JASN Abstract Supplement
ASN Kidney Week 2011
November 8 – 13, 2011

Abstract Publication
More than 4,000 abstracts are published in this supplement. Abstracts are arranged by the abstract type**, then by presentation date*, and then by chronological publication number. Abstracts with a "PUB" number will not be presented at the ASN Annual Meeting.

* TH = Thursday, FR = Friday, SA = Saturday
** OR = Oral, PO = Poster, PUB = Publication Only

The presenting author's name is underlined. For the poster sessions, the publication numbers and poster board numbers are the same.

Abstract Author Index
The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Subject Index
The Subject Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Reference Format
To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 22, 2011: Page(s).

For example: Parapas NA, Qui A, Barasch JM: The Kidney Defends the Urinary System from Infection by Secreting NGAL [Abstract]. J Am Soc Nephrol 22, 2011: 1A.

Abstract Experts
Abstract submissions were rigorously reviewed and graded by multiple experts. ASN thanks the abstract category chairs and reviewers for assistance with the abstract process. The *Onsite Program* lists all abstract experts.

Abstract Disclaimer and Copyright
The Abstract Issue of JASN® contains proprietary information belonging to the American Society of Nephrology (ASN). ASN accepts no responsibility for any products, presentations, opinions, statements, or positions expressed, and inclusion of such material within Kidney Week and other ASN publications, or online postings does not constitute an endorsement by ASN.

ASN General Information

Kidney Week Program and Presentations
The Kidney Week 2011 program, which can be found in the *Onsite Program*, includes:
- Early Programs' content
- Plenary Sessions
- Basic and Clinical Science Symposia
- Clinical Nephrology Conferences
- Special Sessions
- Educational Symposia
- Late-Breaking Clinical Trials Session
- Oral Abstract Sessions
- Poster Sessions

Disclosure Statement
ASN requires all individuals in a position to control content for Kidney Week 2011 to complete a disclosure form. Responses are listed in the Kidney Week 2011 *Disclosure Digest*, which is available to each meeting participant.

Program Builder
All abstracts and the complete Kidney Week 2011 program are viewable online through the Program Builder at www.asn-online.org/KidneyWeek with features including keyword search and PDA download.
Support is provided by Mitsubishi Tanabe Pharma.

Top Abstracts — New for 2011
ASN is pleased to award Top Abstracts for young investigators and physicians-in-training as lead authors. The *Onsite Program* lists all top oral and poster presentations by young investigators and physicians-in-training as lead authors.

Posters On-Demand™ — New for 2011
Fully paid participants can access electronic versions of the Kidney Week 2011 posters at no additional cost. Search and locate posters easily by authors, categories, or keywords during and after the meeting. Posters can be accessed online at www.asn-online.org/KidneyWeek/PostersOnDemand.
Support is provided by Amgen, Genentech, a Member of the Roche Group, and Mitsubishi Tanabe Pharma.

The Kidney Defends the Urinary System from Infection by Secreting NGAL

Neal A. Paragas, Andong Qiu, Jonathan M. Barasch. *Medicine, Columbia University, NY, NY.*

Background: NGAL is a critical component of innate immunity because it binds catecholate-siderophores which microorganisms require to capture iron. Urinary(u) NGAL is expressed at mg/L levels after either septic or aseptic diseases of the kidney and it has two potential functions, epithelial growth and/or bacteriostasis. Here we examined the activity of uNGAL in the growth of CFT073, a uropathogenic E. coli (UPEC).

Methods: To examine the role of uNGAL in bacteriostasis. (1) We designed a conditional allele of NGAL. (2) We created a bioluminescent mouse that releases Luciferase and mCherry when the NGAL locus is activated.

Results: We found NGAL significantly inhibited UPEC growth in vitro, which could be rescued by the addition of iron. In a mouse pyelonephritic model, the intensity and timing of urinary CFUs was mirrored by uNGAL, including a decrease in uNGAL coincident with the resolution of infection. To determine the source of uNGAL, we made a NGAL reporter mouse NGAL-Luc2/mC to visualize kidney expression in vivo and we found that UPEC detritus introduced into the bladder induced NGAL-Luc2/mC expression distantly in the kidneys. Reporter expression was consistent with the bladder and kidney Ngal expression according to QPCR. By high power in situ hybridization we located Ngal to alpha intercalated cells. To determine the physiological role of uNGAL, we made a global NGAL KO and found that UPEC infections had delayed resolution. We verified by knocking out Ngal in the intercalated cells by HoxB7-cre of the CD. To determine whether UPEC signaling directly activates kidney epithelia, we developed an in vitro assay using the CDs of Ngal-Luc2/mC kidneys. These cells express Ngal-Luc2/mC in response to co-culture with UPECs and expression was reversed by antibiotics. Additional studies suggest that TLRs are the critical local sensors of infection.

Conclusions: uNGAL is essential for clearance of a UPEC in a model of acute UTI. The kidney responds to infections localized to the bladder by secreting NGAL. These findings provide an explanation for the massive secretion of NGAL from the kidney in both septic and aseptic diseases, demonstrating that the kidney defends the urinary system via exocrine delivery of NGAL.

Proximal Tubule Specific Expression of Heme Oxygenase-1 Is Protective in Acute Kidney Injury

Subhashini Bolisetty,[1,2] Abolfazl Zarjou,[1,2] Amie Traylor,[1,2] Anupam Agarwal.[1,2] *[1]Medicine, University of Alabama at Birmingham, AL; [2]Division of Nephrology, Nephrology Research and Training Center, University of Alabama at Birmingham, AL.*

Background: Heme Oxygenase-1 (HO-1), an anti-oxidant enzyme is induced during oxidative stress and has cytoprotective properties. HO-1 deficient mice are highly sensitive to acute kidney injury (AKI) secondary to ischemia, rhabdomyolysis and nephrotoxins. Although HO-1 is cytoprotective, it has been suggested that generalized HO-1 overexpression might lead to harmful effects due to excessive amounts of its reaction-products: iron, carbon monoxide, biliverdin and bilirubin.

Methods: Proximal tubules are the target of maximal injury in models of AKI and are also the site where HO-1 induction is most abundant. Hence, we hypothesized that targeted overexpression of HO-1 in the proximal tubule segment of the kidney will confer cytoprotection against AKI. Therefore, we generated proximal tubule specific HO-1 overexpressing (PEPCK-HO-1) mice using the cre-lox system and tested them in models of AKI.

Results: Compared to age and sex matched HO-1wildtype littermates, PEPCK-HO-1 mice demonstrated significant renal protection (structural and functional) in two different intrinsic models of AKI: cisplatin nephrotoxicity and glycerol-induced rhabdomyolysis. Following rhabdomyolysis, HO-1 wildtype mice demonstrated significantly higher mortality compared to PEPCK-HO-1 mice, along decreased tubular casts and necrosis and better preserved kidney function (BUN-control: 145 ± 17; PEPCK-HO-1: 42.8 ± 6; $P < 0.001$, creatinine-control: 1.55 ± 0.25; PEPCK-HO-1: 0.3 ± 0.14; $P < 0.001$). In the cisplatin model of AKI, PEPCK-HO-1 mice had significantly fewer casts, necrotic tubules and better-preserved kidney architecture along with preserved renal function (BUN-control: 106.67 ± 13.5; PEPCK-HO-1: 32.5 ± 3.8; $P < 0.001$, creatinine-control: 0.63 ± 0.1; PEPCK-HO-1: 0.28 ± 0.04; $P < 0.05$).

Conclusions: These studies demonstrate for the first time that proximal-tubule specific HO-1 overexpression alone is sufficient to protect against AKI and targeting the HO-1 system may serve as a novel therapeutic strategy.

TH-OR003

Endothelial HIF2, but Not HIF1 Modulates Inflammation and Protects from Renal Ischemia-Reperfusion Injury

Hideto Sano, Hanako Kobayashi, Volker H. Haase. *Nephrology and Hypertension, Vanderbilt University Medical Center, Nashville, TN.*

Background: Hypoxia inducible factors (HIF)-1 and -2 are basic helix-loop-helix transcription factors that regulate cellular responses to hypoxia. Pharmacological activation of HIF signaling prior to injury protects kidneys from ischemia-reperfusion injury (IRI). However, it is unclear which HIF homolog, cell type, and which HIF target genes confer cytoprotection.

Methods: To address this question, we inactivated HIF-1 (HIF-1eKO), HIF-2 (HIF-2eKO) or both (HIF-1/HIF-2eKO) in endothelial cells using VEcadherin-driven Cre recombinase. KO mice and Cre-negative littermates were subjected to unilateral or bilateral IRI. Renal injury was assessed by histologically, mRNA and protein analysis, and by analysis of inflammatory cell infiltration at 2 hours, day 1 and 3 days after reperfusion.

Results: At day 3 following IRI renal injury was exacerbated in HIF-1/HIF-2eKO mice compared to control as determined by BUN levels (1.4-fold increase), histological injury score (1.5-fold increase), Kim-1 expression (1.6-fold increase) and inflammatory cell infiltration (8.5-fold increase). To determine which HIF homolog was cytoprotective, we subjected HIF-1eKO and HIF-2eKO mice to unilateral IRI. Injury in HIF-2eKO IRI kidneys was increased, whereas renal injury between HIF-1eKO and littermate controls was not different. Increased presence of CD45-positive cells in IRI kidneys from HIF-1/HIF-2eKO and HIF-2eKO correlated with enhanced VCAM-1 expression, whereas E-selectin and ICAM-1 did not change significantly. To examine whether endothelial HIF modulated HIF-mediated ischemic preconditioning, we activated HIF prior to injury with a prolyl-hydroxylase inhibitor (PHI). Although PHI treatment was cytoprotective in wild type mice, cytoprotection was not found in HIF-1/HIF-2eKO mice compared to vehicle-treated KO mice.

Conclusions: Our data suggest that a) endothelial HIF-2 but not HIF-1 is cytoprotective in renal IRI and that b) endothelial HIF-2 exerts its cytoprotective effect partly by suppressing IRI-associated inflammation. Furthermore, we provide evidence that endothelial HIF is required for HIF-mediated ischemic preconditioning.

Critical Role of Sphingosine Kinase-1 Signaling in A_1 Adenosine Receptor-Mediated Renal Protection

Sang Won Park,[1] Mihwa Kim,[1] Kevin M. Brown,[1] Volker H. Haase,[2] H. Thomas Lee.[1] *[1]Anesthesiology, Columbia University, New York, NY; [2]Medicine, Vanderbilt University, Nashville, TN.*

Background: Acute kidney injury (AKI) is a devastating clinical problem without effective therapy and renal ischemia reperfusion (IR) injury is a major cause of AKI. We previously demonstrated that activation of renal A_1 adenosine receptors (ARs) attenuated multiple pathways of cell death including necrosis, apoptosis and inflammation after renal IR.

Methods: Here, we tested the hypothesis that renal A_1AR activation protects against IR injury by induction of sphingosine kinase-1 (SK1) and sphingosine-1 phosphate (S1P) synthesis.

Results: In cultured human proximal tubule epithelial (HK-2) cells, a selective A_1AR agonist 2-chlorocyclopentyladenosine (CCPA) significantly induced SK1 (without changing SK2) mRNA and protein expression and increased the synthesis of S1P. CCPA also induced SK1 and S1P in mouse kidney cortex. Further supporting a critical role of SK1 in A_1AR-mediated renal protection, A_1AR agonist failed to protect $SK1^{-/-}$ mice (Cr=2.7±0.1mg/dL, N=6) but protected $SK2^{-/-}$ mice (Cr=1.2±0.2mg/dL, N=6, $P<0.01$) subjected to 30 min of renal ischemia and 24 h of reperfusion. In addition, *in vivo* gene knockdown of $S1P_1$ receptors with small interfering RNA (Cr=2.2±0.2mg/dL, N=6, $P<0.01$) or a selective $S1P_1$ receptor antagonist W146 (Cr=2.4±0.2mg/dL, N=6, $P<0.01$) completely abolished the renal protection provided by CCPA (Cr=1.2±0.2mg/dL, N=5). Finally, mice specifically deficient in proximal tubule $S1P_1$ receptors ($S1P_1R^{flox/flox}PEPCK^{Cre/-}$, Cr=2.3±0.2mg/dL, N=6) were not protected against renal IR with CCPA. Mechanistically, A_1AR activation increased HIF-1a nuclear translocation in HK-2 cells and in mouse kidney cortex. Furthermore, 2-methoxyestradiol (a selective HIF-1a inhibitor) blocked A_1AR-mediated induction of SK1 in HK-2 cells and in mouse kidney cortex.

Conclusions: Taken together, our data show that induction of proximal tubule SK1 and subsequent $S1P_1$R activation is critical for A_1AR-mediated renal protection. Selective renal proximal tubular induction of SK1 and $S1P_1$ receptor signaling after IR may provide a novel therapeutic approach for the prevention and treatment of AKI.

Activation of Proximal Tubule Sphingosine 1 Phosphate Receptor-1 (S1P1) Ameliorates Cisplatin Induced Nephrotoxicity in Mice

Amandeep Bajwa,[1,3] Sang Ju Lee,[1] Krishna Dondeti,[1] Hong Ye,[1,3] Diane L. Rosin,[2,3] Kevin Lynch,[2] Mark D. Okusa.[1,3] *[1]Departments of Medicine, University of Virginia, Charlottesville, VA; [2]Departments of Pharmacology, University of Virginia, Charlottesville, VA; [3]Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia, Charlottesville, VA.*

Background: Sphingosine 1-phosphate (S1P), a sphingolipid that is the natural ligand for a family of five G-protein coupled receptors (S1P1-5Rs), regulates cell survival and lymphocyte circulation. The pan S1PR agonist, FTY720 (fingolimod) attenuates ischemia-reperfusion injury (IRI) by activating S1P1 on proximal tubule-PT cells directly, an effect previously thought to be due predominantly to their canonical effects of S1P1 activation on B and T cells leading to lymphopenia.

Methods: FTY720 reduced cisplatin-induced AKI, therefore in the current study we sought to determine whether the protective effect was mediated by proximal tubule (PT) S1P1. We used conditional renal PT S1P1 null (*PEPCK-CreS1pr1$^{fl/fl}$*) and control mice (*PEPCK-Cre)* to assess renal injury by monitoring plasma creatinine (mg/dl), flow cytometry to analyze inflammatory cell infiltration and Real Time RT-PCR for changes pro-inflammatory cytokines.

Results: Compared to control mice (0.79±0.02) cisplatin induced more injury in PT S1P1 null mice (1.22±0.13, $p<0.05$) and FTY720 reduced injury in control mice (0.47±0.06, $p<0.01$) but not in PT S1P1 null mice (1.32 ±0.22, p=n.s.). There were no differences in

circulating lymphocytes counts in FTY720 treated control and S1P1 null mice. Control or PT S1P1 null mice treated with cisplatin have significantly higher levels of pro-inflammatory cytokines (CXCL1, MCP-1, TNF-α and IL-6) compared to vehicle-treated mice. Treatment of control mice with FTY720 significantly attenuates the mRNA levels of afore mentioned cytokines. Decrease in cytokine production with FTY720 results in less neutrophils and macrophages infiltration at day 3 in kidneys.

Conclusions: In summary, S1P1 expressed in PT attenuates cisplatin-induced AKI. We conclude that FTY720 administration might represent a novel strategy in the prevention of cisplatin-induced AKI.

IL-2/anti-IL-2 Antibody Complexes Attenuate Renal Ischemia-Reperfusion Injury through Expansion of Regulatory T Cells Myung-Gyu Kim,[1] Han Ro,[1] Curie Ahn,[2] Jaeseok Yang.[1] *[1]Transplantation Center, Seoul National University Hospital, Seoul, Republic of Korea; [2]Division of Nephrology, Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Regulatory T cells (Tregs) can contribute to suppression of immunologic damage or facilitation of the recovery process following renal ischemia-reperfusion injury (IRI). However, isolation and expansion of rare Tregs are practically hard for clinical application. Recently, complexes (IL-2C) of interleukin-2 (IL-2) and anti-IL-2 antibodies have been shown to control various inflammatory diseases by inducing expansion of Tregs. Therefore, we investigated whether IL-2C can control renal IRI.

Methods: C57BL6/J mice underwent bilateral renal ischemia. IL-2C or vehicles were administered for 3 consecutive days from 5 days before or 1 day after renal IRI. Renal function was assessed with infiltration of inflammatory cells, tissue cytokines and tissue recovery. Anti-CD25 antibodies (PC61) were administered to assess the effect of DC depletion on impacts of IL-2C. We also performed IRI using IL-10 knockout mice to clarify the role of IL-10.

Results: IL-2C induced a 3-5 fold expansion of Tregs in both spleen and kidney. IL-2C treatment before renal IRI significantly improved renal function, attenuated histological renal injury and apoptosis. IL-2C significantly decreased expression of pro-inflammatory cytokines (MCP-1, IL-6) and also reduced infiltration of both neutrophils and macrophages. IL-2C treatment after IRI significantly increased tubular cell proliferation in recovery phase. Depletion of Tregs using PC61 abrogated the beneficial effects of IL-2C. When the IL-10 knockout mice were used, the beneficial effects of IL-2C were abrogated, and these results suggested that IL-10 might mediate the renoprotective effect of IL-2C.

Conclusions: IL-2C attenuated acute renal damage and also facilitated renal recovery in renal IRI, by inducing Tregs with an IL-10-dependent manner. Because IL-2C are easy to manipulate as well as effective for renal IRI, IL-2C is promising for clinical application to renal IRI.

TH-OR007

Pentraxin-3 Suppresses Postischemic Acute Kidney Injury by Inhibiting P Selectin-Mediated Renal Leukocyte Recruitment Maciej Lech,[1] Christoph Roemmele,[1] Regina Groebmayr,[1] Cecilia Garlanda,[2] Alberto Mantovani,[2] Bernd Uhl,[3] Christoph A. Reichel,[3] Fritz Krombach,[3] Hans J. Anders.[1] *[1]Klinische Biochemie, Medizinische Poliklinik der LMU, Munich, Germany; [2]Instituto Clinico Humanitas, Rozzano, Italy; [3]Walter Brendel Centre of Experimental Medicine, Munich, Germany.*

Background: Ischemia-reperfusion injury is a neutrophil-dependent sterile inflammation that is unable to control the causative trigger and therefore induces unnecessary tissue damage. Little is known about the factors that limit postischemic inflammation, e.g. in acute kidney injury, a common medical problem associated with poor survival. The long pentraxin PTX3 regulates multiple aspects of host defense and tissue inflammation therefore we hypothesized that PTX3 would be involved in ischemia-reperfusion injury.

Results: PTX3 induction in postischemic kidneys was largely limited to CD11c+ renal dendritic cells. Lack of PTX3 aggravated postischemic acute renal failure and kidney injury as evidenced by massive tubular necrosis and TNF or IL-6 release. Remarkably, neutrophil and macrophage infiltrates were also massively increased in Ptx3-deficient mice although intrarenal chemokine CXCL2 and CCL2 expression were independent of the PTX3 genotype. PTX3 rather modulated leukocyte recruitment via interacting with P-selectin as P-selectin inhibition completely abrogated the enhanced leukocyte recruitment and tissue injury in postischemic kidneys of Ptx3-deficient mice. In-vivo microscopy revealed increased leukocyte adhesion and transmigration in postischemic microvessels of Ptx3-deficient mice. Finally, intravenous injection of recombinant PTX3 shortly after surgery suppressed renal leukocyte recruitment and prevented postischemic kidney injury.

Conclusions: Together, PTX3 is an endogenous suppressor of ischemia reperfusion injury by blocking P-selectin-mediated adhesion of leukocytes to activated endothelia of postischemic tissues, a mechanism that can be mimicked with recombinant PTX3 for therapeutic purposes. Vice versa, Ptx3 loss-of-function mutations may predispose to ischemia-reperfusion injuries such as postischemic acute renal failure.

TH-OR008

TRPM2 Channels Mediate Hypoxic Cell Death and Contribute to Ischemic AKI William Brian Reeves, Weiwei Wang, Guofeng Gao, Wenyi Zhang, Barbara A. Miller. *Departments of Medicine and Pediatrics, Penn State College of Medicine, Hershey, PA.*

Background: TRPM2 channels belong to the TRP family of non-selective cation channels. TRPM2 channels are activated by TNFα and by oxidant stress, and TRPM2 expression enhances susceptibility to cell death in certain in vitro settings. However, the role of TRPM2 in cell injury or cell death in vivo is unknown. Since TNFα and oxidant stress have been implicated in the pathogenesis of AKI, we evaluated the role of TRPM2 channels in AKI.

Methods: We created mice with the TRPM2 gene flanked by loxP sites and then bred them with Ella-cre mice which express Cre recombinase ubiquitously to create a global TRPM2 knockout mouse. The resulting mice developed normally and had normal kidney function and histology. Ischemic AKI was induced in the TRPM2 KO mice and control littermates by clamping both renal arteries for 28 minutes. Renal function was assessed by measurements of BUN and creatinine. Histology and histochemistry of kidney sections were used to measure structural injury, apoptosis and neutrophil infiltration. Gene expression was determined using quantitative RT-PCR.

Results: Ischemia-reperfusion injury in TRPM2 KO mice

		BUN			Creatinine	
	0 hrs	6 hrs	24 hrs	0 hrs	6 hrs	24 hrs
WT	19±1	59±2	118±19	0.27±.03	0.64±.03	1.1±
TRPM2 KO	20±1	47±4	69±10	0.26±.03	0.47±.04	0.60±.05
P value	0.5	0.01	0.002	0.9	0.001	0.02

BUN and creatinine levels at 6, 24 and 48 hrs (not shown) after ischemia were significantly lower in the TRPM2 KO mice compared to littermates. Likewise, tissue injury scores, apoptosis and kidney neutrophil infiltration at both 24 and 72 hrs post ischemia were all significantly lower in TRPM2 KO vs WT mice. Analysis of gene expression showed >2-fold increases in certain pro-survival genes, e.g. akt, peroxiredoxin-2 and BCL2L10, in kidneys of KO vs WT mice. Primary cultures of proximal tubule cells prepared from WT and TRPM2 KO kidneys were subjected to hypoxia by incubation in a GasPak chamber for 24 and 48 hours. At both time points, cell survival in the TRPM2 KO cells exceeded that of the WT cells (<0.001).

Conclusions: These results point to an important role for TRPM2 channels, likely via direct effects in renal epithelial cells, in the pathogenesis of ischemic AKI.

TH-OR009

Mice with Absent Heat Shock Protein Induction Are Protected Against Ischemic Renal Injury Rajasree Sreedharan, Shaoying Chen, Melody A. Miller, Dipica Haribhai, Calvin B. Williams, Scott K. Van Why. *Pediatrics, Medical College of Wisconsin, Wauwatosa, WI.*

Background: Heat Shock Factor 1 (HSF1) regulates inducible heat shock protein (HSP) expression, and HSPs protect against renal cell injury *in vitro*. Whether HSPs provide protection against ischemic renal injury *in vivo* is unclear.

Methods: To determine whether inducible HSPs protect against ischemic renal injury *in vivo*, inducible HSP70 and 25 expression and renal injury from bilateral renal ischemia was studied in HSF1 functional knock-out mice (HSF KO) and compared with HSF wild type (WT).

Results: There was no difference between WT and HSF KO in baseline renal HSP70 or 25 levels. WT kidneys had the expected induction of HSP70 and 25 after 45 min of bilateral ischemia and 24 hr reflow, but KO mice had no induction of either HSP. Baseline serum creatinine was also comparable (0.22 mg/dL WT versus 0.19 mg/dL KO). Serum creatinine at 24 hrs reflow in WT was 2.1 mg/dL compared with 0.9 mg/dL in HSF KO (p=0.0002).

Flow cytometry was used to study mononuclear cells isolated from kidneys from both strains. In sham operated kidneys, there was no difference in number of CD4+ and CD8+ T cells in WT compared with HSF KO. However, after 45 min of bilateral ischemia and 1 hr reperfusion, CD4+ and CD8+ cells in WT kidneys increased by 58% (p=0.02) and 75% (p=0.08) respectively from uninjured controls. There was no significant change in either CD4+ or CD8+ cells (p=0.6 and 0.77 respectively) in the HSF KO kidneys after ischemia compared to uninjured controls. In addition, Fox p3+ T regulatory cells decreased by 40% in WT kidneys after ischemia, but did not change in HSF KO (p=0.02 WT versus KO).

Conclusions: This study demonstrates 1) HSP induction is completely absent in HSF1 KO mice kidneys subjected to ischemia, 2) absence of HSP induction, contrary to expectation, is associated with protection against ischemic renal injury *in vivo*, and 3) HSF1 KO mice kidneys have altered T-cell infiltration immediately following ischemia. So, inducible HSPs may contribute to early ischemic renal injury by facilitating T cell response.

TH-OR010

miR-21 Contributes to Renal Protection Conferred by Delayed Ischemic Preconditioning Alison J. Kriegel,[1] Xialian Xu,[1,2] Yong Liu,[1] Kristie Usa,[1] Domagoj Mladinov,[1] Yi Fang,[2] Xiaoqiang Ding,[2] Mingyu Liang.[1] *[1]Department of Physiology, Medical College of Wisconsin, Milwaukee, WI; [2]Division of Nephrology, Fudan University Zhongshan Hospital, Shanghai, China.*

Background: Delayed ischemic preconditioning (IPC) effectively protects kidneys from ischemia-reperfusion (I/R) injury. We examined the in vivo role of microRNA miR-21 in the renal protection conferred by delayed IPC in C57BL/6J mice.

Methods: Mice were subjected to 15min ischemic preconditioning and, 4 days later, 30min bilateral renal ischemia and 24h reperfusion. Tail vein injection of locked nucleic acid(LNA)-modified anti-miR (10 mg/kg) was used to knock down miR-21 in vivo. Renal injury was evaluated by the plasma creatinine, histological change, and TUNEL assay. A miR-21 target protein was analyzed by Western blot.

Results: A 15 min renal IPC substantially attenuated I/R injury induced 4 days later in mice, as indicated by decreases of plasma creatinine and histology damage score ($P<0.05$). Renal abundance of miR-21 expression was increased in the delayed IPC + I/R group by 179% ± 17% compared to the Sham + I/R group ($p<0.05$; n=6/group). Time-course analysis indicated that miR-21 was upregulated at 4 h after IPC compared to the Sham mice, and remained significantly higher 4 days after IPC (n=6/group each time point; $P<0.05$). Administration of LNA anti-miR-21 at the time of IPC decreased miR-21 levels in the kidney detectable by real-time PCR by 98% ($p<0.05$; n=5-6/group), and significantly exacerbated functional and histological damage of subsequent I/R injury in the mouse kidney ($P<0.05$). Knockdown of miR-21 resulted in significant upregulation of PDCD4 protein, a pro-apoptotic target gene of miR-21 (arbitrary unit, 89 ± 27 vs. 20 ± 10, $P<0.05$), and a substantial increase in tubular cell apoptosis in the mouse kidney as determined by TUNEL staining (proportion of positive cells, 16% ± 3% vs. 3% ± 1%, $P<0.05$). In the absence of delayed IPC, knockdown of miR-21 did not significantly affect I/R injury in the mouse kidney.

Conclusions: These data support a novel mechanism in which upregulation of miR-21 contributes to the protective effect of delayed IPC against subsequent renal I/R injury.

TH-OR011

Anti-TGF-β Antibody (1D11) May Attenuate High-Turnover Renal Osteodystrophy by Stimulating Sost Expression Shiguang Liu, Joseph H. Boulanger, Wenping Song, Susan Ryan, Brian S. Kelley, Russell Gotschall, Wen Tang, Yves Sabbagh, Susan Schiavi. *Genzyme Corporation.*

Background: TGF-β1 plays an important role in normal bone remodeling. Its elevated expression in the bone and bone marrow of patients with high-turnover renal osteodystrophy suggests that this growth factor may also contribute to the pathogenesis of bone disease in the setting of chronic kidney disease. We have previously reported that anti-TGF-β antibody (1D11) prevents the onset of high bone turnover in an adenine induced rat model of CKD-MBD.

Methods: To further explore the potential efficacy and mechanism of action of 1D11 on high-turnover renal osteodystrophy, we administered 1D11 to Jck mice, a genetic model of CKD-MBD that had established high-turnover renal osteodystropy. 1D11 was injected IP at doses of 0.5, 2 or 5 mg/kg three times a week for 7 weeks.

Results: Bone histomorphometric analysis indicated that 1D11 significantly suppressed the elevated bone turnover in a dose-dependent manner. To explore the possible mechanism of 1D11's action on bone, we examined expression of genes associated with key pathways regulating bone turnover using a TaqMan Low Density Arrays (TLDA). We have previously shown that expression of the Wnt antagonist, SOST is elevated in early CKD in Jck mice and humans, but this increase is attenuated by rising PTH levels late in disease. In this study, Sost expression was significantly suppressed in Jck relative to wild-type littermate control mice at 17 weeks of age (late in CKD). Importantly, 1D11 treatment resulted in a significant increase in Sost expression in parallel with reduction in bone turnover despite elevated serum PTH levels.

Conclusions: Our data suggest that antagonism of TGF-β attenuates high-turnover renal osteodystrophy independent of changes in serum PTH levels and the effect of 1D11 on bone may be at least partially mediated by stimulation of Sost expression.

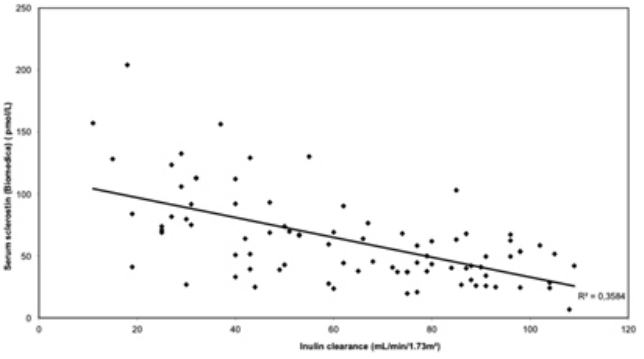
TH-OR012

Sclerostin, a Bone osteopenic Factor, Is Increased in Chronic Kidney Disease Solenne Pelletier,[1,3] Aoumeur Hadj-Aissa,[3] Laurence Dubourg,[3] Denis Fouque.[1,2] *[1]Nephrology, Hopital Edouard Herriot, Lyon, France; [2]U1060, INSERM, Lyon, France; [3]UJERNE, Hopital Edouard Herriot, Lyon, France.*

Background: Sclerostin is a small peptide secreted by osteocytes. Recent experimental data suggest that sclerostin blocks bone formation and better predicts bone turnover than parathormone. We assessed the relationship between serum sclerostin and glomerular filtration rate (GFR) in CKD patients

Methods: A prospective cohort of 86 patients (43 women, 7 diabetic) was studied. Glomerular filtration rate was measured by the gold standard inulin clearance. Serum sclerostin was measured by EIA (Biomedical, Wien). Normal values were 46.4 ± 23.3 pmol/L

Results: Mean age was 51 ± 19 years, GFR 63 ± 27 mL/min/1.73 m2, sclerostin 68.8 ± 36.1 pmol/L, and serum phosphate 1.11 ± 0.24 mmol/L. Sclerostin was strongly and inversely correlated with GFR ($r=-0.6$, $p< 0.001$), positively with age ($r=0.38$, $p< 0.001$) and with serum phosphate ($r=0.25$, $p=0.02$).



By multiple regression, only GFR was associated with the observed sclerostin increase

Conclusions: We found a new and strong inverse relationship between sclerostin and GFR in CKD patients (Fig 1). Since sclerostin reduces bone turnover, and accumulates in CKD, this may suggest a role on renal osteodystrophy. As in postmenopausal osteoporosis, for which sclerostin antagonists have been developed, sclerostin might soon become a new player in CKD mineral and bone disease.

TH-OR013

Decreased Trabecular Tissue Mineralization Is Associated with Fracture in Patients with Kidney Disease Thomas L. Nickolas, Xiaowei Sherry Liu, Chiyuan Amy Zhang, Donald J. McMahon, Elizabeth Shane. *Columbia University.*

Background: In renal osteodystrophy (ROD), abnormal Vitamin D metabolism and remodeling cause defects to tissue mineral density (TMD), which affects tissue-level mechanical properties. Abnormal TMD may contribute to high fracture (Fx) risk in CKD patients. Previously, invasive iliac crest bone biopsy was required to evaluate mineralization. We have now noninvasively measured TMD on high resolution peripheral QCT (HRpQCT) scans of the distal radius (DR) and tibia (DT). We hypothesized that trabecular (Tb) TMD is lower in CKD patients with fractures (Fx) than both CKD patients without Fx and healthy Controls. We also hypothesized that TbTMD is inversely related to calciotropic hormones and bone turnover markers (BTM).

Methods: We performed HRpQCT (Scanco Medical; voxel size 82μm) of the DR and DT in 47 patients with CKD (n=23 Fx; 24 nonFx) and 21 age, sex and race matched Controls without Fx. By digital topological analysis (DTA), Tb bone voxels were classified into one of 3 envelopes: surface (s), central (c) and intervening (middle (m); between surface and central). TMD was calculated for each envelope. Serum iPTH, 25OHD and bone formation (BSAP, P1NP) and resorption (CTX, Trap5b) markers were measured.

Results: CKD-Fx, CKD-nonFX, and Controls were well matched for age, sex and race (all p=NS). TbTMD was significantly lower in CKD-Fx than Controls. At the DR, s- and m- TMD were lower by 2.6% and 3.0%, respectively (all $p<0.05$). At the DT, s-, m- and c- TMD were lower by 2.2%, 2.6% and 3.1%, respectively (all $p<0.05$). TMD in patients with CKD-nonFx did not differ from that of either CKD-Fx or Controls. At the DT, each SD decrease in s-, m- and c- TMD was associated with 1.7%, 1.4% and 1.1% increased odds of Fx ($p<0.05$ for all). Higher levels of iPTH, BSAP, P1NP and CTX were significantly and inversely correlated with s-, m- and c- TMD; r values ranged from -0.40 for P1NP vs DT sTMD ($p<0.009$) to -0.53 for iPTH vs DR sTMD ($p<0.0005$).

Conclusions: CKD patients with Fx have low TbTMD that is likely related to SHPT and high bone turnover. HRpQCT may provide a noninvasive approach to measurement of TbTMD in CKD; validation against iliac crest bone biopsy is needed.

TH-OR014

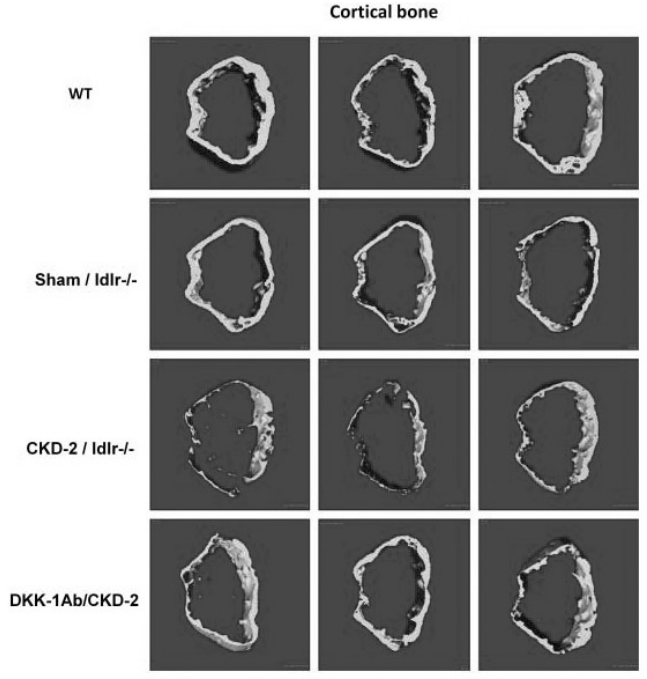
The Pathogenesis of the Early CKD-MBD in Stage 2 CKD Keith A. Hruska, Yifu Fang. *Pediatrics, Washington University School of Medicine, St. Louis, MO.*

Background: CKD induces the CKD-MBD associated with increased mortality by stage 2. Vascular calcification (VC) is a strong risk factor in CKD. The CKD-MBD in stage 2 CKD consists of stimulation of VC, the onset of osteodystrophy, and an increase in FGF23 levels, while Ca, Pi and PTH levels remain normal. The increase in FGF23 serves as a biomarker of the CKD effect on the skeleton. We have linked the skeleton in CKD to stimulation of VC. The pathogenesis of the initial stimulus for osteocytic secretion of FGF23 is unclear. Early changes in phosphate homeostasis, changes in bone remodeling, and PTH are the candidate factors under investigation. Here we examine the actions of either modifying Pi balance through intestinal Pi binding or a skeletal anabolic factor (a neutralizing monoclonal antibody to a Wnt inhibitor, DKK1) on the early CKD-MBD.

Methods: Ldlr deficient mice fed high fat diets were subjected to partial kidney ablation at 12 weeks of age to create an early CKD-MBD mouse model. Treatment protocols with Vehicle, CaAc (3% w/w mixed in diet), or the DKK1 mab (30 mg/kg tiw IP) were conducted from 14-22 wks or 22-28 wks.

Results: The reduction in the GFR measured by inulin clearance was 75% of normal (stage 2 CKD). Aortic Ca levels were increased by CKD at 22 weeks of age

and progressively increased to 28 wks. The serum levels of BUN, Ca, Pi and PTH were normal, but a transient elevation of PTH at 14 weeks was discovered. MicroCT of the femurs revealed cortical but not trabecular bone loss which was corrected by the DKK1 mab but not by CaAc therapy.



FGF23 levels were decreased by CaAc but not by the DKK1 mab. Vascular Ca levels were decreased by the DKK1 mab but not by CaAc therapy.

Conclusions: We conclude that an early osteodystrophy in CKD may be causatively associated with the stimulation of VC, and that the stimulus to FGF23 secretion is independent and may be Pi or PTH.

Effect of Calcium Carbonate Supplement on Phosphate Balance and Homeostasis in Patients with Stage 3 and 4 Chronic Kidney Disease

Kathleen M. Hill,[1] Berdine Martin,[2] Sharon M. Moe,[3] George P. McCabe,[4] Connie M. Weaver,[2] Munro Peacock.[1] *[1]Endocrinology, Indiana University School of Medicine, Indianapolis, IN; [2]Foods and Nutrition, Purdue University, West Lafayette, IN; [3]Nephrology, Indiana University School of Medicine, Indianapolis, IN; [4]Statistics, Purdue University, West Lafayette, IN.*

Background: In chronic kidney disease (CKD), calcium carbonate ($CaCO_3$) given with meals is used to bind dietary phosphate (Pi) and thus lower plasma Pi. Data on the effect of $CaCO_3$ on Pi balance and homeostasis in CKD are limited.

Methods: Three patients, of a projected eight, with stage 3/4 CKD participated in two 3wk balance studies using a randomized crossover design. Patients received 500 mg elemental Ca as $CaCO_3$ or placebo with meals 3x/24h. Diets consisted of 957 mg Ca/24h and 1500 mg Pi/24h. Wk 1 was outpatient equilibration period. Patients were inpatients wk 2-3, and all 24h urine and feces were collected and analyzed for Ca & Pi. Ca & Pi balances were calculated as diet (mg/24h) – fecal (mg/24h) – urine (mg/24h). Fasting blood and urine were collected for biochemistries at the end of each week. Repeated measures ANOVA for crossover designs was used to test differences between $CaCO_3$ and placebo.

Results: As compared to placebo, net and percent Pi absorption were lower with $CaCO_3$ (495 mg/24h, 32% v. 710 mg/24h, 45%); urinary Pi excretion was lower with $CaCO_3$ (650 v. 877 mg/24h); fecal Pi excretion was higher with $CaCO_3$ (1061 v. 852 mg/24h); and Pi balance was similar (-155 v. -167 mg/24h). Ca balance was higher with $CaCO_3$ (404 v. 57 mg/24h). Biochemistries did not differ between $CaCO_3$ and placebo: serum Ca 9.4 & 9.3 mg/dL, Pi 4.0 & 4.1 mg/dL, Cr 2.5 & 2.4 mg/dL, PTH 70 & 78 pg/mL, FGF23 77 & 74 pg/mL, 25(OH)D 21 & 22 ng/mL, $1,25(OH)_2D$ 46 & 48 pg/mL, osteocalcin 21 & 23 ng/mL, bone alkaline phosphatase 36 & 33 U/L, urine N-telopeptide crosslinks:Cr 54 & 38 nM BCE/mM, urine Ca:Cr 0.07 & 0.05, Pi:Cr 0.29 & 0.39.

Conclusions: A $CaCO_3$ supplement providing 500 mg elemental Ca given with meals as a Pi binder lowers through put of Pi by only 200 mg/24h and does not change Pi balance or fasting serum biochemistries of Ca & Pi in early CKD.

Funding: Pharmaceutical Company Support

TH-OR016

Reduced Fracture Risk with Early Corticosteroid Withdrawal after Kidney Transplant: An Analysis of the USRDS

Lucas Nikkel,[1] Sumit Mohan,[1] Chiyuan Amy Zhang,[1] Donald J. McMahon,[1] Stephanie Boutroy,[1] Geoffrey K. Dube,[1] Bekir Tanriover,[1] David J. Cohen,[1] Lloyd Ratner,[1] Christopher S. Hollenbeak,[3] Mary B. Leonard,[2] Elizabeth Shane,[1] Thomas L. Nickolas.[1] *[1]Columbia University; [2]Children's Hospital of Philadelphia; [3]Penn State Hershey.*

Background: Co-administration of calcineurin inhibitors (CNI) with corticosteroid (CS) after kidney transplant (KTx) results in severe bone loss and very high fracture (Fx) risk. Early CS withdrawal (ECSW) has not been associated with bone loss in comparison to CS based immunosuppression (CSBI) after KTx. We hypothesized that Fx rates in KTx recipients managed with ECSW are lower than with CSBI.

Methods: Using the United States Renal Data System (USRDS), 77,625 adults undergoing first KTx between January 1, 2000 and December 31, 2006 were identified. CS use was determined from UNOS immunosuppression forms completed at KTx in an intent-to-treat analysis. Fx after KTx was identified from hospitalization discharge ICD9 codes. Continuous characteristics (age, BMI, HLA mismatches) were compared by Students t tests and binary characteristics were compared by chi-square. Time to first Fx was modeled after KTx using Kaplan-Meier and Cox methods.

Results: Patients on ECSW differed slightly from those on CS in age (49.9 vs. 48.2 years; $p<0.001$), gender (62% male vs. 60%, $p<0.001$), race (69% white vs. 67%, $p<0.001$), BMI (27.1 vs. 26.6 kg/m2, $p<0.001$), and live donor (48% vs. 39%; $p<0.001$). 2395 Fx resulting in hospitalizations were observed during follow-up (307662 person-years); median (IQR) follow-up was 1448 (808-2061) days. There were 5.8 and 8.0 Fx per 1000 patient-year for ECSW and CSBI, respectively. Fx site distribution was similar between groups. Multivariate Cox models demonstrated a 31% ($p<0.001$) Fx risk reduction for ECSW versus CSBI after adjustment for other risk factors for Fx. By 24-months after KTx, Fx risk was significantly lower in the ECSW group.

Conclusions: ECSW is associated with a 31% reduction in serious Fx risk after KTx. Fx risk begins to decrease in ECSW patients by the second year after KTx. There is a need for prospective studies to understand how ECSW affects bone and mechanisms through which Fx risk is decreased.

Effect of Steroid Withdrawal on Growth, FGF23/Klotho and IGF-I/IGFBP3 Axis in Pediatric Kidney Transplantation

Luis Michea,[4] Angela Delucchi,[1] Magdalena Gonzalez,[4] Paulina Salas,[2] Viola Pinto,[2] Francisco Cano,[1] Veronica Mericq.[3] *[1]Pediatric Nephrology, Luis Calvo Mackenna Hospital, Santiago, Chile; [2]Pediatric Nephrology, Exequiel Gonzalez Cortes Hospital, Chile; [3]IDIMI, Santiago, Chile; [4]ICBM. Centro de Estudios Moleculares de la Celula, Falculty of Medicine. University of Chile, Santiago, Chile.*

Background: Successful renal transplant improves growth in pediatric patients. Steroids immunosuppression has adverse effects on growth, bone metabolism and GH/IGF-I axis. The Fibroblast Growth Factor 23 (FGF23) is a phosphatonin produced by bone cells, which is active with its co-receptor Klotho. FGF23 reduces osteoblastic activity and matrix mineralization by autocrine/paracrine mechanisms. We hypothesized that steroids increase the FGF23/Klotho axis activity.

Methods: A prospective, randomized, multicenter study, steroid withdrawal on growth, FGF23/Klotho and IGF-I/IGFBP3 levels in pediatric kidney recipients (2-15 years) was evaluated. Six days post-Tx patients receiving tacrolimus (TAC) and mycophelolate mofetil (MMF) were assigned into two groups: steroid withdrawal (SW, n=9) and steroid control (SC, n=10). The ethics committee approved the protocol, written informed consent was obtained. Growth and biochemical parameters were measured up to 12 months post Tx. Data were presented as means±SD, student-t test, Mann-Whitney and Wilcoxon tests. Regression analysis for repeated measurements (mixed models) was performed.

Results: A significant improvement in height Z-score at 1 year post Tx in SW vs. SC group (-1.02±1.0 vs.-2.25±1.0; p=0.02) was observed. The SW group showed lower FGF23 levels as compared to SC (SW=5.8±3.1pg/mL vs. SC=18.6±11.5 pg/mL; $p<0.003$) at 1 year post Tx; that were similar to those of healthy controls. Delta zIGF-I was higher in SW 1.6±1.2 vs.SC 0.2±2.1;p=0.03. No significant changes in delta IGFBP3 levels between groups were found. An inverse relationship between FGF-23 levels and growth was observed (R^2:0.4 p=0.004).

Conclusions: These results suggest that steroids withdrawal improve growth due to less GH resistance, improvement of IGF-I and/or FGF23/Klotho axis function.

Ezrin Is Essential for the Phosphate Reabsorption in the Renal Proximal Tubule Ryo Hatano,[1] Atsushi Tamura,[2] Hiroko Segawa,[3] Ken-Ichi Miyamoto,[3] Sachiko Tsukita,[2] Shinji Asano.[1] *[1]Department of Molecular Physiology, Ritsumeikan University, Kusatsu, Shiga, Japan; [2]Laboratory of Biological Science, Graduate School of Frontier Biosciences and Graduate School of Medicine, Osaka University, Suita, Osaka, Japan; [3]Department of Molecular Nutrition, University of Tokushima Graduate School, Japan.*

Background: Ezrin is a crosslinker between membrane proteins and actin cytoskeleton and also known to be related with the membrane fusion of gastric vesicles in stomach. In the kidney, ezrin is mainly expressed in the apical membrane of proximal tubules and interacts with scaffold protein as NHERF1, which is essential for membrane localization of some transporters and receptors. However, the physiological roles of ezrin in the kidney are not still unraveled. Therefore, we used ezrin knockdown ($Ezrin^{kd/kd}$) mice as a model for the analysis of the physiological roles of ezrin in the kidney.

Methods: Ezrin knockdown mice was constructed as previously reported (Tamura A *et al. J Cell Biol*. 2005.). Male mice at 4 to 8 week age were kept in the metabolic cages for 7 days and daily urine was collected for the analysis of urinary excretion of phosphate and other substrates. These mice were sacrificed and kidney was collected for the immunohistochemistry and western blot analysis. Right tibiae were also collected for the bone analysis.

Results: Whereas there is no apparent difference in the morphology of the kidney between adult wild type and $Ezrin^{kd/kd}$ mice, $Ezrin^{kd/kd}$ mice showed hypophosphatemia and abnormal bone formation caused by significant urinary loss of phosphate but not calcium. These phenotypes were shown even in the prepubertal mice (4wk). Furthermore, we determined a decreased apical membrane localization of Na^+/phosphate cotransporter, NaPi2a in the proximal tubules by western blot and immunofluorescence analysis.

Conclusions: These results suggest that ezrin is essential for the membrane localization of NaPi2a at the apical membrane in the proximal tubules and functional or genetic disorder of ezrin might be related with the onset of hypophosphatemic rickets.

TH-OR019

NHERF1 Modulates Intestinal NaPi Transporter NaPi2b Expression in Apical Microvilli Yupanqui A. Caldas,[1,2] Hector Giral-Arnal,[1] Luca Lanzano,[3] Enrico Gratton,[3] Moshe Levi.[1] *[1]Department of Medicine, Anschutz Medical Center, University of Colorado Denver, Aurora, CO; [2]Department of Toxicology, Laboratory of Molecular Toxicology, University of Zaragoza, Spain; [3]Laboratory for Fluorescence Dynamics, University of California Irvine, Irvine, CA.*

Background: The regulation of Pi homeostasis is maintained by the coordinated function of the renal and intestinal phosphate transporters. In the intestine the type II sodium-phosphate (NaPi) co-transporter NaPi2b, is considered to be the main mediator of sodium dependent transcellular Pi transport. The PDZ (PSD-95/discs large/ZO-1 homologous) domain proteins, including NHERF1, PDZK1, ShanK2, and PIST play an important role in the regulation of the renal NaPi transporters. However their potential role in regulation of the intestinal NaPi2b transporter is not known.

Methods: For this purpose we performed studies with mouse small intestine, and in cell culture to determine a potential role for NHERF1 in regulation of NaPi2b.

Results: We found that the human intestinal cell CaCo2BBE cells expressed the endogenous NaPi2b transporter, and we used them to study the regulation of NaPi2b. Expression of GFP-NaPi2b was observed in the microvilli, and along of a single microvillus with the novel multitracking technique (MT), from which we measured the diffusion coefficient (D=0.2 um2/s). Cells transiently co-transfected with GFP-NaPi2b and mCherry-NHERF1 were analyzed for molecular interaction using the FLIM-FRET technique which revealed significant FRET between NaPi2b and NHERF1. The functional significance of this interaction was further confirmed in NHERF1 KO mice, where we found that adaptation of NaPi2b was markedly impaired in the KO mice.

Conclusions: Our results therefore indicate a novel and a critical role for NHERF1 in modulation of NaPi2b expression in the microvilli of the mouse intestine.

TH-OR020

Novel Non-Systemic NaP2b Inhibitors Block Intestinal Phosphate Uptake Marc Navre,[1] Eric Daniel Labonte,[1] Christopher Carreras,[1] Andrew G. Spencer,[1] Joanne Marks,[2] Deborah Black,[1] Jason G. Lewis,[1] Jeffrey Jacobs,[1] Dominique Charmot.[1] *[1]Ardelyx Inc., Fremont, CA; [2]University College London, London, United Kingdom.*

Background: The inhibition of intestinal phosphorus (P) uptake via the blockade of NaP2b-mediated transport emerges as a novel approach for P management in CKD. Novel classes of non-systemic NaP2b (SLC34A2) inhibitors were identified and their pharmacodynamic profiles evaluated in various preclinical models.

Methods: Compound IC50s were measured in a 33P uptake assay in NaP2b transfected cells, in a rabbit jejunal brush border membrane vesicle (BBMV) assay, and an everted jejunal sleeve P uptake technique. Pharmacodynamic response was tested by monitoring the uptake of 33P in ligated rat jejunum or by oral gavage in rats. P balance studies were performed where urine P was measured upon treatment with test compound for 4-7 days. NaP2b levels in gut were monitored by immunoblot.

Results: NaP2b inhibitors were evaluated for potency, non-competition with P (to ensure post-prandial inhibition of P absorption), systemic exposure and metabolic stability. Two classes of compounds are represented by NTX116 and NTX2128 with IC50s vs. rat NaP2b of 0.16 and 3.4 μM, respectively. In the BBMV and everted sleeve techniques, NTX116 inhibited sodium-dependent P uptake with an IC50 of ~5 μM. Orally dosing rats with 100 mg/kg NTX2128 resulted in a >50% reduction in serum 33P.

Using these NaP2b inhibitors and a novel Pit-1 (SLC20A1) inhibitor in the BBMV, everted sleeve, and ligated jejunum techniques, Pit-1 was found to contribute less than 10% to jejunal P uptake.

NTX2128 induced a reduction in urine P similar to Renvela but at 1/8th of the dose. The combination of NTX2128 and Renvela was additive in terms of reduction in urinary P, an observation consistent with their complementary mechanisms of action; i.e., intestinal NaP2b blockade and phosphate binding, respectively. In rats, NTX2128 was found to be minimally systemic with a high recovery of intact drug in feces (~95% of dosed material).

Conclusions: NaP2b inhibitors such as NTX2128 suppress active P transport in the gut and may offer a new treatment modality for P management in CKD and ESRD patients.

TH-OR021

Molecular Consequences of the SLC34A3 Mutations of Hereditary Hypophosphatemic Rickets with Hypercalciuria (HHRH) Akiko Ohi,[1] Sakiko Haito Sugino,[1] Mikiko Ito,[2] Yuji Shiozaki,[1] Kengo Nomura,[1] Yuri Kusaka,[1] Shohei Sasaki,[1] Saori Ohnishi,[1] Seiichi Yamaguchi,[1] Shinsuke Kido,[1] Sawako Tatsumi,[1] Hiroko Segawa,[1] Ken-Ichi Miyamoto.[1] *[1]Molecular Nutrition, Institution of Health Bioscience, University of Tokushima Graduate School, Tokushima, Japan; [2]University of Hyogo, Himeji, Japan.*

Background: The majority of the renal handling of phosphate (Pi) occurs via two sodium-dependent Pi cotransporters, SLC34A1 and SLC34A3. Hereditary hypophosphatemic rickets with hypercalciuria (HHRH) is a metabolic disorder due to homozygous loss-of-function mutations in the SLC34A3 gene. SLC34A1 (NaPi-IIa) transporter is the most extensively characterized in terms of function, structure, and regulation, but such information for SLC34A3 (NaPi-IIc) is limited.

Methods: Mutations in the SLC34A3 protein (S138F, G196R, R468W and R564C) are responsible for HHRH. We studied the function and cellular localization of the mutant transporters in Xenopus oocytes and OK cells.

Results: In Xenopus oocytes, the levels of sodium-dependent Pi co-transport activities in G196R and R468W mutants were significantly decreased when comparing with those in wild type transporter. In both mutants, biotinylation assays revealed that lack of cell surface expression was associated with abolition of mature complex glycosylated NaPi-IIc. Immunohistochemical analysis showed that R468W and G196R co-localized with the ER marker protein, demonstrating that they are retained in the ER. In R468W and G196R, cell treatment with proteasome or lysosomal inhibitors failed to restore the loss of complex-glycosylated NaPi-IIc, further eliminating the possibility that the G196R and R468W mutants were processed by the Golgi apparatus. The G196R and R564C mutant proteins were sensitive to Endo H digestion. Reduction of the temperature overcomes trafficking defect of the mutant proteins. The analysis of blue native polyacrylamide gel electrophoresis showed the difference in the complex states between WT and G196R/R468W mutant.

Conclusions: The present data suggest that the G196R and R468W mutants cause the ER retention by protein folding defect, while S138F and R564C mutants stimulate its degradation in renal proximal tubular cells.

TH-OR022

Effect of Conditional PiT-1 Transporter Deletion on Phosphate Uptake and Calcification in Cultured Mouse Vascular Smooth Muscle Cells Matthew H. Crouthamel, Cecilia M. Giachelli. *Bioengineering, University of Washington, Seattle, WA.*

Background: Elevated serum phosphate (Pi) in chronic kidney disease patients is recognized as a major risk factor for cardiovascular events as it predisposes to vascular calcification (VC). *In vitro*, elevated Pi levels stimulate vascular smooth muscle cell (VSMC) calcification. The sodium-dependent uptake of Pi into VSMC is mediated by the membrane bound type III sodium-dependent Pi (NaPi) cotransporters PiT-1 (SLC20A1) and PiT-2 (SLC20A2).

Methods: Using SM-22α driven Cre-recombinase transgenic mice, we have recently generated a conditional, smooth muscle specific PiT-1-deficient mouse ($PiT\text{-}1^{\Delta sm}$) to study the role of PiT-1 in VC. VSMCs were isolated and cultured from aortae of control ($PiT\text{-}1^{fl/fl}$) and $PiT\text{-}1^{\Delta sm}$ mice. RealTime rt-PCR, Pi uptake, and calcification assays were performed with these cells.

Results: RealTime rt-PCR confirmed the absence of full length PiT-1 mRNA in $PiT\text{-}1^{\Delta sm}$; however, PiT-2 expression was increased 2-fold in $PiT\text{-}1^{\Delta sm}$ compared to control VSMC. Pi uptake at normal Pi concentrations (1 mM) showed no significant difference between $PiT\text{-}1^{fl/fl}$ and $PiT\text{-}1^{\Delta sm}$. Interestingly, at hyperphosphatemic levels (2.6mM), while sodium dependent uptake was present in the $PiT\text{-}1^{fl/fl}$ VSMCs, it was absent in the $PiT\text{-}1^{\Delta sm}$ VSMCs. Addition of phosphonoformic acid did not alter Pi uptake, indicating that type II NaPi cotransporters were not contributing to Pi uptake in these VSMCs. Also, $PiT\text{-}1^{\Delta sm}$ VSMCs were larger and grew more slowly than controls. To assess the propensity for calcification, the VSMCs were cultured for 12 days in media containing 1 or 2.6 mM Pi. Final calcification levels were not significantly different between the $PiT\text{-}1^{fl/fl}$ and $PiT\text{-}1^{\Delta sm}$ genotypes.

Conclusions: Deletion of PiT-1 in mouse VSMCs did not cause a change in calcification in high or normal Pi media, or a difference in Pi uptake below 1mM Pi. However, at 2.6 mM Pi, Pi uptake was reduced in $PiT\text{-}1^{\Delta sm}$ VSMCs. These results may be due to PiT-2 compensation, which is currently being investigated.

TH-OR023

Upregulation of the Ca^{2+} Channel TRPV5 by Uromodulin – A Potential Mechanism for Hypercalciuria with *UMOD* Mutations Matthias Tilmann Florian Wolf, Chou-Long Huang. *Pediatrics and Medicine, UTSW Medical Center, Dallas, TX.*

Background: *Uromodulin* (*UMOD)* encodes Tamm-Horsfall protein. *UMOD* mutations result in tubulo-interstitial nephropathies. A genome-wide association study linked nephrolithiasis with a *UMOD* allele. Mouse models of human *UMOD* mutations have hypercalciuria, which exceeds the degree of Na^+ wasting, suggesting defective transcellular Ca^{2+} reabsorption in the distal nephron. We studied if UMOD regulates TRPV5, an apical Ca^{2+} channel in DCT and CNT critical for transcellular Ca^{2+} reabsorption.

Methods: We transfected TRPV5 and UMOD in HEK293 cells and analyzed TRPV5 current by whole cell patch-clamping.

Results: Coexpression of TRPV5 and UMOD showed increased TRPV5 current density (492+/-118 vs 294+/-104 pA/pF for UMOD vs vector; p=0.005). UMOD upregulates TRPV5 extracellularly: supernatant from UMOD - but not from vector-expressing cells - increased TRPV5 current density in TRPV5-transfected cells (856+/-148 vs 446+/-129 pA/pF for UMOD vs vector supernatant; p=0.0005). Biotinylation showed increased surface expression of TRPV5. Half-maximal effective concentration (EC50) for extracellular Tamm-Horsfall protein treatment in TRPV5-expressing cells was approximately 100 ng/ml, which is 100x lower than in human urine, underlining physiological significance. Cotransfection with disease-mutant $UMOD^{C150S}$ resulted in significantly less TRPV5 current compared to wild type UMOD (344+/-98 vs 852+/-121 pA/pF for mutant vs wild type UMOD; p=0.0005). We analyzed if UMOD regulation of TRPV5 is dependent on TRPV5 N-glycosylation by cotransfecting UMOD with glycosylation-defective N358Q-TRPV5 or with wild type TRPV5. We found that UMOD did not increase N358Q-TRPV5 (453+/-111 and 422+/-104 for N358Q+vector and N358Q+UMOD, respectively; ns) while it increased wild type TRPV5 (446+/-90 and 802+/-110 for WT+vector and WT+UMOD, respectively; p= 0.0001).

Conclusions: We show TRPV5 upregulation by extracellular UMOD at physiological levels. TRPV5 upregulation requires N-glycosylation of TRPV5, and is impaired by *UMOD* mutations. We suggest that in *Umod* mutations reduced UMOD secretion from the TAL decreases TRPV5-mediated Ca^{2+} reabsorption in the distal nephron contributing to hypercalciuria.

Kidney-Specific Calcium-Sensing Receptor (CaSR) Deficient Mice Display PTH-Independent Hypocalciuria and NKCC2 Activation Hakan R. Toka,[1,2] David B. Mount,[1] Gary C. Curhan,[1] Martin R. Pollak.[2] [1]*Nephrology, Brigham and Women's Hospital, Boston, MA;* [2]*Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: The calcium-sensing receptor (CaSR) is a central player in regulating calcium homeostasis. Various studies have shown that rare loss-of-function mutations in the CaSR can lead to decreased urinary calcium (Ca2+) excretion in the context of relative hyperparathyroidism and hypercalcemia. In addition to playing a central role in regulating PTH release, evidence suggests that CaSR is directly involved in regulating calcium handling independently of PTH. The current study was designed to specifically examine the role of CaSR in the renal tubule.

Methods: We generated a conditional CaSR knockout (KO) mouse with targeted inactivation of exon 3 using the Cre/Lox system. A nephron-specific knockout of CaSR was generated by crossing CaSR flox/flox mice with animals expressing Cre recombinase driven by the Six2 promoter, targeting tubular epithelial cells throughout the entire nephron except for the collecting duct. Loss of CaSR in the kidneys of the resulting homozygous CaSR floxed mice was confirmed at both the RNA and protein level.

Results: Homozygous CaSR flox/flox mice were viable without gross phenotype. Interestingly, while baseline serum Ca2+, PTH and 1,25 Vitamin D levels showed no significant difference, kidney-specific CaSR KO mice showed a tendency to decreased urinary calcium excretion compared to controls. This effect was significantly increased when mice were challenged with increased dietary Ca2+ (1.5% Calcium water) and disappeared when animals were treated with furosemide. Western blotting analysis from whole kidney lysates with NKCC2-phospho antibody showed increased expression in Six2-Cre animals compared to control animals.

Conclusions: The CaSR expressed in renal tubules regulates Ca2+ re-absorption independently of PTH through the TAL. Further studies analyzing gastrointestinal Ca2+ re-absorption and addressing bone metabolism in these mice will be important to understand Ca+ metabolism regulated by CaSR in the kidney.

Claudin -16-Mediated Renal Magnesium Transport Is Transcriptionally Inhibited by 1,25($OH)_2$VitD Via a Calcium Sensing Receptor-Dependent Mechanism Orly Kladnitsky,[1,2] Julia Rozenfeld,[1,2] Edna Efrati,[1,2] Israel Zelikovic.[1,2] [1]*Lab of Developmental Nephrology, Faculty of Medicine-Technion;* [2]*Pediatric Nephrology, Rambam Medical Center, Haifa, Israel.*

Background: The role of 1,25$(OH)_2$VitD in renal Mg^{2+} handling is obscure. The bulk of filtered Mg^{2+} is reabsorbed in the TAL via the tight junction protein, claudin-16. We have shown that Mg^{2+} depletion increases and 1,25$(OH)_2$VitD inhibits claudin-16 gene (CLDN16) transcription. We aimed to further explore the molecular mechanisms underlying the effect of 1,25$(OH)_2$VitD on claudin-16.

Methods: Adult mice received **1.** 1,25$(OH)_2$VitD or **2.** 1,25$(OH)_2$VitD plus low Mg^{2+} diet for 3 days, and kidneys were harvested. HEK293 cells were exposed to treatments **1.** and **2.** for 24 hours. A luciferase reporter vector containing 2.5 kb human CLDN16 (hCLDN16) 5' flanking DNA sequence, was transfected into CaSR-devoid HEK293 cells (HEK293), HEK293 cells transfected with CaSR (HEK-CaSR), CaSR-harboring OK cells (OK), and OK cells transfected with a dominant negative CaSR construct (OK-DNCaSR).

Results: Treatments **1.** and **2.** in mice increased CaSR mRNA in kidneys. Treatment **1.** decreased claudin-16 mRNA and protein in kidneys but had no effect on claudin-2 mRNA. Treatment **2.** reversed the expected increase in claudin-16 mRNA and protein in Mg^{2+} depleted animals. HEK293 cells treated with **1.** and **2.** showed the same pattern of changes in claudin-16 mRNA as in mice, and no influence on mRNA of the Mg^{2+} channel, TRPM6 . Exposure of transfected HEK293 cells to 1,25$(OH)_2$VitD minimally decreased hCLDN16 promoter activity but markedly inhibited it in HEK-CaSR cells. A 1,25$(OH)_2$VitD induced inhibition of hCLDN16 promoter activity in OK cells was completely abolished in OK-DNCaSR cells. Furthermore, 1,25$(OH)_2$VitD decreased hCLDN16 promoter activity in Mg^{2+} depleted HEK293 cells.

Conclusions: In conclusion, 1,25$(OH)_2$VitD inhibits paracellular, claudin 16 mediated renal Mg^{2+} transport at the transcriptional level via a CaSR dependent mechanism. 1,25$(OH)_2$VitD dampens the Mg^{2+} depletion -induced stimulation of CLDN16 transcription. The 1,25$(OH)_2$VitD-induced repression of renal Mg^{2+} transport may serve as an adaptive mechanism to the 1,25$(OH)_2$VitD-induced increase in intestinal Mg^{2+} absorption.

TH-OR026

1,25$(OH)_2$D Is Essential for PTH Stimulation of FGF23 Bing Dai, Valentin David, Aline Martin, Hua Li, Leigh Darryl Quarles. *Medicine, University of Tennessee Health Science Center, Memphis, TN.*

Background: FGF23 is an bone-derived hormone involved in an endocrine loop where 1,25$(OH)_2$D stimulates FGF23 and FGF23 suppresses 1,25$(OH)_2$D. FGF23 is elevated in CKD, where its relationship to hyperparathyroidism is controversial. FGF23-mediated reduction in 1,25$(OH)_2$D should lead to elevations in PTH, but PTH is reported to variably stimulate FGF23.

Methods: To investigate the role of 1,25$(OH)_2$D and PTH in the regulation of FGF23, we transferred $Cyp27b1^{-/-}$ and $Gcm2^{-/-}$ onto $Col4a3^{-/-}$ mouse CKD model and analyzed the resulting phenotype.

Results: Single mutant $Col4a3^{-/-}$ mice develop progressive renal failure along with elevations of serum PTH and FGF23 levels. $Gcm2^{-/-}$ exhibit low PTH, 1,25$(OH)_2$D and calcium levels. $Cyp27b1^{-/-}$ exhibit high PTH, low calcium and very low 1,25$(OH)_2$D levels. FGF23 levels are reduced in $Gcm2^{-/-}$ mice compared to WT. We have reported that administration of 1,25$(OH)_2$D increases FGF23 in $Gcm2^{-/-}$ mice. In contrast, FGF23 is undetectable in $Cyp27b1^{-/-}$ mice, in spite of high PTH levels. Thus, 1,25$(OH)_2$D can elevate FGF23 in the setting of low PTH, but PTH does not stimulate FGF23 in the setting of low 1,25$(OH)_2$D. Low PTH in compound $Col4a3^{-/-}/Gcm2^{-/-}$ mice and low 1,25$(OH)_2$D in compound $Col4a3^{-/-}/Cyp27b1^{-/-}$ mice are associated with reduced serum FGF23 concentrations. Factors other than 1,25$(OH)_2$D and PTH may also contribute to increased FGF23 in CKD, since FGF23 levels are higher in $Col4a3^{-/-}/Cyp27b1^{-/-}$ than $Cyp27b1^{-/-}$ mice.

Serum Biochemistries

Genotype:	WT	Col 4a3-/-	Cyp27b1-/-	Cyp27b1-/-	Gcm2-/-	Gcm2-/-
[Serum]				Col4a3-/-		Col4a3-/-
FGF23 (pg/ml)	137.3 ± 9.5	1248 ± 188 *	0.00 ± 0.0*	98 ± 34.5	24.1 ± 12.3*	130.2 ± 10.9
PTH (pg/ml)	32.2 ± 3.8	1772.1 ± 452.9*	2504± 530	2802± 459	5.2 ± 0.21	6.1 ± 0.1
1,25(OH)2D (pM)	89.6 ± 13.9	138.9 ± 21.6	6.7± 3.58*	3.1 ± 1.6*	30.1 ± 2.7*	32.6 ± 6.3*
Calcium (mg/dl)	8.7 ± 0.20	9.4 ± 0.3	5.1 ± 0.30*	5.1 ± 0.3*	4.5 ± 0.4*	5.4 ± 0.7 *

Data as mean±SEM. n≥7 per group, *p<0.05 vs. WT.

Conclusions: 1,25$(OH)_2$D plays a dominant role to PTH in regulating FGF23. Further studies are needed to determine the mechanisms for the cross-talk between 1,25$(OH)_2$D and PTH and the variable effects of PTH to regulate FGF23 expression.

Activation of the Calcium-Sensing Receptor Induces Tight Junction Formation in MDCK Cells Francois Jouret, John P. Geibel, Michael J. Caplan. *Cellular and Molecular Physiology, Yale University School of Medicine, New Haven, CT.*

Background: The calcium-sensing receptor (CaSR) belongs to the G-protein-coupled receptor superfamily, and plays a critical role in divalent ion homeostasis, as well as in cell growth and differentiation. Since extracellular Ca2+ (Ca2+e) is essential for the development of stable epithelial tight junctions (TJ), we hypothesized that CaSR contributes to the assembly of TJ during epithelial cell polarization.

Methods: First, we assessed the level of CaSR expression in Madin-Darby Canine Kidney (MDCK) cells following manipulations that modulate TJ assembly. Next, we examined the effects of CaSR agonists and antagonists on TJ assembly.

Results: Real-time RT-PCR and immunoblotting analyses showed that switching MDCK cells from low (5μM) to normal (1.8mM) Ca2+e concentration significantly increases CaSR expression. Exposure of MDCK cells to both type I, i.e. neomycin (1mM), gadolinium (100μM), and type II, i.e. R-568 (800nM), CaSR agonists facilitated TJ formation under normal Ca2+e conditions, as measured by the relocation of Zonula Occludens 1 (ZO-1) and occludin. Moreover, CaSR activation in the absence of Ca2+e initiated TJ assembly, and this effect occurred without inducing the phosphorylation of AMP-activated protein kinase. Co-immunoprecipitation studies further showed that CaSR activation increases the interaction between ZO-1 and the F-actin-binding protein, afadin-I. By contrast, CaSR inhibition by NPS-2143 (800nM) significantly decreased ZO-1/afadin-I interaction and reduced ZO-1 deposits at cell surface following exposure to culture media containing a 200 μM Ca2+e concentration.

Conclusions: These results suggest that CaSR plays a role in the regulation of TJ assembly during epithelial cell polarization.

PINCH-1 and -2 Are Essential for Podocyte Adhesion, Shape Modulation and Maintenance of Glomerular Filtration Barrier Function Jeffrey B. Hodgin,[1] Hong Qu,[3] Xingqun Liang,[4] Simone M. Blattner,[2] Ka Chen,[3] Courtenay M. Vining,[2] Stephanie Wylie,[2] Masashi Nishio,[2] Ju Chen,[4] Chuanyue Wu,[3] Matthias Kretzler.[2] *[1]Pathology, University of Michigan, Ann Arbor, MI; [2]Nephrology, University of Michigan, Ann Arbor, MI; [3]Pathology, University of Pittsburgh, PA; [4]Medicine, University of California, San Diego, CA.*

Background: PINCH proteins are 5 LIM domain-only adaptor proteins that have a key role in cell-extracellular matrix adhesion and communication by linking integrins to the actin cytoskeleton. Two PINCH proteins that share high homology, PINCH-1 and PINCH-2, are expressed in most cells including podocytes. Podocyte-specific PINCH-1 knockout (KO) or global PINCH-2 KO mice exhibit no basal renal phenotype, which suggests a redundant role for these proteins in the kidney.

Methods: Therefore we crossed podocyte-specific PINCH-1 KO with global PINCH-2 KO mice to generate mice doubly homozygous null for PINCH proteins in podocytes. In addition, PINCH-1 and PINCH-2 expression in human podocytes in culture was 'knocked-down' using siRNA technology.

Results: Though normal at birth, double KO podocyte-specific PINCH-1/2 mice displayed severe proteinuria by 4 weeks of age. Morphologically they display focal segmental and global glomerulosclerosis and ultrastructurally, podocytes display diffuse foot process effacement. By 8 weeks proteinuria and glomerulosclerosis has progressed to encompass most of the nephrons (end-stage renal disease) and death follows. In vitro, single knockdown of either protein resulted in minor defects in cell spreading and cell monolayer permeability to albumin. Double knockdown of both PINCH-1 and PINCH-2 demonstrated more severe defects in cell spreading and permeability, and also showed significant decrease in cell adhesion to fibronectin, suggesting that PINCH proteins are critical for optimal podocyte adhesion and shape modulation.

Conclusions: These results demonstrate essential roles for PINCH proteins in maintenance of podocyte integrity and the glomerular filtration barrier, highlighting the importance of studying the role of PINCH proteins in human glomerular disease.

Loss of Talin 1 in Podocytes Results in Severe Progressive Albuminuria and Kidney Failure Xuefei Tian,[1] Keita Soda,[1] Rena Zheng,[1] Roy Zent,[2] Shuta Ishibe.[1] *[1]Internal Medicine/Nephrology, Yale University, New Haven, CT; [2]Internal Medicine/Nephrology, Vanderbilt University, Nashville, TN.*

Background: Talin 1 (Tln1) is a focal adhesion protein, linking beta integrins to the actin cytoskeleton. The importance of Tln1 in podocyte biology is poorly understood.

Methods: Using the Cre-LoxP system, we generated podocyte specific Tln1 KO mice. Albuminuria and creatinine were measured by ELISA. Kidney histology was analyzed by H.E, PAS, trichrome, and electromicroscopy (EM). Apoptosis was assayed by TUNEL. Primary podocytes were isolated by Dynalbeads and sieving. Adhesion was assayed by crystal violet staining. Immunofluorescence was performed for phalloidin and actin related proteins.

Results: Tln1 KO mice were born in the expected mendelian frequency. Compared to wild type littermates, KO showed failure to gain weight by 3 weeks (gms. WT: 9.7±0.4, KO: 7.3±0.4. n=9. P<0.01), progressive albuminuria which started 2 weeks after birth (ug albumin /mg creatinine (WT vs KO): 2 weeks: 21.46±3.29 vs 942.10±69.42; 4 weeks: 16.60±0.97 vs 1357.60±72.08; 6 weeks: 15.68±2.19 vs 1798.60±115.60; 8 weeks: 18.04±3.23 vs 3021.60±469.93. n=4) , and kidney failure (serum creatinine (mg/dl) (WT vs KO): 2 weeks: 0.25±0.15 vs 0.72±0.33; 4 weeks: 0.21±0.13 vs 0.96±0.25; 8 weeks: 0.24±0.12 vs 1.25±0.35. n=6) . The majority of Tln1 KO mice were dead by 8 weeks. Histological examination in Tln1 KO mice revealed glomerular capillary loop dilation which progressed to glomerulosclerosis, and interstitial fibrosis. EM demonstrated foot process effacement and basement membrane thickening. TUNEL staining of kidney sections demonstrated no significant difference in podocyte apoptosis between KO and WT mice at P14. Isolated podocytes from KO demonstrated modest reduction in adhesion on type I collagen and beta 1 integrin activation (OD: WT: 0.28±0.03, KO: 0.19±0.02, n=6, p<0.01). However, Tln1 KO podocytes had a major reduction in stress fiber formation compared to WT.

Conclusions: Loss of Tln1 specifically in mice podocytes results in severe albuminuria progressing to kidney failure and death by 8 weeks of age, suggesting its fundamental role in regulating the structural integrity of the glomerulus.

Requisite Role for Nephrin Tyrosine Phosphorylation in Podocyte Morphology and Response to Injury Laura A. New,[1] Bozena Samborska,[1] Vera Eremina,[2] Susan E. Quaggin,[2,3] Nina Jones.[1] *[1]Molecular and Cellular Biology, University of Guelph, ON, Canada; [2]Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, ON, Canada; [3]Division of Nephrology, St. Michael's Hospital, Toronto, ON, Canada.*

Background: Nephrin is a key component of the kidney slit diaphragm that contributes to podocyte foot process morphology and filtration barrier function. In addition to its structural role, nephrin also serves as an intracellular signalling scaffold through its ability to undergo tyrosine phosphorylation and recruit adaptor proteins, such as Nck, to the slit diaphragm, where they link nephrin to the actin cytoskeleton. However, the physiological significance of nephrin tyrosine phosphorylation and its role in the development of glomerular disease is not well understood.

Methods: To investigate the role of nephrin phosphotyrosine-based signalling in vivo, we have generated mice in which the tyrosine residues at all three complementary Nck binding sites have been altered to phenylalanine to prevent their phosphorylation (herein referred to as nephrinY3F mice).

Results: NephrinY3F mice with disrupted nephrin signalling develop progressive and significant proteinuria beginning at approximately three months of age, and this is accompanied by glomerulosclerosis and widespread foot process effacement. Furthermore, several podocyte signalling proteins appear to be mislocalized from a linear into a granular pattern in nephrinY3F mice. Finally, prior to the onset of proteinuria, nephrinY3F mutant mice display an enhanced susceptibility to podocyte injury induced by nephrotoxic challenge.

Conclusions: Taken together, this model demonstrates that nephrin signalling through these conserved tyrosine motifs is required for maintenance of the glomerular blood filtration barrier. Our findings are consistent with the observation that nephrin phosphorylation is reduced in some glomerular diseases, and they suggest that phosphotyrosine-based signalling pathways at the kidney slit diaphragm provide highly dynamic control over foot process morphology.

GLEPP1 Reduces Endocytosis of Nephrin Eva Koenigshausen, Sarah Grabowski, Laura Gerbaulet, Ivo Quack, Magdalena Woznowski, Paul Probst, Sebastian Alexander Potthoff, Lars C. Rump, Lorenz Sellin. *Nephrology, Heinrich Heine University, Duesseldorf, Germany.*

Background: GLEPP1 is a receptor tyrosine phosphatase expressed in the apical membrane of foot processes. GLEPP1 expression is reduced in proteinuric kidney diseases. Previously we could show that the interaction of nephrin with podocin and β-arrestin2 and endocytosis of nephrin is regulated by src family kinases. This observation led to the concept of the dynamic regulation of the glomerular slit diaphragm. GLEPP1 was implicated to be a protective factor for the glomerular slit. We hypothesize a protective regulatory role for GLEPP1 in respect to nephrin endocytosis.

Methods: We used cells expressing GLEPP1 and nephrin, podocin, src, fyn, β-arrestin2 or paxillin. After cell lysis, co-immunoprecipitation with subsequent western blot analysis was performed. For immunofluorescence, cells expressing GLEPP1 and paxillin.GFP were fixed and permeabilized thereafter. GLEPP1 was visualized by immunofluorescence.

Results: GLEPP1 interacts with the slit diaphragm proteins nephrin and podocin as well as with the src family kinases src and fyn. Furthermore, GLEPP1 enhances the interaction of nephrin with podocin and reduces the interaction of nephrin with β-arrestin2. GLEPP1 dephosphorylates src and fyn at their regulatory Y527. The interaction of src/fyn with a substrate trapping mutant of GLEPP1 is enhanced compared to the wild-type phosphatase which indicates that src and fyn are indeed substrates of GLEPP1. GLEPP1 reduces nephrin endocytosis. In addition, GLEPP1 expression induces cytoskeletal rearrangement.

Conclusions: The integrity of the glomerular slit diaphragm is regulated by src kinase mediated tyrosine phosphorylation of the nephrin C-terminus. We have substantial evidence that GLEPP1 activates src family kinases through interaction and dephosphorylation of src family kinases at their regulatory domain. Activated src family kinases consequently

increase nephrin tyrosine phosphorylation at its C-terminus. Additionally, GLEPP1 seems to force cytoskeletal changes which might be of importance maintaining the delicate shape of healthy foot processes. Via this mechanism, GLEPP1 may support the integrity of the slit diaphragm.

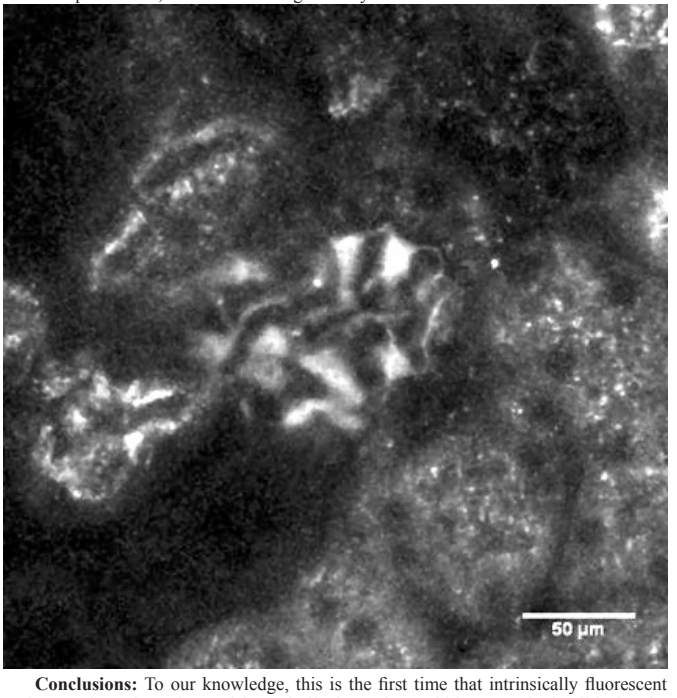
TH-OR032

Intravital Multiphoton Imaging of Mouse Podocytes Mark Fadi Khayat,[1] Charbel C. Khoury,[1] Tet-Kin Yeo,[1] Petr Pyagay,[1] Weiming Yu,[2] Sheldon C. Chen.[1] *[1]Nephrology/Hypertension, Northwestern University, Chicago, IL; [2]Physiology, Northwestern University, Chicago, IL.*

Background: Multiphoton intravital microscopy (MPIM) is an ideal methodology, due to its minimal phototoxicity, to image podocytes in their native glomerular environment. However, most glomeruli in the mouse lie beyond the maximum imaging depth of MPIM in the kidney, which is 150 to 200 μm. We intend to show that intravital imaging of murine podocytes is now feasible with the nephrin knockout/green fluorescent protein (GFP) knock-in mouse (Nphs1tm1Rkl/J).

Methods: The Nphs1tm1Rkl/J mouse was genetically designed to have the nephrin promoter restrict GFP expression to the podocyte in the kidney. Under anesthesia, the mice were perfused with 500-KDa Texas Red dextran via the retro-orbital sinus, using a 28G insulin syringe. The left kidney was then exposed and imaged through a custom-built window on an upright multiphoton microscope.

Results: Optical sections of the renal cortex revealed green fluorescent podocytes, clearly resolvable down to their primary processes, as they lined the glomerular capillaries perfused with Texas Red dextran. In the female Nphs1tm1Rkl/J mouse, the glomerular depth was as shallow as 60 μm. This allowed detailed intravital microscopy of an intact kidney, avoiding the need for surgical sectioning of the renal cortex and enabling repeat imaging in the same mouse. Multiple time-lapse series of different glomeruli were collected, typically for hours per session, while maintaining viability of the mouse.



Conclusions: To our knowledge, this is the first time that intrinsically fluorescent podocytes have been imaged intravitally in an intact kidney, made feasible by the proximity of the glomeruli to the kidney capsule. Our technique offers the opportunity to add a visual and temporal component to the study of podocytopathies in the multitude of mouse models.

TH-OR033

Lack of Functioning HVPS34 in Podocytes Disrupts Cellular Homeostasis and Causes Significant Proteinuria Jianchun Chen, Raymond C. Harris, Jian-Kang Chen. *Medicine, Vanderbilt University, Nashville, TN.*

Background: Podocyte injury is a leading factor of many glomerular diseases and renal failure. Recent studies suggest that autophagy is a key mechanism maintaining the integrity of podocytes. HVPS34 (the homologue of yeast vacuolar protein sorting defective 34 in mammalian cells) has been implicated in the regulation of autophagy, but its role in podocytes has not previously been explored.

Methods: We generated a HVPS34-floxed mouse ($HVPS34^{flox/flox}$) and crossed with Podocin-Cre mice to produce podocyte-specific HVPS34 knockout mice ($HVPS34^{pdKO}$) and compared them with their $HVPS34^{flox/flox}$;Podocin-$Cre^{(-)}$ wild type littermates (*WT*).

Results: $HVPS34^{pdKO}$ mice were smaller (11.86 ± 0.72g, N=7 vs. *WT*: 20.55 ± 0.95g, N=6-7; P<0.0001) without any differences in kidney weight/body weight. $HVPS34^{pdKO}$ developed significant proteinuria at the age of 6 weeks (Alb/Cre (mg/mg): *WT*: 4.020 ± 1.264, vs. $HVPS34^{pdKO}$: 127.9 ± 16.16, N=6-7; P<0.0001). There was striking vacuolization of podocytes in the glomeruli as well as numerous protein casts. Electron microscopy indicated the vacuolated podocytes were filled with numerous autophagic vacuoles and enlarged lysosomes, with foot process effacement/fusion. The GBM was also irregular and thickened. Immunofluorescent staining for the lysosomal marker protein, LAMP1, confirmed that the majority of the vacuoles in the podocytes were LAMP1-positive. Podocin protein levels of the podocytes were markedly down-regulated, revealing a key role for HVPS34 in maintaining the cellular homeostasis of the podocytes.

Conclusions: These novel findings indicate an essential role for HVPS34 to protect the normal cellular metabolism, structure and function of podocytes.

TH-OR034

Inhibition of mTOR in Mice Alters Autophagic Flux in Podocytes and Other Renal Cell Types Davide Pietro Cina,[1,2] Tuncer Onay,[2] Aarti Paltoo,[2] Javier De Arteaga,[3] Chengjin Li,[2] Susan E. Quaggin.[1,2] *[1]Faculty of Medicine, University of Toronto, ON, Canada; [2]Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, ON, Canada; [3]Division of Nephrology, Hospidal Privado, Cordoba, Argentina.*

Background: Inhibitors of the mammalian target of rapamycin (mTOR inhibitors) belong to a family of drugs with potent immunosuppressive, anti-angiogenic and anti-proliferative properties. Although they are approved for the treatment of a number of renal diseases, the use of mTOR inhibitors has been associated with a significant incidence of de novo or worsening proteinuria.

Methods: Here we explore the mechanism of proteinuria induced by mTOR inhibition through the generation and characterization of mice carrying a podocyte-selective knockout (mTOR pod-KO) or global postnatal knockout of the mTor gene resulting in a loss of both mTORC1 and mTORC2 functions.

Results: Our results show that while mTOR is dispensable in developing podocytes, mTOR pod-KO mice develop nephrotic-range proteinuria by 3 weeks of age, and progress to endstage renal failure by 5 weeks of age. Human podocytes treated with the mTOR inhibitor rapamycin accumulate autophagolysomes, damaged mitochondria and increased levels of reactive oxygen species. In vivo, podocytes of mTOR pod-KO mice exhibit an accumulation of the autophagosome marker LC3 (rat microtubule-associated protein 1 light chain 3), autophagosomes, autophagolysosomal vesicles and damaged mitochondria. Global postnatal deletion of mTOR affects all renal cells leading to marked enhancement of renal injury, demonstrating that mTOR function is not only important for podocytes, but also for the tubular epithelium.

Conclusions: Taken together, our results suggest that disruption of the autophagic pathway may play a role in the pathogenesis of proteinuria in patients treated with mTOR inhibitors and that multiple renal cell types may be affected.

Translational Profiling of Podocytes in Focal Segmental Glomerulosclerosis Ivica Grgic,[1] Giulio Genovese,[2] Martin R. Pollak,[2] Benjamin D. Humphreys.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]BIDMC, Boston, MA.*

Background: Identifying new biomarkers and therapeutic targets for podocytopathies such as focal segmental glomerulosclerosis (FSGS) requires a detailed understanding of the earliest events in disease pathogenesis. Transcriptional profiling has already provided important insight into gene expression changes in FSGS. Yet, a key limitation of this approach to define the podocyte transcriptome in FSGS has been the analysis of whole glomerular mRNA rather than podocyte-specific mRNA.

Methods: We have engineered a novel transgenic mouse line that allows extraction of podocyte-specific mRNA from whole kidney by translating ribosome affinity purification (TRAP). In this model, a GFP-tagged ribosomal protein (eGFP-L10a) was expressed under the control of the collagen 1α1 promoter.

Results: Expression of eGFP-L10a was restricted to podocytes in kidney cortex. Expression analysis of TRAP-isolated RNA by whole genome arrays confirmed robust enrichment of podocyte-specific mRNA (podocin: ~60-fold, nephrin: ~32-fold, MYH9: ~47-fold compared to whole cortex), permitting establishment of a podocyte expression fingerprint. We next crossed col1α1-L10a mice with actn4+/- and mutant actn4+/K228E mice to study expression profiles of podocytes in a genetic form of FSGS. RNA was extracted by TRAP from cortex of bigenic col1α1-L10a;actn4-/- and col1α1-L10a;actn4+/K228E and single-transgenic col1α1-L10a littermate controls at 2 and 6 weeks of age. Regression analysis comparing podocyte expression profiles between genotypes with age as a covariate identified significantly up- and downregulated genes, including Cxcl1 (~12-fold up, p<0.0001) and Gadd45b (~5-fold up; p<0.001) for actn4-/- vs actn4+/+ and DMPK (~5-fold up; p<0.0001) for actn4+/K228E vs. actn4+/+. We confirmed some of the largest changes in gene expression at the protein level by immunostaining.

Conclusions: In conclusion, we have developed a new approach to define podocyte-specific gene expression in vivo. We used this technique in a model of FSGS and identified new candidate genes that hold promise in elucidating the earliest signaling events in FSGS, and thereby provide potential new therapeutic targets for FSGS.

Multiphoton Imaging of the Development of Glomerulosclerosis In Vivo
James L. Burford,[1] Andy Salmon,[1,2] Anush Gevorgyan,[1] Janos Peti-Peterdi.[1] *[1]Dept. of Physiology, Medicine, University of Southern California; [2]Dept. of Physiology and Pharmacology, University of Bristol, United Kingdom.*

Background: The development of podocyte injury/dysfunction and albuminuria in glomerulosclerosis (GS) are still incompletely understood due to technical limitations in studying the glomerular filtration barrier (GFB) in its native environment in vivo. We aimed to directly visualize the early morphological and functional changes in GFB using in vivo multiphoton microscopy (MPM) and the puromycin (PAN) model of focal segmental GS.

Methods: Munich-Wistar-Fromter rats (200 g) were given 100 mg/kg body weight PAN ip and surgically instrumented for MPM 4-10 days later. The plasma was labeled using albumin-Atto565, and Lucifer yellow (LY) was infused into the carotid artery to visualize GFB elements.

Results: Hypertrophy and cystic dilatations of the sub-podocyte space developed in several, but not all podocytes 4 days after PAN. The largest podocyte cysts, as the core structure, formed small, focal adhesions of the glomerular tuft to the parietal Bowman's capsule (synechiae) 7-10 days after PAN. The thin podocyte wall of these core cysts were highly permeable to albumin indicated by the intense red fluorescence of cyst fluid. Intact, healthy podocytes (normal shape and no albumin permability) were also observed making contact with parietal cells in other glomerular regions, but never developed synechiae. Numerous new, densely packed small cells that appeared to be healthy and migrating were observed on the outside of the core cysts, forming a continuous cell layer (bridge) between podocytes and parietal cells. Interestingly, most synechiae were positioned next to a collecting duct segment; intense infiltration of immune cells with high albumin uptake was visible in this region of the periglomerular interstitium. Similar results were obtained in 3-6mo old MWF rats, a model of spontaneous FSGS.

Conclusions: In several animal models of GS, high albumin permeability is focal, restricted to the most injured podocytes and to the area of synechiae. The formation of synechiae appears to involve multiple intra- and extraglomerular cell types. Signs of podocyte repair (replacement) were evident, but their mechanism needs further study.

Novel Concepts in Nephrotic Syndrome: Angiopoietin-Like 4 Induced Hypertriglyceridemia Results from a Multisystem Effort To Reduce Proteinuria
Lionel C. Clement, Camille E. Mace, Sumant S. Chugh. *Medicine/Nephrology, University of Alabama at Birmingham, AL.*

Background: Hypertriglyceridemia is a cardinal feature of nephrotic syndrome. A recent study (Clement Nature Medicine 2011) shows that podocyte secreted, but not circulating Angiopoietin-like-4 (Angptl4) also noted in minimal change disease, induces proteinuria. Here, we investigated the role of circulating Angptl4 in nephrotic syndrome.

Results: Circulating Angptl4 is known to inhibit endothelium bound lipoprotein lipase, which reduces tissue uptake of triglycerides from circulation, resulting in hypertriglyceridemia. We induced the gamma2-NTS and LPS models of proteinuria in Angptl4 -/- and +/+ mice. Angptl4 -/- mice did not develop hypertriglyceridemia despite significant residual proteinuria, suggesting that Angptl4 is the key determinant of hypertriglyceridemia in nephrotic syndrome. Next, we studied albuminuria in adipose tissue specific Angptl4 transgenic rats (aP2-Angptl4), that have hypertriglyceridemia due to increased circulating Angptl4, and noted reduced albuminuria in transgenic compared to wild type rats ($P<0.05$). Induction of PAN in these rats caused lower levels of proteinuria (Day 8 wild type 315±2 mg/18 hours, transgenic 194±25 mg/18 hours, mean + SE, $P<0.05$). Immunogold EM showed binding of Angptl4-V5 to glomerular endothelial surface. Cultured rat glomerular endothelial cells were protected from oxidative stress by recombinant neutral pI Angptl4 similar to that present in the circulation ($P<0.001$). By inducing puromycin nephrosis in podocyte specific Angptl4 transgenic rats (NPHS2-Angptl4), we determined that beyond the initial stages, the bulk of the circulating Angptl4 is contributed to by peripheral tissues, predominantly adipose tissue. In addition, injection of recombinant neutral pI Angptl4 reduces proteinuria in multiple animal models of proteinuria.

Conclusions: Our studies suggest that in later stages of nephrotic syndrome, adipose tissue secretes Angptl4 into the circulation to reduce proteinuria by glomerular endothelial stabilization, but this increase in circulating Angptl4 also results in hypertriglyceridemia.

Acute Podocyte VEGF-A Knockdown Disrupts αVβ3 Integrin Signaling in the Glomerulus
Delma Veron,[1] Guillermo A. Villegas,[2] Pardeep Kumar Aggarwal,[1] Claudia A. Bertuccio,[1] Heino Velazquez,[1] Gilbert W. Moeckel,[1] Michael Kashgarian,[1] Alda Tufro.[1] *[1]Yale University School of Medicine, New Haven, CT; [2]AECOM, Bronx, NY.*

Methods: To study the molecular mechanism involved in the pathogenic effects of podocyte VEGF-A knockdown, we developed a mouse model that silences all VEGF-A isoforms in the podocyte using an inducible shRNA approach, and we generated an immortalized podocyte cell line ($VEGF^{KD}$) that downregulates VEGF-A upon doxycycline exposure.

Results: *Tet-O-siVEGF:podocin-rtTA* (*siVEGF*) mice express VEGF shRNA in podocytes in a doxycycline-regulated manner, decreasing VEGF-A mRNA and VEGF-A protein levels in isolated glomeruli to ~20% of non-induced controls and urine VEGF-A to ~30% of control values a week after doxycycline induction. VEGF knockdown in adult *siVEGF* mice causes acute renal failure and proteinuria, associated with decreased glomerular volume, mesangiolysis and microaneurisms. Glomerular ultrastructure revealed endothelial cell swelling, GBM lamination and podocyte effacement. VEGF knockdown downregulates podocyte fibronectin and glomerular endothelial αVβ3 integrin in vivo, as determined by immunoblotting and dual-labeling immunohistochemistry. Co-immunoprecipitation showed that VEGFR2 interacts with β3 integrin and neuropilin-1 in the kidney in vivo and in cultured podocytes. Podocyte VEGF knockdown disrupts αvβ3 integrin activation in glomeruli, as determined by WOW1 Fab immunolabeling, while VEGFR2-αvβ3 integrin interaction and phosphorylation remain intact. VEGF silencing in cultured $VEGF^{KD}$ podocytes downregulates fibronectin and disrupts αvβ3 integrin activation cell-autonomously.

Conclusions: 1) *In vivo* podocyte VEGF-A regulates αvβ3 integrin signaling in the glomerulus; 2) decreased autocrine and paracrine VEGFR2 signaling induced by podocyte VEGF knockdown disrupts VEGFR2 - αvβ3 integrin crosstalk and damages the three layers of the glomerular filtration barrier, resulting in proteinuria and acute renal failure. The present studies uncover a specific molecular mechanism mediating VEGF-A requirement in the adult glomerulus, i.e. activation of αvβ3 by VEGFR2 signaling.

TGF-β1 Signals through Smad4 to Diversely Regulate Renal Inflammation and Fibrosis by Impairing TGF-beta/Smad3 and Smad7 Transcriptionally
Xiaoming Meng, Xiao Ru Huang, Jun Xiao, Wei Qin, Haiyong Chen, Arthur Chi-Kong Chung, Hui Y. Lan. *Department of Medicine and Therapeutics, Li Ka Shing Institute of Health Sciences, The Chinese University of Hong Kong, Shatin, NT, Hong Kong, China.*

Background: TGF-β1 plays distinct roles in renal inflammation and fibrosis, but signaling mechanisms by which TGF-β1 diversely regulates these processes remain largely unclear. The present study tested the hypothesis that Smad4 may be a key regulator of TGF-β signaling in renal disease.

Methods: We first generated the kidney-specifically conditional Smad4 KO mouse by crossing $Smad4^{F/F}$ to KspCre mouse in which Smad4 was specifically deleted from tubular epithelial cells. To determine the functional role of Smad4 in renal inflammation and fibrosis, a mouse model of unilateral ureteral obstructive nephropathy (UUO) was induced in conditional Smad4 KO mice. Furthermore, role and mechanisms of Smad4 in regulating renal inflammation and fibrosis were investigated in vitro in macrophages and fibroblasts that lack Smad4.

Results: Disrupted Smad4 significantly enhanced renal inflammation by a much greater CD45+ leukocyte(25% ↑) and F4/80+ macrophage infiltration (60%↑) and upregulation of IL-1β, TNFα, and MCP-1 in the UUO kidney and in IL-1β-stimulated macrophages (all $p<0.05$). In contrast, deletion of Smad4 inhibited kidney fibrosis and TGF-β1-induced collagen I expression by fibroblasts ($p<0.01$). Further studies revealed that loss of Smad7 and its responsive promoter activity, thereby inhibiting IκBa expression while enhancing NF-κB activation, were a central mechanism by which disrupted Smad4 promoted renal inflammation. Interestingly, impaired Smad3 transcription such as Smad3 responsive promoter activities and the binding of Smad3 to collagen promoter (COL1A2), but not Smad3 activation, was an underlying mechanism whereby disrupted Smad4 blocked fibrosis in vivo and in vitro.

Conclusions: TGF-β1 acts by stimulating Smad4 to diversely regulate renal inflammation and fibrosis. Transcriptionally impaired Smad7-dependent anti-inflammatory activity and Smad3-mediated fibrogenesis may be key mechanisms by which disrupted Smad4 enhances renal inflammation while inhibiting fibrosis in vivo and in vitro.

Dot1 Deficiency Facilitates Derivation of Renal Intercalated Cells from AQP2-Positive Cells and Increases Water Excretion Hongyu Wu,[1] Lihe Chen,[1] Qiaoling Zhou,[2] Mary R. Reisenauer,[1] Stefan Berger,[3] Günther Schütz,[3] Dennis Brown,[4] Hua Ann Jenny Lu,[4] Yang Xia,[1] Wenzheng Zhang.[1] *[1]University of Texas Medical School at Houston; [2]Central South University; [3]German Cancer Research Center; [4]Massachusetts General Hospital and Harvard Medical School.*

Background: The mammalian kidney has three distinct types of collecting duct cells: principal cells (PC), α-intercalated cells (α-IC) and β-intercalated cells (β-IC), which are responsible for sodium and water balance, acid secretion, and bicarbonate secretion, respectively. The epigenetic players regulating differentiation of these cells remain elusive. Histone H3 K79 methyltransferase Dot1 may regulate this process as it is expressed in PC in mouse kidney.

Methods: To test this hypothesis, the Cre-LoxP system was used to develop a mouse model lacking Dot1 in AQP2-expressing cells (Dot1f/f AQP2Cre). Double immunofluorescence staining and metabolic analysis were performed to identify the cellular and renal phenotype.

Results: With AQP2 and V-ATPase subunits B1/B2 as PC and IC markers, respectively, we found that the mutant mice had ~20% fewer PC in cortex, outer medulla and inner medulla vs controls. This change was coupled with a similar increase in α-IC, featured by AE1 expression. Dot1 deletion in PC abolished histone H3 K79 methylation and had no effect on total H3 or methylation of all other H3 residues tested. Unexpectedly, 68-75% of ICs in Dot1 mutant mice also had no detectable H3 K79 methylation. At least some of these IC also expressed other IC markers (V-ATPase subunit A and carbonic anhydrase II) and/or the β-IC marker pendrin. In contrast, all PC and IC in controls had H3 K79 methylation. The mutants had significantly increased urine volume (by 40%), 18% decreased urine osmolarity, and 12% lower urinary [Na+] vs. controls.

Conclusions: We show here that Dot1 is solely and specifically responsible for H3 K79 methylation in mouse kidney, and at least some α-IC and β-IC may be derived from AQP2-expressing progenitor cells or can be derived from mature PC. We have, in conclusion, identified Dot1 as a new regulator of PC and IC differentiation and, thus, water, Na+ and possibly pH regulation.

CTGF Influences Blood Pressure and Albumin Excretion in Mice Leighton R. James,[1,2] Catherine Le.[2,3] *[1]Medicine, University of Florida, Jacksonville, FL; [2]Medicine, UT Southwestern Medical Center, Dallas, TX; [3]Department of Cellular and Molecular Biology, Colorado State University, Fort Collins, CO.*

Background: CTGF (CCN2) is a pleiotropic growth factor belonging to the 30-40kDa CCN family of proteins that have been shown to exhibit a diverse array of cellular effects. We, and others, have shown that reduced ctgf expression attenuates the response to hyperglycemia. CTGF protein levels are increased in resistance and capacitance vessels in spontaneously hypertensive rats (SHR) and maneuvers that reduce blood pressure also lead to reduced CTGF expression. Given the role of CTGF in extracellular matrix production, it is proposed that ctgf expression will impact on glomerular physiology and function.

Methods: The potential effect(s) of CTGF on blood pressure, albumin excretion and kidney histopathology was tested in mice models. We studied CTGF knockout and gene-duplicated mice, both generated through gene targeting using standard gene-targeting methodologies.

Results: We observed a graded increase in CTGF gene expression with increasing gene copy number. There was no significant difference in expression between mice or mice embryonic fibroblasts (MEFs) with 3 and 4 copies of ctgf, suggesting a possible plateau effect in which expression does not increase above a specific number of copies of ctgf gene. Analysis of blood pressure by automated tailcuff method revealed an increasing mean systolic blood pressure with ctgf gene copy-number, suggesting that ctgf expression may influence blood pressure in this line of mice. There was attenuation of basal albumin excretion rate (AER) in CTGF heterozygotes and increased excretion in 3-copy animals compared to 2-copy (wt) mice. In 9 month mice, there was evidence of increased interstitial fibrosis in kidney sections from 3- and 4-copy animals compared with wildtype and heterozygous age-matched animals.

Conclusions: These observations suggest that CTGF expression may be a determinant of blood pressure and kidney function in mice.

The Role of Erythropoietin Receptors in Kidney Disease Progression Masayuki Takase,[1] Jin Nakamura,[1] Atsushi Fukatsu,[1] Masayuki Yamamoto,[2] Motoko Yanagita.[1] *[1]Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]Graduate School of Medicine, Tohoku University, Sendai, Miyagi, Japan.*

Background: Erythropoietin (EPO) is a hormone indispensable for red blood cell production, and mainly produced in the fibroblast-like cells in the kidney after birth. In addition to the role in erythropoiesis, potential protective activity of EPO is reported in various tissues. EPO binds to receptor complex consisting of EPO receptor (EPOR) and ß common receptor (CD131) subunit for tissue protective effect, while it binds to homodimeric EPOR for maturation of erythrocytes. However molecular mechanism and the contribution of endogenous EPO in tissue protection remained elusive.

Methods: In the present study, we analyzed the renoprotective function of endogenous EPO utilizing EPOR knock out mice.

Results: First we analyzed the expression of EPO receptors during kidney injury. The expression of EPOR was decreased whereas the expression of CD131 was increased in mouse models of kidney disease. We further demonstrated that the administration of EPO significantly ameliorated renal dysfunction, and restored the expression of EPOR in cisplatin nephrotoxicity.

We further analyzed renal phenotypes of EPOR null mutant mice expressing EPOR in hematopoietic lineage (EpoR-/-:Tg mice). In the baseline analysis, kidney function, blood pressure and histological observation in the kidney of EpoR-/-:Tg mice was indistinguishable from those of EpoR+/+:Tg mice, while serum EPO concentration of EpoR-/-:Tg mice was higher than that of EpoR+/+:Tg mice. EPO expression in the kidney, liver, brain and testis was indistinguishable between both genotypes, suggesting that elevated serum EPO concentration in EpoR-/-:Tg mice might be due to lack of endocytosis via EPOR. We also induced cisplatin nephrotoxicity to both genetypes, and found that the expression of osteopontin and TGF-β in the kidney of EpoR-/-:Tg mice was higher than that of EpoR+/+:Tg mice

Conclusions: Taken together, endogenous EPO exerts tissue protective function during kidney injury.

Rap1b Ameliorates the DN Progression Via Modulating Mitochondrial Homeostasis Lin Sun,[1] Xuejing Zhu,[1] Li Xiao,[1] Guanghui Ling,[1] Yashpal S. Kanwar,[2] Fu-You Liu,[1] You-Ming Peng.[1] *[1]Dep. Nephrology, Second Xiangya Hospital, Central South University, Changsha, Hunan, China; [2]Dep. Pathology, Northwestern University, Chicago, IL.*

Background: We have demonstrated that Rap1b modulates the progression of diabetic nephropathy (DN), and ameliorates glucose-induced mitochondrial dysfunction in renal tubular cells (KI 2001, JBC 2002, JASN 2008) , However, it is unclear whether or how Rap1b can protect the tubular cell from damage induced by hyperglycemia.

Methods: 12 DN patients were observed and 24 Rats with STZ-induced DN were used in this study. Rap1b gene was transferred into the kidney of rats with DN by an ultrasound-microbubble-mediated technique(UMT). Immuno-EM was used to evaluate the localization of Rap1b in mitochondria of HK2 cell. Gene and protein expression analyses were carried out by the QPCR, Western blotting and IF. Mitochondrial functional analysis were carried out by measuring ROS, TMRE, ATP and mitochondrial apotosis genes.

Results: Rap1 expression was decreased in renal proximal tubular cells of DN patients, which was related to the tubular atrophy and decreased tubular functions. Although overexpression of Rap1b in DN Rats by UMT had no effect on blood glucose levels, it significantly attenuated the development of microalbuminuria, inhibited mitochondria mediated renal tubular cells death and ameliorated mitochondrial dysfunctions in proximal tubular cells. *In vitro*, Rap1b expression was localized to mitochondrial cristae of HK2 cells. Compared to control, 30 mM D-gluocse (HG) induced mitochondrial dysfunction, altered mitochondrial morphology, transmembrane potential, ATP levels, increased expression of mitochondrial fission gene Drp1. While a decreased expression of mitochondrial fusion gene in HK2 cells was observed. In addition, HG enhanced the overproduction of mitochondrial superoxide, decreased antioxidant enzymes and mitochondrial biogenesis genes expression. Increased expression of apoptosis related gene and protein expression was observed, and these effects were partially reduced with the transfection of Rap1b in HK2 cells.

Conclusions: These data indicate that Rap1b is capable of dampening the DN progression via modulating mitochondrial homeostasis.

Bif-1 Regulates Mitochondrial Dynamics during ATP Depletion-Induced Apoptosis Sunggyu Cho,[1] Zheng Dong.[1,2] *[1]Department of Cellular Biology and Anatomy, Georgia Health Science University, Augusta, GA; [2]Charlie Norwood VA Medical Center, Augusta, GA.*

Background: Originally identified as a Bax-interacting factor, Bif-1 has sequence homology to endophilins and is also called endophilin B1. Nevertheless, Bif-1 does not play an essential role in membrane trafficking or endocytosis. It has been suggested that Bif-1 may contribute to mitochondrial damage and the consequent release of apoptotic factors during apoptosis. However, it is largely unclear how Bif-1 regulates mitochondria under these conditions.

Methods: In this study, we have examined the role of Bif-1 in mitochondrial regulation during ATP-depletion-induced apoptosis.

Results: In renal proximal tubular cells, Bif-1 translocated to mitochondria during ATP-depletion. Knockdown of Bif-1 in these cells suppressed apoptosis. Consistently, Bif-1-knockout mouse embryonic fibroblasts (MEFs) were resistant to ATP-depletion-induced apoptosis. Interestingly, Bif-1 knockout did not affect Bax translocation to mitochondria during ATP-depletion, but it prevented cytochrome c release from mitochondria. Mitochondrial fragmentation induced by ATP-depletion was markedly suppressed in Bif-1-knockout cells, suggesting that Bif-1 may participate in changes of mitochondrial dynamics resulting in mitochondrial damage. Mechanistically, Bif-1 was shown to interact with prohibitin-2, which regulates OPA1, a key regulator of mitochondrial inner membrane fusion.

Conclusions: Together, the results reveal a novel pathway of mitochondrial regulation by Bif-1 during apoptosis.

Cathepsin-Mediated Depletion of Sirtuin-1 (SIRT1) in Endothelial Progenitor Cells (EPC) Jun Chen,[1] Eliza Moskowitz-Kassai,[1] Robert Chen,[1] Connie Y. Lu,[1] Ales Spes,[2] Boris Turk,[2] Michael S. Goligorsky.[1] *[1]Medicine, New York Medical College, Valhalla, NY; [2]Biochemistry and Molecular and Structural Biology, Jozef Stefan Institute, Ljubljana, Slovenia.*

Background: Stress-induced premature senescence (SIPS) of endothelial cells has emerged as a notable contributor to global endothelial cell dysfunction (ECD) in diverse diseases. One of the critical cellular abnormalities mechanistically linked to SIPS is lysosomal dysfunction. In the present study, we attempted to integrate the previous findings on endothelial SIPS with the exponentially growing field of SIRT1 effects on aging processes as applied to senescence of EPC.

Methods: Specifically, we examined the impact of a range of relevant cardiovascular risk factors on the expression of SIRT1, SIPS and apoptosis and documented the role of SIRT1 in the changes of EPC viability.

Results: Furthermore, studies showed reciprocal relations between SIRT1 and p62/SQSTM-1 expression in stressed EPC, thus demonstrating an attendant abnormality of autophagy. The described effects of stressors could be partially mimicked by inducing lysosomal membrane permeabilization or inhibiting autophagy and effect of stressors could be reversed by a cell-permeable inhibitor of cathepsins. Here we provide evidence, for the first time, that SIRT1 is an important substrate of cysteine cathepsins B, S and L. An antioxidant/peroxynitrite scavenger, ebselen, shown in the previous studies to protect endothelial cells and EPC from SIPS, prevented stress-induced SIRT1 depletion and subversion of autophagy by mitigating lysosomal dysfunction.

Conclusions: 1) these data advance the concept of "stem cell aging" by establishing the critical role of lysosomal dysfunction in the development of SIPS through the cathepsin-induced depletion of SIRT1, a hitherto hidden mechanism linking cell stress with apoptosis or SIPS; 2) Ebselen potently protects lysosomal membrane integrity, preventing cathepsin-induced cleavage of SIRT 1 in murine EPC, as well as blunting SIPS and apoptotic cell death induced by relevant cardiovascular stressors; 3) The proposed mechanism of SIRT1 depletion in stress has all the attributes of being a paradigm of SIPS.

TH-OR046

Protein Domains of Kidney Injury Molecule 1 That Mediate Phagocytosis and Induction of Autophagy Craig R. Brooks, Joseph V. Bonventre. *Medicine/Renal, Brigham and Women's Hospital, Boston, MA.*

Background: Autophagy has been shown to protect against acute kidney injury *in vitro* and *in vivo*. We have found that Kidney injury molecule-1 (KIM-1) expression induces autophagy, which is enhanced following phagocytosis. Kim-1 is a type I transmembrane phosphatidylserine receptor which is highly upregulated by proximal tubule cells in the injured kidney. Upon recognition, Kim-1 induces the phagocytosis of apoptotic cells, ox-LDL and other ligands. To identify regions of KIM-1 important for its functions and for therapeutic targeting, we examined which domains of Kim-1 are important for phagocytosis and autophagy.

Methods: We utilized KIM-1 constructs which have mutations in the phosphatidylserine binding site or which produce truncated proteins lacking either the extracellular domain or the cytosolic domain. Phagocytosis was studied by the uptake of fluorescently labeled apoptotic cells and oxidized low density lipoprotein. Autophagy was measured by formation of LC3-GFP puntae and LC3-II bands by western blot analysis.

Results: Expression of wild-type KIM-1 induces autophagy in renal proximal tubule cells, which is enhanced following phagocytosis. Mutation of the phosphatidylserine binding domain of the protein (which recognizes apoptotic cells) inhibits phagocytosis and blocks autophagy induction. The KIM-1 extracellular domain together with the transmembrane domain of the protein was sufficient to induce both phagocytosis and autophagy. Thus the cytosolic domain of Kim-1 was not required for phagocytosis or autophagy. Indeed, when the cytosolic domain was expressed alone there was no phagocytosis or upregulation of autophagy. In addition, wild-type KIM-1 and KIM-1 ectodomain were found to localize to the autophagosome following phagocytosis, while KIM-1 cytodomain or phosphatidylserine binding site mutants were absent from the autophagosome.

Conclusions: KIM-1 induces autophagy through its phagocytotic function. Targeting of KIM-1 to the autophagosome is also dependent on the phagocytic function of the protein. Both KIM-1 phagocytosis and the role of KIM-1 in autophagy are independent of the intracellular domain of the molecule.

TH-OR040

Signaling Mechanisms for Targeted Inactivation of Epidermal Growth Factor Receptor-Elicited Inhibition of Renal Fibrogenesis Shougang Zhuang.[1,2] *[1]Department of Medicine, Rhode Island Hospital, Brown University School of Medicine, Providence, RI; [2]Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China.*

Background: Although development and progression of renal fibrosis is associated with enhanced activation of epidermal growth factor receptor (EGFR), the underlying mechanisms by which EGFR mediates renal fibrosis remain elusive.

Methods: We used genetic, pharmacologic, in vivo, and in vitro experiments to study the molecular basis of EGFR-mediated renal fibrogenesis.

Results: In a mouse model of obstructive nephropathy, a sustained EGFR phosphorylation was detected in the kidney of wild-type mice, and these mice developed more severe renal fibrosis than waved-2 mice that have reduced EGFR tyrosine kinase activity. Attenuation of renal fibrosis in waved-2 mice was associated with reduced numbers of renal tubular cells arrested at G2/M, inhibition of α-smooth muscle actin (α-SMA) expression, down-regulation of gene expression of multiple profibrogenic cytokines including transforming growth factor-β1 (TGF-β1), and dephosphorylation of Smad3, STAT3 and ERK1/2. This phenotype was fully recapitulated in injured kidney of wild-type mice given gefitinib, a specific EGFR inhibitor. Furthermore, inactivation of either EGFR or STAT3 reduced UUO-induced expression of lipocalin–2, a molecule associated with the pathogenesis of chronic kidney disease. In cultured renal interstitial fibroblasts, inhibition of EGFR also abrogated TGF-β1 or serum-induced phosphorylation of EGFR, STAT3, ERK1/2 and Smad3 as well as expression of α-SMA and extracelluar matrix proteins.

Conclusions: These data suggest that EGFR may mediate renal fibrogenesis via induction of transition of renal epithelial cells to a profibrotic phenotype, overproduction of inflammatory factors, and activation of renal interstitial fibroblasts. Inhibition of EGFR may hold a therapeutic potential for treatment of fibrotic kidney disease.

TH-OR048

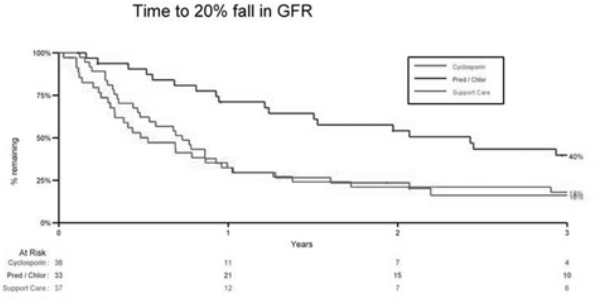
The UK Randomised Controlled Trial of Immunosuppression for Progressive Membranous Nephropathy Peter W. Mathieson. *Academic Renal Unit, University of Bristol, Bristol, United Kingdom.*

Background: Optimal treatment for idiopathic membranous nephropathy (IMN) remains controversial despite numerous controlled trials, not least because the condition has a variable natural history and even severely affected individuals can undergo spontaneous remission. Only a subset of patients (25-30% in most series) develops progressive loss of kidney function and since the available therapies have considerable adverse effects, a prominent school of thought is that aggressive therapy should be reserved for that subgroup.

Methods: In the mid 1990s we embarked on a multicentre randomised controlled trial to compare the three approaches that were popular at that time (and remain so today): six months of alternating cycles of prednisolone and chlorambucil (PC), twelve months of cyclosporine (Cy); or supportive therapy alone (ST) in patients with IMN who had shown a 20% deterioration in excretory renal function.

Results: 108 patients were recruited from centres across the UK (33 randomised to receive PC, 36 Cy, 37 ST, 2 proved ineligible). Recruitment was completed in 2008; analysis commenced when two year follow-up was complete for the last recruited subjects. Primary end-point was a further 20% decline in renal function; secondary end-points were proteinuria and adverse effects.

Regarding renal function, there was a highly statistically significant difference ($p<0.004$) in favour of PC.



Comparisons: Hazard Ratio (95% CI) and p-value
Cyclosporin vs Supportive care. HR 1.17 (0.7, 1.96), 2p=0.5
Prednisolone / Chlorambucil vs Supportive care. HR 0.43 (0.25, 0.76), 2p=0.004

This group also showed the greatest fall in proteinuria. Adverse events were common in all 3 groups, significantly higher in PC and Cy compared to ST but not significantly different between PC and Cy.

Conclusions: We conclude that six months' therapy with prednisolone and chlorambucil is superior to cyclosporine or supportive therapy alone in patients with IMN whose renal function is deteriorating. This effect is maintained to at least 3 years.

Oral Calcitriol for Reduction of Proteinuria in Patients with IgA Nephropathy: A Randomized, Controlled Trial

Lijun Liu,[1] Jicheng Lv,[2] Sufang Shi,[3] Yuqing Chen,[4] Hong Zhang.[5] *[1]Renal Division, Peking University First Hospital, Institute of Nephrology, Peking University, Beijing, China; [2]Renal Division, Peking University First Hospital, Institute of Nephrology, Peking University, Beijing, China; [3]Renal Division, Peking University First Hospital, Institute of Nephrology, Peking University, Beijing, China; [4]Renal Division, Peking University First Hospital, Institute of Nephrology, Peking University, Beijing, China; [5]Renal Division, Peking University First Hospital, Institute of Nephrology, Peking University, Beijing, China.*

Background: Vitamin D has shown efficacy in the reduction of proteinuria in patients with chronic kidney disease. This study aimed to determine the effect of calcitriol on urinary protein excretion in patients with IgA nephropathy.

Methods: In this open-labeled, blank-controlled study, 50 IgA nephropathy patients were enrolled. The main criterion for inclusion was urinary protein excretion greater than 0.8g/d following renin-angiotensin-system (RAS) inhibitor treatment for at least three months. Patients were randomly assigned (1:1) to receive two doses (0.5 μg) of calcitriol per week or no treatment, for 48 weeks. The primary endpoint of urinary protein excretion was measured from the baseline to 24 hours post-treatment. Concentrations of monocyte chemoattractant protein 1 (MCP-1) and transforming growth factor- β (TGF-β) in serum and urine were also measured.

Results: Measurement of the primary endpoint showed changes in the urinary protein excretion of +21% (from 1.29 to 1.58 g/24 h; 95% CI -9 to 52) in the control group and -19% (from 1.60 to 1.30 g/24 h; 95% CI -42 to 4) in the calcitriol-treated group (*p=0.03*). A 15% decrease in proteinuria was measured in controls (7 of 24, 29.2%) and the calcitriol-treated treatment group (17 of 26, 65.4%; *p=0.02*). No significant differences were observed in the decline in the estimated glomerular filtration rate (eGFR) and changes in blood pressure. Incidence of recorded adverse events was similar between the two groups.

Conclusions: Addition of calcitriol to RAS inhibitor resulted in a safe reduction of proteinuria in patients with IgA nephropathy.

Funding: Government Support - Non-U.S.

The Effect on the Microcirculation of Ergocalciferol (Vitamin D2) Versus Placebo in Chronic Kidney Disease 3-4 and Vitamin D Deficiency: A Pilot, Double Blind, Randomised Controlled Trial

Gavin Dreyer,[1] Arthur Tucker,[2] Martin J. Raftery,[1] Magdi Yaqoob.[1] *[1]Renal Unit, Royal London Hospital, United Kingdom; [2]Ernest Cooke Microvascular Unit, Barts and the London NHS Trust, United Kingdom.*

Background: Observational studies have demonstrated reduced cardiovascular disease (CVD) in patients with kidney disease who receive vitamin D therapy. The exact mechanism leading to these observations is unclear and there are very few prospective studies of vitamin D therapy in kidney disease. We conducted a pilot randomised trial testing the hypothesis that vitamin D therapy improves microcirculatory function, a known surrogate marker for future cardiovascular dysfunction and disease.

Methods: 38 non-diabetic, non-transplant patients with CKD 3-4 and vitamin D deficiency (25 OH vitamin D < 40nmol/L) were enrolled. 20 received ergocalciferol as 50,000 iu weekly for 1 month followed by 50,000 iu monthly for 5 months. 18 patients received a matching placebo. The primary endpoint was microcirculatory function after 6 months therapy assessed by % change in skin vessel flux measured by laser doppler flowmetry after iontophoresis of acetylcholine (AcH).

Results: Treatment groups were similar at baseline with respect to age, sex, eGFR, blood pressure, proteinuria, medication and tobacco use, Hb, CRP and 25 OH vitamin D levels. After 6 months, 25 OH vitamin D levels were 91.4 nmol/L in the treatment vs 26.2 nmol/L in the placebo group (p<0.001). Percentage increase in flux after iontophoresis of AcH was similar at baseline in both groups (ergocalciferol - 826.0% +/- 170.0%, placebo - 785.9% +/- 121.3%, p=0.85) but was significantly higher in ergocalciferol treated patients at 6 months (ergocalciferol 1130% +/-182.3%, placebo 540.6% +/- 112.6%, p=0.012). eGFR, blood pressure, proteinuria, Hb and CRP did not change with treatment.

Conclusions: Improved microcirculatory function after treatment with vitamin D compounds may be contributing to the reduced burden of CVD in previous observational studies. Multi-centre, randomised trials which compare different vitamin D compounds and include measurement of both microcirculatory and hard cardiovascular endpoints are now required to optimise therapy in this patient group.

TH-OR051

Effect of Dual Blockade of Renin Angiotensin System on the Progression of Type 2 Diabetic Nephropathy

Jose Luno,[2] Fernández Gema Maria,[1] Soledad Garcia de Vinuesa,[2] Manuel Praga.[3] *[1]Nephrology, Hospital Universitario Fundacion Alcorcon, Madrid, Spain; [2]Nephrology, Hospital Universitario Gregorio Marañon, Madrid, Spain; [3]Nephrology, Hospital Infanta Sofia, Madrid, Spain; [4]Nephrology, Hospital Universitario 12 de Octubre, Madrid, Spain.*

Background: The blockade of the RAAS has been shown to reduce the rate of loss of glomerular filtration rate in proteinuric nephropathies, including diabetic nephropathy. It's possible the combination therapy of ACE inhibitors (ACEi) and ARBs may offer more complete blockade of the RAAS than monotherapy.

Methods: Clinical trial phase III, randomized (1:1:2), multicenter, open to compare the effect of lisinopril (40 mg), irbesartan (600 mg) or combination (lisinopril 20 mg + irbesartan 300 mg) on the progression of established diabetic nephropathy.

Primary composite outcome: ↑ 50% of the Cr or dialysis or renal transplantation. Secondary outcomes: ↓baseline proteinuria and cardiovascular events Inclusion criteria: Age 35-75 y, diabetes 2, CKD stage 2-3, ratio MAU/cr>300 mg/g All patients gave informed consent. (EUDRACT 2004-002470-31)

Results: We have included 131 patients in 23 units of Nephrology. The baseline characteristics of patients were: age 65 ± 8.3 y, BMI 34.8 kg/m2, SBP 155±19 mmHg, DBP 81±11 mmHg, Hemoglobin 13.4 ± 2.6 g / dl, LDL 104±36 mg / dl, GlicoHb 7±1.2%, SCr 1.5±0.5 mg /dl, Ks 4.5±0.6 mEq /l, eGFR MDRD4 45±24 mL/min/1.73m2, proto 2.6±1.8 g/24 h. The median follow up time was 49 months.

The frequency of the composite primary outcome was similar: lisinopril 7/35 (20%); irbesartan 6/28 (21.4%); lisinopril+irbesartan 16/70 (22.8%) (NS).

Loss Renal function was similar in the three groups: lisinopril 5, Irbesartan 3 .5, Lisinopril+irbesartan 3.5 mL/min/1.73 m2 year (NS) .

BP control was not optimal but there were no differences between groups. The lipid and glycemic control was optimal. There were no differences between groups. 4 patients discontinued the study because of hyperkalemia. ACEi (2) ARBs (1) combinated treatment (1)

Conclusions: In patients with established diabetic nephropathy, the monotherapy with ACEi and ARBs in high doses provides equivalent renoprotection combined treatment at equipotent doses.

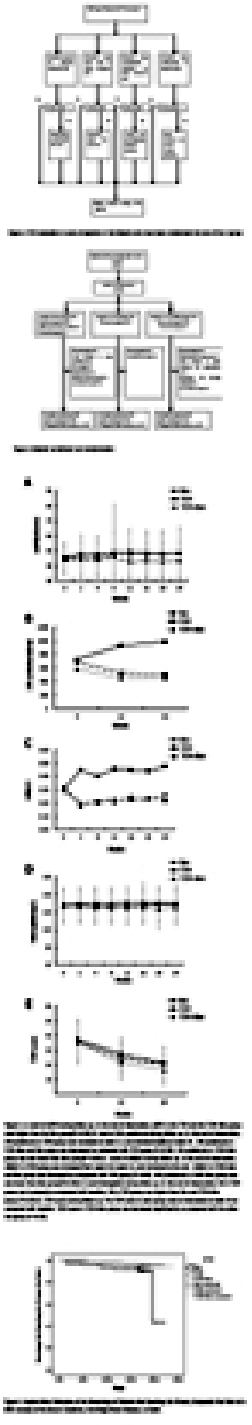
Optimized Project of Traditional Chinese Medicine in Treating Chronic Kidney Disease Stage 3: A Multicenter Randomized Double-Blinded Controlled Trials (RCT Registration Code: ChiCTR-TRC-00000204)

Yongjun Wang,[1] Wei Sun,[2] Li-Qun He.[3] *[1]Nephrology, Hangzhou Hospital of Traditional Chinese Medicine affiliated to Zhejiang University of Chinese Medicine, China; [2]Nephrology, Shanghai Shuguang Hospital, China; [3]Nephrology, Affliated Hospital, Jiangshu University of Chinese Medicine, China.*

Background: Stage 3 is the key phase of chronic kidney disease. Traditional Chinese Medicine has been used for the treatment of Chronic Kidney Disease. But a large sample multicenter randomized double-blinded controlled trial is desirable.

Methods: A total of 578 Chinese patients with primary glomerulonephritis in CKD stage 3 were randomly assigned to: Patients received TCM decoction granules(TCM group), benazepril (Ben group), TCM decoction granules combined with benazepril (TCM+Ben group) and followed up for 24 weeks. The primary endpoint was the time to the composite of 50% increased of serum creatinine, end stage renal disease or death.

Results: eGFR in the TCM and the TCM+Ben group were improved (week 24 vs. baseline, *P*<0.05) while eGFR in the Ben group was decreased (week 24 vs. baseline, *P*>0.05). 24h urinary protein excretion (UP) and urinary albumin/creatinine (UAlb/Cr) were decreased in the TCM+Ben (week 24 vs. baseline, *P*<0.05) and the Ben group (week 24 vs. baseline, *P*>0.05). UP and UAlb/Cr were increased in the TCM group to week 12, then was stable (week 24 vs. baseline, *P*<0.05). The hemoglobin in the TCM group was improved (week 24 vs. baseline, *P*<0.05). The accumulative survive rate in the TCM+Ben group was higher than that in the other 2 groups (P=0.14). The patients with dry cough in TCM group was decreased as compared with the other 2 groups(*P*<0.05)



Conclusions: For the patients with CKD stage 3, TCM can improve eGFR and hemoglobin. Chinese medicine integrated with benazepril can ameliorate renal function and decrease proteinuria synergistically.

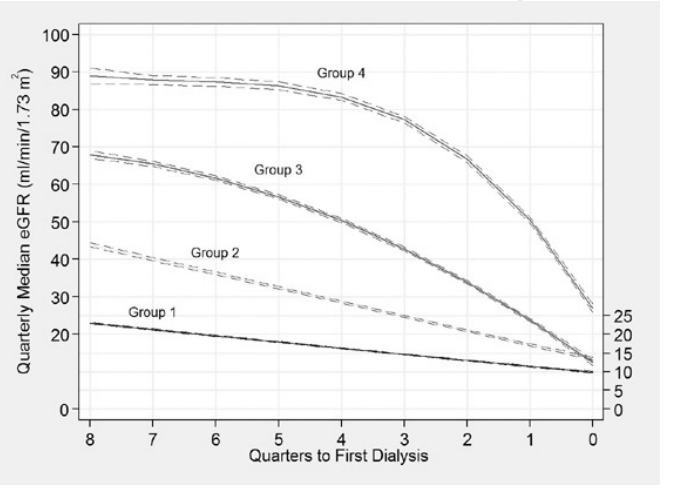
Trajectories of Kidney Function before Initiation of Chronic Dialysis Ann M. O'Hare,[1] Adam J. Batten,[1] Meda E. Pavkov,[2] Nilka Rios Burrows,[2] Indra Gupta,[1] Jeffrey Todd-Stenberg,[1] Rudolph A. Rodriguez,[1] Fliss E. Murtagh,[4] Leslie L. Taylor,[1] Eric Larson,[3] Desmond Williams.[2] *[1]Medicine, University of Washington and VAPSHCS, Seattle, WA; [2]CDC, Atlanta, GA; [3]GHRI, Group Health, Seattle, WA; [4]Kings College, London, United Kingdom.*

Background: Little is known about patterns of kidney function decline leading up to initiation of chronic dialysis.

Methods: We used data from the VA, Medicare and USRDS to model pre-dialysis eGFR trajectories among 7,322 patients who initiated chronic dialysis in 2001-2003.

Results: We identified four distinct trajectories of eGFR during the two year period before dialysis initiation: 63% of patients experienced relatively slow loss of eGFR from levels that were already severely reduced two years before initiation (Group 1); 25% declined from moderately reduced levels of eGFR two years before initiation (Group 2); 9% had normal levels of eGFR until two years before initiation (Group 3), and 3% had normal levels of eGFR until six months or less before initiation (Group 4).



More rapid loss of eGFR was associated with a greater likelihood of hospitalization and inpatient acute kidney injury and a lower likelihood of outpatient nephrology care and vascular access placement during the two year period before initiation. Those with more rapid loss of eGFR were more likely to initiate dialysis in the hospital, at a higher level of eGFR and in the setting of an acute kidney injury. Median survival ranged from 1.0 year (25th to 75th percentile, 0.3 to 4.4 years) for Group 4, to 3.2 years (25th to 75th percentile, 1.3 to 6.2 years) for Group 1. Differences in survival persisted in analyses adjusted for patient characteristics and care practices.

Conclusions: Patterns of eGFR decline before initiation of chronic dialysis are heterogeneous and are strongly associated with pre-dialysis care and survival after initiation.

TH-OR054

A Breath Test for Chronic Kidney Disease and Disease Progression Farid M. Nakhoul,[1] Ophir Marom,[2] Ulrike Tisch,[2] Ala Shiban,[2] Zaied Abassi,[3] Hossam Haick.[2] *[1]Nephrology Division, Poria Med Ctr, Tiberias; [2]Depart.of Chemical Engineering & Nanotechnology, Technion; [3]Research, Rambam, Haifa, Israel.*

Background: A novel approach that overcomes many of the conventional diagnostic techniques relies on patterns of volatile biomarkers in the exhaled breath. Some of the volatile organic compounds among the plasma chronic kidney dis.(CKD) biomarkers, or their metabolic products,are transmitted to the alveolar exhaled breath through exchange via the lung, at the very onset of the disease,Accurate determination of kidney function is essential in the treatment of CKD in order to identify patients with early renal impairment and to follow the course.we report a novel method to identify CKD and progression that is based on breath testing by using acustom-designed, nanoscale artificial NOSE(NA-NOSE).

Methods: Alveolar exhaled breath samples were collected from 62 volunteers and were analyzed using a custom-designed array of nanosensors that is based on organically functionalized gold nanoparticles, combined with support vector machine (SVM) analysis, to detect statistically significant differences between the sub-populations. Sensitivity and specificity with reference to CKD patient classification according to eGFR, were determined using cross-validation. Chemical composition of the breath samples was studied using gas chromatography linked with mass spectrometry (GC-MS).

Results: Excellent distinction was achieved with the nanosensor array between: (i) early stage CKD and healthy states, and (ii) stage-4 and stage-5 CKD states, with an accuracy of 79% and 85%, respectively. Several substances in the breath were identified and could be associated with CKD related biochemical processes or with the accumulation of toxins through kidney function loss.

Conclusions: This study focuses on testing the feasibility of a novel method in nanomedicine for identifying early stage of CKD and monitoring disease progression from exhaled breath of patients. The biomarker-based NA-NOSE breath test could form the basis of a future cost-effective, fast and early diagnostic test for CKD and progression. The nanosensor array could distinguish with high accuracy between the exhaled breath of (i) early &advanced CKD syages.

A New Equation To Estimate GFR from Standardized Creatinine and Cystatin C Lesley Stevens Inker,[1] Christopher H. Schmid,[1] Hocine Tighiouart,[1] John H. Eckfeldt,[2] Harold I. Feldman,[3] Tom H. Greene,[4] Jane Manzi,[5] John W. Kusek,[6] Josef Coresh,[5] Andrew S. Levey.[1] *[1]Tufts Medical Center; [2]University of Minnesota; [3]University of Pennsylvania; [4]University of Utah; [5]John Hopkins University; [6]NIDDK; [7]Cleveland Clinic.*

Background: GFR estimates based on serum creatinine (cr) are routinely used, however, are imprecise due to variation among people in non-GFR determinants of creatinine. Cystatin C (cys) is a potential alternative filtration marker.

Methods: We developed estimating equations based on cys alone (eGFRcys) and in combination with cr (eGFRcr-cys) in a cross-sectional analysis using separate databases for equation development (13 studies of 5352 people) and validation (5 studies with 1119 people). GFR was measured (mGFR) using urinary clearance of iothalamate in the development dataset, and clearance of other markers in the validation dataset. Cr and cys assays were traceable to high-level reference materials.

Results: Mean mGFR (SD) was 68 (39) and 70 (41) ml/min/1.73m^2 in the development and validation dataset, respectively. eGFRcr-cys performed better than eGFRcys or eGFRcr, with similar bias, improved precision, and greater accuracy (table). Compared to eGFRcr, eGFRcr-cys improves classification of subjects with mGFR ≥ or < 60 ml/min/1.73m^2 [net reclassification improvement (NRI) (95% CI) 4.93% (2.19%-7.67%)]. In the subgroup of eGFRcr of 45-59 ml/min/1.73 m^2, NRI was 32.7% (15.4-50.1%).

Metric	Equation	Overall	Estimated GFR		
			<60	60-89	>90
Bias, Median Difference	Cr	3.7	1.8	6.6	11.5
	Cys	3.4	0.4	6.0	8.5
	Cr-cys	3.9	1.3	6.9	10.6
Precision, IQR of the Difference	Cr	15.4	10.0	19.6	25.0
	Cys	16.4	11.0	19.6	22.6
	Cr-cys	13.4	8.1	15.9	18.8
Accruacy,1-P30	Cr	12.8	16.6	10.2	7.8
	Cys	14.1	21.4	12.7	2.2
	Cr-cys	8.5	13.3	5.3	2.3

Difference refers to mGFR - eGFR. Interquartile range refers to the 25-75th percentile. Units are ml/min per 1.73 m 2. 1- P30 refers to the percent of GFR estimates that deviate by > 30% of mGFR.

Conclusions: The combined Cr-Cys equation is more accurate than equations with either marker alone, and can be used as a confirmatory test for people decreased eGFRcr.

TH-OR056

Assessing Improvement of eGFR Risk Classification in Meta-Analysis: An Example of CKD-EPI and MDRD Study Equations (for the CKD-PC Collaborators) Kunihiro Matsushita, Yingying Sang, Mark Woodward, B. Khan Mahmoodi, Brad C. Astor, Andrew S. Levey, Josef Coresh. *Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Background: Risk prediction models are assessed by calibration, discrimination, and reclassification. Net reclassification improvement (NRI) is a popular reclassification statistic in clinical epidemiology. However, methods to assess NRIs in a meta-analysis are not well described. Using an example of the CKD-EPI and the MDRD Study equations, we demonstrate a method to meta-analyze NRIs for eGFR category based on different equations.

Methods: In a sample of 16 of 46 cohorts joining the CKD Prognosis Consortium (CKD-PC), NRI was calculated for reclassification across the following six eGFR categories (≥90, 60-89, 45-59, 30-44, 15-29, <15 ml/min/1.73m^2) for CKD-EPI vs. MDRD Study equations. Standard errors of NRIs were calculated in analogy to McNemar's test for paired proportions as √{(proportion of reclassification to high risk [low eGFR] category in those who developed events + proportion of reclassification to low risk [high eGFR] category in those who developed)/(# of events) + (reclassification to low risk category in those who did not develop events + reclassification to high risk category in those who did not develop)/(# of no events)}. NRIs were meta-analyzed in a random effects model applying the *metan* command in STATA.

Results: There were a total of 85,245 participants and 16,864 deaths. NRIs for death based on eGFR category varied from 0.01 to 0.24 (p-values from <0.001 to 0.860) among cohorts. Standard errors also varied from 0.005 to 0.049. Meta-analyzed NRI was 0.10 (95% CI: 0.07-0.14, p<0.001), suggesting that the CKD-EPI equation classifies individuals more correctly than the MDRD Study equation. The I-squared was 95.8% (p<0.001), suggesting significant heterogeneity across studies.

Conclusions: We demonstrated how to meta-analyze NRIs, which will precisely estimate clinical impact of new eGFR equations or other prediction tools for CKD outcomes.

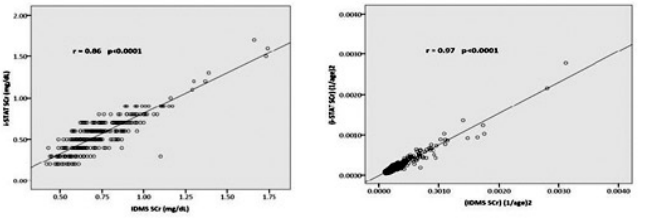
Comparison of Serum Creatinine Measured with a Point-of-Care Testing Device (i-STAT) and with IDMS Methodology among Mexico's Kidney Early Evaluation Program (KEEP) Participants Gregorio T. Obrador,[1,2] Nadia Olvera,[2] Daniela Ortiz de la Peña,[2] Veronica Gutierrez,[2] Antonio Villa.[1] *[1]Universidad Panamericana School of Medicine; [2]Mexican Kidney Foundation.*

Background: Measurement of serum creatinine (SCr) with a method traceable to IDMS is optimum to estimate GFR (eGFR) in CKD screening programs. Unfortunately, most Mexican laboratories don´t use IDMS methods to measure SCr. KEEP Mexico is a CKD screening program directed to high risk individuals, including those with DM, HTN, or family history of DM, HTN, or CKD. Escalation of KEEP Mexico to other Mexican states as well as some Latin American countries has been challenged by variability in SCr measurements due to use of non-IDMS methods and to significant differences in quality control among laboratories. The aim of this study was to compare SCr measured with a point-of-care testing (POCT) device (i-STAT) and with IDMS methods in a representative sample of KEEP participants.

Methods: TThe i-STAT SCr method was assessed by analyzing capillary blood samples of 282 KEEP participants and comparing POCT results with those of an Olympus 5400 spectrophotometry instrument, which measures IDMS SCr in venous blood. Correlation between i-STAT and IDMS SCr was calculated.

Results: Mean age ± SD of the 282 participants was 53.4±15.1 and 76% were women. Mean SCr±SD by the i-STAT method was 0.56±0.23 mg/dl and by the IDMS method 0.73±0.20 mg/dl. Mean eGFR±SD estimated with the MDRD and CKD-EPI equations from the IDMS SCr were 102±25 and 97±19 ml/min/1.73m2, respectively. Correlation for i-STAT and IDMS SCr was high (r= 0.86, p<0.0001) and improved when a correction factor (1/age)2 was applied (r = 0.97, p<0.0001).



Conclusions: i-STAT SCr measured in capillary blood is as accurate as IDMS SCr when a correction factor is applied. Further linear regression analysis will be done to use i-STAT SCr for GFR estimation with equations.

Rapid Kidney Function Decline in Young Adults without Chronic Kidney Disease: Data from the CARDIA (Coronary Artery Risk Development in Young Adults) Study Carmen A. Peralta,[1,2] Eric Vittinghoff,[1] Michael Shlipak,[1,2] David Siscovick,[3] David R. Jacobs,[7] Holly J. Kramer,[4] Michael Steffes,[5] Paul Muntner,[6] Kirsten Bibbins-Domingo.[1] *[1]UCSF, SF, CA; [2]SFVAMC, SF, CA; [3]U Washington, Seattle, WA; [4]Loyola, Maywood, IL; [5]U Minnesota, Minneapolis, MN; [6]U Alabama Birmingham, Birmingham, AL; [7]U Minnesota Public Health, Minneapolis, MN.*

Background: Blacks have been reported to have faster rates of kidney function decline in middle-aged or older adults with or without chronic kidney disease (CKD). Whether race differences in kidney function decline are detectable in young adults without CKD is not well studied.

Methods: CARDIA is a longitudinal cohort of young blacks and whites (age 18-30 at enrollment) with over 20 year follow-up. We included participants at years 10, 15 and 20 with at least two measures of cystatin C (N=3658). Rapid kidney function decline was defined as annual eGFRcys decline ≥3% per year. We evaluated race differences in rapid decline by study period (period 1: year 10-15 (age 28-40) and period 2: years 15-20 (age 33-45)) using Poisson regression. We adjusted for age, sex, diabetes, albuminuria, and time-averaged cumulative exposure to systolic blood pressure ≥120mmHg throughout follow up.

Results: At baseline, mean age was 35 ± 4, eGFRcys 112 ± 26ml/min/1.73m² for blacks and 105 ± 21ml/min/1.73m² for whites. Blacks were more likely to have rapid eGFRcys decline during both periods, but the magnitude of the differences varied by period. After age adjustment, during period 1, 14.3% of Blacks had rapid decline vs,1.8% of whites. During period 2, 26.4% of Blacks and 8.7% of whites had rapid decline. Multivariate adjustment did not attenuate race differences: blacks were nearly 8 times as likely to have rapid decline in kidney function as whites during the first period (prevalence ratio for blacks to whites=7.6 (5.1-11.3)) and nearly three times as likely during period 2 (prevalence ratios 2.7 (2.3-3.2)).

Conclusions: Among young adults without chronic kidney disease, Blacks were more likely to have rapid decline in eGFR than whites. Future studies are needed to elucidate the mechanisms predisposing young blacks to rapid kidney function decline.

***APOL1* Variants Are Associated with Subclinical Albuminuria and Lower Glomerular Filtration Rate in the Black Young Adults: Findings from the Coronary Artery Risk Development in Young Adults (CARDIA) Study**

Kirsten Bibbins-Domingo,[1] Eric Vittinghoff,[1] Myriam Fornage,[2] George W. Nelson,[3] Cheryl Ann Winkler,[3] Jeffrey B. Kopp.[3] *[1]Department of Medicine and of Epidemiology and Biostatistics, University of California, San Francisco, CA; [2]University of Texas Health Science Center at Houston, Houston, TX; [3]National Institutes of Health, Bethesda, MD.*

Background: Genetic variants in *APOL1*, encoding apolipoprotein L1, are strongly associated with focal segmental glomerulosclerosis, HIV-associated nephropathy, and hypertensive kidney disease, but the association with subclinical kidney disease has not been examined.

Methods: The Coronary Risk Factors in Young Adults (CARDIA) is an on-going longitudinal study that enrolled 5115 participants age 18-30 years in 1985-6. We genotyped *APOL1* kidney risk mutations in all participants with samples at Year 10 and explored the association of 2 *APOL1* mutations with repeated measures of albuminuria (urine albumin/creatinine ratio >30 mg/g) and cystatin C-estimated glomerular filtration rate (eGFR) from Years 10, 15, and 20 among 1764 black participants. We also assessed effects of metabolic syndrome.

Results: The *APOL1* risk genotype (2 *APOL1* risk alleles as homozygotes or compound heterozygotes) was present in 12.6% of black participants. After adjustment for visit year, age, and sex, albuminuria (nearly all of which-86%- was microalbuminuria) was associated with the *APOL1* risk genotype (adjusted prevalence 17.2% vs 6.0%, p<0.0005). The *APOL1* risk genotype was associated with 5.5% lower eGFR at each exam year (p=0.003) and also predicted eGFR<60 ml/min (adjusted prevalence 3.3% vs 1.0%, p=0.02). Compared to normal controls, participants with both *APOL1* risk genotype and metabolic syndrome had 14.6% lower average eGFR (p=.003), while those with either metabolic syndrome (5.3% lower, p<0.0005) or the *APOL1* risk genotype (4.8% lower, p=.009) had intermediate levels. Annual rates of eGFR decline were similar across the four groups (p for heterogeneity = 0.36).

Conclusions: The increased prevalence of albuminuria and reduced eGFR may indicate subclinical kidney disease associated with *APOL1* risk alleles.

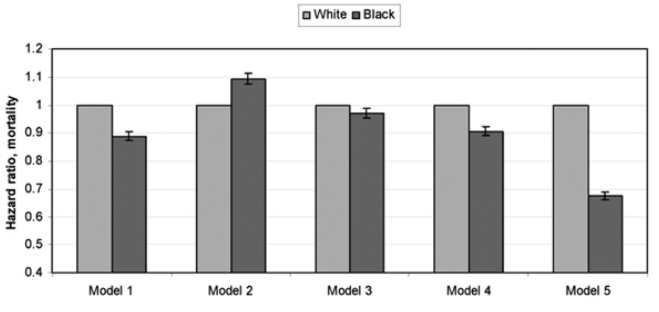
Black Patients Experience Lower Mortality Compared to White Patients in a Large Cohort of US Veterans with Non-Dialysis Dependent CKD

Csaba P. Kovesdy,[1,2] Evan H. Lott,[3] Jun Ling Lu,[4] Sandra M. Malakauskas,[1,2] Jennie Z. Ma,[2] Mark D. Okusa,[2] Kamyar Kalantar-Zadeh.[5] *[1]Salem VA Medical Center; [2]University of Virginia; [3]VA Informatics and Computing Infrastructure; [4]Salem Research Institute; [5]Harbor UCLA.*

Background: Blacks with end stage renal disease experience significantly lower mortality compared to whites. A similar paradoxical association in non-dialysis dependent CKD is unknown.

Methods: We compared 54,154 black and 468,233 white patients in a nationally representative cohort of US veterans with non-dialysis dependent CKD stages 1-5 in 2005-2006. Crude mortality rates (Model 1) were compared with the Kaplan Meier method and in Cox models. In order to explain observed differences in mortality, models were adjusted for age (Model 2), sociodemographics (Model 3), comorbidities (Model 4), and laboratory variables (Model 5).

Results: Blacks were younger, more likely to be unmarried and uninsured and to have diabetes and hypertension, but less likely to have coronary artery disease. Over a median follow-up of 4.7 years, 14,848 blacks (64.3 deaths/1000 patient-years (95% CI: 64.3, 63.3-64.5)) and 143,107 whites died (75.2 (71.8-72.5)). Black race was associated with lower crude mortality (hazard ratio, 95%CI: 0.89, 0.88-0.90), which reversed after adjustment for age (1.09, 1.07-1.11). Further adjustments resulted in black race being again associated with lower mortality (Figure; all p values <0.001). Similar trends were seen in all stages of CKD.



Conclusions: Blacks with non-dialysis dependent CKD experience lower mortality compared to white patients, which reverses after controlling for age. A survival advantage of blacks re-emerges upon controlling for differences in various characteristics. General population studies are needed to clarify the reasons for the selection of black patients with CKD possessing such different characteristics.

TH-OR061

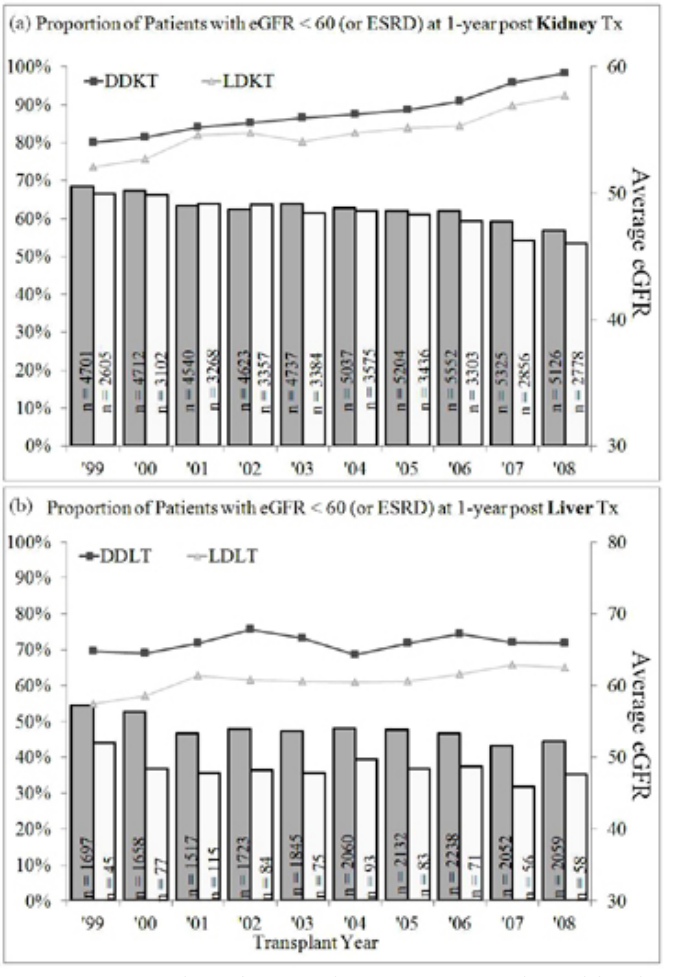
National Trends in Prevalence of Chronic Kidney Disease in Kidney & Liver Transplant Recipients

Anca Tilea,[1] Yihung Huang,[1] Vahakn B. Shahinian,[1] Vanessa Grubbs,[2] Neil R. Powe,[2] Nilka Rios Burrows,[3] Desmond Williams,[3] Rajiv Saran.[1] *[1]U of MI; [2]UCSF; [3]CDC.*

Background: High prevalence of CKD has been recognized as a major complication of solid organ transplantation. We postulated that prevalence of CKD in organ transplant recipients may be on the rise, as average age of both transplant donors and recipients has increased.

Methods: Adult solid organ (kidney (KT) and liver (LT)) transplant recipients (age>20) engrafted between 1999 and 2008 were identified in the US Scientific Registry of Transplant Recipients (SRTR). Patients with a death event or missing eGFR prior to 1-year post-transplant were excluded. GFR was estimated by the MDRD equation. Logistic regression was used to model the probability of eGFR<60 ml/min/1.73m^2 or ESRD at 1-year post-transplant, adjusted for transplant year, recipient and donor demographics by donor type (deceased (DD) or living (LD) donor).

Results: In adjusted models, the odds of CKD at 1-year post KT were significantly lower for both DDKT recipients and LDKT recipients (OR=0.96, and OR=0.93 respectively, Figure Panel [a], bars). Correspondingly, there was a significantly higher mean eGFR (lines) for both donor types (p<0.05). Similar results were seen in CKD prevalence for LT recipients (Panel [b]). In adjusted models, the odds of CKD at 1-year post LT were 3.4% lower per year (p=0.01) for DDLT recipients, but remained relatively unchanged for LDLT recipients (p=0.47). The average eGFR was significantly higher for DDLT recipients (β=0.53,p<0.05). There was no significant trend for the relatively small numbers of LDLT recipients.



Conclusions: Prevalence of post-transplant CKD among KT and LT recipients has steadily decreased in the US over the last decade, despite aging donors and recipients. Explanations for such overall trends may include changes in immunosuppression practices or other practices, and require further study.

TH-OR062

Pregnancy in a Prospective Cohort of Women with CKD 3-5: Maternal Outcomes Sajeda Youssouf,[1] Matt Hall,[1] Liz Lightstone,[3] Nigel J. Brunskill,[1] Sue Carr.[1] *[1]John Walls Renal Unit, Leicester General Hospital, Leicester, United Kingdom; [2]Renal Section, Dept of Medicine, Imperial College Healthcare NHS Trust, London, United Kingdom.*

Background: CKD is associated with an increased risk of adverse fetal outcomes at all levels of renal dysfunction. For some women, pregnancy is associated with an accelerated decline in renal function. This retrospective analysis of data collected prospectively since 2003 sought to identify maternal outcomes in women with excretory renal dysfunction at conception.

Methods: We analysed prospective data from 3 specialist renal-obstetric services in the United Kingdom and identified those with excretory renal dysfunction (CKD 3 to 5) as women with a pre-conception estimated GFR <60ml/min or a serum creatinine >110µmol/l (>1.25mg/dl) prior to 12 weeks gestation.

Results: 42 pregnancies in 39 women with CKD stage 3 to 5 were identified, of whom sufficient data was available in 30 women. Mean maternal age at conception was 32±4.5 years. Mean eGFR prior to conception was 46 ± 10 ml/min, with 4 (12.5%) having eGFR<30ml/min. Eleven women (34%) were treated for hypertension prior to conception, 4 (12.5%) had a renal transplant and 5 (16%) had diabetes mellitus.

6 women (20%) required renal replacement therapy (RRT); 1 during pregnancy and 5 starting 469 to 1319 days postpartum. Preconception eGFR (39.3 vs 47.5ml/min, p=0.083) and serum creatinine (154 vs 115 µmol/l, p=0.059) identified more advanced renal dysfunction in those going on to require RRT.

Baseline renal function was worse in women with a 25% increase in serum creatinine in pregnancy (eGFR 30.0 vs 46.3 ml/min, p=0.022) and persistent 25% increase in serum creatinine at 6 months post-partum (eGFR 40.2 vs 51.9 ml/min, p=0.019). No association with blood pressure, proteinuria, medication or co-morbidity was identified.

The risk of a persistent 25% increase in serum creatinine at 6 months post-partum was 100% in women with eGFR ≤30ml/min and 33% in those with eGFR>30ml/min (p=0.385). The risk of requiring RRT was 50% in women with eGFR ≤30ml/min and 15% in those with eGFR>30ml/min (p=0.169).

Conclusions: Women with CKD 3 to 5 are at risk of loss of renal function as a result of pregnancy, particularly if eGFR ≤ 30ml/min.

TH-OR063

Serum Uric Acid Predicts Incident Stage 3 Chronic Kidney Disease in a Middle Aged Population with Excess Obesity and Diabetes: The Strong Heart Family Study Jason G. Umans,[1,2] Hong Wang,[1] Nawar M. Shara.[1,2] *[1]MedStar Health Research Institute; [2]Georgetown-Howard Universities Center for Clinical and Translational Science.*

Background: Hyperuricemia has been associated with prevalent and incident CKD, with hypertension, and with the metabolic syndrome in observational studies of unselected and low risk populations. Studies in higher risk populations are limited by concerns that serum uric acid (UA) may more sensitively detect subtle decrements in GFR than creatinine-based methods. We sought to determine if elevated UA predicted incident stage 3 CKD (CKD3) in a population with high prevalence of obesity, diabetes and at high risk for CKD and CVD.

Methods: The genetic epidemiologic Strong Heart Family Study (SHFS) included 3665 American Indians (60% female) with median age 39(14-93)y. At the baseline examination (2001-03), 22.8% of participants had DM, 33.4% had HTN, 57.3% were obese with BMI ≥30, 18% (648) had albuminuria (UACR ≥ 30mg/g), and 6% (217) had CKD3-5 (MDRD eGFR ≤60ml/min/1.73m2 or ESRD). After excluding those with albuminuria or decreased eGFR at baseline, we assessed the association of serum UA and incident CKD3 in the remaining 2896 participants by conditional logistic regression, accounting for the extended family structures in the study population.

Results: Over a median 5.2y follow up, there were 170 incident cases of CKD3. The 1st, 2nd, 3rd, and 4th quartiles of serum UA spanned values from 0.5-4.0, 4.1-5.0, 5.1-6.0, and 6.1-11.1 mg/dl, respectively; mean serum UA in the 4th quartile was 7.04±0.84 mg/dl. The multivariate-adjusted (for age, sex, LDL-C, HDL-C, HTN, DM, and smoking) odds ratios for incident CKD3 (95% CI) across increasing quartiles of serum UA were: 1 (referent), 0.98(0.48-1.99), 1.46(0.71-2.99), and 2.65(1.17-6.00).

Conclusions: In this high risk group with an excess of obesity and DM, clinically-elevated values of serum UA, occurring only in the 4th quartile of our population, were significantly associated with incident CKD3. This extends observations from other populations with lesser burdens of disease

Association of Tenofovir Exposure with Kidney Disease Risk in HIV-Infection Rebecca Scherzer,[1,2] Michelle M. Estrella,[3] Yongmei Li,[1] Steven Deeks,[4] Carl Grunfeld,[1,2] Michael Shlipak.[1,2] *[1]Medicine, San Francisco VA Medical Center, SF, CA; [2]Medicine, University of California, San Francisco, CA; [3]Johns Hopkins School of Medicine; [4]Positive Health Program, San Francisco General Hospital, SF, CA.*

Background: Despite the widespread use of highly active antiretroviral (ARV) therapy, HIV disease remains associated with increased risk of kidney disease. Whether or not tenofovir use is associated with higher risk of kidney disease is controversial.

Methods: We designed a cohort of 10,841 HIV-infected patients who initiated antiretroviral therapy in the Veterans Health Administration from 1997-2007. Using proportional hazards survival regression and marginal structural models, we evaluated association of cumulative exposure to tenofovir with kidney outcomes: first occurrence of (1) proteinuria, (2) rapid decline in kidney function (≥3ml/min/1.73m² annual decline), and (3) estimated glomerular filtration rate (eGFR) <60ml/min/1.73m². Time-dependent models adjusted for antiretroviral drugs, demographics, baseline comorbid conditions, and current measurements.

Results: During follow-up, 3,400 proteinuria, 3,078 rapid decline, and 1,712 CKD events occurred. After multivariable adjustment, each year of exposure to tenofovir was associated with increased risk of all 3 endpoints. Other ARVs showed weaker or inconsistent associations with kidney disease risk. Among those who discontinued tenofovir use, the risk of kidney disease events did not appear to decrease during follow-up.

Conclusions: Tenofovir exposure was independently associated with increased risk for kidney disease events, and did not appear to be reversible. The balance between tenofovir's efficacy and these probable adverse effects requires further study.

Association of Cumulative Tenofovir Exposure with Risk of Kidney Disease Outcomes

Outcome	Hazard Ratio (95% CI) per year of Tenofovir	P Value
Proteinuria (n=3400 events)	1.34 (1.25-1.45)	<0.0001
Rapid decline (n=3078 events)	1.11 (1.03-1.18)	0.0033
CKD (n=1712 events)	1.23 (1.12-1.35)	<0.0001

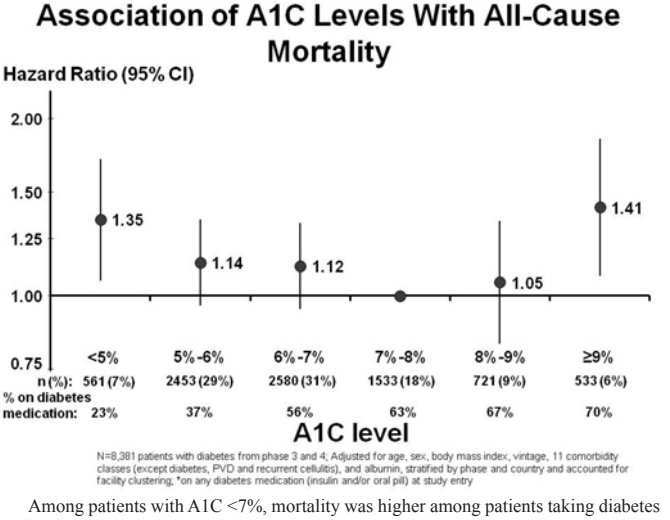
Hemoglobin A1C Levels and Mortality in the ESRD Population: Findings from the DOPPS Sylvia Paz B. Ramirez,[1] Jyothi R. Thumma,[1] Francesca Tentori,[1] Brenda W. Gillespie,[2] Masaaki Inaba,[3] Robert G. Nelson,[4] Ronald L. Pisoni,[1] Bruce M. Robinson.[1,2] *[1]Arbor Research, MI; [2]Univ of MI, MI; [3]Osaka City Univ, Japan; [4]NIDDK, AZ.*

Background: Lowering hemoglobin A1C (A1C) levels to <7% can lower the risk of developing the microvascular complications of diabetes, but the value of maintaining this A1C goal in diabetic patients (pts) who have already progressed to kidney failure is less certain. In this study, we present analyses evaluating the relationship between glycemic control based on mean A1C levels and mortality in international DOPPS data.

Methods: 8,437 hemodialysis pts from 12 countries (DOPPS 3 & 4, 2006-2010) were identified who had diabetes at study entry. Associations between average A1C over 8 months (mo) after study entry and subsequent mortality was assessed using multivariable Cox regression models adjusting for age, sex, body mass index, vintage, comorbid conditions and serum albumin.

Results: Pts had 1 to 3 reported A1C values over 8 mo. 5th and 95th %ile A1C levels were 4.9 and 9.2%. The relationship between average A1C levels and mortality risk was U-shaped, with the lowest risk associated with A1C levels of 7-8%. All-cause mortality risk appears to be greatest at A1C levels ≥9% and <5%, however a trend toward higher mortality risk was seen below A1C levels of 7%.



Among patients with A1C <7%, mortality was higher among patients taking diabetes medications (p<0.01 for interaction).

Conclusions: These analyses support the importance of measuring A1C levels in the ESRD population. Target A1C levels may be higher among ESRD pts as compared to the general population since mortality risk appears to be lowest at A1C levels of between 7-8%. Use of diabetes medications is common among patients with A1C <7%; avoiding excessively low blood glucose levels by tapering these medications may be a readily modifiable practice to improve outcomes.

TH-OR066

Intensive Glucose Lowering and End Stage Kidney Disease Vlado Perkovic,[1] Hiddo Jan Lambers Heerspink,[1,2] John P. Chalmers,[1] Mark Woodward,[1] Min Jun,[1] Alan Cass,[1] Mark E. Cooper,[4] Michel Marre,[5] Carl Erik Mogensen,[6] Sophia Zoungas.[1] *[1]George Institute for Global Health, University of Sydney, NSW, Australia; [2]Clinical Pharmacology, University Medical Centre Groningen, Netherlands; [3]Monash University, Melbourne, Victoria, Australia; [4]Baker IDI Heart and Diabetes Institute, Melbourne, Victoria, Australia; [5]Hospital Bichat - Assistance Publique des Hôpitaux de Paris, Paris, France; [6]Aarhus Kommunehospital, Aarhus, Denmark.*

Background: Blood glucose levels have been linked to the risk of kidney disease, but the effects of intensive glucose control on major kidney outcomes among people with diabetes are not known.

Methods: This analysis from ADVANCE compared the effects of an intensive glucose lowering target (HbA1c < 6.5%) using a gliclazide MR based regimen to a standard target (below 7%) on major renal events. The outcomes assessed were end-stage kidney disease (ESKD, defined as maintenance dialysis or transplantation), renal death, confirmed doubling of creatinine to above 200 mcmol/L, and sustained doubling of creatinine to the same level (final recorded value consistent with the doubling criteria).

Results: 11,140 patients were randomised to intensive or standard glucose lowering. The mean HbA1c levels were 6.5% in the intensive and 7.3% in the standard arm. After 5 years average follow up, the risk of ESKD was significantly lower in the intensive glucose lowering arm: hazard ratio [HR] 0.35, 95% confidence interval [CI] 0.15-0.83, p= 0.02. There was a non-significant trend towards benefit for renal death (HR 0.85, CI 0.45-1.63, p=0.63) and the composite of ESKD and renal death (HR 0.64, CI 0.38-1.08, p=0.09). No clear effect on doubling of creatinine (HR 1.15, CI 0.82-1.63, p= 0.42) or sustained doubling of creatinine 0.83 (0.54- 1.27, p= 0.39) was observed.

Conclusions: An intensive blood glucose lowering regimen based on gliclazide MR reduced the risk of ESKD in the ADVANCE study, but the effects on other renal outcomes were less clear. The interpretation of doubling of creatinine as a component of renal endpoints requires further consideration. Additional studies of glucose lowering in people with diabetes at high risk of ESKD are needed.

TH-OR067

Correlation of Plasminogen Activator Inhibitor-1 and Its Gene Polymorphism with Diabetic Nephropathy in Type 2 Diabetes Mellitus Liu Hui Lan, Xu Feng Bo. *Department of Nephrology, Fuxing Hospital, Capital Medical University, Beijing, China.*

Background: In this study, plasma plasminogen activator inhibitor-1(PAI-1) level of type 2 diabetes was measured and PAI-1 genotype was determined in order to elucidate the association of plasma PAI-1 level and its 4G/5G insertion/deletion polymorphism with type 2 diabetic nephropathy.

Methods: A total of 107 patients with type 2 diabetes were randomly recruited in the study. These patients were further divided into three groups according to their urinary albumin to creatine ratio. Group A(n=44) consised of type 2 diabetic patients without diabetic nephropathy(serum creatinine<106umol/L and normoalbuminuric). Group B consisted of patients (n=30) with microalbuminuria(A/C 20-200mg/g). Group C consisted of patients(n=33) with macroalbuminuria(A/C>200mg/g). At the same time 102 healthy controls were selected for the healthy controls. Plasma level of PAI-1 was measured by ELISA and PAI-1 polymorphism was measured DNA sequencers.

Results: (1)The plasma PAI-1 level in type 2 diabetes is higher than these in healthy controls. (2)Plasma PAI-1 level was correlated positively with glocuse,Triglyceride, High-density lipoprotein and uric acid. (3)The genotype 4G/4G distribution frequency in group C were 42.4%, which were significantly higher than those normal controls (28.7%). (4) The PAI-1 level are (68.33±15.95)ng/L, (64.57±19.39)ng/L and (58.00±18.34)ng/L in genotype 4G/4G, 4G/5G and 5G/5G. (5)Multiple logistic analysis showed that the plasma PAI-1 were the important risk factors of type 2 diabetic nephropathy.

Conclusions: (1) Plasma PAI-1 level goes up in 2 diabetes. High PAI-1 level is an important risk factor for type 2 diabetic. (2) Individuals with 4G/4G gene have higher plasma PAI-1 level. (3) PAI-1 4G/5G polymorphism is associated with the development and progression of predominant proteinuria diabetes nephropathy. 4G/4G gene probably is a susceptible gene of predominant proteinuria diabetes nephropathy.

TH-OR068

Low Plasma Adiponectin Levels Predict Increase of Urinary Albumin/ Creatinine Ratio in Type 2 Diabetes Patients Ina Maria Kacso,[1] Alina Lenghel,[1] Remus Aurel Orasan,[3] Rodica Rahaian,[2] Mirela Gherman.[1] *[1]University of Medicine and Pharmacy, Cluj Napoca, Romania; [2]Emergency County Hospital, Cluj Napoca, Romania; [3]Nefromed Dialysis Centers, Cluj Napoca, Romania.*

Background: Experimental studies have shown that adiponectin has antiproteinuric and nephroprotective effects. The purpose of the study was to assess the value of plasma adiponectin as a predictor for progressive diabetic kidney disease in type 2 diabetes (T2D) patients.

Methods: In a one-year prospective follow-up study we included microalbuminuric type 2 diabetes patients. Exclusion criteria were acute infection/inflammation, uncontrolled hypertension or history of coronary heart disease, stroke, atherosclerosis obliterans. The main outcome measure was difference in urinary albumin/creatinine ratio (UACR) between one year and baseline (Δ UACR).

Results: Fifty-six patients (66% males) completed the study. Mean UACR was in the microalbuminuric range (81.58±26.42 mg/g creatinine) and GFR close to normal (mean GFR=81,63±4,00ml/min). At baseline, simple regression disclosed significant correlations between UACR on one hand and plasma adiponectin (r=0.54, p=0.00002) and GFR (r=-0.29, p=0.03) on the other hand, findings confirmed by multiple regression analysis (p=0.0007). Baseline plasma adiponectin was significantly correlated to body mass index (r=-0.28, p=0.04), waist circumference (r=-0.27, p=0.05), HDL cholesterol (r=0.35, p=0.01), LDL cholesterol (r=0.27, p=0.04). Δ UACR correlated in simple regression significantly to baseline adiponectin values (r=-0.38, p=0.004); in multiple regression baseline plasma adiponectin remained the only predictor of Δ UACR (p=0.001). If patients are divided according to Δ UACR in nonprogressors (Δ UACR<0) and progressors (Δ UACR >0), logistic regression shows that baseline GFR (OR=1.04, CI95%: 1.00-1.09, p=0.048) and plasma adiponectin (OR=1.16, CI95%: 1.02-1.32, p= 0.02) are the only factors that predict weather the patient will be a progressor or not.

Conclusions: In microalbuminuric T2D patients lower plasma adiponectin levels seem to be predictive of increasing UACR.

TH-OR069

The Majority of Type 2 Diabetic Patients with Renal Impairment Have Non-Albuminuric Renal Disease – The Swedish National Diabetes Register (NDR) Hanri Afghahi,[1] Mervete Miftaraj,[2] Ann-Marie Svensson,[2] Henrik Hadimeri,[1] Bjorn Eliasson,[3] Maria Svensson.[4] *[1]Nephrology, Kärnsjukhuset, Skövde, Västra Götaland, Sweden; [2]Center of Registers in Region Västra Götaland, Center of Registers in Region Västra Götaland, Gothenburg, Västra Götaland, Sweden; [3]Medicine, Sahlgrenska University Hospital, Gothenburg, Västra Götaland, Sweden; [4]Nephrology, Sahlgrenska University Hospital, Gothenburg, Västra Götaland, Sweden.*

Background: Albuminuria and renal impairment are two manifestations of renal disease but are not entirely linked in patients with type 2 diabetes (T2D). The aim of this cross-sectional study was to study prevalence and clinical characteristics associated with non-albuminuric renal impairment in T2D in a nation-wide population-based diabetes register.

Methods: 94446 patients with T2D and serum creatinine reported to the Swedish National Diabetes Register in 2009 were included. Renal impairment was defined as eGFR < 60 ml/min/1.73 m^2 (MDRD) and albuminuria as AER > 20 µg/min. A registry linkage was performed between the NDR and the Swedish Prescribed Drug Register to evaluate ongoing anti-diabetic, lipid-lowering, anti-hypertensive and aspirin medication.

Results: 17% of all patients had renal impairment and 62% of these were non-albuminuric. Patients with non-albuminuric renal impairment were more often women, non-smokers and more seldom had a history of CVD and heart failure and had lower HbA1c, triglycerides, BMI and systolic blood pressure compared to patients with albuminuric renal impairment. 27% of the patients with non-albuminuric renal impairment had no ongoing treatment with any RAAS-blocking agent. These patients had lower BMI and systolic blood pressure and were older, more often women and smokers and fewer patients had a history of CVD and heart failure compared to patients with non-albuminuric renal impairment and ongoing RAAS-blockade.

Conclusions: The majority of patients with type 2 diabetes and renal impairment were non-albuminuric. Non-albuminuric renal impairment can be explained by the use of RAAS-blockers but since only 75% of these patients were treated with RAAS-blockade this also supports the concept of different underlying pathophysiology mechanisms.

TH-OR070

Effect of Fenofibrate on Cardiovascular Events According to Changes in Plasma Creatinine Levels during the Pre-Randomization Period: The Fenofibrate Intervention and Event Lowering in Diabetes (FIELD) Study Jean-Claude Ansquer,[1] Karine Le Malicot,[1] Ru-Dee Ting,[2] Anthony C. Keech.[2] *[1]Laboratoires Fournier SA, Daix, France; [2]NHMRC-CTC University of Sydney, Australia.*

Background: Assessment of renal function (eGFR and albuminuria) is essential in risk stratification for cardiovascular disease (CVD) in subjects with type 2 diabetes mellitus (T2DM). FIELD was a double-blind, placebo-controlled, randomized study in

9795 T2DM subjects to assess the effects of 200mg/day micronized fenofibrate for an average 5 years on CVD events.

Methods: Prior to randomization, all the participants underwent sequentially 2 successive 6-week run-in periods with placebo and then fenofibrate 200 mg/day. This permitted an unbiased evaluation of the effect of treatment on CVD events (CVD death, non fatal MI or stroke, coronary or carotid revascularisation) according to tertiles of both baseline renal function and short term effect of fenofibrate. Analysis was intent to treat with time to first CVD event evaluated by log-rank and Cox proportional hazards model to adjust for covariates.

Results: The absolute risk reduction (ARR) in CVD events was 1.4% (relative reduction 11% p=0.035). Plasma creatinine changes in the upper tertile (>16%) were associated with the highest 5-year risk on placebo (17.7%) and the largest ARR with fenofibrate (3.5% p=0.005). ARR was 0.6% and 0.4% in the middle and lower tertile (≤8%), respectively. These results persist after adjustment for age, gender, prior CVD, use of ACE inhibitors, angiotensin receptor blockers and diuretics. Conversely, lower eGFR by tertiles or by chronic kidney disease stage is associated with higher risk of CVD.

Conclusions: The implications for CVD events of baseline renal function and the early changes in creatinine on fenofibrate treatment are different. Whereas eGFR using pre-treatment creatinine values predicted CVD events in the study, in contrast, relative changes in creatinine observed early with fenofibrate were associated with the largest reduction in CVD events.

Funding: Pharmaceutical Company Support, Government Support - Non-U.S.

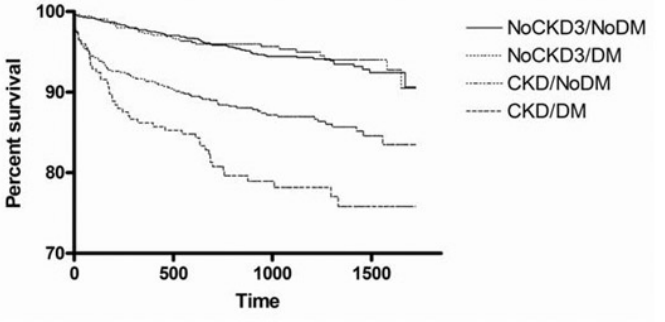
TH-OR071

Chronic Kidney Disease and Diabetes Mellitus: Can We Do More To Modify Cardiovascular Risk after Coronary Bypass Graft Surgery? Sean Gallagher, Matt Lovell, Dan A. Jones, Andrew Wragg, Akhil Kapur, Rakesh Uppal, Magdi Yaqoob. *Cardiac and Renal, Barts and the London NHS Trust, United Kingdom.*

Background: Chronic kidney disease stage 3 (CKD3) and diabetes mellitus (DM)in combination is anecdotally associated worse outcomes following coronary artery bypass graft surgery (CABG). Long term mortality data upon patients with both CKD3 and DM following CABG is currently lacking.

Methods: We analysed prospective data upon 2713 consecutive patients undergoing CABG at a tertiary cardiac centre between 2003 and 2007. Patients were divided into 4 groups for analysis: NoCKD/NoDM. NoCKD/DM. CKD/NoDM and CKD/DM. All-cause mortality was determined via Office of National Statistics data.

Results: There were 1286 No CKD/NoDM patients, 553 NoCKD/DM patients, 611 CKD/NoDM patients and 263 CKD/DM patients. In hospital mortality (0.78vs0.54%, p=0.373) and 5 year mortality (94.3vs94.8%, p=0.685)were not different between NoCKD/NoDM and NoCKD/DM groups despite more LV dysfunction (41.4vs 35.8%, p=0.037), and more previous MIs (54.0vs48.0%, p=0.0001) in the NoCKD/DM group. Comparing CKD/NoDM with CKD/DM; there was no difference in hospital mortality (2.45vs1.90%, p=0.806) but significant difference in 5 year mortality (86.2vs78.0%, p<0.0261).



CKD/DM patients had more previous MIs (53.8vs43.3%, p=0.003), more LV dysfunction (53.2vs41.9%, p<0.0001), more PVD (26.1vs16.1%, p=0.0014), and lower eGFR (45.6+/-11.9vs48.3+/-9.44, p=0.0005).

Conclusions: DM is not associated with increased mortality following CABG when eGFR is more than 60mls/min. The combination of CKD3 and DM, is associated with worse long term outcomes following CABG than with CKD3 alone. Excess late mortality is likely due to the augmentation of vascular risk factors and therapeutic nihilism. Currently, aggressive medical therapy is the mainstay of therapy but further research within this high risk group is urgently needed.

TH-OR072

Sevelamer Carbonate Improves Metabolism and Reduces Risk Factors for Progressive Nephropathy in Type 2 Diabetics with Stage 2-4 CKD by Sequestering Oral Advanced Glycation End Products Helen Vlassara,[1] Jaime Uribarri,[1] James B. Post, Fabrizio Grosjean,[3] Gary E. Striker.[1] *[1]Medicine and Geriatrics, Mount Sinai School of Medicine, New York, NY; [2]Epidemiology, University of Sydney, Australia; [3]Medicine, University of Pavia, Italy.*

Background: Increased inflammation and oxidative stress (Infl/OS) in stable diabetes mellitus (DM) are partly due to advanced glycation end products from food, and restricting AGE-intake significantly reduces these risk factors in DM. High levels of circulating advanced glycation end products (AGEs) and TNFR1/2 have been shown to be associated with progression in diabetic nephropathy. We hypothesized that sevelamer carbonate (SC), but not calcium carbonate (CC), would sequester AGEs in the GI tract and reduce Infl/OS, including circulating AGEs and TNFα, in T2DM with Stage 2-4 CKD. We conducted a proof-of-concept trial.

Methods: In a randomized two-month crossover study we compared stable diabetic patients with stage 2-4 CKD treated with either SC or CC for 2 months, a 1 week wash-out, and then the opposite drug for 2 months. There were no changes in medications and food intake.

Results: Urinary phosphate excretion was decreased by both SC and CC. Serum AGEs, lipids, HbA1c, FGF23, and 8-isoprostanes were significantly reduced by SC, but not by CC. In addition, serum chloride and potassium levels were decreased, and cystatin C showed a trend to decrease. Peripheral blood mononuclear cell AGE-receptor 1 and SIRT1 levels were decreased and TNFα were decreased by SC. These changes did not occur with CC. SC bound AGEs (AGE-BSA) (but not BSA) at pH 7.0, but not at pH 1.0 in vitro. BSA binding was <5% at either pH.

Conclusions: Sevelamer carbonate reduces circulating HbA1c, AGEs, FGF23, lipids, TNFα, other markers of inflammation and oxidative stress in stage 2-4 diabetic CKD. The proposed mechanism of action is sequestration of dietary AGEs in the GI tract and elimination in the stool. These changes were not seen with calcium carbonate. A larger and longer trial is indicated to confirm these results.

Funding: Pharmaceutical Company Support

TH-OR073

Advanced Diabetic Nephropathy with Nephrotic Range Proteinuria: Long-Term Efficacy of Subcutaneous Adrenocorticotrophic Hormone (ACTH) Therapy on Proteinuria and Urinary Vascular Endothelial Growth Factor (VEGF) Levels James A. Tumlin,[1] Claude Mabry Galphin,[3] Brad H. Rovin.[2] *[1]Internal Medicine/Nephrology, University of Tennessee College Medicine, Chattanooga, TN; [2]Renal Division, Ohio State University, Columbus, OH; [3]Clinical Research, Southeast Renal Research Institute, Chattanooga, TN.*

Background: Activation of melanocortin receptor-1 (MC1R) in podocytes and endothelium can lower proteinuria. We have shown that 6 months of ACTH gel reduces proteinuria in over 50% of patients with nephrotic diabetic nephropathy. Because ACTH increases expression of vascular endothelial growth factor (VEGF), we investigated whether the reduction in proteinuria with ACTH gel involves alteration of VEGF expression.

Methods: A total of 14 patients with diabetic nephropathy and 3.0 gm proteinuria/24 hrs on ACE inhibitor alone or 2.0 gm/24 hrs on combination ACE/ARB were enrolled. All patients had eGFR≥20 mls/min and HgBA1c ≤ 9%. Patients were randomized to ACTH gel (16U or 32U) SQ daily for 6 months. Using a Luminex or ELISA assay, urinary VEGF and monocyte chemotactic protein-1 (MCP-1) were measured at baseline and after 6 months of ACTH gel. All urinary samples were normalized to Cr.

Results: Table-1 Data

ACTH gel-16U	Baseline	6 Mth ACTH	6 Mth Post ACTH
Proteinuria	6395±735	2237±399*	1248±235*
Urinary VEGF	379±107	1539±403*	
Urinary MCP-1	569±254	1401±735	

*=P<0.05

ACTH gel (16U) reduced proteinuria from 6395 to 2237 mg/24 hrs (P=0.015). After drug withdrawal (6 mths), proteinuria further fell to 1248 mg/24 hrs (P=0.08). ACTH gel 16U increased urinary VEGF (379 to 1539 pg/mg Cr) (P=0.04). Patients responding to ACTH gel therapy (>50% reduction in proteinuria) had lower baseline urinary VEGF than non-responders (388 vs 689 pg/mg Cr)(P=0.022). Urinary MCP-1 tended to rise following treatment but did not reach statistical significance.

Conclusions: ACTH gel reduces urinary protein in diabetic nephropathy for up to 6 months after withdrawal of therapy. ACTH gel increased urinary VEGF 5-fold with a non-significant trend toward increased MCP-1. ACTH gel may represent a novel therapy for advanced diabetic nephropathy, and may act in part by restoring appropriate expression of VEGF.

TH-OR074

Assessment of Markers of Glycemic Control in Diabetic Patients with Chronic Kidney Disease Using Continuous Glucose Monitoring Frederiek E. Vos, John B.W. Schollum, Carolyn V. Coulter, Patrick Manning, Stephen Duffull, Robert J. Walker. *University of Otago, Dunedin, New Zealand.*

Background: Due to altered red blood cell survival and erythropoietin therapy glycated hemoglobin (HbA1c) may not accurately reflect long-term glycemic control in patients with diabetes and chronic kidney disease (CKD). Glycated albumin (GA) and fructosamine are potential alternative markers since their production is not affected by anemia or ESA. The exact relationship between glucose and the different indices of glycemia in advanced CKD have yet to be established. The aim of this study was to determine the correlation of indicators of diabetic control CKD to continuous glucose monitoring (CGM). to investigate the accuracy of HbA1c, GA and fructosamine as indicators of glycemic control using continuous glucose monitoring (CGM).

Methods: HbA1c, GA and fructosamine concentrations were measured in 25 diabetics with CKD stages 4 and 5 (eGFR < 30 mL/min/1.73m2) and 25 diabetics without nephropathy otherwise appropriately matched to the CKD subjects. Simultaneous real-time glucose concentrations were monitored by CGM over 48 hours.

Results: Mean glucose, GA and fructosamine concentrations were similar in both groups, HbA1c tended to be lower in CKD diabetics. GA correlated significantly to mean glucose concentrations in diabetics with and without CKD (r = 0.54 vs 0.49, p < 0.05). A

similar relationship was observed with fructosamine relative to glucose. A poor correlation between HbA1c and glucose was observed with CKD ($r = 0.38$, p=ns) but was significant in the non-CKD group ($r = 0.66$, $p < 0.001$). The GA/HbA1c ratio was significantly higher in diabetics with CKD compared to controls (2.5 ± 0.4 vs 2.2 ± 0.4, $p < 0.05$). HbA1c values were significantly lower in CKD diabetics, relative to non-CKD diabetics at comparable mean glucose concentrations.

Conclusions: HbA1c significantly underestimates glycemic control in CKD stage 4 & 5 diabetics. In severe CKD, GA more accurately reflects glycemic control compared to fructosamine and HbA1c in this patient cohort and should be the preferred marker of glycemic control.

TH-OR075

Identification of Novel Genetic Factors for Congenital Anomalies of the Kidney and Urinary Tract (CAKUT) Kirsten Y. Renkema,[1,2] Ernie M.H.F. Bongers,[2] Iris Van Rooij,[3] Loes F.M. Van der Zanden,[3] Nel Roeleveld,[3] Wout F. Feitz,[4] Helen McNeill,[5] Barbara Franke,[2] Nine V. Knoers.[1] *[1]Medical Genetics, University Medical Center Utrecht, Netherlands; [2]Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [3]Epidemiology, Biostatistics, and HTA, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [4]Pediatric Urology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [5]Molecular Genetics, Samuel Lunenfeld Research Institute, University of Toronto, Toronto, Canada.*

Background: CAKUT occur frequently in man and comprise the most common cause of end-stage renal disease in children. Structural anomalies belonging to the CAKUT spectrum include renal agenesis, multicystic dysplastic kidney, and duplex collecting system. Not much is known about the origin of CAKUT. Often, renal abnormalities are found in close relatives of CAKUT cases, showing a genetic contribution to CAKUT pathogenesis. In particular, alterations in genes expressed during nephrogenesis are considered to be important. The aim of this study is to identify new genetic factors involved in CAKUT aetiology.

Methods: Over 700 well-documented CAKUT case-parent triads and 45 families with multiple affected members were included in this study via the AGORA biobank project and European CAKUT consortium (EUCAKUT).

Results: Mutation analysis in a systematically selected and enriched set of CAKUT candidate genes was performed and revealed novel variants implicated in CAKUT pathogenesis. Moreover, linkage analysis in a multiplex family with 8 members dysplaying duplex collecting system identified suggestive linkage for loci on chromosome 3 and 4. Interestingly, the powerful combination of linkage analysis and next generation sequencing approaches brought disease-gene identification in close proximity.

Conclusions: The present identification and characterization of novel genetic factors for CAKUT contributes to the understanding of the pathogenesis and the design of genetic diagnostic screening tests, facilitating early detection and improving genetic counseling for CAKUT patients and their relatives.

Funding: Government Support - Non-U.S.

TH-OR076

Novel Amniotic Fluid Biomarkers of Congenital Anomalies of the Kidney and Urinary Tract Wendy Heywood, Darrell Wang, Kevin Mills, Paul J.D. Winyard. *Institute of Child Health, University College London, London, United Kingdom.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) are often detected on pregnancy ultrasound, yet we lack good antenatal markers of prognosis. Amniotic fluid (AF) is 95% fetal urine and is collected during amniocentesis for karyotyping. We predict that changes in AF reflect the underlying severity of CAKUT. Hence, AF biomarkers may correlate with long-term prognosis.

Methods: After research ethical approval and maternal consent, we collected AF fluid from 10 controls, and 12 CAKUT cases comprising 6 isolated kidney malformations and 6 lower urinary tract obstruction. These were then analysed independently using three proteomic techniques: SELDI-TOF MS, 2D DiGE and label free quantitation (LC/MSE).

Results: In obstruction, SELDI-TOF revealed two down-regulated proteins of 11,789 and 26,301Da and two up-regulated proteins of 8,080 and 15,078Da; 2D DiGE identified significant down-regulation of alpha-1-microglubulin (AMBP) and gelsolin. Reduced AMBP was confirmed by LC/MSE, and this technique also revealed down-regulation of transthyretin, transforming growth factor-beta-induced protein ig-h3, SPARC, and plasma C1-inhibitor.

In renal malformations, SELDI-TOF detected a down-regulated protein of 40,890Da, whilst both 2D DiGE and LC/MSE identified down-regulation of collagen type-1 proteins and glycodelin; LC/MSE identified increased immunoglobulins, kininogen and IBP1.

Transthyretin and AMBP were reduced in both obstruction and kidney malformations by label free quantitation, but none of the other factors were consistently abnormal for both conditions using the same technique.

Conclusions: Many studies demonstrate common molecular pathology in CAKUT, usually with up-regulation of factors in kidney parenchyma. We identified markers that discriminate within the CAKUT spectrum, and most are down-regulated rather than increased. Key factors reduced included AMBP and glycodelin. Moreover, use of more than one proteomic technique identified a wider range of candidates. Further evaluation is needed to determine if these novel biomarkers are consistently deranged in CAKUT, with robust collection of outcome data for prognostic significance.

TH-OR077

Angiotensin (Ang) II Stimulates Papillogenesis during Late Metanephric Development Renfang Song, Graeme James Preston, Ihor V. Yosypiv. *Pediatrics, Tulane University, New Orleans, LA.*

Background: We tested the hypothesis that lack of Ang II production in angiotensinogen (*AGT*)-null mice impairs papillary collecting duct elongation thus contributing to the hypoplastic renal medulla phenotype observed in these mice.

Methods: Papillas were dissected from *AGT*+/+, +/- and -/- mouse metanephroi on postnatal day P3 and grown in 3-dimentional collagen matrix gels located on air-fluid interface in the presence of media (control, n=6/genotype) or Ang II (10^{-5}M, n=6/genotype) for 24 hours. Images were acquired at time of dissection ("0" hours) and after 24 hours of culture. Percent change in papillary length, determined by Slide book 4.0 software, at 24 hours relatively to time "0" was compared between the groups. We next examined the role of Ang II AT1R in papillary collecting duct growth, cell proliferation and apoptosis using P3 papillas from Hoxb7-GFP+ mouse grown ex vivo for 24 hours in the presence of the specific AT1R antagonist, candesartan (10^{-6}M, n=5) or media (control, n=5).

Results: Observed reduction in papillary length was attenuated in *AGT*+/+ compared with *AGT*-/- papillas (26±2 vs. 35±3%, p<0.01). Treatment with Ang II blunted the decrease in papilla length observed in respective media-treated controls (*AGT*+/+: 16±1.3 vs. 24±1.6%, p<0.01; *AGT*+/-: 16±1.1 vs. 23±0.9%, p<0.001; *AGT*-/-: 28±1.3 vs. 35±1.4%, p<0.01). Treatment with AT1R antagonist candesartan decreased papillary length after 24 hours of culture (87±4.2 vs. 100±0%, p<0.01). In contrast, papillary length in control group (media, n=5) did not differ from baseline (101±4.3 vs. 100±0%, p=0.6. The number of proliferating phospho-histone H3 (pH3)-positive collecting duct cells, visualized with anti-pancytokeratin antibody, was lower whereas the number of caspase 3 (Casp 3)-positive cells undergoing apoptosis was higher in candesartan- vs. media-treated papillas (pH3: 12±1.4 vs. 21±2.1, p<0.01; Casp 3: 3.8±0.5 vs. 1.7±0.2, p<0.01).

Conclusions: In summary, Ang II, acting via the AT1R, promotes papillary growth by stimulating collecting duct cell proliferation and survival. We conclude that defects in collecting duct elongation may be causally linked to medullary hypodysplasia observed in *AGT*- and *AT1R*-null mice.

MRI Reveals Postnatal Functional Obstruction and Abnormal Peristalsis in Crim1KST264/KST264 Mice Lorine J. Wilkinson,[1] Nyoman Dana Kurniawan,[2] Yu Leng Phua,[1] Joan Li,[1] Melissa H. Little,[1] Richard J. Lang.[3] *[1]Institute for Molecular Bioscience, University of Queensland, Brisbane, Queensland, Australia; [2]Centre for Advanced Imagin, University of Queensland, Brisbane, Queensland, Australia; [3]Department of Physiology, Monash University, Melbourne, Victoria, Australia.*

Background: Crim1 hypomorphic (Crim1KST264/KST264) mice display renal disease characterised by podocyte effacement, excessive glomerular permeability, leaky peritubular vasculature, focal glomerular cysts and progressive interstitial fibrosis. A portion of Crim1KST264/KST264 mice develop hydronephrosis of unknown aetiology.

Methods: To investigate this phenomenon, the clearance of the contrast agent Magnavist® from the kidneys was analysed using dynamic contrast enhanced Magnetic Resonance Imaging (DCE-MRI). To examine the potential for a functional obstruction, ureteropelvic peristalsis was investigated using live imaging of whole kidney hemimounts.

Results: Using DCE-MRI, 95% of Magnavist was cleared from wild-type kidneys by 140 minutes after injection, however, contrast continued to accumulate in the kidneys of the Crim1KST264/KST264 mice over the imaging period of two hours. This result suggested obstructed flow of filtrate from these kidneys. Similarly, DEC-MRI was performed on a model of unilateral ureteral obstruction showed a similar accumulation of Magnavist in the obstructed kidneys. Immunofluorescence of kidney sections from Crim1KST264/KST264 mice after tail-vein injection of rhodamine dextran (10KDa) showed accumulation of dextran in the collecting ducts, particularly in the papilla. Peristalsis in the wild-type kidney originated at the kidney/pelvis junction and propagated distally along the pelvis and ureter. In contrast in the Crim1KST264/KST264 mouse peristalsis consisted of either small contractions that appeared near synchronously along the full length of the renal pelvis or appeared to originate in the distal pelvis, but only partially propagated in the proximal direction along the pelvic wall.

Conclusions: These results reveal a functional obstruction in the Crim1KST264/KST264 mouse resulting from abnormal ureteropelvic peristalsis and suggest a role for Crim1 in the development and/or maintenance of the peristaltic machinery.

Identification of microRNA and microRNA Targets in Human Podocyte Culture: A Deep Sequencing Approach Iddo Zeev Ben-Dov,[1] Moin Saleem,[2] Thomas Tuschl.[1] *[1]Rockefeller University, New York, NY; [2]Bristol Royal Hospital for Children, Bristol, United Kingdom.*

Background: Disruption of miRNA processing in mouse podocytes results in lethal glomerulopathy. Systematic identification of podocyte-specific miRNA and miRNA targets may thus facilitate further studies.

Methods: We profiled miRNA in cultured human podocytes using barcoded RNA sequencing. miRNA were grouped by sequence or genomic clustering. We also sequenced

argonaute-bound RNA by immunoprecipitation of in-vivo crosslinked miRNPs ('PAR-CLIP') to identify engaging miRNA and their targets.

Results: Podocyte miRNA profiles were typical of epithelial cells. Top miRNA sequence families were miR-21(1), let-7a-1(12), miR-27a(2), miR-30a(6), miR-29a(4) and miR-17(8) (parenthesis denote # of members). sf-miR-30a(6) ranked higher in mature cells, while sf-miR-17(8) were higher in immature. Higher expression of miR-29a(4), miR-10a(1) and several additional miRNA genomic clusters was found in podocytes compared to other epithelia (panel A).

PAR-CLIP on mature cells identified 860 high confidence mRNA clusters (showing a unique photo-crosslinking signature); a lower estimate of the true number of miRNA targets in podocytes due to the scale of the experiment. The clusters mapped to 634 genes (1 to 5 mRNA clusters per target gene). 89% of clusters matched exons. Of these, 70% mapped to 3'UTRs and 28% to CDS (28%). mRNA clusters were enriched with 7-mer seed complementary sequences to top miRNA, but the overall correlation was low (r=0.17, p<0.01), i.e., some abundant miRNA had only few matches and vice versa (see example in panel B)

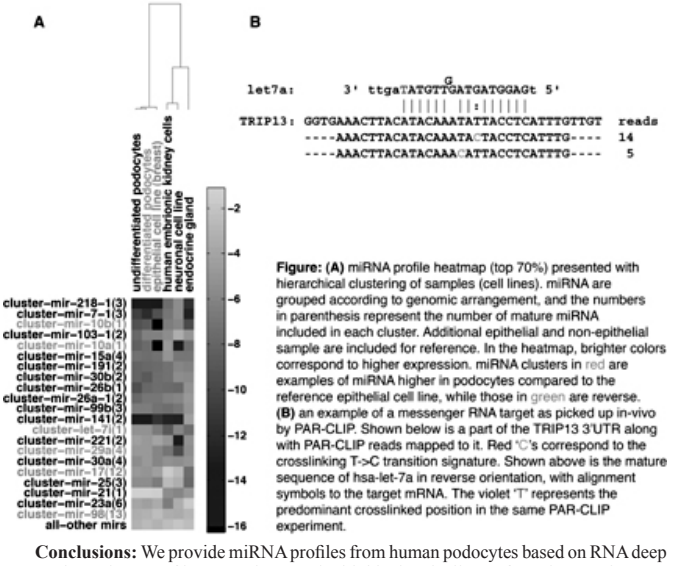

Figure: (A) miRNA profile heatmap (top 70%) presented with hierarchical clustering of samples (cell lines). miRNA are grouped according to genomic arrangement, and the numbers in parenthesis represent the number of mature miRNA included in each cluster. Additional epithelial and non-epithelial sample are included for reference. In the heatmap, brighter colors correspond to higher expression. miRNA clusters in red are examples of miRNA higher in podocytes compared to the reference epithelial cell line, while those in green are reverse. **(B)** an example of a messenger RNA target as picked up in-vivo by PAR-CLIP. Shown below is a part of the TRIP13 3'UTR along with PAR-CLIP reads mapped to it. Red 'C's correspond to the crosslinking T->C transition signature. Shown above is the mature sequence of hsa-let-7a in reverse orientation, with alignment symbols to the target mRNA. The violet 'T' represents the predominant crosslinked position in the same PAR-CLIP experiment.

Conclusions: We provide miRNA profiles from human podocytes based on RNA deep sequencing. These profiles, complemented with biochemically confirmed transcriptome-wide in-vivo mRNA target PAR-CLIP data, can serve to direct further research on miRNA involvement in podocyte development and disease.

High Resolution Genome Scans Combined with Principal Component Analysis Identifies Two Novel Nephropathy Loci

Roel Sterken, Natalia Papeta, Vivette D. D'Agati, Ali G. Gharavi. *Medicine, Columbia University, New York, NY.*

Background: HIV associated nephropathy (HIVAN) is a secondary form of collapsing glomerulopathy and a major complication of HIV-1 infection. Previous analysis of an F2 intercross between HIV-transgenic FVB/NJ, the murine model for HIVAN, and C57BL/6J, identified two QTL on chr. 13 and 4 (HIVAN1 and HIVAN2 loci). We further investigated nephropathy QTLs in this cross, through increased mapping resolution, measurement of 12 new metabolic traits and principal component (PC) analysis.

Methods: 189 F2 mice were genotyped at 718 informative SNPs and 17 traits were measured; glomerulosclerosis (GS), tubular epithelial re-/degeneration (T-R), tubular casts/dilatation (T-C), podocyte hypertrophy (PH), proteinuria (Prot), blood urea nitrogen (BUN), calcium (Ca), phosphorus (P), uric acid (UA), cholesterol (Chol), amylase (Am), creatinine phosphokinase, albumin (Alb), alkaline phosphatase (AP), alanine transaminase (ALT), aspartate transaminase (AST), and glucose levels (Gl). Traits were transformed and standardized prior to non-parametric linkage analysis. To augment the power of linkage analysis, we also performed PC analysis of 7 nephropathy relevant traits (GS, T-C, T-R, PH, Prot, BUN & Alb).

Results: Using GS and sex as covariates, we found significant novel QTLs for PH on chr. 10 (LOD = 3.7, 40.7 cM), and for BUN on chr. 8 (LOD = 4.1, 63.9 cM). A highly significant QTL was found for Chol on chr. 1, (LOD = 8.6, 77.8 cM), co-localizing with Apoa2, a well-documented QTL for Chol. Suggestive QTL were identified for PH, T-C, Chol, BUN, Am, Al, Ca, UA, P, Gl, ALT, AST, & AP. We identified two PCs: PC1 captured 55% variance of the 7 nephropathy traits and mapped to HIVAN2 and HIVAN3. PC2 explained 17% of the variation and identified a novel QTL on chr. 8 (LOD = 4.6, 65.9 cM).

Conclusions: Increased mapping resolution and PC analysis identified two new nephropathy QTL, on chr. 10 and on chr. 8. These QTLs influence global components of disease as well as a specific histologic subcategory (podocyte hypertrophy), reflecting the genetic complexity of disease. These approaches may enable dissection of the different pathogenic mechanisms underlying HIVAN.

An ENU-Induced Mutation Mapping to Chromosome 9 Is Associated with Diabetic Nephropathy in Mice

Elena E. Tchekneva,[1] Jennifer Kearney,[2] Agnes B. Fogo,[3] John N. Calley,[4] Jeffrey K. Cecil,[4] Matthew D. Breyer.[4] *[1]Medicine/Nephrology, Vanderbilt University, Nashville, TN; [2]Division of Genetic Medicine, Vanderbilt University, Nashville, TN; [3]Pathology, Vanderbilt University, Nashville, TN; [4]BioTechnology Discovery Research, Eli Lilly and Company, Indianapolis, IN.*

Background: Accumulating evidence suggests heritable factors predispose 25-40% of diabetic patients to diabetic nephropathy (DN). In mice, genetic background also appears to critically determine predisposition to DN. We mutagenized C57BL/6 mice, which are relatively resistant to DN, using ethyl-nitrosourea, and generated a dominant mutation designated Nphrp2 predisposing B6 mice to DN on a sensitizing type 1 diabetic background contributed by the dominant Akita mutation in insulin2 gene.

Methods: To map the genetic interval in which this mutation reside we performed a backcross of these C57Bl/6 mutant mice to Balb/c background. Genome scanning was performed using a panel of 478 SNPs. A reduction of interval of interest was performed using DNA microsatellite markers analysis.

Results: About 50% of the progeny of Nphrp2/Akita mutants, backcrossed B6 to Balb/C showed persistent albuminuria. N2 mutants exhibited renal failure within 19 months of age with an increase of BUN (90±15 mg/dl vs. 25±1 mg/dl in control Balb/cAkita mice, p<0.005) and by progressively increasing albuminuria. Renal hypertrophy,glomerular mesangial expansion and mesangial nodules, and pronounced tubulointerstitial fibrosis in Nphrp2 congenic mice demonstrated the persistence a dominant trait associated of the DN phenotype. Affected N2-N6 Nphrp2 mice were genotyped. Haplotype data showed retention of alleles from C57Bl/6 mutagenized strain with the only linkage being to distal Chr. 9 (LOD of 5.34). Association of the C57BL/6J chromosomal segments inherited in the backcross with the albuminuria in diabetic Balb/C mice allowed us to determine a candidate locus within which the ENU mutagenized genes reside at [101515262-104018155 bp].

Conclusions: We mapped the DN trait to 2.5 Mb locus in Chr.9. The identification of the gene involved in this mutation should facilitate the identification of new molecular pathways of DN.

Systems Approach Identifies HIPK2 as a Critical Regulator of Kidney Tubulointerstitial Fibrosis

Yuanmeng Jin,[2] Peter Y. Chuang,[1] Vivette D. D'Agati,[3] John C. He.[1] *[1]Medicine, Mount Sinai School of Medicine, New York, NY; [2]Nephrology, Ruijin Hospital, Shanghai Jiaotong University, Shanghai, China; [3]Pathology, Columbia University, New York.*

Background: Tubulointerstitial fibrosis is a common process that leads to the progression of kidney disease. We describe an integrated computational/experimental approach to identify upstream protein kinases that regulate gene expression changes in kidneys of HIV-1 transgenic mice (Tg26), which exhibits significant tubulointerstitial injury. Using this approach, we identify the homeo-domain interacting protein kinase 2 (HIPK2), a previously unrecognized protein kinase for kidney disease, is critically involved in the regulation of the gene network in HIVAN kidney. We find that HIPK2 expresses mostly in renal tubular epithelial cells (RTEC) of HIVAN kidneys. We confirm that HIPK2 mediates HIV-induced apoptosis of renal tubular epithelial cells (RTEC). HIPK2 also mediates TGF-beta and HIV-induced expression of EMT markers. Here, we further determined the role of HIPK2 in vivo by crossing HIPK2-/- with Tg26.

Methods: HIPK2-/- mice on a mixed C57B6/129svj background were first backcrossed onto the FVB/N background for 6 generations and then cross with Tg26 to generate mice that are HIPK2 deficient and express the HIV-1 transgene. HIPK2-/-;Tg26 mice were compared to HIPK2+/+;Tg26 at 8 weeks of age. Renal function, proteinuria, and kidney histology were assessed in these mice. The activation of signaling pathways were also studied in kidneys of these mice.

Results: Compared to HIPK2+/+;Tg26 group, the HIPK2-/-;Tg26 mice had a significant decrease in serum urea nitrogen, urine protein/creatinine ratio, collagen deposition and tubulo-interstitial injury and fibrosis scores. Knockout of HIPK2 also significantly attenuated the activation of TGF-beta/smad, Wnt/beta-catenin, Notch, and p53 pathway in kidneys of Tg26 mice.

Conclusions: HIPK2 is a critical regulator of kidney fibrosis in the HIVAN model and a potential target for anti-fibrosis therapy.

Geographic Differences in Genetic Susceptibility to IgA Nephropathy: GWAS Replication Study and Geospatial Risk Analysis Krzysztof Kiryluk,[1] Yifu Li,[1] Mersedeh Rohanizadegan,[1] Simone Sanna-Cherchi,[1] Murim Choi,[2] Francesco Scolari,[3] Loreto Gesualdo,[4] Silvana Savoldi,[5] Antonio Amoroso,[6] Bruce A. Julian,[7] Jan Novak,[7] Robert J. Wyatt,[8] Marie Metzger,[9] Benedicte Stengel,[9] Lise Thibaudin,[10] Francois C. Berthoux,[10] Frank Eitner,[11] Jurgen Floege,[11] Ulf Panzer,[12] Judit Nagy,[13] Richard P. Lifton,[2] Ali G. Gharavi.[1] *[1]Columbia U, US; [2]Yale U, Howard Hughes Med Inst, US; [3]U of Brescia, Italy; [4]U of Foggia, Italy; [5]Ciriè Hosp, Italy; [6]U of Torino, Italy; [7]U of Alabama at Birmingham, US; [8]U of Tennessee, US; [9]INSERM, France; [10]U N Hosp, St Etienne, France; [11]U of Aachen, Germany; [12]U Clin Hamburg-Eppendorf, Germany; [13]U of Pécs, Hungary.*

Background: In a recent GWAS, we localized 5 common susceptibility loci for IgAN. The goals of this study are to replicate these findings in independent cohorts and to model the genetic risk for IgAN in the worldwide populations.

Methods: We tested for association, assessed heterogeneity, and calculated a genetic risk score for IgAN in independent cohorts of 5 nationalities (French, Italian, German, Hungarian & AA; 1,120 cases & 1,665 controls) in addition to the original GWAS cohorts (Asians and Europeans; combined N=8,687). After validation, the risk model was applied to 1,042 HGDP individuals (57 populations); spatial interpolation of the risk trend surface was used to construct topographical IgAN risk maps across 6 continents.

Results: 4 of 5 loci demonstrate significant replication and no heterogeneity (OR=0.70-0.86, P=9x10-8-1x10-2). Heterogeneity is observed only for the MHC locus of TAP1/2-PSMB8/9 (I2=75%, p<0.01). This locus replicates in Italians & Germans (OR=0.60-0.67, P=5x10-3-2x10-2), but not in French, Hungarians, or AAs. In the combined analysis, all 5 loci remain highly significant with minor alleles conferring protection (OR=0.66-0.81, P=10-27-10-10). In the geospatial analysis, the genetic risk increases sharply with distance from Africa (P=2x10-16), and thus closely parallels the geographic distribution of IgAN.

Conclusions: These data suggest that the five IgAN risk loci contribute to the known geographic variation in disease prevalence.

TH-OR084

Mitochondrial Mistargeting Causes Autosomal Dominant Renal Fanconi Syndrome Markus Reichold,[1] Enriko Klootwijk,[2] Horia Stanescu,[2] Detlef Bockenhauer,[2] Carsten Broeker,[1] Dominika Peindl,[1] Kathrin Renner,[1] Karin Eberhart,[1] Joerg Reinders,[1] Katja Dettmer,[1] Robert Kleta,[2] Richard Warth.[1] *[1]University of Regensburg, Regensburg, Germany; [2]University College London, United Kingdom.*

Background: Renal Fanconi syndromes are characterized by a generalized renal proximal tubular dysfunction. For this study the causative genetic factor as well as the underlying molecular pathology in an extended family with autosomal dominantly inherited renal Fanconi syndrome without kidney failure was unraveled.

Methods: Whole genome multipoint parametric linkage analysis was performed resulting in a significant LOD score (> 3) for a single locus. All genes in the linked area were sequenced resulting in the identification of a heterozygous mutation in a gene, which we call Fanconin that leads to a de-novo formation of a mitochondrial targeting motif. To assess the functional impact a stable permanently transfected inducible renal proximal tubular cell model was generated. Immunohistochemical analysis showed appropriate intracellular localization for the wild type and mitochondrial mistargeting for mutant Fanconin.

Results: Since Fanconin is mistargeted to mitochondria the impact of this mutation on mitochondrial function was investigated. When mutated Fanconin was overexpressed, lactate levels in the medium were increased and cells consumed more glucose compared to overexpression of wild type protein pointing towards enhanced glycolysis. Respirometric measurements of these cells indeed showed a reduced response to ADP-triggered stimulation of the respiratory chain. According to our hypothesis, mutated Fanconin is interfering with oxidative phosphorylation leading to diminished ATP production in mitochondria.

Knockout mice for Fanconin, as expected, did not show a proximal tubular transport defect as assessed by aminoacid analysis using GC-MS.

Conclusions: We therefore hypothesize that the renal Fanconi phenotype in our family is not caused by haploinsufficiency rather than by a dominant negative effect of the Fanconin protein.

To our knowledge this is the first description of a genetic defect leading to intracellular mistargeting of a mutant protein resulting in mitochondrial pathology.

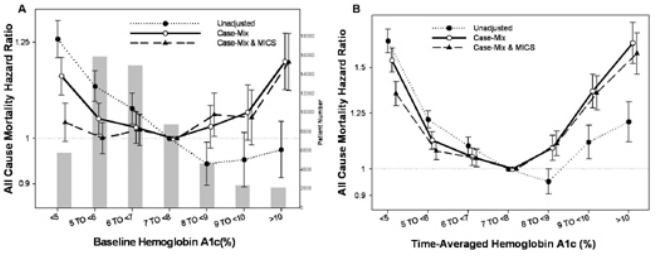
TH-OR085

Glycemic Control and Mortality in Hemodialysis Patients with Diabetes Mellitus: A Six Year Cohort Study Miklos Z. Molnar,[1] Joni L. Ricks,[1] Csaba P. Kovesdy,[2] Anuja P. Shah,[1] Allen R. Nissenson,[3] Mark E. Williams,[4] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Torrance, CA; [2]Salem VA Medical Center, Salem, VA; [3]DaVita, Inc, Denver, CO; [4]Joslin Diabetes Center, Harvard Medical School, Boston, MA.*

Background: Observational studies examining the association of hemoglobin A1c (A1c) with outcomes in diabetic patients (pts) on maintenance hemodialysis (MHD) have used different methodologies & reached somewhat contrasting conclusions.

Methods: We examined mortality-predictability of A1c & random serum glucose over time in a cohort of diabetic MHD pts treated in DaVita dialysis clinics from July 2001 through June 2006 with follow-up through June 2007.

Results: We identified 54757 diabetic MHD pts with A1c data (age, 63±13 years, 51% men, 30% African Americans). Adjusted all-cause death hazard ratio (HR) and 95% confidence interval for baseline A1c increments of 8.0-8.9%, 9.0-9.9% and ≥10%, compared to 7.0-7.9% (reference), were 1.06(1.01-1.12), 1.05(0.99-1.12), & 1.19(1.12-1.28); and for time-averaged A1c were 1.11(1.05-1.16), 1.36(1.27-1.45), & 1.59(1.46-1.72), respectively. A consistent increase in mortality also occurred with time-averaged A1c levels in the low range 6.0-6.9% (1.05(1.01-1.08), 5.0-5.9% (1.08(1.04-1.11)) & ≤5% (1.35(1.29-1.42)) compared to 7.0-7.9% A1c in fully adjusted models.



Adjusted all-cause death HR for time-averaged blood glucose 175-199 mg/dl, 200-249 mg/dl, 250-299 mg/dl & ≥300 mg/dl, compared to 150-175 mg/dl (reference), were 1.03(0.99-1.07), 1.14(1.10-1.19), 1.30(1.23-1.37) and 1.66(1.56-1.76), respectively.

Conclusions: Poor glycemic control (A1c ≥ 8% or serum glucose ≥ 200mg/dl) appears associated with high death in MHD pts. Very low glycemic levels also add mortality risk. Clinical trials are needed to better define the target A1c levels in long-standing diabetic pts on MHD.

Funding: NIDDK Support

TH-OR086

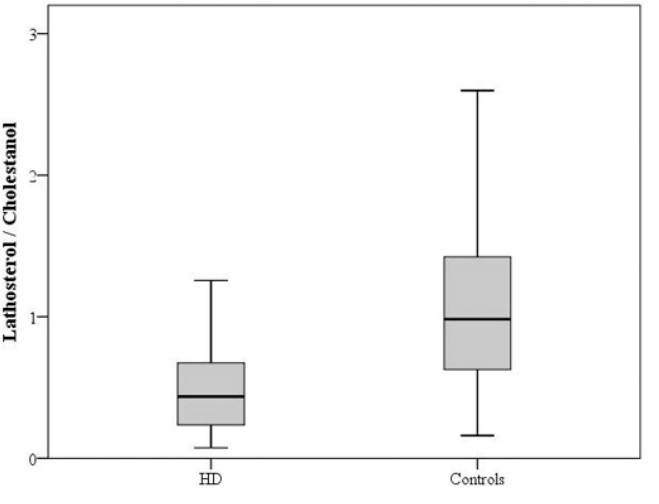
Analysis of Cholesterol Homeostasis Characterizes Dialysis Patients as "Cholesterol Absorbers" Kyrill S. Rogacev,[1] Tobias Pinsdorf,[2] Oliver Weingärtner,[4] Julius Popp,[3] Danilo Fliser,[1] Dieter Lutjohann,[2] Gunnar H. Heine.[1] *[1]Nephrology & Hypertension, Saarland University Hospital, Homburg, Germany; [2]Clinical Chemistry/Pharmacology, University of Bonn, Bonn, Germany; [3]Psychiatry, University of Bonn, Bonn, Germany; [4]Cardilogy, Angiology, Intensive Care, Saarland University Hospital, Homburg, Germany.*

Background: Recent clinical trials on cholesterol-lowering in chronic kidney disease patients yielded conflicting results, which might result from different treatment strategies used. Serum cholesterol levels are determined by both endogenous synthesis and intestinal absorption, which are differentially influenced by various classes of cholesterol-lowering agents. Assessment of cholesterol homeostasis has thus been proposed for guidance of lipid-lowering therapy. We analysed established surrogate markers of cholesterol homeostasis in patients with chronic kidney disease.

Methods: In 113 hemodialysis patients, we measured lathosterol and desmosterol as markers of cholesterol synthesis, and cholestanol, sitosterol and campesterol as markers of cholesterol absorption via gas chromatography. 229 healthy subjects served as controls. Overall survival in dialysis patients was recorded over a follow-up of 28 months.

Results: Hemodialysis patients displayed a striking shift towards cholesterol absorption compared to synthesis (p<0.001). High absorption markers and concomitantly low synthesis markers indicated poor outcome among dialysis patients in univariate Kaplan-Meier analysis, and in multivariate Cox regression analysis after adjustment for potential confounders.

Conclusions: Our analysis of cholesterol homeostasis characterises hemodialysis patients as "cholesterol absorbers". These findings supplement data from a recent randomised controlled trial on dual cholesterol-lowering therapy in chronic kidney disease.



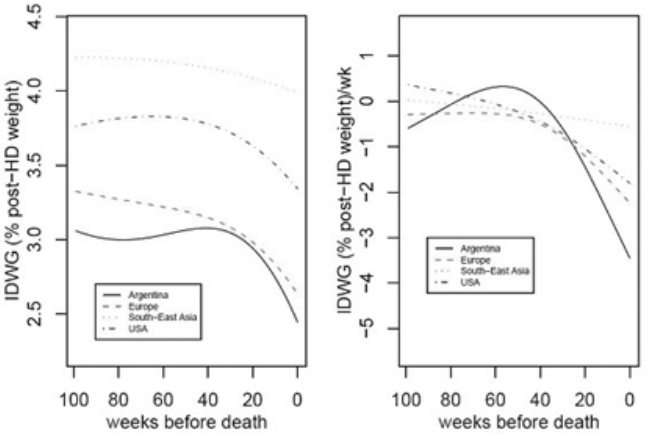
TH-OR087

Declining Interdialytic Weight Gain (IDWG) in Chronic Hemodialysis Patients (HD) – An Ominous Sign? Results of an International Study Adrian Marcos Guinsburg,[1] Cristina Marelli,[1] Adam Tashman,[2] Michael Etter,[3] Daniele Marcelli,[4] Gero D. von Gersdorff,[6] Mathias Schaller,[6] Yuedong Wang,[2] Nathan W. Levin,[5] Peter Kotanko,[5] Len A. Usvyat.[5] *[1]FMC Latin America, Buenos Aires, Argentina; [2]University of California - Santa Barbara, Santa Barbara, CA; [3]FMC Asia Pacific, Hong Kong, Hong Kong; [4]FMC Europe, Bad Homburg, Germany; [5]RRI, NY, NY; [6]University of Cologne Medical Center, Germany.*

Background: Chronic HD patients (pts) frequently present with high IDWG, presumably due to high fluid intake. It has been reported that in pts from US, contrary to widespread believe, declining IDWG precedes death (Kotanko 2009). We extend this observation to diverse HD populations from 3 continents.

Methods: HD databases from FMC clinics in Europe, Asia, Latin America, RRI clinics in US, and KfH in Germany were queried. IDWG was calculated as % of post-HD weight. IDWG dynamics were analyzed by estimating the mean IDWG level before death and its 1st derivative using quintic splines.

Results: Chronic HD pts from 23 countries were studied (Europe 17 [N=12333; age 71.7, 59% males]; South-East Asia 4 [N=1484; age 68; 53% males]; Argentina [N=10517; age 63.1; 58% males]; USA [N=3473; age 69.9; 56% males]). IDWG [mean (SD)] before death was 2.3 (2.6); 3.8 (3.2); 2.9 (3.1); 2.9 (3.1); same order as above. Irrespective of the region, IDWG dropped in males between 0.23% in South-East Asia and 0.68% in Europe in the 2 years preceding death (left).



The rate of IDWG change was identical in Europe, Argentina, and US, and less in South-East Asia (right). The results were materially identical in females and pts from KfH (not shown).

Conclusions: This international study corroborates that opposite to common believe, a decline in IDWG may be an ominous sign. Insights into pre-death biology may aid the development of alert systems to facilitate timely interventions.

TH-OR088

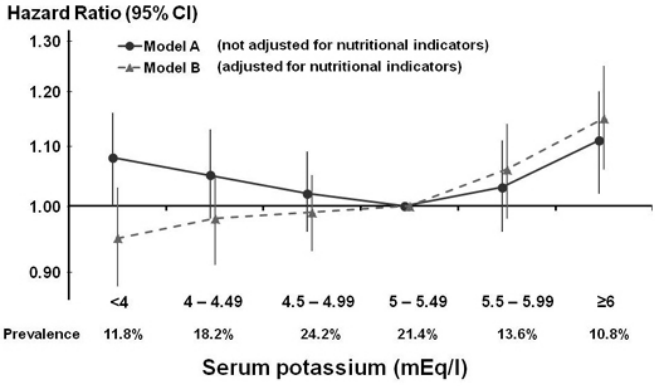
Associations of Serum Potassium with All-Cause Mortality: Results from the Dialysis Outcomes and Practice Patterns Study (DOPPS) Rajiv Saran,[1] Jinyao Zhang,[2] Ananda Sen,[1] Hal Morgenstern,[1] Francesca Tentori,[2] Antonio Alberto Lopes,[3] David C. Mendelssohn,[4] Vittorio E. Andreucci,[5] Hideki Kawanishi,[6] Bruce M. Robinson.[1,2] *[1]University of Michigan; [2]Arbor Research Collaborative for Health; [3]Bahia da Universidade Federal da Bahia; [4]Humber River Regional Hospital; [5]Universita Federico II; [6]Tsuchiya General Hospital.*

Background: Severe hyperkalemia, defined here as serum potassium (SK) > 6 mEq/l, has been observed in approximately 10% of maintenance hemodialysis (HD) patients. We investigated the relation between SK and mortality in a large international HD cohort study.

Methods: We analyzed data on 37,967 in-center hemodialysis (HD) patients from 12 countries in DOPPS phases 1-3 (1996-2008). Patient demographics, laboratory values and dialysis treatment data were obtained at study enrollment. Cox regression was used to estimate the hazard ratio (HR and 95% CI) for the effect of SK on all-cause mortality, adjusting for several potential confounders, excluding and including 4 nutritional markers. SK was categorized and treated as 5 indicator variables in the model (<4, 4-4.49, 4.5-4.99, 5-5.49 [ref.], 5.5-5.99, 6+ mEq/l).

Results: When adjusting for patient demographics, 13 summary comorbid conditions, socioeconometric status, dialysis treatment and adherence indicators, but not nutritional markers, there was a U-shaped association between SK and mortality (Figure, Model A). When also adjusting for BMI, albumin, creatinine and normalized PCR, a positive monotonic association was observed (Model B).

Conclusions: The association between hypokalemia and mortality seems to be confounded by poor nutritional status. Therefore, SK < 4.0 mEq/l should alert physicians to the potential presence of poor nutritional status in HD patients. Levels approaching 6 mEq/l or higher, however, warrant appropriate therapeutic maneuvers.



N=37,967 patients; models stratified by country and phase, and accounted for facility level clustering
In Model A, the HR is adjusted for age, sex, race, vintage, 13 comorbidities, smoking, prior TX, catheter use, employment status, education level, living status, marriage status, skipped≥1 hemodialysis session in past 30 days, shortened≥1 hemodialysis session by ≥10 minutes in past 30 days, IDWG >5.7% of dry weight, PO4 >7.5 mg/dl, spKt/V, and hemoglobin. In Model B, the HR is adjusted for the Model A covariates plus BMI, albumin, creatinine and normalized PCR

Economic Evaluation of Frequent Home Nocturnal Hemodialysis Based on a Randomized Trial Scott Klarenbach,[1] Robert P. Pauly,[1] Michael Walsh,[3] Marcello Tonelli,[1] Helen Lee,[2] Brenda Hemmelgarn,[2] Braden J. Manns.[2] *[1]University of Alberta; [2]University of Calgary; [3]McMaster University.*

Background: There is interest in providing frequent home nocturnal hemodialysis (NHD) to patients on dialysis, and decision makers require information on its cost-effectiveness.

Methods: We did a cost-utility analysis of frequent home NHD compared with conventional hemodialysis (4 hours thrice weekly, including in-centre, satellite, and home HD) taking the perspective of the health payer over a lifetime horizon. Data on transition between health states, quality of life, costs, and other inputs were from a recent RCT. Costs, including training costs, were obtained using micro-costing, trial, and administrative data (CAN$). We determined the incremental cost per quality adjusted life year (QALY) gained, and robustness was assessed using scenario, sensitivity, and probabilistic sensitivity analyses.

Results: Compared with conventional HD (61% in-centre, 14% satellite, and 25% home as in the trial), frequent home NHD led to incremental costs of $290 and additional 0.38 QALYs, with a cost/QALY gained of $740. In sensitivity analyses, when the annual probability of failing home NHD and commencing conventional HD was assumed to be ≤ 6%, home NHD was dominant (greater benefit at lower costs), however if ≥19%, the cost/QALY was >$75k/QALY. The cost/QALY gained increased to $29k if average training time for NHD increased from 3.65 weeks to 6 weeks. Results were sensitive to quality of life estimates. In scenario analyses where the comparator modality was changed, frequent home NHD was dominant compared to in-centre HD, and was associated with a cost/QALY gained of $35k, $203k, and $481k when compared with satellite HD, home HD, and peritoneal dialysis respectively.

Conclusions: By current standards used to inform reimbursement decisions in publically funded health care systems, frequent home NHD appears attractive compared with conventional HD. However, the attractiveness varies based on the mix of comparator dialysis modalities. The modality mix provided by a health system and used in patients who would be offered frequent home NHD is a critical factor when considering establishing a program.

TH-OR090

Anti-Inflammatory & Anti-Oxidative Nutrition in Hypoalbuminemic Dialysis Patients (AIONID) Double-Blind Randomized Placebo-Controlled Trial Kamyar Kalantar-Zadeh, Martin Lee, Ramanath B. Dukkipati, Jennie Jing, Youngmee Kim, Anne Coble Voss, Deborah A. Benner, Miklos Z. Molnar, Iain C. Macdougall, John Tayek, Keith C. Norris, Csaba P. Kovesdy, Joel D. Kopple. *LABioMed/Harbor-UCLA.*

Background: Low serum albumin (alb) is common & associated with wasting, inflammation & poor outcomes in hemodialysis (HD) patients (pts). We hypothesized that high protein oral nutritional supplements (ONS) tailored for HD pts combined with anti-oxidants & anti-inflammatory ingredients with/without anti-inflammatory appetite stimulator (pentoxifylline, PTX) is well tolerated & improves albumin level.

Methods: 84 adult hypoalbuminemic (<4.0 g/dL) HD pts in several DaVita clinics were double-blindly randomized (2x2 factorial) to receive 16 wks of placebo-controlled interventions including: (1) ONS consisting of high (19 g) protein supplement (Nepro™, 8 oz/d) combined with a concentrated anti-oxidant module (fish oil, borage oil, beta-carotene, vit C & E, zinc &selenium, 2 oz/d) vs. same volume placebo ONS without protein or anti-oxidants; &/or (2) PTX, 400 mg/d, vs. placebo pill.

Results: Out of 84 pts (age: 59±12 yrs, vintage: 33 mo), 74 completed the entire 16 wks.

Group (n)	A (n=19)	B (n=22)	C (n=22)	D (n=21)	ANOVA-p
Assignments	ONS+PTX	ONS+placebo	PTX+placebo	placebo+placebo	-
Age (yrs)	59.2±13.6	54.6±10.3	57.7±13.9	63.9±9.1	0.09
Gender (% men)	53	45	55	62	0.77
Pre-trial albumin (g/dl)	3.46±0.38	3.56±0.45	3.60±0.45	3.60±0.20	0.51
Change in albumin	+0.18±0.23	+0.21±0.30	+0.14±0.26	+0.03±0.24	-
Paired t-test p	0.001	0.004	0.008	0.587	-

Paired t-test showed significant alb increase of +0.14 to +0.21 g/dl in any intervention other than combined placebos. However, the intention-to-treat analysis of changes in alb using predetermined equation (*post-albumin = pre-albumin+A+B+C)* showed that only ONS was associated with a significant change: ONS, PTX or both were associated with change in alb of +0.17 (p=0.02), +0.11 (p=0.12) & -0.16 g/dL (p=0.10), respectively. No serious adverse events were observed.

Conclusions: Daily intake of CKD-specific high-protein ONS with anti-inflammatory/ anti-oxidative ingredients for 16 wks was well tolerated and associated with improved albumin level of about +0.17 mg/dL per ITT (p=0.02).

TH-OR091

More Efficient Removal of Serum Bilirubin by a Novel Artificial Liver Support System: A Pilot Study Dehua Gong, Dongdong Zhu, Daxi Ji, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.*

Background: In this study, we established a novel artificial liver support (ALS) system based on fractionated plasma separation and adsorption system integrated with continuous veno-venous hemofiltration (FPSA-CVVH), and compared its efficacy with the traditional system of plasma separation and adsorption (PSA).

Methods: Sixteen patients with hyperbilirubinemia due to acute liver failure were included. For PSA, plasma was separated and perfused through an adsorber. For FPSA-CVVH, albumin-rich plasma was separated using a fraction plasma separator, followed by a concentration through ultrafiltration using a hemofilter; The concentrated plasma was then perfused through an adsorber and returned to the patients with a simultaneous infusion of the same amount of replacement fluid via a predilution route into blood. The duration for each session of ALS was 8 hours.

Results: The comparisons of total bilirubin clearance (TB, ml/min) by PSA versus FPSA-CVVH at the time points of 0.5, 2, 4, 6 and 8 hour were as follow: 22.3 ± 2.2 vs. 28.7 ± 13.1, 12.2 ± 4.4 vs. 21.9 ± 9.1 (P<0.05), 9.0 ± 2.8 vs. 16.1 ± 4.3 (P<0.01), 9.5±3.9 vs. 11.2±3.7, and 8.3±3.0 vs. 9.3±4.1, respectively. The average reduction rates (%) of TB, bile acid, urea and creatinine after a single session of PSA versus FPSA-CVVH were 46.1 ± 8.3 vs. 54.4 ± 5.2 (P<0.05), 36.5 ± 5.2 vs. 47.6±14.7, -14.9±16.8 vs. 31.4±10.6(P<0.01), and -17.1±14. 7 vs.36.3±9.2 (P<0.05), respectively. On the other hand, there was a significant decline of albumin level (11.8±5.9%, P<0.001), prolongation of prothrombin time (41.1±27.2%, P<0.01) and activated partial thromboplastin time (26.6±30.4%, P<0.05) observed after PSA but not FPSA-CVVH. The survival rates at the 30th day of ICU and hospital discharge were 69% and 56%, respectively.

Conclusions: In conclusion, compared with PSA system, the novel FPSA-CVVH system provides a more efficient removal of both albumin-bound toxins, like bilirubin, and water-soluble toxins, like urea and creatinine, with less deleterious effects on serum albumin level and blood coagulation.

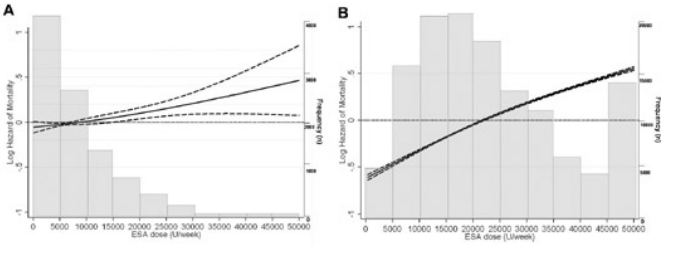
TH-OR092

Comparing Erythropoiesis Stimulating Agent Dose and Responsiveness between Peritoneal and Hemodialysis Patients Uyen Duong,[1] Kamyar Kalantar-Zadeh,[1,2] Miklos Z. Molnar,[1,3] Joshua Zaritsky,[2] Isaac Teitelbaum,[4] Csaba P. Kovesdy,[5] Rajnish Mehrotra.[1,2] *[1]Harold Simmons Center, Torrance, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Semmelweis University, Hungary; [4]University of Colorado, Denver, CO; [5]Salem VA Medical Center, VA.*

Background: We hypothesized that peritoneal dialysis (PD) patients (pts) required lower erythropoiesis stimulating agent (ESA) dose for the same achieved hemoglobin compared to hemodialysis (HD) pts & that ESA dose-mortality associations were different between PD and HD patients.

Methods: We compared the prescribed doses of ESA between 139,103 HD & 10,527 PD pts treated from 7/2001 through 6/2006 using adjusted Poisson regression & examined mortality-predictability of prescribed ESA dose & ESA resistance index (ESA/hemoglobin) in PD & HD with follow-up through 6/2007 using Cox regression models.

Results: Poisson adjusted relative ratio of ESA dose of HD to PD was 3.6 (95% confidence interval: 3.5-3.7). In PD patients, adjusted all-cause death hazard ratios (HR) for ESA doses of 3,000-5,999, 6,000-8,999 & ≥9,000 U/week (reference<3,000 U/week) were 0.97(0.87-1.07), 0.85(0.76-0.95) & 1.08(0.98-1.18), respectively (Figure A); whereas in HD pts across ESA dose increments of 10,000-19,999, 20,000-29,999 and ≥30,000 U/ week (reference <10,000 U/week) were 1.14(1.11-1.17), 1.54(1.50-1.58) & 2.15(2.10-2.21), respectively (Figure B).



In PD and HD pts, the adjusted death HR of the 4th to 1st quartile of ESA resistance index were 1.14(1.04-1.26) & 2.37(2.31-2.43), respectively.

Conclusions: During the 2001-2006 time period most PD patients received substantially lower ESA dose for same achieved hemoglobin levels, consistent with the known selection bias for patients with less comorbidities benign on PD. ESA resistance was associated with much higher mortality in HD than PD patients.

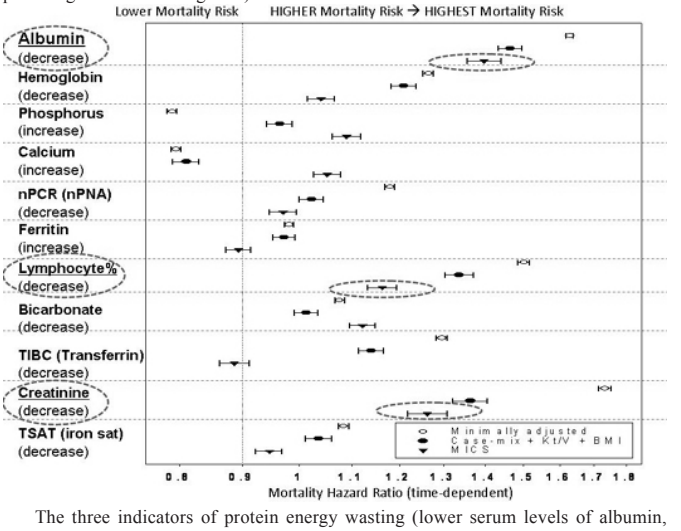
TH-OR093

Superiority of the Survival-Predictability of Laboratory Measures of the Nutritional Status in Hemodialysis Patients: A Comparative Effectiveness Study Jessica Miller,[1] Csaba P. Kovesdy,[2] Miklos Z. Molnar,[1] John J. Sim,[3] Ramanath B. Dukkipati,[4] Parta Hatamizadeh,[1] Deborah A. Benner,[5] Joel D. Kopple,[4] Kamyar Kalantar-Zadeh.[1,4] *[1]Harold Simmons Center, Torrance, CA; [2]Salem VA Medical Center, Salem, VA; [3]Kaiser Permanente, Los Angeles, CA; [4]Harbor UCLA, Torrance, CA; [5]DaVita Inc., Denver, CO.*

Background: It is not clear which potentially modifiable laboratory measures are associated with greater survival in maintenance hemodialysis (MHD) patients (pts).

Methods: In a large cohort of 140146 MHD pts who underwent MHD treatment for at least 3 months in all legacy DaVita dialysis clinics between July 2001 & June 2006, changes in values across consecutive 20 calendar quarters for laboratory measures that may represent "malnutrition inflammation complex syndrome" (MICS) were calculated. Values were standardized with mean of 0 and standard deviation of 1, and hazard ratios for the increase or decrease (as commensurate) in 1 standard deviation were estimated.

Results: Pts were 61.5±15.5 years old & included 45% women, 32% African Americans, 14% Hispanics & 44% diabetics. Cox models were case-mix adjusted (sex, age, race/ethnicity, diabetes, dialysis vintage, Kt/V, BMI) & MICS adjusted (serum creatinine, albumin, calcium, nPCR, ferritin, bicarbonate, TIBC, TSAT, phosphorus, lymphocyte percentage & blood hemoglobin):



The three indicators of protein energy wasting (lower serum levels of albumin, creatinine & lymphocyte percentage) showed the strongest association with death risk, followed by lower serum bicarbonate & higher levels of serum phosphorus & calcium.

Conclusions: Measures of nutritional/inflammatory status are by far the strongest predictors of survival in MHD patients. Interventions to improve nutritional/inflammatory status may improve longevity. This hypothesis needs testing in randomized trials.

Hepcidin Isoforms – Biomarkers for Optimal Managements of Renal Anemia in Hemodialysis Patients Satoshi Yamazaki,[1] Yusuke Sasaki,[2] Masahiro Hagiwara,[1] Shunichi Furuhata,[1] Minoru Murakami,[1] Yasushi Shimonaka,[2] Masaya Ikezoe.[1] *[1]Dept. of Nephrology, Saku Central Hospital, Minamisaku-Gun, Nagano, Japan; [2]Product Ressearch Dept., Chugai-pharmaceutical Co., Ltd., Kamakura-shi, Kanagawa, Japan.*

Background: It has been known that serum levels of hepcidin-25 (Hep-25) and its isoforms, hepcidin-20 and -22, are significantly higher in hemodialysis (HD) patients than in healthy subjects, however, the significance of these isoforms have not been well elucidated. In the present study, we analyzed the relationship between serum levels of hepcidin isoforms and clinical parameters in HD patients to clarify the possibility of hepcidin isoforms as biomarkers for anemia treatment.

Methods: We enrolled 100 HD patients, provided written informed consent in Saku Central Hospital. Patients with infection, severe inflammatory disorders or hematologic disorders were excluded. Anemia and other complications were treated according to national and K/DOQI guidelines. Erythropoiesis stimulating agents (ESA) was used to maintain a target hemoglobin (Hb) level of 10-11 g/dL. Clinical parameters including iron parameters and serum hepcidin isoforms were measured. Patients characteristics were analyzed in 4 groups divided by median of serum levels of Hep-25 (High, Low) and the ratio of active hepcidin (Hep-25/total hepcidin isoforms levels) (High, Low).

Results: Patients with high Hep-25 levels and low active hepcidin ratio, named HL group, showed the lowest Hb and highest mean cellular hemoglobin (MCH) than any other groups. HL group also exhibited high transferrin saturation (TSAT) and serum ferritin levels. Instead, patients with low Hep-25 levels and low active hepcidin ratio (LL group) showed the highest Hb and lowest MCV than any other groups. LL group exhibited low TSAT and serum ferritin levels. There was no difference in ESA dosage between groups.

Conclusions: Present results indicate that patients with high Hep-25 levels and low active hepcidin ratio characterized enough iron storage and supply but low hematopoietic activity. It is recommended that these patients should be treated ESA rather than iron supplementation. Moreover, iron status and hematopoietic activity might affect proteolysis of hepcidin isoforms.

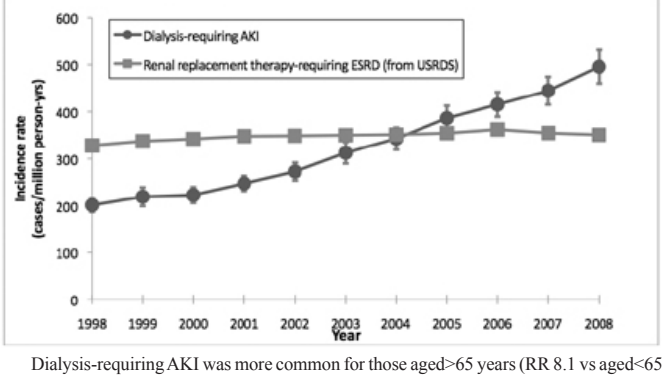
TH-OR095

Dialysis-Requiring AKI Is Now More Common Than Renal Replacement Therapy-Requiring ESRD Raymond K. Hsu, Charles E. McCulloch, Lowell J. Lo, R. Adams Dudley, Chi-Yuan Hsu. *UCSF.*

Background: There are limited data on the population epidemiology of acute kidney injury (AKI).

Methods: To determine the incidence rate of dialysis-requiring AKI from 1998-2008, we analyzed data from the US Census and the Nationwide Inpatient Sample (NIS), a nationally representative sample of hospitalizations, accommodating for NIS's sampling scheme. Cases were identified using validated ICD9 codes (Waikar 06). To explore reasons for temporal trends, we used multivariate logistic regression, with dialysis-requiring AKI as the primary outcome, year as main predictor, and additional covariates such as demographic variables and prespecified AKI risk factors.

Results: From 1998-2008, the incidence rate of dialysis-requiring AKI increased from 201 to 496 cases/million person-yrs, averaging 9% per yr (OR 1.09, 95% CI 1.08-1.10). Since 2005, the population incidence of dialysis-requiring AKI has exceeded that of renal replacement therapy (RRT)-requiring end-stage renal disease (ESRD).



Dialysis-requiring AKI was more common for those aged>65 years (RR 8.1 vs aged<65 years, 95% CI 7.9-8.3), blacks (RR 1.7 vs whites, 95% CI 1.6-1.8), and men (RR 1.3 vs women, 95% CI 1.2-1.4). Accounting for temporal changes in population distribution of age, race, gender, as well as trends of sepsis, acute heart failure, and receipt of cardiac catheterization and mechanical ventilation only slightly attenuated this trend to an adjusted rate of 8% per yr (OR 1.08, 95% CI 1.07-1.09).

Conclusions: The incidence of dialysis-requiring AKI has increased rapidly in the past decade and now exceeds the incidence of RRT-requiring ESRD. Factors such as changing demographics, increased incidence of sepsis and acute heart failure, or increased utilization of cardiac catheterization and mechanical ventilation do not appear to account for this strong secular trend. The public health burden of AKI is larger than previously appreciated.

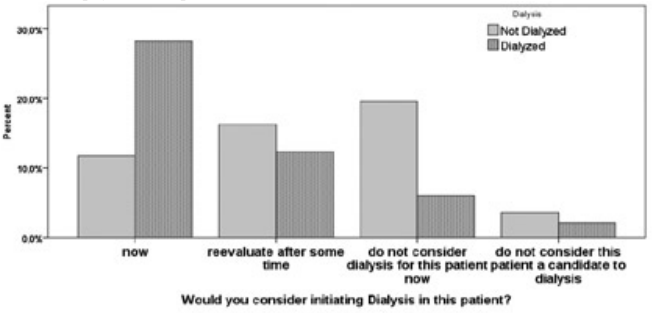
TH-OR096

Factors Associated with the Decision Making Process in Dialysis Initiation in AKI: Results of a Survey Etienne Macedo,[1] Josee Bouchard,[2] Jorge Cerda,[3] Ashita J. Tolwani,[4] Anjali Acharya,[5] Gary R. Cutter,[4] Ravindra L. Mehta.[6] *[1]University of Sao Paulo, Brazil; [2]Hôpital du Sacré-Coeur de Montréal, Canada; [3]Albany Medical College; [4]University of Alabama; [5]Jacobi Medical Center; [6]University of California San Diego.*

Background: In AKI, the benefits of dialysis must outweigh the associated risks. We hypothesized that physician decisions for initiating dialysis in AKI are affected by patient and processes of care factors.

Methods: We utilized a web-based survey to present 22 real case scenarios. For each case we asked whether physicians would initiate dialysis and the reason for their choice. The presentation included all pertinent clinical and laboratory data from 48 to 72 hours prior and up to the day of dialysis in actually dialyzed patients (n=12) or the day of peak creatinine in those patients that where not dialyzed (n=10).

Results: There were a total of 332 questionnaires representing 12-28 physician responses to each case. Physicians preferred to initiate dialysis immediately in 40%; reevaluate after some time in 29%; did not think the patient needed dialysis in 26%; and considered the procedure futile in 5% of the responses. There was substantial discordance between the physician responses and the actual events.



Process-of-care factors frequently influenced the decision: Nurse availability (27%); vascular access issues (25%); dialysis need at night time (17%) or holiday and weekends (17%). Physician's perception of futility correlated well with their choice to withhold dialysis, whereas prediction of renal recovery was associated with greater likelihood that the patient did not need dialysis.

Conclusions: Decisions to initiate dialysis are widely variable and uncertainty is common. Perception of patient prognosis and process-of care-factors influence the decisions.

TH-OR097

A Multi-Center Pilot Study To Assess the Safety and Efficacy of Selective Cytopheretic Device (SCD) Therapy in Patients with Acute Kidney Injury (AKI) James A. Tumlin,[1] Lakhmir S. Chawla,[2] Ashita J. Tolwani,[3] John J. Dillon,[4] Ravindra L. Mehta,[5] Kevin W. Finkel,[6] J. Ricardo Da Silva,[7] Alexander S. Yevzlin,[8] David Humes.[9] *[1]SERRI; [2]George Washington University; [3]University of Alabama; [4]Mayo Clinic; [5]UCSD; [6]University of Texas; [7]Cytopherx, Inc.; [8]University of Wisconsin; [9]University of Michigan.*

Background: Dialysis requiring AKI in critically ill patients is associated with hospital mortality rates between 50-60%. Currently, there are no proven therapies that can improve renal function or reduce overall mortality.

Methods: To address this problem, we conducted a multicenter, single arm, pilot study of the Selective Cytopheretic Device (SCD), a novel cartridge that is able to selectively bind and deactivate activated neutrophils from the circulation. Enrolled patients received up to 7 days of SCD therapy in conjunction with citrate-based continuous renal replacement therapy (CRRT). The primary endpoints of the study were safety of the SCD and mortality at 28 and 60 days.

Results: A total of 35 patients were enrolled by 6 centers in the United States between May 2010 and January 2011. The mean age of patients enrolled was 56.9 years with 60.0% (21/35) male. The mean Sequential Organ Failure Assessment (SOFA) score at baseline was 11.3 and 88.6% (31/35) were ventilated. The overall mortality rate was 28.6% (10/35) in hospital, 25.7% (9/35) at 28 days and 31.4% (11/35) at 60 days. The rate of renal recovery in survivors was 73.1% (19/26) by day 28 and 100% (24/24) by day 60. During the study, a total of 28 serious adverse events were reported of which 7.1% were determined to by investigators to be related to the SCD device. Elastase, IL-6, and sICAM, markers associated with inflammation, decreased substantially over the course of therapy.

Conclusions: This trial provides preliminary data of the safety and efficacy of the SCD treatment. The SCD compares favorably to the 50-60% mortality reported in previous AKI trials. The addition of the SCD to conventional citrate-based CRRT was well tolerated and led to a reduction in serum markers of activated neutrophils.

High Cut-Off Hemodialysis for the Management of Myeloma Kidney: An International Study Colin A. Hutchison,[2] Anne Bevins.[1] *[1]The Binding Site Group Ltd, Birmingham, United Kingdom; [2]Renal Unit, University Hospital Birmingham, United Kingdom.*

Background: The early reduction of serum free light chains (FLC) improves clinical outcomes for patients with acute kidney injury secondary to multiple myeloma. We studied an international cohort of patients treated FLC removal by high cut off (HCO) hemodialysis to determine treatment patterns and clinical outcomes associated with its use in this setting.

Methods: Data was collected from 54 patients, from 18 centers in 10 countries, using electronic case report forms. Rates of renal recovery were determined in relationship to baseline variables, treatment patterns and degree of FLC reduction achieved.

Results: Patients were predominately Caucasian, median age 65 years (range 43-81), with a median GFR of 8 (1-27). Baseline serum biochemistry was: creatinine 633.5µmol (168-2263); calcium 2.3mmol (0.91-3.83); albumin 34g/L (14-46) and β2M 9.45mg/L (0-55.7). Myeloma kidney was the primary diagnosis in 88.1% of the population who had a renal biopsy. Monoclonal κ and λ FLCs levels were: κ 5070mg/L (range 2250-20200) and λ 4200mg/L (range 300-13300), respectively at presentation. 68.75% of patients were treated with the Theralite dialyzer; another 31.25% used the HCO1100. 78% received bortezomib and 34% received thalidomide as part of their initial treatment. In total there were 626 HCO dialysis sessions, with a median of 13 (3-35) treatments per patient. HDF was used in 3 patients. Median FLC reduction was 72.96% (15.09-99.62%) by day 12 and 93.03% (40.23-99.96%) by the last dialysis treatment. There was no difference in the percentage FLC reduction achieved between bortezomib and thalidomide treatment groups (p=0.140). Dialysis independence occurred in 55.6% of patients, median time 32 days (10-249). Independence of dialysis was greater in patients who had a reduction in serum FLCs by day 12 (p=0.038). No significant adverse events related to the study device were reported.

Conclusions: Targeting early FLC reductions in patients with AKI secondary to multiple myeloma should become standard of care. This study adds further weight to the potential benefit of FLC removal by HCO-HD in this setting.

