Methods: PCT levels were estimated in haemodialysis patients with sepsis (according to ACCP/ ISCCM criteria and/or isolation of microorganism). PCT levels were also checked in a control population: haemodialysis patients without sepsis, other inflammatory conditions, acute myocardial infarction, cirrhosis of liver, malignancy, burns, recent surgery or trauma. patients recieving immunomodulatory or anti- inflammatory drugs were excluded. PCT concentrations were measured by Chemiluminiscence assay in pre- dialysis samples. All patients underwent intermittent haemodialysis with a low flux polysulfone membrane.

Results: The patients in both groups were well matched for age, gender and co-morbidities; duration on dialysis.and adequacy. In controls (n= 19), mean PCT was 0.3611 (95% CI 0.2215 to 0.5006). In haemodialysis patients with sepsis (n= 17), mean PCT was 8.94 (95% CI 3.54 to 14.35). Focus of sepsis: UTI 2, Pneumonia 8, CRBSI 1, SSTI 2, Peritonitis 2, Undetermined – 1. Micro-organisms were isolated in 12 and 5 were diagnosed on ACCP/ ISCCM criteria. Of patients on haemodialysis 95 percentile patients without infection have PCT values <0.9. On taking 0.45 as a cut off value, below which the test was considered negative for sepsis in haemodialysis patients and a value of 0.93 above which the test was considered positive for sepsis: Sensitivity 94.4% and Specificity 87.5%. So diagnostic algorithm which may be formulated: <0.5: unlikely, 0.5- 0.9 possible, >0.9 most likely to have sepsis.

Conclusions: Procalcitonin is useful in diagnosing bacterial sepsis in haemodialysis patients

FR-PO2048

Safety and Efficacy of High Cut-Off Hemodialysis in Chronic Dialysis Patients: A Randomized Controlled Trial Bertrand Gondouin,[1] Anne Bevins,[2] Paul Cockwell,[3] Colin A. Hutchison.[3] *[1]Centre de Néphrologie, Hôpital de la Conception, Marseille, France; [2]The Binding Site Group Ltd, Birmingham, United Kingdom; [3]Renal Unit, University Hospital Birmingham, United Kingdom.*

Background: High cut off hemodialysis (HCO-HD) membranes provide increase removal of middle molecular weight uremic toxins by their increased membrane permeability. This study investigated the safety and efficacy of their use in a stable chronic dialysis cohort.

Methods: Patients (n-29) were randomized into groups (A or B) in a cross-over study design: (A) received 1 HCO (Gambro HCO1100) and 2 standard HD sessions (Polyflux 170H) per week for 8weeks, followed by 3x HCO for 8weeks; (B) received these treatments in reverse. Safety was defined by serum albumin levels, Kt/V and adverse events. Patients were withdrawn if albumin loss was >25% or a thrombotic event occurred. Efficacy was assessed by removal of middle molecules, phagocyte function.

Results: The use of HCO 3x weekly caused a significant reduction in serum albumin levels (40.6±3.4g/L to 36.7±2.6; p<0.01) during the first 4weeks, but this remained stable from weeks 4 to 8 (37.4±3.4). No significant reduction in serum albumin levels was seen with 1x HCO. No patients were withdrawn for albumin loss, and normal albumin levels were restored 4 weeks following trial completion (41.2±2.7). There was no difference in adverse events between 1x and 3x weekly HCO-HD. Serum CRP concentrations did not change with 3x or 1x HCO. Mean Kt/V for HCO was decreased compared to standard dialysis: 1.03±0.17 and 1.31±0.21 (p<0.05). There was a significant reduction in middle molecules in the 3x weekly group compared to the 1x weekly, κFLC (median 11.59% vs -2.03%; p<0.01), λFLC (15.43 vs -2.68%; p<0.01) and β2M (2.02 vs -8.201%; p=n/s). Phagocyte function increased over the 3x weekly period from 91.2%±9.4 to 98.1%±2.1 (p=0.02).

Conclusions: HCO-HD provides increased removal of middle molecules and the albumin loss associated with its use appears to be tolerated. Possible clinical benefit could be suggested by the increased phagocytic function. Further work is now required to assess potential clinical benefit of HCO-HD in a larger population.

FR-PO2049

Continuous Online Monitoring of Ionic Dialysance in Acute and Chronic Maintenance Hemodialysis Pei-Chen Wu,[1] Ravindra L. Mehta.[2] *[1]Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; [2]Medicine, University of California San Diego, San Diego, CA.*

Background: Hemodialysis (HD) adequacy is strongly correlated with clinical outcomes. Continuous online monitoring of ionic dialysance, using sodium flux rather than urea, allows HD sessions to be modified on a real-time and individual basis. We compared single-pool ionic dialysance (Kt/V_{ID}) with traditional blood-side measurements (urea Kt/V and urea reduction ratio [URR]).

Methods: We analyzed 2242 HD sessions from 418 hospitalized patients at an academic medical center. The patients were treated with HD with or without heparin anticoagulation for AKI (n=906 sessions) or as chronic maintenance therapy (n=1327 sessions). Kt/V_{ID} was obtained from Fresenius 4008® machine, and blood-side urea Kt/V was calculated using the second generation formula of Daugirdas.

Results: Mean and SD Kt/V_{ID} was 1.25±0.47, mean urea Kt/V was 1.40±0.46, and mean URR was 67.8±0.3%. Both urea Kt/V and URR moderately correlated with Kt/V_{ID} (r=0.668, p<0.001 and r=0.652, p<0.001, respectively). The discrepancy between Kt/V_{ID} and urea Kt/V in acute and chronic settings was -0.13±0.40 and -0.15±0.36, respectively, and there existed a significant difference between these 2 clinical conditions (p=0.021). AKI (r=0.143), larger post-HD weight (r=0.444), lower blood flow (r=0.383), and higher post-HD urea (r=0.499) were related to a lower Kt/V_{ID} (all p<0.001). In addition, the total body water derived from anthropometric formula, which is incorporated in Kt/V_{ID} monitoring, and that from urea Kt/V (spV) only weakly correlated with each other (r=0.18, p<0.001). The anthropometric volume was significantly larger than spV (46.6±14.9 L and 37.7±21.3 L, respectively, p<0.001).

Conclusions: Our results show that Kt/V_{ID} is lower than urea Kt/V and these 2 measurements are moderately correlated. The difference between the two could be accounted for by the overestimation of total body water by the anthropometric method. Moreover, the discrepancy is present in both acute and chronic settings, suggesting that dialysis delivery can be monitored with Kt/V_{ID} and periodically confirmed with urea Kt/V in hospitalized patients.

FR-PO2050

Improvement of the Removal of Medium-Sized Molecules in Hemodiafiltration by the Use of a Very High Permeability Dialyzer Piotr Seniuta, Thierry Baranger, Valerie Drouillat, Emmanuelle Rosier, Frank Bergé, Carlos Frangié. *Dialysis, PBNA, Bordeaux, France.*

Background: The removal of uremic toxins of a medium molecular weight (MW) is one of the main objectives in hemodialyzed patients. The appearance of a very high permeability dialyzer which presents in vivo ultrafiltration coefficients (UCF) greater than 100,led to us testing it on 16 of patients in on-line pre-dilution hemodiafiltration.

Methods: 16 patients,8 men and 8 women, average age 75.5 years were dialyzed with on-line HDF,240 minutes per session, for 6 months period on the Xevonta 20 dialyzer,(polysulfone,2.0 m2,UCF of 110.They had previously been dialyzed on a polysulfone dialyser, with UCF of 80. During this period,each dialysis session was analyzed and recorded on a data checklist for information concerning the clinical and technical parameters.The extraction coefficients of urea, creatinine, phosphorous, beta2-microglobulin, myoglobin, prolactin and Retinol Binding Protein(RBP) were recorded 3 times.The nutritional and inflammatory parameters which were protein, pre-albumin, albumin and CRP were recorded for the same period.

Results: The extraction coefficients were not statistically different for small compounds: urea, creatinine and phosphorous. The removal of molecules of mean MW demonstrates, an improvement for a mean MW of 11800 Kd (Beta 2M, p < 0.05) was very significative for the molecules of MW greater than 17800 Kd (Microglobulin, p<0.000001) until 21000 Kd (Prolactin, p<0.00001), it is reduced for the high MW, 230000 Kd (RBP, p< 0.01. Concerning the nutritional parameters, only the loss of albumin is statistically significant (p<0.001) to 4 grams, without a reduction of pre-albumin.

Conclusions: The superiority of the Xevonta dialyzer could, therefore, come from its own structure, diameter and thickness. This will lead to a higher cut-off, making it possible to improve the removal of uremic toxins of a mean MW. Although albumin loss was significative, it does not accompany a total protein loss.

This study, carried out on elderly patients of a dialysis unit, demonstrates the interest in the use of a very high permeability membrane in pre-dilutional HDF, in order to improve the removal of uremic toxins of a mean MW.

FR-PO2051

Impact of Hemodialytic Procedures and Dialytic Doses on Erythrocyte Glutathione s-tranferase (e-GST) Activity Roberto Palumbo,[1] Annalisa Noce,[2] Michele Ferrannini,[1] Mariarita Dessì,[3] Simone Manca di Villahermosa,[2] Nicola Di Daniele.[2] *[1]Nephrology and Dialysis Department, S.Eugenio Hospital, Rome, Italy; [2]Nephrology and Dialysis Unit, Tor Vergata University, Rome, Italy; [3]Department of Chemical Science and Technologies, Tor Vergata University, Rome, Italy.*

Background: Glutathione-S-Transferases (GST) represent a superfamily of ubiquitous enzymes devoted to the cell protection and play an important role in the detoxification of both endogenous and exogenous compounds. Previous study demonstrated an increased erythrocyte-GST (e-GST) activity in uremic patients. The aim of this preliminary study is to compare e-GST activity in normal and uremic subjects, and to correlate e-GST activity with different hemodialysis technique and with dialytic dose.

Methods: Eighty healthy controls, 44 uremic patient on bicarbonate hemodialisis (HD group) and 59 on online-hemodiafiltration (ol-HDF group) were investigated. E-GST activity was assayed using an automated procedure. Dialytic dose was expressed as Kt/Vurea and weekly Kt/Vurea. To correlate e-GST activity with dialytic dose, all 103 uremic patients (HD and ol-HDF groups) were stratified into two subgroups with a cut-off Kt/Vurea of 1.3.

Results: E-GST activity was significantly increased in the 103 uremic patients compared to controls (9.0±3.1 vs. 5.6±1.7U/grHb respectively, p<0.0001). In ol-HDF group we observed a lower e-GST activity (p=0.0036) and an higher Kt/Vurea (p=0.0007) and weekly Kt/Vurea (p=0.0004), than in HD group. Conversely, there was no difference in e-GST activity between patients with Kt/Vurea <1,3 compared to patients with Kt/Vurea ≥1.3 (9,67±3,23 vs. 8,65± 2,96U/grHB, p=0,156).

Conclusions: Our results suggest that e-GST could be a potential biomarker of uremic status and of dialysis adequacy.

FR-PO2052

Comparison of Na-Analysis during Hemodialysis: Reflection of a Decrease in Plasma Water Adrianus L.H.J. Aarnoudse,[1] Jurgen A. Riedl,[2] Gijs M.T. De Jong.[1] *[1]Internal Medicine, Albert Schweitzer Hospital, Dordrecht, Netherlands; [2]Clinical Chemistry, Albert Schweitzer Hospital, Dordrecht, Netherlands.*

Background: Na and K can be measured by different methods: flamephotometer (NaF, KF), direct ion-selective electrode (NaDSE, KDSE), indirect ion-selective electrode (NaISE, KISE) or Na can be derived from the conductivity of blood (NaC). Hemodialysis (HD) may change plasma water (PW) and Na. NaDSE and NaISE are differently influenced by PW allowing a computational estimate of PW. Changes in Na en PW may be of clinical relevance in HD.

Methods: In 45 HD-patients blood was drawn and NaC was registered before, halfway and after HD. Simultaneously, blood was analyzed for NaDSE and -ISE, KDSE and -ISE, hematocrit, total protein (TP), albumin, cholesterol, triglycerides (TG) and urea. PW was computed from the difference between NaDSE and –ISE. Mean Na was compared between methods and between sampling times using paired tests. A backward stepwise linear regression model was used to explain NaC from NaF, NaDSE, NaISE, PW and measured variables.

Results: Mean(SD) concentrations at start, during and after HD were for NaC 141.2(2.6), 140.2(1.8), and 139.4(1.3) , NaF 136.6(2.6), 136.8(1.7) and 136.2(1.7), NaDSE 136.9(2.8), 136.9(2.0) and 137.3(1.7), NaISE 135.9(3.0), 135.4(1.9) and 135.3(1.7) mmol/l, respectively. PW was 0.93(0.01), 0.92(0.01) and 0.91(0.01) respectively. NaC was always higher than NaF, NaDSE or NaISE and declined during dialyses. NaDSE and –ISE were stable during HD and NaDSE was always higher than -ISE. Using stepwise backward regression NaC before HD without adjusting for PW was best explained using DSE by NaDSE, KDSE, TP and TG (r2=0.72). Including PW in the model improved this to r2 = 0.74. Doing the same with NaISE R2 improved from 0.63 to 0.73 when including PW in the model.

Conclusions: NaC is strongly affected by HD and is substantially higher than NaDSE and -ISE. This may be relevant to HD practice. NaF was structurally higher then NaDSE and –ISE. This can be explained by the fact that flamephotometry measures total Na whereas DSE and ISE measure active Na. NaISE is progressively lower than NaDSE during HD, indicating a decreasing PW. This may be relevant for understanding the effects of HD.

FR-PO2053

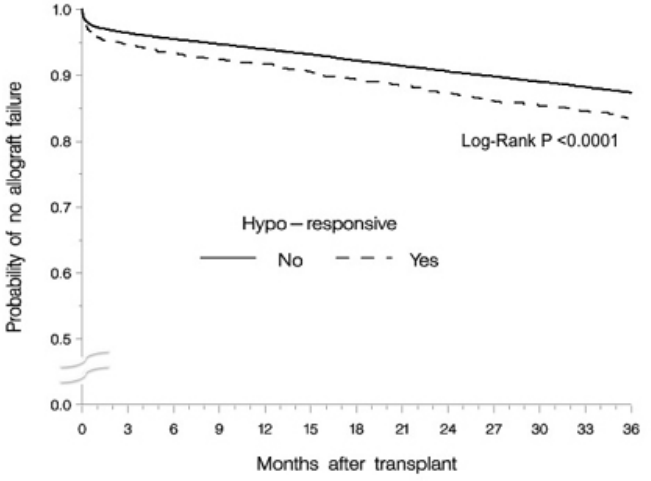
Pre-Transplant Erythropoiesis Stimulating Agent Response as a Predictor of Post-Transplant Allograft Failure & Mortality Nadiesda A. Costa, Abhijit V. Kshirsagar, Lily Wang, Randal K. Detwiler, M. Alan Brookhart. *University of North Carolina, Chapel Hill, NC.*

Background: The effect of dialysis-dependent factors on post-kidney transplant outcomes has not been well studied. We examined whether erythropoiesis stimulating agent (ESA) response during hemodialysis was associated with allograft failure and mortality.

Methods: We identified 36,450 adults from the United States Renal Data System who had received a kidney transplant during years 2000-2007 and at least 6 months of hemodialysis prior to the transplant date. ESA response during the 6-month pre-transplant period was determined using Medicare billing claims for Epoetin alpha and associated hematocrit labs. We defined ESA hypo-responsive patients to be those who experienced three consecutive months with a monthly ESA dose ≥75,000 units while hematocrit remained ≤33%. Cox proportional hazards models and Kaplan-Meier methods were used to estimate the association between ESA hyporesponsiveness and allograft failure and

mortality. Time to allograft failure was examined with and without censoring by death. Models were adjusted for age, gender, race/ethnicity, dialysis duration, dialysis catheter, diabetic status, and donor type.

Results: Baseline characteristics were similar in both hypo-responsive and comparison groups. The adjusted hazard ratios for allograft failure and all-cause mortality post-transplant were 1.26 (95%CI 1.10, 1.45) & 1.63 (95%CI 1.46, 1.82), respectively. A sensitivity analysis showed similar results. The probability of allograft failure was higher in the ESA hypo-responsive group compared to those not hypo-responsive (Figure).



Conclusions: Dialysis patients with decreased response to ESAs are more likely to experience post-transplant allograft failure and mortality. ESA response during dialysis may be used to identify high-risk kidney transplant recipients both before and after transplant.

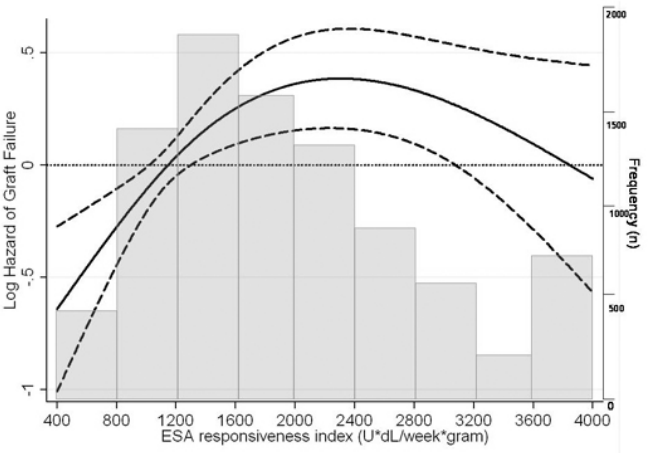
Association of Pre-Transplant Erythropoiesis Stimulating Agent Responsiveness with Post-Transplant Graft Loss and Delayed Graft Function Miklos Z. Molnar,[1,2] Suphamai Bunnapradist,[3] Edmund Huang,[3] Mahesh Krishnan,[4] Csaba P. Kovesdy,[5] Kamyar Kalantar-Zadeh.[1,3] *[1]Harold Simmons Center for Chronic Disease Research & Epidemiology, Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA; [2]Institute of Pathophysiology, Semmelweis University, Budapest, Hungary; [3]David Geffen School of Medicine at UCLA, Los Angeles, CA; [4]DaVita, Inc, Denver, CO; [5]Salem VA Medical Center, Salem, VA.*

Background: The role of pre-transplant erythropoiesis stimulating agent (ESA) responsiveness in affecting post-transplant graft loss and delayed graft function is not clear.

Methods: Linking the 5-year patient data of a large dialysis organization to the *Scientific Registry of Transplant Recipients*, we identified 9,281 hemodialyzed patients who underwent first kidney transplantation. Graft failure, delayed graft function (DGF) and acute rejection risks were estimated by Cox regression (hazard ratio [HR]) and logistic regression, respectively.

Results: Patients were 48±14 years old and included 38% women and 36% diabetics. Compared to renal allograft recipients who were in first quartile of pre-transplant ESA responsiveness index (ERI) i.e., ESA dose divided by hemoglobin, recipients in second, third and fourth quartiles had higher death-censored graft failure HR of 2.1 (1.3-3.5), 2.3 (1.4-3.8) and 2.1 (1.2-3.5), respectively.



However the OR of DGF was similar in the second 1.10 (0.87-1.39), third 1.13 (0.88-1.45) and fourth 1.28 (0.97-1.67) quartiles. No significant association between pre-transplant ESA responsiveness index and post-transplant acute rejection was noticed.

Conclusions: Higher pre-transplant ESA responsiveness index during hemodialysis treatment period was associated with worse post-transplant risk of graft failure.

Funding: NIDDK Support

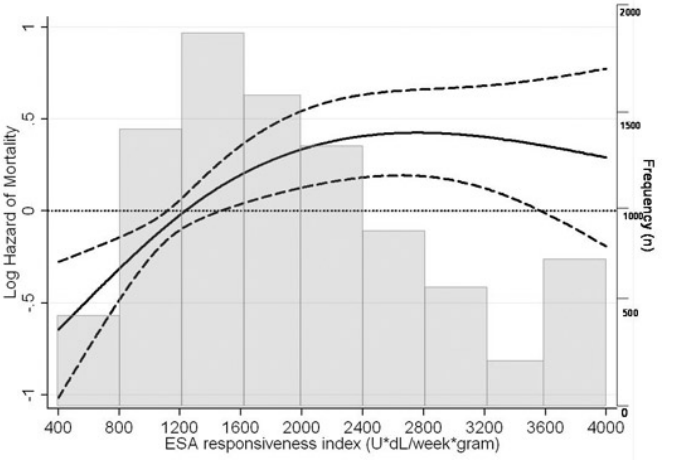
FR-PO2055

Association of Pre-Transplant Erythropoiesis Stimulating Agent Responsiveness with Post-Transplant Mortality Miklos Z. Molnar,[1] Edmund Huang,[2] Suphamai Bunnapradist,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1,2] *[1]Harold Simmons Center for Chronic Disease Research & Epidemiology, Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Salem VA Medical Center, Salem, VA.*

Background: Studies have shown an association between erythropoiesis stimulating agent (ESA) responsiveness & mortality in CKD patients (pts), but the role of pre-transplant ESA responsiveness & post-transplant mortality is unknown.

Methods: Linking the 5-year patient data of a large dialysis organization to the *Scientific Registry of Transplant Recipients*, we identified 9281 hemodialyzed pts who underwent kidney transplantation. All-cause & CV mortality were estimated by Cox regression (hazard ratio [HR]).

Results: Pts were 48±14 years old and included 38% women and 36% diabetics. The crude all-cause mortality rate was increasing across pre-transplant ESA responsiveness index quartiles, it was 26.2/1000 pt-years (95% confidence interval [CI]: 22.4–30.6)) in the first quartile and 29.9/1000 pt-years (25.6–35.0), 33.0/1000 pt-years (28.5–38.2), 44.5/1000 pt-years (39.1–50.6) in the second, third and fourth quartiles, respectively. Compared to renal allograft recipients who were in first quartile of pre-transplant ESA responsiveness index (ERI) i.e., ESA dose divided by hemoglobin, recipients in second, third and fourth quartiles had higher adjusted graft-censored death HR (and 95% confidence intervals) of 1.7(1.0-2.8), 2.2(1.3-3.5) and 2.4(1.4-3.9), respectively. Figure shows the cubic spline models for the association of the entire range of pre-transplant ERI with post-transplant mortality.



Similar results were found for cardiovascular mortality.

Conclusions: Higher pre-transplant ERI during hemodialysis treatment period was associated with worse post-transplant mortality.

FR-PO2056

Anemia Control in Kidney Allograft Recipients with Once Monthly C.E.R.A.: Results from the BEAT Study Thomas Rath,[1] Klemens Budde.[2] *[1]Hospital, Kaiserslautern, Germany; [2]Charite University, Berlin, Germany.*

Background: Post-transplant anemia (PTA) is highly prevalent in kidney transplant recipients (KTxR). Yet, course and etiology of renal anemia in these patients (pts) differ from the type seen in chronic kidney disease (CKD) pts not on dialysis with respect to overall morbidity and immunosuppressive therapy. The BEAT-study was designed to capture data about efficacy and safety of Continuous Erythropoietin Receptor Activator (C.E.R.A.) therapy in KTxR.

Methods: This single-arm, non-interventional study was conducted in 37 centres in Germany. 288 pts were enrolled, with 276 pts representing the safety population (SP). The analysis was performed in a descriptive way on the efficacy population (EP) (definition: at least one Hb measurement and one C.E.R.A. dosing available at months 7-9).

Results: 180 pts formed the EP. Mean age was 50.8 ± 14.3 years (48.9% male) and pts had a weight of 71.3 ± 13.7 kg and a BMI of 24.8 ± 4.23 kg/m^2, respectively (SP). The mean time since kidney transplantation was 7.2 ± 6.1 years, with 19,6% living donations. Previous ESA -treatment was documented as follows (21.4% missing): darbepoetin alpha (96; 34.8%), epoetin alpha (7; 2.5%), epoetin beta (61; 22.1%), epoetin delta (11; 4.0%), C.E.R.A. (42; 15.2%). During the study the average C.E.R.A dose was 95.3 ± 54.6 µg, given every 35.4 ± 15.8 days (SP). Overall, 73 (40.6%) of pts were within the 10-12 g/dL Hb range during EP (Table1).

Percentage of pts within pre-defined Hb-ranges

Hb-range (g/dL)	10-12	10-13	11-12	11-13
(%)	40,6	63,9	20,0	40,0

27.9% of pts with a GFR < 30ml/min vs. 42.1% of KTxR with a GFR > 60ml/min were within the 10-12-corridor; in parallel, 37.4% of recipients of cadaveric grafts vs. 54.6% of patients with transplants from live donors.

Mean Hb deviation from intra-individual mean was 0.50±0.6 g/dL and in 157 (87.2 %) pts the intra-individual Hb cycled by ≤ 1.0 g/dL. The pts stayed on average 8.6 ± 6.5 months on the actual C.E.R.A. dose. Overall, there were no specific drug related safety events throughout the study.

Conclusions: Recipients of kidney allografts with PTA benefit from a once-monthly C.E.R.A. regimen, arriving at stable Hb-targets with few dose adaptations and an excellent tolerability

FR-PO2057

Interstitial Fibrosis at 0-Hr Biopsy as a Useful Predictor for Early Post Transplant Anemia Akihiro Tsuchimoto,[1] Kosuke Masutani,[1] Naoki Haruyama,[1] Hideko Noguchi,[1] Hidehisa Kitada,[2] Kazuhiko Tsuruya,[1] Takanari Kitazono.[1] *[1]Medicine and Clinical Science, Kyushu University, Fukuoka, Japan; [2]Surgery and Oncology, Kyushu University, Fukuoka, Japan.*

Background: Anemia is a common complication that can lead to cadiovasucular events in renal transplant recipients. So far, several studies have determined predictors for post transplant anemia (PTA). However, the association between pathological features at 0-hr biopsy and PTA was not intensively reported.

Methods: This is a retrospective cohort study consisted of 167 consecutive patients who underwent renal transplantation (RTx) in Kyushu University Hospital from January 2006 to December 2009. The patients who received 0-hr biopsy were divided into the two groups according to the percentage of fibrosis area in cortical area at 0-hr biopsy. Patients with fibrosis area > 5% were defined as Fibrosis group (F group) (n=82), and patients with fibrosis area ≤ 5% as Non-fibrosis group (Non-F group) (n=85). We examined hemoglobin (Hb) levels of the recipients at 1, 3, 6, 12, 24 and 36 months after RTx. We compared Hb levels between the two groups. The statistical significance of differences between two groups was assessed by nonparametric tests. Univariate analyses followed by multivariate logistic regression analyses were performed to clarify association between interstitial fibrosis at 0-hr biopsy (IF-0h) and severe PTA (Hb < 10.0 g/dL).

Results: In F group, Hb levels were significantly lower than those in Non-F group at 1, 3, 6, 12 months after RTx. Differences in Hb level at 24 and 36 months were not statistically significant between the two groups (p value is 0.08 and 0.07, respectively). Logistic regression analyses showed that IF-0h was a significant risk factor for severe PTA at 1 and 12 months [Odds ratio (OR) is 3.26 and 3.45, respectively]. In multivariate analyses, even after adjustment for several confounders, IF-0h was an independent risk factor for severe PTA at 1 month [OR, 2.55; 95%CI, 1.04-6.44].

Conclusions: IF-0h is an useful predictor for PTA, especially at an early stage after RTx. Early treatment of PTA should be considered in some patients when we recognize graft fibrosis at 0-hr biopsy.

FR-PO2058

Donor Factors Determining Anemia at 1 Year Post Living Donor Kidney Transplant Richard A. Fatica, Milen Amde, Titte Srinivas, Jesse D. Schold, Emilio D. Poggio. *Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH.*

Background: Post transplant anemia (PTA) is common (30-80% prevalence) and attributed to a variety of factors including persistent malnutrition-inflammation complex, iron deficiency, impaired GFR, and immunosuppressant medications. Donor factors are important to the overall outcome of kidney transplant recipients. We sought to relate donor features with the presence of PTA.

Methods: Living kidney donors between Jan 2005 and Dec 2009 at our institution were studied. Donor data included age, gender, race, and donated kidney volume. Recipient data included age, sex, race, kidney volume, delayed graft function (DGF), clinical acute rejection in the first year, and pre-transplant hemoglobin. Continuous variables were compared between groups using independent samples t test, categorical variables were compared using chi square and Fisher's exact tests utilizing a 2 sided p value < 0.05. The relationship between risk factors and post transplant anemia was further explored using linear regression.

Results: 340 live kidney donors were identified. Donor factors associated with recipient PTA at 1 year were donor age (p = 0.001) and donated kidney volume adjusted for recipient body surface area (BSA), (p = 0.005). Recipients who were female were more likely to have PTA (p < 0.0001). Recipients with clinical acute rejection and delayed graft function displayed a trend towards more anemia, but these findings were not statistically significant.

Clinical variables associated with PTA at 1 year

Parameter	Estimate	p value
Donor age	-0.05	0.001
Adjusted kidney vol	-0.003	0.005
Female recipient	-0.53	< 0.0001

Conclusions: Recipient factors are frequently cited as causes of persistent post transplant anemia, however we have identified several donor factors associated with PTA as well. Donor age and adjusted kidney volume are most likely associated with the nephron mass donated to the recipient. Recipient gender however does not have an immediately identifiable association with donated GFR or persistence of anemia. These findings deserve further investigation and mechanistic explanation.

FR-PO2059

Blood Pressure Follows the Living Donor Kidney: Role of Donor GFR Laura V. de Vries,[1] H. Tent,[1] Johannes S. Sanders,[2] Hendrik Sijbrand Hofker,[1] Stephan J.L. Bakker,[1] Gerjan Navis.[1] *[1]Nephrology, UMCG; [2]Surgery, UMCG.*

Background: Hypertension is common in renal transplant recipients. It has been suggested that hypertensive traits of the donor may be transferred with the transplanted kidney. Direct proof for this "hypertension follows the kidney" hypothesis is, however, lacking. Here we study the effect of systolic blood pressure (SBP) and GFR of living donors on SBP in recipients.

Methods: We included 367 consecutive donor-recipient pairs transplanted between 1991 and 2010 at our center. GFR (^{125}I-iothalamate) was measured two months pre-donation in the donor, and three months and one year (n=267) post-transplantation (tx) in the recipient. Donors were allowed to donate with well controlled blood pressure on a maximum of two antihypertensive drugs. Donor and recipient demographics, transplantation characteristics and immunosuppressive and antihypertensive drug use were adjusted for in multivariate analysis.

Results: Donor and recipient characteristics are shown below. 22 donors used one antihypertensive drug, 15 used two drugs. Short term recipient SBP associated negatively to donor GFR (R -0.13). At one year post-tx, recipient SBP associated with both donor GFR and SBP (R -0.24 and 0.16). In a multivariate analysis, short term recipient SBP was predicted by recipient age and cyclosporine use. At one year post-tx, recipient age and donor GFR gave the best prediction (R^2 0.16). Recipient GFR was influenced by donor GFR (R 0.31 and 0.34) and donor SBP (R -0.18 and -0.25); at both short term and one year post tx.

Conclusions: Higher donor GFR and lower donor systolic blood pressure are associated with lower recipient blood pressure, independent of recipient renal function. Thus, regulatory impact of the kidney on blood pressure appears to be an intrinsic renal property within kidneys from generally normotensive donors. In living kidney donation, hypertension follows the kidney.

	Donor	Recipient	
		3 months post-tx	1 year post-tx
N (% female)	367 (54)	367 (38)	267 (40)

Ammoniagenesis Is Associated with Blood Pressure in Renal Transplant Recipients Else van den Berg,[1,2] Marielle Francis Engberink,[1,3] Reinold O.B. Gans,[2] Gerjan Navis,[2] Stephan J.L. Bakker,[1,2] Elizabeth Brink.[1,4] *[1]Top Institute Food&Nutrition, Wageningen, Netherlands; [2]Kidney Center Groningen, University Medical Center Groningen, Netherlands; [3]Division of Human Nutrition, Wageningen University, Wageningen, Netherlands; [4]Pharmacokinetics & Human Studies Group, TNO, Zeist, Netherlands.*

Background: Hypertension is common in renal transplant recipients (RTR) and a risk factor for graft failure and mortality. Animal data suggest that high dietary acid load contributes to hypertension by stimulating renal ammoniagenesis, leading to tubulo-interstitial damage. This may provide a new target for intervention. Therefore, we studied the association between dietary protein intake, urinary ammonium and blood pressure in a large single center RTR cohort.

Methods: Dietary intake was assessed in 580 outpatient RTR (≥1 y after transplantation) by a food-frequency questionnaire focusing on differentiation of animal and vegetable protein, since animal protein is the main source of dietary acid. Ammonium excretion was assessed from 24h urine collections. Blood pressure was measured automatically for 15 min and last 3 measurements were averaged

Results: Mean age was 53±13 y, 58% was male. Estimated total protein intake was 83±21 g/d (52±16 g/d from animal sources). Urinary ammonium excretion was 19.3 [IQR:12.4-29.4] mmol/24h. Ammonium excretion correlated positively with animal protein intake (r=0.12; p<0.01), but not with vegetable protein intake. Mean arterial pressure (MAP) was 100±12 mmHg on a median of 2.1 [IQR:1-2] anti-hypertensives. In multivariable linear regression analysis, ammonium excretion was significantly associated with MAP (β=0.12 mmHg per mmol/24h; p=0.007) independent of age, sex, BMI, renal function and use of anti-hypertensives.

Conclusions: Higher intake of animal protein is associated with more renal ammoniagenesis. Higher urinary ammonia excretion is positively associated with blood pressure. These cross-sectional data suggest that modulation of renal ammonia production, either by reducing intake of acidifying animal protein or by increasing alkali by diet or bicarbonate suppletion, may be a new therapeutic strategy with the potential to reduce blood pressure and renal damage in RTR.

FR-PO2061

Blood Pressure Treatment Lowers Mortality in Kidney Transplant Recipients Geir Mjøen,[1] Hallvard Holdaas,[1] Gudrun E. Norby,[1] Alan G. Jardine,[2] Bengt C. Fellstrom.[3] *[1]Medical Department, Rikshospitalet, University of Oslo, Norway; [2]Department of Nephrology, University of Glasgow, United Kingdom; [3]Department of Nephrology, Uppsala University, Uppsala, Sweden.*

Background: There are uncertainties regarding cardiovascular medication in renal transplant recipients and all-cause mortality. We assessed possible associations in a post-hoc observational analysis of the ALERT trial.

Methods: ALERT was a randomized, double-blind, placebo-controlled study to investigate the effect of fluvastatin on cardiovascular and renal outcomes in 2102 renal transplant recipients, followed by a 2-year extension. Patients were recruited at a median time of 4.5 years after transplantation with a stable renal function. We investigated the relationship between cardiovascular medication at baseline and all-cause mortality using Cox regression adjusted for demographic variables, other medication and known cardiovascular risk factors.

Results: In total, 1868 out of 2102 patients were available for analysis. During a median follow-up of 7.4 years, there were 334 deaths. In multivariate analysis, significantly reduced mortality was seen in relation to treatment with Calcium antagonists (HR 0.72, CI 0.56-0.92), beta blockers (HR 0.64 CI 0.51-0.81), or ACE/ARB (HR 0.58 CI 0.46-0.73). Treatment with diuretics was associated with increased mortality (HR 1.79 CI 1.38-2.33). No associations were seen for nitrates or warfarin. Borderline significance was seen for ASA (HR 0.80 CI 0.63-1.02).

Conclusions: Blood pressure treatment at baseline seems associated with a favourable outcome in kidney transplant recipients.

Renal Allograft Survival Is Decreased in Patients with Thrombotic Disorders Steven Wagner,[1] Sandra Herrmann,[1] Iasmina Craici,[1] Andrew D. Rule,[1] Fernando G. Cosio,[1] Hatem Amer.[1] *[1]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Health Sciences Research, Mayo Clinic, Rochester, MN.*

Background: Kidney allograft survival in patients with thrombotic disorders pre-transplant is not well studied. We used a matched cohort study design to examine the impact of thrombotic disorders on kidney allograft survival.

Methods: We identified kidney allograft recipients in a single center, transplanted between 2001 and 2010 who had: Lupus anticoagulant (LAC), anti-phospholipid antibodies (APLA), Factor V Leiden (FVL), or a prothrombin gene mutation (PGM). For each case 2 controls were chosen. Proportions were compared by the Chi-square test. Death censored graft loss (DCGL) was assessed with Cox proportional hazard models.

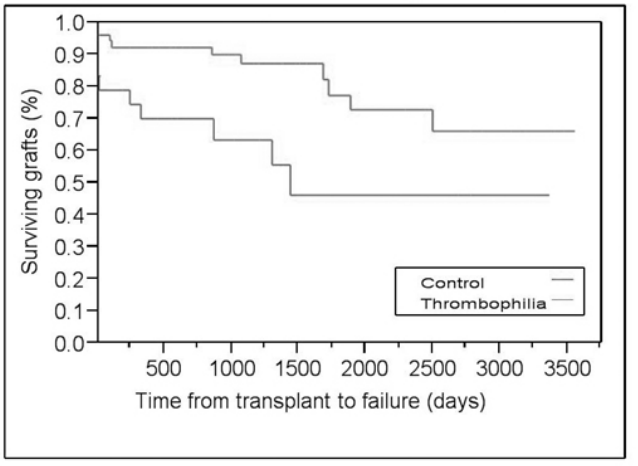
Results: Twenty nine patients were identified with a thrombotic disorder (LAC=8, APLA=8, FVL=10, PGM=4). Between patients and controls, there was no difference in gender (55% vs 59% male, p=0.76), age (46.3 vs 46.5 years, p=0.9), or follow-up (4.8 vs. 4.2 years, p= 0.42).

In the first 30 days, 5 grafts were lost in cases (17%), with four due to thrombosis; only 2 grafts (3.5%) were lost in controls, one due to thrombosis (p=0.03).

Thrombophilic patients had higher overall DCGL (HR 3.06, p=0.02), as well as higher risk for DCGL in the first 30 days (HR 5.73, p=0.03) and in the first year (HR 3.10, p=0.02). After 30 days, however, there was no difference in DCGL (HR 2.22, p=0.18).

There were no differences in DCGL between patients with LAC or APLA compared to those with other disorders.

Figure 1: Death censored graft survival



Conclusions: Patients with thrombotic disorders pre-transplant have higher DCGL. This is entirely due to graft loss in the first 30 days, mostly due to graft thrombosis. Further research is necessary to determine whether anticoagulant use might affect the rate of early graft loss in thrombophilic patients.

FR-PO2063

CUBN as a Novel Locus for ESRD: Insights from Renal Transplantation Anna Reznichenko,[1] Harold Snieder,[2] Marc Seelen,[1] Gerjan Navis.[1] *[1]Internal Diseases, Division of Nephrology, University Medical Center Groningen; [2]Epidemiology, Unit of Genetic Epidemiology & Bioinformatics, University Medical Center Groningen, Groningen, Netherlands.*

Background: Chronic kidney disease (CKD) is a complex disorder with an important genetic component. As urinary protein loss is a risk factor for progressive CKD and a recent genome-wide association study identified the cubilin gene CUBN as a locus for albuminuria, we investigated whether common genetic variance in CUBN is associated with end-stage renal disease (ESRD).

Methods: A total of 1271 patients with ESRD, admitted for renal transplantation between 1993 and 2008, with their 1271 donors as a control population were genotyped for SNPs rs7918972 and rs1801239 in CUBN (case-control study). After transplantation the recipients were followed for a median 5.5 [IQR 2.9-8.9] years and time to graft failure (GF) was documented (longitudinal study).

Results: The minor allele frequency (MAF) of rs7918972 was significantly higher in ESRD patients as compared to kidney donors, implicating an increased risk for ESRD (OR 1.38, p=0.0002).

During follow-up 215 (16.9%) cases of death-censored GF occurred. Donor rs7918972 MAF, reflecting genetic make-up of the kidney, was 14% in GF versus 11% in cases with functioning graft. Consistently, a multivariate Cox regression analysis showed that donor kidney rs7918972 is an independent predictor of GF (HR 1.41, 95% CI 1.00-1.98, p=0.05, per copy of the minor allele). There was no association of recipient rs7918972 with GF.

Conclusions: In the case-control study we identified CUBN SNP rs7918972 as risk locus for ESRD. Independently, follow-up data after transplantation showed direction-consistent association of donor rs7918972 with GF. Thus, rs7918972 was associated with susceptibility to develop ESRD in two settings in a single population, namely ESRD in native kidneys and GF in transplanted kidneys. Kidney genotype was associated with increased risk, suggesting impact of intra-renal pathways on organ damage. Our study set-up – analyzing both donor and recipient genotypes – provides a powerful design for hypothesis-driven studies on risk loci for renal damage enabling differentiation between intra-renal and systemic influences.

FR-PO2064

Body Mass Index and Outcomes after Deceased Donor Kidney Transplantation Joseph Kim,[1] Olusegun Famure,[1] Daniel C. Cattran,[1] Edward H. Cole,[1] Jeffrey Schiff,[1] Kathryn J. Tinckam,[2] Carl J. Cardella.[1] *[1]Medicine (Nephrology), Toronto General Hospital, University Health Network, Toronto, ON, Canada; [2]Laboratory Medicine and Pathobiology, Toronto General Hospital, University Health Network, Toronto, ON, Canada.*

Background: Increased body mass index (BMI) has been associated with adverse kidney allograft outcomes but its effects on delayed graft function and acute rejection are less clear.

Methods: We studied deceased donor kidney transplant recipients from 1 Jan 2000 to 31 Dec 2010 at the Toronto General Hospital . BMI (kg/m2) at transplant was categorized as < 20, 20 to 24.9 [referent], 25 to 29.9, 30 to 34.9, and ≥ 35. Outcomes included delayed graft function (DGF; dialysis in the first week post-transplant), biopsy-proven acute rejection (BPAR), death-censored graft failure (DCGF), and death with graft function (DWGF). Recipient, donor, and transplant factors were included in logistic and Cox regression models.

Results: There were 42, 225, 190, 92, and 43 patients in the first to fifth BMI groups (N = 592). Higher proportions of females were seen at the extremes of BMI. More Whites, diabetics, and male donors were noted in the highest BMI group. DGF rates were 35.7%, 32.0%, 36.3%, 48.9%, and 65.1%, respectively. The table shows results from the logistic and Cox models. Odds ratios for DGF were significantly increased in higher BMI groups. Hazard ratios for BPAR showed a similar trend. Most of this effect was due to an increase in acute cellular rejections in the higher BMI groups. There was a trend to an increased risk of DCGF and DWGF in the highest BMI group.

Conclusions: Larger BMI is associated with a greater risk of DGF and BPAR. The mechanisms by which BMI increases the risk of DGF and BPAR require further study.

Outcome Measures by Body Mass Index Category

Outcomes	Outcome Measures	BMI < 20	BMI 20 to 24.9	BMI 25 to 29.9	BMI 30 to 34.9	BMI > 35
DGF	OR (95% CI)	1.37 (0.65, 2.91)	1	1.19 (0.78, 1.83)	1.96 (1.16, 3.32)	4.33 (2.07, 9.08)
BPAR	HR (95% CI)	0.57 (0.21, 1.53)	1	1.03 (0.61, 1.77)	2.05 (1.17, 3.62)	2.10 (1.04, 4.26)
DCGF	HR (95% CI)	0.92 (0.32, 2.61)	1	1.02 (0.52, 1.99)	0.97 (0.40, 2.33)	2.13 (0.84, 5.40)
DWGF	HR (95% CI)	3.75 (1.22, 11.5)	1	0.80 (0.44, 1.82)	0.87 (0.35, 2.11)	2.05 (0.72, 5.86)

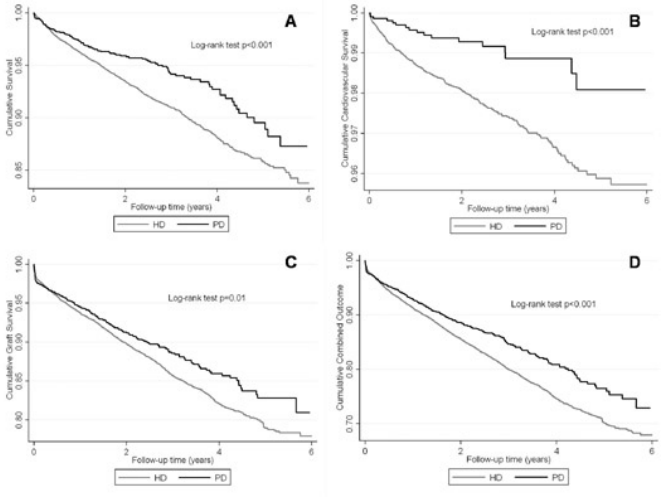
FR-PO2065

Dialysis Modality and Outcomes in Kidney Transplant Recipients Miklos Z. Molnar,[1,2] Rajnish Mehrotra,[3] Uyen Duong,[1] Suphamai Bunnapradist,[3] Lilia R. Lukowsky,[1] Mahesh Krishnan,[4] Csaba P. Kovesdy,[5] Kamyar Kalantar-Zadeh.[1,3] *[1]Harold Simmons Center, Torrance, CA; [2]Semmelweis University, Budapest, Hungary; [3]David Geffen School of Medicine at UCLA, Los Angeles, CA; [4]DaVita, Inc, Denver, CO; [5]Salem VA Medical Center, Salem, VA.*

Background: The role of pre-transplant dialysis modality in affecting post-transplant outcomes is not clear. We examined associations of pre-transplant dialysis modality with short- and long-term post-transplant outcomes.

Methods: Linking the 5-year patient data of a large dialysis organization to the *Scientific Registry of Transplant Recipients*, we identified 12,416 hemodialysis (HD) and 2,092 peritoneal dialysis (PD) patients who underwent first kidney transplantation. Mortality or graft failure, and delayed graft function (DGF) risks were estimated by Cox regression (hazard ratio [HR]) and logistic regression (odds ratio [OR]), respectively.

Results: Patients were 48±14 years old and included 39% women and 35% diabetics. Patients treated with PD pre-transplant had 43% (HR:0.57[0.38-0.87]) lower adjusted death risk compared to those treated with HD. Similar association was found for cardiovascular death (adjusted HR:0.34[0.14-0.88]).



Conclusions: Compared to HD, PD modality before transplantation appears associated with lower all-cause and cardiovascular mortality. This outcome mirrors the survival benefit previously attributed to the selection bias for patients on PD, and as such confounding by residual selection bias cannot be ruled out.

Common Genetic Variance in Glucocorticoid Receptor Locus Associates with Graft Failure in Renal Transplant Recipients Anna Reznichenko, Laura V. de Vries, Stephan J.L. Bakker, Gerjan Navis. *Internal Diseases, Division of Nephrology, University Medical Center Groningen, Groningen, Netherlands.*

Background: Glucocorticoid receptor, encoded by the gene NR3C1, functions as a responsive element forcorticosteroid hormones. We hypothesized that common genetic variance in NR3C1 influences tissue sensitivity and responsiveness to glucocorticoid effects of corticosteroids. Since corticosteroids are used in clinical practice as immunosuppressive treatment in kidney transplantation, we investigated whether polymorphisms in NR3C1 are associated with development of renal graft failure (GF) in renal transplant recipients (RTR) treated with corticosteroids.

Methods: A total of 1271 patients, admitted for renal transplantation between 1993 and 2008, and their 1271 donors (kidney genotype) were genotyped for SNPs rs852977, rs17209258, rs852978, rs10482672 and rs10482682 in NR3C1. After transplantation, the RTR were followed for a median of 5.5 [IQR 2.9-8.9] years. Time to GF, which was censored for death, was documented. For the subsequent graft survival analyses we selected a subset of 1096 RTR receiving corticosteroids.

Results: During follow-up, 175 (16.0%) RTR developed GF and 191 (17.4%) died with functioning graft. Minor allele frequency and genotypes distribution of donor rs852978 were 0.14 and 3/43/129 in cases with GF versus 0.12 and 14/201/705 in cases without GF, respectively. In a multivariate Cox regression analysis, donor rs852978 genotype appeared to be an independent predictor of GF (HR 2.93, p=0.035, for the minor allele homozygote genotype) in a model adjusted for donor and recipient age and sex, donor type (living or deceased) and episodes of acute organ rejection. There was no association of recipient genotypes with GF or of either donor or recipient genotypes with patient survival.

Conclusions: We found that donor NR3C1 genotype impacts long-term graft survival in RTR treated with corticosteroids. Donor kidney rs852978 genotype was associated with significantly increased risk for GF, highlighting involvement of intra-renal pathways in organ damage.

FR-PO2067

Distinct Morphological Features of Acute Tubular Injury (ATI) in Renal Allografts: Relation to Clinical Factors and Outcome Andrea Bohlmann, Anette Melk, Roland Schmitt, Verena Broecker, Jan U. Becker, Irina Scheffner, Hermann G. Haller, Wilfried Gwinner. *Medical School Hannover, Germany.*

Background: ATI is common in kidney transplants within the 1st year of transplantation (approx. 40% in protocol biopsies and 50% in biopsies for cause) and may be associated with an inferior allograft outcome. Commonly used criterions to diagnose ATI are loss of the brush border, flattening and cytoplasmatic lucency of proximal tubular epithelial cells. We examined whether additional features of tubular cell injury and semi-quantification of these alterations can help to classify the injury better.

Methods: Analyses included 204 patients with their protocol biopsies taken at 6 weeks, 3 and 6 months and biopsies for cause. Categories of injury included brush border loss, cytoplasmatic lucency, cell flattening, karyopyknosis, mitoses and loss of nuclei of the tubular epithelium and luminal debris which were graded semi-quantitatively. Scores were related to clinical parameters and allograft function.

Results: Inter-observer reproducibility was good for karyopyknosis (r=0.92), cell flattening (r=0.86), loss of brush border (r=0.6), fair for cytoplasmatic lucency (r=0.54) and poor (r<0.5) for the remaining scores. Delayed graft function was associated with higher scores of brush border loss, cytoplasmatic lucency and karyopyknosis. Organs from deceased donors had higher cytoplasmatic lucency and karyopyknosis scores. Grafts from combined kidney/pancreas recipients had lower scores for brush border loss and epithelial cell flattening. Scores were lower for MMF-treated patients (brush border loss, karyopyknosis) and for organs from female donors (tubular cell flattening). Brush border loss and loss of nuclei in biopsies at 6 months correlated with a worse function at the time of biopsy (p<0.05). The finding of karyopyknosis and cellular flattening was related to a further deterioration at 1 year after transplantation (p<0.05).

Conclusions: Distinct features of tubular cell injury like karyopyknosis and tubular cell flattening appear to be best suited to assess acute allograft damage and the functional consequences of this damage, particularly when used with a semi-quantitative scoring system.

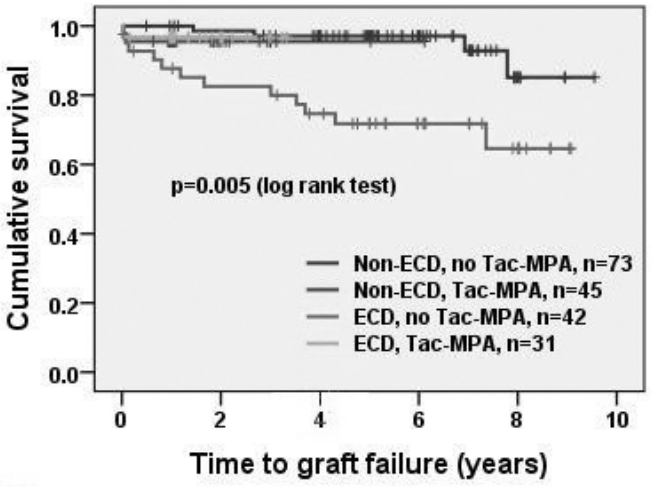
FR-PO2068

Outcome of Expanded Criteria Donor Kidney Transplants in Patients without Donor Specific HLA-Antibodies Claudia Praehauser,[1] Kiymet Saydam Bakar,[2] Patrizia Amico,[2] Eliane Vogler,[2] Patricia Hirt-Minkowski,[2] Stefan Schaub,[2] Michael Mayr.[1,2] *[1]Medical Outpatient Department, University Hospital Basel, Switzerland; [2]Clinic for Transplantation Immunology and Nephrology, University Hospital Basel, Switzerland.*

Background: Due to disparity between organ supply and demand, utilization of kidneys from expanded criteria donors (ECD) has become inevitable. Outcome data of ECD kidneys revealed poorer graft survival but might be confounded by immunological events. Therefore, we investigated outcome of ECD kidneys in an immunological low-risk population.

Methods: We retrospectively analyzed deceased-donor kidney transplantations without pre-transplant donor specific HLA-antibodies (HLA-DSA) performed between 1999-2008. The primary endpoint was graft survival, secondary endpoints were rejection rate and graft function.

Results: Overall, 73 (38%) of 191 transplants were ECD organs. The 1, 3 and 5-year graft survival rates were 98%, 96% and 96% for non-ECD and 91%, 87% and 76% for ECD kidneys (p=0.003). When stratified by IS, graft survival of ECD kidneys treated with tacrolimus-mycophenolate (Tac-MPA) was comparable to non-ECD (96% at 1 and 3-year), whereas graft survival of ECD kidneys not treated with Tac-MPA was significantly decreased (88%, 83% and 72%)(figure).



ECD kidneys not treated with Tac-MPA that experienced rejection showed the worst graft survival (79%, 68% and 43%, p<0.001). At one year, eCrCl was significantly lower in ECD kidneys (38 vs 58 ml/min, p<0.001). When treated with Tac-MPA, however, eCrCl was significantly higher than without Tac-MPA (non-ECD: 65 vs 54ml/min, p=0.010; ECD: 43 vs 35 ml/min, p=0.028).

Conclusions: Patients without pre-transplant HLA-DSA receiving ECD kidneys show excellent graft survival that is similar to non-ECD kidneys when treated with Tac-MPA. Tac-MPA impressively preserves graft function in ECD and non-ECD kidneys.

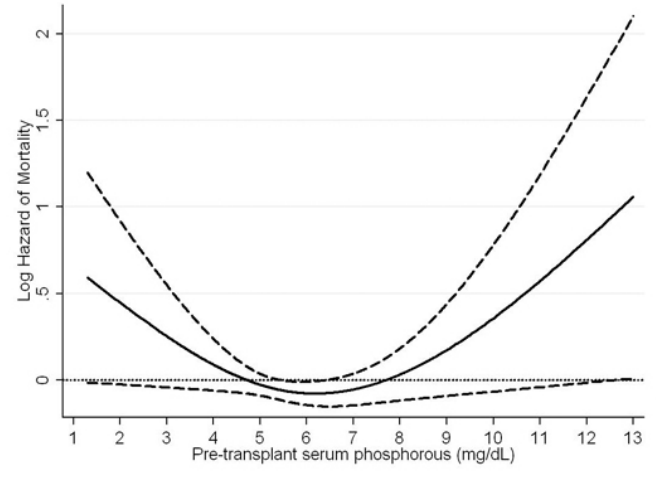
FR-PO2069

Association of Pre-Transplant Serum Phosphorous with Post-Transplant Outcomes Marcelo Santos Sampaio,[1] Miklos Z. Molnar,[1,2] Csaba P. Kovesdy,[3] Mahesh Krishnan,[4] Allen R. Nissenson,[4] John Tayek,[5] Rajnish Mehrotra,[5] Kamyar Kalantar-Zadeh.[1,5] *[1]Harold Simmons Center, Torrance, CA; [2]Semmelweis University, Budapest, Hungary; [3]Salem VA Medical Center, Salem, VA; [4]DaVita, Inc, Denver, CO; [5]Harbor-UCLA, Torrance, CA.*

Background: Serum phosphorous levels are associated with mortality, cardiovascular disease, & renal function loss in CKD patients. The association of pre-transplant serum phosphorus (13-week interval before transplantation were averaged) levels with transplant outcomes is unknown.

Methods: Data of the *Scientific Registry of Transplant Recipients* up to June 2007 were linked to the database (2000-6) of a US-based large dialysis organization. The selected 9384 primary kidney recipients were divided in five groups according to pre-transplant serum phosphorous levels (mg/dL): <3.5, 3.5-<5.5 (reference group), 5.5-<7.5, 7.5-<9.5 and ≥9.5.

Results: Patients were 48±14 years old & included 37% women & 27% African Americans. Unadjusted & adjusted risks for transplant outcomes were compared. After full adjustment, all-cause & cardiovascular death risk was 2.4 (HR: 2.44,95% CI:1.28-4.65) & 3.6-fold (HR: 3.63,95% CI: 1.13-11.64) higher, respectively in recipients in the ≥9.5 group; & graft loss risk was 1.4 (HR:1.42,95% CI:1.04-1.95) & 2.4-fold (HR: 2.36,95% CI:1.33-4.17) higher in recipients with 7.5->9.5 & ≥9.5, respectively. The association of pre-transplant serum phosphorous level with all cause mortality was U-shaped; both very low & very high phosphorous level was associated with higher mortality risk.



We did not find significant association with delayed graft function.

Conclusions: Pre-transplant phosphate levels >7.5mg/dL and >9.5 mg/dL were associated with increased risk of functional graft failure and increased risk of all-causes and cardiovascular death, respectively when compared to 3.5-<5.5 mg/dL.

FR-PO2070

Depressive Symptoms after Kidney Transplantation Are Associated with Decreased Survival Dorien M. Zelle,[1] Judith Rosmalen,[2] Eva Corpeleijn,[2] Reinold O.B. Gans,[3] Willem Van Son,[1] Gerjan Navis,[1] Stephan J.L. Bakker.[3] *[1]Kidney Center, University Medical Center Groningen, Netherlands; [2]Psychiatry, UMCG; [3]Internal Medicine, UMCG.*

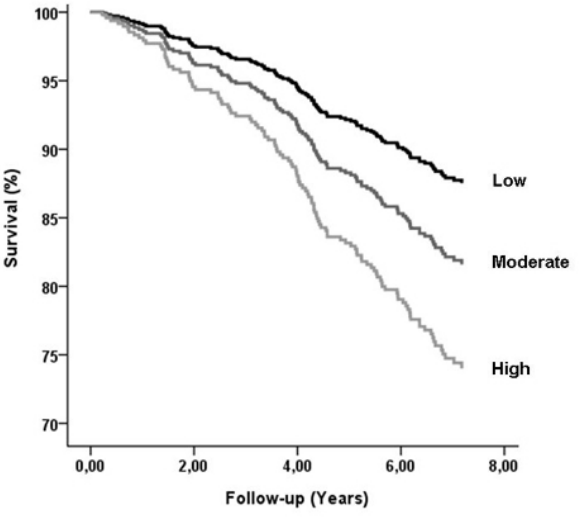
Background: Renal transplantation is the treatment of choice for end stage renal disease; it is nevertheless highly stressful for many patients. We aimed to investigate the association of depression with mortality and graft failure in renal transplant recipients (RTR).

Methods: RTR were investigated between 2001-2003. Depressive symptoms were assessed using the subscale of the Symptom Checklist (SCL-90).SCL-90 scores (SCL-90s) were grouped using standardized scales. We compared SCL-90s of our RTR with a healthy Dutch reference population. Mortality and graft failure were recorded until May 2009.

Results: A total of 527 RTR (age 51±12 yrs,55% men) participated at median time of 6.0 yrs post-transplant. SCL-90s were higher in RTR than in the reference population (24vs.22; p< 0.001). Risk factors for depressive symptoms were being unfit to work, living alone, dialysis duration, low physical activity, female gender and low creatinine clearance (p<0.05). During median follow-up for 7 yrs, 37 (15%) RTR died in the low SCL-90s group (n=243), while 21 (21%), and 56 (31%) died in the groups with moderate (n=102) and high SCL-90s (n=182)(P=0.01,fig.1). In univariate Cox-regression analyses high SCL-90s was associated with increased risk for mortality (HR=2.22[1.46-3.36],P<0.001), while no association was found for graft failure. Adjustment for potential confounders, including dialyses duration and creatinine clearance did not materially change the association.

Conclusions: Our results show that depression after kidney transplantation is associated with decreased survival. Additional studies on the effect of depression treatment on survival after renal transplantation are needed.

Figure 1: Kaplan-Meier curve of mortality according to SCL-90 score.



FR-PO2071

Incidence of Metabolic Syndrome in the First Year of Kidney Transplant and Its Effect on Graft Function Luis Alberto Evangelista-Carrillo,[1] Jorge Andrade-Sierra,[1] Enrique Rojas-Campos,[2] Salvador Mendoza Cabrera,[1] Celina Mora,[1] Maria Del Carmen Alvarado Velarde,[1] Diana Cristina Soria,[1] Abel Puentes Camacho,[1] Ana Maria Contreras,[1] Alfonso M. Cueto-Manzano,[2] Benjamin Gomez-Navarro.[1] *[1]Department of Nephrology and Transplantation, Hospital de Especialidades, CMNO, IMSS, Guadalajara, Jalisco, Mexico; [2]Medical Research Unit in Renal Disease, CMNO, IMSS, Guadalajara, Jalisco, Mexico.*

Background: The Metabolic Syndrome (MS) during the first year of kidney transplant (KT) has not been completely evaluated. **Aim:** Describe the incidence of MS at 6/12 (early/late) months after KT and its impact on graft function according to time of development.

Methods: Prospective cohort (Mar/2009-Apr/2010) of 197 kidney recipients. Diabetic patients before transplant were excluded. MS was defined using the ATP III criteria.

Results: The accumulated incidence of MS at 12 months was 32%, 69% were male, 66% had tacrolimus, mofetil and prednisone scheme and 11% were steroids-free. Majority (75%) of patients with early MS receive peritoneal dialysis. In a logistic regression analysis, risk factors to early MS were CRP (RR 4; *p*=0.043) and weight (RR 9.7; *p*=0.002) before KT. Other results are shown in Table.

Comparison according to develop of MS after KT

	6 months (n=39;61%)	12 months (n=25;39%)	Non MS (n=133; 100%)
Mean age (yr)	29(±10)	25(±10)	26(±7)*
Weight pre KT (kg)	67(±14)	62(±13)	56(±12)*
BMI pre KT	24(±4)	23(±3)	21(±3)*
CRP pre KT (mg/l)	8.3	8.7	5.1
Insulin pre KT (mUI/ml)	8(±4)	9(±7)	6(±4)*
BMI 6 mth	24(±4)	23(±2)	21(±3)*
SCr 6 mth (mg/dl)	1.1	1.1	1.2
Insulin 6 mth (mUI/ml)	10(±5)	13(±11)	10(±6)
CrCl measure 6 mth(ml/min)	67(±20)	72(±26)	73(±20)
BMI 12 mth	24(±4)	24(±2)	22(±3)*
SCr 12 mth (mg/dl)	1.1	1.5	1.3
Insulin 12 mth (mUI/ml)	11(±6)	13(±4)	10(±4)
CrCl measure 12 mth(ml/min)	73(±19)	71(±28)	77(±27)

*p=<0.05 between groups; CRP: C reactive protein

Conclusions: Majority of MS incidence was in the early phase. Patients with early MS were older and had more pre transplant weight. Insulin, CRP and BMI at 6, 12 months, were different in all MS (early and late) patients compared to Non-MS. The graft function at first year was not affected by the early or late onset of MS. Further follow is necessary.

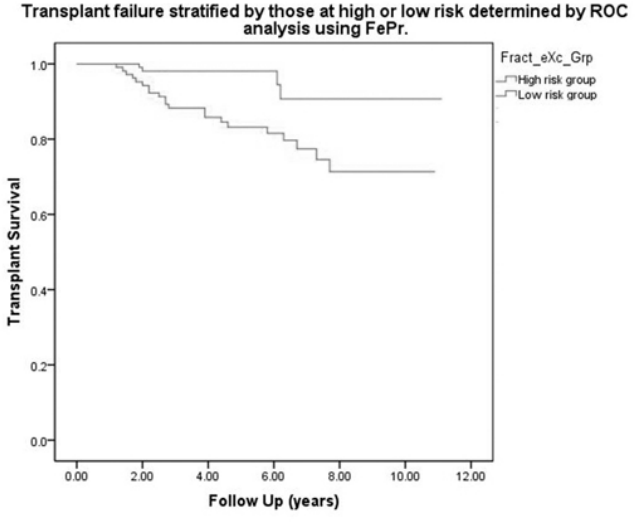
FR-PO2072

Fractional Excretion of Protein May Have Superior Predictive Value over Traditional Proteinuria Measures in Renal Transplant Recipients Kathryn K. Stevens, Rajan Kantilal Patel, Patrick Barry Mark, Colin C. Geddes, Marc J. Clancy, Alan G. Jardine. *Renal Transplant Unit, Western Infirmary, Glasgow, United Kingdom.*

Background: Proteinuria is associated with poorer outcomes in renal transplant recipients. Fractional excretion of total protein (FePr) may better reflect renal excretion of protein than traditional measures. We assessed FePr and protein: creatinine ratio (PCR) as predictors of transplant failure.

Methods: Data were collected from the electronic patient record for recipients of a first renal transplant. FePr and PCR were calculated (FePr = (Serum creatine * Urine protein)/ (Serum protein * Urine creatinine) %, PCR = ((Urinary Protein / UrinaryCreatinine) * 1000). The primary endpoint was transplant failure. ROC analysis was performed for each test and patients were stratified into high/low risk groups. Kaplan Meier and Cox survival analysis was then performed.

Results: 219 recipients were followed up for a median of 4.9 years. 11.4% (n=25) of the transplants failed at a median of 2.7 years. Mean eGFR at 1 year post transplant was 48.5mls/min/1.73m2 ±16.7. Using ROC analysis, both FePr and PCR predict transplant failure. FePr had the higher sensitivity and specificity. In the high risk FePr group the risk of transplant failure was increased by 3.4 fold (p=0.003).



One year eGFR was significantly lower (p<0.001). For PCR, the risk of transplant failure was increased 2.1 fold in the high risk group. In multivariate analysis, both tests remain independently predictive of transplant failure.

Conclusions: FePr and PCR predict transplant failure but FePr is more sensitive and specific. It may be superior at predicting those at risk of transplant failure. Our study is limited by its retrospective nature and the small number of events. Comparison should be made between these tests and measures of albuminuria.

FR-PO2073

Chronic Kidney Disease Stage: Impact on Long-Term Graft Survival Following Kidney Transplantation William Irish,[1] Schiffon L. Wong,[2] Debora Bowers,[1] Digisha Trivedi,[2] Tony Hebden.[2] *[1]CTI Clinical Trial and Consulting Services; [2]Bristol-Myers Squibb.*

Background: Renal function (RF) after kidney transplant has been shown to be a strong predictor of graft survival (GS). We characterized the relationship between early change in post-transplant RF and GS.

