group compared with 66.7% in the fluid restriction group (P=0.005). The mean cumulative fluid balance was 12.7±8.5 L in the fluid overload group and 0.9±3.6 L in the fluid restriction group (P<0.001). During the interval from admission to the initiation of CRRT, the fluid overload group showed significantly higher incidence of mechanical ventilation apply (85.7% vs. 66.7%, P<0.001), and higher use of inotropics (88.6% vs. 66.7%, P<0.001) than the fluid restriction group.

Conclusions: In critically ill patients with AKI, fluid accumulation poses a higher risk of death. Our data supported the concept that fluid accumulation is at least partially responsible for a poor outcome in patients with AKI and defends the strategy of attempting to achieve fluid restriction if tolerated hemodynamically. Thus carefully verification of the daily fluid balance is a great help to decrease mortality for critically ill patients with AKI.

TH-PO871

Phosphate Balance in Critically Ill Patients on Continuous Venovenous Hemofiltration Shilpa Sharma, Sushrut S. Waikar. *Brigham & Womens' Hospital, Boston.*

Background: Hypophosphatemia is a frequent complication during continuous renal replacement therapy (CRRT), and may contribute to poor patient outcomes due to phosphate's critical role in energy metabolism in every organ system. We sought to quantify phosphate clearance during CVVH in our institution.

Methods: By adding a T-connector to the effluent line, approx. 1% of the 24 hr effluent volume was diverted to a collection bag. Estimated phosphate removal was calculated by multiplying the total effluent volume with concentration of phosphate in the effluent fraction. Results were verified by comparison to 4 hr complete collections in a subset of enrolled patients.

Results: Seventy-eight 24-hr effluent collections and thirteen 24-hr urine collections were performed on 25 patients. Most patients were anuric and received intravenous or oral phosphate.

Patient	CVVH days	Serum phos range(mg/dl)	Net phos removed(mg)	Net Infused phos(mg)	Net Phos Balance(mg)
1	4	2.3-3.4	5400.7	2574.8	-2825.9
2	6	2.2-3.8	11780.6	4322	-7458.6
3	7	2- 4.3	15684.9	1901.6	-13783.3
4	2	2.8-3.1	5273	558	-4715
5	7	2.2-6.8	8217.22	2116	-6101.22
6	2	1.7	5661.1	1088	-4573.1
7	2	2.4-2.6	6040.7	798	-5242.7

Conclusions: CVVH results in a negative phosphate balance despite protocol-driven phosphate repletion strategies. Substantial amounts of phosphate may be cleared by CVVH before overt hypophosphatemia develops. Further study is warranted to determine

the physiologic consequences of CVVH-induced phosphate depletion on bone health, energy metabolism, 2,3 biphosphoglycerate levels and subsequent oxygen delivery to peripheral tissues.

Plasma IL-10 Level and Monocyte HLA-DR Expression as Predictors in Critically Ill Patients Undergoing Continuous Renal Replacement Therapy

Chen Yu. *Nephrology, East Hospital, Shanghai, China.*

Background: To determine whether interleukin 10 (IL-10) level and monocyte expression of antigen-DR (HLA-DR) are predictors of infection and prognosis in critically ill patients undergoing continuous renal replacement therapy (CRRT).

Methods: A total of 43 critically ill patients undergoing continuous veno-venous hemofiltration (CVVH) were recruited from the intensive care unit (ICU). Anti-coagulated blood was obtained on the 1st, 4th, and 7th days after taken CRRT, and ELISA and flow cytometry were performed to determine serum IL-10 level and HLA-DR expression on the surface of $CD14^+$ monocytes, respectively.

Results: (1) Eighteen patients had no infection and negative cultures (Group 1) during the study; 19 patients had infection and positive cultures (Group 2) at entry; 6 patients had no infection (Group 3) at entry but became infected within 2 weeks after beginning CVVH; 7 patients died. (2) The IL-10 level was higher in patients than in healthy subjects ($P<0.001$), rapidly decreased in Group 1 after treatment ($P<0.05$), was unchanged in the remaining patients, and was closely related to the APACHE II score and duration of hospitalization ($P<0.05$). (3) Monocyte HLA-DR expression was lower in patients than in healthy individuals ($P<0.01$). After CVVH, most patients with increased HLA-DR expression were uninfected. However, patients with unchanged or declining HLA-DR expression were infected or developed post-treatment infection. The patients who died had persistent and extremely low HLA-DR expression.

Conclusions: IL-10 is an indicator of disease severity, and persistently high IL-10 level predicts poor prognosis. Persistently low monocyte HLA-DR expression can be used to predict concomitant or future infection.

Rational Use of Polymethilmetacrylate Dialysis Membrane To Remove Serum Free Light Chains

Paolo Fabbrini, Andrea Stella, Mariarosa Viganò. *Clinica Nefrologica Ospedale San Gerardo, Università degli Studi di Milano Bicocca, Milano, Italy.*

Background: in vitro study showed that PMMA dialysis membrane can remove at least up to 2 grams of FLCs through an absorption mechanism, but in vivo application showed variable results and no study have investigated maximum adsorbent capacity and time before membrane saturation in a 4 hours dialysis treatment. Aim of this study was to measure sFLC removal kinetic through PMMA membrane in order to optimize its use in clinical practice.

Methods: we performed 24 hemodialysis sessions (dialisys lenght 4 hours, dialyzer PMMA BK 2.1 Toray inc) in 7 consecutive patients with dialisys dipendent ESRD associated to elevated sFLC levels (4 l e 3 k) In each treatment we measured sFLC hour removal to calculate sFLC plasma reduction rate of each hour and of the entire session. According to these results we then performed 10 dialysis sessions of 4 hours substituting PMMA dialyzer every 2 hours using a specifically design circuit that allowed dialyzer switch without stopping dialysis session. Per hour and total treatment sFLC removal rate was calculated.

Results: the 24 single dialyzer sessions resulted in an hourly average reduction rate of 12,3 % (between 5% and 17%) that was effective only for the first two hours of treatment indicating saturation of PMMA membrane adsorption capacity. Coherently, entire session average sFLC removal was 23% (between 3% and 76%). During 10 double dialyzer sessions we measured average sFLC total removal of 50.9%(between 33,3 and 69%, $p<0.05$ vs single dialyzer) with an hourly rate removal of 12,5% ($p>0.05$ vs single dialyzer). Double dialyzer treatments did not change heparin use and albumin depletion in comparison with single dialyzer treatments.

Conclusions: dialysis with PMMA BK 2.1 can efficiently remove sFLC through absorption mechanism that reach saturation after 2 hours of treatment. The use of a dedicated dialysis circuit with membrane substitution after 2 hours improved treatment efficacy up to values that are usually reported for high cut off treatments indicating that PMMA can be considered a valid and not expensive therapy in FLCs removal.

TH-PO874

Evaluation of Free Light Chain Removal by Various Blood Purification Methods

Kyoko Kanayama, Midori Hasegawa, Yukio Yuzawa. *Nephrology, Fujita Health University School of Medicine, Toyoake, Aichi, Japan.*

Background: We evaluated various blood purification methods other than plasma exchange to remove free light chains (FLCs).

Methods: [CLINICAL study]Two patients of IgG kappa multiple myeloma and two patients of IgG lambda multiple myeloma with acute renal failure were treated by hemodiafiltration(HDF) using protein leaking dialyzer PES210Dα™ or hemodialysis(HD) using PMMA dialyzer. [IN study vitro]Dialysis using HCO membrane Theralite2100™ or plasma separator Evacure1A20™, diafiltration using protein leaking dialyzer PES210Dα™ and adsorption using β2microglobulin adsorption column LixelleS-35™ were performed in an *in vitro* circuit.

Results: [CLINICAL study]Removal rate of kappa FLC was from 21.8% to 71.6% by HDF using PES210Dα™ and from 38.3% to 71.0% by HD using PMMA dialyzer. Removal rate of lambda FLC was from 48.5% to 53.1% by HDF using PES210Dα™ and from 29.6% to 45.6% using HD using PMMA dialyzer. There was blood residue after HD using PMMA dialyzer when serum levels of FLCs were high. [IN study vitro]The highest removal rate was obtained by Theralite2100™dialysis among the four blood purification methods. Albumin loss was also the greatest in Theralite2100™dialysis. The removal content of FLCs per 1g albumin loss was better in PES210Dα™ diafiltration. The removal rate of FLCs by Evacure1A20 ™dialysis was the third highest. Adsorption of FLCs by the β2 microglobulin adsorption column Lixelle S-35™ was confirmed.

Conclusions: Theralite2100™dialysis was the best in removal of FLCs. In countries where Theralite2100™ is not available, HDF using protein leaking dialyzer could become an alternative option.

TH-PO875

Myoglobin Removal in Rhabdomyolysis: Clinical Studies and a Mathematical Model

Paolo Fabbrini,[1] Richard T. Keir,[2] Andrea Stella,[1] Colin A. Hutchison.[3] *[1]Clinica Nefrologica H San Gerardo, Monza, Italy; [2]University of Warwick, United Kingdom; [3]Renal Unit, University Hospital Birmingham, United Kingdom.*

Background: Acute kidney injury secondary to high serum myoglobin levels is a frequent cause of morbidity and mortality for patients with rhabdomyolysis. Theoretically rapid removal of myoglobin by protein permeable dialyzers would improve clinical outcomes for these patients by reducing the tubules exposure to myoglobin. The purpose of this study was to determine the optimum strategies for the removal of myoglobin in rhabdomyolysis using a high cut-off dialyzer.

Methods: Myoglobin clearance rates were studied in four patients with the HCO 1100, these were compared with those for high flux dialyzers and the larger 2.1m high cut-off dialyzer (Theralite). A four compartment model was then used to simulate use of these different membranes on different treatment schedules: continuous venous-venous hemofiltration and 2 and 8 hours of HD (each for a period of 3 days).

Results: The median percentage reduction in serum myoglobin levels was 52% (range 35-89) with HCO-HD. This equated to a median clearance rate of 34mls/min (range 10-63). The mathematical model parameters were fitted to these patients data and then simulated for treatment regimes of 2 hours at a myoglobin clearance rate of 2.2 ml/min (high flux dialyzer), 2 + 8 hours at 70 ml/min (Theralite 2.1m dialyzer) and continuous treatment at 34 ml/min (CVVH using the HCO 110 dialyzer). The simulations demonstrated that use of either of the two HCO dialyzers on both HD and CVVH settings resulted in greatly reduced renal exposure to myoglobin . Of the treatment options over a 3 day window CVVH using the HCO 1100 dialyzer reduced the area under the curve by 87% compared with standard HD. Simulations of HD using the Theralite dialyzer revealed a reduction in the AuC of 39 and 72% for 2 and 8 hour treatments respectively. All four patients recovered renal function and became independent of dialysis.

Conclusions: In summary, the HCO dialyzers provide a rapid reduction in myoglobin levels in rhabdomyolysis, clinical studies are now required to determine if this translates to improved patient outcomes.

TH-PO876

Light Chain Removal by Means of Adsorption in the Extracorporeal Treatment of Myeloma-Induced Cast Nephropathy

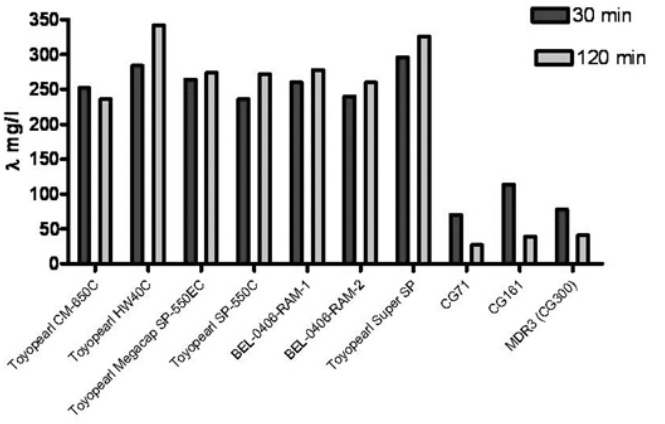
Elena Mancini,[1] Giuseppe Palladino,[2] Antonio Santoro.[1] *[1]Nephrology Dialysis Hypertension, Policlinico S.Orsola-Malpighi, Bologna, Italy; [2]Bellco s.r.l., Mirandola, Modena, Italy.*

Background: The combination of chemotherapy with dialysis removal of light chains (LC) has been described as a new therapeutic strategy for cast nephropathy (CaN). However, due to their hign molecular weight (κ 12,000; λ 24,000 daltons), LC could also be adsorbed by resins. Coupled plasma-filtration adsorption (CPFA), presents as an ideal technique. A different efficacy, in terms of LC removal may be expected on the grounds of the sorbent resin used.

Methods: We performed an *in-vitro* study to identify the resin with the best adsorptive capacity, followed by an *in-vivo* study to verify the magnitude of LC removal. In some patients, a longitudinal evaluation was carried out to obtain information on the LC trend.

In vitro: serum from different patients was perfused onto different sorbent resins. LC after 30 and 120 minutes perfusion were compared. In vivo: 4-hour CPFA was performed in 10 CaN patients utilising the cartridge whose adsorptive capacity proved best. Apart from blood (start and end-treatment), pre- and post-resin plasma samples were taken every hour

Results: The MDR3 resin showed the best adsorptive capacities.



In vivo, the mean LC adsorption by the MDR3 cartridge was better for κ (28%) than for λ chains (22%). The pre-to-post treatment blood reduction ratio was 31% for κ and 26% for λ chains. In patients treated with at least 6 sessions, the LC concentration progressively decreased (κ 68±11% , λ 55±9% ; p=0.05)

Conclusions: Extracorporeal LC removal may be performed not only by diffusion but even by adsorption in 4-hour treatments. The effect of variables such as the resin volume in the cartridge, plasma flow, treatment time, are to be tested. The best schedule for associating chemotherapy with extracorporeal adsorption still needs investigation.

The Incidence of the Citrate Accumulation during Continuous Veno-Venous Haemodialysis with Regional Citrate Anticoagulation – A Monocentric Retrospective Study Dmytro Khadzhynov, Torsten Slowinski, Christin Baumann, Ina Lieker, Hans-Hellmut Neumayer, Harm Peters. *Department of Nephrology, Charite Campus Mitte, Charite Universitätsmedizin, Berlin, Germany.*

Background: Systemic citrate accumulation due to compromised citrate metabolization is a complication of a continuous renal replacement therapy (CRRT) with regional citrate anticoagulation (RCA). Impaired liver function and arterial hypoxia are described in literature as risk factors for citrate accumulation. Metabolic acidosis, increased total calcium/ionized calcium ratio (total-Ca/iCa>2.25) and increased demand for systemic calcium substitution are the common markers for citrate accumulation. The aim of the present study was to assess the incidence and clinical characteristics of the citrate accumulation on the basis of representative patient population.

Methods: The data from all ICU at our university hospital in 2010 was retrospectively analyzed. Weight adapted RCA for continuous veno-venous hemodialysis (CVVHD) was performed according to the protocol published by Morgera et al.

Results: 13 (3.6%) of 365 patients treated with citrate-based CVVHD (66.4±12.9 years old treated, 53.8% male, APACHE score 31.5±8.6) have developed the characteristics of citrate akkumulation. Six of 13 Patients (46%) had pre-existing liver dysfunction (mean S-bilirubin before treatment: 7.7 mg/dL). Elevated Ca substitution demand (up 123±18% compared to baseline rate), simultaneous decrease in systemic iCa concentration (decrease by 10% to 1.04±0.09 mmol/L) and the increase in total-Ca/iCa ratio (2.31±0.26 mmol/L) have been observed in all 13 patients. At the time when citrate accumulation was diagnosed all 13 patients developed severe lactic acidosis (pH 7.20±0.13, lactate 126±59 mg/dL, bicarbonate 15.0±3.5 mmol/L). Anticoagulation modality was immediately changed to heparin in all 13 patients. 12 of 13 patients died from the therapy-resistant shock at the ICU.

Conclusions: The incidence of citrate akkumulation was 3.6% of all CVVHD treatments based on RCA. Citrate akkumulation was found exclusively in patients with severe lactic acidosis in septic shock and was associated with poor prognosis (mortality> 90%).

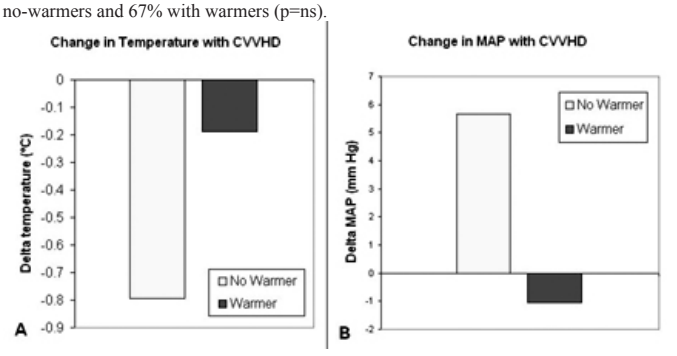
TH-PO878

Safety and Impact of CVVHD without Dialysate Warmers: A Difference of Opinion Swati Arora, Ayuk Eric Tabi, Leonardo P. Machado, Kalathil K. Sureshkumar, Rita L. McGill, Richard J. Marcus. *Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA.*

Background: Continuous veno-venous hemodialysis (CVVHD) is used to dialyze hemodynamically unstable patients. When the manufacturers of the device (NxStage®) had removed dialysate warmer from CVVHD circuit, intensive care unit (ICU) physicians expected adverse patient outcomes from the resulting hypothermia, but nephrologists expected cooled dialysate to be beneficial. This provided us a unique opportunity to study the impact of CVVHD with no warmers in critically ill patients.

Methods: We retrospectively reviewed the charts of patients who had CVVHD with or without warmers over a 6 month period. We calculated Sequential Organ Failure Assessment (SOFA) scores (range 0-24, higher the score, sicker the patient is), and collected core body temperature (cBT), mean arterial pressure (MAP), use of vasopressor drugs, ICU length of stay (LOS), and mortality.

Results: Thirty three patients without warmers had significantly lower cBT over the first 24 hours of CVVHD compared to 37 patients on warmers (35.4°C vs. 35.9°C, $P<0.05$). Fall in cBT from baseline was greater in the no-warmer group (0.79°C vs. 0.18°C, $p<0.05$), (figure 1A). Though there was a trend of higher MAP in patients with no warmers, absolute MAP during CVVHD did not differ between groups (77 mmHg vs. 73 mmHg, p=0.32), nor did ΔMAP from baseline (+5 mmHg vs. -1 mmHg, p=0.10), (figure 1B). SOFA scores did not significantly differ between no-warmer vs. warmer groups either at ICU admission (9±4 vs. 10±4) or 24 hours into CVVHD (12±3 vs. 12±4), nor did LOS (29±37 days vs. 29±31 days) or vasopressor use (1.3±1.0 vs. 1.2±1.3 agents). ICU mortality was 60% with no-warmers and 67% with warmers (p=ns).



Conclusions: Our study showed that CVVHD without dialysate warmer induced modest hypothermia. This did not adversely impact outcomes in critically ill patients.

TH-PO879

Pharmacokinetics of Ertapenem in Critically Ill Patients Receiving Continuous Venovenous Hemodialysis (CVVHD) or Hemodiafiltration (CVVHDF) Rachel F. Eyler,[1] A. Mary Vilay,[3] Michael Heung,[1] Melissa Pleva,[1] Kevin M. Sowinski,[2] Daryl Depestel,[1] Bruce A. Mueller.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Purdue University, West Lafayette, IN; [3]University of New Mexico, Albuquerque, NM.*

Background: Ertapenem (E) is a broad spectrum carbapenem antibiotic indicated in many infections found in the ICU. No dosing recommendations exist for E in critically ill patients receiving continuous renal replacement therapy. The purpose of this study is to determine the pharmacokinetics (PK) of E in critically ill adults receiving CVVHD/F.

Methods: This study was approved by the U Michigan IRB, and was a prospective, open-label first dose PK study of E in critically ill adults receiving CVVHD or CVVHDF. One gram E was infused over 30 minutes. Effluent and pre-filter blood samples were collected at 1, 2, 4, 8, 12, 18 and 24 hours following E infusion. Samples were analyzed by HPLC-MS/MS. Non-compartmental methods were used to estimate PK parameters.

Results: Eight subjects ([mean ± SD] age 62 ± 16 years, weight 78.9 ± 19.8 kg) were enrolled. CVVHD/F was delivered at effluent rates of 38 ± 9.7 mL/kg/hr. The half-life, apparent volume of distribution at steady state, area under the concentration-time curve from 0-24 hours, and the E serum concentration at 24 hrs were 8.8 ± 3.2 hrs, 0.19 ± 0.060 L/kg, 710 ± 150 mcg/mL*hr, and 10 ± 4.0 mcg/mL, respectively. The total clearance (CVVHD/F and systemic clearance) was 21 ± 5.7 mL/min. The sieving coefficient was 0.21 ± 0.065 and CVVHD/F clearance was 10 ± 4.2 mL/min.

Conclusions: E half-life was twice as long as what is reported in normal volunteers. CVVHD/F was responsible for substantial E clearance in these subjects. The one gram E dose produced serum E concentrations above the MIC sensitive breakpoint of 2 mcg/mL for *Enterobacteriaceae* spp. for 100% of the dosing interval for all 8 patients.

TH-PO880

Sulfamethoxazole and Trimethoprim Transmembrane Clearance during Modeled Continuous Hemofiltration A. Mary Vilay,[1] Jacob M. Kesner,[1] Renee-Claude Mercier,[1] Dean P. Argyres,[2] Scott E. Walker,[3] Craig S. Wong.[1] *[1]Univ. New Mexico; [2]VA Cooperative Studies Program; [3]Sunnybrook HSC.*

Background: Sulfamethoxazole (SMX) and trimethoprim (TMP) are administered concomitantly to treat a variety of infections. The physicochemical properties of SMX/TMP suggest they may be removed during continuous hemofiltration (CH). However, SMX/TMP removal during CH has not been systematically examined. The purpose of this study was to estimate SMX/TMP transmembrane clearance (CLtm) during modeled CH.

Methods: The invitro model consisted of 0.9 L heparin anticoagulated human blood continuously stirred at 37 °C. SMX/TMP was added to achieve concentrations of 160 ug/mL and 8 ug/mL respectively. Urea was added to serve as control. CH was performed with two commonly used hemofilters: HF1000 polysulfone (n=5) and M100 AN69 (n=5) hemofilters. Spent ultrafiltrate was recirculated back into blood to create a closed system. Ultrafiltration rates (Quf) of 1, 2, 3, and 6 L/h were investigated. At each Quf, prefilter blood and spent ultrafiltrate were collected and assayed for urea, SMX, and TMP. The concentration of solute in spent ultrafiltrate was divided by that in prefilter blood to calculate the extraction coefficient (E) of each solute. CLtm=E*Quf. Student's t-test was used to compare E between hemofilter types and ANOVA was used to compare E within each hemofilter type. P<0.05 was considered significant.

Results: Urea, the control solute, E was approximately 1 at all Quf rates studied.
SMX/TMP E and CLtm

Quf (L/h)	1	2	3	6	ANOVA p-value
SMX HF1000 E	0.39±0.03	0.38±0.03	0.40±0.03	0.40±0.03	0.71
SMX HF1000 CLtm (mL/min)	6±1	13±1	20±1	40±3	
SMX M100 E	0.31±0.03	0.33±0.05	0.32±0.02	0.33±0.04	0.74
SMX M100 CLtm (mL/min)	5±1	11±2	16±1	33±4	
t-test p-value for E	**0.01**	0.14	**0.01**	**0.02**	
TMP HF1000 E	0.62±0.05	0.58±0.04	0.64±0.05	0.64±0.05	0.19
TMP HF1000 CLtm (mL/min)	10±1	19±1	32±2	64±5	
TMP M100 E	0.67±0.07	0.75±0.12	0.74±0.07	0.73±0.10	0.57
TMP M100 CLtm (mL/min)	11±1	25±4	37±3	73±10	
t-test p-value for E	0.20	**0.02**	0.05	0.17	

Mean±SD

Conclusions: Substantial SMX/TMP CLtm was observed during CH with a HF1000 or M100 hemofilter at Quf between 1 and 6 L/h. Considering the CLtm observed and the nonrenal clearance reported to occur with SMX/TMP, SMX/TMP dosing adjustments during CH is required.

Funding: Other U.S. Government Support

TH-PO881

Piperacillin Clearance in Continuous Renal Replacement Therapy (CRRT) Predicts Failure To Reach Pharmacodynamic Targets Seth R. Bauer,[1] Peilin Wei,[2] Charbel A. Salem,[3] Joseph J. Groszek,[3] Maria E. Taylor,[2] Michael J. Connor,[4] Ashita J. Tolwani,[2] William Fissell.[3] *[1]Pharmacy, Cleveland Clinic, Cleveland, OH; [2]Nephrology, University of Alabama, Birmingham, AL; [3]Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH; [4]Pulmonology and Critical Care, Emory University, Atlanta, GA.*

Background: Sepsis is the leading cause of death in acute kidney injury (AKI). Early appropriate antimicrobial therapy improves survival in sepsis, raising concerns about interactions between CRRT dose and pharmacodynamics in sepsis. In an IRB-approved multicenter study, we measured piperacillin levels in patients receiving CRRT. Drug levels were compared with pharmacodynamic (PD) goals, and we identified factors associated with failure to reach PD goals.

Methods: Inclusion: Patients with acute or chronic renal failure receiving CRRT. Exclusion: ESLD, age < 18, pregnancy. Patient demographic and CRRT parameters were recorded. Sampling: After the fourth dose of antibiotic during uninterrupted CRRT, trough, 30 minute post infusion peak, and second trough blood and effluent samples were drawn and stored on ice. Drug analysis: Total, free, and effluent piperacillin levels were measured by HPLC. Data analysis: Traditional PK parameters (volume of distribution, elimination rate) were calculated. Logistic regression (JMP 9 for Windows) was used to test the association between PK and CRRT parameters and PD goals.

Results: 48 patients had data for analysis, of whom 36 had complete data. 11 patients had therapy interruptions between the peak and the second trough, and one had an error in sample collection. Pharmacokinetic parameters predicted attainment of PD goals of %t>MIC=64, as did total daily piperacillin dose. When total clearance was divided into CRRT and endogenous clearance, CRRT clearance was strongly and negatively predictive of achieving a PD goal of >50%T>MIC of 64 mcg/mL (OR 0.80 [95% CI 0.60-0.94] per mL/min of CRRT clearance).

Conclusions: CRRT significantly affects piperacillin PD. Higher CRRT clearance increases the risk of failing to meet PD goals. A larger multicenter study may permit more detailed analysis of the effect of PD on survival in CRRT.

TH-PO882

Piperacillin Pharmacodynamics Are Associated with Survival in Continuous Renal Replacement Therapy (CRRT) Charbel A. Salem,[1] Peilin Wei,[2] Maria E. Taylor,[2] Seth R. Bauer,[3] Michael J. Connor,[4] Joseph J. Groszek,[1] Ashita J. Tolwani,[2] William Fissell.[1] *[1]Nephrology and Hypertension, Cleveland Clinic, Cleveland; [2]Nephrology, University of Alabama, Birmingham, AL; [3]Pharmacy, Cleveland Clinic, Cleveland, OH; [4]Pulmonology and Critical Care Medicine, Emory University, Atlanta, GA.*

Background: Sepsis is the leading cause of death in acute kidney injury (AKI). Early appropriate antimicrobial therapy improves survival in sepsis, raising concerns about interactions between CRRT dose and pharmoacodynamics in sepsis. In an IRB-approved multicenter study, we measured piperacillin levels in patients receiving CRRT. We performed a logistic regression analysis to determine the impact of achieving phamacodynamic targets on survival in acute kidney injury.

Methods: Inclusion: Patients with acute or chronic renal failure receiving CRRT in the ICU. Exclusion: ESLD, age < 18, pregnancy. Patient demographic and CRRT parameters were recorded. Sampling: After the fourth dose of antibiotic during uninterrupted CRRT, trough, peak, and second trough blood and effluent samples were drawn. Drug analysis: Total, free, and effluent piperacillin levels were measured by HPLC. Data analysis: Standard PD parameters were calculated from plasma levels. We a priori analyzed age and severity adjusted hospital survival for percentage time that free drug exceeded MIC = 50% (fT>MIC 50%) and 90% (fT>MIC 90%) at an MIC of 64 ug/ml using logistic regression (JMP 9 for Windows).

Results: 48 patients had data for analysis, of whom 33 had acute renal failure and complete data for analysis. Age- and severity-adjusted hospital survival was not associated with the fraction of time the MIC exceeded fT> MIC > 50% , but fT>MIC>90% was strongly associated with survival (OR 21.9 [2.1-665], p < 0.008).

Conclusions: Piperacillin pharmacodynamics appear to be associated with survival in patients treated with CRRT, but the association was only seen at a PD target of fT > MIC > 90%, rather than a more conventional PD target to fT > MIC > 50%. This suggests that survival in dialysis-dependent acute renal failure might be improved by tailored antibiotic dosing, but more study is needed.

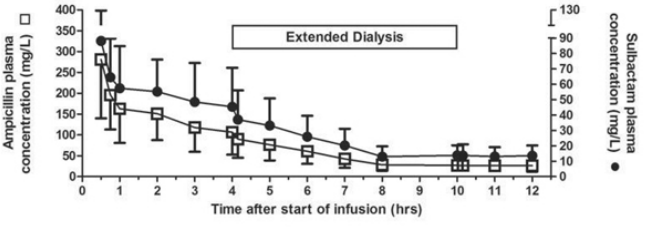
TH-PO883

Single and Multiple Dose Pharmacokinetics of Ampicillin/Sulbactam in Critically Ill Patients with Acute Kidney Injury Undergoing Extended Dialysis Johan M. Lorenzen, Jan T. Kielstein. *Nephrology, Hanover Medical School, Hannover, Germany.*

Background: The fixed antibacterial combination of ampicillin and sulbactam is frequently used for various infections. Intact kidneys eliminate ~ 60% of both substances. Patients on thrice weekly low flux haemodialysis exhibit an ampicillin half life of 2.3 h on and 17.4 h off dialysis. Despite its frequent use in intensive care units there are no dosing recommendations for patients with acute kidney injury (AKI) undergoing renal replacement therapy (RRT) available. Aim of this study was to evaluate pharmacokinetics of ampicillin/sulbactam in critically ill patients with AKI undergoing extended dialysis (ED) and to establish dosing recommendations for this treatment method.

Methods: Twelve critically ill patients with anuric AKI being treated with ED we enrolled in a prospective, open-label, observational pharmacokinetic study. Pharmacokinetics after a single dose of ampicillin/sulbactam (2g/1g) was obtained in twelve patients. Multiple dose pharmacokinetics after four days of twice daily ampicillin/sulbactam (2g/1g) was obtained in three patients.

Results: The mean dialyser clearance for ampicillin /sulbactam was 80.1 ± 7.7 / 83.3 ± 12.1 ml/min. The half life of ampicillin and sulbactam in patients with AKI undergoing ED was 2.8 ± 0.8 h and 3.5 ± 1.5 respectively.



There was no significant accumulation using a twice daily dose of 2g/1g ampicillin/sulbactam.

Conclusions: Our data suggest that patients treated with ED using a high-flux dialyzer (polysulphone, 1.3 m2; blood and dialysate flow, 160 ml/min; treatment time 480 min) a twice daily dosing schedule of 2g/1g ampicillin/sulbactam is necessary to avoid underdosing.

Clinical Data Imperfectly Predict Piperacillin Pharmacokinetics in Patients on Continuous Renal Replacement Therapy Peilin Wei,[1] Seth R. Bauer,[2] Charbel A. Salem,[3] Joseph J. Groszek,[3] Maria E. Taylor,[1] Michael J. Connor,[4] Ashita J. Tolwani,[1] William Fissell.[2] *[1]Nephrology, University of Alabama at Birmingham, AL; [2]Pharmacy, Cleveland Clinic, Cleveland, OH; [3]Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH; [4]Nephrology and Pulmonology and Critical Care Medicine, Emory University, Atlanta, GA.*

Background: Sepsis is the leading cause of death in acute kidney injury (AKI). Early appropriate antimicrobial therapy improves survival in sepsis, but dose calculations depend on knowledge of pharmacokinetic (PK) parameters, particularly the volume of distribution and the clearance. In an IRB-approved multicenter study, we prospectively measured piperacillin levels in patients receiving CRRT in the ICU. PK were compared to anthropomorphic data and CRRT prescription.

Methods: Inclusion: Patients with acute or chronic renal failure receiving CRRT in the ICU. Exclusion: ESLD, age < 18, pregnancy. Patient demographic and CRRT parameters were recorded. Sampling: After the fourth dose of antibiotic during uninterrupted CRRT, trough, 30 minute post infusion peak, and second trough blood and effluent samples were drawn and stored on ice. Drug analysis: Total, free, and effluent piperacillin levels were measured by HPLC. Data analysis: Linear regression (JMP 9 for Windows) was used to determine the associations between clinical data and PK parameters.

Results: 48 patients had data for analysis, of whom 35 had complete data. 12 patients had therapy interruptions between the peak and the second trough, and one had an error in sample collection. A multivariate linear regression model fitted Vd ($r^2 = 0.49$) and Ke ($r^2 = 0.30$) to patient and dialysis prescription data. Age ($p<0.01$) and weight gain since admission ($p<0.002$) were the only factors independently associated with Vd, whereas CRRT dose ($p<0.003$) was the only factor independently associated with Ke.

Conclusions: PK parameters needed to calculate piperacillin dose in patients receiving CRRT are imperfectly predicted by clinically available data. More information is needed to prospectively calculate optimal piperacillin doses for patients with AKI receiving CRRT.

A Mathematical Model To Predict Two-Phase Calcium Supplementation in Continuous Venovenous Hemofiltration with Regional Citrate Anticoagulation Yin Zheng, Zhongye Xu, Feng Ding, Chuan-Ming Hao. *Nephrology, Huashan Hospital, Shanghai, China.*

Background: Calcium substitution is a determinant of the safety and efficacy of regional citrate anticoagulation (RCA) during continuous renal replacement therapy . We developed and clinically validated a mathematical model of two-phase calcium supplementation during continuous venovenous hemofiltration (CVVH).

Methods: Thirty-two critically ill patients who required CVVH treatment with citrate anticoagulation were enrolled in the study. A two-phase mathematical model using patients' clinical characteristics (body weight, Hct, serum proteins concentration) and related treatment parameters (Qpw, Qsub, Quf, Qcit) was proposed to predict the need for calcium supplementation. By measuring systemic and extracorporeal citrate and calcium concentrations repeatedly, two coefficients in the mathematical equation, namely, the proportion of filterable calcium and the correlation between the concentration of calcium and citrate were studied. The model was validated in patients receiving RCA-CVVH.

Results: The calcium supply during RCA-CVVH can be divided into two phases by reaching the steady-state of citrate. The two pivotal coefficients were solved.The filterable calcium accounted for 87 ± 1% of total calcium. The highest correlation was found between the increased bound calcium concentration and the citrate plasma level ($r = 0.70$, $p < 0.001$). Applied the modeling method to 15 patients' treatments, it was able to control the level of systemic and circuit ionized calcium at a safe and steady range in the setting of different treatment parameters. Afterwards, it had been validated in more treatments of RCA-CVVH in our institute. The incidence of hypercalcemia or hypocalcemia was reduced (4.9% vs 16.7%) with less frequency of ionized calcium monitoring. However, the model appeared less precise after 24 hours of treatment.

Conclusions: In this study, a methodology of a two-phase calcium supplementation during RCA-CVVH was developed. With the aid of the mathematical model, safer calcium supplementation can be performed with less frequency of calcium monitoring.

In Spite of Positive Charge on Polyethyleneimine, AN69 ST Membrane Does Not Tightly Adsorb Heparin during Continuous Renal Replacement Therapy Jun Seok Choi, Su-Kil Park, Jung-Sik Park. *Nephrology, Asan Medical Center, Seoul, Republic of Korea.*

Background: Owing to the positive charge of polyethyleneimine (PEI), AN69 ST membrane adsorbs heparin 600 IU/m2 at the priming with the mixture of heparin and normal saline (5000 IU/1L). More heparin attached to AN69 ST membrane may increase the longevity of filter life. Without continuous systemic administration of heparin during renal replacement therapy (RRT), washing with normal saline 1L for 5~7 minutes after priming could remove the bleeding risk due to not adsorbed heparin. We compared the effects of priming with different heparin doses (5000 IU/L in group A vs. 20000 IU/L in group B) on filter life span and systemic coagulation parameters in critically ill patients with acute kidney injury in this randomized cross-over study.

Methods: Different doses of heparin were randomly assigned to 30 patients (M:F = 22:8, median of age 70 (range, 50~96 years)) at the 1st and 2nd filter during RRT.

Results: There was no difference of median values in baseline hemoglobin (9.2 (7.1~14) g/dL vs. 9.4 (8.3~14.2) g/dL, p=NS), platelet count (123000 (37000~475000)/mm³ vs. 115000 (23000~485000)/mm³, p=NS), activated partial thromboplastin time (aPTT, 39.1 (27.2~84.8) sec vs. 36.0 (27.2~69.6) sec, p=NS), prothrombin time (PT, 1.19 (0.98~1.76) INR vs. 1.17 (0.97~1.86) INR, p=NS), collagen/epinephrine clotting time (205 (69~300) sec vs. 214 (42~300) sec, p=NS), APACHE II scores (24 (7~34) vs. 24 (10~39), p=NS) and filter life span (15 h 15 min (5 h 5 min~71 h 47 min) vs. 15 h 59 min (3 h 40 min~71 h 32 min), p=NS) between two groups. Compared with baseline value of aPTT, its prolongation did not appear in 30 minutes after starting RRT in group A (from 39.1 (27.2~84.8) sec to 38.7 (25.3~98.6) sec, p=NS). However, aPTT significantly increased in group B (from 36.0 (27.2~69.6) sec to 38.9 (29.7~86.8) sec, p=0.012) without clinical events.

Conclusions: Priming with the higher dose of heparin and washing did not reveal the beneficial effect on filter life but prolonged aPTT. It suggests that PEI does not strongly enough bind heparin and requires heparin-coated filter where heparin can be adhered more tightly.

TH-PO887

The Evodialyser™ Can Be Used as a Heparin Free Alternative for SLED in ICU Monica Doyle,[1] Iain R. Macleod,[2] Sean McArtney,[1] Sally Crofts,[3] Judith A. Joss,[3] Iain S. Henderson,[1] Samira Bell.[1] *[1]Department of Renal Medicine, Ninewells Hospital, Dundee, United Kingdom; [2]Department of Intesive Care Medicine, Aberdeen Royal Infirmary, Aberdeen, United Kingdom; [3]Department of Intensive Care Medicine, Ninewells Hospital, Dundee, United Kingdom.*

Background: Sustained Low Efficiency Dialysis (SLED) has been increasing in popularity particularly in the care of critically ill patients within intensive care. Currently, most SLED treatments require the use of heparin to achieve prolonged dialysis times with slower blood pump speeds. Critically ill patients often have a bleeding tendency and thus a strategy to minimise or completely avoid systemic anti-coagulation would be clinically advantageous.

Evodialyser™ is a heparin impregnated dialysis membrane that has been developed to minimise the quantity of systemic heparin required for conventional intermittent haemodialysis.

We aimed to evaluate the use of the Evodialyser™ as a means of avoiding systemic heparinisation in intensive care patients with acute kidney injury (AKI) undergoing SLED.

Methods: We collated data prospectively in all patients in intensive care who required SLED from 01/07/2010 until 30/05/2011. The Evodialyser™ was used when the nephrologist felt it was indicated.

Results: During the study period 27 SLED treatments were carried out in 13 patients using the Evodialyser™. The median age of the study population was 71 years (IQR 65 – 77 years) The median APACHE II score was 26 (23-28) The indications for the use of the Evodialyser™ included coagulopathy, post major surgery and the use of Activated Protein C.

The standard treatment time was 8 hours with a mean time of 7 ± 2 hours achieved. 24 treatments (89%) were successful and achieved over 4 hours of SLED. Only 3 treatments were terminated at less than 4 hours and this was due to increased venous pressure in all cases. No systemic heparin was required in any patient. Ultrafiltration averaged 1.34 litres per session (Range 0-2L) and was achieved in all patients.

Conclusions: As far as we are aware, this is the first report of the use of the Evodialyser™ as an alternative means to avoid systemic heparinisation in critically ill patients undergoing SLED treatment in intensive care.

TH-PO888

Study on a Regional Citrate Anticoagulated Continuous Venovenous Hemodiafiltration Protocol with Variable Treatment Dose Ina Lieker, Dmytro Khadzhynov, Harm Peters, Hans-Hellmut Neumayer, Torsten Slowinski. *Department of Nephrology, Charite Universitätsmedizin, Berlin, Germany.*

Background: In order to add convective solute transport to a recently described citrate-CVVHD protocol we established a citrate anticoagulated CVVHDF protocol with variable treatment dose. To allow convective transport, we designed a new citrate-CVVHDF protocol with a postdilution hemofiltration dose.

Methods: Prospective observational study. A CVVHDF-based citrate anticoagulation protocol on the MultiFiltrate™ CRRT-device (Fresenius Medical Care, Germany (FMC)) using a 4% trisodiumcitrate solution, the dialysate fluid Ci-Ca™Dialysate K2 (FMC), and a continuous calciumchloride (91 mmol/L) infusion. For the filtration dose we used a standard bicarbonate-buffered substitution fluid (MultiBic™, FMC) in postdilution. 60 patients on ICU with acute kidney injury and need for RRT were included. For variable dose patients were divided in 3 groups according to their bodyweight.The initial flows for dialysate/substitution fluid in the groups were 1400/800, 1800/1000, and 2200/1200 mL/h, blood flow 80, 100, 120 mL/min, citrate flow 145, 175, 220 mL/h, and calcium flow 32, 45, 57 mL/min. Citrate flow was adjusted to postfilter ionized calcium measurements, target range 0.25-0.35 mmol/l, Calcium flow was adjusted to patients systemic iCa. Treatment time was limited to 72 hours.

Results: 49 of 60 patients reached the maximum treatment time of 72 h without clotting. Acidbase control: mean [95%CI] pH; st-bicarbonate at 48 h: 7.42 [7.38-7.44]; 24.6 [21.3-27.8] mmol/L, at 72 h: 7.39 [7.35- 7.43]; 25.0 [21.3-27.6] mmol/L. Electrolyte control: mean [95% CI] s-sodium; s-potassium at 48 h: 139 [137- 141]; 4.8 [4.4-5.2] mmol/L, at 72 h: 139 [137-142]; 4.9 [4.4-5.4] mmol/L. Mean [95%CI] treatment dose was 41 [37-46] mL/kg/h, mean [95%CI] s-urea at 48 h: 51 [37-66] mg/dL, at 72 h: 50 [35-65] mg/dL.

Conclusions: The citrate-CVVHDF protocol allows combined hemodialysis and -filtration in CRRT with variable treatment dose and with the advantages of regional citrate anticoagulation. In this study in 60 patients filter run-time in citrate-CVVHDF was remarkable and metabolic control excellent.

TH-PO889

Prescribing for Regional Citrate Anticoagulated Continuous Venovenous Hemodiafiltration (CVVHDF) Michele Giuseppe Messa,[1] Vittorio Ortalda,[1] Antonia Fabris,[1] Saulle Mazzolini,[2] Antonio Lupo.[1] *[1]Università Verona, Italy; [2]AOU Udine, Italy.*

Background: Although the use of regional citrate anticoagulation (RCA) for continuous renal replacement therapy (CRRT) continues to grow, current approaches have many drawbacks, including the use of unphysiologic, concentrated citrate solutions and the requirement of infusion pumps external to the CRRT device. For the study purpose we used a diluted citrate anticoagulant solution (sodium citrate12 mmol/l) in combination with a CRRT device which has an integrated pump specifically designed for the infusion of fluids proximal to the blood pump. Aim of the study was to identify the primary factors influencing calcium balance at different target citrate doses during CVVHDF therapy

Methods: In 17 acute kidney injury (AKI) pts, RCA was performed with different blood (Qb), citrate (Q_{Ci}), and dialysate (Qd) flow rates at target pre-filter blood citrate concentrations of 3, 4, 5 mmol/l_Qb. Postfilter ionized calcium (iCa_{post}) was measured for each Q_{Ci}, while total calcium in the effluent (Ca_e) was measured for each of the resulting flow combinations. Systemic haemoglobin (Hb), hematocrit (Htc), serum total calcium (sCa), total protein (sProt) and albumin (sAlb) concentration were also measured before starting each study procedure. Calcium mass transfer rate (MTRCa) was estimated from the product of Ca_e and the effluent flow rate. Based on multivariate regression analysis (MVRA), equations providing predicted values of iCa_{post} and Ca_e were developed

Results: MVRA indicated iCa_{post} was influenced by Q_{Ci} ($p < .0001$), sProt ($p < .001$) and sCa ($p < .0001$). MVRA also demonstrated that calcium in the effluent (Ca_e) depends largely on Q_{Ci} ($p < .0001$), Qd ($p < .0001$), sCa ($p < .0001$) and Qb ($p < .0001$). A significant correlation between observed and predicted values was determined for both iCa_{post} and Ca_e.

Conclusions: Our results characterize the important treatment-related factors influencing calcium balance during RCA with a diluted citrate anticoagulant solution. These data also suggest the possibility for development of a model in which calcium parameters are predicted based on these treatment-related factors.

TH-PO890

Regional Citrate Anticoagulation during Continuous Veno-Venous Hemodialysis: Two-Year Single-Center Experience Dmytro Khadzhynov, Christin Baumann, Torsten Slowinski, Ina Lieker, Hans-Hellmut Neumayer, Harm Peters. *Department of Nephrology, Charite Campus Mitte, Charite Universitätsmedizin, Berlin, Germany.*

Background: Regional citrate anticoagulation(RCA) has been shown to be a safe and effective form of anticoagulation for continuous renal replacement therapy(CRRT) in patients with high risk of bleeding. More over, it was recently assumed that the citrate application can bring a benefit in survival. We report a two-year single-center experience of renal replacement therapy based on a continuous veno-venous hemodialysis(CVVHD) with regional citrate anticoagulation.

Methods: Results of CRRT conducted in years 2008 and 2009 at 6 intensive care units at our university clinic are retrospectively analysed. CVVHD with RCA is a modality of choice at our campus and is initially used in the majority of cases, regardless of the patients bleeding risk and/or liver function. Collected data included demographic features, dialysis circuit life-time, overall mortality at ICU discharge.

Results: We detected 703 patients(in average 67.6±12.4 year old, 64.6% male, average APACHE score 26.2±8.5) treated with CVVHD with RCA from 01.01.2008 till 31.12.2009. Mean uncensored filter life-time was 66.4±42.5 hrs. CVVHD was performed in 181 patients (63.4±43.5 hrs) at general anaesthesiology ICU, 252 patients (66.0±42.1 hrs) at cardio-surgery ICU, 62 patients (76.3±41.1 hrs) at general surgery ICU, 68 patient (67.5±42.5 hrs) at cardiology ICU, 23 patients (77.5±46,8 hrs) at neurological ICU and 117 patients (65.9±42.4 hrs) at infection ICU. The incidence of citrate accumulation was 3.7% of all CVVHD treatments based on citrate anticoagulation. Renal recovery in patients treated with CVVHD based on RCA was 60,1% at ICU discharge. Overall mortality of the patients treated with citrate based CVVHD was 36.4% at ICU discharge.

Conclusions: Protocol of RCA for CVVHD was used as a standard modality of CRRT, regardless of the patients bleeding predisposition. The modality of CRRT was applied with equal success at 6 differently orientated ICUs of our university hospital. This approach allows reaching perfect regional extracorporeal anticoagulation efficacy with an adequate metabolic control.

TH-PO891

Digoxin Intoxication in Acute or Chronic Kidney Failure – Elimination of Digoxin Bound to Fab-Fragments (Digifab®) with High Cut-Off Filter Dialysis Susanne V. Fleig, Roland Schmitt, Jan T. Kielstein, Bernhard M.W. Schmidt. *Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.*

Background: The cardiac glycoside digoxin is renally eliminated and not dialyzable. In cases of symptomatic intoxication, serum digoxin can be bound by anti-digoxin-antibody-fragments (Digoxin Immune Fab) and thereby inactivated; digoxin-antibody-complexes are then renally excreted. Digifab® (Digoxin Immune Fab) has a molecular size of 46kDa and does not pass normal dialysis filters. In dialysis-dependent patients, digoxin is set free again after degradation of Fab-fragments and symptoms of intoxication may reoccur.

Methods: We report two cases of dialysis-dependent patients (one with end- stage renal disease, one with acute postoperative renal failure) with symptomatic digoxin intoxication.

Results: Both had been given Digoxin Immune Fab (digifab®), which led to relief of symptoms for several hours. Yet, symptoms reappeared as the agent could not be excreted and was set free again after degradation of the antibody fragments.Six hours after a second dose of Digoxin Immune Fab (digifab®), we performed extended dialysis (Genius® singlepass dialysis system (Fresenius Medical Care)) with high cut-off dialyzers (Theralite®, HCO1100®, both for removal of plasma components with a molecular weight up to 45kDa). This way, we were able to eliminate fab-fragment bound digoxin. After dialysis with these filters, symptoms did not recur in both patients, and serum digoxin levels remained low (Digoxin levels: 4.72 nmol/l and 5.0 nmol/l before treatment, 2.08 nmol/l and 2.01 nmol/l directly after dialysis and 2.66 nmol/l and 2.50 nmol/l 12 hours after dialysis).

Conclusions: We show that dialysis with high cut-off filters can eliminate fab-fragment bound digoxin in patients with symptomatic digoxin intoxication and severely impaired kidney function.

TH-PO892

Path Batch Hemodialysis (PBH): A Safe and Efficient Method for Acute Kidney Injury (AKI) Cancer Patients in the Intensive Care Unit (ICU) Veronica T. Costa e Silva,[1] Ana Paula Leandro Oliveira,[1] Henrique Palomba,[1] Ludhmila Abrahão Hajjar,[2] Elerson Costalonga,[1] James Hung,[1] Luciane Oikawa,[1] Juliana Silva Bezerra,[1] Emmanuel A. Burdmann,[1] Luis Yu.[1] *[1]Nephrology Division, Sao Paulo State Cancer Institute - University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [2]Intensive Care Unit Department, Sao Paulo State Cancer Institute - University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: The adequacy and safety of BPH have not been studied in ICU cancer patients (pcts).

Methods: We prospectively analyzed all PBH performed in AKI adult cancer pcts in the Sao Paulo State Cancer Institute ICU from June 2010 to May 2011.

Results: A total of 242 PBH were performed in 76 AKI pcts. Pcts' characteristics were age 61 ± 14 y, 60.5% male, 17.8% on vasopressors and 12.4% on mechanical ventilation. Most (82.9%) patients had solid cancer (genitourinary tract 38.2%, gastrointestinal tract 11.8% and gynecologic system 11.8%). The most important AKI etiologic factors were sepsis (48.7%), obstructive uropathy (24.7%) and surgery (21.1%). General ICU mortality was 50.7%. Venous access was temporary catheter in 97.9% (58% femoral and 41% internal jugular veins), high-flux polysulphone membrane in all filters (FS80 in 63.2%) and median blood and dialysate flow 250 (200 – 300) mL/min. Systemic anticoagulation was not used in 69.4% due to heparin contraindications. Median pre and post serum urea levels were 154 (109 – 199) and 62 (47 – 89), respectively. Urea reduction rate > 55% was observed in 62% of dialysis. The prescribed UF was 1500ml (1000 – 2000), which was attained in 66.2% of the procedures. The prescribed dialysis time was 240 (240 – 315) min, which was attained in 77.7% of dialysis. The main complications were hypotension (mean blood pressure <70 mmHg) in 27.3% (8.3% required dialysis interruption), prescribed blood flow reduction in 7.9%, lines reversion in 16.9% and system coagulation causing dialysis interruption in 16%. Clotting was associated with the need for decreasing blood flow (OR 6.3/CI 2.3 – 17.3) and heparin use (OR 0.31/IC 0.1 – 0.9).

Conclusions: In conclusion, PBH seems to be a safe and efficient alternative for dialysis in AKI ICU cancer pcts.

TH-PO893

Application of Plasmadiafiltration in Porcine Sepsis Models Induced by Laparoscopic Cecal Ligation and Puncture Jun Xue. *Nephrology, Huashan Hospital, Fudan University, Shanghai, China.*

Background: To study whether plasmadiafiltration (PDF) can reduce the circulating levels of critical inflammatory macromolecules, thus improve hemodynamics and increase survival time after establishing a porcine sepsis model by laparoscopic cecal ligation and puncture (CLP).

Methods: Twelve 80-day and 36-kilogram domestic male swine which fitted the diagnostic criteria of sepsis induced by laparoscopic CLP, were randomly treated either by PDF or by normal saline. PDF was performed with a selective filter with molecular weight cut-off (MWCO) of 60-70KD. The circulating levels of TNF-α trimer and high mobility group box 1(HMGB1), blood pressure and pulmonary arterial wedge pressure (PAWP) averaged cardiac output were assessed.

Results: Total of the 12 swine were successfully made as sepsis models. The odds ratios of PDF to reduce the circulating levels of TNF-α trimer and HMGB1 were 1.97(95%CI, 1.64-2.51, *P*=0.012), and 1.97(95% CI, 1.67-2.46, *P*=0.007), respectively. The odds ratios of PDF to improve systolic pressure and PAWP averaged cardiac ouput were 1.07(95%CI, 1.00-2.59, *P*=0.001) and 6.34(95% CI, 2.89-25.3, P=0.032), respectively. A linear relation was found between diastolic pressure and TNF-α trimers through multiple linear regression analysis (*P*=0.032).We also found a linear relation between PAWP averaged cardiac ouput and TNF-α trimer (*P*=0.043). The mean survival time was 36.3 hours for PDF group and 31.5 hours for control. In PDF group the risk ratio of death of all-cause was 0.11 (*P*=0.046), as compared with control.

Conclusions: We can successfully make porcine CLP sepsis models through laparoscope. PDF can reduce the circulating levels of critical inflammatory macromolecules, therefore improve the hemodynamics and increase survival time in animal sepsis models.

Membrane vs. Centrifuge Based Therapeutic Plasma Exchange – A Clinical Cross-Over Comparison Jan T. Kielstein, Carsten Hafer, Ansgar Reising, Bernhard M.W. Schmidt. *Department of Hyertension and Nephrology, Medical School Hannover, Hannover, Germany.*

Background: Therapeutic plasma exchange (TPE) is either performed using a centrifugation device (cTPE), a method preferred by hematology or blood bank-based physicians or by using a highly permeable filter with standard hemodialysis equipment (mTPE), a method preferred by nephrology-based physicians. The aim of the study was to perform the first direct comparison of these two techniques.

Methods: We performed a prospective, cross-over study comparing mTPE using the OctoNova device using the Plasmaflo OP 05W (Asahi Kasei Medical, Japan) with cTPE using the Spectra Optia (Caridian BCT). Seventeen patients that underwent TPE against albumin based substitution fluid were randomized to start either with cTPE or mTPE. The second treatment was done in a cross over design. We did choose this approach to allow

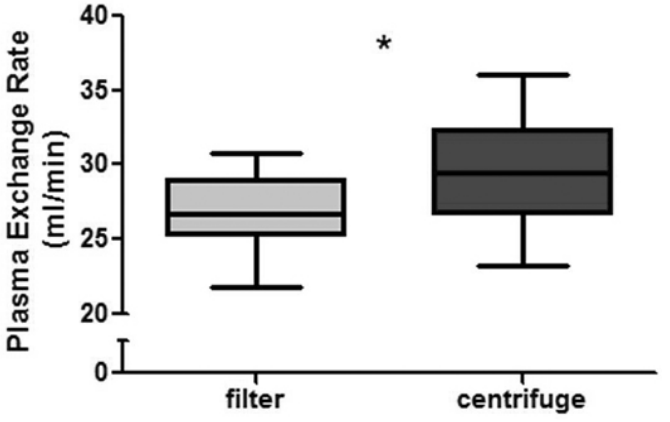
the measurement of the total removed immunoglobulines in the waste bag. We also took samples for complete blood count, immunoglobulines and fibrinogen before and after treatment and recorded the treatment time without any adverse effects on parameters measured in the complete blood counts.

Results: While there was no difference in the reduction rate as well as the absolute amount of immunoglobolines removed by the different techniques, cTPE allowed a faster exchange/treatment time (plasmavolume/treatment time).

Comparison of cTPE and mTPE

Parameter	unit	mTPE	cTPE
Pre-treatment IgG	g/L	6.05 ± 2.65	6.49 ± 2.84
Post-treatment IgG	g/L	2.15 ± 0.79	2.35 ± 1.15
Pre-treatment IgM	g/L	0.76 ± 0.34	0.81 ± 0.40
Post-treatment IgM	g/L	0.38 ± 0.13	0.44 ± 0.15
Total IgG in waste bag	g	12.31 ± 5.20	11.91 ± 6.29
Total IgM in waste bag	g	1.27 ± 0.57	1.50 ± 0.84

Data presented as mean ± SD



Conclusions: Centrifuge based techniques allow faster clearance of plasma from marker substances like IgG and IgM without any adverse events.

TH-PO895

Can MARS Be a Solution for Type 1 Hepatorenal Syndrome? Siba Kallab, Laurence Lavayssiere, Nadine Bassil. *Nephrology-Dialysis-Transplantation, CHU Rangueil, Toulouse, France.*

Background: Hepatorenal syndrome (HRS) is the development of acute renal failure due to excess splanchnic and systemic vasodilation in patients with severe liver failure. The molecular adsorbent recirculation system (MARS) is a liver support system based on albumin dialysis which can potentially reduce systemic vasodilatation by removing protein-bound vasodilators.

The aim of this study was to determine whether the MARS technique is able to improve renal function in patients with type 1 HRS.

Methods: A four-year retrospective study (2006-2010) was carried out in a specialized nephrology intensive-care unit (ICU) .The study group comprised 32 patients who had type 1 HRS and who underwent MARS treatment. Our endpoint was the complete, partial and the absence of renal recovery at 28 days after the diagnosis of type 1 HRS. We considered complete renal recovery (CRR) as a serum-creatinine level less than 133 µmol/L after treatment. Partial renal recovery (PRR) was defined as a 10% decrease in baseline serum creatinine level. We considered non-responders as all patients who required hemodialysis (HD). We made a one month follows up to assess renal recovery for the patients who received during the study period a liver transplantation .

Results: On admission to the ICU, the median MELD and SOFA score were 36 and 13 respectively ; 52 % had F score for RIFLE criteria .There was no significant difference between 24-h urine volume prior to and after MARS treatment ($p=0.7$).Thirteen of the 32 (40.6%) patients survived at 28 days. Of these, 5 patients (15.7%) had CRR, 5 other patients had PRR (15.7%) and in the 3 last patients kidney function did not recover. All the patients who died (19/32) required HD . Six patients had received a liver transplant during the period of study. Only one of these died due to severe hemorrhage during the transplantation while, in a one month follows up, 2 patients had CRR, 2 other patients had (PRR) and one patient required chronic hemodialysis.

Conclusions: In the present study, MARS therapy did not allow improving renal function in patients with type 1 HRS. MARS was a *bridge* to liver transplantation in two patients who had a complete renal recovery at a one month follows up.

Funding: Government Support - Non-U.S.

TH-PO896

Intraoperative Slow Low-Efficiency Dialysis during Emergency Surgery in Critically Ill Patients Joanna Matuszkiewicz-Rowinska, Grzegorz Ostrowski, Mariusz Mieczkowski, Pawel Kulicki, Tadeusz Grochowiecki, Waldemar Patkowski, Krzysztof Dudek, Bohdan Solonynko. *Medical University of Warsaw, Warsaw, Poland.*

Background: There is some positive experience with intraoperative hemodialysis in cardiac and liver transplant surgery, however data concerning other surgical procedures are scarse.In this study we present our experience with intraoperative slow low-efficiency dialysis (SLED) performed during emergency laparotomy.

Methods: In all cases SLED was chosen since it remains the method of choice in hemodynamically unstable critically ill patients in our center. The Genius® single-pass system was used, with blood flow 160, and dialysate flow 80 ml/min.

Results: Intraoperative SLED was performed in four men, aged 30-59 years. The diagnoses were as follows: reoperation due to massive hemorrhage after bilateral adrenalectomy, intestinal ischemia after abdominal aortic stent-graft placement, multiorgan injury after traffic accident, and liver retransplantation. All presented pts were hemodynamically unstable, 3 of them were given catecholamines. One of the pts had chronic kidney disease Stage 3, and the remaining 3 – acute kidney injury; in 3 pts anuria was present. The indications for emergency dialysis were: severe uncompensated lactic acidosis (3 pts) with tissue necrosis (2 pts), life-threatening hyperkalemia (3 pts) with need for RBC transfusion (3 pts), and massive overhydration (1 pt). In all cases SLED was well tolerate and successfully perfomed for 12 hours. Although only one pt received heparine, and 3 pts were given only saline flushes no filter circuit clotting was observed. The pt with intestinal necrosis died in 14 hours later, in the remaining 3 dialysotherapy was continued, however all of them died due to multiorgan failure.

Conclusions: In conclusion, our data suggest that intraoperative SLED is a safe procedure, and can be used in hemodynamically unstable pts with life- threatening fluid, electrolyte and acid-base disorders who need emergency surgery

TH-PO897

Pediatric CRRT for Severe Hyperosmolarity and AKI Timothy E. Bunchman. *Pediatric Nephrology, VCU School of Medicine, Richmond, VA.*

Background: Renal replacement therapy (RRT) for AKI with associated severe hyperosmolality may result in dialysis disequilibrium, cerebral edema or death. This is in part due to rapid changes in osmols related to the "normal" osmlarity of the dialysate as well as the volume of the dialysis solution per a RRT prescription. The osmolality of the dialysate in hemodialysis (HD) can be adjusted only within constraints of the conductivity of the HD machine, but the dialysate of Peritoneal Dialysis (PD) and CVVHD can be adjusted as needed. Further PD and CVVHD have an advantage over HD as a relative "inefficient" mode of clearance.

Methods: Two teens presented within 2 weeks of each other with new onset diabetes (glucose 550 mg/dl and 1300 mg/dl), oliguric AKI, with severe metabolic acidosis (pH 7.02) in one and severe hypernatremia (uncorrected Na of 175 mmol/L) in the other, each with neurologic deterioration and coma. The measured osmolality in the first child was 380 (also had received mannitol) while the second child was 488 mOsm/kg.

CVVHD was begun in both with NaCl added to the dialysate to minimize the osmolar gradient between the dialysate and the patient's osmols. In the first patient NaCl was added to make a total Na dialysate of 170 mmol/L (340 mOsm/l) in the second patient the total NaCl dialysate was 200 mmol/L (400 mOsm/L). Each patient had a purposeful low clearance prescription at 6-8 mls/kg/hour. Every 3 hours the total and calculated osmolality was measured and the Na supplementation in the dialysate was decreased by 10 mmol/L each time on an average of 2 times per day based upon an improvement in the child's osmolality. The hyperglycemia was treated per insulin protocol.

Results: In the first patient the pH was normalized slowly over 30 hours and the osmolality normalized over 60 hours when CVVHD was discontinued with renal recovery. In the second patient the osmolality normalized over 5 days when CVVHD was discontinued with renal recovery. Both teens had reversal of coma with a normal neurologic exam.

Conclusions: In conclusion, purposefully inefficient " hyperosmolar " CVVHD allows for a slow improvement in pH and a slow and safe normalization of the hyperosmolar with preservation of neurologic function in the setting of hyperosmolar AKI.

TH-PO898

Outcomes in Neonates on Renal Replacement Therapy; a Single Center Experience Shivanand S. Medar, Pamela S. Singer, James S. Killinger, Robert Woroniecki. *Department of Pediatrics, Children's Hospital at Montefiore, Bronx, NY.*

Background: Initiating dialysis in newborns is controversial. Data on outcomes following Renal Replacement Therapy (RRT) is inconsistent. Reports from Israel/Europe on outcomes of dialysis in newborns (0-28 days) show 75% mortality rate; North American Pediatric Renal Transplant Collaborative Studies (NAPRTCS) data (based on voluntary reporting) shows 24% mortality. We hypothesize that RRT in newborns is associated with high morbidity and mortality.

Methods: Records of patients who had RRT initiated before 28 days of age at our institution between January of 1997 and January 2011 were reviewed. Dialysis treatment during the study period was offered to all neonates and infants that required it, unless they had life-threatening co-morbidities. The RRT physicians and nurses, equipment,

methods and procedures associated with RRT delivery during this time period remained consistent. The end-point for time period on RRT treatment was death, January 2011 or first renal transplant (Tx).

Results: 19 neonates (age of initiation: 9.1±5.7d, birth weight: 3.0±0.58 kg, gestational age: 37.2±2.3wks) were identified. PD was administered in 13 (68%), HD in 4 (21%), CVVHDF in 5 (26%), and 4 (21%) had more than one modality. Indications for RTT: fluid overload in 10 (53%), acidosis in 3 (16%), genetic defect in 4 (21%). 3 (16%) had congenital heart defect, and 2 (11%) multi-organ failure. 9 (47%) had severe electrolyte abnormalities, 13 (68%) required inotropes, 15 (79%) multiple blood products, and 18 (95%) ventilatory support. 8 (42%) had peritonitis, 3 (16%) had cerebral vascular event and 1 (5%) had arterial hypertension. ICU length of stay was 32±33d. 6 patients survived to ICU discharge, with 1 requiring chronic RRT and none received a renal Tx. 13/19 (68%) subjects died during observation period.

Conclusions: Newborns on RRT have high mortality and morbidity and poor outlook for renal Tx. Our patient mortality rate is in concordance with European/Israeli published series and contrasts NAPRTCS registry data possibly due to selection bias. Nephrologists should report their center RRT outcomes to parents of newborns before initiating the treatment.

TH-PO899

Combined Hemodialysis and Plasma Exchange Is Safe and Faster as Compared to Sequential Treatment in Children Betti Schaefer,[1] Ranny Goldwasser,[1] Akos Ujszaszi,[2] Susanne Schaefer,[1] Karl Heinz Heckert,[1] Franz S. Schaefer,[1] Claus P. Schmitt.[1] *[1]Center for Pediatric and Adolescent Medicine, Heidelberg; [2]Institute of Pathophysiology, Semmelweis University, Budapest.*

Background: Patients with immune-mediated kidney disease and liver failure often require plasma exchange (PE) and hemodialysis (HD). Combining both methods, i. e. connecting the PE and HD circuit in series, should allow for a more efficient treatment. The outcome has not yet been evaluated.

Methods: 15 out of 46 children (7.8-38.5 kg) were treated with combined (c) PE/HD, nine alternately with both c and sequential (s) PE/HD (9.5-80.9 kg), and 22 (5-75 kg) with sPE/HD only. Treatment modalities, efficacy, anticoagulation and clinical findings were analyzed retrospectively.

Results: Mean treatment duration was 3.9±2.2h per session for cPE/HD and 5.8±1.6h with sequential therapy (HD 3.8±1.6h, PE 2.2±0.6h; p<0.001). Dialysate flow was 490±201 with cPE/HD and 324±172 ml/min/m² with sPE/HD (p<0.01). PE/HD filter size per m² BSA and blood flow rates were similar (cPE/HD 112±44, sPE 92±22, sHD 111±28 ml/min/m²; all p=n.s.). Initial bolus of heparin consisted of 999±729 for cPE/HD, 389±475 for sPE and 305±457 IU/m² for sHD (p=n.s. for cumulative dose). The dose of continuous and total heparin infusion and Activated Clotting Time were similar, as was the cumulative amount of citrate and calcium chloride infused in children treated with either method (n=16). Dialysis efficacy (creatinine, phosphate, urea and bilirubin removal) and ultrafiltration rates were comparable (cPE/HD 821±648 vs. sPE/HD 925±528 ml/m², p=n.s.). The decrease in INR was comparable in patients with liver failure. Both methods were well tolerated. Blood leakage and hemolysis occurred in 8 out of 89 cPE/HD sessions (9%) and in 4 out of 111 sPE/HD sessions (4%), hypothermia in one sPE/HD session (1%).

Conclusions: PE/HD performed in series within one session is safe and allows for a more rapid purification as compared to sequential therapy. This should be beneficial in patients with severe diseases and reduce work load. Careful dialysator pressure control, however, is required to prevent hemolysis and capillary leaks.

TH-PO900

Two Year Study of Bone Metabolism with Acetate-Free Bicarbonate Dialysate Buffered by Citric Acid Junji Uchino. *Mihama Hospital, Chiba, Japan.*

Background: To correct metabolic acidosis, sodium bicarbonate was added to the dialysate to achieve a blood plasma bicarbonate concentration of 24 mmol/L prior to maintenance dialysis. It has been reported that comparison of bone biopsy findings between before and after the correction of metabolic acidosis showed inhibition of secondary hyperparathyroidism and stimulation of the turnover of hypoplastic bone.

Methods: To investigate the effects of acetate-free bicarbonate dialysate (Carbostar Citric Acid 2 containing 35 mmol/L of bicarbonate; CB) on bone metabolism in patients on maintenance dialysis.

Subjects: Two-hundred and ninety eight of maintenance dialysis patients were studied. Their age was 66.5±11.7 and the duration of dialysis was 9.4±8.1 years.

The patients were classified into low (i-PTH < 60 pg/mL), normal (i-PTH 60-180 pg/mL) and high (i-PTH > 180 pg/mL) PTH groups based on measurement of intact PTH during the previous year of treatment with acetic acid dialysate (Kindaly solution AF-2P containing 8 mmol/L of acetate and 30 mmol/L of bicarbonate: KP). Then i-PTH and Ca levels were compared between before and after CB. Statistical analysis was performed using Wilcoxon's signed rank sum test and significance was set at $P < 0.05$.

Results: The median plasma bicarbonate concentration before dialysis (21.7 mmol/L [min.16.7, max. 23.9]) was increased to 24.1 mmol/L (min. 20.7, max. 26.8) at 22 months after changing the dialysate. Nineteen months after changing from KP to CB, intact PTH was increased to 68.0 pg/mL (26.0, 380.0) from 24.5 pg/mL (6.0, 58.0) in the low PTH group, to 183.5 pg/mL (6.0, 382.0) from 102.0 pg/mL (61.0, 180.0) in the normal PTH group, and to 245.5 pg/mL (134.0, 454.0) from 238.5 pg/mL (155.0, 793.0) in the high PTH group, resulting in near-normal values for the low and high PTH groups. During treatment with KP, plasma Ca levels were low before dialysis in the normal group compared with the low and high PTH groups. During treatment with CB, pre- and post-dialysis plasma Ca levels were similar in the high PTH group.

Conclusions: Adding sodium bicarbonate to the dialysate through use of CB may correct bone turnover.

TH-PO901

Hypophosphatemia and Phosphate Supplementation during Continuous Renal Replacement Therapy (CRRT) in Adult Young Hye Song,[1] Kyoung Hee Jeong,[1] Hyun Jeong Jeong,[1] Young-Il Jo.[1,2] *[1]Dialysis Center, Konkuk University Hospital, Seoul, Republic of Korea; [2]Nephrology, Konkuk University Medical Center, Seoul, Republic of Korea.*

Background: Hypophosphatemia is a common complication of CRRT. However, there are a few studies in critically ill adults undergoing CRRT in which phosphate was added to the replacement and dialysate solutions. The objectives of this prospective study were to evaluate the incidence of hypophosphatemia during CRRT and the efficacy and safety of phosphate supplementation in critically ill adults undergoing CRRT.

Methods: Adult patients who admitted to the ICU and undergoing CRRT for at least 48 hours were recruited in this prospective randomized two-arm comparative study. All patients were randomly assigned to the P-15.0 group and P-22.5 group. If hypophosphatemia was detected during CRRT, we added phosphate 15.0 mEq or 22.5 mEq to both the replacement solution (5L) and the dialysate solution (5L) in the P-15.0 or P-22.5 group, respectively. The phosphate, calcium and potassium levels were recorded before CRRT and every 24 hours after starting CRRT.

Results: A total of 29 adult patients were enrolled (P-15.0 group, n=16; P-22.5 group, n=13). The mean levels of serum P at the beginning of of CRRT was 4.9±1.5 mg/dL. During CRRT, 24 patients (82.7%) were found to have hypophosphatemia (mean levels of serum P, 2.2±0.3 mg/dL) which occurred at 52.0±39.2 hrs following initiation of CRRT. After adding of phosphate to the replacement and dialysate solutions, serum P levels for the P-15.0 and P-22.5 group were 4.1±1.2 mg/dL and 4.6±0.8 mg/dL, respectively ($p>0.05$). Following phosphate addition, the times of restoration to normal values of serum P levels for the P-15.0 and P-22.5 groups were 37.7±18.1 hrs and 26.7±8.0 hours, respectively ($p=0.030$). Except one patient (3.5%), intravenous phosphate supplementation was not needed. No serious adverse effects of phosphate supplementation during CRRT have been observed.

Conclusions: These results indicated that the incidence of hypophosphatemia in critically ill adults undergoing CRRT is very high and the phosphate addition to replacement and dialysate solutions is safe and effective on correcting hypophosphatemia during CRRT.

TH-PO902

The Effect of Continuous Veno-Venous Haemodiafiltration on Monocyte Function in Canine Model for Multiple Organ Dysfunction Syndrome Chen Ji Hong. *Department of Nephrology, First Affiliated Hospital of Xinjiang Medical University, Urumqi, XinJiang Province, China.*

Background: Continuous veno-venous haemodiafiltration (CVVHDF) has gained wide acceptance for the treatment of multiple organ dysfunction syndrome (MODS) in intensive care. This study evaluated specific effects of CVVHDF on the monocyte counts, apoptosis rate, expression rate of DLA-DR, secretary function in Canine model for MODS.

Methods: 12 beagle dogs were subjected to hemorrhagic shock plus resuscitation and endotoxiemia to set up MODS model. Shock was produced according to the method of Wiggers. Then the animals were resuscitated by infusion of Ringer's solution at twice the volume of shed blood. After 12 hours of the resuscitation, Escherichia coli endotoxin (LPS) was dropped in a dose of 1.5 mg/kg in 500 ml of normal saline for 12 hours. Then 12 dogs were randomly divided into two groups: CVVHDF group and MODS group. Measurements of variables were obtained at baseline(T_1),before LPS injection(T_2) and 0h(T_3),3h(T_4),6h(T_5),9h(T_6),12h(T_7),15h(T_8) and 24h(T_9) after LPS injection was finished.

Results: 1 After treatment of CVVHDF, MAP and heart rate remained stable, with decreased body temperature, increased urine output, decreased total number of white blood cell and improved lung and renal function . 2 Early and late monocyte apoptosis rate in CVVHDF group was significantly lower than the MODS group, and the number of monocyte was significantly increased ($p<0.01$). 3 The expression of CD_{14}^+ DLA-DR in CVVHDF group was significantly higher than in MODS group ($p<0.01$). CVVHDF facilitated monocyte antigen-presenting function in the inhibitory state to recover gradually. 4 CVVHDF improved the secretion of IL-1β and IL-4 by monocytes, upregulated secretary strength of the anti-inflammatory factor IL-4 thus facilitating the gradual recovery of secretary function of monotyes in inhibitory state($p<0.01$).

Conclusions: Our results suggested that treatment with CVVHDF effectively removed cytokines from the circulation, reduced monocyte apoptosis, increased number of monocyte, and improved the monocyte function of presentation and secretory. Thus, it facilitated reconstruction of immune homeostasis.

Management and Practice of CRRT in ICU: A Survey of Italian Nurses Flavio Basso,[1] Mariangela Mattifogo,[1] Dinna N. Cruz,[1] Nathan W. Levin,[2] Zaccaria Ricci,[3] Alessandra Brendolan,[1] Federico Nalesso,[1] Francesco Garzotto,[1] Claudio Ronco.[1] *[1]Nephrology Dialysis and Transplantation, San Bortolo Hospital, Vicenza, Italy; [2]Renal Research Institute, New York; [3]Cardiosurgery, Bambino Gesù Hospital, Rome.*

Background: Nursing in continuous renal replacement therapy (CRRT) requires specific expertise for its correct implementation. The nurses' role is fundamental in the prevention and management of adverse events.

Our aim was to explore nursing practice in Italy in CRRT management in order to identify strategies to improve treatment quality.

Methods: During the course on "Nursing skill and practice for adequate CRRT" (Vicenza 2010), participants were surveyed about CRRT management, including the complications leading to loss of the circuit and the most important limitations for CRRT.

Results: The questionnaires were correctly filled out by 113 of 126 Italian nurse participants (89.7%).

CRRT was managed by either ICU nurses (42.8%) or nephrology nurses (49.6%).

The most frequent cause for discontinuation of treatment was circuit loss (59%), then high circuit pressures (28%), and problems such as hypotension (13%). 78.5% of nurses often/always performed coagulation tests q6hr, while 21.5% never did any.

Nurses indicated as limitations of CRRT the absence of comprehensive training (38%), frequent filter clotting (32%) and lack of a checklist (24%).

When an alarm is triggered, 86% of nurses identified the cause immediately and resolved it while 9% performed a full system check. Of note, 5% muted the alarm without investigation of the cause. This dangerous practice is a further demonstration of the need for better training of CRRT for nursing staff.

Conclusions: The results of the survey indicate that more careful training in the correct methods for CRRT is required. Such training would bring direct benefits to critically ill patients undergoing this procedure. Periodic surveys on nursing practice could identify potential areas for improvement.

TH-PO904

Renal Failure Requiring Dialysis after Slow Continuous Ultrafiltration in Patients with Advanced Heart Failure Edgard I. Wehbe,[1] Maria M. Patarroyo,[2] Jonathan J. Taliercio,[1] W.H. Wilson Tang,[2] Sevag Demirjian.[1] *[1]Nephrology and Hypertension, Glickman Urological and Kidney Institute; [2]Cardiology, Cleveland Clinic.*

Background: Slow continuous ultrafiltration (SCUF) has been increasingly utilized in patients with acute decompensated heart failure (ADHF). However, a subsets of patients develop worsening renal function requiring dialysis. We aim to describe the incidence and outcome of those patients.

Methods: Our cohort consisted of 63 patients who underwent SCUF as initial modality of ultrafiltration in patients with ADHF from 2004 till 2009. The cohort was divided in 2 groups; those who needed only SCUF and those who transitioned to continuous venovenous (CVVHD) or intermittent (IHD) hemodialysis.

Results: Out of 63 patients (mean age 59+/-11, 76% male) 37(59%)transitioned to CVVHD or IHD. There were no differences in demographics, comorbidites, medications and ejection fraction between the 2 groups. Patients who required transition had a higher creatinine at baseline(1.44+/-0.43 vs 1.87+/-0.76 P= 0.0135), at SCUF initiation and after 48 h(1.7+/-0.7vs 2.9+/-0.9 P=<0.001), lower systolic blood pressure at baseline and at time of initiation of SCUF(112+/-2 vs 101+/-2 P=0.003), lower systemic vascular resistance at baseline and at time of initiation of SCUF(1189+/-494 vs 826+/-229 P=0.008). There was no difference in mean pulmonary arterial pressure, central venous pressure, cardiac index/output, pulmonary capillary wedge pressure and pulmonary vascular resistant. Table 1 summarizes the clinical outcomes.

Conclusions: This study shows that a large number of patients required dialysis support after SCUF. Those patients had a higher creatinine and lower systolic blood pressure at baseline and at time of SCUF initiation. Transition to dialysis was associated with very high one year rate of mortality.

	SCUF only n= 26(41%)	Convert from SCUF to CVVHD or IHD n= 37(59%)	P value
Hospital stay in days	16+/-11	28+/-18	0.0093
Time on SCUF in days	2.3+/-1	3.5+/-2	0.06
Discharged from the hospital on dialysis	0(0%)	9(24%)	<0.001
Death at 30 days since SCUF start date	1(3.8%)	23(62%)	<0.001
Death at 90 days since SCUF start date	4(15%)	30(81%)	<0.001
Death at one year since SCUF start date	9(34%)	35(94%)	<0.001

TH-PO905

Weigth Gain after Renal Transplantation: Combined Effects of Nutritional Factors and Lower Physical Activity Eva Corpeleijn,[2] Dorien M. Zelle,[1] Willem Van Son,[1] Gerjan Navis,[1] Stephan J.L. Bakker.[1] *[1]Kidney Center, University Medical Center Groningen, University of Groningen, Netherlands; [2]Dept of Epidemiology, University Medical Center Groningen, University of Groningen.*

Background: Weight gain after renal transplantation is related to increased cardiovascular risk and decreased graft survival. Our aim was to identify lifestyle factors related to gain in fat mass, and its association with cardio-metabolic risk factors at one year after renal transplantation.

Methods: At 6 weeks and 3, 6 and 12 months after transplantation, post-transplant weight gain, changes in body composition (bio-electrical impedance, Biostat), cardio-metabolic risk factors, renal function, nutritional intake (24h recall and interviews; 24h urine collections) and physical activity (SenseWear diaxial accelerometer; SQUASH questionnaire) were assessed.

Results: From 29 participants, 26 (48% men, age 51 ± 12 yrs) completed the measurements. At 12 months, patients had gained on average 5.7 ± 5.0 kg (range -2 to + 20 kg) in weight, mainly fat tissue. Gain in body fat was positively associated with serum total cholesterol (r=0.46, P=0.02) and triglycerides (r=0.51, P=0.01) at 12 months. In the patients who gained most in body fat (>3% fat gain, N=13), cardiovascular risk factors at 12 months were higher, i.e. LDL-cholesterol (+ 0.8 mmol/l, P=0.02), total cholesterol (+1.2 mmol/l. P=0.006), and triglycerides (+1.0 mmol/l, P=0.03) compared to those who remained weight stable (<3% fat gain, N=13). Immunosuppressive therapy, renal function, random glucose and HbA1c were comparable. Those who gained in body fat showed lower daily physical activity (-39%, P=0.04) and walked fewer steps per day (-33%, P=0.01). In addition, body fat gain was related to a 30% lower intake in vegetables (P=0.04) and a 20% higher consumption of mono and disaccharides (P=0.02), mainly due to the consumption of energy-rich drinks and sugared dairy (P=0.05).

Conclusions: Daily physical activity, vegetable intake and high consumption of energy-rich drinks and dairy may provide targets for lifestyle intervention to prevent weight gain and improve long term cardiovascular and renal outcomes.

TH-PO906

Treating Post Transplant Anaemia with EPO Improves Quality of Life Taryn Pile,[1] Martin J. Raftery,[2] Magdi Yaqoob.[1] *[1]Translational Medicine and Therapeutics, Queen Mary College, London, United Kingdom; [2]Department of Kidney Medicine and Transplantation, Barts and the London NHS Trust, United Kingdom.*

Background: Anaemia affects 30-45% of renal transplant recipients. Treatment with ESAs has not been well studied and the effects of long term treatment are not known.

Methods: An exploratory study to assess the effect of treatment with Epoetin beta (EB) on renal progression in anaemic renal transplant recipients was performed. The effect on Health Quality of Life (HQOL) and Left Ventricular Hypertrophy was also assessed. The treatment arm received EB to achieve a target of 12-13.5g/dL. The No Treatment group (NT) was treated with EB if the Hb fell below 9g/dL. The primary end-points were progression of CKD, blood pressure and proteinuria. Secondary end-points were HQOL assessed by SF-36 and Left Ventricular Hypertrophy assessed by LVMI.

Results: 55 patients were recruited (NT N= 27, EB N=28) with a median of 23.34 months follow-up. At the end of the study the Hb was significantly higher in the EB group (EB: 12.3 ± 0.18 vs. NT: 9.99 ± 0.22 g/dL, $P < 0.0001$). There was no significant difference in delince of eGFR, PCR or blood pressure between the 2 groups throughout the study. Similarly LVMI was not significantly different.

Conclusions: However, an improvement was seen in Vitality (Baseline: 39.81 ± 2.55 vs. End of Study: 44.54 ± 2.66, $P = 0.03$), Physical Function (Baseline: 42.04 ± 2.28 vs. End of Study: 48.29 ± 2.62, $P = 0.01$) Domains as well as Physical Component Summary (Baseline: 38.76 ± 2.94 vs. End of Study: 44.69 ± 2.81, $P = 0.002$) in the EB group. There was also a small , but significant improvement in the Physical Function Domain in the NT group (Baseline: 39.27 ± 2.21 vs. End of Study; 42.52 ± 2.48 , $P = 0.03$). A trend to improvement in change from baseline was seen in the EB group when compared to the NT group. A significant improvement was seen in the Vitality domain (NT 3.12 (-3.1;6.24) vs. EB: 6.25 (3.12,12.5); $P = 0.02$).

Anaemic renal transplant patients treated with EB benefit from improved Vitality in this small exploratory RCT. A large, multi-centred RCT is warranted to study quality of life benefits in of long-term ESA treatment in PTA.

TH-PO907

Residence Location and Likelihood of Transplantation among Pediatric Patients with End-Stage Renal Disease Susan M. Samuel,[1] Brenda Hemmelgarn,[1] Bethany J. Foster,[2] R. Todd Alexander,[3] Andrea Soo,[1] Alberto Nettel-Aguirre,[1] Marcello Tonelli.[3] *[1]University of Calgary, Calgary, Canada; [2]McGill University, Montreal, Canada; [3]University of Alberta, Edmonton, Canada.*

Background: Due to Canada's large size, many pediatric end-stage renal disease (ESRD) patients reside far from a pediatric renal care centre. It is unknown whether this potentially reversible geographical barrier affects likelihood of kidney transplant.

Methods: Population-based retrospective cohort study using data from national ESRD registry. Children (age 0-18) initiating renal replacement therapy between 1992-2007 were followed until death or last contact. Primary outcome was kidney transplant (living or deceased donor). Distances between nearest pediatric transplant centre and each patients' residence were calculated using geographic information software, and categorized as: <50 km, 50.0-149.9 km, 150-299.9 km, and ≥300 km. Cox proportional hazards models were used to compare likelihood of transplant by distance category, adjusting for gender, age, socioeconomic status and primary disease. Separate models were used for whites and non-whites due to a significant interaction between ethnicity and distance.

Results: 728 patients were included (52.2% males; 62.5% white). 38.5% lived <50 km, 20.1% lived 50-149.9 km, 14.3% lived 150-299.9 km and 27.2% lived ≥ 300 km away from a pediatric transplant center. Among whites, compared to those living <50 km, patients living between 150-299.9 km and ≥300 km from a transplant centre were less likely to receive a deceased donor transplant (adjusted hazard ratios [95% CI]: 0.55[0.33-0.92] and 0.61[0.39-0.94] respectively). There were no differences in likelihood of living donor transplant by distance to care centre among whites. Among non-whites there was no association between distance to a transplant centre and likelihood of transplant for both living and deceased donor transplants.

Conclusions: White pediatric ESRD patients living ≥150 km away from a transplant centre are less likely to receive deceased donor transplant. Further evaluation is necessary to determine barriers in access to deceased donor transplant among remote dwelling patients.

Risk Factors for Efficacy Failure with Tacrolimus-Based Immunosuppression after Kidney Transplantation – The OSAKA Study Bernhard Banas,[1] Laetitia Albano,[2] Lionel P.E. Rostaing.[3] *[1]University Medical Center Regensburg, Germany; [2]Centre Hospitalier Universitaire de Nice, France; [3]Toulouse University Hospital, France.*

Background: OSAKA is one of the largest clinical trials ever conducted in *de novo* kidney transplantation (n=1,251). This allows an analysis of donor and recipient risk factors that impact on the risk of efficacy failure on tacrolimus (Tac)-based immunosuppression.

Methods: Adult kidney recipients were randomized 1:1:1:1 to starting doses of Tac immediate release (BID) 0.2mg/kg/day (Arm 1), Tac prolonged release (QD) 0.2mg/kg/day (Arm 2), Tac QD 0.3mg/kg/day (Arm 3), all with MMF + corticosteroids (CS) for 24 weeks, or Tac QD 0.2mg/kg/day + MMF + basiliximab + CS (perioperative bolus only) (Arm 4). The primary composite endpoint was efficacy failure rate (graft loss, biopsy confirmed acute rejection, graft dysfunction [eGFR (MDRD) <40mL/min/1.73m^2] at 24 weeks). Logistic regression (LR) and a simplified Classification And Regression Tree (CART) method were used to quantify risk factors.

Results: Efficacy failure rates as defined (PPS) were 40.6% (Arm 1), 42.2% (Arm 2), 44.2% (Arm 3), and 48.2% (Arm 4). LR analysis identified donor age, female donor, donor death, and underlying focal segmental glomerulosclerosis (FSGS) as the most relevant risk factors, with donor age the most statistically significant factor. Each additional year of donor age increased the odds of efficacy failure by more than 4% on average. FSGS doubled the risk, a female donor increased the risk by nearly 28%, each point of mismatch by almost 10%, and a cadaveric donor by nearly 50%. CART confirmed that patients with the highest risk were those with a donor age over 61 years, and identified more than four mismatches and a female donor as additional risk factors.

Conclusions: With Tac-based therapy, donor age was the overriding risk factor for the composite endpoint of efficacy failure (as well as its single components).

		Wald test	
Risk factor	Odds ratio (95% CI)	Parameter estimate	P-value (chi-square)
Donor age	1.045 (1.034; 1.057)	0.0442	<0.0001
Female donor	1.276 (0.996; 1.634)	0.2434	0.0537
Deceased donor	1.496 (0.987; 2.265)	0.4025	0.0574
Underlying FSGS	1.921 (0.897; 4.112)	0.6528	0.0928

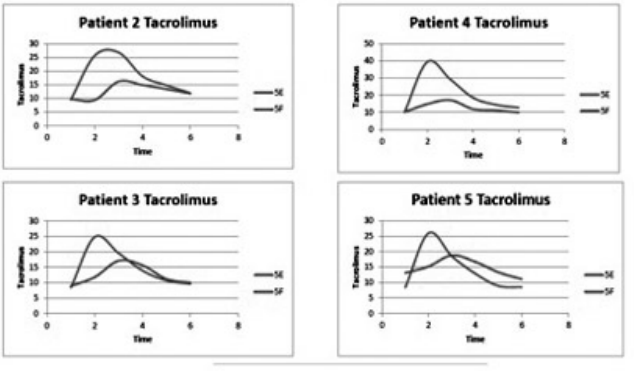
Concomitant Food Ingestion Decreases Tacrolimus Absorption Well Below FDA Standards for Approved Generics Linda Awdishu,[1] Son Ho,[1] Amol Shah,[2] Robert W. Steiner.[2] *[1]Clinical Pharmacy, UCSD Skaggs School of Pharmacy, La Jolla, CA; [2]Medicine, Division of Nephrology, UCSD Medical Center, San Diego, CA.*

Background: The predictability and degree of diurnal tacrolimus (TAC) exposure in chronic renal transplant recipients (CRTRs) has received increased attention due to the availability of generic alternatives. Concern about TAC exposure is appropriate considering the disappointing increase in long term kidney transplant survival in the current "TAC decade."

Methods: TAC area under the curve (AUC0-12) was estimated in 15 CRTRs taking TAC (as Prograf), MMF, and prednisone. TAC was taken under direct observation simultaneously with a 700 kcal breakfast and on a second day 1 hour before eating. TAC concentrations were measured at 0, 1, 2, 4, 6 and 8 hours.

Results: Absorption profiles with and without food in 4 patients are shown in Figure 1.



Fasting curves were relatively uniform with robust early peaks. The fasting state AUC0-12 ranged from 120.05 to 249.98 ng*mL/hr. The fed state AUC0-12 ranged from 56.83 to 199.93 ng*mL/hr. The ratio of the fed to fasting state AUC ranged from 38 to 111%. We calculated the natural logarithm of the difference in peak concentration (Cmax), time to peak concentration (Tmax), and AUC between fasting and fed states. The difference in lnCmax was 0.24 ±0.27 ng/mL (p<0.001), Tmax was -0.93 ± 1.14 hr (p=0.008) and lnAUC0-12 was 0.24 ± 32 ng*mL/hr (p=0.005). Importantly, drug concentrations at 8 hrs post dose was similar between fed and fasting states demonstrating the importance of Cmax for drug exposure.

Conclusions: Ingestion of TAC with food reduces exposure well beyond any effect of an FDA approved generic when taken under the same circumstances. The food effect may be responsible for suboptimal immunosuppression and graft survival in some adherent patients. Such underexposure will not be detected by 12 hour trough TAC levels.

Predialysis Nephrology Care, Early Transplant Assessment and Patient Satisfaction with Physician Interaction Nancy G. Kutner,[1] Rebecca H. Zhang,[1] Kirsten L. Johansen.[1,2] *[1]USRDS Rehabilitation/QoL Special Studies Center, Emory University, Atlanta, GA; [2]Nephrology Section, San Francisco VA Medical Center, San Francisco, CA.*

Background: Satisfaction with physician interaction is a key component of dialysis patients' satisfaction with their care. We hypothesized that whether patients receive predialysis nephrology care and have early assessment for transplantation may influence their satisfaction.

Methods: In phone interviews the Comprehensive Dialysis Study (CDS) surveyed 1473 incident HD patients and 169 incident PD patients aged >18 from 296 randomly selected clinics throughout the US. Thinking about the kidney doctor they saw most often, respondents rated "the amount of time your kidney doctor spends with you" and "your kidney doctor's explanations of medical procedures and tests" [Medical Outcomes Study items].

Results: Although most respondents rated their interaction with their kidney doctor as good to excellent (76% for time spent, 83% for procedure/test explanations), in a linear regression analysis with adjustment for patient clustering in clinics, patients on HD, Hispanics, and patients who lacked predialysis nephrology care were significantly less satisfied with both aspects of physician interaction, and patients with less than high school education were less satisfied with their doctor's explanation of procedures/tests. No age, gender, or race differences were significant. The ESRD Medical Evidence Report indicated that 245 CDS participants had not been assessed for transplantation. Compared to those reported informed of transplant options, patients who had not been assessed were less satisfied with the time their doctor spent with them ($p < 0.05$) and with their doctor's explanations of procedures and tests ($p < 0.05$).

Conclusions: Congruence between expectations and perceived experience influences satisfaction. Patients who lack predialysis nephrology care may expect more time and information from their physicians, especially with regard to provider/patient communication related to kidney transplant options.

Evaluation of the Living Kidney Donor Programme in the United Kingdom Cheralathan Arunachalam, Mila Garrues, Fiona Biggins, Aimun Ahmed. *Department of Renal Medicine, Royal Preston Hospital, Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom.*

Background: Living kidney donation (LKD) has increased in the UK by 12% (1037 donors) in 2010 which is 38% of the total UK kidney transplant activity. There has been growing evidence and evolving guidelines for LKD. However there are still inconsistencies in practice between renal units. We aim here to study LKD assessment across the UK centres.

Methods: A structured questionnaire relating to LKD assessment was sent by post to 74 renal units across the UK between October to December 2010

Results: 19 of 23 (83%) transplant units (TU) and 21 of 51 (42%) non transplant units (NTU) responded. 12 TU perform both ABO and HLA incompatible transplantation. 4 TU perform ABO incompatible transplantation only and 3 TU do not perform either. 85% of the units are without a set upper age limit for donors, where as 15% of units excluded donors older than 70 years. 83% of the units have no lower age limit. 22% of units accept donors with BMI up to 35 and 10% of centres did not have upper limit for BMI. 27% of centres exclude hypertensive donors on more than one antihypertensive drug, 60% of units exclude donors if they are taking more than 2 drugs. 65% of centres rely on urine PCR to assess proteinuria and 27% of units perform 24 hour urine collection for protein estimation.

60% of centres perform CT angiography to assess renal vessels while 40% use MR angiography. 78% of centres perform split kidney function routinely where as 21% use this test only if there is a discrepancy in kidney size noted from other imaging studies. Removal of recipients who have a live donor from the deceased donor list is also inconsistent, 50% of centres suspend the recipient when theatre date has been set

Conclusions: This survey provides insight into contemporary UK practice for LKD assessment. We demonstrate significant variability regarding acceptance of donors based on age, BMI, and hypertension. Investigations used for LKD assessment also differ markedly within the UK. Unified and clear guidelines are needed as well as strong evidence on the most appropriate investigations to assist clinical decision-making in live donor assessment.

Conversion to LCP-Tacro™ Tablets Once-Daily from Prograf® Capsules Twice-Daily in Kidney Transplant Patients: Central Pathology Results from a Phase III, Open-Label, Multicenter Trial Suphamai Bunnapradist,[1] Klemens Budde,[2] Shamkant P. Mulgaonkar,[3] Lionel P.E. Rostaing.[4] *[1]UCLA; [2]Charite Universitatsmedizin; [3]St. Barnabas Med. Ctr.; [4]CHU Rangueil.*

Background: Phase II studies of de novo and stable renal and liver recipients showed improved pharmacokinetics (PK) and a tendency toward fewer treatment failures and SAEs for extended-release tacrolimus tablets (LCP-Tacro) administered once-daily (qd) vs. immediate release tacrolimus capsules (Prograf) administered twice-daily (bid). A Phase III study of stable renal transplant patients converted to LCP-Tacro qd from Prograf bid showed noninferiority for LCP-Tacro vs. Prograf. Here we report pathology results from centrally read, blinded biopsies.

Methods: Kidney transplant patients 3-60 mos. post-transplant taking Prograf bid with tacrolimus trough levels 4-15 ng/mL were randomized to LCP-Tacro qd or to maintain their Prograf regimen for 12 mos. Initial LCP-Tacro dose was 30% lower (15% for African Americans) than the pre-conversion Prograf daily dose. Subsequently, trough levels of 4-15 ng/mL were targeted in both drugs.

Results: The mITT groups (LCP-Tacro: n=162; Prograf: n=162) were similar in demographics and tacrolimus trough levels throughout the study; 35 biopsies were centrally read (23 LCP-Tacro, 12 Prograf). One LCP-Tacro patient had 1 biopsy-proven acute rejection (BPAR) episode vs. 7 BPARs in Prograf patients (5 Prograf patients with BPAR; 2 patients had 2 episodes) (p=0.21). Tacrolimus trough levels preceding each BPAR were in target range. All BPARs were mild; BANFF chronicity score (chronic glomerular damage+interstitial fibrosis+tubular fibrosis+vascular intimal thickening) tended to be greater in the Prograf group (LCP-Tacro=2; Prograf mean=3.6).

Conclusions: LCP-Tacro qd-based therapy was associated with a numerically lower number of BPARs and the data suggest a tendency for less severe histological changes. Whether a statistically significant lower incidence of BPAR will be seen in studies with a larger sample and whether LCP-Tacro is associated with improved long-term outcomes remains to be examined. These results and the previous PK results suggest LCP-Tacro may be an attractive alternative to Prograf.

Early Steroids Withdrawal Improves Hemodynamic Profile and Does Not Increase Acute Rejection Risk in Kidney Transplant Recipients Jorge Andrade-Sierra,[1,3] Enrique Rojas-Campos,[1] Ernesto Cardona,[3] Luis Alberto Evangelista-Carrillo,[2] Trinidad Orlando Lugo Lopez,[2] Abel Puentes Camacho,[2] Salvador Mendoza Cabrera,[2] Benjamin Gomez-Navarro,[2] Mario Sandoval Sandoval,[2] Alfonso M. Cueto-Manzano.[1] *[1]Medical Research Unit in Renal Diseases, Instituto Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico; [2]Department of Nephrology and Organ Transplant Unit, Instituto Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico; [3]Department of Physiology, CUCS. University of Guadalajara, Guadalajara, Jalisco, Mexico.*

Background: Early steroids withdrawal (ESW) improve cardiovascular profile but could increase the risk of acute rejection (AR). **Objective:** To compare the effect of ESW on metabolic profile and AR frequency

Methods: Open label, randomized clinical trial; 55 KTR, with PRA<20%, between Jul/10-Jun/11; 28 in the ESW-G / 27 in the control group (CG), maintenance was with TAC and MMF and PDN in C-G; ESW-G, had a daily steroid reduction (250/day1-0mg/day5). Metabolic and hemodynamic profile, eGFR and graft biopsy were done at baseline, 3,6 months. Comparisons between groups, were done with Mann-Whitney U and χ^2 tests.

Results: Main results are shown in Table. At 3 moths, ESW-G had 4 (14%) borderline, CG had 3 (11%) Banf IA rejections; at 6 months ESW-G 3 (11%) borderline, CG had 3 (11%) borderline and 2 (7%) Banf IA rejections.

Conclusions: ESW-G shows a better control of blood pressure and trend to show lower AR frequency and severity compared to CG.