TH-OR099

Exposure to Potentially Toxic Hydro- and Halocarbons Released from Dialyzer and Tubing Sets during Hemodialysis Hyun Ji Julie Lee,[2] Madeleine V. Pahl,[1] Nosratola D. Vaziri,[1] Donald R. Blake.[2] *[1]Nephrology and Hypertension, University of California, Irvine, CA; [2]Chemistry, University of California, Irvine, CA.*

Background: While much is known about the effect of ESRD and dialysis on the composition of solutes in the plasma, little is known about their impact on composition of gaseous compounds in the exhaled breath. This study was designed to explore the effect of uremia and hemodialysis (HD) on the composition of exhaled breath.

Methods: Exhaled breath samples were collected from 10 ESRD patients immediately before, during and after dialysis. Ten age-matched healthy subjects served as controls. To determine the potential introduction of gaseous compounds from the components of dialysis, gasses were eluded from dialyzers, tubing sets, dialysate and water supplies. A five column/detector gas chromatography (GC) system was employed to measure different hydrocarbon, halocarbon, oxygenate, and alkyl nitrate sulfur containing compounds.

Results: The concentration of 11 hydrocarbons and 4 halocarbons in the patients' breath rose rapidly after the onset of the HD. All of the 15 compounds appearing in the breath (and 5 others not found in the breath) were eluded from the dialyzers and tubing sets, but not the water supplies or final dialysate solution.

Breath Composition. Average breath concentrations collected before, at the start (0 minutes) and 3 minutes after start of HD. Number of samples averaged were labeled as n.

Compounds	Average ± SE, pptv			p-value	
	pre (n = 60)	0 (n = 20)	3 (n = 20)	pre vs 0	0 vs 3
i-butane	1703 ± 271	1511 ± 245	1908 ± 297	0.5	0.3
n-butane	2144 ± 477	1873 ± 459	3523 ± 671	0.6	0.05
n-pentane	1639 ± 420	1364 ± 307	2492 ± 426	0.5	0.04
n-hexane	454 ± 68	388 ± 52	2059 ± 595	0.3	0.01
n-heptane	865 ± 234	925 ± 267	1963 ± 411	0.8	0.04
n-octane	161 ± 24	134 ± 15	961 ± 140	0.2	8 E-07
n-nonane	6870 ± 1444	6633 ± 1486	456170 ± 96808	0.9	4 E-05
n-decane	208 ± 65	198 ± 52	231 ± 45	0.9	0.6
3-methylpentane	343 ± 62	288 ± 51	1729 ± 639	0.4	0.03
3-methylhexane	380 ± 67	312 ± 51	677 ± 129	0.3	0.01
3-methylheptane	98 ± 25	54 ± 11	800 ± 133	0.1	2 E-06
CH_3CH_2Cl	37 ± 13	27 ± 10	78 ± 16	0.5	0.01
CH_2CHCl	1 ± 1	1 ± 0.4	22 ± 44	0.5	0.04
CH_2Cl_2	1453 ± 279	1371 ± 200	41873 ± 11822	0.8	0.001
$CHCl_3$	156 ± 28	143 ± 25	319 ± 101	0.7	0.1

Contrary to earlier reports which showed increased ethane levels during HD, exhaled breath ethane concentrations remained virtually unchanged during HD and mirrored the concentrations found in room air.

Conclusions: The present study documented release of several potentially toxic hydrocarbons and halocarbons to the circulation from the dialyzer and tubing sets during HD. The long-term exposure to these compounds may contribute to the morbidity and mortality in ESRD population and this issue should be considered in manufacturing of new generation of dialyzers and dialysis tubing sets.

Muller,[5] Kai-Uwe Eckardt,[1] Friedrich C. Luft,[4] Michael Uder,[3] Jens Titze.[2] *[1]Nephrology & Hypertension, University of Erlangen-Nuremberg, Erlangen, Germany; [2]Interdisciplinary Centre for Clinical Research, University of Erlangen-Nuremberg, Erlangen, Germany; [3]Radiology, University of Erlangen-Nuremberg, Erlangen, Germany; [4]Experimental & Clinical Research Centre, Charité & MDC, Berlin, Germany; [5]Experimental Medicine I, University of Erlangen-Nuremberg, Erlangen, Germany.*

Background: Sodium and water are removed by hemodialysis. While water removal can easily be determined by ultrafiltration rates and weight loss, no valid method for the assessment of tissue Na^+ content is available. ^{23}Na magnetic resonance could offer spectroscopic and imaging (MRI) options.

Methods: We used ^{23}Na magnetic resonance spectroscopy and imaging at 3Tesla (T) to quantify Na^+ content in skeletal muscle of the left lower leg. 15 dialysis patients (9 men, 6 women) were measured before and after regular dialysis with ^{23}Na MRI. Blood pressure was measured before and after dialysis treatment. Ultrafiltration rate was adjusted to individual interdialytic weight gain.

Results: Initial sodium content of M. triceps surae in dialysis patients was 21.2±6.3 mmol/l and decreased significantly to 17.1±6.8 mmol/l after dialysis treatment, while serum Na^+ concentrations were unaffected by dialysis. Muscle Na^+ content before dialysis was higher in men than in women; however, age was the strongest predictor for muscle Na^+ content in patients with endstage renal disease (< 60 years, n=7: 17.8±2.7 mmol/l; > 60 years, n=8: 24.5±7.2 mmol/l). Na^+ removal from muscle tissue with dialysis treatment was inversely correlated with ultrafiltration rate (y=-0.00007x+0.90452, R^2 = 0.47), but not with blood pressure.

Conclusions: Non-invasive measurement of tissue Na^+ content with ^{23}Na MRI provides a novel clinical tool to assess Na^+ removal in patients with end-stage renal disease during hemodialysis treatment. The method could allow efficacy monitoring for Na^+ removal and permit a better understanding of the relationship between body-Na^+ accumulation, blood pressure, and cardiovascular disease in patients with end-stage renal disease.

Increasing Protein-Bound Solute Clearances Independent of Urea Clearance Tammy L. Sirich,[1] Frank Jiann-Gang Luo,[1] Thomas H. Hostetter,[2] Timothy W. Meyer.[1] *[1]Medicine, Stanford, Palo Alto, CA; [2]Medicine, AECOM, New York, NY.*

Background: The toxicity of bound solutes could be evaluated better if we could adjust the clearance of such solutes independent of unbound solutes. This study evaluated a means to increase the clearance of bound solutes independent of unbound solutes during nocturnal dialysis. It tested the hypothesis that bound solute clearances could be increased by raising the dialysate flow and dialyzer size above the low levels which are sufficient to achieve target Kt/V_{urea} values during the extended hours of nocturnal treatment.

Methods: Nine patients on thrice-weekly in-center nocturnal dialysis underwent two experimental sessions one week apart. The sessions were designed to provide the same urea clearance but widely different bound solute clearances. The *Low* K_oA-Q_d session employed a small dialyzer, dialysate flow of 300 ml/min, and blood flow of 350 ml/min. The *High* K_oA-Q_d session employed a larger dialyzer and dialysate flow of 800 ml/min while restricting blood flow to 270 ml/min. The bound solutes p-cresol sulfate (PCS) and indoxyl sulfate (IS) were measured by HPLC and the unbound solute urea was measured enzymatically.

Results: Results showed (mean±sd; [a], p<0.05 *High* K_oA-Q_d vs *Low* K_oA-Q_d; [b], p<0.05 PCS and IS clearance vs urea).

		Low K_oA-Q_d	*High* K_oA-Q_d
Urea	Clearance (ml/min)	193 ± 16	204 ± 20
	Kt/V_{urea}	1.8 ± 0.3	1.9 ± 0.4
	Removed in dialysate (g)	43 ± 6	41 ± 11
PCS	Clearance (ml/min)	14 ± 6 [b]	27 ± 9 [a, b]
	Removed in dialysate (mg)	207 ± 86	375 ± 200 [a]
IS	Clearance (ml/min)	14 ± 5 [b]	26 ± 8 [a, b]
	Removed in dialysate (mg)	153 ± 74	201 ± 137 [a]

Urea clearance and removal were similar during both treatments. As expected, the clearances of the bound solutes PCS and IS were much lower than the clearance of urea. But the *High* K_oA-Q_d session nearly doubled the clearances of PCS and IS without changing the urea clearance. Higher clearances during the *High* K_oA-Q_d session resulted in the removal of more PCS and IS in the dialysate.

Conclusions: Increasing dialyzer size and dialysate flow during nocturnal dialysis increases the clearance of bound solutes and could provide a means to further test the contribution of such solutes to morbidity in ESRD.

Associations of Dialysate Bicarbonate (DB) with Mortality: Results from the Dialysis Outcomes and Practice Patterns Study (DOPPS) Francesca Tentori,[1] Jinyao Zhang,[1] Ananda Sen,[2] Hal Morgenstern,[2] Bruce M. Robinson,[1,2] Hugh C. Rayner,[3] Rachel B. Fissell,[4] Raymond C. Vanholder,[5] Tadashi Tomo,[6] Friedrich K. Port.[1,2] *[1]Arbor Research Collaborative for Health; [2]University of Michigan; [3]Birmingham Heartlands Hospital; [4]Cleveland Clinic Foundation; [5]University Hospital Gent; [6]Oita University.*

Background: Severe pre-dialysis metabolic alkalosis has been associated with elevated mortality risk in patients on maintenance hemodialysis (HD) [Bommer AJKD 2004]. We hypothesized that use of high dialysate bicarbonate (DB), which could result in severe post-dialysis metabolic alkalosis, may adversely affect clinical outcomes.

Methods: This study included 16,899 patients on thrice-weekly in-center HD using DB as the predominant dialysate buffer (20 to 45 mEq/L) from 12 countries in DOPPS 2 (2002-2004) and 3 (2005-2008). Cox regression was used to estimate the effect of DB on all-cause mortality, adjusting for potential confounders including predialysis serum bicarbonate. DB was analyzed as a continuous variable and as a categorical variable (<33, 33-36.9, ≥37 mEq/L).

Results: DB varied across facilities and countries. The overall median facility mean DB was 35 mEq/L (inter-quartile range=33.2, 36.5), with the lowest median level in Japan (30) and the highest level in the US (37). About 65% of facilities prescribed the same DB dose to more than 90% of its patients. DB was positively associated with all-cause mortality in the total sample and in facilities using a single DB for most patients (Table). The adjusted HR for DB did not vary appreciably by level of pre-dialysis serum bicarbonate, serum or dialysate potassium, serum or dialysate calcium.

Conclusions: High DB was associated with elevated mortality risk in the DOPPS. Changes in DB can easily be implemented in dialysis treatment and may have a beneficial impact on clinical outcomes.

Table: Adjusted HR (95% CI)* for all-cause mortality, by category of dialysate bicarbonate or continuous DB and patient sample

Dialysate bicarbonate (mEq/L)	All patients (N=16,899) %	HR	95% CI	P-value	Facilities with more than 90% patients on the same dialysate bicarbonate prescription (N=8,345 patients)** HR	95% CI	P-value
Per 10 mEq/L (continuous)	-	**1.21**	**(1.03,1.43)**	**0.02**	**1.28**	**(1.01,1.61)**	**0.04**
By DB category:							
<33	24%		Ref.			Ref.	
33-36.9	51%	1.09	(0.97,1.24)	0.15	1.19	(0.97,1.46)	0.10
≥37	25%	**1.21**	**(1.05,1.40)**	**0.01**	**1.37**	**(1.08,1.74)**	**0.01**

*Adjusted for serum bicarbonate, age, sex, BMI, vintage, 13 comorbidities, albumin, hemoglobin, SBP, residual kidney function, catheter use, and spKt/V, stratified by country and study phase, and accounted for facility level clustering
**Restricted to patients from the initial cross-section and facilities with at least 5 patients and ≥90% of patients prescribed the same dialysate bicarbonate

Resource Conservation in Hemodialysis: Two Simple, Practical, Eco-Sensitive, Cost Efficient Initiatives Alwie Tjipto, John W.M. Agar. *Renal Unit, Geelong Hospital, Melbourne, Victoria, Australia.*

Background: Conventional hemodialysis (HD) is a rapacious (ab)user of water and power, yet most HD services ignore its environmental impact. While HD session duration, frequency and equipment varies, our measured mean mains water use (4-5 hr x 3/wk HD) is ~450L/treatment using a low-efficiency reverse osmosis (RO) plant (dialysate flow rate 500ml/min: 66% reject rate). Further, the metered power-draw from our paired Fresenius 4008B + Aquauno RO home systems is ~1.3kWh/hr. If similar data are notionally applied to all 2.0 x 10^6 HD patients world-wide, the extrapolated annual world-wide water use would approximate 33.7 trillion liters and the power draw 1.62 trillion kWh.

Methods: Two parallel eco-sensitive programs now address resource utilization in our service. From 2004/5, a range of simple, inexpensive RO reject water (RW) systems recycle the biochemically and biologically WHO and EPA 'potable' RO RW generated at our in-centre, multiple satellite and home patient HD sites for use in: surgical instrument sterilization, janitor services, off-site sporting facility and garden maintenance. From June 2010, 18 solar panels (area = 23.41m^2: cost = A$16,219), have powered our 4 chair home HD facility (HTU) - the first known solar-assisted HD project in the world.

Results: The water reuse program reclaims up to 100,000L RO RW/week. The return on investment (RoI) for capital outlays are accrued within 36 months. In the 1st 11 months of operation, our solar project has created 107% of all the HD-process-related power needs of the HTU. Total solar power generated 3,496 kWh, total power drawn 3,262 kWh. Power use is currently billed at A$0.267/kWh. Power generation is grid-reimbursed at A$0.235/kWh, we are meeting 94.3% of the power cost for the HTU. The current modeled RoI for capital repayment = 19.7 years. The estimated panel life is 30 years. This should result in free power and a future income stream in the 3rd operational decade. With electricity costs projected to double over coming years, there is a potential that the modeled RoI will improve significantly.

Conclusions: Solar assisted power generation for dialysis is feasible and we recommend similar practices be considered by all dialysis services.

TH-OR104

The Long Interdialytic Interval and Mortality in Hemodialysis Patients Robert N. Foley,[1,2] David T. Gilbertson,[1] Thomas A. Murray,[1] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN.*

Background: As end-stage renal disease limits the tolerance of metabolic and volume-related excursions from normality, and cardiovascular disease is highly prevalent, we set out to address the hypotheses that the long interdialytic interval is associated with adverse events in hemodialysis patients.

Methods: We studied 32,065 participants in the CMS End-Stage Renal Disease Clinical Performance Measures (CPM) Project, a nationally representative sample of US patients receiving hemodialysis three times weekly at the end of the calendar years 2004 through 2007. We compared rates of death and cardiovascular hospital admissions on the day following the long (two-day) interdialytic interval with rates on other days.

Results: Mean age of the cohort was 62.2 years; 24.2% had been receiving dialysis treatment for ≤ 1 year. Over a mean follow-up interval of 2.2 years, the following event rates were higher on the day after the long interval: all-cause mortality (22.1 versus 18.0 per 100 person-years, $P < 0.001$), cardiac mortality (10.2 versus 7.5, $P < 0.001$), infectious mortality (2.5 versus 2.1, $P = 0.007$), mortality from cardiac arrest (1.3 versus. 1.0, $P = 0.004$), mortality from myocardial infarction (6.3 versus 4.4, $P < 0.001$); admissions with myocardial infarction (6.3 versus 3.9, $P < 0.001$), congestive heart failure (29.9 versus 16.9, $P < 0.001$), stroke (4.7 versus 3.1, $P < 0.001$), dysrhythmia (20.9 versus 11.0, $P < 0.001$), and any cardiovascular event (44.2 versus 19.7, $P < 0.001$).

Conclusions: The long interdialytic interval is a time of heightened risk in hemodialysis patients.

TH-OR105

Overexpression of Mouse Angiotensinogen in Renal Proximal Tubule Causes Salt-Sensitive Hypertension in Mice Donald E. Kohan, Deborah Stuart, Jean-Marc Lalouel, Jian Ying. *University of Utah Health Sciences Center, Salt Lake City, UT.*

Background: The role of proximal tubule angiotensinogen (AGT) in modulating blood pressure has previously been examined using mice co-expressing proximal tubule human AGT and human renin. These animals are hypertensive, however the question remains whether alterations in "endogenous" mouse proximal tubule AGT, interacting with endogenous renin, affects blood pressure (BP).

Methods: Mouse AGT cDNA was knocked-in to the endogenous kidney androgen promoter (KAP) gene using an internal ribosomal entry site-based strategy.

Results: The KAP-mAGT animals showed kidney-specific KAP-AGT mRNA expression; renal immunostaining detected AGT only in proximal tubule. Urinary uncleaved AGT was markedly increased in KAP-mAGT mice (5.3 ± 2.1 nmole) vs. wild-type controls (0.1 ± 0.1 nmole, p<0.001, N=4). On a high Na diet, radiotelemetric BP showed a mean systolic BP elevation of 5 ± 2 mmHg during the day and a 10 + 2 mmHg elevation during night in KAP-mAGT animals comparing to litermater control mice; no significant difference in BP was observered when fed a normal salt diet. Plasma renin concentration was reduced to 80% of control animal values by proximal tubule mAGT overexpression in animals given a high Na diet, but was not different between mouse lines during normal Na intake (n=7). Plasma AGT concentration was not altered by overexpression of proximal tubule mAGT (n=7). Renal renin mRNA tended to decrease in targeted mice (79 ± 7% of controls, N=7, p=0.08), while renal NHE3 and ENaC-α mRNA tended to increase (134 ± 14% of controls, N=7, p=0.06 for NHE3; 151 ± 25% of controls, N=7, p=0.09 for ENaC). No changes were detected in renal mRNA levels for ACE, NKCC2, ENaC-β, or NCC.

Conclusions: In summary, proximal tubule overexpression of mAGT leads of hypertension and salt-sensitivity without recruitment of the systemic renin-angiotensin system. The mechanisms responsible for the hypertensive effects of mAGT overexpression are unresolved, but studies suggest that further attention should be focused on alterations in NHE3 and ENaC-α.

TH-OR106

Angiotensin II Type 1A Receptors in Vascular Smooth Muscle Cells Contribute to Blood Pressure Control, Salt Sensitivity and Hypertension Matthew A. Sparks, Johannes Stegbauer, Susan B. Gurley, Thomas M. Coffman. *Nephrology, Duke Hospital.*

Background: Ang II acting through AT1 receptors promotes hypertension. However,AT1 receptors are expressed in many tissues relevant to BP control. In previous studies, we found that AT1 receptors in proximal tubule play a key role in determining level of BP. Here,we examine the impact of vascular actions of AT1 receptors in chronic BP homeostasis.

Methods: We generated a mouse with a conditional allele of the Agtr1a gene encoding the major AT1 receptor isoform, AT1A. To eliminate AT1A from VSMCs, we used transgenic mice with Cre driven by SM22 promoters. In a previous study, we found that a heterologous SM22-Cre transgene induced deletion of AT1A from large conduit arteries, but not resistance vessels. In these mice, BP and hypertensive responses were unaffected. Therefore, we now utilize a transgenic line with Cre knocked-in to the SM22 locus(KISM22-Cre).

Results: KISM22-Cre mice were crossed with the mTmG reporter to map Cre expression, documenting Cre in SM throughout the vasculature including small arterioles. We then generated mice homozygous for the conditional Agtr1a allele also bearing KISM22-

Cre(SMKOs). Compared to controls, acute constrictor responses to ang II were decreased by 25% in SMKOs(P<0.05), consistent with partial deletion of AT1A from resistance arteries and arterioles. Resting BP measured by telemetry was reduced in SMKOs(105.6 2.3 mmHg vs. 114.3 1.8 mmHg; P=0.01). While BPs in the control mice were not affected by varying sodium, MAP fell by 5mmHg in SMKO(P=0.01) mice during low salt and increased in the SMKO mice by 7 mmHg(P=0.01) on high salt. Similarly, hypertension induced by chronic infusion of ang II was attenuated in SMKOs(MAP:121.7 2.8 mmHg vs. 145 3.5 mmHg; P=0.004) and this was associated with diminished aortic media thickening(63 3.8 vs. 82 2.8 m; P<0.006) and reduced cardiac hypertrophy(5.5 0.2 vs. 7.4 0.6 heart/body,mg/g; P=0.01)in SMKOs.

Conclusions: Thus, a mutation causing partial attenuation of Ang II-induced vasoconstriction reduces BP, enhances sodium sensitivity and confers substantial resistance to hypertension indicating a major role for vascular AT1A receptors in BP control and hypertension pathogenesis.

TH-OR107

Responses of the Renal Afferent Arterioles to Increased Perfusion Pressure and Angiotensin II: Role of $P47^{phox}$

Enyin Lai, Christopher S. Wilcox, Anton Wellstein, Zaiming Luo, Kathryn Sandberg, William J. Welch. *Nephrology and Hypertension, Georgetown University, Washington, DC.*

Background: The tone of the renal afferent arteriole regulates renal vascular resistance (RVR) and transmission of arterial pressures into the kidneys. We reported that mouse isolated perfused afferent arterioles challenged with either angiotensin II (Ang II; 10^{-6} M) or an increasing perfusion pressure generated reactive oxygen species (ROS: from PEG-SOD inhibitable ethidium: dihydroethidium fluorescence, E:DHE) and that the contractile responses to both were blunted by 10^{-4}M tempol. We detected the mRNA for $p47^{phox}$, Nox-2 and -4 in a gene array from individual microdissected afferent arterioles. Since Ang II infusion downregulated Nox-4 and only Nox-2 requires $p47^{phox}$, we tested the hypothesis that Nox-2/$p47^{phox}$ is the source of the ROS that enhanced afferent arteriolar tone and thereby RVR with Ang II infusion. Ang II increased MAP and RVR in $p47^{phox}$ +/+ mice (77±2 to 91±3 mmHg; P<0.05 and 7.5±0.4 to 10.5±0.8 mmHg/mL/min/100 g; P<0.05) but did not change these variables in -/- mice (74+/-3 to 76+/-1 mmHg; NS and 8.9±0.5 to 9.7±0.7 mmHg/mL/min/100 g; NS). Afferent arterioles dissected from mouse kidneys and perfused at 40 mmHg had similar basal diameter in $p47^{phox}$ +/+ and -/- mice (8.8±0.6 vs 9.1±0.5 μm; NS). Compared to isolated perfused afferent arterioles from $p47^{phox}$ +/+ mice, those from -/- mice had a lesser myogenic response (MR; increase in active wall tension with perfusion pressure from 40 to 135 mmHg: 3.1±0.4 vs 1.4±0.2 dynes/cm/mmHg; p<0.02) and a lesser change in luminal diameter with 10^{-6}M Ang II (-4.6±0.4 vs -2.9±0.3 μm; p<0.03). These were accompanied by lesser increases in E:DHE. Two weeks Ang II infusion (200 ng/kg/min) enhanced the reduction in luminar diameter with 10^{-6}M Ang II in afferent arterioles from $p47^{phox}$ +/+ mice (-5.9±0.4 μm; P=0.05) but not from -/- mice (-2.5±0.5; NS). We concluded that ROS derived from Nox-2/$p47^{phox}$ enhanced Ang II hypertension by augmenting the increase in renal vascular resistance and the afferent arteriolar myogenic and Ang II contractile responses.

TH-OR108

Intrarenal Dopamine Counteracts Angiotensin II-Mediated Progressive Renal Injury

Ming-Zhi Zhang,[1] Suwan Wang,[1] Xiaofeng Fan,[1] Shilin Yang,[1] Raymond C. Harris.[1] *[1]Medicine, Vanderbilt University, Nashville, TN; [2]Vanderbilt University, Nashville, TN; [3]Nashville, TN.*

Background: Angiotensin II (Ang II) is a mediator of progressive renal injury. Previous studies by us and others have indicated that dopamine may modulate actions of Ang II in the kidney. The current studies examined the role of altering intrarenal dopamine on Ang II-mediated renal fibrosis.

Methods: Mice were subjected to chronic Ang II infusion by osmotic minipumps. We utilized a model of increased intrarenal dopamine, COMT KO mice, which have increased kidney dopamine levels due to deletion of a major intrarenal dopamine metabolizing enzyme. We also used a model of intrarenal dopamine deficiency due to selective proximal tubule AADC deletion (AADC KO), which inhibits dopamine synthesis.

Results: In wild type mice, Ang II infusion increased expression of both of the major dopamine metabolizing enzymes, COMT and MAO. After 8 weeks of Ang II infusion, there were no significant differences in blood pressure between either wild type and COMT KO or AADC KO mice. Compared to wild type, AADC mice had increased, and COMT mice had decreased albuminuria and tubulointerstitial injury. In response to Ang II, there was increased expression of both glomerular and tubulointerstitial injury markers (fibronectin, CTGF, FSP1, KIM-1, collagen I podocyte VEGF) in AADC KO mice and decreased expression in COMT KO mice. There was also differential macrophage infiltration in the two models. We have recently reported that Ang II-mediated tubulointerstitial fibrosis is mediated by src-dependent EGFR activation. In AADC KO mice, Ang II infusion further increased expression of p-src and pTyr845-EGFR, while their expression was markedly attenuated in COMT KO mice.

Conclusions: These results demonstrate a role for intrarenal dopamine to buffer the detrimental effects of angiotensin II upon the kidney.

Impaired Pressure Natriuresis Is Associated with Interstitial Inflammation in Salt Sensitive Hypertension

Martha Franco Guevara,[1] Tapia Edilia,[1] Ursino Pacheco,[1] Jose Santamaria,[1] Yasmir Quiroz,[2] Richard J. Johnson,[3] Bernardo Rodriguez-Iturbe.[2] *[1]Nephrology, Instituto Nacional de Cardiologia I.Ch., Mexico City, Mexico; [2]Renal Service, Hospital Universitario, Zulia, Maracaibo, Venezuela; [3]Nephrology, University of Colorado, Denver, CO.*

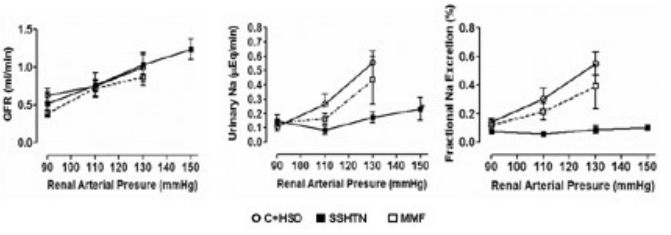
Background: Impairment of pressure natriuresis is a physiopathological characteristic of salt-sensitive hypertension. The shift to the right of the pressure natriuresis is likely a consequence of changes present in tubulointerstitial areas of the kidney, among them, accumulation of immunocompetent cells and increase in renal angiotensin II (AII) activity.

Methods: We studied the pressure natriuresis relationship in relation to severity of interstitial inflammation in salt sensitive hypertension (SSHTN). SSHTN was induced in 250-270g male Wistar rats by administration of L-NAME for 3 weeks; after a 2 week washout period a high (4%) salt diet was given (SSHTN group, n=6). One group received mofetil mycophenolate (MMF) (20mg/kg/day) during the L-NAME administration for reduction of tubulointerstitial inflammation and amelioration of salt-induced hypertension (MMF group, n=8) (AJP2001;281:F38-F47). Controls were untreated rats under high (C-HSD, n=5) and normal (0.4%) salt diet (C-NSD, n=9). Pressure natriuresis was evaluated after 6 weeks using an aortic clamp to modify renal artery pressure (RAP) with measurements at 90, 110, 130 and 150 (hypertensive rats) mmHg of RAP.

Results:

	SSHTN	MMF	C-HSD	C-NSD
CD5+CD68	84.4±5.6°	50.2±2.3°	21.6±1.2	17.6±1.1
AII+cells	31.4±9.0*	19.5±6.9	10.6±1.0	8.8±0.8

*p<0.05 vs. MMF; °p<0.001 vs. the rest



Conclusions: Impairment of pressure natriuresis in salt sensitive hypertension is associated with tubulointerstitial infiltration of immune cells and AII expressing cells and corrected by suppression of tubulointerstitial inflammation.

Intra-Renal Delivery of Autologous Endothelial Progenitor Cells (EPC) Improves Renal Function after Revascularization in Swine Renal Artery Stenosis (RAS)

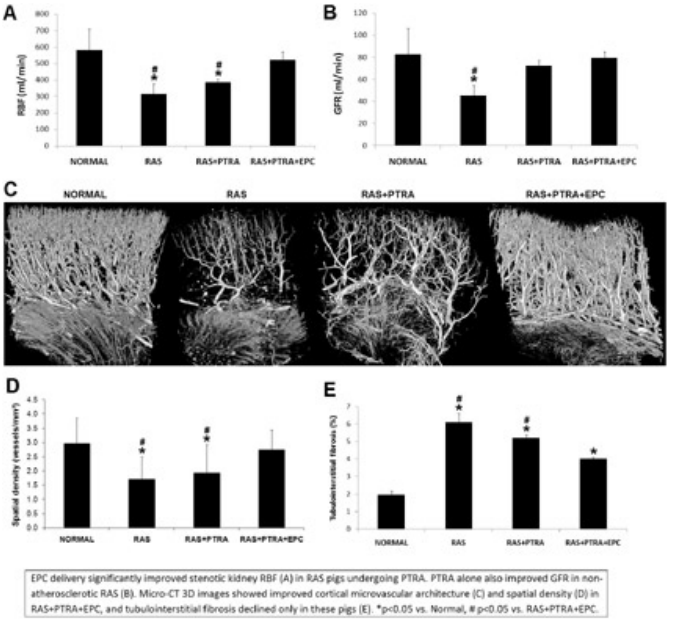
Xiang-Yang Zhu,[1] Alfonso Eirin,[1] Behzad Ebrahimi,[1] Zilun Li,[1] Amir Lerman,[2] Stephen C. Textor,[1] Lilach O. Lerman.[1] *[1]Divisions of Nephrology and Hypertension, Mayo Clinic; [2]Cardiovascular Diseases, Mayo Clinic, Rochester, MN.*

Background: Percutaneous transluminal renal angioplasty (PTRA) alone fails to restore the renal function and microvascular network in a swine model of RAS. This study tested if replenishment with EPC in conjunction to PTRA would improve renal function in swine RAS.

Methods: Pigs with 10 weeks of RAS were studied 4 weeks after PTRA (+stenting) or sham, with or without adjunct intrarenal delivery of autologous EPC expanded from peripheral blood, and controls (n=7 each). Stenotic kidney renal blood flow (RBF) and glomerular filtration rate (GFR) were evaluated in vivo with multidetector computed tomography, and microvascular remodeling and fibrosis ex vivo with micro–CT and trichrome staining respectively.

Results: PTRA normalized blood pressure and GFR in all revascularized pigs (p<0.05 vs. RAS, p>0.05 vs. Normal). EPC were retained (~12%) and engrafted in injected kidneys. Stenotic kidney RBF, tubulo-interstitial fibrosis, and microvascular rarefaction were normalized only in PTRA+EPC-treated pigs (Figure).

Conclusions: A single intrarenal infusion of EPC following PTRA preserved microvascular architecture and function and decreased fibrosis in the stenotic kidney, suggesting a unique and novel therapeutic potential for adjunctive EPC delivery in improving PTRA outcomes in chronic experimental renovascular disease.



EPC delivery significantly improved stenotic kidney RBF (A) in RAS pigs undergoing PTRA. PTRA alone also improved GFR in non-atherosclerotic RAS (B). Micro-CT 3D images showed improved cortical microvascular architecture (C) and spatial density (D) in RAS+PTRA+EPC, and tubulointerstitial fibrosis declined only in these pigs (E). *p<0.05 vs. Normal, # p<0.05 vs. RAS+PTRA+EPC.

TH-OR111

Increased Expression and Activity of the Sodium Chloride Cotrasnporter Mediates Salt Sensitivity in Mice Xiaoyan Wang, Laureano D. Asico, Ines Armando, Pedro A. Jose. *Center for Molecular Physiology Research, Chilren's National Medical Center, Washington, DC.*

Background: We have reported that C57BL6 and SJL mice from Jackson Laboratory have different responses to a chronic salt load: blood pressure increases in C57BL6 but not in SJL mice. Our purpose for the current study is to determine if the salt sensitivity of C57BL6 mice is related to increased expression of sodium transporters in renal distal convoluted tubule.

Methods: We examined the protein abundance of the sodium chloride cotransporter (NCC) which is predominantly expressed in the distal tubule by semiquantitative immunoblotting and measured blood pressures, urinary sodium excretion and aldosterone levels in the two mouse strains (10 weeks old, male) on normal (0.8%, NS) and high NaCl (6%, HS) diets (n=5/group).

Results: The blood pressures (telemetry) were similar at baseline and increased in C57BL6 but not in SJL mice after 1 and 3 weeks of HS. The urinary sodium excretions were also similar at baseline (2.3±0.3 vs 2.3±0.2,mEq/mg Cr, respectively) and increased to a lesser extent in C57BL6 than in SJL mice (1 wk: 4.5±1 vs 8.0±0.6, P<0.05; 3 wks: 3.5±0.4 vs 5.0±0.9, P=0.16, respectively). On NS, the renal protein expression (immunoblotting) of NCC was greater in C57BL6 (167±24, % of SJL mice) than in SJL mice (100±16, %, P<0.05). Urinary aldosterone excretion and renal aENaC expression were decreased by HS to a similar extent in the two mouse strains. In contrast, HS decreased NCC in SJL mice (58±4, % of SJL-NS) but not in C57BL6 mice (146±20, %, P<0.05). The NCC inhibitor, hydrochlorothiazide (30 mg/kg, IP), increased sodium excretion to a greater extent in C57BL6 (NS=0.054±0.01, HS=0.975±0.106, mEq/6hrs) than in SJL (NS=0.023±0.01, HS=0.56±0.147, P<0.01) mice on both diets indicating increased transporter activity. No differences were found in food and water intakes between strains.

Conclusions: We conclude that increased renal NCC expression and activity, which is independent of aldosterone levels, may be responsible for the salt sensitivity in C57BL6 mice.

The Glutathione S-Transferase µ-1 Null Allele GSTM1(0) Is Associated with an Accelerated Progression of Hypertensive Kidney Disease in the African American Study of Kidney Disease (AASK) Jamison W. Chang,[1] Jennie Z. Ma,[1] Qing Zeng,[1] Michael S. Lipkowitz,[2] Thu H. Le.[1] *[1]University of Virginia; [2]Georgetown University.*

Background: We previously identified *Gstm1* as a candidate gene influencing susceptibility to renal vascular injury in a mouse model with lesions that closely resemble renal vascular pathology in human hypertensive nephrosclerosis (HN). There is also evidence that humans who are homozygous for the null allele of *GSMT1 (0)* have increased risks of vascular disease. We evaluated whether the null allele of *GSMT1* modifies the clinical course of African Americans with CKD due to hypertension in the African American Study of Kidney Disease (AASK).

Methods: 722 AASK trial participants with DNA samples were genotyped and classified into three groups based on the number of null alleles: homozygous null (0/0), heterozygous (0/1), and homozygous active (1/1). Differences in the time to 50% or 25ml/min/1.73m^2 decline in glomerular filtration rate (GFR), time to dialysis, or the composite events of time to GFR event or dialysis or the time to GFR event, or dialysis or death were compared between genotype groups. The effect of the *GSTM1* genotype was explored using Cox regression.

Results: The genotype groups differed significantly in the time to a GFR event or dialysis (p=0.04) and in time to a GFR event, dialysis, or death (p=0.02, figure 1). The hazard ratios for the time to GFR event or dialysis in those with 2 (0/0) or 1 (0/1) null alleles relative to those with none (1/1) were 1.96 (95% CI, 1.12 to 3.44, p=0.01) and 1.72 (95% CI, 1.02 to 2.89, p=0.04), respectively. For the time to GFR event, dialysis, or death the hazard ratios (in same order) were 2.15 (95% CI, 1.26 to 3.69, p=0.005) and 1.73 (95% CI, 1.05 to 2.87 and p=0.03).

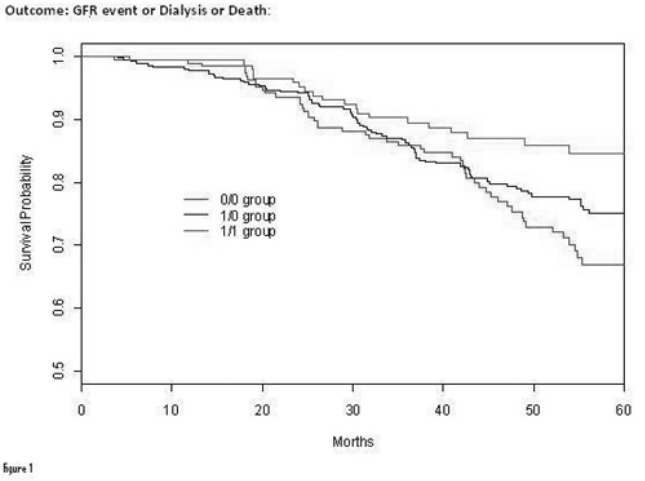

figure 1

Conclusions: The *GSTM1* null allele is associated with a more rapid progression to important clinical outcomes in the AASK trial participants.

Blood Pressure Components and Decline in Kidney Function in Older Adults Dena E. Rifkin,[1] Ronit Katz,[2] Michel B. Chonchol,[3] Michael Shlipak,[4] Mark J. Sarnak,[5] Linda F. Fried,[6] Anne B. Newman,[6] David Siscovick,[2] Carmen A. Peralta.[4] *[1]UCSD; [2]Univ. of Washington; [3]Univ. of Colorado; [4]UCSF; [5]Tufts Univ.; [6]Univ. of Pittsburgh.*

Background: Progressive decline in kidney function(KF) is associated with mortality in older adults. Although hypertension is known to contribute to KF decline in the general population, the relative contributions of elevated systolic(SBP), diastolic(DBP), and pulse pressure(PP) to KF decline in community dwelling older adults are not known.

Methods: We used linear and logistic regression to examine the separate and combined associations of SBP, DBP, and PP at baseline with KF decline among 4365 older adults in the Cardiovascular Health Study. We used cystatin C to estimate glomerular filtration rate(eGFRcys) at three occasions over seven years of follow-up. Rapid decline in KF was defined as loss of ≥3ml/min/year.

Results: Average age was 72.2 and mean(SD) SBP, DBP and PP were 135(21), 71(11) and 65(18) mm Hg, respectively. SBP and PP were significantly associated with KF decline. In adjusted linear models, each 10 mm Hg increment in SBP was associated with an added decline of 0.13 ml/min/year (-0.19, -0.08, p < 0.001); each 10 mm Hg increment in PP associated with an added decline of 0.15 ml/min/yr (-0.21, -0.09, p < 0.001). Each 10 mm Hg increment in DBP was associated with a more modest decline of 0.10 ml/min/yr (-0.20, 0.01, p < 0.051). In adjusted logistic models, SBP had the strongest associations with rapid decline, with each 10 mm Hg increase conferring a 14% increased hazard of rapid decline (95% CI 10%, 17%, p < 0.01). In models combining BP components, only SBP was independently associated with rapid decline. Findings were similar regardless of BP medication use.

Conclusions: Our findings suggest that elevated BP, particularly SBP, contributes substantially to declining KF in older adults.

Improvement of Vascular Function and Cardiac Autonomic Control Following Renal Transplantation: A Prospective Longitudinal Study

Roberto S. Kalil,[1] Kimberly Ferrante,[2] Harald M. Stauss,[2] William G. Haynes.[1] *[1]Dept. of Internal Medicine, University of Iowa, Iowa City, IA; [2]Health and Human Physiology, University of Iowa, Iowa City, IA.*

Background: Uremic state is strongly associated with autonomic nervous system dysfunction and impaired endothelial vascular function. Furthermore, decreased heart rate variability (HRV) in patients with ESRD is associated with higher rates of cardiovascular events and predicts progression of chronic kidney disease.

Methods: Therefore, we studied endothelial vascular function and cardiac autonomic control in patients with ESRD before and 3 months, 12 months, and 36 months following renal transplantation (RT). Vascular function was assessed by flow mediated dilatation (FMD) and cardiac autonomic control was assessed by time- and frequency-domain HRV analysis.

Results: FMD increased by 50% at one year after RT, indicating improved endothelial vascular function. During the first year following RT, time- and frequency-domain HRV parameters tended to increase (e.g., RMSSD 20.7±1.9 ms before RT vs. 25.3±5.4 ms one year after RT), indicating improved autonomic cardiac control and suggesting reduced cardiovascular risk. Compared to one year following RT, HRV parameters tended to be slightly lower at 3 years following RT (e.g., RMSSD 21.7±2.3 ms), but were still greater than before RT. Importantly, HRV (SDNN) correlated significantly (R=0.4, P<0.05) with FMD.

Conclusions: We conclude that renal transplantation in ESRD patients chronically improves endothelial vascular function and cardiac autonomic control for at least 3 years. Because of the significant correlation between the recovery of FMD and HRV, we speculate that improved endothelial vascular function contributes to reduced cardiovascular events following RT in ESRD patients.

Women with a History of Hypertensive Pregnancy Disorders Are at Increased Risk for Future Cardiovascular and Renal Disease: A Population-Based Cohort Study

Vesna D. Garovic,[1] Catherine M. Brown,[1] Slavica Katusic,[2] Cynthia L. Leibson,[2] Jeanine Ransom,[2] Stephen T. Turner,[1] Veronique L. Roger.[2] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Health Sciences Research, Mayo Clinic, Rochester, MN.*

Background: Using the unique population-based longitudinal resources of the Rochester Epidemiology Project (REP), we tested the hypothesis that hypertensive pregnancy disorders (HPD) are a risk factor for future renal and cardiovascular disease (CVD) among women in the community.

Methods: Using REP resources we retrospectively identified female residents of Rochester, MN and the surrounding townships in Olmsted County who delivered in 1976-1982. We used the REP diagnostic index and International Classification of Diseases codes to identify women with (cases)and without (controls) diagnostic codes consistent with HPD and followed them after age 40 years for diagnostic codes consistent with adverse CVD and renal outcomes.

Results: We identified 6051 mothers who delivered between 1976-1982, of whom 607 women (mean age 26 years) had diagnostic codes consistent with HPD and 5444 women (mean age 27 years) had no such codes. Follow up after age 40 years was available for 465 of the 607 (77%) cases and 3898 of the 5444 (72%) controls. The percentage assigned renal and CVD diagnoses was significantly greater among cases than controls for hypertension diagnosed after age 40 (p<0.0001), renal disease (p<0.01), and stroke (p<0.001).

Table 1 Results of outcome events cases vs. controls

Follow up at ≥40 years of age	Cases n=465	Controls n=3898	P value
Outcome event	288(62%)	1839(47%)	p<0.0001
Median age in years (range) *	44 (40-67)	50 (40-72)	p<0.0001
Hypertension	236(51%)	1222(31%)	p<0.0001
Coronary heart disease	110(24%)	823(21%)	p=0.38
Renal (proteinuria, CKD or ESRD)	63(14%)	374(10%)	p<0.01
Stroke	35(8%)	160(4%)	p<0.001
Venous thromboembolism	13(3%)	75(2%)	p=0.21

* Age at first outcome event.

Conclusions: A history of hypertensive pregnancy disorders among women in the community is associated with significantly increased risks of future hypertension, renal and stroke events compared to women who have had normotensive pregnancies.

TH-OR116

Factors Contributing to the Development and Control of Elevated Blood Pressure in Pediatric CKD Patients

Amy Kogon,[1,2] Christopher B. Pierce,[2] Tammy M. Brady,[2] Mark Mitsnefes,[2] Bradley A. Warady,[2] Susan L. Furth,[2] Joseph T. Flynn.[1,2] *[1]Seattle Childrens's Hospital; [2]CKiD Study Group.*

Background: Few data exist regarding longitudinal blood pressure(BP) status changes in pediatric chronic kidney disease(CKD). Using Chronic Kidney Disease in Children(CKiD) cohort study data, we assessed factors associated with the rates at which normotensive patients develop elevated BP(eBP) and patients with eBP develop controlled BP.

Methods: *Development of eBP*: Children with no history of eBP, measured BP<90th %ile and no BP medication use at baseline, were followed prospectively with annual visits for the outcome of a measured BP>90th %ile. Analysis was performed using Cox proportional hazards models. *Control of eBP*: Children with measured BP>90th %ile were followed prospectively for the outcome of measured BP<90th %ile at two consecutive visits. To account for the competing events of progression to replacement therapy(RT) or death, cause-specific relative hazards are reported.

Results: Of 124 children(21% of CKiD cohort) with normal baseline BP and median follow-up of 1.5 years(IQR:0.9, 3.0), 50% were estimated to develop eBP within 2.5 years, regardless of glomerular filtration rate(GFR), race and gender. 205 children(35% of cohort) had baseline eBP; 85 developed controlled BP and 43 progressed to RT with median follow-up of 1.4 years(IQR: 0.6,3.0). African American(AA) race and urine protein:creatinine(uP:C)>2 were associated with persistently eBP. Older age, glomerular CKD and GFR<45 showed an increased risk of RT or death.

Results of Multivariate Cause-specific Relative Hazards Models, N=205

Factor	HR for BP Control, Estimate (95% CI)*	HR for RT/death, Estimate (95%CI)*
Age, per year	0.96(0.92,1.02)	1.14(1.03,1.26)
Male	1.31(0.81,2.11)	2.25(0.95,5.31)
AA race	0.54(0.29, 0.98)	0.99(0.47, 2.10)
Glomerular CKD	0.9 (0.47, 1.97)	2.10(1.00, 4.39)
GFR<45	0.79(0.50, 1.27)	7.09(2.70, 18.62)
uP/C		
<0.2	-	-
0.2-2.0	0.72(0.45, 1.16)	1.26(0.26, 6.12)
>2.0	0.17(0.05, 0.61)	4.54(0.95, 21.61)

* HR=Hazard ratio; adjusted for variables show plus BP med use.

Conclusions: In pediatric CKD, eBP develops irregardless of GFR and demographics. In those with eBP, achieving controlled BP is more difficult in AA patients and those with uP:C>2.

Renal Inflammation and Injury Signals in Patients with Atherosclerotic Renal Artery Stenosis (ARAS)

Alfonso Eirin,[1] Monika L. Gloviczki,[1] Hui Tang,[1] Mario Gossl,[2] Kyra L. Jordan,[1] John R. Woollard,[1] Amir Lerman,[2] Joseph P. Grande,[3] Stephen C. Textor,[1] Lilach O. Lerman.[1] *[1]Divisions of Nephrology and Hypertension, Mayo Clinic; [2]Cardiovascular Diseases, Mayo Clinic; [3]Pathology, Mayo Clinic, Rochester, MN.*

Background: The mechanisms underlying irreversible renal injury in ARAS patients have not been elucidated. This study tested the hypothesis that the injured ARAS kidney releases inflammatory mediators and retains circulating endothelial progenitor cells (EPC) to promote regeneration.

Methods: We prospectively measured renal vein (RV) and inferior vena cava (IVC) levels of inflammatory biomarkers and CD34+/KDR+EPC in essential hypertensive (EH) and ARAS patients (n=24 each) studied under constant sodium intake and anti-hypertensive regimens. Cytokine gradient (RV-IVC) and net renal release (gradient x RBF) were estimated for each product and compared to systemic levels in age-matched normotensive subjects (n=24).

Results: Blood pressure was similar in ARAS and EH, but glomerular filtration rate was lower in ARAS. RV levels of inflammatory cytokines (Table) and EPC homing factors (SCF and SDF-1) were higher in the stenotic ARAS kidney vs. normal and EH RV (p<0.05), and their net release increased. Conversely, RV levels and net release of anti-inflammatory IL-10 were decreased in the stenotic ARAS kidney. Moreover, there was a negative gradient of CD34+/KDR+ EPC across the ARAS kidney, suggesting EPC retention (Figure).

Conclusions: These studies demonstrate for the first time that the post-stenotic human ARAS kidney releases inflammatory biomarkers and retain circulating EPC. These cytokine likely accelerate kidney injury and provide signals to EPC that may participate in reparative processes within the affected kidneys. These observations identify novel therapeutic targets to attenuate tissue injury and promote repair in the stenotic kidney.

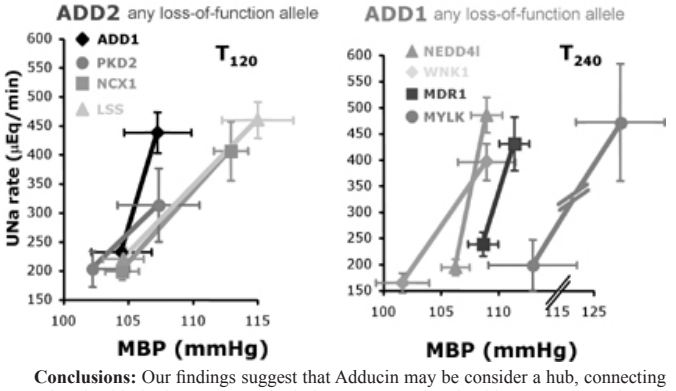
Network of Salt-Senstive Hypertension: Time Effect of a Genetic Hub Marco Simonini, Guido Gatti, Simona Delli Carpini, Simona Pozzoli, Lorena Citterio, Chiara Lanzani, Elena Brioni, Stefano Tentori, Paolo Manunta. *Chair of Nephrology, San Raffaele Scientific Institute, Milan, Italy.*

Background: The emerging tools of network of hypertension offer a platform to explore systematically not only the molecular complexity of a particular disease, leading to the identification of disease modules and pathways, but also the molecular relationships among apparently distinct phenotypes. The effects of ADD1and ADD2 mutated allele and how they interact with other genes affecting the Pressure Natriuresis relationship (PNat) have been tested.

Methods: We performed a Na load test (iv. infusion of 2L of 0.9% NaCl in 2h) in 513 new diagnosed, never treated essential hypertensive patients. We tested relationship between BP change and urinary sodium excretion during the test (samples were collected every 120 min).

Results: We studied the slope of PNat at the end of infusion time (T_{120}) and after recovery (T_{240}). No differences are identifiable under the ADD1 and ADD2 wild-type allele background. A time-depending effect of ADDs genes was detected. We observed an epistatic ($p<0.001$) effect on PNat of ADD2 with the recessive alleles of ADD1, PKD2, SLC8A1 (NCX1), and LSS all related to vascular component at T_{120}. However, after recovery (T_{240}) we found an epistatic interaction on PNat ($p<0.01$) between ADD1 and genes related to tubular transporters (WNK1, MDR1, NEDD4L) and MYLK gene, encoding myosin light chain kinase which is a calcium/calmodulin dependent enzyme.



Conclusions: Our findings suggest that Adducin may be consider a hub, connecting genes involved in both vascular and tubular transporter involved in pressures natriuresis control.

TH-OR119

Vascular Endothelial Growth Factor C Levels Are Modulated by Dietary Salt Intake in Humans Arjan J. Kwakernaak,[1] Maartje C.J. Slagman,[1] Saleh Yazdani,[1] Gozewijn Dirk Laverman,[1] Jacob Van den Born,[1] Jens Titze,[2] Gerjan Navis.[1] *[1]Department of Nephrology, University Medical Centre Groningen, Netherlands; [2]Department of Nephrology and Hypertension, Friedrich-Alexander University, Erlangen-Nürnberg, Germany.*

Background: Recent experimental findings demonstrate vascular endothelial growth factor C (VEGF-C) mediated water-free storage of salt in the interstitium, which prevents a salt-sensitive blood pressure state. It is unknown whether this mechanism plays a role in salt homeostasis and regulation of blood pressure in humans as well. Therefore, we investigated circulating VEGF-C levels and blood pressure during different well-controlled salt intakes in healthy subjects and in chronic kidney disease (CKD) patiens.

Methods: In two cross-over studies, non-diabetic proteinuric CKD patients (n=32), and healthy subjects (n=31) were treated with consecutively a high sodium diet (HS, aim 200 mmol Na^+/d) and a low sodium diet (LS, aim 50 mmol Na^+/d) in random order, during two 6-week (CKD) and two 1-week (healthy subjects) periods.

Results: We found that VEGF-C levels are higher during HS than during LS in CKD patients (median (IQR) 1228 (1024-1471) and 1004 (857-1177) pg/mL, resp; p=0.034) as well as in healthy subjects (881 (758-1023) and 773 (748-921) pg/mL, resp; p=0.070). In CKD patients HS was associated with higher NT-proBNP levels (HS: median (IQR) 91 (60-137) and LS: 62 (41-93) pg/mL, resp; p=0.005) and body weight (HS: mean (SD) 91 (3) and LS: 89 (3) kg, resp; p=0.013), consistent with ECV expansion, and with higher mean arterial pressure (HS: mean (SD) 105 (15) and LS: 101 (11) mmHg, resp; p<0.001), indicating salt-sensitivity. In healthy subjects blood pressure was not affected by dietary salt (HS: 87 (7) and LS: 86 (8) mmHg, resp; p=0.251), despite a rise in ECV (HS: mean (SD) 20.8 (0.5) and LS: 19.8 (0.5) L, resp; p=0.023).

Conclusions: Our findings support a role for VEGF-C mediated salt homeostasis in humans. Considering the salt-sensitivity of blood pressure, this buffering mechanism appears to be insufficient in proteinuric CKD patients. Future studies should investigate the clinical and therapeutic relevance of this VEGF-C regulatory mechanism in humans.

TH-OR120

Cardiovascular Disease in Fabry Patients Is Related to Dysfunctional Circulating Angiogenic Cells Johan M. Lorenzen,[1] Hermann G. Haller,[1] Christoph Wanner,[2] Thomas Thum.[1] *[1]Nephrology, Hanover Medical School, Hannover, Germany; [2]Nephrology, University Hospital Würzburg, Würzburg, Germany.*

Background: Fabry disease is an X-chromosomal recessive deficiency of the lysosomal hydrolase alpha-galactosidase A (alpha-Gal A), which catalyzes the hydrolytic cleavage of the terminal galactose from globotriaosylceramide (GL-3). This results in an accumulation of GL-3 in a variety of cells such as endothelial cells, smooth muscle cells and cardiomyocytes impairing their physiological function. Enzyme replacement therapy can prevent or attenuate onset of cardiovascular complications. We investigated the impact of this disease on the biology of circulating angiogenic cells (CACs) and endothelial function in patients with Fabry disease and healthy controls.

Methods: 26 patients with untreated Fabry disease, 16 patients after enzyme replacement therapy (ERT) and 26 healthy controls were investigated. Endothelial function was assessed by the EndoPat device, left ventricular hypertrophy by echocardiography. Circulating angiogenic cells were analyzed by fluorescence associated cell sorting (FACS) analysis (CD34+/CD133+/KDR+). The migratory capacity of CACs was assessed by a modified Boyden chamber. GL-3 was visualized by immunofluorescence and electron microscopy. Alpha-Gal A was knocked out in CACs by a specific siRNA.

Results: Fabry patients showed a hyperactive, but impaired endothelial function and signs of cardiac hypertrophy, which normalized after enzyme replacement therapy. Fabry patients displayed increased numbers, but impaired function of CACs. We performed immunofluorescence and electron microscopy of CACs to further investigate causes of this functional impairment and identified an excessive accumulation of GL-3 in Fabry disease CACs. Enzyme replacement therapy attenuated CAC dysfunction in patients via a reduction in GL-3 accumulation in vitro and in vivo. SiRNA-mediated knockdown of alpha-Gal A in healthy CACs also led to an impairment of migratory capacity.

Conclusions: Cardiovascular disease in Fabry patients may be in part related to CAC dysfunction. Enzyme replacement therapy improves CAC function and may attenuate development of cardiovascular disease in the long-term.

Funding: Government Support - Non-U.S.

TH-OR121

Gitelman Syndrome: Hypertension in Adulthood Is a Common Sequela, and Female Patients Have Higher Potassium Requirements Miriam Rose Berry,[1] Caroline M. Robinson,[2] Fiona E. Karet.[1, 2] *[1]Renal Medicine, Addenbrooke's Hospital, Cambridge, United Kingdom; [2]Medical Genetics, University of Cambridge, United Kingdom.*

Background: Gitelman Syndrome (GS) is a rare inherited disorder caused by mutations in *SLC12A3*, which encodes the thiazide-sensitive NCC transporter in the distal tubule. GS is characterised by potassium (K) and magnesium (Mg) wasting, relative hypotension and usually, hypocalciuria; however there is wide phenotypic variability.

Methods: We performed a retrospective study of all patients with genetically proven Gitelman syndrome known to our specialist adult nephrology service. Differences between group medians were tested for significance by Mann-Whitney U-testing.

Results: 37 patients (21 male and 16 female) with median age 39 ± 14 y were studied. All were hyper-reninemic at diagnosis. 35% (n=13) patients were hypertensive (defined as BP > 130/80 despite amiloride or anti-hypertensive agents). Of these 13, 11 were male (p=0.017) with median age 53 y, *vs* two female, 45 y (p=0.55). One patient was already hypertensive by age 21 y. Overall, currently normotensive patients were significantly younger: median 37.5 y (p=0.03), and also younger at the time of genetic diagnosis: 35.5 *vs* 47 y (p=0.04).

Females required significantly higher daily doses of K compared to males: median 124 *vs* 72 mmol (p=0.007). There was also a trend towards higher Mg requirements: 30 *vs* 15 mmol (p=0.15). 5 patients were in the top quartiles of both K and Mg requirements, 4 female and 1 male (p=0.14), median age 36 y. Patients with mutations in exon 26 had significantly higher K requirements than others: 120 mmol *vs* 80 (p=0.018).

Conclusions: Despite obligate salt-wasting in GS, secondary hypertension has developed in more than one third of our cohort, and may be an expected feature of the aging GS population. It appears to be more prevalent in male patients. It may be related to chronic hyperreninism and/or hyperfiltration. The higher female requirement for potassium supplementation we observed may be related to the effects of oestrogens on expression or function of the NCCT. Mutations in exon 26 (C-terminal) may affect targeting of NCCT and hence explain the apparently more severe phenotype observed in these patients.

TH-OR122

An ADPKD Cyst Epithelial Cell Secreted Factor Activates STAT3 and Promotes M2-Like Polarization in Macrophages Katherine Swenson-Fields, Jacqueline D. Peda, Sally M. Salah, Carolyn J. Vivian, Darren P. Wallace, Timothy A. Fields. *Kidney Institute, University of Kansas Medical Center, Kansas City, KS.*

Background: Alternatively-activated macrophages (M2 MΦ) are known to play a pro-fibrotic role in chronic kidney disease (CKD). Since MΦ have been demonstrated within the stroma of autosomal dominant polycystic kidney disease (ADPKD), we assessed whether M2 MΦ are present and whether ADPKD cells affect their polarization.

Methods: Immunohistochemical characterization of macrophages in human ADPKD tissue was performed using HAM56 and anti-CD163 antibodies. Primary human ADPKD cyst cells were co-cultured with murine bone-marrow derived macrophages (BMDM) and a murine macrophage-like cell line, RAW264.7 (RAW). Signaling was assessed using phospho-specific Western analysis; gene expression was analyzed using qRT-PCR.

Results: HAM56 identified MΦ within ADPKD stroma, especially adjacent to basement membranes underlying cysts. Many of these MΦ also stained for the M2 marker CD163. Since murine proximal tubule epithelial cells have been shown to influence MΦ polarization in vitro, we tested whether ADPKD epithelial cells could effect polarization of BMDM. Strikingly, ADPKD cell co-culture caused a >200 fold induction of the M2 MΦ marker Arg1 in both BMDM and RAW cells, while the inflammatory MΦ marker Nos2 was not induced. ADPKD cell conditioned media (ADPKD CM) also induced Arg1 expression (~75 fold), indicating the presence of an ADPKD cell-derived, soluble, M2-polarizing factor. STAT6 activation, which is essential for Arg1 induction and M2 polarization induced by the cytokines IL4 and IL13, was not detected in RAW cells after ADPKD CM treatment. However, ADPKD CM induced a rapid activation of STAT3 in RAW cells, and the presence of a STAT3 inhibitor completely blocked the ADPKD CM Arg1 induction.

Conclusions: ADPKD cyst cells produce a soluble factor that activates STAT3 and induces Arg1 expression and M2-like macrophage polarization. M2 MΦ in the ADPKD environment are likely to promote disease progression. Thus, understanding the mechanisms by which polarization occurs could allow the development of targeted therapies to diminish M2 polarization and disease progression in ADPKD.

Polycystin-1 Binds Par3-aPKC To Control Polarized Cell Migration and Renal Tubular Morphogenesis Maddalena Castelli,[1,2] Manila Boca,[1,2] Marco Chiaravalli,[1,2] Alessandra Boletta.[1,2] *[1]Dulbecco Telethon Institute - DTI, Milan, Italy; [2]Genetics and Cell Biology, San Raffaele Scientific Institute, Milan, Italy.*

Background: Loss of function mutations in the PKD1 gene, encoding Polycystin-1 (PC-1) result in Autosomal Dominant Polycystic Kidney Disease (ADPKD), characterized by renal cyst formation. PC-1 is a large receptor localized in cilia and at sites of cell adhesion. Its precise function remains largely elusive. It was recently proposed that renal cystogenesis results from defective planar cell polarity. Here we link PC-1 to a highly conserved polarity pathway, showing that PC-1 interacts with a complex composed of aPKC and Par3, both in vitro and in vivo.

Results: In previous studies we have demonstrated that PC-1 regulates cell migration. Furthermore, we found that Pkd1-/- Mouse Embryonic Fibroblasts (MEFs) in wound-healing assays do not migrate in a directional manner and are not able to establish front-rear polarity, as compared to controls. This phenotype depends on the dynamic interplay between the actin and the microtubular cytoskeleton.

We next tested a potential role of the Pars/aPKC polarity complex. Using a novel system carrying endogenous tagged PC-1, we found that PC-1 interacts with Par3/aPKC, but not with Par6 in vitro. Moreover, PC-1 favors the association of aPKC with Par3 at the expense of Par6 to achieve polarized migration. Interestingly, this effect appears to be non cell-autonomous.

Furthermore we found that PC-1 associates with Par3/aPKC in the developing kidneys in vivo and that PC-1 and Par3 appear to undergo a similar regulation of expression during renal development. In line with this, developing kidneys of Pkd1 mutants show defective convergent extension and tube morphogenesis accompanied by defective association of aPKC/Par3.

Conclusions: We propose that Par3 and Par6 compete with each other for binding aPKC and that PC-1 associates with and favors aPKC/Par3 complex to control polarized migration, convergent extension and tube morphogenesis, thus preventing cystogenesis.

TH-OR124

PDE1 and AKAP79 Interact with B-Raf To Mediate cAMP-Induced ERK Activation and Proliferation of Human ADPKD Cells Cibele S. Pinto, Gail Reif, Emily Nivens, Corey White, Darren P. Wallace. *Internal Medicine, University of Kansas Medical Center, Kansas City, KS.*

Background: cAMP plays a central role in the pathogenesis of ADPKD by activating the B-Raf/MEK/ERK signaling pathway and promoting cyst epithelial cell proliferation. By contrast, cAMP fails to stimulate B-Raf and ERK-mediated proliferation of normal human kidney (NHK) cells. The molecular mechanism for this difference in cAMP-dependent B-Raf signaling is still unclear. Scaffolding proteins, such as A-kinase anchoring proteins (AKAPs), assemble multi-enzyme signaling complexes with cAMP effector molecules (i.e phosphodiesterases (PDEs) and B-Raf) to promote spatial and temporal regulation of the cAMP signal. PDEs, enzymes that degrade cAMP, also function as scaffolding proteins to compartmentalize cAMP signal. In melanoma cells, PDE4 has been shown to interact with Raf-1, and switch the Raf isoform involved in growth factor signaling; thereby causing hyperactivation of the MEK/ERK pathway. Previously, we showed that PDE1, a Ca^{2+}-regulated isoform, is involved in the phenotypic switch in the mitogenic response of ADPKD cells to cAMP. We hypothesize that cAMP induces the formation of macromolecular complexes involving AKAPs and PDEs that facilitate the cAMP-dependent B-Raf activation and coordinate the cross-talk between cAMP and ERK pathways in ADPKD cells.

Methods: To determine if PDE1 and AKAP79 interact with B-Raf, ADPKD and NHK cells were treated with 100 μM cAMP or 10^{-9} M AVP for 15 min, and PDE1 and AKAP79 were immunoprecipitated and immunoblots were probed for B-Raf.

Methods: Here, we show that AKAP79, an isoform expressed in ADPKD and NHK cells, directly interacts with B-Raf. Surprisingly, cAMP caused a 40% increase in the AKAP79 and B-RAF interaction in ADPKD cells, while causing a small decrease in this interaction in NHK cells. PDE1 was found to also be part of the AKAP79/B-Raf complex. Treatment with cAMP or AVP caused a 70% increase in the interaction between PDE1 and B-Raf in ADPKD cells, while having no effect in NHK cells.

Conclusions: These data indicate that the assembly of a multi-protein signaling complex involving AKAP79, PDE1 and B-Raf may be differentially regulated by cAMP in ADPKD cells.

Ire1-Xbp1 Unfolded Protein Response (UPR) Pathway Is a Genetic and Molecular Regulator of Cystogenesis through a Polycystin-1 (PC1) Dependent Mechanism Sorin V. Fedeles,[1] Ann-Hwee Lee,[2] Seung H. Lee,[1] Ming Ma,[1] Rachel Gallagher,[1] Laurie H. Glimcher,[2] Stefan Somlo.[1] *[1]Internal Medicine/Nephrology, Yale School of Medicine, New Haven, CT; [2]Immunology/ Infectious Diseases and Medicine, Harvard Medical School, Boston, MA.*

Background: This work examined the relationship between up-regulation of the unfolded protein response (UPR, a housekeeping pathway involved in counteracting ER stress) and cyst formation due to the absence of the Autosomal Dominant Polycystic Liver Disease (ADPLD) gene orthologs, *Prkcsh* and *Sec63*, both of which are involved in ER protein biogenesis.

Methods: We used mouse models of *Prkcsh*, *Sec63*, and *Xbp1* based on conditional inactivation in the kidney by *Ksp-Cre*, as well as kidney tubule cell lines isolated from these models.

Results: Inactivation of *Prkcsh* did not result in up-regulation of any of the three branches of the UPR pathway. Inactivation of *Sec63*, on the other hand, resulted in selective activation of the Ire1-Xbp1 pathway, as evidenced by *Xbp1* splicing, protein expression and up-regulation of Xbp1 transcriptional targets. The other two branches of the UPR pathway, Atf6 and Perk, remained at basal levels. Double knockout (DKO) animals with conditional inactivation of *Sec63* and *Xbp1* in distal nephron segments (*Sec63$^{flox/flox}$;Xbp1$^{flox/flox}$;Ksp-Cre*) showed a marked exacerbation of the cystic phenotype compared to single knockout (SKO; S*ec63$^{flox/flox}$;Ksp-Cre*) mice; *Xbp1$^{flox/flox}$;Ksp-Cre* mice had no cysts. DKO mice had a ~2.5 fold increase in kidney weight (KW), kidney-to-body weight ratio (KW/BW), cystic index (CI) and BUN compared to SKO animals. Introduction of a 3-copy *Pkd1BAC* trangene in DKO mice resulted in a significant reduction in the KW, KW/BW ratio, CI and BUN compared to the DKO animals alone. Furthermore, expression of the Xbp1 transcriptional target ER chaperone BiP was decreased in the cystic epithelia of DKO vs. SKO animals. This correlated with a decrease in the expression of PC1 and PC2 in the DKO vs. SKO backgrounds.

Conclusions: Taken together our data demonstrate that the most conserved branch of the UPR pathway, Ire1-Xbp1, can act as a modifier of cyst formation by impacting the biogenesis of PC1/PC2.

Pyrimethamine: A Potential Novel Therapeutic Intervention for ADPKD
Ayumi Takakura,[1] Erik A. Nelson,[2] Nadeem Haque,[1] Benjamin D. Humphreys,[1] Kambiz Zandi-Nejad,[1] David Frank,[2] Jing Zhou.[1] *[1]Renal Division, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Department of Medical Oncology, Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a commonly inherited disorder mostly caused by mutations in PKD1. The disease is characterized by development and growth of epithelium-lined cyst in kidney. There is no specific treatment for ADPKD. The signal transducer and activator of transcription (STAT) pathway is critical for developmental regulation and growth control in organs.

Methods: We measured STAT3 activation in kidneys from Col2Cre+Pkd1flox/flox conditional knockout, Mx1Cre+Pkd1flox/flox inducible knockout and their littermate wild-type mice by western blot and immunostaining. We performed cell based functional assay of FDA-approved compounds to identify small molecule inhibitors of STAT3 transcriptional activity. Two PKD mouse models were used for the treatment: 1) an adult-onset PKD mouse model (adult inactivation of Pkd1 followed by renal injury), and 2) a neonatal PKD mouse model (Pkd1 inactivation at P7). The kidney weight, the kidney body weight ratio, serum creatinine, cyst volume were measured. Proliferation index was assessed using Ki67 and BrdU incorporation.

Results: A sustained activation of the transcription factor STAT3 was observed in ischemic injured and uninjured mouse polycystic kidneys and in human ADPKD kidneys. Furthermore, Jak2 inhibitors reduced STAT3 activation in human ADPKD cells in a dose-dependent manner, indicating increased Jak2 activity in ADPKD cells. Through a chemical library screen, we identified the anti-parasitic compound pyrimethamine as an inhibitor of STAT3 function. Treatment with pyrimethamine decreased STAT3 activation and cell proliferation preferably in human ADPKD cells and reduced renal cyst formation in an adult and a neonatal PKD mouse models. Moreover, we demonstrated that another STAT3 inhibitor, S3I-201, reduced cyst formation and growth in a neonatal PKD mouse model.

Conclusions: Blocking STAT3 signaling with pyrimethamine or similar drugs may be an attractive therapy for human ADPKD.

Smac-Mimetic Prevents Renal Cyst Formation by Inducing TNFa-Dependent Cystic Epithelial Cell Death
Lucy X. Fan,[1,2] Xia Zhou,[1,2] Wei Liu,[1,2] William E. Sweeney,[1,2] Ellis D. Avner,[1,2,3] Xiaogang Li.[1,2,3] *[1]Children's Research Institute, Children Hospital of Wisconsin; [2]Pediatrics, ; [3]Physiology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Past efforts to pharmacologically interfere with the development and growth of cystic renal lesions have been designed to "normalize" the activity of a specific signaling molecule. Recent efforts in our laboratory have focused on developing a novel strategy by targeting pathways that can induce only cystic renal epithelia apoptosis, leading to remove the dead cells from kidney tissues, to prevent cyst formation.

Results: In this study, we present for the first time evidence that second mitochondria-derived activator of caspase (Smac) or a Smac mimetic induces cell death in a TNFα-dependent manner, in Pkd1 mutant (*Pkd1*$^{-/-}$) renal epithelial cells without any effect on Pkd1 wild type (*Pkd1*$^{+/+}$) or Pkd1 heterozygous (*Pkd1*$^{+/-}$) renal epithelia. Following activation by TNF-α, the C-tail death domain of TNF-α receptor 1 (TNFR1) recruits a multimeric protein complex that includes receptor associated protein kinase 1 (RIPK1), and the cellular inhibitor of apoptosis proteins 1 and 2 (cIAP1 and cIAP2), to form a pro-survival signaling complex. In Pkd1 mutant (*Pkd1*$^{-/-}$) renal cells, both TNFR1 and cIAP1 but not cIAP2 are upregulated compared to levels in Pkd1 wild type and Pkd1 heterozygous renal epithelia. A Smac-mimetic (GT13072) induced the degradation of cIAP1 in (*Pkd1*$^{-/-}$) renal epithelia but had no effect on cIAP1 in Pkd1 wild type or heterozygous epithelia. Degradation of cIAP1 releases RIPK1 from the TNFR1 complex, and leads to the formation and activation of RIPK1-dependent caspase-8, pro-death complex. This complex specifically induces cell death in mutant Pkd1 renal epithelia only. In addition, we found that Smac-mimetic alone or in combination with TNF-α, stimulated further expression of TNF-α only in cystic renal epithelia. Furthermore, we found that treatment with the Smac-mimetic only prevented edema and cyst formation in Pkd1 knockout embryos and kidneys.

Conclusions: These data suggest the use of Smac-mimetics alone provide a novel and specific therapeutic approach to prevent cyst formation in ADPKD patients.

TH-OR128

Hepatocyte Nuclear Factor 1 beta (HNF1b/MODY5) Controls Nephron Morphogenesis
Filippo Massa, Evelyne Fischer, Serge Garbay, Marco Pontoglio. *Genetics and Development, Cochin Institute, Paris, France.*

Background: The deficiency for Hepatocyte Nuclear Factor 1 Beta (HNF1B), a gene encoding for a homeobox-containing transcription factor, is a major cause for developmental renal malformation characterized by the occurrence of cysts and hypo-dysplasia. The current knowledge about its molecular and cellular mechanisms is still incomplete.

Methods: A homozygous germ-line deletion of Hnf1b in mouse leads to embryonic lethality shortly after implantation (E6.5) due to defective differentiation of extraembryonic tissues. To circumvent this early lethality we inactivated this gene specifically in the embryo proper and not in the extraembryonic compartment with a set of Cre recombinases (Mox2Cre, RARbCre and Six2-GFP::Cre).

Results: Similarly to what was already shown (Lokmane et al,2010), we found that a total embryonic (Mox2-Cre driven) Hnf1b inactivation led to a drastic defect of renal morphogenesis. Branching of the Ureteric Bud (UB) was distorted and the induction of renal vesicles was impaired.

Our results also demonstrated that Hnf1b-deficient embryos displayed Wolffian duct malformations, characterized by the emergence of multiple bulges (ectopic UBs).

To further identify the potential role played by Hnf1b in developing nephrons, we used a Cre recombinase specifically expressed in Metanephric Mesenchyme (MM) and not in the UB (Six2-GFP::Cre). Contrary to the Mox2-Cre driven deletion, this inactivation did not prevent the induction of renal vesicles. However, nephron precursors gave rise to aberrant globular structures and did not produce renal tubules.

Interestingly, with a highly chimeric inactivation of Hnf1b in the MM (RARb-Cre), we were able to identify a further crucial role of Hnf1b in proximal tubular morphogenesis. In fact, partial loss of Hnf1b led to defective lengthening of this segment, and mutant animals suffered from defective reabsorption of glucose.

Conclusions: Our results demonstrate that HNF1 beta plays essential roles in the first morphogenetic events that shape nephrons and, subsequently, in proximal tubular elongation.

These results provide a novel perspective on the function of a gene that is frequently mutated in children or fetuses with cystic/dysplastic kidneys.

Hedgehog Signaling Is Increased in Glis2 Knockout Kidneys Resulting in the Persistence of Nephron Developmental Programs
Binghua Li,[1] Alysha Rauhauser,[1] Anton M. Jetten,[3] Massimo Attanasio.[1, 2] *[1]Departments of Internal Medicine; [2]Eugene McDermott Center for Growth and Development, UT Southwestern Medical Center, Dallas, TX; [3]Cell Biology Section, Division of Intramural Research, NIEHS, Research Triangle Park, NC.*

Background: Nephronophthisis (NPHP), an autosomal recessive cystic kidney disease, is the most frequent genetic cause of chronic renal insufficiency in the first three decades of life (1). Glis2/NPHP7 loss of function causes NPHP type 7 in humans and mice (2). Kidney tubular cells in Glis2 knockouts acquire mesenchymal phenotype, but the cellular mechanisms of this transition are unknown.The high sequence homology between Glis2 and Gli proteins, key effectors in the Hedgehog (Hh) pathway and the localization to the primary cilia, suggest that Glis2 is a functional component of Hh signaling, a pathway activated during embryonic kidney development (3).

Results: To test this hypothesis we crossed Glis2 knockout with the Gli1+/lacZ transgenic mouse (4), which were used as an in vivo reporter of Hh activity; β-gal activity in Glis2+/-;Gli1+/lacZ kidneys was significantly increased, indicating that Glis2 is a repressor of Hh. Glis2 suppression in cultured IMCD3 cells by shRNA interference resulted in the acquisition of mesenchymal hallmarks that was partially rescued by treatment with the specific Gli inhibitor GANT58. We found, by chromatin immunoprecipitation using an anti-Glis2 antibody, that Glis2 binds regulatory elements in the promoters and inhibits the transcription of the epithelial-to-mesenchymal regulator Snai1 and of the developmental gene Wnt4 through a competition with Gli1.

Conclusions: According to our results, Glis2 is a repressor of the Hh pathway, which is unexpectedly latent in postnatal kidneys, and sustains the aberrant persistence of developmental programs. This is the first description of a molecular mechanism that links the hedgehog signaling pathway to cystic kidney diseases and can open new avenues for treatment of diverse ciliopathies.

Identification of 3 Novel NPHP Genes by Whole Exome Capture (WEC) Implicates DNA Damage Response (DDR) Signaling in the Pathogenesis of Nephrono-Phthisis-Related Ciliopathies
Friedhelm Hildebrandt,[1, 2] Rannar Airik,[1] Moumita Chaki,[1] Toby W. Hurd,[1] Andrew Cluckey,[1] Sivakumar Natarajan,[1] Weibin Zhou,[1] Amiya K. Ghosh,[1] Corinne Antignac,[3] Sophie Saunier,[3] Edgar Otto.[1] *[1]Departments of Pediatrics and of Human Genetics, University of Michigan, Ann Arbor, MI; [2]Howard Hughes Medical Institute, University of Michigan, Ann Arbor, MI; [3]INSERM U-983, Hopital Necker-Enfants Malades, Universite Paris Descartes, Paris, France.*

Background: Nephronophthisis-related ciliopathies (NPHP-RC) are recessive disease of kidney, retina, and cerebellum. Identification of 10 disease-causing genes revealed that their products are located at primary cilia and centrosomes, but disease mechanisms remain poorly understood.

Methods: We identify by whole exome capture (WEC), mutations of the centrosomal proteins FAN1, ZNF423, and CEP164, as novel causes of NPHP-RC. Surprisingly, these genes serve functions within the DNA damage response (DDR) pathway.

Results: Specifically, we identify a homozygous truncating mutation (W707X) of *FAN1* in 2 siblings who exhibit NPHP with karyomegaly. FAN1 is essential for the DNA interstrand crosslink (ICL) repair pathway of DDR signaling. Second, we detect in 2 siblings with NPHP and cerebellar hypoplasia a homozygous missense mutation in *ZNF423*. Interestingly, ZNF423 interacts with the DNA ds-break sensor PARP1, ATM

to sites of DNA damage. Third, we show that ATM is activated in turn by the 'TIP60 complex'. And we demonstrate colocalization to TIP60-positive nuclear foci for other products of NPHP-RC genes. In 4 different families with NPHP-RC we identify mutations of *CEP164* as a novel cause of NPHP-RC. CEP164 acts in the ATR-Chk1-related arm of DDR, where it is necessary for ATR-dependent Chk1 activation upon induced replication stress (Sivasubramaniam 2008).

Conclusions: We suggest a new pathogenic working hypothesis for NPHP-RC proposing the following cascade of events: i) defects of DDR - lack of Chk1 (Chk2) activation - inadequate G_2/M cell cycle arrest.

Disrupted Retrograde Ciliary Transport Causes Sensenbrenner Syndrome with Nephronophthisis Heleen H. Arts,[1,2] Cecilie Bredrup,[3,4] Machteld Oud,[1] Torunn Fiskerstrand,[3] Alexander Hoischen,[1] Damien Brackman,[5] Sabine Leh,[6] Marit Midtbø,[7] Christian Gilissen,[1] Olav H. Haugen,[3,8] Helge Boman,[4] Eyvind Rødahl,[3,8] Joris A. Veltman,[1] Per Knappskog,[4,8] Nine V. Knoers,[2] Ronald Roepman.[1] *[1]Department of Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Department of Medical Genetics, University Medical Center Utrecht, Netherlands; [3]Department of Opthalmology, Haukeland University Hospital, Bergen, Norway; [4]Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway; [5]Department of Pediatrics, Haukeland University Hospital, Bergen, Norway; [6]Department of Pathology, Haukeland University Hospital, Bergen, Norway; [7]Department of Clinical Dentistry, University of Bergen, Bergen, Netherlands; [8]Institute of Clinical Medicine, University of Bergen, Bergen, Netherlands.*

Background: Intraflagellar transport (IFT) occurs along microtubules in the cilium, an antenna-like organelle present on the apical surface of almost any vertebrate cell (including renal cells). The IFT-B and IFT-A protein complexes regulate upward- and downward ciliary transport, respectively, in association with motor proteins such as kinesins and dynein. The IFT-A complex consists of 6 proteins of which 3 (IFT122, IFT121 and IFT43) are associated with Sensenbrenner syndrome, an autosomal recessive disorder characterized by skeletal- and ectodermal defects.

Methods: Exome-sequencing; SNP array analysis; Sanger sequencing; Immunocytochemistry.

Results: We used exome-sequencing to identify the genetic defect in a Norwegian family with Sensenbrenner syndrome accompanied by nephronophthisis-like nephropathy. We identified multiple genomic variants, however, only the compound heterozygous mutations in *WDR19* encoding IFT144 (an IFT-A protein) segregated with disease in the family. IFT144 is normally present in the base and the tip of the cilium. However,IFT144 was absent in cilia from fibroblasts from one of our patients.

Conclusions: We conclude that *WDR19* is a novel Sensenbrenner gene and that defective tip-to-base (retrograde) ciliary transport causes Sensenbrenner syndrome.

Funding: Private Foundation Support, Government Support - Non-U.S.

Proteomic Analysis of Class IV Lupus Nephritis: Global Versus Segmental Mamdouh N. Albaqumi, Dania Alkhafaji, Lutfi Alkorbi. *KFSHRC, Saudi Arabia.*

Background: There have been several attempts to standardize definitions and increase reproducibility in classifying lupus nephritis. The last classification added subcategories global (IVG) and segmental (IVS). Whether this subdivision has an impact on clinical practice or patient's outcome is controversial.

Methods: A retrospective reviewe with 2DE gel electrophoresis and MALDI-TOF/MS analysis of renal biopsies

Results: Renal biopsies from patients with IVG, IVS, ANCA, normal were used to extract proteins. Proteins were then separated by 2D gel electrophoresis and the expression levels of the protein spots were determined. Principal Component Analysis (PCA) Plot was applied for the four groups using the dataset of statistically differentially expressed protein spots. Global and segmental groups cross over each other and clearly separate away from both normal biopsies and those with ANCA indicating that both IVG and IVS may represent a similar entity .42 protein spots corresponding to 28 protein species were successfully identified by MALDI-TOF/MS. We then compared IVG vs. IVS using the quantitative expression levels of the 28 identified differentially expressed proteins. IVG and IVS were similar in their expression levels of these proteins; supporting the notion that they are similar entity. When IVG and IVS are classified as one group and compared to ANCA and normal tissue, the differences were significant across nine proteins. Using a quantitative expression of these nine proteins, there is no statistical difference between IVG and IVS, but when compared to ANCA or normal tissue, there are several differences among the expression level of these proteins.

To examine whether these data can be correlated with clinical outcome, a total of 78 patients were re-classified. 50 patients had class IVG LN while 28 patients had class IVS LN. Serum creatinine showed no statistical difference at baseline between the two groups. .

There was no statistical difference in therapy between the two groups. The probability of renal survival and patient survival were not statistically different between the two groups as.

Conclusions: There is no strong evidence to support a different outcome or etiology between the two subcategories of class IV LN

TH-OR133

C3 Glomerulonephritis Is a Disease of the Alternative Pathway of Complement Sanjeev Sethi,[1] Fernando C. Fervenza,[1] Yuzhou Zhang,[2] Samih H. Nasr,[1] Richard J. Smith.[2] *[1]Mayo Clinic, Rochester, MN; [2]University of Iowa, Iowa City, IA.*

Background: C3 Glomerulonephritis (C3GN) is a recently described glomerulonephritis (GN) with extensive C3 deposits. The purpose of this study was to describe the clinicopathologic findings and study the alternate pathway of complement (AP) in cases of C3GN.

Methods: The diagnosis of C3GN was based on a proliferative GN on light microscopy (LM) with extensive C3 deposits and absence of immunoglobulins (Ig's), kappa and lambda light chains on immunofluorescence microscopy (IF).

Results: Ten cases of C3GN were studied. There were 6 male and 4 female patients. The age ranged from 4 to 73 yrs (mean 44.4 yrs). The serum creatinine ranged from 0.5 to 3.1 mg/dL (mean 1.52 mg/dL). Urinary protein ranged from 0.3 to 9 gms (mean 2.7 gms/day). UA showed hematuria and proteinuria in all cases. All cases had low C3 and normal C4 levels. LM showed a membranoproliferative GN with extensive C3 deposition in the mesangium and capillary walls on IF. IF was negative for Ig's, kappa and lambda light chains. EM often showed large confluent hazy electron dense deposits in the mesangium, with subendothelial, intramembranous and occasional subepithelial deposits. Based on the presence of subepithelial deposits, 4 of the 10 cases were previously diagnosed as post-infectious GN. Three cases were previously labeled MPGN type I. Evidence of AP activation was demonstrable in all cases. Specific abnormalities of the AP were as follows: Autoantibodies to C3 convertase (2 cases), antibodies to factor H (1 case), homozygous risk alleles for p.His 402 (1 case), c.C2867T p.T956M factor H missense mutation (2 cases), heterozygous risk alleles for factor H p.Val62 and p.His402 (1 case), mutation in factor I gene and polymorphisms in factors B and H (1 case), frameshift c.2171delC, p.Thr724fsSTOP725 variant mutation in factor H resulting a truncated factor H (1 case), and deletion of CFHR3-CFHR1 (1 case).

Conclusions: This study show that C3GN can result from a diverse set of abnormalities affecting the AP. Treatment needs to be tailored based on the underlying etiology of AP dysfunction. Finally, C3GN should be considered in differential diagnosis of post-infectious GN.

TH-OR134

Association of Anti-PLA2R with Disease Activity and Outcome in Idiopathic Membranous Nephropathy Durga A.K. Kanigicherla,[1] Paul E. Brenchley,[1] Michael Venning,[1] Kay V. Poulton,[1] Edward A. McKenzie,[2] Jennet O. Gummadova,[2] Colin D. Short.[1] *[1]Renal Medicine, Manchester Royal Infirmary, United Kingdom; [2]FLS, Manchester University, United Kingdom.*

Background: Antibodies to PLA2R have been identified in 70% cases of idiopathic membranous nephropathy (IMN), which has a strong association with HLA DQA1. The interaction between anti-PLA2R levels, HLA genes and PLA2R polymorphism is unknown. We measured anti-PLA2R antibodies in 88 IMN patients typed for DQA1: DQB1 and PLA2R 292 SNP and describe the results in the context of disease activity and outcome.

Methods: Biopsy proven IMN patients (mean age 55.6 yrs; 63 M, 25 F; mean follow up 65±11 months) were selected for a retrospective cross sectional study of clinical outcomes with samples obtained from our BioBank. 40 patients had active disease, 22 were in partial and 26 in complete remission. DQ high resolution typing used LABType ®RSSO (One Lambda Inc). The PLA2R gene M292V SNP, was typed by TaqMan PCR. PLA2R was cloned and expressed in HEK cells and protein purified for use in an ELISA. 38 normal plasma samples defined the normal range (mean +2SD =32 units). Clinical status, pre and post plasma sample, (earliest sample available) was recorded.

Results: High anti-PLA2R levels were significantly associated with active disease (73% positivity; median=171 units) compared to remission (15% positivity; median=24units; $p< 0.001$; ANOVA). Antibody level was associated with concurrent proteinuria ($p<0.001$) but not with gender or ethnicity. High antibody level was associated with DQA1 05:01 (p adj<0.001) and DQB1 02:01 (p adj=0.05) and PLA2R 292 M allele (ptrend=0.04). Of the 29 patients positive for anti-PLA2R with active disease, 9/17 with high anti-PLA2R compared to 1/12 with low antibody reached CKD5 or doubling of serum creatinine within 10 years.

Conclusions: High anti-PLA2R levels are associated with active disease, possession of DQA1 05:01; DQB1 02:01 tissue type and poor long term outcome, suggesting that anti-PLA2R may be pathogenic.

Monitoring antibody levels over time in response to treatment will help to define anti-PLA2R as a surrogate marker of the immunopathological mechanism.

TH-OR135

Response of Anti-PLA2R to Adrenocorticotropic Hormone (ACTH) Gel in Membranous Nephropathy Laurence H. Beck,[1] Fernando C. Fervenza,[2] Andrew S. Bomback,[3] Rivka Ayalon,[1] Maria V. Irazabal,[2] Alfonso Eirin,[2] Daniel C. Cattran,[4] Gerald B. Appel,[3] David J. Salant.[1] *[1]Boston University; [2]Mayo Clinic; [3]Columbia University; [4]Toronto General Hospital.*

Background: Autoantibodies to the phospholipase A2 receptor (PLA2R) define most cases of primary membranous nephropathy (MN); their presence correlates with clinical disease activity. We analyzed anti-PLA2R in patients treated with long-acting ACTH gel

(H.P. Acthar® Gel, repository corticotropin; Questcor) to better understand its potential mechanism of action.

Methods: Samples were collected from 14 patients in 2 pilot studies (Mayo Clinic, n=9; Columbia, n=5) that treated MN patients with ACTH gel for 6 mo. Longer term follow-up samples were available in 11 cases. Serum was assayed for anti-PLA2R by immunoblotting and subsequent densitometry.

Results: 86% of patients were anti-PLA2R positive at baseline (Mayo Clinic, n=8; Columbia, n=4). Two patients with undetectable baseline anti-PLA2R rapidly achieved clinical remission and may have already entered immunologic remission prior to treatment. All 12 patients experienced a reduction in anti-PLA2R (17-100%) by 6 mo with disappearance of anti-PLA2R in 5 cases. There were 5 partial remissions at 6 mo: 3 in patients who cleared their anti-PLA2R and 2 in those lacking baseline anti-PLA2R. Another patient later achieved a 96% reduction in anti-PLA2R without further treatment while 2 others, after receiving rituximab for perceived failure of ACTH gel, fully cleared anti-PLA2R. With long term (12-18 mo) follow-up of those with undetectable anti-PLA2R at baseline or after ACTH gel ± rituximab, there were 4 complete and 2 partial remissions, one non-responder, and a final patient who achieved partial remission but relapsed coincident with a return of anti-PLA2R. Two other patients also showed an increase in anti-PLA2R after discontinuing treatment with ACTH gel.

Conclusions: Measurement of anti-PLA2R provides useful information relating immunological and clinical disease activity in MN patients treated with new agents such as ACTH gel. This study suggests that ACTH gel may work in part by suppressing autoantibody production; the duration and degree of this response need further study.

Clinical Pathologic Correlations in 190 Multiple Myeloma Patients with Kidney Biopsy Samih H. Nasr,[1] Anthony M. Valeri,[2] Sanjeev Sethi,[1] Mary E. Fidler,[1] Lynn D. Cornell,[1] Nelson Leung.[3] *[1]Pathology, Mayo Clinic, Rochester, MN; [2]Nephrology, Columbia University, New York, NY; [3]Nephrology, Mayo Clinic, Rochester, MN.*

Background: Renal involvement is common in multiple myeloma (MM). In this largest study to date, we examined kidney biopsy (KBx) findings in MM patients (pt) and correlated them with clinical data at KBx and outcome.

Methods: The characteristics of 190 Mayo Clinic pts with MM who underwent KBx between 1997-2011 are provided. MM was diagnosed before or at time of KBx.

Results: On KBx, paraprotein-related lesions (PRL) were seen in 73% of pts, non-PRL in 25%, and no pathology in 2%. PRL were myeloma cast nephropathy (MCN)(33% of pts), monoclonal immunoglobulin deposition disease (MIDD)(22%), amyloid (21%), fibrillary GN (FGN)(1%), immunotactoid GN (0.5%) and light chain proximal tubulopathy (0.5%). Two forms of PRL were seen in 6% (MCN and MIDD in 5 pts, MCN and amyloid in 4, MIDD and amyloid in 2, and MCN and FGN in 1). Direct MM infiltration was seen in 1%. Non-PRL included ATN (9%), HTN arteriosclerosis (6%), diabetic nephropathy (5%), FSGS (3%), APIGN (3%), and interstitial nephritis (2%). 1/3 of MIDD pts were <50 yrs vs. 9% of MCN and 9% of amyloid pts (p=0.035). Serum complete Ig was more common in MCN than amyloid or MIDD. The size of urine paraprotein and % of plasma cells in bone marrow were higher in MCN than amyloid or MIDD. Markedly abnormal FLC ratio was more common in MCN than amyloid. 37% of MCN pts required dialysis at KBx vs. 22% of MIDD and 9% of amyloid pts. >50% albuminuria on UPEP was highest in amyloid>MIDD>MCN. After a mean follow-up of 30 mos, 52% died. Median pt survival was 45 mos for MCN, 61 for amyloid and 84 for MIDD (p=0.193). Independent predictors of death were reaching ESRD, no treatment with stem cell transplant, and hypercalcemia. Median renal survival was 36 mos for MCN vs. 113 for amyloid vs. 74 for MIDD (p=0.003). The only independent predictor of progression to ESRD was dialysis at KBx.

Conclusions: The current spectrum of renal lesions in MM pts is more heterogenous than previously reported. KBx is essential to establish the individual diagnoses and provide important prognostic and therapeutic information.

TH-OR137

Natural History of Serum Free Light Chains Prior to the Clinical Presentation of AL Amyloidosis Joseph D. Hebreo,[1] Kevin C. Abbott,[1] Brendan M. Weiss,[2] Stephen W. Olson.[1] *[1]Department of Medicine, Nephrology Service, Walter Reed Army Medical Center, Washington, DC; [2]Department of Medicine, Hematology/Oncology Service, Walter Reed Army Medical Center, Washington, DC.*

Background: AL amyloidosis is a rare plasma cell dyscrasia with significant morbidity (including acute kidney injury) and mortality, in the absence of timely diagnosis and treatment. Abnormal serum free light chain (SFLC) ratios are associated with AL amyloidosis at time of diagnosis but no prior studies have evaluated the natural history of SFLC prior to diagnosis.

Methods: Using serum from the Department of Defense Serum Repository (DoDSR), we assessed SFLC levels in up to three longitudinal serum samples per patient for 20 AL amyloidosis cases and 20 healthy controls matched for age, sex, race, and age of serum.

Results: A greater percent of cases versus controls had a single abnormal serum free light chain ratio (0.26-1.65 mg/L) any time prior to diagnosis (90% vs. 5%, p<0.001), <4 years prior to diagnosis (92% vs. 0%, p<0.001), 4 to 11 years prior to diagnosis (67% vs. 7%, p<0.001), and >11 years prior to diagnosis (42% vs. 0%, p=0.015). In the 75% of cases with an elevated lambda light chain (LLC) level, a rise in LLC of greater than 1mg/L per year was 100% sensitive and specific for future disease (100% vs. 0%, p<0.001).

Conclusions: An abnormal SFLC ratio and a LLC rate of rise greater than 1 mg/L per year were associated with the subsequent diagnosis of AL amyloidosis. Our data could allow for an earlier diagnosis in those with clinical concern or asymptomatic elevations in SFLC prior to extensive end organ damage that prohibits a definitive stem cell transplant.

Novel Noninvasive Biomarkers for Disease Activity of IgA Nephropathy (IgAN) Yusuke Suzuki,[Inst#1] Keiichi Matsuzaki,[Inst#1] Hitoshi Suzuki,[Inst#1] Keiko Okazaki,[Inst#1] Hiroyuki Yanagawa,[Inst#1] Norio Ieiri,[Inst#2] Mitsuhiro Sato,[Inst#2] Toshinobu Sato,[Inst#2] Yoshio Taguma,[Inst#2] Jan Novak,[Inst#3] Osamu Hotta,[Inst#2] Yasuhiko Tomino.[Inst#1] *[1]Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Sendai Shakaihoken Hospital, Sendai, Japan; [3]University of Alabama at Birmingham.*

Background: The primary abnormal manifestation in IgAN is recurring bouts of hematuria with or without proteinuria. Although immunohistochemical analysis remain the gold standard not only for diagnosis but also for evaluating the activity of IgAN, new sensitive and reasonably specific tests are emerging to guide therapeutic strategy applicable to all stages of IgAN. Present study examined serum levels of galactose-deficient IgA1 (GdIgA1) and IgA-IgG immune complex (IgA-IgGIC) as noninvasive markers for the disease activity.

Methods: We enrolled patients (n=48) with IgAN who showed complete or partial clinical remission after tonsillectomy and steroid-pulse therapy (TSP) and were followed up for 3-5 years. Baseline clinical data were evaluated just before TSP; serum levels of GdIgA1 and IgA-IgGIC and seminquantitative hematuria and proteinuria were assessed just before TSP, 1 year, and 3-5 years after TSP. GdIgA1 and IgA-IgGIC were measured by ELISA.

Results: Cross-sectional analysis revealed that the degree of hematuria and proteinuria were significantly associated with levels of GdIgA1 (p for trend=0.004), and IgA-IgG IC (p for trend<0.001), respectively. Longitudinal analysis showed that from the group of 91.7% patients with heavy hematuria (≥3+) just before TSP, 64.6% patients showed complete disappearance of hematuria (group A), but the remaining patients did not (group B), during the 3-5-year follow up. Although the levels of GdIgA1 and IgA-IgG IC in the two groups just before TSP were similar (A vs. B; 122.2 vs 107.7 units p=0.36, and 0.77 vs 0.85 OD p=0.43), decrease of GdIgA1 levels in group A was significantly higher than that in group B (27.4 vs 13.6%, p=0.02).

Conclusions: Disease activity of IgAN assessed by hematuria and proteinuria correlated with changes of serum levels of GdIgA1 and IgA-IgG IC, respectively. These new noninvasive disease activity markers can be used to guide the therapeutic approaches.

TH-OR139

APOL1 Is Expressed in Human Kidney with Dynamic Cellular Localization Patterns in Health and Disease Sethu M. Madhavan, John F. O'Toole, Martha Konieczkowski, Leslie A. Bruggeman, John R. Sedor. *MetroHealth System, Case Western Reserve University, Cleveland, OH.*

Background: Genetic variants in *APOL1* , which encodes apolipoprotein L1 (APOL1), associate with the non-diabetic kidney diseases in patients of African ancestry. APOL1 is a component of HDL_3 particles and mediates trypanolytic activity. Renal disease-associated APOL1 variants have been positively selected in African populations by conferring resistance to trypanosomiasis. Mechanisms by which *APOL1* variants promote nephropathy are unknown.

Methods: APOL1 localization was examined using immunohistology in normal human kidney sections and in FSGS, HIVAN, diabetic and hypertensive-associated nephropathy and minimal change disease (MCD) biopsies. Biopsies were genotyped for *APOL1* variants. APOL1 expression was also examined in human podocytes, endothelial and proximal tubular cells.

Results: APOL1 was only present in podocytes in normal glomeruli. Podocyte staining of APOL1 was decreased in diseased glomeruli, although podocyte markers, GLEPP1 and synaptopodin, were maintained. Only in MCD glomeruli, APOL1 expression was induced in endothelia concomitant with the loss of podocyte APOL1. APOL1 localized to proximal tubular epithelia in a vesicular pattern and was detected in the arteriolar endothelium of normal and diseased kidney sections. Unexpectedly, in biopsies but not normal kidney, medium artery and arterioles contained a subset of α-smooth muscle actin-positive cells that stained for APOL1. RT-PCR demonstrated *APOL1* transcripts in podocytes and normal glomeruli. By immunoblotting, podocyte, proximal tubular and vascular endothelial cell lines expressed APOL1. Stimulation of human endothelial cells with TNF or LPS induced expression of APOL1.

Conclusions: APOL1 is present in normal kidney, suggesting that a functional role in normal kidney. The cell compartments in which it localizes change with disease, and the patterns do not appear to correlate with kidney disease-associated APOL1 variants, suggesting that these variants do not cause disease by altering APOL1 trafficking or protein levels. Rather the risk variants of *APOL1* may dysregulate its function within the kidney cells where it is localized.

Chronic West Nile Nephropathy: A New Clinical Entity Amber S. Podoll,[1] Nashila Abdul Rahim,[1] Kevin W. Finkel,[1] Kristy Murray.[2] *[1]Division of Renal Diseases and Hypertension, University of Texas Health Science Center, Houston, TX; [2]School of Public Health-Center for Infectious Diseases, University of Texas Health Science Center, Houston, TX.*

Background: Infection with West Nile Virus (WNV), an RNA flavivirus, occurs in 25,000 people worldwide annually and results in more than 1,000 deaths. Symptoms of infection range from a nonspecific febrile illness with fatigue, lymphadenopathy and malaise, to more serious consequences of meningitis and encephalitis. Although previously thought to be a self-limited disease, we have shown that some patients have persistent infection with WNV up to 9 years based on elevated serum WNV IgM and viral shedding in the urine. Hamsters infected with WNV develop chronic infection of distal renal tubule epithelium and shed virus in the urine. Immunohistochemical staining of hamster kidney tissue shows evidence of WNV RNA. This data raises the possibility that persistent viral infection of the kidney occurs in humans.

Methods: From a cohort of 131 patients with a history of WNV infection, 45 were found to have persistent shedding of WNV RNA in the urine. Full medical assesments were performed. Four patients were found to have impaired renal function or abnormal urinalysis and underwent a percutaneous renal biopsy.

Results: Examination of the renal tissue revealed a prominant mononuclear infiltrate with signficant chronic tubulointerstitial changes. The degree of chronic changes correlated with diminished renal function. The renal tubules showed reactive epithelial changes with focal hyaline proteinaceous casts. Abnormal inclusion vescicles, presumed viral particles, were identified within renal epithelial cells by electron microscopy. No glomerular abnormalities or immune complexes were noted. PCR of renal tissue verified the presence of WNV-specific RNA.

Conclusions: These results demonstrate persistent renal infection by WNV in humans that results in chronic tubulointerstitial nephritis associated with varying degrees of CKD. Whether treatment of the infection will alter the course of CKD requires further study. This is an important question given the high incidence of infection worldwide and may reveal a new occult pathologic process.

A Comparative Histomorphological, Immunohistochemical and Ultrastuctural Study on Pre and Post Calcineurin Inhibitor Therapy Renal Biopsy of Childhood Steroid Resistant Nephrotic Syndrome: An Insight for Pathogenesis of Its toxicity Amit K. Dinda, Arvind Bagga, Lavleen Singh. *All India Institute of Medical Sciences, New Delhi, Delhi, India.*

Background: Long term calcineurin inhibitor (CNI) therapy is a common practice in childhood steroid resistant nephritic syndrome (SRNS). Current study has been undertaken to study the early renal injury with treatment.

Methods: 24 children of SRNS with a mean age of 4.2±2.8 years (M:F = 4.8:1) were included with paired renal biopsies, before initiation and 1 year after CNI therapy with standard dosage. Semi-quantitative grading was done on light microscopic (LM) features for assessing CNI toxicity. Ultrastructural study was done with special emphasis on mitochondrial morphology in the tubular epithelial and endothelial cells. The mitochondrial alterations were segregated (*Walker et al)* into four semi quantitative grades. Immunohistochemical (IHC)staining for nitrotyrosine, eNOS and TGFβ1 was performed and graded.

Results: Out of 24, 15 cases were diagnosed as minimal change disease, and 9 cases focal segmental glomerulosclerosis. With CNI therapy remission was obtained in 75% cases. Serum creatinine and CNI level were with in normal limits in all cases. Post-treatment biopsies showed significant increase in glomerulosclerosis, JGA hyperplasia, tubular atrophy, interstitial fibrosis, arteriolar hyalinosis and smooth muscle vacuolization ($p<0.05$ to <0.001). Grade 2/3 alterations were seen in endothelial mitochondria in 79.1% biopsies with CNI therapy, while such change was not seen in pre-treatment group. Significantly higher expression of eNOS was noted (91.6%) with increased nitrotyrosine (75%) and TGFβ1 (79.1%) after treatment.

Conclusions: Ultrastructural alterations in endothelial mitochondria may be related to endothelial injury which are early and constant features associated with CNI therapy.

Free radical (peroxynitrite) mediated endothelial injury with higher eNOS expression may be an important event associated with development of CNI toxicity.

The increased TGFβ1 expression supports that with prolonged CNI therapy there may be initiation of events leading to chronic CNI toxicity with normal renal parameter and drug level in cases of SRNS.

There Is an Increased Risk of Peritonitis in the 21 Days Prior to Death in Peritoneal Dialysis Patients: A Case-Crossover Study Neil Boudville,[1 2] Anna Kemp,[2] Philip A. Clayton,[1] Wai Hon Lim,[1] Carmel M. Hawley,[1] Sunil V. Badve,[1] Fiona Brown,[1] Brian E.R. Livingston,[1] Stephen P. McDonald,[1] Kym M. Bannister,[1] Kathryn J. Wiggins,[1] David W. Johnson.[1] *[1]Australia and New Zealand Dialysis and Transplant (ANZDATA) Registry, Adelaide, SA, Australia; [2]University of Western Australia, Perth, WA, Australia.*

Background: Peritoneal dialysis(PD)-related peritonitis may be associated with increased risks of both infectious and non-infectious death as a result of inflammation, declining health and other factors. However, the evidence for this is primarily descriptive. Our aim was to examine the relationship between mortality and peritonitis in PD patients, utilising a novel method of analysis, where patients serve as their own controls.

Methods: All patients on the ANZDATA Registry receiving PD for ≥7 months between 1/5/2004 and 31/12/2009 and who died on PD or within 30days of transferring to HD were included. We used a case-crossover design so patients had to be on PD for ≥7months to allow a comparator time period. Conditional logistic regression was used to compare the risk of peritonitis in the 'case' window 21days immediately before death, and a 'control' window of 21days 6months before death. This method eliminated the influence of patient-level confounders.

Results: 1316 PD patient were included with a mean age at death of 70.5±11.7years, 44.2% female, and a mean time on dialysis of 3.2±2.2years. 1446 peritonitis episodes were documented, with 43.1% experiencing ≥1 episode. 5.9% of deaths were documented as being due to peritonitis, with 207 (15.7%) experiencing an episode in the 21days before death. There was a significant 8.0 fold increased odds ratio (95%CI=5.3-12.1) of an episode of peritonitis in the 21days before death compared to a 21day window 6months prior. Sensitivity analysis showed no significant difference in the odds of having peritonitis in a 21day window 60days prior to death compared to 120, 190 and 250days.

Conclusions: We have established that there is a significantly increased risk of peritonitis in the 21days prior to death. An examination of the definition of peritonitis-related mortality is required.

TH-OR143

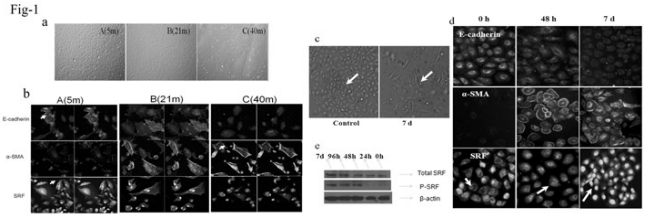
Translocation of Nuclear Transcription Factor Serum Response Factor Expedites Epithelial-to-Mesenchymal Transition in Human Peritoneal Mesothelial Cells Lijie He,[1] Nan Zhang,[2] Hanmin Wang,[3] Shiren Sun.[4] *[1]Department of Nephrology, Xijing Hospital, the Fourth Military Medical University, Xi'an, Shaan Xi, China; [2]Department of Nephrology, Xijing Hospital, the Fourth Military Medical University, Xi'an, Shaan Xi, China; [3]Department of Nephrology, Xijing Hospital, the Fourth Military Medical University, Xi'an, Shaan Xi, China; [4]Department of Nephrology, Xijing Hospital, the Fourth Military Medical University, Xi'an, Shaan Xi, China.*

Background: Epithelial-to-mesenchymal transition (EMT) causes denudation of mesothelial cells and peritoneal fibrosis, so the molecular is thus of significance. Serum response factor (SRF) could regulate tumor cell migration by expediting EMT,but the mechanism is unclear.

Methods: We isolated mesothelial cells from effluents in dialysis fluid from 30 patients, undergoing continuous ambulatory peritoneal dialysis for less than 6 months or more than 20 months. All these cells were characterized by phenotype markers. The location of SRF were tested by confocal immunofluorescence. We also tested location of SRF and EMT markers in HPMCs in vitro.

Results: With the dialysis time of 5 m (A), 21m (B) to 40 m (C), human peritoneal mesothelial cells underwent a transition from an epithelial phenotype to a mesenchymal phenotype with a progressive loss of epithelial morphology [figure1a], a decrease in the expression of E-cadherin, an increase in the expression of SMA and the translocation of SRF from cytoplasm into nucleus [figure1b]. In vitro analysis, during the inducing time, high glucose-induced HPMCs were changed into fibroblast-like cells [figure1c], downregulation of E-cadherin, upregulation of SMA and translocation into nucleus of SRF [figure1d]. The p-SRF was also upregulated after being induced for 48 h [figure1e].

Fig-1



Conclusions: The findings suggest SRF might be a potential targets and marker for the design and monitor of new dialysis solutions of patients.

Funding: Government Support - Non-U.S.

TH-OR144

Distinctive Role of Smad2 and Smad3 in Peritoneal Dialysis-Related Peritoneal Fibrosis and Mesothelial-Myofibroblast Transition *In Vivo* and *In Vitro* Wenjuan Duan,[1,2] Xueqing Yu,[1] Xiao Ru Huang,[2] Xiaoming Meng,[2] Hui Y. Lan.[2] *[1]Department of Nephrology, First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; [2]Department of Medicine and Therapeutics, and Li Ka Shing Institute of Health Sciences, Chinese University of Hong Kong, Hong Kong, China.*

Background: It is well accepted that TGF-β signaling plays an essential role in peritoneal fibrosis including the process of mesothelial-myofibroblast transition (EMT). However, the functional role and the underlying mechanisms by which TGF-β1 signals through to mediate peritoneal fibrosis under peritoneal dialysis (PD) conditions remain largely unclear.

Methods: We first examined TGF-β/Smad signaling in peritoneal tissues from patients with PD. Then, the role of Smad2 and Smad3 in peritoneal fibrosis including EMT was determined in a mouse model of PD induced in Smad3 KO and conditional Smad2 KO

mice. Mechanisms of Smad2 and Smad3 in PD-associated peritoneal fibrosis was studied in primary culture of peritoneal mesothelial cells (PMCs) that lack Smad3 or have conditional KO for Smad2.

Results: We found that TGF-β/Smad2/3 was markedly activated in PD patients with severe peritoneal fibrosis and EMT. In a mouse model of PD, mice lacking Smad3 were protected against peritoneal PET dysfunctions and peritoneal fibrosis including EMT such as increased collagen matrix and α-SMA$^+$ myofibroblast accumulation(Col1 86.6%↓α-SMA44.9↓ all P<0.05), but diseased E-cadherin expression. Surprisingly, in contrast to Smad3 KO mice, mice with conditional Smad2 KO from the peritoneal tissues substantially enhanced peritoneal fibrosis(Col1 79.9%↑P<0.01) and EMT. Similarly, deletion of Smad3 from PMCs prevented, but disruption of Smad2 enhanced TGF-β1-induced collagen matrix expression and EMT *in vitro*. Further study revealed that increased peritoneal fibrosis in conditional Smad2 KO mice and PMCs was associated with enhanced Smad3 signaling *in vivo* and *in vitro*.

Conclusions: The present study demonstrates that Smad3, but not Smad2, plays an essential role in PD-related peritoneal fibrosis and EMT. Enhanced Smad3 signaling may be a mechanism by which disrupted Smad2 promotes peritoneal fibrosis and EMT *in vivo* and *in vitro*.

Funding: Government Support - Non-U.S.

TH-OR145

Effect of Treatment Time Per Session and Dialyzer Phosphate Clearance on Predialysis Serum Phosphorus Concentration during Short Daily Hemodialysis

J. Ken Leypoldt, Baris U. Agar, Alp Akonur, Mary E. Gellens, Bruce F. Culleton. *Renal (Medical Products), Baxter Healthcare Corporation, McGaw Park, IL.*

Background: Short daily hemodialysis (SDHD) has the potential to reduce predialysis serum phosphorus (P) concentrations; however, not all previous SDHD studies have demonstrated this clinical benefit. In this study we use P kinetic modeling to determine the effect of treatment time per session (T) and dialyzer phosphate clearance (K) on predialysis serum P concentration during SDHD.

Methods: We recently demonstrated that a pseudo-one compartment kinetic model, including P mobilization from other body compartments into extracellular fluids, can be used to describe P kinetics during conventional (4 hr) and short (2 hr) HD treatments (Hemodial Int 2011, in press). This kinetic model is advantageous since it characterizes individual patient differences in P removal by a single parameter, the P mobilization clearance (KM, determined range: 45-208 ml/min). We used this model, combined with a P mass balance relationship, to perform computer simulations of predialysis serum P concentrations during 6-times per week SDHD.

Results: Results from representative simulations are tabulated for patients at steady state with a P central distribution volume of 10 L (estimate of extracellular fluid volume); it was assumed that net P intake was increased by 20% during SDHD. K values were varied over the range reported in previous clinical studies.

Simulated Predialysis Serum P Concentrations (mg/dL)

	KM = 50 ml/min (Low)			KM = 150 ml/min (High)		
	CHD	SDHD	SDHD	CHD	SDHD	SDHD
T (min)	240	120	180	240	120	180
K = 80 ml/min	8.34	8.53	6.38	6.98	7.85	5.52
K = 110 ml/min	7.11	6.97	5.36	5.62	6.22	4.42
K = 140 ml/min	6.43	6.10	4.80	4.86	5.29	3.80

Doubling HD treatment frequency without a change in total weekly treatment time (CHD vs SDHD at T=120 min) may result in either an increase or a decrease in predialysis serum P concentration. Further, SDHD with low K does not result in reductions in predialysis serum P concentration unless T is increased substantially.

Conclusions: Both increasing T and maintaining a high K during SDHD are important to provide significant reductions in predialysis serum P concentrations.

TH-OR146

Histone Acetyltransferase Activity Is Involved in the Pathogenesis of Experimental Peritoneal Fibrosis

Akihiro Sagara,[1] Norihiko Sakai,[1] Yasuyuki Shinozaki,[1] Shinji Kitajima,[1] Tadashi Toyama,[1] Akinori Hara,[1] Kiyoki Kitagawa,[1] Miho Shimizu,[1] Kengo Furuichi,[1] Shuichi Kaneko,[1] Takashi Wada.[2] *[1]Department of Disease Control and Homeostasis, Institute of Medical, Pharmaceutical and Health Sciences, Faculty of Medicine, Kanazawa University, Kanazawa, Ishikawa, Japan; [2]Division of Nephrology, Department of Laboratory Medicine, Institute of Medical, Pharmaceutical and Health Sciences, Faculty of Medicine, Kanazawa, Ishikawa, Japan.*

Background: Peritoneal fibrosis is a serious complication in long-term peritoneal dialysis. However, the precise pathogenic mechanisms of peritoneal fibrosis remain to be determined. Circulating mesenchymal progenitor cells 'CD45/COLI dual positive cells', originally named as fibrocytes, have been reported to participate in tissue fibrosis. In addition, histone acetyltransferase (HAT) has also been demonstrated to be involved in the pathogenesis of fibrotic conditions. Therefore, we examined the participation of CD45/COLI dual positive cells dependent on HAT activity in experimental mouse model of peritoneal fibrosis.

Methods: To address this, peritoneal fibrosis was induced by the injection of 0.1% chlorhexidine gluconate (CG) into the abdominal cavity in mice.

Results: A considerable number of CD45/COLI dual positive cells infiltrated in the peritoneum accompanied with the progression of peritoneal fibrosis. CG injection also increased number of cells immunoreactive for acetylated histone H3. The treatment with curcumine, a potent inhibitor of HAT, reduced the extent of peritoneal fibrosis, peritoneal transcripts of transforming growth fatcor-β1 as well as the numbers of acetyl-histone H3 positive cells and infiltraled CD45/COLI dual positive cells. In isolated CD45/COLI dual positive cells from human peripheral blood, pre-treatment with curcumin inhibited transforming growth fatcor-β1-induced expression of pro-collagen type Iα.

Conclusions: These results suggest that HAT activity contributes to peritoneal fibrosis via regulation of CD45/COLI dual positive cells.

LPA-LPA1 Signaling Drives Peritoneal Fibrosis by Inducing Fibroblast Accumulation and MRTF-SRF-Dependent Profibrotic Gene Expression

Norihiko Sakai,[1] Jerold Chun,[4] Takashi Wada,[3] Andrew Luster,[1] Andrew M. Tager.[2] *[1]Division of Rheumatology, Massachusetts General Hospital, Boston, MA; [2]Pulmonary and Critical Care Unit, Massachusetts General Hospital, Boston, MA; [3]Division of Nephrology, Kanazawa University, Kanazawa, Ishikawa, Japan; [4]Scripps Research Institute, San Diego, CA.*

Background: Peritoneal fibrosis (PF) is a potentially fatal complication of peritoneal dialysis, but the mechanisms driving it remain to be fully identified. We have previously implicated the lipid mediator lysophosphatidic acid (LPA) and one of its receptors, LPA_1, in lung and skin fibrosis. Additionally, LPA induces actin polymerization, which has recently been shown to induce profibrotic gene expression through a myocardin-related transcription factor (MRTF)-serum response factor (SRF) axis.

Methods: We therefore examined the role of LPA-LPA_1 signaling in PF induced by intraperitoneal injection of chlorhexidine gluconate (CG).

Results: CG-induced increases in peritoneal thickness and hydroxyproline content were significantly attenuated in LPA-deficient mice (LPA_1 KO) compared with wild-types (WT). Peritoneal accumulation of myofibroblasts and connective tissue growth factor (CTGF) expression induced by CG were also significantly reduced in LPA_1 KOs. To determine whether LPA and LPA_1 mediated the accumulation of peritoneal fibroblasts as a source of myofibroblasts, we determined the effect of the LPA_1-selective antagonist AM095 on CG challenge of mice whose fibroblasts could be identified by fibroblast-specific expression of EGFP. AM095 dramatically attenuated CG-induced increases of EGFP-positive fibroblasts. We also found that LPA directly induced CTGF gene expression by mouse primary peritoneal mesothelial cells. To determine the molecular pathway through which LPA induced CTGF expression, we performed a series of experiments genetically deleting, knocking down or chemically inhibiting potential components of this pathway. We found that this pathway involves LPA_1 signaling, RhoA activation, actin polymerization, and the transcription factors MRTF-A, MRTF-B and SRF.

Conclusions: Our results suggest that LPA and LPA_1 drive PF by inducing fibroblast accumulation and MRTF-SRF-dependent profibrotic gene expression.

Association of Angiotensin Converting Enzyme Inhibitors and Angiotensin Receptor Blockers on Peritoneal Dialysis Technique Survival

Manpreet Samra,[1] Jason Jones,[2] David C. Selevan,[3] Peggy Balcius,[2] Victoria A. Kumar,[1] Scott A. Rasgon.[1] *[1]Nephrology, Kaiser Permanente, Los Angeles, CA; [2]Research and Evaluation, SCPMG, Pasadena, CA; [3]Renal Business Group, SCPMG, Pasadena, CA.*

Background: Recent studies suggest that angiotensin converting enzyme inhibitors (ACE) and angiotensin receptor blockers (ARB) exert a protective effect on peritoneal membrane transport status, thereby preserving membrane function in peritoneal dialysis (PD) patients. We therefore sought to examine the association of ACE and ARB use on technique survival in our PD patients.

Methods: We identified patients in our database who initiated PD at our institution between January 1, 2001 and December 31, 2010. We used our pharmacy database to identify patients who filled prescriptions for ACEs/ARBs at least 60% of the time during the second year of therapy (ACE/ARB access). We excluded patients who remained on PD less than one year. Patients who received a renal transplant were censored from the analysis. Results were adjusted for age, sex and Charlson co-morbidity index (CCI).

Results: Baseline patient demographics are presented in the table below by ACE/ARB access status. The unadjusted hazard ratio (HR) for technique survival in patients with ACE/ARB access was 0.72 (p=0.010) and the adjusted HR was 0.68 (p=0.003).

Patient Demographics

	ACE/ARB access (n=318)	<60% ACE/ARB access (n=637)	p value
Median age in years	57.6 (49.5-66.9)*	56.5 (46-64.9)*	0.049
Number of females (%)	144 (45.3)	303 (47.6)	0.536
Number of diabetics (%)	222 (69.8%)	339 (53.2)	<0.001
CCI	6 (5-7)*	5 (3-7)*	0.004
PD first modality	237 (74.5)	390 (61.2)	<0.001

* 95% confidence interval

Conclusions: We found that PD patients who had access to ACE/ARBs at least 60% of the time during the second year of PD were approximately 30% less likely to transition off PD for any reason (other than transplant) compared to patients who had no or less access to ACE/ARB. Our data suggest that ACE/ARB therapy may be associated with longer time on therapy for PD patients, though the exact mechanism for this has not been determined.

Abstract Withdrawn

TH-OR150

Effect of BMP-7 and Tamoxifen in Animal Model of Peritoneal Fibrosis Developed in Uremic Rats Filipe Miranda Silva,[1] Dayana G. Viloslada,[1] Humberto Dellê,[1] Erik Halcsik,[2] Mari C. Sogayar,[2] Irene L. Noronha.[1] *[1]Nephrology, Univ. Sao Paulo, Brazil; [2]Chemistry Institute, Univ. Sao Paulo, Brazil.*

Background: Progressive increase in the thickness of peritoneal membrane and peritoneal sclerosis are considered serious complications of long-term peritoneal dialysis. There is still no recognized treatment to reduce these fibrotic changes. In this context, the use of drugs with anti-fibrotic properties such as bone morphogenic protein-7 (BMP-7) and tamoxifen (TAM) may be of relevance. The aim of this study was to analyze the effect of BMP-7 and TAM in an experimental model of peritoneal fibrosis induced by chlorhexidine gluconate (CG), developed in uremic rats.

Methods: End stage chronic kidney disease (CKD) was induced in male Wistar rats using diet containing 0.75% adenine for 30 days. At day 15, rats with CKD, characterized by hypertension (168±13mm/Hg), high BUN (64±25mg/dL) and high serum creatinine (0.70±0.4mg/dL) levels, were subjected to intraperitoneal injections of 0.1% CG daily for 15 days to induce peritoneal fibrosis (PF). The animals were divided into 4 groups (n=5 per group): **CKD,** CKD rats receiving only vehicle; **CKD+PF**, peritoneal fibrosis induced in CKD rats; **CKD+PF+BMP7**, CKD rats with PF treated with BMP-7 (30ng/Kg every 3 days intraperitoneally), and **CKD+PF+TAM**, CKD rats with PF treated with TAM (10mg/Kg/day) by gavage.

Results: Treatment with BMP-7 and TAM was effective in reducing the thickness of the peritoneal membrane and the number of macrophages and T-lymphocytes. Reduction of TNF-α and collagen III mRNA levels was also observed.

	CKD	CKD+PF	CKD+PF+BMP7	CKD+PF+TAM
Thickness of peritoneal membrane (μm)	30±24	123±32*	41±10#	44±4#
Macrophages (cells/mm²)	311±115	1380±295*	685±185#	453±65#
T-lymphocytes (cells/mm²)	14±12	119±71*	89±20#	31±17#
TNF-α (mRNA level)	1.0±0.8	8.0±0.3*	1.4±0.9#	2.9±0.5#
Collagen III (mRNA level)	1.0±0.8	18.9±2.4*	2.6±1.5#	2.6±1.5#

*p<0.05 vs. CKD, #p<0.05 vs. CKD+PF

Conclusions: BMP-7 and TAM were effective in reducing the thickness of peritoneal membrane in the experimental model of peritoneal fibrosis induced by CG developed in uremic rats, possible due to their anti-fibrotic effects.

Intensive Home Hemodialysis and Patient Survival: A Multinational Cohort Study Gihad E. Nesrallah,[1] Robert M. Lindsay,[1] Meaghan S. Cuerden,[1] Amit X. Garg,[1] Friedrich K. Port,[2] Peter Austin,[3] Louise M. Moist,[1] Rita Suri.[1] *[1]IQDR Investigators; [2]DOPPS, Arbor Research; [3]ICES, Canada.*

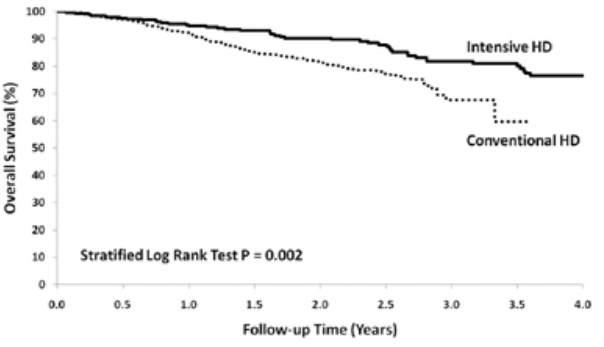
Background: Patients undergoing hemodialysis (HD) typically receive 3 sessions per week, each lasting 2.5-5.5 hours (conventional HD). Recently, the use of more intensive HD (>5.5 hours, 3-7 times per week) has increased, but the effects of these regimens on survival is uncertain.

Methods: We conducted a retrospective cohort study to examine whether intensive HD is associated with better survival than conventional HD. We identified 420 patients in the International Quotidian Dialysis Registry (IQDR) who received intensive home HD in France, the US, and Canada between January 2000 and August 2010. We matched 338 of these patients by country, duration of end-stage renal disease before study enrollment, and propensity score, to 1388 patients in the Dialysis Outcomes and Practice Patterns Study (DOPPS) who received in-center conventional HD during the same time period. We compared mortality rates using Cox regression.

Results: The intensive HD group received 4.8±1.1 sessions/week, with a mean treatment time of 7.4±0.87 hours/session, while the conventional HD group received 3 sessions/week, with a mean treatment time of 3.9±0.32 hours/session. During 3008 patient-years of follow-up, 45/338 patients receiving intensive home HD died, compared with 293/1388 patients receiving conventional in-center HD (6.1 vs. 10.5 deaths per 100 person-years, HR=0.55 (95% CI 0.34-0.87; p=0·01). This effect estimate was robust across all pre-specified subgroups and sensitivity analyses.

Conclusions: We demonstrate a strong association between intensive home HD and improved survival. Since we cannot exclude residual confounding in this observational study, confirmation in a large clinical trial is desirable, but may not be feasible.

Figure 1. Kaplan-Meier plot for intensive and conventional hemodialysis. Two-sided p = 0.002 by log rank test, stratified by matched set and country.



TH-OR152

Development of Circulating Anti-HLA Antibodies Is Associated with Acute Rejection after Conversion: Interim Report of CTOT-02 Sacha A. De Serres,[1] Indira Guleria,[1] Nader Najafian,[1] David N. Ikle,[3] Flavio G. Vincenti,[2] William E. Harmon,[1] Mohamed H. Sayegh,[1] Anil K. Chandraker.[1] *[1]Brigham and Women's Hospital and Children's Hospital Boston, Boston, MA; [2]UCSF, San Francisco, CA; [3]Rho Federal Systems Division, Chapel Hill, NC.*

Background: The clinical characteristics and the impact of development of anti-HLA alloantibodies (Abs) in renal transplant recipients is not well defined. This report looks at possible associations between Ab development, clinical characteristics, allograft histology at time of Ab development, and acute rejection following Ab conversion.

Methods: Over 750 subjects have been enrolled in the screening phase of the NIH CTOT-02/CCTPT-02 study, a multi-center prospective trial where unsensitized kidney transplant recipients are screened for development of de novo anti-HLA Abs up to 48 months post transplant. Subjects were divided into those who developed anti-HLA antibodies (Ab+) and those who did not (Ab-) as detected by Luminex. Ab+ subjects were offered treatment with anti CD20 therapy.

Results: 92 (15%) subjects developed Abs, at a fairly constant rate throughout the study period. 26, 51 and 15 subjects developed class I, II or both I & II Abs respectively. Mean time of Abs development was 18±10 months post transplant. Compared to Ab- subjects, Ab+ subjects were younger (36±18 vs. 43±17; p<0.01) and had lower serum creatinine (SCr) (1.3±0.5 vs. 1.4±0.5; p=0.03) at enrollment. There was no evidence of an association between Ab development and gender, donor type or DGF status. SCr at time of Ab conversion in Ab+ subjects was similar to the last SCr at follow-up in Ab- subjects (1.5±1.8 vs. 1.4±0.6; p=0.65). The proportion of subjects who developed acute rejection (AR) was higher in the Ab+ group (14 vs. 3%; p<0.01); most of the AR (77%) were noted after Ab development, at a mean time of 4.8±4.8mo post conversion. Moreover, biopsies in 7/18 Ab+ subjects prior to treatment showed evidence of acute rejection.

Conclusions: This interim analysis of CTOT-02 reveals unexpected differences in the baseline characteristics and a high proportion of subclinical and clinical rejection associated with anti-HLA Abs.

TH-OR153

The Joint Economic Impact of Acute Rejection and Glomerular Filtration Rate in Contemporary Kidney Transplantation Adrian Gheorghian,[1] Mark Schnitzler,[1] Gilbert Litalien,[2] Anupama Kalsekar,[2] Krista L. Lentine.[1] *[1]Saint Louis University; [2]Bristol-Myers Squibb.*

Background: The economic implications of acute rejection (AR) in contemporary kidney transplant are not defined. We assessed the combined impact of 1st year AR and estimated glomerular filtration rate (eGFR) on 2nd and 3rd yr Medicare costs.

Methods: Data for Medicare-insured kidney transplant recipients in 2000-2007 (n=32,520) who survived with graft function to12 mo were drawn from the United States Renal Data System. AR events were ascertained from OPTN reports. AR was classified as Antibody-Treated AR (Ab-AR) or other management (non-Ab-AR). The primary cost measure was payments for all healthcare services made by Medicare during intervals of the 2nd and 3rd yrs post-transplant. Multivariate linear regression was used to quantify: 1) the marginal cost impact of first-year AR and eGFR on subsequent costs, and 2) total predicted costs. Covariates included recipient, donor and transplant factors in the UNOS Kidney Allocation Review Committee survival model.

Results: Ab-AR and non-Ab-AR within the 1st yr were associated with significant increases in 2nd yr costs of $5,755 and $5,019, respectively, after adjustment including eGFR and baseline factors (**Table**). AR was also significantly associated with 3rd yr costs.

Total 2nd & 3rd costs were higher in those with AR compared to no AR. However, markedly stronger variation in costs was seen across eGFR levels **(Figure).** For example, among those with non-Ab-AR, adjusted total 2nd yr costs were $22,747 with eGFR >60 but $43,881 with eGFR ≤30 ml/min/m². Cost impacts of AR and eGFR were similar but of lower magnitude after additional adjustment for death and graft failure.

Table. Associations of AR within the 1st Yr and 12-month eGFR with Costs in Years 2 and 3 after Transplant by Multivariate Regression.

P-values: † P 0.0001–0.01; ‡ P < 0.0001	2nd Year Costs*	2nd Year Costs,* Adjusted for death and graft failure	3rd Year Costs*	3rd Year Costs,* Adjusted for death and graft failure
	$ per yr	$ per yr	$ per yr	$ per yr
Ab-treated in Yr1	5,755.40‡	1,923.02	7,962‡	7,838‡
Non-Ab-treated in Yr1	5,019.69‡	3,483.01‡	4,502‡	3,059‡

Efficacy and Safety of Early Cyclosporine Conversion to Sirolimus with Continued MMF: 5-Year Results of the Post-CONCEPT Study Yvon Lebranchu,[1] Matthias Buchler,[1] Eric Thervet,[2] Isabelle Etienne,[3] Pierre-Francois Westeel,[4] Jean-Philippe Rerolle,[5] Sandrine Girardot-Seguin,[6] Bruno Moulin.[7] *[1]CH Bretonneau; [2]CHU Necker; [3]CH Bois Guillaume; [4]CH Sud; [5]Civil Dupuytren; [6]Roche, Neuilly-sur-Seine; [7]Civil Hospital.*

Background: CNI induces long-term nephrotoxicity and is associated with moderate renal dysfunction.

The *de novo* introduction of sirolimus (SRL) has demonstrated a positive impact on renal function. However, the adverse effects of early SRL introduction could limit this approach. In the CONCEPT study, the delayed conversion to SRL demonstrated an improved renal function with a similar tolerance, at one year. 60 months follow up study investigates the long term impact of this strategy.

Methods: In this prospective trial, renal function by simplified MDRD formula and safety were assessed from 12 to 60 months post transplantation in the two groups (group A: SRL+MMF, group B: CsA+MMF).

Results: Among the 162 patients (89.5%) entered in the follow up at M12, 139 patients were evaluated at M60; 67 in group A, 72 in group B. eGRF was significantly higher in group A, 58.31 vs 49.89 ml/mn/1.73m², respectively (p=0.0012). This difference was observed particularly in population "on treatment" (group A, n= 39) 65.05 ml/mn/1.73m² vs (group B, n= 67) 50.31 ml/mn/1.73m² (p<.0001).

On ITT analysis, 7 deaths (3 in SRL group and 4 in CsA group) not related to immunosuppressive treatment, 2 graft losses in group A and 4 BPAR (2 in each group) were observed between M12 and M60.

Concerning the lipid profile and proteinuria, the two groups were not different at M60.

The occurrence of cancers was lower in patients treated by MMF+SRL (n= 4) than MMF+CNI (n=12).

Conclusions: The significant improvement in renal function observed at 12 months in patients receiving MMF + SRL was maintained at 60 months compared to MMF + CSA and the occurrence of cancers was lower in patients treated by MMF + SRL

Funding: Pharmaceutical Company Support

TH-OR155

A Multicentre RCT of Early Switch to Everolimus Plus Steroids or Everolimus Plus CsA Versus CsA, MPA and Steroids in *De Novo* Kidney Transplant Recipients: 12 Month Analysis Steven J. Chadban,[1] Graeme Russ,[2] John Kanellis,[3] Helen L. Pilmore,[4] Yu Seun Kim,[5] Si-Yen Tan,[6] Nicol Kurstjens,[7] Josette M. Eris.[1] *[1]Royal Prince Alfred Hospital; [2]Royal Adelaide Hospital; [3]Monash Medical Centre; [4]Auckland City Hospital; [5]Severance Hospital; [6]University Malaya Medical Centre; [7]Novartis Australia.*

Background: To determine whether addition of everolimus(EVR) to cyclosporine(CsA), mycophenolic acid(MPA) and steroids at 2 weeks post-kidney transplantation can enable elimination of either CsA and MPA or steroids and MPA without compromising efficacy and safety.

Methods: SOCRATES is a 36-month(M), prospective, multi-centre, randomised, open-label study. Kidney transplant recipients(KTR) received CsA, MPA, prednisone and basiliximab and were randomized commencing week2 to: add EVR and withdraw CsA&MPA(CsA-WD); add EVR and withdraw steroids & MPA(steroid-WD); or remain on CsA, MPA & steroid(control). Primary outcome was non-inferiority at M12 eGFR(Nankivell formula). Key secondary endpoints were a composite of biopsy proven acute rejection(BPAR), graft loss, death, loss to follow-up and each of these individually.

Results: 126 KTR were randomized to CsA-WD n=49, steroid-WD n=30, or control n=47. The steroid-WD arm was prematurely terminated due to a higher treatment discontinuation rate attributed to acute rejection, unsatisfactory effect, or other reasons. At M12, CsA-WD was non-inferior to control for eGFR 72.3 vs 71.3 mL/min/1.73m²(p=0.006). Change in mean eGFR from week2 to M12 was numerically greater for CsA-WD vs control(+17.5 vs +5.7mL/min/1.73m²).

Key M12 efficacy parameters (ITT population)

	EVR with CsA-WD n=49 (%)	Control n=47 (%)	EVR with Steroid-WD n=30 (%)	P-value*
Composite efficacy failure by Month 12	16 (32.7)	8 (17.0)	11 (36.7)	0.1001
BPAR	15 (30.6)	6 (12.8)	5 (16.7)	0.0479
Graft loss	0 (0.0)	2 (4.3)	0 (0.0)	0.2371
Death	0 (0.0)	1 (2.1)	0 (0.0)	0.4896
Loss to follow-up	1 (2.0)	0 (0.0)	6 (20.0)	1.0000

*The p-value is from Fisher's exact test comparing CsA-WD versus control.

Conclusions: Early switch to everolimus enabled withdrawal of CsA and MPA without compromising M12 eGFR. This regimen was associated with improved eGFR from week2 to M12 but a higher rate of acute rejection. Continuation of MPA may be preferred when switching from a CNI to everolimus strategy.

Endothelial Dysfunction in Renal Transplant Recipients with Functioning Arteriovenous Fistula Yasar Caliskan,[1] Mehmet Besiroglu,[1] Halil Yazici,[1] Ibrahim Altun,[2] Ahmet Gurdal,[2] Tevfik Ecder,[1] Aydin Turkmen,[1] Mehmet Sever.[1] *[1]Division of Nephrology, Department of Internal Medicine, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey; [2]Department of Cardiology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey.*

Background: Endothelial dysfunction is a common precursor and denominator of atherosclerosis and atherosclerotic cardiovascular diseases (CVD) are still the major cause of death among renal transplant recipients. We investigated the effects of functioning arteriovenous fistula (AVF) on endothelial functions in renal transplant recipients.

Methods: A total of 82 renal transplant recipients who were undertaken hemodialysis or peritoneal dialysis before transplantation enrolled in this study. Patients were divided into three subgroups [patients with functioning AVF (n=46), patients whose fistulas were spontaneous stopped or closed (n=25) and peritoneal dialysis patients who had never been constructed AVF]. Serum creatinine, uric acid, albumin, calcium, phosphorus, albumin, PTH, triglyceride, total, LDL- and HDL- cholesterol levels were measured. Endothelial function was measured non-invasively with high resolution ultrasound equipment as the percentage of post-ischemic flow-mediated dilation (FMD) of the brachial artery of the non-dominant or non- fistula arm**.**

Results: There were no significant differences regarding age, gender, smoking status, time on dialysis, immunosuppressive treatment, blood pressures, serum creatinine, uric acid, albumin, hs-CRP, calcium, phosphorus, albumin, intact PTH, triglyceride, total, LDL- and HDL- cholesterol levels among the study groups. Pulmonary artery pressure and ejection fraction were also similar among the three groups. FMD value of patients with functioning AVF (7.9±6.1%) were significantly lower then patients with non-functioning AVF (12.2±5.8%) and patients never been constructed AVF (10.4±5.8%) (p=0.017). In correlation analysis, FMD was not significantly correlated with any laboratory parameters.

Conclusions: Endothelial dysfunction which is a common precursor of cardiovascular events is more prominent in renal transplant recipients with functioning AVF.

TH-OR157

Short Course, High Dose Erythropoietin in Deceased Cardiac Death Kidney Transplant Recipients Zeynep Aydin, Marko J. Mallat, Ton J. Rabelink, Johan W. De Fijter. *Nephrology, Leiden University Medical Center, Leiden, Netherlands.*

Background: Ischemia-reperfusion injury is a problem in kidneys derived from DCD donors. In preclinical models with ischemic insults, exogenously administered Erythropoietin proved to be renoprotective.

Methods: All consecutive DCD transplant recipients were included in this single center prospective, randomized, double blind, placebo-controlled study. Erythropoietin-was administered to the recipient as an intravenous bolus of 3.3 x 10^4 IU, 3-4 hours before the transplantation, as well as 24 and 48 hours after reperfusion.

Primary end point was the composite of delayed graft function/primary non function. Secondary end points included duration of DGF, acute rejection, measured creatinine clearance (mGFR) and survival at 1 year after transplantation.

For safety purposes any arterial or venous thrombosis was recorded.

Results: A total of 92 patients were included in the study. DGF occurred in 39/45 recipients in the EPO treated group (86,7%) as compared with 41/47 patients in the placebo group (87,2%) (P=1.00).

The incidence of PNF was 6.7% in the EPO group (3 patients) and 2.1% in the placebo group (1 patient).

If DGF developed, the median duration was 10 days in the EPO group and 9 days in the placebo group (NS).

Acute rejections occurred in 20.5% in the EPO group and in 26.1 % in the placebo group (P=0.62).

The measured creatinine clearance showed no difference at 6 weeks (44±19 ml/min and 46±18 ml/min in EPO and placebo group respectively), but was significantly better in the EPO group 1 year after transplantation (68±23 vs 57±25 ml/min) (P<0.05).

One-year patient and graft survival were respectively 96/93% and 96/96% in the EPO and placebo group.

Thromboembolic events occurred in 14 patients in the total group, the majority consisted of thrombosis of the vascular access (4 in EPO group, 1 in placebo group).

Conclusions: High-dose Erythropoietin did not reduce the incidence or duration of DGF. However, treatment with EPO resulted in a significantly better recovery of mGFR, but also more thrombotic events.

TH-OR158

Replacement of Vitamin D by Cholecalciferol or Cholecalciferol Plus Doxercalciferol Lowers Parathyroid Hormone Levels without Raising FGF23 or Altering Kidney Function in Kidney Transplant Recipients Mariana S. Markell, Sima Terebelo. *Medicine, SUNY Downstate Medical Center, Brooklyn, NY.*

Background: Hypovitaminosis D (HYPOD) and hyperparathyroidism (HPTH) occur commonly in kidney transplant recipients (KTR's). Optimal vitamin D replacement has not been established because of concerns regarding hypercalcemia, immune stimulation and potential increase in FGF23 secondary to increased 1,25 Vit D levels.

Methods: 39 stable KTR's with HPTH and HYPOD were enrolled. Pts were randomized to receive cholecalciferol 1000U daily plus placebo (CHOLE) or cholecalciferol plus 0.5 mcg doxercalciferol (DOXE) for 6 months. PTH values were measured at 4 weeks and doxercalciferol (or placebo) dose was titrated up by 0.5mcg if PTH values had not fallen. Full-length FGF-23 levels were determined using an ELISA assay.

Results: 33 pts completed the study, 3 pts dropped out from each group. No pt dropped out because of hypercalcemia. No pt had rejection. One CHOLE pt developed hypophosphatemia. 4 pts had constipation (3 DOXER/1 CHOLE) but none had hypercalcemia. The population included 16 men (37%), 29 Blacks (68%). Mean age was 49.2±13.5; 43.6±6.5 months since last transplant, creat 1.5±0.7 (GFR 54.8±3.1 by MDRD). By ANOVA, there was no difference in response to CHOLE vs DOXER as regards effect on PTH so the groups were combined for evaluation of treatment effect. By paired sample t-test there were no differences for creat, GFR by MDRD, prot/creat ratio, calcium or phosphorous after 6 month treatment. PTH fell from 189.7±11.8 to 134.7±10.8 (p<0.0001), 25-OH Vit D rose from 16.4±0.7 to 30.8±1.4 (p<0.001), while 1,25 Vit D remained the same (53.5±3.4 vs 56.1±3.5) as did FGF23 (97.9±8.9 vs 102.9±12.4).

Conclusions: 1. Cholecalciferol 1000U with or without doxercalciferol up to 1 mcg has a low side effect profile in stable long-term KTR's with HPTH. 2. Repletion of vitamin D can be accomplished within 6 months and results in an average decrease in PTH of 30%. 3. Repletion of Vitamin D with cholecalciferol or active vitamin D (doxercalciferol) does not cause an increase in 1,25 Vit D or FGF23 or adverse effects on kidney function 4. These regimens should be studied in KTR's with advanced CKD as a therapy for HPTH.

FR-OR159

Macrophages Play an Essential Role in Renal Repair Following Apoptotic Tubule Injury Bing Yao,[1] Shilin Yang,[1] Ming-Zhi Zhang,[1] Raymond C. Harris.[1] *[1]Medicine, Vanderbilt University, Nashville, TN; [2]Vanderbilt University, Nashville, TN; [3]Nashville, TN.*

Background: There is increasing evidence that macrophages may contribute to both injury and repair in different experimental models of acute kidney injury.

Methods: To study the role of macrophages in recovery from acute kidney injury characterized predominantly by epithelial apoptosis, we utilized a transgenic mouse expressing the human diphtheria toxin receptor (DTR) selectively in kidney proximal tubule.

Results: DT administration induced acute kidney dysfunction in transgenic (TG) mice but not wild-type (WT) mice following DT administration, with increased creatinine and BUN and renal proximal tubule dilation, cell sloughing and cast formation. Marked renal proximal tubular cell apoptosis was detected by TUNEL-staining. In the TG mice, macrophage/monocyte depletion by clodronate either prior to, or after induction of injury by DT administration led to significantly greater functional and histologic injury, increased and prolonged KIM-1 expression, increased apoptosis and delayed cell proliferation. Similar results were seen with macrophage deletion in γ-GT/CD11c-DTR double transgenic mice. Following ischemia-reperfusion, there was an early increase in macrophages with "M1" (inflammatory) markers. In contrast, in injury induced by DT, there were no increases in M1 macrophages but significant increases in M2 (wound healing) macrophages; expression of these M2 markers was markedly inhibited by clodronate or in the double transgenic mice. Of interest, prior splenectomy did not alter the recovery in this model. Furthermore, unlike ischemia/reperfusion injury, there was no increase in renal accumulation of labeled monocytes in DT-induced injury above that seen in kidneys from untreated animals, but there was an increase in cells double labeled with F4/80 and Ki67, a marker of proliferation.

Conclusions: In this model of AKI characterized by renal tubular apoptosis, M2 macrophages increase in response to injury and serve as a crucial component mediating epithelial regeneration. There appears to be an important role for local macrophage proliferation in the reparative process.

FR-OR160

Oxygen-Sensing Prolylhydroxylases (PHDs) in Acute Kidney Injury Alexander Badulak, Douglas Ridyard, Eunyoung Tak, Holger Eltzschig, Almut Grenz. *Dept. of Anesthesiology, UC Denver, Denver, CO.*

Background: During renal ischemia, shifts in the metabolic supply to demand ratio – particularly for oxygen – result in severe tissue hypoxia. Cellular responses to hypoxia are regulated by enzymes that sense cellular oxygen levels and coordinate transcriptional responses to hypoxia or ischemia. Central among these enzymes are three oxygen-sensing prolyl hydroxylases (PHD1-3). Limited oxygen availability results in inhibition of PHDs with subsequent stabilization of hypoxia-inducible factors (HIFs). Activation of HIF results in a transcriptionally regulated response that re-programs cellular metabolism towards hypoxia adaptation. *Thus, we hypothesize that genetic deletion or pharmacologic inhibition of PHDs mediates kidney protection from ischemia.*

Methods: Gene targeted mice for PHD1, 2 and 3 ($PHD1^{-/-}$, $PHD2^{+/-}$, $PHD3^{-/-}$) were studied in an ischemic model of acute kidney inury (AKI) by utilizing a hanging weight system. Renal function was determined by FITC-labeled inulin clearance, serum creatinine, renal cytokine levels, renal myeloperoxidase (MPO ELISA), histology and TUNEL staining.

Results: To pursue our hypothesis, we first treated wild type mice with a PHD inhibitor (DMOG, dimethyloxallyl glycine) before renal ischemia. Mice with DMOG treatment showed attenuated kidney injury following renal ischemia compared to vehicle treated mice. The decrease in GFR following ischemia was attenuated and the increase in serum creatinine reduced. Furthermore, inflammatory cytokines (TNF-alpha, IL-6) and neutrophil infiltration (MPO assay) were attenuated in DMOG treated mice compared to vehicle treated mice. Further studies in gene-targeted mice for PHD1, 2 or 3 showed a selective phenotype in $Phd1^{-/-}$ mice with remarkable protection from ischemic AKI. The GFR was tremendously improved, serum creatinine significant lower and histological damage attenuated.

Conclusions: In summary, we could show a selective phenotype in Phd1-/- mice with improved renal function following AKI due to ischemia. Thus, PHD inhibitors could prove to be a novel therapeutic agent in the treatment of AKI in the near future.

FR-OR161

Chitinase 3-Like 1 Regulates the Renal Response to Ischemic Injury and Predicts Delayed Allograft Function Insa Marie Schmidt,[1] Isaac E. Hall,[1] Gilbert W. Moeckel,[2] Chirag R. Parikh,[1] Lloyd G. Cantley.[1] *[1]Department of Internal Medicine, Section of Nephrology, Yale University School of Medicine, New Haven, CT; [2]Department of Pathology, Yale University School of Medicine, New Haven, CT.*

Background: Acute kidney injury can trigger a series of responses that promote tubule repair. Defining those pathways may provide novel targets for therapeutic intervention to promote the repair process.

Methods: Using proteomic analysis, western analysis and quantitative PCR, we found that Chitinase 3-like 1 (Chi3l1,named Brp-39 in mouse,YKL-40 in humans), is highly upregulated in the kidney and urine during the repair phase after ischemia/reperfusion (I/R) injury. The functional importance of this pathway was analyzed using Brp-39 null mice, cultured epithelial cells and urine from patients after kidney transplant.

Results: Mice lacking Chi3l1 demonstrate significantly worse outcomes following AKI compared to control animals, with more severe tubular injury, increased apoptosis, decreased reparative tubular proliferation, a persistent reduction of kidney function and decreased survival. Stimulation of mouse tubular epithelial cells with Brp-39 induces activation of Akt and Erk, with a reduction of H2O2-induced apoptosis by 50%. Inhibition of Brp-39 stimulated PI3-K/Akt activation prevented the anti-apoptotic effect, suggesting that this pathway is critical for the protective effects of Brp-39. In recipients of deceased-donor kidney transplants who exhibited delayed graft function (DGF, indicative of severe ischemic injury,n=26), urinary YKL-40 levels at 0 (immediately post-op) and 1 day after

transplant were markedly higher as compared to patients without DGF (indicative of less severe ischemic injury, n=51). Receiver-operating characteristic analysis revealed urinary YKL-40 had an area under the curve for the development of DGF of 0.84.06 immediately post-op and 0.88.05 1 day after transplant.

Conclusions: These studies demonstrate that Chi3l1 is expressed in a graded fashion in response to ischemic kidney injury where it acts to limit tubular apoptosis and promote kidney repair. This newly identified pathway may thus serve as both a potential therapeutic target and biomarker for AKI.

PTEN Loss Defines the Tubule Phenotype of Failed Differentiation Associated with Kidney Fibrosis in Rodent Models and Human Disease

Rongpei Lan,[1] Hui Geng,[1] Aaron Polichnowski,[2] Prajjal Kanti Singha,[1] Pothana Saikumar,[1] Karen A. Griffin,[2] Anil K. Bidani,[2] Wilhelm Kriz,[3] Manjeri A. Venkatachalam.[1] *[1]U TX; [2]Loyola U Med Ctr; [3]U Heidelberg.*

Background: High TGFβ after acute kidney injury (AKI) leads to failed differentiation of regenerating epithelium, defective tubule repair, and fibrosis.

Methods: We studied how the "failed differentiation" tubule phenotype develops in cultured cells, mice with tubule specific TGFβ induction, rat models of ischemic and maleate AKI, and human chronic kidney disease.

Results: Tubule specific induction of TGFβ in vivo led to loss of tumor suppressor PTEN and increased Jun N-terminal kinase (JNK) signaling in proximal tubules (PT), and to fibrosis. In cultured PT cells, high TGFβ depleted PTEN, raised JNK signaling and inhibited differentiation. Conversely, TGFβ antagonism increased PTEN, decreased JNK signaling and promoted differentiation. Selective Cre-Lox PTEN deletion suppressed PT differentiation despite TGFβ status, triggered PI3K and JNK signaling, and induced growth arrest. PTEN declined in a subpopulation of PT during repair of AKI in vivo. These cells lacking PTEN were growth arrested, but showed increased PI3K and JNK signaling, failed to re-differentiate, expressed vimentin and keratin, produced PDGF-B and CTGF, and were surrounded by fibrosis; whereas PTEN recovery was associated with PT re-differentiation and normal repair. Pharmacologic TGFβ antagonism promoted PTEN recovery, PT differentiation, and normal repair. Similar improvement of low PTEN and tubulo-interstitial pathology were induced by contralateral nephrectomy done 2 weeks after unilateral ischemia, showing reversibility of this dysfunctional phenotype. Vimentin and keratin expressing tubules with low PTEN and increased phospho-c-Jun were associated with fibrosis also in human chronic kidney disease of diverse etiology.

Conclusions: The low PTEN, vimentin-keratin positive tubule phenotype that expresses phlogistic JNK-Jun signaling and fibrogenic peptides is associated with fibrosis in diverse animal models and human disease. We propose that it plays a central pathogenic role in triggering fibrotic events in the renal interstitium, and is potentially treatable.

Exosome-horizontal Transfer of IGF-1 Receptor to Cisplatin-Damaged Tubular Cells Potentiates the Reparative Effect of Mesenchymal Stem Cells (MSC)-Derived IGF-1

Susanna Tomasoni,[1] Lorena Longaretti,[1] Cinzia Rota,[1] Marina Morigi,[1] Sara Conti,[1] Martino Introna,[2] Chiara Capelli,[2] Giuseppe Remuzzi,[1] Ariela Benigni.[1] *[1]Mario Negri Institute, Bergamo, Italy; [2]Laboratory of Cellular Therapy, Ospedali Riuniti, Bergamo, Italy.*

Background: Bone marrow MSC ameliorate renal dysfunction and repair tubular damage of acute kidney injury through their ability to locally release growth factors including IGF-1. Beside soluble factors, cell-cell communication occurs through vesicles named exosomes containing mRNA that can be delivered and translated into the recipient cell. Finding few MSC at the site of injury led us to investigate a possible gene-based communication mechanism between MSC and tubular cells amplifying the renoprotective effect of IGF-1.

Methods: Transmission electron microscopy allowed identification of microvesicles (MV) and exosomes by size and expression of antigen surface proteins CD63 and CD9 by immunogold. Expression profile of genes involved in the insulin-signalling pathway was assessed by PCR arrays in MV/exosomes and donor MSC.

Results: MV (110-150 nm) and exosomes (45-90 nm) released from either serum-free cultured mouse and human MSC did not contain DNA but were enriched in mRNA (10-60 ng and 20-300 ng/1x10^6 cells for mouse and human MSC). Gene profile analysis revealed the presence of selected pattern of transcripts in MV/exosomes versus donor cells. MV/exosomes expressed IGF-1 receptor (IGF-1R) but not IGF-1 mRNAs, while MSC contained both mRNAs. Human tubular cells exposed to mouse MSC-derived exosomes acquired mouse IGF-1R transcript demonstrating genetic exchange between MV/exosomes and tubular cells. mRNA shuttled by exosome was functional as addition of human MV/exosomes to cisplatin-damaged mouse tubular cells (MTC) significantly increased MTC proliferation. Gene silencing of IGF-1R in MSC significantly reduced the proliferative effect induced by exosome on damaged MTC suggesting that MTC proliferation was exosome-IGF-1R dependent.

Conclusions: Horizontal transfer of mRNA for the IGF-1R to tubular cells through MV/exosomes potentiates tubular cell sensitivity to locally produced IGF-1 providing a new mechanism underlying the powerful renoprotection of MSC.

Exploring the Origin of the Cells Responsible for Regeneration, and the Mechanism of Repair in the Kidneys

Tomomi Endo, Tomohiko Okuda, Jin Nakamura, Atsuko Y. Higashi, Atsushi Fukatsu, Motoko Yanagita. *Graduate School of Medicine, Kyoto University, Kyoto, Japan.*

Background: Kidneys repair after acute kidney injury (AKI) with a rapid proliferative response, which leads to the restoration of nephron structure and function. However the origin of the proliferating cells after AKI remains controversial. We hypothesized that the mature proximal tubule cells proliferate and repair kidney after injury.

Methods: To test the hypothesis, we generated proximal tubule-specific inducible Cre mice (NDRG1CreERT2/+ mice), which could achieve almost 100% recombination in proximal tubules without any leakage, only after the administration of tamoxifen. To explore the origin of the proliferating cells after AKI, we performed ischemia-reperfusion injury (I/R injury) to NDRG1CreERT2/+:R26R mice, and administered BrdU.

Results: Many LacZ/BrdU double positive cells were observed within injured tubules, indicating that mature proximal tubule cells proliferated. Furthermore, no dilution of genetic label was observed in the proximal tubules of the repaired kidney at day45, despite of extensive proliferation after I/R injury.

We also analyzed whether other cell source is employed after repeated injury. Even after three times I/R injuries, however, no dilution of the genetic label was observed in the repaired proximal tubules, indicating that proximal tubule cells are the only cell source to repair proximal tubules even after repeated injuries.

Furthermore, the size of the injured kidney decreased after repeated injuries, even after the repair of tubules was completed. We further demonstrated that the complexity of proximal tubules decreased significantly after repeated injuries. Because the volume of proximal tubules is about 80 % of whole kidney, the shortening of proximal tubules might account for the size reduction of kidneys after repeated injuries.

Conclusions: Proximal tubule is a unique segment of nephron, which is capable of self-proliferation and self-repair, although the repair capacity is not sufficient after repeated injuries.

IQGAP1 Is Critical for Recovery from AKI by Enhancing Tubular Cytoskeleton Regeneration

Li-Wen Lai,[1] Kim-Chong Yong,[1] Yeong-Hau Howard Lien.[2,3] *[1]Pharmacology & Toxicology, University of Arizona, Tucson, AZ; [2]Medicine, University of Arizona, Tucson, AZ; [3]Arizona Kidney Disease and Hypertension Center, Tucson, AZ.*

Background: IQ-domain GTPase-activating protein 1 (IQGAP1) is a scaffold protein that plays a critical role in regulating actin cytoskeleton by interacting with actin, via Rac1/Cdc42, Arp2/3 and N-WASP signaling. Since actin cytoskeleton remodeling plays an import role in the repair of acute kidney injury (AKI), we investigated the role of IQGAP1 in tubular regeneration after endotoxin induced AKI.

Methods: IQGAP1 knock out (KO) mice and wild type control (WT) received lipopolysaccharide (LPS, 10 mg/kg, i.p.) or vehicle and blood and kidneys were collected 24 h after for BUN, histology and immunofluorescence staining (IF).

Results: KO had normal baseline renal function (BUN: 21±3). After LPS treatment for 24 h, BUN and acute tubular necrosis (ATN) score were significantly higher in KO vs. WT (BUN: 151±23 vs. 37±8; ATN: 4.2±0.3 vs. 1.6±0.2, both $p<0.05$). Interaction between IQGAP1 and F-actin was analyzed using IF and confocal microscope. In WT proximal tubule, IQGAP1 and F-actin co-localized in the apical microvillar. In distal convoluted tubules, IQGAP1 was diffusely expressed and co-localized with F-actin at lateral cell-cell junctions. In collecting ducts, F-actin co-localized with IQGAP1 in both intercalated and principal cells. After LPS treatment, the cytoskeleton was disrupted with the reduction of both IQGAP1 and F-actin in the damaged renal tubules. The reappearance of IQGAP1 along with F-actin was observed in the damaged renal tubules after 24 h of LPS treatment, suggesting the regeneration of actin cytoskeleton. Uninjured KO showed normal distribution of F-actin, however, there was no reappearance of F-actin in the damaged renal tubules of KO at 24 h after LPS.

Conclusions: The co-localization of IQGAP1 with F-actin suggests that IQGAP1 is important in actin cytoskeleton organization. During the early phase of AKI, IQGAP1 is removed from the apical membrane along with the loss of F-actin and regenerated along with F-actin during the recovery phase, suggesting that IQGAP1 is critical for tubular regeneration after AKI.

FR-OR166

Understanding Endogenous Repair Following Acute Kidney Injury Using Macrophage Profiling and Phenotypic Analysis

Sharon D. Ricardo, Maliha A. Alikhan, Daniel S. Layton, Timothy Williams. *Monash Immunology and Stem Cell Laboratories, Monash University, Clayton, Victoria, Australia.*

Background: Ischemia-reperfusion (IR) injury is characterised by the production of pro-inflammatory cytokines, such as IL-6, TNF and MCP-1, that drive M1 macrophage polarisation resulting in tissue damage. We have reported that colony stimulating factor (CSF)-1 stimulates macrophage differentiation towards a reparative phenotype leading to accelerated kidney repair following IR (Alikhan et al. Am J Pathol 2011). Identifying

further cytokines and growth factors involved in macrophage polarisation may lead to the development of therapeutics aiding in the rapid reversal of the inflammatory response and promotion of tissue remodeling.

Methods: Flow cytometry was used to assess macrophage phenotype during the inflammatory and tissue remodeling phases of IR injury (n=5/group) with/without the administration of CSF-1. The production of IFN-γ, TNF, IL-6, IL-10, IL-12p70 and MCP-1 was assessed using cytokine bead arrays. In conjunction, macrophages (CD45+CD11b+CD11c-) from damaged kidneys were FACS sorted and subjected to microarray gene expression profiling using IlluminaTM Mouse gene expression arrays. Candidate therapeutic target genes were identified using the Ingenuity Pathway Analysis software.

Results: Total kidney cellularity decreased over the time course of injury but with a concomitant rise in CD45+ cells. Ly6Chigh inflammatory monocytes comprised the majority of the infiltrate at 24hrs. This was followed by the rapid maturation of macrophages, identified by the upregulation of MHC class II and F4/80. Gene profiling arrays showed the increased expression of the M2 associated glucocorticoid receptor, IL-10 and IGF-1 genes at day 5 and repair associated PDGF, GM-CSF and apoptosis signaling pathways by day 7 in CSF-1 treated mice.

Conclusions: Macrophages play a central role in the endogenous repair process following IR injury as evident by the phenotypic switch from a pro-inflammatory to an anti-inflammatory cell type. Further gene profiling of the cells involved in CSF-1 enhanced repair has highlighted potential therapeutic targets that may prevent or retard the progression of renal disease.

FR-OR167

Hedgehog Signaling Pathway Is Activated during Kidney Repair Massimo Attanasio,[1,2] Alysha Rauhauser,[1] Binghua Li.[1] *[1]Department of Internal Medicine, UT Southwestern Medical Center, Dallas, TX; [2]McDermott Center for Growth and Development, UT Southwestern Medical Center, Dallas, TX.*

Background: Acute kidney injury (AKI) is a frequent cause of long term renal failure or death (1). Unilateral ureteral obstruction (UUO) in mice has been widely used as a model of severe AKI. Hedgehog (Hh) is a core signaling pathway implicated in fundamental processes during embryonic kidney development (2) but its role in the adult kidney has not been explored.

Experiments performed in our laboratory show that persistence of hedgehog signaling in the adult kidney leads to acquisition of mesenchymal hallmarks by tubular epithelial cells, similarly to what is observed after AKI. This similarity prompted us to test the participation of Hh pathway in kidney repair.

Results: Using Gli1lacZ transgenic mice (3) as an in vivo reporter of Hh activity, we found that Hh signaling is latent in adult fully developed kidneys and is significantly upregulated after UUO. Increased Gli1 activity was more evident at the cortico-medullary junction, where it is mostly concentrated in interstitial cell populations, but was also sparsely detected in cells of various tubular segments.

To test if pharmacological modulation of Hh activity would affect kidney repair, we inhibited Hh signaling at different time points after injury using the specific Smoothened inhibitor, cyclopamine. Hh inhibition resulted in net improvement of kidney morphology, significant reduction of collagen deposition and diminished apoptosis, indicating a central role of Hh signaling in kidney repair. Interestingly, the favorable effects of Hh inhibition on the injured kidney were dependent on the time of the drug administration, suggesting that Hh might have different functions and signal to different cell populations in different phases of the repair process.

Conclusions: We conclude that activation of the Hh signaling pathway has a key role in kidney repair and its modulation might be useful for future therapy of AKI.

Microparticles from Kidney Derived-Mesenchymal Stem Cells Act as Carriers of Proangiogenic Signals and Contribute to Renoprotection in Acute Kidney Injury Hyeong Cheon Park, Hoon Young Choi, Geum-Ock Kim, Jin Seol An, Sun Hee Ahn, Sung-Kyu Ha. *Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea.*

Background: Microparticles (MP) shed from bone marrow mesenchymal stem cells (MSC) conferred protective effects against acute tubular injury via transfer of messenger RNA and microRNA. We recently demonstrated that in vitro expanded kidney derived-MSC (KMSC, Kidney International 2008; 74:879-889) protected peritubular capillary endothelial cells in acute ischemic reperfusion injury (IRI).

Methods: KMSC were cultured in hypoxic chamber in serum deprived MEM with hydrogen peroxide (200 μM) for 24 hours. MP were isolated from supernatants by differential ultrafiltration (2,000x g, 10 min, 100,000x g, 1hr) for electron microscopy and flowcytometric characteriaztion and MP RNA was extracted using ExoMir kit (BIOO Scientific). Isolated MP were co-cultured with human umbilical vein endothelial cells (HUVEC) on growth factor reduced Matrigel to assess their effect on endothelial tube formation. Mice subjected to bilateral IRI were injected with PKH26 stained MP ($4x10^6$/mice) to assess its renoprotective effects.

Results: Presence of MP was confirmed by electron microscopy. Flow cytometric analysis of MP demonstrated presence of several adhesion molecules shown to be expressed on KMSC membrane such as CD29, CD44, CD73, alpha4- and alpha 6 integrins. Quantitative real time PCR confirmed the presence of 3 splicing variants of VEGF-A (120, 164, 188) and IGF-1 in isolated MP. MP labeled with PKH26 red fluorescence dye were incorporated by cultured HUVEC via surface molecules such as CD44 and CD29. MP dose dependently improved in vitro HUVEC viability and promoted endothelial tube formation. Furthermore, injection of MP after IRI significantly improved renal function in mice subjected to 32 minutes of bilateral IRI.

Conclusions: Our results support the hypothesis that KMSC-derived MP may act as a source of proangiogenic signals and confer renoprotective effects.

Therapeutic Targeting of Vascular Klotho Inhibits Calcification and Unmasks FGF23 Vasculo-Protective Effects in CKD Kenneth Lim,[1,2] Tzong-Shi Lu,[1] Guerman Molostvov,[2] Daniel Zehnder,[2] Li-Li Hsiao.[1] *[1]Brigham and Women's Hospital, Harvard Medical School; [2]Warwick Medical School, United Kingdom.*

Background: Klotho-FGFR1 functions as a receptor for the phosphatonin, FGF23 at the kidney. FGF23 levels rise in CKD despite progressive vascular calcification (VC). We postulate functional vascular Klotho expression as a therapeutic target for VC in CKD.

Methods: In vitro model: Human aortic smooth muscle cells (HA-SMCs) +/- Klotho siRNA. Calcification: Alizarin red and Arsenazo III detection.

Results: We show for the first time Klotho expression in human arteries and HA-SMCs. Analysis of human arteries from CKD and healthy controls revealed CKD as a state of vascular Klotho and FGFR1/3 deficiency. Klotho and FGFR1/3 deficiency was driven by uremic serum, calcification medium (CM: 2.7mM CaCl2 +/- 2mM β-glycerophosphate) and TNF-α (20ng/ml), in vitro. Klotho knockdown potentiated development of accelerated calcification. These cells exhibited osteogenic transformation (increased Cbfa1 and ALP), and concomitant loss of myocardin-SRF regulated contractile phenotype. In addition, in vitro studies revealed that vascular cells are a Klotho-dependent target for FGF23. FGF23 (5ng/ml) induced cellular activation of ERK, AKT and proliferative effects, which were abrogated by Klotho knockdown. We next showed that calcitriol or calcidiol reversed loss of Klotho and FGFR1/3 in HA-SMCs. Human arterial organ cultures from CKD patients confirmed these findings, with upregulation of Klotho and FGFR1 mRNA after calcitriol and paricalcitol treatment. Furthermore, calcitriol or FGF23 pre-treatment alone followed by combined treatment with CM did not modulate development of HA-SMC calcification. However, pre-treatment with calcitriol and FGF23 together, significantly inhibited the development of calcification. These effects mitigated by Klotho knockdown.

Conclusions: Chronic metabolic stress factors found in CKD promote vascular Klotho deficiency. Functional studies reveal a bifunctional role for vascular Klotho, first as an endogenous inhibitor of VC, and second as a co-factor for FGF23 signaling. Furthermore, VDR activators can restore Klotho expression and unmask FGF23 vasculo-protective effects.

FGF23 Inhibits Innate Immune Responses to Vitamin D in Human Monocytes Justine Bacchetta, Thomas S. Lisse, Jessica L. Sea, Rene Chun, Katherine Wesseling-Perry, Isidro B. Salusky, Martin Hewison. *David Geffen School at UCLA, Los Angeles, CA.*

Background: Vitamin D is a potent stimulator of innate immunity. This facet of vitamin D physiology is highly dependent on efficient synthesis of 1,25-dihydroxyvitamin D (1,25D) by monocytes, the 1-alpha hydroxylase CYP27B1 being induced by immune activators. FGF23 suppresses renal CYP27B1 but its role in non-classical actions of vitamin D is less clear. We hypothesized that FGF23 inhibits vitamin D-induced antibacterial activity by targeting monocyte CYP27B1 similar to its actions in the kidney.

Methods: We performed rt-PCR, Western blots and immunohistochemistry in human monocytes obtained from healthy donor peripheral blood mononuclear cells (PBMCm) and from peritoneal dialysate effluent (PDm).

Results: In untreated PBMCm, initial rtPCR studies confirmed the presence of receptors for FGF23, with klotho and FGFR1 being more strongly expressed than FGFR2, 3 or 4; there was a positive relationship between FGFR1 and klotho expression, as well as between FGFR-1 and CYP27B1. Immunohistochemistry showed that klotho and FGFR1 proteins colocalize, this effect being enhanced following treatment with FGF23. Western blot analyses showed that treatment with FGF23 activated both Erk1-2 and Akt pathways, known to be downstream of FGFRs. Treatment of PBMCm with FGF23 (100 ng/ml) demonstrated a downregulation of Klotho, FGFR1 and CYP27B1 expression, as determined by rtPCR. This effect was also observed in PBMCm pre-treated with IL-15 to stimulate CYP27B1 expression. As a consequence of decreased CYP27B1 expression, FGF23-treated PBMCm showed lower levels of antibacterial LL37, and other 1,25D targets such as CYP24A1. Similar observations were also made in PDm, which showed stronger expression and colocalization of klotho and FGFR1 at baseline.

Conclusions: These data show for the first time that FGF23 can inhibit extra-renal metabolism and function of vitamin D. We therefore propose that elevated expression of FGF23 may play a crucial role in defining immune responses to vitamin D and this, in turn, may be a key determinant of infection in patients with CKD.

FR-OR171

Chronic Phosphate Restriction Fails To Prevent Fibroblast Growth Factor 23 (FGF23) Elevation in Chronic Kidney Disease Mouse Model Jason R. Stubbs, Shiqin Zhang, Ryan Gillihan. *Kidney Institute, University of Kansas Medical Center, Kansas City, KS.*

Background: FGF23 is a phosphaturic and vitamin D regulatory hormone that is markedly elevated in end-stage renal disease (ESRD). While elevations in FGF23 are associated with morbidity and mortality in ESRD, the mechanism responsible for this elevation is unclear.

Methods: We tested the hypothesis that phosphate retention in chronic kidney disease (CKD) is the primary stimulus for FGF23 elevations by studying the effects of dietary phosphate restriction on FGF23 levels in Col4a3 null mice, a proteinuric mouse model with a mineral metabolism profile that mimics that found in humans with CKD.

Results: We observed a significant increase in serum FGF23 in Col4a3 null mice at 8 weeks-of-age (1160.8 ± 401.1 vs 183.5 ± 11.3 pg/ml for WT controls; $p<0.05$), with a marked elevation by 12 weeks (5407.0 ± 1269.0 vs 236.3 ±23.2 pg/ml for WT controls; $p<0.001$), when mice were uremic. Severe phosphate restriction (0.02%) initiated at weaning failed to prevent the rise in FGF23, with Col4a3 null mice on phosphate restriction demonstrating FGF23 levels similar to those of null mice on the control diet at 8 (1304.0 ± 151.0 pg/ml; p=NS) and 12 weeks (8228.3 ± 2314.0 pg/ml; p=NS). Col4a3 null mice also exhibited a decline in serum $1,25(OH)_2D$ levels by 8 weeks (142.0 ± 16.5 vs 215.5 ± 39.7 pmol/l for WT controls; p=0.06), with severe deficiency present by 12 weeks (39.0 ± 10.5 vs 175.7 ± 31.9 pmol/l for WT controls; $p<0.01$). At 8 weeks, a 3-fold increase in renal Cyp24 gene expression was present in Col4a3 null mice ($p<0.05$ vs WT), suggesting the activation of vitamin D degradation pathways. Phosphate restriction improved $1,25(OH)_2D$ levels in these mice (192.0 ± 71.7 pmol/l at 12 weeks; $p<0.05$ compared to null mice on control diet) and normalized the renal Cyp24 gene expression, despite persistent elevation of FGF23 levels.

Conclusions: Our data suggest that phosphate retention may not be the primary cause for the elevated FGF23 levels in CKD. However, phosphate restriction can improve $1,25(OH)_2D$ levels in advanced CKD despite persistent FGF23 elevations, suggesting a retained capacity for renal $1,25(OH)_2D$ generation in ESRD.

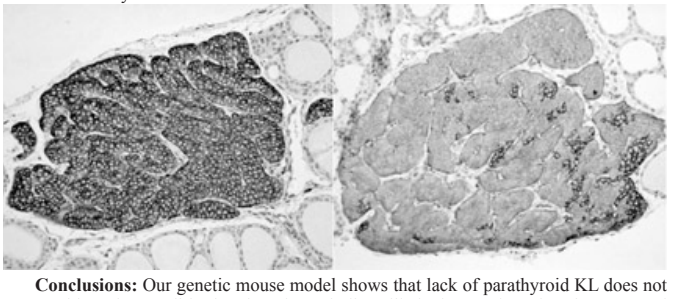
FR-OR172

Role of Parathyroid α-Klotho in Maintenance of Mineral Metabolism Hannes Olauson,[1] Karolina Lindberg,[1] Göran Andersson,[2] Tobias Larsson.[1] *[1]Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden; [2]Department of Pathology, Karolinska Institutet, Stockholm, Sweden.*

Background: Parathyroid type 1 membrane-bound α-Klotho (KL) has been reported to mediate PTH secretion at low extra-cellular calcium concentrations. KL also functions as a co-receptor for FGF23, mediating its suppressive action on PTH release. Thus, the overall physiological role of parathyroid KL remains unclear. Further, KL expression is reduced in CKD patients, possibly leading to secondary hyperparathyroidism (sHPT) through loss of FGF23 inhibition.

Methods: We generated mice with a targeted deletion of parathyroid KL (PTG-KL-/-) by employing Cre-Lox recombination using transgenic PTH-Cre mice. Immunohistochemical detection showed efficient deletion of KL in the parathyroid glands of PTG-KL-/- mice compared to wild-type controls.

Results: No gross phenotypic changes were observed in adult PTG-KL-/- mice, although female PTG-KL-/- mice were smaller than its wild-type counterparts. In 3 and 8 week-old mice, no gross histological- or serum abnormalities were found. When challenged with a low calcium diet, PTG-KL-/- mice had a trend towards lower PTH levels than controls although statistically non-significant (p=0.07), however calcium, phosphate and FGF23 remained normal. Immunohistological analysis revealed reduced expression of CaSR and VDR in PTG-KL-/-. There were no changes in gland size or cell proliferation as determined by Ki67 index.



Conclusions: Our genetic mouse model shows that lack of parathyroid KL does not cause evident abnormalities in mineral metabolism, likely due to adaptations in CaSR and VDR expression. Reduced KL, as found in CKD patients, is therefore unlikely to play a primary pathogenic role in development of sHPT.

FR-OR173

Possible Involvement of PTH in the Secreted Frizzled Related Proteins (sFRPs) Regulation and Wnt Signalling Pathway Natalia Carrillo-Lopez, Maria Arias, Pablo Roman-Garcia, Sara Panizo, Manuel Naves, Jorge B. Cannata-Andia. *Bone and Mineral Research Unit, Hospital Universitario Central de Asturias. Instituto Reina Sofía de Investigación. REDinREN del ISCIII. Universidad de Oviedo, Oviedo, Asturias, Spain.*

Background: The aim of this study was to evaluate in vivo and in vitro the effect of different degrees of secondary hyperparathyroidism and different PTH concentrations on bone turnover-related and Wnt pathway signaling-related gene expression.

Methods: After inducing chronic renal failure (CRF) by 7/8 nephrectomy in 36 rats, one group was fed normal phosphorus (P) diet (NPD) (0.6%P) and other was fed high P diet (HPD) (0.9%P). Rats were sacrificed at 8, 16 and 20 weeks. Blood samples were collected and the left tibia was removed to assess gene expression. In the in vitro study, UMR106 cells were exposed to vehicle or different concentrations of PTH (1-34). After 24 hours, cells were collected to analyze gene expression.

Results: After 20 weeks, CRF rats fed HPD diet showed a significant increase in serum PTH and P levels, together with a significant decrease in serum calcium. Moreover, the bone gene expression of bone turnover markers together with Wnt inhibitors, such as sFRP1, sFRP2, sFRP4 and DKK1, was significantly increased. In vitro, cells exposed to PTH were able to significantly increase FGF23, osteocalcin, OPG, Cbfa1 and cathepsin K gene expression. Like in the in vivo experiments, PTH were also able to significantly increase sFRP1, 2 and 4 gene expression in a concentration dependent manner.

Conclusions:

Bone gene expression of bone turnover markers and Wnt-related gene expression measured by qRT-PCR in the *in vivo* and *in vitro* studies. R.U.: Relative Units referred to Reference group (rats with normal renal function and NPD diet) (*in vivo* study) and to Vehicle group (*in vitro* study). *In vivo* study: $^{\#}p<0.05$ compared to time-matched NPD group and $^{*}p<0.05$ compared to Reference group. *In vitro* study: $^{*}p<0.05$ compared to Vehicle group.

IN VITRO STUDY	DKK1 (R.U.)	sFRP1 (R.U.)	sFRP2 (R.U.)	sFRP4 (R.U.)
Vehicle	1.00±0.00	1.00±0.00	1.00±0.00	1.00±0.00
10-8M PTH	1.10±0.15	1.52±0.54	1.56±0.43	1.93±0.37
10-7M PTH	0.99±0.2	1.97±0.51*	5.90±1.68*	4.43±0.55*
10-6M PTH	1.07±0.36	2.05±0.36*	11.01±0.86*	6.72±1.11*

In vivo, the PTH increments were associated with a significant increase in the expression of genes involved in bone turnover and Wnt pathway inhibition. The in vitro study partly confirmed the in vivo results, demonstrating for the first time that PTH directly increase sFRPs, suggesting that PTH is involved in the sFRPs and Wnt signaling pathway regulation.

Conditional Knockout of Dicer in the Parathyroid Shows That miRNAs Are Necessary for the Response of the Parathyroid to Short and Long-Term Hypocalcemia Vitali Shilo, Chofit Chai, Justin Silver, Tally Naveh-Many. *Nephrology, Hadassah Hebrew University Medical Center, Jerusalem, Israel.*

Background: MicroRNAs (miRNAs) are short non-coding RNA molecules that affect protein levels by sequence-specific repression of translation and mRNA degradation. The final step in miRNA maturation is mediated by Dicer, a RNase III-like enzyme expressed in all cell types that is essential for life.

Methods: We have disrupted miRNA maturation specifically in the parathyroid using parathyroid specific *dicer* knock-out (PT-*Dicer*$^{-/-}$) mice to study the role of miRNAs in parathyroid physiology and the development of SHPT.

Results: The PT-*Dicer*$^{-/-}$ mice develop normally and are fertile with no marked differences in serum PTH and calcium levels compared to control littermates. However, a short-term decrease in serum Ca^{2+} by EGTA administration at 40 min did not increase serum PTH in the PT-*Dicer*$^{-/-}$ mice but led to the expected 3-fold increase in serum PTH in the control mice. To induce secondary hyperparathyroidism (SHPT) mice were fed a calcium depleted diet for 3 weeks. PT-*Dicer*$^{-/-}$ mice showed only a moderate 2-fold increase in serum PTH compared to the 10-fold increase in control mice. Moreover, chronic hypocalcemia also failed to increase PTH mRNA levels in the PT-*Dicer*$^{-/-}$ mice.

Conclusions: These results show that parathyroid miRNAs are necessary for the response of the parathyroid to both acute and chronic hypocalcemia. The impaired response of the PT-*Dicer*$^{-/-}$ mice to the challenge of hypocalcemia may be due to an effect of miRNAs on calcium sensing, PTH secretion, gene expression and/or parathyroid cell proliferation.

FR-OR175

Transgenic Approach Reveals Strong Protective Effects of Vitamin D Signaling on Podocytes Youli Wang, Dilip K. Deb, Yan Chun Li. *Department of Medicine, University of Chicago, Chicago, IL.*

Background: Podocytes play a key role in maintaining the integrity of the glomerular filtration barrier, and podocyte injury is a major cause for renal dysfunction in diabetic nephropathy. Clinical and animal studies have demonstrated potent anti-proteinuric activity for vitamin D and its analogs, suggesting podocytes as important reno-protective target of vitamin D signaling.

Methods: To test this hypothesis, we targeted Flag-tagged human (h) VDR to podocytes in DBA/2J mice using the 2.5 kb podocin gene promoter. The transgenic (Tg) mice were analyzed using the model of streptozotocin (STZ)-induced diabetic nephropathy.

Results: Podocyte-specific expression of hVDR was confirmed by Western blotting and immunostaining in hVDR-Tg mice. Diabetic hVDR-Tg mice exhibited less albuminuria compared to wild-type (WT) counterparts. While treatment with a low dose vitamin D analog doxercalciferol (Dox, 30 ng/kg bw, i.p. 3x/wk) had little effects on the progression of diabetic nephropathy in WT mice, this treatment almost completely prevented albuminuria and markedly reduced glomerular fibrosis in diabetic hVDR-Tg mice. WT1 and synaptopodin staining demonstrated decreased podocyte injury, and TUNEL assays showed attenuation of podocyte apoptosis in the hVDR-Tg mice. Dox treatment also prevented the elevation of renal renin and fibronectin and preserved the expression of nephrin in the hVDR-Tg mice. Moreover, when the hVDR transgene was bred into VDR-null mice to generated VDR knockout (KO) mice that express hVDR only in podocytes, the hVDR transgene was able to partially rescue the severe renal damages seen in VDR KO mice in the STZ-diabetic model, manifested by marked reduction in albuminuria and podocyte loss. In podocyte culture exposure to high glucose (30 mM) induced apoptosis with up-regulation of p53, Bad, Bak and p-Erk, and vitamin D treatment blocked this pro-apoptotic pathway and podocyte apoptosis.

Conclusions: Taken together, these data provide strong evidence that vitamin D signaling plays a critical role in the protection of podocytes from diabetic injury.

Cardiac Remodeling and Vitamin D Status in Chronic Kidney Disease: A CRIC Study Bonnie Ky,[2] Justine Shults,[2] Martin Keane,[2] Myles S. Wolf,[3] Harold I. Feldman,[2] Mary B. Leonard.[1] *[1]Childrens Hospital of Philadelphia; [2]University of Pennsylvania; [3]University of Miami.*

Background: Animal studies link abnormal vitamin D metabolism and left ventricular (LV) hypertrophy. The objective was to determine associations between vitamin D levels and LV remodeling in CKD.

Methods: We evaluated 1283 CRIC study participants with vitamin D levels and echocardiography at Year 1 [52% male, 53% Caucasian, 40% African American; median (interquartile range, IQR) age 62 (54-67) yrs, and eGFR 45 (35-55) ml/min/1.73m^2]. Serum 25(OH)D and 1,25$(OH)_2$D were measured by tandem mass-spectrometry and I^{125} RIA, respectively. LV mass index (LVMI) was calculated by the area-length method and volumes by Simpson's method. Linear and logistic regression analyses were used to determine the relations between 25(OH)D and 1,25$(OH)_2$D and echo. LV hypertrophy (LVH) was defined as LVMI >50 in males and >47g/m$^{2.7}$ in females.

Results: The median (IQR) 25(OH)D levels were 32 (23-41) in Caucasians and 18 (11-27) ng/ml in African Americans. The median LVMI was 48.4 in males and 46.1g/m$^{2.7}$ in females. LVH was present in 46% of participants. Lower 25(OH)D levels were significantly associated with greater LVMI in univariate models ($p<0.001$). This remained significant ($p = 0.04$) in multivariable models adjusted for age, sex, race, BMI, eGFR, cardiac disease history, smoking, diabetes, and anti-hypertensive therapy. Compared to a 25(OH)D level ≥20 ng/mL, a level <20 ng/mL was associated with an odds ratio of LVH of 1.36 (95% CI 1.01, 1.84, $p<0.05$) in adjusted models. Lower 1,25$(OH)_2$D levels were associated with greater LVMI in both unadjusted ($p<0.001$) and adjusted analyses ($p=0.03$). Vitamin D levels were not associated with volumes.

Conclusions: These data demonstrate a significant association between lower 25(OH)D and 1,25$(OH)_2$D levels and higher LVMI in CKD.

Figure: LVMI According to 25(OH)D Levels

Calcitriol Promotes Vascular Calcification in Renal Failure through Systemic Rather Than Local Activation of Vitamin D Receptors Koba A. Lomashvili, Faten Hasounah, W. Charles O'Neill. *Renal Division, Emory University, Atlanta, GA.*

Background: Calcitriol promotes vascular calcification in experimental renal failure but it is not known whether this is due to local or systemic activation of vitamin D receptors. This was examined by transplanting aortas from mice lacking the vitamin D receptor (VDR-/-) into wild-type mice.

Methods: Sections of abdominal aorta (5-8 mm) were transplanted from 4 month old VDR-/- mice into 5 wild type (WT) littermates using end-to-end anastomosis. A second group of 8 wild-type animals received abdominal aortic grafts from wild-type littermates and was used as a control. Uremia was induced by feeding powdered chow with 2% phosphorus and 0.6 % adenine, and calcitriol (1 microgram/kg) was given by subcutaneous injection three times per week. After two months, aortas were removed and the calcium contents of the allograft and adjacent native aorta were compared (excluding the suture lines).

Results: Plasma calcium, phosphorus, and urea were 1.9 ± 0.1mM, 2.8 ± 0.3mM, and 68.7 ± 9.1 mg/dl respectively, with no difference between the two groups. Staining of calcium with alizarin red showed no difference between transplanted aortas and native aortas. The ratio of the calcium content in transplanted aortas to that in adjacent native aortas was 2.1 ± 0.74 (mean ± SE) for VDR-/- transplants and 1.5 ± 0.58 for the WT transplants, with no significant difference between the two groups.

Conclusions: Vascular calcification was the same in VDR-/- and wild-type aortas. This indicates that calcitriol promotes vascular calcification through stimulation of systemic rather than local vitamin D receptors.

Mutations in CYP24A1 Encoding Vitamin D-24-hydroxylase Cause Idiopathic Infantile Hypercalcemia Karl P. Schlingmann,[1] Martin Kaufmann,[2] Stefanie Weber,[3] Guenter Klaus,[4] Henry Fehrenbach,[5] Ulrike John,[6] Joachim Misselwitz,[6] Tulay Guran,[7] Joost G. Hoenderop,[8] Rene J. Bindels,[8] David E. Prosser,[2] Glenville Jones,[2] Martin Konrad.[1] *[1]Pediatrics, Wilhelms University, Münster, Germany; [2]Biochemistry, Queen's University, Kingston, Canada; [3]Pediatrics, University of Duisburg-Essen, Essen, Netherlands; [4]KfH Pediatric Kidney Center, Marburg, Germany; [5]Children's Hospital, Memmingen, Germany; [6]Pediatrics, Schiller University, Jena, Germany; [7]Pediatrics, Marmara University, Istanbul, Turkey; [8]Physiology, Radboud University, Nijmegen, Netherlands.*

Background: Vitamin D supplementation during infancy to prevent rickets is one of the most effective prophylactic measures in medicine. Though the margin between prophylactic and toxic doses is broad, an increased incidence of Idiopathic Infantile Hypercalcemia (IIH) was observed in the 1950s during a period of high vitamin D content in fortified milk products in Great Britain. IIH is characterized by severe hypercalcemia, vomiting, dehydration, and nephrocalcinosis. Laboratory evaluation reveals a suppressed PTH and high normal 1,25(OH)2-VitD3 levels.

Methods: In a cohort of familial cases with IIH and suspected autosomal recessive inheritance, we performed an extended candidate gene approach to identify the causative genetic defect.

Results: We detected homozygous or compound-heterozygous mutations in CYP24A1 encoding Vitamin D-24-hydroxylase responsible for the inactivation of 1,25(OH)2-VitD3. CYP24A1 mutations were not only identified in IIH patients given regular 500 IU VitD daily, but also in a second cohort of patients from German Democratic Republic who presented during infancy with suspected VitD intoxication after receiving a bolus prophylaxis of 600.000 IU VitD2 in the late 1980s. The functional analysis of mutant CYP24A1 in a mammalian overexpression system revealed a lack of 24-hydroxylated VitD metabolites after incubation with radioactively labeled 1,25(OH)2-VitD3 indicating a complete loss-of-function.

Conclusions: In conclusion, we not only highlight the role of CYP24A1 mutations as causative for IIH but identify a genetic risk factor for the development of a serious adverse effect of generally advocated VitD prophylaxis.

FR-OR179

Risks of ESRD and Death Following Coronary Revascularization in Individuals with CKD

David M. Charytan,[1] Shuling Li,[2] Charles A. Herzog.[2] *[1]Medicine, Brigham and Women's Hospital, Boston, MA; [2]CVSSC, USRDS, Minneapolis, MN.*

Background: Surgical (CABG) and percutaneous (PCI) intervention revascularization are frequently deferred in individuals with CKD out of concern that they will precipitate ESRD, but reliable estimates of the absolute and relative risks of death and ESRD following PCI and CABG are unavailable.

Methods: Individuals with CKD undergoing PCI (8,620) or CABG (4,547) were identified using the 5% Medicare sample. Long-term outcomes were tracked, and ESRD was identified via linkage to the USRDS. Multivariable Cox regression was used to asses the relative hazards (HR) of death and ESRD.

Results: PCI patients were older, less likely to have heart failure, arrhythmias, anemia, COPD, diabetes, or cerebrovascular disease, and more likely to have a myocardial infarction (P<0.001 for all comparisons). The overall HR for death was lower with CABG than PCI (HR 0.89, P<0.001). Early mortality was higher after CABG, but the HR increasingly favored CABG over time [figure 1]. Results were similar when death was censored for ESRD. Conversely, the risk of ESRD was higher throughout follow-up following CABG (HR 1.18, P=0.04). The absolute incidence of ESRD at 3 years was markedly lower (PCI-3.0%, CABG-3.6%) than the incidence of death (PCI-20.1%, CABG-15.6%). As result, the adjusted HR of the combined outcome of ESRD or death was higher during the first 3 months (HR 1.30, P<0.01) and lower from 6-36 months (HR 0.66, P<0.001.

Conclusions: Among individuals with CKD undergoing coronary revascularization, the incidence of death is much higher than ESRD. The risk of ESRD is lower throughout follow-up with PCI, but the long-term risk of death or combined death and ESRD is lower with CABG. Our data suggest that overall clinical outcomes are better with CABG than PCI in patients with CKD.

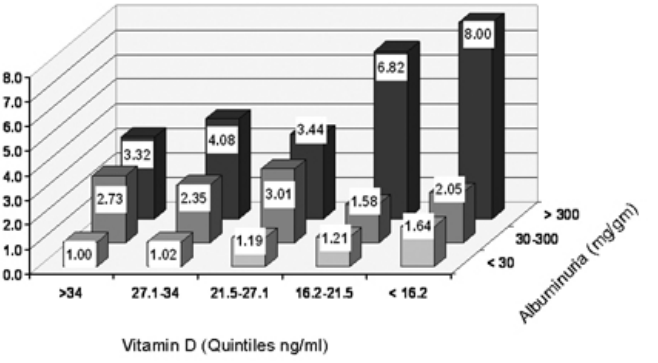
The Impact of Low Vitamin D Levels on Mortality Is Influenced by Urinary Albumin Excretion Rates in Chronic Kidney Disease

Austin G. Stack,[1, 2] Arif I.F. Mutwali,[1] Rajiv Saran.[2] *[1]Regional Kidney Centre, Letterkenny General Hospital, Letterkenny, Donegal, Ireland; [2]Kidney Epidemiology & Cost Center, University of Michigan, Ann Arbor, MI.*

Background: Reduced 25-(OH)-Vitamin D (Vit D) levels and the presence of albuminuria are independent predictors of mortality in chronic kidney disease. The combined impact of these two potentially modifiable risk factors on mortality has to our knowledge not been explored in a population-based cohort.

Methods: We tested this hypothesis in cohort of 13,455 subjects age >= 20 without diabetes or pre-diabetes, and representative of the U.S. population from the Third National Health and Nutrition Examination Survey (1988-1994). Vital status through to 2006 was obtained from linkage with the National Death Index. The interaction of Vit D and albumin/creatinine ratio with mortality was tested. Vit D levels in quintiles [Q1< 16.2, Q2 16.2-21.5, Q3 21.5-27.1, Q4 27.1-34, Q5 > 34 ng/ml] and urinary albumin/creatinine ratio categorized as < 30, 30-300 and > 300 mg/gm was modeled with all-cause and cardiovascular mortality using weighted Cox regression with Q5 Vit D and albumin < 30 as a single referent. Adjustment was made for demographic factors, cardiovascular conditions, hypertension, body mass index, physical inactivity, smoking, CRP, and eGFR

Results: The p-value for interaction was 0.02. The relative mortality risks were significantly greater for subjects in the lowest quintile of Vit D, and for subjects with the highest albumin excretion rates. Subjects who fell into both categories experienced the greatest mortality risks. The patterns of association were similar for CV mortality (data not shown).



Conclusions: Vit D deficiency and albuminuria were synergistically associated with higher mortality risk. Combined strategies to correct these related abnormalities could therefore yield greater benefit than therapy focused on either alone.

FR-OR181

Mortality in Individuals with Acute Coronary Syndrome and CKD: An Analysis of the Myocardial Infarct National Audit Project (MINAP) Database

Catriona Shaw,[1] Sapna Shah,[1] Cornelia Junghans,[1] Donal O'Donoghue,[2] Claire C. Sharpe.[1] *[1]Renal Medicine, King's College London, London, United Kingdom; [2]Salford Royal Foundation Trust, United Kingdom.*

Background: CKD is a recognised risk factor for cardiovascular mortality. Our aim was to assess the mortality risk following acute coronary syndrome (ACS) across all stages of CKD using the UK's MINAP database.

Methods: Data from January 2007 to April 2011 on 94,165 individuals with NSTEMI and 54,824 individuals with STEMI were included in multivariate Cox regression models to investigate the association of eGFR and intervention (CABG/PCI) with mortality and in multivariate logistic regression models to study the association between intervention and eGFR.

Results: eGFR is strongly associated with mortality after adjustment for confounders following ACS (p<0.0001). After NSTEMI, an increase in hazard ratio (HR) for mortality from 1.23 (1.11,1.36) to 3.38 (2.97,3.84) was demonstrated in those that did not receive an intervention as eGFR declined from CKD3a to CKD5 compared to those with CKD1. In those who received an intervention, an increase in HR from 1.68 (1.29, 2.18) to 7.38 (4.50,11.03) was seen across the same eGFR categories.

After STEMI, an increase in HR for mortality from 1.17 (0.99,1.38) to 4.01 (3.21,5.02) in the non-intervention group and an increase in HR from 1.22 (0.99,1.49) to 4.87 (3.24,7.30) in the intervention group was demonstrated as eGFR declined.

Intervention in all stages of CKD demonstrated a survival benefit compared with no intervention (p<0.001). After an NSTEMI, the odds ratio (OR) of receiving an intervention decreased from 0.87 (0.82,0.94) to 0.34 (0.28,0.42) as eGFR declined from CKD3a to CKD5 and from 0.66 (0.61,0.72) to 0.26 (0.20,0.34) in the STEMI population.

Conclusions: eGFR is strongly associated with increased mortality after ACS. The greater increment in risk in individuals with NSTEMI who underwent intervention, likely reflects the increased severity of their cardiac disease. In all stages of CKD, intervention demonstrated a survival benefit. However individuals with increasingly severe renal dysfunction were less likely to receive an intervention compared to those with normal kidney function.

FR-OR182

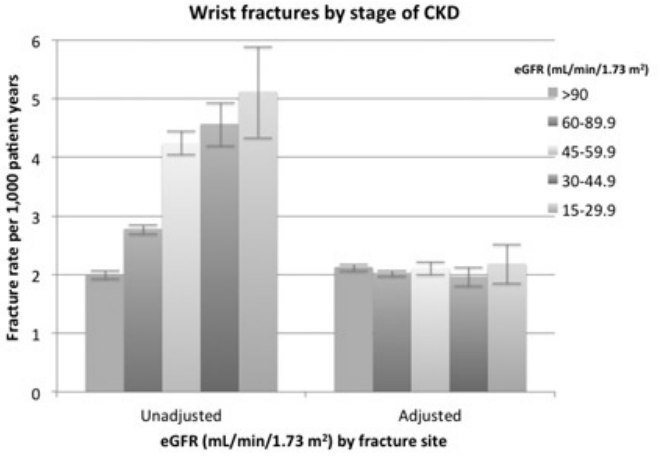
Fracture Risk Is Not Increased in Patients with Chronic Kidney Disease

Meghan J. Elliott,[1] Marcello Tonelli,[2] Braden J. Manns,[1] Gregory Kline,[1] Matthew T. James,[1] Andrea Soo,[1] Brenda Hemmelgarn.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]University of Alberta, Edmonton, AB, Canada.*

Background: In patients with end-stage kidney disease, fractures occur four-times more frequently than in the general population. The incidence of fractures in those with chronic kidney disease (CKD) not receiving renal replacement treatment has not been well-studied.

Methods: We did a population-based longitudinal study with participants aged ≥18 years identified from a province-wide laboratory database from Alberta, Canada between 2002 and 2008. 1,815,957 patients had at least one outpatient serum creatinine measurement and did not require renal replacement therapy at baseline. The eGFR was estimated using the CKD-EPI equation, and categorized as ≥90, 60-89, 45-59, 30-44, 15-29 mL/min/1.73 m². The cohort was linked to administrative data to define demographics, comorbidities and outcomes. Outcomes of non-traumatic incident hip, wrist or clinical vertebral fractures were identified during the follow-up period to March 31, 2009. Poisson regression was used to determine unadjusted and adjusted rates of each fracture outcome by level of eGFR.

Results: The mean (SD) age of patients was 47.7 (17.2) years, and 7.1% had eGFR <60 mL/min/1.73 m². Unadjusted rates of wrist fractures increased at lower levels of eGFR, however, after adjusting for age, sex, diabetes and hypertension, the wrist fracture rate was similar across all eGFR levels. Similar trends in the unadjusted and adjusted results were observed for hip and clinical vertebral fractures.



Conclusions: Lower levels of kidney function are associated with an increased risk of non-traumatic fractures, an association that is primarily related to confounding by age. Future studies of fracture risk should include adjustment for potential confounders, and in particular patient age.

FR-OR183

Effect of IL-1β Inhibition with Canakinumab Compared to Triamcinolone Acetonide on Pain Intensity and New Flares in Gouty Arthritis Patients with Chronic Kidney Disease Stage 2-5 P. Sunkureddi,[1] A. So,[2] T. Bardin,[3] R. Alten,[4] M. Bloch,[5] T. Kiechle,[6] G. Krammer,[6] A. Shpilsky,[7] N. Schlesinger.[8] *[1]Clear Lake Rheumatology Center; [2]University of Lausanne, Switzerland; [3]Hôpital Lariboisière, France; [4]Charité Teaching Hospital, Germany; [5]Holdsworth House General Practice, Australia; [6]Novartis Pharma AG, Switzerland; [7]Novartis Pharmaceuticals Corporation; [8]UMDNJ-RWJMS.*

Background: Many patients with gouty arthritis (GA) have pre-existing comorbidities. Chronic kidney disease (CKD) is one of the most common comorbidities and significantly limits treatment options with standard therapy. Canakinumab, a fully human monoclonal anti-IL-1β antibody, is a potential new therapy for treating GA pain and delaying new flares. We present 24-week data for a subgroup of patients with renal insufficiency.

Methods: In 2 multicenter, double-blind, active controlled studies (β-RELIEVED, N=228; β-RELIEVED-II, N=226), patients, ≥18-≤85 yrs meeting ACR 1977 criteria for acute GA and contraindicated, intolerant or unresponsive to NSAIDs and/or colchicine received canakinumab 150 mg sc or triamcinolone acetonide (TA) 40 mg im. The co-primary endpoints were pain intensity at 72h post dose on a 0-100 mm visual analog scale (VAS) in the most affected joint and time to first new GA flare.

Results: A total of 380 (83.7%) patients had renal impairment (baseline eGFR <90mL/min/1.73m²; corresponding to CKD stages 2-5): 188 (83.6%) canakinumab group and 192 (83.8%) TA group. Mean VAS scores for canakinumab and TA were 73.9mm vs 73.8mm at baseline and 24.4 mm vs 35.3 mm at 72h (Diff: -10.9 mm; 95% CI: -16.1, -5.8, p<0.0001), respectively. The significant difference was maintained up to 7 days. At 24 weeks, significantly fewer canakinumab patients experienced new flares vs TA (25.5% vs 47.4%, OR 0.38, 95% CI 0.25-0.59, p<0.0001). 66.5% of patients had adverse events (AEs) with canakinumab vs 52.6% with TA. Serious AEs (canakinumab: n=15, 8%; TA: n=6, 3.1%) were not considered to be related to treatment by the investigator.

Conclusions: In GA patients with CKD stage 2-5 canakinumab was superior to the TA in reducing pain and the risk of new flares.

FR-OR184

Coronary Artery Calcification and Risk of Cardiovascular Disease among Patients with Chronic Kidney Disease: A Prospective Analysis from the CRIC Study Jing Chen, Matthew Jay Budoff, Muredach Reilly, Wei Yang, Sylvia E. Rosas, Jackson T. Wright, Mahboob Rahman, Eva Lustigova, Lisa C. Nessel, Xiaoming Zhang, Virginia Ford, Dominic S. Raj, Anna C. Porter, Elsayed Z. Soliman, Myles S. Wolf, Jiang He. *Tulane University.*

Background: Vascular calcification is associated with increased cardiovascular disease (CVD) risk and mortality in dialysis patients. However, the predictive value of coronary artery calcification (CAC) on clinical CVD has not been well studied in chronic kidney disease (CKD) patients.

Methods: We examined the prospective association of CAC and risk of CVD events among 1,704 participants who had electron beam computed tomography (EBCT)/ multidetector CT measures in the Chronic Renal Insufficiency Cohort (CRIC) study. Patients aged 21 to 74 years old with an estimated glomerular filtration rate (eGFR) of 20-70 mL/ min/1.73 m² were recruited from 7 clinical centers in the US. CAC was classified as none (0), moderate (>0-100) or severe (>100) according to Agatston scores.

Results: Compared to those without CAC, the patients with moderate and severe CAC had higher event rates (1000 person-years) for myocardial infarction (MI): 1.3, 3.9 and 13.2; congestive heart failure (CHF): 7.8, 13.5 and 30; total CVD: 11.1, 25.8, and 50.2; and all-cause mortality: 3.2, 8.6, and 18.0. After adjusting for age, gender, race, and clinical sites, the hazard ratio (95% confidence interval) associated with moderate and severe CAC was 3.1 (0.6-16.5) and 11.3 (2.4-52.5) for MI; 1.8 (0.8-3.8) and 4.4 (2.2-8.9) for CHF; 2.3 (1.2-4.1) and 4.5 (2.5- 8.1) for total CVD; and 2.2 (0.7- 6.5) and 4.1 (1.5-11.6) for all-cause mortality. After further adjustment for established CVD risk factors including eGFR and history of CVD, severe CAC was only significantly related to MI with a hazard ratio of 6.0 (1.2 -29.5).

Conclusions: These data indicate that CAC provides additional predictive value for the risk of MI in CKD patients.

FR-OR185

A Multi-Centre, Double-Blind, Randomised, Placebo-Controlled, Multiple Fixed-Dose Study of Colestilan (MCI-196) Versus Placebo in Chronic Kidney Disease Stage 5 Subjects on Dialysis (CKD 5D) with Hyperphosphatemia and Dyslipidemia (DL): Efficacy Results Francesco Locatelli,[1] Nada Dimkovic,[2] Goce Spasovski.[3] *[1]Nephrology, Ospedale Manzoni, Lecco, Italy; [2]Zvezdara University Hospital, Belgrade, Serbia; [3]University of Skopje, Macedonia, The Former Yugoslav Republic of.*

Background: Hyperphosphatemia in CKD 5D is associated with increased mortality. Colestilan (COL) is a new non-metallic, non-calcium anionic resin that binds both phosphate (P) and bile acids.

Methods: In this global, 642 patient (100 site) study, after washout of lipid-lowering medication (8 weeks) and P binders (1-4 weeks) subjects received fixed doses of COL (3, 6, 9, 12 or 15 g/day) for 12 weeks or 9, 12 or 15 tablets/day placebo. 99-104 pts were randomised to each dose COL and 132 total to placebo. Primary objectives were to demonstrate efficacy of COL compared to placebo in control of both serum P and serum LDL cholesterol (LDL-C) in subjects with CKD 5D. Secondary objectives were to study the efficacy of COL in control of other lipid parameters, iPTH, serum calcium and safety.

Results: The overall withdrawal rate was 36.1%. After 12 weeks treatment or Last Observation Carried Forward, serum P was reduced from baseline by 0.18 (pooled placebo) and 0.28, 0.72, 0.87 and 1.06 mg/dl in the 3, 6, 9 and the pooled 12+15g/day groups respectively, p<0.05 versus placebo for 6, 9 and 12+15g groups. LDL-cholesterol was raised 4.1% by pooled placebo and reduced by 15.9, 23.6, 27.6 and 27.6% in 3, 6, 9 and pooled 12+ 15g/day groups respectively (p<0.001 versus placebo in all cases). Similarly oxidised LDL-C was significantly reduced in all treated groups. HDL-C, iPTH and serum calcium were not significantly altered. COL produced limited reduction in overall HbA1c but in patients with high baseline HbA1c values (>7%), HbA1c was substantially reduced by up to 1.2%. Uric acid was also reduced significantly by up to 40.9 mcmol/L.

Conclusions: This study suggests that COL is effective as a combined treatment for reducing P and LDL-C in CKD 5D. Significant reductions in high HbA1c and uric acid could offer additional benefits. The safety profile suggested COL to be safe and well-tolerated.

AKB-6548, a Novel Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitor Reduces Hepcidin and Ferritin While It Increases Reticulocyte Production and Total Iron Binding Capacity in Healthy Adults Robert Shalwitz,[1] Charlotte Hartman,[1] Cindy Flinn,[1] Isaiah Shalwitz,[1] Douglas K. Logan.[2] *[1]Akebia Therapeutics, Inc., Cincinnati, OH; [2]Medpace, Inc., Cincinnati, OH.*

Background: Current treatment of anemia associated with chronic kidney disease with erythropoiesis-stimulating agents can lead to unusually sustained, high levels of circulating erythropoietin (EPO). Therefore, a drug that more closely mimics physiologic conditions by replicating more intermittent daily rises in EPO may be a very effective and well-tolerated treatment. AKB-6548, a new short-acting hypoxia-inducible factor (HIF) prolyl hydroxylase inhibitor, was selected to induce daily rises in EPO at a level that closely simulates physiologic responses changes in altitude. This physiologically similar mechanism, which is characterized by stabilization of HIF, is hypothesized to also improve iron mobilization.

Methods: In a double-blind, placebo-controlled Phase 1b study, 33 healthy males were randomized to three treatment groups of 500, 700, or 900mg AKB-6548. In each dosing group, 8 volunteers received AKB-6548 and 3 received placebo once daily for 10 days. Pharmacodynamic response was evaluated on Day 11.

Results: Dosing was generally well tolerated, and the results show a dose-related increase in maximum EPO, reticulocytes, and total iron binding capacity (TIBC), as well as dose-related reductions in hepcidin and ferritin.

Conclusions: From this study, we conclude that AKB-6548 enhances erythropoiesis by inducing controlled increases in EPO production in concert with enhanced iron mobilization and could represent a safer and more effective approach to treating anemia than currently available agents.

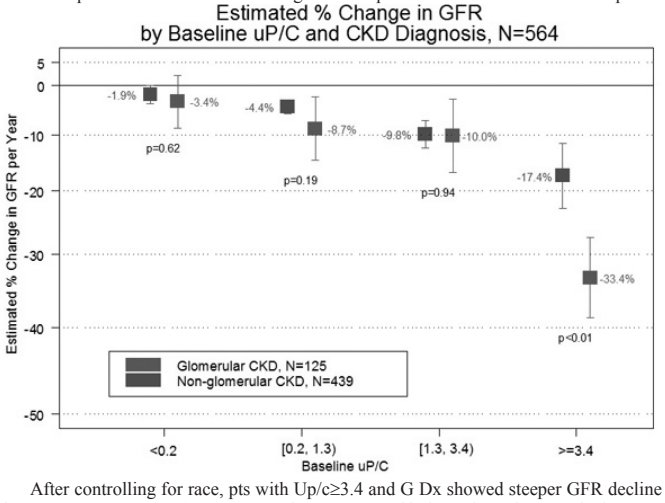
Proteinuria Predicts a Decline in Glomerular Filtration Rate Particularly in African-Americans and Glomerular Chronic Kidney Disease Sahar A. Fathallah-Shaykh,[1] Christopher B. Pierce,[2] Tom D. Blydt-Hansen,[2] Alison G. Abraham,[2] Susan F. Massengill,[2] Bradley A. Warady,[2] Susan L. Furth,[2] Craig S. Wong.[2] *[1]Pediatrics, University of Alabama at Birmingham, AL; [2]CKiD Study.*

Background: Proteinuria is associated with progressive kidney disease. CKiD cohort cross-sectional data revealed a log-linear relationship between proteinuria and glomerular filtration rate (GFR). Here we evaluate a relationship between urine protein-to-creatinine ratio (Up/c) level and prospective changes in GFR

Methods: GFR was measured in the first two visits and then annually by Iohexol blood-disappearance or estimated using the CKiD equation; proteinuria was assayed by first morning baseline Up/c. We used a linear mixed model with random intercept and slope to account for individual variability in baseline GFR and % decline.

Results: 564 CKiD subjects with median age 11 yrs, GFR 44 ml/min/1.73 m^2, and baseline Up/c 0.47 were studied: 62% males, 24% African Americans (AA), 22% glomerular (G) cause CKD, 54% on ACE/ARB. For both non-G and G CKD, GFR % decline increased with rising baseline Up/c; linearly in non-G pts and biphasic in G CKD pts. Those with baseline Up/c≥ 3.4 had GFR decline larger than expected under a linear relationship.



After controlling for race, pts with Up/c≥3.4 and G Dx showed steeper GFR decline than non-G CKD (p<0.01). As compared to non-AA and independent of Dx, AA had steeper decline in GFR beginning at Up/c = 0.2; this disparity increased with higher levels of Up/c. Baseline use of ACE/ARB did not affect GFR.

Conclusions: Up/c level predicts magnitude of future decline in GFR. In pts with G CKD, baseline Up/c is associated with a biphasic rate of decline in GFR, which is accelerated when Up/c≥ 3.4. The effects of Up/c are more pronounced in AA.

FR-OR188

Determinants of Progression of Microalbuminuria in Non-Diabetic Persons from the General Population Marit D. Solbu,[1] Bjorn Odvar Eriksen,[1,2] Trond G. Jenssen.[2] *[1]University Hospital of North Norway, Tromsø, Norway; [2]University of Tromsø, Norway.*

Background: Low-grade albuminuria is a risk factor for chronic kidney disease and cardiovascular disease. Knowledge about predictors and consequences of change in albuminuria over time in non-diabetic populations is incomplete. Our aim was to assess predictors for increase in urinary albumin-creatinine ratio (ACR) in a non-diabetic population.

Methods: From the population based Tromsø study, non-diabetic persons with morning ACR in the upper tertile at least two out of three consecutive days at baseline (1994/1995), and who were attending follow-up (2006/2007), were divided into two groups; upper tertile ("increasers") vs. the two lower tertiles ("non-increasers") of ACR change. Logistic regression was used to assess predictors of being an "increaser".

Results: Among the 6528 non-diabetic baseline participants, 2001 had ACR in the upper tertile in at least two specimens. Between baseline and follow-up, 715 participants died. At follow-up 662 persons participated and were divided into 221 "increasers" (ACR change ≥0.45 mg/mmol) and 441 "non-increasers" (ACR change <0.45 mg/mmol). Baseline predictors of being an "increaser", were age (OR per 5 years 1.26; 95% CI 1.10 – 1.46; P=0.001), gender (OR for men 1.92; 95% CI 1.23 – 2.99; P=0.004), waist circumference (OR per 5 cm 1.12; 95% CI 1.01 – 1.24; P=0.03) and cystatin C (OR per 0.1 mg/L 1.15; 95% CI 1.04 – 1.28; P=0.006). Increase in systolic blood pressure (OR per 10 mm Hg 1.17; 95% CI 1.08 – 1.27; P<0.001), increase in HbA1c (OR per % 1.38; 95% CI 1.04 – 1.84), and increase in cystatin C (OR per 0.1 mg/L 1.16; 1.07 – 1.26; P<0.001) also were significant predictors. Smoking cessation, initiation of antihypertensive medication or physical activity were not significant predictors.

Conclusions: In non-diabetic persons with elevated ACR, gender, age, obesity, increasing glucose and blood pressure predicted further increase in ACR. However, most of the increase was not explained by cardiovascular risk factors. Increasing albuminuria seemed to parallel changes in renal function more closely than changes in cardiovascular risk factors.

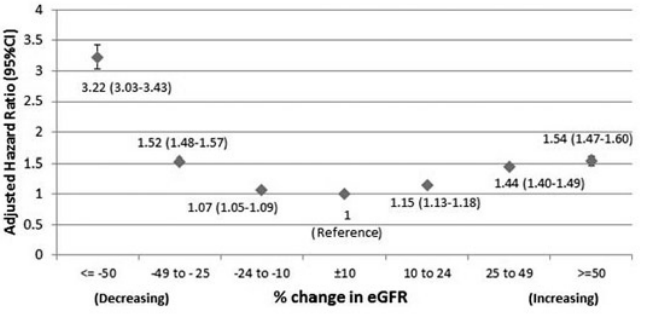
FR-OR189

Association between Change in eGFR and Mortality Tanvir Chowdhury Turin,[1] Josef Coresh,[2] Marcello Tonelli,[3] Paul E. Stevens,[4] Brenda Hemmelgarn.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]Johns Hopkins University, Baltimore, MD; [3]University of Alberta, Edmonton, AB, Canada; [4]East Kent Hospitals University Foundation NHS Trust, Canterbury, Kent, United Kingdom.*

Background: The effect of change in kidney function, in particular the degree of change, and risk of death is not well understood. We aimed to investigate the association between change in eGFR over a one year period and risk of mortality in a community based population.

Methods: We included 843,417 adults who had at least 2 outpatient eGFR measurements in a one-year period, separated by at least two weeks, from a laboratory registry from Alberta, Canada. The percent change in eGFR was calculated using the first and last eGFR within the period. Change in eGFR was categorized as: ≤ -50%; -49 to -25%; -24% to -10%; ±10%; 10 to 24%; 25 to 49%; and ≥50% to reflect both decline and increase in eGFR. Cox hazard models, adjusting for baseline covariates, kidney function and proteinuria, were used to estimate the HR of all-cause mortality (follow-up to March 31 2009) associated with categories of percent change in eGFR. Stable eGFR (change ±10%) was the reference.

Results: Among the participants (mean age 55.6 years, 42% male), 61.2% had stable, 19.9% had an increase and 18.9% had a decline in eGFR. Compared to participants with stable eGFR, those with the largest decline in eGFR (change ≤-50%) had a greater than three-fold increased risk of death.



Participants with moderate declines also exhibited a higher mortality risk, as did participants with the greatest increase in eGFR

Conclusions: Our results demonstrate an independent and graded association between change in kidney function and mortality, with both a decline and increase in kidney function associated with increased risk. These results suggest that overall variation in eGFR over time, rather than decline alone, may be an important prognostic marker.

FR-OR196

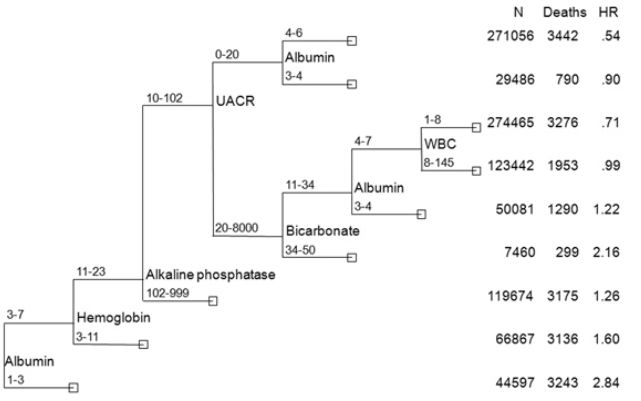
Comparative Effectiveness of Modifiable Risk Factors To Predict Mortality in a Large Cohort of US Veterans with Non-Dialysis Dependent CKD Csaba P. Kovesdy,[1,2] Evan H. Lott,[3] Jun Ling Lu,[4] Sandra M. Malakauskas,[1,2] Jennie Z. Ma,[2] Mark D. Okusa,[2] Kamyar Kalantar-Zadeh.[5] *[1]Salem VA Medical Center; [2]University of Virginia; [3]VA Informatics and Computing Infrastructure; [4]Salem Research Institute; [5]Harbor-UCLA.*

Background: CKD results in the development of multiple metabolic disorders which individually are associated with increased mortality. The head-to-head relative importance of these abnormalities remains unclear.

Methods: We determined the hierarchy of multiple modifiable risk factors (blood pressure, urine albumin/creatinine ratio (UACR), serum albumin, bicarbonate, calcium, alkaline phosphatase, hemoglobin, white blood cell count (WBC) and cholesterol) in predicting all-cause mortality in a nationally representative cohort of 657,614 US veterans with non-dialysis dependent CKD stage 1-5 in 2005-06. The comparative effectiveness of the modifiable risk factors was examined by constructing classification and regression

trees (CART) from time-dependent Cox models adjusted for non-modifiable risk factors of mortality (age, gender, race, marital and insurance status, geographic location and comorbidities).

Results: Patients were 73.9±9.8 years old, 97% were males and 71% were white. 189,565 patients died over a median follow-up of 4.7 years. Of the modifiable risk factors included in the CART model low serum albumin, low hemoglobin, high alkaline phosphatase, high UACR, high bicarbonate and high WBC predicted mortality in decreasing order of significance (Figure).



Conclusions: In a comparative effectiveness model in CKD patients markers of protein-energy wasting, anemia and increased bone turnover appeared to be the most important predictors of mortality, followed by albuminuria. Since these risk factors are readily modifiable, therapeutic interventions targeting them may hold the largest promise of significant benefit towards lowering mortality in CKD.

Comparative Effectiveness of Incident Oral Antidiabetic Drugs on Kidney Function: A National Veterans Cohort Study

Adriana Hung,[1,2] Christianne Roumie,[1,2] Robert Greevy,[2,4] Xulei Liu,[2,4] Carlos Grijalva,[2,3] Harvey J. Murff,[1,2] Talat Alp Ikizler,[1,2] Marie Griffin.[1,2,3] *[1]Medicine, Vanderbilt University, Nashville, TN; [2]Veterans Administration TVHS, Nashville, TN; [3]Department of Preventive Medicine, Vanderbilt University, Nashville, TN; [4]Department of Biostatistics, Vanderbilt University, Nashville, TN.*

Background: Diabetes is a major cause of chronic kidney disease (CKD). Oral antidiabetic drugs (OADs) are the mainstay of therapy for most patients with type 2 diabetes; however, data comparing their effect on kidney function decline are sparse.

Methods: We used national Veterans Administration (VA) databases to assemble a retrospective cohort of 93577 diabetic veterans who filled an incident OAD prescription between 10/1/2001 and 9/30/2008, and had an estimated glomerular filtration rate (eGFR) ≥60 ml/min. Exposure groups were incident users of metformin (n=61104), sulfonylurea (n=30550), or rosiglitazone (n=1923). The primary composite outcome was persistent decline in eGFR from baseline of ≥25% (GFR event) or diagnosis of end-stage renal disease (ESRD). The secondary outcome was an eGFR event, ESRD or death. Sensitivity analyses included 1) using a more stringent definition of eGFR event which required reaching an eGFR<60ml/min in addition to a persistent 25% decline in GFR, 2) controlling for baseline proteinuria, restricted to those with this measurement (n=15065); and 3) not requiring persistent exposure to the initial OAD.

Results: Mean age was 62 (23-97), 78% were whites and 96% were males. Compared with metformin users, sulfonylurea use was associated with an increased risk for both the primary outcome, adjusted hazard ratio (*aHR*) 1.20 (95% confidence interval1.13, 1.28) and the secondary outcome *aHR* 1.20 (95% CI 1.13, 1.28). This association was observed across all planned sensitivity analyses. There was no difference in risk between rosiglitazone and metformin for either the primary *aHR* 0.92 (0.71, 1.18) or the secondary outcome: *aHR* 0.89 (0.69, 1.12).

Conclusions: Compared with metformin, initiation of sulfonylureas is associated with increased the risk of eGFR decline, ESRD or death.

Association of Kidney Function with Abnormal Cardiac Structure and Function by Echocardiography in the Chronic Renal Insufficiency Cohort (CRIC) Study

Meyeon Park,[1] Chi-Yuan Hsu,[1] Yongmei Li,[2] Rakesh Mishra,[2] Martin Keane,[3] Sylvia E. Rosas,[4] Alan S. Go,[5,6] Michael Shlipak.[6] *[1]Nephrology, University of California, San Francisco, CA; [2]Medicine, SF VA Medical Center, San Francisco, CA; [3]Cardiovascular Division, University of Pennslyvania, School of Medicine, Philadelphia, PA; [4]Renal Division, University of Pennsylvania, School of Medicine, Philadelphia, PA; [5]Kaiser Permanente of Northern California, Oakland, CA; [6]Departments of Epidemiology, Biostatistics and Medicine, University of California, San Francisco, CA.*

Background: Heart failure (HF) is a common consequence of chronic kidney disease (CKD) and portends high risk for mortality. The prevalence of abnormalities in cardiac structure and function preceding clinical HF in a community-based population with CKD is not known.

Methods: We evaluated cross-sectionally the association of kidney function with echocardiographically determined stages of cardiac structural and functional abnormalities among 3496 participants in CRIC without a diagnosis of HF. Kidney function was defined by glomerular filtration rate estimated from cystatin C (eGFRcys) (≥ 60 ml/min/1.73m^2, 45-59, 30-44, or <30).

Results: The prevalence of left ventricular hypertrophy (LVH) was 27%, 39%, 44%, and 54% for eGFRcys categories ≥ 60, 45-59, 30-44, and <30 respectively. In fully adjusted multivariate analyses, subjects with eGFRcys levels of <30 ml/min/1.73m^2 had nearly 3-fold odds of LVH (2.8; 1.9-4.1) relative to subjects with eGFR ≥ 60. This reduction in kidney function was also significantly associated with abnormal LV geometry (2.1; 1.6-2.9) and diastolic dysfunction (1.4; 1.1-1.9), but not systolic dysfunction (1.0, 0.6-1.7); an eGFR of 30-44 was also significantly associated with LVH and abnormal LV geometry compared with eGFR≥60.

Conclusions: In this large CKD cohort, reduced kidney function appears to have substantial associations with abnormal cardiac structure, weaker associations with diastolic dysfunction, and no independent association with systolic dysfunction.

Chronic Kidney Disease (CKD) Progression and Death among Hispanics and Non-Hispanics in the Chronic Renal Insufficiency Cohort (CRIC) Study

Michael J. Fischer,[1] Ana C. Ricardo,[1] Wei Yang,[3] Claudia M. Lora,[1] Amanda Hyre Anderson,[3] Lydia Bazzano,[3] Magdalena M. Cuevas,[3] Chi-Yuan Hsu,[3] John W. Kusek,[2] Amada Lopez,[3] Akinlolu O. Ojo,[3] Dominic S. Raj,[3] Sylvia E. Rosas,[3] Leigh Rosen,[3] Valerie L. Teal,[3] Kristine Yaffe,[3] James P. Lash.[1] *[1]Jesse Brown VA/U.Illinois; [2]NIH/NIDDK; [3]CRIC Study Group.*

Background: Despite the high prevalence of end-stage kidney disease (ESKD) in Hispanics, little is known about the earlier stages of chronic kidney disease (CKD) in this group. We compared CKD progression and death in Hispanics and non-Hispanics.

Methods: We conducted a prospective longitudinal analysis of CRIC participants. Race/ethnicity was self-reported and classified in three exclusive categories: Hispanic, non-Hispanic White (NHW), and non-Hispanic Black (NHB). Cox proportional hazards models were used to determine the association between race/ethnicity, 50% eGFR loss or incident dialysis/transplantation (renal outcome), and death.

Results: Among 3785 participants, 13% were Hispanics, 43% NHW, and 44% NHB. Over 3 years of follow up, Hispanics had significantly higher rates of the renal outcome compared with both NHW and NHB (p<0.05) but similar death rates.

	Hispanic (H)*	White (NHW)*	Black (NHB)*	Model 1 HR (H v. NHW)	Model 2 HR (H v. NHW)	Model 1 HR (H v. NHB)	Model 2 HR (H v. NHB)
50% eGFR loss or incident dialysis/ transplantation	10.7	2.7	6.2	2.49**	0.94	1.12	0.63**
death	2.3	1.8	2.3	0.84	0.66	0.68	0.60

*rates per 100 person-years, **p<0.05

In regression models adjusted for sex and gender (Model 1), Hispanic ethnicity was associated with a higher risk of the renal outcome compared with NHW and a similar risk compared with NHB. However, in regression models adjusted for demographics, comorbidities, eGFR, and proteinuria (Model 2), Hispanic ethnicity was associated with a similar risk for the renal outcome compared with NHW and a lower risk compared with NHB.

Conclusions: Although Hispanics have higher crude rates of CKD progression, Hispanic ethnicity is independently associated with similar or lower rates of this outcome relative to non-Hispanic race/ethnicity in CRIC. Disparities in renal outcomes for Hispanics appear to be explained by factors other than race/ethnicity.

FR-OR194

Chronic Kidney Disease and End Stage Renal Disease Predict Higher Mortality in Primary Upper Gastrointestinal Bleed Patients

Puneet Sood,[1] Gagan Kumar,[1] Ankit Sakhuja,[1] Edward A. Ross.[2] *[1]Medical College of Wisconsin; [2]University of Florida.*

Background: The outcome from upper GI bleeding (UGIB) in CKD and ESRD patients is difficult to discern from the older literature of small patient numbers prior to advanced endoscopy, proton pump inhibitors or H. pylori treatment. We sought a large national database to quantify the role of CKD and ESRD as independent predictors of mortality for patients hospitalized with a principal diagnosis of primary UGIB.

Methods: We used the Healthcare Cost and Utilization Project's Nationwide Inpatient Sample (NIS) 2007, the largest US all-payer database publicly available: an administrative dataset for approx. 8 million admissions in 1,000 hospitals approximating a 20% stratified sample of all US hospitals. Patients over 18 years, discharged with primary diagnoses of UGIB and CKD or ESRD were identified by ICD-9-CM codes. The outcome variables included frequency and in-hospital mortality in CKD and ESRD patients as compared to non-CKD patients. We also analyzed the effect of other risk factors and co-morbid conditions on outcomes of primary UGIB and all-cause mortality using multiple regression modeling.

Results: In the NIS dataset, out of a total of 398,213 admissions with a diagnosis of primary UGIB, 35,985 were for CKD patients, 14,983 for ESRD patients and the remaining 347,245 for patients without renal problems. Primary UGIB hospitalizations in CKD and ESRD patients were 30% and 84% higher respectively, compared to no-renal disease group, after controlling for potentially confounding covariates and adjusting for interaction between the independent variables (OR 1.30, 95% CI 1.17-1.46, P< 0.001 and OR 1.84, 95% CI 1.61-2.09, P<0.001). The CKD patients had 47% higher adjusted all-cause in-hospital mortality when compared to the no-renal disease group (OR 1.47, 95% CI 1.21-1.78, P< 0.001). The ESRD patients with UGIB three times higher adjusted all cause mortality as compared to the no-renal disease group (OR 3.02, 95% CI 2.23-4.1, P<0.001).

Conclusions: Patients with CKD or ESRD admitted with primary UGIB have up to three times higher all-cause in-hospital mortality. The clinicians need to be exceptionally vigilant in the care of these renal patients.

FR-OR195

A Varying Patient Safety Profile across Racial Groups with Chronic Kidney Disease

Clarissa Jonas Diamantidis,[1] Stephen L. Seliger,[1] Loreen D. Walker,[3] Van Doren Hsu,[3] Jeffrey C. Fink,[1] Min Zhan,[2] Gail B. Rattinger.[3] *[1]Nephrology, University of Maryland School of Medicine, Baltimore, MD; [2]Epidemiology and Public Health, University of Maryland School of Medicine, Baltimore, MD; [3]Pharmaceutical Research Computing, University of Maryland School of Pharmacy, Baltimore, MD.*

Background: Chronic kidney disease (CKD) is a high risk condition for a variety of adverse safety events yet little is known about differential rates of safety events across racial groups with CKD. We sought to examine the incidence of an array of disease-specific adverse safety events in black versus non-black patients with CKD.

Methods: A retrospective observational study of a national VA cohort of veterans with CKD and race/ethnic designation, and at least 1 hospitalization during federal fiscal year 2005 (n= 70,154). Primary measures included hospital discharge coding for Agency for Healthcare Research and Quality Patient Safety Indicators (AHRQ PSI), laboratory records for detection of hyperkalemia and hypoglycemia, and pharmacy records to determine dosing of four selected medications with potential safety hazards in CKD (atenolol, glyburide, allopurinol, digoxin).

Results: The majority of participants had at least one adverse safety event during the study period (57%, n=40,003). Black veterans (16% of study cohort) were more likely than non-black veterans to experience 1 safety event (33% versus 32%, respectively), and multiple safety events (32% versus 23%, respectively, both < 0.001). After adjustment, black veterans were 21% and 50% more likely to have at least one episode of hyperkalemia or hypoglycemia respectively, than non-black veterans, but were 22% less likely to experience a medication error (all p < 0.001). There was no association between the occurrence of AHRQ PSI and race after adjustment.

Conclusions: Black veterans with CKD are more likely to experience a broad array of safety events than non-blacks with CKD with a preponderance of electrolyte disturbances rather than medication errors or AHRQ PSI. The differential safety phenotype in blacks versus non-blacks may have implications for preventive strategies to improve patient safety in an integrated health system.

Antibiotics in Patients with Severe Chronic Kidney Disease: An Epidemic of Dosing Errors

Alexandra Farag,[1] Amit X. Garg,[1,2,3] Lihua Li,[1] Arsh Jain.[1] *[1]Division of Nephrology, University of Western Ontario, London, ON, Canada; [2]Department of Epidemiology and Biostatistics, University of Western Ontario, London, ON, Canada; [3]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada.*

Background: Antibiotics are frequently misprescribed in patients with chronic kidney disease (CKD) and are implicated in over one third of preventable adverse drug events in these patients. To improve the safety of CKD patients, in January 2006, outpatient laboratories in Ontario, Canada began reporting estimated glomerular filtration rate (eGFR). We sought to describe the rate of ambulatory antibiotic dosing errors in Southwestern Ontario and examine the impact of eGFR reporting on these errors.

Methods: We linked health administrative data for ambulatory residents in Southwestern Ontario from January 2003 to April 2010. Patients had severe CKD (eGFR < 30 ml/min/1.73m^2) and were 66 years of age or older. We conducted a population-based intervention analysis with time-series modeling on the monthly rate of dosing errors.

Results: Of the total 1464 prescriptions filled for study antibiotics throughout the study period, 970 (66%) were dosed in excess of guidelines. Nitrofurantoin, which is contraindicated in patients with creatinine clearance < 60 ml/min, was prescribed 169 times. The initiation of eGFR reporting was not associated with a decline in the rate of antibiotic dosing errors (p =0.85, Figure 1). Prior to eGFR reporting the average rate was 636 per 1000 antibiotic prescriptions; after eGFR reporting, the rate was 680 per 1000 antibiotic prescriptions.

Conclusions: Our findings demonstrate that ambulatory antibiotic dosing errors are exceedingly common among severe CKD patients. Moreover, eGFR reporting has not impacted the rate of these errors at the population level. Further interventions to reduce medication errors in CKD patients may therefore be warranted.

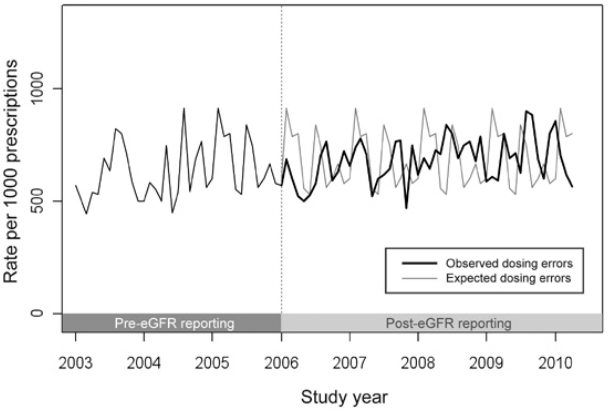

Figure 1. Antibiotic dosing errors among severe CKD patients of Southwestern Ontario.

Beyond Measured GFR: Prognostic Importance of Novel and Traditional Filtration Markers

Navdeep Tangri,[1] Lesley Stevens Inker,[1] Hocine Tighiouart,[1] Eric P. Sorensen,[1] Vandana Menon,[1] Gerald J. Beck,[2] Michael Shlipak,[3] Josef Coresh,[4] Andrew S. Levey,[1] Mark J. Sarnak.[1] *[1]Tufts Medical Center, Boston, MA; [2]Cleveland Clinic, Cleveland, OH; [3]UCSF, San Francisco, CA; [4]Johns Hopkins, Baltimore, MD.*

Background: Decreased GFR is a risk factor for kidney failure, cardiovascular disease (CVD), and all cause mortality. GFR can be estimated from serum creatinine, cystatin C or beta trace protein (BTP). The prognosis related to these filtration markers beyond GFR has not been determined.

Methods: Serum creatinine, cystatin C and BTP were assayed at baseline in 816 participants from the Modification of Diet in Renal Disease Study. GFR was measured using 125-I iothalamate. All markers were transformed to inverse variables and associations were examined per 1 SD to allow standardized comparisons with measured GFR. We examined the association of each filtration marker with kidney failure (dialysis or transplantation), all cause mortality and CVD mortality, in Cox proportional hazards models with and without adjustment for GFR.

Results: The mean (SD) GFR was 33 (12) ml/min/1.73 m2. Median follow up was 16.6 years. In univariate analysis, each filtration marker was associated with a higher risk for all outcomes. After adding GFR to the model, the associations differed among filtration markers. A 1 SD lower 1/Screat was independently associated with a higher risk of kidney failure (HR 1.79, 95% CI 1.54 - 2.08), but a lower risk of all-cause mortality (HR 0.82, 95% CI 0.69 - 0.96). A 1 SD lower 1/Scyc was associated with higher risk of kidney failure (HR 1.62, 95% 1.37 - 1.91), all-cause mortality (HR 1.72, 95% CI1.38 - 2.15) and CVD mortality (HR 1.90, 95% CI 1.37 - 2.63). A 1 SD lower 1/SBTP was associated with higher risk of kidney failure (HR 1.73, 95% CI 1.48 - 2.01), all-cause mortality (HR 1.33, 95% CI 1.10 - 1.61) and CVD mortality (HR 1.24, 95% CI 0.94-1.63).

Conclusions: The risks related to creatinine, cystatin C and BTP are similar for kidney failure, but differ for mortality when GFR is included in the multivariate model. These risks may be due to non-GFR associations of filtration markers or residual confounding due to error in measurement of GFR.

Biochemical Data and Growth in Children with Chronic Kidney Disease: A Report from the Chronic Kidney Disease in Children (CKiD) Cohort Study
Nancy MacDonald Rodig,[1,2] Kelly C. McDermott,[2] Michael F. Schneider,[2] Hilary M. Hotchkiss,[2] Ora Yadin,[2] Frederick J. Kaskel,[2] Susan L. Furth,[2] Bradley A. Warady.[2] *[1]Nephrology, Children's Hospital Boston, Boston, MA; [2]Members of the CKiD Study Group, NIDDK, Bethesda, MD.*

Background: Growth failure is common among children with chronic kidney disease (CKD) and is associated with declining glomerular filtration rate (GFR). However, its relationship to a variety of biochemical parameters is poorly characterized.

Methods: We examined the cross-sectional association of baseline growth parameters (height [Ht] and weight [Wt] age-gender specific standard deviation scores [SDS]) with hemoglobin (Hg), C-reactive protein (CRP), and serum levels of CO_2, phosphate and albumin while adjusting for GFR, CKD cause, recombinant human growth hormone usage, and gender among 430 children (median age: 11 yo; median GFR via plasma disappearance of iohexol: 45 ml/min/1.73m^2) from the CKiD cohort study using two multivariate linear regression models.

Results: The median SDS for Ht and Wt were -0.70 (IQR: -1.42, 0.13) and -0.08 (IQR: -0.94, 0.84), respectively. When compared to children with serum CO2 ≥ 22mEq/L, children with serum CO2 <18mEq/L had heights that were on average 0.56 SDS lower (95% CI: -1.01, -0.10); Wt SDS were similar. Children with serum albumin < 3g/dL had weights that were on average 2.46 SDS lower (95% CI: -4.28, -0.65) than children with albumin ≥ 3 g/dL; Ht SDS were similar. Children with CRP > 10mg/L had SDS for Ht and Wt that were lower than children with CRP between 0.03 and 10mg/L, but the difference was not significant. Higher Hg and elevated phosphate levels (age-based) were associated with non-significantly higher Ht and Wt SDS.

Conclusions: Moderate to severe metabolic acidosis was associated with deficits in height, whereas low serum albumin was associated with severe deficits of weight. Longitudinal analysis of biochemical data in the CKiD cohort will allow further assessment of the risk factors associated with growth failure and targets for intervention in children with CKD.

High NaCl-Induced Nuclear Accumulation of the Osmoprotective Transcription Factor NFAT5 Depends on Binding to Osmotic Response Elements (OREs)
Yuichiro Izumi,[1] Morgan Gallazzini,[2] Maurice B. Burg,[1] Joan D. Ferraris.[1] *[1]NHLBI/SBC, National Institutes of Health, Bethesda, MD; [2]Centre de Recherche Croissance et Signalisation, Institut National de la Sante Et de la Recherche Medicale, Paris, France.*

Background: Nuclear Factor of Activated T-Cells 5 (NFAT5), also called TonEBP/OREBP, induces transcription of osmoprotective genes in response to hyper tonicity. High NaCl causes translocation of NFAT5 from cytoplasm to nucleus. Threonine 298 is a known DNA contact site in NFAT5.

Methods: The effects of mutation of threonine 298 on binding of NFAT5 to its cognate DNA element and its nuclear localization were examined. We measured binding of NFAT5-V5 to OREs by Electrophoretic Mobility Shift Assay (EMSA), using an IR-800 labeled probe and whole cell extracts from HEK293 cells. We measured nuclear localization of NFAT5-V5 by quantitative Western analysis of nuclear and cytoplasmic proteins. We also used confocal microscopy to confirm effects on nuclear localization with NFAT5-GFP in HeLa cells.

Results: Mutating NFAT5-T298 to aspartate (T298D), which introduces a negative charge, inhibited binding to OREs. Specificity of binding of wild type NFAT5-V5 was confirmed with a non labeled probe. High NaCl increases the nuclear to cytoplasmic ratio of wild type NFAT5-V5, but not of NFAT5-T298D-V5. That result was confirmed by confocal microscopy of HeLa cells in which high NaCl increases nuclear localization of wild type NFAT5-GFP, but not of NFAT5-T298D-GFP.

Conclusions: Substitution of a negatively charged amino acid for NFAT5-T298 inhibits both its specific DNA binding and its high NaCl-induced nuclear localization. We suggest that binding to OREs may contribute directly to high NaCl-induced nuclear localization of NFAT5. We are currently investigating possible phosphorylation of NFAT5 at threonine 298.

Vasopressin Receptor Type 2 Membrane Trafficking and Protein Interaction at the Plasma Membrane
Richard Bouley, Matthew J. Webber, Hiroyuki Hosokawa, Sudha Krishnan, Dennis Brown. *Program in Membrane Biology and Nephrology division, Massachusetts General Hospital, Boston, MA.*

Background: Cell membrane water permeability increases due to vasopressin-induced accumulation of the water channel, AQP2, at the plasma membrane of kidney principal cells. Activation of the vasopressin type 2 receptor (V2R) by VP is terminated by the downregulation of V2R. In contrast to the V2R downregulation mechanism, events taking place at the cell surface following ligand binding are still elusive.

Methods: We used total internal reflection fluorescence (TIRF) microscopy to study V2R trafficking at the cell surface prior to endocytosis.

Results: Under basal conditions, green fluorescent protein tagged V2R (V2R-GFP) is very mobile, moving randomly in all directions with erratic velocity, but with an average speed of movement of 0.2 μm/sec in human embryonic kidney cells. In the presence of our newly developed fluorescent VP ligand (VP-TMR), the average speed of V2R-GFP movement was reduced to an average of 0.1 μm/sec. During its time at the cell surface, TIRF and subsequent fractionation and western blot analysis revealed that the V2R moves rapidly through lipid raft domains. Next, the VP-TMR-receptor complex is immobilized in specific structures that recruit beta arrestin-GFP and then clathrin-GFP, confirming the role of clathrin-coated pits in V2R internalization. Cell fractionation and western blot analysis showed that internalized VP-V2R moves from light vesicles to heavier vesicles along with β-arrestin. We also observed a similar pattern of distribution of the Gs alpha subunit (Gs) protein, which despite being in the same membrane domains as the V2R, did not seem to interact directly with the receptor by immunoprecipitation. In contrast, immunoprecipitated c-myc tagged V2R expressed in HEK cells co-IP'd with β-arrestin .

Conclusions: This result suggests that cell surface mobility of the V2R is reduced by ligand binding, and that V2R is then immobilized in specific membrane domains along with proteins that may or may not interact directly with the receptor, but that are involved in its trafficking and/or signaling after VP binding and subsequent internalization.

Genetic Ablation of Aquaporin-2 in the Mouse Connecting Tubules Results in a Mild Urinary Concentrating Defect
Marleen L.A. Kortenoeven,[1] Nis B. Pedersen,[1] R. Lance Miller,[2] Raoul D. Nelson,[2] Robert A. Fenton.[1] *[1]Department of Biomedicine, Faculty of Health Sciences, Aarhus University, Aarhus, Denmark; [2]Division of Nephrology, Department of Pediatrics, University of Utah, Salt Lake City.*

Background: Body water balance is regulated in the kidney via the vasopressin (AVP) regulated water channel aquaporin-2 (AQP2) expressed in the connecting tubule (CNT) and the collecting duct (CD). Although crucial for the urinary concentrating mechanism, the relative role of AQP2 in the CNT and CD are not fully understood.

Methods: To study the role of AQP2 in the CNT we generated and characterized a mouse model with a CNT-specific knock-out of AQP2.

Results: Confocal immunofluorescence microscopy of kidney sections demonstrated an absence of AQP2 immunolabeling in the CNT of the knock-out animals. 24 hour urine output was significantly increased (KO: 3.0 ± 0.3 mL/20 g BW versus WT: 1.9 ± 0.3 mL/20 g BW) and urine osmolality decreased (KO: 1179 ±107 mOsm/kg versus WT: 1790 ±146 mOsm/kg) in knock-out mice compared to controls. After a 24 hour water restriction, urine volume was decreased in both groups, while urine osmolality was increased. Urine osmolality was still significantly lower in knock-out mice (KO 2087 ±169 mOsm/kg versus WT: 2678 ±144 mOsm/kg), although 24 hour urine output was not significantly different between groups. A significant difference in urine osmolality before intraperitoneal injection of dDAVP (KO: 873 ± 129 versus WT 1387 ± 163 mOsm/kg) was no longer observed 2 hours after injection, where urine osmolality had increased significantly from baseline in both groups (KO: 2944 ±41; WT 3133 ±66 mOsm/kg). Immunoblotting demonstrated a significant decrease in AQP2 abundance in cortical kidney fractions with no compensatory changes in the AVP-regulated transporters NKCC2, AQP3 and AQP4.

Conclusions: In conclusion, we have demonstrated that deletion of AQP2 from the CNT results in a mild urinary concentrating defect, without diminished maximal urinary concentrating ability. Our studies suggest that the CNT plays a minor role in regulation of whole body water balance, or that dysfunction of the CNT can be compensated for by increased water reabsorption in the collecting duct.

FR-OR202

Inhibition of GSK3α Is Critical for Lithium-Induced NDI
Reena Rao,[1] Line Nilsson,[2] Raymond C. Harris,[1] Rikke Norregaard.[2] *[1]Nephrology, Vanderbilt University Medical Center, Nashville, TN; [2]Institute of Clinical Medicine, Aarhus University, Aarhus, Denmark.*

Background: Glycogen synthase kinase 3 (GSK3) is a protein kinase, which occurs in two isoforms, 3α and 3β. Lithium (Li), a potent inhibitor of GSK3 and a treatment for bipolar disorders, causes nephrogenic diabetes insipidus (NDI) in up to 40% of patients. In previous studies using renal collecting duct (CD) specific GSK3β knockout mice (3β-CDnull), we showed that GSK3β deletion reduced CD's response to vasopressin. However, these mice did not become polyuric when treated with Li. Hence, to compare the isoform specific roles of GSK3α and GSK3β in renal urine concentration and Li induced NDI, we used wild type (WT), 3β-CDnull, GSK3α global knockout (3α-/-) and 3α+/-/3β -CDnull mice.

Results: Our attempts to make a CD specific total knockout of both α and β isoforms resulted in total renal agenesis. The 3β–CDnull, 3α-/- and GSK3α+/-/3β-CDnull mice showed normal development. Baseline urine output in 3α-/- and 3α+/-/3β-CDnull mice was 2-fold higher than WT, accompanied by reduced urine osmolality and aquaporin 2 levels. Though 3β–CDnull mice showed 48% increase in urine output compared to WT, their urine osmolality and AQP2 levels were not different. To examine if renal GSK3 is the target for Li, mice were treated with lithium chloride (4mmol/Kg, daily IP injection). By day 9 of Li treatment, urine output increased by 7 fold and osmolality decreased by 3-fold in WT mice compared to their baseline levels. 3β-CDnull mice also showed a 3-fold increase in urine output and a 22% decrease in urine osmolality. In comparison, the 3α-/- and 3α+/-/3β-CDnull mice did not show any significant change in urine volumes or osmolality.

Conclusions: These studies show for the first time that GSK3 is critical for renal development and that 3α and 3β isoforms compensate for each other. Also, GSK3α may play a more important role in renal urine concentration than GSK3β because: 1) at basal levels GSK3α deletion caused higher urinary concentrating defect and polyuria compared to GSK3β; and 2) GSK3α, rather than GSK3β, is a critical target for Li.

Pharmacological Blockade of $P2Y_{12}$ Receptor Ameliorates Lithium-Induced Polyuria in Rats

Bellamkonda K. Kishore,[1] Ioana L. Pop,[1] Noel G. Carlson,[2] Yue Zhang.[1] *[1]Medicine, Nephrology, VAMC & Univ of Utah; [2]Neurovirology & GRECC, VAMC & Univ of Utah, Salt Lake City, UT.*

Background: Previously, we showed the potential involvement of ATP/UTP/UDP-activated $P2Y_2$ or $P2Y_4$ receptors in a rat model of lithium (Li)-induced polyuria, and observed that genetic deletion of $P2Y_2$ receptor results in significant resistance to Li-induced polyuria. In contrast, $P2Y_{12}$ receptor ($P2Y_{12}$-R) is an ADP receptor expressed predominantly in blood platelets, and in the brain (microglia and astrocytes). Stimulation of $P2Y_{12}$-R also inhibits adenylyl cyclase. We discovered that $P2Y_{12}$-R mRNA and protein are expressed in rat kidney, and pharmacological blockade of $P2Y_{12}$-R with clopidogrel bisulfate (Plavix®) results in increased urinary concentration in rats, independent of $P2Y_2$ receptor (companion abstract). Here we document that pharmacological blockade of $P2Y_{12}$-R with Plavix® significantly ameliorates Li-induced polyuria in rats.

Methods: Groups of rats were fed normal (ND) or Li-added (LD; 40 mmol/kg food) diets with free access to drinking water and with/without added Plavix® (20 mg/kg/day in water) for 14 days, and then euthanized. Water intake and urine output were monitored and kidney tissue was analyzed.

Results: Co-administration of Plavix® resulted in significant improvement in: 1) Li-induced polyuria ($P < 0.01$) and polydipsia ($P < 0.001$), and decreased urinary concentration ($P < 0.05$); and 2) effectively reversed Li-induced increased solute-free water excretion ($P < 0.01$). These changes in whole body water metabolism were matched with a significant improvement in Li-induced decrease in APQ2 water channel in the inner medulla (2-fold difference; $P < 0.04$). Co-administration of Plavix® also significantly augmented Li-induced urinary AVP levels (1.7-fold vs. Li alone group; $P < 0.05$). The observed effects of Plavix® were not due to a reduction in blood Li levels or kidney medullary accumulation of Li. Finally, co-administration of Plavix® significantly improved Li-induced polyuria in mice also.

Conclusions: Taken together, these data unravel the potential therapeutic utility of drugs that target $P2Y_{12}$-R to ameliorate Li-induced polyuria and possibly, other forms of acquired nephrogenic diabetes insipidus.