Methods: Adult Medicare beneficiaries in the US Renal Data System who received kidney-only transplant (2001 - 2008) were eligible. RF, measured by estimated glomerular filtration rate (eGFR), was calculated by the Modification of Diet in Renal Disease 4-variable formula. eGFR at 6 and 12 months was categorized using the National Kidney Foundation CKD staging (Stage 1 (eGFR ≥90), 2 (60≤eGFR<90), 3 (30≤eGFR<60), 4 (15≤eGFR<30), and 5 (eGFR<15)). GS was estimated using the life-table method. Hazard ratios (HRs) for graft failure (GF) and associated 95% confidence intervals (CIs) were estimated using Cox hazards model.

Results: At 6 months, 77,206 patients (Mean age: 50 years, 29% Black, 61% males) were alive with a functioning graft and eGFR (Median followup: 4 years). Association between change in CKD stage from 6 to 12 months post-transplant and 4 year GS is shown in **Table 1**. Patients in CKD stage 2, 3, or 4 at month 6 who had a one stage worsening in CKD stage by month 12 had a significantly greater risk of GF at 4 years. A majority of patients were in CKD stage 3 at month 6. Those that moved to stage 4 at 12 months had a 3.5 fold increased risk of GF and a 32% lower GS at 4 years (p<0.001).

Table 1: Change in CKD Stage and GS

CKD Stage at Month 6	CKD Stage at Month 12	GS at 4 Years (%)	HR	95% CI for HR
Stage 1 (n=4,695)	Stage 1	88	1.0	
	Stage 2	87	1.2	1.0 - 1.4
	Stage 3	74	2.1	1.7 - 2.7
	Stage 4	61	3.4	1.9 - 5.9
	Stage 5	36	7.4	3.5 - 15.6
Stage 2 (n=27,041)	Stage 2	90	1.0	
	Stage 3	84	1.5	1.4 - 1.6
	Stage 4	45	7.2	5.9 - 8.6
	Stage 5	15	16.5	11.6 - 23.5
Stage 3 (n=40,772)	Stage 3	85	1.0	
	Stage 4	53	3.5	3.3 - 3.7
	Stage 5	20	11.5	9.6 - 13.7
Stage 4 (n=4,218)	Stage 4	55	1.0	
	Stage 5	18	3.7	3.1 - 4.4

Conclusions: Worsening of CKD stage in the first year post-transplant is associated with increased GF. Results suggest that patient management strategies targeted at preserving RF in the early post-transplant period will have a positive impact on long-term GS.

FR-PO2074

Metabolic Syndrome Defined by ATP III Classification Predicts Better the Glomerular Filtration Rate Decline Than Its Individual Components after Renal Transplantation Nabil Mohsin, Georges J. Mourad, Magalie Faure, Ilan Szwarc, Fernando Vetromile. *Nephrology Department, University of Montpellier, France.*

Background: Individual components of the metabolic syndrome (MS), especially obesity and hypertension have a deleterious effect on renal graft outcome. Whether MS is better than its individual components to predict the decline of renal function is unknown. We studied the presence of MS and its individual components at 3 and 12 months (m3, m12) after transplantation according to the ATP III Classification, and their influence on graft function.

Methods: A cohort of 322 patients transplanted between 1996 and 2003 who accepted to have their glomerular filtration rate measured by urinary clearance of Tc*-DTPA (mGFR) at 3, 12, 48, 60 and 96 months after transplantation were included. The patients were followed till patient death, graft loss or till December 2009 (Mean F-U: 3 + 2.8 yrs). Linear mixed effect model for longitudinal repeated measures was applied. To compare MS versus its components we used the Akaike information Criterion (AIC) in which a lower value indicates a better model.

Results: MS was present in 34%, 37% and 25% of recipients at m3, m12, and both m3 and m12(m3&12). MS, waist circumference (WC), high triglycerides (TG), high systolic blood pressure (SBP) at m3 and m12 are all associated with a significant decline of mGFR as indicated by the negative sign of the coefficient (Table 1). HDL at m3 has a beneficial effect as shown by the positive sign. Body mass index, glycemia and diastolic BP at m3 and m12, WC and HDL at m12 had no significant effect (p value >0.05. Not shown). MS (m3&12), m12, and m3 had the lowest AIC indicating that they are the best predictors of graft deterioration and that MS is consistently a better model than its individual components.

MS vs its components effect on GFR .

	MS m3/m12/m3&12	TG m3/m12	SBP m3/m12	WC m3	HDL m3
mGFR coefficient	-6.7/-7.8/-8.7	-3.04/-3.85	-0/17/-0.13	-0.20	+12.8
p-value	<0.001/<0.001/<0.001	0.001/<0.001	0.003/0.028	0.012	0.028
AIC	11722/11717/11715	11726/11727	11733/11737	11734	11727

Conclusions: MS is a better predictor of mGFR decline than its individual components. We recommend routine assessment of MS during the clinical visits.

FR-PO2075

De Novo Thrombotic Microangiopathy after Kidney Transplantation: Clinical Features, Treatment and Long-Term Patient and Graft Survival

Liliany P. Repizo,[1] Victor Sato,[1] Renato Antunes Caires,[1] Igor Marques,[2] Lilian P.F. Carmo,[2] David Machado,[2] Flavio De Paula.[2] *[1]Nephrology, University of Sao Paulo School of Medicine, Brazil; [2]Urology-Renal Transplants Service, University of Sao Paulo School of Medicine, Brazil.*

Background: Post transplantation thrombotic microangiopathy/hemolytic uremic syndrome (PT TMA/HUS) can occur as a recurrent or *de novo* disease.

Methods: Retrospective single-center observational study to examine the incidence and outcomes of *de novo* PT TMA/HUS among transplants performed between 2000 and 2010. Recurrent HUS or antibody-mediated rejection were excluded.

Results: Seventeen (1.1%) among 1549 KTR fulfilled criteria for *de novo* TMA. The mean follow-up was 572 days (range, 69–1769). All patients received induction therapy. Maintenance immunosuppression was prednisone, tacrolimus (TAC) and mycophenolic acid in 15 patients (88%). Mean age at onset was 40±15 yrs, and serum creatinine was 6.1±4.1mg/dL. TMA occurs at a median of 25 days (range, 1–755) after transplantation. Nine (53%) patients developed TMA within 1 month of transplantation and only 12% after 1 year. Clinical features were anemia (Hb<10g/dL) in 9 (53%) patients, thrombocytopenia in 7 (41%), and increased lactate dehydrogenase in 12 (70%). Decreased haptoglobin was observed in 64% and schistocytes in 35%. CNI withdrawal or reduction was the first step in the management of 10/15 (66%) patients, and 6 (35%) received fresh frozen plasma (FFP) and/or plasmapheresis. The mean trough level of TAC at diagnosis was 11.5 ng/mL (range, 1.2–31). TAC was successfully reintroduced in 6 patients after a mean of 17 days. Eight (47%) patients needed dialytic support after TMA diagnosis and 75% remained on dialysis. Death censored graft survival was worse for TMA group (91.4% vs 84.7%, log rank =0.001; HR= 3.74). There was no difference in patient survival (90.4% vs 92.9%).

Conclusions: *De novo* TMA after kidney transplantation is a rare but severe condition with poor graft outcomes. This syndrome may not be fully manifested and clinical suspicion is essential for early diagnosis and treatment, based mainly in CNI withdrawal and FFP infusions and/or plasmapheresis.

FR-PO2076

Impact of Tacrolimus Variability and *CYP3A5* Genetic Polymorphism on Renal Allograft Outcomes

Yoonjung Kim,[3] Han Ro,[1,2] Myung-Gyu Kim,[1] Jong Cheol Jeong,[3] Curie Ahn,[1,2,3] Jaeseok Yang.[1,2] *[1]Transplantation Center, Seoul National University Hospital, Seoul, Korea; [2]Transplantation Research Institute, Seoul National University College of Medicine, Seoul, Korea; [3]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea; [4]Department of Surgery, Seoul National University College of Medicine, Seoul, Korea.*

Background: Wide intra-individual variation (IIV) in tacrolimus levels was reported to be associated with poor renal graft outcomes in Caucasians. We investigated whether the tacrolimus IIV or tacrolimus trough concentrations can influence kidney allograft outcomes in Korean, and whether *CYP3A5* polymorphism (rs776746) can affect this relationship.

Methods: We enrolled 249 patients that got kidney transplant from 1996 to 2010 in Seoul National University Hospital, Seoul, Korea. The tacrolimus IIV and the mean tacrolimus trough concentrations were calculated from the concentrations between 6 and 12 months after transplantation.

Results: The patients with higher tacrolimus IIV had longer rejection-free survival rate (p=0.002) and higher mean tacrolimus trough concentrations (p<0.001). On the other hand, there was no difference in either rejection-free survival rate or mean tacrolimus trough concentration between CYP3A5 expressers and non-expressers. The tacrolimus IIV was not associated with the *CYP3A5* polymorphism. Interestingly, the association of the tacrolimus variability with the rejection-free survival was significant only in CYP3A5 expressers (p=0.001 in CYP3A5 expressers, p=0.267 in CYP3A5 non-expressers). High IIV of tacrolimus was the independent risk factor (hazard ratio (HR) 1.052, 95% confidence interval (CI) 1.027-1.079) for biopsy-proven acute rejection after adjusting with mean tacrolimus concentration (HR 0.780, 95% CI 0.647-0.939), *CYP3A5* polymorphism (HR 1.139, 95% CI 0.649-2.001), number of HLA mismatch, donor type, and donor gender.

Conclusions: The IIV of tacrolimus trough levels had a significant impact on rejection-free survival independently of mean tacrolimus trough levels. Both *CYP3A5* polymorphism and environmental factors including compliance might contribute to the impact of tacrolimus IIV.

FR-PO2077

Low Dose of Thymoglobulin as Induction Therapy in High Risk Kidney Transplant Recipients

Daniel Perez-Vega,[1] Enrique Rojas-Campos,[2] Luis Alberto Evangelista-Carrillo,[1] Salvador Mendoza Cabrera,[1] Jorge Arturo Leal Romero,[1] Francisco Molina-Ruiz,[1] Benjamin Gomez-Navarro.[1] *[1]Nephrology and Organ Transplant Unit, IMSS Hospital de Especialidades, Guadalajara, Jalisco, Mexico; [2]Medical Research Unit in Renal Diseases, IMSS Hospital de Especialidades, Guadalajara, Jalisco, Mexico.*

Background: Acute rejection (AR) in high risk recipients is a concern in renal transplant setting. Information regarding Thymoglobulin (rATG) is scarce in low dose schemes. The aim of this study was to show AR incidence, adverse effects, and renal function after 6 months in a cohort (Jan-2010, Dec-2010), of high risk kidney recipients (KR).

Methods: KR were classified with high risk if they had second transplant, crossmatch or PRA ≥10% and deceased donor. FIfty five KR were prospectively analyzed according to total rATG dose (<4.5 vs 4.5-6mg/kg). The primary endpoint was the rate of acute rejection and graft failure. The secondary endpoints were serum creatinine, hematological adverse effects and infections.

Results: In group 1 the mean accumulated dose was 3.7 vs 5.5mg/kg in group 2. There were no patients with graft failure and there was no difference in AR(biopsy proved) frequency (p = 0.574) as shown in Table 1. Infection was significanttly more frequent in those with higher dose (71 vs 44%; p=0.044), compared to lower dose.

Six month Outcomes according to rATG total dose

Variables	All(n=55)	<4.5mg/kg(n=34)	4.5-6mg/kg(n=21)
Acute Rejection n(%)	6(11)	3(8.8)	3(14.2)
Infections n (%)	30(54.5)	15(44.1)	15(71.4)*
Urinary Tract Infection n(%)	22(40)	11(32.3)	11(52.3)
Sepsis n(%)	2(3.6)	1(2.9)	1(4.7)
CMV n(%)	1(1.8)	1(2.9)	0 (0)
Death n(%)	3(5.4)	1(2.9)	2(9.5)
Serum Creatinine(mg/dl)	1.13±0.45	1.17±0.53	1.04±0.22
Creatinine Clearence (ml/min)	77.90±19.13	75.56±19.16	81.84±18.92
Lymphocyte count(cels/ mm3)	1024±045	1005±079	1057±108
Platlet count(cels/mm3)	210,150±61,485	208,060±10,745	213,790±14,357
Hemoglobin(gr/dl)	13.6±1.1	13.4±0.4	13.8±0.4

* p value < 0.05.

Conclusions: Low dose of rATG was not associated to more AR or graft failure and it appears to be associated to lower infection frequency compared to those with higher dose in high risk kidney transplant receptors.This is one of the first reports of the use of rATG in Latin America.

FR-PO2078

Metabolic Syndrome Occurring during the First Year of Renal Transplantation Is Associated with Impaired Graft Function

Georges J. Mourad, Nabil Mohsin, Magalie Faure, Ilan Szwarc, Fernando Vetromile. *Department of Nephrology and Transplantation, University of Montpellier, France.*

Background: Metabolic syndrome (MS) is a frequent observation in renal transplant recipients (RTR). The aim of this study was to analyze the influence of MS occurring at 3 and 12 months (M3, M12) after transplantation on the long-term renal graft function as well as on the patient and graft survival (PS, GS).

Methods: RTR having had received their transplant between January 1996 and December 2003 underwent prospective and sequential measurements of their renal graft glomerular filtration rate (mGFR) using isotopic methods. The RTR had to be at least 3 months post transplant and to have had at least two mGFR. A cohort of 322 out of 665 RTR were included after informed consent.

Clinical parameters (Body Weight, Height, Waist circumference, Blood Pressure), immunosuppressive and anti-hypertensive drugs, Tc*****-DTPA urinary clearance, proteinuria, serum creatinine, lipids and glycemia were measured at M3, M12, M24, M48, M60 and M96. The patients were followed until their death, graft loss or until December 2009 (Mean F-U: 3 + 2.8 yrs). MS was assessed according to three classifications: ATP III, WHO and IDF. PS and GS were analyzed using the Cox proportional hazard ratio and a linear mixed effect model for longitudinal repeated measures was used to assess the evolution of mGFR.

Results: Using ATP III, MS was present in 34 % and 37 % of RTR at M3 and M12 respectively; MS at M3 or M12 did not have an influence on PS, GS or death-censored GS. In contrast, MS at both M3 and/or M12 was significantly associated with an impaired graft function (ΔGFR: - 6.7 and - 7.8 ml/min/yr at M3 and M12 respectively with a p-value <0.001 for both). MS according to WHO or IDF had no significant influence on mGFR. In multivariate analysis, the deleterious effect of MS on graft function remained significant, in addition to transplant duration, dialysis duration, donor age, acute rejection and delayed graft function]

Conclusions: MS has a negative impact on long term graft function. Whether its correction would improve the renal outcome warrants further investigation.

FR-PO2079

The Impact of Pre-Transplant Dialysis Modality on the Outcome of Kidney Transplantation

Yong Chul Kim,[#1] Do Hyoung Kim,[#1] Ran-Hui Cha,[#2] Curie Ahn,[#1] Suhnggwon Kim,[#1] Yon Su Kim.[#1] *[1]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Department of Internal Medicine, National Medical Center, Seoul, Republic of Korea.*

Background: Preemtive transplantation shows the best clinical outcome in kidney transplantation, but majority of the patients should be instituted a renal replacement because of the lack of donor. We hypothesized that the pre-transplant dialysis modality [pre-emptive, hemodialysis (HD), peritoneal dialysis (PD)] may affect the probability of transplantation as well as the clinical outcome.

Methods: We performed a retrospective cohort study of 577 patients who received kidney transplantation between January 1996 and December 2009 in Seoul National University Hospital (SNUH). The three groups were compared with the rates of graft and patients survival. The mean follow-up duration was 58.1 ± 48.4 months. And then we analyzed 975 patients who had maintenance dialysis (HD: 256, PD: 719) between January 1996 and December 2009 in SNUH for the rates of mortality and probability of kidney transplantation.

Results: Patients who had less than 1month of dialysis before kidney TPL (i.e. preemptive group) had survival benefit compared with non-preemptive group (P=0.010), but no difference in graft survival rate (P= 0.966). When non-preemptive group is subdivided into HD and PD groups, there were no significant difference in patient survival and graft survival rate (P=0.392, P=0.226, respectively). Patients with maintenance HD had high mortality rate than in patients with maintenance PD in our center (P=0.006). But the recipients on maintenance PD had higher probability for kidney transplantation in cohort between 2005 and 2009 (P=0.009), yet no difference in patient cohort between 1996 and 2004.

Conclusions: Based on the higher probability of kidney transplantation in patients on PD, we may recommend the patients to institute PD if the patients are suitable for PD and transplantation candidates.

FR-PO2080

Hemoglobin Variability Is a Strong Predictor for Mortality in Renal Transplant Patients Alexander Kainz,[1,2] Julia Wilflingseder,[1,2] Rainer Oberbauer.[1,2,3] *[1]Department of Nephrology, Medical University of Vienna, Vienna, Austria; [2]Department of Nephrology, KH Elisabethinen, Linz, Austria; [3]Austrian Dialysis and Transplant Registry, Austria.*

Background: Anemia is a common problem after renal transplantation. Therefore patients are treated with erythropoietin stimulating agents. The varying response to treatment contributes to hemoglobin variability. It remains unclear however, whether hemoglobin variability is negatively associated with outcomes.

Methods: We conducted a retrospective cohort study of all first kidney allograft recipients between January 1990 and December 2008 represented in the Austrian Dialysis and Transplant Registry (OEDTR). We included 1441 patients of which 683 received erythropoietin stimulating agents at any time after transplantation. Analysis was conducted by Cox proportional hazard regression with cubic splines and linear estimates and the purposeful selection algorithm of covariables. The measure of variability was the moving standard deviation meaning it was computed for every possible four quarters of a year in a row.

Results: The hazard ratio (HR) of mortality and graft loss in the spline models increased with hemoglobin variability. In the linear model the slope for mortality was 2.35 (95 % confidence interval 1.75 – 3.17, p<0.001) and functional graft loss 2.45 (1.76 – 3.40, p<0.001). In the clinical expertise Cox model adjusted for ESA use, hemoglobin, age at transplantation, diabetes, days on dialysis, estimated glomerular filtration rate, biopsy confirmed acute rejection and year of transplantation hemoglobin variability was associated with mortality (HR: 2.11; 1.51 – 2.94; p<0.001). No association with functional graft loss could be detected (HR: 1.34; 0.93 – 1.93; p=0.121). The purposeful selection model was also significant when mortality was the outcome (HR: 2.63; 1.70 – 4.08; p<0.001) whereas a nonsignificant result was obtained for functional graft survival (HR: 1.27; 0.63 – 2.54; p=0.509).

Conclusions: These findings suggest that hemoglobin variability accounts for mortality in renal transplant patients.

Funding: Government Support - Non-U.S.

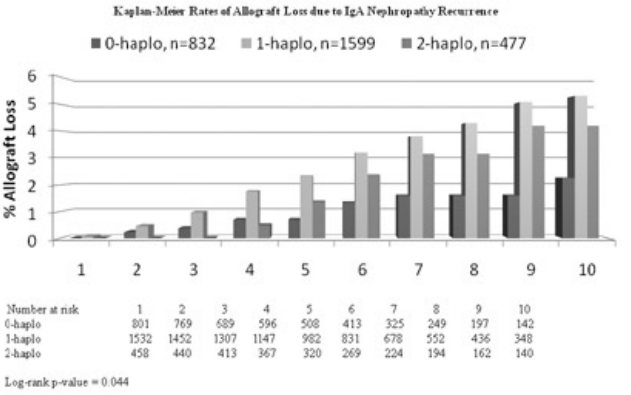
FR-PO2081

IgA Nephropathy Recurrence in Living Related Kidney Transplantation P.T. T. Pham,[1] P.C. T. Pham.[2] *[1]Kidney and Pancreas Transplant, David Geffen UCLA Medical Center, Los Angeles, CA; [2]Nephrology Division, UCLA-Olive View Medical Center, Sylmar, CA.*

Background: Current data suggest that living related kidney transplantation (LRKT) among recipients with the native kidney diagnosis of IgA nephropathy (IgAN) may be associated with an increased risk of histological recurrence. The current study aims to determine whether increasing haplotype match among LRKT affects the rate of actual allograft loss due to IgAN recurrence (IgANR).

Methods: Data were provided by the Organ Procurement and Transplantation Network, United Network for Organ Sharing (OPTN/UNOS). Primary LRKT performed between 1/1/1988-12/31/2007 (as of 10/29/10) with the native kidney diagnosis of IgAN for all patients alive and with functioning graft at discharge were included. The Kaplan Meier rates of allograft loss due to IgANR stratified by haplotype match were obtained.

Results: There were 832, 1599, 477 recipients with 0-, 1-, and 2-haplotype matched kidneys respectively, with mean age: 40.3 +/- 0.4, 37.1 +/- 0.4, 37.1 +/- 0.4 respectively. The Kaplan Meier rates of graft loss due to IgAN recurrence in primary LRKT recipients receiving any kind of immunosuppressive therapy were 2.3% (n=832), 5.3% (n=1599), 4.2% (n=477) for recipients with 0-, 1-, and 2-haplotype matches, respectively, log rank p-value 0.04, at 10-year follow-up.



Chi-square analyses did not reveal any significant differences among the different haplotype groups in terms of gender or ethnic backgrounds.

Conclusions: In accordance with previous reports of increased histological recurrence of IgAN among LRKT, OPTN/UNOS data suggest increased actual graft loss due to IgAN recurrence in living related renal transplant among 1- and 2-haplotype compared with zero match recipients. Potential contributory factors to this observation are not known.

FR-PO2082

Membranous Glomerulonephritis (GN) Is the Most Common Primary GN Associated with Acute Rejection after Transplantation Sanjeev R. Shah, Vijay Vidyasagar, Sumaira Talib Shaikh, Maha A. Mohamed, Brenda L. Muth, Glen E. Leverson, Jose R. Torrealba, Arjang Djamali. *Medicine and Surgery, UW-SMPH, Madison, WI.*

Background: It is unclear whether the type of primary glomerulonephritis predicts acute rejection after transplantation.

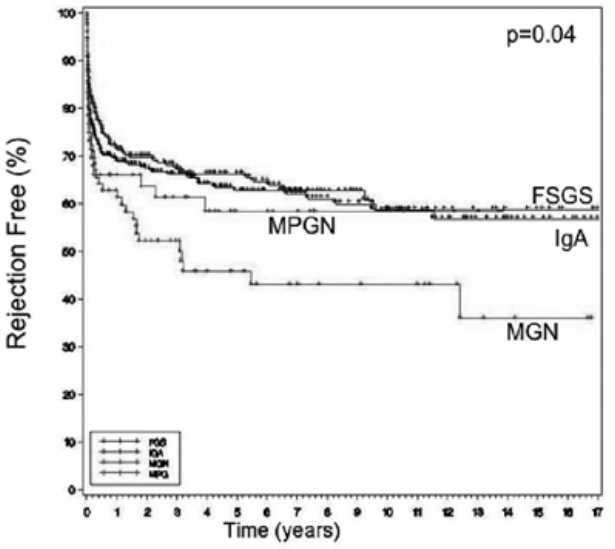
Methods: In a retrospective study of kidney transplant recipients with biopsy confirmed primary glomerulonephritis (n=598 from 1993 to 2009), we compared rejection rates between patients with Membranous GN (MGN), IgA nephropathy (IgA), focal segmental glomerulonephritis (FSGS) and membranoproliferative GN (MPGN).

Results: Baseline characteristics are displayed in Table 1

	MGN	IgA	FSGS	MPGN
N	76	226	239	57
Mean Age	47.1	41.5	47.1	42.9
Male Gender	55 (72.3)	160 (70.8)	137 (57.3)	28 (49.1)
Caucasian	68 (89.4)	201 (88.9)	188 (78.6)	47 (82.4)
Duration disease pre-transplant	11.4	8.5	10.2	14
Donor Age	39.1	40	40.6	39.2
Basiliximab Induction	24 (31.56)	101 (44.69)	94 (39.33)	24 (42.11)
DGF	9 (11.8)	17 (7.52)	47 (19.67)	6 (10.53)
Deceased donor	43 (56.5)	92 (40.7)	150 (64.4)	30 (52.4)
Previous Transplant	21 (27.6)	36 (15.9)	50 (20.9)	22 (38.6)
HLA MM > 2	48 (63.1)	147 (65.3)	161 (67.3)	35 (61.4)

The risk of rejection was 59% greater in patients with MGN compared to other GNs (HR 1.59, 95% CI 1.13 to 2.24, p=0.007). At 3 years, 50% of patients with MGN had an episode of acute rejection (p=0.04)

Figure 1. Rejection was highest in MGN



Univariate analyses including all the variables in Table 1 determined that delayed graft function (DGF) (HR 2.7, 95% CI 1.2 to 6.2, p=0.01) and basiliximab induction (HR 0.39, 95% CI 0.16 to 0.94, p=0.03) were predictors of acute rejection in patients with MGN. Mutivariate analyses retained these covariates as independent predictors of acute rejection.

Conclusions: MGN was the most common primary GN associated with acute rejection after transplantation. DGF and basiliximab induction were independent positive and negative predictors of acute rejection in these patients.

Funding: NIDDK Support

FR-PO2083

Outcomes of Transplantation in Primary Systemic Amyloidosis Horacio E. Adrogue, Jerry D. Estep, Rammurti Kamble, George Carrum, Lawrence Rice, Kelty Ruth Baker, Larhea Nichols, Catherine Frenette, Harish Seethamraju, Luan D. Truong, Lillian W. Gaber, A. Osama Gaber. *Methodist J.C. Walter Jr. Transplant Center at the Methodist Hospital, Houston, TX.*

Background: Primary systemic amyloidosis (AL) is a clonal plasma cell disorder that results in light chain deposition in organ tissues manifesting primarily as nephrotic syndrome, cardiac failure, and neuropathy. Treatment of AL is complex since organ failure may preclude intended treatment with an AHSCT. To address the challenges presented, we initiated an individualized, multi-disciplinary, and multi-specialty Amyloid Clinic at The Methodist Hospital, Houston, Texas.

Methods: Medical charts of patients (January 1998- 2011) with AL receiving solid organ transplants (SOT) and autologous hematopoietic stem cell transplant (AHSCT) were reviewed for patients, disease and transplant related characteristics.

Results: Our table depicts the outcomes of solid organ transplants (SOT) in 8 patients. Overall heart transplant pateint survival was 5/6 (83%) with a median follow-up of 20 months (range 4-90) from the date of SOT (DOT). A total of 18 patients received AHSCT. At median follow-up of 36 months (range 3-150), 15/18 (83%) patients are alive. Treatment related mortality with AHSCT was 5.5%. Mutliorgan transplants are rare for AL. They are possible but must be very carefully screened since they present unique challenges and a higher mortality.

Outcomes of SOT for AL at The Methodist J. C. Walter Jr. Transplant Center

Age/Sex	SOT	DOT	AL treatment	Date of AHSCT	Outcome	SO FU (months)
64/F	Heart	02/09	Len	03/10	Alive	28
62/F	Heart	07/09	Mel/Len	11/10	Alive	30
46/M	Heart/Kidney	01/11	Dex/Len	09/06	Alive	4
57/M	Kidney	09/07	Dex/Thal	06/06	Alive	44
45/M	Heart	06/10	Mel/Len	NA	Alive	12
72/M	Heart	12/04	Mel/Dex	NA	Alive	90
63/M	Heart	04/10	Dex/Thal	NA	Dead	6
63/F	Liver/Kidney	11/10	Dex/Velcade	NA	Dead	1

Conclusions: SOT/AHSCT should be considered an excellent treatment option for selected AL patients. Renewed hope exists especially for AL patients with heart failure. Since the median survival for an AL pateint with end stage heart failure is 6 months, our data show very favorable long-term outcomes for these patients.

FR-PO2084

Low Recurrence Rate of Primary Disease after Kidney Transplantation in Children Yuko Hamasaki,[1] Seiichirou Shishido,[3] Riku Hamada,[1] Tomoyuki Sakai,[1] Kenji Ishikura,[1] Hiroshi Hataya,[1] Hiroyuki Satoh,[2] Masataka Honda.[1] *[1]Nephrology, Tokyo Metropolitan Children's Medical Center, Fuchu, Tokyo, Japan; [2]Urology, Tokyo Metropolitan Children's Medical Center, Fuchu, Tokyo, Japan; [3]Pediatric Nephrology, Toho University Omori Medical Center, Ota-ku, Tokyo, Japan.*

Background: The incidence of acute rejection after kidney transplantion (KTx) has decreased owing to improvement of early immunosuppression but the importance of primary disease recurrence is becoming relatively high. We evaluated that the frequency of the recurrence of primary glomerular disease and outcomes after KTx in our hospital.

Methods: We analyzed that after June 1986, a total of 79 patients who received first KTx and they were treated with calcineurin-based immunosuppressive therapy. Twenty-nine were diagnosed as focal segmental gromeruloscrelosis (FSGS), 16 congenital nephrotic syndrome (CNS), 9 IgA nephropathy, each 6 rapid progressive glomerulonephritis (RPGN) and Henoch-Schonlein purpura nephritis, 5 Alport syndrome, 3 Lupus nephritis, each 2 membranoproliferative glomerulonephritis type1 and atypical hemolytic uremic syndrome, 1 membrenus nephropathy. The original diagnosis was biopsy-proven in every case. Survival curves were estimated by Kaplan-Meier method.

Results: The median age was 12.0 years at the KTx. The mean observation period was 8.5 years. Posttransplant recurrence of primary diseases was confirmed in 10 patients (12.6%): 8 FSGS, 1 RPGN, and 1 CNS. Among the 10 patients who had recurrence of primary disease, 3 lost their graft (FSGS, RPGN and CNS in each 1). Of the 7 patients with FSGS achieved remission by steroid pulse therapy. In contrast, 69 patients who did not have recurrence of primary disease, 8 lost their graft. Graft losses due to acute and choronic rejection were in 2 and 6, respectively. Probability of graft survival at 10-year follow-up was 84%.

Conclusions: Recurrence rate of primary glomerular disease after KTx is lower than the previous reports (30-50%) and graft survival rate is favorable may due to calcineurin-based immunosuppressive therapy.

FR-PO2085

Recurrent Membranous Nephropathy Post-Transplant: Is Rituximab an Option? Tripti Singh, Craig E. Gordon, Laurence H. Beck, Jean M. Francis. *Department of Medicine, Renal Section, Boston University Medical Center, Boston, MA.*

Background: Membranous Nephropathy (MN) is a leading cause of adult nephrotic syndrome. MN recurs in the transplant kidney with recurrence rates between 10 to 45%. Treatment of recurrent MN after transplant remains a challenge since all patients are already on immunosuppressive therapy. Rituximab (RTX), a monoclonal anti CD 20 antibody which targets B cells and decreases antibody production has emerged as a possible treatment option.

Methods: A literature search was performed using PUBMED from inception to Dec 2010. Studies reporting the use of RTX for treatment of recurrent MN after kidney transplant were reviewed and relevant data was extracted. Studies reporting use of RTX for treatment of native MN were excluded. Descriptive statistics were used to determine means (with 95% confidence intervals) for categorical and continuous variables and medians for non parametric variables. The primary outcome was proportion achieving complete remission (CR), defined in source studies as proteinuria<0.3gm/24hr with preserved renal function.

Results: Eight studies met the inclusion criterion. All patients had primary MN and mean time to recurrence was 29.5 months. Mean proteinuria and creatinine on diagnosis were 5.9 g/d and 1.6 mg/dl, respectively. All patients were treated with tight BP control using ACE-I/ARB. RTX was the primary immunomodulator used for treatment. RTX treatment resulted in CR in 72% of reported patients. Mean time to response was 2.6 months. Mean proteinuria and creatinine after treatment were 1.1 g/d and 1.5 mg/dl, respectively. Studies reporting peripheral B cells showed a decrease in the concentration from mean of 97/µl to 5/µl after treatment. Mean follow up after treatment with RTX was 22.6 months. The drug was well tolerated with no reported side effects in the follow up period.

Conclusions: RTX appears to be an effective treatment for recurrent MN with a high rate of response and low adverse event rate. However, this study was limited by both publication and selection bias. The limited toxicity profile of RTX as compared to alkylating agents makes it a preferred option for treatment in this patient population.

FR-PO2086

Limited Utility of Routine Electron Microscopy (EM) in the Diagnosis of Kidney Allograft Dysfunction Maytee Boonyapredee, Jack Moore. *Nephrology, Washington Hospital Center, Washington, DC.*

Background: Biopsy of the transplanted kidney serves a definitive role in elucidating the possible causes of allograft dysfunction. Of the histologic imaging modalities, EM is the most costly and labor-intensive. We have informally noted that EM tends not to modify the findings disclosed by light microscopy with direct immunofluorescence (DIF). We therefore chose to study whether EM results differ from or add to the LM results.

Methods: We compared the LM and EM reports of 65 renal transplant biopsies performed on 60 patients over 2 years. Different pathologists independently interpreted the biopsy specimens; a separate pathologist performed all the EM. We classified biopsy interpretations were into 15 possible diagnoses and categorically by glomerular (e.g. transplant glomerulopathy) versus nonglomerular (cellular rejection) disease. We analyzed agreement between LM and EM reports by kappa statistics and applied the McNemar test

to determine if EM interpretation yielded significantly more glomerular diagnoses on the same biopsy samples.

Results: The biopsies (N=65) represented a sample population with native kidney disease including diabetes (34%), hypertension (36%), FSGS (12%), SLE (5%), chronic glomerulonephritis (1%), and other (12%). There was very good agreement (Kappa= 0.94, 95% CI 0.88-1.00), between the EM- and LM-based interpretations. EM did not detect significantly more glomerular disease than LM/DIF alone (discordance rate 4.6%, 95% CI -1.92% to 4.62%, p=0.25). Furthermore, EM did not add to the diagnosis of rejection. EM described 3 more cases of transplant glomerulopathy than did LM/DIF but did not result in a change in management.

Conclusions: When EM is routinely performed for kidney transplant dysfunction, electron microcopy does not substantially add to LM/DIF evaluation.

FR-PO2087

Corticosteroid Withdrawal in Renal Transplant Recipients: One Year Analysis of the Mycophenolic Acid Observational Renal Transplant Registry V. Ram Peddi,[1] Kimi Ueda Stevenson,[1] Kevin M. McCague,[2] Anne Wiland.[2] *[1]California Pacific Medical Center; [2]Novartis.*

Background: Corticosteroid withdrawal (CSW) is desired by renal transplant recipients (RTRs) given the potential for reduction of CS adverse effects (AEs).

Methods: Using data from the Mycophenolic Acid Observational Renal Transplant (MORE) registry, a prospective study of RTRs receiving mycophenolate (MPA) either as enteric-coated mycophenolate sodium (EC-MPS) or mycophenolate mofetil (MMF) based on local clinical practice at 40 US sites, 12-month CSW (withdrawal of steroids by 3-months posttransplant)outcomes were analyzed. A total of 847 tacrolimus-treated RTRs (352 CSW, 495 CS) were included.

Results: Demographics were similar (mean age 52 yrs, 64% male, 25% AA). Nearly all RTRs received at least one induction agent (CS/CSW: 58.6/63.1% thymoglobulin; 4.7/22.7% alemtuzumab; 26.3/11.1% basiliximab; 9.9/0.9% daclizumab). Tacrolimus trough levels were similar. Biopsy-proven acute rejections (BPAR) were low (9.6% CS/7.4% CSW, p=0.20). Interim results at 1, 3, 6 and 12 months showed that significantly (p=<0.01) more of the CS patients were maintained on full dose MPA (CS/CSW: 83.0/68.5%; 73.1/52.6%; 58.4/37.6%; 51.3/36.1%). In the CS RTRs, a significantly higher % of EC-MPS-treated RTRs were maintained on full MPA doses compared to MMF-treated RTRs but this was not observed in the CSW RTRs. A difference in graft survival (99.4/97.4%, p=0.02) favoring the CSW group was observed. Patient survival was similar. The CS RTRs had a higher mean serum creatinine (CS 1.53/CSW 1.40 mg/dL, p=0.02) and there were no differences in reported infections (including CMV and BK), bone disease, cardiovascular events, diabetes or malignancies. There were more reported GI AEs in the MMF treated CSW RTRs (73.6 MMF/66.1% EC-MPS, p = 0.15). There were more hematological AEs in the CSW RTRs (61.4/28.5%, p=<0.01), mainly driven by leukopenia.

Conclusions: CS allowed for better tolerance of full dose MPA with no difference in BPAR. More RTRs in the CSW group received depleting antibody induction (87/61%). Graft survival was better in the CSW group at 1 year. CS AEs were similar between groups; longer follow-up is needed to assess long-term outcomes of CSW.

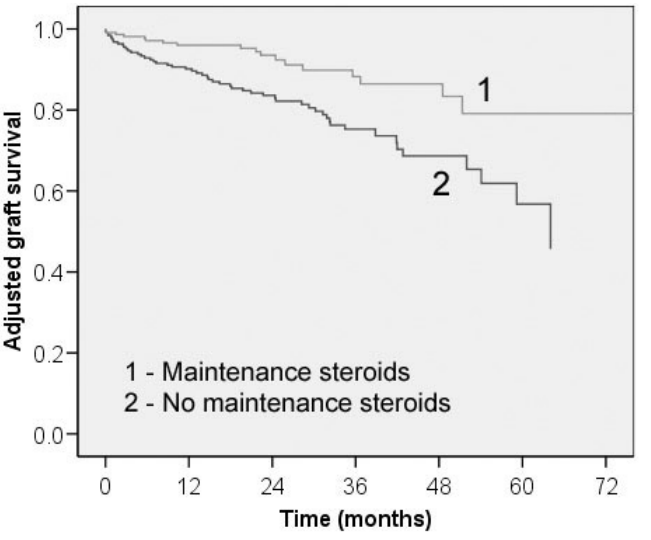
Which Repeat Kidney Transplant Recipient Benefits from Maintenance Steroids? Influence of Induction Agent Kalathil K. Sureshkumar, Sabiha M. Hussain, Richard J. Marcus. *Nephrology & Hypertension, Allegheny General Hospital, Pittsburgh, PA.*

Background: Steroid free maintenance immunosuppression is increasingly used following kidney transplantation and many patients will eventually receive a repeat transplant. It is not clear which re-transplant recipient would benefit the most from maintenance steroids. We aimed to look at the graft survival benefits of maintenance steroids in repeat deceased donor kidney transplant (DDKT) recipients with respect to the type of induction agent.

Methods: Using OPTN/UNOS database, we identified patients (≥18 years) who received a repeat DDKT from January 2000 to December 2008 following induction with rabbit antithymocyte globulin (r-ATG), alemtuzumab (ALE) or an IL-2 receptor blocker (IL-2B) and were discharged on a calcineurin inhibitor/MMF regimen with or without maintenance steroids. A multivariate analysis was performed by including confounding variables to evaluate the independent influence of maintenance steroids on graft survival in different induction groups.

Results: Median follow-up was 29.6 months (range 10.7-60.1 months). There were 3643 patients in the r-ATG (steroid = 3157, no steroid = 486), 448 in ALE (steroid= 196, no steroid = 252) and 1543 in IL-2B (steroid 1465, no steroid = 78) groups. In the unadjusted model, maintenance steroids failed to significantly improve graft survival in r-ATG (p=0.103), ALE (p=0.179) and IL-2B (p=0.23) groups. After adjusting for confounding variables, steroid use significantly improved graft survival in the ALE group (p=0.002) but neither in r-ATG (p=0.191) nor IL-2B (p=0.955) groups. Adjusted graft survival in ALE group with and without maintenance steroids is shown in the figure.



Conclusions: Our analysis shows a graft survival benefit for adding steroid to a calcineurin inhibitor/MMF regimen in repeat DDKT recipients who received ALE but not r-ATG or IL-2B induction.

FR-PO2089

Alloantibody Sensitization Does Not Impede Graft Survival in African American Living Donor Kidney Transplant Recipients Basit Javaid, Ahmadshah Mirkhel, Joseph Keith Melancon. *Georgetown Transplant Institute, Georgetown University Hospital, Washington, DC.*

Background: To study the effects of elevated panel reactive antibody (PRA) titers on renal allograft survival in African American (AA) living donor (LD) kidney transplant recipients.

Methods: All patients in the UNOS database were eligible. Patients were categorized as Highly Sensitized (HS) if PRA value was at or above 95th percentile of all PRA values in the cohort, or as Non-sensitized (NS) if PRA value was zero. Graft survival was compared in the HS and NS Caucasian (CC) and AA LD kidney transplant recipients.

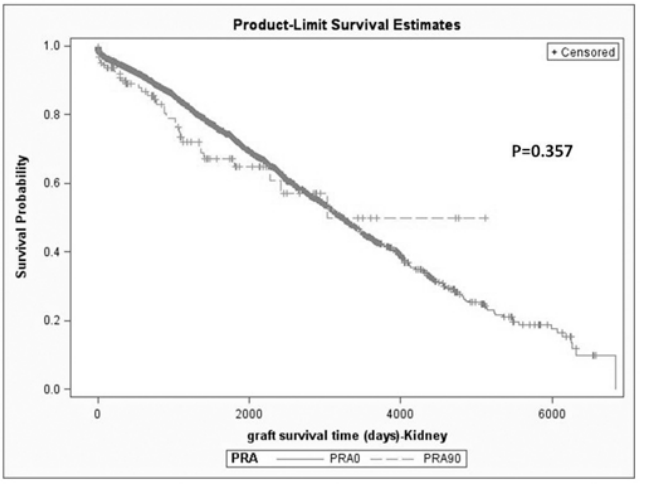
Results: From Oct 1987 to Feb 2009, 271,867 patients underwent a kidney transplant. Of these, 93,899 patients received a kidney from a LD, 64,923 of whom were CC and 13,141 were AA.

AA kidney transplant recipients had longer wait-list time (690.3±663.5 days vs. 434.6±489.2 days; p<0.001) and were less likely to receive a LD kidney transplant (OR=0.41; 95%CI=0.40-0.42; p<0.001), compared with CC recipients. PRA value at 95th percentile was 90.

HS (PRA>=90) CC LD kidney transplant recipients had a higher risk of graft loss compared with the NS CC LD transplant recipients (HR=1.59; 95%CI=1.28-1.97; P<0.001). This difference remained significant after adjustment for confounders (HR=1.50; 95%CI=1.21-1.87; p<0.001).

The risk of graft loss in HS AA LD kidney recipients was similar to NS AA patients who received a kidney from a LD (HR=1.18; 95%CI=0.83-1.66; p=0.358; Fig. 1). The risk difference was unchanged when adjusted for confounders (HR=1.15; 95%CI=0.80-1.64; p=0.394).

Figure 1: Kaplan-Meier Estimates for Post-Transplant Renal Allograft Survival in Highly Sensitized (PRA>=90) and Non-Sensitized (PRA=0) African American Living Donor Kidney Transplant Recipients.



Conclusions: Pre-sensitization did not impair kidney transplant survival in AA LD kidney recipients. Given longer wait-list time and lower odds of LD kidney transplantation, utilization of antibody desensitization techniques in such individuals could improve transplant rates, with expected graft survival comparable to NS recipients.

FR-PO2090

Effect of Immunosuppressive Treatment Withdrawal on Kidney Recipient Sensitization after Allograft Failure Gulnara Rackauskas,[1] Khazenay Bakhsh,[1] Siegmund Teichman,[1] Navin Jaipaul.[1,2] *[1]Nephrology, Loma Linda University Medical Center, Loma Linda, CA; [2]Nephrology, VA Loma Linda Healthcare System, Loma Linda, CA.*

Background: Sensitization to human leukocyte antigens (HLA) and the development of donor specific antibodies (DSA) create barriers to kidney transplantation. Kidney allograft recipients may become sensitized by defining events such as blood transfusion, pregnancy, and previous transplant. Another factor after allograft failure which may cause sensitization is withdrawal of immunosuppressive treatment (IST). However, universally accepted standards for IST after allograft failure do not exist and it is unclear whether withdrawal of IST in this context may independently sensitize patients.

Methods: We conducted a single center retrospective chart review of 242 adult renal allograft recipients with documented allograft failure between January 1, 2000 and January 1, 2010, to determine whether withdrawal of IST after allograft failure is an independent risk factor for sensitization. Sensitization was defined by the presence of Class I or Class II DSA, and/or a panel-reactive antibody level ≥80%.

Results: The 242 patients had the following characteristics: mean age 43.1 (+/- 16.4) years; 58.3% male; 43.0% Hispanic, 40.9% White, 8.3% Black race; 43% hypertensive or diabetic; 66.9% deceased-donor recipient; mean transplant duration 66.9 (+/- 48.9) months; and majority receiving IST with tacrolimus, mycophenolate mofetil, and prednisone. The effects of IST withdrawal after allograft failure and other potentially sensitizing events are shown in Table 1.

Table 1. Sensitization after various exposures

Exposure	Not sensitized	Sensitized	p-value
IST Withdrawal, n(%)	4(0.09)	8(1.0)	0.83
Blood Transfusion, n(%)	25(48.1)	55(56.1)	0.35
Pregnancy, n(%)	6(35.2)	33(66.0)	0.03
Previous Transplant, n(%)	4(0.08)	22(22.2)	0.03
Transplant Nephrectomy, n(%)	10(19.2)	28(30.1)	0.15

Note: Total n varies for each exposure

Conclusions: These findings suggest that withdrawal of IST after allograft failure is not an independent risk factor for sensitization. We believe that our results are valid due to the confirmed risk of other known sensitizing events such as pregnancy and previous transplant.

FR-PO2091

HLA Class II Antibodies and CD4 Peritubular Capillary Deposits in Pediatric Renal Transplantation: Influence on Estimated GFR and Graft Survival Marta Monteverde, Alicia Chaparro, Juan Ibañez, Cintia Marcos, Mario Diaz, Amalia Turconi, Ziomara Balbarrey. *Nephrology, Hosp JP Garraham, Bs As, Argentina.*

Background: C4d peritubular capillary deposits and donor specific HLA class II antibodies (abs) have been associated with vascular rejection, transplant dysfunction and failure. We studied the incidence of C4d deposits and HLA class II abs in kidney transplanted children and the influence of C4d deposits and HLA abs on graft survival and estimated GFR (eGFR).

Methods: We reviewed 78 children (43 males, mean age at RTX 9.9 ± 3.8 y) biopsied at 41.9 months after renal transplantation (RTX, r: 0.33-175.73) because of creeping creatinine n=75, and nephrotic proteinuria: n=3. Fifty two pats received a cadaveric graft; 74 were first RTX. Mean HLA mm: 3.16±098. All were on steroids and MMF/MPS with CYA (n=61), SRL (n=8) or TAC (n=9). Median follow-up after kidney biopsy was 9.16 m (r: 0.33-70.5).Classes II HLA abs were analyzed by Luminex and C4d by monoclonal antibody-immunofluorescence.

Results: Histological findings were: IFTA: n= 40(51%), ACR: n= 25 (32%), ATN: n=6 (8%), de novo membranous glomerulopathy: n= 2 (2.6 %), TX Glomerulopathy: n=(5.2%), TMA: n= 2(2.6%). Positive C4d: 40 pats (51.3%), focal in 10, diffuse 30. HLA class II abs were present in 27 pats (34.6.%). There was a significant association between HLA class II abs and diffuse c4d capillary deposits (p=0,000). The association of ACR with HLA class II abs and diffuse c4d deposits (p=0.000) was also statistically significant. The presence of Class I abs (n=4) was mainly seen during the first year (n=20), always associated to class II atbs All DQ positive pats (n=8) had positive DR. Thirty seven pats (47%) showed no adherence. Eight children lost their graft (10.2%). Graft survival after biopsy in pats without and with diffuse C4d was: 97% and 91% at 12m, 97% and 58% at 36m (p=0.026). HLA clas II abs (p=0.018), diffuse c4d (p=0.002) and ACR (p=0. 001) were associated with transplant failure; eGFR was lower in pats with HLA abs (mean: 79.0±5.9 vs.42.8±6.1;p= 0.0000).

Conclusions: HLA class II abs was associated with diffuse c4d+ peritubular capillary deposits, worst eGFR and graft survival.

FR-PO2092

Serum NGAL and Cystatin C: 2 Early Biomarkers Predicting Delayed Graft Function after Kidney Transplantation Marine Berguignat,[1] Ahmed Jeribi,[1] Fanny Boullenger,[1] Olivier Moranne,[2] Elisabeth Cassuto,[1] Laetitia Albano.[1] *[1]UMC Transplantation Rénale, CHU Nice, Nice, France; [2]Nephrology, CHU Nice, Nice, France.*

Background: Delayed Graft Function (DGF) occurs in 25% of kidney transplant recipients from deceased donors, and is predominantly caused by ischemia-reperfusion injury. While urinary neutrophil gelatinase-associated lipocalin (uNGAL) has been shown to be predictive of DGF, Cystatin C (Cyst C) has not yet been studied as a DGF biomarker. The aim of our work was to assess whether serum NGAL (sNGAL) and Cyst C could predict DGF.

Methods: We conducted a monocentric, prospective cohort study in our transplantation unit, collecting serial serum samples of deceased-donor kidney recipients to investigate these potential biomarkers. We analyzed serum levels of creatinine, sNGAL and Cyst C at day 1 post-transplantation in recipients with immediate graft function (IGF) compared to those with DGF. DGF was defined as the need for dialysis within the first 7 days after transplantation.

Results: Our cohort consisted of 54 recipients, including 13 with DGF. Medians (min-max) of serum creatinine (µmol/L), sNGAL (ng/mL) and Cyst C (mg/L) in IGF vs DGF were 597 (318-1269) vs 700 (354-1098) (p=ns), 307 (59-813) vs 514 (383-1010) (p =.0022), 2.89 (1.35-5.92) vs 3.93 (2.70-5.73) (p =.0004), respectively. ROC analysis for day 1 serum creatinine, sNGAL and Cyst C predicted DGF with an AUC of 0.69 (95%CI 0.53-0.85), 0.78 (95%CI 0.68-0.91), and 0.84 (95%CI 0.73-0.95) respectively. The cutoff levels predicting DGF were >378 ng/mL (Sp 100%-Se 69%) for sNGAL and >2.69 mg/L (Sp 90%-Se 59%) for Cyst C.

Conclusions: Cyst C and sNGAL measured at postoperative day 1 were found to be more reliable biomarkers than serum creatinine for predicting DGF. While sNGAL is less studied than uNGAL, it could be more relevant to cases of oligoanuria. However, we found Cyst C to be a more specific marker than sNGAL in our study. The major advantage of using Cyst C is that it is already measured by a standardized assay in routine labs. Further studies are needed to confirm our findings on Cyst C using larger transplant cohorts.

FR-PO2093

Creatinine Reduction Ratio on Day Two Is an Objective and Effective Tool To Stratify Delayed Graft Function Mahendra V. Govani,[#1] Alvin Wee,[#2] Jay H. Weiss.[#1] *[1]Medicine/Nephrology, St. Vincent Hospital, Indianapolis, IN; [2]Transplantation, St. Vincent Hospital, Indianapolis, IN.*

Background: Creatinine reduction ratio on day 2 (CRR2) < 30%, a simple, objective and well-defined criterion for diagnosis of DGF (instead of necessity for dialysis within a week of kidney transplantation), has not been used effectively to stratify DGF into mild to moderate DGF (MM-DGF) and severe DGF (S-DGF), each of which may have different prognosis.

Methods: We stratify all adult deceased donor kidney transplants performed at our center begining 1/1/2009 according to CRR2 pattern: Immediate graft function (IGF, CRR2 ≥ 30%), MM-DGF (10% ≥ CRR2 < 30%) or S-DGF (CRR2 < 10%). We study variables including demographics, cold ischemia time (CIT), SCD/ECD/DCD status, patient survival (PS), graft survival (GS), dialysis need with a week of transplantation (DGFRD), acute rejection rate (ARR), serum creatinine (SCR), and GFR. We present interim results of 57 transplants performed within the first 2 years and followed until 3/31/2011. Median follow-up was 12.1 ± 6.5 (range 4.2-27.1) months.

Results: Twenty-four of 57 (42%) patients had IGF, 13 (23%) had MM-DGF, and the remaining 20 (35%) had S-DGF. Four of 20 (20%) patients with S-DGF had DGFRD. No patients with MM-DGF had DGFRD. PS and GS were 100% at 3 months (57 pts), at 6 months (50 pts), and at 1 year (28 pts). SCR and GFR at follow-up were respectively higher and lower in MM-DGF (p>0.05) and S-DGF (p<0.05) patients compared to those of IGF patients.

Demographics, Risk Factors, and Outcomes

Variable	IGF (N=24)	MM-DGF (N=13)	S-DGF (N=20)
Age in yrs, mean±SD	57.6±12.7	50.3±15.1	57.2±10.7
Gender Male, n(%)	14(58)	9(69)	15(75)
Race AA, n(%)	9(38)	7(54)	7(35)
ECD/DCD, n(%)	8(33)	3(23)	14(70)*#
CIT in hrs, mean±SD	12.7±4.0	15.2±5.0	16.5±5.8*
Donor age in yrs, mean±SD	44.6±14.0	41.3±18.2	52.7±9.4*
ARR, n(%)	0	1(8%)	3(15)*
SCR mg/dl, mean±SD	1.3±0.4	1.7±0.6	2.1±1.3*
MDRD GFR ml/min, mean±SD	60.4±19.3	49.9±13.5	39.9±14.3*

p < 0.05 compared to IGF pts, # p < 0.05 compared to MM-DGF pts.

Conclusions: Our interim results show that CRR2 is an effective tool for DGF stratification, which may be useful in the management of patients and to compare studies objectively.

FR-PO2094

Using Simulect Plus Low Dose Thymoglobulin in Renal Transplant Recipients with Poor Graft Function Ahmad M. Tuffaha, James B. Wetmore, Da Zhang, Connie J. Wang. *Nephrology and Pathology, University of Kansas Medical Center, Kansas City.*

Background: Simulect and thymoglobulin (rATG) are widely used induction agents in renal transplantation. In patients with poor postoperative graft function (PGF), whether using low-dose rATG by targeting CD3+ cell count, can delay calcineurin inhibitor (CNI) introduction has not been studied. We report our experience with an induction protocol using single-dose simulect plus a CD3+ count-based rATG regimen employed when the creatinine (Cr) reduction rate is < 30% over 24 hours (CRR24hr <30%).

Methods: The cohort included 84 consecutive patients who experienced PGF (CRR24hr <30%). Patients received a single dose simulect intra-operatively; rATG was initiated and titrated to keep CD3+ count < 30 cells/ml. CNI was introduced when Cr fell < 4mg/dL or < 50% of pre-transplant level. We examined the initiation, total dose and duration of rATG, resultant CD3+ count, the initiation of CNI; 1-year patient and graft survival.

Results: rATG was initiated by POD 2 in 77% (mean onset POD 2.0 ± 0.8). Mean cumulative dose was 5.1 ± 4.5mg/kg and duration of therapy was 8.5 ± 6.0 days (Fig 1A). Mean CD3+ count was 16.7 ± 17.0 cells/ml; rATG dosing permitted CD3+ counts to be maintained < 30 most of the days(Fig 1B) and in all but 7 patients(Fig 1C). CNI was introduced at POD 10.3 ± 6.2. One year patient and graft survival were 97.6% and 92.9%. Acute rejection occurred in only 3 (8.6%)recipients. Cytomegalovirus and BK virus infection occurred in 3 and 8(3.6% and 9.5%)recipients. No malignancies were diagnosed.

Figure 1A

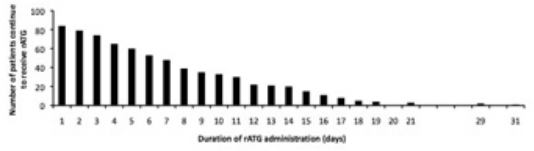

Figure 1B

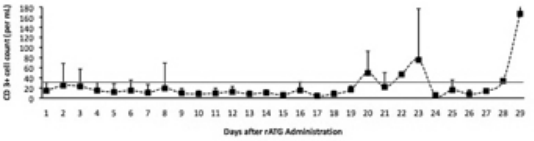

Figure 1C

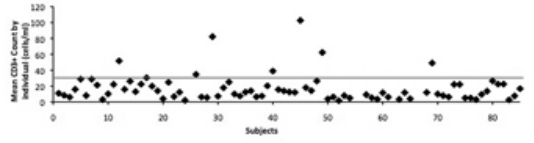


Conclusions: Our findings suggest that in recipients with PGF, simulect plus a CD3 count-based rATG regimen, reliably leads to sufficiently-low CD3+ counts to prevent rejection. The rATG dose is lower than traditional exposure, yet permits delayed introduction of CNI. Excellent long-term graft outcomes are achieved without an increased risk.

FR-PO2095

Associations between MMP-2 Gene Polymorphisms and Post-Transplantational Diabetes Mellitus in Korean Renal Allograft Recipients Sunwoo Kang, Yang Wook Kim, Hyun Ju Kim, Tae Hee Kim. *Inje University, Republic of Korea.*

Background: Post-transplantational diabetes mellitus (PTDM) is a serious metabolic complication that may follow renal transplantation. Matrix metalloproteinase-2 (*MMP2*) function is indispensable for pancreatic beta islet formation and endocrine cell differentiation. Thus, specific *MMP2* gene polymorphisms are considered to be risk factors for diabetes. In this study, we investigated the association between *MMP2* gene polymorphisms and the occurrence of PTDM in Korean patients who had undergone renal transplants.

Methods: A total of 311 patients who had received kidney transplants without a prior history of diabetes were included. Four single nucleotide polymorphisms (SNPs) of the *MMP2* gene were genotyped from genomic DNA with direct sequencing.

Results: PTDM developed in 56 patients (18.0%). The results showed that the allele frequencies of *MMP2* gene polymorphisms rs1132896*C and rs243849*C were significantly higher in the patients with PTDM than in those without PTDM. In multiple logistic regression analysis, 2 SNPs (rs1132896 and rs243849) of the *MMP2* gene were significantly associated with the development of PTDM in the codominant and recessive or, codominant and dominant models, respectively.

Conclusions: Our results indicated that genetic polymorphisms of the *MMP2* gene were associated with PTDM, suggesting that the *MMP2* gene might confer susceptibility to PTDM in patients who receive renal transplants.

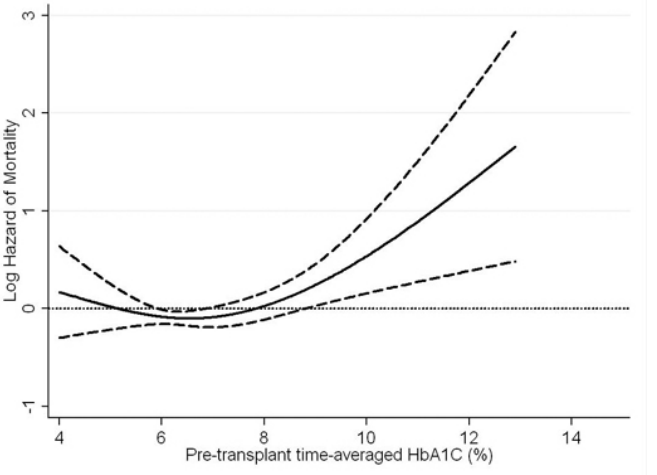
FR-PO2096

Association of Pre-Transplant Glycemic Control with Post-Transplant Outcomes in Diabetic Kidney Transplanted Recipients Miklos Z. Molnar,[1,2] Edmund Huang,[3] Junichi Hoshino,[4] Mahesh Krishnan,[5] Allen R. Nissenson,[5] Csaba P. Kovesdy,[6] Kamyar Kalantar-Zadeh.[1,3] *[1]Harold Simmons Center, Torrance, CA; [2]Semmelweis University, Budapest, Hungary; [3]David Geffen School of Medicine at UCLA, Los Angeles, CA; [4]UCLA School of Public Health, Los Angeles, CA; [5]DaVita, Inc, Denver, CO; [6]Salem VA Medical Center, Salem, VA.*

Background: Studies yielded inconsistent findings regarding the association of hemoglobin A1c (A1c) with survival in diabetic patients (pts) on dialysis. The association between pre-transplant glycemic control & post-transplant outcomes in kidney transplant recipients is not clear.

Methods: Linking the 5-year patient data of a large dialysis organization (DaVita) to the *Scientific Registry of Transplant Recipients*, we identified 2872 diabetic dialysis pts who underwent kidney transplantation. Mortality or graft failure & delayed graft function (DGF) risks were estimated by Cox regression (hazard ratio [HR]) and logistic regression, respectively.

Results: Pts were 53±11 years old and included 36% women and 24% African Americans. In our fully adjusted model, allograft failure censored all-cause death HRs and 95% confidence interval (95% CIs) for time-averaged pre-transplant A1c increments of 7-<8%, 8-<9%, 9-10% & ≥10%, compared to 6-<7% (reference), were 0.89(0.59-1.36), 2.06(1.31-3.24), 1.41(0.73-2.74) & 3.43(1.56-7.56), respectively; and graft failure censored cardiovascular death HRs were 0.38(0.13-1.05), 1.78(0.69-4.55), 1.59(0.44-5.76) & 4.28(0.85-21.64), respectively.



We did not find any difference in risk of death censored graft failure or DGF in different pre-transplant A1c levels.

Conclusions: Poor pre-transplant glycemic control (A1c≥ 9%) appears to be associated with decreased post-transplant survival in kidney transplant recipients although allograft outcomes do not appear to be affected.

The Incidence of New Onset Diabetes after Kidney Transplantation in Korea Joon Seok Oh, Joong Kyung Kim, Seong Min Kim. *Division of Nephrology, Internal Medicine, Bong Seng Hospital, Busan, Korea.*

Background: New onset diabetes after transplantation (NODAT) is a major metabolic complication in renal transplant recipients. It is associated with poor graft and patient survival. However, the incidence, risk factors and clinical relevance of NODAT vary among reports from single-center observational studies and clinical trials in Korea. So, we investigate the incidence and clinical correlations of NODAT in Korean renal transplant population.

Methods: We studied 967 patients receiving a living or deceased donor kidney transplant at 12 institutions between 1 January, 1999 and 31 December, 2007. Patients with graft failure or death within 1month post-transplant, multi-organ transplant recipients and patients who had a diagnosis of diabetes mellitus and severe metabolic disease prior to transplant (either as native kidney disease or co-morbidity) were excluded.

Results: The cumulative incidence of NODAT was 7.65%, 10.24%, 11.27%, 11.70%, 12.10%, 13.03% and 13.65% at 1, 3, 6, 12, 24, 36 and 48 months post-transplant, respectively. Using Cox's proportional hazards analysis, risk factors for NODAT included the use of tacrolimus as the initial maintenance immunosuppressive medication (hazard ratio 1.28, p = 0.03). Factors that reduced the risk for NODAT included living donor (0.69, p=0.00) and the use of cyclosporine (0.78, p=0.03).

Conclusions: We conclude that incidences of NODAT may be associated with the use of tacrolimus, cyclosporine and living donor. Efforts should be made to minimize the risk of this important complication.

FR-PO2098

New Onset Diabetes after Transplantation: Incidence and Risk Factors. Experience from a Single Centre Aikaterini K. Nikolopoulou, Thomas Alexander Vale, Catriona Hilton, Edward Sharples. *Oxford Kidney Unit, Headington, Oxford, United Kingdom.*

Background: New Onset Diabetes after Transplantation (NODAT) is associated with increased morbidity and mortality.

Methods: We performed a retrospective review of 199 kidney transplants performed at the Oxford Transplant Centre between 2007 and 2009. Immunosuppression was tacrolimus and mycophenolate with either basiliximab induction and tapered steroid withdrawal or steroid avoidance in association with alemtuzumab induction. NODAT was diagnosed in patients with more than 2 consecutive random plasma glucose concentrations >9 within the first twelve months post transplant, or required treatment for hyperglycaemia at any time during this period.

Results: The incidence of NODAT requiring oral hypoglycaemic agents was 6.32% (11 patients), with 3 recipients diagnosed late (>12 months). These recipients had an average age of 51 years (range 28-70) and average BMI 27.7 (range 24-30) at the time of transplantation. The majority of patients that developed NODAT (81.8%, n=9) received basiliximab at induction and were on steroids at 8 weeks post transplant (RR 1.94 , 95%CI 0.42-8.32). The rest (18.2%) received alemtuzumab induction with no adjunctive steroids. All patients were on Tacrolimus, average level 8.64ng/ml (range 7.6-11.5). Biopsy proven acute rejection episode was noted in 4 patients in the Basiliximab group and three of them received high dose methylprednisolone prior to developing NODAT. Graft survival was not affected [average eGFR at 12months was 44.5mls/min/1.73m2(range 23-61)].

Conclusions: Primary renal diagnosis did not predispose to NODAT. Elevated BMI at transplantation as expected was noted in the majority of patients developing NODAT.

Our findings suggest that NODAT is associated with use of high dose steroids in the context of a rejection episode, and patients with tapered steroid withdrawal were at higher risk than those in whom steroids were not used.

FR-PO2099

Innovator Versus Generic Mycophenolate Mofetil and Mycophenolate Sodium in Renal Allograft Recipients in India Basu Gopal,[1] Vellaichamy M. Annapandian,[1] Binu S. Mathew,[2] Kuppusamy Saravanakumar,[2] Denise H. Fleming,[2] George T. John,[3] Chakko Korula Jacob,[1] Veerasamy Tamilarasi.[1] *[1]Nephrology, Christian Medical College, Vellore, Tamil Nadu, India; [2]Clinical Pharmacology, Christian Medical College, Vellore, Tamil Nadu, India; [3]Renal Medicine, Royal Brisbane and Women's Hospital, Queensland, Australia.*

Background: KDIGO guidelines endorse use of low cost generics. However, risks and benefits of generic (G) vs. innovator (I) brands of mycophenolate acid (MPA) in renal allograft recipients is unclear.

Methods: Renal allograft recipients, who underwent transplantation at our center between January 2003 & June 2010, on innovator brands of Mycophenolate Mofetil / Sodium (MMF-I / MPS-I) or its generic equivalents (MMF-G1, MMF-G2 / MPS-G1) along with prednisolone and tacrolimus underwent extrapolated MPA-$AUC_{0\text{-}12h}$ measurements at specific intervals and adhoc, for MPA dose adjustment to achieve a target AUC of 30-60mg.h/L. The difference in the dose, AUC, dose controlled AUC (Dc-AUC = AUC/ Dose), number of tests, graft function, graft survival, rejections, infections, leucopenia, diarrhea and cost of MPA between the innovator and generic MMF/MPS users were analyzed.