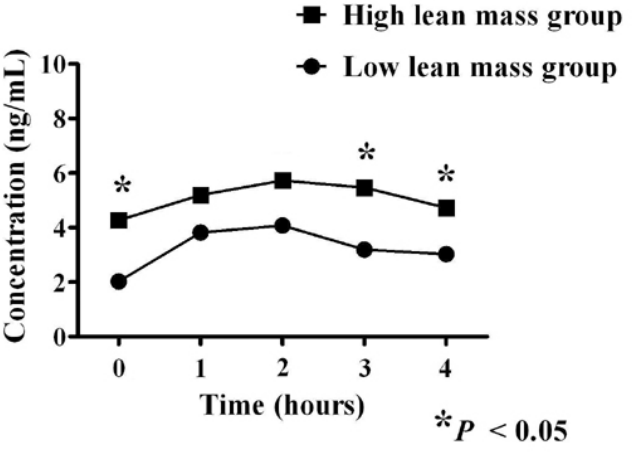
Pharmacokinetics of Tacrolimus According to the Body Composition in Korean Kidney Transplant Recipients Seung Seok Han,[1] Curie Ahn,[1] Jin Suk Han,[1] Suhnggwon Kim,[1] Yon Su Kim.[1,2] *[1]Internal Medicine, Seoul National University College of Medicine, Seoul, Korea; [2]Clinical Research Center for End Stage Renal Disease, Korea.*

Background: Current dosing of calcineurin inhibitor after transplantation is based on the patient's body weight. However, kidney transplant recipients have a low correlation between body weight and body composition. Here, we evaluate the pharmacokinetics of tacrolimus according to the body composition in 17 Korean kidney recipients with stable graft function.

Methods: The body compositions such as lean and fat mass were calculated using the bioelectrical impedance analysis. Pharmacokinetic profiles were taken at 0, 1, 2, 3, and 4 hours after application of tacrolimus and compared between the low and the high level groups according to the median of body composition. The values of C_0, C_1, C_2, C_3, and C_4 were used in determining abbreviated area under the concentration–time curve (AUC) for tacrolimus.

Results: The medians of body mass index (BMI) and body compositions were as follows: BMI, 25.0 kg/m^2 [interquartile range (IQR, 22.2–26.3)]; fat mass, 17.7 kg (IQR, 14.2–20.1); lean mass, 49.4 kg (IQR, 43.2–58.1). There were no statistical differences in pharmacokinetic profiles according to BMI. However, the concentrations (C_3 and C_4) in the high fat group were higher than the low fat group (*P*s = 0.060 and 0.034, respectively). The concentrations (C_0, C_2, C_3, and C_4) and the AUC were significantly different between the two groups of the lean mass (*P*s were 0.012, 0.068, 0.043, 0.021, and 0.027).



Other variables such as waist circumference, waist-hip ratio, and arm circumference did not differentiate the pharmacokinetic profiles of tacrolimus.

Conclusions: Taken together, these data provide the suggestion that the monitoring of the dose of tacrolimus should be based on the individual body compositions for further improvement of kidney transplant outcomes.

TH-PO915

Response to Cinacalcet in Renaltransplant Patients with Secondary Hyperparathyroidism and Hypercalcemia: What Is the Role of the Magnesium? Victor Martínez Jiménez.[1] *[1]Nephrology, Hospital Reina Sofia, Murcia, Spain; [2]Nephrology, Hospital Virgen Arrixaca, Murcia, Spain.*

Background: Cinacalcet is able to bind to the calcium-sensing receptor in parathyroid to modify it allosterically, being useful in controlling severe hyperparathyroidism with persistent hypercalcemia in renal transplant.

It is known that before correcting hypocalcemia is necessary to solve the deficit of magnesium, due to the hypomagnesemia would activate the calcium-sensing receptor. However, we found no studies evaluating the effect of magnesium on the hypercalcemia and the response of cinacalcet in these patients.

Objectives:

To evaluate the effectiveness of treatment with cinacalcet in renal transplant with severe hyperparathyroidism and hypercalcemia.

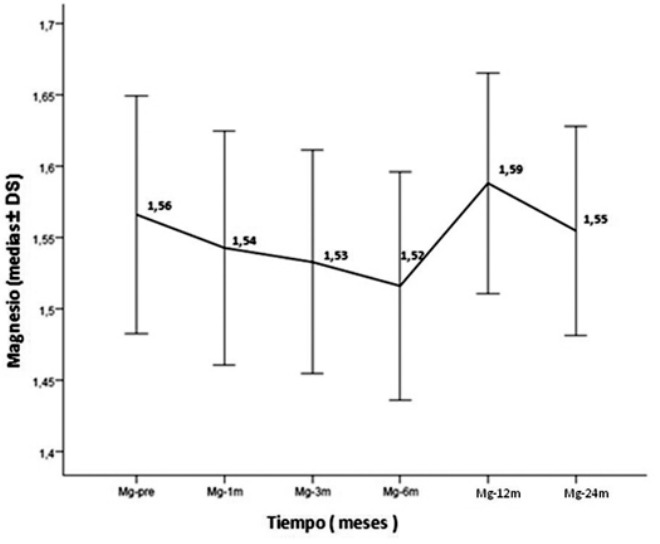
To study the role of magnesium in the response of cinacalcet.

Methods: -37 renal transplant with creatinine clearance>50 ml/min, Ca>10.5 mg/dl and PTH> 65 pg/ml have been studied for 3months to 4years

- Parameters to analyze: Ca, P, PTH and magnesium pretreatment with cinacalcet, 1month, 3months, 6months and annually. If the magnesium < 1.65 mg/dl iniciated oral magnesium tablets to maintain stable nivels of magnesium.

- Cinacalcet dose: 30-90 mg / day.

Results:



- Decreased calcium and PTH

- Increased phosphorus

- 14 patients (37.8%) had hypomagnesemia pretreatment, 13 of them were treated with oral magnesium.

- Patients with lower initial levels of magnesium (before starting treatment with cinacalcet) had, significantly, a greater decrease in PTH and calcium ($p < 0.05$), as shown on table 1.

Conclusions: Cinacalcet is effective in controlling hypercalcemia in renal transplant with secondary hyperparathyroidism.

Pretreatment hypomagnesemia seems to favor the response of cinacalcet.

In view of these results, should we try to correct magnesium deficiency in all cases or only in symptomatic patients?

TH-PO916

ABO Incompatible Living Donor Kidney Transplantation(ABOi KT): Minimal Dose of Rituximab and Not a Routine but As-Needed Posttransplant Plasmapheresis Jin M. Kong,[1] Jeongmyung Ahn,[1] Byung Chang Kim,[2] Mi Young Jeon.[2] *[1]Nephrology, Maryknoll Hospital, Busan, Korea; [2]Pathology, Maryknoll Hospital, Busan, Korea.*

Background: ABOi KT is now an established procedure with outcome equivalent to ABO compatible KT. There are various protocols in different parts of the world, and the refinement of the protocol is necessary to improve outcome, safety and cost.

Methods: Since the initiation of ABOi KT in 2007 in our center, the protocol has been being evolved. Conventional dose(375mg/m2) of rituximab was used initially, the dose halved subsequently, and recently 100mg fixed dose was used. Pretransplant plasmapheresis aimed anti-ABO titer ≤8 on transplant day, but patients with higher(≥16) titer whose antibody could not be lowered to target on transplant day were also allowed to transplant. Posttransplant plasamperesis was not done routinely but as needed in patients with higher antibody titer or increase in creatinine while awaiting biopsy result during the critical period.

Results: A total of 36 ABOi KT was done since Feb. 2007. Median follow up was 17(0-52)months. Patient and graft survival is 100%. There was only 1 clinical acute AMR. Median(range) anti-ABO titer at initial, on transplant day and at 2 weeks was 64(8-1024), 2(1-16) and 2(1-16), respectively. The duration of the depletion of peripheral CD19+ cells among patients with different dose of rituximab seems not different. There was no CMV disease or BKV nephropathy. One patient developed progressive multifocal leukoencephalopathy with recovery of neurologic symptom by reduction of immunosuppressants.

Conclusions: ABOi KT with minimal dose of rituximab and restricted use of posttransplant plasmapheresis can be performed with excellent outcome, reduced cost and safety.

TH-PO917

Identification of Potential Criteria for Rituximab Responsiveness in Patients with Standard-Therapy Resistant Kidney Allograft Rejection Maximilian Ernst Daemmrich,[1] Jan U. Becker,[1] Verena Broecker,[1] Clemens L. Bockmeyer,[1] Wilfried Gwinner,[2] Anke Schwarz,[2] Cornelia Anneliese Blume.[2] *[1]Institute of Pathology, Medical School Hannover, Hannover, Lower Saxony, Germany; [2]Dept. of Nephrology and Hypertensiology, Medical School Hannover, Hannover, Lower Saxony, Germany.*

Background: Rituximab (anti-CD-20 antibody) is used in kidney transplant rejection refractory to standard therapy, although it carries a risk for serious complications and is not effective in all cases. In a retrospective study, we therefore aimed to identify clinical or histopathological criteria to predict Rituximab response.

Methods: 19 renal transplant recipients who received Rituximab (375 g/qm^2 body surface, 1-2 courses, 15 x combined with up to 5 courses of plasmapheresis) for therapy refractory rejection were included in the study. 10 lost their transplant function (non-responders), in 9, kidney grafts were rescued (responders). Clinical parameters and Banff components of the last biopsy prior to Rituximab were compared between both cohorts by Wilcoxon- or chi-square tests. Observation time after therapy was not different between groups (26±26 vs. 49±24 months; $p=0.07$).

Results: More responders had donor-specific antibodies (6/9 vs. 1/10; $p=0.01$). Responders had lower serum creatinine before therapy (175 vs. 291 µm/l; $p=0.003$). Banff glomerulitis ($p=0.014$) and C4d staining of peritubular capillaries (C4d ptc, $p=0.03$) was less severe in responders. Other clinical (recipient gender and age, number of HLA-mismatches, living or cadaveric donor, previous renal transplant, time after transplantation) and histopathological criteria (glomerular C4d staining, tubulointerstitial edema, cell type, ptc, peritubular and glomerular endothelial swelling) were not different between groups. Responders had a mean serum creatinine of 189 ± 45 µm/l at the end of the observation time.

Conclusions: In this retrospective analysis, lower serum creatinine before therapy, positive donor specific antibodies, less transplant glomerulitis and C4d staining of ptc were identified as potential criteria to predict Rituximab responsiveness. These criteria need validation in future prospective randomized studies.

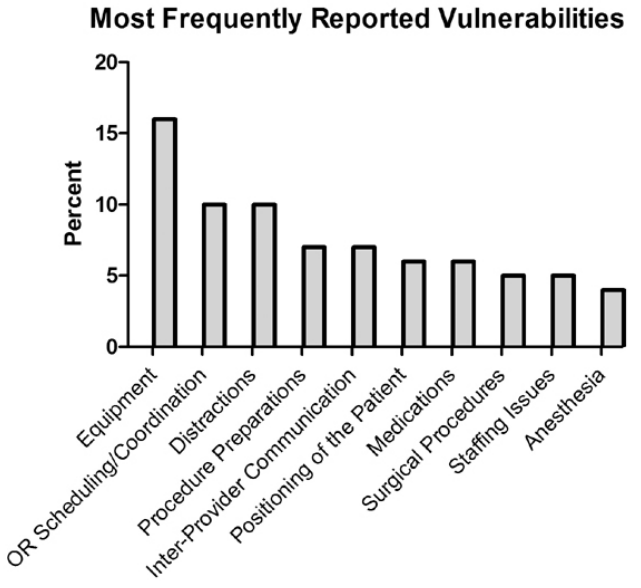
TH-PO918

Safety Issues Identified by Proactive Living Donor Kidney Transplant (LDKT) Safety Debriefing Daniela Ladner, Olivia A. Ross, Anton I. Skaro, Donna Woods, Vadim Lyuksemburg, Krutika Lakhoo, Renee Ziomek, Michael Abecassis, Jane Holl. *Northwestern University Transplant Outcomes Research Collaborative.*

Background: Little is known about the extent of safety vulnerabilities surrounding LDKT. Hospital incident reporting systems exist, but are known to vastly underestimate rates. To comprehensively assess vulnerabilities surrounding LDKT surgery, clinicians were asked to complete a debriefing survey.

Methods: A 28 question web-based debriefing was developed by an interdisciplinary team of patient safety experts and transplant clinicians. Comments were solicited on all safety related system or process issues. All clinicians in the LDKT surgery were asked to complete the anonymous survey immediately following the surgery. All incidents reported online or by phone to the hospital-wide reporting system for these LDKTs were reviewed.

Results: 210 debriefings were submitted on 83 LDKT procedures. Debriefings were completed by the entire clinical team: 40% by the surgical team, 37% by the nursing team, 16% by the anesthesia team, and 7% by others (e.g. lab tech, etc.). 213 vulnerabilities related to transplant systems and processes of care were reported. The most frequently reported included Equipment (e.g. broken surgical instruments), OR Scheduling/Coordination (e.g. avoidable delays), and Distractions (e.g. cell phones/pagers ringing).



In stark contrast, hospital-wide reporting systems identified just 22 reports for these LDKTs. 13 of these incidents were also captured by the safety debriefings.

Conclusions: Anonymous, short, proactive online debriefings can successfully elicit rich information on the safety risks related to LDKT surgery far beyond hospital wide reporting systems, which captured just 10% the number reported in the debriefings. This is supporting evidence that to date safety risks associated with LDKT are poorly described and vastly underestimated.

Incidence and Costs Associated with New-Onset Diabetes and Cardiovascular Events after Kidney Transplantation in a Commercially Insured Population

Suphamai Bunnapradist,[1] Schiffon L. Wong,[2] Brett Pinsky,[3] Fang Liu,[3] Cynthia Taylor,[3] Digisha Trivedi,[2] Tony Hebden.[2] *[1]Department of Medicine, UCLA, Los Angeles, CA; [2]Health Services, Bristol-Myers Squibb, Plainsboro, NJ; [3]Observational Research, OptumInsight, Eden Prairie, MN.*

Background: Kidney recipients are at increased risk of developing diabetes and cardiovascular (CV) events which adversely impact graft and patient survival. Our objectives were to describe the prevalence of pre-transplant diabetes and CV events; incidence of new-onset diabetes after transplant (NODAT) and CV events post-transplant; and associated costs in commercially insured kidney transplant recipients.

Methods: Adults with evidence of a kidney transplant (2004-2008) were identified using healthcare claims from a large U.S. managed care plan. "Incident" recipients (IR) had a transplant date within the study period. Medical claims with diagnoses for diabetes and CV events (stroke, coronary artery disease, revascularization, or myocardial infarction) were identified in the year prior to transplant and during the study period (earliest evidence of transplant until death, end of continuous enrollment, or 31Dec2009). Patient- and health plan-paid amounts for NODAT (costs for diabetes, insulin, or antihyperglycemic medication) and CV events (total costs) were assessed from NODAT onset or from CV event through the end of the study period.

Results: Among 1364 recipients, 25.7% had evidence of diabetes and 23.1% had a CV event in the year prior to transplant. Among patients without prior evidence of diabetes, 19.3% developed NODAT with a median (range) onset of 2.6 (0.0-59.1) months. 11.4% of IR without a prior CV event had an event post-transplant with median time to occurrence of 4.3 (0.0-53.9) months. Mean monthly costs associated with NODAT and post-transplant CV events were $953 and $21,439, respectively.

Conclusions: Kidney recipients have a substantial pre- and post-transplant prevalence of diabetes and CV events. Post-transplant onset of these morbidities is early and the associated costs are high. Strategies that reduce risk factors for diabetes and CV events may reduce the associated morbidity and costs of these conditions.

Funding: Pharmaceutical Company Support

TH-PO920

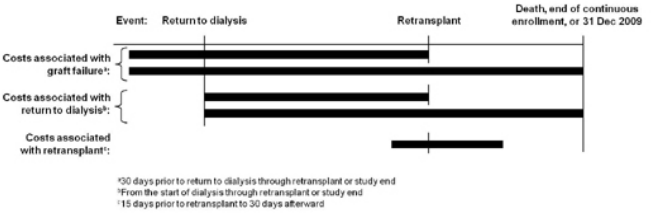
Incidence and Cost of Renal Graft Failure in Commercially Insured Kidney Transplant Recipients

Suphamai Bunnapradist,[1] Schiffon L. Wong,[2] Brett Pinsky,[3] Fang Liu,[3] Cynthia Taylor,[3] Digisha Trivedi,[2] Tony Hebden.[2] *[1]Department of Medicine, UCLA, Los Angeles, CA; [2]Health Services, Bristol-Myers Squibb, Plainsboro, NJ; [3]Observational Research, OptumInsight, Eden Prairie, MN.*

Background: The USRDS Annual Data Report cites a renal graft failure rate of 6.5 per 100 patient years in 2008 but little is known about the impact of graft failure on costs among commercially insured patients.

Methods: Adults with evidence of kidney transplant (2004-2008) were identified from US managed care healthcare claims. "Incident" recipients (IR) had a transplant date within the study period. "Prevalent" recipients (PR) had evidence of a transplant but an unknown transplant date. Graft failure was the first of retransplant or return to dialysis (2 or more dialysis visits in a 30 day period for 2 consecutive 30 day periods) and was identified from the earliest evidence of transplant until death, end of continuous enrollment, or 31Dec2009. Graft failure costs were patient and health plan-paid medical and pharmacy costs (Figure 1).

Timing of Cost Accrual for Graft Failure



*30 days prior to return to dialysis through retransplant or study end
†From the start of dialysis through retransplant or study end
‡15 days prior to retransplant to 30 days afterward

Results: Among 1364 IR, 11.8% had graft failure (10.9% returned to dialysis, 1.9% retransplant). Among 6753 PR, 8.4% had graft failure (8.2% returned to dialysis, 1.1% retransplant). Mean graft failure cost was $25,380/month. Return to dialysis was a major cost driver with a mean monthly cost of $16,867. Retransplant averaged $87,062. Median healthcare costs 3, 6, and 12 months post-transplant were $23,189 greater, $41,794 greater, and $55,789 greater, respectively, for patients with graft failure than for patients without failure in those time frames.

Conclusions: Graft failure occurred in 8-12% of these commercially insured kidney recipients and was associated with high costs for patients and commercial payers whether or not the transplant was paid for by the health plan. Strategies to mitigate graft failure may reduce these costs.

TH-PO921

Incidence and Costs Associated with New-Onset Diabetes and Cardiovascular Events after Kidney Transplantation in Medicare Population

William Irish,[1] Schiffon L. Wong,[2] Debora Bowers,[1] Digisha Trivedi,[2] Tony Hebden.[2] *[1]CTI Clinical Trial and Consulting Services; [2]Bristol-Myers Squibb.*

Background: New-onset diabetes after transplantation (NODAT) and cardiovascular (CV) events increase the risk for late graft loss and patient death. The incidence and economic implications of these have not been fully explored.

Methods: Adult Medicare beneficiaries in the US Renal Data System who received kidney-only transplant (2001 - 2008) were eligible. Patients with evidence of diabetes or CV events (stroke, coronary artery disease, revascularization, or myocardial infarction) pre- and post-transplant based on ICD-9-CM diagnosis codes were identified. Patients with diabetes or CV disease prior to transplantation were subsequently excluded. Total Medicare costs (Institutional and Physician/Supplier claims) were calculated from date of first claim until permanent dialysis, retransplantation, death, end of continuous enrollment or followup. Costs are for the first year following the first claim (adjusted using the annual medical care component of the Consumer Price Index).

Results: Among 84,819 recipients, 38% had diabetes and 24% had CV disease prior to transplantation. NODAT occurred in 16,518 patients with a median onset of 4 months (range: <1-60 months) post-transplant. Incidence was 13.6 per 100 patient-years (PTY) (95% confidence interval [CI] = 13.4 to 13.8 per 100 PTY). Costs were categorized by diabetes-related complications. The most frequent complication was nephropathy (26.3%) with a median total one year cost of $1,205 while ketoacidosis (4.4%) was the most expensive (Median total one year cost=$10,079). Peripheral circulatory disorder occurred in 4.1% of NODAT patients and was the least expensive (Median total one year cost = $621). The incidence of CV events (n=12,863) was 7.5 per 100 PTY (95% CI=7.3-7.6 per 100 PTY) with median onset = 7.5; range: <1-60 months post-transplant. Total one year costs for CV events were $99,228.

Conclusions: NODAT and CV events may present early post-transplant and are associated with high healthcare costs. Strategies are needed to minimize the risk of diabetes and CV disease to lower their economic and clinical impact.

TH-PO922

Kidney Disease Characteristics in Transplant Patients: Comparison between PREPARE and ANTICIPE Studies Laurent Juillard,[1] Eric Daugas,[2] Bertrand Dussol,[3] Patrick Henri,[4] Paul Stroumza,[5] Malik Touam,[6] Georges J. Mourad.[7] *[1]Nephrology, CHU Lyon, Lyon, France; [2]Nephrology, CHU Paris, Paris, France; [3]Nephrology, CHU Marseille, Marseille, France; [4]Nephrology, CHU Caen, Caen, France; [5]Nephrology, Clinique de la Residence du Parc, Marseille, France; [6]Nephrology, AURA Paris, Paris, France; [7]Nephrology, CHU Montpellier, Montpellier, France.*

Background: Comparing the chronic kidney disease (CKD) and its care in transplant patients (TP) and patients with CKD on native kidneys.

Methods: Comparison of characteristics of patients with CKD stage IIIB / IV based on the ANTICIPE and PREPARE studies. Prospective and observational studies. Collection during one week in TP for over one year and patients treated for CKD (eGFR < 60 ml/ min/1. 73m ²), respectively.

Results: 546 TP (373 stage IIIB, 173 stage IV) were compared to 1405 patients from PREPARE (659 stage IIIB and 746 stage IV). TP were younger (median 57 vs. 73, p <0.05) were less at vascular risk (BMI> 30, diabetes, smoking, dyslipidemia, p <0.05 for each) except for hypertension identically distributed (> 85% of patients). The occurrence of cardiovascular diseases was significantly lower in transplant patients and they receive fewer treatments for cardiovascular indications (RAS blockers, statins). Conversely, some of the complications associated with CKD are more common in TP: Anemia is more common, despite greater use of ESA (stage IV, Hb <12g/dL: 71 % vs 56%, p <0.05, ESA: 47% vs 35%, p <0.05), Only hyperparathyroidism is more frequent (stage IV, PTH> 150 ng/L: 47% vs. 39%, p <0.05), despite the most common therapeutic use of vitamin D. TP have more visits (monthly in stage IV: 47% vs 20%, p <0.05). In case of progression to stage V, the intention for transplantation is more common for transplant patients (60% vs 17%, p <0.05) including the pre-emptive transplantation.

Conclusions: Chronic renal transplant has its own characteristics including more frequent biological complications despite more frequent and closer monitoring of specific therapeutic targets, potentially more difficult to achieve.

myTRACKER – A Nordic Myfortic Observational Study Tracking the Gastro Intestinal (GI) Tolerability of Myfortic in Renal Transplant Recipients Converted to Myfortic Due to Cellcept Related GI Symptoms Sadollah Abedini, Morten Reier-Nilsen, Geir Nordbo, Kristian Heldal. *Medical Clinic, Vestfold Hospital Trust, Toensberg, Norway.*

Background: Clinical trails have demonstrated that *Myfortic* and *Cellcept* are equivalent in safety and efficacy but differences in occurrence of GI tolerability have not been examined in these trials. The primary objective was to evaluate if conversion from *Cellcept* to equivalent dose *myfortic* is associated with an improvement in patient-reported GI symptom during 3 months after the conversion. The secondary objectives were to assess compliance to treatment and overall safety and efficacy of *myfortic*.

Methods: Multi-centre, observational, non-interventional study in renal transplant recipients from Scandinavian centers converted to *myfortic* due to *Cellcept* related GI symptoms. The patients completed the Gastro Intestinal Symptom Rating Scale (GSRS) at baseline, 1 and 3 months after conversion. Treatment adherence was evaluated based on dosing information and from the Immunosuppressant Therapy Adherence Scale (ITAS). The assessment of safety and efficacy was based on collected adverse event data. Analysis, using descriptive statistics, was performed based on patient reported outcomes (GSRS) and Overall Treatment Effect (OTE) scales for GI symptoms.

Results: The study was terminated due to difficulty with patient recruitment and the presented data is based on 51 included patients (planned 150 patients), 33 males and 18 females with a mean age of 56 (13.3) years. The patients experienced about twice as many dose changes during the last 3 months before conversion while receiving *Cellcept* compared with the 3 months treatment with *myfortic* after conversion. After conversion to *myfortic* the patients experienced lower rate of abdominal pain (p<0.0001), constipation (p<0.076), diarrhea (p<0.0005), indigestion (p<0.0004) and reflux (p<0.0001) compared with baseline.

Conclusions: This study suggests that conversion to *myfortic* from *Cellcept* in kidney transplants results in improvements of GI related symptoms at 1 month and maintained at 3 months after conversion. Fewer dose-changes and lower occurrence of GI related symptoms are seen at equivalent therapeutic doses.

Comparisons of Enteric-Coated Mycophenolate Sodium and Mycophenolate Mofetil from the Mycophenolic Acid Observational Renal Transplant Registry Anthony J. Langone,[1] Richard W. Carson,[2] Fuad S. Shihab,[3] Oleh G. Pankewycz,[4] Anne Wiland,[5] Kevin M. McCague,[5] Laurence Chan.[6] *[1]Vanderbilt University; [2]Providence Sacred Heart Medical Center; [3]University of Utah; [4]Buffalo General Hospital; [5]Novartis; [6]University of Colorado.*

Background: The Mycophenolic Acid Observational Renal Transplant (MORE) Registry is a prospective, observational study of de novo renal transplant recipients (RTRs) receiving mycophenolic acid (MPA) therapy designed to determine effectiveness, tolerability and safety of enteric-coated mycophenolate sodium (EC-MPS) vs. mycophenolate mofetil (MMF)-based regimens based on local practice at 40 US sites.

Methods: Outcomes analyzed included: graft survival (GS), patient survival (PS), first biopsy-proven acute rejection (BPAR), mean serum creatinine (SCr), adverse event (AE) rates, and percentages of RTRs maintained on full MPA dose (1.44/2.0 g/day, EC-MPS or MMF respectively). Preliminary data from 901 patients (age 51.5, 64% male, 43% living donor transplant recipients) receiving tacrolimus were analyzed.

Results: Interim results at 1, 3, 6 and 12 months (613 EC-MPS/288 MMF patients) showed that more EC-MPS patients were maintained on full dose MPA (ECMPS/MMF: 79.2/71.2%, p=0.01; 68.6/55.6%, p<0.01; 52.7/43.0%, p=0.02; 47.3/39.4%, p=0.08). Actual mean MPA doses (SD) standardized to MMF dosing for EC-MPS/MMF were: 1853 (378)/1789 (441) mg, p=0.04; 1753 (465)/1648 (493) mg, p<0.01; 1590 (521)/1494 (529) mg, p=0.03; and 1532 (511)/1453 (522) mg, p=0.08 at months 1, 3, 6 and 12 posttransplant. Comparable 12-month clinical outcomes were achieved for effectiveness, tolerability and safety. There were no significant differences between EC-MPS and MMF treated RTRs in GS (96.9/97.6%, p=0.48), PS (99.3/98.4%, p=0.31), BPAR (9.6/8.0%, p=0.30), mean SCr (1.49/1.49 mg/dL, p=0.97) or reported incidence of AEs by organ system, infections or neoplasia.

Conclusions: The majority of renal transplant recipients who received tacrolimus as maintenance immunosuppression are maintained on full doses of MPA early posttransplant. Early significant dosing differences are seen between EC-MPS and MMF which may impact outcomes at later time points in this study.

Projection of Kidney Graft Survival Probabilities: An Evaluation of Methodologies Jiannong Liu, Yi Peng, Jon J. Snyder, Nicholas J. Salkowski, Ajay K. Israni, Kenneth E. Lamb, Bertram L. Kasiske. *SRTR, MMRF, Minneapolis, MN.*

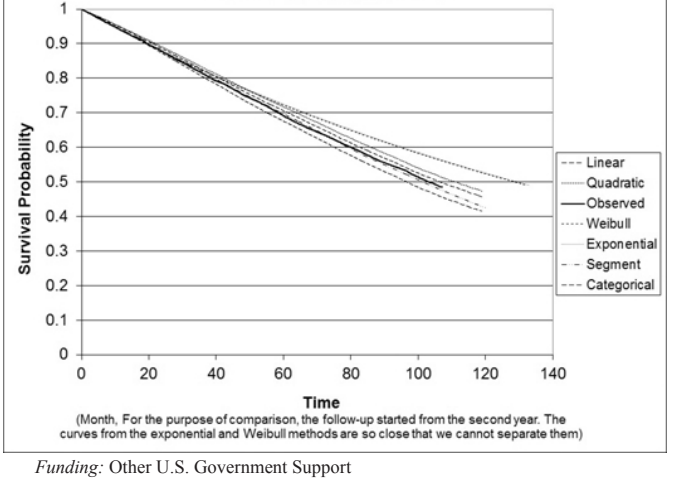
Background: Projected half-life is used to monitor post transplant patient and graft survival. A common method for projection, the exponential method, uses failure/death rate after the 1st year, assumes it is constant over time, and extrapolates it to the time when 50% of patients would be expected to lose the graft or die. Using the Scientific Registry of Transplant Recipients data, we evaluated this method and compared it with others.

Methods: Adult, deceased donor, 1st kidney transplant recipients in the US, 1991-2000, were included in the analysis. The outcome was all-cause graft failure. Observed and projected graft survivals (GSs) were calculated for the 2000 cohort. Patients were followed until the end of 2009 for observed GS. Data through 2002 were used to project GS. Methods for projecting GS included (1) exponential method, (2) Weibull method, (3) combining the 1991 cohort's GS (through 2002) and the temporal trend estimated from the 1991-2000 cohorts (using linear, quadratic, and categorical cohort year separately), and (4) segment method using the second-year death rate of the 2000 cohort, the third-year death rate of the 1999 cohort, and so on, to construct a piecewise survival curve for the 2000 cohort.

Results: Figure 1 displays the observed and projected GSs. For short-term projection, all methods work well. Long-term, the exponential and Weibull methods overestimate survival probability substantially; the segment and linear methods give the best estimates. For estimates of half-lives, the exponential and Weibull methods overestimated up to 32 months; estimate errors from the other methods were within 6 months and less than 2 months for the segment method.

Conclusions: The exponential method, currently widely used, can overestimate survival probability/half-life substantially; the segment and linear methods provide better estimates.

Figure 1. Projected and Observed Post Transplant Survival, 2000 Kidney Transplant Cohort



(Month, For the purpose of comparison, the follow-up started from the second year. The curves from the exponential and Weibull methods are so close that we cannot separate them)

TH-PO926

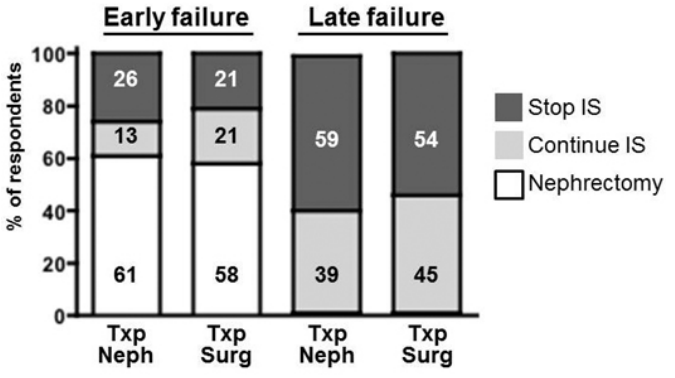
Time-to-Failure after Initial Transplantation Dictates Care for Repeat Kidney Transplantation Candidates Rowena B. Delos Santos,[1] Jordana Gaumond,[2] Roger Yuh,[1] Jennifer W. Leach,[1] Jagdeep Obhrai,[1] John M. Barry,[3] Mitchell Henry.[4] *[1]Dept Medicine, Division of Nephrology, Section of Transplant Medicine, OHSU, Portland, OR; [2]Dept Surgery, Portland VA Medical Center, Portland, OR; [3]Dept Surgery, Divisions of Urology and Abdominal Organ Transplantation, OHSU, Portland, OR; [4]Dept Surgery, Division of Transplantation, Ohio State University, Columbus, OH.*

Background: One in six patients on the waiting list for kidney transplantation in the US has received a prior kidney transplant. There are 3 strategies for managing asymptomatic patients with failed kidney transplants: elective transplant nephrectomy (N-TXP), discontinuance of immunosuppression (IS), and IS without N-TXP until the next transplant. We surveyed transplant nephrologists and surgeons to examine practice patterns or management of repeat transplant candidates.

Methods: We developed and validated internet based survey and sent it to transplant nephrologists and surgeons at all active US adult kidney transplant centers.

Results:

Figure 1 Management of Early and Late Allograft Failure for Transplant Nephrologists and Surgeons



More than 60% of centers responded. Management strategy depended on time of graft loss (< 6 months post-transplant or >10 years post-transplant). For early graft loss, most transplant nephrologists and surgeons chose N-TXP or discontinuance of IS. For late graft loss, most transplant nephrologists and surgeons chose discontinuing IS or IS without N-TXP. Surprisingly, neither patient-specific factors (co-morbidities or HLA-antigen sensitization), nor center-related factors (center size, academic affiliation, and location) influenced management. There was significant intra-center variability in management.

Conclusions: Time to graft failure was the primary factor for management of candidates awaiting a second kidney transplant. Provider-specific factors, rather than patient- or center-specific factors determined care strategy.

Urinary NGAL in Early Post-Transplant Period Predicts Long-Term Graft Function after Renal Transplant Hye Min Choi, Sung Yoon Lim, Sang-Kyung Jo, Won-Yong Cho, Hyoung-Kyu Kim. *Nephrology, Korea University Hospital, Seoul, Republic of Korea.*

Background: Graft function in early post-transplant period is known to affect long-term graft outcome, and several recent reports demonstrated the usefulness of urinary NGAL or IL-18 in predicting delayed graft function (DGF) with subsequent poorer graft outcome. However, the usefulness of urinary biomarkers in transplant patients with immediate graft function (IGF) or slow graft function (SGF) for predicting long-term graft outcome has never been assessed.

Methods: This was a single center, prospective observational cohort study of renal transplant patients (n=60, 33 deceased donor, 27 living donor). Only patients with IGF (n=43) or SGF (n=14) were enrolled to test whether urinary NGAL or liver type fatty acid binding protein (L-FABP) might be useful as biomarkers for predicting long-term graft outcome. Urine samples obtained at 0 hr, day 2 and day 6 were used for measurement of NGAL, L-FABP by ELISA. We examined long-term graft outcome by eGFR at 1yr after transplant.

Results: NGAL level on day 2, but not L-FABP or serum creatinine, was significantly higher in the SGF compared to IGF group. When patients were divided into 2 groups according to NGAL level on day 2, patients with higher NGAL level on day 2 were associated with significantly lower 1yr eGFR. In multivariate logistic regression analysis, day 2 urine NGAL was a significant, independent factor for predicting poor long-term outcome (1yr eGFR<55ml/min/1.73m^2). ROC curve analysis showed the ability of urine NGAL on day 2 for predicting lower 1yr eGFR was moderately accurate (AUC 0.742, cut-off value 86.7ng/ml with sensitivity 83.3% and specificity 67.0%).

Conclusions: We conclude that urinary NGAL at early post-transplant period is a useful predictor of long-term graft function even in patients with relatively good early graft function.

TH-PO928

Progression of Aortic Calcifications and Their Impact on Renal Function after Kidney Transplantation Carlo Maria Alfieri, Maria Daniela Croci, Brigida Brezzi, Francesco Barretta, Maria Teresa Gandolfo, Maria Meneghini, Manuela Curreri, Maria Pia Rastaldi, Piergiorgio Messa. *Nephrology and Dialysis, IRCCS Fondazione Ca' Granda Ospedale Policlinico, Milan, Italy.*

Background: Vascular calcifications (VCs) progress even after a well functioning kidney transplant (KTx).The main related factors and which impact, if any, VCs could have on the graft outcome is still unclear. The aims of our study were to evaluate: a) the factors associated with VC progression in the first year after KTx; b) VC impact on graft outcome over a 2-year follow-up period.

Methods: Abdominal aortic calcification index (ACI), FGF23, OPG, Fetuin, mineral metabolism (MM) parameters, were evaluated in 95 KTx pts (transplanted between 2006 -2008) at the 1st and at 12th months after KTx. All patients were followed-up over a 2-year period. Statistics: univariate and multivariate analyses (values: mean ± sd).

Results: In the overall cohort, mean ACI increased from 4.85 ± 5.84 (1st mo) to 5.23 ± 6.12 (12th mo) (p = 0.01). However, ACI increased (8.08±5.86 à10.25±5.60; p=0.0001) in 25% (Progr +), while it remained stable or improved (3.76±5.45 à 3.53±5.33; p ns) in 75% pts (Progr-). Progr + Pts were older (53±9 vs 46±11 yrs, p=0.01), had lower eGFR (MDRD: 50±15 vs 58±16 ml/min, p = 0.03), higher Ca (10.4±0.76 vs 9.93±0.65 mg/dl, p=0.002) and OPG (6±1.37 vs 4.8±1.55, p 0.002) levels at the 12th month, without any other significant differenc, including cumulative steroid doses.

In the Logistic RA, only serum Ca (p=0.004, OR 3.56) and OPG (p=0.01, OR 1.75) were significantly and positively associated with ACI progression. Over the 2-year follow-up, 3 patients died (2 Progr + , 1 Progr-) and 1 pt (Progr -) restarted dialysis. At the end of follow-up no significant difference was found in blood pressure control, in eGFR and urinary protein between the 2 groups

Conclusions: VCs progress even in the early post-KTx period. Higher levels of Ca and OPG seem to be associated with an increase in VCs . However, no major impact of VC progression on graft function was evident, at least over a 2-year follow-up. Studies on larger cohorts and over a longer period are needed for a definitve conclusion on this issue.

TH-PO929

The Burden of Chronic Kidney Disease-Mineral Bone Disorder (CKD-MBD) in Successful Renal Transplant Recipients: The ABC-Heart Study Sinead Kinsella, Joseph A. Eustace. *Department of Renal Medicine, Cork University Hospital, Cork, Ireland.*

Background: The burden of Chronic Kidney Disease Mineral Bone Disorder (CKD-MBD) in successful kidney transplant recipients is poorly defined.

Methods: We conducted a prospective observational study to quantify the presence and severity of CKD-MBD in first renal allograft recipients (eGFR > 30ml/min/1.73m^2). Patients underwent routine lab tests, iPTH, 25 OH Vitamin D, lumbar X-ray, DXA scan (Lunar IDXA), qCT of lumbar spine, pulse wave velocity measurement and measures of bone turnover (serum BAP and TRAC5B, urine NTx).

Results: 89 patients with mean age of 46.8 yrs, median dialysis and transplant vintage of 2.3 and 2.6 yrs were studied. Mean eGFR and iPTH was 54ml/min/1.73m^2 and 100ng/ml. 82% had iPTH > 65ng/ml, which was higher at lower eGFR. iPTH levels were similarly high in 8 pts with history of parathyroidectomy. iPTH correlated with total serum calcium (r=0.35, p<0.001) and phosphate (r= -0.43, p<0.001). The mean 25-OH Vitamin D level was 42nmol/l, 71% were Vitamin D deficient (<50nmol/l). Excluding 5 active vitamin D treated subjects, 25 OH Vitamin D was significantly associated with iPTH in normocalcemic but not in hypercalcemic subjects. 38% were hypercalcemic; spot urine calcium creatinine ratio (mean 0.16 mmol/mmol) was not associated with serum calcium but was increased in a dose dependant fashion in 9 subjects on cinacalcet. 22/69 pts had a venous pH <7.33. 25% of patients had osteoporosis, iPTH significantly correlated with bone density using DXA, especially at radial site, and with qCT at lumbar cortical sites. Fourteen patients suffered a post transplant low impact peripheral fracture. Forty-eight percent of subjects had evidence of aortic calcification which was higher in those with past cardiovascular history. Overall 97% had at least one element of CKD-MBD present.

Conclusions: The burden of CKD-MBD in successful renal allograft recipients is substantial and may contribute to their long term morbidity.

TH-PO930

Cholecalciferol Supplementation Reduces Proteinuria after Kidney Transplantation Ines Aires, Manuel A. Ferreira, Fernando Barbosa Nolasco. *Nephrology, Hospital Curry Cabral, Lisbon, Portugal.*

Background: Reduced native vitamin D (25-OH vit.D) levels are frequently found in chronic renal failure patients (pts.), but less is known in kidney transplant (KTx) population.

Methods: We prospectively evaluated the effects of 6 month cholecalciferol supplementation, in 124 KTx pts, 84 men, mean age 53.4±14.1 years, 29 diabetic, with a mean post transplant follow up of 79.3±63 months. All pts were naïve to 25-OH vit.D therapy. Immunosuppression regimen was tacrolimus in 74% and sirolimus in 21% pts.

Pts. were supplemented accordingly to basal (T0) calcidiol serum levels (ng/mL): deficiency (<15), insufficiency (15 to 30) and normal (>30).

Wilcoxon paired and Anova tests were used.

Results: At T0, 25-OH vit.D levels were 14.6±7.8 ng/mL. 58.9% pts had deficiency and 30.6% had 25-OH vit.D insufficiency. Mean plasma creatinine was 1.44±0.6 mg/dL.

At 6 months (T6), 64 pts. completed daily 25-OH vit.D supplementation (median dose 2664 UI). Mean calcidiol serum levels increased to 30.5±12.3 ($p< 0.001$). Only 6.2% remained in deficiency, and 46.9 % pts achieved normal serum levels (vs 10.5% at T0).

Proteinuria was significantly reduced from 0.931±1.48 g/dL (T0) to 0.685±0.66 g/dL (T6), p=0.03.After supplementation proteinuria levels were inversely correlated with 25-OH vit.D levels (r=-0.30: p=0.01).

Intact PTH decreased from 146.2±130 pg/mL (T0) to 118±112 pg/mL (T6), p=NS. No differences were observed in serum calcium, phosphorous and plasma creatinine. 25-OH vit.D supplementation was well tolerated, and no adverse events were reported.

Conclusions: Accordingly to our results, native vitamin D deficiency is highly prevalent among KTx pts. Oral supplementation with cholecalciferol is efficient, cheap and safe in the correction of calcidiol serum levels and leads to significant reduction in proteinuria.

Larger and longer randomized controlled studies are needed to confirm these relevant protective effects of cholecalciferol in kidney allograft survival.

TH-PO931

Should We Maintain Cinacalcet after Kidney Transplantation in Patients Receiving It on Dialysis Raphael Pereira Paschoalin, Jose-Vicente Torregrosa, Xoana Barros Freiria, Carlos Durán Rebolledo, Josep Maria Campistol Plana. *Nephrology Department, Hospital Clinic, Barcelona, Spain.*

Background: Nowadays, the treatment of secondary hyperparathyroidism (SHPT) with cinacalcet in patients that are on waiting list for kidney transplant (KT) is habitual. However, it is not clear if the treatment should be maintained after KT, and if so, which factors may define it.

The aim of this study was to evaluate the follow-up of KT recipients who discontinued cinacalcet just before the transplant.

Methods: Single center retrospective observational study. Enrollment began in June 2005 and ended in December 2010. 114 patients (75 men) were engaged. They were receiving cinacalcet on dialysis before KT. Median age: 51.3 years (22.5 to 78.5). The time on dialysis was 8.6± 8.4 years. All of them had three months follow-up and 92 completed one year of follow-up after KT. Criteria to reintroduce cinacalcet was serum calcium ≥ 10.5 mg/dL. We assess the factors involved in the reintroduction of cinacalcet after transplant (age, gender, time on dialysis, cinacalcet dose before KT, Ca / P / alkaline phosphatases / PTH at surgery, immunosuppression and renal function after KT. After KT biochemical parameters were measured at day 7, 15, 30, 60, 90, 180 and 365. Statistical analysis was made with SPSS-15.

Results: At three months 14 patients needed reintroduction of Cinacalcet and at the end of first post KT year, 20 patients (21.7%; group 1) were on cinacalcet treatment. Ninety-four patients did not need Cinacalcet reintroduction (group 2). Time on dialysis (131 ± 94 months and 97 ± 102 months; $p = 0.0267$) and the dose of cinacalcet before the KT ≥ 60mg per day (45 [30-120] y 30 [30-60] mg per day; p=0.039) were the only significant factors related to the reintroduction of cinacalcet.

Conclusions: The dose of cinacalcet before the transplant and the time on dialysis seems to be the most important factors related to the reintroduction of the drug during the first year after KT.

TH-PO932

Periodic Limb Movements in Sleep Are Associated with Serum Parathyroid Hormone in Kidney Transplant Recipients Zoltán Kiss,[1] Anett Lindner,[2] Rezso Zoller,[3] Katalin Fornadi,[2,3] Alpar S. Lazar,[3,4] Maria Eszter Czira,[3] Andrea Dunai,[3] Orsolya Agnes Veber,[3] András Szentkirályi,[3,5] Marta Novak,[3,6] Miklos Z. Molnar,[7,8] Istvan Mucsi.[3,8,9] *[1]Medical Affairs, Amgen Limited, Budapest, Hungary; [2]Dept. of Neurology, Semmelweis University, Budapest, Hungary; [3]Institute of Behavioural Science, Semmelweis University, Budapest, Hungary; [4]Surrey Sleep Research Centre, Faculty of Health and Medicinal Science, University of Surrey, Guilford, United Kingdom; [5]Institute of Epidemiology and Social Medicine, University of Muenster, Germany; [6]Dept. of Psychiatry, University Health Network, University of Toronto, Canada; [7]Harold Simmons Center for Chronic Disease Research & Epidemiology, Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA; [8]Institute of Pathophysiology, Semmelweis University, Budapest, Hungary; [9]Dept. of Medicine, Division of Nephrology, McGill University Health Centre, Montreal, QC, Canada.*

Background: Several reports suggested an association between Restless Legs Syndrome (RLS) versus serum iPTH concentration. No data has been published about iPTH and Periodic Limb Movements in Sleep (PLMS). We tested the hypothesis whether serum iPTH is associated with PLMS in kidney transplant recipients.

Methods: Data were obtained from 100 stable, prevalent kidney transplant recipients (Tx) (randomly selected from more than 1200 Tx patients followed at one outpatient transplant clinic) in a cross-sectional survey. The patients underwent a standard, one-night supervised polysomnography.

Results: The prevalence of PLMS (defined as PLMS-index > 5/hour) was 52% and prevalence of severe PLMS (PLMS-index > 25/hour) was 16% . Patients with severe PLMS had higher iPTH (median [IQR} 104[134] vs 59[53] pg/ml). The PLMS-index was significantly and positively correlated with serum iPTH (rho 0.327, p=0.019). This association remained significant after adjusting for age, gender, eGFR and co-morbidity.

Conclusions: In our research, severe PLMS was associated significantly with higher iPTH level and the PLMS-index was positively correlated with serum iPTH level even after statistical adjustment for several covariables.

TH-PO933

Vitamin D Therapy Post Renal Transplantation and a Potential Pothole Gauri Bhutani,[1] Horace J. Spencer,[3] Sundararaman Swaminathan.[2] *[1]Internal Medicine, University of Arkansas for Medical Sciences, Little Rock, AR; [2]Nephrology, University of Arkansas for Medical Sciences, Little Rock, AR; [3]Biostatistics, College of Public Health, UAMS, Little Rock, AE.*

Background: 1,25(OH)2 Vitamin D3 has been shown to directly decrease IFN-y production in T cells by its action on two IFN-y promoter elements. Impaired viral specific immune response has been noted in patients developing reactivation of the BK virus. CD 4+ T cell related IFN production is thought to be the key factor in keeping this virus in check.

Methods: A case-control study was undertaken with an adult post renal transplant patient population. All patients were transplanted at our center between 2007 to 2009 (n=180). Cases included patients with new reactivation of BK virus post renal transplantation - patients with viruria, viremia or nephropathy (cases, n=29). Controls were patients with no known reactivation of the BK virus (controls, n=151). Percentage of Calcitriol and Ergocalciferol use was compared between cases and controls. Chi square and T test analysis were amongst the methods used to evaluate the statistical significance of the difference in percentage of Vitamin D use.

Results: Vitamin D use (Calcitriol and/or Ergocalciferol) was 63.35% in all patients with at least one year follow up (n = 131). No significant difference was noted in the 25 (OH) Vitamin D3 levels between cases (18.75) and controls (19.66), $p = 0.733$. Cases were found to have a higher percentage of Vitamin D use. The difference in percentage of use between cases and controls with at least one year follow up (n = 102) was, however, not statistically significant. This was consistent for Calcitriol use alone (27.59 vs 19.06%, $p = 0.736$), Ergocalciferol use alone (24.14 vs 15.02%, $p = 0.358$) and Calcitriol and/or Ergocalciferol use (68.97 vs 59.80%, $p = 0.397$). No significant difference was also noted in BK virus reactivation between patients on vitamin D (n= 102) and patients not on vitamin D (n = 80), 20.69% vs 12.5% (p= 0.169).

Conclusions: Our study indicates likely safety of vitamin D use in renal transplant patients in relation to reactivation of latent BK virus and perhaps other similar viral infections as well.

TH-PO934

Comparison of Estimated Glomerular Filtration Rate (eGFR) Calculations to Measured GFR in Kidney Transplant Recipients V. Ram Peddi, Maria A. Miguel, Kimi Ueda Stevenson. *California Pacific Medical Center, San Francisco, CA.*

Background: No clear consensus exists regarding the most accurate calculation to estimate GFR in renal transplant recipients (RTRs). The two most frequently used equations are the Modification of Diet in Renal Disease (MDRD) and Cockroft-Gault equations. However, neither of these has demonstrated consistency or accuracy in RTRs and each calculation has limitations that preclude their use.

Methods: Radionuclear GFR was performed using radiopharmaceutical I-125 agent (Glofil®) in 13 stable RTRs between 3 and 12 months post-transplantation. Additionally, blood draws for BUN, creatinine, and albumin were obtained at the same time as the radionuclear GFR for use in the various eGFR equations: Cockroft-Gault, MDRD (Levey), abbreviated MDRD, CKD-EPI, Nankivell and Jelliffe. Statistical comparisons were made between the measured radionuclear GFR and the eGFR calculations.

Results: The mean age was 55y. 6 of the 13 RTRs (46%) were ≥ 60 years. 9 (69.2%) were male. One was African American. 25 radionuclear GFR measurements were available for analysis. 12 pts had 2 measurements each and 1 pt had 1 measurement. 6 measurements (in 3 patients) corresponded with Chronic Kidney Disease (CKD) Stage III (CrCl 30-59ml/min); 15 corresponded with CKD Stage II (60-90ml/min); and 4 corresponded with CKD Stage I (>90ml/min).

	Mean	Median	Standard Deviation	Standard Error	p value*
Radionuclear study	75.1	77	21.3	4.3	-

CKD-EPI	57.3	56.6	16.3	3.3	<0.001
Nankivell	72.6	74.9	13.5	2.7	NS
Jelliffe	74.3	77.5	11.1	2.2	NS

*paired t-test; **IBW-ideal body weight; ***ABW-absolute body weight

Conclusions: The Nankivell and Jelliffe equations for estimating GFR produced values that were closest to the measured GFR in stable RTRs. The Cockroft-Gault equation tended to overestimate whereas both MDRD equations and CKD-EPI underestimated the GFR. This demonstrates that the most frequently used equations in RTRs (MDRD and Cockroft-Gault) may not be the most ideal for use in drug dosing in kidney transplant recipients.

TH-PO935

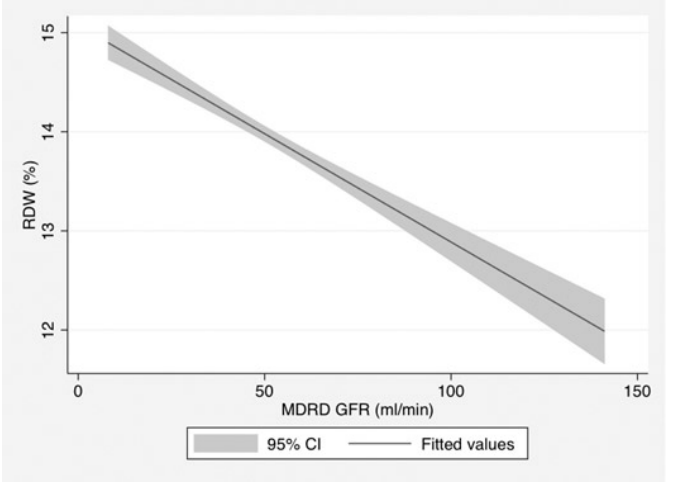
Renal Function Is Associated with Red Cell Distribution Width Independent of Iron Deficiency and Nutritional Status in Kidney Transplant Recipients

Istvan Mucsi,[1,2] Maria Eszter Czira,[2] Akos Ujszaszi,[2] Csaba P. Kovesdy,[3,4] Miklos Z. Molnar.[2,5] *[1]McGill University, Montreal, QC, Canada; [2]Semmelweis University, Budapest, Hungary; [3]Salem VA Medical Center, Salem, VA; [4]University of Virginia, Charlottesville, VA; [5]Harbor-UCLA, Torrance, CA.*

Background: Red cell distribution width (RDW) is a measure of heterogeneity in the size of circulating erythrocytes, which reflects iron deficiency, inflammation and nutritional status, predicts mortality in various patient populations. Impaired renal function is also a predictor of mortality and is associated with inflammation and protein-energy wasting. We assess if renal function is associated with RDW independent of iron deficiency, inflammation and nutritional status in stable kidney transplant (KT) recipients.

Methods: We examined the association of RDW with eGFR in a cohort of 807 prevalent KT recipients not receiving erythropoietin stimulating agents. Associations were examined in regression models adjusted for age, sex, Charlson Comorbidity Index, blood hemoglobin, percentage of hypochromic reticulocytes, soluble transferrin receptor, serum ferritin and transferrin, serum CRP and albumin, PO4 and iPTH and the use of immune suppressants.

Results: Lower eGFR was associated with significantly higher RDW (r=-0.399, -<0.001).



This association remained highly significant even after multivariable adjustments (beta=-0.178, p<0.001). The results were consistent in subgroups of patients with different levels of kidney function and various sensitivity analyses.

Conclusions: Lower eGFR is associated with higher RDW, a predictor of mortality, independent of comorbidity, iron deficiency, inflammation and nutritional status in kidney transplant recipients. Further studies need to determine the mechanisms linking impaired renal function to increased RDW and to increased mortality.

Estimating Glomerular Filtration Rate in Renal Transplantation: A Comparison between Serum Creatinine and Cystatin C-Based Equations

Jorge Malheiro, Isabel Fonseca, Manuela Almeida, La Salete Martins, Antonio Andresen Henriques, António Manuel Nunes Cabrita. *Nephrology Unit, CH Porto, Porto, Portugal.*

Background: Accurate monitoring of estimated Glomerular Filtration Rate (eGFR) is essential for an optimal management of kidney transplant (KT) patients. eGFR is often calculated using creatinine-based (SCRb) equations. Alternatively, cystatin C-based (CYSb) eGFR equations have been developed, but their exactness is still uncertain.

Methods: Creatinine Clearance (CrCl) in a 24-hours urine collection was the reference test. eGFR was calculated using CYSb equations (Le Bricon, Stevens) and SCRb equations [Cockcroft-Gault (CG), abbreviated MDRD (aMDRD)]. After evaluating randomly selected results of 215 KT patients with stable renal function and over 1 year post-transplant (PT), 173 were included. We excluded patients in the first and tenth deciles (in each gender) of 24-hours urine creatinine excretion divided by weight to deal with inaccurate urine collections. Bias, precision and accuracy of each equation were determined. Kappa statistics evaluated the concordance between the reference test and eGFR formulas in categorizing patients' renal function (positive test: <60 ml/min).

Results: Patients (108 males) had a mean age of 48.6 years and a median PT time of 6.8 years. Mean CrCl was 69.3 (range: 32 – 105) ml/min. The CYSb equations estimates (Le Bricon, Stevens) had the highest accuracy (83.8% and 87.9% within 30% of CrCl result, respectively). Le Bricon, Stevens and aMDRD precision was similar (13.5 ml/min) and much better than CG (22.5 ml/min). The lowest bias was seen in Le Bricon (-1.2 ml/min), followed by CG, Stevens and aMDRD (-2.6, -9.5, -16.5 ml/min, respectively). Kappa coefficient was higher in CYSb equations (0.53) in contrast with CG (0.48) and aMDRD (0.40). Stevens had a high sensitivity (90.8%) and low specificity (66.7%) and, conversely, Le Bricon had 64.6% sensitivity and 87.0% specificity for identifying patients with CrCl <60 ml/min.

Conclusions: CYSb equations showed the best accuracy and a low bias. Stevens performed better than Le Bricon in identifying patients with a lower CrCl. The inverse was observed in patients with mild or no kidney graft dysfunction.

TH-PO937

Renal Transplant Recipients Are at High Risk To Develop Precancerous Lesions of the Cervix

Suchita J. Mehta,[1] Mario R. Castellanos,[1] Suzanne E. El Sayegh,[1] Kathleen Ahern,[2] Morton J. Kleiner.[1] *[1]Dept. of Medicine, Staten Island University Hospital, NY; [2]Nursing Program, Wagner College, NY.*

Background: Immunosuppressive regimens improve survival of renal transplant recipients (RTR);however, a long-term complication is increased risk of developing cancer. Human papillomavirus (HPV) associated cancers of the genital tract are of particular interest, since they are sexually transmitted and in theory preventable. Cervical cancer rates are high in RTR but the data on the natural history of HPV infection in RTR are limited. Therefore, we investigate HPV and the development of cervical neoplasia.

Methods: A review was conducted in Medline database for articles in English investigating cervical HPV infection in RTR. Eligible studies included those that examined HPV infection by PCR testing and/or obatined cervical biopsies. Three reviewers extracted the data and compared rates to the general population.

Results: Out of 157 relevant citations, 12 met our inclusion criteria: 4 prospective studies included 231 RTR, 26.9% became HPV (+) and 13.2% that went for biopsy had a severe dysplasia. Six cross-sectional studies examined 187 RTR, 21.9% were HPV(+) and 16.7% had a high grade lesion. Two retrospective studies included 276 patients, only 25 RTR were sent for biopsy with 32% having severe dysplasia. The average duration of immunosuppression was 3.21 years to diagnose HPV or dysplasia.

Type of Study	No. of Studies	Duration of Immuno Suppression (yrs)	Frequency of HPV DNA (+) (PCR)	Frequency of Cervical Abnormalities among Patients sent for Biopsy	
				HPV or Mild Dysplasia	High Grade Dysplasia
Prospective Studies Total RTR=231	4	3.08	29.4% (68/231)	71.43% (30/42)	13.2% (7/53)
Cross-sectional studies Total RTR= 187	6	3.95	21.9% (41/187)	47.4% (54/114)	16.7% (17/102)
Retrospective Total RTR=276	2	2.6	Not Done	60% (15/25)	32% (8/25)
General Population Estimates (Peak Incidence) Am J Ob Gyn 2004;191: 105	N/A	N/A	10-33%	0.5%	0.8%

Conclusions: Studies on HPV and premalignant lesions of the cervix in RTR are limited, however, in our review we examined a large cohort. At about 3.1 years of immunosuppression 20-30% of RTR were HPV (+), rates similar to the general population. However, 13-32% of RTR biopsied had high grade dysplasias, while the general population rate is only 0.8%. Cervical cancer screening and prevention is important in RTR. Counseling should be aimed at limiting risky sexual behaviors post transplantation

TH-PO938

HLA-DR4 Protects Transplant Recipients from Cancer Mortality

Jennifer A. McCaughan,[1,2] Aisling E. Courtney,[1] A.J. McKnight,[2] Alexander P. Maxwell.[1,2] *[1]Department of Nephrology, Belfast City Hospital, Belfast, United Kingdom; [2]Nephrology Research Group, Queen's University, Belfast, United Kingdom.*

Background: Long term immunosuppression is associated with increased risk of malignancy. This is due in part to impaired immune surveillance and attenuation of the host response to certain oncogenic viruses. HLA DR4 is a key molecule in the presentation of tumour and viral antigens which trigger the development of activated T lymphocytes with potent anti-tumour action.

Methods: We investigated whether the presence of HLA-DR4 in renal transplant recipients conferred a survival benefit by reducing death from malignancy.

All patients receiving first deceased donor kidney transplants in Belfast between May 1986 and April 2005 had their clinical data recorded prospectively. Calcineurin inhibitors were introduced as part of the immunosuppressive regimen in 1989 and prior to this, all patients received dual immunosuppression with corticosteroids and azathioprine. All 707 recipients had their serologically defined HLA DR status recorded.

Survival analysis was performed using Kaplan-Meier and Cox-Regression plots.

Results: Renal transplant recipients with HLA DR4 were significantly less likely to die from malignant causes than those without a DR4 antigen (p = 0.037). This relationship persisted after correction for transplant recipient age.

There was no difference in overall mortality or death from infective causes between the two groups.

Conclusions: This study suggests that possession of an HLA-DR4 antigen provides significant protection from death due to malignant disease in renal transplant recipients. If this finding is confirmed in replication studies, then the presence or absence of a recipient HLA-DR4 antigen could help nephrologists stratify patients for future risk of cancer death and influence the choice of immunosuppression regimens.

TH-PO939

Ionizing Radiation Exposure from Medical Imaging in Renal Transplant Recipients Kim N. Nguyen, Francis L. Weng, Anup M. Patel. *Renal and Pancreas Transplant Division, Saint Barnabas Medical Center, Livingston, NJ.*

Background: Ionizing radiation and immunosuppression are risk factors for malignancies. Occupational radiation exposure is limited to 100 millisieverts (mSv) every 5 years and 50mSv in any single year. We analyzed the radiation exposure from medical imaging in renal transplant recipients (who have a higher risk of malignancy) from the time of transplant evaluation up to 3 months post-transplant.

Methods: We retrospectively analyzed 172 patients who received their first renal transplant during 2008. We determined types and numbers of medical imaging procedures from initial evaluation to three months post-transplant. For pre-transplant exposure, only imaging required for placement and maintenance on the transplant list were included. Estimates of radiation exposure for each procedure type were obtained from published literature.

Results:

mSv	Pre-Transplant	Post-Transplant	Total (n=172)
0-20	78 (45.3%)	110 (63.9%)	45 (26.1%)
>20-50	50 (29.1%)	44 (25.6%)	50 (29.1%)
>50-100	35 (20.4%)	16 (9.3%)	50 (29.1%)
>100	9 (5.2%)	2 (1.2%)	27 (15.7%)

An annual exposure (mSv/year) of 0-3, >3-20, >20-50, >50-100, >100, occurred in 10 (5.8%), 75 (43.6%), 65 (37.8%), 17 (9.9%), and 5 (2.9%) patients, respectively.

Multivariate Analysis of Factors Associated with Radiation Exposure >50mSv

		OR	95% CI	P value
Black race (vs. non-Black)		1.9	0.9-4.2	0.09
DGF (vs. no DGF)		3.6	1.3-10.3	0.01
Charlson Co-Morbidity Index (vs. 2-3)				0.01
	4-5	2.9	1.2-6.7	
	6-8	3.8	1.3-11.0	
Total Years of Follow-up (vs. </=1 year)				<0.001
	>1 to 2 years	1.6	0.5-4.7	
	>2 to 4 years	4.7	1.6-13.7	
	>4 years	11.2	4.1-30.9	

The tests responsible for the most exposure were nuclear stress tests (50.5% of total mSv) and CT scans of the abdomen/pelvis (22.7%).

Conclusions: Renal transplant recipients are exposed to significant amounts of ionizing radiation from medical imaging during their pre-transplant work-up and early post-transplant care. Strategies to reduce exposure, such as reducing the frequency of screening nuclear stress tests and following established guidelines for performance of CT scanning, should be considered.

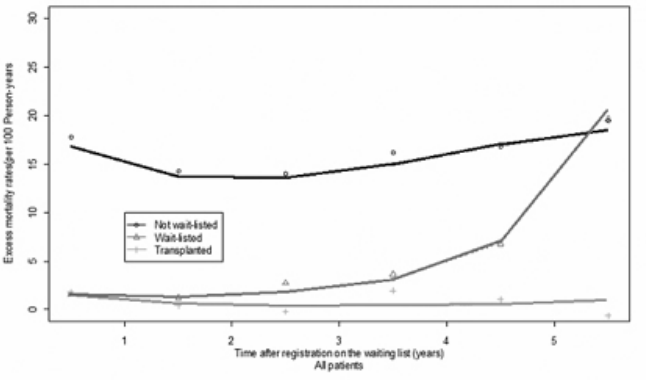
TH-PO940

Should We Change Our Renal Allograft Allocation Policy? Emmanuel Villar,[1] Liacine Bouaoun,[3] Cécile Couchoud,[2] Rene Ecochard.[3] *[1]Nephrology, Hospices Civils de Lyon, Pierre Benite, Rhone, France; [2]Registre REIN, Agence de la Biomedecine, La Plaine St Denis, Seine St Denis, France; [3]Biostatistics, Hospices Civils de Lyon, Lyon, Rhone, France.*

Background: Our aim was to quantify the evolution with time of excess mortality in end stage renal disease (ESRD) patients registered on renal transplant waiting list compared with non-transplant candidates and transplant patients.

Methods: We included all incident ESRD patients from 2002 and 2009 registered in the French REIN Registry. Excess mortality was computed each year after first dialysis in patients at risk stratified as follow: patients registered on renal transplant waitlist and never transplanted over study period (waitlist group), transplanted patients (transplant group), and patients never registered (dialysis group). Excess mortality was computed against French general population using relative survival method. Comparisons were adjusted for patients' characteristics.

Results: The study included 21 079 incident ESRD patients. There was no characteristic difference between waitlist and transplant patients. Dialysis patients were older and had more comorbidities. Variations of excess mortality were:



In waitlist group, excess mortality increased by 45% (p=0.0005) per year. Delay from first dialysis to registration (p=0.0004), age >65 (p=0.008), original nephropathy as diabetes or vascular cause of ESRD (p=0.028) and number of comorbidities (p=0.035) were independent predictors of excess mortality for patients registered on waiting list and not yet transplanted.

Conclusions: Our study quantifies annual increase of excess mortality while waiting for renal transplant. Results raised the question about priority of access to transplant in ESRD patients with comorbidities and/or older, considering as well access equity for all patients in the setting of organ shortage. These urge us to screen early high risk patients for transplantation.

TH-PO941

Listing Pre Dialysis Patients for Transplantation Increases Preemptive and Early Transplantation Post Starting Dialysis Wendy Brown, Damien Ashby, Megan Griffith. *Renal Unit, Imperial College Healthcare NHS Trust, London, United Kingdom.*

Background: Transplantation provides excellent outcomes for patients with ESRD and preemptive transplantation gives better outcomes compared to transplantation after commencement of dialysis. Planned living donor (LD) transplantation has increased rates of preemptive transplantation and UK guidelines recommend that people with advanced CKD (GFR<15mls/min) are activated for transplantation within 6 months of predicted need to start dialysis. We examined the effect of pre dialysis listing on LD and deceased donor (DD) transplantation.

Aim: to investigate the outcome of pre dialysis patients listed for transplantation

Methods: All patients in our low clearance clinics, anticipated to require dialysis in the next 6 months and deemed fit for transplantation were offered work up and listing for transplantation. The outcomes of those patients listed from Jan 2006-April 2011 were analysed

Results: 295 pre dialysis patients were worked up and listed on the national kidney allocation register. Table 1 summarises patient outcomes.

Outcomes	n	%	Median time to outcome in months
LD	66	22.5	2.6 [1.0-6.5]
DD	24	8.1	6.5 [2.6-11.9]
SPK	21	7.1	3.9 [1.6-8.8]
Dialysis	96	32.5	5.4 [3.9-17.9]
RRT not started	88	29.8	

In addition 10 of the patients who started dialysis subsequently received a transplant within 90 days. Therefore 55% (121/217) patients requiring RRT were transplanted before or within the first 90 days of starting dialysis. A small number of patients (3) not transplanted still did not require dialysis at 3 years. 15 patients were suspended due to medical reasons or stabilisation of CKD. 2 patients died.

Conclusions: Pre dialysis workup for renal transplantation successfully enables significant numbers of patients to receive both LD and DD preemptive renal transplants, and facilitates early transplantation post starting dialysis. However, predicting the time until dialysis will be required is difficult in some patients and better measures of this are required to optimize timing of transplantation and fair allocation of a scarce resource.

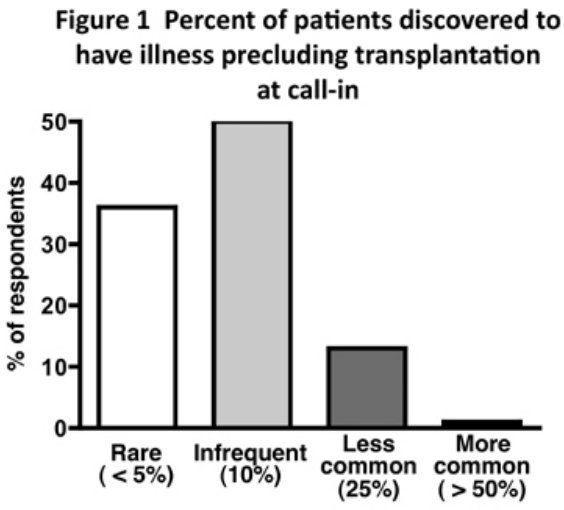
TH-PO942

Managing the Kidney Transplant Waitlist: 10 Years Later, More Patients and More Challenges Rowena B. Delos Santos, Jennifer W. Leach, Roger Yuh, Raghav Wusirika, Jagdeep Obhrai, Douglas J. Norman. *Dept Medicine, Division of Nephrology, Section of Transplant, Oregon Health Science University, Portland, OR.*

Background: The waitlist for kidney transplant (txp) has increased by 40% in the last 10 years. Waitlist management can impact cold-ischemic time at call-in for transplantation and overall cost of txp. However, no guidelines exist for waitlist care and little data exist on current practice.

Methods: To determine how care evolved since the 2002 national survey of waitlist management, we conducted an internet-based survey approximating the questions asked in the first assessment.

Results:



Respondents were asked to indicate what percent of patients called-in for transplant have problems that preclude transplantation.

This data reflects responses from a third of centers in the US. More centers follow patients after listing than in 2002 (96% vs 71%), and 2/3 risk stratify patients for follow-up frequency, up from 1/3. Compared to the previous survey that found that physicians frequently reported interval illness, patients are now more likely to be responsible for illness reporting. This change is associated with poor reporting efficiency at 70% of centers. An important measure of waitlist management efficiency is the detection of illness at call-in that prevents txp. At 64% of centers, >10% of patients called-in for a graft have problems preventing txp, up from 16% of centers. Timely illness reporting is uniformly correlated with dialysis staff involvement in illness reporting and low rates of cancellation of txp for medical illness.

Conclusions: More centers follow patients after listing now than in 2002. Despite this, interval illness is poorly reported and is associated with high rates of detection of illness preventing txp at call-in. Systems that improve timely reporting of illness may decrease cancellation of txp for medical illness discovered at the time of call-in.

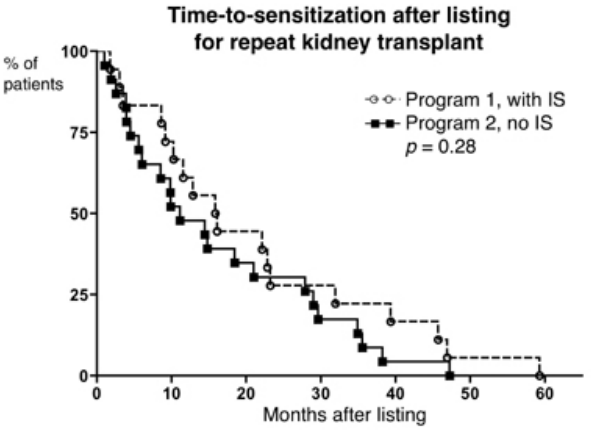
TH-PO943

Comparative Efficacy of Treatment Options for Patients Awaiting Repeat Kidney Transplantation Feroz Aziz, Rowena B. Delos Santos, Jagdeep Obhrai, Douglas J. Norman. *Medicine, Nephrology, Transplant Medicine, Oregon Health & Science University, Portland, OR.*

Background: Care of patients awaiting repeat renal transplantation can be complicated by sensitization stimulated by the failed transplant or by graft intolerance syndrome (GIS, rejection of the failed transplant). Early failure of renal transplants is usually treated either with elective transplant nephrectomy (N-TXP) or stopping immunosuppression (IS) without N-TXP. For late graft failure, most clinicians stop IS or continue some IS until the next transplant.

Methods: To determine whether there was a benefit for elective N-TXP for early transplant failure and IS for late failure, we retrospectively analyzed outcomes for waitlisted patients with a history of a prior transplant at two programs with similar patient populations but different treatment strategies. Program #1 (P#1) did elective N-TXP for all patients with early graft loss (< 2 years) and continued IS (prednisone + antiproliferative drug) for patients with late graft loss (≥ 2 years). Program #2 (P#2) discontinued IS in all patients with a failed graft while they awaited repeat transplantation.

Results: P#1 had 10/11 patients get N-TXP, but most P#2 patients with early graft loss ultimately required N-TXP (8/12). For patients with late graft lost, there was no difference in rates of N-TXP (p=0.12), sensitization (p=0.09), or time-to-sensitization at the 2 centers.



Immunosuppression (IS) does not impact time-to-sensitization for patients awaiting repeat kidney transplantation.

Conclusions: Our data indicate that N-TXP may be inevitable for patients with early transplant failure and support elective N-TXP for these patients. For patients with late graft loss, continuation of IS does not prevent sensitization or the need for N-TXP.

TH-PO944

Outcome after Late Conversion to Sirolimus Depends on Proteinuria and Renal Function Klemens Budde,[1] Wolfgang Arns,[2] Marcel Naik,[2] Fritz Diekmann,[2] Michael Fischereder,[2] Jan Gossmann,[2] Wilfried Gwinner,[2] Nils Heyne,[2] Jan Steffen Jürgensen,[2] Katharina M. Pressmar,[2] Christian Morath,[2] Frank Eitner.[2] *[1]Nephrology, Charité, Berlin, Germany; [2]German Sirolimus Study Group.*

Background: To better define predictors for a favourable outcome after late conversion to sirolimus (SRL)

Methods: We investigated all renal allograft recipients converted to SRL between 11.1.2000 and 12.12.2008 from 10 german transplant (Tx) centers. All data were retrospectively entered into a large national database.

Results: In total 726 pts started SRL after a median of 55 months (Mo) after Tx with a median follow-up of 24 Mo. In 75% it was their first Tx, 10% had received a combined Tx and 33% had experienced at least one rejection episode before conversion. Reasons for conversion included 26.3% CNI toxicity, 22.9% malignancy, and 17.6% chronic allograft nephropathy (CAN).

During the observation period 53 pts died, and 134 pts returned to dialysis. Overall patient and graft survival (including death) at 1, 3 and 5 yrs after conversion was 96%, 90.8%, 82.4% and 86.5%, 71.8%, and 57.7% respectively. In 33% renal function (GFR) improved and in 28% GFR deteriorated after conversion, resulting in overall stable GFR in the first year after conversion (40.4±18.4 before vs. 41.2±20.4ml/min after conversion; p=ns). Pts, who survived with a functioning graft had better GFR (42.8±19.5 vs. 27.7±13.8ml/min; p<0.001) and less frequent proteinuria >400mg/l (39.7% vs. 60.3%; p<0.001) at the time of conversion. Age, gender, time after Tx and previous rejection episodes did not differ between survivors and non-survivors. Pts with proteinuria >400mg/l, poor (<40ml/min) GFR, and CAN had significantly (p<0.001) inferior 5 year graft survival (75.1% vs. 88.9%, 55.0% vs. 75.7% , and 38.9% vs. 62.9%, respectively). Pts with malignancy had better graft survival (89.1% vs 60.7%; p<0,001), while pts with CNI toxicity had similar overall graft survival (64.7% vs. 68.4%; p=ns).

Conclusions: Conversion to SRL is a valid option for patients with malignancy and CNI toxicity, especially for those patients with adequate renal function and no severe proteinuria.

TH-PO945

Long-Term Experience with Everolimus in Kidney Transplantation in the United States Diane M. Cibrik,[1] William Irish.[2] *[1]University of Michigan Health System; [2]CTI Clinical Trial and Consulting Services.*

Background: Limited long-term data exist on US kidney transplant patients who have received everolimus (Zortress®) at time of transplantation.

Methods: Using data from the UNOS/OPTN database, we described outcomes among adult patients who received a kidney transplant between 1998 and 2007 and everolimus maintenance immunosuppression at time of discharge. Outcomes included acute rejection (AR), new onset diabetes after transplant (NODAT), primary graft failure and serum creatinine (SCr, mg/dL). We included single organ, first-time transplants between 1998 and 2007 as a reference group. Survival rates and associated 95% confidence intervals (CIs) were estimated using the Life Table method. The complimentary log-log model was used to estimate the rates of AR and NODAT.

Results: A total of 392 patients received everolimus maintenance immunosuppression at time of discharge. Mean age was 47.5 years, 21% were Black and 65% males. Median followup was 3 years. Unadjusted primary graft survival at 3 and 5 years post-transplantation

was 87.2% (95% CI: 82.5-90.7%) and 77.4% (95% CI: 70.8-82.7%), respectively, in the everolimus group and 82.7% (95% CI = 82.4-82.9%) and 72.6% (95% CI = 72.2-72.9%) in the reference group. Primary graft survival rates stratified by living versus deceased donors are provided in Table 1. Cumulative incidence of AR and NODAT at 3-years post-transplant with everolimus were 11% and 8.5%, respectively, and 5% and 9% in the reference group. Mean SCr at 3 years post-transplant was 1.8 with everolimus versus 1.6 in the reference group.

Table 1: Life Table Primary Graft Survival Post-Transplantation

	Everolimus		UNOS/OPTN Reference	
Time Post-Transplant	Living Donor (n=199)	Deceased Donor (n=193)	Living Donor (n=49,066)	Deceased Donor (n=72,199)
1 Year	95.6%±1.5%	92.3%±2.0%	95.1%±0.1%	89.4%±0.1%
3 Years	90.3%±2.6%	87.2%±2.8%	88.5%±0.2%	79.7%±0.2%
5 Years	83.0%±3.9%	72.0%±4.5%	80.3%±0.2%	67.3%±0.2%
Log-rank test	p=0.1033		p<0.0001	

Conclusions: Incidence of AR and NODAT was slightly higher in the everolimus-treated patients. Primary graft survival at 3 and 5 years post-transplantation seem to favor everolimus. This favorable effect was more notable in recipients of deceased donor renal transplants.

TH-PO946

Determinants of Successful Use of Sirolimus (SRL) in Renal Transplantation (Tx) Wilfried Gwinner,[1] Wolfgang Arns,[2] Klemens Budde,[3] Fritz Diekmann,[3] Frank Eitner,[4] Michael Fischereder,[5] Jan Gossmann,[6] Nils Heyne,[7] Marcel Naik,[3] Christian Morath,[8] Katharina M. Pressmar,[9] Jan Steffen Jürgensen.[3] *[1]Medical School Hannover, Germany; [2]Klinikum Koeln-Merheim, Germany; [3]Charite, Berlin, Germany; [4]University Aachen, Germany; [5]LMU, Munich, Germany; [6]University Frankfurt, Germany; [7]University Tuebingen, Germany; [8]University of Heidelberg, Germany; [9]University Erlangen-Nuernberg, Germany.*

Background: The German SRL Study Group has established a database among 10 German Tx-centres to better define indications, contraindications, adverse events & outcomes for SRL therapy in renal Tx patients (pts).

Methods: Included are 726 pts with conversion to SRL 3 months post-Tx or later in 2000-2008 (total observation 1582 patient-years, median 22.4 months).

Results: 462 males and 264 females (age 50±13) were put on SRL 80±74 (range 3-343) months post-Tx. SRL was initiated because of malignancies (23%), CNI side effects (26%), chronic allograft nephropathy (18%), creeping creatinine (23%), or a study protocol (11%). S-creatinine at SRL initiation was 2.2±1.0 mg/dl, proteinuria was 349±755 mg/l (range 1-5480). Before, 85% pts had CNI's, after SRL initiation 69%. SRL was terminated in 328 pts (45%), mostly early (1st year: 184; 2nd: 64; 3rd: 36; 4th: 17; 5th: 11). Main causes were renal impairment (52%; GFR decline, gross proteinuria, rejection, return to dialysis), infections & pulmonary complications (20%), musculoskeletal & skin problems (7%), gastrointestinal & metabolic complications (4%), neurological or psychiatric symptoms (1%), disturbed wound healing/before elective surgery (4%), patient's request (18%). Graft function at SRL initiation was slightly better in pts who continued on SRL (41±19 vs. 36±20 ml/min; p<0.001). The major difference between pts with and without continued SRL therapy was the degree of proteinuria at SRL initiation (means: 192 vs. 534 mg/l, medians: 75 vs. 133 mg/l, range 1-2473 vs. 5-5480; p<0.0001). Further, multivariate analysis revealed age, time of SRL initiation after Tx, and cause for SRL initiation as significant variables.

Conclusions: Absence of significant proteinuria is the major determinant for successful conversion to SRL.

TH-PO947

Management of Rapamycin-Associated Side Effects in Kidney Transplant Recipients Heloise Cardinal,[1] Raymond Dandavino,[2] Marie-Josee Hebert,[1] Suzon Collette,[2] Catherine Girardin,[1] Anne Boucher.[2] *[1]Nephrology, Centre Hospitalier de l'Université de Montréal, Montreal, QC, Canada; [2]Nephrology, Hopital Maisonneuve Rosemont, Montreal, QC, Canada.*

Background: Rapamycin-based immunosuppression may preserve kidney graft function. The side effects of rapamycin can limit its usefulness, but their management and evolution are rarely reported in clinical trials.

Methods: We performed a retrospective cohort study on KTR who received a single kidney graft before December 31st, 2008 and who received rapamycin after the 1st post-transplant month to replace or use in combination with low-dose calcineurin-inhibitors (CNI). We determined the incidence, management and evolution of rapamycin-related side effects.

Results: Amongst the 301 patients studied, new or worsened dyslipidemia occurred in 56%. Decreased rapamycin dose, diet and lipid-lowering drugs led to successful control in 98%. Cytopenia was observed in 40%. Decreased rapamycin dose, supplementing with iron or erythropoietin for anemia, folic acid for leucopenia, as well as the withdrawal of other cytopenic agents resulted in acceptable control in 94%. Peripheral edema was observed in 35%. Although decreased rapamycin dose, salt and water restriction, and diuretics were used, 20% of subjects with peripheral edema had to discontinue rapamycin. New or worsened proteinuria occurred in 26%. Despite decreased rapamycin dose, salt and water restriction, and renin-angiotensin inhibitors, 27% had to discontinue rapamycin. Acne developed or worsened in 25%. Decreased rapamycin or prednisone dose, topical or oral antibiotic therapy resulted in acceptable control in 86%. Rapamycin was discontinued for related side effects in 135 subjects (45%). Increased body mass index (OR per 10 point increase: 1.80, 95% CI 1.09, 2.96) was associated with discontinuation, and there was a trend for older subjects (OR per 10-year increase: 1.19, 95% CI 1.00, 1.43) to be more likely to stop rapamycin.

Conclusions: Successful control of dyslipidemia, cytopenia and acne can usually be achieved without discontinuing rapamycin, whereas proteinuria and edema are harder to manage. Leaner, and perhaps younger patients are less likely to discontinue rapamycin due to side effects.

TH-PO948

Race Is Associated with New Onset Hypertension and Diabetes after Living Kidney Donation Brian Boyarsky, Kyle Van Arendonk, Neha Deshpande, Nathan James, Robert Avery Montgomery, Dorry L. Segev. *Johns Hopkins.*

Background: While living kidney donation is generally considered safe, long-term development of co-morbidities is not well characterized. The goals of this study were to quantify new onset hypertension (HTN) and diabetes after living kidney donation and to explore risk factors associated with their development.

Methods: We surveyed 460 patients who donated a kidney at our center between 1984-2011. Median follow-up time was 4.4 years (IQR 2.1-7.9). Participants were asked to report new onset diagnoses of HTN and diabetes since donation, as well as all current medications. Multivariate logistic regression was used to examine the independent association of donor characteristics with HTN; because of low event rate, Fisher's exact test was used for diabetes.

Table 1. Multivariable models of associations between various donor factors and post-donation HTN

	Development of HTN		Requirement for anti-HTN therapy	
Factor	OR (95% CI)	p-value	OR (95% CI)	p-value
Black race	2.28 (1.04-5.47)	0.04	3.50 (1.41-8.67)	0.007
Age ≥ 50 at donation	1.80 (1.02-3.17)	0.04	2.91 (1.48-5.72)	0.002
Female sex	0.99 (0.56-1.74)	0.9	1.08 (0.56-2.05)	0.8
HS° education or less	1.42 (0.81-2.51)	0.2	1.12 (0.58-2.15)	0.7
Ever smoked*	0.64 (0.37-1.12)	0.1	0.54 (0.29-1.02)	0.06

° HS: high school; *Smoked ≥5 packs of cigarettes in life

Results: Of black living donors, 20.9% developed HTN and 7.0% developed diabetes. Conversely, of non-black donors, 12.7% developed HTN and 1.2% developed diabetes. Black race was significantly associated with new onset diagnoses of hypertension (p=0.04) and diabetes (p=0.03) in comparison to non-black race. After adjusting for multiple donor characteristics, black race was independently associated with new onset HTN (OR 2.28 95%CI 1.04-5.47) & HTN requiring pharmacologic therapy (OR 3.50; 1.41-8.67).

Conclusions: Black donors are at a greater risk for developing new onset HTN and diabetes after living kidney donation. Our findings through primary data collection in a large cohort of donors confirm previous suggestions of this effect made using administrative claims data.

TH-PO949

Patterns of Physician Visits before and after Living Kidney Donation Brian Boyarsky, Kyle Van Arendonk, Neha Deshpande, Nathan James, Robert Avery Montgomery, Dorry L. Segev. *Johns Hopkins.*

Background: Few transplant centers follow their donors on a long-term basis, leaving much of the role of follow-up care in the hands of primary care physicians (PCPs). Annual physician visits are generally recommended post-donation. The objective of this study was to describe the frequency of PCP and nephrologist visits among living kidney donors before and after kidney donation.

Methods: We surveyed 460 patients who donated a kidney at our center between 1984-2011. Median follow-up was 4.4 years (IQR 2.1-7.9). Frequency of visits to PCPs and nephrologists pre- and post- donation was categorized as more than annually, annually, less than annually, or not at all. Multivariate logistic regression was used to examine the independent associations of donor characteristics with seeing a PCP less than annually post-donation, with seeing a nephrologist post-donation, and with an increase in frequency of PCP visits after donation.

Results: Table 1. Frequency of visits to PCP and nephrologist pre-and post-donation

	PCP pre-donation	PCP post-donation	Nephrologist post-donation
>1x per year	18.0%	28.3%	5.0%
1x per year	62.7%	51.5%	5.0%
<1x per year	15.2%	10.7%	3.3%
Not at all	4.1%	9.6%	86.7%

After kidney donation, 20.3% reported seeing a PCP less than annually. In an adjusted model, men (OR 2.30 95%CI 1.43-3.69), donors with less education (OR 1.87; 1.14-3.06) and younger donors (OR 1.73; 1.05-2.85) were more likely to report seeing a PCP less than annually. 10.0% required nephrologist visits at least annually post-donation. Older donors were more likely (OR 1.84; 1.04-3.25) to have seen a nephrologist post-donation. Compared to before donation, 17.4% reported an increase in frequency of visits post-donation, 11.1% a decrease, and 71.5% no change. Males (OR 1.70; 1.04-2.78) and those ≥50 years old at donation (OR 1.59; 0.97-2.63) were most likely to increase PCP visit frequency after donation.

Conclusions: 20.3% of donors still saw a PCP less than the recommended frequency of once per year. Male sex, younger age, and lower education were associated with inadequate follow-up. Older donors were more likely to report seeing a nephrologist post-donation.

TH-PO950

Establishing an Incident Cohort of U.S. Living Kidney Donors by Direct Recruitment: The Kidney HALO Study Molly McGovern, Gary C. Curhan, Julie Lin. *Renal Division, Department of Medicine, Brigham and Women's Hospital, Boston, MA.*

Background: Although recent publications have contributed important new information about long-term outcomes in living kidney donors (LKD), almost all have been retrospective studies, which are subject to survival bias. We performed a pilot investigation to assess participant interest as well as the feasibility of direct recruitment of incident U.S. LKD for a new longitudinal cohort study.

Methods: In collaboration with the U.S. Health Research Services Administration, we obtained access to the mandatory registry of LKD to assess the feasibility and interest in their participation in a longitudinal cohort study (**K**idney **H**ealth **A**fter **L**iving **O**rgan donation or K-HALO) using a brief questionnaire. With a target 50% participation rate, K-HALO aims to recruit 6000 incident LKD participants over 2 years.

Results: In August 2010, we selected 405 consecutive LKD who donated at either 6 or 12 months earlier and sent each a questionnaire to assess interest in a proposed national living donor study. Addresses were invalid for 28 donors and 5 informed us they were liver donors. Of the remaining 372 donors, 210 (57%) completed the survey, 20 (5%) declined and 142 (38%) did not respond after three mailings. Of the 210 respondents, median age was 42 years, 143 (68%) were women, 153 (73%) were White, 15 (7%) were Black, 31 (15%) were Hispanic, 10 (5%) were Asian/other. This is representative of U.S. LKD according to 2009 UNOS/OPTN data (median age 41 years, 61% women, 69% White, 12% Black, 14% Hispanic, and 5% Asian/others). In addition, 198 (94%) were willing to participating in a longitudinal cohort study with biennial questionnaires, and 95% were interested in research on how dietary and lifestyle factors are related to continued health and quality of life after donation.

Conclusions: Direct recruitment of incident living kidney donors into a nationally representative and contemporary longitudinal cohort is feasible. Living kidney donors are interested in participating in research on dietary and lifestyle factors related to health outcomes as well as quality of life data after donation.

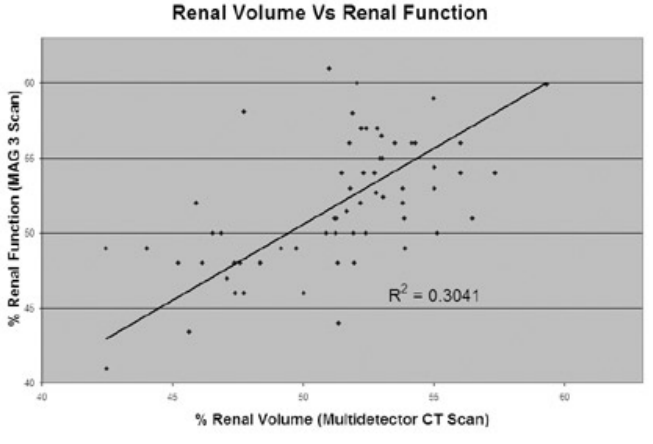
TH-PO951

Correlation between Relative Computed Tomography Based Renal Volumes and Split Renal Function in Living Kidney Donors Alejandro Diez, Tim E. Taber, Muhammad Ahmad Mujtaba, Muhammad S. Yaqub, John A. Powelson, Chandru Sundaram, Asif A. Sharfuddin. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Multi-detector computerized tomography with 3-dimensional reconstruction (MDCT) provides a reliable method to calculate renal volumes. Technetium-99m mercaptoacetyltriglycine (MAG3) split function scans are used to determine the relative contribution of each kidney to a patient's overall renal function. Whereas MDCT provides morphologic information about each kidney and MAG3 split function testing provides functional information, data suggest that there might be correlation between both tests. Herein we perform a head-to-head comparison of both techniques.

Methods: Single center retrospective review of patients > 18 years of age who presented for living kidney donor evaluation. Patients with both a MDCT and a MAG3 performed were included. Each kidney's relative volume was calculated as a percentage of the sum of the total renal volume. The relative volume of each kidney was then compared to the percent renal uptake on MAG3 of each kidney.

Results: 340 charts were reviewed, of which 64 patients fit the inclusion criteria. The average total renal volume was 364.9 ml (Left: 187.06 ml [SD: 54.78], Right: 177.84 ml [SD: 49.76]). The relative left kidney size was larger than the right (Left: 51.15%, Right: 48.85%) (P=0.0049). The average split renal function was higher on the left kidney than the right (Left: 51.52%, Right: 48.23%). Calculation of Pearson's correlation coefficient was 0.3041.



Conclusions: Although the data provided by each technique is useful, there is insufficient correlation between both techniques. In select cases data from both tests may still be equivocal. Factors other than renal volume and function, such as vasculature, may be the deciding factor of which kidney to select for donation.

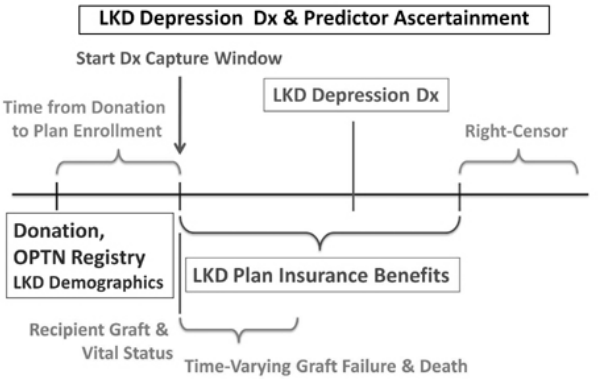
TH-PO952

Associations of Recipient Outcomes with Depression Diagnoses after Living Kidney Donation Krista L. Lentine,[1] Mark Schnitzler,[1] Daniel C. Brennan.[2] *[1]Saint Louis Univ; [2]Washington Univ.*

Background: We linked Organ Procurement & Transplantation Network (OPTN) registry data for a national sample of prior living kidney donors (LKD) with billing claims of a private insurer to study post-donation depression diagnoses (dx).

Methods: Participants (n=4,650) had OPTN records of donating in 1987-2007 and post-nephrectomy benefits at some point in the available claims (2000-2007). 81.2% of LKD were biologically related to their recipient, 7.6% were spouses, and 11.2% were non-spousal unrelated. Depression dx were ascertained from ICD-9-CM codes (296.2, 296.3, 311) on claims. Risk time began at start of post-donation benefits in the plan (Figure). We estimated associations of recipient graft failure and death with LKD depression by time-dependent Cox's regression. Depression dx rates in LKD were also compared with non-donors after 1-to-1 matching with general insurance beneficiaries by gender and age at benefits start.

Results: The median times from donation to start and end of captured benefits were 4.9 and 7.7 yrs, respectively. The cumulative frequency of depression dx after benefits start was 4.2% at 1yr and 11.5% at 5yr. After adjustment for baseline demographics, recipient graft failure and death were each associated with 2-to-3 times the relative risk of subsequent depression dx among non-spousal unrelated LKD (Table). There were trends towards increased depression risk after adverse recipient events in spousal LKD, but no associations in related LKD. Other correlates of LKD depression dx included female gender and white race. In matched-pairs comparison, the depression dx rate in LKD vs controls was 5.0 vs 7.1 per 100-PY (rate ratio 0.70, 95% CI 0.61-0.80).



Associations of Baseline LKD Factors & Recipient Outcomes with LKD Depression Dx

	Model 1 –Recipient Graft Failure as Predictor	Model 2 –Recipient Death as Predictor
	aHR (95% CI) for LKD Depression Dx	aHR (95% CI) for LKD Depression Dx
Time-Varying Recipient Event, by Relationship *		
If Recipient Biologically Related	1.06 (0.76–1.49)	1.11 (0.84–1.45)
If Recipient Spouse	2.04 (0.76–5.50)	2.00 (0.86–4.64)
If Recipient Not Biologically Related or Spouse	**3.30 (1.49–7.34)†**	**2.23 (1.11–4.48)†**
Donor Demographic Traits		
Female Gender	**2.44 (1.91–3.11)†**	**2.43 (1.90–3.10)†**
White, Non-Hispanic	**2.11 (1.53–2.92)†**	**2.12 (1.53–2.94)†**

†P<0.05

Conclusions: Recipient death and graft failure predicted depression dx risk among unrelated LKD. Informed consent and post-donation care should consider the impact of recipient outcomes on the LKD's psychological health.

TH-PO953

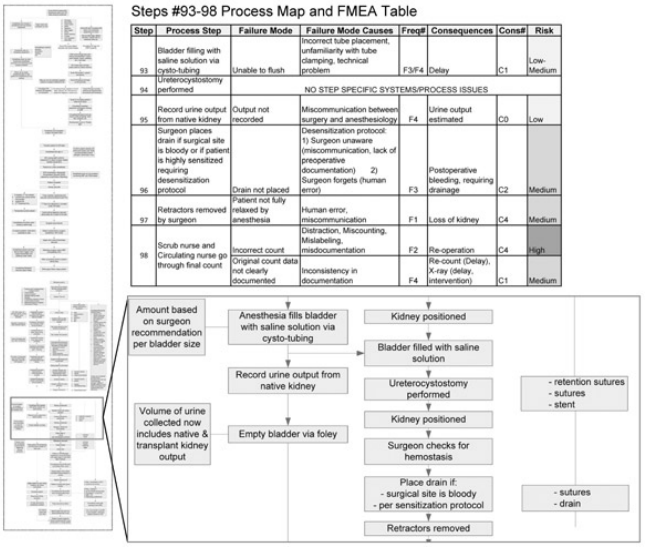
Knowing the Enemy – The First Step to Improving Safety in Living Donor Kidney Transplantation Daniela Ladner, Olivia A. Ross, Anton I. Skaro, Donna Woods, Vadim Lyuksemburg, Krutika Lakhoo, Anna Torricelli, Renee Ziomek, Gwen McNatt, Michael Abecassis, Jane Holl. *Northwestern University Transplant Outcomes Research Collaborative (NUTORC), Chicago, IL.*

Background: Safety in living donor kidney transplantation (LDKT) is essential as it involves not only a recipient but also a healthy donor. To assess LDKT proactively, rather than reactively after an adverse event has occurred, we performed a failure modes effects analysis (FMEA), a systematic methodology developed by industrial engineering.

Methods: FMEAs were performed for analysis of LDKT surgery. Safety experts led a series of FMEAs with all clinicians (surgeons, anesthesiologists, technicians, nurses, etc) involved in the LDKT surgery. Process maps were created, documenting each step in the

LDKT surgery. Then potential pitfalls (failure modes) were identified together with the potential causes, the frequencies, and the severity of the consequences. Ultimately pitfalls were categorized as low, medium, and high safety risk based on the frequency and severity of consequence (risk binning).

Results: 10 FMEAs were conducted involving a total of 17 clinicians. A total of 115 process steps were identified for LDKT surgery. Based on the results of the FMEA, 6 failure modes were classified as high risk, 44 medium risk, and 35 low risk. Predominant failure mode causes were communication, distraction, documentation errors, and protocol violations. Figure 1 highlights 6 steps of the process to provide an example of the LDKT procedure process map and the corresponding FMEA results (Figure 1).



Conclusions: FMEA of LDKT demonstrated a broad array of vulnerabilities in the systems and processes of care. The proactive analysis and systems and process improvement of LDKT is paramount to improving safety for donors and recipients alike.

TH-PO954

Post Nephrectomy Kidney Function in Living Kidney Donors Imran Sajjad,[1] Molly McGovern,[1] Stefan Tullius,[2] Sayeed Khan Malek,[2] Julie Lin.[1] *[1]Renal Division, Brigham and Women's Hospital; [2]Transplantation Surgery, Brigham and Women's Hospital, Boston, MA.*

Background: Few published data are available on change in kidney function after living donor (LD) nephrectomy.

Methods: We analyzed 169 LD's who donated between 2006 and 2010 at a single U.S. transplant center. Plasma creatinine (pCr) at 1 year post-nephrectomy was the primary outcome. We compared donors who had ≥25% increase in pCr vs. those with <25% increase in pCr at 1 year and constructed a logistic regression model to examine associations between this outcome and pre-donation characteristics.

Results: Demographic and clinical characteristics of those with ≥25% (78%) vs. those with <25% increase in pCr at 1 year are shown in **Table1**. In addition, 27% had ≥50% and 31% had ≥0.4 mg/dl increase in pCr 1 year after nephrectomy. On univariate analyses, donor age, sex, race, MAP, and fasting glucose were associated with higher pCr ($p < 0.20$) and were selected for the MV model. In logistic regression, each 1 mmHg increase in MAP at time of donation was significantly associated with a ≥25% increase in pCr at 1 year [OR=1.06, 95% CI 1.01-1.11].

Conclusions: One year after nephrectomy, a substantial proportion of healthy kidney donors have persistently lower renal function. Longer term follow-up in LD's is needed to assess the time course of renal function recovery. Higher pre-donation MAP is associated with a ≥25% increase in pCr at 1 year after donor nephrectomy.

Table 1: Demographic and Clinical Characteristics of the LD Study Population

	<25% increase in pCr at 1 year (n=38)	≥25% increase in pCr at 1 year (n=131)	p-value
Age (years)	43 (34, 49)	45 (38, 54)	0.07
Male (%)	26	50	0.02
Caucasian (%)	89	79	0.23
Current smoker (%)	11	9	0.74
Past smoker (%)	56	50	0.80
BMI (kg/m2)	25.2 (22.2, 30.8)	26 (23.9, 29.1)	0.54
AER ≥5mcg/min (%)	18	17	0.81
MAP (mmHg)	85 (77, 91)	90 (83, 95)	0.003
Fasting glucose (mg/dl)	84 (81, 91)	87 (78, 93)	0.21
Baseline pCr (mg/dl)	0.81 (0.80, 1.00)	0.88 (0.74, 1.00)	0.66
pCr on POD # 1 (mg/dl)	1.10 (1.00, 1.20)	1.30 (1.03, 1.60)	0.14
pCr at 1 year (mg/dl)	1.00 (0.96, 1.10)	1.30 (1.10, 1.49)	n/a

Results expressed as median (25th and 75th percentile range) or %. MAP= Mean arterial pressure, pCr=plasma creatinine.