Vasopressin V1a Receptor Is Required for Nucleocytoplasmic Transport of Mineralocorticoid Receptor

Takanori Nagai,[1] Kahori Hori,[1] Yuichiro Izumi,[2] Yukiko Hasuike,[1] Yushi Nakayama,[3] Yoshinaga Otaki,[1] Masayoshi Nanami,[1] Takahiro Kuragano,[1] Katsumasa Kawahara,[4] Akito Tanoue,[5] Takeshi Nakanishi,[1] Hiroshi Nonoguchi.[1] *[1]Division of Kidney and Dialysis, Int Med, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; [2]Epithelial Sysytems Biology Laboratory, NHLBI, National Institutes of Health, Bethesda, MD; [3]Nephrology, Kumamoto University, Kumamoto, Kumamoto, Japan; [4]Physiology, Kitasato University Sch Med, Sagamihara, Kanagawa, Japan.*

Background: Type 4 renal tunbular acidosis (RTA) is caused by insufficient aldosterone action. We reported that the dificiency of vasopressin V1a receptor resulted in type 4 RTA by decreasing the expressions of H,K-ATPase and Rhcg and by increasing the expression of H-ATPase in the intercalated cells of the collecting ducts. We investigated the mechanisms of regulation of aldosterone action by vasopressin in the intercalated cells.

Methods: Mice lacking V1a receptor and the cell line of intercalated cells (IN-IC cells) from SV40 Tg rat were used in this study. V1a receptors in the IN-IC cells were knocked down by siRNA and the effects of aldosterone and vasopressin on the nuclear translocatoin of mineralocorticoid receptor (MR) was examined by Western blot. Immunohistochemistry of MR expression in IN-IC cells was also examined.

Results: Fludrocortisone stimulated MR and 11βHSD2 expression in wild type imce and those effects were largely depressed in the V1aR dificient mice. Aldosterone dose-dependently increased MR expression in whole IN-IC cells. Aldosterone decreased cytoplasmic and increased nuclear expression of MR after 30 min and 24 hr. Immunohistochemistry revealed nuclear expression of MR after 30 min and 24 hr stimulation by aldosterone. Vasopressin mimicked the effects of aldosterone on the nuclear expression of MR, and knockdown of V1a receptor abolished the effects of aldosterone. Although vasopressin stimulated PKC α and β1 expressions, aldosterone stimulated not PKC α and β1 but PKC ζ expressions.

Conclusions: Our data show that vasopressin regulates nucleocytoplasmic transport of MR and aldosterone requires vasopressin V1a receptor for nucleocytoplasmic transport of MR.

Microtubule Remodeling by Hyperosmotic Stress

Udo Hasler,[1] Paula Nunes,[1] Isabelle Roth,[1] Thomas Ernandez,[1] Richard Bouley,[2] Dennis Brown,[2] Eric Feraille.[1] *[1]Department of Cellular Physiology and Metabolism, University of Geneva, Switzerland; [2]Program in Membrane Biology/Nephrology Division, Harvard Medical School, Boston, MA.*

Background: Acute increase of extracellular osmolyte concentration is a common challenge that induces cell shrinkage and increases intracellular ionic strength, Cell survival depends on intracellular trafficking events that help restore cell volume and eliminate protein damage. Microtubules (MT), together with actin filaments, play an outstanding role in membrane trafficking. While effects of hyperosmotic stress on actin structure is well described its effect on MTs is unknown. The aim of this study was to examine whether hyperosmotic stress affects MT structure and behavior and the consequences that such changes may impart on actin structure and vesicle motility.

Methods: We examined MT and actin remodeling in porcine proximal LLC-PK1 cells before and after hyperosmotic challenge (NaCl or urea 500 mOsmol/kg) by tubulin immunostaining, phalloidin microscopy, Western blot analysis of free and polymerized tubulin and actin and live cell imaging of actin, tubulin and end-binding protein 1, a MT plus-end binding factor. Motility of endosomes loaded with FITC-dextran was examined by live cell imaging and analyzed using ImageJ software.

Results: Data shows that MTs are immediately immobilized by hyperosmotic stress and that this is accompanied by their dramatic depolymerization and subsequent repolymerization. A comparison between events induced by hyperosmotic stress and chemicals that interfere with MT and actin polymerization revealed that while MT remodeling participates in triggering actin polymerization MT depolymerization, more specifically, reduces spatial movement patterns of F-actin networks. MT remodeling and altered actin behavior both contribute to endosome paralysis during early phases of challenge. Endosome motility recovers as cytoskeletal remodeling matures, during and well after cell volume is restored.

Conclusions: These data link changes of cell volume by hyperosmotic stress to cytoskeletal remodeling and demonstrate ensuing consequences on endosome motility.

miR-148b Upregulation Modulating Core 1, β1,3-Galactosyltransferase 1 Expression Explains the Abnormal Glycosylation Process of IgA1 in IgA Nephropathy

Grazia Serino,[1,2] Fabio Sallustio,[1,2] Sharon N. Cox,[1] Francesco Pesce,[1] Francesco Paolo Schena.[1,2] *[1]Nephrology, Dialysis and Transplantation Unit, Department of Emergency and Organ Transplantation, University of Bari, Bari, Italy; [2]C.A.R.S.O. Consortium, Valenzano (Ba), Italy.*

Background: IgA nephropathy (IgAN) is the most common form of primary glomerulonephritis worldwide characterized by aberrant O-glycosylation in the hinge region of IgA1 involving the enzyme core 1, β1,3-galactosyltransferase 1 (C1GALT1). To date, the role of microRNAs (miRNAs) in the IgAN pathogenesis has not yet been reported.

Methods: Global miRNA profile of peripheral blood mononuclear cells (PBMCs) from IgAN patients and healthy subjects (HS) were identified using miRNA microarrays V2 Agilent. To study the molecular mechanisms in which the miRNAs were involved, we performed a bioinformatic analysis to predict target genes of the modulated miRNAs. To validate biologically miRNA targets, we performed transient transfection experiments ex vivo using PBMCs from an independent group of IgAN patients and HS.

Results: We identified 37 miRNAs differentially expressed in IgAN patients. Among them, upregulated miR-148b targeted C1GALT1, involved in abnormal glycosylation processes. C1GALT1 expression levels in IgAN patients were reduced and negatively correlated with the miR-148b expression. We demonstrated that miR-148b decreased the C1GALT1 levels in IgAN patients and that the loss of function of miR-148b in PBMCs led to an increase of C1GALT1 mRNA and protein levels similar to that observed in HS. Moreover, we showed that the upregulation of miR-148b directly correlated with the galactose-deficient (Gal-deficient) IgA1 levels supporting our data on C1GALT1 regulation by miR-148b and explaining the abnormal increase of Gal-deficient IgA1 consequent to higher miR-148b levels in IgAN patients. Finally, we validated the upregulated miR-148b in a population of 50 IgAN patients and 50 HS.

Conclusions: All together our data support the unreported role of miRNAs in the pathogenesis of IgAN by discovering the deregulation of miR-148b, which could explain the aberrant glycosylation of IgA1 and provide a potential pharmacological target for new therapeutic approaches in IgAN.

FR-OR207

Genetic Basis for Disease Severity in a Mouse Model of MPO ANCA Glomerulonephritis

Dominic J. Ciavatta,[1,2] Hong Xiao, David L. Aylor,[2] Peiqi Hu, Fernando Pardo-Manuel de Villena,[2] Ronald J. Falk,[1,3] J. Charles Jennette.[1,3] *[1]UNC Kidney Center, University of North Carolina at Chapel Hill, NC; [2]Genetics, University of North Carolina at Chapel Hill, NC; [3]Pathology and Laboratory Medicine, University of North Carolina at Chapel Hill, NC.*

Background: Differences in disease severity among ANCA vasculitis patients may arise from genetic variability. Using a mouse model of MPO ANCA disease we tested the hypothesis that ANCA disease severity is genetically determined.

Methods: After i.v. injection of mouse anti-MPO IgG, glomerular crescents were measured in 4 inbred mouse strains: C57BL/6J, 129S6, 129S1/SvImJ, and LP/J. Genetic variation among the inbred strains was determined with the Mouse Diversity Array high-density genotypes. Genomic clustering of identical genotypes was performed to identify regions that are identical by descent (IBD). Glomerular crescents were also measured in a cohort of 100 mice from a C57BL/6Jx129S6 F2 population.

Results: The average percent glomerular crescents in each of the inbred strains ranged from 9% in C57BL/6 to 64% in 129S6, with 129S1/SvImJ and LP/J having 21% and 20% glomerular crescents, respectively. In the F2 mice the % glomerular crescents spanned the range observed in C57BL/6 and 129S6 mice. The C57BL/6J strain is IBD with each of the other three strains over a modest 28% of the genome and the LP/J strain is 72-74% IBD with the 129 substrains. Surprisingly, the 129 substrains, which have striking phenotypic differences, are IBD over 96.7% of their genome.

Conclusions: Differences in percent glomerular crescents among the 4 inbred strains of mice indicate that ANCA disease severity is genetically determined, and the distribution among F2 mice indicates the trait is polygenic. The IBD analysis between the 129 substrains reduced the fraction of the genome that contains candidate loci for ANCA disease severity to 90.8 Mb or 3.3% of the genome distributed among 15 regions. Mapping quantitative trait loci in the F2 population may corroborate one of the 15 candidate regions or identify additional modifier loci.

FR-OR208

The Role of C5a Receptors (C5aR and C5L2) and C6 in the Pathogenesis of Glomerulonephritis Induced by Myeloperoxidase (MPO) Specific Antineutrophil Cytoplasmic Autoantibodies (ANCA) Hong Xiao,[1] Bao Lu,[2] Peiqi Hu,[1] Ronald J. Falk,[1,3] Craig Gerard,[2] J. Charles Jennette.[1,3] *[1]Pathology and Laboratory Medicine, University of North Carolina, Chapel Hill, NC; [2]Pediatrics, Childrens Hospital, Boston, MA; [3]Kidney Center, University of North Carolina, Chapel Hill, NC.*

Background: Anti-mouse MPO IgG causes GN in mice that mimics human ANCA GN. Alternative pathway complement activation is required for GN induction. C5a appears to mediate GN by chemotactic recruitment and priming of neutrophils for activation by ANCA. Engagement of C5a receptor (C5aR) is an important pathogenic event. The role of C5b and full MAC formation in anti-MPO GN has not been determined. We investigated the pathogenic roles of C6, C5aR and C5L2 (an alternative receptor for C5a).

Methods: Induction of GN was assessed after injection of 50mg/kg anti-MPO IgG into control B6 (n=7) or C3H/HeJ (n=5) wild type (WT), C3H C6-/- (n=5), B6 C5-/- (n=6), B6 C5aR-/- (n=6), or B6 C5L2-/- (n=7) mice. Mice were sacrificed at day 6 .

Results: C6-/- mice that received anti-MPO developed GN with % glomeruli with crescents (4.2%) similar to WT mice (5.2%, p=0.63). C5-/- mice that received anti-MPO developed no lesions. Only 1 of 5 C5aR-/- mice developed 1% crescents while the other 4 had no crescents. C5L2-/- mice developed more severe crescents (18.0%) compared to WT mice (8.14%, p=0.0035).

Conclusions: Absence of C6 has no effect on induction of anti-MPO GN, thus C5bC6 and MAC formation are not required. Absence of C5 and of C5aR abrogate induction of GN whereas absence of C5L2 enhances induction of GN by anti-MPO. Thus, engagement of C5aR has a pro-inflammatory effect whereas engagement of C5L2 has an anti-inflammatory effect. More severe disease in C5L2-/- mice is in line with observation that C5L2-/- mice have neutrophils with increased response to C5a (J Biol Chem 2005;280:39677). C5L2 may function as a decoy receptor reducing availability of C5a or by dominant-negative signaling that counteracts pro-inflammatory signaling from C5aR. Antagonists of C5, C5a or C5aR, but not of C6 or C5L2, may have therapeutic benefits in ANCA disease.

Renal IL-17 Expression in Human ANCA-Associated Glomerulonephritis Joachim Velden,[1] Hans-Joachim Paust,[2] Elion Hoxha,[2] Jan-Eric Turner,[2] Saskia Schröder,[2] Ursula Kneissler,[1] Oliver M. Steinmetz,[2] Erik M. Disteldorf,[2] Hans-Willi Mittrücker,[3] Rolf A. Stahl,[2] Udo Helmchen,[1] Ulf Panzer.[2] *[1]Inst. f. Pathologie, Nierenregister, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]III. Med. Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [3]Inst. f. Immunologie, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: Interleukin-17A (IL-17) promotes inflammatory renal tissue damage in mouse models of crescentic glomerulonephritis (GN) including murine experimental autoimmune anti-MPO GN, which most likely depends on IL-17 producing Th17 cells. In human ANCA-associated GN (ANCA-GN), however, the cellular sources of IL-17 remain to be elucidated.

Methods: We studied IL-17 expression in human kidney biopsies of acute necrotizing and crescentic ANCA-GN (n=20) by immunohistochemistry and immunofluorescence co-localization analysis. Further, we measured IL-17 levels in lysates and supernatants from purified human blood leukocytes by ELISA.

Results: Numerous IL-17 expressing (IL-17+) cells were detected in acute ANCA-GN biopsies, specifically in glomeruli with capillary necroses or cellular crescents and in the periglomerular as well as peritubular interstitium. Most of these IL-17+ cells (>80%) were MPO+ polymorphonuclear neutrophilic granulocytes. The small remaining fractions of IL-17+ mononuclear cells were tryptase+ mast cells and unexpectedly low numbers of CD3+ T cells (Th17). IL-17 was not detectable in other infiltrating or resident kidney cells. In vitro, purified human neutrophils were capable to release significant amounts of IL-17 upon stimulation.

Conclusions: We have shown that neutrophils are the numerically most abundant IL-17+ cell type in human kidneys affected by acute ANCA-GN, by far outnumbering IL-17+ mast cells and T cells, and that neutrophils can release IL-17 in vitro. Together, our findings suggest that neutrophils may contribute significant amounts of IL-17 to the sites of glomerular and tubulointerstitial inflammation in human ANCA-GN.

Etanercept Delays the Progression of Alport Glomerulosclerosis by Preventing Tumor Necrosis Factor-Driven Loss of Podocytes Hans J. Anders,[1] Mi Ryu,[1] Shrikant Ramesh Mulay,[1] Oliver Gross.[2] *[1]Department of Nephrology, Universitiy of Munich, Munich, Germany; [2]Department of Nephrology and Rheumatology, Georg August University Göttingen, Göttingen, Germany.*

Background: Chronic renal failure involves the progressive loss of renal parenchymal cells. For example, Alport nephropathy develops from mutated type IV collagen which fosters the digestion of the GBM and podocyte loss, followed by progressive glomerulosclerosis. We found that Alport nephropathy in Col4a3-deficient mice is associated with an increased intrarenal expression of the proapoptotic cytokine tumor necrosis factor-alpha (TNF-α) in glomerular cells, particularly in podocytes as well as in infiltrating leukocytes. We therefore hypothesized that TNF-α contributes to Alport glomerulosclerosis by inducing podocyte apoptosis.

Methods: We treated 4 week old Col4a3-deficient mice on a 129/SvJ genetic background either with vehicle or the TNF-α antagonist etanercept, or an equivalent dose of human IgG as a control intraperitoneally for a period of 5 weeks. Lifespan was monitored and renal pathologic evaluations were performed (e.g. immunohistochemistry, TUNEL, FACS, electron microscopy, real time-RT-PCR, western blot, and functional assessment).

Results: Etanercept treatment prolonged mean survival compared to vehicle-treated Col4a3-deficient mice (p=0.0016). The beneficial effect of etanercept on survival was associated with a significant improvement of the glomerulosclerosis score, renal function (proteinuria, plasma creatinine, and BUN) and the glomerular filtration rate (GFR) at 9 weeks of age. Etanercept treatment specifically improved the numbers of glomerular podocytes (WT-1 and nephrin co-staining) and significantly increased the renal mRNA expression of nephrin and podocin without affecting markers of renal inflammation. The increased number of podocytes was consistent with less TUNEL-positive podocytes that undergo apoptosis.

Conclusions: Together, we concluded TNF-α-induced podocyte loss via apoptosis is a previously unrecognized pathomechanism of Alport nephropathy; hence, TNF-α blockade might be a therapeutical option to delay the progression of Alport nephropathy and potentially of other forms of glomerulosclerosis.

FR-OR211

Podocyte-Specific Inhibition of Signal Transducer and Activator of Transcription (STAT) 3 Attenuates Nephrotoxic Serum-Induced Glomerulonephritis Yan Dai,[1,2] Michael J. Ross,[1] John C. He,[1] Peter Y. Chuang.[1] *[1]Dept of Medicine, Div of Nephrology, Mount Sinai School of Medicine, New York, NY; [2]Medicine, Div of Nephrology, Shanghai First Affiliated Hopsital, Shanghai, China.*

Background: STAT3 activation correlates with cell proliferation in Bowman's space and renal injury in glomerulonephritis (GN). Podocytes are involved in the formation of cellular crescents in GN. We hypothesize that STAT3 activation in podocytes causes the development of GN.

Methods: To test our hypothesis mice with podocyte-specific Cre recombinase-mediated excision of exons encoding for the SH2 domain of the STAT3 allelle (Cre F/F), which is required for STAT3 activation, were generated. Cre F/F and control littermates (Cre +/+) were generated by crossing Cre F/+ mice. GN was induced by tail vein injection of a sheep anti-mouse glomerular basement membrane antibody (NTS). Mortality was monitored. Urine, serum, total kidney, and isolated glomeruli were collected.

Results: Cre F/F lack renal phenotype and are born with the expected Mendelian frequency. Podocyte-specific deletion of the SH2 domain of STAT3 was confirmed by PCR using primers flanking the excised exons and DNA extracted from isolated glomeruli. Suppression of STAT3 signaling in Cre F/F mice was confirmed by a reduction of STAT3 phosphorylation at Y705. NTS induced a significant increase in albuminuria in Cre +/+, but not in Cre F/F (1.07+/-0.20 vs 0.20+/-0.02 g albumin/g creatinine, 8d post injection). Proteinuria correlated with glomerular deposition of mouse and sheep IgG. BUN of NTS-injected Cre +/+ mice was higher than NTS-injected Cre F/F mice (68.95+/-9.91 vs 21.90+/-4.30 mg/dl, 14d post injection). NTS failed to activate STAT3 in Cre F/F mice as demonstrated by reduced phospho-STAT3 (Y705) immunostaining. NTS-injected Cre F/F have preserved nephrin and synaptopodin immunostaining. NTS increased the glomerular expression of STAT3 target genes (ICAMI and MCP1) in Cre +/+, but not Cre F/F mice.

Conclusions: STAT3 activation in podocytes is required for the development of renal injury in NTS-induced GN. Additional studies to examine the underlying mechanism of STAT3 are needed. Inhibition of STAT3 activation is a potential therapeutic option for GN.

Podocyte Injury Specific Microangiopathy in Collapsing FSGS; the Role of PAI-1 and the Beneficial Effect of Its Inhibitor TM5484 Namiko Kobayashi,[1] Toshiharu Ueno,[1] Toshio Miyata,[2] Taiji Matsusaka,[3] Michio Nagata.[1] *[1]Department of Pathology, University of Tsukuba, Ibaraki, Japan; [2]United Centers, Tohoku University School of Medicine, Sendai, Miyagi, Japan; [3]Internal Medicine, Tokai University School of Medicine, Isehara, Kanagawa, Japan.*

Background: We previously established transgenic model of podocyte-specific injury resulting collapsing FSGS (NEP mice with LMB2).This model showed distinct microangiopathy at the site of glomerular epithelial hyperplasia suggesting podocyte injury provokes microangiopathy. This microangiopathy is associated with podocyte reduction, thrombosis and glomerulosclerosis. In addition, reduction of VEGF and eNOS, and increase of PAI-1 was observed. This suggests that podocyte injury causes dysregulation in podocyte-endothelial cells(ECs) homeostasis resulting site specific microangiopathy. To test whether microangiopathy promotes collapsing FSGS, present study administered novel PAI-1 inhibitor (TM5484) in this model.

Methods: Two groups of NEP mice, with (TM group, n=9) and without (controls, n=5) PAI-1 inhibitor (TM5484) were induced collapsing FSGS by LMB2. Immediately after injection of LMB2, TM5484 was administered orally for 12 days.

Results: Proteinuria was significantly reduced in TM 5484 group compared to controls on day12 ($p<0.05$). Of note, WT1 positive cells were not reduced in TM5484 group, whereas significant podocyte reduction was noted in controls on day8 (20.2 ± 2.39 vs. 9.23 ± 1.98 $p<0.001$) and day12(15.1 ± 2.42 vs. 4.44 ± 0.95 $p<0.001$). TI is significant lower in TM5484 on day8 (0.03 ± 0.05 vs. 0.12 ± 0.10, $p<0.05$) and day12 (0.05 ± 0.04 vs. 0.24 ± 0.10 $p<0.05$). SI was lower in TM5484 (0.05 ± 0.04 vs. 0.24 ± 0.1, $p<0.05$). Compared to controls, TM5484 group revealed significant reduction in mRNA levels of PAI-1 on day12, conversely VEGF on day8 and 12, eNOS on day8 and 12, u-PA on day8, and c-met on day12 was significantly increased in TM 5484 group.

Conclusions: Podocyte-specific injury mice model of collapsing FSGS showed corresponding microangiopathy due to increase of PAI-1. TM5484 significantly ameliorated progression of collapsing FSGS *via* protection of podocyte injury and epithelial hyperplasia.

FR-OR213

Intrauterine Growth Restriction Leads to Dysregulation of WT 1 and to Early Podocyte Alterations Carlos Menendez-Castro,[1] Fabian Fahlbusch,[1] Karl F. Hilgers,[2] Kerstin U. Amann,[3] Andrea Hartner,[1] Wolfgang Rascher.[1] *[1]Department of Pediatrics, University Hospital; [2]Department of Nephrology, University Hospital; [3]Department of Nephropathology, University Hospital, Erlangen, Germany.*

Background: Intrauterine growth restriction (IUGR) leads to a reduced nephron number and a higher incidence of renal disease. We tested the hypothesis that IUGR interferes with nephrogenesis by altered expression patterns of Wilms' tumor suppressor gene 1 (WT 1), a key player of renal development, and mediator of podocyte integrity in the mature kidney. We further hypothesized that early dysregulation of WT 1 results in later podocyte damage.

Methods: IUGR was induced in rats by maternal protein restriction (8.4% vs 17.2% casein diet) during pregnancy. Kidneys were harvested from offspring at day 1 and 70 of life. qRT-PCR, immunohistology and electron microscopy (EM) was performed in renal tissue. Albuminuria was assessed by ELISA.

Results: In neonatal kidneys of IUGR rats a significant reduction of the nephrogenic zone was observed. Furthermore, IUGR led to an increased expression (1.78-fold; $p<0.001$) of WT 1 and an imbalance of its splice variants +KTS and –KTS, persisting until adulthood. At day 70 of life IUGR rats showed increased glomerular immunoreactivity ($9.36\pm1.03\%$ positive glomerular cells vs $3.35\pm0.34\%$, $p<0.01$) and expression (1.93-fold, $p<0.05$) of desmin, a marker of podocyte injury. EM revealed overt alterations of podocyte ultrastructure in IUGR rats with podocyte enlargement and foot process effacement. Albuminuria was detected in IUGR rats at day 70 of life ($201.7\pm56.48\mu g/24h/100g$ vs 63.35 ± 19.29, $p<0.05$).

Conclusions: IUGR results in early podocyte damage possibly due to a persistent dysregulation of WT 1 and its isoforms. –KTS plays the major role during embryonal renal development. We suggest that early imbalance of WT 1 isoforms to the disadvantage of -KTS lead to the reduced nephron number in neonates. Since developmental pathways are also important for regeneration/repair, we assume that persistent dysregulation of WT 1 results in a reduced ability to compensate for renal damage, rendering IUGR rats more susceptible for renal disease.

Proximal Tubule Autophagic Changes Are Associated with the Development of Microalbuminuria in the PEXTKO Mouse Delecia R. Lafrance,[1] George Rhodes,[2] Bruce A. Molitoris,[2] Deborah J. McCarthy,[1] Kevin J. McCarthy.[1] *[1]Pathology, LSU Health Sciences Center, Shreveport, LA; [2]Medicine, Division of Nephrology, Indiana University Purdue University at Indianpolis, Indianapolis, IN.*

Background: PEXTKO mouse podocytes (Kidney Int. 74: 289-299, 2008) cannot assemble heparan sulfate glycosaminoglycans (HS) thus the anionic charge of the GBM is substantially depleted. The animals do not develop overt proteinuria over their lifetime, but gradual microalbuminuria does develop (>2yrs). Development of vacuolar changes in the proximal tubule cells (PTC) was coincident with the development of microalbuminuria. The purpose of this study was to investigate the functional status of the vacuolated PTE.

Methods: Control and PEXTKO mice (3,6, and 9 months old) were used in the study. Kidneys were removed and processed for frozen and paraffin sections and for electron microscopy (TEM) studies. Sections were stained for TUNEL and for autophagy (LC-3). For multiphoton microscopy studies, animals were injected with fluorescently labeled albumin 30 minutes prior to imaging. Intravital Z-stack images were collected during imaging. Post-imaging, the kidneys were processed for paraffin embedding, and sections re-imaged using widefield fluorescence microscopy.

Results: TEM of PEXTKO tubules showed PTE with large, lamellar vacuoles resembling lysosomes. PTE vacuolization were seen by 3 months of age and increased in size in PTE of older animals. No difference in the pattern or degree of TUNEL staining was seen between control and PEXTKO tissue sections but the vacuolated PTE of PEXTKO animals were LC-3 positive. Confirmation of autophagy was done by western blot for the processed form of LC-3. Intravital microscopy showed that the vacuolated PTE were incapable of resorbing albumin whereas the non-vacuolated PTE were capable of resorbing albumin. Widefield microscopy studies of sections from the same kidneys confirmed multiphoton observations.

Conclusions: The vacuolated PTE cells of PEXTKO tubules are dysfunctional, incapable of resorbing protein. The development of microalbuminuria in the PEXTKO mouse may be due to PTE autophagic change as shown by the TEM and validated by LC-3 staining.

Light Chain-Associated Renal Fanconi Syndrome Triggers Oxidative Stress, Dedifferentiation and Defective Receptor-Mediated Endocytosis in Proximal Tubule Cells Sara Terryn,[1] Claudia Raggi,[1] Christophe Sirac,[2] Pierre Aucouturier,[3] Pierre M. Ronco,[3] Frank Bridoux,[4] Olivier Devuyst.[1,5] *[1]UCL Nephrology, Brussels, Belgium; [2]CNRS, Limoges, France; [3]INSERM, Paris, France; [4]CHU Jean Bernard, Poitiers, France; [5]University of Zurich, Switzerland.*

Background: Renal involvement often complicates multiple myeloma, and storage of monoclonal immunoglobulin light chain (LC) within the lysosomes of proximal tubule cells (PTC) may lead to LC-associated renal Fanconi syndrome (RFS). The pathogenic mechanisms linking accumulation of LC in lysosomes and dysfunction of PTC remain unknown.

Methods: To investigate the cellular mechanisms involved in PTC dysfunction after LC-accumulation, we used a transgenic mouse model overexpressing a pathogenic human monoclonal κLC (CHEB mouse) and primary cultures of PTC.

Results: The CHEB mice showed low-molecular weight (LMW) proteinuria, glucosuria and phosphaturia, indicating PTC dysfunction and RFS. Immunostaining in CHEB kidneys revealed a decreased expression of the endocytic receptors megalin and cubilin in segments accumulating the κLC, associated with oxidative stress and proliferation markers. Decreased expression of megalin/cubilin, with defective endocytosis of LMW ligands and oxidative stress was also observed in primary cultures of PTC from CHEB kidneys. The changes were specifically related to κLC purified from patients with κLC-RFS, as they were not observed with κLC from patients with cast nephropathy (CN). The link between lysosomal accumulation of LC and defective endocytosis was substantiated by exposing PTC to RFS-associated or CN-associated κLCs. Exposure to RFS κLC, but not to CN κLC, triggered the expression of ZONAB, a transcription factor which induces cell proliferation, dedifferentiation and repression of megalin/cubilin. The increased expression of ZONAB in the PTC resulted in loss of polarization as evidenced by the loss of apical megalin expression and disorganization of the tight junctions.

Conclusions: These results suggest that the lysosomal accumulation of specific κLC within PTC triggers a transcriptional mechanism of cellular dedifferentiation which leads to defective endocytosis and RFS.

Nicotine and Chronic Kidney Disease: Role of the Alpha 7 Nicotinic ACh Receptor Gabriel Rezonzew,[1] Phillip H. Chumley,[1] Gene P. Siegal,[1] Wenguang Feng,[1] Ping Hua,[1] Edgar A. Jaimes.[1,2] *[1]U of Alabama at Birmingham; [2]VA Medical Center, Birmingham, AL.*

Background: Cigarette smoking is an important risk factor in the progression of Chronic Kidney Disease (CKD). We have previously demonstrated that mesangial cells are endowed with nicotine receptors (nAChR) and that nicotine increases mesangial cell fibronectin via the α7-nAChR (AJP' 07). Herein, we tested the hypothesis that nicotine worsens the severity of renal injury in 5/6 nephrectomized rats (5/6Nx) and that these effects are mediated via the α7-nAChR.

Methods: SD rats were divided in the following groups: Sham, 5/6Nx, 5/6Nx + Nicotine (NIC, 0.1 gm/L, DW), 5/6Nx + NIC + α7-nAChR blocker methyllicaconitine (MLA,3 mg/Kg/day, SQ), Sham + NIC. Urine was collected for proteinuria and blood pressure (SBP) was measured by tail cuff. Rats were euthanized after 12 weeks, kidneys saved for histology and western blot (WB) and serum saved for creatinine (Cr).

Results: Rats with 5/6Nx developed progressive proteinuria associated with increases in Cr, glomerular injury score (GIS) and fibronectin (WB). The administration of nicotine to 5/6Nx rats did not modify SBP and resulted in worse renal injury as assessed by proteinuria, GIS, Cr and fibronectin (table). The expression of fibronectin was predominantly interstitial and perivascular (IF). The administration of MLA ameliorated the effects of

NIC suggesting they were mediated via the α7-nAChR. Sham + NIC rats had increased proteinuria, fibronectin and Cr but had no significant increase in GIS.

Table

	Sham (n=3)	5/6Nx (n=9)	5/6Nx + NIC (n=7)	5/6Nx + NIC + MLA (n=7)	Sham + NIC (n=7)
Proteinuria (mg/mg Cr)	21.5 ± 0.8	94 ± 8.3 *	153 ± 9.1 *#	84± 11.1 *	120 ±5.8 *
GIS	0.27 ± 0.1	0.85 ± 0.3 *	1.60 ± 0.3 *#	0.9 ± 0.4 *	0.2± 0.1 #
Serum Creatinine (mg/dL)	1.6 ± 0.1	2.5± 0.6 *	2.6 ± 0.3 *	1.7 ± 0.1 #	2.9± 0.2 *
SBP (mmHg)	140 ± 19	162 ± 8.4	159 ± 7.8	143 ± 6.5	149 ± 8.5
Fibronectin (fold increase)	1	5.6 ± 0.6 *	7.6 ± 1.3 *#	1.4 ± 0.3 *#	3.3 ± 0.7 *#

* p<0.05 vs Sham, # p<0.05 vs 5/6Nx.

Conclusions: The administration of nicotine worsens the severity of renal injury in a rat model of CKD via activation of the α7-nAChR suggesting a critical role for this receptor in the accelerated progression of CKD in smokers.

FR-OR217

Diffusion of Laminin-521 in the Glomerular Basement Membrane Jung Hee Suh, Jeffrey H. Miner. *Renal Division, Department of Internal Medicine, Washington University School of Medicine, Saint Louis, MO.*

Background: Laminin-521 (α5β2γ1) is the major laminin isoform in the mature glomerular basement membrane (GBM). Lamβ2 defects cause congenital nephrotic syndrome in humans and mice. Laminin-521 trimers are secreted by both podocytes and glomerular endothelial cells and self-polymerize into a supramolecular network essential for GBM formation. Although laminin secretion and polymerization are relatively well understood processes, laminin dynamics within basement membranes is an unexplored area with relevance to glomerular disease.

Methods: To investigate the hypothesis that laminin diffusion in the GBM occurs, we produced chimeric mice by aggregating pairs of genetically distinct 4-celled mouse embryos, one expressing rat Lamβ2 in podocytes, and one expressing lacZ in all cells.

Results: Chimerism was confirmed by Xgal staining, which revealed a mosaic pattern. Using confocal microscopy we observed distinct segmental rat Lamβ2 deposition in the GBM in some glomeruli, but many glomeruli showed rat Lamβ2 deposition throughout the GBM, along with the presence of Xgal-positive (rat Lamβ2-negative) podocytes. The presence of segmental rat Lamβ2 deposition in the GBM implies that the diffusion of laminin-521 trimers is limited. However, because we observed many continuously rat Lamβ2-positive GBMs in glomeruli containing Xgal-positive podocytes, we conclude that secreted laminin-521 trimers can diffuse within the GBM to regions covered by rat Lamβ2-negative podocytes.

Conclusions: Laminin-521 trimers can diffuse in the GBM. These results contrast with the conventional view of type IV collagen α3α4α5 trimers, which are thought not to diffuse freely within the GBM, perhaps due to extensive cross-linking that fixes their location. These results have implications for Alport syndrome and other glomerular diseases with deposition of ectopic laminins that may contribute to filtration barrier defects.

FR-OR218

Inhibiting Discoidin Domain Receptor 1 Expression Protects Mice Against the Development of Crescentic Glomerulonephritis Monique Kerroch, Dominique Guerrot, Sophie Vandermeersch, Laurent Mesnard, Eric Rondeau, Pierre M. Ronco, Christos Chatziantoniou, Jean-Claude Dussaule. *INSERM UMR 702, Tenon Hospital, Paris, France.*

Background: The present study investigated the role of discoidin domain receptor 1 (DDR1), a non-integrin collagen receptor displaying tyrosine-kinase activity and mediating vascular inflammation and fibrosis, in the development of crescentic glomerulonephritis

Methods: Experimental glomerulonephrits was induced by administration of nephrotoxic serum (anti-glomerular basement membrane) in wild type mice, mice treated daily either with antisens oligonucleotids against DDR1 or with 'scrambled' oligonucleotids, and mice lacking expression of DDR1 (KO).

Results: Anti-GBM administration resulted in a progressive glomerulonephritis in the wild type and scrambled groups as evidenced by the increasing levels of proteinuria and uremia, the presence of cellular infiltrate (mainly macrophages), and the formation of glomerular crescents, fibrin deposits and interstitial fibrosis. These pathological features were concomitant to a several- fold upregulation of mRNA and protein expressions of DDR1 within glomeruli (mainly podocytes). In sharp contrast, mice treated with DDR1 antisens or DDR1 KO mice displayed a significantly lower proteinuria ($p<0.001$) and uremia ($p<0.01$), a blunted infiltration of inflammatory cells ($p<0.05$), a decrease in the formation of glomerular crescents and fibrin deposits and a preserved renal structure ($p<0.01$). This protection was associated to decreased expressions of pro-inflammatory (ICAM, VCAM, MCP1, IL-1b) and pro-fibrotic (TGFb, Col I and III) factors. In addition, nephrin and podocin expressions were preserved in glomeruli of the antisens and KO groups. In separate experiments, we tested DDR1 presence in human biopsies of rapidly progressive glomerulonephritis (Goodpastures's syndrome and lupus nephritis). Interestingly, DDR1 was expressed in glomeruli, especially in crescents when they were visible whereas it was absent in glomeruli of control kidneys

Conclusions: DDR1 is a major mediator of renal inflammation and fibrosis; blocking DDR1 expression can be a novel, promising treatment against the progression of glomerulonephritis.

Funding: Government Support - Non-U.S.

FR-OR219

Sonic Hedgehog Signaling Promotes Myofibroblast Activation and Renal Interstitial Fibrosis Hong Ding, Sha Hao, Weichun He, Youhua Liu. *Department of Pathology, University of Pittsburgh, PA.*

Background: Sonic hedgehog (Shh) signaling is a developmental signal cascade that plays an essential role in regulating embryogenesis and tissue homeostasis. Hedgehog transmits its signaling through binding to the plasma membrane receptor, Patched 1 (Ptch1), leading to the de-repression of Smoothened (Smo). Activated Smo then moves from an intracellular vesicle to the cell membrane, where it activates the Gli family of transcription factors. Here we investigated the potential role of Shh signaling in renal interstitial fibrogenesis. Both Shh and Gli1 were induced in the fibrotic kidneys in obstructive nephropathy. Using the $Gli1^{lacZ}$ 'knock-in' mutant mice, we found that Shh/Gli1 signaling specifically targeted on renal interstitial myofibroblasts. *In vitro*, recombinant Shh did not promote renal fibroblast proliferation, but induced Gli1, Snail1, α-SMA, fibronectin and collagen I expression, suggesting a role of this signaling in myofibroblast activation and matrix production. *In vivo*, disruption of *Gli1* gene in mice protected kidneys against development of interstitial fibrosis, as evidenced by a decreased expression of α-SMA, fibronectin and collagen I after obstructive injury. Blockade of hedgehog signaling with cyclopamine abolished the Shh-mediated Gli1, Snail1, α-SMA, fibronectin, and collagen I induction in renal fibroblasts. Cyclopamine did not affect renal Shh expression but inhibited Gli1 and Snail1 induction in obstructive nephropathy. Accordingly, cyclopamine also inhibited renal α-SMA and matrix expression and mitigated fibrotic lesions. These results indicate that Shh signaling plays a critical role in the pathogenesis of myofibroblast activation, matrix production and renal interstitial fibrosis.

Pericyte Derived TIMP3 and ADAMTS1 Regulate Vascular Stability in the Kidney after Injury Claudia Schrimpf,[2] Benjamin D. Humphreys,[2] Jeremy S. Duffield.[1] *[1]Medicine, University of Washington, Seattle, WA; [2]Medicine, Brigham & Womens' Hospital, Boston, MA.*

Background: Recently we identified mural cells of peritubular capillaries called kidney pericytes (kPC) as progenitors of scar forming myofibroblasts but regulatory mechanisms by which kPC differentiate into myofibroblasts are unknown & molecular mechanisms by which kPC detachment from endothelial cells leads to microvascular instability is poorly understood.

Methods: Microarray analysis and vascular stabilization assay

Results: Using microarray analysis, we identified more than 1000 genes that are regulated in kPC during detachment in response to kidney injury. Among the enriched functional categories were genes involved in migration, chemotaxis, extracellular matrix & angiogenesis. Among these genes we identified the metalloproteinase ADAMTS1 as highly up-regulated early during kPC detachment & its endogenous inhibitor TIMP3 as down-regulated during detachment. The specificity of these observations was confirmed by ISH, immunostaining, quantitative assays & by cell purification. In order to study the role of these genes in kPC function we generated & characterized primary kPC cultures, & developed a 3D capillary tube stabilization assay. Primary kPC strongly expressed TIMP3 which was down regulated in primary myofibroblasts. ADAMTS1 was not expressed by kPCs but was highly expressed by myofibroblasts. In a functional 3D regression assay primary kPC attached to capillary tubes with characteristic processes & stabilized the microvasculature with similar capacity to brain PC, while fibroblast cultures did not show these stabilizing effects. In the absence of kPCs, recombinant TIMP3 stabilized 3D capillary tubes, whereas ADAMTS1 accelerated destabilization. Lower levels of TIMP3 stimulated & ADAMTS1 inhibited kPC function in stabilizing capillaries in this assay. Consistent with these in vitro findings, mice deficient in TIMP3 had a spontaneous microvascular phenotype, impaired angiogenesis & accelerated fibrosis in response to kidney injury.

Conclusions: kPC-derived TIMP3 and ADAMTS1 are important regulators of vascular integrity and fibrosis after renal injury.

Inhibition of Mitochondrial Fission by the DRP1-Inhibitor Mdivi Blocks High-Glucose and TGF-beta Induced PAI-1 and Fibronectin Expression in Renal Cells Jens Gaedeke, Hans-Hellmut Neumayer. *Nephrology, Charité, Campus Mitte, Berlin, Germany.*

Background: Mitochondria are dynamic networks that constantly change morphology through fusion and fragmentation (fission).

A known stimulus for fragmentation is exposure to high glucose. In a previous study, we showed that mild inhibition of mitochondrial respiration blocked TGF-beta effects in renal cells. Recently, an inhibitor of the mitochondrial fission protein DRP-1 (Mdivi) has been described (Dev Cell 2008:14(2)).

Here we analysed if inhibition of mitochondrial fission by Mdivi has effects on glucose and TGF-beta mediated fibrotic effects in renal cells.

Methods: Rat renal fibroblasts (NRK-49F) were kept in DMEM containing 1g/l Glucose and stimulated with 4.5 g/l glucose or TGF-beta (0-5 ng/ml).

Mdivi (Calbiochem) was used at 0-25μM. PAI-1 and fibronectin (FN) was measured by western blot. Signaling pathways were analysed by western blot using phospho-specific antibodies for SMAD3, ERK-, p-p38-MAPK and AMPK.

Results: Treatment of fibroblasts for 48hrs in high glucose led to a strong increase in PAI-1 and FN production. A single dose of Mdivi (25μM) reduced high-glucose induced PAI-1 (-72%) and FN (-88%) significantly.

Similarly, the increase in PAI-1 and FN induced by TGF-beta was blocked by pre-treatment with Mdivi at 12.5 and 25 μM (PAI-1: -64% at 12,5μM, 88% at 25 μM; FN: -55 % at 12,5μM, -76% at 25μM).

Pre-treatment with Mdivi failed to block TGF-beta induced activation of p-p38-MAPK and SMAD3, and Mdivi failed to induce the inhibitory SMAD7 (mRNA analysed by real-time PCR).

Treatment with Mdivi alone led to a time and dose-dependent activation of ERK-MAPK and AMP-activated kinase (AMPK) starting at doses of 12.5 μM, but not at lower doses.

Conclusions: The data show that inhibition of the mitochondrial fission protein DRP-1 blocks expression of high glucose and TGF-beta induced markers of fibrosis. This was associated with an activation of ERK-MAPK and AMPK.

We did not observe any direct effect on the TGF-bta signaling pathway, indicating that Mdivi blocks the nuclear effects of activated SMAD proteins.

Our data raise the possibility that changes in mitochondrial morphology are involved in cellular responses to fibrotic stimuli.

FR-OR222

Regulation of Renal Fibroblast Function by Potassium Channels Michael Kacik, Joachim Hoyer, Brajesh Pratap Kaistha. *Philipps-University-Medical Center, Nephrology, Marburg, Hessen, Germany.*

Background: Potassium channels are important regulators of cellular function during cell cycle and proliferation. In recent studies proliferation of renal fibroblasts has been shown to depend on Ca-activated potassium channels.In the present study we identified a new type of potassium channels and characterized its role in resting and proliferating fibroblasts.

Methods: Potassium channel function was characterized in murine renal fibroblasts with whole cell and single channel patch-clamp experiments and cell potential recordings. Expression of potassium channels was determined with quantitative RT-PCR. Channel localisation was examined by immunofluorescence microscopy. Fibroblast proliferation was activated by TGF-β or bFGF and quantified with a colorimetric assay(MTT).

Results: In murine renal fibroblasts we newly identified the THIK-1 potassium channel, a member of two-pore-domain potassium channel (K2P) family.In resting fibroblasts next to the Kv potassium channel THIK-1 was the predominant potassium channel and responsible for maintaining the hyperpolarized cell membrane potential after activation of resting fibroblast. THIK-1 current was Ca-independent and typically activated by arachidonic acid (AA) at a EC50 of 13 ± 2 μmol/L leading to a mean current of 45,9 pA/pF at 0mV. THIK-1 was blocked by typical K2P blockers chlorpromazine and flupentixol.

After treatment (24h) with profibrotic factors like bFGF or TGF-β the proliferating fibroblasts THIK-1 current was down regulated by about 70%. Instead potassium current was carried by the Ca-activated potassium channel KCa3.1. Tyrosine kinases are important pathways by profibrotic agents. The incubation (24h) with the TK inhibitor genistein led to a significant reduction of the channel activity of THIK-1.

Conclusions: During transition from resting to proliferation state fibroblasts show a distinct switch in potassium channel expression and function. A newly identified Ca-independent THIK-1 is predominant in resting fibroblasts and enables a hyperpolarized membrane potential. During proliferation the channel is downregulated and substituted by the Ca-activated KCa3.1 channel which then regulates Ca2+ ion fluxes in the proliferation state.

FR-OR223

CXCR6 Mediates Recruitment of Bone Marrow-Derived Fibroblast Precursors in Renal Fibrosis Song-Chang Lin, Jiyuan Chen, William E. Mitch, Yanlin Wang. *Medicine-Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Renal fibrosis is a prominent pathological feature of chronic kidney disease. Although activated fibroblasts are responsible for the production and deposition of the extracellular matrix, the origin of activated fibroblasts mediating renal fibrosis has been controversial. Recent evidence indicates that circulating fibroblast precursors termed fibrocytes contribute to the pathogenesis of renal fibrosis. However, the mechanisms accounting for the recruitment of bone marrow-derived fibroblast precursors into the kidney are not fully understood. We have found that circulating fibroblast precursors express CXCR6. In the present study, we examined the role of CXCR6 in the recruitment of bone marrow-derived fibroblast precursors and renal fibrosis.

Methods: Chimeric mice that express GFP driven by collagen α1(I) promoter were used to demonstrate the bone marrow origin of fibroblast precursors. Unilateral ureteral obstruction was performed to induce renal fibrosis in wild-type (WT) and CXCR6-deficient (CXCR6-KO) mice.

Results: We found that bone marrow-derived GFP positive cells were present in kidneys 5 days post obstructive injury while not in normal kidneys. Furthermore, most of the GFP positive cells stained positively for α-smooth muscle actin. Immunohistochemical studies revealed that a significant number of bone marrow-derived fibroblast precursors dual positive for CD45 and vimentin accumulated in obstructed kidneys of WT mice. In contrast, these infiltrating bone marrow-derived fibroblast precursors were significantly reduced in obstructed kidneys of CXCR6-KO mice. Using immunohistochemistry and Western blot analysis, we found the expression of collagen type I, fibronectin, and α-SMA was upregulated in obstructed kidneys of WT mice. These responses were significantly reduced in obstructed kidneys of CXCR6-KO mice.

Conclusions: These data indicate that bone marrow-derived fibroblast precursors are recruited into the kidney and capable of differentiating into myofibroblasts during the pathogenesis of renal fibrosis and CXCR6 plays a pivotal role in the development of renal fibrosis by recruiting bone marrow-derived fibroblast precursors.

FR-OR224

Basement Membrane Proteoglycans Mediate Leukocyte Influx in Renal Ischemia/Reperfusion Jacob Van den Born,[1] Gerjan Navis,[1] Azadeh Zaferani,[1] Johanna W.A.M. Celie,[2] Raija Soininen,[3] Ritva Heljasvaara.[3] *[1]Nephrology, University Medical Center, Groningen, Netherlands; [2]Molecular Cell Biology and Immunology, Vrije Universiteit, Amsterdam, Netherlands; [3]Medical Biochemistry and Molecular Biology, University of Oulu, Finland.*

Background: Basement membranes (BM) have important roles in trafficking, signaling, differentiation, and regeneration of cells. Perlecan, collagen XVIII and collagen XV are three major proteoglycans of BM. Renal ischemia/reperfusion (I/R) is characterized by early renal injury and inflammation, followed by regeneration and resolution phase.

Methods: To investigate the role of perlecan, collagen XVIII and collagen XV in renal I/R, we used mice mutated for perlecan (Hspg2Δ3/Δ3), collagen XVIII (Col18a1-/-), collagen XV (Col15a1-/-), and compound mutants (Hspg2 Δ3/Δ3 x Col18a1-/- and Col18a1-/- x Col15a1-/-). Serum urea and creatinine, tubular injury, neutrophil and macrophage influx were determined at day 1, 5 and 10 after 25 minutes of bilateral renal arteries clamping. Wild type (WT) male adult C57BL/6 mice were used as controls. To mimic migration over BM, transwell migration experiments were done with freshly isolated human monocytes.

Results: One day after I/R, Hspg2 Δ3/Δ3 mice showed a transient, but 3-fold rise in serum urea and creatinine compared to WT, (both $p< 0.05$). Five days after I/R, Col15a1-/- and especially Col15a1-/- x Col18a1-/- compound mutant mice showed a reduction of serum urea and creatinine compared to WT mice ($p<0.05$ and $p<0.01$ respectively). Histology showed significantly less tubular damage and reduced leukocytes influx in (Col18a1-/- x) Col15a1-/- mutants at day 1 and 5 after I/R (p-values between $p<0.05$ and $p<0.01$). In a transwell system, the migration of monocytes towards MCP-1 increased over 2-fold ($p<0.05$) when heparin-albumin was immobilized on the filter, confirming involvement of proteoglycans in leukocytes migration.

Conclusions: BM proteoglycans modulate inflammation and tubular damage after renal I/R, probably via the formation of stable chemokine gradients and/or interaction with leukocyte receptors. Thus proteoglycan- leukocyte interaction might be a potential intervention target for heparinoids in order to reduce inflammation.

FR-OR225

Mast Cell Degranulation Promotes Renal Fibrosis in Murine Unilateral Ureteric Obstruction Shaun A. Summers,[1] Poh-Yi Gan,[2] David J. Nikolic-Paterson,[1] A. Richard Kitching,[1] Stephen R. Holdsworth.[1] *[1]Department and Medicine and Nephrology, MMC and Monash University; [2]Departmnet of Medicine, Monash University.*

Background: Mast cells (MCs) are pluripotent innate immune cells. After degranulation MCs release cytokines, chemokines and pro-fibrotic factors including transforming growth factorβ (TGFβ)and matrix metalloproteinases (MMPs). In human and experimental studies MCs are linked with progressive fibrosis. We explored the role of MCs in renal fibrosis induced by unilateral ureteric obstruction (UUO).

Methods: To define a role for MCs in renal fibrosis, we performed UUO on C57BL/6 wild type (WT) and mast cell deficient, KitWsh/Wsh mice. Experiments ended 7 days later. We measured collagen deposition (%), intrarenal mRNA expression of pro-fibrotic factors, TGFβ, MMP and smooth muscle actin (αSMA)relative to a house-keeping gene and interstitial leukocyte recruitment. To confirm these results were exclusively due to MC deficiency we measured renal fibrosis in KitWsh/Wsh mice reconstituted with MCs from WT mice. Finally we assessed renal fibrosis after administration of sodium chromoglycate, a mast cell stabiliser.

Results: Compared to WT mice, renal fibrosis was decreased in KitWsh/Wsh mice 7 days after UUO. Histological assessment demonstrated decreased collagen deposition (12.7±1.2 vs. 9.9±0.9%, $P<0.05$). Intrarenal TGFβ (1.0±0.1 vs.0.7±0.1, $P<0.05$), αSMA (1.0±0.1 vs. 0.7±0.1, $p<0.05$) and MMP12 mRNA expression was decreased in KitWsh/Wsh mice. Fewer interstitial macrophages (score 2.4±0.1 vs. 1.6±0.1 $P<0.001$) and CD4+T cells (7.1±0.4 vs. 4.1±0.6cells/ high power field, $P<0.001$) were seen in KitWsh/Wsh mice. Collagen deposition (17.0±2.5 vs.9.1±1.2%, $P<0.05$) and mRNA expression of TGFβ and αSMA was decreased in (unreconstituted) KitWsh/Wsh mice compared to KitWsh/Wsh mice reconstituted with MCs from WT mice. Pre-emptive administration of sodium chromoglycate to WT mice resulted in decreased collagen deposition (16.3±1.3 vs. 10.5±0.7%, $P<0.01$) and decreased intrarenal mRNA expression of TGFβ (1.0±0.1 vs.0.7±0.1, $P<0.01$) and αSMA (1.0±0.2 vs. 0.6±0.1, $P<0.05$).±

Conclusions: MCs mediate renal fibrosisi after UUO. MC stabilisation is a potential novel therapy for treating renal fibrosis.

Ciliary Neurtrophic Factor Deficiency Protects Against Angiotensin II-Dependent Hypertension Sebastian Alexander Potthoff, Henning Hoch, Paul Probst, Eva Koenigshausen, Magdalena Woznowski, Oliver Vonend, Lorenz Sellin, Lars C. Rump, Johannes Stegbauer, Ivo Quack. *Department of Nephrology, University of Duesseldorf, Germany.*

Background: JAK2/STAT3 signaling cascade modulates AngII dependent hypertension. Ciliary neutrophic factor (CNTF) is an interleukin-6-like cytokine which plays a distinct role in survival and differentiation of neuronal cells by activating the JAK2 / STAT3 signaling cascade. However, CNTF function in other tissues is poorly understood. This study focuses on the role of CNTF in AngII-dependent hypertension model.

Methods: One week after uninephrectomy, Ang II osmotic minipumps (1000 ng/min/kgBW) were implanted in CNTF KO and age-matched C57Bl/6J male mice (WT). Blood pressures (BP) were measured for 3 weeks, starting one week before implantation. Histological and mRNA analysis were performed at the end of the observation period. Renal vascular function was evaluated in the isolated perfused kidney.

Results: Baseline systolic BPs were similar in CNTF KO and WT mice (119±2 vs.124±1 mmHg). Chronic AngII infusion caused a significantly attenuated increase in BP in CNTF-KO mice compared to WT mice (week 1: 139±3 vs. 153±3 mmHg; week 2: 151±5 vs. 168±4 mmHg; n=19; $P<0.01$). Heart hypertrophy was significantly less in the CNTF KO compared to the WT-group (6.5±0.4 vs. 8.2±0.6 mg/g BW; $P<0.01$). Histological and mRNA analysis revealed significantly attenuated renal vascular hypertrophy, tubulo-interstitial damage and CD4/CD8 positive cell infiltration as well as reduced NGAL expression (3.2±0.8 vs. 13.9±2.6 arbitrary units; $P<0.01$) in kidneys of AngII treated CNTF KO mice compared to WT mice. In the isolated perfused kidney, pressor response to AngII was significantly attenuated in CNTF KO mice. AG-490 (5 mM), a JAK2/STAT3 inhibitor, reduced the pressor response to AngII in kidneys of WT mice but had no effect in CNTF KO mice.

Conclusions: CNTF has a major impact on blood pressure regulation in Ang II-dependent hypertension. CNTF seems to modulate the Ang II induced renal pressor response via a JAK2/STAT3 dependent mechanism. Thus, CNTF could be an important regulatory cytokine in the pathogenesis of AngII-dependent hypertension.

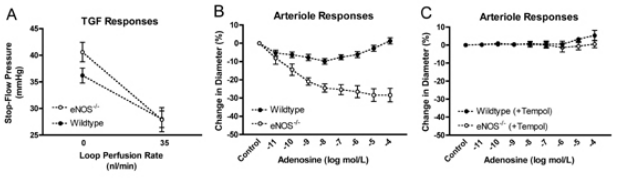
FR-OR227

Adenosine-Mediated Tubuloglomerular Feedback Responses Are Modulated by eNOS in the Afferent Arteriole Mattias Carlstrom, Enyin Lai, Zaiming Luo, Christopher S. Wilcox, William J. Welch. *Dept. of Medicine, Georgetown University, Washington, DC.*

Background: Tubuloglomerular feedback (TGF) is mediated via activation of A1 receptors on the afferent arteriole, and A2 receptors attenuate the response. Whereas NO derived from nNOS in macula densa regulates TGF, the role of eNOS is not clear. We tested the hypothesis that eNOS in the afferent arteriole modulates adenosine-mediated TGF responses by reducing oxidative stress.

Methods: TGF was measured in eNOS-knockout (eNOS-/-) and wildtype mice, as changes in proximal stop-flow pressure (ΔPSF) in response to increased loop perfusion (0 to 35 nl/min). Isolated and perfused afferent arterioles, the effector of TGF, were used to study adenosine responses (10-11 to 10-4 M) with or without simultaneous application of superoxide scavenger (Tempol; 10-4 M).

Results: TGF responses (ΔPSF) were significantly stronger in eNOS-/- mice (12.7±0.7 mmHg) than in wildtypes (8.2±0.5 mmHg) (A). Adenosine caused a biphasic response with contraction in the lower concentration range (-10±2% at 10-8 M) and dilatation in the higher concentration range (1±1% at 10-4 M). In eNOS-/- mice the contractile response to adenosine was significantly stronger (-25±2 % at 10-8 M), with absence of dilatation at higher concentrations (-28±4 % at 10-4 M) (B). Simultaneous application with Tempol prevented adenosine-mediated contraction in both eNOS-/- and wildtype mice, but did not significantly influence dilatation at higher concentrations (C). Western Blot analysis of renal cortex revealed no differences between genotypes in adenosine A1, A2A or A2B receptors.



Conclusions: eNOS in the afferent arteriole importantly regulates TGF by modulating the contractile response to adenosine. Mechanistically, adenosine-mediated contraction is linked to increased superoxide production in the arteriole, and the contractile response is attenuated by eNOS-derived NO.

FR-OR228

Activation of Adenosine A3 Receptor in the Afferent Arteriole (Af-Art) Blunts the Effect of A1 Receptor and AngII Stimulation Yan Lu,[1] Ying Ge,[1] Luis A. Juncos,[2] Ruisheng Liu.[1] *[1]Physiology & Biophysics, University of Mississippi Medical Center, Jackson, MS; [2]Medicine, University of Mississippi Medical Center, Jackson, MS.*

Background: Adenosine plays an important role in tubuloglomerular feedback and renal microcirculation.There are 4 known receptors for adenosine, A1,A2a,A2b and A3(A3R).Activation of the A1 receptor constricts,whereas activation of the A2 receptor dilates the Af-Art.Whether the A3R exists in the Af-Art and its function are not clear.

Methods: A superficial Af-Art was microdissected from a mouse kidney, and mRNA of the A3R was measured with RT-PCR and real-time PCR. We found that the A3R is expressed in the Af-Art. Then, a superficial Af-Art with its attached glomerulus was microdissected from a mouse kidney and perfused at 60 mm Hg.

Results: We measured the diameter of the Af-Art when stimulated with selective A3 receptor agonist IB-MECA at 10-4 M and found no effect. Next, we used a selective A1receptor agonist CHA at concentrations from 10-6 M to 10-4 M. CHA induced a dose-responsive vasoconstriction of the Af-Art, and diameters were 10.9±0.2 μm at control,9.0±0.4 μm at 10-6 M,8.5± 0.5 μm at 10-5 M,8.0± 0.4 μm at 10-4 M. When we repeated the CHA dose response experiment in the presence of the A3R agonist IB-MECA, we found that activation of A3 receptor blocked the constrictive effect of A1 receptor on the Af-Art.We measured intracellular calcium concentration with fura-2.In the presence of IB-MECA, the CHA-induced calcium increase was blocked. Next, we used AngII at concentration from 10-9 M to 10-8 M. AngII induces a dose-responsive vasoconstriction of the Af-Art, and diameters were 10.7±0.4 μm at control,9.3±0.6 μm at 10-9 M, 9.0±1.1 μm at 10-8 M. When we repeated the AngII dose response experiment in the presence of the A3 receptor agonist IB-MECA, we found that activation of A3 receptor blocked the constrictive effect of AngII on the Af-Art.

Conclusions: We conclude that A3 receptor is expressed in the Af-Art and activation of A3 blunts the vasoconstrictive effect of A1 receptor and AngII stimulation. Therefore, the adenosine A3 receptor may play an important role in modulating the tubuloglomerular feedback response and renal hemodynamics.

FR-OR229

Increased Na-Cl Cotransporter Phosphorylation in Hyperinsulinemic db/db Mice Is Regulated by Insulin/PI3K Pathway Hidenori Nishida,[1] Eisei Sohara,[1] Dario Alessi,[2] Naohiro Nomura,[1] Tatemitsu Rai,[1] Sei Sasaki,[1] Shinichi Uchida.[1] *[1]Department of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Bunkyo-ku, Tokyo, Japan; [2]MRC Protein Phosphorylation Unit, University of Dundee, United Kingdom.*

Background: The metabolic syndrome causes hyperinsulinemia, as a result of insulin resistance, and hyperinsulinemia causes an aberrant increase in sodium reabsorption by the kidney. However, the mechanism responsible for this greater salt-sensitivity in hyperinsulinemic patients is still unknown. We recently discovered the WNK kinase-OSR1/SPAK kinases-NCC transporter phosphorylation cascade, whose abnormal activation results in salt-sensitive hypertension in pseudohypoaldosteronism type II.

Methods: In this study, we investigated whether and how WNK-OSR1/SPAK-NCC cascade is activated in kidney of the db/db mouse, a model of hyperinsulinemic metabolic syndrome.

Results: Thiazide sensitivity in terms of sodium excretion was increased in the db/db mice compared to wild-type mice, suggesting greater activity of NCC in the db/db mice. In fact, increased phosphorylation of OSR1/SPAK and NCC was observed in the db/db mice kidney. This increase in NCC phosphorylation was decreased when 1) the db/db mice were mated with the SPAK(T243A/+) and OSR1(T185A/+) knockin mice which carry the mutations disrupting the signal from WNK kinases, and 2) the db/db mice were treated with a PI3K inhibitor, NVP-BEZ235. Furthermore, increased blood pressure in the db/db mice disappeared when they were mated with the SPAK/OSR1 knockin mice.

Conclusions: We conclude that WNK-OSR1/SPAK kinase cascade is activated in the db/db mouse kidney, and that PI3K is an upstream regulator of this cascade. This mechanism may be one of the pathogenesis of salt sensitive hypertension in hyperinsulinemic conditions, such as metabolic syndrome.

Nitric Oxide Decreases Transforming Growth Factor Beta Type I Receptor Surface Expression through a Dynamin 2-Mediated Process Michael B. Hovater,[1] Wei-Zhong Ying,[1,2] Paul W. Sanders.[1,2] *[1]Department of Medicine, Division of Nephrology, University of Alabama at Birmingham, AL; [2]Medicine, Veterans Affairs Medical Center, Birmingham, AL.*

Background: Transforming growth factor-β (TGF-β) is widely accepted as a profibrotic growth factor, and signal propagation is responsible for deposition of extracellular matrix proteins and promotion of vascular fibrosis. Previous studies from our lab demonstrated that nitric oxide (NO) mitigates the deleterious effects of TGF-β. Studies in bladder endothelial cells and human embryonic kidney (HEK) cell lines indicated that NO activates dynamin 2. We hypothesized that NO increases endocytosis of the TGF-β type I receptor (TBRI) in vascular smooth muscle cells (VSMC) through activation of dynamin 2, potentially shielding the cells from the effects circulating TGF-β.

Methods: Primary cultures of VSMC from Sprague-Dawley rats were treated with dynamin 2 siRNA or control 48 hours prior to treatment with NOR3, a NO chemical donor, ODQ, an inhibitor of soluble guanylyl cyclase, or vehicle. Dynamin 2 was detected using a commercially available rabbit polyclonal IgG antibody, 1:1000 dilution. Surface expression of TBRI was detected with fluorescence-activated cell sorting (FACS).

Results: NO stimulated a time- and dose-dependent endocytosis of TBR1. This effect was independent of guanylyl cyclase since ODQ did not inhibit the NO-mediated decrease in surface expression of TBRI. Physiological levels of NO also stimulated in a dose-dependent fashion dynamin 2 multimerization indicating activation of dynamin 2. Cells pretreated with dynamin 2 siRNA did not demonstrate a NO-stimulated decrease in surface expression of TBRI.

Conclusions: NO decreased TBRI surface expression in VSMC through a dynamin 2-mediated process. This may help explain an important way in which NO protects the vasculature by decreasing TGF-β surface expression and, therefore, decreasing the cellular response to this profibrotic growth factor.

Intravital Reactivity to Angiotensin II and In Vitro Preglomerular Myogenic Constriction Predict Renal Damage after 5/6 Nephrectomy Peter Vavrinec, Robert H. Henning, Maaike Goris, Hendrik Buikema, Richard P. Van Dokkum. *Dep of Clinical Pharmacology, UMCG, Groningen, Netherlands.*

Background: Susceptibility to renal injury varies among individuals. Previously, it was shown that individuals with healthy baseline endothelial dilatory ability in isolated renal arterioles developed less renal damage after 5/6 Nx. Whether in vivo pre-existing vascular integrity also predicts subsequent renal damage to 5/6 Nx is subject of the current study using intravital microscopy. In addition, we explored whether in vitro myogenic constriction of small renal arteries extirpated at 5/6 Nx surgery also predicts subsequent development of renal damage in the animal.

Methods: Anaesthetized rats underwent intravital microscopy to visualize glomerular afferent and efferent arterioles, with continuous measurement of arterial blood pressure, heart rate and renal blood flow. After stabilization on saline infusion, Ang II (30 ng/kg/min) was infused for 10 min. Thereafter, 5/6 Nx was performed and blood pressure and proteinuria were assessed weekly for 12 weeks. Images of glomeruli were recorded for measurements of vascular diameter of afferent and efferent glomerular arterioles. Small arteries were isolated from the extirpated kidney at 5/6 Nx and myogenic constriction was assessed in a perfused vessels setup.

Results: Infusion of Ang II induced significant contraction of both afferent and efferent glomerular arterioles ($p<0.001$ compared to saline). The contraction in afferent and efferent glomerular arteriolar diameter upon Ang II infusion correlated strongly with proteinuria 12 weeks after 5/6 Nx ($r = 0.73$; $p=0.01$ and $r = 0.90$; $p=0.01$, respectively). Additionally, in vitro measured myogenic constriction of small renal arteries correlated negatively with proteinuria 12 weeks after 5/6 Nx ($r = - 0.71$, $p = 0.02$).

Conclusions: Both in vivo afferent and efferent responses to Ang II and in vitro myogenic constriction of small renal arteries in the healthy rat predicts the severity of renal damage induced by 5/6 Nx. Further research into this relationship may lead to novel preventive renoprotective therapies.

Sympathetic Nerves Are in Close Proximity to Vasa Recta Pericytes, and the Co-Transmitters Noradrenaline and ATP Evoke Pericyte-Mediated Regulation of Vasa Recta Diameter Carol Crawford,[1] Teresa M. Kennedy-Lydon,[1] Liam Sawbridge,[1] Jessica Munday,[1] Robert J. Unwin,[2] Scott S.P. Wildman,[1] Claire M. Peppiatt-Wildman.[1] *[1]Royal Veterinary College, London, United Kingdom; [2]University College London, United Kingdom.*

Background: Pericytes reside at regular intervals along vasa recta capillaries and have been shown to regulate *in situ* vasa recta diameter, in response to a number of vasoactive agents, including the co-transmitters noradrenaline (NA) and ATP (1, 2). Here we show vasa recta pericytes exist in close apposition to sympathetic nerves, a potential endogenous source of NA and ATP, and determine the mean distance between sympathetic nerves and pericytes in the inner and outer medulla.

Methods: Live kidney slices, obtained from adult male Sprague Dawley rats, were secured in an open bath chamber set on the stage of an upright microscope and continually superfused with oxygenated physiological saline solution. Video-imaging techniques were used to capture pericyte-mediated changes in vasa recta diameter following exposure of live slices to NA and ATP. Pericytes and sympathetic nerves were labeled in fixed kidney slices using anti-NG2 and anti-TH antibodies and appropriate fluorescently-conjugated secondary antibodies. Fluorescent images of sympathetic nerves and pericytes in the inner and outer medulla were taken with a Zeiss LSM 510 confocal microscope and the distance between sympathetic nerves and the nearest pericyte measured using LSM image browser software. Data are mean±SEM.

Results: NA (10 nM) and ATP (100 μM) evoked a significantly greater constriction of vasa recta at pericyte sites (20.8±5.1% and 19.4±2.8%, respectively) compared with non-pericyte sites (7.6±2.0% and 3.3±2.9%, respectively). Sympathetic nerves were identified in both the inner and outer medulla, and varicosities were found to be 3.5±0.5 μm from the nearest pericyte.

Conclusions: Given the close proximity of sympathetic nerves to pericytes in the medulla, they are a likely endogenous source of the co-transmitters NA and ATP, which we demonstrate evoke pericyte-mediated constriction of vasa recta.

FR-OR233

Adenosine Receptors Regulate Fluid Uptake in the Proximal Tubule Carolina Panico, Zaiming Luo, William J. Welch. *Medicine, Division Nephrology, Georgetown University, Washington, DC.*

Background: Adenosine enhances fluid uptake in the proximal tubule (PT) via adenosine type 1 receptors (A1-AR). The effect of adenosine type 2 receptors (A2-AR) on PT function is unknown. We showed that fluid uptake (Jv) in the S2 segment of the PT was lower in adult spontaneously hypertensive rats (SHR) compared to normotensive rats, therefore we hypothesized that Jv in this model is reduced by changes in adenosine receptor activity.

Methods: We measured Jv by microperfusion and recollection of accessible S2 segments of the PT in WKY and SHR.

Results: An A1-AR antagonist reduced Jv in normotensive rats (WKY: 2.7±0.3 vs A1-AR Ant: 1.3±0.3 nl/min/mm, $p<0.001$), but had no effect on the lower Jv in SHR (SHR: 1.1±0.2 vs A1-AR Ant 1.3±0.3 nl/min/mm, ns), suggesting that A1-AR activity is impaired in the SHR. However, microperfusion of an A2-AR antagonist (ZM241385 10-7 M) increased Jv in WKY (WKY: 2.6±0.3 vs ZM: 3.1±0.2 nl/min/mm, $p<0.01$), and completely restored Jv in SHR (SHR: 1.2±0.3 vs SHR + ZM: 2.9±0.3 nl/min/mm, $p<0.0001$).

Conclusions: This suggests that A2-AR inhibits Jv in the PT and that A2-AR activity is increased in SHR. Protein expression of A1-AR in microdissected PTs was not different between strains, however A2-AR expression was 2.4 fold higher in PT from SHR. This suggests that activation of A2-ARs normally inhibits Jv and therefore offsets the action of A1-ARs in the PT and that PT dysfunction in SHR is related to overexpression of A2-AR.

FR-OR234

Endothelin-A Receptor Blockade in Chronic Renovascular Disease: A Novel Therapeutic Application Alejandro Chade. *Physiology and Biophysics, Medicine, University of Mississippi, Jackson, MS.*

Background: Circulating and renal endothelin (ET)-1 is increased in patients with chronic renovascular disease (RVD). We have recently shown that chronic blockade of the ET-A receptor prevents functional and structural damage in the stenotic kidney of experimental RVD. This study was designed to extend those observations and determine whether chronic ET-A blockade can halt the progression and reverse renal injury in RVD.

Methods: Unilateral RVD was induced in 8 pigs. After 6 weeks, single-kidney blood flow (RBF) and glomerular filtration rate (GFR) was quantified in the RVD kidney using multi-detector CT (MDCT), before and after endothelium-dependent challenge (acetylcholine, Ach). Then, RVD pigs were randomized in either untreated (RVD, n=4) or treated with chronic-oral ET-A blocker (RVD+ET-A, 0.75 mg/kg/day, n=4) and observed for 4 additional weeks. At 10 weeks, *in vivo* MDCT studies were repeated, and renal microvascular (MV) density quantified *in situ* using 3D micro-CT.

Results: Stenotic kidney RBF, GFR, and MV density and function were similarly blunted after 6 weeks of RVD in all pigs. Untreated RVD showed no changes after 10 weeks, while RVD+ET-A showed improved RBF, GFR and MV endothelial responses to Ach, accompanied by a significant expansion of the renal microcirculation (Figure). Renal artery stenosis and hypertension were similar in RVD and RVD+ET-A at 6 and 10 weeks (P=NS)

Conclusions: This study shows renoprotective effects of chronic ET-A blockade in the stenotic kidney and underscores the importance of renal MV integrity as a determinant of the progression of renal injury. Furthermore, it supports the potential of a novel therapeutic approach to protect the kidney in chronic RVD.

Increased Protein Abundance of the Mutant WNK4 May Be a Cause of the Increased WNK4 Kinase Activity in the Mouse Model of Pseudohypoaldosteronism Type II (PHA II) Mai Wakabayashi, Shotaro Naito, Eisei Sohara, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: Mutations in two WNK kinase genes, WNK1 and WNK4, lead to PHA II characterized by hypertension, hyperkalemia and acidosis. We previously generated *Wnk4* $^{D561/+}$ knock-in mice, carrying a heterozygous D561A mutation, and found that phosphorylation of NaCl cotransporter (NCC) was increased by the activation of WNK-OSR1/SPAK kinase cascade. However, mechanism(s) how the mutant WNK4 activated the kinase cascade remains to be determined. In this study, we investigated biochemical characteristics of the mutant WNK4 (D561A) protein in vivo and in vitro.

Methods: To perform in vivo analyses, we used the *Wnk4* $^{D561A/D561A}$ homozygous knock-in mice since they only have the mutant WNK4 protein.

Results: We first confirmed that the homozygous mice showed PHA II phenotypes, indicating the same pathogenic mechanism(s) are working in the homozygous mice as in the heterozygous mice. We also confirmed the increased phosphorylation of OSR1/SPAK and NCC. Using a new anti-WNK4 antibody, we could detect increased WNK4 protein expression (2.2 fold) in the homozygous knock-in mice. Although intrarenal and intracellular localization of the mutant WNK4 was not different from those in wild-type mice, the increased signal was also evident under immunofluorescence. Total WNK4 kinase activity in kidney measured on immunoprecipitated WNK4 was 2.8 times higher in the homozygous mice. However, the kinase activity of the mutant WNK4 per molecule was only slightly (1.3 times) increased after correction by the increased WNK4 protein abundance in the homozygous mice. Since WNK4 mRNA expression in kidney was not increased in the homozygous mice, we measured protein stability of the mutant WNK4 in MDCK cells. Pulse-chase experiment revealed that the stability of mutant WNK4 was significantly increased.

Conclusions: These results suggested that the increasing WNK4 kinase activity in the PHAII model mice could result mainly from the increased WNK4 protein abundance probably due to its increased protein stability.

Improvement of Mild and Moderate Hyponatremia Is Associated with Enhanced Cognitive Function Rick P. Vaghasiya, Maria V. DeVita, Michael F. Michelis. *Division of Nephrology, Lenox Hill Hospital, New York, NY.*

Background: Hyponatremia affects as many as 15-30% of hospitalized patients. Mild hyponatremia has generally been considered asymptomatic. However, a recent study showed that patients with mild to moderate chronic hyponatremia had an increased risk of falls, as well as impairments in gait and attention. This study was designed to assess cognition levels using the Mini-Mental Status Exam (MMSE) in hospitalized patients with varying degrees of hyponatremia pre and post serum sodium (SNa) improvement.

Methods: Thirty patients with SNa values ≤134 mEq/L were included. The MMSE was administered to these patients and scores recorded to a maximum of 30. SNa improved appreciably in 24 of these patients (improved group) after management with 0.9% saline, fluid restriction, vasopressin receptor antagonists, withholding medications, or 3% saline as clinically indicated. The remaining 6 patients (control group) had no change in SNa levels (±1 mEq/L). The MMSE was readministered to all 30 patients after at least 72 hrs. MMSE scores were compared between the improved group and control group.

Results: The initial SNa levels of the improved group ranged from 117 to 134 mEq/L with a mean of 124.3 mEq/L (SD±4.4) and post-improvement SNa ranged from 127 to 143 mEq/L with a mean of 133.7 mEq/L (SD±4.1, p=0.016). The control group had a mean SNa level of 128.9 mEq/L (range 127-131 mEq/L). Twenty-one patients of the improved group (88%) had an increase in MMSE score: 9 patients had a 4-10% increase, 8 patients had an 11-20% increase, 3 patients had a 21-35% increase and 1 patient had a 100% increase on retesting. Of note, 7 improved patients had mild hyponatremia with pre SNa ≥ 127 meq/L. In the control group, 67% had no change, 1 patient had a 3.5% increase and 1 patient had a 7.4% increase on MMSE retesting.

Conclusions: Improving hyponatremia at all levels, mild, moderate and severe, was associated with higher cognitive function on MMSE when compared to patients without correction. Correcting hyponatremia to improve cognitive function should be considered.

FR-OR237

Prognostic Impact of Severe Hyponatremia Following Liver Transplantation Jeonghwan Lee,[1] Jung Pyo Lee,[2] Dong Ki Kim,[1] Yon Su Kim,[1] Curie Ahn,[1] Jin Suk Han,[1] Kwon Wook Joo.[1] *[1]Internal Medicine, Seoul National University Hospital, Seoul, Korea; [2]Internal Medicine, Seoul National University Boramae Hospital, Seoul, Korea.*

Background: Hyponatremia is known as a risk factor of reduced survival in patients with end stage liver disease. But, the result on the outcomes after orthotopic liver transplantation (OLT) according to the degree of hyponatremia is controversial.

Methods: We conducted a retrospective analysis of 517 adult patients who underwent OLT at Seoul National University Hospital between 1 January 2005 and 31 December 2010. Patients were divided into three groups according to serum sodium values; normal (more than 135 mEq/L), mild hyponatremia (125-134mEq/L), and severe hyponatremia (<125 mEq/L). In-hospital mortality, duration of admission on ICU and ward, delirium, neurologic complications, acute kidney injury (AKI) and infections were analyzed by ANOVA, Chi-square and logistic regression method.

Results: Out of 517 patients, mild hyponatremia was present in 235 (45.5%) and severe hyponatremia in 75 (14.5%). Hyponatremia had no impact on in-hospital mortality (odds ratio=1.48, p=0.38). Compared with patients of normal serum sodium, patients with severe hyponatremia did not differ in the duration (days) of admission either on ICU (9.6±7.5 vs. 8.1±11.1, p=0.24) or general ward (28.8±16.7 vs. 24.9±32.0, p=0.51). Patients with severe hyponatremia had higher rates of delirium (56.0%/29.5%; OR=1.44, p=0.018), neurologic complications (24.0%/7.2%; OR=1.538, p=0.037), and AKI (57.3%/35.3%; OR=1.35, p=0.045). In 75 patients with severe hyponatremia, patients with rapid correction of hyponatremia over 12 mEq/L/24hr showed higher mortality than others (16.2%/5.3%, p=0.002). Rapid correction of hyponatremia was associated with higher mortality in univariate logistic regression analysis (OR=4.90, p=0.042) but not in multivariate analysis (OR=3.53, p=0.149).

Conclusions: Pre-OLT hyponatremia does not affect on the outcomes of in-hospital mortality or the duration of admission. Hyponatremia is independently associated with post-OLT delirium, neurologic complications and AKI. Rapid correction of serum sodium is associated with higher mortality after OLT, but statistically not significant.

FR-OR238

3% Saline and DDAVP: A Simple Strategy for Safe Correction of Severe Hyponatremia Lonika Sood,[1] John Kevin Hix,[1,2] Richard H. Sterns.[1,2] *[1]Dept. of Medicine, Rochester General Hospital, Rochester, NY; [2]Nephrology Division, University of Rochester School of Medicine and Dentistry, NY.*

Background: Prompt but limited correction of severe hyponatremia is important to avoid morbidity and mortality. An unanticipated water diuresis can destabilize the pace of therapy causing an unintended overcorrection (>10 mEq/L/24 hrs and/or >18 mEq/L/48 hrs)(Clin J Am Soc Nephrol. 2007;2:1110-7). After success treating a patient with a serum sodium(sNa) of 96 mEq/L with 3% saline and DDAVP (AJKD 2010;56:774-9), we adopted this strategy more routinely in managing severe hyponatremia.

Methods: Case records of all 12 patients with sNa <120 mEq/L who received 3% saline and DDAVP concurrently between 11/01/2008 and 01/31/2011 were reviewed retrospectively to determine effectiveness in achieving treatment goals, predictability of response to 3% saline, and optimum dosage of DDAVP.

Results: Eight patients (sNa 106-118 mEq/L) were treated with 2 mcg DDAVP every 8 hours and 3% saline (initially 0.2 to 0.7 ml/kg/hr, usually for less than 24 hours): all met treatment goals at 24 hrs (5.4 ± 1.4 mEq/L); the observed increase in sNa was close to that predicted by the Adrogue-Madias formula (4 ± 2.7 mEq/L), with deviations from predicted ranging from -2 to +5.3 mEq/L. Four patients (sNa 111-113 mEq/L) were treated with 1 mcg DDAVP and 3% saline (0.3 to 0.8 ml/kg/hr): two exceeded treatment goals at 24 hours with increases of 10 and 11 mEq/L, 5.5 and 7.5 mEq/L higher than predicted, in one case because of 3.3 liters urine output despite DDAVP. All 12 patients treated concurrently with DDAVP and 3% saline met the 48 hour treatment goal (9.8 ± 3.0 mEq/L). Except for one patient with preexisting heart disease who developed rapid atrial fibrillation and mild CHF, 3% saline and DDAVP were well tolerated without neurological complications.

Conclusions: Concurrent infusion of 3% saline along with 2 mcg DDAVP every 8 hours is an effective strategy to achieve controlled and predictable correction of severe hyponatremia. Lower doses of DDAVP have little advantage and do not always prevent an unwanted water diuresis.

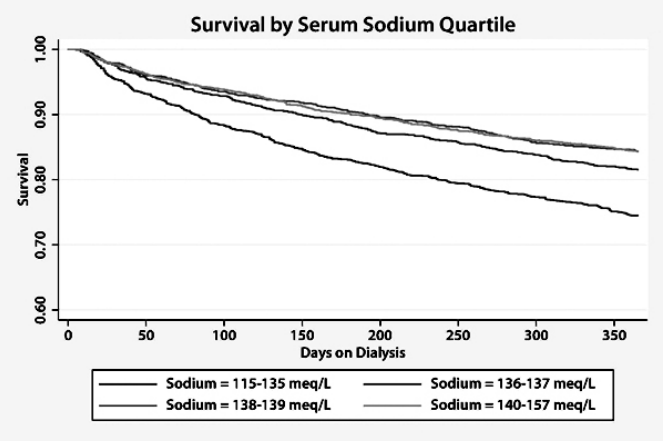
FR-OR239

Low Serum Sodium, Bone Mineral Disease and Mortality in Incident Chronic Hemodialysis Patients Sagar U. Nigwekar, Julia Beth Wenger, Ravi I. Thadhani, Ishir Bhan. *Massachusetts General Hospital.*

Background: In the general population, hyponatremia has been associated with mortality. In addition, recent data suggest that hyponatremia may contribute to a reduction in bone mass. It is unclear whether these associations exist in the hemodialysis (HD) population. We tested the hypothesis that low serum sodium predicts mortality and correlates with markers of bone disease in hemodialysis patients.

Methods: We studied 7,972 patients in the Accelerated Mortality in Renal Replacement (ArMORR) cohort of incident HD patients. Baseline serum sodium, calcium, phosphorous, alkaline phosphatase (AP), and parathyroid hormone (PTH) levels were obtained from blood samples taken at the time of HD initiation. Baseline sodium levels were analyzed by quartile. Hazard of all cause and cardiovascular mortality were calculated using Cox proportional hazard models. Multiple linear regression models were used to predict change in serum calcium, phosphorus, AP, and PTH across the 1-year period.

Results: Lower sodium levels were associated with older age (p=0.007), Hispanic ethnicity (p<0.001), congestive heart failure (p=0.004), diabetic nephropathy (p<0.001), lower BMI (0.008), and catheter access (p<0.001). In multivariate Cox models adjusted for demographic, clinical and laboratory factors, lower sodium levels were independently associated with an increased risk for 1-year all cause mortality (quartile 1 vs quartile 4, HR 1.75, p<0.001) and cardiovascular mortality (HR 1.72, p<0.001).



Lower sodium was independently associated with a progressive decrease in serum calcium, phosphorus, and PTH (p<0.05); however, no association was seen with AP levels.

Conclusions: In a cohort of incident HD patients, low serum sodium is independently associated with all cause and cardiovascular mortality. Additionally, low sodium produces an effect on mineral metabolism consistent with PTH suppression.

FR-OR240

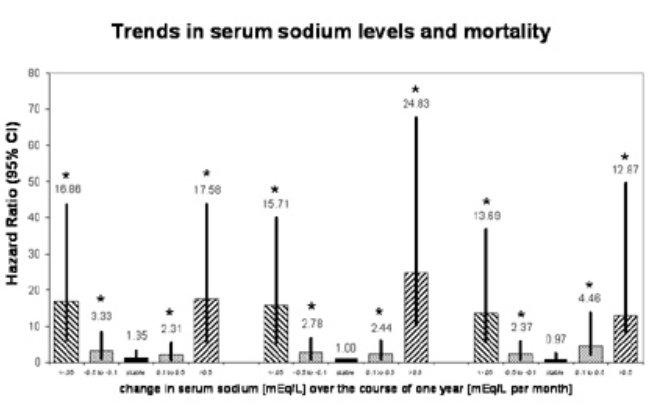
Trends in Serum Sodium Levels (SNa^+) Relate to Mortality in Incident Hemodialysis (HD) Patients Jochen G. Raimann,[1,2] Len A. Usvyat,[1] Jeroen Kooman,[3] Frank Van der Sande,[3] Stephan Thijssen,[1,2] Peter Kotanko,[1,2] Nathan W. Levin.[1,2] *[1]Renal Research Institute; [2]Beth Israel Medical Center; [3]University of Maastricht.*

Background: Low pre-HD SNa^+ is related to increased mortality in HD patients (pts; Waikar 2011). It is not yet clear if this is the reflection of disease or a causal determinant of mortality. This analysis aims to investigate the relation of mortality and temporal evolution of SNa^+ in incident patients during the first two years of HD.

Methods: Pts who started HD between 1/1/2001 and 7/30/2008, with at least 3 SNa^+ during the first 3 months were included and observed over 2 years. SNa^+ changes were quantified as slopes [mEq/L/month], computed by linear regression of SNa^+. Pts were stratified in groups of SNa^+ (average over the first three months): (1) <138, (2) 138 to 141, (3) > 141 mEq/L; and by the slope of SNa^+ change over time: (1) decreasing (<-0.1 mEq/L/month), stable (-0.1 to -0.5) and increasing (>0.1 mEq/L/month). Cox Regression was used to compute hazard ratios (HR) adjusted for age, race, gender, diabetes (DM), ultrafiltration volume, albumin, and pre HD systolic blood pressure and pre HD weight.

Results: Out of 4012 eligible pts (56% males, 43% black, 48% white, 50% DM, age 61.5±15.3 yrs) 607 pts (15%) died in the first 2 years. In the presence of stable SNa^+ over time, low SNa^+ levels during the first three months were not associated with increased mortality. Both in unadjusted and adjusted analysis rising or falling SNa^+ levels over time were significant predictors of outcomes (**Figure 1**).

Conclusions: In incident HD pts changes of SNa^+ over time appear to be a novel and significant predictor of mortality, outweighing the effects of absolute SNa^+ levels. Within the limitations of an observational study these findings suggest that low SNa^+ levels are rather a reflection of yet to be defined underlying illnesses than a direct cause of death.



FR-OR241

Is the Hyponatremia Related to Mortality in Peritoneal Dialysis Patients? A Single-Centre Retrospective Observational Study Seokhui Kang, Jun-Young Do, Kyu-Hyang Cho, Jong-Won Park, Kyung-Woo Yoon. *Division of Nephrology, Department of Internal Medicine, Yeungnam University Hospital, Daegu, Korea.*

Background: Hyponatremia is one of the most common electrolyte abnormality. There are few reports on the incidence, etiology and mortality of the peritoneal dialysis (PD) patients with hyponatremia.

Methods: We reviewed the medical records and identified all the adults who received PD between May 2001 and March 2010. Hyponatremia was defined as a serum sodium concentration less than 135 mmol/L. We enrolled 99 patients who did not show hyponatremic episodes and 297 who showed hyponatremia during follow-up. For evaluation of volume status, all patients had undergone bioelectrical impedance analysis every 6 months. Water gain as a cause of hyponatremia was defined as more than 5% increase of mean total body water (TBW) during normonatremia in the patient with hyponatremic episodes.

Results: The incidence of hyponatremia increased as the grade of the Davies risk index increased. The most common cause of hyponatremia was sodium chloride deficit (39.5%).

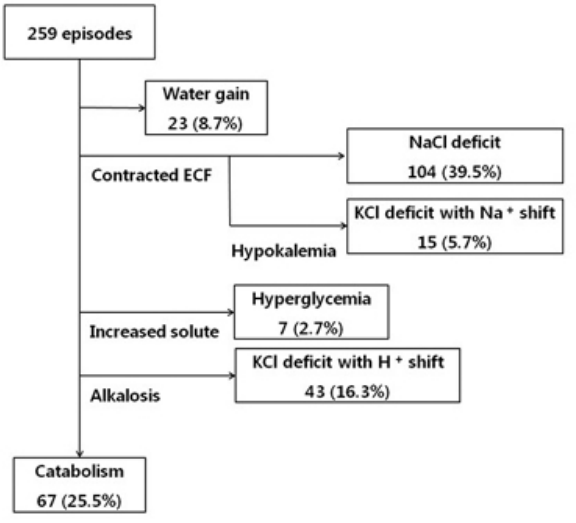


Figure 1. Summary of a diagnostic approach for hyponatremia in peritoneal dialysis patients. Abbreviations: ECF, extracellular fluid; NaCl, sodium chloride; KCl, potassium chloride; Na^+, sodium ion; K^+, potassium ion; H^+, hydrogen ion.

On the univariate analysis, old age (≥65-years-of-age), presence of hyponatremia during follow-up, hypoalbuminemia (<35g/L), residual renal function (RRF) (<2ml/min) and high comorbidity conditions are associated with mortality in the PD patients. On the multivariate analysis, old age, hypoalbuminemia, low RRF and high comorbidity conditions are associated with mortality in the PD patients.

Conclusions: The risk for hyponatremia was associated with higher comorbidity in the PD patients. However, the comorbidity conditions are more important than hyponatremia per se in predicting the mortality. For prevention or management of hyponatremia in the PD patients, we should pay more attention to correct fluid-electrolyte abnormalities but also the underlying comorbidity.

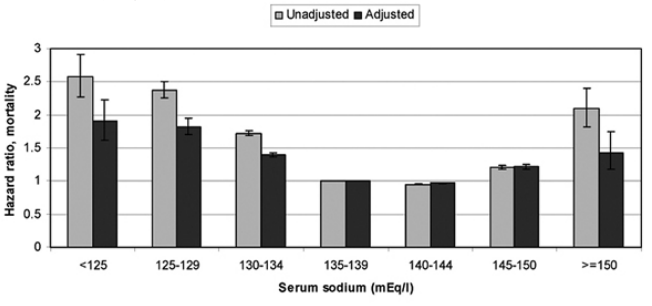
FR-OR242

Association of Serum Sodium (SeNa) Concentration with Mortality in a Large Cohort of US Veterans with CKD Csaba P. Kovesdy,[1,2] Evan H. Lott,[3] Jun Ling Lu,[4] Sandra M. Malakauskas,[1,2] Jennie Z. Ma,[2] Mark D. Okusa,[2] Kamyar Kalantar-Zadeh.[5] *[1]Salem VA Medical Center; [2]University of Virginia; [3]VA Informatics and Computing Infrastructure; [4]Salem Research Institute; [5]Harbor-UCLA.*

Background: The association of serum sodium concentration with mortality in patients with various stages of CKD is not well characterized.

Methods: We examined the association of SeNa with all-cause mortality in a nationally representative cohort of 655,493 US veterans with non-dialysis dependent CKD stages 1-5. Associations were examined in time-dependent Cox models. Non-linear associations were examined by categorizing SeNa in increments of 5 mEq/l. Models were adjusted for sociodemographics, comorbidities (including congestive heart failure (CHF) and liver disease), blood pressure and laboratory variables. Analyses were repeated in patients without CHF or liver disease.

Results: Patients were 73.9±9.8 years old, 97% were males and 71% were white. During a median follow-up of 5.5 years 193,956 patients died (mortality rate, 95%CI: 62.5/1000 patient-years, 62.2-62.8). The association of SeNa with mortality was U-shaped: compared to patients with SeNa 135-139 mEq/l, patients with SeNa <125, 125-129, 130-134, 140-144, 145-149 and ≥150 had adjusted mortality hazard ratios (95%CI) of 1.90 (1.62-2.26), 1.82 (1.71-1.95), 1.40 (1.36-1.43), 0.97 (0.98-0.99), 1.22 (1.18-1.26) and 1.43 (1.18-1.74)(Figure).



Associations were similar when restricting the study cohort to patients without CHF or liver disease.

Conclusions: Both lower and higher SeNa are associated with higher mortality in patients with CKD. These associations are present even in patients without significant comorbid conditions known to affect SeNa, suggesting that abnormal SeNa may not be merely a surrogate of more sever comorbid states. Therapeutic interventions targeting abnormal SeNa will need to be tested in clinical trials.

Nephrocystins Regulate the Wnt Pathways and Are Required for Ciliogenesis and Epithelial Morphogenesis Helori-Mael Gaudé,[1] Celine Burckle,[1,2] Rodrick Montjean,[1] Flora Silbermann,[1] Emilie Montenont,[1] Thierry Blisnick,[3] Anthony Henneveu,[4] Cecile Jeanpierre,[1] Alexandre Benmerah,[4] Philippe Bastin,[3] Corinne Antignac,[1] Sylvie Schneider-Maunoury,[2] Sophie Saunier.[1] *[1]INSERM U983, Hopital Necker Enfants Malades, Paris, France; [2]CNRS UMR 7622, UPMC, Paris, France; [3]CNRS URA 2581, Institut Pasteur, Paris, France; [4]INSERM U1016, Institut Cochin, Paris, France.*

Background: Nephronophthisis is a hereditary nephropathy characterized by interstitial fibrosis and cyst formation that is caused by mutations in NPHP genes encoding the nephrocystin family of ciliary proteins.

Methods: We have previously shown that nephrocystin-1 and -4 associate with tight junction protein complexes and that depletion of NPHP1 or NPHP4 by shRNA-mediated knockdown in MDCK cells led to a delay in tight junction formation and disorganized structures in 3D culture.

Results: Interestingly, knockdown of either gene in MDCK and IMCD also increased cell migration and enhanced spreading on collagen. This was accompanied by over-activation of proteins regulating focal adhesions (p130cas and Pyk2), as well as of RhoGTPases, disorganisation of the actin cytoskeleton, enhancement of microtubule polymerization and alteration of ciliogenesis. In vivo experiments performed in zebrafish demonstrate that nephrocystin-4 depletion results in abnormal ciliogenesis and planar cell polarity (PCP) defects, leading to convergent extension defects and pronephric cysts associated with alterations in early cloacal morphogenesis. Depletion of either inversin, nphp2 gene product, or of Wnt-PCP pathway components increases cyst formation in nphp4-depleted embryos. In agreement with these observations, we demonstrate that nephrocystin-4 interacts with inversin and dishevelled and regulates dishevelled stability and subcellular localization in mammalian kidney cells, thus repressing the Wnt-beta-catenin pathway.

Conclusions: Altogether, our data point to crucial functions of nephrocystins in epithelial cell organization and kidney morphogenesis, tight regulation of cytoskeleton organization, cell adhesion and the PCP pathway, through their functional interaction with dishevelled and other polarity determinants such as focal adhesion complexes.

FR-OR244

Toward Understanding Pkd1 Cystogenetic Mechanism Marie Trudel, Almira Kurbegovic. *Molecular Genetics and Development, Institut de Recherches Cliniques de Montreal, Montreal, QB, Canada.*

Background: Autosomal dominant polycystic kidney disease(ADPKD) is a genetic disease that displays renal and extrarenal phenotypes. The PKD1 gene responsible for most cases of ADPKD, was shown to have developmentally regulated expression pattern. The pathogenetic mechanism underlying ADPKD induced by mutations in the PKD1 gene is an enigma. While evidence of Pkd1 loss-of-heterozygosity and hypomorph alleles can cause renal cyst in mice, paradoxically high levels of human PKD1 are detected in ADPKD kidneys/tissues.

Methods: To determine whether enhanced Pkd1 expression could be a pathogenetic mechanism, 3 transgenic mouse lines were generated with a tagged Pkd1-BAC.

Results: These mice overexpressed wild type Pkd1 transgene with proper temporal regulation in renal and extrarenal tissues from ~2- to 15-fold over Pkd1 endogenous levels. All mice reproducibly developed tubular and glomerular cysts leading to renal insufficiency that correlated with level of Pkd1 imbalance. $Pkd1_{TAG}$ mouse model also displayed hepatic cyst, brain aneurysm, cardiovascular defect and provide evidence that gain-of-function can be a pathogenetic mechanism. To verify that the Pkd1-BAC transgene produced a functional protein, we questioned whether low and high transgene expressor could rescue the lethality of Pkd1 null newborn. The low Pkd1 expressor in Pkd1 null newborn did not prevent renal cystic or pancreatic phenotypes. These results contrast with those of Pkd1 hypomorphic alleles at 15-20% Pkd1 with less severe renal cysts than null Pkd1 mice. It suggests that either targeted hypomorphic Pkd1 produce abnormal transcripts that protect from cyst formation or the $Pkd1_{TAG}$ transgene lack regulatory elements for proper expression. However, the high Pkd1 transgene expressor (>endogenous) on a null Pkd1 background are healthy with no evidence of renal or extrarenal PKD phenotype and displayed complete rescue, supporting proper transgene regulation. Only older adult mice showed renal cystic anomalies, much milder than in the high transgene expressors.

Conclusions: Together our data support a Pkd1 gene dosage pathogenetic mechanism for ADPKD and highlight our $Pkd1_{TAG}$ mouse as the model most closely mimicking ADPKD phenotype and progression.

Copeptin, a Surrogate Marker for Vasopressin, Is Associated with Disease Progression in the CRISP Cohort of ADPKD Patients Wendy E. Boertien,[1] Esther Meijer,[1] Li Jie,[2] James E. Bost,[2] Joachim Struck,[3] Michael F. Flessner,[4] Ron T. Gansevoort,[1] Vicente E. Torres.[5] *[1]On behalf of the CRISP Consortium; Nephrology, UMC, Groningen, Netherlands; [2]Biostatistics, University of Pittsburgh; [3]BRAHMS Biomarkers, ThermoFisher Scientific, Hennigsdorf, Germany; [4]NIH/NIDDK, Bethesda; [5]Nephrology, Mayo Clinic, Rochester.*

Background: Experimental studies suggest a detrimental role for vasopressin in the pathogenesis of ADPKD. The significance of vasopressin in human ADPKD, however, is yet unclear. We therefore investigated whether vasopressin is associated with disease progression in a cohort of ADPKD patients.

Methods: Baseline plasma copeptin, a reliable surrogate for vasopressin, was measured in 241 ADPKD patients who participated in the CRISP study (a longitudinal, observational study). Patients were followed for 3 years. Every year total kidney volume (MRI) and renal function (iothalamate clearance) were measured.

Results: In these 241 patients (age 32.4 ± 8.9 years, 40% male, GFR 97.8 ± 24.7 ml/min/1.73m^2), median copeptin level was 2.9 (IQR 1.8 – 5.0) pmol/L. Copeptin concentration was higher in males than in females. Remarkably, baseline copeptin concentration was not associated with plasma osmolality ($p = 0.29$), urine osmolality ($p = 0.16$) and 24 hour urine volume ($p = 0.17$). In contrast, baseline copeptin concentration was significantly associated with change in total kidney volume during follow-up (std. Beta = 0.24, $p < 0.01$). This association remained significant after adjusting for gender, age, cardiovascular risk factors and baseline TKV (std. B = 0.14, $p = 0.03$). Baseline copeptin concentration was also significantly associated with change in GFR after adjusting for gender, age cardiovascular risk factors and baseline GFR (std. B = -0.15, $p = 0.03$).

Conclusions: These data show that in ADPKD patients, copeptin levels, as a marker for vasopressin, are not correlated with normal physiologic parameters as plasma nor urinary osmolality or urine volume. Most importantly, high copeptin levels are independently associated with disease progression in ADPKD patients, confirming experimental studies suggesting a detrimental role for vasopressin.

FR-OR246

Expression of the Cytoplasmic Tail of Fibrocystin Causes Cystogenesis through PI3K/Akt/mTOR Pathway Shixuan Wang,[1] Gang Yao,[1] Maoqing Wu,[1] Jingjing Zhang,[2] Jing Zhou.[1] *[1]Medicine, Brigham and Women's Hospital, Boston, MA; [2]Medicine, Mount Auburn Hospital, Cambridge, MA.*

Background: FPC (fibrocystin or polyductin) is a single transmembrane receptor-like protein, responsible for the human autosomal recessive polycystic kidney disease (ARPKD). It was recently proposed that FPC could undergo a Notch-like cleavage and subsequently releases the cleaved carboxy(C)-terminal fragment that enters the nucleus of the cell. However, the functions of the cleaved C-tail are unknown.

Methods: We have used a series of morphological, biochemical, immunological, and cell biology approaches to explore the roles of the isolated FPC C-tail.

Results: By 3D tubulogenesis assay and confocal microscopy, we found that in contrast to tubule-like structures formed by vector-transfected control cells (100%), these hICD-expressing cells (hICD) form cyst-like structures (100%). By western blotting and immunostaining, we observed altered expression of integrins (alpha2, 3, beta1), translocation of E-Cadherin from adherent junctions to the cytoplasm, reduced cell growth rate, and increased apoptosis/autophagy in hICD cells. Flow cytometry analysis showed an increased accumulation of hICD cells in S-phase after 48-h serum starvation (G0). Furthermore, the Akt/mTOR pathway, demonstrated by increased phosphorylation of Akt at serine 473 and S6 kinase 1 at threonine 389, are constitutively activated. More importantly, rapamycin of mTOR inhibitor or wortmannin and LY294002 of phosphoinositide 3-kinase (PI3K) inhibitors can inhibit the activation of mTOR and partially rescue the cyst-forming phenotype in hICD cells. Interestingly, hICD cells display cell attachment defects upon FBS deprivation and high osmolality, which can also be partially rescued by mTOR and PI3K inhibitors.

Conclusions: FPC C-tail overexpression leads to activation of mTOR pathway, reduced cell growth rate, increased apoptosis and autophagy, altered cell cycle profile and cyst formation in 3D cultures in mIMCD3 cells. We propose that FPC C-tail modulates tubulogenesis through PI3K/Akt/mTOR pathway.

The Role of the Exocyst in Renal Cilia Assembly and Function Ben Fogelgren,[1,3] Shin-Yi Lin,[2] Xiaofeng Zuo,[3] Kimberly Jaffe,[2] Sarah McKenna,[3] Ryan J. Reichert,[4] Kwon Moo Park,[5] P. Darwin Bell,[4] Rebecca D. Burdine,[2] Joshua H. Lipschutz.[1, 6] *[1]University of Hawaii; [2]Princeton University; [3]University of Pennsylvania; [4]Medical University of South Carolina; [5]Kyungpook National University, Korea; [6]Philadelphia VAMC.*

Background: The pathogenesis of polycystic kidney disease (PKD) is dependent on disruptions in primary cilia function in renal epithelial cells. Despite intense study, it remains poorly understood how proteins are targeted and delivered to cilia.

Methods: We established in vitro and in vivo models to analyze the role of the exocyst complex and one of its regulating GTPases (Cdc42) in cilia assembly and function. shRNA was used to knockdown exocyst Sec10 and Cdc42 expression in MDCK cells, and antisense morpholinos were used to disrupt Sec10 during zebrafish development.

Results: In Sec10-knockdown MDCK cells, ciliogenesis was severely disrupted and the cellular phenotype recapitulated that seen in ADPKD cells: loss of flow-generated calcium increases; hyperproliferation; and overactivation of the MAPK pathway. The exocyst bound to the Par complex, which co-localizes with the exocyst at the primary cilium. Dominant negative Cdc42 expression, shRNA-mediated knockdown of Cdc42, and shRNA-mediated knockdown of Tuba, a Cdc42 GEF, all prevented ciliogenesis in MDCK cells. In vivo, Sec10 knockdown in zebrafish phenocopied many aspects of polycystin-2 knockdown, including: curly tail up; left-right patterning defects; glomerular expansion; and MAPK activation. Sec10 morphants also had disorganized cilia. Importantly, there was a synergistic genetic interaction between zebrafish sec10 and pkd2, in that co-injection of small amounts of sec10 and pkd2 morpholinos, which individually had no effect, together resulted in a severe phenotype. Supporting this observation, the Sec10 protein pulled down and co-immunoprecipitated with polycystin-2 and intraflagellar transport proteins IFT20 and IFT88.

Conclusions: Taken together, these data support a model of exocyst ciliary trafficking whereby Cdc42 localizes the exocyst to primary cilia, the exocyst binds to the Par complex, and the exocyst then docks Rab8-positive vesicles carrying ciliary proteins.

FR-OR248

Induction of Ran GTP Drives Ciliogenesis Shuling Fan,[1] Eileen L. Whiteman,[1] Toby W. Hurd,[3] Benjamin L. Margolis.[1,2] *[1]Department of Internal Medicine; [2]Department of Biological Chemistry; [3]Department of Pediatrics and Communicable Disease, University of Michigan Medical School, Ann Arbor, MI.*

Background: The small GTPase Ran and its binding partners, the Importins, regulate transport from the cytoplasm into the nucleus. New evidence suggests that Ran GTP and the Importins are also involved in regulating protein movement into the cilia. Our previous studies found that importin beta2 collaborates with Ran to promote cilia targeting of Retinitis Pigmentosa 2 and the Kif17 motor protein.

Methods: We used Retinal Pigment Epithelial (RPE), Human Primary Airway Epithelial or MDCK cells to study ciliogenesis. Ciliogenesis was induced in RPE cells by serum starvation and in MDCK and Human Primary Airway Epithelia by growing the cells to confluence. Ran GTP levels were measured with Ran GTP specific antibodies or by pull down with GST Importin beta1 followed by immunoblotting with Ran antibodies.

Results: We found that Ran GTP can be localized to centrosomes/basal bodies as well as the tips of cilia. Strikingly, we find that Ran GTP accumulation at basal bodies is coordinated with the initiation of ciliogenesis. The Ran Binding Protein 1 (RanBP1), which accelerates hydrolysis of Ran GTP to Ran GDP also localizes to basal bodies and cilia. To confirm the crucial link between Ran GTP and ciliogenesis, we manipulated the levels of RanBP1 and determined the effects on Ran GTP and primary cilia formation. We discovered that RanBP1 knockdown in RPE cells results in an increased concentration of Ran GTP at centrosomes leading to ciliogenesis. In contrast, overexpression of RanBP1 in RPE cells antagonizes primary cilia formation and attenuates Ran GTP accumulation at centrosomes. Furthermore, we demonstrate that RanBP1 knockdown disrupts the proper localization of Kif17 at the distal tips of primary cilia in MDCK cells.

Conclusions: Our studies illuminate a new function for Ran GTP in stimulating cilia formation and reinforces the notion that Ran GTP and the Importins play key roles in ciliogenesis and ciliary protein transport.

FR-OR249

The Cilia-Associated Protein NPHP4 Translocates Canonical Wnt-Regulator Jade-1 to the Nucleus Lori Borgal,[1] Sandra Habbig,[1,2] Max C. Liebau,[1,2] Claudia Dafinger,[1] Roman-Ulrich Mueller,[1] Thomas Benzing,[1] Bernhard Schermer.[1] *[1]Renal Division, Department of Medicine and Center for Molecular Medicine Cologne, University of Cologne, Germany; [2]Department of Pediatrics, University of Cologne, Germany.*

Background: Nephronophthisis is the most common genetic cause of endstage renal disease in children, with no causative treatment currently available. The disease is characterized histologically by a hallmark triad of tubular basement membrane disruption, interstitial inflammation and fibrosis, and corticomedullary cyst development. Pathogenesis involves the loss of function of one or more nephrocystin proteins (NPHPs), leading to the disease classification of a "ciliopathy" because all NPHPs localize to primary cilia or centrosomes. Cystogenesis is thought to involve over-activation of canonical Wnt signaling, but the mechanism remains unclear.

Jade-1 has recently been identified as a novel ubiquitin ligase targeting beta-catenin for proteasomal degradation. Jade-1 was further shown to be regulated by pVHL. Here, we demonstrate that Jade-1 localizes to the ciliary base, and interacts with NPHP4. NPHP4 stabilizes protein levels of Jade-1 and is involved in the translocation of Jade-1 to the nucleus. Finally, NPHP4 and Jade-1 were demonstrated to additively inhibit Wnt signaling, and this interaction was shown to exist genetically in zebrafish.

The stabilization and nuclear translocation of Jade-1 by NPHP4 enhances the ability of Jade-1 to negatively regulate canonical Wnt signaling. Mutation of NPHP4 in Nephronophthisis could disrupt this mechanism, leading to increased Wnt activation and contributing to cyst formation.

FR-OR250

Generation of a Mouse Knockout Model To Functionally Characterize the New Ciliopathy Gene Sdccag8 Rannar Airik,[1] Friedhelm Hildebrandt.[1,2] *[1]Departments of Pediatrics and of Human Genetics, University of Michigan, Ann Arbor, MI; [2]Howard Hughes Medical Institute, Chevy Chase, MD.*

Background: Nephronopthisis (NPHP) is a heterogenetic autosomal recessive renal ciliopathy that represents the most frequent cause of kidney failure in the first 30 years of life. It is frequently associated with retinal degeneration, liver fibrosis, mental retardation or malformations of brain, heart and bone. We have previously shown that recessive truncating mutations in the human gene SDCCAG8/NPHP10 gene cause NPHP with retinitis pigmentosa (Otto et al., Nat Genet 42:840, 2010) and primary cilia dyskinesia (Dollfus H, unpublished communication). We demonstrated that SDCCAG8 localizes to several different subcellular structures, including centrioles and cell-cell junctions. However, the pathogenic mechanism of SDCCAG8 mutation remains unknown.

Methods: We therefore generated an Sdccag8 knock-out mouse model to study the function of Sdccag8 in tissues affected by its ablation.

Results: Our first data indicate that Sdccag8 is strongly expressed in nephron segments of the cortico-medullary zone of the developing mouse kidney and in bronchioles of the developing mouse lung. Morphologically, Sdccag8$^{-/-}$ mice display hindlimb polydactyly with triphalangeal thumbs. In addition, we demonstrate that Sdccag8 is also localized to nuclear speckles – foci of mRNA synthesis.

Conclusions: The nuclear localization indicates that Sdccag8 may be involved in regulating processes so far not ascribed to NPHP-causing genes. Further understanding of Sdccag8 subcellular and signalling functions will provide valuable insight into the pathogenetic mechanisms of NPHP.

Otto EA, Hurd TW, Airik R, et al. Candidate exome capture identifies mutation of SDCCAG8 as the cause of a retinal-renal ciliopathy. Nat Genet 42:840-850, 2010

FR-OR251

Renal Phenotype of a Mouse Model of HANAC Syndrome Revealing a New Role for Col4a1 in Glomerulogenesis Emmanuelle M. Plaisier,[1] Zhiyong Chen,[1] Migeon Tiffany,[1] Mohamad Zaidan,[1] Dontscho Kerjaschki,[2] Pierre M. Ronco.[1] *[1]INSERM UMRS 702, Tenon Hospital, Paris, France; [2]Medical university of Vienna, Austria.*

Background: We have described a multisystemic dominant syndrome called HANAC (Hereditary Angiopathy, Nephropathy, Aneurysms, and Cramps) related to *COL4A1* mutations. Renal abnormalities include hematuria and renal cysts. To get insight into the pathogenesis of HANAC, we have generated *Col4a1*^{G495V} mutant mice.

Methods: The *Col4a1*^{G495V} mouse strain was generated by homologous recombination, using a targeting construct containing a 16kb *Col4a1* genomic region, in which the c.1706G>T mutation was introduced in exon 25.

Results: Despite intracerebral bleeding and growth retardation at birth, homozygous mice lived through adulthood. At birth, albuminuria and hematuria were detected in homozygous and heterozygous animals. Homozygous neonates showed morphological glomerular defects with ultrastructural abnormalities of podocytes and glomerular

basement membrane (GBM). Focal proximal tubular dilation and cell vacuolization were present. Basement membrane expression of the α1α1α2(IV) molecule persisted at a low level in homozygous mutants, demonstrating that the mutation did not abolish the trimer formation and secretion. Abnormal expression of nephrin was detected in mutants as well as accumulation of the ER stress protein Bip in podocytes. Albuminuria progressively disappeared during the first week and neonate morphological changes resolved. However, at 3 months, renal defects developed in both heterozygous and homozygous animals, that associated bilateral glomerular cysts and large periglomerular and vascular inflammatory infiltrates.

Conclusions: Renal phenotype of the Col4a1^{G495V} mice reveals a potential contribution of the α1α1α2(IV) collagen network to glomerulogenesis. Because HANAC mutations affect an integrin-binding site domain of the α1(IV) chain, and given that glomerular defects observed in Col4a1^{G495V} neonates are similar to the ones observed in α3-integrin deficient mice, we speculate that the α1α1α2(IV) molecule expressed in embryonic GBM, contribute to a developmental pathway through the interaction with the α3β1 integrin expressed in podocytes.

Dicer$^{flox/flox}$-Pax8$^{Cre/+}$ Mice a Model for Studying the Role of miRNAs in Renal Cysts Development Anna Iervolino,[1] Francesco Trepiccione,[1] Daniela Frezzetti,[2] Marzia Scarfò,[2] Mario De Felice,[2] Giovambattista Capasso.[1] *[1]Chair of Nephrology, Second University of Naples, Naples, Italy; [2]Institute of Genetic Research, Biogem, Ariano Irpino, Italy.*

Background: MicroRNAs (miRNAs) are small, non-coding, regulatory RNAs that control gene expression at the post-transcriptional level. Dicer1 is a RNAse III protein essential for the biogenesis of active miRNAs. Here we want to assess the role of miRNA in renal cysts development in mice cko for Dicer1.

Methods: We studied mice cko for Dicer1 in Pax8 expressing organ, namely thyroid gland and kidney. We matched Pax8-Cre mice with mice carrying a Dicer floxed allele. The loxP sequences were intercalated around exons 22 and 23 of the Dicer gene, encoding for catalytic RNAseIII domains. Mice carrying both Pax8-Cre and floxed-Dicer alleles had an impairment in miRNA generation.

Results: Dicer cko mice have morphological and functional signs of hypothyroidism. They have a smaller size and a higher mortality rate. Kidneys were smaller than age-matched control mice, but they do not show any difference in KW/BW ratio. At 1 month, histological examination does not demonstrate macroscopic changes as a further evidence of lack of renal organogenesis impairment. At 2 months cko mice have multicystic kidneys. Renal cysts are mainly located in the cortex, but also in outer and inner medulla as well. Some cysts appear as an enlargement of the Bowman'space, containing the glomeruli, others look like more tubular dilatations. Only few cysts present a AQP2 positive staining. Dicer cko mice have a higher cellular turn-over as shown by increased cellular proliferation (ki-67) and apoptosis (cleaved caspase-3) markers. At 2 months cko mice are characterized by increased urine volume associated with reduced urine osmolality. This is coupled with a lower expression of inner medullar AQP2 protein. Dicer cko mice at 2 months are also affected by severe proteinuria.

Conclusions: In conclusion Dicer cko mice have no renal morphological alteration until 1 month from the birth but then, they progressively develop a multicystic kidney phenotype at 2 months. It is therefore evident that our Dicer cko mice are a good model to investigate the miRNA function in cystogenesis.

FR-OR253

Robust Assays Confirm the High Prevalence of Antibodies to LAMP-2 in European Patients with Pauci-Immune FNGN (piFNGN) Andrew J. Rees, Renate Kain. *Clinical Department of Pathology, Medical University of Vienna, Vienna, Austria.*

Background: We reported that antibodies to LAMP-2 were detected in 93% of a cohort of patients presenting with piFNGN but not found once remission had been induced (Nature Med. 14:1088. 2008) but these findings have been challenged. The present study had two purposes: to test the robustness of three independent assays for anti-LAMP-2 antibodies and the concordance between them; and to re-asses the prevalence of antibodies to LAMP-2 in piFNGN in three new groups of European patients from Austria, UK and the Netherlands.

Methods: The patient groups were: newly presenting and relapsing patients from Vienna (n=11) together with healthy and disease controls; cohorts of newly presenting patients with piFNGN (n=55) from Cambridge, UK (kindly provided by Professor K. Smith); and newly presenting and sequentially followed patients from Groningen, Netherlands (n=48) (kindly provided by Professor C Kallenberg and C. Stegeman). Antibodies to LAMP-2 were assayed using three independent tests; an ELISA using unglycosylated recombinant human LAMP-2 extracellular domain expressed in E.coli; Western blots using the same substrate; and indirect immunofluorescence of ldlD cells expressing human LAMP-2 with a mutation in the cytoplasmic lysosmal retrieval signal that targeted it exclusively to the cell surface.

Results: Inter- and intra-assay variation was less than 10% for each assay and all three assays gave the same result in 121 of 144 patient sera. This gives a concordance rate of 84% proving the assays measure authentic antibodies to LAMP-2. We detected antibodies to LAMP-2 in piFNGN in 9/11 (82%) Vienna patients; 38/55 (69%) of the Cambridge cohort; and 40/48 (82%) of the Groningen cohort. Sera taken from the Groningen cohort 1, 2, 3, 6 and 12 months after starting treatment showed rapid resolution of the antibodies which were uniformly negative at 1 month. Subsequently anti-LAMP-2 antibodies became detectable again in 5 patients.

Conclusions: These results confirm a uniformly high prevalence of anti-LAMP-2 antibodies in European cohorts with piFNGN and show the antibody concentrations fall rapidly after the start of treatment.

FR-OR254

Human Anti-PR3 ANCA Recapitulate Systemic Vasculitis in Mice with a Humanised Immune System Jeremy S. Duffield,[1] Mark Little,[3] Bahjat Al-Ani,[2] Charles E. Alpers,[1] Caroline O.S. Savage.[2] *[1]Medicine, University of Washington, Seattle, WA; [2]Medicine, Birmingham University, Birmingham, United Kingdom; [3]Medicine, UCL, London, United Kingdom.*

Background: Evidence is lacking for a direct pathogenic effect of anti-proteinase 3 (PR3) antibodies. Progress has been hampered by different PR3 expression patterns in the mouse, the neutrophils of which do not express PR3 on the cell surface, and by the presence of different Fc receptors across the two species. Therefore, we sought to test whether human anti-PR3 ANCA were capable of inducing acute vasculitis in mice with a human immune system.

Methods: We generated chimeric mice by injecting mobilised human haematopoetic stem cells into NOD.Cg-Prkdcscid Il2rgtm1Wjl/SzJ mice, which lack functional B, T and NK cells. We confirmed myeloid chimerism Mean achieved human CD45+ cell chimerism was 18.5% of circulating cells (range 6.3-38.2). Both human monocytes & granulocytes were detectable by FACS using human CD11b, CD15 & CD66b antibodies. Human neutrophils were detectable in the bone marrow, with typical c-ANCA and p-ANCA staining demonstrated using human anti-PR3 & anti-MPO antibodies.

Results: We injected IV 4mg of protein G purified human IgG from patients with Renal $ Lung vasculitis (anti-PR3, n=18 mice from 3 donors), patients with non-vasculitic renal disease (disease controls, n=5) and healthy controls (n=3). To maximise myeloid cell recruitment mice were pre-treated with LPS 1500EU/g. By sacrifice on day 6, seven of anti-PR3 treated mice (39%) had haematuria, whereas none of the control animals did. There was punctate haemorrhage on the surface of the lungs of anti-PR3 treated animals, with histological evidence of acute vasculitis and haemorrhage. Anti-PR3 treated mice had mild pauci-immune proliferative glomerulonephritis, with infiltration of human & mouse leukocytes. In 3 mice (17%) more severe glomerular injury was present. There were no glomerular changes in controls. There were no glomerular changes in control mice.

Conclusions: Human anti-PR3 autoantibodies are pathogenic. This model of anti-PR3 associated vasculitis may be useful in dissecting mechanisms of vascular injury.

FR-OR255

Mast Cells Attenuate Autoimmune Anti-Myeloperoxidase Glomerulonephritis by Mast Cell IL-10 Directed Enhanced T Regulatory Cell Immunosuppression Poh-Yi Gan, Shaun A. Summers, A. Richard Kitching, Stephen R. Holdsworth. *Medicine, Monash Medical Centre, Monash University, Clayton, Victoria, Australia.*

Background: Mast cells (MCs) are pleiotrophic and can release cytokines that mediate effector or regulatory immune responses. We previously showed that MCs are protective in anti-myeloperoxidase (MPO) GN. This study explores the mechanism of this protection.

Methods: Autoimmunity to MPO and anti-MPO GN was examined among MC deficient (Wsh) and Wsh mice reconstituted with WT (WTMC→Wsh) or IL-10-/-MC (IL-10-/-MC→Wsh). MPO immunization with Freunds adjuvant was used to induce autoimmunity and GN was triggered using low dose of anti-glomerular basement membrane antibody.

Results: WTMC→Wsh mice developed significantly less intense anti-MPO autoimmunity and renal injury than Wsh mice confirming that protection is MC dependent (proteinuria; 10.1±1.3 vs 4.8±0.8mg/24hr and glomerular CD4 cells; 0.8±0.1 vs 0.5±0.1c/gcs). MPO autoimmunity measured by dermal DTH (1.1±0.1 vs 0.7±0.1Δmm), CD4 anti-MPO proliferation responses (19.2±2.2 vs 13.3±1.8 x10^{3}counts/min) and IL-17A (15.8±1.3 vs 9.5±1.4ng/ml). The proportion of LN Tregs was decreased in Wsh mice (12.2±1.2 vs 13.4±0.4 %CD4+Foxp3+) all P<0.05.

Reconstitution with IL-10-/-MC offered no protection compared with WTMC→Wsh mice, confirming that protection is MC IL-10 dependent. Proteinuria (13.0±2.2 vs 6.8±0.4) and glomerular CD4 cells (0.8.0±0.1 vs 0.6±0.01). Dermal MPO DTH (0.8±0.1 vs 0.4±0.1), MPO recall proliferation (12.8±1.5 vs 8.1±1.3 x10^3) and IL-17A (7.0±1.8 vs 2.5±0.9).

Tregs (CD4+Foxp3+) and Teffectors (CD4+Foxp3-) were isolated from LNs of MPO immunized Foxp3-GFP mice. The capacity of Tregs to suppress MPO recall responses of Teffs was assessed in the absence and presence of either WT or IL-10-/- MCs. WT MCs induced Treg production of IL-10, TGFβ and enhanced Treg suppression of Teff responses (17.1±1.0 vs 10.6±1.7 x10^{2}counts/min). Whereas IL-10-/- MCs induced no increase in production of IL-10, TGFβ and had significantly less capacity to enhance Treg suppression of Teffectors (15.7±1.3 vs 14.2±17.3 x10^2).

Conclusions: MCs play a protective role in autoimmune anti-MPO GN by enhancing T regulatory cell suppression mediated by MC production of IL-10.

FR-OR256

Neutrophil Serine Proteases Mediate Anti-Myeloperoxidase Antibody Induced Crescentic Glomerulonephritis Adrian Schreiber,[1,2] Christine T.N. Pham,[3] Friedrich C. Luft,[1] Ralph Kettritz.[1,2] *[1]Experimental Research Center (ECRC), Charite Berlin-Buch, Berlin, Germany; [2]Medizinischen Klinik mit Schwerpunkt Nephrologie und internistische Intensivmedizin am Campus Virchow-Klinikum der Charité, Charite Berlin, Berlin, Germany; [3]Division of Rheumatology, Washington University School of Medicine, St. Louis, MO.*

Background: Anti-neutrophil cytoplasmic antibodies (ANCA) are associated with necrotizing crescentic glomerulonephritis (NCGN) and their pathogenicity has been firmly established in several animal models. Dipeptidyl peptidase I (DPPI) is a cysteine protease required for the activation of neutrophil serine proteases (NSP) cathepsin G (CG), neutrophil elastase (NE), and proteinase 3 (PR3), enzymes that are thought to play an important role in inflammation. We tested the hypothesis that active NSP are essential to anti MPO Ab-induced NCGN.

Methods: An experimental model of anti-MPO induced NCGN was used in which MPO-deficient animals were immunized with murine MPO followed by irradiation and bone marrow (BM) transplantation with MPO-positive bone marrow cells.

Results: Mice transplanted with wild type (WT) BM developed NCGN whereas mice transplanted with DPPI-/- BM were protected (37.4±8.2% crescents in WT vs. 1.3±0.7% crescents in DPPI-/-). This protective effect correlated with inactivation of NSP as mice reconstituted with NE-/-xPR3-/- BM were equally protected against NCGN induced by anti-MPO Ab. Protection was accompanied by a significant reduction in in vivo IL-1β generation by DPPI-/- BM-reconstituted animals (103.0 ± 29.6 pg/ml in WT kidneys vs. 5.9±1.1 pg/ml in DPPI-/-) and in vitro production of IL-1β by anti-MPO Ab-activated protease-deficient monocytes. Lastly, the specific IL-1 receptor antagonist Anakinra protected animals against anti-MPO Ab-induced NCGN (16.7±6.0% crescents in untreated mice vs. 2.4±1.7% crescents in Anakinra-treated mice), suggesting that IL-1β is a critical inflammatory mediator in this model.

Conclusions: Our data strongly suggest that NSP-dependent IL-1β generation is required for the development of anti-MPO Ab-induced NCGN and together NSP and IL-1β may provide novel therapeutic targets for ANCA-mediated diseases in humans.

Membranous Nephropathy-Associated Anti-Phospholipase A2 Receptor IgG4 Autoantibodies Activate the Lectin Complement Pathway Hong Ma, Laurence H. Beck, David J. Salant. *Medicine, Boston University Medical Center, Boston, MA.*

Background: IgG4 is the major IgG subclass in the glomerular immune deposits of patients with primary membranous nephropathy (MN). IgG4 antibodies to the phospholipase A2 receptor (PLA2R) also predominate in the serum of most cases of MN, and IgG4 anti-PLA2R can be eluted from their glomerular deposits. Whereas IgG4 does not activate complement via the classical pathway, C3 and C5b-9 are typically present in MN glomerular deposits in the absence of C1q, which suggests that another complement pathway might be involved. Given that mannan-binding lectin (MBL) has been found in MN glomeruli, we hypothesized that IgG4 might bind MBL and activate complement via the lectin pathway.

Methods: IgG4 from normal and MN sera was isolated and IgG4 anti-PLA2R was further purified from the total MN IgG4 by affinity chromatography on an immunoreactive fragment of PLA2R. MBL binding to IgG4 anti-PLA2R was assessed by Far-Western blot analysis and by ELISA on IgG4 anti-PLA2R-coated plates. The ability of IgG4 anti-PLA2R to activate complement via MBL was assessed by generation of C4b in the presence of high salt buffer to inactivate the classical pathway.

Results: For the Far-Western assay, normal human IgG4, IgG4 anti-PLA2R, and MN IgG4 that had been preabsorbed with PLA2R was resolved by SDS-PAGE, transferred to nitrocellulose membranes and incubated with purified MBL. MBL bound strongly to the anti-PLA2R IgG4 band and only weakly to normal IgG4 and MN IgG4 that had been depleted of anti-PLA2R. Under reducing conditions, MBL bound exclusively to the H chain of anti-PLA2R IgG4. ELISA assay further demonstrated that MBL binding to IgG4 anti-PLA2R was significantly greater than to normal control IgG4 (0.317±0.148 vs -0.007±0.007, N=3, P<0.05). Moreover, IgG4 anti-PLA2R significantly activated C4 to C4b in the presence of MBL as compared to control IgG4 (0.193±0.084 vs -0.012±0.012, N=3, P<0.05).

Conclusions: MN-associated IgG4 anti-PLA2R autoantibodies are able to bind MBL directly and activate complement in situ. These findings suggest that the Fc region of anti-PLA2R IgG4 may possess unique properties and explain how complement is activated in the glomeruli of patients with MN.

Exosomes Released from Dendritic Cells Are Taken up by Kim-1-Expressing Proximal Tubule Cells and Increase Cellular MHC-II Protein Levels Dhruti D. Patel,[1,2] Suetonia Palmer,[1] Craig R. Brooks,[1] Takaharu Ichimura,[1] Joseph V. Bonventre.[1] *[1]Renal Division, Brigham and Women's Hospital, Boston, MA; [2]School of Medicine, University of North Carolina, Chapel Hill, NC.*

Background: Chronic kidney disease is often marked by an infiltration of inflammatory cells. The mechanisms underlying the facilitation of this inflammatory response and the role of antigen presentation by the proximal tubule remains incompletely defined. Kidney Injury Molecule 1 (Kim-1) recognizes phosphatidylserine and converts proximal tubule cells to phagocytes. We evaluated whether Kim-1 mediates uptake of exosomes released from denditic cells and whether this process results in enhanced proximal tubule presentation of antigen by upregulation of major histocompatibility complex class II (MHC-II).

Methods: The relationship between Kim-1 and MHC-II expression was determined by immunocytochemical techniques in a novel transgenic animal model of Kim-1 expression which results in chronic kidney disease. Isolated exosomes from cultured mouse dendritic cells were presented to proximal tubule cells. MHC-II and Kim-1 co-expression was evaluated by flow-cytometry and MHC-II RNA expression levels through real time PCR.

Results: In the animal model there was a marked increase of MHC-II expression in tubular cells expressing Kim-1. After treatment of proximal epithelial cells in culture with exosomes derived from DC, MHC-II expression was increased in the tubular cells, specifically in cells expressing higher levels of Kim-1. There was no significant difference in MHC-II mRNA expression levels, indicating the protein is transferred from exosomes, and not newly synthesised in the Kim-1 expressing epithelial cells.

Conclusions: Dendritic cell-derived exosomes confer antigen-presentation capabilities to proximal tubule cells. This process is facilitated by Kim-1 mediated uptake of exosomes from dendritic cells, resulting in the transfer of MHC-II to tubular cells. Increasing the antigen presentation capability of renal tubule cells through transfer of exosomes after injury may lead to propagation of inflammatory changes resulting in fibrosis and eventual renal failure.

FR-OR259

Autocrine Adenosine 2A Receptor Signaling Promotes PD-1 Expression and Innate Regulatory T Cell Function during Ischemic Kidney Injury Gilbert R. Kinsey, Liping Huang, Konstantine Khutsishvili, David Becker, Hong Ye, Peter I. Lobo, Mark D. Okusa. *Department of Medicine and Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia.*

Background: Regulatory T cells (Tregs) suppress innate inflammation and injury associated with kidney ischemia-reperfusion injury (IRI). Tregs express CD73, which is the final enzyme in production of extracellular adenosine and previous studies have demonstrated that adenosine 2A receptor ($A_{2A}R$) activation on immune cells inhibits inflammation and preserves kidney function after IRI. We hypothesized that the production of adenosine by Tregs is required to block innate immune responses in kidney IRI and that the Treg-generated adenosine would signal through $A_{2A}Rs$ in an autocrine manner on Tregs.

Methods: Freshly-isolated $CD4^+CD25^+$ Tregs from WT, $A_{2A}RKO$ or CD73KO mouse spleen were adoptively-transferred to naive C57/Bl6 (WT) mice 18 hr prior to bilateral renal ischemia or sham surgery. Kidney function was estimated by plasma creatinine measurement and kidney inflammation was assessed by flow cytometry and immunohistochemistry. The $A_{2A}R$ specific agonist ATL1222 (0.1 to 30 nM) and $A_{2A}R$ specific antagonist ZM241385 (100nM) were used *in vitro* to investigate the role of $A_{2A}R$ signaling in Tregs.

Results: Adoptively-transferred WT Tregs protected WT mice from kidney IRI, but in the absence of adenosine generation (CD73KO Tregs) or $A_{2A}Rs$ ($A_{2A}RKO$ Tregs), Treg function was completely inhibited. *In vitro* activation of $A_{2A}Rs$ on CD73KO Tregs, prior to adoptive transfer, restored their protective ability, and augmented the ability of WT Tregs to suppress kidney IRI (an effect blocked by pretreatment with ZM241385). ATL1222 dose-dependently enhanced surface expression of the negative co-stimulatory molecule PD-1 on Tregs. PD-1 blocking antibody treatment of Tregs, prior to adoptive transfer, reversed their protective effects *in vivo,* even if they had been pre-treated with ATL1222.

Conclusions: Taken together these findings demonstrate that the simultaneous ability to generate and respond to adenosine is required for Tregs to suppress innate immune responses in ischemia-reperfusion injury through a PD-1-dependent mechanism.

Funding: NIDDK Support

FR-OR260

Critical Role of the Chemokine Receptor CXCR6 for Renal NKT Cell Localization and Function in Murine Crescentic Glomerulonephritis Jan-Hendrik Riedel,[1] Hans-Joachim Paust,[1] Jan-Eric Turner,[1] Erik M. Disteldorf,[1] Joachim Velden,[2] Hans-Willi Mittrücker,[3] Rolf A. Stahl,[1] Oliver M. Steinmetz,[1] Ulf Panzer.[1] *[1]Universitätsklinikum Hamburg Eppendorf, III. Medizinische Klinik, Hamburg, Germany; [2]Universitätsklinikum Hamburg Eppendorf, Institut für Pathologie, Hamburg, Germany; [3]Universitätsklinikum Hamburg Eppendorf, Institut für Immunologie, Hamburg, Germany.*

Background: The chemokine receptor CXCR6 is expressed on T cells and Natural Killer T (NKT) cells and might play a role in trafficking or activation of these cells via its unique chemokine ligand CXCL16.

Methods: To investigate the role of CXCR6 in renal inflammation we induced a T cell-dependent model of glomerulonephritis (nephrotoxic nephritis) in BL6/CXCR6$^{-/-}$ and BL6 WT mice.

Results: Induction of nephritis resulted in upregulation of renal CXCR6 and CXCL16 mRNA expression. CXCL16 expression peaked between days 7-10 and was mostly detectable in periglomerular and tubulointerstial areas. Unexpectedly CXCR6$^{-/-}$ mice developed an aggravated course of nephritis (day 8) in terms of T cell recruitment, tissue injury, serum creatinine and BUN level compared to WT mice. In the inflamed kidney CXCR6 was highly expressed (> 90%) on invariant NKT (iNKT) cells and to a much lesser degree on CD4 and CD8 T cells. In contrast to the enhanced numbers of T cells, the infiltration of iNKT cells into the kidney was markedly reduced in nephritic CXCR6$^{-/-}$ mice. RT-PCR and FACS analyses revealed the production of anti-inflammatory IL-4 and TGFβ but no proinflammatory IL-17 by renal iNKT cells, supporting their protective role. To assess the function of CXCR6^{+} NKT cells, FACS-sorted TCRb^{+}NK1.1^{+} NKT cells from livers of WT mice (purity >95%) were transferred into WT and CXCR6$^{-/-}$ mice (10^6 NKT cells/animal) followed by nephritis induction. The transfer of CXCR6^{+} NKT cells resulted in an almost identical course of nephritis (day 8) in WT and CXCR6$^{-/-}$ mice (assessed by morphological and functional parameters) demonstrating the protective role of CXCR6^{+} NKT cells in glomerulonephritis.

Conclusions: Nephritic CXCR6$^{-/-}$ mice had a defect in the recruitment of protective NKT cells into the kidney, resulting in an accelerated course of nephritis.

FR-OR261

Complement C3a Induces IL-1beta Production in Human Monocytes Which Leads to Th17 Lineage Decisions Elham Asgari, Steven H. Sacks, Esperanza Perucha, Claudia Kemper. *MRC Centre for Transplantation, King's College London, London, United Kingdom.*

Background: IL-1beta is among the most potent pro-inflammatory cytokines and mediates important immune functions such as promoting Th17 linage commitment. Monocytes/macrophages are the major IL-1beta sources. IL-1beta secretion by these cells requires TLR (LPS) and P2X7-receptor (ATP) signals, which in turn activate the inflammasome. However, how exactly LPS signals and ATP availability are regulated during monocyte activation is unclear and the requirement for a second danger signal has long been proposed. Considering the importance of anaphylatoxins C3a and C5a in innate immunity, we hypothesised that they participate in IL-1beta production.

Methods: Freshly isolated monocytes have been stimulated with C3a or C5a with and without LPS at different concentrations and time points and IL-1beta measured as an indication of inflammasome activation. Relationship of inflammasome activation with pannexin 1 channel has been investigated by inhibition of the channel with carbenoxolone.

For assessing Th17 induction, activated monocyte supernatants were used in T cell cultures and IL-17 production was measured.

Results: Both LPS and C3a were absolutely required for IL-1beta production in human macrophages while in monocytes, C3a increased LPS-induced IL-1beta dramatically. Neither C3adesArg, nor C5a showed any effect on IL-1beta production. We suggest that C3a drives IL-1beta production by controlling the release of intracellular ATP into the extracellular space via regulating the function of the ATP-releasing channel pannexin 1.

Importantly, we found that C3a/LPS-stimulated monocytes induce strong Th17 cell induction in in vitro cultures.

Conclusions: Our data indicate that C3aR-mediated signalling events are important components of the IL-1beta/Th17 axis in humans. This has significant implications in IL-17-driven disease states such as rheumatoid arthritis or asthma as well as kidney transplantation where Th17 cells have been shown to participate in allograft rejection and causing resistance to tolerance induction.

Role of a Novel Rat-Specific Fc Receptor in Macrophage Activation Associated with Crescentic Glomerulonephritis Jacques Behmoaras,[3] Theresa H. Page,[1] Zelpha D'souza,[2] Charles D. Pusey,[3] Timothy J. Aitman,[2] H. Terence Cook.[3] *[1]Kennedy Institute of Rheumatology; [2]MRC Clinical Sciences Centre; [3]Renal Medicine, Imperial College London, United Kingdom.*

Background: Crescentic glomerulonephritis (Crgn) is a complex disease where the initial insult is often the glomerular deposition of antibodies against intrinsic or deposited antigens in the glomerulus. The role of Fc receptors in the induction and progression of Crgn is increasingly recognised and our previous studies have shown that copy number variation in *Fcgr3* partially explains the genetic susceptibility of the Wistar-Kyoto (WKY) rat to nephrotoxic nephritis (NTN), a rat model of Crgn. The Fcgr3-related sequence (*Fcgr3-rs*) is a novel rat-specific Fc receptor with a cytoplasmic domain 6 amino acids longer than its paralogue, *Fcgr3*. The Fcgr3-rs gene is deleted from the NTN-susceptible WKY rat genome and this deletion is associated with enhanced macrophage activity in this strain. Here, we have investigated the mechanism by which the deletion of *Fcgr3-rs* in the WKY strain leads to increased macrophage activation.

Methods: By lentivirus-mediated gene delivery, we have generated stably transduced human U937 cells expressing either *Fcgr3-rs* or *Fcgr3*.

Results: In these cells, which lack endogenous Fcgr3 receptors, we show that Fcgr3-rs interacts with the common Fc-gamma chain but that Fc receptor-mediated phagocytosis and signalling are defective. Furthermore, in primary macrophages, expression of *Fcgr3-rs* inhibits Fc-receptor mediated functions, as WKY bone marrow derived macrophages (BMDMs) transduced with *Fcgr3-rs* had significantly reduced phagocytic activity. This inhibitory effect on phagocytosis was mediated by the novel cytoplasmic domain of *Fcgr3-rs*.

Conclusions: In conclusion, these results suggest that the rat specific *Fcgr3-rs* may act to inhibit *Fcgr3*-mediated signalling and phagocytosis and could be considered as a novel mechanism in the modulation of Fc receptor mediated cell activation in autoimmune diseases.

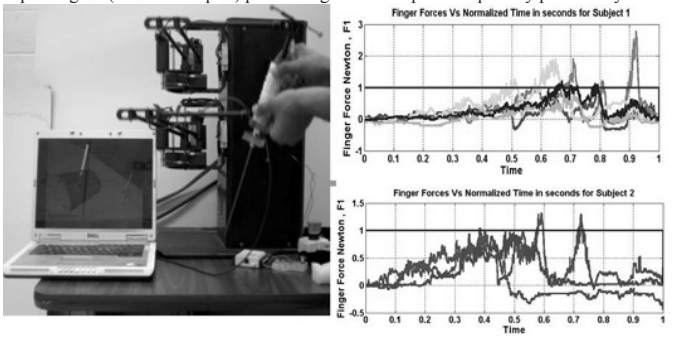
FR-OR263

Quantitative Skill Evaluation for Kidney Biopsies Sudha Garimella,[1] Madusudanan Sathia Narayanan,[2] Xiaobo Zhou,[2] Seung-Kook Jun,[2] Wayne R. Waz,[1] Frank C. Mendel,[3] Venkat N. Krovi.[2] *[1]Pediatric Nephrology, State University of New York at Buffalo, Buffalo, NY; [2]Mechanical and Aerospace Engineering, State University of New York at Buffalo, Buffalo, NY; [3]Pathological and Anatomical Sciences, State University of New York at Buffalo, Buffalo, NY.*

Background: Certification in kidney biopsy procedures requires both cognitive and sensorimotor skill acquisition which has been linked to duration, realism and diversity of training exposure. There is a critical need for a comprehensive and realistic training system which also facilitates monitoring and evaluation of procedural skills.

Methods: We created SIMBiopsies, a visual and kinesthetic environment that mimics the look and feel of a kidney biopsy, to allow trainees to improve their skills while performing simulated biopsies. A mock-biopsy needle mounted on a haptic device produces the appropriate 'feel' as the trainee inserts a needle into the virtual model of a Blue Phantom®, a block of tissue-like gel with inclusions of denser gel (to mimic different tissues). This virtual model was created by coupling material-testing data with a 3D visual model of the Blue Phantom.

Results: A series of needle insertion studies were carried out by two nephrologists and sample characteristic haptigrams (force-motion profiles) were recorded. We are currently working on comparing, cataloging and validating captured haptigrams of a range of nephrologists (novice to expert) performing virtual biopsies to quantify proficiency.



Conclusions: The SIMBiopsies virtual immersive environment offers a convenient interactive means to develop, practice and quantitatively assess biopsy skills. By overcoming various economic, logistical and safety issues that hinder extensive conventional training on real patients, we anticipate it will also provide a standardized means for certification in this critical skill.

Education Intervention Increases Patient Knowledge about Chronic Kidney Disease Julie A. Wright, Jane H. Greene, Kenneth A. Wallston, Tom A. Elasy, Svetlana Eden, Ayumi Shintani, Russell Rothman, Talat Alp Ikizler, Kerri L. Cavanaugh. *Vanderbilt University Medical Center, Nashville, TN.*

Background: We evaluated the impact of a 2-3 minute, physician delivered, literacy sensitive education worksheet on patient knowledge about chronic kidney disease (CKD).

Methods: Adult patients with CKD Stages 1-5, seen in nephrology clinic, were enrolled into an education intervention pilot (April-October 2010) and compared to a historical cohort (April-October 2009). A validated survey assessing CKD awareness and knowledge was given to patients in both the pilot intervention group and historical cohort. Areas of low knowledge from the historical cohort informed development of a patient CKD education worksheet (adapted from: National Kidney Disease Education Program). This worksheet was reviewed by nephrologists with patients during appointments for the pilot intervention. The proportion of patients correctly answering survey questions was compared between groups.

Results: 401 patients were in the historical cohort, and 155 received the intervention. The mean (SD) age of the combined population (N=556) was 57 (16) years. 53% were male, 81% White, and 78% had CKD Stage 3-5. There were no significant differences in patient demographics by intervention status. Unadjusted analysis showed a higher proportion of patients receiving the intervention were aware of CKD diagnosis (78% vs. 69%; p=0.04), and correctly defined "GFR" (85% vs. 68%; p<0.001), their kidney function (68% vs. 49%; p<0.001), and their stage of CKD (65% vs. 36%; p<0.001). Compared to controls, patients receiving the intervention had higher odds of knowing they had CKD [OR 2.20, CI 1.16-4.17; p=0.016], of knowing their kidney function [OR 2.25, CI 1.27-3.97; p=0.005], and of knowing their stage of CKD [OR 3.22, CI 1.49-6.92; p=0.003] in

analyses adjusted for age, sex, race, health literacy, income, number of provider visits, eGFR, and knowing someone with CKD. 80% of patients deemed the worksheet helpful, and 98% recommended it for future use.

Conclusions: A physician delivered education intervention taking less than 3 minutes, increased patient knowledge on topics important to understanding CKD diagnosis.

FR-OR265

International Society of Nephrology Sister Renal Center Program between Gold Coast Hospital and Adam Malik Hospital, North Sumatra, Indonesia

Siddharth Sharma, Jagadeesh Kurtkoti. *Nephrology, Gold Coast Hospital, Southport, Queensland, Australia.*

Background: Gold Coast Hospital (GCH) renal department has provided education and experience to hospitals in the Tsunami devastated North Sumatra. This partnership was formalized in 2011 by ISN SRC program and a team comprising Nephrologist and Advanced trainee spent 1 week in Medan and Banda Ache, assessing the needs of the department and educating clinicians in areas of interest and concern in order to build strong partnership and advance the practice of Nephrology in North Sumatra.

Methods: GCH team toured both major public hospitals in Medan. We made ward and dialysis rounds with the renal doctors to get a thorough understanding of the renal service and the medical system. During these, diagnostic and treatment protocols present in Medan public hospitals were reviewed directly with the local clinicians. The GCH team compared these protocols or the lack thereof with those established in GCH. An assessment was presented to the department and a plan to improve the service and practice of nephrology was constructed. Regular teaching and meetings between the two centers via videoconference should commence within 3 months.

Results: We identified that renal biopsy service was virtually non-existent in North Sumatra. After deliberation with the renal and pathology departments, renal biopsy process was reviewed and encouraged. Ultrasound guided biopsy technique was taught and a post biopsy observation protocol was implemented. Also, prevalence of AV fistulas and access surveillance was low. Use of access blood flow is now being implemented.

Conclusions: Appropriate diagnosis and directed treatment of renal conditions was found to be lacking in North Sumatra and was strongly related to the poor renal biopsy service. This service is being developed while collaborating with Gold Coast Hospital.

Patient's Perception of Life on Hemodialysis Scale: Instrument Development and Psychometric Evaluation

June Creina Twomey,[1] Patrick S. Parfrey,[2] Brendan J. Barrett,[2] Christine Y. Way,[1] David N. Churchill.[3] *[1]School of Nursing, Memorial Univeruity, St. John's, NL, Canada; [2]Dept Clinical Epidemiology, Memorial University, St. John's, NL, Canada; [3]AMGEN Canada Inc, Mississauga, ON, Canada.*

Background: Using a grounded theory approach the overall psychosocial and physiological experience of patients with treated with in-center hemodialysis was examined. Three theoretical constructs emerged from the research: Physical Health, Quality of Supports, and Psychosocial Health. Researchers developed a 64 item rating instrument titled the Patient's Perception of Hemodialysis Scale (PPHS) to measure these concepts.

Methods: Using a cross-sectional design, data collection was completed in the hemodialysis units in two Canadian provinces (N =236). The purpose of the research was to examine data quality, internal consistency, reliability and validity of the instrument.

Results: Limited missing data and good ceiling/floor statistics for each question were observed. Following correlation of items within each scale the number of questions was reduced by 28. Five scales were identified: Physical Health, Emotional Well-being, Psychosocial Distress, Nurse Support, and Physician Support. The Cronbach's alpha for the new scales was 0.70-0.89, suggesting good internal consistency.

Construct validity was examined using factor analysis, with a principal component approach and varimax rotation. The total factor structure explained 51% of the variance, and eigenvalues implied no further item reduction was necessary. Convergent validity was confirmed for Physical Health, Emotional Well-being and Psychosocial Distress by comparison with SF-36, and divergent validity by the poor correlation of Nurse and Physician support scales with SF-36. Test-retest analysis demonstrated that the instrument was stable over time and intraclass correlation ranged from 0.72 to 0.94.

Conclusions: The PPHS is a valuable instrument for measuring disease specific concerns as patients experience hemodialysis.

Funding: Kidney Foundation of Canada

FR-OR267

US Non-Renal Internal Medicine Subspecialty Fellow Survey on Nephrology

Seyyar A. Khan,[1] Matthew A. Sparks,[3] Arun Chawla,[1] Emily L. Petersen,[2] Hitesh H. Shah,[1] Mark G. Parker,[4] Donald E. Kohan,[2] Kenar D. Jhaveri.[1] *[1]Nephrology, Hofstra North Shore-LIJ School of Medicine; [2]University of Utah; [3]Duke University; [4]Maine Medical Center.*

Background: Nephrology is facing a workforce shortage in the U.S, particularly among U.S. medical graduates. We designed a survey to explore the reasons why fellows from other internal medical subspecialties did not choose nephrology.

Methods: The anonymous survey was created online using SurveyMonkey in May 2011 and was distributed to all non-renal fellowship program directors in the US. The survey contained 11 questions regarding nephrology and choices of fellowship.

Results: Preliminary results have a 10% response rate with 650 subspecialty fellows responding. Over 75% of fellows did not know that a shortage of nephrologists is estimated to develop by 2020. When asked if nephrology was the most difficult physiology course in their medical school, 68.4% said "no" . 26.5% had considered nephrology as a career at some point and only 11% indicated that nephrology was their second choice. 40.9% of endocrinology fellows had considered nephrology at one point ($P<0.0072$) and GI fellows (17.7%) were least likely to consider nephrology($P<0.05$). For those who had considered nephrology, reasons for not choosing included: 86.8% "fell in love with another field", 16.2% were concerned about work hours and 16.2% felt that compensation was not adequate. Interestingly, 23.9% would have considered nephrology if it were taught better and 23% would have considered nephrology if nephrologists had higher incomes. When asked what they did not like about nephrology, 37.3% said that "dialysis and transplant patients are too complicated to take care of" and 29.1% said "No role model or mentor to guide me towards nephrology."

Conclusions: The majority of non-renal fellows never considered nephrology as a career choice. Among those who considered a nephrology career, a significant proportion was dissuaded by several factors, including lifestyle, income, patient complexity and lack of role models. Each of these factors can be addressed, but will require the concerted efforts of nephrologists throughout our training community.

FR-OR268

Pediatric Nephrology as a Specialty: Survey of USA Non-Renal Pediatric Fellows

Maria E. Ferris,[1] Howard Trachtman,[2] Kenar D. Jhaveri,[3] M. Ahinee Amamoo,[1] Keisha L. Gibson,[1] Tejas P. Desai,[4] William A. Primack.[1] *[1]University of North Carolina at Chapel Hill Kidney Center; [2]Cohen Children's Medical Center; [3]North Shore/LIJ Health System - Hofstra Medical School; [4]East Carolina University - Brody School of Medicine.*

Background: The U.S. pediatric nephrology workforce is aging with an insufficient number of graduating fellows. The purpose of this survey is to assess why non-renal fellows choose areas of concentration other than nephrology.

Methods: A web-based self-administered survey was sent to all accredited ACGME pediatric fellowship programs. The survey focused on the perceived difficulty of nephrology as a discipline and factors involved in fellowship choice.

Results: Of the 313 responses, 294 (94%) were from pediatric programs; 194 (62%) females; and 236 (75%) graduated from USA schools. When asked about how difficult nephrology was, 194 (59%) respondents said it was difficult or very difficult. For all respondents, the odds of reporting nephrology as difficult among females was 1.3 times higher than among males and 2.3 higher for USA graduates. The odds of reporting nephrology as difficult among fellows in a non-acute specialty is 8% higher than among those in an acute specialty. Acute kidney injury and hypertension were rated with the lowest levels of difficulty whereas renal tubular acidosis, dialysis and transplantation had the highest.

At one point, 15% of respondents considered nephrology. Of those who did not consider nephrology, 80% stated that they were not attracted to the field because they did not like the work hours, patients/families, monetary benefits or pediatric nephrologists (10% each). When asked what would have made them consider nephrology, the most common responses were: more appealing teaching sessions (30%); higher income (16%); if they had not matched into their current specialty (11%).

Conclusions: Overall, pediatric fellows in non-renal specialties rated nephrology as a difficult specialty. This perception is stronger among females. Efforts to make pediatric nephrology more appealing to medical students and residents are necessary to address the perception of this specialty and deter gender disparities in the future workforce.

FR-OR269

Creative Nephrology Elective during Medical Residency: A Single Center Experience

Kenar D. Jhaveri, Peter B. Schrier, Hitesh H. Shah. *Nephrology, Hofstra North Shore- LIJ School of Medicine, NY.*

Background: Traditionally, most institutions offer a "pure" inpatient consult rotation as a standard elective for internal medicine residents and medical students (MS). Embarking on a combined inpatient (IP) and outpatient (OP) form of elective might spark more interest and give a better " flavor of nephrology" to the trainees.

Methods: From 2009-present, we randomly assigned medical residents and students taking the renal elective at our institution to either a "pure" inpatient form of elective group (Group A) or a combined elective group (Group B). The combined elective started with 2 weeks of IP consult rotation followed by 2 weeks of OP rotation. The OP rotation included: HD & PD unit rounding, several renal(glomerular, ckd, stones) and kidney transplant clinic sessions, and a research session with a faculty member. The trainees also completed a small assignment using games or concept maps and shared in a small group setting. After the elective,all trainees were asked to complete an anonymous survey of their nephrology rotation experience.

Results: 26 trainees completed the survey, 38.5% PGY1, 34.6% PGY3, 19.2% PGY2 and 7.6% were MS. 68% did a "pure" inpatient elective (Group A). In this group, 47.5% felt that a combined elective would have been more beneficial and 63% felt that they would have learned more renal medicine if they had done a combined elective. 50% of group A would consider a career in nephrology. 75% of group A had exposure to 2 faculty mentors. 32% of the trainees did a combined elective (Group B). 80% of group B thought that they had learned more renal medicine as a result of the combined experience and all 100% of them

would not have chosen to do a "pure" inpatient elective. 80% would consider a career in nephrology in group B. 60% of them worked with more than 3 faculty mentors. All trainees felt the need for combined electives and more mentorship by nephrologists.

Conclusions: Combined inpatient and outpatient nephrology elective during medical residency training with increase exposure to several nephrology faculty members seems to create a more positive and enriching experience perhaps leading to a more likelihood of choosing nephrology as a career choice.

FR-OR270

Career Choice Selection and Satisfaction among US Nephrology Fellows

Hitesh H. Shah,[1] Matthew A. Sparks,[2] Prasanth Krish,[1] Kenar D. Jhaveri.[1]
[1]Nephrology, Hofstra North Shore-LIJ School of Medicine; [2]Duke University.

Background: Interest in obtaining training in nephrology continues to decline. We wanted to find out why current fellows selected nephrology and if they are satisfied with this choice. We conducted an online survey with current US nephrology fellows.

Methods: The anonymous survey was created online using SurveyMonkey in May 2011 and was subsequently distributed to US nephrology training program directors.

Results: On initial evaluation, 137 respondents to our survey (10% of total nephrology fellows in the US), of which 55.1% were graduating from their training program. 41.4% were US medical school graduates. 65.8% chose nephrology during either their 1st or 2nd year of residency; 24.3% made this decision during medical school. The most common reasons for choosing nephrology included: interesting subject matter and excellent mentoring in nephrology. Interesting, only 55.7% of respondents were either extremely or very satisfied with their decision to enter nephrology fellowship. 32.8% were somewhat or slightly satisfied and 11.4% were not satisfied at all with their decision. Statistically, no differences were seen between graduating and non-graduating fellows or US and non-US medical school graduates. The top reasons respondents cited for being extremely or very satisfied with nephrology included: excellent teaching and mentoring by faculty, "variety of stimulating cases" and association between general medicine and nephrology. In contrast, top reasons that respondents were somewhat, slightly or not satisfied with nephrology were: poor income and job potential, and long work hours.

Conclusions: Majority of the current US nephrology fellows selected nephrology as their career choice during medical residency training. Strong mentorship and teaching was highly associated with both the decision to enter nephrology as well as satisfaction during nephrology fellowship. Reasons for less or no satisfaction with nephrology as a career choice included poor job opportunities, poor income potential, long work hours and poor teaching and mentoring by faculty. The nephrology training community should take measures to ensure higher level of satisfaction among US nephrology fellows.

FR-OR271

Using Community Kidney Disease Detection (CKDD) as a Community-Based Platform for Student Leadership Cultivation in Nephrology

Jin Woo Yoo,[1] Li-Li Hsiao.[2,3] *[1]Harvard College, Cambridge, MA; [2]Renal Division, Brigham and Women's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA.*

Background: Chronic Kidney Disease (CKD) is a major public health problem. Patient awareness of CKD is very low especially among the racial minorities, who often have poorer access to health care and are particularly vulnerable. However, despite the growing significance of CKD, there exists a disproportionate shortage of nephrologists and a diminishing interest in the field of nephrology that raise concerns about adequate renal health care provisioning in the future.

Methods: Here, we present Community Kidney Disease Detection (CKDD), a community outreach program for undergraduate students, as a viable solution for promoting prevention of CKD whilst cultivating student leadership and exposure to nephrology. CKDD holds monthly renal health screenings in underserved areas in Greater Boston to facilitate awareness and early detection of CKD. Such health screenings are entirely run by student volunteers, and hence offer undergraduates an unparalleled hands-on clinical experience and exposure to nephrology. CKDD also provides extensive pre-medical training by hosting workshops attended by nephrologists who teach and certify students for knowledge and command of a range of medical techniques, which include practicing universal precaution, obtaining pertinent medical history, measuring blood pressure, operating glucometers, and conducting urinalysis. At each health screening, students have the opportunity to undertake leadership roles as the clinic manager or as station leaders, through which they can develop leadership skills important for the medical career.

Results: Since its establishment in 2007, CKDD has recruited a stable volunteer base of more than 200 undergraduates, of which 78 students have been successfully trained and certified. Our preliminary data showed that the majority of participants found CKDD to be valuable and graded 4.5 out of 5 on CKDD's services.

Conclusions: Collectively, CKDD serves as an effective platform for undergraduate student's community outreach for CKD prevention, promoting student leadership, recruitment of interest, and exposure to nephrology.

FR-OR272

Examining the Role of Education of Nephrology Fellows in Utilization of Peritoneal Dialysis in the United States

Nand K. Wadhwa,[1] Catherine R. Messina,[2] Nasser M. Hebah.[3] *[1]Nephrology, Stony Brook University, Stony Brook, NY; [2]Preventive Medicine, Stony Brook University, Stony Brook, NY; [3]Corporate Home Dialysis, Dialysis Clinic Inc., Nashville, TN.*

Background: The 2009 US Renal Data System annual report revealed that peritoneal dialysis (PD) was used by only 7.2% of end stage renal disease (ESRD) patients (vs. use of hemodialysis (HD) by >90% of patients), a decline from a 1984 peak of 15%. We examined whether education of nephrology fellows contributed to the underutilization of PD in the US.

Methods: Self-report questionnaires were administered via Survey Monkey to nephrology fellowship training program directors during October 2010-March 2011. Names/addresses of all US training program directors were obtained from the American Society of Nephrology list-serve. Project protocol was approved by the Stony Brook University IRB. Statistical analyses included: descriptive statistics (frequencies and proportions) and Wilcoxon signed-rank tests for comparisons.

Results: 55% (78) of program directors responded. Median number of training faculty and patients/fellow were significantly lower for PD training vs. HD training (0.5 vs. 1.2, $p<0.001$ and 5 vs. 37.5, $p<0.001$; respectively). Hours of didactic teaching for fellows over their 2 year training period was also lower for PD vs. HD (6 vs. 10 hours, $p<0.001$). Most nephrology programs provide training in PD and HD; however, PD training was only 20% of total training vs. 80% for HD. Among program directors, 76% indicated that >5% of PD training and 81% indicated that >5 PD patients/fellow were adequate for PD training over a 2 year training period. 87% believed that PD training for fellows was inadequate because of lack of trained faculty in PD and insufficient PD patient population. 67% reported that fellows did not participate in ESRD/chronic kidney disease education to patients.

Conclusions: Current US nephrology fellowship training in PD is inadequate and contributes significantly to the underutilzation of PD. The adequacy of PD training resources needs vigorous discussion and evaluation by the nephrology community.

Funding: Private Foundation Support

FR-OR273

Association of Serum Glycated Albumin and Fructosamine with Outcomes in Incident Hemodialysis Patients

Tariq Shafi,[1] Stephen M. Sozio,[1] Bernard G. Jaar,[1] Rulan S. Parekh,[2] Laura Plantinga,[3] Neil R. Powe,[3] Josef Coresh,[1] Elizabeth Selvin.[1] *[1]Johns Hopkins University; [2]University of Toronto; [3]University of California, San Francisco.*

Background: Serum total glycated proteins (fructosamine) and the more specific glycated albumin may be better indicators of glycemia in dialysis patients compared with hemoglobin A1C as they are not affected by red cell turnover. However, the association of glycated albumin and fructosamine with long-term outcomes in dialysis patients is not well-described.

Methods: We measured baseline levels of glycated albumin and fructosamine in 503 incident hemodialysis (HD) participants of the CHOICE Study, a national prospective cohort study. The association of these glycemic markers with mortality and infection-related hospitalizations were determined using Cox proportional hazards and Poisson models, adjusting for potential confounders.

Results: Mean age was 58 years; 64% white; 54% male; and 57% had diabetes. Higher baseline levels of glycated albumin and fructosamine were independently associated with higher risk of death in patients with and without diabetes over a median follow-up of 3.1 years. There was a non-significant trend towards higher risk of infection-related hospitalizations.

Association of Glycemic Markers and Outcomes in 503 Incident HD Patients

	Diabetes (n=287)		No Diabetes (n=213)	
	Glycated Albumin %	Fructosamine	Glycated Albumin %	Fructosamine
Mean±SD	24±9%	360±94 umol/L	14±2%	271±46 umol/L
All-Cause Mortality*	**1.22(1.02-1.45)**	**1.24(1.05-1.46)**	**1.29(1.03-1.61)**	1.28(0.99-1.67)
Cardiovascular Mortality*	1.15(0.90-1.47)	1.15(0.90-1.47)	1.35(0.97-1.86)	**1.86(1.13-3.06)**
Infection-Related Hospitalizations†	1.12(0.98-1.28)	1.09(0.96-1.24	0.85(0.66-1.08)	1.01(0.84-1.20)

*HR per SD increase adjusted for age, sex, race, smoking, BMI, pulse pressure, comorbidities, albumin, hemoglobin and CRP. †Incidence rate ratio per SD increase adjusted for age, sex, race and comorbidities.

Conclusions: In this national cohort, glycemic markers glycated albumin and fructosamine were associated with adverse outcomes in HD patients with and without diabetes. Measurements of these serum glycemic markers may be useful for management of diabetes in dialysis patients.

Funding: NIDDK Support, Private Foundation Support

FR-OR274

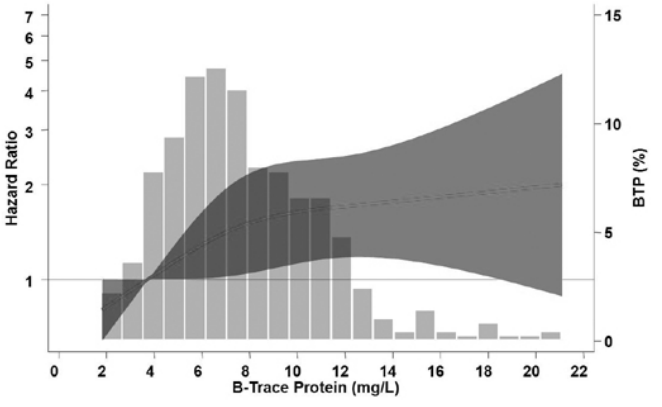
Serum Beta-Trace Protein Marks Low Residual Kidney Function and Risk of Mortality in Incident Hemodialysis Patients Tariq Shafi,[1] Rulan S. Parekh,[2] Bernard G. Jaar,[1] Laura Plantinga,[3] Pooja C. Oberai,[1] John H. Eckfeldt,[4] Andrew S. Levey,[5] Neil R. Powe,[3] Josef Coresh.[1] *[1]Johns Hopkins University; [2]University of Toronto; [3]University of California, San Francisco; [4]University of Minnesota; [5]Tufts Medical Center.*

Background: Residual kidney function (RKF) in dialysis patients is associated with improved survival, but there are no simple methods for assessing RKF. Beta-trace protein (BTP) is a novel endogenous filtration marker of kidney function that is not removed during hemodialysis and may serve as a marker for RKF, similar to serum creatinine in patients not on dialysis.

Methods: We measured serum BTP in 503 participants of the CHOICE Study, a national prospective cohort of incident dialysis patients. Outcomes analyzed were all-cause and cardiovascular disease (CVD) mortality using Cox proportional hazards regression adjusted for demographic (age, race, gender, education, marital status and employment) and clinical and treatment factors (smoking, pulse pressure, body mass index, cause of kidney failure, Index of Coexistent Disease (ICED) score (0-3), cardiovascular disease, congestive heart failure, left ventricular hypertrophy, diabetes, serum albumin).

Results: Serum BTP levels were higher in individuals with no self-reported urine output at baseline (p<0.001) or year 1 (p=0.001).There were 321 deaths (159 from CVD) over 1,814 person-years of follow-up. Higher BTP levels were independently associated with higher risk of all-cause and CVD mortality.

Figure 1: Adjusted Relative Hazard of All-cause Mortality with Serum Beta Trace Protein (BTP) in 503 Incident Hemodialysis Participants of the CHOICE Study.



Bars, distribution of serum BTP; **Line**, association of serum BTP with mortality, modeled as a cubic spline.

Compared with the lowest tertile, adjusted HR and 95% CI for all-cause mortality in the middle and highest tertile were: 0.95 (0.69-1.32) and 1.72 (1.25-2.37); p-value for linear trend 0.001. Similar results were noted for CVD mortality.

Conclusions: The serum level of BTP, a novel marker of residual kidney function, is an independent predictor of death and CVD mortality in hemodialysis patients.

FR-OR275

Effects of Six Versus Three Times Per Week Hemodialysis on Physical Performance, Health and Functioning: Frequent Hemodialysis Network (FHN) Trials Yoshio N. Hall,[1] Brett Larive,[2] Patricia Lynn Painter,[3] George A. Kaysen,[4] Robert M. Lindsay,[5] Allen R. Nissenson,[6] Mark L. Unruh,[7] Michael V. Rocco,[8] Glenn M. Chertow,[9] The FHN Trial Group.[10] *[1]University of Washington; [2]Cleveland Clinic; [3]University of Minnesota; [4]UC Davis; [5]University of Western Ontario; [6]DaVita Inc.; [7]University of Pittsburgh; [8]Wake Forest University; [9]Stanford University; [10]NIDDK, Bethesda, MD.*

Background: Relatively little is known about whether and to what extent the frequency of hemodialysis may influence the substantial disability and functional dependence of patients with end-stage renal disease.

Methods: We examined changes in physical performance, health and functioning among subjects randomized to frequent (six times per week) as compared with conventional (three times per week) hemodialysis in both the Frequent Hemodialysis Network Daily (n=245) and Nocturnal (n=87) Trials. The primary outcomes were adjusted change in scores over 12 months on the short physical performance battery (SPPB), RAND 36-item self-reported physical health composite (PHC) and physical functioning subscale (PF).

Results: In the Daily Trial, subjects randomized to frequent as compared with conventional in-center hemodialysis experienced no significant change in SPPB (adjusted mean change of -0.14 ± 0.19 vs. -0.39 ± 0.21, P=0.38), but experienced clinically significant improvements in PHC (3.4 ± 0.8 vs. 0.2 ± 0.8, P=0.004) and in PF (4.8 ± 2.1 vs. -0.3 ± 2.2, P=0.081). The effects of frequent in-center hemodialysis did not appreciably differ according to sex, race or diabetic status. In the Nocturnal Trial, there were no significant differences among subjects randomized to frequent as compared with conventional hemodialysis in SPPB (adjusted mean change of -0.89 ± 0.44 vs. -0.44 ± 0.43, P=0.45), PHC (2.8 ± 1.5 vs. 1.8 ± 1.5, P=0.64), or PF (-3.1 ± 3.5 vs. 1.0 ± 3.5, P=0.41).

Conclusions: Frequent in-center hemodialysis, as compared with conventional in-center hemodialysis, improved self-reported physical health and functioning but had no significant effect on objective physical performance.

FR-OR276

Both Excessive Weight Loss and Gain over Time Are Associated with Increased Mortality in Incident Dialysis Patients Sunil V. Badve, Carmel M. Hawley, Stephen P. McDonald, Kym M. Bannister, Neil Boudville, Fiona Brown, Philip A. Clayton, Brian E.R. Livingston, Kevan R. Polkinghorne, Kathryn J. Wiggins, David W. Johnson. *Australia and New Zealand Dialysis and Transplant Registry, Australia.*

Background: The prevalence of obesity is increasing in incident dialysis patients. There is limited information on the association between longitudinal changes in body mass index (BMI) and mortality in incident dialysis patients.

Methods: The study included all adult patients from the ANZDATA Registry who started hemodialysis (HD) or peritoneal dialysis (PD) between 2001 and 2008 with ≥ 2 measurements of dry weight and ≥ 6-mo follow up. Annualized change in BMI was calculated using a least-squares regression slope. Patients were divided into quintiles of slope of annual BMI change (Q1 to Q5). Dialysis modality was classified according to modality in use at 90 d. Survival analysis was done using Cox proportional hazards model.

Results: A total of 16,869 incident dialysis patients were included in the study (mean age 60 yrs, male 60%, obese 29%, HD 64%). The median[interquartile range] slopes of annual BMI change in Q1, Q2, Q3, Q4 and Q5 were -2.3[-3.5, -1.6] kg/m²/yr, -0.7[-0.9, -0.5] kg/m²/yr, -0.2[-0.3, -0.5] kg/m²/yr, 0.3[0.2, 0.4] kg/m²/yr and 1.2[0.9, 1.9] kg/m²/yr, respectively. There was a significant interaction between the dialysis modality and the slope of annual BMI change. Over a mean follow up of 2.8 yrs, 5896 patients died. Compared to Q3, the adjusted hazard ratio (95%CI) for mortality in Q1, Q2, Q4 and Q5 were 3.97(3.43 – 4.58), 1.52(1.35 – 1.72), 1.09(0.95 – 1.26) and 2.41(2.13 – 2.72), respectively.

Conclusions: A U-shaped association was present between the slope of annual BMI change and mortality, suggesting both excessive weight loss and gain over time may be associated with increased mortality in incident dialysis patients.

FR-OR277

Limitations in Activities of Daily Living Independently Influences One-Year Survival of Hemodialysis Patients Eiichiro Kanda,[1] Jenna O. Krisher,[2] William M. McClellan.[3] *[1]Tokyo Kyosai Hospital, Japan; [2]ESRD Network 6; [3]Emory University.*

Background: We examined the independent contribution of activities of daily living (ADL) limitations with one-year mortality among incident hemodialysis patients.

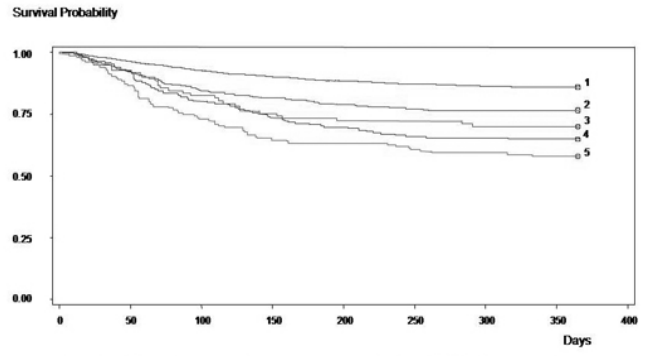
Methods: We enrolled 6217 incident hemodialysis patients and followed up these individuals for up to one year. ADL limitations were assessed using data from the Centers for Medicare & Medicaid Services (CMS) 2728 Form including inability to ambulate, inability to transfer from bed to chair, and the need for assistance with daily activities. The patients were categorized into five groups according to their ADL limitations.

ADL Groups

ADL Group	Inability to ambulate	Inability to transfer	Needs assistance with daily activities
Group 1	No	No	No
Group 2	No	No	Yes
Group 3	Yes	No	No
Group 4	Yes	No	Yes
Group 5	Yes	Yes	Yes

Mortality was evaluated using a fully adjusted Cox proportional hazard model.

Results: The mean age was 61.3 years; 47.7% were female; 46.3% had diabetes. Group 1 consisted of 5414 patients (87.1% of sample); Group 2, 363 (5.8%); Group 3, 97 (1.6%); Group 4, 188 (3.0%); Group 5, 150 (2.4%). ADL limitations correlated with mortality: no ambulation, hazard ratio (HR) 2.12 (95% confidence interval 1.77-2.53); unable to transfer 2.13 (1.64-2.76); need for assistance with daily activities, 1.58 (1.34-1.85). Patients in Group 5 had the worst outcomes.



Unadjusted Kaplan-Meier survival curve showing survival probability by strata of ADLs

Log rank test P<0.0001, Wilcoxon test P<0.0001

HRs (CIs) for Groups 2 to 5 compared with Group 1 (no disability) were as follows: Group 2, 1.29 (1.02-1.63); Group 3, 1.87 (1.28-2.71); Group 4, 2.07 (1.60-2.68); Group 5, 2.38 (1.82-3.07).

Conclusions: Inability to ambulate and transfer and need for assistance with daily activities strongly associated with a higher risk of one-year mortality among hemodialysis patients. More attention should be given to the evaluation of ADL limitations and their improvement.

FR-OR278

Influence of Dialysis Unit Affiliation on Involuntary Discharges (IVD) Brian T. Chu,[1] Abey K. Thomas,[2] Senthil P. Ramaiyah,[2] Carol Lyden,[3] Chaim Charytan,[2] George N. Coritsidis.[1] *[1]Nephrology, Elmhurst Hospital Center, Elmhurst, NY; [2]Nephrology, New York Hospital Medical Center of Queens, Flushing, NY; [3]ESRD Network of New York, IPRO, Lake Success, NY.*

Background: Dialysis facilities (DF) may need to involuntarily discharge patients under certain circumstances set forth in Medicare's conditions of coverage. Minimal literature has been published on IVD. We wanted to analyze IVD rates by the different types of DF and by insurance status of patients as this may have significant implications in the bundling payment era.

Methods: We collected IVD data reported to ESRD Network 2 (EN2) between July 2006 and March 2011. We used the annual average EN2 population in that period to calculate IVD incidence rate for various types of DF. We looked at facility characteristics like profit status, large dialysis organization (LDO) affiliation and hospital/nonhospital based DF. We also looked at the initial insurance status of IVDs. Data was analyzed by chi square test to look for statistical significance.

Results:

	IVDs	Anualized average IVDs	Anualized average EN2 population	Annual IVD Incidence	P-value
Profit Status					
Profit	55	10.48	14427	0.073	
Non-Profit	17	3.24	10307	0.031	0.002
Unit Type					
Non-Hospital Based	69	13.14	24806	0.053	
Hospital Based	3	0.57	4070	0.014	0.004
Affiliation					
LDO	44	8.38	9285	0.09	
Other	28	5.33	15449	0.035	<0.0001
LDO					
LDO 1	28	5.33	5051	0.106	
LDO 2	12	2.29	3459	0.066	*0.04
LDO 3	4	0.76	1030	0.074	

*comparing LDO 1 to LDO 2

Reasons for IVD were the following: behavioral 76.4%, nonpayment 16.7%, noncompliance 2.8%, and unknown 4.2%. Initial insurance coverage was the following: Medicaid 34.7%, Medicare 20.8%, other 12.5%, none 4.2%, and unknown 27.8%. Initial insurance status was similar in IVD patients regardless of the unit affiliations.

Conclusions: Our analysis of EN2 data shows IVD rates are significantly higher in LDOs, non hospital based units and for-profit DFs. The rates also vary significantly among the different LDOs. Medicaid is the most common primary insurance among IVD patients. Interestingly most IVDs are reported to be due to behavioral reasons with financial concerns cited in only 17% of cases. These intriguing findings need to be compared to national trends and further monitored during the new bundled era.

FR-OR279

The End-Stage Renal Disease (ESRD) Prospective Payment System (PPS): Who Gains and Who Loses? Fredric O. Finkelstein,[2] Alan S. Kliger,[1] Peter Juergensen,[1] John J. Kochevar,[3] John Mark Stephens.[3] *[1]Medicine, Hospital of St. Raphael, New Haven, CT; [2]Medicine, Yale University School of Medicine, New Haven, CT; [3]Kochevar Associates, Boston, MA.*

Background: The ESRD PPS was designed to reduce dialysis facility Medicare payment (pymt) by 2% without introducing disparities. There was no demonstration project and the potential impact of the PPS on independent and small chain dialysis organizations (SDOs) has raised concerns. The study objective was to determine which patient (pt) and facility characteristics would be associated with income gains and losses under the PPS.

Methods: We recruited SDOs stratified by region, size, urbanicity and minority zip code. Facilities entered 2009 pt demographics, comorbidities and Medicare pymts into a HIPAA compliant database. We calculated pt pymt gains/losses under the PPS compared to 2009 prior pymts, updated for inflation, systematically evaluated their association with pt demographics, comorbidities, outcomes, Erythropoiesis-Stimulating Agent (ESA) use, and facility characteristics.

Results: A total of 41 facilities (SDOs) entered data on 3039 pts. Overall,the PPS led to a 5.1% reduction in Medicare income. The top 20% of pts (outliers) lost $6.1 Million (about - $102 per treatment, - $10,000 per pt), 72% of all losses. They were more likely to have died, be Black and live in rural areas. About 60% of their losses were from ESA use. Most clinicians did not know if they could reduce outlier pt ESA use by 25% and still meet treatment guidelines. Main gains were among pts new to dialysis and with low ESA use.

Average PPS/Tx Gains/Losses, Patient disposition, Race and Rural Location

	Losses/Gains by Quintile				
N	607	608	608	608	608
Ave $ Loss/Gain Tx	- $101.63	-$30.08	-$181	$21.04	$54.46
% Died 2009	19.5%	14.9%	13.8%	10.5%	11.3%
% Black	38.2%	30.9%	27.2%	26.6%	24.3%
% Rural	14.5%	10.2%	8.2%	8.2%	11.0%
% New to Dialysis	9.2%	8.4%	10.4%	17.4%	45.9%

Conclusions: Pymt reductions in this sample of SDOs were more than twice those mandated and due largely to high cost pt outliers that were not compensated by PPS case mix adjustors. Losses may produce adverse treatment incentives and increase disparities.

Higher Weekend Mortality in Teaching Hospitals in End Stage Renal Disease Patients Ankit Sakhuja, Gagan Kumar, Aaron T. Dall, Rahul S. Nanchal, Puneet Sood. *Medicine, Medical College of Wisconsin, Milwaukee, WI.*

Background: We have previously demonstrated that patients with End Stage Renal Disease (ESRD) admitted over weekends have worse outcomes than those admitted over weekdays. In this study we analyzed if the outcomes of patients admitted to teaching hospitals on weekends were different than those admitted to non-teaching hospitals.

Methods: We analyzed the data from years 2004-2008 using the Nationwide Inpatient Sample (NIS) database. Adult patients (age ≥18 years) with ESRD were included. The primary outcome measured was all cause in-hospital mortality. Chi square test was used to compare the variables for univariate analysis and logistic regression was used to obtain adjusted Mortality odds ratios (OR) in teaching and non-teaching hospitals. We then compared the two Mortality ORs by using Cochran-Mantel-Haenszel (CMH) test. Alpha was set at 0.05. The teaching hospital status was defined as hospitals with either an American Medical Association approved residency program, or those that are members of the Council of Teaching Hospitals, or those that have fulltime equivalent interns and residents to patient ratio of 0.25 or higher.

Results: Of total 756,987 admissions in ESRD patients, 19.5% (147,730) were admitted over a weekend. A total of 49.9% (73,684) of weekend admissions were admitted to teaching hospitals. The unadjusted all cause mortality was 6.1% on weekends in comparison to 5.4% on weekdays ($p < 0.001$). On adjusting for patient and hospital characteristics the overall Mortality OR for weekend admissions was 1.15 (95% CI: 1.12-1.18). On further stratifying the overall weekend mortality into teaching and non-teaching hospitals, Mortality OR in teaching hospitals was 1.22 (95% CI: 1.17-1.26) in comparison to 1.09 (95% CI: 1.06-1.13) in non-teaching hospitals. The difference between the two Mortality ORs was statistically significant (CMH $p<0.001$).

Conclusions: ESRD patients admitted over weekends have a higher mortality. This weekend mortality is significantly higher in teaching hospitals as compared to non-teaching hospitals. Further research and effort is needed to elucidate the reasons for this difference.

FR-OR281

Treatment of Hepatitis C in Hemodialysis Patients Is Associated with Markedly Decreased Mortality, but Is Rarely Prescribed David A. Goodkin,[1] Brian Bieber,[1] Bruce M. Robinson,[1, 2] Michel Y. Jadoul.[3] *[1]Arbor Research Collaborative for Health; [2]U. of Michigan; [3]Univ. Cathol. de Louvain.*

Background: Hepatitis C infection is common among HD patients internationally, with a prevalence exceeding 9%. Data regarding antiviral treatment of HCV among HD patients are very limited.

Methods: The DOPPS is a cohort study of HD patients in Australia, Belgium, Canada, France, Germany, Italy, Japan, New Zealand, Spain, Sweden, the UK, and the US . We examined data from 43,828 patients, collected between 1996 and 2010. Patients were defined as HCV+ if they had the diagnosis in their medical record or if they tested positive for HCV antibody. Patients with prescriptions for an interferon or ribavirin were classified as "treated" for HCV. Cox regression was used to compare survival between treated HCV+ patients, and untreated HCV+ patients, stratified by country and adjusted for case-mix (age, sex, vintage, US black race, and 14 comorbid conditions) to match the treated patients.

Results: Out of a total of 4,494 HCV+ patients, only 35 (0.8%) were treated with antiviral medication. Median duration of follow-up was 1.4 years. The treated patients were younger, less often male, and had lower prevalence of CAD, cerebrovascular disease, CHF, DM, HT, and PVD. None of the treated patients died. 861 of the 4,459 untreated HCV+ patients (19%) died. Mortality risk was significantly worse for untreated patients, even after adjustment for case-mix ($P = 0.01$).

Conclusions: HCV infection among HD patients is very rarely treated internationally. Antiviral therapy is associated with significantly lower mortality risk. This first study of mortality among treated versus untreated HCV+ HD patients suggests that HD patient survival may be increased if HCV+ patients are treated with antiviral therapy.

FR-OR282

Higher Serum Phosphorous Is Associated with Increased Risk for End Stage Renal Disease across All Stages of Chronic Kidney Disease Simran K. Bhandari,[1] John J. Sim,[1] Antoine C. Abcar,[1] Ning Smith,[2] Joanie Chung,[2] Dean A. Kujubu,[1] Scott A. Rasgon,[1] Kamyar Kalantar-Zadeh.[3] *[1]Nephrology and Hypertension, KPSC LAMC, Los Angeles, CA; [2]Research and Evaluations, KPSC, Pasadena, CA; [3]Nephrology, Harbor UCLA, Torrance, CA.*

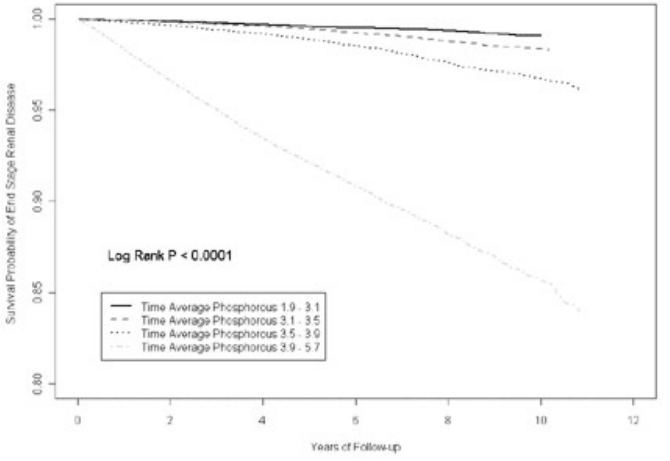
Background: We sought to determine whether higher levels of serum phosphorus (Phos) increased risk for end stage renal disease (ESRD) in a large ethnically diverse population of primarily non-CKD subjects.

Methods: Retrospective cohort study of persons age ≥ 18 yrs during 1/1/1999-12/31/2008 with ≥ 1 Phos and 1 yr min follow up. Subjects categorized into population-based quartiles by time dependent average Phos: 1.9-3.1, 3.1-3.5, 3.5-3.9, 3.9-5.7. The association between Phos quartiles and incident ESRD defined as need for dialysis, transplant, or estimated glomerular filtrate rate [eGFR (mL/min/1.73 m^2)] < 15 using Kaplan Meier survival curve and Cox proportional hazard modeling to calculate hazard ratios (HR) after adjusting for age, gender, race, HTN, DM, eGFR, and Charlson comorbidity index.

Results: 209,865 subjects were evaluated. Mean eGFR was 82; 24% eGFR > 90, 21% eGFR 60-89, and 13% eGFR < 60. Compared to the lowest Phos quartile adjusted HR for ESRD was greater across the 3 higher quartiles.

Phos Quartile	HR for ESRD	95%CI
1.9-3.0	-	-
3.1-3.4	1.47	1.20-1.79
3.5-3.8	2.89	2.41-3.46
3.9-5.7	13.58	11.53-16.01

Linear analysis for ESRD found HR of 1.7 for every 0.5mg/dL increase in Phos. Survival curve also demonstrated ESRD free survival with lower serum Phos.



ESRD rates were evaluated across eGFR (<30, 30-59, 60-89, ≥ 90) and the highest quartile of Phos demonstrated significantly greater HR for ESRD within each eGFR class.

Conclusions: In a large ethnically diverse population primarily without CKD, higher Phos was associated with greater rates of incident ESRD.

FR-OR283

Effects of Rituximab in 100 Consecutive Patients with Idiopathic Membranous Nephropathy (IMN) and Nephrotic Syndrome Despite RAS Inhibition Piero Ruggenenti, Paolo Cravedi, Maddalena Marasa', Barbara Ruggiero, Antonietta Chianca, Giuseppe Remuzzi. *Mario Negri Institute for Pharmacological Research, Bergamo, Italy.*

Background: B-cell depleting therapy has been suggested to reduce proteinuria in patients with IMN and nephrotic syndrome.

Methods: We prospectively studied over a median (range) follow-up of 30.5 (1-115) months, 100 consecutive patients with biopsy-proven IMN and persistent proteinuria >3.5g/24h despite ≥6 months RAS inhibition therapy, who received rituximab therapy at our center.

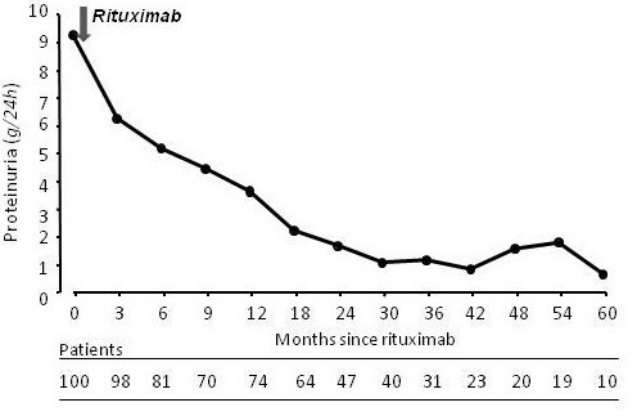
Baseline patients' characteristics

Age (y)	51.3±16.0
Male gender (n)	69 (69%)
Serum creatinine (mg/dL)	1.4±0.7
Serum albumin (g/dL)	2.2±0.6
Total Cholesterol (mg/dL)	274.1±72.3
Proteinuria (g/24h)	10.6±6.4

Proteinuria was the primary outcome.

Results: Mean(± SD) proteinuria significantly decreased from 10.6±6.4, to 4.7±0.5, 3.0±0.5, and 2.0±0.4 g/24h at 1, 2, and 3 years after rituximab, respectively (P <0.05 for all comparisons with Bonferroni adjustment, in parallel with normalization of edema, hypoalbuminemia and hypercolesterolemia.

Figure. Changes in 24-h proteinuria after rituximab therapy



At 3 years, 94.4% of patients reached complete (47.2%) or partial (47.2%) remission defined as proteinuria <0.3g/24h, or <3.5 g (with ≥50% reduction vs. baseline) in 2 consecutive evaluations, respectively. Six patients with baseline creatinine 1.9±0.6 mg/dL reached ESRD over 35 (7-68) months. In the remaining 94 patients serum creatinine was stable from basal (1.4±0.7 mg/dL) to final visit (1.6±1.4 mg/dL). Circulating B cells were fully depleted shortly after rituximab and recovered to basal in 9-12 months. Treatment was well tolerated.

Conclusions: Rituximab safely induced sustained remission in a large cohort of IMN patients with severe nephrotic syndrome. The long-term risk/benefit profile of this selective therapy seems much more favorable than that of commonly used immunosuppressive regimens.

FR-OR284

Phospholipase A_2 Receptor Autoantibodies (PLA_2R-AB) and Increased PLA_2R Expression in Glomeruli Discriminate Primary from Secondary Membranous Nephropathy (MN) Elion Hoxha,[1] Gunther Zahner,[1] Joachim Velden,[2] Kai Fechner,[3] Gesa Stege,[1] Sigrid Harendza,[1] Rolf A. Stahl,[1] Udo Helmchen.[2] *[1]III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Nierenregister Hamburg, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [3]Institute of Experimental Immunology, Euroimmun AG, Lübeck, Germany.*

Background: M-Type PLA_2R is a target antigen in MN. Autoantibodies against PLA_2R are detected in up to 80% of patients with MN. Since PLA_2R-AB in the serum can become or be negative, PLA_2R-AB detection does probably not allow to differentiate in every single patient between primary and secondary MN.

Methods: In order to achieve higher specificity in the diagnosis of patients with MN, we performed a prospective study. Between November 2009 and April 2011, in 81 consecutive patients with the histologic diagnosis MN, PLA_2R-AB were measured in the serum with an indirect immunofluorescence test (Hoxha et. al. NDT in press). In 64 of these patients, in addition to standard histology, kidney biopsies were immunohistochemically stained for PLA_2R (Atlas Antibodies) and IgG4 (Binding Site).

Results: The mean age of the patients, (60 males, 21 females) was 55.9 ± 15.3 years. In 53 patients (65%) serum was positive for PLA_2R-AB: All these patients were positive for IgG4-PLA_2R. Immunohistochemistry for PLA_2R was only faintly positive in normal renal biopsies and biopsies from patients with minimal change disease (n=11). In 47 patients PLA_2R expression was strongly increased in glomeruli, 45 (96%) of those patients were positive for PLA_2R-AB in serum, 44 (94%) stained positive for IgG4. In all 13 PLA_2R-AB negative patients (which had a secondary diagnosis of MN such as SLE, Hep. B, malignancies, NSAID-related MN) PLA_2R and IgG4 staining in renal biopsies were negative.

Number of patients (%)	PLA2R-AB in Serum	PLA2R staining	IgG4 staining
42 (66%)	+	+	+
3 (5%)	+	+	-
13 (20%)	-	-	-
4 (6%)	-	-	+
2 (3%)	-	+	+
64 (100%)			

Conclusions: Measurement of PLA_2R-AB in the serum, in combination with PLA_2R and IgG4 staining of renal biopsies can discriminate between primary and secondary MN and may become a standard approach in the diagnosis of MN.

Funding: Government Support - Non-U.S.

Abstract Withdrawn

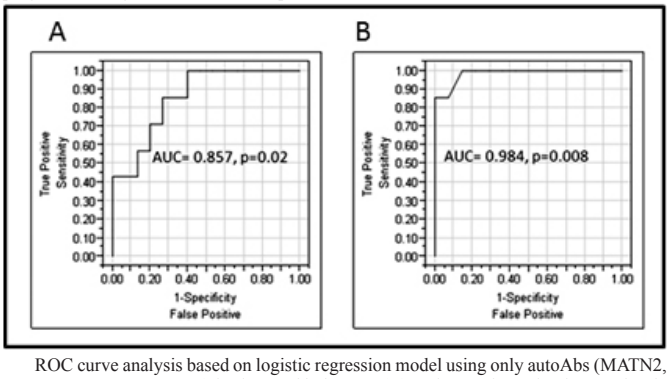
FR-OR286

Integrative Antibiomics Identifies Potential Novel Autoantibody Biomarkers for IgA Nephropathy Tara Sigdel,[1] Sang Hoon Woo,[2] Purvesh Khatri,[1] Li Li,[1] Minnie Sarwal,[1] Richard A. Lafayette.[2] *[1]Department of Pediatrics-Nephrology, Stanford University, Stanford, CA; [2]Department of Medicine, Stanford University, Stanford, CA.*

Background: Immunoglobulin G (IgG) often deposits with Immunoglobulin A in the glomerular mesangium of patients with IgA nephropathy (IgAN) but its clinical relevance is unclear. Autoantibody (autoAb) biomarkers to detect and track progression of IgAN is an unmet need.

Methods: Protein microarrays were used to evaluate IgG autoAbs in the serum of IgAN patients (n=22) and controls (n=10). Clinical parameters were collected on all patients over 5 years. Bioinformatics analysis was performed to choose the targets for further validation by immunohistochemistry (IHC). Significance of autoAbs in IgAN was determined by regression analysis using clinical parameters.

Results: A total of 117 (1.4%) unique antibodies were found to be increased in IgAN. IgAN specific autoAb (~50%) were mounted against proteins predominantly expressed in glomeruli and tubules. The presence of selected antigens in kidney tissue was verified by IHC. ROC analysis demonstrated that IgG autoAbs levels (MATN2, UBE2W, DDX17, PRKD1) might be used in combination with 24 hr proteinuria to improve prediction of the progression of IgAN (AUC = 0.857, p=0.02).



ROC curve analysis based on logistic regression model using only autoAbs (MATN2, UBE2W, DDX17, PRKD1) is showen if Figure 1 (A) and autoAbs and 24hr proteinuria (AUC=0.984; p=0.0008) is shown in Figure 1 (B).

Conclusions: This first analysis of the repertoire of autoAbs in IgAN identified novel, immunogenic protein targets, expressed in the kidney glomerulus and tubules that may be relevant in the pathogenesis and progression of IgAN. Our data suggests that using IgG autoAbs in addition to 24hr proteinuria could improve the ability to predict the progression of disease.

FR-OR287

IgA Nephropathy with Minimal Change like Lesion:Clinicopathologic Features and Response to the Therapy of Steroid Xiran Zhang, Qingwen Wang, Hui-Ping Chen, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.*

Background: Immunoglobulin A nephropathy (IgAN) is the most common glomerular nephritis in the world. Some patients of IgAN manifest minimal change like lesions which have not been well characterized. The purpose of this study was to investigate the clinicopathologic features and response to prednisone treatment of the patients of IgAN with minimal change like lesion.

Methods: 61 patients [46 males and 15 females with an average age of 23.92±8.65] of biopsy-proven IgAN with minimal change like lesions were enrolled in this retrospective study.

Results: All patients had edema, and infection is the major cause in 15 patients (24.6%). Nephrotic syndrome was the primary clinical manifestation. 14 patients (23.0%) had AKI, 5 patients (8.2%) had hypertension and 14 patients (23.0%) had hematuria. The elevation of urine n-acety glucosaminidase (NAG) and urine retinol binding protein (RBP) were observed in the majority of the patients (78.7% and 75.4% respectively). Glomerular changes were minimal with deposition of immunoglobulin A alone (14.3%) or together with immunoglobulin M (61.9%) in mesangial region. 80.3% of the patients manifested acute tubular injury, while 65.6% had interstitial injury. During the follow-up of 46.00±13.93 months (24~70 months), 91.8% of the patients responded to the treatment of prednisone, but 76.8% of which relapsed. Compared with the responders, the non-responders had a higher incidence of hematuria and manifested more severe ($P<0.01$), and their hypoproteinemia was not as evident as the former ones ($P<0.05$). Besides, tubular atrophy, interstitial fibrosis and hyaline degeneration of arteriole were seen more often in non-responders ($P<0.01$). Until the last follow-up, 59 patients (96.7%) still had normal renal function as evidenced by normal serum creatinine**.**

Conclusions: In conclusion**,** IgAN with minimal change like lesion was similar to minimal change disease both in clinical manifestation and pathologic features. Most patients of the patients were remitted with steroid treatment, and had good prognosis.

FR-OR288

Tacrolimus Is an Effective Steroid Sparing Treatment for Lupus Nephritis in Pregnancy Alexander Paul Wardle,[1] Kate Bramham,[2] Catherine Nelson-Piercy,[3] Liz Lightstone.[1] *[1]Imperial College Kidney and Transplant Institute, Hammersmith Hospital, London, United Kingdom; [2]Maternal and Fetal Research Unit, King's College London, London, United Kingdom; [3]Obstetric Medicine, Guy's & St Thomas' Hospitals NHS Foundation Trust, London, United Kingdom.*

Background: Treatment options for pregnant women with lupus nephritis (LN) were previously limited to steroids +/- azathioprine (aza). Steroids in pregnancy are linked with increased pre-term delivery, infection & gestational diabetes. In non-pregnant women we have successfully treated LN with tacrolimus (Tac) in steroid-sparing regimens. Safety of Tac in pregnancy has been established in transplant patients. We report our use of Tac both as maintenance & as an alternative treatment for LN flare in pregnancy, where steroid avoidance was desirable.

Methods: 5 pregnant women taking Tac or Tac added for control of LN. Tac dosed to trough levels of 5-8ng/ml. Remission- Complete (CR): urine PCR <50mg/mmol; Partial (PR): PCR non-nephrotic + >50% fall

Results:

Renal & pregnancy outcomes

Case	Class LN	Immunosuppression	Gestation at flare	Urine PCR	Pre preg CKD stage	Gestation Delivery (wks)	Birth Weight (g)
1	V	Started Tac/MPx2/Aza	10/40	10/40 600, PR 23/40, CR 3/12 post	1	38	3320
2	IV-G (A/C)	Tac maintained	No flare	Pre 106; CR by 23/40	2	37	2500
3	IV-G (A/C)	Tac maintained	No flare	Pre 149, 35/40 129, 37/40 663, CR 1yr post	2	37	2780
4	IV	Aza, Tac started	8/40	Pre 24, 8/40 302, 30/40 777, CR 3/12 post	3	30	1100
5	IV-G (C)	Pred/Aza increased, Tac started	8/40	Pre 52, 8/40 222, 35/40 563, PR 4/12 post	3	35	2910

Delivery: all spontaneous labour; 1 emergency C-section; all live births. In both cases with CKD stage 3, creatinine rose during pregnancy; by 3/12 post partum case 5 eGFR returned to baseline but case 4 had persistent reduction.

Conclusions: To our knowledge, this is the first case series reporting Tac enabling induction of disease remission with steroid sparing in LN in pregnancy. Tac was well tolerated, avoided steroid associated complications and resulted in a reduction or stabilisation of proteinuria, even in women with CKD 3. We propose that it may be considered as an adjuvant or alternative therapy to steroids for pregnant women with LN for maintenance or treatment of disease flare.

FR-OR289

Tacrolimus as an Induction Agent for Proliferative Lupus Nephritis Is as Effective as Cyclophosphamide Sanjay Gupta,[1] Sheel Bhadra Jain,[1] Uma Kumar,[2] Amit K. Dinda.[1] *[1]Nephrology, AIIMS, India; [2]Medicine, AIIMS, India.*

Background: Conventional therapy for lupus nephritis has limitations, cyclophosphamide (cyclo) carries the risk of severe infections, ovarian failure and malignancies mycophenolate has risk of infections. Less toxic treatment with at least equal efficacy is necessary. Tacrolimus (tac) target B cells indirectly by interfering with T cell help by inhibiting IL-6, IL-10 production. The aim of study was to assess the efficacy and safety of Tacrolimus as induction therapy in class III and IV lupus nephritis and compare it with cyclo.

Methods: In an open label non randomized control trial involving 40 female patients with biopsy proven class III and class IV lupus nephritis, we compared the Tac in combination with steroid as an induction therapy with cyclo monthly pulses (NIH protocol). Twenty patients were treated with Tacrolimus, starting at 0.1 mg/kg/day in divided doses maintaining trough levels 5-8 ng/ml and prednisolone at 0.6 mg/kg/day for 6 weeks and then tapered. Response rate and adverse effects were compared with 20 consecutive patients treated with IV cyclo.

Results: The tac group and cyclo group had similar baseline characteristics. Histopathology was similar, in tac group class III in 10, IV in 9 & III+V in 1 and in cyclo group class III in 6, IV in 13 & IV+V in 1. After 6 months in Tac group, complete remission was achieved in 11(55%), partial response in 4 (20%) and no response in 5 (25%) while it was 8(40%), 9 (45%) and 3 (15%) in Cyclo respectively (p=0.23). Proteinuria decreased from 2.2±0.8 to 0.85±1.1 gm/day in tac group & 2.8±2 to0.78±1.2gm/day in Cyclo group(p=0.8) & S albumin increased from 3.1±0.7 to 4.1±0.5 g/dl in tac group & from 2.8±0.8 to 4±0.7 in cyclo group(p=.46). In both groups there was significant improvement in C3 level and decline in dsDNA (IU/ml) titre from baseline. There were more infections in Cyclo group, total 6 episodes (including 2 tubercular) versus 3 episodes in tac group (p=.45). There was no case of hyperglycemia or nephrotoxicity in both groups.

Conclusions: Induction with Tac is as effective as cyclo for proliferative lupus nephritis. It is an option for females desirous of preserving ovarian function or not tolerating Cyclo.

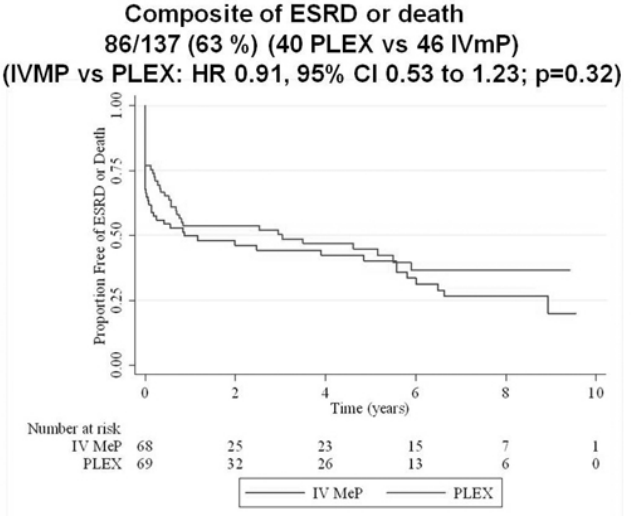
A Long-Term Analysis of the MEPEX Trial: Plasma Exchange for Severe Renal ANCA Vasculitis Alina L. Casian,[1] Michael Walsh,[2] David R.W. Jayne.[1] *[1]Vasculitis, Cambridge University NHS Foundation Trust, United Kingdom; [2]Epidemiology and Biostatistics, McMaster University, Hamilton, Canada.*

Background: Whether plasma exchange (PLEX) reduces end-stage renal disease (ESRD) and mortality in patients with severe ANCA vasculitis (AAV) is unclear. We examined the effect of PLEX on patient outcomes in the long term follow-up of the MEPEX trial.

Purpose of study: To determine whether PLEX compared to IV methylprednisolone (IVMeP) reduces the composite endpoint of ESRD or death or the endpoint of relapse in severe AAV.

Methods: Patients in MEPEX had severe AAV with a serum creatinine >500 µmol/L (5.8 mg/dl). They were randomized to receive either 7 treatments of PLEX or 3 pulses of IVMeP as adjunctive therapy to oral cyclophosphamide and prednisolone. Differences in ESRD/death between the groups were assessed using Cox proportional hazards models and differences in relapse were assessed using competing risk time to event models.

Results: 137 patients were included with a median follow-up time of 4 years. 70 (51%) developed ESRD, 56 (41%) died, and 26 (19%) experienced at least one relapse. The hazard ratio (HR) for the primary composite endpoint of ESRD and death was 0.91 (95% CI 0.53 to 1.23; p=0.32) for PLEX vs IVMeP.



For the endpoint of ESRD alone, the HR was 0.64 (95% CI 0.4 to 1.05, p=0.08) and for the endpoint of death alone the HR was 1.08 (95% CI 0.67 to 1.73). 37 out of 137 patients were alive and not ESRD at 5 years, with a median creatinine of 176 µmol/L in the PLEX group vs. 158 µmol/L in the IVMeP group (p=0.43). When considering the competing risk of death, the HR for relapse was 0.56 (95% CI 0.26 to 1.21, p=0.14) in patients treated with PLEX compared to IVMeP.

Conclusions: We were unable to demonstrate a long-term benefit of PLEX over IVMeP. Further trials are needed to determine if PLEX reduces the occurrence of clinically important outcomes in patients with AAV

FR-OR291

Aberrations in Genes Encoding CFHR5 and Terminal Complement Pathway Components in Patients with Atypical Hemolytic Uremic Syndrome Dineke Westra,[1] Katherine Anne Vernon,[2] Elena Volokhina,[1] Matthew C. Pickering,[2] Cees van Kooten,[3] Nicole Van De Kar,[1] Lambertus V. Heuvel.[1,4] *[1]Radboud University Nijmegen Medical Centre, Netherlands; [2]Imperial College, United Kingdom; [3]Leiden University Medical Centre, Netherlands; [4]University Hospital Leuven, Belgium.*

Background: Atypical HUS (aHUS) is a rare and severe renal disorder thought to be caused by predisposing aberrations in complement proteins. Previously, complement deficiencies in *CFH*, *CFI*, *MCP*, and *CFB*, or the presence of αFH were identified in 37% of our cohort of Dutch and Belgian patients. More than 4% of the patients carried an alteration in more than one gene. In this study, we identify potentially pathogenic aberrations in the regulator CFHR5 (*CFHR5*) and the terminal complement complex (TCC) components C8α (*C8A*), C8β (*C8B*), and C9 (*C9*).

Methods: Mutational screening was performed in *CFHR5*, *C8A*, *C8B*, and *C9* in 65 aHUS patients. Potential pathogenicity of genetic alterations was checked in literature, evolutionary conservation, and *in silico* mutation prediction programs. Influence of mutations in *C8A* on protein structure was analyzed with respect to available structural data. Hemolytic assays were performed for functional analysis of aberrations in TCC proteins. CFHR5 was detected in available serum by means of western blotting analysis and ELISA.

Results: In eleven patients (16.9%) we identified a potentially pathogenic sequence variation in a TCC gene or in *CFHR5*. The p.Arg444His aberration in C8α, located in the proximity of the interface with C8γ and in the binding site for CD59, results in increased hemolytic activity. Serum levels of CFHR5 were not altered. In three patients, a genetic defect was also found in one of the previously screened genes (*CFH*, *CFHR5*, and *C8A*: 2x; *CFHR5* and *CFH*: 1x).

Conclusions: A potentially pathogenic genetic abnormality in one of the components of the membrane attack complex or in *CFHR5* was observed in 16.9% of the patients. In total, in 51% of the patients at least one potentially pathogenic defect was identified in one of the complement genes screened in this cohort. The combined genetic defects identified in 9.2% might partly explain the incomplete penetrance described in the disease.

Podocyturia Is an Early Marker That Distinguishes among Normotensive Pregnancy, Gestational Hypertension, and Preeclampsia Iasmina Craici,[1] Steven Wagner,[1] Juan C. Calle,[1] Christina Wood-Wentz,[3] Kent R. Bailey,[3] Stephen T. Turner,[1] Joseph P. Grande,[2] Vesna D. Garovic.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; [3]Biostatistics, Mayo Clinic, Rochester, MN.*

Background: Preeclampsia (PE) is a disorder of hypertension and proteinuria that affects 3% to 5% of pregnancies. We have previously shown that podocyturia, the shedding of live podocytes, is present at delivery in patients with PE. We aim to test whether podocyturia is predictive of later development of PE, and whether it can differentiate among normotensive pregnancies, gestational hypertension (GHTN), and PE.

Methods: From a prospective cohort of 315 patients, 15 developed PE and 15 developed GHTN. Forty four normal controls were selected. Blood pressure and protein/creatinine ratios were checked at mid-gestation prior to the onset of PE or GHTN. Urine sediments collected in mid pregnancy, prior to 210 days gestation, were cultured for 24 hours to select for viable cells. Podocytes were then identified on the basis of podocin staining.

Results: Age was not different between groups. At mid-pregnancy, the patients who later developed PE or GHTN had higher mean arterial pressure (MAP). There was an insignificant trend toward a higher protein:creatinine ratio in those who later developed PE. Of the 15 patients who later went on to develop PE, all had positive podocyturia early in pregnancy. None of the 44 normal pregnancies or 15 pregnancies complicated by gestational hypertension had podocyturia before 210 days gestation (Table 1).

Table 1

	Normotensive	GHTN	PE	p (anova)
Maternal age (years)	28.8 ± 4.4	29.9 ± 3.5	29.3 ± 6.4	0.72
Mid gestation MAP (mmHg)	77.6 ±7.1	84.0 ± 7.4	84.1 ± 8.4	0.002
Protein:creatinine ratio	0.06 ± 0.12	0.04 ± 0.02	0.25 ± 0.76	0.17
Podocyturia N (%)	0/44 (0%)	0/15 (0%)	15/15 (100%)	

Conclusions: Mid pregnancy, podocyturia is a highly accurate test for prediction of later development of PE. Podocyturia can also differentiate between later development of GHTN and PE. We postulate that the high accuracy of this test further supports the role of podocyte loss in the mechanism of proteinuria in preeclampsia.

FR-OR293

Mechanism of Selective Proteinuria in Minimal Change Nephrotic Syndrome Satoshi Kinugasa,[1] Akihiro Tojo,[1] Tatsuo Sakai,[2] Toshiro Fujita.[1] *[1]Department of Internal Medicine, University of Tokyo, Japan; [2]Department of Anatomy and Life Structure, Juntendo University School of Medicine, Tokyo, Japan.*

Background: As a mechanism of selective proteinuria in minimal change nephrotic syndrome, we have previously demonstrated albumin transport through the podocyte cytoplasm. In this study we investigated the time course of podocyte albumin transport by confocal laser-scanning microscopy, utilizing GFP-transgenic rats in which a minimal change nephrotic syndrome model was induced, and examined the role of FcRn as albumin receptor in podocytes.

Methods: A minimal change nephrotic syndrome model was induced in GFP-transgenic rats by puromycin aminonucleoside (PAN). After injection of Evans blue (EB)-labeled human serum albumin, kidneys were observed in vivo by real-time confocal microscopy. Subsequently, we observed the localization of EB-labeled human serum albumin in vibratome sections. We treated PAN nephrotic rats with anti FcRn antibody, and observed its effect on proteinuria and podocyte uptake of EB-labeled albumin.

Results: PAN nephrotic rats presented with selective proteinuria, which was confirmed by urine SDS-PAGE, and the urine IgG/Albumin ratio, an index of selectivity, was comparable with controls. In PAN nephrotic rats, fluorescence of EB was absent in the proximal tubular lumen until 5 minutes after injection, and increased at 15 minutes in PAN nephrotic rats, whereas it was almost negative in controls, indicating that a large proportion of albumin is transported slowly through podocytes. The cytoplasm of some podocytes appeared yellow in PAN nephrotic rats, due to merging of the green fluorescent signals of GFP expressed in podocytes and the red fluorescence of EB-labeled albumin, which was not observed in controls. Immunoprecipitation analysis showed an increase in Evans blue-labeled human serum albumin bound to FcRn. PAN nephrotic rats treated with antibody against rat FcRn showed significantly decreased proteinuria, compared to untreated animals (40.5±6.3 vs. 22.1±4.2 mg/mgCr, $p<0.05$), and podocyte uptake of EB-labeled albumin.

Conclusions: Podocyte albumin transport by FcRn may contribute to the selective albuminuria in minimal change nephrotic syndrome.

FR-OR294

Dynamin Oligomerization Cycle Directly Reglates the Actin Cytoskeleton and Alleviates Proteinuria Changkyu Gu, Sanja Sever. *Nephrology, Massachusetts General Hospital, Charlestown, MA.*

Background: Dynamin oligomerization into rings or spirals/helices has been linked to membrane tubulation and fission of clathrin coated vesicles at the plasma membrane. Recently, we implicated dynamin oligomerization in the regulation of the actin cytoskeleton. We now show that dynamin oligomerization in live cells is dependent on dynamin-actin interactions and GTP-binding. To elucidate the role of dynamin oligomerization in cells we turned to a small molecule that alters the dynamin oligomerization cycle by a novel mechanism. We identify Bis-T-23</A> as an archetypical small molecule "ring stabilizer" that promotes dynamin oligomerization into rings *in vitro* and in cells, promoting an activated conformation and reducing disassembly rates. In podocytes, Bis-T-23 promoted formation of focal adhesions and stress fibers independently of the RhoA pathway. Thus dynamin rings directly stimulate actin assembly by a novel mechanism. In contrast, dynole 34-2, a dynamin inhibitor lacking ring stabilizer activity, exhibited opposing cellular effects, ruling out endocytosis as an underlying mechanism for actin dynamics. Bis-T-23 protected against cathepsin L-driven proteolysis of dynamin *in vitro* and in podocytes. This in turn restored wild type organization of the actin cytoskeleton and protected podocytes from lipopolysaccharide (LPS)-induced apoptosis. Administration of Bis-T-23 in two different rodent models of proteinuric kidney disease significantly reduced proteinuria. Our study reveals that oligomerised dynamin directly regulates the actin cytoskeleton and identifies dynamin ring stabilizers as a potential novel therapeutic approach for proteinuria.

FR-OR295

Hyposialylation of Glycoproteins in the UDP-N-Acetylglucosamine-2-Epimerase/N-Acetylmannosamine Kinase (GNE) Point Mutant Mice Gives Rise to a Renal Impairment That Is Prevented by Sialic Acid Administration Mitutoshi Ito,[1] Tomoya Asaka,[2] Kazushi Sugihara,[1] Toru Yoshihara,[1,3] Takashi Wada,[4] Masahide Asano.[1] *[1]Advanced Science Research Center, Kanazawa University, Kanazawa, Japan; [2]Nanao National Hospital, Nanao, Japan; [3]Research Center for Child Mental Development, Kanazawa University, Kanazawa, Japan; [4]Department of Laboratory Medicine, Kanazawa University Graduate School of Medical Science, Kanazawa, Japan.*

Background: Sialic acid is one of acidic carbohydrates and well known to modify non-reducing terminal carbohydrates on glycoproteins and glycolipids. It is reported that mutations in the key enzyme of sialic acid biosynthesis, GNE, result in distal myopathy with rimmed vacuole (DMRV) in human. In this study, we generated mice with a point mutation (V572L) in its kinase domain.

Methods: Kidneys of GNE homozygous mutant mice (mt-mice) were investigated using biochemical, histopathological, and glycobiological analysis. N-acetylneuraminic acid (Neu5AC) treatment was carried out as follows. Before birth, pregnant heterozygous mutant mice were administrated with Neu5AC (1 g/kg/day) in drinking water. After birth, babies as well as mothers were administrated with Neu5AC (0.2 g/kg/day) in drinking water.

Results: Unexpectedly apparent myopathic features were not observed in mt-mice. However, they showed renal impairment with proteinuria and high level of serum cystatin C. Furthermore, abnormal structure of podocyte foot processes, hypoplastic glomeruli and cystic degeneration were observed in the mt-mice. Glycan analysis using several lectins showed that hyposialylation of renal tubules and renal corpuscles were observed, particularly, hyposialylation of a major podocyte sialoprotein, podocalyxin, was observed in the mt-mice. Administration of Neu5AC to the mt-mice from embryonic stage significantly supressed proteinuria and improved renal pathology with recovered sialylation of renal corpuscles.

Conclusions: These findings suggest that the proteinuric glomerular disease in the mt-mice was caused by impaired glomerular filtration due to hyposialylation of podocyte glycoproteins. Moreover, the renal disease in the mt-mice was prevented by the administration of Neu5AC from embryonic stage.

Single Injection of Stem Cells Derived from Amniotic Fluid Slows down the Progression of Kidney Failure in a Mouse Model of Alport Syndrome Laura Perin,[1] Sargis Sedrakyan,[1] Stefano Da Sacco,[1] Astgik Petrosyan,[1] Liron Shiri,[1] Kevin V. Lemley,[2] Roger E. De Filippo.[1] *[1]Urology, Children's Hospital of Los Angeles, Los Angeles, CA; [2]Nephrology, Children's Hospital of Los Angeles, Los Angeles, CA.*

Background: Alport Syndrome (AS) is a useful model for studying chronic kidney disease (CKD). This hereditary form of glomerulonephritis leads to interstitial fibrosis and eventual loss of renal function. Stem-cell based therapies may provide alternative therapeutic opportunities to treat CKD. Amniotic fluid stem cells (AFSC) present pluripotential capabilities and are reno-protective in mouse models of acute kidney injury. Herein, we investigate the potential of AFSC as a new approach to current therapies for CKD.

Methods: In this study we have administered AFSC in a murine model of AS (Col4a5-/-) before the onset of proteinuria. Mice were sacrificed at 5 days, 1 and 2 months post treatment and kidneys were harvested for molecular and histological analysis. Kidney function was assessed with serum creatinine measurements.

Results: AFSC infusion resulted in delayed renal fibrosis and prolonged animal survival, slower progression of glomerulosclerosis and ameliorated kidney function. Furthermore, injected animals exhibited decreased recruitment of macrophages within the kidney and an apparent preference towards M2 type macrophages favoring tissue remodeling. Our investigation supports a mechanism of renal protection through modulation of expression of genes promoting fibrosis such as Twist1, Snai2, Wnt11, Zeb1, Zeb2, SPARC and two potent BMP antagonists, Chordin and Noggin. Important changes in genes stimulating new extracellular matrix, such as Coll1A1, Fn1, Vcan, Itgb5, Coll3A1 and Coll5A2 appear to also be involved. Furthermore, injected AFSC are capable of downregulating MMP2 and MMP9 enzyme activity, critical modulators in GBM remodeling during disease progression.

Conclusions: Although injection of AFSC does not entirely reverse kidney disease, taken together our finding suggest that a single AFSC treatment delays progression of CKD and significantly improves survival in treated AS mice.

FR-OR297

Role of Endothelin-1 in Podocyte-to-Endothelial Cross-Talk in Podocytopathies Ilse S. Daehn, Taoran Zhang, Gabriella Casalena, Franz Fenninger, Erwin P. Bottinger. *Medicine, Nephrology, Mount Sinai School of Medicine.*

Background: Podocyte-initiated glomerular diseases (podocytopathies) can progress to glomerulosclerosis with mesangial expansion. The molecular signaling mechanisms between glomerular cell types during initiation/progression of primary podocytopathies remain poorly understood. The purpose of this study was to examine cellular culprits and consequences of glomerular mitochondrial dysfunction (MD)and oxidative stress responses in-situ.

Methods: We assessed glomerular MD and oxidative stress in glomeruli of a Doxycycline (DOX)-inducible expression of a ligand-independent, constitutively active TGFβ receptor type 1 (Tgfbr1) mutant selective to podocytes; NPHS2-rtTA_tet-O-Tgfbr1(AAD) double transgenic mice (PodTbr1(AAD)), which develops progressive glomerulosclerosis characterized by mesangial expansion, podocyte apoptosis and depletion [Zhang et al, ASN 2010 free communication].

Results: After 2 days of DOX chow, markers of oxidative stress (3NT) and oxidative DNA damage (8-oxoguanine) were detected in mtDNA of endocapillary cells, but not in podocytes. 8-oxoG exclusively colocalized with endothelial-specific marker CD31. Because endothelin-1 receptor A (ETA) expression was increased already after 1day of DOX in glomerular endothelial cells, we applied inhibitor of ETA, BQ-123, by subcutaneous osmotic pump together with DOX chow in double transgenic mice. Inhibition of ETA signaling ameliorated endothelial oxidative mtDNA damage and MD, and prevented subsequent podocyte apoptosis, depletion, proteinuria and glomerulosclerosis. Conditioned media from DOX-treated podocyte cultures established from PodTbr1(AAD) mice induced mtDNA damage, loss of mitochondrial membrane potential and apoptosis of glomerular endothelial cell cultures, that were prevented in the presence of BQ-123 in conditioned media.

Conclusions: Our in-vivo and in-vitro studies of podocyte-restricted TGFβ signaling identify endothelin-1/ETA-mediated podocyte-to-endothelial crosstalk and suggest that TGFβ activation in podocytes induces endothelin-1 as essential mediator of endothelial mitochondrial dysfunction, oxidative stress and mtDNA damage, and that ETA inhibition prevents subsequent podocyte injury.

Changes in Proximal Tubule Cell Phenotype Induced by Glomerular Proteinuria Sara Terryn,[1] Vanessa Guy-Viterbo,[1] Geraldine Mollet,[2] Marie-Claire Gubler,[2] Corinne Antignac,[2] Olivier Devuyst.[1,3] *[1]UCL Nephrology, Brussels, Belgium; [2]Inserm U983, Paris, France; [3]University of Zurich, Switzerland.*

Background: Glomerular proteinuria is a strong predictor of renal function decline in chronic kidney diseases, and the interaction between proteins filtered in excess and proximal tubule (PT) cells participates in the interstitial damage. The timing, nature and mechanisms of phenotype changes in PT cells remain poorly documented.

Methods: We analyzed the phenotype of PT cells exposed to a strictly time-controlled glomerular proteinuria, using the Nphs2flox/-Cre+ mice in which conditional inactivation of podocin induces a massive proteinuria followed by tubulo-interstitial lesions.

Results: Histological analysis revealed changes in PT morphology starting 5 days after podocin inactivation, as shown by dilated tubules with brush border disappearance progressing from the early to the straight proximal tubule, resulting in atrophic, dedifferentiated tubules at day 12. These changes in PT morphology coincided with the onset of low-molecular weight (LMW) proteinuria, glucosuria and phosphaturia. Immunostaining revealed a decreased expression of the multi-ligand receptor megalin starting 5 days after podocin inactivation, with further decline mirroring LMW proteinuria. The pathways involved were investigated in primary cultured PT cells exposed to albumin. Exposure of PT cells to high albumin concentration (10mg/ml) decreased the expression of the megalin and cubilin receptors and induced oxidative stress and fibrosis. These changes were associated with an increased expression of ZONAB, a transcription factor promoting epithelial cell dedifferentiation and a direct repressor of megalin/cubilin, paralleled by increased cell proliferation (PCNA) and a loss of polarization as evidenced by the disappearance of tight junctions (ZO-1).

Conclusions: These results show that exposure of PT cells to an excess of albumin in vivo or in vitro triggers a transcriptional mechanism that leads to cellular dedifferentiation and generalized dysfunction. Glomerular proteinuria is thus causing a rapid and specific toxicity on PT cells, involving their endocytic machinery.

FR-OR299

Urinary Cystatin C Excretion Is Controlled by Megalin Mediated Proximal Tubule Endocytosis Danny Jensen, Rikke Nielsen, Henrik Birn. *Dept. of Anatomy, Aarhus University Faculty of Health, Aarhus, Denmark.*

Background: Cystatin C is a protease inhibitor produced in all nucleated cells. Urinary Cystatin C is an established marker of kidney injury. Cystatin C is filtered freely in the glomeruli and in the normal kidney this is followed by complete reabsorption by the proximal tubule. Megalin and cubilin are endocytic receptors involved in the proximal tubule reabsorption of filtered proteins and the current study was undertaken to establish the role of these receptors for the urinary excretion and tubular uptake of endogenous Cystatin C.

Methods: Binding of recombinant Cystatin C to purified megalin and cubilin was analyzed by surface plasmon resonance analysis. Urinary excretion and proximal tubule uptake of endogenous Cystatin C was studied by immunoblotting and immunohistochemistry in wildtype and in conditional megalin and cubilin knockout (KO) mice as well as in rats treated with L-lysine known to inhibit proximal tubule protein uptake.

Results: Surface plasmon resonance analysis revealed a high affinity binding of Cystatin C to megalin (Kd ~78 nM) and to cubilin (Kd ~50 nM). Receptor associated protein, a known inhibitor of ligand binding to megalin, inhibited Cystatin C binding to megalin with 76%. Urinary excretion of Cystatin C was identified in megalin KO, but not in cubilin KO or wildtype mice. Immunocytochemistry showed vesicular labeling for Cystatin C in wildtype proximal tubular cells consistent with endocytic uptake of endogenous Cystatin C. Similar labeling was observed in cubilin deficient cells, however, no uptake in was identified in proximal tubule cells not expressing megalin. Finally, no uptake of endogenous Cystatin C was observed in proximal tubule cells from L-lysine treated rats.

Conclusions: The endocytic receptors megalin and cubilin bind Cystatin C with high affinity. Inactivation of megalin, but not cubilin, is associated with increased urinary excretion and inhibition of proximal tubule uptake of Cystatin C. These observations identifies megalin as essential for the normal, tubular recovery of endogenous Cystatin C. Increased urinary excretion of Cystatin C, as observed in kidney injury, is a marker of proximal tubule endocytic dysfunction.

Resveratrol, an Activator of Sirt1, Ameliorates Renal Damage in 5/6 Nephrectomized Rats Via the Smad Pathway Xinzhong Huang, Donghai Wen, Chuan-Ming Hao. *Division of Nephrology, Huashan Hospital, Fudan University, Shanghai, China.*

Background: Fibrosis plays an important role in the pathogenesis and progression of CKD. Resveratrol(RSV) is a polyphenol with antifibrotic properties. It has also been shown to activate Sirt1 which has health beneficial effect. In the present study, we investigated the effect of RSV on a 5/6 nephrectomized CKD rat model.

Methods: Three groups of rats were studied: sham operated, 5/6Nx+vehicle, and 5/6Nx+RSV 20mg/kg. RSV or vehicle was administered one week after 5/6 nephrectomy surgery.

Results: Subtotal nephrectomy significantly increased proteinuria (152.14±30.48mg/day vs 25.34±7.54 mg/day), blood urea nitrogen (16.75±3.99mmol/L vs 8.03±1.2mmol/L) and serum creatintine(111.6±21.5μmol/L vs 53.9±11.6μmol/L) at 12 weeks. RSV treatment significantly reduced urinary protein excretion (79.87±34.27mg/day), blood urea nitrogen (11.95±1.88mmol/L) and serum creatinine levels(83±14.69μmol/L). The glomerular sclerosis index (1.56±0.34 vs 0.35±0.08) and tubulointerstitial fibrosis (1.47±0.29 vs 0.18±0.04) were increased in nephrectomized rats, which were significantly reduced by RSV treatment. Further study shows that treatment of nephrectomized rats with RSV significantly reduced acetylation levels of Smad3. Immunoprecipitation studies revealed a binding of acetylated Smad3 with silent information regulator 1(Sirt1). In cultured murine mesangial cells, down-regulation of Sirt1 increased acetylation levels of Smad3, consistent with deacetylation effect of Sirt1. RSV significantly down-regulated TGF-β-induced fibronectin and type IV collagen expression in a dose- and time-dependent manner by immunoblot in cultured cells. Knocking-down Sirt1 using a RNAi markedly attenuated these effects of resveratrol, supporting that Sirt1 mediates the effect of RSV. In contrast, forced up-regulation of Sirt1 in cultured mesangial cells significantly reduced fibronectin and type IV collagen expression.

Conclusions: RSV attenuates renal damage in 5/6Nx rats. The renal protective effect is associated with reduced Smad acetylation and TGFβ signaling. These findings indicate that Sirt1 may be a potential therapeutic target for the treatment of CKD.

FR-OR301

Mesangial Cell Susceptibility to IgA1 Is Important for Disease Development Kerstin Ebefors,[1] Ying Sun,[2] Johannes Elvin,[3] Borje Haraldsson,[3] Jenny C. Nystrom.[1] *[1]Physiology, Neurosience and Physiology, Gothenburg, Sweden; [2]AstraZenca, Sodertalje, Sweden; [3]Molecular and Clinical Medicine, Medicine, Gothenburg, Sweden.*

Background: IgA nephropathy (IgAN) is the most common type of glomerular nephropathy, with IgA depositions containing under-galactosylated IgA1 in the mesangial matrix as one of the key findings. However, these depositions are sometimes also found in kidneys of asymptomatic individuals. We therefore hypothesize that there must be both mesangial cell susceptibility to IgA, and under-galactosylated IgA1 in order for IgAN to develop.

Methods: To test the hypothesis, two protocols were used. Firstly, we collected and microdissected biopsies from patients with IgAN (n=15) and healthy kidney donors (n=23). Global gene expression was investigated with focus on matrix-associated genes. Secondly, we developed a unique method for culturing mesangial cells from patients with IgAN and healthy controls. These cells were treated with IgA1 purified from patients with IgAN (n=3) or healthy controls (n=3) and the expression of extracellular matrix (ECM) genes were studied.

Results: Patients with IgAN have increased gene expression of several ECM genes and a KEGG pathway analysis showed that the most up-regulated pathway was the ECM-receptor interaction pathway. Mesangial cells cultured from patients with IgAN had changed basal gene expression of several ECM genes including: COL1A1, DCN and SDC1 compared to control. Treating cells with purified IgA1 increased the changes in expression further. These changes in matrix gene expression may be necessary for the IgA depositions to be pathogenic.

Conclusions: To conclude, these experiments show that the gene expression of matrix genes is affected in IgAN, both on a systemic and cell-specific level. This strengthens the hypothesis that the mesangial cell response to IgA1 is important for the disease to develop and may differ between individuals.

FR-OR302

A Small-Molecule Inhibitor of Stat3 Prevents Muscle Wasting in Chronic Kidney Disease Liping Zhang, Yanlan Dong, William E. Mitch, David J. Tweardy. *Medicine, Baylor College of Medicine, Houston, TX.*

Background: Chronic kidney disease (CKD) is characterized by increased circulating IL-6, insulin/IGF-1 resistance, and abnormal protein metabolism causing body and muscel mass loss; administration of IL-6 alone to mice causes cachexia. There are no approved treatments for CKD-induced cachexia. Activation of signal transducer and activator of transcription (Stat) 3 is a key component of IL-6 signaling. We developed a small-molecule probe (C188-9) that targets the Src-homology 2 domain of Stat3 thereby blocking two steps in IL-6-mediated Stat3 activation—recruitment to the IL-6-activated receptor and Stat3 dimerization. We examined if C188-9 treatment improves muscle metabolism in mice with CKD.

Methods: Subtotal nephrectomy and a high protein diet were used to create mice with BUNs>80 mg/dL. The mice were paired by BUN and body weight and injected daily for 14 days with either C188-9 (6.25 mg/kg) in D5W or D5W alone.

Results: CKD mice developed weight loss and reduced muscle mass accompanied by increased muscle Stat3 activation. C188-9 treatment increased body weight (9.8% ±0.31, mean ± S.E.) and muscle weights (13.2±1.2% & 7.9±0.8 for gastrocnemius and tibialis anterior (TA) muscles, respectively) compared to D5W treatment ($p<0.05$ for all). C188-9 treatment also increased myofiber cross sectional areas in TA muscles by 41% (avg., 2400 mm^2 vs 1700 mm^2; control), increased muscle protein synthesis, and decreased protein degradation; the latter coincided with decreased expression of the E3 ligase Atrogin-1 (39.8%, $p<0.01$), indicating suppression of CKD-induced activation of ubiquitin-proteasome system. C188-9 treament reduced muscle Stat3 phosphorylation and decreased expression of the Stat3 gene target, SOCS3, while increasing Akt phosphorylation. These effects most likely were direct effects of C188-9 because C188-9 treatment of C2C12 muscle cells blocked the catabolic effects of IL-6 while improving insulin/IGF-1 intracellular signaling.

Conclusions: Thus, C188-9 treatment blocked the pathogenesis of CKD-induced cachexia in mice. Since C188-9 was well-tolerated and is water soluble, it, or a derivative, shows promise as an oral therapy for patients with CKD-induced cachexia.

Hypertension in African American Live Kidney Donors Mona D. Doshi,[1] Mariella Goggins,[2] Amit X. Garg.[3] *[1]Internal Medicine, Wayne State University, Detroit, MI; [2]Internal Medicine, Henry Ford Transplant Institute, Detroit, MI; [3]Nephrology, London Health Science Centre, London, ON, Canada.*

Background: Compared to those of Caucasian race, African Americans (AA) are at higher risk of developing hypertension (HTN). It is unclear if live kidney donation further increases this risk. We conducted a retrospective cohort study of donors and non-donors to examine this issue.

Methods: We enrolled 138 AA who underwent donor nephrectomy at Harper Hospital or Henry Ford Transplant Institute in Detroit between 1993-2007. We also enrolled 48 AA non-donors who were suitable candidates for live kidney donation but did not donate due to non-medical reasons. None of the donors were hypertensive or diabetic prior to donation. In follow-up, HTN was defined as either systolic BP > 140 or diastolic BP > 90 or use of antihypertensive agent(s). We used multivariable logistic regression models to account for differences in baseline characteristics between the two groups.

Results: The baseline characteristics of donors and non-donors at time of follow up are are shown in the table.

Comparison of characteristics between donors and non-donors at time of follow-up

	Donors (n=138)	Non-Donors (n=48)	p-value
Age (years)	45±10	42±11	0.05
% Women	63%	67%	0.60
Body Mass Index (kg/m^2)	32±5	28±6	0.39
Serum creatinine (mg/dL)	1.2±0.3	0.9±0.3	0.01

Mean ± standard deviation

Non-donors were younger than the donors by 3 years. At median follow up of 7 years (range 4-18 years), 50% of donors exhibited HTN compared to 27% of non-donors (p<0.01). The odds ratio for exhibiting HTN in donors was two and a half fold higher compared to non-donors (unadjusted odds ratio 2.7 (95% CI: 1.3-5.5; p<0.01), adjusted odds ratio 2.4 (95% CI: 1.1-5.3; p=0.01)). Since donation, 52% of donors were not seeing a physician regularly, and 49% of 69 donors with HTN were without treatment.

Conclusions: Live kidney donation increases the risk of hypertension in AA. In the US, many donors lack appropriate medical follow-up and care to maintain good long-term cardiovascular and renal health.

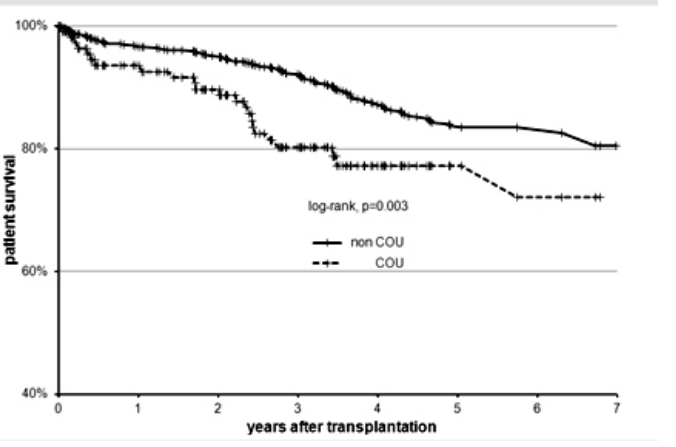
FR-OR304

History of Chronic Opioid Usage and Clinical Outcomes Post Kidney Transplantation Fidel Barrantes,[1] Fu L. Luan,[1] Mallika Kommareddi,[1] Kareem Alazem,[1] Alan B. Leichtman, Tareq Yaqub,[1] Diane M. Cibrik,[1] Randy S. Roth,[2] Silas Norman,[1] Randall Sung,[3] Timothy A. Horwedel,[4] Milagros D. Samaniego-Picota.[1] *[1]Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Physical Medicine and Rehabilitation, University of Michigan, Ann Arbor, MI; [3]General Surgery, University of Michigan, Ann Arbor, MI; [4]Pharmacy, University of Michigan, Ann Arbor, MI.*

Background: Chronic use of opioid analgesics for pain management is common among patients with end stage renal disease. We hypothesized that chronic opioid usage (COU) prior to kidney transplantation can negatively affect post-transplant outcomes.

Methods: We examined retrospectively the risk of graft loss and death in adult kidney transplant recipients according to their history COU prior to transplantation. Kaplan-Meier-survival and multivariate Cox-regression analysis were performed to compare patient and graft survival with and without COU.

Results: Among 1064 adult kidney transplant patients, 108 patients (10.2%) reported a history of COU. The cumulative mortality rate at one, three and five years was 6.5% vs. 3.2%, 18.5% vs. 7.5% and 20.4% vs. 12.7% for patients with and without a positive history of COU, respectively. A positive history of COU prior to transplantation was associated with a 65% increase in the risk of death (AHR 1.65, 95% CI 1.04, 2.60, p=0.033).



Furthermore, COU was associated with increased risk of graft loss within the first year (5.6% vs. 1.6%, p=0.005, AHR 2.90, 95% CI 1.10, 7.64, p=0.031), which did not persist during the subsequent follow up.

Conclusions: A positive history of COU prior to transplant is associated with inferior clinical outcomes after kidney transplantation.

FR-OR305

Recipient *klotho* genotypes Affect Outcome after Human Kidney Transplantation Leandro Cunha Baia, Gerjan Navis, Martin H. De Borst. *On behalf of the REGaTTA (REnal GeneTics TrAnsplantation) Groningen group, University Medical Center Groningen, Dept of Nephrology, Netherlands.*

Background: In experimental studies genetic or environmental loss of Klotho contributes to premature aging, renal damage and vascular calcification. As these factors may influence graft function and surivival, we studied the association between klotho gene variants and outcome after human kidney transplantation.

Methods: Thirteen tag SNPs covering all known variants in the human Klotho gene were genotyped in 1271 donor-recipient pairs transplanted between 1993 and 2008. Only SNPs in Hardy Weinberg equilibrium (HWE) were considered. With minor allele frequencies (MAF) <5%, dominant models were used. Donor and recipient genotypes were analyzed for associations with mortality, death-censored graft loss and clinical data (serum creatinine, PTH, phosphate) obtained 60 (range 58-64) months post-transplantation.

Results: During followup of median 5.5 [IQR 2.9-8.9] years, 175 (16.0%) recipients developed graft loss and 191 (17.4%) died with a functioning graft. On multivariate Cox regression analysis, recipient rs577912 major allele homozygote genotype (CC) was associated with mortality, also when adjusted for donor and recipient age, ischemia times, % of panel reactive antibodies and HLA mismatches (RR 1.606 (1.164-2.215), p=0.004).

The minor recipient rs553791 allele (TT, MAF 0.07) was associated with death-censored graft loss as compared to TG/GG genotypes (RR 1.903 (1.116-3.245), p=0.018). Oppositely, the GG genotype protected against graft loss (multivariate: RR 0.526 (0.308-0.896), p=0.018). In TT (n=57) as compared to age-matched GG/GT genotypes (n=135), serum creatinine (3.7±0.6 vs 2.3±0.2 mg/dl, p=0.002), PTH (505±171 vs 162±29 pg/ml, p<0.0001), and phosphorus (3.7±0.3 vs 3.1±0.3 mg/dl, p=0.02) were elevated 5 yrs post-transplantation.

Conclusions: Recipient but not donor klotho variants are associated with mortality (rs577912), in line with prior data in hemodialysis patients, and with death-censored graft loss, serum creatinine, PTH and phosphate 5 years after transplantation (rs553791). These findings link extrarenal Klotho to outcome after human kidney transplantation.

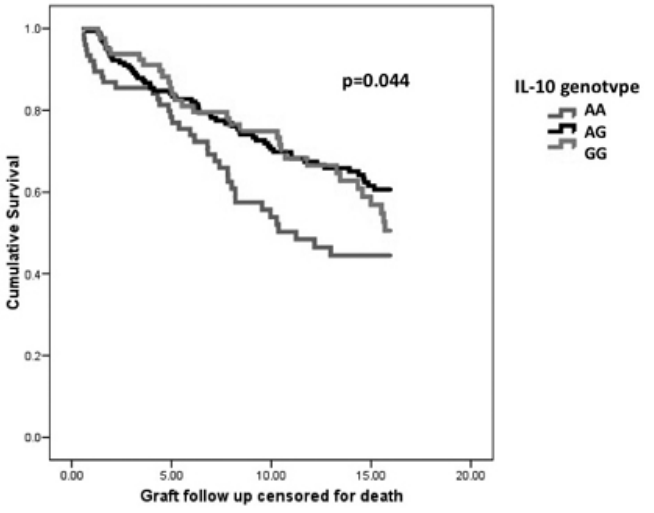
The Impact of Interleukin-10 Genetic Polymorphism on Long-Term Graft Survival in Kidney Transplantation Patrick Barry Mark,[1] Jamie P. Traynor,[2] Kathryn K. Stevens,[1] Rajan Kantilal Patel,[1] Alan G. Jardine.[1] *[1]BHF Cardiovascular Research Centre, University of Glasgow, Scotland, United Kingdom; [2]Renal Unit, Monklands Hospital, Airdire, Scotland, United Kingdom.*

Background: Immunologically mediated damage contributes to chronic allograft nephropathy. Interleukin-10 (IL-10) has anti-inflammatory effects. Low IL-10 production is associated with the A allele of the IL-10-1082 G/A single nucleotide polymorphism (SNP). Transforming growth factorβ1 (TGFβ1) has pro-inflammatory, fibrotic and immunosuppressive actions. The implications of genetic polymorphisms encoding these cytokines on graft survival are unclear.

Methods: We studied 422 first renal transplant patients (median age 42.6 years; 56.6% male; 10% live donors). Patients were surveyed in 1994 and followed up after 16 years. Patients were genotyped for SNPs encoding IL-10 (G/A at position - 1082) and TGFβ1(C/T, C/G at codons 10 and 25).

Results: There were 179 (42.2%) deaths and 154 (36.5%) death-censored graft failures. No significant differences existed in patient survival between the polymorphisms studied. Age (HR 1.07, p<0.001) and diabetes (HR 2.54, p<0.01) were independent predictors of mortality on multivariate analysis. Graft survival was reduced in patients with IL-10 genotype AA but other polymorphisms did not influence graft survival.



Higher serum creatinine at one year (p<0.001), deceased donor transplantation (p<0.05), younger age (p<0.01) and IL-10 genotype AA (p<0.05) were associated with reduced graft survival on univariate analysis. Creatinine at 1 year (p<0.001) and IL-10 genotype (p<0.05) were independent predictors of long-term graft failure on multivariate analysis.

Conclusions: In addition to conventional risk factors for graft loss, polymorphism of SNPs encoding IL-10 may predict long-term graft failure.

FR-OR307

Disparities in Kidney Transplant Education for Patients with End-Stage Renal Disease Lauren M. Kucirka,[1] Morgan E. Grams,[2] Dorry L. Segev.[1] *[1]Surgery, JHU; [2]Medicine, JHU.*

Background: Inequitable transplant education might contribute to disparities in access to transplant (ATT). CMS recently began asking providers on Form 2728 whether they educated patients about transplant, and if not, to select a reason. The goals of our study were to describe national transplant education practices and to analyze associations between these practices and ATT.

Methods: We studied 236,079 incident ESRD patients captured in USRDS from 2005-2007. Multinomial logistic regression was used to examine factors associated with not being educated about KT, and modified Poisson regression was used to examine associations between not being educated and ATT. All models were adjusted for demographic factors and comorbidities.

Results: Patients under nephrology care prior to ESRD and those with private insurance were more likely to be educated about transplant. However, 30.1% of patients were not educated about transplant, for reasons reported by the provider as follows: 43.1% unassessed, 32.3% medically unfit, 25.5% unsuitable due to age, 3.1% psychologically unfit, and 1.5% declined counseling. Patients at for-profit centers, older, obese, uninsured, or those who had Medicaid were more likely to be unassessed. Women were 23% more likely to be reported as unsuitable due to age, 7% more likely to be reported as medically unfit, and 25% more likely to be reported as having declined counseling. Patients not educated about transplant had a 53% lower rate of ATT (RR 0.41, 95% CI: 0.39-0.42), a disparity that persisted even in the subgroup who were simply unassessed at the time of Form 2728 reporting.

Table 1: Multivariate Multinomial Logistic Regression Accounting for Dialysis Center Clustering to Estimate the Relative Rate of Reasons for Not Informing Patients about Transplant, Including: (1) Patient Unassessed, (2) Unsuitable Due to Age, (3) Medically Unfit, (4) Declined Information, or (5) Psychologically Unfit, Compared to Being Informed about Transplant

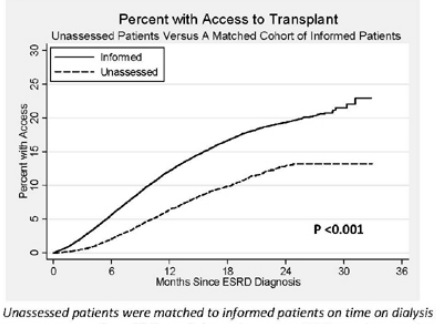
**Bold indicates statistical significance, defined as a p-value < 0.05*
Model also adjusted for other insurance, time on dialysis when 2728 form was filled out and all major comorbidities captured on 2728 form

Figure 1



Unassessed patients were matched to informed patients on time on dialysis when 2728 form was filled out, age, cause of renal failure, diabetes, insurance, COPD, cerebrovascular disease, congestive heart failure, artherosclerotic heart disease, peripheral vascular disease, and malignant neoplasm/cancer.

Conclusions: Disparities in ATT may be partially explained by disparities in the provision of transplant education; dialysis centers should ensure that this critical intervention is offered to all patients in an equitable and timely manner.

FR-OR308

Demonstrating Geographic Equity in Kidney Organ Allocation – Satisfying the Final Rule at Last Ashley E. Davis, Daniela Ladner, John J. Friedewald, Sanjay Mehrotra, Mark S. Daskin, Anton I. Skaro, Michael Abecassis. *Transplant Outcomes Research Collaborative (NUTORC), Comprehensive Transplant Center, Northwestern University, Chicago, IL.*

Background: The US Department of Health and Human Services' Final Rule dictated that organ allocation policies should not be biased towards a transplant candidate's place of residence or listing. Since this mandate, little has been done to lessen geographic disparities in kidney transplant rates. This study analyzes current cadaveric kidney allocation and compares present kidney transplant rates to those of an alternative strategy focused on optimally improving geographic equity.

Methods: Distribution of 2000-2009 kidney transplant candidates, recipients, and standard criteria donors (SCD) were obtained for each Donor Service Area (DSA) from United Network for Organ Sharing (UNOS) data. The proposed alternative kidney allocation sharing strategy allocates SCD kidney organs between DSAs but maintains current levels of local allocation. The DSA sharing levels minimizing the overall variability in transplant rates over a ten year period are determined through a mixed-integer, multi-period, linear optimization model, KSHARE.

Results: From 2000-2009, approximately 77% of procured SCD kidney organs were allocated within the UNOS Region of procurement, and in 2009, DSA SCD transplant rates ranged by 27%. With 600 mile optimized KSHARE SCD kidney organsharing, the geographic range in DSA SCD kidney transplant ratesfalls to 7.5%. Further, KSHARE allocates over 87% of procured SCD kidney organs within the UNOS Region of procurement. Extending the feasible sharing radius to a national kidney organ sharing strategy only incrementally improves the variability.

Conclusions: Enhancing the practice of sharing SCD kidney organs can increase geographic equity in DSA kidney transplant rates over time. The 600 mile sharing of SCD kidney organs employs a multi-period optimization model, KSHARE, to increase geographic equity in SCD kidney allocation while not affecting current local allocation.

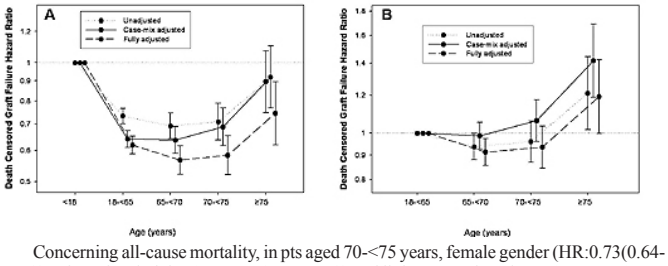
FR-OR309

Predictors of Kidney Transplantation Outcomes in the Elderly Miklos Z. Molnar,[1,2] Elani Streja,[1] Csaba P. Kovesdy,[3] Anuja P. Shah,[1] Edmund Huang,[4] Suphamai Bunnapradist,[4] Mahesh Krishnan,[5] Joel D. Kopple,[4] Kamyar Kalantar-Zadeh.[1,4] *[1]Harold Simmons Center, Torrance, CA; [2]Semmelweis University, Budapest, Hungary; [3]Salem VA Medical Center, Salem, VA; [4]David Geffen School of Medicine at UCLA, Los Angeles, CA; [5]DaVita, Inc, Denver, CO.*

Background: Recent studies show a survival advantage with kidney transplantation amongst elderly patients (pts) compared to those on dialysis.

Methods: We examine the predictors of outcome of kidney transplantation in different ages of elderly recipients. Using the Scientific Registry of Transplant Recipients, we identified 155005 kidney transplanted pts. Mortality&death censored graft failure risks were estimated by Cox proportional regression (hazard ratio(HR) and 95% of confidence interval) analysis over a median follow-up period of 4 years.

Results: Pts were 45±16(mean±SD) years old and included 40% women and 19% diabetics. Figure shows an association between age groups % death censored graft failure using different reference groups. The association between age groups&death censored graft failure was U-shaped.



Concerning all-cause mortality, in pts aged 70-<75 years, female gender (HR:0.73(0.64-0.85)), Hispanic ethnicity (HR:0.75(0.58-0.95)) and living transplant donor (HR:0.70(0.57-0.86)) were protective predictors and diabetes mellitus (HR:1.21(1.05-1.39)) and Black race (HR:1.22(1.03-1.45)) were risk factors. In pts ≥75 years old, only a living donor kidney (HR:0.64(0.44-0.93)) was an important predictor of lower all-cause mortality.

Conclusions: The strong association between living donor kidneys & all cause mortality suggest that, pts ≥70 years old should receive living donor kidney transplants. Having an expanded criteria donor kidney was not a predictor of either mortality or graft failure; consequently these kidneys may be used in elderly transplantation.