Results: Of the 305 renal allograft recipients (mean age =36.6±11.8 yrs, M:F=3.1:1), 19.3,18.0,20.3,14.8 & 27.5% were on MMF-I,MPS-I,MMF-G1,MMF-G2 & MPS-G1 respectively. The AUC profiles of MMF-I, MMF-G1 & MMF-G2 were similar. MPS-G1 had a lower, delayed C_{max} compared to MPS-I only in the first 3 months (9.8 vs. 17.4ng/ml p=0.01). MPA Dose, AUC and Dc-AUC of I & G forms of MMF were similar, but MPS-G1 had a Dc-AUC lower than MPS-I. The number of AUC tests required during the first 6 months, graft survival, change in graft function, rejections, urinary tract infections, CMV disease, tuberculosis, systemic mycosis, leucopenia and diarrhea were not different between I & G forms of both MMF and MPS. However, the cost of G forms was significantly lower than MMF-I & MPS-I (by 16.0-20.8%; p<0.01).

Conclusions: Among renal allograft recipients in India, generic MMF exhibited comparable pharmacokinetics to innovator brand, but generic MPS did not. However, generic MPA use resulted in similar survival and post transplant events with lower cost of therapy.

FR-PO2100

Outcomes of Pediatric Kidney Transplantation in Korea over the Last Thirty Years Hee Gyung Kang,[1] Se Eun Lee,[1] Yo Han Ahn,[2] Seong Heon Kim,[1] Kyoung Hee Han,[1] Min Hyun Cho,[3] IL-Soo Ha,[1] Hae Il Cheong.[1] *[1]Department of Pediatrics, Seoul National University Children's Hospital, Seoul, Republic of Korea; [2]Center for Pediatric Oncology, National Cancer Center, Goyang, Republic of Korea; [3]Department of Pediatrics, Kyungpook National University Hospital, Daegu, Republic of Korea.*

Background: The first pediatric kidney transplantation in Korea was performed in 1979 and today kidney transplantation is the most common modality of renal replacement therapy for Korean children with end stage renal disease. This study was done to evaluate the outcomes of Korean pediatric kidney transplantations and related factors.

Methods: The experiences of five major transplant centers in Korea were reviewed.

Results: Until 2010, 498 cases of kidney transplantation were recorded in 488 (M: F=311:177, living donor (LD): deceased donor (DD)=386:112) Korean children younger than 18 years (mean 11.7±4.0 years). Common primary diagnoses were focal segmental glomerulosclerosis (19.4%), reflux nephropathy (12.2%), chronic glomerulonephritis (8.2%), and aplasia/hypoplasia/dysplasia (5.3%). Since 2000, induction monoclonal antibodies were used in 69.4% of DD and in 28.6% of LD, and in > 75% of the cases the maintenance immunosuppressive medication regimen was mainly triple therapy of prednisolone, tacrolimus, and mycofenolate mofetil.

Acute rejection occurred in 40.4% of the cases and its significant risk factors were transplants before 2000, dialysis before transplantation, previous hemodialysis, and recurrence of the primary disease. Median graft survival was 14.9 years for grafts earlier than 2000 and undetermined for those since 2000, with 5 year graft survival of 89.7% for LD and 78.2% for DD. A history of acute rejection, recurrence of primary disease, and a recipient age younger than 6 years or older than 12 years were significant hazard factors for graft loss.

Conclusions: Overall, the outcomes of Korean pediatric kidney transplantations are satisfactory. In this homogenous North-Eastern Asian ethnicity population with high proportion of LD, the favorable effect of pre-emptive transplantation and deleterious effect of recurrence of disease on the outcome of pediatric kidney transplantation were confirmed.

FR-PO2101

Outcome of Renal Transplantation in a Developing Country, like Bangladesh Shahidul Islam. *Department of Nephrology, Bangabandhu Sheikh Mujib Medical University, Dhaka, Bangladesh.*

Background: Renal transplantation is a best form of management in the selective ESRD patients. Outcome of renal transplantation has been steadily improving with the advance immunosuppression. Recently interleukin 2 (IL2) receptor antibody specially Basilaximab (Simuleet) use as induction therapy followed by maintenance dose with Tacrolimus, MMF & prednisolone in most of the transplant centre. Though the cost of induction therapy is enormously high but episode of acute rejection is negligible. Steroid withdrawal protocol and introduction of Sirolimus also introduce in some transplant centers of developed countries.

Methods: In our centre 214 ESRD Patients were transplanted from July 1995 to December 2005. All patients were live related donor & received triple immunosuppression (cyclosporine 6mg/kg, MMF 1000 mg & prednisolone 0.5mg/kg per day initially). After one year of transplantation, patients were received Azathioprine 2mg/kg & prednisolone 7.5 to 10 mg per day.

Results: Over all graft survival rate in 1st year 85%, 3rd year 75%, 5th year 65% & 10 year 50%.

Conclusions: In conclusions, out-come of Renal Transplantation in the developing country like our Bangladesh is good as compared to developed county. Through only live related transplantation has been existing now a days.

FR-PO2102

Living Donation – A District General Hospital Experience in the United Kingdom Andrew K. Coutinho, Girish S. Namagondlu, Emma D'amato, Brian Camilleri. *Renal Unit, The Ipswich Hospital NHS Trust, Ipswich, Suffolk, United Kingdom.*

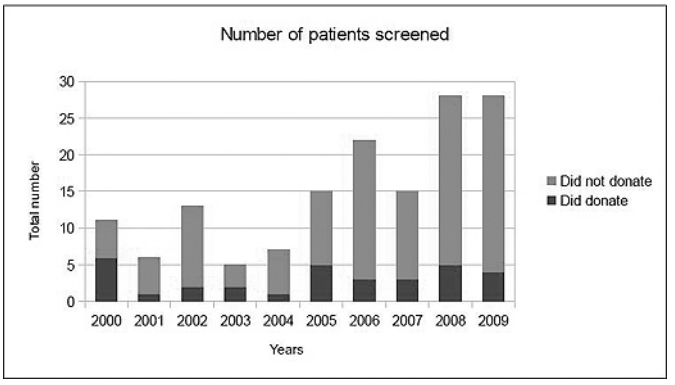
Background: In the United Kingdom the living donor is assessed using the British transplantation society guidelines. A committed time span is not kept for these evaluations. The contribution of a District General hospital (DGH) to donor evaluations are vital as currently many are performed in University teaching hospitals.

Methods: A retrospective study of all potential living donors for kidney transplantation was conducted at Ipswich Hospital from January 2000 to December 2009. Data was got from an electronic database and patient case notes. The Tissue typing (TT) report was taken as the starting point to calculate the duration of time from donor agreement to donation.

Results: 151 potential donors were identified and 32 donated. The ratio of females to males and unrelated to related is 2.02:1 and 1.16: 1 respectively among all the potential donors. Time elapsed at various stages is shown below.

Year	TT report to Nephrologist review in weeks	Nephrologist review to surgical referral in weeks	Surgical referral to donation in weeks	TT to donation in weeks
2000	4.6	21.6	18.5	44.7
2001	3	28	11	42
2002	6	12	11	29
2003	14	23	12	49
2004	6	35	30	81
2005	7	15.3	17.6	39.9
2006	3.5	25	12.5	41
2007	8	15.5	23	46.5
2008	1	18	13	32
2009	6	16.5	12	35
Mean	5.5 (38 days)12.3%	19.75 (138 days)44.8%	16.6 (116 days)37.6%	44 (308 days)

Waiting for appointments and final results before proceeding further accounted for the time elapsed. The number of potential donors evaluated increased over the years but did not affect the donation rate.



Conclusions: Time and resources in evaluation can be saved at the Transplanting centre if done at a DGH. Our study showed that increased donor evaluation does not necessarily contribute to increased number of donations. This study gives a scale of time involved and encourages DGHs to undertake more live donor assessments.

SA-PO2103

Urinary L-FABP and N-Acetyl-β-D-Glucosaminidase Predict AKI after Adult Cardiac Surgery Daisuke Katagiri,[1] Kent Doi,[1] Kenjiro Honda,[1] Kousuke Negishi,[1] Toshiro Fujita,[1] Motoyuki Hisagi,[1] Minoru Ono,[1] Takayasu Ohtake,[2] Shuzo Kobayashi,[2] Takeshi Sugaya,[3] Eisei Noiri.[1] *[1]University of Tokyo, Japan; [2]Shonan Kamakura General Hospital; [3]CMIC, Co, Ltd.*

Background: Urinary L-FABP, a new AKI biomarker, could detect pediatric post-cardiac surgery AKI (KI 2007). However, it is unclear whether urinary L-FABP shows a similar performance in more heterogeneous population of adult patients. Urinary N-acetyl-β-D-glucosaminidase (NAG) is a brush border enzyme and a more established renal injury marker. This study evaluated a biomarker panel consisting of these renal markers for adult post-cardiac surgery AKI.

Methods: 77 adult patients who had cardiac surgery were analyzed. Urinary L-FABP and NAG were measured before surgery, at ICU arrival after the surgery (0 h), 4 and 12 h after. AKI was diagnosed by the AKIN criteria.

Results: 28 patients (36.4%) developed AKI after surgery. Urinary L-FABP (0, 4, 12 h) and NAG (4 and 12 h) in AKI were significantly higher than non-AKI. The highest AUC-ROC values were observed with urinary L-FABP and NAG at 4 h (Table). Urinary L-FABP and NAG showed high sensitivity and high specificity, respectively. The combination can detect AKI with higher accuracy than each biomarker measurement [ROC-AUC 0.81 (0.68-0.90)].

Urinary L-FABP and NAG

		AKI (n=28)	non-AKI (n=49)	AUC-ROC (95%CI)	sensitivity (%)	specificity (%)
L-FABP (ng/ml)	pre	1.7 (0.7-6.8)	1.7 (0.9-4.5)	0.51 (0.37-0.65)	18.5	100.0
	0h	63.3 (27.4-246.9)*	43.1 (11.0-89.4)	0.65 (0.51-0.77)*	42.9	85.4
	4h	120.9 (53.8-274.7)*	49.6 (12.4-149.4)	0.72 (0.59-0.82)*	92.9	44.9
	12h	76.4 (28.6-176.6)*	20.1 (12.7-45.7)	0.76 (0.62-0.86)*	64.3	78.7
NAG (U/l)	pre	5.7 (2.4-12.6)	2.9 (1.9-5.6)	0.63 (0.49-0.76)	53.6	72.9
	0h	9.8 (3.9-23.9)	6.9 (4.0-10.6)	0.60 (0.45-0.73)	35.7	91.2
	4h	22.0 (6.7-30.6)*	6.0 (3.6-11.0)	0.75 (0.61-0.86)*	53.6	100.0
	12h	11.1 (7.2-21.3)*	6.5 (4.8-10.1)	0.67 (0.51-0.79)*	75.0	60.0

Data as median (IQR); *, p<0.05

Conclusions: Urinary L-FABP and NAG can detect AKI accurately in an adult post-cardiac surgery population, when these biomarkers are combined. Combining two markers with different features (sensitivity and specificity) will be a good strategy to improve diagnostic performance of AKI biomarkers.

SA-PO2104

Calcitriol Levels in Acute Kidney Injury in the Critically Ill Anitha Vijayan, Adriana S. Dusso, Sanjay Jain, Daniel W. Coyne. *Renal Division, Washington University in St. Louis, St. Louis, MO.*

Background: Acute kidney injury (AKI) is a devastating complication in the critically ill patient and despite advances in renal replacement therapy (RRT), it is associated with hospital mortality of 50%. Low 1,25 OH Vitamin D (1,25VitD) levels are associated with increased mortality in CKD and given the lack of data regarding 1,25VitD levels in the setting of AKI, we conducted a pilot study to evaluate the relationship between 1,25VitD and mortality in AKI.

Methods: We analyzed serum from 34 critically ill patients who had AKI from acute tubular necrosis (ATN) and had a baseline GFR> 60ml/min. Vitamin D (VitD), 1,25VitD, intact PTH (iPTH), calcium (Ca) and phosphorus (P) were measured and compared to 12 healthy controls. Protocol was appoved by human research protection office and informed written consent was obtained. VitD, 1,25VitD and iPTH levels were quantified using radioimmunoassay (Immunodiagostic Systems). ANOVA was performed using Tukey's multiple comparisons test (Graph Pad InStat).

Results: The mean age of AKI patients was 51.9 yrs (controls - 45.3yrs) with 56% female and 91% caucasian.The mean serum creatinine (SCr) was 4.6mg/dL in the AKI group, with mean Ca of 8.1mg/dl±0.8 and P of 5.1mg/dl±1.9. The VitD and calcitriol levels in AKI (12.6ng/ml±1.059 and 41.6pg/ml±5.7 respectively), were significantly lower than controls (29.2ng/ml±2.7, p<0.01 and 76.1pg/ml±5.3, p<0.01, respectively), while iPTH levels were significantly higher (134.4 pg/ml ± 24.7) vs. (12.3 ± 3.7pg/ml, p <0.05). The in-hospital mortality for AKI was 30%. Univariate analysis showed that the 1,25VitD was significantly higher (62pg/ml±13.1) in non-survivors vs. survivors (32.7pg/ml±5.1, p=0.049). There was no difference in Ca levels between the 2 groups. Multiple regression analysis (Ca, P, Vitamin D, iPTH and 1,25VitD levels, age, sex, race, SCr) showed that higher 1,25VitD levels was significantly associated with increased mortality.(p=0.043, adjusted R^2 of 0.47).

Conclusions: In conclusion, increased mortality was inexplicably associated with higher 1,25VitD levels despite controlling for other variables. A large multicenter study is required to examine the effects of 1,25VitD on mortality in AKI.

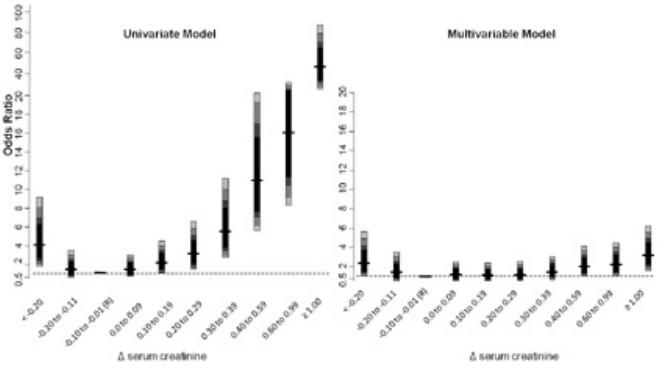
SA-PO2105

Minimal Changes of Serum Creatinine Do Not Predict Prognosis Following Cardiothoracic Surgery If Adjusted for Renal Complications Diana L. Deitzer,[1] David G. Anthony,[2] Jesse D. Schold,[3] Allen Bashour,[2] Sevag Demirjian.[1] *[1]Nephrology, Cleveland Clinic, Cleveland, OH; [2]Anesthesiology, Cleveland Clinic, Cleveland, OH; [3]Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH.*

Background: Severe acute kidney injury (AKI) has been associated with poor prognosis in a myriad of clinical settings; in recent years, even minimal changes in serum creatinine (sCr) have been implicated to carry long term prognostic value. We examined the relationship of sCr change in the post-operative period with in-hospital mortality.

Methods: Prospective cohort of 25,898 subjects who underwent cardiac surgery at Cleveland Clinic between April 2000 and January 2008. Change in sCr (ΔCr) was calculated using peak sCr within 2 weeks following surgery, and divided to 10 intervals (reference interval is ΔCr: -0.1 to -0.01). The multivariable model adjusted for nadir serum bicarbonate, serum sodium, peak serum potassium, and delayed extubation.

Results: Median age was 65 years; 67% were male, and 89% white. In univariate analysis ΔCr less than -0.2, and greater than 0.1 mg/dl were associated with increased in-hospital mortality. Whereas, in the multivariable model, only ΔCr of ≥0.6 mg/dl was associated with higher mortality; and the magnitude of the effect of changes were substantially reduced.



Conclusions: Consistent with prior studies, minimal changes in sCr following cardiothoracic surgery are associated with mortality. However, this association is largely explained by other renal parameters which may suggest a reduced independent impact of creatinine changes alone and reclassification of AKI risk based on combined indicators.

SA-PO2106

Prediction of AKI Is Not Improved by Cystatin C in Critically Ill Patients – Preliminary Results of a Longitudinal Analysis Silvia Coelho,[1] Pedro Fidalgo,[1] Inês Barbosa,[2] Bruno Rodrigues,[1] Ana P. Fernandes,[2] Ana Luisa Papoila,[3] Karina Soto.[1] *[1]Nephrology, Hospital Fernando Fonseca, Lisbon, Portugal; [2]Intensive Care, Hospital Fernando Fonseca, Lisbon, Portugal; [3]Biostatistic, Faculdade de Ciências Médicas, Lisbon, Portugal.*

Background: The utility of Cystatin C (CysC) as AKI biomarker in critically ill patients remains unknown, especially in those with renal replacement therapy (RRT) requirements. The aim of this study was to evaluate the performance of serum CysC associated with severity indexes in a prediction model of AKI and RRT in ICU setting.

Methods: We prospectively studied a cohort of 128 consecutive ICU adult patients over 6m. AKI was defined according to RIFLE criteria. Baseline characteristics, sequential organ failure and severity indexes were record and creatinine and CysC were measured daily. Generalized linear models and linear mixed-effects models for the analysis were used.

Results: Patients, mean age of 57.1y (SD 16.8), 61.7% male, showed median SAPS II and APACHE II scores of 56.5 (CI 50-58) and 24.0 (CI 22-26), respectively. Crude in-hospital mortality was 31.3%. A total of 33.6% developed AKI (91% within 24 hours of admission) and 44.2% were treated with RRT. AKI patients were older (p=0.028), with more commorbidities (p=0.004), higher severity indexes (p<0.001). 76.7% had septic shock and 91% MOF compared to only 26.2% and 16.7% of non-AKI, respectively, p<0.001). Crude in-hospital mortality was 60.5 % in AKI vs. 16.5% in non-AKI (p<0.001).

AKI was associated with both SAPS II and APACHE II index: ROCAUC 0.94 (CI 0.90-0,98) and 0.92 (CI 0.87-0.97). When CysC was added to the model, the discriminative ability was 0.94 (CI 0.89-0.98); 0.93 (CI 0.88-0.97), respectively. When discriminative ability to RRT was analyzed, the performance of both indexes was poor ROCAUC 0.60 (0.43-0.76) and 0.46 (0.29-0.64): without improving by adding CysC to the model (ROCAUC 0.64; CI 0.47-0.80).

Conclusions: Patients with AKI were more severely ill and had a higher mortality. Severity scores showed a good performance for AKI prediction but not for RRT. Cystatin C did not improve discriminative ability. Future larger studies should be done to confirm these results.

SA-PO2107

The Identification of Renal Angina Improves AKI Prediction in Critically Ill Children Rajit K. Basu,[1] Lori Brunner,[1] Derek Wheeler,[1] Lakhmir S. Chawla,[2] Stuart Goldstein.[1] *[1]Center for Acute Care Nephrology, Cincinnati Children's Research Foundation, Cincinnati, OH; [2]Anesthesia and Critical Care, George Washington University Medical Center, Washington, DC.*

Background: Earlier detection of acute kidney injury (AKI) with novel biomarkers holds promise to expedite treatment and improve outcomes. Unfortunately, AKI lacks physical signs and symptoms to identify patients at-risk for AKI to trigger biomarker assessment. We recently proposed the empiric concept of Renal Angina (ANG), to "rule-in" or "rule-out" children at-risk for AKI in the pediatric intensive care unit (PICU). ANG stratifies known AKI risk factors (RF; e.g., intubation, stem cell transplantation) and pairs them with early clinical AKI signs (graded thresholds of small decreases in estimated creatinine clearance (eCCl) or fluid accumulation increase).

Methods: We performed a retrospective review of 135 children admitted to PICU (median age 4.3 [1.2, 12.6]) with a diagnosis of "shock" to determine if ANG on Day 0 or Day 1 improved the ability to predict severe AKI (>50% eCCl decrease; pRIFLE-I or F) on Day 3 or Day 4 over RF alone.

Results: ANG on Day 0 yielded better PPV and NPV for AKI presence on Day 3 than RF alone; Day 1 ANG precision improved further for Day 4 AKI prediction (Table). We observed similar ANG-associated improved prediction for CRRT initiation. ANG was also associated with higher mortality. In summary, we found 1) Lack of ANG was associated with a very low likelihood of AKI development in the next 72 hours, 2) RF alone were poorly predictive of AKI development, and 3) ANG presence was fair at predicting AKI development.

	Day 0		Day 1	
	RF	ANG	RF	ANG
n (%)	95 (70.4)	40 (29.6)	91 (67.4)	44 (32.6)
Age*	2.9 [0.8,10.3]	8.3 [2.3,14.3]	2.9 [0.9,11.3]	7.8 [2.1,14.6]
Male (%)	53 (55.8)	23 (57.5)	56 (61.5)	20 (45.4)
Ventilated	43 (45.3)	17 (42.5)	52 (57.1)	24 (54.5)
Inotropy	31 (32.6)	14 (35)	43 (47.2)	23 (52.3)
Mortality*	5 (5.3)	7 (17.5)	4 (4.4)	8 (18.2)
PPV/NPV to predict pRIFLE-I/F 3 days later	0.14/0.53	0.47/0.86	0.08/0.43	0.57/0.92

* $p < 0.05$

Conclusions: In summary, we suggest fulfillment of renal angina criteria identifies patients for whom biomarker testing would have the highest yield, improving the efficiency of biomarkers to predict severe AKI.

Funding: Other NIH Support - UL1-RR026314-01 NCRR/NIH

SA-PO2108

Role of Statins in Prevention of Contrast Induced Nephropathy Majed Samarneh, Norbert Shtaynberg, Suzanne E. El Sayegh, Morton J. Kleiner. *Nephrology/Cardiology, Staten Island University Hospital, Staten Island, NY.*

Background: Contrast-induced nephropathy (CIN) remains one of the most important clinical complications associated with the intravascular administration of radio-contrast media. A potential role for statins in CIN prevention is suggested by findings in animal models where statins prevent ischemic nephropathy by stabilizing the endothelium and acting as free radical scavengers.

Methods: We carried out a retrospective chart review at our institution to evaluate a possible association between statin pre- treatment and prevention of contrast induced nephropathy. At our institution, 282 charts of patients who underwent a cardiac catheterization or a CT scan with an intravenous contrast were reviewed. Patients presenting with acute renal failure or who have end stage renal disease were excluded. We defined Contrast-induced nephropathy as an increase in serum creatinine by ≥ 0.5 mg/dL or an increase of 25% of the baseline within 72 h following the procedure

Results: Subjects who had CIN (contrast-induced nephropathy) were significantly older (69.6 ± 11.9 vs. 63.2±14.7; p=.0006) and had significantly higher baseline creatinine levels (1.6±0.84 vs. 1.14±0.98; p<.0001). Subjects aged ≥ 65 were twice more likely to develop CIN compared to subjects aged <65 yrs [95% CI: (1.2, 3.2)]. Subjects with baseline creatinine ≥1.5 were 4 times more likely to develop CIN compared to subjects with baseline creatinine<1.5 [95% CI: (2.3, 7.3)] Subjects with HTN were 4.6 times more likely to develop CIN compared to subjects who did not have HTN yrs [95% CI: (2.4, 8.6). Subjects with all three risk factors, including hypertension, diabetes mellitus, and age>65 were 11.6 times more likely to develop post-CIN.

Conclusions: Statin therapy was not effective in prevention of CIN in our study. However, these subjects who were on statins had higher prevalence of risk factors such as hypertension, age >65, and a higher baseline creatinine which may have contributed to the higher incidence on CIN. A larger randomized sample size may elucidate the beneficial effects of statins in prevention of CIN.

SA-PO2109

Safety and Efficacy of Citrate Anticoagulation in Septic Shock Patients Treated with Coupled Plasma Filtration Adsorption (CPFA) Marco Pozzato, Fiorenza Ferrari, Pasqualina Cecere, Paola Mesiano, Antonella Vallero, Sergio Livigni, Francesco Quarello. *Nephrology & Dialysis Unit and ICU, S. Giovanni Bosco Hospital, Turin, Italy.*

Background: From 2001 to 2010 we treated 87 septic shock pts with CPFA, an extracorporeal therapy that combines unselective plasma adsorption resins (MediaSorb) with continuous hemofiltration. CPFA proved to be an effective treatment of septic shock with or without acute kidney injury (AKI), improving hemodynamics, amine reduction and potentially survival.

Study aim was to evaluate a citrate anticoagulation in CPFA to improve the treatment efficiency and simplifying its management. We evaluate the treatment duration, coagulative parameters, bicarbonate and ionized plasma calcium.

Methods: Seven (3 M/4 F) mechanical ventilated with septic shock and multiorgan failure(2/7 had AKI) pts were treated. Prescribed CPFA parameters were: Qb 150 ml/min, plasma flow rate (Qp)30 ml/min, predilution solution (Na+ 136, citrate 10, citric acid 2 in mmol/) infused to keep inlet citratemia at 3mmol/L, postdilution solution (Na+ 139, K+ 1.5, Ca++ 2, 0.75, HCO3- 35, glucose 5.55 in mmol/l) and postdilution CaCl at a rate restoring the plasma Ca++ to 1.1 mmol/l (tab.1) and adjusted according to the pts' need.

Results: We performed 50 treatments accounting for 432 hrs, mean duration 8.5±1.6 hrs, mean plasma volume of 10.8±2.8 l, Qb 142±15 ml/min, Qp 23±2.4 ml/min, a treated plasma dose/kg body weight of 0.88±0.34 l/kg. Mean $CaCl_{10\%}$ infusion of 4.6±1.5 ml/h, with a citratemia, evaluated as total Ca++/iCa++ ratio, always <2.5 (1.96±0.07), also in 3 patients with liver dysfunction (mean 2.06±0.20. Plasma HCO3- was 26±4.8 mmol/l, pH 7.43±0.05, ATIII (median 84%), PTT (49±12 sec) and Ca2+ 1.1±0.1 mmol/l.

Conclusions: Our protocol allowed a high plasma dose, with a safe coagulative status, acid-base balance and calcemia correction. Survival rates at 28 and 90 days were 85.7 and 71.5%, respectively. Citrate CPFA seems a viable and safe treatment for the septic shock pts.

SA-PO2111

Electronic Alerts To Prevent Contrast-Induced Nephropathy among Hospitalized Patients Ji Hyeon Park, Ajin Cho, Seung Tae Han, Jaeyoung Yoon, Hye Ryoun Jang, Jung Eun Lee, Wooseong Huh, Dae Joong Kim, Yoon-Goo Kim. *Department of Medicine, Samsung Medical Center, Seoul, Korea.*

Background: Contrast-induced nephropathy (CIN) is a common cause of hospital acquired kidney injury. However, CIN preventive strategy using extracellular volume expansion remains still underused. We evaluated the institution of alert program can increase the use of standard prevention for CIN and reduce the incidence of CIN in hospitalized patients with chronic kidney disease (CKD) undergoing computed tomography (CT).

Methods: We developed a computer program in which physicians were alerted to a patient's risk of CIN when they ordered contrast enhanced CT in patients with CKD (defined as estimated GFR <60 mL/min per 1.73 m^2). The physicians were required to acknowledge the alert and order preventive strategy, including hydration with 0.9% saline or sodium bicarbonate, N-acetylcysteine administration, and follow-up serum creatinine level within 24-72 hours. This electronic alert program was applied to all hospitalized patients from March, 2010. We identified 618 hospitalized patients with pre-end stage renal disease who underwent contrast-enhanced CT. CIN was defined as an increase in the serum creatinine level after contrast administration of ≥ 25% or ≥ 0.5mg/dl from the baseline level.

Results: 463 patients were eligible in the study: 258 patients in the pre-alert program group and 205 patients in the post-alert program group. The two study groups were well balanced with respect to baseline characteristics. The post-alert program group were considerably more likely to receive pre- and post-hydration and NAC (55% vs 25%, P<0.001). CIN occurred in 3 patients in the post-alert program group (2%), as compared with 12 patients in the pre-alert program group (8%, P=0.029). Logistic regression models revealed computer electronic alerts reduced the incidence of CIN (Odds ratio 0.26, 95% confidence interval 0.07 to 0.95, P=0.041).

Conclusions: Our results suggest that hospitals with adequate information-systems resources should consider implementing electronic alerts to increase physicians' awareness of the risk of CIN, to increase the use of prophylaxis, and to reduce the rates of CIN.

SA-PO2112

Survival and Mortality Risk Factors in Mexican Patients with Acute Kidney Injury Miguel De Jesus Beltran-Perez,[1] Luis Alberto Evangelista-Carrillo,[1] Salvador Mendoza Cabrera,[1] Jorge Andrade-Sierra,[1] Enrique Rojas-Campos,[2] Miguel Medina Perez,[1] Basilio Jalomo Martínez,[1] Benjamin Gomez-Navarro.[1] *[1]Department of Nephrology, CMNO, IMSS, Guadalajara, Jalisco, Mexico; [2]Medical Resarch Unit in Renal Diseases, CMNO, IMSS, Guadalajara, Jalisco, Mexico.*

Background: Acute Kidney Injury (AKI) information is scarce in Latin American ICU and non ICU patients.

Aim: To determine patient survival, mortality risk factors and treatment in AKI patients from a hospital of the West of Mexico.

Methods: Prospective cohort (Jan-May2011) of 79 patients with AKI (AKIN classification), diagnosed and treated by Nephrologists, were recorded at admission, at AKI diagnosis and daily for 1 month: age, gender, time between AKI onset and Nephrology diagnosis, fluid balance, SOFA, APACHE II, ISI, treatment (IHD, CCRT, conservative), date of death or patient discharge and other clinical and biochemical variables.

Results: Mean age was 52±18 years, 61% were male, 48% were from ICU, 50% had surgery, 25% had sepsis; 59% had AKIN 3, mean time between AKI onset and Nephrology consultation was 59±48 hours, 56% received conservative treatment, 28% IHD and 16% CCRT; mean hospitalization was 15±9 days; Mortality was 51% (according to treatment was 46% conservative, 41% IHD and 92% CCRT) Results are shown in Table. Mortality predictors at day of diagnosis were: Δ SCr, Uresis volume and diuretic use (χ2=11.4; p=0.01); and predictors 24-Hrs after were: Diuretic use and SOFA score (χ2=7.1; p=0.03).

Comparisons according to hospitalization site and mortality

	ICU (n=30)	General ward(n=49)
Fluid balance(Lt)	6.7 (3.3-11.3)	3.1 (0.8-6.4)*
SCr Δ	1.8±1.5	3.6±3.1*
Mortality n(%)	20(67)	20(42)*
	Alive (n=39)	Dead (n=40)
Fluid balance(Lt)	2.08 (-0.38-5.4)	6.8 (3.3-11.4)*
SCr Δ	3.7±3.2	2±1.8*
SOFA (pts)	10±3	13±3*
Diuretic use N (%)	21 (70)	19 (40)*
ISI (pts)	0.37±0.2	0.57±0.3*

* p< 0.05

Conclusions: Mortality was similar to other studies, was high in general ward (42%) and was significantly predicted at diagnosis by small changes in serum creatinine. At 24 hours evaluation, SOFA and conservative treatment significantly also predict mortality.

SA-PO2113

A Real Time Electronic Alert System To Identify and Stage Acute Kidney Injury in a Large Acute NHS Trust Linda H. Bisset,[1] Christine Porter,[1] Irene Juurlink,[1] Mark A.J. Devonald.[1,2] *[1]Nottingham Renal and Transplant Unit, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom; [2]School of Clinical Sciences, University of Nottingham, United Kingdom.*

Background: Acute Kidney Injury (AKI) is associated with significant morbidity and mortality. The 2009 NCEPOD report highlighted deficiencies in diagnosis and management of AKI in the U.K. To improve detection of AKI, we developed an automated alert system which identifies and stages AKI in our large NHS hospital.

Methods: Algorithms compare admission serum creatinines (SCr) with actual baseline SCr (lowest SCr 7 days to 1 year before admission). Where no actual baseline exists, SCr is calculated assuming eGFR 75 mL/min. Where RIFLE or AKIN criteria are fulfilled, an alert is displayed on the computer screen. All subsequent SCr results are compared with SCr from previous 48 h (AKIN) and previous 7 days (RIFLE); if these differ, the higher stage is reported. Staging is thus continually updated. Sensitivity is increased by use of both AKIN and RIFLE (retrospective analysis of AKI incidence at our hospital revealed that AKIN detects 60% more episodes of stage 1 than RIFLE but RIFLE detects 30% more stage 3 than AKIN). For each patient admission, the worst AKI stage is allocated using a hierarchy: A3, R3, A2, R2, A1, R1. This gives an idea of the numbers at each stage that would be missed if only one staging system were used. Clinical coding is used to exclude patients with known end stage renal disease.

Results: Sample data from Oct-Dec 2010 are reported. A total number of 7699 alerts were generated, representing 3518 patient admissions. The worst overall AKI stage for each admission is shown (table 1). Mean age 67 y, 48% male.

Worst AKIN (A) or RIFLE (R) stage alerted during admission							
	A3	R3	A2	R2	A1	R1	Total
n=	302	71	399	178	2325	243	3518

Conclusions: Our AKI alert system is fully automated, real time and continuously revises staging. Using actual baseline SCr increases specificity. Combining AKIN and RIFLE systems maximizes sensitivity and specificity. Prospective data are collected automatically, facilitating audit and research.

SA-PO2114

The Impact of Early Initiation of Continuous Renal Replacement Therapy on Outcomes of Critically Ill Patients with Acute Kidney Injury Hideo Yasuda,[1] Akihiko Kato,[2] Yukitoshi Sakao,[1] Naro Ohashi.[1] *[1]First Department of Medicine, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan; [2]Division of Blood Purification, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan.*

Background: Acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT) is a potent risk factor for mortality in critically ill patients. Accumulating evidences suggested that later initiation of CRRT might be associated with worse outcomes in AKI patients. However, it remains to be fully determined as to the appropriate timing to start CRRT therapy in intensive care unit (ICU) patients. The aim of the present study is to clarify the impact of duration from the diagnosis of AKI to CRRT initiation on fluid overload and total mortality in ICU patients.

Methods: We retrospectively collected the data of 67 ICU patients (age: 66.9 ± 19.3, male/female = 47/20) suffering from AKI requiring CRRT in our hospital from 2006 to 2010. We divided all patients into the two groups according to durations until the start of CRRT; the early group (n = 30) that conducted CRRT treatment within 24 hr after the diagnosis of AKI, and the late group (n = 37) that did 24 hr later. We compared clinical parameters at the start of CRRT and prognosis after CRRT therapy between the two groups.

Results: There was a significant difference in serum urea nitrogen (51.5 ± 30.8 vs. 70.1 ± 35.7 mg/dl, $p < 0.05$) and platelet counts (158 ± 111 x 10^3 vs. 98 ± 69 x 10^3 /μl, $p < 0.05$) . The late group disclosed a higher rate of total mortality at 30-day (33.3 vs. 73.0%), 60-day (43.3 vs. 75.7%), and in-hospital mortality (43.3 vs. 78.4%). No significant difference was found in fluid balance from admission of ICU to initiation of CRRT (1124 ± 2414 vs 2313 ± 4392 ml) and central venous pressure (8.2 ± 5.7 vs 8.8 ± 5.6 cm) between the both groups.

Conclusions: It follows from these observations that early initiation of CRRT within 24 hr may provide a better prognosis independently of fluid balance in ICU patients with AKI.

SA-PO2115

Acute Kidney Injury after Off-Pump Cardiac Surgery Stratified by Stages of Pre-Existing Renal Disease Rachita Sethi Reddy, Michael F. Michelis, Nirav C. Patel, Maria V. DeVita. *Lenox Hill Hospital, New York, NY.*

Background: Acute Kidney Injury (AKI) is common among hospitalized individuals, particularly those undergoing cardiac surgery. Studies have shown ≥20% drop in glomerular filtration rate, prolonged hospital stay, progression to end stage renal disease (ESRD), and increased mortality following cardiac surgery. However, many were unable to adjust for baseline kidney function or specifically assess off-pump cardiac surgery.

Our study investigates the association between preoperative stages of chronic kidney disease (CKD) and AKI after off-pump cardiac surgery, defined as 25% increase in serum creatinine (SCr). We also assessed significant predictors for AKI and mortality.

Methods: Using the cardiac surgery database from Lenox Hill Hospital, we performed a single-center, retrospective analysis on all off-pump cardiac surgery patients from June 2009 to January 2011. Extracted data included: age, sex, race, preoperative SCr, postoperative peak SCr, comorbidities [diabetes, dyslipidemia, hypertension (HTN), peripheral vascular disease (PVD), cardiovascular disease (CVD)], urgent versus elective surgery, complications during postoperative period, use of ACEI/ARBs, mortality. Exclusion criteria included on-pump cardiac surgery, preoperative dialysis (ESRD or prior 60 days), intraoperative death, missing data points.

Results: Of the 441 patients that met inclusion criteria, 23.8% had AKI. Incidence of AKI by CKD stages 1-4 was 32.7%, 17.6%, 20.7%, 28.6%, respectively. There were no stage 5 CKD patients. Chi-squared analyses compared risk factors between patients with and without AKI. Patients with AKI were more likely to be diabetic (p=0.038) and have postoperative complications (p=0.014), mainly atrial fibrillation and prolonged ventilation. Mortality rates were six times higher when compared to those without kidney injury (p=0.08). Age, sex, dyslipidemia, HTN, PVD, CVD, urgent versus elective surgery, and use of ACEI/ARBs showed no significant difference in predicting risk of kidney injury.

Conclusions: Patients with AKI after off-pump cardiac surgery are more likely to be diabetic and have postoperative complications. They also have higher rates of mortality during hospitalization.

SA-PO2116

A Simple Method To Classify Acute Kidney Injury (AKI) in Children Alexandre Braga Liborio,[1] Ticiana Andrade Castelo Branco Diniz,[1] Natalia Albuquerque Rocha,[2] Elizabeth De Francesco Daher.[2] *[1]UNIFOR; [2]UFC.*

Background: A RIFLE criteria adaptation has been proposed to classify AKI in children (pRIFLE). However, pRIFLEcr requires eGFR and consequently patients' height. Besides, eGFR is not routinely performed in daily practice, complicating promptly AKI-diagnosis.

Methods: Through mathematical calculation using Schwartz equation(GFR (ml/min/1.73m2) =0.413(height)/Scr, with height in cm) and considering the decline in eGFR as: (baseline eGFR – lowest eGFR/baseline eGFR)x100, we defined the equation:(0.413(height)/Scr1 – 0.413 (Height)/Scr2 / 0.413 (height)/Scr1) x100

Where,Scr1:Scr at baseline,Scr2:Scr at end-point.

Cutoff values of ΔSCr to maintain same performance of eGFR decline were determined for each RIFLE stage. It was tested in 260 hospitalized children in a general pediatric hospital. In patients with no baseline Cr, it was estimated considering normal GFR(120ml/min/1.73m2).

Results: Using mathematical formulas, values required for classification as RIFLE R(1.3xbaseline SCr);I(2.0xbaseline SCr) and F(4.0xbaseline SCr). Patients used to validate this classification were aged 30 days to 12 years and the main diseases were Kala-Azar(56%),pneumonia(14%) and dehydration(8%). Agreement was 100% between pRIFLEcr classified by reduction in eGFR and by increment in sCR.

Distribution of pRIFLE according to eGFR and ΔScr

	No AKI	Rise to 1,3xbaseline Scr	Rise to 2,0-3,9xbaseline Scr	Rise >4xbaseline Scr
No AKI	161	-	-	-
RIFLE R(eGFR decreased by 25%)	-	52	-	-
RIFLE I(eGFR decreased by 50%)	-	-	38	-
RIFLE F(eGFR decreased by 75%)	-	-	-	9

When the GFR reduced to less than 30ml/min/1.73m2, all patients had an increment of at least four times in Scr. The described increments in Scr are different from those suggested by AKIN and by RIFLE for adult patient.

Conclusions: Mathematically, sCr increment was determined to maintain the same performance when compared with eGFR decline. This demonstrates that eGFR decrease magnitude in children is independent from any constant or height. Scr increments used for adults are not applicable to children. Moreover, this simplified classification facilitates a prompt AKI diagnosis and makes retrospective studies possible when height is missing.

SA-PO2117

Acute Kidney Injury Following Heart Surgery: A Comparison between Infants and Neonates Abdullah E. Alabbas, Andrew I. Campbell, Peter Skippen, Cherry Mammen. *BC Children's Hospital, Vancouver, BC, Canada.*

Background: Acute kidney injury (AKI) is associated with increased mortality in critically-ill children and adults. Heart surgery is a known risk factor for AKI. The incidence of AKI in children following heart surgery ranges from <1 to 30% depending on various AKI definitions. However, there are no AKI studies specific for infants or neonates undergoing heart surgery. Our objective was to compare the clinical characteristics of post-heart surgery infants (>28days-1year) and neonates (≤28days) with AKI, utilizing the AKIN definition.

Methods: Retrospective descriptive study. We included all post-operative heart surgery patients ≤1year old who were admitted to our PICU between January 2006 and May 2009 with AKI defined by their maximal AKIN stage. Patient data was collected from a PICU database and medical charts.

Results: 280 infants and 122 neonates had heart surgery in the study period. We identified 125 (45%) infants and 76 (62%) neonates with AKI. The following variables were significantly higher ($p<0.05$) in neonates: Pediatric Risk of Mortality (PRISM) III scores (median 8 vs 10), ventilation days (median 4 vs 5), cardiopulmonary bypass time (median 102 vs 128 min), need for ECMO (5.6 vs 18.4%), PICU and hospital length of stay (median 6 vs 7.5 & 11 vs 18 days respectively). AKI occurred early as 75% of neonates and 76% of infants reached their maximal AKIN stage within 48 hours of admission. The mortality rates of infants and neonates were 7/280 (2.5%) and 11/122 (9%) respectively. Of those who died, 5/7 infants & 11/11 neonates were classified as AKIN stage 3. 15/16 who died in AKIN stage 3 were defined by urine output criteria only.

Conclusions: The incidence of AKI and mortality rate was higher in neonates (62% & 9%) compared to infants (45% & 2.5%). This may be explained in part by increased severity of illness in neonates. Most patients who died were defined by stage 3 urine output criteria alone. Therefore, AKIN urine output criteria may have a stronger association with mortality as compared to creatinine criteria in this population. Further prospective studies are needed to confirm our findings.

SA-PO2118

Acute Kidney Injury Due to Fibrates in the Absence of Rhabdomyolysis. A Common and Occasionally Irreversible Complication Natalia I. Polanco Fernandez, Eduardo R. Hernandez, Eduardo Gutierrez, Victor Gutierrez-Millet, Esther Gonzalez Monte, Enrique Morales, Manuel Praga. *Nephrology, H. U. 12 de Octubre, Madrid, Spain.*

Background: Fibrates are increasingly prescribed for the treatment of hypertriglyceridemia.Several case reports have described acute kidney injury (AKI) in patients treated with fibrates, although most of them were due to rhabdomyolysis.

Methods: Single-center analysis of patients who showed fibrate-induced AKI (FB-AKI) in the period 2007-2010.Definition of FB-AKI included a >20% serum creatinine (sCr) increase in at least two consecutive measurements after the onset of fibrate therapy, absence of other possible causes of AKI and improvement of renal function after fibrate withdrawal.

Results: We collected 60 cases of FB-AKI (37/23 M/F, aged 69±11 yr). Forty-three (71%) had stage 3 CKD at the onset of fibrate treatment, 52 patients (87%) hypertension, 37 patients (62%) type2 diabetes, 39 patients (66%) hyperuricemia.Clinical or analytical signs of rhabdomyolysis were not detected in any patient.Median sCr increase from baseline values was 53.4%(r 23-286). Baseline sCr was 1.2±0.25 mg/dl, peak sCr 2±0.45 mg/dl and final sCr after fibrate discontinuation 1.26±0.28 mg/dl. Renal function improved in all the patients after fibrate withdrawal but 9(15%) did not recover baseline values of renal function. As shown in the table, these patients had a better renal function at baseline, had shown a greater sCr peak and had tended to receive fibrates for a longer time.

Characteristics of patients with complete or incomplete recovery of baseline renal function after fibrate withdrawal

	Complete recovery (51)	Partial recover (9)	p
Age (yr)	69±11	66±13	0,6
Baseline sCr (mg/dl)	1,2±0,6	1±0,7	0,07
Peak sCr (mg/dl)	1,94±0,26	2,2±0,66	0,43
Final sCr (mg/dl)	1,23±0,29	1,4±0,2	0,04
% increase of sCr (range)±	51.6 (23-141)	86.4 (43.6-286)	0,05
Duration of fibrate treatment (months)	13.5 (2-132)	29 (7-45)	0,27

Conclusions: FB-AKI in the absence of rhabdomyolysis is not an uncommon complication. Most of the cases were due to fenofibrate. Although renal function improved after fibrate withdrawal 15% of patients exhibited a partial recovery of baseline renal function values.

SA-PO2119

The Epidemiology of Acute Kidney Injury in Canadian Critical Care Units Ayodele Odutayo,[1] Sasha P. Litwin,[1] Bonnie R. Richardson,[2] Neill Adhikari,[1] James William Barton,[3] Jan O. Friedrich,[1] Amit X. Garg,[2] Stephen Lapinsky,[1] Rahim Moineddin,[1] Michelle A. Hladunewich,[1] Ron Wald.[1] *[1]University of Toronto; [2]University of Western Ontario; [3]University of Saskatchewan.*

Background: There is limited information regarding the epidemiology and outcomes of acute kidney injury (AKI) in Canadian intensive care units (ICUs). Although AKI is frequently diagnosed early, the ability to predict dialysis and death is limited.

Methods: We conducted a prospective cohort study of consecutive patients admitted to critical care units in five Canadian ICUs over a 30-day period. Each patient was followed until hospital discharge or for a maximum of 30 days. The Acute Kidney Injury Network system was used to identify and classify individuals with AKI. We used descriptive statistics to characterize patients with AKI and their outcomes. Among AKI patients, we used multivariable logistic regression to identify predictors of dialysis and the composite outcome of dialysis or death.

Results: We identified 603 patients of whom 161 (26.7%) developed AKI. Patients with AKI were more likely to die (29.2% vs. 8.6% of those with no AKI, $p<0.001$) and the risk of death escalated with AKIN stage (19.2, 37.9 and 51.5% for AKIN stages 1, 2 and 3, respectively). Nineteen (12%) patients received dialysis a median of 1 (1-2) days after AKI diagnosis. Increments in plasma urea and urine output < 400 mL/day on the day of AKI diagnosis accurately predicted the receipt of dialysis (area under the receiver operator curve 0.85). The composite outcome of death or receipt of dialysis occurred in 57 (35.4%) patients with AKI. The combination of plasma urea, urine output <400 mL/day and decrements in serum bicarbonate on the day of AKI diagnosis predicted this occurrence (AUC 0.83).

Conclusions: AKI is a common complication of critical illness in Canadian ICUs. Even mild AKI is associated with a substantial risk of death. At the time of AKI diagnosis, clinical data may be helpful in identifying individuals with a high likelihood of developing progressive disease.

SA-PO2120

Determinants of Nutritional Support in Patients with Acute Kidney Injury (AKI): The PICARD Experience Soo Young Yoon,[1] Sharon Soroko,[1] Glenn M. Chertow,[2] Jonathan Himmelfarb,[3] Talat Alp Ikizler,[4] Emil P. Paganini,[5] Ravindra L. Mehta.[1] *[1]Univ of California San Diego, San Diego, CA; [2]Stanford Univ, Palo Alto, CA; [3]Univ of Washington, Seattle, WA; [4]Vanderbilt Univ, Nashville, TN; [5]Cleveland Clinic Foundation, Cleveland, OH.*

Background: There is limited information on the timing, route, and amount of nutrition required for ICU patients with AKI. We assessed the pattern of nutritional support (NUTS) and utilization of enteral (EN) and parenteral (PN) nutrition in patients enrolled in the PICARD study (KI, 2004, 66: 1613-1621). We hypothesized that AKI severity and comorbidities would influence the mode of nutrition (MON).

Methods: We analyzed data from 615 of the 618 patients who stayed in ICU >48 hours. We assessed the MON provided in the ICU and its relationship to underlying disease severity and other factors.

Results: Among 615 patients, 199 ate orally without NUTS (Oral), 183 received EN, 66 PN, 91 EN+PN, and 76 no oral or NUTS (None). A subset of the NUTS patients had oral intake for part of their ICU stay (EN n=81; PN n=22; EN+PN n= 27). Overall, nutrition was provided for 65.4% of the ICU stay (range 2-100; NUTS 60.9 vs Oral 73.2%; $p<0.001$).

Parameters on ICU admission	None (n=76)	EN (n=183)	PN (n=66)	EN+PN (n=91)	Oral (n=199)	Total (n=615)
%Sepsis*	58.2	62.0	61.4	62.7	42.9	55.3
%Mech Vent*	84.2	86.4	78.3	87.2	78.4	82.7
%Oliguria**	36.8	27.2	15.3	19.3	25.8	25.3
%CKD*	26.8	19.1	21.2	19.8	41.2	27.5
%Diabetes*'**	32.9	34.5	15.6	20.9	33.2	29.8
%CAD*	33.8	35.9	40.6	26.4	47.2	38.5
%CHF*	24.6	21.1	26.2	21.8	40.7	28.6

*p<.05 among groups when including Oral; **excluding Oral

In logistic regression, significant determinants for each MON (Odds ratio) were: None: oliguria (.999), shorter ICU stay (.859), EN: lower body weight (.986) and medical

ICU (.198), EN+PN: lower creatinine (.598) and CRRT (4.882), and Oral: surgical ICU (3.525), preexisting CKD (2.594), shorter ICU stay (.946) and shorter ventilation days (.896).

Conclusions: Nutritional support was required in over 2/3 of patients with AKI. Oral intake and transition between nutritional modes was common. Further studies should determine the relationship between changes in patient's illness and transition of the nutritional mode.

Urinary Liver-Type Fatty Acid-Binding Protein Predicts Mortality in Critically Ill Patients Eunjung Cho, Sang-Kyung Jo, Won-Yong Cho, Hyoung-Kyu Kim. *Department of Internal Medicine, Korea University Hospital, The Institute of Renal Disease, Seoul, Republic of Korea.*

Background: Although several urinary biomarkers including neutrophil gelatinase associated lipocalin (NGAL) have been characterized and validated as useful biomarkers for the early detection of acute kidney injury (AKI), their usefulness as outcome predictors is not well established. Here, we determined the diagnostic and prognostic ability of urinary liver-type fatty acid-binding protein (L-FABP), one of the newly recognized candidate biomarkers for kidney injury, in heterogeneous intensive care unit (ICU) patients, comparing with those of NGAL.

Methods: We prospectively collected data of patients admitted to medical and surgical ICUs from July, 2010 to January, 2011, and urine NGAL and L-FABP at the time of admission to ICU were quantitated.

Results: Among 96 patients enrolled, 35 (36.5%) had AKI and 9 patients required renal replacement therapy. Urinary NGAL and L-FABP were significantly higher in patients with AKI compared to non-AKI ICU patients. The diagnostic performance of these biomarkers, assessed by the area under the receiver operating characteristic curve (ROC-AUC), was 0.811 (95% C.I. 0.718 - 0.903) for NGAL and 0.796 (95% C.I. 0.700 - 0.892) for L-FABP, demonstrating their usefulness in diagnosing AKI. In addition, urinary L-FABP was also found to be useful in predicting in-hospital mortality in multivariate analysis along with SAPS II score, whereas urinary NGAL failed to demonstrate it. The ROC-AUC of urinary L-FABP in predicting in-hospital mortality was 0.743 (95% C.I. 0.635 - 0.851, with a sensitivity of 72% and a specificity of 70% at a cutoff value of 44.5ng/ml).

Conclusions: L-FABP, an emerging urinary biomarker, seems to be promising both for the diagnosis of AKI and the prediction of prognosis in heterogeneous ICU patients. It needs to be further examined and validated for clinical utility. Discovery of biomarkers to stratify patients at risk of poor prognosis might improve ultimate outcomes in critically ill patients.

SA-PO2122

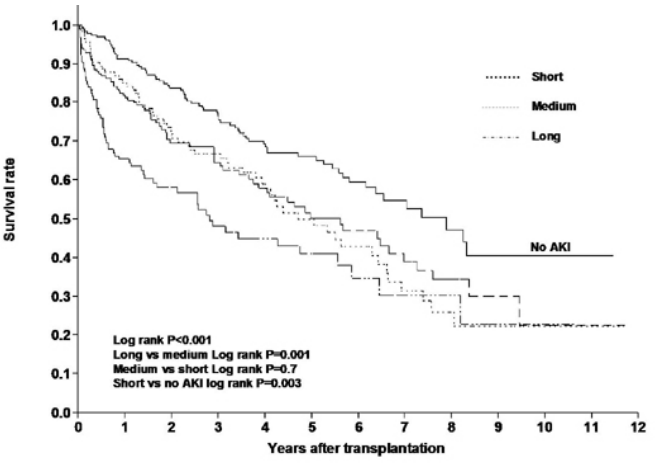
The Duration of Postoperative Acute Kidney Injury and Risk of Long Term Mortality after Lung Transplantation Edgard I. Wehbe,[1] Marie M. Budev,[2] Rachel Lauren Brock,[1] Sevag Demirjian,[1] Martin J. Schreiber,[1] Brian R. Stephany.[1] *[1]Nephrology and Hypertension, Glickman Urological and Kidney Institute; [2]Pulmonary and Critical care, Cleveland Clinic.*

Background: To determine if the duration of Acute kidney injury(AKI)after lung transplantation predicts long term mortality

Methods: We retrospectively evaluated data on 657 patients who underwent lung transplantation from 1997 to 2009. AKI was defined by absolute rise in creatinine by >= 0.3 mg/dl and categorized into three stages by the magnitude rise in creatinine according to the AKIN classification and by the duration from baseline to nadir of creatinine (short (less than 5 days), medium (5–10days) or long (10 days or more)). Outcomes analyzed were all cause mortality.

Results: We identified 424 patients (65 %) who had at least one AKI event in the first 2 weeks after transplantation. 115 (17.5%), 184(28%) and 125(19%) experienced short, medium and long duration AKI respectively. After a median follow up of 2.2 year (0.4-6.9), a total of 277 (42%) died. One year patient survival was 84%, 81%, 65% in the short, medium and long duration AKI respectively. The survival curve (figure 1) showed that long-term survival decreased according to the duration of AKI with significant difference between long duration vs medium or short duration AKI. Adjusting for age, gender, race, type and cause of lung transplant, diabetes and hypertension, the hazard ratio for death was 1.6 (95% CI 1.1-2.3), 1.6(95% CI 1.1-2.2), and 2.7 (95% CI 1.9-3.79) for short, medium and long duration AKI respectively

Conclusions: This study showed that the duration of AKI is independently associated with long-term mortality and may provide additional prognostic information in patients undergoing lung transplantation.



SA-PO2123

Tubular Dysfunction in American Cutaneous Leishmaniasis: Evolution after Treatment Rodrigo Alves de Oliveira,[1] Alexandre Braga Liborio,[2] Geraldo B. Silva,[1,2] Antonio C. Seguro,[3] Elizabeth De Francesco Daher.[1] *[1]School of Medicine, UFC; [2]UNIFOR; [3]School of Medicine, USP.*

Background: Leishmaniasis is an infectious,zoonotic disease.Various types of kidney injury have been reported in visceral type.There are few reports of renal lesions in American Cutaneous Leishmaniasis (ACL). The aim of this study was to determine tubular function in ACL.

Methods: Prospective study,conducted in Brazil.Thirty-seven patients diagnosed with ACL based on histopathological and Montenegro test. Prior and 48 hours after treatment with Glucantime®,tubular function was tested and the results were compared with those obtained for 8 control subjects.Urine and plasma osmolality (Uosm and Posm) were tested before and after intranasal DDAVP.Bicarbonate (sBic), urinary pH (UpH) were evaluated before and after acidification test with CaCl2 (acid test). UpH>5.5 after CaCl2 test and U/POsm<2.8 with UOsm<700mOsm/KgH20 after DDAVP were considered abnormal.

Results: Age was 35±6 years against 29±5 years in control group. The study group comprised 19 men with a mean disease time of 31±22 days. At ACL diagnosis, 27 patients had urinary concentration dysfunction. From these, only seven presented normal urinary concentration after ACL treatment ($\chi 2$ p=0.4). About urinary acidification, 15 patients presented an abnormal acid test at the diagnosis. From these, six had sBic<22mEq/L. After treatment, six patients (40%) maintained urinary acidification defect ($\chi 2$ p=0.01) with three presenting sBic<22mEq/L. Overall, 12 patients had combined tubular dysfunction before treatment and 5 persisted after treatment.

Conclusions: ACL is associated with renal tubular dysfunctions and these are only partially reverted after treatment,especially urinary concentration ability.Glucantime has no detrimental effect.

Renal function before and after treatment vs controls

	Diagnosis	After treat.	Control

SA-PO2124

Acute Kidney Injury and AKI Biomarkers Are Associated with Fluid Overload in Critically Ill Children Ana Palijan,[1] Prasad Devarajan,[2] Joseph V. Bonventre,[3] Michael R. Bennett,[2] Qing Ma,[2] Venkata Sabbisetti,[3] Michael Zappitelli.[1] *[1]Pediatrics, McGill University Health Centre, Montreal, Canada; [2]Cincinnati Children's Hospital Medical Centre, Cincinnati; [3]Brigham and Women's Hospital, MA.*

Background: Little data exist on fluid overload (FO) of all ICU children and the relation between acute kidney injury (AKI) and FO. We hypothesized that ICU-admitted children with AKI develop worse FO and that urine AKI biomarkers help predict worse FO.

Methods: We prospectively followed 160 non-transplanted children admitted to ICU≥1day. Serum creatinine (SCr) and fluid intake/output were recorded daily. FO% was calculated as (fluid in-out [L]/weight)X100. AKI was defined as≥50% or 27 umol/l SCr rise from baseline. Risk factors for Day 3 FO were evaluated by multiple linear regression. The association of AKI and Day 3 FO on ICU stay was evaluated by Cox regression. Area under the curve (AUC) was used to evaluate clinical factors to predict presence Day 3 FO≥3% (median FO). In 51 pts with biomarkers measured, first ICU urine neutrophil gelatinase-associated lipocalin (NGAL), interleukin-18 (IL-18) and kidney injury molecule-1 (KIM-1) were added to the clinical model predicting Day 3 FO≥3%, to determine if this increased prediction.

Results: Mean[SD] age, ICU stay and Day 3 FO% were 4.5[5.7] yrs, 9.3[8.7] d and 4.6[4.9%]; 62% were boys, 4% had sepsis, 65% received pressors, 45% had AKI. Day 3 FO was higher in AKI pts(6.2[5.6] vs. 3.9[3.3]%,p=0.02). AKI was associated with worse Day 3 FO(p=0.03), independent of age, gender, and fluid (ml) per kg in the first 6 ICU hours(p=0.001).AKI and higher Day 3 FO predicted longer ICU stay, controlled for age and gender. A clinical model including AKI, age, gender and fluid in first 6 ICU hrs predicted presence of Day 3 FO≥3% with AUC=0.67. When first ICU urine NGAL, IL-18 and KIM-1 were added to the model, AUC increased to 0.76.

Conclusions: When all ICU children are studied, FO is not as severe as previously described, but is associated with presence of AKI and longer ICU stay. Combining clinical risk factors and AKI biomarkers leads to enhanced prediction of more severe FO development and may assist in FO prevention strategies.

SA-PO2125

Fighting Bloody Diarrhea for HUS Prevention and Mitigation: Lombardy Regional HUS Network Gianluigi Ardissino, Francesca Tel, Sara Testa, Fabio Paglialonga, Stefania Salardi, Silvana Tedeschi, Nicolò Borsa, Rosaria Colombo, Manuela Colosimo, Erminio Torresani, Alberto Edefonti. *Center for HUS Control, Fondazione Ca' Granda Osp Maggiore Policlinico, Milano, Italy.*

Background: Typical hemolytic uremic syndrome (tHUS), although rare, still represents a major public health problem in industrialized countries caused by a Verotoxin-producing Escherichia coli (VTEC) intestinal infection often presenting with bloody diarrhea.

Methods: In order to identify patients at risk of tHUS early in the course of the disease, a network connecting pediatric hospitals in Lombardy Region (10 millions gp) was developed.

Results: Fifty-three units presently partecipate in the network and since May 28, 2010 (founding day) children with bloody diarrhea were centrally tested for Shigatoxin (Stx) 1 and 2 with a rapid immunochromatographic test and multiplex PCR test. The objectives of the project were: 1. to increase the ability of the surveillance system in identifying the sources of VTEC infection and its spreading; 2. to understand the mechanisms of Stx delivery to target organs endothelia; 3. to test the potential role of overhydration and/or leukoapheresis to prevent or mitigate renal and CNS involvement. So far 248 patients have been tested. Hereafter are the preliminary results concerning the 80 samples for which all the procedures were completed. Ten out of 80 (12.5%) were positive for VTEC. Among negative samples Salmonella (25%) and Campylobacter (11%) were the most common identified bacteria. Among patients with negative colture (47%) 1 patient had Henoch Schonlein purpura, 1 ulcerative colitis and 1 Meckel diverticulum.

Conclusions: In conclusion, our findings point out an unexpected very high frequency of VTEC among bloody diarrhea in children in our region. No conclusion can be anticipated on the remaining objectives.

Acknowledgement: the project is feasible thanks to the collaboration of the members of the Regional HUS Network whose complete list is available at www.centroseu.org. The project has been supported by the " PROGETTO ALICE ONLUS – Associazione per la lotta alla SEU"

SA-PO2126

Impact of Acute Kidney Injury (AKI) and Chronic Kidney Disease (CKD) on Re-Admissions in Hospitalized Patients with Congestive Heart Failure (CHF) Charuhas V. Thakar,[1] Pratik Parikh,[3] Yan Liu,[3] Anthony Leonard.[1] *[1]Internal Medicine/Nephrology, University of Cincinnati, OH; [2]Medical Service/ Renal Section, Cincinnati VA, Cincinnati, OH; [3]Biomedical, Industrial and Human Factors Engineering, Wright State University, Dayton, OH.*

Background: Reducing readmission rate in patients hospitalized with CHF improves quality of care and reduces healthcare costs. Effect of AKI and CKD on readmissions in patients with CHF is not well understood.

Methods: We examined the state inpatient database (SID; derived from AHRQ-HCUP) for the state of Washington. 6,535 patients were discharged with a primary diagnosis of CHF from all hospitals in the state between 1/1/06 and 9/30/06.

The primary endpoint was re-admission within 30 days from the index discharge with either primary or secondary diagnosis of CHF. Patients were classified based on diagnosis of AKI, CKD and other co-morbid diseases based on ICD-9 codes. Logistic regression analysis was adjusted for demographics, co-morbidites, and procedures, and economic indicators.

Results: Patients in the sample had a mean age of 73.8 years (standard deviation, SD, 14.6). 51.3% were female, 25% had diabetes, 51% had hypertension. Medicare was the payor in 71% of patients. 6.5% of patients developed AKI during the index hospitalization for CHF; 124/424 (29%) of AKI cases developed AKI with underlying CKD. 14% of the sample had CKD. but did not develop AKI. Results are shown in Table 1.

Results

	AKI- CKD-	AKI- CKD+	AKI+ CKD-	AKI+ CKD+	
N (%)	5211 (80)	900 (14)	300 (5)	124 (2)	
Index Hosp Mortality	1.7%	3.3%	11.2%	12.7%	p < 0.0001
30-day Readmission Rate	13.9%	18%	23%	16.9%	p < 0.0001
Mean length of stay per patient within 30 days	5.2 (SD, 4.8)	6.1 (SD, 4.7)	8.5 (SD, 7.6)	9.4 (SD, 7.1)	p < 0.0001
Odds Ratio of 30-day Readmission*	Ref	1.3 (1.1 - 1.6)	1.8 (1.4 - 2.4)	1.2 (0.7 - 1.8)	

*Case-mix adjusted model

Conclusions: AKI in the absence of CKD significantly increases the risk of re-admission within 30 days in CHF patients. This association also raises the possibility of a pathophysiological link between AKI and recurrent admissons for CHF. Prevention or management of AKI in these patients may improve quality of care and reduce healthcare costs.

SA-PO2127

Piecewise Analysis of Mortality Hazard and Survival Probability in Patients with Acute Kidney Injury (AKI) Jane Hongyuan Zhang,[1] Paul M. Palevsky,[2,3] Glenn M. Chertow,[4] Bingqing Zhou.[5] *[1]VA Cooperative Studies Program Coordinating Center, West Haven, CT; [2]VA Pittsburgh HCS, Pittsburgh, PA; [3]Univ of Pittsburgh Sch of Med, Pittsburgh, PA; [4]Stanford University School of Medicine, Palo Alto, CA; [5]Yale University School of Public Health, New Haven, CT.*

Background: AKI is a life-threatening complication of critical illness associated with acute mortality rates of 40-70%. However, the mortality-hazard is not constant but decreases over time. We utilized survival data from the 1124 participants in the VA/NIH Acute Renal Failure Trial Network (ATN) study to analyze the hazard-function for mortality in critically ill patients with severe AKI requiring renal replacement therapy.

Methods: We used piecewise log-linear models to examine patient survival and fit the hazard of death utilizing models with no change (inflection) points (1 piece), 1 change point (2 piece) and 2 change points (3 piece).

Results: There was an initial steep decrease in the hazard of death, followed by a more gradual decline, suggesting the existence of a critical change point between an acute and convalescent phase of illness. There was excellent fit of both the 2- and 3-piece models (Table). The change-point for the 2-piece model was at 44 days while the change points for the 3-piece model were at 34 and 145 days. The 3-piece model provided the best fit to the data, with a likelihood value of -3906, representing an increase of 114 from the 1-piece model.

	1 Segment	2 Segments	3 Segments
loglikelihood	-4020	-3914	-3906
1st change point (day)		44	34
2nd change point (day)			145
Log(hazard(t)): 1st piece	-3.78 – 0.021*t	-3.15 - 0.058*t	-3.14 – 0.060*t
Log(hazard(t)):2nd piece		-5.31 – 0.009*t	-4.54 – 0.018*t
Log(hazard(t)):3rd piece			-6.82 – 0.003*t

Conclusions: These results are consistent with a clinical course comprised of an acute phase (days 0-34) followed by an early convalescent phase (days 34-145) and a late convalescent phase (beyond day 145). These results should inform the design of design of future clinical trials of interventions in AKI, supporting the use of an early survival endpoint at 1 month and a later endpoint at 3 to 6 months.