TH-PO955

Living Donor Kidney Transplants: Trends in Results throughout 20 Years of Experience Carlos R. Chiurchiu, Javier De Arteaga, Walter Guillermo Douthat, Jorge Luis De la Fuente, Pablo U. Massari. *Renal Service, Kidney Transplant Program and Postgraduate School of Nephrology, Hospital Privado-Centro Médico de Córdoba and Catholic University, Córdoba, Argentina.*

Background: Since the late nineties changes in immunossupressive protocols, introducing of living unrelated donors and Banff scoring might have influenced results in living kidney donors transplantation (LKT).

Methods: Our objetive was to study the impact of these changes altogether in the results of a cohort of LKT transplanted between 1988 up to 2007 (n:308). Results were analyzed in two cohorts according decade of transplantation: first decade 88' to 97' (n:121) and second decade 98' to 07' (n:187).

Results: Donor and recipient age increased from 39.9±12.8 to 44.8±12.2 ($p<0.001$) and from 30.5±12.4 to 35.5±15.2 ($p< 0.002$) respectively. HLA missmatch number increased from 1.9±1.2 to 2.4±1.2 ($p<0.001$). Months in dialysis also changed from 21.1±22.9 to 29.3±32.6 ($p<0.01$). Five years graft survival improved from 77% to 88% (logrank $p <0.05$), and patient survival from 91% to 97% (logrank $p<0.03$) between first and second cohort. Incidence of acute rejection (AR) decreased from 47.1% to 20.3% ($p<0.0001$). Delayed graft function was present in 26.4% and 10.2% of patients in first and second cohort respectively ($p<0.0001$). Urologic complications declined from 27.2% to 10.1% ($p<0.001$) and vascular complications remained unchanged 23,9% to 19.2% (p:n.s.) across decades. Multivariate analysis shows that only absence of AR was an independent risk factor for graft survival (OR: 0.46, 95%CI: 0.26-0.79, $p<0.005$). Worst patient survival was associated with patient's age (OR: 1.07, 95%CI: 1.03-1.12, $p<0.001$) and transplant in first decade (OR: 5.76 95%CI: 1.61-19.70, $p<0.001$).

Conclusions: Improvements across decades in patient care and immunosuppressive protocols have improved outcomes in LKD despite transplantation of patients with increasing risk factors and HLA missmatching.

TH-PO956

Comparison of Two Nuclear Scan Tracer Methods for Accurate Assessment of Kidney Donor Glomerular Filtration Rate Anna C. Porter, Nidhi Aggarwal, Ignatius Yun-Sang Tang, Sanjeev Akkina. *Nephrology/Transplant Surgery, University of Illinois at Chicago, IL.*

Background: Accurate assessment of the glomerular filtration rate (GFR) is essential to assess candidacy for kidney donation, but is often difficult to do, especially in obese donors. Collection of 24 hour urine specimens is often unreliable. Though it is considered the best method for donor GFR evaluation, iothalamate clearance measurement availability is limited. Nuclear scans are often used due to availability and perceived accuracy. However, the tracer used may influence the accuracy and therefore effectiveness for kidney donor evaluation. We assessed how two radioactive tracers correlate to commonly used GFR estimation equations which have been validated against iothalamate clearance studies in order to compare different nuclear tracer GFR measurement methods for GFR evaluation of obese donors.

Methods: GFR measurements (mGFR) from nuclear scans conducted between 2009-September 2010 using mercapto-acetyl triglycine (MAG3) and September 2010-present using Tc-99m-diethylenetriaminepentaacetic acid (DTPA) were compared to the Cockcroft-Gault, Modification of Diet in Renal Disease (MDRD), and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations (eGFR). We assessed bias (eGFR-mGFR), precision (R2 of regression), and accuracy (percent within 30% of mGFR).

Results: Average age, BMI, gender and ethnicity makeup were similar between the two groups. The DTPA scan had better precision with the Cockcroft-Gault, MDRD, and CKD-EPI equations compared to the MAG3. Accuracy and bias were statistically similar.

	MAG3	DTPA	p-value
Age	38.2±11.2	37.3±13.8	0.71
Male	44%	56%	0.26
BMI	30.9±5.8	33.5±8.0	0.11
Ethnicity			0.66
White	23%	33%	
Black	43%	41%	
Hispanic	26%	22%	
Asian/Other	7%	4%	
Cockroft-Gault			
R2	0.102	0.391	
% within 30%	64%	74%	0.31
Bias	19.2±22.6	12.7±17.3	0.16
MDRD			
R2	0.025	0.23	
% within 30%	70%	81%	0.20
Bias	2.3±27.1	-6.8±19.6	0.10
CKD-EPI			
R2	0.03	0.20	
% within 30%	70%	70%	0.93
Bias	-1.8±26.7	-10.9±20.8	0.09

Conclusions: In obese donors, the DTPA tracer offers improved precision while accuracy and bias were similar or slightly better and should be the preferred method if iothalamate clearance is unavailable at the transplant center.

TH-PO957

Structural and Mechanical Properties of Large Arteries after Kidney Transplantation: Major Impact of Donor Age and Living Donor Kidney Transplantation Michel Delahousse,[1] Alexandre Karras.[2] *[1]Nephrology and Transplantation, Foch Hospital, Suresnes, France; [2]Nephrology, Georges Pompidou European Hospital, Paris, France.*

Background: Damage to large arteries in ESRD patients is characterized by an outward remodeling of the carotid artery leading to an increased circumferential wall stress (CWS) and by increased aortic and carotid stiffness.

Methods: We measured carotid-femoral pulse wave velocity (PWV), aortic pressure and carotid remodeling and stiffness parameters at three months (M3) and one year (M12) post-transplantation in 77 consecutive kidney recipients (57 cadaveric kidney and 20 living donor kidney recipients).

Results: PWV decreased (10.8 + 2.5 vs 11.6 + 2.7 m/s, p = 0.015) independently of mean aortic pressure. CWS decreased (67.6 + 16 vs 71.4 + 16, p = 0.03) as a result of a decrease in carotid internal diameter. PWV change (PWVM12-PWVM3) correlated with mean aortic pressure change(MAP) (R=0.348, p = 0.003), donor age (R-0.308, p=0.008), living donor (R= -0.330, p = 0.004), plasma phosphate concentration at one month (R=0,309, p = 0,008, body mass index (BMI) change (R=0.310, P=0.006), M3 PWV (R=-0.260, p = 0.026), but not with isotopic GFR. MAP, donor age, living donor and BMI change remained independently related to PWV change in multivariate analysis.

In deceased donor kidney recipients, donor age was the main determinant of isobaric PWV change (improvement with young donors), confirming our previous results in an independent cohort of kidney recipients (J Am Soc Nephrol 19: 798 –805, 2008).

In living donor kidney recipients, the improvement of aortic stiffness, carotid remodeling and stiffness parameters was remarkable and highly significant.

Arterial parameter	M3	M12	P
Aortic stiffness (m/s)	11.4±3.4	9.8±1.9	0.002
Carotid stiffness (m/s)	6.8±1.5	5.9±1.3	0.005
Young elastic modulus (kPa)	520±224	352±126	0.003
Carotid internal diameter (mm)	6.44±1.03	6.22±0.94	0.039
Carotid IMT ([mum])	608±128	628±137	0.192
CWS (kPa)	76.2±16.3	65.4±14.8	0.007

Conclusions: Damage to large arteries can reverse after kidney transplantation. Donor age (in cadaveric kidney recipients) and living donor kidney transplantation are the main determinants of this improvement.

TH-PO958

Changes in Soluble Tumor Necrosis Factor Receptor-2 (sTNFR-2) after Living Donor Nephrectomy Molly McGovern, Julie A. Berkley, Sushrut S. Waikar, Julie Lin. *Renal Division, Department of Medicine, Brigham and Women's Hospital, Boston, MA.*

Background: Higher plasma sTNFR-2 levels have been strongly associated with subsequent kidney function decline in people with well preserved kidney function. Animal studies suggest sTNFR-2 is primarily renally cleared, but no studies in humans currently exist.

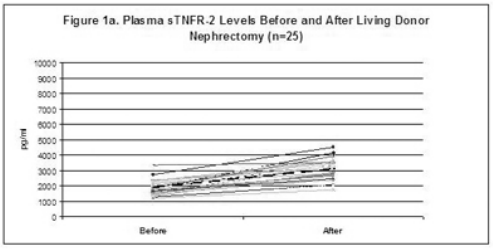
Methods: We studied 25 consecutive living kidney donors (LKD) at our center who had measurements of sTNFR-2 before and 24 hours post-nephrectomy as well as 5 patients who underwent CABG surgery with plasma collected prior to surgery and 24 hours post-op. sTNFR-2 was measured by an ELISA assay from R & D Systems using a quantitative sandwich enzyme immunoassay technique. Directly measured CV was 5% in blinded split samples.

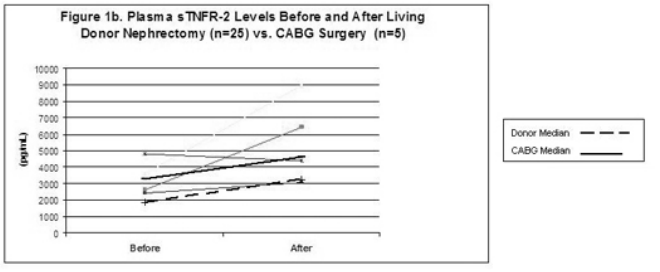
Results: Clinical characteristics for both groups are summarized in Table 1.

	LKD (n=25)	CABG (n=5)
Age (median and range) (years)	51 [27, 67]	79 [63, 84]
Sex (M/F)	48%/52%	40%/60%
White	96%	100 %
Non-white	4%	0%
Median pre-PCr (mg/dL)	0.81	1.03
Median post-PCr (mg/dL)	1.31	1.01
Median pre-sTNFR-2 (pg/ml)	1848	3285
Median post-sTNFR-2(pg/ml)	3293	4621
Median change sTNFR-2 (pg/ml)	1212	1336

pCr = plasma creatinine

Our preliminary data show that sTNFR-2 consistently increases after donor nephrectomy in patients (Figure 1a).





The CABG patients had a higher baseline level of sTNFR-2 (median 3285 vs. 1848 in LKD) that also increased post-operatively (median change 1336 vs. 1212 in LKD) (Figure 1b).

Conclusions: Plasma sTNFR-2 levels are universally increased after living donor nephrectomy; however, this phenomenon is also seen in post-CABG patients. We therefore conclude that increases in sTNFR-2 after donor nephrectomy do not primarily reflect loss of glomerular filtration rate.

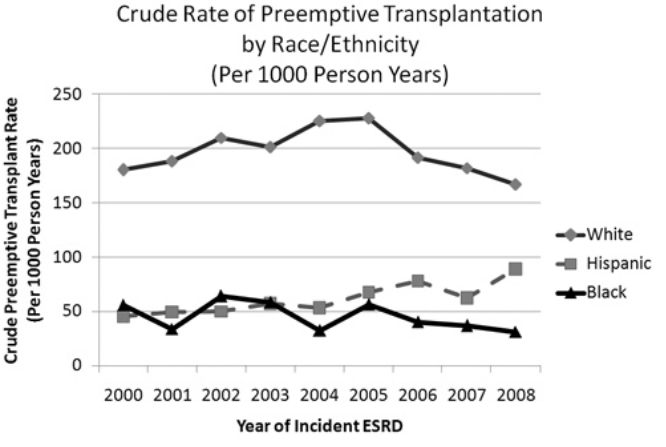
TH-PO959

Racial Disparities in Access to Preemptive Kidney Transplantation among the National Pediatric ESRD Population Rachel E. Patzer, Sandra Amaral, Nancy G. Kutner, William M. McClellan. *School of Medicine, Emory University, Atlanta, GA.*

Background: Kidney transplantation is the preferred treatment for pediatric End Stage Renal Disease (ESRD), and preemptive transplant may reduce morbidity and mortality. It is unknown how race and poverty impact access to preemptive transplant in the pediatric ESRD population.

Methods: We examined the incidence rate of preemptive renal transplant by race/ethnicity among the national pediatric (< 21 yrs) ESRD population using United States Renal Data System data from 2000-2008. Annual rates were calculated as incident preemptive transplant count divided by ESRD patient years. Rate Ratios for preemptive transplant by race/ethnicity were calculated using adjusted generalized linear Poisson models. We considered neighborhood poverty and health insurance as socioeconomic status (SES) measures.

Results: Among 10,855 pediatric ESRD patients (pts) from 2000-2008, a total of 1,287 patients (11.9%) had a start date of ESRD equivalent to their transplant date and no history of dialysis. The average annual rate of preemptive transplant was higher among whites (202/1000 person-years[PY]) than Hispanics (59/1000 PY) and blacks (48/1000 PY). Racial differences were evident in the type of preemptive transplant received, where more white pts had a living donor (78.8%) vs. Hispanics (57.3%) and blacks (48.8%)(p<0.0001). In adjusted analysis, Hispanics had a 50% (95% CI: 0.41-0.61) and blacks a 56% (95% CI: 0.36-0.54) lower rate of preemptive transplant vs. whites.



The effect of race on preemptive transplant was not modified by SES, and racial differences persisted after adjustment for SES.

Conclusions: Pediatric racial minorities have a significantly lower incidence of preemptive transplantation, which was unexplained by SES. Further studies are needed to elucidate why minority groups with pediatric ESRD are less likely to receive early renal transplantation.

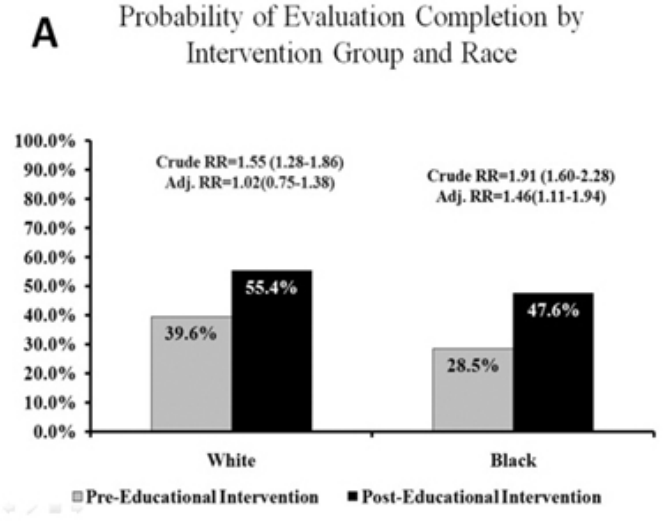
TH-PO960

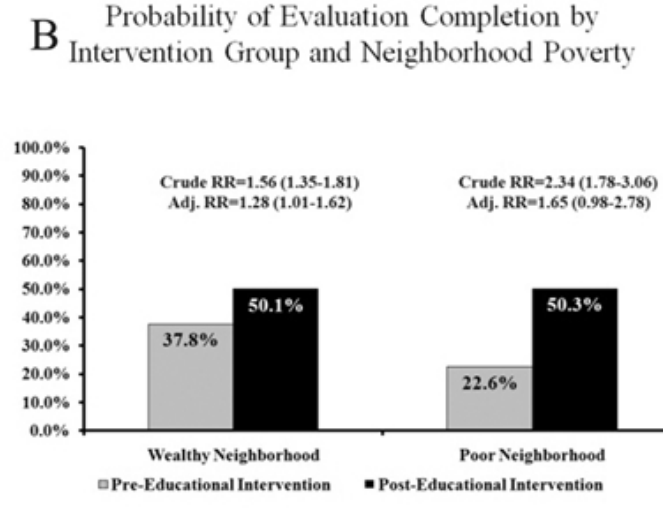
Reduced Racial and Socioeconomic Disparities in Kidney Transplant Evaluation Completion after Start of a Required Patient Education Program Rachel E. Patzer, Jennie P. Perryman, Stephen O. Pastan, Sandra Amaral, William M. McClellan. *School of Medicine, Emory University, Atlanta, GA.*

Background: In 2007, the Emory Transplant Center (ETC) kidney transplant program implemented a patient education class for End Stage Renal Disease (ESRD) patients referred for transplant. The purpose of this intervention was to improve patient awareness about the transplant process and to increase evaluation completion.

Methods: We examined one-year evaluation completion among ESRD patients referred 2005-2007. Patient data were abstracted from medical records and linked with the United States Renal Data System. Adjusted Risk Ratios (RR) by intervention group were calculated from binomial regression models adjusting for time trends. We also examined how the intervention impacted evaluation completion across levels of race and poverty (health insurance, education, employment, and neighborhood poverty by census tract).

Results: A total of 1,126 adult ESRD patients were examined in two transplant evaluation eras (75% pre- and 25% post-intervention). Evaluation completion at one year was higher among those in the post- vs. pre-intervention group (80.4% vs. 44.7%, p<0.0001), and was 38% higher (95% CI:1.12-1.71) after controlling for time trends. In crude and adjusted analyses, improvement in evaluation completion in the post- (vs. pre-) intervention group was greater among blacks (Panel A) and those living in poor neighborhoods (Panel B)(p for interaction<0.05).





Conclusions: The implementation of a required education program increased evaluation completion for all patients. The effect of the intervention was stronger among black and poor patients, resulting in reduced disparities in evaluation completion. These results suggest that standardizing transplant education may help reduce some of the racial and socioeconomic disparities observed in early stages of access to kidney transplantation.

TH-PO961

Potential of Kidney Transplantation in Undocumented Immigrants (UI) with End Stage Renal Disease Ellena A. Linden, George N. Coritsidis. *Nephrology, Elmhurst Hospital Center, Elmhurst, NY.*

Background: By virtue of our location in Queens, NY (the most ethnically diverse county in US) we have a large population of UI who are receiving dialysis. These treatments are covered by NY State Emergency Medicaid. Transplantation costs, however, are not covered under the same program. Our hypothesis is that UI have potential living kidney donors and that paying for the transplantation costs of those with available living donors is cost-effective.

Methods: We conducted a cross-sectional survey of UI at our outpatient dialysis unit. 50 patients qualified, 45 completed the questionnaire. We used our documented dialysis population as comparison group.

Results: Our UI are significantly younger and healthier than their documented counterparts.

	undocumented, n=45	documented, n=82	p value
average age, yrs (sem)	44 (2)	60 (1)	<0.005
DM, %	40	68	<0.005
CAD, %	7	33	<0.005
hospitalizations/yr/pt	0.9	1.0	ns
employed, %	51	6	<0.005

They are much more likely to be employed (51 vs 6%). The vast majority of our UI came to US to work and not to seek medical care. If transplanted, all UI who are employed will continue working. Of those who are unemployed, 82% state that they will seek work if transplanted. 60% were able to identify at least one potential donor. Among those with donors, the average number was 1.9. These donors are young and healthy. 64% of donors already reside in North America.

Conclusions: Life expectancy of an average 40-44 year old US dialysis patient is 8 years. Our UI are younger and healthier and will likely have a greater life expectancy. They have potential kidney donors. Paying for living donor transplantation for the UI would translate into savings of at least $342,000 per patient for NY State. Beyond these savings and improved quality of life, society will also benefit in that most of the patients would be willing and able to reenter the workforce. Lawmakers in New York State and other states that provide emergency medicaid coverage for UI should consider living-donor transplantation for those UI with available living donors. This strategy will significantly reduce the cost of caring for our undocumented patients.

TH-PO962

What Factors Influence Access to Renal Transplantation in Patients Undergoing In-Center Dialysis? Lina Mackelaite, Adam E. Gaweda, Zygimantas C. Alsauskas. *Division of Nephrology, University of Louisville, KY.*

Background: Patients with renal failure have a choice of different renal replacement therapies, including in-center hemodialysis (HD), peritoneal dialysis and renal transplantation. It is known that kidney transplant recipients live longer compared to patients on dialysis. Despite that only a small fraction of dialysis patients are on the transplant list.

Methods: We interviewed a total of 129 patients undergoing in-center hemodialysis. Data was obtained from standard questionnaires and CMS Medical Evidence Form 2728. Statistical analysis was performed using SPSS. We built a binary logistic regression model to evaluate predictors of being on the transplant list. We used Hosmer & Lemeshow model selection method to select the most influential predictors (with initial threshold $p \leq 0.3$ for the univariate models and $p \leq 0.05$ for the final multivariate model).

Results: We analyzed multiple factors, including age, education, weight, ethnicity, employment, discussing transplantation with nephrologist after initiation of RRT, dialysis vintage etc. In univariate analysis these factors where associated with higher likelihood of being on a transplant list: talking about transplantation with a nephrologist after initiation of HD(OR 22, P=0.003), presentation of different treatment options prior to starting HD(OR 2.8, p=0.05), knowing somebody with a transplant (OR 1.6, p = 0.27), knowing the benefits of kidney transplantation (OR 1.7, p=0.23). In multivariate analysis the only factor that was associated with being on a transplant list was talking about renal transplantation with nephrologist after initiation of RRT (OR 19, p=0.005).

Only 48 % of people with hemodialysis vintage of less than 1 year had discussion about renal transplantation compared to 73% of patients who were on dialysis for more than 1 year.

Conclusions: The most significant factor that determines access to renal transplantation is discussion about kidney transplantation with their nephrologist. Despite better post transplant patient survival with shorter dialysis vintage, discussion about renal transplantation happens in less than 50% of ESRD patients within the first year of initiation of dialysis.

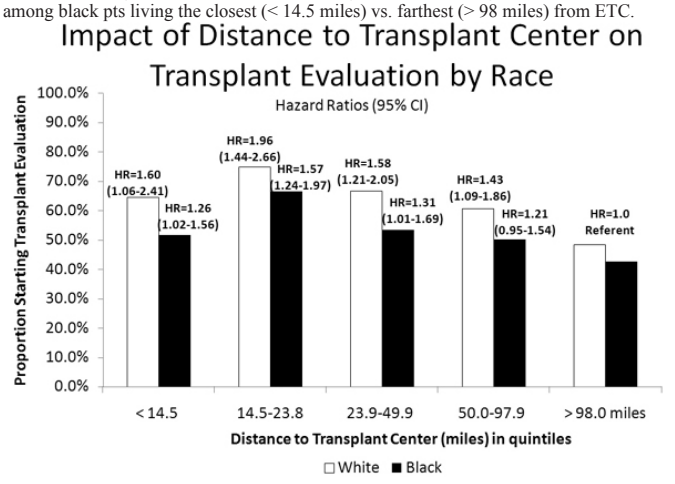
TH-PO963

Distance to Transplant Center Associated with Delayed Renal Transplant Evaluation in the Southeastern United States Rachel E. Patzer,[1] Sumit Mohan,[2] Richard Mutell,[3] Stephen O. Pastan,[1] Jennie P. Perryman,[1] Sandra Amaral,[1] Nancy G. Kutner,[1] William M. McClellan.[1] *[1]School of Medicine, Emory University, Atlanta, GA; [2]Department of Medicine, Columbia University, New York, NY; [3]DaVita Clinical Research, Minneapolis, MN.*

Background: Geographic variations in access to renal transplant have been reported but considered all prevalent ESRD patients, rather than only those referred for transplantation. Less is known about barriers to transplant evaluation, the first step in the transplant process.

Methods: We examined adult, ESRD patients (pts) referred to the Emory Transplant Center (ETC) kidney transplant program 2005-2007. Patient data were abstracted from medical records and linked with United States Renal Data System. Adjusted Cox models were used to examine the effect of distance on time from referral to start of the evaluation process by race.

Results: Among 2,228 ESRD pts referred to ETC, 55.3% (61.3% white vs. 52.1% black, p <0.0001) started the transplant evaluation. Mean age at referral was 51.1 years. Pts who started the evaluation (n=1,233) lived significantly closer to ETC than those who did not (35.3 vs. 51.8 miles) and the median distance to ETC was lower among black vs. white patients (27 vs. 53 miles) (p<0.0001). Blacks were less likely to start the evaluation than whites, regardless of distance to center (p for interaction = 0.7548). The rate of evaluation start was 60% higher (95% CI:1.06-2.41) among white and 26% higher (95% CI:1.02-1.56) among black pts living the closest (< 14.5 miles) vs. farthest (> 98 miles) from ETC.



Conclusions: Pts residing closer to ETC were more likely to initiate their renal transplant evaluation than those living farthest away. Distance to transplant center may be a potentially modifiable barrier to transplant evaluation, and barriers to transplant access may be mitigated by implementing outreach clinics.

TH-PO964

Effect of Diabetes Mellitus on Access to Renal Transplantation Bhanu K. Patibandla, Akshita Narra, Ranil N. Desilva, Alexander S. Goldfarb-Rumyantzev. *Division of Nephrology, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA.*

Background: Previous studies have shown that diabetics with ESRD were less likely to receive a renal transplant. The goal of our study was to evaluate whether the decreased access to renal transplantation is mediated by increased co-morbidities and greater BMI.

Methods: Study cohort included all ESRD patients from January 2000 to September 2007 using data from the United States Renal Data System (USRDS). We analyzed two outcomes in Cox regression model: (1) likelihood of being placed on the waiting list for renal transplantation or transplanted without wait-listing (2) likelihood of receiving transplant in patients previously placed on the waiting list. Multivariate models were adjusted for age, sex, race, duration of pre-ESRD nephrology care, levels of albumin, hemoglobin and creatinine. In addition we performed subgroup analysis based on age, race, sex, co-morbidity index, and duration of nephrology care.

Results: We analyzed 721,521 patients (age of ESRD onset 63.6±15.3 years, 54.6% males, 64.7% white and 29.2% African American). When compared with non-diabetic population, diabetes was associated with reduced transplant access: both for wait listing/transplant [HR 0.87, p<0.001] and for transplant after being listed [HR 0.77, p<0.001]. When proportional hazard models were adjusted for BMI and co-morbidity index, the association changed dramatically, so that patients with diabetes had better access to transplantation, i.e., [HR 1.61 (p<0.001)] for wait listing/transplant and [HR 1.51 (p<0.001)] for transplant after being listed. This trend was the same in the subgroups studied.

Conclusions: Diabetics are less likely to be placed on the waiting list for kidney transplant; and once on the list are less likely to be transplanted. Our analysis suggests that effect is mediated by higher level of co-morbidity and greater BMI.

TH-PO965

Improving Access to Living Donor Kidney Transplantation Jonathan Reaney, Monica Monaghan, Aisling E. Courtney. *Department of Nephrology, Belfast City Hospital, Belfast, United Kingdom.*

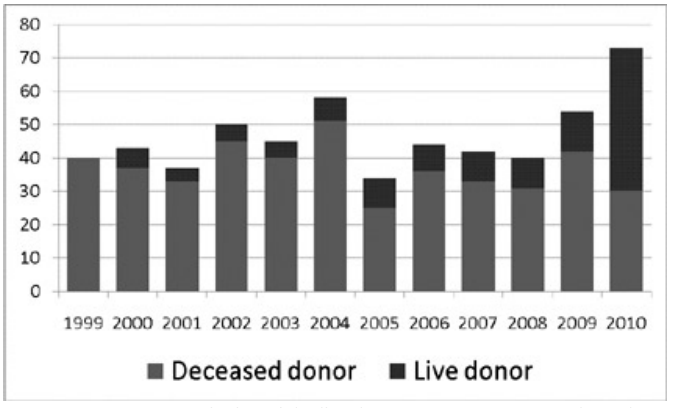
Background: Live donor transplantation is the optimal form of renal replacement therapy for the majority of patients with end-stage renal disease. There is considerable geographical variation in the opportunity for patients to access this treatment.

Methods: This study assesses the impact of reorganisation of services on the delivery of live donor transplantation in a single UK region.

Methods: Traditionally the assessment process for a potential live donor in Northern Ireland was long and cumbersome, requiring multiple attendances at hospital. It was customary for it to exceed 2 years. The number of live donor transplantations remained static at a maximum of 20% of all renal transplants per annum.

The donor pathway was reorganised with a one-day assessment combining all routine investigations and nephrology assessment. A formal multidisciplinary meeting was established weekly allowing a swift decision on suitability.

Results: The results were an increase in live donor transplant procedures from 9 to 48 per annum (an increase to 58% of all kidney transplants being live donor organs), a reduction in time to transplantation to five months from assessment with an substantial increase in pre-emptive transplantation especially in the paediatric population. This 400% increase in live donor transplants occurred over an 18 month period. Figure 1 Renal Transplantation in Northern Ireland.



Conclusions: Reorganisation of the live donor assessment process reduces donor fatigue and drop-out, reduces the time to transplantation, and increases the number of live donor transplant procedures. This can be achieved without a substantial increase in resources, providing opportunity for improved clinical outcomes and more economically viable renal replacement therapy programmes for populations with end-stage renal disease.

TH-PO966

Excellent Kidney Transplant Outcomes in a Safety Net County Hospital Giselle Kohler,[1] Merit E. Qviste,[3] John R. Hartono,[1] Christopher Y. Lu,[1] Nilum Rajora,[1] Meelie Debroy,[2] Doris L. Sweatt,[3] Miguel A. Vazquez.[1] *[1]Department of Internal Medicine, University of Texas Southwestern Medical Center at Dallas, TX; [2]Department of Surgery, University of Texas Southwestern Medical Center, Dallas, TX; [3]Kidney Transplantation, Parkland Health and Hospital Systems, Dallas, TX.*

Background: Race and insurance status are important factors limiting access to kidney transplantation and associated with poor outcomes. The kidney transplant program at Parkland Health and Hospital Systems (PHHS) serves a predominantly indigent and minority population. PHHS is an integrated health care system that serves as primary teaching hospital for UT Southwestern Medical Center and, via a central campus and a network of primary health care clinics and specialty/subspecialty clinics, makes health care available to indigent patients in Dallas County.

Methods: We conducted a retrospective review of recent kidney transplants (2005-2010) performed at Parkland Hospital in Dallas, including racial/ethnic distribution of transplant recipients, insurance status and kidney transplant outcomes.

Results: Seventy-five percent of kidney transplant recipients during our study period were enrolled in Parkland Health Plus, which is a Parkland-based county assistance program to provide health care services and medications to indigent patients who do not have other means to cover health expenses.

n=26, (7/09-6/10)	Parkland	Region	US
White	7.7	34.5	44.9
African-American	38.5	27.8	32.3
Hispanic/Latino	46.2	32.4	15.2
Asian	7.7	3.7	6.2

	Parkland	Parkland	US	US
	1 Year (n=90)	3 Years (n=61)	1 Year	3 Years
Observed graft survival (%)	97.78	89.89	93.51	84.72
Expected graft survival (%)	(92.64)	(81.36)		

Conclusions: Efforts to allocate professional resources and multi-institutional commitments to provide integrated health care and assistance with health care costs, including access to medical services and assistance with medications can improve access to kidney transplantation and lead to superior transplant outcomes for patients who are under-insured or belong to underserved minority populations.

TH-PO967

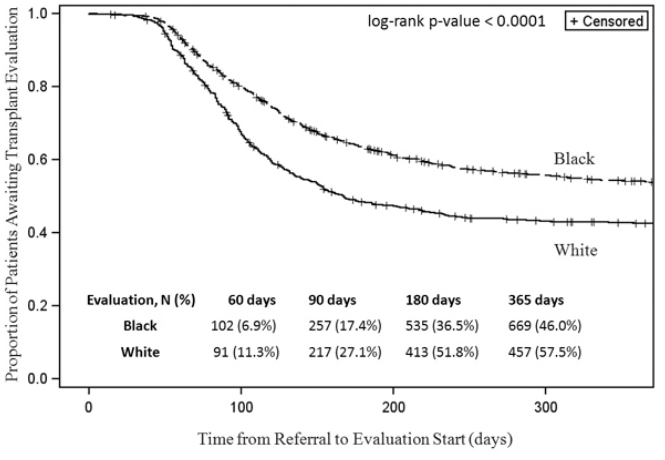
Race and Access to Renal Transplantation Evaluation in the Southeastern United States Justin D. Schrager,[1] Rachel E. Patzer,[1] Jennie P. Perryman,[3] Stephen O. Pastan,[3] Nancy G. Kutner,[3] William M. McClellan.[2] *[1]School of Medicine, Emory University, Atlanta, GA; [2]Emory Transplant Center, Atlanta, GA.*

Background: Disparities exist among End Stage Renal Disease (ESRD) patients in access to renal transplant. The effect of race and socioeconomic status (SES) on start of the kidney transplant evaluation following referral has not been thoroughly explored.

Methods: This study examined the effect of race on renal transplant evaluation, defined as the first scheduled on-site visit at the Emory Transplant Center (ETC), from 2005-2007 and followed through 2010. Patient characteristics were abstracted by chart review and linked with the United States Renal Data System and census tract poverty. Kaplan-Meier methods and Cox models were used to examine racial differences in access to evaluation. We used neighborhood poverty and health insurance as measures of SES.

Results: 2,291 prevalent ESRD patients were referred to ETC during the study period. Of these, 1015 (44.3%) never started the renal transplant evaluation process. Compared to patients who started the evaluation process, those who did not start were significantly more likely to be black (69.5% vs. 61.1%), black health insurance (17.7% vs. 14.5%) or have Medicaid (22.9% vs. 14.5%), to reside in the poorest census tracts (40.1% vs. 28.2%) and spend a longer time on dialysis prior to referral (314 days vs. 124 days). In crude Cox models, black (vs. white) patients were 28% less likely to start the evaluation at any given time during follow-up (HR=0.72; 95% CI: 0.65-0.81). After adjusting for demographic, clinical, and SES factors, this disparity persisted (HR=0.82, 95% CI: 0.73-0.93).

Conclusions: Racial disparities exist in renal transplant evaluation. Black patients were 18% less likely to start the evaluation process following referral, even after adjusting for clinical and SES characteristics.



TH-PO968

Access to Renal Transplantation at Nottingham University Hospitals Linda H. Bisset, Linda Evans, Catherine Byrne. *Nottingham Renal and Transplant Unit, Nottingham University Hospitals NHS Trust, City Campus, Nottingham, United Kingdom.*

Background: Early transplant referral and listing confers advantages in terms of life expectancy, quality of life, and graft survival. In the UK, equity to access and activation appears largely centre specific. Current recommendations are for pre-dialysis patients to be listed when eGFR <15. Previous work from our unit suggested fewer than expected patients were active on the renal transplant waiting list. We determined the timeline for referral and listing in our prevalent transplant waiting list population.

Methods: We retrospectively analysed all adult prevalent pre-dialysis (eGFR <15), dialysis (HD, PD) and failing transplant recipient patients to determine the timeline from first doctor meeting (FDM), and start of RRT to referral, assessment and transplant list activation.

Results: Of 691 prevalent patients, (193 pre-dialysis, 390 HD, 108 PD), 159 were listed for transplantation (25 pre-dialysis, 84 HD, 51 PD). Of those listed, 57% were male, 42% aged ≥50 and 9% had diabetes mellitus.

The table illustrates median times in the referral process. Only 8% HD and 24% PD patients were listed pre-dialysis, despite 74% and 88% patients having a FDM >90 days respectively. 13% of pre-dialysis patients were listed. Delays were identified in 21 patients, mainly relating to investigations. Within the cohort not listed, 37 patients (19% pre-dialysis) are being assessed and 19 have been referred (26% pre-dialysis). All patients not listed had an appropriate reason documented.

	Listed n= (%)	Referral to surgeon (wks)	Surgeon to list (wks)	Referral to list (wks)	Referred pre-dialysis n= (%)	Listed predialysis n= (%)	FDM > 90 days to RRT n= (%)
Pre-dialysis	25 (13%)	11	14.2	22	NA	NA	NA
HD	84 (22%)	10.8	9	21.8	20 (24%)	7 (8%)	62 (74%)
PD	51 (47%)	13	4	17.3	23 (45%)	12 (24%)	45 (88%)

Conclusions: Timeline for referral and listing is suboptimal. Data is retrospective and median times may be skewed due to historic long waits and many pre-dialysis patients were seen in advance of the need for listing. Delays were mainly related to cardiology investigations. Prospective audit shows significant improvements in the 18 week pathway over the last 12 months.

TH-PO969

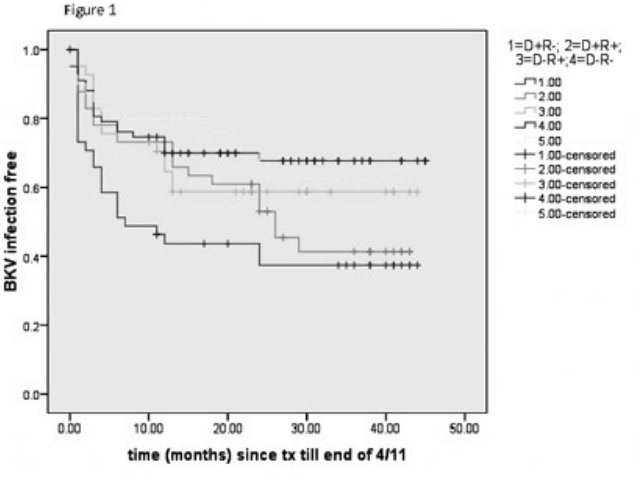
Combination of Pre-Transplant BKV Specific IgG Donor Positivity and Recipient Negativity Correlates with Post-Transplant BKV Infection Puneet Sood, Shamila Chaturi Senanayake, Kumar Sujeet, Christopher Johnson, Sundaram Hariharan. *Medical College of Wisconsin, Milwaukee, WI.*

Background: BKV infection can manifest as viremia/viruria which may lead to nephritis and graft failure. Risk factors for BKV infection have not been well defined. In our prospective study, we analyzed the effect of donor and recipient BKV specific antibody IgG status at time of transplant on the development of post-transplant BKV infection.

Methods: 240 patients were prospectively enrolled from July 2007 to July 2010 and followed until May2011. Baseline data on donor/recipient age, gender, race, cold ischemia time, donor source, PRA, induction therapy, HLA match, donor BKV immune status and prospective data on occurrence of rejection and quantitative BK viruria and viremia at 1,3,6 and 12 months was collected. Positive BKV specific antibody was defined as IgG EIA≥8 units. Study population was divided into D+R+/D+R-/D-R+/D-R- groups based on donor and recipient immune status. Occurrence of post transplant BKV infection defined by detection of BKV DNA in plasma or urine at the end of study period was used as endpoints. Kaplan-Meier survival curves were used to look at the difference between groups and Log-Rank test was used to test for significance.

Results: Patients were divided into 4 groups based on donor and recipient BKV specific positivity and negativity. Group 1(D+R-)n=41 pairs, group 2(D+R+)n=42 pairs, group 3(D-R+)n=41 pairs and group 4(D-R-)n=68 pairs. The demographic, transplant and post-transplant variables were similar in 4 groups. Recipients from group 1(D+R-) had the highest chance of developing post-transplant BKV infection (figure1), Log Rank p=0.009.

Conclusions: Pre-transplant BKV specific IgG antibody status in subjects with D+/R- is associated with a higher rate of post-transplant BKV infection and predominantly occurs in the early period.



TH-PO970

Risk Factors for BKV Infection after Renal Transplantation Puneet Sood, Shamila Chaturi Senanayake, Kumar Sujeet, Christopher Johnson, Sundaram Hariharan. *Medical College of Wisconsin, Milwaukee, WI.*

Background: BKV infection manifests as viremia or viruria which may progress to BKVN. Graft survival rates in patients with BKVN are worse than acute rejection and calcineurin inhibitor (CNI) toxicity. In our prospective study, we evaluated the risk factors for the occurrence of all BKV infections defined as any degree of viruria and/or viremia.

Methods: 240 patients were prospectively enrolled from July 2007 to July 2010 and followed until May 2011. Baseline data on donor/recipient age, gender, race, cold ischemia time, donor source, PRA, induction therapy, HLA match, donor BKV immune status and prospective data on the occurrence of rejection and quantitative BK viruria and viremia at 1, 3, 6 and 12 months was collected. Logistic regression modeling was used to ascertain risk factors for any level of BKV infection. T-test and Chi-sq test were used for continuous and categorical variables, respectively.

Results: Characteristics of BKV infected and non infected patients are summarized in table 1.

Risk factors	BKV infection (N=93)	No NKV infection (N=147)	P-value
Donor Source (LD/DD)	39/54	53/92	P=0.42
Donor age (>60/<60)	8/85	14/131	P=0.78
Donor race (AA/W+ others	11/82	17/127	P=0.99
Donor BKV specific IgG: EIA units ≥vs<8	37/47	52/67	P=0.96
Recipient age (>60/<60 yrs)	21/72	29/116	P=0.63
Recipient race (AA/W+ others)	13/80	48/99	**P=0.001**
Cold ischemia time (>14 /≤14 hrs)	30/60	51/84	P=0.49
HLA mismatch (>4/≤4)	40/51	75/66	P=0.17
PRA (>20%/<20%)	24/67	38/96	P=0.74
Induction therapy (Thymoglobulin/ IL-2R)	46/47	78/69	P=0.58
Acute rejection (Y/N)	18/75	30/117	P=0.84

African American recipients had lower risk of developing BKV infection compared to Caucasians and other races. This effect remained significant after controlling for other potential confounding variables (OR 0.38, 95% CI 0.16-0.84, P=0.018). Actuarial Kaplan-Meier curves for the occurrence of BKV infection was significantly more in Caucasians as opposed to African Americans.

Conclusions: African Americans had a lower incidence of BKV infection compared to Caucasians. This association with race needs further investigation in larger prospective studies.

TH-PO971

Low Physical Activity in Renal Transplant Recipients Is Associated with Mortality Independent of Markers of Subclinical Heart Failure and Cardiac Ischaemia Dorien M. Zelle,[1] Eva Corpeleijn,[1] Reinold O.B. Gans,[2] Gerjan Navis,[1] Stephan J.L. Bakker.[2] *[1]Kidney Center, University Medical Center Groningen, Netherlands; [2]Internal Medicine, UMCG.*

Background: We previously showed that low physical activity (PA) is a strong risk factor for mortality in renal transplant recipients (RTR). Although RTR with overt heart failure were excluded from our study, it was, not discerned whether this association could be driven by subclinical heart failure or cardiac ischaemia. We therefore investigated whether cardiac markers N-terminal pro-B-type natriuretic peptide (NT-proBNP) or hs-Troponin T (TNT) explain the association between PA and mortality in RTR.

Methods: Baseline assessments were done between 2001-2003. PA was assessed using validated questionnaires. Mortality was recorded until August 2007. NT-proBNP and TNT were measured on the Roche Modular E170.

Results: A total of 539 RTR (age 51 yrs,54% male) were studied. NT-proBNP and (r=-0.24,p=0.001) and TNT (r=-0.30,p=0.001) were inversely associated with PA. During follow-up for 5.3 years [4.7-5.7], 81 RTRs died (37 cardiovascular). In a Cox regression analysis, PA (HR=0.75 [95%CI 0.60-0.92], P=0.007) was associated with mortality, independent of age, sex, creatinine clearance and systolic blood pressure. In a further multivariate analysis, including NT-proBNP (1.51 [1.13-2.02], P=0.05) and TNT (1.42 [1.03-1.95, P= 0.03), PA (0.79 [0.64-0.98], P=0.04) remained independently associated with mortality. Similar results were found for cardiovascular mortality (PA 0.67 [0.49-0.92], P=0.01).

Conclusions: Only a small part of the association of low PA with mortality can be explained by markers of subclinical heart failure and cardiac ischaemia, while a much larger part is independent. This stresses the potential relevance of PA intervention programmes for improvement of survival in RTR.

TH-PO972

The Deterioration of Serum Sulfatide Level, a Novel Risk Factor of Cardiovascular Disease, Is Dramatically Improved by Kidney Transplantation in ESRD Patients Yuji Kamijo,[1] Makoto Harada,[2] Yasufumi Takahashi,[2] Makoto Higuchi.[2] *[1]Department of Metabolic Regulation, Shinshu University Graduate School of Medicine, Matsumoto, Nagano, Japan; [2]Department of Nephrology Internal Medicine, Shinshu University School of Medicine, Matsumoto, Nagano, Japan.*

Background: Sulfatide is a major component of glycosphingolipids in lipoproteins. Recently, we reported that a low serum level of sulfatide in hemodialysis patients is related to the high incidence of cardiovascular diseases. This earlier study suggests that the deterioration of serum sulfatide level would be a novel risk factor of cardiovascular disease. However, the serum kinetics of sulfatide in kidney disease patients and the function of endogenous serum sulfatide are still unclear.

Methods: To obtain novel knowledge concerning these issues, we investigated the serum kinetics of sulfatide in 5 adult kidney transplant recipients. We also analyzed the correlated factors influencing the serum sulfatide level, using multiple regression analysis.

Results: Kidney transplantation caused a dramatic increase of serum sulfatide without an alteration of its composition in all recipients in a time-dependent manner; however, the recovery speed was slower than that of the improvement of kidney function and the serum sulfatide reached a nearly normal level after 1 year. Multiple regression analysis showed that the significant correlated factor influencing the serum sulfatide level was log duration (time parameter) throughout the observation period, and the correlated factors detected in the stable phase were the decrease of serum concentration of malondialdehyde (an oxidative stress marker) as well as the elevation of platelet count.

Conclusions: The current study results demonstrate the deterioration of serum sulfatide level in ESRD patients is dramatically improved by kidney transplantation for the first time. The recovery of serum sulfatide might derive from the attenuation of systemic oxidative stress. The normal level of serum sulfatide in kidney transplant recipients might affect platelet function, and contribute to the reduction of cardiovascular disease incidence.

TH-PO973

Cardiovascular Risk and Stress Testing in Kidney Transplantation Rowena B. Delos Santos, Jagdeep Obhrai, Suzanne Watnick. *Division of Nephrology, Oregon Health and Science University, Portland, OR.*

Background: Kidney transplantation improves quality of life and life expectancy in the ESRD population. Cardiovascular disease is a significant cause of morbidity and mortality in this population. We aimed to identify baseline characteristics predictive of a positive stress test as well as cardiovascular outcomes in kidney transplant patients.

Methods: We conducted a retrospective review of 679 kidney transplant patients who underwent cardiac stress testing using exercise and pharmacological modalities with nuclear or echocardiography imaging. The composite outcome included: new MI, ACS, CVA, cardiac death, arrhythmias. We used logistic regression to evaluate eleven characteristics for their contribution to a positive stress test then at their contribution to cardiovascular outcomes along with a positive stress.

Results:

Multivariable logistic regression of predictive characteristics for positive stress and composite outcome

	Positive stress test		Composite outcome	
Predictor Variable	Odds ratio	p-value	Odds ratio	p-value
Age	1.1	< 0.001	1.0	< 0.001
BMI	1.0	0.02	1.0	0.8
Gender	1.4	0.09	0.9	0.9
Race	1.2	0.1	1.0	0.8
Smoking	1.1	0.6	0.9	0.6
MI/ACS	3.3	0.004	3.0	0.01
Diabetes	2.3	<0.001	1.9	0.02
METS	0.9	0.7	0.9	0.5
Hypertension	1.2	0.5	1.2	0.6
Dyslipidemia	1.1	0.6	1.0	0.9
Months on dialysis	1.0	0.02	1.0	0.1
Positive stress test	NA	NA	1.3	0.3

Of 679 patients, 158 had a positive stress test. The multivariable logistic regression showed age, prior cardiac disease, body mass index, diabetes and dialysis vintage were predictive of a positive stress test; metabolic equivalents were not. After adding a positive stress test to the model, only age, diabetes, and previous cardiac disease were significant.

Conclusions: Traditional and kidney specific risk factors are predictive of a positive stress test, but not necessarily cardiovascular outcomes. Some traditional predictors were not significant. Current recommendations for pre-operative testing may not be sufficient to predict cardiovascular outcomes post transplantation. Future studies could investigate methods of better identifying pre-kidney transplant patients who are at higher risk for post-transplant cardiovascular events.

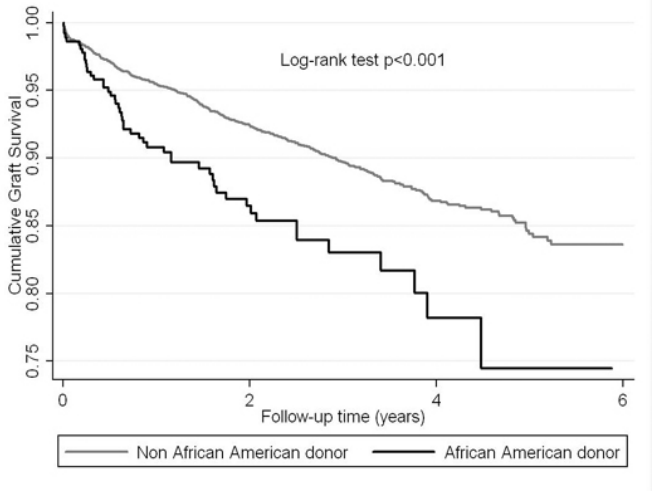
African American Donor Race Is Associated with Increased All-Cause and Cardiovascular Mortality and Graft Loss, but Not with Delayed Graft Function Miklos Z. Molnar,[1,2] Csaba P. Kovesdy,[3] Suphamai Bunnapradist,[4] Elani Streja,[1] Mahesh Krishnan,[5] Allen R. Nissenson,[5] Istvan Mucsi,[2,6] Keith C. Norris,[4] Kamyar Kalantar-Zadeh.[1,4] *[1]Harold Simmons Center, Torrance, CA; [2]Semmelweis University, Budapest, Hungary; [3]Salem VA Medical Center, Salem, VA; [4]David Geffen School of Medicine at UCLA, Los Angeles, CA; [5]DaVita, Inc, Denver, CO; [6]McGill University, Montreal, QC, Canada.*

Background: In the last few years genetic factors were identified to explain the higher prevalence of end stage renal disease in African American (AA). We examined associations of donor race & post-transplant outcomes in a large national cohort of kidney transplant recipients.

Methods: Linking the 5-year patient data of a large dialysis organization to the *Scientific Registry of Transplant Recipients*, we identified 13692 hemodialysis patients who underwent kidney transplantation. Mortality or graft failure & delayed graft function (DGF) risks were estimated by Cox regression and logistic regression, respectively.

Results: Patients were 48±14 years old and included 39% women and 26% diabetics. AA donor race was associated with 39%, 80% & 30% higher all-cause mortality (1.39(1.09-1.78)), cardiovascular mortality (1.80(1.17-2.76)) & death-censored graft loss (1.30(1.03-1.64)), respectively over the 6-year observation period after adjusting for several relevant clinical & transplant-related variables. In non-AA recipients AA donor race was associated with significantly higher risk of graft loss.



In AA recipients AA donor race was not associated with significantly higher risk of outcomes. The risk of DGF did not show association with AA donor race.

Conclusions: AA donor race was associated with increased all-cause & cardiovascular mortality in non-AA recipients & graft loss, but not with DGF.

TH-PO975

Effects of Kidney Transplantation on Echocardiographic Abnormalities Ana Sofia Rocha, Nihil Chitalia, Helen Gregson, Rajan Sharma, Juan Carlos Kaski, Debasish Banerjee. *Renal & Transplantation and Cardiology Units, St Georges Hospital, London, United Kingdom.*

Background: Kidney transplantation (KT) decreases cardiovascular (CV) events in patients with chronic kidney disease, but reasons for this are unclear. Cardiac echocardiographic (ECHO) abnormalities are predictors of CV mortality, but scant data exist on long-term progression of these alterations after KT.

Methods: This study aimed to assess the progression of ECHO variables in KT recipients compared to patients who remained on the waiting list.

The study cohort included all patients on transplant waiting list with repeat ECHO at least one year apart; and all transplanted patients at least one year after KT, between January 2004 and December 2010. We excluded patients with previous AMI, valve heart disease and other structural cardiac abnormalities.

Results: We assessed 79 patients (57% male; age 55±11 [mean±SD] years; 27% diabetes); of these, 63 patients remained on waiting list (51% on dialysis) and 16 underwent KT. Of the latter, 12 (75%) were on dialysis for a median duration of 17±29 mo, and 4 (25%) had preemptive transplants.

On baseline ECHO, left ventricular (LV) hypertrophy [left ventricular mass index (LVMI) ≥110 g/m in females, ≥125 g/m² in males] using the Penn formula and indexed for height, was present in 54% of patients, left atrium (LA) enlargement (LA≥4 cm) in 41% and systolic dysfunction [fractional shortening (FS) ≤30%] in 23%.

Follow-up ECHOs (performed 35±20 mo after baseline ECHOs) on patients who remained on waiting list showed significant increases in LVMI (133±43 *vs.* 146±50 g/m, *P*=0.018) and LA diameter (3.8±0.6 *vs.* 4.1±0.8 cm, *P*=0.02), whereas in KT recipients, LVMI (135±48 *vs.* 136±43 g/m, *P*=0.9) and LA diameter (4.0±0.7 *vs.* 4.0±0.7 cm, *P*=0.8) did not change significantly. In KT patients, FS increased (32±6 *vs.* 41±10%, *P*=0.03), whilst it did not change in patients on the waiting list (37±8 *vs.* 36±9%, *P*=0.7).

Conclusions: These data suggest that kidney KT has a favorable impact on ECHO abnormalities by halting progression of LVH and LA enlargement, and improving systolic dysfunction. This may explain, at least in part, the reduced CV mortality reported in kidney transplant recipients.

TH-PO976

EFfect of Left Ventricular Dysfunction on the Development of Renal Transplantation. Case-Control Study with Paired Kidneys from the Same Donor Maria Moya,[1] M. Teresa Mora,[3] Esther Gonzalez Monte,[2] Laura Garcia-Puente Suarez,[2] Ana Huerta,[2] Manuel Praga,[2] Amado Andres.[2] *[1]Nephrology, H.U. La Princesa, Madrid, Spain; [2]Nephrology, H. U. 12 de Octubre, Madrid, Spain; [3]Nephrology, H. San Pedro de Alcantata, Caceres, Extremadura, Spain.*

Background: Heart failure secondary to ventricular dysfunction (VD) is relatively common in dialysis patients.This group of patients usually have a high surgical risk and it isn't clear whether they should be included in the renal transplantation waiting list.There is few data on the evolution of renal transplantation in this population.The aim of our study is to analyze a group of transplant patients with VD (EF≤50%) and asses the evolution of renal function and mortality after transplantation.

Methods: We performed a retrospective study analysing all patients with VD transplanted from January 2005-December 2010 in our medical center and compared them with a control group consisting of their partner transplants, who had received the contralateral kidney from the same donor.

Results: A total of 30 patients (40% male) 15p with VD and 15p without cardiac lesions were analyzed.Mean age was 54.6±15.7 years, 70% were a first transplant. Analyses carried out between the two groups are shown in the table.

	No ventricular injury (15p)	Ventricular dysfunction (15p)	p
Age (years)	55±16	54±16	NS
Delayed graft funtion (%)	33.3	53.3	NS
ATN days	4,5±4,1	9,7±7	0,01
Number of HD sessions	1,6 (r0-6)	3,4(r0-12)	NS
Kidney allograft loss (%)	6,6	13,3	NS
No primary function (%)	0	6,6	NS
Final follow-up sCr	1,3±0,5	2,1±1,9	0,01
Nr of admissions to hospital	1,5±1,4	3±2,6	0,04
Graft survival (%)	100	80	0,05
Patient survival (%)	93,4	80	NS
Follow-up time (months)	43±12	37±19	

In these patients (VD group) there is a tendency to a higher rate of delayed graft function, non-primary function and need of more hemodialysis sessions prior to renal allograft function. Graft survival is lower and there is overall worse final renal allograft function.

Conclusions: Despite the limited number of patients in the study, our data suggest that cardiac evaluation should be performed in all patients on hemodialysis, and the indication for kidney transplantation in patients with VD with an EF≤50% carefully evaluated.

TH-PO977

Arrhythmias and Sudden Cardiac Death Continue To Be Significant Events in Post-Kidney Transplant Patients Rowena B. Delos Santos,[1] Jagdeep Obhrai,[2] Suzanne Watnick.[1] *[1]Medicine, Division of Nephrology and Hypertension, OHSU, Portland, OR; [2]Medicine, Transplant Section, OHSU, Portland, OR.*

Background: Kidney transplant candidates undergo extensive cardiac evaluation for coronary artery disease. However, these tests do not detect the risk for arrhythmias and sudden cardiac death, which can be unrelated to coronary artery disease sequelae. We sought to investigate the rates and proportions of arrhythmias and sudden cardiac death in kidney transplant patients to compare them to those on dialysis.

Methods: We conducted a retrospective chart review of 679 post-kidney transplant patients from two transplant centers in Portland, OR. Specific outcomes of interest included death from cardiac cause, arrhythmias, acute coronary syndome, myocardial infarction and congestive heart failure episodes. Descriptive analyses were conducted and outcomes are expressed as percentages.

Results:

Cardiovascular outcomes post kidney transplant in 679 patients

Outcome	Total events N = 135 (%)
CHF	27 (20%)
ACS	16 (12%)
MI	17 (13%)
Arrhythmias	52 (38%)
Afib/Aflutter	32 (24%)
Vtach/Vfib	4 (3%)
PEA	4 (3%)
SVT/other rhythm	9 (6%)
Other rhythm nos	3 (2%)
Death CV cause	12 (9%)
Sudden death	7 (5%)
MI	2 (1%)
CHF	1 (1%)
Death non-CV cause	11 (8%)

A total of 135 events occurred in 679 post transplant patients. Of these events, 20 were arrhythmias that were not atrial fibrillation or atrial flutter while 7 events were sudden cardiac death. We found that of all these events, 38% were arrhythmias, 13% were MI, 12% were ACS, 20% were CHF. For causes of death, 9% were due to cardiovascular causes of death while 8% were due to non-cardiovascular causes of death. In comparison, rates for the ESRD population in general per USRDS data on causes of death include: arrhythmia/ arrest 26%, acute MI 5%, CHF 5% and CVA 4%.

Conclusions: Despite significant non-invasive and invasive cardiovascular testing prior to transplant, these patients have a large percentage of events that may not necessarily be related to coronary artery disease, which is similar to the ESRD population. Our cardiac evaluations may not be sufficient to predict other significant cardiac events.

TH-PO978

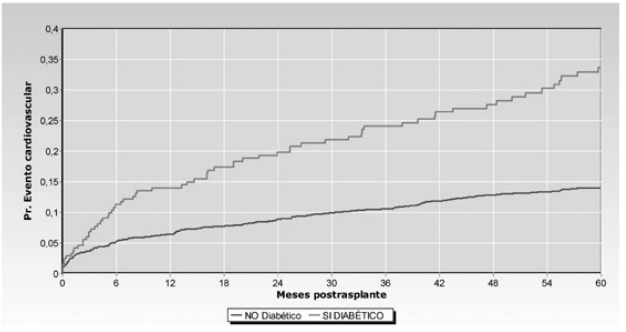
Pretransplant Diabetes Mellitus Doubles the Risk of Cardiovascular Events after Renal Transplantation. A Prospective Multicenter Study Jose M. Morales,[1] Robert Marcen-Letosa,[2] Amado Andres.[1] *[1]S. Nefrologia, H. 12 de Octubre, Madrid, Spain; [2]Grupo Forum Renal, Spain.*

Background: Cardiovascular disease (CD) is the main cause of death after transplantation. The aim of study was to investigate the influence of pretransplant diabetes (Pre-DM) on the presence of posttransplant cardiovascular events and survival figures after renal transplantation (RTx).

Methods: From a database of 2591 RTx patients performed in Spain during 2000-02 we prospectively analyzed the results at 5yr in patients with Pre-DM (n: 247, 9.5%) vs non-diabetic patients (n:2344, 90.4%)

Results: Pre-DM patients were significant older, males, with a higher body mass index and 30% of them had had higher pre-transplant CVE (30.4% vs 13% p 0.001 vs

non-diabetics). Immunosuppression was Steroids, Tac/CyA and MMF. No difference in acute rejection at 1yr (15% Pre-DM vs 16.7 % non-diabetic, p ns) and acute tubular necrosis (ATN) among groups. Graft survival at 5yr were lower in Pre-DM (uncensored death 63.8% vs 78%, censored death 77.8 vs 85% p<0.05). Patient death was the most frequent cause of graft loss in both groups (34.7% vs 27.8%) Patient survival was 78.5% vs 90% p<0.05) and CD and infections were the most frequent causes of death. Cox-regression model showed that donor age, patient age, ATN, pretransplant cardiovascular events, hepatitis C and pre-DM were independent risk factors for mortality. Pre-DM patients exhibited more major CVE during follow-up and the presence of diabetes doubled the risk of cardiovascular events (HR 2.03, 1.40-2.92% p<0.001).



Conclusions: RTx in patients with pre-DM offer acceptable results although showed lower survival figures at 5yr than non-diabetic patients. The presence of Pre-DM doubles the risk for posttransplant CD events. Therefore, pre and postransplant measures to improve CD especially in diabetic patients are mandatory

TH-PO979

Rate of mGFR Decline Associates with Mortality in Transplant Kidney Recipient Olivier Moranne,[1] Lise Thibaudin,[2] Nicolas Maillard,[3] Christopher R. Mariat.[3] *[1]Nephrology & Public Health, Hospital, Nice, France; [2]Service de Néphrologie et Laboratoire d'Explorations Fonctionnelles Rénales, CHU de Saint-Etienne, France; [3]Nephrology CHU de Saint-Etienne, France.*

Background: Longitudinal declines in kidney function were found independently associated with increased all-cause mortality in adults and older with native kidney. Based on these observations, we wanted to test this hypothesis in transplant kidney recipient.

Methods: Out of 610 patients having received a kidney transplant between 1989 and 2000 at our institution, 488 (86%) were longitudinally screened for their GFR by performing urinary clearance of Inuline (mGFR) at one year post-transplant and then every 5 years. The mean follow-up was 12 ± 4 yrs with a total of 1,330 mGFR. Annual individual slopes in mGFR were calculated with joint modeling random effect and secondary divided into quartiles of mGFR decline. Crude and adjusted hazard ratios (HR) of quartiles of slope, for all cause mortality (i.e. death censored-graft loss and death occurring before or after starting dialysis) were analyzed into a Cox regression model.

Results: Baseline recipient characteristics were as follows : mean age 47±19 yrs, men 70%, diabetes 6%, first kidney transplant in 84%, preemptive transplantation in 7% ; donor age 38±14 yrs. After one year post-transplant: inulin clearance: 46±19 ml/min/1.73m2 and Uprot/creat > 300 mg/g in 20% of patients. 89% were treated with anticalcineurin inhibitor. During follow-up, 136 patients (28%) returned dialysis and 139 deceased (after returning dialysis for 30 of them). The mean [IQ] slope of mGFR for the whole population was -1.8 [-2.8;-0.5] mL/min/1.73m2/yr. HR of quartiles of mGFR slope for all cause mortality censored graft loss and after adjustment on mGFR (at one yr), sex, age recipient, diabetes, proteinuria, cohort period and dialysis duration, were: Q4: HR=2.7 [1.1;6.5] ; Q3 : HR=4.1 [1.9;8.5] ; Q2 : HR=3.5 [1.7;7.1] vs Q1). The association persisted with adjustment on other covariables and were stronger when the death was considered before and after dialysis.

Conclusions: mGFR slope after one year post-transplant is independently associated with all cause mortality risk.

TH-PO980

Left Ventricular Mass in South-East Asian Patients Awaiting Kidney Transplantation Nihil Chitalia, Ana Sofia Rocha, Dimitrios J. Poulikakos, Rajan Sharma, Debasish Banerjee. *Renal and Cardiology Units, St Georges Hospital, London, United Kingdom.*

Background: South-East Asian kidney transplant patients from UK have better survival when compared to other ethnic groups, the reason for which is unclear. Mortality in kidney transplant patients is predominantly cardiovascular, highlighting the possible importance of left ventricular hypertrophy. Ethnicity-related differences in left ventricular (LV) structure have been described in general population, but have not been investigated in patients with chronic kidney disease (CKD).

Methods: This study assessed differences in echocardiographic parameters in a multi-ethnic UK population of patients awaiting kidney transplantation.

The study cohort included 77 patients awaiting kidney transplantation. Left ventricular mass index (LVMI) was calculated using Penn formula and indexed for height. Patients with recent MI, major heart valve disease and other cardiac structural pathology were excluded.

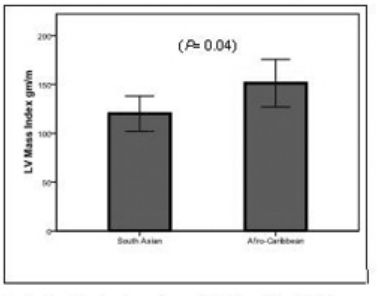
Results: Data were collected in 77 patients (55% male; age of 55±11 [mean±sd] years; 28% diabetes; 46% pre-dialysis, 39% haemodialysis and 15% peritoneal dialysis). 34 (44%) were Caucasian, 25 (32%) South-East Asians and 18 (23%) Afro-Caribbeans. Clinical and echocardiographic data are in table 1. South-east Asians had lower LVMI compared to Afro-Caribbeans (120±44 *v.* 151±50 g/m, *P*=0.04).

Table 1: Comparison of demographic, clinical and echocardiographic parameters across difference ethnic groups in patients on kidney transplant waiting list (n=77)

Variables	South Asian (n=25)	Caucasians (n=34)	Afro-Caribbean (n=20)	*P* value
Age (*years*)	57±11	56±10	51±12	0.24
Gender (*% males*)	48	59	65	0.49
Hypertension (%)	92	94	95	0.91
Diabetes (%)	44	12	30	0.02*
Systolic BP (*mmHg*)	142±17	138±21	147±15	0.38
Pulse pressure (*mmHg*)	65±16	55±16	51±24	0.08
BMI (*kg/m²*)	26±4	27±3	25±3	0.13
Left atrial diameter (*cm*)	3.68±0.63	4.00±0.68	3.98±0.61	0.20
IVS (*cm*)	0.97±0.20	1.08±0.16	1.13±0.21	0.02*
LVPW (*cm*)	0.95±0.16	1.02±0.13	1.06±0.20	0.06
LVEDD (*cm*)	4.66±0.59	4.94±0.53	5.00±0.65	0.10
LVM (*gm*)	187±75	230±63	252±91	0.01*
LVMI (*gm/m*)	120±44	136±38	151±50	0.84
FS (%)	35±7	35±6	36±8	0.50

BP, blood pressure; BMI, body mass index; IVS, intraventricular septum; LVPW, left ventricular posterior wall; LVEDD, left ventricular end-diastolic diameter; LVM, left ventricular mass; LVMI, left ventricular mass index; FS, fractional shortening.
* On ANOVA test, there were statically significant differences in prevalence of diabetes, IVS thickness and LVM between the groups.

Figure 1: LVMI in South-East Asians and Afro-Caribbeans.



South-East Asians have lower LVMI than Afro-Caribbeans (120±44 vs. 151±50 g/m, *P*=0.04)

Intraventricular septum was less thick in South-East Asians compared to Afro-Caribbeans (0.97±0.20 v. 1.13±0.21 cm); however the posterior wall thickness and LV diameter in diastole were not different between the two groups (table 1).

Conclusions: These data demonstrate and LVMI and LV wall thickness are lower in South-East Asian kidney transplant recipients. Less left ventricular hypertrophy may partially explain the improved survival in South-East Asian patients who receive kidney transplantation.

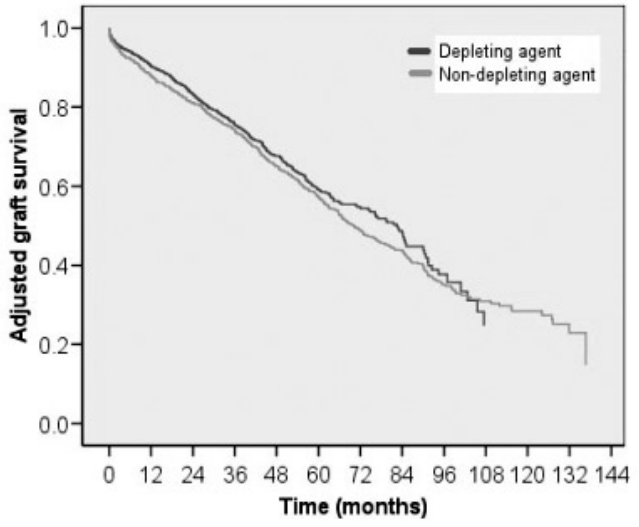
TH-PO981

Kidney Transplantation in Hepatitis C Positive Recipients: Does Type of Induction Influence Outcome? Kalathil K. Sureshkumar,[1] Ngoc L. Thai,[2] Richard J. Marcus.[1] *[1]Nephrolgy and Hypertension, Allegheny General Hospital; [2]Abdominal Trasnplantation, Allegheny General Hospital, Pittsburgh, PA.*

Background: Kidney transplantation in hepatitis C virus seropositive recipients (HCVR+) without advanced liver disease is associated with improved survival compared to staying on waiting-list. A concern for using depleting (versus non-depleting) induction agent for kidney transplantation in HCVR+ is the possibility that the associated enhanced immunusuppression might favor hepatitis C progression leading to adverse outcomes.

Methods: Using OPTN/UNOS STAR files, we identified HCVR+ who underwent deceased-donor kidney transplantation from either HCV seropositive or negative donors (HCVD+ and HCVD-) from 1998 to 2008 and received induction with either a depleting agent (rabbit-antithymocyte globulin or alemtuzumab) (n=1859) or a non-depleting agent (basiliximab or daclizumab) (n=1631). A multi-variate analysis was performed using a Cox regression model to evaluate the independent effects of the type of induction on graft and patient outcomes. Donor, recipient and transplant related covariates thought to affect the outcomes were included in the model.

Results: The median follow-up was 35.5 months (range 18.2 to 59.7 months). Adjusted graft survial for the two groups are shown in figure.



Compared to non-depleting induction, depleting agent induction was associated with neither inferior graft (HR 1.11, 95% CI 0.96-1.28, p=0.16) nor patient (HR 1.12, 95% CI 0.92-1.37, p=0.25) survival. HCVD+ status did not adversly affect either graft (HR 1.11, 95% CI 0.96-1.29, p=0.17) or patient (HR 1.15, 95% CI 0.93-1.42, p=0.2) outcomes.

Conclusions: In summary, our analysis supports the practice of transplanting HCVD+ kidneys into HCVR+ in order to alleviate waiting-list burden in deceased-donor kidney transplantation. Hepatitis C seropositivity should not influence the selection of induction agent.

TH-PO982

Despite More Advanced Kidney Disease, Simultaneous Liver-Kidney Transplant (SLK) Recipients Have Comparable Renal Outcomes in the Pre and Post MELD Era and Are Similar to Deceased Donor Kidney Transplants (DDKT) Mireille El Ters,[1] Ziad El-Zoghby,[1] Stephen C. Textor,[1,2] Fernando G. Cosio,[1,2] Charles B. Rosen.[2] *[1]Nephrology, Mayo Clinic; [2]William Von Liebig Transplant Center, Mayo Clinic.*

Background: Since the introduction of the Model for End-Stage Liver Disease (MELD) in 2002, SLK have been more widely performed in patients with advanced kidney disease raising concerns about possible worsening outcomes. The goal of this study was to compare SLK outcomes in the pre and post MELD era.

Methods: We reviewed clinical data of all 94 SLK adult recipients at our institution (n=35 pre & 59 post MELD). We compared 1) the SLK outcomes in the pre and post MELD era and 2) the outcomes of SLK with DDKT (n=267) in the post MELD era.

Results: The proportion of SLK among all liver transplants increased from 2.8% pre MELD to 7.8% post MELD (p<0.001). Post MELD recipients were slightly older (median age 56 vs. 53 years; p=0.16), had higher MELD score (median 26 vs. 20; p=0.1) and were more commonly on dialysis (68% vs. 62%; p=0.56) with longer dialysis time (22.6 vs. 19 weeks; p=0.85). Major indications for kidney transplantation differed: primary hyperoxalosis in the pre MELD era (31.4% vs. 13.6% post MELD; p =0.037) and acute tubular necrosis/hepato-renal syndrome in the post MELD era (25.4% vs. 8.6% pre MELD; p=0.045). During a median follow up of 4.5 years, 29 patients died (30.9%) and 36 (38%) lost their kidney graft. The most common cause of graft loss was death (n=21, 58.3%) followed by medical complications (6, 16.7%). There was a trend towards better patient and graft survival in the post MELD era.

	Year 1	Year 3	Year 5
Patient Survival*			
Pre MELD	82.3%	80%	71.2%
Post MELD	91.4%	88.3%	84.4%
Graft Survival**			
Pre MELD	77.2%	68.6%	65.6
Post MELD	87.9%	82.3%	71.7%

Pre/Post MELD comparasion: * p =0.56; ** p=0.75 (Log-Rank)

SLK and DDKT graft survival was similar (87.9% vs. 91.8% at 1 year; 82.8% vs. 82% at 3 years and 71.1% vs. 76.2% at 5 years, respectively).

Conclusions: Indications for kidney transplant in SLK recipients changed in the post MELD era however patient & graft outcomes remain comparable. Similarly, kidney graft survival is comparable between SLK and DDKT recipients.

TH-PO983

The Renal Outcome of Hepatorenal Syndrome after Liver Transplantation Yun Jung Oh,[1] Jung Pyo Lee,[2] Do Hyoung Kim,[1] Hyuk Yong Kwon,[1] Yun Kyu Oh,[2] Chun Soo Lim,[2] Yon Su Kim.[1] *[1]Internal Medicine, Seoul National University College of Medicine, Seoul, Korea; [2]Internal Medicine, Seoul National University Boramae Medical Center, Seoul, Korea.*

Background: Hepatorenal syndrome (HRS) is a well-recognized serious complication of end-stage liver disease. Liver transplantation (LTx) is a treatment of choice for the patients. However, HRS is a risk factor for posttransplant chronic kidney disease and mortality. Here, we evaluated change of renal function after LTx and posttransplant recipients' survival in patients with HRS, and analyzed the risk factors for non-recovery of renal function.

Methods: Among 764 consecutive adult Korean patients underwent LTx in a cohort of a single Asian center from 1995 to 2009, a total of 76 patients, who were satisfied with HRS criteria of the International Ascites Club, were enrolled. Patients with prerenal failure, nephrotoxic renal failure, or parenchymal kidney disease or under age 18 were excluded.

Results: Mean age at LTx was 48±9.8 years and proportion of male was 73.7%. The most common etiology of liver disease leading to liver transplantation was HBV (67.1%), followed by alcoholic liver disease (7.9%) and HCV (3.9%). Pretransplant serum creatinine (sCr) level was 3.12±1.71 mg/dL. After LTx, renal function was significantly improved (sCr; at 1st month: 1.52±0.59, at 6th month: 1.63±0.41, at 12th month: 1.54±0.36 mg/dL). Early mortality of recipients with HRS was significantly higher, however, it was not significantly different thereafter compared to those without HRS (3rd month: 79.4% vs 93.1%, $P< 0.01$; 5th year: 83.7% vs. 77.7%, $P> 0.05$). Renal function of 32 patients (51.6%) had been recovered at posttransplant 1 year (sCr, 1.29±0.25 mg/dL). Early resolving of HRS within posttransplant 1 month did not predict the long-term patient survival. But the kidney fucntion at 1 year could predict the patient survival. A multivariate logistic regression analysis revealed that Child-Pugh Score was a significant risk factors for non-recovery of post-LTx renal function (P=0.024, OR 1.52, 95%CI 1.06-2.1).

Conclusions: Liver transplantation is the definitive treatment for HRS, but the non-recovery of kidney function at 1 year was associated with poor patient survival.

TH-PO984

How 'Overt' Is 'Occult Hepatitis C' in Hemodialysis and Kidney Transplant Patients? Seema Baid-Agrawal,[1] Petra Reinke,[1] Ralf Schindler,[1] Ulrich Frei,[1] Thomas Berg.[2] *[1]Dept of Nephrology and Medical Intensive Care, Campus Virchow Clinic, Charite Medical University, Berlin, Germany; [2]Division of Hepatology, University Clinic of Leipzig, Leipzig, Germany.*

Background: Our aim was to asses for the first time the prevalence of a newly defined entity called 'occult hepatitis C virus (HCV) infection', i.e. presence of HCV RNA in liver or peripheral blood mononuclear cells (PBMC) in absence of serum RNA, in large cohorts of chronic hemodialyis (CHD) patients and kidney transplant recipients (KTxR).

Methods: In this cross-sectional study, 421 CHD patients (Group 1), 418 KTxR (Group 2) and 2 control groups: 25 HCV-antibody (Ab)-positive patients with chronic hepatitis C (Group 3, positive controls) and 39 HCV-Ab-negative, HBsAg-negative healthy subjects (Group 4, negative controls) were enrolled. HCV RNA was tested in serum and PBMC using Versant TMA assay (Siemens Healthcare Diagnostics).

Results: CHD (Group 1): 405/421 patients were HCV-Ab-negative (Group 1a) and 16 were Ab-positive (Group 1b). The prevalence of HCV by positive serum RNA was 2.4% (10/421), of which 20% (2/10) were HCV-Ab-negative. Occult HCV was found in 2/405 (0.5%) HCV-Ab-negative patients.

KTxR (Group 2): 403/418 KTxR were HCV-Ab-negative (Group 2a) and 15 were Ab-positive (Group 2b). Prevalence of HCV by serum RNA in this group was 4.3% (18/418), of which 50% (9/18) were HCV-Ab-negative. Occult HCV was found in 2/403 (0.5%) HCV-Ab-negative patients.

	HCV RNA positive in		
	serum only	both serum and PBMC	PBMC only
Group 1a (N=405)	0	2 (0.5%)	2* (0.5 %)
Group 1b (N=16)	1 (6.3%)	7 (43.8%)	0
Group 2a (N=403)	3 (0.74%)	6 (1.5%)	2 (0.5%)
Group 2b (N=15)	0	9 (60%)	0
Group 3 (N=25)	1 (4%)	24 (96 %)	0
Group 4 (N=39)	0	0	0

* The test was weak-positive in both CHD patients and could not be confirmed by repeat testing.

Conclusions: Prevalence of occult HCV was low in both populations. Laborious and expensive testing for occult HCV is not required for screening and diagnosis of HCV infection in these patients. Instead, detection of HCV RNA in serum using ultrasensitive assays, and not HCV-Ab testing, should be the test of choice, as a significant proportion of HCV-Ab-negative infection was found in both groups, which would have gone undetected otherwise.

Antiviral Agents Has Improved the Clinical Outcomes in Renal Transplant Recipients with Chronic Hepatitis B Hyun Gyung Kim, Chul Woo Yang, Cheol Whee Park, Yong-Soo Kim. *Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea.*

Background: The introduction of antiviral agents has reduced complication associated with chronic hepatitis B virus (HBV) infection, which was one of the important causes of morbidity and mortality in renal transplant recipients (RTS) with chronic hepatitis B. However, the relationship between chronic HBV infection and clinical outcome after kidney transplantation (KT) remains controversial.

Methods: Sixty-nine RTR with chronic hepatitis B were included in this study. We compared retrospectively the baseline characteristics and clinical outcomes between the treatment group with prophylactic antiviral agents and the historical control group who received no prophylactic antiviral treatment. There were 25 patients in the treatment group and 44 in the historical control group

Results: There were no significant differences in baseline clinical parameters such as gender, age at KT, primary renal disease, the dialysis modality before KT and HLA mismatch number between the treatment and the control group. Nine patients (20.4%) in the control group received salvage treatment with antiviral agents after HBV reactivation. However, there were no significant differences in lamivudine resistance. The graft survival rate in the treatment group was significantly higher than that in the control group (5-year graft survival rate 81.8% vs. 55.9%, 10-year graft survival rate 81.8% vs. 34.2%, p=0.004). The treatment group also had better patient survival as compared to the control group (5-year patient survival rate 90.9% vs. 70.4%, 10-year patient survival rate 90.9% vs. 57.4%, p=0.014). In the control group, most common cause of graft loss was patient's death (51.6%, n=16) and the leading cause of death was fulminant hepatitis (66.6%, n=14/21), while there was no HBV related death in the treatment group.

Conclusions: Before the era of effective antiviral agents, renal transplant recipients with chronic hepatitis B showed a higher incidence of graft failure and HBV-related mortality. The development of antiviral agents had improved graft and patient survival in renal transplant recipients with chronic hepatitis B.

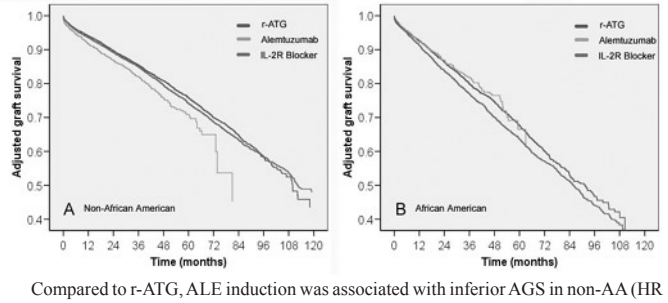
TH-PO986

Effect of Induction Agent on Post-Transplant Outcomes in Deceased Donor Kidney Transplant Recipients: Influence of Race Uzoamaka T. Nwaogwugwu, Kalathil K. Sureshkumar, Tina Y. Ko, Richard J. Marcus, Sabiha M. Hussain. *Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA.*

Background: The effect of induction agents on kidney transplant outcomes with respect to race is not well studied. We aimed to compare the outcomes of deceased donor kidney transplants (DDKT) in African American (AA) and non-AA recipients who underwent induction therapy with rabbit-antithymoglobulin (r-ATG), alemtuzumab (ALE) or IL-2 receptor blocker (IL-2B) and were maintained on a calcineurin inhibitor (CNI)/MMF based regimen with /without steroids.

Methods: Using OPTN/UNOS database, we identified patients (≥18 years) who underwent DDKT from January 2000 to December 2008 and received r-ATG (n=21,506), ALE (n=3476) or IL-2B (n=17869) and were maintained on CNI/MMF based regimen with /without steroids. Multivariate analysis was performed adjusting for steroid use and factors known to adversely impact graft outcome.

Results: The median follow up was 29.6 months (range 10.7-60.1 months). Adjusted graft survival (AGS) for AA and non-AA recipients are shown below.



Compared to r-ATG, ALE induction was associated with inferior AGS in non-AA (HR 1.29, 95% CI 1.14-1.46, p<0.001) but similar AGS in AA (HR 0.96, CI 0.80-1.14, p=0.61) recipients. AGS was similar with IL-2B induction in non-AA (HR 1.04, CI 0.98-1.1, p=0.18) but inferior in AA (HR 1.14, CI 0.80-1.14, p=0.002) recipients in comparison to r-ATG.

Adjusted patient survival was inferior with ALE (HR 1.27,CI 1.08-1.50, p=0.003) and IL-2B (HR 1.08, CI 1.0-1.2, p=0.04) inductions in non-AA but similar with ALE (HR 0.97, CI 0.75-1.26, p=0.82) and IL-2B (HR 1.07,CI 0.94-1.20, p=0.29) in AA recipients when compared to r-ATG .

Conclusions: Our study demonstrates racial differences in the outcomes following alemtuzumab induction in DDKT with inferior graft and patient survival in non AA but not in AA recipients.

TH-PO987

Residential Racial Composition Influences Outcomes Post Kidney Transplant Harini A. Chakkera,[1] Laura Szalacha,[2] Rudolph A. Rodriguez,[3] Brie N. Noble,[1] Ann M. O'Hare.[3] *[1]Mayo Clinic Arizona; [2]ASU; [3]VA Puget Sound Medical Center.*

Background: Dialysis patients living in predominantly black residential areas have less access to kidney transplant and inferior outcomes compared with patients living in other areas. Whether residential area racial composition is associated with outcomes after transplant is not known.

Methods: We used the USRDS and the 2000 US Census data to examine the association between the proportion of black residents in each patient's ZIP code of residence at the time of transplant with time to death and time to graft failure among patients who received their first kidney transplant between Jan 1, 2000 and Sept 30, 2005. ZIP codes were divided into 4 categories according to the percentage of all residents who were black: < 10%, 10 - 24.9%, 25 - 49.9% and ≥ 50%.

Results: Study cohort: 74,482 patients including 17,879 black and 51,442 white patients. Overall, 86% (n=7257) of black and 12% (n=972) of white transplant recipients lived in ZIP codes where 50% or more residents were black.

Transplant recipients living in ZIP codes with higher percentage of black residents were significantly more likely to have: higher BMI, hypertension, been treated with HD vs. PD pre-transplant, on average been on dialysis for longer pre-transplant, and less likely to be employed and be college educated, and were less likely to have received preemptive transplant and more likely to have received a deceased donor transplant.

Association of Percent of Black Residents in Neighborhood and Patient and Graft Survival

Proportion of black residents in the recipient's ZIP code	Unadjusted Patient Mortality *	Adjusted Patient Mortality * ^	Unadjusted Death Censored Graft Loss*	Adjusted Death Censored Graft Loss *^
< 10%	referent	referent	referent	referent
10- 24.9%	1.11 (1.04-1.17)	1.21 (1.07-1.36)	1.16 (1.11-1.22)	1.08 (0.96-1.20)
25- 49.9%	1.16 (1.09-1.25)	1.27 (1.10-1.49)	1.34 (1.27-1.42)	1.13 (1.01-1.27)
≥ 50%	1.29 (1.22-1.38)	1.29 (1.10-1.50)	1.54 (1.47-1.63)	1.14 (1.01-1.29)

* Hazard Ratio (95% CI) ^ adjusted for comprehensive set of recipient, transplant and donor variables

Conclusions: Patient and graft survival is worse for kidney transplant recipients living in predominantly black ZIP codes.

Funding: NIDDK Support

African American Renal Transplant One Year Outcomes from the Mycophenolic Acid Observational Renal Transplant Registry Mohanram Narayanan,[1] Oleh G. Pankewycz,[2] Mohamed A. El-Ghoroury,[3] Fuad S. Shihab,[4] Anne Wiland,[5] Kevin M. McCague,[5] Laurence Chan.[6] *[1]Scott and White Healthcare; [2]Buffalo General Hospital; [3]St. Clair Specialty Physicians; [4]University of Utah; [5]Novartis; [6]University of Colorado.*

Background: The Mycophenolic Acid Observational Renal Transplant (MORE) Registry, a prospective study of de novo renal transplant recipients (RTRs) receiving mycophenolic acid (MPA) therapy, is designed to determine effectiveness, tolerability and safety of enteric-coated mycophenolate sodium (EC-MPS) vs mycophenolate mofetil (MMF) regimens.

Methods: Based on local practices at 40 US sites, outcomes analyzed included: graft survival (GS), patient survival (PS), first biopsy-proven acute rejection (BPAR), adverse event (AE) rates, serum creatinine (SCr) and proportion of RTRs maintained on full MPA dose (1.44/2.0 g/day, EC-MPS/MMF). A total of 217 African American-AA (149 EC-MPS/68 MMF) and 684 non-AA (464 EC-MPS/220 MMF) tacrolimus-treated RTRs were included.

Results: AA RTRs were less likely to receive a living donor (24 v. 49%) and more likely to experience DGF (21 v. 14%) than non-AA RTRs. Mean BMI was similar. At 1, 3, 6 and 12 months, more AA EC-MPS RTRs received full MPA dose (EC-MPS/MMF: 82.2/70.8%, p=0.07; 65.0/ 54.8%, p=0.21; 55.2/36.0%, p=0.05; 45.0/41.5%, p=0.71). Comparable 12-month effectiveness, tolerability and safety outcomes were achieved in both groups. Comparing EC-MPS to MMF in the AA RTRs, there was similar GS (94.5/97.9%, p=0.58), BPAR (14.5/13.1%, p=0.75), mean SCr (1.67/1.74 mg/dL, p= 0.77) and reported AEs by organ system, infections or neoplasia. PS (99.2/96.5%, p=0.04) was higher in the AA EC-MPS group. Similar outcomes were observed between EC-MPS and MMF in the non-AA RTRs. Comparing 12-month outcomes in AA to non-AA RTRs regardless of MPA type, BPAR (14.1/7.5%, p=0.01), GS (95.5/97.7%, p = 0.07) and SCr (1.67/1.43 mg/dL, p<0.01) were worse in the AA RTRs whereas PS (98.3/99.2%, p = 0.69) was similar.

Conclusions: More AA RTRs treated with EC-MPS were maintained on full doses of MPA. Despite this, AA RTRs exhibited higher BPAR, mean SCrs and worse GS than non-AAs which may impact clinical outcomes at later timepoints in this study.

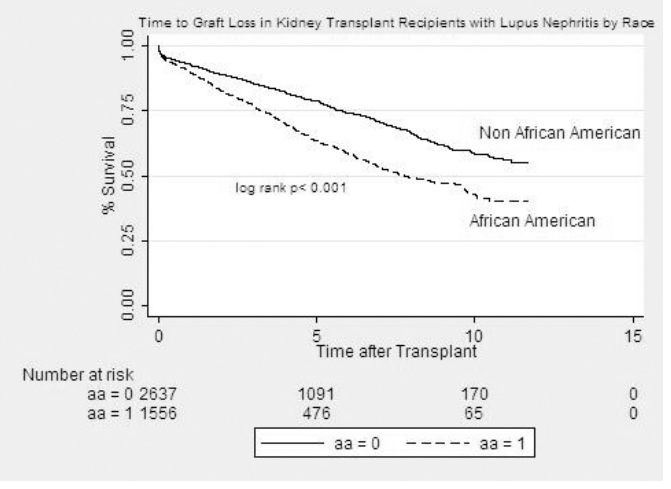
Racial Differences in Allograft and Death Outcomes in Kidney Transplant Recipients with Lupus Nephritis: Analysis of United States Renal Data System Robert Nee,[1] Frank P. Hurst,[1] Lawrence Agodoa,[2] Kevin C. Abbott.[1] *[1]Department of Nephrology, Walter Reed Army Medical Center, Washington, DC; [2]NIDDK, National Institutes of Health, Bethesda, MD.*

Background: African Americans (AF) with lupus nephritis (LN) have an increased risk of graft loss compared to Caucasians in the kidney transplant (KT) population. Whether this disparity is greater than among KT patients without LN, or applies to death, has not been reported.

Methods: In a retrospective cohort of 150,118 patients first transplanted from January 1, 1995 to September 29, 2006, we identified 4,214 patients who had lupus nephritis as the primary cause of ESRD.

Results: In a Cox regression analysis, AF recipients (vs. non-AF) with LN had an increased risk of graft loss (adjusted hazard ratio [AHR] 1.41, 95% confidence interval [CI] 1.37-1.44). At 10 years, the allograft survival rate for AF was 42.9% (95% CI 38.5-47.3) as compared to 58.2% (95% CI 54.8-61.4) in non-AF. Furthermore, AF (vs. non-AF) with LN had an increased mortality rate (AHR 1.07, 95% CI 1.04-1.11). The disparity for graft loss among AF with LN was greater than among AF without LN (AHR 1.51 and 1.41, respectively; p <0.001) as well as for death (AHR 1.37 and 1.05, respectively; p< 0.001). There was significant interaction between AF race and LN for both outcomes. MMF was associated with lower risks for graft loss and death in the lupus cohort as compared to azathioprine, however this was not significant (AHR 0.89, 95% CI 0.51-1.59 and AHR 0.40, 95% CI 0.13-1.28, respectively).



Among KT recipients with ESRD due to lupus nephritis, AF are at increased risk for both graft loss and death as compared to the non-AF population.

Conclusions: The views expressed in this abstract are those of the authors and do not reflect the official policy of the National Institutes of Health, the Department of Defense, or the United States government

TH-PO990

Impact of Racial Differences in Kidney Transplant Recipients with Focal Segmental Glomerulosclerosis Adela D. Mattiazzi, Gabriel Contreras, Giselle Guerra, Warren L. Kupin, David Roth, Jochen Reiser. *Nephrology and Hypertension, University of Miami, FL.*

Background: The recipients of African Americans (AA) lineages have an overall increased risk for allograft failure. Thus, racial differences may impact allograft outcomes in different etiologies of End Stage Renal Disease including Focal Segmental Glomerulosclerosis (FSGS).

Methods: We assessed 10577 kidney transplant recipients with FSGS from the United Network for Organ Sharing files. We then evaluated if AA risk for allograft failure was independent of 1) Socio-demographic factors: donor and recipient age, gender and race-ethnicity; recipient education and insurance; donor-recipient race-ethnicity match; 2) Immunologic factors: donor type, panel reactive antibodies, ABO compatibility, HLA mismatch, pre-transplant dialysis, cytomegalovirus risk and delayed graft function (DGF); 3) Rejection. All hazard models were adjusted for transplant immunosuppression era.

Results: 6036 Caucasian (C), 3437 African (AA), and 1104 Hispanic (H) American recipients were followed for 4.84 ±3.64 years. AA and H were younger than C recipients (35, 33 and 41 years respectively) and received kidneys from younger donors (34, 33 and 37 years respectively). AA versus H and C received more kidneys from deceased donors (70, 53 and 52%) with higher two HLA loci mismatches for HLA-A (55, 44 and 37%), HLA-B (58, 52 and 39%) and HLA-DR (31, 27 and 22%). More AA versus H and C developed DGF (22, 13 and 14%) and rejection (42, 28 and 31%). 916 (27%) AA, 177 (16%) H, and 1001 (17%) C had allograft failure (p< 0.001). AA compared to C had a significantly increased hazard ratio (HR) (1.90 [95% confidence interval 1.74 to 2.08] p< 0.001) for allograft failure in the unadjusted analysis; however, their increased HR for allograft failure became non-significant (1.11 [0.79 to 1.55] p=0.56) after adjusting for transplant era, socio-demographic, immunologic differences, and rejection.

Conclusions: African Americans recipients with FSGS have a higher prevalence of risk factors for allograft failure as compared to other races.

TH-PO991

National Transplantation Pregnancy Registry (NTPR): Pregnancy Outcomes in 156 Female Kidney Recipients on Tacrolimus-Based Immunosuppression Serban Constantinescu,[1] Lisa Coscia,[2] Megan Clary,[2] Carolyn H. McGrory,[2] Michael J. Moritz,[3] Vincent T. Armenti.[2] *[1]Medicine, Temple University School of Medicine, Philadelphia, PA; [2]Surgery, Thomas Jefferson University, Philadelphia, PA; [3]Surgery, Lehigh Valley Health Network, Allentown, PA.*

Background: The purpose of this study is to describe pregnancy outcomes in 156 female kidney transplant recipients receiving tacrolimus-based immunosuppression who reported to the National Transplantation Pregnancy Registry (NTPR).

Methods: Data were collected via questionnaires, phone interviews, and medical records.

Results: There are 156 recipients who reported 250 pregnancies with 255 outcomes (including twins) to the NTPR. There was also mycophenolic acid (MPA) exposure during 61 of these pregnancies. Outcomes included: 179 (70%) livebirths, 66 (26%) spontaneous abortions, 4 therapeutic abortions, 5 stillbirths, and 1 ectopic pregnancy. The mean gestational age of the 179 liveborn was 35.3±3.5 wks and the mean birthweight was 2,487±824 g. There were 4 neonatal deaths. Maternal comorbid conditions during pregnancy included: 55% hypertension, 31% preeclampsia, 21% infections, 9% diabetes mellitus, and 2% acute rejections. Structural malformations were reported in 13 (7.3%) of the 179 livebirths and in 7 (25.9%) of 27 livebirths with MPA exposure. Microtia, an ear deformity, was present in 4 newborn with MPA exposure. There were 30 (49%) pregnancies with MPA exposure that resulted in spontaneous abortions. In October 2007 the FDA category label changed from C to D for MPA. The majority of recipients, 122 (78%) reported adequate kidney function at last follow-up. Only 10 recipients were on dialysis, 6 with reduced/poor function, 5 had died, and 13 were lost to follow-up.

Conclusions: Female kidney transplant recipients continue to report successful pregnancy outcomes. There is an increased incidence of spontaneous abortions and a pattern of birth defects reported with exposure to MPA during pregnancy. Pregnancies in female kidney transplant recipients are high-risk and appropriate counseling and close follow-up are warranted.

TH-PO992

Ex Vivo Study of Transplacental Transfer of Tacrolimus in Renal Transplant Recipients Marion Jobard,[2] Noel Zahr,[3] Simasotchi Christelle,[1] Alexandra Benachi,[7] Marie-Catherine Lott,[2] Laetitia Croux,[2] Christophe M. Legendre,[4, 5, 6] Eric Thervet,[5, 6, 8] Sophie Gil.[1] *[1]Pharmacy, University Paris Sud 11, Chatenay Malabry, France; [2]Pharmacy, Beclere hospital, Clamart, France; [3]Pharmacology, Pitie Salpetriere APHP, Paris, France; [4]Renal Transplantation, Necker Hospital, Paris, France; [5]Universite Paris Descartes, Paris, France; [6]Fondation CENTAURE, Paris, France; [7]Obstetrical, Beclere Hospital, Clamart, France; [8]Nephrology, Hopital European Georges Pompidou, Paris, France.*

Background: Pregnancies in renal transplant recipients (RTR) are associated with an increased incidence of complications e.g. prematurity, intrauterine growth retardation and low birth weight. The role of foetal exposure to immunosuppressive drugs is possible but no information exists for quantitative transplacental transfer. The aim of the study was to evaluate the transplacental transfer of tacrolimus (TAC), using an ex vivo human cotyledon perfusion model.

Methods: Placentas from TAC pregnant RTR (TAC, n=4) and from untreated pregnant women with uncomplicated full-term pregnancies (control, n=6) were collected immediately after delivery. Cotyledons were perfused with TAC. Maternal perfusion was validated by quantification of antipyrine as internal control. Target TAC concentrations (80ng.mL-1) were tested to investigate possible modifications of TAC transport. Main transfer parameters including Fetal Transfer Rate (FTR, foetal to maternal concentrations ratio) and Clearance Index (CI, FTR ratio of tacrolimus vs. antipyrine) were assessed. Antipyrine and TAC concentrations were determined by HPLC and mass spectrometry respectively.

Results: In the TAC group, FTR of tacrolimus was 20.5±9.1% and the CI was 0.53±0.09. In the control group, these values were 19.6±4.8% and 0.62±0.09 respectively. Difference of transfer was not significant (p = 0.15).

Conclusions: TAC transfer through placenta exists, leading to foetal exposition. Transfer is similar in both groups but kinetics are different. By increasing patient numbers, We are studying the possible mechanisms for these differences. The demonstration of the transfer questions the role of foetal exposure in the related foetal complications.

TH-PO993

Predictors of Post Operative Renal Recovery in Orthotopic Liver Transplant (OLT) Patients Experiencing Renal Dysfunction (RD) Prior to Transplantation Jose I. Iglesias,[1] Sushil Mehandru,[1] John Davis,[1] Elliot Frank,[1] Jerrold S. Levine.[2] *[1]Department of Medicine, Division of Nephrology and Department of Surgery, Jersey Shore University Medical Center, Neptune, NJ; [2]Department of Medicine, Division of Nephrology, University of Illinois at Chicago, IL.*

Background: RD commonly occurs in patients with end-stage liver disease (ESLD) awaiting OLT. In patients with ESLD and RD, studies evaluating recovery of renal function post-OLT have yielded conflicting results. Employing the UNOS database we sought to evaluate factors predictive of renal recovery in OLT recipients with pre-OLT RD, transplanted from 1989-2005.

Methods: We defined pre-OLT RD as at least one of the following: serum creatinine (SCr) ≥2 mg/dL at time of registration, dialysis requirement at time of registration, or dialysis requirement at time of transplantation. Patients were excluded if SCr was ≤1.5 at time of transplant. Primary outcome was both recovery of renal function (SCr ≤1.5 mg/dL) at time of discharge and patient survival ≥29 days.

Results: There were 1997 cases of pre-OLT RD. Renal recovery occurred in 1016 cases (51%). Stepwise logistic regression analysis identified the following factors to be independently associated with renal recovery: higher estimated glomerular filtration rate (eGFR) at registration (p=0.01), higher eGFR at time of transplant (p=0.00001), presence of ascites at transplant (p=0.009), and use of thymoglobulin induction (p=0.049). The following risk factors were identified with persistent RD: liver graft dysfunction (p=0.00001), male sex (p=0.00001), higher body mass index (p=0.001), donor age (p=0.045), and tacrolimus use (p=0.039).

Conclusions: Among ESLD patients with pre-OLT RD, a greater eGFR at registration and/or transplant may indicate a greater renal reserve and be predictive of renal recovery. While tacrolimus use was associated with persistent renal dysfunction, thymoglobulin induction may be associated with renal recovery.

Cellular Infiltrates and NF-kB Subunit Signaling in Kidney Allografts of Patients with Clinical Operational Tolerance Luis Eduardo Becker,[1] Matthias Schaier,[1] Lars Kihm,[1] Marie-Luise Gross-Weissmann,[2] Martin G. Zeier,[1] Christian Morath.[1] *[1]Nephrology, University of Heidelberg, Germany; [2]Pathology, University of Heidelberg, Germany.*

Background: NF-kB plays a potential role in allograft tolerance, by orchestrating onset, resolution of inflammation and T-reg differentiation through subunit c-Rel. Our aim was to characterize the cellular infiltrates and the expression of NF-kB1, c-Rel and its upstream regulators phosphoinositide 3-kinase (PI3K)/RAC-alpha serine-threonine kinase (Akt1) in allograft biopsies from patients with spontaneous clinical operational tolerance (COT).