FR-OR310

Differential Survival Rates of Combined Liver Kidney Transplantation (CLKT) vs. Liver Alone Transplantation (LAT) vs. Kidney Alone Transplantation (KAT) David J. Leehey, Susan H. Hou, Holly J. Kramer. *Loyola University Medical Center, Maywood, IL.*

Background: Combined liver kidney transplantation (CLKT) is indicated in patients with combined end-stage liver disease (ESLD) and end-stage kidney disease (ESKD). Controversy exists as to allocation of donor kidneys to patients with ESLD with hepatorenal syndrome (HRS), because some of these patients will recover renal function after liver alone transplantation (LAT).

Methods: UNOS data during the period 1/1/2000 through 9/3/2010 were analyzed to determine one-year kidney allograft survival (defined as allograft failure or patient death) and one-year patient survival.

Results: Among 54,676 liver transplants performed, 8978 recipients had CKD defined as receiving dialysis or serum creatinine > 2.5 mg/dl at wait listing. 3893 recipients with CKD underwent CLKT and 12.8% had a reported diagnosis of HRS. Unadjusted one-year kidney allograft survival: CLKT (all) 82.7%; CLKT receiving dialysis 83.3%; CLKT with no dialysis 82.0%; CLKT with reported HRS 88.8%. One-year patient survival: CLKT (all) 85.4%; CLKT receiving dialysis 83.6%; CLKT with no dialysis 87.7%; CLKT with reported HRS 88.1%. One-year patient survival: LAT with CKD (with and without dialysis) 84.7%; LAT with dialysis 81.6%; LAT with CKD without dialysis 87.5%. A total of 92,771 dialysis-dependent and 7,701 non-dialysis-dependent individuals with no liver disease received a deceased donor KAT during this time period. One-year allograft survival among KAT patients who were or were not receiving dialysis was 93.2% and 95.1%, respectively, and one-year patient survival was 96.0% and 98.4%, respectively.

Conclusions: In summary, one-year patient survival among patients with ESLD receiving dialysis was approximately 2.0% higher with CLKT than with LAT, but there was only a 0.2% difference in patients not receiving dialysis. One-year kidney allograft failure and mortality are approximately 2.5-fold and 4-fold higher, respectively, in patients with ESLD undergoing CLKT as opposed to patients without liver disease undergoing KAT. These data support a reappraisal of the practice of preferential allocation of donor kidneys to patients with ESLD rather than to patients with ESKD.

FR-OR311

Sensitization Rates after 1st Graft Failure in Pediatric Renal Transplant Recipients Are Impacted by a De-Emphasis of HLA Matching in Organ Allocation and by Donor Type Alexander C. Wiseman, Jane Gralla, Suhong Tong. *University of Colorado.*

Background: Despite improvements in immunosuppression, sensitization after 1st renal graft failure remains a barrier to re-transplantation. US allocation policies currently place less emphasis on HLA matching in pediatric renal transplant (tx) candidates to minimize dialysis time, with undetermined long-term consequences.

Methods: Using the SRTR database, we examined HLA sensitization after graft loss and re-graft survival of all pediatric 1st renal tx recipients aged 0-17 yrs transplanted 1990-2008, by peak panel reactive antibody (%PRA), type of 1st graft donor (deceased, DD vs. living, LD) and HLA mismatch (MM) of 1st tx.

Results: Of 13,227 pediatric 1st renal tx recipients, 1,943 received a re-tx (60% of DD and 74% of LD) following 1st graft failure and 948 recipients were relisted but did not receive a re-tx (re-tx WL) by June 2009. Mean PRA increased from 7% prior to 1st tx to 53% after 1st graft failure, with a greater increase in the re-tx WL group for DD and LD (Table 1). The risk of sensitization significantly increased with number of 1st tx HLA MM (DD: p=0.001, LD: p=0.027). Re-graft survival at 5 years was significantly worse with more MM at 1st tx, even for re-tx in 2000-2008 (DD p=0.046, LD p=0.012).

	1st tx DD (N=1388)		1st tx LD (N=1503)	
RR for becoming sensitized, 4-6 MM vs. 0-3 MM at 1st tx	1.16 (95% CI 1.06-1.27), p=0.001		1.12 (95% CI 1.01-1.23), p=0.027	
% Re-tx of those relisted	60% Re-tx (N=838) (24% within 1yr)	40% No re-tx (N=550)	74% Re-tx (N=1105) (32% within 1yr)	26% No re-tx (N=398)
Mean waiting time	22 mo	58 mo	17 mo	56 mo
Mean %PRA increase from 1st tx	8% to 49%	10% to 77%	5% to 41%	5% to 71%

Conclusions: HLA sensitization in pediatric recipients increases with increasing number of MM and is associated with a decreased likelihood of re-tx, for deceased and living donors. Re-graft survival is lower after more HLA MM at 1st tx. The risks of sensitization vs. the benefits of earlier transplantation with a de-emphasis of HLA matching require further study, but these preliminary data suggest that pediatric transplant programs may benefit from evaluating local waiting times and donor type when considering HLA mismatched kidneys for transplant.

FR-OR312

Autoantibodies Specific for the Phospholipase A2 Receptor in Recurrent and De Novo Membranous Nephropathy: Are They Predictive of Recurrence? Hanna Debiec,[1] Laurent Martin,[2] Chantal Jouanneau,[1] Laurent Mesnard,[1] Eric Rondeau,[1] Christiane I. Mousson,[3] Pierre M. Ronco.[1] *[1]INSERM/UPMC UMR_S702, Tenon Hospital, Paris, France; [2]Plateau Technique de Biologie, Dijon, France; [3]University Hospital, Dijon, France.*

Background: Recent findings in idiopathic membranous nephropathy (MN) suggest that in most patients, the disease is due to anti-PLA2R1 autoantibodies. Our aim was to analyze the prevalence of anti-PLA2R1 antibodies in recurrent and *de novo* MN, and to determine whether these antibodies may identify a potential risk of recurrence of disease in the transplant.

Methods: Fifteen patients with recurrent MN, 15 patients with *de novo* MN and 6 patients with an idiopathic MN that did not histologically recur on the graft were included in the study. Diagnosis of recurrent and *de novo* MN was established histologically. Circulating PLA2R1 autoantibodies were assessed by a direct immunofluorescence assay based on human embryonic kidney cells transfected with PLA2R1 cDNA; The presence of PLA2R1 antigen and C4d in immune deposits was detected by confocal microscopy in paraffin-embedded native and graft biopsies with specific anti-rabbit PLA_2R1 or C4d antibody

Results: We showed that PLA2R1 was involved in 6 of 15 patients with recurrent MN, but in none of the 15 patients with *de novo* MN. C4d was detected along glomerular capillary walls in both recurrent and *de novo* MN as a consequence of complement activation by subepithelial immune complexes irrespective of deposited antigen. We also showed a marked heterogeneity in the kinetics and titers of anti-PLA2R1 antibodies which may relate to their different pathogenic potential. We found that 3 patients with PLA2R1-related idiopathic MN and anti-PLA2R1 antibodies at the time of transplantation did not develop histological recurrence.

Conclusions: Our findings indicate that PLA2R1 antibody is specific for recurrent vs de novo MN although 9/15 recurrent diseases were most likely not PLA2R1 related. Furthermore PLA2R1 autoantibody at transplantation was not always associated with recurrence; thus its predictive value should be carefully analyzed in prospective studies.

Differential Effects on Foxp3+ Tregs of Targeting Histone/Protein Deacetylases 6, 9 and Sirtuin-1 Ulf H. Beier,[1,2] Liqing Wang,[1] Tatiana Akimova,[1] Wayne W. Hancock.[1,2] *[1]Children's Hospital of Philadelphia, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA.*

Background: Histone/protein deacetylase (HDAC) targeting augments suppressive functions of human and murine Foxp3+ Tregs, but it is unclear if this involves a single mechanism, such that combined targeting would have little benefit compared to optimal targeting of one or other HDAC.

Methods: We compared the suppressive functions of Tregs of wild-type (WT) C57BL/6 mice or mice with global (HDAC6-/-, HDAC9-/-, dual HDAC6/9-/-) or conditional deletion (CD4-Cre or Foxp3-Cre and floxed Sirt1) alone, or after treatment with pan- or isoform-selective HDAC inhibitors (HDACi).

Results: Tregs deficient in expression of Sirt1, HDAC6 or HDAC9 had increased suppressive function compared to WT Tregs, but treatment with a pan-HDACi (Trichostatin) in each case further increased their suppressive function, indicating the benefit of combined vs. single HDAC targeting. This was reinforced by increased suppressive function of Tregs from HDAC6/9-/- mice vs. HDAC6-/- or HDAC9-/- Tregs. HDAC targeting increased Foxp3 gene expression 2-5 fold over control Tregs and involved different transcription factors. Sirt1 deletion stabilized p65 acetylation and promoted its nuclear translocation. Loss of HDAC6 or HDAC9 increased SMAD3 or STAT5 phosphorylation, respectively, consistent with data that HDAC6 promotes proteasomal degradation of SMAD3 and the STAT5-P dimer is stabilized by acetylation. Deletion of each HDAC increased Foxp3 acetylation, which protects Foxp3 from ubiquitination and proteasomal degradation. Tregs with HDAC6 or HDAC9 deletion had increased transcription of heat shock response (HSR) genes. HSP70 deletion reduced, but did not abolish, the therapeutic effects of HDAC6 inhibition, whereas Sirt1 deletion decreased HSR gene expression but increased Treg resistance to stress and HSP70 protein levels, in conjunction with increased acetylation of HSP70.

Conclusions: Targeting different HDAC can increase Treg function by multiple and additive mechanisms, indicating the therapeutic potential for combinations of HDACi in the therapy of autoimmunity and transplantation.

Strategies To Promote Tolerance through Augmented Treg Homeostasis

Ying Wang, David M. Rothstein. *University of Pittsburgh, PA.*

Background: CD4+Foxp3+ Treg play a key role in transplant tolerance. Treg undergo higher homeostatic proliferation (HP) than Tconv cells. α-CD45RB induces tolerance through a 2X increase in Treg, induced by converting Foxp3- to Foxp3+ cells and by a specific increase in Treg HP. Thus, Treg HP can be specifically regulated to expand Treg in vivo. We asked whether IL2, which also supports Treg HP, synergizes with α-CD45RB. CFSE-stained congenic CD4 cells were transferred into naive wt mice, which were untreated, or received IL2 (1.5ugX9d), α-CD45RB (100ug d-1,0,5), or both. Transferred Foxp3+ and Foxp3- CD4 cells (spleen and LN) were assessed (d10). Both IL2 and α-CD45RB increase Treg HP resulting in a 1.5-3X increase in Treg. Combined, these agents exhibit dramatic synergy. >90% of Treg undergo HP such that 40% of transferred CD4 cells are now Foxp3+ (increase: 8X in % and 5X in #). While α-CD45RB induces >100d graft survival (GS) in 50% of B6 recipients of BALB/c islets, IL2 did not (MST 15d). Despite a marked increase in Treg, IL2+α-CD45RB shortened GS (MST 60d). The failure of regimens with IL2 to prolong GS may be due to a 2X expansion of CD8 effectors and NK cells vs. untreated controls. In this regard, Boyman reported that α-IL2 mAb (JES6-1) allows IL2 to bind the αβγ IL2R on Treg, but not the βγ IL2R on CTLs. They also found JES6-1+IL2 induced long-term islet GS. However, using the same treatments /strains, we found all mice rejected by d18. Moreover, JES6-1+IL2 did not inhibit CD8 effectors, allowing a 2X increase in INF-γ+ CD8 cells, and an ~2X increase in NK, PMNs, DCs and B cells. However, when α-CD45RB was added to IL2+JES6-1, it markedly improved long-term GS (80% >100d) vs. all other regimens. Together, JES6-1+IL2+α-CD45 promoted dramatic Treg expansion, but completely blocked expansion of non-Treg cell types (above) and reduced (70%) IFN-γ+ CD8 cells vs. JES6-1+IL2. Thus: a) Dramatic expansion of Treg is not sufficient to promote tolerance if certain effector, and innate populations also expand. b) α-CD45RB specifically augments the Treg promoting effects of JES6-1+IL2, while inhibiting the expansion of other cell types, resulting in robust and reproducible tolerance.

FR-OR315

CD4 Memory T Cells Persist in the Absence of T Cell Receptor Signals

Jonathan S. Maltzman, Elizabeth Staub, Karla Wiehagen, Evann Corbo. *Department of Medicine and Institute for Immunology, University of Pennsylvania.*

Background: Memory T cells are generated in response to transplant, pathogen exposure, and lymphopenia and are a barrier to tolerance induction. The importance of T cell receptor (TCR)- versus cytokine receptor- generated signals in the differentiation and persistence of CD4+ memory T cell populations has not been well defined. SLP-76 is an adaptor protein critical in mediating proximal TCR signals. We previously showed that continuous expression of SLP-76 is required for activation of naive T cells and for persistence of CD4 memory T cells generated by in vitro stimulation followed by adoptive transfer. The role of TCR signals in pathogen-generated CD4+ memory T cells remains unclear.

Methods: We developed a system combining in vivo temporally-mediated conditional deletion of SLP-76 with viral infection. Lymphocytic choriomeningitis virus (LCMV) Armstrong is used as a model pathogen for acute infection. Following viral clearance and T cell differentiation into memory, SLP-76 is deleted in vivo using a tamoxifen regulated Cre recombinase. Memory cells are identified by I-Ab:GP61 MHC:peptide tetramer staining. Absolute counts of CD4+ memory T cells in the spleen and bone marrow were determined at multiple time points. Homeostatic cell turnover was determined using in vivo BRDU administration. Cytokine production was determined using single cell FACS based assays.

Results: SLP-76 is required for effector function of CD4+ memory T cells. SLP-76 deficient memory T cells fail to produce effector cytokines in response to TCR crosslinking in vitro. Secondary immune responses to LCMV-GP61 are similarly impaired. In contrast to the requirements for effector function and in vitro generated CD4 memory, LCMV-GP61 specific CD4+ T cells persist at wild-type levels until 200 days post deletion regardless of SLP-76 expression.

Conclusions: CD4+ memory T cells have differential requirements for TCR-generated signals depending on the method of their generation. Potential therapeutic approaches that target memory T cell populations in the setting of transplantation and autoimmune disease must account for the diversity of cells in this population.

Recognition of Allogeneic Non-Self by Monocytes Leads to Their Differentiation into Mature Dendritic Cells in a Mouse Heart Transplantation Model

Martin H. Oberbarnscheidt, Fadi G. Lakkis. *Department of Surgery, Thomas E. Starzl Transplantation Institute, Pittsburgh, PA.*

Background: How the innate immune system recognizes an allograft is not known. Here we tested the hypothesis that, akin to sensing microbial non-self, the innate immune system distinguishes between self and allogeneic non-self, leading to APC maturation and activation of the adaptive alloimmune response.

Methods: T, B and NK cell-deficient B6 Rag-/-γc-/-CX3CR1-GFP+/- reporter mice in which monocyte-lineage cells express GFP received either syngeneic (B6) or allogeneic (Balb/c) vascularized heart grafts. Graft-infiltrating cells were analyzed on days 1, 3, 5, 10, 21 and 42 after Tx and the function of monocyte-derived dendritic cells (mono-DC) was tested in vivo and ex vivo.

Results: We found that the vast majority (> 90%) of DC present in allografts within 1 day after Tx was derived from host monocytes. Mono-DC (lineage-Ly-6G-CD45+GFP+CD11b+CD11c+F4/80lo) were present in significantly greater numbers in allogeneic than syngeneic grafts, had a mature phenotype (MHCII+CD80+), expressed IL-12p40, and stimulated allogeneic T cells in an ex vivo MLR both early (days 1–10) and late (days 21–42) after transplantation. In contrast, maturation of monocytes to mono-DC was self-limited in syngeneic grafts (disappearing between days 10 and 21) and no IL-12p40 expression was detected. Recipient monocyte depletion with clodronate abrogated the proliferation of adoptively transferred 1H3.1 CD4+ T cells that recognize BALB/c allopeptide in the context of H-2b (indirect alloreactivity). Except for higher numbers in allografts on day 1, there were no differences in the number of infiltrating total GFP+ cells, monocytes, macrophages, or GFP+ conventional DC between syngeneic and allogeneic grafts. Neutrophils transiently infiltrated allografts and syngeneic grafts in equal numbers.

Conclusions: Our data indicate that monocytes distinguish between self and allogeneic non-self. Non-self recognition causes their differentiation to mature DC long after inflammation (I/R injury) has subsided. The persistence of activated mono-DC in transplanted organs could perpetuate the immune response, eventually leading to allograft failure.

First MicroRNA Transcriptome of Human Renal Allograft Interstitial Fibrosis and Tubular Atrophy

Thangamani Muthukumar,[1] Iddo Zeev Ben-Dov,[2] Fabien Campagne,[1] Ruchuang Ding,[1] Thomas Tuschl,[2] Manikkam Suthanthiran.[1] *[1]Cornell University; [2]Rockefeller University.*

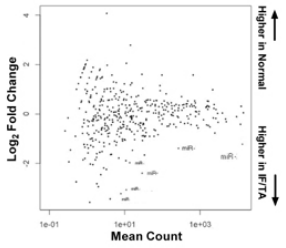
Background: Massively parallel sequencing (Next Generation Sequencing) has revolutionized sequencing. We developed & applied barcoded RNA sequencing to characterize the microRNA (miRNA) transcriptome of human kidney allograft biopsies with interstitial fibrosis/tubular atrophy (IFTA).

Methods: RNA from human renal allograft biopsies (3 IF/TA & 4 Normal, Discovery) were sequenced. Unique ('barcode') 3'-adapters were ligated to each sample & 32 cycle deep sequencing performed on pooled RNA. Using in-house computer pipeline, we extracted barcodes, aligned to genome & assigned read annotations. We determined miRNA abundance by the sum of all reads with up to 1 genome/2 annotation mismatches. We tested for differential expression by DESeq. We used EIMMo target prediction server to identify targets of differentially expressed miRNAs.

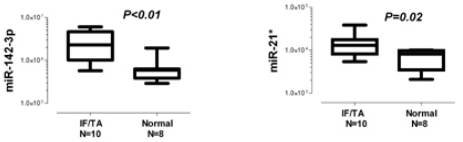
We used RT-PCR to validate selected miRNAs in an independent cohort of 18 kidney recipients; 10 IFTA & 8 Normal (Validation).

Results: The pooled library yielded 1.7 million sequences with overall 8x coverage. Major classes of small RNA annotations were miRNA (64%), synthetic calibrator (26%) and rRNA (4%). Predicted targets for top 3 differentially expressed miRNAs were overrepresented by genes involved in DNA-dependent transcription regulation, transmembrane receptor protein-kinase signaling pathway, protein import into nucleus, & RNA pol II transcription. 6 miRNAs were different between IF/TA & Normal (Top Panel).

Validation of the 2 differentially expressed miRNAs is shown (Bottom Panel).



Scatter plot of log_2 ratio (fold change) versus mean expression. Red data points mark miRNA detected as differentailly expressed at 5% false discovery rate (Benjamini-Hochberg multiple testing adjustment)



Box plots of miR-142-3p (left) & miR-21* (right). miRNA copies (ug total RNA) were normalized to U6 snRNA copies (fg total RNA). miRNA & siRNA were measured by RT-PCR & quantified by standard curve method

Conclusions: To the best of our knowledge, this is the first characterization of the miRNA transcriptome of human renal allograft IFTA using bar coded massively parallel sequencing. Our approach, discovery using deep sequencing and validation with PCR, has identified miRNAs associated with IFTA.

FR-OR318

Extracorporeal Photopheresis (ECP) as an Anti-Rejection Prophylaxis in Kidney Transplant Recipients: Preliminary Results Marian Klinger,[1] Mariusz Kusztal,[1] Katarzyna Koscielska-Kasprzak,[1] Wieslawa Gdowska,[1] Marcelina Zabinska,[1] Marta Myszka,[1] Renata Klak,[1] Magdalena Krajewska,[1] Maria Boratynska,[1] Przemyslaw Szyber,[2] Pawel Chudoba,[2] Dariusz Patrzalek.[2] *[1]Nephrology and Transplantation Medicine, Wroclaw Medical University, Wroclaw, Poland; [2]Vascular, General and Transplantation Surgery, Wroclaw Medical University, Wroclaw, Poland.*

Background: ECP is considered a promising immunomodulatory therapy of acute allograft rejection in organ transplantation and GVHD. We report on early (6 months) results of cadaver donor KTx in 20 paired recipients, all of them on standard immunosuppression (MPA+CNI+prednisone), and 10 of them additionally treated with 12-16 ECP procedures in the first 3 months following KTx.

Methods: There was no significant differences between controls and ECP group in terms of age (47±11 vs 43,4±13y), gender (3vs4 F), cause of kidney disease, cold ischemia time, diabetes, CsA/TAC and MPA doses, BMI, mean HLA mismatch and sensitization. ECP procedures were conducted using UVAR XTS (Therakos, Exton, PA), an automated system for leukocyte separation and photoactivation (with Methoxsalen). All recipients were followed by means of eGFR and peripheral T,B,NK, Treg and dendritic cells (DCs) counts and phenotype.

Results: Acute rejection appeared in one recipient from the control group. In ECP group a positive tendency to higher GFR at month 3 (53±11 vs 47,1±9;p=0.17) and 6 (67,5±10 vs 53,6±3;p=0.03 in Wilcoxon test) was observed. An increase in percent of Treg (CD3+CD4+CD25+) in total CD3 cell count (4,9±1 to 9,4±15%) as well as inducible Treg(CD3+CD8+CD28-) among CD3 cells (3,3±3 to 11,8±8%, p=0.025) was observed within 3 months of ECP treatment. A significant difference in percent of Treg in total CD3 cell count was found at month 3 (completed ECP) between ECP group and controls (9,4±15 vs 3±1%;p=0.01). No change was noticed in DCs count. In ECP group more myeloid DCs (BDCA1,3) were immature then in controls after 6 month (89% vs 69% and 88% vs 73%,p=0.08; BDCA1 and 3 respectively).

Conclusions: An addition of ECP to standard immunosuppression was associated with the significant higher GFR at 6 month and with the significant increase of natural Treg among CD3 cells.

FR-OR319

A New Recombinant MnSoD Restores the Kidney Functions during Chronic Treatment with Cyclosporine A Sara Damiano,[170120] Roberto Ciarcia,[170153] Roberto Scanni,[170120] Leonida Manco,[170153] Salvatore Florio,[170153] Aldo Mancini,[170160] Giovambattista Capasso.[170120] *[1]Chair of Nephrology, Second University of Naples, Naples, Italy; [2]Department of Structures, Functions and Biological Technologies, School of Veterinary, University of Naples Federico II, Naples, Italy.*

Background: Cyclosporine A (CsA) is used for preventing graft rejections and autoimmune disease. Unfortunately, its use is hampered by its nephrotoxic effects and there is evidence suggesting that these effects are associated with free radical involvement. In this work we have tested if a new recombinant superoxide dismutases (rMnSOD) was able to prevent the renal damage induced by CsA.

Methods: Rats were injected i.p. for 7 days as follows: group1: control solution; group 2: CsA (25 mg/Kg/day); group 3: rMnSOD (10 ug/Kg/day); group 4: rMnSOD (10 ug/Kg/day) and CsA (25 mg/Kg/day) administered simultaneously. At the end of the treatment we measured: GFR by inuline clearance, ROS levels by 2'7' dichloroflurescin diacetate assay and morphology.

Results: GFR was significantly decreased in CsA rats as compared to the controls (0,37±0,1ml/min and 0,92±0,05ml/min respectively) while it was completely restored by rMnSOD administration (0,77±0,08 ml/min). ROS levels were larger in CsA rats than the control (3970±300 and 1459±500 IF/gr of tissue/ug of proteins respectively). In group 4 ROS were similar to control (1322±600). On renal histology, CsA treatment showed cellular vacuolization, tubular swelling, dilatation and necrosis. rMnSOD completely restored the renal damage (fig1).

Conclusions: We have showed that rMnSOD administration restored GFR, ROS levels and renal damage of CsA treated rats. This robust effect of rMnSOD is, most probably, related to the presence of leader peptide allowing rMnSOD to enter the cells and thus preventing its degradation by circulating proteases.

Abstract Withdrawn

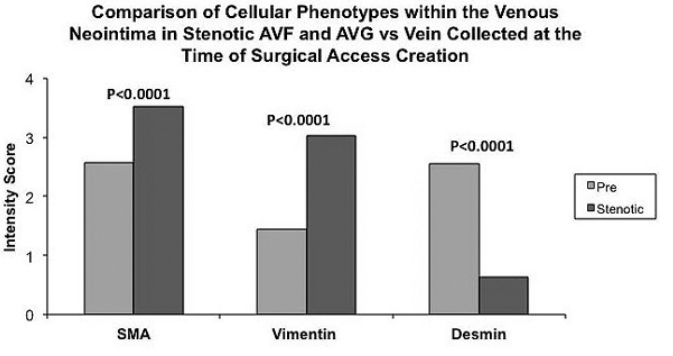
FR-OR321

Comparative Analysis of Cellular Phenotypes between Pre-Existing Venous Neointimal Hyperplasia Prior to Access Surgery and Venous Neointimal Hyperplasia from Stenotic Arteriovenous Dialysis Accesses Timmy C. Lee,[1] Prabir Roy-Chaudhury.[1] *[1]Internal Medicine, University of Cincinnati, OH; [2]Pathology, Johns Hopkins University, Baltimore, MD.*

Background: The histology of vascular access stenosis has been well characterized as aggressive venous neointimal hyperplasia (VNH) in both AV grafts (AVG) and AV fistulas (AVF). Recently we reported that severe VNH occurs prior to vascular access placement. The objective of this study was to perform a comparison of cellular phenotypes between venous tissue samples collected at the time of vascular access creation and stenotic vein samples from patients with failed AVGs and AVFs.

Methods: 55 vein samples,collected at the time of vascular access surgery,and 43 stenotic vein segments from failed AVGs and AVFs were examined. Sections from both groups were evaluated for expression of alpha-smooth muscle actin (SMA), desmin, and vimentin. A semiquantitative scoring system from 0-4+ was used to quantify positive cells for the specific marker compared to total cells (0 indicated 0-10% positive;1+=11-25%;2+=26-50%;3+=51-75% and 4+=76-100%).

Results: Within the neointima, the median semiquantitative scores for SMA, desmin, and vimentin between vein tissue collected at the time of surgery vs. vein tissue obtained from stenotic AVFs and AVGs were 2.57 vs. 3.53, 2.55 vs. 0.63, and 1.45 vs 3.03, respectively.



Conclusions: Our results demonstrate that the predominate cellular phenotype in pre-existing VNH are SMA +ve, desmin +ve, vimentin -ve contractile smooth muscle cells, while in the venous neointima of stenotic fistulas and grafts, SMA+ve, desmin -ve, vimentin +ve myofibroblasts dominate. These phenotypic differences could indicate the need for divergent therapeutic approaches because of differing mechanistic pathways for preexisting VNH compared to the VNH responsible for AVG and AVG stenosis.

Factor V Leiden (F5) Gene Polymorphism Is Associated with Arteriovenous Graft Failure Michael Allon,[1] Li Zhang,[2] Ivan D. Maya,[1] Molly S. Bray,[3] Jose R. Fernandez.[4] *[1]Division of Nephrology, Univ of Alabama at Birmingham, Birmingham, AL; [2]Department of Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH; [3]Department of Epidemiology, Univ of Alabama at Birmingham, Birmingham, AL; [4]Department of Nutrition Sciences, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Dialysis grafts fail due to recurrent stenosis and thrombosis. Vasoactive and pro-thrombotic substances affecting intimal hyperplasia or thrombosis may modify graft outcomes. We evaluated the association between polymorphisms of several candidate genes and graft patency.

Methods: The Dialysis Access Consortium (DAC) Study randomized patients receiving a new graft to treatment with aspirin+dipyridamole vs placebo, and evaluated graft outcomes. DNA samples from 354 subjects were used to measure genetic polymorphisms of methylenetetrahydrofolate reductase (MTHFR), heme-oxygenase 1 (HO-1), Factor V Leiden (F5), transforming growth factor beta-1 (TGF-β1), Klotho, and angiotensin converting enzyme (ACE). We evaluated the association between these polymorphisms and primary graft patency (time to first angioplasty or thrombosis), after adjusting for clinical factors and estimates of genetic admixture for the control of population stratification.

Results: On multivariate analysis, primary graft patency was associated with active drug treatment (HR 0.76; 95% CI 0.60 to 0.96; p=0.02) and with graft placement after starting dialysis (HR 1.38; 95% CI 1.05 to 1.82; p=0.02), but not with patient age, sex, diabetes, cardiovascular disease, graft location, baseline aspirin use, or BMI. After adjusting for the clinical factors and genetic admixture, F5 gene polymorphisms were significantly associated with graft survival in a dominant model (HR 1.70, 95% CI 1.32 to 2.19, p<0.0001 for G/C and G/G genotypes vs C/C genotypes). There was no significant association between primary graft patency and polymorphisms of MTHFR, HO-1, TGF-β1, Klotho, or ACE.

Conclusions: Factor V Leiden (F5), the most common inherited thrombophilia, is associated with an increased risk of graft failure. Anticoagulation may reduce graft failure in patients with the G/C or G/G genotypes (47% of our study).

Wall Shear Stress (WSS) and Oscillatory Shear Index (OSI) in a Porcine Arteriovenous Graft (AVG) Model Yan-Ting E. Shiu,[1,2] Daniel B. Pike,[2] Christi M. Terry,[1] Huan Li,[1] Alfred K. Cheung.[1,3] *[1]Medicine, Univ. of Utah, SLC, UT; [2]Bioengineering, Univ. of Utah, SLC, UT; [3]Medical Service, VASLCHCS, SLC, UT.*

Background: AVG suffer from high rates of stenosis due to NH at the venous anastomosis (VA). Aberrant anastomotic hemodynamics likely play a role in the focal nature of NH formation, but this causal relationship is not well understood. Chronicling in vivo hemodynamics after AVG implantation will help illuminate its role in NH formation and develop therapies for preventing stenosis.

Methods: Four pigs received an AVG between the common carotid artery and the external jugular vein; the un-operated contralateral vessels served as a control. 3D reconstructions of the vessel and graft lumen geometry were created using Amira software from 3D black-blood MRI scans obtained weekly post-implantation. Blood flow rate was simultaneously obtained using cine phase-contrast MRI. CFD simulations of pulsatile blood flow were performed using FLUENT. CFD results were used to calculate WSS (the axial frictional force exerted by flowing blood on the luminal vessel wall) and OSI (a measure of the change in direction and magnitude of WSS, which is calculated from integrals of WSS at one location over the cardiac cycle).

Results: Compared to control vein, mean WSS, averaged over a cardiac cycle at the VA and downstream vein (DV) areas, was increased by 5.0- and 3.8-fold respectively, at day 5. At day 14, WSS at the VA remained 4.5-fold increased, while WSS at the DV almost returned to control vein levels. Similarly, mean OSI averaged at the VA and DV areas increased by 4.8- and 2.6-fold respectively, at day 5, as compared to control vein. At day 14, OSI at the VA remained 4.5-fold increased, while OSI at the DV also returned to near the control vein level.

Conclusions: We have previously shown in our porcine model of AVG stenosis that significant NH develops at the VA by week 6, but not at the DV. Here we found sustained increased WSS and OSI at the VA, the region most susceptible to NH, but not at DV, the region relatively free from NH. These results suggest a role for increased WSS and OSI at the VA in promoting venous NH.

Early Adventitial Activation and Proliferation in a Mouse Model of Arteriovenous Stenosis Begoña Campos, Yang Wang, Meenakshi J. Mistry, Benjamin K. Woodle, Virgilius Cornea, Timmy C. Lee, Prabir Roy-Chaudhury. *Dialysis Vascular Access Research Group, Division of Nephrology and Hypertension, University of Cincinnati, OH.*

Background: Early arteriovenous fistula (AVF) failure remains an important cause of hemodialysis vascular access dysfunction and a major impediment to the Fistula First initiative. Despite the magnitude of the clinical problem, there are currently no effective therapeutic interventions for early AVF failure. In order to better understand the cellular and molecular mechanisms involved in early AVF failure we have previously developed a mouse model which is characterized by significant stenosis at the AV anastomosis 14d post surgery. The aim of this study was to describe the pattern of cellular proliferation and macrophage infiltration at different time points in this model.

Methods: AVFs were created using an end to side anastomosis between the jugular vein and carotid artery in 13 mice. Animals were sacrificed at 2d (n=4), 7d (n=5) and 14d (n=4). A standard immunohistochemical analysis was performed to assess cellular proliferation (Ki-67) and macrophage infiltration (Mac-2), using a semiquantitative scoring scale (0=<10% of total cells positive; 1+=11-25%; 2+=26-50%; 3+=51-75%; 4+=>75%).

Results: Our results (Table shows Adventitial data only) demonstrate an early proliferation within the adventitia (ADV) which peaks at 7d and which is followed by a later endothelial (ENDO) proliferation which peaks at 14d (p<0.05 for ADV proliferation vs ENDO and intimal [INT] proliferation at 2d). This is accompanied by an early macrophage infiltration which peaks at 7d (p<0.05 for ADV macrophage infiltration vs INT and ENDO macrophage infiltration).

Conclusions: Our results suggest that the adventitia could be a key player in the pathogenesis of early AVF failure. In addition it is possible that early peri-adventitial therapies targeting cellular proliferation and macrophage infiltration might be effective in reducing early AVF failure.

Cellular Proliferation and Macrophage Infiltration in the Adventitia

	2 Days	7 Days	14 Days
Cellular Proliferation	1.75+/- 1.03	2.8+/-0.44	2.125+/0.64
Macrophage Infiltration	0.75 +/-0.88	1.6+/-0.69	0.875+/-0.64

Sunitinib Inhibits Venous Neointimal Hyperplasia (NH) Formation in a Perfused Organ Culture System Sun Hyung Kwon,[1] Li Li,[2] Yan-Ting E. Shiu,[2] Seung-Jung Kim,[3] Huan Li,[2] Donald Blumenthal,[1] Alfred K. Cheung.[4,2] *[1]Pharmacology & Toxicology, Univ of UT, SLC; [2]Medicine, Univ of UT, SLC; [3]Nephrology, Ewha Womans Univ; [4]Medicine, VASLHCS, SLC.*

Background: Stenosis associated with arteriovenous (AV) vascular access occurs frequently and predominantly as a result of NH formation at the venous anastomosis. Effective treatment for NH in this setting is lacking. The highly localized nature of NH at the venous anastomosis suggests that aberrant blood flow profiles may play a major role in NH development. We have established a perfused organ culture model that enables us to investigate the effects of various experimental conditions on NH development in intact explanted vessels, and to evaluate the effectiveness of anti-hyperplasia drug candidates.

Methods: In porcine vein segments exposed to non-physiologically low wall shear stress (WSS), we observed significant NH as assessed by intima-to-media (I/M) area ratio, while veins cultured under standard static culture conditions exhibited little or no NH. To evaluate the effect of sunitinib, a multi-receptor tyrosine kinase inhibitor, vein segments were exposed to non-physiological WSS (< 1 or >10 dyne/cm^2) for 12 days with or without 100 nM of sunitinib. Formalin-fixed vein sections were stained with van Gieson's stain to determine I/M area ratio and probed with antibodies for markers of proliferating cells (Ki-67), smooth muscle cells or transformed myofibroblasts (alpha-actin), and endothelial cells (von Willebrand factor).

Results: Sunitinib significantly inhibited the magnitude of NH formation, with the I/M area ratio decreasing from 0.43±0.26 to 0.15±0.04. Cells in the hyperplastic lesions were primarily positive for Ki-67 and alpha-actin, suggesting that the NH resulted from proliferation and migration of smooth muscle cells and/or myofibroblasts.

Conclusions: In summary, this perfused organ culture system allows for the dissection of the effects of various conditions, such as non-physiological WSS, on intact vein segments that could not be achieved using standard cell cultures or whole animal models. It also provides a more expeditious model than the whole animal for the study of anti-hyperplasia therapies.

FR-OR326

Without Integrin β3, Endothelial Cell Regeneration Is Delayed and Contributes to AV Fistula Failure Jizhong Cheng, Yun Wang, Anlin Liang, Jie Du, William E. Mitch. *Nephrology Division, Baylor College of Medicine, Houston, TX.*

Background: The Achilles heel of dialysis patients is a functioning arteriovenous fistula (AVF). Failure of an AVF is generally due to proliferation of vascular smooth muscle cells forming a neointima. Whether endothelial cell (EC) damage contributes to this process is unclear. In AVF created in mice, there was an initial denudation of ECs followed by endothelial regeneration. Since integrin β3 is involved in angiogenesis and is essential for normal EC function, we studied how integrin β3 influences the course of endothelial regeneration in AVFs created in WT and integrin β3 KO mice.

Methods: regeneration and differentiation of endothelial progenitor cells (EPC) in AVF were studied *in vitro* and *in vivo* in WT and integrin b3 KO mice.

Results: AVF failed in 80% of integrin β3 KO mice but in only 5% of WT mice. Cultured bone marrow-derived EPCs (Sca-1$^+$) from integrin β3 KO mice showed suppressed attachment to extracellular matrix and differentiation into mature ECs vs WT BM EPCs. These changes were reflected *in vivo:* AV fistulas created in integrin β3 KO mice had fewer Sca I$^+$ EPCs in the denuded vessel wall compared to AVFs created in WT mice. Likewise, endothelial regeneration occurred at 5 days in AVFs in WT mice but was delayed to 10 days in AVFs of integrin β3 KO mice. The defects in AVFs of β3 integrin KO mice were

rescued when the mice received a bone marrow (BM) transplant from WT mice. AVFs in integrin β3 KO mice transplanted with WT BM cells and BM cells from integrin β3 KO mice indicated that WT BM cells were the principal contributor to new endothelium in AVFs of integrin β3 KO mice. Cell proliferation in neointima in the same AVFs was reduced by 40% and was due to impaired SGK-1 phosphorylation and decreased PI3K activity as found in our report about mechanisms of smooth muscle cell proliferation.

Conclusions: Integrin β3 is required for endothelial regeneration in newly created AV fistulas. The mechanism includes an improvement in the attachment and differentiation of EPCs in the AV fistula.

Quaking as a Critical Determinant of Neoimtima Formation and Vascular Smooth Muscle Cell Homeostasis

Eric P. Van der Veer,[1,2] Ruben G. De Bruin,[1,2] ChunYu Wong,[1,3] Margreet De Vries,[2,3] Ton J. Rabelink,[1] Joris I. Rotmans,[1] J. W. Jukema,[4] Paul Quax,[2,3] Anton Jan Van Zonneveld.[1,2] *[1]Nephrology, LUMC, Leiden, Netherlands; [2]Einthoven Laboratory for Experimental Vascular Medicine, LUMC, Leiden, Netherlands; [3]Surgery, LUMC, Leiden, Netherlands; [4]Cardiology, LUMC, Leiden, Netherlands.*

Background: Patients undergoing hemodialysis require a patent, vascular access point that can withstand high-flow rates. For this, an arteriovenous fistula (AVF) is commonly surgically created in the arm. However, low patency rates due to insufficient remodeling and excessive neointima formation are frequently observed in the clinic. Here, we present the mRNA-binding protein Quaking (QKI) as a critical regulator vascular smooth muscle cell (VSMC) homeostasis through modulation of actin cytoskeletal dynamics, and neointima formation following injury to the vessel wall.

Methods: Quaking viable mouse mutants (Qk^v), which as a result of a megabase deletion in the *qki* promoter region express reduced levels of QKI, were used to study neointima formation upon non-constrictive cuff placement around the femoral artery. Furthermore, we specifically investigated the consequences of abrogated QKI expression on VSMC behaviour in both murine VSMCs derived from C57Bl6 (WT) and Qk^v mice as well as in WT human VSMCs treated with either a non-coding shRNA (shRNA-non) and shRNA targeting QKI (shRNA-qki).

Results: Non-constrictive cuff placement in Qk^v mice resulted in a significant decrease in neointima formation and luminal stenosis as compared to control mice. Furthermore, attenuated expression of QKI in VSMCs (derived from both Qk^v mice or following shRNA-mediated knockdown in human VSMCs) resulted in significantly reduced cellular proliferation, migration and elaboration of extracellular matrix. The targeted disruption of QKI impaired both the capacity to remodel the actin cytoskeleton and perturbed VSMC contractile function.

Conclusions: Collectively, we have uncovered a novel role for QKI in regulating VSMC homeostasis, and propose that intervention in QKI activity could be an effective modality in the prevention of AVF stenosis, and potentially shunt failure.

FR-OR328

Matrix-Embedded Endothelial Cells Are Protected from the Uremic Milieu

Vipul C. Chitalia,[1,2] Joseph Franses,[1] Rachel Valdez,[1] Laura Indolfi,[1] Elazer Edelman.[1,3] *[1]Harvard-MIT Division of Health Sciences and Technology, Massachusetts Institute of Technology, Cambridge, MA; [2]Renal Section/ Department of Medicine, Boston Medical Center, Boston University School of Medicine, Boston, MA; [3]Cardiovascular Division, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Endothelial cells (ECs) embedded in 3D matrices (MEECs) of denatured collagen implanted around vascular access anastomoses preserve luminal patency. MEEC implant efficacy depends on embedded EC health. As the uremic milieu inhibits proliferation and induces apoptosis of ECs, we examined whether uremia might impact MEECs.

Methods: ECs grown on 2D gelatin-coated polystyrene culture plates (gTCPS) or in MEEC were treated with sera pooled from 20 control or ESRD patients. EC viability was examined using MTT, cell counting and Trypan blue. Media conditioned (CM) with 2 and 3D-supported ECs were examined for inhibition vascular smooth muscle cell (vSMC) proliferation using 3[H] thymidine and cyclin D1. ECs grown on gTCPS were treated with uremic serum filtered through matrices to examine if matrices retain uremic toxins or whether EC effects were cell-mediated.

Results: Uremic serum significantly reduced viability and number of live, and increased dead ECs on gTCPS, but not in MEECs. EC survival correlated with vSMC inhibition. While CM from ECs grown in gTCPS with uremic serum inhibited vSMC proliferation no better than uremic serum alone (22% vs 27%), MEEC CM inhibited vSMC proliferation by 47% ($p = 0.0004$). Cyclin D1 expression tracked with vSMC proliferation. There was no significant difference in EC viability between EC treated with matrix-filtered or unfiltered uremic serum.

Conclusions: The viability, number and efficacy of MEECs were preserved in uremic serum compared to that of ECs on gTCPS. MEECs are protected from uremic toxicity, not from retention of uremic toxins by matrices, but likely from intrinsic changes in EC sensitivity to uremia. MEECs implanted at vascular access should inhibit neointimal hyperplasia in uremia. This study underscores the robustness of matrix-embedding as cell-protectant, especially in hostile environment like uremia.

Venous Segment Calcification in a Mouse Model of Arteriovenous Stenosis

Prabir Roy-Chaudhury, Nida Nida Safdar, Meenakshi J. Mistry, Yang Wang, Arjan S. Hura, Timmy C. Lee, Virgilius Cornea, Begoña Campos. *Dialysis Vascular Access Research Group, Division of Nephrology and Hypertension, University of Cincinnati, OH.*

Background: Early arteriovenous fistula (AVF) failure remains an important cause of hemodialysis vascular access dysfunction, although the exact biological mechanisms involved remain unclear. Vascular calcification is known to be an important clinical problem in the setting of uremia but the exact role of calcification at different time points following creation of an AVF is unknown. The aim of this study was to describe the extent of venous segment calcification at different time points in a mouse model of AVF stenosis.

Methods: AVFs were created between the jugular vein and the carotid artery with an end to side anastomosis in 13 mice (this model results in significant stenosis at the AV anastomosis 14 days after surgery). Animals were sacrificed at the 2d (n=4), 7d (n=5) and 14d (n=4) time points and examined for calcification within the venous segment of the AVF (including the anastomosis) with a Von Kossa stain. Sections were scored using a semiquantitative scoring scale (1=1-10% calcification; 2=11-25%; 3=26-50%; 4=>51%).

Results: Maximal venous segment calcification occurred at 2d post surgery, often in the setting of a swollen venous wall. Although the magnitude of venous segment calcification appeared to decrease over time this was not statistically significant (see figure).

Conclusions: Our results clearly document the presence of venous segment calcification in a mouse model of AVF stenosis. It is unclear at present as to whether these calcium deposits are secondary to early hemodynamic injury or whether they could play a primary role in the pathogenesis of early AVF failure.

Generation and Examination of Proximal Tubule Specific Na^+/H^+ Exchanger NHE3 Knockout Mouse

Hong C. Li,[1] Zhaopeng Du,[2] Sharon L. Barone,[1] Hassane Amlal,[1] Alicia A. McDonough,[3] Tong Wang,[2] Manoocher Soleimani.[1] *[1]Medicine, University of Cincinnati; [2]Yale University; [3]University of Southern California.*

Background: The conventional NHE3 knockout mouse has a significant intestinal phenotype manifested with electrolyte malabsorption, diarrhea, and volume depletion. As a result the mutant mouse can not tolerate oral salt or acid load, making it unsuitable for the examination of the role of kidney NHE3 *in vivo*.

Methods: To overcome this problem, mice with tissue specific deletion of NHE3 were generated. NHE3 floxed mice were crossed with either the Sglt2 (sodium-glucose transporter 2) cre mice to generate proximal convoluted tubule specific NHE3 knockout (NHE3-PT KO) or with the villin cre mice to generate combined intestine and proximal tubule NHE3 knockout mice.

Results: The intestine and kidney specific NHE3 ko mice are smaller and have loose stool and caecal dilatation, consistent with an important role for NHE3 in salt absorption in the intestine. The NHE3-PT KO mice have ~ 90% ablation of NHE3 as determined by immunofluorescence labeling and western blotting. NHE3-PT KO animals show mild metabolic acidosis (21 mEq/l in ko Vs. 23 in wt, $p<0.05$). In situ microperfusion studies in proximal tubules demonstrate a ~36% reduction in bicarbonate reabsorption (J_{HCO3} = 83 pmol/min/mm in wt Vs. 54 in ko) and a ~27% reduction in volume reabsorption (Jv = 0.92 nl/min/mm in wt Vs. 0.67 in ko) in mutant mice. The NHE3-PT KO mice tolerated NH_4Cl acid load well and showed comparable NH_4 excretion rates Vs. wild type mice at 2 days and 5 days after acid loading.

Conclusions: We conclude that NHE3 plays an important role in bicarbonate reabsorption in the proximal convoluted tubule but does not play a major role in NH_4^+ secretion, at least in the first 5 days of acid loading. Whether the Na^+/H^+ exchanger NHE3 in the S3 segment of the proximal tubule plays a more important role in NH_4^+ secretion than the convoluted segment needs the generation and examination of appropriate mutant animals. The mild metabolic acidosis, despite a significant reduction in net bicarbonate reabsorption in the proximal tubule of NHE3 KO mice, suggests the presence of compensatory mechanisms in other nephron segments.

ErbB1-ErbB2 Heterodimer Activation in Rabbit Renal Proximal Tubules Exposed to Acute Respiratory Acidosis Lara A. Skelton, Walter F. Boron. *Dept. Physiology and Biophysics, CASE Western Reserve University, Cleveland, OH.*

Background: In a previous abstract, we reported that acute exposure of rabbit proximal tubule suspensions (PTs) to respiratory acidosis (RAc) increases both ErbB1 and ErbB2 tyrosine phosphorylation. Zhou et al have shown that single perfused PTs exposed to the ErbB-family inhibitor PD168393 cannot respond to changes in basolateral [CO_2] or [HCO_3]. Here we examine if heterodimers of ErbB1 and ErbB2 are involved in the CO_2/HCO_3 signaling cascade.

Methods: We exposed purified PTs for 5 min or 20 min to: *HEPES* (i.e., HEPES/pH 7.40); *Butyrate* (HEPES/pH 7.10 + 20 mM butyrate); *EGF* (*'HEPES'* + 10 nM EGF); *Physiological CO_2/HCO_3* (5% CO_2/22 mM HCO_3/pH 7.40); *RAc* (10% CO_2/22 mM HCO_3/pH 7.10); *Compensated RAc* (10% CO_2/44mM HCO_3/pH 7.40); or *Metabolic alkalosis* (*MAlk*; 5% CO_2/44 mM HCO_3/pH 7.66). Lysates were probed with phosphotyrosine (pY)-specific antibodies to ErbB1 or ErbB2, or with antibodies to total ErbB1 and ErbB2.

Results: PTs exposed to *HEPES* or *Butyrate* exhibit a low, basal level of pY for both ErbB1 and ErbB2. Exposure to *EGF, Physiological CO_2/HCO_3,* or *RAc* induces ErbB1-pY845, pY1173, and pY1068, as well as ErbB2-pY1221/pY1222 as early as 5 min, a response that is sustained at 20 min. PD168393 inhibited ErbB1 and ErbB2 activation (i.e., tyrosine phosphorylation at the above residues) under all conditions. To detect heterodimers, ErbB1 IPs were probed for ErbB2-pY1221/1222 and ErbB2 IPs were probed for ErbB1-pY1173. Activation of ErbB1-ErbB2 heterodimers occurred after 20-min treatment with *EGF, Physiological CO_2/HCO_3,* or *RAc*. In contrast, a 20-min exposure to *MAlk* versus *Physiological CO_2/HCO_3*, on average, resulted in reduced activation of ErbB1/ErbB2 heterodimers. Exposure to *RAc* appears to induce slightly greater heterodimer activation than exposure to *Compensated RAc*.

Conclusions: The results indicate that exposure of PTs to CO_2/HCO_3, especially during respiratory acidosis, induces rapid ErbB1-ErbB2 activation and heterodimerization.

Vacuolar H^+-ATPase Regulation by AMPK in the Kidney Proximal Tubule Mohammad M. Al-Bataineh,[1] Nuria M. Pastor-Soler.[1,2] *[1]Renal-Electrolyte Division, Department of Medicine, U. of Pittsburgh; [2]Department of Cell Biology and Physiology, U. of Pittsburgh, PA.*

Background: The Vacuolar H^+-ATPase (V-ATPase) is present at the apical membrane of proton secreting cells, such as kidney proximal tubule cells. We previously showed that the V-ATPase at the apical membrane of distal nephron intercalated cells is regulated by the metabolic sensor AMP-activated protein kinase (AMPK). In proximal tubule, the V-ATPase participates in luminal bicarbonate recovery. Defects in V-ATPase and in proximal tubule function can cause renal tubular acidosis with systemic metabolic acidosis. Studying the V-ATPase regulation in the proximal tubule is important as it may differ from regulation in other nephron segments. Here, we examined the role of AMPK, which can become active in settings of ischemia and metabolic stress, in the regulation of V-ATPase subcellular localization and activity in the proximal tubule.

Methods: We examined the effects of an AMPK activator in the S3 segment of rat kidney tissue slices ex vivo and in an immortalized S3 proximal tubule cell line (S3 cells) on subcellular V-ATPase immunolocalization by confocal microscopy and by functional acidification assays.

Results: The V-ATPase had an apical distribution in S3 proximal tubules of kidney slices incubated for 75 min in Ringer buffer alone and in S3 cell polarized monolayers, while the AMPK activator AICAR induced a decrease in V-ATPase apical accumulation in both systems. Moreover, AICAR treatment activated AMPK in S3 cells and decreased the rate of V-ATPase-dependent (bafilomycin-sensitive) extracellular acidification relative to untreated cells.

Conclusions: Taken together, our results suggest that in proximal tubule S3 cells the V-ATPase is inhibited by activation of the metabolic sensor AMPK. This pathway that may be very relevant in the conservation of cellular energy during kidney ischemia.

SA-OR333

The Role of Ile-Pro-Met Tri-Peptide in the C-Terminus of Kidney NBC1 (NBCe1/SLC4A4) in Its Targeting to the Plasma Membrane Hong C. Li,[1, 2] Kamyar A. Zahedi,[1, 2] Manoocher Soleimani.[1, 2] *[1]Medicine, University of Cincinnati, OH; [2]Research Services, Veterans Administration Hospital, Cincinnati, OH.*

Background: The human kidney NBC1 mutant (NBC1Δ65) codes for a C-terminal truncated protein (total length 982 aa Vs. 1035 for wt) that is retained in the cytoplasm. Individuals homozygous for this mutation have proximal renal tubular acidosis (pRTA) and familial migraine (PNAS 2010).

Methods: Here we describe a novel motif in the C-terminus of NBC1 corresponding to the deleted region in NBC1Δ65 that contributes to its accurate targeting to the plasma membrane. Toward this goal, a number of GFP tagged kNBC1 C-terminal subdomain deletion expression constructs were developed and used to transiently transfect polarized MDCK cells. Functional studies were performed in Oocytes.

Results: Confocal microscopy indicates that kNBC1 Δ991-1005 was retained in the cytoplasm, while the wild type, Δ961-975, Δ976-990 and Δ1006-1009 kNBC1 proteins were appropriately targeted to the basolateral membrane. Functional studies in Oocytes indicated that while the electrogenic potential of kNBC1 Δ961-975, Δ976-990 and Δ1006-1009 mutants were not significantly different than that of wild type kNBC1, the kNBC1 Δ991-1005 mutant exhibited a significantly reduced electrogenic potential (*p<0.01). In order to more precisely identify the amino acid residues involved in the targeting of kNBC1, we generated a series of kNBC1 C-terminal subdomain triple-peptide deletions spanning the amino acid residues 991 to 1005. These mutant proteins were then expressed and their localization was examined. Our results indicate that kNBC1 Δ1003-1005 mutant was retained in the cytoplasm while the wild type, Δ991-993, Δ994-996, Δ997-999 and Δ1000-1002 GFP-kNBC1proteins were correctly targeted to the basolateral membrane. Functional studies revealed that only the kNBC1 D1003-1005 mutant was significantly less electrogenic than kNBC1 wild type (Δ1003-1005: -13±5.7mV vs kNBC1 wild type: -54.8±7.4 *p<0.01).

Conclusions: Our data indicate that the tri-peptide Ile 1003-Pro 1004-Met 1005 in the C-terminus of NBC1 is involved in its accurate targeting. These results provide novel insight into the mechanism through which kNBC1 Δ65bp mutation leads to pRTA.

SA-OR334

Lipopolysaccharide (LPS) Inhibits NHE3 and HCO_3^- Absorption in Medullary Thick Ascending Limb (MTAL) through a TLR4-ERK Pathway Upregulated by Sepsis Bruns A. Watts, Thampi George, Edward R. Sherwood, David W. Good. *Medicine and Anesthesiology, Univ TX Med Branch, Galveston, TX.*

Background: Recently we demonstrated that bacterial molecules can act directly through Toll-like receptors (TLR) to impair the transport function of renal tubules. In particular, basolateral LPS inhibits HCO_3^- absorption in perfused rat and mouse MTALs through TLR4-mediated activation of ERK. Here we examined the transport mechanism responsible for this inhibition and whether the LPS-induced pathway is influenced by sepsis.

Results: Activation of ERK can inhibit HCO_3^- absorption in the MTAL through primary inhibition of either basolateral NHE1 or apical NHE3. The inhibition of HCO_3^- absorption by bath LPS was unaffected by maneuvers that inhibit basolateral Na^+/H^+ exchange, indicating that NHE1 is not involved in mediating the inhibition by LPS. Bath LPS decreased apical NHE3 activity due to a decrease in V_{max}. The inhibition of NHE3 by LPS was eliminated by MEK/ERK inhibitors. The effects of sepsis were examined 18 h after surgery using a mouse cecal ligation and puncture (CLP) model. Bath LPS decreased HCO_3^- absorption by 45% in MTALs from CLP mice compared with a decrease of only 26% in tubules from sham-operated controls (P<0.05). MEK/ERK inhibitors eliminated the inhibition of HCO_3^- absorption by LPS in both groups. Exposure to LPS for 15 min increased ERK phosphorylation in sham and CLP MTALs but the level of phosphorylated ERK was higher in MTALs from CLP mice. The increased ability of LPS to inhibit HCO_3^- absorption through ERK in CLP MTALs was associated with increased expression of TLR4 in the basolateral membrane domain.

Conclusions: We conclude: 1) basolateral LPS inhibits HCO_3^- absorption in the MTAL through TLR4-ERK-dependent inhibition of NHE3; 2) this pathway is upregulated during sepsis. These results identify NHE3 as a target of TLR4 signaling in the MTAL and suggest that bacterial molecules can impair absorptive functions of renal tubules important for acid-base and volume homeostasis through inhibition of this exchanger. The ERK pathway links TLR4 to downstream modulation of ion transport proteins and represents a potential target for treatment of sepsis-induced renal tubule dysfunction.

Double-Knockout of Pendrin and NaCl Cotransporter Causes Salt Wasting, Profound Dehydration and Nephrogenic Diabetes Insipidus Manoocher Soleimani,[1, 2] Hassane Amlal,[2] Sharon L. Barone,[1, 2] Jie Xu,[1, 2] Faraaz Siddiqui.[2] *[1]Research Services, Veterans Administration Hospital, Cincinnati, OH; [2]Medicine, University of Cincinnati, OH.*

Background: The Cl^-/HCO_3^- exchanger pendrin (SLC26A4) and the thiazide-sensitive NaCl cotransporter NCC are expressed in the distal nephron and mediate salt absorption. Single deletion of pendrin or NCC does not cause salt wasting or excessive diuresis under basal conditions, suggesting they might be predominantly active during salt depletion.

Methods: Alternatively, we hypothesized that each transporter may compensate for loss of the other under basal conditions, thereby masking the role that each plays in salt absorption.To test our hypothesis, we generated pendrin/NCC double knockout (dKO) mice.

Results: NCC/pendrin double KOs displayed profound polyuria (24 hr urine volume in ml: double KO, 5.3; pendrin KO, 1.5; NCC KO, 1.0; WT, 1.5; p<0.0001 vs single KO and WT) and polydipsia (24 hr water intake in ml: double KO, 8.0; pendrin KO, 4.0; NCC KO, 4.4; WT, 3.5; p<0.001 vs single KO and WT). Urine osmolarity was 790 mosm/kg H2O in double KO vs. 2500 or higher in other genotypes (p<0.001 Vs. single KO and WT). Urine chloride excretion was significantly increased in dKO mice (440 mmole/day Vs. 270 or less in other genotypes). Kidney H&E staining revealed no histological abnormalities, but BUN increased by ~300% in double KOs (p<0.05 Vs. other genotypes), consistent with dehydration. NKCC2 abundance in the thick limb increased by 50% whereas AQP2 abundance in medullary collecting duct decreased by ~70% in double KO mice. Contrary to the normal concordant regulation of AQP2 and NKCC2 in pathophysiologic states, this condition presents with discordant regulation of NKCC2 and AQP2.

Conclusions: In conclusion, combined deletion of pendrin and NCC causes polyuria, salt wasting, dehydration, and nephrogenic diabetes insipidus. These results indicate a major role for both NCC and pendrin in salt and water reabsorption and show that each transporter can provide compensation for loss of the other under basal conditions. We suggest that the role of pendrin and NCC in salt and water reabsorption at basal state in the distal nephron needs complete reevaluation.

SA-OR336

The A-kinase Anchoring Protein AKAP-KL (AKAP2) Is Localized in the Subapical Domain of All Collecting Duct Intercalated Cells and Is Regulated by Disturbance of Acid/Base Balance Annika Andersen,[1] Enno Klussmann,[2] Sebastian Frische.[1] *[1]Biomedical Institute, Aarhus University, Aarhus, Denmark; [2]Max-Delbrück-Centrum für Molekulare Medizin Berlin-Buch (MDC), Berlin, Germany.*

Background: Compartmentalized cAMP/protein kinase A (PKA) signalling mediated by A-kinase anchoring proteins (AKAPs) is an emerging paradigm. AKAP-KL (AKAP2) tethers PKA in lung and renal epithelial cells. However, the detailed localization and function of this AKAP in the kidney is unknown. This study:

a) describes the cellular and subcellular localization of AKAP-KL in the kidney

b) tests if the amount of AKAP-KL in collecting duct (CD) intercalated cells (ICs) correlates with IC subtype activity during acid/base disturbance.

Methods: Paraformaldehyde-fixed parraffin-embedded kidney tissue from untreated, NH_4Cl loaded and $NaHCO_3$ loaded rats were analyzed by immunohistochemistry using a mouse monoclonal antibody against AKAP-KL, fluorescence-coupled secondary antibodies and laser confocal microscopy. Co-labelling for the anion-exchangers pendrin and AE1 allowed identification of IC sub-types. For quantification of fluorescence, ICs were encircled manually and the fluorescences pertaining to AKAP-KL, pendrin and the nuclei were quantified using ImageJ. In total 2445 ICs were analyzed and >60 ICs were analyzed per animal.

Results: AKAP-KL was found in the brushborder of proximal tubule cells and in the subapical domain (predominantly) and cytoplasm (low amounts) of both type A and B CD ICs. In untreated rats (n=5), the fluorescence representing AKAP-KL was not significantly different in the two main classes of ICs (mean signal/cell ± SE: A: 52483±8353, B: 52155±5324 p=0.908). In NH_4Cl loaded rats (n=6), type A cells showed higher abundance of AKAP-KL than type B cells (A: 65003±4653, B: 45995±2674 p=0.002). In $NaHCO_3$ loaded rats (n=3) type B cells showed higher abundance of AKAP-KL than type A cells (A: 46352±3511, B: 58024±5314 p=0.036).

Conclusions: Type A and B-type ICs show inverse transport functions and acid/base transporter expression patterns. However, our studies indicate that in both cell-types, activation induced by disturbed acid/base balance involves compartmentalized signalling involving AKAP-KL.

Acidosis Induces Secretion of SDF-1 by Principal Cells Which Acts on β-Intercalated Cells (β-ICs) To Decrease HCO_3 and Increase H Secretion George J. Schwartz,[1] Jeffrey M. Purkerson,[1] Shuichi Tsuruoka,[2] Qais Al-Awqati.[3] *[1]Pediatrics, University of Rochester Medical Center, NY; [2]Nephrology, University of Tsukuba, Ibaraki, Japan; [3]Medicine, Columbia University College of Physicians & Surgeons, New York, NY.*

Background: Detection of elevated SDF-1 mRNA levels in kidney samples from acidotic mice by microarray and confirmed by RT-qPCR prompted us to study the role of the SDF-1/CXCR4 pathway in adaptation of the rabbit CCD to acidosis.

Methods: We performed immunofluorescence of sections and microdissected CCDs and in vitro microperfusion and incubation of CCDs at pH 7.4, pH 6.8, and ± 12.5 nM SDF-1α, or the CXCR4 receptor antagonist AMD3100 (1 mcM). Net HCO_3 flux was measured and expressed as the sum of H flux & HCO_3 flux, using Cl-free perfusate. 3D reconstructions of confocal images of incubated CCDs were stained for pendrin.

Results: Rabbit kidney sections confirmed expression of SDF-1 in CCD and double labeling with B1-V-ATPase indicated that SDF-1 is expressed primarily in principal cells. In microperfused CCDs the CXCR4 antagonist AMD3100 reduced the adaptive decrease in $JHCO_3$ and increase in JH induced by low pH (pH 6.8) by 34% and 36%, respectively, resulting in a 79% reduction in the adaptive change in Jnet. To determine whether SDF-1α is sufficient to induce changes in H/HCO_3 transport, microperfused CCDs were incubated with SDF-1α at pH 7.4 for 3 h. SDF-1 treatment resulted in an 81% reduction in net HCO_3 secretory flux that was comprised of a 23% reduction in $JHCO_3$ and a 32% increase in JH. Microdissected CCDs were incubated in *in vitro* culture medium aerated with 95%O_2/5%CO_2±SDF-1 @ 37 C for 3 h. Morphometric analysis of pendrin staining in images of 3D tubule reconstructions revealed that SDF-1 treatment promoted redistribution of pendrin from an apical cap to a more cytoplasmic distribution, similar to what was observed during incubation at pH 6.8.

Conclusions: Thus SDF-1/CXCR4 signaling is not cell autonomous; rather principal cells receive the acid signal releasing SDF1 which then diffuses to the ICs to change H/HCO_3 transport and regulate pendrin endocytosis from the apical membrane.

Luminal Flow Modulates H^+-ATPase Activity in the Cortical Collecting Duct (CCD) Wen Liu,[1] Nuria M. Pastor-Soler,[2] Carlos Schreck,[1] Thomas R. Kleyman,[2] Lisa M. Satlin.[1] *[1]Mount Sinai School of Medicine, NY, NY; [2]University of Pittsburgh, PA.*

Background: ENaC-mediated Na^+ absorption and BK channel-mediated K^+ secretion in the cortical collecting duct (CCD) are modulated by flow, the latter requiring an increase in $[Ca^{2+}]_i$, microtubule integrity, and exocytic insertion of preformed channels into the apical membrane. As axial flow modulates HCO_3^- reabsorption in the proximal tubule due to changes in both luminal NHE3 and H^+-ATPase activity (Du Z. et al, Am J Physiol Renal Physiol 290:F289, 2006), we sought to test the hypothesis that flow also regulates H^+-ATPase activity in the CCD.

Methods: H^+-ATPase activity was assayed in individually identified cells in microperfused CCDs isolated from NZW rabbits, loaded with the pH-sensitive dye BCECF, and then subjected to an acute intracellular acid load (NH_4Cl prepulse technique). H^+-ATPase activity was defined as the initial rate of bafilomycin-inhibitable cell pH (pH_i) recovery in the absence of luminal K^+, bilateral Na^+ and CO_2/HCO_3^-, from a nadir pH of ~6.2.

Results: We found that (i) an increase in luminal flow rate from ~1 to 5 nl/min. mm stimulated H^+-ATPase activity (pH U/min) in both intercalated (IC; 0.059±0.009 to 0.146±0.023; p<0.03) and principal (PC; 0.050±0.009 to 0.126±0.004; p<0.03) cells, the latter identified by their selective labeling with the apical PC marker Dolichos Biflorus agglutinin, and (ii) flow-stimulated H^+ pumping was Ca^{2+} dependent and required microtubule integrity, based on its inhibition by pretreatment with BAPTA-AM and colchicine, respectively.

Conclusions: We conclude that luminal flow modulates H^+-ATPase activity in the rabbit CCD and that H^+-ATPases therein are present in both PC and IC. We speculate that flow stimulation of H^+ secretion in the distal nephron may contribute to diuretic-induced metabolic alkalosis.

SA-OR339

Movement of NH_3 through the Human Urea Transporter B (UT-B) — A New Gas Channel R. Ryan Geyer,[1] Raif Musa-Aziz,[1,2] Walter F. Boron.[1] *[1]Dept of Physiol & Biophys, Case Western Reserve Univ School of Medicine, Cleveland, OH; [2]Dept of Physiol & Biophys, Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: The urea transporters (UTs) mediate the facilitated diffusion of urea across the plasma membrane. UT-B (SLC14A1) is an integral membrane protein highly expressed in the kidney and red blood cell. A bacterial homolog has been crystallized as a homotrimer. Each monomer forms an independent urea channel. A fourth pore is formed at the three-fold axis of symmetry. Previously, the Boron laboratory showed that multimeric proteins (i.e. Aquaporins and Rh proteins) can function as gas (CO_2 and NH_3) channels. This study explores the CO_2 and NH_3 permeability of human UT-B expressed in *Xenopus* oocytes (*vs* H_2O-injected control oocytes).

Methods: We used microelectrodes to record the maximum transient change in surface pH (ΔpH_S) caused by exposing the oocyte to 5% CO_2/33 mM HCO_3^- (an increase) or 0.5 mM NH_3/NH_4^+ (a decrease). We computed osmotic water permeability (P_f) using video microscopy. Subtracting the respective values for day-matched, H_2O-injected control oocytes yielded channel-specific values (*). The magnitude of ΔpH_S* is a semiquantitative index of maximal CO_2 or NH_3 influx.

Results: $(\Delta pH_S^*)_{CO2}$ was not significantly different in UT-B vs H_2O oocytes (0.082 ± 0.007, n=18 vs 0.068 ± 0.003, n=17). However, with NH_3 addition, $(-\Delta pH_S^*)_{NH3}$ was twice as high in UT-B vs H_2O oocytes (0.058 ± 0.006, n=20 vs 0.030 ± 0.002, n=19). P_f was 8-fold greater in UT-B vs H_2O oocytes. $(-\Delta pH_S^*)_{NH3}$ and P_f* were each significantly greater than 0 for UT-B oocytes, indicating that UT-B can carry NH_3 and H_2O. To explore the pathway of NH_3 and H_2O movement through UT -B, we examined the effect of phloretin (UT inhibitor) and pCMBS (H_2O channel inhibitor). Phloretin (500 μM, 20-min pretreatment) reduced $(-\Delta pH_S^*)_{NH3}$ by 70% and P_f* by 50%. pCMBS (1 mM, 30-min pretreatment) reduced $(-\Delta pH_S^*)_{NH3}$ by 100% and P_f* by 30%.

Conclusions: Thus, our P_f* data confirm that UT-B has significant H_2O permeability and, using the pH_S approach, we show for the first time that UT-B has significant NH_3 but not CO_2 permeability. We propose that all NH_3 passes through the three monomers in UT-B—blocked by phloretin and pCMBS.

Acute Kidney Injury Following CABG Is Related to Long-Term Incidence of Myocardial Infarction Martin Holzmann, Linda Ryden Lujan. *Department of Emergency Medicine, Karolinska University Hospital, Internal Medicine Unit, Karolinska Institutet, Sweden.*

Background: Acute Kidney Injury (AKI) is strongly related to early mortality and postoperative complications following coronary artery bypass surgery (CABG). Recent studies indicate that AKI following CABG is related to long-term mortality. However, there is little information on the long-term risk of myocardial infarction (MI) associated with AKI.

Methods: From the Swedish Heart Surgery Register (Swedeheart), all patients undergoing a first, isolated CABG electively, during 1995-2008 in Sweden, with information on pre- and postoperative serum creatinine, and alive 60 days postoperatively, were included. Information about confounders was found in the Swedish Coronary Angiography and Angioplasty Register and from the Swedish Inpatient Register and Cause of Death Register,

information on incidence of MI and all-cause mortality, was assembled. Acute kidney injury was defined both as an absolute increase in postoperative serum creatinine of 0,3-0,5 mg/dL, 0,5-1,0 mg/dL or > 1,0 mg/dL, and according to AKIN criteria. Hazard ratios (HR) for different levels of AKI were calculated using Cox proportional hazards regression.

Results: The study population consisted of 45,002 patients, with a mean age of 67 years. During a mean follow-up of nine years there were 3,945 (8.8%) MIs and 11,157 (25%) deaths. After adjustment for confounders, the HRs for MI (95 percent confidence intervals) associated with a postoperative increase in serum-creatinine of 0,3-0,5 mg/dL, 0,5-1,0 mg/dL or > 1,0 mg/dL, were 1,52 (1,33-1,61), 1,85 (1,74-2,11) and 2,09 (1,78-2,31), respectively. The corresponding figures for death were 1,48 (1,39-1,53), 2,04 (1,83-2,21) and 3,84 (3,50-4,01), respectively. Similar associations were found when AKI was defined using AKIN criteria.

Conclusions: Acute kidney injury defined according to an absolute increase in postoperative values of serum creatinine or AKIN criteria is strongly associated with both long-term incidence of MI and death. Cardiologists or family doctors following patients with a history of CABG should take into account the long-term prognostic implications of AKI post-CABG.

Temporal Relationship and Predictive Value of Urinary AKI Biomarkers after Cardiac Surgery Prasad Devarajan, Catherine D. Krawczeski, Stuart Goldstein, Yu Wang, Nuntawan Piyaphanee, Qing Ma, Michael R. Bennett. *Cincinnati Children's Hospital, Cincinnati, OH.*

Background: Acute kidney injury (AKI) occurs commonly after cardiopulmonary bypass (CPB). Serum creatinine (SCr) is a delayed marker for AKI. We evaluated the temporal pattern and predictive value of 4 most promising urinary AKI biomarkers: neutrophil gelatinase-associated lipocalin (NGAL), interleukin-18 (IL-18), liver fatty-acid binding protein (L-FABP), and kidney injury molecule-1 (KIM-1), for CPB-associated AKI.

Methods: Urine samples were obtained prospectively before and at several time points after CPB in 220 patients. AKI was defined as a ≥50% increase in SCr from baseline. Biomarker values were correlated with AKI severity and clinical outcomes. Logistic regression was used to assess AKI predictors. Biomarker predictive abilities were evaluated by area under the curve (AUC), net reclassification improvement (NRI) and integrated discrimination improvement (IDI).

Results: AKI occurred in 27% of patients. NGAL first increased in AKI patients at 2h after CPB. IL-18 and L-FABP first increase at 6h and KIM-1 first increased at 12h. Biomarker elevations correlated with disease severity (RIFLE) and clinical outcomes (length of hospital stay, days on ventilator), and improved prediction of AKI above the clinical model. At 2h post-CPB, NGAL alone increased the AUC from 0.74 for the clinical model to 0.85 ($p<0.001$). At 6h post-CPB, NGAL, IL-18 and L-FABP each improved the AUC from 0,72 to 0.91, 0.84, and 0.77 respectively (all $p<0.05$). At the 6h time point, the combination of NGAL + IL-18 provided the best results in terms of AUC improvement, NRI, and IDI. At 12h post-CPB, the best predictive ability was obtained when all four biomarkers were combined.

Conclusions: This is the first large prospective study to (1) establish a temporal pattern of multiple sequential AKI biomarkers after CPB, which correlate with AKI severity and clinical outcomes, and (2) demonstrate the utility of biomarker combinations for the improved prediction of AKI beyond clinical models. Biomarker combinations hold tremendous promise for guiding the application of appropriately timed AKI therapies, based on the underlying pathophysiology.

Identification of Candidate Serum Biomarkers for Severe Septic Shock-Associated Kidney Injury Via Microarray Rajit K. Basu, Derek Wheeler, Prasad Devarajan, Stuart Goldstein, Hector R. Wong. *Center for Acute Care Nephrology, Cincinnati Children's Research Foundation, Cincinnati, OH.*

Background: Effective therapy for septic shock associated acute kidney injury (SSAKI), a disease process carrying significant morbidity and mortality, is lacking. A limitation for such therapy is that detection strategies for SSAKI, traditionally dependent on serum creatinine, are considerably varied and heterogeneous. While existing AKI biomarkers demonstrate relatively improved sensitivity for identification of SSAKI over creatinine, they may still be confounded by the unique pathophysiology of SSAKI.

Methods: We leveraged a previously generated genome-wide expression database of children with septic shock to address the need of identifying novel candidate biomarkers of SSAKI. Thirty-one patients with SSAKI (defined as a doubling of baseline serum creatinine) and 148 patients without SSAKI were identified. SSAKI persisted, to seven days after hospital admission.

Results: SSAKI patients were clinically similar to those without SSAKI but had higher mortality (45% versus 10%). 21 unique gene probes were up-regulated in SSAKI patients compared to patients without SSAKI. Using leave-one-out cross validation and class prediction modeling, the expression patterns of the 21 gene probes predicted SSAKI with a sensitivity of 98% (95% confidence interval (CI) 81-100) and a specificity of 80% (95% CI 72-86). Individual performance calculations were performed using two specific gene products (i.e. serum protein measurements) showing high sensitivity for predicting SSAKI: matrix metalloproteinase-8 (MMP-8) (89%, 95% confidence interval (CI) 64-98) and elastase-2 (83%, 95% CI 58-96). Both candidate biomarkers carried a negative predictive value of 95%. When applied to a separate validation cohort, both candidate biomarkers carried high sensitivity: MMP-8 (100%, 95% CI 68-100) and elastase-2 (100%, 95% CI 68-100).

Conclusions: We conclude that gene probes up-regulated in critically ill pediatric patients with septic shock may allow for the identification of novel candidate serum biomarkers for SSAKI prediction.

Serum Angiopoetin-2 Correlates with Acute Kidney Injury and Outcome in Patients with Acute Liver Failure Alexander Lukasz,[1] Johannes Hadem,[3] Jan T. Kielstein,[1] Philipp Kümpers.[2] *[1]Department of Nephrology, Medical School of Hannover, Hannover, Germany; [2]Department of Nephrology, University Hospital Münster, Münster, Germany; [3]Department of Gastroenterology, Medical School of Hannover, Hannover, Germany.*

Background: Angiopoietin-2 (Ang-2), a circulating antagonistic ligand of the endothelial-specific Tie2 receptor, has been identified as a non-redundant facilitator of endothelial activation. We have recently shown that plasma Ang-2 levels correlate with the severity of Acute Kidney Injury (AKI) in critically ill patients. Moreover, administration of its endogenous competitor, the Tie agonist ligand Ang-1, protects against septic AKI in mice. In this study we ask if Ang-2 levels correlate with AKI, organ dysfunction and outcome in patients with primary acute liver failure (ALF).

Methods: We retrospectively identified 143 patients treated at the ICU of our institution between 1999 and 2009 with primary ALF and documented encephalopathy (secondary ALF due to sepsis etc were excluded). Serum samples obtained at ICU admission were available from 37 patients (Median age 34 years). Ang-2 was measured by in-house immuno-luminometric assay. 20 blood donors served as healthy controls.

Results: Patients who displayed any of AKI stages 1-3 showed significantly higher median [IQR] Ang-2 levels than those without AKI [34.2 (18.7-82.3) vs. 12.9 (6.1-17.2)ng/ml; $p<0,003$]. Ang-2 serum concentrations were increasingly high across healthy controls (1.4 [0.9-1.7] ng/mL), patients with transplant-free recovery (10.0 [4.7-12.1]ng/mL), and patients that died or received transplantation (16.8 [11.3-39.5]ng/mL). Ang-2 release correlated strongly with markers of organ dysfunction and disease severity scores, e.g. Sequential Organ Failure Assessment score [$r=0.492$, $p=0.002$]. Ang-2 was independently associated with the composite endpoint of death and/or Emergency Liver Transplantation on multivariate Cox regression analysis.

Conclusions: In addition to established marker or disease severity scores, circulating Ang-2 appears to be a relevant determinant of organ dysfunction, especially Acute Kidney Failure and outcome in patients with ALF and deserves more attention in patients with acute liver and kidney failure.

SA-OR344

A Prospective Trial Assessing the Effects of Clamp Ischemia during Partial Nephrectomy on Renal Function, Structure, and Biomarkers Dipen J. Parekh,[1] Barbara Ercole,[1] Kathleen Torkko,[2] William M. Hilton,[1] Prasad Devarajan,[3] Manjeri A. Venkatachalam,[1] Joel M. Weinberg.[4] *[1]UTHSC San Antonio; [2]Univ. of Colorado; [3]Univ. of Cincinnati; [4]Univ. of Michigan.*

Background: Tolerance of the human kidney to clamp ischemia (CI) during partial nephrectomy has been considered to be limited to 20-30 min. We have reassessed this question using intraoperative biopsies and have determined the utility of new biomarkers for following injury in this setting.

Methods: 40 patients undergoing open partial nephrectomy either without cooling (N=27, avg clamp time 32.3 min, range 15-53 min., 74% ≥ 30 min.) or with ice-slush cooling (N=13 avg clamp 48 min. range 30-61 min.) had biopsies of uninvolved areas of the kidney preclamp, during clamping. and then 5 min. after clamp release, along with serial measurements of standard renal functional parameters plus measurement of serum cystatin C and NGAL, and of urine NGAL, cystatin C, NAG, LFABP, NGAL, KIM-1 and IL-18.

Results: Serum creatinine transiently increased at 24 hours by 21.9±6.4% after warm CI and 27.2±7.9% after cold CI (Ps < .001), then recovered, but serum cystatin C did not change and serum NGAL was minimally affected. Urine biomarkers increased irrespective of whether they were factored for creatinine, with particularly large changes in KIM-1 and LFABP, but did not correlate with duration of ischemia, the change in creatinine or serum cystatin C, or the use of cold or warm ischemia. Ultrastructure and staining for actin, phosphotyrosine, β1 integrin, and ICAM-1 showed changes consistent with ischemia, but much milder than predicted from animal models and not strictly related to the duration or type of CI. Creatinine has remained stable in the patient cohort at up to 18 months of followup.

Conclusions: The data indicate that the insult to the clamped kidney from 30-60 minutes of clamp under conditions of open partial nephrectomy is well tolerated despite increases of urinary biomarkers, which may in part reflect local effects of the surgery itself. The work expands indications for partial nephrectomy in the management of renal cancers, and supports the use of CI as opposed to more complex procedures for partial nephrectomy.

Early Dynamic Changes in Serum Creatinine Predict Renal and Patient Outcome in Septic ICU Patients Claudio Rigatto, Manish M. Sood, Paul Komenda, Joe A. Bueti, Anand Kumar. *Internal Medicine, University of Manitoba, Winnipeg, MB, Canada.*

Background: AKI predicts poor prognosis in patients with septic shock. It is not known whether early changes in serum creatinine (SCr) measured after ICU admission help predict renal outcome and survival in sepsis. An early drop in SCr may identify a good response to resuscitation and predict better outcomes.

Methods: Data was obtained from the Cooperative Antimicrobial Therapy of Septic Shock database comprising patients from 28 centres worldwide. 6504 had, serum creatinine measured at admission and 6 hours post . Patients requiring immediate initiation of RRT or with SCr > 400 mcmol/L on admission were excluded. The main exposure variable was % change in creatinine over the first 6 hours (PCr6); main outcome variables were need for dialysis and survival at 2 weeks. Multivariate Logistic Regression was used to compare predictive models with and without PCr6

Results: 4826 patients were analyzed. 343(7.1%) required dialysis and 1768 (36.6%) died within 2 weeks. Age, APACHE II, RIFLE stage on admission, centre, and fluid volume in the first 6 hours were the strongest predictors of need for dialysis (Base Dialysis Model). PCr6 was strongly associated with dialysis (OR 1.01 [1.006, 1.02]), was highly significant when added to the Base Dialysis Model (OR 1.02 [1.02,1.03]), and increased model discrimination (c-statistic 0.84 [0.82, 0.86] vs. 0.82 [0.80, 0.85]; p=0.001). Age, sex, Apache II, centre, and Gram negative sepsis were the strongest predictors of survival at 2 weeks post admission (Base Survival Model). Higher PCr6 was significantly associated with poor survival (OR 0.97 [0.97, 0.98]), was highly significant when added to the Base Survival Model, and improved discrimination (c-statistic 0.78 [0.77, 0.79] vs. 0.76 [0.74, 0.77]; p<0.0001). Patients who experienced a drop in creatinine > 10% at 6 hours had a much lower odds of needing dialysis (OR 0.44 [0.33,0.60] or dying (OR 0.41[0.35, 0.48].

Conclusions: In septic patients admitted to ICU, early dynamic changes in creatinine (in the first 6 hours) provide important prognostic information.

SA-OR346

Proximal and Distal Tubule Epithelial Cells Express CD133 during Repair after Acute Kidney Injury in Humans Ping L. Zhang,[1] Joseph V. Bonventre.[2] *[1]Dept of Pathology, William Beaumont Hospital, Royal Oak, MI; [2]Renal Division, Brigham and Women's Hospital, Boston, MA.*

Background: Several recent studies have used CD133 (prominin-1) to identify and isolate renal progenitor cells in parietal epithelial cells (PEC) of glomeruli and proximal tubules in human kidney tissue. However, the "progenitor" status of the cells that express this protein has not been well established. In this study, we evaluated CD133 staining in normal fetal and adult human kidneys, and in various human renal diseases characterized by acute tubular injury (ATI).

Methods: Fetal kidneys (12-32 wks, n=64), normal adult kidneys (n=11) and renal biopsies from patients with ATI (primary or secondary, n=33) were evaluated for expression of CD133 using immunohistochemical techniques with two antibodies (ab)(monoclonal AC133 clone, 1:50, Miltenyi and polyclonal ab, 1:500, Biocare). CD133 expression was compared with expression of kidney injury molecule-1 (KIM-1, using AKG7 ab at 1:10), an injury marker of proximal tubules and cytokeratin-7, a distal-nephron tubular marker.

Results: Both types of CD133 antibodies showed a similar pattern of apical membrane staining. In fetal kidneys, CD133 stained primordial glomerular structures and medullary tubules. In normal kidney sections with negative KIM-1 staining, membrane CD133 staining was seen in PEC of the glomeruli and in less than 5% of proximal and distal tubular epithelial cells. In injured dedifferentiated proximal tubules, confirmed by positive KIM-1 staining, CD133 membrane expression along the apical surface was present in the majority of injured epithelial cells. With ATI, many distal tubule cells expressed both apical CD133 and cytokeratin-7. Tubular expression of CD133 in either proximal or distal tubules was significantly correlated with serum creatinine levels of adult patients.

Conclusions: Under normal conditions, CD133 is expressed in human fetal kidneys. In ATI, diffuse CD133 expression is seen in dedifferentiated injured tubular epithelial cell apical membranes implying that, rather than identify a specific "progenitor" population, CD133 is upregulated in dedifferentiated epithelial cells that are involved in repair of the epithelium after injury.

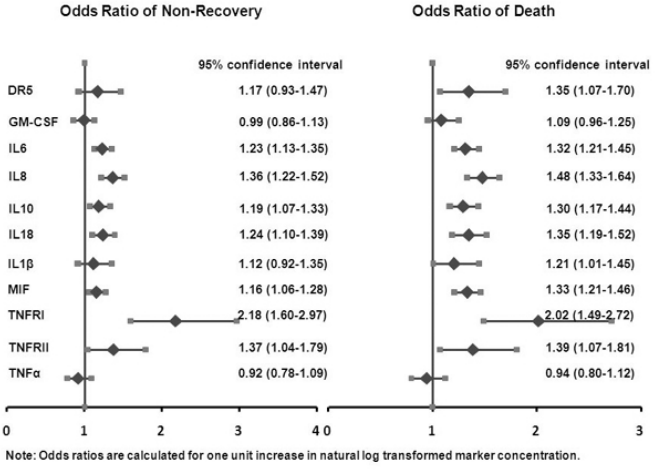
Higher Concentrations of Inflammatory and Apoptotic Biomarkers Are Associated with Mortality and Nonrecovery of Kidney Function Xiao-Yan Wen,[1] Raghavan Murugan,[1] Lan Kong,[1,3] Nilesh Shah,[1,3] MinJae Lee,[1,3] Melinda J. Carter,[1] Michele M. Elder,[1] Paul M. Palevsky,[2,4] Mark L. Unruh,[2] John A. Kellum.[1,2] *[1]Department of Critical Care Medicine, Clinical Research, Investigation, and Systems Modeling of Acute Illness (CRISMA), University of Pittsburgh, Pittsburgh, PA; [2]Department of Medicine, University of Pittsburgh, PA; [3]Department of Biostatistics, University of Pittsburgh Graduate School of Public Health, PA; [4]VA Pittsburgh Healthcare System, Pittsburgh, PA.*

Background: Acute Kidney Injury (AKI) is a common complication of critical illness with high mortality rate despite renal replacement therapy (RRT). Although, higher circulating concentrations of inflammatory and apoptotic biomarkers are associated with AKI, whether these biomarkers predict outcomes in patients with severe AKI who are receiving RRT is unknown.

Methods: In a subset of 819 subjects from the Acute Renal failure Trial Network study, we measured 11 plasma inflammatory and apoptotic biomarkers on day-1 of RRT. Outcomes were 60-day mortality and renal recovery defined as alive and independent from RRT at day-60. We hypothesized that higher inflammatory and apoptotic biomarkers concentrations on day 1 would predict poor outcomes.

Results: 297 subjects (36.3%) died and 107 (13.1%) remained on RRT by day 60. 7 of the 11 plasma markers concentration were significantly lower in survivors and in subjects who recovered. Higher plasma concentrations of inflammatory and apoptotic markers were associated with a higher risk of renal non-recovery and death.



Conclusions: High circulating levels of plasma inflammatory and apoptotic biomarkers are strongly associated with non-recovery and mortality in critically ill patients receiving RRT.

SA-OR348

Endogenous Ouabain Is Implicated in Acute Kidney Injury in Cardiac Surgery and Critically Ill Patients Marco Simonini,[1] Nunzia Casamassima,[1] Chiara Lanzani,[1] Giorgio Slaviero,[1] Stephen S. Gottlieb,[2] Keyur B. Shah,[2] John Hamlyn,[2] Paolo Manunta.[1] *[1]Chair of Nephrology, San Raffaele Scientific Institute, Milan, Italy; [2]University of Maryland, Baltimore.*

Background: Endogenous Ouabain (EO) is an adrenal stress hormone with hemodynamic and renal effects. Acute Kidney Injury (AKI) is frequent post operative complication of major surgery. Preliminary studies have shown a rapid and early increase of EO in association with acute decrease in glomerular filtration rate. Our aim was to identify a new pre-operative marker for development of AKI in major surgery patients (pts) and to address the role in the development of kidney damage in Ouabain Hypertensive Rats (OHR).

Methods: We enrolled 425 consecutive adult pts admitted to elective cardiac surgery and 54 critical ill pts. The primary outcome was AKI according to RIFLE criteria. We also studied the prolonged ouabain effects on renal parameters in OHR.

Results: In cardiac surgery patients, AKI (4%, 7.3%, 12.9%, p=8.92E-08) and in hospital mortality (0.2%, 0.5%, 1.6%, p=0.018) increased with each incremental pre-operative EO tertile. In a linear regression analysis, circulating EO value before surgery resulted the strongest predictor of AKI (b=0.32, p=1.63E-06). Patients in the highest EO tertile had a relative risk of AKI that was 5.1 (p=1.16E-6) fold higher than in those in the lowest tertile. In 54 critically ill patients APACHE II score (11.8±7.4, 14.9±6.2, 19.9±10.2, p=0.02), AKI (11%, 39%, 61%, p=0.008), increased with each EO tertile. All the associations remained independently significant after adjustments for covariates. In the experimental OHR model, chronic infusion of low doses of ouabain lead to a reduction of creatinine clearance (-18%, p<0.05), an increase urinary protein excretion (+54%, p<0.05), associated with a reduction of expression of podocyte protein nephrin (-29%, p<0.01).

Conclusions: Pre-operative plasma EO levels are powerful biomarkers of AKI and post-operative complications within 24-48 hour. The elevated circulating levels of EO are strongly associated with the severity of illness, renal dysfunction, kidney damage and in-hospital mortality.

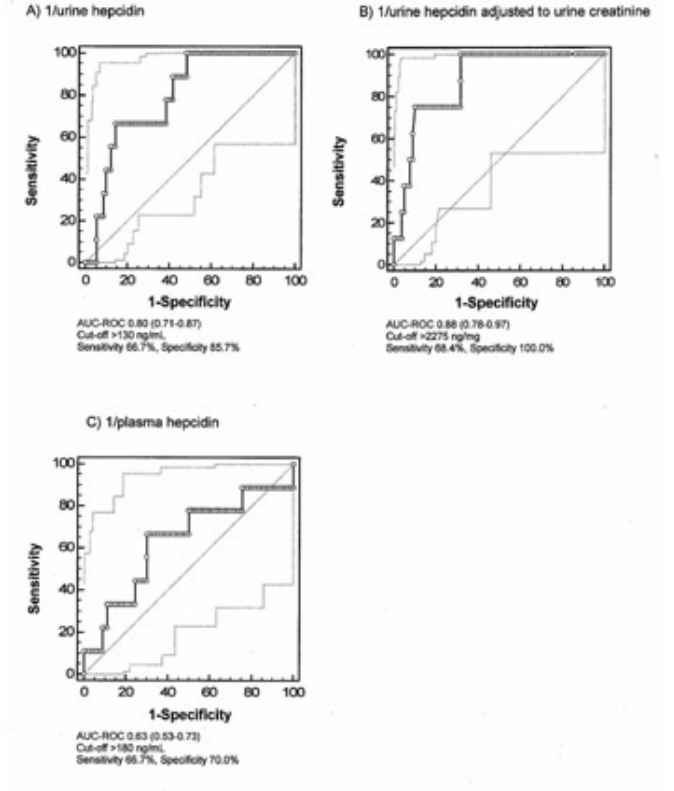
Urine Hepcidin Has Additive Value in Ruling out Cardiopulmonary Bypass-Associated Acute Kidney Injury – An Observational Cohort Study Mark E. Westerman,[3] Michael Haase,[1] Anja Haase-Fielitz,[1] Peter R. Mertens,[1] John R. Prowle,[4] Rinaldo Bellomo.[2] *[1]Nephrology, Otto-von-Guericke University, Magdeburg, Germany; [2]Austin Hospital, Intensive Care, Melbourne, Australia; [3]Intrinsic Life Science, La Jolla; [4]Barts and NHS London Trust, London.*

Background: Conventional markers of acute kidney injury (AKI) lack diagnostic accuracy and are expressed only late after cardiac surgery with cardiopulmonary bypass (CPB). Recently, interest has focused on hepcidin, a regulator of iron homeostasis, as a unique renal biomarker.

Methods: We measured hepcidin (by ELISA) in 100 adult patients in the control arm of a randomized controlled trial (NCT00672334) that were identified to be at increased risk of AKI after cardiac surgery with CPB. AKI was defined according to RIFLE classification. Samples of plasma and urine were obtained simultaneously I) before CPB II) 6 hours and III) at 24 hours after start of CPB.

Results: At 6 and 24 hours after CPB, in AKI-free patients (N=91) urine hepcidin concentrations had largely increased and were 3 to 7 times higher compared to patients with subsequent AKI (N=9) in whom postoperative urine hepcidin remained at preoperative levels ($P = 0.004$, $P = 0.002$). Furthermore, elevated urine hepcidin and, even more so, urine hepcidin adjusted to urine creatinine at 6 hours after CPB discriminated patients who *did not* develop AKI (AUC-ROC 0.80 [95% CI 0.71-0.87]; 0.88 [95% CI 0.78-0.97]) (see Figure) or *did not* need renal replacement therapy (AUC 0.81 [95% CI 0.72-0.88]; 0.88 [95% CI 0.70-0.99]) from those who did. At 6 hours, urine hepcidin adjusted to urine creatinine was an independent predictor of ruling out AKI ($P = 0.011$). Plasma hepcidin did not predict the lack of AKI development.



Conclusions: Our findings suggest that urine hepcidin is an early predictive biomarker of ruling out AKI after CPB thereby contributing to early patients risk stratification.

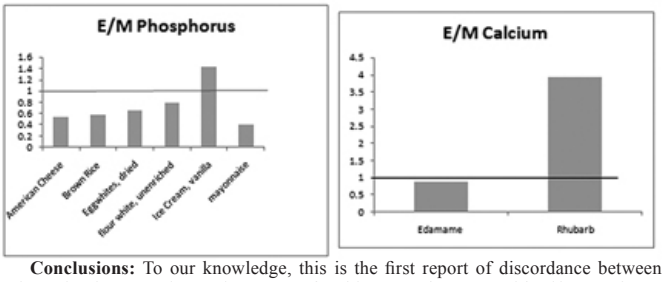
SA-OR350

Discordance between Measured Phosphorus (P) and Calcium (Ca) Content in Foods and Estimates from Nutrient Databases Anuja P. Shah,[1] Rachelle Bross,[2] Joel D. Kopple,[1] Rajnish Mehrotra.[1] *[1]Nephrology and Hypertension, Los Angeles Biomedical Research Institute at Harbor-UCLA, Torrance, CA; [2]General Clinical Research Center, Los Angeles Biomedical Research Institute at Harbor-UCLA, Torrance, CA.*

Background: Current clinical practice uses nutrient databases to counsel patients about dietary P and Ca content. Previous studies revealed that nutrient databases underestimate P content of prepared foods. There are limited data on accuracy of Ca content for any foods and P content of unprocessed foods.

Methods: P and/or Ca content of 34 food items was measured (M) using ICP-MS (inductively coupled plasma-mass spectroscopy) analysis at Michelson Laboratories Inc. (Commerce, CA), and data were compared to P and Ca content estimated (E) from nutrient databases (Nutrition Data System for Research, Minneapolis, MN). Confirmatory analysis of selected food items was performed at Medallion Laboratories, Minneapolis, MN.

Results: The E/M ratio for P content of foods varied widely from 0.55 to 1.40 (Figures). Wide variability was observed for both unprocessed and processed food items. The (E) P content in brown rice of 77 mg/100 g was significantly lower than the (M) 133 mg/100 g. Furthermore, the P content of coffee creamer, negligible by (E), was 107 mg/100 g by (M). The E/M Ca content in the three food items varied from 0.88 to 3.36, and the (M) content was discordant from both the database and the nutrition label. For example, the (E) Ca of 194 mg/100g in rhubarb was notably higher than the (M) 49 mg/100g.



Conclusions: To our knowledge, this is the first report of discordance between estimated and measured Ca and P content of a wide range of unprepared food items. Dietary recommendations for populations in which dietary P and Ca may need to be controlled should consider these discrepancies. Also, labeling of *measured* P and Ca content in foods may be useful.

Dietary Phosphorus Is Associated with Left Ventricular Mass: The Multi-Ethnic Study of Atherosclerosis Kalani T. Yamamoto,[1] Bryan R. Kestenbaum,[1] Cassianne Robinson-Cohen,[1] Marcia C. De Oliveira,[2] Alina Kostina,[1] Jennifer A. Nettleton,[2] Joachim H. Ix,[3] Ha T. Nguyen,[4] John Eng,[5] Joao A.C. Lima,[5] David Siscovick,[1] Noel Weiss.[1] *[1]University of Washington, Seattle, WA; [2]University of Texas Health Sciences Center, Houston, TX; [3]University of California, San Diego, CA; [4]Wake Forest University, Winston-Salem, NC; [5]Johns Hopkins University, Baltimore, MD.*

Background: Dietary phosphorus consumption has steadily increased in the US. Phosphorus alters key regulatory hormones and impairs vascular endothelial function, which may increase left ventricular mass (LVM). We investigated the association of dietary phosphorus intake with LVM in 4,494 individuals.

Methods: We studied participants from the Multi-Ethnic Study of Atherosclerosis, a community-based study of individuals free of cardiovascular disease. We quantified phosphorus intake using a 120-item food frequency questionnaire and measured LVM using cardiac MRI. We used linear and logistic regression models to estimate associations of dietary phosphorus intake with LVM and left ventricular hypertrophy (LVH), respectively.

Results: Mean dietary phosphorus intake was 1,167 mg/day in men and 1,017 mg/day in women. After adjustment for demographics, eGFR, total caloric and sodium intake, lifestyle factors, blood pressure, and other risk factors for LVH, each 20% greater dietary phosphorus intake was associated with an 1.1 gram greater LVM (95% CI 0.54, 1.63). The highest sex-specific quintile of dietary phosphorus intake was associated with an 6.2 gram greater LVM (95% CI 2.5, 9.8) and 2.1-fold greater odds of LVH (95% CI 1.1, 4.1) compared to the lowest sex-specific quintile.

Conclusions: Greater dietary phosphorus consumption is associated with greater LVM and a greater prevalence of LVH in a community-based cohort. If confirmed in future studies, dietary phosphorus may be a novel cardiovascular risk factor.

Effect of Bone Morphogenetic Protein-7 on Vascular Smooth Muscle Cells Calcification Induced by High Phosphorus Yi Yu. *Dept of Nephrology and Hemodialysis, Dongfang Hospital of Fujian Province, Fuzhou, Fujian, China.*

Background: This study is aimed to investigate the effect of Bone Morphogenetic Protein-7 (BMP-7) on vascular smooth muscle cells (VSMCs) calcification induced by high phosphorus in vitro by determining the expression of Pit-1, Cbfα-1 and calcium deposition.

Methods: The explants derived from thoracic aorta were used for primary culture of VSMCs and identification of cells were carried on by morphological identification and direct immunohistochemical staining of α-SMA. Passage 3 to 8 of VSMCs were used for experiments. Briefly, VSMCs were placed in various culture media, including normal phosphorus medium (Pi 1.3mmol/L), high phosphorus medium (Pi 2.6mmol/L), high phosphorus plus rhBMP-7 medium(Pi 2.6mmol/L+ rhBMP-7 100ng/ml), normal phosphorus plus rhBMP-7 medium (Pi 1.3mmol/L+ rhBMP-7 100ng/ml), calcium deposition was quantified and visualized by Alizarin stain method at day 6. Pit-1 mRNA levels was determined by RT-PCR, and Cbfα-1 expression was semi-quantified by RT-PCR and western blot at day 3. All of the experiments were repeated for 3 times at least.

Results: 1. VSMCs were characterized by the ribbon spindle shape. Immunohistochemical staining of α-SMA showed more than 95% positive staining in the cultured VSMCs. 2. Compared with normal phosphorus group, the calcium deposition was significantly increased in high phosphorus group (P<0.01), and BMP-7 reduced the increasing calcium deposition induced by high phosphorus (P<0.01), as were also shown in Alizarin stain. 3. Compared with normal phosphorus group, Pit-1 mRNA expression was significantly increased in high phosphorus group(P<0.01), and BMP-7 reduced the increasing Pit-1 mRNA expression(P<0.01). 4. As were shown in RT-PCR and western blot, Compared with normal phosphorus group, Cbfα-1 expression was significantly increased in high phosphorus group (P<0.01), and BMP-7 reduced the increasing Cbfα-1 mRNA(P<0.01) and protein (P=0.02) expression.

Conclusions: 1.Phosphorus induces VSMCs calcification in vitro. 2.BMP-7 inhibits the transformation of VSMCs into osteoblast-like cells induced by high phosphorus in vitro. 3.BMP-7 inhibits the calcium deposition of VSMCs induced by high phosphorus in vitro.

MicroRNAs Induced by High Concentration of Phosphate and Calcium Are Involved in Vascular Smooth Muscle Cell Calcification Ting Gui, Yujing Sun, Aiko Shimokado, Shunji Itoh, Kosuke Oikawa, Yasuteru Muragaki. *First Department of Pathology, Wakayama Medical University, Wakayama, Japan.*

Background: MicroRNAs (miRNAs) are a recently discovered class of endogenous, small, non-coding RNAs that regulate the expression of protein-coding genes. The role of miRNAs in vascular calcification is currently unclear.

Methods: We examined the alteration of miRNAs in vascular smooth muscle cell (VSMC) calcification in vitro and in vivo to explore how miRNAs are involved in VSMC calcification. Using miRNA array analysis, we demonstrated that miRNAs are aberrantly expressed in the aortic media of 3 week-old klotho knock-out (KO) mice.

Results: The expression levels of miR-135a*, miR-712*, miR-714 and miR-762 in the aortic media of 2 week, 3 week and 4 week-old klotho KO mice were significantly higher than those in wild-type mice according to quantitative real-time polymerase-chain reaction (qRT-PCR). It was further confirmed using by qRT-PCR that these miRNAs were increased in cultured VSMCs treated with phosphate and calcium. We found in the miRNA database that the Ca2+ efflux proteins, PMCA1, NCX1 and NCKX4, frequently appeared as the potential targets of these miRNAs. Transfection of miRNA mimics to cultured VSMCs reduced the protein levels of each potential target as determined by western blot analysis. Conversely, miRNA inhibitors reduced the phosphate and calcium-induced VSMC calcification.

Conclusions: These results suggest that PMCA1, NCX1 and NCKX4 could be the potential targets for these miRNAs and that the reduction of these calcium transporters can cause the VSMC calcification.

SA-OR354

Correction of Hyperphosphatemia in Uremic Npt2b Knockout Mice Treated with Sevelamer Yves Sabbagh, Wen Tang, Christina M. Bracken, Stephen O'Brien, Susan Schiavi. *Endocrine and Renal Sciences, Genzyme Corporation, Framingham, MA.*

Background: Elevation in serum phosphorus even within the normal range is emerging as an important health risk in both normal and chronic kidney (CKD) populations as it is associated with increased incidence of vascular calcification and mortality. Although current CKD therapies such as phosphate binders effectively reduce serum phosphorus, management of individual biochemistry levels to that recommended by the current clinical guidelines is difficult. Limited understanding of the complexity associated with phosphate regulation has further prevented identification of optimal therapeutic strategies.

Methods: We have previously described generation of a conditional Npt2b knockout mouse ($Npt2b^{-/-}$) and demonstrated that ubiquitous deletion of Npt2b in adult mice leads to compensatory changes in critical hormones associated with phosphate regulation and increased expression of the renal transporter, Npt2a. We also demonstrated that Npt2b contributes to >90% of total active phosphate transport using the everted sac method to measure transport in ileum segments isolated from wild-type or $Npt2b^{-/-}$ mice. We therefore, investigated the role of Npt2b in mice with compromised renal function induced by adenine feeding.

Results: Uremic mice with the *Npt2b* deletion had significantly attenuated CKD associated hyperphosphatemia when compared to uremic wild-type mice (WT: 10.04±0.51 vs $Npt2b^{-/-}$: 8.21±0.56mg/dL, p<0.03). FGF23, an important regulator of phosphate was also decreased in uremic $Npt2b^{-/-}$ mice when compared to wild-type mice (WT: 5498±721.02 vs $Npt2b^{-/-}$: 3665.1±455.06pg/ml). We next evaluated whether treatment with the phosphate binder, sevelamer carbonate could further reduce hyperphosphatemia beyond deletion of Npt2b. Serum phosphate levels in the $Npt2b^{-/-}$ mice were normalized by sevelamer treatment (6.5±0.31mg/dl). In addition, serum FGF23 levels were further lowered in the sevelamer treated group compared to the untreated mice (1881.78±359.62pg/ml, p<0.05).

Conclusions: Taken together, these data provide further evidence that Npt2b is a critical component of phosphate homeostasis.

Successful Treatment with Ketoconazole of a Syndrome with Hypercalcemia, Hypercalciuria, Nephrolithiasis, Nephrocalcinosis, Elevated Serum Calcitriol and Mutations in the 24-Hydroxylase (*CYP24A1)* Gene Rajiv Kumar,[1] Peter Tebben,[2] Dawn S. Milliner,[1] Peter C. Harris,[1] Ron Horst,[3] John W. Foreman,[4] Paul Chelminski.[5] *[1]Mayo Clinic, Rochester, MN; [2]Mercy Healthcare, Edmond, OK; [3]Heartland Assays, Ames, IA; [4]Duke University, Durham, NC; [5]University of North Carolina, Chapel Hill, NC.*

Background: We describe the treatment of a novel syndrome in a Caucasian male characterized by hypercalcemia, hypercalciuria, elevated serum 1,25-dihydroxyvitamin D ($1,25(OH)_2D$), undetectable serum 24, 25-dihydroxyvitamin D, nephrolithiasis, and reduced bone mineral density. Bilateral renal cysts and a 6 mm stone were present. The sequence of the 1-hydroxylase *(Cyp27b1)* gene was normal; the 24-hydroxylase (*Cyp24A1)* gene showed 2 intron-exon splice junction abnormalities that result in altered $1,25(OH)_2D$ 24-hydroxylase expression. Family history revealed an unaffected mother and three children among whom a daughter exhibited similar phenotypic features.

Methods: Because of persistent hypercalcemia and hypercalciuria, the patient was treated with ketoconazole, 200 mg orally every eight hours for one month. Relevant analytes were assayed in serum and urine.

Results: Serum $1,25(OH)_2D$ and calcium (Ca) decreased into the normal range ($1,25(OH)_2D$, pg/mL: *before*, 123, *after*, 40; serum Ca, mg/dL: *before*, 10.4, *after*, 9.5). Serum PTH concentration increased into the normal range, (PTH, pg/mL, *before*, 8.1, *after*, 27). Urinary Ca and P diminished (Ca, mg/24h: *before*, 316, *after*, 139; urinary P: *before*, 1525, *after*, 962). Serum inorganic P increased (P, mg/dL: *before*, 3.6, after, 4.4). 25(OH) D decreased (*before*, 50, *after*, 40 ng/mL).

Conclusions: In a syndrome characterized by intermittent hypercalcemia, hypercalciuria, elevated $1,25(OH)_2D$ and undetectable 24, 25 $(OH)_2$ D concentrations, nephrolithiasis, reduced BMD, and splice junction mutations of the *Cyp24A1* gene, treatment with ketoconazole reduces $1,25(OH)_2D$ serum concentrations with attendant decreases in serum Ca concentration and urinary Ca and P excretion. Ketoconazole is an effective treatment for hypercalciuria and hypercalcemia seen in patients with mutations of the *Cyp24A1* gene.

Vitamin D Repletion Does Not Increase Calcium Excretion among Patients with Kidney Stones David E. Leaf,[1] Mantu Gupta,[1] Ruslan Korets,[1] Eric N. Taylor,[2] John R. Asplin,[3] David S. Goldfarb,[4] Gary C. Curhan.[5] *[1]Columbia University Medical Center, New York, NY; [2]Nephrology and Transplantation, Maine Medical Center, Portland, ME; [3]Litholink Corporation, Chicago, IL; [4]Nephrology Section, New York Harbor VA Healthcare System, New York, NY; [5]Nephrology Division, Brigham and Women's Hospital, Boston, MA.*

Background: Despite the important role of vitamin D in maintaining bone health, as well as a variety of other physiological functions, many clinicians are reluctant to treat vitamin D deficiency in kidney stone formers because of the theoretical risk of increasing urinary calcium (UCa) excretion and the risk of calcium stone recurrence. We report on the effect of vitamin D repletion on UCa among stone-formers.

Methods: Patients were recruited from three metabolic stone clinics affiliated with Columbia University Medical Center. Enrollment criteria included: 1) history of nephrolithiasis; 2) UCa between 150 and 400 mg/day; 3) serum 25-hydroxyvitamin D (25(OH)D) level less than 30 ng/ml. Patients were given oral ergocalciferol 50,000 IU weekly for 8 weeks. Serum and 24-hour urine tests were repeated after 8 weeks.

Results: 30 patients were enrolled and 29 completed the study. Vitamin D repletion resulted in no significant change in UCa excretion. Other urinary parameters were similarly unchanged. Subgroup analysis on the basis of initial 25OHD and parathyroid hormone levels revealed no change in UCa excretion in any subgroup. No patient experienced any side effects, including kidney stone recurrence, while taking vitamin D.

Serum and 24hr urine parameters before and after vitamin D repletion (mean±SD)

	Baseline	Follow-up	p-value
U Calcium (mg)	257±54	255±88	0.91
U Oxalate (mg)	42±18	41±15	0.84
U Sodium (mmol)	228±94	202±65	0.23
U Creatinine (mg)	1896±479	1880±468	0.74
25(OH)D (ng/ml)	17±6	35±10	<0.0001
Serum Calcium (mg/dl)	9.3±0.4	9.4±0.4	0.69
PTH (pg/ml)	46±25	48±29	0.61

Conclusions: Among stone-formers with vitamin D deficiency and moderate levels of hypercalciuria, vitamin D repletion does not appear to increase UCa excretion. Vitamin D therapy, if indicated, should not be withheld on the basis of prior stone disease.

SA-OR357

Dietary Calcium Regulates SLC26A6-Mediated Oxalate Secretion Felix Knauf, Robert Brent Thomson, Peter S. Aronson. *Section of Nephrology, Yale University School of Medicine, New Haven, CT.*

Background: Dietary calcium intake is an important determinant of urinary oxalate excretion and risk for calcium-oxalate nephrolithiasis. Net intestinal absorption of dietary oxalate results from passive paracellular oxalate absorption as modified by SLC26A6-mediated back-secretion of oxalate. It has been postulated that dietary calcium restriction leads to increased oxalate absorption by reducing precipitation of oxalate with calcium in the lumen of the intestine, thereby increasing soluble oxalate available for absorption. We tested the hypothesis that dietary calcium also modulates net oxalate absorption by regulating SLC26A6-mediated oxalate secretion.

Methods: Wild-type mice were fed either a regular or low calcium diet. After 2 weeks the duodenum was harvested and probed for SLC26A6 protein expression normalized to actin by Western blot analysis. Active secretion of [14C]-oxalate was measured in vitro across isolated intestinal tissue mounted in Ussing chambers and bathed in standard calcium-containing Ringers solutions. To determine if the effect of lowering dietary calcium is specific for active oxalate secretion, active [14C]-glucose absorption was also assayed. Mannitol permeability and total tissue conductance were measured as markers of paracellular permeability.

Results: Mice fed a low calcium diet showed a 70% reduction of intestinal SLC26A6 protein abundance as compared with animals fed a regular calcium diet. Active oxalate secretion was reduced by 50% in intestinal tissue isolated from mice fed a low calcium diet compared to intestine from mice on a regular diet. Glucose absorption was not changed by modifying dietary calcium, indicating that the effect of a low calcium diet to reduce oxalate secretion is not the result of a general downregulation of intestinal transport processes. Paracellular permeability as measured by mannitol permeability and tissue conductivity was unaffected by dietary calcium.

Conclusions: We demonstrate that dietary calcium regulates SLC26A6-mediated oxalate secretion in the intestine. Downregulation of SLC26A6 may contribute to the increased net absorption of dietary oxalate that results from ingestion of a low calcium diet.

Increased Sensitivity to 1,25$(OH)_2D_3$ in Genetic Hypercalciuric Stone-Forming Rats Kevin K. Frick,[1] John R. Asplin,[2] Christopher D. Culbertson,[1] Daniel M. Asplin,[2] Nancy Krieger,[1] David A. Bushinsky.[1] *[1]Medicine, University of Rochester, NY; [2]Litholink Corporation, Chicago, IL.*

Background: Genetic hypercalciuric stone-forming (GHS) rats, bred to maximize urine (U) calcium (Ca) excretion, exhibit increased intestinal Ca absorption, increased bone resorption and reduced renal tubular Ca reabsorption, all leading to increased UCa compared to controls and all form kidney stones. GHS rats express an increased number of vitamin D receptors (VDR) at these sites of disordered Ca transport.

Methods: To determine if the excess VDR is biologically active, we fed GHS rats a Ca replete diet (NCD, 1.2% Ca) and injected 1,25$(OH)_2D_3$ (1,25D, 25 ng/d) or vehicle (veh) for 9 d. To determine if GHS rats would also show increased UCa in the absence of 1,25D-induced intestinal Ca absorption, GHS and SD rats were fed a low Ca diet (LCD, 0.02%) and again injected with 1,25D or veh for 9 d. To help understand the greater increase in UCa in response to 1,25D in GHS than SD, we measured kidney RNA expression of components of renal tubular Ca transport in the low Ca diet study.

Results: When fed NCD, with 1,25D, UCa in SD increased from 1.7±0.3 mg/d to 24.4±1.2 and in GHS from 10.5±0.7 to 41.9±0.7 and PTH was suppressed to undetectable levels in both groups (all groups n=8, mean ± SEM, all comparisons $p<0.01$). When fed LCD, with 1,25D, UCa in SD increased from 1.3±0.1 mg/d to 9.4±0.9 and in GHS from 4.7±0.3 to 21.5±0.9 and PTH was again suppressed in both groups (all n=8, all comparisons $p<0.02$). When fed LCD, expression of the distal luminal renal Ca transporter TRPV5 and the transcellular Ca transport protein calbindin D_{28k} were both elevated by 1,25D in SD but not GHS rats, consistent with less renal tubular Ca reabsorption in GHS than SD, resulting in greater hypercalciuria.

Conclusions: In both studies, the marked increase in UCa with 1,25D in GHS, which exceeded the increase in SD, indicates that the increased VDR in GHS results in greater biological response to administered 1,25D. In the absence of appreciable dietary Ca, the greater UCa in the GHS rats compared to SD may be secondary to a decrease in distal renal tubular Ca reabsorption mediated by TRPV5.

Randall's Plaques Are Aggregates of Spherical and Elongated Striated Units of Poorly Crystalline Biological Apatite Saeed R. Khan, Manoj Monga. *Pathology, Immunology and Laboratory Medicine, University of Florida, Gainesville, FL.*

Background: Idiopathic calcium oxalate (CaOx) kidney stones develop by deposition of CaOx crystals on Randall's plaques (RP). Mechanisms involved in RP formation are still unclear. It is our hypotheses that RP formation is similar to vascular calcification involving components of extracellular matrix including membrane bound vesicles and collagen fibers. In order to verify our hypothesis we critically examined renal papillary tissue from stone patients obtained at time of stone removal.

Methods: Cold-cup biopsy of renal papilla was performed on 10 idiopathic stone patients undergoing PCNL. Kidney tissue was immediately fixed and processed for light and electron microscopy. All samples were examined by light and transmission electron microscopy (TEM). Some were also examined by scanning electron microscopy (SEM). Energy dispersive x-ray microanalyses and electron diffraction were utilized to identify the crystals.

Results: Multi-laminated spherulitic CaP deposits, the hallmark of RP's, were seen by TEM in interstitium as well as laminated basement membrane of tubular epithelia. In addition CaP crystals were also organized as bundles of elongated striated fibers. Both crystal types were associated with collagen fibers and membrane bound vesicles. Many such vesicles either contained or associated with needle shaped crystals. Some of the striated interstitial crystals were closely aligned with collagen fibers.

Conclusions: Randall's plaques comprise of two types of crystal deposits, the well known spherical units as well as bundles of striated fibers. Both types of deposits are associated with collagen fibers as well as membrane bound vesicles. The vesicles contained needle shaped crystals. We conclude that crystal deposition in renal papillae may start with membrane vesicle induced nucleation and grows by mineralization of interstitial collagen fibers. Similar mechanism has been proposed for calcium phosphate crystal deposition elsewhere in the body.

Six1 Is a Key Mediator of TGF-beta Induced Renal Fibrosis Arthur Chi-Kong Chung,[1] Xiang Zhong,[1,2] Hui Y. Lan.[1,3] *[1]Li Ka Shing Institute of Health Sciences, Chinese University of Hong Kong, Shatin, NT, Hong Kong; [2]Department of Chemical Pathology, Chinese University of Hong Kong, Shatin, NT, Hong Kong; [3]Department of Medicine and Therapeutics, Chinese University of Hong Kong, Shatin, NT, Hong Kong.*

Background: TGF-β/Smad3 signaling is a key pathway that mediates renal fibrosis. However, mechanisms that control the fibrotic gene expression during fibrosis remained unclear. The present study tested the hypothesis that Six1 mediated Smad3-dependent renal fibrosis.

Methods: Six1 expression in tubular epithelial cells (TECs) after TGF-β treatment and diseased kidney was examined by Realtime PCR. The functional role of Six1 in renal fibrosis was determined in vitro by using overexpression and knockdown cell lines of Six1, and in vivo by delivering Six1 overexpression and knockdown plasmid in the obstructive kidneys by ultrasound-microbubble gene transfer system. Expression levels of the fibrotic markers were examined by Realtime PCR and Western blot analyses.

Results: Activation of TGF-β/Smad signaling was necessary for upregulation of Six1 in the fibrotic kidney and TECs in response to TGF-β. Enhanced TGF-β/Smad signaling in Smad7 knockout mice promoted Six1 expression and fibrosis in obstructive nephropathy. In addition, TGF-β induced Six1 expression in time- and dosage-dependent manner. This induction is mediated by Smad3, but not Smad2, because cells lacking Smad3, not Smad2, were protected from upregulation of Six1 and fibrosis in obstructive nephropathy, as well as in TGF-β1-stimulated renal TECs and mouse embryonic fibroblasts. Furthermore, overexpression of Six1 promoted but knockdown of Six1 expression suppressed TGF-β1-induced renal fibrosis in TECs. More importantly, delivery of Six1 knockdown plasmid ameliorated renal fibrosis in mouse model of obstructive kidney diseases, as evidence with reduction of expression of collagen I, fibronectin and α-smooth muscle actin.

Conclusions: Six1, a critical downstream mediator of TGF-β/Smad3 signaling, plays an essential role for renal fibrosis in response to TGF-β1. Targeting Six1 may be an effective therapeutic approach to combat renal fibrosis.

miR-302 Regulation of TGFβ/CTGF Signaling by TGFβ Type II Receptor Targeting: Prospective Data from the UUO Mouse Model Noel Faherty,[1] Simon Curran,[1] Helen O'Donovan,[1] Noelynn Oliver,[4] Catherine Godson,[1] Derek Brazil,[3] John Crean.[1] *[1]UCD Diabetes Research Centre, University College Dublin, Dublin, Ireland; [2]Centre for Vision and Vascular Science, Queen's University Belfast, United Kingdom; [3]FibroGen Inc, San Francisco, CA.*

Background: Signaling interplay between Connective Tissue Growth Factor (CTGF) and Transforming Growth Factor-β1 (TGFβ) is believed to play a role in the progression of glomerulosclerosis in diabetic nephropathy. We demonstrate a mechanism of regulation of TGFβ signalling via CTGF induced microRNA expression and present in vivo data on microRNA expression and signaling activity.

Methods: Expression of microRNAs in human mesangial cells (HMC) in response to treatment with CTGF was determined, target analysis identified putative gene targets. Expression of microRNA and signaling mediators in the 10 day unilateral ureteral obstruction (UUO) mouse model was investigated.

Results: TGFβ receptor II (TβRII) was determined to be a putative target of the miR-302 family, three members of which were increased in expression by CTGF. CTGF decreased expression of TβRII in HMCs concomitantly with increasing levels of miR-302d, as a proxy readout for miR-302 activity. We validated TβRII as a miR-302d target and inhibited miR-302d to attenuate CTGF dependent changes in TβRII levels. Further, we found a relevant signaling context for miR-302 family members, with attenuation of canonical Smad signaling and induction of non-canonical signaling associated with differential expression of miR-302d. In the UUO mouse model, miR-302d expression was increased with a coincident decrease in TβRII, suggesting pathophysiological significance. Decreased expression of the TGFβ type I receptor (TβRI) and an apparent dichotomy between decreased Smad2 and increased Smad3 phosphorylation was also observed.

Conclusions: Opposing levels of activated Smad2 and Smad3 lends support to the hypothesis that differential activity of both Smads is tacit in the progression of fibrosis. Further, the apparent lower levels of TβRI raise the intriguing possibility of chronic Smad3 phosphorylation and fibrotic damage in the UUO mouse being, at least in part, TGFβ receptor independent.

Direct Interaction of the Adapter Protein Dok-4 with Elk-4: A Novel Mechanism for Inhibition of Tyrosine Kinase-Induced Transcription Erika Hooker,[1] Cindy Baldwin,[1] Serge Lemay.[1,2] *[1]Experimental Medicine, McGill University, Montreal, QC, Canada; [2]Medicine (Nephrology), McGill University Health Centre, Montreal, QC, Canada.*

Background: Dok-4 is an adapter protein expressed in epithelial cells and one of 7 members of the Dok family. Whereas Dok-1, 2, and 3 inhibit Src family kinase (SFK) signaling in immune cells by recruiting inhibitory molecules (Csk, p120 RasGAP, and Ship1), the role and mechanism of action of Dok-4 remain obscure because the identity of its partner molecules is unknown. We previously showed that, in epithelial cells, Dok-4 can inhibit the transcription factor (TF) Elk-1, presumably through inhibition of the upstream Erk pathway.

Methods: To better define the mechanism of action of Dok-4 in renal epithelial cells, we sought to identify Dok-4-associated proteins and to define the impact of any such interactions on SFK signaling. We performed a yeast two-hybrid (Y2H) screen with Dok-4 as bait in a mouse kidney library. Subsequent validation was performed in transiently transfected 293 and MDCK cells using co-IP, immunofluorescence localization and a luciferase-based transactivation assay.

Results: Y2H screening identified 6 independent preys representing the C-terminal region of the Elk-1-related TF, Elk-4. Dok-4 and Elk-4 also co-immunoprecipitated in 293 cells. A Gal4-Elk-4 chimera was constructed to assess the impact of SFK and Dok-4 on Elk-4-mediated transactivation of a gal4-luciferase reporter. Elk-4 was exquisitely sensitive to activation by overexpressed SFKs and this was potently and dose-dependently inhibited by co-expression of Dok-4. Inhibition of Elk-4 by Dok-4 correlated with exclusion of Gal4-Elk-4 from the nucleus and its co-localization with Dok-4. Finally, we identified a canonical nuclear export signal in Dok-4, suggesting nucleo-cytoplasmic shuttling of Dok-4.

Conclusions: Elk-4 is a prominent target of activation by SFK and is potently inhibited by Dok-4, in part through a direct interaction with Dok-4. Direct interaction of Dok-4 with a TF represents a novel mechanism of adapter protein action in SFK signaling. Dok-4/Elk-4 interaction may serve to directly and specifically modulate tyrosine kinase-induced transcriptional responses in epithelial cells.

Tyrosine Phosphorylation Sites Y4/8/10 of CD2AP Determine Binding to Nephrin Irini Schaefer, Beina Teng, Kirstin Worthmann, Hermann G. Haller, Mario Schiffer. *Nephrology, Medical School Hannover, Hannover, Germany.*

Background: CD2AP is an adaptor protein that can transmit intracellular signals involved in survival and cytoskeletal regulation of the cell. Until now it is unknown if the activation of CD2AP and its potential to interact with multiple downstream effectors is regulated by phophorylation. The aim of these studies was to identify tyrosine-phosphorylation sites of CD2AP and to analyze in detail if the phosphorylation of these residues are of fundamental importance.

Methods: First we analyzed a potential phosphorylation of CD2AP by 2D-gel-electrophoresis and immunoprecipitation. By alignment of CD2AP of different species we analyze potential tyrosine residues that are evolutionary conserved. To explore if these sites are important for nephrin binding we created CD2AP Tyrosine-mutants and performed immunoprecipitations. Furthermore we generated phospho-specific polyclonal antibodies for these sites.

Results: We can demonstrate a significant shift of the isoeletrical point of CD2AP after VEGF-stimulation. Endogenous immunoprecipitation of CD2AP showed specifically that CD2AP is tyrosine-phosphorylated. Highly conserved tyrosine residues are on position Y4/8/10, Y119 and Y273/280. Cotransfection of the generated CD2AP mutants with nephrin showed a significantly enhanced binding of nephrin to the triple mutant Y4/8/10 compared to WT-CD2AP and to the Y119 and Y273/280 mutants. Stimulation of podocytes with several cytokines showed a typical phosphorylation profile of phosphorylated CD2AP with the generated antibodies. Immunofluorescence of cryosections of mouse and human reveal that the phospho-specific antibodies against Y119 and Y273/280 showed a specific slit diaphragm staining whereas the phospho-specific antibody against Y4/8/10 showed a more cytosol-specific staining. Confocal microscopy with the phospho-specific antibody against Y4/8/10 on murine and human podocytes showed after stimulation with VEGF a colocalization of phospho-CD2AP spots with actin-endings especially at the leading edge.

Conclusions: These results indicate that CD2AP is a tyrosine phosphorylated protein and that phosphorylation on Y4/8/10 determine localization of CD2AP and thereby interaction with nephrin.

SA-OR364

p38-alpha Phosphorylates Nephrin and Induces Its Endocytosis Via Association with beta-arrestin2 Magdalena Woznowski, Sebastian Alexander Potthoff, Eva Koenigshausen, Johannes Stegbauer, Lars C. Rump, Lorenz Sellin, Ivo Quack. *Nephrology, Heinrich-Heine University, Duesseldorf, Germany.*

Background: Podocyte damage leads to foot process retraction, disruption of the slit diaphragm and proteinuria. Human acquired glomerulopathies and diabetic nephropathy are associated with TNF-alpha elevation. Especially the TNF-alpha activated MAPK p38 is known to play a critical role in mediating podocyte injury. Recent advances have also revealed crucial roles of slit diaphragm-associated proteins, including nephrin, podocin and beta-arrestin2. In this regard, beta-arrestin2 was shown to associate with nephrin, leading to nephrin endocytosis and thereby causing proteinuria.

Methods: GST-nephrin fusion proteins containing different fragments of the nephrin cytoplasmatic domain were used in a radioactive kinase assay with recombinant p38. In addition, nephrin mutants containing point mutations of putative p38 phosphorylation sites were generated and tested in these kinase assays. Expression plasmids for nephrin and its mutants as well as for beta-arrestin2 were transfected into HEK293T cells, which were subsequently treated with TNF-alpha. After cell lysis, coimmunoprecipitation with subsequent western blot analysis was performed.

Results: TNF-alpha treatment of podocytes or HEK293T cells leads to a rapid activation of the MAPK p38. Interestingly, nephrin is phosphorylated by p38alpha at Ser 1146. The nephrin mutant S1146A, which is not phosphorylated by p38 anymore, is impaired in its ability to associate with beta-arrestin2 and demonstrate less TNF-alpha-mediated endocytosis. On the other hand, a phospho-mimicry mutant S1146D shows a stronger interaction with beta-arrestin2 and increased endocytosis.

Conclusions: TNF-alpha induces nephrin/ beta-arrestin2 association and nephrin endocytosis. The MAPK p38 acts as a crucial mediator in this regard via phosphorylation of nephrin, thereby regulating its presence in the slit diaphragm. This could represent an important molecular mechanism responsible for TNF-alpha-mediated podocyte damage. In addition, this suggests that inhibition of p38 via pharmacological intervention could protect against inflammation-induced proteinuria.

SA-OR365

Functional Excitatory and Inhibitory Aminoacid Receptors in Primary Cultured Podocytes Maria Pia Rastaldi,[1] Anna Mondini,[1,2] Min Li,[1] Silvia Armelloni,[1] William J. Wilkinson,[2] Piergiorgio Messa,[1] Paul J. Kemp.[2] *[1]Renal Research Laboratory, Fondazione IRCCS Policlinico & Fondazione D'Amico, Milan, Italy; [2]School of Biosciences, Cardiff University, Cardiff, United Kingdom.*

Background: We showed that podocytes express several types of receptors, second messenger systems and proteins usually associated with synaptic communication between neurons. Such information suggests that podocytes have the potential to respond to external stimuli and transduce these signals into rapid, coordinated responses. Although there is molecular evidence for expression of these channels and receptors, almost no data are available which have functionally characterised them in primary podocytes.

Methods: By means of intracellular calcium imaging using the Ca2+-sensitive fluorescent dye Fura-2, we investigated the functional expression in primary cultured podocytes of a wide array of proteins typically involved in neuronal synaptic functions.

Results: Using this approach, we defined the functional expression of the three main subtypes of ionotropic glutamate receptors, by recording increases in [Ca2+]i in response to brief (10s) exposures of primary podocytes to: glutamate (100μM); kainate (100μM); N-methyl-D-aspartic acid (NMDA - 100μM); α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA - 50 μM). Furthermore, both GABAA and GABAB receptors were functionally present, since exposure of cells to GABA (γ-amino butyric acid - 300 μM) evoked an increase in [Ca2+]i which was only partially attenuated upon removal of extracellular Ca2+. Interesting, the rise in [Ca2+]i upon GABAA receptor activation shows that the result of opening Cl- channels in these cells is cell depolarisation and consequent Ca2+ entry through voltage-gated Ca2+ channels, a notion fully supported by the ability of 50 mM extracellular K+ to evoke a large increase in [Ca2+]i.

Conclusions: Our new data provide functional evidence for the existence of kainate, AMPA, NMDA, GABAA and GABAB receptors in primary podocytes and further support the idea that these cells have the potential to respond to external stimuli in a manner which appears similar to that normally associated with neuronal signalling.

Signaling through the NF-kB Essential Modulator NEMO Triggers Podocyte Migration and Prolongs Proteinuria in a Nephrotoxic Nephrits Model Sebastian Braehler,[1] Henning Hagmann,[1] Christina Ising,[1] Friedrich Thaiss,[2] Stuart J. Shankland,[3] Bernhard Schermer,[1] Thomas Benzing,[1] Paul T. Brinkkoetter.[1] *[1]Department of Nephrology, University of Cologne, Germany; [2]Department of Nephrology, University Hospital Hamburg, Hamburg, Germany; [3]Department of Nephrology, University of Washington, Seattle, WA.*

Background: Inflammatory diseases lead to glomerular injury and are a major cause of proteinuria. The Nuclear Factor kappaB is one of the most important regulators of pro-inflammatory signaling. Its role in podocytes, however, is only poorly understood. In this study we inhibited NF-kB signaling in podocytes in vivo by specific ablation of the essential modulator Nemo.

Methods: Nemo flox/flox;Podocin cre/wt mice were viable and showed no proteinuria or changes in kidney morphology under non-stressed conditions. In a nephrotoxic nephritis model both KO and wild-type mice developed severe proteinuria within 3 days. At day 7 KO mice recovered faster and showed decreased levels of proteinuria compared to wild-type littermates. There were no differences in infiltrating inflammatory cells. However, immunohistochemistry and electronmicroscopy revealed restoration of the slit diaphragm morphology in KO mice while wild-type showed significant foot-process effacement.

Results: To address the mechanisms that underlie this beneficial phenotype we established a Nemo-knockdown podocyte culture system. Knockdown of Nemo resulted in reduced production of pro-inflammatory chemokines. In addition, reduced NF-kB activity led to decreased phosphorylation of ERK1/2-MAP-kinases in vitro and reduced cellular migration. Inhibitor studies were carried out to link inactivation of ERK1/2 to the stationary phenotype of Nemo-knockdown podocytes. Our results showed that inhibiting ERK1/2 activation blocked the migratory phenotype in wild-type cells comparable to Nemo-knockdown podocytes.

Conclusions: In conclusion, signaling through Nemo might not only be involved in the production of proinflammatory molecules in inflammatory conditions but also regulates podocyte mobility and structure through activation of MAPK. This pathway might represent a key regulator of podocyte migration in states of disease.

SA-OR367

Dietary Acid Reduction with Added Fruits and Vegetables or Oral Bicarbonate Preserves GFR in Subjects with CKD Stage 4 GFR Nimrit Goraya,[1,2] Chanhee Jo,[3] Donald E. Wesson.[1,2] *[1]Medicine, Texas A & M College of Medicine, Temple, TX; [2]Medicine, Scott & White Healthcare, Temple, TX; [3]Biostatistics, Scott & White Healthcare, Temple, TX.*

Background: Subjects with hypertensive nephropathy (HN) have progressive GFR decline despite blood pressure reduction with ACE inhibition but dietary acid reduction with oral alkali helps preserve GFR in HN patients with moderately reduced GFR. We explored if dietary acid reduction also preserves GFR in HN with severely reduced eGFR (CKD 4 = 15-29 ml/min) and if doing so with base-inducing fruits and vegetables (F+V) was as effective as $NaHCO_3$.

Methods: Subjects with CKD 4 on ACE inhibition were given F+V in an amount designed to reduce potential renal load by 50% (N=36) or oral $NaHCO_3$ at 1.0 meq/ kg lean body weight/day(N=35) and compared to time control subjects without dietary intervention (N= 35). Entry and follow up cystatin C-calculated eGFR (cysGFR), systolic blood pressure (SBP), and plasma potassium (P_K) were measured after one year.

Results: At entry, mean cysGFR was not different among groups (F+V=21.6 ± 4.6 ml/min, $NaHCO_3$ = 21.7 ± 3.4 ml/min, and time control = 21.5 ± 3.0 ml/min) but after 1 year, cysGFR was higher in both intervention groups (F+V =20.7 ± 4.7 ml/min, $NaHCO_3$ = 20.3 ± 3.2 ml/min) than time control (17.6 ± 2.5 ml/min, p<0.002 vs. F+V and $NaHCO_3$). SBP at study entry was not different among groups (F+V =136.3 ± 4.8 mmHg, $NaHCO_3$ = 136.1 ± 4.7 mm Hg and time control =137.0 ± 4.3 mmHg) but follow up SBP was lower than at entry in F+V (-4.6 ± 3.8 mmHg, p <0.001 vs. entry) and was not statistically different from the entry value at follow up for the remaining groups. Despite an increase in urinary potassium excretion with F+V, P_K was not statistically different at follow up compared to the entry value (net change = 0.01 ±0.12 meq/ml, p=0.593).

Conclusions: Dietary acid reduction is an effective adjunct to conventional therapy in preserving GFR in CKD stage 4 HN and doing so with F+V compared to $NaHCO_3$ does not increase P_K and appears to have the added cardiovascular benefit of SBP reduction.

Estimated Net Endogenous Acid Production and Chronic Kidney Disease Progression in African Americans: The African American Study of Kidney Disease and Hypertension (AASK) Julia J. Scialla,[1] Lawrence J. Appel,[1] Brad C. Astor,[1] Edgar R. Miller,[1] Srinivasan Beddhu,[2] Mark Woodward,[3] Rulan S. Parekh,[4] Cheryl A. Anderson.[1] *[1]Johns Hopkins University; [2]University of Utah; [3]University of Sydney; [4]University of Toronto.*

Background: In CKD, increases in per nephron acid excretion needed to counteract the daily dietary acid load may promote renal injury and contribute to disease progression.

Methods: We evaluated the association between the net endogenous acid production (NEAP) determined by the diet, and rates of GFR decline in 632 African Americans with hypertensive CKD from the AASK Trial. Estimated NEAP was calculated from complete 24 hour urine specimens, collected between 12 and 36 months post-randomization, in participants not taking potassium or alkali supplements. Protein and potassium intake were estimated from 24 hour urea nitrogen and potassium excretion, respectively. Estimated NEAP was calculated as previously described: NEAP (mEq/d) = -10.2 + 54.5 [protein intake (g/d) / potassium intake (mEq/d)]. NEAP estimates were averaged to approximate baseline habitual dietary intake (49% of participants had 3 or more measures). I^{125}iothalamate glomerular filtration rate (iGFR) was measured every 6 months over follow up (average 6.9 iGFR measures per participant). The association between estimated NEAP and slope of iGFR from 12 months post-randomization was determined using linear mixed models with adjustment for randomized drug and blood pressure groups, and categories of age, body mass index, baseline GFR and proteinuria on iGFR slope.

Results: Median baseline iGFR was 48.6 (IQR 36.6 - 58.5) mL/min/1.73 m^2. In unadjusted and adjusted models there was a faster rate of decline in iGFR among those in higher quartiles of estimated NEAP (p-trend=0.05 and 0.01, respectively).

iGFR slopes (mL/min/1.73m2/year) by quartiles of estimated NEAP

Quartile (mEq/d)	Unadjusted absolute slope	Adjusted difference from Q1	p-value
1 (18.2 – 57.1)	-1.45	Ref	--
2 (57.2 – 72.8)	-2.11	-0.69	0.08
3 (72.9 – 89.5)	-2.25	-0.85	0.03
4 (89.6 – 232.5)	-2.34	-1.01	0.01
p-trend	0.05	0.01	--

Conclusions: In conclusion, a dietary pattern resulting in higher NEAP may contribute to faster rates of CKD progression.

SA-OR369

Moderate Sodium Diet Potentiates the Renal and Cardiovascular Protective Effects of Angiotensin Receptor Blockers: A Post-Hoc Analysis of the RENAAL and IDNT Trials Hiddo Jan Lambers Heerspink,[1] Frank Holtkamp,[1] Eberhard Ritz,[2] Hans-Henrik Parving,[3] Gerjan Navis,[1] Dick de Zeeuw.[1] *[1]Clinical Pharmacology, University Medical Center Groningen, Groningen, Netherlands; [2]Medical Endocrinology, University Hospital Copenhagen, Copenhagen, Denmark; [3]Internal Medicine, University of Heidelberg, Germany.*

Background: Dietary sodium restriction has been shown to enhance the short-term response of blood pressure and albuminuria to Angiotensin Receptor Blockers (ARBs). Whether this also enhances the long-term renal and cardiovascular protective effects of ARBs is unknown. We conducted a post-hoc analysis of the RENAAL and IDNT trials to test this hypothesis.

Methods: Patients with type 2 diabetes and nephropathy were randomized to ARB or non-Renin-Angiotensin-Aldosterone-System based antihypertensive therapy (control therapy). Treatment effects on renal and cardiovascular outcomes were compared in tertiles of dietary sodium intake, measured as on-treatment 24-hour urinary sodium:creatinine ratio (Na/Cr ratio).

Results: The analysis included 1177 subjects. Urinary sodium excretion was 152 (76), 179 (82) and 209 (90) mmol/24h in the tertiles of increasing Na/Cr ratio. ARB compared with control therapy had the greatest short-term effects in albuminuria and blood pressure in the lowest tertile of Na/Cr ratio. ARB also had the largest long-term effects on renal and cardiovascular events in the lowest Na/Cr tertile. The risk for renal events was reduced by 43% (95%CI 16 to 61), 0% (-42 to 30) and increased by 37% (-4 to 96) in subsequent Na/Cr tertiles respectively (p for trend <0.001). Cardiovascular events were reduced by 37% (8 to 57), and increased by 2% (-27 to 43) and 25% (-11 to 75), respectively (p for trend 0.021).

Conclusions: Reduced dietary sodium intake was associated with enhanced renal and cardiovascular protective treatment effects of ARB therapy as compared with control therapy in type 2 diabetic patients with nephropathy. Remarkably, the large difference in outcome occurred despite a liberal sodium intake even in the lowest tertile. This underscores the call for action to avoid high dietary sodium intake, particularly in type 2 diabetic patients who are receiving ARB therapy.

High Dietary Fiber (DF) Intake Is Associated with ↓Inflammation and Mortality in CKD: National Health and Nutrition Examination Survey (NHANES) III Vidya M. Raj Krishnamurthy,[1,2] Guo Wei,[2] Michel B. Chonchol,[3] Kalani L. Raphael,[1,2] Tom H. Greene,[1,2] Srinivasan Beddhu.[1,2] *[1]VA; [2]Univ Utah, SLC, UT; [3]Univ CO, CO.*

Background: Chronic kidney disease (CKD) is considered an inflammatory state and it is unknown whether high DF intake is associated with a ↓risk of inflammation and mortality in the CKD population.

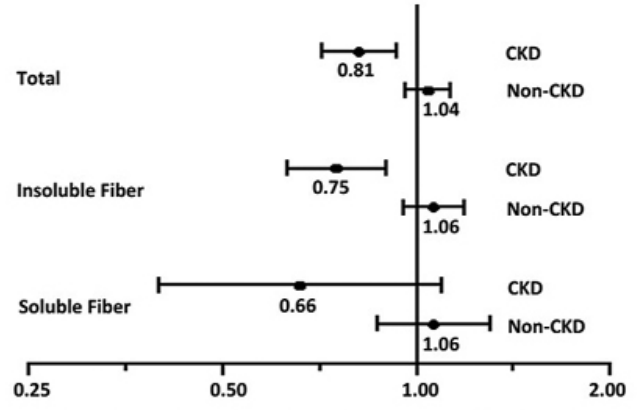
Methods: 14,543 NHANES III participants were studied. DF intake was assessed by standardized 24 h diet recall conducted by trained personnel. Mortality data were obtained by probabilistic matching with vital records.

Results: The mean age was 45.0 ± 15.8 yrs. 48% were men and 10% were black. 5.8% had CKD (eGFR < 60 ml/min/1.73 m2) and 25.7% had inflammation (serum CRP >3mg/L). The associations of DF in CKD and non-CKD groups with inflammation are summarized in the table and mortality in the figure.

Relationship of elevated serum CRP (> 3 mg/L) with DF in non-CKD and CKD

	Non-CKD	CKD
For each 10 g/d ↑ in total fiber	0.89 (0.83, 0.97)	0.62 (0.50, 0.77)
For each 10 g/d ↑ in insoluble fiber	0.87 (0.78, 0.96)	0.55 (0.42, 0.74)
For each 10 g/d ↑ in soluble fiber	0.72 (0.58, 0.90)	0.26 (0.13, 0.53)

Each cell represents a logistic regression model adjusted for demographics, MI, CHF, stroke, cancer, smoking, alcohol use, physical inactivity, SBP, DBP, calorie intake, protein intake, serum triglycerides, HDL and LDL cholesterol



Hazard Ratio for each 10 g/day increase in each type of fiber intake in CKD and non-CKD subpopulations

Models adjusted for age, gender, race, smoking, alcohol, leisure time physical inactivity, calorie intake and protein intake

The relationships of total fiber with elevated CRP and with mortality differed significantly between the non-CKD and CKD groups (p=0.002 for CRP and p=0.006 for mortality).

Conclusions: High DF intake is associated with lower risk of inflammation and mortality in CKD and these associations are stronger in magnitude in the CKD than in the non-CKD population. Increasing DF might decrease inflammation and mortality in the CKD population. Interventional studies are warranted to test this hypothesis.

SA-OR371

Lifestyle Factors and the Development of Stage 3 Chronic Kidney Disease in the Framingham Heart Study

Meredith C. Foster,[1] Shih-Jen Hwang,[1] Paul F. Jacques,[2] Caroline S. Fox.[1,3] *[1]Framingham Heart Study, Framingham, MA; [2]Tufts University, Boston, MA; [3]Harvard Medical School, Boston, MA.*

Background: Modifiable lifestyle factors may be targeted as part of stage 3 chronic kidney disease (CKD) prevention. We sought to investigate the association of these factors with the development of stage 3 CKD in the Framingham Offspring cohort.

Methods: Participants (n=1802, mean age 59 years, 54% women) attended Offspring Exams 7 (1998-2001) and 8 (2005-08) and were free of baseline stage 3 CKD (baseline estimated glomerular filtration rate [eGFR] ≥60mL/min/1.73m²). Lifestyle characteristics were measured at baseline and included diet quality assessed using the 2005 Dietary Guidelines for Americans adherence index (DGAI), physical activity index (PAI), alcohol intake (none, low-to-moderate, high), and current smoking status. The MDRD Study equation was used to determine eGFR; incident stage 3 CKD was defined as eGFR<60mL/min/1.73m² at Exam 8 and was modeled using logistic regression.

Results: Over 6.6 years of follow-up, 7.7% (n=139) of participants developed stage 3 CKD. Higher levels of dietary quality were associated with a decreased odds ratio [OR] of stage 3 CKD (Table; DGAI Quartile 4 vs. Quartile 1: OR 0.43, p=0.004; DGAI Quartile 3 vs. Quartile 1: OR 0.57, p=0.04). We did not observe associations with physical activity, smoking status, or alcohol intake with stage 3 CKD (Table, all p>0.25).

	OR (95% CI)	p
Dietary quality (DGAI)		
Quartile(Q) 1	1.0 (referent)	
Q2	0.71 (0.43-1.19)	0.20
Q3	0.57 (0.33-0.97)	0.04
Q4	0.43 (0.25-0.76)	0.004
Physical activity index (PAI)		
Q1	1.0 (referent)	
Q2	1.09 (0.64-1.86)	0.76
Q3	0.83 (0.48-1.45)	0.51
Q4	1.10 (0.65-1.88)	0.72
Current Smoker		
No	1.0 (referent)	
Yes	1.04 (0.53-2.04)	0.92
Alcohol Consumption		
None	1.0 (referent)	
Low-to-moderate	0.92 (0.61-1.39)	0.70
High	0.71 (0.39-1.27)	0.25

*Model covariates included all lifestyle factors simultaneously, age, sex, baseline eGFR, body mass index, hypertension, diabetes, and dipstick proteinuria.

Conclusions: Higher dietary quality is associated with a decreased risk of incident stage 3 CKD. Whether dietary modifications can prevent stage 3 CKD warrants further study.

Funding: Other NIH Support - The Framingham Heart Study is supported by the National Heart, Lung and Blood Institute (N01-HC-25195).

Vitamin D Levels and Chronic Kidney Disease Progression: A CRIC Study

Mary B. Leonard,[1] Wei Yang,[1] Dawei Xie,[1] Myles S. Wolf,[2] Harold I. Feldman.[1] *[1]University of Pennsylvania; [2]University of Miami.*

Background: Studies of vitamin D receptor agonist (VDRA) therapy in animal models of kidney disease demonstrated reductions in albuminuria and amelioration of progression of podocyte injury. A recent randomized controlled trial demonstrated that VDRA therapy was associated with reductions in proteinuria in patients with diabetic nephropathy. The objective of this study was to examine the associations between vitamin D levels and chronic kidney disease (CKD) progression in CRIC participants.

Methods: Vitamin D levels were available in 1560 participants (44% diabetic) at Year 1 with a median (interquartile range [IQR]) age of 62 (55-68) years and eGFR of 45 (34-54) ml/min/1.73m^2. Cox proportional hazards models were censored at death.

Results: Median (IQR) serum 25(OH)D levels were 27 (16-37) ng/mL and 1,25$(OH)_2$D levels were 27 (18-37) pg/mL. During a median follow-up of 4.7 (IQR 3.8-5.5) years, 167 participants reached ESRD (24.1/1000 person-years), and 207 reached the composite of end-stage renal disease (ESRD) or halving of eGFR (29.8/1000 person years). Higher serum 1,25$(OH)_2$D levels were associated with lower risk of ESRD [hazard ratio (HR) per 10 pg/mL greater 1,25$(OH)_2$D level: 0.78 (95%CI 0.66-0.91), p<0.01) and the composite outcome [HR 0.79 (0.69-0.90), p<0.01], adjusted for age, race, diabetes, season, systolic blood pressure and eGFR (Model 1). After further adjustment for proteinuria, PTH and FGF-23 levels (Model 2), the associations remained significant for ESRD [HR 0.84 (0.71-0.99), p=0.04] and the composite outcome [HR 0.86 (0.75-0.99), p=0.03). Higher serum 25(OH)D levels were also associated with lower risk of ESRD [HR per 10 ng/mL greater 25(OH)D 0.83 (0.73-0.96), p=0.01] and the composite outcome [HR 0.84 (0.74-0.94), p< 0.01) in Model 1; however, the results for ESRD [HR 0.95 (0.80-1.11)] and the composite outcome [HR 0.96 (0.84-1.11)] were no longer significant after adjustment in Model 2.

Conclusions: Higher vitamin D levels are associated with less CKD progression. The persistent 1,25$(OH)_2$D association after adjustment for multiple measures of CKD severity (proteinuria, PTH and FGF-23 levels) suggested minimal confounding by CKD severity.

Chronic Kidney Disease Awareness and Healthy Behaviors in the REasons for Geographic and Racial Differences in Stroke (REGARDS) Cohort

Delphine S. Tuot,[1] Suzanne E. Judd,[2] Paul Muntner,[2] Laura C. Plantinga,[1] Chi-Yuan Hsu,[1] David G. Warnock,[2] Orlando M. Gutierrez,[2] Monika M. Safford,[2] Neil R. Powe,[1] William M. McClellan.[3] *[1]University of California at San Francisco, CA; [2]University of Alabama at Birmingham, AL; [3]Emory University, Altanta, GA.*

Background: The association between chronic kidney disease (CKD) awareness and healthy behaviors is unknown. We examined whether CKD self-recognition is associated with behaviors that may slow CKD progression.

Methods: We conducted a cross-sectional analysis using baseline data from 3670 adults with CKD (eGFR <60 ml/min/1.73 m2) participating in REGARDS, a prospective cohort study of risk factors for stroke. CKD awareness was a "yes" answer to "Have you ever been told you have kidney disease?" Self-reported outcomes included current tobacco use, use of non-steroidal anti-inflammatory medications (NSAIDs), and angiotensin-converting enzyme inhibitor/angiotensin receptor blocker (ACEI/ARB) use, based on pill review. Measured outcomes included blood pressure control (<140/<90 mmHg) and among self-reported diabetics, glycemic control (fasting glucose <126 mg/dl). Multivariable logistic regression adjusted for sociodemographics, co-morbidities, eGFR and albumin-creatinine ratio was used to estimate the odds of each behavior in individuals aware vs. unaware of their CKD.

Results: Only 10% of individuals were aware of their CKD. Those who were aware had nearly 60% lower odds of current tobacco use compared to those unaware [adjusted odds ratio 0.43, 95%CI (0.22-0.87)]. However, CKD awareness was not associated with reduced NSAID use [0.77 (0.38-1.55)], ACEI/ARB use [1.24 (0.87-1.76)], or blood pressure control [1.06 (0.76-1.48)]. Among diabetics, CKD awareness was not associated with glycemic control [0.81 (0.60-1.43)] or ACEI/ARB use [0.92 (0.60-1.43)].

Conclusions: Awareness of CKD was associated with decreased current tobacco use but was not associated with greater odds of other healthy behaviors. While the cross-sectional design and potential misclassification of awareness by survey question may limit interpretation, results suggest that a more nuanced understanding of the association among patient knowledge, awareness, and behaviors is needed.

Association of Obesity and Kidney Function Decline in Persons without Chronic Kidney Disease: Multi-Ethnic Study of Atherosclerosis (MESA)
Anna Malkina,[1] Ronit Katz,[3] Michael Shlipak,[1,2] Ian H. de Boer,[3] Joachim H. Ix,[4] Mark J. Sarnak,[5] Julie Lin,[6] Matthew Allison,[4] Holly J. Kramer,[7] David Siscovick,[3] Carmen A. Peralta.[1,2] *[1]Univ California San Francisco; [2]SFVAMC; [3]Univ Washington; [4]Univ California San Diego; [5]Tufts Medical Center; [6]Harvard; [7]Loyola.*

Background: Obesity has been associated with increased risk for chronic kidney disease (CKD) in some studies. Whether anthropometric measures of obesity are associated with renal function decline prior to onset of CKD (defined as estimated glomerular filtration rate (eGFR)<60ml/min/1.73m2) is not well known.

Methods: We studied the association of body mass index (BMI), waist circumference (WC), waist/hip ratio (WHR), and percent adulthood weight change with kidney function decline among 5160 White, Black, Hispanic and Chinese adults without CKD. GFR was estimated by creatinine (eGFRCr) and cystatin C (eGFRCys) with repeated measures over five years. We adjusted for age, sex, race, hypertension, and diabetes.

Results: Mean age was 60±10 years, 48% men, baseline mean eGFRCr was 82±13 and eGFRCys 95±17 ml/min/1.73m2. Mean eGFRCr decline was 1.55 (SD 2.85) and eGFRCys 1.12 (4.37) ml/min/1.73m2 per year. Persons with high WHR(≥0.9 men; ≥0.7 women) had 20-30% faster decline by eGFRCr (β -0.22, 95%CI -0.38 to -0.06) and eGFRCys (β -0.34, -0.57 to -0.12) after adjustment, including BMI, compared to persons with normal WHR. Persons with larger waist circumference (≥ 102cm for men; ≥ 90cm for women) had moderately faster rates of decline: (β -0.10, (-0.20 to -0.01) by eGFRCr, and β -0.07, (-0.21 to 0.07) by eGFRcys). In contrast, compared to persons with BMI 19 to 25 kg/m2, only persons with BMI ≥ 35 had faster decline by eGFRCr (β -0.19 ml/min/1.73m2 per year, 95%CI -0.37 to -0.004), but not by eGFRCys (β 0.11, -0.15 to 0.37). Weight gain or loss was not associated with eGFR decline (all p>0.05).

Conclusions: Central obesity, rather than weight or BMI, is more consistently associated with kidney function decline among persons without CKD. Further studies with imaging measures of fat distribution are needed to further evaluate these associations as potential modifiable risk factors for CKD.

Funding: Other NIH Support - NHLBI, Veterans Administration Support

Physical Activity, Death and Kidney Function Decline in Chronic Kidney Disease
Cassianne Robinson-Cohen, Gregory Levin, Ian H. de Boer, Jonathan Himmelfarb, Bryan R. Kestenbaum. *Nephrology, Kidney Research Institute, Seattle, WA.*

Background: Physical activity promotes diverse metabolic benefits that may counteract the toxic biochemical environment of chronic kidney disease (CKD). We tested the hypotheses that greater physical activity levels are associated with lower risks of death and kidney disease progression in a prospective cohort study of stage III-IV CKD patients.

Methods: We studied 294 participants from the Seattle Kidney Study, a Nephrology clinic-based study of CKD, who had an estimated glomerular filtration rate (eGFR) of 15-59 mL/min/1.73 m2. Participants self-reported type, frequency, and intensity of physical activity (PA), and we converted these responses to metabolic equivalent task (MET) min/week. PA levels of 100 MET-min/week are equivalent to leisurely walking for 30 minutes per week. We used proportional hazards models to quantify associations of PA with time to death and Poisson regression models to estimate associations of PA with a 25% decline in kidney function, defined using longitudinal serum cystatin C.

Results: Mean eGFR at baseline was 42 mL/min/1.73 m2) and mean age was 62 years. During a median 2.6 years of follow-up, 42 participants died ((14.3%) 5.7 deaths/100 person-years). After adjustment for demographics, eGFR, prevalent coronary artery disease and functional status, PA levels of 100-500 MET-min/week and >500 MET-min/week were associated with 35% (95%CI -69%,+37%) and 43% (95%CI -79%,+53%) lower risks of death, respectively, compared to PA levels <100 MET-min/week. Among 206 participants who completed at least one follow-up kidney function measurement, 53 (26%) lost ≥25% of GFR (11.7 events/100 person-visits). After adjustment, the estimated risk of GFR decline was 15%(95%CI -50%,+46%) lower in the highest PA group, relative to the lowest group.

Conclusions: Greater physical activity levels trended toward being associated with lower risks of death and kidney function decline in a longitudinal study of CKD. Physical activity, at even moderate levels, may be sufficient to confer health benefits among CKD patients and is emerging as one of few modifiable risk factors for major adverse health outcomes in this high risk population.

A One-Year Lifestyle Intervention Improves Myocardial Function and Exercise Capacity in Patients with Chronic Kidney Disease
Erin Howden, Jeff S. Coombes, William G. Petchey, Nicole M. Isbel. *Centre for Clinical Research Excellence - Cardiovascular and Metabolic Disorders, University of Queensland, Brisbane, QLD, Australia.*

Background: Myocardial dysfunction (MD) is common in pts with chronic kidney disease. We sought the effect of a lifestyle intervention (LI) that included exercise training on MD and exercise capacity in CKD.

Methods: 83 pts with stage 3-4 CKD were randomized to standard care (control) or LI. LI included access to multidisciplinary care through a nurse practitioner led CKD clinic, which included a nephrologist, social worker, diabetes educator and exercise physiologist. LI involved 8 weeks supervised, gym-based individualized exercise training followed by home based training with ongoing telephone support and gym refresher sessions for 12m. Pts attended 4 week behavior-lifestyle change program led by a psychologist and dietician. MD was assessed at baseline and 12m using standard echo and tissue Doppler. Anthropometric, biochemical and fitness data were collected at baseline and follow-up. The effect of intervention was determined using analysis of covariance (ANCOVA). Change scores were compared between groups.

Results: 72 pts completed follow-up (LI=36, control =36). There were no baseline differences (Table 1). LI resulted in a significant (33%) increase in exercise capacity, with decreases in BMI. This group also showed improved diastolic function (increased e'). There were no changes in systolic function, blood pressure or biochemical parameters between groups.

Conclusions: The LI significantly improved exercise capacity and diastolic function in CKD. Lifestyle and exercise interventions may assist in managing the deleterious effects of reduced kidney function on the myocardium.

Table 1. Effect of one-year lifestyle intervention

	Control group		LI group

Reprogramming of Adult Proximal Tubular Epithelium to an Embryonic Nephron Progenitor State
Melissa H. Little, Caroline E. Hopkins, Norseha Suhaimi, Fiona Rae, Joan Li. *Institute for Molecular Bioscience, University of Queensland, St. Lucia, Brisbane, Queensland, Australia.*

Background: The mammalian kidney arises from the ureteric bud and the metanephric mesenchyme, the latter giving rise to a cap mesenchyme nephron progenitor population. This Six2 positive cap mesenchyme surrounds the ureteric tips of the developing kidney and contains self renewing nephron stem/progenitors. Lineage tracing has shown that Six2+ cells give rise to all segments of the uriniferous tubule except the collecting ducts(1). Nephron formation ends around birth via the terminal commitment of this progenitor field to nephron formation, hence this stem cell population does not persist postnatally. As a result, no new nephrons arise after birth and total nephron number is determined by the balance between cap mesenchyme self-renewal, differentiation and death.

Methods: In this study, we investigated whether the adult proximal tubular population could be reprogrammed to this earlier nephron progenitor state via the enforced reexpression of a cap mesenchymal transcriptional state. 15 key genes were cloned into lentiviral vectors and a combinatorial screen was performed via infection of the human proximal tubular cell line, HK2.

Results: Four stages of validation were performed, including i) epithelial to mesenchymal morphological change, ii) production of the cap mesenchyme-specific Cited1 protein, iii) re-expression of key cap mesenchyme genes and iv) successful integration into the cap mesenchyme of an ex vivo embryonic kidney reaggreagtion (2). In this way, we identified a combination of genes (Osr1, Six1, Six2, Hoxa11, Eya1, Snai2) capable of inducing a nephron progenitor state according to all four criteria. Approximately 0.875% of infected cells incorporated into cap mesenchyme in comparison to 0.05% for control HK2 cells cultured under identical conditions .

Conclusions: This is the first demonstration of reprogramming to the progenitor state of a solid organ and is the first evidence that it may be feasible to regenerate a cap mesenchyme population. These results open up the possibility of reinitiation of nephron formation but also to manipulation of the nephrogenic process to prolong nephron endownment.

Induced Pluripotent Stem Cells from Patients with Genetic Kidney Disease: Applications for Disease Modeling and Therapeutic Screening
Sharon D. Ricardo,[1] Bi Song,[1] Jonathan Niclis,[1] Andrew L. Laslett,[3] Peter G. Kerr.[2] *[1]Monash Immunology and Stem Cell Laboratories, Monash University, Clayton, Victoria, Australia; [2]Medicine, Nephrology, Monash Medical Center, Clayton, Victoria, Australia; [3]Materials Science and Engineering, CSIRO, Clayton, Victoria, Australia.*

Background: The reprogramming of somatic cells to induced pluripotent stem (iPS) cells has attracted considerable attention for disease modeling, drug screening and regenerative medicine. We have recently shown that iPS cells can be derived from human kidney mesangial cells (JASN; May 2011).

Methods: In the present study, fibroblasts grown from skin biopsies of patients with Alport Syndrome and polycystic kidney disease (PKD) were reprogrammed by retroviral transduction using OCT4, SOX2, KLF4, and c-Myc. The DNA methylation profiles of skin-derived iPS cells were analysed by bisulfite sequencing using the OCT4 promoter, compared to kidney cell-derived iPS cells. The iPS cells were analysed for stem cell marker

expression using immunofluorescence microscopy and qPCR. The pluripotent capacity of the undifferentiated iPS cells was tested by the formation of teratomas following injection into immunodeficient mice and the directed differentiation into embryoid bodies.

Results: The disease-specific iPS cells resembled human embryonic stem cells (hES) in morphology and gene expression localising for OCT3/4, SSEA-4, TRA-1-60 and TRA-1-81 proteins. Using qPCR, the iPS cells expressed stem cell marker genes and exhibited silencing of the retroviral transgenes by passage four. DNA methylation profiles showed that fibroblast and mesangial-derived iPS cells had OCT4 methylation patterns similar to hES cells, but different to the primary target cells. Furthermore, iPS cells formed embryoid bodies and expressed markers of all three germ layers by immunostaining and RT-PCR. The injection of undifferentiated iPS colonies into immunodeficient mice formed teratomas, thereby demonstrating pluripotency.

Conclusions: The derivation of iPS cells from Alport Syndrome and PKD patients advances the potential of human pluripotent cells for modeling the genetic disorders, the directed differentiation of kidney cells and screening of new drug compounds.

Identification of Early Stage Renal Progenitors in E9.5 Embryos by Using Osr1-GFP Knock-In Mice Atsuhiro Taguchi, Ryuichi Nishinakamura. *Kidney Development, Institute of Molecular Embryology and Genetics, Kumamoto, Kumamoto, Japan.*

Background: Though many groups are trying to induce renal progenitor cells from ES or iPS cells, it remains unclear to which in vivo stage those cells correspond. In this study, we propose the stepwise induction model by analyzing the in vivo developmental process of renal progenitor cells.

Methods: Osr1 is one of the earliest markers of the IM and most of the cell types within the kidney arise from the Osr1+ population. Thus we have generated Osr1-GFP knock-in mice and murine ES cells. By sorting Osr1-GFP+ cells from embryos and applying them to the colony- forming assay that promotes renal progenitor differentiation, we have confirmed the existence of renal progenitors in embryos at the early developmental stages.

Results: Consecutive application of Osr1-GFP+ kidney precursors to colony forming assay on Wnt4-expressing feeders, from E8.5 intermediate mesoderm to the E11.5 metanephric mesenchyme, revealed that the Osr1+ cells after E9.5 do contain colony-forming cells. Osr1-GFP+ cells at E8.5, however, formed no colonies. Further analyses of expressed genes of colonies derived from E9.5 implied that these colonies are progenitors of mesonephroi and distinct from metanephric progenitors at E11.5.

Conclusions: We have identified the functional difference of renal progenitor cells in the early stage embryo between E8.5 to E11.5 by colony-forming assay. Our data suggests a transition from the primitive to the definitive state between E8.5 and 9.5. These data imply the existence of cues which promote maturation of primitive progenitors to the functional progenitor cells between these developmental stages.

Developmental Regulators in Cap Mesenchyme Are Epigenetically Poised Nathaniel J.D. McLaughlin, Xiao Yao, Zubaida R. Saifudeen, Samir S. El-Dahr. *Pediatrics, Tulane University School of Medicine, New Orleans, LA.*

Background: In embryonic stem cells, the promoters of developmental regulators are held in a "poised" state by carrying activating (H3K4me3) and repressive (H3K27me3) chromatin domains. Upon receiving a differentiation signal, these bivalent domains resolve either into actively transcribed regions or silenced by packing into inaccessible heterochromatin. We hypothesized that progressive restriction of cell fate which occurs during differentiation of renal progenitors to epithelia involves conversion of bivalent chromatin into chromatin regions accessible or inaccessible to the transcription machinery.

Results: We show here that self-renewing Six2+ cap mesenchyme cells are enriched with polycomb protein Ezh2 (H3K27 methyltransferase) as compared to nascent nephrons, and exhibit a bivalent chromatin signature (H3K4me3/K27me3). This bivalency resolves during nephron differentiation via downregulation of repressive H3-K27me3 and acquisition of additional activating H3-R8me2/R17me2 marks. Cre-mediated deletion of *Ezh2* from the Six2 cell population in vivo eliminates H3K27me3 and compromises the size of this progenitor pool. ChIP-Seq of chromatin landscapes in progenitor and differentiating metanephric mesenchyme-derived cell lines revealed that bivalent chromatin domains in developmental regulators resolve during differentiation. Induction of *Pax8*, a known target of Wnt-β-catenin signaling, by exogenous Wnt3a is associated with recruitment of the H3K27 demethylase, KDM6b, and displacement of Ezh2, thus loss of repressive H3K27me3.

Conclusions: We conclude that "epigenetic poising" is not unique to pluripotent cells and represents a key mechanism for a cell fate decisive switch during nephron differentiation. Polycomb(Ezh2)-mediated silencing may represent an epigenetic mechanism to maintain the pool of renal progenitors.

KIF3A Controls Nephrogenesis by Regulating FGF8 Lijun Chi, Norman D. Rosenblum. *Paediatrics, Prog Dev & Stem Cell Biology, Hosp Sick Child, U Toronto, Canada.*

Background: The primary cilium is critical for Hedgehog (HH)-dependent signaling in nonrenal tissues. The functional contribution of the primary cilium to early renal embryogenesis is undefined. We hypothesized that the primary cilium controls embryonic kidney morphogenesis by modulating HH signaling.

Methods: Mice with primary cilium deficiency were generated by inactivating *Kif3a*, which encodes a primary cilium motor protein, in the metanephric mesenchyme (*Kif3a-MM* null mice) using *Rarb2-Cre* and *Kif3a*^{loxP} mice. Metanephric and primary metanephric mesenchyme primary cultures were generated from WT and mutant mice.

Results: Confocal immunofluoresence imaging of WT and *Kif3a-MM* null kidney tissue demonstrated that KIF3A expression is restricted to the primary cilium. Nephrogenesis was reduced by 35% at P0 and 22% at E12.5 ($P<0.05$) in *Kif3a-MM* null mice. Surprisingly, HH signaling, assayed by expression of *Ptc1* mRNA and a *Ptc1-lacZ* reporter in E11.5-E17.5 kidney tissue, was similar to that in controls. In contrast, expression of *Fgf8* was almost undetectable by E15.5, at which stage the number of primary cilia was reduced by 70%. The significance of decreased *Fgf8* expression was determined in organ culture. Addition of FGF8 protein to *Kif3a-MM* null metanephroi, harvested at E11.5 and separated from the ureteric bud and then cultured on spinal cord, increased the number of PAX2-positive tubules 1.7-fold ($P<0.001$) compared to untreated *Kif3a-MM* controls. The functional contribution of KIF3A was investigated in cultured WT and *Kif3a-MM* null primary MM cells isolated from E11.5 WT and mutant kidneys. Cilia length was decreased 5-fold in *Kif3a-MM* null MM cells versus WT cells ($P=0.003$). Transfected *Kif3A-GFP* localized to the primary cilium and increased primary cilium length in null MM cells 1.7-fold compared to transfection with GFP alone ($P=0.04$). While transfected *Kif3A-GFP* exerted no significant effect on the expression of the HH response genes, *Ptc1* or *Gli1*, in *Kif3a-MM* null MM cells ($P<0.002$), expression of *Fgf8* mRNA increased 2.2-fold compared to controls ($P<0.002$).

Conclusions: We conclude that KIF3A acts in the primary cilium of metanephric mesenchyme cells to control nephrogenesis by regulating *Fgf8* expression.

Structural Changes in the Cytoplasmic Domain of Integrin β1 Due to the Mutations in NPxY Motifs Induce Kidney Developmental Phenotypes Sijo Mathew,[1] Riya Jose Palamuttam,[1] Glenda Mernaugh,[1] Zhenwei Lu,[2] Leslie S. Gewin,[1] Nada Bulus,[1] Ambra Pozzi,[1] Charles R. Sanders,[2] Roy Zent.[1] *[1]Division of Nephrology and Hypertension, Vanderbilt University Medical Center; [2]Biochemistry and Center for Structural Biology, Vanderbilt University Medical Center, Nashville, TN.*

Background: Integrins are the principal receptors that regulate cell extracellular matrix interactions. β1 integrins are the major integrins found in the kidney and are required for its development and function. The two NPxY motifs in the cytoplasmic tail of the integrin β1 subunit are proposed to be critical for β1 integrin function. In this study, we defined the importance of the NPxY motifs in ureteric bud (UB)development.

Results: We generated mice that selectively express β1 integrin in the developing UB where the tyrosines (Y) in both NPxY motifs were mutated to alanines (A) or phenylalanines (F). The Y/A mutations caused severe developmental abnormalities; however, mice with the Y/F mutations developed normally, but were more susceptible to injury in comparison to wild type mice. Consistent with the *in vivo* data, collecting duct cells expressing the mutant β1 integrins had abnormalities in cell adhesion, migration, proliferation and tubule formation. Interestingly, only cells expressing the Y/A mutations failed to activate intracellular signaling mediated by GDNF or FGF, two growth factors critical for UB development. We further defined the molecular mechanism for the functional alterations induced by these mutations by solving the structure of the β1 integrin tail and transmembrane domain by NMR spectroscopy in DMPC/DHPC bicelles. We demonstrated there were significantly more structural disruptions in the Y/A compared to the Y/F mutants.

Conclusions: This study shows that the NPxY motifs in the integrin β1 tail regulate UB development by altering integrin dependent cell functions and growth factor signaling. Furthermore, it shows the structural alterations of the β1 integrin tail carrying mutations in these critical tyrosine residues. This observation has major implications in our understanding how the cytoplasmic tail of β1 integrins regulate cell and tissue function.

Podocyte-Selective Loss of the Basic Helix-Loop-Helix Transcription Factor, Pod1/Tcf21 Results in Podocyte Defects and Massive Proteinuria Yoshiro Maezawa,[1] Tuncer Onay,[1] Chengjin Li,[1] Susan E. Quaggin.[1,2] *[1]Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, ON, Canada; [2]Department of Medicine and Division of Nephrology, St Michael's Hospital and University Health Network, Toronto, ON, Canada.*

Background: Podocytes are highly differentiated cells that are essential for function of the glomerular barrier. Although a number of transcription factors are known to be expressed in podocytes, their function(s) in orchestrating development of specialized features such as slit diaphragms and foot processes, is largely unknown.

Pod1/Tcf21 belongs to the bHLH family of transcription factors and is expressed in condensing metanephric mesenchyme, and immature and mature podocytes. We generated

a standard KO mouse that dies in the perinatal period with striking renal defects including severely disrupted and delayed glomerulogenesis, arrested differentiation of tubular epithelium, and abnormal branching of the ureteric bud. However, given the complexity of the Pod1 KO phenotype and early lethality, the precise role of pod1 in podocytes remains unclear.

Methods: To understand the role of Pod1 in podocyte development and function, we further analysed the standard KO mice, and developed podocyte-selective KO mice as well. A conditional floxed Pod1 allele was created using Bac cloning strategy and embryonic stem cell targeting, placing loxP sites around the first exon of Pod1. The floxed mice were bred with Podocin-Cre mice to delete the Pod1 gene specifically in podocytes.

Results: Analysis of conventional KO mice reveals defects in podocyte foot process formation. Podocyte-specific KO mice develop massive proteinuria at 4 weeks of age. Histological analysis reveals striking glomerulosclerosis and loss of podocytes at this stage. In contrast to conventional KO mice, glomerular tuft development and mesangial cell migration is normal, suggesting that these functions depend on Pod1 expression in the mesenchyme and NOT the podocyte lineage.

Conclusions: Together, these data demonstrate crucial but distinct role for Pod1 in renal mesenchymal and podocyte cell lineages. Furthermore, these mice represent a valuable tool to identify the transcriptional targets regulated by Pod1 in podocytes.

Deletion of Fgfr2 from the Peri-Wolffian Duct Stroma Leads to Induction Abnormalities, and Congenital Vesicoureteral Reflux Kenneth A. Walker,[1] Sunder Sims-Lucas,[1] Whitney Sunseri,[1] Caitlin M. Schaefer,[1] Feng Chen,[2] Carlton M. Bates.[1] *[1]Children's Hospital of Pittsburgh, Pittsburgh, PA; [2]Medicine, Washington University School of Medicine, St Louis, MO.*

Background: Kidney development begins when the ureteric bud (UB) invades the metanephric mesenchyme (MM). The site of UB induction is strongly influenced by the peri-Wolffian duct stroma (ST). Previously, conditional deletion of fibroblast growth factor receptor 2 (Fgfr2) in both MM and ST was shown to cause ureteric induction defects, CAKUTs, and high rates of vesicoureteral reflux (VUR).

Methods: The purpose of this study was to elucidate the role of Fgfr2 signaling in the ST during kidney development through conditionally deleting *Fgfr2* in ST using Tbx18cre (*Fgfr2*$^{St-/-}$) mice; that drive cre expression in the ST, as well as in bladder mesenchyme but not in MM.

Results: Analysis at E11.5 showed *Fgfr2*$^{St-/-}$ mutants have a highly variable UB induction site compared to controls. At E10.5, during early UB induction, *Fgfr2*$^{St-/-}$ embryos exhibit reduced *Bmp4* and *Sprouty1* mRNA expression (67% and 59% respectively, of control expression levels). At birth, *Fgfr2*$^{St-/-}$ mice present with CAKUT phenotypes, and have higher rates of VUR (79%) than control mice (3%). Ureters from both genotypes show similar morphology however analysis of cultured E12.5 explants indicated that *Fgfr2*$^{St-/-}$ ureters display abnormal peristaltic contractions. Lastly, adult *Fgfr2*$^{St-/-}$ mice continue to have high rates of VUR (via live and euthanized cystogram methods) and often exhibit abnormal voiding behavior, megabladder and hydronephrosis compared to age-matched controls. In conclusion, Fgfr2 signaling in ST is required for normal induction of the UB (regulated by *Bmp4* and *Sprouty1*) and for normal ureteral peristalsis.

Conclusions: These combined ureteric induction and peristaltic defects have novel implications for understanding the developmental mechanisms of VUR. Furthermore, the bladder abnormalities (voiding dysfunction, megabladder and hydronephrosis) seen in mutants suggests critical roles for Fgfr2 in bladder development and could represent a novel biological/genetic link between VUR and voiding dysfunction; as is often associated in humans.

Congenital Hydronephrosis and Delayed Distal Ureter Maturation in Discs-Large 1 (*Dlg1*) Null Mice Is Associated with Reduced Retinoic Acid Signaling and Impaired Apoptosis Via a Non-Epithelial Cell Autonomous Mechanism Sung Tae Kim,[1] Wojciech Swat,[2] Jeffrey H. Miner.[1] *[1]Renal Division, Washington University, St. Louis, MO; [2]Dept. of Pathology & Immunology, Washington University, St. Louis, MO.*

Background: The absence of Discs-large 1 (*Dlg1*), the mouse ortholog of the *Drosophila* discs-large tumor suppressor, results in congenital hydronephrosis characterized by urinary tract abnormalities, reduced ureteric bud branching, and delayed disconnection of the ureter from the common nephric duct.

Methods: To define the cellular requirements for *Dlg1* during urogenital development, we used a floxed *Dlg1* allele and Pax2Cre, Pax3Cre, and HB7Cre transgenes to generate tissue-restricted *Dlg1* mutants. In addition, we mated *Dlg1* heterozygote mice with Ret-GFP knockin, retinoic acid response element-LacZ transgenic mice, or HB7-GFP knockin to see specific compartments of urogenital system.

Results: Mutation in urothelium and collecting ducts (via by HoxB7Cre or Pax2Cre) and in nephrons (via Pax2Cre) resulted in no apparent abnormalities in ureteric bud branching or in distal ureter maturation and no hydronephrosis. Mutation in nephrons and ureteric smooth muscle (via Pax3Cre transgene) resulted in congenital hydronephrosis accompanied by reduced branching, a delay in distal ureter maturation, and smooth muscle orientation defects, phenotypes very similar to *Dlg1* null mice. *Dlg1* null mice showed reduced apoptosis and evidence of reduced retinoic acid signaling in the kidney, shown both by real-time PCR and immunofluorescence. These results were confirmed using Ret-GFP knockin and retinoic acid response element-LacZ transgenic mice.

Conclusions: Taken together, these results suggest that *Dlg1* expression in ureteric smooth muscle cells is essential for ensuring distal ureter maturation by facilitating retinoic acid signaling and apoptosis.

Obstructive Nephropathy in Megabladder Mice Is Due to a Novel Hypomorphic Myocardin Allele Brian Becknell,[1] Ashley R. Carpenter,[2] Michael L. Robinson,[3] Kirk M. McHugh.[2] *[1]Department of Pediatrics, Nationwide Children's Hospital, Columbus, OH; [2]Center for Molecular and Human Genetics, Nationwide Children's Hospital Research Institute, Columbus, OH; [3]Department of Zoology, Miami University, Oxford, OH.*

Background: Megabladder (mgb-/-) mice exhibit impaired bladder smooth muscle development, resulting in megacystis and hydronephrosis in utero and renal failure in adults. We previously identified the insertion of a portion of chromosome (chr) 16 into chr 11 of mgb-/- DNA, but its significance was unclear.

Methods: To further refine the genetic alteration in mgb-/- mice, DNA was subject to fluorescence in situ hybridization (FISH) and comparative genomic hybridization (CGH). RNA was evaluated by microarray, in situ hybridization, and QRT-PCR. Mice with a fully disrupted myocardin (myocd) allele (myocd+/-) were crossed with mgb-/- mice to generate myocd-mgb- animals.

Results: FISH demonstrated a megabase insertion of chr 16 into chr 11, inclusive of 4 genes on chr 16. CGH confirmed this and identified a 26 kilobase (kb) deletion of chr 11. This insertion/deletion occurred in a gene sparse region of chr 11, 300 kb upstream of myocd, a transcription factor that cooperates with the serum response factor (SRF) to initiate myogenesis. Transcriptome profiling of mgb-/- E15 bladders demonstrated intact expression of early markers of muscle patterning, but impaired expression of 27 downstream targets of the myocd/SRF transcriptional complex. Myocd expression was diminished in E15 mgb-/- bladders by in situ hybridization and QRT-PCR versus controls. Compound heterozygotes (myocd-/mgb-) phenocopied mgb-/- bladders. Myocd-/mgb- embryos showed a further reduction in myocd expression versus mgb-/- mice resulting in the development of patent ductus arteriosus (PDA) postnatally.

Conclusions: The mgb-/- phenotype occurs as a result of a long-range, position effect mutation on chr 11 that results in a hypomorphic myocd allele. Further reduction of myocd gene expression in myocd-/mgb- mice results in the emergence of PDA, providing the first evidence that decreased myocd gene dosage results in congenital anomalies involving these two disparate organ systems.

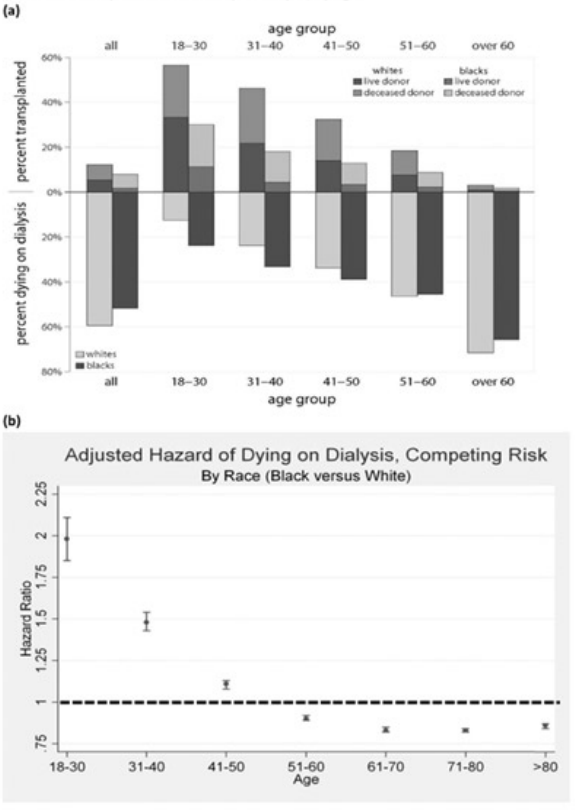
Age and Racial Disparities in Dialysis Survival Lauren M. Kucirka,[1] Morgan E. Grams,[2] Dorry L. Segev.[1] *[1]Surgery, JHU; [2]Medicine, JHU; [3]Epidemiology, JHU.*

Background: Many studies have reported that blacks survive longer on dialysis than whites. This observation is paradoxical given racial disparities in access to and quality of care, and is inconsistent with observed lower survival among blacks with chronic kidney disease. The perception of improved dialysis survival has affected clinical decision-making and engendered complacency about the low rates of kidney transplantation among blacks. We hypothesized that age and the competing risk of transplantation modify survival differences by race. The goal of our study was to estimate death on dialysis by race, accounting for age as an effect modifier and kidney transplantation as a competing risk.

Methods: We studied 909,841 incident end-stage renal disease patients captured in USRDS between 1995 and 2005. Multivariate age-stratified Cox proportional hazards and competing risk models were constructed to examine death on dialysis comparing black and white patients.

Results: Similar to previous studies, blacks had an overall 17% lower death rate on dialysis compared with whites (adjusted hazard ratio (aHR) 0.83, $p<0.001$). However, stratifying by age blacks under 50 had significantly higher mortality than their white counterparts (Figure 1a). This finding persisted in adjusted analyses treating kidney transplant as a competing risk (aHR 1.98 for 18-30; aHR 1.51 for 31-40; aHR 1.10 for 41-50; $p<0.001$, Figure1b); only those over 50 had lower death rates (aHR 0.87 for 51-60; 0.85 for 61-70; 0.83 for 71-80; 0.86 for >80; $p<0.001$).

Figure 1: (a) Percent of Incident ESRD Patients Who Received a Transplant (Upper Panel) or Died on Dialysis (Lower Panel) During the Study Period, by Race and Age Category, and (b) Relative Adjusted Hazard of Death (Black versus White) on Dialysis, by Age



Conclusions: The commonly cited dialysis survival advantage among blacks applies only to older adults. Blacks under the age of 50 die on dialysis at as much as twice the rate of their white counterparts.

SA-OR388

End-of-Life Care Intensity in Older Adults on Chronic Dialysis Susan P.Y. Wong, William Kreuter, Ann M. O'Hare. *University of Washington.*

Background: Survival after initiation of chronic dialysis is often limited in older adults, fostering a growing interest in advance care planning in this population. Little is known about their treatment choices at the end-of-life (EOL) and the major determinants of their choices.

Methods: Using data from USRDS, we performed a retrospective mortality study on 43,768 Medicare beneficiaries age ≥65 years who initiated chronic dialysis from 6/1/2005-12/31/2007 and died within 1-year of initiation. Using linked Medicare inpatient claims, we examined the following EOL care measures during the last 6-months of life: hospitalization, intensive care unit (ICU) admission, and receipt of an intensive procedure (mechanical ventilation, feeding tube placement, and cardiopulmonary resuscitation [CPR]). We examined the adjusted association of these measures with patient characteristics and regional patterns of healthcare spending (end-of-life expenditure index or EOL-EI).

Results: Most (79.5%) patients were hospitalized at least once in the last 6-months of life. Of these, 31.5% received at least one intensive procedure. Receipt of an intensive procedure was associated with Black race (24.8% v. 14.7%; OR 1.56, 95%CI 1.44-1.68) and age ≤75 years (48.1% v. 38.5%, 1.37, 1.29-1.46). Sex, cause of ESRD, and co-morbidities did not show strong and consistent associations with receipt of an intensive procedure. After adjustment for differences in patient characteristics, we found a stepwise increase in the likelihood of ICU admission and receipt of an intensive procedure during the last 6-months of life from regions with the lowest to highest healthcare spending (Figure 1).

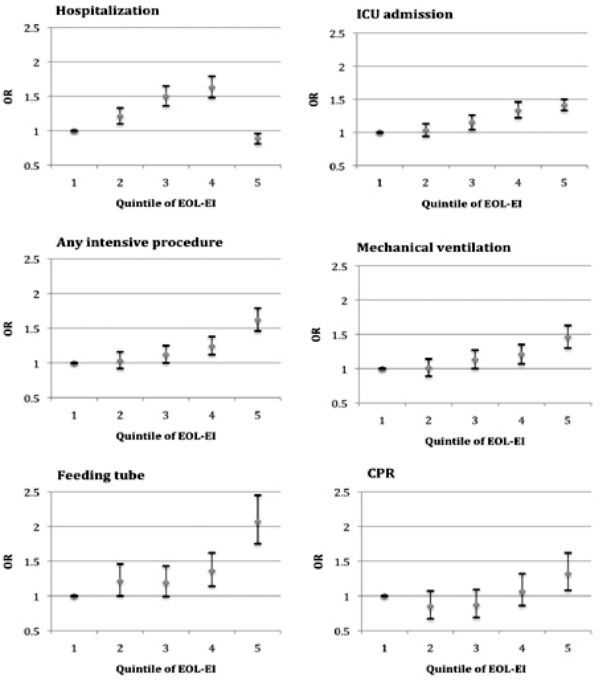

Figure 1. Adjusted OR for hospitalization, ICU admission and receipt of an intensive procedure, including mechanical ventilation, feeding tube, and CPR in the last 6-months of life according to quintile of EOL-EI.

Conclusions: Hospitalization, ICU admission and receipt of intensive procedures are common at the EOL among older dialysis patients. In general, utilization of intensive procedures in this population seems to be shaped more by regional treatment patterns than by patient characteristics.

SA-OR389

Lower Dialysate Na+ Impacts Weight Gain & Fluid Overload Hospitalizations Eduardo K. Lacson,[1] John Rogus,[1,2] Peter Kotanko,[2] Nathan W. Levin,[2] Raymond M. Hakim.[1] *[1]Fresenius medical Care, North America, Waltham, MA; [2]Renal Research Institute, New York, NY.*

Background: Interdialytic weight gain (IDWG) and fluid overload hospitalizations (FOH) increased with greater dialysate to serum sodium (sNa+) gradient. However, many physicians keep the base dialysate sodium (dNa+) formulation constant in a facility. We hypothesized that lowering dNa+ will decrease IDWG and FOH in prevalent hemodialysis (HD) patients.

Methods: A phased roll-out (Jan-Jun 2009) of dialysate formulation for Fresenius Medical Care, North America facilities decreased base dNa+ from 140 to 137 mEq/L. We identified 592 facilities with median dNa+ drop of 3.0 meq/L and 188 facilities where physicians kept the base sodium unchanged, when comparing 6-months before (Jul-Dec 2008) to 6-months after (Jul-Dec 2009) the conversion period. We identified all adult, in-center HD patients that survived for the entire 18-month study period divided into 25,653 patients with lower facility dNa+ and 9,613 controls that maintained dNa+. We estimated the change in key variables for each patient between the baseline and post-conversion periods to determine if they differed between cases and controls.

Results: We verified that post-conversion mean dNa+ was lower in study patients vs. controls (mean: 137 vs. 139 mEq/L, $p<0.0001$). Mean IDWG decreased in facilities with lowered dNa+ by 0.14 kg vs. controls' 0.03 kg ($p<0.0001$), accompanied by a larger decline in pre-HD weight (0.74 vs.0.57 kg, $p=0.01$) respectively. At baseline, FOH was higher in study patients (5% vs. 4%, RR=1.18, $p=0.002$). Post-conversion, overall FOH rate increased in both groups but the difference between groups lost significance (13.3% vs. 12.5%, RR=1.06, $p=0.055$). No significant differences in period changes between groups were noted in pre-HD sNa+, albumin and hemoglobin, pre- and post-HD systolic blood pressure (SBP) or post-HD weight.

Conclusions: Lowered dNa+ was accompanied by a greater decline in IDWG and pre-HD weight along with attenuation of the propensity for greater FOH over time. No accompanying differential changes in sNa+, SBP, post-HD weight, albumin or hemoglobin were observed.

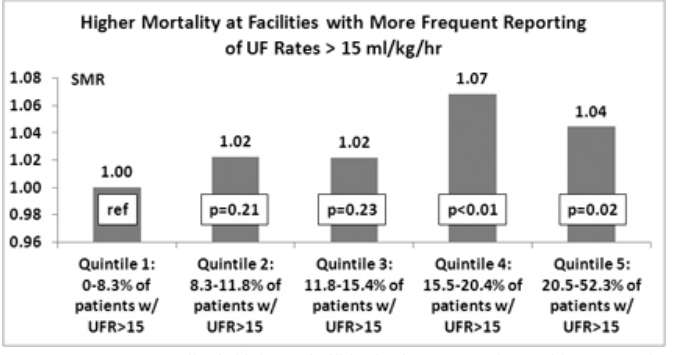
SA-OR390

Dialysis Facility Use of High Ultrafiltration Rates Is Associated with Higher Standardized Mortality Joseph M. Messana,[1] Dori Bilik,[2] Brett Lantz,[2] Robert A. Wolfe,[2] Jeffrey Pearson,[2] Rajiv Saran.[1] *[1]University of Michigan Kidney Epidemiology and Cost Center, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Observational patient-level studies have associated hemodialysis (HD) ultrafiltration rates (UF) above 10-13 ml/kg/hr with more intradialytic hypotension, unstable sessions and higher mortality. The current study validates this using the % of pts at a dialysis facility with UF>15 ml/kg/hr data from the July-December 2009 CROWNWeb collection period.

Methods: Facility-level UF practice pattern was calculated from monthly patient treatment fluid removal and treatment time data. Facility % of patient-months with UF>15 were related to the 2009 standardized mortality ratio (SMR) using Poisson regression. To avoid patient-level treatment-by-indication bias, we analyzed death rates among all patients at a facility, categorizing facilities by their UF practice pattern. The SMR used CMS data sources adjusted for case-mix including patient age, sex, race, ethnicity, cause of ESRD, time since start of ESRD, comorbidities at ESRD incidence, nursing home status, and state general population death rate.

Results: 3,153 dialysis facilities were grouped into quintiles according to the % UF>15. Mortality was higher for facilities in the two highest quintiles relative to the lowest quintile. Findings were similar after adjustment for other facility practice patterns (achieved hemoglobin, URR, vascular access type).



Conclusions: Mortality is higher at facilities having more patients with UF>15. The reasons for prescribing high UF and approaches to reducing/optimizing UF requirements in dialysis patients deserve urgent attention by the dialysis community. Death rates could plausibly be lowered by 4-7% at the 40% of facilities with the highest % of pts UF>15 if those facilities adopt the practice facilities in the lowest qunitile.

SA-OR391

Effects on Ventricular Volumes by Frequent Hemodialysis: Results from the Frequent Hemodialysis Network (FHN) Trials Christopher T. Chan, Gerald J. Beck, Glenn M. Chertow, John T. Daugirdas, Tom H. Greene, Peter Kotanko, Brett Larive, Nathan W. Levin, Ravindra L. Mehta, Michael V. Rocco, Javier Sanz, Brigitte Schiller, John B. Stokes, Alan S. Kliger. *FHN Trials Group, NIDDK.*

Background: Increased cardiac ventricular volume is an independent risk factor for death in patients with end-stage renal disease (ESRD). As part of the FHN trials, the impact of daily in-center hemodialysis (DHD) and nocturnal home hemodialysis (NHD) on left and right ventricular (LV, RV) volumes and function were investigated. We hypothesized that frequent hemodialysis would lower LV and RV volumes.

Methods: The FHN trials randomized 245 patients to 12 months of DHD or conventional hemodialysis (CHD), and 87 patients to 12 months of NHD or CHD. LV and RV volumes and function were ascertained by cardiac MRI at baseline and at the end of the study.

Results: The absolute (mean± SD) intradialytic weight loss per session achieved during the Daily and Nocturnal Trials were: DHD (2.11 ± 0.86kg) and conventional HD (3.10 ± 1.04kg), p<0.001 and NHD (2.04 ± 0.87kg) and conventional HD (2.55 ± 1.02kg), p <0.01 respectively. Table 1 shows changes from baseline to 12 months. Reductions in LV and RV volumes were higher with DHD than with CHD. Changes in cardiac volumes were not significantly different between NHD and CHD.

Mean Change From Baseline to 12 Months in Cardiac Indices

Variables	CHD (Daily Trial)	DHD (Daily Trial)	CHD (Nocturnal)	NHD (Nocturnal)
Intradialytic weight loss (kg)	-0.1 ±0.1	-1.0±0.1*	0.2±0.2	-0.3±0.1*
LVEDV (ml)	-1.9±4.0	-21.9±3.7*	6.4±7.8	0.0±8.0
LVESV (ml)	-2.2±2.9	-10.8±2.7	5.0±5.8	-1.4±6.0
Left cardiac output (L/min)	0.075±0.22	-0.55±0.20*	0.21±0.36	0.39±0.37
LV ejection fraction (%)	0.2±1.0	1.5±1.0	-1.3±2.1	1.0±2.2
RVEDV (ml)	-15.0±5.1	-33.4±4.8*	-13.5±7.4	-9.0±7.6
RVESV (ml)	-9.1±3.4	-16.5±2.7*	-6.2±4.5	-6.1±4.6
Right cardiac output (L/min)	-0.38±0.24	-1.04±0.22*	-0.56±0.37	0.054±0.38
RV ejection fraction (%)	1.1±1.2	1.1±1.1	-0.8±2.2	2.0±2.3

*p<0.05 between CHD and DHD or CHD and NHD, ESV = end-systolic volume, EDV = end-diastolic volume

Conclusions: DHD lowered left and right ventricular volumes. The pathophysiological importance of these reductions in intracardiac volumes requires further investigations.

SA-OR392

Increasing Diffusive Sodium Removal Improves Blood Pressure Control through Volume-Independent Effect in Hemodialysis Patients Yi-Lun Zhou, Jing Liu, Li-Jie Ma, Fang Sun, Yang Shen, T.G. Cui. *Department of Nephrology, Chao-yang Hospital, Capital Medical University, Beijing, China.*

Background: Sodium overload is a predominant factor in the pathophysiology of hypertension in end stage renal disease. Lowering dialysate sodium concentration has been demonstrated to improve blood pressure (BP) control, and this phenomenon is considered to be a result of an improvement in volume status via increasing sodium removal. However, sodium, apart from volume, may have an independent effect on BP regulation.

Methods: 16 non-diabetic stable hemodialysis patients were recruited, who are hypertensive, have achieved their dry weight assessed by both clinical and bioimpedance methods, without intradialytic symptoms, with their pre-dialysis plasma sodium levels slightly higher than the facility dialysate sodium concentration 138mmol/L. After 1 month period with standard dialysate sodium concentration of 138mmol/L, the patients were followed up for a 4 months period with dialysate sodium set at 136mmol/L, without changes in instructions to patients about dietary sodium control. During the period of study, the dry weight was adjusted monthly under the guidance of bioimpedance spectroscopy (BCM, Fresenius Medical Care), to maintain post-dialysis volume status within normal range.

Results: Along with lowering dialysate sodium, systolic and diastolic home-monitored BPs progressively decreased and reached statistical significance by the end of month 2. There was a significant decrease (-10 mmHg and -6mmHg) in 44-hour ambulatory systolic and diastolic BP by the end of the trial as well. Interdialytic weight gain adjusted to the estimated dry weight mildly but significantly decreased (4.81±1.51% vs 4.36±1.37%, p=0.047). No changes in monthly incidence of dialysis-related symptoms and pre-dialysis plasma sodium concentration were observed. The post-dialysis volume parameters were maintained in a steady state throughout the study period.

Conclusions: In selected hypertensive hemodialysis patients without volume overload, increasing diffusive sodium removal by lowering dialysate sodium concentration resulted in significant BP decrease. It is most likely due to the volume-independent effect.

SA-OR393

Aldosterone Deficiency as the Cause of Intradialytic Hypotension and Its Successful Management with Fludricortisone Daniel L. Landry,[1] Seyedeh S. Hosseini,[2] Osazee J. Osagie,[2] Arley F. Diaz,[1] Benjamin J. Freda,[1] Gregory Lee Braden.[1] *[1]Renal Division, Baystate Medical Center, Springfield, MA; [2]Internal Medicine, Kindred Parkview Hospital, Springfield, MA.*

Background: Intradialytic hypotension (IDH) occurs in many patients on maintenance hemodialysis. While there is evidence to suggest that aldosterone (Aldo) has non-genomic effects on vascular tone independent of sodium retention in oligo-anuric dialysis patients, the presence of Aldo deficiency as a cause of IDH has not been defined.

Methods: Twelve chronic hemodialysis patients with refractory IDH despite aggressive medical management had plasma cortisol, renin and Aldo levels measured randomly before dialysis. Those patients that failed to have an Aldo level above 5 ng/dL were then given fludrocortisone (FC) 0.1 mg bid. Pre- and post-dialysis blood pressures (BP), average ultrafiltration volumes and frequency of IDH (SBP < 100 mmHg) were measured on 12 separate occasions prior to and after FC initiation.

Results: Of 12 patients with severe IDH, five had low random plasma Aldo levels in the setting of symptomatic IDH. None of the patients had cortisol deficiency on cosyntropin stimulation testing. All 5 patients with Aldo deficiency had improvement in pre-dialysis (110.1±2.2 v. 133.0±2.0, p<.0001) & post-dialysis systolic BP (103.8±1.4 v. 123.2±2.4, p<.0001) & pre-dialysis diastolic BP (61.0±1.4 v. 73.0±2.0, p<.0001) & post dialysis diastolic BP (56.1±1.2 v. 66.6±2.0 mmHg, p<.0001) after the initiation of FC. Ultrafiltration volumes (2.8 ± 0.26 v. 3.6 ± 0.40 liters, P=.0012) and the frequency of IDH events (2.9 ± 0.27 v. 0.7 ± 0.13 events per treatment, p<0.0001) improved as well. Three of the 7 patients with normal adrenal hormones were also empirically tried on FC with no improvement in any of the above-mentioned parameters.

Conclusions: Aldo deficiency is a clinical entity present in some chronic hemodialysis patients suffering from IDH that is readily treatable. Furthermore, this study supports the premise that Aldo – in the absence of changes in sodium balance in oligo-anuric dialysis patients - has direct effects on vascular resistance and deserves further investigation in the chronic dialysis population.

SA-OR394

Acetate-Free Biofiltration Reduces Intradialytic Hypotension in the Long-Term: A Randomized Controlled European Multicenter Trial Nicola Tessitore,[1] Giovanni O. Panzetta,[2] Antonio Santoro,[3] Rafael Perez-Garcia,[4] Albino Poli.[5] *[1]Nephrology, AOUI, Verona, Italy; [2]Nephrology, Trieste, Italy; [3]Nephrology, Policlinico S.Orsola Malpighi, Bologna, Italy; [4]Hospital Infanta Leonor, Madrid, Spain; [5]Public Health Dpt, AOUI, Verona, Italy.*

Background: Intradialytic hypotension (IH) is a common complication of conventional bicarbonate hemodialysis (BD) and it may contribute to the high cardiovascular morbidity and mortality among dialysis patients, a risk that can be contained by the use of convective therapies.

Methods: We have analysed data from a controlled randomised trial to evaluate whether acetate-free biofiltration (AFB), a hemodiafiltration technique with buffer-free dialysate, a high-flux membrane and sterile bicarbonate infusion in post-dilution mode which improved dialytic cardiovascular stability in short-term nonrandomized studies, may influence long-term IH rate, predialysis Sistolic Blood Pressure(SBP), Left Ventricular Mass Index(LVMI), cardiovascular morbidity and mortality by comparison with BD.

Results: The study enrolled 371 patients, 194 on BD and 177 on AFB. During a 3-year follow-up, the IH rate did not change for BD (3.2 to 3.1 session/pt-month,p=ns) and dropped significantly for AFB (4.1 to 2.5 session/pt-month,p<0.0001), equal to a significant IH risk reduction for AFB (incidence rate ratio 0.81[95% CI 0.76-0.86],p=0.0001). Median predialysis SBP did not change for BD, and dropped by 7 mmHg for AFB(p=0.01). Median LVMI increased for BD (4.2 g/m^2), and decreased for AFB (2.2 g/m^2), with no significant differences within or between each group. There was no difference in annual cardiovascular morbidity and mortality between BD and AFB (8.8% and 6.9% vs 9.0% and 5.9%,p=ns). AFB, however, reduced long-term case fatality (cardiovascular death among patients who had a nonfatal cardiovascular event) by comparison with BD (27% vs 59%,p=0.019).

Conclusions: In conclusion, compared to BD, AFB reduced both the IH rate and predialysis SBP in the long-term. It does not affect, however, LVMI, cardiovascular morbility and mortality, but it contains the risk of cardiovascular death after a nonfatal cardiovascular event, possibly thanks to the better intradialytic cardiovascular stability.

SA-OR395

Short-Term Versus Long-Term Effects of Depressive Symptoms on Cardiovascular and Non-Cardiovascular Mortality in Incident End-Stage Renal Disease Patients Tessa O. Van den Beukel,[2,3] Marion Verduijn,[2] Friedo W. Dekker,[2] Adriaan Honig,[4] Carl E.H. Siegert,[3] Elisabeth W. Boeschoten,[5] Raymond T. Krediet,[6] Sandra Van Dijk.[1] *[1]Dept of Medical Psychology, Leiden University Medical Center; [2]Dept of Clinical Epidemiology, Leiden University Medical Center; [3]Dept of Nephrology, Sint Lucas Andreas Hospital; [4]Dept of Psychiatry, Sint Lucas Andreas Hospital; [5]Hans Mak Institute; [6]Dept of Nephrology, Academic Medical Center, Netherlands.*

Background: Dialysis patients with depressive symptoms (DS) have a higher mortality rate compared to patients without DS, even after adjustment for a wide array of covariates. It is unknown whether short-term mortality differs from long-term mortality and whether this depends on the cause of mortality. The objective of this study is to assess whether DS in incident hemodialysis and peritoneal dialysis patients are related to short-term (0-6 months), medium-term (6-24 months), and long-term (24-52 months) cardiovascular and non-cardiovascular mortality.

Methods: 1528 patients participating in the NECOSAD study, a prospective multicenter cohort study of dialysis patients in the Netherlands, completed the Mental Health Inventory, which was used as a measure of DS (cut-off point of ≤ 52), at the starting period of dialysis therapy. Cox regression analyses were used to examine survival.

Results: The adjusted hazard ratio for mortality (HR) for patients with DS compared to patients without DS was 1.43 (95% CI, 1.08-1.88) for cardiovascular mortality and 2.07 (95% CI, 1.62-2.64) for non-cardiovascular mortality. DS posed a strong risk factor for non-cardiovascular mortality at the short-term (HR=2.82, 95% CI, 1.58-5.05), medium-term (HR=2.02, 95% CI, 1.36-3.01) and long-term (HR=1.74, 95% CI, 1.18-2.58), whereas the association between DS and cardiovascular mortality was not observed during the first 6 months of follow-up (HR=1.03, 95% CI, 0.49-2.15).

Conclusions: DS at the start of dialysis therapy pose a risk factor for cardiovascular and / or non-cardiovascular mortality, depending on the length of follow-up. The cause-specific mortality rates over time may help clinicians to understand the association between DS and survival in dialysis patients.

An Important Novel Association between Circulating Endothelial Progenitor Cells and Residual Kidney Function in Peritoneal Dialysis Patients Angela Yee Moon Wang,[1] Sharon Shee Yin Wong,[1] Ruijie Li,[2] Qing Shang,[2] Wai Kei Lo,[3] Cheuk-Man Yu,[2] Kar Neng Lai.[1] *[1]Medicine, Queen Mary Hospital, University of Hong Kong, Hong Kong; [2]Medicine & Therapeutics, Prince of Wales Hospital, Chinese University of Hong Kong, Hong Kong, Hong Kong; [3]Medicine, Tung Wah Hospital, Hong Kong, Hong Kong.*

Background: Bone marrow-derived circulating endothelial progenitor cells (EPCs) plays an important role in vascular repair & maintaining vascular homeostasis. Given the increasing recognition of the significance of residual kidney function (RKF) in end-stage renal disease (ESRD) patients receiving long-term peritoneal dialysis (PD) , this study aimed to determine the association, if any, between circulating EPCs cells (defined as cells that are both CD34+ and kinase insert domain receptor [KDR]+) and RKF in PD patients.

Methods: Forty-one ESRD patients (mean age: 58 ± 8 years) receiving long-term PD treatment (mean ± SD duration on PD: 22 ± 27 mos) were recruited with flow cytometric analysis of circulating CD34+KDR+CD45$^-$ cells & assessment of RKF, urea (Kt/V) and creatinine clearance (CrCl), clinical and biochemical data.

Results: The median (interquartile range) residual glomerular filtration rate (GFR) was 2.5 (0.7, 4.9)ml/min per 1.73m^2. The total weekly Kt/V and CrCl was 2.17 ± 0.51 and 87 ± 41 L/wk per 1.73m^2, respectively. On univariate analysis, circulating CD34+KDR+CD45$^-$ cells showed significant association with total CrCl (β=0.40; P=0.009) and was contributed by its association with RKF (β=0.41; P=0.008) but not with PD CrCl (β = -0.19; P=0.23). Using multiple linear regression analysis and adjusting for confounding covariates, a significant and independent association remained between circulating CD34+KDR+CD45$^-$ cells and RKF (β=0.40; P=0.005).

Conclusions: RKF but not PD clearance showed an independent, positive association with circulating CD34+KDR+CD45$^-$ cells in PD patients. These data provide important novel evidence that reduced level of circulating EPCs may be the missing link between loss of RKF and increased cardiovascular events and mortality in PD patients. The exact cause and effect relationship between circulating EPCs and RKF in PD patients warrant further investigation.

SA-OR397

Low Vitamin E Levels, Cerebrovascular Events and Mortality in Hemodialysis Patients Christiane Drechsler,[1] Katharina Espe,[2] Christoph Wanner.[1] *[1]Dept of Medicine 1, Div of Nephrology, University of Wuerzburg, Germany; [2]Institute of Nutritional Science, Potsdam, Germany; [3]Center for Cardiovascular Research, Charité, Berlin, Germany.*

Background: Hemodialysis patients suffer from increased oxidative stress and experience an exceedingly high mortality as compared to the general population. Trials with the antioxidant vitamin E have shown controversial results. Considering the different causes of death in the dialysis population, this study investigated the effect of vitamin E on specific clinical outcomes in hemodialysis patients.

Methods: In 1046 diabetic hemodialysis patients (participants of the 4D study) alpha-tocopherol was measured by RP-HPLC. By Cox regression analyses, hazard ratios (HR) were determined for pre-specified endpoints according to baseline alpha-tocopherol levels: sudden death (n=134), myocardial infarction (n=172), stroke (n=89), combined cardiovascular events (n=398), fatal infection (n=107), and all-cause mortality (n=508).

Results: Patients had a mean age of 66 (30-83) years and mean alpha-tocopherol level was 22.8 (3.35-87.1)µmol/L. Patients with lower alpha-tocopherol levels in the first quartile (<18.3µmol/L) had an adjusted 2fold higher risk of stroke than those in the fourth quartile (>29.1µmol/L) (HR 2.00, 95% confidence interval 1.11-3.61). Especially patients without a history of cerebrovascular events in the past were affected [HR 3.01 (1.43-6.33)]. Low alpha-tocopherol levels particularly increased the risk of ischemic stroke by 3fold [HR 2.95 (1.43-6.08)], while they did not associate with hemorrhagic stroke [HR 1.10 (0.17-7.32)]. Furthermore, all-cause mortality was significantly increased [HR 1.31 (1.01-1.69)].

Conclusions: Low alpha-tocopherol was strongly associated with stroke, particularly ischemic stroke, in diabetic hemodialysis patients, and contributed to an increased mortality. Whether vitamin E supplementation decreases the occurrence of ischemic stroke, requires further evaluation.

SA-OR398

Oxidized High-Density Lipoprotein as a Risk Factor for Cardiovascular Events in Prevalent Hemodialysis Patients Hirokazu Honda,[1] Masashi Ueda,[2] Shiho Kojima,[2] Shinichi Mashiba,[2] Tetsuo Michihata,[3] Keiko Takahashi,[4] Kanji Shishido,[4] Tadao Akizawa.[1] *[1]Division of Nephrology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan; [2]Ikagaku Co. Ltd, Kyoto, Japan; [3]Ebara Clinic, Tokyo, Japan; [4]Kawasaki Clinic, Kawasaki, Japan.*

Background: The present study assessed the impact of oxidized high-density lipoprotein (oxHDL), dysfunctional HDL, on mortality and cardiovascular disease (CVD) events in prevalent HD patients and compared oxHDL to interleukin-6 (IL-6), a strong predictor for CVD events in HD patients.

Methods: This prospective study examined a cohort of prevalent HD patients (n=412). Blood samples were obtained at baseline to measure lipids, high sensitive-C reactive protein (hsCRP), IL-6, oxidized low-density lipoprotein, N-terminal pro B-type natriuretic peptide, inter-cellular adhesion molecule 1 (ICAM-1), myeloperoxidase, adiponectin, and oxHDL.

Carotid intima-media thickness (CIMT) was assessed at baseline and the 3-year follow-up. Nutritional status was assessed by subjective global assessment (SGA), body mass index, and geriatric nutritional risk index (GNRI). After the baseline assessment, study patients were prospectively followed-up (mean observational period, 40 months).

Results: At baseline, patients with high oxHDL had a worse nutritional state and higher HDL-cholesterol (chol), ICAM-1, and adiponectin levels and a higher oxHDL/HDL-chol ratio than low oxHDL patients. A combination of high oxHDL and high IL-6 was significantly associated with increased CIMT at baseline and a larger increase in CIMT at the 3-year follow-up. High oxHDL did not predict all-cause mortality; however, it was significantly associated with CVD-related mortality and composite CVD events, particularly with concomitant high IL-6. Those associations were confirmed in multivariate Cox hazard models adjusted with confounding variables.

Conclusions: A high oxHDL level may be associated with CVD events and CVD-related mortality, particularly with concomitant high IL-6 in prevalent HD patients.

SA-OR399

The Activation of mTOR Pathway Induced by Inflammation Accelerates the Progression of Atherosclerosis in Hemodialysis Patients Kun Ling Ma, Jing Liu, Min Gao, Xiaoliang Zhang, Bi-Cheng Liu. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiangsu Province, China.*

Background: Chronic inflammation is an independent risk factor in the progression of atherosclerosis (AS) in hemodialysis patients. Our previous studies *in vivo* and *in vitro* demonstrated that inflammation accelerated the progression of AS via the dysregulation of low lipoprotein receptor (LDLr) pathway, which was inhibited by Rapamycin, an inhibitor of mammalian target of Rapamycin (mTOR). This study was to investigate whether inflammation exacerbates lipid accumulation in the tissues of radial arteries in hemodialysis patients and its underlying mechanisms.

Methods: Thirty-one hemodialysis patients receiving arteriovenostomy were divided into two groups by the plasma level of C-reactive protein: Control (n=16), inflamed group (n=15). Hematoxylin-eosin staining and Oil Red O staining were used to check foam cell formation and lipid droplets accumulation using the tissues surgically removed from radial artery. Immunohistochemistry and immunofluorescent staining were used to check protein expressions related with intracellular cholesterol trafficking.

Results: There was a significant increasing of lipid accumulation in the radial artery in inflamed group compared to control, which was correlated with the increased protein expressions of LDLr, sterol regulatory element binding protein-2 (SREBP-2), and SREBP cleavage-activating protein (SCAP). Confocal microscopy observation showed that inflammation enhanced the translocation of SCAP escorting SREBP-2 from the endoplasmic reticulum to the Golgi, thereby activating LDLr gene transcription. Further analysis showed that dysregulation of LDLr pathway induced by inflammation was associated with the increased protein expression of mTOR, especially with the enhanced co-expression of mTOR and SREBP-2.

Conclusions: This study suggested that inflammation accelerated the progression of atherosclerosis in hemodialysis patients through the disruption of LDLr pathway, which could be partly through the activation of mTOR pathway.

Pharmacologically-Relevant Concentrations of Intravenous Iron Preparations Promote Endothelial Injury and Monocyte Adhesion/Infiltration Vaijinath (Vijay) S. Kamanna,[1,2] Shobha H. Ganji,[1,2] Nosratola D. Vaziri.[1] *[1]Department of Medicine, University of California, Irvine, CA; [2]Medical Research Service, VA Health Care System, Long Beach, CA.*

Background: Intravenous iron (IV Fe) preparations are widely used in the management of anemia in ESRD populations. With recent implementation of bundling reimbursement policy, the use of these agents in ESRD patients has dramatically increased to lower the cost of anemia treatment by limiting the use of expensive ESA products. In many instances iron preparations are administered on a routine basis with insufficient attention to the status of total body iron stores or the underlying inflammation which can be aggravated by iron. Endothelial injury and dysfunction are critical steps in the pathogenesis of atherosclerosis, thrombosis and cardiovascular disease. Non-transferrin-bound iron avidly promotes oxidative stress which is a major mediator of endothelial damage and dysfunction. In fact, administration of these agents has been shown to raise markers of oxidative stress in ESRD patients. This study was undertaken to assess the effect of pharmacologically-relevant concentrations of IV iron preparations on endothelial cells and monocytes and interaction thereof in vitro.

Methods: Morphological changes in human aortic endothelial cells (HAEC) were examined by phase contrast microscopy. Cell viability was tested by a cell growth kit. Monocyte adhesion to HAEC was done using fluorescently labeled monocytes.

Results: In contrast to the control HAEC which showed normal morphology, cells treated with iron sucrose (50 and 100 µg/ml) for 4 h showed loss of normal morphological characteristics with cellular fragmentation, shrinkage, detachment, and features of apoptosis including nuclear condensation/fragmentation. Iron sucrose (10-100 mg/ml) robustly increased monocyte adhesion to HAEC by 5-25 folds.

Conclusions: The study documents the potential adverse effects of IV iron preparations on endothelial cells and their interactions with monocytes. These events can contribute to endothelial dysfunction, atherosclerosis, thrombosis and cardiovascular disease which are the major cause of premature death in ESRD population.

Intradialytic Protein Supplementation Attenuates Dialysis-Associated Inflammation and Reduces Co-Morbid Disease Risk Emily Tomayko,[1] Pei-Tzu Wu,[1] Hae Ryong Chung,[1] Peter Fitschen,[1] Brandon Kistler,[1] Barbara Yudell,[1] Elizabeth Jeanes,[2] Shane Phillips,[2] Ken Wilund.[1] *[1]Kinesiology and Community Health, University of Illinois, Urbana, IL; [2]Physical Therapy, University of Illinois, Chicago, IL.*

Background: Inflammation may be both cause and consequence of protein malnutrition, cardiovascular disease, and bone disease in dialysis patients; improving nutritional status may reduce inflammation and the risk for these conditions. This study examines the effects of intradialytic protein intake on circulating inflammatory markers and disease risk factors during a single dialysis session and also over a 6-month period.

Methods: Hemodialysis patients were randomly assigned to the following groups: whey protein (n=20), soy protein (n=15) or placebo (n=10). Blood was drawn immediately after start of dialysis treatment and three hours later on two days one week apart and analyzed for plasma interleukin-6 (IL-6) levels. On day 1, patients did not receive a study beverage but on day 2 consumed their assigned beverage before treatment. A subset of 19 patients continued with the beverage at every dialysis session for 6 months; blood was collected monthly and analyzed for standard clinical chemistries.

Results: All groups had a day 1 increase in IL-6 levels during dialysis indicating an acute inflammatory effect of a single dialysis session; this increase was attenuated in the groups consuming protein on day 2 compared to the placebo group ($p<0.05$). For the 6 month intervention, regression modeling showed a significant increase in albumin levels over time in the whey protein group ($p<0.05$). Alkaline phosphate levels declined in the protein groups compared to placebo ($p<0.05$) suggesting improvement in bone and cardiovascular disease risk. Furthermore, there were no significant group differences for plasma phosphorus, calcium, or potassium, suggesting neither soy nor whey protein intake during dialysis treatment adversely affects these clinically-relevant minerals.

Conclusions: These data support the safety and efficacy of intradialytic protein supplementation for attenuating increases in dialysis-associated inflammation and reducing co-morbid disease risk over a six-month period.

SA-OR402

Effect of Brazilian Nut Supplementation on Antioxidant and Inflammatory Status in Hemodialysis Patients Denise Mafra,[1] Milena Barcza Stockler-Pinto,[2] Julie Lobo,[2] Cristiane Moraes,[1] Najla Elias Farage,[3] Gilson Teles Boaventura,[1] Denis Fouque,[4] Maria Thereza Batista Wady,[1] Wellington Seguins da Silva,[5] Olaf Malm.[2] *[1]Clinical Nutrition, Federal University Fluminense, Niteroi, Rio de Janeiro, Brazil; [2]Institute of Biophysics Carlos Chagas Filho, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; [3]Nutrition, RenalCor Clinic, Rio de Janeiro, Brazil; [4]Nephrology, Hôpital Edouard Herriot- Université Claude Bernard, Lyon, Rhone, France; [5]Oswaldo Cruz Foundation (FIOCRUZ), Rio de Janeiro, Brazil.*

Background: Cumulative evidence indicates that oxidative stress and inflammation frequently occurs in hemodialysis (HD) as a result of a decrease of antioxidant defenses and an overproduction of reactive oxygen species (ROS). Dietary intake of selenium (Se) has been associated with increased activity of glutathione peroxidase (GSH-Px) and, Se also plays an important role as an anti-inflammatory agent. The richest known food source of Se is the brazilian nut (Bertholletia excelsa, family Lecythidaceae), found in the Amazon region. The aim of this study was to evaluate the effect of Brazil nut supplementation on GSH-Px, TNF-α and IL-6 levels in HD patients.

Methods: Forty HD patients (57.5% men, 53.3 ± 16.1 yr) from RenalCor Clinic at Rio de Janeiro, Brazil were studied. All patients received 1 nut (around 5g) a day for three months. The GSH-Px, TNF-α and IL-6 levels were determined by ELISA.

Results: The cytokines levels were above the normal values and, the activity of GSH-Px was below the normal values before nut supplementation. After 3 months supplementation, cytokines levels decreased and the activity of GSH-Px increased significantly ($p< 0.001$).

Parameters before and after nut supplementation

Parameters	Before supplementation	After supplementation
GSH-Px (nmol/ml/min)	34.06 ± 5.2*	40.3 ± 8.4
IL-6 (pg/mL)	67.1 (21.1-80.2)*	13.5 (12.8-22.2)
TNF-α (pg/mL)	21.0 ± 0.3*	13.9 ± 8.7

*p<0.001

Conclusions: Our results indicate that brazilian nut increases the antioxidant status and plays an important role as an anti-inflammatory agent and in HD patients.

Funding: Government Support - Non-U.S.

Effect of Phosphate Binders on Serum Inflammatory Profile, Soluble CD14 and Endotoxin Levels in Hemodialysis Patients: A Prospective, Randomized, Controlled Trial

Juan F. Navarro Gonzalez,[1] Mercedes Muros,[3] Carmen Mora,[2] Patricia García-García,[1] Nieves Del Castillo Rodriguez,[1] Javier Donate,[2] Violeta Cazaña,[2] Javier García-Pérez.[1] *[1]Nephrology, University Hospital Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain; [2]Research Unit, University Hospital Nuestra Señora de Candelaria; [3]Clinical Biochemistry, University Hospital Nuestra Señora de Candelaria.*

Background: Hyperphosphatemia and subclinical endotoxemia are important sources of inflammation in hemodialysis (HD). Pro-inflammatory cytokines are strong correlates of soluble CD14 (sCD14) concentrations, an independent predictor of mortality in this population. We evaluated the effects of calcium acetate and Sevelamer hydrochloride on serum inflammatory profile, endotoxin concentrations and sCD14 levels in HD patients.

Methods: This prospective, randomized, open-label, parallel design trial included 59 stable HD patients, 30 receiving Sevelamer and 29 calcium acetate. Serum levels of inflammatory parameters (high-sensitive C-reactive protein (hs-CRP), tumor necrosis factor-α, interleukin (IL)-1, 6, 10, and 18), as well as serum endotoxin and sCD14 concentrations were measured at baseline and after 3 months of therapy.

Results: Serum IL-6 increased in patients receiving calcium acetate, whereas hs-CRP and IL-6 significantly decreased in subjects treated with Sevelamer, with IL-10 experienced a trend to increase (p=0.052). Serum endotoxin and sCD14 levels did not change after treatment with calcium acetate. However, these parameters decreased by 22.6% and 15.2%, respectively (p<0.01), in patients receiving Sevelamer. Multiple regression analysis showed that variation in serum endotoxin concentrations was the strongest factor associated with IL-6 change, whereas the only variables independently associated with changes in sCD14 levels were the variations in serum IL-6 and endotoxin concentrations.

Conclusions: Administration of the non-calcium phosphate binder Sevelarmer to maintenance HD patients is associated with a significant decrease in hs-CRP and IL-6. In addition, Sevelamer therapy was also associated with reductions of serum endotoxin levels and sCD14 concentrations.

SA-OR404

Mechanism of Increased Renal Angiotensin II in Glomerular Disease

Taiji Matsusaka,[1] Fumio Niimura,[1] Akihiro Shimizu,[1] Akihiko Saito,[2] Akira Nishiyama,[3] Iekuni Ichikawa.[1,4] *[1]Tokai University, Japan; [2]Niigata University, Japan; [3]Kagawa University, Japan; [4]Vanderbilt University.*

Background: Earlier studies by others demonstrated that intrarenal angiotensin II (AII) is increased in various kidney diseases independently of plasma AII.

Methods: We explored the mechanism of this using 2 types of tissue-specific angiotensinogen (Agt) knockout (KO) mice.

Results: Kidney Agt KO showed 85.6% decrease in renal Agt mRNA; however, renal Agt protein was unaffected. Nevertheless, urinary Agt/creatinine was significantly decreased to 47%, indicating that Agt protein synthesized in the kidney is immediately secreted into the urine.

Liver Agt KO mice were near-completely deficient in Agt mRNA and protein in the liver, and in plasma Agt, as well. Remarkably, in the kidney of liver Agt KO, Agt protein was undetectable. Immunostaining of Agt in mosaic proximal tubule-specific megalin KO mice revealed that Agt uptake is completely dependent on megalin. Prior to assessing AII content next, we verified the RIA method by observing undetectable AII in whole body Agt KO. With this method, we found that renal AII content is similar in kidney KO (n=9, 286±38 fmol/g) and control mice (n=8, 315±15), whereas both liver KO (n=8) and kidney/liver dual KO (n=10) have lower AII (110±16, 74±4, both p<0.05).

We, then, assessed the impact of glomerular sieving dysfunction on renal Agt and AII using the immunotoxin-inducible podocyte injury model. After selective podocyte injury, renal Agt protein was dramatically increased. Renal AII content was also increased upon podocyte injury (364±33 fmol/g, n=10), compared with mice without injury (155±27, n=10, p<0.05).

Conclusions: These results indicate that 1) liver Agt is the major source of renal AII, 2) a fraction of circulating Agt, which is originated in the liver, is filtered through the glomerulus, delivered into the urinary space and reabsorbed by PTCs via megalin, and 3) glomerular damage increases the leakage of Agt into the urinary space, which leads to increase in both renal Agt and AII. The data also offer one mechanistic explanation for the notion that proteinuria is a significant risk factor for the progression of glomerular diseases.

Mesenchymal Stem Cells Infusion after Revascularization of Atherosclerotic Renal Artery Stenosis Improves Renal Tubular Transport Function

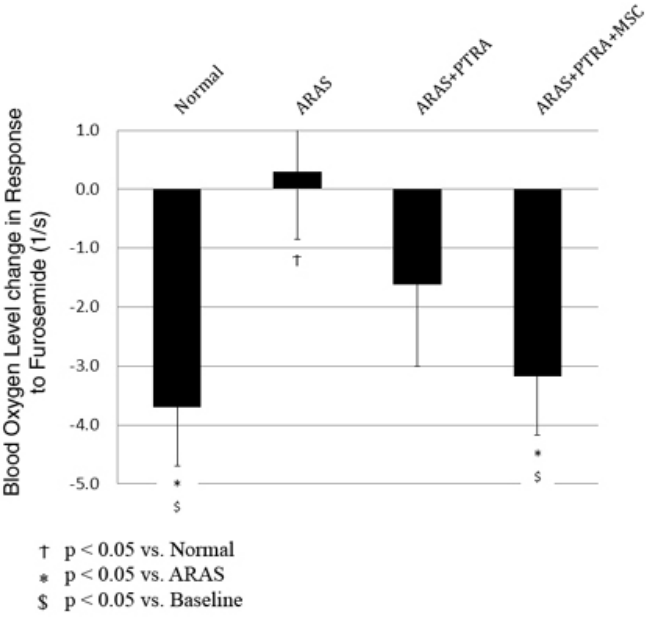
Behzad Ebrahimi, John R. Woollard, Alfonso Eirin, Xiang-Yang Zhu, Stephen C. Textor, Lilach O. Lerman. *Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Atherosclerotic renal artery stenosis (ARAS) leads to reduced blood flow, reduced GFR, and fibrosis, which often fail to recover after percutaneous transluminal renal angioplasty (PTRA). We have shown ARAS is characterized by impaired tubular function and mesenchymal stem cells (MSC) decrease renal injury in untreated ARAS.

Methods: Pigs studied after 10 weeks of untreated unilateral ARAS, treated 4 weeks earlier with PTRA and stenting, w/wo adjunct intra-renal MSC infusion (10^7); normal pigs served as controls (n=4 each group). Medullary oxygenation in stenotic kidneys (R2*) and changes in transport-related oxygen consumption were assessed using blood oxygen-level-dependent (BOLD) magnetic resonance imaging (MRI) before and 15 min after administering furosemide (0.05 ml/kg IV).

Results: Blood pressure was increased in ARAS but decreased in ARAS+PTRA and ARAS+PTRA+MSC (-14.5 and -12 mmHg). In normal kidneys medullary R2* declined after furosemide (Figure, -12.5±7%). This response was blunted in stenotic ARAS medulla (1.0±2.6%), and remained limited in pigs with PTRA (-4.0±7.5%). In contrast, ARAS+PTRA+MSC restored the ΔR2* (-8.5±4.8%) to normal levels.

Conclusions: These data demonstrate MSC infusion immediately after technically successful PTRA allows recovery of measured furosemide-inhibited solute transport beyond that achieved with revascularization alone. Our results support MSC administration as an adjunct intervention for improved viability of the stenotic kidney.



Volume, flow and GFR, 10 weeks after ARAS or sham.

	Volume (cc)	Renal Blood Flow (ml/min)	GFR
Normal	130.2±11.8	534.7±74.7	92.1±7.3
ARAS	100.3±8.8*	385.3±19.2*	57.7±7.3*
ARAS+PTRA	110.4±5.7	438.0±28.1*	63.4±3.1
ARAS+PTRA+MSC	130.8±6.8	508.6±23.8	85.3±8.6

* P<0.05 vs Normal

Silencing of Endothelial Cell Enriched MicroRNA-126 Is Associated with Elevated SDF-1 Levels and the Increase of Circulating Sca-1$^+$ Progenitor Cells after Ischemia Reperfusion Injury

Anton Jan Van Zonneveld,[1,2] Coen van Solingen,[1,2] Hetty C. de Boer,[1,2] Roel Bijkerk,[1,2] Eric P. Van der Veer,[1,2] Alexander F. Schaapherder,[3] Paul Quax,[2,3] Ton J. Rabelink.[1,2] *[1]Nephrology, LUMC, Leiden, Netherlands; [2]Einthoven Laboratory for Experimental Vascular Medicine, LUMC, Leiden, Netherlands; [3]Surgery, LUMC, Leiden, Netherlands.*

Background: Stromal cell-derived factor-1 (SDF-1) expression has been shown to be upregulated in the kidney following ischemia reperfusion injury and may serve a reparative response by recruiting CXCR4-positive cells to the kidney. As SDF-1 mRNA contains a potential seed sequence for microRNA-126 (miR-126), we investigated the regulatory role of this endothelial cell (EC) enriched miR in SDF-1 expression and peripheral progenitor mobilization in mouse models of ischemia-reperfusion.

Methods: Using miR-reporter constructs and Western blots, we demonstrated that SDF-1 mRNA is a direct target of miR-126 in HUVEC. Using a transwell system and conditioned medium harvested from HUVEC incubated with antagomir-126 or scramblemir we assessed the effect of miR-126 on chemotaxis of CD34$^+$ cells. Finally, we injected mice with antagomir-126 and performed either hind limb ischemia (HLI) or ischemia-reperfusion injury of both kidneys (IRI) to assess the effect of miR-126 silencing on progenitor cell mobilization.

Results: *In vitro* experiments showed that silencing of miR-126 in HUVEC enhanced SDF-1 expression and stimulated migration of CD34$^+$ cell. After IRI or HLI, qRT-PCR on whole kidney lysates and immunohistochemistry in the ischemic hind limb displayed elevated levels of SDF-1 in the animals injected with antagomir-126. In both models of ischemic injury, FACS-analysis revealed a marked upregulation of the number of circulating Sca-1$^+$/Lin$^-$ progenitor cells in the antagomir-126 treated mice. In contrast, in the absence of ischemia silencing of miR-126 had no effects on progenitor cell mobilization.

Conclusions: We demonstrate that silencing of endothelial miR-126 can enhance the expression of SDF-1 in an ischemia-dependent way, leading to the mobilization of Sca-1$^+$/Lin$^-$ progenitor cells into the circulation.

Chronic Perturbation of the Endothelial Surface Glycocalyx Results in Proteinuria without Morphological Changes of the Glomerulus Martijn Dane,[1,2] Daniel R. Potter,[2] Ton J. Rabelink,[1] Hans Vink,[2] Bernard Van Den Berg.[1] *[1]Nephrology, LUMC, Leiden, Zuid-Holland, Netherlands; [2]Fysiology, MUMC, Maastricht, Limburg, Netherlands.*

Background: The glomerular filtration barrier consists of podocytes, glomerular basement membrane and the endothelial layer with its surface bound glycocalyx. Although the sequence of events that can result in proteinuria is not known for cardiovascular conditions such as T2D, the endothelial glycocalyx has been shown to be damaged in proteinuric T2D. We hypothesize that damage of the glycocalyx can initiate proteinuria.

Methods: In C57BL/6J mice, vascular surface hyaluronan is enzymatically degraded through chronic infusion of hyaluronidase (hyal). After two weeks, systemic vascular glycocalyx volume, urine prot/creat- and dex500/dex40 ratios, as well as dry/wet kidney ratio and blood pressure were determined. EM analysis was performed for ultrastructural changes in the glomerular barrier. After four weeks, localization of the lectins LEA, WGA and BSI (binding N-acetyl-β-D-glucosamine, N-acetyl-β-D-glucosaminyl and N-acetyl-α-D-galactosaminyl, resp.) within the glomerulus were analyzed according to CD31 position using confocal microscopy.

Results: After two weeks hyal glycocalyx volume was decreased ($P<0.05$) to(mean 0.27 ml ± 0.04 SD vs. hyal-inact 0.51 ml ± 0.11). Pooled urine samples after hyaluronidase showed a 5-fold increase in prot/creat ratio and accompanied by an increased Dex500/Dex40 leakage (0.22 ± 0.06 vs. 0.62 + 0.26, $P<0.05$). After 4 weeks hyal, luminal endothelial LEA and BSI staining was decreased compared to hyal-inact (LEA: 4%vs. 75%; BSI: 11%vs 65%, of positive staining). WGA staining was only present outside of the CD31 perimeter (GBM, podocytes) and remained unchanged. No change in blood pressure and heart rate was observed during two weeks of infusion.

Conclusions: Chronic hyaluronidase treatment damaged the glomerular endothelial glycocalyx and was associated with development of proteinuria. This insult was without changes in extravascular carbohydrate content, or with overt histopathological changes, such as microaneurisms, GBM thickening or podocyte flattening. Loss of endothelial glycocalyx function can cause the onset of proteinuria.

In End-Stage Renal Disease Serum Amyloid A Accumulates in Plasma and HDL of Patients Leading to Diminished Anti-Inflammatory Capacity of HDL Tao Huang, Markus Tolle, Mirjam Schuchardt, Markus van der Giet. *Med. Klinik mit SP Nephrologie, Charite - Campus Benjamin Franklin, Berlin, Germany.*

Background: The reduction in renal function correlates with an increase in cardiovascular mortality. Epidemiological studies demonstrate that high density lipoprotein (HDL) loses its anti-inflammatory properties. The chemokine monocyte chemoattractant protein-1 (MCP-1) production is crucial for inflammatory response in the vascular wall by recruitment of monocytes. The aim of this study was to investigate structural modifications in HDL of ESRD patients leading to reduced protective function.

Methods: HDL was isolated from serum of donors via ultracentrifugation Separation of HDL in lipid/protein fraction was done by isopropanol/hexan method. Rat vascular smooth muscle cells (VSMCs) were used. MCP-1 expression was detected by real-time PCR and secretion by Luminex™ technology. Serum amyloid A (SAA) level was quantified by ELISA.

Results: HDL isolated from healthy donors as well as from ESRD patients dose-dependently reduced the thrombin-induced MCP-1 expression and secretion in VSMCs, but with a reduced capacity of HDL from patients. HDL from ESRD patients significantly induced MCP-1 secretion, whereas HDL from healthy controls had no effect. Therefore, HDL from ESRD patients was separated in protein/lipid fraction and the stimulatory potential of each fraction was analyzed. The protein fraction strongly induced MCP-1, whereas the lipid fraction showed basically no activity. Mass-spectrometry analysis of the fraction leading to a strong MCP-1 induction identified SAA. Enrichment of SAA in HDL from healthy donors showed comparable reduced anti-inflammatory potential of HDL. SAA levels were markedly increased in both serum and HDL of ESRD patients compared to healthy controls. There is a correlation of SAA content in HDL and the reduced anti-inflammatory capacity.

Conclusions: Here we present evidence that HDL from ESRD patients rendered pro-inflammatory by SAA accumulation. SAA enrichment leads to dysfunctionality of the particle HDL. The decreased anti-inflammatory properties of HDL may substantially contribute to the excessive cardiovascular microinflammation in ESRD patients.

SA-OR409

Knockout of the Vascular Endothelial Glucocorticoid Receptor Accelerates Atherosclerosis in a Mouse Model Julie Goodwin,[1] Xinbo Zhang,[2] Jun Yu.[2] *[1]Pediatrics, Yale University School of Medicine, New Haven, CT; [2]Cardiology, Yale University School of Medicine, New Haven, CT.*

Background: Cardiovascular complications, and in particular atherosclerosis, are a major source of morbidity and mortality in patients with chronic kidney disease. The therapeutic potential of alterations in glucocorticoid metabolism in cardiovascular disease has recently become a focus of investigation. We hypothesize that the endothelial glucocorticoid receptor is a critical mediator of atherosclerosis through changes in eNOS metabolism that promote a pro-inflammatory state.

Methods: Mice with knockout of the endothelial glucocorticoid receptor were bred onto an ApoE knockout background. Control and knockout animals were fed an atherogenic diet for 14 weeks. Then mice were sacrificed and atherosclerotic lesion development was assessed in the aorta and brachiocephalic artery by Oil Red O and H & E staining. Total cholesterol and triglycerides were also measured at baseline and after feeding periods in each group.

Results: Knockout animals had higher mortality with only 35% surviving until the end of the feeding period compared to 85% of the wild-type animals ($p=0.039$). Knockouts also demonstrated more severe atherosclerotic lesions in both the aorta (69.8±8.2% vs. 44.8±2.3%, $p=0.019$) and brachiocephalic artery (70±10.3% vs. 33±10.8%, $p=0.031$) compared to controls. There was no difference in cholesterol or triglyceride levels between the groups either at baseline or after 14 weeks of atherogenic diet. Lesion analysis in knockout animals fed for only 5 weeks appears similar to that of wild-type animals fed for 14 weeks.

Conclusions: These studies suggest that:

(1) knockout of the endothelial glucocorticoid receptor results in a more severe atherosclerotic phenotype

(2) differences in lipid levels cannot account for the observed phenotype

(3) the endothelial glucocorticoid receptor may be a critical mediator of local inflammation in this model.

Type-I Interferon Enhances Arterial Intimal Hyperplasia Mark S. Segal, Pui Lee, Laura Sautina, Yanpeng Diao. *Medicine, University of Florida, Gainesville, FL.*

Background: System Lupus Erythematosis (SLE) patients have a significantly increased risk of coronary heart disease and premature atherosclerosis. Interestingly, approximately half of SLE patients have an elevated serum level of Type-I Interferon (INF-I) and IFN-I has been shown to induce the production of pro-atherosclerotic chemokines. We hypothesized that IFN-I would accelerate arterial intimal hyperplasia (IH) by altering the ratio of endothelial progenitor cells (EPC) to smooth progenitor muscle cells (SMPC).

Methods: In-vitro, SMPC and EPC were cultured with or without INF-I. In-vivo, femoral artery injury was performed in a mice expressing INF-I via electroporation of an INF-I expression plasmid into the gastrocnemius and analyzed 4 weeks after injury.

Results: SMPC number was significantly higher after the treatment of INF-1. However, no difference was observed in EPC clone number. In mice with elevated systemic levels of INF-I, there was a greater degree of lumen narrowing than in controls. Meanwhile, while there was a significant increase in proliferating SMC within the neointima in INF-I treated animals, but there was no difference in media SMC proliferation and endothelial cell proliferation between INF-I treated and control animals.

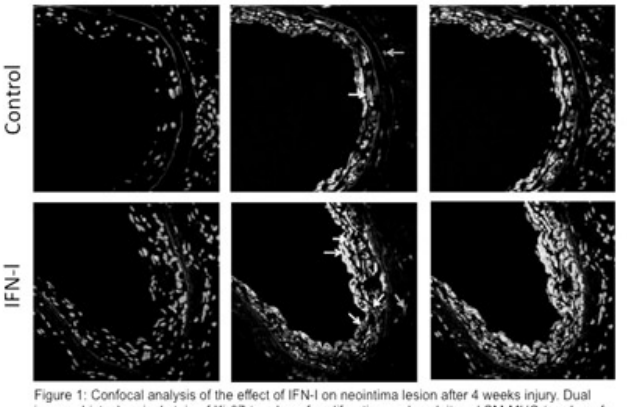

Figure 1: Confocal analysis of the effect of IFN-I on neointima lesion after 4 weeks injury. Dual immunohistochemical stain of Ki-67 (marker of proliferation; red nuclei) and SM-MHC (marker of SMC; green cytosol) indicates that an increased number of proliferating (yellow arrows) SMC within neointima in INF-I treated animals (lower panels) than control (upper panels). Note: Only the cells with red nuclei and green cytosol were identified as proliferating SMC, most of the red nuclei without green cytosol identified as leukocytes (CD45 staining cells; orange arrows), data not shown. All sections were counterstained with DAPI (blue). Object: 40X

Conclusions: Our finding that IFN-I accelerates IH in an arterial injury model has profound implications for patients with SLE. The mechanisms appear to involve altering the balance of EPC and SMPC, but may also affect progenitor SMC within the arteries itself. These studies shed light on the increased cardiovascular risk in SLE patients.

MicroRNA-21 and TGF-beta in Diabetic Glomerulopathy Jennifer Yi-Chun Lai,[1] Viji Nair,[1] Wenjun Ju,[1] Jinghui Luo,[1] Stuart Orkin,[2] Robert G. Nelson,[3] Matthias Kretzler,[1] Markus Bitzer.[1] *[1]Medicine, University of Michigan, Ann Arbor, MI; [2]Dana Farber Cancer Institute, Boston, MA; [3]NIDDK, National Institutes of Health, Phoenix, AZ.*

Background: Glomerulopathy is an early finding in Diabetic Nephropathy (DN) associated with activation of TGFβ signaling and podocyte apoptosis. Pima Indians exhibit high rates of type 2 diabetes mellitus and DN. MicroRNAs (miRs) are implicated in mediating development of DN. We previously showed that miR-21 inhibits renal cell apoptosis in cultured renal cells and in vivo. We examined regulation of miR-21 expression in human and murine models of DN and further explored miR-21 functions in miR-21 null mice.

Methods: Total RNA was extracted from micro-dissected glomeruli of kidney biopsy tissues from 26 diabetic Pima Indians. Small RNA fraction was obtained from the flow-through of silica-membrane RNA columns. MiR-21 expression was quantified using Taqman qrt-PCR (Applied Biosystems) and correlated with urinary albumin-creatinine ratio (ACR) using Pearson correlation. Mice ubiquitously deficient for miR-21 generated by cre-mediated deletion of the floxed pre-miR-21 coding sequence were crossed with Albumin-TGFβ1 transgenic mice. PAS-staining was used for histologic analysis. Albuminuria in mice was determined semi-quantitatively.

Results: MiR-21 exhibited high relative expression in glomeruli and excellent correlation with ACR (Correlation coefficient = 0.8, FDR = 0, $p < 0.001$). TGFβ1/miR-21 null mice exhibited strongly increased deposition of PAS-positive material, and loss of glomerular cells and open capillary loops. In TGFβ1/miR-21 null mice albuminuria was already increased at 2 weeks of age and exceeded 5g albumin/1g creatinine at 4 weeks of age in over 50% of mice but was less than 0.5g/g in all wildtype littermates.

Conclusions: MiR-21 expression is abundant in glomeruli and associated with ACR in human diabetic nephropathy. Loss of miR-21 results in progressive glomerular injury induced by TGFβ1. We propose that miR-21 expression increases with injury as an attempt by glomerular cells to limit damage. Studies exploring the underlying mechanisms are underway.

DNA Aptamers Raised Against AGEs Improve Diabetic Nephropathy in KK/Ay-Ta Mice Yusuke Kaida,[#1] Kei Fukami,[#1] Seiji Ueda,[#1] Sho-Ichi Yamagishi,[#2] Seiya Okuda.[#1] *[1]Division of Nephrology, Department of Medicine, Kurume University, Kurume, Fukuoka, Japan; [2]Department of Pathophysiology and Therapeutics of Diabetic Complications, Kurume University, Kurume, Fukuoka, Japan.*

Background: Diabetic nephropathy (DN) is one of the most common causes of end-stage renal disease and accounts for the morbidity and mortality in these patients. There is a growing body of evidence that advanced glycation end products (AGEs) and their receptor (RAGE) system plays a role in DN. In this study, we selected AGEs-DNA aptamer directed against AGEs *in vitro*, and examined their protective effect on DN in KKAy/Ta mice, an animal model of type 2 diabetes.

Methods: We identified high-affinity DNA aptamers directed against AGE-human serum albumin (AGEs-aptamers) using combinatorial chemistry *in vitro*. AGEs-aptamers (CCGAAACCAGACCACCCCACCAAGGCCACTCG GTCGAACCGCCAACACTCACCCCA) and control-aptamers were administrated to KKAy/Ta mice and non-diabetic control C57BL/6J mice (Ctrl mice) for 8 weeks using an osmotic mini pump. Urinary albumin excretion (UAE) was measured by enzyme-linked immunosorbent assay (ELISA). RAGE expression was evaluated by real-time PCR. Glomerular injury and fibrosis were evaluated by periodic acid-Schiff staining (PAS) and Masson-trichrome staining, respectively.

Results: Plasma levels of glucose and HbA1c were increased by about 1.5-2-folds in 16-week diabetic mice compared with Ctrl mice (plasma glucose; 298+/-59.6 mg/dl, HbA1c; 5.8+/-0.52 % in 16-week diabetic mice). Serum levels of blood urea nitrogen (BUN), creatinine (Cr) and UAE were significantly increased in diabetic mice, all of which were inhibited by the administration of AGEs-aptamers (BUN; 33.1+/-12.6 vs 27.5+/-1.7 mg/dl, $p<0.05$, Cr; 0.15+/-0.061 vs 0.09+/-0.003 mg/dl, $p<0.01$, UAE; 709+/-43 vs 234+/-21 mg/mgCr, $p<0.01$). Further, AGEs-aptamers suppressed RAGE expression and improved glomerular injury and sclerosis index in DM mice.

Conclusions: We demonstrated for the first time that administration of AGEs-aptamers significantly prevented the progression of DN in KKAy/Ta mice. The present study suggests that AGEs-aptamers may be a novel therapeutic tool for the treatment of DN.

SA-OR413

Epigenetic CpG Methylation of Tight Junction Protein, Claudin-1 through Sirt1 and Dnmt1 Controls Albuminuria in Diabetic Nephropathy Kazuhiro Hasegawa, Shu Wakino, Koichi Hayashi. *Keio University.*

Background: We previously reported that our **Tg mice with kidney-specific overexpression of Sirt1** protected against **AKI** (JBC 2010). However, a correlation between renal Sirt1 and **CKD** is unclear. Here, we explore the role of renal Sirt1 in **diabetic nephropathy (DN)** and **the regulatory mechanism** of the expression of claudin-1 by Sirt1.

Methods: WT or Tg mice were rendered DN by the treatment with streptozotocin (STZ). We also utilized cultured **podocytes** and human renal epithelial cell, **HRE cells** to explore **epigenetic** regulatory mechanism by Sirt1 by performing bisulfite sequences, methylation-specific PCR (MSP), real-time MSP and ChIP assay.

Results: WT+STZ mice were presented with prominent albuminuria with podocytes foot process effacement. Sirt1 expression was decreased in proximal tubules as well as podocotyes. Among various molecules, tight junction protein claudin-1, a parietal epithelial cell marker, was ectopically upregulated in podocytes. Conversely, these findings were attenuated in **Tg+STZ**. In podocytes with the direct **transfection of claudin-1**, the expressions of slit diaphragm proteins, podocin and synaptopodin were downregulated and albumin permeability was significantly increased. Notably, we identified a claudin-1 CpG island. In HREs, **high glucose (HG)** decreased the expression of Sirt1 and reduced the methylation of claudin-1 CpGs, concomitant with the increased claudin-1 expression. Contrarily, **Sirt1 cDNA transfection** induced hypermethylation in claudin-1 CpGs and this increase was blocked by DNA methyl transferase (Dnmt)-1 silencing. Additionally, Sirt1 transfection protected against both HG-induced hypomethylation of claudin-1 CpGs and upregulation of claudin-1 expression. Finally, ChIP revealed that Sirt1 deacetylated histone H3 H4 and methylated H3K9 within claudin-1 CpGs, which activated Dnmt1.

Conclusions: In **non-DN** state, Sirt1 downregulated claudin-1 expression through Dnmt1-dependent epigenetic regulation. Oppositely, in **DN**, HG-induced Sirt1 downregulation increased the claudin-1 expression leading to the downregulation of slit diaphragm proteins and to the increase in podocytes' albumin permeability. This novel epigenetic mechanism contributes to albuminuria in DN.

SA-OR414

Proximal Tubules-Specific Sirt1-Deficient Mice Aggravates Albuminuria in Diabetic Nephropathy by Accelerating De-Diffrentiation of Podocytes Kazuhiro Hasegawa, Shu Wakino, Koichi Hayashi. *Keio University.*

Background: NAD-dependent deacetylase, Sirt1 confers protective effects in various tissues. We previously reported that proximal tubules (PT)-specific Sirt1 transgenic mice protected against acute kidney injury (JBC 2010) and diabetic nephropathy (DN) (oral presentation at ASN 2010). In this study, we newly developed **PT-specific conditional Sirt1-deficient mice** to investigate if its role in the initiation and progression of DN.

Methods: We generated PT-specific Sirt1 deficient mice (conditional knockout mice, CKO) by crossing $Sirt1^{flox/flox}$ mice with KAP-Cre mice. Wild-type (WT) or CKO mice were injected with saline (control) or streptozotocin to be rendered DN. The phenotypes of four groups of mice, **WT+Sal, CKO+Sal, WT+STZ, CKO+STZ** were analyzed 24 weeks after the treatment.

Results: Sirt1 expression was specifically reduced in PTs in CKO. Immnostaining showed that Sirt1 expression in PTs and podocytes was reduced in WT+STZ compared with that in WT+Sal. This reduction was further prominent in CKO+STZ. Urinary analysis demonstrated that the increase in **urinary albumin excretion** in WT+STZ was further augmented in CKO+STZ. PAS staining and electron microscopy showed the increase in mesangial matrix accumulations or GBM thickness in WT+STZ mice were not altered in CKO+STZ. However, the increase in **podocyte foot process effacement** in WT+STZ as compared in WT+Sal was further augmented in CKO+STZ. Real time PCR assay after laser microdissection of glomerus demonstrated that **a tight junction protein, claudin-1** was elevated in WT+STZ as compared with WT+Sal and that this increase was further enhanced in CKO+STZ. Conversely, **slit-diaphragm proteins**, nephrin, podocin, synaptopodin were further decreased in CKO+STZ as compared with reduction in WT+STZ.