Funding: NIDDK Support, Veterans Administration Support

SA-PO2128

Application of the Acute Kidney Injury Network Definition in Post-Heart Surgery Neonates: A Retrospective Study Abdullah E. Alabbas, Peter Skippen, Andrew I. Campbell, Douglas G. Matsell, Cherry Mammen. *BC Children's Hospital, Vancouver, BC, Canada.*

Background: Heart surgery is a known risk factor for acute kidney injury (AKI) in children. The incidence of AKI post-heart surgery ranges from <1 to 30% depending on various AKI definitions and the population of interest. AKI in neonates following cardiac surgery has not been well-studied. Our objectives were: 1) To describe the clinical characteristics of post-heart surgery neonates with AKI, utilizing the AKIN definition 2) To explore potential risk factors for mortality in this population.

Methods: Retrospective, single center observational design. We included all post-operative heart surgery neonates admitted to our PICU between January 2006 and May 2009 with AKI defined by their maximal AKIN stage. Clinical characteristics were compared between the patients' AKIN stages (1,2 and 3). Patient data were collected from a PICU database and medical charts. Multiple logistic regression analyses were performed to evaluate possible risk factors of mortality.

Results: We identified 76 out of 122 (62%) post-heart surgery neonates with AKI during the study period. Overall mean age was 8.4±7.6 days with 90% being term gestation. When compared to stage 1 and stage 2, AKIN stage 3 patients were younger (mean 9.68 vs 11.63 vs 6.03 days for stages 1, 2, and 3 respectively), had higher ventilation days (median 5 vs 4 vs 7), PICU length of stay (median 7 vs 6 vs 9 days), and Pediatric Risk of Mortality (PRISM) III scores (mean 9.68 vs 8.68 vs 13.49) (all p< 0.05). Eleven neonates died after AKI, all with AKIN stage 3. Age <5 days (OR=25.5, 95%CI=2.3-279) and use of ECMO (OR=53.2, 95%CI=5.4-525.5) were independently associated with mortality.

Conclusions: The incidence of AKI in neonates post-heart surgery is high (62%). Those with severe AKI are younger, require longer ventilatory support, stay longer in the PICU and are more critically ill. The development of severe AKI, age < 5 days and need for ECMO are all potential independent risk factors for mortality in this cardiac population. These findings need to be supported by larger prospective studies.

SA-PO2129

The Risk Factors on the Prognosis of Acute Kidney Injury under AKIN Definition in Critical Ill Patients Yang Lichuan, Ping Fu. *Department of Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

Background: Despite significant advances in the medical management and therapeutics, acute kidney injury (AKI) is still a familiar and serious complication with enhanced morbidity and mortality in hospitalized patients, especially in intensive care units (ICUs). The primary purpose of this study is to apply the definition proposed by the Acute Kidney Injury Network (AKIN) workgroup to assess the incidence, the short-time (28 days) outcomes and the risk factors on the prognosis of AKI in ICU.

Methods: In this retrospective study, we collected the data from a cohort of 4642 patients admitted in ICUs from Dec 2009 to march 2011. Univariate and multivariate analysis were performed to investigate the risk factors for short-time mortality of AKI (AKI definited by the increase of serum creatinine by 26.4 umol/L) in ICU.

Results: After further exclusion, there were 1036 patients of ICU admissions enrolled in this research. We found AKI occurred in 353 of the 1036 patients (34.1%) under the AKIN criteria and the mortality was 54.4%. The variables that were related to the prognosis of AKI in multivariable analysis were as follows: AKI III [odds ratio (OR), 12.5338), AKI II (OR, 4.6625), **SAP** (OR,2.3522), renal replacement therapy (RRT, OR = 2.1113;), the timing of AKI in ICU (OR = 1.2351), base serum creatinine (OR = 1.0059),the length of stay in ICU (OR = 1.0546) and age (OR = 1.0223).The area under the receiver operator characteristic (ROC) curve for 28 days mortality was 0.7571 for the AKIN criteria ($p < 0.001$).

Conclusions: In these ICU patients, the mortality of AKI is correlated with various risk factors, especially AKI II,AKI III, SAP , the timing of AKI was independent risk factor for ICU mortality. Our results support the utility of the AKIN criteria in predicting outcomes for patients with AKI.

SA-PO2130

Acute Kidney Injury and Its Severity Are Independently Associated with 10-Year Survival and End Stage Renal Disease Following Cardiac Surgery, Resembling a Dose-Response Pattern Alejandro Ferreiro,[1] Raul Lombardi,[1] Emma Schwedt,[2] González-Bedat Carlota María,[2] Nelson Mazzuchi.[2] *[1]National Institute for Cardiac Surgery, Uruguay; [2]Uruguayan Dialysis Registry, Uruguay.*

Background: Acute kidney injury (AKI) has been associated with long-term mortality and ESRD in large medical claim-based databases. The relationship between multivariate adjusted and prospectively collected Scr-diagnosed AKI and long-term outcomes is mostly scarce. The aim of the study is to evaluate the multivariate-adjusted impact of postoperative (PO) AKI severity on long-term ESRD incidence and mortality after cardiac surgery (CS).

Methods: All adult patients submitted to cardiac surgery between 1/1/2000 and 12/31/2009 (n=7773) were enrolled. Co-morbidities, type of CS procedure, and outcomes were prospectively registered. Long-time survival (up to 10 year) was obtained from a telephone survey and/or National Population Registry. The ESRD status was obtained from the Uruguayan Dialysis Registry which includes all dialysis units in the country. Baseline renal function (eGFR) was assessed by the Cockroft-Gault formula. AKI was defined according to RIFLE criteria, and staged according to the peak minus baseline PO Scr (5 categories). Additive EuroSCORE was used for risk-adjustment. Statistical analysis included "t"test, $\chi 2$ test, Kruskal-Wallis test, Kaplan-Meier curves with long-rank test and Cox regression for multivariate-adjusted survival analysis

Results: AKI incidence: 24.2%. Renal replacement therapy (RRT): 1.7%. Operative mortality: 5.2% (no AKI: 3.1%, AKI no RRT 12.6%, AKI-RRT: 62%, $p<0.001$). Long-term (10 years) actuarial survival after hospital discharge was 0.77 in non AKI patients, being progressively worse according to AKI staging in a dose-response pattern ($p<0.0001$). 10-year ESRD free survival was statistically different inΔ Scr 1 to 1.9 mg/dl (0.98) and $\geq$ 2 mg/dl (0.84) groups ($p<0.001$). In multivariate analysis, AKI (OR 4.21), EuroSCORE (OR 1.16) and eGFR (ml/min) (OR 0.991) were independently associated with long-term survival.

Conclusions: AKI is independently associated with long term survival (10 year) and ESRD in cardiac surgery, related with its severity and resembling a dose-response pattern.

Serum Metabolomic Profiles from Patients with Acute Kidney Injury(AKI): A Pilot Study Richard D. Beger,[1] Jinchun Sun,[1] Melissa Lamb Shannon,[2] Yosuke Ando,[1] Laura Schnackenberg,[1] Didier Portilla.[2] *[1]Division of Systems Biology, National Center for Toxicological Research, US FDA, Jefferson, AR; [2]Division of Nephrology, Department of Internal Medicine, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare Systems, Little Rock, AR.*

Background: The aim of this pilot study was to demonstrate that systemic metabolic alterations associated with AKI could be evaluated using a rapid metabolomics screening technique.

Methods: AKI was defined by an increase in serum creatinine level of 50% or more from previous baseline value. Serum samples obtained from 17 patients admitted to Central Arkansas Veterans Healthcare System (CAVHS) with newly diagnosed AKI as well as pooled serum samples obtained from individuals with normal renal function from National Institute of Standard and Technology (NIST) were analyzed by MS-based metabolomics procedures and the resulting data was analyzed for potential biomarkers.

Results: Five out of 17 AKI patients required dialysis as a form of therapy. Mortality rate in our study was 47 % (8/17 patients) after a follow up of one year. Amino acids, including homocystine, pyroglutamate, phenylalanine and tryptophan, were significantly increased in the serum from AKI patients. Free carnitine and acylcarnitines were significantly increased (about 30 to 500 times increase) in the serum from AKI patients. The traditional clinical biomarkers, creatinine and uric acid, were also elevated in serum from AKI patients when compared to the serum from the NIST standard. LysoPC, citric acid and benzoic acid were significantly decreased at $p<0.0001$ in AKI patients.

Conclusions: 1) Metabolomics data detected increases in homocystine and pyroglutamate in AKI patients, which are commonly recognized as major risks factors for having cardiovascular disease,2) Our metabolomic study is the first one to show a marked elevation in serum carnitine and acylcarnitines concentrations in hospitalized patients with newly diagnosed AKI. These results support the notion of a reduced activity of fatty acid oxidation enzymes during acute kidney injury, a metabolic abnormality we have described in kidney tissue from animal models of acute kidney injury.

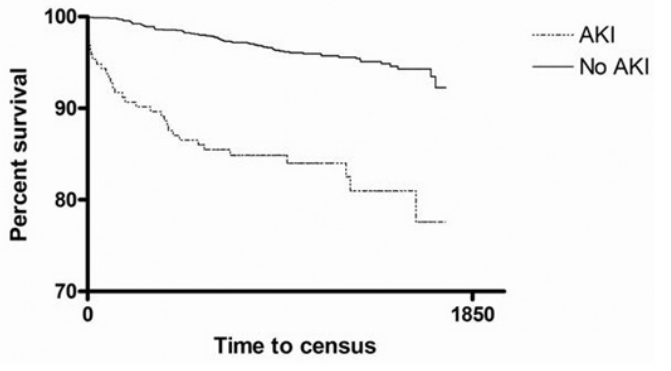
SA-PO2132

Acute Kidney Injury Is Associated with Increased Mortality after Cardiac Surgery in Patients without Pre-Existing Renal Impairment Sean Gallagher, Matt Lovell, Dan A. Jones, Krishnaraj S. Rathod, Akhil Kapur, Andrew Wragg, Magdi Yaqoob, Rakesh Uppal. *Cardiac and Renal, Barts and the London NHS Trust, London, United Kingdom.*

Background: Acute kidney injury (AKI) following coronary artery bypass graft surgery (CABG)has been associated with increased mortality. The incidence and prognostic implications of AKI following CABG in patients without pre-existing renal impairment is unknown.

Methods: An analysis of prospectively collected data was undertaken in 1838 patients without pre-existing renal impairment (eGFR rise >60mls/min) undergoing CABG at a tertiary Cardiac centre between Jan 2003 and Dec 2007. AKI was defined by a 50% increase in serum creatinine post-operatively. All-cause mortality was determined via Office of National Statistics data.

Results: The incidence of AKI was 10.5%. Patients developing AKI were older (67.0vs64.1, $p<0.0001$), with more previous MIs (53.9 vs 40.5%, $p=0.0005$), more LV impairment (47.6vs35.9%, $p=0.002$), more diabetes (45.6vs28.3%, $p<0.0001$), more hypertension (88.6vs79.1%, $p=0.0012$), more PVD (18.7vs11.2%, 0.0047) and Euroscore (a model used to estimate risk of death following cardiac surgery) was higher (5.03vs3.21, $p<0.0001$). In-hospital mortality was significantly increased in patients with AKI (5.6vs0.12%, $p<0.0001$). 5 year survival was also worse among patients with AKI (82.9vs95.7%, $p<0.0001$).



AKI was the strongest independent predictor of long term mortality with an adjusted HR of 3.27 (CI 2.09 to 5.12). Only LV function (adjusted HR1.98 (CI 1.38 to 2.85) and age (adjusted HR 1.07 (CI 1.03 to 1.1)) were also independently associated with 5 year all cause mortality.

Conclusions: The development of AKI following CABG in patients without pre-existing renal imapairment is associated with worsening of 5 year mortality. Patients that develop AKI following CABG are high risk and aggressive subsequent medical therapy may be warranted.

SA-PO2133

Preoperative Prescription of Diuretics, but Not Inhibition of Renin-Angiotensin-System, Predicts Acute Kidney Injury after Non-Cardiac Surgery Miho Tagawa,[1] Takayuki Hamano.[2] *[1]Nephrology, Kyoto Katsura Hospital, Kyoto, Japan; [2]Center for Clinical Epidemiology and Biostatistics, University of Pennsylvania, Pennsylvania, PA.*

Background: Angiotensin converting enzyme inhibitors (ACE-I) or angiotensin II receptor blockers (ARB) are reported to be an independent risk factor for acute kidney injury (AKI) in cardiac surgery. No study has evaluated which kind of preoperative prescription of antihypertensives are risk factors of AKI after non-cardiac surgery.

Methods: This is a retrospective observational study. Inclusion criteria were adult (age ≥ 18) patients who underwent non-cardiac surgery under general anesthesia from 2007-2009 at our institute. Exclusion criteria were urological surgery, those without creatinine (Cre) values, and who had underwent dialysis preoperatively. Exposure of interests are preoperative use of anti-hypertensives including ACE-I/ARB and diuretics. Outcome variable was postoperative acute kidney injury defined by AKI network (increase in Cre ≥ 0.3 mg/dL or 150 %, or urine output < 0.5 ml/kg/hour for > 6 hours). Multivariable logistic regression was performed. We adjusted for 23 covariates including kinds of surgery. A propensity score (PS) of receiving ACE-I/ARB therapy preoperatively was estimated and PS analyses were performed including PS adjustment and PS matching as sensitivity analyses.

Results: There were 123 AKI (5.0 %) among 2472 subjects.

Odds ratio of AKI by multivariable logistic regression analysis

	Odds ratio	95 % CI	p value
ACE-I/ARB	0.833	0.503-1.379	0.477
Diuretics	2.360	1.288-4.325	0.005

PS analyses yielded similar results with regard to ACE-I/ARB therapy. Other independent predictors of AKI included male sex, intrathorasic, intraperitoneal surgery, surgery with large fluid shift, emergent surgery, insulin-dependent diabetes, hypertension, cerebrovascular disease, intraoperative use of pressors.

Conclusions: Not prescription of ACE-I/ARB, but of diuretics was an independent risk factor for postoperative AKI in non-cardiac surgery.

SA-PO2134

The Impact of Early Nephrology Follow-Up among Survivors of Acute Kidney Injury Requiring Dialysis Ziv Harel,[1,4] Ron Wald,[1,4] Muhammad Mamdani,[1,3,4] Joanne M. Bargman,[4] Amit X. Garg,[2,3] Robert R. Quinn,[3,5] Joel Ray,[1,3,4] Jin Luo,[3] Chaim Bell.[1,3,4] *[1]St. Michael's Hospital; [2]London Health Sciences Centre; [3]Institute for Clinical Evaluative Sciences; [4]University of Toronto; [5]Foothills Medical Centre and University of Calgary.*

Background: Acute kidney injury (AKI) is associated with an increased risk of death and kidney disease progression. However, the optimal management of AKI survivors is unclear. We postulate that early follow-up with a nephrologist following a hospitalization for AKI may modify the risk of death.

Methods: Using linked administrative databases for all of Ontario for the period April 1994 to March 2008, we conducted a cohort study of all adults with AKI who received in-hospital dialysis and remained dialysis free at least 90 days after discharge. The exposure of interest was early nephrology follow-up, defined as at least one nephrologist visit within 90 days of discharge. A propensity-score was used to match those who did versus those who did not receive early nephrology follow-up after discharge. A Cox Proportional Hazards model was used to estimate the treatment effect. The primary endpoint was all-cause mortality within 2 years of cohort assembly.

Results: Of the 3877 eligible patients, 1553 (40%) received early nephrology follow-up. We successfully matched 1184 individuals who received early follow-up to 1184 of those who did not. The incidence of death was 0.02 per 100 person-years among individuals receiving early follow-up compared to 0.03 per 100 person years in those who did not (hazard ratio of 0.76, 95% confidence interval 0.62-0.93).

Conclusions: Early nephrology follow-up after a hospitalization with AKI requiring in-hospital dialysis was associated with improved survival. Whether this is a reflection of better care provided by nephrologists, or a biased tendency to bring less morbid individuals to nephrology care, is unknown. In light of these results, further research is needed to evaluate the processes of care undertaken by nephrologists when following-up patients hospitalized with AKI requring in-hospital dialysis.

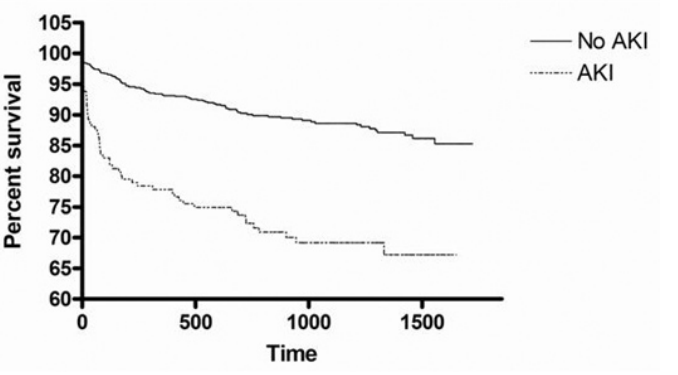
Acute Kidney Injury Is Associated with Increased Mortality after Cardiac Surgery in Patients with Pre-Existing Renal Impairment Sean Gallagher, Matt Lovell, Dan A. Jones, Krishnaraj S. Rathod, Akhil Kapur, Andrew Wragg, Magdi Yaqoob, Rakesh Uppal. *Cardiac and Renal, Barts and the London NHS Trust, United Kingdom.*

Background: Acute kidney injury (AKI) following coronary artery bypass graft surgery(CABG)has been associated with increased mortality. Whether AKI is as prognostically important in patients with pre-existing renal impairment remains unclear.

Methods: An analysis of prospectively collected data upon 874 patients with renal impairment (eGFR <60mls/min) undergoing CABG at a tertiary Cardiac centre between 2003 and 2007 was undertaken. AKI was defined by a 50% increase in serum creatinine post operatively. All-cause mortality was determined via Office of National Statistics data.

Results: The incidence of AKI in this cohort was 20.1%. Patients that developed AKI had lower pre-operative eGFR (45.2vs48.0mls/min, p=0.0014), more diabetes (38.1vs28.1%, p<0.0128) and Euroscore (a risk model used to estimate risk of death following cardiac surgery) was also higher (6.7vs5.7, p<0.0004). In hospital mortality was dramatically increased in patients that developed AKI (11.4vs 1.23%, p<0.0001). Moreover, long term survival was worse among patients that developed AKI (68.9vs88.1%, p<0.0001) with an adjusted hazard ratio of 3.57 (CI 2.28 to 5.61) when compared with patients that did not develop AKI.



After multivariate analysis impaired LV function (adjusted HR 1.96 (CI 1.38 to 2.79)) and age (adjusted HR 1.07 (CI 1.03 to 1.1)) were also additional factors independently associated with 5 year all cause mortality.

Conclusions: The development of AKI following CABG surgery is associated with worse 5 year mortality in patients with pre-existing renal impairment. Improved strategies to protect renal function during CABG surgery and more aggressive and timely medical therapy following CABG may be warranted to improve prognosis in this high risk patient group.

SA-PO2136

Kidney Biopsy in Intensive Care Units: Is it Realisable? Is it Useful? Results of the COBRRA Study Group Carole Philipponnet,[1] Saleh Kaysi,[1] Anne-Elisabeth Heng.[1] *[1]Nephrology, CHU G Montpied, Clermont-Ferrand, France; [2]Nephrology, CHU St Etienne, St Etienne, France; [3]Nephrology, CHU Poitiers, Poitiers, France.*

Background: In ICUs, Kidney biopsy (KB) is considered complex and dangerous to achieve. We describe the complications, diagnostic and therapeutic contributions of the KB in ICUs .

Methods: A Retrospective study was done in 5 ICUs. Inclusion criteria: Patients admitted between 01/00 and 09/10 with a Sequential Organ Failure Assessment score (SOFA) ≥ 3 (at least 1 organ other than kidney) and with a KB performed during ICU stay. Exclusion criteria: Autopsy. KB was contributive if it revealed a non-expected diagnosis or changed the patient management (start or stop a treatment, start a renal replacement therapy, or taking the decision of reducing the global medical management).

Results: Forty-six KB were analyzed. The patients Simplified Acute Physiology Score, SOFA at ICU admission was 54+/-19 and 10+/-4, respectively. ICU mortality was.21%. KB was performed as an average 8 days [1-126] after admission: 45 percutaneous and 1 trans-jugular ; 35 echo-guided in ICU and 7 CTscan guided. At the KB day, 16 patients had a SOFA score ≥3 (respiratory or hemodynamic) ; 6 KB content < 5 glomeruli.

Histological finding: 24 Acute Tubular Necrosis (ATN) ; 12 Acute Glomerular Lesions (3 Crescentic , 3 Cryoglobulinemia, 3 Wegner, 1 Lupus, and 2 Membranoproliferative), 7 Acute Vascular Lesions (5 Thrombotic microangiopathy, 1 Cholesterol Embolism Disease, and 1 Malignant Nephroangiosclerosis), 4 Acute Interstitial Nephritis, 2 Myeloma and 1 Amyloidosis. These findings led to start new treatments (n=20), to stop treatments (n=7), to start chronic hemodialysis (n=12) and to reduce global medical management (n=4). KB was contributive in 43 cases (diagnostic n=26 and therapeutic n=34) and not contributive .in 3 (1 expected ATN and 2 inadequate materials). Complications (bleedingt that necessitated transfusion of ≥2 blood units within 7 days of KB) occured in 5 patients, one of these was dead as a result of this complication.

Conclusions: KB is rarely performed in ICUs. However, it could be performed even in very ill patients and its diagnostic and therapeutic contribution could be very important.

SA-PO2137

AKIN (Acute Kidney Injury Network) Score Did Not Predict Survival after Orthotopic Liver Transplantation (OLT) Thais Nemoto Matsui, Maria C.C. Andreoli, Cláudia Tótoli, Maria P.V. Coelho, Nadia K. Guimaraes, Fellype Barreto, Jose Ben-Hur Ferraz-Neto, Bento Santos. *Einstein Dialysis Center & Liver Transplantation Unit, Albert Einstein Jewish Hospital, São Paulo, Brazil.*

Background: Previous studies have shown that perioperative renal failure exerts a significant negative impact on liver transplantation outcomes. However, serum creatinine cut-offs used in those studies tends to underestimate renal failure in patients with cirrhosis. The aim of the present study was to determine the impact of preoperative kidney dysfunction as assessed by the AKIN score on mortality rates within 28 days and 1 year after OLT.

Methods: This retrospective study included 286 patients with chronic liver disease who were consecutively admitted in an urban tertiary medical center to undergo OLT from June 1st, 2005, to December 31, 2009. AKIN score was determined at the moment of admission and immediately before OLT. AKI was defined according to the AKIN criteria as a 50% or greater increase of baseline creatinine level.

Results: From the 286 included patients (52.3±11.7 yrs), 54% had viral-related disease, with MELD of 19.4±9.8, and 21% had diabetes mellitus. AKI at admission and on the day of OLT was observed in 84 (29%) and 73 (26%) subjects, respectively, with the following AKIN scores: 1=48%, 2=23%, 3=29% at admission; 1=48%, 2=22%, 3=30% on the day of OLT. RRT was needed in 81 cases (28%). Mortality rate at 28 days was

6%, with similar rates across AKIN scores (1=7%, 2=5%, 3=4% at admission, p=0.597; 1=6%, 2=12%, 3=5% on the day of OLT, p=0.954). Likewise, mortality rate 1 year after OLT (14%) was not influenced by pretransplant AKIN scores (1=17%, 2=26%, 3=17% at admission, p=0.939; 1=11%, 2=19%, 3=18% on the day of OLT, p=0.462). After adjustment for MELD and diabetes mellitus, RRT (OR 4.036, CI95% 1.793–9.084, p=0.001) and older age (OR 1.039, CI95% 1.002–1.078, p=0.039) were independently associated with death within 1 year of OLT.

Conclusions: Unexpectedly, the AKIN score did not predict the mortality rates within 28 days and 1 year after OLT. The most important prognostic factor for survival was the need for peritransplant RRT.

SA-PO2138

Renal Function in Patients with Multiple Myeloma Treated with Bortezomib-Based Regimens: A Single-Center Cohort Analysis Catarina Calado Teixeira, Mário Raimundo, Jose António Lopes, Antonio Gomes da Costa. *Department of Nephrology and Renal Transplantation, Hospital de Santa Maria, Lisbon, Portugal.*

Background: Bortezomib is a proteasome inhibitor that blocks several molecular pathways in a cell and may cause cancer cells to die. When added to standard therapy significantly improves time to progression and overall survival in patients with multiple myeloma (MM). The aim of our study was to evaluate the effect of bortezomib-based regimens in renal function in patients with MM.

Methods: In all, 34 patients (mean age: 63 years; 18 male; 30 Caucasian) with MM treated with bortezomib-based regimens were studied retrospectively. Bortezomib was administered at the dose of 1.3mg/m^2 on days 1, 4, 8 and 11 of each cycle of 21 days. Twenty patients, eligible to stem cell transplantation (SCT), were treated with bortezomib, doxorubicin (40mg/m^2/4thd) and prednisolone (60mg/m^2/d). Six patients, not eligible to SCT, were treated with bortezomib, melfalan (9mg/m^2/d) and prednisolone (60mg/m^2/d). Eight patients, with relapsed or refractory MM, were treated with bortezomib and prednisolone (60mg/m^2/d). Glomerular filtration rate (GFR) was calculated by the Modification of Diet in Renal Disease equation. Comparisons between GFR values determined at the beginning of the first cycle and one month after the last cycle were performed by paired-samples T test. Pre-existing chronic kidney disease (CKD) was considered whenever baseline GFR was lower than 60 ml/min/1.73m^2. A *P*-value <0.05 was considered statistically significant.

Results: There were no statistically significant differences between GFR values determined at the first cycle and GFR values determined one month after the last cycle, both when evaluating all patients (97±49 ml/min/1.73m^2 *vs* 124±138 ml/min/1.73m^2, *P*=0.182) and when evaluating exclusively those patients with pre-existing CKD (N=6) (37±13 ml/min/1.73m^2 *vs* 56±28 ml/min/1.73m^2, *P*=0.077), although there was a trend towards improved renal function associated with bortezomib-based regimens.

Conclusions: Our results suggest that in patients with MM bortezomib-based regimens are not harmful to kidney: On contrary, such regimens can improve renal function mainly in patients with pre-existing CKD.

SA-PO2139

Nephroprotection: PBI-4419, a Novel Orally Active Anti-Fibrotic Agent, Reduces Doxorubicin-Induced Nephrotoxicity in Mice Brigitte Grouix, Kathy Hince, François Sarra-Bournet, André Doucet, Shaun Abbott, Jean-François Bienvenu, Jean-Simon Duceppe, Boulos Zacharie, Christopher Penney, Pierre Laurin, Lyne Gagnon. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: PBI-4419 is a novel, first-in-class, orally active low molecular weight compound which displays anti-fibrotic activity via inhibition of CTGF expression and production. The clinical use of doxorubicin (Dox), a potent anticancer agent; is associated with marked nephrotoxicity characterized by tubulo-interstitial lesions. The aim of this study was to investigate the anti-fibrotic activity of PBI-4419 on Dox-induced nephrotoxicity in mice.

Methods: On day 0, BALB/c mice were immunosuppressed with 10 mg/kg intravenous administration of Dox. The first experiment was undertaken with oral administration of PBI-4419 (1 and 10 mg/kg) from day -3 to day 10, and the second with intravenous administration of PBI-4419 (0.1 mg/kg) on day-3, 3 and 10. Mice were sacrificed at day 11 (oral treatment) or 14 (intravenous treatment).

Results: Treatment with oral (10 mg/kg) or intravenous (0.1 mg/kg) administration of PBI-4419 significantly reduced Dox-induced nephrotoxicity as measured by a reduction of serum albumin loss induced by doxorubicin. Histological lesions were also significantly reduced in PBI-4419-treated mice [Lesion scores determined by HPE staining: reduction of 70% with oral treatment (10 mg/kg, p=0.008); reduction of 50% with intravenous treatment, (0.1 mg/kg, p<0.05)]. Dox induced an increase in CTGF mRNA expression in the kidney. Treatment with PBI-4419 (10 mg/kg, oral daily and 0.1 mg/kg, i.v. administration once a week) resulted in a significant reduction (27%, p=0.007 and 20%, p=0.008, respectively) in the expression of CTGF in the kidney.

Conclusions: These results suggest that PBI-4419 acts as an anti-fibrotic agent in the acute phase of doxorubicin-induced toxicity. The nephroprotective effect of PBI-4419 relies, in part, on PBI-4419's ability to reduce CTGF expression and hence fibrosis.

SA-PO2140

Nephroprotection: PBI-4050, a Novel Orally Active, Anti-Inflammatory/ Anti-fibrotic Agent, Reduces Doxorubicin-Induced Nephrotoxicity in Mice Brigitte Grouix, Kathy Hince, André Doucet, Nathalie Julien, Liette Gervais, Valérie Perron, Jean-Simon Duceppe, Abdallah Ezzitouni, Boulos Zacharie, Christopher Penney, Pierre Laurin, Lyne Gagnon. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: PBI-4050 is a novel, first-in-class, orally active low molecular weight compound which displays its anti-inflammatory/anti-fibrotic activity via inhibition of TGFβ and CTGF expression and production.

Methods: The anti-inflammatory activity was evaluated in the LPS-induced air pouch rat model. The anti-fibrotic activity was studied using the doxorubicin-induced nephrotoxicity mouse model. The clinical use of doxorubicin (Dox), a potent anticancer agent; is associated with marked nephrotoxicity characterized by tubulo-interstitial lesions. BALB/c mice were randomized in three groups; Control, Dox (10 mg/kg) and Dox (10 mg/kg) + PBI-4050 (200 mg/kg). Mice were treated with oral administration of PBI-4050 from day -3 to day 10. On day 0, mice were immunosuppressed with intravenous administration of Dox.

Results: In LPS-induced air pouch model, PBI-4050 (200 mg/kg) inhibits PGE2 production to the same extend as indomethacin (50 mg/kg). However, in contrast to indomethacin, PBI-4050 has no effect on cyclooxygenase and lipoxygenase pathways. Treatment with PBI-4050 significantly reduced Dox-induced nephrotoxicity as demonstrated by a reduction of serum albumin loss induced by doxorubicin. Histological lesions were also significantly reduced (p<0.05) in PBI-4050-treated mice (Lesion scores determined by HPE staining at Day 7 Dox: 1.03; Dox + PBI-4050: 0.18; at Day 11; Dox: 2.0; Dox + PBI-4050: 0.72). The Dox treated group showed an increase in TGFβ and CTGF mRNA expression in the kidney. Treatment with PBI-4050 gave a significant reduction (p=0.03) of the expression of TGFβ (26%) and CTGF (33%) in the kidney.

Conclusions: These results suggest that PBI-4050 exerts anti-inflammatoy and anti-fibrotic properties in the acute phase of doxorubicin-induced toxicity. The nephroprotective effect of PBI-4050 relies, in part, on the antifibrotic activity as suggested by a decrease of TGFβ and CTGF expression in the kidney.

SA-PO2141

Elucidating the Role of Notch Signaling in Acute Kidney Injury Jin Nakamura, Nariaki Asada, Tomomi Endo, Motoko Yanagita. *Graduate School of Medicine, Kyoto University, Kyoto, Japan.*

Background: Notch signaling plays a crucial role in the regulation of cell proliferation, stem cell maintenance and differentiation during embryonic and adult development. Recent studies reported that the activation of Notch signaling in tubular epithelial cells augments interstitial fibrosis. However, the role of Notch signaling in tubule cell maintenance and regeneration remains unclear.

Here we analyzed the role of Notch signaling in the regeneration of proximal tubules during AKI, utilizing RBP-j conditional knockout mice and proximal tubule-specific inducible Cre mice that we recently generated, in which Cre is activated only after the administration of tamoxifen.

Methods: We bred RBP-j conditional knockout mice to the proximal tubule-specific inducible Cre mice (NDRG1-CreERT2 mice) to generate RBP-j knockdown (RBP-j flox/-:NDRG1-CreERT2) and control (RBP-j flox/+ :NDRG1-CreERT2) littermates.

We administered tamoxifen at 4 wks of age, performed ischemic reperfusion (I/R) injury 2 wks after the adminstration of tamoxifen, and analyzed the kidneys 4 days after the operation.

Results: The expression of RBP-j mRNA in the whole kidneys of knockdown mice was reduced to about 30% of control kidneys, indicating the effective deletion of RBP-j in the proximal tubules. Unexpectedly, however, the proliferation of tubular epithelial cells and severity of tubular injury was indistinguishable between both genotypes. The expression of Cyclin D1, HSP47, and osteopontin in the knockdown kidneys tended to be lower compared to that of control kidneys, but the difference was not statistically significant.

Conclusions: Reduction of Notch signaling in proximal tubules during AKI did not cause significant change in the proliferation of tubular epithelial cells and severity of tubular injury. Considering the role of tubular Notch signaling in the progression of interstitial fibrosis, it is likely that epithelial Notch signaling affects the neighboring fibroblasts, but not neighboring epithelial cells.

SA-PO2142

Six2-GDNF Pathway Is Activated during Experimental Acute Kidney Injury and Plays a Crucial Role in Renal Tubular Regeneration Seiki Hirano,[1] Nazuki Okada,[2] Madoka Urushido,[2] Masayuki Bun,[2] Masayuki Hisa,[2] Koji Ogata,[1] Yoshiko Shimamura,[1] Kosuke Inoue,[1] Masayuki Ishihara,[1] Toru Kagawa,[1] Toshihiro Takao,[1] Yoshio Terada.[1] *[1]Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi University, Kochi, Japan; [2]Centre for Innovative and Translational Medicine, Kochi Medical School, Kochi University, Kochi, Japan.*

Background: The transcriptional regulator Six2 emerged as a key factor in kidney development and maintenance of nephron progenitor cells. GDNF (glial cell-derived neurotrophic growth factor) is also reported to play an important role for nephrogenesis.

However, the roles of Six2-GDNF pathway in tubular proliferation and regeneration are poorly understood in acute kidney injury (AKI).

Methods: The aim of this study is to understand the functional roles of Six2 and GDNF in tubular damages in AKI *in vivo* and *in vitro*.

Results: To clarify the significance of Six2-GDNF pathway in AKI, we used a rat AKI model *in vivo* and renal tubular cells (NRK-52E cells) as an *in vitro* model. After clamping left rat renal artery for 1h, kidney homogenates from 3 to 72h after reperfusion were extracted. In Western blot analysis, Six2 and GDNF expressions were increased at 3-12h and 6-24h, respectively. In immunohistological examinations, Six2 positive cells and GDNF positive cells were observed in proximal tubules after AKI. In *in vitro* experiments, hypoxia stimulated mRNA expression and protein expression of Six2. To understand the downstream signaling of Six2, we transfected Six2 expression vector to NRK-52E cells. Overexpression of Six2 caused increments of GDNF promoter activity and the expressions of mRNA and protein. Overexpression of Six2 increased ^{3}H-thymidine uptake. Furthermore, we used 3D gels to examine the role of Six2 for tubular formation. Overexpression of Six2 promoted tubular formation, while tubular formation was inhibited by transfection of Six2 siRNA.

Conclusions: Six2 and GDNF were up-regulated in AKI at proximal tubular cells *in vivo*, and Six2 could regulate cell proliferation and tubular formation by regulating GDNF expression. The current study therefore unveils pathophysiological significance of Six2-GDNF pathway in AKI *in vivo* and *in vitro*.

SA-PO2143

Protective Effect of Human Umbilical Cord Blood-Derived Mesenchymal Stem Cells on Experimental Kidney Warm Ischemia-Reperfusion Injury in Mice Hye Ryoun Jang,[1] Ji Hyeon Park,[1] Seung Tae Han,[1] Jaeyoung Yoon,[1] Soo Jin Choi,[2] Wonil Oh,[2] Yoon Sun Yang,[2] Jung Eun Lee,[1] Wooseong Huh,[1] Dae Joong Kim,[1] Ha Young Oh,[1] Yoon-Goo Kim.[1] *[1]Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; [2]Biomedical Research Institute, MEDIPOST Co., Ltd., Seoul, Korea.*

Background: Kidney ischemia-reperfusion injury (IRI), the leading cause of acute kidney injury (AKI), is characterized with robust inflammatory response. Human umbilical cord blood-derived mesenchymal stem cells (hUCB-MSCs) have been reported to show hypo-immunogenic property and exert anti-inflammatory and regenerative effects in a cerebral IRI model. We investigated the effects of hUCB-MSCs on renal injury following warm IRI in mice.

Methods: C57BL/6 mice were randomly allocated into 2 groups: control group (IRI without medication, n=13) and hUCB-MSCs group (n=15). A total of $1.5X10^{6}$ hUCB-MSCs were injected into the peritoneal cavity twice: 24 hour prior to IRI and right before reperfusion. Serum creatinine was measured for 48 hours. The trafficking of PKH-26 labeled hUCB-MSCs was assessed with immunofluorescence staining.

Results: Renal functional impairment was attenuated in the hUCB-MSCs group compared with the control group (serum creatinine mean ± SE, Day 0: 0.49±0.044 in the control group, 0.50±0.014 in the hUCB-MSCs group, Day 1: 2.16±0.037 in the control group, 1.75±0.097 in the hUCB-MSCs group, Day 2: 2.68±0.115 in the control group, 1.89±0.184 in the hUCB-MSCs group). PKH-26 labeled hUCB-MSCs were found in the post-ischemic kidneys of the hUCB-MSCs group on both day 1 and day 2 after IRI.

Conclusions: The hUCB-MSCs were trafficked into the post-ischemic kidneys and attenuated renal injury following IRI.

SA-PO2144

Improving Ischemia-Reperfusion-Induced Acute Kidney Injury by Treating with Induced Pluripotent Stem Cells Pei-Ying Lee,[1] Der-Cherng Tarng.[1,2] *[1]Institute of Physiology, National Yang-Ming University, Taipei, Taiwan; [2]Division of Nephrology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: Induced pluripotent stem (iPS) cells are novel stem cell populations induced from somatic cells, but the effects of iPS cells on acute kidney injury (AKI) are not currently known.

Methods: To investigate effects of iPS cells on AKI, iPS cells were injected via the renal artery into rats with ischemia-reperfusion (I/R) AKI and compared with PBS-treated AKI rats. Renal function,histopathological findings, blood reperfusion ratio, and the levels of ROS-related factors and inflammatory cytokines were measured and analyzed.

Results: Our findings showed that iPS cells injected into kidney of AKI rats reduced the impairment of renal functioning and tissue injury compared to PBS-treated rats, and that maximal improvement was observed at a cell dose of iPS 5×10^{5}. However, transplantation of large number (5×10^{7}) of iPS cells may decrease blood flow recovery, which was measured by laser Doppler imaging. At 48 hours after I/R, the iPS cells had mobilized to peritubular area and significantly diminished the histopathological changes associated with AKI, such as macrophages infiltration and the presence of apoptotic cells; in addition there was an enhancement of cell proliferation. Notably, iPS cell transplantation reduced the response to I/R injury in relation to ROS-related factors and inflammatory cytokines.

Conclusions: Injection of iPS cells into AKI rats provided a significantly beneficial effect by diminishing the impairment of renal functions, reducing tissue injury and protecting rats from the lethal effects of AKI. The effect to rescue AKI may be mediated by a reduction in ROS production and inflammation.

SA-PO2145

Effects of Adipose-Derived Mesenchymal Cells on Ischemia-Reperfusion Injury in Kidney Kengo Furuichi,[1] Yasuyuki Shinozaki,[2] Shuichi Kaneko,[2] Takashi Wada.[3] *[1]Division of Blood Purification, Kanazawa University Hospital, Kanazawa, Ishikawa, Japan; [2]Department of Disease Control and Homeostasis, Kanazawa University, Kanazawa, Ishikawa, Japan; [3]Department of Laboratory Medicine, Kanazawa University, Kanazawa, Ishikawa, Japan.*

Background: Acute kidney injury (AKI) is critical condition for kidney and other remote organs including lung. However, currently available treatments for AKI are limited. In this study, we explored the effect of adipose-derived mesenchymal cells on a mouse model of AKI.

Methods: Adipose-derived mesenchymal cells was isolated from mouse subcutaneous and peritoneal adipose tissue by digestion with collagenase type I. The left renal artery and vein of C57BL/6 mice were clamped for 45 minutes to induce ischemia, and were injected with the adipose-derived mesenchymal cells from GFP mice(1 x 10∧5 cells/0.2 mL PBS) or 0.2 ml PBS via the tail vein on Days 0, 1 and 2. In each group, mice were sacrificed on Day 2, 4 and 7. Blood was collected from the inferior vena cava of each sacrificed mouse, accompanied by collection of kidney, lung, brain, spleen and liver.

Results: The adipose-derived mesenchymal cells had stem cell surface markers and multi-lineage differentiating potentials. Administered adipose-derived mesenchymal cells were mainly to home into lung. Interrestingly, repeated administration of adipose-derived mesenchymal cells reduced acute tubular necrosis and interstitial macrophage infiltration in the injured kidney accompanied with reduction in cytokine and chemokine expression in the injured kidney. Moreover, Ischemic kidney injury affected lungs. The number of F4/80-positive cells was lower in the adipose-derived mesenchymal cells administration group than in the control group 7 days after kidney ischemic injury. In vitro study indicated that adipose-derived mesenchymal cells produced anti-inflammatory cytokines such as TGF-β and GCSF, as well as others inflammatory cytokines and chemokines under stimulation of pro-inflammatory cytokine; IL-1.

Conclusions: Adipose-derived mesenchymal cells can be used as cell-based therapy for ischemic kidney injury.

SA-PO2146

Hydrogel-Embedded Endothelial Progenitor Cells Evade LPS and Mitigate Endotoxemia Tammer N. Ghaly, May Rabadi, Mia Weber, Seham Rabadi, Michael Bank, John Grom, Michael S. Goligorsky, Brian B. Ratliff. *New York Medical College, Valhalla, NY.*

Background: Sepsis and its complications are associated with poor clinical outcomes. The circulatory system is a well-known target of lipopolysaccharide (LPS). Recently, several clinical studies documented mobilization of endothelial progenitor cells (EPCs) during endotoxemia, with the probability of patients' survival correlating with the rise in circulating EPCs. This fact combined with endotoxemia-induced vascular injury lead us to hypothesize that the developing functional EPC incompetence could impede vascular repair and that adoptive transfer of EPCs could improve hemodynamics in endotoxemia.

Methods: We used LPS injection to model endotoxemia.

Results: EPCs isolated from endotoxemic mice exhibited impaired clonogenic potential and LPS exerted TLR4-mediated cytotoxic effects toward EPCs, which was mitigated by embedding them in hyaluronic acid (HA) hydrogels. Therefore, intact EPCs were either delivered intravenously or embedded within pronectin-coated HA-hydrogels. Adoptive transfer of EPCs in LPS-injected mice improved control of blood pressure and reduced hepatocellular and renal injury. Specifically, EPC treatment was associated with the restoration of renal microcirculation and reduction in renal dysfunction. EPC therapy was most efficient when cells were delivered embedded in HA-hydrogel.

Conclusions: These findings establish major therapeutic benefits of adoptive transfer of EPCs, especially when embedded in HA-hydrogels, in mice with LPS-induced endotoxemia, and argue that hemodynamic and renal abnormalities of endotoxemia are in significant part due to developing incompetence of endogenous EPCs.

Intravenous Renal Cell Transplantation (IRCT) for Renal Failure Katherine J. Kelly,[1] Jesus H. Dominguez.[1,2] *[1]Medicine Nephrology, IUMC, Indianapolis, IN; [2]Nephrology, VAMC, Indianapolis, IN.*

Background: AKI is unpredictable and its outcome ranges from minor to end-stage renal disease (ESRD). Multiple therapies have failed. We now propose to test in rats the hypothesis that AKI can be markedly improved by intravenous renal cell transplantation (IRCT) with primary renal epithelial cells.

Methods: The cells were derived from normal male rat tubules transfected with empty vector, and plasmids designed to express cytosolic GFP and nuclear BFP ("A" cells), or with plasmid expressing tubulogenic Serum Amyloid A1 protein (SAA) plus the other tracking vectors ("B" cells). AKI was induced by 50 min ischemia and reperfusion (I/R) injury in 2 groups of Sprague Dawley female rats.

Results: After 24 hrs post I/R serum creatinine (CR) was 2.62 ±0.29 mg/dl (N = 14 M±SE) in group A and 2.79 ±0.19 in B (N= 12), and "A" cells were infused to A group and "B" cells to group B. The following day CR was 3.94 ±070 in A rats and much lower, 1.01 ±0.29 in B rats, $p<0.007$. The severity of AKI is emphasized by 5 deaths in A rats and zero deaths in B rats, $p = 0.02$. BUN followed same pattern for A and B rats and remained higher in A rats for the 7 day study, at this point rats in group A had more fibrosis and tubular atrophy. There was substantial B cell engraftment on surfaces vacated by dead tubular cells

as indicated by co-expressed cytosolic GFP, nuclear BFP and SAA. Also male SRY gene was retained by female kidneys.We then studied a model of CKD from platinum (Plt, 1.5 mg/kg daily X 3) and three weeks later BUN was 115±3 in A and 121±13 in B rats (mg/dl; N =3). The rats were uni-nephrectomized, tubules transfected and cultured X 7 days with growth promoters and cells infused (auto-transplant). After 12 days BUN was 101±15 in A and 53±5 in B rats, p <0.02.

Conclusions: IRCT is an effective therapy to promote recovery of renal failure and is subject to amplification, where one rat donates to six rats. IRCT acts acutely by paracrine mechanisms and long-term by structural integration of transplanted cells. IRCT can also be used as auto-transplantation, where damaged cells are recovered, healed in vitro, and injected with successful improvement of renal function.

Adipose-Derived Stem Cells Transfected with Hypoxia Inducible Factor-Lα Could Lessen the Injury of HK-2 Cells Indcued by Cisplatin Weiwei Wang, Jinyuan Zhang. *Division of Nephrology, Jimin Hospital, Shanghai, China.*

Background: Adipose-derived mesenchymal stem cells (ADSCs) maybe an alternative cell source in cell therapy for some advantages. We hypothesize that ADSCs transfected by HIF-1α gene will have a positive effect on the cisplatin-induced HK-2 cells.

Methods: The hADSCs were transfected by lentiviral vector containing EGFP-HIF-1α genes. Cells expressing EGFP was sorted by flow cytometer. The expression of HIF-1α was examined by immunocytochemical method. The following groups were made: I: Cisplatin-induced group: Cisplatin (3μg/ml)-induced HK-2 cells; II: Transfected group: HIF-1α-transfected hADSCs and cisplatin-induced HK-2 cells were incubated; III: Non-transfected group: hADSCs and cisplatin-induced HK-2 cells were incubated; IV: Control group: HK-2 cells. The ultrastructural changes of HK-2 cells was observed by electron microscopy. Apoptosis index of HK-2 cells was tested by TUNEL. Western blot was performed to examine the expression of caspase-3 and Bcl-2 in HK-2 Cells and also the expression of EPO, HO-1 and VEGF in hADSCs cells. The concentration of NGAL, KIM-1, EPO, HO-1, VEGF and HIF-1α in media were tested by ELISA.

Results: The apoptosis in coincubation groups were decreased compared with the cisplatin group. The expression of caspase-3 in HK-2 cells in coincubation groups was lower than that in cisplatin group and the expression of Bcl-2 in HK-2 cells in coincubation groups was increased. The injury of HK-2 cells coincubated with hADSCs tranfected with HIF-1α were lessened. The concentration of KIM-1 increased markedly in cisplatin-induced HK-2 group and that was decreased after coincubated with hADSCs. The protein expression of EPO, HO-1 and VEGF in hADSCs cells tranfected with HIF-1α were increased compared with the vector transfected group. The concentration of HO-1 and VEGF in media of gene-transfected group were higher than in vector transfected group and the variation of HIF-1α and EPO were not obvious.

Conclusions: The hADSCs could lessen the apoptosis of HK-2 cells induced by cisplatin, especially after transfected with HIF-1α and the protection may be related to the higher expression of growth factors. Specific mechanism needs further experimental study.

The Alteration of Macrophage Polarisation and Phenotype Via Mesenchymal Stem Cells In Vitro and In Vivo Sharon D. Ricardo, Maliha A. Alikhan, Junli Zhuang, Andrea Wise. *Monash Immunology and Stem Cell Laboratories, Monash University, Clayton, Victoria, Australia.*

Background: Monocyte-derived macrophages comprise a heterogenous population of cells that govern tissue remodeling and repair following acute kidney injury. Infiltrating monocytes can differentiate into a pro-inflammatory/deleterious (M1) or anti-inflammatory/reparative (M2) polarisation state depending on the inflammatory stimuli. Mesenchymal stem cells (MSCs) may exert therapeutic effects through their unique immunomodulatory properties, which enable them to interact with various cells of the immune system. This study determined whether human bone marrow derived MSCs (hMSCs) can modulate the polarisation state of macrophages in vitro, following macrophage and hMSC co-culture, and in vivo, following the exogenous administration to mice with induced ischemia-reperfusion (IR) injury.

Methods: C57BL6/J mice (20-25g; n = 5/group) underwent 40 minutes of unilateral IR injury and following reperfusion were injected with 1x106 hMSCs (i.v) or vehicle. Flow cytometry was used to assess macrophage polarisation following hMSC therapy at 1, 3, 5 and 7 days post-treatment. In vitro, hMSCs and bone marrow-derived macrophages were co-cultured both directly and indirectly for up to 72 hours and macrophage phenotype was assessed using qPCR.

Results: In comparison to vehicle-treated IR kidneys that exhibited widespread damage, hMSC-treated mice with IR injury demonstrated structural repair showing reduced interstitial matrix expansion and cellular replacement at 7 days post-hMSC treatment. IR resulted in a significant infiltration of CD45+CD11b+F4/80+ macrophages expressing mannose receptor and MHC class II. hMSC treatment did not significantly alter the number of infiltrating inflammatory cells in IR injury in vivo, however in vitro evidence suggests they modulate macrophage phenotype via paracrine mechanisms.

Conclusions: The administration of hMSCs to mice with induced IR ameliorates injury and promotes renal regeneration and repair. hMSC treatment does not alter the number of macrophages infiltrating the kidney post-IR however, may promote the polarization of a M2 macrophage that leads to downstream tissue remodeling.

SA-PO2150

Mesenchymal Stem Cells and Endothelial Progenitor Cells Improve Renal Function in Experimental Swine Renal Artery Stenosis through Different Mechanisms Xiang-Yang Zhu,[1] Alfonso Eirin,[1] James Krier,[1] Stephen C. Textor,[1] Amir Lerman,[2] Lilach O. Lerman.[1] *[1]Nephrology & Hypertension, Mayo Clinic; [2]Cardiovascular Diseases, Mayo Clinic.*

Background: Both endothelial progenitor cells and mesenchymal stem cells can augment tissue repair. Whether cell phenotype affects the efficacy of cell therapy in the stenotic kidney is unclear.

Methods: Peripheral blood EPC and adipose derived MSC were expanded and characterized by cell surface markers (e.g. CD34 and KDR, or CD44 and CD90 respectively). Single kidney hemodynamics and function were assessed using multi detector CT in pigs after 10 weeks of renal artery stenosis treated 4 weeks earlier with an intra-renal infusion of vehicle EPC (10x10^6, RAS+EPC, n=6) or MSC (10x10^6, RAS+MSC, n=6), and normal controls. Kidney microvascular structure, growth factors, apoptosis, oxidative stress and inflammatory pathways were evaluated in vitro.

Results: The degree of stenosis and hypertension were similar in RAS, RAS+EPC and RAS+MSC. Renal blood flow and glomerular filtration rate in RAS were lower than normal controls, but similarly improved in RAS+EPC and RAS+MSC. EPC mainly improved renal growth factor expression and oxidative stress, whereas MSC significantly attenuated inflammatory cytokines, endoplasmic reticulum stress related protein expression, and apoptosis.

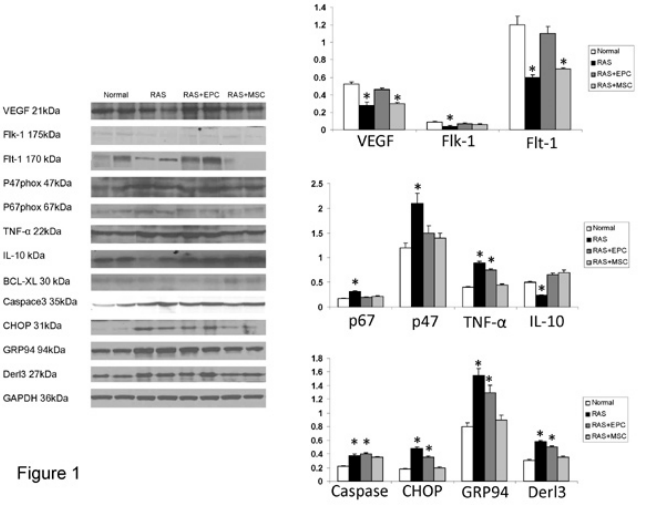

Figure 1

Conclusions: Intra-renal delivery of EPC and MSC similarly improved renal function, but through different pathways. These results support development of selective cell based approaches for management of kidney disease.

SA-PO2151

Human Umbilical Cord Blood CD133$^+$ Cells Exacerbate Acute Kidney Injury in NOD-SCID Mice Dylan Burger, David Allan, Alex Gutsol, Anthony Carter, Rhian Touyz, Kevin D. Burns. *Kidney Research Centre, Division of Nephrology, Dept. of Medicine, Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada.*

Background: Acute kidney injury (AKI) occurs in 5% of hospitalized patients, with a 50% mortality. An increase in circulating vascular progenitor cells occurs in humans with AKI, and certain blood-derived progenitor cells facilitate recovery in animal models of tissue injury, including AKI. CD133$^+$ cells isolated from human umbilical cord blood are associated with improvement following acute injury in several settings. We examined the effects of CD133$^+$ progenitor cells in a mouse model of AKI, induced by ischemia-reperfusion (I/R).

Methods: In non-obese diabetic severe combined immunodeficient (NOD-SCID) mice, I/R was induced by bilateral clamping of the renal artery and vein for 60 min, followed by clamp release. Human cord blood CD133$^+$ cells or a mixed population of CD133$^-$ cells (10^6/mouse) were injected via the jugular vein at reperfusion.

Results: Fluorescently-labeled CD133$^+$ cells were detected in blood at 2 min following i.v. injection (35% bioavailability) but numbers decreased rapidly (2% at 1 hr). Homing to the kidney, liver, spleen, brain, lung, bone marrow, or heart was not reliably detected. Administration of CD133$^+$ cells did not alter plasma urea or creatinine in sham-operated mice. In contrast, in mice subjected to I/R, CD133$^+$ cells significantly increased plasma urea at 24 hrs (CD133$^+$: 63 vs control: 34 mM, $p<0.01$, n=11-12), and serum creatinine at 6 and 24 hrs (respectively, CD133$^+$: 47 and 95 vs control: 18 and 43 μM, $p<0.05$). Administration of CD133$^+$ cells exacerbated histologic tubular necrosis. No change in blood pressure occurred at 6 hrs in mice treated with CD133$^+$ cells. CD133$^-$ cells did not alter blood urea, creatinine or histologic indices of injury compared with I/R alone ($p>0.05$). Administration of CD133$^+$ cells to immunocompetent mice (FVB/N) with I/R also increased renal injury.

Conclusions: These data indicate that human cord blood-derived CD133$^+$ cells exacerbate murine I/R renal injury, possibly via release of soluble factors. Our study highlights the importance of organ-specific responses and caution in any cell-based therapies for AKI.

Adult Renal Progenitor Cells Revert Acute Renal Tubular Cells Injury by Means of TLR2-Driven Specific Paracrine Factors Fabio Sallustio,[1,2] Vincenzo Costantino,[1] Sharon N. Cox,[1] Antonia Loverre,[1] Marco Rizzi,[3] Francesco Paolo Schena.[1,2] *[1]Department of Emergency and Organ Transplantation, University of Bari, Bari, Italy; [2]C.A.R.S.O. Consortium, Valenzano, Bari, Italy; [3]Department of Human Anatomy and Histology, University of Bari, Bari, Italy.*

Background: Acute Kidney Injury (AKI) is emerging as a public health problem worldwide, characterized by acute tubular apoptosis and necrosis. Tubular damage may recover, although a critical number of surviving cells is required to reconstitute structural integrity. Recently, many researchers focused their attention on the possibility of using adult renal progenitor cells (ARPCs) to improve regeneration in AKI. We studied the influence of ARPC on the regenerative process of cisplatin-injured renal proximal tubular epithelial cells (RPTECs) and injured Human Kidney 2 (HK2) cells.

Methods: We set up an in vitro model of cisplatin-induced toxicity, in which RPTECs were co-coltured with ARPCs, and performed proliferation and apoptosis assays to study regenerative effect of ARPCs on RPTECs. Moreover, we performed multiplex ELISA assays to identify molecules responsible for regenerative processes.

Results: Exposure of RPTECs or HK2 cells to cisplatin markedly reduced cell number and their viability, but co-culture with tubular ARPCs (TARPCs) provided a protective effect by promoting tubular cell proliferation of survival cells and inhibiting cisplatin-induced apoptosis. Tubular cell regeneration process was specific of TARPCs and occurred only following the sensing of a damage. On the contrary, when glomerular ARPCs were cocultured with damaged tubular cells, any effect of regeneration was observed. Surprisingly, regenerative effect was completely cancelled blocking the TLR-2, expressed by TARPC. By bioinformatic analyses on microarray data and by multiplex cytokine assays, we identified some specific citokines, growth factors and microvescicle-shuttled mRNAs, secreted by ARPCs and dependent from TLR2 activation, that worked synergistically and were essential in the regenerative process.

Conclusions: In conclusion, we identified for the first time a regenerative mechanism, driven by the TLR2, by which ARPCs induced regeneration of tubular epithelial cells.

SA-PO2153

Modulation of Kidney Injury by Mesenchymal Stromal Bone Marrow Cells (MS-BMC) in a Novel Puromycin Single Kidney Injury Model Dileep Kumar, Kang Cheng, Partab Rai, Rivka Lederman, Mohammad Husain, Ashwani Malhotra, Pravin C. Singhal. *Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY.*

Background: Puromycin has been demonstrated to induce podocyte apoptosis. Mesenchymal stromal bone marrow cells (MS-BMCs) have been demonstrated to provide cytoprotection by the modulation of cytokine production in several cytotoxic models. In the present study, we evaluated the effect of MS-BMCs on puromycin-induced podocyte injury.

Methods: MS-BMCs were harvested from bone marrows of mice and their profile was characterized (reported in another abstract). Mice in groups of six were administered either buffer (group A), puromycin alone (group B, 150 mg/Kg, subcutaneously), intracapsular instillation of MS-BMCs in left kidney 24 hours prior to puromycin administration (group C, 150 mg/Kg, subcutaneously). All mice were sacrificed on 5th day; urine and blood samples were collected for BUN and albumin: creatinine ratio. Kidneys were harvested for histology and TUNEL staining. Immunoblots were prepared and probed for nephrin and CD2AP expression. Immunohistochemical studies were carried out to study interstitial inflammatory milieu. In parallel sets of experiments, conditioned media of MS-BMC was collected. The effect of conditioned media of MS-BMC was evaluated on puromycin-induced podocyte apoptosis in in vitro studies.

Results: Group C mice displayed decrease($P<0.05$) in albumin: creatinine ratio vs. Group B mice. Immunoblotting studies revealed decreased ($P<0.01$) nephrin and CD2AP expression in renal tissues from group B and right kidneys of group C vs. group A. On the other hand, renal tissues of the Left kidneys from Group C displayed increased ($P<0.01$) expression of renin and CD2AP when compared to contralateral kidneys. Similarly, left kidneys from the group C displayed decreased number for TUNEL +ve glomerular cells when compared to the contralateral kidney of the same group and kidneys from group B. In in vitro studies, conditioned media from MS-BMC provided partial protection to podocytes from pro-apoptotic effect of puromycin.

Conclusions: These findings indicate that MS-BMCs provide protection from injurious effect of puromycin by modulating pro-apoptotic milieu.

SA-PO2154

Therapy of Acute Kidney Injury in Pigs with Porcine Mesenchymal Stromal Cells Is Ineffective Because They Possess Inadequate Immune-Modulating Activity Anna Gooch,[1] Barbel Brunswig-Spickenheier,[2] Janna Boche,[2] Frauke Peimann,[2] Achim Gruber,[2] Kai Jaquet,[2] Korff Krause,[2] Jozef Zustin,[2] Axel Zander,[2] Claudia Lange,[2] Christof Westenfelder.[1,3] *[1]Medicine/Nephrology, University of Utah and VA Medical Centers, Salt Lake City, UT; [2]Clinic for Stem Cell Transplantation, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Physiology, University of Utah and VA Medical Centers, Salt Lake City, UT.*

Background: We demonstrated that allogeneic mesenchymal stromal cells (MSC) are highly renoprotective in rats with AKI, and promising in a Phase I Trial (*Nature Rev Nephrol* 2010), and this without eliciting an antibody response. We showed earlier that human MSCs in rats with AKI afford significant renoprotection, while followed by an antibody response to human MSCs. In vitro, we confirmed substantial phenotypic overlaps between rat, human, and porcine MSCs (pMSC), all of which exhibited tri-lineage differentiation, antigen profiles, and secretion of renoprotective VEGF-A and IGF-1. However, in striking contrast to human and rat MSCs, pMSCs failed to inhibit the mixed lymphocyte reaction and induced robust production of pro-inflammatory IL-6.

Methods: We then tested the hypothesis that the full expression of the immune-modulating/anti-inflammatory activities of MSCs is critical for their protective actions in experimental AKI. Groups of female pigs with bilateral ischemia/reperfusion AKI were infused with autologous or male allogeneic pMSCs.

Results: Strikingly, MSC therapy had no beneficial effects on kidney function and histopathology.

Conclusions: Summary: in contrast to allogeneic or xenogeneic rodent models (human MSC into rats), infusion of pMSCs into pigs with AKI was not kidney-protective. Conclusion: This therapeutic ineffectiveness is due to the inadequate immune-modulating activity of pMSCs, clearly demonstrating that effective therapy of AKI with MSCs depends critically on both their anti-inflammatory and trophic actions, rendering the pig model of AKI and its therapy with pMSCs not informative for human studies. We expect, however, that treatment of human AKI with immune-modulating, allogeneic MSCs will be as effective as in rodent models.

SA-PO2155

Bone Marrow-Derived Mesenchymal Stem Cells (BM-MSC) Provide Partial Protection Against Kidney Injury Kang Cheng,[1] Kuldeep K. Bhargava,[2] Christopher J. Palestro,[2] Ashwani Malhotra,[1] Sanjeev Sanjeev Gupta,[3] Pravin C. Singhal.[1] *[1]Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY; [2]Nuclear Medicine, North Shore LIJ Hofstra Medical School, New Hyde Park, NY; [3]Medicine, Albert Einstein College of Medicine, Bronx, NY.*

Background: The immunomodulatory potential of BM-MSC is of much interest for cell-based therapies in multiple disorders, including acute kidney injury (AKI). To define the therapeutic potential of BM-MSC in cisplatin-induced AKI, we studied syngeneic mice.

Methods: Primary mouse MSC were isolated from compact bone of healthy syngeneic C57BL/6-GFP donors. To determine biodistributions of transplanted MSC, we injected ^{111}In-oxine labeled MSC i.v. into healthy and cisplatin (12.7mg/kg) -treated mice. Since only limited numbers transplanted MSCs were localized in the kidneys, we examined whether MSC served roles through paracrine signaling. The conditioned medium from BM-MSC was probed by high density protein arrays for 97 cytokines.

Results: Cellular phenotype was verified by FACS for CD11b, CD14, CD45, CD86, CD90, CD105, and their differentiation into adipocytes or chondrocytes. Transplanted cells were localized by GFP immunostaining and DNA PCR. BM-MSC accumulated primarily in the lungs (67%), followed by liver (13%), spleen (11%), and kidneys (5%). These cells were rapidly destroyed in pulmonary capillaries and other organs after 7 days. In mice treated with cisplatin, significant AKI was observed. By contract, BM-MSC transplantation provided partial protection to cisplatin-treated mice (on day 5, BUN 56mg/dl vs 44mg/dl; $P<0.05$; severe vs moderate tubular cell apoptosis). Protein arrays of the condition media identified 30 cytokines, including osteoponin, osteoporotegerin, galectin-1, decorin MMP2, gas6, RANTES, sTNFR1, CXCL1, CXCL16, VCAM-1, MCP1, MIP1 alpha, MIP2, IL6, etc.

Conclusions: Targeting of BM-MSC via i.v. injection resulted in cells confined largely to pulmonary capillaries, most of which were rapidly destroyed. BM-MSC did exert beneficial effects on cisplatin-induced AKI due to release of soluble factors capable of modifying pathophysiological processes

Funding: NIDDK Support

SA-PO2156

The Bone Marrow-Derived Mesenquimal Stem Cells Repair the Acute Kidney Injury Induced by Acyclovir Joelma Santina Christo, Paulo Maciel Lopes, Waldemar S. Almeida, Luciana Aparecida Reis, Nestor Schor. *Medicina, UNIFESP, São Paulo, Brazil.*

Background: The Acyclovir is an antiviral drug used to treat herpes simplex type 1 and 2 and varicella zoster. This drug is widely distributed in all body tissues, being very high in the kidneys, which may induce nephrotoxicity characterized by an acute injury. Several groups have reported the contribution BMSC in repair processes employing different animal models.

Methods: The BMSC were characterized for FACS analysis and then, differentiation into adipocytes and osteocytes. After, the cells were cultured and used 4th passages for all experiment. The female Wistar rats received acyclovir (80mg/Kg/BW) (Acyclovir group) or water (CTL) in a dose intraperitoneally (N=10) during 5 days. After 48, 72 hours, the female rats received iv BMSC (1X10^{6}cells). Then, blood and 24 hours blood were collected for urea (U), creatinine (Cr) evaluations. The animals were sacrificed and kidneys were perfused and removed for histology

Results: It was observed that Cr increased in acyclovir group (1.7± 0.1 mg/dl) and U (174.5±0.2 mg/dl p<0.05) when compared to CTL (0.7±0.01cr and U 56.0±0.1 mg/dl p<0.05) after 5 days of treatment with acyclovir. The Acyclovir+BMSC groups, observed a decrease Cr and U serum after 48 hours (Cr 1.3±0.1 Acyclovir vs Acyclovir+ BMSC 0.9±0.2 and U 143.5±0.2 vs Acyclovir+ BMSC 89.2±0.2 P< 0.05), 72 hours (Cr 1.7±0.1 Acyclovir vs Acyclovir+ BMSC 1.0±0.11 and U 174.5±0.2 Acyclovir vs Acyclovir+ BMSC 112.9±0.01 P< 0.05) when compared to in acyclovir groups. After 5 days of treatment with acyclovir was observed glomerular congestion, cell damage, tubular dilation and pyknotic nuclei. The acyclovir+BMSC after 48 and 72 hours, histological analysis was observed glomerulos and tubule changed less with dilation of the lumem and less cell.