Methods: Paraffin fixed kidney allograft biopsies from 28 patients with COT (n=4), acute interstitial rejection (IR) (n=12) and borderline changes (BC) (n=12) with eGFR (MDRD) >40ml/min at biopsy and no significant loss of allograft function in the following 12 months were used in the study. Cellular infiltrates and immunohistochemical expression of key proteins of the NF-kB pathway were evaluated using digital image analysis software. Results are given as percentage of area positively stained, positive cells/mm^2 or percentage of positive cells/infiltrating cells.

Results: Biopsies from subjects with COT exhibited comparable amount of cellular infiltrate to IR and BC (COT: 190±161; IR 291±230; BC 178±161 cells/mm^2), but reduced c-Rel expression in the infiltrates (COT: 1.7±1.4; IR: 8.7±6.4; BC: 5.9±5.8 cells/mm^2, p=0.03). In contrast, FOXP3 positive cells in the infiltrates were markedly increased in COT as compared to IR and BC (COT: 13±5.6%; IR: 3.2±2.2%; BC: 3.4±2%, % of positive cells, p<0.01). This was paralleled by a significantly lower tubular PI3K and c-Rel expression by COT compared to IR and BC (PI3K: COT: 3.1±0.27%; IR 7.5±3.2% and BC 7.4±3.2%, % of area positively stained, p=0.03) and (c-Rel: COT: 1.4±0.51%; IR 7.2±4.3% and BC 5±3%, p=0.009). HLA-DR tubular expression was significantly lower in COT compared to IR (COT: 0.23±0.1% and IR: 0.71±0.54%, p=0.02).

Conclusions: Though displaying significant infiltrates, allografts from COT patients show less PI3K and c-Rel expression but high FOXP3 positivity.

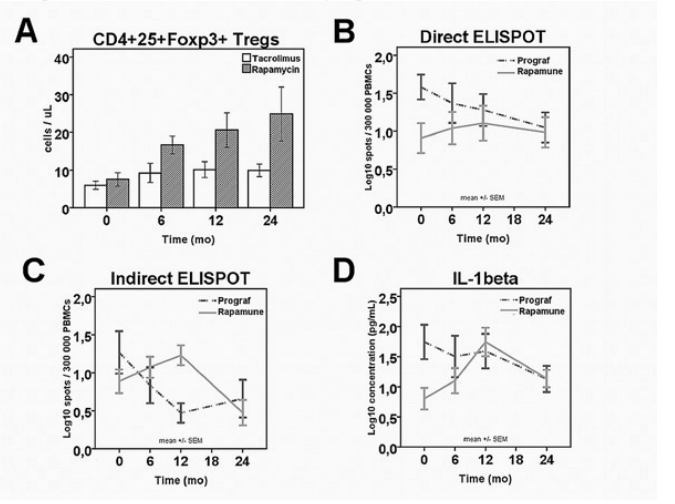
TH-PO995

Effects of Rapamycin Conversion on Cellular Immune Profile and Alloreactivity in Renal Transplant Recipients Sacha A. De Serres,[1] Monica Grafals,[1] Ciara N. Magee,[1] Luting Xu,[2] Usaila Ahmad,[1] Lorenzo G. Gallon,[2] Nader Najafian.[1] *[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Division of Nephrology, Northwestern University, Chicago, IL.*

Background: While rapamycin (Rapa) is known to expand regulatory T cells (Tregs), it has also been associated with inflammatory side effects. The aim of this study was to simultaneously characterize the Treg and donor-alloreactive T cell frequency and the cellular inflammatory profile in a cohort of renal transplant recipients enrolled in a randomized trial of conversion from tacrolimus (Tac) to Rapa at 12 months (mo) post transplant.

Methods: Blood was collected in 30 subjects (Rapa n=18; Tac n=12) at 0, 6, 12 and 24mo post randomization. T cell subset frequency was measured by flow cytometry, alloreactivity by the IFN-γ ELISPOT assay and cell culture supernatant cytokines by Luminex. Generalized estimating equations were used for analysis.

Results: Conversion to Rapa led to a sustained increase in CD4+25+Foxp3+ Tregs (Fig. A; p<0.01), but had no effect on the frequency of direct alloreactive T cells (Fig. B). Despite Treg expansion, there was a transient increase in indirect alloreactivity at 12mo, followed by a decrease at 24mo, a pattern mirrored by the cytokines IL-1B, IL-6 and TNF-α (Fig. C & D; all p<0.05). In contrast, subjects maintained on Tac displayed decreased direct and indirect alloreactive responses throughout the study (p≤0.01). The direct and indirect alloresponses were similar between the two groups at 24mo.



Conclusions: These data suggest that, despite Treg expansion, conversion to rapamycin results in a transient inflammatory response that concurs with increased indirect alloreactivity. We speculate that Tregs may initially be functionally impaired by the inflammatory milieu, but eventually succeed in attenuating the alloimmune response.

TH-PO996

Differential Impacts of Calcineurin and Mammalian Target of Rapamycin Inhibition on Alloreactive T Helper Cells Lorenzo G. Gallon, Giovanna La Monica, Luting Xu. *Medicine/Comprehensive Transplantation Center, Northwestern University, Chicago, IL.*

Background: Immunosuppressive drugs calcineurin inhibitor (tacrolimus,TAC) and mTOR inhibitor (sirolimus,SRL) affect naïve T cell differentiation and memory T cell expansion; however, their effects on the generation and expansion of different subpopulation of T helper cells are not fully elucidated.

Methods: Alloreactive CD4 T cells generated in a MLR were enriched and re-stimulated with autologous APCs with anti-CD3 plus TAC, SRL or the combination of TAC/SRL. At the end of culture, cells were restimulated and intracellular staining was used for detection of IFN-gamma, IL-17, and FOXP3 expression. Cytokine secretions from the supernatants were quantified with flowcytomix assay. Western blot was used for detection of DNA methyltransferase1 expression. SRL-derived Treg were tested for their suppressive activity by adding them in a new MLR. Thymidine incorporation and CFSE dilution technique were used as readouts.

Results: Alloreactive Th1/Th17 cells were differentially inhibited by TAC and SRL. Over 90% of the production of IFN-gamma and IL-17 and the percentage of intracellular expression of IFN-gamma (Th1) and IL-17 (Th17) were inhibited by TAC while SRL had only a moderate effect. FOXP3 expression (Tregs) was markedly increased in SRL treatment compared to TAC (average 3-fold increase). When used in combination, TAC at 2-5ng/ml with SRL at 2.5-10ng/ml achieved the maximal effect in inhibiting the productions of IFN-gamma and IL-17 while maintaining a high level of FOXP3 expression. When mimicking an inflammatory setting by adding cytokines (IL-1beta/IL-6/TNF-alpha) to the cell cultures, there was a marked decrease of SRL-induced FOXP3+Tregs. SRL-derived Tregs expressed normal surface markers, were anergic to allostimulations, and suppressed the proliferation of allogeneic effector T cells (Th1 and Th17). SRL significantly decreases DNMT1without affecting FOXO3/FOXP3 interaction thus maintaining a long-term FOXP3 expression by stabilizing FOXP3 transcription.

Conclusions: These findings can help to guide the clinical use of immunosuppressive drugs to promote Treg expansion while controlling Th1 and Th17 alloimmunity.

TH-PO997

DR^{high+}CD45RA^{-}-Tregs Disappear Excessively in Patients with Acute Kidney Rejection, Causing a Reduction in the Suppressive Activity of the Total Treg Pool Matthias Schaier,[1] Nicole Seissler,[1] Friederike Hug,[1] Martin G. Zeier,[1] Andrea Steinborn.[2] *[1]Department of Nephrology, University of Heidelberg, Germany; [2]Department of Gynaecology, University of Heidelberg, Germany.*

Background: Recent studies show that regulatory T cells (Tregs) play an essential role in tolerance induction after organ transplantation.

Methods: In order to examine whether there are differences in the composition of the total Treg cell pool between stable transplant patients and patients with biopsy proven rejection (BPR), we compared the percentages and the functional activity of the different Treg cell subsets (DR^{high+}CD45RA^{-}-Tregs, DR^{low+}CD45RA^{-}-Tregs, DR^{-}CD45RA^{-}-Tregs, DR^{-}CD45RA^{+}-Tregs). All parameters were determined during the three different periods of time after transplantation (G2: 0-30 days, G3: 31-1000 days, G4: >1000 days).

Results: Among 157 transplant patients, 38 patients suffered from BPR. Sorting and subsequent differential testing of all four Treg cell subsets revealed that the DR^{high+}CD45RA^{-}-Tregs, and to a slightly lower degree, the DR^{low+}CD45RA^{-}-Tregs had the highest suppressive activity within the total Treg pool. The significantly reduced suppressive activity of the total Treg cell pool obtained from transplant patients with BPR correlated both with a significantly reduced HLA-DR mean fluorescence intensity (MFI) of the DR^{+}CD45RA^{-}-Treg subset and a significantly reduced percentage of DR^{high+}CD45RA^{-}-Tregs within the total Treg pool. Therefore, it could be assumed that DR^{high+}CD45RA^{-}-Tregs potentially affect the suppressive activity of the total Treg pool and that the disappearance of this Treg subset gives a strong indication for acute rejection processes.

Conclusions: Therefore, both the monitoring of its percentage within the total Treg pool and the monitoring of the HLA-DR MFI of the DR^{+}CD45RA^{-}-Treg subset may be useful tools for the prediction of graft rejection.

Contrasting Effects of Immunosuppression on FOXP3+ Treg Biology in Liver and Kidney Allograft Recipients Tatiana Akimova,[1] Matthew H. Levine,[1] Ulf H. Beier,[1] Binita Kamath,[2] Elizabeth Rand,[1] Kevin E.C. Meyers,[1] Jens W. Goebel,[3] John Bucuvalas,[3] Wayne W. Hancock.[1] *[1]Children's Hospital of Philadelphia and University of Pennsylvania; [2]Toronto Hospital for Sick Children; [3]Cincinnati Children's Hospital Medical Center.*

Background: The effects of calcineurin inhibitor (CNI) therapy post-transplantation (Tx) on FOXP3+ Treg numbers and function are somewhat controversial.

Methods: We analyzed Treg numbers, FOXP3 methylation and suppressive function (SF) in 12 adults (8 liver, 4 kidney with serial sampling) and 46 children (38 liver, 8 kidney) on CNI or rapamycin (RPM)-based immunosuppression.

Results: In liver Tx recipients, CNI use led to decreased Treg numbers, viability and SF compared to use of RPM, but no significant differences were seen post-kidney Tx. In children with long-term grafts (8.5±0.6 y after Tx) and on CNI, Tregs of liver Tx recipients had more FOXP3 methylation ($p<0.05$) and 2-fold weaker SF but 23% more Tregs vs. children with kidney Tx. In mice, the liver can reportedly promote Tx tolerance, at least in part, by inducing T cells to become iTregs. Compared to thymic Tregs, iTregs can have increased FOXP3 methylation and suboptimal SF. We considered if clinical liver Tx might promote Treg conversion and thereby explain the greater higher number of Tregs, but weaker SF and increased FOXP3 methylation, in clinical liver vs. kidney Tx recipients. We found that murine and human liver samples contain 5-10% of Tregs within the intrahepatic lymphocyte population, whereas kidneys had no comparable resident component. Expression of the transcription factor, Helios, is reportedly a specific marker for thymic-derived nTregs, but no differences in Treg expression of Helios were found pre- or post-liver Tx, or between Tregs of kidney vs. liver Tx recipients. However, in studies of human and murine Tregs we noted that Helios was not specific to thymic nTregs and is best viewed as a marker of cell activation.

Conclusions: Tregs of kidney Tx recipients showed an unexpected greater resistance to CNI use than Tregs of liver Tx recipients. This may reflect CNI-linked impairment of the iTreg population developing within the liver and is the subject of ongoing studies in our lab.

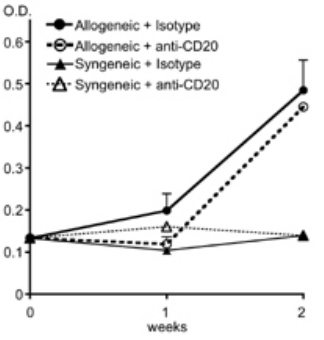
Allogeneic Transplantation Mitigates the Efficiency of B Cell Depletion with Anti-CD20 Antibody Lindsay A. Hilken, Clare E. Parker, Jagdeep Obhrai. *Medicine, Nephrology, Transplant Medicine, Oregon Health & Science University, Portland, OR.*

Background: Antibody-mediated rejection (AMR) in solid organ transplants is common, difficult to treat, and often results in irreversible organ dysfunction. Strategies to prevent AMR include B cell depletion (BCD) with monoclonal antibodies targeting CD20.

Methods: To examine the impact of BCD on the development of AMR, we treated mice with anti-CD20 antibody and then performed vascularized cardiac transplants.

Results: In mice that did not receive a transplant, CD20-targeted therapy rapidly and efficiently depleted naïve and germinal center B cells. Plasma cells (PC) in the spleen and bone marrow were also depleted but at a delayed tempo. Allogeneic transplantation reduced the efficiency of PC depletion and accelerated the repopulation of GC B cells. These recovering B cells produced high concentrations of donor-specific antibodies. Even when anti-CD20 antibody was given with sirolimus to block the T cell response, evidence of vascular antibody deposition (C4d deposition) and vasculitis was observed.

Allogeneic organ transplantation stimulated donor specific antibody expression in spite of anti-CD20 therapy



Mice received antibody (anti-CD20 or control IgG2a), and the next day received syngeneic or allogeneic heart transplants. Serum was collected from mice 1 and 2 two weeks after these treatments and was used to examine expression of donor specific antibody using a cellular ELISA. An O.D. of 0.6 equates to 4 μg/ml.

Conclusions: These data show that acute antigen challenge, such as an allogeneic transplantation, can facilitate the escape of responding B cells from BCD and that these B cells can cause the histological features of AMR. The limited efficacy of BCD, even in unsensitized animals, emphasizes the challenges of preventing AMR and highlights the need for a more detailed understanding of the processes that mediate B cell recovery after BCD.

The Effects of Desensitization Treatment with IVIG and Rituximab on Blood Gene Expression Profiles by Microarrays Kwaku Marfo,[1] Yi Bao,[1] Robert Brent Calder,[2] Min Ling,[1] Enver Akalin.[1] *[1]Einstein/Montefiore Kidney Transplant Program; [2]Computational Genomics Facility, Albert Einstein College of Medicine, Bronx, NY.*

Background: We aimed to investigate the effects of intravenous immune globulin (IVIG) and rituximab desensitization treatment on kidney transplant rate and blood gene expression profiles by microrarrays.

Methods: We enrolled patients with PRA levels >50% and on the deceased-donor waiting list for >5 years. Patients received IVIG (2.0 g/kg) on day 0 and 30; and rituximab (375 mg/m^2) on day 15. The antibodies with mean fluorescence intensity (MFI) values > 5,000 were reported to UNET as unacceptable antigens. The gene expression profiles of blood samples collected in PAXGene were studied by Affymetrix HuGene 1.0 ST expression arrays.

Results: 40 of the 415 patients (10%) on the waiting list were eligible for desensitization treatment and 11 completed the treatment. While 15 of the remaining 29 patients (52%) received a transplant without therapy, only 2 of the 11 desensitized patients (18%) received transplant during a median follow-up of 217 days. While there were no statistically significant difference in demographics, desensitized patients had higher cPRA values (97% vs. 77%, $p=0.0005$) and more number of unacceptable antigens (39 vs. 10, $p=0.0001$). There was no significant change in the mean number of unacceptable antigens (39 ± 22 versus 39 ± 23) or reduction in the mean MFI values (11,333 ± 3,133 vs 11,289 ± 3,386). Analysis of genes chosen as significantly differentially expressed revealed downregulation of genes involved in B cells and immune system (CD79a, B and T lymphocyte associated transcript, B cell scaffold protein, CD22, CXCR5, fas apoptotic inhibitory protein). Gene set enrichment analysis using Pathogenesis Based Transcripts created by Edmonton Group demonstrated significant downregulation of B cell associated ($p=0.04$) and immunoglobulin transcripts ($p=0.03$).

Conclusions: Although, desensitization with IVIG and rituximab decreases the expression of B cell and immunoglobulin associated transcripts, it was not successful in increasing kidney transplant rate or in decreasing the number of unacceptable antigens.

TH-PO1001

De Novo Donor Specific Antibodies among Non-Desensitized Renal Transplant Patients Predicts Antibody Mediated Rejection but Does Not Predict Renal Function at 1 Year Praveen Kandula, Sanjiv Anand, Muhammad Ahmad Mujtaba, Asif A. Sharfuddin, Muhammad S. Yaqub, Tim E. Taber. *Nephrology, Indiana University School of Medicine, Indianapolis, IN.*

Background: Pre and post-transplant DSA is associated with poor kidney allograft survival in desensitized patients. The significance of routine monitoring of post-transplant de novo DSA in non-desensitized patients is not well known. We prospectively evaluated

renal transplant patients at our academic transplant center for the significance of DSA in predicting renal function at 1 year and AMR.

Methods: All patients undergoing renal transplant were offered to be enrolled in an ongoing prospective study monitoring DSA since January 2010. DSA testing was done with single antigen luminex bead assay (One lambda Inc, Lab Screen) antibody screening at 1, 2, 3 and 6 month post-transplant.

Results: In this ongoing study 140 patients have been enrolled so far. Twelve desensitized patients and 7 patients with no DSA data were excluded. Of the remaining 121 patients, 20 (16.5%) patients developed DSA. Overall mean baseline creatinine (at 1 month post-transplant) was 1.38 (±0.52) and at 1 year was 1.34 (±0.47). Mean age was 49 years (±14) and 43% were females. Twenty one (17%) patients had rejection episodes of which 19 were acute cellular rejection (ACR) and 2 were AMR. Among patients who developed DSA (n=20), 2 patients (10%) developed AMR whereas none of the patients without DSA developed AMR (p=0.02). There was no significant difference in the incidence of ACR among patients with DSA (p>0.05). Among those who developed DSA, baseline median creatinine was 1.29 (0.61-2.7) and at 1 year was 1.2 (0.6-4.1) which was not significantly different.

Conclusions: From our preliminary data development of post-transplant de novo DSA may be associated with higher incidence of AMR in non-desensitized kidney allograft recipient. However it is difficult to recommend routine monitoring of DSA in non-desensitized transplant recipients to predict AMR based on this study. DSA do not predict renal allograft function at 1 year. However larger studies with longer duration of follow up are needed to further evaluate the role of DSA.

TH-PO1002

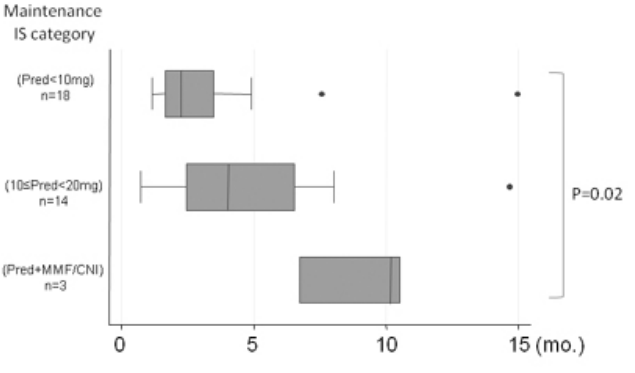
When De Novo DSA Appears after Reducing Immunosuppressants? Junichi Hoshino,[1,2] Hugo Kaneku,[2] Matthew J. Everly,[3] Paul I. Terasaki.[2,3] *[1]University of California Los Angeles, school of Public Health, Los Angeles, CA; [2]Terasaki Foundation Laboratory, Los Angeles, CA; [3]One Lambda Inc., Los Angeles, CA.*

Background: Weaning of immunosuppression (IS) is a common practice in transplant today. Based on the humoral theory, adequate HLA antibody monitoring is the most appropriate. However, the risk of de novo donor specific HLA antibody (DSA) after weaning is still unclear. Here we examine the duration of de novo DSA appearance after reducing IS.

Methods: Of the kidney transplantation patients (pts) from IKDRC-ITS, India under clonal deletion protocol, 72 pts, without pre–formed DSA, identical donor, nor splenectomy, were monitored presence of de novo DSA by LABScreen mixed/single antigen beads (one Lambda Inc.) for every month or every outpatient service. All pts had stable allograft functions and no DSA at the time of IS weaning. Positive DSA was defined as MFI >1,000.

Results: Within 72 pts (mean observation period, 12.4±8.1 months), 35 pts experienced de novo DSA. The half of them had class I DSA. To determine if the degree of reduction was important, we further evaluated patients into three groups: group 1 – 18 out of 26 pts on <10mg of prednisone(Pred) alone after weaning, Group 2 – 14 out of 24 pts on Pred ≥10mg after weaning, and Group 3– 3 out of 22 pts on Pred ≥10mg and MMF (or CNI). The mean time to de novo DSA was shorter according to IS levels (Group1, 3.3±3.2; Group 2, 4.8±3.6; and Group 3, 9.1±2.1 months, respectively) (p=0.02, Kruskal-Wallis).

Figure 1:Month after IS weaning to de novo DSA



Conclusions: This study highlights de novo DSA appears rapidly after weaning in low dose IS condition. Frequent HLA monitoring could be used to allow for early recognition of humoral activation when scheduled weaning is initiated.

TH-PO1003

Novel Risk Factors for Antibody-Mediated Rejection in Luminex Based Desensitization Strategies Maha A. Mohamed, David P. Foley, Brenda L. Muth, Vijay Vidyasagar, John D. Pirsch, Jose R. Torrealba, Dixon Kaufman, Arjang Djamali. *Medicine and Surgery, UW-SMPH, Madison, WI.*

Background: We sought to determine novel risk factors for acute rejection in Luminex-based desensitization strategies.

Methods: We performed a prospective analysis of 116 consecutive patients with a negative CDC crossmatch. All patients were desensitized based on pre-transplant immunodominant DSA (SAB-Luminex one-Lambda)(n=47, 12, 6, 16 and 35 in protocols D1, D2, D3, D4 and D5).

Desensitization Protocols

Protocol	Donor	iDSA	Induction	PE + IVIG	TAC + MPA
D1	Live	100-500	Simulect		Day -7
D2	Live	501-1000	Simulect	Days (-3, -1, 1, 3)	Day -7
D3	Live	1001-3000	Simulect	Days (-7, -5, -3, -1, 1, 3)	Day -7
D4	Deceased	500-1000	Thymo (5-7 mg/kg)		
D5	Deceased	1001-3000	Thymo (5-7 mg/kg)	Days (-1, 1, 3)	

Results: Mean peak PRA and DSA at transplant were 40% and 894 MFI respectively. There was a significant association between DSA, PRA and flow crossmatch (Fig 1)

Figure 1. There was a linear correlation between DSA, peak PRA and positive FXM

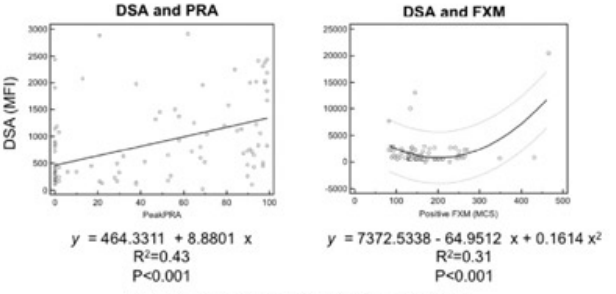


Figure 2. Acute Rejection after desensitization

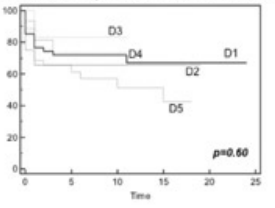

One year patient and graft survival were 100%. Rates of any acute rejection (including indication and protocol biopsies), acute antibody-mediated rejection (AMR), acute cellular rejection (ACR) and acute mixed rejection were at 33%, 12%, 13%, 8% in the first year. These differences were not statistically different between protocols (Fig 2). Median time to rejection was 6 months. Uni and MV regression analyses including demographics, PRA, DSA, retransplant status, immunosuppression and desensitization protocols demonstrated that delta DSA at 3 months (HR 1.003, 95% CI 1.0001 to 1.0004, p=0.0002) and positive c4d staining (focal or diffuse) in post-reperfusion biopsy (HR 4.3, 95% CI 1.6 to 11.3, p=0.002) were the most important factors associated with AMR.

Conclusions: Delta DSA at 3M and C4d staining in post-reperfusion biopsy are novel risk factors for AMR in sensitized patients undergoing Luminex based preconditioning regimens.

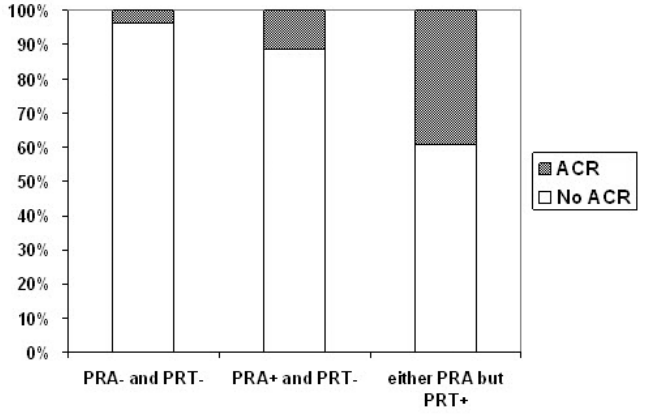
TH-PO1004

Pretransplant Cellular Allosensitization as a Predictor of Transplant Rejection Opas Traitanon, Titte Srinivas, Emilio D. Poggio. *Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH.*

Background: Cellular alloreactivity is prevalent in dialysis patients and when present may relate to transplant rejection. It may occur independently from humoral allosensitization. Pre-transplant anti-donor alloreactivity has been shown to correlate with acute cellular rejection (ACR) but donor cells are often difficult to obtain. In this study, we evaluated recipient third party cellular alloreactivity as a surrogate for anti-donor cellular alloreactivity to predict ACR.

Methods: We prospectively studied 62 kidney transplant recipients in whom we tested peripheral blood mononuclear cells against donor when available (n=35), and a panel of third party allogeneic B cell stimulators (Panel of Reactive T cells or PRT assay) by IFN-γ ELISPOT assays at time of transplantation. The results were then correlated with ACR episodes.

Results: Mean age was 49±13 yo, 42% female, 30.6% AA. We found a correlation between anti-third party and anti-donor cellular alloreactivity (R^2=0.17, p=0.014). Percent reactivity to the panel expressed was higher in patients with ACR than in those with no ACR (53±8 vs 22±3%respectively, p=0.003). Significantly more patients with ACR were found to be PRT positive (defined as >40% reactivity to the panel) compared to those w/o ACR (78% vs 25%, p=0.002). PRT positivity (with either PRA results) predicted ACR in 39% of the recipients while PRA positivity only predicted it in 11%.(p=0.008)



Neither PRA or PRT can help predict acute humoral rejection. This result was independent of induction or immunosuppressive therapy.

Conclusions: Pretransplant third party cellular alloreactivity can serve as a surrogate of anti-donor cellular alloreactivity. PRT can complement the information obtained by PRA to predict ACR but not humoral rejection.

TH-PO1005

Characteristics of Immune Profile in Renal Transplant Recipients with Long Term Allograft Acceptance Byung Ha Chung, Yu Ah Hong, Hyun Gyung Kim, In O Sun, Bumsoon Choi, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang. *Department of Internal Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea.*

Background: We evaluated the immunologic profile in patients with stable allograft function during long term follow up compared to patients with deteriorated allograft function.

Methods: Twenty-four renal transplant recipients (RTR) who have showed stable allograft function for more than 10 years were included (Long term stable group (LS group). We compared the immunologic characteristics of these patients with age and post-transplant duration matched chronic rejection group (CR group). Patients with biopsy-proven acute rejection (AR, n=9), healthy group (HC, n=21) and end stage renal disease patients on hemodialysis (HD, n=23) was included as control group in this analysis as well.

Results: In effector T cell subset, the percentage of Th17 cell showed significant increase in the CR group compared to LS group ($P < 0.05$). The percentage of Th1 and Th2 cell did not differ significantly between LS and CR group ($P > 0.05$). In the chemokine receptor analysis, $CCR4^{-}CCR6^{+}$ T cell and $CCR4^{+}CCR6^{+}$ T cell was significantly increased in the AR group and the proportion of interleukin-17 producing in those cells was significantly increased in AR group as well (vs. all another groups, $P < 0.05$). The percentage of naïve T cell was increased in LS group compared with CR and AR group ($P < 0.05$, respectively) and the value of LS group was similar with that in HC group. In contrast, memory T cell (effector memory T cell (T_{EM}) and central memory T cell (T_{CM})) did not show significant differences between LS and CR group. In B cell subset, memory B cell was increased in LS group. Immature B cell did not differ significantly among LS, CR and AR group. The percentage of IL-10 producing immature B cell was increased in CR and AR group compared with LS group.

Conclusions: In renal transplant recipient who showed long term acceptance with minimal immune suppressant, the decrease of Th17 response was significantly dominant compared with patients with chronic rejection.

TH-PO1006

High Serum Soluble CD26 Levels in Acute Cellular Rejection in Recipients with Renal Transplant Sanjay Gupta,[1] Ankit Saxena,[2] Dipendra Kumar Mitra,[2] Amit K. Dinda,[2] Sandeep Guleria.[3] *[1]Nephrology, All India Institute of Medical Sciences, India; [2]Immunogenetics, AIIMS, India; [3]Surgery, AIIMS, India.*

Background: Cell mediated allograft rejection is one of the major causes of early renal graft dysfunction. Information regarding the presence of markers indicating activation of immune cells can help in early monitoring graft status. The T-cell activation marker, CD26 possesses dipeptidyl peptidase IV (DPP IV) enzymatic activity. Costimulatory efficacy and immunocompetence are associated with the enzymatic activity. Also CD26 is an important dipeptidly peptidases which is known to activate some of the important chemokine ligands (RANTES and CXCL10) that are involved in the recruitment of T cells in the rejected graft. Aim was to study any association of serum soluble CD26 levels with early clinical events of allograft viz acute cellular rejection (ACR), calcineurin inhibitor toxicity (CNI).

Methods: The serum sample was collected from the 44 renal transplant recipients: renal allograft dysfunction for the first time within first year n=22 and recipients with well functioning grafts (WFG)(n=22). Patients were on Tacrolimus (Tac), Mycophenolate Mofetil and Steroids. None had induction with antibodies. Allograft biopsies performed for all the graft dysfunction cases showed ACR n=11 (Banff Grade-IA-2, IIB-4, II-1, III-4) and CNI n=11. The serum soluble CD26 (sCD26) levels was analyzed by ELISA.

Results: Mean duration post transplant in ACR, CNI and WFG was 3.4±2.5, 4.8±3.4, 5.6±4.1 months respectively and mean tac levels in respective groups was 7.4±3.8, 9.1±5.7, 8.3±3.7 μg/L. Significantly high serum sCD26 levels were observed among patients with ACR (1.92±0.9 μg/ml) in comparison to the non-immunological graft dysfunction cases CNI toxicity (1.08±0.4 μg/ml (p=0.008) and WFG (1.05±0.3 μg/ml)(p=0.001). Tac levels did not correlate with sCD26 levels. All the 7 patients with sCD26 levels above 1.6μg/ml had ACR.

Conclusions: The high serum sCD26 levels are associated only with ACR suggesting T cell activation and not with CNI toxicity and well functioning graft. The sCD26 seems to be a promising biomarker to assess adequate immunosuppression in the early phase after kidney transplantation.

Polyclonal Immunoglobulin Free Light Chains Provide a Novel insight into Immunosuppressant Use in Renal Transplant Recipients Shazia Shabir,[1] Anne Bevins,[2] Paul Cockwell,[1] Richard Borrows,[1] Colin A. Hutchison.[1] *[1]Renal Unit, University Hospital Birmingham, United Kingdom; [2]The Binding Site Group Ltd, Birmingham, United Kingdom.*

Background: Polyclonal free light chain (FLC) levels in part represent B-cell activity. The rapid clearance of FLC (2-6h) compared to immunoglobulins (Ig) (5-21 days) highlights a potential for FLCs to provide real-time monitoring of immune activity and dosing anti-proliferative medication. We investigated whether FLC levels were affected by routine immunosuppressants used in renal transplant recipients.

Methods: Serum samples were studied in two renal transplant populations: a cross-sectional prevalent cohort (n399) and an incident cohort (n40) with serial samples. Creatinine, polyclonal FLCs (κ+λ), Ig & cystatin C were measured, FLC production rates were calculated. Results were compared to a non-transplanted CKD cohort (n872).

Results: In the cross-sectional transplant cohort, total FLCs correlated with renal function, including eGFR (-0.537), cystatin C (0.594) and creatinine (0.531), all $p<0.001$. The median total FLC level(47.4mg/L, range 11.6-204.8) was lower than the CKD cohort, $p<0.001$ (62.5mg/L, 19.2-335.0), but stayed above the normal range ($p<0.001$). Patients receiving anti-proliferative therapy had lower total FLC (46.6mg/L, 11.6-262.0) than those not, $p<0.001$ (70.2mg/L, 23.2-431.0). Patients receiving Tacrolimus had lower FLC (45.0mg/L 11.6-366.0) than those on Cyclosporin, (53.0mg/L 12.3-431.0) p=0.002. There was no difference in FLCs between patients receiving prednisone or not (p=0.186). The intra-patient analysis showed a sharp decline in total FLC in 32/40 patients within 14 days of transplantation. FLC production was decreased at 2 weeks post transplant ($p<0.001$), and remained decreased over the 12month period ($p<0.001$). This was also true for IgG (2wk $p<0.001$, 12mth $p<0.001$) and IgA (2wk p=0.034, 12mth p=0.018). 26/32 patients had a gradual rise in FLC production between 2weeks and 12months as immunosuppression was reduced (p=0.001).

Conclusions: Polyclonal FLC levels vary with different immunosuppressant regimes and doses within the renal transplant population. Potentially FLC measurement could monitor immunosuppression in these patients.

TH-PO1008

In-Vitro Immunomodulatory Effect of Qu Mai (Dianthus Superbus) on Human Alloreactive T Cells Jessica A. Reid-Adam,[1] Nan Yang,[2] Ying Song,[2] Peter S. Heeger,[3] Xiumin Li.[2] *[1]Pediatric Nephrology, Mount Sinai School of Medicine, NY, NY; [2]Pediatric Allergy & Immunology, MSSM, NY, NY; [3]Nephrology, MSSM, NY, NY.*

Background: Immunosuppression for transplantation and autoimmunity is suboptimal, supporting the need for discovery of novel agents. We have been evaluating immune effects of traditional Chinese herbs.

Methods: We initially tested the effects of >50 herbs on human alloreactive T cell cytokine profiles using ELISPOT-based mixed lymphocyte cultures. This screening approach identified 4 candidate preparations that increased the IL-10/IFNγ ratio. Among these was Qu Mai (QM, Dianthus Superbus), an herb used to treat urinary tract disorders. We generated 3 fractions of QM with HPLC fingerprints and performed dose response curves for each fraction to assess effects on cytokine production in MLRs using PBMC from 12 normal volunteers. Flow cytometry was used to identify which cell types within the PBMC were altered by the therapy.

Results: Assays showed that 1 of the fractions (QM-AD, which contains flavonoid-rich compounds) exhibited a dose dependent inhibitory effect on alloinduced IFNγ (median decrease of 72% at 200 μg/ml) while enhancing IL-10 production 40 fold ($p<0.05$ vs. controls for each) and resulting in a marked change in IL-10:IFNγ ratios (0.2:1 in untreated MLR to 17:1 at 200 μg/ml, $p<0.05$). No effect on T cell apoptosis was observed. Flow cytometry and intracellular cytokine staining showed that in CD4 cells (including memory CD4 cells) QM-AD directly prevented production of IFNγ (mean 2.16% vs. 1.074% in QM-AD treated MLR), increased production of IL-10 (median 3.98% vs. 6.17% in QM-AD treated MLR), and induced CD4 CD25 Foxp3 Treg cells (mean 2.77% vs. 3.36% in QM-AD treated MLR).

Conclusions: Our data demonstrate that Chinese herbs, specifically QM-AD, contain compounds that favorably alter naïve and memory alloreactive T cell immunity toward an immune suppressive/Treg phenotype in vitro. These novel findings support the continued isolation and characterization of the QM-derived flavonoid compounds and testing them in in-vivo models as primary or adjuvant treatments of pathogenic immune responses, including autoimmunity and transplant rejection.

PARVG Gene Polymorphism May Be Associated with Operational Renal Allograft Tolerance Eric Thervet,[2,3,4,7] Richard Danger,[4,5] Marie-Lise Grisoni,[6] Pierre Laurent-Puig,[7] Annaick Pallier,[4,5] Delphine Le Corre,[7] Christophe M. Legendre,[1,3,4] Sophie Brouard.[4,5] *[1]Renal Transplantation, Hopital Necker, Paris, France; [2]Nephrology, Hopital European Georges Pompidou, Paris, France; [3]Universite Paris Descartes, Paris, France; [4]Fondation Centaure, Paris, France; [5]ITERT, CHU Hotel DIeu, Nantes, France; [6]INSERM, INSERM UMR S937, Paris, France; [7]INSERM, INSERM UMR S775, Paris, France.*

Background: Drug-free operationally tolerant kidney recipients (TOL), with long term stable graft function and low-grade proteinuria in an immunosuppression-free environment, were characterized by a specific set of 55 genes with differential blood transcriptional expression compared to contrasted clinical situations and healthy volunteers. The aim of this study was to investigate whether these expressions could be influenced by genetic polymorphisms located in the corresponding genomic sequences and whether some of these single nucleotide polymorphisms (SNPs) could be associated with clinical status of kidney transplanted patients.

Methods: 1152 candidate tag SNPs spanning the 55 genes were genotyped using a Golden Gate Illlumina assay in a sample of 163 kidney transplant patients consisted in 11 TOL patients, 36 patients with antibody mediated chronic rejection defined by the last Banff classification (CR) and 116 patients with a stable graft function while under immunosuppressive treatment (STA). We then analyzed gene expression and clinical status according to the different SNPs.

Results: Among the genes demonstrating strong expression difference between TOL compared to CR & STA patients, PARVG, which is a member of a family of actin-binding proteins associated with focal contacts, stands out with two SNPs, (rs139144 and rs5764592) explaining about 15% of the gene expression variability. Linkage disequilibrium analysis of these two SNPs showed the rs139144-GG genotype was associated with decreased PARVG expression and tended to be more frequent in TOL (60%) than in CR&STA (28%) patients ($p = 0.068$).

Conclusions: These preliminary results that should be confirmed in a larger population open new perspective of regulation pathways and hypothesis in operational tolerance mechanism.

TH-PO1010

Interventions in Purine Metabolism toward Immunosuppression Oshri Naamani,[2] Yair Cohen,[2] Moshe Zlotnik,[1] Amos Douvdevani.[1,2] *[1]Department of Nephrology, Soroka Medical Center, Beer-Sheva, Israel; [2]Department of Clinical Biochemistry, Ben-Gurion University of the Negev, Beer-Sheva, Israel.*

Background: Purine metabolites have potent immunoregulatory roles. ATP, mainly by its P_2X_7 receptor promotes inflammation and increases lymphocyte proliferation. ATP is degraded to adenosine which can also support inflammation by its Gi-coupled A_1 receptor (A_1R) or suppress inflammation and cellular immunity by its Gs-coupled $A_{2A}R$. We reported that activation (preconditioning) of the A_1R upregulates the anti-inflammatory $A_{2A}R$.

Our aim is to modulate the purinergic network toward immunosuppression by upregulation of the antiinflammatory $A_{2A}R$, conversion of ATP to adenosine and maintaining high adenosine levels. In addition we apply an innovative antiinflammatory purine derivate to attenuate T cell activation.

Methods: Preconditioning was induced by injection of A_1R agonist (CCPA) at 24 h and 12 h before splenectomy. Splenocytes from preconditioned or control animals were stimulated with Con A, anti-CD3 or cultured in a mixed lymphocyte reaction in the presence of apyrase (ATPase), adenosine deaminase (ADA), ADA inhibitor (EHNA), inosine-monophosphate (IMP) alone or combined. T-cell activation was assessed by cell proliferation and interferon-gamma (IFN-gamma) secretion.

Results: A decrease in proliferation and IFN-gamma secretion of lymphocyte from preconditioned animals was observed. ATP depletion by apyrase reduced splenocytes proliferation (46%). Reduction of adenosine levels by ADA increased T-cell activation while elevation of adenosine by EHNA caused the opposite effect. Furthermore, we showed that IMP reduces T-cell activation in a dose dependent manner, and when combined with EHNA, T-cell proliferation was eliminated (95%) as effectively as with mycophenolic acid (CellCept®).

Conclusions: Elevation of $A_{2A}R$, ATP depletion and adenosine elevation effectively decelerate T-cell activation. In addition, for the first time IMP was shown to function as an independent immunosuppressant agent. We believe that deeper understanding of the immuno-modulatory mechanisms in which purine metabolites participate, can provide a basis for further therapeutic developments.

TH-PO1011

Targeted Inhibition of Renal Rho Kinase: A Novel Approach To Reduce Macrophage Infiltration and Lymphangiogenesis in Acute Renal Allograft Rejection Fariba Poosti,[1] Saleh Yazdani,[2] Maria Emma Dolman,[4] Robbert J. Kok,[4] Jai Prakash,[3] Jacob Van den Born,[2] Jan-Luuk Hillebrands,[1] Harry Van Goor,[1] Martin H. De Borst.[2] *[1]Pathology & Medical Biology, UMCG, Groningen, Netherlands; [2]Nephrology, UMCG, Groningen, Netherlands; [3]Pharmacokinetics, UMCG, Groningen, Netherlands; [4]Pharmaceutics, Utrecht University, Netherlands.*

Background: Renal allograft rejection is associated with lymphangiogenesis, a process at least in part driven by inflammatory cell infiltration. RhoA is activated early in lymphangiogenesis and also plays a role in renal inflammation. We therefore investigated whether tubular cell-specific Rho kinase inhibition reduces lymphangiogenesis and macrophage influx in a rat model of kidney transplantation.

Methods: The Rho kinase inhibitor Y27632 was chemically bound to lysozyme (LZM), allowing selective uptake of the compound (Y27632-LZM) by proximal tubular cells upon its systemic administration. Renal allografting (Fisher->Lewis, n=12 per timepoint) was performed. The contralateral kidney was left in situ. Rats were not treated with immunosuppressive drugs to induce acute rejection. Animals were treated daily with Y27632-LZM (10 mg/kg equivalent to 278 µg/kg of free Y27632) or placebo until sacrifice at 1 or 4 d post-transplantation. Kidney sections were examined for macrophage influx (ED1) and lymphangiogenesis (Podoplanin).

Results: Y27632-LZM strongly reduced interstitial macrophage accumulation at day 1 (placebo 13.3±2.7; Y27632-LZM 10.8±7.1 macrophages/tubulo-interstitial field, $p<0.05$) and day 4 (177.6±62.1 vs 101.0±47.0, $p<0.05$) after allograft transplantation. Similarly, Y-27632-LZM reduced the numbers of lymph vessels at both day 1 (2.6±0.1 vs 2.0±0.2 lymph vessels/tubulo-interstitial field, $p<0.05$) and day 4 (4.2±0.4 vs 3.1±0.2, $p<0.05$) in allografts. Tubulo-interstitial macrophage and lymph vessel numbers were strongly correlated ($r^2=0.476$, $p<0.001$). Y27632-LZM did not affect blood pressure, suggesting local delivery of the compound.

Conclusions: Tubular cell-specific Rho kinase inhibition decreased renal lymph vessel numbers which may be secondary to reduced macrophage influx. Renal Rho kinase inhibition may be a valuable approach to treat allograft rejection.

TH-PO1012

Effect of Haemodialysis Membrane Exposure on Anti-HLA Antibody Formation in Incident Dialysis Patients Awaiting Renal Transplantation Claire Kennedy, Frank J. O Brien, Colm Magee, Peter J. Conlon. *Department of Nephrology, Beaumont Hospital, Dublin, Ireland.*

Background: Pre-emptive renal transplantation has superior outcomes to standard transplantation, particularly in terms of acute rejection rates. This suggests an immunological advantage for those patients who do not receive dialysis prior to transplantation.

In patients awaiting heart transplantation, left ventricular assist device have been associated with increased anti-HLA-antibody formation. New exposure to a 'foreign' haemodialysis membrane has not been compared to peritoneal dialysis (self) or no dialysis in terms of anti-HLA antibody formation. We assessed whether starting haemodialysis was associated with a subsequent increase in anti-HLA antibodies as opposed to starting peritoneal dialysis or not receiving any renal replacement therapy.

Methods: A retrospective cohort study of all patients who had been listed for a pre-emptive first renal transplant in Ireland was performed. Anti-HLA antibody formation was compared over time in patients who subsequently started haemodialysis, to those that started peritoneal dialysis and to those that started neither modality. Sensitizing events (pregnancies and blood transfusions) were also recorded.. We defined a significant increase in HLA antibodies as any increase in calculated PRA (determined by Luminex mehod) of 10%.

Results: 161 patients were included. Of these, 31 (19%) subsequently started haemodialysis (with a mean time on hemodialysis of 23 months), 18 (11%) started peritoneal dialysis (with a mean time of 14 months) and 112 (70%) started neither (with a mean follow-up time of 20 months). Baseline cPRAs were 19%, 29% and 24% respectively. There were no significant differences in age, gender, comorbidities, number of pregnancies or blood transfusions between the 3 groups. Rates of new anti-HLA antibody formation over time remained similar in all three groups: 22% of those who started haemodialysis, 16% of those who started peritoneal dialysis and 24% who started neither had a significant rise in cPRA..

Conclusions: Starting maintenance haemodialysis (and exposure to haemodialysis membranes) is not associated with an increase in production of anti-HLA antibodies.

TH-PO1013

Increased Interleukin-17 Producing Effector T Cells during Early Post-Transplant Period Byung Ha Chung, In O Sun, Hyun Gyung Kim, Yu Ah Hong, Bumsoon Choi, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang. *Division of Nephrology, Department of Internal Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea.*

Background: The change of precise immune profile during early post-transplant period has not been fully investigated. In present study, we investigated the response of immune cell subset during early post-transplant period in renal transplant recipients.

Methods: Twenty-nine living donor renal transplant recipients were enrolled in this study. We used triple immune suppressant composed of tacrolimus, mycophenolate mofetil and steroid and performed induction therapy by basilliximab in those patients.

We prospectively investigated the immune cell profile before and at 1 month after transplantation.

Results: The total lymphocyte counts did not differ significantly before and after transplantation ($P > 0.05$). The percentage of Th1 cell ($P < 0.05$) and Th2 cell ($P < 0.05$) in $CD4^+$ T cell significantly decreased after transplantation compared to before transplantation. In contrast, the percentage of Th17 cell did not reduce after KT compared to before KT ($P > 0.05$). The percentage of naïve T cell (T_{NAIVE}) and central memory T cell did not alter after KT ($P > 0.05$, respectively). In contrast, the percentage of effector memory T cell (T_{EM}) significantly decreased after KT compared to before KT ($P < 0.05$). However, the proportion of IL-17 producing cell out of T_{EM} was significantly increased after KT ($P < 0.05$). In $CD8^+$ T cell, the percentage of T_{EM} significantly decrease as like in CD4+ T cell ($P < 0.05$), and the proportion of IL-17 producing T cell in T_{EM} showed increasing pattern, even though it did not reach statistical significance. In B cell subset, all of memory B cell mature B cell, immature B cell in $CD19^+$ B cell did not show significant change after transplantation ($P > 0.05$, respectively).

Conclusions: In contrast with another helper T cell subset, Th17 cell response did not decrease and rather IL-17 producing T_{EM} cell increased after transplantation. It suggest that current immune suppressant is not enough to suppress allo-immune responses by Th17 cell during early transplant period.

TH-PO1014

Spleen Tyrosine Kinase Activation in Human and Experimental Acute Renal Allograft Rejection Sharmila Ramessur,[1,2] Frank Yuanfang Ma,[1,2] Jessica Ryan,[1,2] William Richard Mulley,[1,2] John Kanellis,[1,2] David J. Nikolic-Paterson.[1,2] *[1]Nephrology, Monash Mediacl Centre, Clayton, Victoria, Australia; [2]Medicine, Monash University, Clayton, Victoria, Australia.*

Background: Syk is an adapter molecule involved in B cell receptor and Fcγ-receptor signalling. Syk has also been implicated in neutrophil recruitment and platelet activation. These data suggest that Syk might play an important role in acute allograft rejection. To investigate this we examined Syk activation (phosphorylation of Tyr525/526 in the Syk activation loop) in human and experimental acute renal allograft rejection.

Methods: Three cases each of biopsy proven acute antibody-mediated rejection (AMR) and cell mediated rejection (CMR) of human renal allografts were analysed for p-Syk by immunostaining. A group of 5 Sprague-Dawley rats was immunised with Wistar spleen cells and three weeks later received an orthotopic Wistar renal allograft (one native kidney remained). Recipient rats were killed 7 days later.

Results: Normal human kidney shows no p-Syk immunostaining. In human AMR, p-Syk+ cells were prominent within glomerular capillary loops and in some interstitial areas. In CMR, many p-Syk+ cells were seen in the interstitium, with only small numbers of p-Syk+ cells in glomeruli. Most p-Syk+ cells appeared to be infiltrating leukocytes. In the rat model, all allografts showed severe renal arterial occlusion, thrombosis and areas of infarction with severe tubular necrosis. Other areas showed severe glomerulopathy, peritubular capillaritis and tubulitis. Rat allografts also exhibited rat IgG and C3 deposition, indicating elements of both AMR and CMR. Many infiltrating cells were stained for p-Syk. Double immunostaining identified Syk activation in both neutrophils and macrophages. Furthermore, phospho-p38 staining (a downstream Syk target) was evident in infiltrating leukocytes in a pattern similar to that of p-Syk, possibly indicating Syk-dependent leukocyte activation.

Conclusions: Prominent activation of Syk signalling is evident in infiltrating leukocytes in human and experimental allograft rejection. These findings suggest that Syk is a potential therapeutic target in acute renal allograft rejection.

Comparison of Antibody Monitoring System with Single Antigen Luminex Assay in Renal Transplant Recipient Hyeonseok Hwang, Byung Ha Chung, Bumsoon Choi, Yong-Soo Kim, Suk Young Kim, Chul Woo Yang. *Division of Nephrology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea.*

Background: The antibody monitoring system (AMS) is a recently developed ELISA crossmatch assay to detect donor-specific anti-HLA IgG antibodies (DSA). This study was performed to compare the AMS with DSA detected by single- antigen Luminex panel reactive antibody assay in renal transplant recipients.

Methods: One hundred and one sera were screened from 71 patients on the waiting list for kidney transplantation for the presence of DSA. When anti-HLA Ab was detected by Luminex assay and the matched donor had the corresponding mismatched HLA antigen, it was considered to indicate DSA. The results of AMS and Luminex assay were compared.

Results: Twenty-nine (28.7%) sera were positive for DSA detected by Luminex assay. The DSA was directed against HLA class I Ag in 12 (11.9%) sera, against HLA class II Ag in 17 (16.8%) sera, and against both class I and class II Ag in 6 (5.9%) sera. AMS assay showed that the number of compatible sera with DSA was 79 (78.2%) and it was a significantly concordant ($k = 0.469$, $p < 0.001$). The sensitivity of the AMS assay for detection of DSA was 37.9%; the specificity was 97.2%; the positive predictive value was 84.6%, and the negative predictive value was 79.5%. Compared to complement dependent cytotoxic crossmatch test (CDC), AMS showed higher concordance rate than Luminex assay ($k = 0.541$ for AMS vs. $k = 0.458$ for Luminex). For flowcytometric crossmatch test, the concordance rate was similar between AMS and Luminex assay ($k = 0.432$ for AMS vs. $k = 0.436$ for Luminex). The estimated glomerular filtration rate at 12 months after transplantation was significantly lower in positive AMS patients than in negative AMS patients (46.8 ± 4.1 vs. 60.7 ± 25.4, $p = 0.009$), but the DSA positivity did not predict the lower glomerular filtration rate at 12 months (59.1 ± 25.0 vs. 59.2 ± 24.7, $p = 0.99$).

Conclusions: While AMS assay is less sensitive to detect DSA than Luminex assay, it is useful to predict relevant CDC crossmatch in positive DSA recipients and one-year graft function after transplantation.

UGT2B7 -900 C>G Predicts Leucopenia in Pediatric Kidney Transplant Recipients David K. Hooper,[1] Barry L. Warshaw,[2] Tsuyoshi Fukuda,[1] Cassie L. Kirby,[1] Hiren P. Patel,[3] Deepa H. Chand,[4] Gina-Marie Barletta,[5] Scott K. Van Why,[6] Rene' G. VanDeVoorde,[1] Donald J. Weaver,[7] Lisa Martin,[1] Alexander A. Vinks,[1] Jens W. Goebel.[1] *[1]Cincinnati Children's Hospital; [2]Emory University; [3]Nationwide Children's Hospital; [4]Akron Children's Hospital; [5]Phoenix Children's Hospital; [6]Medical College of Wisconsin; [7]Levine Children's Hospital.*

Background: Mycophenolate Mofetil (MMF) causes leucopenia in a substantial proportion of kidney transplant (KT) recipients, prompting empiric dose reduction which can increase rejection risk. Single nucleotide polymorphisms (SNPs) in genes encoding uridinediphosphate glucuronosyltransferases (UGTs) and multi-drug resistance protein (MDR) have been associated with altered exposure to MMF.

Methods: A case-control gene association study was performed to determine whether UGTs and MDR1 SNPs would predict MMF-related leucopenia in pediatric KT pts. Pts were identified retrospectively and matched by race, center, induction therapy, steroid duration and age. Pts experiencing MMF-related leucopenia prompting dose reduction within the first year of KT were considered cases, whereas controls received full-dose MMF for 1 year following KT without leucopenia. Pts with lupus, liver disease, active nephrotic syndrome, alemtuzumab induction, and non-adherence were excluded. A paired t-test assuming an additive model was used to compare frequency of alleles between cases and controls.

Results: 54 of 225 (24%) pts qualified as cases, and 59 (26%) qualified as controls. 66 (29%) pts had transient leucopenia not requiring MMF dose change, 30 pts had other MMF-related side effects and 16 pts had leucopenia from other causes (e.g. cytomegalovirus). We enrolled 29 matched pairs for genetic analysis. The odds of UGT2B7 -900 G allele in cases were 2.4 times greater than in controls (p=0.03). SNPs at MDR1 3435, UGT1A9 -2152, and UGT1A9 -440 were not significantly associated with leucopenia (p =0.72, 0.16, 0.16 respectively).

Conclusions: MMF-related leucopenia prompting dose reduction was seen in 24% of pts. UGT 2B7 -900 C>G may be associated with an increased risk of leucopenia. Larger studies are needed to confirm this result.

TH-PO1017

Racial Influence on ABCB1 Gene Expression in Peripheral Blood Mononuclear Cells in Stable Renal Transplant Recipients Kathleen M. Tornatore,[1,3] Daniel Brazeau,[1] Aijaz A. Gundroo,[3] Rocco C. Venuto.[3] *[1]Pharmacy, Pharmacy; [2]Pharmaceutics, School of Pharmacy; [3]Medicine, Erie County Medical Center; SUNY/Buffalo, Buffalo, NY.*

Background: Immunosuppressive therapy (IT) such as tacrolimus are influenced by p-glycoprotein (P-gp) which modulates cellular efflux of this drug. P-gp is present on peripheral mononuclear cells (PBMC) and is encoded by the ABCB1 gene. No data are available regarding the impact of race on ABCB1 gene expression in PBMCs post-transplant over IT dosing interval.

Methods: An observational study was completed in 20 African American (AA) and 11 Caucasian (C) stable renal transplant recipients (RTR) (ages 30-74 yrs) receiving tacrolimus (trough: 5 - 10 ng /ml), and enteric coated mycophenolate sodium. At time 0 (prior to IT) & 4, 8 and 12 hours after immunosuppression, PBMCs were collected for ABCB1 gene expression analysis by quantitative real-time-polymerase chain reaction (QRT-PCR). The target ABCB1 gene PCR product was cloned, and verified by sequencing. The cloned ABCB1 gene was used to establish standard curves (linear[K1] over 6 orders of magnitude; $r^2 = 0.996$) and assess PCR efficiencies. Total ABCB1 copies and normalized copies using Alien RNA were assessed.

Results: The normalized ($p<0.0006$) and non-normalized ($p< 0.0001$) ABCB1 gene expression was higher among Caucasians and at each time until 12 hours.

ABCB1 Gene Expression in PBMC

ABCB1 Copies x10 ^{6} Total RNA	0 hours	4 hours	8 hours	12 hours
African Americans	28.0±14.6	25±16.8	26±15.2	33.4±24.7
Caucasians	61.1±46.3	57.2±48.6	56.5±47.8	53.8±24.2
Post hoc Pairwise p values	0.003	0.004	0.006	0.08

Conclusions: A racial difference in ABCB1 gene expression was noted with greater expression in C than AA. These racial differences in ABCB1 gene expression may influence intracellular tacrolimus concentrations mediated by P-gp and affect clinical outcomes relative to African Americans and Caucasians.

B Cell Depletion Synergizes with ECDI-Fixed Rat Splenocyte Infusions To Induce Concordant Rat to Mouse Islet Xenotransplantation Tolerance
Shusen Wang, Taba Kheradmand, James Tasch, Jie Yang, Xun-Rong Luo. *Medicine, Northwestern University Feinberg school of Medicine, Chicago, IL.*

Background: Previously we demonstrated that infusions of ethylene carbodiimide (ECDI)-fixed donor splenocytes (SP) could only prolong concordant rat to mouse islet xenograft survival but fail to induce tolerance. The aim of this study was to determine whether combination of B cell depletion and rat ECDI-SP infusions could induce tolerance to islet xenografts in a rat-to-mouse transplant model.

Methods: Rat ECDI-SPs were infused i.v. to diabetic C57BL/6 (B6) mice at day -7 and day 1. 650 Lewis rat islets were transplanted into the renal subcapsular space of recipient B6 mice at day 0. Recipients were treated with 250 ug anti-CD20 mAb i.v. on day -10 and day 1.

Results: Mice receiving rat ECDI-SP infusions had prolonged islet xenograft survival (median of 48, range 27-61 days) compare with control group (median of 18, range 15-25, p=0.0026). In contrast, 100% of xenografts were indefinitely accepted (> 150 days post transplant) in mice treated simultaneously with anti-CD20 and rat ECDI-SP infusions (p=0.0018, compare with rat ECDI-SP infusion group). Moderate to high levels of mouse anti-rat antibodies could be detected in subtypes IgG1, IgG2a, IgG2b, and IgG3 in the serum at two weeks after infusion of rat ECDI-SP alone despite the observed graft prolongation. Conversely, with combination therapy, minimal levels of all subtypes of anti-rat IgG were detected in the serum, which correlated with indefinite graft survival. In long-term protected islet xenografts, histological examination revealed minimal deposition of IgG, IgM, or C3, in contrast to acutely rejected grafts. Furthermore, protected islet grafts harbored a significant number of Foxp3+ cells among peri-islet graft infiltrates, which was minimal in rejected islet xenografts. Furthermore, there was a significant decrease in spleen CD4+ effector memory T cell population (CD44highCD62LlowCD69low) in long-term tolerized mice compared with controls.

Conclusions: Simultaneously with anti-CD20 and donor ECDI-SP infusions may be a promising regimen for tolerance induction in xenogeneic islet transplantation.

Tolerance and Efficacy of Intravesical Bacille Calmette Guérin (BCG) Treatment in Non Muscle-Invasive Bladder Cancer after Renal Transplantation
Avinash Jayaswal,[1] Thierry Roumeguere,[2] Nilufer Broeders,[1] Thierry Quackels,[2] Sandrine Rorive,[3] Anne Lemy,[1] Joelle L. Nortier.[1] *[1]Nephrology, Erasme Hospital, Université Libre de Bruxelles, Brussels, Belgium; [2]Urology, Erasme Hospital, Université Libre de Bruxelles, Brussels, Belgium; [3]Pathology, Erasme Hospital, Université Libre de Bruxelles, Brussels, Belgium.*

Background: Given the carcinogenicity of aristolochic acids, kidney recipients for end-stage AA nephropathy (AAN) benefit from a bilateral nephroureterectomy and regular cystoscopic examination in order to detect bladder tumors at an early stage. Intravesical instillations of BCG are the treatment of choice for these tumors, in spite of contra-indication due to immunosuppression. We evaluated the feasibility, efficacy and tolerance of BCG therapy in such kidney recipients.

Methods: According to guidelines for BCG usage, namely non-muscle invasive carcinoma of high grade (pT1G3) and/or carcinoma in situ (CIS), 7 patients were treated. Precautions were applied: double dosage of tacrolimus and prophylactic antituberculous treatment (isoniazid 150mg/d and rifampicin 300mg/d) at day -1, 0 and +1 of BCG instillation (Oncotice®) under ciprofloxacin prophylaxis. The tolerance to BCG was recorded clinically (pain, hematuria, fever). Regular follow-up with fluorescence cystoscopy (Hexvix®) was performed after 6 weekly cures, 3 maintenance cures and then every 3-6 months.

Results: So far, 6 patients are free of relapse since the beginning of BCG treatment with a follow-up period of 7-44 months. 5 patients had prior relapsed under intra-vesical Mitomycine C treatment. A 7th patient is just starting the treatment cycle. No change in renal function was observed. The tolerance was optimal, except in 1 patient who had to stop after 5 cures. No systemic tuberculous infection was observed.

Conclusions: We report here the successful treatment of non-muscle invasive bladder cancer with immunotherapy based on intravesical BCG in kidney recipients for end-stage AAN. Standardized conditions allowed the implementation of this treatment whose superiority to Mitomycin C needs to be validated in a larger cohort.

Further Elucidation of Mechanisms Mediating Reduced Autoregulatory Tone in Diabetes
Tsuneo Takenaka,[1] Tsutomu Inoue,[1] Takashi Miyazaki,[1] Yoichi Ohno,[1] Akira Nishiyama,[2] Naohito Ishii,[3] Hiromichi Suzuki.[1] *[1]Saitama Medical University, Japan; [2]Kagawa University, Japan; [3]Kitasato University, Japan.*

Background: We demonstrated that diabetes altered connexin (Cx) expression in the juxtaglomerular apparatus, impairing purinergic tubuloglomerular feedback (TGF) signaling (Diabetologia in press).

Methods: Using 12 Zucker lean (ZL) and diabetic fatty (ZDF) rats with normal and high (6%) salt diet, renal hemodynamics and renin-angiotensin system (RAS) were characterized.

Results: On normal salt diet, glomerular filtration rate (GFR) was higher in ZDF than ZL rats (1.16±0.06 vs. 0.92±0.05 ml/min/g.kidney.wt (gkw), p<0.05). Autoregulatory index (AI) of GFR was worse in ZDF rats (0.92±0.10 vs. 0.01±0.11, p<0.01). Lithium clearance was lower in ZDF than ZL rats (0.26±0.01 vs. 0.32±0.01 ml/min/gkw, p<0.05). High salt diet for a week failed to alter blood pressure in both strains. However, salt load similarized GFR in 2 strains (1.05±0.06 (ZDF) vs. 0.95±0.05 ml/min/gkw (ZL)). AI of GFR was partly improved (0.47±0.12, p<0.05 vs. ZDF on normal salt) despite of restoration of lithium clearance (0.32±0.01 ml/min/gkw) in ZDF rats on high salt diet. The administration of 8-cyclopentyl-1,3-dipropylxanthine (0.3mg/kg iv.), a selective adenosine-1 receptor antagonist, but not GAP peptide for Cx40 (5mg ia.), to ZDF rats with high salt diet abolished an improvement in AI of GFR (to 0.94±0.10). Plasma angiotensin II was similar between 2 strains. Renal angiotensin II was higher in ZDF than ZL rats on normal salt diet (338±33 vs. 204±34 fmol/gkw, p<0.05), but the difference was disappeared by salt load (166±21 vs. 152±19 fmol/gkw).

Conclusions: Our results demonstrated an elevated renal AngII in ZDF rats. The present data implicate that in addition to Cx alterations, enhanced proximal reabsorption in early diabetes attenuates TGF, underlying glomerular hyperfiltration and RAS activation. Our findings suggest that high salt diet standardizes distal delivery in diabetes, suppressing RAS and improving GFR autoregulation and hyperfiltration via activation of adenosine-1 receptors. The present study may provide a basis for the applicability of glucose transport inhibitor for diabetic nephropathy.

The Impact of Gender on Arterial Stiffness and the Renin Angiotensin System in Healthy Humans
Magdalena A. Sarna,[1] Jennifer M. MacRae,[1,2] Brenda Hemmelgarn,[1,2] Daniel A. Muruve,[1,2] Darlene Y. Sola,[1] Sofia B. Ahmed.[1,2] *[1]Department of Medicine, University of Calgary, Calgary, AB, Canada; [2]Alberta Kidney Disease Network, AB, Canada.*

Background: Women are protected compared to men in terms of kidney and cardiovascular (CV) disease and this protection may be mediated in part by gender differences in the renin-angiotensin-system (RAS). However, the impact of gender on RAS control of arterial stiffness, an important marker of future CV risk in both healthy and chronic kidney disease (CKD) populations is unknown.

Methods: Thirty-four healthy subjects (20 women, 14 men, age 35 ± 2 yr) were studied in high salt balance, a state of maximal RAS suppression. Arterial stiffness, measured as carotid-radial pulse wave velocity (PWV) and aortic augmentation index (AIX) by tonometry, circulating components of the RAS (plasma renin activity (PRA), angiotensin II (AngII), and aldosterone) and blood pressure (BP) were measured at baseline and in response to graded AngII infusion (3ng/kg/min x 30 minutes followed by 6ng/kg/min x 30 minutes), a well-accepted indirect measure of intrinsic vascular RAS activity. Post-menopausal women were excluded from the study. Women were studied in the same phase of the menstrual cycle.

Results: At baseline, women demonstrated similar PWV values compared to men (7.4 ± 0.2 m/s vs 8.0 ± 0.3 m/s, p=0.057), greater AIX values (12 ± 3 % vs 1.9 ± 3.0 %, p=0.017) and lower levels of circulating RAS components (PRA, p=0.012 vs men; AngII, p=0.041 vs men; aldosterone, p=0.031 vs men). Arterial stiffness increased in all subjects in response to AngII challenge (PWV, p<0.001; AIX, p<0.001 vs baseline, respectively). Though women demonstrated a greater arterial sensitivity to AngII challenge, this did not achieve statistical significance (ΔPWV: 1.8 ± 0.3 m/s vs 1.3±0.3 m/s, p=0.23; ΔAIX: 11.9 ± 3.2 % vs 11.3 ± 4.0 %, p=0.98).

Conclusions: Renin angiotensin system control of the vasculature does not appear to differ between healthy women and men. Future studies are required to determine the impact of gender on RAS control of arterial stiffness in patients at high risk of CV disease, such as those with CKD.

TH-PO1022

Protective Effect of AT1-Blockade on the Oxidative Stress and the Profibrogenic Response Produced in the Kidney of Normal Rats Fed with a High Salt Diet
Silvana L. Della Penna,[1] Gabriel F. Cao,[2] Maria Ines Rosón,[1] Carolina S. Cerrudo,[1] Jorge E. Toblli,[2] Belisario E. Fernandez.[1] *[1]Pathophysiology, Faculty of Pharmacy and Biochemistry, University of Buenos Aires, Buenos Aires, Argentina; [2]Laboratory of Experimental Medicine, Hospital Aleman, Buenos Aires, Argentina.*

Background: Ang II and AQPs alter the renal ability to reabsorb water from the tubular fluid. Renin is co-localized with AQP-1 and AQP-2 in proximal tubules and collecting ducts, respectively, suggesting that renal Ang II may modulate AQPs expression in tubular cells. We evaluate the effects of the AT1-antagonist, losartan on oxidative stress, renal fibrogenesis and AQP-1 and AQP-2 expression in renal tissues from normal rats fed with a high sodium diet, an experimental model characterized by decreased circulating Ang II levels and increased renal Ang II.

Methods: Rats were fed during three weeks with: regular rat chow (NS), high-salt (8%) chow (HS), and NS and HS fed rats together with losartan (NS-L and HS-L) administration ($40mg.kg^{-1}$ in drinking water). We evaluated: systolic blood pressure (SBP); renal function; intrarenal levels of Ang II, TGF-β_1, α-smooth muscle actin (α-SMA), $p47^{phox}$ NADPH oxidase subunit and eNOS enzyme by immunohistochemistry; and AQP-1 and AQP-2 by western blot and immunohistochemistry.

Results: High salt increased SBP and induced overexpression of Ang II, TGF-β_1, α-SMA and p47^{phox} NADPH oxidase subunit, and decreased eNOS, AQP-1 and AQP-2. Losartan reduced SBP in NS and HS groups and exerted diuretic and natriuretic effects in HS. Losartan reduced fibrosis and oxidative stress markers, and restored eNOS expression and AQP-2 levels in HS-L group. Losartan upregulated AQP-1 immunoexpression, independently of dietary sodium, favouring sodium urinary concentration.

Conclusions: SBP reduction, together with increased natriuresis and diuresis, induced by AT1 blockade in HS fed animals, depend on intrarenal Ang II inhibition, when circulating Ang II is simultaneously decreased. Intrarenal Ang II, through AT1 receptor stimulation, may be responsible for oxidative stress, profibrogenic response and decrease of AQP-1 and AQP-2 in the kidneys of rats fed with a high salt diet.

Is Vascular Mineralocorticoid Receptor Involved in Cyclosporine A Nephrotoxicity? Jenny Lancon,[1] Jean-Philippe Bertocchio,[3] Soumaya El Moghrabi,[1] Guillaume Galmiche,[1] Jean-Paul Duong van Huyen,[2] Philippe Rieu,[3] Frederic Jaisser.[1] *[1]U872 Team 1, INSERM, Paris, France; [2]Laboratoire d'Anatomie Pathologique, Hôpital Européen Georges Pompidou, Université René Descartes, Paris, France; [3]Service de Néphrologie-Hémodialyse-Transplantation, Hôpital Maison Blanche, CHU de Reims, France.*

Background: Cyclosporine A (CsA) nephrotoxicity is one of its most frequent adverse effect but its physiopathology remains unclear. Pharmacological blockade of the Mineralocorticoid Receptor (MR) has been reported to prevent CsA nephrotoxicity in the rat by modulating the expression of vaso-active factors (Perez-Rojas et al. AJPRP 2005). We have recently shown that MR is expressed in the endothelium and the vascular smooth muscle of the renal vasculature (Nguyen Dinh Cat et al. FASEB J 2010) Moreover genetic manipulation of MR expression in the endothelium (Nguyen Dinh Cat et al. FASEB J 2010) or the smooth muscle (unpublished data) alters vascular function Our working hypothesis is that the activation of vascular MR plays a key role in CsA nephrotoxicity.

Methods: We studied the effect of the effect of pharmacological blocade of MR on acute CsA toxicity in the mousemale mice of the under low salt diet: control, Ctrl (vehicle), CsA (CsA 100mg/kg/d) and CsA+Can (CsA + canrenoate 30mg/kg/d in the drinking water)

Results: At day 7, 40% of the CsA mice were dead versus 0 in the CsA+Can mice ($p<0,05$). Kidney dysfunction induced by CsA is prevented with canrenoate Creatinine clearance, mL/min/100g; Ctrl: 1.15 +/- 0.13; CsA: 0.74 +/- 0.17; CsA+Can: 1.31 +/- 0.24, $p<0.05$. CsA-induced proximal tubular vacuolizations were partially prevented by canrenoate. The induction of BIP/GRP478, a marker of endoplasmic reticulum stress, was also blunted. Canrenoate prevented the increase in urinary renal excretion of NGAL, a biomarker of renal damage, observed in CsA.

Conclusions: In conclusion, we demonstrate that pharmacological MR antagonism has beneficial effects on survival and prevents histological and functional alterations in a mouse model of acute CsA nephrotoxicity. The implication of vascular MR is currently under investigation using genetically modified models.

TH-PO1024

Urinary Albumin and Protein Excretion Are Associated with Increased Vascular Renin-Angiotensin System Activity in Healthy Humans David Donald McTavish Nicholl, Brenda Hemmelgarn, Tanvir Chowdhury Turin, Jennifer M. MacRae, Daniel A. Muruve, Darlene Y. Sola, Sofia B. Ahmed. *Medicine, University of Calgary, Calgary, AB, Canada.*

Background: Albuminuria and proteinuria, both linked to augmented renin angiotensin system (RAS) activity, are associated with adverse kidney and cardiovascular (CV) events. However, the relationship between urinary albumin excretion (UAE) and protein excretion (UPE) in the normal range and RAS activity is unclear. We examined the association between measures of UAE and UPE and the hemodynamic response to angiotensin II (AngII) challenge, a well-accepted indirect measure of RAS activity, in healthy individuals with normal UAE and UPE.

Methods: Forty subjects (15 men, 25 women; 38±2 yrs), were studied in high salt balance. All subjects had normal UAE (3.32±0.55 mg/day) and UPE (57±4 mg/day). Blood pressure (BP), arterial stiffness (aortic augmentation index (AIx) and carotid-radial pulse wave velocity (PWV_{cr})), and circulating RAS components were measured at baseline and in response to graded AngII infusion (3ng/kg/min x 30min followed by 6ng/kg/min x 30min). All studies were performed during the same phase of the menstrual cycle in women. The primary outcome was the hemodynamic response to AngII challenge at 30 and 60 minutes.

Results: UAE was associated with a blunted diastolic BP response to AngII infusion (30min, $r=-0.44$, $p=0.005$; 60min, $r=-0.23$, $p=0.2$), a relationship which remained even after adjustment for covariates (30min, $\beta=-0.72$, $p<0.001$; 60min, $\beta=-0.77$, $p=0.04$). Similar results were observed with UPE (30min, $r=-0.34$, $p=0.03$; 60min, $r=-0.53$, $p=0.001$), even after multivariate analysis (30min, $\beta=-0.076$, $p=0.02$; 60min, $\beta=-0.20$, $p<0.001$). Neither UAE nor UPE were associated with the systolic BP, AIx, PWV_{cr}, PRA, or aldosterone responses to AngII challenge.

Conclusions: Even in our healthy population with 'normal' urinary albumin and protein excretion, increased levels of albuminuria and proteinuria are independently associated with augmented vascular RAS activity which is known to be deleterious to both renal and cardiac function. Larger, prospective studies are required to determine whether albuminuria and proteinuria have a causal role in kidney and CV disease.

TH-PO1025

Autonomic Nervous System Activation during Intradialytic Hypertension Dvora Rubinger, Rebecca Backenroth, Dan Sapoznikov. *Nephrology and Hypertension Services, Hadassah University Medical Center, Jerusalem, Israel.*

Background: To define the relationship between heart rate (HR) and blood pressure during intradialytic hypertensive episodes (HD-HyE), continuous interbeat intervals (IBI) and systolic blood pressure (SBP) were monitored in 108 patients during 113 HD sessions.

Methods: HD-HyE, defined as an increase of at least 10 mmHg in SBP between the beginning and the end of dialysis, or hypertension resistant to ultrafiltration occurring during or immediately after dialysis, were detected in 62 sessions. SBP and IBI variability and baroreceptor sensitivity (BRS) in the low (LF) and high frequency (HF) ranges were assessed using complex demodulation method (CDM). LF and HF oscillations are believed to be representative of sympathetic and parasympathetic activation respectively.

Results: HD-HyE were associated with increased (↑, n=45) or decreased (↓, n=17) HR. Mean SBP, IBI and their variability, BRS and LF/HF ratio, representative of sympatho-vagal bala Table 1.

	↑HR			↓HR		
	Before	*During*	p	*Before*	*During*	p
SBP (mmHg)	139 (24)	158 (30)	0.001	141 (37)	159 (25)	0.001
IBI (msec)	868 (201)	822 (191)	0.001	848 (167)	917 (177)	0.001
LF SBP (mmHg)	1.71 (0.88)	2.28 (0.95)	0.001	2.02 (1.03)	1.81 (0.70)	NS
HF SBP (mmHg)	1.56 (0.86)	1.85 (0.87)	0.001	1.90 (1.24)*	1.77 (0.93)	NS
LF IBI (msec)	6.49 (7.10)	8.41 (7.08)	0.011	6.62 (4.47)	5.95 (5.21)	NS
HF IBI (msec)	6.43 (4.55)	6.31 (3.96)	NS	5.92 (4.16)	5.82 (3.98)	NS
LF BRS (msec/mmHg)	4.63 (3.62)	3.81 (2.70)	0.001	3.05 (2.46)	3.77 (2.48)	NS
HF BRS (msec/mmHg)	4.62 (2.97)	3.69 (3.34)	0.001	2.88 (3.45)*	3.55 (2.56)	NS
LF IBI/HF IBI	1.02 (0.35)	1.22 (0.58)	0.007	0.92 (0.70)*	1.06 (0.60)	NS

* $p<0.05$ vs. ↑HR *Before* nce, *before* and *during* HD-HyE were (median and interquartile range):

Conclusions: Maximal SBP was similar in both groups. In ↑ HR , HD-HyE were associated with increased SBP and IBI variability, suppressed BRS and enhanced LF/HF ratio, while in ↓ HR, there were no significant changes in the above parameters. Our data point to sympathetic overactivity as an important mechanism of ↑ HR and hypertension in a significant proportion of patients. In those with ↓ HR, sympathetic activity seems to be counterbalanced by vagal effects. The triggers of increased sympathetic activity during HD remain to be determined.

TH-PO1026

Reduced Aortic Relaxation Rate in Rats with Adenine-Induced Chronic Renal Failure Lisa Nguy,[1] Jaana Lundgren,[1] Holger Nilsson,[2] Gregor S. Guron.[1] *[1]Department of Molecular and Clinical Medicine, Institute of Medicine, Gothenburg, Sweden; [2]Department of Physiology, Institute of Neuroscience and Physiology, Gothenburg, Sweden.*

Background: The aim was to investigate vascular function in rats with adenine-induced chronic renal failure (A-CRF).

Methods: Male Sprague-Dawley rats received either chow containing adenine for 6-12 weeks (0.5% for 3 weeks, 0.3% for 2 weeks, 0.15% thereafter) or were pair-fed with an identical diet without adenine (controls). Systolic blood pressure (SBP) and plasma were analyzed, at 2, 4 and 6 weeks. Segments of thoracic aorta and mesenteric arteries (2nd order) were analyzed with wire myograph. Data are means±SEM.

Results: A-CRF rats showed a marked increase in serum creatinine (281±25 vs. 28±1 µmol/L, $P<0.05$) and parathyroid hormone levels were increased approximately 9-fold vs. controls ($P<0.0001$). SBP was significantly increased in A-CRF rats (at 6 weeks 164±2 vs. 131±2 mmHg, $P<0.05$). There were no significant differences between groups in EC50 values for norepinephrine/phenylephrine, acetylcholine (ACh) or sodium nitroprusside (SNP) in either the aorta or mesenteric arteries. The rate of relaxation was markedly decreased specifically in the aorta of A-CRF rats in response to wash in KCl precontracted vessels (0.06±0.01 vs. 0.21±0.02 mN/s, $P<0.0001$) and this abnormality was evident also in calcium-free buffer. In addition, aortas from rats with A-CRF showed reduced relaxation rates in response to different vasodilators, e.g. SNP, ACh and forskolin. Concentration-response curves for KCl and calcium showed an increased KCl sensitivity and an attenuated response to calcium in A-CRF aortas compared to controls. Aortas from A-CRF animals did not show any calcifications on von Kossa-stained sections.

Conclusions: Rats with A-CRF did not show an impaired sensitivity to ACh or SNP in the aorta or mesenteric arteries in spite of severe renal insufficiency. The major vascular abnormality in A-CRF rats was a reduced rate of relaxation specifically in the aorta, which was evident also in the absence of extracellular calcium. We speculate that a reduced aortic relaxation rate might contribute to aortic stiffness independently of calcifications in chronic renal failure.

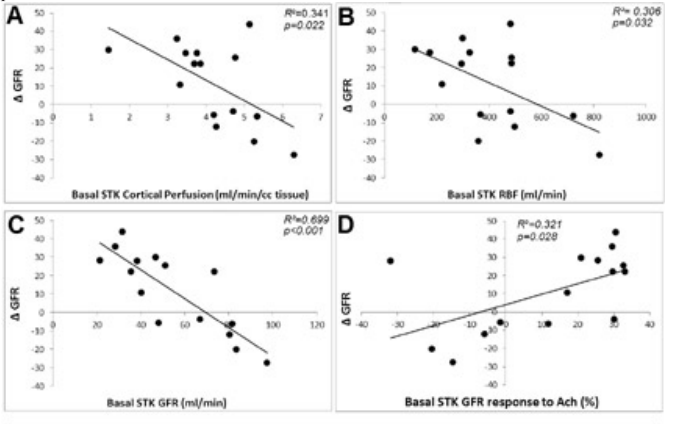
Basal Stenotic-Kidney Hemodynamics and Function Correlate with Response to Revascularization in Swine Renal Artery Stenosis (RAS) Alfonso Eirin,[1] Xiang-Yang Zhu,[1] James Krier,[1] John A. Crane,[1] Stephen C. Textor,[1] Amir Lerman,[2] Lilach O. Lerman.[1] *[1]Divisions of Nephrology and Hypertension, Mayo Clinic; [2]Cardiovascular Diseases, Mayo Clinic, Rochester, MN.*

Background: Percutaneous transluminal renal angioplasty (PTRA) can restore vessel patency in RAS, but selection of subjects likely to improve glomerular filtration rate (GFR) after revascularization is difficult. This study examined hemodynamic factors linked to improved renal function after PTRA in a swine model of RAS.

Methods: Pigs (40-55kg) after 6-weeks of hemodynamically significant RAS (60-99%) were studied immediately before and 4 weeks after technically successful PTRA and stenting (n=15) or sham (n=7). Stenotic kidney (STK) hemodynamics and function were evaluated by multidetector computerized tomography before and after challenge with the endothelium-dependent vasodilator and diuretic acetylcholine (Ach, 0.5 μg/kg/min IV). Response to PTRA was evaluated by the change in GFR (Δ GFR).

Results: Four weeks after PTRA blood pressure was normalized in all pigs, and single-kidney GFR increased in 9/15 (ΔGFR= 27.3±3.1 mL/min). A positive functional change in GFR to Ach (possibly reflecting preserved tubular response) directly correlated with ΔGFR (Figure).

Conclusions: The combination of preserved functional stenotic-kidney GFR response to Ach and lower basal GFR may prove to be a powerful and potentially clinically applicable predictor of benefit from revascularization in RAS.



In RAS pigs treated with percutaneous transluminal renal angioplasty (PTRA), ΔGFR correlates inversely with basal STK cortical perfusion (A), RBF (B), and GFR (C), but directly with GFR responses to Ach (D).

Kruppel-Like Factor 4 Mediates High Phosphate-Induced Conversion of Vascular Smooth Muscle Cells into Osteoblast-Like Cells Tadashi Yoshida, Maho Yamashita, Matsuhiko Hayashi. *Apheresis and Dialysis Center, Keio University School of Medicine, Tokyo, Japan.*

Background: Cardiovascular complications are the leading cause of death in patients with chronic kidney disease. These patients often have vascular calcifications, which have been associated with hyperphosphatemia. Previous studies have shown that high phosphate-induced phenotypic switching of vascular smooth muscle cells into osteoblast-like cells plays an important role in the calcification process. In the present study, we determined if phosphorylated Elk-1 and Kruppel-like factor 4 (Klf4), which are critical regulators of smooth muscle marker gene expression, were involved in this process.

Methods: Cultured rat aortic smooth muscle cells were incubated in the medium with normal or high phosphate concentration (5 mmol/l) and were harvested for subsequent analyses.

Results: After the incubation with high phosphate medium for 10 days, severe calcification was observed by von Kossa staining. Expression of SM a-actin was decreased, whereas Runx2 expression was induced, as determined by real-time RT-PCR. In this culture system, Klf4 expression was markedly induced at mRNA and protein levels. However, phosphorylation of Elk-1 was undetectable at any time points examined. Furthermore, knockdown of Klf4 by siRNA attenuated high phosphate-induced repression of SM a-actin expression.

Conclusions: Results suggest that Klf4 mediates high phosphate-induced phenotypic switching of vascular smooth muscle cells into osteoblast-like cells.

TH-PO1029

Candesartan Inhibits Toll-Like Receptor Expression in Human Renal Tubular Epithelial Cells Chen Yu. *Department of Nephrology, East Hospital, Shanghai, China.*

Background: Toll-like receptors (TLRs) play a key role in the innate immune system and are found to be crucial in inflammatory respond. Recent research found that TLR4 was upregulated in the inflammatory diseases, such as hypertension, arteriosclerosis and renal fibrosis. Angiotensin II is involved in inflammatory responds via Angiotensin II type-1 receptor, whereas Angiotensin II type-1 receptor blockers (ARB) exert anti-inflammatory effect. The aim of present study is to investigate whether candesarsan, an ARB, exerts its anti-inflammatory effect through Toll like receptors pathway.

Methods: Human renal tubular epithelial cells (HKC) were stimulated with LPS (200ng/ml) in the absence or presence of candesartan and TLR4 protein expression was measured by flow cytometry. Knocked down AT1R in HKC using AT1R siRNA and then tested AT1R expression induced by LPS. LPS and/or candesartan stimulated HKC for 0.5hrs, 1hrs and 3 hrs, and collected cells for phosphorylation of NF-kB using western blot. Stimulation with LPS and candesartan (10^{-5}mol/L,10^{-7}mlo/L,10^{-9}mol/L) and extracted RNA to test mRNA expression of inflammatory factors MCP-1 and RANTES.

Results: LPS increased TLR4 protein expression in HKC, which was inhibited by candesartan markedly. Silence of AT1R improved LPS-induced TLR4 expression. Pretreatment of HKC with candesartan significantly decreased LPS induced NF-kB activity and TLR4 expression ($P < 0.05$ vs. control) along with decrease in the mRNA expression of MCP-1 and RANTES in a concentration-related pattern.

Conclusions: LPS induced TLR4 expression, NF-kB activity and further inflammatory factors expression are inhibited by candesartan. Thus, we define a novel pathway by which candesartan could induce anti-inflammatory effects, that is through Toll like receptors pathway.

Key Words: Toll-like receptors (TLRs), LPS, Angiotensin II, ARB

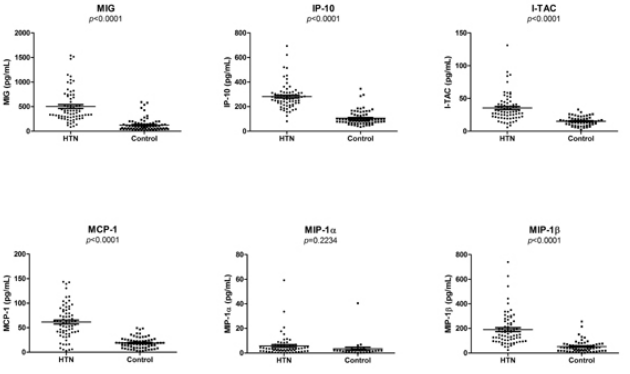
Hypertensive Nephrosclerosis Is Associated with Periarteriolar T Cell Infiltrates and Increased Level of Serum T Cell-Driven Chemokines Beom Jin Lim,[1] Youn Jong-Chan,[2] Hyeon Joo Jeong,[1] Sungha Park.[2] *[1]Department of Pathology, Yonsei University College of Medicine, Seoul, Korea; [2]Department of Internal Medicine, Severance Cardiovascular Center, Yonsei University College of Medicine, Seoul, Korea.*

Background: The contribution of chemokines in primary hypertension has been recently proposed in animal models, however, their roles in human hypertension are not well known. We evaluated the infiltration of chemokine-producing T cells in renal tissue of hypertensive nephrosclerosis and circulating levels of chemokines in hypertensive patients.

Methods: We evaluated infilatration of T lymphocytes and their expression of chemokines in 10 hypertensive nephrosclerosis cases by immunohistochemistry and compared with normal control group. We measured circulating levels of 6 chemokines (MIG, IP-10, I-TAC, MCP-1, MIP-1α, MIP-1β) in 71 hypertensive patients (51.6±11.2 yrs, M:F=35:36) and in age, sex-matched 71 control subjects by cytometry bead array method. We also analyzed the expression of CXCR3 and CCR2 in peripheral blood mononuclear cells of hypertensive patients using multicolor flow cytometry.

Results: Periarteriolar inflammatory cells were increased in hypertensive nephrosclerosis and most of them are composed of T lymphocytes. Some of infiltrating cells express chemokines. Circulating chemokine levels were significantly higher in patients with hypertension than in control subjects. CXCR3 were mainly expressed in CD8 T cell subset, which co-expresses CX3CR1 as well.



Conclusions: Although this observation does not provide direct evidence of T cell function in human hypertension, increased T cells and chemokines in hypertensive patients suggest the role of T cell-associated imflammatory pathway. More detailed characterization of T cells, associated chemokines and the expression of chemokine receptors in renal tissue may offer a new insight in the pathophysiology of primary hypertension.

TH-PO1031

High Throughput Screening of Drugs That Inhibit WNK-OSR1/SPAK Signaling Cascade Takayasu Mori, Eisei Sohara, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Department of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Bunkyo-ku, Tokyo, Japan.*

Background: WNK kinases were identified as causative genes of pseudohypoaldosteronism type II (PHA II), a hereditary hypertensive disease with hyperkalemia and acidosis. We identified that WNKs form a signal cascade with OSR1/SPAK kinases and Slc12a transporters (NKCC1, NKCC2, and NCC). We also found that this signal cascade have a pivotal role in controlling vascular tone as well as renal NaCl excretion. Therefore, inhibiting this signal cascade could be a new type of antihypertensive drugs.

Methods: To explore this possibility, we adopted a strategy to inhibit the binding of WNKs with their substrates OSR1/SPAK since the binding domains are already known. Furthermore, we introduced a Fluorescence Correlation Spectroscopy (FCS) method to efficiently screen the inhibitors. FCS is a method to be able to measure fluctuation rate of a fluorescence-labeled single peptide. We labeled an RFxV/I motif of WNK4 with TAMRA, mixed it with the CCT domain of SPAK fused with GST, and could confirm the binding of these two molecules by FCS in 384-well plates. Using this newly developed system, we could screen chemical compounds to inhibit the binding.

Results: As a result of initial screening of 16,000 compounds owned by Tokyo Medical and Dental University Chemical Biology Screening Center, we found 10 different primary candidates. We then tested whether these compounds could inhibit the signals from WNKs to OSR1 in vivo in COS7 cells, and finally obtained three compounds showing the concentration-dependent inhibitory effect on endogenous OSR1 phosphorylation by WNKs.

Conclusions: These compounds could be promising seeds for new types of antihypertensive drugs, and the method we developed in this study could be applicable to any screenings for compounds that inhibit binding of two molecules.

Funding: Government Support - Non-U.S.

TH-PO1032

WNK-OSR1/SPAK-SLC12A Phosphorylation Cascade in the WNK1 (+/-) Mice Koichiro Susa,[1] Eisei Sohara,[1] Tatemitsu Rai,[1] Satomi Kita,[2] Takahiro Iwamoto,[2] Dario Alessi,[3] Sei Sasaki,[1] Shinichi Uchida.[1] *[1]Department of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Tokyo, Japan; [2]Department of Pharmacology, School of Medicine, Fukuoka University, Fukuoka, Japan; [3]MRC Protein Phosphorylation Unit, MSI/WTB Complex, University of Dundee, Dundee, United Kingdom.*

Background: We found that hypertension in pseudohypoaldosteronism type II (PHA II) caused by a WNK4 missense mutation was the result of activation of WNK-OSR1/SPAK-SLC12A phosphorylation cascade (Cell Metab 2007, J Cell Sci 2010). On the other hand, pathogenic effect of the large intronic deletions of WNK1 gene also observed in PHA II remains to be determined. To understand the physiological roles of WNK1 in vivo, WNK1(+/-) mice has been analyzed and was shown to have lower blood pressure compared with wild-type mice. However, detailed analyses in kidney and other organs of WNK1(+/-) mice have not been performed.

Methods: We analyzed WNK1(+/-) mice focusing on the status of WNK-OSR1/SPAK-SLC12A signal cascade.

Results: First, we confirmed by immunoblotting and real time PCR that WNK1 expression was reduced by half in brain, aorta, and kidney cortex. Blood pressure of WNK1(+/-) mice measured by tail-cuff method was not decreased compared with that of wild-type mice, even under low salt diet, which was not consistent with the previous report. We then evaluated the phosphorylation status of OSR1, SPAK, and SLC12A in kidney, and no significant decrease of the phosphorylation was observed in WNK1(+/-) mice. Furthermore, we mated WNK1(+/-) mice with WNK4(D561A/+) knockin mice, in which WNK-OSR1/SPAK-SLC12A cascade was constitutively activated. Even under the WNK4(D561A/+) background, the heterozygous deletion of WNK1 did not affect the phosphorylation of SLC12A. These results suggest that the contribution of WNK1 to the whole WNK kinase activity in kidney to stimulate SLC12A phosphorylation may be small. On the other hand, we observed significant decrease of NKCC1 phosphorylation in aorta, and blunted myogenic tone of mesenteric arteries (resistance vessel), in WNK1(+/-) mice.

Conclusions: WNK1 may have substantial roles in arteries, rather than in kidney, in terms of blood pressure regulation.

TH-PO1033

Inhibition of Uricase Plus Physiological Amounts of Fructose and Glucose: A Model of Metabolic Syndrome and Glomerular Hypertension in Rats More Related to the Human Condition Tapia Edilia,[1] Magdalena Cristobal,[1] Fabiola Monroy,[1] Ursino Pacheco,[1] Takahiko Nakagawa,[2] Richard J. Johnson,[2] L. Gabriela Sanchez-Lozada.[1] *[1]Nephrology, INC Ignacio Chavez, Mexico City, DF, Mexico; [2]Renal Diseases & Hypertension, U Colorado, Aurora, CO.*

Background: A 60% fructose diet to rats is a model of metabolic syndrome (MS) and renal damage characterized by glomerular hypertension and renal vasoconstriction. Febuxostat treatment improved these alterations suggesting the participation of uric acid in these processes. The purpose of the present study was to evaluate whether murine uricase blockade with oxonic acid (OA, 750 mg/day/kg BW) concomitant to a combination of glucose-fructose (GF, ratio G 3.8%: F 7.2%) in drinking water might induce similar renal alterations.

Methods: We studied three groups of rats: Water+OA (n=4), FG+Veh (n=4) and FG+OA (n=6) for 8 wks. At the end of the study body weight (BW), fasting plasma triglycerides (TG), MAP (under anesthesia), GFR and glomerular pressure (PGC, by renal micropuncture) were evaluated.

Results:

Group	BW (gr)	TG (mg/dL/kg BW)*	MAP (mmHg)	GFR (mL/min)*	PGC (mmHg)
Water+OA	316±12	226±41	143±4.5	1.1±0.2	63±2
FG+Veh	334±6	284±15	130±10	0.7±0.1	53±4[1]
FG+OA	349±14	341±31	154±5.4	0.6±0.1	70±1[2]

*=p<0.05 linear trend; 1=p<0.05 vs W+OA; 2=p<0.05 vs FG+Veh

Conclusions: Inhibition of uricase concomitant to physiologic amounts of FG combination induced higher plasma TG and hypertension, lower GFR and higher PGC compared to OA or FG alone. Thus, this murine model is more representative to the human situation characterized by the lack of uricase and FG consumption. Moreover, these results support the synergistic role of uric acid on the development of the MS secondary to high carbohydrate consumption and the renal damage associated to it.

Functional Vascular Dysfunction Related to *COL4A1* Gene Mutation Emmanuelle M. Plaisier,[1] Sandrine Placier,[1] Jean-Claude Dussaule,[1] Migeon Tiffany,[1] Christos Chatziantoniou,[1] Gerard M. London,[2] Pierre M. Ronco,[1] Mohamad Zaidan.[1] *[1]INSERM UMRS 702, Paris, France; [2]Mahnes Hospital, Fleury Merogis, France.*

Background: HANAC (Hereditary Angiopathy, Nephropathy, Aneurysms, Cramps) is a multisystemic autosomal dominant syndrome related to mutations of *COL4A1* gene, that encodes the collagen IV component of basement membrane (BM). Vascular defects in HANAC associate a small vessel brain disease, cerebral aneurysms and Raynaud phenomena. This study further evaluated structural and functional vascular properties in HANAC patients and in mice bearing the *Col4a1* G495V mutation .

Methods: Non-invasive analysis of the arterial geometry and of the arterial and endothelial functions was performed in 4 HANAC patients from 2 families. Systemic and renal hemodynamic parameters of adult Col4a1^{G495V} mice and wild-type littermate were evaluated under basal conditions and after exposure to vasoactive agents.

Results: Compared to controls, HANAC patients showed a low intima/media thickness with elevation of the compliance and distensibility of the brachial artery. Very low basal flow, shear rate and shear stress were recorded, as well as a very low dilation response to shear stress that was corrected by exogenous nitrite oxide (NO) administration. Under basal conditions, both Col4a1$^{+/G495V}$ and Col4a1$^{G495V/G495V}$ mice showed a lower systolic and mean blood pressure compared to wild-type. Vasodilation response and decrease of the renal blood flow (RBF) after acetylcholine infusion was significantly lower in homozygous animals contrasting with a normal response to bradykinine. While the systemic blood pressure response to angiotensin II and norepinephrine was not affected in mutant mice, the decrease of RBF after angiotensin II exposure was significantly lower in homozygous females.

Conclusions: These data point to an essential structural and functional role for the collagen IV network of the vascular BM. Abnormal dilation response to acetylcholine in mice and to shear stress in patients suggest either a primary endothelial dysfunction with defect in NO production and/or a abnormal cross talk between endothelial cells and the adjacent vascular smooth muscle cells.

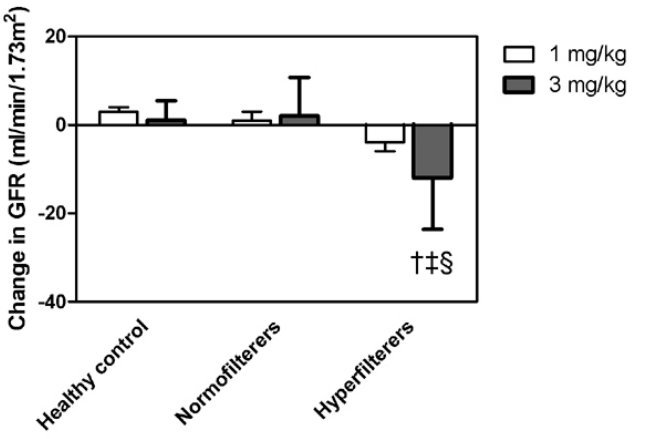
Hyperfiltration and the Effect of Nitric Oxide Inhibition on Renal Hemodynamic and Endothelial Function in Humans with Uncomplicated Type 1 Diabetes Mellitus David Cherney,[1] Heather N. Reich,[1] Shan Jiang,[1] Vesta S. Lai,[1] James W. Scholey.[1] *[1]Medicine, Division Nephrology, University of Toronto, University Health Network; [2]Pediatrics, Pediatric Endocrinology, University of Toronto, The Hospital for Sick Children.*

Background: Experimental models of diabetes mellitus (DM) have been associated with increased renal nitric oxide (NO) bioactivity, leading to hyperfiltration. Paradoxically, type 1 DM is also associated with impaired brachial flow mediated dilatation (FMD), suggesting an opposite suppression of systemic NO bioactivity. Our aim was to clarify the role of the NO system in the pathophysiology of early renal hyperfiltration and peripheral vascular dysfunction in patients with type 1 DM.

Methods: Renal hemodynamic function, FMD, urinary and circulating cGMP and NO levels were obtained before and after a graded IV infusion of L-LNMMA (1 mg/kg and 3 mg/kg) during clamped euglycemia in type 1 DM patients with renal hyperfiltration (n=15) or normofiltration (n=19). Healthy control subjects (n=20) underwent identical studies.

Results: Baseline characteristics were similar in the three groups. In response to L-NMMA, hyperfiltering subjects exhibited exaggerated declines in effective renal plasma flow (806±96 to 540±83 ml/minute/1.73 m^2) and GFR vs. normofiltering and healthy subjects (repeated measures ANOVA, p<0.05).



In contrast with renal hemodynamics, baseline FMD was lower in the hyperfiltering group (repeated measures ANOVA, $p<0.05$). Furthermore, FMD declined in healthy control and normofiltration groups in response to L-NMMA but did not change in the hyperfiltration group.

Conclusions: Renal hyperfiltration is associated with increased renal NO bioactivity and impaired endothelial function in patients with uncomplicated type 1 DM, suggesting that a paradoxical state of high renal and low systemic vascular NO bioactivity exists in humans.