Conclusions: The present study revealed that deficiency of Sirt1 in PT had unfavorable effects on the phenotype of podocytes including the foot process effacement, the downregulation of slit diaphragram proteins and the upregulation of tight junction protein, claudin-1 in DN. Sirt1 in PT is the safeguard against the initiation and progression of DN-induced **podocytes' de-diffrentiation** though the novel mechanism of **PT-podocyte communication**.

SA-OR415

Human Adipose-Derived Adult Stem Cells Attenuates Podocyte Injury of Rats with Diabetic Nephropathy Li Zhang, Xiangfei Liu, Bo Fu, Dian Geng Li, Qinggang Li, Xiang-Mei Chen. *Chinese PLA Institute of Nephrology, Chinese PLA General Hospital, Beijing, China.*

Background: Diabetic nephropathy (DN) is a common complication of diabetes mellitus. Once diabetic nephropathy becomes overt, there is no curative therapy, and most patients will eventually progress towards end-stage renal disease. Adipose-derived adult stem cells (ADSCs) have been shown to possess self-renew and pluripotent capabilities, and to protect against acute renal injury. This study was conducted to investigate the effects of ADSCs on DN in rats.

Methods: ADSCs were isolated from adipose tissue of patients undergoing tumescent liposuction. Adult male Sprague-Dawley rats underwent right nephrectomy followed by streptozotocin (STZ) injection intraperitoneally (65mg/kg) two weeks later. Diabetic rats received daily subcutaneous injections of protamine zinc insulin to maintain blood glucose level (BG) between 16.7-33.3mmol/L. 12 weeks after STZ injection, the rats were divided into two groups, control group (NX+STZ) and hADSCs group (NX+STZ+ hADSCs). 5×10^6 hADSCs were intravenously injected into tail vein of the rats in hADSCs group once every four weeks for 20 weeks, while PBS was injected as control. 32 weeks after STZ injection, the rats were sacrificed and samples of 24-h urine, blood, kidney and pancreas were collected.

Results: Treatment with hADSCs had no effect on blood glucose levels and pancreatic histological damage in the DN rats, but did lower 24-hour urine protein excretion, lighten kidney weight, reduce glomerular hypertrophy (mean cross-sectional area of glomerular

tuft) and podocyte loss, ameliorate inflammatory cell infiltration and renal interstitial fibrosis. Both in vivo and in vitro assay demonstrated that hADSCs could decrease podocyte apoptosis and upregulate podocyte VEGF protein expression. Real-time PCR indicated that the expression of IL-1 and IL-4 was downregulated, while IL-6 and IL-10 was upregulated.

Conclusions: These results suggested that hADSCs therapy can protect against diabetic renal injury through attenuating podocyte injury and modulating inflammatory response.

BMP4 Regulates Podocyte Injury in the Diabetic Nephropathy Tatsuya Tominaga,[1] Hideharu Abe,[1] Seiji Kishi,[1] Kojiro Nagai,[1] Otoya Ueda,[2] Kou-Ichi Jishage,[2] Naoshi Fukushima,[2] Toshio Doi.[1] *[1]University of Tokushima; [2]Chugai Pharmaceutical Co. Ltd,.*

Background: We have shown that bone morphogenetic protein 4 (BMP4) signaling leads mesangial matrix hyperplasia in diabetic nephropathy (DN). Degeneration and loss of podocyte provide the important pathological mechanism for DN.

Methods: In order to analyze the molecular mechanism of podocyte injury, the effect of Bmp4 in vitro was investigated in the cultured podocyte. We studied the role of Bmp4 in streptozotocin (STZ)-induced diabetic mice. The induced-Bmp4 transgenic mice (Bmp4 tgm) were generated by the tamoxifen-regulated Cre-loxP system in order to examine the role of Bmp4 in vivo. Finally diabetic Bmp4 heterozygous knockout mice (Bmp4+/-) were analyzed to investigate suppressant effect of Bmp4 in vivo.

Results: Cultured podocyte showed the activation of p38 by Bmp4 treatment. The expression of nephrin was decreased by Bmp4 treatment in a dose dependent manner in vitro. Diabetic mice represented the positive expression of Bmp4, which degrees were associated with the levels of glomerular matrix hyperplasia in STZ mice ($r = 0.927$, $p < 0.01$). Bmp4 tgm were indicated significant mesangial matrix expansion and thickening of glomerular basement membrane, which showed similar glomerular alteration to diabetic glomerulosclerosis. Albuminuria was dramatically increased in Bmp4 tgm compared with non-inducible mice. Moreover, we confirmed podocyte injury in Bmp4 tgm. The Bmp4 tgm decreased both the expression of nephrin and the count of WT-1 positive cells. The glomerular matrix hyperplasia progressed in accordance with the decreased number of WT1 positive cells. The number of podocyte also decreased inversely with an increase of the albuminuria. To confirm the direct evidence of Bmp4 signaling in vivo, we investigated whether the reduction of Bmp4 expression improved the diabetic glomerular changes by using Bmp4+/- mice. The diabetic Bmp4+/- mice showed to improve the nephrin expression compared with diabetic wild mice. Proteinuria also decreased in diabetic Bmp4+/- mice compared with diabetic wild mice.

Conclusions: These data suggest that BMP4 plays an essential role for development of podocyte injury in DN.

Funding: Government Support - Non-U.S.

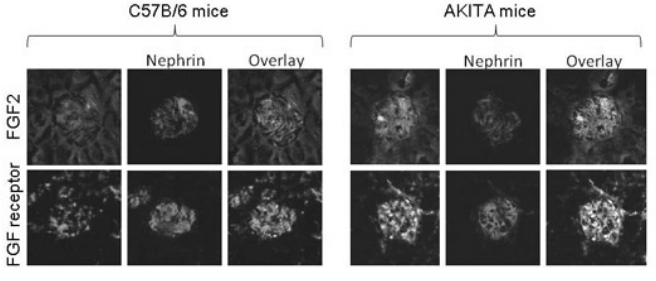
SA-OR417

FGF Signaling Predisposes Podocyte Injury in Diabetic Nephropathy (DMN) Koji Okamoto, Tomoko Ishizu, Kenjiro Honda, Kent Doi, Takehiko Wada, Toshiro Fujita, Eisei Noiri. *Departments of Nephrology & Endocrinology, Hemodialysis & Apheresis, University Hospital, The University of Tokyo, Japan.*

Background: Genome-wide association study for DMN revealed FGF2 pathway related genes as DMN susceptibility genes (*Nature Genetics 2011*). However, the relationships between FGF2 signaling and DMN was not fully elucidated.

Methods: FGF2 ligands and FGFRs expression were studied in mice model (AKITA mice vs. sib control mice) and mice podocyte cell line. To analyze the resistance to FGF2 in mice model, exogenous FGF2 (5 μg/animal/day i.v., day0-3) was administered to AKITA mice or sib control mice. To analyzed the efficacy of FGF antagonist to mice model, puromycin aminonucleoside and/or FGF antagonist (50 μg/animal/day i.p. day 0-4) was injected in AKITA mice.

Results: FGF2 level of renal cortex was increased in AKITA compared with control mice, (AKITA 0.86 ± 0.08 vs. sib control 0.46 ± 0.02 pg/μg protein). In addition, mRNA expression of FGFRs in total renal cortex (187%), and intraglomerular protein expression of FGFRs were increased in AKITA.



In vitro assay, high glucose medium significantly induced mRNA expression of FGFRs in mouse podocyte cell line (138%). Microalbuminuria in AKITA+FGF2 was significantly increased on day 10-15 (231.7 ± 64.8 / 88.6 ± 11.7 mg/gCr). In contrast, microalbuminuria was not induced in control mice. Next, the FGF antagonist was evaluated as a therapeutic agent to the accelerated diabetic nephropathy using puromycin aminonucleoside and AKITA. When PAN (10 mg/animal/day i.v., day0) was administered to AKITA, microalbuminuria in AKITA+PAN was significantly increased on day 5-10 (AKITA+FGF2 527 ± 64.8 mg/gCr). In contrast, microalbuminuria was not increased in those treated by FGF antagonist.

Conclusions: Both FGF2 and FGF receptors were induced under hyperglycemia and play a crucial role of podocyte injury in DMN.

Funding: Government Support - Non-U.S.

SA-OR418

Translationally Controlled Tumor Protein Is Associated with Podocyte Hypertrophy in a Mouse Model of Type 1 Diabetes Dong Ki Kim,[1] Yon Su Kim,[1] Shin-Wook Kang.[2] *[1]Internal Medicine, Seoul National University Hospital, Seoul, Korea; [2]Internal Medicine, Yonsei University College of Medicine, Seoul, Korea.*

Background: Translationally controlled tumor protein (TCTP) is thought to be involved in various intracellular processes by regulating mammalian target of rapamycin complex 1 (mTORC1) signaling. Because diabetes characteristically induces hypertrophy in podocytes in the early stage of the disease and mTORC1 signaling has been implicated in this process, TCTP may have a role in the pathogenesis of podocyte hypertrophy in diabetic nephropathy.

Methods: We examined the changes in TCTP expression in experimental diabetic glomeruli. To characterize the role of TCTP in podocyte hypertrophy, we conducted in vivo gene silencing of TCTP through the hydrodynamic injection of TCTP shRNA expressing lentivirus (LV-shTCTP).

Results: Glomerular expression of TCTP were higher in DM mice compared with C mice. Double immunostaining for TCTP and synaptopodin revealed that podocytes were the main cells responsible for this increase. TCTP knockdown by RNA interference ameliorated the activation of mTORC1 downstream effectors and the overexpression of cyclin dependent kinase inhibitors (CKIs) in diabetic glomeruli. Light microscopic examination revealed a marked glomerular hypertrophy in DM mice compared with C mice. In contrast, transduction of LV-shTCTP in DM mice attenuated the glomerular hypertrophy. The mean volume of podocyte measured by an unbiased stereological technique using optical disector were significantly higher in DM mice compared with control, whereas numerical density of podocytes were lower in diabetic mice. These morphologic changes were significantly ameliorated by the LV-shTCTP treatment. Electron microscopy of glomeruli revealed that podocytes of DM mice were enlarged with mild thickening of GBM, whereas the foot process was mostly intact. However, the diabetes-induced hypertrophy of podocytes, but not the GBM thickening, was substantially reduced in DM+LV-shTCTP1 mice.

Conclusions: These findings suggest that TCTP might play an important role in the process of podocyte hypertrophy under diabetic conditions via the regulation of mRNA translation and the induction of cell cycle arrest.

Transcriptome Analysis of Human Diabetic Kidney Disease Ae Seo Deok Park,[1] Karolina Woroniecka,[1] Davoud Mohtat,[1] David B. Thomas,[2] Katalin Susztak.[1] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Nephrocor, Uniondale, NY.*

Background: Diabetic kidney disease (DKD) is the single leading cause of kidney failure in the United States. The aim of this study was to provide an unbiased catalogue of gene expression changes in human diabetic kidney samples.

Methods: Affymetrix expression array was used to identify differentially regulated transcripts in 22 microdissected human renal glomerular and 22 tubular samples. Stringent statistical analysis was used to identify differentially expressed transcripts in control and diseased glomeruli and tubuli. Two different web-based algorithms were used to define differentially regulated pathways.

Results: The DKD samples were significant for racial diversity, decreased eGFR (DKD glomeruli 31.08±13.36 ml/min vs. Control 80.91±23.42; DKD tubuli 21.85±11.54 ml/min vs. Control 73.77±21.08), increased proteinuria, serum creatinine, and BUN, and presence of diabetes and hypertension. Histological changes showed consistent with DKD, increased glomerulosclerosis, tubular atrophy, interstitial fibrosis, vascular sclerosis, and mesangial matrix expansion. The phenotype was significant for advanced CKD (Stage IV).

Statistically significant, 1,700 differentially expressed probesets in DKD glomeruli were identified, and 1,831 in DKD tubuli. And 330 probesets were commonly differentially expressed in both compartments. Almost all podocyte specific transcripts showed decreased expression and there was excellent correlation between the protein and mRNA level data.

Pathway analysis highlighted the regulation of the complement system, actin cytoskeleton pathways like RhoA and Cdc42, extracellular matrix (ECM)-receptor interaction like integrin and ILK, and VEGF signaling in DKD glomeruli among other 22 canonical pathways. The DKD tubulointerstitial compartment showed strong enrichment for inflammation related pathways. The canonical complement signaling pathway was determined to be statistically differentially regulated in both DKD glomeruli and tubuli, and was associated with increased glomerulosclerosis.

Conclusions: Our studies identified multiple novel genes and pathways that may play a role in the pathogenesis of DKD or could serve as biomarkers.

MiR-21 Is a Key Mediator in the Development of Diabetic Kidney Injury in db/db Mice and In Vitro under Diabetic Conditions Xiang Zhong,[1,3] Arthur Chi-Kong Chung,[3] Haiyong Chen,[2,3] Xiaoming Meng,[2,3] Yuan Dong,[3] Rong Li,[1,3] Xiao Ru Huang,[3] Hui Y. Lan.[2,3] *[1]Chemical Pathology, Chinese University of Hong Kong, Hong Kong, China; [2]Medicine and Therapeutics, Chinese University of Hong Kong, Hong Kong, China; [3]Li Ka Shing Institute of Health Sciences, Chinese University of Hong Kong, Hong Kong, China.*

Background: Our recent studies found that miR-21 plays a pathological role in TGF-β/Smad3-driven renal fibrosis. In the present study, we hypothesized that miR-21 may also act as a key mediator and therapeutic target for diabetic nephropathy.

Methods: miR-21 expression was examined in diabetic kidney of db/db mice. The functional role and therapeutic potential of miR-21 in diabetic kidney injury was examined in db/db mice by an ultrasound-microbubble-mediated anti-miR-21 gene transfer. In addition, role and mechanisms of miR-21 in diabetic renal injury was examined in vitro under diabetic conditions in a rat mesangial cell (MC) line / NRK52E tubular epithelial cell (TEC) line by overexpressing or down-regulating of miR-21.

Results: Renal miR-21 was markedly upregulated (two folds increased) in db/db mice, which was associated with the development of renal fibrosis including collagen I and IV (a 1.5-fold increased), and the severity of microalbuminuria ($p<0.01$). Similar results were also evidenced in high glucose-stimulated MC and TEC. The functional role of miR-21 was further examined in vitro that knockdown of miR-21 suppressed, but overexpression of miR-21 enhanced, high glucose-induced Col I, Col IV, and fibronectin expression ($p<0.05$). More importantly, ultrasound-microbubble-mediated gene transfer of miR-21 knockdown plasmid into the diabetic kidney of db/db mice at week 10 resulted in a significant improvement of microalbuminuria ($p<0.01$) and renal fibrosis ($p<0.01$) on weeks 20, revealing a therapeutic potential for diabetic nephropathy by targeting miR-21.

Conclusions: In conclusion, miR-21 is a key mediator for the development of diabetic kidney disease. Targeting miR-21 may represent a novel and effective therapy to combat diabetic nephropathy.

Identification of the Site of Endothelin A Receptor Antagonist-Induced Fluid Retention Donald E. Kohan, Deborah Stuart, Kevin A. Strait, Peter K. Stricklett, Mark Chapman. *University of Utah Health Sciences Center, Salt Lake City, UT.*

Background: Endothelin (ET) receptor antagonist-induced fluid retention has been responsible for discontinuation and/or failure of several large clinical trials. ETB receptor inhibition causes fluid retention though reduction of the known natriuretic effects of renal ET-1, however how ETA receptor (ETAR) antagonism elicits fluid retention is uncertain.

Methods: The relatively ETAR-selective antagonist, ambrisentan (ETA:ETB selectivity 29-4000:1 depending on the assay), was administered to mice in which ETAR were selectively deleted in cardiomyocytes (CM ETA KO), vascular smooth muscle (VSM ETA KO), or the renal collecting duct (CD ETA KO) as well as mice with intact ETAR.

Results: All gene targeting utilized mice with loxP-flanked ETAR and Cre recombinase expressed in a tissue-specific manner. Mice were given a 4% NaCl diet to exacerbate Na retention. Animals were treated with vehicle alone for 1 week, followed by 2 weeks of 100 mg/kg/day ambrisentan or vehicle by oral gavage (N=5-10 per group). Baseline radiotelemetric blood pressure and pulse were not different between groups, nor did ambrisentan treatment alter these parameters. Two weeks of ambrisentan treatment increased body weight in control and CM ETA KO, but not in VSM ETA KO or CD ETA KO. Ambrisentan decreased hematocrit in control, CM ETA KO and VSM ETA KO, but not in CD ETA KO animals. Body fluid volume compartments were determined by impedence plethysmography. Ambrisentan tended to increase extracellular fluid volume in all mouse groups except in CD ETA KO mice. At the conclusion of the experimental study, plasma volume was determined by Evan's blue dye dilution; no alterations in plasma volume were detected, although the technique was unlikely to detect the magnitude of predicted changes.

Conclusions: In summary, ambrisentan causes fluid retention in controls and animals deficient in ETAR in the heart or vasculature, however absence of CD ETAR prevented the ambrisentan response. These data suggest that the CD is the site responsible for ETAR antagonist induced fluid retention; concurrent treatment with diuretics targeting the CD may mitigate ETAR-induced fluid retention.

The Role of mTOR and SGK1 in Mediating Aldosterone Regulation of ENaC In Vivo Atif A. Kidwai,[1] Chih-Jen Cheng,[2] Jian Wang,[1] Michel G. Baum,[2] David Pearce.[2] *[1]Division of Nephrology, UCSF, San Francisco, CA; [2]University of Texas Southwestern Medical Center, Dallas, TX.*

Background: SGK1 is a key mediator of aldosterone activation of ENaC in the kidney tubules. The protein kinase mammalian target of rapamycin, mTOR, has been shown in cultured cells and *in vitro* to phosphorylate SGK1, and stimulate ENaC.

Methods: To determine the importance of this effect *in-vivo*, we monitored Na+ balance in mice following intraperitoneal injection of the mTOR inhibitor PP242 (30mg/kg; n = 10). To better understand the effect of mTOR on current in the native collecting duct, we examined the effect of PP242 using *in-vitro* microperfusion of collecting ducts. Cortical collecting ducts were harvested and subjected to microperfusion according to standard techniques. Potential difference (PD) measurements were made following treatment with PP242 (1 μM, N = 7) or rapamycin (0.1 μM, N = 5).

Results: We found that urine volume (ul) was increased by 56% (609 +/- 55 vs 953 +/- 152 ul $p = 0.048$), sodium (mmol/L) was increased by 79% (19.1 +/- 3.51 vs 53.4 +/- $p = 0.034$), total sodium excreted (mmol) was increased by 167% (11.7 +/- 2.46 vs 42.9 +/- 11.1 $p = 0.014$). The Urine sodium to potassium ratio increased by 62% (0.20 +/- 0.03 vs 0.53 +/- 0.13 $p = 0.026$), suggesting ENaC inhibition, possibly due to decreased SGK1 phosphorylation. In the microperfusion data, PD (mV) decreased from 9.1 +/- 2.76 to 4.92 +/- 1.29 with PP242 treatment ($p= 0.03$ paired t-test vs control), and recovered to 6.98 +/- 1.71 ($p = 0.11$). Effects were amiloride sensitive, indicating ENaC dependence. Rapamycin had no effect on PD.

Conclusions: Together with cell culture and in vitro data, these data strongly suggest that mTOR —in particular mTOR complex 2—regulation of SGK1 plays a physiologically important role in ENaC regulation in the kidney tubules. (NIH DK085101 NIH DK056695)

Impaired Phosphorylation of Na-K-2Cl Cotransporter by OSR1 Deficiency Manifests Hypotension and Bartter-Like Syndrome Sung-Sen Yang,[1] Pauling Chu,[1] Shinichi Uchida,[2] Sei Sasaki,[2] Shih-Hua P. Lin.[1] *[1]Division of Nephrology, Department of Medicine, Tri-Service General Hospital, and National Defense Medical Center, Taipei, Taiwan; [2]Department of Nephrology, Graduate School of Medicine, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: Na^+-(K^+)-(2)Cl^- cotransporters [N(K)CCs], including NKCC1 and renal-specific NKCC2 and NCC, play pivotal roles in the regulation of blood pressure and renal NaCl reabsorption. Oxidative stress-responsive kinase-1 (OSR1) is a known upstream regulator of N(K)CCs.

Methods: We generated and analyzed global and kidney tubule-specific (KSP-) OSR1 knockout mice to elucidate the physiologic role of OSR1 *in vivo*, particularly on blood pressure and kidney function.

Results: Although global $OSR1^{-/-}$ mice were embryonically lethal, $OSR1^{+/-}$ mice had lower blood pressure associated with reduced phosphorylated (p-)NKCC1 abundance in aortic tissue but intact renal Na^+ reabsorption. KSP-$OSR1^{-/-}$ mice were normotensive but primarily exhibited impaired Na^+ reabsorption in the thick ascending loop (TAL) on a low Na^+ diet accompanied by remarkably decreased expression of p-NKCC2 and a blunted response to furosemide, a NKCC2 inhibitor. The expression of total SPAK and p-SPAK was significantly increased in parallel to that of total NCC and p-NCC despite unchanged total NKCC2 expression. KSP-$OSR1^{-/-}$ mice also manifested hypokalemia with renal K^+ wasting and hypercalciuria, associated with reduced ROMK1, enhanced ENaC (β), and epithelial Ca^{2+} channels (TRPV5 and 6) expression.

Conclusions: These results suggest that globally, OSR1 is involved in the regulation of blood pressure and renal tubular Na^+ reabsorption mainly via the activation of NKCC1 and NKCC2. In the kidneys, NKCC2 but not NCC is the main target of OSR1 and the reduced p-NKCC2 in KSP-$OSR1^{-/-}$ mice may lead to a Bartter-like syndrome.

SA-OR424

A SPAK/OSR1 Isoform Network Regulates Renal Sodium Transport James A. McCormick,[1] Kerim Mutig,[2] Joshua N. Curry,[1] Eric J. Delpire,[3] Sebastian C. Bachmann,[2] David H. Ellison.[1] *[1]Department of Nephrology, Oregon Health & Science University, Portland, OR; [2]Department of Anatomy, Charité Universitätsmedizin, Berlin, Germany; [3]Department of Anesthesiology, Vanderbilt University School of Medicine, Nashville, TN.*

Background: SPAK (Ste20-related Proline Alanine rich Kinase) and the related OSR1 (Oxidative Stress Responsive 1) kinase phosphorylate several renal ion cotransporters, including NCC, NKCC2 and NKCC1, increasing cotransporter activity. Knock-in of a dominant-negative SPAK mutant (Thr243Ala) in mice suppresses activity of both NCC and NKCC2. However, targeted disruption of SPAK *reduces* NCC activity, but *increases* NKCC2 activity. We recently cloned a novel SPAK isoform that lacks the majority of the kinase domain including the T-loop activation residue (Thr243); we hypothesized that it acts as a dominant-negative inhibitor of full-length SPAK and OSR1.

Results: First, we confirmed that this isoform is expressed almost exclusively in kidney by performing RT-PCR on a broad panel of tissues, and named it KS-SPAK. Next, we performed immunofluorescence on kidney sections using an antibody against the C-terminus of SPAK, which recognizes both full-length SPAK and KS-SPAK, and an antibody against the N-terminus of SPAK, which recognizes only full-length SPAK. We found that the majority of SPAK expressed in the thick ascending limb is truncated at the N-terminus, while in the distal convoluted tubule, most SPAK is full-length; OSR1 is expressed in both segments. *In vitro* kinase assays showed that KS-SPAK inhibits phosphorylation of the N-terminus of NKCC2 by full-length SPAK or OSR1. Western blotting of kidney lysates from mice showed that changing extracellular fluid volume (by sodium restriction or NCC knockout), but not potassium loading or aldosterone infusion, leads to a striking shift in the ratio of KS-SPAK to full-length SPAK.

Conclusions: Taken together, these data suggest KS-SPAK acts as an inhibitor of NKCC2 activity *in vivo*, providing an explanation for the opposing effects of SPAK manipulation on NKCC2 activity in mice, and identify a novel kinase network that modulates responses to changes in extracellular fluid volume.

T60M Mutation in Thiazide-Sensitive Na^+-Cl^- Cotransporter (NCC) Causes Defective NCC Expression and Reverses Gordon Syndrome Sung-Sen Yang,[1] Sei Sasaki,[2] Shinichi Uchida,[2] Shih-Hua P. Lin,[1] Pauling Chu.[1] *[1]Division of Nephrology, Department of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; [2]Department of Nephrology, Graduate School of Medicine, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: Defective phosphorylation of the thiazide-sensitive sodium-chloride cotransporter (NCC) on T60 residue, the most important phosphoacceptor site of SPAK/OSR1 kinases, abolished its functional activity without affecting surface expression in Oocytes. T60M-NCC mutation is common in Asian patients with Gitelman's syndrome (GS).

Methods: To explore the pathophysiological importance T60 residue of NCC *in vivo*, we created T58M-Ncc knock-in mice to model human GS with T60M -NCC.

Results: $Ncc^{T58M/T58M}$ mice exhibited typical features of GS with a blunted response to thiazide, confirming that Ncc function was markedly diminished. In the kidneys, total and p-Ncc (T53, T58, and S71) of $Ncc^{T58M/T58M}$ mice were remarkably reduced despite normal abundance of Ncc mRNAs, and immuno-gold staining also showed that T58M Ncc almost located in the sub-apical region of the DCT cells, suggseting that phosphorylation of T60 may play a pivotal role in the NCC trafficking/sorting. In MDCK cells, NCC interacts with adaptor protein (AP)-3, a lysosomal sorting-related protein. An increased T60M-NCC-AP3 interaction with an attenuated T60M-NCC expression which could be reversed by AP3 knockdown was observed. Furthermore, phenotype of $Wnk4^{D561A/+}$ knock-in mice, a Gordon syndrome animal model with an activated Spak/Osr1-Ncc phosphorylation signaling and increased p-Spak/Osr1/Ncc expression featuring the mirror image of GS, was reversed by Ncc T58M mutation accompany with a reduced total and p-Ncc expression.

Conclusions: Our results indicated that phosphorylation of NCC T60 is involved in its trafficking/sorting and thus activity *in vivo*. Defective NCC phosphorylation by T60M could reduced its expression by an enhanced AP3-associated lysosomal degradation, and reverses the phenotype of Gordon syndrome.

The Calcineurin Inhibitor Tacrolimus Activates the Renal Sodium Chloride Cotransporter To Cause Hypertension Ewout J. Hoorn,[1] Stephen B. Walsh,[2] James A. McCormick,[3] Antje Furstenberg,[2] Chao-Ling Yang,[3] Tom Roeschel,[3] Alexander Paliege,[4] James P. Conley,[3] Sebastian C. Bachmann,[4] Robert J. Unwin,[2] David H. Ellison.[3] *[1]Erasmus Medical Center, Rotterdam, Netherlands; [2]UCL, London, United Kingdom; [3]OHSU, Portland; [4]Charite University, Berlin, Germany.*

Background: Calcineurin inhibitors (CNIs) are immunosuppressive drugs, which are used widely to prevent rejection of transplanted organs and treat autoimmune disease. Hypertension, hyperkalemia and acidosis often complicate their use. These side effects resemble familial hyperkalemic hypertension, a genetic disease characterized by over-activity of the renal sodium chloride co-transporter (NCC) and caused by mutations in WNK kinases. We hypothesized that CNIs induce hypertension by stimulating NCC.

Methods: The effects of the CNI tacrolimus on NCC were studied in mice and kidney transplant patients by characterizing renal tubular function, and by using immunoblotting and immunofluorescence.

Results: In wild-type mice, tacrolimus caused salt-sensitive hypertension, hyperkalemia, and acidosis. In kidney homogenates, tacrolimus increased phosphorylated NCC and the NCC regulatory kinases WNK3, WNK4, and SPAK. Immunofluorescence confirmed that NCC co-localized with calcineurin. The functional importance of NCC was demonstrated by showing that tacrolimus had no effect on blood pressure in NCC knockout mice. Moreover, hydrochlorothiazide reversed the hypertension induced in wild-type mice. In contrast, the hypertensive response to tacrolimus was exaggerated in mice over-expressing NCC. Kidney transplant recipients who were treated with tacrolimus and who had hypertension, hyperkalemia and/or acidosis demonstrated a higher fractional chloride excretion in response to a thiazide and had increased NCC abundance and phosphorylation in their biopsies compared to CNI-free patients or healthy controls.

Conclusions: These findings indicate that tacrolimus-induced hypertension is largely mediated by NCC activation. WNK and SPAK kinases may link NCC with calcineurin, which is a phosphatase. Finally, our data suggest that thiazide diuretics may be especially effective in preventing the complications of CNI treatment.

***In Vivo* Activation of NCC by Angiotensin II Requires Integrity of the WNK4-SPAK Pathway** Maria Castañeda-Bueno,[1] Luz Graciela Cervantes-Perez,[1] Norma Hilda Vázquez,[1] Norma O. Uribe-Uribe,[1] Norma Bobadilla,[1] Dario Alessi,[2] Gerardo Gamba.[1] *[1]Nephrology, Instituto Nacional de Nutrición SZ and UNAM, Mexico City, Mexico; [2]Dundee University, Scotland, UK.*

Background: We have previously reported, using *Xenopus laevis* oocytes and mpkDCT cells, that NCC activity is modulated by angiotensin II (AngII) through the WNK4-SPAK pathway, suggesting that PHAII-type mutations in WNK4 imitate the AngII effect on NCC leading to arterial hypertension (PNAS, 2009). Additionally it has been shown in vivo that AngII promotes NCC phosphorylation independently of aldosterone.

Methods: To test this hypothesis *in vivo*, a complete WNK4-knockout mouse strain was generated by targeted disruption by Pfizer Inc and donated to our Unit. Control littermates and $WNK4^{-/-}$ mice of 14 weeks were characterized and exposed to regular vs. low salt diet. In addition, under normal diet, animals were also infused for 4 days with AngII at non-pressor dose. WNK4 expression was assessed by real time PCR. NCC and SPAK expression and phosphorylation (pNCC-T58; pSPAK-S373) were assessed using specific antibodies.

Results: $WNK4^{-/+}$ and $^{-/-}$ mice born at expected Mendelian rates and grew normally. No transcripts for WNK4 were detected from $WNK4^{-/-}$ renal mRNA. $WNK4^{-/-}$ mice exhibited a mild hypokalemia and metabolic alkalosis, with normal glomerular filtration rate, blood pressure and calciuria, together with increased plasma renin activity and decreased aldosterone. Control littermates exhibited increased expression and phosphorylation of NCC and increased phosphorylation of SPAK after nine days of low salt diet or four days of AngII infusion. In contrast, WNK4-/- mice exhibited lower level of NCC expression, while SPAK expression was similar to control. Immunohistochemistry revealed normal morphology of distal convoluted tubule, with lower NCC expression. Under low salt diet or AngII infusion, no increased expression or phosphorylation of pNCC-T58 or pSPAK-S373 was observed.

Conclusions: Our observations reveal that absence of WNK4 *in vivo* precludes the NCC and SPAK phosphorylation promoted by low salt diet or AngII infusion, suggesting that this peptide hormone action on NCC occurs by signaling through a WNK4 dependent mechanism.

Funding: Private Foundation Support

SA-OR428

Role and Mechanism of WNK1-OSR1/SPAK Cascades in the Regulation of Sodium Homeostasis in Mice Jian Xie, Joonho Yoon, Zhen Liu, Thao Truong, Chou-Long Huang. *Department of Medicine, UT Southwestern Medical Center, Dallas, TX.*

Background: WNK1 is a ubiquitous protein kinase of which increased expression causes hypertension at least partly by increasing renal Na reabsorption. *In vitro*, WNK1 phosphorylates and activates Ste20-related protein kinases OSR1 and SPAK, which in turn activate NCC and NKCC2. Alternatively, others reported that WNK1 activates these transporters independently of OSR1/SPAK. We examine the *in vivo* role and mechanism of WNK1 regulation of Na transport.

Methods: Mice with global inactivation of Wnk1 are embryonic lethal from cardiovascular (CV) developmental defects. We generated mice with conditional knockout of WNK1 in the kidney by crossing homozygous exon2-floxed mice with transgenic mice carrying a kidney-specific Cre. Mouse lines that allow conditional tissue-specific expression of constitutive-active (CA) OSR1 or SPAK were generated by targeting respective cDNA preceded by floxed transcriptional terminator to the ROSA26 locus.

Results: Mice with conditional KO of WNK1 in the kidney exhibited increased 24-h urinary Na excretion (168 ± 26 vs 131 ± 12 $_{\mu}$mol, $p < 0.01$) and lower blood pressure (SBP 114 ± 1 vs 123 ± 3 mmHg, $p < 0.05$) versus wild type when fed a normal Na diet *ad lib*. Conditional KO mice had defect in conserving Na during transition from pair-fed normal Na diet (0.49%) to Na-deficient diet (0.01%) (24-h Na excretion 1 and 2 days after Na-deficient diet: 20 ± 4 and 3 ± 0.1 in KO vs 13 ± 0.8 and 1.3 ± 0.3 $_{\mu}$mol in WT, $p < 0.01$). Mice with global deletion of Osr1 exhibited CV developmental defects similar to mice with global Wnk1 deletion, but with ~0.5 day delay in onset (begins at embryonic day E10.5 vs E11). Endothelial-specific expression of CA-OSR1 rescued lethality from global Osr1 deletion.

Conclusions: These results indicate that WNK1 plays an important role in regulation of renal Na reabsorption. Similar timing and developmental defects between Wnk1 and Osr1 deletion indicate potential interactions of WNK1 and OSR1 signaling cascades. Further studies will investigate which ion transporters are regulated by WNK1 and OSR1, and whether CA-OSR1/SPAK can complement developmental and renal defects of WNK1 deficiency.

SA-OR429

Pathophysiology of Familial Hyperkalemic Hypertension Related to Deletions of the First Intron of WNK1 Juliette Hadchouel,[1] Emmanuelle Vidal-Petiot,[1] Christelle Soukaseum,[1] Veronique Baudrie,[1] Lydie Cheval,[2] Xavier Jeunemaitre.[1,3] *[1]Paris Centre for Cardiovascular Research (INSERM U970), Paris, France; [2]Cordeliers Research Centre (INSERM U872), Paris, France; [3]Hôpital Européen Georges Pompidou, Paris, France.*

Background: Mutations in the serine-threonine kinase WNK1 are responsible for Familial Hyperkalemic Hypertension (FHHt), an autosomal dominant form of hypertension associated with hyperkaliemia and hyperchloremic metabolic acidosis. WNK1 gives rise to a long ubiquitous isoform, L-WNK1, and a shorter isoform lacking a functional kinase domain and expressed exclusively in the distal nephron, KS-WNK1. FHHt mutations are large deletions of the first intron of the gene, but the consequences of these deletions on the expression of L-and KS-WNK1 and on renal ion transport are unclear.

Methods: In order to elucidate the mechanisms underlying the deregulation of renal ion handling in WNK1-related FHHt patients, and thereby the role of WNK1 on blood pressure and ion homeostasis, we generated WNK1+/Δi1 knock-in mice harboring a deletion of the first intron of WNK1.

Results: WNK1+/Δi1 mice display high blood pressure, hyperkalemia and hyperchloremic metabolic acidosis. We show that L-WNK1 expression is increased in the Distal Convoluted Tubule (DCT) and, to a lesser extent, in the connecting tubule, whereas KS-WNK1 expression is not modified upon deletion of WNK1 first intron. As

expected from in vitro studies, the modification of L-WNK1 expression leads to increased expression and activity of the sodium-chloride cotransporter NCC. In addition, the blood pressure and metabolic disorders are reversed by administration of hydrochlorothiazide. Finally, the increased sodium transport in the DCT is associated with a decreased activity of the Epithelial sodium Channel (ENaC), as illustrated by a blunted diuretic response to amiloride, which could explain the hyperkalemia and the acidosis.

Conclusions: Our study demonstrates that, by increasing L-WNK1 expression in the DCT, the deletion of WNK1 first intron leads to the stimulation of NCC activity and the development of FHHt. The contribution of L-WNK1 activation in the CNT remains to be defined.

SA-OR430

RDX5791, a Non-Systemic NHE3 Inhibitor, Normalizes Blood Pressure and Reduces Salt-Induced Organ Damage in Uremic Rats Andrew G. Spencer,[1] Marc Navre,[1] Craig F. Plato,[2] Kristin M. Joly,[2] Eric Daniel Labonte,[1] Jeffrey Jacobs,[1] Dominique Charmot.[1] *[1]Ardelyx, Inc., Fremont, CA; [2]Plato BioPharma, Inc., Westminster, CO.*

Background: Excess dietary Na+ exacerbates hypertension and accelerates cardiac and renal dysfunction in CKD patients. RDX5791 is a potent, non- systemic inhibitor of the intestinal Na+ antiporter NHE3 and shifts Na+ excretion from urine to feces. The current study evaluated the effects of RDX5791 on systemic hemodynamics and organ damage in uremic rats fed a 4% NaCl diet for four weeks.

Methods: At study inception, 5/6th nephrectomized rats were functionally matched to a vehicle group (n=24) or one of three groups of prophylactically dosed RDX5791 (0.3, 1, or 3 mg/kg/d; n=12/group). At mid-study, half the vehicle group was functionally matched to continue vehicle treatment or begin 3 mg/kg/d RDX5791 treatment (therapeutic arm). Diastolic and systolic blood pressure (DBP, SBP) and serum and urine chemistry were measured weekly or biweekly. Extracellular fluid volume (ECFV) and total body water (TBW) were monitored via bioimpedance spectroscopy. At endpoint (day 28), rats were sacrificed and morphological analyses of heart and kidney were performed.

Results: Compared to vehicle rats, prophylactic RDX5791 (1 mg/kg/d) reduced DBP by 26% (144 to 107 mmHg), SBP by 21% (204 to 161 mmHg), albuminuria by 78% (97.1 to 21.4 mg/d), left ventricle:tibia length ratio by 20% (27.7 to 22.1 mg/mm), ECFV/TBW (43.5% to 41.5%), and weight of remnant kidneys, (1.88 to 1.43 g) which were analyzed for the extent of fibrotic injury. Importantly, the cardiorenal effects of RDX5791 were dose-dependent. In the therapeutic arm, RDX5791 reduced established albuminuria, hypertension and the expanded ECFV to values similar to those in prophylactically-treated animals.

Conclusions: RDX5791 provides robust antihypertensive, cardiac and renal protective effects in uremic rats fed a high sodium diet. Those effects are likely mediated by the shift in sodium clearance from the kidneys to the GI tract. RDX5791 replicates many of the clinical benefits of low sodium intake in hypertension and CKD; it may act synergistically with RAAS antagonists to improve patient outcomes.

SA-OR431

Renal Allograft Rejection and Delayed Graft Function Regulated by miRNAs Julia Wilflingseder,[1,2] Alexander Kainz,[1,2] Rainer Oberbauer.[1,2] *[1]Nephrology, KH der Elisabethinen, Linz, Austria; [2]Nephrology, Medical University of Vienna, Vienna, Austria.*

Background: Aim of this study was the identification of deregulated miRNAs in renal biopsies from patients who developed acute vascular rejection, acute interstitial rejection, antibody mediated rejection (ABMR) and delayed graft function (DGF).

Methods: Sixty-five selected post-transplant FFPE biopsy samples (30 acute cellular rejection (15 Banff-1, 15 Banff-2), 11 ABMR, 14 DGF, 10 protocol biopsies) were analyzed. Affymetrix GeneChip® miRNA Arrays holding 904 unique small RNA sequences based on the Sanger miRBASE version 11 were used for miRNA profiling. Differentially regulated miRNAs were identified by Student's t-test and Bonferroni correction. First experimentally validated targets according to mirTarBase were used as basis for functional interpretation. Second predicted target genes were identified using in-silico approaches (miRror – combination of databases like TargetScan and mirRanda, miTALOS) and also interpreted on the functional level.

Results: Patients with acute rejection (AREJ), ABMR and DGF discriminate from the control group (protocol biopsies) in the unsupervised cluster analysis and also in the principal component analysis suggesting miRNAs play an important role in rejection and DGF. Seven miRNAs are up-regulated in DGF. Four up-regulated and 17 down-regulated miRNAs are identified in acute rejection episodes compared to control group and six miRNAs are up-regulated in ABMR. Mir-21 and mir-182 are up-regulated in DGF and ABMR and mir-663 is up-regulated in both rejection groups.

Conclusions: These preliminary data suggest that a distinct miRNA signature is associated with rejection and delayed graft function. A detailed analysis of the miRNAs and target genes will be presented at the meeting. The identified miRNAs and target genes may provide novel insights in the molecular regulation of acute rejection and delayed graft function and the identified molecules may serve as novel diagnostic markers and therapeutic targets.

SA-OR432

Urinary miR-210 as a Mediator of Acute T-cell Mediated Rejection in Renal Allograft Recipients Johan M. Lorenzen, Hermann G. Haller, Wilfried Gwinner, Thomas Thum. *Nephrology, Hanover Medical School, Hannover, Germany.*

Background: microRNAs (miRNAs) are small ribonucleotides regulating gene expression. microRNAs are present in the blood in a remarkably stable form. We tested whether miRNAs are also detectable in urine and may serve as new predictors of outcome in renal transplant patients with acute rejection.

Methods: We profiled urinary miRNAs of stable transplant patients and transplant patients with acute rejection. The results were validated in a validation cohort of 62 patients with acute rejection, 19 control transplant patients without rejection and 13 stable transplant patients with urinary tract infection by quantitative RT-PCR.

Results: miR-10a, miR-10b and miR-210 were strongly deregulated in urine of patients with acute rejection. We confirmed these data in urine of a validation cohort of 62 patients with acute rejection, 19 control transplant patients without rejection and 13 stable transplant patients with urinary tract infection by quantitative RT-PCR. miR-10b and miR-210 were down-regulated and miR-10a up-regulated in patients with acute rejection compared to controls. Only miR-210 differed between patients with acute rejection when compared to stable transplant patients with urinary tract infection or transplant patients before/after rejection. Low miR-210 levels were associated with higher decline in GFR one year after transplantation.

Conclusions: Selected miRNAs are strongly altered in urine of patients with acute renal allograft rejection. miR-210 levels identify patients with acute rejection and predict long-term kidney function. Urinary miR-210 may thus serve as a novel biomarker of acute kidney rejection.

SA-OR433

Impact of Inflammation in Protocol Biopsies Taken at Week 6 after Transplantation on Fibrosis in Biopsies Taken at One Year Willy Aasebo,[1] Hallvard Holdaas.[2] *[1]Akershus University Hospital; [2]Oslo Universtity Hopsital - Rikshospitalet.*

Background: To assess if inflammation in protocol biopsies taken 6 weeks after kidney transplantation predict inflammation and fibrosis one year after transplantation.

Methods: All single kidney transplant recipients that had a protocol biopsy taken at week 6 and week 52 (n = 157) were included. Recipients with donor specific antibodies at transplantation, AB0 incompatibility transplantations and recipients with indication biopsies taken between week 4 and 8 were excluded. The immunosuppressive protocol consisted of induction therapy with two doses of basiliximab, thereafter calcineurine inhibitors + mycophenolate + steroids.

All biopsies were classified according to Banff criteria. Recipients with rejection in protocol biopsies at week 6 received treatment with Solu-medrol and temporarily increased oral steroids dosages.

Results: Of the 100 biopsies that were negative at week 6, 69 were also negative at one year (69%), 26 had borderline and 5 had rejection. In the Borderline-group at week 6 (n = 43), 20 were negative at one year (47%), 19 had borderline and 4 had rejection. Of the 14 recipients with subclinical rejection at week 6 (9%), 10 had negative biopsies at one year (71%), 3 had borderline and 1 had rejection.

Fibrosis/atrophy in biopsies at one year according to inflammation in protocol biopsies taken at week 6 after transplantation. N = 157.

	Classification of biopsies at week 6.					
	Negative	Borderline	Rejection	P	P	P
At one year	N = 100	N = 43	N = 14	Neg vs. bord	Neg vs. rej	Bord vs. rej
Interst Inflam.	0.80 (0.71)	0.91 (0.43)	0.71 (0.47)	0.36	0.66	0.17
Tub. atrophy	1.03 (0.63)	0.98 (0.34)	0.71 (0.46)	0.60	0.073	0.028

Mean (SD)

Conclusions: Inflammation in protocol biopsies at week 6 does not predict interstitial fibrosis or tubular atrophy at one year in low-risk single kidney transplant recipients.

Recipients with subclinical rejections at week 6 had less tubular atrophy than the other groups and low degree of inflammation at one year. This finding indicates that identifying and treating these 9% of the recipient may be important.

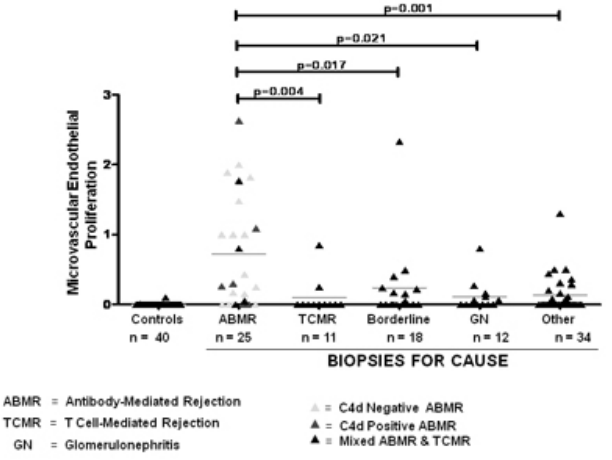
SA-OR434

Microcirculation Endothelial Cell Cycling Is Selectively Increased in Antibody-Mediated Rejection of Kidney Transplants, but Not in Other Diseases Stephen Adebayo Osasan, Declan G. de Freitas, Jessica Chang, Michael Mengel, Philip F. Halloran, Banu Sis. *ATAGC, University of Alberta, Edmonton, AB, Canada.*

Background: Antibody-mediated rejection (ABMR) is dominated by microcirculation inflammation and endothelial injury, caused by donor specific antibodies. We hypothesized that ABMR is associated with a greater endothelial repair response than other diseases in kidney transplants.

Methods: We related microcirculation endothelial cell cycling(MECC) to histopathology lesions, diagnoses, and whole-genome microarrays in 100 kidney transplant and 40 normal implantation biopsies. We performed double immunostaining for Ki-67 and CD31 to identify capillaries with cycling endothelial cells. We quantified MECC by counting number of Ki-67+CD31+ glomerular and peritubular capillaries in the entire cortical area of the biopsies.

Results: Transplant biopsies showed higher numbers of capillaries with cycling endothelial cells than controls (p=0.003). MECC was higher in ABMR than other diseases.



Increased MECC correlated with donor specific HLA antibody (p=0.003), microcirculation lesions (glomerulitis, capillaritis, transplant glomerulopathy), and C4d staining (p<0.05). Furthermore, transcript sets representing the molecular burden of active ABMR (endothelial cell, NK-cell, and macrophage-associated transcripts as well as interferon gamma regulated transcripts) correlated with increased MECC (p<0.05). Within the ABMR biopsies, increased MECC correlated with higher grades of glomerulitis (p=0.01) and peritubular capillaritis (p=0.08). Interestingly, endothelial cycling was not increased in TCMR, suggesting that T cells cross the microcirculation in TCMR without damaging the capillaries.

Conclusions: The endothelial repair response is selectively increased in kidneys with ABMR, reflecting the burden of active microcirculation injury.

SA-OR435

Ischaemic Glomeruli Are Increased in Protocol Biopsies after Transplantation, in Association with Peritubular Capillary (PTC) Loss, Inflammation and IF/TA Floortje Steegh,[1] Marielle Gelens,[2] Mat Daemen,[3] Ernest Van Heurn,[4] Maarten H.L. Christiaans,[2] Carine Peutz-Kootstra.[1] *[1]Pathology, Academic Hospital Maastricht, Maastricht, Netherlands; [2]Nephrology, Academic Hospital Maastricht, Maastricht, Netherlands; [3]Pathology, Academic Hospital Amsterdam, Amsterdam, Netherlands; [4]Surgery, Academic Hospital Maastricht, Maastricht, Netherlands.*

Background: Chronic transplant dysfunction is a major cause of renal allograft loss, preceded by inflammation and IF/TA in the renal biopsy. Recently we showed that PTC loss occurs within the three months after transplantation, and predicts lower renal function at 1 year. We hypothesized that capillary loss also occurs in the glomerular capillary bed, resulting in more ischemic glomeruli.

Methods: Protocol biopsies of 89 patients taken 0, 3 and 12 months (M0, M3, M12) after renal transplantation were studied. Recipients received kidneys from living (n=23), deceased after brain death (n=26) or deceased after cardiac death (n=40) donors. Biopsies were scored according to Banff09 with a total inflammation (ti) score. Ischemic glomeruli were scored as percentage of the total glomerular number. In a subgroup of 48 patients PTC number was determined as described (Steegh et al. JASN 2011). Statistical analysis was performed by T-test, Pearson correlations and multivariate analysis.

Results: Compared to M0, the mean number of ischemic glomeruli at M3 and M12 increased significantly from 7.86% to 20.64% and 23.79% (0-3 months p<0.001, 0-12 months p<0.001). The progression of ischemic glomeruli correlates with PTC loss at M3 (r=0.397, p=0.030). Increase in ischemic glomeruli correlates with ti and IF/TA scores at M3 and M12. Significant predictors for increased ischemic glomeruli at M12 are donortype and donor age (r2=0.165,p=0.005).

Conclusions: This study shows for the first time that the loss of PTCs is associated with an increase of ischemic glomeruli at M3 after transplantation. We hypothesize that interstitial and glomerular microvasculature loss is interrelated and may be initiated by similar mechanisms, leading to decreased renal function and worse prognosis for allograft survival.

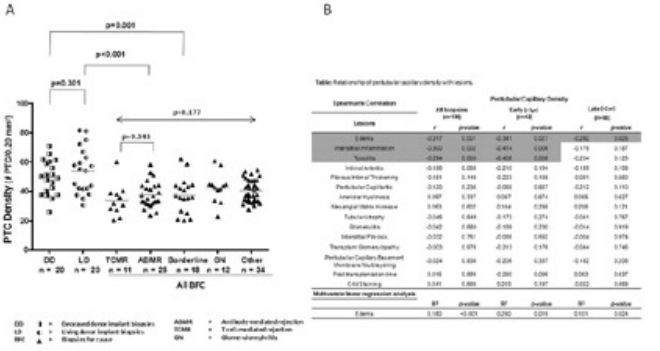
SA-OR436

Kidney Transplant Fibrosis Is Not Dependent on Peritubular Capillary Loss Stephen Adebayo Osasan, Jessica Chang, Declan G. de Freitas, Michael Mengel, Philip F. Halloran, Banu Sis. *ATAGC, University of Alberta, Edmonton, AB, Canada.*

Background: It has been suggested that progressive loss of peritubular capillaries (PTC) contributes to kidney fibrosis. We hypothesized that kidney transplant fibrosis is associated with and dependent on microcirculation loss.

Methods: We related PTC density to histopathology lesions, diagnoses, and post-transplant time in 100 kidney transplant biopsies for cause with 40 normal implantation biopsies as control. We performed CD31 immunostaining to identify the PTCs and counted total number of CD31+ PTCs in the entire cortical area of the biopsies. The PTC density was calculated by dividing the total number of PTCs by the number of ocular grid areas (0.2mm2).

Results: The PTC density was lower in transplant biopsies compared to controls, but did not differ among diagnoses in the transplant cases.



In early (<1 year) transplant biopsies, PTC density was lower in those with increased edema and tubulointerstitial inflammation. In late (>1 year) cases, only edema correlated with decreased PTC density. However, increased interstitial fibrosis, tubular atrophy, arterial fibrous intimal thickening, transplant glomerulopathy, peritubular capillary basement membrane multilayering, and time post-transplant did not relate to reduced PTC density. In multivariate regression analysis, edema was the only determinant of reduced PTC density in both early and late transplant biopsies.[Figure1B]

Conclusions: Contrary to our predictions, our results indicate that atrophy and fibrosis were not accompanied by reduction in capillary density. The histologic feature that correlated with reduced capillary density was edema, not fibrosis. Edema expands the peritubular interstitium, giving a false impression of reduced PTC density in biopsies. Thus kidney transplant fibrosis and nephron loss are not due to microcirculation loss.

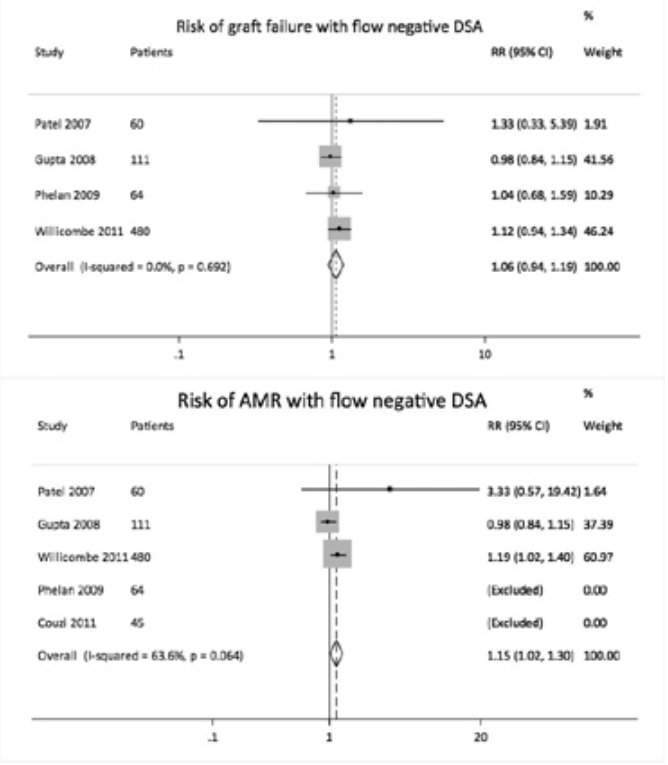
SA-OR437

Systematic Review & Meta-Analysis of Graft Outcomes Associated with Donor Specific Antibodies (DSA) & Negative Crossmatch Amudha Palanisamy, Sumit Mohan, Russell J. Crew, Bekir Tanriover, Geoffrey K. Dube, David J. Cohen, Jai Radhakrishnan. *Columbia University.*

Background: The introduction of solid phase methods provides increased sensitivity and specificity for the detection of DSA. However, the clinical relevance of DSA in the presence of negative CDC and flow crossmatches is unclear.

Methods: We identified 415 studies for review using the search term "(antibodies OR solid-phase assay OR luminex OR antibody mediated rejection) AND kidney AND crossmatch" which investigated allograft outcomes in patients with DSA detected by Luminex but not by cytotoxic or flow crossmatches. In addition, abstracts presented at the ASN & NKF between 2005 – 2010 were hand-searched for inclusion. 54 studies were identified for further review and 17 studies were extracted for review of full text. Ultimately, 5 retrospective studies with data comparing the incidence of AMR and graft survival in DSA positive and DSA negative groups detected by Luminex alone were pooled for analyses.

Results: All 5 studies reported the incidence of AMR, but only 4 studies reported the occurrence of graft failure. The time to follow-up was variable (range 9 months-4 years). Our pooled analysis included 104 DSA positive patients and 676 patients without DSA. There was an overall increased risk of AMR associated with the DSA positive group compared to patients without DSA (RR=1.149, 95% CI 1.017–1.299, p=0.026). The heterogeneity between the studies was not significant(I^2= 63.6%,p= 0.06). However, no increased risk of graft failure was detectable (RR=1.06, 95% CI 0.944–1.91, p=0.325) and there was no heterogeneity between studies(I^2=0%,p=0.69).



Conclusions: Our systematic review and pooled analysis underlines the paucity of outcomes data associated with preformed DSA detected by luminex but suggests an increased risk of AMR and no significant impact on overall graft survival in the short term.

SA-OR438

The Serum *p*-Cresol and Indoxyl Sulfate Correlated with Cardiovascular Disease in Mild-to-Moderate Chronic Kidney Disease of Renal Transplant Recipients Cheng-Hsu Chen,[1,2,3] Chi-Hung Cheng,[1,4] Ming-Ju Wu,[1,4] Tung-Min Yu,[1,2] Ya-Wen Chuang,[1] Kuo-Hsiung Shu.[1,4] *[1]Division of Nephrology, Department of Internal Medicine, Taichung Veterans General Hospital, Taichung City, Taiwan; [2]School of Medicine, China Medical University, Taichung City, Taiwan; [3]Department of Life Science, Tunghai University, Taichung City, Taiwan; [4]Department of Medicine, Chung Shan Medical University, Taichung, Taiwan.*

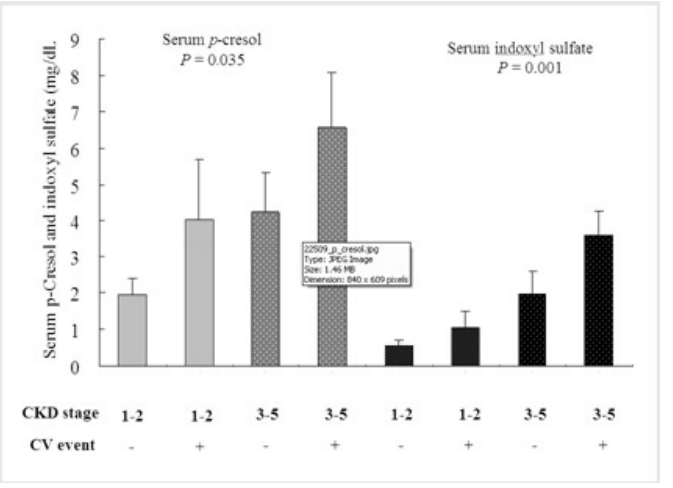
Background: Cardiovascular disease (CVD) is the major cause of death after renal transplantation (RTx). The *p*-cresol (pCS) and indoxyl sulfate (IS), anionic uremic toxins, markedly accumulated in serum and deteriorated of chronic kidney disease (CKD), are associated with CVD.

Methods: We recruited 95 RTx recipients with mean follow-up duration 6.3 ± 4.9 years. Their mean age was 48.7 ±14.1 years; and 56.8% (54/95) male patients. According the eGFR staging, we divided RTx recipients into stage 1-2 group and stage 3-5 group, then, examined pCS and IS and CVD events in these two group RTx recipients.

Results: The CKD staging is significantly different in the follow-up duration (5.0 ± 3.2 vs. 7.1 ± 5.6; P = 0.037). The serum pCS (2.4 ± 3.1 vs. 5.2 ± 6.8 mg/dL, P = 0.020) and IS (0.7 ± 1.0 vs. 2.7 ± 3.4 mg/dL, P = 0.001) was also significantly different between groups.

	Stage 1-2 (n = 37)	Stage 3-5 (n = 58)	P value
Age of RTx (yrs)	43.3 ± 15.2	41.9 ± 13.8	0.644
Follow-up duration (yrs)	5.0 ± 3.2	7.1 ± 5.6	0.037
Hb (mg/dL)	13.4 ± 1.6	11.8 ± 2.2	0.000
Albumin (mg/dL)	4.4 ± 0.3	4.1 ± 0.4	0.000
Serum p-cresol	2.4 ± 3.1	5.2 ± 6.8	0.020
Serum indoxyl sulfate	0.7 ± 1.0	2.7 ± 3.4	0.001

Interestingly, the CV event was correlated with the serum levels of pCS and IS between the CKD groups.



Conclusions: These findings suggest that serum pCS and IS may help to predict CVD risk in different CKD stage recipients. Whether pCS and IS is a modifiable cardiovascular risk factor in RTx recipients remains to be proven.

SA-OR439

Longer CMV Prophylaxis May Prevent Low Level CMV Reactivation but May Not Prevent Primary CMV Infection Christine M. Ribic,[1] Sundus A. Lodhi,[3] Jon A. Gregg,[3] Kenneth E. Lamb,[3] Herwig-Ulf Meier-Kriesche.[3] *[1]Medicine, McMaster University, Hamilton, ON, Canada; [2]Medicine, University of Florida, Gainesville, FL.*

Background: Whether longer valganciclovir (VG) prophylaxis prevents primary CMV disease after kidney transplantation(tx) is still debatable even after the published IMPACT trial and especially considering the subsequent editorials. For this reason, we analyzed data from our own center where we have been using extended VG prophylaxis since 2005.

Methods: This single centre retrospective study evaluated 690 tx recipients who received VG prophylaxis with a mean follow-up of 2.6 (SD+/-2.35) years. CMV event-free survival was calculated from the time of completion of prophylaxis and the primary endpoint was defined as positive CMV viremia identified by quantitative PCR (≥200 copies/ml) or positive pp65 antigenemia.

Results: There was no significant difference in CMV event-free survival (p=0.68) in high-risk (D+/R-) tx recipients who received prophylaxis for a median duration of 227 (n=55) versus 125 days (n=63) (Fig 1A). Likewise, when changing the endpoint to different CMV PCR thresholds (100, 200, 250, 500, 1000, 5000 or 10,000 copies/ml of plasma), there was also no significant difference between long and shorter prophylaxis.

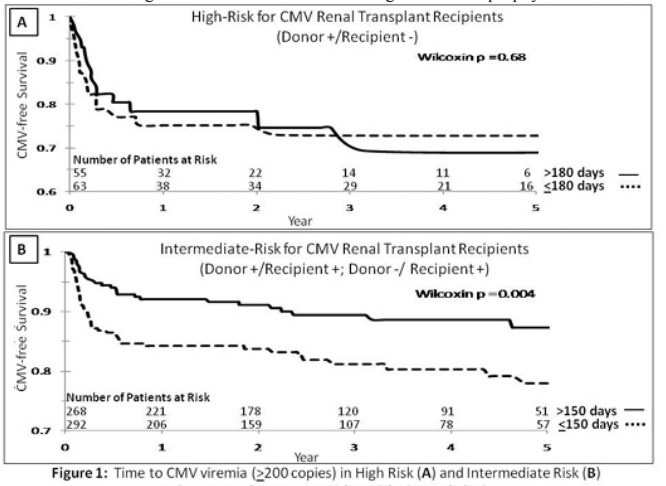


Figure 1: Time to CMV viremia (≥200 copies) in High Risk (**A**) and Intermediate Risk (**B**) patients up to 5 years post Valganciclovir prophylaxis.

Conversely in intermediate-risk patients, there were significantly (p= 0.004) higher rates of CMV viremia in those patients who received shorter prophylaxis for a median duration of 186 (n=263) versus 116 (n=292) days (Fig 1B). However this effect was driven by low level viremia results as the reduction in events in the longer prophylaxis group did not persist for the endpoint of CMV PCR ≥500 copies/ml.

Conclusions: In summary, our data suggests that longer prophylaxis may not impact the cumulative incidence of primary CMV infection but may prevent low level CMV reactivation.

SA-OR440

Significance of Persistent Asymptomatic EBV Viral Load in Pediatric Renal Transplant (TX) Recipients Asha Moudgil,[1] Karen Martz,[2] Therese Moore,[3] William E. Harmon,[4] Vikas R. Dharnidharka.[5] *[1]Nephrology, Children National Medical Center, Washington, DC; [2]NAPRTCS DCC, EMMES Corporation, Rockville, MD; [3]Nephrology, Mayo Clinic, Rochester, MN; [4]Pediatric Nephrology, University of Florida, Gainesville, FL; [5]Nephrology, Children Hospital, Boston, MA.*

Background: Children, in particular EBV naïve at TX, are at risk of developing post-transplant lymphoproliferative disorder (PTLD). Currently, many centers are prospectively monitoring EBV viral load (VL) by real time quantitative PCR (qPCR) and intervening (reducing immunosuppression {IS}, therapy with antiviral drugs in response to + VL to prevent PTLD. However, acute rejection (AR) may occur due to reduction in IS causing graft failure (GF). Outcome of these strategies is not clear.

Methods: EBV asymptomatic VL subregistry was created within NAPRTCS to study prevalence of PTLD on AR and GF in pts with persistent + VL for 6 months and in those with high VL ($>10^2$ times over the number detected by qPCR) in comparison to EBV -VL pts from the same centers.

Results: 14 centers enrolled 425 children (63 {14.8%} with +VL and 362 (85.2%} with -VL) from 2005 onwards. Of 60 with +VL and complete data, 40% were <5yrs age at TX, 31 M: 29F, 68.3% Caucasians and 8.3% Blacks, 79.3% and 75% were EBV and CMV naïve at TX. Of donors, 3.3% and 45% were EBV and CMV naïve. Thymoglobulin induction was used in 43.3% and 35% in EBV +VL and -VL pts (p=ns). Asymptomatic +VL developed 6.4± 6.5 months after TX, 50% with +VL had reduction in IS and 10% treated with antivirals. PTLD developed in 3/60 pts with +VL and 4/362 pts with -VL, 6.7-8.1 and 5.9-8.8 months after TX (5% vs 1.1% P=0.06). Of pts with high VL 3/39 (7.7%) and 0/21 with low VL developed PTLD (high VL vs low VL, p=ns and high VL versus -VL, p 0.02). The hazard ratio for time to AR and GF using Cox regression model with EBV +VL as a time-varying co-variate were 1.5(95% CI 0.8 to 2.9, p=ns) and 0.61(95% CI 0.2 to 2.01, p=ns).

Conclusions: Children with persistent high EBV viral load may be at higher risk for development of PTLD, but not at higher risk for AR or GF.

SA-OR441

Aberrant mTOR Signaling Contributes to Cardiac Remodeling and Renal Fibrosis in Fibroblast Growth Factor Receptor 2 Conditional Knockout Mice Christina R. Nguyen, Sunder Sims-Lucas, Carlton M. Bates. *Nephrology, Children's Hospital of Pittsburgh, Pittsburgh, PA.*

Background: Cardiovascular disease is the leading cause of early death in pediatric chronic kidney disease (CKD), but a clear mechanism connecting the heart and kidney pathology is not understood. Mice with conditional knockout of fibroblast growth factor receptor 2 in the ureteric bud ($Fgfr2^{UB-/-}$) result in a 75% reduction in nephron number and progressive cardiac remodeling, mimicking pediatric structural CKD.

Methods: Serial serum studies, echocardiograms, and renal ultrasounds were obtained at 2, 6, and 9 months in $Fgfr2^{UB-/-}$ mice and littermate controls. Telemetric blood pressure and inulin clearance were assessed in males and tissue was examined via histology and Western blot at 9 months in both genders.

Results: At 2 months, $Fgfr2^{UB-/-}$ mice appear similar to controls. By 5 months, mutants have loss of corticomedullary differentiation, reduced kidney size (p=0.004), and higher blood urea nitrogen (BUN) (p=0.0045). At 5 and 9 months, the left ventricular mass (LVM)/body weight of mutant males is greater than controls (p=0.008, 0.03). Inulin GFR is lower in mutant males. Histological assessments reveal progressive fibrosis in mutant hearts and kidneys. Western blots suggest increased phospho-Akt (pAkt), phospho-p70S6 kinase, and phospho-tuberin (components of the mTOR pathway) in mutant hearts and kidneys.

Conclusions: $Fgfr2^{UB-/-}$ mice are a model of progressive structural chronic kidney disease leading to cardiac remodeling with normal blood pressure. Preliminary results suggest aberrant signaling through the mTOR pathway in both the kidney and heart may contribute to progressive fibrotic changes. This model will be useful in understanding the pathophysiology of normotensive chronic kidney disease and in providing therapeutic targets to prevent cardiac and renal fibrosis.

The Hedgehog Pathway Is Strongly Activated in Stromal Cells during Renal Fibrosis Steven L. Fabian,[1] Radostin Penchev,[1] Petra Sipilä,[2] Anjali N. Rao,[1] Andrew P. McMahon,[3] Benjamin D. Humphreys.[1] *[1]Renal, Brigham and Women's Hospital, Boston, MA; [2]Mouse Biology and Genetics, University of Turku, Finland; [3]Molecular and Cellular Biology, Harvard University, Cambridge, MA.*

Background: The Hedgehog (Hh) pathway is best known for its role in regulating tissue patterning during development but can be reactivated in cancer and tissue injury. Although Hh plays a role in renal development, nothing is known about its role in adult kidney. Here we report strong activation of epithelial to stromal Hh signaling in renal fibrosis.

Methods: Hh pathway member expression was defined using reporter mice, in situ hybridiztaion, qPCR and immunofluorescence in two renal fibrosis models: unilateral ureteral obstruction (UUO) and unilateral ischemic reperfusion injury (UIRI).

Results: Indian Hedgehog (Ihh) reporter mice demonstrated Ihh expression in outer medullary proximal tubules while lineage analysis of Sonic Hedgehog (Shh) cells disclosed papillary collecting duct expression of Shh. These results were confirmed by in situ hybridization and qPCR. Gli1 reporter mice showed Gli1 expression in the papilla and in PDGFRβ+, CD31-, F4/80- interstitial pericytes in the outer medulla with enrichment around vasculature. A similar pattern using reporter mice was found for the Hh effector Gli2. Gli1 is a readout of Hh pathway activity, and in UUO and UIRI was increased in pericytes 14 and 25-fold respectively, with increased Gli2, Gli3 and Ptch1 expression. Ihh expression also increased 4-fold in UUO. Over the course of fibrosis, Gli1+ cells increased 11-fold and acquired the myofibroblast marker αSMA. In the pericyte-like cell line 10T1/2, Hh agonists triggered cell proliferation.

Conclusions: These results are the first to document strong activation of Hh signaling during renal fibrosis, and they suggest paracrine signaling of epithelial Hh ligand to stromal pericytes and myofibroblasts. The ability of Hh to trigger pericyte proliferation in culture suggests a possible role for Hh signaling in pericyte and myofibroblast proliferation in the early phases of renal fibrosis. These studies introduce the Hh signaling pathway as a novel therapeutic target in renal fibrosis.

SA-OR443

Endothelial HIF Signaling Modulates Renal Fibrosis Pinelopi P. Kapitsinou,[1] Mark Michael,[1] Timothy A. Sutton,[2] Volker H. Haase.[1] *[1]Nephrology, Vanderbilt University, Nashville, TN; [2]Nephrology, Indiana University, Indianapolis, IN.*

Background: Hypoxia and increased activity of hypoxia-inducible factor (HIF) is commonly found in chronic kidney disease. We previously identified tubular epithelial HIF-1 as a promoter of renal fibrosis, however the role of HIFs in other renal cell types remains unclear. Here we used a genetic approach to investigate the role of endothelial HIF-1 and HIF-2 in health and in response to chronic renal injury.

Methods: To delete HIF-1 and -2 in endothelial cells Vecadherin (Cdh5)-Cre transgenic mice were crossed to mice carrying conditional HIF-1A and/or HIF-2A alleles (Cdh5Cre;Hif1f/f,Hif2f/f: double mutants, Cdh5Cre;Hif1f/f, Cdh5Cre;Hif2f/f). To assess the HIF deficient vasculature, mutant transgenics were crossed to a reporter line. Unilateral ureteral obstruction (UUO) was used as a renal fibrosis model.

Results: Endothelial HIF-1/HIF-2 double mutants developed and aged normally, had no defects in renal morphology and function and possessed intact renal vasculature. When we exposed double mutants to 12 days of UUO, we found a 32% increase in collagen deposition compared to controls based on Sirius Red staining (n=10-11, P=0.03). Capillary density assessed by CD31 immunohistochemistry was reduced by 25% in double mutants compared to controls (n=4-6, P=0.03). This was associated with a 2.4-fold reduction in CD31 mRNA levels (n=4-6, P=0.009). In addition, mutant UUO kidneys showed a 25% increase in F4/80+ve cell infiltration. No difference in collagen accumulation was found when UUO experiments were performed with either endothelial HIF-1 or HIF-2 single mutants. However, capillary density by CD31 and cablin staining was decreased by 32% in endothelial HIF-2 single mutants compared to controls (n=5-6, P=0.03).

Conclusions: Our data show that endothelial HIF-1 and HIF-2 are dispensable under physiologic conditions, whereas both endothelial HIF-1 and HIF-2 in concert suppress the fibrotic response to chronic kidney injury. Furthermore, we identified HIF-2 as a critical regulator of the capillary maintenance during fibrosis. Our data provide new insights into the cell type-specific role of individual HIF transcription factors in renal disease.

Macrophage HIF Suppresses Renal Inflammation in Chronic Kidney Disease Hanako Kobayashi,[1] Detlef O. Schlondorff,[2] Volker H. Haase.[1] *[1]Medicine, Vanderbilt University, Nashville, TN; [2]Medicine, Mount Sinai Medical Center, New York, NY; [3]Medicine, Vanderbilt University, Nashville, TN.*

Background: Hypoxia has been implicated as an important microenvironmental factor involved in the development of fibrosis in chronic kidney disease (CKD), and hypoxia inducible factor (HIF) has been shown to be a key regulator in this process. Our previous studies showed that deletion of HIF-1a in proximal tubule epithelial cells decreases renal fibrosis, indicating that HIF-1 activation in epithelial cells is fibrogenic. However systemic pharmacologic HIF activation in certain animal models can slow CKD progression indicating cell-type dependent functions of HIF with regard to renal fibrogenesis.

Methods: We used a genetic approach and studied the effect of HIF activation (HIF-1 and HIF-2) in the unilateral ureteral obstruction (UUO) mouse model. HIF was activated by global deletion of von Hippel-Lindau tumor suppressor gene (*Vhl*) using inducible Cre-loxP-mediated gene targeting system (*Ubc-Cre*).

Results: Unexpectedly, global activation of HIF ameliorates renal fibrosis following UUO and is associated with a marked decrease in macrophage (MØ) infiltration. To test the hypothesis that HIF activation of MØ changes their responses and thereby fibrosis, we performed UUO in mice in which *Vhl* is deleted in MØ ($LysM\text{-}Vhl^{-/-}$). We found that MØ infiltration is decreased by 40% in the $LysM\text{-}Vhl^{-/-}$ mice compared to cre-negative littermate controls following UUO. Moreover, we found that *Ccr2*, the major receptor for Monocyte/MØ (M/M) chemotaxin, is downregulated in cultured M/M by *Vhl* deletion. However, despite the marked decrease in the MØ infiltration, there is no reduction in collagen accumulation in $LysM\text{-}Vhl^{-/-}$ mice.

Conclusions: The decrease in inflammation that is associated with reduced MØ infiltration in $Ubc\text{-}Vhl^{-/-}$ UUO kidneys is partly due to the effect of MØ HIF; however, it is not sufficient to reduce renal fibrosis, and suggests that HIF activation in other cell types modulates collagen production in this model. Detailed analysis of MØ regulation by HIF will be further discussed.

SA-OR445

Iron Facilitates Kidney Inflammation in a Model of Chronic Renal Failure Induced by Persistent Expression of Kidney Injury Molecule-1 Dhruti D. Patel,[1,2] Liangying Gan,[1] Ningning Wang,[1] Takaharu Ichimura,[1] Benjamin D. Humphreys,[1] Joseph V. Bonventre.[1] *[1]Renal Division, Brigham and Women's Hospital, Boston, MA; [2]School of Medicine, University of North Carolina, Chapel Hill, NC.*

Background: Chronic renal failure is characterized by tubular degeneration, fibrosis and often tissue iron deposition. In humans and rodent models of progressive kidney disease, Kidney Injury Molecule-1 (Kim-1) is persistently expressed in the proximal tubule (PT) and released into the urine.

Methods: A transgenic mouse was created, using Cre-Lox technology, which overexpresses Kim-1 primarily in the PT. Tissues were stained for iron using Prussian blue. Tubular Kim-1 expression and surrounding inflammatory cells were characterized by immunofluorescence. Primary PT cells were treated with media containing bovine Holo-Transferrin and 100 μM ferric ammonium citrate to model tissue iron overload. MHC-II expression was evaluated by flow cytometry. RAW macrophage activation was evaluated by TNFα production after exposure to conditioned media from Kim-1 expressing cells.

Results: The Kim-1 transgenic mouse develops progressive kidney disease with fibrosis, anemia, cardiac hypertrophy and suffers a uremic death. Urinary transferrin levels, tubule-interstitial inflammation and heme oxygenase-1 are increased. There are large amounts of iron deposition in PT cells and surrounding macrophages. We studied the role of this iron maldistribution in the modulation of inflammatory changes leading to renal failure. In primary cultures of mouse PT cells, addition of transferrin upregulated MHC-II levels. Iron loading of cells also eventually resulted in cell death of PT cells. Conditioned media from transferrin-treated tubular cells produced a marked induction of TNFα production by macrophages.

Conclusions: Increased PT cell iron is associated with upregulation of MHC-II in vivo. In vitro, increased cellular iron uptake results in increased cellular MHC-II expression, and eventually leads to cell death. Iron-enriched PT cells release pro-inflammatory agents which increase activation of macrophages and may contribute in an important way to progression of chronic kidney disease.

SA-OR446

Platelet-Derived Growth Factor Receptor Signaling Activates Pericyte-Myofibroblast Transition in Progressive Kidney Fibrosis Yi-Ting Chen,[1,2] Fan-Chi Chang,[1] Ching-Fang Wu,[1] Yu-Hsiang Chou,[1] Wen-Chih Chiang,[1] Yung-Ming Chen,[1] Jeremy S. Duffield,[3] Shuei-Liong Lin.[1] *[1]Department of Medicine, National Taiwan University Hospital, Taipei, Taiwan; [2]Department of Medicine, E-DA Hospital, Kaohsiung, Taiwan; [3]Institute of Stem Cell & Regenerative Medicine, University of Washington, Seattle.*

Background: Pericytes are the major source of scar producing myofibroblasts following kidney injury; however, the mechanisms of this transition are unclear.

Methods: We examined Collagen 1 (α1)-GFP reporter mice (pericytes and myofibroblasts express GFP) following ureteral obstruction or ischemia-reperfusion injury and focused on the role of platelet-derived growth factor (PDGF)-receptor (PDGFR) signaling in these two different injury models.

Results: Pericyte proliferation was noted after injury with reactivation of α-smooth muscle actin expression, a marker of the myofibroblast phenotype. PDGF expression increased in injured tubules, endothelium, and macrophages after injury, whereas PDGFR subunits α and β were expressed exclusively in interstitial GFP-labeled pericytes and myofibroblasts. When PDGFR α or β activation was inhibited by receptor-specific antibody following injury, proliferation and differentiation of pericytes decreased. The antibodies also blunted the injury-induced transcription of PDGF, transforming growth factor β1, and chemokine CCL2. They also reduced macrophage infiltration and fibrosis. Imatinib, a PDGFR tyrosine kinase inhibitor, attenuated pericyte proliferation and kidney fibrosis in both fibrogenic models.

Conclusions: PDGFR signaling is involved in pericyte activation, proliferation and differentiation into myofibroblasts during progressive kidney injury. Hence, pericytes may be a novel target to prevent kidney fibrosis by means of PDGFR signaling blockade.

SA-OR447

Angiotensin II Induces Progressive Renal Injury by Activating the TGF-beta/Smad Pathway through Activation of Sustained EGFR-ERK Signaling Jianchun Chen, Jian-Kang Chen, Raymond C. Harris. *Medicine, Vanderbilt University, Nashville, TN.*

Background: Although it is well recognized that angiotensin II can mediate progressive renal fibrotic injury, the underlying mechanisms are not completely understood.

Methods: We generated renal proximal tubule cell-specific EGF receptor knockout mice (*EGFR*^{ptKO}) by crossing EGFR$^{flox/flox}$ mice with gGT-Cre mice and chronically infused angiotensin II (Ang II) into these mice and their wild type littermates (*WT*). Blood pressures were similar in the two groups.

Results: In *WT*, Ang II infusion increased TGF-beta expression and $Smad_{2/3}$ phosphorylation in isolated renal proximal tubule epithelial cells, decreased E-cadherin expression, up-regulated vimentin, N-cadherin and snail expression and increased tubulointerstitial fibrosis. Ang II also markedly induced EGFR phosphorylation at Tyr845, a Src-dependent phosphorylation site. In Ang II-infused *WT*, Tyr845-phosphorylated EGFR associated with the adaptor proteins, Shc and Grb2 and increased ERK phosphorylation. In LLCPKcl4 cells stably transfected with AT1R (*AT1/Cl4*), Ang II stimulated ROS production, TGF-beta *de novo* synthesis and $Smad_{2/3}$ phosphorylation. Antioxidants or siRNA knockdown of Src kinase or EGFR blocked Ang II-induced ERK activation, inhibited TGF-beta/Smad2/3 signaling. *In vivo*, *EGFR*^{ptKO} mice had decreased ERK signaling, TGF-beta expression and $Smad_{2/3}$ phosphorylation, and significantly less tubulointerstitial fibrosis in response to Ang II perfusion. Administration of a specific EGFR tyrosine kinase inhibitor, erlotinib, to the wild type FVB/NJ mice, had a similar inhibitory effect on Ang II infusion-induced renal cortical tubules injury.

Conclusions: This study demonstrates that ROS-dependent Src activation-mediated prolonged-EGFR-ERK signaling, inducing TGF-beta de novo synthesis and Smad2/3 signaling activation, is a novel molecular mechanism underlying Ang II-induced progressive renal injury.

NADPH-Oxidase 4 Knock-Out Mice Display Increased Tubular Apoptosis and Interstitial Fibrosis in the Unilateral Obstruction Model Stellor Nlandu Khodo,[1] Eva Bernabeu Dizin,[1] Pierre-Yves F. Martin,[1] Eric Feraille,[1] Karl-Heinz Krause,[2] Sophie M. De Seigneux.[1] *[1]Nephrology, University of Geneva, Switzerland; [2]Pathology, University of Geneva, Switzerland.*

Background: Kidney interstitial fibrosis is correlated with chronic kidney disease (CKD) progression. NOX4 is the major kidney NADPH-oxidase expressed mostly in the tubular compartment. In the kidney NOX2 is expressed at lower levels. NOX isoforms are involved in apoptosis and prosurvival pathways as well as in hypoxia signaling and may therefore play a role in fibrosis progression.

Methods: We studied unilateral urinary obstruction (UUO) in wild type and NOX4 knock-out (KO) mice as well as in NOX2/4 double-KO mice to decipher the role of these enzymes in kidney fibrosis progression. mCCDcl1 cells were specifically used to examine their role in apoptosis.

Results: NOX4 was expressed in the proximal tubule and collecting duct whereas NOX2 was expressed at low levels along the nephron. Kidney development was not altered by the absence of NOX2 and NOX4. Interstitial fibrosis assessed by Sirius red staining and collagen-I Western blot after 7 and 14 days UUO was two times higher in NOX4 KO and NOX2/NOX4 mice than in wild type mice. Tubular apoptosis was significantly enhanced in NOX4 and NOX2/NOX4 KO mice compared to wild type. Peritubular capillary density and VEGF expression assessed by Western blot were significantly lower in UUO kidneys of NOX4 and NOX2/NOX4 KO mice compared to wild type. Oxidative stress was increased in the interstitium of obstructed kidneys of NOX4 KO mice whereas it was attenuated in NOX2/NOX4 KO animals. In mCCDcl1 cells NOX4 si-RNA silencing led to apoptosis in the presence of TGF-b1.

Conclusions: We demonstrate that NOX4 deletion is deleterious in the UUO model and increases tubular cell apoptosis under conditions of tubular cell stress. NOX4 deletion decreases kidney peritubular vascularisation via decreased tubular VEGF production in UUO. NOX2 has a different role from NOX4 and does not compensate for the absence of NOX4.The role of NOX4 in tubular cell might be different from other cell types. These effects of NOX4 may explain enhanced kidney fibrosis in UUO NOX4 KO mice.

SA-OR449

Inhibition of microRNA-21 as a Therapeutic Strategy for Kidney Fibrosis Jeremy S. Duffield,[1] Deidre Mackenna,[2] Phong T. Tran,[2] Kara Kersjes,[2] Aaron Chang,[2] B. Nelson Chau.[2] *[1]Medicine, University of Washington, Seattle, WA; [2]Regulus Therapeutics, Lo Jolla, CA; [3]Medicine, Harvard Medical School, Boston, MA.*

Background: Fibrosis is an underlying pathology involved in disease progression and is associated with poor prognosis in a variety of chronic kidney diseases (CKD). microRNAs are ~22 bp evolutionarily conserved non-coding RNAs that regulate multiple mRNA targets and their dysregulation has been implicated in multiple disease processes including fibrosis. In particular, miR-21 is up-regulated in cardiac, lung & liver fibrosis & oligonucleotide-mediated inhibition of miR-21 is effective in mouse models of heart & lung fibrosis. We investigated if antagonizing miR-21 could represent a novel therapeutic approach for CKD.

Methods: We used mouse models of kidney injury with fibrosis, genetic and oligonucleotide silencing of miR21 in vivo, and bioinformatics to study miR21 in kidney disease.

Results: miR-21 was upregulated in two different models of kidney fibrosis: unilateral ureteral obstruction (UUO) and unilateral ischemia-reperfusion injury (IRI). Genetic deletion of miR-21 prevented kidney fibrosis in both models as measured by fibrotic gene expression, quantitative histology and biochemical analyses. To assess the therapeutic potential of inhibiting miR-21, high affinity oligonucleotide-based anti-miRs were administered to mice prophylactically or therapeutically in UUO or IRI models. These compounds delivered effectively to renal tubule epithelium and were detected in various interstitial cell types, including pericytes and interstitial myofibroblasts. Anti-miR-21 improved fibrosis in both models that largely phenocopied miR-21-/- mice. To investigate the role of miR-21 in fibrosis, we evaluated mRNA expression profiles of miR-21 deficient kidneys. Surprisingly, the expected global de-repression of potential miR-21 target mRNAs

was only observed when miR-21 deficient mice were subjected to stress (UUO or IRI). Such global analysis has revealed key miR-21 targets and corresponding downstream pathways that may mediate the anti-fibrotic effect miR-21 inhibition.

Conclusions: miR21 is an important new therapeutic target in kidney disease

T Lymphocytes Lacking Sphingosine Kinase 2 Attenuate Folic Acid Induced Kidney Fibrosis in Mice

Amandeep Bajwa,[1,3] Krishna Dondeti,[1] Hong Ye,[1,3] Diane L. Rosin,[2,3] Kevin Lynch,[2] Mark D. Okusa.[1,3] *[1]Department of Medicine, University of Virginia, Charlottesville, VA; [2]Department of Pharmacology, University of Virginia, Charlottesville, VA; [3]Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia, Charlottesville, VA.*

Background: Epidemiological studies indicate some survivors of AKI who regain renal function have a progressive decline in kidney function leading to end stage renal disease-ESRD. Sphingosine-1-phosphate (S1P) is generated by phosphorylation of sphingosine by sphingosine kinases (SphK1 and SphK2).

Methods: WT, SphK1$^{-/-}$ and SphK2$^{-/-}$ mice were administered Folic Acid-FA (250 mg/kg, ip) and followed for 14 days. mRNA changes were measured with RT-PCR and protein changes with IHC and western blots.

Results: SphK2$^{-/-}$ mice exhibited lower fibrosis (trichrome staining) compared to WT or SphK1$^{-/-}$ mice at day 14 post FA. Compared to kidneys of FA treated SphK1$^{-/-}$ mice, SphK2$^{-/-}$ mice expressed lower levels of mRNA encoding TGF-β (15.79%, $p<0.001$), α-SMA (30.8%, $p<0.01$) and fibronectin (36.9%, $p<0.01$). Likewise, kidney sections of FA-treated SphK2$^{-/-}$ mice displayed lower levels of collagen and fibronectin immunoreactivity compared to SphK1$^{-/-}$ mice. FA-treated SphK2$^{-/-}$ mouse kidneys had reduced infiltration of macrophages (45.1%, $p<0.05$)) and neutrophils (27.9%, $p<0.01$) compared to SphK1$^{-/-}$ mice. SphK2$^{-/-}$ CD4^{+} T cells have a hyper-proliferative response with significantly higher amounts of IFN-γ compared to WT or SphK1$^{-/-}$ cells. In fibrosis, IFN-γ is anti-fibrotic; therefore, we tested the role of CD4^{+} T cells from SphK2$^{-/-}$ mice transfered into WT and SphK1$^{-/-}$ mice. Transfer of SphK2$^{-/-}$ CD4^{+} T cells to either WT or SphK1$^{-/-}$ mice attenuated the progression of fibrosis at day 14 in the recipients.

Conclusions: We conclude that: 1) FA induces fibrosis to a similar degree in WT and SphK1$^{-/-}$ mice, 2) the lack of SphK2 attenuates FA-induced fibrosis possibly due to hyper-proliferative T cells. Understanding the function of SphK2 may contribute further to our understanding of the pathogenesis of fibrosis and development of a SphK2 selective inhibitor may lead to a new therapeutic agent that impede the progression of kidney disease to ESRD.

SA-OR451

Risk of Vascular Access Events in the FHN Daily Trial

Rita Suri,[1] Brett Larive,[2] Susan G. Sherer,[2] Jennifer J. Gassman,[2] Daniel B. Ornt,[3] Michael V. Rocco,[4] Sam H. James,[5] Robert M. Lindsay,[1] George O. Ting,[6] Paul W. Eggers,[7] Alan S. Kliger,[8] The FHN Trial Group.[7] *[1]U Western Ontario; [2]Cleveland Clinic; [3]Case Western Reserve U; [4]Wake Forest U; [5]UCSF; [6]El Camino Renal Medical Gp; [7]NIDDK; [8]Yale U.*

Background: Daily hemodialysis (HD) improves several patient outcomes, but the potential risks are unclear. We evaluated the risk of vascular access complications in the Frequent Hemodialysis Network (FHN) Daily Trial.

Methods: We randomized 245 patients with end-stage renal disease to receive daily HD (6 days/wk, 1.5-2.75 hrs/session) or conventional HD (3 days/wk, 3-4.5 hrs/session) for 12 months. All patients were dialyzed in-center. Using proportional hazards regression, we compared the time from randomization to first access event (repair or loss) between groups. Fistula and graft repairs included angioplasty, stenting, thrombolysis, thrombectomy, and surgical revision. Catheter repairs included fibrin sheath stripping. Accesses that were removed or could no longer be used were defined as losses. Catheter removals performed electively once a fistula or graft was in use were not counted as events. We adjusted for age and diabetes. In a secondary analysis, we evaluated fistulae and graft events separately from catheters. For this, we considered the first catheter and fistula/graft that was used for each patient at or after randomization.

Results: After mean followup of 8.8 months, there were 75 events in 245 patients (daily group: 33 repairs, 14 losses; conventional group: 17 repairs, 11 losses). Compared to conventional HD, the hazard ratio of first access event with daily HD was 1.77 (95% CI 1.11-2.84 p=0.017). In the 220 patients with arteriovenous fistulae/grafts, the HR of first access event with daily HD was 1.69 (95% CI 1.002-2.78, p=0.049). A similar trend was observed in the 52 patients who had catheters (HR with daily HD=1.40, 95% CI 0.47-4.24, p=0.54).

Conclusions: In the FHN trial, patients receiving daily HD had an increased risk of vascular access events, and this did not differ by access type. Whether this risk is due to increased HD frequency or heightened surveillance is the subject of further study.

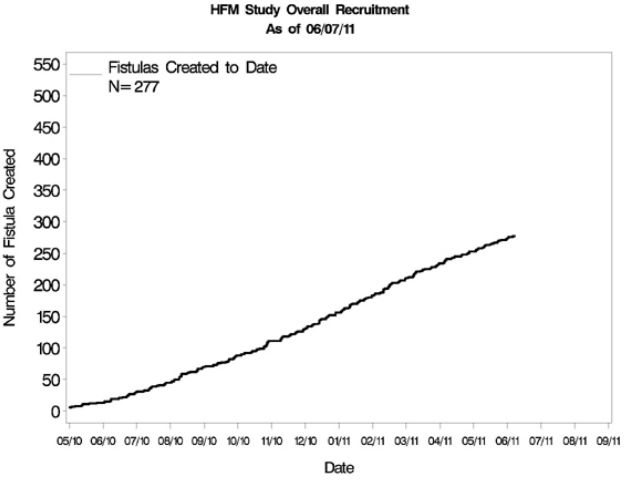
Progress of the Hemodialysis Fistula Maturation (HFM) Study

Gerald J. Beck,[1] Alfred K. Cheung,[2] Laura M. Dember,[3] Harold I. Feldman,[4] Jonathan Himmelfarb,[5] Thomas S. Huber,[6] John W. Kusek,[7] Prabir Roy-Chaudhury,[8] Miguel A. Vazquez,[9] Charles E. Alpers,[2] Michelle L. Robbin,[10] Joseph Vita,[5] The HFM Study Group.[7] *[1]Cleveland Clinic; [2]U Utah; [3]Boston U; [4]U Penn; [5]U Washington; [6]U Florida; [7]NIDDK; [8]U Cincinnati; [9]U Texas Southwestern; [10]U Alabama Birmingham.*

Background: The NIDDK-sponsored HFM Study is designed to identify predictors and causes of AVF maturation failure. HFM will enroll 600 patients undergoing AVF creation. The study group includes 6 clinical centers (Boston U, U Cincinnati, U Florida, U Texas Southwestern, U Utah, U Washington), a Data Coordinating Center (Cleveland Clinic), and 3 Cores: Ultrasound (U Alabama Birmingham), Vascular Function (Boston U) and Histology (U Washington).

Methods: The protocol includes 1) pre-operative assessment of vascular anatomy and function with measurement of flow-mediated dilation, pulse wave velocity, and venous capacitance; 2) detailed intra-operative documentation of surgical procedures; 3) serial post-operative ultrasounds, and 4) uniform characterization of AVF function. Maturation is declared after 4 weeks of successful use under routine clinical care. Follow-up continues until AVF abandonment. Serum, plasma, DNA and vein tissue are collected for biomarker and mechanistic studies.

Results: Enrollment began in 5/2010 and study completion is expected in 2013.



As of 6/7/2010, 277 participants have had AVF creation: 180 were receiving dialysis before surgery; 97 had not yet initiated dialysis. 26 others have not yet had AVF surgery. Baseline characteristics are: 70% male, median age 56 yr, 48% white, 43% black, 57% have DM.

Conclusions: The HFM Study is enrolling participants at a steady rate and successfully collecting multifaceted data that should identify early predictors of AVF maturation and elucidate underlying mechanisms.

SA-OR453

Modern Era Access Outcomes: Comparison of Fistulas (AVF) vs. Grafts (AVG) after Year 2000

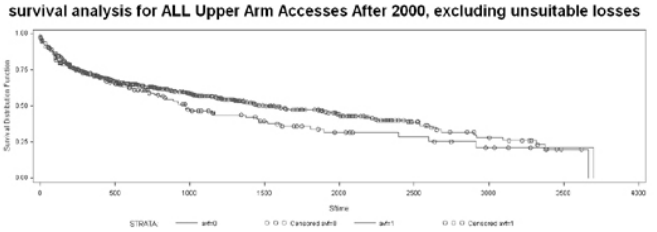
Charmaine E. Lok,[1] Cynthia B. Bhola,[1] Louise M. Moist,[2] Dheeraj Rajan.[1] *[1]Toronto General Hospital, Toronto, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada.*

Background: Fistulas have been promoted to have longer patency and lower complication rates compared to AVGs based on data prior to year 2000 which largely excluded AVFs that were not suitable for dialysis.

We sought to compare the cumulative patency of AVFs and AVGs created after 2000 from the time of their creation to their final abandonment.

Methods: Cumulative patency was compared with Kaplan Meier curves (log rank test). Further analysis of vascular accesses (VA) were based on whether they 1) were first or subsequent VA and 2) failed to mature (FTM) or not. Intervention rates were compared using the exact binomial test (SAS, v9.2).

Results: 1740 VA created (1375 AVF; 365 AVG) between Jan 2000-June 2010 were followed. The mean age was 59 yrs, 63% male, >50% Caucasian, 42% had DM and 68% had HTN. There was no difference in cumulative patency between AVFs (median 7.1months) and AVGs (11.3<INS cite=mailto:t67medc dateTime=2011-06-08T12:23> </INS>months) p= 0.12 when FTM was included. AVFs had superior patency (53.8 months) compared with AVGs (27months) when FTM was *excluded*. This finding of AVF superiority was due to forearm VA only. No differences were found in comparisons of upper arm VA (n=850), regardless of whether AVF that FTM were included or not, or if they were first or subsequent VA.



Grafts had a higher rate of angioplasties (3.18/1000 days) compared to AVF (1.36/1000 days) to maintain patency after cannulation (p<0.001). Grafts also required more thrombolysis vs. AVF (0.98/1000 days vs. 0.06/1000 days; p<0.0001). The intervention rates to attain AVF maturation is not included in this analysis.

Conclusions: AVFs and AVGs created after year 2000 have similar cumulative patency rates. Factors important in VA choice, such as patient preference, complications, interventions to attain function should be considered.

SA-OR454

Pre-Existing Venous Calcification Prior to Dialysis Vascular Access Surgery

Timmy C. Lee, Nida Nida Safdar, Meenakshi J. Mistry, Yang Wang, Begoña Campos, Prabir Roy-Chaudhury. *Internal Medicine, University of Cincinnati, OH.*

Background: Vascular calcification is present in arterial vessels used for dialysis vascular access prior to surgical creation of the access. Calcification in the veins used to create a new vascular access has not previously been documented. The objective of this study was to describe the prevalence of calcification in vein samples collected at the time of new vascular access creation.

Methods: 67 vein samples, collected at the time of new access creation, were studied. Routine immunohistochemistry, using a von Kossa stain, was performed to quantify calcification. A semiquantitative scoring system from 0-4+ was used to quantify the percentage positive area (brown or black) as a fraction of total area (0 = 0-10% positive; 1+ =11-25%; 2+ = 26-50%; 3+=51-75%; and 4+=76-100% positive) for each vascular layer (endothelium, intima, media, and adventitia).

Results: 22/67 (33%) samples showed evidence of calcification.

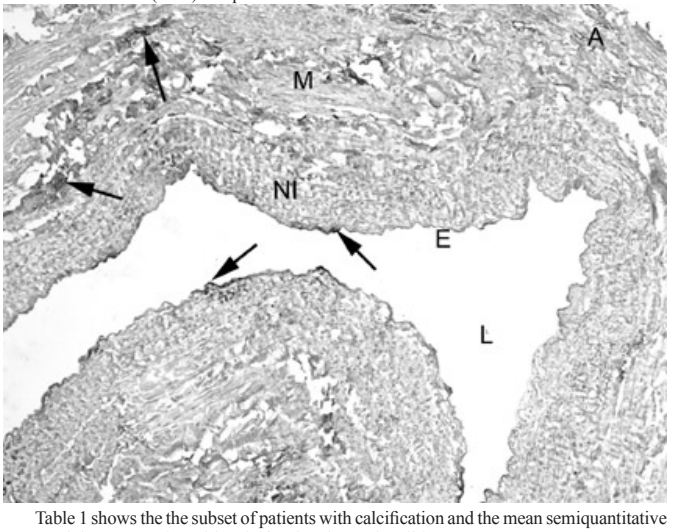


Table 1 shows the the subset of patients with calcification and the mean semiquantitative scores of the 22 samples with calcification for each cell layer.

Table 1:Proportion of Vascular Calcification and Semiquantitative Score by Cell Layer

	Endothelial	Intima	Media	Adventitia
Proportion of Vascular Calcification	4/22 (18%)	19/22 (86%)	22/22 (100%)	7/22 (32%)
Semiquantitative Score	00.18±0.39	1.2±0.66	1.6±0.59	0.36±0.58

Conclusions: Our results are the first to demonstrate that vascular calcification is present within veins used to create new dialysis vascular access. In samples with vascular calcification, the calcification was present predominately within the intimal and medial layers. Important questions that remain to be answered include the pathogenetic role of uremia in the development of venous calcification and clinical impact of vascular calcification on vascular access stenosis and outcomes.

Funding: NIDDK Support

SA-OR455

Primary Arteriovenous Fistula Patency Is Dependent on Venous Distensibilty, Not on Proinflammatory, Procoagulant Markers or Vascular Functional Parameters

Milan M. Radovic,[1,2] Tamara K. Jemcov.[1] *[1]Clinic of Nephrology, Clinical Center of Serbia, Belgrade, Serbia; [2]University of Belgrade, School of Medicine, Belgrade, Serbia.*

Background: Role of vascular functional parameters, procoagulant and proinflammatory factors that influenced success of primary arteriovenous fistula for hemodialysis (AVF) patency were not elucidated completely. The aim of the study was to explore their correlation with outcome of AVF 4 weeks after creation.

Methods: Prospective, observational, cross sectional study was performed on 114 patients (59 male, age 55.8±15.5) who underwent primary non-dominant forearm AVF creation for hemodialysis. Cephalic vein (CVr) and radial artery radius (RAr), venous distensibility (VD), resistance index (RI) and endothelial function by flow mediated dilatation (FMD) were determined by Doppler sono examination. Serum levels of tissue plasminogen activator (tPA), vascular endothelial growth factor (VEGF), vascular cell adhesion molecule (VCAM) and interleukin 6 (IL-6) were determined by ELISA. Their concentrations and blood vessels examinations were compared between groups based on outcome after 4 weeks of maturation: 1–primary AVF success (n=76), group 2–secondary success (n=30), group 3–AVF creation failure (n=8).

Results: Primary AVF success was reached in 66.7% of patients, secondary in 26.3%. Only 7% patients failed to mature AVF. Comparison between groups showed significant difference in CVr (p=0.039), RAr diameter (p=0.006) and venous distensibility (p=0.044), unlike RI, FMD, serum tPA, VEGF, VCAM and IL-6 levels (p>0.05). Significant correlation was found between outcome and CVr (p=0.028), VD (p=0.017) and RAr (p=0.002). RI correlated with age (p=0.018), and inversely with CVr (p>0.001) and RAr (p=0.013). Significant correlation was found between IL-6 and tPA, VEGF and VCAM (all p<0.05), VEGF and VCAM (p=0.002). Linear regression was only significant for VD (B=0.517, 95% CI 0.0.054-0.981, p=0.029).

Conclusions: Venous distensibility showed to be the most important factor for primary AVF patency after 4 weeks of maturation. Significant correlation was found among procoagulant and proinflammatory biomarkers, but their impact was not significant for an early AVF outcome.

Funding: Pharmaceutical Company Support, Government Support - Non-U.S.

SA-OR456

Clinical vs. Surgical Fistula Failure Risk Assessment

Mohammad Z.H. Joarder,[1] Louise M. Moist,[2] Timmy C. Lee,[3] Charmaine E. Lok.[1] *[1]Toronto General Hospital, Toronto, ON, Canada; [2]London Health Science Centre, London, ON, Canada; [3]University of Cincinnati.*

Background: Fistulas (AVF) are preferred for vascular access (VA), but ≈ 50% fail. We derived and validated a prediction equation (Risk Score) for AVF failure risk based on age, ethnicity, presence of coronary artery disease (CAD) and peripheral vascular disease (PVD) (Lok, 2006). It is unknown how the Risk Score compares with the surgeon's preopertive evaluation (SPE).

This study compared their predictive ability.

Risk of FTM (%)	FTM Risk Score	Surgeon Assess
Low (25%)	<2.0	Excellent
Moderate (35%)	2.0-3.0	Good
High (50%)	3.1-7.9	Marginal
Very high (70%)	>=8.0	Poor

Methods: AVFs created (2006-2011) were followed for 6 mos to ascertain maturity and need for intervention (n=467). The Risk Score and the SPE were determined by the clinician and surgeon, respectively. The Risk Score was independently validated using strict definitions of CAD and PVD via medical records (V_Score). Kappa statistics compared the Score vs. V_Score and the agreement between the Risk Score and the SPE.

Results: The failure outcomes of 322 AVF by the Risk Score were: low risk-33%; moderate risk-43%; high risk-55%; and very high risk-73% (p=0.001). The Risk Score had a Kappa agreement of 0.85 with the V_Score (15% difference). The AVF failure outcomes by the SPE were: low risk-14%; moderate risk-27%; high risk-69%; and very high risk-70% (p<0.0001). There was fair correlation between the Risk Score and SPE for AVF outcomes, yet both predicted failure well. Despite the ability of both to accurately predict AVF failure, 71% of patients with a >50% risk of AVF failure still underwent AVF creation and 70% of them failed. Of all AVFs created, 36% had interventions; of those AVFs that failed, 42% had interventions.

Conclusions: The FTM Risk Score is strengthened when definitions of CAD and PVD are strictly followed. The surgeon's evaluation correlates poorly with the FTM Risk Score, suggesting that they use parameters not accounted for by the Risk Score and may be complimentary. High failure risks indicated by these two evaluations should prompt serious consideration for an alternate VA. There is need to determine patient eligibility for AVF creation.

SA-OR457

Effect of Recombinant Human Type 1 Pancreatic Elastase (PRT-201) Treatment on Fistula Patency Bradley S. Dixon,[1] Eric K. Peden,[2] David B. Leeser,[3] Mahmoud T. El-Khatib,[4] Prabir Roy-Chaudhury,[4] Jeffrey Lawson,[5] Matthew Menard,[6] Marc H. Glickman,[7] Laura M. Dember,[8] Steven K. Burke.[9] *[1]U Iowa, IA; [2]Weill Cornell MC, NY; [3]Methodist Hospital, TX; [4]U Cincinnati, OH; [5]Duke U, NC; [6]Brigham & Womens' Hospital, MA; [7]Sentara Heart Hosp, VA; [8]Boston U, MA; [9]Proteon Therapeutics, MA.*

Background: Stenosis is a common cause of fistula (AVF) failure. We conducted a phase 1/2 randomized, double-blind, dose-escalation trial to determine if PRT-201 treatment was safe, would promote dilation & prevent failure of newly created AVFs.

Methods: A single dose of PRT-201 (N=45) or placebo (N=21) in 2.5 mL of saline was dripped onto the outside of the AVF over 10 min immediately after creation. Doses were aggregated into low (LD, 0.003, 0.010 & 0.033 mg), medium (MD, 0.1, 0.33 & 1 mg), & high (HD, 3, 6, 9 mg) groups (N=16, 17, 12). Patients were followed for up to 12 mon. Blinded duplex Doppler ultrasound evaluation was done at 6 weeks, & 3 & 6 months. Primary outcomes were safety & immediate change in outflow vein diameter (VD) & blood flow (BF). Secondary efficacy endpoints were AVF maturation (lumen VD ≥4 mm & BF ≥500 ml/min at 6 weeks), & time to primary patency loss (AVF occlusion or procedures required to maintain or restore patency).

Results: No safety concerns occurred. There was a modest but statistically significant immediate change in PRT-201 treated VD (5±6%, p<0.01). Lumen VD and BF increased in all groups with no difference in maturation at 6 weeks. Primary patency at 6 months was not statistically different among groups (Placebo 60%, LD 81%, MD 76%, HD 73%, p=NS). If immediate post-surgical complications that caused patency loss were excluded from the analysis (N=3 patients in LD group) patency loss was reduced in LD versus placebo (HR 0.28, 95% CI=0.08-0.93, p=0.04) and versus HD (HR 0.07, 95% CI=0.01-0.52, p=0.01). Angioplasty was the most common reason for patency loss (placebo 43%, LD 12%, MD 35%, HD 33%), with a trend toward less hemodynamically significant lumen stenosis in LD (placebo 47%, LD 31%, MD 62%, HD 50%).

Conclusions: PRT-201 was safe. At LD, PRT-201 might decrease lumen stenosis & prolong fistula patency but an adequately powered trial is needed.

Far Infrared Therapy Improves Endothelial Function and Access Flow of Newly-Created Arteriovenous Fistula in Patients with Stage 5 Chronic Kidney Disease Chih-Ching Lin.[1,2] *[1]School of Medicine, National Yang-Ming University, Taipei, Taiwan; [2]Divsion of Nephrology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: Endothelial dysfunction plays a significant role in the pathogenesis of malfunction of vascular access. The aim of this study is to evaluate the effect of far infrared (FIR) therapy on endothelial function and access flow (Qa) of newly created AV fistula.

Methods: We enrolled 75 patients (in stage 5 CKD) who were randomly allocated to treatment group (receiving 40 minutes of FIR therapy three times weekly for 3 months postoperatively, N=37) and control group (without FIR therapy, N=38). Access flow of AV fistula was measured by Doppler ultrasonography at 4 timings, including 2 days, 1 month, 2 and 3 months after vascular surgery. Markers of Endothelial function, including asymmetric dimethyl arginine (ADMA) and L-arginine, were measured both immediately before and 3 months after the creation of AV fistula.

Results: Finally, 67 patients completed the study, including 33 in FIR group and 34 controls. In comparison with controls, patients in FIR group had lower values of incremental change of ADMA as well as higher values of Qa at all of the 4 timings and incremental change of L-arginine, thus leading to a higher incremental change in the ratio of L-arginine to ADMA 3 months later (as shown in table 1).

Comparison of the endothelial function and access flow of AVF between HD patients with and without FIR therapy for 3 months

	Control group	FIR group	P value
Case number completing study	34	33	
Qa0 (ml/min)	259.1±85.5	337.9±111.3	0.002
Qa1 (ml/min)	597.9±230.1	805.2±315.7	0.003
Qa2 (ml/min)	681.8±275.2	925.8±354.6	0.002
Qa3(ml/min)	770.6±344.0	987.3±375.1	0.016
Δ L-arginine 3-0 (μM)	-0.7± 2.9	2.2± 5.2	0.007
ΔADMA 3-0 (μM)	0.01±0.05	-0.05±0.07	<0.001
(L-arginine3/ADMA3)/ (L-arginine0/ ADMA0)	0.98± 0.08	1.09±0.12	<0.001

Qa0 /Qa1/ Qa2/ Qa3: Qa measured at 2 days, 1, 2, or 3 months after AVF creation; ADMA0/3 or L-arginine0/3 indicates the concentration measured 1 day before/3 months after AVF creation

Conclusions: In conclusion, 3 months of FIR therapy improves endothelial function and access flow of newly created AVF in patients with stage 5 CKD.

Funding: Government Support - Non-U.S.

Improved Arteriovenous Fistula Maturation with Intra-Operative Implant of a Perianastomotic Sirolimus Eluting Collagen Membrane (Coll-R) Maria V. DeVita,[1] Eric S. Chemla,[4] Kipshidze Nickolas,[2] Surendra Shenoy,[3] Sriram Iyer.[1] *[1]Lenox Hill Hospital, New York, NY; [2]Center of Angiology and Vascular Surgery, Tbilisi, Georgia; [3]Washington U School of Medicine, St Louis, MO; [4]St. George's Healthcare NHS Trust, London.*

Background: Nonmaturation of arteriovenous fistulae (AVF) remains a major limiting factor for their use in hemodialysis patients(pts). Etiologies include perianastomotic stenosis and neointimal hyperplasia of the draining vein. Since there is no proven solution, novel approaches are needed. The Coll-R, an investigational product (Vascular Therapies, NJ, USA) is indicated and designed for perivascular implantation. It consists of collagen, a topical hemostat and sirolimus, an anti-proliferative agent with proven efficacy for suppressing neointimal tissue growth when delivered locally to the vascular wall. The goal of this study was to evaluate the performance and safety of the Coll-R when applied around the anastomotic site and outflow vein during creation of AVF. In this first in human study, endpoints were freedom from Coll-R related adverse effects and time to maturation.

Methods: Pts. from 2 hospitals inTbilisi, Georgia, scheduled for AVF creation were invited to participate. Venous mapping was performed to assure suitable vascular anatomy. The Coll-R was implanted intra-operatively during AVFcreation. Data collected included technical success of the implantation, wound healing, time to unassisted maturation and whole blood sirolimus levels.

Results: Thirty pts, 17 male, mean age 51 years (range 25-77) underwent radiocephalic (n=22) or brachiocephalic(n =8) AVF creation with implantation of the Coll-R (675μg of sirolimus). All completed a minimum of 11 weeks of follow up. There were no Coll-R related technical failures or adverse events. AVF matured in 26 pts. (87%); mean maturation time was 27±18 days; 4 pts thrombosed in <4 weeks; mean peak sirolimus level was 4.13 ng/ml seen 6 hr post-op. Two late AVF failures occurred at 119 and 170 days respectively.

Conclusions: Coll-R implantation during AVF creation does not cause systemic immunosuppression and improves fistula maturation. Use of this novel therapy may provide an unmet clinical need.

Frequent Hemodialysis Fistula Infectious Complications Charmaine E. Lok,[1] Sarah Daisy Kosa,[1] Christopher T. Chan,[1] Deborah Lynn Zimmerman.[2] *[1]Toronto General Hospital, Toronto, ON, Canada; [2]Ottawa Hospital, Ottawa, ON, Canada.*

Background: Frequent hemodialysis (FHD) is associated with many beneficial clinical outcomes. Fistulas (AVF) are the preferred access for FHD; however there is a paucity of data on the impact of frequent cannulation and infectious complications. We compared the rate of infections in patients on FHD who cannulated their AVF using buttonhole (BH) vs. stepladder (SL) techniques. A second comparison was made with conventional intermittent HD (CIHD) patients using SL cannulation.

Methods: Patients who received short daily hemodialysis (SDH)(≥5x/wk) and nocturnal hemodialysis (NHD) (≥3 x/week, ≥5 hrs/session) who were dialyzed with an AVF were prospectively followed for infectious complications between Jan 2001-Dec 2010. Rates of bacteremia and BH site infections were compared using the exact binomial test.

Results: Forty-six patients had SDH and 128 had NHD. For self cannualtion, 50% of SDH and 72% of NHD used BH technique. In total, the BH technique was used on 198,910 fistula days while SL cannulation was performed on 99,681 fistula days. There were 39 BH-related bacteremias and at least 2 local BH-site infections (BHI). The BH bacteremia rate was 0.196/1000 fistula days. Staphylococcus aureus accounted for 85% of bacteremias. There were 5 related hospitalizations, and 3 metastatic infections (endocarditis, septic arthrisit, mycotic aneurysim and loss of fistula). In comparison, there was 1 possible fistula related infection in CIHD between Jan 1 2000-dec 31 2010 (rate of 0.002/1000 fistula days).

Conclusions: The rate of BH related infection is high in patients who self cannulate on FHD. The rate of bacteremia is >50 times that on CIHD. The majority of bacteremias are due to s. aureus and the consequences are serious with 13% requiring hospitalization and 10% with metastic spread or loss of access. The risks and benefits of BH cannulation require individual consideration with careful monitoring, prophylaxis and management.

Response of the Human Kidney to Clamp Ischemia Dipen J. Parekh,[1] Barbara Ercole,[1] Claudia Schrimpf,[2] Manjeri A. Venkatachalam,[1] Joel M. Weinberg.[3] *[1]UTHSC San Antonio; [2]Harvard Institutes of Medicine; [3]University of Michigan.*

Background: Structural changes in tubule cells during clamp ischemia are well characterized for animal models, but their timing and extent in the human kidney has not been established and may differ significantly, depending on the clinical setting.

Methods: We biopsied uninvolved areas of kidney in patients undergoing open partial nephrectomy for renal masses before renal artery clamping, then during periods ranging from 15 to 60 min. of warm and cold ischemia (80% > 30 min.), and then after 5 minutes of reflow for ultrastructure (N=39) and for immunofluorescence and rhodamine phalloidin staining (N=22).

Results: During the clamp period, apical membrane structure was remarkably well preserved with only patchy brush border clubbing, fragmentation, desquamation and blebbing and not in all patients. Mitochondria developed progressive swelling, which paradoxically was more prominent in distal than proximal tubule cells. This resolved during the 5 minutes of reflow in most cells in most patients, but persistence of swelling and development of matrix condensation occurred occasionally. Using a composite 0-5 scale covering the full spectrum of ultrastructural changes, average scores were: Preclamp 1.02±0.07, End clamp 2.18±0.07, Post clamp 1.86±0.09. Consistent with the ultrastructure, staining for F-actin with rhodamine phalloidin was well preserved. Immunostaining for phosphotyrosine, which reflects cellular ATP content, was decreased in 68.4% of the clamp biopsises and 52.6% of the postclamp biopsies with larger changes in proximal tubules, however β1 integrin was decreased in only one post clamp biopsy. ICAM-1 expression in peritubular capillaries was increased in 46.7% of the clamp biopsies and 66.7% of post clamp biopsies. None of the patients developed acute kidney injury.

Conclusions: These data provide the first detailed analysis of the structural response of the human kidney to clamp ischemia and document many of the expected structural alterations based on prior animal work, but indicate a greater than expected resistance to injury in this commonly used clinical application of clamp ischemia.

MicroRNA-687 Targets PTEN To Regulate Hypoxic/Ischemic Kidney Injury Kirti Bhatt, Qingqing Wei, Zheng Dong. *Department of Cellular Biology and Anatomy, Georgia Health Science University and Charlie Norwood VA Medical Center, Augusta, GA.*

Background: MicroRNAs are small, endogenous, non-coding RNAs that are critical regulators of gene expression in various pathophysiological conditions. Recent studies have suggested an emerging role of microRNAs in both renal development and pathophysiology. Targeted deletion of Dicer (a key enzyme for microRNA biogenesis) from proximal tubules protects against renal ischemia-reperfusion injury (IRI), demonstrating a pathogenic role of microRNAs in renal IRI. Despite these findings, the specific microRNA species that contribute to renal IRI are not known.

Methods: To identify the pathogenic microRNAs, we analyzed microRNA expression by microRNA microarray.

Results: Out of 220 detectable microRNAs, 138 were decreased to varying degrees while 70 microRNAs were induced during renal IRI in C57BL/6 mice. Among these microRNAs, microRNA-687 (miR-687) was most dramatically up-regulated. miR-687 was also induced by hypoxia in cultured renal proximal tubular cells. Bioinformatic analysis suggested that the tumor suppressor PTEN is a top candidate target of miR-687. The 3'UTR of PTEN gene contains a miR-687 binding sequence, which was shown to be a target sequence of miR-687 in a luciferase reporter assay. Consistently, miR-687 induction during hypoxia in cultured cells and renal ischemia-reperfusion in mice was followed by a concomitant decrease in PTEN expression. Notably, blockade of miR-687 with anti-miR-687-LNA could prevent PTEN decrease under these conditions. Functionally, anti-miR-687-LNA reduced apoptosis and induced cell cycle arrest in hypoxic cells.

Conclusions: Together, this study has identified miR-687 as a novel regulator of PTEN during renal hypoxia and ischemia-reperfusion injury. Targeting specific microRNAs may offer a new strategy for renoprotection.

TH-PO003

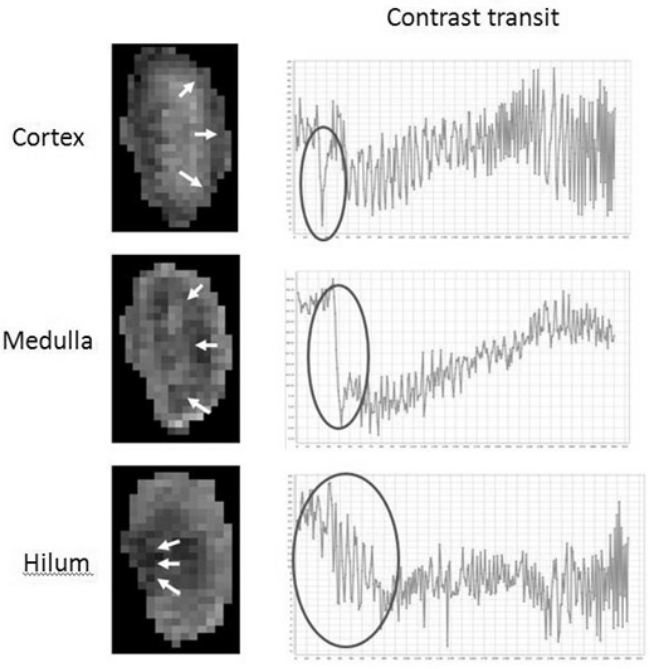
Utility of Local Arterial Input Function in Dynamic Susceptibility Magnetic Resonance Imaging To Identify Regional Renal Perfusion Defect Andrew M. Siedlecki. *Internal Medicine, Washington University in St. Louis, St. Louis, MO.*

Background: Rapid acquisition of magnetic resonance signal in tissue may offer a highly sensitive platform for the study of renal blood flow. We hypothesize that dynamic susceptibility contrast-magnetic resonance imaging (DSC-MR) can accurately measure regional renal blood flow in the kidney when the standard global arterial input function is replaced by per voxel local arterial input function (LAIF).

Methods: We performed mild ischemic injury in mice and measured renal perfusion after injury by means of magnetic resonance imaging and Doppler flowmetry. For MR studies, a multi-dimensional integral was constructed to account for the properties of gadolinium contrast flow, within single voxels of space. Posterior probabilities were derived from conditional probabilities by applying Bayesian evidential theory. Invasive measurement of cortical and medullary blood flow was performed by Doppler flowmetry.

Results: Invasive measurement of surface cortical blood flow by Doppler flowmetry returned to baseline within 35 minutes following mild (15 minute) ischemic injury (IRI, n=5; sham, n=5). In a separate cohort (IRI, n=5; sham, n=5), MR imaging showed a delayed transit in contrast through the kidney vasculature at a more distant time point, 45 minutes following ischemic injury. Perturbed blood flow in procedurized animals compared to shams was manifest in a significatnly prolonged contrast outflow, β, and mean transit time (MTT)(seconds) ($p<0.01$).

Conclusions: We apply for the first time the concept of convolution-free local arterial input function in the kidney using nuclear magnetic resonance technology. This study is an advancment in the analysis of renal blood flow as it obviates computational deconvolution and offers a non-invasive assessment of regional blood flow.



TH-PO004

Over-Expression of cGMP-Dependent Protein Kinase I (PKG-I) Attenuates Ischemia Reperfusion Induced Kidney Injury Shuxia Wang. *Graduate Center for Nutritional Sciences, University of Kentucky, Lexington, KY.*

Background: cGMP-dependent protein kinase (PKG) is a multifunctional protein. Whether PKG plays a role in ischemia/reperfusion induced kidney injury (IRI) is unknown.

Methods: In this study, using an in vivo mouse model of renal IRI, we determined the effect of renal IRI on kidney PKG-I levels and also evaluated whether overexpression of PKG-I attenuates renal IRI.

Results: Our studies demonstrated that PKG-I levels (mRNA and protein) were significantly decreased in the kidney from mice undergoing renal IRI. Moreover, PKG-I transgenic mice had less renal IRI, showing improved renal function and less tubular damage as compared to their wild type littermates. Transgenic mice in renal IRI group had decreased tubular cell apoptosis accompanied with decreased caspase 3 activity and increased expression of Bcl-2, Bag-1 and p-AKT. In addition, transgenic mice undergoing renal IRI demonstrated reduced macrophage infiltration into the kidney and reduced production of inflammatory cytokines. In vitro studied showed that peritoneal macrophages isolated from transgenic mice had decreased migration as compared to control macrophages.

Conclusions: Taken together, these results suggest that PKG-I protects against renal IRI, at least in part through inhibiting inflammatory cell infiltration into the kidney, reducing kidney inflammation, and inhibiting tubular cell apoptosis.

Thrombin and PAR-1 Regulate Sphingosine Kinases 1 and 2 and Sphingosine-1-Phosphate Receptors Following Renal Ischaemia and Reperfusion Injury Jonathan H. Erlich,[1,2] Anthony Chuang,[1] Sean E. Kennedy,[3] Dian Purnamasari.[3] *[1]Prince of Wales Clinical School, University of New South Wales, Sydney, NSW, Australia; [2]Nephrology, Prince of Wales Hospital, Randwick, NSW, Australia; [3]School of Women's & Children's Health, University of New South Wales, Sydney, NSW, Australia.*

Background: Recent studies have suggested sphingosine-1-phosphate signaling (S1P) via the S1P receptor-1 (S1Pr1) contributes to protection following renal ischaemia reperfusion injury (IRI). S1P generation via expression and activation of sphingosine kinase (SPHK) has been suggested to be a potentially important downstream secondary signaling system for protease activated receptor-1 (PAR-1).

Methods: In an established model of renal IRI using 25 min bilateral renal ischaemia and varying times of reperfusion (2, 5 and 24h) we examined the effects of PAR-1 deficiency, PAR-1 inhibition using hirudin and reduced thrombin generation using low-TF mice. As previously shown, all strategies that reduced PAR-1 signaling resulted in reduced renal injury.

Results: In wild type (WT) mice SPHK-1 mRNA was slightly induced at 2 and 5 h with just over a doubling by 24h (2.31 ± 0.35 units). In contrast SPHK-2 showed a similar level of induction at 2h but decreased at 5 and 24 (0.76 ± 0.35 units) compared to sham control. PAR-1 deficient mice had mild induction of both SPHK-1 and -2 mRNA at 2h with 5 to 10-fold induction at 5h and in excess of 100-fold by 24h. Of note PAR-1 deficient mice had higher basal SPHK-2 mRNA expression. Hirudin treated and low-TF mice had elevated basal SPHK-1 and -2 mRNA that initially decreased but subsequently increased by 24h reperfusion. At all times those mice had higher levels of SPHKs than WT mice. WT and PAR-1 deficient mice showed different patterns of S1P receptor mRNA induction with WT showing early induction of S1Pr1 and latter reductions compared to PAR-1 deficient mice that showed no induction of S1P r1 and r3 at 2h but dramatic up regulation at 5 and 24h.

Conclusions: Taken together the data suggests that thrombin negatively regulates SPHK and S1P receptor expression via PAR-1 signaling. This suggests at least some of the protective effect of PAR-1 deficiency on renal IRI may be via increased S1P signaling.

The Role of Fibrinogen in Ischemic Acute Kidney Injury Inga Soerensen, Nathan D. Susnik, Hermann G. Haller, Roland Schmitt. *Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.*

Background: Fibrinogen (Fib) has heterogeneous roles in tissue injury, inflammation and repair. We studied the role of Fib in ischemic acute kidney injury (AKI).

Methods: Intrarenal Fib was analyzed in post-ischemic mouse kidneys using immunohistochemistry, immunoblot, PCR and In situ hybridization. Fib -/- and +/- mice that underwent unilateral or bilateral renal clamping were followed for survival and renal function. Post-ischemic kidneys were analyzed by quantification of damage markers, inflammatory infiltrates, apoptosis and cell proliferation. In transplant experiments kidneys from Fib +/- and -/- mice were transplanted into -/- recipients. In vitro, primary renal tubular epithelial cells and proximal tubular epithelial cells lines were stimulated with different conditions to test for Fib expression by qPCR.

Results: .27 min of transient renal ischemia was associated with more than a 10-fold increase in intrarenal Fib levels. While Fib signal was confined to the intravascular space in control kidneys, it was found throughout the tubulointerstitium in postischemic kidneys. In agreement with recent microarray data, Fib de novo expression was also found in a subset of epithelial cells of postischemic kidneys by immunofluorescence and in situ hybridization. A significant renal mRNA up-regulation of Fib alpha, beta and gamma subunits was confirmed by qPCR. In vitro, Fib was induced in renal tubular epithelial cells by exposure to homogenate from ischemic kidneys, Oncostatin-M and hyper-IL6. In vivo, Fib -/- mice subjected to renal ischemia showed reduced survival and worse renal function but levels of tubular injury markers Kim-1 and NGAL were significantly lower than in Fib +/- kidneys. To address discrepancies between local and systemic effects of Fib deficiency, kidneys were transplanted from Fib -/- and +/- mice into Fib -/- recipients.

Conclusions: Our data indicate that Fib is expressed in small but significant amounts by tubular epithelial cells in response to inflammatory signals in AKI. Although genetic deletion of systemic Fib is associated with higher mortality, our results suggest that the deletion of intrarenal Fib expression may be protective against post-ischemic damage.

Tumor Necrosis Factor alpha Downregulates Tamm-Horsfall Protein (Uromodulin) Expression in Acute Kidney Injury Tarek M. El-Achkar,[1] Ruth A. McCracken,[1] Soline Bourgeois,[3] Ziyad Al-Aly.[2] *[1]Saint Louis University and Saint Louis VA Medical Center; [2]Saint Louis VA Medical Center; [3]University of Zurich.*

Background: Acute kidney injury (AKI) is a common disease with serious health implications. We recently described a protective role for Tamm-Horsfall protein (THP) against AKI. THP is expressed exclusively in the thick ascending limbs (TAL) of the kidney, but the factors that regulate the expression of THP in AKI are still unknown. In this study, we investigate whether tumor necrosis factor alpha (TNFα), a cytokine expressed by TAL and up-regulated during AKI, is a major regulator of THP in AKI.

Methods: We used a mouse model of ischemia-reperfusion injury (IRI) achieved by bilateral pedicle clamping. We also performed in vitro IRI on a pure thick limb cell line (MKTAL) using an established model of mineral oil layering.

Results: Using real-time PCR, we show that THP mRNA is transiently down-regulated in the kidney after IRI. Concomitantly, we observed an increase in TNFα mRNA levels after injury. Using immunofluorescence microscopy, we localized this TNFα up-regulation to TAL and S3 segments of the outer medulla. Similarly, in MKTAL cell culture, IRI increased TNFα expression while suppressing THP expression. Incubating MKTAL cells with TNFα suppresses THP mRNA in a dose dependent manner, and reproduces the findings seen in ischemic injury in vivo. Blocking TNFα after IRI significantly abrogates the suppression of THP expression.

Conclusions: In conclusion, our data suggest that the surge of TNFα at the onset of AKI down-regulates THP expression. Because of the protective function of THP, modulation of THP expression by TNFα blockade could present a therapeutic opportunity to prevent and attenuate AKI.

Nitric Oxide Induced Regulation of Renal Organic Cation Transport after Renal Ischemia/Reperfusion Injury Reinhard Schneider,[1] Boris Betz,[1] Kerstin Moeller-Ehrlich,[2] Christoph Wanner,[1] Hermann Koepsell,[3] Christoph Sauvant.[4] *[1]Dept. Medicine I, Div. Nephrology, University Hospital, Wuerzburg; [2]Center of Experimental Molecular Medicine, Wuerzburg; [3]Instiute of Anatomy I, Bay. Julius-Maximilians University, Wuerzburg, Germany; [4]Clinic for Anaesthesiology, University Hospital, Halle (Saale), Germany.*

Background: Renal organic cation transporters (Oct) are downregulated by inflammatory nitric oxide (NO) production in rat endotoxemia. NO generated by inducible NO synthase (iNOS) is substantially increased in renal cortex after renal ischemia/reperfusion (I/R) injury. Therefore, we investigated effects of iNOS-specific NO inhibition on the expression of the organic cation transporters rOct1 and rOct2 (Slc22a1, Slc22a2) after I/R injury; both *in vivo* and *in vitro*.

Methods: *In vivo*, I/R injury was induced by bilateral clamping of the renal arteries for 45 min in SD-rats, while I/R injury was simulated *in vitro* in renal proximal tubular cells (NRK-52E) by a condition of oxygen depletion, aglycemia and acidosis for 120 min. N^6-(1-iminoethyl)-L-lysine (L-NIL) was applied as specific iNOS inhibitor.

Results: *In vivo*, L-NIL inhibited NO generation after I/R injury. Moreover, L-NIL abolished I/R-induced downregulation of rOct1 and rOct2 as determined by qPCR and western blotting. Functional evidence was obtained by measuring fractional excretion (FE) of the endogenous organic cation serotonin. Concordant with the expression of the rate-limiting Oct, the FE of serotonin decreased after I/R injury and was abolished by L-NIL. *In vitro*, I/R downregulated both rOct1 and rOct2, which were also abolished by L-NIL; the same was true for the uptake of the organic cation MPP.

Conclusions: We showed that renal I/R injury downregulates rOct1 and rOct2 expression as well as concomitant transport function; both most probably mediated via NO. In principle, this may be an autocrine effect of proximal tubular epithelial cells. Moreover, we conclude that rOct1, or rOct1 and rOct2 limit (also NO-dependent) the excretion rate of endogenous serotonin; this may have additional clinical impact due to its potential of inducing vascular damage.

Effect of Gender Differences on Renal Inflammatory Response after Renal Ischemia-Reperfusion Injury in Mice Kyung Pyo Kang, Jung Eun Lee, Aesin Lee, Yujin Jung, Ki Dong Lee, Sik Lee, Sung Kwang Park, Won Kim. *Department of Internal Medicine, Research Institute of Clinical Medicine and Diabetes Research Center, Chonbuk National University Medical School, Jeonju, Republic of Korea.*

Background: Male gender is associated with more rapid progression in renal disease, while female gender is slowly. This gender disparity may be influenced by sex hormonal milieus. The purpose of this study is to investigate the effect of gender differences on the renal inflammatory responses after acute ischemia-reperfusion injury in mice.

Methods: Experiments were performed in male and female C57BL/6 by bilateral renal ischemia-reperfusion injury. In other study, orchiectomy or ovariectomy was carried out 14 day before I/R injury. Different groups of animals were treated by testosterone and 17β-estradiol. Histologic examination and qRT-PCR for TNF-α, IFN-γ, and MCP-1 were performed.

Results: In acute ischemia-reperfusion kidney injury model, female gender was more resistance to the kidney injury compared to the male gender. The tubular injury score and the number of F4/80(+) macrophages were increased in male mice compared to the female mice. The expressions of TNF-α, IFN-γ, and MCP-1 were increased at 2 d of AKI in male mice compared to female. Orchiectomised male mice were more resistance to renal injury compared to the normal male mice. But, treatment of testosterone to the orchiectomised mice increased renal injury and infiltration of F4/80(+) macrophages. Ovariectomized female mice were prone to renal injury and associated with increased infiltration of F4/80(+) macrophages. The expressions of TNF-α, IFN-γ, and MCP-1 were decreased in the orchiectomised male mice, while increased in the ovariectomized female mice compared to the normal male and female mice. Hormone replacement such as testosterone and estrogen reverse these cytokine expressions.

Conclusions: These results suggested that male gender is more susceptible to the ischemia-reperfusion renal injury. The testosterone may be one of causes of increased susceptibility, while estrogen may be protective in renal inflammatory response after ischemia-reperfusion injury.

ADAM-10 Is the Major Sheddase of Membrane-Associated Meprin A Release during Acute Kidney Injury Christian Herzog, Sudhir V. Shah, Gur P. Kaushal. *Medicine, UAMS, Little Rock, AR.*

Background: Meprin A, comprised of α and β subunits is a potent membrane-bound metalloproteinase highly expressed in proximal tubules of the kidney cortex where it is bound by its β subunit to the brush-border membrane. In acute kidney injury (AKI) meprin A is released and redistributed to the cytosol and may become deleterious to the kidney. The present study has identified the protease involved in the release of meprin A during AKI.

Methods: Meprin A localization was determined by double-immunofluorescence staining and Western blot of mouse kidneys exposed to cisplatin (CP) or ischemia-reperfusion (IR) injury. Stable transfectants of meprin β and cotransfectants of α+β subunits in HEK cells served an in vitro model to investigate the protease involved in meprin A shedding. Broad-spectrum inhibitors to serine-, metallo-, acidic-proteases and the ADAM family of proteases followed by highly specific inhibitors were examined for their ability to prevent shedding of meprin A in the presence / absence of the inflammatory agent phorbol myristate acetate (PMA). Knockdown experiments with siRNAs to ADAM-9, -10 and -17 and overexpression of ADAM-10 with a plasmid construct confirmed the putative sheddase.

Results: Meprin A localization was altered from the brush-border membrane towards the cytosol and the basolateral membrane in mice subjected to CP and IR injury. Broad-spectrum inhibitors of various classes of proteases indicated involvement of proteases of the ADAM family. Since ADAM-9, -10 and -17 are known for ectodomain shedding we determined wether one or all of them are involved in the shedding. GI-254023X, a highly potent inhibitor of ADAM-10 and to a lesser degree of ADAM-17, reduced meprin shedding significantly in HEK cells stably transfected with meprin β and αβ. SiRNA to ADAM-10 reduced shedding to less than 50% whereas siRNAs to ADAM-9 and -17 were much less effective (-30% or -10%). Overexpression of ADAM-10 by transient transfection ± PMA led to a 2-fold increase in shedding in both the meprin β and αβ transfectant.

Conclusions: Our results demonstrate that ADAM-10 is the major sheddase for meprin A release and both meprin A and ADAM-10 can therefore be valuable therapeutic targets in the prevention of AKI.

TH-PO011

SFKs Regulate Both Pore and Leak Pathways of Paracellular Permeability in Renal Epithelial Cells Devin S. Caswell, Shuchie Jaggi, Danielle Janosevic, Victoria V. Rohring, Josephine Axis, Kurt Amsler. *Biomedical Sciences, New York College of Osteopathic Medicine, Old Westbury, NY.*

Background: Regulation of renal epithelial cell paracellular permeability is critical for normal renal tubular function. Dysregulation is associated with many renal pathogenic states, including renal ischemia/reperfusion injury, radiocontrast-induced nephropathy, and exposure to calcium oxalate crystals. We have begun investigating the role of src Family Kinases (SFKs) in regulating steady state renal epithelial cell paracellular permeability.

Methods: Renal cells were grown on semipermeable membranes. Paracellular permeability was quantitated by measuring calcein flux and TER. Protein content was quantitated by Western blot.

Results: As reported previously, under steady state conditions renal epithelial cells (LLC-PK1, mIMCD3, and MDCK) maintain a barrier to the paracellular movement of both small ions (pore pathway; measured as TransEpithelial Resistance (TER)) and large solutes (leak pathway; measured as flux of calcein and fluorescein-dextran4000). PP1 and PP2 (well-characterized, broad spectrum SFK inhibitors) but not PP3 (an inactive analog) produced a concentration-dependent increase in both pore and leak pathway permeabilities without producing significant cell death (Trypan Blue-staining nuclei). This effect was observed within 1-2 hours. Neither basal nor the PP1/2-mediated increase in paracellular permeability was markedly affected by c-src knockdown or expression of either dominant-negative or wild type c-src. PP1/2 treatment did not produce changes in the cellular contents of occludin, ZO-1, ZO-2, or claudin-1. PP1/2 treatment also did not affect claudin-1 partitioning between Triton X-100 soluble and insoluble fractions.

Conclusions: These results demonstrate that SFK activity regulates renal epithelial cell paracellular permeability through both the pore and leak pathways under steady state conditions. This regulation is not dependent on c-src activity, implicating another SFK (c-yes or fyn).

TH-PO012

miR-127 Regulates Trafficking in Proximal Tubule Cells Trough Its Target KIF3B in Response to Ischemia/Reperfusion Elia Aguado Fraile, Edurne Ramos, Nuria Villegas, Elisa Conde, Ignacio Blanco Sanchez, Laura Garcia-Bermejo. *Pathology, Hospital Universitario Ramón y Cajal.*

Background: Acute renal failure and renal trasplant are clinical situations associated to ischemic insult. In kidney, ischemia/reperfusion (I/R) provokes proximal tubule cell adhesion alterations and dysfunction, including cell trafficking. Cellular transport is mainly regulated by tubuline and adaptors proteins such as kinesin and kinesin-associated proteins, including KIF3B. miRNAs are key regulators of the cell response to stress and we have previously reported that miR-127 is a mediator of proximal tubule cells response to ischemia.

The aim of this work is to identify miRNAs and their targets mediating the proximal tubule cell response to ischemia

Methods: Rat proximal epithelial cells (NRK-52E) were submitted to hypoxia and nutrient deprivation (H/R), mimicking I/R. Monolayer impedance was estimated by RTCA device. Pinocytosis was determined by cell incubation with DEXTRAN-FITC. KIF3B expression was measured by western blot and qRT-PCR. Cytoskeleton and tight junctions (TJ) organization was studied by immunofluorescence.

Results: In this work, we demonstrated using pre/anti-miR-127 transfection that this miRNA is promoting cell adhesion after H/R. miR-127 overexpression increases monolayer impedance and maintains ZO-1 localization in cell membrane assuring TJ integrity. Moreover, tubulin cytoskeleton alterations during H/R are reduced by miR-127 overexpression. On the other hand, NRK-52E cells pinocytosis capacity is increased when miR-127 is inhibited, indicating that cell trafficking is controlled by this miRNA. Therefore, we have identified KIF3B as a real target of miR-127. Indeed, overexpression and inhibition of this miRNA leads to KI3FB mRNA and protein modulation.

Conclusions: These results demonstrate that KIF3B is a real target of miR-127 in NRK-52E cells, modulating proximal tubule pinocytosis function. These miRNA is involved also in cell-cell adhesion maintenance, playing a critical role in preservation of epithelial barrier function. Thus, miR-127 appears as a key regulator of tubular response to ischemia and could be considered as a potential therapeutic target in renal ischemic injury.

Acute Kidney Injury but Not Bilateral Nephrectomy Increases Metabolism, Reactive Oxygen Species, and Mitochondrial Mass in Tubular and Mesenchymal Stem Cells Jon D. Ahlstrom,[1] Daniel Oldroyd,[1] Florian Togel,[2] Zhuma Hu,[1] Ping Zhang,[1] Christof Westenfelder.[1,3] *[1]Medicine, University of Utah and VA Medical Centers, Salt Lake City, UT; [2]Medicine, Cornell College of Medicine, New York, NY; [3]Physiology, University of Utah, Salt Lake City, UT.*

Background: Acute kidney injury (AKI) is a treatment-resistant syndrome in which complex mechanisms mediate injury and repair. We demonstrated that mesenchymal stem cells (MSC) are highly renoprotective in rats with AKI, and promising in a Phase I Trial (*Nature Rev Nephrol* 2010). "Uremic" changes in the internal milieu caused by I/R-induced AKI result in pathological manifestations in virtually all major organs.

Methods: To further investigate in rats the systemic effects of comparable levels of acute azotemia, induced either by bilateral IR-AKI or bilateral nephrectomy (NPHX), we exposed cultured normal rat kidney cells (NRK, proximal) and rat MSC to 10% serum obtained from rats 24 hrs post either 50 min IR-AKI, NPHX or from shams. Both AKI and NPHX resulted in similar increases in serum creatinine (AKI: 4.9; NPHX: 4.8 mg/dL).

Results: Exposure of cells to 10% AKI sera x 48 hrs caused, compared to incubation with NPHX or sham sera, increased metabolic activity (CellTiter-Blue/Alamarblue cell viability assay), greater reactive oxygen species activity (CM-H2DCFDA, flow cytometry), and increased mitochondrial mass (Mitotracker Green, flow cytometry).

Conclusions: Summary: At comparable levels of azotemia (AKI vs. NPHX), AKI induced distinct changes in the internal milieu that adversely and similarly affected NRK and MSC. This indicates that the injured kidney per se generates harmful signals that target NRK and MSC, and, by inference, renal and extra-renal cells in vivo. Conclusion: These data identify yet inadequately understood pathogenic signals that are generated by the injured kidney, and whose nature, once defined, should advance our understanding of the acute uremic state and how it affects renal and other organ functions. And, these initial observations provide the basis for the development of interventions that are both renoprotective and that optimize MSC-based therapies of AKI.

Collecting Duct Specific Mitochondrial Injury Aggravates Unilateral Ureteral Obstruction Renal Injury in Mice Young Tai Shin,[1] Jin Young Jeong,[1] Bo Ra Lee,[1] Won Ik Jang,[1] Hyunjun Ju,[1] Yoon-Kyung Chang,[2] Seong Suk Kim,[3] Dae Eun Choi,[1] Ki Ryang Na,[1] Kang Wook Lee.[1] *[1]Internal Medicine, Chungnam National University, Daejeon, Korea; [2]Internal Medicine, Daejeon Saint Mary Hospital, Daejeon, Korea; [3]Internal Medicine, Sun Hospital, Daejeon, Korea.*

Background: In various renal injuries including toxins, drugs, and ischemia, mitochondrial injury plays important role in renal injury. There are few model of mitochondrial injury in kidney. Also, there is few study for roles of mitochondria on collecting ducts. We generated collecting duct specific mitochondrial injury model. And, we evaluated the effects of mitochondrial dysfunction on collecting ducts in unilateral ureteral obstructed mice kidney.

Methods: For generation of collecting duct specific mitochondrial injury mice, CRIF flox/flox mice were bred with Hoxb7-Cre mice. For evaluation of influence of CRIF1 deletion on mitochondrial function, we measured O2 consumption and membrane potential in control and silencing RNA treated mIMCD cells. For evaluation of effect on UUO induced renal injury, We divided mice into the following 4 groups: CRIF1flox/flox(WT) group; CRIF1 flox/flox-Hob7 Cre (CRIF1-KO) group; WT UUO group; and CRIF1-KO UUO group. We evaluated MCP-1, osteopontin, F4/80, TGF-b, a-SMA. We measured 8-OHDG for oxidative stress.

Results: Inhibition of Crif1 mRNA in mIMCD cell reduced O2 consumption and membrane potential. There are no significant differences in blood and urine chemistry including Na, K, Cl, urea nitrogen, and creatinine between WT and CRIF1-KO mice. Renal expression of MCP-1, OPN, Numbers of F4/80 positive cells, TGF-b, a-SMA, and Masson Trichrome stained area were significantly increased in CRIF1-KO-UUO kidneys compared

with WT UUO kidneys., Urinary 8-OHDG was increased in CRIF1-KO-mice compared with WT mice. Also, Crif1-KO mice showed significantly increase of 8-OHDG-positive cell recruitment compared to WT mice. CRIF1-KO-UUO-kidneys were shown more increase recruitment of 8-OHDG-positive cells compared to WT-UUO-kidneys.

Conclusions: Collecting duct specific mitochondrial injury increases oxidative stress. Oxidative stress induced by mitochondrial injury aggravates UUO induced renal injury.

Chronic Nicotine Exposure Induces p66shc Expression in Renal Proximal Tubule Cells: Impact on Oxidative Stress and Injury

Istvan Arany,[1] Jeb S. Clark,[1] Luis A. Juncos.[2,3] *[1]Pediatrics, University of Mississippi Medical Center, Jackson, MS; [2]Medicine, University of Mississippi Medical Center, Jackson, MS; [3]Physiology and Biophysics, University of Mississippi Medical Center, Jackson, MS.*

Background: We reported that chronic NIC exposure exacerbates oxidative stress and consequent injury in a mice model of AKI. Since the adaptor protein p66shc mediates ROS release via cytochrome c binding we tested the hypothesis that chronic NIC exposure aggravates oxidative stress-linked ROS production and injury through increase in cytochrome c-bound p66shc in proximal tubule cells.

Methods: Wild type (w.t.), p66shc knockdown (k.d.) or cytochrome c binding deficient (W134F-p66shc) mouse renal proximal tubule cells were treated with 200 μM NIC for 24 hours prior to treatment with 200 μM H_2O_2 and ROS production as well as LDH release was determined. Immunoprecipitation studies were performed to determine mitochondrial as well as cytochrome c binding of p66shc. The fluorescent dye JC-1 was used to determine mitochondrial depolarization.

Results: Chronic NIC treatment increased H_2O_2-induced mitochondrial and cytochrome c-binding of p66shc and also exacerbated H_2O_2-induced ROS production, depolarization of the mitochondria and LDH release. Conversely, NIC+H_2O_2-induced ROS production and LDH release was attenuated in p66shc k.d or W134F cells compared to w.t. cells. Ser36 phosphorylation of p66shc –which is necessary for its mitochondrial localization- was increased by NIC+H_2O_2 but not by NIC treatment. Surprisingly, chronic NIC treatment increased expression of p66shc through dose-dependent induction of its promoter. Importantly, increased expression of p66shc was detected in the kidneys of mice that were chronically exposed to NIC.

Conclusions: Chronic NIC treatment increases expression of p66shc, which in turn, Ser36 phosphorylated via oxidative stress. The result is augmented mitochondrial/cytochrome c binding of p66shc and consequent ROS production/injury through opening the mitochondrial permeability transition pore. This mechanism may be responsible for the augmented oxidative stress in the ischemic kidney of mice with chronic nicotine exposure.

Role of Nonesterified Fatty Acids in Respiratory Impairment and Mitochondrial Deenergization of Proximal Tubules Secondary to Hypoxia/Reoxygenation

Anja H. Bienholz,[1,2] Thorsten Feldkamp,[2] Joel M. Weinberg.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of Essen, Essen, Germany.*

Background: Hypoxia/reoxygenation (H/R) of proximal tubules leads to persistent ATP depletion due to decreased mitochondrial membrane potential (MMP) resulting from nonesterified fatty acid (NEFA)-mediated uncoupling that is paradoxically accompanied by respiratory inhibition rather than the stimulation expected for uncoupled states.

Methods: Since NEFA have been reported to directly inhibit electron transport in some settings we assessed respiratory function in tubules after H/R as a function of NEFA availability.

Results: Compared to respiration supported by the complex II-dependent substrate, succinate, which was highly uncoupled after H/R but relatively well preserved (ADP-stimulated respiration (S3) of permeabilized tubules 71.0±8.5% of normoxic control (NC)), respiration supported by complex I-dependent substrates that normally predominate in cells was also uncoupled, but S3 was reduced to 26.9±3.3% of NC, $P < 0.001$ vs. succinate, N=5. With complex I substrates, acutely lowering NEFA after permeabilization improved coupling but only minimally increased S3. In contrast, lowering NEFA during 60 min. of reoxygenation prior to permeabilization increased S3 supported by complex I substrates, but it remained lower (55.7±7.5% of NC) than with succinate after the same treatment, 80.0±4.8%, $p < 0.02$. MMP at the end of H/R was much lower with complex I substrates (30.7±9.2% NC) than with succinate (67.4±4.5%), $P < 0.004$. Lowering NEFA during 60 min. of reoxygenation strongly improved recovery and decreased the MMP difference between complex I substrates (73.3±5.1% of NC) and succinate (83.4±6.6%).

Conclusions: The studies indicate that selectively impaired utilization of complex I substrates to support respiration after H/R promotes NEFA-induced deenergization and is only minimally improved by acutely removing NEFA. In the presence of NEFA, the higher efficiency of complex I substrates to support electron transport does not mitigate the impact of the impaired respiration on MMP. However, lowering NEFA within cells for 60 min. allows strong recovery of MMP despite persistence of some respiratory impairment.

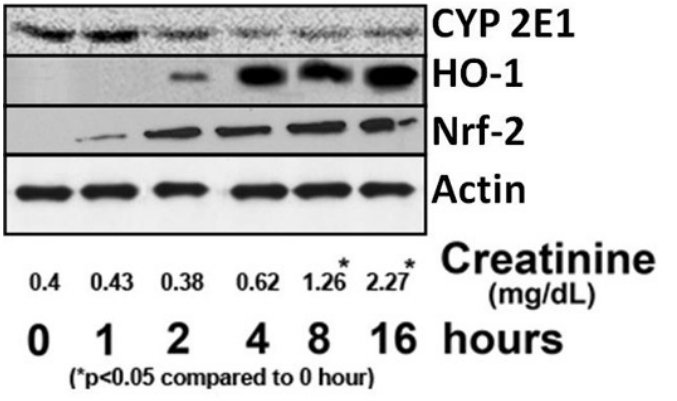
Transcription Factor Nrf2 Regulates CYP2E1 Mediated Rhabdomyolysis Induced Acute Kidney Injury

Radhakrishna Baliga, Zhe Wang. *Pediatrics, University of Mississippi Medical Center, Jackson, MS.*

Background: CYP2E1 is a member of the Cytochrome P450 family that plays an important role in the rhabdomyolysis induced AKI (JASN 21: 289A, 2010). Nfr2 regulates the expression of anti-oxidative and other cytoprotective genes against variety of insults. The purpose of the current study was to 1. Evaluate the role of Nrf2 in the up regulation of anti-oxidative protective factors generated in response to CYP2E1 induced oxidative stress and 2. Examine the ability of Nrf2 to protect against the cytotoxic actions of CYP2E1.

Methods: Male S-D rats were injected with 50% glycerol following an overnite deprivation of water. Specific CYP2E1 inhibitor Chlormethiazole (CMZ) was administered prior to glycerol injection. Both mRNA and protein expression of Nrf2, heme-oxygenase-1 (HO-1) including other Nfr2 regulated enzymes were studied invivo and in LLC-PK1 cells exposed to myoglobin. Cytotoxicity was measured by the LDH release.

Results: Increases in the Nrf2 mRNA and nuclear protein including upregulation of the HO-1 and other Nrf2 regulated genes were observed in the kidney in the glycerol treated rats with the breakdown of the CYP2E1 protein and prior to AKI as measured by SCr.



Administration of CMZ significantly decreased oxidative stress and blocked the increases in the Nrf2 mRNA and nuclear protein including HO-1. Pre-treatment of the LLC-PK1 cells with an activator/inhibitor of Nrf2 prior to myoglobin exposure significantly decreased/increased ROS generation and cytotoxicity.

Conclusions: Nrf2 plays a key role in the adaptive response against increased oxidative stress caused by CYP 2E1. Inhibition of CYP2E1 coupled with prior activation of Nrf2 may be a valuable approach to reduce CYP2E1 mediated rhabdomyolysis induced AKI.

TH-PO018

Activation of Protein Kinase Cα Promotes Mitochondrial Function and Cell Survival in Renal Proximal Tubular Cells Injured by Oxidant

Grazyna Nowak, Diana Bakajsova. *Pharmaceutical Sciences, University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Previously, we have shown that protein kinase C (PKC) activation promotes recovery of mitochondrial function and active Na^+ transport following oxidant injury in renal proximal tubular cells (RPTC). However, the specific PKC isozyme involved in the recovery of mitochondrial function is unknown. This study investigated the role of PKCα in decreases and recovery of mitochondrial functions and cell survival in RPTC injured by an oxidant.

Methods: Wild-type PKCα and inactive PKCα mutants were overexpressed in primary cultures of RPTC prior to oxidant exposure (0.35 mM *tert*-butyl hydroperoxide, TBHP; 45 min). PKCα activation, mitochondrial functions associated with oxidative phosphorylation, production of reactive oxygen species (ROS), and cell viability were determined after TBHP treatment.

Results: TBHP exposure in RPTC was followed by PKCα activation and translocation to mitochondria. State 3 respiration in TBHP-injured RPTC decreased to 48% of controls. Mitochondrial membrane potential increased 50% at 4h and decreased to 48% of controls at 24h following TBHP injury. F_0F_1-ATPase activity and ATP content decreased to 59% and 60% of controls, respectively, in TBHP injured RPTC. Oxidant exposure increased ROS production by 200% and induced 47% RPTC lysis. Blocking PKCα activation by overexpressing inactive PKCα exacerbated oxidant-induced decreases in state 3 respiration, blocked the increases in ROS production, but had no effect on mitochondrial hyperpolarization, decreases in F_0F_1-ATPase activity and ATP content, and increases in RPTC lysis. In contrast, increasing activation of PKCα by overexpressing wild-type PKCα improved state 3 respiration and mitochondrial coupling, prevented mitochondrial hyperpolarization, and restored F_0F_1-ATPase activity and ATP content in TBHP-injured RPTC. PKCα activation did not block TBHP-induced increases in ROS production but reduced RPTC lysis to 17%.

Conclusions: We conclude that: 1) activation of PKCα during oxidant injury in RPTC promotes mitochondrial functions and decreases cell death and 2) blocking ROS production does not prevent oxidant-induced RPTC death.

Carbonyl Stress Induced Protein Modification in Snake-Bite Mediated Acute Renal Failure – A Pathogenesis Link Pinaki Mukhopadhyay,[1] Debarati Mukherjee,[2] Raghwendra Mishra,[2] Monoj Kar.[2] *[1]Nephrology, NRS Medical College, Kolkata, West Bengal, India; [2]Biochemistry, NRS Medical College, Kolkata, West Bengal, India.*

Background: To identify the role of damaged proteins in association with oxidative stress (OS) and carbonyl stress (CS) in the pathogenesis of snakebite mediated acute renal failure (SARF).

Methods: Oxidative stress index, MG (methylglyoxal), thiobarbituric acid reactive substances (TBARS), AOPP, AGE, pentosidine and dityrosine were measured in 41 CRF and 58 SARF patients and compared with 36 normal control subjects. One way analysis of variance (ANOVA) followed by Bonferroni post hoc analysis was performed to check any statistical difference, significance level was considered at $p< 0.05$. Pearson correlation coefficient (r) was evaluated between the studied parameters from the aggregate of patients and control. Receiver-operating characteristic (ROC) curve analyses were performed regarding all parameters of CRF and SARF groups.

Results: SARF had significantly elevated level of oxidative stress index (OSI) compare to normal control ($p=0.020$) and CRF ($p=0.019$).This may be attributed to increased total oxidative stress (TOS) level in SARF compare to control ($p=0.007$) and CRF ($p=0.009$). Both MG and TBARS level were found to be significantly raised ($p<0.001$) in SARF and CRF group compare to normal controls. AOPP level of SARF was higher than that of CRF ($p=0.002$) and control ($p<0.001$).SARF group has significantly higher level of AGE ($p=0.002$), dityrosine ($p<0.001$) and pentosidine ($p=0.001$) than control. CRF shows significantly higher level of all protein damage markers than control ($p<0.001$). The studied protein damage markers were found to be positively correlated with the surrogate renal failure marker, i.e. serum creatinine, oxidative cellular damage marker TBARS and the carbonyl stress marker MG.

Conclusions: The toxins of snake venom induce protein damage associated with carbonyl and oxidative stress. Although it is still uncertain that whether these damages are cause or effect of SARF, this study indicates that they might play a pivotal role in pathogenesis of SARF in a similar way which occurs in CRF with only difference in the time course of the disease.

Adenosine A1 Receptor Agonism as an Activator of Mitochondrial Biogenesis in the Kidney Sean Robert Jesinkey, Jason A. Funk, Lauren P. Wills, Rick G. Schnellmann. *Pharmaceutical and Biomedical Sciences, Medical University of South Carolina, Charleston, SC.*

Background: Adenosine receptor agonism is a beneficial physiological stress response observed in multiple organs. Recently, we have shown that mitochondrial biogenesis is important in the recovery of renal cells from injury. The goal of this study was to determine if adenosine receptors play a role in mitochondrial biogenesis.

Methods: Using a mitochondrial biogenesis assay that incorporates the Seahorse Biosciences analyzer and FCCP-uncoupled oxygen consumption with primary cultures of renal proximal tubular cells (RPTC), we determined the efficacy of pharmacological agonists and antagonists for both adenosine Gi/o receptor subtypes (A1 and A3) to induce mitobiogenic signaling. We further examined changes in mRNA levels of mitochondrial genes in renal cortices of C57BL/6 mice exposed to CCPA (0.1mg/kg) for 24 h via real-time PCR. Immunoblot analysis was performed to determine alterations of electron transport chain proteins.

Results: We discovered that the specific adenosine A1 receptor agonist 2-chloro-N6-cyclopentyladenosine (CCPA) (20 nM) increased FCCP-uncoupled respiration by 21% after 24 h. However, treatment with the adenosine A1 receptor antagonist 8-cyclopentyl-1,3-dipropylxanthine (DPCPX) resulted in no change of FCCP-uncoupled respiration. In addition, exposure to various A3 receptor agonists and antagonists, such as Hemado and MRS1334, respectively, had no effect on basal and uncoupled oxygen consumption. The master regulator of mitochondrial biogenesis PGC-1α, the complex 1 proteins NDUFB8 (nuclear-encoded), COX1 (mitochondrial-encoded) and ND6 (mitochondrial-encoded), and ATP synthase β (nuclear-encoded), all displayed increased gene expression following CCPA exposure. Furthermore, immunoblot analysis revealed CCPA also increased COX1 and NDUFB8 protein levels in mouse renal cortical tissue.

Conclusions: These novel results provide evidence that the adenosine A1 receptor is linked to mitochondrial biogenesis and that activation of this receptor results in renal mitochondrial biogenesis.

Preconditioning with Meclizine Protects the Kidney Against Ischemia Reperfusion Injury Liangying Gan,[1] Gabriela Campanholle,[1] Vishal M. Gohil,[2] Venkata Sabbisetti,[1] Vamsi K. Mootha,[2] Takaharu Ichimura,[1] Joseph V. Bonventre.[1] *[1]Renal Division, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Center for Human Genetic Research, Massachusetts General Hospital, Harvard Medical School, Boston, MA.*

Background: Renal ischemia-reperfusion (I/R) injury is a major cause of acute kidney injury (AKI). Preconditioning is a powerful way to protect the kidney against subsequent ischemic injury. It would be of great importance to be able to mimic ischemic preconditioning by a pharmacologic intervention. Meclizine has anti-histaminergic and anti-muscarinic activities and has been reported to reduce mitochondrial oxygen consumption.

Methods: C57bl/6 mice were pretreated with two i.p. injections of 100 mg/kg of meclizine, or vehicle, at 17 and 3 hrs before renal I/R injury. Serum, urine and kidney tissue samples were collected at 24 hrs after surgery for further evaluation. Cytoprotective effects of meclizine on renal tubular cells subjected to hydrogen peroxide injury was also evaluated in vitro.

Results: Meclizine pretreatment protected mice from I/R injury in a dose dependent fashion, as reflected by a significantly lower serum creatinine, BUN and Kim-1 levels. Meclizine pretreatment also reduced tubular necrosis, neutrophil and macrophage infiltration and decreased expression of inflammatory cytokines IL-1β, TNF-α, MCP-1 and IL-6. These protected kidneys expressed lower levels of injury associated iNOS and heme oxygenase-1. Meclizine did not protect kidneys from I/R when administrated after injury and did not protect from aristolochic acid or cisplatin nephrotoxic kidney injury. Meclizine reduced oxygen consumption of isolated kidney mitochondria. In vitro, Meclizine-preconditioning of renal tubular cells against oxidative injury was confirmed.

Conclusions: Meclizine preconditioning protects the kidney against I/R injury and proximal tubular cells in vitro. There is no protection against nephrotoxic injury. The protection is both functional as well as morphological with suppression of the inflammatory response and injury-associated gene expression. Meclizine may be an important candidate for a pharmacological renal preconditioning agent.

A Novel Class of Small Molecule Mitochondria-Targeted ROS Scavenger Attenuates Cisplatin Induced Nephrotoxicity Dae Eun Choi,[1] Jin Young Jeong,[1] Bo Ra Lee,[1] Bong-Hyun Ahn,[2] Soon Ha Kim,[2] Ki Ryang Na,[1] Kang Wook Lee,[1] Young Tai Shin.[1] *[1]Internal Medicine, Chungnam National University, Daejeon, Korea; [2]LG Life Sciences, Daejeon, Korea.*

Background: Although cisplatin is highly effective anti-cancer drug, nephrotoxicity is a major clinical problem. Mitochondrial injury and reactive oxygen species (ROS) generation play a role in cisplatin induced nephrotoxicity. LG life sciences developed a novel class of small molecule mitochondrial ROS scavenger NecroX series that can reduce mitochondrial reactive oxygen species and improve cell survival. We therefore investigated the effect of NecroX-7 on nephrotoxicity in mice for development of a therapeutic candidate of renal injury.

Methods: We used male C57BL/6 mice. Mice were divided into 4 groups; normal control group (n=5), NecroX-7 treated control group (n=5), vehicle with cisplatin (15mg/kg, intraperitoneal injection) treated group (n=9), and NecroX-7 (2mg/kg, intraperitoneal injection) with cisplatin treated group (n=9). In mice, we measured BUN and serum creatinine. We examined 8-OH deoxyguanosine in kidney tissue. We examined TUNEL and light microscopic findings (H&E and PAS stain).

Results: The levels of BUN and serum creatinine in NecroX-7 with cisplatin treated mice were significantly lower than that of vehicle with cisplatin treated mice (BUN: 143.7±9.3 vs. 102.1±14.9 mg/dL, serum creatinine: 0.38± 0.03 vs. 0.29±0.03 mg/dL, $p<0.05$ respectively). In microscopy, NecroX-7 significantly reduced renal tubular epithelial cell necrosis and detachment. NecroX-7 significantly reduced 8-OH deoxyguanosine positive cells in cisplatin treated mice.

Conclusions: In conclusion, NecroX-7 attenuates cisplatin induced nephrotoxicity

TH-PO023

Pharmacological and Genetic Blockade of Autophagy Sensitizes Kidneys to Acute Injury Man Jiang, Zheng Dong. *Georgia Health Sciences University and Charlie Norwood VA Medical Center.*

Background: Autophagy is induced during cell stress and may either contribute to cell death or serve as a survival mechanism. Recent studies have demonstrated autophagy in renal tubular cells following acute kidney injury (AKI). However, how autophagy is induced and what role it plays in renal pathophysiology is not well understood.

Methods: Here we have examined the role of autophagy in AKI by using pharmacological inhibitors and a conditional Atg-7-knockout model.

Results: Chloroquine, a pharmacological inhibitor of autphagy, blocked autophagic flux and notably, enhanced cisplatin and ischemia-reperfusion -induced kidney injury in C57Bl/6 mice. To gain definitive evidence, we established a proximal tubule specific Atg7-knockout (PT-Atg7-KO) mouse model. Knockout of Atg7 led to the impairment of autophagy-conjugation systems, resulting in the loss of LC3-II and accumulation of p62 (an autophagy-selective substrate) during cisplatin treatment. Importantly, compared with their wild-type littermates, PT-Atg7-KO mice showed significantly more severe kidney injury and rapid progression of renal failure. Five days after cisplatin treatment, wild-type mice had 1.15mg/dl serum creatinine and 244 mg/dl BUN, which were increased respectively to 3.24mg/dl and 351mg/dl in PT-Atg7-KO mice. Consistently, kidney tissue damage and tubular apoptosis were aggravated in PT-Atg7 KO mice. Nonetheless, cisplatin-induced p53 activation was not affected by Atg7 deficiency, suggesting that autophagy protects kidneys without blocking upstream signaling. Primary proximal tubular cells isolated from PT-Atg7 KO mice were more sensitive to cisplatin-induced caspase activation and apoptosis than the cells from wild-type mice. Finally, PT-Atg7 KO mice were also more sensitive to renal ischemia-reperfusion injury than their wild-type littermates.

Conclusions: Together, these results demonstrate compelling evidence for a renoprotective role of autophagy during acute kidney injury.

Selective Stabilization of HIF-1α in Renal Tubular Cells by 2-Oxoglutarate Analogues Gunnar Schley,[1] Bernd Klanke,[1] Yohannes Hagos,[2] Kerstin U. Amann,[3] Birgitta C. Burckhardt,[2] Kai-Uwe Eckardt,[1] Carsten Willam.[1] *[1]Department of Nephrology and Hypertension, University of Erlangen-Nuremberg, Erlangen, Germany; [2]Center of Physiology and Pathophysiology, University Göttingen, Göttingen, Germany; [3]Institute of Pathology, University of Erlangen-Nuremberg, Erlangen, Germany.*

Background: 2-oxoglutarate dependent enzymes, which comprise e.g. the hypoxia inducible factor (HIF), represent promising therapeutic targets to prevent progressive renal fibrosis or to preserve renal function in acute kidney injury. Lipophilic 2-oxoglutarate analogues (2OGAs), which are widely taken up in many cells of most organs, have been explored as inhibitors of these enzymes. Given the selective expression of organic anion transporters (OAT) in renal tubular cells we hypothesized that hydrophilic 2OGAs could be used to specifically target these cells.

Methods: HIF stabilization and HIF target gene induction by hydrophilic and lipophilic 2OGAs were analyzed in different cell lines and in C57BL/6N mice. Mice were subjected to bilateral renal ischemia-reperfusion 6h after ip injection of 2OGAs and kidney function and morphology were evaluated 3 days later.

Results: In vitro analyses showed that in contrast to the lipophilic 2OGA, HIF stabilization and target gene induction by the hydrophilic 2OGA was dependent on the expression of OAT1. In vivo the functional effects of hydrophilic 2OGAs are largely limited to the kidney, particularly in renal proximal tubular cells expressing OAT1. Lipophilic 2OGAs resulted in HIF accumulation in tubular and interstitial renal cells and extra-renal tissues. Both lipophilic and hydrophilic 2OGAs induced HIF-dependent genes expressed in tubular cells, but only lipophilic 2OGAs induced erythropoietin synthesis. Preconditional application of the lipophilic 2OGA protected the kidney against ischemia-reperfusion injury, surprisingly the hydrophilic 2OGA did not, suggesting that HIF stabilization in proximal tubular cells is insufficient to achieve organ protection.

Conclusions: This study provides proof of concept for selective drug targeting of proximal tubular cells. This may expand the options for therapeutic use of 2OGAs by limiting undesired side effects.

Funding: Government Support - Non-U.S.

Pharmacological Modulation of Soluble Epoxide Hydrolase Activity Attenuates Ischemia Reperfusion Injury in Kidney Yun Jung Oh,[1] Jung Pyo Lee,[1,2,3] Seung Hee Yang,[1,3] Dong Ki Kim,[1,3] Chun Soo Lim,[1,2,3] Yon Su Kim.[1,3] *[1]Internal Medicine, Seoul National University College of Medicine, Seoul, Korea; [2]Internal Medicine, Seoul National University Boramae Medical Center, Seoul, Korea; [3]Seoul National University Kidney Research Institute, Seoul, Korea.*

Background: Soluble epoxide hydrolase (sEH) in endothelial cells determines the plasma level of epoxyeicosatrienoic acids (EETs), which may control the vascular tone as one of the vasoactive materials. We hypothesized that the regulation of sEH activity may have a therapeutic value in the prevention of acute kidney injury by the control of EETs level.

Methods: Ischemia-reperfusion injury (IRI) was induced in C57BL/6 mice, and sEH activity was controlled by the intraperitoneal administration of 12-(3-adamantan-1-ylureido)-dodecanoic acid (AUDA).

Results: The deterioration of kidney function induced by IRI was partially moderated and prevented by AUDA treatment. In addition, AUDA treatment significantly attenuated tubular necrosis induced by IRI, especially inner medulla area. sEH was expressed prominently in the intraglomerular capillary loops and periglomerular arterioles under normal condition. Ischemic injury induced the down-regulation of sEH, while AUDA administration did not generate an impact on the expression pattern of sEH induced by IRI. in-vivo activity of sEH was assessed by the measurement of substrate (EpOME) and its metabolite (DHOME) using LC/MS/MS. Ischemic injury did not change the plasma levels of EpOME and DHOME, but sEH inhibition by AUDA significantly elevated plasma EpOME and EpOME/DHOME ratio. The protective effect of sEH inhibitor was derived from the suppression of proinflammatory cytokines and the up-regulation of regulatory cytokines. AUDA treatment prevented the intrarenal infiltration of inflammatory cells, but promoted the endothelial cell migration and neovascularization.

Conclusions: Taken together, these data provide evidence that the control of sEH activity might be a feasible therapeutic strategy to prevent acute kidney injury.

TH-PO026

Preservation with Cardiotrophin-1 Prevents Cold Ischemia Injury and Inflammatory Response and Improves Survival and Graft Function in a Syngeneic Rat Kidney Transplant Model Jose M. Lopez-Novoa,[1,3] María Begoña García-Cenador,[2] Maria Pilar Perez de Obanos,[4] Juan Ruiz,[4] Francisco Javier García-Criado.[2] *[1]Department of Physiology and Pharmacology, University of Salamanca, Spain; [2]Department of Surgery, University of Salamanca, Spain; [3]Bio-inRen S.L., Salamanca, Spain; [4]Digna Biotech S.L., Madrid, Spain.*

Background: Reperfusion injury (RI) in grafted kidneys due to warm and cold ischemia (CI) is clinically manifested as a high incidence of delayed graft function. Cardiotrophin-1 (CT-1), a member of the interleukin-6 (IL-6) family, has been shown to have a protective effect on myocardial and liver damage induced by RI. The purpose of the present study has been to assess the effect of CT-1 added to perfusion and preservation fluid on renal inflammation induced by CI and in renal function in the Fisher-Fisher rat model of syngenic kidney transplantation (KTx).

Methods: Once extracted, kidneys were perfused with University of Wisconsin (UW) fluid at 4ºC containing CT-1 (0.2 mg/L) and immersed in 15 ml of cold UW with or without CT-1(0.2 mg/L). Orthotopic transplantation of the left donor kidney was performed after 24 h of cold storage as above reported. The receptor's right kidney was removed at the time of KTx. At different time points after CI or KTx, kidneys were obtained, frozen and several markers of inflammation (superoxide anion (SOA) production, TNF-α release, iNOS expression, serum levels of soluble ICAM-1 and VCAM-1 and NFκB activation) were evaluated.

Results: 24 or 48 h after CI without CT-1, there was a marked increase in SOA and TNF-α production, iNOS, and VCAM-1 expression and NFκB activation. The presence of CT-1 in the UW fluid completely prevented these increases. When kidneys were grafted after 24 h preservation, the addition of CT-1 to the UW fluid reduced reperfusion injury (lower serum creatinine and higher creatinine clearance), improved early) and long-term survival, and reduced renal SOA production, iNOS expression and NFκB activation, and serum levels of TNF-α, soluble ICAM-1 and VCAM-1.

Conclusions: Preservation with CT-1 of kidneys to be grafted improves short- and long-term outcomes and inflammatory response after CI and syngeneic KTx in rats.

Klotho Ameliorates Cisplatin Nephrotoxicity Monica Chang Panesso,[1] Mingjun Shi,[1] Han Ju Cho,[1] Dihua Zhang,[1] Makoto Kuroo,[2] Orson W. Moe,[1] Ming Chang Hu.[1] *[1]Charles and Jane Pak Center for Mineral Metabolism and Clinical Research, Department of Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX; [2]Department of Pathology, University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Cisplatin is a powerful anti-cancer agent but nephrotoxicity is one serious side effect which limits its use. Klotho was shown to protect the kidney from ischemia-reperfusion injury, but there is no information about the Klotho effect on nephrotoxic agents. We tested whether Klotho protects the kidney from cisplatin.

Methods: 1) Cisplatin (10 mg/Kg) was intraperitoneally injected into *WT*, Klotho deficient (*Kl*$^{-/+}$) or transgenic overexpressing (*Tg-Kl*) mice. 2) Normal rat kidney (NRK) epithelial cells, were treated with cisplatin and cytotoxicity was examined. 3) The effect of Klotho was compared to blocker of cisplatin uptake (cimetidine: inhibitor of organic cation transporter, OCT) on cisplatin cytotoxicity.

Results: Cisplatin injection increased plasma creatinine and induced histological renal damage. These changes were exaggerated in *Kl*$^{-/+}$ mice; and ameliorated in *Tg-Kl* mice. NGAL expression (a marker of renal damage) in the kidney was significantly higher in *Kl*$^{-/+}$ and lower in *Tg-Kl* compared to *WT* mice. Likewise, the addition of Klotho to NRK cells decreased cisplatin-induced LDH release and apoptosis. Next, we examined cisplatin uptake by NRK cells to examine if Klotho protection is mediated by suppression of cisplatin uptake. Klotho inhibited cisplatin uptake from basolateral compartment and suppressed cisplatin cytotoxicity, similar to cimetidine. However, unlike cimetidine which only suppressed cisplatin uptake, Klotho had an additional protective effect on NRK cells even when Klotho was added to NRK cells 20 minutes after cisplatin addition when uptake is already completed.

Conclusions: Our results indicate that Klotho has dual beneficial effects on cisplatin nephrotoxicity: (1) Suppression of basolateral uptake of cisplatin; (2) Direct cytoprotective effect. Klotho may present a useful agent to prevent cisplatin-induced nephrotoxicity and can potentially remove this dreaded complication from patients who benefit from cisplatin.

Renoprotective Effect of Sulfotransferase (SULT) Inhibitors on Ischemia/Reperfusion (IR)-Induced Acute Kidney Injury (AKI) Rats Megumi Komori,[1] Misato Yoshimura,[1] Masataka Sagata,[1] Kazuhiko Nishi,[2] Akinobu Hamada,[1,3] Hideyuki Saito.[1,3] *[1]Clinical Pharmaceutical Sciences, Kumamoto Univ Grad Sch of Pharm Sci, Kumamoto, Japan; [2]Hemodialysis and Apheresis, Kumamoto Univ Hosp, Kumamoto, Japan; [3]Pharmacy, Kumamoto Univ Hosp, Kumamoto, Japan.*

Background: Since AKI appears to be the high risk disease state developing into chronic kidney disease, early detection of AKI and prompt treatments are required. However, adequate therapeutic strategies and/or medications have not been established due to the lack of sufficient information for effective treatments of AKI. IR-induced AKI is evoked by diverse pathophysiological or surgical situations. In this study, we explored the biotoxicological features of these uremic toxins and evaluated renal preventive effects of AST-120 and SULT inhibitors, which obstruct hepatometabolic generation of indoxyl sulfate (IS) and p-cresyl sulfate (PCS), in IR-AKI rats.

Methods: AKI was produced by clamping isolated arteries of right and left kidneys for 30 min, followed by reperfusion of the kidneys. IS and PCS in serum and urine were assayed by HPLC technique. Kidney injury molecule-1 (Kim-1) was measured by ELISA kit.

Results: IR evoked severe renal injury with the marked increases in Scr (12.6-fold vs sham-operated rats) and BUN (13.6-fold), in association with a significant accumulation of both IS (23.2-fold) and PCS (>105.6-fold) in the serum, and the urinary excretion of Kim-1. Oral administration of AST-120 to IR rats resulted in the remarkable restoration of Scr and BUN levels with the marked decline of serum levels of IS, PCS and urine levels of Kim-1. Administration of quercetin, a typical SULT inhibitor, appeared to suppress serum

levels of both uremic toxins, i.e., 0.39- and 0.23-fold decline vs those levels in untreated rats for IS and PCS, respectively, accomapnied with a significant alleviation of renal injury (Scr, 0.45-fold and BUN, 0.52-fold).

Conclusions: In conclusion, the sulfate-conjugated uremic toxins could be key metabolic factors influencing the development or progression of IR-AKI, therefore proposing suppression of their serum accumulations might be a possible renopreventing treatment against derangements in AKI.

Therapeutic Potential of Anti-Transforming Growth Factor-β Antibody on Acute Tubulo-Interstitial Injury in Aristolochic Acid Nephropathy Laetitia Giordano,[1] Nathalie Caron,[1] Thomas Baudoux,[2] Eric De Prez,[2] Marie-Hélène Antoine,[2] Steven R. Ledbetter,[3] Joelle L. Nortier,[2] Agnieszka Anna Pozdzik.[2] *[1]Physiology-NARILIS, University of Namur, Belgium; [2]Experimental Nephrology Unit, ULB Erasme, Brussels, Belgium; [3]Cardio-Metabolic and Renal Research, Genzyme Corporation, New-York.*

Background: Aristolochic acid nephropathy (AAN) characterized by rapidly progressing renal fibrosis of toxic origin is primed by acute injury of proximal tubular epithelial cells (PTEC). Anti-transforming growth factor-β (TGF-β) antibody has been shown to improve renal fibrosis in various models of glomerular diseases, but its roles in primary tubulo-interstitial nephropathies are not yet well known.

Methods: We studied the efficacy of a murine pan-specific anti-TGF-β monoclonal antibody (1D11) in an acute phase of AAN. Weight matched rats were daily sc. injected with AA (15 mg/kg/day) or vehicle (polyethylene glycol-PEG) from day 0 to day 5. Four groups (n=6/group) were randomly assessed: PEG+1D11; AA alone; AA+1D11 and AA+control isotype (13C4). The anti-TGF-β and control isotype antibodies (5 mg/kg) were administered ip. at days -1, 0, 2 and 4.

Results: After 5 days of treatment, renal function and morphology remained normal in the control group PEG+1D11. Anti-TGF-β antibody statistically attenuated AA induced acute kidney injury, as attested by less increased creatininemia and urinary excretion of N-acetyl-β-glucosaminidase, less severe necrosis of PTEC from S3 segment and reduced macrophages infiltration (ED-1 staining) in outer medulla. Intrarenal regulatory T cells (CD4+CD25+ highFoxp3+) infiltration and neo-angiogenesis (FVIII staining) around the injured areas were also reduced by 1D11 as compared with 13C4. The proliferation of PTEC from S1-3 segments (neutral endopeptidase/proliferating nuclear cell antigen double staining) did not seem to be affected by 1D11.

Conclusions: Our results demonstrate that anti-TGF-β antibody significantly attenuates acute PTEC injury, reduces macrophages infiltration and modulates the regulatory T cells immune response. Therefore, 1D11 could be a potential, new renoprotective therapy interfering with early fibrogenesis events after a toxic insult.

TH-PO030

Apolipoprotein A-I Mimetic Peptide 4F Attenuates Kidney/Heart Injury and Endothelial Dysfunction in Sepsis Roberto De Souza Moreira,[1,2] Maria Irigoyen,[2] Maria Heloisa M. Shimizu,[1] Niels O.S. Camara,[3] Rildo A. Volpini,[1] Antonio C. Seguro,[1] Lucia Andrade.[1] *[1]Nephrology, University of São Paulo, Brazil; [2]Heart Institute, USP, Brazil; [3]Immunology, USP, Brazil.*

Background: Kidney injury, heart injury and cytokine-induced vascular hyperpermeability are associated with high morbidity and mortality in sepsis. Although the mechanism is unknown, 4F reduces inflammation and protects HDL, the levels of which are reduced in sepsis. We hypothesized that 4F also protects kidneys and hearts in a rat model of cecal ligation and puncture (CLP).

Methods: We divided Wistar rats into control (sham-operated), CLP and CLP+4F (10mg/kgBW, i.p., 6 h after CLP) groups. At 24 h post-CLP, we evaluated cardiac function, mean arterial pressure (MAP), heart rate (HR), baroreflex sensitivity, total cholesterol (TC), LDL, HDL and inulin clearance (ml/min/100gBW), as well as performing immunoblotting for protein regulators of vascular permeability (Slit2 and Robo4) and eNOS in kidney tissue. We also measured serum IL-6, IL-10, IL-18, and TNF-α. Data are mean±SEM.

Results:

Group[a]	CO (ml/min)	MPI	EF (%)	LVEDP (mmHg)	TC (mg/dl)	HDL (mg/dl)	LDL (mg/dl)
Control	73±2.3	0.45±0.04	75 ±2.7	7.5±0.5	65±3.0	42±2.3	11±1.4
CLP	50±6.2[b]	0.64±0.02[c]	67.6±2.8[b]	4.6±0.4[c]	38±4.1[c]	19±1.7[c]	18±2.7[b]
CLP+4F	77±8.1[d]	0.37±0.03[c]	79±2.0[d]	7.9±0.6[c]	51±3.8[b,d]	34±2.9[b,e]	8±2[d]

CO: cardiac output; MPI: myocardial performance index; EF: ejection fraction; LVEDP: left ventricular end-diastolic pressure. [a]n=10/group; [b]p<0.05 vs. control; [c]p<0.001 vs. control; [d]p<0.05 vs. CLP; [e]p<0.001 vs. CLP.

Although there were no intergroup differences in MAP, HR was significantly higher in CLP rats than in control and CLP+4F rats. Baroreflex sensitivity was worsened by CLP and completely restored by 4F. GFR was lower in CLP rats than in control rats (0.5±0.06 vs. 0.8±0.03, p<0.01) and was completely restored in CLP+4F rats (0.8±0.06, p<0.01). All cytokines were lower in CLP+4F rats than in CLP rats. CLP reduced Slit2, Robo4 and eNOS expression by 30%, 40% and 60%, respectively, and 4F completely restored such expression.

Conclusions: 4F inhibits inflammatory responses and strengthens the vascular barrier, protecting kidneys and hearts in an HDL-dependent manner.

Cardiotrophin-1 Protects the Kidney from Contrast Agent-Induced Nephropathy Jose M. Lopez-Novoa,[1,2] Yaremi Quiros-Luis,[2] Penelope D. Sanchez-Gonzalez,[2] Maria Pilar Perez de Obanos,[4] Juan Ruiz,[4] Francisco J. Lopez-Hernandez,[1,2,3] Ana Isabel Morales Matin.[4] *[1]Department of Physiology and Pharmacology, University of Salamanca, Spain; [2]Bioinren S.L., Salamanca, Spain; [3]IESCYL, Hospital Universitario de Salamanca, Salamanca, Spain; [4]Digna Biotech S.L., Madrid, Spain.*

Background: Cardiotrophin-1(CT-1) is a cytokine of the IL-6 family that protects liver and heart from chemical damage. Contrast nephropathy (CN), although generally reversible, is often associated to longer hospitalization time, dialysis and higher incidence of cardiovascular events. The purpose of this study was to assess if CT-1 administration could protect the kidney function in an experimental model of CN in rats receiving previously a low doses of gentamicin as a predisposing agent.

Methods: The study has been performed in 6 groups of Wistar rats: Control group (C): rats receiving saline solution; Gentamicin group (G): rats receiving G (50mg/kg/day, ip) for 6 days; Contrast agent gastrographin (Gg) group: rats receiving a single dose of Gg (3.7mg/Kg i.v.); Cardiotrophin group (CT-1): rats receiving CT-1 (100 µg/Kg/day i.v.) for 6 days; G + Gg group: rats receiving G for 6 days and then Gg as above described. G +CT-1 + Gg group: rats receiving G and CT-1 for 6 days and then Gg (as described). CN severity was assessed by measuring plasma urea (pU) and creatinine (pCr), creatinine clearance (CrCl), glomerular filtration rate (GFR), renal blood flow (RBF), urinary excretion of tubular damage markers (NAG, KIM-1 and PAI-1), renal cell apoptosis and lipid peroxidation (TBARS) and by histological studies.

Results: G, CT-1 or Gg alone did not produce any change in the parameters studied. In the group G +Gg there was an increase in pCr and pU, a decrease in CrCl, a lower GFR and RBF, a high urinary excretion of NAG, KIM-1 and PAI-1, and marked tubular necrosis. These increases were markedly lower in the group that also received CT-1 (G+ CT-1+Gg). The number of apoptotic cells and the amount of TBARS were markedly lower in the kidneys from the group G+CT-1 +Gg than in those from the G +Gg group

Conclusions: CT-1 administration prevents most of the alterations in kidney function and structure associated to this model of CN.

Cardiotrophin-1 Protects from Gentamicin- and Cisplatin-Induced Acute Kidney Injury Jose M. Lopez-Novoa,[1,2] Yaremi Quiros-Luis,[2] Penelope D. Sanchez-Gonzalez,[2] Rebeca Nunez-Lozano,[2] Maria Pilar Perez de Obanos,[3] Juan Ruiz,[3] Francisco J. Lopez-Hernandez,[1,2,4] Ana Isabel Morales Matin.[1] *[1]Department of Physiology and Pharmacology, University of Salamanca, Spain; [2]Bio-inRen S.L., Salamanca, Spain; [3]Digna Biotech S.L., Madrid, Spain; [4]Unidad de Investigacion, IESCYL-Hospital Universitario de Salamanca, Salamanca, Spain.*

Background: Gentamicin and cisplatin are widely used drugs whose major limitation is nephrotoxicity. Cardiotrophin-1 (CT-1) is a cytokine belonging to the IL-6 family that has been demonstrated to protect liver and heart from chemical and ischemic damage. The purpose of this study has been to assess if CT-1 administration could protect the kidney function in experimental models of gentamicin and cisplatin-induced acute kidney injury (AKI) in rats.

Methods: The study has been performed in 5 groups of Wistar rats: Control group (C): rats receiving saline solution i.p. for 6 days. Cardiotrophin group (CT-1): rats receiving CT-1 i.v. (100µg/Kg/day) for 6 days; Gentamicin group (G) rats receiving gentamicin (150mg/kg/day, i.p.) for 6 days; Cisplatin group (Csp), rats receiving a single dose of cisplatin (6 mg/kg i.p); CT-1 + G group: rats receiving CT-1 and G at the doses above described. CT-1 + Csp group: Rats receiving CT-1 and Csp at the doses above described. AKI severity was assessed by measuring plasma urea (pU) and creatinine (pCr), creatinine clearance (CrCl), urinary flow, urinary protein excretion, urinary excretion of total proteins and AKI markers (NAG, KIM-1 and N-GAL), and by histological studies.

Results: Gentamicin or Csp administration at these doses induced a marked AKI characterized by an increase in urinary flow, and in pCr and pU, a decrease in CrCl, and an increase in urinary excretion of proteins, NAG KIM-1 and N-GAL. Administration of CT-1 in G-treated (CT-1 + G)or Csp-treated (CT-1 + Csp) rats induced a significant reduction in pCr, pU, and urinary excretion of proteins, NAG, KIM-1 and N-GAL and an increase in CrCl, compared with the G group. CT-1 also prevented the structural kidney alterations induced by G or Csp.

Conclusions: Our results demonstrate that CT-1 protects rats from the AKI induced by either gentamicin or cisplatin administration.

Probenecid Prevents Acute Tubular Necrosis and Interstitial Fibrosis in a Mouse Model of Aristolochic Acid Nephropathy Thomas Baudoux,[1] Agnieszka Anna Pozdzik,[1] Volker Manfred Arlt,[2] Jean-Michel Hougardy,[1] Eric De Prez,[1] Nathalie Quellard,[3] Jean-Michel Goujon,[3] Joelle L. Nortier.[1] *[1]Experimental Nephrology Unit, Fac. Medicine, Univ. Libre de Bruxelles, Brussels, Belgium; [2]Section of Mol. Carcinogenesis, Inst. Cancer Research, Sutton, United Kingdom; [3]Dept of Pathol & Electron Microscopy, CHU La Miletrie, Poitiers, France.*

Background: Aristolochic acid nephropathy (AAN) is characterized by early tubulo-interstitial (TI) injury (i.e necrosis of proximal tubular epithelial cells [PTEC] and inflammatory infiltrate) and chronic lesions (i.e. tubular atrophy and interstitial fibrosis). In vitro, probenecid (PBN) inhibits AA entry through organic anion transporters (OATs), thereby reducing the formation of specific AA-DNA adducts and preserving cellular viability.

Methods: To confirm these results in vivo, 4 groups of C57BL/6 mice were injected ip with AA (dissolved in polyethylene glycol [PEG]); AA+PBN ; PEG+PBN or PEG. AA (5 mg/kg bw) or equivalent vehicle volume were given once a day and PBN (150 mg/kg bw) twice a day. Plasma creatinine level (Pcr), TI lesions, DNA repair processes (PCNA immunostaining) and AA-DNA adduct formation were studied in 6 mice/group after 2, 4, 5 and 8 days.

Results: No structural and functional abnormalities were found in mice receiving PEG or PEG+PBN. In contrast, AA induced severe necrosis of PTEC (days 4-5) leading to a transient acute kidney injury (day 5). Mononuclear cells infiltration, tubular atrophy and interstitial fibrosis were prominent on day 8. In the AA+PBN group, no Pcr elevation was observed. TI injury scores and PCNA positive cell were significantly reduced as soon as day 5. AA-DNA adduct levels were significantly lower at day 8. PBN reduced both the extent and the severity of ultrastructural lesions induced by AA (i.e. loss of brush border, mitochondrial edema and disappearance of mitochondrial crest).

Conclusions: Our data show that PBN, as an OATs inhibitor, reduces AA-DNA adduct formation and AA-induced tubulotoxicity, possibly by attenuation of mitochondrial injuries. This study demonstrates for the first time the nephroprotective effect of PBN towards acute PTEC toxicity and interstitial fibrosis in a mouse model of AAN.

TH-PO034

Sildenafil and N-Acetylcysteine Role in Renal Ischemia Reperfusion Syndrome Is Time Dependent Maria De Fatima Vattimo,[1] Cassiane Dezoti Fonseca,[1] Mirian Watanabe,[1] Fernanda Teixeira Borges.[2] *[1]School of Nursing, University of Sao Paulo, SP, Brazil; [2]Nephrology Division, Federal University of Sao Paulo, Sao Paulo, SP, Brazil.*

Background: Severity related to time of ischemia can determine the effect of the renoprotective agents and the prognosis of acute kidney injury (AKI). Sildenafil citrate (SIL) has shown a role in vasoconstriction damage while N-acetylcysteine (NAC) increases intracellular glutathione and scavenges reactive oxygen species (ROS). This study evaluated the effect of SIL and NAC in a time dependent ischemic AKI model.

Methods: Adult, male, Wistar rats (260–310 g) were divided into groups: ***SHAM***, ***Ischemia 30*** (Isch, renal pedicles clamping, RPC, for 30 min), ***Isch 30 + SIL*** (0.25 mg/kg 60 min before RPC), ***Isch 30 + NAC*** (150 mg/kg before and after RPC), ***Isch 45*** (45 min RPC), ***Isch 45 + SIL***, ***Isch 45 + NAC***. Renal function (RF, creatinine clearance, crCl); oxidative injury (urinary peroxides, UP; TBARS; nitric oxide, NO and thiols in renal tissue); expression of inducible nitric oxide synthase (iNOS), heme oxygenase-1 (HO-1) (western blotting) and tubulointerstitial (TI) injury were evaluated.

Results: table 1: Renal function,oxidative profile and TI.

Groups(n)	crCL/100g (ml/min)	UP (nmol/ gcr)	Thiol (nmol/ mg protein)	TBARS (nmol/g cr)	NO (µmol/g cr)	TI
SHAM (7)	0.97±0.02	1.7±0.1	170±16	57±7	30±2	0.2±0.1
Isch 30 (6)	0.12±0.01a	5.9±0.2a	117±10a	114±16a	77±7a	2.5±0.2a
Isch 30+Sil (6)	0.55±0.07abc	2.3±0.3bc	111±11a	48±2b	36±4b	1.8±0.3a
Isch 30+NAC (6)	0.57±0.08abc	3.2±0.5bc	89±4a	58±7b	31±2b.1	1.6±0.4ab
Isch 45 (5)	0.04±0.01a	9.7±1.8ab	129±17a	117±33a	76±15a	3.2±0.2a
Isch 45+Sil (5)	0.10±0.01a	4.0±0.6c	68±12ac	45±7bc	47±5c	2.2±0.4ac
Isch 45+ NAC (5)	0.04±0.01a	7.8±1.6a	104±9a	117±13a	83±5a	3.6±0.2a

a p<0.05 versus SHAM;b p<0.05 versus Isch 30; c p<0.05 versus Isch 45

Conclusions: SIL and NAC treatment increased RF, decreased oxidation, NO levels and induced iNOS absence and HO-1 expression in 30 min RPC. In the 45 groups, only SIL protected those paramethers. Histology results were in favor of SIL, once it was able to reduce TI at 30 and 45 min RI. It can be concluded that SIL renoprotecive action is more effect than NAC´s for severe ischemia reperfusion syndromes and that HO-1 may be considered a cellular protecting mediator.

Therapeutic Effects of GLP-1 Agonist in Gentamicin-Induced Kidney Injury in Rats Joon Seok Choi, Chang Seong Kim, Jeong-Woo Park, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Internal Medicine, Chonnam National University Medical School, Gwangju, Republic of Korea.*

Background: Glucagon-like peptide-1 (GLP-1) has various extra-pancreatic actions. Although the kidney also has GLP-1 receptors, a role GLP-1 in aminoglycoside-induced nephropathy has not been examined. We investigated effect of exendin-4 in gentamicin (GM)-induced nephropathy in rats.

Methods: Two groups of rats were treated with GM (100 mg/kg/day), one of which was cotreated with exendin-4 (5 µg/kg/day) for 14 days and the other was not. The control group was treated with vehicle only. We evaluated renal function and the expression of inflammatory cytokines and adhesion molecules. In another series of experiment, effects of exendin-4 were determined in human proximal tubular cells (HK-2 cells) cultured in the presence of GM.

Results: Fasting blood glucose levels, blood pressure, creatinine clearance and albuminuria were not affected by exendin-4 in GM-treated rats. There was an upregulation of inflammatory cytokines such as IL-1β, IFN-r and TNF-α, which was prevented by exendin-4. Exendin-4 also effectively reversed the increases of ICAM-1, VCAM-1and MCP-1 mRNA expression in GM-treated rats. The expression of ED-1 and i-NOS was increased by GM, of which magnitude was attenuated by exendin-4. In HK-2 cells, GM increased connective tissue growth factor(CTGF) and iNOS expression compared to the control, and this effect was inhibited by exendin-4 treatment. Exendin-4 treatment attenuated the expression of phosphorylated ERK1/2.

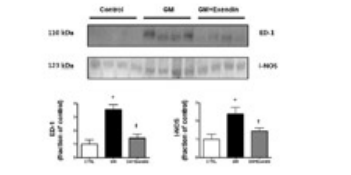

Figure 1. Effects of exendin-4 on inflammatory cell infiltration and inducible nitric oxide synthase (iNOS) expression. Semiquantitative immunostaining of ED-1 and i-NOS. Each column represents the mean±s.e.m. (n=4). * p<0.05 compared to the control † p<0.05 compared to GM treated rat

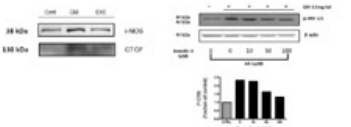

Figure 3. In vitro analysis of i-NOS, CTGF and p-ERK 1/2. Semiquantitative immunoblotting of iNOS, CTGF and p-ERK 1/2 expression in HK-2 cells incubated with GM (0.5 mg/ml) in the absence or presence of exendin-4.

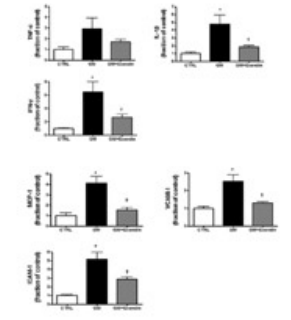

Figure 2. Effects of exendin-4 on inflammatory cytokines and adhesion molecules. Real-time polymerase chain reaction(PCR) was used to examine the expression of tumor necrosis factor (TNF)-α, interferon (IFN)-γ, interleukin (IL)-1β, monocyte chemoattractant protein (MCP)-1, intercellular adhesion molecule (ICAM)-1, and vascular cell adhesion molecule (VCAM)-1. Each column represents the mean±s.e.m. (n=5). * p<0.05 compared to the control † p<0.05 compared to GM treated rat

Conclusions: Exendin-4 has reno-protective effects through its anti-inflammatory actions. Its underline mechanism may include inhibition of MAPK signaling pathway.

TH-PO036

Acute Testosterone Supplementation Improves Renal Ischemia/Reperfusion-Induced Acute Kidney Injury (I/R-AKI) Andrea P. Soljancic,[1] Arnaldo F. Lopez-Ruiz,[1] Kiran B. Chandrashekar,[1] Rodrigo Maranon,[1] Ruisheng Liu,[2] Luis A. Juncos.[1] *[1]Medicine-Division of Nephrology, University of Mississippi Medical Center, Jackson, MS; [2]Physiology and Biophysics, University of Mississippi Medical Center, Jackson, MS.*

Background: Testosterone (TST) administration has beneficial effects during certain conditions (*e.g.* stroke, myocardial infarction) due to its antinflammatory property and perhaps by improving local blood flow. Because renal I/R-induced AKI is associated with renal hemodynamic impairment, inflammation and reduced vascular endothelial growth factor (VEGF) expression (which may have cytoprotective effects), we tested the hypothesis that TST improves AKI and preserves the abovementioned renal parameters in established AKI.

Methods: We randomized 3 groups of adult male SD rats (n=5-6): **1)** Sham (S), **2)** I/R-AKI Control (CT), **3)** I/R-AKI + testosterone propionate (TP). Renal I/R was induced by clamping both renal pedicles for 40min. TP (20 ng/kg/min x 10 min IV) was administered using a femoral catheter 3 hours after reperfusion. Animals were followed for 48 hours post ischemia, during which plasma creatinine, urine protein excretion and a urinary marker of AKI (KIM-1) were monitored at 24 hours. At the end of the study, outer medullary blood flow (OM-RBF) was measured by laser Doppler in anesthetized animals and then kidneys were harvested to evaluate renal inflammation (TNFα) and renal cytoprotective factor (VEGF).

Results:

Groups	PLCreat(mg/dl)	OM-BRF (TPU)	UrKIM-1(pg/ml)	UrProt(mg/24h)	TNF(pg/ml)	VEGF pg/ml)
S	0.54±0.04	19.3±1.4	712±20	30.95±3.4	16.4±0.3	376±5.7
CT	2.46±0.3*	11.4±0.3*	4576±75*	129.2±8.7*	61.8±1.1*	105±2.3*
TP	1.4±0.07*#	19.9±2.1#	1722±29*#	67.8±6.3*#	31.3±0.2*#	230±7.3*#

Data: Mean±SEM. *p<0.05 vs S, #p<0.05 vs CT

Conclusions: Our data suggest that TST improves AKI as demonstrated by: 1) reversing of OM-RBF impairment, 2) attenuation of renal injury and inflammation (Proteinuria, KIM-1, TNFα), 3) blunting of AKI-induced VEGF reduction. In conclusion, acute TST infusion improves renal hemodynamics, function, injury, and VEGF expression after I/R-induced AKI.

Preconditioning Effects of Rituximab on Subsequent Ischemia-Reperfusion Injury in Mouse Kidney Hyeonseok Hwang,[1,2] Sang Ju Lee,[1] Suk Young Kim,[1] Chul Woo Yang.[1] *[1]Division of Nephrology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea; [2]Clinical Research Institute, DaeJeon St. Mary's Hospital, Korea.*

Background: The adaptive immune system contributes to robust inflammatory response after Ischemia-reperfusion (I/R) renal injury. There is growing evidence of the roles of B-cell in postischemic kidney, and we investigated preconditioning effects with rituximab against subsequent I/R injury in mouse kidney.

Methods: Male C57BL/6 mice were used. Rituximab (5, 10 and 40 mg/kg) was administered 7 days before I/R injury by clamping both renal pedicles for 22 min. The effect of rituximab pretreatment was evaluated in terms of renal function, tubular necrosis score, serum immunogologulin (Ig) G and IgM levels.

Results: Pretreatment with 10 and 40 mg/kg rituximab decreased blood urea nitrogen and serum creatinine at 1, 3 and 10 days postischemia. Renal function was not improved in mice treated with 5 mg/kg rituximab. Tubular necrosis scores were lower in mice with 10 mg/kg rituximab treatment than in control mice. The serum IgG level was not different between control and rituximab-treated mice, but serum IgM level was tended to be reduced in rituximab-treated mice.

Conclusions: Our study demonstrates that preconditioning with more than 10 mg/kg rituximab exerts a protective effect against subsequent renal I/R injury.

TH-PO038

Gamma-Tocotrienol Protects Against Oxidative Damage in Renal Proximal Tubule Cells Corey J. Hayes, Diana Bakajsova, Cesar M. Compadre, Grazyna Nowak. *Dept. of Pharmaceutical Sciences, University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: *Alpha, beta, gamma,* and *delta* tocopherols and tocotrienols are well known for their antioxidant properties. Oxidative stress is a major mechanism of acute kidney injury, diabetic nephropathy, and chronic kidney disease. This study tested if gamma-tocotrienol (GT3) protects against oxidative stress and mitochondrial dysfunction in renal cells.

Methods: Primary cultures of renal proximal tubular cells (RPTC) were treated with *tert*-butyl hydroperoxide (0.35 mM TBHP; 45 min), a model oxidant. Some RPTC were pre-treated with 5 μM GT3 prior to TBHP exposure. Production of reactive oxygen species (ROS), mitochondrial functions, and cell viability were measured after TBHP exposure.

Results: ROS production in injured RPTC increased 200% and was followed by decreases in state 3 respiration (50%) and respiratory control ratio (47%). Mitochondrial membrane potential decreased 39% and 82% at 4h and 24h, respectively, in TBHP-injured RPTC. Oligomycin-sensitive respiration declined 63%, F_0F_1-ATPase activity decreased 31%, and ATP content decreased 65% in TBHP-injured RPTC. Cell death increased to 22% and 52% at 4h and 24h, respectively, after TBHP exposure. Pretreatment of RPTC with GT3 blocked production of ROS, prevented the decreases in state 3 respiration, and maintained the respiratory control ratio in TBHP-injured RPTC. TBHP-induced decreases in oligomycin-sensitive respiration and F_0F_1-ATPase activity in mitochondria were prevented by GT3. Further, GT3 ameliorated decreases in ATP content after TBHP exposure. Finally, pretreatment with GT3 blocked cell lysis at 4h and reduced it from 52% to 13% at 24h after injury.

Conclusions: This is the first report demonstrating the protective properties of GT3 in renal cells. GT3 protects against RPTC injury by: 1) decreasing production of ROS, 2) improving mitochondrial respiration and coupling, 3) maintaining mitochondrial membrane potential, 4) blocking decreases in F_0F_1-ATPase function, 5) maintaining intracellular ATP levels, and 6) preventing RPTC lysis and death. This study suggests that GT3 could be used as a potential treatment to prevent renal injury associated with oxidative stress.

Role of Cilastatin Against Cisplatin-Induced Nephrotoxicity and Inflammation in Rats Alberto Lázaro Fernández,[1] Blanca Humanes Sanchez,[1] Sonia Camaño Paez,[1] José Antonio Lázaro Manero,[1] Jose Manuel Lara Martinez,[2] Alberto Tejedor Jorge.[1] *[1]Laboratory of Renal Physiopathology, Hospital General Universitario Gregorio Marañón, Madrid, Spain; [2]Department of Pathology, Hospital General Universitario Gregorio Marañón, Madrid, Spain.*

Background: Cisplatin is a major antineoplastic drug for the treatment of solid tumors, but its nephrotoxicity is a major complication and a dose limiting factor for anticancer theraphy. Several evidences have shown that inflammation contribute to the pathogenesis of cisplatin-induced acute renal failure. In this study, we have investigated the potential use of cilastatin, a renal dehydrodipeptidase I inhibitor as nephroprotector on cisplatin-induced renal injury and inflammation in rats.

Methods: Male Wistar rats were divided into 4 groups: control rats, cilastatin-control rats, cisplatin-injected rats, cilastatin-treated cisplatin-injected rats. Nephrotoxicity was assessed 5 days after cisplatin treatment, by measuring serum creatinine, blood urea nitrogen (BUN), glomerular filtration rate, proteinuria and renal morphology. Inflammation was measured by electrophoretic mobility assay (EMSA) and immunohistochemical studies.

Results: Cisplatin-treated rats showed significant elevations in BUN, creatinine, and proteinuria and decreased the glomerular filtration rate when compared with control rats. Cisplatin rats also exhibited severe morphological changes such as necrosis and extensive vacuolization of the proximal tubule and inflammatory mediators were increased. Cilastatin significantly prevented partial or totally these changes in renal function and ameliorated histological damage in cisplatin-treated animals. Cilastatin also reduced serum tumor necrosis factor-alpha (TNF-a) levels, nuclear factor κB activation and ED1 (monocytes/macrophages) positive cells.

Conclusions: This study provides evidence that cilastatin reduces in vivo cisplatin nephrotoxicity by preventing inflammation and might represent a novel strategy in the prevention of cisplatin-induced acute renal injury.

CD73-Deficiency Protects in Kidney Ischemia Reperfusion Injury: The Role of Adenosine A1, A2A, A2B and A3 Receptors Siddharth V. Rajakumar,[1] Bo Lu,[1] Simon C. Robson,[2] Anthony J. d'Apice,[1] Peter J. Cowan,[1] Karen M. Dwyer.[1] *[1]Immunology Research Centre, St Vincent's Hospital, Melbourne, Victoria, Australia; [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA.*

Background: Adenosine, acting at A1, A2A, A2B and A3 receptors, is protective in numerous models of ischemia reperfusion injury (IRI). Extra-cellular adenosine is generated by the successive hydrolysis of nucleotides by the ecto-enzymes CD39 and CD73. CD39 over-expression protects in kidney IRI while CD73 deficiency and inhibition also confer protection. Given CD73-deficiency results in reduced adenosine generation, the mechanism by which this protection is achieved remains unclear. We aim to determine the role of A1, A2A, A2B and A3 receptors in the protective effect of CD73-deficiency in kidney IRI.

Methods: Wild-type (WT) and CD73-deficient (CD73KO) mice underwent right nephrectomy and 18 minutes left renal ischemia. After 24 hour reperfusion, renal function (serum creatinine, umol/l) and histological renal injury (scored S:1-9) were assessed. Mice were pre-treated with specific A1, A2A, A2B or A3 receptor antagonists.

Results: Compared to WT mice [Cr=96,S:3.6,n=5], CD73KO mice are protected [Cr=45,S:0.8,n=5,p<.05]. A1-antagonist treatment has no significant effect on WT mice (trend toward protection) [Cr=64,S:2.7,n=4] and protection is maintained in CD73KO mice [Cr=59,S:1.0,n=4,p<.05]. A2A-antagonist treatment worsens renal function and histological damage in both WT [Cr=145,S:4.8,n=4, trend:p=.08] and CD73KO mice [Cr=82,S:2.8,n=6,p<.05], but its detrimental effect is still attenuated in CD73KO mice [p<.05]. A2B-antagonist treatment has minimal effect on WT mice [Cr=85,S:4.0,n=3] but significantly worsens renal dysfunction in CD73KO mice [Cr=146,S:5.3,n=5,p<.01]. A3-antagonist treatment abrogates injury in WT mice [Cr=49,S:1.5,n=4,p=.05] and protection in CD73KO mice is maintained [Cr=43,S:0.5,n=4,p<.05].

Conclusions: CD73-deficiency and A3 receptor inhibition protect in kidney IRI. Protection mediated by CD73-deficiency is not dependent on A1, A2A or A3 receptor signaling and is dependent on A2B receptor signaling. The A2B receptor plays a protective role in states of lower adenosine generation.

TH-PO041

Increased Angiopoietin-Like Protein 4 (Angptl4) Expression and Hyperlipidemia in Acute Kidney Injury Syed M. Ali,[1] Shenyang Li,[1] Neriman Gokden,[2] Didier Portilla.[1] *[1]Nephrology, Internal Medicine, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR; [2]Pathology, .*

Background: In the present study we examined the mechanisms by which cisplatin causes hyperlipidemia and the potential role of hyperlipidemia in nephrotoxicity. We studied whether changes on Lipoprotein Lipase(LPL) activity, the enzyme responsible for the hydrolysis of triglycerides(TG), and changes in the expression of Angptl4, a potent inhibitor of LPL account for CP-mediated hyperlipidemia.

Methods: Wild type mice fed a normal diet or a diet containing peroxisome proliferator activated receptor-alpha ligand WY received a single intraperitoneal injection of saline or CP(25 mg/kg BW). Serum, white epididymal adipose tissue, liver and kidney tissue were collected after CP exposure.

Results: CP caused a time-dependent reduction in white epididymal adipose tissue mass by 40% at day 3, that was accompanied by focal necrosis and increased lymphocytic infiltration. LPL activities measured in serum and adipose tissue were inhibited by 70% when compared to saline treated mice. CP also inhibited kidney tissue LPL activity by 40%. Angptl4 mRNA levels were increased by 9-fold in liver and kidney tissue and by 2-fold in adipose tissue of CP-treated mice. Treatment of adipose tissue cells in culture with 25 micromolar CP for 24 hrs led to 70% reduction in LPL activity and a two-fold increased expression of Angptl4 mRNA levels. CP also increased the accumulation of TG in serum and kidney tissue. Renal function, CP-mediated inhibition of LPL activity, increased expression of Angptl4, and accumulation of TG in kidney tissue were ameliorated by the use of a PPARalpha ligand.

Conclusions: 1) Cisplatin mediated hyperlipidemia is caused by direct effects of CP on adipose tissue LPL activity, 2) Inhibition of LPL activity and increased Angptl4 gene expression in adipose, liver, and kidney tissue represent a common biochemical mechanism

involved in CP-mediated hypertriglyceridemia, 3) Fibrates ameliorate renal function and prevent the accumulation of TG in kidney tissue by preventing CP-mediated inhibition of LPL activity via reduced expression of Angptl4 in the proximal tubule.

TH-PO042

Regulation of Nrf2 Mediated Signaling during Acute and Chronic Hypoxic Stimulation of Human Proximal Tubular Epithelial Cells

Haranatha Reddy Potteti,[1] Narsa Machireddy,[1] Manchang Liu,[2] Hamid Rabb,[2] Sekhar P. Reddy.[1] *[1]Pediatrics, University of Illinois at Chicago; [2]School of Medicine, Johns Hopkins University, Baltimore.*

Background: Acute kidney injury (AKI) caused by ischemia reperfusion (IR) is a major clinical problem in both native and transplanted kidney, but mechanisms by which IR contributes to AKI are largely undefined. We have previously shown that genetic deletion of Nrf2 enhances susceptibility to ischemic AKI in mice. Because Nrf2-dependent transcriptional response is essential for mitigating cellular stress, we investigated whether hypoxic reoxygenation impairs activation of Nrf2 signaling in kidney epithelial cells, thereby worsening tubular injury in AKI.

Methods: Human renal proximal tubular epithelial cells, HK2, were exposed to acute (2 h) and chronic (12 h) hypoxic conditions with and without re-oxygenation for up to 6 h. The expression levels of *Nrf2*, *Keap1* (an endogenous inhibitor of Nrf2), and several antioxidant genes, as well as Nrf2 recruitment to the endogenous antioxidative genes were evaluated.

Results: Gene expression analysis revealed a distinct and dynamic regulation of expression levels of *Nrf2* and *Keap1* in response to acute and chronic hypoxic-reoxygenation conditions. Hypoxia alone stimulated significantly *Nrf2* mRNA expression, whereas re-oxygenation had a modest effect. However, immunoblot analysis revealed enhanced levels of Nrf2 after 6 h post-reoxygenenation. Hypoxia and reoxygenation also altered the expression level of Keap1. There was persistently elevated level of *Hmox1* expression during reoxygenation, while *Nqo1* expression was transiently induced. The analysis of Nrf2 recruitment to the antioxidative gene promoters using chromatin immunoprecipitation (ChIP) assays revealed an increased Nrf2 binding to the antioxidant response elements (AREs) of *Hmox1* and *Nqo1* promoters during acute hypoxic-reoxygenation condition, but not in the chronic exposure.

Conclusions: Our data demonstrate a dynamic and distinct regulation of Nrf2 activation by hypoxia in kidney epithelial cells. Modulation of Keap1 expression may play a role in regulating ARE-mediated gene expression during hypoxic-reoxygenation in AKI.

Renal Dysfunction Associated with Increased Intra-Abdominal Pressure in Experimental Heart Failure: Nephroprotective Effects of Phosphodiesterase-5 Inhibition

Zaid Abassi,[1] Niroz Abu Saleh,[1] Hoda Awad,[1] Nabil Ghrayeb,[2] Ilia Goltsman,[1] Suheir Assady,[3] Zaher Armaly,[4] Bishara Bishara.[5] *[1]Department of Physiology and Biophysics, Technion-IIT, Haifa, Israel; [2]Orthopedics, Rambam Medical Center, Haifa, Israel; [3]Nephrology, Rambam Medical Center, Haifa, Israel; [4]Nephrology, Anglican Hospital, Nazareth, Israel; [5]General Surgery, Rambam Medical Center, Haifa, Israel.*

Background: The deleterious effects of elevated intra-abdominal pressure (IAP) on the kidneys are widely recognized in abdominal compartment syndrome, visceral edema and laparoscopic surgery. Previously, we demonstrated that rats with congestive heart failure (CHF) exhibited exaggerated sensitivity to the adverse renal effects of elevated IAP compared with sham controls. In the present study we tested whether IAP induces acute kidney injury (AKI), and whether phosphodiesterase-5 (PDE5) inhibition ameliorates the adverse renal effects of elevated IAP in rats with CHF.

Methods: Following a baseline period, rats with high- and low-output CHF induced by the placement of aorto-caval fistula or LAD ligation, respectively, and sham-controls were subjected to consecutive IAPs of 7, 10, or 14 mmHg for 45 min each by CO_2 insufflation. Urine flow (V), Na+ excretion (UNaV), glomerular filtration rate (GFR), renal plasma flow (RPF) and NGAL excretion were determined. The effects of pretreatment with Tadalafil (10 mg/day, PO) on the adverse renal effects of elevated IAP were examined in these rats.

Results: While IAP of 7 mmHg in sham-controls did not affect V, UNaV, GFR and RPF, IAPs of 10 and 14 mmHg produced dose-dependent reductions in these parameters. Basal kidney function and renal hemodynamics were lower in both low- and high-output CHF rats. When subjected to 10 and 14 mmHg, CHF rats exhibited exaggerated declines in V, UNaV, GFR, RPF and increased NGAL excretion compared to sham controls. Pretreatment with Tadalafil ameliorated the deleterious renal effects of high IAP in both CHF models.

Conclusions: Rats with CHF are vulnerable to the adverse renal effects of pneumoperitoneum. Tadalafil abolishes renal dysfunction and AKI induced by high IAP, supporting a therapeutic role for PDE5 inhibition in laparoscopic surgery in CHF states.

TH-PO044

Role of Autophagy for Tubular Maintenance, Aging and Stress Adaptation

Shuya Liu, Bjorn Hartleben, Tobias B. Huber. *Renal Division, University Hospital Freiburg, Germany.*

Background: Autophagy is a major pathway that delivers damaged proteins and organelles to lysosomes to maintain cellular homeostasis. Recent studies indicate an upregulation of autophagy in tubular cells under stress conditions. However, the precise function of tubular autophagy in vivo remained unclear. To determine the role of autophagy in tubular cells, we generated Atg5 flox/flox: Pax8 rtTA: Teto-Cre mice and Atg5 flox/flox: Ksp-Cre mice where Atg5 is deleted in all tubular segments or only the distal tubular compartment, respectively. Atg5 deletion in the complete tubular system resulted in accumulation of p62-positive protein aggregates and increased serum creatinine 4 months after doxycycline administration. Under pathophysiological condition such as ischemia/reperfusion injury, proximal tubules displayed upregulated autophagic activity and autophagy-deficient mice exhibited significantly increased signs of tubular injury. Otherwise, Atg5 deletion restricted only to the distal tubular system did not result in histological abnormalities or increased serum creatinine levels for up to 1 year of age. These data suggest that autophagy is a critical regulator of proximal tubular homeostasis and protects tubular cells from acute kidney injury.

The Impact of Protein Kinase C λ/ι Deficiency in Proximal Tubule Epithelial Cells

Kirstin Worthmann,[1] Nathan D. Susnik,[1] Michael Leitges,[2] Hermann G. Haller,[1] Roland Schmitt,[1] Mario Schiffer.[1] *[1]Nephrology, Medical School of Hannover, Hannover, Germany; [2]Biotechnology Centre of Oslo, University of Oslo, Norway.*

Background: Podocyte specific deletion of atypical protein kinase C λ/ι (PKCλ/ι), in mice, leads to a severe glomerular phenotype with mislocated slit diaphragms, atypical cell-cell junctions and proteinuria. Because of the great effect of PKCλ/ι on podocyte polarity we wanted to investigate the role of PKCλ/ι in the highly polarized kidney tubules using a transgenic mouse model.

Methods: We specifically deleted PKCλ/ι in proximal tubule epithelial cells by breeding transgenic Sglt2-Cre mice with PKCλ/ι floxed mice. Offspring of these mice were tested for renal function before and after treatment with aristolochic acid to induce the murine model of acute kidney injury aristolochic acid nephropathy (AAN). Sections of kidney were examined for proliferation by Ki67 staining. Furthermore, cDNA of WT and KO kidneys was tested via realtime PCR for the gene expression of acute kidney injury markers, NGAL and Kim-1. To investigate the PKCλ/ι deficiency in vitro we isolated proximal tubule epithelial cells from WT and KO kidneys and analyzed them in a Ca^{2+} switch assay.

Results: The histology of the PKCλ/ι Sglt2-Cre mice revealed no obvious renal phenotype up to 6 month after birth. After injection of aristolochic acid, both WT and KO mice developed acute renal injury marked by an increase of serum creatinine and serum urea at day 3-6. On day 14 we sacrificed the animals, and compared the histology of WT and KO by HE stainings. We detected a different amount of tubular damage by a semiquantitative damage scoring. Realtime PCR analysis confirmed the damage score with the expression measurements of NGAL and Kim-1. In stainings we found an increase of Ki67 positive cells in the KO mice.

In isolated PKCλ/ι deficient proximal tubule epithelial cells we could demonstrate a disturbed expression pattern of the junction protein E-cadherin, especially in the Ca^{2+} switch assay.

Conclusions: In summary, we found that atypical PKCλ/ι is an important factor for the reorganization of proximal tubular epithelial cells after acute kidney injury.

TWEAK Modulates Proliferation, Matrix Remodeling and Migration in Renal and Embryonic Fibroblasts through Ras Signaling

Alberto Benito Martin,[1] Alvaro C. Ucero,[1] Isabel Fuentes-Calvo,[2] Beatriz Santamaria Pérez,[1] Carlos Martinez-Salgado,[2] Jose M. Lopez-Novoa,[2] Marta Ruiz-Ortega,[1] Jesus Egido,[1] Alberto Ortiz.[1] *[1]Nefrologia Experimental, IIS-FJD/Univ. Autonoma de Madrid, Madrid, Spain; [2]Fisiopatologia Renal y Vascular, Univ. de Salamanca, Salamanca, Spain.*

Background: TWEAK is a TNF superfamily member involved in different processes. In the kidney, TWEAK induces proliferation and an inflammatory phenotype in renal tubular cells. TWEAK blockade ameliorates renal damage in mice AKI models, but there is scarce information about the role of TWEAK in tissue repair after injury. Renal fibroblasts and their matrix-related properties are key players in tissue remodeling after injury and in renal fibrosis.

Methods: TWEAK induced proliferation in cultured renal fibroblasts (TFB cells) through ERK pathway. Looking for the link between TWEAK signaling and ERK, we tested Ras/ERK pathway. TWEAK treatment of renal fibroblasts resulted in an early activation of Ras and ERK. Ras inhibition blocked TWEAK-induced activation of ERK and proliferation. These results represent the first evidence of Ras involvement in TWEAK signaling. Murine embryonic fibroblasts (MEF) also increased proliferation in response to TWEAK, whereas MEF cells lacking N- and H-Ras isoforms did not, supporting the Ras involvement.

Results: Renal fibroblasts are characterized by an active role in extracellular matrix remodeling. TFB cells stimulated with TWEAK drastically reduced collagen type I and fibronectin synthesis and secretion. By contrast, TWEAK increased the activity of MMP-9 and PAI-1 production. Similar effects over collagen type I and fibronectin were observed in MEFs and seemed to be Ras-dependent. These results suggested that TWEAK modulates tissue remodeling through the Ras pathway, so we tested the potential functionality of this pathway in a wound healing assay. Wound-closure time was smaller in MEF with active Ras in the presence of TWEAK. This effect disappeared in Ras-deficient MEFs.

Conclusions: TWEAK regulates fibroblast proliferation, matrix proteins production and wound closure capacities depending on Ras. These results suggest that TWEAK/Ras pathway may contribute to tissue remodeling during tissue repair.

Signalling Pathways Responsible for Proximal Tubule Cell Adhesion Promotion during I/R by Darbepoetin α: New Therapeutic Targets for a New Use of Darbepoetin α

Ignacio Blanco Sanchez,[1] Marina Arranz,[1] Elisa Conde,[1] Elia Aguado Fraile,[1] Edurne Ramos,[1] Nuria Villegas,[1] Rafael Selgas,[2] Jose-Antonio Sanchez-Tomero,[3] Laura Garcia-Bermejo.[1] *[1]Pathology, Hospital Ramon y Cajal, Madrid, Spain; [2]Nephrology, Hospital Universitario La Paz; [3]Nephrology, Hospital Universitario la Princesa.*

Background: Several therapeutic approaches to AKI assayed during last ten years did not showed a great impact in clinical practise. It has been described that EPO exerts cytoprotection against ischemic injury in several tissues. We previously reported that Darbepoetin α (DPO) treatment in mice protected animals from renal ischemic injury (Blanco-Sanchez et al., ASN 2009). Renal structure and function, altered during reperfusion, are restored after DPO treatment since DPO protects proximal tubule cell adhesion. We studied several signalling pathways underlying these effects, in particular cytoskeleton organization regulators.

Methods: We used a mice model of I/R and an *in vitro* model of hypoxia/reoxygenation (H/R) in mouse proximal tubule cells (MCT) where DPO is administered after ischemic insult. LIMK phosphorylation was studied by WB, Rac1, RhoA and PKCa traslocation were observed by immunofluorescence and cell adhesion was estimated by cell impedance studies.

Results: DPO promotes LIMK phosphorylation *in vitro,* in a dose dependent manner. LIMK can be regulated by Rho-GTPAses, thus we determined localization of RhoA and Rac1 in cells submitted to H/R and treated with DPO. Our results indicated that Rac-1 was traslocated to the cell membrane during reoxygenation, indicating Rac1 activation, and this traslocation is promoted by DPO treatment. In contrast, RhoA traslocation is not increased by DPO. Finally, we checked PKCa activity *in vitro* and *in vivo* finding that DPO does not exert any effect on its traslocation. Moreover, *in vitro* use of GO9760, a specific PKCa inhibitor, did not affect cell adhesion.

Conclusions: DPO exhibited a beneficial effect in experimental acute kidney injury activating Rac-1-LIMK pathways, avoiding cytoskeleton reorganizations without PKCa contribution. New targets for DPO in cytoprotection have been identified and they may be relevant for a new therapeutic use of EPO.

TH-PO048

Renal Ischemia Reperfusion Injury Promotes Mid-Term Tubular Senescence

Yoichiro Ikeda, Reiko Inagi, Toshiro Fujita, Masaomi Nangaku. *Division of Nephrology and Endocrinology, University of Tokyo School of Medicine, Japan.*

Background: Renal ischemia reperfusion injury (IRI) leads to acute kidney injury, but the changes have not been studied so much after mid-to-long term of this injury. Levels of serum creatinine and urea nitrogen in this model increased within a day, but recovered some days after injury. And morphologically, most tubular damages repaired after a month or later, but fibrosis was observed depending on the magnitude of ischemia. It is unknown that tubulointerstitial areas other than the fibrotic areas remain normal or not. Here we revealed the enhanced senescence status in renal tubules in outer medulla 15-30days after IRI.

Methods: We evaluated histological changes in rat kidney 1, 5, 15, 30 days after IRI (n=6). Senescence status was also evaluated with senescence-associated β galactosidase (SABG) staining, immunohistochemistry of p21, quantitative PCR of p21, and immunoblot of p53 and p16. Mitochondrial DNA copy number was also calculated by quantitative PCR of mitochondrial DNA of the kidney.

Results: After IRI, repairing tubules were observed within day 5, and the repair was completed and patchy fibroses were observed 15 and 30 days after IRI. Fibrotic areas significantly increased in a time-dependent manner after IRI (0% in control, 12% in IRI-day 30). SABG positive areas in outer medulla also significantly increased with the days after IRI (2% in control, 10% in IRI-day 30). The SABG positive areas were limited mainly in tubules. Tubules were positively stained for p21 from 5 days after IRI until 30 days. Transcript levels of p21 after 30 days of IRI increased by 8 fold to control. Protein levels of p53 and p16 increased from day 5 to day 30 after IRI. Mitochondrial DNA copy number, which is parallel with mitochondrial number, decreased in a time-dependent manner after IRI (100% in control, 70% in IRI-day 30).

Conclusions: Renal IRI promotes mid-term tubular senescence. This alteration may be causative of long-term deterioration of renal function after AKI.

TH-PO049

Hypothermia Attenuates Ischemia-Reperfusion Renal Injury Via Preservation of ERK Phosphorylation

Ki Ryang Na,[1] Dae Eun Choi,[1] Jin Young Jeong,[1] Bo Ra Lee,[1] Hyunjun Ju,[1] Won Ik Jang,[1] Yoon-Kyung Chang,[2] Seong Suk Kim,[3] Kang Wook Lee,[1] Young Tai Shin.[1] *[1]Internal Medicine, Chungnam National Univeristy, Daejeon, Korea; [2]Internal Medicine, Daejeon Saint Mary Hospital, Daejeon, Korea; [3]Internal Medicine, Sun Hospital, Daejeon, Korea.*

Background: It is known that hypothermia during ischemic period is protective against ischemia reperfusion renal injury. Although it is thought that decrease of metabolic demand and free radical generation may involve in hypothermia, the exact explanation is not known. We evaluate whether molecular pathway might be involved in renal protection against IR renal injury at hypothermia (32°C).

Methods: C57Bl/6 mice were divided into six groups; sham operatative mice, 32°C temperature (cold) IR mice, 37°C temperature (warm) IR mice (reperfusion 27 minutes after clamping of both renal artery and vein) and PD98059 with 32°C temperature IR mice, L-NAME with 32°C temperature IR mice. Kidneys were harvested at 10min and 27min after both renal artery ischemia and 24hr after IR injury. Renal ERK, iNOS, eNOS, caspase-3 activation was evaluated by western blot. We examined BUN, serum creatinine (s-Cr), TUNEL and light microscopic findings.

Results: Serum level of BUN and s-Cr in cold IR mice was significantly lower than that of warm IR mice ($p<0.01$). Hypothermia decreased tissue injury score and TUNEL positive cells in IR kidney. pERK and eNOS expression were increased in cold IR mice at ischemic kidney(10min and 27min after both renal artery clamping). Inhibition of p-ERK using PD98059 elevated the levels of BUN and s-Cr in cold IR mice than control cold IR mice. Also it increased tissue injury score and TUNEL positive cells that were decreased in cold IR kidney. However, there were no differences of BUN, s-Cr and tissue injury score between cold IR mice and L-NAME with cold IR mice.

Conclusions: In conclusion, the results of the present study suggest that hypothermia has reno-protective effect on IR injured mice. Renoprotective effect of hypothermia may be involved in ERK phosphorylation

TH-PO050

Hypoxia-Inducible Factor Mediates Hypoxia-Induced Up-Regulation of microRNA miR-21 in Human Renal Epithelial Cells

Xialian Xu,[1,2] Yong Liu,[1] Alison J. Kriegel,[1] Domagoj Mladinov,[1] Xiaoqiang Ding,[2] Mingyu Liang.[1] *[1]Department of Physiology, Medical College of Wisconsin, Milwaukee, WI; [2]Division of Nephrology, Fudan University Zhongshan Hospital, Shanghai, China.*

Background: Hypoxia-inducible factor (HIF) is an important transcriptional regulator in cellular response to hypoxia. We have found that miR-21 contributes to the protective effect of delayed ischemic preconditioning on renal ischemia-reperfusion injury in mice. In the present study, we examined the role of HIF in the regulation of miR-21 expression in primary cultures of human renal epithelial cells (HRE).

Methods: HRE cells were treated with cobalt chloride (300uM for 4h) or hypoxia (2% O_2 for 24h). HIF decoy oligodeoxynucleotides (40nM) were used to block the activity of HIF. miR-21 and PDCD4 levels were analyzed by real-time PCR.

Results: Treatment of HRE cells with cobalt chloride or hypoxia, which are classical inducers of HIF activation, caused significant up-regulation of miR-21 by 183% ± 9% (vs. control, n=6, $P<0.05$) and 168% ± 22% (vs. normoxia, n=6, $P<0.05$), respectively. Blockade of HIF activity with a decoy significantly reduced miR-21 levels in HRE cells treated with cobalt chloride by 42% ± 13%, compared to scrambled oligonucleotides (n=6, $P<0.05$). The up-regulation of miR-21 expression by cobalt chloride was correlated with down-regulation (by 57% ± 8%, $P<0.05$) of mRNA levels of programmed cell death protein 4 (PDCD4), a pro-apoptotic target gene of miR-21. The HIF decoy significantly blunted the down-regulation of PDCD4 ($P<0.05$).

Conclusions: These findings suggest a new mechanism in which HIF activation mediates up-regulation of miR-21. The mechanism may be relevant to renal protection against ischemic injury.

TH-PO051

Predictive Performance of Biomarkers in Acute Kidney Injury (AKI) Using AKI Network (AKIN) Serum Creatinine or Urine Output Criteria

Josee Bouchard,[1] Rakesh Malhotra,[2] Ashita J. Tolwani,[3] Ravindra L. Mehta.[2] *[1]Universite de Montreal, Canada; [2]University of California San Diego; [3]University of Alabama at Birmingham.*

Background: There is limited information on the value of biomarkers to diagnose acute kidney injury (AKI) according to AKIN serum creatinine compared to urine output criteria.

Methods: We conducted a prospective, multicenter observational study to compare the usefulness of urine neutrophil gelatinase–associated lipocalin (NGAL), kidney injury molecule-1 (KIM-1), cystatin C, osteopontin, interleukin-18 (IL-18) and N-acetyl-beta-D-glucosaminidase (NAG) levels to diagnose AKI in 51 critically ill patients using the AKIN urine output and serum creatinine criteria. Biomarkers samples were collected every 12 hours after intensive care unit (ICU) admission for a ≥48 hours and up to 10 days.

Results: The Area Under the Curve (AUC) of the different biomarkers to predict AKI are included in the table:

	AKIN serum creatinine (n=17)*	AKIN urine output alone (n=23)	AKIN urine output and/or serum creatinine (n=40)
urine NGAL	0.598 (0.489-0.707)	0.302 (0.180-0.425)	0.342 (0.230-0.455)
urine KIM-1	0.783 (0.680-0.886)	0.523 (0.388-0.658)	0.601 (0.481-0.720)
urine cystatin C	0.710 (0.619-0.801)	0.432 (0.303-0.561)	0.497 (0.376-0.617)
urine osteopontin	0.630 (0.510-0.749)	0.540 (0.410-0.670)	0.543 (0.422-0.664)
urine IL-18	0.545 (0.423-0.668)	0.684 (0.558-0.810)	0.655 (0.541-0.769)
urine NAG	0.582 (0.431-0.734)	0.708 (0.568-0.847)	0.694 (0.562-0.826)

*11 patients also met urine output criterion

Conclusions: In our cohort, urine NGAL, KIM-1, cystatin C and osteopontin offered their best performance when used to predict AKI according to AKIN serum creatinine criteria while urine IL-18 and NAG were best using AKIN urine output criteria. The different performances of these biomarkers may represent their propensity for distinguishing structural injury vs functional change. These results can be helpful to plan further studies using biomarkers in AKI.

TH-PO052

Long-Term Outcome of the Hemolytic Uremic Syndrome: Observations from a Prospective Multicenter Study Alejandra Rosales,[1] Johannes Hofer,[1] Magdalena Riedl,[1] Therese C. Jungraithmayr,[1] Dorothea Orth-Höller,[3] Burkhard Toenshoff,[2] Reinhard Würzner,[3] Helge Karch.[4] *[1]Department of Pediatrics I, Innsbruck Medical University; [2]University Children's Hospital Heidelberg; [3]Division of Hygiene and Medical Microbiology, Innsbruck Medical University; [4]University of Münster.*

Background: Hemolytic uremic syndrome (HUS) is one of the most common causes of acute renal failure in childhood. The long-term prognosis of patients with HUS is not well delineated to date.

Methods: Over a six-year period, 619 patients under 21 years of age with the clinical diagnosis of HUS were registered in Austria and Germany in the largest prospective multicenter study so far.

Results: An infection with enterohemorrhagic E. coli (EHEC) was confirmed in 79% of cases. 70% of EHEC+ patients totally recovered after 5 years. Long-term sequelae such as proteinuria (18.3%), hypertension (8.6%) and/or decreased GFR (6.8%) were present in 30% of EHEC+ HUS patients and were also observed secondarily after apparent complete recovery. Neurological symptoms dropped from 25% during acute phase to 4% after 1 year, not increasing afterwards. Certain risk factors for presenting HUS after an infection with EHEC such as more virulent serotypes, Shiga toxin 2 production or *eae* positivity were not associated with long-term sequelae. The use of antibiotic therapy in the diarrheal phase was not associated to poor outcome (p=0.95). Plasma treatment was more frequently used in severe cases (presenting hypertension, neurological symptoms and needing dialysis; all p<0.005). In these high-risk EHEC+ HUS patients, the use of plasma therapy was associated with poor long-term outcome at all follow up points (all p< 0.05). Patients presenting long-term problems required dialysis for longer periods than patients who did not present sequelae (median dialysis duration 15 day vs. 9 days; p=0.001).

Conclusions: Because of frequent long-term sequelae (30%), which partly develop after apparent full recovery, follow-up investigations for at least 5 years are recommended. Early identification of the cause of disease is mandatory and has great influence on the selection of the best treatment option.

TH-PO053

Biomarkers of Kidney Injury and Risk of AKI Progression Following Cardiac Surgery Jay L. Koyner, Amit X. Garg, Steven G. Coca, Kyaw Sint, Heather Thiessen Philbrook, Uptal D. Patel, Michael Shlipak, Chirag R. Parikh. *TRIBE AKI Consortium.*

Background: Acute kidney injury (AKI) following cardiac surgery is associated with poor patient outcomes.

Methods: Using samples from the Translational Research Investigating Biomarker Endpoints in AKI (TRIBE AKI) study, we evaluated whether biomarkers of kidney function and injury could forecast the severity of AKI at the time of a clinical diagnosis of AKI. Among 426 individuals who developed at least Acute Kidney Injury Network (AKIN) Stage 1 AKI, serum creatinine (Scr), urinary IL-18, urinary albumin to creatinine ratio (ACR) and urinary and plasma NGAL were measured on the day of AKI diagnosis. The primary end point was progression of AKI, defined by worsening of AKIN Stage (e.g. from Stage 1 to Stage 2) prior to hospital discharge. We categorized each biomarker into quintiles (Q) and grouped them [Low (Q1 & Q2), Intermediate (Q3 & Q 4) and High Q5]. Using multivariable logistic regression, we determined the adjusted odds of AKI progression.

Results: The 50 subjects (11.7%) who progressed beyond their original AKIN Stage needed more dialysis, had longer ICU and hospital stays and higher inpatient mortality (p<0.0001 for all). After adjustment for clinical predictors, when compared to Q1 and Q2, the highest quintile of each biomarker remain associated with AKI progression; [Odds ratio (95% CI)] percent change SCr 3.6 (1.6-8.2), IL-18 3.5(1.5-8.0), ACR 4.6 (1.8-11.7), urine NGAL 2.2 (0.99- 4.7), and plasma NGAL 11.64 (4.2-32.4). After including post operative changes in SCr in the clinical model, IL-18 3.2 (1.4-7.6), ACR 4.0 (1.5-10.4) and plasma NGAL 9.7 (3.4-27.5) were all independently associated with AKI progression. Each biomarker provided improvement in risk classification over the clinical model alone with plasma NGAL performing the best: Net Reclassification Index 0.33 (p<0.0001) and Integrated Discrimination Improvement 0.11 (p<0.0001).

Conclusions: Biomarkers of AKI at the time clinical creatinine rise improve risk stratification and identify patients with newly diagnosed AKI who are at the highest risk for the most severe forms of AKI and the worst patient outcomes.

TH-PO054

Multiple Nephrotoxic Events and Associations with Acute Kidney Injury and Mortality Katherine Rausa, Ladan Golestaneh, Michal L. Melamed. *Nephrology, Albert Einstein College of Medicine - Montefiore Medical Center, Bronx, NY.*

Background: Acute kidney injury (AKI) occurs in 15% of hospitalized patients and is associated with significant morbidity and mortality. We hypothesized that patients would encounter multiple potentially nephrotoxic events, and that those experiencing more events would be at higher risk of AKI and mortality.

Methods: We investigated all patients greater than 18 years old admitted between 2008 and 2010 at Montefiore Medical Center, a tertiary medical center in the Bronx, NY. We examined 16 potentially nephrotoxic exposures including systolic blood pressure < 90 mm Hg, ICD-9 diagnoses of sepsis, and exposure to different medications (e.g. NSAIDs, iv contrast). AKI was defined as a 50% increase in serum creatinine over a pre-admission creatinine. Mortality data was collected via linkage to the Social Security Death Index.

Results: There were 46,754 admissions meeting our eligibility criteria. 2,111 patients developed AKI (5%). Those developing AKI were more likely to have higher Charlson scores (2.3 versus 2.0, p=0.002) ,diabetic complications (5.8% versus 4.4%, p<0.001) or an eGFR that was < 60 ml/min/1.73 m(2) (37% versus 22% p<0.001).

In a multivariable model, NSAID use was associated with a higher risk of AKI (OR 1.58, 95% CI: 1.40, 1.78), and statin use was associated with a lower risk (OR 0.86, 95% CI: 0.77, 0.96).

The median number of potential nephrotoxic events was 2 (IQR 1 to 3). Each additional renal insult increased the multivariable-adjusted odds risk of AKI by 4% (95% CI 1%, 7%, p=0.006).

A total of 4788 patients died. Of those that died, 22% had a prior episode of AKI compared to 11% mortality without previous AKI (p<0.001). AKI was associated with a multi-variable adjusted higher risk of mortality (OR 1.5, 95% CI 1.3, 1.8). Each additional potential nephrotoxic event was associated with a 21% higher odds of mortality (95% CI 19%, 24%) even after adjusting for AKI.

Conclusions: In hospital acquired AKI, a greater number of potential nephrotoxic events is associated with a higher risk of AKI and mortality. Future research should focus on trying to minimize the number of nephrotoxic events in hospitalized patients.

TH-PO055

Acute Kidney Injury Time as a Predictor of Adverse Clinical Outcomes in Critically Ill Hospitalized Patients Guillermo G. Garcia, Jonathan Chavez, Jaime Briseño. *Nephrology, Hospital Civil de Guadalajara, Guadalajara, Mexico.*

Background: Acute kidney injury (AKI) is a complex and frequent complication of many diseases with a high mortality rate. Recent evidence shows that in addition to AKIN staging of severity, the duration of kidney failure is associated to poor outcomes. Prognostic classification systems such as RIFLE and AKIN do not take into account the etiology, duration or recovery time of AKI. Studies in diabetic patients have suggested that the time resolution of AKI is an independent prognostic factor for mortality. We report a similar finding in a population of critically ill hospitalized patients.

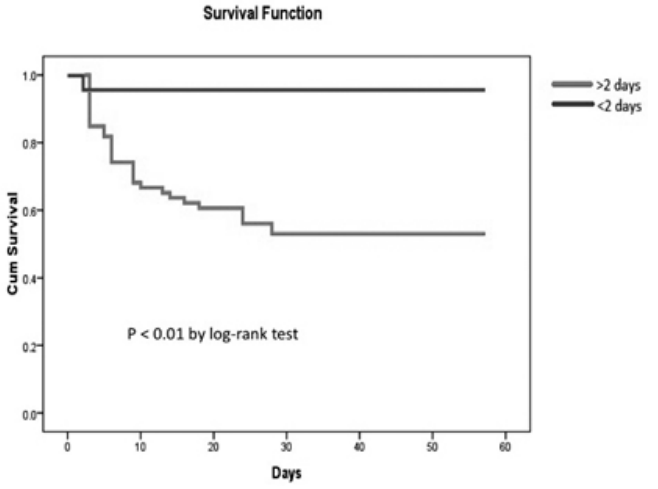
Methods: To determine the association between length of AKI and adverse clinical prognosis, we performed a cohort study in a hospitalized patients at the Hospital Civil de Guadalajara, from January 2009 to January 2010 that met the criteria for AKI by AKIN. Association was determined by Pearson's X2 or t-test depending on the nature of the variable. Correlation of data was analyzed using Pearson's correlation coefficient. Survival was determined by Kaplan-Meier method. A p <0.05 value was considered statistically significant.

Resutls:

Length of AKI and outcomes

	≤ 2 days n=47	> 2 days n=66	RR (IC 95%)	p
Age (y)	47.16±12.32	66.24±17.6		0.01†
Mechanical Ventilation, %	4	27	4.82 (1.27-18.3)	0.02
Vasopressors, %	11	41	3.31 (1.44-7.62)	<0.01
RRT, %	0	12		
Death, %	4	47	9.28 (2.38-36.05)	<0.01
Final S creatinine >1.5 mg/dl	2	52	9.48 (2.26-39.47)	<0.01

†t-test



Conclusions: AKI duration regardless of stratification by AKIN, is independently associated with poor outcomes. It could provide additional prognostic information than the rise of serum creatinine alone. These data needs to be validated by prospective studies of AKI. Finally, the longer duration of renal failure is associated with a risk of a high final serum creatinine. The latter could be a risk factor for CKD in the long term.

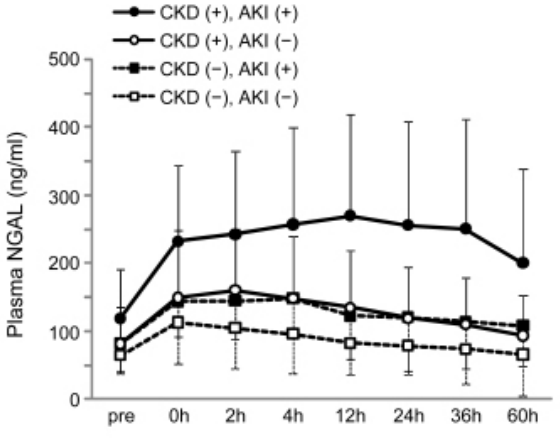
TH-PO056

Plasma Neutrophil Gelatinase-Associated Lipocalin Predicts Acute-on-Chronic Kidney Injury after Adult Cardiac Surgery: A Multicenter Prospective Study Kent Doi,[1] Masahiro Urata,[2] Daisuke Katagiri,[1] Kousuke Negishi,[1] Toshiro Fujita,[1] Seiichiro Murata,[2] Motoyuki Hisagi,[3] Minoru Ono,[3] Eisei Noiri.[1] *[1]Nephrology and Endocrinology, University of Tokyo, Japan; [2]Cardiovascular Surgery, Itabashi Central General Hospital, Japan; [3]Cardiothoracic Surgery, University of Tokyo, Japan.*

Background: Plasma NGAL is a recently developed new AKI biomarker and previous clinical evaluations for plasma NGAL focused on only AKI occurred in patients without CKD. It is unclear whether plasma NGAL can predict acute-on-chronic kidney injury after cardiac surgery, because CKD significantly increases plasma NGAL levels in stable condition and may hamper the prediction of AKI by plasma NGAL.

Methods: The present study prospectively evaluated 143 adult patients who had cardiac surgery at two general hospitals. Plasma NGAL was measured before surgery, at ICU arrival (0 hr), and 2, 4, 12, 24, 36, 60 hr after. AKI was diagnosed by the AKIN criteria. 67 patients (46.9%) were complicated with CKD (eGFR<60) before surgery.

Results: Of 143 patients, 54 patients (37.8%) developed AKI after surgery and a multiple logistic regression analysis revealed that complication of CKD was significantly associated with AKI occurrence. Plasma NGAL before surgery, at 0, 2, 4, 12, 24, and 36 hr after ICU arrival in AKI were significantly higher than non-AKI both in CKD and non-CKD populations (Figure). ROC analysis showed the highest area under the ROC curve with plasma NGAL at 4 hr in CKD and non-CKD populations (CKD 0.738, non-CKD 0.809). The cutoff values of AKI prediction were 158 ng/ml in CKD and 97 ng/ml in non-CKD.



Conclusions: Plasma NGAL measured at pre-surgery and early time points in the post-surgery (4 hr) will predict AKI not only in non-CKD patients but CKD patients when the cutoff values properly determined.

Funding: Government Support - Non-U.S.

TH-PO057

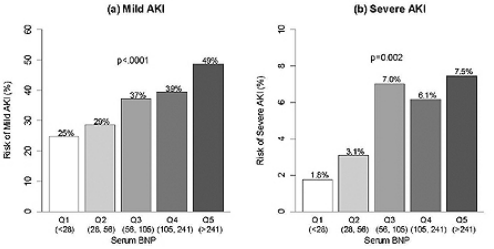
Pre-Operative Serum Brain Natriuretic Peptide and Risk of Acute Kidney Injury after Cardiac Surgery Uptal D. Patel, Amit X. Garg, Harlan M. Krumholz, Michael Shlipak, Steven G. Coca, Kyaw Sint, Heather Thiessen Philbrook, Jay L. Koyner, Madhav Swaminathan, Cary Steven Passik, Chirag R. Parikh. *TRIBE-AKI Consortium.*

Background: Acute kidney injury (AKI) following cardiac surgery is associated with poor outcomes and is difficult to predict. We conducted a prospective study to evaluate whether pre-operative brain natriuretic peptide (BNP) levels predict postoperative AKI among patients undergoing cardiac surgery.

Methods: The TRIBE-AKI Consortium enrolled 1,139 adults undergoing cardiac surgery at six hospitals from 2007-2009, who were selected for high AKI risk. Pre-operative BNP was categorized into quintiles (Fig).

Results: AKI was common using AKI Network definitions; at least mild AKI was a ≥0.3mg/dL or 50% rise in creatinine, n=407 (36%), and severe AKI was either a doubling of creatinine or the requirement of acute renal replacement therapy, n=58 (5.1%). In analyses adjusted for pre-operative characteristics, pre-operative BNP was a strong and independent predictor of mild and severe AKI. Compared with the lowest BNP quintile the highest quintile had significantly higher risk of mild AKI (risk ratio [RR] 1.87; 1.40-2.49) and severe AKI (RR 3.17; 1.06-9.48). After adjustment for clinical predictors, addition of BNP improved the area under the curve to predict mild (0.67 to 0.69, p=0.02) and severe AKI (0.73 to 0.75, p=0.11). Compared with clinical parameters alone, BNP also improved risk prediction of AKI cases into lower and higher risk [net reclassification index was 22.8% (p 0.0003) for mild AKI and 38.0% (p 0.0049) for severe AKI].

Figure. Incidence of Mild AKI (a) and Severe AKI (b) by Quintiles of Pre-operative BNP



AKI defined as during entire hospitalization, at least mild AKI defined as ≥50%, ≥0.3 mg/dL or dialysis; severe AKI defined as ≥100% or dialysis. BNP measured in pg/mL. *Abbreviations:* Acute kidney injury (AKI), brain natriuretic peptide (BNP)

Conclusions: Pre-operative BNP level is a strong independent predictor of post-operative AKI in high-risk patients undergoing cardiac surgery. If confirmed in other types of patients and surgeries, pre-operative BNP levels may improve risk stratification and discrimination among surgical candidates.