Conclusions: These results strongly suggest that BMSC minimize AKI induced by acyclovir. This protocol can be a potential tool for treatment of this disease with impressive high morbid- mortality.

SA-PO2157

Therapeutic Potential of Human Placenta-Derived Mesenchymal Stem Cells for Ischemia/Reperfusion Acute Kidney Injury Dong Ho Yang,[1] So-Young Lee,[1] Yoon Hee Lee,[2] Hoon Jung.[3] *[1]Internal Medicine, Bundang CHA General Hospital, CHA University, Seongman-ci, Gyeonggi-do, Republic of Korea; [2]Pathology, Gangnam CHA Hospital, CHA University, Seoul, Republic of Korea; [3]Internal Medicine, Seoul Bukbu Geriatic Hospital, Seoul, Republic of Korea.*

Background: Mesenchymal stem cells derived from both bone marrow and umbilical cord blood have been shown to be beneficial in animal models of acute kidney injury. Human placenta-derived mesenchymal stem cells (hPMSCs) are free of ethical concerns, easily accessible, abundant, and strongly immunosuppressive. Recently, transplantation of hPMSCs into rodents with lung or liver cirrhosis was shown to reduce disease activity. The aim of this study was to evaluate the therapeutic potential of hPMSCs in rats subjected to ischemia/reperfusion (I/R).

Methods: Male Sprague-Dawley rats (200±10 g) were randomly assigned into three groups: hPMSC-treated (n=14), PBS-treated controls (n=14), and sham-operated (n=6). The treated groups underwent 45 min of ischemia by renal artery clamping and contralateral nephrectomy. hPMSCs [1×10^6 (or 0 PBS control)] were then intravenously injected into the rats subjected to ischemia. Serum creatinine (SCr) was measured 24, 48, and 72 hours after surgery, and renal tissue was obtained the first 2 days post-surgery.

Results: hPMSC treatment significantly improved renal function [48 hour SCr: 2.00±0.14 mg/dL (control group) vs. 1.16±0.69 mg/dL (hPMSC-treated group), p<0.05]. Histological analysis demonstrated a significant decrease in tubular casts and necrosis in hPMSC-treated rats [Day 2 cast scores: 3.34±0.02 (control) vs. 0.21±0.08 (hPMSC-treated); Day 2 necrosis scores: 5.67±0.01 (control) vs. 0.81±0.05 (hPMSC-treated), p<0.05]. In renal tubular epithelial cells, hPMSC treatment significantly increased the expression of PCNA (p<0.05) and significantly reduced apoptosis (p<0.05). Caspase-3 levels were significantly lower (p<0.01) and Bcl-2 levels were significantly higher (p<0.01) in the hPMSC-treated group compared to the controls.

Conclusions: These results suggest the use of hPMSCs as a novel renoprotective therapy for patients who develop ischemic renal injury.

SA-PO2158

Effect of Erythropoietin on Mesenchymal Stem Cells Proliferation In Vitro under Acute Kidney Injury Microenvironment and Its Mechanism Nanmei Liu, Weiwei Wang, Jinyuan Zhang. *Division of Nephrology, Jimin Hospital, Shanghai, China.*

Background: To investigate the effect of erythropoietin (EPO) on mesenchymal stem cells(MSCs) proliferation under acute kidney injury (AKI) microenvironment, and to study its possible mechanism.

Methods: C57BL/6 mice's mMSCs had been successfully isolated by Percoll density gradient centrifugation and adherence cultivation, surface markers were identified by flow cytometry. To make AKI mice models by clamping bilateral renal pedicles 30 minutes and reopening 30 minutes. Then immediately drew both renal cortex to make ischemia/reperfusion(I/R) kidney homogenate supernatant.P3-mMSCs were treated with different group: ①Group A:low glucose DMEM medium with 10% fetal bovine serum; ②Group B: low glucose DMEM medium with 10% fetal bovine serum plus I/R kidney homogenate supernatant; ③Group C: low glucose DMEM medium with 10% fetal bovine serum plus I/R kidney homogenate supernatant and different concentrations of EPO(1,5,10,50IU/ml). Each group was incubated for 1d, 3d, 5d, 7d. Proliferation of mMSCs was detected by CCK-8, apoptosis was detected by TUNEL. The protein expression of erythropoietin receptor (EPOR) and the proteins of proliferation/apoptosis related signal pathway were examined by Western blot.

Results: Under I/R kidney homogenate supernatant, the proliferation ability of mMSCs decreased significantly, while the apoptotic percentage was significantly higher than Group A. After intervention of EPO, their proliferation enhanced, at the same time, the apoptotic percentage decreased, present dose-dependent manner (P<0.05 or P<0.01). P3-mMSCs were positive for EPOR. EPO decreased the expression of Caspase-3 in mMSCs under AKI microenvironment in a dose and time dependent manner, but it increased the expression of Bcl-2.The expression of phosphor-Janus kinase2 (pJAK2) and phosphor-signal transducer and activator of transcription (pSTAT-5) was significantly higher in 10 IU/ml EPO cultured 5d.

Conclusions: Erythropoietin can promote proliferation of mMSCs in vitro under AKI microenvironment, which is mediated by EPOR, and related with proliferation/apoptosis signal pathway.

Funding: Government Support - Non-U.S.

SA-PO2159

The Effect of Bone Marrow Mesenchymal Stem Cells (BMSC) or Conditioned Medium (CM) in Rats with Acute Kidney Injury (AKI) Induced by Lipopolysaccharide (LPS) Luciana Aparecida Reis,[1] Joelma Santina Christo,[1] Nestor Schor.[1] *[1]Nephrology, UNIFESP/EPM, Sao Paulo, SP, Brazil; [2]Morphology Department, UNIFESP/EPM, Sao Paulo, SP, Brazil.*

Background: Sepsis is characterized by a severe inflammatory response to infection, and its complications, including AKI, can be fatal. BMSC can act on several levels of endogenous repair to bring about resolution of diseases and its mechanism of action may be due to paracrine modulation and conditioned medium. The aim of this study is to evaluate the BMSC or CM effect at cellular modulation and/or repairment on LPS in rats.

Methods: BMSC were collected from male Wistar rats, characterized by FACS and differentiated into osteocytes and adipocytes. Female Wistar rats received LPS (10mg/Kg/BW) (LPS group) or water (CTL) in a single dose *i.v.* (N=10). After 24 or 72 hr, the female rats received *i.v.* BMSC (1X10^{6}cells) injection or CM (500µl), 1 or 3 doses via the tail vein. Blood and urine 24 hours were collected to creatinine (Cr), urea (U) and FE_{Na} evaluations. The kidneys were perfused and removed for HE, KI67, caspase 3 and Y chromosome analysis.

Results:

GROUPS	Cr [mg/dl]	U[mg/dl]	FENa [%]
CTL24h	0.6±0.04	25±3.1	2.6±0.02
CTL72h	0.7±0.08	27±1.8	2.5±0.01
LPS24h	1.7 ±0.14*	87.7±2.1*	0.7±0.03*
LPS72h	2.2±0.04*	146±4.6*	0.6±0.02*
LPS72h+BMSC1x	0.9±0.03#	59±3.1#	1.7±0.04#
LPS72h+BMSC3x	0.9±0.01#	50±4.3#	1.9±0.04#
LPS72h+CM1x	1.1±0.03#	66±4.9#	2.0±0.03#
LPS72h+CM3x	0.9±0.1#	49±2.7#	2.2±0.02#

*p<.05 vs. CTL24,72h; #p<.05 vs. LPS24, 72h

In LPS-group the kidneys showed a small marked KI67 and intensive caspase 3 expression but it was highly marked for KI67 and lower expression for caspase 3 in LPS+BMSC and LPS+CM groups. However, a striking difference was observed in the BMSC or CM treated animals where the presence of KI67 and Y chromosome was detected and no histological ATN lesions were observed. This effect was maximized when the doses of BMSC or CM were higher.

Conclusions: These results strongly suggest that BMSC or CM can minimize AKI in this sepsis model. This therapeutics effects have a significant impact on renal function observed holds substantial promise for its use in this pathological situation with high morbidity and mortality.

Angiopoetin-2 – A Dose Dependent Modulator of Syngeneic Murine EPCs in Acute Ischemic Kidney Injury Daniel Patschan,[1] Susann Patschan,[1] Gerhard A. Mueller.[1] *[1]Nephrology and Rheumatology, University Hospital Göttingen, Göttingen, Niedersachsen, Germany; [2]Göttingen; [3]Göttingen.*

Background: Exogenously administered endothelial progenitor cells (EPCs) can protect the kidney from acute ischemic injury (iAKI). The proteins Angiopoietin-1 and -2 play essential roles in regulating vascular regeneration and function. Aim of the study was to analyze to possible effects of Ang-2 on EPCs in an EPC-based therapeutic regimen of iAKI.

Methods: EPCs were isolated from male C57BL/6N mice and, after 5-7 days of culturing, incubated with Ang-2 at different concentrations for one hour, respectively. Pretreated, dye-labelled cells were systemically injected into recipient animals after bilateral renal ischemia of 40 minutes. Two days later, renal function and histology were investigated. In vitro studies with cultured EPCs were performed in order to analyze the cells´ migratory activity under the influence of Ang-2.

Results: Systemic injection of 0.5 × 10^6 untreated EPCs did not prevent mice from acute renal failure. The consequences of cell pretreatment with Ang-2 were dose-dependent: at 200 ng/ml renal function remained unaffected. At 400 ng/ml, renoprotective effects of EPCs were significantly stimulated, indicated by lower postischemic serum creatinine levels. Incubating the cells with Ang-2 at 800 ng/ml dramatically reduced renoprotective effects of the cells, renal outcome was the worst of all four groups. Ang-2 did not have any influence on the migratory activity of cultured EPCs.

Conclusions: Ang-2 acts as dose-dependent modulator of syngeneic murine EPCs in iAKI. Renoprotecive effects of the cells can either be stimulated or reduced. Although the exact mechanisms responsible for these diametral actions remain speculative at the moment, Ang-2 at least does not modulate EPC migration.

SA-PO2161

A Phase I Trial of Human Allogeneic Mesenchymal Stem Cells for the Prevention of Acute Kidney Injury in Cardiac Surgery Subjects John R. Doty,[1] David G. Affleck,[2] Benjamin D. Horne,[1] Joseph Brent Muhlestein,[1] Matthew Psioda,[3] Viken Paragamian,[5] David G. Warnock.[4] *[1]Surgery, Intermountain Medical Center, Salt Lake City, UT; [2]Surgery, St. Mark's Hospital, Salt Lake City, UT; [3]Kendle International, Cincinnati, OH; [4]Medicine, University of Alabama at Birmingham, AL; [5]Allocure, Inc, Burlington, MA.*

Background: Acute kidney injury (AKI) is common and has no effective treatment. Pre-clinical studies have shown that mesenchymal stem cells protect kidney function and stimulate repair. AlloCure has developed a proprietary process to isolate and expand allogeneic human MSC (AC607).

Methods: In this dose escalation phase I study, 16 subjects undergoing on-pump CABG and/or valve surgery who were at high risk for developing AKI were treated with 3 doses of AC607 [7 x 10E5 (n=6), 2 x 10E6 (n=5), and 7 x 10E6 (n=5) cells].

Results: All subjects were Caucasian, mean age and weight (± SD) were 72.1 yrs (±7.8), and 92.1 Kg (±15.9), respectively. Fifteen subjects had CKD (II-III), 13 were hypertensive, and 6 had diabetes. The mean cardiopulmonary bypass time was 135.7 min (±45.5). The primary endpoint for the study was safety. None of the study subjects developed adverse or serious adverse events attributable to AC607 therapy, at any dose delivered. To enable a preliminary assessment of efficacy, study subjects were matched to historical controls (n=64). Overall, 12.5% of AC607 subjects developed AKI (AKIN criteria), compared to 29.7% of historical controls (p=0.214). Additionally, hospital length of stay was reduced in the AC607 group [6.5 days (±3.1) vs. 9.3 (±5.4), p=0.049]. Hospital readmission rates were 6.3% vs. 12.5% for AC607 subjects and historical controls respectively (p=0.679). One subject died within 30 days of surgery in the treated group (unrelated to AC607) vs. 2 of the historical controls. No subjects in either group received dialysis.

Conclusions: In this study, AC607 was safe and well tolerated. Furthermore, this study provides initial evidence that AC607 may be effective for the management of AKI in this population. Phase II studies are under development.

SA-PO2162

I KappaB Kinase Alpha Promotes Repair after Ischemic Acute Kidney Injury Changchun Cao, Xin Wan, Li Fan, Bo Hu. *Nephrology, Nanjing First Hospital Affiliated to Nanjing Medical University, Nanjing, Jiangsu, China.*

Background: Understanding the mechanisms of repair and regeneration of the kidney after injury is of great interest because there currently are few therapies that promote repair, and kidneys frequently do not repair adequately. We studied the capacity of I kappaB kinase alpha (IKKα) on the recovery phase to promote kidney repair and regeneration using an established ischemia/reperfusion injury model in mice.

Methods: Renal ischemia/reperfusion injury was induced by clamping bilateral renal artery for 25 min in C57BL/6J mice (wild type), $IKKa^{TKO}$ mice (tubule epithelial cells-specific IKKa knockout mice), and $IKKa^{TG}$ mice (KAP-IKKa transgenic mice). The reperfusion time was 1, 2, 4, 7 and 30 days respectively. Blood was harvested for biochemistry; and kidney tissues for histopathological examination, and for study of renal expression of IKKa, intercellar adhesion molecule-1 (ICAM-1), interleukin-10 (IL-10), colony- stimulating factor-1 (CSF-1), and Ki67.

Results: Postischemic kidneys of $IKKa^{TG}$ mice expressed higher IKKa compared with wild-type and $IKKa^{TKO}$ mice, associated with enhanced repair of the tubule epithelial cells, and enhanced functional recovery.

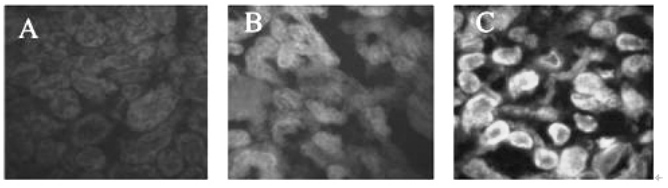

Fig1. Expression of IKKα in postischemic mouse kidneys. The reperfusion time was 96h. A, $IKKα^{TKO}$ group; B, wild type group; C, IKK^{TG} group

$IKKa^{TG}$ mice synthesized higher IL-10, which was an anti-inflammatory cytokine, and less ICAM-1, which was regarded as an pro-inflammatory cytokine, and expressed higher levels of CSF-1 and Ki67, which promoted proliferation of tubule epithelial cells. While $IKKa^{TKO}$ mice espressed higher ICAM-1 and reduced tubular proliferation compared with wild-type and $IKKa^{TG}$ mice, indicating that IKKa mediated renal repair is by limiting inflammation and promoting proliferation.

Conclusions: Our data confirms that IKKa promotes kidney repair and regeneration during the healing process after ischemia/reperfusion injury, likely through modulation of inflammatory cytokine and increasing tubule epithelial cell proliferation.

A Model of Tubular Regeneration after Surgical Injury in Adult Rat Kidney Natalia O. Litbarg,[1, 2] Snezana Vujicic,[1, 2] Suman Setty,[1] George Dunea,[3] Jose A.L. Arruda,[1] Ashok K. Singh.[3] *[1]U of Illinois Chicago, Chicago, IL; [2]JB VAMC, Chicago, IL; [3]Hektoen Institute, Chicago, IL.*

Background: Wound repair after surgical injury is used to investigate mechanisms of tissue regeneration. The mechanisms of surgical wound regeneration in the adult kidney have not been explored.

Methods: To address this issue we subjected adult rats to uninephrectomy and surgical polectomy of the contralateral kidney. We enclosed the remnant kidney in an inert plastic pouch to prevent adhesions. Control rats underwent uninephrectomy and the uninjured contralateral kidney was placed in a pouch. We examined serial kidney sections by immunohistology at 1, 2 and 4 weeks after surgery.

Results: As compared to controls, tubular cells of the wounded kidney edge lost terminal differentiation markers (*Phaseolus vulgaris* hemagglutinin and aquaporin2) and acquired markers of both mesenchymal transition (vimentin and FSP1) and embryonic nephrogenesis (cadherin6, NCAM and Pax2). Similar changes, suggestive of cell dedifferentiation, have been described in tubular epithelium after acute tubular necrosis (ATN). However, as opposed to classical ATN models, we observed new growth of injured tubules. Tubular epithelial outgrowths (TEOs) extended from the wound edge into adjacent granulation tissue and formed branching tubular structures. TEOs were abundant in markers of proliferation (PCNA, Ki67 and phosphohistone H3), and were positive for markers of epithelial differentiation (pancytokeratin and E-cadherin). They lacked aquaporin2 and vimentin expression thus distinguishing them from normal adult collecting ducts as well as injured tubules. Notably, TEOs strongly expressed developmental markers Pax2 and *Dolichos biflorus* agglutinin. Overall their branching and staining pattern resembled that seen in primitive branching epithelium of ureteric bud. The morphologic connection between TEOs and wounded tubules suggested that TEOs were derived from injury-induced dedifferentiated tubular epithelium.

Conclusions: In conclusion, these results suggest that the adult rat kidney has the potential for *de novo* tubulogenesis. Our model provides a simple and reproducible tool for exploring this potential.

SA-PO2164

Role of the BMP-7/Gremlin Pathway in the Tubular Epithelial-Mesenchymal Transition Induced by TGF-β1 Mirian A. Boim, Edgar Maquigussa, Luciana G. Pereira, Carine Prisco Arnoni. *Medicine - Renal Division, Federal University of Sao Paulo, Sao Paulo, Brazil.*

Background: TGF-β1 is a potent inducer of the epithelial-mesenchymal transition (EMT). Tubular cells undergoing to EMT, invade the interstitium and synthesize interstitial matrix contributing to the tubulointerstitial fibrosis. Bone morphogenetic protein-7 (BMP-7) plays a critical role in the repairing process of the damaged tubular cells by a inhibiting EMT. Gremlin is an endogenous antagonist of BMP-7. Our objective was to evaluate the role of BMP-7/Gremlin pathway in the induction and reversion of EMT induced by TGF-β1 *in vitro* by stimulating immortalized human proximal tubular cells (HK-2) with TGF-β1.

Methods: HK-2 cells were treated with TGF-β1 (3ng/ml) for up to 72 hours. The role of BMP-7/gremlin pathway was analyzed by Gremlin mRNA silencing technique (siRNA). The expression of EMT markers (a-SMA, E-cadherin and FSP1), fibronectin, collagen, TGF-b1, BMP-7 and gremlin were estimated by real time PCR and western blot.

Results: TGF-β1 induced EMT was evidenced by upregulation in a-SMA and fibronectin expressions with a decrease in E-cadherin. Gremlin levels were increased in TGF-β1 stimulated cells and Gremlin siRNA was able to prevent the increase in the EMT markers including FSP1 and fibronectin. In contrast the addition of BMP-7 to the culture medium had no effect on the expression of these markers. Results suggest that BMP-7 was unable to prevent cells to undergo EMT and gremlin may have direct effect contributing to TGF- β1 inducing EMT in HK-2 cells.

Conclusions: In conclusion Gremlin suppression may be more efficient than BMP-7 treatment to prevent cells to undergo EMT induced by TGF-β1.

Important Repair/Protective Process of Papillae in Renal Function and Morphology Demonstrated by Use of 14 Days-UUO-Released Model and Small Synthetic Compounds in Rats Michio Ishibashi,[1] Yoshikatsu Kanai,[2] Masayuki Iwano.[3] *[1]Department of Urology, Nara Medical University, Kashihara, Nara, Japan; [2]Department of Pharmacology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [3]Department of Internal Medicine, Nara Medical University, Kashihara, Nara, Japan.*

Background: Using 14 days-UUO released model established in rats and small newly synthetic gammalactone compounds (#1376 or #NK0075), the important repair or protective process of papillae in renal morphology associated with renal function and involved in activation of protein molecules of rBAT, E-cadherin and galectin-3 after ureteral obstruction were presented.

Methods: In UUO-release model, complete ureteral obstruction was released by ureterouretrostomy and contra lateral nephrectomy (CNx) was done. After release of 14-days UUO with CNx in control animals (n=16), 8 weeks old male SD rats, plasma creatinine (pCr) level was recovered from 4.8± 0.6 mg/dl on day 2 to 2.2±0.1mg/dl on day 6. Treatment of #1376 at the dose of 30mg/kg/day s.c. throughout the 21 days of period ameliorated renal recovery to a better pCr level to 1.45± 0.25 mg/dl.

Results: Using pCr category of recovered renal function from UUO, two kinds of animals treated with #1376 were classified into group-1 (excellent pCr: less than 1.5mg/dl) and group-2 (intermediate pCr:1.5-1.7mg/dl). Renal morphology of group-1 animals was well preserved having almost normal transitional cell layer (TCL) covering papillae, and showed dominant collagen fiber response at the base of papillae. In group-2 cases, TCL was proliferated into more than four or five layers with loose connection, and the dominant cellular response at the base of papillae, close to TCL, with large amount of mononuclear cell accumulation, including angiogenesis detected by E-PHA or tubular regeneration, was observed. A strongly positive staining of galactin-3 concomitant with rBAT-positive intertubular mononuclear cells, E-cadherin-positive of TCL and distal tubulus, and E-PHA-positive angiogenesis were remarkable.

Conclusions: In conclusion, the repair process of papillae might be important to preserve renal function and morphology in the disease progression of UUO model.

NF-E2 Related Factor-2 (Nrf-2) Signaling Promotes Survival and Healing of Tubular Epithelial Cells

Jan H. Hagemann, Dana Thomasova, Hans J. Anders. *Medizinische Poliklinik Innenstadt, Klinikum der Universitaet Muenchen, Munich, Germany.*

Background: Oxidative stress is a clinically relevant trigger for tubular cell death and insufficient tubular repair both commonly leading to tubular atrophy and renal failure. The transcription factor Nrf-2 induces a number of genes that counterbalance oxidative stress in injured cells. Hence, we hypothesized that Nrf-2 activation can promote tubular epithelial cell survival and repair.

Methods: We assessed three elements of tubular survival and healing: 1. Cell survival during cell isolation (oxidative stress): primary tubular epithelial cells were isolated from wild type C57BL6 mice at 2-3 weeks of age and then cultured in fresh-made hormone-conditioned medium. The cells were characterized by immunofluorescence microscopy, flow cytometry, and qPCR for the expression of tubular marker genes. 2. Regenerative expansion of the surviving cells: confluence was assessed every 24h for a period of 6 days by means of digital morphometry; and 3. Repair by scratch assay experiments: Cells were grown to complete confluence either with the Nrf-2 agonist Sulforaphane/DMSO or DMSO for 4 hours prior to artificial scratch wounding. Wound closure was analyzed by digital morphometry after different timepoints.

Results: Isolated cells in culture extensively expressed epithelial markers such as E-Cadherin and Cytokeratin 7 (immunostaining), and were positive for the tubular cell marker FXYD2, a specific ion channel protein. Sulforaphane increased tubular cell survival at 30 hours after the isolation procedure in a dose-dependent manner. In vitro expansion as well as wound closure upon scratching monolayers were 30% faster upon Sulforaphane stimulation. By contrast, a cell cycle inhibitor (p53 agonist) lead to dramatic decrease of the regeneration capacity in our model.

Conclusions: Nrf-2 activation with Sulforaphane promotes renal epithelial healing in-vitro after ischemic or mechanical injury. Therefore, Nrf-2 seems to be a potential therapeutic target to increase healing and regenerative response after ischemic injury in the kidney in order to prevent tubular atrophy.

Urinary Thioredoxin 1 Is an Oxidative Stress-Specific Biomarker of Acute Kidney Injury

Kenji Kasuno,[1] Eri Muso,[2] Hideki Kimura,[1] Naoki Takahashi,[1] Yasunari Nobukawa,[5] Kiyoshi Mori,[3] Haruyoshi Yoshida.[4] *[1]Nephrology and Clinical Laboratories, University of Fukui Faculty of Medical Sciences, Eiheiji-cho, Fukui, Japan; [2]Nephrology and Dialysis, Kitano Hospital, The Tazuke Kofukai Medical Research Institute, Osaka, Japan; [3]Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan; [4]Nephrology and Dialysis, Sugita Genpaku Memorial Obama Municipal Hospital, Obama, Fukui, Japan; [5]Intensive Care Unit, University of Fukui Faculty of Medical Sciences, Eiheiji-cho, Fukui, Japan.*

Background: Oxidative stress is an important etiology of acute kidney injury (AKI); however, few existing AKI markers are directly involved in oxidative stress or redox regulation.

Methods: We investigated urinary levels of redox regulatory protein thioredoxin 1 (TRX1) in patients with various kidney diseases and mice with renal ischemia/reperfusion (rI/R) injury.

Results: Urinary TRX1 levels were markedly increased in patients with AKI as compared to chronic kidney disease and healthy subjects. In receiver operating characteristic curve analysis to differentiate between AKI and other renal diseases, the area under the curve of urinary TRX1 was 0.90, and the sensitivity and specificity were 0.90 and 0.82, respectively, at the optimal cutoff value of 35.2 ng/mg creatinine. Immunostaining of TRX1 was observed diffusely in the tubules of normal kidney, whereas it was shifted to brush borders in injured tubules which abundantly expressed 8-hydroxydeoxyguanosine. In cultured human proximal tubular epithelial cells, the supernatant levels of TRX1 were specifically increased by addition of hydrogen peroxide in a dose dependent manner. In animal experiments, the kidney of TRX1-transgenic mice contained lesser amount of an oxidative stress marker, protein carbonyl, than that of wild-type mice.

Conclusions: These findings suggest urinary TRX1 is a novel biomarker useful in distinguishing AKI from chronic kidney disease and healthy conditions, and the source of urinary TRX1 is renal tubules injured by oxidative stress.

Identification and Validation of microRNAs as New Biomarkers of Acute Renal Failure

Elia Aguado Fraile,[1] Edurne Ramos,[1] Francisco Díaz Crespo,[2] Nuria Villegas,[1] Elisa Conde,[1] Ignacio Blanco Sanchez,[1] Angel M. Candela-Toha,[3] Fernando Liano,[2] Laura Garcia-Bermejo.[1] *[1]Pathology, Hospital Ramon y Cajal; [2]Nephrology, Hospital Ramon y Cajal; [3]Anesthesia, Hospital Ramon y Cajal.*

Background: miRNAs are small non-coding RNAs which regulate gene expression. They are crucial regulators of cell responses to external stimuli such as ischemia/reperfusion and nephrotoxic compounds. Recently, it has been demonstrated that miRNAs could be detected in body fluids, including serum, where they have revealed a strong stability. Moreover, changes in miRNAs profiles in serum have been associated with several pathologies. All these features join to the non-invasive extraction method to obtain serum, have unveiled miRNAs as potential biomarkers of acute kidney injury (AKI).

The aim of this work is to identify and validate microRNAs as potential AKI biomarkers in serum from acute renal failure patients.

Methods: RNA was extracted from ARF patient serum using an optimized protocol for these samples. Firstly, we have performed a massive screening experiment using TLDA platform in serum samples from ischemic, toxic and septic ARF patients. A pool of healthy volunteers was used as control. Next, the expression of selected miRNAs was confirmed by qRT-PCR in a larger ARF patient cohort with different aethiologies. Samples from Day 0 (diagnosis) to day 7 were used for miRNA detection and serum creatinine levels were estimated in all the analyzed samples.

Results: TLDA analysis revealed several altered miRNAs in ARF patients vs healthy controls. We have chosen miR-101-1, miR-127-3p and miR-210 for further confirmation because all these miRNAs were significantly downregulated in ARF patients. miR-101-1 recovered healthy-like expression levels correlating with normalized creatinine values. Expression of miR-127-3p and miR-210 is restored in ischemic ARF patients who exhibited almost normal levels of creatinine.

Conclusions: In summary, miRNAs could be easily detected in serum and could be used for diagnosis and prognosis of ARF. In particular, miR-101-1, miR-127-3p and miR-210 could be considered as new biomarkers of AKI. Moreover, miR-127-3p and miR-210 appeared as specific markers of ischemic ARF outcome.

The Molecular Phenotype of Acute Kidney Injury Is Also Found in Progressing Chronic Kidney Disease: A Human Kidney Transplant Study

Konrad S. Famulski, Declan G. de Freitas, Michael Mengel, Philip F. Halloran. *Alberta Transplant Applied Genomics Centre, University of Alberta, Edmontion, AB, Canada.*

Background: Because of frequent biopsies and follow-up, early kidney transplants without rejection provide a unique opportunity to study molecular features of human acute kidney injury (AKI) that is a major impediment to transplant function.

Methods: We performed microarrays on early transplant biopsies with AKI and compared them to protocol biopsies of stable kidney transplants, Our aim was to tease out the molecular component of AKI as opposed to injury of transplantation procedure alone.

Results: Transplants with AKI expressed transcripts reflecting the injury-repair response (IRRAT), including some known (ITGB6, LCN2), but also novel kidney injury molecules e.g. OLFM4, SERPINA3. Many represented tissue remodelling, reminiscent of wound repair and cancer e.g. VCAN, CADH6. In transplants with AKI, IRRAT expression correlated with depression of function (r= -0.77), need for dialysis, and future recovery of function (r=0.62), whereas histologic features claimed to reflect tubular injury showed no correlations with these features.

	Bottom Tertile AKI biopsies	Middle Tertile AKI biopsies	Top Tertile AKI biopsies
eGFR at time of biopsy (mean ±SE)	35 ±2	27 ±3	15 ±2**
Delta eGFR from biopsy to 6 months (mean ±SE)	10 ±3	25 ±6	40±8**
Delayed / immediate graft function	0 / 9	0 / 8	8 / 1**
Histologic evidence of tubular injury	6	6	9

Figure 1. Relationship between the IRRAT scores, histopathology, delayed graft function and eGFR in transplants with AKI. ** significant difference between the top tertile versus remaining tertiles.

IRRAT were also expressed in rejecting kidneys, indicating that rejection triggers injury-repair. Surprisingly, IRRAT selected in acute kidney injury were induced in transplants with chronic kidney diseases (glomerulonephritis, antibody-mediated rejection) and correlated with progression to failure and with the previously published molecular risk score.

Conclusions: Transcripts strongly induced in AKI are also induced in progressive chronic kidney diseases. Thus both AKI and chronic progressive kidney diseases induce the same signal, analogous to wound repair. The extent of this response correlates with the extent of dysfunction and future recovery in pure acute kidney injury, but indicates serious ongoing nephron damage in progressive chronic kidney disease.

Kidney Injury Biomarkers Kim-1, NGAL, Clusterin, and Cystatin C in Mouse Models of Ischemia Reperfusion Injury Venkata Sabbisetti, Chang Wang, Kazumi Ito, Joseph V. Bonventre. *Renal Division, Department of Medicine, Brigham and Women's Hospital, Boston, MA.*

Background: The application of kidney biomarkers to mouse models of kidney injury and nephrotoxicity will enhance our understanding of pathophysiology and facilitate the development of safe drugs. Kim-1, NGAL, clusterin, & cystatin C are capable of detecting kidney toxicity at early stages. However, the lack of reliable assays and urine volume requirements have hampered the utilization of these markers in preclinical studies. The goal of the current study was to establish a high-through multiplex bead based assay to measure these biomarkers, characterize their kinetics in urine and serum, and validate them vs histopathology after ischemia/reperfusion (I/R).

Methods: BALB/C mice were subjected to I/R injury for 10, 20, & 30 min and urine and serum specimens were collected for 14 days and evaluated for Kim-1, NGAL, clusterin, & cystatin C using microbead-based ELISA assays which we developed. Serum creatinine, BUN, NAG and total protein were measured spectrophotometrically.

Results: Microbead-based ELISA assays were developed that can measure the four biomarkers in duplicate in 10 µl of biological sample. The lower detection limits for Kim-1, NGAL, clusterin & cystatin C assays are 12, 10, 290 & 10 pg/ml with dynamic ranges of 0.01-50, 0.01-50, 0.29-1200, 0.01-50 ng/ml respectively. In mice exposed to 10 and 20 min I/R injury serum creatinine levels did not change, but there was a robust ischemic time-dependent increase in each of the novel markers and histopathology reflecting tubular injury. With 10 & 20 min I/R injury, NAG & total protein levels returned to baseline within 12 hours, while Kim-1, NGAL and cystatin C levels remained elevated for 5 days after the injury. Similarly, in mice subjected to 30 min I/R injury, NAG and total protein levels returned to baseline within 48 hours after injury, while Kim-1 & NGAL levels remained elevated for the entire duration of the study.

Conclusions: An assay panel for mouse urinary and serum biomarkers has been developed and validated which can measure four biomarkers in duplicate in very small sample volumes. This will greatly facilitate kidney injury studies in the mouse.

SA-PO2171

Soluble RAGE Prevents Sepsis-Induced Acute Kidney Injury Sun Ha Lee, Jisun Paeng, Seung Hyeok Han, Tae-Hyun Yoo, Shin-Wook Kang. *Dept. of Int. Medicine, College of Medicine, BK21, SBSI, Yonsei Univ., Seoul, Korea.*

Background: The receptor for advanced glycation endproducts(RAGE) is involved in the pathogenesis of inflammatory diseases. Soluble RAGE(sRAGE) competitively inhibits the binding of RAGE ligands and is proposed as a potential therapeutic agent. However, little is known about the efficacy of sRAGE in septic acute kidney injury (AKI), which is mainly mediated by inflammation. This study was undertaken to investigate the effect of sRAGE on renal function, epithelial-mesenchymal transition(EMT), and inflammatory cells infiltration in septic AKI.

Methods: In vivo, C57/BL6 mice were subjected to cecal ligation and puncture(CLP) or sham operation(control, C) and were maintained for 24 hours. CLP mice were pretreated either with diluent or sRAGE intraperitoneally(CLP+sRAGE) at 1 hr before operation. In vitro, NRK-52E cells were cultured in DMEM media with or without lipopolysaccharide(LPS). To examine the effect of sRAGE on LPS-induced tubular cell injury, LPS-treated NRK-52E cells were also incubated with sRAGE or RAGE siRNA. Western blot analysis was performed to evaluate E-cadherin, α-smooth muscle actin(α-SMA), and ICAM-1 protein expression. Immunohistochemistry was carried out with renal tissues.

Results: The increase in serum BUN levels in CLP mice was significantly abrogated by the administration of sRAGE($p<0.05$). The ratios of α-SMA/E-cadherin protein expression and the expression of ICAM-1 protein were significantly higher in CLP model compared to C mice($p<0.05$). These changes in CLP model were significantly abrogated by sRAGE pretreatment($p<0.05$). sRAGE also significantly reduced the number of infiltrated inflammatory cells within kidney in CLP mice. In vitro, RAGE protein expression was significantly increased in LPS-stimulated tubular epithelial cells, and this increase was ameliorated by sRAGE and RAGE siRNA($p<0.05$). The increases in the ratios of α-SMA/E-cadherin and the expression of ICAM-1 protein in LPS-stimulated cells were also significantly attenuated by RAGE inhibition($p<0.05$).

Conclusions: These findings suggest that RAGE plays a role in the pathogenesis of septic AKI and its inhibition by sRAGE may be a potential therapeutic target for AKI in severe sepsis.

SA-PO2172

Sepsis-Induced Glomerular Endothelial Dysfunction Mediates Reductions in GFR and Increases in Protein Filtration Ruben M. Sandoval,[1] George Rhodes,[1] Exing Wang,[1] Silvia B. Campos-Bilderback,[1] Sarah E. Wean,[1] Bruce A. Molitoris.[1,2] *[1]Medicine/Div of Nephrology, Indiana Univ. School of Medicine, Indianapolis, IN; [2]Roudebush VAMC, Indianapolis, IN.*

Background: Sepsis is now the leading cause of acute kidney injury (AKI) known to decrease Glomerular filtration rate (GFR) and increase proteinuria. There also exists a discrepancy between renal perfusion and GFR.

Methods: To evaluate the potential role of the glomerulus in the overall pathogenesis of these abnormalities, we studied surface glomeruli in 8-10 week old Munich Wistar Frömter rats using intravital 2-photon microscopy in a cecal ligation and puncture (CLP) model of sepsis to ask targeted questions and compare the metric of measured GFR to serum creatinine changes at 24 hours post CLP.

Results: Male rats undergoing CLP showed an increase in serum creatinine from 0.23 +/- 0.06 mg/dl to 0.80 +/-0.17 ($P\leq0.01$) and a decrease in real time GFR from 0.69 +/- 0.06 ml/min/100gm body wt to 0.34 +/-0.15 ($P\leq0.01$). Hemodynamic monitoring revealed normal and hyperdynamic cardiac status within the CLP group. Quantitative analysis of 15 glomeruli in three CLP septic rats revealed a reduction in red blood cell flow rates within capillary loops from 1,771 +/- 467 to 576 +/- 327 um/sec ($P\leq0.01$); an increase in WBC adherence to glomerular capillary endothelial cells from 0.42 +/-0.33 to 7.25 +/- 5.82 WBC's/standardized glomerular volume ($P\leq0.05$) in CLP rats; and an increase in the glomerular sieving coefficient (GSC) of a 150kD dextran from 0.007 +/- 0.003 to 0.097 +/- 0.046 ($P\leq0.05$). Rouleaux formations were seen only in septic rats.

Conclusions: These data indicate glomerular endothelial-WBC interactions during sepsis, in part, explain the reduction in GFR and increased filtration of large molecular weight proteins. The results from real time GFR accurately detected the drop in renal function for this model of sepsis.

SA-PO2173

Chronic Kidney Disease Amplifies Sepsis-Induced Acute Kidney Injury and Spleen Apoptosis Via Toll-Like Receptor 4 Signaling Takayuki Tsuji, Ana Carolina Souza, Xuzhen Hu, Taro Horino, Peter S.T. Yuen, Robert A. Star. *Renal Diagnostics and Therapeutics Unit, NIH/NIDDK, Bethesda, MD.*

Background: Patients with chronic kidney disease (CKD) have increased risk of morbidity and mortality from sepsis and acute kidney injury (AKI), an effect mimicked in our mouse model of sepsis following CKD. To further study the mechanism of amplification by CKD, we studied Toll-like receptor 4 (TLR4), which plays a major role in systemic inflammation after endotoxemia, and has been implicated in sepsis-AKI and in renal fibrosis.

Methods: We used C3H/HeJ (TLR4-) and C3H/HeOuJ (TLR4+) mice as matched controls. We performed sham(CKD) or 5/6 nephrectomy (5/6Nx) to induce CKD, waited 8 weeks, then performed sham(sepsis) or cecal ligation and puncture (CLP). Outcomes were measured at 24h.

Results: In both TLR4+ and TLR4- mice, 5/6Nx induced mild CKD at 8 weeks [BUN 42-52.5 mg/dl; serum creatinine (Scr) 0.265-0.300 mg/dl; histologic fibrosis], although urinary albumin excretion was significantly higher in TLR4+ than TLR4- mice (186.1 vs 34.5 ug/mg Cr, $p<0.05$). CKD intensified sepsis-AKI, as SCr, BUN, and tubule damage score (TDS) were significantly higher after CKD-sepsis vs sham(CKD)-sepsis in TLR4+ mice ($p<0.05$). However in TLR4- mice, SCr ($p>0.05$), BUN ($p<0.05$), and TDS ($p<0.05$) increases were blunted [CKD-sepsis vs sham(CKD)-sepsis]. Spleen apoptosis (by active caspase 3) was significantly increased in CKD-sepsis vs sham(CKD)-sepsis ($p<0.001$) in TLR4+ but not in TLR4- mice. Interestingly, sepsis increased TNF-α and HMGB1, but pre-existing CKD had no further effect in either TLR4+ or TLR4- mice.

Conclusions: Much of the CKD-driven amplification of sepsis-AKI is TLR4-dependent in this milder version of the mouse acute-on-chronic kidney disease model. Sepsis-induced spleen apoptosis was greatly amplified by CKD, which was TLR4-dependent. The amplification occurred without changes in TNF-α and HMGB1 (classic early and late inflammatory mediators). Therefore spleen apoptosis is driven by TLR4 signaling, and may represent an important amplifier in acute-on-chronic kidney disease.

Distinct Pathophysiology of Septic Acute Kidney Injury – Role of Immune Suppression and Apoptosis So-Young Lee,[1] Sang-Kyung Jo,[2] Won-Yong Cho,[2] Hyoung-Kyu Kim.[2] *[1]Nephrology, Eulji university hospital, Seoul, Republic of Korea; [2]Nephrology, Korea University Hospital, Seoul, Republic of Korea.*

Background: Sepsis is the most common cause of acute kidney injury(AKI) in critically ill patients. However, the mechanisms leading to AKI in sepsis remain elusive. Although, sepsis is traditionally considered an excessive systemic inflammatory response, according to recent observations, sepsis induced organ dysfunction might be associated with paradoxical immune suppression. The purpose of this study was to examine the pathophysiology of septic AKI focusing on immune suppression and apoptosis of kidney and immune cells by providing on-site comparison between septic vs ischemia/reperfusion(I/R) induced AKI, a well known disease mediated by activation of innate immunity.

Methods: At 24 h after cecal ligation & puncture (CLP) or I/R injury, biochemical, histologic kidney injury and cytokine profiles were compared. Apoptosis of immune cell

and renal cell was assessed by TUNEL staining and measurement of caspase 3 activity. We also examined the effect of caspase 3 inhibition and IL-10 blocking on renal function. Finally, we observed $CD4^+CD25^+$regulatory T cells(Tregs) frequency and the effect of depletion of these cells in renal function.

Results: Acute tubular necrosis or inflammation were hardly observed in septic kidneys. However, tubular cell apoptosis was prominent and caspase 3 activity showed a positive correlation with plasma cr. Pretreatment with caspase 3 inhibitor resulted in attenuation of renal dysfunction in septic AKI with reduced apoptosis. Septic AKI was associated with increased IL-10, and massive immune cell apoptosis with increased percentage of Tregs. In contrast to I/R injury that depletion of Tregs aggravates renal injury, depletion of these cells resulted in significant renoprotection and IL-10 blocking was also associated with renoprotection in septic AKI.

Conclusions: Our data showed a link between apoptosis, immune suppression and kidney dysfunction during sepsis and suggest that inhibition of apoptosis and recovered immune balance might be useful to decrease mortality or organ dysfunction. Future studies are needed to clarify the exact pathophysiology of this devastating disease.

Role of Renal Cell Apoptosis in Pathogenesis of Septic Acute Kidney Injury Sung Yoon Lim, Sang-Kyung Jo, Won-Yong Cho, Hyoung-Kyu Kim. *Korea University Anam Hospital.*

Background: The presence of acute kidney injury (AKI) in septic patients is known to be associated with worse outcome. However, mechanisms of septic AKI remains elusive and several recent reports suggest that excess immune suppression characterized by massive lymphocytes apoptosis might be causally linked to sepsis mortality or sepsis induced organ dysfunction. In addition to immune cell apoptosis, renal cell apoptosis has also been demonstrated in animal models of sepsis or some autopsies. However, the exact role of renal cell apoptosis in the development of AKI in sepsis has never been assessed.

Methods: To examine the role of renal cell apoptosis in septic AKI, we used cecal ligation and puncture (CLP) method in mice.

Results: In C57/BL6 mice, plasma creatinine increased on day 1 and despite lack of overt tubular necrosis, significantly increased numbers of renal cell apoptosis were observed and kidney caspase 3 activity showed positive correlation with plasma creatinine. Although pretretreatment with caspase 3 inhibitor markedly attenuated functional impairment, this renoprotective effect was accompanied by decreased apoptosis of both immune cells and renal cells. Therefore, to further dissect out the role of renal cell apoptosis independent of immune cell apoptosis, we performed CLP in mature T and B lymphocyte deficient RAG-1 deficient mice. Similar with WT mice, CLP also evoked mixed gram negative and positive bacterial peritonitis induced sepsis with multiple organ dysfunction in RAG-1 deficient mice. Furthermore, in the absence of mature T and B lymphocytes, that are known to undergo apoptosis in sepsis, pretreatment with caspase 3 inhibitor still partially rescued RAG-1 deficient mice from development of AKI with significant reduction of plasma cytokines (IL-6, IL-10, TNF-a, MCP-1).

Conclusions: These results demonstrated the important role of renal cell apoptosis in the development of AKI and strategies that suppress renal cell apoptosis might be useful in preventing or treating AKI associated with sepsis.

Lipopolysaccharide Causes Marked Changes in Tubular Zonula Occludens-1 Michael T. Eadon, F. Gary Toback, Patrick Cunningham. *Section of Nephrology, University of Chicago, IL.*

Background: Tight junctional (TJ) proteins maintain an integral role in tubular ion transport and waste excretion. Disruption of TJs contribute to decreased GFR in acute kidney injury (AKI) via the tubular backleak mechanism. TJ protein derangements have been shown following a variety of insults to intestine, lung, and kidney *in vivo*, as well as in response to TNF-α in cultured MDCK cells. The lipopolysaccharide (LPS) model of AKI yields subtle pathologic findings on light microscopy, raising concern that this model's injury is chiefly hemodynamic, as opposed to structural. We hypothesized that LPS would cause a disruption in tubular TJ proteins such as Zona Occludens-1 (ZO-1) and Occludin.

Methods: C57/BL6 mice were injected with LPS (10 mg/kg) and sacrificed 6, 24, and 48 h after injection. Kidney cortex was harvested and prepared for analysis by light microscopy, immunoblot, immunofluorescence, and RT-PCR for occludin, ZO-1, and claudin-1. AKI was confirmed via measurement of blood urea nitrogen and creatinine.

Results: Immunoblot showed significantly decreased ZO-1 expression by densitometry 24 h after LPS (decrease of 56.0 +/- 4.6%, $p = 0.009$), with recovery at 48 h. However, ZO-1 mRNA was unchanged at 24 h, with a trend for increase at 48 h (increase of 68.0 +/- 11.9% from baseline, $p = 0.12$). Immunofluorescence 24 h after LPS revealed a marked change in ZO-1 localization from its usual circumferential pattern to one with greater fragmentation, decreased basolateral staining, and greater apical distribution. Staining showed decreased tubular co-localization of occludin and ZO-1. Occludin and claudin-1 protein and RNA expression were not significantly altered at 24 h.

Conclusions: ZO-1 protein expression after LPS administration was markedly decreased at 24 h, with subsequent recovery at 48 h. Membrane localization of TJ proteins was disrupted by LPS. As RNA expression was unchanged, the results suggest disruption of renal tubular epithelial TJs in LPS-induced AKI is not mediated by transcriptional regulation, but may involve degradation or protein trafficking. This study provides important evidence that LPS-induced AKI is associated with structural injury and not merely hemodynamic changes.

Dexamethasone Attenuates Septic Acute Kidney Injury by Reducing Apoptosis of Spleen Immune Cells and Renal Tubule Cells Hye Min Choi,[1] So-Young Lee,[2] Sang-Kyung Jo,[1] Won-Yong Cho,[1] Hyoung-Kyu Kim,[1] Young Youl Hyun,[3] Dae R. Cha.[3] *[1]Nephrology, Korea University Hospital, Seoul; [2]Nephrology, Eulji University Hospital; [3]Nephrology, Korea University Hospital, Ansan.*

Background: Sepsis is the most common cause of acute kidney injury (AKI) in hospitalized patients and the clinical outcome is very poor, whereas our understanding of pathogenesis and treatment for septic AKI has remained limited. Low-dose glucocorticosteroids (GCs) has been clinically recommended in refractory septic shock patients through Surviving Sepsis Campaign, and in rat endotoxemia model, GCs were shown to ameliorate renal dysfunction. However, the mechanisms for the beneficial effects of GCs on septic shock and possibly on septic renal injury are still unclear. In this study, we purposed to investigate the pathophysiology of septic AKI and the effect of GCs using septic mice.

Methods: We induced AKI by polymicrobial sepsis using a CLP (cecal ligation and punture) model in 8~10wk-old C57BL/6 mice. Saline or dexamethasone (DEX) dissolved in saline was administered right after CLP surgery. We examined hemodynamic, biochemical and histological changes in a time-course manner.

Results: Mean arterial Blood pressure (BP) significantly decreased starting at 3hr after CLP. Fractional shortening which estimate cardiac systolic function significantly increased and remained high until 24hr, suggesting hyperdynamic "warm shock" state. Serum Creatinine started to increase after 12hr. Many apoptotic cells were observed even at 3hr after CLP in spleen and mainly located in lymphoid tissue. Renal tubular apoptosis was also prominent in cortex and outer medulla although acute tubular necrosis or infiltration of neutrophils and macrophages was not distinct.

We compared hemodynamics, renal function and apoptosis of tissues between CLP and CLP+DEX. BP, Heart rate and fractional shortening was not significantly different between CLP and CLP+DEX. However mice with CLP+DEX had a significant reduction in serum creatinine and decreased apoptosis of spleen and kidney compared to CLP.

Conclusions: DEX attenuates septic AKI, and the beneficial effect might be associated with reduced apoptosis of renal tubule cells and spleen immune cells.

Calpain 10 Loss Mediates Increased Susceptibility to Nephrotoxicity Ryan Whitaker, Marisa D. Covington, Matthew Allen Smith, Rick G. Schnellmann. *Pharmaceutical and Biomedical Sciences, Medical University of South Carolina, Charleston, SC.*

Background: Age and certain disease states such as diabetes predispose humans to AKI; however, few studies have examined the mechanism of increased sensitivity to AKI in these patient populations. Our laboratory has determined that calpain 10 protein and mRNA is down-regulated in aged kidneys from multiple species. In addition, recent studies showed that mitochondrial calpain 10 is decreased in a rat model of diabetes and renal calpain 10 mRNA is decreased in human diabetics. Furthermore, knock down of mitochondrial calpain 10 in renal proximal tubular cells (RPTC) alone disrupts mitochondrial functions as evidenced by accumulation of mitochondrial calpain 10 substrates, and decreased basal and uncoupled respiration. The goal of these experiments is to test the hypothesis that decreased calpain 10 sensitizes RPTC to toxicant injury.

Methods: We used adenovirus delivered shRNA to knock down calpain 10 in RPTC. Controls received adenovirus delivered scrambled shRNA. Two days later, RPTC were exposed to paraquat (100-300 μM), or $HgCl_2$ (0.1-3 μM) for 24 hours. Cell death was measured via propidium iodide staining. Additionally, RPTC were cultured in high (17 mM) glucose as a cellular model of diabetes for 48 hours. Control cells were cultured in normal (5 mM) glucose. RPTC were then exposed to 100 uM paraquat μM for 24 hours. ATP levels were measured by using an ATP Determination Kit (Invitrogen).

Results: RPTC treated with adenovirus delivered calpain 10 shRNA exhibited 62% and 84% increases in cell death with paraquat and $HgCl_2$ respectively, compared to controls. RPTC cultured in 17 mM glucose media demonstrated a 75% greater reduction in ATP levels when exposed to paraquat compared to 5 mM glucose controls.

Conclusions: We hypothesize that the loss of renal calpain 10 in aging or diabetes leads to accumulation of mitochondrial calpain 10 substrates, causing mitochondrial dysfunction; thereby, sensitizes RPTC to a "second hit" such as I/R or drug/toxicant-induced injury that initiates AKI. Because calpain 10 is ubiquitously expressed, these findings may have broader implications in other tissues and disease states.

STAT3 Activation Via Tyrosine Phosphorylation Is Cytoreductive during Cisplatin-Induced Acute Kidney Injury Robert L. Safirstein,[0071] Judit Megyesi,[0071] Adel Tarcsafalvi,[0071] Rawad Hodeify,[0071] Peter M. Price.[0071] *[1]Medicine Service, Central Arkansas Veterans Healthcare System, Little Rock, AR; [2]Department of Internal Medicine, University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: The Stat3 transcription factor is a member of a family proteins that play a significant role in signal transduction from cytokine and chemokine receptors. We showed that Stat3 is activated during cisplatin-induced acute kidney injury at both serine

and tyrosine residues. Transduction of proximal tubule cells with a dominant negative (DN) Stat3(tyr) construct renders them resistant to oxidant stress showing that the Stat3 tyrosine phosphorylation is cytoreductive during oxidant-induced injury.

Methods: We transduced proximal tubule cells with a DN-Stat3(tyr) construct and created a transgenic mouse strain in which the DN-Stat3(tyr) cDNA was conditionally expressed in proximal tubule cells under the control of the testosterone-responsive KAP2 promoter.

Results: Transduced cells were resistant to cisplatin-induced apoptosis. The transgenic mouse strain showed significant protection from cisplatin-induced AKI, as creatinine levels in serum 3 days after cisplatin exposure were reduced from (mean and SE) 2.37 ± mg/dL (wt) to 0.84 ± .42 in transgenic mice ($p<01$). Similarly, morphologic protection from cisplatin cytotoxicity was also conferred by transgene expression.

Conclusions: These studies identify the Stat3 protein as a significant target of both cisplatin and oxidant injury to kidney cells. Furthermore, these transgenic animals should help to identify the link between proximal tubule damage, cytokine expression, leukocyte activation and physiologic events downstream of Stat3(tyr) phosphorylation.

Essential Role for Apoptosis Signal-Regulating Kinase 1 in Free Light Chain-Mediated Apoptosis Wei-Zhong Ying,[1,2] Pei-Xuan Wang,[1,2] Paul W. Sanders.[1,2] *[1]Medicine, University of Alabama at Birmingham, AL; [2]Medicine, Birmingham Veterans Affairs Medical Center, Birmingham, AL.*

Background: A major attendant complications of multiple myeloma is renal failure, which is related to deposition of monoclonal immunoglobulin free light chains (FLC) and directly contributes to morbidity and mortality in this disease. Because our prior studies demonstrated that FLC generated intracellular oxidative stress, the present studies focused on the redox-sensitive mitogen-activated protein kinase kinase kinase known as Apoptosis Signal-regulating Kinase 1 (ASK1).

Methods: The mechanism of cytotoxicity of monoclonal FLC was determined by incubating human proximal tubular epithelial cells (HK-2) in medium containing two human monoclonal FLC (termed κ2 and λ3). Cytoplasmic caspase 3 and 9 activities were determined using ELISA. The percentage of apoptotic cells in each population of HK-2 cells was determined by flow cytometry using MitoTracker® Red and annexin V conjugated to Alexa Fluor 488. RNA interference was accomplished using small interfering RNA (siRNA) that targeted human ASK1. Western analyses determined ASK1 protein levels, using rabbit-anti-human polyclonal antibody to ASK1, and activity, by use of an antibody that detected phosphorylated ASK1 at residue T845.

Results: Incubation of HK-2 cells with each FLC, 1 mg/ml, promoted activation of caspase 9 and caspase 3. Therefore, the intrinsic (mitochondrial) pathway mediated FLC-induced apoptosis. A time-dependent increase in phosphorylation of ASK1 at T845, indicating activation of this enzyme, was also observed. Incubation of HK-2 cells for 24 and 48 hours with either FLC increased the apoptotic rate. siRNA designed to reduce ASK1 expression in HK-2 cells successfully decreased ASK1, which was confirmed by western blot analysis. Incubation of ASK1-depleted HK-2 cells with the two FLC prevented the increase in apoptosis, while pre-treating HK-2 cell with non-targeting siRNA did not prevent FLC-mediated apoptosis.

Conclusions: Monoclonal FLC triggered the intrinsic apoptotic pathway in renal epithelial cells by activation of ASK1. The ASK1 pathway provides a potential therapeutic target in renal failure in multiple myeloma.

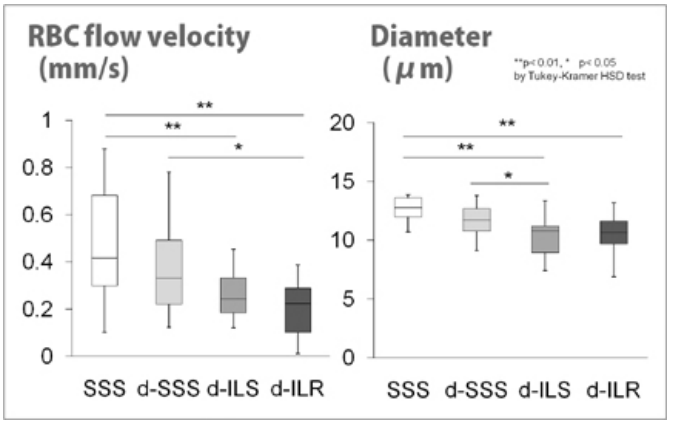
Renal Peritubular Hypoperfusion in Subcapsular Cortex Is Inversely Correlated with Urinary L-FABP in Mouse Radiocontrast-Induced Acute Kidney Injury Kousuke Negishi,[1] Eisei Noiri,[1] Kent Doi,[1] Toshiro Fujita,[1] Takeshi Sugaya.[2] *[1]Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan; [2]CMIC Co., Ltd., Tokyo, Japan.*

Background: Radiocontrast-induced AKI (RC-AKI) is characterized by maldistribution of renal microcirculation. We recently demonstrated that L-type fatty-acid binding protein (L-FABP) expressed in human and mouse proximal tubules was markedly upregulated in ischemic conditions, and shed into the urine via hypoxia response element in its promoter region. The aim of this study is to evaluate the correlation between urinary L-FABP and renal peritubular capillary (PTC) blood perfusion in RC-AKI.

Methods: Mice were subjected unilateral nephrectomy 7 days before RC injection. After water restriction/ dehydration for 24 h, mice were intraperitoneally injected indomethacin (I), L-NAME (L) and low-osmolar RC iohexol (3g Iodine/kg, R). Equivalent volume of saline was injected as control for each reagent (S). In addition to serial urine and blood sampling, renal PTC blood flow of subcapsular cortex at 12 h was directly monitored by intravital CCD video-microscope.

Results: Urinary L-FABP in dehydrated (d-) mice with I, L, and R injection (d-I-L-R) at 12 h significantly increased up to 3000-fold from the baseline. BUN was also peaked at 12 h. PTC flow velocity and diameter in the d-I-L-R group was significantly decreased than that in mice injected saline alone (S-S-S). Moreover, log converted urinary L-FABP was inversely correlated with the lowest PTC flow velocity at 12h ($r2 = 0.248$, $p = 0.022$). Histological analysis revealed vacuolation and increased L-FABP expression in proximal tubules were limited to the d-I-L-R group.



Conclusions: Not only direct tubular toxicity but PTC hypoperfusion in subcapsular cortex is suggested to induce shedding of L-FABP into the urine in RC-AKI.

Afferent Arterioles but Not Efferent Constrict to Iodinated Contrast Media in Mice – A New Feature in the Pathophysiology of Contrast Induced Nephropathy Zhizhao Liu, Vinicius Urbano Viegas, Andrea Perlewitz, Pontus Persson, Andreas Patzak, Mauricio Michalak Sendeski. *Institut für Vegetative Physiologie, Charité-Universitätsmedizin, Berlin, Germany.*

Background: Contrast induced nephropathy (CIN) is an important cause for in-hospital acute kidney injury. A key feature of the pathophysiology of CIN is the reduction in renal blood flow. We investigated the influence of iodinated contrast media (CM) on afferent and efferent arterioles which help explain disturbances of renal hemodynamic present in CIN.

Methods: Afferent and efferent arterioles were isolated from C57Bl6 mice and perfused with either vehicle solution or 23mg iodine/ml CM. L-NAME (10-4 mol/l), a non-selective nitric oxide synthesis inhibitor, was also applied to investigate a possible role of nitric oxide. Angiotensin II concentration responses (10-12 to 10-6 mol/l) were performed after 20 minute treatment. Changes in luminal diameter were used for analysis of vessel tone and reactivity.

Results: Diameters of afferent arterioles were significantly reduced by treatment with CM (86.3%), L-NAME (70.7%), and CM+L-NAME (52.9%) compared to the control group. CM+L-NAME induced a significantly more pronounced constriction than CM alone. Moreover, subsequent angiotensin II application showed a further more pronounced constriction. This constriction was concentration dependent and increased after CM and CM+L-NAME treatment, but not after L-NAME alone. In contrast, neither the diameters of efferent arterioles after 20 minute treatment nor the responses to angiotensin II were significantly affected by CM.

Conclusions: The result shows a stronger effect of CM on afferent arterioles tone and reactivity compared to efferent arterioles. Moreover, CM+L-NAME constricts afferent arterioles more than CM alone, reinforcing that other mechanisms besides nitric oxide contribute to the CIN blood flow disturbances. Our results suggest an important contribution of afferent arterioles for the reduction in renal blood flow and in glomerular filtration rate observed in CIN.

Deletion of Longevity Gene p66ShcA Rescues Cisplatinum-Induced Acute Renal Failure Rungwasee Rattanavich, Fnu Washdave, Partab Rai, Dileep Kumar, Mohammad Husain, Ashwani Malhotra, Pravin C. Singhal. *Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY.*

Background: Cisplatimum has been demonstrated to induce acute renal failure both in human and animal experimental models. Cisplatinum directly causes tubular cell apoptosis. This cytotoxic effect of cisplatinum has been attributed to the induction of reactive oxygen species (ROS) generation. p66ShcA$^{-/-}$ mice have been demonstrated to have ROS resistance phenotype and have diplayed a longer life span when compared to normal mice. In addition, deletion of p66ShcA in both cardiac and renal genomes has been demonstrted to provide protection agaist glucose induced injury in diabetic animal experimental animal models. On that account, we hypothesized that p66ShcA$^{-/-}$ mice would also display resistant to cytotoxic tubular cell injury induced by cisplatinum. In the present study, we evaluated whether cisplatinum would be able to induce acute renal failure in p66ShcA$^{-/-}$ mice.

Methods: Control and p66ShcA$^{-/-}$ mice in groups of four were administered either vehicle or cisplatinum (12.5 mg/Kg, intraperitoneal). All mice were sacrificed on day 3; urine and blood samples were collected for BUN and albumin: creatinine ratio. Kidneys were harvested for renal histology and TUNEL staining. Immmunoblots were prepared from renal tissues and evaluated for the activation of the redox-sensitive stress response program in the form of phosphorylation of Foxo3A.

Results: Control mice receiving cisplatinum displayed elevated BUN (68.0 ± 7.0 mg/dl) when compared to control mice receiving vehicle (40.9 ± 2.0 mg/dl). However, p66ShcA$^{-/-}$ mice receiving-cisplatinum displayed nomrla levels of BUN (34.0 ± 8.0 mg/dl). Number of TUNEL +ve cells was many fold greater in control mice-receiving cisplatinum when

compared to p66ShcA$^{-/-}$ mice-receiving cisplatinum. Control mice-receiving cisplatinum displayed inactivation of redox-sensitive stress response program; whereas, p66ShcA$^{-/-}$ mice-receiving cisplatinum showed adequate response of the stress response program.

Conclusions: These findings indicate that deletion of p66ShcA from renal cell genome provides protection against cisplatinum induced acute renal failure.

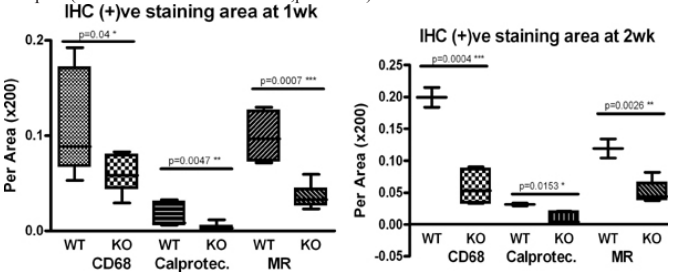
The Role of Mannose Receptor in Acute Folic Acid Nephritis Hsu-Han Wang,[1] Sally Hamour,[2] Ruth J. Pepper,[1] Mark Little,[1] H. Terence Cook,[2] Alan D. Salama.[1] *[1]Centre for Nephrology, University College London, United Kingdom; [2]Renal Medicine, Imperial College London, United Kingdom.*

Background: Folic acid (FA) induces acute tubular injury, characterised by tubular apoptosis/necrosis, followed by both repair and scarring and is associated with macrophage infiltration. FA nephritis is therefore a good model of acute renal failure secondary to tubular damage. We have previously demonstrated requirement of mannose receptor (MR) for induction of immune mediated glomerulonephritis, and we have now evaluated the role of MR in acute kidney injury.

Methods: MR+/- mice and control WT C57BL6 mice were used at 8-12 weeks age. Folic acid 240mg/kg was injected intraperitoneally with 0.2ml $NaHCO_3$ as vehicle. Mice are sacrificed at 7 or 14 days after injection. We assessed renal function, histological damage (by acute tubular injury score) and degree of macrophage/cell infiltration (by staining for CD68, calprotectin, and mannose receptor) which was enumerated using Image Pro software.

Results: At day 7 following injury, serum urea/creatinine were similar between WT and MR+/- mice; however, acute tubular injury score was higher in WT mice (46.0±1.4 vs 20.5±3.7,p=0.009). WT mice had greater activated macrophage infiltration than MR+/-, assessed by CD68 staining (relative area 0.113±0.025 vs 0.061±0.006,p=0.04) and greater levels of calprotectin (0.016±0.006 vs 0.004±0.0009,p=0.0047) and predictably mannose receptor (0.099±0.012 vs 0.036±0.004,p=0.0007).



Two weeks following injury, there was increased staining in the WT mice (0.199±0.016 for CD68, 0.031±0.002 for calprotectin and 0.119±0.015 for mannose receptor) compared to MR+/- animals (0.058±0.010, 0.009±0.004, 0.049±0.007, respectively), all p<0.05.

Conclusions: Mannose receptor insufficiency protects mice from acute macrophage mediated kidney damage and may be a novel non-immunosuppressive therapeutic target for acute kidney injury.

SA-PO2185

Adrenomedullin Has Protective Effects on Renal Descending Vasa Recta and Endothelian Cells Against Functional and Morphologic Impairment by Iodinated Contrast Media Mauricio Michalak Sendeski,[1] Anja Bondke Persson,[1] Pontus Persson,[1] Andreas Patzak.[1] *[1]Institut fuer Vegetative Physiologie, Charite Universitaetsmedizin Berlin, Berlin, Germany; [2]Uppsala University, Sweden.*

Background: Contrast induced nephropathy (CIN), a complication of iodinated contrast media (CM), is a frequent cause of acute kidney injury. Renal medullary ischemic damage is a hallmark of CIN. CM causes functional impairment of isolated outer medullary descending vasa recta (DVR) and lower endothelial nitric oxide production. We investigated the effect of adrenomedullin—an endogenous peptide with endothelial protective effects—in the prevention of CM deleterious effects on DVR and endothelial cells from renal interlobar arteries.