Altered Endothelial Glycocalyx in Albuminuria: A Potential Link between Albuminuria and Widespread Vascular Dysfunction

Andy Salmon,[1,2,3] Joane Ferguson,[1] James L. Burford,[3] Anush Gevorgyan,[3] David O. Bates,[1] Steve Harper,[1] Janos Peti-Peterdi.[3] *[1]Microvascular Research Laboratories, School of Physiology & Pharmacology, University of Bristol, United Kingdom; [2]Academic Renal Unit, School of Clinical Sciences, University of Bristol, United Kingdom; [3]Department of Physiology, University of Southern California.*

Background: Widespread vascular dysfunction occurs in albuminuria. Endothelial glycocalyx (GLX), a glycosaminoglycan/proteoglycan mesh lining all blood vessels, regulates glomerular permeability and extra-renal vascular function. We hypothesised that GLX is damaged in albuminuria, mediating widespread vascular dysfunction.

Methods: GLX and vascular function (permeability) were assessed in glomeruli & mesentery of rats (4-6mo old Munich-Wistar-Fromter (MWF)) with spontaneous FSGS & 10-fold albuminuria*.

*$p<0.05$ v non-albuminuric rats; ‡$p<0.05$ or ^{ns}not sig v baseline.

Results: In glomeruli of albuminuric MWF rats, albumin sieving coefficient (Θalb: multiphoton microscopy measurements *in vivo*) was elevated (0.0004 to 0.0009)*, ultrafiltration coefficient (L_p-area product: L_pA; isolated single glomerular measurements) was elevated 2.4-fold*, & GLX coverage (multiphoton microscopy of lectin (WGA) binding to GAG constituents of GLX *in vivo*) was reduced (87% to 25%)*.

In mesenteric microvessels of albuminuric MWF rats, hydraulic conductivity (L_p: single perfused microvessel measurements *in vivo*) was elevated 2.3-fold*, GLX depth was reduced (0.65 to 0.20μm)*, & GLX vessel coverage was reduced (89% to 25%)*.

In healthy rats, GLX removal with neuraminidase increased Θalb (0.0004 to 0.001)‡, reduced GLX coverage in glomeruli (83% to 31%)‡, & reduced mesentery vessel GLX coverage (89% to 15%)‡ & depth (0.65 to 0.17μm)‡.

However in albuminuric rats, GLX removal with neuraminidase was without effect (pre- and post-neuraminidase: Θalb (0.0009 to 0.0009)^{ns}; GLX coverage in glomeruli (39% to 32%)^{ns} & mesentery (25% to 16%)^{ns}).

Conclusions: Our results demonstrate functionally important loss of GLX in albuminuric animals.

Damaged GLX in albuminuria may contribute to the systemic vascular dysfunction/disease that characterises albuminuria, as well as the pathophysiology of glomerulosclerosis.

Adenosine Receptors Modulate Angiotensin II-Mediated Effects on Tubuloglomerular Feedback

Mattias Carlstrom, Christopher S. Wilcox, William J. Welch. *Dept. of Medicine, Georgetown University, Washington, DC.*

Background: Tubuloglomerular feedback (TGF) response is mediated via activation of A1 receptors, and modulated by A2 receptors on the renal afferent arteriole. Synergistic interaction between angiotensin II (Ang II) and adenosine has been described in the renal microvasculature; however, the underlying mechanism and its role in TGF regulation are unclear. We tested the hypothesis that adenosine A1 and A2 receptors modulate Ang II-mediated effects on TGF.

Methods: TGF responses were measured in adenosine A1 receptor knockout (A1-/-) and wildtype mice (A1+/+), as changes in proximal stop-flow pressure (ΔPSF) in response to increased perfusion of loop of Henle (0 to 35 nl/min). Maximal TGF responses were studied during perfusion with artificial tubular fluid (ATF) alone, or ATF supplemented with i) Ang II (10-9 M), ii) Ang II (10-9 M)+Tempol (10-3 M), or iv) Ang II (10-9 mol/L)+A2 receptor antagonist (10-7 M).

Results: TGF response (ΔPSF) during control (ATF alone) was 8.1±0.6 mmHg in A1+/+, whereas TGF responses were abolished in A1-/- mice. Perfusion with Ang II enhanced ΔPSF in A1+/+ (12.3±0.8 mmHg), whereas an inverse TGF response was observed in A1-/- mice (+3.5±0.5 mmHg). Co-treatment with superoxide dismutase-mimetic (Tempol) during Ang II perfusion normalized TGF responses in both A1+/+ (8.6±0.6 mmHg) and A1-/- mice (+0.6±0.8 mmHg). Simultaneous application of Ang II and A2 antagonist enhanced ΔPSF in A1+/+ (14.5±0.8 mmHg), and induced TGF response in A1-/- mice (3.5±0.8 mmHg).

Conclusions: Adenosine A1 receptors enhance, whereas A2 receptors attenuate Ang II-mediated effects on TGF responses. Mechanistically, Ang II-induced oxidative stress may increase adenosine formation, which during A1-deficiency causes A2 receptor-mediated dilatation.

Non-Steroidal Anti-Inflammatory Drugs Modulate Vasa Recta Diameter

Teresa M. Kennedy-Lydon,[1] Carol Crawford,[1] Liam Sawbridge,[1] Robert J. Unwin,[2] Scott S.P. Wildman,[1] Claire M. Peppiatt-Wildman.[1] *[1]Royal veterinary College, London, United Kingdom; [2]UCL Medical School, London, United Kingdom.*

Background: Non-steroidal anti-inflammatory drugs (NSAIDs) are nephrotoxic and reduce medullary blood flow (MBF). NSAIDs inhibit cyclooxygenases (COX) and endogenous production of medullary prostaglandin E_2 (PGE_2). PGE_2 has been shown to attenuate the vasoconstrictor effects of endothelin-1 (ET-1) and angiotensin-II (Ang-II) at vasa recta. Here we investigate the responses of *in situ* vasa recta pericytes to (i) PGE_2 (ii) ET-1 and Ang-II plus and minus PGE_2 (iii) NSAIDs, and the location of medullary COX-1 and 2 in the kidney slice model.

Methods: Live kidney slices obtained from adult male Sprague-Dawley rats were secured in an open-bath chamber on the stage of an upright microscope and continuously superfused with oxygenated physiological saline solution. Real time images of *in situ* vasa recta were recorded and vasa recta diameter at pericyte and non-pericyte sites was measured off-line.

Results: Application of PGE_2 to live kidney slices evoked dilation of vasa recta specifically at pericyte sites. PGE_2 significantly attenuated pericyte-mediated constriction of vasa recta evoked by both ET-1 and Ang-II. Indomethacin a non-selective inhibitor of COX evoked a significantly greater constriction of vasa recta capillaries at pericyte sites than at non-pericyte sites. The COX-1 selective inhibitor SC-560 and COX-2 selective inhibitors meloxicam and celecoxib also evoked a significantly greater constriction at pericyte sites than at non-pericyte sites. COX-1 and -2 were identified in vasa recta endothelial cells by immunohistochemistry.

Conclusions: Data presented show (i) PGE_2 dilates vasa recta at pericyte sites and reverses the ET-1- and Ang-II-evoked constriction of vasa recta at pericytes, (ii) vasa recta endothelial cells are a source of COX-1 and -2, (iii) application of selective and non-selective COX inhibitors leads to pericyte-mediated constriction of vasa recta. These data re-iterate the key role of PGE_2 in regulation of medullary blood flow and reveal that attenuation of PGE_2 production causes pericyte-mediated constriction of vasa recta. Thus pericytes may be key in NSAID-evoked reduction in MBF.

TH-PO1040

Rapid, Dynamic Increases in Glomerular Permeability during Angiotensin-II (AII) Infusion in Rats. Reactive Oxygen Species (ROS) May Be Involved

Josefin Axelsson, Anna Rippe, Kristinn Sverrisson, Bengt Rippe. *Department of Nephrology, Lund University, Lund, Sweden.*

Background: This study was performed in order to investigate the dynamics and mechanisms of action of AII on glomerular permeability.

Methods: In anaesthetized Wistar rats (250-280g) the left ureter was cannulated for urine collection, while simultaneously blood access was achieved. Rats were continuously infused i.v. with AII [62 ng/min (Lo-AII; n=5) or 250 ng/min (M-AII; n=8) or 500 ng/min (Hi-AII; n=8)], respectively, and with polydisperse fluorescein isothiocyanate (FITC)-Ficoll-70/400 (mol.radius 13-90Å) and ^{51}Cr-EDTA for 2 h. Plasma and urine samples were taken at 5, 15, 30, 60 and 120 min of AII infusion, and analyzed by high performance size exclusion chromatography (HPSEC) for determination of glomerular sieving coefficients (θ) for Ficoll. GFR was also assessed (^{51}Cr-EDTA).

Results: In all AII groups there was a rapid (within 5 min), marked increase in glomerular permeability to Ficoll molecules >34Å in radius. θ for Ficoll of radius 70Å increased 20-fold (Lo-AII) up to 30-fold (Hi- and M-AII), respectively. For the Lo-AII group the permeability increase was reversible within 15-60 min, whereas in the M-AII and the Hi-AII groups there was only a partial reversibility within this time frame. Thus, a moderate, sustained increase in glomerular permeability remained even at 120 min. GFR was well maintained in the Lo-AII group, but (somewhat) decreased in the M-AII and Hi-

AII groups. The AII-receptor blocker, candesartan, completely abrogated the AII response. The ROS inhibitor, DMTU (dimethylthiourea), partly reduced the AII response.

Conclusions: AII infusion into rats caused a rapid, marked and partly reversible increase in glomerular permeability with a maximum at 5-15 min after start. AII blockade completely abrogated this response, while DMTU, a ROS-inhibitor, partly reduced it. The glomerular permeability increase occurring to Ficoll molecules >34Å in radius is compatible with an increase in the number of "large pores" of the glomerular filter. ROS may be partly involved in the permeability increase induced by AII.

Charge Modified, Conformationally Intact Anionic Ficoll Is Retarded Relative to Neutral Ficoll across the Rat Glomerular Filtration Barrier *In Vivo* Josefin Axelsson,[1] Kristinn Sverrisson,[1] Anna Rippe,[1] William Fissell,[2] Bengt Rippe.[1] *[1]Department of Nephrology, Lund University, Lund, Sweden; [2]Biomedical Engineering, Cleveland Clinic, Cleveland, OH.*

Background: The glomerular filtration barrier (GFB) is commonly conceived as a negatively charged sieve. Recent studies, however, indicate that glomerular charge effects are small for anionic, carboxymethylated (CM) dextran *vs*. neutral dextran. Two studies assessing the glomerular sieving coefficients (θ) for CM-Ficoll *vs*. native Ficoll have actually demonstrated an "anomalous" behavior of these polysaccharides, i.e. a higher glomerular permeation of anionic than neutral Ficoll. The CM-Ficoll used in these studies showed a larger Stokes-Einstein radius (a_e) than neutral Ficoll. Hence, it was proposed that the introduction of negative charges in the Ficoll molecule had made it more extended and flexible, and thereby, more permeable.

Methods: Recently, a negatively charged fluorescein isothiocyanate (FITC) labeled CM-Ficoll was produced with a conformation identical to that of native FITC-Ficoll. Using these probes we determined their θ:s in anesthetized Wistar rats (259±2.5 g). After blood access had been achieved, the left ureter was cannulated for urine sampling. Either polysaccharide was continuously infused (i.v.) in parallel with a marker of glomerular filtration rate (GFR), while urine and plasma were collected. Assessment of FITC-Ficoll in plasma and urine was achieved by high performance size-exclusion chromatography (HPSEC).

Results: CM-Ficoll and native Ficoll had identical elugrams on the HPSEC. Diffusion of anionic Ficoll was significantly reduced compared to that of neutral Ficoll across the GFB for molecules of a_e ~ 20-35Å, while there were no charge effects for Ficoll of a_e = 35-80Å. The data are consistent with a charge effect present in "small pores", but not in "large pores", of the GFB and mimicked those obtained for anionic membranes *in vitro* for the same probes.

Conclusions: In conclusion, the GFB is negatively charged. However, the negative charge selectivity was found to be much less pronounced than previously demonstrated for sulphated *vs*. neutral dextran.

Decrease in Retinal Arteriolar Caliber Is Associated with a Lower Renal Function in Normotensive and Never-Treated Hypertensive Subjects Vincent Daien,[2] Ryo Kawasaki,[3] Jean Ribstein,[1] Guilhem Du Cailar,[1] Max Villain,[2] Albert Mimran,[1] Pierre Fesler.[1] *[1]Department of Internal Medicine, Lapeyronie Hospital, Montpellier, France; [2]Department of Ophtalmology, Gui de Chauliac Hospital, Montepellier, France; [3]Retinal Vascular Imaging Centre, Centre for Eye Research Australia, Melbourne, Australia.*

Background: Microvascular change has been postulated to represent one of the key mechanisms of kidney aging. Retinal arteriolar narrowing has been used as a marker of the altered microcirculation. The primary objective was to assess the association between retinal arterial caliber and renal function in normotensive (NT; <140/90 mmHg) and never-treated hypertensive (HT) subjects.

Methods: Study subjects were 57 persons with NT and 48 persons with never-treated essential HT with serum creatinine (SCreat) < 130 µmol/L and without diabetes. Retinal arteriolar caliber was measured from fundus photographs using a computer-assisted program and summarized as central retinal artery equivalent. Glomerular filtration rate (eGFR) was estimated from the MAYO clinic quadratic equation.

Results: Mean age of study subjects was 48+/-13 (mean +/- SD), and 50% were women. Mean SCreat was 0.79+/-0.17 mg/dl and eGFR was 113.7 ml/min/1.73m², and there was no difference between persons with NT and HT. Mean retinal arteriolar caliber in persons with NT and HT were 147.6 +/- 12.7 µm and 135.1 +/- 10.9 µm, respectively (p=0.001). In the whole population, retinal arteriolar caliber was positively and significantly correlated to eGFR (univariate r^2=0.16; p = 0.001), even after adjustement for age, gender, mean arterial blood pressure, smoking, glycemia, body mass index, total cholesterol, triglycerides (model r^2 =0.49, p=0.0001). When replacing eGFR by 1/Screat and adding size and weight as predictive variables, the association between retinal arteriolar caliber and renal function remained significant (model r^2=0.22, p=0.0001).

Conclusions: In never-treated NT or HT subjects, a decrease in retinal arteriolar caliber is associated with a lower kidney function, independently of other potential determinants of retinal vascular changes. The mechanisms of this apparent common aging process remain to be documented.

TH-PO1043

Endothelial Deletion of Sirtuin 1 (SIRT1) in Mice Impairs Vasomotion, Angiogenesis and Accelerates Senescence Sandhya Xavier, Radovan Vasko, Jun Chen, Frank Fan Zhang, Alberto Nasjletti, Michael S. Goligorsky. *New York Medical College, Valhalla, NY.*

Background: Stress-induced premature senescence (SIPS) of endothelial cells (EC) has emerged as a notable contributor to global endothelial cell dysfunction (ECD) in diverse diseases. SIRT1, a member of a family of histone deacetylases involved in metabolism and differentiation, has been implicated in cellular and organismal longevity. SIRT1 mutant mice carrying a deletion of exon 4 die perinatally and exhibit developmental defects of retina and heart.

Methods: To define the role of SIRT1 in vascular homeostasis, we generated mice with deletion of SIRT1 in vascular endothelial and endothelial progenitor cells by mating mice homozygous for the floxed SIRT1 allele with mice heterozygous for Cre-recombinase under the control of Tie2-promoter. From these matings $SIRT^{Flox/Flox}$ (WT-control), $SIRT^{Flox/WT}$ (Het-control), Tie2-Cre;$SIRT^{Flox/Flox}$ (KO) and Tie2-Cre;$SIRT^{Flox/WT}$ (Het) mice were obtained at Mendelian ratios.

Results: Loss of SIRT1 in the endothelium under basal conditions did not affect thriving, caused microalbuminuria or elevation of serum creatinine levels and no hypertension in mice aged 12 weeks or less was detected. Glucose tolerance was not impaired. However, when aortic rings from control, KO and Het mice were subject to acetylcholine-induced vasorelaxation, a mild reduction in vasorelaxation was observed in $SIRTendo^{-/-}$ mice, but not in controls, an indication of developing endothelial dysfunction. This was paralleled by accelerated endothelial senescence. In an *ex vivo* aortic ring assay, sprouting and microvessel formation were both inhibited in endothelial-deleted SIRT1 mutant mice, indicating that Sirt1 in the endothelium controls angiogenesis *ex vivo*.

Conclusions: We developed a model system to study consequences of the isolated defect in endothelial cell function. Under basal conditions, SIRT1 deficiency in endothelial cells did not lead to systemic hemodynamic abnormalities, but significantly accelerated endothelial senescence and impaired angiogenic competence and vasorelaxation at the early age.

Renal Responses to Administration of a Peroxynitrite Scavenger in Anesthetized Wild Type and Knockout Mice Lacking the Gene for Extracellular Superoxide Dismtase Dewan S. Majid, Alexander Castillo, Purnima Singh. *Physiology, Tulane University School of Medicine, New Orleans, LA.*

Background: Peroxynitrite ($OONO^-$) is continuously being produced in the body via interaction of nitric oxide and superoxide (O_2^-). However, its potential role in regulating cardiovascular and renal function is not yet clearly defined. In the present study, we assessed its regulatory role in the control of systemic arterial pressure (SAP) as well as renal hemodynamics and excretory function in mice.

Methods: $OONO^-$ scavenger, mercaptoethyl guanidine (MEG), was administered intravenously at an incremental doses (10, 30 and 50 µg/kg/min for 45 min each) in anesthetized wild type (C57BL6; n=6) as well as knockout mice lacking the gene for extracellular superoxide dismutase (ecSOD KO; n=4) which would have a higher level of $OONO^-$ due to enhanced O_2^- and NO interaction. SAP was recorded using a pressure transducer connected to a cannula placed in the left carotid artery. Renal blood flow (RBF) and glomerular filtration rate (GFR) were determined by PAH and inulin clearances respectively. A cannula was inserted into the urinary bladder for collection of urine.

Results: Infusion of MEG doses caused small but significant increases in SAP in both WT and ecSOD KO mice. The highest dose of MEG increased mean SAP from 93±3 to 99±4 mmHg in WT and from 81±5 to 87±5 mmHg in ecSOD KO mice. Although MEG did not cause significant changes in RBF (6.8±0.7 to 7.4±1.4 mL/min/g) or in GFR (0.96±0.12 to 1.01±0.14 mL/min/g) in WT mice but there was a marked decrease in GFR (1.00±0.17 to 0.77±0.12 mL/min/g; P<0.05) without appreciable change in RBF (5.9±0.9 to 5.6±0.8 mL/min/g) in ecSOD KO mice. MEG infusion increased urinary sodium excretion ($U_{Na}V$) and fractional excretion of sodium (FE_{Na}) in both WT ($U_{Na}V$, 0.62±0.17 to 1.65±0.24 µmol/min/g ; FE_{Na}, 0.43±0.11 to 1.17±0.03%) and ecSOD KO mice ($U_{Na}V$, 0.77±0.19 to 1.42±0.21 µmol/min/g; FE_{Na}, 0.52±0.09 to 1.25±0.19%).

Conclusions: These results indicate that endogenous formation of $OONO^-$ contributes to arterial vasodilator tone systemically and provides a renoprotective role in maintaining GFR in the condition where dismutation of O_2^- is limited due to SOD deficiency.

Vitamin D Status, Arterial Stiffness, and the Renin Angiotensin System in Healthy Humans Ahmed Abdi Ali, David Donald McTavish Nicholl, Brenda Hemmelgarn, Jennifer M. MacRae, Darlene Y. Sola, Sofia B. Ahmed. *University of Calgary.*

Background: Vitamin D (VD) status is an increasingly notable predictor of kidney and cardiovascular (CV) risk. While the mechanism is unclear, VD appears to modulate RAS activity.We sought to clarify the influence of VD in modulating RAS control of arterial stiffness, an important parameter for the assessment of CV risk in both the healthy and CKD populations.

Methods: Forty-one normotensive, non-obese, healthy subjects (26 females and 15 males) were studied in a high salt balance, a state of maximal RAS suppression. Women

were studied in the same phase of their menstrual cycle. Arterial stiffness, expressed as aortic augmentation index (AIx) and brachial pulse wave velocity (PWV) was measured by tonometry at baseline and in response to AngII infusion (3ng/kg/min x 30 min then 6ng/kg/min x 30 min). The primary outcome was the effect of VD status on the arterial stiffness response to AngII challenge, a well-accepted marker of the intrinsic RAS activity of the vasculature.

Results: Results were analyzed according to serum 25(OH)-VD status: deficient (<50nmol/L, n=12), insufficient (50-80nmol/L, n= 15), and sufficient (>80nmol/L, n=14). Increasing 25(OH)-VD status was associated with improved arterial stiffness (AIx: VD deficient, 17.3±3.4%; VD insufficient, 11.3±4.0%; VD sufficient, -2.0±5.6%; p=0.015, p =0.009 for trend), though a similar relationship was not observed between VD status and PWV (p=0.5). As anticipated, all subjects demonstrated an increase in AIx (p<0.001) and PWV (p<0.001) in response to AngII challenge, though the AIx response did not differ by 25(OH)-VD status (AIx: VD deficient, 19.1±4.7%; VD insufficient, 22.2±5.3%, sufficient 12.5±4.3%; p=0.3). In contrast, the brachial PWV response to AngII differed according 25(OH)-VD status (ΔPWV: VD deficient, 2.6±1.1m/s; VD insufficient, 3.4±0.7m/s; VD sufficient, 1.4±0.3m/s; p=0.032).

Conclusions: Improved VD status is associated with reduced arterial stiffness in healthy humans, possibly through an RAS-dependent mechanism which appears to differ according to VD level and the vascular bed. Further studies are needed to clarify optimal VD status and the role of VD supplementation on CVD risk.

TH-PO1046

25-hydroxyvitamin D insufficiency, Which Can Be Improved with Rosuvastatin Treatment, Is Associated with Renal Endothelial Function

Christian Ott, Ulrike Raff, Marina V. Lehmann, Markus P. Schneider, Stephanie Titze, Roland E. Schmieder. *Nephrology and Hypertension, University Hospital Erlangen, Erlangen, Germany.*

Background: Vitamin D deficiency is considered as cardiovascular and renal risk factor. We tested the hypotheses whether vitamin D level is related to endothelial function of the renal vasculature. Since statin treatment is known to improve endothelial function, we analyzed the impact of statins on vitamin D levels and renal endothelial function.

Methods: In a double-blind, randomized study 31 hypercholesterolemic patients with at least vitamin D insufficiency (< 30 ng/ml) were randomly assigned to rosuvastatin (10 mg/d) and placebo for 6 weeks. Renal hemodynamics were determined by constant input clearance technique with p-aminohippurate (PAH) and inulin. Basal NOS activity of the renal vasculature, was assessed by measuring renal plasma flow (RPF) both before and after blockade of NOS with systemic infusion of N(G)-monomethyl-L-arginine (L-NMMA). In parallel, 25(OH)D was measured.

Results: Compared to placebo treatment, rosuvastatin increased 25(OH)D levels (21.6±4.0 vs 24.1±8.0 ng/ml, p=0.039). Moreover, the decrease in RPF in response to L-NMMA (an estimate of basal NO activity) was significantly more increased after 6-week therapy with rosuvastatin than with placebo (-94.8±70 vs. -68.2±32 ml/min, p=0.044), indicating increased basal NOS activity after 6 weeks of rosuvastatin treatment. The change of basal NO activity in the placebo phase treatment was correlated inversely with 25(OH) D (r=-0.385; p=0.027). Multiple regression analysis revealed that at baseline 25(OH)D, but not blood pressure and cholesterol levels, is an independent determinant of basal NO activity (β=-0.446, r=0.015). In contrast, no correlation was evident between 25(OH)D and basal NO activity after rosuvastatin treatment.

Conclusions: Thus, rosuvastatin may beneficially influence the impact of vitamin D insufficiency on renal endothelial function.

TH-PO1047

Ambulatory Arterial Stiffness Index (AASI) and All Cause Mortality

Rupesh Raina, Alaine E. McGarry-Gada, George Thomas, Mohammad Rafey, Martin J. Schreiber. *Dept. of Nephrology and Hypertension, GUKI Institute, Cleveland Clinic Foundation, Cleveland, OH.*

Background: Ambulatory Arterial Stiffness Index (AASI) and pulse pressure (PP) are indices of arterial stiffness that can be computed from 24-hour ambulatory BP measure (ABPM). We investigated the association of AASI and PP with all-cause mortality.

Methods: AASI (1 minus the slope of diastolic on systolic BP in individual 24 hr ABPM) was calculated for182 pts. from 1994 through 1997. Data collected included demographic characteristics and treatment for hypertension (HTN) or diabetes mellitus (DM). Mortality data (date of death) was obtained from the Social Security death registry in February 2011.We applied Cox regression to relate mortality to AASI and PP while adjusting for sex, age, BMI, 24-hr ABPM, smoking, DM , chronic kidney disease (CKD) and cardiovascular disease (CVD).

Results: Mean age was 58 ±14 yrs, 33% were female and 22% were African-American. Mean BMI was 27.2 ± 4.5 kg/m^2, and treatment for HTN (58%) and DM (23%). Eighteen deaths occurred during the 15 year period.AASI mean score >0.51 U was associated with higher all cause mortality (16 /18, P =0.001).However this correlation was not seen with pulse pressure.

AASI Quartiles and PP Quartile and its Correlation with All Cause Mortality

AASI Quartiles	HRs (95% CIs)	24-Hour PP	HRs (95% CIs)
<0.39	0.81 (0.67, 0.99)	<45.8	0.63 (0.50, 0.78)
0.39–0.45	0.86 (0.72, 1.06)	45.8–50.2	0.91 (0.53, 1.55)
0.45–0.51	0.90 (0.74, 1.09)	50.2–55.6	0.92 (0.56, 1.16)
>0.51	1.47 (1.33, 1.85)*	>55.6	1.04 (0.83, 1.31)

HRs- Hazard Ratio:CIs Confidence Interval and * P<0.05

Patient with high AASI index (>0.51 U) were older (P < 0.003), more likely to be non white (P < 0.05), and had higher rates of smoking, DM, HTN, CVD, and CKD (P < 0.01).

Conclusions: AASI, a measure of the dynamic relation between diastolic and systolic blood pressure through the day, was a better predictor of all cause mortality compared to the 24-hr ABPM pressures, anthropometric characteristics, and / or cardiovascular risk factors. Based on the current data, coupling a physiological characterization of the 24 hr ABPM pressures with AASI- indices may improve their prognostic ability to evaluate vascular health.

TH-PO1048

Preservation of Cortical-Medullary Oxygen Gradients in Human Hypertension, Despite a Fall in Blood Flow with Age in Caucasians and Greater Medullary Hypoxia in African-Americans

Stephen C. Textor,[1] Monika L. Gloviczki,[1] Luis A. Juncos,[2] David A. Calhoun,[3] James Glockner,[1] Joseph P. Grande,[1] Lilach O. Lerman.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]University of Mississippi, Jackson, MS; [3]University of Alabama, Birmingham, AL.*

Background: Regulation of kidney cortical and medullary oxygenation as a function of age, ethnicity and regional blood flows in essential hypertension (HTN) remain poorly understood.

Methods: We studied 32 Caucasian (C) and 23 African-American (AA) non-diabetic subjects with treated HTN and normal GFR during 3 days with 150 mEq/d Na+ intake and ACE/ARB Rx. Single-kidney volumes and blood flow were measured using Multidetector CT. De-oxyhemoglobin levels (R2*) and cortical-medullary oxygen (O2) gradient (difference in R2* between superficial cortex and deep medullary segments) were measured by Blood Oxygen Level Dependent (BOLD) MRI at 3T before and after furosemide suppression of solute transport. On the first day, urinary (U) Na+, GFR, isoprostanes, microalbumin, protein and TGF-beta were also measured.

Results: Average Age was 58 (26-85) years. BP: 135±2 / 75±2 mmHg. Single kidney GFR: 49±2 ml/min/1.73m2.

	Cortex	Medulla	p-value
Tissue volume (cc/kidney)	97±2.5	54±2	p<.0001
Blood flow (ml/min)	354±15	71±3	p<.0001
Oxygenation (R2*/sec)	17.9±0.3	38.1±0.6	p<.0001

Cortical-Medullary Gradient averaged 20.1±0.6 /sec which fell to 12.1±0.6/sec after furosemide (p<.0001). Age was inversely related to GFR, diastolic BP, and isoprostane excretion. Cortical perfusion and blood flow fell with advancing age only in C with preserved cortical-medullary O2 gradients. Urinary microalbumin rose with SBP. Kidney injury markers including U protein and TGF-beta were directly related to SBP and initial Na+ excretion (R=0.546, p<.0001).

Conclusions: These data demonstrate preserved cortical-medullary O2 gradients and furosemide-suppressible O2 consumption in essential HTN, despite loss of cortical blood flow in C. Isoprostane differed between C and AA, whose levels rose with age and blood flow to medulla. Correlation between fibrogenic and oxidative biomarkers suggest that prior Na+ intake and microvascular dysfunction contribute to renal injury in essential HTN.

Effect of One Week Naproxcinod Treatment on Sodium Balance and Acute Natriuretic Effect of Furosemide: A Randomized Double-Blind Placebo and Naproxen-Controlled Trial in Healthy Volunteers

Nicolas Glatz,[1] Grégoire Wuerzner,[1] Marc P. Maillard,[1] Bruno Vogt,[1] Caroline Roger,[2] Michel Burnier.[1] *[1]Nephrology, CHUV, Lausanne, Switzerland; [2]NiCox, Sophia Antipolis, France.*

Background: Naproxcinod (CIN) is a cyclooxygenase inhibiting nitric oxide (NO) donor developed for the treatment of osteoarthritis. The objective of the study was to evaluate the effects of CIN on sodium (Na) balance and response to furosemide (FUR).

Methods: 31 healthy male volunteers were randomized into three parallel groups: CIN 750 mg *bid*, naproxen (NAP) 500 mg *bid* or placebo (PLA) *bid* during eight days (D1-D8). 24h-Na and aldosterone excretions were measured from D -1 to D4. On D8, natriuresis, plasma renin activity (PRA) and glomerular filtration rate (GFR), using inulin clearances, were measured before and after 40 mg of intravenous FUR.

Results: On D-1, 24h Na excretion and aldosterone excretion were respectively 193 ± 34 mmol/24h and 5.2 ± 0.9 µg/24h for PLA, 174 ± 40 mmol/24h and 5.4 ± 0.7 µg/24h for CIN, 196 ± 54 mmol/24h and 6.5 ± 0.8 µg/24h for NAP. On D1, 24h Na excretion was 182 ± 49 mmol/24h for PLA, 147 ± 34 mmol/24h for CIN, 140± 45 mmol/24h for NAP. On D4, aldosterone excretion was 6.2 ± 1.0 µg/24h for PLA, 2.9 ± 0.5 µg/24h for CIN, 2.7 ± 0.4 µg/24h. Table 1 shows Na excretion, GFR and PRA before and after FUR on day 8.

Table 1

Day 8		FUR (Baseline)	FUR + 60'	FUR + 120'
Natriuresis (mmol/h)				
	PLA	38.2 ± 12.1	136.5 ± 34.7	53.5 ± 10.8
	CIN	32.7 ± 5.2	129.9 ± 17.5	54.7 ± 21.3
	NAP	27.2 ± 9.9	131.2 ± 19.1	54.8 ± 14.3
GFR (ml/min)				
	PLA	117 ± 36	105 ± 13	108 ± 55
	CIN	94 ± 22	94 ±20	79 ± 24
	NAP	103 ± 21	96 ± 28	79 ± 22
PRA (ng/ml/h)				
	PLA	0.82 ± 0.52	1.79 ± 0.91	2.72 ± 0.81
	CIN	0.32 ± 0.21	0.84 ± 0.36	1,37 ± 0.63
	NAP	0.35 ± 0.19	1.01 ± 0.49	1.91 ± 0.89

Values are means ± SD

Conclusions: CIN and NAP had some degree of Na retention (progressive decrease in 24h urinary aldosterone excretion) compared to PLA. After 8 days of treatment, no difference in Na excretions after FUR was detected between groups, but PRA response to FUR were slightly blunted in the CIN and NAP groups. The addition of NO moiety to naproxen does not seem to influence the Na balance or the natriuretic response to FUR compared to naproxen alone in healthy volunteers.

The mTOR Inhibition Reduces the In Vitro Mineralization of Vascular Smooth Muscle Cells Jasmin Pruefer,[1] Mirjam Schuchardt,[1] Markus Tolle,[1] Matthias Höhne,[2] Markus van der Giet.[1] *[1]Med. Klinik mit SP Nephrologie, Charite - Campus Benjamin Franklin, Berlin, Germany; [2]Novartis Pharma AG, Nürnberg, Germany.*

Background: Vascular disease contributes to the high cardiovascular mortality among organ transplant recipients. The immunosuppressive regimes, necessary for preventing transplant rejection, have different side effects on the vascular system. The aim of this study was to investigate whether the mTOR inhibitor rapamycin (RPA) is also effective for the prevention of vascular calcification in an in vitro mineralization assay using vascular smooth muscle cells (VSMCs).

Methods: In vitro calcification in VSMCs were induced with calcification medium (CM: DMEM containing 4.5 g/L glucose supplemented with 15% FCS, 10 mmol/L sodium pyruvate, 50 µg/mL ascorbic acid, and 10 mmol/L ß-glycero phosphate) and dexamethasone (DEX, 100 nmol/L). Calcium deposition was quantified by O-cresolphthalein complexone method. Alkaline phosphatase (ALP) enzyme activity was measured by p-nitrophenol method.

Results: Cultivation of VSMCs in CM induced mineralization of VSMCs, which could be enhanced in the presence of DEX. The calcification was quantified by measuring the extracellular calcium content and visualized by Alizarin Red staining. Pretreatment with RPA could significantly and time-dependently decrease the mineralization of VSMCs by reducing extracellular calcium. For the precipitation of calcium phosphate, the activation of ALP is necessary. CM and +DEX led to a significant and time-dependent increase in ALP enzyme activity, which is significantly diminished by pretreatment with RPA.

Conclusions: In this study we were able to show that the mTOR inhibitor RPA diminished the mineralization of VSMCs in vitro. Therefore, it seems possible that RPA might be effective in the prevention of arteriosclerosis after organ transplantation that would contribute to a better cardiovascular outcome of these patients.

Reactive Oxygen Species Acutely Stimulate Renin Release in Mouse Juxtaglomerular Cells Mariela Mendez, Jeffrey L. Garvin. *Hypertension and Vascular Research. Department of Internal Medicine, Henry Ford Hospital, Detroit, MI.*

Background: Renin and its enzymatic product Angiotensin I, are essential in the regulation of blood pressure. Chronically enhanced circulating renin induces hypertension and renal damage. Low levels of reactive oxygen species (ROS), such as hydrogen peroxide and superoxide, play a role in renal hemodynamics and tubular NaCl transport. Enhanced ROS in the kidney are involved in the development of hypertension and kidney disease. However, it is not known whether ROS affect renin release from juxtaglomerular (JG) cells.

Methods: We generated primary cultures of mouse Juxtaglomerular cells (JG) cells and measured the effect of H2O2 or superoxide on renin release to the media and total renin content.

Results: Treatment with H2O2 (1 hour) at 100 or 500 nM increased renin release by 101±43% ($p = 0.08$) and 166±47% ($p < 0.04$), respectively. In addition, decreasing endogenous hydrogen peroxide levels by treating JG cells with catalase (1mU/ml) decreased basal renin release by 45±9% ($n = 6$; $p < 0.05$). These data indicate that endogenously produced H2O2 tonically stimulates renin release. H2O2 peroxide had no effect on total renin content in JG cells ($n = 6$; p = n.s.) suggesting that H2O2 stimulates renin exocytosis. Superoxide produced by surrounding cells or endogenously by JG cells may influence renin release. Increasing extracellular superoxide by adding xanthine oxidase/hypoxanthine (XO/HY) increased renin release by 334±140% ($p < 0.03$; $n = 4$). In the presence of the superoxide scavenger tempol, enhancing extracellular superoxide did not stimulate renin release (56±30% *vs* control, n.s). Treating JG cells with tempol alone did not affect basal renin release ($n = 4$).

Conclusions: We concluded that the ROS, hydrogen peroxide and superoxide, stimulate renin release from mouse JG cells. These data suggest a novel and rapid pathway for the stimulation of renin release that may be involved in the development of hypertension and kidney damage during enhanced ROS production in the renal cortex.

The Ratio of alpha-1-Acid Glycoprotein to alpha-1B Glycoprotein in Urine Is an Early and Accurate Predictor of Acute Kidney Injury Joseph Alge,[1] Lakhmir S. Chawla,[4] James A. Tumlin,[5] John M. Arthur.[1,2] *[1]MUSC; [2]Ralph H Johnson VAMC; [3]Duke University; [4]George Washington University; [5]University of Tenessee Chattanooga.*

Background: Acute kidney injury (AKI) is a common complication of cardiac surgery. A biomarker that is diagnostic of AKI earlier in the course would facilitate intervention and improve patient outcomes. We identified early biomarkers of AKI using a mass spectrometry based proteomics approach.

Methods: Urine samples were obtained from patients shortly (mean 10 hours) after cardiac surgery. Four patients developed severe AKI (mean increase Cr 3.3 mg/dl), and 4 did not (mean increase 0.2). Proteomic analysis was done by liquid chromatography and tandem mass spectrometry. Proteins were identified with Mascot and validated with Scaffold. The exponentially modified protein abundance index (emPAI) was used for quantification. Candidate biomarkers were identified by comparison of emPAI values.

Results: We identified 227 high confidence proteins with >2 peptides (FDR <1%). The high abundance proteins albumin, lambda light chain, and kappa light chain did not differ in abundance between the two groups. Previously described AKI biomarkers alpha-1-acid glycoprotein (AGP-1), cystatin-C , hemopexin and NGAL were different between the groups. AGP-1 and Alpha-1B-glycoprotein (A1BG) changed in opposite directions with AKI. The mean emPAI value of AGP-1 was 0.33±0.06 in the AKI group and 0.15±0.04 in the non-AKI group (p=0.04). The mean emPAI value of A1BG was 0.06±0.02 in the AKI group and 0.19±0.03 in the non-AKI group (p=0.04). Furthermore, when the ratio of APG-1 to A1BG was calculated we found that it was able to predict AKI at this early time point with 100% accuracy. The segregation between the AGP-1:A1BG ratios for AKI and non-AKI patients was large. The mean difference in ratios between groups was over nine-fold and the smallest difference between individual members of the groups was greater than 2-fold.

Conclusions: The ratio AGP-1 to A1BG is a potential early marker of AKI. The use of a ratio of proteins which change in opposite directions enhances the sensitivity of the predictor and obviates the need for normalization.

FR-PO1053

Biomarkers in Acute Kidney Injury: Should We Assess Them in Serum or Urine? Josee Bouchard,[1] Rakesh Malhotra,[2] Ashita J. Tolwani,[3] Ravindra L. Mehta.[2] *[1]Universite de Montreal, Canada; [2]University of California San Diego; [3]University of Alabama at Birmingham.*

Background: There is limited information on the value of serum vs. urine biomarkers in acute kidney injury (AKI) diagnosis. The aim of this study was to compare the predictive capacity of serum and urine biomarkers to diagnose AKI.

Methods: We conducted a prospective, multicenter observational study to evaluate the role of serum vs. urine neutrophil gelatinase–associated lipocalin (NGAL), kidney injury molecule-1 (KIM-1), cystatin C and osteopontin levels to diagnose AKI in 51 critically ill patients. AKI was defined according to the AKIN creatinine criterion. Samples were collected every 12 hours after intensive care unit (ICU) admission for a ≥48 hours and up to 10 days.

Results: From the 51 patients enrolled, 17 developed AKI on average 1.5 ± 1.7 days after ICU admission. The Area Under the Curve (AUC) of the different biomarkers to predict AKI are included in the table:

	in serum	in urine
NGAL	0.482 (0.343-0.622)	0.598 (0.489-0.707)
KIM-1	0.714 (0.613-0.814)	0.783 (0.680-0.886)
Cystatin C	0.650 (0.549-0.750)	0.710 (0.619-0.801)
Osteopontin	0.651 (0.540-0.762)	0.630 (0.510-0.749)

Conclusions: In our cohort, NGAL, KIM-1 and cystatin C offered a better discriminative performance in urine than in serum for AKI diagnosis. These results are helpful to plan further studies using biomarkers in AKI.

MYH9 Gene Variant Is a Risk Factor for Acute Kidney Injury after Severe Trauma Michael G. Shashaty, Paul Lanken, Scarlett L. Bellamy, Sandra Kaplan, Jason Christie, Nuala J. Meyer. *University of Pennsylvania School of Medicine.*

Background: Acute kidney injury (AKI) is a source of substantial morbidity and mortality. Clinical factors incompletely explain AKI risk. Multiple studies have highlighted a locus at chromosome 22, encompassing the APOL1 and MYH9 genes, as strongly associated with chronic kidney disease (CKD). We hypothesized that these genetic variants may be associated with increased risk of AKI.

Methods: Patients admitted to our ICU with severe trauma were prospectively followed for AKI, defined by Acute Kidney Injury Network (AKIN) creatinine criteria. We tested the association of two candidate gene single nucleotide polymorphisms (SNPs) previously associated with CKD—rs4821480 (MYH9) and rs73885319 (APOL1)—with AKI. Taqman genotyping of genomic DNA was performed. As the APOL1 SNP is private to African populations, only African ancestry (AA) subjects were typed for this variant. Significance of odds ratios was determined with χ^2 testing assuming an additive model of genetic risk. Multivariable logistic regression was used to adjust for clinical confounders.

Results: Of 443 subjects enrolled, 112 (25.3%) developed AKI. The cohort was 46% African and 49% European ancestry. MYH9 rs4821480G was significantly associated with AKI (OR 1.39, 95% CI 1.03,1.88, p=0.030). There was no confounding of this association by sex, age, ancestry, baseline creatinine, hypertension, diabetes, or Injury Severity Score (OR 1.49, 95% CI 1.09,2.04, p=0.011). APOL1 rs73885319 did not show a significant association with AKI in the AA population (OR 1.40, 95% CI 0.78,2.49, p=0.256).

Conclusions: MYH9 rs4821480G was significantly associated with AKI after severe trauma, highlighting possible mechanistic overlap between AKI and CKD. The function of rs4821480, an intronic SNP, is not yet known, though MYH9 encodes a protein that may be involved in podocyte structure and function. An association of AKI with APOL1 rs73885319 could not be ruled out given the limited AA sample size. Genetic risk factors offer the potential to improve AKI risk stratification and better elucidate AKI pathogenesis.

FR-PO1055

Genetic Variation in SLC22A2 Organic Cation Transporter 2 (OCT2) Influences Cisplatin (CDDP)-Induced Nephrotoxicity in Cancer Patients Kazufumi Iwata,[1] Keiji Aizawa,[1] Saori Kamitsu,[1] Eiko Fukunaga,[1] Minoru Yoshida,[2] Akinobu Hamada,[3] Hideyuki Saito.[3] *[1]Pharmacy, Kumamoto Red Cross Hospital, Kumamoto, Japan; [2]Medical Oncology, Kumamoto Red Cross Hospital, Kumamoto, Japan; [3]Pharmacy, Kumamoto University Hospital, Kumamoto, Japan.*

Background: CDDP has been a mainstay for chemotherapy of multiple solid tumors. However, CDDP is clinically often complicated due to its dose-limiting nephrotoxicity. As the organic cation transporter SLC22A2/OCT2 is highly expressed in the basolateral membrane of proximal tubules, thereby being considered as a predominant transporter mediating active accumulation of CDDP in the kidney. Besides, single-nucleotide polymorphism (SNP) in the OCT2 808G>T (Ala270Ser) has been suggested to correlate with the reduced CDDP-induced nephrotoxicity. In this study, we explored the effect of 808G>T SNP in the OCT2 gene on the adverse events and the systemic exposure of CDDP in cancer patients.

Methods: We evaluated 53 patients with urothelial, lung, esophagus, head-neck, stomach and mesotheliomas carcinomas who had been treated with CDDP at a dose of over 60 mg/m^2. Genotyping was performed by using TaqMan SNP Genotyping Assays. The plasma concentration of CDDP was evaluated on day 3 and 6 after the treatment, as the free platinum level measured by ICP-MS. The toxicity grade was evaluated by CTCAE version 4.0 criteria.

Results: The number of patients who had the OCT2 808GG, GT and TT was 44, 9 and none, respectively. Differences in serum creatinine (SCr) levels between the baseline and cycle 1 in the patients with the GG and GT were increased by 1.43 and 1.19 folds, respectively. In the total treatment cycles, 12 patients (27%) with the GG experienced the grade2 SCr elevation, whereas the patients with GT showed no apparent toxicity. White blood cell and platelet levels showed no difference between the both groups. On day 3, the plasma concentrations of CDDP in the patients with the GG and GT were 75 and 63 ng/mL, and on day 6, those in GG and GT were 70 and 57 ng/mL, respectively.

Conclusions: In conclusion, 808G>T SNP in the OCT2 gene appeared to be associated significantly with the CDDP-induced nephrotoxicity, but not with the pharmacokinetic profile of CDDP.

Funding: Government Support - Non-U.S.

FR-PO1056

Natural History of Acute Kidney Injury in Intensive Care Unit Patients: The Multicenter International O'Brien Center Registry Josee Bouchard,[1] Jiandong Wei,[2] Sharon Soroko,[2] Anjali Acharya,[3] Jorge Cerda,[4] Elizabeth R. Maccariello,[5] Rajasekara Chakravarthi Madarasu,[6] Ashita J. Tolwani,[7] Xinling Liang,[8] Ping Fu,[9] Zhi-Hong Liu,[10] Ravindra L. Mehta.[2] *[1]U de Montreal; [2]UCSD; [3]Jacobi Medical Center; [4]Albany Medical College; [5]Rede d'Or; [6]CARE Hospitals; [7]UAB; [8]Guangdong General Hospital; [9]Sichuan Univ; [10]Nanjing Univ.*

Background: Although AKI is common and associated with increased mortality, there is a lack of multicenter prospective large databases on mild to severe AKI throughout the world.

Methods: We conducted a prospective observational study to determine the incidence of AKI in ICU patients in 13 countries using AKIN criteria and to characterize differences in etiology, clinical factors and process of care among patients.

Results: Between 2008 and 2011, 778 of 3879 critically ill patients (20%) had AKI during the first week of ICU admission, and 479 (62%) were enrolled in our registry. Mean age was 59±17 yrs, 69% were male, 66% were non-caucasian, 16% had CKD, 40% were mechanically ventilated, 26% on pressors, 42% on diuretics and 65% were oliguric. Mean SOFA score was 6.5±4.1. Pre-renal factors were the most common risk factors for AKI (64%). 16% required renal replacement therapy (RRT). Continuous RRT, intermittent hemodialysis and sustained low-efficiency dialysis were used in 51%, 26% and 20% of patients, respectively, while peritoneal dialysis was used in 3%. 15% of patients were dialysis-dependent at hospital discharge. Overall hospital mortality was 19% (33% in patients who required RRT vs. 17% in patients who did not require RRT;p=0.005). Independent risk factors for hospital mortality among AKI patients included use of pressors (OR 1.80; 95%CI 1.01-3.19;p=0.04) and mechanical ventilation (OR 5.75; 95%CI 2.86-

11.60;p<0.001) while the use of diuretics was associated with a protective effect on mortality (OR 0.43; 95%CI 0.23-0.80;p=0.008).

Conclusions: We describe an ongoing registry of AKI in ICU patients. AKI incidence was 20% and was associated with a 19% mortality rate. This multicenter multinational registry also provides a contemporary overview of clinical factors and management of AKI in ICU worldwide.

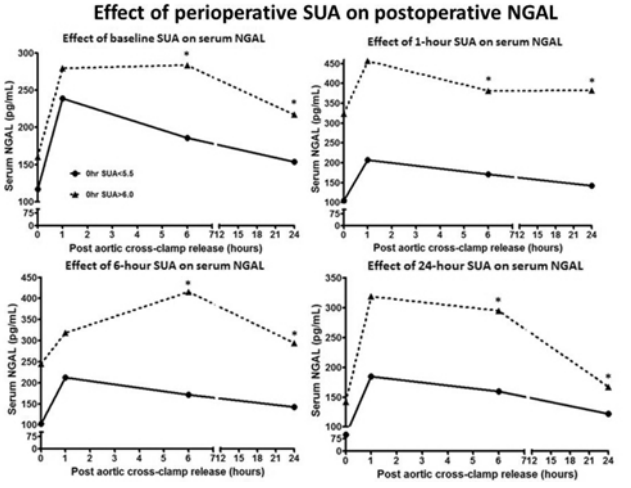
FR-PO1057

Perioperative Serum Uric Acid Affects Serum NGAL Concentrations A. Ahsan Ejaz,[1] Abdo Asmar,[1] Michiko Shimada,[2] Ganesh Kambhampati,[1] Noel I. Ejaz,[1] Amir Ahsan Arif,[1] Mourad Alsabbagh,[1] Richard J. Johnson.[3] *[1]Division of Nephrology, Hypertension and Transplantation, University of Florida, Gainesville, FL; [2]Division of Cardiology, Respiratory Medicine and Nephrology, Hirosaki University Graduate School of Medicine, Hirosaki, Aomori, Japan; [3]Division of Renal Diseases and Hypertension, University of Colorado Health Sciences Center, Denver, CO.*

Background: We have previously demonstrated that preoperative serum uric acid (SUA) is an independent risk factor for AKI and that SUA >6mg/dL was associated with a 4-fold increased risk factor for AKI in patients undergoing cardiac surgery. Since NGAL is a reliable biomarker of early AKI, we investigated the effect of SUA serum on serum NGAL concentrations in the same reported cohort of cardiac surgery patients.

Methods: SUA and NGAL were measured from stored, frozen serum samples obtained at 0, 1, 6 and 24 hours post aortic cross-clamp release in our previously reported cohort. The relationship of SUA and NGAL were investigated using appropriate statistical tests. At every time point of measurement of SUA, its effect on 0, 1, 6 and 24-hr NGAL were assessed.

Results: 37 patients were included for analyses. The effects of SUA>6mg/dL on NGAL were compared in relation to reference SUA<5.5mg/dL, the level above which uric acid manifests its pro-inflammatory effects. At any given time of SUA measurement, SUA>6mg/dL was associated with significantly elevated serum NGAL concentrations measured at 6 and 24hrs. SUA>6mg/dL was also associated with significantly elevated SCR values at postoperative days 1-5.



Conclusions: These data provides biomarker evidence of early renal parenchymal damage associated with elevated SUA in patients undergoing cardiac surgery.

FR-PO1058

Risk Factors and Etiology of Acute Kidney Injury in Intensive Care Unit Patients: The Multicenter International O'Brien Center Registry Josee Bouchard,[1] Jiandong Wei,[2] Sharon Soroko,[2] Sam Kuo,[2] Anjali Acharya,[3] Jorge Cerda,[4] Elizabeth R. Maccariello,[5] Rajasekara Chakravarthi Madarasu,[6] Ashita J. Tolwani,[7] Xinling Liang,[8] Ping Fu,[9] Zhi-Hong Liu,[10] Ravindra L. Mehta.[2] *[1]U de Montreal; [2]UCSD; [3]Jacobi Medical Center; [4]Albany Medical College; [5]Rede d'Or; [6]CARE Hospitals; [7]UAB; [8]Guangdong General Hospital; [9]Sichuan Univ; [10]Nanjing Univ.*

Background: AKI is frequent in ICU patients and is associated with increased mortality. However, there is a lack of information on the risk factors and etiologies of AKI across the world.

Methods: We conducted a prospective observational study to compare etiology of AKI and risk factors for AKI in ICU patients with and without AKI in 13 countries.

Results: Between 2008 and 2011, 778 of 3879 patients (20%) developed AKI during the first week of ICU admission. AKI patients were older (61±18 vs. 57±19 yrs;p<0.001) and had more comorbidities than non-AKI (diabetes 24% vs. 14%;p<0.001, obesity 30% vs. 24%;p=0.004, liver failure 11% vs. 5%;p<0.001, heart failure 19% vs. 9%;p<0.001 and CKD 20% vs. 11%;p<0.001). Mean patient age and AKI incidence were similar between developed and emerging countries. However, patients in emerging countries were less likely to be male (58% vs. 63%;p=0.004), obese (15% vs. 30%;p<0.001), and have liver failure (5% vs. 7%;p=0.001); they were more likely to have heart failure (14% vs. 10%;p<0.001) and CKD (20% vs. 12%;p=0.02). AKI etiologies in patients enrolled in our registry (n=479/778;62%), included acute tubular necrosis (ATN) (21%), glomerulonephritis (GN) (4%), interstitial nephritis (2%), and prerenal (64%). 65% had multifactorial etiologies. Sepsis was present at AKI diagnosis in 50%. ATN and prerenal were more frequent in developed countries (27 vs. 15%;p<0.001 and 76 vs. 52%;p<0.001), while GN was more common in emerging countries (7% vs. 0.5%;p=0.004).

Conclusions: We describe an ongoing multicenter multinational registry of AKI in ICU patients. Risk factors and etiologies of AKI differed considerably between emerging and developed countries. These comparisons are useful to establish preventive and therapeutic strategies to improve AKI outcomes.

FR-PO1059

Study on the Usefulness of Urinary Parameters in Early Detection of Acute Kidney Injury after Cardiac Surgery in Adults Katsuomi Matsui, Takeshi Sugaya, Takashi Yasuda, Kenjiro Kimura. *Department of Nephrology and Hypertension, Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Kanagawa, Japan.*

Background: Acute kidney injury (AKI) is a common complication after cardiac surgery. Urinary liver-type fatty acid-binding protein (L-FABP) reflects the presence of renal tubular injury. The aim of this study was to evaluate the utility of urinary L-FABP compared with other urinary parameters for the early detection of postoperative AKI among adult patients undergoing cardiac surgery.

Methods: Adult patients undergoing cardiac surgery in our hospital were eligible for enrollment. A total of 85 patients were prospectively studied from August 2009 to October 2010. Patients who depended on chronic dialysis support, patients undergoing emergency operation (operation performed within 24 hours after admission) and patients who died within the first 24 h after surgery were excluded from this study. Patients were divided into the AKI and non-AKI groups according to whether they developed AKI within 48 h after surgery. Postoperative AKI was defined according to AKIN criteria. Changes in various parameters, such as serum creatinine, urinary L-FABP, urinary neutrophil gelatinase-associated lipocalin, urinary albumin, and urinary *N*-acetyl-β-D-glucosaminidase, were evaluated. Urine and serum samples were obtained from each patient at the following time points: preoperative, immediately postoperative, and 3, 6, 18, 24, and 48 h postoperatively.

Results: The urinary L-FABP level was significantly higher in the AKI group than in the non-AKI group at every time point, while other parameters did not show such tendency. The parameter with the largest area under the curve at every time point for predicting the onset of AKI was urinary L-FABP. On multiple logistic regression analyses, the urinary L-FABP level pre-operation and within the first 6 h after cardiac surgery was significantly associated with the onset of AKI.

Conclusions: Our study suggests that urinary L-FABP was a useful biomarker for early detection of AKI and was an early good predictor of the onset of AKI.

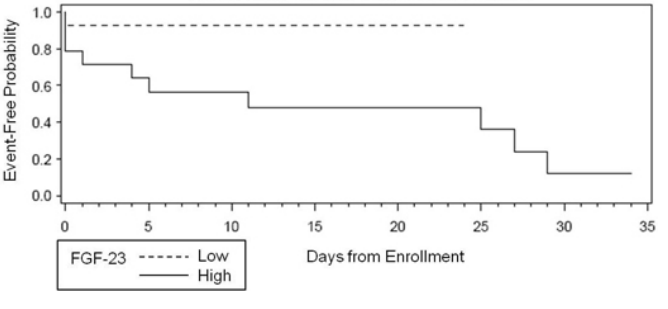
FR-PO1060

Fibroblast Growth Factor 23 as a Biomarker in Acute Kidney Injury David E. Leaf,[1] Myles S. Wolf,[2] Leonard Stern.[1] *[1]Department of Medicine, Division of Nephrology, Columbia University Medical Center, New York, NY; [2]Division of Nephrology and Hypertension, University of Miami, FL; [3].*

Background: Fibroblast growth factor 23 (FGF-23) regulates phosphorus and vitamin D homeostasis. Elevated levels are independently associated with increased mortality in patients with chronic kidney disease and ESRD. Whether FGF-23 levels are elevated and associated with adverse clinical outcomes in patients with acute kidney injury (AKI) has not been studied.

Methods: We recruited 28 participants with AKI and 30 controls from the medical intensive care unit and general hospital wards of Columbia University Medical Center. FGF-23 levels were measured at baseline and repeated 5 days later (Immunotopics ELISA assay). The combined clinical outcome was death or need for renal replacement therapy (RRT).

Results: FGF-23 levels were significantly higher among participants with AKI than controls [median(IQR) 1546 (253-2988) and 263 (87-577) RU/ml, respectively, p=0.003]. Among participants with AKI, baseline FGF-23 levels above versus below the median were associated with a significantly higher probability of death or need for RRT (log rank test, p=0.03).



Conclusions: FGF-23 levels are elevated in AKI and are associated with greater risk of death or need for RRT. Additional work is needed to determine potential mechanisms underlying these preliminary findings.

Urinary IL-18 Is the Most Useful Early Predictive Biomarker of Contrast-Induced Nephropathy (CIN) on Chronic Kidney Disease (CKD) Stage 3 Patients in Comparison with NGAL and L-FABP Kosuke Inoue, Yoshiko Shimamura, Koji Ogata, Masayuki Ishihara, Toru Kagawa, Yoshio Terada. *Endocrinology, Metabolism and Nephrology, Kochi Medical School, Nankoku, Kochi-prefecture, Japan.*

Background: Contrast-induced nephropathy (CIN) is the important cause of hospital-acquired acute kidney injury (AKI) on Chronic kidney disease (CKD) patients. However, some urinary biomarkers for AKI were reported to be high in CKD patients. Thus, sensitivity and specificity of these urinary biomarkers are not determined for the diagnosis of AKI in CKD patients. This study was designed to investigate whether human urinary interleukin-18 (IL-18), neutrophil gelatinase-associated lipocalin (NGAL), and liver-type fatty acid binding protein (L-FABP) are early predictive markers for CIN after coronary angiography in CKD patients.

Methods: 41 patients of CKD Stage 3 undergoing coronary angiography were enrolled. Urine samples were collected before, 3 h, 6 h, 24 h after coronary angiography and IL-18, NGAL, and L-FABP levels measured by using an ELISA kit. Urinary creatinine values were measured and the values of urinary biomarkers were corrected by the creatinine concentration because of urinary concentration. This study is in accordance with the Declaration of Helsinki (2002) and was approved by Kochi Medical School review boards. All patients provided written informed consent.

Results: eGFR (estimated glomerular filtration rate) decreased more than 10 ml/min in 14 patients (decreased eGFR group) and did not decrease in remaining 27 patients (non-decreased group) after coronary angiography. At 3 h, 6 h, and 24 h after the procedure, the ratio with the previous value of the urinary IL-18 and L-FABP were significantly increased in the decreased eGFR group, but not in the non-decreased group. In contrast, NGAL are rapidly increased in both group, however, no statistically significant difference of NGAL was observed between two groups. When we used uncorrected biomarker values by creatinine, the specificity and sensitivity were significantly decreased. Rather more, urinaly IL-18 was better than urinaly L-FABP on ROC analysis.

Conclusions: We conclude that urinary IL-18 could be early biomarkers of CIN in CKD Stage3 patients.

FR-PO1062

Urine Biomarkers of Aminoglycoside Nephrotoxicity in Children Zubaida Al-Ismaili,[1] Joseph V. Bonventre,[3] Prasad Devarajan,[2] Melissa Piccioni,[1] Venkata Sabbisetti,[3] Michael R. Bennett,[2] Qing Ma,[2] Michael Zappitelli.[1] *[1]McGill University, Canada; [2]Cincinnati Children's Hosp Med Center; [3]Brigham and Women's Hospital.*

Background: Aminoglycosides(AG) are commonly used in children but are nephrotoxic. Acute kidney injury(AKI) biomarkers and serum Cystatin C(CysC) have not been validated for AG-AKI. We hypothesized that AKI biomarkers are diagnostic of AG-AKI and the association is stronger when defining AKI by CysC.

Methods: We reported on 86 prospectively studied AG treatments(tx) in children on non-critical care units. Daily urine neutrophil gelatinase-associated lipocalin(NGAL), interleukin-18(IL-18) and kidney injury molecule-1(KIM-1) were measured. AKI was defined as 1)AKItrad("traditional": >50% or 27 umol/l rise from baseline in 3 months prior); 2)AKIfirst(same definition but baseline was SCr within 72hrs of AG start); 3)AKIcysc(like AKIfirst, but CysC change instead). We calculated area under the curve (AUC) of a)Peak biomarker levels and b)Tx day 1 or 2 levels to predict AKI by all 3 definitions. We calculated Spearman correlation between Peak biomarker levels and days with AKI.

Results: Mean[SD] age and tx duration were 8.3[4.9] yrs and 8.4[8.8] days; 51% were boys, 74% on oncology wards, 77% tobramycin. 53% developed AKItrad, 19% AKIfirst, 21% AKIcysc. AUC's to predict AKItrad using Peak NGAL, IL-18 and KIM-1 were: 0.53, 0.46, 0.63; to predict AKIfirst: 0.52, 0.44, 0.61; for AKIcysc: 0.51, 0.54, 0.52. Combined AUC's (logistic regression) to predict AKItrad, AKIfirst and AKIcysc including all 3 Peak biomarkers were: 0.61, 0.57, 0.68. AUC's to predict AKItrad using Tx days 1 or 2 NGAL, IL-18 and KIM-1 were: 0.53, 0.38, 0.54; to predict AKIfirst: 0.43, 0.35, 0.56; for AKIcysc: 0.23, 0.32, 0.52. The combined AUC's to predict AKItrad, AKIfirst and AKIcysc including all 3 Tx 1-2 biomarkers were: 0.55, 0.69, 0.79. Only Peak KIM-1 on treatment correlated with number of days with AKI ($r = 0.23$, $p = 0.03$).

Conclusions: Urine KIM-1 was more strongly associated with AG-AKI and AKI severity. Combining information from multiple biomarkers enhanced AG-AKI prediction. AKI-biomarker associations were strongest when defining AKI by CysC.

FR-PO1063

Biomarkers of Cisplatin and Ifosfamide Nephrotoxicity in Children Melissa Piccioni,[1] Zubaida Al-Ismaili,[1] Prasad Devarajan,[2] Joseph V. Bonventre,[3] Venkata Sabbisetti,[3] Michael R. Bennett,[2] Qing Ma,[2] Michael Zappitelli.[1] *[1]McGill University Health Centre, Canada; [2]Cincinnati Children's Hospital Medical Center; [3]Brigham and Women's Hospital.*

Background: Cisplatin (Cis) and Ifosfamide (Ifos) are nephrotoxic. Improving Acute kidney injury (AKI) diagnosis using new biomarkers may improve management of AKI and complications.

Methods: We prospectively collected serum creatinine (SCr), urine neutrophil gelatinase-associated lipocalin(NGAL), interleukin-18(IL-18) and kidney injury molecule-1(KIM-1) during 16 Cis and 21 Ifos treatments(Tx's) in children with cancer(mostly solid tumours) in an ongoing pilot study. We characterized biomarker increases on Tx and used Kruskal-Wallis test to evaluate rise. We defined AKI as >=50% or 27 umol/l SCr rise from baseline. We calculated area under the curve(AUC) for a)Peak biomarker concentration and b)Day 2 biomarker concentration to predict AKI during Tx (Cis and Ifos combined). We used logistic regression to calculate combined AUC for Peak and Day 2 biomarker concentration to predict AKI during Tx.

Results: Mean[SD] age was 9.8[4.3] yrs; 41% were boys; 31% had AKI on Cis and 48% on Ifos. All 3 biomarkers rose during the first 4 days of Cis and Ifos; only KIM-1 rise was statistically significant: Days 1 to 4 of Cis, median KIM-1 (pg/ml): 36.1, 52.1, 174.4, 208.2, respectively ($p=0.009$); Days 1 to 4 of Ifos, median KIM-1 (pg/ml): 94.3, 165.5, 196.2, 339.8, respectively ($p=0.002$). AUC's for Peak NGAL, IL-18 and KIM-1 to predict AKI were 0.58, 0.64, 0.71; when combining all 3 biomarkers, the AUC increased to 0.75. AUC's for Tx Day 2 NGAL, IL-18 and KIM-1 to predict AKI were 0.42, 0.37, 0.69; when combining all 3 biomarkers, the combined AUC increased to 0.76.

Conclusions: AKI during Cis and Ifos was common. All 3 biomarkers rose during Tx but only KIM-1 rose significantly and KIM-1 most strongly predicted AKI on treatment. Given previous literature on very early rise of NGAL and IL-18 with AKI, it may be necessary to collect these biomarkers very shortly after Cis or Ifos dosing to best evaluate their diagnostic value.

FR-PO1064

Risk Factors and Severity of Illness of Contrast-Induced Nephropathy in Elderly Patients with Diabetes Zhan Li,[1] Hua Wu.[2] *[1]Nephrology, Beijing Hospital; [2]Nephrology, Beijing Hospital.*

Background: To analyze the risk factors and the severity of contrast-induced nephropathy (CIN) in the elderly patients with diabetes during PCI.

Methods: We studied and analyzed retrospectively 269 elderly patients who were done coronary angiography and PCI from January 2007 to December 2009 in our hospital. The patients were divided into two groups according to developing CIN or not. The possible risk factors for CIN were compared between the two groups. Then, the patients with CIN were divided into the serume creatinine increasing <50% or ≥50% to determine the possible risk factors to aggravating CIN.

Results: 269 patients, the average age is 72.69±4.74 years(65~86 years); BMI 25.61±3.15 kg/m2. HbA1c 7.37±1.38%. The prevalence of hypertension was 80.7%, CKD was 29.7%, myocardial infarction was 24.2%. The incidence of DN was 25.7% and DR 21.9%. The mean eGFR of preoperation was 70.14±21.55ml/min and Scr was 83.90±34.71μmol/L. The mean dose of Iohexol was 176.83±71.75ml. 97 patients(36.1%) did the intravenous hydration peri- PCI.

The incidence of CIN was 9.3%(25/269). According to e-GFR: ≥90ml/min, 90-60ml/min, 60-30ml/min, <30ml/min, then the incidence of CIN for subgroup is 2.2%(1/45), 4.4%(6/135), 17.3%(14/81), 50%(4/8)respectively. The incidence of CKD, diabetic complication, preoperative e-GFR, dosage of contrast medium, serume creatinine concentration, ACEI and loop diuretic usage in CIN group were significantly higher than those in the non-CIN group($P<0.01$ or 0.05). Multivariate logistic gradual regressive analysis showed that loop diuretic usage, preoperative e-GFR(<60ml/min), dosage of Iohexol(≥200ml), CKD were independent risk factors of CIN. Their odds ratio(OR)was 6.07, 3.27, 3.26, 2.80, respectively, $P = 0.001, 0.024, 0.015, 0.048$, respectively. In analysis for severity of CIN, CKD, preoperative e-GFR, diabetic nephropathy and retinopathy,LVEF between two groups were significantly different($P<0.05$).

Conclusions: Loop diuretic use, preoperative GFR(<60ml/min), dosage of contrast medium (≥200ml), CKD are independent risk factors of CIN. CKD, preoperative GFR(<45ml/min), diabetic nephropathy and retinopathy have an effect on the severity of CIN.

FR-PO1065

Cystatin C as a More Precise Measure To Estimate Glomerular Filtration Rate in Critical Ill Patients Than the MDRD Formula Gisela Schieren,[1] Detlef Kindgen-Milles,[3] Ralf Westenfeld,[2] Lars C. Rump.[1] *[1]Nephrology, University Hospital Düsseldorf, Düsseldorf, Germany; [2]Cardiology and Pneumology, University Hospital Düsseldorf, Düsseldorf, Germany; [3]University Hospital Düsseldorf, Anesthesiology, University Hospital Düsseldorf, Germany.*

Background: Accurate knowledge of renal function on the intensive care unit (ICU) is not only of prognostic value, but also imperative for medical decisions such as drug dosing and begin of dialysis. In clinical practice creatinine and creatinine based formulae are commonly used to estimate glomerular filtration rate (GFR). Recently cystatin c based formulae were proposed as more accurate indicator of renal function in elderly, children or tumor patients. In ICU patients significant differences in creatinine- and cystatine C based

GFR estimates were seen, but accuracy of the different GFR estimates not compared to a reference method such as creatinine clearance (ECC) or inulin clearance.

Methods: Retrospectively we analyzed the accuracy of creatinine-based MDRD formula and cystatine c-based Larsson, Behring and Hoek formulae with ECC as reference method in ICU patients. Correlation between estimated GFR and ECC-based GFR was analyzed by Bland Altman statistics. When ECC was < 20 ml/min, mean urea and creatinine clearance was used as reference value as recommended (K/DOQI).

Results: 47 observations were recorded in 32 ICU patients. Mean difference between ECC and GFR estimates for MDRD formula was 22 ml/min (95%CI 15.8 - 28.9), for the cystatine C based formulae -3,07 ml/min (95%CI -9.47 - 3.33) [Behring], -0.82 ml/min (95%CI -7.22 - 5.58) [Larsson] and 2.19 ml/min (95%CI -4.07 - 8.45) [Hoek]. Bland altman analysis revealed significant overestimation of GFR by the MDRD formula (bias 22,4; p<0.001), but no statistical significant difference between reference method and cystatin C based GFR estimates. Limitation of the study was its retrospective character.

Conclusions: The MDRD formula significantly overestimates GFR in ICU patients and should be avoided, while cystatin c based formulae provide more accurate estimates of renal function.

FR-PO1066

The Epidemiology of Acute Hemodialysis in Pennsylvania, 2005-2007

Sarah Ramer, Elan Cohen, Mark L. Unruh, Amber E. Barnato. *University of Pittsburgh School of Medicine.*

Background: Although the US Renal Data System provides detailed information about patients with end-stage renal disease (ESRD) undergoing chronic hemodialysis (HD), little is known about the epidemiology of acute HD. Here we describe the epidemiology of acute HD, including patient- and hospital-level predictors, in >3 million consecutive inpatient admissions.

Methods: We conducted a retrospective cohort analysis of all adult acute-care hospitalizations in Pennsylvania (PA) from October 2005 to December 2007 using data from the PA Health Care Cost Containment Council. We defined acute HD by the ICD-9-CM procedure code for HD in any field, excluding patients with diagnosis codes indicating imminent, current, or prior ESRD (including history of kidney transplant) and patients with procedure codes for peritoneal dialysis or kidney transplant. We descriptively summarized the characteristics of the acute HD patients and then, controlling for Charlson Comorbidity Index, used multivariable hierarchical logistic regression to identify patient- and hospital-level independent predictors of acute HD.

Results: Among 3,184,361 admissions of non-ESRD patients age ≥21 in PA in this period, 7960 patients had 8888 admissions in which they received acute HD, yielding an annual incidence of 4.3 admissions with acute HD per 10,000 non-ESRD PA residents age ≥21. Independent predictors of acute HD were:

	Adjusted odds ratio	95% confidence interval
Age <65 (per yr)	1.01	1.01-1.01
Age ≥65 (per yr)	0.96	0.96-0.97
Female	0.80	0.76-0.83
Black	1.42	1.33-1.51
Uninsured (vs. Medicare / commercial)	0.58	0.44-0.72
Uninsured (vs. Medicaid)	0.48	0.36-0.59
Primary diagnoses (top 3 by z-score)		
Acute / unspecified renal failure	54.3	50.4-58.4
Sepsis	20.4	18.7-22.3
Complication of device, implant, or graft	15.3	14.0-16.8
Admission to hospital with high-intensity end-of-life care	2.07	1.71-2.51

Conclusions: We have provided one of the first descriptions of the epidemiology of acute HD in a large US population of adults age ≥21. Receipt of acute HD varied by age, sex, race, insurance status, and hospital treatment intensity. Future research should elucidate reasons for such marked variations in provision of care thought to be necessary for patients with acute kidney failure.

FR-PO1067

Fluid Balance and Acute Kidney Injury: A Prospective Observational Study

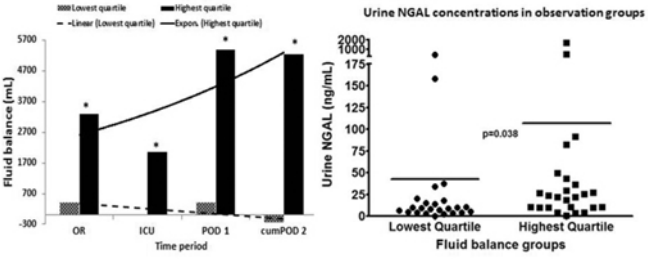
Ganesh Kambhampati,[1] Uma Krishna Pakkivenkata,[1] Amer Abouhamze,[1] Mourad Alsabbagh,[1] Abdo Asmar,[1] Gurjit Dhatt,[1] Imtiaz M. Ather,[1] Noel I. Ejaz,[1] Amir Ahsan Arif,[1] A. Ahsan Ejaz.[1] *[1]Division of Nephrology, Hypertension and Transplantation, University of Florida, Gainesville, FL; [2]Department of Surgery, University of Florida, Gainesville, FL.*

Background: It is unclear whether FB is the cause or result of AKI. We therefore performed a prospective, observational study to investigate this relationship.

Methods: Adult, non-transplant cardiovascular surgery patients were divided into quartiles based on FB status. Incidences of AKI, urine NGAL and IL-18, serum cytokine and SCr concentrations were compared between the lowest (Low-FB) and highest (High-FB) quartiles.

Results: 100 patients were analyzed. The major finding: High-FB group had a six-fold increased risk for AKI (adjusted OR 6.48, CI95%1.37-30.51, p=0.018) and was associated with higher urine NGAL (p=0.038) concentrations. An important observation was that positive FB occurred early in the intraoperative period and continued into the initial ICU period. Positive FB preceded the development of AKI. The High-FB group received more blood product transfusions (p=<0.001), medications (p<0.001) and fluids (p<0.001) and had longer duration of surgery (p=0.003) and time on cardiopulmonary bypass machine (p=0.018). Urine output was not different (p=0.483) between groups in the intraoperative period. Both groups demonstrated a 35-40% reduction in intraoperative MAP from baseline values, but significant differences between them were not observed (p=0.954). High-FB group had longer ICU-LOS (p=0.001) and hospital-LOS (p=0.048) but duration of mechanical ventilation were not different (p=0.650).

Figure 1. Emergence of FB and relationship with urine NGAL



Conclusions: Positive FB in the first 24-hours from initiation of surgery may be an independent risk factor for postoperative AKI.Positive FB is an excellent and simple predictive marker that precedes the rise in SCr.

FR-PO1068

Preoperative Low HDL Level Is Associated with Increased Risk of Acute Kidney Injury Postprocedure/Surgery for Peripheral Vascular Disease

Pradeep Arora,[1,2] Nauman Tahir,[1] Pooja Mahajan,[1] James W. Lohr,[1,2] Hassan H. Dosluoglu,[4] Nader Nader.[3] *[1]Department of Medicine, SUNY, Buffalo, NY; [2]Division of Nephrology, VAMC, Buffalo, NY; [3]Department of Anesthesiology, VAMC, Buffalo, NY; [4]Department of Surgery, VAMC, Buffalo, NY.*

Background: High-density lipoproteins (HDL) have been shown to reduce organ injury and mortality in animal models of shock via modulation of the expression of adhesion molecules and pro-inflammatory enzymes. However clinical studies are lacking.

Methods: We studied the association of HDL level and acute kidney injury (AKI) in patients, who have undergone lower extremity revascularization as the primary procedure at VA Western New York Healthcare System between January 1, 2001 and December 31, 2009. Patients with primary amputation or ESRD were excluded. All data were collected prospectively. Patients were divided in 2 groups; Group A included patients who had preoperative HDL level <40 mg/dl and group B who had HDL >40 mg/dl. Multivariate and propensity score analyses were performed to evaluate the association of AKI and low HDL level.

Results: Study population included 740 patients, 61% of patients had low HDL. Patients in group A were more likely to have hypertension, diabetes, high LDL level, and CKD compared with group B patients. Patients in Group A were significantly more likely to be on ACEI/ARB and statins preoperatively. 9.5% of patients developed AKI by AKIN criteria and 2.7% by RIFLE criteria. Multivariate logistic model results are shown in the table.

Mutiple Logistic Regression Analysis

Parameter	Odds Ratio	95% CI
HDL (low/high)	13.43	8.62-20.92
Age	0.96	0.95-097
CAD	1.24	0.76-2.04
CKD	2.81	1.65-4.77
DM	1.28	0.78-2.08
HTN	0.91	0.53-1.53

Propensity score analysis showed that patients with low HDL level had 40% higher odds of having AKI (OR 1.41 with 95% CI 1.14-1.73).

Conclusions: We conclude that low HDL level is associated with higher odds of AKI postoperatively. Although, low HDL was very common in this population, only 3% were on niacin. It needs to be determined if use of niacin preoperatively will decrease prevalence of AKI.

FR-PO1069

Acute Kidney Injury in Hospitalised Patients Is Under-Recognised and Under-Treated

Jennifer R. Joslin, Hannah R. Wilson, Amy Irvine, Hannah E. Wilkinson, Scott R. Henderson, Deepasree Bangaru-Raju, Bernard Freudenthal, Thomas Sanctuary, Mark T. Kinirons, Maria Ostermann. *Guy's & St Thomas' NHS Trust.*

Background: Acute kidney injury (AKI) is associated with significant morbidity and mortality. In 2009, the National Confidential Enquiry into Patient Outcomes and Death (NCEPOD) identified significant failings in the recognition and management of hospitalised patients with AKI. Our aim was to explore the prevalence, recognition and quality of early management of level 1 patients with AKI in a London teaching hospital.

Methods: During a 7 day period in May 2011, electronic patient records of all level 1 medical and surgical patients were screened daily. AKI was defined by KDIGO criteria. Independent assessors reviewed the medical notes using similar criteria as the NCEPOD report.

Results: 99 out of 1379 level 1 patients (7.2%) had AKI (53% male; mean age 72.6 years; 64% medical and 36% surgical patients). 93% of these patients had risk factors for AKI (median number 2 [range 0-6]).

Data of 266 AKI patient-days were available. 22 were excluded due to limitations of care. In 59% of cases, AKI was recognised by the treating team. Of these, 83% had a documented management plan regarding AKI, 85% had an early senior review, and 54% had a urine dipstick recorded. Management was worse when AKI was not recognised by the treating medical team (Table 1). On 3 occasions, the independent assessors noticed potentially life threatening problems and intervened.

Table 1: Early management based on recognition of AKI

	Recognised AKI (n=144 AKI days)	Unrecognised AKI (n=100 AKI days)
Assessment of fluid status	49%	21%
Complete fluid balance chart	36%	25%
Discontinuation of nephrotoxics	45% (29/65)	13% (6/47)
Adherance with contrast nephropathy prevention guideline	40% (4/10)	50% (4/8)

Conclusions: AKI is prevalent among hospitalised non-critically ill patients. Only 60% of cases are recognised by the treating team. Even when recognised, a significant proportion of AKI patients do not receive appropriate simple early management. More education and awareness about AKI is necessary, especially among junior medical staff.

FR-PO1070

Acute Kidney Injury in Neonates Undergoing Complex Cardiac Surgery Is Associated with Adverse Outcomes Catherine Morgan,[1] Michael Zappitelli,[2] Charlene Robertson,[1] Gwen Alton,[1] Ari Joffe.[1] *[1]Pediatrics, University of Alberta, Edmonton, AB, Canada; [2]Pediatrics, McGill University, Montreal, QC, Canada.*

Background: Neonates represent one of the most fragile and largest pediatric groups having cardiac surgery (CS). Very little data on neonatal acute kidney injury (AKI) epidemiology and outcomes are available.

Methods: We evaluated prospective data on 248 neonates ≤6 weeks old who had biventricular cardiac repairs from Jan '02-Dec '09. We 1) calculated the CS-AKI rate (≥50% postoperative creatinine (Cr) rise), 2) evaluated pre-/intra-operative AKI risk factors (age, gender, preoperative ventilator days and inotrope use, gestation, weight percentile at surgery, preoperative Cr, bypass time (CPBt), surgical group, deep hypothermic circulatory arrest (DHCA)) using stepwise logistic regression and model area under the curve (AUC), 3) evaluated the effect of AKI on short-term outcomes (death, death-censored length of stay and ventilator days) using survival analysis and on long-term health care use using Poisson regression, and adjusting for severity of illness.

Results: Mean(SD) gestation, birth weight and surgery age were 38.7(2.0) weeks, 3.2(0.6) kg and 17(20) days. 63% had post-operative AKI. Independent (adjusted) AKI risk factors were pre-op Cr (higher SCr = lowest AKI risk), lower gestational age, younger surgical age, DHCA use, longer CPBt and surgical group. The clinical model's AUC for AKI prediction was 0.77. AKI was independently associated with longer time to extubation (adjusted HR 0.76, p=0.04) and longer time to ICU discharge (adjusted HR 0.75, p=0.04). Adjusted risk for mortality in infants with more severe AKI (a doubling of Cr) was higher than those without AKI (HR 2.9, p=0.02). AKI was independently associated with higher number of non-cardiology specialists seen at 2 year follow up (incident rate ratio 1.31 p=0.04).

Conclusions: CS-AKI is very common in neonates and is associated with adverse hospital outcomes and long-term health care use. In addition, preoperative and intraoperative clinical variables may provide a significant contribution to predictive modelling for neonatal AKI.

FR-PO1071

Early Changes in Transgastric Renal Doppler Indexes Predict Acute Kidney Injury after Major Heart Surgery Giuseppe Regolisti,[1] Carola Cademartiri,[1] Simona Gualtieri,[1] Umberto Maggiore,[1] Aderville Cabassi,[1] Loredana Belli,[2] Sandra Pincolini,[2] Elena Cremaschi,[1] Alberto Caiazza,[1] Tiziano Gherli,[2] Enrico Fiaccadori.[1] *[1]Intern Med & Nephrology, Parma University, Parma, Italy; [2]Heart Surgery, Parma University, Parma, Italy.*

Background: We investigated if early changes in Doppler indexes reflecting intrarenal hemodynamics may predict acute kidney injury (AKI) after major heart surgery (MHS).

Methods: We studied renal hemodynamics by transgastric echo-Doppler in 60 consecutive pts (mean age 69.5 ys, range 30-88 ys; 41 m) undergoing MHS. Measurements were taken before (anesthesia induction), and after (at 2 and 4 hours) cardiopulmonary bypass (CPB) start. Resistance (RI) and pulsatility indexes (PI) were derived both at renal sinus at the level of the left renal artery trunk (***rs*RI** and ***rs*PI,** respectively), and intraparenchymally at the level of the interlobular/arcuate arteries (***intra*RI** and ***intra*PI**, respectively). Serum neutrophil gelatinase-associated lipocalin (NGAL) was measured at the same time points, plus at 24 hours after CPB start (Triage NGAL Test). Statistical analyses were based on linear mixed models for repeated measures and least-square regression.

Results: AKI developed in 27/60 pts (45%); two required dialysis. Systemic hemodynamic parameters(Swan-Ganz catheter) were similar in pts who did and who did not develop AKI. rsRI increased significantly at 2 and 4 hours in both groups (P=0.04), with higher absolute values in AKI pts (average difference between groups, P=0.03). intraRI values were also significantly higher at all time points in the AKI pts (P<0.001), although no clear-cut intraoperative increase was observed (mean rate of change P=0.91). rsPI and intraPI displayed similar changes, though with greater variability. Serum NGAL increased significantly in both groups (P<0.001) early after surgery, with significantly higher values in the AKI pts at all time points (average difference between groups, P<0.01). Within the whole patient population serum NGAL significantly correlated with rsRI, intraRI, and rsPI (P<0.05 for all).

Conclusions: Early intraoperative changes in renal Doppler indexes may help identify the pts with the highest risk of developing AKI after MHS.

FR-PO1072

Does Acute Kidney Injury Cause or Worsen Chronic Kidney Disease? Mark Dominic Uniacke,[1,2] Robert Lewis,[1] Scott Harris,[2] Paul J. Roderick.[2] *[1]Wessex Renal and Transplantation Service, Portsmouth, United Kingdom; [2]Public Health Sciences and Medical Statistics, University of Southampton, United Kingdom.*

Background: The impact of mild to moderate AKI on baseline renal function remains unknown. We have therefore studied AKI in hospitalized patients and explored its effect on the development of de novo CKD and progression of known CKD.

Methods: Prospective single centre observational study. Subjects were recruited over 17 months from Nov. 2009 to April 2011 from unselected admissions to a general hospital with a catchment population of 600,000. Two groups were recruited - Group 1: with previously normal kidney function developing AKI and Group 2: with background of CKD developing AKI. Baseline kidney function was identified from measurements of eGFR from the previous year. AKI was defined by elevations in serum creatinine from baseline using the AKIN criteria. Recovery of function is defined as a return to within 5mls/min of baseline eGFR. Hospital outcomes were recorded and function was reassessed after 6 months using the same laboratory. 6 month follow-up is ongoing and will finish in October 2011. Preliminary 6 month follow-up data for n=89 is presented here.

Results: 375 patients were recruited for follow up (Group1 n=189, Group 2 n=186). Mean age was 72 years (range 18-97, 53% male, 47% female). In hospital mortality was 4.2% in Group 1 and 9.2% in Group 2. At discharge failure to return to baseline function was seen in 54.9% of Group 1 and 34.3% of Group 2. Failure to recover was seen across all AKIN stages even mild AKIN stage 1. Preliminary data shows that after six months from AKI, recovery is not complete in 50% (21/42) of Group 1 and 27.6% (13/47) of Group 2. This failure to recover at six months is again seen across all AKIN stages. So far we have found a high readmission rate of 41.5% in both groups during follow up with 14% having at least one more AKI.

Conclusions: AKI across all AKIN stages appears to be failing to recover after six months in some patients and may be resulting in incident CKD and contributing to further irreversible loss in some existing CKD patients. These findings have important implications for clinical practice and population health.

FR-PO1073

Hemoglobin and Acute Kidney Injury after Noncardiac Surgery Michael Walsh,[1] Philip J. Devereaux,[1] Amit X. Garg,[2] Daniel Sessler.[3] *[1]McMaster; [2]UWO; [3]Cleveland Clinic.*

Background: Over 200 million adults undergo noncardiac surgery annually and it is frequently complicated by acute kidney injury (AKI). We assessed the association between postoperative changes in hemoglobin (Hgb) and AKI.

Methods: All patients undergoing noncardiac surgery at the Cleveland Clinic between January 2005 and December 2009 with at least one preoperative and one postoperative creatinine within 7 days of surgery, a preoperative estimated glomerular filtration rate of >60 ml/min, and did not undergo a urologic procedure were eligible. AKI was defined as >1.5 fold increase or >0.3 g/dL increase in creatinine within 7 days. Change in Hgb was the difference in the preoperative value and lowest value within the first 24 hours of surgery. All associations were assessed using logistic regression adjusted for age, sex, Risk Stratification Index (a validated score for mortality), surgery type, preoperative blood pressure, baseline Hgb and intraoperative transfusions.

Results: 41,498 patients met the eligibility criteria. The mean (standard deviation) age was 56 (16) years, creatinine was 0.82 (0.18) mg/dL and preoperative Hgb was 13.1 (2.0) g/dL. AKI occurred in 2654 patients (6.4%). AKI was associated with 30 day mortality with an adjusted odds ratio of 2.73 (95% confidence interval (CI)2.24 to 3.34). The median change in Hgb was a 2.2 g/dL decrement. Both preoperative Hgb <12 g/dL and a drop in Hgb of ≥2 g/dL was associated with a graded increase in the risk of postoperative AKI (Table 1). These associations were consistent when AKI was defined by more marked changes in creatinine.

Table 1. Association between AKI and drop in hemoglobin.

	Adjusted Odds Ratio (95% CI)	p-value
Drop in Hemoglobin (g/dL)		
No Drop	Reference	
<1	1.15 (0.96-1.37)	0.12
1-1.99	1.04 (0.86-1.24)	0.23
2-2.99	1.40 (1.16-1.70)	<0.001
3-3.99	1.88 (1.54-2.22)	<0.001
≥4	2.70 (2.22-3.29)	<0.001
Baseline Hemoglobin (g/dL)		
≥12	Reference	
10-11.9	1.70 (1.50-1.92)	<0.001
8-9.99	2.32 (1.97-2.73)	<0.001
<8	2.40 (1.72-3.33)	<0.001

Conclusions: AKI is an independent risk factor for postoperative mortality. Preoperative Hgb and early decrements in Hgb are independent risk factors for AKI and may be modifiable.

FR-PO1074

A Comparison of the Acute Kidney Injury Network and Kidney Disease: Improving Global Outcomes Criteria for Acute Kidney Injury in Critically Ill Patients Hibiki Shinjo,[1] Waichi Sato,[1] Tomoki Kosugi,[1] Hiroki Hayashi,[2] Shoichi Maruyama,[1] Enyu Imai,[1] Yukio Yuzawa,[2] Seiichi Matsuo.[1] *[1]Division of Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Division of Nephrology, Fujita-Health University, Toyoake, Japan.*

Background: Acute kidney injury (AKI)-associated hospital mortality can strikingly increase in comparison with patients without AKI. In order to have a uniform standard for classify AKI, the AKI Network (AKIN) group has proposed modifications to the previous criteria referred to the RIFLE and suggested staging of AKI based on changes in creatinine (Cr) within 48 hours. In actual clinical practice, however, the peak of Cr may be missed. More recently, Kidney Disease: Improving Global Outcomes (KDIGO) group proposed a new definition for AKI, which is defined as an abrupt reduction within 7 days in kidney function. We evaluated the incidence of AKI and compared the ability of the AKIN (48h) and KDIGO (7d) criteria in predicting hospital mortality of intensive care unit (ICU) patients.

Methods: We performed a retrospective cohort study on 2582 patients admitted between June 2005 and May 2009 in an ICU of the Nagoya university hospital. Chronic kidney disease patients undergoing dialysis and renal transplant patients were excluded.

Results: The KDIGO and AKIN criteria were total incidences of AKI (38.5 vs. 29.6%). KDIGO criteria significantly increased the number of patient classified as AKI in all stage compared with AKIN criteria (stage 1; 24.7 vs. 20.7%, stage2; 6.2 vs. 3.4%, stage3; 7.6 vs. 5.5%). 238 patients (9.2%) that classified as no AKI by AKIN and AKI by KDIGO, were similar hospital mortality for Stage 1 by both criteria. In both criteria, AKI were associated with hospital mortality after adjusting for multiple covariates. And the odds ratio was elevated, according to the severity of AKI. The area under the receiver operator characteristic curve for hospital mortality estimated by KDIGO and AKIN criteria were 0.76 and 0.73.

Conclusions: Both criteria might be reliable for predicting severity and outcome of AKI. Particularly, 7d time window in KDIGO improve on the sensitivity of the AKI diagnosis and the ability in predicting hospital mortality.

FR-PO1075

The Epidemiology of Contrast-Induced Nephropathy in the Era of Hydration Protocols Corinne E.A. Balemans,[1] Jan A.J.G. van den Brand,[1] Louis J.M. Reichert,[2] Jack F. Wetzels.[1] *[1]Nephrology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [2]Nephrology, Rijnstate Hospital, Arnhem, Netherlands.*

Background: Acute renal failure can complicate the use of iodinated contrast media. This contrast-induced nephropathy(CIN) is associated with marked morbidity and mortality. Current guidelines advise identification of high risk patients and hydration as preventive measure. We evaluated the incidence of CIN and determined risk factors associated with CIN in patients receiving intravenous contrast and treated according to the guidelines.

Methods: All patients with an eGFR<60ml/min/1.73m^2 were seen at the outpatient clinic. Patients were stratified for the risk of CIN; high risk (HR) or low risk (LR) based on absolute GFR (MDRD x BSA/1.73 m^2) and the presence of risk factors; diabetes, peripheral arterial disease, heart failure, age, anemia and use of diuretics and/or NSAID's. HR patients were hydrated with isotonic saline 1000ml before and 1000ml after contrast exposure. Serum creatinine was measured 3-5 days later, CIN was defined as a ≥25% rise from baseline.

Results: We evaluated 1420 procedures performed in 1111 patients in the period from Sept 2007 until Dec 2010. Mean age was 71.7 years and there were 45% females. In 757 procedures (53%) patients were hydrated. We observed CIN after 37 procedures (2.6%). (table1) In multivariate analyses heart failure (Odds ratio (OR)=2.47 95%confidence interval(CI) 1.14-5.36 p=0.02) and repeated contrast (OR=1.87 CI 0.96-3.64 p=0.06) were found to be independent predictors of CIN. The mean interval between contrast exposures was 4.4 months.

Conclusions: The incidence of CIN in this population was low and renal insufficiency and diabetes were no longer identified as risk factor. This supports the efficacy of the current strategy.

We identified heart failure and repeated contrast as risk factors for CIN. This last finding requires validation, but might suggest that subclinical injury remained present after first contrast exposure.

Risk category (N) (Risk)	Incidence CIN
GFR ≥60 (426) (LR)	2.1%
GFR 45-60 <2 risk factors (310) (LR)	2.9%
GFR 45-60 ≥ 2 risk factors (355) (HR)	2.5%
GFR <45 (329) (HR)	3.0%

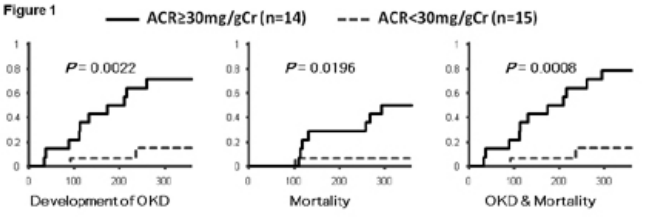
FR-PO1076

Development of Microalbuminuria Following Hematopoietic Stem Cell Transplantation Is Associated with Near-Term Loss in Renal Function and Mortality Taku Morito,[1,2] Minoru Ando,[1] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Department of Nephrology, Tokyo Metropolitan Komagome Hospital, Bunkyo-ku, Tokyo, Japan; [2]Department IV of Internal Medicine, Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan.*

Background: Microalbuminuria is a risk factor for overt kidney disease (OKD), cardiovascular disease and mortality. Therefore, the presence of microalbuminuria could be a sign of the future OKD or death in the setting of hematopoietic stem cell transplantation (SCT).

Methods: A 1-year prospective cohort study was conducted in 29 patients (46.3±12.5 years) receiving allogeneic myeloablative SCT. The urinary albumin to creatinine ratio (ACR) was consecutively measured before conditioning therapy (baseline), at the time of SCT, and on days 7, 14 and 28 after SCT. Microlbuminuria was defined as ACR ≥30mg/gCr. OKD was defined as persistent loss in renal function, that is, eGFR <60 ml/min/1.73m^2. Cumulative incidence of OKD or mortality or both was assessed by the Kaplan-Meier analyses. Multivariate Cox regression analysis was used to calculate the HR of developing OKD and mortality for microalbuminuria on 1 month (day 28) after SCT. Patients with OKD at baseline and those who died by 1 month after SCT were excluded.

Results: The prevalence of microalbuminuria was 6.9% at baseline, and increased to 62.1% at the day of SCT. It varied among the time points; 62.1% on day 7, 48.3% on day 14 and 51.7% on 1 month, respectively. Cumulative incidence of OKD or mortality or both was significantly higher in the group with 'microalbuminuria on 1 month'.



In addition, the presence of 'microalbuminuria on 1 month' was significantly associated with either the development of OKD or death (adjusted HR 17.4; 95% CI 3.66 to 134.9, *P*=0.0001).

Conclusions: The presence of 'microalbuminuria on 1 month' is a promising predictor of near-term development of loss in renal function and mortality in the setting of SCT.

FR-PO1077

Study of Acute Kidney Injury (AKI) on Admission to the Emergency Assessment Unit (EAU) Nihal Y. Abosaif, Lee J. Dowson, Ewa Werpachowska, Rhys Lodwick. *Medicine, Royal Liverpool University Hospital, West Midlands, United Kingdom.*

Background: Mortality rates from AKI are increasing in hospitalised patients in the UK because of increased rates of sepsis and circulatory failure. The National Confidential Enquiry into Patient Outcome and Death (NCEPOD) report has shown that most patients admitted with AKI were not assessed properly especially by trainees. Onward referral to renal physicians was also delayed. In this study, we evaluated the incidence of AKI in our EAU and estimated the risk of death among patients admitted according to the definition of AKI. Also for new patients admitted to EAU, we aim at implementing a new risk assessment tool to score patients on admission for the risk of developing AKI and hence establish their level of care.

Methods: All patients admitted to the EAU with a serum creatinine(S.Cr) >100 mmol/L between April 2010 and October 2010 were screened. Patients with known chronic kidney disease (CKD) or unknown baseline Cr were excluded. 1530 patients were found to match the inclusion criteria from which 54 patients were randomised. Medical notes, laboratory results and radiological investigations were extracted and examined for the purpose of the study, 23 out of 54 patients died because of the original presentation or secondary to AKI per se. The characteristics of those patients who died (group D) were compared with those of survivors (group S). We also assessed compliance with NCEPOD guidelines.

Results: Group D was significantly older than group S. There was no significant difference as regards their demographic, clinical or laboratory parameters apart from admission S.Cr, eGFR, follow up Cr, S.urea, S.albumin and platelets that were significantly deranged in group D. The Hazard Ratio (HR) of recognition of AKI {HR 3.475 (CI; 0.3-35.3)}, its cause { HR 2.3 (CI; 0.25- 21.2), p<0.001}and management {HR 0.52 (CI; 0.05-5.12), p<0.001 } showed very highly significant bivariate correlation to group D.

Conclusions: The cohort with a poor outcome was correctly identified and managed according to NCEPOD guidance implying that further steps are required. Development of a new scoring system for diagnosis of AKI in high risk patients may help target interventions.

FR-PO1078

Nutritional Support Influences Outcomes in Intensive Care Unit (ICU) Patients with Acute Kidney Injury (AKI) Soo Young Yoon,[1] Sharon Soroko,[1] Glenn M. Chertow,[2] Jonathan Himmelfarb,[3] Talat Alp Ikizler,[4] Emil P. Paganini,[5] Ravindra L. Mehta.[1] *[1]Univ California San Diego, San Diego, CA; [2]Stanford Univ, Palo Alto, CA; [3]Univ Washington, Seattle, WA; [4]Vanderbilt Univ, Nashville, TN; [5]Cleveland Clinic Foundation, Cleveland, OH.*

Background: Nutritional support (NUTS) is commonly utilized to manage ICU patients however it is unclear whether enteral (EN) or parenteral nutrition (PN) influence outcomes in AKI. We assessed the pattern of NUTS and its relationship to outcomes in AKI patients enrolled in the PICARD study (KI, 2004, 66: 1613-1621). We hypothesized that NUTS would be associated with improved survival and shorter ICU duration.

Methods: We analyzed data from 615 of the 618 patients who stayed in ICU >48 hours. We assessed mode of nutrition (MON), duration, amount and timing for NUTS and examined the relationship to fluid overload >10% body weight (FL/BW), hospital mortality (HOM), ICU length of stay (LOS) and dialysis requirement at hospital discharge (DIAL) in survivors.

Results: Among 615 patients, 199 ate orally without any NUTS (Oral), 76 received no oral or NUTS (None), 183 received EN, 66 PN, and 91 both EN+PN. A subset of the NUTS patients had oral intake for part of their ICU stay (EN n=81; PN n=22; EN+PN n= 27).

	None	EN (+oral)	PN (+oral)	EN+PN (+oral)	Oral	p*	p**
#Pts	76	102 (81)	44 (22)	64 (27)	199		
%HOM	59.2	54.9 (27.2)	63.6 (36.4)	54.7 (25.9)	15.1	0.000	0.000
Mean LOS	10.2	24.8 (21.8)	21.4 (20.6)	32.8 (29.1)	8.8	0.000	0.000
%DIAL	32.9	31.4 (13.6)	36.4 (18.2)	31.3 (22.2)	18.1	0.004	0.039
%FL/BW	12.1	21.1 (15.5)	37.2 (27.3)	12.1 (23.1)	14.6	0.000	0.000

*including Oral; **excluding Oral

In Cox proportional hazard model, FL/BW (HR 14.928), no NUTS (HR 5.185 vs. Oral), and single NUTS mode (HR 1.899 in EN and 2.863 in PN vs. Oral) predicted mortality. Nutritional duration and calories were not independent predictors for mortality. Transitions in MON from any nutrition to oral eating were associated with improved survival (HR 0.160 for mortality vs.oral to any nutrition).

Conclusions: In patients with AKI in the ICU, requirement for NUTS is associated with worse outcomes. Patients who can eat have the best outcomes regardless of underlying severity of kidney disease and underlying co-morbidities.