Funding: Other NIH Support - The research reported in this article was supported by the American Heart Association Clinical Development award, the grant R01HL-085757 from the National Heart, Lung, and Blood Institute. The study was also supported by CTSA Grant Number UL1 RR024139 from the National Center for Research Resources (NCRR). The plasma BNP assay was donated by Biosite. The granting agencies and Biosite, Inc. did not participate in the protocol development, analysis and interpretation of the results.

TH-PO058

PCreatinine Production Is Reduced in Septic Patients on Continuous Renal Replacement Therapy Pei-Chen Wu,[1] Ravindra L. Mehta.[2] *[1]Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; [2]Medicine, University of California San Diego, San Diego, CA.*

Background: Doi *et al*. reported that sepsis resulted in reduced creatinine production (Pc) in a cecal ligation and puncture of nephrectomized mouse model (*J Am Soc Nephrol*. 2009; 20(6): 1217-21). Reduced Pc may hinder the elevation of serum creatinine (SCr) and thus delay the diagnosis of acute kidney injury (AKI). This finding has not yet been validated in humans.

Methods: This is a retrospective study of patients treated with CVVHDF from June 2008 to August 2010 at an academic medical center. Sepsis was defined as ≥ 2 SIRS signs suspected or known to be caused by a bacterial or fungal infection. All patients had serum and effluent samples analyzed for urea nitrogen and creatinine every 12 hours during therapy. Once patients were in steady state, usually at least 48 hours after CVVHDF initiation, we computed daily Pc using an equation published previously (*Am J Kidney Dis.* 1998; 32**:** 444-453). Pc of the first 4 days in steady state was recorded and analyzed. Every SCr was adjusted with the cumulative daily fluid balance.

Results: There were total 221 treatment-days in steady-state in 65 patients (mean age ± SD was 55.7 ± 14.9 years, 81.5% was male). Pc was lower in septic patients.

Pc (mg/day)	Septic (N = 143)	Non-Septic (N = 31)	p-Value
Mean ± SD	536.0 ± 361.8	710.5 ± 230.4	0.011

During the first 4 days of steady state, Pc remained lower in septic group in spite of antibiotic treatment. Higher Pc was significantly associated with male gender (R = 0.23, p = 0.003), African Americans, non-ESRD CKD, HIV infection (R = 0.27, $p < 0.001$), and higher BW (R = 0.16, p = 0.041), but not with inotropic use (p = 0.268), intubated status (p = 0.069), or age (p = 0.460).

Conclusions: Our results show that creatinine production is altered in septic patients requiring CVVHDF. Additional studies are required to ascertain the mechanisms for reduced creatinine production. Serum creatinine levels may underestimate the severity of renal dysfunction in septic patients requiring dialysis and should be used with caution as a marker of AKI in sepsis.

TH-PO059

The Utility of Fractional Excretion of Sodium and Urea in Advanced Chronic Kidney Disease Tarik Noureldeen, Joel Topf. *Nephrology, St John Hospital and Medical Center, Detroit, MI.*

Background: The most common etiologies of acute renal failure are prerenal azotemia and acute tubular necrosis (ATN). The fractional excretion of sodium (Fe Na) and urea (Fe urea) are often used to differentiate between these two entities. Little is known regarding the effect of advanced chronic kidney disease on the validity of these measurements.

Methods: We retrospectively analyzed 33 patients with acute renal failure. Data elements included Fe Na, Fe urea, baseline creatinine, estimated glomerular filtration rate, age, diuretic use and time from diagnosis to measurement of acute renal failure indices. Patients were classified to be ATN or pre-renal azotemia based on response to therapy, judgment of the treating nephrologist and objective data including ultrasound, microscopic urine analysis and biochemical findings. Data were analyzed using χ^2 and ROC analysis.

Results: Fe urea did not assist in differentiating pre-renal azotemia from ATN. The data shows, however, that as kidney function deteriorates the fractional excretion of sodium increases independent of diuretic use. Using ROC analysis we found that a cut point of 2.4% rather than 1% increased the accuracy of Fe Na in discriminating pre-renal azotemia vs. ATN in our population of patients with advanced chronic kidney with a mean glomerular filtration rate of 39 ml/min.

Conclusions: Fe urea was not a reliable indicator of pre-renal azotemia vs. ATN. However, Fe Na was a useful test using a cut point of 2.4% in our population with advanced kidney disease presenting with acute renal failure.

TH-PO060

Plasma and Urine Neutrophil Gelatinase-Associated Lipocalin (pNGAL and uNGAL) as a Novel Indicator for Early Identifying Critically Ill Acute Kidney Injury (AKI) Patients Who Subsequently Require Replacement Therapy Khajohn Tiranathanagul, Sukgasem Amornsuntorn, Paweena Susantitaphong, Somchai Eiam-Ong. *Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand.*

Background: The high mortality in critically ill AKI patients still persisted despite the advancement in renal replacement therapy (RRT). This might be explained by a delay in initiating RRT caused by using current traditional indications. The levels of pNGAL and uNGAL which were correlated with the degree of tubular cell injury might be utilized as the novel indicator for early initiation of RRT. This prospective cohort study was conducted to determine the accuracy of using pNGAL as a predictor in early identifying the AKI patients who subsequently needed RRT.

Methods: Forty seven critically ill AKI patients with RIFLE stage II-III who did not reach the traditional indications for RRT were enrolled in this study. The pNGAL and other parameters were determined in each patient daily for two consecutive days during the seven day follow-up. The primary endpoint was the RRT initiation according to the traditional indications within the further seven days.

Results: Of forty-seven critically ill AKI patients (31 males) with mean age 63.0±18.1 years had APACHE II score 18.8±7.7. The serum creatinine level at enrollment was 2.35±0.93 mg/dL. pNGAL could predict further RRT requirement with area under ROC 0.813 ($p<0.001$, 95%CI 0.66-0.90). At cut-point of 960 ng/mL provided sensitivity and specificity of 72.2 and 89.6% as well as positive and negative predictive of 81.25 and 83.8%. The uNGAL which could be obtained from thirty-three non-anuric patients were provided slightly lower area under ROC 0.806 ($p=0.005$, 95%CI 0.63-0.98). At cut-point of 2600 ng/mL provided sensitivity and specificity of 54.5 and 90.9% as well as positive and negative predictive of 75.0 and 80.0%.

Conclusions: The pNGAL is an excellent early biomarker for RRT-initiation in critically ill AKI patients. Moreover, the cut-point 960 ng/mL might be used as the early new indicator for early initiation of RRT that might improve patient survival.

TH-PO061

Evaluation of the Effect of Renin Angiotensin Aldosterone System (RAAS) Blockade on Glomerular Hemodynamic and Renal Function in Patients Undergoing Intravenous Contrast Studies Shitij Arora, Prachi Aggarwal, Anubhav Kaul, Ammar Husan, Shivtej Kaushal, Manu Bansal, Ajay Gupta, Ajith K. Chickaballapur Narayanaswamy, Frantz M. Duffoo. *Internal Medicine, Wyckoff Heights Medical Center, Brooklyn, NY.*

Background: Contrast induced nephropathy (CIN) is the third leading cause of acute renal failure. Along with other preventive measures, there are studies suggestive of improvement in renal hemodynamics and function with the use of RAAS blockade. Current recommendations are to withhold ACEI and ARB 48 hours prior to administration of contrast. Our study aims to evaluate the effect of RAAS blockade on renal function in patients with intravenous (IV) contrast exposure.

Methods: In a retrospective study, 239 patients who had received IV contrast and hydration as per protocol were selected. Group I (study group) included patients on RAAS blockade and group II (control group) patients were without RAAS blockade. Creatinine clearance was calculated using the Cockcroft-Gault (C-G) formula before and 48-72 hours after contrast exposure. CIN was defined as 25% or 0.5mg/dl increase in creatinine from baseline.

Results: The prevalence of CIN was 14.6% in patients within the control group versus 17% in the study group, demonstrating no significant difference. Patients in the study group had a mean change in GFR of 2.77 ± 2.11 ml/min compared to 8.24 ± 2.70 ml/min in the control group, demonstrating neither significant difference between the two groups ($p=0.112$) nor any decline in renal function post IV contrast administration. Linear regression analysis identified no major independent variables predicting change in GFR; however, the presence of hypertension had a partial correlation of -0.227 ($p=0.35$) with change in GFR in the study group; whereas age had a partial correlation of -0.180 ($p=0.036$) with change in GFR in the control group.

Conclusions: Our study demonstrates that there was no significant difference in the serum creatinine and GFR post contrast administration with or without RAAS blockade. Therefore, we theorize the fact there is no beneficial effect in withholding RAAS therapy prior to contrast exposure.

TH-PO062

Evaluation of 4 Urinary Biomarkers in Assessing Renal Failure in Cirrhosis. Role for Urinary Neutrophil Gelatinase-Associated Lipocalin Cláudia Fagundes, Marie-Noelle Pepin, Monica Guevara, Elisabet Garcia Lopez, Gregori Casals, Manuel Morales, Gustavo Henrique Santos Pereira, Ezequiel Rodriguez, Elsa Sola, Rogelio Barreto, Wladimiro Jimenez, Vicente Arroyo, Pere Gines. *Hospital Clinic, Barcelona, Spain.*

Background: Urinary biomarkers are useful in assessing acute renal failure and outcome prediction in various clinical settings. There is little information on their relevance in cirrhosis

Methods: Aim: evaluate the usefulness of 4 urinary biomarkers in the differential diagnosis of renal failure and evaluate prognosis in cirrhotic patients. Urinary neutrophil gelatinase-associated lipocalin(uNgal), Kidney injury molecule (KIM1), ß2-microglobulin, and N-Acetyl glucosaminidase(NAG) were measured in 241 patients.

Results: 71 without ascites, 88 with ascites without renal failure, and 82 with ascites and renal failure (defined by serum creatinine > 1.5mg/dL) due to different causes. All biomarker levels, except ß2-microglobulin, were higher in patients with renal failure compared to those without renal failure. Of all biomarkers, uNGAL was the best to discriminate among the different causes of renal failure. Patients with acute tubular necrosis(ATN, n=11) and infection-associated renal failure(n=12) had higher values (324(195-1018) and 284(73-486) ng/mg creatinine, respectively) median (IQR), while patients with hypovolemia-related renal failure(n=16) and hepatorenal syndrome(n=22) had lower values (30(20-59) and 74(43-147) ng/mg creatinine, respectively). Neither KIM-1 nor NAG were able to discriminate between causes of renal failure.ß2-microglobulin was similar in all causes except for higher levels in patients with ATN. Patients with high uNgal (≥44 ng/mg creatinine) had lower 3mth survival compared to patients with low uNgal (67% vs 85%, respectively; $p=0.0038$). A logistic model performed to estimate the effect of biomarkers on 3mth survival showed that only uNgal and the presence of renal failure had independent prognostic value

Conclusions: In conclusion, only uNgal was capable of distinguishing between causes of renal failure and to predict mortality. Measurement of uNgal could be useful in assessing renal failure in cirrhosis.

Funding: Government Support - Non-U.S.

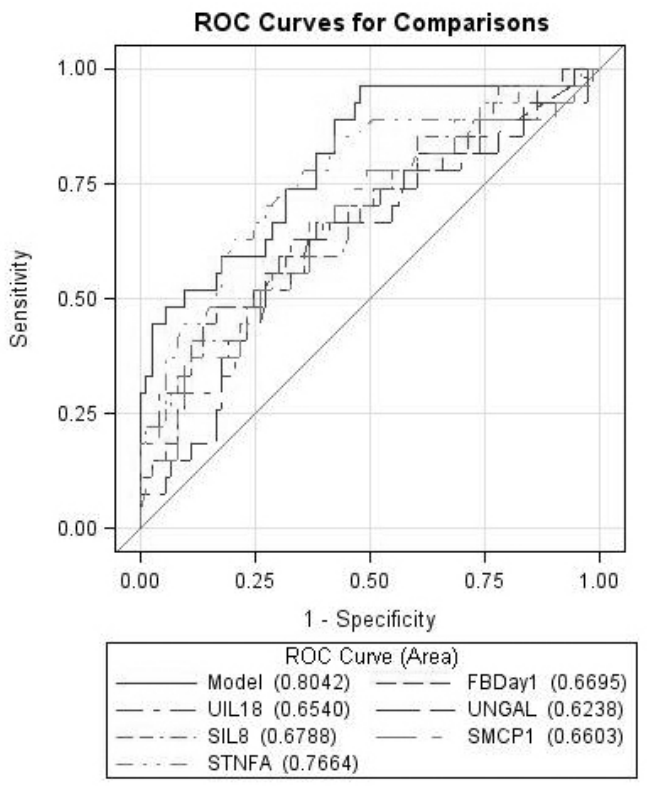
Comparison of Clinical, Biochemical and Biomarker Predictors of Acute Kidney Injury in Cardiac Surgery Ganesh Kambhampati, Mourad Alsabbagh, Gurjit Dhatt, Abdo Asmar, Uma Krishna Pakkivenkata, A. Ahsan Ejaz. *Division of Nephrology, Hypertension and Transplantation, University of Florida, Gainesville, FL.*

Background: We investigated the utility of clinical, biochemical and novel biomarkers to predict acute kidney injury in cardiac surgery.

Methods: Data from a prospective observational study were analyzed to compare the utility of positive fluid balance, serum MCP-1, TNF-alpha, IL-8, urine NGAL and urine IL-18 to predict acute kidney injury as measured by serum creatinine.

Resutls: 100 patients were analyzed. Receiver operating characteristic (ROC) curve analyses were used to determine each test's overall accuracy, as measured by the area under the curve

The diagnostic performance of the various tests as measured from the AUC (95%CI) is as follows- AUC for 24 hr FB was 0.6695 (0.5434-0.7955, $p= 0.004$), uIL-18 was 0.6540 (0.5247 0.7833, $p= 0.0100$), uNGAL was 0.6238 (0.4952-0.7523, $p=0.2114$), sIL-8was 0.6788(0.5554 0.8023, $p= 0.0042$), sMCP1 was 0.6603 (0.5339-0.7867, $p=0.0195$) and sTNF-alpha was 0.7664 (0.6556-0.8771, $p= 0.0004$). At 24hours, positive FB provided similar information as urine NGAL and urine IL18 to predict acute kidney injury. The predictive power of sIL-8, sMCP-1 and sTNF-alpha was better compared to 24hr fluid balance.



Conclusions: Positive FB at 24-hours following cardiac surgery may be an early and simple diagnostic tool to predict AKI. It is as good as the novel biomarkers such as urine NGAL and urine IL18. sIL-8, sMCP-1 and sTNF-alpha were better predictors of AKI compared to positive FB.

TH-PO064

Iodine/eGFR Is a Simple, Useful Indicator for Determining the Safe Contrast Media Dosage To Avoid Contrast-Induced Nephropathy during Coronary Angiography Moon-Jae Kim.[1] *[1]Division of Nephrology & Hypertension, Inha University Hospital, Incheon City, Korea; [2]Division of Nephrology, Department of Internal Medicine, Soonchunhyang University Bucheon Hospital, Bucheon-Si, Korea.*

Background: Contrast-induced nephropathy (CIN) has been commonly defined as a sudden, rapid deterioration in renal status after study of iodinated contrast medium (CM) in the absence of any other causes. To avoid the risk of developing contrast-induced nephropathy (CIN), it has been suggested that patients be subjected to a minimal necessary dose of contrast medium (CM-dose).

Methods: The ratio of CM-dose to eGFR in predicting the risks of CIN was assessed and sought to determine the safe level of CM-dose/eGFR in patients undergoing coronary angiography (CA). We enrolled a total of 226 patients and calculated the ratio of CM-dose using grams of iodine (g-I) to eGFR, thus expressing it as g-I/eGFR. Among the CIN patients, those requiring dialysis were also evaluated.

Results: Overall, there were 16 cases (7.1%) of CIN. On univariate and multivariate regression analysis, g-I/eGFR alone was found to be an independent predictor for CIN (hazard ratio=10.73, p<0.001). In an receiver operating characteristic analysis, fair discrimination for CIN was found at a g-I/eGFR level of 1.42 (C statics=0.867), and at this value, the sensitivity and specificity were 81.3% and 80%, respectively. Of patients (n=51) with g-I/eGFR ≥1.42, 23.6% (13/51) and 7.8% (4/51) developed, while those with g-I/eGFR <1.42 (n=171) had a lower incidences of CIN (1.8%, 2/171, p<0.001).

Conclusions: G-I/eGFR is a simple, useful indicator for determining the safe CM-dose based on the pre-CA eGFR values. Furthermore, g-I/eGFR might have a close relationship with the development of renal failure requiring dialysis as well as CIN not-requiring dialysis.

TH-PO065

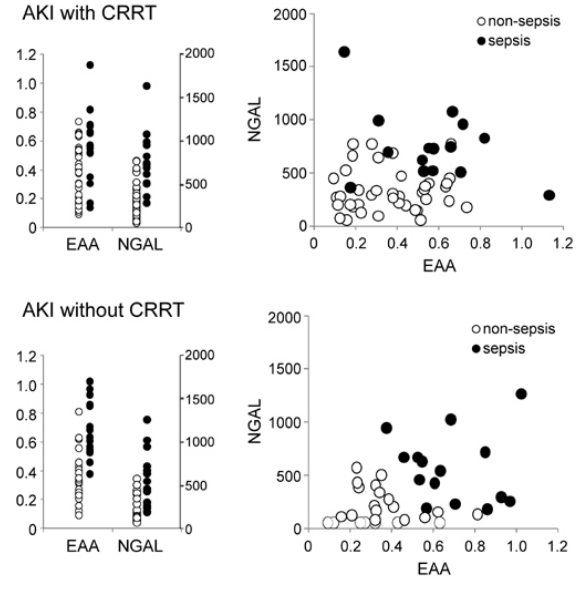
A Biomarker Panel of Plasma Neutrophil Gelatinase-Associated Lipocalin and Endotoxin Activity Assay in Septic Acute Kidney Injury Daisuke Katagiri,[1] Kent Doi,[1] Kousuke Negishi,[1] Takehiro Matsubara,[2] Naoki Yahagi,[2] Toshiro Fujita,[1] Eisei Noiri.[1] *[1]Nephrology and Endocrinology, University of Tokyo, Japan; [2]Critical Care Medicine, University of Tokyo, Japan.*

Background: Plasma NGAL and endotoxin activity assay (EAA), which is a rapid ex vivo diagnostic test using the biological response of patient neutrophils to an immunological complex of endotoxin, are predictive for sepsis. This study evaluated a biomarker panel consisting of these two markers in AKI.

Methods: We evaluated two cohorts of 55 AKI patients who needed CRRT and 40 AKI patients who did not receive CRRT in ICU. Plasma NGAL and endotoxin activity (EA) in whole blood were measured using the Triage NGAL Device (Alere, USA) and the EAA system (Spectral Diagnostics, Canada).

Results: Plasma NGAL and EA values in septic AKI patients were significantly higher than in the other AKI patients (Table). A scatter diagram of plasma NGAL and EAA demonstrated the combination of these biomarkers enhanced the accuracy over each biomarker (Figure). The combination can detect sepsis in AKI with high AUC-ROC values both in the CRRT and the non-CRRT group (AUC-ROC 0.92 and 0.98, respectively).

		AKI with RRT		AKI without RRT	
		Sepsis (n=15)	Non-sepsis (n=40)	Sepsis (n=15)	Non-sepsis (n=25)
NGAL (ng/ml)	0 hr	748±333*	334±199	568±324*	194±158
	24 hr	705±230*	333±186		
	48 hr	652±255*	313±156		
EAA	0 hr	0.56±0.25*	0.37±0.19	0.69±0.20*	0.34±0.17
	24 hr	0.48±0.20*	0.30±0.16		
	48 hr	0.48±0.31*	0.26±0.13		



Conclusions: Sepsis and septic AKI are extremely complex and have multiple pathophysiological mechanisms. Therefore, combinations of biomarkers reflecting different pathways might be necessary for these complicated conditions. The present report describes a new biomarker panel of septic AKI with plasma NGAL (AKI and neutrophil activation) and EAA (endotoxemia), which is a useful diagnostic tool for septic AKI.

Funding: Government Support - Non-U.S.

Plasmapheresis Rescue Therapy in Progressive ANCA-Associated Systemic Vasculitis Anoek A.E. Joode,de, Johannes S. Sanders, Coen A. Stegeman. *Internal Medicine/Nephrology, University Medical Center Groningen, Groningen, Netherlands.*

Background: We evaluated outcome of 25 patients with ANCA-associated vasculitis (AAV) with progressive disease despite treatment with cyclophosphamide and high dose steroids treated with additional plasmapheresis (PPh). Outcome was compared with 47 matched-controls (C).

Methods: Patients newly diagnosed with AAV from January 1990 until December 2009 were evaluated (n= 272). Patients were included when PPh was not started at diagnosis but was added for progressive disease during the course of initial standard therapy (n=25). We selected controls matched for BVAS and creatinine at diagnosis. Primary endpoint was eGFR or death.

Results: Plasmapheresis was added in 25 patients at 22 (range 2 to 51) days after start of therapy. In 20 of 25 patients a rise in serum creatinine > 30% despite induction therapy led to PPh. In 14, renal biopsy showed ongoing disease-activity, in 6 the decision was

made on clinical ground. Progressive pulmonary disease and progressive necrotic lesions were other indications.

Renal involvement was present in all patients; in the PPh- group, 5 patients temporarily needed dialysis,1 patient needed dialysis in the C-group. At 6 months and 5 years, 2 and 5 patients had died in both groups (RR 1.29; 95% CI 0.37-4.75).

At baseline mean eGFR was 46 ml/min/1.73m2 in PPh-group versus 43 in C-group, while at start of PPh eGFR was 25 ml/min/1.73 m2. At 6 months mean eGFR in the PPh-group had significantly improved (p<0.0001) and was 49 and 50 respectively in both groups. During long-term follow-up there was no difference in renal function between the groups at 12 months and 5 years.

Relapses occurred in 13 patients in PPh-group and in 20 in C-group (p=0.44). However, time to first relapse differed significantly between the PPh- and C- group (p=0.0084).

Conclusions: Patients with progressive disease despite induction therapy with cyclophosphamide and steroids in whom plasmapheresis was added, had significant improvement in renal function and similar long-term outcome as matched controls. Research is needed to determine factors that identify patients early in the course of therapy in whom plasmapheresis should be instituted.

TH-PO067

Proteinuria Independently Associate with the Development of Acute Kidney Injury in Intensive Care Unit Fen Jiang, Xinling Liang, Wei Shi, Yuan Han Chen, Wenjian Wang, Penghua Hu. *Division of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, GuangDong Province, China.*

Background: Proteinuria as a very important factor for the increasing mortality of chronic kidney injury(CKD),but the role of proteinuria for acute kidney injury(AKI) is still unclear. The purpose for the study is to analyze the relationship between proteinuria and AKI in adute Intensive care unit(ICU).

Methods: From October 2009 to July 2010 patients(≥18 years) who in ICU were enrolled and retrospectivelyevaluated .All patients were free of chronic dialysis for three months before admission and both of the levels of serum creatinine and urinary protein in the first 48 hours after admitted in ICU were recorded. Both RIFLE and AKIN criteria were employed for the diagnosis and staging of AKI in ICU.Dip-stick was used to detect proteinuria,andcoverthreecategory:no-proteinuria,mild-proteiuriaand heavy-proteinuria by the level of urine protein .

Results: Five hundred and twenty-four patients were included in this study. Ninety-nine patients were diagnosied as AKI by RIFLE criteria,while the number increased to one hundred and five according to AKIN criteria One hunderd and fifty-eight patients had proteinuria. Fifty-one patients with proteinuria developed to AKI by RIFLE criteria, while more seventeen patients with proteinuria had AKI according to AKIN criteria. The AKI patients had a different level of urinary protein compared with the no-AKI patients according to the AKIN criteria (P<0.05). Multiple logistic regression analysis suggested that heavy proteinuria was a risk factor for AKI in ICU regardless by RIFLE (odds ratio [OR] 3.478; 95%CI 1.544-7.839; p=0.003) or AKIN criteria(OR 3.589; 95%CI 1.679-7.668; p=0.001).Whlie proteinuria showed no direct effect on hospital mortality for AKI patients (OR1.451; 95%CI 0.906-2.322; p=0.121).

Conclusions: Proteinuria appears to be a key factor for the development of AKI in ICU, and the dip sticks maybe an effective method for early diagnosis of AKI.

TH-PO068

Utility of Urinary HGF for Differential Diagnosis of Acute Kidney Injury in Cirrhotic Patients Won K. Han, John R. Fontanilla. *Medicine/Nephrology, Thomas Jefferson University Hospital, Philadelphia, PA.*

Background: To test the utility of a single measurement of urinary biomarkers in distinguishing acute tubular injury from prerenal azotemia (PRA), a prospective study was conducted in 90 cirrhotic patients with or without acute kidney injury (AKI) at a single institution.

Methods: Urine samples were collected within 48 hours from initial admission and/or at the time of renal consultation during hospitalization (63 AKI and 27 non-AKI). Urine concentrations of hepatocyte growth factor (HGF), kidney injury molecule-1 (KIM-1), and *N*-acetyl-b-D-glucosaminidase (NAG) were measured. AKI was defined as a greater than 50% increase in serum creatinine from baseline. Patients were followed during their hospital course through clinical and laboratory data to determine etiology of AKI.

Results: Patients with acute tubular injury (n=21) had a significantly elevated median urinary HGF level compared with PRA and non-AKI groups (n=48) (1.81 ng/mg urine creatinine, P<0.0001). At a cutoff value of 0.88 ng/mg urine creatinine, sensitivity and specificity of HGF for detecting acute tubular injury were 0.86 (95% CI, 0.64 to 0.97) and 0.83 (95% CI, 0.70 to 0.93), respectively. These values were superior to those for KIM-1 and NAG. Urinary KIM-1 was not a sensitive biomarker for distinguishing AKI in this study.

Conclusions: In conclusion, our results demonstrate that a single measurement of urinary HGF helps to distinguish acute tubular injury from normal function and PRA in patients with cirrhosis.

TH-PO069

Urinary Cystatin C as a Marker for Tubular Dysfunction Associated with Sepsis in Patients with Severe Sepsis and Septic Shock Francisco Ortuño Anderiz,[1] Alberto Barrientos,[2] Antonio Cruceyra,[3] Gonzalo Navarro,[1] Marta Cubells,[1] Carmen Gijon,[1] Enrique Morales,[1] Antonio Blesa,[1] Miguel Angel Gonzalez,[1] Fernando Martinez,[1] Sonia Vazquez,[1] Miguel Sanchez Garcia.[1] *[1]Critical Care, Hospital Clinico San Carlos, Madrid, Spain; [2]Nephrology, Hospital Clinico San Carlos, Madrid, Spain; [3]Biochemistry, Hospital Clinico San Carlos, Madrid, St. Helena.*

Background: Preliminary data in heterogeneous patient groups suggest that urinary cystatin C (UCysC) increases as a function of renal tubular injury, independent of glomerular filtration rate. We prospectively studied the correlation of UCysC levels with renal function and the need for renal replacement therapy (RRT) in patients presenting to our ICU with severe sepsis or septic shock (SS/SS).

Methods: Consecutive patients with SS/SS were included if plasma creatinine (Pcr) < 2 mg/dl. We also studied a control group of simultaneous patients admitted without SS/SS. Cases were followed for 5 days infno acute kidney injury (AKI) ensued and until recovery of renal function or for a maximum of 30 days. We used univariate analysis with Student's t-test or non-parametric tests as appropriate.

Results: We enrolled 53 cases, 50 (84.7%) in septic shock, and 44 controls, 9 (20.5%) in non-septic shock, over 20 months. Age, sex and admission group were similar between groups, 80% required mechanical ventilation. Mean APACHE II (16.5±6.1 *vs* 12.8±7.7, p=0.01) and SOFA scores (7.8±3.1 *vs* 3.5±2.7, p=0.001) and plasma creatinine (Pcr) (1.3±0.4 *vs* 1±0.4, p=0.001) were significantly higher in cases compared to controls, although ICU mortality was similar, 19 (35.8%) *vs* 10 (22.7%) (NS), respectively. UCysC was significantly increased in all septic patients on ICU admission compared to the non-septic control group (6.17±9.92 vs. 0.76±2.82 mg/creatinine in gram, p=0.001), irrespective of renal function, however (Pcr 1.3±0.3 mg/dl, urea 68±39.6 mg/dl, urea fractional excretion 32±15%). This difference was maintained in patients of both groups with normal renal function (5.89 ± 10.4 vs 0.82 ± 2.93 mg/g, p = 0.003). There was a poor association between plasma CysC and UCysC (r = 0.164, p = 0.022).

Conclusions: Our findings confirm that a high urinary excretion of CysC may occur, independent of renal function or subsequent development of AKI, and suggest a role for UCysC as an early marker of sepsis. In the subset of patients with SS/SS, in particular, elevated UCysC concentrations may be an early and sensitive sign of "septic tubular dysfunction", undetectable by routine laboratory tests.

TH-PO070

Early Detection of Acute Kidney Injury (AKI) in Severe Sepsis and Septic Shock. The Role of Plasma Cystatin C Francisco Ortuño Anderiz,[1] Alberto Barrientos,[2] Antonio Cruceyra,[3] Gonzalo Navarro,[1] Marta Cubells,[1] Carmen Gijon,[1] Enrique Morales,[1] Antonio Blesa,[1] Miguel Angel Gonzalez,[1] Fernando Martinez,[1] Sonia Vazquez,[1] Miguel Sanchez Garcia.[1] *[1]Critical Care, Hospital Clinico San Carlos, Madrid, Spain; [2]Nephrology, Hospital Clinico San Carlos, Madrid, Spain; [3]Biochemistry, Hospital Clinico San Carlos, Madrid, Spain.*

Background: Cystatin C (CysC) has been studied as a biomarker for early detection of acute kidney injury (AKI) in heterogeneous clinical settings. In the critically ill patient AKI is most frequently associated with sepsis. Given the prognostic implication of septic AKI, we studied the potential of plasma CysC (PCysC) for early prediction in patients with severe sepsis or septic shock (SS/SS).

Methods: We included patients with SS/SS and ICU-admission plasma creatinine (Pcr) < 2 mg/dl. RIFLE criteria, blood chemistry and PCysC measurements were obtained daily. Cases were followed for 5 days if no AKI ensued or until recovery of renal function (follow-up censored at 30 days). We used Student's t-test or non-parametric tests as appropriate, and logistic regression model to assess the association between CysC and mortality, including variables with p <0.05 on bivariate analysis.

Results: 50 cases were enrolled over 20 months. PCysC concentrations were determined in 232 plasma samples. 29 were male, 21 female, mean age was 61.3±16.7, 56% were medical, 40% surgical and 4% trauma patients, 44 (88%) were in septic shock and 40 (80%) required mechanical ventilation. Mean APACHE II score was 16.3±6 and SOFA score 7.5±3. ICU mortality was 36%. AKI occurred in 20 (40%) patients (RIFLE criteria: R 8, I 5, F 7), with 7 (14%) requiring renal replacement therapy (RRT). PCysC on day 1 was significantly higher in patients later developing RIFLE-F (2.11 ± 1.27 mg/L) than in those who did not (1,15 ± 0,57) (p=0,041), while Pcr was not (1.48 ± 0.44 mg/dl *vs* 1.28 ± 0.32; p=0,2). PCysC had an area-under-ROC curve of 0.76 for AKI and of 0.82 for RIFLE-F. The PCysC-Pcr correlation was r = 0.246 (p=0.003). PCysC level on day 1 was associated with 30-day survival (1.1 ± 0.07 mg/L *vs* 1.5 ± 0.6 in non-survivors, p = 0.009), OR 0.167, 95% CI 0.033-0.851 (p=0.031,). Values > 1 mg/L on day 1 were associated with decreased ICU and hospital-survival (p=0.01 and 0.001, respectively).

Conclusions: In patients with SS/SS PCysC rises earlier than Pcr and predicts severe renal dysfunction, need for RRT and death in patients admitted to ICU for SS/SS.

TH-PO071

The Value of Urine LFABP Level as a New Biomarker after Cardiac Surgery in Adults Liu Shang, Miaolin Che, Renhua Lu, Zhaohui Ni, Jia Qi Qian, Yucheng Yan. *Renal Division, Renji Hospital,Shanghai Jiaotong University School of Medicine, Shanghai, China.*

Background: Acute kidney injury (AKI) is one of the most common and serious complications of cardiac surgery associated with substantial morbidity and mortality. A good biomarker can help early detection of AKI and perhaps, interventions. This study is to evaluate the value of uL-FABP of predicting the development and the prognosis of AKI following cardiac surgery.

Methods: By examining serum creatinine and uL-FABP corrected by urine creatinine at preoperative, 0h and 2h postoperative time points, we compared the differences between AKI and non-AKI groups, complete and uncomplete renal recovery groups, patient survival and death groups. ROC curves were used to evaluate their predictive accuracy.

Results: As a Result, We found the levels of urine L-FABP were both significantly higher in AKI patients compared to non-AKI at 0h and 2h after cardiac surgery (7247.68 vs 174.43 ng/mg and 3478.99 vs 118.71 ng/mg,both P<0.001),and the AUCs at 0h and 2h postoperative to predict AKI and AKI stage II-III were 0.844,0.818 and 0.832,0.805 respectively. Patients with uncomplete renal recovery at discharge had higher levels of urine L-FABP at 2h postoperative(12051.90 vs 2870.11ng/mg,P<0.05),and it showed good predictive values for detecting renal prognosis with the AUCs of 0.775. Similar results were found the level of uL-FABP at the two time points postoperation might be useful in predicting hospital mortality (14093.98 vs 292.11ng/mg and 7528.33 vs 200.68ng/mg,both P<0.05),with the AUCs of 0.893 and 0.873.

Conclusions: In conclusion, urine L-FABP which increased at the early stage after cardiac surgery might be an alternative biomarker for the early detection of AKI and composite end points.

TH-PO072

A Comparison of Clinical Outcomes between the Selective Cytopheretic Device and Case-Matched Historical Controls from the PICARD Database Ravindra L. Mehta,[1] Alexander S. Yevzlin,[2] James A. Tumlin,[3] Lakhmir S. Chawla,[4] Ashita J. Tolwani,[5] John J. Dillon,[6] Kevin W. Finkel,[7] J. Ricardo Da Silva,[8] David Humes.[9] *[1]UCSD; [2]University of Wisconsin; [3]SERRI; [4]George Washington University; [5]University of Alabama; [6]University of Texas; [7]Cytopherx, Inc.; [8]University of Michigan.*

Background: Dialysis-dependent acute kidney injury (AKI) is a significant complication in ICU patients and is associated with hospital mortality rates between 50-60%. A recent pilot study of the Selective Cytopheretic Device (SCD), a novel cartridge that is able to selectively bind and deactivate neutrophils as an adjunct to CRRT therapy, showed improvement in kidney function and mortality rate.

Methods: We conducted a retrospective analysis of the PICARD database and the SCD pilot study, comparing mortality and dialysis dependence in both groups. 35 subjects from PICARD were matched to 35 subjects from the SCD pilot study using the diagnosis of AKI, CRRT therapy, and SOFA score. Logistic regression was used to compare mortality as the dependent variable and age, SOFA score, and presence of SCD therapy as independent variables.

Results: Mean age did not differ significantly between the two groups: 60.2 vs. 56.9 in PICARD vs. SCD, respectively (t-test, p=0.54). Mean SOFA score did not differ significantly between the two groups: 12.38 vs. 11.3 in PICARD vs. SCD, respectively (t-test, p=0.80). The in-hospital mortality rate was 62.9% in PICARD vs. 31.4% 60 day mortality in SCD (chi square, p=0.008). Logistic regression revealed odds ratio of death to be 1.02 (CI 0.9804 to 1.0535, p=0.38) for age, 1.22 (1.0205 to 1.4635, p=0.03) for SOFA score, and .28 (0.0974 to 0.7971, p=0.02) for SCD therapy. 7.7% (1/13) of survivors from the PICARD group were dialysis dependent at day 60 vs. 0% (0/24) from the SCD group (t-test, p=0.12).

Conclusions: The management of critically ill patients with AKI may have changed since the PICARD study. Nevertheless, this study suggests that SCD therapy is associated with significant improvement in mortality in critically ill patients with AKI receiving CRRT therapy.

TH-PO073

Renal Function Follow-Up Evaluation Using Cystatin C in Neonates Prenatally Diagnosed for Congenital Anomalies of the Kidney and Urinary Tract Paloma Parvex,[1] Christophe Combescure,[2] Jacques Birraux,[3] Alexandra Wilhelm-Bals,[1] Eric Girardin.[1] *[1]Pediatric Nephrology, Universitiy Hospital, Geneva, Switzerland; [2]Clinical Epidemiology, University Hospital, Geneva, Switzerland; [3]Pediatric Surgery, Universitiy Hospital, Geneva, Switzerland.*

Background: Congenital abnormalities of the kidney and urinary tract (CAKUT) account for 20% of all significant anomalies detected on prenatal ultrasound. Despite this frequent occurrence, no reliable method to measure renal function (RF) is validated in neonates. Cystatin C (CysC) has been proposed to be an accurate renal marker for the neonatal period. The *aims* of this study were to assess long term RF prospectively from birth in neonates prenatally diagnosed with CAKUT.

Methods: Among 47 neonates with CAKUT diagnosed prenatally, 21 pts with severe kidney malformation (KM) had renal function follow-up with the measure of CysC and creatinine on the same day. Median follow-up was of 235 (137-739) days. KM were repartee as follow: 12 pelvic dilatations >10mm; 5 hypo-dysplastic or ectopic kidney (2 withTCF2 mutation); 3 posterior urethral valves; 1 uretherocele; 1 megabladder. 6 pts underwent interventions. One of pts was start on dialyses and exclude from analyses. Factors influencing CysC were analyzed performing a linear mixed model to take account of the repeated measures.

Results: In our 20 pts, CysC decreases rapidly in the first month (M) (16.2%) p<0.001), slower between 1 M and 1 year (y) (3.9% per month, p<0.001) and stabilizes after 1 y (0.2% per month, p=0.83). CysC was significantly increased in pts with bilateral KM compared to pts with unilateral KM (p=0.02) and in TCF2 pts (p=0.002). The decrease of the CysC over time was less pronounced in pts with bilateral KM (p=0.04) and in TCF2 pts (p<0.001), these pts therefore presenting a worse prognosis in RF. Creatinine decrease with age, rapidly the first M (p=0.0001) and then stabilized.

Conclusions: Renal function follow-up in pts diagnosed with CAKUT, using CysC showed a worse prognosis over time in pts with bilateral kidney malformation or TCF2 mutation.

TH-PO074

Early Urinary Levels of Cell Death Markers Predict AKI after Cardiopulmonary Bypass Michael R. Bennett, Nuntawan Piyaphanee, Catherine D. Krawczeski, Prasad Devarajan. *Cincinnati Children's Hospital Medical Center.*

Background: Acute kidney injury (AKI) occurs commonly after cardiopulmonary bypass (CPB), often as a result of ischemia reperfusion injury (IRI). Serum creatinine (SCr) is an inadequate marker for AKI. Studies of animal models of IRI have demonstrated that the apoptotic pathway plays a significant role in the development of AKI. We set out to determine if apoptotic markers could be detected in the urine of patients undergoing CPB to determine if they could predict AKI, and to help pinpoint the timing of kidney cell death in these patients.

Methods: Urine samples were obtained prospectively before and at intervals after CPB in 391 patients. AKI was defined as a ≥50% SCr rise within 48h of CPB. For this pilot - we selected 35 patients, 18 of which developed AKI, and measured caspace-cleaved cytokeratin 18 (M-30, a marker of apoptosis), as well as total cytokeratin (M-65, total cell death) using commercially available ELISAs. Measurements were made at 0, 4 and 12 hours post CPB. These markers have recently been found to be elevated in urine of patients with chronic kidney disease.

Results: Defined by pRIFLE criteria, the AKI group consisted of R (n=8), I (n=8) and F (n=2). AKI and non-AKI groups did not differ significantly by race, sex or length of CPB. The median age of the AKI group (0.5 yrs IQR=0.4-1.8) was significantly lower than the non-AKI group (p=0.001; 7 yrs IQR=4.7-13.6). M30 levels were not significantly different between AKI and non-AKI groups at any time point. Markers of total cell death, however, were markedly increased at 4 hours post CPB in the AKI group (median 1467 U/L, IQR=429-3060) vs the non-AKI group (p=0.003; 158 U/L, IQR=62-507). Total cell death levels did not differ at 0 or 12 hours post CPB.

Conclusions: While urinary levels of the apoptotic marker M30 were not different between AKI and non-AKI groups, total cell death was greatly increased at as little as 4 hours post CPB. This indicates that significant cellular damage occurs very early after CPB and makes early diagnosis and intervention imperative. This data also indicates that urinary markers of cell death may be valuable early biomarkers of AKI.

TH-PO075

Efficacy of Urine Neutrophil Gelatinase-Associated Lipocalin as a Predictive Marker for Acute Kidney Injury in Different Patient Populations Kianoush Banaei-Kashani,[1] Laura N. Hanson,[2] Otto Stephan Schwarz Vignolo,[3] John C. Lieske.[1] *[1]Nephrology and Hypertesnion, Mayo Clinic, Rochester, MN; [2]Mayo Validation Support Services, Mayo Clinic, Rochester, MN; [3]Pulmonary Critical Care, Atlanta Pulmonary Group/Critical Care of Atlanta, Atlanta, GA.*

Background: Increased urine NGAL (uNGAL) excretion is a promising biomarker to predict subsequent Acute Kidney Injury (AKI). In this study we evaluated its utility among specific patient populations within a single center prospective cohort at a tertiary medical center.

Methods: All ICU admissions were screened and high risk patients with at least 30 minutes of hypotension were evaluated for possible inclusion. All patients who met RIFLE criteria at enrollment were excluded. After consent, 204 patients were followed for seven days or until hospital discharge for AKI as defined using RIFLE criteria (I or greater). ROC curves were prepared to assess uNGAL at ICU admission as a predictor of subsequent AKI, stratified by patient characteristics.

Results: Baseline serum creatinine was an overall poor predictor of AKI. uNGAL performed reasonably well in medical but not surgical ICU patients (AUC 0.71 vs 0.53, Table 1). When stratified by diagnosis (Table 2), in a univariate analysis uNGAL performed better in patients with congestive heart failure and sepsis (AUC 0.70 and 0.66) as compared to those with diabetes (AUC 0.53).

Conclusions: uNGAL performance as a biomarker of AKI varies between patient groups. When assessing biomarkers for detection of AKI, it is important to take into account the diagnoses, type of patients and comorbidities of the patients being evaluate.

		AUROC (p-Value)	
	Number of patients	Serum Creatinine	uNGAL
All ICU patients	204	0.55 (0.4)	0.62 (0.027)
Medical ICU	73	0.60 (0.2)	0.71 (0.008)
Surgical ICU	80	0.59 (0.2)	0.53 (0.7)
Congestive heart failure	34	0.46 (0.4)	0.70 (0.053)
Diabetes	41	0.68 (0.1)	0.53 (0.7)

TH-PO076

Comparison of the Recognition and Management of Early Acute Kidney Injury Compared to Delayed AKI in Hospitalised Patients Hannah R. Wilson, Jennifer R. Joslin, Amy Irvine, Scott R. Henderson, Hannah E. Wilkinson, Bernard Freudenthal, Deepasree Bangaru-Raju, Thomas Sanctuary, Mark T. Kinirons, Maria Ostermann. *Guy's and St Thomas' NHS Foundation Trust.*

Background: Acute kidney injury (AKI) is associated with significant morbidity, mortality and healthcare costs. In 2009, a National Confidential Enquiry into Patient Outcomes and Death (NCEPOD) report identified significant failings in the recognition and management of hospitalised patients with AKI and issued guidance on early management. We aimed to explore whether patients with AKI on admission to hospital were managed better than patients who developed AKI whilst in hospital.

Methods: During a 7 day period in May 2011, electronic patient records of all level 1 medical and surgical patients in a London teaching hospital were screened. Medical notes of patients with AKI as defined by the KDIGO criteria were reviewed by doctors independent from the treating team to assess compliance with NCEPOD recommendations.

Results: 50 patients had AKI on admission (52% male; mean age 73 years; 66% medical, 34% surgical). 94% had risk factors for AKI (median 2 [range 0-5]). 24 patients developed AKI in hospital (50% male; mean age 72 years; 58% medical, 42% surgical). 92% had risk factors for AKI (median 2 [0-4]).

AKI was recognised on the first day of onset in 50% of both cohorts and more often in medical specialties. When recognised, early management strategies were initiated in <50% of patients (Table 1).

Management of Early Versus Late AKI

	AKI on admission to hospital (1st day AKI)	AKI developed as inpatient (1st day AKI)
Recognised by team	50%	50%
Documented plan if recognised	72%	100%
Senior review if recognised	84%	92%
Fluid balance chart complete	20%	33%
Clinical fluid status assessed	42%	42%
Fluids given if hypovolaemic	75%	67%
Nephrotoxic drugs stopped	36%	10%
Urine dipstick if recognised	52%	50%

Conclusions: Despite increasing publicity, AKI is poorly recognised both when present on admission and when developed as an inpatient. Even when recognised, adherence with NCEPOD recommendations is poor. More awareness and better tools are necessary to recognise AKI early and guide management.

TH-PO077

In Acute Kidney Injury; NGAL in Contrast to Procalcitonin Is a Biomarker of Injury Irrespective of Sepsis; Whereas the Latter of Sepsis Regardless of Injury Ahmed G. Adam,[1] Amr Soliman,[1] Muhamad Alsawy,[3] Ahmed Aglaan.[2] *[1]Internal Medicine - Nephrology, Dialysis, Transplantation Unit, Faculty of Medicine; [2]ER, Faculty of Medicine, University of Alexandria; [3]Clinical Pathology, Faculty of Medicine.*

Background: Acute Kidney Injury is associated with a mortality rate which varies according to definition that of severe injury (RIFLE category F) approximates 50%. Although, it has been argued that patients die with AKI rather than of AKI and that AKI is simply an expression of illness severity, consistent and strong evidence supports the notion that AKI has an independent impact on outcome.

Methods: This study was done to illustrate the incidence of septic and non septic acute renal failure in patients admitted to Alexandria main university hospitals. 170 patients were included over 6 months. NGAL and Procalcitonin beside serum creatinine was measured.

Results: 3 main categories of diagnosis: AKI group 57.7% , Acute on top of CKD group 25.4%, GN group 16.9%. According to prognosis 35.2% Died, 25.4% CKD, 16.9% ESRD, 16.9%Recovered, 5.6%Unknown. As regard sepsis, 42.25% of the patients were septic while 57.75% of the patients were non septic. Urinary NGAL was significantly higher in the patient group. There was no statistically significant difference between the level of uNGAL in the different groups of diagnosis. There was no statistically significant difference between the level of uNGAL in the different groups of prognosis. Serum Procalcitonin was significantly higher in the septic patients than that in the non septic patients. The serum Procalcitonin level was the highest in the group of septic patients who died..

Conclusions: The correlation between serum creatinine and serum procalcitonin (r = 0.108, p = 0.649) is weak and insignificant preserving the diagnostic capability of procalcitonin as a marker of sepsis even in the setting of AKI , also the correlation between uNGAL and serum procalcitonin (r = 0.094, p = 0.655) is weak and of no statistical significance. From the fact that procalcitonin is a well established marker for sepsis and the weak correlation between urinary NGAL and serum Procalcitonin we can conclude that uNGAL is indeed unique for AKI regardless of sepsis.

TH-PO078

Novel Biomarkers of AKI: Multicenter Prospective Cohort Study Kianoush Banaei-Kashani,[3] Daniel Laskowitz,[1] Ludwig Wagner,[2] Aysegul Ilhan,[2] John C. Lieske.[3] *[1]Department of Medicine, Duke University School of Medicine, Durham, NC; [2]Department of Medicine, University of Vienna, Austria; [3]Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Novel biomarkers are needed for early diagnosis of AKI to allow early initiation of new and established therapeutic options.

Methods: All ICU admissions in three tertiary medical centers were screened, and high risk patients with at least 30 minutes of hypotension, or sepsis were evaluated for possible inclusion. All patients who met RIFLE criteria at enrollment were excluded. After consent, 342 patients were followed for seven days or until hospital discharge for AKI as defined using RIFLE criteria (I or F). Blood and urine samples were collected at enrollment, 12 and 24 hour and then daily up to 7 days to measure serum creatinine, other known AKI biomarkers, and more than 140 novel biomarker candidates.

Results: Urinary NGAL predicted AKI 24 hours before RIFLE criteria with a concordance statistic (C-stat) of 0.72, which was the best among known AKI biomarkers. However, by multivariate logistic regression analysis identified a panel of 2 urine biomarkers that performed even better (C-stat of 0.8). The addition of uNGAL to the 2 biomarker panel did not improve the model.

Conclusions: We have identified two novel biomarkers that together predict AKI stages I and F 24 hours before RIFLE criteria. These biomarkers need to be validated in a second prospective cohort, and in other patient populations.Multivariate logistic regression analysis

	p-Value	C Stat

Epidemiology of Acute Kidney Injury in Newborns Born with Perinatal Depression David J. Askenazi, Hayden Hundley, Angela Montesanti, Pushkar Pawar, Namasivayam Ambalavanan. *Pediatrics, University of Alabama at Birmingham, AL.*

Background: Infants born with perinatal depression are at risk for AKI. Based on studies conducted in the 1990's, the incidence of AKI in infants with 5 minute Apgar scores ≤ 6 is reported between 40-60%. Fluid overload has been shown to be independently associated with poor outcomes in pediatric and adult populations. This association has not been described in neonates.

Methods: Between February 2010 and May 2011, we screened 146 infants of which 58 met inclusion criteria (birth weight (wt) > 2000 grams, gestational age > 34 weeks and 5 minute Apgar ≤ 7) consented to the study. Serum creatinine (SCr) was measured daily for the first 4 days of life. AKI was defined as a rise in SCr of > 0.3 mg/dl or persistent SCr above 1.5 mg/dl.

Results: AKI occurred in 9 / 58 (15.6%) subjects. AKI was associated with higher birth wt, male infants, lower Apgar scores at 5 minutes, lower cord pH, and intubation in the delivery room. Infants of mothers with pre-eclampsia were protected against AKI. Fluid status, [(birth wt / wt at day of life 3) – 1]*100, during the first 3 days of life differed between those with AKI (net gain of 12.0 ± 14.4%) an those without AKI (net loss of 2.8 ± 7.0) (p<0.001). Survival was worse in those with AKI [7/9 (77.8%)] as all infants without AKI survived (p<0.02).

Conclusions: The incidence of AKI in this tertiary hospital was lower than those reported previously, possibly due to improved care of infants shortly after birth. Risk factors for AKI in this population are described. Infants with AKI are more likely to die and have a net positive fluid balance over the first few days of life which could be a potentially modifiable variable in the course of AKI.

TH-PO080

Impact of Radiocontrast-Induced Nephropathy Following Coronary Angiography in Hospitalized Patients Javier Neyra,[1] Sunay Shah,[1] James E. Novak.[2] *[1]Department of Internal Medicine, Henry Ford Hospital, Detroit, MI; [2]Division of Nephrology and Hypertension, Henry Ford Hospital, Detroit, MI.*

Background: Radiocontrast-induced nephropathy (RCIN) is the third leading cause of hospital-acquired acute kidney injury in the United States and is associated with unfavorable outcomes.

Methods: We retrospectively utilized a population-based linked administrative database of hospitalized patients who underwent coronary angiography from January 2008 through December 2009 to analyze in-hospital and long-term outcomes associated with RCIN. RCIN was defined as an increase in serum creatinine > 25% from baseline, absolute increase in serum creatinine ≥ 0.5 mg/dL, or decrease in estimated glomerular filtration rate (eGFR) ≥ 25% within 72 hours after contrast exposure. Patients with end-stage kidney disease and those exposed to other contrast medium or acute dialysis before the procedure were excluded.

Results: A total of 1,168 patients were included in the study. RCIN occurred in 82 of 382 patients (17.7%) with eGFR < 60 mL/min/1.73m² and in 108 of 596 patients (15.3%) with eGFR ≥ 60 mL/min/1.73m². In the group with lower eGFR, the in-hospital mortality for those who developed RCIN was 12.2% (10/82) vs. 2.9% (11/382) for those without RCIN (P = 0.0002) but the 1-year mortality was not significantly different (6.9% [5/72] vs. 6.2% [23/371], P = 0.812). Additionally, patients with lower eGFR had more frequent irreversible increase in serum creatinine (> 0.5 mg/dL) and outpatient dialysis initiation when they developed RCIN (23.6% [17/72] vs. 10.8% [40/371], P = 0.0029 and 5.6% [4/72] vs. 1.1% [4/371], P = 0.009, mean follow up of 16 months, respectively). In the group with higher eGFR, both in-hospital and 1-year mortality were significantly higher in those who developed RCIN (5.6% [6/108] vs. 0.5% [3/596], P < 0.0001 and 8.8% [9/102] vs. 2.5% [15/593], P = 0.0013, respectively).

Conclusions: The occurrence of RCIN following coronary angiography in hospitalized patients is associated with higher in-hospital mortality independently of baseline eGFR. Patients with impaired baseline eGFR who develop RCIN tend to have more frequent long-term kidney function deterioration and subsequent dialysis initiation.

TH-PO081

Quality of Care and Outcomes in Hospitalized Patients with Acute Kidney Injury (AKI) Emmett D. Ratigan,[1] Ravindra L. Mehta.[1] *[1]Medicine, University of California San Diego, San Diego, CA; [2]Medicine, University of California San Diego, San Diego, CA.*

Background: AKI is common in hospitalized patients and is associated with adverse outcomes including in-hospital mortality, development of chronic kidney disease (CKD), progression to end-stage renal disease (ESRD), and long-term mortality. A recent cohort from the UK (NCEPOD; 2009) demonstrated significant lapses in quality of care (QC) for hospitalized patients with AKI. We assessed the QC in a consecutive cohort of 100 hospitalized patients discharged with an ICD-9 coded diagnosis of AKI. We hypothesized that the recognition and management of AKI would be variable and influenced by time of development of AKI.

Methods: We reviewed charts and extracted data on timing of AKI, rapidity of diagnosis, nephrotoxic administration, management of AKI complications, and in-hospital outcome. All survivors were reviewed to one year post-discharge for incidence of nephrotoxic exposures, re-hospitalizations, repeat AKI, development of ESRD, and all-cause mortality. Patients were characterized having AKI at admission (AKIADMIT, n= 75) and those developing it during the hospitalization (AKIPOST, n=25).

Results: All patients were verified to have AKI by the acute AKIN and RIFLE serum creatinine criteria. Amongst the cohort, the mean age was 59, 65% were male, 47% had hypertension, 43% CKD, and 35% diabetes. QC parameters were different for AKIADMIT vs AKIPOST.

	Delayed Diagnosis	Nephrotoxin Administration	Prompt Treatment of Hyperkalemia	Length of Stay (Days)	In-hospital Mortality
AKIADMIT	9%	49%	82%	10.2	12%
AKIPOST	40%	76%	50%	22.6	36%
P value	<0.01	0.04	0.04	<0.01	<0.01

Of the 82 patients surviving the index admission, variable follow-up occurred in 66, and at one year post-discharge, repeat AKI was 33%, readmission 53%, ESRD 3%, and all-cause mortality 15%. At six years post-discharge, 63% of the initial 100 patient cohort had died

Conclusions: Despite advances in the understanding of AKI, in-hospital management for AKI has room for improvement. The timing and quality of follow-up care of AKI survivors is highly variable and may contribute to the lack of recognition and development of CKD post AKI.

TH-PO082

The Risk Factors and Impact of AKI Following Stroke Rupesh Raina, Charbel A. Salem, Martin J. Schreiber, Sevag Demirjian. *Nephrology, Cleveland Clinic Foundation, Cleveland, OH.*

Background: Acute Kidney Injury (AKI) has been shown to be an independent predictor of long-term mortality and cardiovascular outcomes following acute stroke. However, these studies were not based on strict definitions of AKI and the risk factors of AKI in this population were not assessed before.

Methods: We ran a retrospective analysis on 628 patients who were admitted with their first ever acute stroke. AKI was defined as a rise in Cr of ≥0.3 mg/dl or a percent increase of ≥50% from baseline or a reduction in Urine output as defined by AKIN criteria. Hospital discharge disposition was dichotomized to poor (death, nursing facility, ventilator weaning facility) or good (acute rehabilitation or home). Multivariable models were used to assess the correlation between outcomes (AKI, persistence of AKI) and the risk factors (age, gender, race, HTN, CKD, DM, CAD, HPL). Using chi-square test, outcomes were compared for patients with AKI and those with no AKI.

Results: The mean age was 63, and 50.6 % were females. 90 patients developed AKI and seventy-one patients had persistent AKI. The results of the regression analysis for AKI on admission are shown in the table.

Factor	OR (p-value)	95% Confidence Limits
Male	4.01 (<0.001)	2.2 to 7.5
Hypertension	3.09 (0.005)	1.4 to 6.8
CKD	42.98 (<0.001)	20.2 to 89.9

The risk factors for AKI persistence were very similar with CKD remaining the leading risk factor. 32 patients with AKI (36%) were discharged to acute rehab, while 32 (36%) were discharged to home, and 9 (10%) died. Patients with persistent AKI on discharge were 2.4 times more likely to have a poor discharge disposition than those without AKI (p<0.01)

Conclusions: Using a strict definition of AKI following stroke, we identified the risk factors behind the development and persistence of AKI. We also showed a significant impact of AKI on short-term outcomes. CKD was the most significant risk factor for both AKI on admission and its persistence on discharge, followed by HTN and age. Patients with these risk factors and acute stroke should be monitored closely and renal protective measures should be applied.

TH-PO083

Acute Kidney Injury Is Associated with Increased Odds of CKD and Death among Patients Who Undergo Revascularization for Peripheral Vascular Disease Pradeep Arora,[1,2] Pooja Mahajan,[1] Nauman Tahir,[1] James W. Lohr,[1,2] Nader Nader,[3] Hassan H. Dosluoglu.[4] *[1]Department of Medicine, SUNY at Buffalo, Buffalo, NY; [2]Divison of Nephrology, VAMC, Buffalo, NY; [3]Department of Anesthesiology, VAMC, Buffalo, NY; [4]Department of Surgery, VAMC, Buffalo, NY.*

Background: Several databases, sub-analyses of existing studies and single center studies have shown that acute kidney injury (AKI) is associated with development of chronic kidney disease (CKD) in long term follow up. However, the impact of AKI on long term survival has not been studied. We determined the impact of AKI on survival in peripheral vascular disease patients undergoing vascular procedures/surgery.

Methods: Study population included 740 peripheral vascular disease patients undergoing lower extremity revascularization as the primary procedure at VA Western New York Healthcare System between January 1, 2001 and December 31, 2009. All data were collected prospectively. Kaplan Meier and Cox proportional analyses were performed to study the impact of AKI on survival. Logistic regression was performed to evaluate the impact of AKI on development of CKD.

Results: 70 patients developed AKI as defined by AKIN criteria. 39 of these patients had died by the last follow up date. 188 of 670 patients died among those who did not have AKI. Results of Cox regression are shown in the table. 149 patients developed CKD by the last follow up date(analysis was done after excluding pre procedure CKD patients). 50% of those patients who had AKI subsequently developed CKD, compared to 22% who did not have AKI. Logistic regression results are shown in the table.

Cox Proportional Hazards Method and Logistic Regression Analyses

Parameter	Hazard ratio	Odds ratio
Age	1.05 (1.04-1.07)	3.01 (2.51-3.63)
AKI	2.24 (1.58-3.20)	3.20 (1.75-5.84)
CAD	1.61 (1.21-2.15)	1.51 (1.03-2.22)
DM	1.34 (1.02-1.76)	1.88 (1.29-2.74)
HTN	0.94 (0.69-1.26)	0.84 (1.29-2.74)
Pre Creatinine	1.49 (1.08-2.07)	
Type of surgery	1.00 (0.75-1.32)	

Hazard ratio is for survival model and OR is for development of CKD

Conclusions: AKI following vascular interventions in peripheral vascular disease patients are associated with a significant increase in CKD and mortality.

TH-PO084

Long-Term Risk of Mortality for Acute Kidney Injury in HIV-Infected Patients Mário Raimundo, Maria Joao Melo, Antonio Gomes da Costa, Jose António Lopes. *Nephrology and Renal Transplantation, Hospital de Santa Maria- CHLN, Lisbon, Portugal.*

Background: Acute kidney injury (AKI) is a common complication in human immunodeficiency virus (HIV)-infected patients and it is associated with increased in-hospital mortality. The impact of AKI on long-term mortality of hospitalized HIV-infected patients has however not been extensively addressed. The aim of the present study was therefore to evaluate the influence of AKI on long-term mortality of HIV-infected patients who are hospitalized and survive to acute episode.

Methods: Three hundred ninety nine HIV-infected patients (mean age: 41 years; 265 male; 288 caucasian) who were hospitalized in the Department of Infectious Diseases of our Hospital (Hospital de Santa Maria, Lisboa, Portugal) between January 2005 and December 2007 and were discharged alive were studied retrospectively. Acute kidney injury was defined according to Risk Injury Failure Loss End-stage kidney disease (RIFLE) classification based on serum creatinine. The outcome measure was mortality at 2 years of follow-up. Kaplan-Meier method was used to determine survival curves and log-rank test was employed to evaluate statistical differences between the survival curves. Cox regression method was used to determine independent predictors of 2-year mortality. Risk factors were assessed with univariate analysis, and variables that were statistically significant (P<0.05) in the univariate analysis were included in the multivariate analysis.

Results: Patients who had AKI within the hospitalization (N=59) had higher 2-year mortality than those patients who did not develop AKI (N=340) (22% versus 10.9%; log-rank P=0.008; unadjusted hazard ratio 2.3, 95% confidence interval 1.2 to 4.3, P=0.01). After

adjusting for other covariates with prognostic importance, AKI still remained associated with increased 2-year mortality (adjusted hazard ratio 2.1, 95% confidence interval 1.1 to 3.9, *P*=0.024).

Conclusions: Acute kidney injury was independently associated with increased 2-year mortality of hospitalized HIV-infected patients who were discharged alive.

TH-PO085

Validation of the Acute Kidney Injury Risk Index for Patients Undergoing General Surgery at the Philippine General Hospital Rommel P. Bataclan. *Section of Nephrology, Dept. of Medicine, Philippine General Hospital, Manila, Philippines.*

Background: Post-operative Acute Kidney Injury (AKI) is one of the most common cause of hospital morbidities, and an independent risk factor for in-hospital mortality. A General Surgery AKI Risk Index can be used to stratify pre-operatively, patients at high risk to develop AKI post-operatively.

Methods: This is a validation study of an AKI Risk Index Score. All adult patients who underwent general surgery at the Philippine General Hospital from June 1, 2010 to May 31, 2011 will be included. They will grouped into a particular Risk Group depending on the presence of certain risk factors. It will then be determined if AKI happened in the patient using the RIFLE Criteria. Based on the incidence of AKI in the Risk Groups, Sensitivity, Specificity, Positive & Negative Predictive Values will be computed. A Receiver Operating Curve (ROC) will also be constructed.

Results: 824 general surgeries were included. Frequency of AKI among patients who underwent general surgery was 3.4% (n=28) and the mortality rate of patients with AKI was 17%(n=5), with overall mortality of 0.6%. Based on the scoring system, patients under Class I (presence of 0-2 risk factors), Class II (3 risk factors), Class III (4 risk factors), Class IV (5 risk factors) and Class V (6-8 risk factors) and were associated with risk of developing AKI of 0.05%, 0.10%, 2.91%, 3.88% and 6.15% respectively. Overall, sensitivity and specificity were 82.2% and 51.1% respectively. Discrimination test by receiving operating characteristics (ROC) curve showed an area under the curve (AUC) of 0.731.

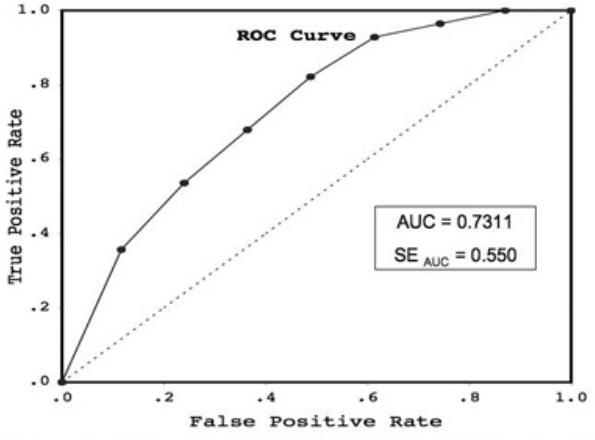

Figure 1. ROC curve for the prediction of AKI after General Surgery using the Scoring System by Kheterpal et. al

Conclusions: The General Surgery Acute Kidney Injury Risk Index can be used in our local setting to predict AKI among stable chronic kidney disease patients after general surgery.

TH-PO086

Risk Factors and Outcomes of Acute Kidney Injury (AKI) Associated with Outpatient Parenteral Anti-Infective Therapy (OPAT) Charuhas V. Thakar,[1, 2] Sashi Ameneni,[1] Loretta Simbartl,[2] Stephen Kralovic,[1, 2] George Smulian.[1, 2] *[1]Internal Medicine, University of Cincinnati, OH; [2]Medical Service, Cincinnati VA, Cincinnati, OH.*

Background: Treatment of infections in hospitalized patients frequently requires OPAT. Incidence, risk factors and outcomes of AKI associated with OPAT are not well studied.

Methods: We studied 244 acute care discharges between 2006 and 09 requiring OPAT in a VA healthcare system. We examined the association of patient characteristics and drug exposure with AKI (defined by AKIN criteria). In patients recieving vancomycin (Vanc), average trough levels before meeting AKI criteria were used for analysis. Chi-square, t-tests and logistic regression was used for analysis.

Results: Sample was 99% male, with mean age of 61 [standard deviation (SD) 10.9], and mean baseline creatinine of 1.1 mg/dl (SD 0.5). 71% of cases received Vanc based regimen. 111/244 (45%) patients developed AKI (Stages I – 63%, II – 12%, III – 25%); of whom 10 required dialysis. Of the AKI cases 63% met AKI criteria after discharge. Older age (p = 0.014), high Vanc trough (p = 0.0002), high baseline creatinine (p = 0.005), diabetes (p = 0.001), ICU admission (p < 0.0001), proteinuria (p = 0.004) diuretic use (p = 0.02), and aminoglycoside use (0.004) were associated with AKI by univariate analysis. In a multivariate model, ICU stay [odds ratio (OR): 4.1, 95% confidence interval (CI), 1.1 – 14.1], proteinuria (OR: 3.3, 95% CI, 1.1 – 10.2), and Vanc trough levels (OR per unit increase: 1.08, 95% CI, 1.01 – 1.15) were associated with AKI. In a separate model that included patients recieving Vanc based regimens, an average trough of ≥ 20 vs < 20 was associated with AKI (OR 3.8, 95% CI, 1.6 - 8.9)

Re-admission at 90-days was 57% in AKI vs 38% in no AKI group (p = 0.003). Creatinine at 2-years was higher in AKI versus no AKI group [1.54 (SD, 0.92) versus 1.09 (SD, 0.72) respectively]. In 7/10 patients dialysis was deemed permanent.

Conclusions: AKI is a significant and under-recognized complication associated with OPAT, frequently occurs after discharge, and may result in irreversible damage. Risk stratification and monitoring of these patients is needed to reduce kidney toxicity.

Funding: Veterans Administration Support

TH-PO087

Determination of Renal Function Improves Significantly the Prediction of Survival in Palliative Care Patients Scott O. Grebe,[1] Oliver Schmalz,[1] Ruediger Trebst,[1] Thomas F. Mueller,[2] Manfred F. Weber.[3] *[1]Medizinische Klinik 1, HELIOS-Klinikum Wuppertal, Univ. of Witten/Herdecke, Wuppertal, Germany; [2]Div. of Nephrology and Transpl. Immunology, Univ. of Alberta, Edmonton, AB, Canada; [3]Medizinische Klinik 1, Klinikum Köln-Merheim, Univ. of Witten/Herdecke, Cologne, Germany.*

Background: One of the most important challenges in palliative care medicine is an exact estimation of patient survival. For this purpose various clinical scoring systems such as the palliative prognostic score (PPS) are used. Despite impaired renal function is a known risk factor for patient outcome in general, its influence on the survival of palliative care patients has not yet been studied.

Methods: All patients admitted to our palliative care unit in 2008 were included in the study. The relation between renal function and survival was prospectively analyzed and compared to currently used scores. Besides clinical routine measurements serum creatinine (S-Crea), the eGFR using the simplified MDRD-formula, dipstick proteinuria (U-Prot), the Karnofsky-Index (KI) and the PPS were determined at admission. In addition to descriptive statistics the influence of these parameters on survival was tested using Kaplan-Meier estimates and Wilcoxon scores. In order to identify the most important prognostic factors a multiple regression analysis based on the Cox proportional hazards model was performed.

Results: Overall 308 patients (mean age=70.2±12.9 years, 58.4% male, mean survival 45±96 days) were included. The mean values of S-Crea and eGFR were x=1.5±1.6 mg/dl and x=86.2±65.8 ml/min, resp. The percentage of patients with significant U-Prot was 35.2%. The median KI and PPS were 40% (Range:10-90%) and 30-50% (Range:<30%->70%), resp. In the univariate survival analysis only age (p=0.0016), KI (p<0.0001), PPS (p<0.0001), S-Crea (p=0.0074) and eGFR (p=0.0213) showed a significant association with patient outcome. The strongest predictors in the age-adjusted stepwise multiple regression model were PPS (p<0.0001), KI (p=0.0002) and eGFR (p=0.0053). None of the other parameters met the 0.05 significance level.

Conclusions: The determination of the eGFR adds significantly to a reliable prediction of survival in palliative care patients.

TH-PO088

Identification of Potentialy Controllable Riskfactors for AKI after Cardiac Surgery Sanne Vellinga, Gert A. Verpooten, Karin Janssen van Doorn. *Nephrology-Hypertenson, University Hospital Antwerp, Edegem, Antwerp, Belgium.*

Background: Acute kidney injury (AKI) in the immediate postoperative period after successful cardiac surgery was proven to be of major influence on morbidity and mortality. Our study investigates the potential prognostic value of perioperative packed-cell transfusion on the development of AKI.

Methods: Retroscpectively, we reviewed 565 patients who underwent coronary artery bypass grafting (CABG). In the perioperative period, following parameters were examined: demographic characteristics, diabetes, history of congestive heartfailure, urgency of surgery, lowest perioperative hematocrit, intra- and postoperative packed cell transfusion, serumcreatinine (at admission, every 24h minimum 48h during 7 days and after 8 weeks), eGFR (MDRD-formula), postoperative administration of furosemide, duration of cardiopulmonary bypass and crossclamping and need for renal replacement therapy. AKI was defined by the AKIN-criteria.

Results: A total of 83 patients (14,7%) evolved to AKI in the post-operative period. Two patients needed renal replacement therapy in the first seven days and both died. AKI was associated with age (mean 66,5y ± 9,4 No-AKI vs 69,6y ± 10,2 AKI p<0,05), pre-existing renal function (mean eGFR 86,7 ± 51,8 mL/min/1,73m² vs 70,6 ± 24,0 mL/min/1,73m², p<0,01), urgency of surgery (5,3% vs 13,4%, p=0,03), both intra- and postoperative packed cell transfusion (9,9% intra-operative transfusion vs 25,3%, p<0,01 and 16,3% postoperative transfusion vs 42,2%, p<0,01) and postoperative administration of furosemide (60,0% vs 84,3%, p<0,01). In multivariate analysis pre-operative creatinine (p<0,01), postoperative packed cell transfusion (p<0,01) and postoperative administration of furosemide (p<0,01) remained significant.

Conclusions: Our study clearly shows that pre-existing renal disease, postoperative packed cell transfusion and postoperative administration of furosemide are important risk factors for the development of AKI after CABG. As two of these factors are easily controllable our results advocate further exploration of these factors and their potential to reduce AKI related morbidity.

TH-PO089

Improved Survival in Patients Requiring Dialysis after Pediatric Hematopoietic Cell Transplantation (HCT) Jurat S. Rajpal, Rachel I. Vogel, Clifford E. Kashtan, Angela R. Smith. *University of Minnesota, Minneapolis, MN.*

Background: HCT, a critical therapy for many children with life threatening illnesses, is associated with a substantial risk of acute kidney injury (AKI) requiring dialysis. The purpose of this study is to compare survival in these patients in two decades, 1990-1999 and 2000-2009.

Methods: 1427 patients <21 years old who had their first HCT at the University of Minnesota between January 1990 and December 2009 were reviewed using the center database. Kaplan-Meier estimates and 95% confidence intervals for 100 days and 1 year post-HCT overall survival (OS) are reported by dialysis group and treatment decade (1990-1999 vs. 2000-2009) and compared using the log-rank test.

Results: The incidence of AKI requiring dialysis was not significantly different between the two cohorts (1990-99: n=65/778, 8.35% vs. 2000-09: n=62/649, 9.55%, p = 0.42).

Proportion of patients surviving by decade based on need for dialysis

	100 days post transplant			1 year post transplant		
	Dialysis	No dialysis	p value	Dialysis	No dialysis	p value
1990-1999	0.18 (0.10, 0.29)	0.85 (0.82, 0.87)	<0.0001	0.11 (0.05, 0.20)	0.64 (0.61, 0.68)	<0.0001
2000-2009	0.42 (0.30, 0.54)	0.92 (0.89, 0.94)	<0.0001	0.23 (0.13, 0.34)	0.79 (0.76, 0.82)	<0.0001

Patients requiring dialysis in the 2000-2009 cohort had significantly higher survival than those in the 1990-1999 cohort at both +100 days and at 1 year (+100 days: 42% vs. 18%, p = 0.0090; 1 year: 23% vs. 11%, p = 0.0010).

Conclusions: AKI requiring dialysis is an important complication of pediatric HCT that has shown no change in incidence over the last two decades. Survival has significantly improved at both 100 days and 1 year post-transplant, regardless of dialysis status. Despite a recent reduction in mortality for those who require dialysis, mortality remains significantly higher than for patients who do not need dialysis.

Uni- and multi-variate analyses of risk factors for AKI requiring dialysis in pediatric HCT recipients are in progress. Development of effective preventative strategies will likely lead to reduced mortality in this patient population.

TH-PO090

The SAFE-T Consortium: A Collaborative Approach for the Qualification of Novel Kidney Biomarkers with the Regulatory Authorities Joe Keenan,[1] Ralf Schindler,[3] Patrick T. Murray.[4] *[1]SAFE-T Consortium, Argutus Medical Ltd, Dublin, Ireland; [2]SAFE-T Consortium, AstraZeneca, Wilmington, DW; [3]SAFE-T Consortium, Charite, Berlin, Germany; [4]SAFE-T Consortium, UCD Mater, Dublin, Ireland; [5]SAFE-T Consortium, Hoffman La Roche, Basel, Switzerland.*

Background: Drug-induced kidney injury is not an uncommon adverse event in drug development. The greatest issue is the late identification of Acute Kidney Injury due to the current standards (i.e. serum creatinine (sCr) and blood urea nitrogen (BUN)) which are delayed indicators of injury and may not be significantly changed until 2/3 of the kidneys function has already been lost. Over the last three years there has been progress with preclinical qualification processes for kidney biomarkers (PSTC and HESI qualification with EMA and FDA). These landmark qualifications mean that drug companies may now use certain novel preclinical markers for real decision making within their qualification context.

Methods: The principal objective of this new project is to collect and generate sufficient clinical data from a number or candidate kidney biomarkers, that will provide convincing evidence for the health authorities to endorse these biomarkers for the detection and monitoring of drug induced kidney injuries in specific clinical situations. 22 kidney biomarker have been selected and are being analytically validated by a number of technologies (bead-based, electrochemiluminescence, LC/MS, and standard microtitre ELISA) by the participants of the consortium. A number of patient clinical studies have been started in key areas (Cisplatin toxicity, Contrast induced nephropathy and acute GN) and these samples will provide the basis for the exploratory phase of the project.

Results: SAFE-T have gained regulatory feedback on this project and are actively recruiting patients and collecting samples. More than half of the 22 kidney markers have been analytically validated through a series of internal bar meetings and this list will be displayed.

Conclusions: A SAFE-T status update including regulatory strategy, assay validation and study designs will be provided.

TH-PO091

Safety and Tolerability of a Novel siRNA To Prevent Acute Kidney Injury in Cardiac Surgery: Initial Results from a Double-Blind, First-in-Man Study Sevag Demirjian,[1] Gorav Gorav Ailawadi,[2] Michel Burnier,[3] Dani Bitran,[4] Shuli Silberman,[4] Stanton Shernan,[5] Victor Baum,[2] Lakhmir S. Chawla.[6] *[1]Nephrology, Cleveland Clinic, Cleveland, OH; [2]Surgery and Anesthesiology, University of Virginia, Charlottesville, VA; [3]Nephrology, Hôpitaux Univérsitaire de Lausanne, Lausanne, Switzerland; [4]Shaare Zedek Medical Center, Jerusalem, Israel; [5]Anesthesiology, Brigham & Womens' Hospital, Boston, MA; [6]Anesthesiology, George Washington University, Washington, DC.*

Background: Acute kidney injury (AKI) results in appreciable mortality after cardiac surgery and is most commonly due to ischemia-reperfusion injury (IRI). IRI is thought to lead to renal dysfunction via p53-mediated apoptosis. An analogue of QPI-1002, a synthetic small interfering RNA (siRNA), has been shown in preclinical models to temporarily silence p53 gene expression and attenuate renal dysfunction. We report safety results from a first-in-man (FIM) study of QPI-1002 in pts undergoing cardiac surgery under cardiopulmonary bypass (CPB).

Methods: A total of 16 pts (4/cohort) at variable risk for AKI were enrolled at 6 centers globally. Pts were randomized 3:1 to receive an IV bolus injection of either placebo or QPI-1002, 0.5, 1.5, 5.0, or 10.0 mg/kg in dose escalation fashion 4 hrs post-CPB. The primary outcomes measured were safety and tolerability [dose-limiting toxicities (DLTs)] through 30 days post-dose.

Results: No DLTs were observed. Initial safety data included 107 adverse events (AEs); 90(84.1%) were severity grades 1-2 [scale: 1 (mild)-5]. Those most frequently reported were hypotension, anemia, pleural effusion, atrial fibrillation and leukocytosis (in 43.8%,37.5%,37.5%,31.3%,and 31.3%, resp.). No relationship between dose and any AE was seen.

Conclusions: In this FIM Phase I dose escalation study, there were no reported DLTs or evidence of a dose-dependent change in the number or severity of AEs. The observed AE profile appeared consistent with that expected for cardiac surgical patients post-operatively. The safety data support continued evaluation of QPI-1002 for prophylaxis of AKI in pts undergoing cardiac surgery.

(Unblinded data will be available at presentation.)

Age-and-Gender-Adjusted eGFR To Estimate Baseline Creatinine for RIFLE Classification Simone Spoorenberg,[1] Sabine Meijvis,[1] Gerjan Navis,[2] Douwe Hedde Biesma,[1] Jan Grutters,[1] Willem Jan W. Bos.[1] *[1]St Antonius Hospital; [2]University Medical Centre Groningen.*

Background: Risk, Injury, Failure, Loss and End-Stage kidney failure (RIFLE) criteria, based on rise in serum creatinine compared to baseline value, are used to classify acute kidney injury. If baseline creatinine is not available, ADQI recommends to estimate it, using a fixed eGFR of 75 mL/min/1.73m2. As GFR declines over age, we investigated RIFLE classification using age-and-gender-adjusted eGFR.

Methods: In 271 patients with community-acquired pneumonia, we compared RIFLE classification using either fixed eGFR of 75 mL/min (creatinine-75) or age-and-gender-adjusted eGFR (creatinine-age), with RIFLE classification based on actual baseline creatinine value(creatinine-actual).

Results: Use of creatinine-75 resulted in RIFLE over-classification of 46/271 patients and under-classification of 19/271 patients (p<0.001). Use of creatinine-age resulted in over-classification of 29/271 patients and under-classification of 20/271(p=0.04).

RIFLE classification for all patients

RIFLE Class (creatinine-75)

RIFLE Class (creatinine-actual)	0	1	2	3	Total n (%)
0	**199 (73)**	24 (8.9)	10 (3.7)	4 (1.5)	237 (88)
1	16 (5.9)	**5 (1.8)**	5 (1.8)	3 (1.1)	29 (11)
2	1 (0.4)	2 (0.7)	**2 (0.7)**	0 (0.0)	5 (1.8)
3	0 (0.0)	0 (0.0)	0 (0.0)	**0 (0.0)**	271
Total n (%)	216 (80)	31 (11)	17 (6.3)	7 (2.6)	271 (100.0)

Over-classification: 46 pt
Correct classification: 206 pt
Under-classification: 19 pt

RIFLE Class (creatinine-age)

RIFLE Class (creatinine-actual)	0	1	2	3	Total n (%)
0	**215 (79)**	16 (5.9)	3 (1.1)	3 (1.1)	237 (88)
1	18 (6.6)	**4 (1.5)**	4 (1.5)	3 (1.1)	29 (11)
2	1 (0.4)	1 (0.4)	**3 (1.1)**	0 (0.0)	5 (1.8)
3	0 (0.0)	0 (0.0)	0 (0.0)	**0 (0.0)**	0 (0.0)
Total n (%)	234 (86)	21 (7.7)	10 (3.7)	6 (2.2)	271 (100.0)

Over-classification: 29 pt
Correct classification: 222 pt
Under-classification: 20 pt

RIFLE classification calculated with actual creatinine ("gold standard") compared to RIFLE classification based on use of a fixed eGFR of 75 mL/min/1.73m^2 (creatinine-75) (p<0.001), and compared to RIFLE classification based on use of an age-and-gender-adjusted eGFR (creatinine-age) (p=0.04).

Next, we compared presence (RIFLE 1-3) and absence (RIFLE 0) of acute kidney injury. Using creatinine-75, 216/271 patients were classified correct, 38/271 were over-classified,

and 17/271 were under-classified (p=0.007). The use of creatinine-age classified 230/271 correct, over-classified 22/271 and under-classified 19/271 (p=0.76).

For patients >76 years use of creatinine-75 resulted in over-classification of 27/96 patients, and under-classification of 4/96 (p<0.001). Using creatinine-age resulted in over-classification of 12/96 patients, and under-classification of 6/96(p=0.10).

Conclusions: Use of an age-and-gender-adjusted eGFR improves RIFLE classification compared with use of a fixed eGFR, especially in elderly. If actual baseline creatinine is not available, we propose to use an age-and-gender-adjusted baseline creatinine for RIFLE classification.

TH-PO093

Proteinuria in Community-Acquired Pneumonia as a Prognostic Marker for Outcome Simone Spoorenberg,[1] Sabine Meijvis,[1] Gerjan Navis,[2] Jan Grutters,[1] Douwe Hedde Biesma,[1] Henk J.T. Ruven,[1] Johannes C. Kelder,[1] Willem Jan W. Bos.[1] *[1]St Antonius Hospital; [2]University Medical Centre Groningen.*

Background: Acute Kidney Injury (AKI), classified according to the Risk, Injury, Failure, Loss and End-Stage kidney disease (RIFLE) criteria, is occasionally seen in patients with Community Acquired Pneumonia (CAP). It is known that RIFLE criteria may underestimate the occurrence of AKI. We investigated the incidence and predictive value of proteinuria in patients with CAP, and compared the results with the RIFLE criteria.

Methods: We retrospectively investigated RIFLE criteria and proteinuria in patients hospitalized with CAP. Proteinuria, defined as total-protein/creatinine ratio>23mg/mmol, was measured in a urine sample from the day of admission. Primary outcome was length of hospital stay (LOS). Secondary outcomes were in-hospital mortality and one-year mortality.

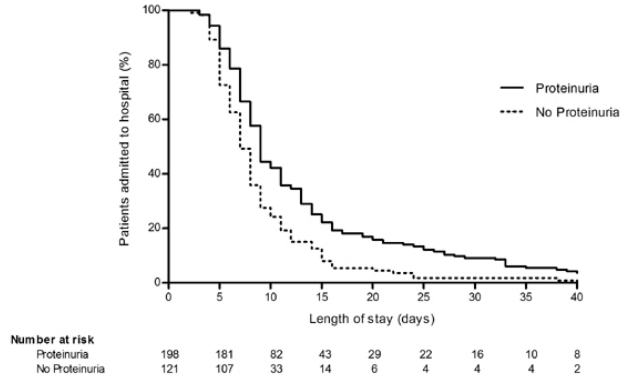
Results: In 319/496 patients (64%) a urine sample was available. 198 patients (62%) had proteinuria. Patients with proteinuria had a significant longer LOS and an increased in-hospital mortality. RIFLE class was a predictor for LOS, in-hospital mortality and one-year mortality. In multivariate analysis, proteinuria only was an independent predictor for LOS.

	Proteinuria		RIFLE 1-3	
	OR or HR	95% CI	OR or HR	95% CI
Length of stay				
Unadjusted[2]	1.63	1.28-2.06	1.55	1.12-2.15
Adjusted[2]	1.38	1.08-1.75	1.21	0.86-1.71
In-hospital mortality				
Unadjusted[1]	5.59	1.27-24.63	3.81	1.40-10.35
Adjusted[1]	3.27	0.69-15.45	1.81	0.62-5.27
One-year mortality				
Unadjusted[2]	1.74	0.94-3.22	3.06	1.69-5.55
Adjusted[2]	1.09	0.56-2.10	1.81	0.97-3.37

OR=[1]: Odds ratio and HR=[2]: Hazard ratio

Conclusions: The incidence of proteinuria during CAP is high. Proteinuria and RIFLE criteria are both associated with adverse outcome in CAP. Only proteinuria is an independent predictor for LOS. Proteinuria can be a marker for outcome and might be used to assess the severity of CAP.

Figure 1: Length of stay for patients with proteinuria (total protein >23 mg/mmol creatinine) and patients without proteinuria (Log Rank p<0.001).



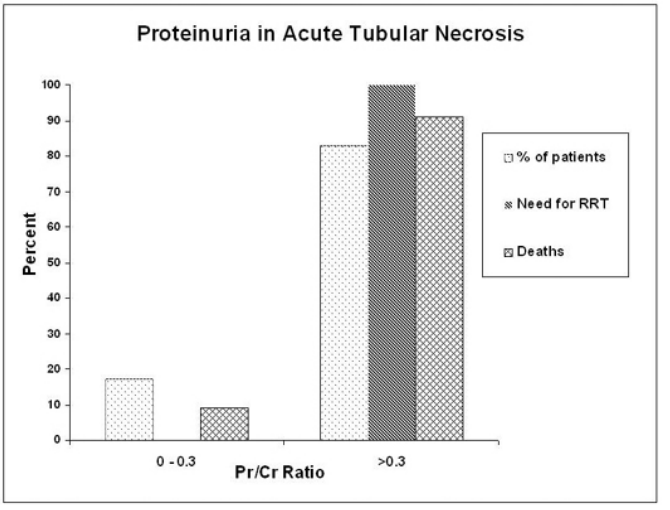
TH-PO094

Proteinuria in Acute Tubular Necrosis Kevin K. Pandya, Kavitha Potluri, David J. Leehey, Alexander R. Chang, Holly J. Kramer. *Divison of Nephrology, Loyola University Medical Center, Maywood, IL.*

Background: Acute kidney injury (AKI) as defined by well-established criteria is observed in about 5-7 percent of hospitalized patients and 66% of intensive care patients. ATN accounts for nearly 50% of AKI cases in hospitalized patients. Because of tubular damage in ATN, the normal mechanism of protein reabsorption is likely to be altered, with receptor- mediated endocytosis of albumin expected to decrease, leading to overt proteinuria. However, data on the incidence of proteinuria in the setting of ATN are sparse. We examined the changes in urine protein excretion after an episode of ATN in adults without protienuria.

Methods: This is an observational study focused on patients age > 18 years who experienced an episode of AKI as defined by AKIN/RIFLE criteria. Criteria to select patients with ATN included FENa > 2%, serum urea nitrogen-to-creatinine ratio < 20, urine-to-plasma creatinine ratio < 20, as well as the nephrologist's clinical determination based on available data. Patients with known proteinuria (UA showing >1+ proteinuria) were excluded from the study. Proteinuria (based on Pr/Cr ratio) was measured at time of diagnosis of ATN. All study patients were followed during the hospitalization for secondary endpoints: mortality and need for dialysis.

Results: A total of 32 patients with absence of proteinuria prior to ATN episode were identified over an approximately 7 months time period. 83% of the patients (24/32) had urine Pr/Cr > 0.3 (g/g). Of the patients who required dialysis, 100% (13/13) were noted to have Pr/Cr > 0.3. Lastly, of the patients who died within the selected cohort, 91% (10/11) had Pr/Cr ratio > 0.3.



Conclusions: The majority of patients with ATN in this study had a Pr/Cr > 0.3 g/g and these patients had higher mortality and need for RRT. Urine Pr/Cr may be a simple and readily available biomarker to predict outcome in ATN.

TH-PO095

The Capacity of Nephrology and Critical Care Services in England and Wales To Manage Acute Kidney Injury Ben Bray,[1] Beverley Matthews,[2] Donal O'Donoghue.[3] *[1]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom; [2]NHS Kidney Care, London, United Kingdom; [3]Salford Royal Foundation NHS Trust, Salford, United Kingdom.*

Background: Acute Kidney Injury is increasingly recognised as an important quality and safety challenge in all health economies. In England, coded admissions for AKI are rising by over 10% per annum (Department of Health) and a national audit of AKI deaths (NCEPOD 2009, *Adding Insult to Injury*) highlighted access to specialist nephrology and critical care specialist services as a factor in many deaths from AKI. Here we report the result of a survey of the capacity of nephrology and critical care units in England and Wales to meet the demand for managing AKI.

Methods: A web based questionnaire was sent to clinicians representing all hospitals in England and Wales offering inpatient nephrology and critical care services. The questionnaire included items relating to staffing, facilities, use of guidelines and AKI related bed occupancy on World Kidney Day 2011. The AKIN classification of AKI was used.

Results: Complete results were obtained from 41/59 (69%) nephrology centres and 45/175 (26%) critical care centres in England and Wales. There was variation in the model of AKI management between centres – only 29% of nephrology centres had dedicated high dependency facilities. Bed occupancy in nephrology centres was 97%. 23% of nephrology beds were occupied by patients with AKI (Stage I-III), 57% of whom had RRT dependent AKI. The prevalence of RRT dependent AKI amongst critical care patients was 9%. Although the majority of nephrology centres have agreed guidelines for the clinical management of AKI (63%) and contrast nephropathy (89%), only 37% have protocols concerning the transfer and referral of patients from hospitals without nephrology services.

Conclusions: Delays in access to specialist nephrology and critical care services may lead to worse outcomes for patients with AKI. High bed occupancy in nephrology services in England and Wales suggests that there is little scope for increasing access to these services without increasing efficiency or increasing capacity. One suggested solution would be better use of protocols to define planned pathways of care for patients with AKI.

TH-PO096

Stress-Induced Hyperglycemia and Acute Kidney Injury in Critically Ill Children Roberto Gordillo,[1] Robert Woroniecki.[2] *[1]Pediatrics, University of Illinois College of Medicine at Peoria, IL; [2]Pediatrics, Albert Einstein College of Medicine, Bronx, NY.*

Background: Stress-induced hyperglycemia (SIH) is common in critically ill patients and has been associated with increased mortality and morbidity. However, it is not clear if SIH is associated with acute kidney injury (AKI) in children. We hypothesized that SIH is associated with intensity of AKI.

Methods: We analyzed the records of children with SIH admitted between 01/2005-01/2010 to the pediatric intensive care unit (PICU). Subjects with prior kidney disease and diabetes were excluded. Intensity of AKI was defined by pediatric RIFLE criteria. Serum glucose (SG) and estimated glomerular filtration rate (eGFR) on admission, 48 hours, and at 7 days after admission were obtained. Delta glycemia (DG) was defined as the difference between the peak and the lowest SG during PICU stay.

Results: Out of 37 subjects, 13 (35%) had AKI. Results are shown in Table. We found no correlation between SG and eGFR at 0hr, 48hr and 7days. Subjects with SIH and AKI stayed longer in PICU and hospital, and we found a positive correlation between DG and length of stay in PICU (p=0.0003, r2=0.3) and length of hospital stay (p=0.0005, r2=0.34).

	AKI (n=13)	No-AKI (n=24)	p
Age (years)	4.1 ± 1.1	6 ± 0.9	0.88
Caucasian (%)	31	45.8	0.49
Female (%)	46	41	0.99
Serum glucose on admission (mg/dl)	148 ± 22.49	135.8 ± 13.2	0.6
Peak Glucose (mg/dl)	235 ± 19.9	212 ± 66.31	0.2
Days of hospital stay	31.23 ± 3.7	24.1 ± 3.7	0.05
Days of PICU stay	20 ± 2.6	16.25 ± 2.99	0.06
Death	1	0	

Conclusions: In children with SIH, SG and DG is not associated with intensity of AKI, but it does correlate with length of hospital and PICU stay.

TH-PO097

Natriuretic Peptide and Loop Diuretic Agents in Cardiac Surgery Associated Acute Kidney Injury Prevention Sagar U. Nigwekar, Khuloud Shukha, Sushrut S. Waikar. *Brigham and Women's Hospital.*

Background: In animal studies, natriuretic peptide (NP) and loop diuretics (LD) are shown to prevent cardiac surgery associated acute kidney injury (CSAKI). However, randomized controlled trials (RCTs) in humans have shown inconsistent results and are underpowered for evaluation of hard outcomes such as renal replacement therapy requirement (CSAKI-R) and mortality. There also remains a question regarding their safety. Our study aimed to systematically review these RCTs to ascertain efficacy and safety of these agents in CSAKI prevention.

Methods: We searched MEDLINE, EMBASE, and Google Scholar for RCTs evaluating NP or LD for CSAKI prevention. Outcomes analyzed were CSAKI (defined per the individual RCT), CSAKI-R, mortality and durations of intensive care unit (ICU) and hospital stay. Statistical analyses were performed using the random effects model and results expressed as relative risks (RR) for dichotomous outcomes and weighted mean difference (WMD) for continuous outcomes, with 95% confidence intervals (CI). Methodological quality assessment was performed by Jadad score.

Results: Fourteen RCTs (12 NP, 2 LD) involving 1,599 patients met the inclusion criteria. NP dose administered in these RCTs was noted to be lower than that administered in Auriculin Anaratide Acute Renal Failure Study. Pooled analysis of RCTs evaluating NP showed reduction in CSAKI (RR 0.48, [0.23 to 0.96]), CSAKI-D (RR 0.23, [0.08 to 0.70]) , mortality (RR 0.50, [0.27 to 0.93]), ICU length of stay (WMD -0.44 days, [-0.82 to -0.06 days]) and hospital length of stay (WMD -4.08 days, [-6.32 to -1.83 days]) in the NP group. There was no statistical heterogeneity in these analyses. Statistical analysis could not be performed due to limited number of RCTs evaluating LD. Both NP and LD agents were well tolerated. Methodological quality of the RCTs was variable; however, sensitivity analysis of high quality studies did not change the findings.

Conclusions: NP agents, in low doses, are well tolerated and may prevent CSAKI and its associated complications. Appropriately powered RCT is urgently needed to confirm these results. Role of LD agents is not adequately studied in this population.

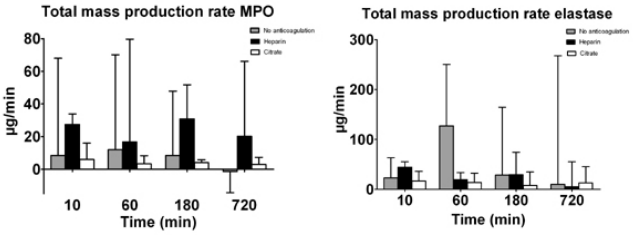
TH-PO098

Regional Citrate Anticoagulation Decreases the Degranulation of Neutrophils in Continuous Venovenous Hemofiltration in Critically Ill Patients Louise Schilder,[1] Shaikh Azam Nurmohamed,[1] Albertus Beishuizen,[2] Pieter M. Ter Wee,[1] Johan Groeneveld.[2] *[1]Nephrology, VU University Medical Center, Amsterdam, Netherlands; [2]Intensive Care, VU University Medical Center, Amsterdam, Netherlands.*

Background: During continuous venovenous hemofiltration in critically ill patients, anticoagulation is administered to prevent clotting of the hemofilter. In case of a high bleeding tendency, regional anticoagulation using citrate is an option. Citrate creates an almost calcium-free environment in the extracorporeal circuit, not only preventing coagulation, but potentially also downregulating the degranulation of neutrophils, as indicated by decreased plasma levels of myeloperoxidase (MPO) and elastase levels.

Methods: Three anticoagulation regimes were compared: no anticoagulation (n=13), unfractionated heparin (n=7) and trisodium citrate (n=17). The data were obtained during prospective observational and randomised studies. At initiation of CVVH (cellulose triacetate membrane, t=0) prefilter blood was collected. Thereafter, blood samples were collected from pre- and postfilter at 10, 60, 180 and 720 min. MPO and elastase were determined by ELISA.

Results: Plasma levels of MPO and elastase increased over time in the patients during heparin-CVVH relatively to citrate-CVVH (P<0.001 resp P=0.015). The production rates of MPO and elastase in the extracorporeal circuit were lowest when citrate was administered. For MPO, citrate was superior to heparin in this respect (P=0.002) and for elastase, citrate was superior to no anticoagulation (P=0.04) and heparin (trend, P=0.07). High plasma levels of MPO and elastase were associated with higher mortality rates (P=0.006 resp P<0.001).



Conclusions: Regional citrate anticoagulation is superior to heparin and to no anticoagulation in CVVH with respect to biocompatibility in terms of neutrophil degranulation. This effect of citrate could favour patient survival.

TH-PO099

Selective A2B Adenosine Receptor Activation Protects from Kidney Injury in a Model of Auto-Immune Disease Gabriela E. Garcia,[1] Luan D. Truong,[2] Almut Grenz,[1] Holger Eltzschig,[1] Richard J. Johnson,[1] Lili Feng.[3] *[1]Medicine, University of Colorado Denver, Aurora, CO; [2]Pathology, The Methodist Hospital, Houston, TX; [3]Medicine, Baylor College of Medicine, Houston, TX.*

Background: A_{2B} adenosine receptor ($A_{2B}R$) activation has been previously implicated in attenuating tissue inflammation under conditions of limited oxygen availability. In addition, this adenosine receptor can modulate tissue protection by stimulating angiogenesis. We investigated the role of $A_{2B}R$ in a model of severe, macrophage-mediated and cytokine-dependent anti-glomerular basement membrane antibody-associated glomerulonephritis (GN).

Methods: We activated $A_{2B}R$ with the selective $A_{2B}R$-agonist BAY 60-6583 during GN to determine its effects on kidney injury, expression of cytokines/chemokines, and recruitment of inflammatory infiltrates.

Results: Normal kidneys had little $A_{2B}R$ mRNA expression; however, its expression was increased in nephritic kidneys. Activation of $A_{2B}R$ in the acute inflammatory phase of GN did not attenuated $CD8^+$ infiltrates but increased $ED1^+$ accumulation compared with the control group. However, necrotizing lesions and glomerular hypercellularity were markedly attenuated in the $A_{2B}R$-agonist treated group. As a result of the attenuation of kidney damage, reduced proteinuria and serum creatinine were observed in the $A_{2B}R$ agonist-treated group. The expression of CX_3CL1, CCL2, CCL4, CCL5, CCL19, and CCL22 chemokines, was not different between both groups. In contrast, the expression of the anti-inflammatory cytokine, TGF-β1 was significantly induced in the $A_{2B}R$ agonist-treated group. In addition, activation of $A_{2B}R$ reduced the expression of osteopontin-1 a pro-inflammatory and anti-angiogenic mediator. Notably, in both groups macrophages were predominantly MI phenotype, however, in the control group 71% of macrophages were M1 phenotype compared with 51% in the $A_{2B}R$ agonist-treated group.

Conclusions: These findings suggest that $A_{2B}R$ could protect from kidney injury by modulating pro-and-anti-inflammatory mediators. Similarly, markedly reduction in necrotizing lesion by $A_{2B}R$ activation suggests a potential angiogenic capillary repair for this adenosine receptor.

TH-PO100

EP2-Receptor Deficiency Ameliorates the Course of Crescentic Glomerulonephritis in Mice Gunther Zahner, Malte A. Kluger, Ulf Panzer, Rolf A. Stahl, Andre Schneider. *III. Medizinische Klinik, Universitätsklinikum Hamburg Eppendorf, Hamburg, Germany.*

Background: Prostaglandin E2 (PGE2) has important immune modulatory roles in various diseases in different organs. PGE2 mediates its effects through four different EP-receptors, named EP1 to EP4. Different intracellular signals of the receptor-subtypes and different combinations of subtypes on the cell surface may partly be responsible for the diverse effects of PGE2 in inflammation.

Methods: Clinical parameters: measurement of BUN and albuminuria.

Histological assessment of renal damage on PAS-stained tissue sections and immunohistochemistry against CD3 and F4/80.

Quantitative PCR of Cox-2, CCL2, IL-6 and TNFalpha.

FACS-based intracellular staining of IL-17 and IFN gamma.

Results: In order to elucidate the potential role of the EP2 receptor in glomerulonephritis, the nephrotoxic-serum-nephritis (NTN) was induced in EP2 deficient (EP2-/-) and in wildtype (WT) mice (C57bl6 background). Succesful onset of the disease was evaluated functionally at day 4 after NTN-injection. No differences between EP2-/- and WT mice was detected in this early phase of the disease.

10 days after induction of the nephritis (during the T-cell dependent autologous phase), EP2-/- mice developed less severe nephritis in terms of significantly better preserved kidney function, less glomerular damage, reduced renal infiltration of CD3+ T-cells and F4/80 positive macrophages/dendritic cells and less RNA-expression of the pro-inflammatory mediators Cox-2, CCL-2, IL-6 and TNFalpha when compared with nephritic WT-mice. Interestingly, renal Th-17 immune response seemed to be impaired in nephritic EP2 -/- mice.

Conclusions: Thus, the EP2 receptor seems to play an important role in the development of NTN.

Suppression of Hyaluronan Synthesis with 4-Methylumbelliferone in NZB/W F1 Mice Is Associated with Reduced Renal Inflammation and Renal Function Improvement Daniel Tak Mao Chan, Wan Wai Tse, Mel Chau, Susan Yung. *Department of Medicine, University of Hong Kong, Hong Kong.*

Background: We previously demonstrated that glomerular hyaluronan (HA) expression is increased in lupus nephritis, but its role in pathogenesis remains to be determined. This study investigated the effect of 4-methylumbelliferone, a specific inhibitor of HA synthesis, on disease manifestations in a lupus mouse model.

Methods: Female NZB/W F1 mice with established nephritis and proteinuria greater than 3g/l were randomized to receive treatment with sterile PBS, vehicle alone (1% Arabic Gum in PBS) or 4-methylumbelliferone in 1% Arabic Gum (MU, 3g/kg/day) for 2, 4, 8 and 12 weeks (n=6 for all time points for each group), after which the mice were sacrificed, blood collected and kidneys harvested for assessment of histology and expression of inflammatory mediators. Spot urine was obtained for the measurement of albumin-to-creatinine ratio.

Results: Serum HA levels increased in a time-dependent manner as disease progressed in PBS and vehicle treated mice. This was associated with increased periglomerular and tubulo-interstitial HA expression. MU treatment for 12 weeks reduced serum HA level by 30% and decreased renal HA expression to near normal levels. Urine albumin-to-creatinine ratio and serum levels of urea and creatinine increased in both PBS and vehicle treated mice with progressive disease, but were significantly decreased in mice after 12 weeks of MU treatment ($P<0.05$ for all, compared to both control groups). MU-treated mice also showed reduced glomerular deposition of IgG and C3, IL-6 and TNF-α expression, and glomerular infiltration by $CD4^+$ T cells, $CD19^+$ B cells and macrophages compared to controls.

Conclusions: These results suggest that HA plays an important role in the pathogenesis of lupus nephritis and suppression of HA synthesis can ameliorate disease manifestations.

Connective Tissue Growth Factor (CTGF) Induces a Chronic Th17 Inflammatory Response in the Kidney Raquel Rodrigues-Diez,[1] Raúl R. Rodrigues Díez,[1] Sandra Rayego-Mateos,[1] Carolina Lavoz,[1] Matilde Alique Aguilar,[1] Alberto Ortiz,[2] Jesus Egido,[2] Marta Ruiz-Ortega.[1] *[1]Universidad Autonoma; [2]ISCFJD, Madrid, Spain.*

Background: Several studies have suggested that plasma or urine CTGF levels is a useful risk marker for renal damage in chronic kidney diseases (CKD). However, the renal effects of CTGF has not been fully investigated. Until now, CTGF has been considered as a profibrotic mediator, although growing evidences suggest that could also participate in inflammation. In vivo CTGF induces an acute renal inflammatory response in mice, observed at 24 hours and characterized by upregulation of Th1/Th2 cytokines and chemokines. However, there is no studies at longer times. IL-17-producing CD4(+) T helper (Th17) cells have been identified as novel effector immune cells. IL-17, besides participating in immune diseases, is involved in chronic inflammatory diseases, including CKD.

Methods: Systemic administration of CTGF (2.5 ng/g BW) was done in mice. Blockade of Th17 response was done by a neutralizing antibody against IL-17.

Results: CTGF caused a sustained Th17 inflammatory response in the kidney, observed at 5 days and remained elevated until 15 days. At 10 days, CTGF-treated mice presented focal interstitial infiltration of monocytes/macrophages and T lymphocytes, including CD4+/IL-17 expressing cells, and upregulation of chemokines. In contrast, there was no fibrosis or proteinuria. Elevated renal gene and protein levels of IL-17 were found in CTGF-treated mice, compared to controls, while tissue levels of INF-γ and IL-4 (Th1 and Th2 hallmark cytokines, respectively) were not changed between groups. The main factors involved in the regulation of Th17 cell differentiation in mice (IL-6 and RORγt) were elevated in the kidney of CTGF-treated mice. The blockade of Th17 response, by a neutralizing antibody against IL-17, diminished CTGF-induced inflammatory response at 10 days (infiltrating cells and upregulation of proinflammatory factors), clearly demonstrating the involvement of Th17 response in CTGF-mediated renal damage.

Conclusions: Our findings indicate that CTGF is a potential therapeutic target for CKD, as it promotes chronic kidney inflammation by activating Th17 response.

TH-PO103

Fully Human Anti-Macrophage Migration Inhibitory Factor (MIF) Antibody Is Effective in Treatment of Established Experimental Glomerulonephritis Frederick W.K. Tam,[1] Gurjeet Bhangal,[1] Jennifer Smith,[1] John P. McDaid,[1] Dirk Voelkel,[2] Manfred Rieger,[2] H. Terence Cook,[1] Charles D. Pusey,[1] Scheiflinger Friedrich,[2] Randolf Kerschbaumer.[2] *[1]Imperial College Kidney and Transplant Institute, Imperial College London, London, United Kingdom; [2]Baxter Innovations GmbH, Vienna, Austria.*

Background: The macrophage migration inhibitory factor (MIF) is a pro-inflammatory cytokine placed high upstream in the cytokine cascade. Early studies have shown that MIF is upregulated in glomerulonephritis in humans and administration of murine anti-MIF antibodies reduced the severity of experimental glomerulonephritis. A clinical therapy targeting MIF using fully human anti-MIF antibodies is of major interest.

Methods: A highly diverse panel of fully human MIF-specific monoclonal antibodies (mAbs) was selected from a phage display library and antibodies were produced as human IgGs. The effect of mAbs with pronounced in vitro neutralizing properties was assessed in a series of pilot studies using the model of nephrotoxic nephritis in Wistar Kyoto rats. The mAb BaxB01 was chosen for further studies. Treatment was started after onset of proteinuria (day 4) to assess the antibody in a clinically relevant design. Rats were randomised into three treatment groups (isotype control, 20 mg/kg and 40 mg/kg anti-MIF mAb) and treated on day 4 and day 6.

Results: The severity of glomerular injury was assessed on day 8. Proteinuria, glomerular macrophage infiltration and glomerular crescents were reduced dose dependently following treatment with anti-MIF mAb [Table 1]. In addition, urinary levels of proinflammatory cytokines like TNFα and IL-1β were reduced.

mAb	isotype control	BaxB01 (20 mg/kg)	BaxB01 (40 mg/kg)
Proteinuria (mg/day)	129.7±6.5	105.6±8.7	85.4±4.9 **
Macrophage (glomerular cross section)	30.5±1.5	22.0±1.4 *	19.3±1.5 ***
Crescent (%)	93.9±0.7	86.3±1.4*	78.3±3***

*p<0.05, ** p<0.005, ***p<0.001

Conclusions: A fully human anti-MIF mAb was able to neutralize the proinflammatory effects of MIF in vitro and was effective for treating antibody-mediated experimental glomerulonephritis even after onset of proteinuria. This antibody has important potential for clinical use in nephritis and other MIF-related diseases.

The Cross-Talk between NKT Cell and Th17 Response in the Experimental Autoimmune Glomerulonephritis Ji In Park,[1] Seung Hee Yang,[1] Ran-Hui Cha,[2] Jung Pyo Lee,[1] Dong Ki Kim,[1] Yon Su Kim.[1] *[1]Department of Internal Medicine, Seoul National University College of Medicine; [2]Department of Internal Medicine, National Medical Center.*

Background: Th17 cells are emerging as a major player in several autoimmune diseases such as multiple sclerosis and rheumatoid arthritis which were known as Th1 mediated diseases. NKT cells, which have a role of linkage between the innate and adaptive immune response, are also associated with autoimmune diseases. But the cross-talk between NKT cell and Th17 has not been evaluated in the context of autoimmune disease. In present study, we examined the role of NKT cell/Th17 response in autoimmune glomerulonephritis (AGN) utilizing a murine model of chronic graft-versus-host disease.

Methods: AGN was induced by the adoptive transfer of lymphocytes from (C57BL/6 x DBA/2J) F1 hybrids into wild C57BL/6, type I/II NKT cell deficient, and type I NKT cell deficient mice. The transferred lymphocytes infiltrated into the glomeruli inducing cellular proliferation.

Results: The severity of AGN, confirmed by deterioration of kidney function, proteinuria, and renal pathology, was attenuated with the absence of NKT cells compared to wild type mice. Complement 3 deposition and T cell infiltration were consistent with the severity of AGN. NKT cells were recruited into glomerulus with the induction of AGN. The systemic immune responses as measured by splenic T cell activation, intracellular IL-17, and inflammatory cytokines, are enhanced with the induction of AGN. But the absence of NKT cells, especially both of type I and II NKT cells, reduced the systemic immune responses. The intrarenal immune response induced by AGN was paralleled with systemic responses. Moreover, intrarenal STAT3 phosphorylation, which is the major transcription factor for Th17 response, was significantly attenuated in NKT cell deficient hosts. NKT cells secreted IL-17 as well as inflammatory cytokines (TNF-α, IL-6, IL-12, IFN-g) when activated. Blocking of IL-17 signaling reduced the mesangial cell responses against the stimuli induced by the nephritogenic lymphocytes.

Conclusions: Taken together, the cross-talk between NKT cell and Th17 response might be a pivotal linkage for the development of AGN.

CXCL5/CXCL1-CXCR2 Axis Drives Neutrophil Infiltration in Murine Experimental Glomerulonephritis in a Time and Compartment Specific Manner Erik M. Disteldorf,[1] Markus Koch,[4] Mischo Mischo Kursar,[4] Jan-Eric Turner,[1] Hans-Joachim Paust,[1] Joachim Velden,[3] Hans-Willi Mittrücker,[2] Rolf A. Stahl,[1] Stefan H.E. Kaufmann,[4] Ulf Panzer.[1] *[1]III. med. Klinik, Universitätsklinikum Hamburg Eppendorf, Hamburg, Germany; [2]Immunology, Universitätsklinikum Hamburg Eppendorf, Hamburg, Germany; [3]Pathology, Universitätsklinikum Hamburg Eppendorf, Hamburg, Germany; [4]Institut für Infektionsbiologie, Max Planck Institut, Berlin, Germany.*

Background: Crescentic glomerulonephritis is characterized by the recruitment of leukocyte subsets including neutrophils that cause renal tissue damage. The mechanisms of neutrophil migration in glomerulonephritis are not well characterized. In this study we investigate the role of the chemokine receptor CXCR2 and its ligands CXCL1, CXCL2 and CXCL5 in renal neutrophil trafficking and organ injury.

Methods: Experimental glomerulonephritis was induced in mice.

Results: Induction of nephritis resulted in early (12 hours) up-regulation of glomerular CXCL1 and CXCL2 mRNA expression that preceded glomerular neutrophil accumulation. CXCR2-deficiency resulted in reduced neutrophil infiltration and less damage at day 3, demonstrating the importance of the CXCL1/2 - CXCR2 axis during the early course of nephritis. In contrast, CXCL5 expression peaked at day 14 and was localized to the tubulointerstitial area. At this time neutrophils migrate into the same compartment. To investigate the functional role of CXCL5, nephritis was induced in CXCL5-/- mice. CXCL5-/- mice developed an ameliorated course of disease as a consequence of reduced tubulointerstitial neutrophil infiltration at day 14, whereas at day 3 neutrophil accumulation and disease severity was unaltered. In vitro experiments identified the cytokine IL-17A

as a strong inductor of CXCL5. IL-17A expression in NTN peaked at day 7-10 preceding renal CXCL5 expression. In line, CXCL5 expression was downregulated in nephritic IL-17A-/- mice.

Conclusions: In conclusion, our study shows that the CXCL5/CXCL1-CXCR2 axis orchestrates renal neutrophil recruitment in a time and compartment specific manner. CXCL5 mediated neutrophil recruitment is driven by IL-17 and contributes to renal tissue injury in crescentic glomerulonephritis.

TH-PO106

IFN-αand IFN-β Specifically Affect Renal Progenitors and Podocytes In-Vitro and In-Vivo A. Migliorini,[1] C. Sagrinati,[2] M.L. Angelotti,[2] E. Parente,[2] L. Ballerini,[2] E. Ronconi,[2] A. Peired,[2] L. Lasagni,[2] E. Lazzeri,[2] Paola Romagnani,[2] Hans J. Anders.[1] *[1]Medizinische Poliklinik, LMU, Munich, Germany; [2]Excellence Centre for Research, DENOthe, University of Florence, Florence, Italy.*

Background: Viral infections can be associated with glomerulonephritis in various ways which is likely to involve antiviral immunity. IFNα and IFNβ orchestrate antiviral defence and potentially contribute to GN. For example, lack of the IFNα-R ameliorates murine immune complex disease complicated by glomerulonephritis but local effects of IFNα/β on glomerular pathology remain speculative.

Methods: C133+CD24+ human renal progenitors and podocytes cultured +/- hIFNα and hIFNβ. SCID mice injected with adriamycin +/- recombinant mIFNα and mIFNβ.

Results: IFNα and IFNβ both activated renal progenitors to express several interferon-related (antiviral) genes such as MX1, IFIT1 and CXCL10. IFN-α significantly decreased the proliferation of human renal progenitors, by contrast IFNβ inhibited differentiation of renal progenitors towards podocytes as determined by induced nephrin expression. Next we compared the impact of recombinant IFNα and IFNβ injections on adriamycin-induced nephropathy in SCID mice which allowed us to exclude IFN-dependent effects on adaptive immunity. Both IFNs increased proteinuria as compared to control mice injected with adriamycin only. Quantitative morphometry by confocal microscopy revealed that IFNβ injections had specifically reduced the number of WT1+/nephrin+ podocytes while IFNα injections specifically reduced the numbers of proliferating parietal epithelial cells, respectively. In summary, both type I IFNs can aggravate glomerular pathology, albeit in different ways. IFNα impairs the proliferation of potential podocyte progenitors, while IFNβ mostly impairs progenitor differentiation in vitro.

Conclusions: These data propose that IFNα and IFNβ contribute to glomerulosclerosis and proteinuria by specifically affecting homeostasis of podocytes and their potential repair by local progenitors, a mechanism that may contribute to in viral infection-associated glomerular pathology.

Human Bone Marrow Derived Mesenchymal Stromal/Stem Cells Attenuate Tubular Inflammation upon Albumin Challenge Hao-Jia Wu, Wai Han Yiu, Joseph C.K. Leung, Loretta Y.Y. Chan, Lian Qizhou, Miao Lin, Hung-Fat Tse, Kar Neng Lai, Sydney C.W. Tang. *Department of Medicine, University of Hong Kong, Hong Kong, Hong Kong.*

Background: Emerging evidence indicates that bone marrow derived mesenchymal stem cells (BM-MSC) protect against many forms of chronic renal diseases (CKD). The mechanism underlying this effect is not completely understood. We have previously shown the tubular expression of proinflammatory mediators induced by proteinuria play a vital role in the pathogenesis of CKD. This study aims to explore whether BM-MSC exerted anti-inflammatory effects in renal proximal tubular cells (PTEC) under milieu mimicking proteinuric nephropathy.

Methods: PTEC were treated with human albumin serum (HSA) and co-cultured with BM-MSC for 6 hours and 24 hours. Transcription and secretion of proinflammatory mediators were measured by real-time qPCR and ELISA, respectively. NF-κB signalling was assessed by western blot.

Results: Real-time qPCR revealed that co-culture with BM-MSC significantly reduced the up-regulated mRNA transcripts including IL6, CCL2, CCL5, IL8, TNF-alpha, IL1-beta, and ICAM-1 in PTEC exposed to HSA. The suppression of proinflammtory genes translated into reduced secretion of IL-6, CCL2, CCL5, IL8 and TNF-alpha proteins as detected by ELISA. In addition, the reduction of these proinflammtory cytokines and chemokines by BM-MSC was associated with attenuation of HSA induced I-κB phosphorylation in PTEC. To dissect the potential mechanism, we detected that the anti-inflammatory genes, HGF and IL1RN (IL1 receptor antagonist), were significantly induced in BM-MSC during co-culture with PTEC under protein overload condition.

Conclusions: Our *in vitro* data suggest an anti-inflammatory role of BM-MSC in HSA-elicited PTEC inflammation, probably through paracrine effects of HGF and IL1RN via NF-κB signaling.

Macrophage-Specific Thymosin β4 Knockout Protects Against LPS-Induced Inflammation Li-Jun Ma,[1] Bridgette Corsa,[1] Yiqin Zuo,[1] Paul Riley,[2] Agnes B. Fogo.[1] *[1]Pathology, Vanderbilt University Medical Center, Nashville, TN; [2]Molecular Medicine Unit, UCL Institute of Child Health, London, United Kingdom.*

Background: Macrophages are a rich source of thymosin β4 (Tβ4), but little is known about the role of Tβ4 in macrophage response. We investigated whether Tβ4 modulates macrophage function.

Methods: Floxed Tβ4 short hairpin RNA (T4shRNAflox) mice were crossed with lysMcre mice to generate macrophage-specific Tβ4 KO (Mac-Tβ4 KO) mice. Peritoneal thioglycolate-elicited macrophages from wild type (WT, n=3) and Mac-Tβ4 KO (n=3) mice were isolated and exposed to LPS (50 ng/ml) or buffer for 48 hrs to induce inflammation. Expressions of Tβ4 protein, phospho-c-Jun and total cJun in macrophages were examined by Western Blot. Unilateral ureteral obstruction (UUO) was performed in adult male WT (n=5) and Mac-Tβ4 KO (n=4) mice. Macrophage infiltration was assessed at day 7 after UUO. Data are expressed as mean±SE.

Results: Macrophage Tβ4 protein level was markedly diminished in Mac-Tβ4 KO vs WT by 87%. P-c-Jun expression was robustly induced by LPS in WT macrophages, but was significantly reduced by 52±8 % in macrophages from Mac-Tβ4 KO mice. UUO-induced kidney macrophage infiltration was significantly inhibited in Mac-Tβ4 KO vs WT by 28.5%.

Conclusions: Macrophage Tβ4 deletion protects against LPS-induced inflammation, and decreases macrophage infiltration in obstructed kidneys. Our data suggests that targeting macrophage Tβ4 may offer novel treatment of inflammation.

Mice Fed Adenine-Containing Diet Is Optimal Model of Tubulointerstitial Damage with Renal Dysfunction Izumi Yamamoto,[1] Keitaro Yokoyama,[1] Ichiro Ohkido,[1] Taketo Uchiyama,[1] Ichiaki Ito,[2] Akiko Murayama,[2] Jun Yanagisawa,[2] Tatsuo Hosoya.[1] *[1]Department of Internal Medicine, Division of Kidney and Hypertension, Jikei University School of Medicine, Tokyo, Japan; [2]Graduate School of Life and Environmental Sciences, University of Tsukuba, Ibaragi, Japan.*

Background: Adenine is produced endogenously as a by-product of the polyamine pathway and is salvaged by adenine phosphoribosyltransferase (APRT:EC 2.4.2.7). APRT deficiency leads to the accumulation of 2,8-dihydroxyadenin(DHA)crystals in human(OMIM:102600). Mice fed the overload of the adenine-containing diet are mimic to APRT deficiency mice and both were used as human DHA disease model that showed DHA crystals in the tubular lumens with fibrosis and renal dysfunction.

Methods: The aim of this study is to evaluate the protocol for the optimal mice model of tubulointerstitial damage (TID) with renal dysfunction induced by adenine feeding. Inbred male C57BL/6 mice (9 weeks old) were fed a standard laboratory powder diet or a powder diet containing 0.25% adenine (0.25%Ad). Mice fed 0.25%Ad were euthanized on days 3, 7, and 14 (Group 1,3,5), and mice fed the control diet were euthanized on days 3, 7, 14 (Group 2,4,6). Additionally, we analysed mice fed 0.25%Ad for 7 days with subsequent control diet euthanized on days 14 (Group7).

Results: Mice fed 0.25%Ad showed nephrolithiasis, extensive tubular dilation, inflammation, necrosis and fibrosis (Masson's Trichrome stain) with the elevation of serum creatinine, urea and TID area (%) in a time-dependent manner. The discrepancy of serum creatinine and urea possibly due to dehydration observed in Group 3 were ameliorated in Group 7. The observation of Group 3 and 7 showed that once 0.25%Ad stopped, renal dysfunction recovered and TID did not advance.

Conclusions: These datum showed that mice fed 0.25%Ad with short term exposure is one of the candidate of optimal mice models of tubulointerstitial damage and repair with renal dysfunction.

	Group 1	Group 3	Group 5	Group 7	P value

TH-PO110

Reduction of Renal Fibrosis and TGF-β Production by Late Treatment with a Spleen Tyrosine Kinase Inhibitor in Experimental Glomerulonephritis John P. McDaid,[1] Jennifer Smith,[1] Gurjeet Bhangal,[1] Mei-Ching Yu,[1] Stephen Paul McAdoo,[1] H. Terence Cook,[1] Charles D. Pusey,[1] Esteban S. Masuda,[2] Frederick W.K. Tam.[1] *[1]Kidney and Transplant Institute, Imperial College, London, United Kingdom; [2]Rigel Pharmaceuticals, Inc, San Francisco, CA.*

Background: Spleen tyrosine kinase (Syk) is important in antibody mediated inflammation. Treatment with fostamatinib, a selective Syk inhibitor, is effective in reducing inflammation in experimental glomerulonephritis (GN). However, the effect on fibrosis has not been investigated. The aim of this study is to investigate whether inhibition of Syk at the fibrotic stage will reduce renal fibrosis and glomerular synthesis of profibrotic factors.

Methods: Fostamatinib (40 mg/kg) or vehicle was given daily to Wistar Kyoto rats from day 14 to 28 after nephrotoxic serum. Renal injury was assessed by creatinine clearance

(CrCl), proteinuria and histology. Effect of Syk inhibition on TGF-β production was investigated by incubation of glomeruli *ex vivo* in the presence of R406 (active metabolite of fostamatinib) or control medium.

Results: On day 14, all 20 rats had GN with proteinuria. By day 28, rats treated with fostamatinib had better renal function (CrCl) and less glomerular α-smooth muscle actin (SMA), interstitial fibrosis, infiltrating macrophages and crescents (table) than those treated with vehicle only. One rat in the vehicle group died. Proteinuria was unaffected in treated animals. Incubation of nephritic glomeruli *ex vivo* with R406 reduced the glomerular production of TGF-β by 68 % ($p<0.01$).

	CrCl (ml/day)	Proteinuria (mg/day)	Interstitial Collagen (IU)	Glomerular αSMA (IU)	Glomerular Crescent (%)	Interstitial Mø (IU)	Glomerular Mø (GCS)
Vehicle (n=9)	0.33±0.07	165±18	1.72±0.2	0.26±0.02	99.6±3.5	1.05±0.12	3.4±0.45
Fostamatinib (n=10)	0.92±0.04***	175±7.6 ns	0.9±0.9 **	0.08±0.01***	84.4±3.1***	0.59±0.4*	0.7±0.25***

* p<0.05, **p<0.01, *** p<0.001, ns not significant; IU imaging analysis unit; Mø macrophage; GCS glomerular cross section

Conclusions: To our knowledge, this is the first report showing that Syk inhibition reduces glomerular TGF-β synthesis and renal fibrosis. Syk is a potential therapeutic target in prevention of antibody mediated renal fibrosis.

TH-PO111

The Blockade of IL-17 Ameliorates the Hypertension and the Upregulation of Profibrotic and Proinflammatory Mediators in Kidney of DOCA-Salt Rats

Cristian A. Amador, Juan P. Peña, Magdalena Gonzalez, Luis F. Michea. *Facultad de Medicina, Universidad de Chile, Santiago, Región Metropolitana, Chile.*

Background: Inadequate levels of aldosterone cause hypertension, inflammation and fibrosis in the kidney. Recent findings have implicated the Interleukin-17 (IL-17) pathway in hypertension, and we showed that aldosterone promotes autoimmune damage and Th17 inflammatory response in experimental Autoimmune Encephalomyelitis. We hypothesized that hypertension and the upregulation of profibrotic/proinflammatory mediators induced by DOCA-salt in the kidney are dependent on the increase of IL-17.

Results: First, we evaluated if in the DOCA-salt model the Th17 response is caused by high-blood pressure per-se. Uninephrectomized DOCA-salt rats (0.5mg/0.1kg + 0.9% NaCl/0.3% KCl in drinking water; n=4, 16 days) presented high systolic blood pressure (140 mmHg vs. vehicle 96 ± 1mmHg, $p<0.05$), increased renal abundance of IL-17 and of IL-23, a cytokine that maintains the IL-17 phenotype (IL-17; 11 fold vs. control, IL-23; 2 fold vs. control, $p<0.05$ mRNA/protein). Changes in blood pressure were prevented by spironolactone (SPIRO; 50mg/kg/d) and anti-hypertensive Triple Therapy (TT; 0.32mg/kg/d reserpine, 6.5mg/kg/d hydralazine, 4mg/kg/d hydrochlorothiazide). However, the increase of IL-17 and IL-23 caused by DOCA-salt was prevented only by SPIRO but not by TT (n=4, N.S.). In a second set of experiments, we studied if fibrotic/inflammatory damage in kidney of DOCA-salt rats is dependent on IL-17. We treated rats with DOCA-salt for 16 days, and then with Anti-IL-17antibody (100μg/day), control IgG (100μg/day) or only DOCA-salt for the last 12 days of treatment. Anti-IL-17 ameliorated hypertension (112 ± 3mmHg vs. DOCA-salt 138 ± 6mmHg or IgG groups $p<0.05$). Moreover, Anti-IL-17 reverted the upregulation of Collagen I, Monocyte chemoattractant protein-1, Osteopontin and NADPH oxidase.

Conclusions: Our results suggest that the mineralocorticoid receptor activation but not hypertension induces the Th17 response, and that IL-17 is implicated in hypertension and renal damage due to high-salt+mineralocorticoids in rats.

Loss of Extracellular Adenosine Induced by Knock Out of the CD73/Ecto-5'-nucleotidase in Mice Leads to Age Dependent Proteinuria

Cornelia Anneliese Blume,[1] Kathrin Eller,[3] Hermann G. Haller.[1] *[1]Nephrology and Hypertensiology, Medical School Hannover, Hannover, Lower Saxony, Germany; [2]Transplant Immunology, Medical School Hannover, Hannover, Lower Saxony, Germany; [3]Nephrology, University Hospital Graz, Graz, Austria.*

Background: Adenosine is relevant for the normal physiology of the kidney and protective within ischemia and inflammation. We addressed the role of extracellular adenosine formed by the ectoenzyme CD73 on proteinuria and renal inflammation using CD73-deficient ($CD73^{-/-}$) mice and wild-type (WT) controls. The $CD73^{-/-}$mutant exhibits a lack of adenosine in renal tissue to appr. 70 % and a vascular proinflammatory phenotype.

Methods: Renal function and proteinuria were screened 4 weekly in young CD73-/-mice. At the onset of significant proteinuria as compared to WT mice, kidneys were harvested and analysed by electrone microscopy and immune fluorescence for inflammatory cells, IgG, C3, podocytes. Serum chemokines and cytokines were screened using bioplex protein assays.

Results: Already 13 weeks old $CD73^{-/-}$mice showed increased proteinuria (0.1 ± 0.13 vs. 0.04 ± 0.004 g/g creatinine in WT), increasing to 3-fold at 6 months (0.29 ± 0.03 vs. 0.05 ± 0.02 g g/g creatinine). Glomerulitis and peritubular capillaritis observed in $CD73^{-/-}$mice were associated to glomerular deposition of IgG, C3 and to the presence of CD11b, CD8, CD25 and GR-1-positive cells in the renal cortex. Serum total IgG and the cytokine IL-18 were up-regulated as compared to WT-mice. In $CD73^{-/-}$ mice kidneys, a reduced number of podocytes per glomerulus was associated to decreased expression of synaptopodin and nephrin. Ultrastructural analysis showed endotheliosis and reduced fenestration of the glomerular endothelium.

Conclusions: Our findings indicate that lack of extracellular adenosine formed by the 5´ectonucleotide nucleotidase CD73 age-dependently causes kidney injury with proteinuria ongoing with a loss of podocytes and a proinflammatory renal phenotype. Importantly, increased serum IL-18 votes for an autoimmune phenotype known to promote glomerulonephritis.

Characterization of Pathogenic Macrophages and CCL2 in Diabetic Nephropathy

Mary A. Markiewicz,[1] Xiaobo Lin,[1] Andrey S. Shaw,[1,3] Jeffrey H. Miner.[2] *[1]Pathology and Immunology, Washington University School of Medicine, St. Louis, MO; [2]Renal Division, Washington University School of Medicine, St. Louis, MO; [3]Howard Hughes Medical Institute, Washington University School of Medicine, St. Louis, MO.*

Background: Recent evidence suggests macrophage-mediated inflammation and expression of the macrophage chemoattractant protein CCL2 in the glomeruli may be critical in the development of diabetic nephropathy. However, the phenotype of the macrophages infiltrating diabetic kidneys, the critical effector molecules they produce, and whether interaction of CCL2 with its major receptor, CCR2, affects this phenotype has not been determined. Therefore, a thorough understanding of the phenotype of kidney-infiltrating macrophages in the presence and absence of intact CCR2 signaling is a necessary first step to developing more targeted and safer therapies.

Methods: Using multi-color flow cytometry, we have characterized the surface phenotype of the macrophage populations present in whole kidneys, purified glomeruli, and peripheral blood in non-diabetic, wild-type (C57BL/6) mice. We are now comparing these populations to those present in the kidneys and peripheral blood of mice with diabetic nephropathy, with or without intact CCR2 signaling, using two models of the disease, namely streptozotocin-injected eNOS-/- or db/db mice.

Results: Compared with non-diabetic mice, albuminuric mice had increased macrophage numbers in both the kidneys and blood, with the major population expressing the surface markers CD11b, F4/80 and CD11c. This increase was inhibited by the administration of a CCR2 antagonist prior to albuminuria development, and this correlated with a decrease in disease severity in the db/db model.

Conclusions: These results suggest this macrophage population may be responsive to CCR2 signaling and involved in the pathogenesis of diabetic nephropathy. Studies are now underway to determine whether these macrophages are concentrated in the glomeruli of diabetic kidneys, the cytokines these cells produce that may have nephrotic potential, and the effect of CCR2 inhibition on cytokine production.

Adrenocortocortropin (ACTH) Gel Suppresses Renal Tubulointerstitial Inflammation and Injury by Direct Stimulation of the Melanocortin 1 Receptor (MC1R)

Rujun Gong, Lance D. Dworkin. *Brown Medical School, Providence, RI.*

Background: ACTH is a pituitary neuro-immuno-endocrine hormone and a prototype agonist of the melanocortin system. Clinical and experimental evidence demonstrates that ACTH has beneficial actions in chronic kidney disease; however, the mechanism(s) remain uncertain. This study examined the effect of ACTH gel (Acthar Gel, Questcor Pharmaceuticals, Inc.) on progressive renal tubulointerstitial injury.

Methods: Following unilateral ureteral obstruction (UUO) surgery with or without simultaneous adrenalectomy, rats were administrated ACTH gel (10 IU/kg) or saline (CON) every other day for 2 weeks. Renal histology was assessed. Expression of cognate receptors of ACTH was evaluated *in vivo* and in cultured murine renal tubular epithelial cells (TEC).

Results: Compared to CON, ACTH gel prevented enlargement of the obstructed kidney as assessed by the increase in kidney to body weight ratio (1.13±0.14 *vs* 0.67±0.09 g/100g *wt*, $P=0.02$). Morphologically, renal interstitial fibrosis and tubular atrophy were significantly ameliorated by ACTH gel. In addition, renal inflammation, marked by ED-1 positive macrophage infiltration, and UUO induced expression of chemokines MCP-1 and RANTES in tubules, were also attenuated by ACTH gel treatment. Although somewhat diminished, the beneficial effects of ACTH gel were still evident in UUO rats that underwent adrenalectomy, suggesting a steroid independent mechanism. Consistently, abundant expression of MC1R was observed in renal tubules of rat kidneys and in cultured TEC. *In vitro*, ACTH gel markedly suppressed TNF-α induced proinflammatory events in cultured TEC, including NFκB activation and downstream target gene expression. This effect was significantly diminished in TEC in which MC1R expression was silenced by RNAi, demonstrating that ACTH gel induced anti-inflammatory signaling in TEC requires MC1R.

Conclusions: ACTH gel markedly suppresses tubulointerstitial inflammation, tubular atrophy and fibrosis in progressive chronic kidney disease due, at least in part, to direct, anti-inflammatory effects on TEC. By silencing MC1R expression for the first time in kidney cells, we have also shown that these effects are mediated *via* the MC1R.

Effects of Rho Kinase Inhibitor, Fasudil on Spontaneously Hypercholesterolemic Rats Taketoshi Kushiyama,[1] Takashi Oda,[1] Takahiro Uchida,[1] Atsushi Watanabe,[1] Kojiro Yamamoto,[1] Keishi Higashi,[1] Naoki Oshima,[1] Yutaka Sakurai,[2] Soichiro Miura,[1] Hiroo Kumagai.[1] *[1]Nephrology, National Defense Medical Collage, Tokorozawa, Saitama, Japan; [2]Preventive Medicine and Public Health, National Defense Medical Collage, Tokorozawa, Saitama, Japan.*

Background: Recent reports indicate the renoprotective effects of rho kinase inhibitor, fasudil by the inhibition of macrophage infiltration. Therefore we examine the long term therapeutic effects of fasudil on the spontaneously hypercholesterolemic (SHC) rat, paying special attention to the phenotypic changes in macrophages.

Methods: Eight-week-old male SHC rats were randomly assigned to 6 groups (n=7 each): 1) the vehcle-treated group (Ve), 2) the low dose fasudil-treated group (f30, 30mg/kg/day), 3) the high dose fasudil-treated group (f100, 100mg/kg/day), 4) the OL-treated group (OL, 5mg/kg/day), 5) the combination of low dose of fasudil and OL treated group (c30), 6) the combination of high dose of fasudil and OL treated group (c100). As a healthy control group, SD rats were treated with vehicle alone (n=7). Rats were killed after treating for 24 weeks.

Results: Urinary protein excretion in f100, OL and c30 groups was significantly less than that in Ve group. Surprisingly urinary protein excretion level in c100 decreased to the same level as control group. The total collagen content was significantly decreased in the c100 group compared with Ve group. Prominent interstitial ED-1 positive cells observed in the Ve group were significantly attenuated in the all treatment groups. The CD80 and CCL3 (M1 macrophage marker) mRNA level relative to the GAPDH mRNA level was significantly decreased in c100 group. The relative expressions of CD206 (M2 macrophages marker), as assessed by the ratio of the CD206 mRNA to CD68 mRNA levels, was significantly greater in c100 than other treatment groups.

Conclusions: Fasudil showed significant beneficial effects on the interstitial fibrosis of SHC rats, the mechanism of which may be associated with antiproteinuric effects and increment in M2 macrophages.

TH-PO116

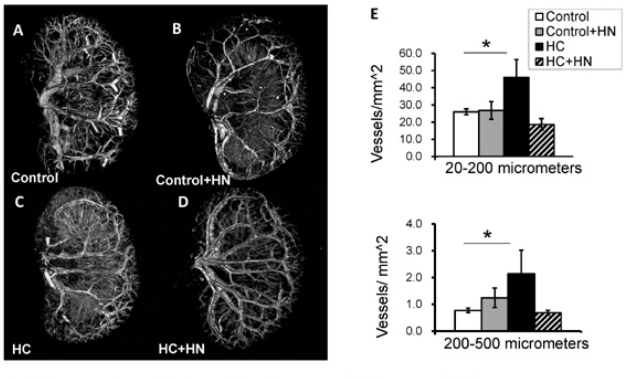
Humanin Prevents Intra-Renal Microvascular Remodeling, Inflammation, and Fibrosis in ApoE Knockout Mice Xin Zhang,[1] Victor Urbieta Caceres,[1] Caitlin C. Bell,[1] John A. Crane,[1] Hui Tang,[1] Kyra L. Jordan,[1] Yun Kyu Oh,[2] Pinchas Cohen,[3] Amir Lerman,[2] Lilach O. Lerman.[1] *[1]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Division of Cardiovascular Disease, Mayo Clinic, Rochester, MN; [3]Department of Pediatrics, UCLA, Los Angeles, CA.*

Background: Atherosclerosis promotes chronic kidney disease. Humanin (HN) is an endogenous mitochondria-derived cytoprotective peptide, but its role in atherosclerosis-induced kidney damage is unknown.

Methods: Ten C57BL/6 and 12 ApoE KO mice were fed 16 wks of normal or high cholesterol (HC) diet, respectively, supplemented daily with Intraperitoneal Injection of saline (Control, n=4, HC, n=6) or +HN (4 mg/kg/d, Control+HN, n=6, HC+HN, n=6). Microvascular remodeling was assessed ex-vivo with micro-CT and alpha-SMA staining. Angiogenesis, inflammation and apoptosis were evaluated in kidney tissue by Western-blots, and fibrosis by trichrome staining.

Results: ApoE KO mice had elevated serum cholesterol but normal creatinine levels. Cortical microvascular spatial density and media/lumen ratio were significantly increased in HC and restored in HC+HN.

Figure1



A-D Representative 3-dimensional tomographic images of kidney microvasculature; E HN decreased the spatial density of both small (20-200μm) and large (200-500μm) cortical microvessels that proliferated in ApoE KO HC kidneys. * p<0.05 vs. normal.

VEGF (P<0.05) and angiopoietin-1 (P=0.07) expression increased in HC+HN, but HN also significantly upregulated anti-angiogenic angiostatin and thrombospondin-1. HN downregulated the expression of inflammatory cytokines MCP-1 and TNF-alpha in HC+HN. Furthermore, pSTAT3 significantly declined in HC, and HN restored pSTAT3 and attenuated Bax in HC+HN, suggesting blunted apoptosis, and HN blunted a trend for renal fibrosis observed in HC.

Conclusions: HN attenuates murine HC-induced renal microvascular proliferation and remodeling by upregulating anti-angiogenic factors, and mitigates inflammation, apoptosis, and fibrosis. These findings suggest HN as a novel therapeutic target in atherosclerosis.

Role of mTOR Signaling in Interstitial Inflammation and Kidney Fibrosis Guochun Chen,[1] Lin Sun,[1,2] You-Ming Peng,[1] Hong Liu,[1] Guanghui Ling,[1] Li Xiao,[1] Fu-You Liu.[1] *[1]Department of Nephrology, Second Xiangya Hospital, Central South University, Changsha, Hunan, China; [2]Departments of Pathology and Medicine, Northwestern University, Chicago, IL.*

Background: Progressive inflammation and fibrosis are responsible for chronic kidney failure, however, the molecular mechanism remains obscure. Recent studies have highlighted the mammalian target of rapamycin (mTOR) as a regulator of inflammatory reaction and collagen expression. In this study, we revealed a role of mTOR signaling in the progression of interstitial infiltration and fibrosis after kidney injuries.

Methods: Ischemic-reperfusion injury (IRI) or unilateral ureteral obstruction (UUO) mouse models were used in the experiment. Daily administration of Rapamycin was performed to inhibit mTOR signaling in designated groups. Immunohistochemical staining and western blot were performed to evaluate the activation of mTOR signaling. Expression of inflammatory chemokines was analyzed by realtime PCR.

Results: mTOR signaling was significantly up-regulated 24-48 hours post-injuries in rodent models of either IRI or UUO. Confocal imaging confirmed that pS6K, a downstream target of mTOR signaling, was expressed in de-differentiated epithelial cells, myofibroblasts and macrophages in mouse models of severe IRI and UUO. Up-regulation of SMA, vimentin and collagen-I correlated well with the expression of pS6K in fibrotic kidneys. Interestingly, although high expression of pS6K was observed in macrophages, little could be detected in migrated T cells or neutrophils, which suggested macrophages may be primary effectors of mTOR signaling that triggered the inflammatory cascade at the onset of kidney fibrosis. Administration of rapamycin, a specific mTOR complex inhibitor, significantly reduced renal fibrotic production (SMA and collagen I) and interstitial inflammation in a mouse UUO model, including chemokines production (MCP-1,TNF-a,IL-1beta and CXCL-1) and cells infiltration.

Conclusions: Taken together, our data suggest that activation of mTOR signaling mediates persistent tubulointerstitial inflammation and fibrosis after kidney injuries. Inhibition of mTOR signaling may be potential of anti-fibrosis in chronic kidney diseases.

Ischemic Preconditioning Lowers Renal Reperfusion Injury and Inflammatory Stress Leonella Luzardo,[2] Elia Ripoll,[1] Marcel.la Franquesa,[1] Liliana Gadola,[2] Nuria Lloberas,[1] Inmaculada Herrero,[1] Ana Panuncio,[2] Josep M.B. Grinyo,[1] Joan Torras.[1] *[1]Laboratory of Experimental Nephrology, IDIBELL. Hospital Universitari de Bellvitge, Spain; [2]Departamento de Fisiopatología, Hospital de Clínicas, Hospital de Clínicas Facultad de Medicina, Montevideo, Uruguay.*

Background: Acute kidney injury is associated with major in-hospital morbidity and mortality. In addition to ischemia, inflammation linked to reperfusion injury amplifies tissue damage. The aim of the study was to evaluate the effect of ischaemic preconditioning (IP) on a kidney ischemic-reperfusion injury model.

Methods: Male Wistar rats were randomly distributed in four groups (n=8 each). 1) SHAM; 2)ISCHEMIA, both renal pedicles occluded for 40 minutes; 3)IP-10 ten minutes of ischaemic preconditioning, 10 minutes of reperfusion and 40 minutes of ischemia; 4)IP-15 fifteen minutes of ischaemic preconditioning, 10 minutes of reperfusion and 40 minutes of ischemia. Under tiopental i/p, laparotomy was performed and renal pedicles were occluded using Aescula Braun clamps. Ischemia and reperfusion were confirmed visually. A blood sample was obtained (tail vein) prior to surgery and 24 hs later. 48 hs after procedure, animals urine and blood samples were taken. Left kidney tissue sections were obtained for immune-histochemistry using anti-nitrotyrosine antibody. On right kidney tissue we measured CD40, IL6, IL10, TNF-α, TGF-β, TLR 3 and TLR 4 by RT-PCR. Values are reported as mean ± SD and statistical analysis was performed by ANOVA test.

Results: IP vs ISCHEMIA groups had significantly lower plasma urea levels at 48 hs (37.6 vs 112.5; P<0,0002) and creatinine levels at 24 hs (0.76 vs 2.06; P=0.004) and at 48 hs (0.57 vs 1.17; P=0.002). PI groups showed lower expression of pro-inflammatory molecules CD40, TNF-α and TLR3 (P<0.05) but not TLR4 (P=0.06). IL6, IL10 and TGF-β expression was no significantly different. IP groups showed less anti-nitrotyrosine staining than ISCHEMIA group (IP-10: 0.29±0.19; IP-15: 0.52±0.14; ISCHEMIA: 1±0.13; P=<.0001)

Conclusions: Ischaemic preconditioning, either 10 or 15 minutes, showed a protective effect from a further prolonged ischemic injury. This could be explained, at least in part, due to a lower inflammatory stress.

TH-PO119

Activation of Type II NKT Cells Mediates Kidney Ischemia/Reperfusion Injury Li Li,[1] Liping Huang,[1] Steven P. Song,[1] Hong Ye,[1] Diane L. Rosin,[2] Mark D. Okusa.[1] *[1]Division of Nephrology, Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia, Charlottesville, VA; [2]Department of Pharmacology, University of Virginia, Charlottesville, VA.*

Background: CD1d-restricted type I and type II natural killer T (NKT) cells bridge innate and adaptive immune responses in kidney ischemia-reperfusion injury (IRI). Although type II NKT cells have not been as extensively studied as type I NKT cells, these cells have been shown to play a critical role in cancer and autoimmune diseases. We hypothesized that type II NKT cell activation is also involved in the immune response of kidney IRI.

Methods: We subjected mice to bilateral pedical clamp for 24 min followed by 24 hrs reperfusion, and plasma were collected for creatinine measurement.

Results: Compared to WT mice, CD1dKO mice (both type I and type II NKT cell deficient) were markedly protected, while Ja18KO mice (type I NKT cell deficient) showed an intermediate degree of protection ($P<0.05$). Plasma creatinine was (mg/dl): 1.38±0.19, 0.73±0.17 and 0.29±0.02, respectively. An optimal dose of sulfatide (1 μg/g) significantly and specifically activates type II NKT cells and promoted mild kidney IRI; plasma creatinine was 1.11± 0.10 vs. 0.47±0.04, respectively ($P<0.01$). IL-12(p35/p40) and IL-23 pathways are required for sulfatide-induced inflammation in kidney IRI as a protective effect was shown in sulfatide treated IL-12p35KO, IL-12p40KO and IL-23p19KO mice ($P<0.01$). IL-17AKO and IL-17RKO mice protected kidneys from sulfatide-mediated kidney injury in IRI ($P<0.01$), while IFN-γKO mice did not ($P>0.05$). Taken together with our prior studies, this indicates that IL-17A/R and IFN-γ contribute differentially to type I and type II NKT cell activation in kidney IRI. Co-stimulatory molecules CD40 and OX40L are required to mediate type II NKT cell activation, as CD40KO mice or mice injected with anti-OX40L mAb were resistant to sulfatide-induced kidney inflammation compared with WT mice (P all < 0.01).

Conclusions: Understanding the pathogenic role of NKT cells in the initiation of the immune response will provide new information for designing novel therapeutic strategies for AKI.

TH-PO120

Mannose-Binding Lectin Mediates Renal Ischemia Reperfusion Injury Independent of Complement Activation Cees van Kooten,[1] Pieter van der Pol,[1] Nicole Schlagwein,[1] Danielle Van Gijlswijk,[1] Stefan P. Berger,[1] Ingeborg M. Bajema,[2] Gregory L. Stahl,[3] Johan W. De Fijter,[1] Mohamed R. Daha.[1] *[1]Nephrology, LUMC, Leiden, Netherlands; [2]Pathology, LUMC, Leiden, Netherlands; [3]Center for Experimental Therapeutics, Harvard Instirute of Medicine, Boston.*

Background: Ischemia/reperfusion injury (IRI) is an inevitable event in kidney transplantation and has a major impact on short- and long-term graft survival. Complement activation, a central component of innate immunity, is one of the hallmarks of renal IRI. Genetically-determined low serum levels of Mannose Binding Lectin (MBL) have been associated with improved renal allograft survival.

Methods: We used an experimental rat model of IRI by 45 minute ischemia of uni-nephrectomized Lewis rats and investigated the role of MBL-mediated complement activation using blocking antibodies against MBL or C5, followed by functional and histological analysis. In vitro cultured human proximal tubular epithelial cells (PTEC) were used to investigate direct effects of MBL on tubular integrity

Results: Transient inhibition of MBL completely preserves renal function and tubular integrity and prevents influx of neutrophils and macrophages following experimental renal IRI in rats. Although complement deposition (C3 and C5b-9) is observed from 24 hours onwards in non-treated rats, inhibition of the down stream complement mediators C3 and C5 was not protective. Histological signs of tubular injury were already observed within hours after reperfusion, accompanied by vascular leakage of MBL into the interstitium, reaching tubular epithelial cells in ischemic but not control kidneys. Exposure of in vitro cultured human PTEC to purified MBL resulted in specific binding and internalization of MBL, followed by a dose- and time-dependent induction of cell death.

Conclusions: In conclusion, we demonstrate a novel role for MBL in the pathophysiology of IRI, independent of its capacity to activate the lectin pathway of complement. As a consequence of vascular leakage, exposure of renal tubular cells to MBL results in a rapid induction of tubular cell death, one of the earliest events in IRI, making MBL an interesting target for therapy.

TH-PO121

The Role of Toll-Like Receptors Adaptor Protein MyD88 and Activation of Nrf2 in Ischemic/Hypoxic Injury of the Kidney Min Li, Altaf-M Khan, Eric E. Simon, Vecihi Batuman. *Department of Medicine/Nephrology, Tulane University School of Medicine, New Orleans, LA.*

Background: Inflammation is a critical component of innate immunity that is triggered by Toll-like receptors through activation of its adaptor protein MyD88 in acute kidney injury (AKI). We previously demonstrated the pivotal role of MyD88-dependent mechanisms in the coordination of innate immune responses to ischemic/hypoxic acute renal tubular injury.

Methods: In the present study, we found that the exposure of human proximal tubule epithelial cells (HK-2) to hypoxia and wild-type mice kidneys to ischemia activated NF-E2-related factor 2 (Nrf2), a basic leucine zipper transcription factor that regulates inflammation, leading to expression of Nrf2-regulated genes including heme oxygenase-1 (HO-1).

Results: Suppression of MyD88 by specific shRNA transfection in HK-2 cells and MyD88-deficient murine kidneys elevated the base level of Nrf2 expression. The activation of Nrf2 and tissue production of HO-1 was significantly increased in MyD88 knockdown cells subjected to hypoxia in vitro and in MyD88-/- mice after ischemia/reperfusion in vivo. However, compared with the normal HK-2 cells and sham operated mice, the production of IL-6 and MCP-1 was still increased but was markedly lowered in MyD88 knockdown cells and in MyD88-/- mice subjected to ischemic/hypoxic injury. By using pharmacological and genetic analyses, we found that activation of Nrf2 in response to hypoxia/ischemia is dependent on MyD88 for the production of pro-inflammatory cytokines.

Conclusions: Our results show that MyD88 dependent signaling tempers activation of Nrf2 in response to ischemic/hypoxic injury resulting in exaggerated injury. In contrast, blocking MyD88 is associated with more brisk Nrf2 response leading to higher levels of HO-1, reduced levels of IL-6 and MCP, and better preservation of kidney after ischemia/reperfusion injury.

TH-PO122

Acute Kidney Injury in Cisplatin Nephrotoxicity Is Dependant on Mast Cell Degranulation and TNF Release Shaun A. Summers,[1] Poh-Yi Gan,[2] David J. Nikolic-Paterson,[1] Oliver M. Steinmetz,[2] A. Richard Kitching,[1] Stephen R. Holdsworth.[1] *[1]Department of Medicine and Nephrology, MMC and Monash University; [2]Department of Medicine, Monash University.*

Background: Mast Cells (MCs) are pluripotent innate immune cells, which contain a large number of vasoactive and inflammatory molecules, which are released after degranulation. Previously we demonstrated that compared to C57BL/6 wild type (WT) mice, mast cell deficient, KitWsh/Wsh mice, are protected from cisplatin nephrotoxicity (CN) . In these studies we sought to define the pathophysiological role of MCs in CN.

Methods: Initially we assessed the role of MC degranulation after cisplatin treatment. To determine the role of MCs in AKI we administered cisplatin to WT and KitWsh/Wsh mice. We assessed kidney TNF mRNA expression and serum TNF production as well as pro-inflammatory chemokines. Subsequently we reconstituted KitWsh/Wsh mice with MCs from WT and TNF-/- mice, and then administered cisplatin. Renal injury and leukocyte recruitment was assessed 4 days later.

Results: Administration of cisplatin resulted in an increase in serum (control 33.4±2.7 vs. cisplatin treated 53.2±7.1 ng/ml tryptase, $P<0.05$) and kidney (control 1.7±0.7 vs. cisplatin treated 7.6±1.5 ng/ml tryptase , $P<0.01$) MC degranulation. Serum TNF levels (84.4±7.4 vs. 60.5±4.9pg/ml) were lower in KitWsh/Wsh mice. Intrarenal TNF mRNA expression, as well as mRNA for key T cell (RANTES/CCL5, IP-10/CXCL10), and neutrophil chemokines (KC/CXCL1 and MIP2/CXCL2) were also decreased in KitWsh/Wsh mice. To define the mechanism of MC-mediated AKI, KitWsh/Wsh mice, reconstituted with MCs derived from WT or TNF-/- mice, were given cisplatin. Compared to KitWsh/Wsh mice reconstituted with WT MCs, renal injury was attenuated in KitWsh/Wsh mice reconstituted with TNF-/- MCs (BUN 100.3±16.2 vs. 41.6±15.9mmol/l, $P<0.01$; histological injury assessed semiquantatively 3.3±01 vs. 2.2±0.2, $P<0.001$). Compared to mice reconstituted with WT MCs there was a decrease in serum TNF production (WT MCs 104.8±5.7 vs. TNF-/- MCs 50.9±8.9 pg/ml, $P<0.001$) and kidney neutrophil recruitment.

Conclusions: Acute kidney injury induced by cisplatin is dependent on MC degranulation and TNF release.

Autoantibodies to LAMP-2 in ANCA Negative Pauci-Immune Focal Necrotizing Glomerulonephritis (piFNGN) Andrew J. Rees, Renate Kain. *Clinical Department of Pathology, Medical University of Vienna, Vienna, Austria.*

Background: piFNGN occurs characteristically in people with ANCA-associated vasculitis. However, ANCA assays are negative in up to 10% of patients; antibodies to MPO and PR3 cannot be detected thus leaving the cause of injury obscure. We reported a high prevalence of antibodies to LAMP-2 in patients with active piFNGN (including one ANCA negative individual) and showed they could induce piFNGN in rats. The purpose of this study was to ascertain the frequency of antibodies to LAMP-2 in ANCA negative piFNGN more generally and to determine why the antibodies concerned fail to bind to LAMP-2 in neutrophils by indirect immunofluorescence.

Methods: Eleven ANCA negative patients were studied (10 with isolated piFNGN and 1 with renal, lung and skin involvement). We confirmed standard fluorescent ANCA assays and ELISA for MPO and PR3 were negative in all 11. All 8 patients' autoantibodies also bound glycosylated hLAMP targeted to the cell surface and expressed in CHO cells. Neutrophil LAMP-2 has a unique glycosylation pattern with complex poly-lactosamine chains and we confirmed that this carbohydrate moiety resulted in the contrasting binding to human LAMP-2 in neutrophils and CHO cells.

Results: We showed that: (i) removal of poly-lactosamines with endo-β-galactosidase from neutrophil LAMP-2 decreased its molecular mass to that of LAMP-2 purified from glomeruli or expressed in CHO cells; and (ii) ANCA assays became positive for all 8 patients when the ANCA slides were pre-treated with this enzyme. This treatment had no effect in control slides. Lastly, we confirmed immunoblot that antibodies to LAMP-2 in ANCA negative patients bind native LAMP-2 purified from glomeruli.

Conclusions: In summary, we demonstrated that some ANCA negative patients with piFNGN have antibodies to LAMP-2 that bind glomerular LAMP-2 but not that of neutrophils. We suggest that these autoantibodies contribute to pathogenesis in the absence of canonical ANCA.

By contrast, 8 of the 11 (73%) had circulating autoantibodies that bound to unglycosylated human recombinant LAMP-2 extracellular domain in our standard ELISA and by immunoblot.

Expression of the PTPN22 Gain-of-Function Variant Results in ERK Inhibition Leading to Down-Regulation of IL-10 Expression Yali Cao,[1,2] Jia Jin Yang,[1] Susan L. Hogan,[1] Yichun Hu,[1] Caroline E. Jennette,[1] Elisabeth Berg,[1] J. Charles Jennette,[1] Ronald J. Falk,[1] Gloria A. Preston.[1] *[1]UNC Kidney Center, UNC-CH, Chapel Hill, NC; [2]Nephrology, China-Japan Friendship Hospital, Beijing, China.*

Background: We predicted that cellular signaling dynamics would be disrupted by expression of the disease-associated allele of the protein tyrosine phosphatase PTPN22 (R620W), conferring a gain-of-function phenotype. This change negatively affects SRC activation due to loss of CSK sequestration. Signaling through RAS is also affected through GRB2-PTPN22 (R620W) interactions.

Methods: Phosphatase activity was measured in leukocytes from patients with anti-neutrophil cytoplasmic autoantibody (ANCA) disease, comparing patients with the gain-of function allele to patients with the normal allele. PTPN22 protein was captured using an anti-PTPN22 antibody on two separate microtiter plates. One was analyzed for total protein captured and the other for activity status of the captured protein, reported as an activity/protein ratio. Activation of downstream signaling pathways was determined by western blot analysis. IL-10 transcription was quantitated by TaqMan PCR.

Results: Basal activity of PTPN22(R620W) variant was persistently elevated in leukocytes (p<0.0001), neutrophils (p=0.0004) and lymphocytes (p=0.0003), while undetectable in leukocytes expressing normal PTPN22. Inappropriate activity of the gain-of-function phosphatase resulted in downregulation of ERK, opposite to controls. Instead, p38 MAPK was up-regulated. *IL-10* transcription, which is reliant on the ERK pathway, was negatively affected by expression of the variant with reduced levels compared to controls (n=26, p<0.0001). Over the course of disease, patients expressing variant PTPN22(R620W) did not show a spike in IL-10 transcription as they entered remission in contrast to controls, implying that environmentally triggered signals were blunted (p<0.0001).

Conclusions: Sustained activity of PTPN22, due to the gain-of-function mutation, acts as a dominant negative regulator of ERK activity leading to blunted cellular responsiveness to environmental stimuli and expression of protective cytokines.

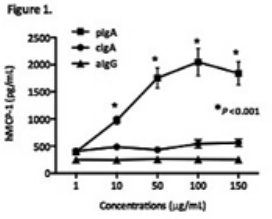
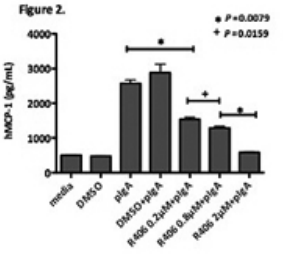
Spleen Tyrosine Kinase Is Involved in the Production of Pro-Inflammatory Cytokines by Human Mesangial Cells Following Stimulation with Polymeric IgA1 Isolated from IgA Nephropathy Patients Min Jeong Kim,[1] Jonathan Barratt,[2] Karen Molyneux,[2] Esteban S. Masuda,[3] Charles D. Pusey,[1] Frederick W.K. Tam.[1] *[1]Imperial College Kidney and Transplant Institute, London, United Kingdom; [2]Dept. of Infection, Immunity & Inflammation, Univ. of Leicester, United Kingdom; [3]Rigel Pharmaceuticals, South San Francisco.*

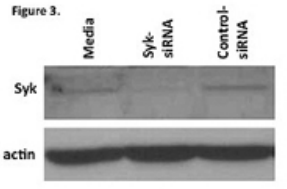
Background: Polymeric IgA1 (pIgA) isolated from the serum of IgAN patients stimulates human mesangial cells (HMC) to produce pro-inflammatory cytokines. The aim of our study was to determine if spleen tyrosine kinase (Syk) is involved in HMC in the downstream signaling pathway of IgA receptors, leading to the production of pro-inflammatory cytokines.

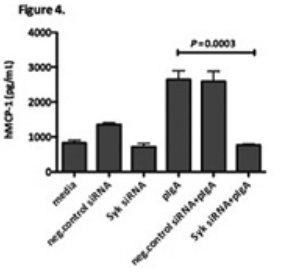
Methods: HMC were incubated with pIgA, control IgA from healthy human (cIgA), or heat aggregated IgG (aIgG). We measured MCP-1 by ELISA and additional 26 cytokines by multiplex cytokine assay from the culture supernatant after 24h. We then incubated HMC with a Syk inhibitor, R406, 1h before stimulation with pIgA (50μg/mL) and performed real-time RT-PCR and ELISA. HMC were then transfected with Syk siRNA or negative control siRNA, 72h before stimulation with pIgA. Transfection efficiency was proved by Western blot.

Results: MCP-1 was significantly higher upon stimulation with pIgA than cIgA or aIgG in a dose dependent manner, and this was inhibited significantly by R406 (Fig1,2). The same was true for other cytokines (IL-6, IL-8, IL-9, IP-10 and RANTES). The MCP-1 mRNA was also reduced significantly. The Syk expression was effectively suppressed and MCP-1 protein level after stimulation with pIgA was significantly reduced upon transfection with Syk siRNA (Fig3,4).









Conclusions: Our data strongly suggest the involvement of Syk in HMC in the production of pro-inflammatory cytokines upon stimulation with pIgA, and its role in the pathogenesis of IgAN. Syk may be considered as a potential target in the treatment of IgAN.

TH-PO126

HIV Induces Activation of Renin Angiotensin System in Lymphocytes through Downregulation of Vitamin D Receptor Nirupama Chandel, Hersh Goel, Shabina Rehman, Ashwani Malhotra, Mohammad Husain, Pravin C. Singhal. *Medicine, North Shore LIJ Hofstra medical School, Great Neck, NY.*

Background: Interstitial lymphocytes aggregation is frequently associated with renal fibrosis. Activation of the renin-angiotensin system (RAS) has been demonstrated to play a key role in the progression of HIV-associated nephropathy (HIVAN). Interstitial lymphocytes serve as a source for profibrotic cytokines and vasoactive agents such as Ang II. Vitamin D receptor (VDR) has been reported to be a negatively regulator of renin transcription. In the present study, we evaluated the effect of HIV infection on lymphocyte VDR expression and activation of the RAS.

Methods: Lymphocytes (LY) were isolated from human blood obtained from the New York Blood Bank (n=5). LYs were incubated with X4 virus or buffer for two hours and then washed and re-incubated in media for 24 hours. RNA and proteins were extracted from lymphocytes. Immunoblotting and real time PCR studies were performed for expression of VDR, angiotensinogen (Agt) and renin. Ang II ELISA was carried out on lymphocytes prepared under similar conditions. To establish a causal relationship between VDR and the RAS activation, lymphocytes with or without silenced VDR (siRNA-VDR/LY) were evaluated for the expression of Agt and renin and production of Ang II. To confirm the relationship between HIV and VDR, LYs and HIV/LY were treated with Vitamin D2 analogue for 24 hours; subsequently, VDR, renin, and Agt expression was determined by immunoelectrophoresis.

Results: HIV/LY showed attenuated (P<0.01) expression of VDR but displayed enhanced expression of Agt and renin (P<0.01) . Moreover, HIV/LY showed 2.5 fold increased Ang II production (P<0.01) when compared to control lymphocytes. On the the other hand, Vit D treated HIV/LY not only showed upregulation of VDR but also displayed attenuated expression of renin and diminished (P<0.05) production of Ang II.

Conclusions: These findings indicate that HIV enhances lymphocyte RAS activation through VDR downregulation. The present study provides mechanistic insight into the role of lymphocytes in the activation of the RAS in HIVAN.

TH-PO127

Angiotensin II Stimulates S100A12 Production in Macrophages Eiko Matsuoka,[1] Yasukiyo Mori,[1] Yayoi Shiotsu,[1] Atsushi Kosaki.[2] *[1]Department of Cardiology and Nephrology, Kyoto Prefectural University of Medicine, Kyoto, Japan; [2]Department of Medicine II, Kansai Medical University, Osaka, Japan.*

Background: S100A12, formerly called EN-RAGE, is an endogenous ligand for the receptor for advanced glycation end products (RAGE). Our working hypothesis is that S100A12 protein might contribute to the development of atherosclerosis. We recently found that plasma S100A12 level was an independent factor associated with the prevalence of cardiovascular disease in hemodialysis patient (Shiotsu Y and Mori Y et al. Clin J Am Soc Nephrol 2011; 6: 718-723). S100A12 is reported to be abundantly expressed and secreted from neutrophils and monocytes/macrophages in human. However, the detail of regulatory mechanism of S100A12, especially in chronic kidney disease, remains unknown. In this study, we evaluate the effect of Angiotensin II (Ang II) on S100A12 transgenic mice (S100A12tg).

Methods: We exploited the fact that S100A12 is not present in mice and generated the mice (C57BL6/J) expressing human S100A12 in myeloid cells under the control of CD11b promoter. RT-PCR using the specific primer for human S100A12 and ELISA for human S100A12 protein, which was developed by our laboratory, were used to evaluate the S100A12 transcripts and its protein. Macrophages were collected from peritoneal cavities of S100A12tg. Because we found the expression of S100A12 in HepG2, the cell line from human hepatic carcinoma, in the preliminary experiment, HepG2 was used as a reference.

Results: In HepG2, Ang II increased the level of S100A12 mRNA in a time-dependent(8h: 1.2-fold, 16h: 1.6-fold). The stimulating effects were abolished by pretreatment with Olmesartan, Ang II type 1 receptor blocker. The effect of AngII on S100A12 was greater in peritoneal macrophages from S100A12tg. Ang II increased the level of S100A12 transcripts by 6-fold. Although the peritoneal macrophages from wild type mice had no transcripts as well as protein of S100A12, S100A12 proteins in culture medium of peritoneal macrophages from S100A12tg was detectable (1.44ng/mL) after the treatment with Ang II.

Conclusions: These findings suggest that Ang II stimulates S100A12 production in macrophages.

TH-PO128

Effects of Uremic Toxins on the Cross-Talk between Leukocytes and the Vessel Wall in an In Vivo Rat Model Anneleen Pletinck, Griet L.R.L. Glorieux, Eva Schepers, Wim Van Biesen, Raymond C. Vanholder. *Internal Medicine, Nephrology, University Hospital Ghent, Ghent, Belgium.*

Background: The major cause of death in CKD-patients is cardiovascular disease. Accumulation of uremic toxins is partly involved in this condition. *In vitro* models showed that p-cresylsulfate (pCS) and indoxylsulfate (IS) have an effect on leukocyte activation and/or vascular integrity. These models however miss the complicated cross-talk between different cell systems as present *in vivo*. This study evaluated the effects induced by acute exposure to uremic toxins on the recruitment of circulating leukocytes in the rat peritoneal vascular bed, using an intravital microscopic model.

Methods: The peritoneum of rats was exposed to HBSS or HBSS containing an uremic toxin at a concentration relevant in uremia. Leukocyte-endothelial interactions, bloodflow rate and vessel diameter were analyzed in postcapillary venules during 120 min.

Results: In the control condition,no effect on the number of rolling and adhering leukocytes was observed. The number of extravasated leukocytes increased moderately, but significantly after 20 minutes. Exposure to pCS significantly increased the number of rolling leukocytes already after 2 min ($p<0.05$). Adhering was significantly increased at 120 min ($p=0.011$). The number of extravasated leukocytes was significantly increased from 20 min on ($p<0.05$),which became significantly higher compared to the control group after 30 and 60 min. Exposure to IS only caused a strong and fast extravasation of leukocytes after 10 min of exposure ($p<0.05$). This became significantly higher compared to the controls after 30 min ($p<0.05$). In 5/7 rats, an interruption of blood flow was observed after ± 30-60 min exposure to IS. Vasoconstrictive properties of IS were tested with a wire myograph, but results were negative.

Conclusions: These results provide clear evidence that pCS and IS exert a proinflammatory effect that could contribute to the propensity for vascular disease in uremic patients. Tissue factor will be investigated to reveal a possible role of the coagulation-cascade in the interrupted blood flow, observed after IS-exposure. Other toxins (SDMA,ADMA,p-cresylglucuronide) are currently being analyzed.

TH-PO129

Aberrantly Glycosylated IgA1 Diminishes Adiponectin Expression in Glomerular Mesangial Cells *In Vitro* and *In Vivo*: A Novel Anti-Inflammatory Mechanism in IgA Nephropathy Hitoshi Sugiyama, Tatsuyuki Inoue, Masashi Kitagawa, Keiichi Takiue, Hiroshi Morinaga, Yoko Kikumoto, Ayu Ogawa, Shinji Kitamura, Yohei Maeshima, Hirofumi Makino. *Okayama University Graduate School, Okayama, Japan.*

Background: The pathogenesis of IgA nephropathy (IgAN) may be associated with the mesangial deposition of aberrantly glycosylated IgA1. However, the effect of desialylated and degalactosylated (deSial/deGal) IgA1 on human mesangial cells (HMCs) *in vitro* and *in vivo* still remains unknown.

Methods: Enzymatically modified deSial/deGal IgA1was generated to identify mediators affected by aberrantly glycosylated IgA1 in cultured HMCs. The presence of deglycosylated IgA1 was confirmed by lectin binding to *Helix aspersa* (HAA) and *Sambucus nigra agglutinin* (SNA). The deposition of deglycosylated IgA1 was investigated with dual staining of HAA and IgA in human renal biopsy specimens from patients (n=53) including IgAN and lupus nephritis. The urinary HAA/SNA ratio was determined in spot urine samples from patients with IgAN (n=78) and other kidney diseases (n=142).

Results: A cytokine array analysis revealed that 52 proteins were upregulated and 34 were downregulated in cultured HMCs after stimulation with deSial/deGal IgA1. Among them, the secretion of adiponectin was suppressed in HMCs after stimulation with deSial/deGal IgA1. HMCs expressed mRNAs for adiponectin and its type 1 receptor, but not the type 2 receptor. There was a significant downregulation of adiponectin expression in the glomeruli of renal biopsy specimens from patients with IgAN in comparison to those with lupus nephritis. In addition, the deposition of aberrantly glycosylated IgA1 was observed in the mesangium of patients with IgAN by dual staining of HAA and IgA. Moreover, the urinary HAA/SNA ratio of lectin binding was significantly higher in IgAN in comparison to other kidney diseases.

Conclusions: In conclusion, these results indicate that aberrantly glycosylated IgA1 downregulated the adiponectin expression in HMC *in vitro* and in the glomeruli of human IgAN *in vivo*. Glomerular lectin binding assays using HAA demonstrated the presence of aberrantly glycosylated IgA1 in the glomeruli, predominantly in IgAN.

Stimulation of Wnt/beta-Catenin Signaling by Paricalcitol Prevents oxLDL-Induced Tregs Apoptosis and Restores Their Function Pascal Meier. *Service of Nephrology, RSV - Hôpital du Valais, Sion, Switzerland.*

Background: OxLDL induce Tregs cell cycle arrest and apoptosis affecting their suppression capacity and finally promote a constant micro-inflammatory state in patients with ESKD. This is partly due to the down-regulation of the Wnt/beta-catenin signaling that promotes phosphorylation of beta-catenin leading this latter to its ubiquitinylation and degradation by the proteasome. Because vitamin D analogs can modulate beta-catenin in other tissues, we tested whether the vitamin D analog paricalcitol could ameliorate Tregs response by stimulating Wnt/beta-catenin signaling in presence of oxLDL.

Methods: Tregs from healthy blood donors were incubated for up to 72 h in RPMI alone with oxLDL (100 µg/mL) before washing and then treated with paricalcitol (1.5 ng/ml). To better analyze the effects of paricalcitol, Tregs were stimulated with Abs to CD3/CD28 (10 µg/mL). RT-PCR and Western blot analyses were performed. Cell viability was measured using a MTT assay and apoptosis indirectly assessed by Fas staining (flow cytometry) and confirmed by DNA fragmentation. To address their suppressive capacity, activated Tregs were analyzed in co-culture with $CD4^+/CD25^-$ T cells (T_{eff}) in presence of APC.

Results: Compared with vehicle-treated Tregs, paricalcitol significantly upregulated beta-catenin in activated Tregs after oxLDL treatment. Quantitative determination showed a more than 150-fold and 80-fold induction of beta-catenin protein over the controls and vehicle-treated Tregs, respectively. Immunohistochemical staining confirmed the beta-catenin upregulation in cytoplasm and nucleus. The expression of the anti-apoptotic protein, Bcl-x_L an upstream mediator of the Wnt/beta-catenin signaling in Tregs was examined. Bcl-x_L was markedly down regulated in oxLDL-treated Tregs; and administration of paricalcitol largely stimulated nuclear Bcl-x_L synthesis in parallel with the lower expression of cell-surface apoptotic marker Fas and less DNA fragmentation.

Conclusions: Thus paricalcitol improves the cytosolic and nuclear expression of beta-catenin that in its turn favors Bcl-x_L transcription protecting Tregs to enter into apoptosis; and finally, significantly ameliorates oxLDL-treated Tregs function.

Neutrophilic Granulocytes Modulate T Lymphocytic Response in Peritonitis in Mice and Humans Sibylle Von Vietinghoff,[1,2] Gerhard Wingender,[2] Marcus Hiss,[1] Klaus Ley,[2] Hermann G. Haller,[1] Mitchell Kronenberg.[2] *[1]Medicine, Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]La Jolla Institute for Allergy and Immunoloy, La Jolla, CA.*

Background: In patients undergoing peritoneal dialysis, peritonitis is a common complication and can limit this treatment. Under resting conditions most peritoneal leukocytes are T lymphocytes, but neutrophilic granulocytes invade the peritoneal cavity in large numbers during peritonitis. Here we investigated how neutrophilic granulocyte accumulation alters cellular antigen-specific host response by glycolipid specific invariant natural killer T (iNKT) lymphocytes.

Methods: Leukocytes were recovered from peritoneal fluid from stable patients on peritoneal dialysis and patients with acute peritonitis. Neutrophilic peritonitis was induced in mice by thioglycollate injection. T lymphocytes were co-incubated with granulocytes in vitro. iNKT cells were stimulated with the specific antigen alpha-Galactosyl-ceramide. Multi-color flow cytometry and cytokine ELISA were used for analysis.

Results: Neutrophilic inflammation in experimental peritonitis in mice decreased iNKT cell transcription factor expression and antigen-induced cytokine production in vivo. This was reverted by blockade of neutrophil mobilization. Transcription factor expression was decreased in glycolipid-reactive iNKT cells from the neutrophil rich bone marrow compared to spleen in mice. In vitro, the function of both mouse and human iNKT cells was inhibited by co-incubation with neutrophils. This required cell-cell contact with live neutrophils. During peritonitis, transcription factor T-bet expression was reduced in peritoneal compared to peripheral blood iNKT lymphocytes in patients on peritoneal dialysis.

Conclusions: Our data reveal a novel regulatory axis whereby neutrophils reduce iNKT lymphocyte responses. This may be important in shaping the extent of inflammation in both host defense and destructive inflammation.

Lipoxin A4 Reprogrammes CD16+ Mononuclear Cells Eileen Nolan,[1,2] Debra F. Higgins,[1,2] Paula Maderna,[1,2] Yvonne M. O'Meara,[2,3] Catherine Godson.[1,2] *[1]UCD Diabetes Research Centre, UCD Conway Institute of Biomolecular and Biomedical Research; [2]UCD School of Medicine and Medical Science, University College Dublin, Belfield, Dublin 4; [3]Mater Misericordiae University Hospital, Dublin 7, Ireland.*

Background: The diversity of macrophage influence on kidney disease is related to their phenotypic and functional heterogeneity. $CD16^+$ macrophages (M1) are pro-inflammatory, contributing to renal fibrosis and progression of CKD, whereas $CD16^-$ cells (M2) are anti-inflammatory and pro-resolving. Monocytes exhibit similar non-uniformity,

with upregulation of a $CD16^+$ subset occurring in haemodialysis, and contributing to increased cardiovascular risk. Lipoxins are endogenously-produced eicosanoids, with established anti-inflammatory and pro-resolving properties. The purpose of this study was to determine whether lipoxin A_4 (LXA_4) would prove effective in reducing pro-inflammatory mononuclear cell populations.

Methods: The human monocyte cell line THP-1 was differentiated into a macrophage-like phenotype, by treatment with PMA (10 nM) for 48 hours. Both THP-1 monocytes and THP-1-derived macrophages were treated with LXA_4 (10nM) or vehicle (0.1% ethanol) for 30 minutes, before exposure to pro-inflammatory stimuli (LPS 100ng/ml or IFN-γ 10ng/ml). Cells were then stained with CD16 antibody and analysed by flow cytometry. Supernatants were retained for cytokine analysis by ELISA.

Results: Treatment of both monocytes and macrophages with LXA_4 resulted in a significant ($p < 0.05$) decrease in CD16 expression, as compared with IFN-γ treated cells, suggesting that LXA_4 reduces the monocyte and macrophage inflammatory subsets, and promotes the macrophage M2 phenotype. Analysis by ELISA of supernatants revealed significantly reduced macrophage production of the pro-inflammatory cytokines IL-6 and TNF-α ($p < 0.05$), following treatment with LXA_4, again suggesting a role for this agent in directing macrophage phenotype.

Conclusions: Lipoxin A_4 may have therapeutic potential in reprogramming pro-inflammatory monocytes and macrophages, thereby inducing a diminution of their detrimental influence, but a beneficial promotion of the anti-inflammatory and pro-resolving activities of M2 macrophages.

Funding: Government Support - Non-U.S.

TH-PO133

Interactions between Complement and Kidney Cells: Implications in Renal Diseases Isabell Kopka,[1] Peter F. Zipfel,[1] Gunter B. Wolf.[2] *[1]Leibniz Institute for Natural Product Research and Infection Biology, Hans Knöll Institute, Jena, Germany; [2]Internal Medicine III, University of Jena, Jena, Germany.*

Background: The complement system is an enzyme cascade of more than 60 proteins and activation products which are involved in innate immune activation and regulation that leads to effector functions including the deposition of the C3b, release of the anaphylatoxin C3a, and formation of the terminal complement complex (TCC). Recently, complement has been implicated in the pathogenesis of primary renal disease and renal transplant rejection. These are caused by complement gene mutations of components, changes in complement levels in the circulation, or presence of complement components in renal tissues. This study focuses on the expression and activity of complement components and regulators of renal cells and their modification during lysis.

Methods: Since kidney cells are damaged when exposed to normal human serum (NHS) in most kidney diseases, human renal proximal tubular cells (HK-2) were challenged with NHS and viability, complement activation, TCC deposition, and presence of complement membrane regulators were assayed using flow cytometry, real time RT/PCR and viability assays.

Results: Exposure to increasing amounts of NHS caused damage revealed by C3b deposition, C3a generation, surface deposition of TCC and decreased viability of the renal cells. However, complement regulators CD46, CD55 and CD59 were detected on the surface of the cells. The complement regulator CD59 was also upregulated in HK-2 cells upon NHS incubation as shown in real time PCR. Moreover, HK-2 cells produced C3 which could be cleaved by Kallikrein and Thrombin, two members of the coagulation system.

Conclusions: The generated C3a acts as an effector molecule and as a cytokine and initiates the induction of tissue factor expression primarily on macrophages which induces an anti-inflammatory response of lysed kidney cells. These results show that exposure to NHS affects viability of renal cells due to activation of the complement system. However, renal cells respond by expressing membrane complement regulators like CD59. Thus, the complement system plays an essential role in the pathogenesis of renal diseases.

TH-PO134

Overexpression of Human Liver-Fatty Acid-Binding Protein (L-FABP) Endogenously Enhances Peroxisome Proliferator-Activated Receptor (PPAR)-α Activity Possibly Via Inducing Hepatocyte Nuclear Factor (HNF)-4α in Immortalized Mouse Proximal Renal Tubular Cells (mProx) Hideki Kimura,[1] Daisuke Mikami,[1] Kazuko Kamiyama,[1] Kenji Kasuno,[1] Naoki Takahashi,[1] Takeshi Sugaya,[2] Haruyoshi Yoshida.[3] *[1]Div of Nephrol, Dept of General Med, Sch of Med, Univ of Fukui, Fukui, Fukui, Japan; [2]CMIC Co, Ltd, Tokyo, Japan; [3]Dept of Med, Obama Municipal Hosp, Obama, Fukui, Japan.*

Background: PPAR reportedly exerts anti-inflammatory and anti-fibrotic actions in proximal renal tubular cells (PRTCs) under inflammation and hypoxia. L-FABP abundantly expressed in PRTCs of human kidney may modulate PPAR activity via their molecular interaction as well as serves as an anti-oxidant. However, no information has been known about the effects of L-FABP induction on PPAR activity in PRTCs.

Methods: Human L-FABP-overexpressed mProx (hL-FABP-mProx) was generated by transfection of the genomic DNA, and analyzed for specific factors involved in PPAR pathway and inflammatory effector molecules, because mouse L-FABP is scarcely expressed in mProx.

Results: In hL-FABP-mProx, hL-FABP expression was up-regulated by over 300-fold as compared with mProx. PPAR-α expression was increased by 10-fold, while PPAR-γ was down-regulated by 5-fold. Palmitate-induced PPRE-luciferase activity (PPAR-α activity) was increased by 2-fold, while PPAR-γ activity was unchanged. mRNA levels of mouse L-FABP, a target gene of PPAR-α, were 40-fold greater in hL-FABP-mProx than in mProx, which was not further augmented by an exogenous PPAR-α activator (fenofibrate), while those of heart-FABP, a target gene of PPAR-γ were unchanged. Concerning known stimulators for PPAR-α expression, hL-FABP overexpression enhanced HNF-4α expression by over 100-fold, but had no affect on Lipin 1 expression. Hypoxia decreased HNF-4α and PPAR-α expression by 40-50% in hL-FABP-mProx. Finally, hL-FABP mProx showed not only reduced basal expression of MCP-1, PAI-1 and CTGF, but also reduced TNF-α-stimulated expression of MCP-1 by 40-70% as compared with mProx.

Conclusions: hL-FABP overexpression in mProx endogenously enhances PPAR-α activation possibly via inducing HNF-4α expression. PPAR-α and HNF-4α induction may cause the reduced inflammatory response in hL-FABP mProx.

TH-PO135

Uremic Priming of a Macrophage Pro-Inflammatory Response Neal B. Blatt,[1] Patricia L. Christopherson,[1] Timothy Cornell,[2] Thomas P. Shanley.[2] *[1]Pediatrics - Nephrology, University of Michigan, Ann Arbor, MI; [2]Pediatrics - Critical Care, University of Michigan, Ann Arbor, MI.*

Background: Monocytes from ESRD patients demonstrate increased cellular activation including increased pro-inflammatory cytokine production. These findings implicate these cells as a key player in the development of ESRD-mediated chronic inflammatory state and excess cardiovascular disease. However, the majority of monocyte samples have been obtained from patients on dialysis (with bioincompatible cuprophane membranes), making it difficult, if not impossible to distinguish the impact of dialysis from the impact of ESRD itself on monocyte function. Our goal is to use a mouse model of chronic renal failure to determine the impact of uremia on macrophage function.

Methods: 129 SvJ mice underwent subtotal nephrectomy (SNx) or a sham procedure. Bone marrow-derived macrophages (BMDM) were isolated from sham and SNx mice and then stimulated with the Toll-like receptor (TLR) ligands lipoteichoic acid (LTA) or lipopolysaccharide (LPS).

Results: SNx mice developed an approximate doubling in BUN values within 4 weeks post-surgery that remained stable for at least 6 months (SNx: 47 ± 9 vs Sham: 24 ± 3 mg/dL, $P<0.001$) indicating the development of uremia. BMDM from SNx mice show increased TNF-α production in tissue culture supernatants following stimulation with both LPS (SNx: 661 ± 74 vs sham: 394 ± 42 pg/mL, $P<0.05$) and LTA (SNx: 2248 ± 100 vs sham: 1808 ± 62, $P<0.05$). At the mRNA level, SNx BMDM show 50% less TNF-α transcript in unstimulated conditions (SNx 0.5 ± 0.1 vs sham 1.0 ± 0.1 fold-induction, $P<0.05$), however upon LPS stimulation, the TNF-α transcript increases in parallel to what is seen at the protein level (SNx: 40.5 ± 8.7 vs sham: 5.9 ± 6.7 fold-induction, $P<0.05$).

Conclusions: We have utilized a well-established mouse model of chronic renal failure to demonstrate that macrophages from uremic mice are primed to respond to TLR ligands. These findings suggest that uremia by itself is able to reprogram the bone marrow to foster the development of a chronic inflammatory state. Additional experiments are in progress to look at epigenetic regulation of these pro-inflammatory macrophage cytokine responses.

Thrombin Stimulates Production of Colony Stimulating Factors in Proximal Tubular Epithelial Cells – Possible Role for Tubulointerstitial Injury Via Chemokine Regulations Michiko Shimada, Yuko Shimaya, Hideaki Yamabe, Yoshiko Shutto, Takeshi Fujita, Norio Nakamura, Ken Okumura. *Department of Nephrology, Hirosaki University, Hirosaki, Japan.*

Background: Colony-stimulating factors (CSFs) are well-known hematopoietic growth factors. However, recent studies revealed that CSFs are involved in many inflammatory conditions. In the experimental anti-glomerular membrane glomerulonephritis, both glomerular lesions and tublointerstitial lesions were attenuated in the granulocyte-macrophage CSF (GM-CSF) knockout mice. Whereas, it is suggested that Granurocyte-CSF (G-CSF) may attenuate cisplatin-induced acute kidney injury by accelerated re-generation and decreased apoptosis of tubular cells. However, the local productions of CSFs and its regulation in the kidney is not well elucidated.

Methods: We used primary human proximal tubular epithelial cells (PTEC) to test the effect of thrombin for CSFs production, since thrombin is suggested to induce tubulointerstitial injury. PTEC were incubated with thrombin (0.5-5U/ml) and the effect on the production of GM-CSF, G-CSF, macrophage-CSF (M-CSF), interleukin-8 (IL-8) and monocyte chemoattractant protein-1 (MCP-1) were measured in the cell supernatant by enzyme-linked immunosorbent assay (ELISA) and mRNA expressions were analyzed by quantitative RT-PCR. Also, we used direct thrombin inhibitor argatroban to verify the specific effect of thrombin. Furthermore, we assessed the role of CSFs for the chemokine expressions, using transient blockade of CSFs by siRNA technique.

Results: Thrombin stimulated the production of CSFs (GM-CSF, G-CSF, M-CSF) and chemokines (MCP-1 and IL-8) demonstrated by ELISA for protein expression and by quantitative RT-PCR for mRNA expressions. These effects of thrombin were significantly reduced by argatroban demonstrating specific effects of thrombin. Besides, induction of MCP-1 by thrombin was attenuated by M-CSF knockdown, and IL-8 induction was attenuated by G-CSF knockdown, showing chemokine expressions in PTEC were at least in part regulated by CSFs produced locally by PTEC.

Conclusions: Thrombin stimulates the production of CSFs by PTEC. Locally produced CSFs at least in part regulates chemokine expressions in PTEC.

PGA-Peptoid 1 Inhibits Apoptosis and Inflammation in Renal Cells Alvaro C. Ucero,[1] Sergio Berzal,[1] Monica Sancho,[3] Carlos Ocaña,[1] Marta Ruiz-Ortega,[1] María Jesús Vicent,[2] Alberto Ortiz,[1] Adrian Mario Ramos.[1] *[1]Nefrología Experimental, IIS-FJD/Univ. Autonoma de Madrid, Madrid, Spain; [2]Peptide and Protein Lab, Centro de Investigación Príncipe Felipe, Valencia, Spain; [3]Polymer Therapeutics Lab, Centro de Investigación Príncipe Felipe, Valencia, Spain.*

Background: Tissue injury is an unwanted adverse effect of inflammation. Inflammatory stimuli may induce cell injury and death and, in turn, injured cells may promote inflammation. Thus, a therapeutic agent that targets both cell death and inflammation may be of particular interest.

Results: A family of Apaf-1 inhibitory nanomedicines that modulate apoptosis includes PGA-peptoid 1 (QM56). We now report that QM56 inhibits apoptosis in renal tubular cells co-stimulated by the lethal cytokine cocktail TWEAK/TNFa/INFγ. In addition, QM56 inhibited MCP-1 and Rantes chemokine expression in response to this stimulus. The anti-inflammatory effect of QM56 was independent from protection of apoptosis, since it also inhibited the inflammatory response to TWEAK (a cytokine that alone promotes tubular cell proliferation but not apoptosis) in tubular cells as well as renal fibroblasts. In addition, the anti-inflammatory effect showed by QM56 was independent from Apaf-1, since it was observed in MEF-Apaf-1$^{-/-}$ cells. TWEAK-induced MCP-1 and Rantes synthesis is NF-kB-dependent and is prevented by the NF-kB inhibitor parthenolide. TWEAK also activated the JAK/STAT pathway. JAK2/STAT3 activation was required for the full expression of TWEAK-induced chemokine mRNA, but not for p65 nuclear translocation. In this regard, QM56 also failed to inhibit p65 nuclear translocation and DNA binding in response to TWEAK while it was inhibiting the JAK2/STAT3 phosphorylation/activation and hence chemokine expression elicited by the cytokine. Along with the inhibition of chemokine synthesis, blockade of the JAK2/STAT3 pathway by QM56 was also corroborated in MEF-Apaf-1$^{-/-}$ treated with TWEAK.

Conclusions: We conclude that the anti-inflammatory activity of QM56 was independent of its role as inhibitor of apoptosis and that it could have potential therapeutic relevance.

TH-PO138

Serum CRP and IgA1 O-Glycosylation as Predictors of Disease Progression in IgA Nephropathy Karen Molyneux,[1,2] Demetris Christou,[1] Javeria Peracha,[1] John Feehally,[1,2] Alice C. Smith,[1,2] Joanna Boyd,[1] Chee Kay Cheung,[1] Jonathan Barratt.[1] *[1]John Walls Renal Unit, Leicester General Hospital, Leicester, Leicestershire, United Kingdom; [2]Department of Infection, Immunity and Inflammation, University of Leicester., Leicestershire, United Kingdom.*

Background: IgA nephropathy (IgAN) is an inflammatory glomerulonephritis which is progressive in some patients. We have shown that abnormal O-glycosylation of serum IgA1 early in the disease is associated with risk of progression. C-reactive protein (CRP) may also be associated with progression but the relationship between CRP and IgA1 O-glycosylation has not been investigated.

Methods: We studied sera from 70 patients with biopsy-proven IgAN obtained early in the course of their disease while renal function was normal, and 70 healthy controls. The patients were classified as progressors (serum creatinine increased by >100% during follow up, n=32), or non-progressors (serum creatinine remained normal after a minimum ten years follow up, n=38). CRP was measured by ELISA. IgA1 O-glycosylation was previously measured.

Results: In our study, the mean serum CRP was higher in patients than controls (IgAN 2.86±0.49μg/ml, controls 1.78±0.27μg/ml, p=0.012). Furthermore, the progressors had higher CRP than non-progressors (progressors 3.18±0.52μg/ml, non-progressors 2.59±0.79μg/ml, p=0.023). However, there was no correlation between IgA1-HA and CRP in progressors, non-progressors or controls. We compared the number of progressors and non-progressors with high or low CRP and IgA1-HA (defined as above or below median respectively). Combining the two markers, 12 progressors and 6 non-progressors had both high IgA1-HA and high CRP, compared to 4 progressors and 15 non-progressors with both low IgA1-HA and low CRP (p=0.008).

Conclusions: Our results confirm that both high IgA1-HA and high CRP at an early stage of IgAN are associated with subsequent development of progressive renal disease. However, neither could individually account for progression. We found no correlation between IgA1-HA binding and CRP, indicating that they are independently associated with progression in IgAN. Combining them gave a better indication of a subsequent course of the disease.

TH-PO139

Enhanced VASP Expression during Human Glomerulonephritis and Diabetic Nephropathy Bernd Hohenstein, Christian Hugo. *Division of Nephrology, Department of Internal Medicine III, University Hopsital Carl Gustav Carus, Dresden, Germany.*

Background: Vasodilator stimulated Phosphoprotein (VASP) is a central cytoskeletal protein that has been involved in platelet adhesion, migration and endothelial barrier function and integrity in several experimental disease models including passive crescentic nephritis by our group (JASN 2005 Apr;16(4)) but not in human kidney disease such as glomerulonephritis (GN) or diabetic nephropathy (DN).

Methods: We performed immunohistochemical staining in 120 human renal biopsies with minimal-change GN, FSGS, MGN, IgAN, lupus nephritis, vasculitis, Schoenlein-Henoch, endocapillary GN, MPGN or crescentic nephritis and 50 biopsies with DN. We investigated VASP in glomerular and tubulointerstitial (TI) compartments regarding expression and distribution and compared data to biopsies without apparent renal disease (n=8).

Results: Compared to controls where VASP expression was low, biopsies from most GN demonstrated enhanced VASP expression in glomeruli ($p<0.05$ for IgAN, vasculitis, MPGN, lupus N, crescentic nephritis, endocapillary GN) and also in the TI ($p<0.05$ for crescentic N, vasculitis, MGN, MPGN). In most biopsies there was a prominent endothelial expression pattern of VASP in glomerular as well as peritubular capillaries. Immigrating inflammatory cells also expressed relevant amounts of VASP. Endothelial VASP was prominent in mild diabetic lesions but demonstrated no further increase with ongoing injury. In GN, TI VASP expression correlated with the decline in GFR as estimated by the MDRD equation ($P<0.0001$, $r=0.34$).

Conclusions: VASP as a known important regulator of EC barrier and function shows a prominent endothelial expression pattern in human GN and DN, where EC function is markedly disturbed. The correlation of TI VASP and falling GFR also indicates this functional link.

TH-PO140

Upregulation of Serum Amyloid A in ESRD Patients Is Associated with the Presence of a Unique Biomarker Identified by Protein Chip Array Analysis Vinod K. Bansal,[1] Debra Hoppensteadt,[2] Walter Jeske,[3] Jawed Fareed.[2] *[1]Nephrology, Loyola University Medical Center; [2]Pathology, Loyola University Medical Center; [3]Throacic and Cardiovascular Institute, Loyol University Medical Center.*

Background: Serum amyloid A (SAA) is an acute phase reactant which is regulated by IL1, IL-6 and TNFα. The circulating levels of serum amyloid A are markedly increased in inflammatory conditions. SAA is a 104 amino acid polypeptide with a molecular mass of 12-14 KDa. Protein Chip Array methods have been used to identify unique biomarkers in ESRD patients. The purpose of this study was to determine the relationship of a previously reported biomarker in ESRD with circulating levels of SAA.

Methods: Plasma samples from 117 ESRD patients, over the age of 18 on maintenance hemodialysis and 50 age matched controls (healthy volunteers) were included in this study. SAA levels were measured by using a sandwich ELISA method (Abazyme, Needham, MA). Proetin Chip Array profiling was carried out utilizing surface enhanced laser desorption (SELDI; BioRad Corp, Hercules, CA) utilizing gold chips.

Results: The plasma SAA levels were markedly elevated in ESRD (41.8+12.6; range 4.6-98.1 μg/ml) in contrast to the normals (4.5+1.2; range 1.1-9.8 μg/ml). SELDI analysis revealed a unique biomarker signal in 78 out of 117 (67 %) in the ESRD patients and 2 out of 50 (4%) in the normal individuals. The presence of the 11.6 KDa biomarker correlated with the high SAA levels.

Conclusions: These studies suggest that SAA level upregulation is associated with the presence of the 11.6 KDa biomarker. Protein Chip Array profiling may be useful in the risk stratification of ESRD patients.

In Situ Immune Complex (MPO-Anti MPO Antibody) & Complement 3 Cause Glomerular Capillary Injury in Human MPO-ANCA Associated Glomerulonephritis Soko Kawashima, Yoshihiro Arimura, Yoshinori Komagata, Shinya Kaname, Akira Yamada. *First Department, Kyorin University School of Medicine, Mitaka, Tokyo, Japan.*

Background: Myeloperoxidase anti-neutrophil cytoplasmic antibody (MPO-ANCA) associated glomerulonephritis(GN) is characterized by pauci-immune necrotizing glomerulonephritis(NCGN). MPO-ANCA has been thought to be involved in the activation of neutrophils in the pathogenesis of NCGN. Recent studies suggest that immunoglobulins precipitated on the glomerular capillaries might play some role in the pathogenesis of MPO-ANCA associated GN. Here, we investigated a possible role of MPO, IgG, complements and MPO-positive cells in the pathogenesis of MPO-ANCA associated GN.

Methods: Renal specimen including 317 glomeruli obtained from 20 patients with MPO-ANCA associated GN were analyzed. Glomerular infiltration of MPO-positive cells, deposition of extracellular MPO and endothelial cell injury were analyzed and the number of infiltrating MPO-positive cells was scored in each glomerulus, especially in early stage of the disease. Colocalization of MPO, IgG, C3 and CD34 deposition was analyzed. Immunofluorescence staining for triple staining (MPO, IgG and CD34) were performed for samples of renal biopsies.

Results: All of 20 patients showed a weak but significant staining for IgG (pauci-immune GN), which was often accompanied by MPO deposition along the glomerular capillary walls. Triple positive (MPO, IgG & C3) deposition was detected in 15 glomeruli (5%) mainly with low activity and chronicity. CD34 staining was lost around the area where MPO and IgG were detected, suggesting the endothelial injury may be induced by MPO- and IgG-associated pathogenic mechanism. Deposition of MPO, IgG and C3 was observed along the glomerular capillary walls predominantly in the early stage of MPO-ANCA associated GN.

Conclusions: These results indicate that not only the activation of neutrophils, but also MPO and the immune complexes composed of MPO-anti MPO antibody may play some direct roles in the pathogenesis of glomerular capillary injury in the early phase of human MPO-ANCA associated GN.

TH-PO142

The Activation of Renin-Angiotensin System Is Involved in Hyperlipidemia Mediated Renal Injuries in Apolipoprotein E Knockout Mice Jie Ni, Kun Ling Ma, Jing Liu, Wenjin Huang, Bi-Cheng Liu. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiangsu Province, China.*

Background: The activation of renin-angiotensin system (RAS) and hyperlipidemia play crucial roles in the progression of chronic kidney disease (CKD). Whether there is the interaction of hyperlipidemia with RAS activation in accelerating the progression of CKD remains unknown. This study was to investigate the role of RAS activation in hyperlipidemia mediated renal injuries using an atherosclerotic mouse model from apolipoprotein E knockout mice (apoE-/- mice).

Methods: Male apoE-/- mice were respectively fed with high fat diet (HF group, containing 40% fat and 0.15% cholesterol, n=8) and normal chow diet (control, n=8) for 8 weeks. Lipid profile in the plasma was analysed by clinical biochemistry assay. The plasma levels of prorenin, rennin, and angiotensin II were checked by radiommunoassay. The protein expressions of angiotensinogen, angiotensin II, renin, angiotensin converting enzyme (ACE), angiotensin II type 1 receptor (AT1) and angiotensin II type 2 receptor (AT2) in kidneys of apoE-/- mice were checked by immunohistochemical staining and Western Blot. The extracellular matrix deposition in kidneys was evaluated by Masson-staining.

Results: It was fiund that mice fed with high fat diet developed hyperlipidemia with significant extracellular matrix deposition in renal tubular interstitium of kidneys compared to the controls . The plasma levels of renin and angiotensin II didn't present signifciant changes between groups except that plasma prorenin level was significantly reduced in HF group. The protein expressions of angiotensinogen, angiotensin II, rennin, ACE, AT1 and AT2 in the kidneys in HF group were significantly increased, which was significantly associated with the extracellular matrix deposition.

Conclusions: Our study demonstrated that the activation of intra-renal RAS might be involved in hyperlipidemia mediated renal injuries, suggesting a new potential mechanism for the synergistic effect between hyperlipidemia and RAS activation in accelerating the progression of CKD.

Funding: Government Support - Non-U.S.

TH-PO143

Role of Mineralocorticoid Receptor and Rac1 in Inflammatory Cytokine Production in Rat Peritoneal Macrophages Kenichi Ishizawa, Miki Nagase, Shigetaka Yoshida, Wakako Kawarazaki, Toshiro Fujita. *Department of Nephrology and Endocrinology, University of Tokyo Graduate School, Japan.*

Background: Mineralocorticoid receptor (MR) plays an important role in the progression of target organ damage, possibly via induction of inflammation, fibrosis, macrophage infiltration, and oxidative stress. Recent reports demonstrated that macrophage-specific MR knockout mice are protected from DOCA/salt-induced myocardial fibrosis, and from angiotensin II/L-NAME/salt, suggesting the role of MR signaling in macrophage function. We reported that small G protein Rac1 activates MR directly in a ligand-independent pathway. In the present study, we examined whether MR and Rac1 signalings affect pro-inflammatory cytokine production using rat peritoneal macrophages.

Methods: Rat resident peritoneal macrophages were collected by peritoneal lavage after injection of phosphate-buffered saline. The cells were resuspended in RPMI1640 medium with 10% FBS, and plated on culture dish. After vigorous washing, the attached macrophages were incubated in the presence or absence of lipopolysaccharide (LPS). Gene expression was analyzed using quantitative real-time PCR, and protein level was analyzed by immunoblotting and immunocytochemistry. Rac1 activation assay was performed using GST pull-down assay.

Results: Most of the attached cells were positive for a pan-macrophage marker ED-1. LPS increased TNFα, IL-6,and IL-1β generation in peritoneal macrophages, and Rac-specific inhibitor markedly inhibited the responses. Macrophage Rac1 was activated by LPS treatment. MR mRNA and protein were detected in peritoneal macrophages. LPS-induced TNFα, IL-6,and IL-1β production was dramatically suppressed by treatment with spironolactone.

Conclusions: Our findings suggest that MR participates in the inflammatory cytokine secretion in peritoneal macrophages, implicating the cross-talk between Rac1 and MR cascades.

TH-PO144

Perivascular Immune Cell Infiltration in Aging Kidneys and Identification of Associated Genes Yuan Huang,[1,2] Gerda A. Noordmans,[1] Jan-Luuk Hillebrands,[1] Peter Heeringa,[1] Ron Korstanje,[3] Harry Van Goor.[1] *[1]Department of Pathology and Medical Biology, University Medical Center Groningen, Netherlands; [2]Department of Pathology, Fudan University, China; [3]The Jackson Laboratory.*

Background: Dysregulated immune responses play a major role in age-related organ deterioration. The study of immune alterations in the aging kidney and the genes involved in this process may pave the way for the discovery of new strategies for healthy aging.

Methods: Kidneys from aged mice (www.jax.org/phenome) sacrificed at 2 years were collected. Females from 23 strains and males from 20 strains were evaluated. PAS staining and immunohistochemical staining of CD45 and CD3 were performed. The size of the perivascular immune cell clusters was measured in all mice on PAS staining. Haplotype Association Mapping (HAM) was used to identify genetic loci associated with perivascular infiltration.

Results: CD45 staining showed marked renal perivascular immune cell clusters. 90% of the clusters were positive for the T cell marker CD3 in all mice. Females from strains (C57BR/CDJ, C57L/J, NON/LtJ, P/J) had larger clusters ($P < 0.05$). Quantitative data were used for HAM analysis in females. Significant association with loci on Chr1, Chr5, Chr14, distal Chr17, and proximal Chr17 were detected. We identified candidate genes *Mapk14 (*associated with macrophage infiltration), and *Man2a1 (*associated with autoimmune disease mimicking human SLE). In male mice, strains (129S1/SvImJ, C57L/J, C57BL/6J, LP/J, NON/LtJ, P/J) had significantly larger clusters. Binary data were used for HAM analysis in males. Significant association with loci on Chr1, Chr2, Chr8, and Chr14 were detected. *Wisp2* showed the highest peak. *Wisp2* encodes the protein WISP2 (WNT1 inducible signaling pathway protein 2), which is associated with proliferation, extracellular matrix regulation, angiogenesis and fibrosis.

Conclusions: Our study identified strain differences with respect to the presence and number of perivascular immune cell clusters in aged kidneys. A genetic analysis identified novel candidate genes that might participate in renal aging and provide novel means to prevent aging-related diseases.

TH-PO145

Continuous Monitoring of Hemodialysis with Pulse-Wave Analysis Rita L. McGill,[1] Jan K. Berkow,[2] Richard J. Marcus.[1] *[1]Division of Nephrology, West Penn Allegheny Health System, Pittsburgh, PA; [2]iNTELOMED, Inc., Pittsburgh, PA.*

Background: Blood pressure (BP) and pulse (HR) monitoring can't always predict symptomatic circulatory stress during hemodialysis (HD), which doesn't always indicate simple hypovolemia. In pulse-wave analysis (PWA), pulse strength from a pulse-oximetry waveform analyzes the combined hemodynamic effects of cardiac ejection and arterial distensibility, expressed as effective circulatory flow (eCf). Comparing eCf to HR estimates hemodynamic stress and provides a real-time estimate of autoregulatory reserve capacity.

Methods: We studied 24 subjects with known heart disease or frequent symptoms with the CV Insight™, a novel PWA device, during 33 HD. PWA data was compared to continuous HR and BP monitoring, with clinical observation to detect dialysis symptoms such as cramps and nausea. We analyzed observations post-hoc to develop algorithms to predict events/symptoms.

Results: 16/33 HD had PWA patterns resembling volume depletion in lower body negative pressure experiments. eCf fell progressively with volume removal. HR typically increased when eCf had decreased to <60% of initial values; hypotension or dialytic symptoms often followed within 25-45 min. Such patients typically felt cold during stress. In 6 HD starting with marked volume expansion, eCf increased and HR decreased during the first 1-2 hours, before a typical pattern emerged. In 7 HD, eCf was consistently high, even with increased HR and symptoms; these patients typically felt uncomfortably hot under stress, suggesting inappropriate peripheral vasodilation. In 2 HD, arrhythmia interfered with interpretation of PWA.

Conclusions: PWA is a novel non-invasive technique yielding valuable information about circulatory stress and autoregulatory capacity during HD. This pilot study shows distinct patterns of compartment hydraulics which may explain patient variability in ultrafiltration tolerance. PWA profiling may assist clinicians in assessing optimal target weights & providing comfortable ultrafiltration. Further study is warranted to refine predictive algorithms that anticipate symptoms and hemodynamic insufficiency, which may improve evaluation of strategies to support circulation during HD.

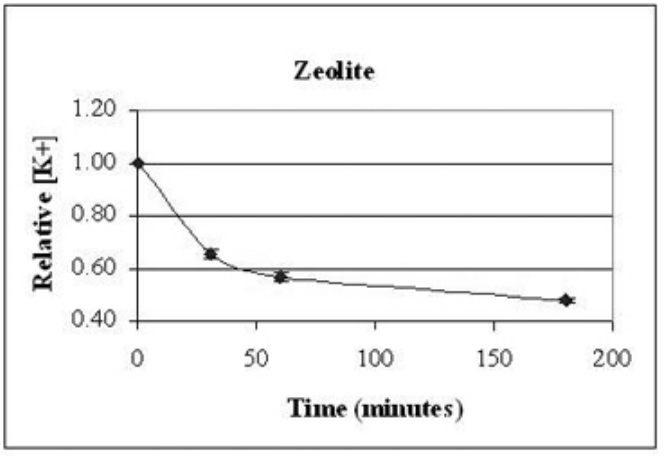
Tests with Novel Adsorbents In Vitro Maarten Wester,[1] Frank Simonis,[2] Jeroen Kooman,[3] Jaap A. Joles.[1] *[1]Nephrology & Hypertension, University Medical Center Utrecht, Netherlands; [2]Nanodialysis, Eindhoven, Netherlands; [3]Nephrology, Maastricht University Medical Center, Maastricht, Netherlands.*

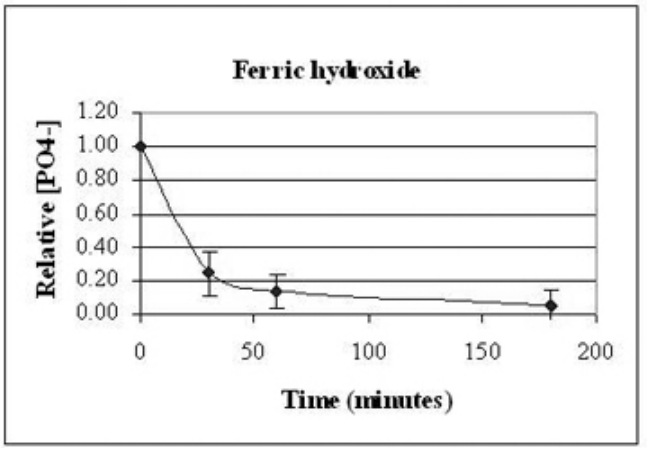
Background: As part of the Dutch/European consortia iNephron/Nephron+ we are involved in the development of an adsorbent-based wearable artificial kidney device (WAKD). With this WAKD we aim to replace renal function continuously 24h/d. Currently we tested adsorbance by a zeolite targeting K+, a ferric hydroxide targeting PO4-, and a modified carbon targeting protein-bound substances, such as PAH.

Methods: Plasmapheresis plasma of Goodpasture and anti-GBM nephritis patients (N=3) was exposed to 100mg of each matrix for 1 to 3 hours.

Results: After one hour K+ decreased from 4.11±0.30 to 2.51±0.30 mM ($P<0.001$). Relative PO4- concentration from 100% to 14±10% ($P<0.001$), and the relative PAH concentration from 100% to 50±31% ($P<0.001$).

The saturation of the zeolite and ferric hydroxide was tested by extending the exposure time up to 3 hours.





Most of the adsorbance occurred in the first hour of exposure, reaching saturation after 3 hours.

Conclusions: In conclusion, the daily production of toxins should be readily removed by these adsorbents. Preclinical in vivo experiments will be performed in goats.

Funding: Private Foundation Support

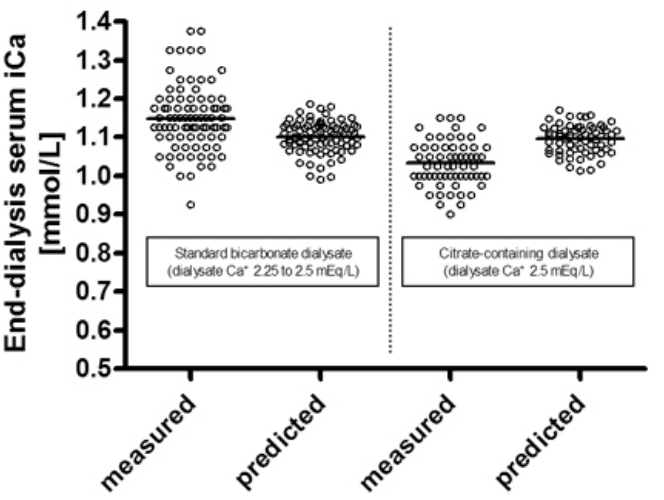
Independent Validation of a Versatile Citrate Dialysis Model Stephan Thijssen,[1] Len A. Usvyat,[1] Jeffrey J. Sands,[2] Nathan W. Levin,[1] Peter Kotanko,[1] Jose A. Diaz-Buxo.[2] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care, Waltham, MA.*

Background: Citrate dialysis (CD) offers many advantages over heparin dialysis, but calcium kinetics in CD are complex. We recently introduced a versatile mathematical model of CD (Thijssen S et al., Blood Purif 2010). The goal of this study was to validate a refinement of this model in a new setting using data from an independent clinical trial.

Methods: Data from a recently completed trial on the effects of citrate-containing dialysate on heparin requirements (Sands et al., ASN 2010) were used. Briefly, patients were studied prospectively on standard bicarb dialysate as well as on Citrasate® dialysate (citrate, 2.4 mEq/L; Ca, 2.5 mEq/L). Pre- and post-HD serum iCa was simulated with our model and compared to measured values. For post-HD simulations, starting iCa levels in the model were adapted to measured values to assess the intra-HD simulation quality.

Results: Pre-HD iCa was underestimated by about 0.12±0.06 mmol/L with both dialysates. This was fairly consistent across the spectrum of iCa levels. End-HD iCa was underestimated by 0.046±0.074 mmol/L on bicarb dialysate and overestimated by 0.077±0.046 mmol/L on Citrasate® (Fig. 1). The prediction errors with both dialysate types were less variable with this refined model than our previously published model.

Conclusions: Average prediction quality for serum iCa was good. Efforts have to be directed towards further explaining and reducing the spread of the prediction error, e.g. by taking into account individual pre-HD serum citrate levels, pH levels and shifts, and better estimates of bone Ca buffering. Although prediction errors were small on average, the model should be adjusted to avoid underestimation of end-HD serum iCa in regular bicarb dialysate treatments and overestimation with use of citrate-containing dialysate.



TH-PO148

***p*-Cresol Sulfate and Indoxyl Sulfate Induce Similar Cellular Inflammation and Immune Response in Cultured Proximal Renal Tubular Cells** Chiao-Yin Sun. *Nephrology, Chang Gung Memorial Hospital, Keelung, Taiwan.*

Background: Uremic toxins, *p*-cresol sulfate (PCS) and indoxyl sulfate (IS), have important roles in the progression of CKD. Previous study has shown that IS induces cellular oxidative stress.The aim of this study is to find the cellular inflammation responses to PCS and IS.

Methods: Cultured mouse proximal renal tubular cells (PKSV-PRs) treated with PCS or IS at concentrations of 0, 1, and 5 mg/L were analyzed by PCR array with inflammation and immune panel. The gene-annotation enrichment analysis and functional annotation clustering were analyzed with the DAVID v6.7. The functional networks of target genes were analyzed by the GeneMANIA.

Results: There were 12 and 30 genes up-regulated by PCS at concentrations of 1 and 5 mg/L greater than 1.5 × respectively. There were 13 and 32 genes up-regulated by IS at concentrations of 1 and 5 mg/L greater than 1.5 × *vs.* control respectively. Ccr2, Csf2 and Ptprc were down-regulated by PCS and IS. Sixteen up-regulated functional annotation clusters of cells treated with PCS or IS at a concentration of 5 mg/L were noted by functional annotation clustering analysis. Eleven common functional annotation clusters of up-regulated genes were noted in cells treated with PCS or IS. The calculated function networks were similar between the PCS and IS. Tgfb1, Fasl, Il6/15, Il15, Csf1/3 and Cxcl10 were the major cytokines in the functional networks of PCS and IS. Stats, Smads, Nfkb2, Ikbkb, Bcl2 and Bax were the major intracellular signals for PCS and IS. Real-time PCR results showed that PKSV cells treated with PCS or IS had significantly increased Tgfb1 expression. The molecular functional networks with the highlight of Tgfb1 for the cells treated with PCS and IS at a concentrations of 5 mg/L were analyzed. In both PCS and IS, Col4a5, Cxc10, Fasl, Stat1 and Ikbkb were the target genes in the predicted molecular functional networks with the Tgfb1.

Conclusions: PCS and IS stimulated significant cellular inflammation reactions. The cellular inflammation and immune response induced by PCS and IS were similar in cultured proximal renal tubular cells.

TH-PO149

Distribution of Hydrogen Sulfide (H_2S)-Producing Enzymes and the Roles of H_2S in Diabetic Nephropathy Jun-Ichiro Yamamoto,[1,2] Waichi Sato,[1] Tomoki Kosugi,[1] Shoichi Maruyama,[1] Seiichi Matsuo,[1] Yukio Yuzawa.[1,3] *[1]Division of Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Aichi-Ken, Japan; [2]Division of Nephrology, Tsushima City Hospital, Tsushima, Aichi-Ken, Japan; [3]Division of Nephrology, Fujita Health University School of Medicine, Toyoake, Aichi-Ken, Japan.*

Background: Hydrogen sulfide (H_2S) has recently been found to play beneficial roles in ameliorating several diseases. Cystathionine β-synthase (CBS) and cystathionine γ-lyase (CSE), the main enzymes in the transsulfuration pathway, catalyze H_2S production in mammalian tissues. However, the distributions and precise roles of these enzymes in the kidney have not yet been identified.In this study,we examined the localization of CSE and CBS in kidney and the effect of H_2S donor, NaHS in renal peritubular capillary (PTC) blood flow velocity, diameter and blood flow.

Methods: The normal mice (nTg) and pancreatic β-cell-specific calmodulin-overexpressing transgenic mice (CaMTg) as a model of diabetes at 3 month old were used. Immunohistochemical studies examined localize of CSE and CBS expression in nTg kidneys. We compared with the expression levels of CSE and CBS in CaMTg and nTg by Western blot analysis. And then we examined effect of NaHS on PTC blood flow velocity,diameter in nTg and CaMTg by obtained using an intravital video CCD.

Results: In the nTg kidney, we detected expression of both CBS and CSE in the brush border and cytoplasm of the proximal tubules, but not in the glomeruli or distal tubules.CSE

expression was markedly reduced under diabetic conditions, whereas CBS expression was unaffected. Administration of the NaHS increased PTC diameter and blood flow. Progressive diabetic nephropathy showed vasoconstriction and a loss of blood flow in PTCs that was ameliorated by NaHS treatment.

Conclusions: The biological profile of CSE resembles that of endothelial nitric oxide synthase (eNOS). These findings suggest that CSE expression in the proximal tubules may also regulate tubulointerstitial microcirculation via H_2S production. H_2S could represent a target of treatment to prevent progression of ischemic injury in diabetic nephropathy.

***In Vitro* and *In-Vivo* Characterization of New Pumping System in a New Hemodialysis Device**

Matthew R. Muller,[1] Neil Tiwari,[1] Martin Desch,[3] Jeff McKee,[2] Benjamin Brooks,[2] Angelito A. Bernardo.[1] *[1]Baxter Healthcare Corporation, McGaw Park, IL; [2]Baxter Healthcare Corporation, Roundlake, IL; [3]DEKA Research and Development, Manchester, NH.*

Background: Hemodialysis devices typically use peristaltic pumping technology. A new hemodialysis device under development uses a pneumatically controlled diaphragm pump (PDCP). The pump contains a fluid and air compartments with flexible diaphragm separating the two sides. Positive or negative pressure is applied to the air compartments to move fluid into and out of the fluid compartment of the pump.

Methods: *In vitro* studies (n=12) were performed during simulated hemodialysis treatments (4 h, blood flow Qb 400 ml/min) with bovine blood and donated human blood in the new device and hemodialysis device with peristaltic roller pump (PRP). For bovine blood, PCDPs were heat aged for 3-year shelf life (70° C, 40 days, 65±5% humidity) per American Society for Testing and Materials standards (ASTM F1984). Hemolysis was evaluated by modified index of hemolysis (MIH) per ASTM F1841-97. *In vivo* studies in sheep (n=6) were done with the PCDP device during simulated 4 h dialysis at Qb 400 ml/min. Hemolysis was assessed by mean cell volume (MCV), mean cell hemoglobin concentration (MCHC), mean cell hemoglobin (MCH), plasma free hemoglobin, and lactate dehydrogenase (LDH) levels.

Results: The MIH in the heat aged PCDP was 0.68±1.32 and 1.86±0.53 for the PRP (p=0.01). When human blood was used, the MIH was 0.55±0.09 for PCDP in contrast to 1.16±0.36 for PRP (p=0.0007). Using the sheep model during simulated dialysis the PCDP device showed stable levels of MCV, MCH and MCHC during the 4 h treatment. The LDH levels and free hemoglobin levels were maintained at baseline levels throughout the 4 h session.

Conclusions: The new device using PCDP demonstrated significantly reduced hemolysis as compared to the device with PRP *in vitro* using bovine and human blood. Data from sheep dialysis showed stable markers of hemolysis. Therefore, the PCDP in the new hemodialysis device may provide an alternative option for hemodialysis. Additional testing will be performed in human clinical trials.

Autologus Adipose Tissue Depots To Inhibit Arteriovenous Graft (AVG) Stenosis

Christi M. Terry,[1] William G. Sanders,[2] Huan Li,[1] Yuxia He,[1] Alfred K. Cheung.[3,1] *[1]Medicine, Univ. of UT, SLC; [2]Pharmaceutics, Univ. of UT, SLC; [3]Medicine, VASLHCS, SLC, UT.*

Background: AVG often fail after clotting due to underlying neointimal hyperplasia (NH). Adipose tissues (AT) produce adiponectin (ADPN), that inhibits smooth muscle cell (SMC) proliferation, a contributor to NH. The anti-diabetic vasculoprotective glitazones induce ADPN from AT. The transplant of autologous AT mixed with glitazone to the AVG perivascular surface to serve i)as an *in situ* bioreactor of ADPN, and ii) as a sustained delivery depot of glitazones, was examined as a novel means to inhibit AVG stenosis.

Methods: Human AT was mixed with dry glitazone (rosiglitazone (ROS) or pioglitazone (PGZ)) and cultured. Culture media was analyzed by ELISA for ADPN and monocyte chemotactic protein-1 (MCP-1), and for drug by HPLC-MS/MS. The effect of conditioned media on platelet-derived growth factor (PDGF)-induced SMC proliferation (CyQuant), and LPS-induced release of TNFα from monocytes was assessed (ELISA). The feasibility and safety of a perivascular AT-PGZ depot was examined in a porcine model.

Results: ADPN release was similar from AT-ROS and untreated AT (ND-AT) at day 2 but increased 4-fold from AT-ROS over ND-AT by day 8. In contrast, ADPN release from AT-PGZ was 4-fold above ND-AT at day 2 but dropped to levels similar to ND-AT by day 8. MCP-1 release from ROS-AT or PGZ-AT was attenuated compared to ND-AT ($p<0.005$). LDH release, a marker of toxicity, was similar between treated and untreated AT. Forty percent of drug was released from ROS-AT by day 13. The conditioned media from day 6 ROS-AT or ND-AT inhibited SMC proliferation (~55% or 35%, respectively); however only media from ROS-AT attenuated TNF release from LPS-treated monocytes implicating glitazones in the monocyte inhibition. An autologous AT-PGZ(100μM) depot was applied perivascularly to the jugular vein in a pig. No overt inflammation or necrosis was noted when explanted at 6 days.

Conclusions: ADPN release was enhanced from glitazone-AT and prolonged release of drug from the depot was observed. In vivo transplant of the PGZ/AT was well-tolerated. These data support the testing of glitazone-AT perivascular transplants for the prevention of AVG stenosis in the porcine model.

Enhancement of Middle-Molecular-Weight Solute Clearance by Mechanical Vibration: *In Vitro* Study

Mauro Neri,[1,2] Jeong Chul Kim,[1,2] Francesco Garzotto,[1] Massimo de Cal,[1] Dinna N. Cruz,[1,2] Federico Nalesso,[1] Alessandra Brendolan,[1] Claudio Ronco.[1,2] *[1]Nephrology, San Bortolo Hospital, Vicenza, Italy; [2]International Renal Research Institute Vicenza, Italy.*

Background: Phenomena such as concentration polarization and protein gel layering on the dialyzer membrane surface can significantly reduce middle molecule clearance. Previous simulation studies showed that high wall shear stress and vortices induced by a shaking motion could reduce the development of resistance layers on membrane surfaces. We analyzed the effects of mechanical shaking of hemodialyzers on the clearance of β-2 microglobulin (β-2MG) in HD mode using 2 different membranes (PS vs PAN).

Methods: We collected spent dialysate from a patient with high initial concentration of β-2MG and concentrated this using HF with a low flux dialyzer. We added urea to check for a mass balance error. We applied HD treatment in a crossover study with a mechanical shaker (driven by a crank-slide mechanism) at 0,1,2,3,4 Hz (cycles/sec) of lateral shaking frequency and 20mm of amplitude. Samples were taken every 4 minutes at blood inlet, blood outlet and dialysate outlet for urea and β-2MG measurements.

Results: The blood side clearance (Kb) of β-2 MG increased in PS while in PAN the dialysate side clearance (Kd) increased. Vibration frequency was not linearly proportional to β-2 MG clearances in PS. It increased desorption of proteins into blood and dialysate compartments in PAN, so the concentrations in blood outlet and dialysate outlet increased. (Kb-Kd) indicates the removal by adsorption.

f	Kb in PS	Kd in PS	Kb-Kd in PS	Kb in PAN	Kd in PAN	Kb-Kd in PAN
0	87.9	84.9	3	130.2	2.5	127.7
1	94.8	93	1.8	110.8	53.4	57.2
2	104.5	83.7	20.8	105,7	11.2	94.5
3	95.7	90.8	4.9	90.1	18.5	71.6
4	95	94.2	0.8	88.6	21.4	67.2

Conclusions: Shaking motions of PS and PAN hemodialyzer could increase the clearance of β-2 MG. To apply this dynamic dialysis method to clinical practice, appropriate selection of membrane material and optimal shaking conditions should be investigated considering hemolysis and mechanical fracture of membrane.

TH-PO153

A Biodegradable Perivascular Wrap for Controlled and Directed Drug Delivery To Prevent Arteriovenous Graft (AVG) Stenosis

William G. Sanders,[1] Paul C. Hogrebe,[4] Alfred K. Cheung,[3,2] Christi M. Terry.[2] *[1]Pharmaceutics, Univ. of UT, SLC; [2]Medicine, Univ. of UT, SLC; [3]Medicine, VASLHCS, SLC, UT; [4]Bioengineering, Univ. of UT, SLC.*

Background: Stenosis of AVG due to neointimal hyperplasia (NH) at the anastomoses is common. Sunitinib decreases smooth muscle cell (SMC) proliferation and angiogenesis; both processes are integral for NH formation. We report the development of a biodegradable perivascular wrap that provides unidirectional diffusion of sunitinib towards the graft and vascular walls, and should minimize drug loss to the extravascular tissues while inhibiting NH.

Methods: Two formulations were created: In "A", sunitinib was dissolved in a non-porous poly(lactic-co-glycolic acid) (PLGA) wrap. In "B", dry sunitinib was mixed into a hyaluronic acid (HA) hydrogel which was then infused into a porous PLGA network. A pliable non-porous PLGA backing without drug was incorporated onto both formulations to promote unidirectional diffusion. The in vitro drug release from the formulations into the media was assayed by HPLC-tandem mass spectrometry. Unidirectional drug release was tested using a modified co-culture chamber with the non-porous backing as the separating insert. Drug traffic from "A" into tissue was tested with an explanted porcine artery in an ex vivo flow chamber.

Results: Formulation "A" yielded a slow release rate, with drug exhausted after 40 days. Formulation "B" produced a high initial burst with almost complete release by 14 days. The non-porous PLGA backing effectively prevented drug diffusion into the lower co-culture chamber. The sunitinib concentration within the artery wall tissue at 24 h after wrap placement was 17.8 nM, corresponding to three times the in vitro EC50 for SMC inhibition and 0.4% of the total drug load. Concentrations in the circulating media were 0.72 nM (0.014% of total load) after 24 h, suggesting some trafficking of the drug through the vessel wall into the lumen.

Conclusions: Our biodegradable formulation "A" polymer wrap provided a directed, sustained release of sunitinib that rapidly achieved high vascular wall tissue drug concentrations. This data supports the further characterization of the formulation in vivo in a porcine model of AVG stenosis.

TH-PO154

Prototyping a Peritoneal Dialysis (PD)-Based Automated Wearable Artificial Kidney (AWAK): A Progress Report Christian G. Bluchel,[1] Martin Roberts,[2-4] Jui Pin Er,[1] David B. Lee.[2-4] *[1]Temasek Engineering School, Temasek Polytechnic, Singapore; [2]VAGLA Healthcare System, Los Angeles, CA; [3]David Geffen School of Medicine at UCLA, Los Angeles, CA; [4]AWAK Technologies, Singapore.*

Background: AWAK is designed to provide round-the-clock, dialysis-on-the-go for patients with end-stage renal disease (ESRD). Based on sorbent technology, and tidal peritoneal dialysis (TPD), AWAK continuously regenerates spent dialysate and recycles fresh dialysate at rates up to 96 L/day. This is an update on our prior reported prototype.

Methods: The first prototype consists of a disposable and a non-disposable assemblies. TPD is conducted by first draining the tidal volume (TV) out of the peritoneal cavity (PC) into the disposable assembly (outflow mode, OM). Following regeneration of the spent dialysate, the fresh dialysate is returned into the PC (inflow mode, IM). Cycles of OM-IM continued until the time for sorbent cartridge (SC) replacement. The PC is then completely drained into an UF receptacle. A volume equal to TV plus RV is returned to the PC and the remainder fluid is discarded as UF. Several improvements have been made on this prototype and using the new set up we have validated the regeneration and reconstitution of spent peritoneal dialysate.

Results: In the updated design all wetted components are completely housed in the disposable assembly, which is replaced with each cartridge exchange, i.e. every 7 or 12h, depending of the type of cartridge used. A common non-disposable assembly controls all fluid movements. It runs no contamination risk, given its never wetted by the dialysate. The configuration using the "regular", 7h SC weighs less than 1kg and is easily wearable, e.g., in a shoulder bag, without attracting undue attention. It regenerates and reconstitutes fresh dialysate (similar in composition to the "2 bag bicarbonate dialysate") from both a synthetic spent peritoneal dialysate and spent dialysate from PD patients. The intermittent UF phase with complete drainage of the PC makes the "overfill"syndrome unlikely

Conclusions: Further safety measures and miniaturization have been successfully engineered into the AWAK prototype for animal and clinical trials.

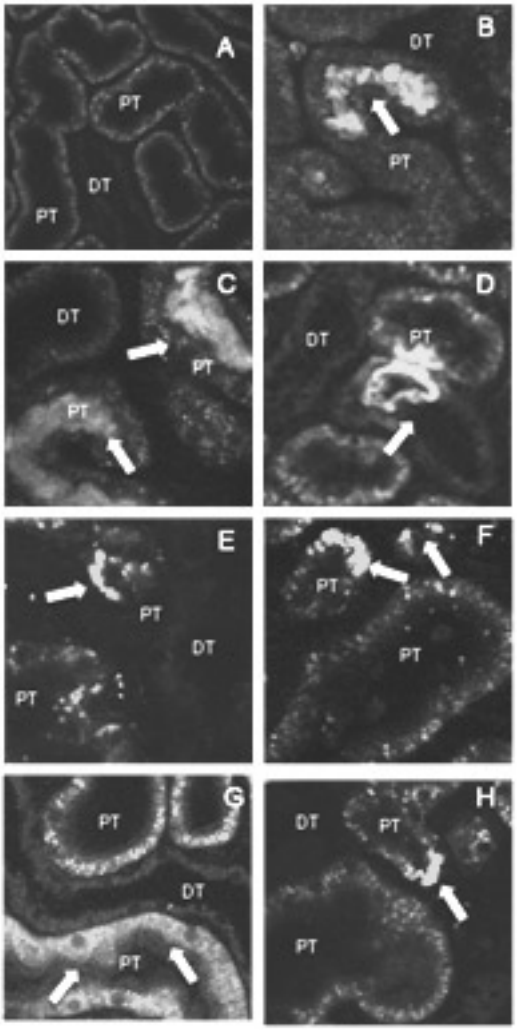
Hydrodynamic-Mediated Transgene Expression of Baculovirus Vectors in Live Mammalian Kidneys Peter R. Corridon, George Rhodes, Simon J. Atkinson, Robert L. Bacallao. *Medicine, Indiana University, Indianapolis, US.*

Background: Viral vectors have been investigated for their use in mammalian gene transfer for decades. While gene transfer has been difficult to accomplish in the kidney, reports have indicated that hydrodynamic cavitation may be used to facilitate renal gene transfer.

Methods: We present a method that utilizes tissue cavitation to deliver bacuolvirus vectors for relatively rapid renal transfection in live animals. In devising this approach we hypothesized that the hydrodynamic forces generated from pressured injections were sufficient to facilitate both the passage of baculoviral particles across epithelial and endothelial layers, and ultimately their endocytic cellular uptake. We tested this hypothesis using Green fluorescent protein (GFP) and GFP-actin chimeric bacuolvirus vectors.

Results: GFP and GFP tagged actin expressing baculovirus vectors were introduced into 30 rodent kidneys using renal vein guided, retrograde pressurized injections. Transgene incorporation and expression was examined using intravital multiphoton fluorescence microscopy. This method produced detectable levels of protein expression in various tubular, glomerular and vascular segments, throughout a period of 3 weeks. Figure 1 shows intravital multiphoton microscopy images taken from kidney proximal tubules (PT) and distal tubules (DT) from Sprague-Dawley rats that received GFP-actin baculovirus vectors. The images were taken across a 3 week time frame, post viral delivery: (A) tissue autofluorescence, (B) Day 1, (C) Day 2, (D) Day 3 (E) Day 4, (F) Day 5, (G) Day 6 and (H) Day 21. Arrows are used to indicate regions with transgene expression. Moreover, we found that transgene expression was stable for 21 days.



Conclusions: These results outline a potential approach for renal gene transfer in live animals employing a simple, reproducible delivery system.

Funding: NIDDK Support

TH-PO156

Physiologic Assessment of Arteries for Arterio-Venous Fistula (AVF) Creation for Hemodialysis Access Rosa M. Marticorena,[1] Cesar Ginocchio,[1] Arash Jaberi,[2] Niki Dacouris,[1] Vern Malcolm Campbell,[1] Sandra A. Donnelly.[1] *[1]Nephrology, Keenan Research Centre Li Ka Shing Knowledge Institute, St. Michael' Hospital, University of Toronto, Toronto, ON, Canada; [2]Radiology, Ottawa Hospital, Ottawa, ON, Canada.*

Background: Achieving adequate flow for hemodialysis treatment is the primary goal of fistula creation. Arterial dilatation is essential to increase radial artery flows from 20-30 mL/min to 600-1200 mL/min. Arterial size is insufficient to determine if fistula maturation will occur as evident by a 40% rate of failure to mature in spite of having the requisite 2mm diameter and the successful creation of fistula in children. The increased blood flow provides the necessary hemodynamic change in venous wall shear stress that is a key determinant of outflow vein dilatation. The objective of this work was to determine if healthy arteries defined by normal physiologic parameters of pulse wave velocity (PWV), augmentation index (AIX) and elasticity was associated with adequate vascular remodeling to generate successful AVF maturation.

Methods: End stage renal disease patients of a tertiary care academic hemodialysis program were studied between June 2009 and Dec 2010. Patients who had functioning fistulas (Group I n=28) were compared to patients who had a failed fistula (Group II n=10). Blood pressures and radial artery waveform were recorded with HDI/Pulsewave CR-2000 Research CardioVascular Profiling Systems (Hypertension Diagnostics, Inc,Minnesota, USA) and large and small artery elasticity were estimated by a modified Windkessel model. Carotid, radial and femoral pulse wave velocity and waveform were evaluated with SphygmoCor® (AtCor Medical, Inc., IL, USA).

Results:

	Group I	Group II
Age (years)	52±14	59±11
AIX	26.0±10.2*	35.2±11.1
PWV (M/sec)	8.6±1.3*	7.2±1.3
Mean±SD *p<0.05 Group I vs Goup II		

In multivariate analysis, successful AVF maturation was negatively correlated with AIX and DM and was positively correlated with PWV and male sex. Measures of large artery stiffness and small artery elasticity were not associated with successful AVF maturation.

Conclusions: These preliminary observations suggest that physiologic assessment of arteries may enhance vessel selection for AVF creation.

TH-PO157

Generation of Infusible Dialysate through a New Hemodialysis System

Angelito A. Bernardo, Winnie Kubey, William Han, Paul Straka, Matthew R. Muller, Clifford J. Holmes. *Baxter Healthcare Corporation, McGaw Park, IL.*

Background: A new hemodialysis system under development generates online infusible dialysate for priming, bolus and rinse back eliminating the need for bagged solutions. To meet the American Association for Medical Instrumentation (AAMI) standards for infusible dialysate, the system is required to achieve 9-log reduction in bacteria and at least 2-log reduction in endotoxin. The system uses sequential ultrafiltration via an endotoxin and bacterial retentive ultrafilter and a polyethersulfone (PES) dialyzer as the redundant filter. The system also employs high temperature non-chemical heat disinfection to maintain high level of microbial control over time.

Methods: The ultrafilters and PES dialyzers were exposed to 90 and 30 cycles respectively of 75 ± 5° C hot water for 45 min to simulate maximum heat stress. This system was challenged in triplicate with at least 40 liters of bacterial suspension containing 10^6 CFU/ml and endotoxin content of 10^2 IU/ml. American Type Culture Collection isolates of *B. cepacia, P. aeruginosa, B. diminuta* and *M. abscessus* were used for microbial challenge. During repeated simulated dialysis sessions, bacterial and endotoxin levels were measured pre- and post-ultrafilter and post-dialyzer (venous line sample).

Results: Dialysate fluid post ultrafilter, met AAMI ultrapure dialysate standards with bacteria levels of <0.1 CFU/ml, and endotoxin level of <0.03 IU/ml. The quality of the post-dialyzer venous blood line samples (for priming, bolus and rinse back) met the AAMI standards for infusible dialysate with no bacteria being cultured (0 CFU/L) from all samples representing 9 log reduction and endotoxin levels of <0.03 EU/ml, representing greater than 2 log reduction in endotoxin.

Conclusions: A new hemodialysis system using sequential ultrafiltration via endotoxin and bacterial retentive filter and PES dialyzer is capable of generating infusible dialysate when challenged with markedly high levels of bacteria and endotoxin. Therefore, generation of infusible quality dialysate has been shown using a robust *in vitro* testing procedure.

Effect of Serum Thyroid Stimulating Hormone Levels on Glomerular Hemodynamics Examined by Inulin and Para-Amino-Hippuric Acid Clearance

Akihiro Tsuda, Eiji Ishimura, Yoshiteru Ohno, Hideaki Shima, Shinsuke Yamada, Toshiki Nagasaki, Katsuhito Mori, Hideki Tahara, Masaaki Inaba. *Osaka City University Graduate School of Medicine, Osaka, Japan.*

Background: Glomerular hemodynamics can be examined by the method of Gomez's formula, in which both inulin and para-amino-hippuric acid (PAH) clearance are simultaneously measured. Although the effect of drugs is examined, few have examined the effect of intrinsic hormones on glomerular hemodynamics. Hypothyroidism is reported to reduce glomerular filtration rate (GFR), although its mechanism is unknown. In the present study, we examined the effect of serum levels of thyroid stimulating hormone (TSH), which has been demonstrated to affect peripheral arterial resistance (J Clin Endocrinol Metab 89:3455, 2004), on glomerular hemodynamics.

Methods: Twenty eight patients (60.6 12.8 years, 9 males and 19 females, serum creatinine < 1.0 mg/dl) with mild IgA glomerulonephritis (n = 5) or type 2 diabetes (n = 23) ,who agreed with the study, were examined. All patients were of euthyroidism. Inulin and PAH clearance were simultaneously measured according to the methods of Horio et al (Clin Exp Nephrol 13:50, 2009). Resistance of afferent arteriole (R-a) and efferent arteriole (R-e) was calculated with use of Gomez's formula.

Results: Both R-a and R-e correlated with age (r = 0.352, p = 0.0353; r = 0.311, p = 0.0647, respectively). There was a significant positive correlation between serum TSH and R-a (r = 0.531, p = 0.0063), but not between serum TSH and R-e. Renal plasma flow (RPF), renal blood flow (RBF), and GFR tended to negatively correlate with serum TSH levels (r = - 0.351, p = 0.0850; r = - 0.354, p = 0.0821; r = - 0.389, p = 0.0547, respectively). In a multiple regression analysis, serum TSH was significantly and positively associated with R-a (= 0.459, p = 0.0240), after adjustment of blood pressure and age (R^2 = 0.330, p = 0.0350), although it was not with R-e.

Conclusions: Using inulin and PAH clearance, present study indicates that TSH, which causes increased peripheral arterial resistance, increases R-a, possibly being a cause of decrease in RBF, RPF, and GFR. Subclicical hypothyroidism is suggested to affect renal hemodynamics.

TH-PO159

Usability Testing of an Educational Website for Patients with Chronic Kidney Disease: Results from Safe Kidney Care

Clarissa Jonas Diamantidis,[1] Marni Zuckerman,[1] Saurabh Aggarwal,[2] Divya Prakash,[3] Jeffrey C. Fink.[1,4] *[1]Nephrology, University of Maryland School of Medicine, Baltimore, MD; [2]Novel Health Strategies, LLC, Columbia, MD; [3]Tech Moksha Consulting, Herndon, VA; [4]Epidemiology and Preventive Medicine, University of Maryland School of Medicine, Baltimore, MD.*

Background: Web-based technology is critical to the future of healthcare. As part of a larger study (Safe Kidney Care [SKC]) evaluating patient safety in chronic kidney disease (CKD), we sought to determine how well a representative sample of patients with CKD could interpret and use the SKC website (www.safekidneycare.org), an informational website aimed at providing disease-specific safety information to patients with CKD.

Methods: Participants enrolled from CKD clinics at the University of Maryland underwent formal usability testing administered to each participant independently by a single interviewer with a second recording observer. Each participant was provided a list of 21 tasks to complete as part of formal computer-based testing, including items such as "Go to the internet", "What kinds of information do you think you could get from this website?", "Point to 2 places where you can find a calculator to estimate your kidney function", and "Click on the link to a page that talks about safety concerns with fluids." Tasks were rated as either "easily completed or a non-critical error", or "critical error" (user cannot complete a task without significant interviewer intervention).

Results: 8 participants representative of the CKD population completed formal usability testing. Median completion time for all tasks was 17.5 minutes (range 10-39 minutes). In total there were 32 critical errors in 162 tasks (19%), with the highest proportion of critical errors occurring when participants were asked to find the website on the internet, increase font size, scroll to the bottom of the webpage, or find information on treatments that may damage kidneys. Participants were generally satisfied with the content and usability of the website.

Conclusions: Web-based educational materials for patients with CKD should target a wide-range of computer literacy levels and anticipate variability in competency in use of the computer and internet.

Predicting the Risk of Type I Diabetic Nephropathy with Single Nucleotide Polymorphisms Using Support Vector Machines

Duncan Renfrow-Symon,[1] Christina Chen,[2] Navdeep Tangri,[3] Madhumathi Rao.[3] *[1]Tufts University, Somerville, MA; [2]Internal Medicine, Tufts Medical Center, Boston, MA; [3]Nephrology, Tufts Medical Center, Boston, MA.*

Background: In a prior genome wide association study (GWAS) of Type 1 diabetic nephropathy (GoKinD study), Pezzolesi et al identified 13 SNPs associated with disease utilizing logistic regression (LR) models. Support vector machine (SVM) is a novel machine learning classifier that has been shown to be superior for multidimensional data such as GWAS data.

Methods: We utilized the PLINK whole genome association analysis toolset, for performing quality control of the GoKinD dataset. We used WEKA, an open source data mining package that provides multiple classifiers, to run both logistic regression and SVM with the Radial Base Function (RBF) kernel model.

Results: We identified 11 markers at a threshold of p<10-5, two of which (rs1411766, rs10868025) overlapped with SNPs identified using LR (Pezzolesi et al), and a third, rs10868025 was in compete linkage disequilibrium with rs1411766; we also noted that p-values were roughly similar, using both approaches. Higher p-value thresholds using larger feature spaces, improved the sensitivity and specificity of SVM prediction over the LR approach.

Comparison of p-values generated between our results and Pezzolesi et al. (2009)

SNP	P value Pezzolesi et al. (2009)	Our P-value
rs39059	5.0 x 10-6	1.9 x 10-4
rs10868025	5.0 x 10-7	1.27 x 10-7
rs739041	6.4 x 10-6	6.3 x 10-5
rs451041	3.1 x 10-6	3.6 x 10-5
rs1041466	3.1 x 10-6	1.5 x 10-5
rs1411766	1.8 x 10-6	4.0 x 10-6
rs64922208	6.1 x 10-6	1.8 x 10-5
rs7989848	7.0 x 10-6	2.3 x 10-5
rs9521445	2.9 x 10-6	1.0 x 10-5

Conclusions: Using SVMs, we were able to identify several novel SNPs correlated to type 1 diabetic nephropathy. Taking a wide net approach and testing all highly correlated SNPs will generate more accurate models. We intend to validate the models on an external data set (DCCT-EDIC).

TH-PO161

In Vivo siRNA Targeting to the Podocyte John N. Vassiliadis,[1] Stephen O'Brien,[1] Pradeep K. Dhal,[2] Susan Schiavi,[1] Steven R. Ledbetter,[1] Cynthia M. Arbeeny,[1] Stefan Wawersik.[1] *[1]Renal and Endocrine Sciences, Genzyme Corporation, Framingham, MA; [2]Polymer Chemistry, Genzyme Corporation, Waltham, MA.*

Background: Development of methods for rapid in vivo knockdown of gene function by siRNA would greatly aid in the validation of therapeutic targets for drug discovery. Because of the central role of the podocyte in glomerular disease, siRNA targeting to these cells is of particular interest. Here, we test the ability of polymer-bound siRNA to reduce gene expression in podocytes, focusing on the slit diaphragm protein nephrin. In the kidney, nephrin is expressed solely in the podocyte, and loss of nephrin function leads to rapid increase in urinary protein excretion.

Methods: Nephrin-specific siRNA was complexed with a poly(ethylene glycol)-poly(L-lysine) block copolymer and the complex was administered intraperitonially.

Results: After 72 hours, quantitative real-time PCR showed a 70% decrease in nephrin mRNA and a 68% decrease in nephrin protein levels when compared to animals injected with a non-targeting siRNA. In addition, we observed a doubling of urinary albumin levels after nephrin siRNA administration.

Conclusions: We are currently testing whether multiple doses of nephrin siRNA can further knock down gene expression and induce more severe proteinuria, as well as evaluating the targeting of siRNA to other tissues through this method. Taken together, these data show a rapid and effective method to target gene expression in the podocyte which may drastically reduce the time and cost of validating new therapeutic targets for glomerular disease.

Quantification of Interstitial Fibrosis by Second Harmonic Imaging in Rat Kidney Tissue Sections Hu Sheng Qian,[1] Damian C. Matera,[1] Steven M. Weldon,[1] Chung-Wein Lee,[1] Agnes B. Fogo,[2] Glenn A. Reinhart.[1] *[1]CardioMetabolic Disease Research, Boehringer Ingelheim Pharmaceutics, Inc, Ridgefield, CT; [2]Department of Pathology, Vanderbilt University School of Medicine, Nashville, TN.*

Background: Interstitial fibrosis is a powerful indicator of nephropathy in chronic kidney diseases. However, accurate quantitative analysis of fibrosis by Sirus Red morphometry (SRM) remains a challenge. Our aim was to establish an imaging technique that would enable us to easily and accurately quantitate fibrillar collagen in rat kidney tissues.

Methods: We used a Multiphoton System to develop the novel methodology of Second Harmonic Generation (SHG) for imaging renal fibrosis. 3μm unstained sections of rat kidney at day 5 after unilateral ureteral obstruction (UUO) were assessed for cortical fibrosis. The Two Photon Excitation Fluorescence (TPEF) allowed for the visualization of kidney background and tubular organization, while SHG was used for the display of the architecture of fibrillar collagen.

Results: To validate the specificity of the fibrillar components detected by the SHG in renal fibrosis, the relationship between SHG signal and immunohistochemistry for collagens Type I, III, and IV was analyzed. Our results showed that the SHG signal strongly co-localized with fibrillar collagens I and III, but not with collagen IV. To examine relationship between SHG imaging and traditional SRM analysis of global fibrosis, kidneys from rats at day 5 after UUO treated with ACEI (n=6 /group) were also assessed by both methods with similar trends of quantitative fibrotic area. However, SRM showed 23.2% to 38.9% reduction of fibrotic area by ACEI, while SHG showed 36.1% to 50.2% reduction of fibrosis. Our results demonstrate that SHG imaging can be used for specific detection of the main types of fibrillar collagens involved in renal fibrosis, and can offer more sensitive and a greater dynamic range for evaluation of the therapeutic effects on interstitial fibrosis.

Conclusions: We conclude that combination of SHG and TPEF imaging of unstained kidney tissues provide a novel alternative to traditional SRM and is a powerful tool for the quick visualization and quantitative assessment of renal fibrosis

TH-PO163

Assessment of Renal TSPO Expression Using Micro PET Imaging in Mice Mohammed Noor Tantawy,[1] H. Charles Manning,[1] Keiko Takahashi,[2] Hiroki Fujita,[3] Christopher Chad Quarles,[1] Raymond C. Harris,[2] John C. Gore,[1] Takamune Takahashi.[2] *[1]Vanderbilt University Institute of Imaging Science, Nashville, TN; [2]Vanderbilt O'Brien Mouse Kidney Physiology and Disease Center, Nashville, TN; [3]Akita University Graduate School of Medicine, Akita, Japan.*

Background: Translocator protein18-kDa (TSPO) is a crucial mitochondrial protein involved in various cellular functions, including cholesterol metabolism, steroidogenesis, and apoptosis. TSPO is abundantly expressed in kidney tissue; however, its involvement in renal pathology is poorly understood. To effectively characterize the TSPO expression in mouse models of kidney diseases, here we evaluated a TSPO PET imaging assay for mouse kidney using a novel radioligand, [^{18}F]PBR06.