Methods: We studied isolated, perfused DVR and interlobar arteries from Sprague-Dawley rats. Iodixanol, a dimeric non-ionic CM, was applied intraluminally to DVR and interlobar arteries using microperfusion techniques (23mg iodine/ml). Control experiments used vehicle solution. Diameter changes of DVR were serially monitored. The reactivity to angiotensin II was tested after 20 minutes of CM application. The inner surface of fixated interlobar arteries was studied with scan electron microscopy (SEM). Adrenomedullin (10-7M) was applied intra- and extra-luminally to DVR and interlobar arteries, with and without concomitant use of CM.

Results: Perfusion with CM caused a marked constriction of DVR (nearly 50% of initial diameter). CM induced anatomical damage of endothelial cells from interlobar arteries (nuclear protrusion, cell shrinking, fenestration of the endothelial layer, and "blebbling"). Adrenomedullin significantly prevented DVR constriction and increased DVR response to angiotensin II. Structural damage of endothelial cells was also effectively prevented by adrenomedullin.

Conclusions: Adrenomedullin is effective in preventing structural damage and vascular functional changes caused by CM. Our results point out that avoiding the structural damage of endothelial cells may also prevent functional changes caused by CM on DVR. This suggests that prophylaxis of CIN should focus on the prevention of cell damage by CM in order to diminish overall renal tissue injury by CM.

SA-PO2186

Bactericidal Antibiotics Temporarily Increase Inflammation and Worsen Acute Kidney Injury in Experimental Sepsis Anan Chuasuwan,[1] Zhiyong Peng,[1] Hongzhi Wang,[1,2] Nattachai Srisawat,[1] Xiao-Yan Wen,[1] Thomas Rimmelé,[1] Jeffery Bishop,[1] Kai Singbartl,[1] Raghavan Murugan,[1] John A. Kellum.[1] *[1]Department of Critical Care Medicine, Clinical Research, Investigation, and Systems Modeling of Acute Illness (CRISMA), University of Pittsburgh, Pittsburgh, PA; [2]Beijing Cancer Hospital & Institute, Beijing, China.*

Background: Acute kidney injury (AKI) is a common disorder in critically ill patients, and mortality reaches 70% when combined with sepsis. Bactericidal antibiotics release bacterial products including pathogen-associated molecular patterns (PAMPs) which could trigger inflammation and induce or worsen severity of AKI.

Methods: Sepsis was induced by cecal ligation and puncture (CLP) in fifty-two Sprague-Dawley rats and was treated with either bactericidal antibiotics (ampicillin/sulbactam) or placebo (saline). Serial blood specimens were obtained from 18 hrs up to day 7 after CLP for serum creatinine, interleukin (IL)-6, and neutrophil gelatinase-associated lipocalin (NGAL) concentrations. RIFLE criteria were used to assess severity of AKI. All animals were observed for survival at one week. In a separate experiment, 12 animals were sacrificed 2 days after CLP for histology.

Results: Survival in placebo-treated animals was 50% compared to 82% with antibiotics (P <0.05). Most animals (93%) without antibiotics developed AKI, of which 39% exhibited greater than a 3-fold rise in serum creatinine (RIFLE-F). Furthermore, survival decreased as AKI severity increased. Surprisingly, all animals treated with antibiotics developed AKI, of which 68.6% reached RIFLE-F. However, renal dysfunction was less persistent in antibiotic-treated animals indicated by both serum creatinine and plasma NGAL concentration. Patterns of plasma IL-6 were similar to creatinine. Histological findings were consistent with functional parameters showing that antibiotics worsened AKI.

Conclusions: Bactericidal antibiotic therapy during sepsis improved survival but resulted in higher IL-6 concentration and more severe AKI. Animals without antibiotics had less evidence of early inflammation and AKI but failed to recover. Mortality was associated with failure to recover from AKI.

SA-PO2187

The Constant Region Contributes to the Antigenic Specificity and Potential Nephritogenicity of Anti-DNA Antibodies Chaim Putterman, Yumin Xia. *Albert Einstein College of Medicine.*

Background: Certain IgG subclasses are particularly enriched in kidney Ig eluates in active lupus nephritis, suggesting that antibody (Ab) isotype is one important feature determining the outcome of Ab binding to renal antigens. Although the variable region was believed to be the sole determinant of antigenic specificity, more recent studies have shown that isotype switching leads to altered binding of a protective Ab. Our hypothesis was that Ab isotype may affect the renal pathogenicity of anti-DNA Ab, by influencing antigen binding.

Methods: PL9-11 is an IgG3 anti-DNA Ab isolated from a MRL/+ mouse. To obtain IgG1, IgG2b and IgG2a forms of this Ab, the PL9-11 hybridoma clone was isotype switched in vitro by stimulation with IL-4 and TGF-β. The PL9-11 (IgM) variant was generated by cloning the PL9-11 VDJ into an IgM expression vector, followed by transfection into a cell line expressing only the PL9-11 light chain. The affinity/specificity of the PL9-11 Ab panel were analyzed by ELISA, surface plasmon resonance, and cross-inhibition. Antigenic specificity was studied by binding to mesangial cells, isolated glomeruli, and glomerular proteome arrays. Finally, renal deposition and pathogenicity were assayed by analyzing kidneys of SCID mice injected with the PL9-11 Ab panel.

Results: We found that PL9-11 and its isotype switched variants had differential binding to ssDNA, dsDNA, chromatin and mesangial cells in order of IgG3>IgG2a>IgG1>IgG2b>IgM. This order of relative affinities of the different IgG isotypes for dsDNA was confirmed in a competition ELISA. In contrast, in binding to Matrigel, laminin, and collagen IV the IgG2a isotype actually had the highest affinity, followed by IgG3>IgG1>IgG2b>IgM. In concert with ELISA assays, assessing antibody specificity in glomerular proteome arrays also revealed significant differences between the members of the PL9-11 panel in binding to multiple antigens.

Conclusions: Our data suggest that the constant region plays an important role in the affinity and specificity of anti-DNA Ab, and that IgG2a and IgG3 isotypes may be more nephritogenic due to higher potential for binding to multiple glomerular and nuclear antigens.

TWEAK/Fn14 Pathway Blockade Attenuates Renal Disease in Autoantibody-Induced Nephritis Chaim Putterman,[1] Jennifer Michaelson,[2] Linda Burkly.[2] *[1]Albert Einstein College of Medicine; [2]Biogen Idec.*

Background: TNF-superfamily members are instrumental in the pathogenesis of lupus nephritis. Previously, we found that TWEAK (TNFSF12)-mediated activation of its receptor, Fn14, stimulates the secretion of MCP-1, RANTES, IP-10 and KC by mesangial

cells and podocytes. TWEAK also modulates renal cell survival and proliferation. Thus, we hypothesized that TWEAK blockade may be therapeutically beneficial in autoantibody-mediated nephritis.

Methods: Nephrotoxic serum nephritis (NTN), a murine model for lupus nephritis, was used to study the role of the TWEAK/Fn14 pathway in the pathogenesis of renal disease induced by pathogenic antibodies.

Results: We induced NTN by passive transfer of pre-formed nephritogenic rabbit antibodies into 129 Fn14 knockout (KO) and wildtype (WT) mice that had been preimmunized with heterologous rabbit IgG. On days 7, 14, and 21 after antibody transfer, Fn14KO mice had significantly decreased levels of proteinuria as compared to Fn14 WT mice (day 7: 61±24 vs 220±42 mg/dl, $p<0.01$; day 14: 99±50 vs. 678±205 mg/dl, $p=0.02$; day 21: 101±49 vs 678±205 mg/dl, $p=0.02$). Moreover, crescent formation and tubular dilatation were significantly decreased in Fn14KO mice, as were MCP-1, RANTES, and IP-10 kidney mRNA expression levels. To confirm the protective effect of TWEAK inhibition with a pharmacological approach, we induced nephrotoxic nephritis in 129 Fn14 WT mice and initiated treatment with an anti-TWEAK mAb or isotype matched control Ig. Similar to results in Fn14KO mice, significant amelioration of proteinuria and improvement in renal histology was observed in mice with induced nephritis receiving treatment with anti-TWEAK mAb. Anti-TWEAK mAb treatment did not appear to affect the systemic immune response, as no alteration in murine anti-rabbit IgG subclass antibody titers was evident.

Conclusions: TWEAK/Fn14 interactions promote the pathogenesis of nephritis in the NTN model, likely playing a role in pathologic events locally in the kidney rather than impacting the systemic immune response. Thus, disrupting TWEAK/Fn14 interactions may be an innovative approach for the treatment of lupus and other antibody-induced renal diseases.

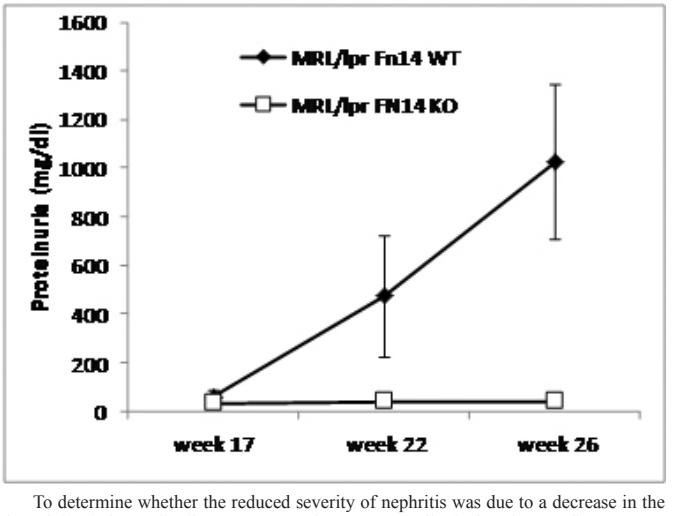
Deficiency of the TWEAK Receptor Fn14 Is Protective in the MRL/lpr Mouse Model of Lupus Nephritis Chaim Putterman,[1] Jennifer Michaelson,[2] Linda Burkly.[2] *[1]Albert Einstein College of Medicine; [2]Biogen Idec.*

Background: Renal mesangial cells and podocytes express Fn14, the receptor for TWEAK (TNFSF12). TWEAK engagement of Fn14 induces kidney resident cells to produce multiple inflammatory mediators including MCP-1 and RANTES, which have been linked to the pathogenesis of lupus nephritis. In cGVH induced nephritis, genetic deficiency of Fn14, or treatment with an anti-TWEAK mAb, decreases kidney inflammation and proteinuria without affecting autoantibody titers. These studies suggested that inhibition of TWEAK/Fn14 might be efficacious in spontaneous models of lupus.

Methods: We assessed the role of the TWEAK/Fn14 pathway in the pathogenesis of lupus nephritis (LN) by evaluating the effect of Fn14 deficiency in the MRL/lpr spontaneous mouse model of lupus.

Results: We found that kidney Fn14 was significantly increased in MRL/lpr mice at 26 as compared to 7 weeks of age, while splenic Fn14 expression actually decreased over time. Kidney TWEAK expression also increased over time in MRL/lpr mice, and was significantly higher by 19 as compared to 7 weeks, and when compared to MRL/+ mice.

At 26 weeks MRL/lpr Fn14 WT mice (n=10) had significantly higher levels of proteinuria as compared to MRL/lpr Fn14KO (n=9).



To determine whether the reduced severity of nephritis was due to a decrease in the titer of circulating antibodies, we compared serum autoantibody titers in MRL/lpr Fn14WT and KO mice. There were no differences between the groups in anti-dsDNA antibody titers, suggesting that TWEAK likely acts by modulating events locally in the kidney.

Conclusions: TWEAK/Fn14 interactions are instrumental in the pathogenesis of LN in the MRL/lpr mouse model. Our results suggest that blocking the effects of TWEAK may be a novel therapeutic approach to the treatment of the kidney disease associated with SLE, without inducing systemic immunosuppression.

Activated Protein C Attenuates Systemic Lupus Erythematosus and Lupus Nephritis in MRL-Fas(lpr) Mice Julia Lichtnekert, Khader Valli Rupanagudi, Onkar Kulkarni, Hans J. Anders. *Medizinische Poliklinik, LMU, Klinikum der Universitat Munchen, Munich, Germany.*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease leading to inflammatory tissue damage in multiple organs, e.g. lupus nephritis. Current treatments including steroids, antimalarials, and immunosuppressive drugs have significant side effects. Activated protein C (APC) is a natural protein with anticoagulant and immunomodulatory effects and its recombinant version has been approved by the FDA to treat severe sepsis. Given the similarities between overshooting immune activation in sepsis and autoimmunity, we hypothesized that recombinant APC would also suppress SLE and lupus nephritis.

Methods: Autoimmune female MRL-Fas(lpr) mice were injected with either vehicle or recombinant human APC from week 14 to 18 of age.

Results: APC treatment significantly suppressed lupus nephritis as evidenced by decrease in activity index, glomerular IgG and complement C3 deposits, macrophage counts as well as intrarenal IL-12 expression. Further, APC attenuated cutaneous lupus and lung disease as compared to vehicle-treated MRL-Fas(lpr) mice. In addition, parameters of systemic autoimmunity, such as plasma cytokine levels of IL-12p40, IL-6, CCL2/MCP-1 and numbers of B cells and plasma cells in spleen were suppressed by APC. The latter was associated with lower total plasma IgM and IgG levels as well as lower titers of anti-dsDNA IgG and rheumatoid factor.

Conclusions: Together, recombinant APC suppresses the abnormal systemic immune activation in SLE of MRL-Fas(lpr) mice which prevents subsequent kidney, lung and skin disease. These results implicate that recombinant APC might be useful for the treatment of human SLE.

Serum IgG Binding to Human Mesangial Cells in Patients with Lupus Nephritis and Its Correlation with Disease Activity Desmond Y.H. Yap, Susan Yung, Owen Chan, Qing Zhang, Daniel Tak Mao Chan. *Department of Medicine, University of Hong Kong, China.*

Background: Mesangial immunoglobulin deposition is a hallmark in lupus nephritis. We previously demonstrated that human anti-dsDNA antibodies could bind to human mesangial cells (HMC). In this study we investigated the binding activity of serum IgG to HMC and its correlation with clinical parameters in lupus patients.

Methods: Serial serum samples were obtained from 23 patients with biopsy-proven diffuse proliferative lupus nephritis over a mean follow-up of 74 months. Binding activity (expressed as OD) of total serum IgG and its subclasses (IgG_1, IgG_2, IgG_3, IgG_4) to HMC was measured using a cellular ELISA and its correlation with clinical or laboratory parameters investigated. Sera from 23 healthy individuals were used as controls.

Results: A total of 189 samples were collected - 48 samples during active and 141 during inactive disease, defined according to clinical assessment. Binding of serum total IgG to HMC was 0.12±0.09, 0.59±0.37 and 0.74±0.43 OD for healthy controls, inactive lupus, and active lupus respectively (P=0.023 active vs inactive, P<0.001 controls vs active or inactive disease). Binding of serum IgG_1 to HMC was 0.05±0.05, 0.41±0.38 and 0.55±0.40 OD for the three groups respectively (P=0.037 active vs inactive, P<0.001 controls vs active or inactive disease). Controls and lupus patients did not differ in the binding of serum IgG_2, IgG_3 or IgG_4 to HMC. HMC-binding activity of total IgG and IgG_1 correlated with anti-dsDNA antibody levels (r=0.26 and 0.39 respectively, P<0.001 for both), and inversely correlated with C3 levels (r=-0.17 and -0.45 respectively, P<0.05 for both). No correlation was observed between IgG binding to HMC and clinical parameters such as serum creatinine, albumin, or proteinuria. Sensitivity/specificity of total IgG or IgG_1 binding to HMC in the prediction of renal flare in the patients was 81.3%/39.7% (ROC AUC 0.61, P=0.03) and 83.3%/41.8% (AUC 0.63, P=0.009) respectively.

Conclusions: We conclude that total IgG and IgG_1 in the serum of patients with lupus nephritis bind significantly to mesangial cells, especially during flare, and this binding correlated with the level of anti-dsDNA antibodies.

Involvement of $CD11b^+$ $GR\text{-}1^{low}$ Cells in Autoimmune Disorder in MRL-*Fas^{lpr}* Mouse Yasunori Iwata, Kengo Furuichi, Takashi Wada. *Nephrology, Kanazawa University, Kanazawa, Ishikawa, Japan.*

Background: Myeloid derived suppressor cells (MDSCs) have been identified as immunosuppressive cells in tumor related inflammation. However, the pathogenesis of MDSCs for autoimmune disease has not been investigated yet. The aim of this study is to address whether MDSCs contribute to autoimmune organ injury in lupus prone mice.

Methods: MDSCs were analyzed by flow cytometric staining of $CD11b^+$ $GR\text{-}1^+$ in MRL-*Fas^{lpr}* mice. $CD4^+$ T cell proliferation assay was performed by the co-culture with $CD11b^+$ $GR\text{-}1^+$ splenocytes. The percentage of immunosuppressive cells was examined during disease progression. The expression of chemokine receptor on immunosuppressive cells was analyzed. Moreover, chemotaxis assay was performed.

Results: $CD11b^+$ $GR\text{-}1^{low}$ cells had a suppressive effect on $CD4^+$ T cell proliferation, which was restored by an arginase-1 inhibitor. $CD11b^+$ $GR\text{-}1^{low}$ cells increased in percentage during disease progression in kidney and blood. The number of migrated $CD11b^+$ $GR\text{-}1^{low}$ cells increased in the presence of monocyte chemoattractant protein (MCP)-1/CCL2.

Conclusions: We assessed the involvement of $CD11b^{+}$ $GR\text{-}1^{low}$ cells in autoimmune disorder in MRL-*Fas*^{lpr} mice. These cells regulate immunological responses via CCL2/CCR2 signaling. The regulation of immunosuppressive monocytes may provide novel therapeutic strategy for organ damage in autoimmune diseases.

Anti-Glomerular Basement Membrane Antibodies Against Certain Linear Epitopes on Goodpasture Antigen Are Associated with Clinical Phenotypes and Disease Severity Zhao Cui, Xiao-Yu Jia, Rui Yang, Ming-Hui Zhao. *Renal Division, Department of Medicine, Peking University First Hospital, Beijing, China.*

Background: Anti-glomerular basement membrane (GBM) disease could be initiated by nephrogenic linear epitopes which stimulate both T and B cell responses in experimental autoimmune glomerulonephritis. Linear epitopes involved in human anti-GBM disease have not been fully defined. In this study, we investigated the linear epitopes recognized by circulating antibodies in sera from patients with anti-GBM disease, aiming to identify the potential nephrogenic linear epitopes and their clinical and pathological significance.

Methods: 68 patients with anti-GBM disease were enrolled. A panel of 23 overlapping linear peptides was synthesized across the whole sequence of human α3(IV)NC1. Among them, P14 contained the previous known immunodominant regions E_B and a T cell epitope of patients. Circulating antibodies against linear epitopes were detected by enzyme-linked immunoabsorbent assay. The associations between linear epitopes recognition and clinical and pathological data of patients were further analyzed.

Results: Antibodies against linear peptides were detected in sera from 55 (80.9%) patients. Three major epitopes were identified with high frequencies: P14 (amino acid residues 131-150) 41%, P16 (amino acid residues 161-180) 36.8% and P18 (amino acid residues 181-200) 57%. Antibodies against P14 were frequently detected in patients with positive ANCA (39.3% vs. 12.5%, P=0.010). Patients with antibodies against P16 presented with higher concentration of serum creatinine on diagnosis (665.5±227.2 vs. 443.7±296.8 μmol/L, P=0.001). The levels of antibodies against P18 were positively correlated with the percentage of crescentic formation in glomeruli (r=0.54, P=0.008).

Conclusions: Antibodies against certain linear epitopes could be detected in patients with anti-GBM disease and were associated with clinical phenotypes and disease activity. Antibodies against P14 were associated with coexistence of ANCA. Antibodies against P16 and P18 were associated with the severity of crescentic glomerulonephritis.

Extensive Antigen Receptor Editing Modifies Autoimmunity in Anti-Glomerular Basement Membrane Disease Inge Maria Schudel, Melissa L. Weston, Amy G. Clark, Mary H. Foster. *Medicine, Duke University Medical Center and DVAMC, Durham, NC.*

Background: In anti-glomerular basement membrane disease autoantibodies against the NC1 domain of the alpha3 chain of type IV collagen can lead to autoimmune nephritis and severe kidney damage. To determine the origins of and tolerance mechanisms regulating the pathogenic autoantibodies, we developed an anti-alpha3(IV)NC1 IgM/kappa autoantibody transgenic (Tg) mouse model. Initial analysis of immunoglobulins (Ig) in serum and on spleen B cell surfaces revealed that anti-alpha3(IV)NC1 B cells are regulated by deletion and receptor editing that replaces Tg with endogenous Ig receptors. To further examine the extent and nature of editing and to dissect independent Ig chain contributions within individual anti-alpha3(IV)NC1 B cells, we used a combined genetic and cell fusion approach.

Methods: Anti-alpha3(IV)NC1 Ig Tg mice were bred with mice carrying a knockout of both endogenous kappa alleles, such that any kappa light chain derives only from the transgene. Spleen B cells from four mice then were fused with myeloma cells. The resulting hybridoma cells were analyzed by ELISA and PCR for expression of Tg (IgMa, kappa) and endogenous (IgMb, lambda) Ig.

Results: Of 65 IgM-secreting hybridomas recovered (mean 16 clones/spleen), 60% secrete variable amounts of transgenic IgMa and/or kappa chain. Strikingly, 94% of hybridomas show editing, detected as secretion of endogenous IgMb, lambda, or both (82%). In addition, differentiation of the four murine lambda subtypes by PCR shows restricted lambda chain usage.

Conclusions: These results indicate that extensive heavy and light chain editing occurs at the single cell level to modify expression of pathogenic anti-GBM autoantibodies. Ongoing studies should shed light on the molecular basis for this unexpected requirement for multiple editors and provide insights into disease origins.

SA-PO2195

Modifiers of Susceptibility to Anti-Glomerular Basement Membrane Antibody Disease in Fc Gamma Receptor 2B Deficient Mice Ruth M. Tarzi,[1] Phoebe E.H. Sharp,[1] Javier Martín Ramírez,[2] Sara M. Mangsbo,[2] John Reynolds,[1] Charles D. Pusey,[1] H. Terence Cook,[1] Sjef Verbeek.[2] [1]*Renal Department, Imperial College, London, United Kingdom;* [2]*Department of Human Genetics, Leiden University Medical Center, Leiden, Netherlands.*

Background: Anti-glomerular basement membrane antibody disease (anti-GBM disease) is an autoimmune disease, leading to crescentic glomerulonephritis. Fc gamma receptor 2B (Fcgr2B) is the only inhibitory Fc receptor for IgG in humans and mice. The purpose of this study was to compare the susceptibility to anti-GBM disease of mice lacking Fcgr2B on a pure C57BL/6 background (Fcgr2B-B6), with mice lacking Fcgr2B created in 129 embryonic stem cells and backcrossed to C57BL/6 (Fcgr2B-129/B6), therefore having 129 sequences flanking the Fcgr2B deletion. We then compared the susceptibilty of mice with cre-mediated conditional deletion of Fcgr2B on B cells and monocytes/macrophages to anti-GBM disease.

Methods: Anti-GBM disease was induced by subcutaneous immunization with a recombinant peptide of the NC1 domain of alpha 3 Type IV collagen at day 0, with boosts at day 7, 14 and 21. Mice were sacrificed 20 weeks after immunization.

Results: In two experiments, there was a higher incidence of crescentic glomerulonephritis in Fcgr2B-129/B6 mice compared with Fcgr2B-B6 mice (Experiment 1: 6/8 (75%) vs 2/8 (25%) vs WT (0/4) (0%); Experiment 2: 8/12 (66%) vs 4/11(37%) vs WT 1/9 (11%). However, in those mice that developed disease, there was no difference in the severity of the crescentic glomerulonephritis.

In the second part of the experiments, 4/11 (37%) Fcgr2B-B6 mice developed crescentic glomerulonephritis, compared to 2/9 Fcgr2B-CD19cre mice (22%), 1/12 Fcgr2B-LysM mice (8%) and 1/9 WT mice (11%).

Conclusions: The incidence of crescentic glomeruonephritis was higher in the Fcgr2B-129/B6 mice than the Fcgr2B-B6 mice, indicating that genetic modifiers located near to Fcgr2B on the 129 genome increase the tendency of Fcgr2B-/- mice to develop anti-GBM disease.

Secondly, Fcgr2B-LysM mice had the same incidence of anti-GBM disease as WT mice. Our preliminary results indicate that loss of Fcgr2B on B cells alone did not increase the incidence of anti-GBM disease as much as the full deletion.

Pathogenesis of IgA Nephropathy: Characterization of the Kinetics and Site-Specificity of GalNAc-Transferase 2, the Enzyme Initiating O-Glycosylation of IgA1 Kazuo Takahashi,[1] Milada Horynova,[2,1] Milan Raska,[2,1] Stacy D. Hall,[1] Bruce A. Julian,[1] Zina Moldoveanu,[1] Jiri F. Mestecky,[1] Matthew B. Renfrow,[1] Jan Novak.[1] [1]*University of Alabama at Birmingham, AL;* [2]*Palacky University in Olomouc, Olomouc, Czech Republic.*

Background: IgA1 with galactose-deficient hinge-region (HR) *O*-glycans (Gd-IgA1) plays a key role in IgA nephropathy (IgAN). IgA1 HR has up to 6 of the 9 potential *O*-glycosylation sites occupied; some Gd glycans consist of terminal *N*-acetylgalactosamine (GalNAc). As *O*-glycosylation of IgA1 is initiated by a GalNAc-transferase, namely GalNAc-T2, understanding the kinetics and site-specificity of this enzyme will provide insight into the pathogenesis of IgAN.

Methods: We used recombinant GalNAc-T2 in an *in vitro* system to study kinetics of site-specific glycosylation using high-resolution mass spectrometry (MS). We used two synthetic HR peptides (sHR) as acceptors: VPSTPPTPSPSTPPTPSPSC (short sHR) and VPSTPPTPSPSTPPTPSPSCCHPR (long sHR)

Results: Time-course analysis showed that the number of added GalNAc residues increased with time. GalNAc-T2 showed higher activity, *i.e.,* faster rate of glycosylation, with long sHR than with short sHR. The reaction reached plateau when seven sites were glycosylated in the long sHR and eight sites were glycosylated in short sHR. Thus, the sequence and length of acceptor substrate affect *O*-glycosylation, particularly the maximal number of GalNAc residues attached and the kinetics of the reaction. sHR *O*-glycoforms were subjected to tandem MS to localize glycosylated sites. GalNAc-T2 added GalNAc residues in an ordered fashion: to T7 first and then to T15, followed by S11, T4, S9, S17 and S19. Glycosylation sites on sHR were consistent with the sites previously described on IgA1, except the last two sites, S17 and S19, that are not usually glycosylated in serum IgA1. S230, the dominant site with terminal GalNAc in Gd-IgA1 myeloma proteins that mimic Gd-IgA1 from patients with IgAN, corresponds to S9 in sHR; this site is ineffectively glycosylated by GalNAc-T2.

Conclusions: Detailed studies of GalNAc-T2 kinetics and specificity using this new tool will yield new information relevant to the pathogenesis of IgAN.

Funding: NIDDK Support

SA-PO2197

Effect of gp130 Cytokines on IgA1-Producing Cells from Patients with IgA Nephropathy Koshi Yamada,[1,2] Milan Raska,[1,5] Zina Moldoveanu,[1] Hitoshi Suzuki,[2,1] Krzysztof Kiryluk,[3] Bruce A. Julian,[1] Robert J. Wyatt,[4] Yasuhiko Tomino,[2] Jiri F. Mestecky,[1] Ali G. Gharavi,[3] Jan Novak.[1] *[1]University of Alabama at Birmingham, AL; [2]Juntendo University, Tokyo, Japan; [3]Columbia University, New York, NY; [4]University of Tennessee, Memphis, TN; [5]Palacky University, Olomouc, Czech Republic.*

Background: A recent GWAS study identified five loci associated with IgA nephropathy (IgAN). One locus was Chr. 22q12.2 that includes genes encoding Leukemia Inhibitory Factor (LIF) and Oncostatin M (OSM), IL-6-related cytokines using gp130 for signal transduction and implicated in mucosal immunity and inflammation. As Chr. 22q12.2 has been associated with serum IgA, LIF and OSM are candidate cytokines to be tested for their effect on IgA1-producing cells.

Methods: Using EBV-immortalized IgA1-secreting cell lines derived from the circulation of patients with IgAN (IgAN cells) and healthy controls (HC cells), we assessed the effects of LIF and OSM, and IL-6 as a control, on IgA1 production and its *O*-glycosylation. Expression of genes encoding the corresponding receptors (IL-6R1, 2, 3; OSMR1, 2; and LIFR) and glycosyltransferases (C1GalT1, GalNAc-T2, GalNAc-T14) was measured by RealTime RT-PCR. IgA level and IgA1 galactose (Gal) deficiency were determined by ELISA.

Results: IgAN and HC cells expressed IL-6R1, 2, 3, OSMR1, and low levels of LIFR, but not OSMR2. Cytokines LIF, OSM, and IL-6 affected IgA1 production in all cells, but increased Gal deficiency of IgA1 only in IgAN cells. In IgAN cells, but not in HC cells, all three cytokines influenced the expression of glycosyltransferases: decreased for C1GalT1 and increased for GalNAc-T2. The expression of GalNAc-T14 has not changed in IgAN cells, but decreased significantly in the HC cells in response to stimulation with each cytokine.

Conclusions: In summary, gp130 cytokines in Chr. 22q12.2 locus affected IgA1-producing cells from IgAN patients and induced differential gene expression of specific glycosyltransferases that may lead to aberrant *O*-glycosylation of secreted IgA1.

Funding: NIDDK Support

SA-PO2198

Characterization of Galactose-Deficient IgA1 Secreted by IgA1-Producing Cell Lines: Implication for Pathogenesis of IgA Nephropathy Kazuo Takahashi,[1] Hitoshi Suzuki,[2,1] Koshi Yamada,[1] Stacy D. Hall,[1] Zina Moldoveanu,[1] Bruce A. Julian,[1] Knud Poulsen,[3] Jiri F. Mestecky,[1] Matthew B. Renfrow,[1] Jan Novak.[1] *[1]University of Alabama at Birmingham, AL; [2]Juntendo University, Tokyo, Japan; [3]Aarhus University, Aarhus, Denmark.*

Background: IgA1 with galactose (Gal)-deficient hinge-region (HR) *O*-glycans plays a key role in IgA nephropathy (IgAN). We established IgA1-producing cells derived from the circulation of IgAN patients and healthy controls (HC). IgA1 secreted by cells from IgAN patients has more Gal-deficient *O*-glycans with terminal or sialylated *N*-acetylgalactosamine (GalNAc) compared to IgA1 from HC cells. To define the glycosylation patterns, including the sites of glycan attachment, we analyzed IgA1 produced by cells derived from an IgAN patient (IgAN-IgA1) and a HC (HC-IgA1).

Methods: IgA1 was treated with bacterial IgA-specific proteases (AK183, TIGR4, or HK50) followed by trypsin and HR glycopeptides were characterized by high-resolution mass spectrometry (MS). Relative abundance of each glycopeptide was expressed as % of total HR.

Results: The number of *O*-glycans per HR ranged from 3 to 6, with 4 to 6 being most abundant on IgAN-IgA1 and 3 to 5 predominating on HC-IgA1. HR variant with 3 *O*-glycans was fully galactosylated; it was the predominant variant in HC-IgA1 but not in IgAN-IgA1 (17.9% vs. 0.8%). N-terminal HR (H208-P227) released by TIGR4 was glycosylated in 98.2% as a disaccharide in IgAN-IgA1 compared to 80.2% in HC-IgA1. This indicated that a disaccharide attached at S224 or T225 was present in the HR with 4 to 6 *O*-glycans, as there was no *O*-glycan at S224/T225 in HR with 3 *O*-glycans in HC-IgA1. Gal-deficient HR variants were more common in IgAN-IgA1 than in HC-IgA1 (24.5% vs. 15.9%). A Gal-deficient GalNAc was detected in N-terminal HK fragment of HR (T228 or S230) and in C-terminal HK fragment of HR (S232 to R245). These findings were corroborated by lectin blotting.

Conclusions: Thus, we confirmed the glycosylation abnormality of *O*-glycans on IgA1 in IgAN using high-resolution MS. This new tool provides useful information relevant to IgAN pathogenesis through the identification of distinct glycosylation patterns.

Funding: NIDDK Support

SA-PO2199

Role of GalNAc-Transferases in the Synthesis of Aberrant IgA1 *O*-glycans in IgA Nephropathy Milan Raska,[1] Koshi Yamada,[1] Milada Horynova,[2,1] Kazuo Takahashi,[1] Hitoshi Suzuki,[3,1] Zina Moldoveanu,[1] Jana Novakova,[2] Alena Kasperova,[2] Bruce A. Julian,[1] Krzysztof Kiryluk,[4] Jiri F. Mestecky,[1] Matthew B. Renfrow,[1] Ali G. Gharavi,[4] Jan Novak.[1] *[1]University of Alabama at Birmingham, AL; [2]Palacky University, Olomouc, Czech Republic; [3]Juntendo University, Tokyo, Japan; [4]Columbia University, New York, NY.*

Background: IgA nephropathy (IgAN) is an autoimmune disease in which IgA1 with galactose (Gal)-deficient *O*-glycans in the hinge region (HR) plays a key role as the autoantigen. The mechanisms involved in the formation of the aberrant glycans are not well understood, but likely include changes in the expression, activity, and/or localization of enzymes involved in the individual glycosylation steps. *O*-glycans of normal IgA1 consist of *N*-acetylgalactosamine (GalNAc) and Gal, with possibly one or both residues sialylated, whereas IgA1 in the circulation and renal deposits of patients with IgAN has some *O*-glycans deficient in Gal. *O*-glycan formation is initiated by attachment of GalNAc to the serine or threonine in IgA1 HR, catalyzed by a GalNAc-transferase (GalNAc-T).

Methods: It has been speculated that GalNAc-T2 is responsible for initiation of *O*-glycosylation in IgA1. However, our recent *in vitro* studies with recombinant GalNAc-T2 demonstrated that some sites with Gal-deficient glycans are added by this enzyme ineffectively, suggesting involvement of another GalNAc-T. Therefore, we analyzed by RealTime RT-PCR the expression of GalNAc-T1 to -T14 in EBV-immortalized IgA1-producing cells derived from blood of IgAN patients and healthy controls.

Results: GalNAc-T14 was among the major GalNAc-Ts transcribed in IgA1-producing cells and its expression was 5-fold greater in the cells from the patients *vs.* the cells from healthy controls. The expression of GalNAc-T2, and other GalNAc-Ts, did not differ between patients and healthy controls.

Conclusions: Based on these results, we speculate that the expression profile of a specific GalNAc-T, such as over-expression of GalNAc-T14, contributes to production of Gal-deficient IgA1 *O*-glycans in patients with IgAN.

Activated Innate Immunity and Involvement of the CX3CR1-FKN Axis in Promoting Hematuria in IgA Nephropathy Patients Sharon N. Cox,[1] Fabio Sallustio,[1,2] Grazia Serino,[1,2] Antonia Loverre,[1] Francesco Pesce,[1] Patrizia Stifanelli,[3] Nicola Ancona,[3] Gianluigi Zaza,[1] Francesco Paolo Schena.[1,2] *[1]Dept. of Emergency and Organ Transplant, Univ. of Bari, Bari, Italy; [2]C.A.R.S.O. Consortium, Valenzano, Bari, Italy; [3]ISSIA, CNR, Bari, Italy.*

Background: The hallmark of IgA nephropathy (IgAN) is gross hematuria (GH) coinciding with or immediately following a respiratory or gastrointestinal tract infection and can represent the disease triggering event.

Methods: Therefore, a whole genomic screening of IgAN patients during the GH was done to clarify the link between mucosal encountered antigens and the occurrence of glomerular hematuria.

Results: The modulated genes during GH showed a clear involvement of the interferon signalling, antigen presenting pathway, and the immuno-proteasome. The gene characterizing cytotoxic effector lymphocytes (*CX3CR1*), implicated in vascular endothelial damage, was found up-regulated at both mRNA and protein level. *In vitro* antigenic stimulation of PBMCs on an independent set of IgAN patients and healthy blood donors (HBD) demonstrated that patients upregulate specifically CX3CR1 in an enhanced and dose dependant manner, while an expected down-regulation occurred in HBD. This enhanced activation occurred in patients both characterized by recurrent GH and by permanent microscopic hematuria (MH). We then analyzed glomerular fractalkine (FKN) expression, since this ligand is involved in the vascular gateway for $CX3CR1^+$ cells towards the inflamed tissues. A significantly higher FKN expression on the capillary vessels and podocytes was found in IgAN patients with recurrent GH compared to permanent MH, suggesting a predisposition for cytotoxic cell extravasation in recurrent GH patients.

Conclusions: Taken together, our findings demonstrate, for the first time, a defect in antigen handling in PBMCs of IgAN patients with a specific up-regulation of CX3CR1. Furthermore, the constitutive up regulation of glomerular FKN, suggests an involvement of the CX3CR1-FKN axis in the exacerbation of GH.

SA-PO2201

IgA-IgG Immune-Complex Formation by Marginal Zone B Cells Is Crucial for the Progression of Murine IgA Nephropathy Keiko Okazaki,[1] Yusuke Suzuki,[1] Mareki Ohtsuji,[2] Qingshun Lin,[2] Sachiko Hirose,[2] Yasuhiko Tomino.[1] *[1]Division of Nephrology, Department of Internal Medicine, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Second Department of Pathology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: Splenic marginal zone B cells (MZB) are potentially poly-reactive and their expansion might be associated with autoimmune diseases, such as SLE or rheumatoid arthritis. Although the pathogenesis of IgA nephropathy (IgAN) has not been clarified, the recent studies have suggested that IgAN may be related to autoimmune disorders including immune-complex (IC) formation with aberrantly glycosylated IgA1 as an auto-antigen. The objective of the present study is to verify whether MZB contribute to the pathogenesis of murine IgAN.

Methods: Two IgAN prone mice, high IgA mice (HIGA) and grouped ddY mice (gddY) that we recently established as 100% onset model (J Am Soc Nephrol, 2005), were employed for present study.

Results: When we evaluated HIGA (N=5) and gddY (N=5) at 12 weeks of age, only gddY showed severe glomerular damage with increased massive albuminuria. Flow cytometry analysis showed that the numbers of MZB ($B220^+CD21^{high}CD23^{low/negative}$) and their precursors ($B220^+IgM^{high}CD21^{high}CD23^+$) in gddY were significantly higher than those in HIGA (gddY vs. HIGA; MZB: 6.1±0.9x106 vs. 3.8±0.6x106, P=0.002, precursors: 2.6±0.6x106 vs. 1.4±0.2x106, P=0.002), suggesting that MZB may be involved in the progression of murine IgAN. For further confirmation, MZB in gddY at 4 weeks of age were selectively depleted by anti-LFA and anti-CD49d monoclonal antibodies. Clinical outcomes (depleted mice; N=5 vs. isotype-control mice; N=5) at 14 days after the treatment were as follows; albuminuria (ng/day): 40.9±19.2 vs. 230.6±146.4 (P=0.02), serum IgA (mg/dl): 47.1±8.5 vs. 43.2±6.4 (P=0.44), serum IgG (mg/dl): 40.9±7.4 vs. 71.1±14.4

(P=0.003), serum IgA-IgG IC (OD): 0.16±0.03 vs. 0.2±0.03 (P=0.05) and intensity of glomerular depositions: IgA, 97.6±13.0 vs. 103.5±9.8 (P=0.49) and IgG: 79.4±11.1 vs. 105.2±11.8 (P=0.02).

Conclusions: MZB may contribute to the progression of murine IgAN via nephritogenic IgA-IgG IC formation.

SA-PO2202

B Cell Depleting Therapies Protect Mice from Adriamycin Nephropathy by Reducing Natural Antibody IgM Joshua M. Thurman, Derek Strassheim, Magdalena Glogowska. *Medicine, University of Colorado School of Medicine, Aurora, CO.*

Background: Recent reports suggest that rituximab, a monoclonal antibody that depletes B cells, may be an effective treatment for some patients with focal segmental glomerulosclerosis (FSGS). It has long been noted that IgM and C3 are detectable in the mesangium of patients with FSGS. We hypothesized that natural antibody IgM binds to specific epitopes expressed in the injured mesangium, and that depletion of this antibody may be a mechanism by which immunosuppressive therapies are protective in FSGS.

Methods: To test this hypothesis, we induced adriamycin nephropathy (AN) in Balb/c mice after injecting them with a monoclonal antibody to murine CD20 or with vehicle control. FACS analysis of peritoneal B cells confirmed that the antibody depleted B-1 cells (the primary source of natural antibody).

Results: Mice treated with anti-CD20 displayed reduced glomerular IgM and C3 when assessed by quantitative immunofluorescence microscopy. The degree of albuminuria was also reduced in the anti-CD20 group compared to the control group (10,500 vs. 19,000 mcg alb/mg creatinine; P = 0.056). To confirm that protection was due to depletion of B-1 cells, we induced AN in another cohort of mice after depleting peritoneal B cells by hypotonic shock. This treatment did not reduce the levels of circulating IgM compared to control animals, but it did reduce glomerular IgM, C3, and collagen IV deposition. It also significantly reduced the degree of albuminuria (16,916 vs. 31,860 mcg alb/mg creatinine; P < 0.05).

Conclusions: Regarded together, these results demonstrate that therapies that deplete peritoneal B-1 cells reduce binding of IgM within the mesangium of mice with AN and prevent glomerular complement activation. These B cell targeting therapies reduce glomerular injury and albuminuria. These experiments reveal a novel mechanism of glomerular injury in FSGS. Our results also suggest that therapies that can specifically target B-1 B cells or that block the glomerular epitope(s) may be effective for the treatment of FSGS.

Anti-LAMP-2 Antibody Responses Correlate with Clinical Relapse and Demonstrate Epitope Spreading during the Evolution of ANCA Associated Pauci-Immune FNGN Andrew J. Rees, Renate Kain. *Clinical Department of Pathology, Medical University of Vienna, Vienna, Austria.*

Background: Autoantibodies to lysosome associated membrane protein-2 (LAMP-2) are highly prevalent in patients with active untreated ANCA associated pauci-immune FNGN but their pathogenicity is uncertain. Autoantibodies to LAMP-2 commonly bind two well-characterised epitopes as well as other less frequently recognised epitopes. The present study was designed to answer two questions: do antibodies to LAMP-2 correlate with clinical relapse; and does the antibody response demonstrate epitope spreading.

Methods: We analysed 274 sera from 39 patients with ANCA associated piFNGN (mean: 6.9 sera per patient). Seventeen were recruited at presentation and 22 later in the disease and subsequently followed for 4 to 12 months. The sera were assayed for antibodies to LAMP-2 by our standard ELISA with recombinant human LAMP-2 expressed in E.coli as substrate. The range of epitopes they recognised was assessed in 3 parallel ELISA with overlapping HIS-tagged fusion proteins expressed in E.coli spanning the hLAMP-2 extracellular domain as substrates. These were designated: hL2/1 (187 amino acids), hL2/2 (181 amino acids) and hL2/3 (111 amino acids) respectively.

Results: Antibodies to LAMP-2 were detected in 56 of 62 (90.3%) sera from patients with active disease - 15 at onset and 41 during relapse - but in only 7 of 212 (3.3%) sera collected from those without signs of active disease. There was a highly significant difference in the breadth of specificity of anti-LAMP-2 antibodies detected at presentation and those detected during relapse: at presentation 8 of 15 (53.3%) reacted with a single peptide; 5 reacted with 2 peptides; and 2 (13.3%) reacted with all three peptides. Whereas during relapse: 15 (36.6%) of 41 sera reacted with all three peptides; 5 bound to 2 peptides and 16 (39%) reacted with a single peptide. Six sera with antibodies to LAMP-2 failed to react with individual peptides, possibly because of conformational differences between them and full length LAMP-2.

Conclusions: Antibodies to LAMP-2 correlate with active disease in piFNGN and demonstrate epitope spreading from presentation to relapse. This suggests they may be pathogenic.

SA-PO2204

Strain Differences in Vasculitis Development upon Administration of Polyclonal and Monoclonal Anti-MPO Antibodies Mirjan M. Van Timmeren, Betty S. Van der Veen, Arjen H. Petersen, Coen A. Stegeman, Peter Heeringa. *Medical Biology, UMCG, Groningen, Netherlands.*

Background: Polyclonal antibodies against myeloperoxidase (MPO) induce vasculitis and crescentic glomerulonephritis (GN) in C57BL/6 (B6) mice. Whether the pathogenic potential of anti-MPO IgG is restricted to a specific subclass and/or epitope is unknown. Our previously generated panel of monoclonal anti-MPO antibodies (anti-MPO moAbs) did not induce GN in B6 mice. However, genetic variation can determine disease susceptibility, hence other mouse strains may be more susceptible.

Aim

To compare vasculitis development in C57Bl/6 (B6), 129S6 (129) and DBA/1 mouse strains upon polyclonal and monoclonal anti-MPO antibodies.

Methods: Mice were injected with polyclonal anti-MPO IgG (1 mg; iv; n=6/group), a mix of three anti-MPO moAbs of different subclass and recognizing different epitopes (10 mg; ip; n=3-6/group) or isotype control moAbs. This was followed by ip LPS injection (150 EU/g). Mice were sacrificed at day 7.

Results: Polyclonal anti-MPO IgG induced GN in B6 and 129 mice, as evidenced by leukocyturia, albuminuria and crescent formation. DBA/1 mice did not develop GN.

Anti-MPO moAbs also induced GN in B6 and 129 mice. DBA/1 mice did not develop GN, but displayed profound lung hemorrhage with inflammatory lesions (neutrophil and macrophage influx). Also, DBA/1 mice displayed liver inflammation and an increase in serum alanine aminotransaminase (ALAT, 66.4±34.1 vs 19.2±7.2 u/L in isotype controls, p<0.01). Isotype control moAbs did not induce disease.

Conclusions: Polyclonal anti-MPO IgG induce GN in B6 and 129 mice, but not in DBA/1 mice. Also, anti-MPO moAbs induce GN in B6 and 129 mice. DBA/1 mice do not develop GN, but develop lung hemorrhage and liver inflammation. DBA/1 mice can potentially serve as a model for anti-MPO IgG-mediated lung vasculitis.

Is CD177 (NB1) Sufficient for the Membrane Expression of PR3 in Myeloid Cells? Veronique Witko-Sarsat,[1] Arnaud Millet,[1] Magali Pederzoli-Ribeil,[1] Luc Mouthon.[2] *[1]Cochin Institute Immunology-Hematology Department, INSERM U1016- University René Descartes, Paris, France; [2]Internal Medine Department, Cochin Hospital, Paris, France.*

Background: Proteinase 3 (PR3), the auto-antigen in granulomatosis with polyangiitis, is a granular serine-proteinase, which is also present at the plasma membrane in a stable neutrophil subset. ANCA binding to PR3 at the surface of primed neutrophils results in their activation. In neutrophils, PR3 has been shown to be associated with CD177 (also called NB1) is a GPI-anchored glycoprotein, which is expressed on the same neutrophil subset than PR3. It has been proposed that CD177 is essential for PR3 membrane expression in the basal state.

Methods: The rat basophilic cell line (RBL) has been used to study the molecular mechanisms leading to PR3 membrane expression after degranulation or apoptosis but unfortunately, RBL-PR3 do not display PR3 membrane expression under the resting state as neutrophil do. The hypothesis was that CD177 favors PR3 membrane expression by binding to PR3 thus resulting in its membrane targeting and surface expression. We generated stable RBL transfectant expressing either human CD177 or human PR3 or both. Membrane expressions of CD177 or PR3 were studied by flow cytometry under basal conditions or following ionophore-induced degranulation or gliotoxin-induced apoptosis.

Results: Stable human CD177-transfected cells show a membrane expression under the basal state in wild type RBL as well as RBL-PR3. However, in RBL-PR3 CD177 failed to trigger PR3 membrane expression under the basal state. After degranulation or apoptosis PR3 membrane expression was similar in RBL PR3 and RBL-PR3 CD177. However, we confirmed that CD177 is a receptor for extracellular PR3, as demonstrated by the binding of exogenous PR3 to RBL-CD177 in the basal state contrary to RBL WT.

Conclusions: We concluded that CD177 appears to be a partner of PR3, which could play a role as a receptor for extracellular PR3, but it seems to be insufficient for PR3 membrane targeting in the basal state in a cell model of neutrophils.

De Novo Protein Synthesis of PR3 and MPO Autoantigens in Mature Neutrophils of Patients with ANCA Vasculitis Anshul K. Badhwar,[1] Elizabeth A. Alderman,[1] Akhil Muthigi,[1] Heng Ge,[1,2] Elisabeth Berg,[1] J. Charles Jennette,[1] Gloria A. Preston,[1] Ronald J. Falk.[1] *[1]UNC Kidney Center, University of North Carolina at Chapel Hill, NC; [2]Xian Jiaotong University, Xian City, Shaanxi Province, China.*

Background: Due to a defect in epigenetic silencing, circulating neutrophils from patients with ANCA disease express PR3 and MPO genes which are normally expressed only in bone marrow cells. We examine the processing of transcripts in mature neutrophils and whether increased transcription results in increased PR3/MPO protein.

Methods: A psoralen-biotin RNA probe complementary to sense PR-3 and MPO was used for hybridization on northern blot. Total RNA from 9 patients and 9 healthy donors was used to characterize the transcripts present. Quantitative RT-PCR of PR3 and MPO transcripts was used to confirm expression levels detected by northern blotting. Nascent protein synthesis was metabolically labeled with a methionine analog, selectively biotinylated, purified by magnetic streptavidin beads and detected by western blotting.

Results: Multiple isoforms of PR3 transcripts were observed by northern blotting of leukocyte RNA from patients with PR3-ANCA. Five of nine patients expressed at least one isoform of PR3 mRNA, and of the five, three patients expressed an alternatively spliced variant larger (approx. 100 to 400 additional nucleic acids) than currently annotated size. Unexpectedly, PR3 transcripts were also detected in three of nine healthy controls. Northern blotting was determined to be quantitative and correlated with levels of expression of both PR3 and MPO by standardized qRT-PCR assay. A novel polyadenylation site distal to the canonical site was associated with expression in circulating mature neutrophils and monocytes. Upregulation of PR3 and MPO transcripts was associated with de novo protein synthesis in four of four patients with MPO-ANCA. None of the 8 healthy donors tested produced significant levels of either protein.

Conclusions: The data indicate that neutrophils in the periphery produce both PR3 and MPO protein de novo and that the presence of previously unidentified isoforms of PR3 may lead to the production of altered forms of PR3 protein.

SA-PO2207

Membrane Association of Proteinase 3, the Autoantigen in Granulomatosis with Polyangiitis (GPA), Expressed at the Membrane of Apoptotic Neutrophils, Is Essential for Impairing Their Phagocytosis by Macrophages Veronique Witko-Sarsat,[1] Arnaud Millet,[1] Magali Pederzoli-Ribeil,[1] Luc Mouthon.[2] *[1]Cochin Institute Immunology-Hematology Department, INSERM U1016- University René Descartes, Paris, France; [2]Internal Medicine Department, Cochin Hospital, Paris, France.*

Background: The removal of apoptotic neutrophils is a key event in the resolution of inflammation, its failure has been incriminated in chronic autoimmune diseases. We described that proteinase 3 (PR3) the autoantigen in granulomatosis with polyangiitis (GPA) was externalized during apoptosis and impaired the phagocytosis of apoptotic neutrophils by macrophages thus acting as a dont eat me signal (Kantari et al, Blood 2007). The aim of the study was to investigate whether PR3 membrane expression and/or its enzymatic activity was essential for this activity

Methods: Stable transfectant in RBL cells expressing a mutant of PR3 (PR34H4A) inable to insert into the plasma membrane was generated. The phagocytosis of apoptotic RBLPR34H4A by human monocyte-derived macrophages was studied in comparison with wild type RBLPR3. The enzymatic activity of apoptosis-induced membrane PR3 was studied for its ability to cleave extracellular matrix proteins such as fibronectin.

Results: The mutations of four hydrophobic (F180, F181, L228, F229) amino acids abrogated PR3 membrane anchorage and cells expressing this hydrophobic patch-deficient PR3 mutant (PR34H4A) did not inhibit macrophage phagocytosis thus confirming this importance of PR3 membrane association in this phenomena. We demonstrated that this "dont eat me" activity of membrane-associated PR3 was independent of its serine proteinase activity because 1) the enzymatically-dead mutant PR3S203A displayed the same activity and 2) that apoptosis-induced PR3 externalization did not result in an increased ability to cleave extracellular matrix proteins such as fibronectin.

Conclusions: Our conclusion is 1) that the molecular basis of PR3 "dont-eat-me signal" relies more on PR3 membrane anchorage but not on its enzymatic activity and ii) that PR3 "dont-eat-me" activity might potentiate the mechanisms of autoimmunity and be involved in the pathophysiology of ANCA-associated vasculitis.

SA-PO2208

Endothelial Lineage Impairment and Increased PR3 Expression on Peripheral Cells of Endothelial Phenotype in Wegener´s Granulomatosis Susann Patschan,[1] Daniel Patschan,[1] Sabine Blaschke,[1] Gerhard A. Mueller.[1] *[1]Nephrology and Rheumatology, University Hospital Göttingen, Göttingen, Niedersachsen, Germany; [2]Göttingen; [3]Göttingen.*

Background: Wegener´s Granulomatosis (WG) is characterized by microvascular endothelial damage and by alterations of the endothelial progenitor cell (EPC) system. Interactions between anti-Proteinase 3 antibodies and their respective antigens (PR3) on neutro-phils are pathogenetically relevant in WG. Aim of this study was (I) to analyze total circulating EPCs and regenerative activity of blood-derived EPCs, and (II) to evaluate PR3 expression patterns on circulating myelomonocytic and endothelial cells in WG.

Methods: Blood samples from WG patients were analyzed for total and for Flk-1+ myolomono-cytic cells. Healthy donors served as controls. For evaluating the proliferative activity of EPCs, a colony forming unit assay (CFU) was performed. PR3 expression by the cells was quantified by cytometric analysis. Serum Angiopoietin 1 and serum TNF-α were measured by ELISA.

Results: A total of 21 healthy donors (12 female, 9 male [40.3 ±9.2 years]) and 31 WG patients (13 female, 18 male [59.2 ±15.3 years]) were included into the study. The total percentages of EPCs were not different between the two groups. WG patients displayed lower proliferate activity of EPCs. In addition PR3 expression was significantly higher in the total as well as in the Flk-1+ (sub)population of myelomonocytic cells in WG. Finally, WG patients showed lower mean serum levels of Angiopoietin 1 and higher mean serum levels of TNF-α as compared to controls, the serum levels of both cytokines did not linearily correlate with either clinical activity or the total number of circulating EPCs or the numbers of colonies formed (EPC regeneration).

Conclusions: In addition to reduced EPC regeneration and decreased serum levels of Angiopoietin 1, both indicating impairement of the endothelial system, patients with WG show sig-nificantly increased expression of PR3 in the total and in the Flk-1+ myelomonocytic cell population. These data imply, that PR3 could be involved in the pathogenesis of microvascular endothelial damage in patients with WG.

SA-PO2209

C4d in Thrombotic Microangiopathy: Cause or Consequence? Jamie S. Chua, Hans J. Baelde, Ingeborg M. Bajema, Jan A. Bruijn, Danielle Cohen. *Pathology, Leiden University Medical Center, Leiden, Netherlands.*

Background: Complement activation, whether caused by excessive activation or inadequate regulation, is known to play a major role in thrombotic microangiopathy (TMA). We previously showed that glomerular C4d deposition is associated to development of TMA in patients with lupus nephritis and antiphospholipid syndrome (APS). The aim of this study was to investigate whether C4d is also present in other forms of TMA and whether this marker for classical complement activation could identify patients with an antibody- or immune complex mediated TMA.

Methods: We investigated the presence of C4d and MBL depositions on 47 renal biopsies or autopsies with histologically proven TMA. Patients were divided into 2 groups: A first group with TMA in association with auto- or alloimmune disease (including SLE, APS, renal transplantation and stemcell transplantation) (n=27) and a second group of patients with clinically confirmed Hemolytic Uremic Syndrome (HUS) (n=20). Deposition patterns of C4d and MBL were scored blindly and semi-quantitatively in glomeruli, peritubular capillaries (PTC), arterioles and arterial branches.

Results: In general, C4d deposition was found in 94% of TMA cases, independent of the underlying clinical setting. Glomerular C4d deposition was present in 85% of allo- and autoimmune cases and in 80% of HUS cases (P=0,456). Arteriolar C4d deposition was found in 48% of allo- and autoimmune cases, in 60% of HUS cases (P=0,421) and was mainly observed in vessels obstructed by microthrombi. Diffuse C4d depositions in PTCs were only present in two cases of *de novo* TMA in renal allografts. Co-localization of C4d with MBL never occurred.

Conclusions: C4d is found in virtually all TMA cases, independent of the underlying clinical condition. Since C4d and MBL do not co-localize, C4d seems to represent classical pathway activation. However, rather than reflecting the cause, the classical pathway may be the consequence of severe endothelial damage or vascular remodeling in TMA. In addition, these data suggest that C5-inhibition (Eculizumab) could benefit the full spectrum of TMA patients, which is in line with recent successful results of C5 inhibitors in Shiga-toxin associated HUS.

Membranoproliferative Glomerulonephritis: Identification of New Diseases Associated Complement Genes Qian Chen,[1] Christoph Licht,[2] Gunter B. Wolf,[3] Christine Skerka,[1] Peter F. Zipfel.[1] *[1]Infection Biology, Leibniz Institue for Natural Product Researach and Infection Biology, Jena, Germany; [2]Hospital for Sick Children, Toronto, Canada; [3]Internal Medicine, University Hospital, Jena, Germany.*

Background: Membranoproliferative glomerulonephritis (MPGN) is a rare kidney disease characterized by hematuria, proteinuria and complement deposit formation, particularly at the glomerular basement membrane of the kidney. In order to define the mechanisms of this severe renal disease, we set up a European MPGN registry. Factor H-, CFHR1-, and Factor B-sequence variations, as well as copy number variations in the Factor H-CFHR gene cluster were assayed for 34 MPGN patients, as well as 67 healthy individuals. Two patients had a three nucleotide deletion causing absence of Lysine 224 in SCR4 Factor H. For the Factor B gene two major allelic variants, i.e. c.95G>A; R32Q- and c.672C>T; Y224Y appeared with higher frequencies in the patients vs controls (0.106 vs. 0.076 and 0.025 vs 0.008, respectively). The CFHR gene cluster shows different CFHR1 haploptypes as well as copy number variations. In the patient group homozygous deletion of a chromosomal segment which includes the CFHR1-CFHR3 genes was more frequent among patients as compared to the control group (Delta CFHR1 17.7%; n=6) vs the control group (Delta CFHR1 3.3%; n=2). The overall frequency of this allelic deletion was similar in both groups, which is explained by a higher frequency of the heterozygous alleles in the control group, suggesting that one copy of CFHR1 has a protective effect. Additional copy number variations were identified in MPGN patients. One patient had three allelic copies of the CFHR3/CFHR1 segment and two related patients showed a novel heterozygous deletion

in exon IV of CFHR2. This deletion correlated with the presence of a new plasma protein, which appeared as a doublet of 65 and 70 kDa bands and which apparently represent different glycosylated forms of a CFHR2-CFHR5 hybrid protein. Thus new gene variations in the Factor H-CFHR gene cluster were identified in the European MPGN registry, indicating a major role of CFHR proteins for disease pathology.

SA-PO2211

Complement-Induced Hemolysis Requires Purinergic Signaling Helle A. Praetorius, Marianne G. Skals, Jens G. Leipziger, Julie L. Hejl. *Dept. of Physiology and Biophysics, Aarhus University, Aarhus, Denmark.*

Background: The complement system is a key element of the innate immune system. The system elicits efficient responses against cells identified as non-self via insertion of Membrane Attack Complexes. It is associated with many types of hemolytic anemia including typical and atypical hemolytic-uremic syndrome as well as paroxysmal nocturnal hemolglobinuria. Recently, we found that hemolysis caused by other types of membrane pore-formers such as α-hemolysin (HlyA) from *Escherichia coli* and α-toxin from *Staphylococcus aureus* inflict their cytotoxic effects through P2 receptor activation.

Methods: To address if P2 receptors are involved in complement-induced lysis, we used simple hemolysis assays of sensitizes human and sheep erythrocytes, combined with time-lapse microscopy.

Results: Here we show that similarly to HlyA-induced hemolysis, red cell lysis caused by complement activation is amplified through ATP release and subsequent P2 receptor activation. Ovine and human erythrocytes were incubated with anti-sheep erythrocyte antibodies or anti-RhD antibodies respectively, with either human plasma or guinea pig serum as complement donors. Non-selective P2 antagonists (PPADS and suramin) concentration-dependently inhibit complement-induced hemolysis. More specific P2 receptor antagonists imply that $P2X_7$ and $P2X_1$ are the main receptors involved in this response. Moreover, complement-activation produced a sustained increase in the $[Ca^{2+}]_i$, which triggered significant erythrocyte shrinkage that preceded swelling and lysis. This early volume reduction is likely to result from activation of the K^+ channel $K_{Ca}3.1$ as TRAM34 and clotrimazole augment the complement-induced hemolysis.

Conclusions: These results indicate that complement, similar to HlyA, requires purinergic signaling for full hemolysis, and that activation of the erythrocyte volume regulation protracts the lysis. This finding points to several new pathways to interfere with hemolytic diseases and implies that P2 receptor antagonists potentially can be used in more broad terms to prevent intravascular hemolysis.

SA-PO2212

A New Model of Atypical Haemolytic Uraemic Syndrome Katherine Anne Vernon, Talat H. Malik, Marina Botto, Matthew C. Pickering. *Centre for Complement and Inflammation Research, Imperial College London, London, United Kingdom.*

Background: Complement factor H (CFH), the major regulator of the alternative pathway, is synthesised by both hepatic and extra-hepatic cells. The physiological role and contribution of extra-hepatic CFH is unknown. Rodent studies suggest that renal-derived CFH is important, with rat podocytes increasing CFH synthesis in membranous nephropathy. To define the physiological roles of hepatic and extra-hepatic CFH we utilised a conditional *CFH* gene-targeted mouse line to generate mice with hepatocyte-specific CFH deficiency.

Methods: Gene targeted mice were generated using recombineering technology in embryonic stem cells. Nephrotoxic nephritis (NTN) was induced using a sheep anti-mouse glomerular basement membrane antibody in pre-immunised animals. Serum CFH, complement component 3 (C3) and urea levels were detected and measured by enzyme-linked immunosorbent assay or Western blot. Haematocrit and peripheral blood film examination were used to assess haematological parameters, whilst histology was examined using light microscopy and immunofluorescence.

Results: Conditional *CFH* gene-targeted animals (in which exons 2 and 3 of the *CFH* gene were flanked by loxP sites) had normal plasma CFH and C3 levels indicating that the conditionally targeted *CFH* gene remained intact. Hepatocyte-specific CFH-deficient mice were generated by inter-crossing these animals with mice expressing Cre recombinase under the control of the murine albumin promoter. Hepatocyte-specific CFH-deficient mice had reduced plasma CFH and C3 levels (15% and 40% of normal respectively). Renal histology (in particular glomerular C3 staining) and urea levels were normal despite the low levels of plasma CFH. However, these animals developed haemolytic uraemic syndrome following induction of NTN, characterised by haemolytic anaemia, thrombocytopaenia and renal failure.

Conclusions: These novel data (1) define the contribution of extra-hepatic CFH to circulating CFH and C3 levels; (2) demonstrate that remarkably low levels of CFH are sufficient to prevent spontaneous glomerular C3 accumulation and (3) provide a new model of CFH-associated atypical haemolytic uraemic syndrome.

Genetic Background Influences VEGFR Pathways and Glomerular Thrombotic Lesions in Nephrotoxic Nephritis Laurent Mesnard,[1, 2] Sophie Vandermeersch,[1, 2] Patrice Callard,[2] Chantal Jouanneau,[1] Alexandre Hertig,[1, 2] Eric Rondeau.[1, 2] *[1]INSERM UMR S702, Paris, France; [2]APHP, Hopital Tenon, Paris, France; [3]APHP, HEGP, Paris, France.*

Background: As genetic background (GB) may play a role in various experimental models, we evaluated its impact on glomerular pathology.

Methods: Mice were evaluated during passive mouse anti-glomerular basement membrane glomerulonephritis (anti-GBM-GN) in leading inbred strains (C57BL/6J, BALB/cbyJ, 129S2SvPas) and their F1 offspring. Glomerular DNA microarray were also performed at early time point (day 4)

Results: Mice exhibited different severity of renal failure, hypertension and pseudocrescentic lesions according their GB. Proteinuria correlated with GB-dependent podocytic lesions, dramatic in 129S2SvPas, intermediate in BALB/cbyJ and some F1, mild in C57BL/6J.

Originally, we discovered that glomerular thrombotic microangiopathy (TMA) was a histopathological hallmark of this model, along with its classical biological abnormalities (anemia, thrombocytopenia, schistocytosis). TMA parameters were also remarkably GB-dependent: major in 129S2SvPas, far less in C57BL/6J, intermediate in F1. Subsequent glomerular DNA microarray analysis comparing C57BL/6J-resistant to 129S2SvPas-disease-prone mice indicated major differences in VEGF/VEGFR pathways, which have already been involved in TMA pathophysiology. Glomerular VEGF-A expression was not different and exogenous vegf165 failed to rescue TMA. Further analysis revealed a glomerular VEGFR2 signaling defect in 129S2SvPas disease-prone mice compared to C57BL/6J.

Conclusions: Differences, and sometimes discordances, between studies about mouse anti-GBM-GN are classically inferred to GB; our results identify glomerular TMA lesions as a GB-dependant hallmark of anti-GBM-GN, which could be related to a genetic difference in VEGFR2 signaling.