Funding: NIDDK Support

FR-PO1079

Dialysis Requirement and Nutritional Support in Intensive Care Unit (ICU) Patients with Acute Kidney Injury (AKI) Soo Young Yoon,[1] Sharon Soroko,[1] Glenn M. Chertow,[2] Jonathan Himmelfarb,[3] Talat Alp Ikizler,[4] Emil P. Paganini,[5] Ravindra L. Mehta.[1] *[1]Univ California San Diego, San Diego, CA; [2]Stanford Univ, Palo Alto, CA; [3]Univ Washington, Seattle, WA; [4]Vanderbilt Univ, Nashville, TN; [5]Cleveland Clinic Foundation, Cleveland, OH.*

Background: Nutritional support (NUTS) is variably utilized in ICU patients with AKI due to concerns of solute load and fluid accumulation. We evaluated the influence of dialysis requirement (RRT) on the application of NUTS in AKI patients enrolled in the PICARD study (KI, 2004, 66:1613-1621). We hypothesized that RRT would allow more nutrition to be given and improve outcomes.

Methods: We analyzed data from 610 of 618 patients who stayed in ICU >48 hrs. We assessed the nutritional mode (Oral=eating; EN=enteral; PN=parenteral; EN+PN=both and None=no oral and no NUTS), duration (%nutrition days/ICU days), amount (delivered/prescribed calories) and the timing for NUTS start (days from ICU admission) and examined the relationship to fluid overload >10% body weight (FL/BW), hospital mortality (HOM) and ICU length of stay (LOS) in survivors in patients with RRT (n=397) or without dialysis (NoRRT n=213).

Results: There was no difference in the mode, duration, or timing of NUTS in RRT vs NoRRT, however RRT patients had a higher % of delivered calories.

	None	EN	PN	EN+PN	Oral	Total	p
NoRRT							
#Pts (%)	28 (13.1)	53 (24.9)	19 (8.9)	17 (8.0)	96 (45.1)	213	
%Duration	-	51.3	48.0	64.7	75.8	56.4	0.000
%Calories	-	81.8	57.5	73.6	-	-	0.025

RRT							
#Pts (%)**	47 (11.8)	126 (31.7)	47 (11.8)	74 (18.6)	103 (25.9)	397	
%Duration#	-	60.5	68.0	67.2	70.7	58.1	0.000
%Calories	-	84.7	71.7**	81.3	-	-	0.011
Timing#	-	4.0	4.4	3.8	1.2	3.2	0.002
LOS	12.7*	24.4*	20.5	33.6	9.6	20.4**	0.000
%FL/BW#	16.2	1.8	13.0	2.9	3.5	5.5	0.000
%HOM	69.8*	46.0	61.7	51.4*	22.3*	45.3**	0.000

Significance vs. NoRRT *p<0.05; **p<0.001; # NS

Conclusions: RRT requirement modifies the amount of calories provided by NUTS in ICU patients with AKI. Oral intake is associated with improved outcomes. Further studies are required to assess the effect combined Oral and NUTS in improving outcomes from AKI.

Funding: NIDDK Support

FR-PO1080

Age Modifies the Predictive Effect of AKIN Staging for Hospitalization Outcome in Elderly Patients Undergoing Major Surgery Chia-Ter Chao, Fan-Chi Chang, Vincent Wu. *Division of Nephrology, Department of Internal Medicine, National Taiwan University Hospital, Taiwan.*

Background: Acute kidney injury (AKI) occurs with increasing frequency in patients admitted to intensive care unit (ICU), and elderly patients are particularly vulnerable. AKIN (AKI network) classification is widely used to gauge severity of AKI, but has not been formally tested in geriatric patients for its efficacy.

Methods: We conduct a multicenter, prospective observational study, based on the NSARF (National Taiwan University Hospital Surgical ICU Associated Renal Failure) database. A total of 4964 elderly patients (defined as age more than 65) who developed AKI after admission for major surgeries between 1 Jan, 2002 and 31 Dec, 2008 were enrolled, divided into 3 categories according to age: younger-old (65-75), old (75-85) and oldest old (>85). Demographic profiles, comorbidities, types of surgery, and ICU treatment variables were all collected. We determined the predictive power of AKIN classification for 180-day in-hospital mortality after adjusting relevant factors.

Results: Overall, 49.2%, 41.4% and 9.4% of patients were each classified in younger old, old and oldest old group. In-hospital mortality increased stepwise from 15% to 16% and 21% as age rose. Age, AKIN stage (hazard ratio (HR) 1.707 for stage III, p<0.001), hypertension (HR 1.345, p<0.001), diabetes mellitus (HR 1.348, p<0.001) and treatment related factors (tracheostomy, Swan-Ghanz catheter use) were associated with higher risk of adverse outcome. Cox multivariate-adjusted analysis showed that patients with AKIN stage I and II had similar outcome across all age categories. In addition, younger-old patients with AKIN stage III had worse outcome than the oldest-old with stage I insult (HR 1.902 vs 1.742), while the old and the oldest-old with stage III insult denoted a higher mortality.

Conclusions: The finding of this study exemplifies the aging effect on utility of AKIN staging for AKI in predicting hospitalization outcome in geriatric population, especially during milder form of AKI.

FR-PO1081

Border-Crossers' Nephropathy: The Risk of Coming to America Nduka-Obi Ossai, Harold M. Szerlip. *Department of Medicine, University of Arizona College of Mdicine, Tucson, AZ.*

Background: The 380 mile border between Mexico and Arizona has become a prime entry point for persons wanting to enter the United States. Because of increased enforcement, these individuals usually attempt to cross the border in desolate areas where they may wander for days without food or water before being "rescued". The Summer of 2010 was one of the five hotest summers on record. During 2010, 232 individuals died trying to cross the into Arizona and 212,202 people were apprehended in the Tucson Sector. The University of Arizona Medical Center, South Campus is one of the closest tertiary care medical centers to the Mexican border. Detainees with medical problems are frequently brought to this campus. Herein we describe our experience with myoglobinuric acute kidney injury (AKI) in these border-crossers.

Methods: We reviewed the records of all individuals admitted between June 1-December 31, 2010 with AKI as defined by AKIN criteria who also had an elevation of CPK > 1000 IU/L. We recorded the age, gender, temperature, creatinine on presentation, CPK on presentation, urine output in first 24 hours, need for dialysis, length of stay and creatinine on discharge.

Results: During this time period 24 people were diagnosed with myolobinuric AKI. On presentation all patients were vigorously resuscitated with either 0.9% NaCl or a mixture of NaCl and NaHCO3. The mean age was 31.7 years (range 18-53). 21 were male and 3 female. They had wandered in the desert between 1and 8 days with a mean of 3.9 days. Five had stage 1 AKI, 7 stage 2 and 12 stage 3. Three patients required dialysis. Only 1 patient was oliguric and only 1 had a temperature > 100.6 on arrival. CPKs ranged between 1355 and 447,966 IU/L. Length of stay was between 2 and 17 days with a mean of 4.3 days. One patient was discharged on hemodialysis and 4 were discharged with creatinines >1.3 mg/dl.

Conclusions: This is the largest series of myoglobinuric AKI reported in border-crossers. The presumed etiology is excessive heat combined with volume depletion and stressful exercise. We have coined the term "border-crossers nephropathy" for this disorder. Many of these patients may develop CKD and require nephrologic care in their home country.

FR-PO1082

Acute Kidney Injury, Length of Stay and In-hospital Mortality in Critically Ill Cirrhotic Patients: A Cohort Study Mário Raimundo, Maria Joao Melo, Ana Cortesao Costa, Antonio Gomes da Costa, Jose António Lopes. *Nephrology and Kidney Transplantation, Hospital de Santa Maria - CHLN, Lisbon, Portugal.*

Background: Recently, members of the Acute Dialysis Quality Initiative (ADQI) and the International Ascites Club (IAC) proposed the definition of AKI in cirrhosis as an increase in serum creatinine of >50% from baseline or a rise in serum creatinine of >26.4 mmol/l (>0.3 mg/dl) in <48 h. The aim of this study was to relate this classification to length of stay and in-hospital mortality in a cohort of critically ill cirrhotic patients.

Methods: One-hundred eighty-two cirrhotic patients [mean age: 56 (12.2) years; 105 Male; 171 Caucasian; Child-Pugh score: 9.3 (2.4); Model for End-stage Liver Disease

(MELD): 36.2 (7.6); and Sequential Organ failure Assessment (SOFA): 5.4 (3.5)] admitted to the Gastrenterology and Hepatology Intensive Care Unit (ICU) of the Hospital de Santa Maria (Lisbon, Portugal) between January 2003 and December 2005 were retrospectively evaluated.

Results: Forty-seven patients (25.8%) developed had AKI during ICU stay. Those patients had lengthened time of ICU (P<0.0001) and hospital stay (P=0.002), as well as higher in-hospital mortality as compared with patients with no AKI (63.8% versus 8.1%, P<0.0001). AKI was independently associated with increased in-hospital mortality (adjusted odds ratio 6.9, 95% confidence interval 2.4-20.2, P<0.0001). The area under the receiver operator characteristic curve for in-hospital mortality was 0.806 for AKI (P < 0.0001).

Conclusions: AKI was associated with increased length of stay and in-hospital mortality among critically ill cirrhotic patients, and it presented good discriminative power regarding in-hospital mortality.

FR-PO1083

Renal Function Estimation Equations Using Non-Steady State Serum Creatinine Perform Better among Patients with Low Baseline Renal Function Sevag Demirjian,[1] Brian R. Lane,[2] Jesse D. Schold,[3] Steve Campbell,[4] Emilio D. Poggio.[1] *[1]Nephrology, Cleveland Clinic, Cleveland, OH; [2]Urology, Spectrum Health and Michigan State University, Grand Rapids, MI; [3]Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH; [4]Urology, Cleveland Clinic, Cleveland, OH.*

Background: Estimation of glomerular filtration rate (eGFR) in subjects with acute kidney injury (AKI) is problematic due to the non-steady state of serum creatinine (sCr). We examined the agreement of sCr based estimation equations with measured GFR (iGFR) during the immediate post-operative course in subjects undergoing nephrectomy.

Methods: we measured GFR using I-iothalamate renal clearance within a week of nephrectomy procedure. Only subjects with post-operative sCr rise of 0.3 mg/dl or higher were included in the analysis. We compared iGFR with eGFR using Pearson's correlation (ρ), and concordance correlation coefficients (CCC) in subjects with or without baseline chronic kidney disease (CKD). CKD was defined as baseline eGFR < 60 mL/min/1.732. eGFR was calculated using MDRD 4-variable, CKD-EPI and Jelliffe estimation equations based on sCr drawn at the time of iGFR measurement.

Results: 69/90 subjects who underwent nephrectomy sustained post-operative sCr rise of 0.3 mg/dl or greater. Mean age was 61 ± 11, and 55/69 were male. Baseline sCr was 1.2 ± 0.4, and 25/69 (36%) had baseline CKD. The correlation of eGFR with iGFR was particularly strong among CKD patients.

Correlation of measured GFR with serum creatinine based estimation equations in all subjects, and per baseline chronic kidney disease:

	All		CKD		No CKD	
	ρ	CCC	ρ	CCC	ρ	CCC
MDRD*	0.81	0.75	0.86	0.75	0.78	0.72
CKD-EPI*	0.81	0.74	0.86	0.73	0.78	0.71
Jelliffe*	0.81	0.77	0.93	0.88	0.76	0.7

*Glomerular filtration rate estimation equations;ρ, Pearson's correlation coefficient; CCC, concordance correlation coefficient.

Conclusions: sCr based estimation equations, particularly Jelliffe's equation, correlate well with measured GFR in subjects with post-operative rise in sCr and baseline CKD. Whereas, all three estimation equations had modest correlation in subjects without baseline CKD.

Funding: Clinical Revenue Support

Red Blood Cell Distribution Width Is an Independent Predictor of Mortality in Acute Kidney Injury Patients Treated with Continuous Renal Replacement Therapy Hyung Jung Oh, Seung Jun Kim, Dong Eun Yoo, Mi Jung Lee, Dong Ho Shin, Seung Hyeok Han, Tae-Hyun Yoo, Shin-Wook Kang. *Dept. of Int. Medicine, College of Medicine, BK21, SBSI, Yonsei Univ., Seoul, Korea.*

Background: Red blood cell distribution width (RDW) has been found to be independently associated with adverse outcomes in patients with heart failure and coronary heart disease. However, little is known on the relationship between RDW and clinical outcomes in acute kidney injury (AKI) patients treated with continuous renal replacement therapy (CRRT). This study was conducted to investigate whether RDW was associated with overall mortality in AKI patients treated with CRRT.

Methods: A total of 470 AKI patients, who were treated with CRRT at Yonsei University Health System, Seoul, Korea, were included. Patients were divided into 2 groups according to the RDW levels at CRRT initiation, and clinical and laboratory data, echocardiographic findings, and overall mortality at 28-day were compared between the two groups.

Results: RDW ranged from 11.7 to 28.0%, and 317 patients (67.5%) had RDW above the upper limit of normal (>14.5%). Patients with high RDW values had higher white blood cell (WBC) counts, and lower hemoglobin (Hb) and total cholesterol levels compared to patients with normal RDW values. In addition, there were significant correlations between RDW values and WBC counts, Hb levels, and total cholesterol concentrations. However, there were no significant differences in age, gender, SOFA score, eGFR, albumin, and echocardiographic parameters between the two groups. Patients with high RDW values exhibited significantly higher 28-day mortality rates than patients with low RDW levels in Kaplan-Meier analysis (p<0.01). Univariate Cox proportional hazard analysis revealed that baseline RDW levels, SOFA score, mean arterial pressure, and total cholesterol concentrations were associated with mortality. In multivariate analysis, RDW value at CRRT initiation was a significant independent predictor of 28-day overall mortality after adjusting for other risk factors.

Conclusions: The results of this study suggest that RDW could be an additive predictor for overall mortality in AKI patients on CRRT.

FR-PO1085

Analysis of Acute Kidney Injury and Its Prediction by Urinary Biomarkers in Adult Japanese ICU Patients Haruyo Ujike,[1] Yohei Maeshima,[1] Masaru Kinomura,[1] Kiyoshi Mori,[2] Daisuke Saito,[1] Hiroko Yamasaki,[1] Hiroyuki Watatani,[1] Norikazu Hinamoto,[1] Hitoshi Sugiyama,[1] Kazuwa Nakao,[2] Hiroshi Morimatsu,[3] Hirofumi Makino.[1] *[1]Medicine and Clinical Science, Okayama Univ. Graduate School of Medicine, Okayama, Japan; [2]Medicine and Clinical Science, Kyoto Univ. Graduate School of Medicine, Kyoto, Japan; [3]Anesthesiology, Okayama Univ. Med. School, Okayama, Japan.*

Background: Acute Kidney Injury (AKI) is frequently complicated in critically ill patients in intensive care unit (ICU), and associated with increased mortality. This study aims to determine the clinical characteristics of AKI and to evaluate urinary biomarkers to predict *de novo* onset of AKI.

Methods: We prospectively collected data of patients admitted to the ICU in the Okayama University Hospital (Nov. 2010-May 2011). Patients already in end-stage renal disease and receiving renal replacement therapy (RRT) were excluded. Urine was collected within 24 h of ICU admission (Day 1). Urinary levels of neutrophil gelatinase-associated lipocalin (NGAL), NAG and albumin were determined and were normalized to creatinine levels.

Results: Of the 86 patients, 23 (26.7%) developed AKI based on the AKIN criteria. The mean age was 65 in non-AKI and 60 in AKI group and the mean baseline eGFR was 72 and 74 ml/min/1.73m2, respectively. Surgical operation in the non-AKI (92%) and the AKI (74%) group was the leading cause of ICU admission. AKI was frequent in the recipients of liver transplantation (7 out of 9 developed AKI). In the AKI group, 2 patients (8.6%) required RRT and a patient died. Overall, the ratio of serum Cr at Day 3 to Day 1 after admission to ICU was positively correlated with urinary NGAL/Cr ratio (R=0.46, P=0.001) or NAG/Cr ratio (R=0.33, P=0.019). In 15 cases developing de novo AKI, the levels of urinary NGAL/Cr and NAG/Cr were significantly elevated compared with non-AKI group (126.2 vs. 40.3 μg/gCr, P=0.003; 58.9 vs. 13.8 U/gCr, P<0.0001, respectively), but urinary levels of albumin/Cr was not significantly elevated.

Conclusions: These findings suggest clinical significance of urinary NGAL and NAG as useful biomarkers superior to urinary albumin in predicting the onset of AKI in critically ill patients.

FR-PO1086

Low Risk of Contrast-Induced Nephrotoxicity after Coronary Angiography and Intervention in Modern Clinical Practice Jonas Spaak, Masih Khedri, Majid Kalani, Stefan H. Jacobson. *Clinical Sciences, Danderyd University Hospital, Karolinska Institutet, Stockholm, Sweden.*

Background: Many patients with kidney dysfunction are not provided invasive diagnostic and therapeutic interventions of concern for contrast-induced nephropathy (CIN), while 40% of all our patients with acute coronary syndrome (ACS) have at least moderately reduced kidney function (GFR<60 mL/min). However, clinical experience indicate that CIN is becoming less frequent than earlier reported. Understanding the clinical risk of CIN is crucial to provide correct treatment to patients with acute or chronic coronary heart disease and reduced kidney function.

Methods: We aimed to assess current incidence and predictors of CIN, and long-term kidney function after coronary angiography (CAG) and/or intervention (PCI) in a modern setting using low amounts of low-osmolality contrast agents.

Results: We retrospectively evaluated all 1227 patients whom during 2009 underwent CAG/PCI at our University Hospital Clinic. S-creatinine levels were assessed within 2-years around the procedure.

Data was available to evaluate CIN in 384 patients. Of these CIN occurred in 21 (5.5%). Of these, 6 patients suffered concomitant severe illness. Six patients (1.8%) of 332 with available follow up data developed persistent kidney injury. CIN was relatively less common in patients with reduced kidney function. GFR was significantly higher in the CIN group (85±31 vs. 69±20 mL/min, p=0.025), and the used contrast amount was significantly lower (86± 42 vs. 110±51, p=0.035).

Conclusions: Our main finding is that current incidence of CIN is lower than previously reported, also among patients with reduced kidney function. The inverse relationship between kidney function and CIN indicate that invasive procedures may be underutilized in these patients.

Vancomycin-Induced Acute Kidney Injury (AKI): An Under-Recognized Issue with Increasing Incidence Preventable by Mandatory Drug and Serum Creatinine Monitoring during Porlonged Administration Talla A. Rousan, Omar S. Abu-Romeh, Ahmad Bilal, Kai Lau. *Medicine, University of Oklahoma, Oklahoma City, OK.*

Background: For decades, IV vancomycin has been used with remarkable efficacy to treat gram positive bacteria, notably methicillin-resistant staphalococcal (MRS) aureus (A) or epidermis (E). When levels are closely monitored & doses continually adjusted based on weights, clinical indications, ongoing & changing renal functions, chronic parenteral vancomycin is generally considered quite safe.

Methods: Recently, acute kidney injury appears to be on the rise, largely due to the increasing incidence of documented MRSA and MRSE and also due to the exponentially growing utilization of vancomcyin for both infections by bacteria with known sensitivity as well as infections like "Health Care Facility Acquired (HCFA)" pneumonia. In the latter scenario, the current Infectious Disease guideline recommends the empiric coverage of presumed MRSA with vacnomycin, hence its widespread prescriptions over the last few years.

Results: In the course of a month on renal consults covering 449 acute adult beds, we encountered & treated 7 cases of significant ARF that developed in patients treated with vancomycin. Based on serial drug levels, daily & cumulative administered doses, the temporal relationship, & the course of renal failure and recovery on stopping vancomycin, we excluded other confounding variables to establish vancomycin as the etiology. The estimated baseline creatinine clearance was 103 mL/min with an estimated nadir of 18.4 mL/min. All patients sustained AKI with a mean decline in clearance of 25 mL/min ($p < 0.01$) with a recovery time of 33 days. On average, patients received drug for 16 days prior to recognizing AKI. Mean cumulative dose was 34.5 g with a mean peak level of 78.3 mg/L.

Conclusions: We recognize the efficacy of vancomycin in treating different infections. Kidney function should be regularly monitored during treatment besides checking vancomycin trough levels for avoidance & early detection of renal failure. At the same time, subtle increments in creatinine values should not be taken lightly as they may reflect decline in kidney function requiring prompt dose adjustment.

Factors Affecting Timing of Dialysis Initiation in Acute Kidney Injury (AKI) in Intensive Care Unit (ICU) Charuhas V. Thakar,[1,2] Anthony Leonard,[1] James Rousseau.[1] [1]*Internal Medicine/Nephrology, University of Cincinnati, OH;* [2]*Medical Service/Renal Section, Cincinnati VA, Cincinnati, OH.*

Background: Although it is argued that early initiation of dialysis may be beneficial in AKI, it remains a subjective clinical decision based on multiple factors.

Methods: We conducted an online survey of U.S. and international nephrologists to study the factors affecting initiation of early dialysis in AKI in ICU. We studied how parameters used in determination of dialysis initiation influenced this decision across three case scenarios (predicted hospital mortality of < 10%, 10 – 30% and > 30% respectively).

For each case, 4 questions were asked about decision to initiate dialysis within 24 hours based on given clinical information; Q1 – subjective likelihood; Q2 – blood urea nitrogen (BUN) levels (< 50, 50 – 75, 76 – 100, > 100 mg/dl) considered in this decision; Q3 – creatinine (Cr) elevation (2 – 3 times; > 3 times; absolute level > 5 mg/dl regardless of change) considered important; Q4 – a rank order of parameters [BUN level, Cr change from baseline, oxygen saturation (O2 sat), potassium (K) level, and urine output]. (1 - most, and 5 - least influential). McNemar's and t-test was used for comparison.

Results: Surveys of 119/172 nephrologists who responded to all questions were analyzed. There were 87% males, 73% were in practice for > 5 years, and 70% practised in the U.S.

The proprtion of subjects likely to initiate early dialysis increased (76% to 94%) with predicted mortality ($p < 0.0001$). Proportion of subjects considering dialysis at a BUN level < 75 mg/dl increased from 17% to 40% across three cases ($p < 0.0001$). Proportion of subjects choosing absolute Cr to be influential went from 60% to 43% across the three cases ($p < 0.0001$). Mean ranking for O2 sat went down (more influential) and K level went up (less influential) as predicted mortality increased ($p < 0.0001$). Rank for BUN and Cr elevation were similar across cases.

Conclusions: More severily ill subjects are more likely to be initiated on early dialysis. Rank order analysis suggests that dialysis decision is influenced by "imminent" indications rather than elevation of Cr from baseline or BUN level.

Recovery from Dialysis-Dependent Acute Tubular Necrosis Sumit Mohan, Edwin D. Huff, William M. McClellan, The FFBI Data Committee. *Fistula First Breakthrough Initiative.*

Background: Acute kidney injury is associated with an increased risk of end stage renal disease and a higher mortality, particularly in patients with underlying CKD. The need for continued renal replacement therapy (RRT) at the time of discharge from a hospitalization for an episode of acute renal failure (ARF) has increased over time. Acute Tubular Necrosis (ATN) remains the one of the most common causes of ARF among hospitalized patients and frequently requires RRT – and at times for prolonged periods. An estimated <1% of patients who experience ATN go on to develop ESRD, but the rate of recovery of renal function among patients who are dialysis dependent after an episode of ATN is unclear.

Methods: We reviewed ESRD registration data from the 2728 form in the United States for 2008 and 2009 and patient record updates signifying change in dialysis services at the patient's dialysis center due to renal recovery.

Results: We found that 3.48% of patients had a primary diagnosis of "Tubular Necrosis" (5836). Discontinuation of dialysis as a result of recovery of renal function over the subsequent 24 months was reported in 6.65% of all ESRD patients and 38% of patients with ATN ($p= 0.01$). Among all ESRD patients with recovery of renal function, 20% had a primary diagnosis of ATN at the initiation of dialysis. The median time to reported recovery of renal function for pts with dialysis dependent ATN was 41 days, compared to a median of 74 days for all pts with recovery of renal function.

Year	Number of new ESRD pts	% of patients with ATN as primary diagnosis	% of patients with recovery of renal function in ≤ 24 months	% of ATN patients with renal recovery in ≤ 24 months	Median duration to recovery of renal function
2008	101,359	3.36%	6.6%	37.6%	41 days
2009	104,040	3.59%	6.7%	38.2%	40 days

Conclusions: Recovery of renal function occurs in over a third of patients with dialysis dependent ATN – a significantly higher rate (see table) than the rest of the US ESRD program.

FR-PO1090

Can Urinary Kidney Injury Biomarkers Affect Clinical Decision Making in the Emergency Department? Kai M. Schmidt-Ott,[1] Thomas L. Nickolas,[2] Eugenia Singer,[1] Catherine Forster,[2] Meghan E. Sise,[2] Abdallah Sassine Geara,[3] Philip Imus,[2] Friedrich C. Luft,[1] Jonathan M. Barasch.[2] [1]*Charite Berlin, Max Delbrueck Center, Germany;* [2]*Columbia University, NY;* [3]*Staten Island University Hospital, NY.*

Background: Conventional diagnostic strategies may inadequately detect patients at risk for poor clinical outcomes. Measuring urinary neutrophil gelatinase-associated lipocalin (uNGAL), a marker of kidney injury, may assist in identifying patients that require evaluation by a nephrologist.

Methods: Unselected patients were recruited from three emergency departments (n=1635) in the United States and Germany and serum creatinine (sCr) and uNGAL levels were measured. The composite outcome of the study was in-hospital hemodialysis initiation or mortality. Nephrology consults ordered within 24 hours of admission served as a surrogate of clinical decision making by physicians who were blinded to uNGAL measurements.

Results: uNGAL was an independent predictor of the composite outcome and improved net reclassification by 26.1% ($p=0.0001$). Patients who had sCr<1.4 mg/dl and uNGAL<104 ng/ml (sCr-/uNGAL-) (n=966) had low rates of clinical events (2.5%) and low rates of early nephrology consultation (2.6%), while patients who had sCr≥1.4 mg/dl and uNGAL≥104 ng/ml (sCr+/uNGAL+) (n=174) had high rates of clinical events (15.5%) and high rates of early nephrology consultation (50.9%). Patients who were sCr-/uNGAL+ (n=227) or sCr+/uNGAL- (n=236) were in an intermediate risk category (clinical event rates 5.3% and 5.1%, respectively). However, nephrology referral rates differed markedly between these categories: sCr-/uNGAL+ had an early referral rate of only 3.1%, while sCr+/uNGAL- patients had an early referral rate of 33.1% ($p<0.001$ by Chi-square test).

Conclusions: Stratification by sCr and uNGAL in the emergency department prospectively separated low risk (sCr-/uNGAL-), intermediate risk (sCr-/uNGAL+ or sCr+/uNGAL-) and high risk (sCr+/uNGAL+) patients. These risk categories were not adequately reflected in nephrology referral rates by physicians unaware of uNGAL levels, suggesting a marked potential for uNGAL to improve clinical decision-making.

Renal Adverse Effects of Sunitinib Seon Ha Baek, Dong Ki Kim, Kook-Hwan Oh, Yon Su Kim, Jin Suk Han, Kwon Wook Joo. *Department of Internal Medicine, Seoul National University Hospital.*

Background: Sunitinib is an oral multitargeted small-molecule tyrosine kinase inhibitor mainly used in the treatment of metastatic renal cell carcinoma and its indication is being extended to other carcinomas. Although cases of mild proteinuria were frequently reported and high grade proteinuria and acute kidney injury have been recently reported, renal adverse effects of sunitinib have not been extensively reported. The aim of this study was to evaluate the incidence and risk factors of proteinuria and renal insufficiency (RI) associated with sunitinib.

Methods: We performed a retrospective medical record review of patients who had received sunitinib for more than 3 months. A new onset proteinuria was defined as ≥ 2+ and aggravation of preexisting proteinuria by more than 2 grades on dipstick test, or more than 2 fold increase on urine protein creatinine ratio. RI was defined as an increase ≥ 50 % or ≥ 0.5 mg/dL in serum creatinine (Cr) level.

Results: A total of 155 patients (mean age 58.7±12.6 yr) were enrolled with a mean baseline Cr of 1.24 mg/dl. Proteinuria developed in 15/111 (13.5%) patients and preexisting proteinuria was aggravated in 6/111 (5.4%) patients. Nephrotic range proteinuria was detected in 4 patients, and nephrotic syndrome was identified in only one patient. Following discontinuation of sunitinib, proteinuria was improved or disappeared in 12/17 (70%) patients but persistent in 5/17 (30%) patients. Risk factors for proteinuria were dyslipidemia (OR=8.38, 95% CI 1.76 to 39.98, $p=0.008$) and renal insufficiency (OR=4.07, 95% CI 1.20

to 13.83, p=0.025) at the start of sunitinib. RI was detected in 12/155(7.7%) patients and maximum Cr was 3.31 mg/dl. Risk factors of RI was old age (OR=1.08, 95% CI 1.01 to 1.16, p=0.023). RI was improved in 2 patients (16.6 %), but persisted in 10 patients (83.4 %) after the cessation of sunitinib.

Conclusions: There is a significant risk of developing renal adverse effects among patients receiving sunitinib. Although clinical significance of those adverse effects is still uncertain, proteinuria and renal dysfunction were common. Regular monitoring of renal adverse effects should be considered in patients who are on sunitinib.

FR-PO1092

Renal Tubular Cells Induce Early Pro-Inflammatory and Late Alternative Activation in Macrophages Sarah C. Huen, Lloyd G. Cantley. *Internal Medicine, Section of Nephrology, Yale University School of Medicine, New Haven, CT.*

Background: Macrophage infiltration into the kidney after ischemia reperfusion can contribute to both the initial injury as well as subsequent recovery. A classically activated inflammatory phenotype predominates early after reperfusion while an alternatively activated, anti-inflammatory phenotype predominates later during the repair phase. How paracrine signals from renal tubular cells influence these macrophage phenotypes is unknown.

Methods: Bone marrow-derived macrophages (BMM) were harvested from wild-type C57BL/6, MyD88-/-, Il-4ra-/-, and Stat6-/- mice. Mouse proximal tubular (MPT) cells were cultured in serum free media for 48 hours to generate MPT conditioned media (CM). BMM were cultured in the presence or absence of MPT CM and harvested for protein or mRNA analysis.

Results: The NF-kB protein p65 (RelA) is rapidly phosphorylated in wild-type BMM cultured in MPT CM, followed by increased expression of the classic pro-inflammatory markers Il-1b, Tnfa, Il-6, and Csf3 within 2 hours. By 12 hours after MPT CM incubation, the pro-inflammatory genes were downregulated, whereas alternative activation markers Arg1 and MR were highly upregulated. The initial pro-inflammatory response was prevented in BMM lacking MyD88 or following inhibition of NF-kB using the IKK2 inhibitor, SC-514. However, the late expression of Arg1 and MR was not prevented in BMM lacking the Il-4/Il-13 receptor Il-4ra or the downstream effector Stat6, suggesting that tubular cell-mediated alternative macrophage activation does not occur via the Il-4/Il-13 signaling pathway. Interestingly, Stat3 is activated in BMM at both early (30 minutes) and late (24 hours) time points after exposure to MPT CM, identifying this as a potential mediator of tubular cell-dependent alternative activation.

Conclusions: Paracrine signals from MPT cells induce sequential macrophage activation from a NF-kB dependent pro-inflammatory phenotype to an anti-inflammatory phenotype that is Il-4 and Stat6 independent. This sequential macrophage activation is similar to that seen in vivo after renal ischemia reperfusion injury, suggesting that tubular cells themselves can regulate the phenotype of infiltrating macrophages.

FR-PO1093

Renal Dendritic Cells Ameliorate Ischemia Reperfusion Injury Anju Yadav, Divya Anna Verghese, Barbara T. Murphy, Bernd Schroppel. *Nephrology and Transplantation Institute, Mount Sinai School of Medicine, New York, NY.*

Background: Renal DC represents an important population of immune cells within the kidney and found to be functionally important in nephrotoxic acute kidney injury (AKI). In this study we explored whether renal DCs are functionally important in ischemia reperfusion (IR) injury.

Methods: DTR-CD11cGFP mice were used with or without Diphtheria toxin injection prior IR injury (4 ng/g; i.p.). Depletion of renal DCs after DT injection was confirmed by flow cytometry analysis and IF. Bilateral renal pedicles were clamped for 30 minutes and kidneys were reperfused for 24 hrs. Renal function was assessed by serum creatinine and injury scored blindly by H&E. Single cell suspensions were made after renal tissue digestion with collagenase-D (2mg/ml) and flow cytometry analysis was done to phenotype renal immune cells.

Results: 30 minutes of IR caused significant renal histological and functional injury compared to sham controls assessed by serum creatinine and HP score. Depletion of CD11c before IR injury significantly worsened IR injury, evidenced by higher serum creatinine and more tubular damage than non-depleted mice (CD11c+).

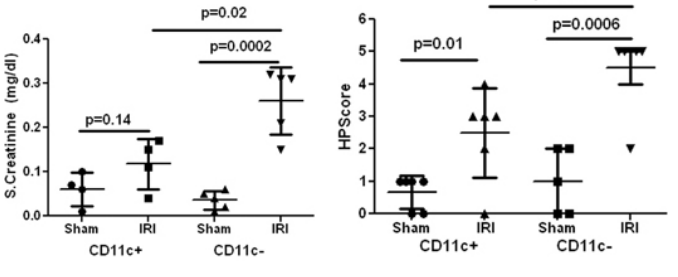

Fig. 1: DC depletion exacerbates IR injury. Serum creatinine (left) and HP score (right) of mice with or without CD11c depletion 24 hr after IR injury.

Renal DCs produced 2-fold more IL-10 by Western blot and 5-fold more mRNA transcripts after IR injury compared to sham controls. Total tissue IL-10 levels were similar in sham and DCs depleted renal immune cells. Furthermore we found that IL-10 gene expression was increased 2-fold when renal DCs were stimulated with the TLR2 ligand PGN, suggesting that IL10 production can be triggered by TLR activation after IR injury.

Conclusions: Renal DCs produce IL-10 after IR injury and afford significant protection for acute kidney injury.

PO1094

Regulatory T Cell Depletion during Established AKI Worsens Subsequent Brain Injury in Mice Manchang Liu,[1] Bing Wang,[1] Sylvain Dore,[2] Hamid Rabb.[1] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]University of Florida, Gainesville, FL.*

Background: Acute kidney injury (AKI) is well-established to lead to neurologic changes. Ischemic AKI in mice leads to brain cellular and soluble inflammation with significant an increase in keratinocyte-derived chemokine (KC) protein (J Am Soc Nephrol 2008 19:1360-70). Ischemic AKI enhances the susceptibility to the subsequent ischemic stroke (PO1748, ASN Renal Week 2009). In this study, we tested the mechanistic role of regulatory T cells (Treg) and KC receptor CXCR2 on ischemic stroke outcomes in AKI mice.

Methods: Young male C57BL/6 wild type mice (6-8 wk old) underwent either a sham operation or a 30 min of bilateral kidney warm ischemia following by reperfusion. On day 4 after kidney surgery, all mice underwent ischemic stroke by permanent (distal) middle cerebral artery occlusion (pMCAO) for 90 min and were followed up for 4 d. Mice were treated with antibody against Tregs (PC61) (500 µg per mouse, i.p.), antisera against CXCR2, or control antibody/sera at day 1 and at day 4 after AKI. Mice were sacrificed 8 days after kidney surgery for brain stroke infarct volume measurement.

Results: Depletion of circulating Treg was confirmed by flow cytometry analysis with a significant decrease in the percentage of CD4+CD25+Foxp3+ Treg of splenocytes (PC61 vs. IgG: 1 % vs. 14 %, p<0.001, n=10). AKI mice had higher brain infarct volumes after stroke compared with sham AKI stroke mice (AKI vs. Sham: 35.2% ± 3.4 vs. 23.9% ± 1.9, p=0.022, n=5). The degree of stroke infarct volume was associated with serum creatinine level (r=0.62, p=0.006, n=18). AKI mice treated with PC61 during established AKI had significant increase in stroke infarct volume when compared to AKI mice with IgG. (39.5% ± 1.6 vs. 32.9% ± 2.5, p=0.04, n=10 per group). No significant change was seen on stroke infarct volumes by blocking KC receptor CXCR2 (CXCR2 sera vs. Normal sera: 24.1% ± 5.1 vs. 20.9% ± 2.6, p=0.57, n=5-6).

Conclusions: These data demonstrate that ischemic AKI exacerbates subsequent stroke, and one underlying mechanism could be via regulatory T cells. Regulatory T cells have the potential, if harnessed appropriately, to decrease the high distant organ effects of AKI.

FR-PO1095

Humoral Immune Response Is Enhanced by Renal Ischemia-Reperfusion Injury Richard C. Fuquay,[1] Brandon Renner,[1] Derek Strassheim,[1] Van Willis,[2] Kim McFann,[1] Joshua M. Thurman.[1] *[1]Nephrology, University of Colorado Denver Health Science Center, Aurora, CO; [2]Rheumatology, University of Colorado Denver Health Science Center, Aurora, CO.*

Background: Ischemia-reperfusion injury (IRI) is a model of acute kidney injury (AKI) that is characterized by robust renal inflammation and temporary renal failure of 48-72 hours. Renal transplant recipients that suffer delayed graft function (DGF) in the setting of prolonged ischemia time are felt to have an increased risk of long-term immunologic injury. We sought to investigate the effect of AKI on the humoral immune response to extra-renal antigens.

Methods: Mice have a reliable immunoglobulin response to nitrophenol keyhole limpet hemocyanin (NP-KLH), an innocuous T-cell dependent antigen.

Results: In mice immunized 24 hours before IRI vs. sham surgery there was no observed difference in NP-KLH specific antibody levels between the two groups up to 56 days after surgery. However, when mice were immunized 24 hours after IRI vs. sham surgery (the peak of renal failure in this model), the IRI-treated mice had increased levels of NP-KLH specific IgG1 (p=0.0376 by mixed model analysis) beginning at 35 days after surgery. The increased IgG1 response was not seen with unilateral ischemia, typified by local inflammation but not renal failure. Furthermore, the total IgG1 and IgM (not antigen-specific) were not different in IRI vs. sham mice; this effect is not due to polyclonal immunoglobulin upregulation. There was no difference between the two groups in the percentage of splenic lymphocytes expressing B220 (B cell marker) or CD 86 (marker of B-cell activation, also known as B7-2).

Conclusions: In summary, IRI-treated mice develop a greater antigen-specific IgG_1 response than sham-treated controls. This effect is not seen with unilateral IRI and is not due to global B cell activation or a polyclonal immunoglobulin increase. Experiments are ongoing with T-cell independent antigens and in mice with targeted deletion of innate immune factors. Ongoing experiments may provide a mechanistic explanation why DGF kidneys suffer long-term immunologic injury and reveal therapeutic interventions that could improve allograft survival.

FR-PO1096

Heat Shock Protein-70 (HSP70) Induced Renoprotective Effect Is Mediated by CD4+ CD25+ Foxp3+ Regulatory T Cells in Ischemia/Reperfusion (I/R) Induced Acute Kidney Injury Kichul Yoon, Won-Yong Cho, Sang-Kyung Jo, Sung Yoon Lim, Hyoung-Kyu Kim. *Internal Medicine, Anam Hospital, Korea University, Seoul, Korea.*

Background: Recent reports has demonstrated the immune modulatory effect of HSPs. HSP70 induced by heat preconditioning(HP) has been shown to decrease inflammation and injury in I/R induced AKI. CD4+ CD25+ Foxp3+ regulatory T cells(Tregs) has recently been recognized as an important player in decreasing kidney injury after I/R. The aim of this study was to test whether HP induced HSP70 exerts renoprotective effect through Tregs.

Methods: Thirty min bilateral I/R injury was done with or without heat preconditioning(42C for 15min) in mice. Quercetin for inhibition of HSP70, or PC61 for depleting Tregs, were administered and various molecular and flow cytometric analyses were performed.

Results: Splenocytes from HP mice demonstrated expansion of Tregs, and reduced proliferative response upon mitogenic stimuli. T cells from HP mice failed to reconstitute postischemic injury when adoptively transferred to T cell deficient mice in contrast to T cells from normal mice, suggesting that HP has immune modulatory function. While depleting Tregs before HP abolished the renoprotective effect, adoptive transfer of the cells back into Treg-depleted mice partially restored the beneficial effect of HP. Significantly increased Foxp3 gene expression as well as increased infiltration of Tregs into kidney were also observed in heat preconditioned ischemic kidneys. Immunohistochemistry and western blot demonstrated that HSP 70 was induced upon HP not only in kidney, liver or lung but also in immune cells in spleen. Inhibition of HSP70 by quercetin before HP suppressed the expansion of Tregs and this was associated with partial loss of beneficial effect of HP in I/R. Finally, transferring Tregs to quercetin-treated HP mice partially restored the beneficial effect of HP.

Conclusions: These results suggest that renoprotective effect of HSP70 might be partially mediated by their direct immune modulatory effect through Tregs. Further understanding of cytoprotective or immune modulatory mechanisms of various stress proteins might facilitate discovery of new targets or drug development in the field of AKI.

FR-PO1097

Inhibition of the c-fms Receptor Prevents Kidney Macrophage Accumulation and Is Renoprotective Following Ischemic Injury Meghan Clements, Michael Gershenovich, Christopher Chaber, Steven R. Ledbetter, Anna Zuk. *Cell Biology, Genzyme Corporation, Framingham, MA.*

Background: Colony stimulating factor-1 regulates proliferation, differentiation and survival of monocytes and macrophages by signaling through the c-fms macrophage receptor. Since the mononuclear phagocyte system mediates renal injury following ischemia-reperfusion (I/R), we hypothesized that inhibition of the c-fms receptor would be renoprotective.

Methods: A small molecule inhibitor of c-fms, was administered prior to and after bilateral renal ischemia.

Results: Vehicle-treated mice had significant increases in the number of CD11b+/F4/80+ macrophages in both the circulation and kidney 24 hrs post-reperfusion, correlating with peak levels of plasma creatinine and blood urea nitrogen (BUN). Treatment with a c-fms inhibitor significantly reduced CD11b+/F4/80+ macrophages in the kidney and blood, kidney levels of MCP-1 and plasma creatinine and BUN by approximately 50%. Thus, antagonism of c-fms prevents kidney macrophage accumulation and is renoprotective. However, macrophages also mediate kidney repair and fibrosis. By examining changes in monocyte/macrophage populations at various times post-reperfusion by CD11b and Ly6C expression, we show that CD11b+/Ly6CHigh cells appear 3 hrs post-reperfusion, which correlates with elevated tissue mRNA of pro-inflammatory IL-6 and CXCL1. This suggests that this population represents M1 macrophages. By 24 hrs post-reperfusion, the CD11b+/Ly6CHigh cells decrease and instead a CD11b+/Ly6CInt population dominates, returning to baseline by 5 wks post-reperfusion. A CD11b+/Ly6CLow population emerges 3 days post-reperfusion and is the only population elevated at 5 wks when interstitial fibrosis and inflammation are observed. Increased tissue mRNA of CD206 and arginase-1 suggest the Ly6CLow population represents M2 macrophages. Similarly, shifts in CD11b+/F4/80high/low populations are seen.

Conclusions: Collectively, these data define three distinct populations of monocytes/macrophages following renal I/R using the markers CD11b and Ly6C. Ongoing studies are investigating the role of these populations in kidney injury and repair and whether antagonism of c-fms could impact fibrosis.

Mechanisms of Uric Acid-Mediated HMGB1 Translocation and Release from Endothelial Cells (EC) May Rabadi, Mei-Chuan Kuo, Tammer N. Ghaly, Seham Rabadi, Mia Weber, Michael S. Goligorsky, Brian B. Ratliff. *New York Medical College, Valhalla, NY.*

Background: Based on findings that after IRI HMGB1 is released by the kidneys into the circulation, we examined the cellular localization and release of HMGB1 in EC. Due to its early and robust release after IRI, uric acid was examined as a potential mediator of HMGB1 release from EC.

Methods: Treatment of EC with uric acid resulted in increased HMGB1 mRNA expression and protein translation, effects that were blocked by inhibition of TLR4 receptor.

Results: Uric acid treatment of EC lead to the translocation of HMGB1 from the nucleus to the cytosol and release from the cell into either the cell culture medium (in vitro) or the circulation (in vivo), as determined by western blot analysis and immunofluorescence. We next aimed at identifying the mechanism by which uric acid induces the release of HMGB1. Treatment of EC with uric acid and an inhibitor of intracellular calcium release (TMB-8) or an inhibitor of MEK/ERK pathway (U0126) resulted in the retention of HMGB1 in the nucleus, while diminishing cytoplasmic and extracellular levels of HMGB1. We also examined the role of HMGB1 acetylation in mediating its translocation. Treatment of EC with uric acid caused acetylation of HMGB1 leading to its translocation and release from EC, an effect blocked by pretreating cells with ethyl pyruvate. Once released, HMGB1 was observed to have a positive feedback mechanism that promoted further translocation and release of HMGB1 from endothelial cells. We also demonstrate that uric acid and released HMGB1 induce EC angiopoietin 2 mRNA expression and protein release while activating intracellular NF-kB (as measured by luciferase reporter assay) and the pro-inflammatory response.

Conclusions: Uric acid through the TLR4 receptor mediates the transcriptional and translational HMGB1 response in EC by a mechanism that involves the release of intracellular calcium and the MEK/ERK pathway and the acetylation of HMGB1, which resulted in its translocation and release from the cell. Angiopoietin 2 expression and NF-kB activity were increased after uric acid and HMGB1 treatment. Mobilization of acetylated HMGB1 was reduced with ethyl pyruvate treatment.

HMGB1 Release from Kidneys during Renal Ischemia-Reperfusion Injury May Rabadi, Tammer N. Ghaly, Seham Rabadi, Michael S. Goligorsky, Brian B. Ratliff. *Medicine, New York Medical College, Valhalla, NY.*

Background: Factors that initiate cellular damage and trigger the inflammatory response cascade and renal injury are incompletely understood after renal ischemia-reperfusion injury (IRI). HMGB1 is a DAMP molecule that binds to DNA, but upon signaling translocates from the nucleus to the cytoplasm and subsequently released from necrotic and/or damaged cells.

Methods: We observed that HMGB1 is released by the IRI kidneys into the venous circulation. Immunohistochemical analysis of kidneys at different times after IRI showed release of HMGB1 into the circulation within minutes and up to 1 hour after the initial insult.

Results: The degree of HMGB1 release by renal cells was dependent on the duration of ischemic insult with progressively increased release occurring when ischemic times increased from 25 min to 50 min. We next examined the effect released HMGB1 has in promoting the pro- and anti-inflammatory cascade. Circulating HMGB1 induced rapid systemic surge (within 1 hour) of cyto- and chemo-kines including TNF-α, eotaxin, G-CSF, IFN-γ, IL-10, IL-1α, IL-6. FACS analysis revealed circulating HMGB1 mobilizes endothelial progenitor cells (Flk+, CD34+, CD45-) from the bone marrow, indicating its potential regeneration promoting effects. To examine the therapeutic efficacy of blocking the release of HMGB1, we treated mice with ethyl pyruvate during IRI. Ethyl pyruvate has previously been shown to block the nuclear-cytoplasmic translocation of HMGB1 in monocytes/macrophages. Here we demonstrated that release of HMGB1 by IRI kidneys into the venous circulation was blocked by ethyl pyruvate pretreatment. Renal function after IRI was improved when HMGB1 release was blocked with ethyl pyruvate, as judged by the serum creatinine retention. In long-term studies, two months after the ischemic insult, renal function continued to show improvement as urine albumin:creatinine ratios were decreased in IRI mice treated with ethyl pyruvate, as compared to non-treated IRI mice.

Conclusions: Despite putative pro-regenerative signaling, HMGB1 exerts a robust systemic pro-inflammatory response in IRI and inhibition of its release results in the short- and long-term functional benefits.

Functional Consequences of Inhibiting Exocytosis of Weibel-Palade Bodies (WPB) in Acute Renal Ischemia (IRI) Kaoru Yasuda,[1,2] Peter Jose Hayek,[1] Brian B. Ratliff,[1] Jonathan Mares,[1] Silvia Bertuglia,[3] Paolo Mascagni,[4] Michael S. Goligorsky.[1] *[1]New York Medical College, Valhalla, NY; [2]Nagoya University Graduate School of Medicine, Japan; [3]University of Pisa Medical School, Italy; [4]Italfarmaco Research Centre, Milan, Italy.*

Background: Exocytosis of WPB represents a distinct response of endothelial cells to stressors and local release of WPB contents leads to systemic escalation of this response.

Methods: We (SB and PM) synthesized a glycine-(Nα-Et)lysine-proline-arginine (ITF1697) peptide and demonstrated that it inhibits IRI-induced exocytosis of WPB and protects microcirculation. Here, mice were implanted with Alzet osmotic pumps (10μg ITF1697/kg/min at volume of 1 μl/h) for the duration of 3 days, and subjected to bilateral renal IRI.

Results: *En face* staining of aortic endothelial cells showed that WPB were depleted after 40-180 min post-IRI and this was significantly blunted in aortic preparations obtained from mice treated with ITF1697. Ischemia resulted in a marked renal injury and elevation of serum creatinine in mice treated with a vehicle. In contrast, renal injury and elevation of creatinine level were significantly ameliorated in mice subjected to IRI and receiving ITF1697. ITF1697 prevented systemic response to IRI: a significant surge in the levels of eotaxin and IL-8 (KC) (both components of WPB), IL-1α and IL-1β, and RANTES

were all prevented or blunted by the administration of ITF1697, whereas the levels of an anti-inflammatory IL-10 and MIP-1α were upregulated in ITF1697-treated animals. WPB exocytosis contributed to IRI-associated mobilization of EPC and HSC and ITF1697 blunted stem/progenitor cell mobilization. One month after IRI, mice treated with ITF1697 showed a significantly more pronounced degree of scarring than non-treated animals.

Conclusions: 1) application of ITF1697 inhibits exocytosis of WPB; 2) the systemic inflammatory response of IRI is in part due to the exocytosis of WPB and its blockade blunts it; 3) ITF1697 improves short-term renal function after IRI, but not the long-term fibrotic complications.

Slit2 Prevents Renal Ischemia Reperfusion Injury Swasti Chaturvedi,[1] Amandeep Bajwa,[3] Liping Huang,[3] Grace Lam,[2] Yi-Wei Huang,[2] Guang-Ying Liu,[2] John Brumell,[2] Mark D. Okusa,[3] Lisa Robinson.[1] *[1]Nephrology, The Hospital for Sick Children, Toronto, Canada; [2]Research Institute, The Hospital for Sick Children, Toronto, Canada; [3]Medicine, University of Virginia Health System, Charlottesville, VA.*

Background: Acute kidney injury (AKI) affects approximately 5% of hospitalized patients and leads to significant morbidity and mortality. Inflammation marked by recruitment of circulating leukocytes, particularly neutrophils, to the injured kidney is a key component of AKI caused by ischemia-reperfusion injury (IRI). The neuronal guidance cue, Slit2 and its receptor roundabout (Robo) prevent axonal migration during the central nervous system development. We have shown that Slit2 inhibits neutrophils chemotaxis towards diverse chemoattractants. We further aimed to determine the effect of Slit2 on individual steps of neutrophil recruitment cascade and to explore its therapeutic role in renal IRI.

Methods: The effect of Slit2 on neutrophil capture and adhesion was studied using microfluidics. Neutrophil transendothelial migration was studied using transwell assays. To test whether Slit2 prevents IRI, we used a mouse model of bilateral renal pedicle clamping. To study the effect of Slit2 on innate immune responses to infection, hepatic bacterial colony counts were measured after inoculating mice with *L.monocytogenes*.

Results: Slit2 reduced both neutrophil capture and adhesion to TNF-α stimulated endothelium under shear stress conditions ($p < 0.05$). Further Slit2 reduced chemoattractant induced neutrophil transendothelial migration in transwell assays ($p < 0.05$). Pre-treatment of mice with Slit2 before inducing renal IRI prevented the rise in serum creatinine in a dose dependent manner ($p < 0.05$ at the highest dose of Slit2 tested). Slit2 also prevented neutrophil and macrophage infiltration into the post-ischemic kidney ($p < 0.05$). Additionally, renal tubular necrosis and injury were significantly reduced by Slit2. The hepatic L.monocytogenes bacterial load was not increased following Slit2 treatment.

Conclusions: These findings suggest that Slit2 could be used to prevent and treat the inflammatory cell recruitment in AKI, without increasing susceptibility to bacterial infection.

FR-PO1102

The Effect p53 Inhibition in Ischemic Acute Kidney Injury Is Species Dependent and Is Determined by the Relative Contributions of Inflammation and Tubular Apoptosis Takashi Hato, Melissa D. Anderson, Timothy A. Sutton, Pierre C. Dagher. *Medicine/Nephrology, Indiana University School of Medicine, Indianapolis, IN.*

Background: Renal ischemia-reperfusion injury (IRI) is characterized by inflammation, tubular cell apoptosis and necrosis. We have previously shown that the p53 inhibitor pifithrin-α mitigates tubular cell apoptosis and protects renal function in a rat model of renal IRI despite the persistence of moderate inflammation.

Methods: To determine if the genetic absence of p53 also confers protection, we compared the outcomes of renal IRI in p53 knockout (KO) and wild-type (WT) mice.

Results: Surprisingly, KO mice have worse renal function after IRI compared to WT (mean creatinine 24 hrs post IRI: 0.96 mg/dl in KO vs. 0.39 mg/dl in WT, $p=0.01$). Histology in p53 KO mice after IRI reveals an increase in tubular necrosis, dilation, and cast formation compared to WT. Leukocyte infiltration is greater in KO mice compared to WT (mean F4/80+ cells 24 hrs post IRI: 788/section in KO vs. 441 in WT, $p=0.03$ and mean esterase+ cells 24 hrs post IRI: 237/section in KO vs. 96 in WT, $p=0.05$). The difference in leukocyte count is sustained one week after IRI. Unexpectedly, the frequency of tubular cell apoptosis is higher in p53 KO mice as compared to WT (TUNEL+ cells 24 hrs post IRI: 4.7 %/field in KO vs. 2.3 % in WT, $p=0.004$). Since these results conflict with the beneficial effects of pifithrin-α in the rat, we examined the effects of pifithrin-α on renal IRI in WT mice. The results were similar to those observed in p53 KO mice.

Conclusions: We conclude that the effects of p53 inhibition or its genetic absence on the outcome of renal IRI is species dependent and is determined primarily by the contribution of inflammation to IRI. In mice inflammation plays an important role in renal IRI and p53 provides an anti-inflammatory effect by reducing leukocyte survival and cytokine secretion, thus p53 inhibition worsens inflammation and renal injury. In rats, inflammation in renal IRI is less prominent and p53 inhibition provides an anti-apoptotic effect on renal tubular cells and improves function. Whether human renal IRI is better modeled by mice or rats remains to be determined.

Renal Tubular and Peritubular Capillary Injury in Hepatic Failure Induced Acute Kidney Injury in Rats Akira Shimizu,[1] Shinya Nagasaka,[1] Ayako Sato,[2] Honglan Piao,[2] Tetsuo Morioka,[2] Yukinari Masuda.[1] *[1]Analytic Human Pathology, Nippon Medical School, Tokyo, Japan; [2]Cellular Physiology, Institute of Nephrology, Niigata University School of Medicine, Niigata, Japan.*

Background: Acute kidney injury (AKI) is a common complication in the acute liver dysfunction. However, little is known about the mechanisms of AKI during the development of acute liver dysfunction. In this study, we characterize a rat model of AKI during the development of acute liver dysfunction following liver transplantation.

Methods: Acute hepatic failure was induced in rat by liver transplantation from DA (RT1a) to Lewis (RT1l) rats without immunosspression. Rats were dead around day 11 with severe acute liver dysfunction. We studied kidney samples at day 5, day 7, and day 9 to 11, focusing on the tubular and peritubular capillary (PTC) injury. In addition, hemodynamic events in PTCs in vivo were evaluated functionally and quantitatively by the use of a real-time confocal laser-scanning microscope (CLSM) system (Kidney Int 59: 252-259, 2001).

Results: During the progression of rejection in hepatic graft, acute liver dysfunction (T-Bil 7.9±1.8, $p<0.01$) and acute kidney injury (BUN 112.0±22.5; Cr 0.6±0.1, $p<0.05$) developed by day 11. During the development of AKI, renal tubular degeneration with bile pigment accumulation, mitochondrial degeneration, KIM-1 expression, and severe disruption of f-actin. TUNEL+ dead cells were noted in tubules and PTCs. In adittion, endothelial dysfunction in PTCs developed with decrease expression of eNOS, and marked reduced blood flow (540±162 vs 860±145 μm/sec in control, $p<0.05$). Interstitial edema occurred with inflammatory cell infiltration.

Conclusions: In conclusion, AKI developed in rats during the development of acute liver dysfunction and was characterized by renal tubular injury as well as endothelial dysfunction in PTCs with marked reduced blood flow.

FR-PO1104

Role of Calcium/Calmodulin-Dependent Kinase Kinase 2 (CaMKK2) in Acute Kidney Injury Christina R. Kahl,[1] Thomas J. Ribar,[2] Gloria A. Preston,[1] Anthony R. Means.[2] *[1]UNC Kidney Center, University of North Carolina at Chapel Hill, NC; [2]Department of Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.*

Background: The multifunctional calcium/calmodulin-dependent kinases (CaMKs) are implicated in the inflammatory response of lymphocytes, dendritic cells and macrophages. Previously published studies have shown that treatment with a non-selective CaMK inhibitor ameliorates disease development and renal injury in a lupus mouse model. Since CaMKK2 regulates the activity of both CaMKI and CaMKIV and inflammation plays a key role in acute kidney injury (AKI), we hypothesized that the loss of CaMKK2 would be protective in mouse models of AKI.

Methods: Cohorts of *CaMKK2* null mice or wild type (WT) mice were injected with LPS (lipopolysaccharide) or folic acid to induce AKI based on established protocols. LPS causes a systemic inflammatory response and subsequent renal injury. Folic acid causes tubular injury and inflammation with AKI dramatically attenuated by neutrophil depletion in mice.

Results: *CaMKK2* null mice demonstrate normal renal function by BUN and creatinine, and kidneys demonstrate normal histology. Following LPS injection, CaMKK2 null mice are indeed protected from renal injury with lower BUN and creatinine values than WT mice (creatinine in mg/dL, 0.26 versus 0.50, $p<0.05$). Surprisingly, folic acid injection causes dramatic renal injury in CaMKK2 null mice similar to WT mice (creatinine 2.36 versus 1.60, not significant). The CaMKK2 null mice with AKI also had significantly higher kidney/body weight ratios than WT mice and extensive renal injury histologically.

Conclusions: Therefore, CaMKK2 is required for AKI following LPS treatment but it is not required for the development of folic acid induced renal injury, suggesting that it may regulate different inflammatory responses in AKI. These results are consistent with previously published studies demonstrating the role of CaMKs in macrophage and dendritic cell activation in response to LPS. The CaMKK cascade may represent a novel pathway for therapeutic modulation of acute kidney injury related to endotoxemia.

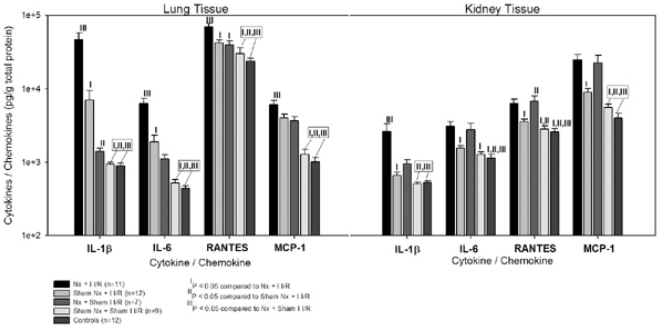
FR-PO1105

Acute Kidney Injury (AKI) in Rats with Pre-Existing Chronic Kidney Disease (CKD) Induces a Major Increase in Pro-Inflammatory Cytokines (IL-1β, IL-6) and Chemokines (RANTES, MCP-1) in Kidney and Lung Martin Skott,[1] Rikke Norregaard,[2] Tae-Hwan Kwon,[3] Jorgen Frokiaer,[2] Soren Nielsen.[1] *[1]Institute of Biomedicine, University of Aarhus, Aarhus, Denmark; [2]Institute of Clinical Medicine, University of Aarhus, Aarhus, Denmark; [3]Department of Biochemistry & Cell Biology, School of Medicine, University of Taegu, Korea.*

Background: AKI in patients with pre-existing CKD have increased co-morbidity and mortality. Although it is well established that AKI is associated with a major increase in pro-inflammatory cytokines and chemokines, it is unknown to which extent AKI in pre-existing CKD leads to changes in the expression of proinflammatory cytokines/chemokines. The aim of this study was to assess the changes in the expression of pro-inflammatory cytokines and chemokines in kidney and lung in response to AKI in rats with pre-existing CKD.

Methods: CKD was induced by 5/6 nephrectomy (5/6 Nx) for 6 weeks. AKI was induced by intestinal ischemia for 45 min followed by reperfusion for 90 min (II/R): 1) Nx+II/R; 2) Sham Nx+II/R; 3) Nx+Sham II/R; 4) Sham Nx+Sham II/R, 5) controls. Cytokines/chemokines were measured in homogenized whole kidney and lung preparations with LuminexTM 100.

Results: S-Cr increased significantly in response to II/R:from 66.2±7.3 to 88.9±8.3 in Nx rats, resp., and from 32.0±0.7 to 54.7±2.9 in Sham Nx rats. The levels of IL-1β, IL-6, RANTES, and MCP-1 in lung and kidney, were significantly higher in rats undergoing II/R compared to sham II/R. Importantly also in the 5/6 Nx rats II/R induced a significant increase in IL-1β, IL-6, RANTES, and MCP-1 expression in kidney and lung compared to sham 5/6 Nx. Morever the response was even more pronounced in the 5/6 Nx compared to the response in sham 5/6 Nx rats.



Conclusions: The results demonstrate a significant increase in pro-inflammatory cytokines and chemokines in response to AKI in rats with pre-existing CKD.

MCP-1 Is Involved in Potentiation of Lung Inflammation by Antecedent Ischemic Acute Kidney Injury Rajit K. Basu, Emily Donaworth, Prasad Devarajan, Hector R. Wong. *Divisions of Critical Care and Nephrology,*

Compartment	Sham-PBS	Sham-LPS	AKI-PBS	AKI-LPS	p value
Kidney	3.2 (2.5-3.9)	2.6 (2.2-3.9)	9.5 (5.2-13.2)	4.0 (2.6-8.2)	.112
Serum	59 (43-75)	69 (56-73)	108 (53-161)	139 (87-230)	< .001
Lung	1.1 (0.7-1.5)	9 (6-10)	1.4 (0.9-1.8)	11 (7-14)	.358
BALF	13.8 (7.2-25.8)	767 (707-1107)	12 (5.2-13)	5388 (4024-6662)	< .001

Figure 1. MCP-1 expression ubiquitously increases in ALI with antecedent AKI. MCP-1 expression, by Luminex xMAP, was elevated in all tissue compartments in AKI-LPS groups versus Sham-LPS groups. Results are medians with interquartile ranges shaded (ng/ml) (p values: Sham-LPS vs. AKI-LPS) (n=10-12/group)

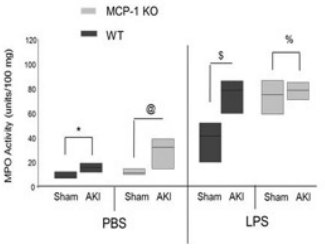

Figure 2. Elimination of MCP-1 abrogates AKI dependent lung priming. Lung myeloperoxidase activity for MCP-1 KO mice and wild type mice subjected to 2-hit model. MCP-1 KO mice receiving LPS did not show an augmented lung inflammation with antecedent AKI as opposed to their WT cohorts. n=6/group. (* p = .025, @ p = .016, $ p = .005, % p = not significant)

Taken together, our two-hit model demonstrates that ischemic AKI primes the lung for a heightened inflammatory response to subsequent injury and MCP-1 may be involved in this potentiation. The findings hold relevance for critically ill patients at risk of deleterious kidney-lung crosstalk.

FR-PO1107

Natural IgM Anti-Leucocyte Autoantibodies(IgM-ALA) Block Immune Mediated Proinflammatory Cytokine Release through Inhibition of NF-kB Activation Sang Ju Lee,[1,2] Amandeep Bajwa,[1,2] Kailo H. Schlegel,[1,2] Liping Huang,[1,2] Mark D. Okusa,[1,2] Peter I. Lobo.[1,2] *[1]Department of Medicine, University of Virginia, Charlottesville, VA; [2]Center for Inflamation, Immunity and Regenerative Medicine, University of Virginia, Charlottesville, VA.*

Background: IgM-ALA reduce kidney ischemia-reperfusion injury (IRI) however, little is known about the mechanisms by which these antibodies attenuate IRI. IgM-ALA bind to receptors on leucocyte and endothelial cell membranes, tissues important in the pathogenesis of IRI. The purpose of the current studies was to examine the effect of IgM on cellular mechanisms that lead to attenuation of kidney IRI.

Methods: Wild type mice and IgM KO mice were subjected to kidney IRI with and without IgM pretreatment. At 24 hours we measured serum creatinine and evaluated kidney histology. In other studies, we cultured mouse glomerular endothelial cells (mGEC) and RAW264.7 macrophage cells using standard methods and tested the effect of IgM (25μg/ml) on these cells activated with LPS(0.1 to 1μg/ml) for 20 min to 24 hrs. We measured proinflammatory cytokine production by real time PCR and immunohistochemistry as well as phosphorylation and nuclear translocation of NF-kB by Western blot.

Results: LPS significantly increased CXCL1 production (p<0.001) by mGEC. IgM, but not IgM adsorbed with leukocytes to remove IgM-ALA, blocked CXCL1 production through inhibition of phosphorylation and nuclear translocation of NF-kB. IgM KO mice showed increased renal injury after IRI. IgM pretreatment, but not IgM depleted of IgM-ALA, significantly decreased sCr and tubular injury in wild type and IgM KO (p<0.01). Similar to in vitro data, IgM treated mice had significantly less labeling of MCP-1 and CXCL1 on kidney vascular endothelial cells co-expressing TLR4 and CD31 after IRI.

Conclusions: We show that IgM-ALA, in physiologic doses, inhibits proinflammatory cytokines production by preventing activation of NF-kB. These studies highlight the importance of naturally occurring IgM-ALA in regulating excess inflammation as occurs after ischemia reperfusion injury despite presence of competent regulatory T cells. IgM could pre-emptively be used to prevent renal IRI.

FR-PO1108

The Effect of mTOR-Inhibition on Cycling of NF-kappa B Activation in Kidney Ischemia-Reperfusion Injury in Mice Aleksandra V. Kezic,[1] Jan U. Becker,[2] Tung Yu Tsui,[3] Friedrich Thaiss.[4] *[1]Univ. Hospital, Dep. Int. Medicine, Belgrade, Serbia; [2]Univ. Hospital, Dep. Pathology, Hannover, Germany; [3]Univ. Hospital, Dep. Transplant Surgery, Hamburg, Germany; [4]Univ. Hospital, Dep. Int. Medicine, Hamburg, Germany.*

Background: Ischemia-reperfusion injury (IRI) remains an important initiator of acute renal transplant rejection and delayed allograft function. Multiple stimuli in IRI activate the NF-kappa B (NF-κB) pathway which plays a central role in the regulation of numerous downstream pathways. We therefore determined cycling of NF-κB activation after induction of IRI and the role mTOR-inhibition (Everolimus; eve) might play.

Methods: C57/BL6 mice were subjected to IRI by clamping both renal pedicles. Application of eve started one day before IRI induction in a dose of 1.5 mg/kg b.w. subcutaneously daily. Both eve treated and non-treated mice were sacrificed 30 min, 1h, 2h, 6h, 12h, 1d, 2d, 3d and 7d after IRI. Kidneys were examined by morphology and standard molecular biology techniques.

Results: After induction of IRI NF-κB was significantly increased at early (6h and 3d) and also later (7d) time points when compared with shame operated animals. NF-κB activation was paralleled by a biphasic increase in TNF-alpha and chemokine CCL2 and CCL5 expression. Eve treatment of mice significantly increased NF-κB activity and inhibited NF-κB cycling at all time points. The second peak of TNF-alpha expression was significantly increased while CCL2 and CCL5 expression was significantly reduced at all time points in eve treated animals. By morphology eve treatment significantly increased injury index at early (2d) (p<0.05), however significantly reduced at later (7d) time points (p<0.004) compared with non-treated mice. Interstitial infiltration of F4/80-positive cells after IRI was significantly reduced at later time points in eve treated animals (P<0.01).

Conclusions: NF-κB cycling could be demonstrated in kidneys after IRI during a 7 days observation period. The peaks of NF-κB activation might represent early epithelial and late immune activation pathways. The influence of mTOR inhibition during early epithelial and late immune mediated activation of NF-κB after IRI warrants further investigation.

FR-PO1109

Activation of the Inflammasome in Cisplatin-Induced Acute Kidney Injury Dong Won Lee, Zhibin He, Quocan Nguyen, Ali Akcay, Alkesh Jani, Sarah Faubel, Charles L. Edelstein. *Kidney Disease and Hypertension, University of Colorado Denver, Aurora, CO.*

Background: We have demonstrated increased caspase-1, IL-1α, -1β and IL-18 in cisplatin (Cis)-induced AKI. As caspase-1, IL-1α, -1β and IL-18 are activated in the inflammasome, the aim of the study was to further investigate the inflammasome in Cis-induced AKI. Inflammasomes are cytosolic complexes composed of NALPs, ASC and caspase-5. BID is a pro-apoptotic protein activated by caspase-1 in the inflammasome.

Results: Mice injected with Cis (25 mg/kg) developed AKI on day 3. On qPCR of whole kidney, NALP3 mRNA was increased on day 3 (p<0.05, 0.75 vs. 0.1 fold change). On immunoblot of whole kidney, there were a 2-fold increase in ASC (22 kDa) (p<0.05), a 3-fold increase in caspase-5 (47 kDa) (p<0.05) on days 2 and 3, and a 2-fold increase in cleaved BID (15 kDa) on day 3 (p<0.05). Caspase-5 activity was increased (p<0.05, 29.2 vs. 11.2 nmol/mg/min in Veh). In summary, the NALP3 inflammasome is activated in AKI as evidenced by increased caspase-1, NALP3, caspase-5, ASC and BID in whole kidneys. On immunoblots, NALP3 was present in the freshly isolated proximal tubules (PT), but not in endothelial cells or macrophages. Thus we further investigated the inflammasome in a model of PT treated with Cis 10 and 50 μM. Caspase-1 activity was increased (p<0.05, 2.3±0.3 and 3.2±0.5 vs. 0.9±0.2 nmol/mg/min in Veh). Active caspase-1 (10 kDa) was increased in Cis-treated PTs (p<0.05 vs. Veh). NALP3 was strongly expressed in PTs, but with no changes between groups. Parent BID (22 kDa), but not cleaved BID, was 2-fold increased in PTs (p<0.05). On ELISA, IL-1α activity was increased with Cis (p<0.05, 1.1 and 1.3 vs. 0.1 nmol/mg/min in Veh). IL-1β was increased in 50 μM Cis-treated PTs (p<0.05, 10.9 vs. 7.6 nmol/mg/min in Veh). In summary, in Cis-treated PTs, there is increased caspase-1, IL-1α and IL-1β.

Conclusions: In conclusion, components of the inflammsome are increased in both whole kidneys in vivo and PTs treated with Cis in vitro.

FR-PO1110

Hypoxic Response of Myeloid Cells in Renal Ischemia-Reperfusion Injury
Gunnar Schley,[1] Bernd Klanke,[1] Jonathan Jantsch,[2] Susanne Olbrich,[1] Kai-Uwe Eckardt,[1] Alexander Weidemann.[1] *[1]Nephrology and Hypertension, University of Erlangen-Nuremberg, Erlangen, Germany; [2]Microbiology, University of Erlangen-Nuremberg, Erlangen, Germany.*

Background: After ischemia-reperfusion injury tubular cells undergo apoptosis and necrosis which triggers an inflammatory cell response. Infiltration of M1-type macrophages is detrimental in early phases, however alternatively activated M2-macrophages promote tissue repair. Hypoxia-inducible factors are critical for inflammatory macrophage responses and are differentially expressed in M1 and M2 macrophages. We therefore investigated whether HIF is critical for macrophage function and plasticity in ischemic kidney injury.

Methods: Floxed alleles of HIF-1α were deleted in myeloid cells by Cre-loxP recombination using LysM-Cre. Kidney ischemia-reperfusion injury was performed by clamping renal arteries for 25 minutes. Animals were analysed at 48 h and 72 h after reperfusion. Creatinine and urea levels were determined as renal function parameters. Gene expression analysis was done by real-time PCR and by immunohistochemistry.

Results: No renal phenotype is observed under control conditions in mice with deletion of HIF-1α in myeloid cells. Functional impairment 48h after renal ischemia reperfusion injury is not significantly different between wildtype and knockout mice. Creatinine levels in wildtype animals 72h after reperfusion are significantly better. Knockout animals do not exhibit this recovery of renal function. Macrophage infiltration is similar in both groups as assessed by F4/80 staining and MCP1 expression. However, TGFβ expression in injured kidneys is significantly lower in knockout animals.

Conclusions: Deletion of HIF-1α in myeloid cells results in a reduced capacity for functional recovery after renal ischemia-reperfusion injury. This is somewhat surprising since HIF-1α is implicated to be major isoform in M1-type macrophages. The observed phenotype does not seem to be the result of defects in motility or invasion of macrophages. Reduced expression of TGFβ in a HIF-dependent fashion indicates that this pathway plays a role in attenuating tissue damage. Thus our data add new and relevant insights into HIF-function in renal inflammatory cells.

Regulation and Protective Role of Autophagy in Cisplatin Nephrotoxicity: zVAD-fmk Blocks Cisplatin-Induced Cleavage of ATG5, Beclin-1, and ATG12 but Impairs Autophagic Flux *In Vitro* and *In Vivo*
Alexandrea Holmes,[2] Cheng Yang,[1] Christian Herzog,[1] Gur P. Kaushal.[1,2] *[1]UAMS, Little Rock, AR; [2]CAVHS, Little Rock, AR.*

Background: Autophagy is a process of degradation of intracellular organelles and long-lived proteins via the lysosome and plays a survival role under stress conditions. We previously reported a cytoprotective role of autophagy in cisplatin-induced cytotoxicity and the current study has determined regulation and role of autophagy in cisplatin injury.

Methods: Autophagy was identified by immunostaining and by GFP-LC3-II formation *in vitro* and *in vivo*. Cleavage of ATG5, beclin-1, and ATG12 during the course of cisplatin injury to renal epithelial cells were determined by western blot. Overexpression of autophagy was done by transfection with mCherry-ATG5 and beclin-1 plasmids. Renal function and histology was determined by the established methods. Autophagic flux was determined by LC3-II and p62 accumulation and lysosomal inhibition.

Results: Cleavage of Atg proteins began as caspase activation was initiated suggesting autophagy proteins are a target of caspases. The pan-caspase inhibitor zVAD-fmk completely prevented cisplatin-induced cleavage of Atg proteins but promoted expression of LC3-II, p62, and blocked lysosomal cathepsins and calpains, suggesting blockage of lysosomal function and impairment in autophagic flux. ZVAD-fmk did not protect from cisplatin nephrotoxicity in vivo as evident from increased levels of BUN, creatinine, and impaired histology. Overexpression of ATG5 and beclin-1 prevented cisplatin-induced cell death signifying autophagy plays a survival role. Administration of the autophagy inhibitor chloroquine enhanced severity of renal dysfunction (BUN in mg/dL Con, 18.5; 3d CP, 75.5; 3d CP+Chlq, 128.5; 3d Chlq, 13.8; Creatinine in mg/dL Con, 0.24; 3d CP, 0.285; 3d CP+Chlq, 1.1; 3d Chlq, 0.155), and impaired histology and autophagic flux.

Conclusions: We demonstrate regulation of autophagy by caspase mediated cleavage of Atg proteins and protective role in cisplatin AKI. ZVAD-fmk did not protect cisplatin-induced AKI and impaired autophagic flux both *in vitro* and *in vivo*. These studies link autophagy as a potential therapeutic target for preventing cisplatin AKI.

TGF-beta Signaling in the Proximal Tubule Modulates the Response to Acute Kidney Injury
Leslie S. Gewin,[1,2] Roy Zent.[1,2] *[1]Medicine, Veterans Affairs Hospital, Nashville, TN; [2]Medicine, Vanderbilt University, Nashville, TN.*

Background: Growth factors play an important role in the proximal tubule's response to acute kidney injury (AKI), but there are conflicting reports on the effects of transforming growth factor-beta (TGF-β) on the response to acute renal injury. Therefore, we investigated how TGF-β signaling in the proximal tubule affects kidney injury and repair after AKI.

Methods: Mice lacking the TGF-beta type II receptor (TβRII) specifically in the proximal tubules (γGT-Cre;Tgfbr2$^{flox/flox}$) were generated using the Cre/lox technique. AKI was induced by mercuric chloride ($HgCl_2$) at either a low or high dose, and morphology and renal function (BUN and creatinine) were assessed. Immunoblots of tissue lysates and immunohistochemistry were used to determine inflammation, proliferation, and apoptosis after injury. To better explain these *in vivo* results, we created proximal tubule epithelial cells (PTEC) with and without TβRII *in vitro*. Apoptosis was induced *in vitro* by both H_2O_2 and detachment (polyHEMA-coated plates) and cell adhesion, migration, and transepithelial resistance (TER) were measured.

Results: The conditional knockout mice were protected from AKI at lower doses of HgCl2. At early time points, there was no difference in inflammation or proliferation, but γGT-Cre;Tgfbr2flox/flox mice had less apoptosis. In contrast, at higher levels of HgCl2, injury was equivalent in both genotypes but the conditional knockout mice also had delayed recovery. Consistent with our in vivo data, the TβRII-/- cells in vitro were protected from apoptosis but had reduced adhesion and migration on collagen IV and fibronectin.

Conclusions: These results suggest that blocking TGF-β signaling in proximal tubules may protect against milder AKI by conferring resistance to epithelial apoptosis. However, in more profound injury, inhibiting TβRII may compromise recovery of the renal epithelium by interfering with cell/matrix interactions such as adhesion and migration. In conclusion, the effect of proximal tubular TGF-β signaling on AKI may vary depending upon the severity of injury.

Acute Reduction in Renal Calpain 10 Causes Mitochondrial and Renal Dysfunction
Matthew Allen Smith, Marisa D. Covington, Rick G. Schnellmann. *Pharmaceutical and Biomedical Sciences, Medical University of South Carolina, Charleston, SC.*

Background: Calpain 10 is a calcium-dependent cysteine protease that is ubiquitously expressed. Calpain 10 is in kidney mitochondria and NDUFB8, NDUFV2 (complex I proteins), and ATP synthase β are mitochondrial calpain 10 substrates. Our laboratory showed that renal calpain 10 decreases with age in humans, rats, mice, and in diabetic rats. Furthermore, over-expression or knockdown of calpain 10 results in cell death. Therefore, we determined the effects of acute reduction of renal calpain 10 on mitochondrial and renal function.

Methods: One IV injection of 20 nmol of calpain 10 or scamble siRNA in the tail vein of 8 week old Fischer 344 rats. Rats were sacrificed at days 2, 5 and 7 for immunoblot analysis.

Results: One injection of calpain 10 siRNA decreased mitochondrial and cytosolic calpain 10 at all time points (days 2, 5, 7) compared to controls. This decrease in calpain 10 was kidney and calpain 10 specific. On day 7, kidney dysfunction was observed with a rise in serum creatinine from 0.8 mg/dL to 1.8 mg/dL. We hypothesized that loss of mitochondrial calpain 10 would cause calpain 10 substrates to accumulate and induce mitochondrial dysfunction. At all time points, ATP Synthase β and NDUFB8 protein levels in rats treated with calpain 10 siRNA increased 2.5-fold in the kidney cortex. In calpain 10 siRNA-treated animals, Mitofusin 2 was decreased at all time points, suggesting decreased mitochondrial fusion. Drp1, a mitochondrial fission protein that is associated with mitophagy and apoptosis, increased in the calpain 10 siRNA-treated animals on day 5. We analyzed markers of mitophagy, the process of removing damaged mitochondria, PINK1 and LC3-II. At days 2 and 5, both PINK1 and LC3-II increased, suggesting mitophagy is occurring. Cleaved caspase 3 was detected at days 5 and 7, providing evidence that calpain 10 is required for cell viability.

Conclusions: These results support our hypothesis that the loss of renal calpain 10 causes renal dysfunction sequentially through 1) the accumulation of mitochondrial calpain 10 substrates, 2) decreased mitochondria fusion and increased mitophagy, 3) increased mitochondrial fission, and 4) apoptosis.

Role of Mitofusin 2 in the Renal Stress Response
Jonathan M. Gall,[1] Zhiyong Wang,[1] Marc Liesa,[2] Anthony J.A. Molina,[2] Andrea Havasi,[1] John H. Schwartz,[1] Steven C. Borkan,[1] Ramon G. Bonegio.[1] *[1]Renal Section, Boston Medical Center, Boston, MA; [2]Obesity Center, Boston Medical Center, Boston, MA.*

Background: Mitochondria are dynamic organelles that undergo constant remodeling, essential to their function as regulators of cell survival. Although mitofusin 2 (MFN2) is critical for mitochondrial morphology and function, its role in the renal stress response is unknown.

Methods: To delete MFN2 in vitro, primary cultures of proximal tubular cells from MFN2 floxed mice (MFN2f/f) mice were treated with Cre-expressing adenovirus or empty adenoviral vector (control). Mitochondrial morphology, outer mitochondrial membrane integrity, Bax activation (6A7 epitope exposure), oxygen consumption, and cell survival were evaluated under resting conditions and following ATP depletion. To conditionally knockout MFN2 (MFN2 cKO) in renal cells in vivo, MFN2f/f mice were crossed with those expressing Cre-recombinase under the control of the Pax2 promoter. Renal histology and organ function were assessed in MFN2 cKO pups and control littermates.

Results: MFN2-deficiency caused profound mitochondrial fragmentation but did not alter baseline oxygen consumption or survival of proximal tubule cells in culture at rest. In contrast, after ATP depletion, proximal tubular cells lacking MFN2 had more mitochondrial outer membrane injury and an 80% increase in apoptosis compared to MFN2-expressing control. Bax activation was comparable in cells that did or did not express MFN2, although MFN2 deficiency significantly increased mitochondrial Bax accumulation and enhanced release of both apoptosis inducing factor and cytochrome c, pro-apoptotic markers of

membrane injury. Conditional MFN2 knockout in vivo also caused severe mitochondrial fragmentation in renal epithelial cells but did not affect renal histology or organ function in newborn mice.

Conclusions: MFN2 is critical for renal epithelial cell survival after ATP depletion but is not required under resting conditions or during renal organogenesis. MFN2 deficiency decreases survival after stress by increasing Bax-mediated mitochondrial outer membrane injury and apoptosis, a primary cause of acute ischemic renal failure.

Tubule-Specific Ablation of Endogenous β-catenin Aggravates Acute Kidney Injury in Mice Dong Zhou,[1] Yingjian Li,[1] Peter Igarashi,[2] Youhua Liu.[1] *[1]Department of Pathology, University of Pittsburgh, PA; [2]Department of Medicine, University of Texas Southwestern Medical Center, Dallas, TX.*

Background: β-catenin is a unique intracellular protein that plays dual functions: as an integral component of the cell adherens junction complex, and as a principal signaling protein that mediates the canonical Wnt signaling. Inappropriate activation of β-catenin occurs predominantly in renal tubular epithelium, and is implicated in the pathogenesis of a variety of progressive chronic kidney disorders, such as diabetic and obstructive nephropathies. However, little is known about its function in normal physiologic state as well as after acute kidney injury (AKI). To explore this issue, we generated conditional knockout mice in which β-catenin gene is specifically ablated in renal tubules (designated as Ksp-β-cat-/-), particularly in the distal tubules and collecting duct epithelia by mating β-catenin floxed mice with Ksp-Cre transgenic mice. Ksp-β-cat-/- mice were phenotypically normal, without any appreciable defect in kidney morphology and function, suggesting that β-catenin is dispensable for renal tissue homeostasis. However, we found that tubule-specific ablation of endogenous β-catenin aggravated acute kidney injury induced by folic acid. Comparing with controls, Ksp-β-cat-/- mice displayed a higher serum creatinine level and more severe morphologic injury at 2 days after folic acid injection. Similarly, more apoptotic cells were detected in Ksp-β-cat-/- kidneys, which was accompanied by an increased Bax protein and decreased survivin mRNA expression in the kidneys. *In vitro*, activation of β-catenin via transfection of either Wnt1 or constitutively active β-catenin expression vectors protected human proximal tubular epithelial cells (HKC-8) from apoptosis induced by staurosporine. Consistently, activation of β-catenin also induced survivin and repressed Bax expression *in vitro*. These results suggest that endogenous β-catenin in renal tubules is pivotal for renal protection after acute kidney injury primarily through activating cell survival signaling.

FR-PO1116

Two Independent Pathways, BNIP3 and Sestrin2, Mediate Autophagy of Renal Tubular Cells in Acute Kidney Injury In Vitro and In Vivo Masayuki Ishihara,[1] Masayuki Bun,[2] Masayuki Hisa,[2] Kazu Hamada,[1] Yoshiko Shimamura,[1] Koji Ogata,[1] Kosuke Inoue,[1] Toru Kagawa,[1] Toshihiro Takao,[1] Yoshio Terada.[1] *[1]Department of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi University, Nankoku, Kochi, Japan; [2]Center for Innovative and Translational Medicine, Kochi Medical School, Kochi University, Nankoku, Kochi, Japan.*

Background: Autophagy is one of the systems which protect life from many kinds of stresses. In the previous study we reported autophagy occurred in acute kidney injury (AKI) mice model. Autophagy is thought to play a protective role in renal tubules from stresses. However, little is known about signal transduction for autophagy in AKI. Bcl-2/adenovirus E1B 19kDa-interacting protein 3 (BNIP3) is one of the target proteins of hypoxia inducible factor -1a (HIF-1a). Sestrin2 is one of the target proteins of p53. The aim of this study is to reveal the roles of BNIP3 and sestrin2 in autophagic pathway in AKI.

Methods: We used rat ischemia/reperfusion (I/R) AKI model in vivo and cultured renal tubular cells as an in vitro AKI model. The expression of BNIP3 and sestrin2 are up-regulated after I/R in proximal tubules in immunostaining and immunoblotting. BNIP3 mRNA and protein expressions were up-regulated in the hypoxia condition via HIF-1a dependently in vivo. Sestrin2 mRNA and protein expressions were up-regulated in the oxidative stress condition (H2O2) via p53 dependently. To examine BNIP3 and sestrin2 regulate autophagy or not, we established NRK cells which stably transfected with a fusion protein between green fluorescent protein and light chain 3 (LC3-GFP) as a marker of autophagy. Overexpression of BNIP3 and sestrin2 both induced autophagy in NRK-LC3-GFP cells and induced LC3 protein expression.

Results: The autophagosome induced by BNIP3 localized in mitochondria. Induction of autophagy by hypoxia was reduced by sestrin2 siRNA. Induction of autophagy by H2O2 was reduced by BNIP3 siRNA.

Conclusions: These observations disclose that autophagy in renal tubules in AKI is induced by at least two independent pathways, p53-sestrin2 pathway and HIF-1a-BNIP3 pathway. These two pathways may work differently according to the types of stresses to protect renal tubules in AKI.

FR-PO1117

Proximal Tubular Cells (PTCs) from AMP-Activated Protein Kinase (AMPK) Knock-Out (KO) Mice Are More Susceptible to Metabolic Stress Than Their Wild-Type WT Controls Wilfred Lieberthal,[1] Meiyi Tang,[1] Vimal Patel,[2] Jerrold S. Levine.[2] *[1]Medicine, Stony Brook Medical Center, Stony Brook, NY; [2]Medicine, University of Chicago, IL.*

Background: We have previously shown that inhibiting AMPK in PTCs from WT mice increases their susceptibility to apoptosis. There are two isoforms of the catalytic domain of AMPK, α1 and α2. In this study we examined the susceptibility to metabolic stress of AMPK KO mice that lack the α1 or α2 isoform of the catalytic domain.

Methods: Primary cultures of PTCs from WT and KO mice were incubated in dextose (6mM, 5mM or 4mM), without or with 2μM antimycin A (anti). Apoptosis, quantified by FACS analysis, was expressed as a % of the total number of cells. In PTCs that were not subjected to metabolic stress, gene expression was determined by real-time PCR and expressed in KO PTCs as a % of WT.

Results: Apoptosis was comparable in α1 KO and WT PTCs incubated in 6mM dextrose in the presence (5.4±2.1%) vs the absence of anti (10.0±3.2%). However, there was more apoptosis in α1 KO vs WT PTCs incubated in 5mM dextrose in the presence (18.2±3.2%) vs absence of anti (3.2±1.2%)($p<0.01$). In 4mM dextrose, the amount of apoptosis was even greater in α1 KO vs WT PTCs in the presence (33.2±.6%) vs absence (3.2±1.9%) of anti ($p<0.001$). In α2 KO and WT PTCs apopotosis was at control levels (~5%) in 6 and 5mM dextrose with and without anti. However, at 4mM dextrose, apoptosis was increased in α2 KO vs WT PTCs in the presence (21±2.1%) vs absence (3.2±1.3) of anti ($p<0.02$). We also found that the expression of genes encoding PPARγ coactivator-1α(PGC-1α) and cytochrome B was reduced to a comparable extent (by ~55%) in α1 and α2 KO mice, while the expression of cytochrome C was reduced to a greater extent in α1 vs α2 KO PTCs (by 42±7% vs 62±8% respectively)($p<0.02$).

Conclusions: Conclusions: i) AMPK KO mice are more susceptible than WT mice to apoptosis induced by metabolic stress; ii) α1 KO PTCs are more sensitive than α2 PTCs to the same metabolic stress; iii) Differences in the reduction in gene transcription between α1 and α2 KO mice may contribute to the differences in sensitivity of the α1 and α2 KO PTCs to metabolic stress.

FR-PO1118

Sexual Dimorphism of ER Stress-Induced Kidney Injury Hossam Mustafa, Adel Tarcsafalvi, Judit Megyesi, Rawad Hodeify, Peter M. Price. *Medicine, UAMS, Little Rock, AR.*

Background: Gender differences can affect the severity of AKI; ischemia-reperfusion AKI is more severe in males whereas cisplatin AKI is more severe in females. Sex hormones are thought to play a key role in these gender-related differences in susceptibility to kidney injury. In this study we observed differences in the severity of kidney injury between male and female mice (strain 129/Sv) in response to tunicamycin, an ER stress agent.

Methods: Tunicamycin was injected subcutaneously into mice, and kidney function, morphology, and proteins were assessed after 1, 3, and 5 days. In addition, some female mice were implanted with testosterone (5 mg/pellet, 21 day release) and some male mice with estrogen (β-estradiol 17-acetate, 5 mg/pellet, 21 day release).

Results: The ER-induced decline in kidney function was most severe five days after tunicamycin injection and was greater in male mice than in female mice. At this time, concentrations of BUN and creatinine in serum of male mice were 82.9 and 1.37 mg/100 ml, respectively, while in female mice were 18.5 and 0.4, which were not significantly different than levels in untreated controls. Similarly, protein markers of ER stress were also significantly more elevated in male mice. Specifically, levels of phosphorylated eukaryotic initiation factor-2α (phospho-eIF-2α), glucose-regulated protein (GRP-78) and CAAT/enhancer binding protein homologous protein (CHOP) were higher in tunicamycin-treated male mice. Testosterone administered to female mice by pellet implantation 2 weeks before tunicamycin resulted in a phenotype similar to male mice with a comparable decline in renal function and induction of ER stress markers. In contrast to testosterone, estrogen administered to male mice was not protective against tunicamycin-induced kidney injury.

Conclusions: We conclude that in response to ER stress, male mice are more vulnerable and have substantially greater acute kidney injury than female mice. The presence of testosterone, rather than estrogen-mediated protection, was responsible for this gender difference. ER stress contributes to AKI arising from several different insults and gender differences in the tolerance to this stress could play a significant role in induction of AKI.

FR-PO1119

Peroxisomal Contribution to LPS Kidney Injury Radovan Vasko, Brian B. Ratliff, Ellen Nadel, Jun Chen, Michael S. Goligorsky. *New York Medical College, Valhalla, NY.*

Background: Peroxisomes (PER) are ubiquitous organelles involved in metabolism of ROS through their generation and detoxification. The role of PER in inflammatory response of AKI remains obscure, although their activation seems to be protective. Our previous metabolomic study of ischemic AKI revealed accumulation of PER markers, suggestive of increased biogenesis of PER.

Methods: Here, we investigated the role of PER in LPS-mediated AKI. Sublethal dose of LPS in C57BL mice (wild-type, WT) did not lead to increased serum creatinine (SCr). However, in C57BL/6J-Lyst mice (model of defective lysosomal autophagy/pexophagy), LPS resulted in a significant increase in SCr and urinary albumin (24h; SCr 0.48+0.07 mg/dl, UACR 193+33 mg/g) compared to WT mice (SCr 0.23+0.03 mg/dl mg/dl, UACR 51+12 mg/g).

Results: Immunoblot analyses of kidney homogenates demonstrated significantly higher increases of PMP70 (a major PER membrane protein) and catalase (a marker for the PER matrix) in WT compared with C57BL/6J-Lyst mice after LPS treatment. Ex vivo, time course studies in HUVEC revealed a biphasic profile of PMP70 expression under LPS: an initial decline, followed by an elevation after 9h. PMP70 normalized after 24h and further increased compared to control cells without LPS stimulation. Expression profile of PMP70 under LPS was paralleled by catalase and p62, protein known to interact with ubiquitin and trigger autophagy. Activation of autophagy decreases the levels of p62. In our in vivo studies, PMP70 levels in autophagy-deficient C57BL/6J-Lys mice were decreased compared to WT, suggesting concomitantly impaired PER biogenesis by LPS. Peroxin14 (Pex14), a PER membrane docking protein that interacts with PER targeting sequence (PTS) containing proteins, showed down-regulation in LPS-treated HUVEC, suggesting impairment of PER assembly due to altered protein import. Fluorescence microscopy of HUVEC transfected with PTS-GFP demonstrated decreased colocalization of PTS with PER under LPS.

Conclusions: 1) LPS exerts a biphasic effect on PER: initial depletion followed by accumulation; and 2) both the impaired biogenesis and autophagic degradation of PER (pexophagy) seems to contribute to aggravation of AKI.

Roles of mTOR Pathway on Autophagy in the Proximal Tubular Epithelial Cells of Rat Kidneys

Shunsaku Nakagawa, Kumiko Nishihara, Satohiro Masuda. *Pharmacy, Kyoto University Hospital, Kyoto, Japan.*

Background: The mammalian target of rapamycin (mTOR) pathway plays important roles in several kidney diseases, including ischemia-reperfusion (IR) injury, chronic renal failure, diabetic nephropathy and polycystic kidney disease. Recently, we showed activation of the mTOR pathway in proximal tubular cells of rat kidneys after subtotally nephrectomy (Nx) (Nakagawa et al., Biochem Pharmacol, 79, 67-76, 2010; Nishihara et al., Am J Physiol Renal Physiol, 298, F923-F934, 2010). Although recent studies proposed that mTOR regulated autophagy through interaction with UNC51-like kinase 1 (Ulk1) in vitro, the regulatory mechanisms of autophagy via interaction between mTOR and Ulk1 in vivo were not clear. In this study, we aimed to clarify roles of the mTOR pathway on autophagy in the renal proximal tubules.

Methods: The amounts of phosphatidylethanolamine-conjugated form of microtubule associated protein 1 light chain 3 (LC3-II), a marker for activity of autophagy, in rat kidneys were examined after Nx, IR and cisplatin treatment.

Results: Immunofluorescent analysis showed that the positive signals for mTOR, Ulk1 and LC3 were detected in the proximal tubular epithelial cells of rat kidneys, and immunoprecipitation revealed the direct interaction between mTOR and Ulk1 in the rat kidneys. The levels of LC3-II in rat kidneys were significantly decreased to 16%, 27% and 52% compared to control rats after Nx, IR and cisplatin treatment, respectively. On the other hands, phosphorylated ribosomal protein S6 (a marker for activation of the mTOR pathway) was significantly increased to 283%, 138% and 152% compared to control rats after Nx, IR and cisplatin treatment, respectively. In addition, the levels of LC3-II in the rat kidneys after Nx, IR and cisplatin treatment were significantly increased to 517%, 147% and 185% as compared to vehicle treated rats by treatment with mTOR inhibitor everolimus.

Conclusions: Activation of the mTOR pathway in proximal tubular epithelial cells caused suppression of autophagy during kidney injury by direct interaction with Ulk1.

FR-PO1121

Extracellular Signal-Related Kinase Inhibition Prevents Autophagy Induction and Sensitizes Proximal Tubular Cells to LPS-Induced Apoptosis

Jeremy S. Leventhal, Michael J. Ross. *Department of Medicine Divsion of Nephrology, Mount Sinai School of Medicine, New York, NY.*

Background: Sepsis-induced acute kidney injury (AKI) is a common and destructive complication encountered in hospitalized patients. Clinical studies have highlighted the negative association between sepsis-induced AKI and short-term and long-term renal function and mortality outcomes. As of yet, there are no approved therapies to treat or prevent sepsis-induced AKI. Autophagy is a complex intracellular degradation mechanism that endows cells with the ability to maintain homeostasis after exposure to stress-inducing stimuli, such as bacterial lipopolysaccharide. In these studies we investigated the autophagic response to bacterial lipopolysaccharide (LPS), the cytoprotective function of autophagy, and the signaling pathways required for autophagy induction.

Methods: Autophagy was evaluated by western blot for LC3II and quantification of fluorescent punctae in GFP-LC3 transfected proximal tubular epithelial cells (PTEC). MAPK inhibitor U0126 was used to determine the effect of Extracellular signal-related kinase (ERK1,2) on autophagy and cell survival in LPS exposed PTEC.

Results: Autophagy induction was demonstrated in LPS exposed PTEC by increased LC3II accumulation and a significantly higher quantity of GFP-LC3 punctae compared to control treated cells. Knockdown of Beclin-1, an essential part of the autophagy machinery, sensitized cells to LPS-induced apoptosis as evidenced by increased PARP-1 cleavage. Incubation of PTEC with the ERK-inhibitor U0126 inhibited the autophagic response to LPS as evidenced by decreased Beclin-1 induction and LC3II accumulation. Moreover, U0126 increased apoptosis in LPS-treated PTEC.

Conclusions: ERK-dependent autophagy induction is a counter-regulatory mechanism preventing apoptosis after LPS exposure and may therefore be an important protective mechanism against sepsis-induced AKI.

FR-PO1122

Sensitivity of Diabetic Mice and High Glucose-Conditioned Renal Tubular Cells to Acute Injury Induced by Ischemia-Reperfusion and ATP Depletion

Jianping Peng, Zheng Dong. *Georgia Health Sciences University.*

Background: Acute kidney injury (AKI) leads to a worse outcome and prognosis in the patients with existing chronic kidney diseases including diabetic nephropathy. We hypothesize that kidney cells and tissues are more sensitive to injury under diabetic condition.

Methods: We tested this possibility by examining kidney cell and tissue injury in hyperglycemic and diabetic conditions.

Results: We first observed that significantly higher kidney injury and mortality were induced by renal ischemia-reperfusion in streptozotocin-induced diabetic mice. Consistently, renal ischemia induced more severe kidney injury in diabetic Akita mice than wild-type mice. In addition, ischemic kidney injury in these diabetic models showed a correlation with their blood glucose levels. To understand the mechanism of the injury sensitivity, we examined that the effect of high glucose on ATP-depletion induced apoptosis in cultured renal proximal tubular cells. The cells were cultured for two weeks in media containing 5.5 mM glucose, 30 mM glucose, or 30 mM mannitol, followed by ATP-depletion with anoxia or azide. ATP-depletion induced significantly higher apoptosis in high glucose-conditioned cells (60%) than the cells cultured with 5.5 mM glucose or 30 mM mannitol (15%). Consistently, caspase activity was significantly higher in high glucose-conditioned cells. During ATP-depletion, high glucose-conditioned cells also showed an earlier and higher Bax translocation and cytochrome c release.

Conclusions: Taken together, these results suggest that high glucose or hyperglycemia may sensitize renal tubular cells to mitochondrial or the intrinsic pathway of apoptosis, resulting in heightened kidney injury.