Methods: Mice were injected with a radioligand, [^{18}F]PBR06. 37 MBq i.v. and imaged by a microPET system for 90 min in a dynamic sequence. The time-activity curves (TAC) of the kidney were recorded over the duration of the scans. Specificity of binding was evaluated by displacement of [^{18}F]PBR06 with excess PBR06. Adding to wild type mice, 20-wks old db/db or non-diabetic db/m mice were subjected to the imaging assay. TSPO protein levels in kidney tissues were assessed by Western blot.

Results: The TACs plateaued in kidney at 50-80 min, indicating a state of equilibrium, and the cold ligand displaced ~75% of the radiotracer. The probe was not present in bladder at this time, indicating that the kidney signals resulted from binding of [^{18}F]PBR06 to renal TSPO but not excretion. Interestingly, [^{18}F]PBR06 binding was remarkably reduced in db/db kidney compared to db/m kidney, while no difference was observed in liver: % injection dose per kidney; db/m 10.5 ± 0.2% vs. db/db 6.2 ± 0.5%. Similar reduction in renal TSPO protein was also observed in db/db mice by Western blot.

Conclusions: Renal TSPO expression can be assessed by *in vivo* PET imaging using [^{18}F] PBR06. Reduced expression in db/db mice suggests a significant role of TSPO in diabetic nephropathy.

α3 Chain Type IV Collagen as an Non-Invasive Optical Biomarker for Chronic Glomerular Diseases Kapil Chaudhary, Nino Kvirkvelia, Maggie McMenamin, Michael P. Madaio. *Department of Medicine, Georgia Health Science University, Augusta, GA.*

Background: Type IV collagen, a major structural component of the GBM, with relatively limited expression including the kidney. Expression of α3 chain of type IV collagen, α3(IV) is altered during the course of chronic kidney disease. Hence, irrespective of the underlying etiology, quantification of α3(IV) expression has a potential as a biomarker of kidney disease progression. For this purpose, we hypothesized that ex vivo quantification of human anti- α3(IV)NC1 antibody (Ab) binding, in real time, could serve this role.

Methods: Human mAb F1.1 against α3(IV)NC1 was conjugated with amine reactive near infrared fluorophore (Dylight 750 or 800). Effective conjugation was determined by 20% SDS PAGE with antigenic specificity of the conjugate maintained. Following injection of conjugated mAb F1.1 into normal mice, live animal imaging was performed by XenogenTM camera; under anesthesia. Kidney specific fluorescence was quantified by software provided with the live imaging system. Pharmacokinetics of fluorophore-mAb F1.1 was studied by imaging the mice at 6,12,24,36 & 72 hrs after injection in the prescence of suitable positive and negative controls. Tissue specificity of fluorophore-mAb F1.1 was evaluated by analysis of formalin fixed kidney, liver, lung, spleen and heart under XenogenTM camera. Glomerular specificity of human mAb F.1.1- fluorophore conjugate was further evaluated by IF on 4 μm kidney tissue sections from same experiment.

Results: Human mAb F1.1 was effectively conjugated with fluorophore Dylight 750 and 800. After injection of conjugated F1.1, kidney specific fluorescence was highest at 24-36 hrs and was detectable after even 72hrs. mAb F1.1-fluorophore conjugate is able to provide non-invasive quantification of α3 chain, type IV collagen in kidney.

Conclusions: The results provide the potential to pursue human mAb F1.1 as an optical biomarker of progressive glomerular disease in experimental kidney disease models by providing non-invasive quantification of type IV collagen. If successful, this approach and reagents/antibody will have a potential application to patients with many forms of chronic kidney disease.

Optimization of High Field MRI Methods for the Mouse Kidney Imaging Feng Wang,[1] Rosie T. Jiang,[2] Mohammed Noor Tantawy,[1] Keiko Takahashi,[2] Raymond C. Harris,[2] Christopher Chad Quarles,[1] Takamune Takahashi.[2] *[1]Vanderbilt University Institute of Imaging Science, Nashville, TN; [2]Vanderbilt O'Brien Mouse Kidney Physiology and Disease Center, Nashville, TN.*

Background: MRI could complement the physiological information obtained from conventional assays of kidney function and facilitate better understanding of pathological process in kidney disease. However, the application of MRI techniques to mouse renal models is highly limited due to the small size and motion artifacts. In this study, high-field MRI methods were optimized for the imaging of mouse kidney, and applied to serial assessment of UUO injured kidney.

Methods: T1W, T2W and MTC imaging protocols were optimized on 7T MRI system to enhance the structural delineation, signal to noise, and image contrast. Several rapid acquisition MRI methods were tested to minimize motion artifacts, including coherent gradient echo and multi-slice inversion-recovery fast gradient echo. Respiratory gating and fat saturation were also considered.

Results: We demonstrate that a coherent GE sequence is superior to IR fast GE for T1W. T1 contrast was optimized with a ~35° flip angle at TR 45ms. A fast spin echo sequence yielded reliable T2W and optimal contrast was achieved with a TE of ~50 ms (TR 2000ms). The MT images were optimized using the GE sequence similar to that used for T1W and the greatest improvement was observed when fat saturation was employed. High-field T1W, T2W and MTC images enabled the qualitative and quantitative evaluation of structural (size, shape, contrast, thickness) variations in mouse UUO model. Structural abnormalities were observed in inner medulla and papilla of UUO kidney as early as 3 hrs after surgery. Deformation of medullary rays of UUO kidney became evident at day 3. In T2W and MTC, the ratio of intensity between cortex and medulla decreased as the disease progressed, while it was not altered in T1W.

Conclusions: We have developed the optimal MRI protocols to allow the visualization of fine renal structural details, achieving resolutions of 0.1 x 0.1 x 0.5 mm^3. These methods should be effectively used for evaluating renal structural integrity in mouse models of kidney diseases.

Funding: NIDDK Support

TH-PO166

MRI Assessment of Mouse Kidney Blood Volume at 7T Feng Wang,[1] Rosie T. Jiang,[2] Mohammed Noor Tantawy,[1] Keiko Takahashi,[2] Raymond C. Harris,[2] Christopher Chad Quarles,[1] Takamune Takahashi.[2] *[1]Vanderbilt University Institute of Imaging Science, Nashville, TN; [2]Vanderbilt O'Brien Mouse Kidney Physiology and Disease Center, Nashville, TN.*

Background: MRI mapping of relative blood volume (RBV) is widely used to assess pathological differences in tissue vascular density. However, this method has not been applied to renal disease. In this study, we optimized MRI acquisition methods for RBV mapping in mouse kidney and assessed the vascular property in UUO model.

Methods: Multi-slice T2-weighted fast spin echo images (TR = 2000ms, TE = 48ms, RARE-factor = 8, 256^2 matrix, 25.6 mm^2 FOV, 0.5 mm slice thickness) of the mouse kidneys were acquired before and after the injection of an iron oxide contrast agent (CA) at 7T MRI. Navigator and respiratory gating was employed to minimize motion artifacts. RBV was calculated pixel by pixel from the steady-state T2-weighted images using a standard formula. The dose of CA was optimized based on the CNS value. Reproducibility of the RBV data was assessed by measuring RBV (n=10) on consecutive days. Renal RBV maps was evaluated in UUO mice (n=6) at 3hrs, 1, 3, 6, and 10 days.

Results: The dose of CA was optimized at 6 mg/kg for RBV mapping in mouse kidney. The mean kidney RBV measured on consecutive days was 19.97 ± 1.50 and 19.86 ±1.62, yielding a concordance correlation coefficient of 0.94, indicating that this approach is highly reproducible. The RBV values of medulla were rapidly reduced in UUO kidney, corresponding to the destructive morphology. The RBV values of cortex was also progressively declined in UUO kidney (~10% at day3, ~20% at day 6, ~50% at day 10), while those of contra-lateral kidney was gradually increased (~10% at day 6).

Conclusions: MRI measurements of renal RBV provide a valuable assay to characterize vascular density in renal disease.

Funding: NIDDK Support

TH-PO167

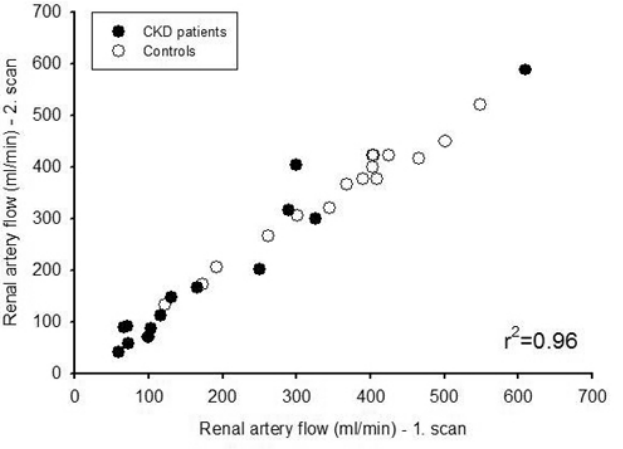
Reproducibility of Renal Artery Blood Flow and Intrarenal Oxygenation Measurements Using Magnetic Resonance Imaging in Patients with Chronic Kidney Disease and Healthy Controls Dinah Sherzad Khatir,[1] Michael Pedersen,[2] Steffen Ringgaard,[2] Bente Jespersen,[1] Niels Henrik Buus.[1] *[1]Department of Renal Medicine, Aarhus University Hospital, Skejby, Aarhus N, Denmark; [2]MR Research Center, Aarhus University Hospital, Skejby, Aarhus N, Denmark.*

Background: To evaluate the reproducibility of measurements of renal artery blood flow (RBF) and renal oxygenation by magnetic resonance imaging (MRI) in patients with chronic kidney disease (CKD) and healthy controls.

Methods: RBF and oxygenation in both kidneys were determined on two occasions with 1-2 weeks interval in 7 CKD patients (mean 65 years, eGFR = 30 ml/min) and 8 healthy volunteers (mean 43 years, eGFR >90 ml/min). All investigations were performed in a 1.5 Tesla Siemens Avanto MRI system. RBF was measured by phase-contrast sequence with velocity gradients applied orthogonally to the renal artery and data were acquired with ECG gating. RBF was calculated as the product of the cumulative vessel blood velocity and the diagonal vessel area. Regions of interest were drawn according to the vessel, and automatic segmentation was done with manual correction. Blood Oxygen Level Dependent (BOLD) MRI using R2*-sensitive echo planar imaging sequence was used as an estimate of renal oxygenation.

Results: Both scan procedures were successful in all subjects. RBF (ml/min/kidney) for patients were 189,5±153,2 and 190,4±158,1 and for controls 356±119,3 and 348,4±107,3 (P<0.05 vs. patients) for first and second scans(figure). In both patients and controls RBF measurements were highly reproducible with a linear correlation coefficient of r2=0.96. Renal medulla R2* (ms-1) for patients were 29,9±2,2 and 26,8±4,4 and for controls 25,9±2,5 and 26,1±2,2 (P>0.05 vs. patients) for first and second scans (r2=0.44).

Conclusions: MRI-based determinations of RBF and R2* are reproducible in CKD patients and healthy controls.



Funding: Government Support - Non-U.S.

TH-PO168

The Usefulness of Contrast-Enhanced Ultrasound (CEUS) for Diagnosis of Renal Cell Carcinoma by Employing a Time-Intensity Curve (TIC): The Characteristics of Microcirculation in Renal Cell Tumor Conformed by Renal Tumor Biopsy under CEUS Tokunori Yamamoto, Hideki Mizuno, Yasushi Yoshino, Momokazu Gotoh. *Urology, Graduate School of Medical Sciences, Nagoya University, Nagoya, Aichi, Japan.*

Background: To evaluate the usefulness of contrast-enhanced ultrasound (CEUS) for diagnosis of renal cell carcinoma by employing a time-intensity curve (TIC).

Methods: From May 2008 to October 2009, CEUS was performed prior to surgery in 30 patients with renal masses. 10 of the 30 patients had cystic renal masses. The final diagnoses of all patients were pathologically confirmed. Contrast enhancement as a function of time was measured in two (tumor or solid component of cystic lesions and normal parenchyma) regions of interest (ROI) and TICs were obtained. The time to the contrast enhancement peak (TTP), intensity change from the baseline to peak (ΔI), and ΔI / TTP of the tumor and the normal parenchyma were measured from the TIC. In adition, we performed renal tumor biopsy under CEUS to conform the characteristics of the TIC

Results: Pathological diagnoses were renal cell carcinoma in 30 patients. The TTP of the cancer was shorter than that of the normal parenchyma in all cases (6.0 ± 2.0 s vs. 10.4 ± 3.0 s; $p < 0.0001$). The ΔI did not differ between the cancer and normal parenchyma (21.3 ±5.9 db vs. 20.9 ± 7.0 db; $p = 0.68$); the ΔI / TTP of the cancer was significantly higher than that of the normal parenchyma (3.9 ± 1.4 db/s vs. 2.2 ± 0.94 db/s; $p < 0.0001$). TIC patterns of solid cancer and cystic cancer were very similar.TIC of the normal tissue and the cancer in pathology conformed by renal biopsy for the tumor under CEUS also demonstrated similar to the characteristics of the TIC, respectively.

Conclusions: An objective and quantitative diagnosis of renal cell carcinoma by CEUS using a second-generation ultrasound contrast agent can be made by employing a TIC. The TIC patterns of solid and cystic cancers were very similar, despite their morphological and vascular differences. CEUS using a TIC is a promising tool in the diagnosis of cystic renal cancer.

TH-PO169

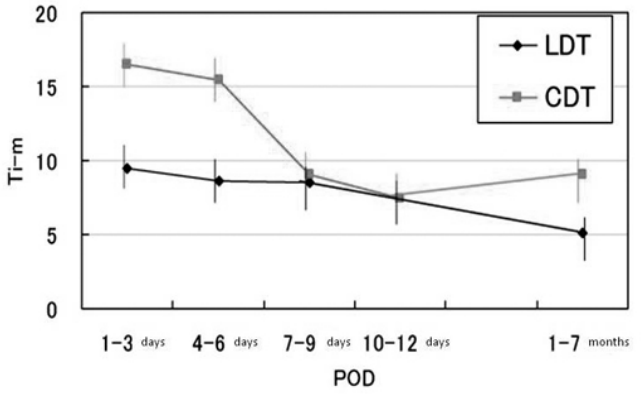
The Usefulness of Contrast-Enhanced Ultrasound (CEUS) for Evalutaion of Transient Time from Lobular Artery Via Glomerular Capillary to Outer Medulla by Employing a Time-Intensity Curve (TIC) Tokunori Yamamoto, Hideki Mizuno, Yasushi Yoshino, Momokazu Gotoh. *Urology, Graduate School of Medical Sciences, Nagoya University, Nagoya, Japan.*

Background: The usefulness of contrast-enhanced ultrasound (CEUS) for evalutaion of the graft function in transient time from lobular artery via glomerular capillary to outer medulla by employing a time-intensity curve (TIC)

Methods: From May 2008 to October 2009, CEUS was performed prior to operation in 12 patients with cadaveric(n=6) and living renal transplantations(n=6) (Figure1). Contrast enhancement as a function of time was measured in two (lobular artery lesions and outer medulla) regions of interest (ROI) and TICs were obtained, respectively. The rise time of defference between lobular artery lesions and outer medulla lesion were measured from the TIC.

Results: In living renal transplantations, initial urine appeared imidiately after the operation in all cases. The transient time are less than 10 sec.

In cadaveric renal transplantations with early ATN, initial urine appeared postoperative days (POD) from 7 to 10 days in all cases. The transient time are less than 10 sec since 10 POD.



Conclusions: An objective and quantitative diagnosis of renal cell carcinoma by CEUS using a second-generation ultrasound contrast agent can be made by employing a TIC. The transient time from lobular artery via glomerular capillary to outer medulla by employing a time-intensity curve (TIC) may be reflect the graft function including ATN.

SPECT Imaging Method for the Assessment of Glomerular Number Mohammed Noor Tantawy,[1] Christopher Chad Quarles,[1] Donald D. Nolting,[1] Rosie T. Jiang,[2] Keiko Takahashi,[2] Mark P. De Caestecker,[2] Agnes B. Fogo,[2] John C. Gore,[1] Raymond C. Harris,[2] Takamune Takahashi.[2] *[1]Vanderbilt University Institute of Imaging Science; [2]Vanderbilt O'Brien Mouse Kidney Physiology and Disease Center.*

Background: Total nephron endowment and thereby glomerular number varies widely between individuals in normal populations. This is of clinical importance as reduced glomerular number is strongly associated with hypertension and CKD. However, there is no non-invasive technique to estimate the total number of renal glomeruli *in vivo*. This study was aimed to develop a non-invasive imaging technique which enables glomerular counting in living subjects (mice).

Methods: 1) Dextran-500 was characterized for glomerular labeling by injecting (i.v.) FITC-Dextran-500 (10mg/kg) to mice. 2) The labeling method to conjugate ^{99m}Tc to Dextran-500 was developed and a novel radiotracer, [^{99m}Tc] Dextran-500, was generated for SPECT imaging. 3) [^{99m}Tc] Dextran-500 was retroorbitally injected to mice and its glomerular binding was assessed by NanoSPECT imaging (30min, temporal resolution;10 sec) at 4 hrs post injection. Kidneys were harvested, sliced, and subjected to autoradiography. 4) Validity of the method was assessed by comparing wild type mice and a model of congenital nephron deficiency Os/+ mice.

Results: FITC-Dextran500 was deposited in glomerular mesangium up to 36 hrs post injection, while it was eliminated from plasma within 6 hrs. In SPECT imaging, renal cortex was strongly labeled with [^{99m}Tc]Dextran-500, yet its binding to other organs was highly limited. The renogram time-activity curves (TACs) displayed a maximum uptake of the radiotracer within the first 2 min followed by some secretion and plateauing of the binding. Glomerular deposition of [^{99m}Tc]Dextran-500 was confirmed by renal autoradiograms. In contrast to wild type, kidneys in Os/+ mice were only weakly labeled with [^{99m}Tc]Dextran-500.

Conclusions: We have developed a SPECT imaging method using [^{99m}Tc] Dextran-500, which could allow non-invasive assessment of glomerular numbers in living subjects.

Positron Emission Tomography and Immunofluorescence Microscopy of Angiotensin II Subtype 1 Receptor in Renal Ischemia Ali Gholamrezanezhad, Jinsong Xia, Majid Chalian, Kelvin Hong, Zsolt Szabo. *Nuclear Medicine/ Radiology, Johns Hopkins Medical institutions, Baltimore, MD.*

Background: Recent *in vivo* evidence from Positron Emission Tomography (PET) has demonstrated increased cortical radioligand binding at the Angiotensin II Subtype 1 Receptor (AT1R) in animal models of renal ischemia. However, the histopathological distribution and cellular components showing upregulation of AT1R remain elusive. We investigated tissue distribution of AT1R expression in experimental models of pig renal ischemia, in order to clarify the significance of AT1R PET as a renal injury imaging biomarker.

Methods: Using domestic pigs, two animal models were developed: 1) chronic renal artery stenosis; and 2) renal artery reperfusion-revascularization by stent treatment. *In vivo* PET imaging of the AT1R was performed with [^{11}C]KR31173. Renal perfusion was estimated with [^{15}O]water PET. Animals were then euthanized and kidneys were removed. The tissues were frozen, and were cut at 10-μm thickness. Tissue level distribution of AT1R, podocin and NGAL (Neutrophil Gelatinase-Associated Lipocalin) were imaged by indirect immunofluorescent staining and laser scanning confocal microscopy using. Cell nuclei were counterstained with 4-6 diamidino-2-phenylindole dihydrochloride (DAPI). *In vitro* AT1R binding was quantified by [I-125]-[Sar1Ile8]angiotensin II autoradiography.

Results: Both *in vivo* and *in vitro* cortical AT1R binding were increased in ischemia but not in normal perfusion. The finding was further supported by immunofluorescence staining of the chronic stenotic kidney tissue, which revealed increased AT1R expression in some glomeruli. There was also a correlation between the distribution of AT1R and NGAL expression.

Conclusions: Increased AT1R binding measured with PET and autoradiography correlates with increased glomerular AT1R in the renal cortex. Thus, Immunofluorescence imaging corroborates well with the PET imaging results and supports the role of AT1R PET as an imaging biomarker of renal ischemic injury.

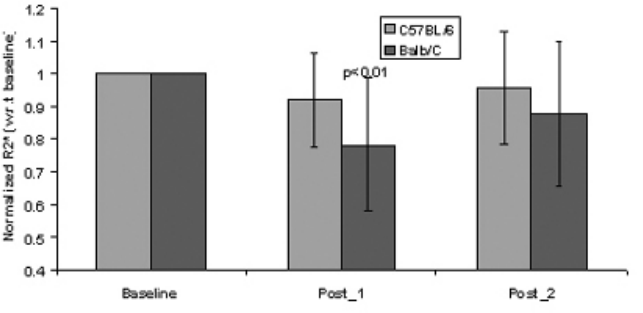
Blood Oxygenation Level Dependent MRI in Reversible Unilateral Ureteral Obstruction Model Tipu S. Puri,[1] Muhammad Haque,[2] Tammy Franklin,[2] Liby Mathew,[1] Pottumarthi V. Prasad.[2] *[1]Medicine/Nephrology, University of Chicago, IL; [2]Radiology, Northshore University HealthSystem, Evanston, IL, Ukraine.*

Background: Reversible unilateral ureteral obstruction (rUUO) provides a useful model of chronic kidney disease (CKD) amenable for longitudinal monitoring of structural and functional changes during development of CKD (Puri T, AJP Renal Physiol 2010). We have reported strain-dependent susceptibility to development of CKD after rUUO in C57Bl/6 (susceptible) and Balb/C (resistant) mice. In this preliminary study, renal BOLD MRI was used to detect any early changes in oxygenation status in this model.

Methods: A total of 31 mice (19 C57Bl/6 and 12 Balb/C) underwent rUUO. Blood samples were obtained via retro-orbital bleeding for BUN measurements at three time points (baseline, ~2days and ~28 days post release of UUO). BOLD MRI was performed on a 4.7 T Bruker Biospec scanner using a 35 mm mouse body coil at the same time points.

Results: BUN showed enhanced values in both strains at day 28 but to a significantly higher value in C57Bl/6 mice compared to baseline (25.6±5.0 to 48.6±13.0 mg/dL, $p<0.01$ in C57Bl/6 and 27.5±3.2 to 36.4±6.0 mg/dL, $p<0.01$ in Balb/C). As shown in figure below, BOLD MRI demonstrated differential response at day 2 probably related to the difference in susceptibility to developing fibrosis.



Conclusions: BUN measurements were consistent with previous findings in this model. BOLD MRI measurements at ~2day time point in Balb/C are consistent with previous reports in kidneys with ureteral obstruction in humans [Thoeny H, Radiology 2008]. While it is not yet clear why C57Bl/6 do not exhibit similar reduction in R2*, it may be suggestive of increased level of hypoxia which in turn can explain higher functional deficit. Future studies should evaluate water content changes at this time point in order to better characterize renal oxygenation changes.

The Utility of Electronic Screening for Enrollment in Clinical Studies: A Descriptive Study Kianoush Banaei-Kashani,[1 and 2] Laura N. Hanson,[3] Man Li,[2] Vitaly Herasevich.[2] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Pulmonary and Critical Care, Mayo Clinic, Rochester, MN; [3]Mayo Validation Support Services, Mayo Clinic, Rochester, MN.*

Background: Enrollment of patients to clinical studies with time sensitive conditions in the critical care field consumes significant portions of study coordinators' time. They need to continuously evaluate patient's medical records for eligibility or rely on the notification from bedside providers.

Methods: METRIC (Multidisciplinary Epidemiology and Translational Research in Intensive Care) Datamart which is a Microsoft SQL-based integrative near-real time (15min to 1 hour delay) database was served as the main data source for rule based alert utility (sniffer). The sniffer engine periodically scans the data under the datamart and sends the alerts to the study coordinator by pager whenever a patient meet predefined alert criteria. Alert was triggered if patient had two consecutive measurements of systolic blood pressure less 90 mmHg or an order for vasoactive agents. The alerts were screened for eligibility criteria by the study coordinators during the work hours. If patient met inclusion criteria, she obtained informed consent and collected time sensitive urine and plasma samples for measurement of acute kidney injury biomarkers. Our institutional review board approved the study procedures

Results: After excluding patients who declined research authorization the number of admited patients between October 2008 and February 2009 was 3779. During the same time period the alert system sent 1044 notifications for patients who met shock state criteria. The distribution of the alerts between work hours (7am- 5pm, Mon-Fri) and off-hours were 345 and 699, respectively. After evaluation for eligibility criteria 121 patients were recruited. Coordinators needed to screen only 27% of total ICU admissions (1044/3779) by using shock state sniffer.

Conclusions: Electronic screening ("shock state sniffer") facilitated the enrollment into clinical study of AKI and potentially saves significant amount of study coordinator's time for electronic medical records screening.

Delivery of Recombinant Erythropoietin (rEPO) in Conjunction with Renal Cell Therapy during Continuous Peritoneal Dialysis P. Smith,[1] L. Charles,[1] K. Johnston,[1] D. Buffington,[1] David Humes.[2] *[1]Innovative BioTherapies, Inc., Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.*

Background: Anemia is a common side effect of chronic kidney disease (CKD). It is postulated that impaired kidney function leads to hypo-responsive EPO release, resulting in reduced red blood cell maturation. Erythropoietic stimulating agents (ESA), including rEPO, and intravenous injections of polysaccharide-conjugated iron have been the corner stone for treating anemia associated with CKD by raising the hemoglobin concentration to 11-13 g/dl. To attempt to improve the treatment of anemia in CKD, a method to deliver rEPO during continuous ambulatory peritoneal dialysis (CAPD) is being tested. As a proof of concept, HEK-293 cells were stably transfected with a human EPO expression cassette and seeded as the surrogate cellular component of a BRECS. Once confluent, the BRECS unit was circulated in 250 ml of serum-containing media for 24 hours, prior to the infusion of this conditioned media into the dry peritoneum of a uremic sheep. Serum was monitored for human EPO every two hours for a 24 hour period using a human-specific EPO ELISA. The EPO concentration peaked between 4 and 8 hours, well within the expected range found in the human population (3.3-16.6 mIU/ml), at >12 mIU/ml, and decayed in a near-linear fashion to 2.5 mIU/ml at 24 hours. As a comparison, a similar experiment was constructed, with the exception that 250 ml of conditioned BRECS media was infused into the peritoneum in the presence of 2 liters of peritoneal dialysis fluid, prior to monitoring serum for the presence of human EPO. In this instance, the serum concentration of EPO peaked between 4 and 8 hours at >4.5 mIU/ml, and decayed in a near-linear fashion to a concentration of 2 mIU/ml at 24 hours. These experiments demonstrate that this approach has the potential to provide hormonal stimulation for erythropoiesis in a manner much more consistent with normal physiology while providing a method that may lead to cost savings over the current treatment regimens.

TH-PO175

Evaluation of Adult Human Renal Epithelial Progenitor Cells in Cell Therapy Devices A. Westover,[1] D. Buffington,[1] David Humes.[1,2] *[1]Innovative BioTherapies, Inc., Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.*

Background: Renal epithelial cell (REC) therapy promises to improve the morbidity of patients with renal disease. To this end**,** therapeutic devices addressing the neglected biologic component of renal replacement therapy are being advanced. Because human donor tissue is limited, an enhanced propagation method to expand REC progenitors from available adult human kidney transplant discards has been established to provide the biomass for REC-based therapeutic products.

Methods: REC progenitor cell isolation has been successful using kidneys from donors including those previously considered suboptimal (n=19). Donor profiles include long-term diabetes, hypertension, greater than 70 years old, donation post cardiac death with prolonged warm ischemia, and one donor with end stage renal disease (ESRD) on dialysis for >2 years.

Results: Cell yields are consistently higher than 10^{11} cells/gram cortex allowing for the manufacture of over 100,000 devices per donor kidney, indicating that autologous therapy may be possible using cells derived from a wedge biopsy taken early in the renal failure cascade. Kidneys from healthy donors (obtained due to anatomical flaw or procedural error) yielded over 10^{12} cells/gram cortex or potentially over 1,000,000 devices per donor kidney. Greater than 10^{9} progenitor cells/gram cortex were isolated from the ESRD kidney indicating that proliferative potential remains and would allow for the manufacture of >100 autologous devices. A cryopreservation procedure, necessary to allow for processing the large cell yields has been advanced using a potentially FDA compliant procedure and cell death from apoptosis post thaw minimized. Additionally, the therapeutic potential of progenitor derived REC was conserved as evaluated using a surrogate panel for efficacy including LPS stimulated IL8 secretion, γGT and 25-hydroxyvitamin D-1-alpha hydroxylase enzyme activities.

Conclusions: Differentiated REC progenitors, integrated into trabeculated carbon disk based bioartificial REC systems (BRECS), continue to be evaluated in previously established large animal models of ovine ESRD and porcine septic shock.

TH-PO176

Immuno-Modulatory Effect of the Bioartificial Renal Epithelial Cell System (BRECS) in an Ovine Model of Uremia D. Buffington,[1] A. Westover,[1] L. Lou,[1] L. Charles,[1] P. Smith,[1] K. Johnston,[1] C. Pino,[1] J. Liu,[3] David Humes.[2] *[1]Innovative BioTherapies, Inc.; [2]Univ. of Mi.; [3]Huashan Hospital.*

Background: Studies were performed to assess BRECS impact on the pro-inflammatory state that develops during chronic uremia. The BRECS is a compact, cryopreservable renal epithelial cell therapy device under development for treatment of renal and inflammatory disease states. The ovine uremic model employs a continuous-flow peritoneal dialysis (CFPD) circuit for uremic control and recycling PD from the host sheep through the BRECS.

Methods: Sequential nephrectomies were performed at the time of PD catheter placement and one day before initiation of CFPD. BRECS containing 10^{8} cells were incorporated into the PD circuits. BRECS O_2 consumption and glutathione (GSH) degradation rates were assessed to monitor cell viability and functionality. Inflammatory indices were measured to assess BRECS impact to modulate the pro-inflamed uremic state. CD11b expression on the neutrophil (NE) cell surface was used as an indicator of the "activated state" of the NE population. Oxidative burst, as a measure of leukocyte function, was monitored and compared to acellular sham devices. Systemic NE apoptotic potential was assessed via Annexin V staining assay. BRECS therapy continued up to seven days, followed by an additional post-therapy evaluation period of 48 hours

Results: BRECS remained viable with detectable O_2 consumption and GSH degradation rates for the entire therapeutic time course. CD11b mean fluorescent intensity was lower beginning after 5 days of BRECS therapy when compared to acellular control sheep. Enhancement in oxidative burst was also seen in the BRECS treatment group. Importantly, these two affects continued during the 48 hour post-BRECS therapy period. BRECS therapy caused a shift in the percent NEs that maintain apoptotic progression, indicating a return to steady state with respect to NE activation and function, as seen in normal, non-uremic sheep.

Conclusions: BRECS therapy positively modulates the inflammatory state of the uremic sheep; indicated by a decrease in the circulating NE activated state, increase in oxidative burst and improved NE apoptotic potential.

TH-PO177

Modeling Ultrasound (US)-Induced Heating of Hemodialysis Grafts Yan-Ting E. Shiu,[1,2] Mark R. Brinton,[3] Alfred K. Cheung,[1,4] Russell Stewart Stewart,[2] Douglas Christensen.[2,3] *[1]Medicine, Univ. of Utah, SLC, UT; [2]Bioengineering, Univ. of Utah, SLC, UT; [3]Electrical and Computer Engineering, Univ. of Utah, SLC, UT; [4]Medical Service, VASLCHCS, SLC, UT.*

Background: Expanded polytetrafluoroethylene (ePTFE) grafts fail at high rates due to stenosis caused by neointimal hyperplasia (NH). Currently there is no effective method to prevent or treat NH. We explored a novel approach to reduce NH in ePTFE grafts using focused US-induced mild hyperthermia. We have previously reported a higher sensitivity to hyperthermia-induced death for cells cultured on ePTFE than on a surrogate tissue surface. We identified the temperature range (45-47°C) necessary to induce significant apoptosis among cells cultured on ePTFE but not on surrogate tissues. The present study addresses the feasibility of selectively heating ePTFE to the optimal temperature by US.

Methods: The acoustic finite-difference time-domain method was used to calculate the beam propagations from 1.5- and 3.2-MHz transducers through a simplified 3-dimensional model containing fat, muscle, blood flow and ePTFE graft. Next, the spatial pattern of the heat derived from the US power was simulated using the COMSOL Multiphysics heat-transfer module. The simulation included skin surface cooling to 20°C, laminar blood flow through the graft lumen, and the effect of blood perfusion on heat transfer in the tissue regions. Cyclic 30-sec heating and cooling periods were used to mimic a pulsed ultrasound cycle.

Results: The greater US attenuation by ePTFE than by tissues caused about 5 times more power deposited in ePTFE than in adjacent tissues. The transducer with a higher frequency produced a more confined power deposition pattern than the transducer with lower frequency. Importantly, high temperatures (48-49°C) were found only on ePTFE, while blood and most tissues remained at 37°C.

Conclusions: Our approach exploits the differential acoustic properties between ePTFE and tissues, and their differential sensitivity to hyperthermia-induced cell death. Our results show promise for the use of focused US as a safe and effective strategy to prevent and treat NH on the ePTFE surface through hyperthermia-induced apoptosis.

ER-Stress Induced Mega-Cluster microRNAs in Mouse Models of Diabetic Nephropathy Mitsuo Kato, Mei Wang, Zhuo Chen, Xiwei Wu, Sumanth Putta, Linda L. Lanting, Rama Natarajan. *Diabetes, Beckman Research Institute of City of Hope, Duarte, CA.*

Background: microRNAs (miRNAs) have been shown to play major roles in renal diseases. However, the comprehensive study of miRNAs has not completed in diabetic nephropathy.

Methods: In this study, we profiled miRNAs in RNA extracted from glomeruli from control and streptozotocin (STZ)-injected type1 diabetic mice by high-throughput sequencing (solexa, Illumina Inc). Expression levels of candidate miRNAs were validated by qPCRs.

Results: Some of confirmed miRNAs are miR-34 family (miR-34a, miR-34b, miR-34c & miR-34c*), miR-486 and miR-379. miR-34 family is regulated by p53 and possibly involved in renal hypertrophy. miR-486 is also involved in renal hypertrophy by targeting Pten and activating Akt kinase under diabetic conditions. miR-379 is a member of miR-495 mega cluster miRNAs (~40 miRNAs). Other members (miR-495, miR-380, miR-376b, miR-382 and miR-379) in this mega cluster were also confirmed to be upregulated in glomeruli from STZ-injected type1 diabetic mice. Interestingly, miRNAs in this cluster were regulated by ER stress inducible transcription factor CHOP upregulated by high glucose conditions (HG) or TGF-b in kidney cells. The potential targets of this mega cluster are Tnrc6b (15 sites by 12 miRs), Cugbp2 (14 target sites by 12 miRs) and Pten (13 sites by 10 miRs). Decrease of these potential targets was confirmed in glomeruli from diabetic mice and in kidney cells treated with HG or TGF-b. Tnrc6b is a mammalian homologue of GW182 which is located in P-bodies and regulates protein translation. Cugbp2 is a regulator of insulin RNA splicing but also a negative translational regulator of Cox2 which is increased in diabetic glomeruli. Pten inhibition by the mega cluster may activate Akt to enhance protein synthesis and hypertrophy.

Conclusions: These results demonstrate that diabetic condition induces renal hypertrophy through down regulation of negative translational regulators targeted by the mega cluster miRNAs upregulated by ER-stress induced CHOP. ER-stress induced mega cluster miRNAs may be therapeutic targets of diabetic nephropathy.

Basement Membrane Remodeling and Endothelial Differentiation When Mouse Stem Cells Are Seeded into Acellular Rat Kidney Scaffolds

Edward A. Ross,[1] Dale R. Abrahamson,[2] Matthew James Williams,[1] Gary W. Ellison,[1] Patricia St. John,[2] Chris Batich.[1] *[1]University of Florida; [2]Kansas University Medical Center.*

Background: Due to transplant organ shortage we have pursued tissue regeneration using decellularized kidneys seeded with pluripotent precursor cells. We hypothesize that these scaffolds retain matrix signals that can induce progenitor cells to differentiate and recapitulate native structures: matrix-to-cell signaling followed by cell-to-cell and then cell-to-matrix interactions that would gradually remodel and replace the original scaffold matrix. This would reduce scaffold antigenicity and enable xeno-allografts.

Methods: We previously showed that when arterially seeded into acellular rat whole kidney scaffolds murine embryonic stem cells (mESCs) attach, multiply and demonstrate morphologic, immunohistochemical and gene expression evidence (Pax2, Ksp-cadherin) for differentiation. We now tested for more specific evidence of differentiation into endothelial lineage and remodeling of the matrix basement membranes from rat to mouse ("murinization"). mESCs were infused arterially into rat kidney scaffolds and incubated for 10 days. Endothelialization of vascular cells was tested by endothelial specific BsLB4 lectin and anti-VEGFR2 (Flk1) antibodies. Matrix murinization was assessed by a monoclonal antibody specific for mouse laminin β1 chain, which does not cross react with rat.

Results: As evidenced by co-localized staining with DAPI nuclear label, cells in arterial vessels and glomeruli were positive for both BsLB4 lectin and VEGFR2. Labeling became progressively intense with longer incubations, from 4 to 10 days. Rat scaffold's basement membrane (co-localized with cell growth) demonstrated IgG-horseradish peroxidase immunolabeling with monoclonal rat anti-mouse laminin β1, again in a time dependent manner.

Conclusions: We have provided new evidence for matrix-to-cell signaling in acellular whole organ scaffolds that induces differentiation of pluripotent precursor cells to endothelial lineage. Production of mouse basement membrane supports remodeling of host (rat)-derived scaffolds and thereby warrants further investigation as a promising approach for xenotransplantation.

TH-PO180

Bio-Mechanical Properties of the Mammalian Urothelium

Mark L. Zeidel,[1] Enhua H. Zhou,[2] Weiqun Yu,[1] John Mathai.[1] *[1]Medicine, Beth Israel Deaconess Medical Center, Boston, MA; [2]Physiology and Bioengineering, Harvard School of Public Health, Boston, MA.*

Background: Successful bladder filling, urine storage and voiding requires an intact urothelium because urothelial surface umbrella cells (UC's) maintain an exceptionally tight barrier between urine and blood. This barrier remains intact despite profound urothelial stretching and subsequent relaxation, during the processes of bladder filling and voiding respectively. Specialized proteins called uroplakins form plaques on the surface of umbrella cell and cover up to 90% of the urothelial surface, and is considered to be rigid. It is not clear how a rigid surface can be flexible as the bladder undergoes stretch and relaxation cycles. The biomechanical properties of UC's, including deformability and spontaneous dynamic remodeling, likely play a critical role in both barrier function and mechanotransduction.

Methods: To develop an understand of the mechanical properties of the urothelial surface we attached magnetic beads coated with polylysine to the apical membrane (AM) surface of intact UC's in intact urothelia and measured their stiffness G, in response to oscillating magnetic fields (optical magnetic tracking cytometry, OMCT) as we varied the frequency of oscillation between 0.1 to 1000 Hz.

Results: Control UC's exhibited G values which tracked closely with highly deformable red blood cells. Removal of surface UC's with protamine exposed underlying intermediate cells, which exhibited G values 12-15 fold higher than UC's, and similar to cultured MDCK cells. Fixation of UC's with formaldehyde raised G by two orders of magnitude. Because submembrane actin often plays a critical role in reducing deformability, we performed confocal microscopy on control UC's and found very little subapical actin. In UC's basolateral actin was abundant, and actin was also abundant under apical and basolateral membranes of intermediate cells.

Conclusions: We conclude that UC's are strikingly deformable, despite the dense array of uroplakins in their apical membranes. Whether this deformability results from the physical effect of uroplakins or the relative lack of subapical actin will be determined using uroplakin knockout mice.

Nephrology Blogs as an Educational Tool: A Survey of Global Blog Readers

Tejas P. Desai,[1] Cynthia R. Christiano,[1] Maria E. Ferris.[2] *[1]Nephrology and Hypertension, East Carolina University, Greenville, NC; [2]Pediatric Nephrology, University of North Carolina-Chapel Hill, NC.*

Background: An increasing number of providers author medical blogs. However, little data exists about reader's perceptions. This information is especially important for nephrology educators who wish to use social media to attract younger students to nephrology careers. Our investigation uncovers the perception of a nephrology-specific blog by its global readership.

Methods: Nephrology On-Demand is a comprehensive educational website that provides multimedia information. We measured the usage & appeal of the blog format.11 blogs from national/international and local meetings were published online, detailing the key learning points of selected seminars. We used Google Analytics to measure usage data for each blog during the first 90 days after publication. Access to any blogs could be achieved by completing a short, Qualtrics-hosted survey.

Results: A total of 828 visitors and 1465 pageviews were recorded. The average number of visitors & pageviews to blogs of local meetings were 32 and 76, respectively. These numbers increased to 112 and 181 for the national/international meeting blogs. International readers contributed between 25-45% of visits to the blogs of local meetings. Of 254 surveys, 94% were completed. More than 80% of non-first-time readers viewed the blogs as accurate (mean 1.44, SD 0.73), current (1.49, 0.79), objective (1.53, 0.81) and useful (1.5, 0.79). These findings were similarly observed at all training levels.

Conclusions: Our investigation has 2 key points. First, local meetings generally attract local providers, but blogs of such meetings can attract a global audience. Albeit a small number of visits, blogs allow presenters of local scientific meetings to showcase their material worldwide. To date there are no nephrology blogs that have published such data. Second, knowledge that blogs are viewed in a positive manner may help attract a younger generation of learners to nephrology. Further data collection is underway to determine if blogging of scientific meetings can increase the awareness and interest of nephrology with students and residents.

TH-PO182

A Knowledge Base Compiling Data from Literature, To Access, At-a-Glance, Gene- and Protein-Expression across Kidney Segments and Kidney Diseases

Julie Klein,[1] Simon Jupp,[2] Panagiotis Moulos,[1] Jean-Loup Bascands,[1] Robert Stevens,[2] Joost Schanstra.[1] *[1]U1048, INSERM, Toulouse, France; [2]School of Computer Science, University of Manchester, United Kingdom.*

Background: Kidney research continues to produce large genomic and proteomic data sets from different part of the kidney and across different diseases. However, not only this information is scattered across hundreds of publications, it is also hidden in figures and supplementary data. To facilitate data exploration and analysis, and to help generate new hypothesis in kidney research, a supporting database related to the kidney and urinary pathways (KUP), compiling existing knowledge from databases and scientific literature, would be of great help.

Methods: We have developed a KUP Knowledge Base (KUPKB) that integrates KUP related gene and protein expression data. A specialized KUP Ontology (KUPO) provides a common schema for annotating the data.

Results: Currently the KUPKB consists of 163 gene and protein expression datasets extracted manually from 66 publications (figures, tables, and supplementary data), from the Gene Expression Omnibus (20 microarrays experiments), or from other databases such as Euregene, the Human Glomerulus Protein Database or the Urinary Exosome Protein Database. Experiments include mRNA, protein and phosphoprotein data, in specific kidney cells (e.g. podocyte), kidney segments (e.g. glomerulus) or urine, and across different kidney diseases or animal models (e.g diabetic nephropathy, interstitial fibrosis and tubular atrophy) and different in vitro models (e.g. TGFbeta, high glucose).

Conclusions: The user can search using a publicly available interface called the iKUP browser for a gene or a list of genes of interest. The result of the query is returned in a tabular format to see at a glance: where are a these genes expressed? In which diseases/models are they expressed? Are they present, up/down-regulated in these conditions? We will present the results of typical queries using the iKUP browser and compare the results of these queries with the classical way of data interrogation to demonstrate the added value of the KUPKB.

The KUPKB and the iKUP browser are available at: http://www.kupkb.org

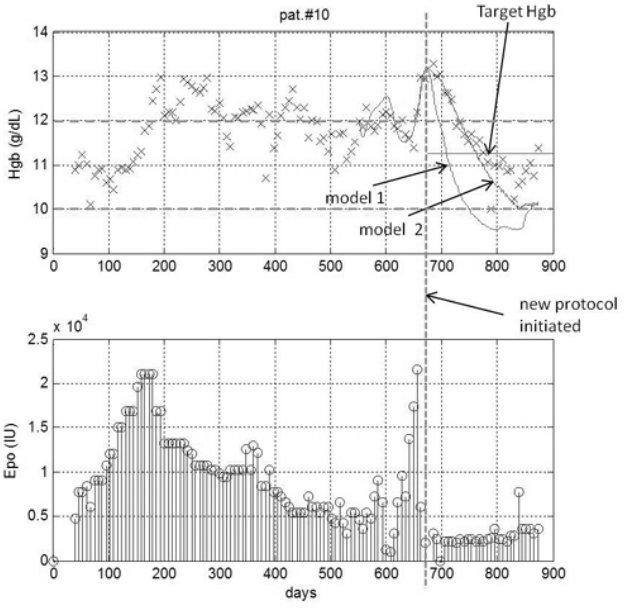
A Novel Anemia Management Protocol (AMP) Yossi Chait,[1] Michael J. Germain,[2] Joseph Horowitz,[1] Christopher V. Hollot,[1] Rajiv P. Shrestha.[1] *[1]University of Massachusetts; [2]Western New England Renal & Transplant Associates.*

Background: We report observations from a pilot clinical study on the feasibility of AMP designs based on mathematical modeling of erythropoiesis and on feedback control. This is in contrast to current AMPs, which are largely rule-based, expert systems formulated on the basis of experience and clinical studies.

Methods: A pharmacokinetic/pharmacodynamic (PK/PD) erythropoiesis model was employed and a new AMP was designed using robust control principles, based on retrospective 3x/week hemoglobin (Hgb) data. The dosing protocols for four ESRD patients were switched to the new AMP designs.

Results: For parsimonious parameter identification, we modeled the erythropoiesis stages using an Epo-stimulated saturable production function with a time delay to model the maturation of the progenitor cells into red blood cells (RBCs). Epo PK was modeled using linear plus nonlinear clearances. The RBC pool was modeled with a 2nd-order gamma distribution describing mean RBC lifespan. Quantitative Feedback Theory was used to design the AMP which used past and current Epo doses and Hgb data to compute the upcoming week's Epo dose. Patient-specific model parameters and corresponding algorithm parameters were periodically updated based on newer Hgb data. Preliminary results support the feasibility of the new AMP in maintaining Hgb within the desired range (10-12 g/dL); with reduced variability and decreased Epo usage; see Figure 1. We also deliberate the hypothesis that variability in Hgb due to iron kinetics or fluid volume cannot be eliminated with an AMP based only on Hgb data.



Hemoglobin (top) and IV Epo doses (bottom) traces of pat. #10 (starting 1.1.2009). Prior to day 675, different AMPs have been used; the new protocol was initiated on day 675 with a target of 11.25 g/dL; model 1 and model 2 correspond to predicted responses using two different sets of estimated parameters, indicating intrapatient variability.

Conclusions: Patient-specific AMPs based on PK/PD models and robust control principles can offer improved Hgb regulation.

Funding: Other U.S. Government Support

TH-PO184

Development of a Clinical Terminology Index by the Spanish Society of Nephrology: Standardization Process Katia Lopez-Revuelta,[1] Elena Corchete,[1] Alberto Ortiz.[2] *[1]Nephrology, Hospital Universitario Fundación Alcorcón, Madrid, Spain; [2]Nephrology, Fundación Jiménez Díaz, Madrid, Spain.*

Background: Achieving a common medical terminology is a main concern for the implementation of electronic medical record. The use of standardized clinical terminology facilitates electronic data collection for multiple purposes: clinical, research, registries and health policy planning. Coding systems, fully implemented in hospitalization are lacking in outpatient care. PURPOSE: To develop a standardized clinical terminology index validated by the Spanish Society of Nephrology, pre-codified by CIE9-MC system to apply in Clinical Nephrology Outpatient Care.

Methods: A systematic review of pathologies was carried out by the research team dealing with terms covering referral findings and diagnosis. Classified terms have been reviewed by groups of experts in different Nephrology fields. The worked up terminology index has been independently codified by two different health coding technicians following CIE9-MC system. Concordance analysis was assessed by Kappa test.

Results: The final version of the terminology index has a total of 1104 items grouped in 14 pathologic categories: Symptoms, Signs and Syndromes referral, Water and Electrolyte Disorders, Inherited Kidney Diseases, Glomerular Disorders, Multisystem Diseases, Diabetic Nephropathy, Infectious Diseases, Vascular Kidney Diseases, Acquired Chronic Tubulointerstitial Nephritis, Urinary Tract Infection, Nephrolithiasis, Hypertension, Renal Neoplasia and Acute Renal Failure.

Each item has its corresponding CIE-9 MC pre-attached code. The global agreement observed between both coding technicians was 95%, 100% in most pathologies except 94% in Water and Electrolyte Disorders and 74% in Vasculitis.

Conclusions: A Standardized Terminology Index by the Spanish Society of Nephrology with CIE9-MC system pre-codified will be a useful tool for Clinical Nephrology Outpatient care that will be available at the Society web site. A preliminary implementation study is needed to validate this classification. It would be desirable to complete the list with dialysis and transplantation terms.

Computer Simulations in the Design and Evaluation of Anemia Management Protocols (AMPs) Yossi Chait,[1] Joseph Horowitz,[1] Michael J. Germain,[4] Rajiv P. Shrestha,[1] Christopher V. Hollot,[1] Adam E. Gaweda.[5] *[1]University of Massachusetts; [3]Western New England Renal & Transplant Associates, PC; [4]University of Louisville.*

Background: Current AMPs rely exclusively on clinical data and physicians' experience. We use computer simulations to compare the performance of two AMPs: a current AMP used at our dialysis facility, and a new one designed on the basis of mathematical modeling and feedback control techniques. A hyper responsive and intermediate responsive patient models are used in the comparison.

Methods: The erythropoiesis model comprises a PK compartment with linear+nonlinear clearance, a PD compartment with a saturable time-delay RBC production function, and a 2nd-order gamma lifespan distribution describing the RBC pool dynamic. Model parameters were estimated to match the each patient's clinical profile.

Results: To study protocol performance under intrapatient variability, we introduced random variations in the response to Epo stimulation and in the mean reticulocyte hemoglobin content. The current AMP is population-oriented and consists of a set of rules based on hemoglobin (Hgb) trending and Hgb ranges whereas the new AMP is patient-specific. Both protocols assume weekly Epo dose adjustments with 3x/week administration. Hgb variability, defined as the sum of absolute consecutive Hgb changes divided by the number of data, is an accurate measure of how 'fast' a variable varies.

type (protocol)	Hgb mean (SD)	Hgb Variation	Hgb In Range [10-12] (%)	Weekly Epo Mean(SD)
Hyper-responsive (new)	10.98(0.52)	6.01	99	2794(1692)
Hyper-responsive (current)	11.13(0.91)	10.29	65	4097(4182)
Intermediate-responsive (new)	11.24(0.42)	7.43	93	14067(1408)
Intermediate-responsive (current)	10.77(109)	33.00	52	11871(8726)

Conclusions: Population-oriented AMP consisting of a single set of rules may not be able to achieve acceptable maintenance for the entire spectrum of hyper-, intermediate-, and hypo-responsive patients. AMPs that can be tuned to individual patients through mathematical modeling, robust control principles, and parameter identification, may offer improved Hgb behavior. In conjunction with clinical trials, simulations could become an essential tool in the design and evaluation of AMPs.

Overweight and Adiposity in Chronic Kidney Disease Patients Rachel Bregman, Barbara Vale, Carla C.S. Lemos, Laura Carvalho Kawakami, Maria Ines Barreto Silva. *Nutrition, Nephrology, State University of Rio de Janeiro, Brazil.*

Background: Central adiposity (CAd) and inflammation are pointed as risk factors for cardiovascular disease (CVD) in chronic kidney disease (CKD) patients. A new index for evaluation of CAd was proposed to CKD patients, named waist-to-height ratio (WheiR).

Methods: We evaluated 134 CKD patients under treatment with a multidisciplinary team. Nutritional status and body composition were determined by body mass index (BMI), serum albumin, waist-to-hip ratio(WHR) and DEXA-dual X-ray absorptiometry. Obesity index WheiR was calculated as waist circumference (WC;cm)/ body height (cm). Glomerular filtration rate was estimated (eGFR) by MDRD. Multiplexed analysis of pro- and anti-inflammatory markers (high sensitive C reactive protein (CRP), interferon gamma (IFN-γ), leptin, intercellular adhesion molecule-1 (ICAM-1), insulin resistance index (homeostasis model assessment: HOMA-IR), high molecular weight (HMW) adiponectin and interleukin-10 (IL-10), were performed. Statistical analysis using StataCorp 8.2.

Results: Data: mean±SD, patients were under treatment for 3±2 years, eGFR: 29±13 ml/min; age: 65±12 years; 56% males, BMI: 26±4 kg/m^2. Patients were divided according to WheiR: Group 1: WheiR<0.55; n=63; Group 2: WheiR>0.55; n=71. Gender, age, albumin and eGFR were not different among groups. Group 2 showed higher WheiR, BMI, WC, WHR, DEXA total and central body fat ($p<0.0001$). WheiR index presented a better correlation with DEXA trunk fat ($p<0.0001$) than with DEXA total fat and WHR. The CRP, leptin, and HOMA-IR were higher in group 2, but HMW adiponectin was lower. The Spearman's coefficient was significant between WheiR and IFN-γ and IL-10. In the stepwise multiple regression analysis, WheiR was positively associated with HOMA-IR and leptin and, negatively associated with HMW adiponectin.

Conclusions: WheiR is very easy to be measured, presented a significant correlation with DEXA, and can be used to evaluate CAd. In this CKD population, high CAd was followed by inflammation. In conclusion present data suggest that body adiposity is an independent risk factor for CVD in patients with CKD and should be a target in the nutritional treatment of this population.

Longitudinal Relationship between Blood Pressure and Left Ventricular Mass in Children with Chronic Kidney Disease Juan C. Kupferman,[1,2] Derek Ng,[2] Joseph T. Flynn,[2] Susan L. Furth,[2] Bradley A. Warady,[2] Mark Mitsnefes.[2] *[1]Maimonides Medical Center, Brooklyn, NY; [2]CKiD investigators.*

Background: The longitudinal association between casual blood pressure (BP) and left ventricular mass index (LVMI) has not been previously studied in children with chronic kidney disease (CKD).

Methods: In a prospective cohort study, BP was assessed annually. Initial echocardiogram was performed 1 year after study entry (V2) and 2 years later (V4). A linear mixed model with a random subject effect assessed the effect of change in BP on LVMI. The main exposure was average BP z-score, defined as the average of 2 BPs spaced 1-year apart prior to each LVMI measurement. Models for systolic and diastolic BP (SBP, DBP) were adjusted for age, sex, race, height, CKD diagnosis, and years with CKD. Each model included a time effect, allowing LVMI to be different at V2-V4. We also allowed the effect (slope) of average BP to be different.

Results: There were 260 subjects with complete follow-up data; age (median [IQR]) 11 [8, 15], 61% male; 21% black; median iohexol GFR 42 ml/min/1.73m^2. Over 2 year follow up, median SBP z-score decreased from 0.34 to 0.07 while DBP z-score decreased from 0.47 to 0.23; median LVMI decreased from 33.8 to 31.8 g/m$^{2.7}$.

Effects of BP and Time on LVMI

	Covariate	Estimated change (95% CI)	p-value
Model 1	Slope of SBPz (V2)	3.9% (1.7%, 6.2%)	<.01
	Slope of SBPz (V4)	6.5% (3.7%, 9.4%)	<.01
	Effect of Time (2 yrs)	-32% (-44%, -17%)	<.01
Model 2	Slope of DBPz (V2)	3.4% (0.8%, 6.1%)	0.01
	Slope of DBPz (V4)	5.8% (2.5%, 9.3%)	<.01
	Effect of Time (2 yrs)	-29% (-41%, -14%)	<.01

LVMI had a 2-year average decrease of 32% when adjusting for SBP and confounders. For every one standard deviation increase in SBP at V2, LVMI increased by 3.9% and this effect increased to 6.5% at V4. The linear association between DBP z-score and LVMI was significant and the effect was higher for V4 compared to V2 (5.8% vs. 3.4%).

Conclusions: BP and LVMI improved in children with CKD over time. Elevated SBP and DBP are associated with increased LVMI. While the effect of BP on LVMI was not significantly modified by time, these results suggest a clinically meaningful effect of long-term elevated BP on LVMI.

Elevated Albuminuria Increases the Risk of Recurrent Venous Thromboembolism: Results from a Population Based Cohort Study Inge van Schouwenburg,[1] B. Khan Mahmoodi,[1,2] Nic Veeger,[1,3] Hanneke C. Kluin-Nelemans,[1] Ron T. Gansevoort,[2] Karina Meijer.[1] *[1]Division of Hemostasis and Thrombosis, Department of Hematology, University Medical Center Groningen (UMCG); [2]Department of Nephrology, UMCG; [3]Department of Epidemiology, UMCG, Netherlands.*

Background: Microalbuminuria has been identified as risk factor for first venous thromboembolism (VTE). Whether it is also a risk factor for recurrence is unknown. Knowledge on this issue is relevant because it may help in assessing the duration of anticoagulant therapy after a first VTE. We therefore investigated the risk of recurrent VTE in patients with elevated albuminuria.

Methods: Data of a prospective population based cohort study (PREVEND), that started in 1997 and included 40.856 subjects aged 28-75 yrs, were used. In all participants, albuminuria was measured and VTE occurrence was monitored. Patients with first VTE between study entry and January 2009 were identified by database record linkage with the national registries of hospital discharge diagnoses and death certificates and the regional anticoagulation clinic. Of identified patients medical records were utilized for verification and for obtaining additional information.

Results: Of 351 subjects with first venous thromboembolism (49% male; median age at first event 64 years, unprovoked 43% and provoked [external risk factor present] 48%), 37 subjects developed a recurrence during a median follow-up period of 3.3 (interquartile range, 1.1-6.4) years. Annual incidence of recurrence in subjects with elevated albuminuria (≥20 mg/L) was 5.00 per 100 person years (95% confidence interval [CI]; 2.16-9.85), compared to 2.38 (95%CI; 1.59-3.41) in subjects with normal albuminuria (<20 mg/L). Hazard ratio for recurrence was 1.95 (95%CI; 0.89-4.30) after adjustment for age and sex. This hazard ratio was 3.35 (95%CI; 1.18-9.47) in patients with first unprovoked, and 1.12 (95%CI; 0.25-5.01) in those with a first provoked event.

Conclusions: Subjects with elevated albuminuria who experience an unprovoked VTE are at an increased risk of recurrence, independent of age and sex. These results implicate that such patients may benefit from long-term anticoagulant therapy.

TH-PO189

Novel Risk Factors for Incident Peripheral Arterial Disease among Patients with Chronic Kidney Disease: A Prospective Analysis from the CRIC Study Jing Chen, Dawei Xie, Michael Shlipak, Raymond R. Townsend, Lawrence J. Appel, Lisa C. Nessel, Dominic S. Raj, Akinlolu O. Ojo, Martin J. Schreiber, Xin Wang, Louise Frances Strauss, Claudia M. Lora, Mahboob Rahman, L. Lee Hamm, Jiang He. *Tulane University.*

Background: Patients with chronic kidney disease (CKD) have an increased risk of developing peripheral arterial disease (PAD) compared to those with normal kidney function. The underlying etiology for this increased risk is not fully understood.

Methods: We studied the effects of novel risk factors on the development of PAD among 3,090 participants in the Chronic Renal Insufficiency Cohort (CRIC) study. Patients aged 21 to 74 years old with an estimated glomerular filtration rate (eGFR) of 20-70 mL/min/1.73 m^2 were recruited from 7 clinical centers in the US. Incident PAD was defined as a new onset ankle-brachial index (ABI) of <0.9 or clinical PAD confirmed by an endpoint assessment committee during the follow-up period among participants with ABI >0.9 and no PAD history at baseline examination.

Results: After adjustment for age, race, gender, and clinical sites, the following novel risk factors were associated with an increased risk of incident PAD (hazard ratio and 95% confidence interval for a one standard deviation higher level): HOMA-insulin resistance (IR) (1.12; 1.05-1.19; p<0.001), hemoglobin (Hb) A1C (1.25; 1.13-1.39; p<0.001), total parathyroid hormone (1.12; 1.01-1.24; p=0.03), C-reactive protein (CRP) (1.11; 1.05-1.18; p<0.001), white blood cell count (1.18; 1.06-1.31; p=0.003), fibrinogen (1.29, 1.15-1.45, p<0.001), alkaline phosphatase (1.18; 1.09-1.29; p<0.001), cystatin C (1.19; 1.06-1.34; p=0.003), and 24-hour urine albumin (1.16; 1.04-1.29; p=0.006). After further adjustment for traditional cardiovascular risk factors including eGFR, the following remained significantly associated with increased risk of PAD: HOMA-IR, HbA1C, CRP, fibrinogen, alkaline phosphatase, and cystatin C.

Conclusions: These data indicate that insulin resistance, inflammation, prothrombotic state, bone metabolism and kidney function are associated with risk of PAD independent from traditional risk factors among patients with CKD.

TH-PO190

Increasing Levels of Novel Kidney Function Markers Predict Outcomes in the General Population: The Atherosclerosis Risk in Communities (ARIC) Study Brad C. Astor,[1] Tariq Shafi,[1] Ron C. Hoogeveen,[2] Christie Ballantyne,[2] Josef Coresh.[1] *[1]Johns Hopkins University; [2]Baylor College of Medicine.*

Background: Decreasing kidney function is associated with higher risk of death, CVD and ESRD. Several novel markers of kidney function have been proposed as adjuncts to serum creatinine (SCr). The risk of outcomes associated with changes in these markers is unknown.

Methods: We examined the association between a ≥25% increase over 6 years in SCr, cystatin C (CysC), beta trace protein (BTP) and beta-2 microglobulin (B2M) and subsequent outcomes (death, coronary heart disease [CHD], hospitalized heart failure [HF], acute kidney injury [AKI] and ESRD) over the following 11 years among 2,186 selected participants in the ARIC Study with an estimated GFR (eGFR) ≥60 mL/min/1.73m^2 at baseline.

Results: An increase in 1 or more markers was associated with death and heart failure after adjustment. Increases in ≥3 markers was strongly associated with all outcomes. Results were similar among participants without a ≥25% increase in SCr (n=1,821) or CysC (n=1,621).

	Adjusted* Incidence Rate Ratio (95% CI)				
# Markers with ≥25% increase	Death (n=536)	CHD (n=459)	Heart Failure† (n= 410)	AKI (n=124)	ESRD (n=115)
0	1.0 (Ref)	1.0 (Ref)	1.0 (Ref)	1.0 (Ref)	1.0 (Ref)
1	1.4 (1.1, 1.7)	0.9 (0.6, 1.2)	1.5 (1.0, 2.0)	1.3 (0.7, 2.7)	0.9 (0.3, 2.8)
2	1.7 (1.2, 2.3)	1.2 (0.8, 1.8)	2.0 (1.3, 3.0)	2.3 (1.0, 5.3)	2.1 (0.7, 6.4)
3	2.0 (1.5, 2.9)	2.0 (1.3, 3.1)	2.4 (1.5, 3.7)	3.1 (1.4, 6.8)	2.9 (0.9, 9.2)
4	2.6 (1.6, 4.0)	1.8 (1.0, 3.4)	2.1 (1.1, 3.8)	4.7 (1.8, 12.0)	9.0 (2.7, 30.2)
p-trend [Overall]	<0.001	0.002	<0.001	<0.001	<0.001
p-trend [eGFR≥60 mL/min/1.73m^2 at 6 year visit (n=1,835)]	<0.001	0.009	<0.001	0.001	0.01

* Adjusted for age, sex, race, eGFR, prevalent CHD, diabetes, blood pressure, anytihypertensive medication, smoking, LDL, HDL, triglycerides. †106 participants with prevalent heart failure excluded.

Conclusions: Increases in multiple markers of kidney function strongly predict subsequent outcomes, even among individuals without a significant rise in SCR or CysC or a decrease in eGFR to <60 mL/min/1.73m^2. These results suggest that serial measurements of multiple markers may add significant prognostic information to that obtained from a single marker.

Endogenous Anti-Atherosclerotic Property Is Decreased in Patients with Renal Dysfunction: Evaluation Form the Circulating Soluble fms-Like Tyrosine Kinase-1 (sFlt-1) Level after Heparin Injection Masaru Matsui, Shiro Uemura, Yukiji Takeda, Takaki Matsumoto, Ayako Senou, Kimihiko Nakatani, Yasuhiro Akai, Masayuki Iwano, Yoshihiko Saito. *First Department of Internal Medicine, Nara Medical University, Kashihara, Nara, Japan.*

Background: CKD is usually associated with atherosclerosis. Placental growth factor (PlGF), a family of VEGF, plays important roles in the development of atherosclerosis, which is antagonized by sFlt-1, a soluble form of PlGF receptor. sFlt-1 is circulating and is also bound to extracellular matrices of vascular bed by its heparin binding motifs. Given that heparin injection increases plasma sFlt-1 levels, we hypothesized that the heparin-induced increment of plasma sFlt-1 level would indicate the antagonizing capacity, but baseline circulating sFlt-1 level wouldn't. Here we verify the hypothesis and investigate significance of PlGF/sFlt-1 system in CKD-related atherosclerosis.

Results: Five minutes after bolus injection of heparin (0.4unit/kg), plasma sFlt-1 levels were increased from 111.8±52.5pg/ml to 291.6±145.7pg/ml ($p<0.001$) in 251 CKD patients. The increment was increased with elevating eGFR ($r=0.746$, $p<0.001$). Consequently, baseline sFlt-1 levels were negatively correlated with eGFR ($r=-0.456$, $p<0.001$), but those after heparin injection were positively correlated ($r=0.549$, $p<0.001$). Plasma PlGF levels were not changed by heparin, and the ratio of PlGF to sFlt-1 was more strongly correlated with eGFR ($r=0.688$, $p<0.001$). The ratio was also significantly associated with severe coronary artery disease in 329 CKD patients, who underwent coronary angiography with (0.4-0.5 unit/kg) heparin injection ($p<0.001$). In mice with 5/6 nephrectomy, sFlt-1 mRNA expression in organs examined (kidney, lung, and heart) was lower by about 20-50% than that in normal mice. In the pharmacokinetic analysis of PlGF, plasma level of human PlGF immediately after injection of recombinant human PlGF (3.0mg/rabbit) was higher in rabbits with 3/4 nephrectomy than in normal rabbits. These findings support the reduction of antagonizing capacity of sFlt-1 for PlGF in CKD.

Conclusions: PlGF and sFlt-1 at least partly play roles in development of atherosclerosis in CKD.

TH-PO192

Atheroprotective Function of High Density Lipoprotein (HDL) Is Defective in End Stage Renal Disease Patients on Hemodialysis (ESRD-HD) Suguru Yamamoto,[1] Patricia G. Yancey,[2] Talat Alp Ikizler,[2] W. Gray Jerome,[4] Ichiei Narita,[3] Macrae F. Linton,[2] Sergio Fazio,[2] Valentina Kon.[1] *[1]Pediatric Nephrology, Vanderbilt University, Nashville, TN; [2]Department of Medicine, Vanderbilt University, Nashville, TN; [3]Department of Medicine, Niigata University, Niigata, Japan; [4]Department of Pathology, Vanderbilt University, Nashville, TN.*

Background: Traditional risk factors do not account for increased cardiovascular disease (CVD) in CKD, particularly in ESRD-HD, who are also resistant to traditional lipid lowering therapies. Since HDL provides important anti-atherogenic benefits through cholesterol efflux and anti-inflammatory capacities, we examined HDL functionality in ESRD-HD.

Methods: Cellular cholesterol efflux and inflammation were assessed in human macrophage THP-1 cells exposed to HDL isolated from ESRD-HD (n=29) and matched normal controls (n=28). HDL was isolated by sequential density ultracentrifugation, and cellular lipid content assessed by gas chromatography measured cholesterol efflux. Inflammatory markers were determined by cytokine mRNA.

Results: There were no differences in plasma lipids, whereas hsCRP was elevated in ESRD-HD. HDL from ESRD-HD was dramatically impaired in facilitating efflux from cholesterol-loaded THP-1 ($p=0.0001$). Efflux impairment was also observed in subgroups of diabetic ESRD-HD vs diabetic controls (8.1 1.6 vs 13.6 1.1%, $p=0.04$) and was not improved in subgroups on statin therapy. HDL of ESRD-HD had less effective anti-chemotactic activity and greater macrophage inflammation for TNF-α, IL-6, IL-1β which was quelled in statin-takers. Notably, there was no correlation between individual HDL impairment in cholesterol efflux and circulating hsCRP or cellular inflammation.

Conclusions: HDL of ESRD-HD has profoundly impaired cholesterol acceptor function and heightened inflammatory capacity. Statins do not improve cholesterol efflux but quell inflammatory response. Findings predict increased foam cell formation and suggest that dysregulated cellular lipid metabolism is a key driver for excess CVD that may explain dissociation of CVD with plasma lipids and resistance to lipid lowering therapies in ESRD-HD.

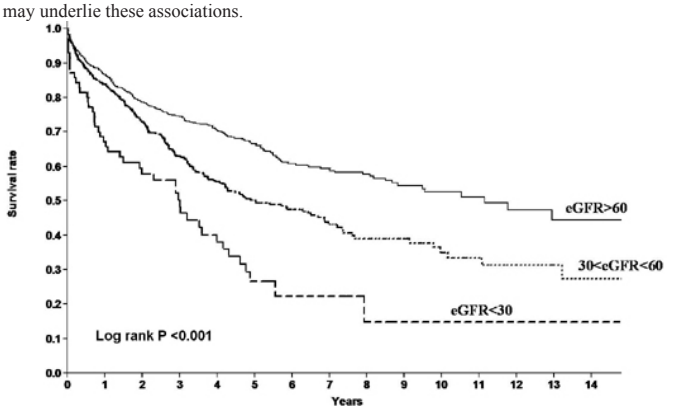
Chronic Kidney Disease, Pulmonary Hypertension and All-Cause Mortality Edgard I. Wehbe,[1] Sankar D. Navaneethan,[1] Jesse D. Schold,[1] Joseph V. Nally,[1] Martin J. Schreiber,[1] Raed A. Dweik.[2] *[1]Nephrology and Hypertension, Glickman Urological and Kidney Institute; [2]Pulmonary and Critical Care, Cleveland Clinic, Cleveland.*

Background: Pulmonary hypertension is associated with high mortality rates. Chronic kidney disease (CKD) is widely prevalent in patients with pulmonary hypertension. We examined the associations of non-dialysis dependent CKD and all-cause mortality in patients with pulmonary hypertension (PH).

Methods: Study population included 1328 patients who underwent right heart catheterization for confirmation of PH (1980-2010). Patients with end stage renal disease (n=15) or who lack serum creatinine levels (n=35) were excluded. We examined the risk factors associated with CKD as well as the association between different stages of CKD and all cause mortality in PH.

Results: Out of 1278 patients, 482 (37.7%) had stage 3 CKD (eGFR 30-59 ml/min/1.73m2) and 70 (5.4%) had stage 4 CKD (eGFR <30 ml/min/1.73 m^2). On multivariable analysis, older age, presence of hypertension, higher pulmonary artery systolic pressure and pulmonary capillary wedge pressure were independently associated with CKD. Kaplan-Meier survival plots indicated significant differences in all-cause mortality for patients with and without CKD (log rank $p<0.001$) (Figure 1). After adjusting for relevant covariates, presence of stage 4 CKD was associated with all-cause mortality (Hazard ratio[HR] 1.59, 95% CI 1.02, 2.40), while stage 3 CKD was not associated with a statistically significant increased hazard for death (HR 1.19, 95% CI 0.94, 1.52). When GFR was examined as a continuous measure, every 5 ml/min decline in GFR was associated with a 3% (95% CI 1.02-1.06) increased hazard for death.

Conclusions: CKD is common in patients with PH. Stage 4 CKD is associated with all-cause mortality in patients with PH. Future studies should explore the mechanisms that may underlie these associations.



TH-PO194

Identification of Differentially Expressed Genes in Arteries from Patients with Renal Failure Jane Stubbe,[1] Vibe Skov,[2] Helle C. Thiesson,[2] Karl-Egon Larsen,[2] Maria Lyck Hansen,[2] Boye Jensen,[1] Bente Jespersen,[3] Lars Rasmussen.[1] *[1]University of Southern Denmark, Denmark; [2]Odense University Hospital, Denmark; [3]Aarhus University Hospital, Denmark.*

Background: The molecular pathology behind arterial disease in uremia is only partially known. Our aim was to identify differentially expressed genes in human arteries from uremic patients by microarray and pathway analysis.

Methods: Tissue samples were obtained from 16 iliac arteries from uremic patients undergoing kidney transplantation and from 19 renal arteries from living kidney donors. In addition, mammary artery samples from 10 patients undergoing coronary by-pass operations were used (5 patients with plasma creatinine above 140 µM and 5 age- and gender-matched individuals with no known kidney disease). Gene expression profiles of these samples were generated using Affymetrix HG-U133A 2.0 microarrays.

Results: We found that 17 gene transcripts differed significantly in iliac samples from patients with uremia with a false discovery rate (FDR)<0.003, $p<1.0*10-5$. Using GenMAPP, we found that 13 pathways were significantly regulated. Both the apoptosis pathway and the TNF-alpha-NFκB pathway were up-regulated, while the smooth muscle contraction- and glycogen metabolism pathways were down-regulated. Verhoeff-van Gieson stained artery samples showed no obvious compositional differences between the 2 groups. To compensate for bias because of different artery location between the uremic and non-uremic groups, we extended our findings with microarray data obtained from the mammary artery samples from the coronary by-pass patients. We then found that 23 gene transcripts were congruently downregulated and 8 gene transcripts upregulated in both comparisons when the setting FDR <0.05 in the iliac/renal artery study and the p-value <0.2 in the mammary artery study were used. This gene transcript group contains vimentin, CD9, hypoxia inducible factor 3A, matrix molecules, and smooth muscle differentiation factors.

Conclusions: The identified genes are likely to be associated with the development of cardiovascular disease in patients with renal failure.

Brain White Matter Abnormalities in Children wth Chronic Kidney Disease
Mina Matsuda-Abedini,[1] Kevin P.V. Fitzpatrick,[1] Colin T. White,[1] Debbie S. Gipson,[3] Steven Miller,[1] Aysenil Belger,[2] Waverly R. Harrell,[2] Gunes H. Yucel,[2] Bruce H. Bjornson,[1] Stephen R. Hooper,[2] Kenneth Poskitt.[1] *[1]University of British Columbia, Vancouver, BC, Canada; [2]University of North Carolina, Chapel Hill, NC; [3]University of Michigan, Ann Arbor, MI.*

Background: There is increasing evidence that children with chronic kidney disease (CKD) have neurocognitive deficits. We hypothesized that these deficits result from subtle brain injury and abnormal brain white matter microstructure. Our objectives were: (1) to determine the prevalence of brain injury or abnormalities and (2) to compare white matter integrity in children with CKD relative to healthy controls.

Methods: Magnetic resonance imaging (MRI) studies were obtained in a prospective cohort of 29 children with CKD (mean age of 14.4 ± 2.7 years (range 9-18)), and 20 healthy age matched controls (mean age of 13.6 ± 2.9 years (range 9 – 18)) at two pediatric renal centres. Conventional MRIs were reviewed by a single blinded neuroradiologist to determine the prevalence of brain injury. Fractional anisotropy (FA) maps calculated from diffusion tensor imaging scans were generated to compare white matter microstructure in both groups using tract-based spatial statistics .

Results: Focal or multifocal white matter injury was seen on conventional MRI in 6 children with CKD (21%) and in 1 control. Relative to controls, reduced white matter FA was seen in the anterior limb of the internal capsule of the CKD subjects, a region that contains white matter pathways involved in cognitive functions. The FA reduction in CKD children was greater in the non-transplant CKD group relative to the transplant group.

Conclusions: In this preliminary study, white matter injuries are observed in children with CKD. Abnormal white matter microstructure, reflected in reduced FA, is also observed in children with CKD. The potential difference observed between children with renal transplant vs. CKD requires further investigation.

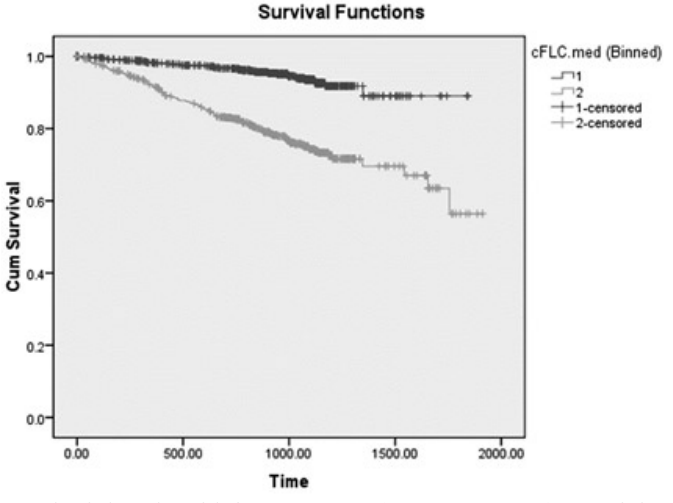
Polyclonal Immunoglobulin Free Light Chain Concentrations and Survival in Patients with Renal Disease
Colin A. Hutchison,[1] Stephen Harding,[2] Anne Bevins,[2] Stephanie J. Stringer,[1] Paul Cockwell.[1] *[1]Renal Unit, University Hospital Birmingham, United Kingdom; [2]The Binding Site Group Ltd, Birmingham, United Kingdom.*

Background: Chronic kidney disease (CKD) affects around 10% of adults, with associated high morbidity and mortality. Enhanced risk stratification to identify those with CKD at highest risk of poor outcomes is required to optimise the management of CKD. Polyclonal immunoglobulin free light chains (FLC) are both markers of kidney function and of systemic inflammation. The purpose of this study was to evaluate the utility of polyclonal serum FLCs for mortality risk in people with CKD.

Methods: Serum concentrations of polyclonal FLCs were measured by immunoassay in 1275 individuals with CKD, these comprised: (i) 848 with CKD stages 1-5; (ii) 382 renal transplant recipients; and (iii) 45 dialysis patients (CKD 5d). The cohort was prospectively followed up for a median of 45 months. Cox regression analysis was undertaken to determine variables associated with survival.

Results: Serum FLC concentrations closely correlated with kidney function. The co-linearity between the two FLC isotypes (κ and λ) and total FLC levels were high, therefore in the survival analysis total levels were used. In the overall cohort, high serum polyclonal FLC levels were an independent risk factor for death: HR 2.06 (1.55-2.75), P<0.001.



Other independent risk factors were age (HR 1.79, 1.54-2.09), pre-existing cardiovascular disease (HR 1.73, 1.2-2.48) and hs-CRP (1.22, 1.09-1.38), all P<0.003. Kidney function was not an independent risk factors for death. On subgroup analysis FLC concentrations were independently associated with death in the CKD and ESRD subgroups.

Conclusions: Serum concentrations of polyclonal FLCs independently predicted survival in patients with CKD and ESRF but not renal transplant recipients. Strategies now need to be devised to apply this observation to clinical practice.

TH-PO197

Rapide Decline of eGFR Predicts Long Term Improvement of Renal Function after Revascularization of Renal Artery Stenosis
Antonio Mannarino, Giuseppe Lucian Spatoliatore. *Nephrology, San Giovanni di Dio, Firenze, Italy.*

Background: to determine if decline of renal function prior to the time of stenting impacts on renal outcome after stenting in a cohort of patients with Atherosclerotic Renal Artery Stenosis (ARAS)

Methods: 30 patients with CKD stages 3 to 4 and ARAS underwent renal stenting. Mean follow up : 33 (SD 21) months ; the change of eGFR before and after stenting was expressed as negative or positive value in mL/month (ΔGFR).

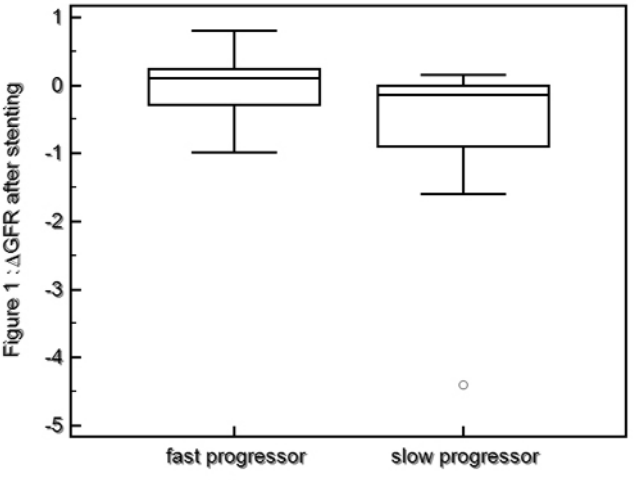
We indentified 2 types of subgroups : the first on the basis of declining of renal function (cut point -0,25 mL/mo) by assessing ΔGFR in a prestenting period of 10 months (Slow or Fast Progressor) N=24 and the second on the basis of stenosis type : 1 (unilateral) N= 13 ; 2 (7 bilateral ; 2 single kidney ; 8 prevalent kidney) N= 17. No difference at baseline was noted between subgroups for the following variables : age, eGFR, renal lenght, resistive index, proteinuria, diabetes and vascular diseases.

Results: 37 stents were placed successfully. No periprocedural death occurred. At latest follow up renal function improved in 14 patients (46,6%) , stabilized in 6 patients (20%) and worsened in 10 patients (33%). 7 of these 10 patients reached ESRD which required hemodialysis.

Being in Fast Progressor subgroup was associated with improved renal function after stenting (8 of 13 patients ; p=0,013; Fisher's test).

Belonging to the subgroup 2 was predictor for improvement of renal function (11 of 17 patients ; p=0,032; Fisher's test)

After stenting median ΔGFR was significantly greater in the Fast Progressor subgroup compared to the Slow Progressor (0,10 vs -0,14 ; p=0,04; Mann Whitney test)



Conclusions: Predictable benefit from renal stenting may be most likely in patients presenting with a rapid decline of GFR associated with ARAS affecting the whole renal mass that is both kidneys or single functioning kidney.

TH-PO198

Lipoprotein Abnormalities, Monocytosis, and Accelerated Atherosclerosis in Patients with CKD
Anjali Ganda,[1] Laurent Yvan-Charvet,[1] Rupali Avasare,[1] Andrew Murphy,[1] Nora Bijl,[1] Bibhas Chakraborty,[2] Linda Vernocchi,[1] Alan Tall.[1] *[1]Medicine, College of Physicians&Surgeons, Columbia University, New York, NY; [2]Biostatistics, Mailman School of Public Health, Columbia University, New York, NY.*

Background: In mouse models, HDL-mediated cholesterol efflux results in decreased expression of the common beta subunit (IL-3Rβ) of the interleukin-3 (IL-3) and granulocyte macrophage colony-stimulating factor (GM-CSF) receptors on the surface of hematopoietic stem cells and monocytes, and decreased IL-3/GM-CSF mediated proliferative responses. Pro-atherogenic CD14++CD16+ monocytes predict CV events in CKD. We hypothesized that monocytosis in CKD may be IL-3/GM-CSF mediated, reflecting HDL dysfunction.

Methods: EDTA-treated blood from adult CKD patients (eGFR<30 ml/min/1.73m²) and matched controls (eGFR≥60 ml/min/1.73m²) was subjected to red blood cell lysis followed by flow cytometry. Monocytes were HLA-DR+, B-cell, T-cell, NK-cell, and granulocyte marker negative, classified into 3 subsets by CD14 and CD16. IL-3Rβ mean fluorescence intensity (MFI) was measured.

Results: CKD patients vs. controls: eGFR/MDRD 19.4±1.0 vs. 81.2±2.7 ml/min/1.73m² p<0.00001, triglycerides 173.4±17.7 vs. 117.4±12.4 mg/dL p=0.02, no difference in sex, % diabetic, systolic BP, HDL, LDL, total cholesterol, total peripheral white blood cell.

Monocytosis in CKD and increase in cell surface IL-3Rβ

Monocytes	Control (n=30) % of leukocytes	CKD (n=30) % of leukocytes	P-value	Control (n=30) IL-3RβMFI	CKD (n=30) IL-3Rβ MFI	P-value
Total	4.41±0.34	6.43 ±0.66	0.008	271.03 ±14.73	341.43±21.04	0.008
CD14++CD16-	3.07±0.24	4.52 ±0.48	0.009	264.50 ± 17.80	329.10±22.71	0.03
CD14dimCD16+	0.96±0.11	1.37±0.19	0.06	322.58 ±18.77	400.40 ±28.14	0.03
CD14++CD16+	0.30±0.04	0.45 ±0.05	0.04	348.97±24.31	437.77±31.76	0.03

Among CKD patients, monocyte counts were strongly correlated with cell surface IL-3Rβ (r=0.7, P<0.0001).

Conclusions: We found monocytosis involving all major subsets in CKD, likely contributing to CVD risk. Monocytosis may reflect increased proliferation secondary to increase in IL-3Rβ. Although HDL levels were unchanged, this abnormality suggests underlying dysfunction of HDL-mediated cholesterol efflux pathways affecting monocytes or their progenitors.

TH-PO199

Effects of Fibrates in CKD: A Systematic Review and Meta-Analysis Min Jun, Alan Cass, Vlado Perkovic. *George Institute for Global Health, Uni of Sydney, Australia.*

Background: Individuals with chronic kidney disease (CKD) often have high triglyceride and low HDL cholesterol levels, but there is limited evidence about the effects of fibrate therapy in this population. A systematic review and meta-analysis was undertaken to synthesize the available evidence.

Methods: MEDLINE, EMBASE, and the Cochrane Library were systematically searched for trials (1950-May 2011). Prospective RCTs assessing the effects of fibrate therapy in CKD and/or on kidney-related outcomes compared with placebo were included. Summary RRs and 95% CIs were calculated using a random effects model. Outcomes included change in kidney function or albuminuria, end-stage kidney disease (ESKD), renal death, and in patients with kidney disease: cardiovascular (CV) events, all-cause death, CV death, and adverse events.

Results: We identified 11 studies (13488 participants) of which 4 were subgroup analyses of larger trials in the general population, while the others were generally small and of suboptimal quality. Fibrate therapy increased the likelihood of albuminuria regression by 19% (95% CI: 8-32%, p<0.0001). There was significant heterogeneity observed in its effect on the progression of albuminuria (RR 0.66, 0.35-1.26; p=0.210; I^2=75.6%, p for hetero=0.043). Due to differences in reporting methodologies, it was not possible to pool effects on change in kidney function. Five studies reported no effect and one showed a significantly delayed GFR loss in the fibrate group. There was limited data regarding the effect of fibrate therapy on ESKD or renal death with no clear effect on either outcome. One study reported a reduced incidence of CV events using gemfibrozil in patients with early CKD (RR 0.76, 0.61-0.94, p=0.010). Most studies reported significantly increased serum creatinine in the fibrate group compared to placebo but also reported normalization or improvement after end of therapy.

Conclusions: Fibrate therapy improves the rate of albuminuria regression in diabetic patients with early stage CKD, but there is limited evidence regarding the effect of fibrate therapy on long-term kidney function. Trials with sufficient power to detect a difference in hard renal outcomes are needed.

TH-PO200

Renal Impairment Profoundly Impairs the Efficacy of Thrombolytic Therapy in Acute Ischemic Stroke Albert J. Power, Daniel Epstein, Diane Ames, Arindam Kar, Dima Dahdaleh, Neill Duncan, David Taube. *Imperial College Healthcare NHS Trust, London, United Kingdom.*

Background: Thrombolysis for acute ischemic stroke is the current standard of care. However there is a lack of comprehensive US data on the safety and efficacy of this treatment in patients with chronic kidney disease [CKD] who are at highest risk for stroke.

Methods: We examined all patients treated with alteplase [0.9mg/kg] for acute ischemic stroke at our center [1st December 2009 – 14th January 2010]. Stroke severity was recorded using the NIH Stroke Scale [NIHSS] at 0, 2 & 24hrs and at 7 days. Time to treatment was the interval between symptom onset and alteplase dosing. Risk factors for stroke were coded on admission, eGFR was calculated using the 4-variable MDRD equation.

Results: 100 patients were treated [mean age 71.5±11.9yrs, 61% male, 29% diabetic, median eGFR 73ml/min. 32% had an eGFR<60ml/min, one was on hemodialysis. Diabetes was more prevalent in patients with eGFR<60ml/min [44% vs 20%, p=0.005], no other significant differences in major comorbidities between the groups.

Median NIHSS score at presentation was 10 [IQR 7-15], median time to treatment 2.5hrs [IQR 2.0-3.3hrs] with no difference between groups [p=0.7 & p=0.8 respectively]. Thrombolysis improved median NIHSS score by 3 at 2hrs, 6 at 24hrs and by 7 at one week [n=82].

Patients with eGFR<60ml/min had on average 32% less improvement in NIHSS score at 24hrs compared to those with eGFR>60ml/min on univariate analysis [p=0.03] and multivariate analysis adjusting for stroke severity [38% less, p=0.02]. Age, gender, ethnicity, time to treatment and comorbidities had no significant effect on outcome. There was no difference in hemorrhagic complications between groups [n=5, 1 with CKD, p=0.9]. 7-day mortality was 4% and not influenced by renal impairment.

Conclusions: In the largest European study of its kind to date we found significant attenuation of neurological outcome following thrombolysis for acute stroke in patients with renal impairment but no excess in hemorrhagic complications. This may relate to greater subclinical cerebrovascular burden and uremic endothelial dysfunction and requires comprehensive study.

TH-PO201

Serum Phosphate Qualify as Atherosclerotic Risk Factor, Particularly in the Setting of Older Chronic Disease Patients Marisa Martin Conde,[1] Victor Lorenzo,[2] Angels Betriu,[1] Adriana S. Dusso,[4] Jose M. Valdivielso,[4] Elvira Fernandez.[1] *[1]Department of Nephrology, Arnau de Vilanova Hospital, Lleida, Spain; [2]Department of Nephrology, Canary Island University Hospital, La Laguna, Tenerife, Spain; [3]Department of Nephrology, Arnau de Vilanova Hospital, Lleida, Spain; [4]Experimental Nephrology, IRB Lleida, Lleida, Spain; [5]Experimental Nephrology, IRB Lleida, Lleida, Spain; [6]Department of Nephrology, Arnau de Vilanova Hospital, Lleida, Spain.*

Background: Translational studies demonstrate that hyperphosphatemia promotes atherosclerotic vascular calcification. However, the association of serum phosphorus (P) with parameters of atherosclerosis (AT) remains controversial in Chronic Kidney Disease (CKD) patients

Methods: This multicenter observational study included 1279 CKD patients from the spanish multicenter study NEFRONA (54, 33 and 14% at CKD stages III, IV and V, respectively), 60±12 years, 63% males, 28% diabetics. We applied a standardized protocol including carotid intima–media thickness, ankle-brachial index and presence/abscense of carotid plaques to determine the AT score (Coll B et al, NDT 2010). The influence of study variables was evaluated applying uni- and multivariate logistic regression model, and using AT score as the dependent variable.

Results: Patients were classified in 2 groups: 1) no or mild AT (44%); 2) moderate to severe AT (56%). The presence and severity of AT was significantly associated with older age (HR 1.087 [CI95% 1.073-1.102], p<0.001), male sex (1.361 [1.007-1.841], p=0.045), higher P (1.354 [1.135-1.616], p=0.001), systolic blood pressure (1.010 [1.004-1.016], p=0.002), smoking (2.056 [1.535-2.754], p=0.001), and diabetes (1.554 [1.148-2.102], p=0.004) in the multivariate model. The level of renal failure, serum calcium, PTH, and dislipidemia were not associated with AT score. In subsequent analysis, the risk for moderate to severe AT is multiplied by a factor of 2.8 for patients >63 years with P>4.2 mg/dl (2.761 [1.639-4.649], p<0.001).

Conclusions: We verified that high P represent a risk for AT in CKD patients with GFR<60 ml/min. This association is more consistent in older patients even with P levels within or close to normal range

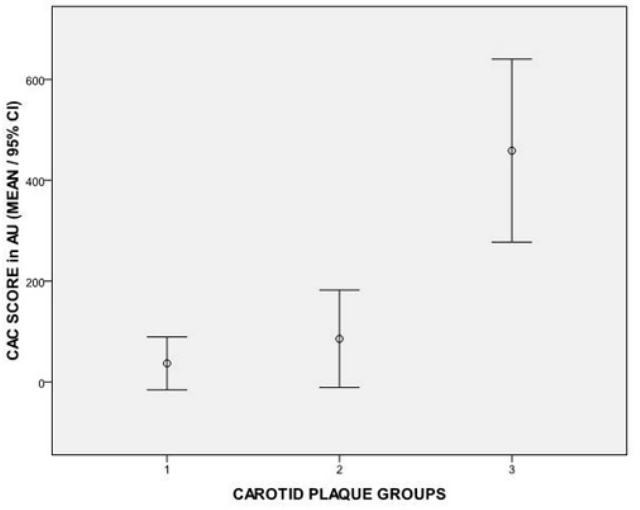
TH-PO202

Carotid Plaques Predict Presence and Severity of Coronary Artery Calcium in Chronic Kidney Disease Luis Gerardo D'Marco,[1] Cristina Karohl,[2] Andrew Smith,[3] Emir Veledar,[3] Paolo Raggi.[3] *[1]Nephrology, Ruiz y Paez University Hospital, Bolivar, Venezuela; [2]Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil; [3]Division of Cardiology and Department of Medicine, Emory University, Atlanta, GA.*

Background: Coronary artery calcium (CAC) measured by multi slice computer tomography (MSCT) is predictive of mortality in CKD. Due to the high cost, radiation exposure and limited availability of MSCT non-radiation based methods such as carotid ultrasound imaging (CUI) may be preferable. We assessed the association of plaque on CUI and CAC in CKD-5D patients.

Methods: Ninety-one CKD-5D patients (mean vintage 31±24 months, 51% women, 71% Black, 68% diabetic) underwent CT for CAC imaging. CAC scoring was performed with the Agatston method and stratified as < 10 (minimal), 10-99 (mild), 100-399 (moderate), and ≥ 400 (severe). Patients were also grouped according to presence of carotid plaques and classified as follows: group 1 (no plaques), group 2 (unilateral plaque/s), and group 3 (bilateral plaque/s).

Results: Carotid plaques were visualized in 74 (81%) patients. CAC score was <10 in 35 (38%), mild in 18 (20%) and moderate to severe in 38 (42%) patients. The mean CAC was 55.6 ± 103 for group 1, 114 ± 150 for group 2 and 586 ± 951 for group 3 (*P= 0.02 for trend*).



The presence of carotid plaques was significantly correlated with CAC in univariate analysis (*r=.277; P=0.008*) and after adjustment for age, gender, race, CKD etiology, and dialysis vintage (*P=0.025)*.

Conclusions: We showed an association between presence of carotid plaques and severity of CAC in CKD-5D patients. These results suggest that CUI may be used to predict the presence of coronary vasculopathy without need to perform radiation based imaging.

TH-PO203

Lipid Profile and Opposing Changes in Intima Media Thickness and Atheromatous Plaque in the Course of Chronic Kidney Disease Angels Betriu,[2] Adriana S. Dusso,[2] M. Vittoria Arcidiacono,[2] Montserrat Martinez-Alonso,[2] Jose M. Valdivielso,[2] Elvira Fernandez.[1] *[1]Hospital Arnau Vilanova; [2]IRBLleida, Lleida, Spain.*

Background: Arterial intima-media thickness (IMT) is an early marker of atheromatous disease, highly influenced by lipid metabolism in normal individuals, but its accuracy to predict atheromatosis in chronic kidney disease (CKD) is poorly understood.

Methods: Cross sectional study examining 1785 patients from the Spanish Multicenter Study NEFRONA, average age 58 years; 62% males; 54% smokers; CKD stages (%) 3:33; 4-5:32; and 5D:35%. IMT was mesured by bilateral carotid ultrasound; values represent mean IMT from common, bulb and internal carotid.

Results: IMT increases with age at all stages of CKD, in both genders.It is higher in men and in patients with atheromatous plaque (0.78 vs 0.67, p<0.001); and lower in CKD4-5 and 5D than CKD3 (0.70, 0.72 vs 0.77; p<0.001) while the % of patients with plaque increases in the course of CKD (3: 55; 4-5: 56; 5D: 62). In the course of CKD, in patients (%) not receiving statins (3:35; 4-5: 29; 5D:47), average LDL and HDL levels decrease (LDL;HDL: 3:117;51; 4-5:108;50; 5D:91;47) and both correlate positively with albumin and BMI, and negatively with ferritin. Also, the % of patients with LDL>145 decrease (3: 11; 4-5: 11; 5D: 6*) and those with LDL<100 increases (3:37; 4-5: 50; 5D: 62*). The % of patients with HDL>60 also decreases (3:22; 4-5:19; 5D:16*), while the % of patients with HDL<40 increases (3:22; 4-5:30;5D: 33*) (*p<0.001). In multivariant analysis, IMT associated positively with age**, smoking**, diabetes**, BMI (p=0.01), pulse pressure** and negatively with female gender**, CKD4-5**, and HDL>40 mg/dl (p=0.02); ** p<0.0001.

Conclusions: In the course of CKD: 1.IMT does not increase in spite of increases in plaque formation. Thus, ITM measurements underestimate the risk of atheromatosis; 2.LDL and HDL decrease in all patients. Thus, LDL levels do not contribute to increase IMT but HDL levels maintain vascular protection; 3.IMT associates with traditional atheromatosis risk factors and their control should slow disease progression; 4.The opposing impact of the lipid profile on IMT and plaque suggests a distinct pathogenesis.

TH-PO204

Atorvastatin Slows the Progression of Chronic Kidney Disease in Patients with Inflammation Robert G. Fassett,[1] Iain Robertson,[2] Madeline J. Ball,[2] Dominic P. Geraghty,[2] Jeff S. Coombes.[3] *[1]Renal Medicine, University of Queensland, Brisbane, Queensland, Australia; [2]Human Life Sciences, University of Tasmania, Launceston, Tasmania, Australia; [3]Human Movement Studies, University of Queensland, Brisbane, Queensland, Australia.*

Background: Inflammation may be present in patients with CKD and associated with its progression. The Lipid lowering and Onset of Renal Disease (LORD) trial was a three-year randomised, double-blind, placebo-controlled trial investigating the effects of atorvastatin on kidney function in CKD patients. The aim of this sub-study was to assess the effects of atorvastatin on inflammation and kidney function in chronic kidney disease (CKD) patients in the LORD trial.

Methods: Eighty-six patients with serum creatinine >120μmol/l were randomized to receive atorvastatin 10 mg/day (47) or placebo (39) and followed for a mean of 2.9 years. Thirty three individuals with normal kidney function were controls. Inflammatory markers measured included plasma pentraxin-3 (PTX3), TNFα, hs-CRP, IL-6, IL-8 and IL-10 and kidney function was assessed using MDRD eGFR. The association (Odds Ratio) between inflammatory markers and eGFR were estimated using repeated measures ordinal logistic regression. An OR >1.00 indicates a positive association, and an OR <1.00 indicates a negative association. General linear modelling was used to determine relationships with the change in eGFR.

Results: At baseline, compared with controls, CKD patients had significantly increased levels of PTX3 (mean, 1.07 vs 0.58 ng/ml; difference, 0.50; 95% CI 0.08-0.92; P=0.02), TNFα (p=0.02) and IL-8 (p=0.01). Baseline plasma PTX3 was associated with eGFR at all time points (OR 0.6, 95% CI 0.5-0.7, P<0.001) but not (P>0.05) the change in eGFR. However, atorvastatin-treated patients with baseline plasma PTX3 levels >1.5 ng/ml had less eGFR decline than placebo-treated patients (atorvastatin, n=8, -0.4; vs placebo n=5, -1.6 ml/min/1.73m²/yr; difference=1.2 95% CI 0-2.4; P=0.058).

Conclusions: Patients had increased levels of inflammatory biomarkers and those with plasma PTX3 >1.5 ng/ml at baseline had less eGFR decline when treated with atorvastatin. Atorvastatin may slow eGFR decline in CKD patients with inflammation.

Funding: Pharmaceutical Company Support

TH-PO205

Serum High Sensitivity Cardiac Troponin T Is a Significant Biomarker of Left Ventricular Diastolic Dysfunction in Patients with Chronic Kidney Disease Masashi Kitagawa, Hitoshi Sugiyama, Hiroshi Morinaga, Tatsuyuki Inoue, Keiichi Takiue, Yoko Kikumoto, Ayu Ogawa, Shinji Kitamura, Yohei Maeshima, Hirofumi Makino. *Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Chronic kidney disease (CKD) is associated with left ventricular diastolic dysfunction (LVDD), which progresses to diastolic heart failure with a poor prognosis. Recently, high sensitivity cardiac troponin T (hs-cTnT) has been utilized in the clinical settings.

Methods: In 132 patients with CKD, the relationships among the results of echocardiography, hs-cTnT, B-type natriuretic peptide (BNP), and renal function were evaluated. The LV mass index (LVMI), peak early diastolic mitral filling velocity (E), peak early diastolic mitral annular velocity (E'), and E/E' were recorded.

Results: Based on our findings, E' significantly decreased, while E/E', BNP, and hs-cTnT significantly increased in association with the progression of CKD stages. The natural logarithm of hs-cTnT negatively correlated with E', whereas it was positively associated with proteinuria, cystatin C, BNP, mean arterial pressure and LVMI. The CKD patients with LVDD who had E' < 5 cm/sec had a significantly higher hs-cTnT level, as well as a significantly higher BNP level, compared to those with E' ≥ 5 cm/sec. The areas under the receiver-operating characteristic curves for hs-cTnT and BNP to detect E' < 5 cm/sec were 0.847 (p = 0.0032) and 0.770 (p = 0.0125), respectively. A hs-cTnT value of 9 pg/mL had a sensitivity of 100%, and a specificity of 67%. A BNP value of 20.3 pg/mL had a sensitivity of 88%, and a specificity of 59%. The univariate logistic regression analyses of the data corroborated the association between E' < 5 cm/sec and the serum hs-cTnT levels per 10 pg/mL increase (odds ratio [OR] 1.48 [95% confidence interval (CI) 1.14-1.96]; p = 0.0004), and the association between the E' < 5 cm/sec and plasma BNP levels per 30 pg/mL increase (OR 1.45 [1.09-1.99]; p = 0.0129).

Conclusions: These data strongly suggest that the newly established parameter, serum hs-cTnT, may be associated with LVDD in CKD patients.

TH-PO206

Progression of Coronary Artery Calcification in CKD: Risk Factors and Association with Mortality Khaled Nashar,[1] Bryan R. Kestenbaum,[2] Mark J. Sarnak,[3] Robert Boudreau,[1] Michael Shlipak,[4] Daniel Edmundowicz,[1] Ali Yazdanyar,[5] Anne B. Newman,[1] Linda F. Fried.[1,6] *[1]Univ. of Pittsburgh, Pittsburgh, PA; [2]Univ. of Washington, Seattle, WA; [3]Tufts New England Medical Center, Boston, MA; [4]San Francisco VA and UCSF, San Francisco, CA; [5]St Luke's Hospital, Bethlehem, PA; [6]VAPHS, Pittsburgh, PA.*

Background: Progression of coronary artery calcification (CAC) has been used as a surrogate outcome in dialysis patients. Risk factors for CAC progression and the association with mortality are not known in moderate-severe CKD.

Methods: We assessed change in CAC in community dwelling older individuals in Pittsburgh participating in the Cardiovascular Health Study. Baseline EBCT was obtained 1998-2000; a follow-up scan was performed a mean of 3.4 years later. The median follow-up after the second EBCT was 5.3 yrs. CAC was assessed using Agatston method. CKD was defined as eGFR < 60 ml/min/1.73m² using the CKD-EPI formula. A clinically relevant change in CAC in individuals with baseline score >0 was defined as absolute change >100 or annualized change > 20%/yr. Logistic regression was used for rapid progression and proportional hazards model for mortality after the second scan.

Results: Of 319 patients with an initial scan > 0, median baseline CAC score was 332, 58% were females 21% were African American, 32% had CKD. Median change in CAC was 111 (IQR 33, 343); 100 died, 191 individuals had change 100/year, 120 had > 20%/y change. Neither CKD nor eGFR were significant predictors of change in CAC (p >0.1). In age, race, gender, baseline CAC adjusted analyses, change > 100 (HR 2.4 (1.1, 5.2)) or 20% change (2.4 (1.2, 4.8) predicted mortality in CKD, but not in those without CKD

(1.0 (0.6,1.7) and 0.9 (0.5, 1.7) respectively. However, the p-values for interaction terms (CKD*change) were not significant (p= 0.36 for change >100 and 0.07 for 20% change). The association of the CAC score at second scan w/o change in model was of borderline significance for mortality (per 100 higher score, 1.03 (0.999, 1.07) and 1.02 (0.997,1.05) in CKD and non-CKD respectively.

Conclusions: CKD did not predict CAC progression in older individuals. However, a CAC change predicted mortality in individuals with CKD.

Hyperleptinemia Is Associated with the Presence and Severity of Myocardial Ischemia in Non-Dialysis Dependent Chronic Kidney Disease

Antonio C. Cordeiro,[1,2] Marco A.C. Oliveira,[1] Paola Smanio,[1] Celso Amodeo,[1] Fernanda C. Amparo,[1] Amanda G.M.R. Sousa,[1] Bengt Lindholm,[2] Juan J. Carrero.[2] *[1]Dante Pazzanese Institute of Cardiology, Brazil; [2]Baxter Novum and Renal Medicine, Karolinska Institute, Sweden.*

Background: Experimental data suggest that leptin receptors are expressed in coronary arteries and that hyperleptinemia causes significant coronary endothelial dysfunction. It is presently unknown if uremic hyperleptinemia is linked to myocardial ischemia (MI) in CKD patients (pts).

Methods: We cross-sectionally evaluated 118 non-dialysis dependent CKD stages 3-5 pts (median age: 59 years [52– 67], 80 men). MI (presence and extension) was screened by 99mTc-sestamibi myocardial perfusion scintigraphy (MPS). All analyses were performed by the same, blinded, physician.

Results: Fifty five pts (33 men) presented an ischemic MPS. MI extension was positively correlated with BMI (rho = 0.25; P <0.01); leptin (rho = 0.26; P < 0.01) and leptin/BMI (rho=0.24; P=0.01). Pts were divided into three groups (no-MI [n=63; 64% men], MI < 10% [n=28; 68% men], and MI ≥ 10% of cardiac area [n=27; 78% men]). Across these groups, and as MI became more severe, BMI (27.8 ± 5.7 vs. 31.7 ± 6.6 vs. 30.8 ± 5.6 Kg/m^2; P <0.01), Leptin (11.9 [4.0 – 25.4] vs. 19.1 [4.9 – 44.2] vs. 26.0 [10.2 – 42.0] ng/mL; P = 0.02), as well as the Leptin/BMI (0.40 [0.17 – 0.85] vs. 0.64 [0.18 – 1.15] vs. 0.74 [0.48 – 1.36]; P = 0.03) were incrementally higher. In crude and adjusted multinomial logistic regressions (considering pts without MI as the reference category), leptin/BMI was associated with higher odds of increased severity in MI **(Table 1)**

Table 1

Model	Covariates	Odds-ratio (95% Confidence Interval)	
		Ischemia <10%	Ischemia ≥ 10%
1	Leptin/BMI	1.84 (0.94 – 3.63)	2.01 (1.03 – 3.95)
2	1 + Age > 60 and gender	2.27 (1.06 – 4.86)	2.89 (1.31 – 6.35)
3	2 + Diabetes and 24h Creatinine Clearance	2.37 (1.10 – 5.15)	2.89 (1.30 – 6.39)
4	3 + Inflammation (CRP >10 mg/L)	2.27 (1.05 – 4.89)	3.33 (1.46 – 7.62)

Conclusions: Excess leptinemia (as depicted by an increased Leptin/BMI) is associated to the presence and severity of MI in non-dialysis dependent CKD pts. Our data suggests further links between hyperleptinemia and cardiovascular risk in CKD.

Funding: Government Support - Non-U.S.

Cardiovascular Injury in Patients with Diabetic Nephropathy

Yuxi Yang, Songmin Huang. *Division of Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

Background: Cardiovascular diseases become the primary death cause of patients with diabetic nephropathy(DN). We investigated the relationship between Urine protein and cardiovascular risk factors in 1046 cases of patients with DN.

Methods: A sample of 1046 adults with DN from West China Hospital of Sichuan University participated in the study. The patients' general situation (gender, age, blood pressure) were recorded. Fasting blood glucose, HbA1c, urinary protein, estimated glomerular filtration rate, serum creatinine, triglyceride, cholesterol, peripheral arterial ultrasound, echocardiography and chest X-ray were observed. The ways of treatments were noted.

Results: The prevalence of DN was higher among male (67.7%) than among female. The prevalence of DN increased with increasing age, which was most common among people 58-70 years old. 70.3% DN patients' fasting blood glucose were below 7mmol/L, but only 22.1% DN patients' blood pressure reached the standard(<130/80mmHg). 26.1% of DN patients had TG<1.7mmol/L and/or CHOL<4.5mmol/L.Only 28.4% of patients had a HbA1c test and 44.4% of them were below 6%. Majority were already in chronic renal failure (82.5% of DN patients'Serum creatinine were above 450umol/L and 86.6% of DN patients' eGFR below 30 ml/min/1.73 m2) when they first visited doctor. 44.5% of DN patients showed abnormal peripheral arterial ultrasound (Atherosclerotic plaque and/or arterial intimal thickening). While 51.4% of DN patients had abnormal echocardiography, including the growing heart and functional damage. Meanwhile 13% of DN patients' chest X-ray showed artery calcification. About half of the DN patients' conditions kept stable by medication, and one third of them chose hemodialysis. Meanwhile less than 20% chose peritoneal dialysis. The survival of patients with hemodialysis and peritoneal dialysis were 96.3% and 99% respectively, while the mortality were 3.7% and 1.0%. The urinary protein was positively correlated with triglyceride and cholesterol(r=0.811, p<0.01;r=0.803, p<0.01). The HbA1c was positively correlated with triglyceride and cholesterol(r=0.896, p<0.01;r=0.908, p<0.01).

Conclusions: The results indicate that DN was positively correlated with Cardiovascular damage.

Time on Kidney Transplant Waiting List Leads to Progression of Echocardiographic Abnormalities Associated with Adverse Outcomes

Ana Sofia Rocha, Nihil Chitalia, Helen Gregson, Rajan Sharma, Juan Carlos Kaski, Debasish Banerjee. *Renal and Cardiology Units, St Georges Hospital, London, United Kingdom.*

Background: Echocardiographic (ECHO) abnormalities are well described in chronic kidney disease and are associated with increased cardiovascular (CV) events and total mortality. Little is known regarding progression of ECHO abnormalities in patients awaiting kidney transplantation (KT).

Methods: This study assessed the progression of ECHO abnormalities in patients awaiting KT between Jan 2004 and Dec 2010 with a repeat ECHO at least 1 year after baseline ECHO. All patients were followed for cardiac events and mortality over 51±20 mo.

Results: We assessed 63 patients (60% male; age 63±10 years; 30% diabetes; 51% predialysis). On baseline ECHO, left ventricular (LV) hypertrophy [left ventricular mass index (LVMI) ≥110 in F, ≥125 g/m in M] using Penn formula and indexed for height was present in 54% of patients, left atrial (LA) enlargement (LA≥4 cm) in 42% and systolic dysfunction [fractional shortening (FS) ≤30%] in 22%.

On repeat ECHO (31±19 mo from baseline) LVMI increased (133±43 to 146±50 g/m, *P*=0.02). The thicknesses of intraventricular septum (1.05±0.26 *v.* 1.12±0.30 cm, *P*=0.01) and LV posterior wall increased (1.01±0.22 *v.* 1.09±0.28 cm; *P*=0.003) and LV end-diastolic diameter did not change (4.8±0.6 *v*. 4.8±0.6, *P*=0.9). Left atrial diameter (LAD) increased (3.8±0.6 to 4.1±0.8 cm; *P*=0.02), whilst FS did not change (37±7 *v.* 36±8%, *P*=0.7). Age, gender, diabetes, baseline SBP and hemoglobin were not predictors of LVMI increase.

During follow up very few deaths and CV events were observed (n=4, 6.4%). Interestingly, patients with adverse outcomes had higher baseline LAD (4.8±0.9 *v.* 3.8±0.6 cm, *P*=0.01), higher LVMI (184±19 *v.* 129±42 g/m, *P*=0.012) and lower FS (26±8 *v*. 37±7%, *P*=0.05). On Cox analysis, in a model adjusted for traditional CV risk factors, LAD (*P*=0.03) and FS (*P*=0.02) were predictors of adverse events.

Conclusions: Echocardiographic abnormalities are prominent in patients awaiting KT. Time on waiting list is associated with increases in LAD and LVMI. Both of these are markers of adverse outcome. This might have implications for timing of KT and ECHO screening.

Advanced Glycation End Products Are Independently Associated with Arterial Stiffness in Patients with Progressive Chronic Kidney Disease

Stephanie J. Stringer,[1,2] Mary Dutton,[1] Chantelle Waite,[1] Cecilio Andujar,[1] Charles Ferro,[1,2] Paul Cockwell.[1,2] *[1]Renal Unit, University Hospital Birmingham, United Kingdom; [2]University of Birmingham, United Kingdom.*

Background: The RIISC (Renal Impairment In Secondary Care) study aims to elucidate the risk factors for progression of CKD and define the bio-clinical characteristics of patients with progressive CKD. Here we report early cross-sectional data with a focus on non-invasive markers of macrovascular (central BP and PWV) and microvascular (AGE reader (skin autofluorescence)) health.

Methods: Patients fulfilled the following criteria for enrolment: (i) progressive CKD and/or (ii) an ACR >70 mg/mmol on 2 consecutive occasions, and CKD 3-5. Patients underwent a detailed CV assessment which included a detailed history, blood pressure by BpTRU (equivalent to daytime ABPM), pulse wave velocity (PWV) by Vicorder, and measurement of AGEs using an AGE reader. These were performed in a temperature controlled room that was maintained between 22-24°C.

Results: To date 100 patients have been recruited. The mean age was 61.3 years (SD 18.1) and 61% were men. 70% were of white ethnicity, 15% each South Asian and Black. The mean eGFR at enrolment was 24ml/min/1.73m^2 (SD 8.9). 29% had a previous diagnosis of CV disease (ischaemic heart disease, cerebrovascular disease and peripheral vascular disease combined) and 37% of the cohort patients had diabetes mellitus. The mean PWV was 9.7 m/s (SD 2.5); the mean AGE reading was 3.1 AU (SD 0.8). In univariate analysis AGEs was significantly associated with PWV (r=0.414; p <0.01). This association persisted after correction by linear regression for renal function, age, BMI, blood pressure and smoking and diabetic status (β=0.393; p=0.001). Similar results were obtained when non-diabetic subjects were analysed separately.

Conclusions: We have found that in both diabetic and non-diabetic patients with progressive CKD, AGEs are significantly associated with arterial stiffness. This raises the possibility that the measurement of AGEs could form part of risk stratification for patients with progressive CKD.

Glomerular Filtration Rate and Cardiovascular Outcomes after Acute Myocardial Infarction: Results from Korea Acute Myocardial Infarction Registry Eun Hui Bae,[1] Sang Yup Lim,[2] Joon Seok Choi,[1] Chang Seong Kim,[1] Jeong-Woo Park,[1] Seong Kwon Ma,[1] Myung Ho Jeong,[1] Soo Wan Kim.[1] *[1]Department of Internal Medicine, Chonnam National University Medical School, Gwnagju, Korea; [2]Department of Internal Medicine, Korea University, Ansan, Korea.*

Background: Renal dysfunction is associated with one of the highest risks, but relation between chronic kidney disease (CKD) stage and cardiovascular outcomes after acute myocardial infarction (AMI) is not well defined.

Methods: As a part of the Korea Acute Myocardial Infarction Registry (KAMIR), we identified 12,636 patients with acute Myocardial infacrtion between November 2005 and July 2008. The glomerular filatration rate (GFR) was estimated by means of the four-component Modification of Diet in Renal Disease equation, and the patients were grouped according to GFR. Primary end points were death and complication in hospital courses. Secondary end points were major adverse cardiac event (MACE) during follow-up.

Results: The mean age was 64 ± 13 years, and 70.4 percent of the group were men. A graded association was observed between GFR and clinical outcomes. The group III, IV and V independently predicted short-term and long-term MACE (hazard ratio, 1.954, 2.764, 2.722; p<0.001; 1.538, 2.194, 2.491; p<0.001). After adjustment with confounders, decreasing GFR was important risk predictors of short-term and long-term MACE. Age, Killip class >1, percutaneous coronary intervention and high-sensetive C-reactive protein also were risk predictors of short-term and long-term MACE. Use of beta-blocker, angiotensin converting enzyme inhibitors (ACEi) or angiotensin receptor blockers (ARB) and statin was associated with reduced risk for MACE.

Conclusions: Renal dysfunction was an independent risk factor for the mortality and complications of AMI, while degree of GFR did not affect the short-term MACE in patients with GFR ≤ 30 mL/min/1.73 m^2. The use of beta-blockers, ACEIs or ARB and statin reduced risk for short-term and long-term MACE

TH-PO212

Relationship between Use of AST-120 and Abdominal Aortic Calcification in Chronic Kidney Disease Patients Shunsuke Goto, Ken Kitamura, Keiji Kono, Kentaro Nakai, Hideki Fujii, Shinichi Nishi. *Division of Nephrology and Kidney Center, Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Although several experimental papers have reported indoxyl sulfate has progressed vascular calcification, little is known about the association between indoxyl sulfate and vascular calcification in human. The aim of the current study was to investigate the relationship between abdominal aortic calcification and use of AST-120, which has adsorption ability for indoxyl sulfate, in pre-dialysis chronic kidney disease (CKD) patients.

Methods: We conducted a retrospective analysis for all the pre-dialysis CKD patients (stage 4 and 5) who underwent abdominal plain computed tomography in our institution between 2005 and 2010. Abdominal aortic calcification was assessed by aortic calcification index (ACI).We divided these patients into two groups by whether AST-120 was taken for at least 6 months or not and compared their ACI between the two groups.

Results: Two hundred patients were enrolled in the present study. ACI was significantly lower in patients taking AST-120 (12.2 [2.5-30.3] vs. 25.8 [13.5-45.3] %, p < 0.05). By multiple regression analysis, use of AST-120 was independently and significantly associated with ACI after adjustment for age, sex, diabetes, hypertension, total cholesterol, estimated glomerular filtration rate, hemoglobin, albumin, calcium, phosphorus, smoking, and use of statin.

Conclusions: It is suggested that AST-120 suppresses the progression of aortic calcification in pre-dialysis CKD patients.

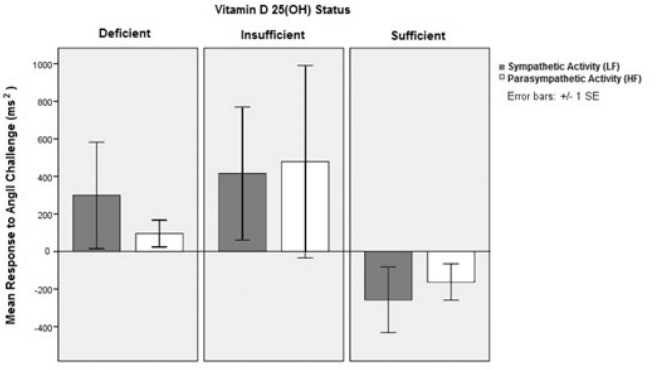
Vitamin D Status and the Cardiac Autonomic Response to Angiotensin II in Healthy Humans Michelle C. Mann,[1] Brenda Hemmelgarn,[1,2] Derek Exner,[1,3] Darlene Y. Sola,[1] Tanvir Chowdhury Turin,[1] Sofia B. Ahmed.[1,2] *[1]University of Calgary, AB, Canada; [2]Alberta Kidney Disease Network, AB, Canada; [3]Libin Cardiovascular Institute, Calgary, AB, Canada.*

Background: Cardiovascular disease (CVD) remains the leading cause of death in chronic kidney disease (CKD) patients. Increased cardiac sympathetic activity [low-frequency (LF) heart rate variability (HRV)] and vagal (high frequency (HF) HRV) withdrawal, are novel risk factors for CVD in CKD. CKD patients also exhibit upregulation of the renin-angiotensin system (RAS) and often low vitamin D (VD) levels, both of which are associated with CVD, thus we sought to evaluate the role of VD status in modulating HRV in response to angiotensin (Ang II) in healthy humans.

Methods: 36 subjects (21 women, 15 men, age 38±2 yrs) were studied in high-salt balance. Subjects were categorized according to serum 25OH VD (nmol/L): deficient (<50, n=9), insufficient (50-79, n=14) and sufficient (>80, n=13). HRV, calculated by spectral power analysis (LF, HF, and LF:HF), was recorded at baseline and in response to AngII (3ng/kg/min x30min, 6ng/kg/min x30min). The primary outcome was the association between VD status and HRV response at 60 minutes.

Results: Baseline cardiac autonomic function differed according to VD status. In response to AngII, increasing VD status was associated with a blunting of an unfavourable increase in sympathetic activity (LF p=0.17 for trend), decrease in vagal activity (HF p=0.23 for trend) and overall shift in sympathovagal balance (LF:HF, p=0.75 for trend).



Conclusions: Poor VD status may be associated with unfavourable cardiac autonomic function. In response to AngII, VD sufficient healthy adults largely maintain sympathovagal balance. This cardioprotective response appears to be impaired in VD insufficient/deficient humans, suggesting that low VD status coupled with RAS activation may augment the risk of CVD in CKD.

TH-PO214

Effect of Elevated Blood Pressure on Quality of Life in Children with Chronic Kidney Disease Cynthia Wong,[1] Matthew Matheson,[2] Juan C. Kupferman,[2] Joseph T. Flynn,[2] Susan L. Furth,[2] Bradley A. Warady.[2] *[1]Pediatrics, Stanford University, Stanford, CA; [2]CKiD Investigator.*

Background: Hypertension (HTN), which is common in children with chronic kidney disease (CKD), has known adverse impact on health-related quality of life (HRQoL) in adults, yet similar pediatric data are lacking.

Methods: Study design and Participants: Cross-sectional and longitudinal analysis of blood pressure (BP), antihypertensive medication use, and HRQoL of children with CKD enrolled in the prospective, multicenter Chronic Kidney Disease in Children Prospective Study (CKiD). BP was measured standardly by auscultation with aneroid sphygmomanometer at annual study visits and HRQoL was assessed using the PedsQL questionnaire. Data analysis: Cross-sectional analysis of BP and PedsQL domain scores at baseline, and longitudinal analysis using logistic regression to assess whether higher baseline BP or use of antihypertensive medications was associated with decline in QOL scores over time.

Results: Univariate baseline comparisons of PedsQL scores across BP groups showed a significant difference (p=0.02) in the child reported physical PedsQL median score for children with diastolic HTN (median score: 78) compared to those with normal diastolic BP (median score: 84). Logistic regression analysis showed children who were taking one or more antihypertensive medication were twice as likely to have decline in physical functioning QOL over time regardless of blood pressure, OR 2.043 (p=0.0042) in model adjusted for systolic BP, and OR 2.069 (p=0.0039) in model adjusted for diastolic BP.

Conclusions: Children with diastolic HTN have significantly lower median physical PedsQL scores at baseline as compared to normotensive children. In this analysis, elevated BP was not associated with a decline in HRQoL over time. However, children on antihypertensive medication are twice as likely to show decline in self-reported physical QOL, regardless of BP status.

TH-PO215

The Association between Arterial Stiffness and Mildly Kidney Damage among a Chinese Population-Based Population Fukun Niu,[1,2] Luxia Zhang,[1] Xingyu Wang,[3] Lisheng Liu,[3] Haiyan Wang.[1] *[1]Institute of Nephrology and Division of Nephrology, Peking University First Hospital, Beijing, China; [2]Nephrology and Rheumatology, First Affiliated Hospital of Zhengzhou University, Zheng Zhou, Henan, China; [3]Beijing Hypertension League, Beijing, China.*

Background: Previous study revealed increased arterial stiffness among patients with advanced chronic kidney disease (CKD), while studies among patients with mildly kidney damage were limited.

Methods: Eight hundred and eight-two community-based participants in Beijing, China were included in the present study. Arterial stiffness was assessed by brachial-ankle Pulse Wave Velocity (PWV). Indicators of kidney damage included estimated glomerular filtration rate (eGFR) and urinary albumin-creatinine-ratio (ACR) were tested. All participants had an estimated glomerular filtration rate (eGFR) >30mL/min/1.73m2, and none of them had ACR meet the definition of macroalbuminuria. Multivariable linear regression models were used to evaluate the associations between kidney damage and PWV.

Results: The average age was 65.4±9.2 years and 45.1% were males. Altogether 105 (11.9%) participants had microalbunminuria, and 28 (3.2%) had eGFR <60 ml/min/1.73m2. PWV was significantly higher among participants with microalbuminuria (1995.4±575.1 cm/s vs 1738.7±357.1 cm/s,P<0.001) and among participants with eGFR

<60 ml/min/1.73m2 (1950.1±416.6 cm/s vs 1763.4±396.0 cm/s,P=0.01). After adjusting for potential confounders,microalbuminuria, but not eGFR, was still positively associated with PWV (β=122.7;p<0.001)

Conclusions: Microalbuminuria was independently associated with arterial stiffness.

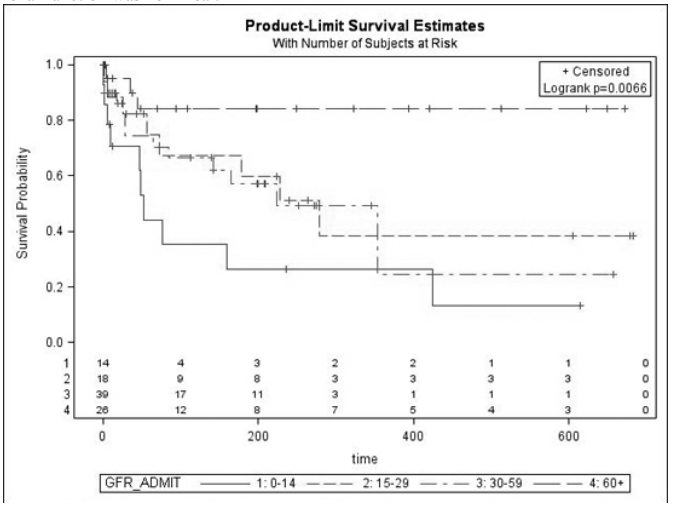
TH-PO216

Outcome of Hyperkalemia in the Emergency Department: Impact of Hyperkalemic Severity, Renal Function and CHF on Survival Venu Velagapudi,[1] Bruce Barton,[2] Jeffrey S. Stoff.[1] *[1]Renal Medicine, UMass SOM; [2]Quant Health Sciences, UMass SOM.*

Background: Hyperkalemia is common and lethal electrolyte disorder with little known long-term consequences. This was retrospective, observational study of hospitalized patients with initial serum K > 5.3 mEq/L. 143 consecutive episodes of hyperkalemia were analyzed in 133 patients. Survival was analyzed by parameters of renal dysfunction (admit eGFR), CHF, admit K and EKG abnormalities.

Methods: Hazard ratios (HR) for mortality were computed by Cox proportional hazards multivariate regression. Primary end point, all-cause mortality determined by Social Security Death Index and medical record review.

Results: Admit eGFR was the most powerful predictor of mortality. The effect of renal function was nonlinear.



Highest mortality is eGFR group of 15-59 HR 6.92. More severe renal impairment with eGFR <15 HR 4.10 and AKI requiring hemodialysis (HD) HR 3.67. ESRD had lower mortality HR 1.33.

Hyperkalemic severity had a modest effect. Compared to patients Admit K 5.3-5.9 mEq/L, patients with K 6-7, HR 2.21 (p=0.0210) and K >7.0, HR 2.62 (p=0.0521). History of CHF, increased mortality by univariate analysis (p<0.0001) but CHF had no independent effect in HD patients. In non-HD patients, CHF had an independent effect when both admit eGFR and K were added to the model. Patients with EKG abnormalities had higher K (p<0.003), but these changes did not impact mortality (p=0.126).

Conclusions: Survival in hyperkalemic patients is predicted by lower admit eGFR in a non-linear fashion. ESRD patients exhibited lower mortality perhaps reflecting adaptation to chronic hyperkalemia. CHF has an additive effect on mortality in non HD patients. We emphasize that 86% of the mortality was after discharge. This extraordinary mortality necessitates the need to develop risk stratification strategies in the long-term care of the hyperkalemic patients.

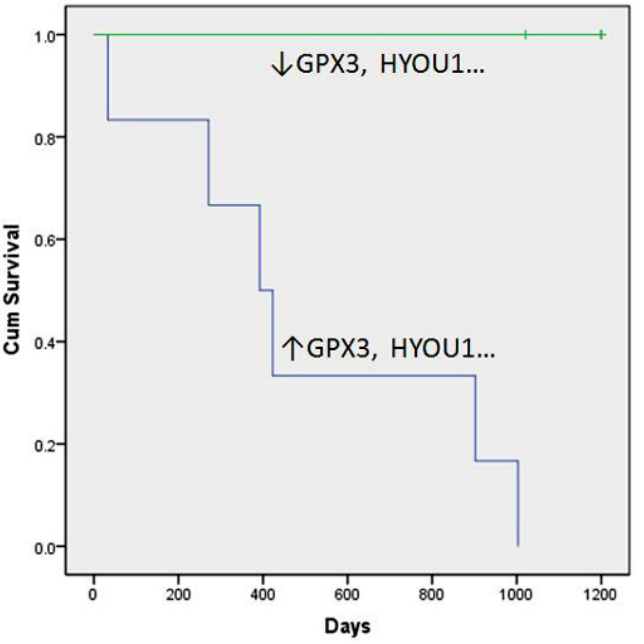
TH-PO217

An Unbiased Proteomic Screen Is Linked to Clinical Outcomes Elucidating the Mechanism of Cardiovascular Disease in Patents with Kidney Disease Andrew M. Siedlecki. *Internal Medicine, Washington University in St. Louis, St. Louis, MO.*

Background: Biomarker discovery is a major goal of proteomic analysis. We hypothesized that certain serum proteins contribute to cardiac disease in patients with chronic kidney disease which can be targeted for therapeutics.

Methods: Each patient was followed prospectively over a 42 month period from October 2007 – March 2011. Participants were monitored for either heart failure exacerbation requiring hospitalization or death. Proteomic analysis was performed on each blood specimen. Relative levels of oligopeptides in each sample were derived from Fourier transformed luminescent intensity. Intensity was normalized to the mean intrasample intensity and to the corresponding unique peptide fragments identified in each sample.

Results: 20 patients were enrolled in the study. Eight were diagnosed with end-stage renal disease and received maintenance hemodialysis for renal replacement therapy at study outset. 7 patients had a cardiac event, 3 of which were diagnosed with chronic kidney disease that did not require dialysis (GFR 20.3 ± 5 mL/min) and 3 of which received intermittent hemodialysis. 182 proteins were identified in each patient. 7 unique proteins were elevated in the cohort of patients that achieved the primary endpoint of heart failure or death.



Unique proteins include glutathione peroxidase 3 precursor (GPX3), hypoxia up-regulated protein 1 precursor (HYOU1), cell surface glycoprotein MUC18 (MUC18), lipopolysaccharide binding protein (LBP), Vitamin K-dependent protein S (PROS), platelet factor 4 variant (PF4V), and retinol-binding protein 4 precursor (RBP4).

Conclusions: Proteomic analysis can identify novel biomarkers that contribute to the renal-cardiac syndrome. The veracity of these markers is confirmed by outcomes analysis which increases the likelihood of clinical impact in diagnosis and therapy .

TH-PO218

Influence of Variations of Inflammatory Markers in the Prediction of Cardiovascular Events from CKD Non-Dialysis Patients Borja Quiroga, Marian Goicoechea, Soledad Garcia de Vinuesa, Ursula Verdalles, Claudia Yuste, Daniel Barraca, Nayara Panizo, Jose Luno. *Hospital General Universitario Gregorio Marañón.*

Background: In CKD patients on dialysis, plasma IL-6 levels have been shown to better predict death than IL-1β, TNF-α and CRP levels. However, only one study has demostrated the predictive role of IL-6 in non-dialysis CKD patients. Besides, the impact of intra-individual changes of inflammation markers on cardiovascular events in CKD patients is unknown.

Methods: The aim of this study was to analyze what is the best inflammatory marker of cardiovascular outcome in non-dialysis CKD patients and to examine whether the simple determination of an inflammatory marker is a better predictor than the variability of the serum levels of the marker over a 6-month period.

Ninety patients (mean age: 68.5±12.8 years) at different stages (1-4) of CKD were evaluated. Serum CRP, IL-6, IL-1β and TNF-α were measured basally and after six months. Three patterns were defined for each inflammatory marker: baseline measurement, mean of two measurements and variation: increase or decrease after six month.

Results: During the follow-up period of the study (mean time of 72.7±19.8 months), 14 patients died, 11 patients were included on dialysis program and 29 patients suffered a cardiovascular event. Patients with persistently elevated IL-6 values had higher risk of cardiovascular events (OR: 1,21 (1,11-1,32), p=0,000). Mean of two measurements of IL-6 was a significantly better predictor than CRP, TNF-α and IL-1β. Patients with a mean IL-6 above 6 pg/mL and patients with previous peripheral vascular disease had an increase risk of having cardiovascular events (2,34 (1,05-5,22), p=0,037 and 2,95 (1,27-6,93) p=0,011, respectively).

Conclusions: IL-6 is better inflammatory marker than PCR, TNF-α and IL1β to predict cardiovascular events in CKD non-dialysis patients. Mean of two measurements is better than simple determinations to predict cardiovascular outcome. Moreover, IL-6 values persistently elevated predicted cardiovascular events in CKD patients.

TH-PO219

Predicting Significant Coronary Angiographic Disease in Patients with Chronic Kidney Disease Using Nuclear SPECT Myocardial Perfusion Imaging Milagros Zegarra,[1] Rabab Moshin,[1] Matthew Whitbeck,[1] Bruce T. Kuo,[1] Claude S. Elayi,[1] Debabrata Mukherjee.[2] *[1]Medicine, University of Kentucky, Lexington, KY; [2]Medicine, Texas Tech University, El Paso, TX.*

Background: Chronic Kidney Disease(CKD) is considered an independent risk factor for coronary artery disease (CAD). The gold standard test to diagnose CAD is coronary angiography. Patients with a Glomerular Filtration Rate (GFR) less than 60 cc/min/1.73m2 are at an increased risk of worsening renal failure and bleeding during this

procedure. Nuclear SPECT MPI remains an attractive modality to evaluate ischemia in this population. Perfusion defects in this population have been associated with an increased risk in cardiac death, but not with significant angiographic disease. Our objective was to determine predictors of significant angiographic disease in patients with CKD using Nuclear SPECT MPI.

Methods: We retrieved from our patient population all patients with a GFR < 60 cc/min/1.73m2, a nuclear SPECT MPI stress test and coronary angiography within 2 years of the test over the last 4 years. Statistical analysis was performed using bivariate analysis and multivariate regression models.

Results: A total of 65 patients were identified among 400 patients. Abnormal myocardial perfusion was considered significant in 46 of them. Of those patients 34 had significant >50% CAD seen on angiography. Significant patient characteristics that predicted angiographic disease were history of hyperlipidemia (p=0.0268) and hypertension(p value =0.0405). The only stress test predictor for significant disease was abnormal wall motion on gated stress imaging (HR 4.24 ; 95% CI 1.39-12.9, p value=0.0109). Usual high risk predictors, such as sum stress, rest and difference score or transient ischemic dilation failed to predict significant angiographic disease(p value=0.14-0.98).

Conclusions: In patients with CKD the presence of abnormal wall motion during stress was the only reliable predictor of significant CAD.

TH-PO220

Cornell Product Is the Best Electrocardiographic Surrogate of Left Ventricular Mass in Non-Dialysis Dependent Chronic Kidney Disease

Antonio C. Cordeiro,[1,2] Márcio G. Sousa,[1] Juan J. Carrero,[2] Gabriel J. Nunes,[1] Marcus R.O. Santana,[1] Waldyr Grimaldi,[1] Celso Amodeo,[1] Fernanda C. Amparo,[1] Amanda G.M.R. Sousa,[1] Bengt Lindholm.[2] *[1]Dante Pazzanese Insitute of Cardiology, Brazil; [2]Baxter Novum and Renal Medicine, Karolinska Institute, Sweden.*

Background: Left ventricular mass indexed to body surface area (LVM/BSA) by echocardiography (ECO) is the most efficient method for left ventricular hypertrophy diagnosis. However, electrocardiographic (ECG) criteria may also be useful. We sought to determine associations between ECG criteria and LVM/BSA in CKD patients (pts).

Methods: In 151 non-dialysis dependent CKD stages 3-5 pts (median age: 59 years [52-67], 96 men), ECO was performed to assess LVM/BSA and ECG was used to assess Cornell and Sokolow-Lyon voltages [respectively CV and SLV] and products [respectively CP and SLP]). Analyses were done by the same, blinded, physician.

Results: All ECG criteria were associated with LVM/BSA in sex adjusted linear regressions (r^2 = 0.15 for SLV, 0.23 for SLP, 0.31 for CV and 0.35 for CP; P < 0.01 for all); and CP showed the strongest association. Pts were divided according to the CP sex specific tertiles (low [n=51], middle [n=52] and high [n=48]). Across the tertiles there were differences in hemoglobin (11.2 ± 2.3 vs. 12.2 ± 1.9 vs. 13.0 ± 5.6 g/dL; P=0.03) and BNP levels (56.2 [27.2- 144.0] vs. 48.8 [22.9 - 129.0] vs. 142.6 [65.1 - 391.3] pg/mL; P <0.01), as well as in LVM/BSA (122 [101-142] vs. 144 [123-166] vs. 175 [147-201] g/m^2; P < 0.01). In a logistic regression analysis (using the lowest CP tertile as the reference category) CP was associated with a higher odds for LVM/BSA (depicted as LVM/BSA higher than the sex adjusted median) in the crude analysis (OR: 3.85 [1.59-9.31] and 11.39 [4.46-29.08]; respectively middle and higher CP tertiles) and even after the adjustment for age, mean blood pressure, hemoglobin, BNP and CKD stages (2.89 [1.17-7.10] vs. 6.13 [2.35-15.99]; respectively middle and higher CP tertiles).

Conclusions: Cornell product associates with LVM/BSA stronger than other electrocardiographic criteria. Our results reinforce the usefulness of ECG, especially assessing CP, as a simple and inexpensive diagnostic method for LVH in CKD.

TH-PO221

Vitamin-K Epoxide Reductase Complex Subunit 1 Genetic Polymorphisms Predict Arterial Stiffness and Serum MGP Levels in Chronic Kidney Disease Patients

Yasmin Yasmin,[1] David Hsing-Yu Chen,[1] Ben Caplin,[2] Cees Vermeer,[3] Leon J. Schurgers,[3] Michael B. Rubens,[4] Carmel M. McEniery,[1] John Cockcroft,[5] Ian Wilkinson,[1] John Cunningham,[2] David C. Wheeler,[2] Kevin O'Shaughnessy.[1] *[1]Clinical Pharmacology Unit, University of Cambridge, United Kingdom; [2]UCL Medical School, London, United Kingdom; [3]University of Maastricht, Netherlands; [4]Royal Brompton Hospital, London, United Kingdom; [5]Cardiff University, United Kingdom.*

Background: Arterial stiffness is an independent predictor of cardiovascular risk in chronic kidney disease (CKD). Calcium deposition is a major determinant of arterial stiffness and common polymorphisms in the Vitamin-K epoxide reductase complex subunit 1(VKORC1) predict aortic calcification scores. We investigated the influence of VKORC1 polymorphisms (-1639G>A, +1173C>T, +1542G>C, +2255C>T, +3730G>A) on arterial stiffness in 280 stage 3-5 CKD patients who are mostly Caucasians.

Methods: Blood pressure (BP), body mass index (BMI), pulse wave velocity (PWV), coronary artery calcification (CAC) and serum uncarboxylated matrix Gla protein (t-ucMGP) were determined, and genotyping performed.

Results: The +1542G>C and +3730G>A polymorphisms showed genotype-specific higher PWV and lower t-ucMGP (P<0.05). The combined recessive allele model showed a significant step-wise reduction in PWV (P<0.005); subjects homozygous for both risk alleles had the highest PWV as compared to those who had one or none. In a regression model after adjustment for age, gender, mean BP, BMI and racial group, each +1542G allele was independently associated with a 0.8 m/s (95% CI 0.09 to 1.57) higher PWV and each +3730A allele was associated with 1.0 m/s (95% CI 0.14 to 1.98) higher PWV. Although in this cohort serum t- ucMGP levels correlated inversely with CAC score (P<0.001), VKORC1 genotypes did not.

Conclusions: We have demonstrated for the first time that VKORC1 polymorphisms (+1542G>C and +3730G>A) influence aortic stiffness and serum t-ucMGP levels in CKD patients. Although needing replication in an independent cohort, these findings suggest that Vitamin-K dependent processes may be important in arterial stiffness through previously un-characterized VKORC1 related mechanisms.

TH-PO222

Fibroblast Growth Factor 23 Predicts Left Ventricular Mass and Induces Cell Adhesion Molecule Formation

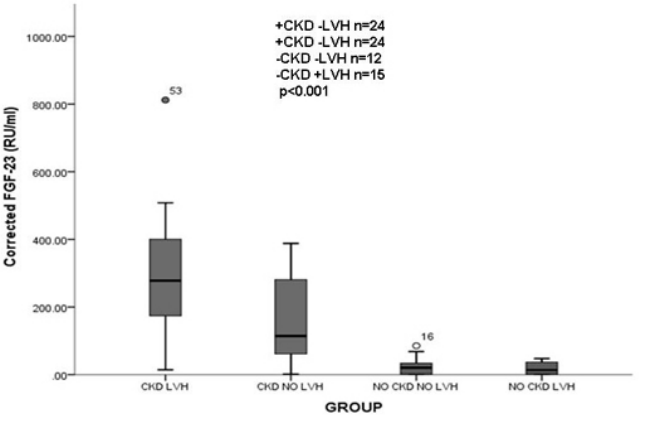
Kathryn K. Stevens,[1,2] Emily P. McQuarrie,[1,2] Dianne Z. Hillyard,[1] Rajan Kantilal Patel,[1,2] Patrick Barry Mark,[1,2] Alan G. Jardine.[1,2] *[1]Renal Research Group, ICAMS, University of Glasgow, United Kingdom; [2]Renal Unit, Western Infirmary, Glasgow, United Kingdom.*

Background: Elevated FGF-23 is associated with left ventricular hypertrophy (measured by echocardiography) in CKD. It may be a biomarker or a direct toxin. We studied FGF-23 and LVH in CKD using CMRI, the gold standard measure of LVH and the effect of phosphate, FGF-23 and Klotho on E-selectin and VCAM production in endothelial cells (HUVECs).

Methods: Patients with CKD stages 3/4 (n=48) or hypertension in the absence of CKD (n=27) were recruited. FGF-23 concentrations were measured by ELISA. Non-contrast CMRI was performed with a 1.5-Tesla Siemens scanner. HUVECs were grown in normal (0.5mM) or high (3mM) phosphate concentration medium and treated with FGF-23/Klotho/both. Cell based ELISA for E-Selectin and VCAM was performed and results normalized to GAPDH.

Results: 50% of CKD and 56% of 'control' patients had LVH. LVMI was similar between the two groups. Patients with CKD had significantly higher phosphate, parathyroid hormone and FGF-23 concentration (237.9RU/ml (109.6-393.3) v 12.5RU/ml (1.5-35.9), p<0.001). Those with CKD and LVH had higher FGF-23 concentrations than those with CKD without LVH (283.4RU/ml v 118.4RU/ml).

Figure 1: FGF-23 concentration stratified according to the presence or absence of CKD and LVH



Multivariate analysis revealed systolic blood pressure, FGF-23 and proteinuria to be independent predictors of LVH in CKD. E-selectin and VCAM production is elevated in HUVECs cultured in high phosphate media with FGF-23 and Klotho (p=0.005 and 0.035).

Conclusions: FGF-23 independently predicts LVH. Our preliminary data support that FGF-23 may be toxic causing activation of the vascular endothelium but do not prove causality with LVH. Whether lowering levels of FGF-23 translates to improved outcomes remains to be seen.

TH-PO223

Ferric Carboxymaltose-Mediated Effects on Platelet Count in Cardio-Renal Patients: Results from the FAIR-HF Trial

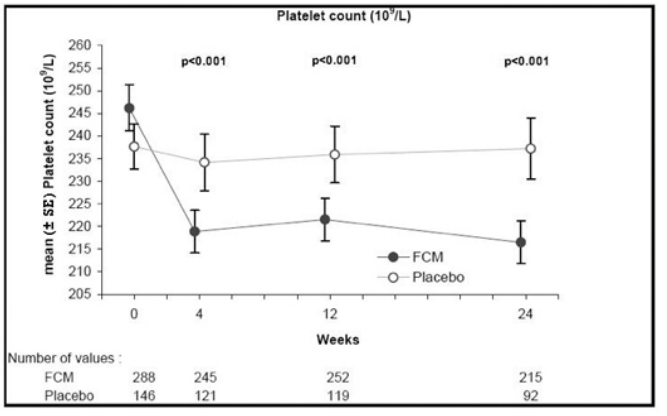
Stephan Von Haehling,[1] Kamyar Kalantar-Zadeh,[2] Viviane Conraads,[3] Giedrius Gaudesius,[4] Claudio Mori,[4] Patrick Johnson,[4] Iain C. Macdougall,[5] Piotr Ponikowski,[6] Stefan D. Anker.[1] *[1]Charité Med Sch; [2]Harbor-UCLA, ; [3]Antwerp Univ Hosp; [4]Vifor Pharma; [5]King's Coll Hosp; [6]Military Hosp.*

Background: Chronic heart failure (CHF) is a hypercoagulable state with an increased incidence of thromboembolic events. Iron deficiency (ID) and treatment with ESAs, particularly high doses, are risk factors for the development of thrombocytosis. Patients (pts) with CHF often suffer from CKD. Both ID and the use of ESAs are common in these cardio-renal pts. Using data from FAIR-HF, we analyzed the effects of intravenous (IV) iron as ferric carboxymaltose (FCM) on platelet count (plt ct) in CHF pts with ID and mild to moderate CKD.

Methods: FAIR-HF was a randomized, double-blind, placebo-controlled trial of IV

iron as FCM in 459 pts with CHF of NYHA class II or III, LVEF ≤40% (NYHA II) or ≤45% (NYHA III), ID (ferritin <100 µg/L or 100–299 µg/L, if TSAT <20%), and Hb 95 to 135 g/L. Baseline characteristics: age 68±11y, NYHA III 82%, LVEF 32±6%, Hb 119±13 g/L, eGFR 64±23 ml/min (42% <60ml/min).

Results: Baseline plt cts were available for 434 (94.6%) pts, 89% of which were within the normal range (140-370 x10^9/L), with 5% below and 6% above this range. Mean plt ct at baseline was 246±86 in the FCM and 238±60 x10^9/L in the placebo group (p=NS). The mean changes in baseline plt ct in the FCM vs placebo group were -27±54 vs -4±48 (4 wk), -24±59 vs -4±46 (12 wk) and -25±56 vs 0±53 (24 wk).



Conclusions: FCM effectively treats ID and reduces the risk of thrombocytosis by decreasing the mean plt ct by 9-10%. This reduction is seen as early as 4 wk after treatment initiation and remains stable over time. This effect may improve potentially detrimental rheological features that are present in pts with cardio-renal syndrome and hence improve their outcomes.

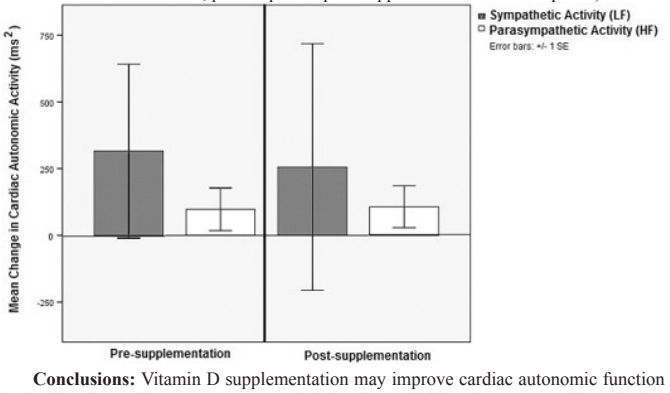
Vitamin D Supplementation and the Cardiac Autonomic Response to Angiotensin II in Vitamin D Deficient Humans Michelle C. Mann,[1] Brenda Hemmelgarn,[1,2] Derek Exner,[1,3] Darlene Y. Sola,[1,2] Tanvir Chowdhury Turin,[1] Sofia B. Ahmed.[1,2] *[1]University of Calgary, AB, Canada; [2]Alberta Kidney Disease Network, AB, Canada; [3]Libin Cardiovascular Institute, Calgary, AB, Canada.*

Background: Cardiovascular disease (CVD) is the leading cause of death in chronic kidney disease (CKD) patients. Vitamin D (VD) deficiency is a risk factor associated with unfavourable cardiac autonomic function (increased sympathetic activity [low-frequency (LF) heart rate variability (HRV)] and vagal [high frequency (HF) HRV] withdrawal) observed in the CKD population, a group that also exhibits upregulation of the renin-angiotensin system (RAS). We sought to determine the effect of VD supplementation on HRV, both at baseline and in response to angiotensin (AngII) in VD-deficient healthy humans.

Methods: 9 VD-deficient subjects (4 men, 5 women) were studied in high-salt balance. HRV (LF, HF, LF:HF), was recorded at baseline and in response to AngII (3ng/kg/min x30min, 6ng/kg/min x30min). Subjects repeated the study following 28 days of oral VD supplementation (5000 IU/day). The primary outcome was the HRV response to AngII at 60 minutes.

Results: Mean 25OH VD levels increased significantly post-supplementation (44±2 vs 82 ±15nmol/L, p=0.03). Post-supplementation, there was a slight improvement in baseline HRV (LF 746±195 vs 1327±522ms^2, p=0.3; HF 375±102 vs 935±608ms^2, p=0.4; LF:HF 2.1±0.4 vs 2.6±0.5, p=0.5 pre- vs. post-supplementation) and a blunting of the unfavourable autonomic response to AngII (LF 315±325 vs 255±462, p=0.6; HF 98±80 vs 107±78, p=0.9; LF:HF 1.9±0.6 vs -0.2±1.0, p=0.09 pre vs. post-supplementation delta response).



Conclusions: Vitamin D supplementation may improve cardiac autonomic function both at baseline and in response to AngII infusion in VD-deficient humans. Studies to further evaluate the association between VD and cardiac autonomic function are required.

TH-PO225

Left Ventricular Mass Index and the Erythropoiesis Stimulating Agent/ Hemoglobin Level Index in Chronic Hemodialysis Patients Ana Cabrita, Anabela Malho, Ana Pinho, Ana Paula Silva, Idalecio Bernardo, Pedro Neves. *Serviço de Nefrologia, Hospital de Faro, EPE, Faro, Portugal.*

Background: Cardiovascular disease and anemia are frequent in chronic kidney disease patients. Left ventricular hypertrophy is an independent predictor of morbidity and mortality in dialysis populations. Recently, the erythropoiesis stimulating agent/ hemoglobin level (ESA/Hb) index emerged as a new factor also associated with increased morbidity and mortality in this population.

Methods: The aim of this study was to evaluate the association between left ventricular mass index (LVMI) and the (ESA/Hb) index in a population of patients on chronic hemodialysis.

Results: We did an observational study with 95 patients (female=31, male=64) on chronic hemodialysis. Clinical and laboratorial data were collected and we calculated the average weekly darbepoetin dose, as well as the average hemoglobin level. The weekly darbepoietin dose/Kg was first multiplied by 200 and after, this figure was divided by the Hb level, to calculate the ESA/Hb index. To evaluate the LVMI we used the Deveraux method. In the statistical analyse we used a linear regression model.

The mean age of the patients was 61.5 ± 16.9 years, the mean time on hemodialysis was 50.9 months, the mean LVMI was 157 .9 g/m2 and the mean weekly dose of erythropoietin was 132 UI/Kg. Forty four patients were medicated with anti-hypertensive drugs (12 were on angiotensin II receptor blockers and 19 were on angiotensin converting enzyme inhibitors). Using a linear regression model, we found a statistically positive correlation between the LVMI and the ESA/Hb index (r = 0.226, p=0.034).

Conclusions: In this study with chronic hemodialysis patients, we found a positive association between the LVMI and the ESA/Hb index, and may explain at least in part, why the ESA/Hb index is a predictor of morbidity and mortality.

TH-PO226

Effect of AST-120 on Aortic and Mitral Valve Calcification in Chronic Kidney Disease Patients at Dialysis Initiation Kentaro Nakai, Hideki Fujii, Keiji Kono, Shunsuke Goto, Shinichi Nishi. *Division of Nephrology and Kidney Center, Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Cardiovascular disease is a major cause of morbidity and mortality in chronic kidney disease (CKD) patients. In CKD patients, valvular calcification is frequently observed as a consequence of aging, lipid abnormalities, and accumulated uremic toxins. AST-120 is an oral charcoal adsorbent that removes uremic toxins, and recently, we demonstrated that AST-120 prevents progression of cardiac damage in a CKD rat model through suppression of oxidative stress. The aim of this study is to investigate the association between AST-120 and valvular calcification in CKD patients at dialysis initiation.

Methods: All the study patients were admitted to our hospital and underwent echocardiography between April 2008 and May 2011. A total of 78 patients at the initiation of maintenance dialysis treatment were included in this study. We divide these patients into two groups based on whether AST-120 had been taken for more than 3 months or not (AST-120 group: n=34, Contorl group: n=44). And we evaluated the relationship of the number of calcified valves (0, no calcification; 1, calcification of the aortic or mitral valve; 2, calcification of both valves) with clinical characteristics and laboratory parameters.

Results: Age, sex, blood pressure, use of rennin-angiotensin system inhibitors, statins, hemoglobin levels, calcium levels, brain natriuretic peptide levels, and estimated glomerular filtration rate did not significantly differ between the AST-120 and control group. Serum phosphorus levels were tended to be lower in the AST-120 group. Despite comparable clinical characteristics and laboratory parameters, the number of calcified valves was significantly lower in the AST-120 group than in the control group. Age, diabetes mellitus, diastolic blood pressure, and the use of AST-120 were significantly associated with the number of calcified valves. Furthermore, multivariate analysis indicated that use of AST-120 tended to be negatively associated with the number of calcified valves.

Conclusions: It is suggested that AST-120 was associated with prevention of aortic and mitral valve calcification.

TH-PO227

Cardiac Dysautonomia in Patients with End Stage Renal Disease on Hemodialysis Hafiz I. Ahmad,[1] Arif Asif,[3] Syed Rizwan Bokhari,[1] Muhammad Zaman Khan Assir,[2] Muhammad Awais,[1] Sabin Nasir.[1] *[1]Department of Nephrology, Allama Iqbal Medical College/Jinnah Hospital, Lahore, Pakistan; [2]Department of Medicine, Allama Iqbal Medical College/Jinnah Hospital, Lahore, Pakistan; [3]Division of Nephrology, University of Miami School of Medicine, FL.*

Background: Sudden cardiac death is common in chronic hemodialysis patients. Cardiac dysautonomia (dysfunction of cardiac autonomic nervous system) has been shown to be associated with increased frequency of cardiac arrhythmias and may be the cause of higher incidence of sudden cardiac death.

Methods: In this observational analysis, we studied the frequency of cardiac dysautonomia in our dialysis population. Seventy hemodialysis patients were enrolled in this study. Three tests to assess the status of cardiac autonomic dysfunction (1] heart rate response to deep breathing, 2] Valsalva ratio, 3] 30:15 ratio of R-R interval measured at beats 15 and 30 after an upright position) were performed. Twenty patients were excluded

because of the inability to perform Valsalva maneuver. Based on previous studies, presence of at least 2 abnormal tests was considered to be positive for cardiac dysautonomia.

Results: Fifty patients completed the tests successfully. 26 were male (52%), 32% were diabetic and the mean age was 43.9 years. Forty four (88%) were found to have cardiac dysautonomia. Abnormal heart rate response to deep breathing (E:I ratio less than 1.17) was found in 47 patients (94%), abnormal Valsalva ratio (longest to shortest R-R ratio less than 1.2) in 45 patients (90%), abnormal 30:15 ratio (30th to 15th R-R ratio on standing less than 1.03) in 34 patients (68%). We found 3 abnormal tests in 32 patients (64%), 2 abnormal tests in 12 patients (24%), 1 abnormal test in 5 patients (10%) and no abnormal test in 1 patient (2%). Overall, 44 (88%) of the patients had cardiac dysautonomia.

Conclusions: This single center study finds a high incidence of cardiac dysautonomia in chronic hemodialysis patients. Future studies should investigate the association between cardiac dysautonomia and sudden cardiac death.

TH-PO228

Optimising the Accuracy of Blood Pressure Monitoring in Chronic Kidney Disease: The Utility of BpTRU in Kidney Disease Shona Brothwell,[2] Mary Dutton,[1] Charles Ferro,[1,2] Stephanie J. Stringer,[1,2] Paul Cockwell.[1,2] *[1]Renal Institute of Birmingham, Department of Nephrology, University Hospitals Birmingham, Birmingham, United Kingdom; [2]University of Birmingham, Birmingham, United Kingdom.*

Background: Accurate blood pressure (BP) monitoring is critical in CKD. However, management is often based on a single BP reading performed in an uncontrolled setting; this will over-diagnose hypertension in up to 30% and miss around one third who are truly hypertensive. Therefore, we compared BP obtained by the routine clinical pathway with BP obtained by BpTRU, which carries out multiple BP measurements to derive a fixed reading and has been validated in a non-CKD setting as being equivalent to (daytime) 24 hour ambulatory BP monitoring (ABPM).

Methods: Patients (n=45) attending renal outpatient clinics had standard BP measurements with a calibrated DINAMAP PRO400 in a clinical assessment room. The patients then underwent repeat assessment with BpTRU.

Results: The clinic mean (± SD) systolic BP (149.7 ± 18.5 (range 117 – 209) mmHg) was significantly higher than the BpTRU reading (122.0 ± 13.9 (96 – 150) mmHg; $P < 0.001$). In a subgroup (n=24), the clinic mean systolic (143.8 ± 15.5 mmHg) was significantly higher than a repeat standard BP in a quiet room (129.9 ± 19.9 mmHg; $P < 0.001$), but the BpTRU reading was significantly lower than both (117.3 ± 14.1 mmHg; $P < 0.001$). The clinic mean diastolic (82.4 ± 11.2 (49 – 100) mmHg) was significantly higher than the BpTRU reading (78.4 ± 10.0 (53 - 97) mmHg; $P < 0.001$; n = 45). Out of 29 patients with a clinic BP above the threshold for altering antihypertensive medication (> 130/80 mm Hg), only 9 were hypertensive with BpTRU. Finally, clinic BpTRU measurements in this setting (CKD) were not significantly different to the day-time mean of 24 hour ABPM.

Conclusions: Standard BP measurements are significantly higher than measurements using a BpTRU machine in a quiet room, which accurately reflects the day-time mean of 24 hour ambulatory BP monitoring in CKD. Adjusting clinic protocols to utilise the most accurate BP device available is a simple manoeuvre that could deliver major improvements in clinical practice.

TH-PO229

Early Detection of Atheromatous Disease at All Stages of Chronic Kidney Disease Improves with Simultaneous Femoral and Carotid Ultrasound Angels Betriu,[1] Adriana S. Dusso,[2] M. Vittoria Arcidiacono,[2] Montserrat Martinez-Alonso,[3] Jose M. Valdivielso,[2] Elvira Fernandez.[4] *[1]UDETMA., Arnau Vilanova Hospital, Lleida, Spain; [2]Experimental Nephrology, IRB Lleida, Lleida, Spain; [3]Estadistic Department, University Lleida, Lleida, Spain; [4]Nephrology Service, Arnau Vilanova Hospital, Lleida, Spain.*

Background: Atheromatous disease occurs early and at high frequency in the course of chronic kidney disease (CKD). The location of the atheromatous lesion in the vascular territory determines the type of adverse cardiovascular events and mortality rates.

Methods: Cross-sectional study to examine whether femoral (common and superficial) ultrasound could help enhance the detection of atheromatous disease achieved with carotid (common, bulb and internal) ultrasound. Left and right carotid and femoral ultrasounds were obtained and analyzed by the same operators from 1785 patients, CKD stages 3 (38%), 4&5 (32%), and stage 5 undergoing dialysis (30%), average age: 57 years±13; 62.4% men; 25% diabetics, from the Spanish Multicenter Study NEFRONA.

Results: The % of patients with arterial plaques is shown in the table below, stratified by gender and stage of CKD.

	stage 3		stages 4&5		stage 5D	
	men	women	men	women	men	women
carotid only	25	40*	23	38*	29	31
femoral only	20	19	18	19	17	15
carotid & femoral	55	41	59	45*	54	51
total carotid	80	81	82	82	83	82
total femoral	75	60*	77	63*	71	66

*p<0.01 compared to men with the same stage of CKD

Conclusions: These results demonstrate that femoral plaques are more prevalent in men at all CKD stages prior to renal replacement. Thus, exclusive carotid ultrasound underestimates atheromatous disease in men. Also, simultaneous femoral and carotid ultrasound increased the detection of atheromatous plaques by 15-20% in both genders at all stages of CKD. Thus, the screening for an early detection of atheromatous disease should include both carotid and femoral ultrasound.

TH-PO230

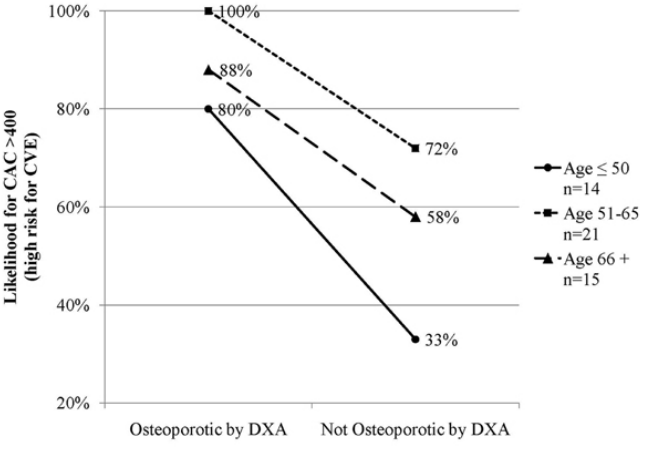
Relationship between Coronary Calcifications and Osteoporosis in Patients with CKD-5 Hartmut H. Malluche,[1] James N. Wise,[2] John Nathan Simmons,[2] Stephanie Fugate,[1] Kimberly McLaughlin,[1] Daniel Davenport,[3] Marie-Claude M. Faugere.[1] *[1]Division of Nephrology, University of Kentucky; [2]Department of Radiology, University of Kentucky; [3]Department of Surgery, University of Kentucky.*

Background: Coronary artery calcifications (CAC) scores were assessed by Agatston scores (Ags) obtained by MSCT in 81 patients (pts) with CKD-5D. In addition, bone mass of the spine and hip was assessed by dual-energy x-ray absorptiometry (DXA) and quantitative computed tomography (QCT).

Methods: There were 42 men (age: 52.2 ± 2.18 yrs) and 39 women (age 56.0 ± 2.25 yrs). Dialysis duration was 59.9 ± 6.54 mos. 36 % of the pts were diabetics. Traditional and nontraditional risk factors for cardiovascular events (CVE) were also recorded.

Results: 21 pts had CAC score of 0, 10 pts had CAC scores between 1-30, 16 pts had CAC scores between 30-400 (low to medium risk for CVE), and 34 pts had CAC scores above 400 (high risk for CVE).

Osteoporosis (OP) diagnosed by DXA and QCT was more frequently found in pts with high CVE risk by Ags than in pts with low to medium CVE risk (DXA 44% vs. 12.5%; QCT 32% vs. 12.5%). There were no differences between the CVE risk groups with respect to age, sex, dialysis vintage, BMI, HTN, and lipids. CAC scores correlated negatively with DXA and QCT results of the hip and spine. With adjustment for age, diagnosis of OP by DXA was a significant predictor of high risk CAC levels (odds ratio 8.92, 95% confidence interval 1.49-53.29). Age group 51-65 had higher incidence of high risk calcification than the younger and older age groups (odds ratio relative to <50 years 5.54; 95% C.I. 1.09-28.2). (See below)



Conclusions: In conclusion, with adjustments for age when non-invasive tests for bone mass demonstrate presence of OP, there is high probability of coexistence of CAC scores known to have high risk for CVE. Other tested risk factors did not influence this relationship.

Funding: NIDDK Support

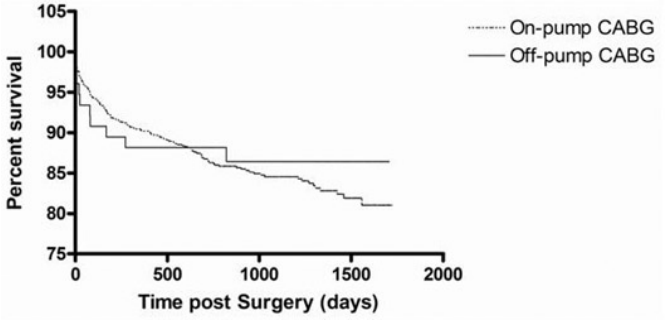
TH-PO231

Is Off-Pump Coronary Artery Bypass Grafting Preferable in Patients with Renal Impairment? Sean Gallagher, Matt Lovell, Dan A. Jones, Zia Buckhoree, Andrew Wragg, Akhil Kapur, Rakesh Uppal, Magdi Yaqoob. *Cardiac and Renal, Barts and the London NHS Trust, United Kingdom.*

Background: Patients with renal impairment undergoing conventional 'on-pump' coronary artery bypass grafting (CABG) have a significant risk of postoperative complications. 'Off-pump' coronary CABG has been reported to be beneficial within this cohort of patients, but this remains a controversial area.

Methods: Analysis of prospectively collected data upon 874 patients with renal impairment (eGFR <60mls/min) undergoing CABG at a tertiary Cardiac centre between 2003 and 2007 was undertaken. We have compared outcomes of 76 patients that had 'off-pump' CABG with 798 that had 'on-pump' All-cause mortality was determined via Office of National Statistics.

Results: Patients selected for 'off-pump' CABG had less previous MIs (27.6vs48.1%, p=0.0209), and more single-vessel coronary disease (14.4vs0.88%, p=<0.0001). Post operatively no difference in incidence of acute kidney injury (AKI) (defined as 50% increase in serum creatinine) (21.1vs20.1%, p=0.8392), peri-procedural stroke (1.3vs1.1%, p=0.5993) or in-hospital mortality (5.2%vs3.1%, p=0.3083) was seen between the groups. At 5 years there was no difference in survival between the groups (86.8%vs84.2%, p=0.5585).



Indeed, the use of 'off-pump' surgery was not independently associated with long term mortality. Only Euroscore (a model use to estimate risk of death following cardiac surgery) HR 1.14 (CI 1.07 to 1.22) and the development of AKI HR 2.38 (CI 1.67 to 3.38) were independently associated with long term mortality.

Conclusions: The use of 'off-pump' surgical techniques do not seem to be associated with improved prognosis within our cohort of patients with renal impairment. The time has come for an adequately powered randomised control trial to definitely determine the value of 'off-pump CABG surgery in patients with renal impairment.

TH-PO232

Heart Rate and Blood Pressure Variability in Children with Chronic Kidney Disease: Report from CKiD Study Gina-Marie Barletta,[1] Joseph T. Flynn,[2] Mark Mitsnefes,[3] Derek Ng,[4] Bradley A. Warady,[5] Joshua A. Samuels,[6] Tim Poffenbarger,[6] Susan L. Furth.[7] *[1]Phoenix Children's Hospital; [2]Children's Hospital and Regional Medical Center; [3]Cincinnati Children's Hospital; [4]Johns Hopkins School of Public Health; [5]Children's Mercy Hospital; [6]University of Texas, Houston; [7]Children's Hospital of Philadelphia.*

Background: Alterations in autonomic nervous system function, including decreased heart rate (HR) variability & differences in blood pressure (BP) variability, are predictors of future cardiovascular events in adults, particularly in those with underlying chronic kidney disease (CKD).

Methods: We examined the degree of HR & BP variability in children with CKD. HR & BP variability were evaluated by 24 hour ambulatory BP monitoring in 104 participants not receiving antihypertensive medications enrolled in CKiD, an observational cohort study of children (1-16 yrs) with Schwartz estimated GFR 30-90 mL/min/1.73 m2. Variability was assessed by coefficient of variation (CV) for HR, systolic (SBP) & diastolic (DBP), and compared across categories of GFR and hypertensive (HTN) status, with adjustment for age, gender & race.

Results: Median age was 11 years (interquartile range: 7, 14), 37% female, 20% black, 58% were HTN, median iohexol GFR: 48 mL/min/1.73 m2 (36, 59); 22% had GFR>60 mL/min/1.73m2, 60 % between 30-60, and 18 % GFR<30.

HR variability was significantly lower in HTN vs. normotensive children when adjusting for age, gender & race, and was independent of activity state and GFR level. Other comparisons are outlined in Table.

Dependent variable Independent variables	HR CV Relative % difference (95%CI)	SBP CV Relative % difference (95%CI)	DBP CV Relative % difference (95%CI)
HTN vs Normotensive	**-16%(-24,-8)**	-3%(-12,+6)	**-13%(-21,-4)**
GFR<30 vs GFR>60	+4%(-10,+19)	+9%(-5,+24)	**+16%(+1,+34)**
GFR 30-60 vs GFR>60	**+14%(+2,+27)**	+3%(-8,+14)	+10%(-1,+24)

Bold indicates p<0.05

Conclusions: The degree of variability in both HR and BP is different among HTN and normotensive children with CKD. These findings are similar to that encountered in adults with CKD and may emphasize the childhood origin and progression of adverse cardiovascular outcomes.

TH-PO233

Suprarenal Aortic Clamp in Open AAA Repair Decreases Postoperative Renal Function Satoshi Unuma,[1] Masaomi Nangaku,[1] Katsuyuki Hoshina,[2] Tetsuro Miyata,[2] Toshiro Fujita,[1] Takamoto Ohse.[1] *[1]Nephrology and Endocrinology, University of Tokyo, Japan; [2]Vascular Surgery, University of Tokyo, Japan.*

Background: Open repair of abdominal aortic aneurysm (AAA) requires infrarenal (IR) or suprarenal (SR) aortic clamping. Since SR leads to renal ischemia, open AAA repair with SR may cause the decrease in renal function. The detail statistical analysis in the change of renal function was performed in this study to clarify the risk factor of AAA repair.

Methods: Retrospective analysis was performed with 178 patients undergoing open AAA repair in the University of Tokyo Hospital between January 2004 and December 2008. After the application of the criteria, 134 patients were enrolled into the 2 weeks study (15±5 days after the operation) and 99 patients were into the 1 year study (360±180 days). We evaluated the change of estimated glomerular filtration rate (eGFR) from the preoperative points to these two points. Furthermore, we conducted multivariate regression analysis with six factors (age, gender, preoperative eGFR, site of clamping, operative duration, diameter of aneurysm) as variables.

Results: The mean age of the patients was 74.1 in the 2 weeks study and 72.9 in the 1 year study. Among the patients in the 2 weeks study and the 1 year study, SR accounted for 14.5%, 13.1% and the mean preoperative eGFR was 58.2mL/min/m², 60.9mL/min/m², respectively.

Statistical analysis revealed the significant difference in the change of eGFR between IR and SR at 2 weeks (+10.3% vs -3.0%, respectively, p<0.05). Also, the significant difference was observed between IR and SR at 1 year (-4.1% vs -15.3%, respectively, p<0.05).

The multivariate regression analysis was performed to find the formula best describing the post-operative eGFR at 1 year with multiple variables. Finally, preoperative eGFR, site of clamping, age were detected as the important factors.

Conclusions: Our statistical analysis revealed eGFR was significantly decreased in SR group when compared to IR group both at 2 weeks and 1 year. Postoperative eGFR was associated with preoperative function, site of clamping and age. These results may suggest the renal ischemia during operation has a high impact on the postoperative renal function.

TH-PO234

Admission Renal Function Has Little Value in Predicting Mortality in Stroke Patients Abhiramy Rudran,[1] Momina Hameed,[1] Abdelgalil Abdelrahman Ali,[1] Velaitham Umachandran,[2] Sumith C. Abeygunasekara,[1] Kakit Chan.[1] *[1]Renal Department, Broomfield Hospital, Chelmsford, Essex, United Kingdom; [2]Stroke Unit, Broomfield Hospital, Chelmsford, Essex, United Kingdom.*

Background: The prevalence of chronic kidney disease [CKD] in elderly patients is unclear, although it is a common finding in those presenting with cerebrovascular accident [CVA]. The impact of CKD on mortality following CVA is poorly described in the literature. In this study, we examine the age-adjusted risk of CKD and lower estimated glomerular filtration rate [eGFR] on mortality in patients with stroke in our unit.

Methods: 406 consecutive patients who presented with CVA in 2009 were included in this study [205f, 201m; mean age 73.9+13.5 yrs; mean eGFR 55.5+18.5 ml/min/1.73m²; 85.5% ischaemic CVA, 4.68% ischaemic with haemorrhagic transformation, 9.85% haemorrhagic]. Of these, 263 [64.8%] patients have CKD stage 3 or above. 46.7% of patients in the older age group [above 84] have eGFR<43.7 ml/min/1.73m2, compared to 8.3% in the younger age group [below 66].

Results: 107 died within the 2 year follow up. Overall patient survival was 80.0%, 76.6% and 72.7% at 6, 12 and 24 months after CVA.

Unadjusted analysis found that haemorrhagic CVA [HR 2.1, 95%CI 1.3, 3.5; p=0.006], older age [Age 66-77.5: HR 3.5; Age 77.5-84: HR 6.1 & Above 84: HR 14.9; p<0.001] and low eGFR [<43.7 ml/min/1.73m²: HR 2.5, 95%CI 1.4, 4.2; p=0.001] are associated with adverse outcome. Albeit statistically significant, these results were confounded by the effect of age and time.

Time and age adjusted survival model was used to correct for confounders. Independent of age, haemorrhagic CVA is associated with 2.4 times risk of death [95%CI 1.4, 4.1; p=0.001]. However, the effect of renal function on survival has diminished; [eGFR< 43.7 ml/min/1.73m2: HR 0.9, 95%CI 0.5,1.6, p=0.747; CKD stage 3: HR 0.4, 95%CI 0.2,1.2; p=0.091; CKD stage 4: HR 1.0, 95%CI 0.3,3.2, p=0.999].

Conclusions: This study demonstrated CKD is common in patients with CVA, and more so in the older age group. Haemorrhagic CVA is an independent risk factor for mortality. Renal function on admission has little impact on survival after adjusting for age.

TH-PO235

Plasma S100A12 Levels and Peripheral Arterial Disease in End-Stage Renal Disease Yasukiyo Mori,[1] Yayoi Shiotsu,[1] Eiko Matsuoka,[1] Atsushi Kosaki.[2] *[1]Department of Cardiology and Nephrology, Kyoto Prefectural University of Medicine, Kyoto, Japan; [2]Department of Medicine II, Kansai Medical University, Hirakata, Japan.*

Background: S100A12, formerly called EN-RAGE, is an endogenous ligand for the receptor for advanced glycation end products (RAGE). Engagement of S100A12 with RAGE promotes the underlying microinflammation. Our working hypothesis is that S100A12 protein might contribute to the development of atherosclerosis, leading to cardiovascular disease (CVD) such as coronary artery disease, stroke and peripheral arterial disease (PAD). The recent clinical study from us showed that the level of plasma S100A12 was an independent factor associated with the prevalence of cardiovascular disease in hemodialysis patient (Shiotsu Y and Mori Y et al. Clin J Am Soc Nephrol 2011; 6: 718–723). In this study, we focus on the relationship between plasma S100A12 levels and PAD.

Methods: A total of 133 subjects who had the medical record of ankle–brachial index (ABI), were selected from 550 HD patients in our affiliated hospital. We investigated the history of PAD and quantified plasma S100A12 levels.

Results: The present study showed that 1) plasma S100A12 levels in HD patients with PAD (n = 26; 21.9 [13.6–33.4] ng/ml) were significantly higher than those in HD patients without PAD (n = 107; 10.7 [7.2–16.7] ng/ml; P < 0.001), 2) in multivariate logistic regression analysis, the plasma S100A12 levels (odds ratio [OR], 7.81; 95% confidence interval [CI], 1.32–46.2; P = 0.023) as well as the presence of diabetes mellitus (OR, 3.77; 95% CI, 1.04–13.6; P = 0.043), high-sensitivity CRP levels (OR, 3.02; 95% CI, 1.01–9.04; P = 0.048), and ABI (OR, 0.53; 95% CI, 0.38–0.74; P < 0.001) were identified as an independent factor associated with PAD prevalence, 3) in another multiple logistic analysis using categorized clinical factors, the higher S100A12 level (≥12.4ng/mL) was associated with PAD prevalence (OR, 5.15; 95% CI, 1.43–18.6; P = 0.012).

Conclusions: These findings indicate that plasma S100A12 is strongly associated with the predicting PAD in ESRD patients.

Occupational Risk and Chronic Kidney Disease: A Population-Based Study in US Adult Population Sofia Rubinstein, Chengwei Wang. *Medicine, Division of Nephrology, Nassau University Medical Center, East Meadow, NY.*

Background: Previous studies on occupational risk for CKD have been limited in the range of occupations with a focus on nephrotoxins. There has not been a population-based study conducted on a nationally representative sample of the US adult population that investigates the association between a comprehensive list of occupations and risk of CKD.

Methods: This population-based complex survey study uses the National Health Interview Survey data from 2004 to 2008 that randomly sampled non-institutionalized adults in the United States. Main outcome measure was self-reported CKD defined as having weakening/failing kidneys in the past 12 months as diagnosed by a physician. Occupation categories were based on US census bureau coding of Standard Occupation Classification. Univariate analysis was used to identify high risk occupations, multivariate logistic regression applying weights necessary to make accurate population prevalence estimates was used to assess the relative risk.

Results: 91,340 adults completed the question of both CKD status and occupation. CKD was reported in 1,197 (1.3%) participants. After applying appropriate weights, controlling for age, gender, hypertension status and education, and with physical and social science occupation as a reference group, respondents working in Building, Grounds Cleaning and Maintenance Occupations were 4.3 times (95% CI: 1.1-17.7) more likely to develop CKD, while the likelihood of developing CKD were 4.4 times higher in Healthcare Practitioners and Technical Occupations (95%CI: 1.1-18.2), 4.7 times higher in Transportation and Material Moving Occupations (95% CI: 1.2-19.0), 4.7 times higher in Computer and Mathematical Occupations (95% CI: 1.1-20.7), 4.8 times higher in Production Occupations (95% CI: 1.2-19.7), 5.3 times higher in Food Preparation and Serving Related Occupations (95% CI: 1.3-20.8), 6.1 times higher in Healthcare Support Occupations (95% CI: 1.5-25.3), and 6.1 times higher (95% CI: 1.2-30.3) in Legal Occupations.

Conclusions: This study compares the prevalence of CKD among US adults in different occupations. Research on characteristics of high risk occupations is needed for guiding prevention in US job settings.

TH-PO237

Joint Associations of Gout and Serum Uric Acid on Mortality among Subjects with Reduced Kidney Function in the General Population Austin G. Stack,[1] Bhamidipati V.R. Murthy,[2] Arif I.F. Mutwali,[1] Hoang Thanh Nguyen.[1] *[1]Regional Kidney Centre, Letterkenny General Hospital, Letterkenny, Donegal, Ireland; [2]Division of Renal Disease and Hypertension, University of Texas Houston, TX.*

Background: Gout is a chronic inflammatory disorder of uric acid metabolism and is associated with increased cardiovascular (CV) risk. Whether gout and hyperuricaemia contribute independently and synergistically to total and CV mortality has not been previously studied.

Methods: A cohort of 15,773 subjects age >= 20, and representative of the U.S. population, was identified from the Third National Health and Nutrition Examination Survey (1988-1994). Vital status was obtained through linkage with the National Death Index through to 2006. Serum uric acid and physician-diagnosed gout was modeled with total and CV mortality according to estimated glomerular filtration rate (eGFR) (< 60, 60-90, >90 ml/min). Cox regression modeled mortality relationships.

Results: In an average of 10 years of follow-up, total mortality was 9.7 % of which 4.4 % were cardiovascular. Adjusting for confounding, the multivariable relative risks (RR) for subjects with gout were 1.30 (95% Confidence Interval [CI] 1.03-1.65) for total mortality and 1.50 (95% CI 1.08-2.07) for CV mortality. The relative mortality risks per 1 mg/dl increase in serum uric acid were 1.12 (95% CI 1.07-1.17) for total mortality and were 1.10 (95% CI 1.06-1.15) for CV mortality. These relationships were significant for subjects with eGFR < 60 and 60-90 ml/min but not > 90 ml/min. In the conjoint analysis, the multivariable mortality risks for subjects with gout and increasing quartile of serum uric acid were significantly greater than for subjects without gout.

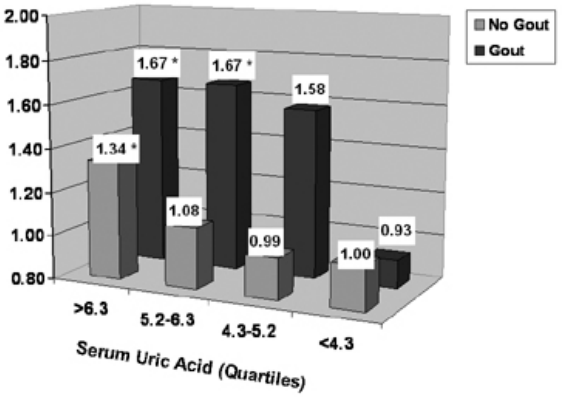

Figure 1. P<0.001 for group comparisons

Conclusions: Both gout and hyperuricaemia independently predicted total and CV mortality. The mortality risks were greatest for those with gout and the highest uric acid concentrations.

TH-PO238

Hypoalbuminemia Is Prevalent and Predictive in Appalachian Patients with Chronic Kidney Disease (CKD) Rebecca J. Schmidt, Bethany S. Pellegrino. *Section of Nephrology, West Virginia University School of Medicine, Morgantown, WV.*

Background: Chronic kidney disease (CKD) has reached epidemic proportions worldwide and in the United States, minorities of race and ethnicity reach end stage renal disease (ESRD) at a disproportionate rate. A rural state in the heart of Appalachia, West Virginia leads the nation in rates of incident ESRD, despite its predominantly Caucasian population.

Methods: Clinical characteristics and demographics of 4258 patients seen between January 1, 2001 and July 31, 2010 by a university-based nephrology group across north central West Virginia were retrospectively analyzed for their impact on progression to dialysis or death. Socioeconomic information for state and county was obtained from census data. Main outcome measures were time from first clinic visit to death or start of dialysis.

Results: Patients were predominantly Caucasian (94.3%), with a mean age of 60.1±16.7, a 39% prevalence of diabetes; 39% presented with an albumin level ≤ 3.5 gm/dl. Patients with higher presenting albumin levels had better survival and less progression to dialysis than those with lower albumin levels ($p<0.0001$). Hypoalbuminemia, hypocalcemia, hyperparathyroidism and anemia all independently correlated with reduced survival and more rapid progression to ESRD ($p<0.0001$). Compared to those from more affluent counties, patients from counties of low socioeconomic status had lower albumin levels (3.36±0.014 vs 3.68±0.079 gm/dl; $p<0.04$) and higher rates of progression to dialysis or death ($p<0.016$).

Conclusions: In this north central West Virginia region of Appalachia, CKD patients were predominantly white, often hypoalbuminemic and most hailed from counties of low socioeconomic status. Hypoalbuminemia and residence in a socioeconomically disadvantaged county independently predicted overall survival and progression to dialysis, suggesting that poverty and culture, irrespective of race, warrant further study for their impact on outcomes in patients with CKD.

TH-PO239

Short Sleep Duration as a Novel Predictor of Proteinuria Ryohei Yamamoto,[1] Yasuyuki Nagasawa,[1] Hirotsugu Iwatani,[1] Yoshitsugu Obi,[1] Maki Shinzawa,[1] Junya Teranishi,[1] Toshihiro Ishigami,[1] Hiromi Rakugi,[1] Yoshitaka Isaka,[1] Toshiki Moriyama.[2] *[1]Department of Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Osaka University Healthcare Center, Toyonaka, Osaka, Japan.*

Background: Although multiple studies revealed that sleep duration was a predictor of cardiovascular diseases and also mortality, few studies reported an association between sleep duration and chronic kidney disease charactrized by impaired renal function and proteinuria.

Methods: The prensent retrospective cohort study included 6020 employees of Osaka University aged 19 - 55 years, who visited Osaka University Healthcare Center for their mandatory annual health examination between May 2006 and September 2010. Questionnaires about their life style, including sleep duration, and blood and urine examinations at the first examination during study period were retrospectively collected as the baseline date. The outcome of interest was time to development of proteinuria defined as ≥1+ by dipstick test after the baseline examination.An association between the baseline sleep duration and the outcome was assessed using conventional multivariate Cox proportional hazards model, propensity score-based models, and disease risk score-based models.

Results: Self-reported baseline sleep duration was 6.0 ± 0.9 hours, which reflected the mean sleep duration during median 2.0 (interquartile range 1.2 to 3.0) years of observational period. After the baseline examinations, proteinuria was observed in 498 employees (8.3%). A multivariate Cox proportional hazards model clarified that shorter sleep duration was associated with proteinuria in a stepwise fashion, even after adjustment for clinically relevant factors (vs. 7 hours; ≤3 hours, hazard ratio 2.76 [95% CI 0.86 to 8.87], P = 0.09; 4 hours, 1.65 [1.08 to 2.54], P = 0.02; 5 hours 1.30 [1.01 to 1.68], P = 0.05; 6 hours, 1.06 [0.84 to 1.34], P = 0.6; ≥8 hours, 0.96 [0.51 to 1.79], P = 0.9). Propensity score-based models and disease risk score-based models also ascertained ≤5 hours of sleep duration were significantly associated with proteinuria.

Conclusions: Short sleep duration, especially ≤5 hours, was a novel predictor of proteinuria.

TH-PO240

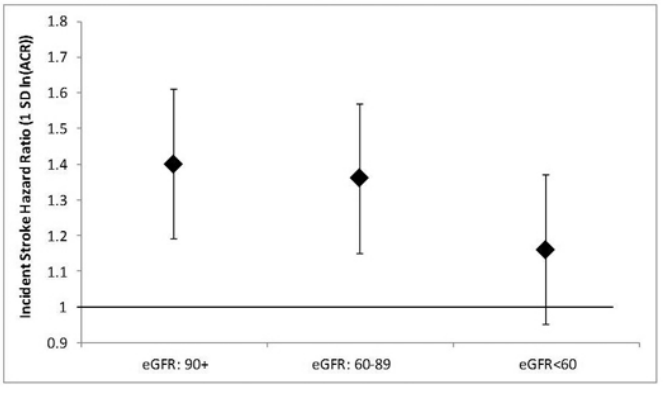
Albuminuria, Kidney Function and Risk of Stroke in the REGARDS Cohort

Orlando M. Gutierrez,[1] Suzanne E. Judd,[1] Dana Rizk,[1] Paul Muntner,[1] William M. McClellan,[2] David G. Warnock.[1] *[1]UAB; [2]Emory; [3]Vermont.*

Background: Chronic kidney disease associates with stroke risk but the independent contributions of higher urinary albumin/creatinine ratio (ACR) and lower estimated glomerular filtration rate (eGFR) are unclear.

Methods: Associations of ACR and eGFR with incident stroke were examined in the REasons for Geographic and Racial Differences in Stroke (REGARDS), a national prospective cohort of 30,239 black and white adults. After excluding those with prevalent stroke, end stage renal disease, or missing data, 24,777 participants were analyzed. Cox regression was used to examine associations of eGFR and ACR at baseline with subsequent, physician-verified incident stroke. Adjustment was made for baseline age, sex, race, age-race interaction, medication use, blood pressure, smoking, atrial fibrillation, diabetes, heart disease, income and education.

Results: In fully-adjusted models, there was no association of eGFR with incident stroke (eGFR 90-120 ref; 60–89, HR 0.92, 95%CI 0.8,1.1; 45-59, HR 0.85, 95%CI 0.6,1.2; <45, HR 1.21, 95%CI 0.8, 1.8). In contrast, there was a step-wise increase in HR of stroke with increasing ACR (<10 mg/g ref; 10–29, HR 1.36, 95%CI 1.1,1.7; 30-300, HR 1.68, 95%CI 1.3,2.1; >300, HR 1.85, 95%CI 1.2,2.8). When examined on a continuous scale, the association of logACR with HR of stroke was modified by eGFR (P for interaction 0.05). In fully adjusted models, each SD increase in logACR was associated with higher HR of stroke in participants with eGFR≥60 but not <60.



Conclusions: Higher ACR was independently associated with higher stroke risk only in those with eGF R≥60. eGFR was not associated with stroke risk after accounting for ACR and other risk factors. These findings suggest that ACR might be helpful to assess stroke risk in adults with eGFR≥60.

TH-PO241

Bone Mineral Density and Fracture Risk in Older Individuals with Chronic Kidney Disease: The Health, Aging and Body Composition Study

Robert H. Yenchek,[1] Joachim H. Ix,[2] Michael Shlipak,[3,4] Doug Bauer,[4] Nahid J. Rianon,[5] Stephen B. Kritchevsky,[6] Tamara Harris,[7] Anne B. Newman,[1] Jane Cauley,[1] Linda F. Fried.[1,8] *[1]Univ. of Pittsburgh, Pittsburgh, PA; [2]University of California, San Diego, CA; [3]San Francisco VA, San Francisco, CA; [4]UCSF, San Francisco, CA; [5]University of Texas Health Sciences Center, Houston, TX; [6]Wake Forest School of Medicine, Wake Forest, NC; [7]NIA, Bethesda, MD; [8]VAPHS, Pittsburgh, PA.*

Background: KDIGO guidelines recommend against bone mineral density (BMD) screening in patients with CKD with mineral bone disease, due to a lack of association of BMD with fractures in cross-sectional studies in CKD patients.

Methods: We assessed whether BMD predicted fracture in participants with and without CKD in the Health, Aging and Body Composition study, a prospective cohort study of well-functioning older individuals. BMD was measured by dual energy x-ray absorptiometry. CKD was categorized as eGFR < 60 ml/min/1.73m^2 using the MDRD formula. Adjudicated incident total non-spine fractures to study year 11 were analyzed using Cox proportional hazards analysis. Interaction terms were tested to assess whether the association of BMD with fracture differed in those with and without CKD.

Results: Of the 2,754 with BMD and laboratory values, mean age was 73.6 ±2.9, 51% were women, 40% were Black, 60% were white, 21% had CKD (96% with stage 3). There were 465 incident non-spine fractures. Femoral neck BMD (FNBMD) and Total Hip BMD (THBMD) were associated with non-spine fracture, regardless of CKD status. After adjustment for age, race, gender, BMI, high PTH ( )65 pg/ml), and low 25-vitamin D (< 20ng/ml) the hazard ratio per standard deviation higher FNBMD was 0.40 (0.30, 0.54) and 0.52 (0.44, 0.60) for those with and without CKD, respectively (p for interaction 0.93). Likewise, the hazard ratio for THBMD for fracture was 0.42 (0.31, 0.57) and 0.49 (0.42, 0.58) for those with and without CKD (p for interaction 0.66).

Conclusions: BMD measurement provides information on a patient's risk for fracture in individuals with or without moderate CKD.

The Structure of Health-Related QOL Varies According to Underlying Diseases of CKD: Results from the CKD-JAC Study

Yasuo Ohashi,[1] Satoshi Iimuro,[1] Tadao Akizawa,[2] Enyu Imai,[2] Seiichi Matsuo,[2] Tsuyoshi Watanabe,[2] Kosaku Nitta,[2] Hirofumi Makino,[2] Akira Hishida.[2] *[1]Univ Tokyo, Japan; [2]CKD-JAC Study Group.*

Background: CKD-JAC was established to prospectively study the renal and cardiovascular outcomes in 2,977 Japanese patients with CKD stages 3-5. CKD is caused by various underlying diseases, and the breakdown of Health Related(HR)-QOL is expected to vary depending on these diseases.

Methods: Data at registration and HR-QOL data were analyzed. In addition, canonical discriminant analysis(CDA) was performed for multidimensional analysis.

Results: Of the 2,526 patients analyzed, 36% had diabetes. The patients were divided into four major groups by disease. As the CKD stages progressed, almost all of the SF-36 domains worsened, especially in GH. PSQI and BDI also worsened. As for disease groups, SF-36, PSQI, and BDI were worse in those with diabetes.

CDA was performed about CKD stages [1] or the disease groups [2] as the criterion variables.

[1]One significant canonical discriminant function was obtained. The standardized discriminant coefficients of GH, RE, and PSQI were large and the mean values of the discriminant function for each stage were 0.14(Stage 3), -0.03(Stage 4), and -0.32(Stage 5).

[2]Two significant discriminant functions were obtained. The first one determined the presence of diabetes, and the second determined the presence of GN or DN(Table1).

Table 1
Canonical discriminant analysis

standardized discriminant coefficient			
var		axis1	axis2
SF-36	Physical functioning(PF)	0.883	0.085
	Role physical(RP)	0.011	-0.199
	Bodily pain(BP)	0.297	-0.658
	General health(GH)	0.026	0.799
	Vitality(VT)	-0.465	0.450
	Social functioning(SF)	-0.157	0.244
	Role emotional(RE)	0.069	-0.004
	Mental health(MH)	-0.077	-0.560
Pittsburgh Sleep Quality Index (PSQI)		0.202	0.304
Beck Depression Inventory (BDI)		0.239	-0.008
mean of discriminant function			
no DM / no GN		0.040	0.155
no DM / GN		0.268	-0.121
DM / no DN		-0.166	0.130
DM / DN		-0.418	-0.166

DM: Diabetis Mellitus, GN: Glomerular Nephritis, DN: Diabetic Nephropathy

Conclusions: As the CKD stage progresses, HR-QOL were found to worsen. A strong correlation was also observed with the underlying disease, and components of HR-QOL that strongly correlated varied with the type of disease.

Funding: Pharmaceutical Company Support

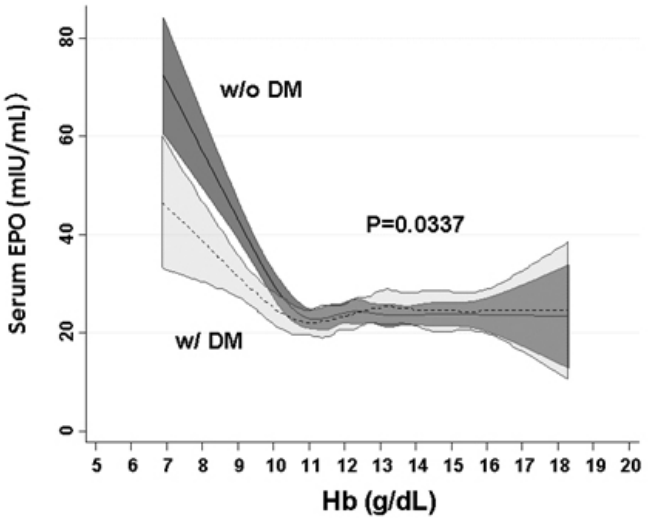
Erythropoietin Responses in Chronic Kidney Disease: A Cross-Sectional Analysis from the CKD-JAC Study

Tadao Akizawa,[1] Takayuki Hamano,[2] Enyu Imai,[2] Seiichi Matsuo,[2] Hirofumi Makino,[2] Tsuyoshi Watanabe,[2] Kosaku Nitta,[2] Yasuo Ohashi,[2] Akira Hishida.[2] *[1]Syowa Univ, Japan; [2]CKD-JAC Study Group.*

Background: Erythropoietin(EPO) production by renal cells is driven by low oxygen levels in the renal tissue. Aim is to elucidate the factors to determine serum EPO in Chronic Kidney Disease(CKD) not on dialysis.

Methods: EPO levels in 1796 ESA therapy-naive patients with CKD stages 3-5 were measured at 1 year after enrollment. We explored associations of EPO levels with various parameters including hemoglobin(Hb), mean corpuscular volume(MCV), eGFR, urinary and serum albumin, C-reactive protein(CRP), and prior cardiovascular disease(CVD) using multiple regression. Restricted cubic spline regression was used for parameters having non-linear relationships with serum EPO.

Results: A significantly non-linear negative relationship between EPO and Hb levels was observed. The threshold of Hb when EPO levels plateaued was 11g/dL on average; this threshold decreased with the advance in CKD stages. The slope between EPO levels and Hb below the threshold was significantly steeper in patients without diabetes(DM), suggesting impaired EPO response to anemia in DM.



There was a U-shaped relationship between MCV and EPO levels with the bottom in the normal ranges of MCV. Albuminuria and eGFR were independent negative and positive determinants of EPO levels, respectively. Low serum albumin, high CRP levels, and prior CVD were associated with high EPO levels.

Conclusions: Given that EPO production is driven by hypoxia, our findings might suggest that targeting Hb levels greater than 11 g/dL does not further improve oxygen status in the kidney. DM was an effect modifier of the association between EPO and Hb. Malnutrition, inflammation, and atherosclerosis were associated with higher EPO levels, possibly because oxygen delivery to renal tissues is disturbed due to microvascular damage.

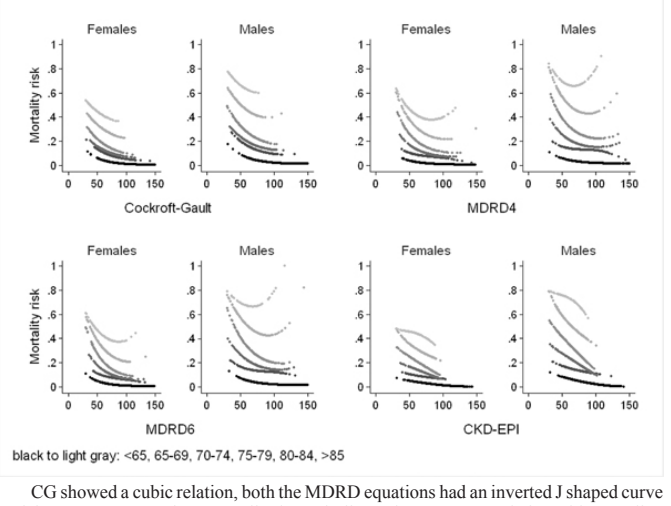
The Role of eGFR, Age and Gender in Mortality Risk Jan A.J.G. van den Brand,[1] Martin Den Heijer,[2] Lambertus Kiemeney,[2] Jack F. Wetzels.[1] *[1]Nephrology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Epidemiology, Biostatistic and HTA, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Background: The effect of eGFR on mortality is modified by age and sex. Our goal was to explore the dose-response relationship of these risk factors and compare GFR estimation equations.

Methods: We obtained data for 2816 male and 3269 female Caucasian participants of the Nijmegen Biomedical Study, a population based, age and sex stratified sample of inhabitants of Nijmegen. Serum creatinine values were determined with the Jaffé method calibrated against mass spectrometry and were used to calculate eGFR with the Cockroft-Gault (CG), MDRD4, MDRD6 and CKD-EPI equations. Demographics, health status and medication use were obtained by postal questionnaire. We used a poisson regression model weighted for sampling fractions to estimate mortality risk for eGFR by age, sex and comorbidities and used fractional polynomials to evaluate non-linear relations.

Results: During 39,855 person-years of follow-up 316 people died. Figure 1 shows the unadjusted association for eGFR and mortality by age and sexe.



CG showed a cubic relation, both the MDRD equations had an inverted J shaped curve and the CKD-EPI equation generally showed a linear dose response relation with mortality. The latter formula thus allowed use of a linear model to describe the association between eGFR and mortality. The adjusted relative risk (RR) of mortality increased with decreasing eGFR. However, the effect of eGFR was attenuated in people >75 years.

Adjusted RR of mortality

	Age			
eGFR-CKD-EPI	<75	75-79	80-84	≥85
90	1 (ref)	1 (ref)	1 (ref)	1 (ref)
60	3.0	1.3	1.2	1.1
30	5.3	1.5	1.3	1.1

Indexed to 90 ml/min/1.73m² for each age category separately

Conclusions: The CKD-EPI equation allows linear modeling of mortality risk. Lower eGFR-CKD-EPI is an important risk factor for mortality, but not in people aged >75 years.

TH-PO245

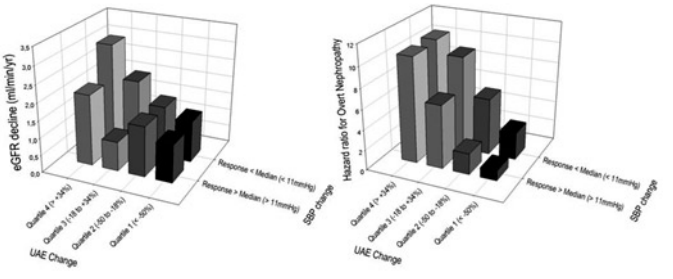
Albuminuria Response to Angiotensin Receptor Blockade Is a Determinant of Renal Protection in Patients with Type 2 Diabetes and Microalbuminuria in the IRMA-2 Trial Merel E. Hellemons,[1] Frederik I. Persson,[2] Peter Rossing,[2] Stephan J.L. Bakker,[1] Dick de Zeeuw,[1] Hans-Henrik Parving,[3] Hiddo Jan Lambers Heerspink.[1] *[1]UMCG; [2]STENO Diabetes Center; [3]University Hospital of Copenhagen.*

Background: Albuminuria (UAE) and systolic blood pressure (SBP) are both renal risk markers in patients with type 2 diabetes (T2DM). ARBs reduce SBP and UAE and are renoprotective. However, UAE and SBP reduction varies and can be discordant within an individual. We tested the SBP and UAE response to ARB and effect on renal function decline in T2DM patients.

Methods: Data from the IRMA-2 trial were used. In this post-hoc analysis we assessed the extent of variability and discordance in SBP and UAE response (0-6 months) in 531 subjects. We analyzed the effect of month 6 SBP and UAE change on renal outcome, looking at glomerular filtration rate (eGFR) changes as well as development of overt nephropathy during 2 years follow-up.

Results: On Irbesartan treatment, 85 (24%) patients had a reduction in UAE but not in SBP at month 6. Conversely, 67 (19%) had a reduction in SBP but not in UAE. A larger reduction in UAE (p=0.0037) but not SBP (p=0.087) was independently associated with a slower rate of eGFR decline. The risk reductions for overt nephropathy per 50% reduction in UAE and 5 mmHg SBP reduction were 44% (95%CI 39-59%; P<0.001) and 9% (95% CI 20 to +2%; P=0.098) resp. Renal function decline according to combined SBP and UAE change demonstrated that across both SBP categories (defined by the median), a progressively lower eGFR decline and lower risk for overt nephropathy was observed with a larger UAE reduction. (figure 1)

Conclusions: SBP and UAE response to ARB therapy may be discordant. The UAE response individually determined renal outcome. The results suggest that in T2DM patients with microalbuminuria both SBP and UAE should be separate targets for renoprotection.



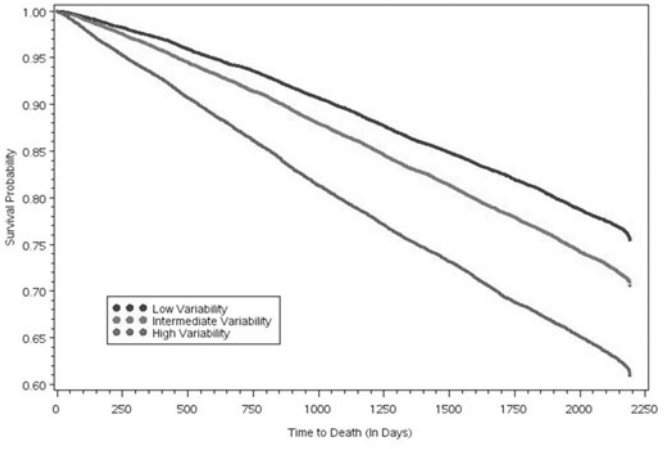
TH-PO246

Variability in Kidney Function and the Risk of Death Ziyad Al-Aly,[1] Tarek M. El-Achkar,[1] Ann M. O'Hare.[2] *[1]Department of Medicine, Division of Nephrology, Saint Louis Veterans Affairs Medical Center, Saint Louis, MO; [2]Department of Medicine, Division of Nephrology, Veterans Affairs Puget Sound Healthcare System, Seattle, WA.*

Background: Intra-individual variability in kidney function is a commonly observed phenomenon. However, predictors of kidney function variability and its prognostic implications are not known.

Methods: We used national data from the Department of Veterans Affairs to assemble a cohort of 60,641 patients with least 3 outpatient serum creatinine measurements between October 1, 1999 and September 30, 2002. Variability in kidney function was defined for each patient as the coefficient of variation of the regression line coefficient fitted to all outpatient measures of estimated glomerular filtration rate (eGFR) during this time frame. We built logistic regression models to examine predictors of variability and Cox survival models to examine the association between kidney function variability and the risk of death.

Results: Black race, female gender, diabetes, cardiovascular disease, peripheral artery disease, chronic lung disease, hepatitis C, dementia, hospitalizations, and the use of angiotensin converting enzyme inhibitors, angiotensin receptor blockers and diuretics were predictors of high variability in eGFR. After a median follow-up of 5.9 years, there were 4,563 (22.57%), 5,552 (27.47%), and 7,493 (36.80%) deaths among patients in low, intermediate, and high tertiles of eGFR variability; respectively. In adjusted analyses, patients in the highest tertile of eGFR variability had an increased risk of death (Hazard Ratio=1.33, 95% Confidence Interval=1.28-1.38) compared with the referent of those in the lowest tertile.



Conclusions: Our results demonstrate that greater variability in kidney function is independently associated with increased risk of death.

TH-PO247

Age and Baseline Kidney Function Modify the Association between Rate of Kidney Function Decline and the Risk of Death Ziyad Al-Aly,[1] Ann M. O'Hare,[2] Tarek M. El-Achkar,[1] Michael I. Rauchman.[1] *[1]Division of Nephrology, Saint Louis Veterans Affairs Medical Center, Saint Louis, MO; [2]Department of Medicine, Division of Nephrology, Veterans Affairs Puget Sound Healthcare System, Seattle, WA; [3]Division of Nephrology, Walter Reed Army Medical Center, Washington, DC.*

Background: The relationship between rate of kidney function decline and mortality has not been examined in different age groups and in patients with kidney disease.

Methods: Using the Department of Veterans Affairs national databases, we built a cohort of 22,568 patients and categorized them into 4 groups: those who experienced no decline (rate of eGFR change greater than 0 ml/min/year) and those with mild, moderate and severe decline defined as eGFR loss of 0-1, 1-4, and greater than 4 ml/min/year; respectively. We built Cox survival models to examine the relationship between rate of kidney function decline and the risk of death in patients according to age groups (less than 60, 60-75, and greater than 75 years old) and eGFR categories (baseline eGFR greater than 90, 60-89, 45-59, 30-44, and 15-29 ml/min).

Results: After a median follow up of 5.9 years, the risk of death in patients with severe decline in eGFR was strongest in the youngest patients (Hazard Ratio (HR) 1.6, Confidence Interval (CI) 1.2-2.1 for <60 years old) and was gradually attenuated across groups of increasing age (HR=1.2, CI=1.0-1.3 for greater than 75 years old, P for interaction=0.0307). In groups according to baseline eGFR, the risk was significant but weak in patients with baseline eGFR greater than 90 ml/min (HR=1.30, CI=1.13-1.50) and became increasingly more pronounced in groups with decreasing baseline eGFR (HR=2.8, CI=1.8-4.2 for 15-29 ml/min, P for interaction <0.001).

Conclusions: Our results show that the independent association between the rate of decline of kidney function and mortality is attenuated with increasing age and may be more pronounced in patients with advanced baseline kidney disease.

Clinical Outcomes of Clostridium difficile Infection in Patients with Chronic Kidney Disease Mira T. Keddis,[1] Sahil Khanna,[2] Larry M. Baddour,[3] Darell S. Pardi,[2] Qi Qian.[1] *[1]Nephrology, Mayo Clinic, Rochester, MN; [2]Gastroenterology, Mayo Clinic, Rochester, MN; [3]Infectious Diseases, Mayo Clinic, Rochester, MN.*

Background: The outcomes of *Clostridium difficile* infection (CDI) in chronic kidney disease (CKD) patients have not been previously described. The objective of this study is to examine clinical outcomes of hospitalized patients with CKD and CDI using the National Hospital Discharge Survey (NHDS) database.

Methods: We analyzed NHDS data for 2005-2009; the database contains demographic information, ICD-9 diagnosis and procedure codes, and discharge information for patients admitted to non-Federal short-stay United States hospitals. Clinical information of patients with CKD and CDI was abstracted and analyzed using SAS version 9.2 and JMP version 9.0.1.

Results: 59,715 hospitalized patients with CKD were identified with mean age 68.5 ±15.8 years, 52.4% male sex. 41.9% of patients had unspecified CKD severity, 37.7% with CKD stage V, 18.6% CKD III and IV, and 1.8% CKD I and II. Of them, 17,189 (28.8%) patients required dialysis during their hospitalization. CDI occurred in 918 (1.5%) patients. CKD patients with CDI were significantly older (72 ±0.5 vs. 68.4 ±0.07 years), required longer length of stay (10 ±0.2 vs. 6.2 ±0.02 days), and were more likely to be dismissed to a care facility (50.5 vs. 25.7%) compared to CKD patients without CDI (all p<0.001). CKD patients with CDI had a higher in-hospital mortality rate (8.50 vs. 3.95%,OR 2.25 [95% CI 1.78-2.85]) and likelihood of requiring colectomy (OR 3.33 [95% CI 1.7-6.54], p<0.001). After adjusting for age, the association of CDI with these clinical outcomes remained significant.

Conclusions: In hospitalized CKD patients, CDI was associated with prolonged hospitalization, and an increased likelihood of both undergoing colectomy and suffering in-hospital mortality. Prevention, early recognition and treatment of CDI in CKD patients are necessary to decrease CDI associated morbidity and mortality in this population.

TH-PO249

Troponin T and B-Type Natriuretic Peptide Are Associated with Cardiovascular Outcome Despite Their Cross-Sectional Association with Chronic Kidney Disease Lieneke Scheven,[1] Paul E. de Jong,[1] Hiddo Jan Lambers Heerspink,[2] Lucas Joost Van Pelt,[3] Jenny E. Kootstra-Ros,[3] Stephan J.L. Bakker,[1] Ron T. Gansevoort.[1] *[1]Nephrology; [2]Pharmacology; [3]Clinical Chemistry, University Medical Centre Groningen, Netherlands.*

Background: It has been suggested that troponins and natriuretic peptides are falsely elevated in chronic kidney disease (CKD) because of decreased renal clearance. The value of these biomarkers to predict cardiovascular (CV) outcome in subjects with CKD has therefore been debated. We investigated this issue in a population based cohort study.

Methods: For the present study 8,121 subjects who participated in the PREVEND Study of whom at baseline high sensitive Troponin T (hsTnT) and N-terminal pro-B-type Natriuretic Peptide (NT-pro-BNP) were available, were included. HsTnT ≥0.01 µg/L and NT-pro-BNP ≥125 ng/L were defined as elevated.

Results: Of our cohort, 6.7% had an elevated hsTnT and 12.2% an elevated NT-pro-BNP. eGFR and albuminuria were significantly associated with hsTnT and NT-pro-BNP in linear regression analyses. After adjustment for age, gender and CV risk factors these associations remained significant. Both hsTnT and NT-pro-BNP appeared associated with CV events during follow-up (both p<0.001). These associations remained significant after adjustment for eGFR, albuminuria, age, gender and CV risk factors (both p<0.001). No interaction was found between eGFR and hsTnT or NT-pro-BNP in predicting CV outcome. Moreover, the value of an increased hsTnT or NT-pro-BNP to predict CV outcome was similar in subjects with or without CKD (in both, for both hsTnT and NT-pro-BNP p<0.001).

Conclusions: These data indicate that a finding of an increased hsTnT or NT-pro-BNP in a subject with CKD should be taken seriously as a prognostic marker heralding an unfavourable CV outcome and not be discarded as merely a reflection of decreased renal clearance.

TH-PO250

Isolated Microalbuminuria Heralds a Poor Medical Prognosis Lieneke Scheven,[1] Paul E. de Jong,[1] Hiddo Jan Lambers Heerspink,[2] Stephan J.L. Bakker,[1] Ron T. Gansevoort.[1] *[1]Nephrology; [2]Pharmacology, University Medical Centre, Groningen, Netherlands.*

Background: Microalbuminuria (MA) is often regarded as a sign of end-organ damage due to diabetes and/or hypertension and to be associated with an increased risk for cardiovascular (CV) events. It has been questioned whether isolated microalbuminuria (IMA) - i.e. microalbuminuria in absence of diabetes, hypertension and/or CV morbidity - has clinical relevance.

Methods: For this study data were used of 8,592 subjects who participated in the first 4 screening rounds of the PREVEND study, a prospective, community-based cohort study with serial measurements during follow-up. IMA was defined as albuminuria 30-300 mg/24hr and a fasting glucose <7.0 mmol/L (no glucose lowering drugs), blood pressure <140/90 mmHg (no antihypertensive drugs) and a negative CV disease history. Logistic regression analyses was used to determine the risk for developing diabetes (ADA criteria) and hypertension (JNC-7 criteria), and Cox regression analysis to determine the risk for CV events.

Results: A total of 300 subjects met the definition of IMA. In subjects with IMA the incidence rates of diabetes, hypertension and CV events were 8.5, 27.0 and 15.3 per 1,000 patient years follow-up, respectively. Subjects with IMA had an increased risk for developing diabetes (Odds Ratio (OR) 4.69 (2.92-7.51); p<0.001), hypertension (OR 1.95 (1.47-2.59); p<0.001) and CV events (Hazard Ratio 2.23 (1.63-3.07); p<0.001), compared to subjects without albuminuria, diabetes, hypertension and CV history. This increased risk remained significant after adjustment for age and gender. The risk held by IMA was similar to the risk held by microalbuminuria in subjects that do have diabetes, hypertension and/or a CV disease history.

Conclusions: Microalbuminuria, even in the absence of diabetes, hypertension and a CV disease history heralds a poor prognosis and warrants medical attention.

TH-PO251

Predictors of Progression in Albuminuria in the General Population Lieneke Scheven, Nynke Halbesma, Paul E. de Jong, Ron T. Gansevoort. *Nephrology, University Medical Centre Groningen, Netherlands.*

Background: Progression of CKD is usually defined as loss of renal function. However, also an increase in albuminuria (UAE) is associated with a poor prognosis, both with respect to CV as well as renal outcome. We investigated which factors predict progressive UAE in the general population using data of subjects participating in a prospective, community-based cohort study with serial follow-up (PREVEND).

Methods: After exclusion of subjects with known renal disease or macroalbuminuria at baseline, or missing follow-up data on UAE, 5,825 subjects were eligible. Subject were defined as having progressive UAE if they belonged to the quintile with the strongest annual increase in UAE, and UAE ≥150 mg/24h during follow-up. Multivariable regression models were built using stepwise backward selection to identify risk factors for progressive UAE.

Results: During a median follow-up of 9.3 years 132 subjects met our definition of progressive UAE (median value at baseline 67.4 versus 252.7 mg/24h at end of follow-up). Univariably associated with progressive UAE were: male gender, history of cardiovascular disease, lower eGFR, higher age, BMI, SBP, glucose and baseline UAE, and use of antihypertensive and lipid lowering medication (all p<0.001). Variables that contributed significantly to the multivariable model are shown in the table. Importantly, most predictors for progressive UAE were, although statistically significant, of limited value when compared to baseline UAE, as indicated by the Wald statistics (table) and a clinical score chart based on the Beta-values of the multivariable model.

Variable	Odds Ratio	p-value	Wald statistic
Male gender	2.26	<0.001	12.2
Age (yrs)	1.03	<0.001	13.1
BMI (kg/m2)	1.06	0.01	6.0
UAE (ln mg/24h)	5.78	<0.001	275.3
* Change in SBP (mmHg)	1.02	0.006	7.4

* Change in systolic blood pressure during follow up

Conclusions: A high baseline UAE is by far the most important predictor of progressive UAE. Thus, screening for baseline UAE will be more important than screening for cardiovascular risk factors in order to identify subjects at risk for progressive UAE.

TH-PO252

Glomerular and Tubular Damage Markers in Subjects with Progressive Albuminuria Ferdau L. Nauta,[1] Lieneke Scheven,[1] Stephan J.L. Bakker,[1] Willem Van Oeveren,[2] Paul E. de Jong,[1] Ron T. Gansevoort.[1] *[1]Nephrology, UMCG; [2]Haemoscan, Groningen, Netherlands.*

Background: Albuminuria is associated with risk for renal and cardiovascular disease. It is difficult to predict which subjects will progress in albuminuria. We investigated whether assessment of urinary markers representing damage to different parts of the nephron help to identify subjects that will progress in albuminuria.

Methods: Subjects were selected from a prospective community-based cohort study with serial follow-up (PREVEND, n=8592) and defined as progressor if they were in the quintile with most rapid annual increase in albuminuria and reached albuminuria 150 mg/d during follow-up. Subjects with known renal disease were excluded. Progressors were 2:1 matched to control subjects based on age, sex and baseline albuminuria. IgG was measured as glomerular marker, KIM-1, NAG, β-2-microglobulin, cystatin C as proximal tubular damage markers and NGAL and MCP-1 as inflammatory markers.

Results: After a follow-up of 9.3 yr 183 subjects met our criteria for progressive albuminuria. Baseline clinical characteristics between progressors and controls were comparable. However, both urinary excretion and fractional excretion of total IgG were significantly higher in progressors (p<0.001), whereas in these subjects urinary and fractional excretion of all tubular markers except cystatin C were lower (all p<0.01).

Urinary excretions

	Progressors	Controls
Albumin (mg/d)	58 (33-106)	52 (31-88)
IgG (µg/d)	1285 (926-2181)	1118 (696-2039)**
KIM-1 (µg/d)	3.9 (1.9-7.0)	7.4 (3.2-15.0)**
CysC (µ/d)	0.011 (0.005-0.030)	0.015 (0.005-0.041)
B2MG (µg/d)	103 (39-395)	169 (58-641)**
NAG (µg/d)	0.011 (0.000-0.255)	0.694 (0.000-1.863)**
NGAL (µg/d)	5.5 (2.7-9.6)	6.7 (3.9-11.4)*
MCP-1 (ng/d)	467 (261-825)	741 (522-911)**

Medians (IQR) * p<0.05, ** p<0.01

Conclusions: These data suggest that albuminuria associated with glomerular damage is more likely to progress, whereas albuminuria associated with tubulointerstitial damage is more likely to remain stable.

TH-PO253

The Effect of Frozen Storage on Urinary Renal Damage Markers Ferdau L. Nauta,[1] Stephan J.L. Bakker,[1] Hiddo Jan Lambers Heerspink,[2] Willem Van Oeveren,[3] Dick de Zeeuw,[2] Henk Bilo,[4] Paul E. de Jong,[1] Ron T. Gansevoort.[1] *[1]Nephrology; [2]Pharmacology; [3]Haemoscan, Groningen; [4]Diabetes Center, Isala Clinics, Zwolle, Netherlands.*

Background: Epidemiological studies that investigate the value of renal damage markers to predict outcome often use urine samples that have been stored frozen for prolonged time. Little is known about the effect of frozen storage on urinary concentrations and variability of renal tubular damage markers. We therefore investigated the effect of storage at -20 and -80 °C.

Methods: Urine samples were collected in 95 patients with diabetes mellitus. In each sample we measured IgG, IgG-4, KIM-1, NGAL, NAG, cystatin C and H-FABP fresh and after 1 week, 6 months and 1 year of frozen storage at -80 C. Furthermore, the effect of 1 year frozen storage at -20 C and the effect of various specific storage protocols was investigated.

Results: Average marker concentrations showed a gradual decrease and an increase in variability after frozen storage at -80 °C.

	Fresh	1 week	6 months	1 year
IgG total (µg/ml)	6.4 (2.1-28.9)	5.7 (1.9-10.7)*	5.2 (3.4-11.0)	5.0 (2.2-15.3)
IgG-4 (µg/ml)	1.2 (0.9-2.6)	0.8 (0.3-2.5)	0.6 (0.6-0.7)**	0.7 (0.3-2.9)
KIM-1 (ng/ml)	1.3(0.7-2.2)	1.0 (0.4-1.5)**	1.0 (0.6-1.7)	0.7 (0.4-1.0)**
NAG (U/L)	8.5 (5.4-13.3)	7.8 (5.4-14.1)	2.0 (1.2-3.6)**	0.3 (0.2-0.3)
Cystatin C (mg/L)	0.03 (0.01-0.05)	0.03 (0.02-0.05)	0.03 (0.01-0.05)	0.04 (0.02-0.06)**
NGAL (ng/ml)	34.2 (13.3-98.3)	32.4 (7.8-89.6)	18.3 (3.7-93.6)	18.3 (7.3-77.5)*
H-FABP (ng/ml)	1.6 (0.4-7.6)	1.5 (0.4-4.3)*	1.0 (0.4-4.6)	1.0 (0.4-4.1)

Medians (IQR). *p<0.05, ** p<0.001 vs fresh

Specific storage protocols (adding protease inhibitors, and alkalizing before and after storage) could not prevent these effects. One year frozen storage at -20 °C yielded essentially similar results. Importantly, after frozen storage all marker concentrations remained significantly associated with the values measured in fresh urine samples (all p<0.001).

Conclusions: Renal damage markers should preferably be measured in fresh urine samples. Marker studies using frozen urine samples should be interpreted with caution.

TH-PO254

The Association of Circulating Fetuin-A with Incident Cardiovascular Disease Differs by Diabetes Status in Community-Living Older Persons: The Cardiovascular Health Study Majken K. Jensen,[1] Traci M. Bartz,[2] Kenneth J. Mukamal,[3] Luc Djousse,[4] Jorge R. Kizer,[5] Russel Tracy,[6] Eric B. Rimm,[1] David Siscovick,[2] Michael Shlipak,[7] Joachim H. Ix.[8] *[1]HSPH, MA; [2]University of Washington, WA; [3]Beth Israel Deaconess Medical Center, MA; [4]Brigham and Women's Hospital, MA; [5]Cornell University, NY; [6]University of Vermont, VT; [7]UCSF, CA; [8]UCSD, CA.*

Background: Fetuin-A inhibits arterial calcification and insulin activity. High fetuin-A levels associate with diabetes, whereas low levels are associated with CVD in ESRD patients. The association with incident cardiovascular disease (CVD), and the potential dependence on prevalent diabetes in non-ESRD is less certain.

Methods: 3,718 participants aged >65 years, free of CVD in 1992, followed for incident CVD (MI, stroke, or CVD death) through 07/2008.

Results: Mean age was 76 years, and mean eGFR was 74 ml/min/1.73m². 1,415 participants had a CVD event. The association of fetuin-A with CVD was modified by diabetes (p interaction=0.02). In participants without diabetes the highest risk was observed for the lowest fetuin-A levels. The adjusted hazard ratio (HR) per each SD higher fetuin-A (0.1 g/L) was 0.94 (0.89-1.01). In contrast, fetuin-A was not associated with CVD in those with diabetes (table).

Table. Association of Fetuin-A Quartiles with Incident Cardiovascular Disease Events in Older Participants without ESRD, Stratified by Diabetes: The Cardiovascular Health Study

Without diabetes, n=3224	Q1	Q2	Q3	Q4	Per SD
HR's*	1 (ref)	0.88 (0.75,1.03)	0.90 (0.76,1.06)	0.91 (0.77,1.08)	0.94 (0.89,1.01)
With diabetes, n=494					
HR's*	1 (ref)	1.37 (0.91,2.05)	1.16 (0.75,1.79)	1.34 (0.88,2.03)	1.06 (0.92,1.22)

*Adjusted for: age, sex, race, center, physical activity, smoking status, use of hormone therapy (women), alcohol, HTN, eGFR, CRP, BMI, triglycerides, HDL, LDL

Among persons without diabetes, similar effect modification was observed by obesity (p=0.2) and in those with HOMA below the median(p=0.02), where fetuin-A was associated with CVD in the non-obese or low HOMA subgroup (HR's per SD=0.92 [0.86-0.98] and 0.87 [0.79-0.96]).

Conclusions: Insulin resistance/diabetes modifies the association of fetuin-A with risk of CVD in older individuals.

Funding: Other NIH Support - The National Heart Lung and Blood Institute (NHLBI) R01 HL094555. TH-PO255

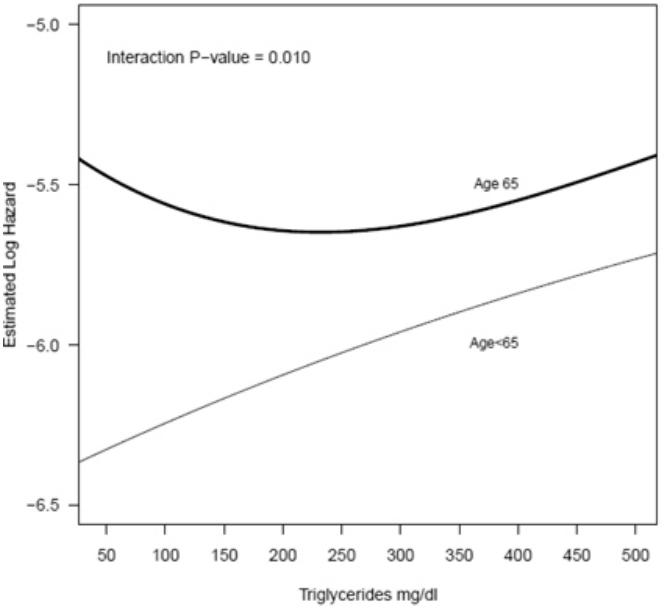
Triglycerides and All-Cause Mortality in Non-Dialysis Dependent Chronic Kidney Disease Sankar D. Navaneethan,[1] Jesse D. Schold,[1,2] Susana Arrigain,[2] Stacey Jolly,[3] John W. Sharp,[2] Anil K. Jain,[3] James F. Simon,[1] Emilio D. Poggio,[1] Titte Srinivas,[1] Martin J. Schreiber,[1] Joseph V. Nally.[1] *[1]Nephrology & Hypertension, Cleveland Clinic; [2]Quantitative Health Sciences, Cleveland Clinic; [3]Medicine, Cleveland Clinic.*

Background: Elevated triglyceride (TG) level is associated with cardiovascular and all-cause mortality in the general population. The association between TG levels and all-cause mortality among chronic kidney disease (CKD) patients is unclear.

Methods: Patients with stage 3 and stage 4 CKD patients who had TG levels measured after the diagnosis of CKD in our health system were included. We examined the associations of TG levels as categorical and continuous variables with all-cause mortality among CKD patients using logistic regression, Cox-proportional hazard models and Kaplan-Meier survival curves.

Results: Out of 23,592 CKD patients, 37.1% (n=8735) had TG levels ≥150 mg/dl. Presence of diabetes, hypertension, obesity and lower eGFR were associated with TG levels ≥150 mg/dl while increasing age, male gender (odds ratio [OR] 0.87, 95% CI 0.82, 0.92), and African American race (OR 0.40, 95% CI 0.37, 0.44) were associated with

lesser risk of ≥150 mg/dl. Kaplan-Meier survival plot did not show significant differences in all-cause mortality in the different TG groups. However, after covariate adjustment, each unit in log transformed TG levels was associated with a 10% increased risk (95% CI 1.01, 1.20) for death. Age modified the association between TG levels and mortality with patients <65 years having 24% higher risk of death (95% CI 1.07, 1.44) and ≥65 years with no increased risk for death.



Conclusions: Elevated TG may be a modifiable risk factor for all-cause mortality in patients <65 years but not in older CKD patients. Future studies should explore the associations of TG with cause-specific mortality in younger CKD patients with high triglyceride levels.

TH-PO256

Chronic Kidney Disease and Fracture Risk in Children and Young Adults: A Population-Based Study Using the Health Improvement Network Database

Michelle Denburg,[1, 3] Kevin Haynes,[2] Justine Shults,[2] Mary B. Leonard.[1-3] *[1]Pediatrics, University of Pennsylvania School of Medicine, Philadelphia, PA; [2]Biostatistics & Epidemiology, University of Pennsylvania School of Medicine, Philadelphia, PA; [3]Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Chronic kidney disease (CKD) may impair bone accrual and is associated with increased fracture risk in older adults. Fracture risk in children and young adults with CKD has not been assessed. The objective was to determine if CKD is associated with greater risk of fracture in this population.

Methods: In a retrospective cohort study using The Health Improvement Network (THIN) Database, subjects with CKD stages 3-5, diagnosed at ≤ 30 years, were identified using serum creatinine values or previously validated diagnosis codes. All sex- and age-matched subjects from a practice with a CKD subject were included for comparison. Cox regression analysis was used to estimate the hazard ratio (HR) for first fracture.

Results: 2,649 subjects with CKD (51% female) and 1,055,056 subjects without CKD (52% female) were identified. 185 first fractures (15/1,000 person-years) occurred in CKD subjects CKD vs 66,982 (9/1,000 pyears) in non-CKD subjects over a median follow-up time of 4 and 5 years, respectively. Overall, the HR for fracture in males vs females was 2.0 (1.97, 2.03), and the effect of CKD differed significantly by sex (interaction p<0.001).

HR for Fracture CKD vs Non-CKD

Age	Male	Female
0-9	1.21 (0.60, 2.41)	1.92 (0.96, 3.85)
10-14	0.70 (0.35, 1.40)	1.25 (0.52, 3.01)
15-19	0.88 (0.49, 1.59)	2.30 (1.09, 4.83)
20-29	1.00 (0.67, 1.48)	3.17 (2.30, 4.38)
30+	1.68 (1.22, 2.32)	2.47 (1.81, 3.39)

Forearm/wrist/hand fractures were the most common site in both groups, but the distribution of site differed in CKD vs non-CKD subjects. Hip fractures comprised a greater proportion of fractures in CKD (3.8% vs 0.9%, p=0.002), while skull and facial fractures represented a greater proportion in non-CKD (1.6% vs 6.7%, p=0.003).

Conclusions: Early onset CKD was associated with significantly increased risk of fracture in adolescent and young adult women. In males, early onset CKD was associated with increased risk of fracture only after age 30.

TH-PO257

Longitudinal Classification of Chronic Kidney Disease Biomarkers and Their Association with Coronary Artery Calcium: The Spokane Heart Study

Sterling McPherson,[1] Celestina Barbosa-Leiker,[1] Robert Short,[1,2] Katherine R. Tuttle.[2] *[1]College of Nursing, Washington State University, Spokane, WA; [2]Providence Medical Center at Sacred Heart Medical Center, Spokane, WA.*

Background: Kidney function decline, marked by decreasing levels of estimated glomerular filtration rate (eGFR) and increasing levels of serum phosphorus, is associated with coronary artery calcification (CAC), but the dynamic nature of this relationship is unclear. The study aim was to examine distinct trajectory classes of serum phosphorus levels, controlling for eGFR, that predict CAC.

Methods: The Spokane Heart Study is a longitudinal prospective cohort study of community-dwelling adults (n=721). Phosphorus and eGFR were classified as a combined biomarker variable via finite growth mixture modeling. Pre-specified variables included: high-density lipoprotein cholesterol, low-density lipoprotein cholesterol, triglycerides, smoking status, systolic and diastolic blood pressure, body mass index, diabetes status, age, and gender. The primary outcome was CAC as both binary (i.e., onset) and continuous (i.e., accumulation) variables. 2-part latent growth curve modeling was the main statistical method used.

Results: Finite growth mixture modeling identified 4 distinct classes of phosphorus trajectories (low to high). Membership in 1 phosphorus trajectory class versus the next highest level predicted an increase in the probability of a positive CAC scan (β=0.26; 95% CI: 0.14-0.38, p<.001) and the amount of CAC burden (β=0.50; 95% CI: 0.38-0.61, p<.001) while controlling for other covariates. The magnitude of this finding is similar to those of major risk factors for cardiovascular disease (CVD), including effects of age (β=0.28; 95% CI: 0.16-0.40, p<.001) and gender on CAC onset (β=-0.34; 95% CI:-0.45- -0.25, p<.001), and gender's impact on CAC accumulation (β=-0.33; 95% CI:-0.44- -0.23, p<.001).

Conclusions: Classification of serum phosphorus into time-dependent trajectories, even within the normative range, indicates a graded association with CAC. Identification of such high-risk individuals could be useful for participant selection in clinical trials assessing effects of phosphorus lowering on CVD.

TH-PO258

Risk of Retinopathy among Individuals with Evidence of Kidney Damage or Dysfunction

Laura C. Plantinga,[1] Vanessa Grubbs,[1] Chi-Yuan Hsu,[1] Rajiv Saran,[2] Vahakn B. Shahinian,[2] Jinan Boghos Saaddine,[3] Desmond Williams,[3] Neil R. Powe.[1] *[1]University of California, San Francisco, CA; [2]University of Michigan, Ann Arbor, MI; [3]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: Both chronic kidney disease (CKD) and retinopathy involve pathogenic changes in microvasculature and are strongly associated with diabetes and hypertension. We examined whether albuminuria and kidney dysfunction are associated with excess risk of retinopathy, beyond that conferred by shared risk factors, in the adult U.S. population.

Methods: Participants ≥40 years (*n*=5119) from the 2005-2008 National Health and Nutrition Examination Survey with complete retinal imaging data and information on diabetes (self-report or glycohemoglobin≥6.5%); hypertension (self-report or measured blood pressure ≥140/≥90 mmHg, in the absence of diabetes); albuminuria [urinary albumin:creatinine ratio 30-299 (microalbuminuria) or ≥300 (macroalbuminuria) mg/g]; and kidney dysfunction [estimated GFR <60 (reduced kidney function) or >120 (hyperfiltration) ml/min/m^2] were examined. Multivariable logistic regression with stratification by diabetes and hypertension was used to assess the independent association of albuminuria and kidney dysfunction with retinopathy (defined as any type of retinopathy, scored by two independent graders, in either eye).

Results: Retinopathy was common, with a prevalence of 9.6% overall and 14.5% in those with either albuminuria or kidney dysfunction. Macroalbuminuria, but not microalbuminuria or kidney dysfunction, was associated with retinopathy among persons with diabetes (OR=2.94, 95% CI 1.51-5.69), after adjustment for demographics, glycohemoglobin, blood pressure, and smoking. Among those with hypertension alone, the association was similar but not statistically significant (OR=2.98, 95% CI 0.55-16.2). Neither albuminuria (*P*=0.79) nor reduced kidney dysfunction (*P*=0.93) was associated with retinopathy among those without diabetes or hypertension.

Conclusions: Further research is needed to determine whether routine retinopathy screening based on the presence of chronic kidney disease markers alone is warranted in the general population.

Funding: Other U.S. Government Support

TH-PO259

Clinico-Histological Examination of Elderly Nephropathy Patients over 65 Years Old

Masayuki Yamanouchi, Yoshifumi Ubara. *Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

Background: Even in Japan where the percentage of elderly patients requiring dialysis is increasing, the primary diseases causing nephropathy are often unclear. To examine the primary disease of elderly nephropathy patients over 65 years old would be useful for improving treatment.

Methods: A total of 503 patients aged over 65 year old who underwent renal biopsy between 1985 and 2010 at our institution were analyzed retrospectively, including 297 men and 206 women.

Results: Renal biopsy was performed for proteinuria of less than 3.5 grams daily (44.5%), nephrotic-range proteinuria over 3.5 grams daily (29.3%), acute kidney damage including rapidly progressive renal failure (19.9%), and chronic-progressive kidney disease (5.8%). Membranous nephropathy (MN) was the most frequent type of nephropathy (19.0%), followed by diabetic nephropathy (DN) (16.7%), IgA nephropathy (IgAN) (13.1%), hypertensive nephrosclerosis (9.1%), crescentic glomerulonephritis (CG) (7.6%), minimal change nephritic syndrome (5.7%), amyloidosis (5.6%), and focal segmental glomerulosclerosis (5.6%). In the 65 - 69 years old group, DM, IgAN, and MN were predominant, accounting for 18.0%, 17.0%, and 14.0%, respectively. In the 70 - 79 years old group, MN, DN and IgAN were predominant (22.4%, 14.2%, and 7.6%, respectively). In the over 80 years old group, CN was the most common diagnosis (20%). Nephrotic-range proteinuria was caused by MN (47.8%), MCNS (21.7%), and DN (8.7%).

Conclusions: MN and DN were the most frequent diagnoses in each group. Renal biopsy is useful for evaluation and treatment of elderly nephropathy patients.

TH-PO260

Depressive Symptoms, Cardiovascular Disease (CVD) Risk Factors, and Subclinical CVD among Individuals in the Chronic Renal Insufficiency Cohort (CRIC) Study Michael J. Fischer,[1] Neil Jordan,[3] Dawei Xie,[3] Virginia Ford,[3] Marie Krousel-Wood,[3] Manjula Kurella Tamura,[3] John W. Kusek,[2] Leigh Rosen,[3] Louise Frances Strauss,[3] Valerie L. Teal,[3] Kristine Yaffe,[3] Willem Johan Kop,[3] Neil R. Powe,[3] James P. Lash.[1] *[1]Jesse Brown VA/U.Illinois; [2]NIH/NIDDK; [3]CRIC Study Group.*

Background: Depression is associated with prevalent cardiovascular disease (CVD) and an increased risk of CVD-related events in adults with chronic kidney disease (CKD). However, the relationship between depression, CVD risk factors, and subclinical CVD is not known.

Methods: We conducted a cross-sectional analysis of depressive symptoms (DS) in adults at entry into CRIC Study. DS were assessed by the Beck Depression Inventory (BDI) and defined by a BDI score ≥11. CVD risk factors were ascertained by questionnaires and lab studies. In addition to self-reported CVD, subclinical CVD measures included left ventricular hypertrophy (LVH), coronary artery calcification (CAC) score >400, and ankle-brachial index (ABI) < 0.9. Logistic regression was used to assess the relation between DS and CVD.

Results: Among 3863 CRIC participants, 28.5% had DS. Self-reported CVD was found in 33.3% and subclinical CVD as follows: 53.6% LVH, 21.6% CAC >400, and 16.1% ABI < 0.9. Adults with DS had a greater burden of traditional CVD risk factors compared to those without DS, including a higher prevalence of diabetes, hypertension, hyperlipidemia, smoking, low eGFR, and elevated urine protein (all $p<0.05$). Control of blood pressure (<130/80 mmHg) and diabetes (HbA1c<7%) was less common in those with DS (both $p<0.05$). DS were also associated with the presence of non-traditional CVD risk factors such as lower serum hemoglobin and albumin, and higher serum phosphorus, parathyroid hormone, and c-reactive protein (all $p<0.001$). In analyses adjusted for sociodemographic and traditional CVD risk factors, DS were associated with self-reported CVD (OR 1.58; 95% CI: 1.32-1.90) and LVH (OR 1.24; 95% CI: 1.00-1.54) but not CAC >400 or ABI < 0.9.

Conclusions: In a large diverse CKD cohort, DS were associated with an adverse profile of traditional and non-traditional modifiable CVD risk factors, and increased odds of self-reported CVD and LVH.

TH-PO261

Low Ankle Brachial Index Is Associated with Rapid Glomerular Filtration Rate Decline Meredith C. Foster,[1] Nimrta Ghuman,[2] Shih-Jen Hwang,[1] Joanne Murabito,[1,2] Caroline S. Fox.[1,3] *[1]Framingham Heart Study, Framingham, MA; [2]Boston University School of Medicine, Boston, MA; [3]Harvard Medical School, Boston, MA.*

Background: A low ankle brachial index (ABI) is associated with increases in serum creatinine. We sought to investigate the association of ABI with the development of rapid kidney function decline or stage 3 chronic kidney disease (CKD).

Methods: Participants (n=2592, mean age 57 years, 54% women) attended Framingham Offspring Exams 6 (1995-98) and 8 (2005-08). Baseline ABI was classified into 3 groups: normal (>1.1 to <1.4; n=1719), low-normal (>0.9 to 1.1; n=822), and low (≤0.9; n=51). Glomerular filtration rate was estimated (eGFR) using the MDRD Study equation. Rapid eGFR decline was defined as eGFR decrease of ≥3mL/min/1.73m²/year. Incident stage 3 CKD was defined as eGFR<60mL/min/1.73m² at Exam 8 among those free of stage 3 CKD at baseline. Rapid eGFR decline and stage 3 CKD were modeled as functions of ABI using logistic regression, with multivariable (MV) adjustment for age, sex, eGFR, and standard CKD risk factors.

Results: Over 9.5 years of follow-up, 11.9% (n=309) experienced rapid eGFR decline. Compared to participants with a normal ABI, those with a low ABI had a 5.8-fold increased odds of rapid eGFR decline ($p<0.0001$), which persisted with further MV adjustment (Table, $p=0.0007$). Among those free of baseline stage 3 CKD, 9.0% (n=219) developed stage 3 CKD. After adjusting for age, sex and baseline eGFR, participants with a low ABI had a 2.9-fold increased odds of stage 3 CKD ($p=0.006$) when compared to those with a normal ABI. We observed some attenuation upon MV adjustment, although low ABI remained associated with a 2.1-fold increased odds developing stage 3 CKD (Table, $p=0.07$). Low-normal ABI was not associated with rapid eGFR decline or incident stage 3 CKD.

Table: Odds ratios (95% Confidence Intervals) of rapid eGFR decline & CKD

	Rapid eGFR Decline		Stage 3 CKD	
Covariates	Low-normal ABI	Low ABI	Low-normal ABI	Low ABI
Age, sex, baseline eGFR	1.3 (1.0-1.9)	5.8 (2.7-12.7)	1.3 (0.9-1.8)	2.9 (1.4-6.3)
Multivariable	1.3 (0.9-1.8)	4.3 (1.9-9.9)	1.2 (0.9-1.7)	2.1 (0.9-4.7)

Referent = Normal ABI

Conclusions: Low ABI is associated with an increased risk of rapid eGFR decline.

Funding: Other NIH Support - The Framingham Heart Study is supported by the National Heart, Lung and Blood Institute (N01-HC-25195).

TH-PO262

Multiple Markers of Kidney Function Predict Mortality and End-Stage Renal Disease in the General Population: The Atherosclerosis Risk in Communities (ARIC) Study Brad C. Astor,[1] Tariq Shafi,[1] Ron C. Hoogeveen,[2] Christie Ballantyne,[2] Josef Coresh.[1] *[1]Johns Hopkins University; [2]Baylor College of Medicine.*

Background: Lower estimated GFR based on serum creatinine ($eGFR_{CKD-Epi}$) or cystatin C ($eGFR_{Cys}$) is associated with higher risk of death and ESRD. Beta-trace protein (BTP) and beta-2 microglobulin (B2M), two novel markers of kidney function, have also been shown to predict events. The prognostic utility of multiple markers of kidney function is undetermined.

Methods: We used data from 10,091 participants in the ARIC Study, a population-based cohort study of 4 US communities, to examine the prospective association between the number of markers indicating kidney dysfunction and death and ESRD over 11 years of follow-up. Kidney dysfunction was defined as $eGFR_{CKD-Epi}$ (n=684) or $eGFR_{Cys}$ (n=1,320) <60mL/min/1.73m² or the upper decile of BTP (n=1,001) or B2M (n=1,006).

Results: The number of markers indicating kidney dysfunction was strongly associated with risk of death and ESRD, even among those with $eGFR_{CKD-Epi}$ and $eGFR_{Cys}$ ≥60mL/min/1.73m². Results were similar after further adjustment for urinary albumin:creatinine.

Adjusted* Incidence Rate Ratio (95% CI) of Death and ESRD

	Death (n=1,675)			ESRD (n=168)		
Number of Markers	**Overall**	**$eGFR_{CKD-Epi}$≥60 mL/min/1.73m²**	**$eGFR_{CKD-Epi}$ and $eGFR_{Cys}$≥60 mL/min/1.73m²**	**Overall**	**$eGFR_{CKD-Epi}$≥60 mL/min/1.73m²**	**$eGFR_{CKD-Epi}$ and $eGFR_{Cys}$≥60 mL/min/1.73m²**
0	1.0 (Reference)	1.0 (Reference)	1.0 (Reference)	1.0(Reference)	1.0(Reference)	1.0(Reference)
1	1.2 (1.0-1.4)	1.2 (1.0-1.4)	1.2 (1.0-1.5)	2.2 (1.2-4.2)	2.3 (1.2-4.6)	2.4 (1.1-5.3)
2	1.7 (1.4-2.0)	1.84 (1.5-2.3)	1.5 (0.9-2.5)	6.1 (3.3-11.4)	6.3 (3.0-13.3)	11.2 (3.8-32.9)
3	2.4 (2.0-3.0)	2.7 (2.1-3.4)	X	8.4 (4.4-16.0)	7.4 (3.2-17.1)	X
4	2.9 (2.4-3.5)	X	X	49.9 (32.5-73.8)	X	X
p-trend	<0.001	<0.001	0.01	<0.001	<0.001	<0.001

* Adjusted for age, sex, race, prevalent coronary heart disease, diabetes, systolic blood pressure, antihypertensivie medication use, current smoking, LDL and HDL cholesterol, and triglycerides

Conclusions: Using multiple markers of kidney function may provide the most accurate prognostic information in the general population. Studies should explore the optimal method for combining information from multiple markers.

Funding: NIDDK Support

A Study of the Association between Cinacalcet Adherence and Biochemical Outcomes Andrew Lee,[1] Vasily Belozeroff,[1] Richard Mutell,[2] T. Christopher Bond,[2] William G. Goodman.[1] *[1]Amgen Inc; [2]DaVita Clinical Research.*

Background: Cinacalcet is used to treat secondary hyperparathyroidism in patients receiving dialysis. As with other oral medications, non-adherence may prevent patients from experiencing the full benefits of therapy.

Methods: This retrospective cohort study of prevalent hemodialysis patients (> 120 d since initial dialysis) in the DaVita Rx and Clinical Data Warehouse assessed the association of cinacalcet adherence with control of serum parathyroid hormone (PTH). The analysis included adult (≥ 18 years old) patients with at least 3 months of data prior to and 12 months (follow up period) after their initial cinacalcet prescription was filled by DaVita Rx between Jan 1 and Dec 31 2009. Patients who had clinically appropriate reasons for discontinuation (eg hypocalcemia, parathyroidectomy, successful kidney transplant) were excluded. Medication possession ratio (MPR) during the follow up period was used to categorize patients by cinacalcet adherence profile as non-adherence (NA): refill gap (RG) ≥ 180 days, low adherence (LA): RG < 180 days and MPR < 0.8, or high adherence (HA): RG < 180 days and MPR ≥ 0.8. Controlled PTH was defined as PTH < 600 pg/ml. We calculated percent of follow up period months with controlled PTH (dependent variable) by adherence category and ran a generalized linear model (GLM) to examine the association while controlling for patient characteristics and co-morbidities.

Results: A total of 2367 patients met the study criteria: 847 NA, 320 LA, and 1200 HA patients. Baseline demographic and clinical characteristics were similar across categories. Percent of months with controlled PTH were higher for HA patients (78.6; SD 28.3) compared to LA (77.1; SD 27.8) and NA (75.3; SD 29.8) patients. Adherence category was statistically significant ($p < 0.001$) in the GLM. When controlled PTH was defined as < 300 or 150-300 pg/ml instead of < 600 pg/ml, the observed patterns persisted but were smaller in magnitude.

Conclusions: Our study suggests that increased adherence to cinacalcet may be associated with improved control of PTH. This is important to consider in light of prior studies linking controlled biomarkers over time with improved survival.

TH-PO264

Comparison of CVD Prevalence between Japanese and American CKD Patients (Collaboration between CKD-JAC and CRIC) Takayuki Hamano,[1] Enyu Imai,[2] Kosaku Nitta,[2] Hirofumi Makino,[2] Akira Hishida,[2] Lisa C. Nessel,[1] Elsayed Z. Soliman,[3] Ana C. Ricardo,[3] Martin J. Schreiber,[3] Dawei Xie,[1] Harold I. Feldman.[1] *[1]Center for Clinical Epidemiology and Biostatistics, University of Pennsylvania, Philadelphia, PA; [2]CKD-JAC Investigators, Japan; [3]CRIC Investigators.*

Background: The DOPPS revealed that the prevalence of cardiovascular disease (CVD) and mortality are much higher in American hemodialysis patients compared to Japanese hemodialysis patients. However, international comparative studies of CVD have not been conducted in predialysis patients with chronic kidney disease (CKD).

Methods: We compared the baseline prevalence of CVD combining the CRIC (Chronic Renal Insufficiency Cohort) and CKD-JAC (CKD-Japanese Cohort) studies, which consisted of 3939 and 2977 patients, respectively.