The Growth Factor Midkine Ameliorates Crescentic Glomerulonephritis through Inhibiting Thrombosis Hiroshi Kojima, Waichi Sato, Tomoki Kosugi, Yuka Sato, Kayaho Maeda, Shoichi Maruyama, Yukio Yuzawa, Seiichi Matsuo. *Department of Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: The growth factor Midkine (MK), a heparin-binding protein, has been implicated in neuronal survival and differentiation, cancer development and inflammation-related diseases. We have previously demonstrated that MK plays deleterious effects for ischemic renal injury, diabetes and hypertension. However, little is known about the kinetics of MK in pathophysiological state. Using mass spectrometry method, a large number of MK-binding proteins such as coagulation- and fibrinogenolysis-related factors were identified. Indeed, MK activates fibrinolysis in bovine endothelial cells. In order to clarify the molecule mechanism of thrombosis *in vivo*, we examined the role of MK in crescentic glomerulonephritis (GN) model.

Methods: MK deficient mice ($Mdk^{-/-}$) or wild-type mice ($Mdk^{+/+}$) were treated with unilateral nephrectomy and the pre-immunization of rabbit IgG, and then injected with rabbit anti-mouse glomerular basement membrane (GBM) antibody (Ab) after 7 days. Mice were sacrificed at 1, 3 and 7 days after injection of anti-GBM Ab. Kidney, serum and urine were collected for immunohistochemistry and biochemical analysis.

Results: There were no differences in rabbit IgG, mouse IgG and C3 depositions of glomeruli in both groups. Blood urea nitrogen levels in $Mdk^{-/-}$ were higher than $Mdk^{+/+}$. Similarly, $Mdk^{-/-}$ developed severer crescentic GN accompanied with marked thrombosis over time. Obvious tubulointerstitial injuries were also found in $Mdk^{-/-}$ compare with $Mdk^{+/+}$. Macrophage and neutrophil infiltrations into glomeruli were more significant in $Mdk^{-/-}$ than $Mdk^{+/+}$. Plasminogen activator inhibitor (PAI)-1 in glomeruli of $Mdk^{-/-}$ was significantly induced, consistent with the result of mass spectrometry.

Conclusions: In contrast to previously reported *in vivo* models such as ischemic reperfusion model, diabetic nephropathy and remnant kidney model, MK might play beneficial effects for crescentic GN though the blockade of PAI-1-mediated thrombosis and be a candidate for preventing or delaying rapidly progressive GN.

SA-PO2215

Endothelial BAMBI: A Novel Modulator of Angiogenesis Dmitrij Kollins,[1] Nicolas Guillot,[1] Victoria Gilbert,[1] Sandhya Xavier,[2] Jun Chen,[2] Maria Pia Rastaldi,[3] Alessandro Corbelli,[3] Detlef O. Schlondorff.[1] *[1]Nephrology, Mount Sinai School of Medicine, New York, NY; [2]Nephrology, New York Medical College, Valhalla, NY; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy.*

Background: BAMBI (BMP and Activin receptor Membrane Bound Inhibitor), was described as a highly conserved protein that can act as a competitive antagonist of type 1 TGFβ receptors. BAMBI is highly expressed in solid tumors, where it has been postulated to contribute to growth and metastasis. There are, however, no data on cell-specific expression of BAMBI in mammalian organs.

Methods: As TGFβ action is highly cell type-specific, we examined the localization of BAMBI in mouse tissues and its function in target cells in-vitro and in-vivo in BAMBI knock-out mice.

Results: By immunohistology, BAMBI is expressed in endothelial cells of the major visceral mouse organs. By EM, the endothelial cell phenotype in BAMBI-/- mice shows signs of cell activation as compared to the wild type mice. In vitro angiogenesis and scratch wound assays using human umbilical vein endothelial cells (HUVEC) show enhanced angiogenesis and cell migration in HUVEC with BAMBI knock-down by siRNA, and the opposite with overexpression of BAMBI. In vivo angiogenesis using s.c. matrigel implantation assays confirmed marked enhancement of angiogenesis in the BAMBI-/- as compared to the wild type mice. To confirm the enhanced angiogenesis in vivo in BAMBI-/- mice, we examined glomeruli as highly-vascularized structures. BAMBI-/- mice have significantly larger glomeruli than wild type mice due to larger capillary endothelial tufts. Furthermore, compensatory glomerular capillary hypertrophy after unilateral nephrectomy was greater in the BAMBI-/- than in wild type mice.

Conclusions: Taken together our data show that BAMBI is expressed in endothelial cells of different organs and support a role for BAMBI in vascular homeostasis. Elimination of BAMBI results in enhanced angiogenesis, which may play a role in neoangiogenesis after renal injury and in renal diseases with capillary loss.

SA-PO2216

Osteopontin Deficiency Results in Severe Glomerulosclerosis in Uninephrectomized Mice Sandra Schordan,[1] Olaf Grisk,[2] Eric Schordan,[1] Baerbel Miehe,[1] Wilhelm Kriz,[3] Karlhans Endlich,[1] Nicole Endlich.[1] *[1]Anatomy and Cell Biology, University Medicine Greifswald, Greifswald, Germany; [2]Physiology, University Medicine Greifswald, Greifswald, Germany; [3]Center for Biomedicine and Medical Technology, University of Heidelberg, Germany.*

Background: Expression of osteopontin (OPN) in podocytes has been reported to be elevated in mechanical stress and in experimental models of renal injury such as diabetic nephropathy or glomerular hypertension.

Methods: To investigate the role of OPN in the development of focal segmental glomerulosclerosis (FSGS), OPN+/+ and OPN-/- mice were subjected to uninephrectomy (UNX) and DOCA-salt treatment for 6 weeks, a model of FSGS through elevation of glomerular capillary pressure. Proteinuria and albuminuria were measured and renal morphology was analyzed by scoring glomerulosclerosis and collagen expansion on kidney sections stained with PAS or Masson trichrome.

Results: Following UNX, OPN-/- mice exhibited prominent glomerular damage as evidenced by severe glomerulosclerosis degree and mesangial matrix (collagen) deposition. After DOCA salt-treatment glomerular lesions between OPN+/+ and OPN-/- mice were not strikingly different anymore. Massive podocyte injury was demonstrated by electron microscopy in response to DOCA-salt treatment. WT-1, podocin, synaptopodin and actin expression were reduced upon UNX in OPN-/- kidneys as evaluated by immunofluorescence and real-time PCR. Integrin αV and β1 mRNA, identified as receptor of OPN mediated mechano-protection, were up-regulated by more than 2-fold in DOCA-salt treated rats.

Conclusions: We conclude that OPN plays a crucial role in adaptation following renal ablation and is renoprotective towards increased mechanical load.

GSK3β Inhibition Protects Against NSAID Induced Acute Kidney Injury: Effects on Mitochondrial Permeability Transition and ATP Production Hao Bao,[1] Zhi-Hong Liu,[1] Shougang Zhuang,[2] Lance D. Dworkin,[2] Rujun Gong.[2] *[1]Research Institute of Nephrology, Nanjing University, Nanjing, China; [2]Brown Medical School, Providence, RI.*

Background: Clinical use of non-steroid anti-inflammatory drugs (NSAID) like Diclofenac (DCLF) is limited by renal toxicity and acute kidney injury (AKI). This study examined the role of glycogen synthase kinase (GSK)3β, a newly recognized modulator of kidney injury, in NSAID induced acute nephrotoxicity.

Methods: Cultured mouse renal proximal tubular epithelial cells were exposed to DCLF in the presence or absence of TDZD-8, a highly selective small molecule GSK3β inhibitor. *In vivo,* mice were administered a nephrotoxic dose of DCLF following pretreatment with TDZD-8 or vehicle. Tubular cell necrosis and apoptosis as well as mitochondrial permeability transition (MPT) and adenosine triphosphate (ATP) production were measured.

Results: *In vitro*, TDZD-8 improved cell viability and suppressed both apoptosis and necrosis in cultured tubular epithelial cells exposed to DCLF. Mechanistically, TDZD-8 normalized the levels of intracellular ATP in DCLF-treated cells and diminished DCLF elicited MPT evidenced by entry of fluorescent calcein from cytoplasm into mitochondrial matrix space as well as blunted calcium-induced mitochondrial swelling. Conversely, ectopic expression of an uninhibitable mutant of GSK3β markedly exacerbated DCLF induced injury and abrogated the protective effects of TDZD-8 on tubular cell apoptosis, necrosis, MPT and ATP production. *In vivo,* DCLF induced a typical pathology of acute tubular necrosis, characterized by epithelial simplification, isometric vacuolization of proximal tubular epithelium, luminal ectasia, epithelial necrosis, sloughing of tubular cell into lumen, loss of brush border, nuclear enlargement and pleomorphism, and prominent inflammation. GSK3β inhibition by TDZD-8 prominently prevented acute kidney dysfunction and ameliorated tubular necrosis and apoptosis. This protective effect was associated with reduced MPT pore opening and preserved ATP homeostasis in DCLF injured kidneys.

Conclusions: Collectively, our findings suggest that GSK3β inhibition ameliorates NSAID-induced AKI by inhibiting MPT and preserving ATP production.

SA-PO2218

Derangement of Oxygen Sensing for Erythropoietin (EPO) Production by Unfolded Protein Response (UPR) Reiko Inagi, Chih-Kang Chiang, Tetsuhiro Tanaka, Toshiro Fujita, Masaomi Nangaku. *Div of Nephrol & Endocrinol, Univ of Tokyo Sch of Med, Tokyo, Japan.*

Background: In addition to loss of renal EPO-producing cells, derangement of oxygen sensing for EPO production contributes to a low level of EPO in advanced CKD patients. Here, We investigated the possibility of derangement of oxygen sensing by UPR, which is a stress signal induced by endoplasmic reticulum (ER) stress and contributes to various kidney disease progression.

Methods: EPO-producing cell line (HepG2) or rats were treated with UPR inducers (thapsigargin: THG or tunicamycin: TUN) or a suppressor (salubrinal: SAL) under normoxia or hypoxia [0.1% O_2 or 100 μM hypoxia-inducible factor (HIF) activator $CoCl_2$, 16hrs]. EPO transcription or plasma EPO level was measured by real-time qRT-PCR or ELISA. The change in hypoxia-induced EPO 3'-enhancer activity by UPR was assessed by 1) Western blotting for detection of HIF-2α nuclear translocation or 2) luciferase assay for EPO 3'-enhancer region or HIF binding site (HRE) in HepG2 treated with UPR inducers or the cells overexpressed UPR transcription factor, ATF4.

Results: UPR activated by THG or TUN as well as overexpression of ATF4 markedly suppressed hypoxia-induced EPO transcription in HepG2 without affecting the cell viability. In contrast, UPR did not alter other HIF target gene expressions such as VEGF or GLUT-1. UPR suppressor, SAL, restored the suppression of EPO transcription by UPR activation. Of note, the UPR activation, especially ATF4 overexpression, significantly blunted the transcriptional activity of EPO 3'-enhancer region, which includes a putative ATF4 binding site located adjacent to HRE. However, the UPR did not directly affect nuclear translocation of HIF-2α and its subsequent binding to HRE. *In vivo* studies showed that UPR activation on renal interstitial cells by non-nephrotoxic dose of TUN suppressed hypoxia-induced plasma EPO production, together with a reduction of renal EPO mRNA in rats ($P<0.05$).

Conclusions: Imbalance of UPR, especially ATF4 activation, deranges EPO transcription by suppressing EPO 3'-enhancer activity without interaction with HIF directly, suggesting the crosstalk between UPR and HIF pathways on oxygen sensing for EPO regulation.

Funding: Government Support - Non-U.S.

SA-PO2219

Effects of MCP-1 Inhibition by Bindarit Therapy in a Rat Model of Polycystic Kidney Disease (PKD) Carlamaria Zoja,[1] Daniela Corna,[1] Monica Locatelli,[1] Daniela Rottoli,[1] Norberto Perico,[1] Andrea Remuzzi,[1] Angelo Guglielmotti,[2] Ariela Benigni,[1] Giuseppe Remuzzi.[1,3] *[1]Mario Negri Institute, Bergamo, Italy; [2]Angelini Research Center-ACRAF, S. Palomba-Pomezia, Italy; [3]Unit of Nephrology, Ospedali Riuniti, Bergamo, Italy.*

Background: Experimental and clinical evidence suggested that the proinflammatory chemokine MCP-1/CCL2 has a role in the development of interstitial inflammation and renal failure in autosomal-dominant PKD. Here we investigated the effects of the MCP-1 synthesis inhibitor bindarit in the PCK rat, a model orthologous to human autosomal-recessive PKD that has also phenotypic characteristics of human ADPKD.

Methods: PCK rats were treated by gavage from 5 to 15wks of age with vehicle (n=10) or bindarit (100mg/kg bid, n=9). Age-matched SD rats (n=8) served as control.

Results: MCP-1 mRNA was two-fold increased in the kidney of PCK rats on vehicle and significantly ($P<0.05$) reduced by bindarit. Bindarit limited overexpression of MCP-1 protein by epithelial cells of dilated tubules and cysts, and interstitial inflammatory cells. Excessive accumulation of monocytes/macrophages in the kidney of PCK rats was lowered by bindarit (-41%, $P<0.05$ vs vehicle). PCK rats developed hypertension (15wks, SBP: 146±2 vs control 127±1 mmHg, $P<0.01$), that was limited by bindarit (138±1mmHg, $P<0.05$ vs vehicle). Serum creatinine increased in PCK rats (0.72±0.03 vs control: 0.58±0.03 mg/dl, $P<0.05$) and was comparable to controls after bindarit (0.64±0.05mg/dl). In PKC vehicle-rats proteinuria progressively increased ($P<0.01$) compared to controls (13wks,144±40 vs 26±1mg/d; 15wks, 232±36 vs 25±1mg/d). Bindarit reduced proteinuria by 57-46% at 13 and 15wks ($P<0.05$ vs vehicle). The antiproteinuric effect was associated with amelioration of the defective nephrin expression in podocytes of PCK rats. Reduced protein filtration translated in less tubular casts. Kidney and liver cysts were not affected by treatment.

Conclusions: Although bindarit did not prevent renal cyst growth, it limited interstitial inflammation and renal dysfunction and reduced proteinuria in PKD. Thus bindarit could be considered as therapeutic intervention complementary to therapies specifically acting to block renal cyst growth.

Chronic Kidney Disease-Induced Cardiac Fibrosis Is Ameliorated by Reducing Circulating Levels of a Non-Dialysable Uremic Toxin, Indoxyl Sulfate Suree Lekawanvijit,[1] Andrew Kompa,[1,2] Bing Hui Wang,[1] Fuyuhiko Nishijima,[3] Darren J. Kelly,[2] Henry Krum.[1] *[1]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Vic, Australia; [2]Department of Medicine, University of Melbourne, Melbourne, Vic, Australia; [3]Pharmaceutical Department, Kureha Corporation, Tokyo, Japan.*

Background: Non-dialysable uremic toxins have been under-explored as a contributor of uremic cardiomyopathy. We have recently demonstrated that one such toxin, indoxyl sulfate (IS), directly contributes to cardiac fibrosis. As an oral adsorbent, AST-120, can

lower serum IS levels, we hypothesized that cardiac fibrosis can be abrogated by this agent in an animal model of CKD.

Methods: We performed subtotal-nephrectomy (5/6-STNx) on Sprague-Dawley rats which were then randomized to receive either AST-120 (n=13) or vehicle (n=17) for 12 weeks. Sham-operated rats (n=12) served as controls.

Results: Left ventricular (LV) diastolic dysfunction was observed in STNx+vehicle rats on echocardiography. A 4.5-fold increase in serum IS ($p<0.001$) was noted in STNx+vehicle vs sham as well as elevated tail-cuff blood pressure (BP) ($p<0.001$) and heart weight ($p<0.001$). Increased LV fibrosis ($p<0.001$), gene expression of pro-fibrotic (TGF-β, CTGF) and hypertrophic (ANP, β-MHC and α-skeletal muscle actin) markers, as well as TGF-β and phosphorylated-NF-κB protein expression were observed in STNx+vehicle rats. Treatment with AST-120 reduced serum creatinine ($p<0.05$) and urine total protein ($p<0.05$) vs STNx+vehicle with no effect on BP (AST-120,227±11 vs vehicle,224±8 mmHg, NS) and heart weight. Compared to vehicle STNx, serum IS was reduced by 79% with AST-120 ($p<0.001$), accompanied by reduced LV fibrosis by 35% ($p<0.01$) as well as TGF-β and phosphorylated-NF-κB protein expression ($p<0.05$).

Conclusions: STNx increased cardiac fibrosis and circulating IS levels, which was significantly reduced by AST-120 independent of any change in BP. These findings support IS as being an important contributor to uremic cardiomyopathy and AST-120 a potential complementary treatment.

SA-PO2221

Renal and Systemic Effects of PGE2 on Nephrotoxic Nephritis by Limiting Synaptopodin Degredation and Modulation of Splenic Stem Cells Nino Kvirkvelia, Maggie McMenamin, Kapil Chaudhary, Ryan Layman, Michael P. Madaio. *Medicine, Georgia Health Sciences University, Augusta, GA.*

Background: The mechanisms leading to podocyte injury are incompletely understood, and current treatments insufficiently promotes recovery. Previously, PGE2 promoted recovery following NTN induction. Initiation of PGE2 therapy even on day 4 after NTS injection, when acute inflammation is well established, resulted in attenuation of proteinuria, and the prostanoid prolonged life expectancy. Furthermore PGE2 limited injury and promoted cellular recovery of NTS injured glomerular endothelial cells and podocytes.

Methods: To further obtain mechanistic insights, the systemic and renal effects were evaluated. Splenocytes were evaluated by FACS; synaptopodin expression was evaluated by FACS and IF of cells and tissues.

Results: Systemically, in NTN-PGE2 treated mice, there was 10-fold decrease in spleen progenitor CD45- cells, compared to NTN mice, suggesting that PGE2 promotes transmigration of spleen stem cells into the injured kidney and subsequent recruitment of progenitor splenocytes into kidney epithelial cells. Additionally, PGE2 treatment restored the NTS induced decrease in CD4+ splenocytes, and reduced the number of CD69+ cells in the spleen. CD69 is transiently expressed upon activation on subsets of T and B cells with a net proinflammatory effect, and depletion of CD69+ cells leads to reduced inflammation and immunity. Within the kidney, improvement in proteinuria was at least partly explained by direct effect of PGE2 on podocytes, as there was a 27.32% increase in synaptopodin expression in kidney in PGE2 treated mice. Similarly, in cultured podocytes, NTS induced 32.21 % decrease in mean fluorescence intensity of synaptopodin staining (FACS), which was prevented by pre-treatment with PGE2 (5ug/ml).

Conclusions: The beneficial effect of PGE2 may be accounted for by PGE2/EP2/EP4 receptor mediated activation of cAMP dependent PKA, which is known to decrease calcineurin activity and protect synaptopodin from degradation. Taken together, the results indicate that PGE2 is a candidate to investigate its therapeutic potential to improve cellular recovery and function during the course of glomerulonephritis.

Myosin Expression and Kidney Structure in Older Heterozygous Myh9 Knockout Mice Mostafa Belghasem, Joseph S. Coppola, Philip A. Bondzie, Hui Chen, Julie A. Tomolonis, Joel M. Henderson. *Pathology, Boston University, Boston, MA.*

Background: The gene MYH9 encodes non-muscle myosin heavy chain IIA (NMHCIIA), an essential podocyte contractile protein. The increased incidence of chronic kidney disease in African Americans has been linked to genetic variation near MYH9, and rare hereditary syndromes involving mutations in MYH9 often include renal involvement. The genetic features of these forms of MYH9-associated kidney disease suggest that altered MYH9 expression levels could play a role in disease pathogenesis. The objective of this study is to determine the long-term effect of MYH9 haploinsufficiency on non-muscle myosin expression and kidney structure, using a pre-existing murine model of Myh9 ablation.

Methods: Kidney tissue was harvested from heterozygous Myh9 knockout (Myh9 HET) and wild type mice on 129/Sv background, aged 9 and 17 months. Kidney structure was evaluated by light microscopy and transmission electron microscopy. Immunohistochemistry was used to assess the expression and distribution of NMHCIIA in the kidney. Kidney glomeruli were isolated using a sieving technique to evaluate Myh9 expression using real time PCR.

Results: Glomeruli from Myh9 HET mice showed a significant decrease in Myh9 mRNA transcription (> 50% decrease; n = 3) relative to wild type mice. However, the diminished expression of Myh9 did not appear to be associated with changes in kidney structure in the Myh9 HET mice. Specifically, kidney histology revealed no pathology, and electron microscopy showed no podocyte or glomerular basement membrane pathology, in either Myh9 HET or wild type mice. Furthermore, both age groups of the Myh9 HET and wild-type mice showed similar intense expression of non-muscle myosin IIA in the glomeruli.

Conclusions: We found that Myh9 haploinsufficiency has no pathologic effect on kidney structure under normal physiological conditions, despite a significant decrease in Myh9 transcription in older Myh9 HET mice. We are currently investigating the possibility that conditions of physiologic stress may cause pathologic changes in the kidneys of Myh9 HET mice that are more severe than those seen in wild type mice.

Experimental Lupus Nephritis Accelerate Mortality and Arteriosclerosis in Apo-E Deficient Mice Yvonne Riedl, Romy Boehme, Thomas Winkler, Christoph Daniel, Kerstin U. Amann. *University Erlangen-Nürnberg, Erlangen, Germany.*

Background: Chronic kidney disease is shown to aggravate arteriosclerosis in man, but the underlying mechanisms are not completely understood. To investigate such mechanisms in an animal model we combined the classical arteriosclerosis mouse model (Apo-E -/-) with a progressive lupus nephritis model (yaaxFcgammaR2 -/-). In this study we investigated the impact of Apo-E deficiency on survival and renal morphology in lupus nephritic mice.

Methods: First we analysed survival during a period of 40 weeks in: 1. FcgammaR2 deficient mice (n=11). 2. A progressive lupus model yaaxFcgammaR2-/- (n=115). 3. YaaxFCgammaR2 -/-xApo-E+/- (n=19). 4. yaaxFcgammaR2xApo-E double knockout mice (n=40). Renal injury including vascular alterations was analysed on week 22 to determine the impact of renal morphological changes on survival. Using enface preparation, arteriotic plaques were analysed in APO-E deficient mice (n=5) and yaaxFcgammaR2xApo-E double knockout mice (n=7).

Results: YaaxFcgammaR2xApo-E double knockout mice had the shortest lifespan of all investigated groups (max. 26 weeks). In contrast, yaaxFcgammaR2 deficient mice being heterozygous for APO-E had a significant reduced mortality of 57% (p=0,0005) surviving mice at week 40, similar to yaaxFcgammaR2-/-xAPO-E+/+ mice (59% survival. In addition, mortality was further significantly reduced in FcgammaR2 deficient lupus mice lacking the yaa modification (91% survival, p=0,048) compared to those bearing this modification. Arteriosclerotic plaques were still found in 4 of 7 yaaxFcgammaR2xAPO-E double knockout mice on week 22 using enface preparations of aortas, whereas mice lacking only the APO-E gene showed no detectable aortic plaque formation. Analysis of renal pathology revealed a tendency to aggravated renal injury, but significantly enhanced vascular injury in yaaxFcgammaR2xAPO-E double knockout mice compared to APO-E and yaaxFcgammaR2 deficient mice (VSI: 0,95±0,34. vs. 0,28±0,16 and 0,17±0,15).

Conclusions: The lack of Apo-E gene in the progressive yaaxFcgammaR2 -/- lupus nephritis model highly increased mortality. Aortic plaque formation and renal vascular impairment is accelerated by lupus nephritis.

Renin -Angiotensin System and Mammalian Target of Rapamycin (mTOR) Pathway Modulate the Course of HIV-Associated Nephropathy through HIV Gene Expression Dileep Kumar, Partab Rai, Mohammad Husain, Ashwani Malhotra, Pravin C. Singhal. *Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY.*

Background: The activation of renin -angiotensin system (RAS) and the mammalian target of rapamycin (mTOR) pathway have been demonstrated to play an important role for the development and the progression of HIV-associated nephropathy (HIVAN). We evaluated the role of the RAS and the mTOR pathway on HIV gene expression on the course of HIVAN.

Methods: To activate endogenous RAS, HIVAN mice (Vpr and Tg26) were bred witn angiotensinogen (Agt) transgenic mice having four Agt copies; this strategy allowed us to develop Vpr/Tg26 mice with 2, 3 and 4 copies of Agt.Vpr-Agt-2,-3, and -4 mice were fed either normal saline or doxycycline for six weeks to induce podocyte expression of Vpr. To inhibit the mTOR pathway, Tg26 (n=6) were administered either vehicle or sirolimus (5 mg/kg/day, intra-peritoneally) for 14 days. At the end of experimental periods, kidneys were isolated and prepared for histology and immunohistochemistry. RNA and proteins were extracted and HIV-1 gene expression was determined by real time PCR and immunoblotting. Renal lesions were graded for sclerosis and tubular dilatation. In in vitro studies, human podocytes were transduced with either HIV-1 or vector constructs, followed by treatment with either vehicle, sirolimus, or Ang II for 72 h. Subsequently RNA and proteins were harvested and HIV-1 gene expression was determined by RT-PCR and immunoblotting.

Results: Doxy fed Vpr Agt-4 mice displayed more advanced renal lesions than to doxy-fed Vpr-Agt-2 mice. Vpr-Agt-4 mice displayed 50% increase in Vpr expression. Saline-treated Tg26 showed two-fold advanced glomerular and tubular lesions vs. sirolimus-treated animals. Whereas, Sirolimus decreased transcription of HIV-genes both in renal tissue as well as in HIV-1 transduced podocytes. Renal tissues of Tg26-Agt-4 displayed 2-4 fold increase in gp120, Vpr, Tat, Nef and Vpu genes.

Conclusions: The RAS activation increased HIV gene trancription; whereas, downregulation of mTOR decreased HIV gene transcription. These gene modulating effects of the RAS and the mTOR pathway may be contributing to the altered course of HIVAN.

SA-PO2225

HIV-Induced Human Podocyte Vitamin D Receptor (VDR) Downregulation Enhances Cathepsin L Expression Bipin Sharma, Dileep Kumar, Ashwani Malhotra, Mohammad Husain, Pravin C. Singhal. *Medicine, North Shore LIJ Hofstre Medical School, Great Neck, NY.*

Background: In HIV-associated nephropathy (HIVAN), podocytes detach and proliferate in Bowman's space. We hypothesized that HIV-induced down regulation of VDR enhances upregulation of cathepsin L, which compromises cytoskeletal integrity of podocytes leading to their detachment and proliferation.

Methods: To determine the effect of HIV on renal tissue VDR, synaptopodin, and cathepsin L expression, immunoblotting and immunohistochemical studies were performed on renal tissue from control and Tg26 mice (n=3). To develop in in vitro model of HIV infection, both mouse and human podocytes were transduced with either empty vector (EV/MP/HP) or NL4-3 (HIV/MP/HP) constructs and evaluated for the expression of VDR, cathepsin L, and synaptopodin (immunoblotting and real time PCR studies). To establish causal relationship between VDR and cathepsin L, human podocytes with silenced VDR were evaluated for cathepsin L expression. To confirm relationship between VDR and cathepsin L, EV/HP and HIV/HP were treated with either buffer or vit D (25 nM) for 24 hours and lysates prepared for VDR, cathepsin L, and synaptopodin expression. To determine the functional status of cathepsin L, cells were labeled with phalloidin and evaluated for the integrity of actin filaments . In addition, migration, adhesion, detachment, and proliferation studies were conducted in cells treated under similar conditions.

Results: Immunoblotting and PCR studies revealed attenuated expression of VDR and synaptopodin but enhanced expression of cathepsin L in renal tissues of HIVAN mice. Similarly, both HIV/HPs and siRNA-VDR/HPs displayed attenuated expression of VDR and enhanced expression of cathepsin L. whereas, vit D treatment of HIV/HPs not only increased VDR and synaptopodin expression but also diminished expression of cathepsin L. HIV/HPs displayed disrupted actin filaments, decreased adhesion, increased detachment, and proliferative phenotype.

Conclusions: These findings indicate that HIV enhances podocyte cathepsin L expression via downregulation of VDR. The former decreases adhesion, eahances detachment and proliferation of podocytes.

SA-PO2226

Renin Inhibition Retards the Progression of HIV-Associated Nephropathy Dileep Kumar,[1] Iti Yadav,[1] Deepti D. Torri,[1] Partab Rai,[1] Mohammad Husain,[1] Ashwani Malhotra,[1] Guohua Ding,[2] Praveen N. Chander,[3] Pravin C. Singhal.[1] *[1]Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY; [2]Medicine, Renmin Hospital of Wuhan University, Wuhan, Hubei, China; [3]Pathology, New York Medical College, Valhalla, NY.*

Background: Blockade of the downstream effect of angiotensin II has been reported to slow down the progression of HIV-associated nephropathy (HIVAN). In the present study, we evaluated the effect of renin inhibition on the progression of renal lesions in a mouse model of HIVAN (Vpr).

Methods: We have used Vpr transgenic mice; they express podocyte specific Vpr after doxycycline administration. In protocol A, Vpr mice were fed either water (W-VprA) or doxycycline (D-VprA) in their drinking water for six weeks. In protocol B, Vpr mice were fed either doxycylcine (D-VprB) in their drinking water + normal saline (by miniosmotic pump) or doxy + aliskiren (by miniosomotic pump, AD-VprB) for six weeks. In protocol C, Vpr mice were fed doxycycline (doxy) for six weeks followed by kidney biopsy to determine baseline kidney lesions. Subsequently, half of the mice were administered either normal saline (NS-VprC) or aliskiren (A-VprC) for 4 weeks. Protocol D was identical to protocol C, except, Vpr mice were administered either normal saline or aliskiren for 8 weeks after kidney biopsy.

Results: All D-VprA showed 2-3 fold greater expression of renin expression when compared to W-VprA. All D-VprA showed overt HIVAN phenotype in the form of focal segmental glomerular sclerosis (FSGS) and microcystic dilatation of tubules. In protocol B, aliskiren slowed the development of HIVAN. In protocol C, A-VprC showed 24.2% increase in number of sclerosed glomeruli (from their baseline) as compared to 139.2% increase in sclerosed glomeruli in NS-VprC ($P<0.01$) from their baseline. Aliskiren also slowed down increase in size of micorycysts in A-VprC. Aliskiren diminished urinary protein creatinine ratio both in protocol B and protocol C. The attenuating effect of aliskiren on the progression of renal lesions continued in A-VprD.

Conclusions: Renin inhibition has a potential to slow down the progression of renal lesions in HIVAN.

Both Lectin and Classical Complement Pathways Determine the Severity of Murine IgA Nephropathy Azusa Hashimoto, Yusuke Suzuki, Isao Ohsawa, Hiroyuki Ohi, Yasuhiko Tomino. *Division of Nephrology, Department of Internal Medicine, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: IgA nephropathy (IgAN) is a common form of primary progressive glomerulonephritis with mesangial cell proliferation and, matrix expansion with mesangial depositions of IgA and complement 3 (C3). Mesangial depositions of circulating aberrantly glycosylated and polymeric IgA1 are discussed as a major paraeters in the pathogenesis of IgAN, but the pathogenic roles of co-deposited C3 or related complement pathways have not been fully clarified.As a basis for confirmation of the role for IgAN, complement activation of two murine IgAN prone models were investigated.

Methods: The high serum IgA mouse (HIGA) and grouped ddY mouse (gddY) which were recently established as 100% onset IgAN prone models, were used in this study. Albuminuria, glomerular injury, complement activation in glomeruli, molecular weight of serum IgA and IgA-IgG2a immune complex (IC), IgA-IgM IC and IgA-mannose binding lectin (MBL)-A/C IC were analyzed in these models.

Results: Levels of albminuria, glomerular injury and complement activation in gddY were significantly higher than those in HIGA. Complements in both classical and lectin pathways of gddY were activated much more than those of HIGA, although glomeruler IgA depositions were similar in both mice. As in the case of human IgAN, gddY had much more aberrantly glycosylated IgA, IgA-IgG2a IC, IgA-IgM IC and IgA-MBL-A/C IC in serum than HIGA, but serum high molecular IgA did not differ in the two models.

Conclusions: These results suggest that levels of aberrantly glycosylated IgA and IgA-IC, but not total IgA, mainly determine the amplitude of activation of both complement pathways, and subsequent glomerular injury. It appears that complement activation of classical and lectin pathways may be one of the critical factors for progression of murine IgAN.

Green Tea Polyphenol (-)-Epigallocatechin-3-gallate Restores Nrf2 Activity and Ameliorates Crescentic Glomerulonephritis Ting Ye,[1,2] Dinesh Rakheja,[2] Nosratola D. Vaziri,[3] Chandra Mohan,[4] Xin J. Zhou.[2] *[1]medicine, Wuhan Tonji Hospital, Wuhan, China; [2]Pathology, UT Southwestern Medical Center, Dallas, TX; [3]Medicine, UC Irvine, Irvine, CA; [4]Medicine, UT Southwestern Medical Center, Dallas, TX.*

Background: Crescentic glomerulonephritis (GN) is the most severe form of GN and is associated with significant morbidity and mortality despite aggressive immunotherapy. Overproduction of free radical species by inflammatory cells can cause further tissue damage, intensify inflammation, promote apoptosis, and accelerate progression of crescentic GN. The green tea catechins, particularly (-)-epigallocatechin-3-gallate (EGCG), are potent anti-inflammatory and anti-oxidant agents shown to inhibit leukocyte chemotaxis, quench free radicals, chelate transition metals, and interrupt lipid peroxidation chain reaction. The present study was undertaken to examine the therapeutic efficacy of EGCG on experimental crescentic GN.

Methods: Crescentic GN is induced in 129/svJ mice by administration of rabbit anti-mouse-glomerular basement membrane (anti-GBM) sera. The anti-GBM antibody-injected mice were allowed to develop full-blown nephritis for 7 days before intervention. On day 7, mice were randomized into either EGCG-treated (50 mg/kg/day, orally x 3 weeks) or vehicle group. Animals were then euthanized on day 28 and routine histology and key molecules involved in inflammatory pathways were studied.

Results: EGCG treatment significantly reduced mortality, decreased proteinuria and serum creatinine, and markedly improved renal histology when compared with vehicle-treated mice. The improvement in renal function and histology were accompanied by the restoration of Nrf2 signaling (which was impaired in vehicle-treated mice) as shown by increase in nuclear Nrf2 and cytoplasmic glutamate cysteine ligase catalytic subunit, glutamate cysteine ligase modifier subunit, and glutathione peroxidase. EGCG-treated mice also showed reduction in p-Akt, p-JNK, p-ERK1/2, PPARγ, and SIRT1 (which were all elevated in vehicle-treated mice).

Conclusions: Our data illustrate the efficacy of EGCG in reversing the progression of crescentic GN in mice by targeting key inflammatory pathways.

p53 Deficiency Exacerbates Immune-Mediated Glomerulonephritis Yuki Hamano,[1] Ryota Kimura,[2] Yuki Udagawa,[2] Yoshihiko Ueda,[3] Osamu Yokosuka,[4] Makoto Ogawa.[1] *[1]Nephrology, Chiba University Hospital; [2]Clinical Education and Research, Graduate School of Pharmaceutical Sciences, Chiba University; [3]Pathology, Dokkyo Medical University Koshigaya Hospital; [4]Medicine and Clinical Oncology, Graduate School of Medicine, Chiba University, Japan.*

Background: p53 tumor suppressor is a key regulator of the response to cellular stress or DNA damage. p53 activation leads to cell cycle arrest, apoptosis, or senescence. p53 has been shown to be an important regulator of renal tubular cell viability in the animal models of ischemic and toxic acute kidney injuries. In theses models, p53 activation induced proapoptotic pathways in renal tubular cells and contributed to kidney dysfunction. In this study, we investigated whether genetic or pharmacological inhibition of p53 provided a protective effect in a mouse model of immune-mediated glomerulonephritis.

Methods: p53-null (KO) and wild-type (WT) mice were immunized subcutaneously with normal rabbit IgG, followed by intravenous injections of rabbit anti-mouse GBM antibodies. In the experiment to test the effect of pharmacological inhibition of p53, C57BL/6J mice were administered pifithrin-α (a chemical inhibitor of p53) at the injections of the anti-GBM antibodies. On day 6, blood and urine samples were collected and mice were sacrificed to obtain tissues for histological analysis.

Results: Upon induction of anti-GBM glomerulonephritis in WT mice, the expression of p53 was upregulated within the glomeruli and tubulointerstitium. Unexpectedly, serum creatinine (Scr) levels and urine albumin excretion were significantly increased in nephritic KO mice compared with nephritic WT mice. The KO mice displayed significant increase in the numbers of $BrdU^+$ cells and macrophages in the glomeruli and interstitial fibrosis.

The upregulation of cyclin E1 and activation of cyclin-dependent kinase 2 (CDK2) were observed in the KO mice. Moreover, Scr levels, the number of $BrdU^+$ cells in the glomeruli and the expression of cyclin E1 were increased by pifithrin-α, which was also reversed by co-administration of roscovitine (CDK2 inhibitor).

Conclusions: p53 exerts anti-inflammatory effects by inhibiting glomerular cell proliferation during anti-GBM disease.

Ephrin-B1 in Podocyte Is Interacted with Nephrin and Is Phosphorylated by a Signal from Nephrin Md. Murad Hossain, Masayuki Tomita, Mihoko Yamazaki, Yoshiyasu Fukusumi, Hiroshi Kawachi. *Department of Cell Biology, Institute of Nephrology, Niigata University Medicine, Niigata, Japan.*

Background: Eph and ephrin are membrane-bound proteins that function as receptor-ligand pairs. The Eph-ephrin-B family is reported to regulate the paracellular permeability of epithelial cells. We have previously reported that ephrin-B1 was expressed at the slit diaphragm (SD) of podocyte (Kidney Int 72: 954-964, 2007). The aim of this study is to elucidate the function of ephrin-B1 in the SD.

Methods: The expression of ephrin-B is analyzed with an Eph-B2-Fc probe as well as a specific antibody against ephrin-B1. The precise localization of ephrin-B and its interaction with other SD molecules in normal rats and in nephrotic models were analyzed by dual labeling techniques with a confocal laser microscopy. We also analyzed the interaction of ephrin-B1 with other SD molecules by a sequential precipitate/Western blot analysis with glomerular lysates. Next, the binding sites of ephrin-B1 and nephrin were determined with HEK293 cells transfected with full length and several domains of these molecules. Then, the mechanisms of phosphorylation of ephrin-B1 and nephrin are analyzed with HEK293 cells cotransfected with these molecules.

Results: Ephrin-B1 staining at the SD is detected with Eph-B2-Fc probe as a same pattern detected with the specific anti-ephrin-B1 antibody. Ephrin-B1 was co-localized with nephrin, and other SD molecules. The staining of ephrin-B detected by Eph-B2-Fc probe was clearly reduced at early stages of proteinuric models. Analysis with normal rat glomerular lysates revealed that ephrin-B1 interacted with nephrin. The analysis with HEK 293 cells showed that ephrin-B1 interacted with nephrin not via PDZ-binding motif of both molecules. Not only nephrin but also ephrin-B1 was phosphorylated by the anti-nephrin antibody binding to nephrin. The phosphorylation of nephrin was prevented by pretreatment with PP2, a src family kinase inhibitor.

Conclusions: Ephrin-B1 is structurally and functionally interacted with nephrin, and plays a role in maintaining the barrier function of the SD.

Novel Roles of Notch Signal in the Pathogenesis of Collapsing FSGS Toshiharu Ueno,[1] Namiko Kobayashi,[1] Takamoto Ohse,[2] Taiji Matsusaka,[3] Jeffrey W. Pippin,[4] Stuart J. Shankland,[4] Michio Nagata.[1] *[1]Department of Pathology, University of Tsukuba; [2]Division of Nephrology and Endocrinology, University of Tokyo; [3]Department of Medicine, Tokai University; [4]Division of Nephrology, University of Washington.*

Background: Glomerular epithelial cell hyperplasia is the hallmark lesion in Collapsing Focal Segmental Glomerulosclerosis (CFSGS) and that may be involved in the disease progression. In two different mice models of CFSGS, we have shown that predominant hyperplastic epithelial cells are parietal epithelial cell (PEC) by genetic tagging of Lac-Z with nephrin promoter (Asano. JASN 2005, and Suzuki. Am J Pathol 2009).

Methods: The present study investigated one of the feasible transgenic models of CFSGS (NEP25 with immunotoxin, Asano et al JASN 2005) looking at expression Notch signal in the development of CFSGS.

Results: In this model, severe proteinuria and histological feature of CFSGS associated with migration/proliferation of PEC were observed at day 12 after single injection of immunotoxin (n = 8). Immunostaining revealed progressive podocytepenia with Lac-Z stain, and co-localization of Claudin1 (as marker of PEC) and Notch signals (cleaved Notch1, Jagged1 and Hes1) in PEC lesions. Real time PCR of isolated glomeruli revealed one third of reduced expression of podocyte marker, Nephrin and Synaptopodin, and fourfold increase of Claudin1. Over expressions of Notch signals were also observed; threefold increase of Notch1, Hes1, and HeyL, and twofold of Jagged1, Hes1, and Hes5, respectively. To determine the function of Notch signal on PEC, we incubated g-secretase inhibitor (GSI) as a blockade of Notch signal on immortalized PEC line. In the wound healing assay, GSI significantly prevented wound closure (91±2.6%) compared with control (64±6.9%). Moreover, GSI drastically repressed Notch down-stream, Hes1-, Hey1-, HeyL-mRNA, in the PEC.

Conclusions: Ectopic Notch signals in PEC may play pivotal roles for PEC migration/proliferation which is the pathologic base of CFSGS in this model. And blockade of Notch signal can become a new therapeutic approach for CFSGS.

SA-PO2232

Enhanced Albuminuria in an Adriamycin Nephropathy Model in Acatalasemic Mice Keiichi Takiue,[1] Hitoshi Sugiyama,[1] Tatsuyuki Inoue,[1] Ayu Ogawa,[1] Masashi Kitagawa,[1] Hiroshi Morinaga,[1] Shinji Kitamura,[1] Yohei Maeshima,[1] Akira Nishiyama,[2] Hirofumi Makino.[1] *[1]Okayama University Graduate School, Okayama, Japan; [2]Kagawa University, Kagawa, Japan.*

Background: Catalase is an important antioxidant enzyme that regulates the level of intracellular hydrogen peroxide and hydroxyl radicals. The adriamycin (ADR) nephropathy mouse is considered to be an experimental model of focal and segmental glomerular sclerosis with significant albuminuria. However, the effect of a functional catalase deficiency on albuminuria and progressive renal injury in an ADR nephropathy model has not yet been elucidated.

Methods: ADR (15 mg/kg BW) was administered intravenously to both homozygous acatalasemic mutant mice ($C3H/AnLCs^bCs^b$) and control wild-type mice ($C3H/AnLCs^aCs^a$). The functional and morphological alterations of the kidneys, including albuminuria, renal function, podocytic, glomerular and tubulointerstitial injury, the activities of antioxidant enzymes including catalase and glutathione peroxidase were then compared between the two groups until 8 weeks after disease induction. Moreover, the presence of a mutation of the toll-like receptor 4 (TLR4) gene, which is reported in the C3H/HeJ strain, was also investigated in both groups.

Results: The ADR-treated acatalasemic mice developed significant albuminuria in association with glomerular hypertrophy at week 4. The degree of albuminuria in the ADR-treated acatalasemic mice was significantly higher than that in the wild-type mice. No significant difference was observed in the degree of glomerulosclerosis between the two groups. Unexpectedly, the degree of renal dysfunction and tubulointerstitial injury were not remarkable in the ADR nephropathy model of the C3H mouse strain. The level of catalase activity was significantly lower in the kidneys of the acatalasemic mice than in the wild-type mice without any compensatory upregulation of glutathione peroxidase. In addition, the C3H/AnL strain was not identified to contain the TLR4 mutation.

Conclusions: These data indicate that catalase deficiency plays an important role in the development of albuminuria possibly via the functional alteration of renal tubular reabsorption in an ADR nephropathy mouse model.

SA-PO2233

Impairment of Podocyte Function by Diphteria Toxin – A New Reversible Murine Proteinuria Model Andreas Goldwich,[1] Alexander Steinkasserer,[1] Andre Gessner,[2] Kerstin U. Amann.[3] *[1]Department of Immunemodulation at the Dermatology, University Hospital Erlangen, Erlangen, Germany; [2]Institute for Medical Microbiology and Hygiene, University Regensburg, Germany; [3]Nephropathology, Institute for Pathology, University Hospital Erlangen, Erlangen, Germany.*

Background: Diphteria toxin (Dtx) receptor-mediated conditional cell ablation in transgenic mice is a powerful tool to analyze cell function *in vivo.* Transgenic mice with cell-specific expression of the human DTx receptor allow conditional depletion of these cells through Dtx administration. We carefully analysed mice after DTx injection and found proteinuria as unexpected renal side effect. Since non-genetic mouse models of proteinuric glomerular damage are limited we aimed to characterize the DTX-induced model of transient proteinuria in mice.

Methods: C57/Bl6 and C3H/HeJ mice were treated with 40µg/kg DTx/bw i.p (day 0 and 1) with DEREG mice as positive depletion controls. To exclude undesired LPS-effects heat-treated DTx and LPS-resistant C3H/HeJ mice were used. For comparison the anti-GBM nephritis and LPS-induced proteinuria models were analysed. Kidneys were investigated by immunofluorescence, confocal and electron microscopy. Cell culture studies (HeLa,NIH 3T3,murine podocyte cell line) were also performed.

Results: C57/Bl6 mice tolerated up to 80µg/kg DTx whereas higher doses were lethal. Injection of 40µg/kg DTx led to a marked transient and completely reversible proteinuria morphologically characterized by foot process fusion. 5-9 days after DTx application mice recovered completely. In i*n vitro* analysis DTx treated podocytes showed diminished attachment to basal membrane proteins.

Conclusions: Most animal models of non-genetic proteinuric glomerular disease were induced in the rat. The advantage of genetic manipulation technology favor the use of murine models. There is, however, only a limited number of murine podocyte injury models. Hence there is need for mouse models resembling human glomerular diseases. We suggest DTx-induced kidney dysfunction as a new reversible model of podocyte injury with transient proteinuria. which could be used as an additional approach to complement studies in humans.

SA-PO2234

Semaphorin 3G and Cystatin C Are Expressed in Podocytes of Rat and Are Differentially Regulated upon Toxic Injury Pierre Moulin,[1] Frank Dieterle,[2] Andre Cordier,[1] Valérie Dubost.[1] *[1]Molecular Pathology & Immunology, Novartis Institutes of Biomedical Research, Basel, BS, Switzerland; [2]Molecular Diagnostics, Novartis AG, Basel, BS, Switzerland.*

Background: Experimental glomerulopathies induced by toxic agents offer the unique opportunity to study the sequence of molecular events leading to podocyte alteration and thereby unveil early biomarkers of glomerular injury.

Methods: This study compared the molecular profile of kidney from rats treated with glomerular (e.g. Puromycin) or with tubular nephrotoxicants (e.g. Cisplatin) for various

durations (3 to 22 d). Samples were processed for gene expression profiling, histopathology and in situ hybridization(ISH)/immunohistochemistry(IHC).

Results: The initial transcriptional analysis compared glomerular and tubular toxicants. The resulting signature suggestive of glomerular damage was subsequently confirmed on laser-capture microdissected glomeruli. Major elements of this signature were CystatinC (Cst3) and Semaphorin3G (Sema3g). Interestingly, Cst3 was upregulated whereas Sema3g was downregulated during glomerular injury. ISH showed Cst3 and Sema3g mRNA expression mainly in podocytes. Moreover semi-quantitative image analysis of the ISH signal on samples from treated animals confirmed the differential regulation of both markers specifically in podocytes. Finally, the comparison between Cst3 ISH and IHC reveals temporal sequence of glomerular and tubular injuries.

Conclusions: In conclusion this is the first report of the expression of Cst3 and Sema3g mRNA in podocytes of rats. In our observations, these two transcripts were differentially regulated early in the course of toxicity and were useful markers to establish the temporal sequence between tubular and glomerular lesions. However, whether the differential regulation of these two transcripts represents distinct aspects of podocyte adaptation or reaction to injury is unclear. Sema3G is a novel podocyte marker, mostly known as a regulator of angiogenesis. Its modulation during glomerular toxicity sheds light on new aspects of podocyte involvement in the pathogenesis of glomerular lesions.

HIV Induces Tubular Cell ROS Generation and DNA Strand Breaks through Down Regulation of Vitamin D Receptor (VDR) Divya Salhan, Shabina Rehman, Ashwani Malhotra, Mohammad Husain, Pravin C. Singhal. *Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY.*

Background: HIV infection of tubular cells has been implicated for tubule cell injury in HIV-associated nephropathy (HIVAN). In the present study, we evaluated the role of vitamin D receptor (VDR) in HIV-induced tubular cell injury.

Methods: To develop *in vitro* model of HIV-infected tubular cells, mouse tubular cells (MCT) were transduced with empty vector (EV/MCT) or NL4-3 (HIV/MCT) constructs. To determine the effect of HIV on mitochondrial ROS generation, EV/MCTs and HIV/MCTs were double labeled with Red-CC1 (ROS labeling) and MITOTracker green (mitochondrial labeling). To study occurrence of double strand DNA breaks, EV/MCTs and HIV/MCTs were labeled with H2AX and examined by confocal microscopy. Immunoblots were probed for VDR expression in EV/MCTs and HIV/MCTs. To establish causal relationship between lack of VDR and ROS generation, siRNA-VDR transfected MCTs and control cells were evaluated for ROS generation and DNA breaks. To confirm the relationship between VDR and DNA injury, EV/MCTs and HIV/MCTs were treated with either buffer or vitamin D2 analogue, followed by evaluation of cells for ROS generation (co-labeling with Red CC1 and MITO tracker green) and DNA repair by labeling for RAD1. Immunoblots were probed for VDR from cells treated under similar conditions.

Results: HIV/MCTs displayed increased (P<0.01) mitochondrial generation of ROS as well as higher number of double strand DNA breaks. Interestingly, HIV/MCTs also showed downregulation (P<0.01) of VDR. siRNA-VDR/MCTs also displayed enhanced generation of ROS and higher number of double strand DNA breaks. However, treatment of HIV/MCTs with a vitamin D2 analogue not only enhanced (P<0.01) expression of VDR by HIV/MCTs but also displayed attenuated (P<0.01) generation of ROS as well as enhanced DNA repair.

Conclusions: Since reversal of HIV-induced attenuated VDR expression by a vit D analogue was associated with attenuated ROS generation and enhanced repair of DNA breaks, it would suggest that HIV-induced tubular cells ROS generation and DNA breaks may be caused by HIV-induced downregulation of VDR and associated signaling events.

SA-PO2236

Effects of Sodium Thiosulfate on Urinary Lithogenicity in Adults with Hypercalciuric Nephrolithiasis Onyeka W. Okonkwo,[1] John R. Asplin,[2] David S. Goldfarb.[3] *[1]Medicine, New York VAMC, New York, NY; [2]Litholink, Chicago, IL; [3]Nephrology Section, New York Harbor VAMC and NYU School of Medicine, New York, NY.*

Background: Sodium thiosulfate (STS) has been shown to reduce calcium stone formation in both humans (Yatzidis; Clin Nephrol 1985), and genetic hypercalciuric stone forming rats (GHS; Asplin at al; 2009). We studied the effects of STS on the urine and serum chemistries in hypercalciuric stone forming adults.

Methods: 5 people with idiopathic hypercalciuria and calcium kidney stones with a mean age of 66 years participated. 2 baseline 24-hour urine collections were performed on days 2 and 3 of 3 days of recorded self-selected diets. Subjects then drank STS 10 mmol BID for 7 days and repeated 24h urines while repeating the 3 days of self-selected diet from the first period. Results were compared by non parametric Wilcoxon signed rank test. Results were also compared to those of a prior study involving healthy non-stone-forming subjects administered STS.

Results: STS administration did not cause a significant change in urinary calcium excretion. It increased 24 hour urinary ammonia (P=0.002) and sulfate excretion (P=0.001) and decreased urinary pH (P=0.001) and citrate excretion (P=0.004). 3 of 5 patients had measurement of serum HCO_3 concentration: it did not change. The findings were similar to those from a prior study involving normal adults with the exception that urinary calcium excretion increased in those subjects.

Effects of STS on 24 hour urine chemistry

	Mean baseline	Mean post STS	p-value
Calcium	279 ± 155	277 ± 144	0.918
pH	6.09 ± 0.58	5.76 ± 0.52	0.001
Ammonium	36 ± 6	56 ± 11	0.022
Citrate	606 ± 195	444 ± 221	0.004
Sulfate	44 ± 14	99 ± 16	0.001

Conclusions: Although STS is apparently effective in preventing stones in humans and did prevent stones in GHS rats, the basis for these effects was not reflected by the changes in urine chemistry seen here. Although serum HCO_3 did not change, urine tests (increased urine ammonium, decreased urine citrate and pH) were suggestive of an increased acid load. Although STS did not change urine calcium, evidence of an acid load suggests that the long term safety of STS with respect to bone needs to be studied.

SA-PO2237

Reduced Bone Mineral Density in Young Adults with Childhood Onset Idiopathic Hypercalciuria Carlos Cuervo, Carolyn L. Abitbol, Jayanthi Chandar, Wacharee Seeherunvong, Gaston E. Zilleruelo, Michael Freundlich. *Pediatric Nephrology, University of Miami, FL.*

Background: Sustained low bone mineral density (BMD) in children with idiopathic hypercalciuria (IH) may lead to reduced peak bone mass and adult osteoporosis, but to date longitudinal studies of BMD with its predictors are lacking.

Methods: Children (81; 9.6±3.8yr) on cross sectional evaluation had IH; 53/81(66%) including 24>16 yr followed longitudinally 4.0±2.8 yr(range1-12) with ≥2 DXA studies (GE-Lunar) at spine (Sp) and femoral neck (Fn). Clinical measurements, K citrate and/or thiazide treatment (Rx) ≥6 months were analyzed.

Results: PTH, Ca, P, CO2, GFR, and final height and BMI Z-scores (-0.02 and 0.19, respectively) were normal. Calciuria (mg/kg/24 hrs)↓from baseline (7.3±3.0 vs.3.0±1.4; p<0.0001) and Rx significantly↓calciuria 3.58±1.7 to 2.7±1.0 (p=0.01). Cross sectional Z-scores <-1 were evident in 37% of patients at both Sp and Fn. Table summarizes BMD Z-scores in the longitudinal subcohort. By univariate analysis initial age, interval time between DXA studies, and Ca, P, PTH did not associate significantly with final Sp or Fn Z-scores. However, initial and final calciuria associated directly with final Sp Z (r=0.33, P=0.01 and r=0.48, P=0.0001) but not with Fn Z. By multiple regression analysis, initial Sp Z was the strongest predictor of final Sp Z (P<0.0001). Patients>16 yr had lowest final Sp (-0.8±1.5) and Fn Z-scores (-1.26±1.23) vs. children<11 yr (-0.7±1.3 and -0.65±1.3) and adolescents >11<16 yr (-0.24±0.3 and 0.1±1.2).

Conclusions: A high patient proportion with childhood onset IH present with reduced BMD and show progressive decline during adolescence with ultimate reduced BMD, particularly those with initial reduced measurements. Early screening with DXA appears indicated to identify patients at risk for adult osteoporosis.

Longitudinal BMD Z-scores in young patients with Idiopathic Hypercalciuria

Spine (n=53)			Femoral Neck (n=28)		
	Initial	Final		Initial	Final
>-1 Z-score (n=31)	-0.02±0.8	0.04±1.2	>-1 Z-score(n=17)	-0.1±0.62	-0.24±0.9
<-1 Z-score (n=22)	-1.83±0.7	-2.1±1.2**	<-1 Z-score(n=11)	-1.63±0.64	-1.66±1.3*

** P<0.0001 and * P=0.002 vs. final values of patients with initial Z-scores>-1

SA-PO2238

Urine pH in Diabetic and Non Diabetic Stone Formers with Different Body Mass Index Elisa Elena Del Valle, Armando Luis Negri, Francisco Rodolfo Spivacow, Juan Ibañez. *Nephrology, Instituto de Investigaciones Metabolicas, Argentina.*

Background: Patients with type 2 diabetes are at increased risk for nephrolithiasis due to low urine pH. Overweight and obesity is frequent in this population. Higher body mass can contribute to the lower urine pH in these patients as there is a strong inverse association between pH and body weight. The purpose of this study was to identify if stone forming diabetics had a lower urine pH independent of their body mass.

Methods: Two groups of individuals were recruited for our outpatient clinic: patients who have type 2 diabetes and were stone formers (DSFn =31) and patients who were stone formers but did not have diabetes (NDSF; n =56). Both groups were paired for age and creatinine excretion. Participants had a complete stone risk analysis that included urine pH. Both groups were divided according to their BMI (kg/m2) in normal (BMI < 24.9) overweight (BMI 25 to 29.9) and obese (BMI ≥30).

Results: DSF had lower 24-h urine pH than NDSF. Urine pH remained significantly lower in DSF than NDSF in Overweight and obese groups: normals: DSF 5.75; NDSF 5.98 (NS); overweight: DSF 5.32; NDSF 5.76 (p<0.04); Obese: DSF 5.15; NDSF 5.79 (p<0.001)

Conclusions: Although higher body mass can contribute to the lower urine pH in stone formers with type 2 diabetes it cannot entirely account for that finding. An increased acid intake or generation could probably explain the difference in urine pH.

SA-PO2239

Blockade of Megalin Attenuates Nephrocalcinosis in Rats Isao Matsui, Kazunori Inoue, Takayuki Hamano, Akihiro Shimomura, Chikako Nakano, Tomoko Namba, Hiroki Omori, Masaru Horio, Hiromi Rakugi, Yoshitaka Isaka. *Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Megalin is an apical membrane protein of proximal tubular cells that works as a multifunctional endocytic receptor. Because megalin regulates the intracellular localization of type IIa sodium-dependent phosphate cotransporter (Na-Pi IIa), it was suggested that megalin plays some roles in the development of nephrocalcinosis.

Methods: We examined whether the blockade of megalin affects the development of nephrocalcinosis in rats. We inhibited the function of megalin by histidine-tagged soluble receptor-associated protein (His-sRAP). Nephrocalcinosis was induced by continuous injection of PTH 1-34 at a dose of 40 μg/kg/day for 48 hours. Rats were randomly divided into three groups; control (group C), PTH + vehicle (group P+V), or PTH + His-sRAP group (group P+H).

Results: In comparison with group C, group P+V developed extensive calcification in the renal cortex and in the outer stripe of outer medulla. His-sRAP injection dramatically reduced the calcification (group P+H). Because urinary calcium and phosphate levels in group P+H were higher than those of group P+V, it was suggested that the urine of group P+H contained inhibitory molecules against crystallization. To investigate the underlying mechanism, we analyzed whether His-sRAP affected the distribution of fetuin-A, a systemic inhibitor against calcification. Although normal rat kidney did not express mRNA for fetuin-A, immunohistochemistry demonstrated a punctate staining of fetuin-A in the megalin expressing proximal tubular cells. The blockade of megalin by His-sRAP attenuated the fetuin-A staining and resulted in a loss of fetuin-A into the urine. Because fetuin-A prevents a mineral precipitation in a solution of calcium and phosphate, the retention of fetuin-A in the tubular lumen explain the reason, at least partly, why His-sRAP attenuated intratubular crystal formation, hence nephrocalcinosis.

Conclusions: Blockade of megalin by His-sRAP attenuates nephrocalcinosis in rats.

Clinical Characteristics of Hypercalcemia Due to Adrenal Insufficiency in Patients on Long-Term Hemodialysis Yukitoshi Sakao,[1] Akihiko Kato,[1] Hideo Yasuda.[2] *[1]Blood Purification Unit, Hmamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan; [2]First Department of Medicine, Hmamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan.*

Background: Hypercalcemia is rarely caused by adrenal crisis. However, the mechanisms for hypercalcemia due to adrenal insufficiency remain to be determined in patients on hemodialysis (HD).

Methods: We examined the clinical characteristics of hypercalcemia caused by acute adrenal failure in 5 HD patients. We also analyzed bone turnover markers before and after the replacement of glucocorticoid agents.

Results: The patients' age and vintage on HD were ranged from 44 to 75 years old and from 7 to 32 years respectively. At the onset of hypercalcemia, all patients were anuric, and under critically ill conditions. The causes of adrenal insufficiency were isolated ACTH deficiency, pituitary apoplexy and glucocortiocoid withdrawal syndrome. Serum calcium (Ca) corrected by serum albumin were maximally increased to 12.9 to 14.9 mg/dl. Intact parathyroid hormone (iPTH) levels were reduced to 4 to 38.5 pg/ml expect for 1 patient with severe secondary hyperparathyroidism. Serum 1,25-dihydroxy-vitamin D3 level was also suppressed to 8.1 to 16.2 pg/ml in 4 cases. Serum levels of type I collagen telopeptides, a marker of bone reabsorption (ICTP), were elevated in all patients. Basal ACTH levels were 2.9 to 40.2 pg/ml, while cortisol levels were as low as <6.5 μg/dl in 4 patients and 15.4 μg/dl in 1 patient. A single corticotropin-releasing hormone injection failed to increase plasma ACTH and cortisol in all patients. Glucocorticoid replacement therapy acutely decreased serum Ca and ICTP levels, while increased serum iPTH. Administration of bisphosphonate also normalized serum Ca without glucocorticoid treatment in 1 patient.

Conclusions: These findings suggest that the adrenal failure-induced hypercalcemia could occur in anuric patients on long-term HD when complicated of acute illness. Increased bone reabsorption due to adrenal insufficiency without any urinary Ca excretion may be related to the development of hypercalcemia.

SA-PO2241

Modulation of FGF23 by Phosphate Binders in Chronic Kidney Disease Stage 4-5 Predialysis (Lanthanum vs Calcium Carbonate) Sagrario Soriano, Raquel Ojeda, Maria Luisa Agüera, Mariano Rodriguez, Alejandro Martin-Malo, Pedro Aljama-Garcia. *Nephrology, Hospital Universitario Reina Sofia, Córdoba, Spain.*

Background: Cardiovascular mortality is increased in Chronic Kidney Disease (CKD) patients with serum phosphate (P) concentration in the upper limit of normality. Increased serum concentration of FGF 23 is also independently associated with cardiovascular mortality. The present study evaluates in CKD 4-5 patients on protein restriction (1g/Kg/day) whether a reasonable dose of calcium carbonate (1.5 g/day) or lanthanum carbonate (1.35 g/day) have an effect on serum FGF23 levels.

Methods: Thirty two patients were selected; after one month wash out they were randomized to receive four months of calcium carbonate or lanthanum carbonate. Patients included had serum P>4 mg/dl, a normal serum calcium, 25(OH) levels >20 ng/ml, no treatment with VDR activators or Cinacalcet. Baseline clinical characteristics of patients were similar in both groups.

Results: Results are presented in the following.

Calcium Carbonate (1) Lanthanum Carbonate(2)

	Baseline(1)	After treatment(1)	Baseline(2)	After treatment(2)
Cr Cl (MDRD-7, ml/min)	15,6±3,6	16.6±7,1	17,8±5,6	17,6±5,5
P (mg/dl)	4,7±0,8	4,5±0,7	5±0,4	4,6±0,5 *
PTH (pg/ml)	195±34	210±87	104±57	130±86
FE (PO4) (%)	46,2±8,9	52,4±17	46,4±9,5	39,2±8,3 *$
Intact FGF23 (pg/ml)	237,8±44	245,9±75	230,4±65	146,2±30 *$

Values are mean ± SD are shown, Cr Cl: Creatinine clearance, P: serum phosphate, FE (PO_4)(%): fractional excretion of phosphate. *P <0,05 vs same group baseline,. **$** P <0,05 vs calcium carbonate after treatment

Conclusions: In CKD 4-5 patients the administration of 1.5 g of Calcium Carbonate produced a non significant decrease serum phosphate levels and, FGF 23 and FE(PO_4) did not change. By contrast, the administration of Lanthanum carbonate (1.35 g) resulted in a decrease in serum phosphate levels together with a reduction of FE(PO_4) and plasma concentration of FGF23. In conclusion, in CKD 4-5 the administration of lanthanum carbonate decreases the phosphate load as reflected by the reduction in FE(PO_4) and the marked decrease in FGF 23.

SA-PO2242

Preliminary Data of the Italian Multicentric Study on the Prevalence of Vascular Calcifications and Vertebral Fractures in Parathyroidectomised Dialysis Patients (CAVE PTX Study) Sandro Mazzaferro.[1,2] *[1]Cardiovascular, Respiratory, Nephrologic and Geriatric Sciences, Sapienza University, Rome, Italy; [2]Mineral Metabolism & Trace Element Study Group, Italian Society of Nephrology.*

Background: The CAVE PTX study is aimed at evaluating, in dialysis patients who received PTX at any time in their life, the biochemical control of divalent ions (phase I), and the prevalence of aortic calcifications and vertebral fractures (phase II).

Methods: We report here data of the phase I. During 2010, values of Ca, P, AP and PTH and pertinent therapies, were asked from 149 dialysis Unit from all over Italy, supplying therapy to 12515 patients (HD = 87.7%; DP = 12.3%)

Results: 123 Units had data of 528 living PTX patients (29 on PD). Prevalence of PTX (4.22%), was different between HD (4.5%) and PD (1.9%). Clinical characteristics were: age 58±13 y.o.; sex: 56% female, dialysis: since 15±8 years; diabetes: 7%; BMI: 25±4, Systolic BP: 126±21 and Diastolic BP: 73±12 mmHg; on antihypertensive drugs: 45%; on EPO: 80%. With the exception of reduced albumin (3.9±0.5 g/dl), biochemical parameters averaged mostly acceptable values: PTH 182 ± 292 pg/ml; Ca 8.8 ± 0.8 mg/dl; P 4.9±1.3 mg/dl; AP 240±210 mU/ml (n.v. 90-270); Hb 11 ± 1 g/dl). Prescribed therapies were: Phosphate binders = 87.8% (Ca based: 67.4%; Sevelamer: 50.5%; Lanthanum 11%; Aluminum: 14.9%); vitamin D = 61.8% (oral calcitriol 71.1%; i.v. calcitriol 6.2%; paricalcitol 22.3%; other D: 1.8%), calcimimetic = 12.8%. PTX had been mostly subtotal (54.8%) or total (38%), with only 4.7% treated with total PTX plus autotransplantation. PTH was optimal (150-300) in a limited 17%; high in 19 and low in 64% of the cases. Serum Ca was optimal (8.5-9.5) in 47%, high in 19% and low in 34%. Serum P was optimal (3.5-5.5) in 54%, high in 33% and low in 14%.