FR-PO1123

Murine Double Minute-2 Links Inflammation and Tubular Healing in Acute Kidney Injury of Mice

Dana Thomasova, Shrikant Ramesh Mulay, Mi Ryu, Hans J. Anders. *Department of Nephrology, Medizinische Poliklinik, University of Munich, Munich, Germany.*

Background: The E3 ubiquitin ligase murine double minute (MDM)-2 promotes cancer cell survival and growth, by degrading p53, hence, MDM2 inhibition with nutlins emerges as novel cancer therapy. To test whether MDM2 also promotes regenerative cell growth we examined the effects of nutlin-3a during postischemic kidney injury (AKI).

Methods: We used bilateral or unilateral renal artery clamping (45 min.) in C57BL/6 wildtype and p53-deficient C57BL/6 mice. Mice were injected with nutlin-3a or vehicle on days -1, +1, +2 and +3. Renal pathological evaluation was performed at day 1 and 5 after IRI (immunohistochemistry, qPCR, western blot). For in vitro studies we stimulated p53-MDM2 double-deficient or p53 single-deficient mouse embryonic fibroblasts (MEFs) with LPS and analyzed them with ELISA, western blot and electrophoretic mobility shift assay.

Results: When nutlin-3a was injected 1 day before renal artery clamping it significantly reduced necrosis and apoptosis of tubular cells, neutrophil infiltration, and mRNA expression of IL-6, TNF-α, CXCL2, CCL2 at 1 day. This effect was identical in wildtype or p53-deficient mice documenting a p53-independent effect of MDM2. In-vitro experiments confirmed that MDM2 is required to induce the mRNA expression and secretion of NFκB-dependent cytokines upon Toll-like receptor stimulation by enhancing NFκB binding to its cytokine promoter binding sites. Although nutlin-3a protected from acute tubular necrosis, tubular damage was aggravated at day 5 in nutlin-treated mice as compared to controls. Nutlin treatment was associated with more TUNEL+ tubular cells but this effect was absent in p53-deficient mice which suggests that MDM2-mediated inhibition of p53 is required to allow tubular repair after AKI.

Conclusions: Together, MDM2's dual role in AKI encompasses NFκB binding to cytokine promoters, a p53-independent proinflammatory effect, as well as p53 inhibition for regenerative cell growth. We conclude that, MDM2 links inflammation and epithelial healing during AKI, two additional biological functions that need to be considered when inhibiting MDM2 for therapy.

FR-PO1124

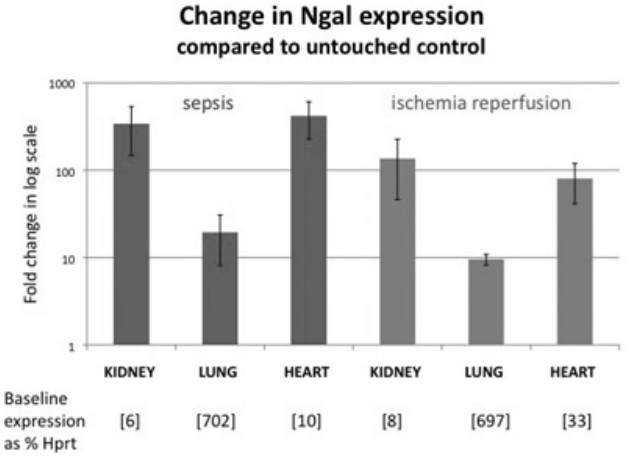
Acute Kidney Injury and Sepsis Independently Induce a Multi-Organ Stereotyped Inflammatory Response

Barbara Pedrycz, Catharine Compston, Valerie A. Luyckx, Thomas F. Mueller. *University of Alberta.*

Background: Acute kidney injury (AKI) and sepsis are independently associated with high mortality and frequently co-exist in critically ill patients who develop multi-organ dysfunction. Animal models have shown that AKI and sepsis are associated with distant organ inflammation. We compared pathways of inflammation and injury associated with AKI and sepsis in multiple organs, to determine whether local injury induces a stereotyped or situation-specific inflammatory response in distant organs.

Methods: 3 month old male C57BL/6 male mice underwent unilateral renal ischemia-reperfusion (IR) or cecal ligation and puncture (CLP) as models of AKI and sepsis respectively. Transcript levels of the acute phase response (APR) genes Osm, Osmr, Il6, Il6r, Lif, Lifr, Serpina3, and Ngal were measured at 24 hours by real-time RT-PCR in hearts, lungs and non-clamped kidneys of control (n=7), IR (n=3) and CLP (n=5) mice. Gene expression is represented as fold change over control and % HPRT.

Results: A similar qualitative inflammatory response was observed in distant organs after IR and CLP for all genes analyzed. Fold change of Ngal served as a general injury/leucocyte infiltration marker. Distant organ expression patterns were similar in CLP and IR mice (Figure 1).



Quantitatively, the degree of injury/inflammation was higher in CLP compared to IR mice. In hearts, kidneys and lungs respectively, Ngal expression increased by 417, 340 and 19 fold in CLP mice, compared to 33, 340 and 9 fold in IR mice. Baseline expression was consistently higher in the lung for all the APR genes, followed by heart and then kidney.

Conclusions: The injury-repair response is highly stereotyped across remote organs regardless of initiating event. Distant organ inflammation is therefore likely a significant mediator of multi-organ dysfunction contributing to the high morbidity and mortality in AKI and sepsis

Endoplasmic Reticulum Stress Links Inflammatory and Fibrogenic Responses To Induce Kidney Fibrosis after Acute Injury Gang Li, Jianhua Huang, Yordanka Ivanova, Anna Zuk. *Genzyme Corporation, Framingham, MA.*

Background: Acute kidney injury (AKI)-induced aberrant repair has been implicated in the progression of chronic kidney disease (CKD), yet the mechanisms linking AKI to CKD are incompletely understood. Here, we examined the unfolded protein response (UPR) following AKI and hypothesized that activation of the maladaptive arm of UPR together with insufficient adaptive UPR induces inflammation and tubulo-interstitial fibrosis post AKI. In a mouse model of bilateral renal ischemia-reperfusion, the UPR is markedly induced post-reperfusion and correlates with renal dysfunction, tubular apoptosis, and inflammation. In contrast to the sustained induction of the adaptive UPR in young mice (8-10 wks), measured by stimulation of IRE1 and ATF6, aged mice (48-50wks) display only transient induction of these pathways. Additionally, in aged mice, there is substantially greater induction of CHOP and its downstream target GADD34, which associates with increased mortality and more severe renal injury. Importantly, CHOP induction is sustained, correlating with greater kidney fibrosis and inflammation 6wks post-reperfusion. To understand how epithelial cells contribute to fibrosis in a setting of AKI, an ATP depletion-repletion model of normal rat kidney epithelial cells was developed to recapitulate ischemia-reperfusion in vivo. Sustained CHOP induction together with transient induction of ATF6 is observed during repletion and is associated with induction of inflammatory (*Mcp-1, Il6,* and *Il8*) and fibrogenic genes (*Ctgf* and *Fgf*). Most importantly, induction of these genes is significantly inhibited when CHOP induction is blocked by siRNA, providing direct causal evidence of CHOP as a mediator of inflammatory/fibrogenic responses. In addition, a specific inhibitor of dsRNA-dependent protein kinase (PKR) substantially suppresses the induction of inflammatory/fibrogenic genes through inhibition of CHOP expression. These data provide new insight into how ER stress in general, and the CHOP branch in particular, contributes to kidney fibrosis and suggest that interventions targeting the CHOP branch of UPR may provide new opportunities to prevent kidney fibrosis.

Suberoylanilide Hydroxamic Acid (SAHA) Suppresses the Progression of Renal Fibrosis in Aristolochic Acid Induced Renal Fibrosis Model in Mice Mineaki Kitamura,[1] Tomoya Nishino,[1] Kumiko Io,[1] Yoko Obata,[1] Yoshitaka Hishikawa,[2] Takehiko Koji,[2] Shigeru Kohno.[1] *[1]Second Department of Internal Medicine, Nagasaki University School of Medicine, Nagasaki, Japan; [2]Department of Histology and Cell Biology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.*

Background: The epigenetic modulation of genes is known to be a key mechanism for the control of gene expression and plays an important role in the progression of fibrosis. Among epigenetic mechanisms, histone acetylation is regulated by histone deacetylases (HDACs) and it leads to the transcriptional activation of genes. In the present study, we investigated the involvement of histone acetylation in the renal fibrosis induced by aristolochic acid (AA), and the effect of suberoylanilide hydroxamic acid (SAHA), which is a HDAC inhibitor on fibrotic lesions.

Methods: Male Balb/c mice were divided into three groups, AA, AA+SAHA, and control group. Renal fibrosis was induced by AA injection. SAHA or saline were injected subcutaneously for 3 weeks. The expression of type IV collagen, acetylated histone and HDAC2 were examined by immunohistochemistry. TUNEL staining was performed to evaluate apoptosis. Serum creatinine and urinary protein were analyzed to evaluate renal function.

Results: The expression of type IV collagen was significantly increased compared to control group and it was significantly attenuated by SAHA treatment. The number of histone acetylated cells was also increased in AA group, while there was no significant difference between AA and AA+SAHA groups. The number of HDAC2-positive and TUNEL-positive cells was significantly increased in AA group in comparison to control group. Of note, SAHA treatment decreased the number of them and inhibited the progression of renal dysfunction.

Conclusions: These results suggested that histone acetylation was involved in the progression of renal fibrosis and SAHA could attenuate renal fibrosis and renal function. The antifibrotic effect of SAHA might exert the suppression of apoptosis via HDAC inhibition. SAHA might be one of the candidates for a novel therapeutic agent in preventing renal fibrosis.

The HDAC-Dependent Suppression of Bmp-7 Transcription Countributes to the Dysregulation of the Innate Repair Mechanisms of the Kidney Following Prolonged Urinary Tract Obstruction Scott R. Manson, Paul F. Austin. *Surgery, Washington University, Saint Louis, MO.*

Background: While BMP-7 inhibits the pathogenesis of renal injury in a variety of disorders of the kidneys and urinary tract, little is known about the regulation of endogenous BMP-7 and its renal protective functions. This study examines the molecular regulation of BMP-7 in obstructive uropathies and the role which it plays in the repair of obstruction-induced renal injuries.

Methods: A reversible model of unilateral ureteral obstruction (UUO) was used to characterize the repair of the kidney following the correction of short-term obstructions that led to reversible renal injury and prolonged obstructions that led to irreversible renal injury. The role of BMP-7 was assessed by treatment with anti-BMP-7 or exogenous BMP-7.

Results: BMP-7 activity is required for the restoration of renal architecture and the resolution of fibrosis following obstruction-induced renal injury. However, prolonged UUO leads to the loss of BMP-7 expression and irreversible renal injury. Importantly, the restoration of BMP-7 activity through treatment with exogenous BMP-7 enhances kidney repair following prolonged UUO. In examining the mechanisms that lead to the loss of BMP-7, we found that UUO results in histone deacetylation in the Bmp-7 promoter and the subsequent repression of its transcriptional activity. Treatment with the histone deacetylase (HDAC) inhibitor trichostatin A during UUO stimulates the expression of BMP-7, the activation of its downstream signaling pathways, and the BMP-7-mediated suppression of TGF-β-dependent pro-fibrotic pathways. Finally, HDAC inhibition enhances kidney repair in obstructive uropathies that typically lead to irreversible injury.

Conclusions: BMP-7 plays a critical role in the repair of acute obstruction-induced renal injuries. However, prolonged obstruction leads to the dysregulation of kidney repair, in part, through the HDAC-dependent suppression of *Bmp-7* transcription. Importantly, HDAC inhibition restores BMP-7 expression and stimulates the innate repair mechanisms of the kidney during the treatment of obstructive uropathies.

A Novel Method To Remove Iron from the Body by Urinary Excretion Andong Qiu,[1] Neal A. Paragas,[1] Roland Strong,[2] Jonathan M. Barasch.[1] *[1]Columbia; [2]Fred Hutchinson.*

Background: There are two types of iron overload disorders, hereditary (HH) and acquired hemochromatosis (AH). HH is caused by loss of function of genes that regulate iron metabolism, and AH is caused by blood transfusions and dietary overload. Since each RBC unit contains 250 mg of iron, rapid clearance of 25% of even a single unit delivers a bolus 10X the daily requirement for iron , resulting in biochemical evidence of toxicity. We sought novel methods to remove iron from the body with low-toxicity and high efficacy.

Methods: NGAL (Siderocalin, Lipocalin 2) is a carrier that can transport iron bound to a catecholate cofactor. The complex (25KDa) of NGAL:catecholate:Fe is filtered by the kidney, and then reabsorbed by the proximal tubule. Consequently, to safely remove iron

from the body (1) iron must be bound in a redox neutral fashion, (2) NGAL-catecholate-iron complex must not be reabsorbed by the proximal tubule, and (3) iron must be bound in a pH insensitive fashion, so that the complex does not dissociate in acidic urine.

Results: We have solved each problem by modifying a number of surface residues of NGAL-Siderocalin based on structural data. The mutant, called NGAL* was competent to bind the bacterial catecholate siderophore, enterochelin, producing a bright red coloration typical of the wild type complex. The complex NGAL*:enterochelin:iron was inactive in assays that measured the conversion of FeIII to FeII, an initiator of the Fenton reaction, and the complex was inactive in radical activation of fluorescein precursors. NGAL* failed to release iron even at pH4.0 consistent with prior studies of enterochelin stability. Finally, unlike the wild type NGAL-Siderocalin, the complex was found in the urine containing iron captured from the body.

Conclusions: Serum NGAL-Siderocalin (sNGAL) is cleared and metabolized by the kidney, while urine NGAL-Siderocalin (uNGAL) derives principally from cells in the distal nephron. However injection of NGAL* in the serum can cross into the urinary compartment by escaping reabsorption. Consequently, we suggest that NGAL* is a tool to treat iron overload syndromes typical of genetic diseases and multiple blood transfusions by safely clearing iron into the urine.

Apelin Ameliorates Renal Ischemia/Reperfusion Injury in Rats Mehmet Koc,[1] Zarife Ozdemir,[1] Naziye Ozkan,[2] Sule Cetinel,[2] Berrak Yegen.[1] *[1]Department of Physiology, Marmara University, Medical Faculty; [2]Department of Histology, Marmara University, Medical Faculty, Istanbul, Turkey.*

Background: Apelin is a peptide identified as the endogenous ligand of the human orphan G-protein-coupled receptor. It is highly expressed in the cardiovascular system and shows significant positive inotropic action and causes endothelium and nitric oxide-dependent vasodilatation. Recently, apelin was reported to protect myocardium against ischemia-reperfusion (I/R) injury by preventing the generation of free radicals. The potential protective effects of apelin in renal I/R injury were elucidated in this study.

Methods: Under ketamine anesthesia (100 mg/kg intraperitoneally, ip) male Sprague Dawley rats underwent right nephrectomy and I/R was induced by placing a microvascular clamp across left renal artery for 60 minutes (n=17), while the control group had sham operation with no clamp placement (n=8). Immediately after clamp placements, the rats were injected ip with either saline or apelin (50 μg/kg). Following a 24-h reperfusion period, the rats were decapitated to obtain serum and kidney tissue samples for the assessment of histopathological changes and the determination of malondialdehyde (MDA, an end product of lipid peroxidation), glutathione (GSH, a key antioxidant) levels and myeloperoxidase (MPO) activity, an index of tissue neutrophil infiltration.

Results: In saline-treated I/R group, serum creatinine and BUN levels were increased significantly as compared to sham-operated group, while apelin prevented I/R-induced elevations in creatinine and BUN ($p<0.05$). Renal MDA level in the saline-treated group was significantly increased ($p<0.05$), while apelin administration prevented I/R-induced increase in MDA level. Neither MPO activities nor GSH levels were significantly different among experimental groups. Histological analysis revealed severe renal injury in the saline-treated rats, while given scores in the apelin-treated I/R group were significantly reduced ($p<0.05$).

Conclusions: The present data demonstrate that apelin ameliorates renal I/R-injury by delimitating oxidative stress. Apelin merits further investigation for its supportive use in post-ischemic renal injury.

FR-PO1130

THR-184, Novel Peptide Agonist of BMP (Bone Morphogenetic Protein) Signaling, Is Efficacious in Preventing Ischemia-Induced AKI in Normal and CKD Rats Silvia B. Campos-Bilderback,[1] Ruben M. Sandoval,[1] Exing Wang,[1] Dattatreyamurty Bosukonda,[2] Peter C. Keck,[2] William Carlson,[2] Bruce A. Molitoris.[1] *[1]Medicine/Div of Nephrology, Indiana Univ. School of Medicine, Indianapolis, IN; [2]Thrasos Innovation Inc, Montreal, QC, Canada.*

Background: BMP 7 is known to reduce ischemic, nephrotoxic and obstructive acute kidney injury (AKI) in preclinical models. However, BMP is a potent bone and cartilage inducer in vivo, and these effects limit its therapeutic use in kidney diseases. To alleviate this side effect novel peptide agonists of the BMP pathway devoid of osteogenic activities have been developed. These peptides exert their beneficial effects in kidney by exerting anti-inflammatory and anti-apoptotic effects in renal proximal tubule cells.

Methods: THR-184 was studied in ischemia reperfusion studies in normal and chronic kidney disease (CKD) rats. THR-184 administered via intravenous infusion or bolus injection 30 min prior to or 30 min post injury to rats undergoing a 40-minute unilateral clamp, with contralateral nephrectomy.

Results: These studies resulted in a dose response with maximal reduction in serum creatinine (SCr) of greater than 50% untreated ischemic controls. IV infusion of THR-184 over 60 min starting thirty minutes post ischemic injury reduced SCr from 4.4 mg/dl ± 0.21 to 3.25 ± 0.17 ($P\leq0.01$) at 24 hours and 3.7 ± 0.15 to 2.5 ± 0.16 ($P\leq0.01$) at 48 hours. Ischemia reduced baseline GFR from 0.77 ± 0.02 ml/min/100g body wt to 0.01 ± 001 and 0.02± 0.01at 24 and 48 hr, respectively. THR-184 resulted in 6 and 5 fold increases in GFR at 24 and 48 hrs, respectively. At 5 days post ischemia THR-184 increased GFR to 0.22 +/-0.11 ml/ml/100gm body wt versus 0.09 +/-0.08 versus untreated ischemic rats ($P\leq0.01$). Finally, in rats with pre-existing ischemia-induced CKD and baseline SCr of 1.0 mg/dl, 30 minutes of clamp ischemia increased SCr to 4.6 mg/dl at 24 hrs and 3.1 at 48 hrs, while post injury treatment with THR-184 minimized the increase in SCr to 2.5 and 2.1 at 24 and 48 hrs, respectively.

Conclusions: These data indicate that THR-184, a peptide agonist of BMP signaling, is efficacious in preventing ischemia-induced AKI in normal and CKD rats.

FR-PO1131

Novel Xanthine Oxidoreductase Inhibitor, Febuxostat, Protects Rat Kidney from Renal Ischemia-Reperfusion Injury Yoshitaka Isaka,[1] Hidetoshi Tsuda,[2] Noritaka Kawada,[1] Hirotsugu Iwatani,[1] Toshiki Moriyama,[1] Shiro Takahara,[2] Hiromi Rakugi.[1] *[1]Department of Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Department of Advanced Technology for Transplantation, Osaka University Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Renal ischemia-reperfusion (I/R) injury is unavoidable during kidney transplantations and leads to both early and long-term graft dysfunction. During I/R injury, the burst of reactive oxygen species (ROS) can trigger the inflammation and the tubular cell injury. Febuxostat is a novel selective inhibitor of xanthine oxidoreductase (XOR), approved for treating hyperuricemia. As XOR is a critical source of ROS, inhibition of XOR could be a therapeutic target for I/R injury. Therefore, we performed this study to test the therapeutic effect of febuxostat on renal I/R injury.

Methods: To test the protective effect of febuxostat, uninephrectomized Sprague-Dawley rats received saline (Veh) or febuxostat (Feb) at a dose of 10 mg/kg body weight orally 24 hour and 60 min prior to I/R injury. Renal I/R injury were induced by clamping the left renal artery for 45 min. At 24 hours after reperfusion, serum and kidney samples were harvested.

Results: Veh-treated I/R injured rats exhibited elevated serum creatinine (1.81±0.29 mg/dl) and BUN (111.2±7.5 mg/dl), which were significantly blunted in Feb-treated I/R injured rats (0.65±0.09 and 40.1±6.4 mg/dl, respectively). Histological analysis revealed that Feb-treated rats showed less tubular injury with reductions in CD68-positive macrophages infiltration and TUNEL positive tubular cells compared to Veh-treated rats.

Conclusions: In conclusion; novel xanthine oxidoreductase inhibitor, febuxostat, can protect kidney from renal I/R injury, and may contribute to preserve early and long-term kidney graft function.

FR-PO1132

Angiopoetin-1 and VE-Cadherin – EPC Antagonists in Acute Ischemic Renal Failure Daniel Patschan, Susann Patschan, Gerhard A. Mueller. *Nephrology and Rheumatology, University Hospital Göttingen, Göttingen, Niedersachsen, Germany.*

Background: Exogenously administered endothelial progenitor cells (EPCs) can protect the kidney from acute ischemic injury (iAKI). Over the last years, several EPC activators have been identified which increase the cells´ renoprotective capacity in iAKI (8-O-cAMP, melatonine). Angiopoietin-1 and -2 play critical roles in vascular homeostasis. Aim of the study was to analyze whether Angiopoietin-1 (Ang-1) modulates EPC-mediated renoprotection in iAKI.

Methods: EPCs were isolated from male C57BL/6N mice. After 5 days of culturing, cells were incubated with different substancies: Ang-1, Ang-1 + blocking peptide, Ang-1 + anti-VE-Cadherin, 8-O-cAMP+cRGD (±anti-VE-Cad.), respectively. After one hour of incubation, dye-labelled EPCs were systemically injected into recipient animals after bilateral renal ischemia of 40 minutes. Two days later, renal function and morphology were analyzed. In addition, the migratory cell activity was investigated in vitro.

Results: Mice were not prevented from acute renal failure if 0.5 × 106 untreated EPCs were injected. Animals injected with Ang-1 pretreated EPCs showed significantly worsening of postischemic renal function. These effects were completely reversible after combined cell incubation with Ang-1 and a specific blocking peptide. In order to analyze whether the effects of Ang-1 are mediated by its agonistic actions on VE-Cadherin, cells were incubated with Ang-1 and anti-VE-Cadherin. Renal function of cell injected mice declined further. Comparable effects were inducable by EPC pretreatment with 8-O-cAMP (+cRGD) and anti-VE-Cadherin (8-O-cAMP stimulates VE-Cadherin expression). In vitro analysis showed significantly reduced migratory EPCs activity after VE-Cadherin blockade.

Conclusions: Ang-1 decreases the renoprotective capacity of syngeneic murine EPCs in iAKI. These effects do not result from agonistic actions on VE-Cadherin. VE-Cadherin rather seems to antagonize Ang-1 in the setting of an EPC-based therapy of iAKI.

FR-PO1133

Intermedin Promotes Recovery from Acute Kidney Injury Induced by Renal Ischemia-Reperfusion Injury Rongshan Li,[1,2] Xi Qiao,[1,2] Li Zhao,[1,2] Haihong Zhao,[1,2] Yudong Chu,[1,2] Guozheng Feng.[1,2] *[1]Department of Nephrology, Second Hospital of Shanxi Medical University, Taiyuan, Shanxi, China; [2]Shanxi Kidney Disease Institute, Taiyuan, Shanxi, China.*

Background: Acute kidney injury (AKI) induced by ischemia-reperfusion injury (IRI) is associated with high morbidity and mortality. The prognosis of renal IRI is determined by the extent of the injury and the process of the recovery. Our previous studies demonstrated that intermedin (IMD) protects against renal IRI by reducing injury, while its role in the recovery process is known yet.In this study, we investigate the effect of IMD on the recovery process after renal IRI and its mechanisms.

Methods: Eukaryotic expression vector encoding rat IMD gene or control empty plasmids was transfected into the kidney using an ultrasound-microbubble mediated system. The transfection rate was detected. Renal IRI model was induced by clamping left renal

artery for 45 min followed by reperfusion. One, 2, 3, 4, 7 and 14d of reperfusion, renal function, tubulointerstitial damage and PCNA positive cells were evaluated. The expression of angiogenesis-related proteins (HIF-1a, VEGF and Tie-2), nephrogenic proteins (Pax-2, ZO-1, Ncam, Wt-1 and Vimentin) as well as cell cycle related proteins (cyclin D1, cyclin E, CDK2 and CDK4) was measured by Western blot analysis or ELISA.

Results: IMD expression was significantly up-regulated in kidneys of rats in IMD transgene group than the control. IMD gene transfer significantly protected renal function and lessened morphological damage. The number of PCNA positive cell increased significantly 1d, 2d, 3d, 4d and 7d after IRI, and reached the peak at 7d. IMD gene transfer further increased the number of PCNA positive cell, which arrived the peak at 3d. The expression of HIF-1a, VEGF, Tie-2, Pax-2, ZO-1, Ncam, Wt-1 and Vimentin was significantly up-regulated 1, 2, 3 and 4d after IRI, and cyclin D1, cyclin E, CDK2 and CDK4 expression was markedly up-regulated 1, 2, 3, 4, 7 and 14d. In rats treated with IMD, we observed a 1- to 4-d earlier and more abundant reexpression of the above proteins than the control.

Conclusions: IMD can induce an earlier regeneration process after renal IRI, thus promotes recovery from renal IRI.

FR-PO1134

DPP4 Inhibition Attenuates Ischemia-Induced Impaired Renal Function in a Unilateral Rat Model of Ischemia Reperfusion Lorenzo Glorie,[1] Anja Verhulst,[1] Veerle Matheeussen,[2] Ingrid De Meester,[2] Joanna Magielse,[3] Nina Hermans,[3] Patrick C. D'Haese,[1] Annelies De Beuf.[1] *[1]Laboratory of Pathophysiology, University of Antwerp, Antwerp, Belgium; [2]Laboratory of Medical Biochemistry, University of Antwerp, Antwerp, Belgium; [3]Laboratory of Nutrition and Functional Food Science, University of Antwerp, Antwerp, Belgium.*

Background: Dipeptidyl peptidase 4 (DPP4) inhibitors increase the half-life of DPP4 substrates and improve glucose tolerance of diabetes patients. It has been shown that DPP4 inhibitors exhibit protective effects on ischemia reperfusion injury (IRI) of heart and lung. We studied the effect of vildagliptin (VG) on IRI-induced acute kidney injury in rats.

Methods: Male Wistars underwent 30' of left renal ischemia, followed by right nephrectomy. Saline, 1 or 10 mg/kg VG (VG1/VG10) was administered iv prior to ischemic or sham operation. Rats were sacrificed after 2, 12, 48 hours of reperfusion.

Results: DPP4 inhibition was confirmed by decreased activity in serum and kidney homogenates. VG resulted in a significant dose-dependent decrease of serum creatinine (1.31±0.32 and 0.70±0.19 mg/dl for VG1 and 10 resp. vs 1.91±0.28 mg/dl for controls at 12h; $p<0.01$). Tubular morphology (PAS-PCNA) revealed reduced necrosis of proximal tubules at 12h (62.1±18.0% in VG10 vs 77.5±22.0% in controls; $p<0.05$). VG had no effect on regeneration. VG resulted in a decreased apoptosis shown by the 2-fold decreased Bax/Bcl-2 mRNA expression and diminished presence of apoptotic bodies on TUNEL stained sections (414.1±231.7 in VG10 vs 1212.0±650.8 in controls; $p<0.05$). VG treatment also resulted in a early downregulation of several pro-inflammatory markers, including IL16 (3-fold), CXCL10 (2-fold), TNFα (2-fold) and upregulation of anti-inflammatory IL10 (1.5-fold). Furthermore, VG results in early downregulation of SOD3 and catalase mRNA at 2h, faster recovery at 12h and sign.reduction in expression of MDA at 48h (0.54±0.17 and 0.56±0.21 for VG1&10 resp. vs 1.00±0.35 µM in controls; $p<0.05$).

Conclusions: DPP4 inhibition results in functional and morphological protection of the kidney against IRI as reflected by changes of expression of relevant genes. The precise mechanism remains to be elucidated.

FR-PO1135

A New Class of Peptide Agonists Share Functional Properties of Bone Morphogenetic Protein To Protect Against Renal Ischemic Damage Dattatreyamurty Bosukonda,[1&3] Peter C. Keck,[1] Silvia B. Campos-Bilderback,[2] Ruben M. Sandoval,[2] Exing Wang,[2] Philippe Bey,[1] William Carlson,[1&3] Bruce A. Molitoris.[2] *[1]Thrasos Innovation, Inc., Montreal, QC, Canada; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Mass General Hospital/ Harvard Medical School, Boston, MA.*

Background: Proximal tubule epithelial cells (PTEC) play a central role in the response of the kidney to insult by the production of chemokines and cytokines that signal inflammatory response. Bone morphogenetic protein-7(BMP-7),a member of the TGF-beta superfamily, has previously been shown to reduce inflammation and tissue damage in animal models of acute renal failure.

Methods: We have designed a new class of peptide agonists of molecular size,2 kDa.

Results: Like BMPs, the peptides bind both type I and type II BMP receptors to induce signal transduction (SMAD 1/5) in PTEC; unlike BMPs, they do not bind ALK6, a type I receptor that plays a predominant role in osteogenesis. Upon injury, PTEC express increased levels of cytokines and chemokines causing inflammation of PTEC which was prevented by the peptide agonists to protect PTEC. SPECT/CT Bio-imaging of rats treated with radioiodinated THR-184 demonstrated that the compound rapidly accumulated in kidneys and stomach, at levels 10 times that for the rest of the body. In kidney cortex, levels rose rapidly within the first 15 min [9.4% +/- 0.9% of injected doses, n=4] and remaining steady over 2 h after injection [private communication, Dr. Mary Rusckowski, U Mass Medical School, Worcester,MA]. In AKI animals after 45 min bilateral renal artery occlusion, and at 24 h after reperfusion, serum creatinine (Cr) increased 18 fold above basal values. The peptide agonist either by iv at 15 min before clamping or by oral at 2 h before and 1 h after clamping, strongly suppressed the serum Cr rise at 24 h after reperfusion, suggesting that the compound preserved kidney function.

Conclusions: These results suggest that the new class of peptide agonists while sharing the beneficial properties of BMP may provide novel therapeutic agents for kidney disorders involving inflammation and ischemic damage of PTEC.

FR-PO1136

Paricalcitol Prevents Cisplatin-Induced Renal Injury by Suppressing Apoptosis and Proliferation Jeong-Woo Park,[1] Soo Yeon Joo,[2] Eun Hui Bae,[1] Seong Kwon Ma,[1] Suhn Hee Kim,[3] Jongun Lee,[2] Soo Wan Kim.[1] *[1]Internal Medicine, Chonnam National University Medical School, Gwangju, Korea; [2]Physiology, Chonnam National University Medical School, Gwangju, Korea; [3]Physiology, Chonbuk National University Medical School, Jeonju, Korea.*

Background: Cisplatin (CDDP) is a widely used chemotherapeutic agent. However, approximately one-third of patients experience kidney injury with CDDP treatment. Paricalcitol is an active vitamin D analog that shows renoprotective action in various experimental nephropathy models. We investigated the efficacy of paricalcitol in preventing the progression of CDDP-induced kidney injury.

Methods: Male Sprague-Dawley rats were treated with vehicle (n=12), single CDDP alone (n=12, 6 mg/kg/day, *i.p.*), or single CDDP+paricalcitol (n=12, 0.2 µg/kg/day, *s.c.*) for 4 days. In another series of experiment, HK-2 cells treated with CDDP (50 µM), either with or without paricalcitol (0.2 ng/ml) were also examined.

Results: Paricalcitol counteracted the CDDP-induced decline in renal function. Paricalcitol also suppressed the expression of transforming growth factor-β1 (TGF-β1), Smad signaling, and the subsequent epithelial-to-mesenchymal process in CDDP-induced nephropathy. In HK-2 cells, paricalcitol suppressed the CDDP-induced increases in ERK1/2 and p38 phosphorylation and in fibronectin/connective tissue growth factor expression. Paricalcitol co-treatment also reduced CDDP-induced over-expression of p53, which coincided with a decrease in pro-apoptotic markers. It also augmented the up-regulated expression of p27kip1 and decreased the number of proliferating cell nuclear antigen-positive cells in CDDP-treated rat kidneys. Accordingly, paricalcitol co-treatment reduced the over-expression of cyclin-dependent kinase2/cyclin E induced by CDDP.

Conclusions: Our results suggest that paricalcitol can attenuate CDDP-induced renal injury by suppressing the induction of fibrotic, apoptotic and proliferative factors. Its underlying mechanisms may include the inhibition of TGF-β1, mitogen-activated protein kinase signaling pathways, p53-induced apoptosis, and the augmentation of $p27^{kip1}$ over-expression.

FR-PO1137

CCL19 and 21 Are Essential for Regulatory T Cell Function in Nephrotoxic Serum Nephritis Kathrin Eller, Alexander R. Rosenkranz. *Clinical Division of Nephrology, Medical University Graz, Graz, Austria.*

Background: CCL19 and CCL21 guide T lymphocytes via binding to CCR7 to the T cell areas in lymph nodes. Recently, we provided evidence that CCR7 knock-out (KO) mice display increased disease indices when subjected to nephrotoxic serum nephritis (NTS). Tregs of CCR7KO mice were found to migrate to the kidneys rather than to the lymph nodes and thereby lost their potential to efficiently suppress NTS.

Methods: To study the CCR7 counterparts CCL19 and CCL21 we used the plt-mouse model, which do not express CCL21 or CCL19 protein in secondary lymphoid organs but continue to express CCL21 at reduced levels in lymphatic endothelium.

Results: When plt-mice were subjected to NTS they displayed significantly increased disease activity as shown by increased albuminuria and histological changes. Even though significantly decreased numbers of CD4+ T cells were detected in the lymph nodes of plt-mice, subtyping revealed significantly increased numbers of activated CD4+CD69+ T cells and decreased numbers of CD4+CD25+FoxP3+ Tregs to infiltrate the lymph nodes of plt-mice after NTS induction. In line, Tbet and TNF-alpha mRNA expression were found to be increased in lymph nodes of plt-mice. Interestingly, significantly increased Tregs were found to infiltrate the kidney of plt-mice as compared to respective controls. When Tregs were transferred to plt-mice a delayed suppression of NTS was observed as compared to wild-type mice.

Conclusions: Together, CCL19 and CCL21 are significantly involved in the Treg homing in NTS. Tregs are only capable to sufficiently inhibit NTS when located to the lymph nodes. Since plt-mice still express CCL21 at reduced levels Treg transfer in plt-mice resulted only in a delayed suppression of NTS.

FR-PO1138

Th17/Treg Imbalance in Patients with Idiopathic Membranous Nephropathy Lili Liu, Yan Qin, Limeng Chen, Xue-Wang Li. *Division of Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: IMN was an autoimmune disease, which involve T and B lymphocyte dysfunction. Recently, regulatory T cells (Treg) cells and Th17 cells had been described as two distinct subsets of T helper cells. Th17/Treg balance may be important in the development/prevention of autoimmunity. The objective of this study was to evaluate whether the Th17/Treg balance was broken in IMN patients.

Methods: Forty-nine patients, diagnosed IMN by renal biopsy and excluded potential secondary factors, were enrolled in this study. Twenty-eight healthy volunteers served as healthy controls (HCs).The frequencies of peripheral Treg and Th17 subsets were evaluated

by flow cytometry. The peripheral relative mRNA expression of key transcription factors were determined by real-time RT-PCR. The concentrations of plasma cytokines were evaluated by ELISA. The infiltration of Treg cells and expression of IL-17 in renal tissue were determined by immunohistochemical staining.

Results: Compared with HCs, the frequency of peripheral Treg cells and plasma TGF-β1 level decreased ,while the frequencies of Th17 cells and plasma IL-23, IL-17 levels increased significantly in IMN patients.The key transcription factors of Treg and Th17(Foxp3 and RORγt), had similar alterations in HC and IMN patients. The Th17/Treg ratios increased along with increased proteinuria and decreased albumin levels in patients with IMN. IL-17 protein expression in the renal tissue of IMN patients increased significantly compared with that in control subjects. Infiltration of Treg cells was also detected in the renal tissue of IMN patients, while rare Treg cells had been seen in normal renal tissue. The infiltration of Treg cells in renal interstitium also related to a higher clinical remission in IMN patients.

Conclusions: Th17/Treg imbalance existed in IMN patients, suggesting a potential role of Th17/Treg imbalance in the pathogenesis of IMN.

FR-PO1139

Sexual Dimorphism of Foxp3+ T-Regulatory Cell Function Is HDAC6-Dependent Tatiana Akimova, Ulf H. Beier, Wayne W. Hancock. *Children's Hospital of Philadelphia & University of Pennsylvania.*

Background: Pre-menopausal women have 2-3 fold higher rates of autoimmune diseases compared to age matched males. While the basis for this difference is likely complex and multifactorial, little attention has been given to whether there are gender-based differences in Treg suppressive function, despite the fact that Foxp3 is an X-linked gene.

Methods: We analyzed Treg gene expression and suppressive function (SF) in normal 6-8 wk male and female littermate C57BL/6 mice, and in various KO strains.

Results: While male and female mice had comparable numbers of Tregs, male Tregs had greater SF. This disparity was also seen using male and female Tregs of various knockout mice, except in HDAC6-/- mice. HDAC6-/- C57BL/6 mice had the same number of Tregs as WT mice, but higher Foxp3 expression per cell (qPCR, Western blot) and a more mature Treg phenotype (assessed using CD44, CD62L, CD69 and CD103 markers). HDAC6-/- Tregs were also more suppressive than WT Tregs, but interestingly, female Tregs had better suppressive function than male Tregs, i.e. there was a gender-based reversal in HDAC6-/- Treg function. The SF mean ratio of adult Tregs was 1 (WT F) to 1.3 (WT M) to 2 (HDAC6 F) to 1.7 (HDAC6 M), and Tregs from HDAC6-/- females had more mature Treg phenotype (10-12% fewer naive Tregs). This difference was also seen upon treatment of Tregs from normal human donors (29 tests) with pan-HDAC or HDAC6-selective inhibitors; while male Tregs had 1.7±0.1 fold enhanced SF, females Tregs showed 2.2±0.2 fold increase (p=0.057). Binding of estrogen to the estrogen receptor-α induces HDAC6 and promotes proteasomal degradation of Smad2 and Smad3, and Tregs from HDAC6-/- mice showed increased phospho-Smad3. We are currently assessing the effects of HDAC6 targeting on Smad2/3-dependent events at the TGF-β-dependent Foxp3 enhancer.

Conclusions: Our studies show HDAC6, also an X-linked gene, is key to regulation of Foxp3 expression and function, and that its targeting can affect estrogen/estrogen receptor signaling. Use of HDAC6 selective inhibitors may provide a means to overcome the gender-based disparity in Treg function and be useful in the therapy of multiple autoimmune diseases, including those affecting the kidney.

IKK2 Is Required for the Development of Regulatory T Cells Eveline Piella,[1] Anna Hermann,[1] Gunther Zahner,[1] Annette Erhardt,[2] Hans-Joachim Paust,[1] Jan-Eric Turner,[1] Ulf Panzer,[1] Joachim Velden,[3] Gisa Tiegs,[2] Rolf A. Stahl,[1] Friedrich Thaiss.[1] *[1]Univ. Hospital, III. Med. Department, Hamburg, Germany; [2]Univ. Hospital, Inst. Exp. Immunology, Hamburg, Germany; [3]Univ. Hospital, Inst. Pathology, Hamburg, Germany.*

Background: Regulatory T cells (Tregs) are characterized by their expression of the transcription factor Foxp3. In experimental glomerulonephritis (GN) Tregs seem to play a pivotal role, since their depletion leads to an aggravation of GN. Recent studies have shown that members of the NF-kappaB-family are involved in Foxp3 gene expression. Phosphorylation of the NF-kappaB inhibitor by the I-kappaB-kinase 2 (IKK2) is one of the crucial steps in NF-kappaB activation. In order to elucidate the potential role of NF-kappaB on the development of Tregs in vivo, mice with IKK2 deficient Foxp3^{+} cells were generated (Foxp3^{Cre}IKK2$^{fl/fl}$).

Methods: Foxp3^{Cre} (YFP) mice have been described by Dr. A.Y. Rudensky and IKK2$^{fl/lf}$ mice were kindly provided by M. Karin. Animals homozygous for Foxp3^{Cre} and IKK2$^{fl/fl}$ were sacrificed on days 3, 7 and >14 after birth. Cells from thymus, spleen and lung were isolated and the frequencies of Tregs analyzed by FACS. Periodic-acid-Schiff staining and immunohistochemistry were performed using standard techniques.

Results: Homozygous Foxp3CreIKK2fl/fl mice spontaneously develop a scurfy-like phenotype at day 12-27 after birth which manifests in a hunched posture and a skin disorder characterized by scaliness, swollen ears and a tail shielded by padded rings. Animals show enlargement of lymph nodes and a significant splenomegaly. Homozygous Foxp3CreIKK2fl/fl mice present a complete disruption of organ architecture at day >14 of the spleen. The kidneys did not show infiltrating inflammatory cells or failed tissue organization. The number of Tregs in the spleen and lung are significantly reduced but are not altered in the thymus compared to control animals.

Conclusions: Our data demonstrate that continuous IKK2 activity is essential to maintain thymic pre-programmed Foxp3 expression in mature Treg cells in the periphery. Thus, continued expression of IKK2 in mature Treg cells is indispensable to maintain the dominant tolerance which is mediated by these cells.

Anti-CD45RB Not Only Augments homeostatic Proliferation but Uniquely Promotes Antigen-Specific Proliferation of Regulatory T Cells In Vivo Ying Wang, David M. Rothstein. *University of Pittsburgh, PA.*

Background: CD4+Foxp3+ Treg play an important role in transplant tolerance. By transferring CFSE-labeled Foxp3+ (Treg) or Foxp3- (Tconv) CD4 cells from congenic Foxp3-reporter mice into naïve WT recipients, we showed that Treg exhibit a higher constitutive rate of homeostatic proliferation (HP) than Tconv (~50% vs. <10% over 10d). Moreover, anti-CD45RB induces tolerance through a 2X increase in Treg which results by dramatically increasing Treg HP, even in the absence of exogenous antigen. While exogenous antigen is not required, Treg HP may still be antigen-driven. To address the signals involved, CFSE-labeled congenic CD4 cells were transferred into naïve wt mice and proliferation of Foxp3+ and Foxp3- cells assessed on d10. Treating mice with Cyclosporin A (CsA) greatly reduced both basal and anti-CD45RB-mediated HP of Treg. This inhibition by CsA was only partly restored by concomitant administration of rIL-2, suggesting that NFAT translocation was required. Moreover, when CFSE-labeled congenic CD4 cells were transferred into MHCII-/- mice, both basal and anti-CD45RB-mediated HP of Treg were markedly reduced. These studies suggest that antigen signaling is required for high rates of HP by Treg. OTII mice (TCR-transgene specific for Ova peptide) on a RAG-/- background, exhibit low but readily detectable Treg. Anti-CD45RB alone had no effect, whereas, immunization with Ova (20μg ip) expanded Treg % and number ~2X. Anti-CD45RB + Ova further increased Treg 3.3X vs. Ova alone, but had no effect on Tconv cell number. Next, OTII (non-RAG-/-) mice were used because they express sufficient Treg (3.6%) for cell transfer studies to assess proliferation. CFSE-stained CD4 cells from these OTII mice were adoptively transferred into congenic mice. Ova + anti-CD45RB specifically augmented proliferation of OTII Treg compared to Ova alone, while Tconv were unaffected. These results demonstrate that both basal and anti-CD45RB-mediated augmentation of Treg HP are antigen-dependent. Moreover, anti-CD45RB can specifically enhance the proliferative response of Treg to exogenous antigen in vivo – a new paradigm for expansion of Treg for therapeutic purposes.

FR-PO1142

Regulatory T Cells Reverse Obesity-Linked insulin Resistance and Diabetic Nephropathy Kathrin Eller,[1] Alexander R. Rosenkranz,[1] Philipp Eller.[2] *[1]Clinical Division of Nephrology, Medical University Graz, Graz, Austria; [2]Clinical Division of Angiology, Medical University Graz, Graz, Austria.*

Background: FoxP3 expressing regulatory T cells (Tregs) are critical for maintenance of tolerance in rodents and men. Evidence is increasing that regulatory T cells improve insulin resistance in type 2 diabetes mellitus.

Methods: The study was designed to evaluate the role of Tregs in type 2 diabetes mellitus and end organ damage in the human and murine setting.

Results: We observed that fat mass, fasting blood glucose levels and TNF-α mRNA expression significantly correlated with FoxP3 transcripts in human visceral adipose tissue. To further evaluate the pathogenic role of Tregs in insulin resistance, we used the db/db mouse model, depleted of or transferred with Tregs, and followed the mice for 56 days. Treg-depletion using an anti-CD25 monoclonal antibody enhanced insulin resistance as shown by increased fasting blood glucose levels as well as an impaired insulin sensitivity. Moreover, Treg-depleted db/db mice developed increased signs of diabetic nephropathy, such as albuminuria and glomerular hyperfiltration. This was paralleled by a pro-inflammatory milieu in both, murine visceral adipose tissue and the kidney. Vice versa, adoptive transfer of CD4+FoxP+ Tregs significantly improved insulin sensitivity and diabetic nephropathy. Accordingly, there was increased mRNA expression of FoxP3 as well as less abundant pro-inflammatory CD8+CD69+ T cells in visceral adipose tissue and kidneys of Treg-treated animals.

Conclusions: In summary, our data suggest a potential therapeutic value of Tregs to improve insulin resistance and end organ damage in type 2 diabetes by limiting the pro-inflammatory milieu in VAT.

FR-PO1143

Early IL-17 Production by gamma-delta T Cells in the Kidney Is Induced by IL-23 and Contributes to Tissue Injury in Murine Crescentic Glomerulonephritis Christian Krebs,[1] Jan-Eric Turner,[1] Hans-Joachim Paust,[1] Andre Pascal Tittel,[2] Sabrina Bianca Bennstein,[1] Oliver M. Steinmetz,[1] Catherine Meyer-Schwesinger,[1] Rolf A. Stahl,[1] Christian Kurts,[2] Ulf Panzer.[1] *[1]III. Medizinische Klinik, UK-Eppendorf, Hamburg, Germany; [2]Institut für Experimentelle Immunologie, Universitätsklinikum Bonn, Bonn, Germany.*

Background: The inflammatory cytokine IL-17A (IL-17) is thought to play a critical role in the pathogenesis of human and experimental crescentic glomerulonephritis. However, the cell types which contribute to renal IL-17 production in glomerulonephritis are not

well characterized. In addition, the mechanisms which induce IL-17 production by renal leukocytes remain to be elucidated.

Methods: To characterize IL-17-producing cells in renal inflammation, we performed a time course analysis (day 1 - 30) of IL17 production in a T cell-dependent model of crescentic glomerulonephritis in mice (nephrotoxic nephritis, NTN).

Results: Ten-colour flow cytometric analysis of intracellular IL-17 staining and surface makers identified gamma-delta T cells (gdTC) as an important source of early IL-17 production (day 3) in the kidney. From day 6 on classical CD4+ Th17 cells were the major source of IL-17. Interestingly, CD3+ T cells that lacked expression of conventional T cell markers (CD4, CD8, dTCR, NK1.1, CD1d-α-GalCer) contributed significantly to renal IL-17 production. Analysis of mice deficient for IL-23-receptor, IL-23p19, or IL-1β-receptor1 showed that early IL-17 production by gdTC in the kidney critically depends on IL-23, but not IL-1β. Upon depletion of dendritic cells in CD11c-DTR mice gdTC were significantly decreased in the kidney with marked reduction of IL-17 production. To address the function of IL-17 production by gdTC in NTN we reconstituted IL-17-deficient hosts with wild-type CD4+ T cells ± co-transfer of wild-type gdTC. The absence of IL-17-producing gdTC resulted in reduced neutrophil infiltration and ameliorated renal tissue damage.

Conclusions: In conclusion, our data identify three major cellular sources of IL-17 in the kidney and demonstrate a previously unrecognized important role of IL-17-producing gamma-delta T cells in the immunopathogenesis of glomerulonephritis.

FR-PO1144

The Function of CD4 Lymphocytes in Experimental Autoimmune Glomerulonephritis Hans-Willi Mittrücker,[1] Julia Holzer,[1] Stefanie Hünemörder,[1] Hans-Joachim Paust,[2] Ulf Panzer,[2] Helmut Hopfer.[3] *[1]Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Nephrology, University Medical center Hamburg-Eppendorf, Hamburg, Germany; [3]Pathology, University Hospital, Basel, Switzerland.*

Background: Autoimmunity against the alpha3IV-NC1 domain of type IV collagen results in antiglomerular basement membrane (GBM) glomerulonephritis. Although auto-antibodies against alpha3IV-NC1 are central for the development of glomerulonephritis, there is increasing evidence for a contribution of alpha3IV-NC1-specific T-lymphocytes in disease. In this study, we will investigate the abundance and function of different T cell subsets at different phases of anti-GBM nephritis.

Methods: Experimental Autoimmune Glomerulonephritis (EAG) was induced in DBA/1 mice by repeated immunization with recombinant human alpha3IV-NC1 protein in complete and incomplete Freund's adjuvant.

Results: Immunized mice develop high serum titers of alpha3IV-NC1-specific antibodies. After 8 to 10 weeks, mice showed signs of progressive loss of kidney function, such as severe proteinuria and edema formation. Eventually, most mice died due to severe renal failure. Kidneys of immunized mice showed IgG deposition along the GBM and in the end stage of disease, a large fraction of glomeruli contained crescent-shaped inflammation, the hallmark of anti-GBM disease. At this time point, there was also massive tubulointerstitial damage with accumulation of T cells and macrophages. Immuno histology and FACS analyses of renal cells revealed massive accumulation of macrophages and T cells. T cells demonstrated a highly activated phenotype and upon polyclonal stimulation, a fraction of CD4 T cells produced IFNgamma and IL-17A.

Conclusions: In conclusion, our EAG model closely reproduces central features of human anti-GBM disease. Cytokine expression analyses point to a contribution of Th1 and Th17 cells in the progression of disease. Our current studies aim at clarifying the role of these different T cell subsets in anti-GBM disease.

FR-PO1145

A Myeloperoxidase Peptide-Specific CD4+ Cell Clone Induces Injury in Murine Anti-Myeloperoxidase Glomerulonephritis Janet Chang, Joshua D. Ooi, Stephen R. Holdsworth, A. Richard Kitching. *Medicine, Monash University, Melbourne, Victoria, Australia.*

Background: Autoimmunity to myeloperoxidase (MPO) is important in vasculitis. Autoreactive CD4+ cells support MPO-ANCA production and may play a direct role in injury, but T cell epitopes are not known and a role for effector CD4+ cells is uncertain.

Methods: An immunodominant MPO T cell epitope was defined by responses to overlapping MPO 20aa peptides in C57BL/6 mice. T cell clones were generated against an MPO peptide, transferred into Rag1-/- mice, then disease triggered with either low dose anti-glomerular basement membrane antibodies (anti-GBM Ab) or anti-MPO Ab/LPS.

Results: Mice were immunized with the 5 strongest responding peptides (by IFN-γ ELISPOT). All peptides responded to themselves and to recombinant mouse MPO, but peptide (pep)52 responded most strongly to rmMPO and itself (proliferation, IFN-γ and IL-17A ELISPOT). Pep52-immunized mice made MPO-ANCA, but at lower titers than MPO immunized mice. MPO pep52 specific CD4+ clones were generated by immunizing C57BL/6 mice. An MPO-specific IFN-γ secreting CD4+ cell clone was transferred into Rag1-/- mice, that were then immunized with MPO pep52 (an OVA-specific clone was a control; these Rag1-/- recipients were OVA pep immunized). 7 days later, low dose anti-GBM Ab was injected. Mice receiving anti-MPO clones developed progressive glomerular disease, but mice receiving anti-OVA clones did not (glomeruli with necrosis: day 5 anti-OVA clone 4±1, anti-MPO clone 49±5; day 14 anti-OVA 7±2, anti-MPO 69±4%; both P<0.001) and albuminuria (alb:creat day 5 anti-OVA 15±2, anti-MPO 276±44; day 14 anti-OVA 19±2, anti-MPO 1080±307 μg/μmol; both P<0.001). In further experiments, the same protocol was followed but disease was triggered with 50μg/g MPO-ANCA iv and 0.5μg/g LPS ip. Only MPO clone recipients developed significant disease (day 14: glomeruli with necrosis, anti-MPO Ab + anti-OVA clone 6±1, anti-MPO clone 41±4%; urine alb:creat anti-OVA 28±5, anti-MPO 1163±124 μg/μmol, both P<0.0001).

Conclusions: These results define a pathogenic MPO T cell epitope and support a role for cell mediated effector responses, along with humoral responses, in the pathogenesis of MPO-ANCA associated glomerulonephritis.

FR-PO1146

Profiles of CD4+ T Cells Reveal a Novel Subset and FoxP3 Splice Variants in ANCA Disease Meghan E. Free,[1] Maureen Su,[2] Donna O. Bunch,[3] J. Charles Jennette,[1] Ronald J. Falk.[3] *[1]Pathology and Laboratory Medicine, UNC Chapel Hill; [2]Pediatrics, UNC Chapel Hill; [3]UNC Kidney Center, UNC Chapel Hill, Chapel Hill, NC.*

Background: We hypothesized that the population dynamics of CD4+ T cells are altered in anti-neutrophil cytoplasmic autoantibody (ANCA) disease. We examined a novel T cell population (defined as CD127high CD25intermediate) and regulatory T cells (defined as CD127low CD25+ FoxP3+).

Methods: Analyses were performed using flow cytometry on lymphocytes stained with appropriate antibodies. Functional studies were completed using a standard suppression assay.

Results: The CD25int population was expanded in patients with ANCA disease (52.3% of CD4+ T cells) and SLE (52.2%) compared to healthy controls (31.2%) (p=0.008). Longitudinally, this CD25int population was stable regardless of disease status and medication. The majority of CD25int T cells expressed CD45RO indicating prior antigen stimulation and a subset of these produced IL-17A and expressed CCR6. Functionally, CD25int T cells from healthy controls moderately suppressed the proliferation of CD25low effector T cells and this suppressive ability was abrogated in ANCA disease. CD25int T cells continued to proliferate despite co-culture with regulatory T cells, demonstrating resistance to traditional suppression.

Regulatory T cells were elevated in active ANCA disease but return to normal levels at remission. These cells were unable to suppress effector cell proliferation which was associated with a FoxP3 splice variant missing exon 2.

Conclusions: In ANCA disease the majority of the CD25int population is 'antigen experienced' and may harbor autoreactive T cells. This expanded CD25int population can migrate into inflamed organs and secrete IL-17A, potentiating an inflammatory cascade with neutrophil influx. This CD25int population is resistant to suppression by regulatory T cells and lends insight into loss of peripheral tolerance in patients with ANCA disease. Lastly, with active disease, regulatory T cells harbor exon 2 deficient FoxP3 which may alter their suppressive function.

FR-PO1147

Interleukin 1 Regulates Localised Proliferation and Activation of T-helper 17 (Th17) Cells in the Acutely Obstructed Kidney Jana Pindjakova, Shirley Hanley, Michelle M. Duffy, Rhodri Ceredig, Matthew D. Griffin. *Regenerative Medicine Institute (REMEDI), School of Medicine, National University of Ireland, Galway, Ireland.*

Background: Interleukin-1 (IL- 1) enhances pathogenic IL-17-producing T-helper (Th17) cells in autoimmunity but its effects on intra-renal Th17 cells during kidney disease are unknown. We have reported that IL-1, produced by mononuclear cells from acutely injured kidneys, enhances IL-17 production by *in vitro*-generated Th17 cells. We have now examined *in vivo* proliferation and activation of Th17 cells in the mouse unilateral ureteral obstruction (UUO) model with and without IL-1 receptor (IL-1R) blockade.

Methods: Groups of mice underwent 72hr UUO with continuous bromodeoxyuridine (BrdU) exposure via drinking water ± 100 mg/kg/day IL-1R antagonist (IL-1Ra, Anakinra). Cell suspensions of obstructed (Obstr) and control (Ctrl) kidneys were analyzed immediately or after 12hr anti-TCR-stimulation culture by multi-color flow cytometry for T-cell markers/chemokine receptors and for intracellular BrdU and IL-17. IL-17 production in kidney cell cultures was measured by ELISA. Relative quantification of IL-17 and IFNγ mRNAs in kidney cortex was performed by qRT-PCR.

Results: *In vivo* proliferation (%BrdU+) of CD4+ T-cells was higher in Obstr compared to Ctrl kidneys. In vehicle-treated mice, 3-6% of CD4+ T-cells from Obstr kidneys were IL-17+ following anti-TCR stimulation. IL-17+ cells were almost exclusively CCR6+. The %BrdU+ among CD4+CCR6+ cells of Obstr kidneys was higher than that of CD4+CCR6- cells (44% vs 25%), indicating greater in vivo proliferation. Compared to vehicle, IL-1Ra was associated with reduced BrdU+CD4+ T-cell numbers in Obstr kidneys, reduced proportion of IL-17+ cells among the BrdU+CD4+ T-cells and reduced IL-17 production by anti-TCR stimulated cells from Obstr. kidney. qRT-PCR indicated reduced mRNA for IL-17 (but not IFNγ) in Obstr kidney cortex of IL-1Ra- compared vehicle-treated animals.

Conclusions: Following UUO, intra-renal CCR6+ Th17 cells undergo high rates of proliferation and activation. IL-1 blockade reduces this accumulation of proliferative, IL-17-competent T-cells and may be of interest in Th17-mediated kidney diseases.

FR-PO1148

Morphine Enhances HIV-1 Entry into Kidney Cells through a Novel Pathway Hersh Goel,[1] Mohammad Husain,[1] Joanna Mikulak,[2] Ashwani Malhotra,[1] Helena Schmidtmayerova,[1] Pravin C. Singhal.[1] *[1]Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY; [2]Istituto Clinico Humanitas, Rozzano (Milano), Italy.*

Background: Opiate addiction is considered to be a risk factor for the development of HIV-associated nephropathy (HIVAN). We hypothesized that opiates might be enhancing HIV entry into kidney cells.

Methods: Morphine pre-treated human tubular cells (HK2 and HRPTECs) were incubated with HIV-infected (HIV-LY) or control lymphocytes (LY) followed by evaluation of HIV infection of tubular cells by gag expression (real time PCR) and T cell apoptosis (FACS analysis). To determine the involved mechanism of T cell apoptosis, HK2s were pretreated with anti-PDL-1 antibody and then co-cultivated with HIV-LYs and LYs. Subsequently, HIV-LYs and LYs were evaluated for apoptosis and tubular cells for HIV expression. In addition, the effect of morphine on tubular cell PDL-1 expression was determined by FACS analysis. To determine the role of phagocytosis of the apoptosed HIV-LYs and opiate receptors, morphine-pretreated HK2s were co-cultivated with HIV-LYs in the presence of a caspase-3 inhibitor, naloxone (opiate receptor antagonist) or cytochalasin-B (an inhibitor of phagocytosis) followed by evaluation for tubular cell HIV expression.

Results: Morphine not only enhanced tubular cell PDL-1 expression but also promoted apoptosis of HIV-infected T cells; whereas, anti-PDL-1 antibody prevented morphine-induced T cell apoptosis. Morphine enhanced tubular cell HIV-1 expression; whereas, naloxone inhibited tubular cell HIV-1 expression. Since both caspase-3 inhibitor and cytochalasin B inhibited tubular cell HIV-1 expression, it would indicate that increased uptake of the apoptosed HIV-LY or its fragments had contributed to tubular cell HIV-1 expression.

Conclusions: Tubular cells not only facilitated apoptosis of HIV-1 infected T cells but also demonstrated capability of phagocytosing them. Morphine enhanced HIV-1 uptake by tubular cells by enhancing apoptosis of HIV-infected T cells. Since direct tubular cell HIV-1 entry did not induce productive infection, this would suggest that phagocytosed apoptosed T cells provided a suitable milieu for productive HIV-1 infection in tubular cells.

FR-PO1149

Adverse Host Factors Exacerbate Occult HIV-Associated Nephropathy Dileep Kumar,[1] Partab Rai,[1] Deepti D. Torri,[1] Rungwasee Rattanavich,[1] Ashwani Malhotra,[1] Praveen N. Chander,[2] Pravin C. Singhal,[1] Iti Yadav.[1] *[1]Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY; [2]Pathology, New York Medical College, Valhalla, NY.*

Background: Animal studies indicate that single HIV gene expression is enough for the development of HIVAN. With the advent of highly active anti-retroviral therapy (HAART) the incidence of HIVAN has gone down and the patients with HIV infection are living almost a normal life. We hypothesized that HIV infection of kidney cells prior to the start of HAART might manifest in the form of overt HIVAN in the presence of adverse host factors during the latter time periods.

Methods: To test our hypothesis, Vpr mice (which display doxycycline [Doxy] specific podocyte Vpr expression) with 2, 3, and 4 angiotensinogen (Agt) copies (Vpr-Agt-2, Vpr-Agt-3, and Vpr-Agt-4) were administered Doxy for 3 weeks (to develop occult HIVAN; to develop overt HIVAN, 6 wks doxy is needed) followed by Doxy-free water during the next 3 weeks. Subsequently, renal biomarkers (urinary protein :creatinine ratio, blood pressure levels) were collected and kidneys were harvested for renal histology, immunohistochemical studies, protein, and RNA extraction.

Results: Vpr-Agt-2 did not develop proteinuria and blood pressure, and displayed minimal glomerular and tubular lesions, without any microcyst formation. Vpr-Agt-3 showed mild glomeular and tubular lesions and microcyst formation; whereas, Vpr-Agt-4 showed moderate proteinuria, hypertension, glomerular sclerosis, tubular dilatation, microcysts and expression of epithelial mesenchymal transition markers. Vpr-Agt-4 not only displayed enhanced renal tissue expression of Agt, renin, and ACE but also showed higher ($P<0.04$) renal tissue concentration of Ang II; there was no difference in plasma concentration of Ang II in Vpr-Agt-2 and Vpr-Agt-4 mice. However, renal tissues in Vpr-Agt-4 showed enhanced ($P<0.01$) expressions of transforming growth factro (TGF)-β, connective tissue growth factor (CTGF), and vascular endothelial growth factor (VEGF) when compared with Vpr- Agt-2.

Conclusions: These findings indicate that adverse host factors such as the activation of the RAS, promotes the progression of occult HIVAN to apparent HIVAN.

Aging Effects on Kidney Cellular and Soluble Inflammation during AKI Nada Alachkar, Yuhong Tao, Elizabeth M. Higbee, Hamid Rabb. *Nephrology, Johns Hopkins University, Baltimore, MD.*

Background: Elderly have more severe course of AKI with increased progression to CKD compared to the young. We hypothesized that changes in kidney inflammation in elderly could contribute to the severity of AKI.

Methods: We performed IRI surgery on young (Y) (5-7 weeks) and elderly (E) (1 year) C57BL/6 male mice using a well-established model. Briefly, microvascular clamp was placed on the left renal pedicle for 45 minutes and then removed. Mice were sacrificed 3 days (D) post-IRI. IRI and contralateral kidneys were harvested. We used Flow cytometry to quantify the percent of CD4+, CD8+, CD69+ and Foxp3+ Tregs in kidney mononuclear cells (KMNCs) population. We measured levels of 9 cytokines (IL-2, IL-6, IFN-γ, TNF-a, IL-1b, IL-10, MCP-1, IL-17 and TGF-β.

Results: Mice were sacrificed at baseline or 3D post-IRI (n=7-9/group). KMNCs count of Y and E mice 3D post IRI was similar (6.2x106±2 vs. 5.3x106 ±0.97, NS). At baseline, the percent of CD4+ was higher in E kidneys (18±1.4 vs. 13.5±1.9, P=0.04), also, the percent of activated cells, CD4+CD69+ was higher in E kidneys (53.5±7 vs. 25.5±5.3, P=0.007). Additionally, CD8+ and CD8+CD69+ were significantly higher in E kidneys at baseline (11.5±1.57 vs. 7.66±0.47, P=0.037) and (48.6±4.6 vs. 25.9±3.4, P=0.002). No difference was noted at baseline in Tregs percent between E and Y kidneys. There was no change in the percent of CD4+ or CD4+CD69+ at 3D post-IRI between E and Y kidneys or in CD8+ or CD8+CD69+. We found that CD8+ and CD8+CD69+ were higher 3D post-IRI in Y kidneys comparing to baseline (7.66±0.47 vs 13.98, P=0.08) and (25.5±5.3 vs 44.65±4.6, P=0.04) respectively; however, there was no difference in E kidney. Both Y and E kidneys showed significant rise in Tregs 3D post-IRI (18.7±5.0 vs. 6.5±1.2, P=0.025) and (14.0±2.4 vs 5.0±1.18, P=0.008). We found that IL-6 was significantly higher in the IRI E kidney compared to Y (13.2±0.85 vs. 10±0.5, P=0.04).

Conclusions: Elderly mouse kidneys at baseline have higher population of activated CD4 and CD8 cells. Furthermore, elderly kidneys have greater postischemic IL-6 production. Both cellular and soluble inflammatory changes in kidney could help explain the worse course of AKI in elderly.

FR-PO1151

Effect of N-acetyl Cysteine on Short- and Long-Term Cyclosporine-Induced Renal Injury in Mice ShangGuo Piao, Seokhui Kang, Sunwoo Lim, Byung Ha Chung, Chul Woo Yang. *Internal Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Seoul, Republic of Korea.*

Background: Previously, we reported that chronic CsA nephrotoxicity suppresses the expression of Klotho, and this is mediated by oxidative stress. This study was examined whether antioxidant, N-acetyl cysterine (NAC), protects the Klotho expression and kidney tissue damage against CsA induced nephrotoxicity.

Methods: Mice were divided 6 groups: vehicle group (VH, olive oil, 1 ml/kg/day), CsA group (30 mg/kg/day), NAC 150 group (150 mg/kg/day), NAC 300 group (300 mg/kg/day), CsA + NAC 150 group, and CsA + NAC 300 group, respectively. Under 0.01% sodium diet, mice received daily administrations of olive oil or CsA subcutaneously for 1 and 4 weeks. Mice also received drinking water with or without NAC. Degree of tubulointerstitial fibrosis (TIF) induced by CsA was expressed in TIF score. Oxidative stress was measured by urinary excretion of 8-hydroxy-2'-deoxyguanosine (8-OHdG). Immunoblot analysis was performed for Klotho protein expression.

Results: Administration of NAC on CsA significantly decreased TIF level (NAC 150 group, 16 ± 4%; NAC 300 group, 17 ± 3% vs. 29 ± 1%, $p < 0.05$ vs. CsA group) compared to CsA group. Moreover, urinary 8-OHdG excretion was decreased in NAC treatment on CsA groups compared to CsA group (CsA + NAC 150 group, 282 ± 74 ng/day; CsA + NAC 300 group, 187 ± 49 ng/day vs. 409 ± 149 ng/day, $p < 0.05$ vs. CsA group). There was no significant different TIF level and urinary 8-OHdG excretion between two NAC treated groups on CsA. 1-week treated CsA plus NAC groups were similar to those of 4-week groups. Amount of Klotho protein in CsA treatment was significantly decreased at 1-week (56 ± 5% vs. 100 ± 8%, $p< 0.05$) and was further decreased at 4-week compared to VH group (13 ± 4% vs. 100 ± 18%, $p < 0.05$). NAC 150 treatment on CsA for 1 or 4 weeks was restored the Klotho protein expression (1-week, 79 ± 3% vs. 100 ± 5%; 4-week, 36 ± 3% vs. 100 ± 11%, $p < 0.05$ vs. CsA group).

Conclusions: NAC may have protective effect in CsA-induced renal injury associated with oxidative stress. Up-regulated Klotho expression may be relevant to improvement against acute and chronic CsA nephrotoxicity.

FR-PO1152

Activation of Hypoxia-Inducible Factor-1alpha Attenuate Inflammation, Fbrosis and Apoptosis in Cyclosporine Induced Nephropathy Sewon Oh,[1] Jeongmyung Ahn,[2] Ho Jun Chin,[1,3] Ki Young Na.[1,3] *[1]Seoul National University Bundang Hospital, Kyeong-Kido; [2]Maryknoll Hospital, Busan; [3]Seoul National University College of Medicine, Seoul.*

Background: Hypoxia-inducible factor (HIF) is a transcription factor that regulates cellular hypoxic responses. The activation of HIF has been proved to be effective in various kidney disease models. We investigated whether HIF activation could improve the renal injury in cyclosporine induced nephropathy, and determined its mechanism.

Methods: Renal tubular epithelial cells (HK-2 cells) were exposed to CsA at 10μM for 24hours and, cobalt chloride ($CoCl_2$) 150μM or dimethyloxalyglycine (DMOG) 1mM was added (CsA+$CoCl_2$, CsA+DMOG). Nuclear factor kappa B (NFκB) p65, phosphorylated NF-κB p65, vimentin and caspase-3 were determined by western blotting. Caspase-3 activity also measured using caspase-3 fluorometric assay. In animal experiments, male Sprague Dawley rats kept on a 0.05% low salt diet were treated with CsA for 28 days (15mg/kg/day, subcutaneous) and received a continuous infusion of $CoCl_2$ (10mg/kg/day) or DMOG (100mg/kg/day) during the whole experimental period. Immunohistochemistry (IHC) of ED-1 and tunnel staining were performed.

Results: CsA+CoCl2 or CsA+DMOG increased renal HIF-1α protein by western blot. Apoptotic cell death was decreased in CsA+CoCl2 both in vivo and in vitro (vs. CsA, $P<0.05$) and in CsA+DMOG, in vitro ($P<0.05$). In HK2 cell, the expression of caspase-3 was reduced in CsA+CoCl2 (CsA, 1.3±0.3; CsA+CoCl2, 0.4±0.1; $P<0.05$). Also, caspase-3 activity was decreased in both CsA+CoCl2 and CsA+DMOG ($P<0.001$). The amount of vimentin was decreased in CsA+CoCl2 (1.8±0.1 vs. 1.2±0.1, $P<0.05$). In addition, rats treated with CoCl2 or DMOG showed the improvements of arteriolopathy (CsA vs. CoCl2,

CsA vs. DMOG, P<0.05) and tubulointerstitial fibrosis (CsA vs. DMOG; P<0.05). The ratio of p NFκB p65 and NFκB p65 was decreased in CsA+CoCl2 (1.6±0.6 vs. 0.5±0.3, P<0.05) in HK2 cell. The number of infiltrating macrophages were reduced by CoCl2 and DMOG treatment (CsA vs. CoCl2, CsA vs. DMOG P<0.05).

Conclusions: Activation of HIF by $CoCl_2$ or DMOG attenuates renal injury by inhibition of inflammation, fibrosis and apoptosis.

FR-PO1153

Induction of Constitutively Active TGFβ Receptor 1 in Kidney Tubules Causes Epithelial Damage with Inflammatory Leukocyte Infiltration and a Switch in Resident Dendritic Cell Phenotype Madeleine E. Gentle, Shaolin Shi, Erwin P. Bottinger, Detlef O. Schlondorff. *Division of Nephrology, Department of Medicine, Mount Sinai School of Medicine, New York, NY.*

Background: Expression of constitutively active TGFβ Receptor 1 (TβR1) in tubular epithelia, using a doxycycline inducible system under the control of the Pax8 promoter, results in tubular cell apoptosis, progressive tubular damage and tubulo-interstitial fibrosis [Shi S et al., ASN2010, free communication].

Methods: To define the role of inflammation in this process we evaluated inflammatory infiltrates by immuno-fluorescence and flow cytometry.

Results: We demonstrate that induction of TβR1 activity in the tubules is associated with a progressive (3-7 days) and widespread tubulo-interstital leukocyte infiltration, including macrophages, T cells and dendritic cells (DC). T cell but not macrophage recruitment was inhibited by mitoTEMPO a scavenger of mitochondrial ROS. Overall DC number did not change following induction of tubular damage, but the predominant DC subtype switched from ~80% F4/80+ CD11c+ DC in the healthy kidney to ~ 60% F4/80- CD11c+ DC following induction of tubular TβR1 signaling.

Conclusions: Mitochondrial ROS is required for T cell recruitment but, surprisingly is dispensable for macrophage infiltration. DC play a key role in activating T cells and shaping subsequent adaptive immune responses. In view of the switch in DC phenotype observed upon disease induction it will be of interest to study the relative contributions of each DC population in disease progression in this model of progressive tubular damage.

Human Proximal Tubule Epithelial Cells Modulate Autologous Dendritic Cell Function Andrew J. Kassianos, Xiangju Wang, Kerry (Kathrein) E. Roper, Helen G. Healy, Ray Wilkinson. *Conjoint Kidney Research Laboratory, Department of Renal Medicine, Royal Brisbane and Women's Hospital, Brisbane, Australia.*

Background: Proximal tubule epithelial cells (PTEC) participate in the disease process in many human kidney diseases. We have recently demonstrated the capacity of activated PTEC to inhibit autologous immune responses (Wilkinson et al, NDT 2011, 26(5):1483-92). In order to further define this regulatory mechanism, we monitored for the first time activated PTEC interactions with autologous dendritic cells (DC), professional antigen-presenting cells that play a pivotal role in the induction and regulation of immune responses.

Methods: Primary PTEC and peripheral blood mononuclear cells were collected from patients undergoing nephrectomies. Purified $CD1c^+$ blood DC were cultured with autologous IFNγ-activated PTEC in the presence or absence of DC activator, polyinosinic:polycytidylic acid (PIC). DC responses were monitored by cytokine secretion, surface antigen expression and antigen-presenting ability.

Results: Unstimulated CD1c+ DC upregulated surface CD40 and CD86 and secreted higher levels of IL-6 and IL-8 in the presence of PTEC compared to DC alone, with minimal changes to CD80, CD83 and HLA-DR expression and no or low levels of IL-1β and IL-10 detected in any culture supernatants. PIC-stimulated CD1c+ DC expressed higher CD40 and CD86, produced elevated IL-6 and IL-1β and lower levels of IL-10 in the presence of PTEC than PIC-stimulated CD1c+ DC alone. Notably, PIC-stimulated CD1c+ DC displayed reduced CD83 levels in all donors and lower expression of HLA-DR in 4/5 donors when cultured with PTEC, with 3/4 of these donor DC inducing lower proliferation of allogeneic T cells in a mixed lymphocyte reaction (MLR) compared to PIC-stimulated CD1c+ DC alone. These results highlight a novel immuno-regulatory role for activated PTEC through inhibition of DC function.

Conclusions: Our data suggest that activated PTEC regulate human autologous immunity via complex interactions with DC. Further dissection of the mechanism of PTEC modulation of autologous immune responses may offer targets for therapeutic intervention in renal medicine.

FR-PO1155

Suppression of Inflammatory Cytokines-Triggered NFκB Activation and iNOS Expression in Renal Tubular Epithelial Cells by Gap Junction Inhibitor Flufenamic Acid: A Critical Involvement of AMPK Yuan Chi, Qiaojing Yan, Ying Zhu, Masanori Kitamura, Jian Yao. *Department of Molecular Signaling, University of Yamanashi, Chuo, Yamanashi, Japan.*

Background: Our previous studies demonstrated that dysfunction of gap junctions (GJs) prevents renal tubular cell injury in several pathological situations (*Br J Pharmacol 2010, 160:2055-68; Antioxid Redox Signal 2011, 14:2427-39*). Because the cytokines-elicited expression of iNOS and production of nitric oxide (NO) contribute to the renal tubular cell injury, we asked whether GJ inhibitors also interfere with the inflammatory responses.

Methods: NFκB activation was evaluated by using NRK/NFκB-SEAP reporter cells. NO was measured by the Griess reagent. Ca^{2+} was measured by using Fura-2 as an indicator. AMPK activation was evaluated by Western blot analysis of phosphorylation levels of AMPK at Thr-172. CAMKKβ was downregulated by siRNA.

Results: 1) Exposure of renal tubular cell line NRK-E52 to inflammatory mediators TNFα and IL-1β resulted in an NFκB-dependent expression of iNOS and production of NO. 2) Among several GJ inhibitors tested, flufenamic acid (FFA) strongly inhibited NFκB activation and suppressed the expression of iNOS and production of NO. In addition, it also inhibited MCP-1 expression. 3) This effect of FFA was mimicked by AMPK activator AICAR and abolished by CAMKKβ inhibitor STO-609, indicating a mediating role of CAMKKβ-AMPK pathway. 4) FFA induced an Ca2+-dependent activation of AMPKα. Indeed, FFA triggered a cyclosporine-preventable rise in intracellular Ca2+ and activation of CAMKKβ. Inhibition of CAMKKβ with specific inhibitor STO-609 or downregulation of CAMKKβ with specific siRNA completely abolished the FFA-induced activation of AMPK.

Conclusions: Taken together, we concluded that GJ inhibitor FFA potently suppressed the inflammatory cytokines-elicited activation of NFκB and expression of iNOS in renal tubular epithelial cells through activation of Ca^{2+}-CAMKKβ-AMPK pathway. FFA may be therapeutically employed for intervention of inflammatory tubular cell injury through suppression of inflammatory responses and disruption of gap junction-mediated propagation of cell death.

FR-PO1156

Characterization and Localization of CD11c+F4/80+ Mononuclear Phagocytes in Healthy and Diseased Kidney Qi Cao, Junyu Lu, Changqi Wang, Vincent W.S. Lee, Ya Wang, Thian Kui Tan, Guoping Zheng, Yiping Wang, David C. Harris. *Centre for Transplant and Renal Research, Westmead Millennium Institute, Sydney, NSW, Australia.*

Background: Kidney tubulointerstitium contains resident macrophages (kMΦ) and dendritic cells (kDCs). Distinguishing between kMΦ and kDCs relies on specific cell-surface markers: CD11c the most reliable marker for DC and F4/80 for macrophages. However, a group of kidney cells has been found to express both dendritic and macrophage markers, but their function and distribution in kidney are unknown. In this study, function and localization of CD11c+F4/80+ cells, kMΦ and kDCs were examined in healthy and diseased kidney.

Methods: Adriamycin nephrosis (AN) was induced by 10 mg/kg adriamycin in BALB/c mice. Localization and function (phagocytosis and antigen presentation) of CD11c+F4/80+ cells, CD11c-F4/80+ kMΦ and CD11c+F4/80- kDCs were examined in normal and AN mice.

Results: CD11c+F4/80- kDCs comprised 0.6% of total kidney cells, CD11c+F4/80+ cells 2% and CD11c-F4/80+ kMΦ 1.6%. CD11c+F4/80- kDCs and CD11c+F4/80+ cells were mainly present in cortex of normal and AN kidney, while CD11c-F4/80+ kMΦ were present in cortex and medulla. CD11c+F4/80+ cells highly expressed macrophage markers including CD68, CD204 and CD206, but had lower expression of DC markers, including CD205 and CD103. Interestingly CD11c+F4/80+ cells from kidneys of mice with or without AN had a higher capability of phagocytosis and lower ability of antigen presentation than CD11c+F4/80- kDCs, indicating that CD11c+F4/80+ cells are more like macrophages.

Conclusions: CD11c+F4/80+ mononuclear phagocytes have high capability for phagocytosis and low for antigen presentation, indicating they should be defined as a subset of kidney macrophages. The function of these cells will be examined *in vivo* by depletion and reconstitution studies.

FR-PO1157

Inflammasome Activation and Processing of IL-1β and IL-18 in Experimental Crescentic Glomerulonephritis in the Rat Simona Deplano,[1] Jennifer Smith,[1] Charles D. Pusey,[1] Robert J. Unwin,[2] Frederick W.K. Tam,[1] H. Terence Cook,[1] Jacques Behmoaras.[1] *[1]Renal Medicine, Imperial College London; [2]UCL Medical School, London, United Kingdom.*

Background: Inflammasomes are molecular platforms activated by cellular infection or stress, which trigger the release of active proinflammatory cytokines such as IL-1β and IL-18 through caspase-1 activation. The role of caspase-1 dependent inflammasome activation in crescentic glomerulonephritis (Crgn) is unknown.

Methods: We studied inflammasome activation in the macrophage-dependent model of nephrotoxic nephritis (NTN) in the Wistar-Kyoto (WKY) rat. Activation of Nlrp3 and AIM2 inflammasomes was studied in bone-marrow derived macrophages (BMDMs) isolated from WKY and NTN-resistant Lewis (LEW) rats. Ex-vivo investigation of the inflammasome activation was performed in cultured glomeruli isolated from WKY and LEW kidneys 4 days following NTN induction, a time point corresponding to maximal macrophage infiltration.

Results: We found that the majority of the Nlrp3-inflammasome genes are up-regulated in WKY BMDMs compared with LEW. Lipopolysaccharide (LPS) primed WKY BMDMs produced significantly higher levels of active IL-1β and IL-18 when stimulated with ATP compared with LEW. Similarly, the activation of the AIM2-inflammasome following LPS and poly(dA:dT) treatment resulted in increased IL-1β secretion in WKY BMDMs, suggesting that the increased IL-1β production is due to a dysregulated caspase-1 activity in the macrophages of this rat strain. This was indeed the case as we showed increased caspase-1 activity in WKY BMDMs when compared with LEW, and caspase-1 dependant

IL-1β and IL-18 production was significantly reduced following a specific caspase-1 inhibitor and after caspase-1 siRNA treatment. Importantly, we showed markedly increased active IL-18 and IL-1β production in WKY nephritic glomeruli, together with significantly increased caspase-1 activity suggesting that caspase-1 dependent inflammasome activation is driven by infiltrating macrophages in NTN.

Conclusions: This is the first report showing inflammasome activation in macrophage-dependant Crgn. These results reveal novel genetic factors controlling susceptibility to Crgn.

FR-PO1158

Proinflammatory Role of the Inflammasome Component Nlrp3, but Not Asc in Murine Immune Complex-Mediated Glomerulonephritis Kirstin Andersen, Nuru Eltrich, Volker Vielhauer. *Nephrologisches Zentrum, Ludwig-Maximilians-University, Munich, Germany.*

Background: Interleukin-1β (IL-1β) is an inflammatory mediator of immune complex-induced glomerulonephritis (GN). Caspase 1 activates IL-1β in an inflammasome-dependent intracellular process. Thus, we examined the functional role of the inflammasome components Nlrp3 and its adapter molecule Asc in autologous murine nephrotoxic serum nephritis (NTN).

Methods: NTN was induced in wild-type, Il1r1-, Nlrp3-, and Asc-deficient C57BL/6 mice after preimmunisation with rabbit IgG. At day 21 functional parameters, renal histology and renal leukocyte infiltrates were compared between the four groups and untreated wild-type controls. In addition, cellular and humoral immune responses against rabbit IgG were analysed.

Results: NTN was not inducible in Il1r1-deficient mice, confirming a crucial role of IL-1 signaling in this model. Nlrp3-deficient mice developed a less pronounced nephrotic syndrome compared to wild-type, including reduced albuminuria, less hypoproteinemia, and a tendency towards lower urea levels. Consistently, renal leukocyte infiltrates were significantly reduced in Nlrp3-/- mice. This correlated with a decrease in renal mRNA expression of inflammatory chemokines and cytokines. In contrast, NTN was not attenuated in Asc-/- mice.

Systemic immune responses were examined after restimulation of splenocytes with rabbit IgG. Nlrp3-/- splenocytes revealed a tendency towards lower INF-γ production and reduced numbers of activated CD69+ CD8+ T cells. Interestingly, the humoral immune response was increased in Nlrp3-/- mice, as indicated by higher autologous anti-rabbit IgG serum titers. Despite developing NTN, Asc-/- mice also demonstrated an attenuated T cell response, but similar anti-rabbit IgG levels compared to wild-type.

Conclusions: We identified Nlrp3 as an important pro-inflammatory mediator of immune complex GN. Surprisingly, we could demonstrate an inflammatory function of Nlrp3 independent of its adapter molecule Asc and the inflammasome, although deficiency of both molecules reduced cellular immune responses against the foreign antigen planted in the glomerulus. Thus, Nlrp3, but not Asc may be a new therapeutic target for immune complex GN.

Accelerated Necrotizing Glomerulonephritis in Response to Nephrotoxic Serum in Mpv17-Deficient Mice Gabriella Casalena, Dmitrij Kollins, Ilse S. Daehn, Madeleine E. Gentle, Erwin P. Bottinger, Detlef O. Schlondorff. *Medicine, Mount Sinai School of Medicine, New York, NY.*

Background: Human MPV17 mutations cause hepatocerebral forms of mitochondrial DNA (mtDNA) depletion syndrome. Insertional deletion of Mpv17 in mouse was initially associated with glomerulosclerosis [Weiher H et al., Cell 1990]. Mpv17 is a mitochondrial protein with unknown function, but may be involved in control of mitochondrial DNA copy number and ROS production. MtDNA copy number was reduced in glomerular tufts of Mpv17-/- mice that manifested reduced lifespan and kidney failure [Viscomi C et al. Hum Mol Genet 2009].

Purpose: To determine whether Mpv17-deficiency alters lesions and manifestations of necrotizing glomerulonephritis (GN) typically associated with nephrotoxic serum nephritis model in mice.

Methods: Mpv17+/+ and Mpv17-/- mice (C57BL/6J inbred background) were injected with sheep nephrotoxic serum and sacrificed after one or seven days.

Results: Tissue oxidative stress assessed by 3-Nitrotyrosine IHC was increased at baseline in glomeruli of Mpv17-/- compared to Mpv17+/+ mice. Day 1 after NTS injection, PAS positive staining was apparently increased in Mpv17-/- but not in Mpv17+/+ mice, compared to controls. By day 7, glomerular lesions were present in all Mpv17-/- and increased compared to Mpv17+/+. Tubular casts were detectable only in Mpv17-/- mice. Serum creatinine was increased in Mpv17-/- compared with Mpv17+/+ (0.74 +/- 0.01 vs 0.48 +/- 0.09; $p<0.05$). ACR was not significantly different. Quantification of infiltrates by staining with anti-CD45 antibody showed no differences between Mpv17+/+ and Mpv17-/- at day 7 after NTS injection.

Conclusions: Loss of mitochondrial membrane protein Mpv17 was associated with increased baseline glomerular oxidative stress, and accelerated the onset and increased the severity of necrotizing GN induced by NTS

FR-PO1160

Leukocyte Syk Activation in Antibody-Dependent Glomerular Injury Jessica Ryan, John Kanellis, David J. Nikolic-Paterson. *Department of Nephrology and Monash University Department of Medicine, Monash Medical Centre, Clayton, Victoria, Australia.*

Background: Spleen tyrosine kinase (Syk) plays an important role in Fc-γ receptor signaling. Recent clinical trials using an Syk inhibitor have shown protection against joint damage in rheumatoid arthritis. However, the potential role of Syk in acute antibody-dependent glomerular disease has not been investigated. Therefore, we examined activation of Syk in human rapidly progressive glomerulonephritis by detecting phosphorylation of Tyr525/526 in the Syk activation loop.

Methods: Immunostaining for phosphorylated-Syk (p-Syk) was performed in renal biopsy sections in cohort of 68 patients, which included: MCD (3), TBMD (8), post-infectious glomerulonephritis (5), Class IV SLE (11), and ANCA vasculitis (9), IgAN (14), membranous nephropathy (7) and FGS (10).

Results: No p-Syk staining was seen in minimal change or thin membrane disease which lack antibody deposition and leukocytic infiltration. In contrast, all cases of post-infectious glomerulonephritis exhibited numerous p-Syk+ cells in glomeruli. Two-colour staining identified p-Syk+ cells as infiltrating neutrophils, and to a lesser extent, macrophages. Furthermore infiltrating leukocytes were also positive for phopspho-p38 and phospho-JNK, known downstream targets of Syk signalling, suggesting Syk-dependent leukocyte activation in post-infectious glomerulonephritis. Glomerular p-Syk+ cells were seen in 8/9 cases of ANCA vasculitis, 7/11 cases of Class IV SLE and 6/14 cases of IgAN. In these diseases, p-Syk staining was also localised to infiltrating neutrophils and possibly to some monocyte/macrophages. In addition, 1/7 cases of membranous and 2/10 cases of FGS exhibited glomerular p-Syk positive cells in areas of glomerulosclerosis. Furthermore, in some cases infiltrating p-Syk+ cells were also seen in areas of interstitial fibrosis and tubular atrophy.

Conclusions: Syk is activated in infiltrating leukocytes, predominantly neutrophils, in acute antibody-dependent glomerular disease. These findings support the therapeutic use of Syk inhibitors in rapidly progressive crescentic glomerulonephritis.

Decreased Plasma RANTES Concentration in Children with Minimal Change Nephrotic Syndrome in Relapse Is Associated with Th2 Cytokine Profile Chang Yien Chan,[1] Wee Song Yeo,[1] Kar Hui Ng,[1] Subhra K. Biswas,[2] Hui Kim Yap.[1] *[1]Pediatrics, Yong Loo Lin School of Medicine, National University of Singapore, Singapore; [2]SIgN, A*STAR, Singapore.*

Background: Cytokine release secondary to viral infections may potentially trigger relapses in minimal change nephrotic syndrome (MCNS). This study aimed at investigating the cytokine profile in MCNS patients during relapse and remission, in order to enhance our understanding of disease pathogenesis.

Methods: Plasma cytokine profile was analyzed using multiplex suspension bead array system in 13 nephrotic children, aged 4 to 25 years with steroid-sensitive nephrotic syndrome in relapse and remission. Thirty-two age-matched healthy controls were included for comparison. Results were expressed as mean±SEM. Statistical analyses was done using a linear mixed model to compare the differences in cytokine levels between MCNS patients and age-matched controls. Wilcoxon signed rank test was used for paired analysis.

Results: As shown in the table below, of the 27 cytokines analyzed, plasma IL-5, IL-9, IL-10, and IL-13 were significantly increased and RANTES concentration was significantly decreased in MCNS relapse compared to age-matched controls ($p<0.05$). There was no significant difference in the concentrations of these cytokines between MCNS remission and controls. However, pairwise comparison showed that only RANTES concentration were significantly lower in patients in relapse compared to remission ($p=0.023$).

Cytokine	Controls (n=32)	MCNS Relapse (n=13)	MCNS Remission (n=13)
IL-5	3.78±0.38	5.09±0.71	5.89±0.72[1]
IL-9	12.7±1.23	18.6±4.14	22.9±4.07[1]
IL-10	1.25±0.24	2.00±0.54	3.77±0.58[2]
IL-13	4.27±0.40	5.42±0.47	6.54±0.64[1]
RANTES	390.6±51.6	231.6±25.6	172.5±14.6[2 3]

[1]$p<0.05$, comparing MCNS relapse with normal controls; [2]$p<0.01$, comparing MCNS relapse with normal controls; [3]$p<0.03$, comparing MCNS relapse with remission (paired)

Conclusions: In conclusion, the findings of increased IL-5, IL-9, IL-10 and IL-13 production during relapses in children with MCNS further support Th2 polarization in this disease. Decrease in RANTES production, a Th1 chemokine normally induced by viral infections, further confirms the immune dysregulation with Th2 polarization associated with relapses of MCNS.

Effects of Everolimus on Proteinuria and Expression of Slit Diaphragm Proteins in Experimental Nephrotic Syndrome Rawi Ramadan,[1] Hoda Awad,[2] Zaid Abassi.[2] *[1]Nephrology, Rambam Medical Center, Haifa, Israel; [2]Physiology and Biophysics, Faculty of Medicine-Technion, Haifa, Israel.*

Background: Everolimus, a mTOR inhibitor, is used as a potent immunosuppressant in renal transplantation. Although various serious side effects of Everolimus have been described, including renal injury and proteinuria, other studies have demonstrated beneficial renal effects of the drug. Therefore, the aim of this study was to examine the effects of

different doses of Everolimus given as either early or late treatment on proteinuria and slit diaphragm proteins in adriamycin (ADR)-induced experimental nephrotic syndrome (NS).

Methods: Low or high dose of Everolimus (20 or 100 mg/L via drinking water) was administered to NS rats, beginning either 3 days prior to NS induction (early treatment) or 2 weeks after the induction of NS (late treatment). Daily and cumulative urinary protein excretion (UprV) were determined throughout the treatment period, which lasted 6 weeks. Moreover, the effects of Everolimus on GFR and key slit diaphragm proteins, namely nephrin and podocin, were assessed at the end of the study.

Results: While the low dose of Everolimus resulted in therapeutic plasma concentration of 4.9±0.6, the high dose yielded supra-pharmacological plasma level of 21.3±4.4 ng/ml. As expected, ADR administration induced gradual significant increase in daily and cumulative UprV, in association with glomerular injury as presented by decrease in nephrin and podocin abundance. Low dose of Everolimus as early, and to a lesser extent as late treatment, reduced UprV and increased plasma albumin levels. These beneficial effects of low dose Everolimus were associated with improvement in GFR and substantial preservation of glomerular podocin and nephrin immunoreactivities. In contrast, high dose of Everolimus aggravated renal dysfunction and did not preserve nephrin/podocin expression. However, protein excretion in NS rats treated with the high Everolimus dose was eventually reduced secondarily to its deleterious effects on GFR.

Conclusions: Our study indicates that Everolimus possesses antiproteinuric effect at a therapeutic dose, whereas at a high dose it aggravates pre-existing glomerular injury.

Angiotensin Receptor Blocker Ameliorates Obesity-Induced Albuminuria and Inflammation and Modulates Adipose Macrophage Polarization

Li-Jun Ma,[1] Jun Zhou,[1] Haijing Li,[1] Yi-Wei Tang,[1] Valentina Kon,[2] Agnes B. Fogo.[1,2] *[1]Pathology, Vanderbilt University, Nashville, TN; [2]Pediatrics, Vanderbilt University.*

Background: Activation of the angiotensin type 1 (AT1) receptor is implicated in the pathogenesis of both obesity and CKD. We investigated the effects of angiotensin receptor blocker (ARB) on obesity-induced albuminuria, adipose tissue macrophage polarization and inflammation.

Methods: WT mice (age 8-10 wks) were fed high-fat diet (HFD) for 24 weeks with or without ARB (HFD, n=5; or HFD+ARB, losartan 80 mg/L DW, n=6) and compared to mice fed normal chow (NC, n=5). Metabolic parameters, urine albumin/creatinine ratio (ACR) were assessed at intervals, and expression of adipose tissue M1 and M2 macrophage markers was assessed by qPCR. Data are expressed as mean±SE.

Results: HFD induced albuminuria, and ARB treatment significantly reduced this parameter (HFD 213.0±44.3, HFD+ARB 99.6±15.1 μg/mg, $p<0.05$). ARB treated mice on HFD also had significantly lower body weight (NC 28.5±0.7, HFD 56.0±3.3, HFD+ARB 41.5±4.0 g, $p<0.01$), body fat percentage (NC 11.6±1.6, HFD 33.7±1.5, HFD+ARB 17.5±2.5 %, $p<0.01$), blood glucose (HFD 191.7±10.3 vs HFD+ARB 140.5±8.4 mg/dl, $p<0.05$) and plasma insulin (HFD 6.8±0.6 vs HFD+ARB 3.0±0.8 ng/ml, $p<0.05$) vs HFD alone although food intake was comparable (HFD 2.6±0.4 vs HFD+ARB 2.6±0.2 g/day/mouse). ARB partially restored obesity-associated decrease in muscle mass (% of muscle mass/body weight: NC 73.1±0.9, HFD 59.5±1.2, HFD+ARB 72.3±2.3, $p<0.05$) and plasma adiponectin (NC 17.4±1.5, HFD 10.9±0.2, HFD+ARB 12.6±0.5 μg/ml, $p<0.05$). ARB abolished obesity-induced adipose tissue macrophage M1 markers (IL-1β mRNA/18srRNA: NC 1.0±0.2, HFD 1.5±0.1, HFD+ARB 1.0±0.2; MCP-1 mRNA/18srRNA: NC 0.6.±0.1, HFD 2.4±0.1, HFD+ARB 0.9±0.1, $p<0.01$ HFD+ARB vs HFD respectively) but further enhanced adipose tissue macrophage M2 markers (Ym-1 mRNA/18srRNA: NC 1.7±0.3, HFD 8.6±2.0, HFD+ARB 28.4±7.6, $p<0.05$ HFD+ARB vs HFD).

Conclusions: ARB protects against obesity and obesity-induced albuminuria, improves adipose metabolism and adipose tissue inflammation, linked to modulation of adipose tissue macrophage polarization. Our data suggest ARB is effective in treatment of obesity-related CKD.

FR-PO1164

Mechanisms of HO-1 Mediated Attenuation of Proteinuria: A Gene Profiling Study

Pu Duann,[1] Ling-Mei Chiang,[2] Elias A. Lianos.[1] *[1]Medicine, UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Pediatrics, Chang-Gung Memorial Hospital, Keelung, Taiwan.*

Background: Using a mouse model of proteinuria induced by administration of antibody (Ab) against the glomerular basement membrane (anti-GBM), and a model of proteinuria induced by administration of the glomerular epithelial cell (GEC) toxin, adriamycin, we assessed the effect of GEC-targeted expression of the cytoprotective enzyme heme oxygenase (HO)-1. A human (h) HO-1 cDNA sequence was targeted to glomerular epithelial cells (GEC) using a GEC-specific murine nephrin promoter. Specifically, we employed a 4.125-kb fragment of a mouse nephrin promoter downstream to which a FLAG-tagged hHO-1 cDNA sequence was inserted and subsequently generated transgenic mice from the FVB/N parental strain. GEC-specific targeting of hHO-1 was verified by immunalocalization of the FLAG-tagged transprotein. Administration of anti-GBM Ab or Adriamycin to transgenic (TG) mice with GEC-targeted hHO-1 induced comparable degrees of proteinuria. Protein excretion was attenuated in transgenic (Tg) mice with anti-GBM Ab or Adriamycin-induced proteinuria compared to wild type (WT) controls. To explore changes in expression of genes that could mediate this salutary effect, we performed gene expression profiling using microarray analysis of RNA isolated from the renal cortex of WT or TG mice with or without anti-GBM antibody induced proteinuria. Significant increases in expression were detected in nine MHC-class II genes, two IFN-γ inducible GTPases and three genes of the ubiquitin-proteasome system. The increase in MHC-class II and proteasome gene expression in TG mice with injury was validated by real time PCR or Western blot analysis.

Conclusions: The observations point to candidate mechanisms whereby GEC-targeted HO-1 over-expression attenuates proteinuria.

FR-PO1165

Hyperglycemia Promotes the Progression of HI-Associated Nephropathy

Partab Rai,[1] Dileep Kumar,[1] Himanshu Vashistha,[2] Mohammad Husain,[1] Ashwani Malhotra,[1] Leonard G. Meggs,[2] Pravin C. Singhal.[1] *[1]Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY; [2]Medicine, Ochsner Clinic, New Orleans, LA.*

Background: After the advent of highly active retroviral therapy patients with HIV infection are living almost a normal life. Thus, they are equally prone to develop diabetes mellitus and its associated complications. We hypothesized that development of hyhperglycemia in HIVAN (HIV-associated nephropathy) patients would exacerbate the progression of HIVAN. In the present study, we evaluated the effect of hyperglycemia on the progression renal lesions in a mouse model of HIVAN (Tg26).

Methods: Four weeks old Tg26 mice develop proteinuira and renal lesions. Four weeks old control (C) and Tg26 (HIV) mice (n=4) were either administered vehicle or streptozotocin (STZ, 150 mg/Kg, intraperitoneal, one dose). At the end of two weeks, mice were sacrificed. Blood and urine were collected and kidneys were harvested for renal histology, imunohistochemical, and immunoblotting studies. Renal tissues were probed for occurrence of oxidative stress and the activation of the renin-angiotensin system (RAS) by immunoblotting for angiotensinogen expression and measurement of Ang II production by ELISA.

Results: STZ-treated mice (C-STZ) developed higher proteinuria vs. control (C) mice (C, 0.3 ± 0.08 vs. C-STZ, 3.1 ± 1.0 g/gm creatinin; $P<0.01$); STZ-treated Tg26 mice (HIV-STZ) displayed greater proteinuria vs. vehicle-treated Tg26 mice (C-HIV) (HIV-STZ, 24.0 ± 0.8 vs. C-HIV, 15.7 ± 1.1 gm/gm creatinine; $P<0.01$). There was no difference in BUN levels between control and C-STZ; HIV-STZ displayed higher BUN levels when compared to C-HIV (C-HIV, 48 ± 2 vs. HIV-STZ, 59 ± 5 mg/dl; $P<0.05$). Although there was no difference in the severity of glomerular and tubular lesions between HIV-STZ and C-HIV but renal tissues of HIV-STZ displayed enhanced oxidative stress and the activation of the RAS.

Conclusions: Development of diabetes mellitus has potential to adversely effect the progression of HIVAN.

Urine Exosomes Maintain a Sterile Renal Tract by Inducing Bacterial Lysis

Thomas F. Hiemstra,[1] Philip D. Charles,[2] Svenja S. Hester,[2] Caroline M. Robinson,[1] Jeremy N. Skepper,[4] Andres R. Floto,[3] Kathryn S. Lilley,[2] Fiona E. Karet.[1] *[1]Medical Genetics, University of Cambridge; [2]Systems Biology Unit and Centre for Proteomics, University of Cambridge; [3]Medicine, University of Cambridge; [4]Anatomy, University of Cambridge, United Kingdom.*

Background: Exosomes are nanovesicles released by many cell types, and may play roles in cell-cell signaling, antigen presentation or apoptosis. Urine exosomes released by the kidney have no known function, are considered waste, and studies to date have focused on biomarker discovery. We asked if urine exosomes were functional.