Results: After adjustment for age, sex, diabetes, and eGFR, the odds ratio (OR)(95% CI) for having prevalent CHF, MI, or stroke for Japanese, compared to American CKD patients, was 0.30(0.24-0.38), 0.40(0.35-0.47), and 1.02(0.85-1.23), respectively. Since the ascertainment processes for CVD at study entry were different between the studies (patient questionnaire in CRIC and medical chart in JAC), we studied the consistency between patient questionnaire and medical record-derived data using a sample of patients in one of the clinical centers of CRIC. Based on these data, we performed multiple imputation for those in CRIC with missing chart-based prevalent CVD as a sensitivity analysis. The ORs for CHF, MI, and stroke comparing Japanese to American study participants were 0.41(0.19-0.90), 0.55(0.40-0.75), and 1.21(0.75-1.94), respectively. With regard to CHF, additional adjustment for HbA_1C or CRP levels eliminated the significance of lower OR for Japanese. However, even extensive adjustment for laboratory data did not eradicate the significantly lower rate of MI in Japanese.

Conclusions: American CKD patients have significantly higher prevalence of CHF and MI compared to their Japanese counterparts and a comparable prevalence of stroke after adjustment for age, sex, diabetes, and eGFR. These data will be the basis for future longitudinal comparisons of incident CVD.

TH-PO265

Differential Response in Serum Potassium, Albuminuria and Blood Pressure to ACEi or ARB Therapy in Individual Type 2 Diabetic Patients Sara S. Roscioni,[1] Dick de Zeeuw,[1] Giuseppe Remuzzi,[2] Philippe J. Vanhille,[3] Hans-Henrik Parving,[4] Hiddo Jan Lambers Heerspink.[1] *[1]Kidney Centre, University Medical Centre Groningen, Netherlands; [2]Mario Negri Institute for Pharmacological Research, Bergamo, Italy; [3]Dept of Nephrology, Hospital Valenciennes, Valenciennes, France; [4]Dept of Endocrinology, Rigshospitalet, Copenhagen, Denmark.*

Background: Treatment with angiotensin-converting enzyme inhibitor (ACEi) or angiotensin II receptor blocker (ARB) reduces blood pressure (BP) and albuminuria (UACR) and increases serum potassium. The BP and UACR reduction affects the renal and cardiovascular (CV) outcome positively while the increase in potassium affects the renal and CV outcome negatively. Determining the net response to these offsetting effects in individual patients may offer unique predictive value for their ultimate renal/CV outcome.

Methods: We conducted a post-hoc analysis in four randomized controlled trials enrolling patients with type 2 diabetes at early (BENEDICT and IRMA-2) and late (RENAAL and IDNT) stage of renal disease. Regression analysis was performed between responses in serum potassium and responses in BP or UACR after 3 months of ACEi or ARB treatment.

Results: ACEi/ARB-induced responses in potassium did not correlate with responses in BP or UACR both in diabetic patients at early and late stage of renal disease (table1). Furthermore, the achieved month 3 potassium levels did not correlate with the respective achieved BP or UACR levels within the same patients (table1). The percentage of patients who developed hyperkalemia was independent of the response in BP or UACR.

Correlations (presented with R^2) between changes in (Δ) potassium and BP/UACR				
	Early stage reanl disease		Late stage renal disease	
	BENEDICT	IRMA-2	RENAAL	IDNT
ΔBP	0.012	0.032	0.000	0.003
ΔUACR	0.002	0.013	0.005	0.004
Correlations between achieved potassium and BP/UACR				
BP	0.001	0.008	0.000	0.003
UACR	0.002	0.014	0.000	0.001

Conclusions: The response in serum potassium to ACEi or ARB therapy does not correlate with the response in BP or UACR. As the response in each of these parameters may affect long-term renal/CV outcome, our data support the need to monitor and optimize the patient response in each parameter to improve long-term renal and CV protection.

TH-PO266

Age Modifies the Prognostic Role of Main Risk Factors for ESRD and Death in Non-Dialysis CKD Patients under Nephrology Care. The TABLE Prospective Cohort Study Luca De Nicola,[1] Paolo Chiodini,[2] Silvio Borrelli,[1] Ciro Gallo,[2] Giuseppe Conte,[1] Roberto Minutolo.[1] *[1]Nephrology, Second University, Naples, Italy; [2]Medical Statistics, Second University, Naples, Italy.*

Background: Prevalence of elderly CKD patients in nephrology clinics is growing. However, how age might affect the prognostic role of the commonly reported risk factors in CKD is undefined.

Methods: We prospectively followed, from 2003 to death or May 2011, 1248 adult patients with CKD stage 3-5 attending 25 Italian outpatient nephrology clinics for ≥12 months before enrolment. Primary endpoints were ESRD and death. We estimated rates of ESRD and death (per 100 patient-year) by age, and tested interactions between age and a number of baseline risk factors (gender, BMI, diabetes [DM], cardiovascular disease [CVD], smoking, systolic blood pressure, hemoglobin, phosphate, cholesterol, uric acid, GFR, 24h proteinuria [Uprot]) in Cox models stratified by center. ESRD was entered as time-dependent covariate when death was assessed.

Results: 481 (38%) patients were less than 65 yrs old, 410 (33%) patients were between 65 and 75 yrs and 357 (29%) patients were over 75 yrs. Within each class, GFR values were equal to 31±15 mL/min/1.73m^2, 32±14, and 29±13, respectively. Rates of ESRD and death were respectively 9.0 (95% confidence interval [CI] 7.8-10.4) and 1.74 (95% CI 1.3-2.3) in <65 yrs, 7.3 (6.1-8.8) and 6.1 (5.1-7.4) in 65-75 yrs, and 7.9 (6.4-9.8) and 14.5 (12.6-16.7) in over 75 yrs. In the final models, age interacted significantly with CVD (P=0.032), GFR (P=0.011), and Uprot (P<0.001) for ESRD risk, and with CVD (P=0.025) and DM (P=0.004) for death risk. Prognostic effect of CVD and DM decreased with older age, while lower GFR and higher Uprot increased the risk of ESRD with advancing age. Male gender, lower BMI, and higher phosphate increased the risk of ESRD independently of age, whereas lower GFR was an independent risk factor for death (P<0.005 for all).

Conclusions: In CKD patients regularly followed in nephrology clinics, age not only is a strong modifier of prognosis but it also selectively changes the prognostic role of other main risk factors. These results may help in identifying the elderly patients at higher risk.

TH-PO267

Prevalent Use of Dietary Supplements Potentially Harmful in Chronic Kidney Disease in the United States Vanessa Grubbs,[1,2] Laura C. Plantinga,[1] Delphine S. Tuot,[1] Elizabeth Hedgeman,[3] Rajiv Saran,[3] Sharon Saydah,[4] Deborah Rolka,[4] Neil R. Powe.[1,2] *[1]University of California, San Francisco; [2]San Francisco General Hospital; [3]University of Michigan; [4]Centers for Disease Control and Prevention.*

Background: The National Kidney Foundation (NKF) identifies 39 herbs that may be harmful in the setting of chronic kidney disease (CKD) (http://www.kidney.org/atoz/content/herbalsupp.cfm), but the prevalent use of such herbs in the U.S. by CKD status is unknown.

Methods: Using 1999-2008 National Health and Nutrition Examination Survey data, we examined the reported use of dietary supplements in the past 30 days among 21,169 non-pregnant adults (age 20+ years). CKD stage 1/2 was defined by urinary albumin:creatinine ratio of ≥30 mg/g with eGFR ≥60 ml/min/1.73 m2 and CKD stage 3/4 by eGFR 15-59 ml/min/1.73 m2. Any dietary supplement containing at least one NKF-identified herb was defined as potentially harmful. The prevalence and odds of taking a potentially harmful supplement by CKD status were estimated via multivariable logistic regression weighted to the U.S. population.

Results: While an estimated 52.4% of participants reported taking any dietary supplement, the supplement was potentially harmful among 15.3%. The crude estimated prevalence of those taking a any dietary supplement increased with greater CKD severity (no CKD 51.4%; CKD stage 1/2 49.1%; CKD stage 3/4 65.8%, p<0.001), but decreased among those taking a potentially harmful supplement (16.1%, 13.0%, and 10.0%, respectively, p<0.001). However, after adjustment for demographics, co-morbid disease, and healthcare visits, CKD status was not a significant determinant of taking any supplement (stage 1/2 0.95, 0.82-1.10; stage 3/4 OR 1.07, 0.93-1.23, vs. no CKD) or a potentially harmful supplement (stage 1/2: OR 0.97, 0.73-1.28; stage 3/4: OR 0.90, 0.67-1.21, vs. no CKD).

Conclusions: The use of dietary supplements potentially harmful in CKD is common and, as use is not statistically different by CKD status, patients with CKD may be unaware of risk. Health care providers, too, may be unaware of potentially harmful supplements and that patients with CKD are taking them. Further research and education are warranted.

Funding: NIDDK Support, Other U.S. Government Support

TH-PO268

Risk Assessment of CKD-EPI Equation Compared with That Based on MDRD Study Equation in the Japanese General Population Masaki Ohsawa. *Department of Hygine and Preventive Medicine, Iwate Medical University, Morioka, Japan.*

Background: Estimated glomerular filtration rate (eGFR ml/min/1.73m^2) calculated by CKD-EPI equation corresponds to the actual measured value more accurately than those estimated by MDRD equation. However, comparative studies between those equations have not been examined based on longtudinal studies in the Japanese general population.

Methods: A prospective cohort study of 25,354 participants was carried out. Participants were divided into ten groups according to eGFR and urinary albumine creatinine ratio (UACR). Sex- and age-adjusted mortality rates (/1000 pys) were calculated using Poisson regression model (see table).

Results: The results are shown in the table.

Numbers of death (crude mortality rates) and sex- and age-adjusted mortality rates (95% CI)

groups stratified by eGFR		eGFR≥90	60≤eGFR<90	45≤eGFR<60	30≤eGFR<45	eGFR<30
estimated by CKD-EPI equation						
subjects (n)		2570	21246	1329	168	41
No. of death (crude mortality)		27 (1.88)	754 (6.34)	112 (15.5)	29 (32.3)	10 (43.3)
adjusted mortality (95%CI)	all subjects	6.92 (4.25-9.58)	3.06 (2.69-3.43)	3.38 (2.57-4.18)	6.18 (3.72-8.64)	9.42 (3.38-15.5)
	ACR<30	4.76 (2.31-7.21)	2.89 (2.51-3.26)	2.96 (2.06-3.87)	4.48 (1.08-7.88)	0.00
	ACR≥30	13.2 (5.38-21.1)	3.74 (3.11-4.38)	4.44 (2.96-5.92)	8.31 (4.49-12.1)	11.7 (4.17-19.2)
estimated by MDRD equation						
subjects (n)		4581	17653	2827	250	43
No. of death (crude mortality)		116 (4.48)	620 (6.28)	151 (9.72)	34 (25.3)	11 (46.6)
adjusted mortality (95%CI)	all subjects	4.14 (3.36-4.92)	3.09 (2.70-3.47)	3.12 (2.49-3.75)	5.91 (3.73-8.09)	10.6 (4.12-17.1)
	ACR<30	3.59 (2.70-4.48)	2.92 (2.53-3.32)	2.74 (2.04-3.43)	4.61 (1.67-7.55)	0.00
	ACR≥30	5.61 (3.98-7.24)	3.72 (3.05-4.39)	4.05 (2.86-5.23)	7.77 (4.30-11.2)	13.0 (5.04-21.0)

Mortality rates are expressed as /1000 person-years.

Conclusions: Classifications by eGFR alone showed undistinguished elevated risks for death among participants with mildly to moderately reduced eGFR (30≤GFR<60) either in estimation by CKD-EPI or estimation by MDRD equation. Combined classification of eGFR and UACR predicted high risks for death among participants with elevated eGFR (GFR≥90) and mildly reduced eGFR (45≤GFR<60), especially in estimation by CKD-EPI equation.

Funding: Government Support - Non-U.S.

The Relationship between Minnesota Code Fndings and CKD: Result from the CKD-JAC Study Satoshi Iimuro,[1] Takeo Okada,[2] Enyu Imai,[2] Kosaku Nitta,[2] Tsuyoshi Watanabe,[2] Seiichi Matsuo,[2] Tadao Akizawa,[2] Hirofumi Makino,[2] Yasuo Ohashi,[1] Akira Hishida.[2] *[1]University of Tokyo, Japan; [2]CKD-JAC Study Group.*

Background: The Japan CKD cohort study (CKD-JAC) was established in September 2007 to prospectively study the renal and cardiovascular outcomes in 2,977 Japanese patients with CKD stage 3-5 visiting 17 outpatient clinics in Japan. To evaluate the electrocardiogram (ECG) findings at enrollment in the study, ECG waveforms obtained from 1,536 patients were analyzed according to the Minnesota Code.

Methods: Two experts independently coded the waveforms using the Minnesota code. In the cases where the two had different opinion in coding a waveform, another expert joined to consult and decide which code to apply. Only the major classification codes and lead information were subjected to the analysis.

Results: Patients' characteristics were: mean age, 61.9 (±11.2) years; diabetes, 41.7%; hypertension, 84.6%; CKD stage 3, 41.8%; CKD stage 4, 41.3% and CKD stage 5, 16.9%. Patients without ECG abnormalities (Code1-0-0) accounted only for 20.2%. The common findings were High Amplitude R waves (16.7%), ST abnormalities (16.5%), and T-wave abnormalities (26.4%). When stratified by CKD stage, these wave abnormalities increased as the CKD stage advanced. When stratified by diabetes, the ratio of ST or T-wave abnormalities increased in patients with diabetes but that of High Amplitude R waves didn't increase. Regarding number of leads, only 1-lead abnormality was most common in patients with High Amplitude R waves (84%). ST or T-wave abnormalities were found more commonly in I, aVL, V5 and V6 leads than in II, III, or aVF lead. Number of leads with abnormal findings tended to increase as CKD stage advanced. On the other hand, the number of leads classified to St or T-wave abnormalities decreased in patients without diabetes but with glomerulonephritis.

Conclusions: In this report, we studied the Minnesota code findings in CKD patients. The findings well reflected CKD stage and patients' characteristics, which suggests that ECGs contain a host of clinical information. This report will be valuable basic data for epidemiologic study.

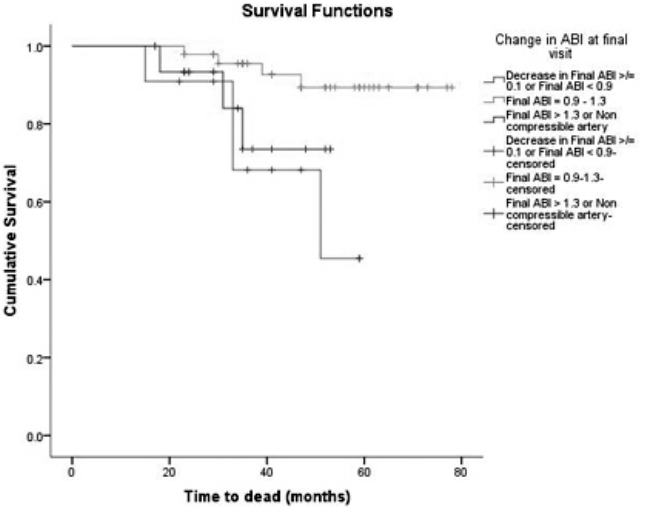
TH-PO270

Change in Ankle-Brachial Indices over Time and Mortality in Diabetics with Proteinuria Sirin Jiwakanon,[1,2] Sharon G. Adler,[1] Rajnish Mehrotra.[1] *[1]Medicine, Los Angeles Biomedical Research Institute at Harbor-UCLA, Torrance, CA; [2]Medicine, Hatyai Hospital, Hatyai, Songkhla, Thailand.*

Background: Peripheral vascular disease is common in diabetic chronic kidney disease (CKD) and is characterized either by abnormally low or high ankle-brachial index (ABI). Whether low or high ABI and the direction of change over time carry similar prognostic value is currently unknown.

Methods: The association of ABI with all-cause mortality over 40 ± 21 months (mean ± SD) was tested in a prospective cohort of 167 individuals with diabetic CKD (age, 57 ± 7 years; median urine protein-creatinine, 2.5 g/g; estimated glomerular filtration rate, 58 ± 23 ml/min/1.73 m2). Association of change in ABI with all-cause mortality was determined in the sub-group of 75 subjects with normal ABI at baseline.

Results: At baseline, 41% had an abnormal ABI:< 0.9, 18%; > 1.3 or non-compressible arteries, 23%. Upon follow-up, 43 subjects died: 0.9-1.3, 18%; < 0.9, 40%; and > 1.3 or non-compressible, 34%. Only individuals with low ABI had a significantly higher risk for all-cause mortality (hazards ratio (95% confidence interval), HR: 2.23 (1.07, 4.65)). In subjects with initially normal ABI, vascular disease worsened over 23 ± 6 months in 39%; 17% had a decrease in ABI by ≥ 0.1 or a final ABI < 0.9, and 21% had a final ABI > 1.3 or non-compressible arteries. Previous cardiovascular disease was the only significant predictor of decline in ABI. Over the subsequent 21 ± 16 months, 15% died. However, only individuals who had a declining had a significantly higher risk for death (adjusted HR, 7.41 (1.63, 33.65)).



Conclusions: Peripheral vascular disease is common and progresses rapidly in proteinuric diabetics. Low or declining ABI is a strong predictor of all-cause mortality. Routine measurement of ABI is a simple bed-side procedure that can permit easy risk-stratification in diabetic CKD patients.

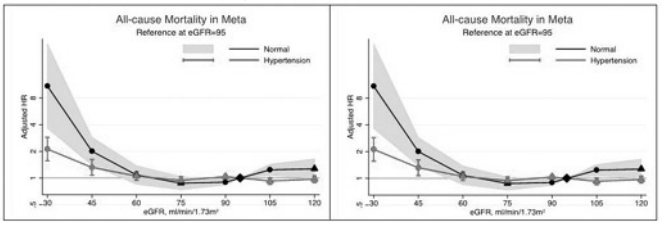
Assessing Interaction on GFR-Risk Association in Meta-Analyses: An Example of Hypertension in the CKD Prognosis Consortium B. Khan Mahmoodi, Kunihiro Matsushita, Yingying Sang, Morgan E. Grams, Brad C. Astor, Mark Woodward, Ron T. Gansevoort, Josef Coresh. *Dep. Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Background: Meta-analysis methods for evaluating interactions are not well described. Assessing interactions with eGFR is particularly challenging due to its non-linear association with risk. We describe methods to evaluate point-wise and overall interactions using an example of hypertension–eGFR interaction on mortality.

Methods: To test the applicability of our methods, we selected nine of 46 cohorts joining CKD Prognosis Consortium. In each study eGFR linear splines (knots at each 15 from 15 to 105 ml/min/1.73m2) and their product terms with hypertension were fitted, providing hazard ratios (HRs) for eGFR (vs. eGFR 95) in both hypertensive and non-hypertensive groups. From this model, the interaction was evaluated as the relative HR (rHR) in hypertension vs. non-hypertension per 1 increment of eGFR from 15 to 120 (point-wise interaction). HRs and rHRs for each eGFR value in each cohort were pooled using random effects models. The overall interaction was assessed as the inverse-variance average of difference in all spline coefficients between hypertensive vs. non-hypertensive groups.

Results: There were 47,893 participants and 7,468 deaths. Low eGFR was associated with increased mortality in the hypertensive (gray line) and non-hypertensive (black line) groups (figure). As depicted by significant rHRs (dashed line), significant interactions by hypertension status were observed at eGFR ranges of 30-40, 85-90, and 100-115. However, the overall interaction was not significant (P=0.44).



Conclusions: We demonstrated meta-analytic methods to assess point-wise and overall interactions in non-linear regression models. Interactions should be tested using both methods and interpreted based on biological and clinical relevance.

Dietary Protein Intake in Chronic Kidney Disease from the National Health and Nutrition Examination Survey Linda W. Moore,[1] Laura Byham-Gray,[2] James S. Parrott,[2] Diane Radler,[2] Stephen L. Jones,[1] Sreedhar A. Mandayam,[3] William E. Mitch,[3] A. Osama Gaber.[1] *[1]Surgery, The Methodist Hospital, Houston, TX; [2]SHRP-Nutrition, UMDNJ, Newark, NJ; [3]Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Dietary protein intake (DPI) is important for metabolic balance and tissue maintenance. Dietary guidelines from the Institute of Medicine (IOM) recommend a DPI that is adequate for 97-98% of the healthy adult population. This amount, 0.8g/kg/day and the estimated average requirement (EAR) 0.66g/kg/day, fulfill their criteria. The Kidney Disease Outcomes Quality Initiative (KDOQI) for Nutrition recommends 0.6-0.75g/kg/day for stage 4 CKD. We evaluated the DPI of people across CKD stages for differences from IOM and KDOQI Guidelines and from DPI of adults without CKD.

Methods: Data from NHANES 2001-2008 were analyzed for the presence of CKD (MDRD formula, staged according to NKF guidelines). DPI was assessed from 24-hr recall, systematically collected by trained interviewers using the Automated Multiple Pass Method. Records from each of the 7 days/week were seasonally obtained. Complex survey analyses were used to report population estimates of CKD, and DPI at each stage of CKD and those who did not have evidence of CKD (NoCKD, no proteinuria, eGFR ≥60).

Results: Of 41,658 NHANES participants, 16,872 (40.5%) were ≥20 years of age and a CKD stage was established. 70% of NoCKD and 60% of stages 1-3 had DPI above the estimated average, while DPI of 50% of those in stages 4&5 (not receiving dialysis) exceeded the KDOQI guidelines. Using DPI of NoCKD as the comparator (mean±SE, 1.34±0.01g/kg/d), lower DPI was reported by adults at stage 2 CKD (1.27±0.03, p=0.0008), stage 3 CKD (1.14±0.2, p<0.0001), and stages 4&5 CKD (not receiving dialysis; 1.04±0.05; p<0.0001). Results from 10% of NoCKD and 20% of stages 2-5 (not yet receiving dialysis) had DPI below IOM or KDOQI Guidelines.

Conclusions: DPI of adults with CKD differed significantly from NoCKD. From stage 2-5 CKD, DPI decreased, but at each stage, the level exceeded IOM or KDOQI Guidelines; only 20% were at risk of eating an inadequate DPI. The majority of adults with or without CKD consume excess protein.

TH-PO273

Screening for Early Impairment of Glomerular Filtration Rate by Means of Urinary Beta-Trace Protein Carlo Donadio, Danika Tognotti, Angeliki Kanaki, Elena Donadio. *Internal Medicine, Nephrology, University of Pisa, Italy.*

Background: The screening for chronic kidney diseases (CKD) patients with impaired GFR needs the measurement of serum creatinine (SCr) or cystatin C (SCys).

Methods: Aim of this study was to evaluate the possibility to screen patients with a GFR < 90 mL/min/1.73 m², by means of serum levels and urinary excretion of different low molecular weight proteins (LMWP), cystatin C (Cys), β2-microglobulin (β2M), retinol-binding protein (RBP), beta-trace protein (BTP), and by means of the derived prediction equations for GFR.

Results: Two hundred ninthy-five adult CKD patients, with various degree of impairment of renal function (SCr 0.40-12.1 mg/dL), were examined.

GFR was measured, with a radio-isotopic method, as the renal clearance of ^{99m}Tc-DTPA.

Creatinine, beta-trace protein, cystatin C, β2-microglobulin, retinol-binding protein, and of urinary albumin were measured with standard laboratory methods.

In the 295 CKD patients (females 137), at all CKD stages, a very high correlation was found between GFR (^{99m}Tc-DTPA), and serum Cr, Cys, β2M, and BTP. All these serum markers showed a similar accuracy as indicators of different GFR impairments. RBP had the lowest correlation with GFR, and was also significantly less accurate. The different prediction formulas derived from gender, anthropometric data and SCr or S-LMWP had a diagnostic accuracy similar to that of serum Cr, Cys, β2M, and BTP. Urinary albumin was inadequate as indicator of any level of GFR impairment. Urinary excretion of Cys and β2M increased significantly only in patients with GFR<30 ml/min/1.73m², while urinary BTP increased already at GFR<90 ml/min/1.73m². In this selected group of CKD patients, the positive predictive value of urinary BTP for GFR<90 ml/min/1.73m² was 85%, indicating that, in CKD patients, a urine-based test can predict a slight GFR impairment.

Conclusions: In conclusion, serum levels of LMWP are not more sensitive or accurate than serum creatinine as indicators of GFR impairment. Urinary BTP had a positive predictive value of 85% for GFR<90 ml/min/1.73m², indicating that, in CKD patients, a urine-based test can predict even a slight GFR impairment.

TH-PO274

Daily Salt Intake Is Associated with Proteinuria and the Systolic Blood Pressure in Japanese Female Patients with Chronic Kidney Disease Hiroshi Morinaga, Hitoshi Sugiyama, Masashi Kitagawa, Keiichi Takiue, Yoko Kikumoto, Ayu Ogawa, Tatsuyuki Inoue, Shinji Kitamura, Shigeru Akagi, Yohei Maeshima, Hirofumi Makino. *Okayama University Graduate School, Okayama, Japan.*

Background: There is a considerable body of literature linking a higher salt intake with higher blood pressure (BP) and increased cardiovascular risk. However, the effects of dietary salt intake on proteinuria, BP and the progression of chronic kidney disease (CKD) are still uncertain. Moreover, few studies have based their assessments on 24 hour urinary sodium excretion, which is the most accurate method for assessing salt intake.

Methods: A total of 159 Japanese outpatients with CKD (mean age: 54 years, males: 50.3%, chronic glomerulonephritis: 60.4%) who underwent 24 hour urine collection in 2007 were enrolled and retrospectively followed-up until 2010. Their baseline salt intake was estimated by the measurement of urinary sodium excretion in 24 hour pooled urine. The predictors for either the doubling of serum creatinine or the introduction of renal replacement therapy were determined.

Results: The median follow-up period was 36 months, during which time, 16 patients reached the renal composite endpoint (10.1%). A significant correlation between the baseline systolic BP and estimated daily salt intake was detected in both all individuals (r=0.260; P<0.01) and in female subjects (r=0.331; P<0.01). A similar correlation was found between common logarithm of the baseline urine protein excretion and daily salt intake in the total (r=0.184; P<0.05) and in the female (r=0.277; P<0.05) subjects. In the Cox regression analysis, the daily salt intake was independently associated with the endpoint, but the risk was not independent of the urinary protein excretion.

Conclusions: In patients with CKD, salt intake was found to be significantly associated with higher systolic BP and proteinuria, especially in female subjects, and it was also associated with renal dysfunction. These findings indicate that salt restriction may have a beneficial effect on BP, proteinuria and the renal outcome in CKD patients. Prospective trials should be performed to confirm the effect of sodium restriction on such patients.

TH-PO275

Initial Reduction in Albuminuria Should Be Sustained over Time To Achieve Optimal Renoprotection Frank Holtkamp,[1] Tineke M. Kats,[1] Zhongxin Zhang,[2] Shahnaz Shahinfar,[3] Dick de Zeeuw,[1] Hiddo Jan Lambers Heerspink.[1] *[1]University Medical Center, Groningen, Netherlands; [2]J&J Pharmaceutical R&D, NJ; [3]Children Hospital Philadelphia, PA.*

Background: Previous studies have shown that the initial reduction in albuminuria during Angiotensin Receptor Blocker therapy partly explains long-term renal protection. However, part of the long-term renal risk remains unexplained, possibly because initial reduction in albuminuria is not always sustained over time. We aimed to assess whether total exposure to albuminuria over time is a better determinant of renal risk.

Methods: A post-hoc analysis in the RENAAL trial was performed. Albuminuria (albumin:creatinine ratio) exposure from month 6 to end of follow-up was assessed by area under the albuminuria curve (AUC) for each subject using the trapezoidal rule. C-statistics compared the predictive performance for End Stage Renal Disease (ESRD) of month 6 albuminuria and total albuminuria exposure from month 6. In addition, subjects who had a reduction in albuminuria ≥ 30% from baseline to month 6 were divided in those in whom reduction was sustained until the end of follow-up and those in whom the reduction was not sustained. Multivariate adjusted Cox regression analysis was applied to compare the risk for ESRD between these two groups.

Results: Subjects who showed a sustained reduction in albuminuria ≥ 30% from month 6 until the end of follow-up had a 55% (95%CI 65 to 14; p=0.010) lower risk for ESRD compared to subjects without a sustained reduction. These data suggest that total albuminuria exposure may be a better indicator of long-term renal risk. Indeed, the C-statistic of the albuminuria AUC from month 6 until the end of treatment was significantly higher (0.84 (0.81-0.87)) than month 6 albuminuria (0.81 (0.78-0.84; p<0.001)).

Conclusions: The overall reduction in albuminuria over time is a better indicator of long-term renal risk than the initial reduction in albuminuria alone. These data imply that one should strive to sustain the initial albuminuria reduction over time in order to optimize long-term renal protection.

TH-PO276

Metabolic Phenotypes Associate with Kidney Function and Chronic Kidney Disease in the General Population Oemer Necmi Goek,[1] Jerzy Adamski,[2] Christian Gieger,[3] Margit Heier,[3] Thomas Illig,[3] Wolfgang Koenig,[4] Timothy D. Spector,[5] Karsten Suhre,[6] Guangju Zhai,[5,7] Anna Kottgen,[1] Christa Meisinger.[3] *[1]University of Freiburg; [2]Genome Analysis Center, Helmholtz Zentrum München; [3]Helmholtz Zentrum München; [4]University of Ulm; [5]King's College London; [6]Weill Cornell Medical College in Qatar, Doha; [7]Faculty of Medicine, Memorial University of Newfoundland.*

Background: Metabolites such as creatinine are established kidney function markers. High-throughput metabolic profiling in large general population studies spanning normal kidney function and chronic kidney disease (CKD) has not been undertaken.

Methods: 151 metabolites were quantified by mass spectrometry in serum from 3,011 KORA F4 study participants. Glomerular filtration rate (eGFR) was estimated separately from cystatin C and creatinine using CKD-EPI equations and related to metabolic phenotypes (metabolites and their 22,650 ratios) by multivariable-adjusted linear regression and corrected for multiple testing. Phenotypes associated with eGFR (p<3.3*10-4 for metabolites and p<2.2*10-6 for ratios) were validated and meta-analyzed with an independent general-population sample, the TwinsUK study (n=984). Replicated phenotypes were related to CKD in KORA F4 (eGFR <60 ml/min/1.73m²; n=172).

Results: Reproducible associations with eGFR were observed for 24 metabolites and 431 ratios. P-values ranged from 1.8*10-3 to 9.6*10-64 for replicated metabolites: acylcarnitines such as glutarylcarnitine were inversely associated with eGFR (-3.4 ml/min/1.73m² per standard deviation (SD), p=9.6*10-64). For replicated ratios, p-values ranged from 1.0*10-6 to 4.6*10-69; many contained amino acids such as serine. Over 98% of replicated phenotypes associated with CKD (p<0.05): per SD increment, odds ratios ranged from 0.35 (phosphatidylcholine diacyl C38-3/glutarylcarnitine, p=1.4*10-14) to 1.90 (decenoylcarnitine/serine, p=8.9*10-16).

Conclusions: Distinct metabolic phenotypes are reproducibly associated with eGFR and CKD, reflecting altered metabolite clearance, synthesis or conversion. Longitudinal studies should clarify whether changes in metabolic phenotypes precede or result from kidney function impairment.

Funding: Government Support - Non-U.S.

CKD Progression Depends upon Degree of Proteinuria but Not Blood Pressure or Serum Bicarbonate Levels in Stage 3 and 4 CKD Patients

Jennifer L. Ennis,[1] Elaine M. Worcester.[2] *[1]Litholink Corporation, Chicago, IL; [2]Section of Nephrology, University of Chicago, IL.*

Background: In several large prospective studies, proteinuria, blood pressure (BP), and serum bicarbonate (CO2) were associated with a more rapid decline in renal function in CKD patients. We sought to confirm these relationships in a cohort of unselected CKD patients from a variety of US primary care and nephrology practices.

Methods: We performed a retrospective analysis of longitudinal data collected on 1721 stage 3 (n=1194) and stage 4 (n=527) US CKD patients enrolled in the Litholink CKD program, a national laboratory based CKD management service. Presence of proteinuria (n=790) was defined as albumin:creatinine ratio >30 µg/mg or protein:creatinine ratio >200 mg/g at enrollment. We excluded patients with a follow-up period of 50 days or less.

Results: In a mean follow-up period of 184 and 182 days, respectively, patients with proteinuria had a mean fall in eGFR of 1.2 ± 0.3 ml/min/1.73m^2, while patients without proteinuria had a mean rise in eGFR of 1.7 ± 0.3 ml/min/1.73m^2. Within stage, significant differences between proteinurics and non-proteinurics remained. For both groups, patients in stage 3 had mean decline in eGFR of 1.1 ml/min//1.73m, while stage 4 patients had mean increase in eGFR of 1.5 ml/min/1.73m^2 In a general linear model with change in eGFR as the dependent variable, and presence of proteinuria, CKD stage, and the cross product of proteinuria with CKD stage as independent variables, presence of proteinuria and CKD stage were both significant predictors of change in eGFR ($p<0.001$). The cross product was not significant. Initial CO2, initial BP, final BP, and gender did not enter the model.

Conclusions: In this cohort of unselected, US stage 3 and 4 CKD patients, eGFR fell more rapidly in patients with proteinuria than in those without proteinuria. BP and CO2 levels were not predictive factors for eGFR decline in this cohort during this short follow-up period. For both groups, stage 4 patients had slight improvement in mean eGFR during the follow up period when compared to stage 3 patients. Reasons for this are presently unclear and warrant further study.

TH-PO278

Nationwide Survey of Familial Juvenile Hyperuricemic Nephropathy (FJHN) Caused by UMOD Mutations

Peter Kotanko,[1] Sian Piret,[2] Gere Sunder-Plassmann,[3] Rajesh V. Thakker,[2] Karl Lhotta.[4, 5] *[1]Renal Research Institute, New York, NY; [2]Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, United Kingdom; [3]Div. of Nephrology & Dialysis, Medical Univ. Vienna, Vienna, Austria; [4]Dept Nephrology & Dialysis, Academic Teaching Hospital, Feldkirch, Austria; [5]Vorarlberg Inst. for Vascular Investigation & Treatment, Feldkirch, Austria.*

Background: FJHN is an autosomal dominant (AD) disease, caused by uromodulin (UMOD) mutations in 40% of patients. FJHN leads to end-stage renal disease (ESRD). This study examines FJHN epidemiology on a nationwide basis.

Methods: All Austrian dialysis and transplant patients are documented in a nationwide database. Following a database query in 2001, patients with unclear renal diagnoses or genetic diseases were asked whether they had (a) family members with kidney disease, and (b) gout. A detailed family history was obtained in patients who provided 2 affirmative answers; if this was suggestive for FJHN, UMOD was genotyped. In addition, data from all Austrian FJHN families known in 2010 were collected. Cox analysis was employed to test for a relationship between UMOD genotype and progression to ESRD.

Results: Based on the database query in 2001, 541 out of 6210 patients were asked to participate in the questionnaire; 19 out of 353 responders gave 2 affirmative answers. A nephropathy compatible with FJHN was present in 7 of them; in 1 patient an UMOD mutation was identified. Independent of the screening project, 4 families were diagnosed on clinical grounds with FJHN due to UMOD mutations. In 2010, 17 FJHN patients from 5 families with UMOD mutations lived in Austria (2.0 per million population), 6 of them require renal replacement therapy (0.73 per 1000 patients).

Progression to ESRD was significantly different for patients with different UMOD mutations.

Conclusions: This first nationwide survey of FJHN caused by UMOD mutations demonstrates its infrequency. FJHN patients in the ESRD population can be identified by a simple questionnaire and a subsequent focused family history. Our data indicate that UMOD genotype may modify renal disease progression.

TH-PO279

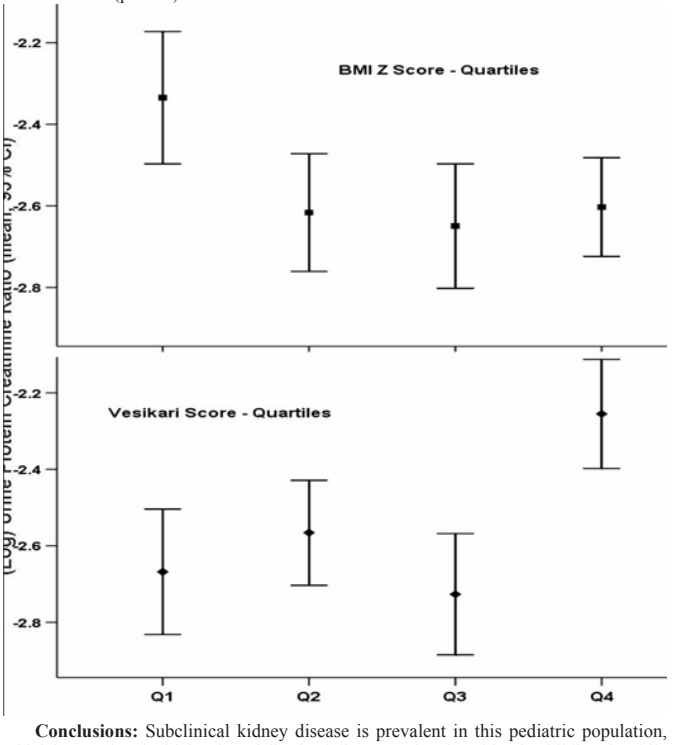
Enteric Infections Are a Risk Factor for Subclinical Proteinuria in Childhood

Lucy E. Horton,[1] Gagandeep Gagandeep Kang,[2] Madhumathi Rao.[3] *[1]Tufts University School of Medicine, Boston, MA; [2]Department of Gastrointestinal Sciences, Christian Medical College, Vellore, Tamil Nadu, India; [3]Division of Nephrology, Tufts Medical Center, Boston, MA.*

Background: India is currently facing an epidemic of chronic kidney disease (CKD), that affects a younger demographic than in the West. The 'hygiene hypothesis' suggests that chronic antigenic stimulation from the environment could generate a low grade nephritogenic immune complex response and increase risk for CKD. We hypothesize that recurrent diarrheal infections and gut antigen exposure in infancy, together with malnutrition, may be a risk factor for CKD in later life.

Methods: We studied a birth cohort of 305 children from an urban slum in South India for enteric infections and nutritional status, from birth (2002) until age 3. At age 7-8 years (2010) we measured anthropometry, blood pressure (BP) and urinary protein creatinine ratio (UPCR). Linear regression was used to determine the association of UPCR with BMI Z-score and severity of diarrhea (measured by Vesikari score).

Results: At age 7-8 years, 30% were underweight, 9% stunted and 92.5% had experienced one or more episodes of diarrhea in infancy (median, IQR 4, 2-7episodes). Proteinuria (UPCR >200) was seen in 8%, and 13% had elevated BP (>90th% systolic BP for age-and-height). Severity of diarrhea, current malnutrition (BMI Z-score) and decreased growth velocity from age 3-7 (change in BMI Z-score) were independent predictors of current UPCR ($p<0.05$).



Conclusions: Subclinical kidney disease is prevalent in this pediatric population, which is associated with burden of diarrheal disease and malnutrition in childhood. While a causal relationship cannot be inferred, public health interventions to reduce the risk of childhood diarrhea may help mitigate adult CKD burden.

Cystatin C Predicts End-Stage Renal Disease Better Than Iothalamate GFR in Patients with Macroalbuminuria and Type 2 Diabetes

Meda E. Pavkov,[1] William Knowler,[2] Robert G. Nelson.[2] *[1]Division of Diabetes Translation, Centers for Disease Control, Atlanta, GA; [2]National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Phoenix, AZ.*

Background: We compared the predictive values of cystatin C (cysC), serum creatinine (SCr), and iothalamate GFR (iGFR) for diabetic end-stage renal disease (ESRD) in patients with type 2 diabetes and macroalbuminuria.

Methods: Individuals were followed from their first diabetic examination with macroalbuminuria (ACR ≥300 mg/g) until December 2010, onset of ESRD, or death,

whichever came first. Incidence rate ratios (IRR) adjusted for age, sex, and diabetes duration were computed by Mantel-Haenszel stratification. The ability of these variables to predict ESRD was compared with receiver operating characteristic (ROC) curves calculated from Cox regression models that included age, sex, diabetes duration, height, weight, HbA1c, ACR and the relevant markers.

Results: 142 Pima Indians with a median age of 44.9 years (range 25.5-67.8 years) were followed for a median of 8.9 years (range 1.5-21.0 years). ESRD developed in 63 subjects. ESRD incidence was significantly higher among patients in the lowest vs. highest tertiles of 1/cysC and iGFR (IRR for 1/cysC=3.5, 95%CI 1.7-7.4; IRR for iGFR=2.4, 95%CI 1.2-4.9), but did not differ significantly for 1/SCr (IRR=1.5, 95%CI 0.8-2.6). The model including all three filtration markers had the highest AUC, but its AUC was indistinguishable from the model with 1/cysC alone. By contrast, models with 1/SCr or iGFR alone had significantly lower AUCs than either the full model or the model with 1/cysC alone.

Conclusions: CysC was a better predictor of diabetic ESRD than either SCr or iGFR in Pima Indians with type 2 diabetes and macroalbuminuria.

Funding: Other U.S. Government Support

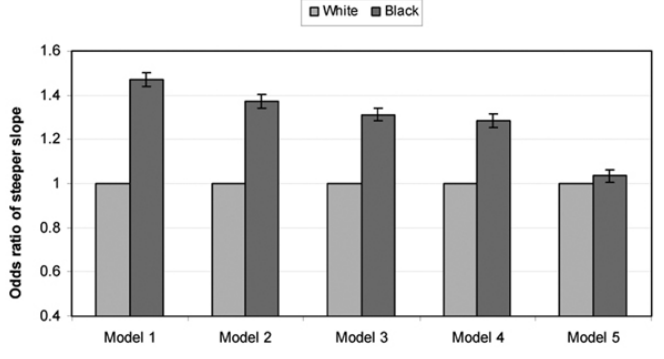
TH-PO281

Black Race Is Associated with Significantly Steeper Decline in Glomerular Filtration Rate (GFR) in a Large Cohort of US Veterans with Non-Dialysis Dependent CKD Csaba P. Kovesdy,[1,2] Evan H. Lott,[3] Jun Ling Lu,[4] Sandra M. Malakauskas,[1,2] Jennie Z. Ma,[2] Mark D. Okusa,[2] Kamyar Kalantar-Zadeh.[5] *[1]Salem VA Medical Center; [2]University of Virginia; [3]VA Informatics and Computing Infrastructure; [4]Salem Research Institute; [5]Harbor UCLA.*

Background: The high prevalence of blacks among patients with ESRD could be due to race-specific differences in the progression of CKD. Causes of faster progression of CKD in blacks with CKD need to be better characterized.

Methods: We compared slopes of eGFR in 48,692 blacks and 422,074 whites in a nationally representative cohort of US veterans with CKD stages 1-4 in 2005-2006. Slopes were calculated using a median (interquartile range) of 8 (5-13) eGFR values over up to 5 years. Unadjusted associations (Model 1) of black race with the odds of steeper slopes (defined as slopes <-4 ml/min/1.73m^2/year) were examined in logistic regression models. The effects of sociodemographic characteristics (Model 2), comorbidities (Model 3), blood pressure (Model 4) and laboratory variables (Model 5) on racial differences in the slopes of eGFR were explored in multivariable models.

Results: Blacks were younger, more likely to have diabetes, and had higher blood pressure, lower bicarbonate and hemoglobin, and higher cholesterol. The median (IQR) of eGFR slopes in blacks was -1.38 ml/min/1.73m^2/year (-4.32, 1.14) and in whites was -0.88 (-3.30, 1.27), p<0.001. Black race was associated with steeper slopes (crude odds ratio (95%CI): 1.47 (1.44-1.50), p<0.001). Adjustments lead to substantial attenuation in this association (Figure).



Conclusions: Black race is associated with steeper slopes of eGFR in patients with CKD. Most of this difference is explained by identifiable risk factors of progressive CKD. The effect of race-specific interventions to slow CKD progression in blacks needs to be tested in clinical trials.

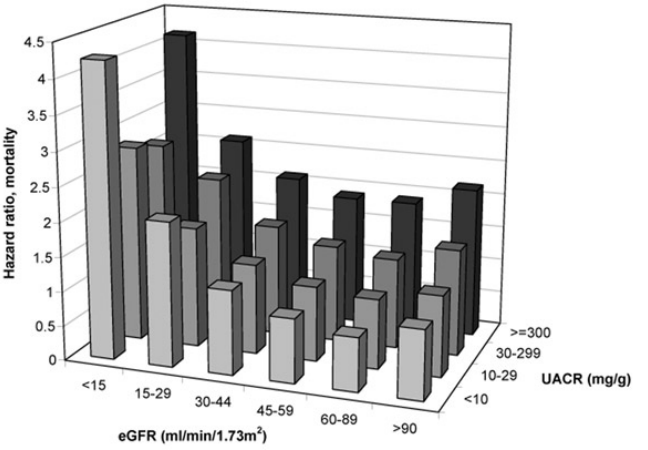
TH-PO282

CKD Stage Modifies the Association of Urine Microalbumin-Creatinine Ratio (UACR) with Mortality in a Large Cohort of US Veterans Csaba P. Kovesdy,[1,2] Evan H. Lott,[3] Jun Ling Lu,[4] Sandra M. Malakauskas,[1,2] Jennie Z. Ma,[2] Mark D. Okusa,[2] Kamyar Kalantar-Zadeh.[5] *[1]Salem VA Medical Center; [2]University of Virginia; [3]VA Informatics and Computing Infrastructure; [4]Salem Research Institute; [5]Harbor-UCLA.*

Background: The association of albuminuria with mortality in patients with various stages of CKD is not well characterized.

Methods: We examined the association of UACR with all-cause mortality in a nationally representative cohort of 298,779 US veterans with eGFR >15 ml/min/1.73m^2 in 2005-2006. Associations of UACR with all-cause mortality overall and stratified by CKD stages were examined in Cox models. Models were adjusted for sociodemographics, comorbidities, blood pressure and laboratory variables.

Results: Patients were 65.4±11.5 years old, 97% were males and 64% were white. Patients with higher UACR were older and had a higher prevalence of diabetes and cardiovascular disease. During a median follow-up of 5.0 years a total of 49,802 patients died (mortality rate, 95% confidence interval [CI]: 35.5/1000 patient-years, 35.2-35.8). A 1-unit increment in UACR on natural-log scale was associated with a crude mortality hazard ratio (95%CI) of 1.31 (1.30-1.32) p<0.001, which remained significant after multivariable adjustments (1.09, 1.08-1.10 p<0.001). The association of higher UACR with mortality was linearly incremental in patients with eGFR≥30 ml/min/1.73m^2, whereas in patients with eGFR<30 ml/min/1.73m^2 this association appeared U-shaped (Figure).



Conclusions: Higher UACR is independently associated with increased all-cause mortality. This association incremental in patients with eGFR≥30 and U-shaped in patients with eGFR <30. Interventions targeting proteinuria-lowering as a means to improve survival in patients with CKD should consider CKD stage as a potential effect modifier.

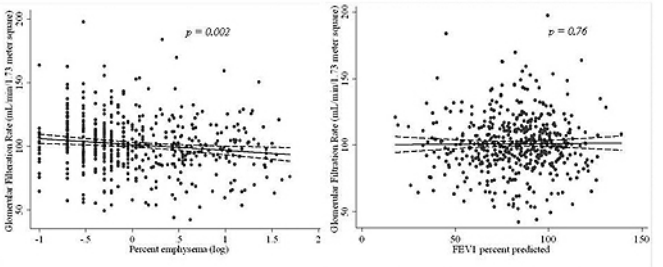
TH-PO283

The Relationship between Pulmonary Emphysema and Kidney Function in Smokers Divay Chandra, Jason Stamm, Yingze Zhang, Sheldon Bastacky, Mark T. Gladwin, Paul M. Palevsky, Frank Sciurba. *University of Pittsburgh Medical Center.*

Background: Kidney disease is prevalent in patients with COPD. We hypothesized that kidney dysfunction would associate with emphysema rather than with airway obstruction in patients with COPD, and the association would be independent of common risk factors for kidney disease.

Methods: 508 participants with >10 pack year smoking history completed a chest CT scan, pulmonary function tests, and measurement of serum creatinine. Glomerular filtration rates (eGFR) were estimated using the method of the Chronic Kidney Disease Epidemiology Collaboration. Severity of emphysema was determined by density mask examination the chest CT.

Results: Mean age of the 508 participants was 66 ± 7 years and mean eGFR 101 ± 22 ml/min/1.73m^2. Percent emphysema was a significant univariate predictor of eGFR: each 10% increase in emphysema was associated with 3.7 mL/min/1.73 meter^2 decline in eGFR (p=0.002), unlike FEV_1 which was not a significant predictor.



The association between emphysema and eGFR was also present on multivariate analysis: each 10% increase in emphysema was associated with a 4.4 ml/min/1.73 meter^2 decline in eGFR (p = 0.007) independent of airflow obstruction (FEV_1), age, gender, diabetes mellitus, hypertension, coronary artery disease, patient reported dyspnea, and pack-years of smoking.

Conclusions: Worsening emphysema, rather than airflow obstruction, predicts kidney dysfunction in patients with COPD, independent of common risk factors for kidney disease. In smokers with kidney dysfunction undetected emphysema may be contributing to diminished exercise capacity and quality of life. This is the first description of a possible emphysema – kidney injury phenotype; further investigation of shared molecular and mechanistic links between emphysema and kidney dysfunction is needed.

Apolipoprotein L1 (*APOL1*) Nephropathy Risk Variants Associate with HDL Subfraction Concentration in African Americans Barry I. Freedman,[1] Carl D. Langefeld,[2] Mariana Murea,[1] Lijun Ma,[1] James D. Otvos,[5] Jolyn Turner,[1] Peter A. Antinozzi,[3] Michael V. Rocco,[1] John S. Parks.[3,4] *[1]Department of Internal Medicine-Nephrology, Wake Forest School of Medicine, Winston-Salem, NC; [2]Division of Public Health Sciences, Wake Forest School of Medicine; [3]Department of Biochemistry, Wake Forest School of Medicine; [4]Department of Pathology-Lipid Sciences, Wake Forest School of Medicine; [5]Liposcience, Ltd, Raleigh, NC.*

Background: Coding variants in the *APOL1* gene (G1: rs73885319, rs60910145 and G2: rs71785313) are strongly associated with non-diabetic etiologies of nephropathy in African Americans. ApoL1 proteins associate with HDL particles in the circulation.

Methods: We compared plasma HDL particle subclass concentrations in 73 African Americans based on their *APOL1* genotypes to detect differences that could potentially contribute to kidney disease. These individuals were first-degree relatives of patients with non-diabetic end-stage renal disease (ESRD). HDL subclass concentrations were measured using nuclear magnetic resonance spectroscopy. Participants had estimated glomerular filtration rates (eGFR) > 80 ml/min and lacked albuminuria. Additive effects of the number of *APOL1* risk variants on natural logarithm transformed HDL subclass concentrations were computed. Analyses were performed unadjusted and after adjustment for log serum triglyceride concentration.

Results: Participants were 58.9% female with mean ± SD age 47.2 ± 13.3 years and eGFR 92.4 ± 18.8 ml/min. The numbers with 2, 1, and 0 *APOL1* nephropathy risk variants, respectively, were 36, 17, and 20. Mean ± SD medium-sized HDL concentrations were significantly lower for each additional *APOL1* risk allele (2 vs.1 vs. 0 risk alleles: 9.0 ± 5.6 vs. 10.1 ± 5.5 vs.13.1 ± 8.2 µmol/L, respectively; p=0.0192 unadjusted; p=0.0190 triglyceride-adjusted).

Conclusions: Lower medium-sized HDL subclass concentrations are present in African Americans based on increasing numbers of *APOL1* nephropathy risk alleles. Mechanistic roles for altered medium HDL concentrations on susceptibility to *APOL1*-associated renal microvascular diseases should be evaluated.

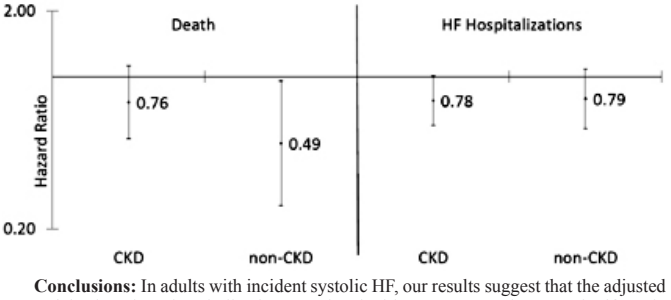
β-Blockers and Outcomes in Systolic Heart Failure with Chronic Kidney Disease Tara I. Chang,[1] Jingrong Yang,[2] James Freeman,[1] Alan S. Go.[2] *[1]Stanford University; [2]Kaiser Permanente.*

Background: There are few data regarding the effectiveness and safety of oral β-blockers (BBs) in patients with systolic heart failure (HF) complicated by chronic kidney disease (CKD).

Methods: We identified 1241 adults in Kaiser Permanente of Northern California with incident clinical HF and reduced left ventricular (LV) function between 2006-2008. We excluded patients with baseline BB use or prior dialysis. Using outpatient serum creatinine values during the year before or on the index date, we classified patients as having CKD if estimated glomerular filtration rate (eGFR) <60 mL/min per 1.73 m2 (n=627). Patients were followed for incident BB use and the outcomes of all-cause death and HF hospitalization through 8/31/10 identified from health plan databases. We analyzed the association of time-varying new BB use with outcomes using extended Cox regression, with adjustment for age, sex, race, smoking, body mass index, systolic blood pressure, LV function, diabetes, cardiovascular disease and other comorbidities, medications, and hemoglobin.

Results: Over a median follow-up of 2.4 years, 75% of patients had new BB use. Compared to patients without CKD, patients with CKD had higher annual rates (per 100 person-years) of death (7.5 vs. 17.1) and HF hospitalization (19.3 vs. 31.7). The Figure shows adjusted hazard ratios (95% confidence intervals) associated with BB use in patients with and without CKD in the setting of systolic HF.



Conclusions: In adults with incident systolic HF, our results suggest that the adjusted rates of death and HF hospitalization associated with new BB use does not significantly vary by CKD status. Given their higher event rates, patients with CKD would gain greater absolute benefits from medications that reduce their risks. Overall, our analysis supports the use of BBs in eligible patients with systolic HF and CKD.

Rural and Micropolitan Disparities in the Quality of Care Prior to Initiation of Renal Replacement Therapy Saugar Maripuri, Talat Alp Ikizler, Kerri L. Cavanaugh. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Pre-ESRD care is associated with improved outcomes on dialysis. It is unknown how rural or micropolitan residence affects the achievement of recommended pre-ESRD care.

Methods: A cross-sectional study was performed utilizing data from the US Renal Data System (USRDS). Patients >18 years of age who initiated renal replacement therapy (RRT) between 1/2006 and 12/2006 were included and classified as rural, micropolitan, or urban based on ZIP code specific rural urban commuting codes. Outcomes of interest included the following prior to initiation of RRT: nephrology referral >12 months prior, permanent vascular access placement (AVF or AVG) in patients choosing hemodialysis, erythropoietin use in moderate to severe anemia (hemoglobin <9.0 g/L), dietary education, and pre-emptive transplant listing. The likelihood of achieving each outcome was estimated using Poisson multivariate regression with robust variances while adjusting for demographic factors, socioeconomic status, medical co-morbidities, and other potential confounders.

Results: Of 102,700 patients included in analysis, 10.2% were micropolitan and 9.9% were rural. Rural and micropolitan patients were older, less racially diverse, had more medical co-morbidities, and more likely to choose peritoneal dialysis compared to urban patients. After adjustment, rural patients were modestly more likely to have early referral to a nephrologist (RR 1.04 CI 1.01-1.08) compared to urban patients. Despite this, both micropolitan and rural patients were significantly less likely to have received dietary education (RR 0.85 CI 0.79-0.91 and RR 0.85 CI 0.80-0.91, respectively) and erythropoietin in the setting of moderate to severe anemia (RR 0.89 CI 0.82-0.97 and RR 0.91 CI 0.83-0.98, respectively). There were no significant differences in the likelihood of permanent vascular access placement or pre-emptive transplant listing.

Conclusions: Non-urban residence is associated with less erythropoietin use in anemic patients and lower likelihood of dietary education prior to the initiation of RRT, despite timely nephrology referral. Non-urban living may be associated with worse pre-ESRD care.

TH-PO287

Rural and Micropolitan Disparities in Dialysis Mortality and Likelihood of Kidney Transplantation Saugar Maripuri, Talat Alp Ikizler, Kerri L. Cavanaugh. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Rural and micropolitan dialysis patients face unique challenges when initiating renal replacement therapy (RRT), including barriers to healthcare access. It is not known if such barriers increase risk for mortality or decrease likelihood of kidney transplantation among rural and micropolitan patients.

Methods: A retrospective cohort study was performed utilizing data from the US Renal Data System (USRDS). Patients >18 years of age who initiated RRT between 1/2006 and 12/2006 were included and classified as rural, micropolitan, or urban based on ZIP code specific rural urban commuting codes. Outcomes of interest included time to death >90 days after initiation, time to wait-listing for kidney transplant, and time to kidney transplantation. Censoring was determined at loss to follow-up or 10/1/2009. Cox proportional hazard regression models were created for each outcome while adjusting for demographic factors, socioeconomic status, medical co-morbidities, eGFR at initiation, dialysis modality, achieved pre-ESRD care, and other potential confounders.

Results: Of 93,148 patients included for analysis, 10.1% were micropolitan and 9.8% were rural. During follow-up, 44.5% and 6.8% of patients either died or where transplanted. An interaction between dialysis modality and degree of rurality (p value 0.001) was observed. Rural and micropolitan peritoneal dialysis (PD) patients were more likely to die on dialysis (HR 1.16 CI 1.02-1.32 and HR 1.29 CI 1.12-1.49, respectively) compared to urban PD patients. Mortality for hemodialysis patients was similar across geographic strata. There was no difference in the likelihood of wait-listing for transplant, but rural and micropolitan patients were more likely to be transplanted (LR 1.21 CI 1.09-1.34 and LR 1.12 CI 1.01-1.23, respectively) compared to urban patients.

Conclusions: For patients who initiate RRT, non-urban residence is associated with increased risk for mortality among patients on PD. However, non-urban patients appear more likely to undergo kidney transplantation. Observed relationships persisted after adjustment for achieved pre-ESRD care.

Funding: NIDDK Support

TH-PO288

Achieved Pre-ESRD Care Is Associated with Greater Likelihood of Kidney Transplantation Saugar Maripuri, Talat Alp Ikizler, Kerri L. Cavanaugh. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Small studies have shown that planning for the initiation of renal replacement therapy (RRT), also known as pre-ESRD care, is associated with decreased mortality on maintenance dialysis. Little is known of the impact of pre-ESRD care on the likelihood of kidney transplantation.

Methods: A retrospective cohort study was performed utilizing data from the US Renal Data System (USRDS). Patients >18 years of age who initiated RRT between 1/2006 and 12/2006 were included. Patients deemed unsuitable for transplant were excluded. Each subject was assessed for the following prior to initiation of RRT: nephrology referral >12 months prior, permanent vascular access placement (AVF or AVG), dietician referral, and pre-emptive transplant listing. Outcomes of interest included incidence of wait-listing

and kidney transplantation. Censoring was determined at loss to follow-up or 10/1/2009. Poisson regression was performed with adjustment for demographic factors, socioeconomic status, medical co-morbidities, kidney function (eGFR) at initiation, and other potential confounders.

Results: 87,294 patients were included for analysis. The overall transplantation rate was 3.91 per 100 ESRD patient-years. After adjustment, early nephrology referral (IRR 1.23 CI 1.18-1.29), permanent access placement (IRR 1.20 CI 1.14-1.26), and dietary referral (IRR 1.19 CI 1.13-1.26) were associated with increased likelihood of wait-listing. Early nephrology referral (IRR 1.27 CI 1.20-1.34), dietary referral (IRR 1.20 CI 1.12-1.29), and pre-emptive listing (3.92 CI 3.65-4.20) were associated with greater likelihood of kidney transplantation. Patients who were listed for transplant within 90 days of RRT initiation were significantly less likely to be transplanted (IRR 0.91 0.82-0.99) compared to those who were pre-emptively listed prior to ESRD.

Conclusions: Achieved pre-ESRD care is associated with increased likelihood of kidney transplantation after initiation of RRT. Listing prior to onset of ESRD significantly increases the likelihood of transplantation, even when compared to patients listed shortly after initiation of RRT.

Life Expectancy of Chinese Patients with Chronic Kidney Disease without Dialysis Chi-Bon Leung, Cheuk-Chun Szeto, Bonnie Kwan, Kai Ming Chow, Philip K.T. Li. *Department of Medicine, Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong.*

Background: Long term dialysis is life-saving for patients with end stage renal disease (ESRD). However, in ESRD patients with multiple comorbid conditions, dialysis may actually be futile, and conservative management is advisable. We studied the life expectancy of Chinese ESRD patients treated conservatively.

Methods: We reviewed 63 consecutive ESRD patients who were treated conservatively in our center. Duration of survival was computed from the date of initial assessment for dialysis, as well as the expected date of needing dialysis based on previous trend of renal function decline.

Results: At the end of the observation period, 55 patients died. Twelve patients died before the expected date of needing dialysis because of unrelated reasons, while 36 deaths were directly attributed to uremia. The median overall survival after initial assessment for dialysis was 41.3 months (95% confidence interval [CI], 33.2 to 49.4 months). The median overall survival was 4.43 months (inter-quartile range, -4.80 to 8.85 months) from the expected date of needing dialysis. The survival from the expected date of needing dialysis did not correlate with patient age, sex, diabetic status, or baseline renal function.

Conclusions: In Chinese ESRD patients treated conservatively, the median survival is around 4 months after the expected date of needing dialysis. Our result provides an important piece of information for the decision of dialysis and patient counseling.

TH-PO290

Different Impacts of Pulse Pressure on Proteinuria or Low eGFR between Diabetic and Non-Diabetic Populations Yuji Sato,[1] Yuichiro Yano,[1] Shouichi Fujimoto,[2] Tsuneo Konta,[2] Tsuyoshi Watanabe.[2] *[1]Internal Medicine, University of Miyazaki, Japan; [2]Steering Committee for the Examination of the Positioning of CKD in Specific Health Check and Guidance, Japan.*

Background: Systolic blood pressure (SBP) is an established risk factor for proteinuria (PRU), while the risk of pulse pressure (PP) remains controversial. Since autoregulation of renal microcirculation is impaired in diabetes (DM) subjects, we hypothesize that PP may be more harmful to DM than non-DM subjects. We examined whether there is a significant association between PP and PRU or a low eGFR.

Methods: This study was a cross-sectional analysis using Japanese nationwide data on subjects aged 20-88 years, who were recruited for a special health checkup system in 2008.

Results: DM was identified by fasting glucose ≥126 mg/dl or HbA1c ≥6.1% or using anti-DM drugs. PRU was defined as at least 1+ positive for the dipstick test, and low eGFR group was defined as <60 mL/min/1.73m2. High PP was defined as the highest quartile of PP (>60mmHg, n=8,903).

Adjusted odds ratios (OR) were calculated using multivariable logistic regression analysis, adjusted for ever reported covariates included SBP.

A total of 228,778 participants were analyzed (mean age: 63.2±8.9 years, 39.3% men). Compared with non-DM subjects, DM subjects had a higher prevalence of PRU (4.4 vs. 11.3%) and low eGFR (13 vs. 14.8%, both P<0.001).

Among DM subjects, those with PRU or low eGFR had a significantly higher level of SBP (140 vs. 133 mmHg or 135 vs. 133 mmHg) and PP (60 vs. 56 mmHg or 58 vs. 56 mmHg; all P<0.001) than those without, and

High PP (>60mmHg) was significantly associated with PRU independently of significant covariates including SBP level (OR: 1.18, P=0.001), an association which was not observed in non-DM subjects (OR: 0.98,P=0.60). In contrast, high PP was significantly and positively associated with eGFR in subjects without DM (OR: 0.93,P<0.001), an association which was not observed in DM subjects (OR: 0.99, P=0.83).

Conclusions: High PP was an independent risk factor of PRU from the SBP level in DM subjects, but not in subjects without DM. In contrast, high PP was associated with high eGFR in subjects without, but not with DM.

Effects of Change in Serum Uric Acid on Cardiovascular Outcome: A Post-Hoc Analysis of the RENAAL and IDNT Trials Paul Smink,[1] Stephan J.L. Bakker,[1] Gozewijn Dirk Laverman,[1] Tomas Berl,[2] Mark E. Cooper,[3] Dick de Zeeuw,[1] Hiddo Jan Lambers Heerspink.[1] *[1]Kidney Center, University Medical Center, Groningen, Netherlands; [2]University of Colorado Medical School, Denver, CO; [3]Baker Heart Research Institute, Melbourne, Australia.*

Background: Emerging data suggest that increased serum uric acid (SUA) is an independent risk marker for cardiovascular (CV) complications. Treatment with the angiotensin-receptor-blocker (ARB) losartan lowers SUA in contrast to other ARBs. Whether reductions in SUA during losartan therapy are associated with CV protection is unclear. We aimed to test this hypothesis.

Methods: In a posthoc analysis of the Reduction of Endpoints in non insulin dependent diabetes mellitus with the Angiotensin II Antagonist Losartan (RENAAL) and Irbesartan Diabetic Nephropathy (IDNT) trials, we determined the relationship of a short-term change in SUA with long-term CV outcome by means of Cox regression.

Results: Compared to placebo, losartan significantly lowered SUA (0.16 mg/dl (95%CI 0.01 to 0.30; p=0.031) whereas irbesartan did not (0.09 mg/dl (95%CI -0.9 to 0.28; p=0.30). Each 0.5 mg/dL decrement in SUA during losartan treatment in the first 6 months resulted in a reduction of long term CV outcome of 5.3% (95%CI 0.9 to 9.9; p=0.017). Adjustment of the CV treatment effect of losartan for month 6 change in SUA attenuated the effect from 9.2% (95%CI -7.9 to 23.6) to 4.6% (95% CI -16.2 to 22.0), suggesting that part of the protective CV effect of losartan is attributable to its effect on SUA.

Conclusions: Losartan but not irbesartan significantly lowers SUA compared to placebo in patients with type 2 diabetes and nephropathy. The degree of reduction in SUA explains part of the CV effect of losartan. This supports the postulate that in type 2 diabetics with nephropathy SUA may be a modifiable risk factor for CV disease.

Epidemiology and Outcomes of Acute Kidney Injury after Cardiac Surgery Robert I. Griffiths,[1] Michelle Gleeson,[1] Viken Paragamian,[2] Mark D. Danese,[1] Robert M. Brenner.[2] *[1]Outcomes Insights, Westlake Village, CA; [2]AlloCure, Burlington, MA.*

Background: While there is substantial literature on associations between various definitions of acute kidney injury (AKI) and outcomes, we sought to examine the relationships between the development of AKI at 24 hours or at 48 hours after cardiac surgery and hospital length of stay, receipt of dialysis, kidney recovery, and mortality.

Methods: Using data from Cerner Health Facts, we identified 6,967 patients across 53 hospitals in the United States who had cardiac surgery between 01/2000 and 06/2010, and also had an increase from baseline serum creatinine ([SCr] 1-14 days before surgery) to ≥ 0.3 mg/dL, ≥ 0.5 mg/dL, ≥ 50%, or ≥ 100% at 24 or at 48 hours after surgery (8 non-mutually exclusive groups). Patients were followed for changes in SCr until hospital discharge or death. We used Kaplan-Meier analysis to describe the time to resolution of AKI, defined as the first SCr ≤ the baseline SCr. Also, we described hospital length of stay, dialysis use (any), and discharge status (alive/dead) in the 8 groups.

Results: AKI was detected in 3,594 (52%) patients at 24 hours and in 3,373 (48%) patients at 48 hours after surgery. The average age in the cohort was 68 years, 67% were male, 85% had ≥ 4 SCr values after surgery, and the mean baseline SCr was 1.37 mg/dL. Overall, development of AKI at 24 hours was associated with greater risk of dialysis (3.5%) and hospital mortality (10.3%), and extended time to kidney recovery, compared to development of AKI at 48 hours (dialysis use 2.2%; mortality 5.3%). Patients in the SCr ≥ 100% group had the highest risk of mortality (31.5% for AKI at 24 hours; 11.5% for AKI at 48 hours). However, there were only 405 (5.8%) patients in this group. The 0.5 mg/dL group had a greater risk of dialysis than did the 50% and 100% groups, likely indicative of the fact that the 50% and 100% groups included patients with very low baseline SCr values.

Conclusions: Earlier development of AKI, at 24 hours after surgery, was associated with worse clinical outcomes. Also, compared to a SCr increase of ≥ 0.3 mg/dL, an increase of ≥ 0.5 mg/dL was associated with higher mortality and dialysis use in this population.

TH-PO293

Prescription of and Adherence to Cardioprotective Drug Therapy in Chronic Kidney Disease Patients: Impact of Referral to Pre-Dialysis Clinics Lorraine Fradette,[1] Marc Dorais,[2] Heloise Cardinal,[3] Stephan Troyanov,[1,3] Jacques Lelorier,[3] Francois Madore.[1,3] *[1]Hopital du Sacre-Coeur de Montreal; [2]StatSciences Inc., , [3]Department of Medicine, Universite de Montreal, Montreal, Canada.*

Background: Cardiovascular disease is highly prevalent in chronic kidney disease (CKD) emphasizing the importance of appropriate cardioprotective drug therapy. However, the impact of referral to pre-dialysis clinics on the prescription of cardiovascular drug therapy and on the adherence to prescribed medications is still unknown. The objectives of this study were to evaluate: a) the prescription of and b) the adherence to lipid-lowering agents (LLA) and antihypertensive agents (AHA) in the year following referral to pre-dialysis clinics compared to that observed in the year preceding the first visit to the clinics.

Methods: Data were collected using medical records and health insurance databases that contain information on drug dispensation. Adherence to drug therapy was defined as

the percentage of days, during a pre-defined observation period, in which patients have on-hand supply of their prescribed medications.

Results: This cohort study included 385 CKD patients (stage 4 and 5). Mean glomerular filtration rate at the time of referral was 15.2/ml/min/1.73m^2. Mean age was 63 ± 13 years and 59% of patients were males. At the time of the first visit in the pre-dialysis clinic, 39% of patients were prescribed LLA (including statins and fibrates). This proportion increased to 47% (McNemar p<0.01) during follow-up. Similarly, there was a significant increase in the prescription of ACE inhibitors (from 34 to 39%), Angiotensin II receptor blockers (from 11 to 14%), β-blockers (from 40 to 51%), and diuretics (from 66 to 78%) (all p-values <0.01 on McNemar). Mean adherence to LLA and AHA did not change significantly in the year following the first visit to the pre-dialysis clinics compared with the preceding year (before: 91% and 95%; after: 84% and 95%; Mann-Whitney p>0.05).

Conclusions: In summary, these results suggest that referral to pre-dialysis clinics may increase the prescription of cardioprotective drug therapy in CKD patients but does not appear to improve the adherence to these therapies.

Funding: Government Support - Non-U.S.

TH-PO294

Low Income and Albuminuria among Reasons for Geographic and Racial Differences in Stroke Study Participants Deidra C. Crews,[1] William M. McClellan,[2] David A. Shoham,[3] Liyan Gao,[4] David G. Warnock,[4] Suzanne E. Judd,[4] Paul Muntner,[4] Brian D. Bradbury,[5] Edgar R. Miller,[1] Neil R. Powe.[6] *[1]Johns Hopkins University, Baltimore, MD; [2]Emory University, Atlanta, GA; [3]Loyola University Chicago, Maywood, IL; [4]University of Alabama at Birmingham, AL; [5]Amgen Corporation, Thousand Oaks, CA; [6]San Francisco General Hospital and University of California-San Francisco, San Francisco, CA.*

Background: Socioeconomic factors are believed to contribute to racial disparities in chronic kidney disease. Albuminuria is an important clinical risk factor for progressive chronic kidney disease (CKD), and is more prevalent among blacks than whites. Our objectives were to determine whether an association between low income and albuminuria exists, and whether this association varies by race.

Methods: In the population-based Reasons for Geographic and Racial Differences in Stroke (REGARDS) study of 22,828 U.S. adults aged 45 years and older, multivariable logistic regression was used to examine the race-stratified association between low income (annual household income < $20,000) and albuminuria and between level of income and albuminuria.

Results: Low income was present for 19.7% of participants; 29.8% of blacks and 12.9% of whites. The geometric mean urinary albumin:creatinine ratio (ACR) for blacks (11.8 mg/g) was higher than for whites (9.3 mg/g), p <0.01. With and without adjustment for demographics, lifestyle factors, comorbid illnesses and kidney function, low income was associated with ACR >30mg/g to a similar degree among blacks [crude odds ratio (OR) 1.5, 95% confidence interval (CI) 1.4-1.7; adjusted 1.2, CI 1.1-1.4] and whites [crude OR 1.8, CI 1.6-2.1; adjusted 1.3, CI 1.1-1.5]. When extremes of income were examined for their association with ACR >300mg/g, low income was statistically significantly associated with albuminuria among blacks (OR 3.4, CI 1.9-6.0, comparing income <$20,000 to >=$75,000), but not among whites (OR 1.5, CI 0.9-2.4).

Conclusions: Black race and low income are independently associated with an increased prevalence of albuminuria, and may interact in determining disparities in significant albuminuria.

TH-PO295

Decline in Kidney Function and Coronary Artery Calcium in Young Adults: Results from the CARDIA Study Nisha Bansal,[1] Eric Vittinghoff,[1] Carmen A. Peralta,[1] Chi-Yuan Hsu,[1] Michael Shlipak,[1] David R. Jacobs,[2] David Siscovick,[3] Michael Steffes,[2] John Jeffrey Carr,[4] Kirsten Bibbins-Domingo.[1] *[1]University of California, San Francisco; [2]University of Minnesota; [3]University of Washington; [4]Wake Forest School of Medicine.*

Background: Presence of coronary artery calcium (CAC) is associated with future cardiovascular events. Whether kidney function decline is associated with subsequent CAC among young adults with preserved estimated glomerular filtration rate ($eGFR_{CYS}$) is unknown.

Methods: The Coronary Artery Risk Development in Young Adults (CARDIA) study is a large biracial cohort of 5,115 young adults (ages 18-30 at enrollment) with over 20 years of follow-up. We included participants who had at least one cystatin C measurement at Years 10, 15, or 20 and CAC measurements at Years 15 or 20. Those with $eGFR_{CYS}$ < 60 ml/min/1.73 m^2 were excluded. We estimated annualized change in $eGFR_{CYS}$ using mixed models, then used a log-link continuation-ratio model with robust standard errors to estimate the association between $eGFR_{CYS}$ decline and detectable CAC (yes/no), adjusting first for age, race, sex, and time-varying body mass index, diabetes, systolic blood pressure, and then also for microalbuminuria (defined as ≥ 30 mg/g of creatinine in spot urine collections).

Results: Among 3,620 participants, (47% black, 55% women), mean age was 35 years and mean $eGFR_{CYS}$ was 109 m/min/1.73m^2 at the Year 10 examination. Nine percent (273) had detectable CAC at Year 15 and an additional 13% (352) developed detectable CAC by Year 20. Each 1% annual decline in $eGFR_{CYS}$ over the 10 years from Year 10 to Year 20 was associated with a 25% increased risk of CAC (95% CI 9%-42%, p<0.001) in models adjusted for age, race, sex, body mass index, diabetes and systolic blood pressure. After additional adjustment for microalbuminuria, the risk of detectable CAC was 17%(95% CI 2%-34%, p=0.02).

Conclusions: Even small decrements in $eGFR_{CYS}$ among young adults less than 50 years of age with $eGFR_{CYS}$ > 60 ml/min/1.73 m^2 are associated with detectable CAC, potentially signaling future cardiovascular risk.

Funding: NIDDK Support

TH-PO296

Family Income and Type of Renal Replacement Therapy (RRT) in Children with Chronic Kidney Disease (CKD). Results from the CKiD Study Guillermo Hidalgo,[1] Derek Ng,[2] Bradley A. Warady,[4] Marva M. Moxey-Mims,[5] Susan L. Furth.[3] *[1]Pediatrics, East Carolina University, Greenville, NC; [2]School of Public Health, John Hopkins University, Baltimore, MD; [3]Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA; [4]Pediatrics, Mercy Children's Hospital, Kansas City, MO; [5]NIDDK, NIH, Bethesda, MD.*

Background: Low socioeconomic status (SES) has been associated with CKD severity and worst outcomes in adults. We sought to describe the association between SES, determined by family income, and the cumulative type of RRT in the CKiD cohort.

Methods: Percentages were used to describe the cumulative incidence of RRT (dialysis or transplant), by income category and CKD diagnosis (glomerular vs. non-glomerular) over time since entry in the CKiD cohort. Fisher's exact test was used to determine differences across income categories.

Results: There were 572 subjects at enrollment with complete family income data and a median follow up of 3.9 years. The cummulative incidence of RRT was the same across income groups (approximately 20%), indicating hogeneity in disease severity. However the type of RRT was significantly different across income. Those with high income were more likely to receive a transplant (11%) than those with low income (4%). The difference was significant after stratification for cause of CKD specially among those with a non-glomerular cause.

Percentage of income category experiencing study events.

RRT	Income <$30K	Income $30K - 75K	Income > 75K	p value
All CKD causes	n=202	n=212	n=158	
Transplant	4%	9%	11%	0.03
Dialysis	15%	9%	8%	0.13
Transplant or dialysis	19%	19%	20%	0.53
CKD. Non-glomerular	n=155	n=166	n=128	
Transplant	4%	8%	12%	0.04
Dialysis	9%	5%	6%	0.34
Transplant or dialysis	40%	41%	29%	0.54
CKD. Glomerular	n=47	n=46	n=30	
Transplant	6%	13%	10%	0.55
Dialysis	34%	28%	19%	0.41
Transplant or dialysis	40%	41%	29%	0.53

Conclusions: Among children enrolled in the CKiD study, the cumulative incidence of RRT was the same across income groups. However those with higher income were more likely to receive transplants while lower income was associated with dialysis. Particulary, those with non-glomerular cause of CKD.

Determining National Priorities: Healthy People 2020 Chronic Kidney Objectives Asel Ryskulova,[1] Lawrence Agodoa,[2] Paul W. Eggers.[3] *[1]Centers for Disease Control and Prevention, Hyattsville, MD; [2]National Institutes of Health, Bethesda, MD; [3]National Institutes of Health, Bethesda, MD.*

Background: An estimated 11.5% of adults ages 20 or older had physiological evidence of chronic kidney disease (CKD) determined from data collected through the 1999-06 National Health and Nutrition Examination Survey (NHANES). Each year in the United States, more than 100,000 people are diagnosed with end stage renal disease (ESRD), the final stage of CKD.

Methods: Reflecting the importance of CKD, fourteen CKD objectives area were included as a new topic area in the Healthy People 2010 national health goals to reduce new cases of CKD and its progression, complications, disability, death, and economic costs. The Healthy People 2020 initiative was launched in December 2010.

Results: After the revision of the objectives by the Healthy People 2020 work group, all Healthy People 2010 objectives were retained with modifications and 6 new Healthy People 2020 objectives were added. New objectives are focused on monitoring and tracking: improvements in cardiovascular care in patients with CKD; increases in proportion of patients with CKD and diabetes who received recommended evaluation and treatment; reductions in death rate and percentage of U.S. population with CKD; and increasing CKD awareness in persons with impaired renal function. In addition to the US Renal Data System, National Health and Nutrition Examination Survey and the National Death Index have been analyzed to provide baselines and tracking data for the HP 2020 objectives.

Conclusions: The presentation will include a review of key Healthy People 2010 final results for CKD objectives, the Healthy People 2020 CKD objectives and targets, and development process used to identify the Healthy People 2020 CKD objectives.

TH-PO298

Contribution of Genetic and Environmental Factors to the Association between Preeclampsia and Later End-Stage Renal Disease Bjorn Egil Vikse,[1,2] Lorentz M. Irgens,[3] S. Ananth Karumanchi,[4] Rolv Skjaerven.[3] *[1]Department of Medicine, Haukeland University Hospital, Bergen, Norway; [2]Institute of Medicine, University of Bergen, Bergen, Norway; [3]Department of Public Health and Primary Health Care, University of Bergen, Bergen, Norway; [4]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston.*

Background: Women with preeclampsia have increased risk of later developing end-stage renal disease (ESRD). To investigate the association further, we have in the present study investigated contribution of genetic and environmental factors.

Methods: The Norwegian Population Registry has registered data on parents and siblings for most inhabitants born since the 1950's. The Norwegian Medical Birth Registry has registered data on all births since 1967 and the Norwegian Renal Registry has registered data on all patients who have developed ESRD since 1980. We linked these registries and investigated whether preeclampsia in first pregnancy of siblings, children or partner were associated with risk of ESRD. Cox regression statistics were used.

Results: In the analyses of siblings' risk, we included 605,231 women of who 312 developed ESRD. As compared to women without preeclampsia who had not had siblings with preeclampsia, women without preeclampsia who had siblings with preeclampsia had a relative risk of ESRD of 0.93 (95% CI 0.58-1.5), women with preeclampsia who had not had siblings with preeclampsia had a relative risk of 5.6 (4.1-7.6) and women with preeclampsia who had siblings with preeclampsia had a relative risk of 2.6 (0.83-8.1). These results were unchanged if the analyses for siblings were performed separately for brothers and sisters. In the analysis of parents' risk, we included 322,974 women of who 450 developed ESRD, similar findings as in the analyses of siblings' risk were made. Male partners of women with preeclampsia had a relative risk of 1.6 (1.03-2.4), 1.5 (0.94-2.5) after adjustment for educational status.

Conclusions: Risk of ESRD is not increased if siblings or children have preeclampsia but partners of women with preeclampsia have a slightly increased risk.

Effect of a Multifactorial Intervention with the Aid of Nurse Practitioners on Renal Outcome in Patients with Chronic Kidney Disease: Results of the MASTERPLAN Study Mieke J. Peeters,[1] Arjan D. Van Zuilen,[2] Jan A.J.G. van den Brand,[1] Peter J. Blankestijn,[2] Jack F. Wetzels.[1] *[1]Radboud University Nijmegen Medical Centre, Nijmegen; [2]University Medical Centre Utrecht, Utrecht, Netherlands.*

Background: Chronic kidney disease (CKD) is a major public health problem worldwide. CKD patients are at risk of progression to end stage renal disease (ESRD). We showed that strict implementation of current guidelines directed at multiple risk factors with the aid of nurse practitioners did not reduce cardiovascular events in patients with prevalent CKD. In the current analysis we evaluated renal endpoints.

Methods: In MASTERPLAN (Multifactorial Approach and Superior Treatment Efficacy in Renal Patients with the Aid of Nurse practitioners) 788 patients with mild to moderate CKD were randomized to receive nurse practitioner support added to physician care (intervention group) or physician care alone (control group). Patients were followed for a median of 4.4 years. Several renal end points were defined.

Results: 395 patients were randomized to the intervention group, 393 to the control group. Baseline variables were balanced. During follow up, mean blood pressure was significantly lower in the intervention group (-3/-2 mmHg). Significant differences were also found for LDL cholesterol (-0.11 mmol/L), phosphate (-0.03 mmol/L), hemoglobin (+0.1 mmol/L), and proteinuria (-0.12 g/24u). No differences were found for smoking, BMI, sodium intake, physical activity level, PTH, and HbA1c.

The intervention did not significantly reduce the incidence of ESRD (hazard ratio 0.86; 95% CI 0.63-1.16). Also, there were no significant differences when using a 50% increase of serum creatinine or the change in eGFR as endpoint. ΔeGFR was -1.52 in the intervention group and -1.74 ml/min/1.73m²/year in the control group, p=0.48.

Conclusions: Additional support by nurse practitioners in CKD patients improved some risk factor levels, but did not significantly attenuate the decline of kidney function or reduce the rate of ESRD.

TH-PO300

A Meta-Analysis on 2100 Non-Dialysis- and Dialysis-Patients Exposed to Once Monthly C.E.R.A. Demonstrates Effective and Safe Treatment Danilo Fliser,[1] Thomas Weinreich,[2] Stefan N. Heidenreich,[3] Fuat Bozkurt,[4] Christoph Wanner.[5] *[1]University of Saarland, Homburg, Germany; [2]Dialysis Center, Vill-Schwenn, Germany; [3]Dialysis Center, Aachen, Germany; [4]Dialysis Center, Daun, Germany; [5]University of Würzburg, Würzburg, Germany.*

Background: In Germany the prospective studies MIRACEL, SESAM, SUPRA, NASA and MERCUR had been initialized in chronic kidney disease (CKD) patients (pts), stages IV and V.

Methods: Data from all five interventional and non- interventional studies were pooled in a single database and analyzed with respect to individual hemoglobin (Hb)-fluctuation and Hb in target range during the evaluation period, and dose adaptations within the individual observation phase. Further analyses were performed for the following subgroups:

- Route of administration (iv, sc)
- Gender (male, female)
- ESA pre-treatment (Darbepoetin, Epoetin, C.E.R.A)
- Diabetes (yes, no)

Additionally, the dialysis and the non dialysis CKD population was compared.

Results: The study population consisted of 1581 dialysis (D) and 519 non-dialysis (ND) pts. The age of the dialysis and non-dialysis pts was 65,1 ±14,4 and 68,4 ±14,5 years, respectively, with 42,8% (D) and 48,7% (ND) being female. 38,7% (n=612) of the D and 44,5% (n= 44,5) of the ND pts suffered from diabetes.

	Deviation from the individual Hb mean ≤ 1g/dl (%)	Pat in Hb target (%)	Dose adaptations (mean)
	D/ND	D/ND	D/ND
Total	84.1/84.7	66.4/67.6	2.1/1.7
Admin route iv	85.1/50	67.3/75	2.0/0.2
Admin route sc	82.3/86	68/67.9	2.2/1.7
Female	82.7/85.4	63.4/63.7	2.1/1.8
Male	85.1/84	68.6/71.6	2.1/1.6
ESA pre Darbepoetin	82.6/76.9	67.1/68.6	2.0/1.6
ESA pre Epoetin	85/92.9	66.4/69	2.0/1.3
ESA pre C.E.R.A.	85.2/100	67.6/50	2.7/0.8
Diabetes no	83.7/84.4	65.4/69.1	2.1/1.6
Diabetes yes	84.7/85.1	68/65.7	2.1/1.7

A comparable safety-profil to other ESA had been observed in all 5 C.E.R.A. studies.

Conclusions: Once monthly C.E.R.A. maintains stable Hb-levels in patients both on D and ND with only minimal Hb fluctuations. These results were confirmed for various subgroups, thus demonstrating that once monthly C.E.R.A. is a suitable treatment for all pts suffering from CKD related anemia with only few dose-changes needed.

TH-PO301

Progression of Chronic Kidney Disease in a National Sample of United States Veterans Ahmad Mahallati,[1] Elizabeth Hedgeman,[1] Brenda W. Gillespie,[1] Meda E. Pavkov,[2] Nilka Rios Burrows,[2] Laura C. Plantinga,[3] Neil R. Powe,[3] Rajiv Saran.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Centers for Disease Control and Prevention, Atlanta, GA; [3]University of California, San Francisco, CA.*

Background: Patterns and clinical indicators of kidney function decline were examined in a population with baseline chronic kidney disease (CKD).

Methods: We identified a cohort of national Veterans Affairs (VA) patients with CKD (eGFR <60ml/min/1.73m² by the MDRD equation) and at least two serum creatinine measurements over 2 to 5 years. Each patient was assigned a best-fit slope of annual eGFR change using linear regression. Those with negative slopes were equally split into slow progression or fast progression groups. Multivariable logistic regression was used to assess clinically important factors associated with fast vs. slow progression of CKD (age, race/ethnicity, gender, diabetes, baseline eGFR, albuminuria, hemoglobin, and serum albumin).

Results: Of the 13,634 patients identified with CKD, 45% (n= 6153) experienced no decline in kidney function and were not included in the multivariable analysis; of those patients experiencing a decline in kidney function, 50% were classified as 'slow' (n= 3,738; slope 0 to -2.18 ml/min/1.73m² per year) and 50% as 'fast' (n= 3,743; slope -2.19 to -25.72 ml/min/1.73m² per year) progressors. Progressors were predominantly male (97.0%), with a mean age of 72.5 years and baseline eGFR of 48.0 ml/min/1.73m². The odds of fast progression were higher with increasing baseline eGFR (OR =1.03, 95% CI 1.02-1.05), and urine albumin-to-creatinine ratio ≥300 mg/g (OR=2.39, 95% CI 1.67-3.42), but lower with increasing serum hemoglobin (g/dl) concentration (OR=0.89, 95% CI 0.83-0.94).

Conclusions: In this U.S. veteran cohort, the overall mean progression of all-cause CKD was relatively slow (-0.08 ml/min/1.72m² per year), with faster progressors experiencing an average decline of -4.67 ml/min/1.72m² per year and nearly half of the population showing no reduction in eGFR over 2 to 5 years. Future studies to link outcomes with these and other risk factors are warranted.

TH-PO302

Plant Protein Intake Is Associated with Fibroblast Growth Factor 23 and Serum Bicarbonate in Patients with CKD: The Chronic Renal Insufficiency Cohort Study Julia J. Scialla,[1] Lawrence J. Appel,[1] Myles S. Wolf,[2] Wei Yang,[3] Xiaoming Zhang,[3] Edgar R. Miller,[1] Stephen M. Sozio,[1] Lydia Bazzano,[4] Magdalena M. Cuevas,[3] Melanie Glenn,[3] Radhakrishna Reddy Kallem,[3] Eva Lustigova,[4] Anna C. Porter,[5] Raymond R. Townsend,[2] Matthew R. Weir,[6] Cheryl A. Anderson.[1] *[1]Johns Hopkins University; [2]University of Miami; [3]University of Pennsylvania; [4]Tulane University; [5]University of Illinois at Chicago; [6]University of Maryland.*

Background: Plant-based proteins have lower bioavailability of phosphorus and lower acid load than animal-based proteins and may be preferred in CKD. Adverse effects due to inhibition of iron absorption and potassium loading are also possible.

Methods: We calculated the percentage of protein intake from plant sources (% plant protein) in 2938 CRIC participants by scoring individual food items from a food frequency questionnaire. Using linear regression we modeled associations between % plant protein and serum phosphate, log fibroblast growth factor 23 (FGF23), log parathyroid hormone (PTH), serum bicarbonate (HCO_3), serum potassium, serum albumin and hemoglobin.

Models were adjusted for age, sex, race, diabetes, body mass index, eGFR, income, smoking, total energy intake, total protein intake, 24 hour urinary sodium, use of ACE inhibitors/ ARBs and use of diuretics.

Results: Adjusted means of FGF23 and HCO_3 across levels of % plant protein are presented in the table.

	<24%	24-29%	30-35%	36-44%	>44%	p-trend
FGF23 (RU/mL)	157.4	154.8	152.8	150.6	146.9	0.05
HCO3 (mEq/L)	24.4	24.5	24.6	24.7	24.8	0.01

Higher % plant protein was associated with lower FGF23 (p=0.05) and higher HCO_3 (p=0.01), but not with serum phosphate (p=0.9) or PTH (p=0.5). There was no association of higher % plant protein with serum potassium (p=0.2), serum albumin (p=0.2) or hemoglobin (p=0.3). The associations of % plant protein with FGF23 and HCO_3 did not differ by diabetes status, sex, race, CKD stage (2/3 vs. 4/5) or total dietary protein intake (≤ 0.8 g/kg/d vs. >0.8 g/kg/d) (p-interaction > 0.10 for each).

Conclusions: In conclusion, consumption of a higher percentage of protein from plant sources may lead to a more favorable metabolic profile in patients with CKD.

TH-PO303

Determinants of sRAGE in a Community-Based Population: The Atherosclerosis Risk in Communities (ARIC) Study

Elizabeth Selvin,[1] Marc Halushka,[1] Ron C. Hoogeveen,[2] Christie Ballantyne,[2] Josef Coresh,[1] Brad C. Astor.[1] *[1]Johns Hopkins University; [2]Baylor College of Medicine.*

Background: Advanced glycation endproducts (AGEs) and their receptors are implicated in the development of diabetic complications and kidney disease. When stimulated by AGEs, the receptor for AGEs (RAGE) induces inflammation and may fuel progression of disease through NF-kB mediated signaling. Soluble circulating RAGE (sRAGE) may counteract the effects of RAGE.

Methods: We identified determinants of low levels (lowest quartile) of sRAGE (ELISA, R&D Systems, CV<3%) from stored plasma in a random sample of 1185 participants in the ARIC Study (ages 47-68) with $eGFR_{CKD-EPI} \geq 60$ mL/min/1.73m^2.

Results: sRAGE was inversely correlated with BMI (Spearman's r=-0.28), HbA1c (r=-0.22), CRP (r=-0.25), $eGFR_{Cystatin}$ (r=-0.17) and $eGFR_{CKD-EPI}$ (r=-0.11). sRAGE was lower among men vs. women (958.5 vs 1100.6 pg/mL, p<0.001), blacks vs. whites (756.6 vs 1118.8 pg/mL, p<0.001), and diabetic vs. nondiabetic adults (901.8 vs 1050.0 pg/mL, p=0.01). Only male sex, black race, smoking, CRP, and eGFR remained associated with low sRAGE after adjustment. $eGFR_{Cystatin}$ was more strongly associated with sRAGE than was $eGFR_{CKD-EPI}$.

Adjusted* ORs (95% CI) for lowest quartile of sRAGE (<708.8 pg/mL) N=1,185

	OR (95%CI)
Age >55 (vs <55)	1.1 (0.8, 1.5)
Male	1.7 (1.2, 2.4)†
Black	4.6 (3.3, 6.5)†
A1c 5.7-6.4% (vs <5.7%)	1.2 (0.7, 2.0)
A1c>6.5% or diabetes (vs <5.7%)	0.9 (0.5, 1.5)
Former smoker (vs current)	1.6 (1.1, 2.5)†
Never Smoker (vs current)	1.0 (0.6, 1.5)
BMI >30 kg/m2 (vs <25kg/m2)	1.5 (1.0, 2.2)
BMI 25-30 kg/m2 (vs <25 kg/m2)	3.0 (1.9, 4.6)†
CRP 1-3 mg/L (vs <1mg/L)	1.7 (1.1, 2.6)†
CRP >3 mg/L (vs <1mg/L)	3.0 (1.9, 4.6)
History of coronary heart disease	1.4 (0.7, 2.6)
eGFR cystatin C (per 10mL/min/1.73 m2)	1.3 (1.1, 1.4)†
	†p-value <0.05

*Adjusted for all variables listed

Conclusions: Low levels of sRAGE may indicate susceptibility to inflammatory processes or a state of increased oxidant stress. The lack of association of sRAGE with diabetes is surprising and suggests that sRAGE may be a generalized measure of ill health and not as specific to diabetes as previously thought. The robust racial difference in sRAGE deserves further examination.

Funding: NIDDK Support

TH-PO304

Development of Chronic Kidney Disease in Rheumatoid Arthritis

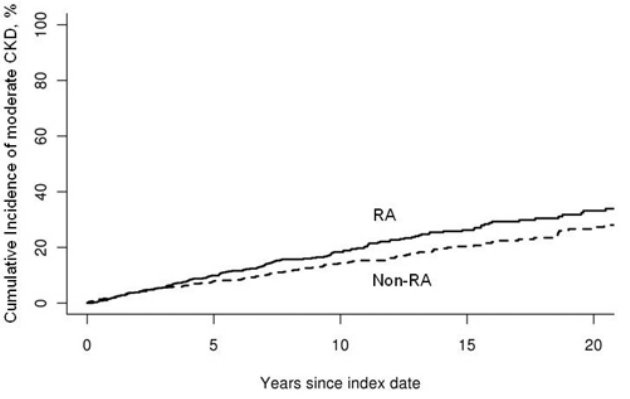
LaTonya J. Hickson,[1] Cynthia S. Crowson,[2] Sherine E. Gabriel,[3] James T. McCarthy,[1] Eric L. Matteson.[3] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Biomedical Statistics and Informatics, Mayo Clinic, Rochester, MN; [3]Rheumatology, Mayo Clinic, Rochester, MN.*

Background: Rheumatoid arthritis (RA) is associated with a variety of kidney disorders. However, it is unclear whether the development of chronic kidney disease (CKD) is higher in patients with RA compared to the general population.

Objective: To elucidate the occurrence of CKD in patients with RA.

Methods: Retrospective review of incident adult onset RA cases from a defined geographic population base from 1980-2007 and a comparison cohort of non-RA patients. CKD was defined by estimated glomerular filtration rate (eGFR) <60 and moderate CKD was eGFR <45 ml/min/1.73m^2. The cumulative incidence of CKD was estimated adjusting for the competing risk of death.

Results: 813 RA patients and 813 non-RA patients were assembled (mean age 55.9, 68% female). There was no difference in the presence of CKD at time of RA development, p=0.84. Among RA patients, 38% had an eGFR<60 and 11% had eGFR<45, similar to non-RA patients (38% and 9%) observed at the RA incidence reference date. The 10 year cumulative incidence of CKD was higher in RA patients compared to non-RA (43% vs 32%, p=0.008). This difference occurred primarily in the first year. The 10 year cumulative incidence of moderate CKD was also higher in patients with RA compared to non-RA (18% vs 14%, p=0.037). This difference became apparent 3 years after incident RA (figure). The development of CKD was associated with erythrocyte sedimentation rate (HR 1.1 per 10 mm/hr, CI 1.03-1.20, p=0.008) and cardiovascular disease (HR 2.1, CI 1.4-3.2, p<0.001).



Conclusions: RA patients were more likely to develop CKD over time. Inflammation and cardiovascular disease appear to play a role in this development. Further studies are needed to improve understanding of these relationships.

TH-PO305

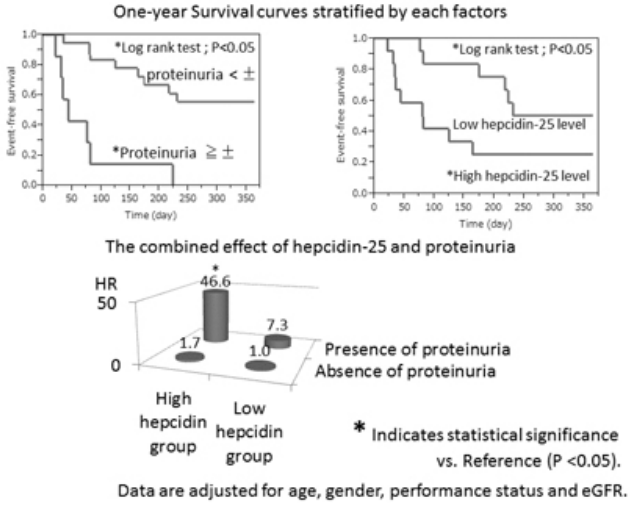
Coexistence of High Serum Hepcidin-25 Level and Proteinuria Has Strong Impact on Short-Term Mortality in Non-Hodgkin's Lymphoma Patients

Hirohiko Nokiba,[1,2] Minoru Ando,[1,2] Masaki Hara,[1,2] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Nephrology, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; [2]Department IV of Internal Medicine, Tokyo Women's Medical University, Tokyo, Japan.*

Background: The excessive hepatic production of hepcidin-25 due to chronic disorders including cancer is responsible for anemia with underutilization of iron. This study addressed the combined impact of hepcidin-25 and proteinuria on short-term mortality in lymphoma patients.

Methods: One-year prospective cohort study was conducted in a total of 24 patients with non-Hodgkin's lymphoma. Serum hepcidin-25 level was measured by liquid chromatography-mass spectrometry. Proteinuria was defined as a dipstick test ≥±. Survival curve was drawn by the Kaplan Meier method, which was stratified into 2 groups by either median value of serum hepcidin-25 (43.1 ng/ml) or presence of proteinuria. In addition, each group which was stratified by hepcidin-25 was divided into 2 subgroups according to presence of proteinuria. Multivariate Cox proportional hazards analysis, adjusted for age, gender, performance status and estimated GFR, was used to calculate mortality HR for the combined impact of hepcidin-25 and proteinuria.

Results: Mean hepcidin-25 level was 53.9±48.9 ng/ml, which was approximately 2-fold greater than the reference value (22.2±12.3 ng/ml). The cumulative survival rate was significantly lower in the high hepcidin-25 group or in the proteinuria (+) group than in each opposite. The mortality HR (95% CI) was 46.6 (6.33-442.54) for patients with both proteinuria and high hepcidin-25; 7.3 (0.80-57.80) for those with proteinuria and low hepcidin-25; and 1.7 (0.30-9.28) for those with no proteinuria and high hepcidin-25, as compared to the reference with neither of them.



Conclusions: Non-Hodgkin's lymphoma patients with both high serum hepcidin-25 level and coexsiting proteinuria are likely at high risk for early mortality.

TH-PO306

Early Invasive Management of Acute Coronary Syndrome and Renal Outcomes Matthew T. James,[1] Marcello Tonelli,[2] Neesh I. Pannu,[2] Scott Klarenbach,[2] Braden J. Manns,[1] Brenda Hemmelgarn.[1] *[1]Medicine, University of Calgary, Canada; [2]Medicine, University of Alberta, Canada.*

Background: Acute kidney injury following coronary angiography is associated with adverse outcomes. The risk of acute kidney injury and other renal complications associated with invasive versus conservative management of acute coronary syndrome is unclear. We examined the relationships between early invasive management and acute kidney injury, dialysis, end-stage renal disease, and survival.

Methods: We performed a retrospective cohort study including all Alberta residents aged 18 year or older with a primary admission diagnosis of non-ST elevation acute coronary syndrome from six acute care hospitals in Alberta, Canada between 1 January 2004 and 31 October 2009. We developed a propensity score for early invasive management (coronary angiography within 2 days of hospital admission). Treatment groups were matched 1:1 on propensity scores, and followed to determine the risks of acute kidney injury (>0.3 mg/dl or 50% increase in serum creatinine concentration in hospital), acute kidney injury requiring dialysis, end-stage renal disease, and mortality.

Results: Of 10,538 included patients, 4,281 (40.6%) received early invasive management. After propensity score matching of conservative management patients with characteristics similar to those who received early invasive therapy (n=7,430), early invasive management was associated with an increased risk of acute kidney injury (8.8 versus 5.6%, risk ratio [RR] 1.52, [95% CI 1.29-1.80]; P<0.001). However, no significant differences were observed between the matched groups in the risks of acute kidney injury requiring dialysis during hospitalization (0.3 vs 0.2%, RR 1.33 [0.56-3.16]; p=0.514) or end-stage renal disease (hazard ratio [HR] 0.81, [0.68-0.96]; p=0.019). Early invasive management was associated with improved long-term survival (HR 0.71, [0.68-0.96]; p=0.019).

Conclusions: Early invasive management of acute coronary syndrome is associated with a modest increase in risk of acute kidney injury but not dialysis or end-stage renal disease. These findings suggest that the risk of acute kidney injury should not preclude early invasive management of acute coronary syndromes

Funding: Government Support - Non-U.S.

TH-PO307

Low Taste Acuity for Salt Indicates Fast Decline of Renal Function in Patients with CKD Stages 4 and 5 Yoshie Kanazawa,[1,2] Toshiyuki Nakao.[1] *[1]Department of Nephrology, Tokyo Medical University, Tokyo, Japan; [2]Tokyo Kasei Gakuin University, Tokyo, Japan.*

Background: Salt restriction is a fundamental issue in the management of chronic kidney disease (CKD). At present, there are few data on taste acuity for salt (TAS) and its association with the decline of renal function in CKD patients.

Methods: Among 248 consecutive CKD patients who were evaluated for TAS in August 2007, 84 patients with CKD stages 4 and 5 who were being assessed for renal function throughout the period of more than 6 months were recruited in this study. All patients were instructed to restrict salt intake. TAS was assessed by determining the threshold of response to a set of test papers with 7 kinds of concentrations of salt crystal (i.e., 0.6% to 1.8%). The evaluated patients were classified into 3 groups according to their thresholds of response to salt concentration: 0.6 and 0.8 as sensitive (S); 1.0, 1.2 and 1.4 as intermediate (I); and 1.6 and 1.8 as insensitive (U).

Results: A total of 38 patients were classified into group S, 25 into group I and 21 into group U. The mean observational period was 21.2 ± 5.1 months, with no significant differences between the groups. The estimated glomerular filtration rate (eGFR: ml/min), serum creatinine level (Cr: mg/dl) and urea nitrogen level (UN: mg/dl) at the start of the study were 14.4 ± 5.8, 3.87 ± 1.55 and 48.4 ± 5.2 in group S, 10.4 ± 5.1, 4.03 ± 1.78 and 53.3 ± 21.2 in group I, and 13.9 ± 5.6, 4.29 ± 2.57 and 50.5 ± 20.4 in group U, respectively. The eGFR, Cr and UN at the end of the study were 10.5 ± 5.9, 5.72 ± 2.81 and 60.8 ± 23.4 in group S, 13.5 ± 6.3, 5.20 ± 2.49 and 60.6 ± 34.5 in group I, and 7.4 ± 4.4, 8.21 ± 4.11 and 67.0 ± 29.2 in group U, respectively. The decline in eGFR (ml/min/month) was -0.20 ± 0.18 in group S, -0.14 ± 0.11 in group I and -0.34 ± 0.28 in group U, with group U showing faster decline than in groups S and I. The elevation rates of Cr (mg/dl/month) were 0.10 ± 0.11 in group S, 0.07 ± 0.10 in group I and 0.25 ± 0.35 in group U, and with group U showing faster elevation rate than groups S and group I.

Conclusions: Low TAS indicates fast decline of renal function in patients with CKD stages 4 and 5.

TH-PO308

Detection of Chronic Kidney Disease and Proactive Referral in the General Population – Results of Three Years Follow-Up of a Community Based Intervention Program Shlomo Vinker, Eran Rotman. *Medical Director Office, Clalit Health Services, Central District, Rishon Lezion, Israel.*

Background: CKD is common, especially among patients with co-morbidities as diabetes, hypertension or cardiovascular disease (CVD). In the early stages of CKD family physicians' awareness is usually low. We aimed to evaluate early detection of CKD and three years nephrologists' follow-up.

Methods: We reviewed all laboratory results of our members in 2007 (about 500000) for the last calculated eGFR using the abbreviated MDRD equation. Patients with eGFR 20-50 ml/min were eligible for the intervention program. We included all patients with eGFR 20-30 ml/min and patients with eGFR >30 ml/min having at least one of the following: diabetes, hypertension or CVD. Patients that visited a nephrologist in 2007 had been excluded.Main outcome: Changes in eGFR and CVD risk factors.

Results: 418 patients with CKD-4 (age 74.0±10.2, eGFR 26.3±2.7 ml/min) and 2067 patients with CKD-3 (age 66.0±7.3) met the inclusion criteria and had been invited to a nephrologist. 201 CKD-4 patients visited a nephrologist. After 3 years, 31 patients died and 53 developed end stage kidney disease (ESKD) and 27 lost from follow-up the rest had stable eGFR (27.6±8.1), Blood pressure (BP)was lower (129.1±14.5/72.1±8.7 vs. 137.7±21.5/77.7±12.5, p<0.05) lower LDL cholesterol (LDL-c) (93.2±28.6 vs. 101.3±32.1, p<0.05), and stable Hemoglobin level. The percent of patients treated with erythropoietin and analogues increased significantly from 11.9% to 36.6%. 630 CKD-3 patients visited a nephrologist. After 3 years, 43 patients died and 27 developed ESKD and 71 lost from follow-up the rest had a decline in eGFR (39.7±11.5 vs. 42.3±5.6), BP was lower (129.3±15.6/73.5±8.8 vs. 138.1±19.3/78.3±10.2, p<0.05) lower LDL-c(93.3±30.5 vs. 101.3±34.2, p<0.05), and stable Hemoglobin level. The percent of patients treated with erythropoietins increased significantly from 1.7% to 8.1%.

Conclusions: A proactive program to detect CKD 4 and high risk CKD 3 patients and the implementation of nephrologists' follow-up service improves treatment. More efforts to recruit all the high risk patients are needed. A longer follow up is needed to evaluate if this will affect prognosis.

TH-PO309

The Association between Serum Uric Acid and Renal Damages in the Japanese Population: The Takahata Study Kazuko Suzuki, Tsuneo Konta, Kazunobu Ichikawa, Yusuke Mashima, Ami Ikeda, Isao Kubota. *Yamagata University School of Medicine, Yamagata, Japan.*

Background: The increase in serum uric acid is frequently observed in the subjects with renal insufficiency.

Methods: However, the association between serum uric acid and renal damages in general population is largely unknown. To clarify this point, we conducted a community-based study, using urinary albumin and beta 2-microglobulin as markers of glomerular and tubular damages.

The subjects studied were 3341 Japanese subjects (1497 men, 1844 women) without history of kidney disease. The urinary albumin-creatinine ratio (UACR) and beta 2-microglobulin-creatinine ratio (UBCR) were assessed in morning spot urine samples.

Results: In this population, the mean values of serum uric acid (mg/dl) were 5.8 ± 1.3 in men and 4.5 ±1.1 in women, respectively. The prevalence of albuminuria (UACR >30 mg/g) were significantly increased along with the increase in uric acid both in men and women (P <0.05). In contrast, the prevalence of high UBCR (>300 μg/g) were deceased along with the increase in uric acid both in men (P <0.01) and women (P =0.056). Multivariate analysis showed that albuminuria was independently related with increased uric acid (>7 mg/dl for men, >6 mg/dl for women, vs. 5.0-5.9 mg/dl) and high UBCR was not associated with uric acid neither in men nor women, after adjustment for possible confounders. The one-year longitudinal analysis in 1517 subjects showed the positive relationship between baseline uric acid and UACR changes across the tertiles of uric acid (P for trend <0.05).

Conclusions: This study showed that uric acid was an independent risk factor for albuminuria, but not high UBCR, suggesting that uric acid might induce glomerular damage, but not tubular damage in general population.

TH-PO310

Etiology, Comorbidity and Factors Associated with Renal Function Decline in Chinese Chronic Kidney Disease Patients Guangyan Cai, Xiang-Mei Chen. *Department of Nephrology, State Key Laboratory of Kidney Disease, PLA Genaral Hospital.*

Background: For the lack of nation-wide investigations in China, features of CKD etiology, comorbidity and factors associated with renal function decline is not clear. The Chinese Society of Nephrology initiated a nation-wide investigation of inpatients with CKD in China.

Methods: A cross sectional study was conducted on inpatients with CKD from 61 big hospitals among 31 provinces in Mainland China. Data on demographic characteristics, lifestyle risk factors, medical records, and laboratory tests results were obtained using a standard questionnaire administered by trained physicians. Estimated GFR was calculated with CKD-EPI equation. Binary logistic regression was used to analyze factors associated with renal function decline.

Results: 10728 patients were included in the analysis, in which male-female ratio was 1.18:1. The mean age was 48.14 ± 17.98 years (15ys-97ys). The distribution in CKD stages was as follows: stage one 28.2%, stage two 15.0%, stage three 12.4%, stage four 8.6% and stage five 35.7%. Primary glomerulopathies accounted for 52.3% diagnosis of the whole inpatients with CKD, in which 18.8% was IgA nephropathy. Diabetic kidney disease accounted for 11.9%, lupus nephritis 6%, hypertensive nephropathy 4.8%, cystic kidney disease 2.4%. The common comorbidities were mineral and bone disorder (66.8%), anaemia (64.4%), hypertension (62.2%), hyperlipemia (56.9%), hypoalbuminemia (49.2%), hyperuricemia (46.2%), diabetes (23.8%) cardiovascular disease (19.1%), cerebrovascular disease (6.1%) and so on. By multivariable logistic regression analysis, renal function decline was significantly associated with age (OR 1.612), male (OR 1.777), hypertension (OR 3.562), diabetes (OR 1.517) , anemia (OR 7.983) and hyperuricemia (OR 3.154).

Conclusions: This investigation described the clinical features of inpatients with CKD in China for the first time. Presently, primary glomerulopathy is the leading cause

of CKD in China. In Chinese CKD patients, the prevalence of hypertension, diabetes, cardiovascular diseases and cerebrovascular diseases were lower, but the prevalence of anemia and hypoalbuminemia are higher than those from developed countries.

TH-PO311

Educational Hospitalization Effectively Delays Progression of CKD Shotaro Naito, Soichiro Iimori, Kayoko Eto, Eisei Sohara, Tomokazu Okado, Yumi Noda, Tatemitsu Rai, Shinichi Uchida, Sei Sasaki. *Department of Nephrology, Tokyo Medical and Dental University, Bunkyo-ku, Tokyo, Japan.*

Background: In Japan, over thirteen million people are diagnosed as chronic kidney disease (CKD). Appropriate diet modification and control of blood pressure are essential for prevention of progression of CKD. However, it is difficult to achieve these goals in the outpatient clinic. In our hospital, we have hospitalized CKD patients as 'Educational Hospitalization' (EH) to provide them with the knowledge of diet and medication, and to control their blood pressure and fluid volume balance. We analyzed the effect of EH on the progression of CKD.

Methods: During the period from January 2007 to December 2010, a total of 712 CKD patients visited our nephrology department. Among them, 206 patients were hospitalized for EH. 199 EH patients, whose estimated GFR (eGFR) were under 60 ml / min / 1.73 m^2, were retrospectively analyzed. The effect of EH was evaluated by the change in eGFR during 6 months (ΔeGFR (ml / min / 1.73 m^2 / year)) before and after hospitalization.

Results: Compared with patients who were not hospitalized, the EH patients had significantly higher male gender, higher diabetes prevalence, older age, lower hemoglobin, lower serum albumin, lower eGFR, lower serum total cholesterol and higher urinary protein ($P < 0.05$). We compared patient status at the point of hospitalization and after 6 months in the EH group. Hemoglobin (10.7 → 10.9 g/dl) and serum albumin (3.7 → 3.8 mg/dl) significantly increased, and eGFR decreased during this period. Changes of serum total cholesterol and urinary protein were not significant. ΔeGFR after hospitalization was improved (-7.5 → -3.0 ml/min/year). When stratified by CKD stage, ΔeGFR in stage 4 and 5 patients were significantly improved but not in stage 3. Moreover the degree of improvement was largest in stage 5.

ΔeGFR before and after EH

	ΔeGFR (before EH)	ΔeGFR (after EH)	P-value
CKD stage 3	-2.5 ± 10.8	-3.3 ± 11.7	0.76
CKD stage 4	-8.6 ± 9.6	-3.5 ± 10.7	0.004
CKD stage 5	-9.3 ± 7.9	-2.4 ± 6.4	< 0.0001

Data are given as the mean ± SD

Conclusions: Educational hospitalization is an effective method to delay progression of CKD, especially in advanced stages.

TH-PO312

The Role of ARB in Treatment of Left Ventricular Hypertrophy in Dialysis Patients: A Meta-Analysis Liya Yang, Ge Xiao, Bi-Cheng Liu. *Institute of Nephrology, Zhongda Hospital, Southeast University School of Medicine, Nanjing, Jiangsu Province, China.*

Background: Left ventricular hypertrophy (LVH) is a major cardiovascular complication and an important predictor of mortality in diaysis patients.Studies have suggested that angiotensin-receptor blockers (ARBs) could ameliorate LVH, but results are controversial. The purpose of this study was to evaluate the effect of ARBs versus placebo or alternative treatments on LVH in dialysis patients.

Methods: We performed systematic searches of PubMed, Embase, Cochrane Central Register of Controlled Trials, reference lists and expert contacts according to a standardized protocol, through November, 2010.

Results: Six studies involving 177 participants reported results of 4 comparisons with hemodialysis patients and 2 comparisons with peritoneal dialysis patients. ARBs ameliorated LVMI compared with non-ARB in dialysis patients (WMD -26.34g/m^2, 95% CI-37.77~-14.90, $p<0.01$). However, there was no significant difference between the ARB group and the non-ARB group (WMD 1 g/m^2, 95% CI -0.56 – 2.56, $p=0.21$) in the study of EF. ARBs treatment induced a greater reduction in LVMI when compared with non-ARB group (WMD -22.4g/m^2, 95% CI -35.37-- -9.11,$p=0.0009$) in heamodialysis patients. Interestingly, ARBs did not work as well as in peritoneal dialysis patients. In alternative treatment groups, the result suggested that losartan were superior than enalapril in the regression of LVMI (WMD -16.23 g/m^2, 95% CI -21.79 – -10.67, $p <0.01$). For left ventricular function, enalapril showed no inferior than losartan reflecting by the parameter of EF (WMD -0.36 g/m^2, 95% CI -2.92 – 2.21, $p =0.79$). One article reported the combination of ARBs and ACE inhibitors further reduced LVH more than either agent alone.

Conclusions: This meta-analysis suggests that ARBs are effective in treatment of left ventricular hypertrophy in patients with hemodialysis.

Patient Referral to Active Supportive Care: A Retrospective, Observational Study of Changes in Demographics and Outcome Thalakunte M. Muniraju,[1] Frances E. Marr,[1] Therese Wood,[1] Christopher John Chisholm,[1] Alison Brown,[1] Neil S. Sheerin.[1,2] *[1]Renal Unit, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; [2]Newcastle University, Newcastle upon Tyne, United Kingdom.*

Background: The majority of patients with advanced chronic kidney disease (CKD) have a significant number of comorbidities and high mortality rate. Renal replacement therapy may not be the ideal or preferred treatment for all patients with advanced kidney disease.

Methods: Active supportive (conservative) care (ASC), is well recognised as one of the management options in patients with advanced CKD and significant comorbidity. This study was undertaken to look at the demographics and survival of patients referred for ASC.

A retrospective, observational study of all patients who were referred for ASC from March 2002 to December 2010 at Newcastle Freeman Hospital Renal Unit (United Kingdom) was undertaken. Patients were identified and demographic data obtained from ASC database. Patients other demographics and estimated Glomerular Filtration Rate (eGFR) were collected using the hospital electronic record.

Results: A total of 387 (186 male and 201 female) patients were referred for ASC during the study period. The number of patients referred more than doubled from 2002 to 2003 and has remained consistent for the 8 years thereafter. The average age of the patients referred was 81.46 years, and it has been gradually increasing since 2006. Average eGFR was 17.00 mls/min/1.73m^2, with no significant difference between years. Out of 387 patients, 286 are deceased and 89 remain under follow up. 12 patients changed modality. The average time on ASC for the 286 deceased patients was 14.02 months.

Conclusions: This study demonstrates that number of patients referred for ASC has increased over time with increasing awareness, patient education and preference. There is no significant difference in eGFR at the time of referral over time, however, the age of referral has gradually increased since 2006. The average time spent on ASC is just over a year. This could represent more effective low clearance care. These findings demonstrate significant service implications to the trust and may reflect a shift in attitude.

TH-PO314

Multiple-Intervention Model May Preserve Better the Renal Function of Patients with Type 2 Diabetes Mellitus and Early Nephropathy Compared with the Standar Care Model Héctor R. Martínez Ramírez, Alfonso M. Cueto-Manzano. *Unidad de Investigación Medica en Enfermedades Renales, Instituto Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico.*

Background: Renal function (RF), can be preserved by trained family physicians (FP), in DM2 and early nephropathy (EN), but negative lifestyle (LS) habits weren't modify. Multiple-Intervention Model (MIM), could be an option. Aim: To determine the effect of two health-care models on RF in DM2/ EN patients.

Methods: One unit received MIM, other standar care model (SCM). All FP were trained on EN. Patients in MIM received 2h/week an educative intervention by a multidisciplinary team for 4 wks in small self-help groups: emotional (social worker); nutritional (dietitian); exercise (physical trainer); and health-related problems (FP); evaluated at 0 and 6 months by LS questionnaires, clinical and biochemical (Mx. score is 100=better SL)

Results: Of 113 patients included; 44 in MIM and 48 SCM ended 6 moths of follow up.

Differences in lifestyle questionnaire habits	MIN (N 44)	SCM (N 48)
Knowledge	2.6 ± 3.0†*	0.8 ± 3.0
Adherence	2.9 ± 11.7	0.6 ± 4.9
Emotion	2.5 ± 3.8†*	0.30 ± 3.3
Exercise	1.6 ± 3.8†*	-0.08 ± 3.5
Tobacco Consumption	0.32 ± 1.3	0.13 ± 1.1
Alcohol Consumption	0.81 ± 2.1*	0.51 ± 2.0
Diet	3.4 ± 5.0*	2.5 ± 5.5*
Total	11.7 ± 12†*	5.6 ± 12*
Differences in clinical and biochemical variables		
Body mass index (Kg/m2)	-0.77 ± 1.3†*	-0.26± 1.07
Waist circumference (cm)	-2.1 ± 3.5†*	-0.14 ± 5.0
Systolic BP (mmHg)	-10.4 ± 20*†*	-14.2 ± 20
Diastolic BP (mmHg)	-3.9 ± 12 *	-5.2 ± 11*
Hb A1C, (%)	-0.84 ± 2.1†*	-0.21 ± 1.9*
Cholesterol (mg/dl)	-6.5 ± 32	-0.47 ± 47

HDL-cholesterol (mg/dl)	1.18 ± 9.5	2.5 ± 11
LDL-cholesterol (mg/dl)	-3.5 ± 26	-0.5 ± 30
Creatinine (mg/dl)	0.04 ± 0.19	0.03 ± 0.16
eGFR (ml/min/1.73m2)	-2.2 ± 14.6	-3.19 ± 15.3
Albumin/creatinine ratio (mg/g)	-32.5 ± 104†	51.0 ± 246

* $p < 0.05$ vs baseline the same model; † vs conventional health-care model

Conclusions: A MIM could helpful to improve the LS of patients with DM2 and EN, and preserve better their renal function

TH-PO315

Epidemiology of Acute Kidney Injury in Critically Ill Patients: A Multicenter-Multinational Study Nattachai Srisawat, Florentina E. Sileanu, John A. Kellum. *For the AKI-6 Investigators, The CRISMA center, Department of Critical Care Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Estimates of the ICU period prevalence of acute kidney injury (AKI) have varied from 20% to 70% across different centers. Estimates of hospital mortality and dialysis rates have also varied. Variation could be due to actual differences in disease incidence and clinical course or it could simply be a function of data ascertainment and application of diagnostic criteria.

Methods: We conducted a retrospective study of ICU patients treated at 6 academic hospitals, 2 each in North America, Europe and Australia. Our aim was to determine and compare the occurrence and outcomes of AKI in the ICU using standard methods across all centers.

Results: Of 15,567 critically ill patients, 435 were excluded due to history of chronic kidney disease or insufficient data. Reference creatinine was defined by the baseline creatinine if available or the lower of the ICU admission creatinine or the creatinine derived from MDRD formula if no baseline was available. We used the modified RIFLE criteria as proposed by the AKI Network (AKIN). Since urine output was not available from some centers, we examined the variation in AKI rates and outcomes using creatinine criteria alone. The ICU period prevalence of AKI (creatinine data only) varied from 14.6% to 43.8% (P<0.001). Hospital mortality rates of AKI patients by center varied from 20.4% to 35.9% (P<0.001). Even after removing the center with the largest difference in AKI event rate compared to the rest and after excluding another center with the largest difference in hospital mortality there was still significant variation in both ICU period prevalence for AKI (P<0.001) and associated hospital mortality (P<0.001).

Conclusions: Variation in occurrence of AKI and in associated hospital mortality is not explained on the basis of varied application of AKI criteria. Differences in epidemiology of AKI across centers may be due to difference in case mix or to secular trends in therapy. Multicenter studies of AKI epidemiology may lead to improved understanding of risk factors and prevention and treatment strategies for AKI.

TH-PO316

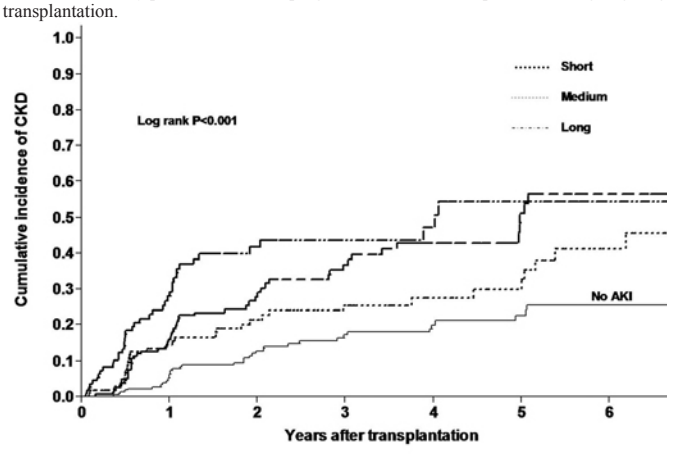
The Duration of Postoperative Acute Kidney Injury and Cumulative Incidence of Chronic Kidney Disease after Lung Kransplantation Edgard I. Wehbe,[1] Martin J. Schreiber,[1] Marie M. Budev,[2] Rachel Lauren Brock,[1] Sevag Demirjian,[1] Brian R. Stephany.[1] *[1]Nephrology and Hypertension, Glickman Urological and Kidney Institute; [2]Pulmonary and Critical care, Cleveland Clinic.*

Background: To determine if the duration of perioperative acute kidney injury (AKI) after lung transplantation predicts chronic kidney disease (CKD)

Methods: We retrospectively evaluated data on 657 patients who underwent lung transplantation from 1997 to 2009. AKI was defined by absolute rise in creatinine by >= 0.3 mg/dl and categorized into three stages by the magnitude rise in creatinine according to the AKIN classification and by the duration from baseline to nadir of creatinine (short (less than 5 days), medium (5–10days) or long (10 days or more)). Outcomes analyzed were the cumulative incidence of CKD stage 4 or 5 (eGFR <30 ml/min/1.73 m2) on long term follow-up

Results: We identified 424 patients (65 %) who had at least one AKI event in the first 2 weeks after transplantation. 115 (17.5%), 184(28%) and 125(19%) experienced short, medium and long duration AKI respectively. At one year the cumulative incidence of CKD was 15%, 16% and 27% in the short, medium and long duration AKI respectively. Figure 1 shows the competing risk analysis for the cumulative incidence of CKD stratified per duration of AKI. After adjusting for appropriate covariates (age, gender, sex, type of lung transplant, post-transplant HTN and DM, baseline creatinine, primary diagnosis leading to transplant), the hazard ratio for CKD was 2.0 (95% CI 1.2-3.3), 2.7(95% CI 1.7-4.2) and 4.4 (95% CI 2.7-7.0) for short, medium and long duration AKI respectively.

Conclusions: This study showed that the duration of AKI is independently associated with CKD and may provide additional prognostic information in patients undergoing lung transplantation.



TH-PO317

Rapid Progression of Chronic Kidney Disease Is Associated with Cardiovascular Mortality in the Japanese Population: The Gonryo Study Tae Yamamoto,[1] Masaaki Nakayama,[3] Mariko Miyazaki,[1] Hiroshi Sato,[5] Toshinobu Sato,[4] Sadayoshi Ito.[2] *[1]Division of Blood Purification, Tohoku University Hospital, Sendai, Japan; [2]Division of Nephrology, Endocrinology and Vascular Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan; [3]Division of Nephrology, Endocrinology Vascular Medicine and Diabetology, Fukushima Medical University, Fukushima, Japan; [4]Nephrology, Sendai Shakaihoken Hospital, Sendai, Japan; [5]Clinical Pharmacology, Tohoku University Graduate School of Pharmacology, Sendai, Japan.*

Background: Chronic kidney disease (CKD) is a public health problem due to a high risk for cardiovascular disease (CVD). Currently, decreased estimate glomerular filtration rate (eGFR) and proteinuria are accepted as independent risk factors. However, the reliability of the decline rate of eGFR for predicting cardiovascular mortality is not fully settled.

Methods: The study comprised 2,694 CKD patients recruited from 11 outpatient nephrology clinics, and they classified by eGFR in six CKD stages including stage 3A and 3B. The progression of CKD was defined as the decrease of eGFR with increasing CKD stages during two years. Risks of CVD, all-cause mortality and initiating dialysis were examined.

Results: During the observation time, 192 cases initiated to chronic dialysis therapy, and CVD events or death occurred in 135 patients. The frequencies of the CKD progression were 10% in stage 1, 30% in stage 2, 22% in stage 3A, 16% in stage 3B and 14% in stage 4, and it did not differ significantly by underlying renal diseases. Not only dialysis induction (6%, 1%, p<.001) but also CVD mortality (8%, 3%, p<.001) increased significantly in the CKD progression group compared to the non-progression group, and the odds ratio for CVD mortality was 2.78 (95% confidence interval, 1.77-4.35) by logistic regression analysis. When we focused for stage3, the CVD mortalities differed significantly between groups of the CKD progress in stage 3B, while it did not in stage 3A.<<

Conclusions: The progression of CKD by eGFR increased risk of CVD events and death. The subdivision of CKD stage 3 is useful to classify the higher risk people in early CKD.

Funding: Government Support - Non-U.S.

TH-PO318

Natriuretic Peptides as Predictors of All-Cause Mortality in Outpatients with Chronic Heart Failure and Renal Dysfunction Bård Waldum,[1] Arne S. Westheim,[2] Ingrid Os.[1] *[1]Department of Nephrology, Oslo University Hospital, Ullevål, Oslo, Norway; [2]Department of Cardiology, Oslo University Hospital, Ullevål, Oslo, Norway.*

Background: Brain natriuretic peptide (BNP) is released from the heart muscle cells in response to wall distension, and is a valuable diagnostic marker of heart failure (HF) and an independent predictor of prognosis in patients with chronic HF. Renal dysfunction is considered a confounding factor in the evaluation of BNP in HF patients, and since renal failure is common in HF patients, the interpretation of BNP levels is often limited in clinical practice. The aim was to investigate the prognostic utility of BNP in outpatients with chronic HF and renal dysfunction.

Methods: Valid data on BNP were available in 1930 outpatients with chronic HF included in the Norwegian heart failure registry from October 2000 to March 2010. Since analyzes were performed locally with various methods, quartiles of BNP at the last visit were defined at each center among patients with normal renal function (MDRD eGFR ≥ 60 ml/min). Patients with renal dysfunction (eGFR < 60 ml/min) were then stratified to four BNP stages according to the same quartile limits. Multivariate Cox regression models were used to investigate the prognostic utility of BNP with respect to all-cause mortality.

Results: Renal dysfunction was present in 734 patients (38 % of the total population). Median age was 76 years and 69 % were men. 58.7 % (431 patients) had BNP levels in the highest stage defined by quartiles in the patients without renal dysfunction. BNP stage independently predicted all-cause mortality (HR 1.47, 95 % CI 1.22-1.76, p< 0.001) together with lower systolic blood pressure, higher NYHA class, age and lower GFR. Two year survival of patients in the highest BNP stage was 61 % compared to 88 % in lowest BNP stage (p<0.001). No interaction between the prognostic information of BNP levels and renal dysfunction were found.

Conclusions: BNP level in outpatients with HF is a strong independent predictor of all-cause mortality and provide important prognostic information also among patients with renal dysfunction even though they are at greater risk of having increased levels of natriuretic peptides.

TH-PO319

How Well Do Family Practitioners Record Chronic Kidney Disease in 6 Million Patients? Poorva Jain,[1] Paul Cockwell.[2] *[1]Primary Care Clinical Sciences, University of Birmingham, Birmingham, United Kingdom; [2]Department of Nephrology, Queen Elizabeth Medical Centre, Birmingham, United Kingdom.*

Background: Chronic Kidney Disease (CKD) prevalence was reported as 10% in a primary care based cohort in the UK. However national estimates are much less at 4.3% but are derived from whether the practices diagnose the patient as having CKD using specific 'codes' introduced in 2007. We investigated the prevalence of CKD and whether these patients were coded as having CKD.

Methods: The Health improvement Network (THIN) is an anonymised database of 6.7 million patients from 426 primary care centres in the UK. THIN contains the patient's demographic information, consultations, laboratory results and prescriptions. We collected the demographics, laboratory creatinines and estimated and the 'codes' for CKD. The age standardised prevalence of CKD stages 3-5 was calculated between 2005-2009 using 1)A single creatinine transformed into MDRD GFR (Note IDMS calibrated creatinine MDRD equation was used for 2009 as only by 50% of UK laboratories) 2)A single laboratory eGFR 3) Codes for CKD.

Results: The mean age of CKD stage 2-5 (77.58±12.94) versus those with a GFR >60 (53.56±16.55) . The majority of patients with CKD were female except in CKD stage 5.The prevalence of CKD stages 3-5 were in years 2005, 2006, 2007, 2008 and 2009, using a single creatinine, 7.32%, 7.70 . 7.81 %, 7.36% and 7.88 respectively. The reduction in prevalence in 2008 estimates was likely due to the change to IDMS creatinine.

In 2009 CKD 3a is the most prevalent in the cohort (5.12%,and CKD was more common in women compared to men The prevalence was lower using lab reported eGFR.

CKD prevalence

%	2005	2006	2007	2008	2009
Using eGFR*	7.32	7.70	7.81	7.36	7.88
Using lab eGFR"	1.09	2.08	5.04	5.73	5.87
Practice Diagnosis of CKD	0.46	1.17	4.05	4.82	5.11

* single creatinine converted to MDRD eGFR "lab reported MDRD eGFR

The coded prevalence was again even further reduced and prevalence of CKD 3-5 was 5.11% in 2009.

Conclusions: The prevalence of CKD is much lower than previously reported studies, especially using laboratory eGFR, but family practice clinicians may not be aware that their patients have CKD.

TH-PO320

A Longitudinal Study of the Effect of Smoking on Progression and Survival in CKD Darren Green, Philip A. Kalra. *Vascular Research Group, Manchester Academic Health Sciences Centre, Salford Royal Hospital, United Kingdom.*

Background: Smoking affects vascular integrity, blood pressure and inflammation. Smoking-related lung disease is associated with polycythemia and loss of acid-base regulation. The theoretical effect of smoking on patients with CKD may therefore be to affect survival, progression of disease or even ESA and oral bicarbonate. However, evidence to support this and to assess the effect of smoking cessation is lacking.

Methods: This was a longitudinal study of the effect of smoking on CKD. 868 patients with CKD stages 3-5 not on dialysis were recruited over 5 years. Patients were classified as current smokers if they had smoked within 12 months, ex-smokers or non-smokers, and were followed up for up to 5 years. End points were death or progression of CKD of eGFR of >3mL/min/1.73m2/year or reaching ESKD. Concomitant clinical data were obtained at baseline and annual intervals.

Results: Baseline characteristics are summarized in table 1.

Table 1. Baseline characteristics.

	Current	Ex	Never

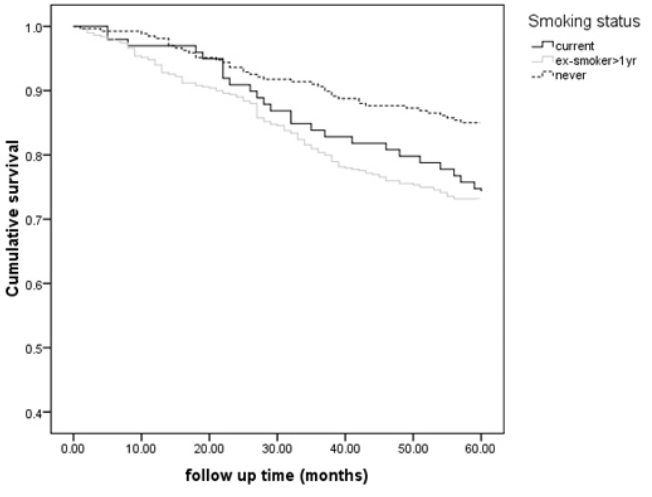
Pack years	30	25	0
CAD%	24	35	19

Current smokers were more likely to develop progressive CKD than ex- or non-smokers. Multivariate logistic regression indicates that this may be due to worse blood pressure control in current smokers. There was no difference in survival between current and ex-smokers but non-smokers showed significantly better outcome.

Figure 1. Survival in CKD according to smoking status



In this model, survival was dependent on pack years of smoking and not whether the patient continued to smoke. COPD did not affect a patient's ESA or oral bicarbonate requirements, nor progression of CKD.

Conclusions: Pack year history and not current smoking predicts survival in CKD. Progression of renal disease in current smokers correlates with poorer blood pressure control. A diagnosis of COPD does not affect patient maedication.

Methods: TH-PO321

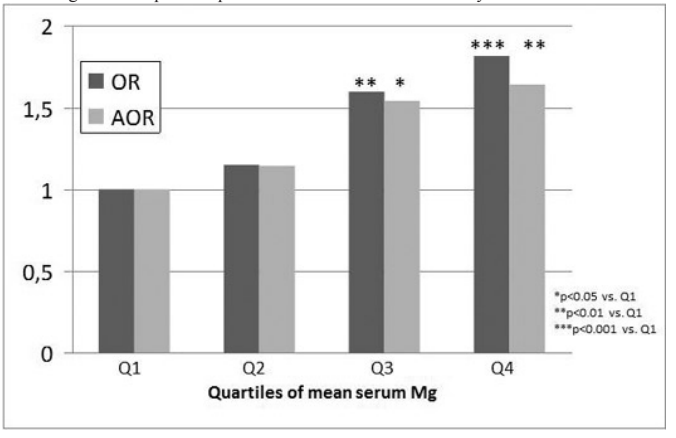
Serum Magnesium as a Predictor of Decline of Kidney Function in Chronic Kidney Disease Steven Van Laecke, Francis Verbeke, Evi V. Nagler, Wim Van Biesen, Raymond C. Vanholder. *Renal Division, University Hospital Ghent, Ghent, Belgium.*

Background: Hypomagnesemia is correlated with endothelial dysfunction, insulin resistance, and hypertension and as such might predict deteriorating kidney function. Analyses on small cohorts of diabetics or renal transplant recipients demonstrated that lower magnesium (Mg) levels are associated with faster decline of estimated glomerular filtration rate (eGFR). The aim was to confirm this association in a larger cohort of prevalent patients with chronic kidney disease (CKD).

Methods: Retrospective single tertiary center analysis of patients with CKD with at least 12 months of follow-up and excluding renal transplant recipients. Adjusted logistic regression analysis to examine the association between mean serum Mg levels and according to quartiles, averaged over the first year of follow-up and stable kidney function based on mean eGFR (CKD-EPI) slope, calculated by linear regression of individual slopes over time. Stable kidney function was defined as a mean eGFR decrease less than -1/ml/min per year during follow-up.

Results: In this cohort of 1670 patients, aged 57.4±17.3 years, 56% male; 97.7% Caucasian and 31.2 percent diabetic, 33.6% had a stable kidney function during a follow-up of 55.±29.9 months. On average, the eGFR slope decreased with -2.42 (IQR 5.44) ml/min/year. Mg was associated with decline in eGFR in univariate analysis and remained so when adjusted for age, diabetes, gender, serum protein, uric acid, C-reactive protein, calcium, phosphorus and hemoglobin (AOR of 1.08 with CI 1.03-1.13; p=0.003 per increase of 0,1mg/dl).The adjusted odds for stable kidney function were 1.66 times higher for the highest vs. the lowest Mg quartile (CI 1.20-2.30; p=0.002).

Conclusions: In a large cohort of diabetic and non-diabetic patients with CKD, low serum Mg is an independent predictor of faster decline of kidney function.



TH-PO322

Blood Pressure and Kidney Failure: A Systematic Review and Meta-Analysis in 2.7 Million People Celine Foote,[1] John Kent Lin,[2] Goodarz Danaei,[2] Majid Ezzati,[3] Mark Woodward,[1,4] Toshiharu Ninomiya,[5] Alan Cass,[1] Josette M. Eris,[6] Vlado Perkovic.[1] *[1]The George Institute for Global Health, AUS; [2]Harvard School of Public Health, USA; [3]School of Public Health, Imperial College London, UK; [4]Johns Hopkins Uni, USA; [5]Kyushu Uni, Japan; [6]Royal Prince Alfred Hosp, AUS.*

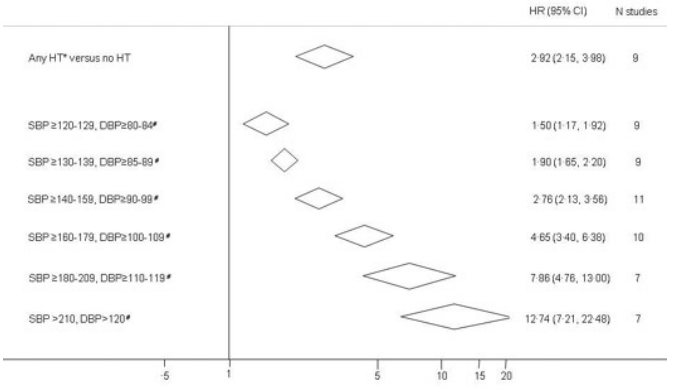
Background: The relative importance of blood pressure (BP) as a risk factor for kidney failure is still not clearly defined. A systematic review and meta-analysis was undertaken to understand the nature and magnitude of the relationship between BP and kidney outcomes.

Methods: We systematically searched MEDLINE and EMBASE for studies published before July 2009. Observational studies assessing the association between BP and kidney failure were included. Summary risk estimates and 95% confidence intervals (CI) were calculated using random effects models. The primary outcome was kidney failure defined as one or both of death due to kidney disease or treated end stage kidney disease (ESKD).

Results: We identified 106 cohorts that included 2.7 million individuals, among whom 7691 cases of kidney failure were observed. A 10mmHg higher systolic BP was associated with a 27% higher risk of kidney failure (95% CI 1.21-1.34, p<0.001) overall, including a 24% higher risk of death due to kidney disease (95% CI 1.16-1.33, p<0.001) and a 38% higher risk of treated ESKD (95% CI 1.32-1.44, p<0.001). The relationship was similar for systolic and diastolic BP, and across participant subgroups.

Conclusions: Association between BP (overall and JNC7 categories) and subsequent kidney failure

P for trend by JNC7 categories<0.001



*SBP≥140mmHg

Reference "optimal BP: SBP <120mmHg, DBP<80mmHg"

Conclusions: BP levels are consistently and directly associated with the risk of kidney failure. The strength of this relationship indicates that lowering BP could lead to a substantial reduction in the burden of kidney failure.

TH-PO323

Pain Management in a Nephrology Department: First Results of the PAIN Study Sarah Zimner-Rapuch,[1] Elisabeth Collin,[2] Nicolas Janus,[1] Sabine Amet,[1] Maud Grimault,[3] Elfie Bruce,[1] Laurence Rouillon,[1] Gilbert Deray,[3] Corinne Isnard-Bagnis,[3] Vincent Launay-Vacher.[1] *[1]Service ICAR Nephrology, Pitie Salpetriere Hospital, Paris, France; [2]Pain Management and Treatment department, Pitie Salpetriere Hospital, Paris, France; [3]Nephrology Department, Pitie Salpetriere Hospital, Paris, France.*

Background: Pain (P) remains a symptom that is underevaluated and not treated as it should be. In renal insufficiency patients (RI), dealing with pain killers is complicated due to dosage adjustment which could frighten the clinician and lead to undertreating patients. The PAIN study (Protocole Antalgie by ICAR in a Nephrology department) aims to evaluate P, its specifics, its management and its consequences on the emotional status of RI patients admitted in our department of nephrology.

Methods: PAIN is a prospective study of all patients who were admitted in our nephrology department. Data collected were: sex, age, weight, height, creatininemia, all the treatments received and if the patient was dialysed or transplanted. For each patient, four forms commonly used in P management were filled to evaluate nociceptive P, neuropathic P, care related P and emotional status respectively.

Results: During 3 months, 34 patients have been included, 59% males; median age 60 years. Eight patients were hemodialyzed and 4 had received a renal graft. Median estimated glomerular filtration rate was 39 ml/min/1.73 m2. 44% of patients received a pain killer. 20% had neuropathic P, among whom 6% were not treated. 76% of patients suffered from care related P and only 18% received a preventive treatment. Anxiety and depression occurred in 27% and 12 % respectively. Only one patient received an antidepressant drug. A dosage adjustment was necessary for 100% of the prescribed treatments and 50 % of drugs were not well renally adjusted. A week before the P evaluation, the mean score was 5 out of 10 in a numeric P scale, and on the day of evaluation, the score was 1.4.

Conclusions: Patients included are not well treated and their emotional status is barely taken into account. Therefore, it is crucial to relieve these patients, with appropriate drugs renally adapted. Relief seems to start with the medical staff being concerned.

TH-PO324

The German Chronic Kidney Disease (GCKD) Study: Design and Methods Kai-Uwe Eckardt, The GCKD Study Group. *Nephrology and Hypertension, University Clinic Erlangen, Erlangen, Germany.*

Background: Chronic kidney disease (CKD) is being recognized as a global health problem, but the conditions leading to CKD, the health impact of CKD and the prognosis of patients affected by CKD differ markedly. In particular renal failure and cardiovascular mortality are competing risks. Opportunities of targeted intervention are very limited so far and require an improved understanding of the natural course of CKD, of risk factors associated with various comorbidities and outcomes of the underlying pathomechanisms.

Methods: The German Chronic Kidney Disease (GCKD) - Study is a prospective observational national cohort study, aiming to enrol 5000 patients with CKD of various aetiology referred to nephrologists. At the time of enrolment patients have an eGFR of 30-60 ml/min x 1.73 m² or overt proteinuria in the presence of an eGFR above 60 ml/min x 1.73 m². A core set of lab parameters is determined in a central lab. Standardized collection of biomaterials, including DNA, serum, plasma and urine will allow identification and validation of biomarkers associated with CKD, CKD progression and related complications using hypothesis-driven and hypothesis-free approaches. Recruitment and patient-follow is organized through a network of academic nephrology centres collaborating with practising nephrologists throughout the country.

Results: Close to 3000 patients have already been successfully enrolled by the beginning of June. Study procedures have proved effective and biomaterials of all patients have been frozen shortly after collection and transferred to the central biobank on dry ice. Patient interview audits and other quality measures indicate good data quality.

Conclusions: The GCKD Study will establish one of the largest cohorts to date with CKD patients not requiring renal replacement therapy within central Europe. Similarities in its design with other observational CKD studies, including cohorts that have already been established in the US and Japan will allow comparative and pooled analyses to identify important regional differences and increase the statistical power.

Kidney Function and Age-Related Macular Degeneration Gareth J. McKay,[1] Chris C. Patterson,[1] Gerard Savage,[1] Orla McNally,[1] A.J. McKnight,[1] Damian G. Fogarty,[1] Giuliana Silvestri,[2] Alexander P. Maxwell.[1] *[1]Centre for Public Health; [2]Vision and Vascular Science, Queen's Universtity Belfast, United Kingdom.*

Background: Age-related macular degeneration (AMD) shares risk factors and pathways with several diseases affecting the kidney most notably those relating to complement activation and premature cardiovascular disease. Previous reports demonstrate association between reduced kidney function and AMD. Our primary analysis sought to assess modulation of AMD risk as a consequence of kidney function using glomerular filtration rate (eGFR) in an AMD case-control cohort, with a secondary analysis to assess genetic variation in key alternative complement pathway genes and their effect on eGFR.

Methods: eGFR was estimated by CKD-EPI equations on serum creatinine levels measured in 307 AMD cases (219 late AMD; 88 early AMD) and 172 no disease controls. Binary logistic regression analysis estimated effect size of eGFR on AMD risk after adjustment for sex and age. Further adjustment was made for additional covariates such as genetic risk in key complement genes, Factor H, Factor B, Component 2 and Component 3 and also smoking status. Ordinal regression was used to evaluate the effect of complement genetic variants on eGFR in a secondary analysis.

Results: In the primary analysis, a non-significant decreased risk for all types of AMD (early and late) was estimated for moderate CKD (eGFR <60ml/min/1.73m²) OR=0.62 (95% CI: 0.24-1.63; P=0.38) after adjustment for age and sex. Subset analysis for late AMD only, showed similar effect. Adjustment for complement genetic covariates and also smoking status failed to further modify risk. Secondary analysis assessing genetic variation in key complement regulatory genes, failed to detect any association with eGFR in an ordinal regression analysis.

Conclusions: Although several independent studies have demonstrated increased risk of AMD associated with impaired renal function, we were unable to replicate these findings in our cohort. The cross-sectional nature of our sample with potential confounding may have limited our findings. Secondary analysis assessing genetic variation in complement-related genes also failed to demonstrate association with eGFR.

TH-PO326

Impaired Kidney Function at Hospital Discharge Has a Major Impact on Long-Term Survival of Critically Ill Patients Recovered from Renal Failure Susanne Stads,[2] Gijs Fortrie,[1] Jasper Van Bommel,[2] Robert Zietse,[1] Michiel G.H. Betjes.[1] *[1]Nephrology, Erasmus MC, Rotterdam, Netherlands; [2]Intensive Care, Erasmus MC, Rotterdam, Netherlands.*

Background: Acute renal failure (ARF) in patients on the intensive care unit (ICU) necessitating renal replacement therapy (RRT) is associated with high mortality. However, little is known about renal recovery in surviving patients and the effect of impaired kidney function on long-term survival after hospital discharge.

Methods: A retrospective cohort study was performed including all patients older than 18 years (n=1218) admitted to the intensive care unit (ICU) of a tertiary care center who received continuous RRT. Data were collected for the period 1994 to 2010.

Results: In-hospital mortality was 54.9%. After hospital discharge, the overall mortality was 75.3 % after a median follow up of 8.5 years (range 1-17 years). Univariate analysis showed that age, surgical or non-surgical patients and kidney function at discharge were associated with survival. Multivariate Cox regression analysis of the association of kidney function and patient survival was performed, adjusting for the variables: age, sex, surgical or non-surgical patients and cause of ARF on the ICU. eGFR at hospital discharge was independently associated with long-term survival (p <0.001). Only 87 (15.8%) patients were discharged with an eGFR > 90 ml/min (using the MDRD formula). In this group 5 and 10-years survival were respectively 77.6% and 66.7%. Mortality risk increased for every increase in stage of CKD (hazard ratio 1.25, p<0.001). Patients discharged with an eGFR <30 ml/min (CKD 4-5, 37.3% of patients at hospital discharge) had a 5 and 10 years survival of only 42.5% and 28.5%. After exclusion of the patients known with CKD before admittance to the ICU, the eGFR at hospital discharge remained strongly negatively associated with long-term survival.

Conclusions: The majority of critically ill patients who received CRRT on the ICU have an impaired kidney function at hospital discharge, which has a major negative impact on their long-term survival. These results stress the importance of preserving kidney function in ICU patients and the need for long-term nephrological follow-up.

Presence of Diabetes in CKD Is Associated with Higher Rates of Comorbidities and Medication Use: Results from a Large US National Healthcare Claims Database Justo Sierra-Johnson, Trong Le, Kecia Godbey, James R. Voelker. *Eli Lilly and Company, Indianapolis, IN.*

Background: To describe the pharmacological treatment pattern and comorbidities among US patients diagnosed with chronic kidney disease (CKD) with and without diabetes (DM).

Methods: Employing a retrospective cohort study design on a large US national healthcare claims database (MarketScan), patients aged 18+ with a diagnosis for CKD (ICD-9 code: 585.x) between January 1, 2007, and December 31, 2008 were identified and the first CKD diagnosis was the index date. All patients selected were required to have 12 months of continuous pharmaceutical and medical benefit enrollment. Descriptive statistics were summarized for patient demographics, comorbid medical conditions, and medication use. Chi-square and Wilcoxon tests were applied.

Results: There were 116,512 patients that met inclusion criteria with a mean age of 65 years and 56% male. The prevalence of diabetes in CKD patients was 45%. Significantly higher proportion of CKD w/DM had a diagnosis code for cardiometabolic risk factors (100% vs. 71%, p<0.0001), anemia (46% vs. 35%, p<0.0001), cardiovascular disease (39% vs. 25%, p<0.0001), nephritis & nephrosis (34% vs. 27%, p<0.0001), other renovascular disease (27% vs. 22%, p<0.0001), disorders of fluid electrolyte & acid-base balance (20% vs. 14%, p=0.0083) and cerebrovascular disease (17% vs. 12%, p<0.0001) than CKD w/o DM . These rates increased as CKD stages increased. CKD w/DM also had significantly higher rates of medication use for hypertension, lipid disorders, diabetes and anemia compared to CKD w/o DM. Furthermore, CKD patients w/DM incurred higher overall costs (total medical and drug costs) compared to CKD w/o DM.

Conclusions: In CKD, patients with DM have higher rates of cardio- and cerebral-vascular diseases, cardiometabolic conditions, anemia, and renal disorders (nephritis, nephrosis, renovascular, fluid, electrolyte & acid-base) than patients without DM. Medication use and medical costs were also higher in the DM cohort. Thus, CKD patients with DM represent a particularly high risk group for associated comorbidities that require extensive medical resources.

TH-PO328

Serum Bicarbonate, Anion Gap, and Cardiorespiratory Fitness in US Adults Matthew K. Abramowitz, Thomas H. Hostetter, Michal L. Melamed. *Department of Medicine, Albert Einstein College of Medicine, Bronx, NY.*

Background: Chronic metabolic acidosis as a manifestation of chronic kidney disease is believed to contribute to skeletal muscle protein breakdown and insulin resistance. In the general population, levels of serum bicarbonate and anion gap (AG) have been associated with reduced muscle strength, insulin resistance, and hypertension. Whether these associations extend to other cardiovascular disease risk factors is unknown.

Methods: We examined the association of serum bicarbonate and AG with cardiorespiratory fitness in adult participants aged 20-49 years in the National Health and Nutrition Examination Survey 1999-2004.Fitness was determined by submaximal exercise testing and categorized based on age- and sex-specific cutpoints.

Results: The mean serum bicarbonate was 24.6 mEq/L (SE 0.1) and the mean AG was 10.26 mEq/L (SE 0.18). After multivariable adjustment, sex, fasting length, soda consumption, systolic blood pressure, serum phosphate, and hemoglobin were independently associated with both serum bicarbonate and AG. For each, the direction of association differed for serum bicarbonate and AG. Low fitness was most prevalent among those in the lowest quartile of serum bicarbonate or highest quartile of AG (18.9% (95% confidence interval (CI) 15.6-22.2) and 20.7% (95% CI 16.8-24.6), respectively). After multivariable adjustment, a 1 SD higher serum bicarbonate or AG was associated with an odds ratio for low fitness of 0.80 (95% CI 0.70-0.91) and 1.30 (95% CI 1.15-1.48), respectively. The associations of bicarbonate with fitness may have been mediated by differences in percent lean body mass (%LBM), which was directly associated with serum bicarbonate. Adjustment for %LBM rendered associations of serum bicarbonate with fitness non-significant.

Conclusions: In conclusion, lower levels of serum bicarbonate and higher levels of AG are associated with lower cardiorespiratory fitness in adults aged 20-49 years in the general US population. Further studies are needed to elucidate the determinants of serum bicarbonate and AG in persons without overt kidney disease and to prospectively examine associations with fitness and other CVD risk factors.

TH-PO329

Benefits of Revascularization for ARVD Patients with Flash Pulmonary Edema James Ritchie, Constantina Chrysochou, Philip A. Kalra. *Vascular Research Group, Manchester Academic Health Sciences Centre, University of Manchester, Salford Royal Hospital, United Kingdom.*

Background: Though there are case series suggesting a benefit of renal artery revascularization in the context of flash pulmonary edema (FPE) and atherosclerotic renovascular disease (ARVD), randomized data is lacking. By analyzing data collected prospectively since 1995 in our local ARVD patient cohort we aimed to quantify any benefits of intervention in patients presenting with ARVD and FPE.

Methods: Clinical data for all patients (n=819) were reviewed for evidence of presentation with FPE (acute decompensated heart failure with preserved ventricular function) prior to diagnosis of ARVD. Annual follow up data (range 1-12 years, mean 5 years) were reviewed for endpoints of death, cardiovascular and dialysis events. Comparisons were drawn between: 1) an interventional group - FPE patients revascularized (n=15) vs. FPE patients not revascularized (n=44) and 2) a medically managed group - FPE patients not revascularized (n=44) vs. non-revascularized ARVD patients without FPE (n=624). Cox proportional hazards corrected for age, sex, BP, eGFR, vessel patency, proteinuria and angiotensin blockade was performed.

Results: When patients with FPE who underwent revascularization were compared to those not revascularized, there was a dramatic and statistically significant reduction in hazard ratio for death (HR 0.08, p=0.015). For the same group, a reduction in cardiovascular events approached statistical significance (HR 0.05, p=0.059). There were insufficient dialysis events in the revascularized group for meaningful analysis.

Comparison of outcomes of non-revascularized patients with and without FPE showed statistically significant increases in HR for death (HR 2.37, p=0.011) and cardiovascular events (HR 2.4, p=0.031) for those with FPE.

	INTERVENTION		MEDICAL	
ENDPOINT	HR (95% ci)	p	HR (95% ci)	p
Death	0.08 (0.01-0.61)	0.015	2.37 (1.22-4.6)	0.011
Cardiovascular	0.05 (0.01-1.12)	0.059	2.4 (1.09-5.32)	0.031
Dialysis			2.66 (0.91-7.8)	0.075

Conclusions: Our observational data confirms that in the context of FPE, renal artery revascularization for ARVD appears to offer significant benefits over medical management.

TH-PO330

Serum Skeletal Alkaline Phosphatase (SAP) Levels Do Not Explain the Associations of Serum Total Alkaline Phosphatase (TAP) with ↑ Serum C-reactive Protein (CRP): National Health and Nutrition Examination Survey (NHANES) Rebecca Filipowicz,[2] Guo Wei,[2] Tom H. Greene,[1,2] Alfred K. Cheung,[1,2] Kalani L. Raphael,[1,2] Srinivasan Beddhu.[1,2] *[1]VA; [2]Univ Utah.*

Background: Higher serum TAP levels are associated with ↑ serum CRP levels in the general and CKD populations. It is unclear to what extent this association is related to bone disease. Therefore, we examined the associations of serum SAP levels with ↑ serum CRP (> 3 mg/L) in 8,515 adult participants in the 1999-2002 NHANES.

Methods: Details of NHANES data and sample collection have been published elsewhere. TAP, SAP, and CRP were measured in central labs following standardized protocols. The component of TAP not explained by SAP was represented from the residuals of a regression of log transformed TAP on log transformed SAP. Stata XI was used to conduct analyses.

Results: The mean (± SD) age was 46.3 ± 14 years, 48.5% were men, and 10% African-Americans. The median serum TAP levels and SAP levels were 73.8 IU/L and 13.1 µg/L, respectively. The median eGFR was 86.1 mL/min/1.73 m². 37% of the cohort had ↑ serum CRP.

Associations of serum TAP and SAP with odds ratios (OR) for ↑ serum CRP

	Entire cohort: OR (95% CI)	Non-CKD: OR (95% CI)	CKD: OR (95% CI)
Model 1*			
OR per doubling of serum TAP	1.78 (1.56, 2.02)	1.75 (1.53, 2.01)	2.08 (1.27, 3.43)
Model 2*			
OR per doubling of serum SAP	0.95 (0.86, 1.06)	0.89 (0.80, 1.01)	1.07 (0.74, 1.52)
OR per doubling of residuals**	3.82 (3.20, 4.57)	3.70 (3.09, 4.41)	5.24 (3.24, 8.47)

**Logistic regression models adjusted for demographics, MI, CHF, stroke, DM, SBP, DBP, waist circumference, eGFR, serum Ca, P, AST, ALT, bilirubin and GGT. **OR per doubling of ratio of observed TAP to the component of TAP accounted for by SAP

Conclusions: Bone disease and liver disease are unlikely explanations for the associations of serum TAP with inflammation. Further studies are needed to unravel the mechanisms of these associations.

Funding: NIDDK Support, Other NIH Support - National Center for Research Resources

TH-PO331

Association between Aortic Pulse Wave Velocity (aPWV) and Kidney Function Decline: The Health ABC Study Magdalena Madero,[1] Carmen A. Peralta,[2] Ronit Katz,[3] Robert B. Canada,[4] Linda F. Fried,[5] Samer S. Najjar,[6] Eleanor Marie Simonsick,[8] Kushang Patel,[9] Kim Sutton-Tyrrell,[7] Michael Shlipak,[2] Edward G. Lakatta,[8] Mark J. Sarnak.[10] *[1]Instituto Nacional de Cardiologia; [2]UCSF; [3]Wash U; [4]Tenesse U; [5]VA Pitt; [6]Medstar; [7]Pitt U; [8]NIA; [9]NIH; [10]Tufts.*

Background: Large vessel arterial stiffness is associated kidney disease in cross sectional studies.The association of large artery stiffness, measured by aPWV, and kidney function decline is less well established.

Methods: 2129 older adults with baseline measurement of aPWV and at least two measurements of cystatin C (year 3 or year 10 of follow-up). Linear regression was used to study the association between log transformed aPWV with kidney function decline (ml/min/1.73 m²/year). Logistic regression was used to evaluate associations with "rapid decline" (defined as $eGFR_{cysC}$ loss of > 3ml/min/1.73m² per year). Models were adjusted for demographics and cardiovascular (CVD) risk factors

Methods: Higher aPWV was associated with faster rates of decline in demographic adjusted models. Adjustment for blood pressure did not attenuate this association. Additional adjustment for CVD risk factors attenuated this association to a small extent.

Association between aPWV and Kidney Function Decline

aPWV	N	Demo adjusted* β(95% CI)	BP adjusted**β(95% CI)	Fully adjusted***β(95% CI)

809-1052	518	-0.30 (-0.57, -0.02)‡	-0.30 (-0.57, -0.02)‡	-0.31 (-0.59, -0.03)‡
>1052	519	-0.27 (-0.54, -0.01)‡	-0.27 (-0.53, -0.0001)	-0.22 (-0.49, 0.04)

per 1SD increase in aPWV, ‡ p<0.05*adjusted for demographics**Model 1 plus SBP, DBP & HTN meds,***Model 2 plus CVD risk factors

Results: Higher aPWV was also associated with "rapid decline" in demographic adjusted models (OR per 1SD higher log aPWV, 95% CI, 1.33, 1.03, 1.72). The relationship was attenuated after adjustment for blood pressure

Conclusions: Large artery stiffness is associated with decline in kidney function among older adults. These relationships are partly attenuated by cardiovascular risk factors and blood pressure

TH-PO332

Vascular Disease-Associated Mortality during CKD Progression: The MDRD Study Morgan E. Grams,[1] Hocine Tighiouart,[2] Josef Coresh,[1] Mark J. Sarnak.[2] *[1]Johns Hopkins University; [2]Tufts University.*

Background: Patients with vascular disease are at high risk for both progression of CKD as well as mortality prior to ESRD. The goal of this analysis was to characterize the competing risks of ESRD and all-cause mortality associated with vascular disease at various levels of eGFR.

Methods: Data from the Modification of Diet in Renal Disease (MDRD) study (N=1,795, including 840 randomized participants) were used to evaluate the risk of ESRD and pre-ESRD death associated with vascular disease, defined as coronary artery, cerebrovascular, or peripheral vascular disease. ESRD outcomes were obtained from USRDS and mortality from NDI. Cox proportional hazards analyses were adjusted for age, race, sex, blood pressure, cholesterol, current smoking, cause of ESRD, log-24-hour-proteinuria, and eGFR, and censored at ESRD, death, or end of study (12/31/2007), whichever came first. Interactions between vascular disease and eGFR were tested.

Results: Of the 1,722 participants with complete data, 224 (13.0%) had vascular disease. Mean GFR was 35 with a range of 5 to 117 ml/min/1.73 m2. Overall, 64% reached ESRD, and 14% died prior to ESRD. Participants with vascular disease were older, more often white, male, and diabetic, with higher systolic blood pressures, lower diastolic blood pressures, and lower HDL levels. The unadjusted incidence of ESRD increased with decreasing GFR (p for trend: <0.001); rates were similar between participants with and without vascular disease (p=0.6). In contrast, unadjusted mortality rates prior to ESRD were significantly higher among participants with vascular disease. In adjusted analyses, vascular disease remained significantly associated with death prior to ESRD (aHR, 1.66, 95% CI: 1.23-2.24, p<0.001) but not ESRD itself (aHR, 1.11, 95%: 0.91-1.35, p=0.3). There was no significant interaction between vascular disease and eGFR for either outcome (p>=0.4 for both interaction terms).

Conclusions: In the MDRD Study, participants with vascular disease were 66% more likely to die prior to ESRD; however, there was no modification of vascular disease-associated mortality risk by eGFR. In contrast, patients with vascular disease were not more likely to reach ESRD.

Funding: NIDDK Support

TH-PO333

The Associations of Serum Total Alkaline Phosphatase (TAP) with ↑ Mortality Is Not Explained by Serum Levels of Skeletal Alkaline Phosphatase (SAP): National Health and Nutrition Examination Survey (NHANES) Rebecca Filipowicz,[1] Guo Wei,[1] Tom H. Greene,[1,2] Alfred K. Cheung,[1,2] Kalani L. Raphael,[1,2] Srinivasan Beddhu.[1,2] *[1]Univ Utah; [2]VA.*

Background: Higher serum TAP levels are associated with ↑ mortality in the general and chronic kidney disease (CKD) populations. It is unclear to what extent this association is related to bone disease.

Methods: Therefore, we examined the associations of serum SAP levels with mortality in the 1999-2002 NHANES adults with estimated eGFR < 150 ml/min/1.73 m^2 (n=8,515). Details of NHANES data and sample collection have been published elsewhere. The component of TAP not explained by SAP was represented from the residuals of a regression of log transformed TAP on log transformed SAP. Mortality data were obtained from the NHANES Linked Mortality File through December 31, 2006. Stata XI was used for statistical analysis.

Results: The mean (± SD) age was 46.3 ± 14 years, 48.5% were men, and 10% African-Americans. The median serum TAP levels and SAP levels were 73.8 IU/L and 13.1 µg/L, respectively. The median eGFR was 86.1 mL/min/1.73 m^2.There were 705 deaths over a total of 2420 years of follow-up. There were 276 deaths over 864 years in the non-CKD and 429 deaths over 556 years in the CKD sub-populations.

Associations* of serum TAP and SAP levels with mortality

	Enitre cohort HR (95% CI)	Non-CKD population HR(95% CI)	CKD population HR (95% CI)
Model 1			
HR per doubling of serum TAP	1.33 (1.10, 1.60)	1.63 (1.24, 2.13)	1.17 (0.82, 1.67)
Model 2			
HR per doubling of serum SAP	1.05 (0.91, 1.22)	1.08 (0.89, 1.30)	1.15 (0.83, 1.59)
HR per doubling of residuals**	1.68 (1.16, 2.42)	2.11 (1.41, 3.17)	0.92 (0.51, 1.66)

*All Models are adjusted for demographics, MI, CHF, stroke, DM, SBP, DBP, waist circumference, eGFR, serum Ca, P, AST, ALT, bilirubin and GGT. **HR per doubling of ratio of observed TAP to the component of TAP accounted for by SAP

Conclusions: The association of serum TAP with ↑ mortality is not explained by SAP. Further studies are warranted to determine the mechanisms by which increased mortality risk is associated with ↑ levels of serum TAP.

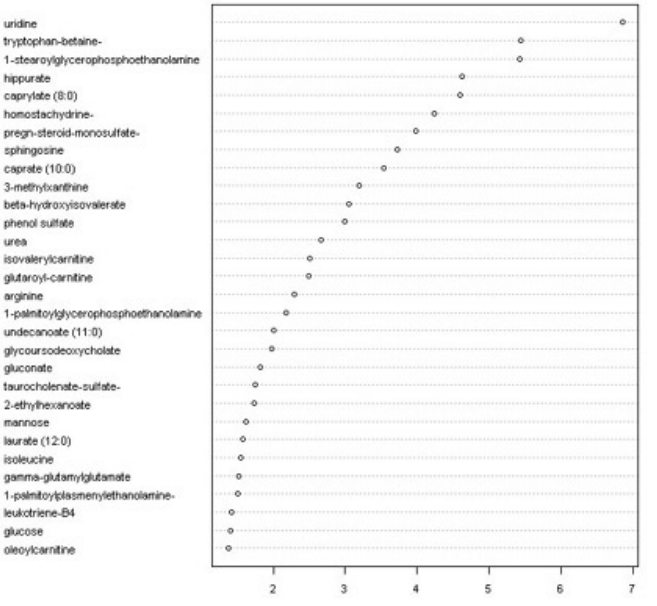
Plasma Metabolic Signature and Renal Function Decline in Subjects with Type 1 Diabetes and Proteinuria Monika A. Niewczas,[1] Jan Skupien,[1] Elizabeth Kensicki,[2] Jacob Wulff,[2] William Walker,[1] Adam Smiles,[1] Robert P. Mohney,[2] James Warram,[1] Andrzej S. Krolewski.[1] *[1]Research Division, Joslin Diabetes Center, Boston, MA; [2]Metabolon, Inc., Durham, NC.*

Background: Diabetes is characterized by significant metabolic disturbances; however, impact of specific metabolites on the diabetic nephropathy progression has not been studied. This study aimed to determine a plasma global metabolic profile and its association with renal function decline in subjects with type 1 diabetes (T1D) and proteinuria.

Methods: This nested case-control study consisted of 60 subjects with T1D, proteinuria and estimated glomerular filtration rate (eGFR) > 60 ml/min/1.73m2 followed for 10 years. Subjects (n=30) with annual eGFR decline greater than -3.5 ml/min/1.73m2 were defined as decliners. The Metabolon mass spectrometry-based platform (UHPLC-MS/MS, GC-MS) was used to measure biochemicals by a non-targeted approach in baseline plasma samples.

Results: Among 335 biochemicals measured, 31 (9.25%) were significantly different (P<0.05) between decliners and non-decliners. Random Forest analysis identified biochemicals involved in the following pathways as important to the classification scheme: arginine metabolism (arginine, creatine), branched-chain amino acids (valine, isoleucine), medium-chain fatty acids (caprylate), and inflammation (prostaglandin E2, leukotriene B4).



The Importance Plot ranks metabolites according to their contribution to the distinction between decliners and non-decliners. Metabolites are listed on the y-axis in order of decreasing importance.

Conclusions: In this global metabolic profiling study, we identified key biochemicals that were altered at baseline in subjects with T1D, proteinuria and subsequent renal function decline. This study provides important insights into markers of metabolic dysfunction as predictors of diabetic nephropathy progression.

TH-PO335

Long Term Decrimant in eGFR Following Leptospirosis Associated Acute Kidney Injury in the South of Ireland Donal John Sexton, Marek J. Mazur, Joseph A. Eustace. *Department of Renal Medicine, Cork University Hospital, Cork, Ireland.*

Background: Leptospirosis induced acute kidney injury (AKI) is a relatively uncommon disorder. Current data suggests that in the majority of cases eGFR returns promptly to premorbid baseline levels following treatment. There is relatively little data on the rate of renal recovery following AKI in a European population.

Methods: We conducted a cross sectional study of eGFR in all patients with previous acute kidney injury (AKI) due to confirmed acute Leptospirosis (n=27) in the southwest of Ireland over the prior ten years. The association, significance and independance of the relationship between baseline variables at the time of acute kidney injury and subsequent decline in eGFR were assessed by linear regression using SPSS v18 with a type one error rate of 0.05. The descriptive statistics are expressed as mean (sd) unless otherwise stated. eGFR was calculated using the CKD-EPI formula.

Results: Mean (sd); age 52(16)yrs, eGFR prior to AKI 91(18)ml/min/1.72m^2, eGFR post AKI 73(25)ml/min/1.73m^2. Median (IQR); follow up 1(0.5-3)yrs, peak serum creatinine during AKI 562(110-1000)µmol/L with 66.7% (18/27) of patients developing AKIN3, 7.4% (2/27) with AKIN2, 25.9% (7/27) with AKIN1, peak Bilirubin 62 (15-450) µmol/L. 88.9% (24/27) of patients were male. 40.7% (11/27) required renal replacement therapy, the Median (IQR) number of hemodialysis treaments in this group was 8 (3-16) treatments. 70.4% (19/27) of cases of AKI had sterile pyuria at presentation. Serovar type was available in 40.7% (11/27) and consisted of icterohaemorrhagica 25.9%, Hardjo 11.1% and Negat 3.7% of cases.On separate univariate linear regression models the β (95% CI) for the association with decrimant in eGFR at follow up were sex 0.02 (9.9, 26), nadir platelet count -0.51 (-0.48, -0.5) and peak serum bilirubin 0.35 (3.1, 22.6). On multivariate modeling using backward stepwise regression the final model β (95% CI) was sex -0.35 (-0.29, -0.04) and nadir platelet count -0.5 (-0.46, -0.06).

Conclusions: Despite recovery from AKI due to leptospirosis, many patients have significant decrimants in renal function which warrant long term follow up and may possibly be predicted by the nadir platelet count.

TH-PO336

Effect of Extended-Release Niacin/Laropiprant on Lipoprotein(a), Apolipoprotein A1, and Apolipoprotein B Levels in Dyslipidemic Stage 3 Chronic Kidney Disease Patients Andrew G. Bostom,[1] Jinyu Zhang,[2] Joachim H. Ix,[3] Nathan Spence,[4] Diane Tipping,[5] Andrew Tershakovec.[6] *[1]Division of Kidney Diseases, Rhode Island Hospital, Providence, RI; [2]Brown Medical School, Providence, RI; [3]Division of Nephrology, UCSD, San Diego, CA; [4]Division of Medicine, Rhode Island Hospital, Providence, RI; [5]Tipping LLC, Green Lane, PA.*

Background: Given the paucity of data regarding niacin's impact on experimental measures of dyslipidemia in chronic kidney disease (CKD), we examined the drug's effect on apolipoprotein (apo) A1 and B, and lipoprotein(a) [Lp(a)] levels among patients with stage 3 CKD.

Methods: Subjects (n=261) with a baseline estimated glomerular filtration rate (eGFR) of 30 to < 60 ml/min/1.73 m^2 were drawn from two completed trials of extended-release niacin/laropiprant (ERN-L, laropiprant being an inhibitor of niacin-induced flushing; ERN-L at 2g/d, n=177; n=84 placebo). Apo A1, apo B, and Lp(a) were measured serially over 24-weeks.

Results: The ERN-L and placebo groups were comparable with respect to baseline mean age, eGFR, apo A1, apo B, and Lp(a) levels, as well as the distribution of gender, concurrent statin use, and diabetes. Repeated measures analyses revealed that ERN-L, relative to placebo, caused a decrease (95% confidence interval) of -20.5% (-25.1.0%, -16.0%) in mean apo B levels, and – 27.8% (-38.4%, -23.2%) in median Lp(a) levels, as well as an increase of +11.1% (+14.7%, +7.4%) in mean apo A1 levels. Stratified analyses revealed that these effects on apo B, apo A1, and Lp(a) were entirely consistent with what was observed among dyslipidemic patients whose eGFR was ≥ 60 ml/min/1.73 m^2.

Conclusions: Niacin treatment results in robust lowering effects on apo B, and Lp(a) levels, as well as substantial increases in apo A1 levels, among patients with stage 3 CKD. Till now, stage 3-4 CKD patients have been significantly under-represented in secondary cardiovascular disease prevention trials. We conclude that a niacin treatment arm merits serious consideration within any future clinical trials targeting stage 3-4 CKD patients for the potential reduction of cardiorenal outcomes.

TH-PO337

Effect of Extended-Release Niacin on Serum Phosphorus and Fibroblast Growth Factor 23 Levels in Stage 2-3 Chronic Kidney Disease Andrew G. Bostom,[1] Andreea Poenariu,[1] Joachim H. Ix,[2] William Hanlon,[3] Darbie Maccubbin,[3] Michael Steffes.[4] *[1]Division of Kidney Diseases, Rhode Island Hospital, Providence, RI; [2]Division of Nephrology, University of California-San Diego, CA; [3]Merck Sharp & Dohme Corp, Rahway, NJ; [4]Merck Sharp & Dohme Corp, Rahway, NJ; [5]Laboratory Medicine and Pathology, University of Minnesota, Minneapolis, MN.*

Background: The hypophosphatemic effect of niacin is now increasingly recognized. We examined whether niacin-induced phosphorus-lowering among dyslipidemic stage 2-3 chronic kidney disease (CKD) patients was accompanied by any impact on their levels of the phosphatonin fibroblast growth factor (FGF)-23.

Methods: Intact serum FGF23 and phosphorus (phos) levels were determined in n=327 patients with a baseline estimated glomerular filtration rate (eGFR) of 30 to 74 ml/min/1.73 m^2 randomized to active extended-release niacin (N) 2g/once daily; with or without the prostaglandin-mediated flushing inhibitor laropiprant), or placebo (n=260 N; n=67 on placebo [P]), at weeks 0 (baseline) and 24.

Results: Mean (± SD) age [N= 61 ± 11; P= 61 ± 9 years], eGFR [N=62.8 ± 8.6; P= 62.2 ± 9.4 ml/min/1.73 m^2], as well as both baseline serum FGF23 [N=44.0 ± 18.9; P= 43.2 ± 18.6 pg/ml] and phos levels [N= 3.33 ± 0.48; P=3.39 ± 0.51 mg/dl] were comparable between the groups. While the 24-week change (mean ± SE) in serum phos among patients on active N (-0.45 ± 0.03; -13.5%) relative to P treatment (+0.03 ± 0.06) was highly significant (p <0.001), N treatment (-0.9 ± 1.0) had no effect compared to P (+1.8 ± 2.0) on serum intact FGF23 levels (p=0.238). Our findings confirm the sustained (i.e., 24-week) and relatively robust (-13.5%) hypophosphatemic effect of N in patients with stage 2-3 CKD. Conversely, such ERN treatment has no apparent impact on serum FGF23 levels at these stages of CKD.

Conclusions: Thus use of FGF-23 levels as a surrogate for phos-lowering effects, or as specific entry criteria for trials ostensibly designed to test the hypothesis that hypophosphatemic therapy will reduce cardiorenal outcomes in stage 3-4 CKD, may not be warranted.

Phosphate, CKD Progression and ACE-Inhibition – *A Post-Hoc Analysis of the REIN Trial* Carmine Zoccali,[1] Piero Ruggenenti,[2] Annalisa Perna,[2] Daniela Leonardis,[1] Rocco Tripepi,[1] Giovanni Tripepi,[1] Francesca Mallamaci,[1] Giuseppe Remuzzi.[2] *[1]CNR-IBIM, Clin. Epid. and Physiopath. of Renal Dis. and Hypert., Reggio Calabria, Italy; [2]Mario Negri Institute, Bergamo, Italy.*

Background: Phosphate has been suggested to play a role in the onset and progression of chronic nephropathies.

Methods: We evaluated the relationships between baseline serum phosphate levels, disease progression and response to angiotensin converting enzyme (ACE) inhibition in 331 patients with proteinuric nephropathies prospectively monitored by gold standard procedures in the setting of the Ramipril Efficacy In Nephropathy (REIN) trial.

Results: Independent of treatment, progression to end stage renal disease (ESRD) alone or in combination with doubling serum creatinine was significantly faster in patients with phosphate levels in the higher 3rd and the 4th quartiles than in those with lower phosphate (P<0.001). Similar findings were observed in crude and adjusted analyses considering phosphate as a continuous variable (P≤0.004). The ramipril renoprotective effect progressively decreased for increasing serum phosphate with a significant (P≤0.008) effect modification by phosphate levels on both outcomes and such an interaction was unmodified after adjustments for potential confounders, such as GFR and urinary protein.

Conclusions: In patients with proteinuric chronic nephropathies, phosphate is an independent risk factor for renal disease progression and may limit or even blunt the renoprotective effect of ACE inhibitor therapy. Trials are needed to test whether reducing phosphate exposure may improve renal outcomes and optimize the renoprotective effect of ACE inhibition in this population.

*On behalf of REIN working group.

Impact of a Chronic Kidney Disease Registry and Provider Education on Guideline Adherence – A Cluster Randomized Controlled Trial Paul E. Drawz,[1,2] Brook Watts,[2] Simran Singh,[2] Elizabeth Frazier Owen Kern,[1] R. Tyler Miller.[1,2] *[1]Nephrology & Hypertension, Case Western Reserve University, Cleveland, OH; [2]Medicine, Louis Stokes Cleveland VAMC, Cleveland, OH.*

Background: Low adherence to KDOQI guidelines may be due to unrecognized CKD and lack of guideline awareness on the part of providers. The goal of this study was to evaluate the impact of provider education and a CKD registry on guideline adherence.

Methods: We conducted a cluster randomized controlled trial at the Louis Stokes Cleveland VAMC. One of two primary care clinics was randomized to intervention. Providers from both clinics received a lecture on CKD guidelines at study initiation. Providers in the intervention clinic were given access to and shown how to use a CKD registry, which identifies patients with CKD and is automatically updated daily. Eligible patients had at least one primary care visit in the last year, had CKD based on eGFR, and had not received renal replacement therapy. The outcome was the percent of patients with at least one PTH measured in the past year and was evaluated at baseline and after the 12 month intervention. Secondary outcomes were percent at goal BP and percent prescribed ACEI/ARB.

Results: At baseline, 387 patients in the control clinic and 357 patients in the intervention clinic were eligible. The percent of patients with a PTH in the past year increased in both clinics from baseline to 12 months (14.7% to 22.7% in the control clinic; 15.4% to 28.4% in the intervention clinic). However, there was no difference between clinics at 12 months (P=0.07). After 12 months, there was no difference in the percent of subjects at goal BP (40.7% vs 44.1%) or the percent of subjects on an ACEI/ARB (74.9% vs 78.2%). Only 5 of the 37 providers in the intervention clinic accessed the registry.

Conclusions: An intervention that included education on CKD guidelines and access to a CKD patient registry did not improve guideline adherence over education alone. Adherence to the primary process measure improved in both clinics, but no improvement was seen in intermediate clinical outcomes. Improving the care of patients with CKD will likely require a multifaceted approach including system redesign.

Does Recognition of Chronic Kidney Disease in the Electronic Health Record Problem List Improve Care? Stacey Jolly, Sankar D. Navaneethan, Jesse D. Schold, Susana Arrigain, John W. Sharp, Anil K. Jain, Martin J. Schreiber, James F. Simon, Joseph V. Nally. *Cleveland Clinic, Cleveland, OH.*

Background: CKD recognition in the clinical setting is low. Whether CKD recognition in a problem list for a patient improves care is unclear.

Methods: Patients entered an electronic health record-based CKD registry if two outpatient eGFRs were <60 ml/min/1.73 m^2 at least 90 days apart from Jan 2005 to Apr 2011. CKD recognition was defined by having CKD in the problem list (ICD-9 codes for CKD, diabetic kidney disease, and hypertensive kidney disease) within 1 yr after entry. We calculated proportion of CKD patients with >1 yr follow-up whose CKD was recognized and examined differences by patient demographics, eGFR, nephrology visit, labs, and metformin prescription among diabetics.

Results: Among 45176 eligible patients, only 3356 (7%) had CKD noted in their problem list which differed markedly by race, age, gender, CKD stage, diabetic status and care by nephrologists (Table 1). Labs (iPTH, Vitamin D and LDL) were significantly more likely checked among patients with CKD in their problem list and inappropriate medication prescription was common among those without CKD in their problem list.

Table 1

Factor	No CKD recognition (n=41820)	CKD recognition (n=3356)	p-value
Age, mean (sd)	70 (12)	66 (14)	<0.01
follow-up, years, mean (sd)	3.4 (1.4)	3.3 (1.6)	<0.01
Male, N (%)	17287 (41)	2017 (60)	<0.01
White, N (%)	36749 (88)	2495 (74)	<0.01
Black, N (%)	4256 (10)	788 (24)	
eGFR at entry, mean (sd)	49 (10)	34 (15)	<0.01
CKD Stage at entry, N (%)			
Stage 3a (45-59)	30007 (72)	916 (27)	<0.01
Stage 3b (30-44)	9328 (22)	1164 (35)	
Stage 4 (15-29)	1996 (5)	790 (24)	
Stage 5 (<15)	489 (1)	486 (14)	
Diabetes, N (%)	8105 (19)	1380 (41)	<0.01
among diabetics, Metformin prescribed, N (%)	1407 (17)	117 (8)	<0.01
HTN, N (%)	33884 (81)	3072 (92)	<0.01
Nephrology visit within 1 yr, N (%)	1229 (3)	1152 (34)	<0.01
labs checked			
iPTH, N (%)	2455 (6)	1059 (32)	<0.01
Vitamin D, N (%)	6209 (15)	796 (24)	<0.01
LDL, N (%)	17393 (42)	1836 (55)	<0.01

Conclusions: There was low CKD recognition which translated into less CKD appropriate care. Targeted awareness along with increased use of the EHR problem list may improve CKD quality of care and outcomes in the clinical setting.

TH-PO342

Racial Disparity between African Americans (AA) and Caucasian Americans (CA) in Pre-ESRD Care: A Multi-Level National Study Guofen Yan,[1] Jennie Z. Ma,[1] Alfred K. Cheung,[2] Tom H. Greene,[2] Mohammed Norman Oliver,[1] Wei Yu.[1] *[1]University of Virginia; [2]University of Utah.*

Background: Pre-ESRD nephrology care is an important predictor for ESRD outcome. Racial disparity in pre-ESRD care is well known, but the cause is multifactorial, including geography. Using USRDS, this study employed a multilevel modeling approach to systematically examine to what extent regional characteristics contribute to the disparity.

Methods: The analysis included all AA or CA incident dialysis patients who completed the new Medical Evidence form in 2005-09. The care indicator examined was whether a patient had seen a nephrologist for at least 6 months prior to ESRD therapy. The three-level logistic regression models corresponding to patients, states and regional divisions were used to estimate the probability of seeing a nephrologist and its variability across states and divisions, and examine patient- and state-level predictors. We compared results of AA and CA by age >65 (1AA: n=36,868; 1CA: n=132,187) and age ≤65yrs (2AA: n=70,444; 2CA: n=109,384).

Results: The estimated probability of seeing a nephrologist was 55.8% for 1AA, 55.6% for 1CA, 48.5% for 2AA and 52.8% for 2CA, suggesting that at the national level the racial disparity (AA vs. CA) was in the younger population, but not in older. The estimated variability across states was 0.46 for 1AA, 0.33 for 1CA, 0.41 for 2AA and 0.35 for 2CA (SD on logit), indicating substantial inter-state differences in all groups (e.g., 60-71% probability in New England states vs. 38-53% in East South Central states). The disparity within state (AA minus CA in probability) varied substantially across states, from -13% to 3% in younger population, and -9% to 12% in older. Strong patient predictors included patient's insurance coverage, working status and comorbid conditions. Strong state predictors for state-to-state variability included state's poverty, racial composition and education level.

Conclusions: Pre-ESRD care depends highly on which state the patient lives in; AA more so than CA. The disparity among states is greater than that within states. Efforts to reduce racial disparity will be more effective by intervention at state level and targeting younger population.

Blood Pressure Lowering Agents for the Primary Prevention of Diabetic Kidney Disease: A Systematic Review and Meta-Analysis Jicheng Lv,[1,2] Vlado Perkovic,[1] Jonathan C. Craig,[3] Celine Foote,[1] Haiyan Wang,[2] Alan Cass,[1] Min Jun,[1] Hiddo Jan Lambers Heerspink,[4] John P. Chalmers,[1] Johannes F. Mann,[5] Giovanni F.M. Strippoli.[3,6,7] *[1]The George Institute for International Health, The University of Sydney, Australia; [2]Renal division, Peking University First Hospital, Institute of Nephrology, Peking University, Beijing, China; [3]Centre for Kidney Research, The Children's Hospital at Westmead, School of Public Health, The University of Sydney, Sydney, Australia; [4]Department of Clinical Pharmacology, University Medical Center Groningen, University of Groningen, The Netherlands; [5]Schwabing General Hospital, and KfH Kidney Centre, Ludwig Maximilians University Munchen, Germany; [6]Department of Pharmacology and Epidemiology, Mario Negri Sud Consortium, S Maria Imbaro, Chieti, Italy; [7]Diaverum Medical Scientific Office, Lund, Sweden.*

Background: We undertook a systematic review and analysis to quantify the benefits and harms of blood pressure lowering agents in normoalbuminuric individuals with diabetes.

Methods: We systematically searched MEDLINE, Embase, Cochrane Library from 1966 to January 2011. We included randomized controlled trials in normoalbuminuric participants with diabetes. Meta-analysis was done with a random effects model.

Results: We identified 28 trials involving 40,688 patients. ACE inhibitors reduced the risk of new onset of micro and/or macroalbuminuria compared with placebo (RR 0.71; 95% CI, 0.56-0.89), and compared to calcium channel blockers (RR 0.60; 95% CI, 0.42-0.85). ACE inhibitors also reduced the risk of death compared with placebo (RR 0.84, 95% CI 0.73-0.97). No effect was observed for ARBs for new onset nephropathy (RR 0.91; 95% CI 0.76-1.09) or death (RR 1.09, 95% CI, 0.89-1.34), compared with placebo, however meta-regression suggested possible benefits of ARBs for the prevention of kidney disease in high risk patients.

Conclusions: ACE inhibitors prevent new onset nephropathy and death in normoalbuminuric people with diabetes, and should therefore be used preferentially in this population. More data are needed to clarify the role of ARBs and other drug classes on the prevention of diabetic kidney disease.

TH-PO344

Assessment of Quality Incentive Program (QIP) Preparedness in Hospital-Based Dialysis Centers (HBDCs) and Independent Dialysis Organizations (IDOs) in 2010 George N. Coritsidis,[3] Gregory A. Maglinte,[1] Chun-Lan Chang,[2] Anjali Acharya,[3] Nathan Thompson,[3] Jerrold W. Hill,[2] Ze Cong,[1] Akhtar Ashfaq,[1] Jeffrey Petersen.[1] *[1]Amgen; [2]SDI Heath; [3]NYC Health and Hospitals Corporation.*

Background: QIP was implemented by Centers for Medicare and Medicaid Services (CMS) in 2011 to ensure that Prospective Payment System changes would not adversely impact ESRD dialysis programs. We assessed preparedness of HBDCs and IDOs for QIP in 2010 compared to 2008 national averages, per CMS methodology.

Methods: We conducted a retrospective analysis of an electronic medical record database from 6348 hemodialysis patients in 52 HBDCs and 31 IDOs in the US (15 states and all payer types) from Jan 1-Dec 31 2010. Analytic cohorts based on QIP criteria each comprised patients ≥18 years of age at first dialysis, and administered erythropoiesis stimulating agents ≥90 days after first dialysis with ≥4 hemoglobin (Hb) measures 5-20 g/dL (Hb cohort), or dialysis <5 times/week with ≥4 urea reduction ratios (URRs) ≥183 days after first dialysis (URR cohort). The proportion of facilities meeting 2008 national performance rates (≤2% of patients with mean Hb <10 g/dL, ≤26% of patients with Hb >12 g/dL, and ≥96% of patients with mean URR ≥65%) was assessed.

Results: Demographics among the cohorts were comparable: 55% men, mean age 60 years, >40% diabetes, >60% hypertension, mean Hb 11.3, and mean URR 73.4%. In 2010, the proportion of patients with mean Hb<10 g/dL, mean Hb>12 g/dL, and mean URR≥65% were similar in HBDCs and IDOs (Table 1). Although 93% of facilities in 2010 met criteria for limiting high Hb, 66% of facilities failed to meet criteria for low Hb and 60% failed to meet URR criteria.

Table 1. Performance Trends of HBDCs and IDOs in 2010 using CMS Methodology for QIP

	HBDCs				IDOs			
	Patient level		Facility level		Patient level		Facility level	
	% of patients[a]	n	% of facilities[b]	n	% of patients[a]	n	% of facilities[b]	n
mean Hb value < 10 g/dL	4.2%	3966	38.5%	52	5.2%	2382	25.8%	31
mean Hb value > 12 g/dL	12.8%	3966	94.2%	52	12.0%	2382	90.3%	31
mean URR ≥ 65%	93.8%	3231	46.0%	50	92.8%	2026	30.0%	30

[a]Proportion of patients with annual mean Hb or URR values as indicated.
[b]Percent of facilities achieving performance rates based on 2008 national averages; ≤2% of patients with mean Hb <10 g/dL, ≤26% of patients with Hb >12 g/dL, and ≥96% of patients with mean URR ≥65%

Conclusions: Improved performance is needed, as only 16.0% of HBDCs and 10.0% of IDOs would have achieved 100% QIP performance.

TH-PO345

Community Based Participatory Approach to Interrelated Epidemics of Obesity Diabetes and Kidney Disease in the Zuni Pueblo Vallabh O. Shah, Donica M. Ghahate, Jeanette Bobelu, Phillip Sandy, Mick T. Romancito, Arlene Bobelu, Philip Zager. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: The Zuni Pueblo has a relatively endogamous population of 6,300. The socio-economically disadvantaged Pueblo faces a public health challenge from interrelated epidemics of obesity, diabetes and kidney disease. Decreasing the impact of these epidemics is complicated by historical, economic and cultural barriers, which limit health care utilization. The Zuni Health Initiative (ZHI) is a chronic care model that accounts for the demographics, family structure, culture and traditions in the pueblo.

Methods: Prior to implementing the ZHI, we conducted a series of 1 hour focus groups with community members of different ages, healthcare workers and public school employees to identify perceived barriers to health care utilization. Community health representatives (CHR) led the sessions and presented a series of questions, developed from a literature review and designed to elicit information on perceived barriers to health care. These included: (1) Are your health care needs being met; if not, why not? (2) What help do you need? (3) What barriers do you encounter? (4) How does your diet and level of physical activity impact your risk for diabetes and kidney disease? Probes and follow-up questions were used to explore dominant themes. Audiotapes were translated and transcribed by bilingual ZHI staff. We reduced text to thematic categories, and constructed a coding dictionary and inserted these into Atlas-TI program.

Results: We identified the following perceived barriers to the participation of the community members in their care: (1) inadequate transportation infrastructure in the pueblo; (2) inadequate transportation between the pueblo and secondary and tertiary care sites; (3) inadequate staffing; (4) lack of staff continuity among Zuni Indian Health Service providers; and (5) lack of awareness of existing health promoting programs in the community.

Conclusions: Development of a CCM that addresses these perceived barriers will improve community access to health care and decrease the impact of interrelated epidemics of obesity, diabetes and kidney disease.

Assessment of Body Composition by Dry Mass Index and a Ratio of Total Body Water to Estimated Volume Based on Bioimpedance Analysis in Chronic Kidney Disease Patients Yasushi Ohashi, Takatoshi Otani, Reibin Tai, Ken Sakai, Sonoo Mizuiri, Atsushi Aikawa. *Nephrology, Toho University School of Medicine, Tokyo, Japan.*

Background: Adequate assessment of fluid and nutritional status is of major importance in monitoring Chronic Kidney Disease (CKD) patients; Body Mass Index and Bioimpedance analysis (BIA) have been proposed as acceptable markers. There remains uncertainty, however, regarding the impact of fluid status in CKD on BMI and the BIA measurements. Dry Mass Index (DMI), which removes TBW from weight, might be able to more adequate assessment tool. The aim of this study was, first, to assess agreement between TBW and estimated Volume (eV) by the Watson formula and second, to assess the reliability of the DMI as a marker of nutritional status.

Methods: A total of 45 CKD patients randomly were measured TBW, Intracellular Water (ICW), Extracellular Water (ECW) and a ratio of ECW to TBW as edematous index using the BIA. The participants were surveyed for age, gender, underlying disease, BMI, blood pressure (BP), serum albumin (Alb), eGFR, and proteinuria. The DMI was calculated by the formula [(weight - TBW)/height^2], and the correlation between DMI and BMI was assessed. As a marker of fluid status, we also evaluated a ratio of TBW to eV. The range of euvolemic status was defined from 0.970 to 1.029.

Results: The formula indicating relationship between BMI and DMI is obtained as [DMI = 0.5595 × BMI 2.091] by the linear regression analysis. Based on BMI, DMI and TBV/eV, the numbers of the participants were categorized among the following: BMI ≥ 25 with hypovolemia: 6, with euvolemia: 10 or with hypervolemia: 3; 18.5 ≤ BMI < 25 with hypovolemia: 11, with euvolemia: 9 or with hypervolemia: 5; and BMI < 18.5 with euvolemia: one patient. The TBW/eV was positively-correlated BP (p=0.02), %ICW (p<0.01) and %ECW in BW (p<0.01), was negatively-correlated age (p=0.01) and Alb (p=0.03). In contrast, the increase in ECW/TBW was not correlated ECW volume excess, but ICW deficit with aging (p<0.01).

Conclusions: Combing DMI to BMI could assess body composition in changes of body weight. The ratio of TBW to eV could be a suitable tool to assess fluid volume status in CKD patients.

TH-PO347

Prevention of Acute Kidney Injury (AKI) in Elective Abdominal Surgery Ana Serrano, Javier Villacorta, Javier Zamora, Beatriz Prada, Alfonso Muriel, Maria Teresa Tenorio, Susana Iglesias, Fernando Liano. *Nephrology, Hospital Universitario Ramón y Cajal, IRYCIS, Madrid, Spain.*

Background: AKI after abdominal surgery is not uncommon and is associated with high morbi-mortality.

Methods: The primary objective was to evaluate the effect of isotonic saline solution (ISS) administration in preventing AKI in patients undergoing elective non-laparoscopic abdominal surgery (Eab-surg) Secondary objective was to determine the incidence of AKI in this context.

Study design: A single center, prospective, randomized, controlled,open label, phase III trial. The study population included adult patients undergoing Eab-surg(ClinicalGovTrial NCT 00953940). Minor surgery procedures, patients with heart failure, GFR <60 ml/min and ASA classification ends scores (1 and 5) were excluded. The sample population necessary to demonstrate a 5% reduction of AKI (a=0.05 and 80% power) was estimated at 300 patients per arm. Intravenous ISS was administered in the treatment group at a dose of 1.5 ml/kg/h 12h before surgery. The control group did not received prior hydration. Serum creatinine and cystatin C were mesured before and 24, 48 and 72h after surgery. These results are from an interim analysis performed with the first 300 patients enrolled.

Results: Both groups were similar in demographics, comorbidity, type of surgery, baseline renal function (median and range) [Crs treated group 0.92 (0.58 to 1.86) SCr untreated 0.92 (0.49 - 1.57)] (similar data for cystatin C) and need for intraoperative volume or ICU requirement. Using the RIFLE classification, 1 patient with ISS was R at 24 hours and 2 patients without prophylaxis were R and F respectively at 48 and 72 hours after surgery. The AKIN classification identified 7 patients (3 in the ISS group) with functional impairment at 24 hours, 3 patients treated with ISS and 4 controls with AKI at 72h.

Conclusions: In non-laparoscopic elective abdominal surgery preoperative hydration in patients with normal renal function does not provide any protection against AKI. In this setting the rate of decline in renal function estimated by AKIN classification was low (2.33%).

Coronary Angiography with Online Hemodialysis To Prevent Contrast-Induced Nephropathy in CKD Patients Georg Schlieper,[1] Thilo Krueger,[1] Malte Kelm,[2] Jurgen Floege,[1] Ralf Westenfeld.[2] *[1]Nephrology, RWTH University Hospital, Aachen, NRW, Germany; [2]Cardiology, Heinrich-Heine University Hospital, Düsseldorf, NRW, Germany.*

Background: Optimal therapy to prevent contrast-induced nephropathy (CIN) in high risk patients with CKD remains a challenge. Hemodialysis after exposure to radiocontrast agents seems to have no benefit for the prevention of CIN but may be too late. In this study we analyzed the effect of online hemodialysis performed during coronary angiography on kidney function.

Methods: In late 2007 we changed our policy for the routine care of CKD 3-5 patients during coronary angiography from supportive care only (hydration with NaCl 0.9%, ACC; group STD) to supportive care plus online hemodialysis (Genius® dialysis via femoral vein access; group STD+HD) whilst performing the coronary angiography. Glomerular filtration rate (GFR) was estimated (MDRD formula) one and three months after angiography and at any other time point available after angiography. Moreover, the need for hemodialysis was determined.

Results: In group STD+HD 22 patients underwent coronary angiography. They were compared to a historical control group of 57 patients with coronary angiography (group STD) of the years 2006 and 2007. Baseline parameters (gender, prevalence of diabetes, body mass index, baseline GFR [30±9 vs. 32±13 ml/min; STD+HD vs. STD], amount of contrast media [93±59 vs. 110±63 ml]) were not significantly (ns) different between the two groups except for age (69 vs. 78 years, p<0.001). After coronary angiography the GFR in STD+HD patients did not differ significantly from that of STD patients (1 month: 25 vs. 31 ml/min; 3 months: 22 vs. 29 ml/min; any time point: 24 vs. 29 ml/min; all ns). The percentage of patients requiring hemodialysis was also not different between the 2 groups during 24 months of follow-up (32% vs. 23%, ns). There were no treatment-related major complications in the STD+HD group.

Conclusions: In conclusion, online hemodialysis during coronary angiography appears to be safe, however it is not superior to coronary angiography with standard supportive therapy. Thus, in high risk patients with CKD stage 3-5 online dialysis during angiography does not reduce the risk for CIN.

Lifetime Costs of Hemodialysis and Peritoneal Dialysis Patients in Taiwan
Shu-Jung Ho, Tze-Wah Kao, Fan-Chi Chang. *Department of Internal Medicine, National Taiwan University Hospital.*

Background: This study compared the lifetime costs between hemodialysis(HD) and peritoneal dialysis(PD) patients in Taiwan.

Methods: The data base of a cohort of patients who had received maintenance dialysis and were registered under the National Health Insurance (NHI) from July, 1997 to December, 2005 was utilized. Patients who were under 18 years old, were diagnosed with cancer or had received both PD and HD were excluded. PD patients were then matched with HD patients on age, sex and diabetic status, and followed up until Dec 31th, 2006. Patients who had stopped using the subsidies of the NHI for at least 3 months were considered dead. Life expectancy, expected years of life lost(EYLL), total lifetime costs(lifetime costs of ambulatory and inpatient care), and costs per year of both HD and PD patients were then compared using the ISQoL software.

Results: There were 3062 pairs of matched HD and PD patients (mean age, 53.2±15.4 years). Life expectancies and EYLL were not different between HD and PD patients. Diabetic patients who underwent HD had a slightly longer life expectancy than those who underwent PD (p=0.0061), while there was no difference in life expectancy between non-diabetic HD and PD patients. For diabetic patients, the total lifetime costs of those treated with HD were higher than those treated with PD, no matter the discount rate was 3% or 5% (P<0.001). For patient without DM, the total lifetime costs of those treated with HD were also higher than those treated with PD, whether the discount rate was 3%(P=0.0186) or 5%(P=0.0018). The costs per year for HD patients were higher than that of PD patients. Lifetime costs of ambulatory care were significantly higher for HD patients than for PD patients no matter the patients had DM or not and the discount rate was 3% or 5%. When lifetime costs of inpatient care were compared, there was no statistical difference between HD and PD. When adjusted by survival, patients undergoing HD had higher monthly health costs than PD patients.

Conclusions: Both the total lifetime costs, lifetime costs of ambulatory care and costs per year paid by the NHI were higher for HD than were for PD in Taiwan.

Serum gamma- Glutamyltransferase Levels Are Inversely Related to Endothelial Dysfunction in Chronic Kidney Disease
Mahmut Ilker Yilmaz,[1] Faruk Turgut,[1] Mehmet Kanbay,[1] Mutlu Saglam,[3] Alper Sonmez,[4] Murat Karaman,[5] Seyid Ahmet Ay,[5] Mujdat Yenicesu,[1] Peter Stenvinkel.[2] *[1]Nephrology, Gulhane School of Medicine, Ankara, Turkey; [2]Clinical Science, Karolinska University, Stockholm, Sweden; [3]Radiology, Gulhane School of Medicine, Ankara, Turkey; [4]Endocrinology, Gulhane School of Medicine, Ankara, Turkey; [5]Internal Medicine, Gulhane School of Medicine, Ankara, Turkey.*

Background: Gamma- glutamyltransferase (GGT) is an enzyme responsible for the extracellular catabolism of the antioxidant glutathione and recently implicated in the pathogenesis of atherosclerosis. Endothelial dysfunction is a prodomal feature of atherogenesis. Since oxidative stress is highly present in uremia and a causally linked to endothelial dysfunction, we hypothesized that GGT may be a factor implicated in this process.

Methods: We investigated the relationship between flow-mediated vasodilatation (FMD) and circulating GGT in a series of 214 nondiabetic nondialyzed patients with stage 3-5 CKD. Exclusion criteria contemplated, among others, alcohol consumption, manifest cirrhosis and established atherosclerotic complication.

Results: Serum GGT levels were negatively associated with FMD (r= -0.41, p<0.001) and eGFR (r= -0.34, p<0.001) in univariate analysis. Multvariate regression analysis showed that the association between GGT and FMD persisted after adjustment for age, sex, smoking, LDL-cholesterol, GFR C-reactive protein, systolic blood pressure, proteinuria, and homeostatic model assessment (HOMA) index.

Conclusions: Circulating GGT levels significantly associate with endothelial dysfunction, an important early feature of the atherogenic process. GGT might be an early marker of oxidative or other cellular stress that it is possibly directly related to the pathogenesis of endothelial dysfunction.

Patient Reported Outcomes Measurement Information System (PROMIS): Pediatric Chronic Kidney Disease
Brett W. Plattner,[1] Susan F. Massengill,[3] John D. Mahan,[3] Maria E. Ferris,[2] Gaurav Kapur,[3] Deepa H. Chand,[3] Gina-Marie Barletta,[3] Jens W. Goebel,[3] Laurence A. Greenbaum,[3] Rasheed A. Gbadegesin,[3] Debbie S. Gipson.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of North Carolina, Chapel Hill; [3]Midwest Pediatric Nephrology Consortium (MWPNC).*

Background: The PROMIS study goal was to create patient reported outcome evaluation tools. 233 children, ages 8-17, with CKD (stages I-V or kidney transplant) were enrolled from MWPNC sites in this cross-sectional study designed to validate the PROMIS instrument in children with CKD.

Methods: Stepwise regression analyses were conducted to assess association of child characteristics with 8 domain scores: peer relationships, depression, anxiety, pain, fatigue, upper extremity dexterity and mobility; regression coefficients must be significant at p < 0.15 to be selected in the model. Significant (p<0.5) results of multivariate analysis are reported (β(SE)).

Results: Patients with recent hospitalizations and with edema were associated with increased domain scores for depression, anxiety, pain, and low energy. Hospitalization and active edema were associated with decreased mobility scores. Co-morbidities negatively affected all domains except for pain. There were not significant changes in domain scores in response to different stages of CKD. Patients did not view ESRD negatively affecting their social relationships.

PROMIS Domain Scores for CKD (β(SE))

Covariate	Depression	Anxiety	Social-Peer Relationships	Pain	Low Energy	Upper Extremity Dexterity	Mobility
Hospitalizations		4.8(1.6)					-2.7(1.2)
Edema	5.9(2.2)	5.2(2.1)		7.4(2.5)	6.7(2.8)		-3.8(1.6)
Co-Morbidities Number	1.7(0.6)	1.8(0.6)	-2.5(0.6)		3.4(0.9)	-1(0.5)	-1.6(0.5)
CKD (stage 1-4)							
ESRD			6.9(2.1)				

Conclusions: The PROMIS domains are sensitive to disease severity indicators in children with CKD. Longitudinal studies documenting the responsiveness to change in disease activity over time will strengthen the validation and future utility of this tool.

TH-PO352

Changes in Serum Creatinine after Bariatric Surgery
Milen Amde,[1] Edgard I. Wehbe,[1] Jesse D. Schold,[1] John P. Kirwan,[2] Sankar D. Navaneethan.[1] *[1]Nephrology and Hypertension, Cleveland Clinic; [2]Pathobiology, Cleveland Clinic Lerner School of Medicine.*

Background: Weight loss after bariatric surgery is thought to improve serum creatinine in patients with and without chronic kidney disease (CKD). These changes in serum creatinine may be mediated through loss of muscle mass rather than improvement in renal function. Therefore, we examined the potential factors influencing the changes in serum creatinine among CKD patients who underwent bariatric surgery.

Methods: We conducted a retrospective study of stage 2-3 CKD patients (eGFR 30-89 ml/min/1.73m^2 and with ICD-9 code diagnosis for various kidney diseases) who underwent both restrictive and malabsorptive types of bariatric surgery. Renal parameters (serum creatinine and eGFR using CKD-EPI equation), body mass index (BMI), and systolic blood pressure (SBP) data were collected at baseline and at 6 months after surgery to analyze changes arising from weight loss. Factors predicting change in serum creatinine were examined using linear regression.

Results: Seventy-eight patients with mean serum creatinine of 1.3 mg/dl and mean eGFR of 52.8 ml/min/1.73m^2 were included. At the end of 6 months, BMI decreased from 44.6 kg/m^2 to 35.0 kg/m^2, SBP decreased from 134 +/- 21 to 130 +/- 17 mm Hg and serum creatinine decreased to 1.09 mg/dl with an improvement in eGFR to 66.5 ml/min/1.73m^2 (all paired t-test p<0.001). Number of antihypertensive and oral hypoglycemic agents decreased after surgery. The decrease in serum creatinine was significantly correlated with the decrease in BMI (r = 0.20) and SBP (r = 0.28). In the regression model, females had a 0.12 mg/dl lesser decline in serum creatinine than males (p=0.01), and Caucasians had a 0.11 mg/dl lesser decline in serum creatinine than African Americans (p=0.04) after surgery.

Conclusions: Serum creatinine decreases with weight loss after bariatric surgery. The decline in serum creatinine is less among females and Caucasians, populations who usually have lower muscle mass compared to males and African Americans. Future studies need to examine how weight loss after bariatric surgery produces a change in renal function, and how these changes in renal function are linked with changes in body composition.

Diet, Physical Activity, Obesity and Intentional Weight Loss in Chronic Kidney Disease: NHANES 1999-2006

Sankar D. Navaneethan,[1] John P. Kirwan,[2] Susana Arrigain,[3] Ashwini R. Sehgal,[4] Jesse D. Schold.[1,2] *[1]Nephrology & Hypertension, Cleveland Clinic; [2]Pathobiology, Cleveland Clinic; [3]Quantitative Health Sciences, Cleveland Clinic; [4]Nephrology, MetroHealth Medical Center.*

Background: Previous reports have shown that the chronic kidney disease (CKD) population has a higher body mass index (BMI) and waist circumference (WC) than non-CKD. We aimed to examine a) the lifestyle (dietary intake and physical activity) and behavioral factors (desire to weigh less) that might explain these differences and b) factors related to pursuing weight loss among a nationally representative sample of adults.

Methods: Cross-sectional analysis of 15,993 adult participants in the National Health and Nutrition Examination Surveys conducted between1999-2006. CKD was defined as patients with estimated glomerular filtration rate < 60 ml/min/1.73m^2 or urine albumin creatinine ratio >30 mg/g. Differences in lifestyle and behavioral factors between CKD and non-CKD participants were compared with sas survey procedures. Factors associated with pursuing weight loss were examined using survey logistic regression.

Results: Participants with CKD (n=2,812) had higher WC (100.2 cm vs. 95.3 cm, p<0.001) and a higher proportion had a BMI >30 kg/m^2 (37% vs. 29%, p<0.001). CKD and non-CKD populations did not differ based on percentage of energy derived from carbohydrate, fat, saturated fat and protein. However, 68% of the CKD population did not meet the minimum recommended leisure time physical activity goals (<450 METS/min/week) compared to 55% among non-CKD (p<0.001). Proportions of CKD and non-CKD participants who expressed desire to weigh less were not different. CKD participants had lower odds (0.84, 95% CI 0.71, 0.98) of pursuing a weight loss program, and so did African Americans (0.67, 95% CI 0.58, 0.76) and elderly adults.

Conclusions: Dietary composition and the desire to weigh less are not different for CKD and non-CKD populations. However, the CKD population is less active and pursues weight loss less often than non-CKD populations. These results suggest the need for studies to examine the underlying reasons for these differences, and studies aimed at developing targeted weight loss programs for CKD patients.

TH-PO354

Albuminuria Is Strongly Associated with Low BMI and Only Weekly to Cardiovascular Risk Factors in Apparently Healthy Subjects Younger Than Forty

Arjan Van der Tol,[1] Wim Van Biesen,[1] Paul Verbeke,[2] Kathleen Eeckhaut,[2] Raymond C. Vanholder.[1] *[1]Internal Medicine, Renal Division, University Hospital Ghent, Ghent, Belgium; [2]Occupational Health Care, Adhesia, Ghent, Belgium.*

Background: Albuminuria reflects increased cardiovascular risk in high risk groups. However, albuminuria occurs also frequently in absence of cardiovascular risk factors. This study evaluated which risk factors are associated with albuminuria depending on age.

Methods: The unreferred renal insufficiency (URI) study is a cross sectional study on the prevalence of metabolic risk factors in Belgian workers. Subjects with abnormal urinary sediment or missing data of interest were excluded, leaving a cohort of 1,361 apparently healthy workers. A single urine sample was used to measure albumin to creatinine ratio (ACR).

Results: As expected blood pressure (p<0.001), heart rate (p<0.001), plasma glucose (p<0.001), serum cholesterol (p<0.001), and BMI (p<0.001) were higher in those ≥40 vs. <40 years (median of age), but in spite of this higher prevalence of traditional cardiovascular risk factors, ln ACR was identical (0.78±1.13 vs. 0.78±1.17, p=0.97). In subjects under 40 years of age (n=668), ACR was strongly associated with BMI < 20 kg/m^2 (p<0.001) whereas it associated only borderline with cholesterol (p=0.03) and with antihypertensive treatment (p=0.01). In contrast, in subjects over forty (n=693), ACR was positively associated with BMI >30 kg/m^2 (p<0.001), heart rate (p<0.001), systolic blood pressure (p<0.001), diabetes (p<0.001), CRP (p=0.001) and smoking (p=0.001)

Conclusions: Screening for cardiovascular risk by using urinary albumin in apparently healthy subjects under 40 years of age was unexpectedly associated with low BMI and with virtually no traditional cardiovascular risk factors. Only in subjects over forty, albuminuria follows the traditional cardiovascular risk pattern.

Corticosteroid Therapy in IgA Nephropathy: A Systematic Review and Meta-Analysis

Jicheng Lv,[1,2] Damin Xu,[1] Hong Zhang,[1] Xinxin Ma,[1] Vlado Perkovic,[2] Haiyan Wang.[1] *[1]Renal Division, Department of Medicine, Peking University First Hospital, Peking University Institute of Nephrology, Beijing, China; [2]The George Institute for Global Health, the University of Sydney, Sydney, Australia.*

Background: Although several trials have evaluated steroids in IgA nephropathy(IgAN), there is still much uncertainty on such a treatment in IgAN. In this study we did a systematic review and meta-analysis to assess the efficacy and safety of corticosteroids in IgAN.

Methods: We systematically searched Medline, Embase, and the Cochrane Library for randomized controlled trials of corticosteroids therapy in IgA nephropathy published between 1966 and 2011.We evaluated the effects of corticosteroid on renal function and proteinuria , as well as adverse events. Meta-analysis was done with a random effects model.

Results: We identified 9 relevant trials with 536 patients with IgAN, the quality of which was suboptimal. Overall steroids therapy was associated with a lower risk of progression to kidney failure (double serum creatinine or ESKD) (RR:0.29, 95%CI: 0.13-0.65, p=0.02, I^2=0.0%, p for heterogeneity =0.47) and proteinuria reduction (WMD:-0.46g/d, 95%CI: -0.63- 0.29).

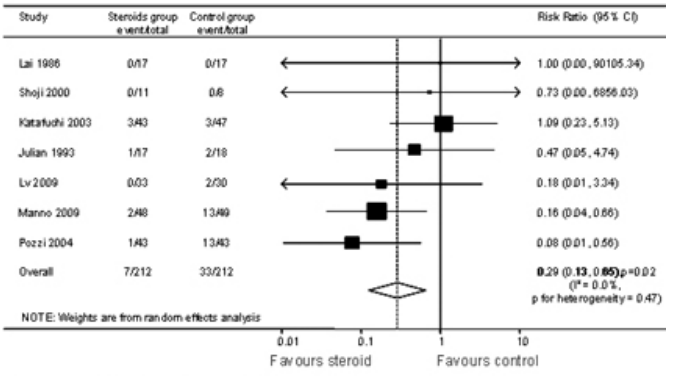

Figure 1 . Effect of corticosteroid on renal function

Subgroup analysis revealed that the effect of steroids is modified by the dose of steroids (p for heterogeneity =0.032) or the risk of kidney failures (p for heterogeneity =0.048). Full dose of steroids produced significant renal protection (RR 0.14, 95%CI: 0.05 - 0.39) while not in low dose steroids (RR 0.84, 95%CI 0.23 - 3.04). Steroids didn't increase the overall risk of adverse events (RR: 1.62, 95%CI: 0.83-3.16, p=0.15).

Conclusions: Corticosteroid produces renal protection in patients with IgAN without increase the risk of overall adverse events. However the low quality of included studies limited the study conclusions.

TH-PO356

Short-Term Effects of a Keto/Amino Acid Supplemented Low Protein Diet on the Delay of Progressive Renal Failure in Chronic Kidney Disease

Hoon Young Choi,[1] Hyeong Cheon Park,[1] Sug Kyun Shin,[3] Sung-Kyu Ha,[1] Hyun Chul Kim,[4] Ho Yung Lee.[2] *[1]Internal Medicine, Gangnam Severance Hospital, Yonsei University Health System, Seoul, Korea; [2]Internal Medicine, Yonsei University, College of Medicine, Seoul, Korea; [3]Internal Medicine, Ilsan Hospital, Seoul, Korea; [4]Internal Medicine, Kyemyung University, Daegu, Korea.*

Background: A protein-restricted diet with keto/amino acids (KA) supplement showed favorable effects on uremia, and delayed renal replacement therapy in patients with chronic kidney disease.

Methods: We conducted an open, prospective, randomized, and multi-center study for 6 months. A total of 67 patients were randomly assigned into two groups. The LPD+KA group was advised to take less than 0.6 g/kg/day of protein with KA. The LPD group was advised to consume less than 0.6 g/kg/day protein. Clinical and biochemical parameters were evaluated at baseline, 3 and 6 months.

Results: Calcium and phosphorous (Ca×P) product level measured at 3 months was significantly lower in the LPD + KA group than in the LPD group (LPD + KA group: 33.5 ± 5.0 mg^2/dL^2 vs. LPD group: 36.9 ± 7.9 mg^2/dL^2, $p < 0.05$), while those at 6 months were not different. The slope of the glomerular filtration rate (GFR slope) and the percentage of the GFR slope (GFR slope %) at 3 months were more preserved in the LPD + KA group than in the LPD group. The GFR slope and GFR slope % at 6 months were not significantly different. In the entire subjects, the GFR slope was negatively correlated with Ca×P product levels at 3 months, total cholesterol at baseline, and urine protein-creatinine ratio at baseline and 6 months (r = -0.255, r = -0.296, r = -0.412, r = -0.371, $p < 0.05$). A multiple regression analysis revealed Ca×P product at 3 months was the only independent factor affecting the GFR slope at 3 months.

Conclusions: The present study suggests that a low protein diet supplemented with keto/amino acids had a beneficial effect on preserving renal function and improving calcium and phosphorus disturbances in patients with chronic kidney disease.

TH-PO357

Baseline Observations from a Randomized Crossover Trial of Lowering Sodium Intake in Chronic Kidney Disease (CKD)-LOSALT Study Rajiv Saran,[1] Robin L. Sands,[1] Brenda W. Gillespie,[1] Michael Heung,[1] Scott L. Hummel,[3] Vimal K. Derebail,[4] Nathan W. Levin,[2] Fansan Zhu,[2] Peter Kotanko,[2] Philip J. Klemmer.[4] *[1]UM-KECC, Univ. of MI, Ann Arbor, MI; [2]Renal Research Institute, New York, NY; [3]Dept. of CV Medicine, Univ. of MI, Ann Arbor, MI; [4]Dept of Medicine, Univ. of NC, Chapel Hill, NC.*

Background: Many patients with stage 3-5 CKD may be overhydrated. We are conducting a randomized crossover trial of sodium (Na) restriction to primarily assess change in hydration status as assessed by bioelectrical impedance (BIA; lower=overhydration). Baseline data were used to explore the relationship between hydration status and GFR.

Methods: Adult patients with Stage 3-4 CKD with stable clinical course were randomized in phase I to a low salt diet (<2g of Na/day) *vs.* 'usual diet' for 4 weeks, with the alternate treatment given in phase II. Weekly dietary monitoring was provided and 24-hour urine Na measurments assessed compliance. A modified spectrum bioimpedance device and a switch box (Xitron 4200) automatically calculated ten measurements for each segment, arm, trunk, leg, calf, and whole body while the patient was in the supine position.

Results: Baseline data prior to randomization are presented in subjects enrolled so far (n=60; target=66). Mean age was 62±13, 56% male, 71% white, 39% diabetic, 87% hypertensive, mean BMI 32±5 g/m^2, eGFR 39±11ml/min/1.73m^2, and 24-hr urine Na 160±148 mEq. The table shows some significant differences in BIA measurements across CKD stages ($p<0.10$), baseline 24-hr urine Na correlated significantly with Calf (ECV/ICV, ECV/TBW, ECV/WT) and Whole Body (ECV/WT) BIA readings.

Conclusions: Baseline measurements in this clinical trial of Na restriction in CKD Stages 3-4 suggest greater degree of hydration across CKD stages 3-4 that may be amenable to Na restriction and/or specific pharmacotherapy.

Baseline BioImpedance Measurements (n=60)

BIA Measurement	Overall	CKD Stage			p-value*

First Human Exposure Suggests a Unique Metabolic Profile with Multiple Active Species for CTP-499, a Novel Agent for Treatment of Chronic Kidney Disease Dolly A. Parasrampuria, Virginia Braman, Changfu Cheng, Brett Grotbeck, David J. Turnquist, Kristine Hogan, Ara Aslanian, Lijun Wu, Robert Zelle, Philip B. Graham, James Shipley, Roger Tung. *Concert Pharmaceuticals Inc, Lexington, MA.*

Background: CTP-499 is a deuterated analog of 1-((S)-5-hydroxyhexyl)-3,7-dimethylxanthine, the active metabolite of pentoxifylline (PTX), a compound reported in multiple clinical trials to have beneficial effects in chronic kidney disease.

Methods: Single 400 mg doses of three different extended-release (ER) formulations of CTP-499 and ER pentoxifylline were administered to 16 healthy subjects in a randomized, crossover study. Blood samples were collected over a 48 hour period for the quantitation of CTP-499, pentoxifylline and their metabolites. Safety measurements included adverse event monitoring, clinical laboratories, 12-lead ECGs, and vital signs.

Results: All treatments were well tolerated. Only 9 adverse events were reported. All were mild in severity and did not require any action or treatment. CTP-499 was absorbed rapidly and metabolized extensively to five metabolites, nominally described as M1-M5. The medium-release formulation had the optimum pharmacokinetics profile based on minimizing peak-to-trough fluctuation and achieving complete drug-release. All metabolites were structurally identical (4 metabolites remained deuterated) to species resulting from ER pentoxifylline. The plasma AUCs for M1, M2 & M5 from CTP-499 dosing were each greater than 10% of parent drug. Whereas CTP-499 and M1 were comparable, M5 was lower and M2 was double the total exposure versus the equivalent non-deuterated moiety from PTX dosing. In whole blood, CTP-499, M1 & M2 demonstrated anti-inflammatory and anti-oxidative burst activity, inhibiting LPS-induced TNF-alpha and anti-CD3-induced INF-gamma secretion, as well as fMLP-induced oxidative burst in human neutrophils.

Conclusions: All treatments were well tolerated. The medium-release formulation was selected for development. The metabolism profile of CTP-499 is unique and may result in favorable biologic activity as an anti-inflammatory, anti-oxidant and anti-fibrotic agent in chronic kidney disease.

Single Ascending Dose Pharmacokinetics, Safety and Tolerability of CTP-499, a Novel Agent Being Investigated for Treatment of Chronic Kidney Disease Dolly A. Parasrampuria, Virginia Braman, Changfu Cheng, James Shipley, Brett Grotbeck, David J. Turnquist, Philip B. Graham, Roger Tung. *Concert Pharmaceuticals Inc, Lexington, MA.*

Background: CTP-499 is a deuterated analog of 1-((S)-5-hydroxyhexyl)-3,7-dimethylxanthine, the active metabolite of pentoxifylline, a compound reported in multiple clinical trials to have beneficial effects in chronic kidney disease.

Methods: This was a two part study. Part A was randomized, double-blind, parallel group evaluation of single ascending doses (6 active, 2 placebo for each dose) of an extended-release (ER) formulation of CTP-499 in healthy adult subjects at doses of 600, 1200, 1800, and 2400 mg. Part B involved open-label administration of a single dose of 400 mg immediate-release (IR) powder in capsule to 6 subjects. Blood & urine samples were collected over 32 hours for the quantitation of CTP-499 & its metabolites. Safety measurements included adverse events, clinical labs, 12-lead ECGs, and vital signs.

Results: A total of 38 subjects participated in the study; none discontinued. Two subjects dosed with 400 mg IR and 4 subjects dosed with 2400 mg ER formulation had emesis, which was thus dose and formulation related, but was not necessarily concentration related. All other adverse events were mild. CTP-499 was rapidly absorbed and extensively metabolized. With increasing doses, exposures increased more or less linearly, although nonlinearity cannot be ruled out. The dose levels were achieved by the use of multiples of 200 mg ER tablets, a factor to be considered in interpreting the data. Five metabolites were quantified in plasma, nominally described as M1-M5. Metabolites M1, M2 & M5 were present at greater than 10% of parent drug. In urine, M5 was the major metabolite, followed by M2 & CTP-499; M1, M3, M4 were negligible. The metabolism profiles were different for IR and ER, with more of the active moieties (M1, M2) formed with ER formulation.

Conclusions: CTP-499 dosed as an ER formulation was well tolerated at single doses of 1800 mg and less. Pharmacokinetic parameters indicate the potential for once daily dosing. Based on these data, further clinical evaluation in patients with chronic kidney disease is planned.

TH-PO360

Prevalence of Advance Directives in Patients with Kidney Disease or Other General Medical Diagnoses Frieder Keller, Florian Driehorst. *Medical Department, Division of Nephrology, University Hospital, Ulm, Germany.*

Background: After the law on living will was released in 2009, an increasing use of advance directives by patients was to observe in Germany. Since kidney patients are facing the potential or real need for dialysis, our hypothesis was that kidney patients less frequently state their living will than patients with other diseases.

Methods: An interview of all patients on our ward was performed who could give signed consent. Excluded were patients unable to talk and patients only admitted for a time period of less than 48 hours. Data are given as percentages or arithmetic means +/- standard deviation. Differences between kidney and other patients were tested for significance by the Student t-test or chi-squared test. Odds ratios with the 95 % confidence interval (CI) were calculated for the prevalence of living will by multiple logistical regression analysis of the main independent variables namely, age, sex and diagnosis.

Results: Among 505 admitted patients, 211 were included (42 %) and 200 patients completed the study. Of them, 75 were female and 125 male, 121 had a renal diagnosis and 79 another diseases. Overall, advance directives were prevalent in 52 cases (26 %). Of them, significantly more patients did forego resuscitation than did dialysis in their living will (31 % vs 8 %, $p = 0.001$). Patients having fixed an advance directive were significantly older (72 +/- 13 vs 59 +/- 16 years, $p = 0.001$) and significantly more women (36 % vs 20 %, $p = 0.01$). Overall, the prevalence of an advance directive was significantly less in kidney patients than in those with other diagnoses (20 % vs 35 %, $p = 0.015$). However, kidney patients were significantly younger than those with other diagnoses (60 +/- 16 vs 67 +/- 17 years, $p = 0.004$). Upon multiple logistical regression analysis the odds ratio for an advance directive was significantly only influenced by age (1.06 CI 1.0 - 1.1, $p = 0.0001$), but no longer by the sex (1.5 CI 0.7 - 3.1, $p = 0.228$) or by the kidney diagnosis (1.5 CI 0.7 - 3.0, $p = 0.287$).

Conclusions: Age was found the more impacting variable than the kidney diagnosis on the prevalence of advance directives. In their living will only a minority stated to forego dialysis (8 %).

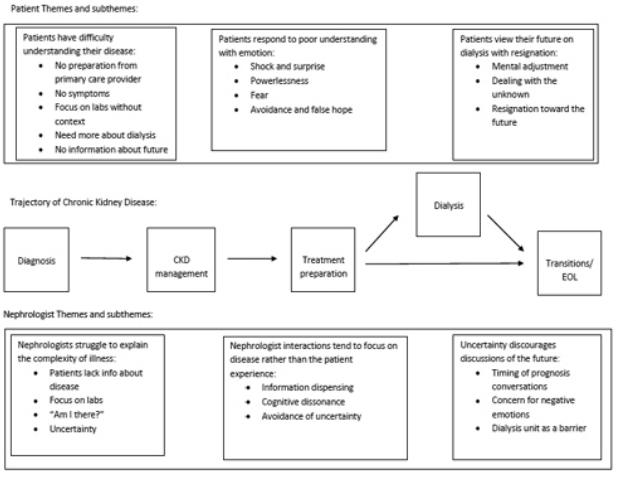
TH-PO361

A Qualitative Study: How Elderly Patients and Nephrologists Discuss the Kidney Disease Course Jane O. Schell,[1] Uptal D. Patel,[1] James A. Tulsky.[2] *[1]Nephrology, Duke University, Durham, NC; [2]Duke Center for Palliative Care, Duke University, Durham, NC.*

Background: Elderly patients with advanced kidney disease often suffer considerable disability, morbidity and mortality. In preparing for this disease trajectory, the impact of the physician-patient interaction toward understanding is not known. We sought to describe how nephrologists and older patients discuss and understand the course of kidney disease and its prognosis.

Methods: We conducted focus groups and semi-structured interviews with 11 nephrologists and 29 patients over age 65 with advanced CKD or receiving dialysis. All interviews were audio-recorded and transcribed. We used qualitative analytic methods to identify common and recurrent themes related to the primary research question.

Results: Prognosis was rarely discussed and the disease course was often followed through test results with less emphasis on the patient experience. We identified 6 themes which describe the challenges and experience of understanding the trajectory of kidney disease: 1) patients have difficulty understanding their disease; 2) patients respond to poor understanding with emotion; 3) patients tend to view their future on dialysis with resignation; 4) nephrologists struggle to explain the complexity of illness; 4) nephrologist interactions tend to focus on the disease rather than the patient experience; 5) uncertainty discourages discussions of the future.



Conclusions: We identify important challenges among patients and nephrologists in understanding and p**Conclusions:** reparing for the kidney disease course. While nephrologists recognize the special needs of elderly patients, communication barriers exist that prevent discussions which address the patient experience. Communication interventions that respond to patient emotion and address uncertainty may impact understanding and preparation.

Mortality and Functional Status in Elderly Dialysis Patients Residing in Assisted Living Care Facilities Keren Mandelzweig, Paul Komenda, Claudio Rigatto, Lisa M. Miller, Joe A. Bueti, Clara Bohm, Manish M. Sood. *Medicine, University of Manitoba, Winnipeg, MB, Canada.*

Background: As the elderly ESRD population grows, a larger proportion will require living in an assisted care facility such as a nursing home. We set out to investigate mortality and functional status in elderly ESRD patients residing in assisted living care facilities compared to age and co-morbidity matched ESRD controls who reside at home.

Methods: We developed a 3:1 age and Charlson co-morbidity score matched cohort of 192 elderly ESRD patients residing at home to 64 residing in an assisted care facility. Patients were identified during an acute hospitalization and with follow up beginning upon discharge. Mortality was examined by Kaplan Meier and multivariate adjusted Cox proportional hazards models with p value<0.05 considered significant.

Results: Individuals residing in assisted living facilities were more likely to have a history of stroke and dementia, have more illness acuity and a longer length of hospital stay compared to the matched controls. Severity and presence of impairments in all 6 domains of the ADL score (bathing, dressing, toileting, feeding, incontinence and transferring) were more likely in the assisted care group. The majority in assisted living (75%) had multiple areas (>1) of severe impairment requiring full care. Survival time was shorter in those residing in assisted living (Median 216 (84-347) vs. 891 days (651-1130), p<0.0001) and this persisted after adjustment for sex, APACHE score, admission diagnosis, history of stroke and dementia and hospital length of stay (HR 1.74, 95%CI 1.12-2.70). The hazard ratio attenuated after addition of ADL score into the model (HR 1.36 95%CI 0.87-2.13).

Conclusions: Elderly ESRD patients discharged to an assisted care facility have a significantly increased mortality compared with age and co-morbidity matched controls. The discrepancy in long-term survival can be predicted by a simple measure of functional status upon admission to hospital.

TH-PO363

Safety, Pharmacokinetics and Efficacy of AP214, a Novel Melanocortin Receptor Agonist, in Patients Undergoing Cardiac Surgery on Cardiopulmonary Bypass Daniel Steinbrüchel,[1] Thomas E.N. Jonassen,[2] Jorgen Frokiaer,[4] Soren Nielsen,[5] Peter A. Pallesen.[6] *[1]Department of Thoracic Surgery, University of Copenhagen, Denmark; [2]Institute of Biomedicine, University of Copenhagen, Denmark; [3]Department of Thoracic Surgery, University of Copenhagen, Denmark; [4]Water and Salt Research Center, University of Aarhus, Aarhus, Denmark; [5]Water and Salt Research Center, University of Aarhus, Aarhus, Denmark; [6]Department of Thoracic Surgery, Odense University Hospital, Odense, Denmark.*

Background: Development of Acute Kidney Injury (AKI) after cardiac surgery is associated with increased morbidity and mortality. Melanocortin receptor (MCr) agonists have marked immune modulating and organ protective effects in sepsis and surgery induced AKI animal models. AP214 is a novel pan-MCr agonist under development for prevention of AKI and organ failure after cardiac surgery.

Methods: Objective: Assessment of safety, pharmacokinetics and efficacy of AP214 in cardiac surgery patients with increased risk for post-OP AKI.

Double-blind placebo controlled randomized clinical trial comparing AP214, administered at three different dose levels (10, 50 or 200 ug/kg, respectively) given as bolus iv infusions, pre- peri- and 6 hours PO to patients (N=42) on cardiopulmonary bypass.

Results: AP214 at 200 ug/kg was safe and well tolerated with a similar side effect profile compared to placebo. Estimated half-life of AP214 was 12-14 min with no signs of accumulation. There was a good relationship between dose and exposure and no dose dependency in any PK parameter observed. In the placebo group 6/13 patients developed AKI compared to 3/12 patients in the AP214 200ug/kg group. Estimated GFR, serum creatinine and additional surrogate markers indicated a high degree of kidney function preservation after AP214 treatment, with no post surgical changes in any of the parameters.

Conclusions: AP214 is safe and well tolerated. Efficacy data suggest that AP214 might be a valuable pharmacological approach to reduce the severity and frequency of post-operative AKI in patients undergoing cardiac surgery on cardiopulmonary bypass.

FG-4592 Oral Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitor Corrects Anemia in Nondialysis CKD Patients without IV Iron Anatole Besarab,[1] Robert Provenzano,[2] Steven Fishbane,[3] Chao H. Sun,[6] Diogo S. Belo,[4] Thomas B. Neff,[5] Tyson T. Lee,[5] Marietta Franco,[5] Robert Leong,[5] Kin-Hung Peony Yu.[5] *[1]Henry Ford Hosp., Detroit, MI; [2]St. Clair Specialty Physicians, Detroit, MI; [3]Winthrop Dialysis Ctr., Mineola, NY; [4]California Inst. of Renal Research, Chula Vista, CA; [5]FibroGen, Inc., San Francisco, CA; [6]Apex Research, Riverside, CA.*

Background: Anemia is largely undertreated in nondialysis CKD. We report data from an ongoing phase 2b, open-label study of FG-4592 to correct anemia in adult nondialysis CKD patients (pts). Ninety-six pts (Hb ≤10.5 g/dL at baseline [BL]) who had not received ESAs for the prior 12 weeks (wks) were randomized to 4 equal cohorts. Cohorts A and B: 16 wks initial tiered, weight-adjusted doses of 60-140 mg FG-4592 thrice weekly (TIW); Cohorts C and D: 24 wks initial fixed doses of 50 and 100 mg FG-4592 TIW, respectively. Cohort-dependent dose adjustment was allowed every 4 wks. IV iron was not permitted. BL demographics were similar across cohorts. For 95 efficacy-evaluable pts, overall mean±SD BL Hb was 9.7±0.7 g/dL. FG-4592 treatment led to increases from BL Hb in all cohorts (Table). After 16 wks of treatment, all A and B pts treated >5 wks (n=46) had a Hb response (≥11 g/dL and ≥1 g/dL from BL), except 3 pts with BL Hb ≤8.5 g/dL who achieved mean Hb 10.4 g/dL. At wk 16, mean doses were 91 and 113 mg in A and B, respectively. B pts who had a Hb response were converted to twice weekly dosing. Responses were observed whether BL ferritin or TSAT was normal or subnormal. After 8 wks of treatment, there was a dose-dependent increase from BL Hb; and for 33 pts with data available, mean hepcidin decreased 36% from BL (p<0.0001). FG-4592 was well tolerated. No treatment-related serious adverse events were reported to date. Treatment with initial weight-adjusted or fixed oral FG-4592 doses corrected anemia in CKD pts in the absence of IV iron repletion.

			Mean±SD ΔHb (g/dL)		
			Wks of Treatment		
Cohort	Starting Dose FG-4592 (mg) TIW	n	4	8	16
A	60-140	24	1.6±1.1	2.4±1.2	2.3±1.2
B	60-140	24	1.1±0.9	1.8±1.0	2.3±1.0
C	50	23	0.6±0.7	1.0±0.9	NA
D	100	24	1.5±1.0	2.1±1.1	NA

TH-PO365

Adherence to Treatment among Children and Adolescents with Chronic Kidney Disease Rita Rosicker,[1] Sudha Chennasamudram,[2] Tetyana L. Vasylyeva.[2] *[1]Department of Family Medicine, Texas Tech University Health Sciences Center, Amarillo, TX; [2]Department of Pediatrics, Texas Tech Unviersity Health Sciences Center, Amarillo, TX.*

Background: Adherence to a prescribed treatment regimen reduces morbidity and mortality among patients with chronic renal diseases (CKD).Children often fail to adhere adequately to their medication plans.This report addresses behavioral functioning and child self-reporting of medication adherence among 10-21 year old patients with CKD.

Methods: The objective of this study was to examine patient-perceived factors that impact adherence to treatment using a qualitative descriptive individual interview approach.The questionnaire included 20 questions, answered by total of 12 children and was administered anonymously.

Results: Children admitted that they skipped their medications an average 1.6 days/ week. One third of the patients "did not like all of their medications." One of the least "favorite" medications was prednisone. Two-thirds of the patients felt either "upset" or "sometimes upset" by taking medications. Although 91.6% were frustrated by having their condition, only 25% stated that taking medications interferes with their daily lives, while 50% stated that taking medications did NOT interfere with their daily lives, and the other 25% were not sure. Most adolescents (66.6%) did not care what their friends think of them having a condition requiring medication. Interestingly, we discovered that the biggest problem in taking medications existed at home, not at school. Thus, 75% forgot to take medications at home, and just 16.6% forgot to take medications at school. The patients surveyed also were more likely to forget to take medications during the week (42%) versus the weekend (33%). As for ideas to help adolescents remember to take their medications, the most popular idea was a pill box with 66.6% saying it would help, while only 33.3% said that a reminder alarm would help, and 25% thought that a better tasting medicine would help.

Conclusions: Adherence to medications among pre-adolescents and adolescents with CKD is a serious medical problem which affects treatments and quality of life and requires developing a systematic approach.

TH-PO366

Ph II Study of Eculizumab (ECU) in Patients (PTS) with Atypical Hemolytic Uremic Syndrome (aHUS) Receiving Chronic Plasma Exchange/Iinfusion (PE/PI) Christoph Licht,[1] Petra Muus,[2] Christophe M. Legendre,[3] Kenneth Douglas,[4] Maryvonne Hourmant,[5] Yahsou Delmas,[6] Maria Herthelius,[7] Antonella Trivelli,[8] Timothy Goodship,[9] Camille Bedrosian,[10] Chantal Loriat.[11] *[1]Hosp for Sick Children; [2]Radboud Univ Nijmegen Med Ctr; [3]Hop Necker; [4]Beaston W Scotland Cancer Ctr; [5]CHU Hotel Dieu-Nantes; [6]CHU Pellegrin; [7]Karolinskia Univ Hosp; [8]Inst G. Gaslini; [9]Newcastle Univ; [10]Alexion Pharm; [11]Hop Debre.*

Background: Permanent uncontrolled complement activation drives systemic thrombotic microangiopathy (TMA) and life threatening complications in aHUS. Despite PE/PI, >50% of pts develop ESRD/die within 1yr of diagnosis. We report final 26wk and follow-up data for pts with aHUS receiving ECU, a terminal complement inhibitor.

Methods: Pts ≥12 yrs with aHUS, receiving PE/PI enrolled in a controlled, open-label, single-arm, PhII trial (pts enrolled 2009-2010). Prim endpt: TMA event-free status (≥12 consecutive wks stable platelet count, no PE/PI, no new dialysis). Sec endpts included TMA intervention rate (# plasma and new dialysis events/pt/day), renal function safety. We report the final 26wk and follow-up results as of data cut-off (10/10).

Results: 20pts received ECU thru wk26. 19pts continued into an extension. Median time from diagnosis to screening=48mths (range:.66-286). ECU median treatment (Tx) duration =40wks (26-52) at time of analysis. Median age=28yrs. Prim & sec endpts were achieved with high clin & stat. significance.

Key Endpoints	Wk 26	Follow-up (ECU=40 wks)
PRIMARY TMA event-free status, n (%)	16* (80)	16* (80)
SECONDARY Median TMA intervention rate (pre-Tx [0.23])	Post-Tx: 0 (*P*<.0001)	Post-Tx: 0 (*P*<.0001)
CKD improvements ≥1 stage, n (%)	7 (35)	7 (35)
Point estimate change in QoL	0.11 (*P*<.0001)	0.12 (P=.001)
Pts achieving a minimally important difference (MID)	8/11 (73%)	8/11 (73%)

*The 4 pts who did not achieve TMA-event free status had normal platelet count at study entry and maintained platelet count ≥150x10^9/L throughout. However, at certain time points, plt count in these pts was >25% change from baseline.
MID= change of at least 0.08 on the US Time Trade-off Value

ECU was similarly effective in pts w/wo identified complement mutations and was well tolerated; only 6pts had AEs deemed related to drug.

Conclusions: Continued ECU Tx resulted in sustained TMA suppression and led to permanent discontinuation of chronic PE/PI. Sustained ECU Tx resulted in stabilized/ improved renal function, was well tolerated and demonstrates potential as the new SOC for aHUS.

TH-PO367

Continued Improvements in Renal Function with Sustained Eculizumab (ECU) in Patients (PTS) with Atypical Hemolytic Uremic Syndrome (aHUS) Resistant to Plasma Exchange/Infusion (PE/PI) Laurence A. Greenbaum,[1] Sunil Babu,[2] Richard Furman,[3] Neil Sheerin,[4] David J. Cohen,[5] A. Osama Gaber,[6] Frank Eitner,[7] Yahsou Delmas,[8] Chantal Loriat,[9] Camille Bedrosian,[10] Christophe M. Legendre.[11] *[1]Emory Univer; [2]Fort Wayne Med; [3]Weill Cornell Med Coll; [4]Newcastle Univ; [5]Columbia Univ Med Center; [6]Methodist Hosp; [7]Univ Aachen; [8]CHU Pellegrin-Bordeaux; [9]Hopital Robert Debre; [10]Alexion Pharmacetuicals, Inc; [11]Universite Paris Descartes & Hopital Necker.*

Background: aHUS is a genetic, devastating, systemic disease, caused by permanently uncontrolled complement activation, resulting in thrombotic microangiopathy(TMA). Despite PE/PI, >50% of pts develop ESRD/die within 1 yr of diagnosis. We report longer follow-up data from a phase II trial of ECU, a terminal complement inhibitor.

Methods: Pts ≥12 yrs with aHUS and persistent TMA despite ≥4 PE/PI sessions 1 wk before screening were enrolled in a 26-wk, controlled, open-label, single-arm phase II trial (2009-2010). Prim. Endpoint: change in platelet (plt) count (a measure of TMA) (73x109/L; p=0.0001). Sec. endpoint: 15/17 pts (88%) achieved TMA event-free status (≥12 wks of stable plt count, no PE/PI and no new dialysis). 4/5 pts on dialysis permanently discontinued dialysis. ECU was well tolerated (Legendre. ASN 2010). We report follow-up results as of data cut-off (10/2010).

Results: 17 pts enrolled (2 discontinued; SLE and an AE unrelated to ECU, respectively). Median time from diagnosis to screening =10mo (range:<1-236). Median age=28 yrs. ECU median duration~38 wks (range: 26-64 wks) at time of analysis. 13 pts entered the extension study. 13 pts with low platelets at baseline had plt normalization at week 26 and continued to maintain normal levels at data cut-off. Renal function improved (≥1 CKD stage=10 pts and ≥25% decrease in creatinine from baseline=11 pts). ECU was well tolerated; 10 pts with adverse events deemed related to ECU (generally mild/moderate). Longer follow-up (>1 yr) will be presented.

Conclusions: In this early intervention study, sustained treatment with ECU prevented TMA and improved renal function. These data further strengthen the evidence for ECU as standard of care for aHUS.

TH-PO368

Neutrophil Gelatinase-Associated Lipocalcin (NGAL) and Alternate Pathway of Complement (APC) Factors as Biomarkers of Response to Treatment in Patients with Focal Segmental Glomerulosclerosis (FSGS) Howard Trachtman,[1] Prasad Devarajan,[2] Michael R. Bennett,[2] Joshua M. Thurman,[3] Milena Radeva,[4] Debbie S. Gipson,[5] Frederick J. Kaskel,[6] Aaron L. Friedman,[7] Marva M. Moxey-Mims,[8] Suzanne M. Vento.[1] *[1]Pediatrics, Cohen Children's Medical Center, New Hyde Park, NY; [2]Pediatrics, Cincinnati Children's Medical Center, Cincinnati, OH; [3]Medicine, University of Colorado Denver School of Medicine, Aurora, CO; [4]Quantitative Health Sciences, Cleveland Clinic Foundation, Cleveland, OH; [5]Pediatrics, University of Michigan, Ann Arbor, MI; [6]Pediatrics, Albert Einstein College of Medicine, Bronx, NY; [7]Pediatrics, University of Minnesota, Minneapolis, MN; [8]NIDDK, KUH, Bethesda, MD.*

Background: The FSGS-Clinical Trial evaluated a 12-month course of cyclosporine (CSA) *versus* combination dexamethasone (DEX) and mycophenolate mofetil (MMF) in 138 patients with steroid-resistant FSGS. This ancillary study evaluated the use of NGAL and APC factors as biomarkers of response to treatment.

Methods: Urine and plasma were obtained at weeks 0, 26, 52, and 78. NGAL and APC factors -- Ba and Bb, and soluble C5b-9 -- were determined by ELISA. Outcomes were defined by a 6-ordinal scale (1, complete remission, 6 no reduction in Up/c). Results are provided as mean±SEM.

Results: 19 patients (10M:9F) were included, 7 received CSA and 12 DEX/MMF. There were no differences between these two groups. There was a decline in plasma sC5b-9 in response to DEX/MMF (P\<0.001); however, there were no therapy-related differences in urinary NGAL or APC levels (ng/mg creatinine). Baseline urinary NGAL excretion correlated with primary outcome at 52 wk (P=0.08). When pooled by outcome, 1-3 *versus* 4-6, baseline urinary NGAL (54±17 vs 227±190) and sC5b-9 (168±36 vs 450±181) levels were numerically lower in those with a favorable response. Urine Ba excretion at the end of treatment correlated with outcome (P<0.01).

Conclusions: Urinary excretion of NGAL and select APC factors may be useful indices for patient stratification to predict outcome and to assess adequacy of response to treatment in patients with primary steroid resistant FSGS.

The Specificity of Urinary Aquaporin-1 and Adipophilin To Diagnose Renal Cell Carcinoma Jeremiah J. Morrissey, Evan D. Kharasch. *Anesthesiology, the Siteman Cancer Center, Biochemistry and Molecular Biophysics, Washington University in St. Louis, St. Louis, MO.*

Background: Renal cancer accounts for about three percent of adult malignancies and is most frequently asymptomatic until late stages of disease. This investigation tested whether aquaporin-1 (AQP-1) and adipophilin (ADFP), sensitive biomarkers of kidney cancer, are specific biomarkers to detect asymptomatic kidney cancer in comparison to patients with common forms of kidney disease.

Methods: Urine samples were obtained from 32 patients with clear cell or papillary kidney cancer undergoing partial or radical nephrectomy, 15 control patients undergoing surgery for non-kidney related reasons, 44 patients with documented urinary tract infection, 24 patients diagnosed with diabetic nephropathy, and 18 patients diagnosed with glomerulonephritis. Samples for the last two patient cohorts were obtained from the Kidney Translational Research Core of the Washington University George M. O'Brien Center for Kidney Disease Research. Urinary concentrations of AQP-1 and ADFP were determined by a sensitive and specific Western blot procedure and corrected for urinary creatinine excretion

Results: Overall, there was a 23- to 46-fold increase in AQP-1 and a 51- to 77-fold increase in ADFP in the median concentration of these two biomarkers in the urine of patients with kidney cancer compared to the median concentrations found in the urine of patients with these 3 common kidney diseases or the urine of the surgical control patients with AROC values of 0.99 to 1.00 ($P<0.001$).

Conclusions: Our study shows that measuring urinary AQP-1 and ADFP concentrations provide a means of screening patients to identify those with kidney cancer without interference from underlying common kidney diseases