Methods: Exosomes were isolated from second morning urine samples from healthy volunteers by differential centrifugation. Exosomal proteins were characterised by LC-MS/MS coupled with novel data-analysis and bioinformatic workflows, and the resulting protein catalogue interrogated for functional enrichment. Proteins with putative functional roles were confirmed by Western blot (WB) and electron microscopy (EM).

Growth of luciferase-expressing laboratory and clinical strains of E. coli and S. aureus was assessed by luminometry, and the morphological effects of exosomes on E. coli studied by EM.

Results: We identified a catalogue of proteins significantly enriched for those involved in innate immunity and bacterial killing ($p = 0.0004$), and confirmed their presence on exosomes by WB and immuno-EM. Intact exosomal protein fractions, but not the abundant urinary protein uromodulin, potently and dose-dependently inhibited the growth of laboratory and clinical isolates of E. coli and S. aureus. Incubation of uropathogenic E coli with urinary exosomes, but not with vehicle alone, resulted in bacterial lysis ($p < 0.0001$).

Conclusions: Urine exosomes are enriched for bacteriocidic and -static proteins, inhibit bacterial growth and induce lysis of uropathogenic bacteria. We propose a novel model of host defence whereby Trojan decoy exosomes are released from the kidney to maintain urinary tract sterility, by delivery to invading organisms of packaged defence proteins.

HD5 Expression in the Human Kidney and Urinary Tract John D. Spencer, Andrew L. Schwaderer, David S. Hains. *Division of Nephrology, Research Institute at Nationwide Children's Hospital, Columbus, OH.*

Background: Urinary tract infections (UTI) are a common bacterial infection. Despite constant exposure to microbes, the urinary tract is usually sterile. Prior studies have indicated that the epithelial antimicrobial peptide (AMP), Human α-defensin 5 (HD5), contributes to the defense of the Gl and reproductive tracts. HD5's role in the kidney and urinary tract is unknown. This study was designed to characterize gene and protein expression of HD5 in the human kidney and urinary tract.

Methods: *Gene expression*: We isolated RNA from non-infected human kidney, pyelonephritic kidney, and bladder tissue and quantified *HBD5* using real-time PCR. *Protein expression*: HD5 expression was localized using immunohistostaining. To examine HD5 expression in the urine, we developed a sandwich ELISA and normalized urinary HD5 concentrations to mg of urine creatinine (UCr).

Results: *Gene expression:* Constitutive HD5 mRNA expression was detected in human kidney and bladder tissue. Absolute real-time PCR quantification revealed HD5 expression of 3583±532 HBD5/10ng total RNA in non-infected renal cortex, medulla, and pelvis. Expression did not vary by location within the kidney. With pyelonephritis, mean HD-5 expression increased to 6208±1056ng HD5/10ng total RNA ($p<0.04$). Protein expression: Immunohistochemistry localized HD5 to the urothelium of the bladder and ureter. In the kidney, expression was primarily in the collecting tubule and loop of Henle. With pyelonephritis, HD5 expression increased throughout the nephron and collecting duct. HD5 was not detected in non-infected human urine samples while mean HD5 expression increased to 27.07±4.67 μgHD5/mg UCr with UTIs ($p<0.01$).

Conclusions: Our results characterize the expression of HD5, a novel human urinary tract AMP. HD5 is expressed in the kidney, ureter, and bladder. HD5 expression and production increase and become detectable in the urine with infection making this molecule a potentially useful biomarker to augment our current urine dipsticks for rapid diagnosis of UTIs.

FR-PO1168

Ribonuclease 7: An Upregulated Antimicrobial Peptide during Urinary Tract Infections John D. Spencer, Andrew L. Schwaderer, David S. Hains. *Division of Nephrology, Research Institute at Nationwide Children's Hospital, Columbus, OH.*

Background: Although the urinary tract is constantly challenged by microbial invasion, it remains free from microbial colonization. Recent studies stress the importance of antimicrobial peptides (AMP) in preventing UTIs. Our lab has previously shown that Ribonuclease 7 (RNase7) is a potent AMP that contributes to urinary tract sterility. At baseline, RNase 7 is expressed in intercalated cells in the renal parenchyma and is secreted in the urine at levels sufficient to kill bacteria. This study was designed to characterize expression, production, and function of RNase7 in the urinary tract during infected states.

Methods: *Gene expression:* We isolated RNA from non-infected and pyelonephritic human kidney tissue and quantified *RNASE7* using real-time PCR. *Protein expression*: RNase7 expression was localized using immunofluorescence (IF). We developed a sandwich ELISA and normalized urinary RNase7 to mg of urine creatinine (UCr) in infected and sterile urine. *RNase7 function*: To evaluate the antimicrobial function of RNase7 on the microbial membrane of uropathogenic bacteria, we used atomic force microscopy (AFM).

Results: *Gene expression:* Absolute quantification of RNASE7 mRNA expression revealed that RNASE7 expression increased from 1028±149ng RNASE7/10ng total RNA in non-infected kidney tissue to 2927±590ng RNASE7/10ng RNA in kidneys with pyelonephritis ($p<0.04$). Protein expression: In infected kidney tissue, RNase7 expression was expanded to include the proximal nephron along with intercalated cells. Urinary RNase7 production increased with UTIs from a mean urinary RNase7 expression of 8.69±0.38μg/mg UCr to 12.53μg/mg UCr during infection ($p<0.02$). RNase7 function: Using AFM, we developed a proof-of-principle study to show that 2.5μM of RNase7 disrupts the microbial membrane of uropathogenic E.coli, Pseudomonas, and Enterococcus, causing cell death.

Conclusions: RNase7 is a potent AMP in the urinary tract. Our results indicate that RNase7 expression and production increases with infection. The functional relevance of increased RNase7 production was demonstrated by disruption of the microbial cell wall of common uropathogenic bacteria.

FR-PO1169

Lanthanum Carbonate Reduces Cumulative Oxalate Absorption and Prevents Nephrocalcinosis after Oxalate Loading in Rats Stef Robijn, Benjamin Arthur Vervaet, Patrick C. D'Haese, Anja Verhulst. *Laboratory of Pathophysiology, University of Antwerp, Belgium.*

Background: Hyperoxaluria is a risk factor for calcium oxalate (CaOx) nephrolithiasis/-calcinosis. Lanthanum carbonate (LC) is used as intestinal phosphate binder in dialysis patients to prevent hyperphosphatemia. As previously shown *in vitro* in our laboratory, lanthanum also has the ability to bind oxalate (Ox) in the pH range of the intestine. To evaluate *in vivo* intestinal Ox binding capacity of lanthanum, we investigated in rats whether LC is able to reduce Ox absorption and to prevent nephrocalcinosis (NC).

Methods: To investigate Ox absorption kinetics, 12 male Sprague-Dawley (SD) rats were divided into 2 groups: a group (n=6) receiving 1000 mg LC followed by 2 mmol Ox (2x molar La/Ox ratio) and a control group (n=6) receiving carboxymethylcellulose (VEH) followed by the same Ox dose by gavage. Serum Ox levels were measured at baseline, 30min and every hour up to 12h after gavage. Oxaluria was measured starting at 4h after Ox loading.

To evaluate the effect of LC on the development of NC, 26 male SD rats were divided into 2 groups: a group (n=13) receiving 1000 mg LC followed by 5 mmol Ox (0.8x molar La/Ox ratio) and a control group (n=13) receiving VEH followed by the same Ox dose by daily gavage for 7 consecutive days. After sacrifice, degree of NC was assessed on Von Kossa stained kidney sections and by renal Ca analysis as a measure of NC.

Results: Ox loading resulted in a biphasic pattern of transiently increased serum Ox levels in controls, which was almost completely abolished in LC treated animals. Lower serum Ox levels sustained in LC treated animals during the study period, resulting in a significantly reduced cumulative Ox absorption compared to controls. Furthermore, 6h after Ox loading oxaluria was blunted in LC treated animals, resulting in a significantly reduced CaOx crystalluria.

Administration of 1000 mg LC resulted in significantly lower median renal Ca content compared to controls: 0.14 (0.08–3.75) vs 1.12 (0.14–7.46) mg/g renal tissue.

Conclusions: LC significantly reduced cumulative Ox absorption and blunted oxaluria compared to controls. Furthermore the degree of NC was significantly lower in LC treated rats.

Oxalobacter Formigenes Conditioned Medium Stimulates Oxalate Transport by Human Intestinal Cells Hatim A. Hassan, Donna L. Arvans, Ming Cheng, Mark W. Musch, Eugene B. Chang. *Medicine, University of Chicago.*

Background: The vast majority of kidney stones are composed of calcium oxalate, and minor changes in urinary oxalate affect stone risk. Intestinal oxalate secretion mediated by anion exchanger SLC26A6 plays a crucial role in preventing hyperoxaluria and related kidney stones. The probiotic bacterium Oxalobacter Formigenes (OF) plays a critical role in preventing recurrent calcium oxalate kidney stones. In addition to degrading intraluminal dietary oxalate, OF also interacts with colonocytes by inducing distal colonic oxalate secretion, leading to reduced urinary oxalate excretion. However, the mechanism(s) underlying OF-colon interaction remain(s) unknown. We therefore examined whether OF culture condition medium (CM) affects intestinal oxalate transport using human intestinal Caco2-BBE cells.

Methods: We measured apical [^{14}C]oxalate influx in the presence of an outward Cl gradient as an assay of Cl-oxalate exchange activity.

Results: Preincubation of Caco2 cells with OF CM (1:50 dilution x 24 hours) significantly stimulated oxalate influx (by >106%) while OF growth medium (OM) has no effect, suggesting that soluble factors in the CM might be responsible for the observed stimulation by modulating the activity of the likely involved transporter(s) {SLC26A6, SLC26A2, and/or SLC26A3}. Importantly, CM from Lactobacillus Acidophilus has no effect on oxalate influx, indicating specificity. TER and incubation medium pH were not affected by the OM and CM. Heat-inactivation of the CM completely abolished the stimulatory effect, indicating that the secreted factor(s) is/are likely to be protein(s) or peptide(s). Pretreatment of the CM with pepsin destroyed the bioactivity of the CM, providing further evidence that the secreted factors are proteins or peptides. Selective ultrafiltration reveals that the secreted factors have a molecular mass between 10-30 kDa. Using real-time PCR, we observed in preliminary experiments that the CM led to a >4.0 fold increase in SLC26A3 mRNA, without affecting SLC26A2 or SLC26A6 mRNA expression.

Conclusions: We conclude that soluble factors from OF activate oxalate transport by Caco2 cells through mechanisms that likely include enhanced SLC26A3 mRNA expression.

Culture of Hepatocytes from Primary Hyperoxaluria Type I Liver Sweaty Koul,[1] Hari K. Koul.[1] [1]*Urology-Surgery, University of Colorado School of Medicine, Aurora, CO;* [2]*Nephrology, Mayo Clinic, Rochester, MN.*

Background: PH-I is an autosomal recessive disorder caused by loss of functional AGT enzyme in the liver, which results in excessive production of oxalate, causing recurring stones from childhood on and end stage renal failure. At present a combined liver and kidney transplants are needed for these patients,but quality of life as well as survival are poor. We evalauted fesibility of generating hepatocyte cell cultures from PH-I patients.

Methods: Liver tissue was obtained form surgical waste of PH-I patients . The liver sapmles were perfused with ice-cold Wisconsin solution. The samples were perfused with PBS supplemented with EGTA followed by Collagenase digenstion. The eluted cells were separated from undigested tissue, colloectd, spun down and separated on percol gradient to remove contaminantating debris. Cells were plated on collagen coated tissue culture dishes. Expression of various markers was visualized by immuno fluorescence microscopy. AGT was cloned from HEPG-2 cells and AGT was tagged with GFP to generate GFP-AGT construct. Replication deficient Adv-system eapressing GFP-AGT was generated as a tool to deliver AGT.

Results: We were able to grow hepatocytes from 4 out of 5 patient samples. The primary cultures of PH-1 hepatocytes stop growing after 4-5 passages. Initial pasage contains both hepatocytes as well as fibroblasts. After selecting the cells in epithelial select media, the cells express cyto-keratin but do not express vimentin, characteristics associated with absence of fibroblasts. Transfection of these cells with h-Tert in a reteroviral vector system resulted in a

cell line that we are able to grow to multiple passages. the cells retain cyto-keratin expresion and lack vimention, indicating maintenance of a phenotype. Adv-GFP-AGT resulted in sucessful transfection of all the cells in culture as visualized by GFP expression.

Conclusions: To the best of our knowledge this is the first report describing generation of hepatocytes from PH-1 patient liver and first direct demonstration of sucessful AGT-transfection of PH-1 hepatocytes in culture. These cells should provide a new tool to investigate cellular and alternate therapies against PH-I

Oxalate Absorption Is Independent of Cation Complex Formation Narae Ko,[1] Felix Knauf,[1] William G. Robertson,[2] Peter S. Aronson.[1] *[1]Nephrology, Yale University, New Haven, CT; [2]Physiology Dept, Royal Free and University College Medical School, London, United Kingdom.*

Background: Intestinal oxalate handling plays an important role in overall oxalate balance and risk for calcium-oxalate nephrolithiasis. We have previously shown that epithelial oxalate absorption is largely passive and paracellular through a low capacity, size-independent pathway for large solutes through the tight junction. A prediction of this model is that permeability to oxalate should be independent of its forming soluble complexes with cations.

Methods: Wild-type mouse duodenum was mounted in an Ussing chamber. Apparent permeability to [14C]-oxalate was measured simultaneously with that of [3H]-mannitol. Various oxalate species in the Ringer's buffer were calculated using the SUPERSAT program.

Results: In standard Ringer's buffer, the apparent permeability values for absorption of oxalate and mannitol were essentially identical. It was calculated that 0.79 of the 2.0 micromolar total oxalate in this solution was available as free oxalate, and the rest in soluble complexes predominantly with sodium, magnesium and calcium. The apparent permeability values for oxalate and mannitol were unchanged when the magnesium concentration was raised from 1.2 to 10 micromolar, which was calculated to decrease the free oxalate concentration from 0.79 to 0.33 micromolar as more oxalate was then complexed with magnesium. In contrast to the lack of effect of oxalate speciation on oxalate absorptive flux, the active component of oxalate secretion was inhibited by 80% when the free oxalate concentration was decreased.

Conclusions: We demonstrate that oxalate absorption in mouse intestine is independent of its forming soluble complexes with cations. In contrast, active oxalate secretion is highly dependent on the concentration of free oxalate.

FR-PO1173

Urinary Tract Infection Increases the Risk of Calcium Oxalate Kidney Stone Formation Suchai Sritippayawan,[1] Somkiat Vasuvattakul,[1] Yasushi Nakagawa.[2] *[1]Renal Unit, Siriraj Hospital, Bangkok, Thailand; [2]Division of Biological Sciences, University of Chicago, IL.*

Background: Calcium oxalate(CaOx) can be complicated by urinary tract infection(UTI). There is no evidence about infection-induced CaOx stone formation. This study demonstrated that UTI can favor CaOx stone formation.

Methods: 73 kidney stones from patients with pyuria(urine white cell>5/HD) were analyzed by FTIR. CaOx monohydrate crystal aggregation assay was used to study the inhibitory activity of protein in fasting urine of 28 kidney stone formers(18CaOx, 10uric) and 85 nonstone formers. The assay was modified from the method described by Hess(Am JPhysiol1989;257(1Pt2):F99-106). The rate of aggregation was measured by a linear slope of the decreasing turbidity rate during particle sedimentation. Sample was 1μg of urine protein in <50μl volume. Negative control was buffer solution. Positive control was 1μg of nonstone former Tamm-Horsfall glycoprotein(THPc). Crystal aggregation was displayed as % of linear slope of sample per negative control. Urine protein having %aggregation greater than THPc(65%) was classified as bad inhibitor.

Results: There were 37CaOx, 27carbonate apatite, 6uric acid, 2struvite and 1ammonium urate stones. 85%of them were mixed stone. Stone formers trended to have %aggregation more than nonstone fomers(52±22%vs47±18%). The proportion of stone formers having bad inhibitor was significantly higher than nonstone formers(39%vs9%,X2p<0.01). Pyuria subjects had %aggregation significantly higher than nonpyuria subjects(55±19%,n=31vs46 ±19%,n=82,p=0.03). Among the nonstone formers, pyuria subjects had significantly more %aggregation than nonpyuria subjects(58±14%,n=14vs45±19%,n=71,p<0.01) and 28% of pyuria subjects had bad inhibitor comparing with 5.6% of nonpyuria subjects(X2p=0.02). In stone fomers, both pyuria and nonpyuria patients had the same %aggregation(52±24 %,n=17vs51±20%,n=11,p<0.01) but there was a trend of higher %aggregation in pyuria CaOx stone subjects than nonpyuria subjects(52±24%,n=11vs46±21%,n=17). Urine citrate/ creatinine was not different between pyuria and nonpyuria groups.

Conclusions: UTI can induced CaOx stone formation by enhancing COM crystal aggregation.

Funding: Government Support - Non-U.S.

FR-PO1174

Bladder Urolithiasis and Spontaneous Pyelonephritis Associated with Cutaneous Vesicostomy in a Murine Model of Functional Lower Urinary Tract Obstruction Brian Becknell,[1] Ashley R. Carpenter,[2] Andrew L. Schwaderer,[3] Kirk M. McHugh.[2] *[1]Department of Pediatrics, Nationwide Children's Hospital, Columbus, OH; [2]Center for Molecular and Human Genetics, Nationwide Children's Hospital Research Institute, Columbus, OH; [3]Division of Nephrology, Department of Pediatrics, Nationwide Children's Hospital, Columbus, OH.*

Background: *Megabladder (mgb-/-*) mice have impaired detrusor smooth muscle development *in utero*, and require cutaneous vesicostomy (CV) to prevent progression to ESRD and death. The long-term sequelae of CV in these mice have not been reported.

Methods: 50 *mgb-/-* males underwent CV at 3-7 weeks. Urine was subject to UA, microscopy, and culture. Moribund animals underwent necropsy, and kidneys and urinary tract were subject to histopathology using standard stains.

Results: CV relieved hydronephrosis in male mgb-/- mice, who otherwise progress to ESRD and die by 8 weeks. Males undergoing CV lived for 20 ± 10 weeks (range 8 - 32). 18% (9/50) mgb-/- males became moribund with palpable bladder masses after a variable observation period (15 ± 11 weeks, range 1 – 27). At necropsy, these animals had bladder stones, which in certain cases fully occupied the lumen, resulting in massive hydroureteronephrosis. No stones were observed in mgb-/- mice prior to CV. UA demonstrated pyuria and struvite crystals, as early as 7 days following CV. Stone analysis revealed 88% struvite. Urine aspirated from the renal pelvis of animals with bladder stones grew organisms associated with urease production and struvite stones, including Enterococcus, coagulase-negative Staphylococcus, and Pasteurella species. Kidney histopathology had features of acute and chronic pyelonephritis.

Conclusions: These findings parallel rare but significant complications observed in patients undergoing CV, and provide a unique murine model for struvite urolithiasis and spontaneous pyelonephritis.

FR-PO1175

Clinical Validation of a Novel Assay Used for Monitoring Treatment of Patients with Cystinuria Aditya Mattoo,[1] Frank Modersitzki,[1] Jacob H. Cohen,[4] Michael Grasso,[4] John R. Asplin,[2] David S. Goldfarb.[1,3] *[1]Nephrology, NYU Langone Medical Center, New York, NY; [2]Litholink, Chicago, IL; [3]Nephrology Section, New York Harbor VAMC, New York, NY; [4]Endourology, Lenox Hill Hospital, New York, NY.*

Background: Traditional cystine assays are unreliable in predicting response to therapy and clinical outcomes of cystinuria. A new assay, cystine capacity (CysCap), may be a superior method of correlating urinary parameters with dietary and pharmacological interventions and may predict disease recurrence.

Methods: We performed a single-center retrospective analysis of cystinuric patients to correlate urinary parameters with clinical outcomes. Patients with at least one CysCap analysis and adequate clinical follow-up, (≥ 1 year of documented clinical events), were included. Chart reviews were performed to obtain demographics, pharmacotherapy, lab values and clinical events, defined as urologic intervention, stone passage, renal colic without stone passage, and either new stone or stone growth seen on imaging.

Results: 37 patients met the inclusion criteria. They had a mean of 2.1 CysCap analyses and mean follow-up of 489 days. They experienced a mean of 3.1 clinical events with time to first clinical event at 258 days. Of the clinical events, 1.1 urologic interventions occurred with mean time to first intervention of 47 days. In a general linear model, CysCap was highly correlated with 24h urine cystine excretion, urine volume and urine pH (r2=0.71; P<0.001). Increasing excretion of urine urea nitrogen and urine sodium over 24h correlated with increasing 24h cystine excretion (r=0.499 and 0.480, respectively, p<0.01), but not with CysCap or cystine supersaturation. The CysCap values of those patients on and off cystine binding thiol drugs did not significantly differ between the two groups. CysCap, CysSS and 24hrCys excretion did not correlate with the number of clinical events or the time to first clinical event.

Conclusions: We conclude that the CysCap assay is internally valid as it correlates with 24h cystine excretion, urine volume and urine pH. However, in this retrospective analysis, we were unable to correlate CysCap with the number of clinical events or the time to first clinical event.

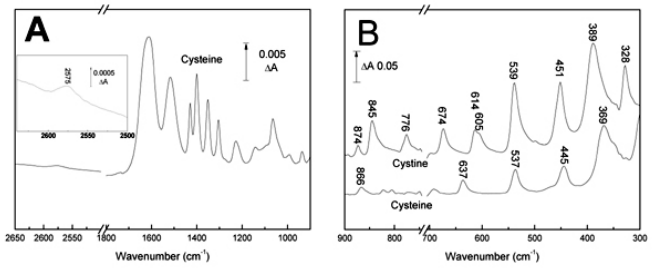
Infrared Vibrational Spectroscopy as a Diagnostic Tool for Cystinuria Robert J. Unwin,[1] Elspeth Anne Macdonald,[2] Amandine Marechal,[2] Peter R. Rich.[2] *[1]UCL Centre for Nephrology, University College London, London, United Kingdom; [2]Institute of Structural and Molecular Biology, University College London, London, United Kingdom.*

Background: Infrared (IR) vibrational spectroscopy can be used to analyze many chemicals and materials, and complex mixtures. Absorption bands arise from molecular vibrations and most molecules have characteristic IR spectra. There is growing interest in medical diagnostic uses of mid-IR 'molecular fingerprints' in the 1800-900 cm-1 range. Spectra can distinguish cells and tissues; deconvolution can provide quantitative analyses of fluid constituents. We assessed whether mid- or far-IR spectroscopy could provide a rapid and direct method for quantitative analysis of cystine in urine - normally 0.2 mM or less, but can be several mM in cystinuria.

Methods: In the mid-IR fingerprint region, cysteine and cystine in urine have similar absorbance spectra, overlapping with many other components, precluding their quantitation in this region. However, cysteine has an S-H absorption band at 2575 cm-1, and cystine has characteristic bands in the low frequency IR range at 845 cm-1 and 674 cm-1. Thus, cystine can be detected at 2575 cm-1 after chemical conversion to cysteine or, more directly, in dried samples from its far-IR absorption bands.

Results:



A. Mid-IR spectra of cysteine; 200 mM at pH 6.0 placed on a silicon ATR microprism; spectrum recorded with an MCT-B detector cooled to 77K and water contribution subtracted.

B. Far-IR spectra of solid cysteine and cystine in their protonated forms; samples in fine powder form placed on a diamond ATR prism equipped with KRS-5 optics; spectra recorded with a far-IR room temperature DTGS detector.

Conclusions: The practical quantitative limits of cysteine/cystine quantitation by these methods will be presented, together with quantitative analyses of IR spectra of urine samples from healthy volunteers and cystinuria patients.

FR-PO1177

Rapid Determination of Urinary 2,8-Dihydroxyadenine with Liquid Chromatography – Electrospray Tandem Mass Spectrometry Vidar O. Edvardsson,[1,2] Baldur Bragi Sigurdsson,[3] Margret Thorsteinsdottir,[2,3] Runolfur Palsson.[1,2] *[1]Landspitali - The National University Hospital of Iceland; [2]University of Iceland; [3]Arctic Mass, Reykjavik, Iceland.*

Background: Adenine phosphoribosyltransferase (APRT) deficiency is an autosomal recessive disorder of purine metabolism that leads to excessive urinary excretion of poorly soluble 2,8-dihydroxyadenine (2,8-DHA), causing radiolucent kidney stones and chronic kidney disease. Treatment with allopurinol reduces 2,8-DHA production and prevents stone formation and kidney injury. The purpose of this study was to develop a fast method for determination of urinary 2,8-DHA and other purines for therapeutic monitoring of allopurinol therapy.

Methods: Liquid chromatography - electrospray tandem mass spectrometry (LC-MS/MS) was designed for rapid quantification of 2,8-DHA and other purines, including 2-deoxyadenosine, adenine, adenosine, hypoxanthine, xanthine and oxypurinol through a series of experiments. Capillary and cone voltage, source and desolvation temperature, flow speed, gradient, gradient slope and salt concentration in the mobile phase were optimized by D-optimal design and related to LC-MS/MS responses, using partial least squares regression. To accurately quantify urinary 2,8-DHA, 6 aliquots of urine were collected immediately after the urine container had been inverted several times to suspend settled particles. The pH of the aliquots was adjusted to 10 with 2 μM NH_4OH which dissolved all precipitates before injection into the LC-MS/MS system.

Results: Quantitative analysis of 2,8-DHA and the other purine metabolites was achieved with 100% specificity in 6 minutes. The coefficient variation for different urine aliquots was <5% indicating a robust sampling method. Validation of the LC-MS/MS-based method, which included selectivity, limit of quantification, response function, intra- and inter-day precision and accuracy as well as recovery of all analytes, was well within pre-defined limits.

Conclusions: We have developed a rapid and reliable LC-MS/MS-based method for determination of urinary excretion of 2,8-DHA and other purine derivatives that will greatly facilitate therapeutic monitoring of allopurinol therapy in APRT deficient patients.

Antiurolithiatic Activity of an Unani HerboMineral Formulation Sayeed Ahmad,[1, 2] Wasim Ahmad,[1] Mohammed Ahmed Khan,[1] Rabea Parveen,[1] Masood Shah Khan,[1] Ashwani Malhotra,[2] Mohammad Husain,[2] S.M. Arif Zaidi.[1] *[1]Hamdard University, New Delhi, India; [2]Division of Kidney Diseases and Hypertension, Feinstien Institute of Medical Research, North Shore LIJ University Hospital, Great Neck, NY.*

Background: Safoof-e-Pathar Phori (SPP) an Unani herbo-mineral formulation have been used since long in Unani System of Medicine for its anti-urolithiatic activity as a good non-invasive remedy. It is a powdered formulation containing *Didymocarpous pedicellata*; *Dolichous biflorus*; *Rheum emodi*; *Raphanus sativus*-processed salt; *Hordeum vulgare*- processed salt and Potassium nitrate. The anti-urolithiatic activity of herbo-mineral formulation (SPP) against induced calcium oxalate nephrolithiasis was carried out using ethylene glycol - ammonium chloride rat model.

Methods: The animals were divided in four groups control, toxic control and treatments (n=6). The drugs and toxicants were administered orally as per the protocol of rat model for 21 days. On 22nd day urine was collected and analyzed for of Ca^{++}, Mg^{++}, Na^{+}, K^{+} levels and crystalluria studies, whereas serum was used for blood urea nitrogen (BUN) and creatinine levels. The antioxidant markers of kidney tissues and histo-pathological examinations were also carried out.

Results: The SPP treatment (500 and 1000 mg/kg/day) significantly lowered the levels of BUN 49.35±2.30 at 500mg/kg and 23.74±2.34 at 1000mg/kg against toxicant 134.7±14.86 (P<0.001), while creatinine 0.27±0.01mg/dL at 500mg/kg and 0.20±0.01mg/dL at 1000mg/kg against toxicant 0.69±0.04mg/dL (P<0.001). The treatment with SPP showed significantly higher levels of Na+ (25.92±0.47mEq at 500mg/kg and 29.92±0.62mEq at 1000mg/kg against toxicant 10.13±0.85mEq), K+ (6.83±0.04mEq at 500mg/kg and 7.5±0.04mEq at 1000mg/kg against toxicant 4.4±0.03mEq) and Ca++ (5.95±0.02mg/dL at 500mg/kg and 6.28±0.16mg/dL at 1000mg/kg against toxicant 3.90±0.06mg/dL) (P<0.001).

Conclusions: The studies on crystalluria, histopathology and anti-oxidant markers supported the anti-urolithiatic potential of SPP in preventing calcium oxalate deposition without producing diuresis. Further, analysis for isolation of active component is under progress.

FR-PO1179

Urinary Uric Acid Excretion in Pediatric Urolithiasis: Which "Cut-Off" Value To Use? Maria Goretti Penido,[1] Uri S. Alon.[2] *[1]Pediatric Nephrology Unit, Federal Univ. of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil; [2]Bone and Mineral Disorders Clinic, Pediatric Nephrology, Children's Mercy Hospital (CMH), Univ. of MO, Kansas City, MO.*

Background: The "gold standard" for normal urinary uric acid (UA) excretion is <815 mg/24h/1.73m^2, but due to difficulties in 24h collection in pediatrics hyperuricosuria is often defined based on random urine UA/Cr ratio (normal <0.65), or UA/Cr factored for GFR [UA/Cr x serum Cr (SCr), normal <0.57, all values in mg/dl]. The latter is regarded as more accurate but requires blood work for SCr determination. However, the above "cut-off" values were established in healthy children; not in pediatric urolithiasis population. Hence the aim of this study was to examine their validity in such population.

Methods: Based on electronic records, we analysed all children diagnosed at CMH between Jan. 1999 and Dec. 2010 with radiologically documented primary urolithiasis who had diagnostic 24-h urine. Data extracted: age at diagnosis, BSA, 24-h urine volume, Cr, UA, and SCr. Tests were performed ≥1 m after stone expulsion.

Results: After excluding 6 with inappropriate collection based on urine creatinine (mg/kg/24h), there were 188 patients who had their urine tested for both UA expressed in mg/24h/1.73m2 and UA/Cr ratio. In 148 of them UA/Cr was also factored for GFR. Age at diagnosis was 11.9±3.7 (median 12.1). 9 patients had UA > 815 mg/1.73 m2/24h, 46 had UA/Cr ratio ≥ 0.65; 12 had UA/Cr x SCr ≥ 0.57. Compared to the "gold standard" the sensitivity of UA/Cr ratio was 64% and specificity 78%; when factored for GFR sensitivity was 30% and specificity 93%. The area under the ROC curve for UA/Cr ratio was 0.802 (95% CI 0.706-0.898) and that for the GFR corrected 0.766 (95% CI 0.661-0.871). The positive predictive value (PPV) of UA/Cr ratio was 15%; the negative predictive value (NPV) 97%; and after factoring for GFR PPV was 25% and NPV 95%.

Conclusions: The current "cut off" values for urine UA/Cr ratio and UA/Cr factored for GFR are good tools to rule out hyperuricosuria but not to positively diagnose it. Furthermore, in school-age children UA/Cr factored for GFR does not provide an advantage; thus it can be omitted and with it serum creatinine determination .

FR-PO1180

Demographic, Clinical, and Laboratory Characteristics of 137 Pediatric Nephrolithiasis Patients David J. Sas,[1] Amy E. Wahlquist.[2] *[1]Pediatrics, Medical University of South Carolina, Charleston, SC; [2]Biostatistics & Epidemiology, Medical University of South Carolina, Charleston, SC.*

Background: Evidence suggests that the incidence of kidney stone disease is increasing in children, yet there are few data documenting characteristics of pediatric stone formers. We sought to thoroughly describe various characteristics of our stone-forming pediatric population. A description of pediatric nephrolithiasis patients of this size and scope has not been performed in almost two decades.

Methods: We retrospectively reviewed the charts of pediatric patients with nephrolithiasis confirmed by imaging and collected data on over 120 demographic, clinical, laboratory, evaluation, management and follow-up variables on each patient.

Results: Data from 137 subjects was collected and analyzed. Forty-nine percent of our patients were female. Twenty-five percent of our stone formers lived in rural environments. The mean age of presentation with first stone tended to be earlier in males than females (8.2 vs. 9.9 years). Males were more likely to be obese than females (23.6% vs. 17.3%) and the rate of obesity was higher than the general pediatric population in both sexes. Ninety-eight percent of the 47 stones that were analyzed contained calcium. Forty percent of our stone formers had elevated calcium excretion. Thirty-six percent and 57% had elevated supersaturation of calcium oxalate and calcium phosphate respectively. Random calcium-to-creatinine ratio correlated with 24-hour calcium excretion 73% of the time. Patients with 1-3 recurrences tended to be older, but those with >3 recurrences had the youngest mean age of first presentation. Each stone former was, on average, exposed to just over two CT scans specifically to evaluate for nephrolithiasis.

Conclusions: Our data summarize many characteristics of pediatric stone formers and reveal intriguing results related to obesity, recurrence rates, and differences related to gender. Further investigation into potential contributors to the increasing incidence of pediatric kidney stone disease is warranted.

FR-PO1181

Vitamin D in Renal Stone Formers Nikhil Johri, Robert J. Unwin. *Nephrology, Royal Free Hospital, London, United Kingdom.*

Background: Vitamin D (vitD) deficiency is common even among western population. There has been a resurgence of interest in the several health benefits of vitD, however concerns remain about vitD supplementation in those with history of kidney stones. We studied our cohort of idiopathic stone formers (ISF) to evaluate their vitD status and the impact of supplementation of 25-OH vitamin D (25D).

Methods: We retrospectively studied the prevalence of vitD deficiency in the ISF and compared metabolic parameters in 25D deficient (<30nmol/L) with those having normal levels (>75nmol/L) using an unpaired t-test. We also prospectively studied the impact of supplementing 25D in ISF. Total of 37 patients (21M, 16F) were prescribed tab colecalciferol 20,000 units once a week for 3 to 6 months along with advice about reducing meat intake, increasing proportions of fruit and vegetables and a list of oxalate-rich foods was provided. Bloods and 24 hr urine collections were done pre and post supplementation, and results compared using a paired t-test.

Results: 464 ISF were included, 67% males and 33% females, aged 15-81(mean 46.9 years). VitD deficiency was noted in 31%, while only 11.6% had normal vitD levels. The groups were no different in terms of age and renal function. Serum PTH levels were significantly higher in low vitD group (5.31±0.39 vs 3.30±0.19). Differences in urinary parameters influencing stone risk, such as U Ca/Cr, U Ox/Cr , U Cit/Cr , U UA/Cr were non significant. Studying vitD supplementation showed serum 25D levels were significantly higher (19.43±5.72 vs 52.76±26.62) and PTH levels (5.91±3.28 vs 4.61±1.95) significantly lower after supplementation. No significant differences were seen in serum calcium, phosphate and creatinine. 24hr U UA/Cr ratio was significantly lower (0.28±0.07 vs 0.25±0.06) and U Phos/Cr ratio significantly higher (2.04±0.46 vs 2.26±0.59) post supplementation. No significant difference was seen in U Ca/Cr, U Ox/Cr and U Cit/Cr pre and post supplementation.

Conclusions: VitD deficiency is common in our ISF cohort. Higher serum 25D levels were not associated with higher urinary calcium, oxalate, citrate and urate excretions. Supplementing 25D when coupled with dietary advice on stone risk does not result in an adverse change in urine composition.

FR-PO1182

Effects of the Calcium Sensing Receptor Promoter Region Polymorphisms in Kidney Stone Disease Andrea Aloia,[1] Annalisa Terranegra,[1, 2] Giuseppe Vezzoli,[2] Teresa Arcidiacono,[2] Elena Dogliotti,[1] Alessandra Mingione,[1] Francesco Rainone,[2] Laura Soldati.[1] *[1]Department of Medicine, Surgery, Dentistry, Università Studi Milano, Milan, Italy; [2]Unit of Nephrology, Dialysis, Hypertension, San Raffaele Hospital, Milan, Italy.*

Background: The calcium-sensing receptor (CaSR) is a candidate gene of calcium nephrolithiasis (CN). Previously, we found an association between the CaSR gene region including P1 and P2 promoters and CN. Particularly, the rs7652589 and rs1501899 SNPs, localized up and downstream of promoters, were strongly associated to CN, both idiopathic and primary hyperparathyroidism CN.

The aims of this study were to test the association of CaSR gene promoter SNPs with CN and their effects on CaSR expression in renal tissue.

Methods: SNPs genotyping was performed by Taqman genotyping assays of rs7648041, rs7648044, rs6776158 and rs1048213, located into P1 and P2, in 165 idiopathic calcium stone formers and 213 controls matched for age and gender. CaSR mRNA level was evaluated in 109 normal kidney medulla tissues by Real-time PCR and genotyped for the rs7652589, rs1501899 and rs6776158 SNPs.

Results: A fine mapping of the CaSR gene promoter region has been performed in controls and stone formers for the SNPs placed in P1 and P2. The data showed that SNP rs6776158, localized in P1, resulted strongly associated with the disease. The rs6776158 minor allele showed a higher frequency in stone formers than in controls (37.8% vs 26.4%, p=0.005). CaSR mRNA of kidney medulla tissues was related to the kidney stones associated SNPs. A decreased CaSR mRNA was found in homozygous subjects for the minor allele of rs6776158 and rs1501899 vs heterozygous and homozygous for the common allele (rs6776158: n=97, 2.75±0.22 vs n=12, 1.69±0.33, p=0.016; rs1501899: n=97, 2.75±0.22 vs n=12, 1.69±0.33, p=0.016). No variation was found with rs7652589. A decreased mRNA was also observed in subjects carrying haplotype combining the variant alleles at rs6776158 and rs1501899 SNPs (2.70±0.21 vs 1.28±0.32 with p=0.0062).

Conclusions: These findings confirmed the association of CN with CaSR promoter region. Moreover, the minor alleles of P1 SNPs were associated to a reduced expression of kidney CaSR mRNA.

FR-PO1183

Protective Effect of Thiazides on Bone Mass in Hypercalciuric Nephrolithiasis Armando Luis Negri, Francisco Rodolfo Spivacow, Elisa Elena Del Valle. *Nephrology, Instituto de Investigaciones Metabólicas, Buenos Aires, Argentina.*

Background: A very important but under addressed area in hypercalciuric nephrolithiasis is the accompanying bone disease. Decreased bone mineral density (BMD) and defects in bone remodeling has been described in these patients. Although thiazide diuretics are useful in preventing stone recurrence, there are still controversies about their efficacy in preventing bone loss.

Methods: We retrospectively analyzed the long term effects of treatment with thiazides on 48 patients (40 women and 8 men) with hypercalciuric nephrolithiasis studied between 2003 and 2010. Their mean age was 45.1 ± 12 years, BMI: 24.2 ±4.2 and normal renal function. Bone densitometry was performed in all patients at the lumbar spine (LS) and femoral neck (FN) at baseline and at the end of follow-up. Urinary Calcium was measured in 24 hour urine collections and bone remodeling was assessed using total and bone ALP, and β crosslaps, The lowest possible dose of a combination of hydrochlorothiazide/ amiloride was used to control calciuria, (range: 12.5 to 50 mg /d and 1.25 to 5 mg, respectively). We also evaluated the appearance of adverse effects to thiazides.

Results: The mean follow-up was 71.3 ± 48.0 months. 24h urinary calcium decreased from 306.5 ± 76.4 to 195.7 ± 58.4 mg/24h (p <0.001), and Ca / kg BW decreased from 5.0 ± 1.1 to 3.24 ± 0.98 (p <0.001). BMD at LS (basal: 1,047 ± 0.22; end follow-up: 1072 ± 0.14 g/cm2;p: NS) and at the FN (basal: 0.855 ± 0.120; end follow-up 0.864 ± 0.130 g/cm2; p: NS) remained stable; The percentage increase of BMD was 2.38 % at the LS and 1.4% at the FN. Bone remodeling markers did not change significantly during follow-up. Mild hypokalemia was observed in 39.4%of the patients, hyperglycemia was seen in 7 patients (2 in the diabetic range), hypotension in 4, palpitations, cramps and headaches in 2 patients in each case. Triglycerides, uric acid and plasma sodium showed no changes.

Conclusions: Low dose thiazide/amiloride combination produced significant long-term reduction in urinary calcium with preservation of bone mass. There were mild adverse effects that did not cause suspension of medication.

FR-PO1184

Race Differences in Patients Receiving Urologic Interventions for Nephrolithiasis in a Large Urban Community Hospital Albert M. Osei, Shweta Punj. *Medicine, Division of Nephrology, John H. Stroger Jr. Hospital of Cook County, Chicago, IL.*

Background: The prevalence of nephrolithiasis has increased and caucasians are more likely than African Americans and Hispanics to have renal stones. However, the race distribution of patients requiring interventions to remove urinary tract stones is unknown.

Methods: We reviewed the electronic and manual surgical logs of all procedures done by our genitourinary service over a two year period. Patients who had any urinary tract stone removal procedures were identified and the full operative reports were retreived and reviewed for the location of the stone, method of removal and the age at the time of the procedure . The demographic characteristics of the patients were also obtained from the hospital electronic records. The racial breakdown of all the patients utilizing the hospital services for that periord was also obtained.

Results: Two hundred and eighty four patients comprising 158 men and 126 women underwent surgical interventions to treat urinary tract stones during that period. The racial distribution were 35% Hispanic, 29 %White, 23% black and 13% for other races. During that same period, the racial distribution of patients using the hospital services were 30%, 20%, 45% and 5% for Hispanics, Whites, Blacks and other races respectively. The mean ages were 43, 46 and 49 years for Hispanics, Whites and Blacks respectively. The male to female ratio was 1.2:1 in all three groups. Thirty one patients had bladder stones and of these 42% percent were black. Nine (43%) of the 21 cases of staghorn calculi were among Hispanics. Extracorporeal short wave lithotripsy(ESWL) at 43% was the commonest procedure but 38%, 45% and 42% of Hispanics, Whites and Blacks respectively underwent the procedure

Conclusions: Hispanics were disproportionately over respresented among patients needing interventions for stone removal in this single center review. This suggests the renal stone burden may be higher among Hispanics than reported or they form stones which tend to require surgical removal. Blacks tend to required surgical removal of bladder stones more than Hispanics or Whites.

FR-PO1185

Regulation of Renal Calcium Reabsorption by Serum Calcium in Hypercalciuric and Control Subjects Kristin J. Bergsland, Elaine M. Worcester. *Nephrology Section, University of Chicago, IL.*

Background: Calcium (Ca) stone formers with idiopathic hypercalciuria (IH) have reduced renal Ca reabsorption, but the mechanism is not understood.

Methods: In the General Clinical Research Center, we studied 29 IH (17 male) and 17 (7 male) control (C) subjects. 27 of 29 IH formed Ca stones. We collected 15 urine and 20 blood samples over a 15 hour day, both fasting and with 3 meals of known composition.

Results: Fractional excretion of Ca (FECa) of all subjects was higher fed than fasting, but FECa of IH exceeded C both fasting and fed (Table). Serum Ca (SCa) and parathyroid hormone (PTH) did not differ significantly between IH and C either fasting or fed. SCa rose and PTH fell with feeding in IH but did not change in C.

	FECa (%)		SCa (mmol/L)		PTH (pg/ml)	
Group	Fast	Fed	Fast	Fed	Fast	Fed
C	1.6 ± 0.3	2.9 ± 0.3[b]	2.33 ± 0.02	2.37 ± 0.02	35 ± 3	28 ± 3
IH	2.7 ± 0.2[a]	5.3 ± 0.2[a,b]	2.31 ± 0.02	2.38 ± 0.02[c]	39 ± 2	29 ± 2[c]

Mean ± SEM; a, differs from C, p<0.01; b, differs from fasting, p<0.01; c, differs from fasting, p<0.05

In a general linear model (GLM) along with subject and food status, SCa varied with FECa (F=7.4, p<0.01), but PTH did not. SCa is part of FECa which presents potential for artifact, so we decomposed FECa into its two terms: urine Ca excretion (UCa) and filtered load of Ca (FLCa, using ultrafilterable Ca). FLCa did not differ between IH and C either fasting or fed. By GLM, UCa varied with FLCa and subject type; SCa had an independent effect on UCa during feeding (F=5.1, p=0.03). The association of SCa with UCa in IH is more striking when SCa is stratified into 'high' or 'low' SCa, defined as above or below the mean

by subject type within food period (Table). High SCa IH had increased UCa compared to low SCa IH, which was significant during feeding (0.52 ± 0.01 vs 0.46 ± 0.01 mmol/hr, p<0.001) and not attributable to FLCa. UCa did not differ by SCa group in C either fasting or fed. In IH, PTH was significantly lower in the high SCa group both fasting and fed (p<0.001), but PTH did not differ in C by SCa group.

Conclusions: SCa appears to modulate the effect of food intake on Ca excretion and PTH level in IH but not C, which implicates altered Ca signaling in the abnormal Ca metabolism of IH.

Funding: NIDDK Support

FR-PO1186

Does FGF23 Play a Role in Pediatric Idiopathic Hypercalciuria? Maria Goretti Penido,[1] Marcelo S. Tavares,[1] Uri S. Alon.[2] *[1]Pediatric Nephrology Unit, Federal Univ. of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil; [2]Bone and Mineral Disorders Clinic, Pediatric Nephrology, Children's Mercy Hospital, Univ. of MO, Kansas City, MO.*

Background: Various mechanisms were proposed as pathophysiology of idiopathic hypercalciuria (IH). Based on recent findings and suggestion by Worcester & Coe (2008), the aim of this study was to explore a potential role for FGF23 in pediatric IH.

Methods: We studied 29 controls (19M) and 58 children with IH (35M); of whom 24 before treatment (untreated) and 34 after 6 months treatment either with K-citrate alone (20) or combined with thiazides (14). Plasma FGF23 was assessed using C-terminal ELISA (Immunotopics, San Clemente, CA). We also measured serum PTH, 25OH Vit D, P, Ca, creatinine; and 24h urine calcium (UCa), phosphate and creatinine.

Results: No differences in age were noted between controls (15.4±8.3) and patients (16.0±5.0), nor between untreated (16.8±5.4) and treated (15.5±4.7), and no difference in gender distribution. The incidence of lithiasis in the untreated (75%) and treated patients (76%) was the same. Plasma FGF23 in controls was 85.5±34.8 compared with all patients 69.6±52.0 RU/mL (p=0.0019). However, FGF23 in untreated patients 77.6±36.9, was not different from controls, whereas in treated patients it was 64.0±60.4, significantly lower than in controls (p<0.0001) and untreated children (p=0.02). In all IH patients combined there was a tendency of correlation between FGF23 and UCa (r= 0.22; p=0.09). There were no differences between the untreated and treated IH children regarding serum creatinine, Ca, 25D, PTH, urine creatinine or phosphate. Treated patients had significantly lower UCa 2.5±0.7 vs. 5.6±1.2 mg/kg in untreated (p<0.0001); higher TP/GFR 4.0±0.6 vs. 3.4±0.7 (p<0.001) and serum P 4.4±0.5 vs. 4.0±0.6 mg/dl (p=0.007).

Conclusions: Treatment of IH patients resulted in significantly lower UCa excretion rate, lower plasma FGF23 and elevated TP/GFR and serum P, without significant changes in serum PTH. We conclude that the reversal of hypercalciuria may directly or indirectly affect phosphate metabolism, perhaps via calcium retention in bone or changes in 1,25 $(OH)_2$ Vit D metabolism. Further studies on this topic are needed.

FR-PO1187

Abnormal Arterial Stiffness and Bone Density in Calcium Renal Stone Formers Antonia Fabris,[1] Antonio Lupo,[1] Francesco Fantin,[2] Pietro Manuel Ferraro,[3] Chiara Caletti,[1] Gabriele Comellato,[2] Mauro Zamboni,[2] Giovanni Gambaro.[3] *[1]Nephrology, University of Verona; [2]Geriatrics, University of Verona; [3]Nephrology, Catholic University, Rome, Italy.*

Background: Kidney stone formers (SF) are at increased risk for myocardial infarction for still unclear reasons. Reduced bone mass is a frequent finding in calcium SF. An inverse relationship between bone density and abnormal arterial stiffness partly related to vessel calcifications has been reported. Abnormal arterial stiffness is a strong predictor of CV mortality.

To elucidate the causes of the increased CV risk in SF we investigated whether they have abnormal arterial stiffness.

Methods: Recurrent calcium SF (23) and 19 age and sex matched controls underwent DEXA to determine bone mineralization, and pulse waive velocity (PWV) by Complior, and augmentation index (AI) by pulse pen. BMI, triglycerides, cholesterol, blood pressure were not different between groups. All had normal renal function. None had diabetes, or hyperparathyroidism or were actual and past smokers. Females were not in menopause. Main characteristics of the 2 groups are shown in the table.

	Stone formers	Controls	P-value
Augmentation Index	12.3±8.2	5.7±11.8	0.042
PWV charotid-radial	10.0±2.0	9.2±2.0	0.202
PWV charotid-femoral	10.6±2.6	9.1±2.8	0.075
T-score LS*	-1.45 (0.80)	-0.10 (0.90)	0.025
T-score femoral neck*	-1.60 (0.70)	0.00 (0.85)	<0.001
T-score hip*	-1.30 (0.40)	0.25 (0.90)	<0.001

Mean ± SD or * median (interquartile range)

Results: A trend to higher values of PWV charotid-femoral in SF was shown; the AI was significantly higher in this group suggesting an increased stiffness of small arteries and a preclinical atherosclerosis condition.

Multivariate analysis, adjusted for age, gender and BMI, disclosed an inverse relationship with femoral neck mineralization (T-score, p= 0.014) and hip mineralization (T-score, p= 0.015).

Conclusions: A bone-vessel liaison which leads to atherosclerosis has been discovered in a number of conditions. Present data extend to calcium nephrolithiasis this paradigma although the mechanisms are not immediately obvious. Certainly, classical CV risk factors were scantly represented in these SF. Our findings may explain the increased CV morbility and mortality of renal SF.

FR-PO1188

Nephrocalcinosis, Renal Failure and Bone Disease in Patients with Dent Disease and Medullary Sponge Kidney: Comparison with Patients with Reccurrent Calcium Nephrolithiasis Antonia Fabris,[1] Antonio Lupo,[1] Luisa Maria Bertizzolo,[2] Franca Anglani,[3] Giovanni Gambaro,[2] Angela D'angelo.[3] *[1]Nephrology, University of Verona; [2]Catholic University of Rome; [3]University of Padua.*

Background: Medullary Sponge Kidney (MSK) is a developmental and functional disorder with Nephrocalcinosis (NC) and Lithiasis (LT); familial occurrence and the discovery of rare GDNF variants suggest a role of genetic factors.Dent Disease (DD) is a X-linked proximal defects, caused by CLCN5^{+} or OCRL1 mutations,which may present with NC and/or CN. RCN is a common disease affecting adults;earlier occurrence may suggest a hereditary cause.

Methods: RCN, MSK and DD groups were divided into subgroups on the base of specific characteristics; the prevalence of 8 cardinal clinical signs tailored to DD clinical pattern were analysed.

Characteristics in pts with RCN, MSK and DD.

Subgroups	RCN +m.a.	RCN -m.a.	MSK Bilt.	MSK Mono.	CLC5+	CLCN5/ OCRL1	Fam.CLCN5
Pts (males)	53(23)	38(14)	36(17)	21(10)	40(100)	17(100)	7(100)
Age	28±11	30±8	32±11	37±7	14±9	17±16	27±16
HyperUCa%	66	0	78	28	97	64	57
HypoPPi%	19	18	21	38	33	44	34
NC%	0	0	100	100	90	29	42
LT%	100	100	100	100	27	29	42
LMWP+UPi%	47	0	41	14	30	52	71
BD%	35	7	52	4	42	17	0
RF%	0	0	0	0	12	35	0

Results: NC, present by definition in all pts with MSK, was not detected in RCN and was significantly (p<,01) more frequent in CLCN5+ than in CLCN5- DD pts. RF, not present in our MSK and RCN pts, was always associated with NC in CLCN5+ DD pts, but only sporadically in CLCN5-DD pts. No pt. among DD familial cases and MSK pts have RF, despite having NC. Bone disease (BD) in each group is similar (31-36%) but higher than in the general population. It correlates to neither age nor gender, but significantly only to renal hypercalciuria (p<,05) thus confirming the secondary nature of BD complication.

Conclusions: Pathogenetic mechanisms other than nephrocalcinosis trigger RF in DD pts. The lack of BD and RF in DD familial case pts indicates that disease phenotype is mitigated and that it might be resulting from the presence of modifier genes. In 1/3 of MSK pts the presence of a Fanconi-like syndrome also suggest proximal tubular damage.

FR-PO1189

Factors Predicting Medical and Nutritional Therapy Adherence for Reccurent Nephrolithiasis Roy A. Jhagroo,[1] Kristina L. Penniston.[2] *[1]Medicine, UW Madison, Madison, WI; [2]Urology, UW Madison, Madison, WI.*

Background: Nephrolithiasis has a 10% lifetime prevalence in the general population as well as carries a 2.1 Billion dollar economic burden per year. While medications as well as nutritional recommendations have been found to prevent kidney stones, factors affecting compliance with these prevention methods remain poorly understood.

Methods: We used targeted patient surveys to access patient compliance with various modalities of treatment. 155 surveys were returned by mail or at time of the next clinic visit. Nutritional advice if given was evaluated for it's clarity of explanation, comprehension as well as implementation. Medical therapy was also assessed for it's clatrity of explanation, comprehsion and adherence.

Results: A patient described understanding of the rationale for the nutritional therapy recommended it was associated with compliance with the diet (p < 0.001)).

Supporting this, it was also noted that if patients felt that the explanation of the dietary recommendations was satisfactory, they were compliant with diet recommendations(p < 0.0001).

In our survey women reported lower compliance with pharmacologic therapy than men.(p < 0.0003) Specifically for Hydrochlorothiazide women reported lower compliance (p = 0.05)).

A tendency was also noted regarding the poor compliance of women with regard to potassium citrate which was not found in men. (p = 0.09)

In addition, a tendency for women to feel that the rationale behind the medications were not well explained to them was noted(0.058).

Conclusions: Compliance with medications as well as nutrition seems to be influenced by gender as well as provider provided education.

Identification of characteristics affecting adherence provides an opportunity for us to maximize the effect of our therapys. It seems that explaination of the rational behind the use of medications and diet modification is vital for compliance.

These results are also suggestive that women should be given more attention to ensure compliance and possibly would benefit from Nutritional consultation routinely rather than as needed.

FR-PO1190

Etiology of Pediatric Primary Urolithiasis: 12 Year Experience in a Mid-Western Children's Hospital Maria Goretti Penido,[1] Tarak Srivastava,[2] Uri S. Alon.[2] *[1]Pediatric Nephrology Unit, Federal Univ. of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil; [2]Bone and Mineral Disorders Clinic, Pediatric Nephrology, Children's Mercy Hospital, Univ. of MO, Kansas City, MO.*

Background: Urolithiasis has become more prevalent due to changes in habits and increasing affluence, and possible ecologic changes. The aim of this study was to evaluate the current etiology of pediatric primary stone disease.

Methods: Using electronic data, we identified all children seen at CMH in Kansas City between Jan. 1999 and Dec. 2010 with radiologically documented urolithiasis who had diagnostic 24-h urine analysis. 56 patients with secondary causes (e.g. CF, Crohn's, primary hyperpara, etc.) were exluded. Data extracted included: age at diagnosis, gender, weight, BMI, imaging thechnique used; 24-h urine volume, creatinine (Cr), Ca, uric acid, citrate, oxalate, cystine; serum Cr, electrolytes and minerals; and costs.

Results: After omitting 11 whose urine Cr (mg/kg/24h) showed inappropriate collection, there were 222 patients (48% male), all with normal serum Cr, electrolytes and minerals. Annual rate of primary urolithiasis tripled from 9.7±6.4 to 27.3±8.0 (p= 0.002); 73% were diagnosed by ultrasound and the rest by CT. Age at diagnosis was 11.8±3.8 and BMI 20.5±5.7: 15% were overweight. 147 patients (63.0%) had urine flow < 1.0 ml/kg/24h; in 54 (24.3%) as only abnormailty. Hypercalciuria was observed in 47% of patients, hypocitraturia in 10%, and 54% had high Ca/citrate ratio (≥0.33). Mild idiopathic absorptive hyperoxaluria was found in 3 patients and hyperuricosuria in 11 (all 14 had at least 1 additional abnormality). 1 had cystinuria.

Conclusions: We conclude that "oliguria" and hypercalciuria continue to be the most common abnormalities, followed by hypocitraturia. The significant increase in stone incidence could not be attributed to increased utilization of CT *per se*. Incidence of obesity in the urolithiasis population was not higher than in the general pediatric population. Hyperoxaluria and cystinuria are rare; to identify 1 patient they require screening of 74 at ≥$3500 in the former, and 222 patients at ≥ $42,000 in the latter entity; hence both may not be indicated in 1st analysis.

FR-PO1191

Metabolic and Medical Risk Factors in Pediatric Patients with Urolithiasis Sermin Saadeh, Brett C. Ferguson, Rossana G. Baracco Maggi, Gaurav Kapur, Amrish Jain, Tej K. Mattoo, Rudolph P. Valentini. *Pediatric Nephrology, Children's Hospital of MI, Detroit, MI.*

Background: Urolithiasis is an uncommon medical condition in pediatrics. However, it can be associated with morbidity and recurrence. Compared to adults, a higher proportion of pediatric stone patients have predisposing conditions for recurrence (metabolic disorders, structural abnormalities, infections) often combined with dietary and environmental factors. **Aim:** Evaluate risk factors for pediatric kidney stone formation and recurrence.

Methods: Retrospective chart review of patients evaluated for urolithiasis in the pediatric nephrology clinic from 2005 to 2010.

Results: Charts of 41 patients were reviewed. Median age was 10.3 years (0.6-17.5 yrs), male to female ratio was 1.6:1. Most patients were Caucasian (24/41). The most common presenting symptoms were abdominal colic (68%), gross hematuria (27%), UTI (24%) and dysuria (24%). The imaging modality leading to diagnosis was CT scan in 46%, ultrasound in 34% and x-ray in 15%.

Metabolic work-up in the form of 24-hr urine collection and/or stone analysis was done. Results of 24-hr urine collection on 34 patients are described in table 1. A metabolic abnormality was found in 88% of patients. Hypercalciuria was the most common metabolic abnormality, followed by hypocitraturia. Stone analysis in 13 patients revealed calcium oxalate stones in 7/13 (54%), followed by calcium phosphate stones in 4/13(31%), cystine stone in 1/13(7.6%), and ammonium urate stone in 1/13 (7.6%). 34% of patients had predisposing conditions (neurogenic bladder, loop diuretics, bladder augmentation, ketogenic diet), and 44% had a positive family history for stones.

Results of 24-hr urine collection in 34 patients

24-hr urine collection results	n (%)
Hypercalciuria	9 (26)
Hypocitraturia	7 (20.5)
Hypercalciuria and hypocitraturia	7 (20.5)
Cystinuria	5 (15)
hyperoxaluria	1 (3)
Hypercalciuria and hypomagnesiuria	1 (3)
Non-diagnostic	4 (12)

Conclusions: Hypercalciuria and hypocitraturia are the most common metabolic disorders in our pediatric population with urolithiasis. Patients with urolithiasis should be evaluated for the presence of predisposing conditions to help reduce the risk of recurrence.

FR-PO1192

Urine Levels of Inter-α-Trypsin Inhibitor Proteins Differ According to Age and Stone Forming Status Ran Pang,[1,2] Michael P. Linnes,[1] Amy E. Krambeck,[3] Samuel Edeh,[1] Andrew D. Rule,[1] John C. Lieske.[1] *[1]Department of Medicine, Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Department of Urology, Guang An Men Hospital, China Academy of Chinese Medical Science, Beijing, China; [3]Department of Urology, Mayo Clinic, Rochester, MN.*

Background: The urine of many individuals is supersaturated favoring the formation of calcium oxalate and calcium phosphate crystals. However, proteins are thought to inhibit nucleation, growth, and aggregation of these crystals. Many protein crystallization inhibitors have been identified, including the inter-α-trypsin inhibitor (IαI) family, which have also been implicated during pathologic calcification in cartilage and vessels. In the current study we investigated urinary levels of IαI proteins in an incident stone forming cohort with matched controls.

Methods: Urine samples were collected from 37 first time stone formers (SF) and controls (C), matched by gender and age. IαI family proteins including heavy chain1 (HC1), heavy chain2 (HC2), and heavy chain3 (HC3) were detected by Western blot and quantitated using Image J. SF and C were divided into four groups based on age: younger (25-50 yrs) SF (n=19), older (51-65 yrs) SF (n=18), younger C (n=20), and older C (n=17).

Results: HC1 was higher in younger SF (1.20±0.70) than in older SF, (0.60±0.32), ($p<0.001$), as were HC2 (1.23±1.24 vs.0.63±0.31, $p<0.01$) and HC3 (1.21±0.34 vs.0.92±0.34, $p<0.05$). Conversely, urinary IαI heavy chains were similar in the younger and older C groups, which also matched the older SF patients.

Conclusions: These results suggest that urinary IαI protein levels differ by age and stone forming status. Although age was not found to affect IαI trimer levels in the controls, significantly higher amounts of the heavy chains were found in the younger SF population. Deposition of IαI heavy chains is thought to protect against pathologic calcification in soft tissues, including cartilage. Therefore, increased levels of heavy chains in the urine of younger SF could represent a feed back protective mechanism against further stone formation. This response seems to be diminished in the urine of older SF, in whom the pathogenesis of kidney stones may differ.

FR-PO1193

Does Dietary Education Improve 24 Hour Urine Stone Risk Profiles in Children? Katherine E. Twombley,[1] Nicol Corbin Bush,[2] Candace F. Granberg.[2] *[1]Pediatrics, UT Southwestern Medical Center, Dallas, TX; [2]Urology, UT Southwestern Medical Center, Dallas, TX.*

Background: Dietary education (DE) is a widely practiced therapy for pediatric stone formers. However, few studies show the effects of dietary intervention on 24hr urine stone risk profiles in children. We analyzed 24hr urines before and after DE among our pediatric stone formers to evaluate if urinary stone risk profiles improved.

Methods: We performed a retrospective review of 24hr urine samples in stone forming children. Inclusion criteria included patient age <18yrs, radiographically-confirmed stones, DE handout and preDE and postDE 24hr urines. DE handout advised increased water, decreased sodium(Na) and oxalate(Ox), and moderate calcium(Ca) intake. Statistical analyses of 24hr urine parameters were performed with paired t-test.

Results: Among 24 patients with an average age of 10.8yrs (3-18), 11M:13F, improvement in urine volume was the only significant change, increasing from 33 to 45ml/kg/day (p=0.03) or 1.1 to 1.6 liters/day (p=0.002). Urine Na (3.5 vs. 3.7mEq/kg/day), Ca (3.5 vs. 4.4mg/kg/day), and Ox (0.66 vs. 0.70mg/kg/day) did not change despite DE. Likewise, there was no improvement in the supersaturations for calcium oxalate (1.7 vs. 1.4, p=0.2), brushite (1.2 vs. 1.3, p=0.6) and sodium urate (2.9 vs. 2.7, p=0.3).

Conclusions: Among pediatric stone formers, urine output improved with DE, however urine supersaturation indices, Na, Ox and Ca did not. Since 24 hour urine is the gold standard measurement for dietary Na intake, our results suggest poor patient compliance with low sodium diet (despite written DE) may contribute to persistent hypercalcuria in some patients.

FR-PO1194

Transglutaminase 2 Accelerates Vascular Calcification in CKD Neal X. Chen,[1] Kalisha O'Neill,[1] Kraiwiporn Kiattisunthorn,[2] Xianming Chen,[1] Sharon M. Moe.[1,3] *[1]Indiana University School of Medicine; [2]Faculty of Siriraj Medical School, Mahidol University, Bangkok, Thailand; [3]Roudebush VA Medical Center, Indianapolis, IN.*

Background: Transglutaminase 2 (TG2) is a calcium dependent enzyme that is a co-receptor with ß1 integrins and fibronectin on the cell membrane, connecting the cytoskeleton and the extracellular matrix (ECM). TG2 can cross link nearly all ECM proteins through transamidation or deamidation, increasing osteoblast differentiation and arterial remodeling. Furthermore, vascular smooth muscle cells (VSMC) from TG2 null mice cannot calcify in response to hyperphosphatemia. We therefore hypothesized that increased TG2 activity leads to accelerated vascular calcification in CKD.

Methods: In the current study, we used thoracic aortas and VSMC form the Cy rat, a model of CKD-MBD compared to normal rats to examine the role of TG2 in vascular calcification using real time PCR, immunostaining, Western blot and biochemical assays.

Results: Histological evaluation revealed that TG2 expression is increased in area adjacent to calcification in arteries from CKD rats, whereas there is minimal TG2 expression in arteries from NL rats. VSMC isolated from CKD rats had a 50% increase in TG2 expression compared to NL rats. We also isolated matrix vesicles (MV) from Rat VSMC incubated with control or calcification media and found high levels of TG2 are present in calcified MV whereas no detectable TG2 was found in control MV. To further confirm the role of TG2 in vascular calcification, VSMC from normal or CKD rats were incubated with calcification media in the presence of various concentrations of the TG2 inhibitor cystamine. The results demonstrated that there is significantly greater calcification and alkaline phosphatase (ALP) activity in VSMC from CKD rats compared to that in VSMC from normal rats (10.9 3.5 vs. 3.3 0.5 mol/mg protein, calcification; 11.4 1.6 vs. 6.7 1.4 U/g, ALP). Inhibition of TG2 activity by cystamine dose dependently decreased calcification and ALP activity in VSMC from CKD rats but had no effect on that in NL VSMC.

Conclusions: These data demonstrate a role of TG2 in the pathogenesis of vascular calcification in CKD, likely through its effects on the ECM.

Magnesium Reduces Vascular Calcification In Vitro Addy Rosa Montes de Oca Gonzalez,[1] Fatima Guerrero,[1] Juan R. Muñoz-Castañeda,[2] Julio Manuel Martínez Moreno,[2] Juan Antonio Madueño Domenech,[2] Carmen Herencia,[2] Yolanda Almaden Peña,[2] Escolastico Aguilera-Tejero,[1] Mirjam Peter,[3] Jutta Passlick-Deetjen,[4] Sonja Steppan,[3] Mariano Rodriguez.[2] *[1]Depto. Medicina y Cirugia Animal, University of Cordoba, Spain; [2]Hospital Reina Sofia, RedinRen, IMIBIC, Spain; [3]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [4]University of Duesseldorf, Germany.*

Background: Vascular calcification (VC) in uremic patients is associated with high serum phosphorus (P). P binders containing magnesium (Mg) are successfully used for control of hyperphosphataemia. An association of increased serum Mg with reduced VC has been described. Thus, the question to be addressed is whether Mg may exert a direct effect on VC.

Methods: Rat aortic rings (AO) were incubated in vitro for 7 days with a P concentration of 2.8mM and 1.8mM calcium (Ca) with increasing concentrations of Mg (0.6, 1.4, 2.6mM).

Results: Ca content in AO increased from (mean±SE) 0.21± 0.04 in controls without P added, to 4.8±0.6 (mcg/mg protein) with 2.8mM P/0.6mM Mg. Increasing the Mg concentration to 1.4 and 2.6mM significantly ($p<0.01$) reduced the AO Ca content to 1.3±0.7 and 0.25±0.08 respectively, the later value was not different from control. Compared to control values, the decrease in VC induced by Mg was associated with decreased expression of the osteogenic markers Cbfa1 and osterix. Similar results were obtained using human vascular smooth muscle cells (VSMC). Even with concentration of P as high as 3.3mM the change in Mg from 0.6 to 1.4mM reduced Ca content from 11.9±1.9 to 2.1±0.2; a higher concentration of Mg did not produce a further decrease in VC. To test the ability of Mg to reverse VC, VSMCs were incubated for 5 days with 3.3mM P. The Ca content was 8.8±0.6 mcg/mg which increased to 12.1±2.0 after 9 days. The addition of 1.4mM Mg at day 5 produced a markedly decreased Ca content at day 9 (2.5± 0.3; $p<0.01$); this value was not different from control without P added.

Conclusions: An increase in Mg to the upper limits of normal, not only prevented, but also reversed VC in vitro. Thus, P lowering with Mg containing P binders may help to reduce VC through a decrease in P and a direct beneficial effect of Mg.

Stanniocalcin-1 (STC1) Is Upregulated in Uremic Rats and Induces VSMC Calcification Magdalena Gonzalez, Rodrigo Andaur, Solange C. Valdés, Peter W. Murphy, Luis F. Michea. *Facultad de Medicina, Universidad de Chile, Santiago, Chile.*

Background: Calcification of arterial vascular smooth muscle cells (VSMC) is frequent in end-stage renal disease and correlates with hyperphosphatemia. VSMC calcification may involve the osteochondrogenic trans-differentiation. STC1 is an autocrine/paracrine homodimeric factor that promotes osteochondrogenic differentiation in developing bone of mammals. We hypothesized that STC1 is an inducer of VSMC calcification that increases in arterial calcification, observed in chronic renal failure (CRF).

Methods: Male SD rats were nephrectomized (5/6 kidney ablation) and separated into the following groups: standard diet, high phosphate diet (HP), vitamin D plus HP and sham operated rats under standard or HP. Physiological parameters were determined, after 5 weeks animals were sacrificed to obtain blood, urine and aorta samples.

Results: We observed hypertension and low creatinine clearence in all NPX groups ($n=5, P<0,05$). HP diet caused increased [Phosphate]plasma in all NPX groups ($n=6, P<0,05$). Plasma STC1 increased in NPX+HP rats, NPX+VD rats and NPX+HP+VD rats (2.0±0.6, $P<0,05$). To test the direct effect of STC1 on VSMC mineralization, we used A7r5 cells (Aortic, ATCC CRL-1444) incubated in the presence of HP (2,5mM) or VD (100nM), with or without STC1 (10nM) up to 12 days. High CaCl2 (2mM)+HP medium was the positive control of mineralizartion. We observed that STC1+HP induced a time-dependent increase in mineralization (measured Alizarin-red staining, 11.4± 2.9 fold of control levels), even higher that HP+CaCl2 medium (7.9± 2.1, $n=6, P<0,05$).

Osteochondrogenic differentiation was evaluated by measuring the mRNA abundance of the Sry-box containing gene-9 (Sox-9) and Core Binding Factor Alpha-1 (Cbfa-1). STC1 induced a dramatic increase of both transcripts (>2000 fold; $n=3-4, P<0.01$). Addition of HP induced a further increase of osteochodrogenic factors mRNAs ($n=3-4; P<0,01$).

Conclusions: Our data demonstrate increased plasma STC1 levels in uremic rats subjected to pro-calcifying conditions and the induction/potentiation of VSMC calcification by STC1. Supported by FONDECYT 1090223, Fondecyt-FONDAP 15010006.

FR-PO1197

Elevated Extracellular Phosphate Levels Down-Regulate Both Akt and AMP-Dependent Kinase in Endothelial Cells Yutaka Taketani, Tomoyo Kitamura, Hironori Yamamoto, Eiji Takeda. *Department of Clinical Nutrition, University of Tokushima, Japan.*

Background: Hyperphosphatemia is an independent risk factor for cardiovascular diseases (CVD) in general population as well as chronic kidney disease (CKD) patients. In addition, phosphate toxity has been emerged from cardiovascular disease to various aging-related diseases such as diabetes mellitus, based on the studies of klotho-deficient mice with premature aging-like phenotype. We hypothesized that hyperphosphatemia can regulate multiple kinases relating on various metabolic processes.

Methods: Most of kinases can be regulated by phosphorylation or dephosphorylation, therefore we investigated the changes of phosphorylation status in response to elevation of extracellular phosphate in human aortic endothelial cells (HAECs) by phosphoproteomic analysis with anti-phospho-signal transduction molecules antibody array.

Results: We found that incubation of HAECs with high phosphate medium (3 mM) decreased phosphorylation of both AMPK at threonine 172 and Akt at serine 473, but control phosphate medium (0.9 mM) did not change them. In addition, high phosphate medium also decreased phosphorylations of the downstream effector proteins of AMPK and Akt, such as endothelial nitric oxide synthase (eNOS), p70S6K and acetyl-CoA carboxylase (ACC).

Conclusions: Akt is a key molecule of insulin signaling pathway. AMPK is known as energy sensor that can regulate glucose and lipid metabolism in response to intracellular AMP/ATP ratio. Therefore, elevated extracellular phosphate levels down-regulated Akt and AMPK, suggesting that hyperphosphatemia may cause abnormal glucose and lipid metabolism found in the klotho-deficient mice.

FR-PO1198

Role of Local and Systemic Pyrophosphate Metabolism in Vascular Calcification Koba A. Lomashvili, Faten Hasounah, W. Charles O'Neill. *Renal Division, Emory University, Atlanta, GA.*

Background: Pyrophosphate (PPi) is an important endogenous inhibitor of vascular calcification but it is not known whether inhibition is dependent on local (vascular smooth muscle) or systemic PPi. PPi is synthesized by ectonucleotide pyrophosphatase/phosphodiesterase 1 (ENPP1) and both humans and mice lacking ENPP1 develop vascular calcification. We transplanted aortas between Enpp1-/- and Enpp+/+ mice to determine the relative role of local and systemic PPi in inhibiting vascular calcification.

Methods: Sections of abdominal aorta (5-8 mm) were transplanted via end-to-end anastomosis between 2-4 month old Enpp1-/- mice and wild-type littermates (Enpp1+/+). Transplants from Enpp1+/+ mice into Enpp1+/+ mice were also were performed as a control. Animals were fed a 1.5% phosphorus diet for 45 days before sacrifice. Calcium was measured in transplanted abdominal aorta grafts (excluding suture lines), recipient abdominal aorta (adjacent to the allograft), and recipient thoracic aortas by the cresopthalein method after drying and extraction with 1 M HCl.

Results: Aortic calcium contents (nmol/mg dry weight) are shown in the table below. Plasma calcium and phosphorus were 1.3 ± 0.05mM and 2.06 ±0.18mM in Enpp1+/+ recipients and 1.24±0.07mM and 1.99±0.19mM in Enpp1-/- recipients. Transplantation into Enpp1+/+ mice substantially reduced but did not eliminate calcification of Enpp1-/- aortas. Enpp1+/+ aortas calcified when transplanted into Enpp1-/- mice but much less than native Enpp1-/- aortas.

Aortic calcium contents (nmol/mg dry weight)

Donor	Recipient	n	Donor aorta	Abdominal aorta	Thoracic aorta
Enpp1-/-	Enpp1+/+	8	32.7 ± 7.2	12.6 ± 3.6	9.7 ±2.9
Enpp1+/+	ENPP1-/-	7	49.3 ± 15.0	475 ±138*	529 ± 132
Enpp1+/+	Enpp1+/+	8	14.4 ± 4.8	10.1 ± 1.2	8.8 ± 0.9

Conclusions: Inhibition of vascular calcification is dependent on both locally produced and systemic pyrophosphate.

Funding: NIDDK Support

FR-PO1199

A Label-free Serum Test Measuring Overall Calcification Inhibition Andreas Pasch,[1,2] Stefan Farese,[1,2] Jurgen Floege,[3] Willi Jahnen-Dechent.[1] *[1]Biomedical Engineering, Biointerface Laboratory, RWTH Aachen University, Aachen, Germany; [2]Department of Nephrology and Hypertension, University Hospital Bern, Inselspital, Bern, Switzerland; [3]Department of Nephrology, RWTH University of Aachen, Aachen, Germany.*

Background: Accelerated vascular and soft tissue calcification is a major problem in patients with chronic kidney disease (CKD). As serum is supersaturated with regard to calcium and phosphate, inhibitors of calcification critically determine pathological calcification. Therefore, an assay measuring the overall calcification inhibitory capacity in blood would be helpful to make informed therapy decisions.

Methods: We developed a label-free assay to quantify calcification-inhibitory properties contained in serum. The assay measures the formation of protein-mineral aggregates in real time.

Results: Using this assay, we demonstrate that in the presence of high amounts of calcium and phosphate, primary calciprotein particles (CPPs) are formed in serum. Primary CPPs are spherical colloidal particles of 50-100 nm diameter. Subsequently, these primary CPPs undergo spontaneous transition to spindle shaped secondary CPPs. Primary CPPs are mainly comprised of fetuin-A and albumin, as demonstrated by protein gel and Western blot analyses. The size of the resulting secondary CPPs is regulated mainly by two serum-inherent proteins: fetuin-A and albumin, with albumin synergistically substituting low fetuin-A concentrations. We furthermore demonstrate that the transition step is delayed in the presence of magnesium, and accelerated in the presence of phosphate.

Conclusions: We have developed a novel test to assess the overall calcification inhibitory capacity of serum. This test may have an important role in the identification and specific treatment of calcification-prone CKD patients.

Funding: Government Support - Non-U.S.

FR-PO1200

Assessment of the Frequency of Pulmonary Calcification and Its Influence on Respiratory Function in Patients with Chronic Kidney Disease Joanna Matuszkiewicz-Rowinska, Magdalena Dylewska, Jerzy Przedlacki. *Nephrology, Dialysis & Internal Diseases, Medical University of Warsaw, Warsaw, Poland.*

Background: The extraosseus calcification accompanying CKD appears, among other, in cardiovascular system and lungs. Disturbed calcium-phosphate (Ca-P) metabolism and alkaline pH are taken as the most important risk factors of pulmonary calcification (PC). The aim of study was to assess the PC frequency and its effect on respiratory function among pts with 3-5D stage of CKD.

Methods: Thirty seven pts with CKD (23 males and 14 females, aged 53.0±8.5 years, 13 in stage 3-4 and 24 in stage 5 (treated with hemodialysis) were included into the study. The exclusion criteria were: obturative, restrictive and interstitial lung diseases, smoking, tuberculosis or anti-mycobacterium therapy actual or in past, neoplasms, heart failure and overhydration. The protocol of the study included: laboratory tests (Ca, P, CaxP product, alkaline phosphatase, PTH), lung tests (spirometry, pletysmography and diffusing capacity of the lung for carbon monoxide (DLCO), high resolution computed tomography (HRCT) of lungs and scintigraphy with the use of 99mTc-MDP.

Results: Only mild PC were found recognized by HRCT alone: in 13/24 pts with 5 CKD and in 1/13 pts with 3-4 CKD ($p<0.01$). Bone scintigraphy did not reveal any calcification. No disturbances of lung tests were found. The mean duration of hemodialysis was longer among the pts with PC (9.9±8.2 years) vs without PC (2.6±6.9 years) ($p<0.01$). No statistical differences in age, gender, duration of CKD, severity of Ca-P disorders and its therapy were found among pts with and without PC. Clinical symptoms: chest pain and dyspnea were observed more frequently in pts with PC (10/13 and 9/13 respectively) than without PC (2/11 and 3/11 respectively) ($p<0.004$ and $p<0.04$ respectively). No difference in frequency of chronic, nonproductive cough was observed among both groups.

Conclusions: We conclude that despite a relatively high frequency of PC, the severity of PC was mild and they were not associated with restrictive disturbances nor impaired DLCO in functional lung tests. HRCT is an useful tool in detection of PC in CKD patients.

FR-PO1201

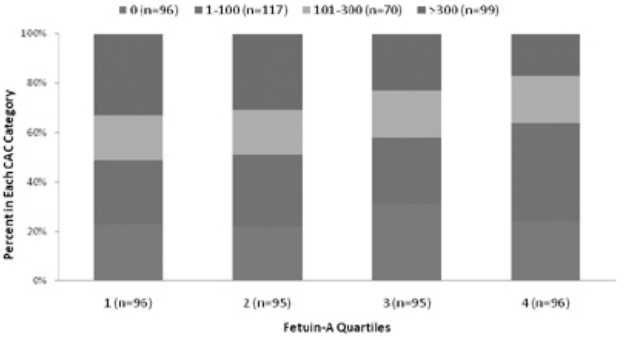
The Associations of Fetuin-A with Subclinical Cardiovascular Disease in Community-Dwelling Persons: The Rancho Bernardo Study Joachim H. Ix,[1] Elizabeth Barrett-Connor,[2] Christina Wassel,[2] Kevin M. Cummins,[2] Jaclyn Bergstrom,[2] Lori B. Daniels,[2] Gail A. Laughlin.[2] *[1]Medicine, UCSD, San Diego, CA; [2]Family and Preventive Medicine, UCSD, San Diego, CA.*

Background: Fetuin-A is a hepatic secretory protein that inhibits arterial calcium deposition in vitro. Lower fetuin-A levels are associated with arterial calcification and death in ESRD populations. The association of fetuin-A with subclinical cardiovascular disease (CVD) in other settings is unknown. In 1,375 community-living individuals without prevalent clinical CVD, we sought to determine the association of fetuin-A with subclinical CVD.

Methods: Plasma fetuin-A concentrations measured by ELISA. Peripheral arterial disease (PAD) was defined by ankle brachial index (ABI) < 0.90, coronary artery calcification (CAC) was defined by CT, and cIMT > 75th% by ultrasound. Logistic regression, ordinal regression, and linear regression evaluated adjusted associations of fetuin-A with each subclinical measure, respectively.

Results: Mean age was 70 ± 11 years, 64% were female, and mean eGFR was 68±16 ml/min/1.73m2. Fetuin-A levels were inversely associated with CAC severity.

Distribution of coronary artery calcification categories by fetuin-A quartiles among 382 community-living individuals without clinically apparent cardiovascular disease: The Rancho Bernardo Study



In ordinal logistic regression using CAC categories (0, 1-100, 101-300, >; 300), each SD higher fetuin-A was associated with a 29% lower odds of CAC severity (proportional odds ratio 0.71; 95% CI 0.58, 0.88; p=0.001) in models adjusted for demographics, lifestyle factors, traditional CVD risk factors and kidney function. In contrast, no association of fetuin-A was observed with PAD or high common or internal cIMT in adjusted or unadjusted models.

Conclusions: Lower fetuin-A levels are associated with greater CAC severity independent of CKD and other covariates, but not PAD or cIMT. If confirmed, fetuin-A may mark calcium deposition within the vasculature, but not atherosclerosis per se.

FR-PO1202

Vitamin E Reduces Calcification in Vascular Smooth Muscle Cells Exposed to High Phosphate Addy Rosa Montes de Oca Gonzalez,[1] Juan Antonio Madueño Domenech,[2] Fatima Guerrero,[1] Juan R. Muñoz-Castañeda,[2] Yolanda Almaden Peña,[2] Ignacio Lopez,[1] Mariano Rodriguez,[2] Escolastico Aguilera-Tejero.[1] *[1]Medicina y Cirugia Animal, Universidad de Cordoba, Spain; [2]Instituto Maimonides de Investigacion Biomedica de Cordoba (IMIBIC), Spain.*

Background: Hyperphosphatemia and oxidative stress are consistent findings in patients with chronic kidney disease. Vascular smooth muscle cells (VSMC) exposed to high phosphate (P) undergo phenotypic transition to osteogenic cells. Recent evidence suggests that reactive oxygen species can also induce calcification in VSMC. In addition, high P levels may result in oxidative stress. The present study investigates whether high P induces oxidative stress in VSMC and the effect of a natural antioxidant (vitamin E) in preventing phosphate-induced calcification.

Methods: Human VSMC were cultured for 9 days in normal P (Control) or high P (3.3mM) with or without vitamin E (10 µM). Lipid Peroxidation –LPO- (spectrophotometry), Advanced Glycation End Products –AGEs- (ELISA), Alkaline Phosphatase –ALP- activity (p-nytrophenyl phosphate method), Cbfa1 mRNA (RT-PCR), and Calcium deposition (spectrophotometry of acid extract) were measured.

Results: High P increased LPO and AGEs, enhanced ALP activity and gain of expression of Cbfa1, and induced calcification of VSMC. The addition of vitamin E to the high P media reduced LPO and AGEs. Furthermore, vitamin E prevented the increase in ALP activity and Cbfa1 expression and attenuated calcification of VSMC.

Treatment	LPO ([MDA] uM/ mg protein)	AGEs (µg/mg protein)	ALP activity/mg protein	mRNA Cbfa1/β-actin	Ca (µg/mg prot)
Control	0.94±0.10	18.64±1.07	57.74±4.89	1.00±0.01	0.42±0.08
P 3.3mM	1.81±0.26 (a)	28.48±3.87(a)	89.12±5.57 (a)	2.87±0.37 (a)	2.72±0.32 (a)
P 3.3mM + Vit.E 10 µM	0.83±0.36 (b)	12.36±1.92 (b)	48.39±3.36 (b)	0.70±0.08 (b)	1.18±0.31(a,b)

Mean±SE; a: P<0.05 vs Control; b: P<0.05 vs P 3.3 mM

Conclusions: In conclusion, oxidative stress seems to play an important role in phosphate-induced VSMC calcification and antioxidants may have a role in preventing vascular calcification.

Vascular Calcification in Kidney Transplantation – A Comparison to Predialysis Chronic Kidney Disease Sinee Disthabanchong, Kotcharat Vipattawat. *Division of Nephrology, Department of Medicine, Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Phayathai, Bangkok, Thailand.*

Background: Vascular calcification (VC) is prevalent in patients with reduced kidney function as a result of mineral metabolism derangement and uremic environment. The increased VC burden has been shown to predict cardiovascular events and mortality. Evidence suggested VC decreased after kidney transplantation (KT) compared to patients who remained on dialysis. The magnitude of VC in KT recipients compared to predialysis CKD patients whose kidney function are equivalent has never been established.

Methods: 91 chronic stable KT recipients who were at least 1 year post surgery and 102 predialysis CKD patients were included in the study. VC was analyzed by plain radiographs, lateral lumbar spine x-ray for abdominal aorta and pelvic x-ray was iliac and femoral arteries, and scored according to the methods described previously. Important factors associated with VC were also determined.

Results: Higher percentages of CKD patients were diabetic. The median KT duration was 7.5 years (range 1-17 yrs). The average GFR of KT and CKD patients were 45.4 and 41.4 mL/min/1.73 m2 respectively. Over 50% of CKD and KT patients had VC, mostly in the abdominal aorta. Substantial increase in pelvic arterial calcification was observed in KT compared to CKD. Total VC score was also significantly higher in KT. In patients without DM, heightened VC scores in abdominal aorta, pelvic arteries and combined sites were observed in KT. Increased pelvic arterial calcification was demonstrated especially in a subgroup with GFR < 45 mL/min/1.73 m2. Age and DM were associated with VC in both groups, whereas dialysis vintage emerged as an independent factor associated with VC in KT. Multivariate analysis of the entire population demonstrated being a KT recipient was the strongest factor associated with VC.

Conclusions: In conclusion, increased VC in chronic stable KT recipients compared to predialysis CKD patients was observed that was likely the result of past dialysis experience. While KT was able to restore renal function, it could not fully reverse VC.

Serum Phosphorus Is Associated with Coronary Artery Calcification and Obstruction in Patients with Preserved Renal Function Ana L.E. Cancela,[1] Raul D. Santos Filho,[2] Silvia M. Titan,[1] Luiz Antonio Machado Cesar,[2] Carlos Eduardo Rochitte,[2] Eulogio Martinez,[2] Luciene M. dos Reis,[1] Fabiana G. Graciolli,[1] Vanda Jorgetti,[1] Rosa M. Moyses.[1] *[1]Nephrology, Universidade de São Paulo, São Paulo, Brazil; [2]Heart Institute (InCor) Universidade de São Paulo, São Paulo, Brazil.*

Background: Serum phosphorus has been associated with mortality and cardiovascular events in the CKD and general populations. In vitro studies suggest that excessive phosphorus induces vascular calcification and endothelial dysfunction. Fibroblast growth factor 23 (FGF23) is a phosphaturic hormone and has been correlated to atherosclerosis in the community.

Methods: This cross-sectional study included 290 patients (167 males) with suspected coronary artery disease (CAD) and a MDRD creatinine clearance > 60ml/min/1,73m^2 undergoing elective coronary angiography. Coronary obstruction was quantified using the Friesinger score (FS). Coronary artery calcification was assessed by MSCT.

Results: Serum phosphorus was higher in patients with an Agatston score (AS) > 10HU when compared to the group with a AS ≤ 10 HU (3.63±0.55 vs 3.49±0.52mg/dL, p=0.019). In the univariate and multivariate analysis, each mg/dL of elevation in the serum phosphorus implied a higher risk of presenting an AS > 10 HU [Odds Ratio (OR) =1.92, CI 1.56-3.19; p=0.01]. Patients were divided using the median Friesinger score (4 points) as the cutoff value. Serum phosphorus was higher (3.6±0.5 vs. 3.5±0.6 mg/dl, p=0.04) and intact FGF23 was lower (median 40.3 IQR 24.1-62.2 pg/mL vs. 45.7 IQR 31.7-76.1 pg/mL, p=0.01) in the FS > 4 group. In the multivariate logistic regression analysis, a rise of 1 mg/dL of serum phosphorus carried a 74% increase in the risk of having a FS higher than 4 (OR 1.74, CI 1.06-2.88; p=0.03) and FGF23 was a negative predictor of FS both in the univariate (OR 0.32, CI 0.14-0.71; p=0.005) and multivariate analyses (OR 0.26, CI 0.11-0.63; p=0.002). Serum calcium and parathormone were not associated with CAD..

Conclusions: In patients with suspected coronary artery disease and preserved renal function, phosphorus was predictive of both coronary artery calcification and obstruction. There was a negative association between FGF23 and coronary obstruction.

Phosphorus (P) Management Trends of Hemodialysis Patients in a Large Dialysis Organization Jamie Heise,[1] Kamyar Kalantar-Zadeh,[2] John Brian Copley,[1] Moshe Fridman,[3] Rajnish Mehrotra.[2] *[1]Medical Affairs, Shire Pharmaceuticals, Chesterbrook, PA; [2]Nephrology, Harbor- UCLA Medical Center, Torrance, CA; [3]Statistics, AMF Consulting, Los Angeles, CA.*

Background: Increased serum P is a robust predictor of all-cause and cardiovascular mortality in dialysis patients. Though P control in the last decade has improved overall, performance varies widely among facilities.

Methods: 104,471 patients treated at a large dialysis provider were selected for analysis. Facilities with at least 50 patients (N=940) were aggregated and ranked by the proportion of patients with serum P < 5.5 mg/dl for the calendar month. The top and bottom 5% of facilities were compared for the achievement of targets for other laboratory measures (calcium, Ca; parathyroid hormone, PTH, and albumin), P-binder and vitamin D use, geographic region, and use of a central pharmacy.

Results: 76% of hemodialysis patients achieved serum P < 5.5 mg/dl. The top 5% of facilities (n=47) treated 4011 patients and the bottom 5% of facilities (n=56) treated 4081 patients. P control was achieved in 91% of patients of top-performing facilities compared to 60% of the bottom-ranked facilities. While there was no difference in the proportion of patients achieving serum albumin target (87% vs. 88%; p=0.40), top-performing facilities were more likely to achieve targets for serum Ca (< 9.5 mg/dl; 99% vs., 97%, p < 0.0001) and PTH (150-600 pg/ml; 74% vs. 70%, p=0.007). Furthermore, top-performing facilities were more likely to use non-calcium P-binders (sevelamer, 69% vs. 61%, p=0.02; lanthanum, 15% vs. 12%, p=0.04). There was no significant difference in the use of either vitamin D (84% vs. 81%; p=0.09) or cinacalcet (29% vs. 28%; p=0.58), or use of a central pharmacy between the top and bottom 5% of facilities.

Conclusions: Despite a high overall rate of P control, differences exist at the unit level in proportion of patients with serum P < 5.5 mg/dl across dialysis facilities. Use of non calcium binders may provide better P, Ca, and PTH control. Identifying practice patterns that allow a larger proportion of patients to achieve P control have the potential of further improving outcomes.

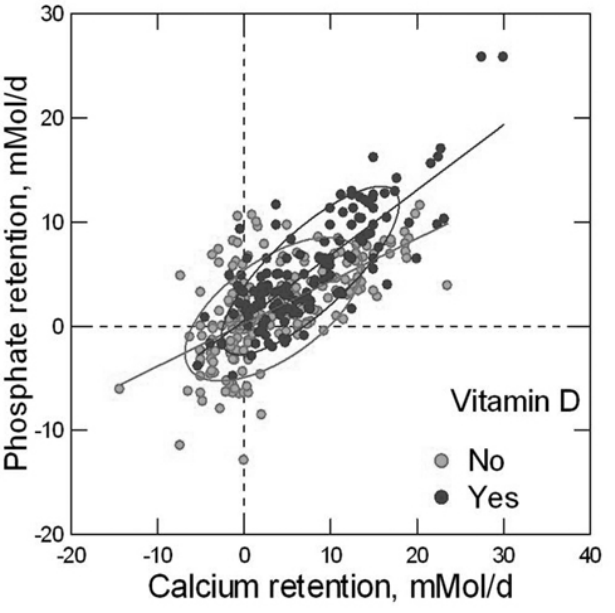
Calcium Retention and Vitamin D Drive Phosphate Retention in Chronic Kidney Disease Anna L. Zisman, Elaine M. Worcester. *Department of Medicine, University of Chicago Pritzker School of Medicine, Chicago, IL.*

Background: Phosphate retention is thought to entrain a sequence of abnormalities that stimulate PTH and FGF23 secretions and suppress activated vitamin D production and secretion. Calcium based phosphate binders are used to offset this, though recently concerns have arisen that this may promote cardiovascular disease in CKD patients.

Methods: We have gathered 233 formal calcium and phosphate balance periods in 30 adult patients with CKD from the literature to test whether intake of calcium or vitamin D promotes phosphate retention.

Results: Patients ranged in age from 19 to 72 (43.1 ± 13.4 yrs) and suffered from either CKD Stage 3 (n=2), 4 (n=5), or 5 (predialysis, n=23). Dietary calcium intake ranged from 96 mg to 9278 mg (1309 ± 1295 mg), and phosphate intake ranged from 191 mg to 1800 mg (786 ± 279 mg) per day. Calcium retention was directly proportional to calcium intake, and increased with vitamin D intake. Phosphate retention was associated with phosphate intake only in the setting of vitamin D supplementation (p<0.001). Vitamin D supplementation was tested in 88 balance periods (32 activated vitamin D, 56 nutritional vitamin D). When calcium retention is not positive, phosphate retention centers around a median and mean of 0 (figure). When calcium retention is >0, virtually all phosphate retention points are >0, and retention varies with that of calcium (p<0.0001). When vitamin D is added, phosphate retention is increased for any degree of calcium retention (1.29 ± 0.29 vs. 6.53 ± 1.11, p<0.0001).



Conclusions: In CKD, phosphate retention varies directly with calcium retention, more so with vitamin D supplementation. As calcium retention is a key driver of phosphate retention in CKD, and is dependent on calcium intake, caution should be exercised in calcium loading in patients with CKD.

Cinacalcet May Prevent Serum Fetuin A Reduction in Dialysis Patients Monika Staszkow,[1] Ewa Wojtaszek,[1] Zbigniew Bartoszewicz,[2] Stanislaw Niemczyk,[1] Jerzy Przedlacki,[1] Joanna Matuszkiewicz-Rowinska.[1] *[1]Nephrology, Dialysis & Internal Diseases, Medical University of Warsaw, Warsaw, Poland; [2]Department of Internal Diseases and Endocrinology, Medical University of Warsaw, Warsaw, Poland.*

Background: Cinacalcet, a novel calcimimetic, targeting the calcium-sensing receptor (CaSR) markedly reduces parathyroids activity. The CaSR has also been found in the arterial wall, and may play a role in the prevention of vascular calcification.

The aim of the study was to examine the impact of cinacalcet on serum fetuin A (sFA), osteoprotegerin (sOPG), and vascular calcification measured by coronary artery calcification score (CAC) in dialysis pts.

Methods: We enrolled 35 pts, aged 53±10years, on dialysis for 55±63 months) with serum iPTH ≥300 pg/ml; 19 of them received cinacalcet (58±32 mg/d) for 52 weeks, 16 pts remained on standard therapy. CAC scores were obtained by multi-detector computed tomography before and after the study.

Results: There was a significant reduction in sFA in the control group (from 31.7 ± 10.6 to 24.8 ± 7.3 ng/ml, p = 0.013), while in cinacalcet group sFA gradually although insignificantly increased (from 31.9±18.4 to 36.4 ± 14.5 ng/ml). This has resulted in a significant difference between the groups at the end of the study (p = 0.034). In both groups a significant increase in sOPG was seen (from 8.3±4.4 to 14.4±4.3 pmol/l, p<0.0001 and from 11.9±10.7 to 20±9.3 pmol/l, p<0.0001, respectively). The mean CAC score increased slightly (18%) in the control group (from 1081±2076 to 1272±1887 jA; NS) and remained unchanged in cinacalcet group. Both proteins correlated strongly with CAC: sFA negatively (r= -0.41, p=0.01) and sOPG positively (r=0.52, p=0.026) indicating an important and opposite their role in vascular calcification. There was also a positive correlation between time on dialysis and sOPG (r=0.47, p=0.006), as well as CAC (r=0.56, p=0.0009).

Conclusions: These data demonstrate that FA and OPG play an important role in vascular calcification in dialysis pts, the first as an inhibitor and the second as a risk factor. Calcimimetic may prevent sFA reduction in this population. Prevention of vascular calcification is probable however the larger randomized studies are needed.

Predominant Osteogenic Characteristics in FGF-23 Secreting Oncogenic Osteomalacic Tumors Yuki Nagata,[1] Yasuo Imanishi,[1] Jun Hashimoto,[2] Keisuke Kobayashi,[1] Akimitsu Miyauchi,[3] Hiroshi Kaji,[4] Koka Motoyama,[1] Katsuhito Mori,[1] Masaaki Inaba.[1] *[1]Department of Metabolism, Endocrinology & Molecular Medicine, Osaka City University Graduate School of Medicine; [2]Osaka Minami Medical Center; [3]Miyauchi Medical Center; [4]Kinki University Faculty of Medicine, Japan.*

Background: Oncogenic osteomalacia (OOM), or tumor induced osteomalacia (TIO), is a rare disease characterized by renal phosphate wasting and hypophosphatemic osteomalacia due to the secretion of fibroblast growth factor 23 (FGF-23) from causative mesenchymal tumors. OOM tumors express phosphate-metabolism related factors such as FGF23, DMP1, MEPE and FRP-4, which are reported to be physiologically expressed in osteogenic lineages. To determine whether OOM tumors have osteogenic characteristics, the expressions of osteoblast/osteocyte specific genes in OOM tumors were investigated at the transcriptional and translational levels.

Methods: Seventeen causative OOM tumors and 6 histopathologic classification-matched non-OOM tumors were analyzed by quantitative real-time RT-PCR and immunohistochemistry. Fluorescent immunohistochemistry was also applied to investigate co-localization of the gene expressions in OOM tumors.

Results: Sixteen genes were significantly elevated in OOM tumors compared to non-OOM tumors in 30 genes for osteoblast/osteocyte or mesenchyme specific genes. In these 16 genes, OOM tumors exhibited positive staining in both phosphate-metabolism related factors (FGF23, DMP1, MEPE) and other osteoblast/osteocyte specific genes (Runx2, osterix, osteocalcin, sclerostin). Fluorescent immunohistochemistry revealed that localizations of FGF23, DMP1 and osterix expressions were well merged in some OOM tumors, however, the predominant localizations of FGF23 was different from those of DMP1 in other OOM tumors. These tumors exhibited co-localizations of FGF23 and osterix, and those of DMP1 and osteocalcin.

Conclusions: OOM tumors have osteogenic characteristics and express phosphate-metabolism related factors. Co-localization of some phosphate-metabolism related factors and osteoblast/osteocyte specific genes suggests osteogenic characteristics contribute to express phosphate-metabolism related factors.

Plasma Concentrations of Klotho Protein in Patients with Chronic Renal Failure Toshiyuki Nakao, Hideaki Iwasawa, Ami Hayashi, Yoshitaka Miyaoka, Yoshie Kanazawa. *Department of Nephrology, Tokyo Medical University, Tokyo, Japan.*

Background: Klotho (Kl) is known as an anti-aging protein predominantly expressed in the kidney, parathyroid gland and choroid plexus of the brain. It is a co-receptor specific to fibroblast growth factor 23 (FGF-23) and regulates metabolism of minerals such as calcium and phosphate. The extracellular domain of Kl is secreted into extracellular fluid, but little is known about the plasma levels of Kl and their contributing factors in patients with chronic renal failure (CRF).

Methods: We measured plasma Kl by sandwich ELISA. The studied subjects were 110 CRF patients, which included 69 non-dialyzed (ND), 25 hemodialyzed (HD) and 16 peritoneal dialyzed (PD) patients. We simultaneously measured the serum levels of FGF-23, intact PTH, creatinine (Cr), calcium (Ca), phosphate (P) and albumin (Alb).