Conclusions: PTX prevalence in Italy is low and is confirmed to involve relatively young patients, mainly female, and with a long history of haemodialysis. These patients show acceptable control of divalent ions, but most of them require active therapies for secondary hyperparathyroidism. Low PTH values are very frequent and associated with low-normal Ca. Evaluation of hard outcomes is mandatory.

SA-PO2243

Increased Platelet Count and Marrow Fibrosis in Rats with Renal Failure and Secondary Hyperparathyroidism Cheryl P. Sanchez,[1] Kristen R. Friedrichs.[2] *[1]Pediatrics, LLUMC, Loma Linda, CA; [2]Pathobiological Sciences, UW Sch Vet Med, Madison, WI.*

Background: Bone marrow fibrosis (BMF) has been associated with elevated PTH levels seen in primary and secondary hyperparathyroidism (SPHT), and may contribute to bone disease and anemia. Recent studies have shown that factors associated with megakaryocytes and platelets such as TGF-b may contribute to BMF.

Methods: To evaluate changes in platelet and megakaryocytes in renal failure and SHPT, 23 male weanling rats (48 ± 3 grams) underwent a 2-stage 5/6 nephrectomy (NX, N=16) or sham Nx (C, N=7). Nx rats were fed standard diet (Nx-C, N=7) or high phosphorus diet, 1.2% (Nx-P, N=9). At the end of 4 weeks, blood was obtained for CBC, PTH and creatinine levels. The femur was used for marrow analysis, sternum for marrow histology and tibia for trichome stain.

Results: Tibial length was shorter in Nx-P, 3.0±0.1 cm, versus Nx-C, 3.2±0.06 cm and C, 3.2±0.03, p<0.0003. Hemoglobin (Hgb) decreased in Nx-P and Nx-C, 10±1.7 g/dL and 13±4 g/dL, compared to C, 15±0.4 g/dL, p<0.05. PTH was higher in Nx-P, 1719±599 pg/mL, versus Nx-C and C, 142±67 pg/mL and 66±78 pg/mL, p<0.0001. In the peripheral blood, platelet count increased in Nx-P, 1221±131 $x10^3$/uL, p<0.002, and similar between Nx-C and C, 933±243 $x10^3$/uL and 905±125 $x10^3$/uL. Mean platelet volume did not change. There was an increase in segmenters in Nx-P and Nx-C, 0.6±0.2 $x10^3$/uL and 0.4±0.1 $x10^3$/uL, compared to C, 0.2±0.1 $x10^3$/uL, p<.05; this may suggest an inflammatory state. Nx-P had significant reticulin staining in the sternum and tibia, 2.8±0.4 and 2.8±0.5, compared

to Nx-C, 0.8±0.4 and 0±0, and C, 0.8±0.7 and 0±0, p<0.01. Marrow core analysis showed similar megakaryocyte score in all groups. Qualitatively, trichome staining was present only in the marrow of Nx-P. Platelet count correlated with reticulin, R=0.7, p<0.0003 and PTH, R=0.6, p<0.002. There was an inverse relationship between Hgb and platelet count, R=-0.5, p<0.009.

Conclusions: An increase in platelet count may contribute to BMF in advanced SHPT without any changes in megakaryocte numbers. Further studies are needed to determine the alterations in growth factors associated with platelet and megakaryocytes in renal failure.

SA-PO2244

Skeletal FGF-23 and DMP1 Expression Increase during Treatment of Secondary Hyperparathyroidism R.C. Pereira,[1] Harald Jueppner,[2] Barbara Gales,[1] Isidro B. Salusky,[1] Katherine Wesseling-Perry.[1] *[1]Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Endocrine Unit, Massachusetts General Hospital, Boston, MA.*

Background: Skeletal FGF-23 expression correlates with plasma FGF-23 levels and vitamin D sterol therapy increases plasma FGF-23 levels in dialysis patients; however, it is unknown how therapy affects skeletal expression of FGF-23 and its regulator DMP1.

Methods: 10 dialysis patients (6M, 4F), age 16.9 ± 0.7 years, with secondary hyperparathyroidism underwent bone biopsy before and after 8 months of therapy with vitamin D sterols and phosphate binders. Biochemical values, bone histomorphometry, and skeletal expression of FGF-23 (determined by immunohistochemistry and quantified by Ariol scanning) were measured at baseline and after therapy (Table 1. *p<0.05). Plasma FGF-23 values were determined by the 2nd generation C-terminal assay (Immutopics).

Results: Plasma FGF-23 increased by 226 ±111% from baseline while other biochemical parameters did not change. Bone FGF-23 and DMP1 expression increased by 340 ± 155% (p<0.05) and 134 ± 45% (p<0.05), respectively.

Variable	Baseline	Post-therapy
Biochemicals		
Ca (mg/dl)	8.7 ± 0.3	9.0 ± 0.1
P (mg/dl)	6.4 ± 0.5	5.4 ± 0.3
PTH (pg/ml)	653 ± 81	717 ± 90
Alkaline phosphatase (IU/l)	314 ± 51	385 ± 152
25(OH)vitamin D (ng/ml)	19 ± 3	26 ± 2
FGF-23 (2nd generation C-terminal, Immutopics) (RU/ml)	743 (478, 1196)	1972 (565, 3973) RU/mL * 226 ± 111%
Bone Histomorphometry		
BFR/BS (um²/mm³/d)	54.7 ± 9.7	39.9 ± 11.6
OV/BV (%)	6.7 ± 1.0	4.7 ± 0.9
OS/BS (%)	40.7 ± 0.6	31.9 ± 3.9*
O.Th (µm)	13.6 ± 0.8	11.5 ± 0.8
OMT (d)	15.0 ± 1.7	15.0 ± 2.0
MLT (d)	38.9 ± 8.4	66.0 ± 32.1
BV/TV (%)	39.9 ± 3.4	36.4 ± 2.8
Tb.N (n/mm²)	2.2 ± 0.1	2.1 ± 0.1
Tb.Sp (µm)	279 ± 19	321 ± 46
Skeletal Protein Expression		
Bone FGF-23 (pixels/mm²)	195 (136, 256)	371 (310, 857) *
Bone FGF-23 (pixels/mm²)	3833 (3456, 6015)	8560 (7459, 10362) *

The percent change in bone FGF-23 correlated with the percent change in plasma FGF-23 (r=0.60, p=0.06).

Conclusions: Therapy with vitamin D sterols increases skeletal FGF-23 as well as DMP1 expression in dialysis patients with secondary hyperparathyroidism, suggesting that dysregulation of osteocyte function may be exacerbated by current therapeutic strategies. How these changes affect long-term outcomes, including bone and cardiac morbidity, remains to be determined.

SA-PO2245

Outcomes of a Large Series of Parathyroidectomies Performed in a Single Centre Satish Babu Ramakrishna. *Renal Medicine, University Hospital Birmingham, Birmingham, United Kingdom.*

Background: Secondary Hyperparathyroidism (SHPT) is an important complications of renal failure and its management remains a challenge. Total parathyroidectomy (PTX) is widely used but questions regarding long term outcomes remain unanswered. Low paratharmone (PTH) levels and adynamic bone disease following

(PTX) are considered significant risk factors for fractures.

Methods: Between 2000 to 2007, 131 total parathyroidectomies were performed without re-implantation at a single centre by a single operator. Clinical information and biochemistry data were obtained along with fracture data. Calcium, phosphate and PTH were recorded pre-operatively and at 1, 6 and 12 months after PTX.

Results: Mean age at the time of PTX was 47 years. Time on RRT before PTX varied from 20 to 100 months with an average of 65 months. Mean follow up period is 3.5±2.06yrs. The PTH fell significantly from a median of 995pg/ml pre surgery to 7.9pg/ml at 1 month and remained low at 6.0pg/ml at 6 months and 33.0pg/ml at 12 months. The average calcium level pre-operative was 2.6mmol/L (SD 0.24mmol/L) which dropped to 2.28mmol/L(SD 0.38mmol/L) at 1 month and 2.36mmol/L(SD 0.3mmol/L) at 12 months. There was no significant fall in phosphate levels after surgery. Six patients who had recurrence of SHPT underwent repeat PTX and one patient required 2 repeat operations. Only four patients had fractures following PTX equating to 7.77 fractures per 1000 patient years. All the four patients who had the fractures had recurrence of SHPT and the 63% of patients with PTH suppressed below 70pg/ml at 12 months had no fractures. There were no cases of laryngeal nerve palsy and no significant surgical complications. There were no deaths in the first year following surgery and 19 deaths thereafter.

Conclusions: In our centre PTX plays an important role in the management of severe SHPT. It can be a safe and effective treatment resulting in significant suppression of PTH, a fall in the mean serum calcium and no increased risk of fractures over 1-7 years following surgery.

SA-PO2246

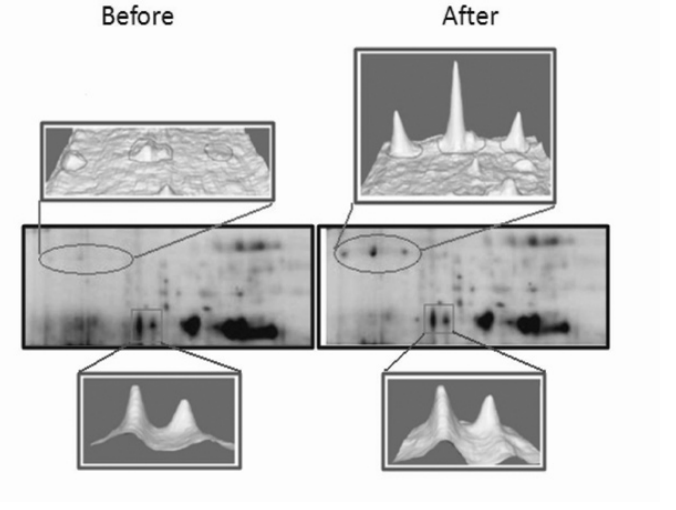
Serum Proteomics Analysis of in a Hemodialysis Patient with Secondary Hyperparathyroidism before and after Parathyroidectomy Operation Itir Yegenaga,[1] Murat Kasap,[2] Gurler Akpinar,[2] Sibel Bek,[1] Sara Yamaner.[1] *[1]Internal Medicine, Nephrology, Kocaeli University Medical School, Kocaeli, Izmit, Turkey; [2]Medical Biology, Kocaeli University Medical School, Kocaeli, Izmit, Turkey.*

Background: Systemic bone and mineral disturbances co exist in CKD patients from the very early stages and effects life quality, morbidity and mortality. Uremic bone disease shows heterogeneity in terms of bone turnover; while most patients suffer with high turnover (secondary hyperparathyroidism-HPT) the others have low turnover (adynamic) bone disease. It is important to know the bone turnover to apply appropriate treatment to these patients.

Methods: We analyzed serum proteome profile pre and post-op of parathyroidectomy operation in a 33 year old male hemodialysis(HD) patient with secondary HPT. We aim to detect some changes in proteome profile correlated PTH level and may be used as a marker to determine the bone turnover. Less abundant protein fractions obtained by microrotofor fractionation were applied to the two D-gel electrophoresis on the pH 3-10 IPG strips, three spots took the attention which appeared after parathyoidectomy and they were cut from the gel and were subjected to MALDI-TOF TOF analysis .

Results: Two of the spots were identified with high confidence and one of them belonged to a protein defined as a zinc finger- FYVE containing domain (ZFYVE). Among ZFYVE Osterix was reported to be involved in bone turnover.This protein might be an Osterix homologue and related to bone turnover.

Conclusions: Since this is only one case and the preliminary results report, this hypothesis needs to be proven and further investigations to understand the relationship and if there is; importance of ZFYVE on bone turnover.



SA-PO2247

Increased Extramedullary Hematopoiesis in Anemic Rats with Renal Failure and Secondary Hyperparathyroidism Cheryl P. Sanchez,[1] Kristen R. Friedrichs.[2] *[1]Pediatrics, LLUMC, Loma Linda, CA; [2]Pathobiological Sciences, UW Sch Vet Medicine, Madison, WI.*

Background: Anemia and secondary hyperparathyroidism (SHPT) are complications of renal failure. Studies have shown that anemia is worst in advanced SHPT. In children, anemia has been correlated with poor growth.

Methods: To demonstrate whether extramedullary hematopoiesis (EMH) is increased in renal failure and severe SHPT, 23 male weanling rats (48 ± 3 grams) underwent a 2-stage 5/6 nephrectomy (NX, N=16) or sham Nx (C, N=7). Nx rats were fed standard diet (Nx-C, N=7) or high phosphorus diet, 1.2% (Nx-Phos, N=9). At the end of 4 weeks, blood was obtained for CBC, PTH, creatinine, calcium and phosphorus. The femur was used for bone marrow analysis and the sternum for bone marrow histology.

Results: Nx-Phos group had lower gain in weight and length, 77±12 grams and 9.8±1.2 cm, compared to Nx-C, 89±7 grams and 11.4±.0 cm and C, 94±9 grams and 12±0.9 cm, p<0.01. Tibial length was shorter in Nx-Phos, 3.0±0.1 cm, versus Nx-C, 3.2±0.06 cm and C, 3.2±0.03, p<0.0003. Hemoglobin (Hgb) decreased in Nx-Phos and Nx-C, 10±1.7 g/dL and

13±4 g/dL, compared to C, 15±0.4 g/dL, p<0.05. Estimated reticulocyte count increased in Nx-Phos, 2.6±1.4 x10^{5}u/L compared to Nx-C and C, 1.4±0.4x10^{5}u/L and 1.0±0.3x10^{5}u/L, p<0.01. Nx-Phos had increased polychromatophil score, 2.0±1.4, compared to Nx-C and C, 1.0±.0 0.7, p<0.01, denoting enhanced peripheral regeneration. When corrected for tibial length, total erythrocyte counts in the marrow were similar in all groups. EMH was more pronounced in the liver of Nx-Phos, 1.33±1.0 versus Nx-C and C, 0.29±0.4 and 0±0, p<0.03, and in the spleen, 2.0±0.4 in Nx-Phos versus Nx-C and C, 1.1±1.4 and 0.3±0.4, p<0.01. Reticulin staining increased in the sternum and tibia of Nx-Phos, 2.8±0.4 compared to Nx-C and C, 0.8±0.4, p<0.01. Hgb correlated with body length, R=0.7, p<0.005. There was an inverse relationship between Hgb and PTH, R=-0.9, p<0.0001.

Conclusions: Findings in the current study suggest that response to anemia in renal failure and severe SHPT may be limited by reticulin in the marrow, and an increase in peripheral regeneration may be due to an enhancement of extramedullary hematopoiesis in the liver and spleen.

SA-PO2248

Decrease of Serum Sphingosine-1-Phosphate Levels in Hemodialysis Patients with Secondary Hyperparathyroidism Treated with Cinacalcet

Keitaro Yokoyama,[1] Ichiro Ohkido,[1] Takeo Iwamoto,[2] Mari Ishida,[3] Mitsuyoshi Urashima,[4] Tatsuo Hosoya.[1] *[1]Division of Kidney and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; [2]Core Research Facilities, Division of Biochemistry, The Jikei University School of Medicine, Tokyo, Japan; [3]Jinyukai Kitasaito Hospital, Asahikawa, Japan; [4]Division of Molecular Epidemiology, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Both cinacalcet, a calcium sensing receptor agonist, and sphingosine-1-phosphate (S1P) affect bone mineral homeostasis(Ishii M. Nature 2009). Consequently, we investigated the effects of cinacalcet on serum levels of SIP in hemodialysis (HD) patients with secondary hyperparathyroidism (SHPT).

Methods: Thirty-four chronic HD patients with SHPT for more than 3 months were enrolled in this prospective intervention study. We measured serum S1P by liquid chromatography-tandem mass spectrometry before and after treatment with cinacalcet.

Results: Serum S1P decreased significantly after 6 month-treatment with cinacalcet in all patients (897.5+/-424.1 to 251.9+/-46.4 nmol/l, P<0.001). Serum S1P level showed no significant associations with age, gender, HD vintage, serum creatinine, urea, calcium, phosphorus, intact parathyroid hormone, alkaline phosphatase, tartrate-resistant acid phosphatase 5b or hematocrit.

	Pre	Post	P value
S1P (nmol/L)	897.5+/-424.1	251.9+/-46.4	<0.001
cCa (mg/dL)	9.53+/-0.55	9.02+/-0.90	<0.01
P (mg/dL)	6.05+/-1.63	4.92+/-1.36	<0.01
iPTH (pg/mL)	248.2+/-164.8	81.8+/-59.5	<0.001
ALP (U/L)	256.0+/-121.95	257.5+/-130.6	0.87604
TRAP5b (mU/dL)	442.9+/-263.5	298.6+/-23.2	<0.001

Changes in various parameters after cinacalcet administration

There were no associations between the decrease of S1P and change of iPTH, TRAP, or ALP.

Conclusions: These results suggest that cinacalcet may reduce serum S1P level in HD patients with SHPT. This mechanism of serum S1P level reduction after cinacalcet administration was unknown. However, since S1P has various physiological actions, this finding may explain some physiological effects of cinacalcet hydrochloride in addition to its known suppression of parathyroid hormone secretion.

Vitamin E Decreases Vascular Calcification in Obese (Zucker fa/fa) Uremic Rats

Alan Peralta-Ramírez,[1, 2,3] Carmen Pineda,[3] Fatima Guerrero,[3] Maria Encarnacion Rodriguez Ortiz,[4] Elisa Diez de Castro,[3] Addy Rosa Montes de Oca Gonzalez,[3] Yolanda Almaden Peña,[4] Mariano Rodriguez,[4] Escolastico Aguilera-Tejero,[3] Ignacio Lopez.[3] *[1]Escuela de Medicina Veterinaria, UNAN-Leon, Nicaragua; [2]Fundacion Carolina, Spain; [3]Dpto. Medicina y Cirugia Animal, Universidad de Cordoba, Spain; [4]IMIBIC, Córdoba, Spain.*

Background: Vascular calcification(VC) is a frequent complication in patients with chronic kidney disease(CKD) and diabetes. Hyperphosphatemia is a major pathogenic factor for uremic VC while chronic inflammation and oxidative stress seem to be related to both uremia and diabetic VC. In addition, mitochondrial ROS-NFκB signaling has been recently shown to be involved in phosphate(P) induced VC. According that, antioxidants, such as vitamin E (vit.E), may protect against VC. We hypothesized that a diet with high vit.E content may decrease VC in an in vivo model of metabolic syndrome and uremia.

Methods: Obese Zucker (fa/fa) rats(n=12) were 5/6 nephrectomized and treated with calcitriol (80ng/kg ip/3 times per week) to induce VC. Rats were randomly allocated in two groups that were fed a diet containing Ca=0.6%, P=0.9% supplemented with normal (Control=27mg/kg) or increased (Vit E=30000 mg/kg) amount of vit.E. After 21 days, rats were euthanized to obtain blood and aortic tissue.

Results: Plasma level of insulin,TNF∝ and FGF21, and Aortic Ca and P content were decreased in VitE group (P<0.05 vs Control).

Table 1. *Results*

Determination	Control	Vit E
Ca^{2+} (mmol/L)	1.31±0.02	1.34±0.03
P(mg/dL)	10.9±1.8	10.3±1.4
Creatinine(mg/dL)	1.1±0.2	1.2±0.1
Glucose(mg/dL)	209.5±40.6	185.8±18.2
Insulin(ng/mL)	10.0±1.6	6.9±0.6*
TNFα(pg/mL)	82.1±4.8	70.3±1.7*
Leptin(ng/mL)	81.9±3.9	82.9±4.3
Adiponectin(μg/mL)	2.2 ±0.4	3.1±0.6
FGF21(pg/mL)	2827 ±303	1501 ±195*
Aortic Ca (mg/g tissue)	5.4±1.42	1.4±0.07*
Aortic P(mg/g tissue)	2.5±0.89	0.1±0.02*

Values are means ± SE. *P < 0.05 vs. Control.

Conclusions: In the present model of obese uremic rats, high dietary intake of vit.E decreases VC without changing plasma Ca, P and creatinine. In addition, supplementation with vit.E seems to improve metabolic syndrome (decreased FGF21 and insulin) and to reduce inflammation associated to uremia and metabolic syndrome (decrease in TNFα).

Funding: Government Support - Non-U.S.

The Association of Fetuin-A with Coronary Artery Calcification in Community-Living Persons: The Multi-Ethnic Study of Atherosclerosis

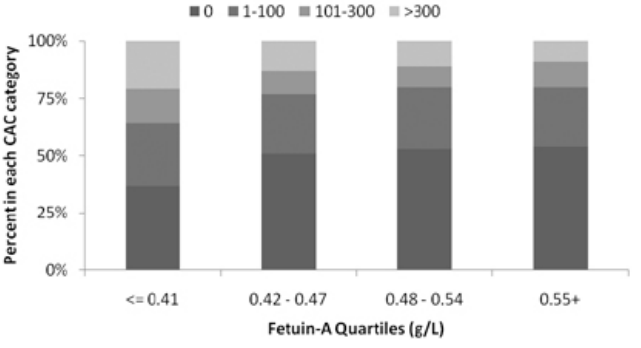
Joachim H. Ix,[1] Ronit Katz,[2] Ian H. de Boer,[3] Bryan R. Kestenbaum,[3] Carmen A. Peralta,[4] Nancy Jenny,[5] Matthew Jay Budoff,[6] Matthew Allison,[7] Michael H. Criqui,[7] David Siscovick,[3] Michael Shlipak.[5] *[1]Medicine, UCSD, San Diego, CA; [2]Biostatistics, University of Washington, Seattle, WA; [3]Medicine, University of Washington, Seattle, WA; [4]Medicine, UCSF, San Francisco, CA; [5]Pathology, University of Vermont, Burlington, VT; [6]Medicine, Harbor/UCLA, Torrance, CA; [7]Family and Preventive Medicine, UCSD, San Diego, CA.*

Background: Fetuin-A inhibits arterial calcium deposition *in vitro*. Lower levels associate with CAC in ESRD. The association of fetuin-A with CAC in other settings is unknown.

Methods: We evaluated the association of fetuin-A with CAC prevalence and severity at baseline, and CAC incidence over 3.2 years among 2,457 participants in MESA. Associations were evaluated using relative risk, linear, and Poisson regression, respectively.

Results: Mean eGFR was 94±21ml/min/1.73m^2. 1,200 (49%) had CAC at baseline, and 272 developed incident CAC during follow-up. There was a threshold effect at the lowest fetuin-A quartile with CAC prevalence. In models adjusted for demographics, traditional CVD risk factors, and kidney function, the lowest fetuin-A quartile had 7% (95% CI 1-13%) greater CAC prevalence compared to quartiles 2-4. Similar associations were observed with CAC severity; a more linear association.

Distribution of Coronary Artery Calcification Scores by Fetuin-A Quartiles n Community-Living Individuals: The Multi-Ethnic Study of Atherosclerosis



Each SD (0.1 g/L) lower fetuin-A was associated with a 12% (95% CI 3-21%) greater CAC severity in adjusted models. There was no association of fetuin-A with incident CAC (RR per SD lower 1.06; 95% CI 0.95-1.19). Associations were similar by sex, race/ethnicity, and diabetes status.

Conclusions: Fetuin-A is inversely associated with CAC severity among community-living individuals without severe CKD.

Funding: Other NIH Support - NHLBI, Veterans Administration Support

SA-PO2251

Restoration of Bone Mineralization by Cinacalcet or Parathyroidectomy Is Associated with a Significant Reduction in Calcitriol-Induced Vascular Calcification in Uremic Rats

Geert J. Behets,[1] Tineke De Schutter,[1] Ellen Neven,[1] Uwe Querfeld,[2] Patrick C. D'Haese.[1] *[1]Pathophysiology, University of Antwerp, Antwerp, Belgium; [2]Center for Cardiovascular Research and Dept. of Pediatric Nephrology, Charité Universitätsmedizin, Berlin, Germany.*

Background: The present study investigated to which extent high dose calcitriol-induced vascular calcifications in uremic rats correspond to defined changes in bone histomorphometry.

Methods: Five groups were studied: sham-operated controls (n=7); subtotally nephrectomised (SNX) uremic animals (U; n=12); U + calcitriol (VitD) (0.25µg/kg/day), (n=12); U + VitD + cinacalcet (CIN) (10mg/kg/day), (n=12); U + VitD + PTX, (n=12). Treatment started 2 weeks after SNX and continued for the next 14 weeks.

Results: Calcitriol treatment went along with the development of distinct vascular calcification which was reduced by > 50% in both the CIN treated and PTX animals. Compared to control animals and those of the U group, PTX, CIN and calcitriol treatment were associated with a significant increase ($p<0.05$) in bone area comprising +/- 60% of the total tissue area. However, whereas excessive woven bone accompanied by a dramatically increased osteoid width/area was seen in the U+vitD group, CIN treatment and PTX resulted in a significant decrease in the double labelled perimeter and normalization of both the bone formation rate and amount of osteoid ($p<0.05$) which was accompanied by a significant reduction in serum PTH levels.

Conclusions: These data indicate that the excessive vascular calcification in vitD treated uremic rats is accompanied by less efficient calcium (Ca) and phosphorus (P) incorporation in bone; a process which is reversed by CIN treatment and PTX corresponding to a decrease in Ca and P deposition in vascular calcifications.

SA-PO2252

The Relationship between FGF-23 and Markers of Cardiovascular Lesions

Wladyslaw Sulowicz,[1] Marcin Krzanowski,[1] Danuta Fedak,[2] Marek Kuzniewski,[1] Maria Kapusta,[2] Beata Kusnierz-Cabala,[2] Pawlica Dorota,[3] Bogdan Solnica.[2] *[1]Department of Nephrology, Jagiellonian University, Collegium Medicum, Cracow, Poland; [2]Department of Clinical Biochemistry, Jagiellonian University, Collegium Medicum, Cracow, Poland; [3]Department of Medical Diagnostics, Jagiellonian University, Collegium Medicum, Cracow, Poland.*

Background: FGF-23 is secreted by osteocytes and influence vitamin D and phosphate metabolism as well as bone mineralization. It rise following progressive loss of renal function and the highest levels were confirmed in dialysis population.

The aim of the study was to investigate the relationship between FGF-23 and markers of heart lesion (NT-proBNP), vitamin D (25-OH D3) as well as the incidence of vascular calcifications (CCA-IMT, CaCs) in patients with ESRD.

Methods: Studied group consisted of 76 patients (36 female and 40 male) of average age 60 12 years on maintenance hemodialysis (25 5 months). Plasma levels of FGF-23, and serum levels of 25-OH D3 were measured by ELISA technique while NT-proBNP were determined based on immunochemiluminescence. CCA-IMT was evaluated by B-mode ultrasound of carotid arteries using Acuson 128 XP apparatus. Coronary artery calcification score (CaSc) was assessed by multi-slice spiral computed tomography (MSCT).

Results: The obtained results indicate elevated plasma concentrations of FGF-23 in ESRD patients (12086 6269 RU/ml). The mean level of FGF-23 correlates well with NT-proBNP (9.72 9.83 ng/ml), CCA-IMT (0.98 0.41 mm), 25-OH D3 (18.22 7.03 ng/ml) and CaSc (1193.07 1706.71 Agatston units).The obtained correlations were shown in table 1.

Correlation between FGF-23 and studied parameters

FGF-23			
Parameter	r (Spearman's)	r^2	p
NT-proBNP	0.491719	0.241787	<0.000013
25-OH D3	0.260696	0.067963	<0.025906
CCA-IMT	0.312896	0.097904	<0.014926
CaCs	0.470679	0.221539	<0.000129

Conclusions: 1. The strong positive relationship between FGF-23 and tested calcification markers (CCA-IMT, CaSc) indicates that FGF-23 may be one of a causative factors for arterial calcifications in ESRD patients.

2. Correlation of increased FGF-23 with NT-proBNP may indicate that patients with advanced renal failure have signs of myocardial damage caused by calcium phosphate disturbances.

SA-PO2253

Persistently Low iPTH Level Predicts Progression of Aortic Arch Calcification in Incident Hemodialysis Patients

Harin Rhee,[#1] Naria Lee,[#1] Il Young Kim,[#2] Sang Heon Song,[#1] Soo Bong Lee,[#2] Ihm Soo Kwak.[#1] *[1]Division of Nephrology, Internal Medicine, Pusan National University Hospital, Busan, Korea; [2]Division of Nephrology, Internal Medicine, Yangsan-Pusan National University Hospital, Yangsan, Korea.*

Background: The aim of this study is to determine the relationship between adynamic bone disease and aortic arch calcification in incident hemodialysis patients.

Methods: From January to December 2008, a total of 94 incident hemodialysis patients were enrolled, whose iPTH level was lower than 300pg/dL throughout the initial one year. They were divided into three groups according to iPTH changing pattern during the initial first year (Group 1: iPTH level persistently below 150pg/dL ; Group 2:iPTH level moves up or down; Group 3: iPTH level persistently over 150pg/dL). Aortic arch calcification was measured on posterior-anterior plain chest X-ray using the specific scale. In each group, aortic arch calcification was scored at the initiation of dialysis and followed up till May 2011. The progression of aortic arch calcification was defined as the increase in the score >50%.

Results: A total of 94 patients were enrolled [Group 1 (N=39), Group 2(N=32), Group 3(N=23)]. Median follow up period was 2.5 years. The prevalence of baseline aortic arch calcification was highest in the persistently low iPTH group (respectively, Group 1, 59.0%; Group2 ,43.8%; Group 3, 21.7%, P=0.017) and , calcification progression was most frequently found in the persistently low iPTH group (repectively, Group 1, 19.1%; Group 2, 7.1%; Group 3, 3.2%, P=0.040). In a multivariate logistic regression analysis, age and persistently low iPTH independently contributed to progression of aortic arch calcification (HR=1.060, 95% CI 1.012-1.110, P=0.013 and, HR=4.89, 95% CI 1.059-22.38, P=0.042, respectively). But, we couldn't find any association between aortic arch calcification and mortality.

Conclusions: Persistently low iPTH and age was an independent risk factor for progression of aortic arch calcification in incident hemodialysis patients.

SA-PO2254

Circulating Vascular Calcification Inhibitors Are Associated with Mortality in Incident Dialysis Patients

Julia J. Scialla,[1] Stephen M. Sozio,[1] Pooja C. Oberai,[1] Bernard G. Jaar,[1] Tariq Shafi,[1] Laura C. Plantinga,[2] Neil R. Powe,[2] Josef Coresh,[1] Wen Hong Linda Kao,[1] Rulan S. Parekh.[1,3] *[1]Johns Hopkins University; [2]University of California San Francisco; [3]University of Toronto.*

Background: Vascular calcification is common among diabetics and dialysis patients and associated with increased mortality. We evaluated whether circulating calcification inhibitors osteoprotegerin (OPG), osteopontin (OPN), bone morphogenic protein-7 (BMP7) and fetuin-A were associated with mortality in 602 incident dialysis participants from the Choices for Healthy Outcomes in Caring for ESRD Study.

Methods: Calcification inhibitors were measured in blood samples collected < 6 months after dialysis initiation. Risk of mortality associated with tertiles of calcification inhibitors was modeled using Cox proportional hazards models adjusted for demographic factors, comorbidities, serum phosphorus, and corrected serum calcium. Prespecified interactions were tested with diabetes.

Results: Mean age of study participants was 58 yrs; 35% were African American, 57% had diabetes and 6% were treated with peritoneal dialysis. There were 423 deaths over a median follow-up of 3.3 years. Higher OPG and lower fetuin-A were associated with increased mortality overall (p-trend=0.02 for both). In stratified models, highest tertiles of OPG, BMP7, and OPN were associated with mortality among non-diabetics, but not among diabetics.

Hazard Ratio of Mortality (95% CI) by Tertiles of Calcification Inhibitor Compared to Tertile 1

Tertile	Overall	Diabetes	No diabetes
OPG: 2	**1.4 (1.0, 1.9)***	1.2 (0.8, 1.8)	1.5 (0.8, 2.7)
3	**1.5 (1.1, 2.1)***	1.2 (0.8, 1.9)	**2.8 (1.5, 5.3)***
BMP7: 2	1.1 (0.8, 1.5)	1.2 (0.8, 1.7)	1.0 (0.5, 1.7)
3	1.1 (0.9, 1.5)	1.1 (0.8, 1.7)	**2.0 (1.1, 3.7)***
OPN: 2	1.1 (0.8, 1.5)	1.2 (0.8, 1.9)	1.1 (0.6, 2.0)
3	1.2 (0.9, 1.7)	1.1 (0.7, 1.7)	**2.2 (1.1, 4.2)***
Fetuin-A: 2	0.9 (0.7, 1.2)	-	-
3	**0.7 (0.5, 0.9)***	-	-

* $p<0.05$; p-interaction for calcification inhibitor and diabetic status: OPG, $p<0.001$; BMP7, $p=0.41$; OPN, $p=0.93$; Fetuin-A, $p=0.63$

Conclusions: Circulating calcification inhibitors may identify dialysis patients at higher risk for mortality, particularly in the absence of diabetes.

SA-PO2255

Overexpression of Muscular Related Proteins and Dowregulation of Lamin A/C Might Be Involved in the Protection Against Vascular Calcification

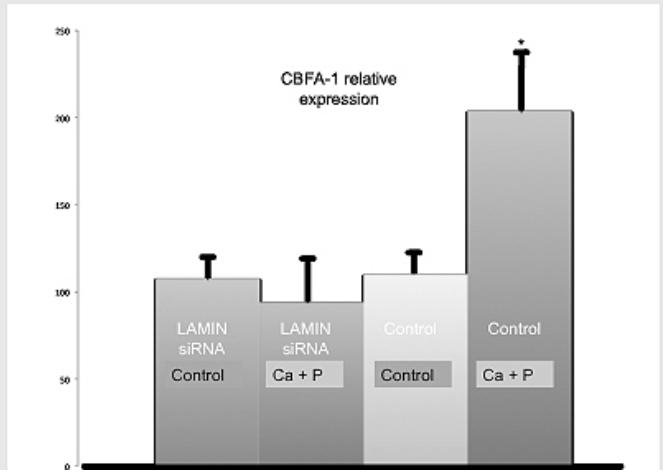
Pablo Roman-Garcia, Natalia Carrillo-Lopez, Sara Panizo, Manuel Naves, Jose L. Fernandez-Martin, Jorge B. Cannata-Andia. *Bone and Mineral Research Unit, Hospital Universitario Central de Asturias, IRSIN-FRIAT, RedinRen, Universidad de Oviedo, Oviedo, Asturias, Spain.*

Background: A variable but not negligible proportion of CKD patients seem to be protected to develop vascular calcification; the causes are unknown. Molecular mechanisms modifying the expression of muscle-related or bone-related proteins may explain this advantageous profile. Among them, defects associated to lamin A have been implicated in vascular damage and senescence. The main objective of this study was to compare the differential protein expression in calcified and non-calcified aortas of uremic rats exposed to a strong calcifying stimulus.

Methods: Rats were nephrectomized (7/8) and fed with high P (HP) diet (0.9%) for 20 weeks (n=20); the abdominal aorta was extracted for Von Kossa staining and proteomic analysis. To confirm the results, in vitro studies were performed: Lamin A expression was knocked down in vascular smooth muscle cells (VSMCs) using siRNA, then VSMCs were cultured using normal o calcifying media (2mM Ca and 3mM P) for 2 days. CBFA-1/runx-2 and Lamin A gene expression were measured by qRT-PCR.

Results: The proteomic analysis revealed that the aortas from rats that after 20 weeks with calcifying stimulus did not develop VC, showed a significant upregulation of transgelin, tropomiosin and actin (all well known muscle-related proteins) and significant

downregulation of lamin A. In addition, further experiments in VSMCs, knocking down Lamin A by siRNA showed a reduction in CBFA1 despite the stimulus of the calcifying medium.



Conclusions: The study demonstrates for the first time that muscle related proteins overexpression and Lamin A downregulation could be involved as part of the mechanisms triggered to protect against vascular calcification.

SA-PO2256

The Reduction of Vertebral Bone Density (VDB) Is Associated with Progression of Coronary Calcification in Pre-Dialysis Patients Renato Watanabe,[1] Marcelo M. Lemos,[1] Lilian Cuppari,[1] Aluizio B. Carvalho,[1] Carlos Eduardo Rochitte,[2] Raul D. Santos Filho,[2] Maria Eugenia F. Canziani.[1] *[1]Nephrology Division, Federal University of São Paulo, São Paulo, Brazil; [2]Cardiology Division, University of São Paulo, São Paulo, Brazil.*

Background: Vascular calcification and low bone density are common findings in chronic kidney disease (CKD) patients and are associated with mortality in this population. We aimed to investigate whether the reduction of VDB was associated with progression of coronary calcification in pre-dialysis patients.

Methods: In a 24-month prospective study a sample of 72 nondialyzed CKD patients (57.6±10.3years, 62%male, creatinine clearance 39.2±15.5ml/min/1.73m2), underwent multi-slice computed tomography in order to determine coronary calcium score and thoracic VBD. The measurements were performed at baseline and at the end of the study.

Results: At the baseline, coronary calcification was observed in 33 patients (46%) [median 316AU(range 123–861.5AU)-calcified group)]. These patients were older, mostly male and had lower VBD, compared to non-calcified patients. There were no differences between groups regarding renal function, proteinuria, lipid profile, ionized calcium, phosphorus, alkaline phosphatase or iPTH levels. During the follow up, although the mean values of VBD did not change in both groups, VBD decreased in 61% and 48% of the patients (non-calcified and calcified group respectively; p=0.27). Thirty out of 33 (91%) patients of the calcified group showed progression of coronary calcification which was inversely related to the change of eGFR (r=-0.38; p=0.039), and to the relative change of VBD (r=-0.56; p=0.001). In multivariate regression analysis, adjusted for age, sex, diabetes and eGFR, calcification progression was independently associated to the relative change of VBD (p=0.01; βcoefficient=-0.419; 95%CI,-0.036 to-0.004). Despite reduction of eGFR, non-calcified patients have not developed of coronary calcification.

Conclusions: This study showed that reduction of VBD is associated with progression of coronary calcification in calcified pre-dialysis patients but not with the development of coronary calcification in the non-calcified ones.

SA-PO2257

A Novel Model of In-Vitro Osteocytogenesis Deborah Mattinzoli,[1] Piergiorgio Messa,[1] Alessandro Corbelli,[1] Masami Ikehata,[1] Cristina Zennaro,[2] Silvia Armelloni,[1] Min Li,[1] Laura Giardino,[1] Maria Pia Rastaldi.[1] *[1]Renal Research Laboratory, Fondazione IRCCS Policlinico & Fondazione D'Amico, Milan, Italy; [2]Renal Physiopathology Laboratory, University of Trieste, Italy.*

Background: Though recent research is more and more highlighting the importance of osteocytes as central players of bone and systemic mineral metabolism, molecular and functional knowledge of osteocyte properties are still incomplete, mostly due to limited availability of in vitro models.

Aim of our study was to find a simple, reproducible method to obtain cultured osteocytes.

Methods: MC3T3-E1 cells were cultivated in α-MEM medium. At 80% confluence, medium was added ascorbic acid/glycerol phosphate (AA/GP) for 5 days, then cells were divided into 3 groups. The 1st group continued in the same conditions (AA/GP). Melatonin (50uM) or All-Trans Retinoic Acid (10uM, ATRA) were respectively added to the 2nd and the 3rd group. Cells were studied from 4 to 25 days.

Morphology was evaluated by light, electron, and atomic force microscopy. Real time RT-PCR arrays were used to compare gene expression between groups. Immunostainings, western blot, and in-cell ELISA were applied to define expression of osteocyte markers. Osteocalcin and FGF23 excretion were determined by ELISA on the supernatant.

Results: Our data show that ATRA, not melatonin, treatment generates a homogeneous population of ramified cells, with distinct features of osteocytes, as we confirm by a detailed morphological and molecular analysis. The phenotype clearly changes as soon as after 4 days of treatment and is completed in 10 days, and consists in the progressive development of ramifications, loss of the ability to produce extracellular matrix, downregulation of osteoblast markers and upregulation of osteocyte-specific molecules, most notably among them sclerostin.

Conclusions: Compared to other published protocols, our method has a number of advantages. It is easy to perform and does not require additional instrumentation, it is highly reproducible, and generates in a ten-day time-frame a mature osteocyte population in complete absence of extracellular matrix, allowing the use of these cells for unlimited biological applications.

SA-PO2258

Experimental CKD-MBD: A Comparison between 5/6 Nephrectomy and Adenine Models Guaraciaba O. Ferrari,[1] Juliana C. Ferreira,[1] Raquel T. Cavallari,[1] Katia R. Neves,[1] Luciene M. dos Reis,[1] Wagner V. Dominguez,[1] Elizabeth M. Oliveira,[1] Fabiana G. Graciolli,[1] Jutta Passlick-Deetjen,[2] Rosa M. Moyses,[1] Vanda Jorgetti.[1] *[1]Sao Paulo University, Brazil; [2]Fresenius.*

Background: Experimental models are important to understand the physiopathology, as well as the effects of therapy of some diesases. Currently, two models are used to evaluate CKD-MBD: 5/6 nephrectomy (NX) and adenine-induced kidney disease (AD). However, they have never been compared using animals in similar housing conditions. To that end, we compared these two models, focusing on biochemical and bone histomorphometric findings.

Methods: Wistar rats, fed with the same diet, were divided into 3 groups: Control (C), NX and AD(diet + adenine). After 9 wks, animals were sacrificed and biochemical and histomorphometric analyses were performed.

Results: NX group presented a greater final weight (FW) and blood pressure (BP) than did AD group. No differences were seen in serum Creatinine (Cr), phosphate (P), ionized calcium (iCa), PTH and FGF23. However, AD rats had a higher FeP and presented a more severe form of high-turnover bone disease.

Table1

	C	AD	NX
FW(g)	366±19	312±17*	385±60
BP(mmHg)	121(103-131)*	147(131-181)*	228(214-230)
LV(g/100g)	0.19(0.17-0.20)	0.21(0.19-0.24)	0.19(0.15-0.31)
Cr(mg/dl)	0.6±0.2*	1.6±0.3	1.3±0.6
iCa(mmol/l)	1.15±0.08	1.07±0.07	1.10±0.09

SA-PO2259

The Role of a Skeletal Anabolic in the Early CKD-MBD of Stage 2 CKD Keith A. Hruska, Yifu Fang. *Pediatrics, Washington University School of Medicine, St. Louis, MO.*

Background: In CKD, osteoblastic differentiation of cells in the neointima causes calcification of atherosclerotic plaques. Both atherosclerotic and medial vascular calcification (VC) are important causes of CV morbidity in CKD. The early CKD-MBD begins in stage 2 CKD patients as shown by HRqCT (Bacchetta J et al JBMR 2009), increased FGF-23 (Pereira RC et al Bone 2009), and decreases in vascular smooth muscle (VSM) contractile phenotype markers (Kokubo et al, JASN 2009). Abnormalities of bone remodeling and the VSM phenotype before abnormalities of mineral metabolism in the early phases of the CKD-MBD make it necessary to define a regulatory system underlying the condition. Here we tested the hypothesis that CKD induces the CKD-MBD in early CKD and that the skeleton participates in stimulation of VC.

Methods: Ldlr-/- mice fed high fat diets were subjected to renal cortical electrocautery and contralateral nephrectomy at 12 weeks of age to produce CKD-MBD, euthanasia was at 22 or 28 weeks. Treatment with vehicle, DKK1 mab (30 mg/Kg tiw IP), or CaAc (3% w/w mixed in diet) was begun at 14 or 22 wks.

Results: A relatively mild reduction in the glomerular filtration rate was seen with 76% of normal {GFR (ml/min/kg) at 22 weeks of age (stage 2 CKD). BUN, Ca, Pi and PTH levels were normal. CKD stimulated and DKK1 mab inhibited the CKD stimulated

accumulation of aortic Ca levels (0.52±0.19 (CKD) vs. 0.26±0.14 (wt), 0.32±0.23 (sham) and 0.4±0.1 (DKK1 mab) mg/g dry weight, p<0.05). CaAc did not affect CKD stimulated VC. CKD decreased aortic smooth muscle actin and the DKK1 mab had no effect. Micro CT analysis of femurs revealed cortical bone loss prevented by the DKK1 mab. Dickkopf-1 (Dkk1), a circulating inhibitor of bone formation, levels were increased from normal wt 1868±772 or sham 1650±882 to 3132±1590 (pg/ml, p<0.01). Increased serum levels of FGF-23 were also detected but not decreased by the DKK1 mab (554±263 (CKD) vs. 242±56 (wt), 309±64 (sham) and 590±185 (DDK1 mab).

Conclusions: We conclude that the skeleton is affected in response to kidney injury and participates in the stimulation of VC.

Upregulation of Osteocyte Fibroblast Growth Factor 23 with Improvement of the Uremic Mineralization Defect Induced by the Vitamin D Analog Paricalcitol

Michael Freundlich,[1] Ezequiel R. Bellorin-Font,[2] R.C. Pereira,[3] Bernardo Rodriguez-Iturbe,[4] Isidro B. Salusky,[3] Jose R. Weisinger.[5] *[1]Pediatric Nephrology, University of Miami, FL; [2]Nephrology, Hospital Universitario, Caracas, Venezuela; [3]Pediatric Nephrology, UCLA, Los Angeles, CA; [4]Nephrology, Hospital Universitario, Maracaibo, Venezuela; [5]Nephrology, University of Miami, FL.*

Background: It has been shown that $1,25(OH)_2D_3$ stimulates both osteoblast and osteocyte fibroblast growth factor 23 (FGF23) production, but little is known on the skeletal response to FGF23 in chronic kidney disease, particularly following paricalcitol (Pc) treatment.

Methods: We evaluated the bone expression of FGF23 by immunohistochemistry with simultaneous quantitated bone histomorphometry in sham (S) and 5/6-nephrectomyzed rats after treatment during 8 weeks with vehicle (U), Pc (IP 0.3 μg/kg/thrice weekly), or enalapril (E) (5 mg/kg/day in drinking water).

Results: Pc and E attenuated renal insufficiency when compared to U (p<0.05). Plasma calcium (Ca) was higher in Pc and phosphorus (P) was similar in all groups (Table). Bone histomorphometry (Table) revealed decreased eroded surfaces (ES/BS) and improved mineralization after Pc. In contrast, E showed less attenuated OS/BS and ES/BS (p<0.05 vs.Pc). Osteocyte FGF23 expression was markedly increased in U when compared to S or E, and even more prominent following Pc.

Biochemical and Bone Histomorphometric Parameters

	Sham	Uremia	Enalapril	Paricalcitol
Creatinine (mg/dL)	0.58 ± 0.08	1.67 ± 0.75*	0.76 ± 0.06**	0.76 ± 0.1**
Phosphorus (mg/dL)	6.72 ± 0.49	7.31 ± 1.89	6.34 ± 1.7	6.46 ± 1.83
Calcium (mg/dL)	7.34 ± 0.28	8.58 ± 0.78	7.68 ± 0.60	9.9 ± 1.74• ♦
OV/TV %	1.78 ± 0.35	3.5 ± 1.9	2.0 ± 0.2	2.65 ± 2.3
OS/BS %	6.36 ± 0.57	15.4 ± 8.1†	8.5 ± 2.8	7.8 ± 3.8
ES/BS %	13.1± 2.0	22.1± 7.9¶	24± 2.6¶	16± 4∞

*p<0.01 vs. S; **p<0.05 vs. U; • p<0.05 vs. En and ♦ p<0.01 vs. sham; † p<0.01 vs sham and p< 0.05 vs Pc; ¶ p< 0.05 vs S; ∞ p<, 0.05 vs En

Conclusions: Pc therapy upregulated bone FGF23 expression and partially improved the mineralization defect without changes in P levels, suggesting that FGF23 in addition to Pc modulates bone mineralization in uremia.

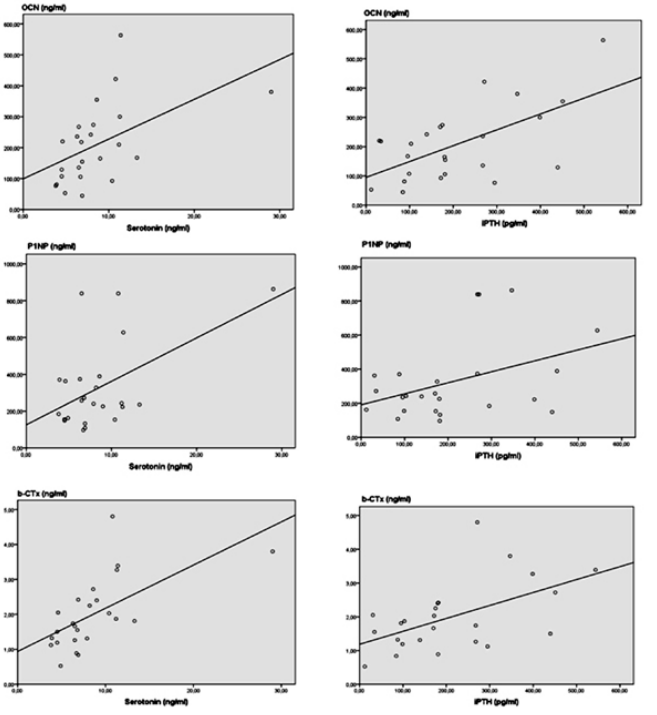
Plasma Serotonin Affects Bone Metabolism in Hemodialysis Patients

Theodoros Eleftheriadis, Vassilios Liakopoulos, Georgia Antoniadi, Ioannis Stefanidis. *Nephrology, Medical School, University of Thessaly, Larissa, Greece.*

Background: Serotonin receptors are present in osteoblasts and osteoclasts and many experimental studies showed that peripheral serotonin affects bone metabolism. In the present study the effect of plasma serotonin on bone metabolism was evaluated in hemodialysis (HD) patients.

Methods: 24 HD patients (11 diabetics) and 22 healthy volunteers enrolled into the study. Serotonin was assessed in platelet free plasma, whereas the markers of osteoblastic activity N-MID osteocalcin (OCN) and total procollagen type-1 amino-terminal propeptide (P1NP) as well as the marker of osteoclastic activity beta-isomerized C-terminal cross-linked peptide of collagen type I (β-CTx) were measured in serum. Serum intact parathyroid hormone (iPTH) was also assessed.

Results: Serotonin did not differ significantly between HD patients and healthy volunteers (8.50±5.12 ng/ml vs 6.44±1.54 ng/ml, p=n.s.). All evaluated markers of bone metabolism and iPTH were much higher in HD patients. Serotonin was positively related to all evaluated markers of bone metabolism in HD patients, and independently of iPTH, which was also positively related to all evaluated markers of bone metabolism.



Serotonin was negatively related to the patients' age. Serotonin, was much lower in diabetic HD patients (6.42±1.99 ng/ml vs 10.25±6.30 ng/ml, p=0.044), which was the case for OCN, P1NP and β-CTx as well.

Conclusions: Serotonin increases both bone formation and bone resorption in HD patients. The negative relation of serotonin to patients' age as well as its lower levels in diabetic HD patients indicate that low plasma serotonin may contribute to the higher incidence of low-turnover bone disease that characterizes old and diabetic HD patients.

SA-PO2262

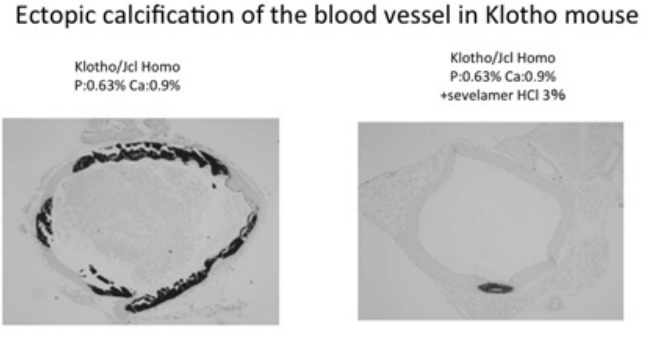
Sevelamer Hydrochloride Inhibits Aortic Calcification Regardless of Serum Phosphorus Concentrations

Ichiro Ohkido,[1] Keitaro Yokoyama,[1] Tomoka Hasegawa,[2] Tatsuo Hosoya.[1] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan; [2]Department of Developmental Biology of Hard Tissue, Graduate School of Dental Medicine, Hokkaido University, Sapporo, Hokkaido, Japan.*

Background: Sevelamer hydrochloride, calcium-free phosphate binder, reduces vascular calcification by preventing episodes of hypercalcaemia and/or hyperphosphatemia in the patients with the CKD. However, the mechanism of this effect on vascular calcification is quite obscure. Pleiotropic effects of sevelamer hydrochloride have been focused. Hyperphosphatemia, high serum FGF23 levels as well as vascular calcification are observed in the patients with the CKD, which were also characteristics of klotho mice. Therefore we examined the pathophysiology of the influences of sevelamer hydrochloride on vascular calcification using klotho mice.

Methods: Klotho mice and control mice(C57BL/jj6) were fed by normal diet group(NPD: Pi 0.6 %) , or low-Pi diet group(LPD : Pi 0.2 %), or NPD with Sevelamer hydrochloride respectively. After 1 week, all mice were sacrificed, then, biochemical analysis of serum and urine was carried out.

Results: Klotho mouse had decreased serum phosphorus concentrations by LPD intake. At the NPD intake with sevelamer hydrochloride administration, in klotho mice, serum phosphorus concentrations decreased similar to LPD. On the other hand, the aortic calcification of klotho mice was inhibited by sevelamer hydrochloride administration although that was not inhibited by a LPD intake.



Conclusions: In our study, sevelamer hydrochloride inhibited aortic calcification regardless of serum phosphorus concentrations. These results might be associated with the pleiotropic effects of sevelamer hydrochloride.

Interaction between RANK/RANKL Positive Macrophages Infiltrating around the Amyloid Deposit in the Yellow Ligament and the Oosteoclasts in Destructive Spondyloarthropathy Patients

Yoshikatsu Kaneko, Yohei Tsuchida, Junichiro J. Kazama, Ichiei Narita. *Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences.*

Background: Destructive spondyloarthropathy (DSA) is one of the symptoms of dialysis-related amyloidosis and is reported to be observed as a complication in approximately 10% of long-term hemodialysis patients. Histological examination shows β2-microglobulin amyloidal deposits in the intervertebral disk, the synovium of apophyseal joints, and the ligaments, however, the precise mechanism in the development of the destructive change of the bone is still unknown. Hence the aim of the study is to clarify the mechanism of the destruction of the vertebrae, focusing on the macrophages infiltrating around the amyloid deposits, and the cytokines and RANK-RANKL system.

Methods: Yellow ligament of the cervical or lumbar vertebrae in the DSA patients were extracted and collected when the posterior spinal fusions were conducted in each case. These yellow ligaments were fixed by 10% formalin, embedded in paraffin. Immunohistochemical study was performed on 5 μm paraffin section to examine the expression of RANK, RANKL, CD68, IL-1β, IL-6, TNF-α, and IL-17. THP-1 cells, monocyte/macrophage cell line, were cultured with various conditions to investigate the induction o RANK and RANKL.

Results: Histological examination revealed that CD68 positive monocyte/macrophage lineage cells infiltrating around the amyloidal deposit expressed both RANK and RANKL. IL-1β, IL-6, and TNF-α were not detected in the CD68 positive cells, nor were the IL-17 producing T cells either. THP-1 cells were cultured with lipopolysaccharide in vitro, and the up-regulation of both RANK and RANKL expression on their cell surface were detected by flow cytometry.

Conclusions: In this study we reported the possibility that monocyte/macrophage lineage cells would be activated by lipopolysaccharide resulting in the expression of RANK and RANKL on their cell surface and facilitate osteoclastgenesis.

SA-PO2264

Alterations in Osteoblastic Gene Expression in Dialysis Patients: A Potential Role in Skeletal Mineralization

R.C. Pereira,[1] Harald Jueppner,[2] Isidro B. Salusky,[1] Katherine Wesseling-Perry.[1] *[1]Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Endocrine Unit, Massachusetts General Hospital, Boston, MA.*

Background: Abnormal skeletal mineralization is common in pediatric CKD. The mechanisms underlying this defect are unknown but osteocyte dysfunction has been characterized in patients with early CKD.

Methods: Primary osteoblasts were cultured from bone biopsies obtained from 6 pediatric PD patients (5M, 1F), age 16.6 ± 1.0 years, not receiving vitamin D sterols for at least 4 weeks prior to patients bone biopsy with varying types of bone histology. Expression of osteoblastic and osteocytic gene expression was evaluated at passage 0 by qPCR and normalized by endogenous GAPDH expression in each sample. Expression in dialysis patients was then normalized by normal control. Bone histomorphometry was measured and biochemical values obtained in all subjects.

Results: Biochemical variables were: Ca: 8.3 ± 0.5 mg/dl, P: 7.2 ± 0.6 mg/dl, Alk P'tase: 289 ± 90 IU/l, PTH: 595 ± 231 pg/ml, FGF-23: 491 (436, 919) RU/ml.

Parameter	Value	Normal Range
Bone Histomorphometry		
Bone volume (BV/TV) (%)	31.9 ± 3.0	8.9 – 34.4
Bone formation rate (BFR/BS) ($um^2/mm^3/d$)	43.4 ± 19.0	8.0 – 73.4
Osteoid volume (OV/BV) (%)	5.2 ± 2.0	0.2 – 5.8
Osteoid surface (OS/BS) (%)	31.0 ± 9.3	4.3 – 37.0
Osteoid thickness (O.Th) (um)	8.0 ± 1.5	2.0 – 13.2
Osteoid maturation time (OMT) (d)	13.8 ± 1.7	1.2 – 11.5
Mineralization lag time (MLT) (d)	58.7 ± 20.3	2.3 – 63.8
Gene (expressed as fold increase from control)		
Alkaline phosphatase	3.53 ± 1.12	
Type I Collagen	1.43 ± 0.06	
FGF receptor 1	1.90 ± 0.11	
PTH receptor	5.04 ± 1.11	
NHERF1	2.31 ± 0.32	
IGF1	7.26 ± 1.71	
VDR	3.23 ± 0.27	
CYP27	1.25 ± 0.20	
CYP24	2.87 ± 1.07	
Osteocalcin	1.14 ± 0.38	
RUNX	3.53 ± 1.12	
Osterix	6.21 ± 2.2	
Matrix gla protein	2.33 ± 0.40	
FGF23	Undetectable	
CaSR	Undetectable	

Overall, mineralization parameters on histomorphometry were within the normal range. As evidenced by bone alk P'tase, osteocalcin and type I collagen expression and lack of DMP1, FGF23, MEPE and sclerostin, cells cultured from bone biopsy specimens retain osteoblast characteristics. Compared to control, Alk P'tase, PTHR1, NHERF1, IGF1, VDR, BMP2, RUNX, osterix, and matrix gla expression are increased in dialysis patients, suggesting an intrinsic upregulation of factors involved in the mineralization process.

Conclusions: The upregulation of pro-mineralization genes in osteoblasts may be required in order to maintain normal mineralization parameters in dialysis patients. Whether these factors vary according to subtype of renal osteodystrophy and how they relate to matrix mineralization remain to be evaluated.

Bisphosphonates Exert Skeletal Benefits without Severe Suppression of Turnover in an Animal Model of Chronic Kidney Disease

Neal X. Chen,[1] Sharon M. Moe,[1,2] Vincent H. Gattone,[3] Xianming Chen,[1] Alexander J. Carr,[3] Paula Leblanc,[3] Drew Brown,[3] Matthew R. Allen.[3] *[1]Medicine, Indiana University School of Medicine; [2]Roudebush VA Medical Center; [3]Antomay and Cell Biology, Indiana University School of Medicine, Indianapolis, IN.*

Background: Patients with chronic kidney disease (CKD) have increased fracture rates. Bisphosphonates are routinely used to reduce fractures in non-CDK patients, but limited data exists concerning their efficacy in CKD. There is also concern that bisphosphonates will induce adynamic bone disease due to severe suppression of bone remodeling in patients with CKD. The goal of this study was to test the hypothesis that zoledronic acid (ZOL) exhibited similar skeletal effects in normal and CKD animals.

Methods: AAt 25 weeks of age, normal rats (NL) were treated with saline or 100 mcg/kg of ZOL while animals with CKD (Cy, GFR of approx 30-40 ml/min) were treated with a single dose of saline, low dose ZOL (20 mcg/kg), or high dose ZOL (100 mcg/kg). Skeletal properties were assessed 5 weeks later using micro-computed tomography (CT), dynamic histomorphometry, and mechanical testing.

Results: Trabecular bone remodeling was 92% lower in NL animals treated with ZOL compared to untreated animals. Cy animals treated with low and high doses of ZOL were 80% lower than untreated Cy animals and were higher than NL animals treated with ZOL. By CT, trabecular bone volume in the proximal tibia was significantly higher in Cy rats treated with low (+73%) and high (+93%) doses of ZOL compared to untreated Cy rats. Mechanical testing showed that cortical bone strength (-28%) and energy absorption (-37%) were significantly lower in untreated Cy rats compared to NL; these effects were partially normalized by ZOL treatment. There were no significant differences between the two ZOL doses in Cy rats for any histomorphometric outcome parameter.

Conclusions: Based on these results we conclude ZOL improves bone volume and strength in the absence of severe remodeling suppression, and thus provides bone protective effects in animals with advanced CKD.

SA-PO2266

The Effects of Phosphate Binders on the Wnt Pathway Gene Expression in Adynamic Bone Disease

Juliana C. Ferreira,[1] Guaraciaba O. Ferrari,[1] Raquel T. Cavallari,[1] Wagner V. Dominguez,[1] Elizabeth M. Oliveira,[1] Luciene M. dos Reis,[1] Fabiana G. Graciolli,[1] Katia R. Neves,[1] Shiguang Liu,[2] Yves Sabbagh,[2] Vanda Jorgetti,[1] Susan Schiavi,[2] Rosa M.A. Moyses.[1] *[1]Nephrology Division, Universidade de São Paulo, Brazil; [2]Genzyme Co.*

Background: The Wnt pathway is involved in bone formation, and high serum levels of sclerostin (SOST), a Wnt inhibitor, are associated with osteoporosis and adynamic bone disease (ABD). In this study, we tested the hypothesis that phosphate (P) binders could modulate gene expression of SOST in an experimental model of ABD.

Methods: Nephrectomized (Nx) rats were divided into 4 groups: Ca (calcium carbonate therapy); Sev (sevelamer carbonate therapy); CKD (untreated); and Control. After 8 wks, biochemical, histomorphometric and bone gene expression (TLDA) analyses were performed.

Results: Histomorphometry confirmed ABD in Nx groups, based on decreased bone formation rate, osteoid volume, osteoblast and osteoclast surfaces without fibrosis. We found no differences among the CKD groups in terms of bone histomorphometric parameters, except for greater eroded surface in the Ca group. The gene expression of SOST was increased in CKD and only Sev administration was able to decrease it significantly.

Biochemical and histomorphometric data

	Ca	Sev	CKD	Control
Creatinine(mg/dl)	1.65±1.01	1.33±0.35	1.29±0.23	0.61±0.10[a]
iCa(mmol/L)	0.60±0.14	0.49±0.16	0.55±0.19	1.15±0.09[a]
P(mg/dl)	10.7±2.4	11.3±2.9	11.1±2.7	5.4±0.4[a]
FeP(%)	4.4±7.6[a]	25.1±11.5[a]	49.2±21.2[a]	6.9±3.4[a]
FGF-23(pg/ml)	271±177	206±183	144±108	279±95
BV/TV(%)	29.1±6.4	25.1±7.5	24.0±6.1	22.3±5.7
OS/BS(%)	2.7±2.3	5.7±6.3	2.1±0.8	17.6±8.3[a]
ES/BS(%)	10.4±2.8[c,d]	6.9±1.3	5.7±2.9	19.1±3.0[a]
Ob.S/BS(%)	2.4±2.0	4.1±4.3	1.7±0.7	14.7±7.2[a]
BFR/BS(μ^3/μ^2/day)	0.01±0.01	0.03±0.03	0.02± 0.01	0.08±0.04[a]
SOST(fold change)	3.9±0.1	2.3±0.5[d]	4.1±0.3	1.2±0.4

iCa: ionized calcium; BV/TV: trabecular bone volume; OS/BS: osteoid surface (S); ES/BS: eroded S; Ob.S/BS: osteoblast S; Oc.S/BS: osteoclast S; BFR/BS: bone formation rate; a=p< 0.05 vs. all; b=p<0.05 vs. Ca; c=p<0.05 vs. Sev; d=p<0.05 vs. CKD

Conclusions: Gene expression of SOST is elevated in ABD and is decreased with Sevelamer. Longer treatment periods may be required to observe improve in histomorphometric parameters.

SA-PO2267

The Expression of Runx2 and Col II in Arteries of Remnant Kidney Rats and Patients with Chronic Renal Failure Yi Yu. *Dept of Nephrology and Hemodialysis, Dongfang Hospital of Fujian Province, Fuzhou, Fujian, China.*

Background: This study is aimed to observe the expression of Runx2 and collagen II (Col II) involved in vascular calcification in remnant kidney rats and patients with chronic renal failure (CRF).

Methods: 1. SD rats underwent 5/6 nephrectomy or sham operation, and rats were fed with high or normal phosphorous diet for 16weeks. They were divided into 4 groups: (1) remnant kidney rats receiving high phosphorous diet (NHP group, n=10); (2) remnant kidney rats receiving normal phosphorous diet (NP group, n=10); (3) sham operation rats receiving normal phosphorous diet (SP group, n=10); (4) sham operation rats receiving high phosphorous diet (SHP group, n=10). At the 16th week, Scr, P, LDL were examined and thoracic aorta was removed. 2. Pieces of radial arteries were taken from 40 CRF patients at the time of arteriovenous fistula operation, while 10 subtotal gastrectomy patients with normal renal function were chosen as control. Serum Ca, P and iPTH were detected. The vessels were examined for calcification by von Kossa stain and for the expression of Runx2 and Col II by immunohistochemistry, RT-PCR or Western Blot.

Results: 1. After 16 weeks, Scr were higher in 5/6 nephrectomy rats, and serum P increased significantly in NHP group ($P< 0.05$). 2. Overt vascular calcification was found in NHP group while NP and SHP group occasionally had vascular calcification; SP group had none. 3. The expression of Runx2 and Col II increased in NHP group ($P<0.05$) by immunohistochemistry. In NHP group, the aorta mRNA expression of Runx2 and Col II, and the aorta protein expression of Runx2 increased significantly ($P<0.05$). 4. In CRF patients, positive staining of Runx2 and Col II was found in the smooth muscular cell plasma of medial layer in the vessels with overt calcification, and was also observed in 78.3% of no calcification group. Serum P was positively correlated with staining score of Runx2 and Col II ($P<0.01$).

Conclusions: Serum P, Runx2 and Col II are involved in the vascular calcification in remnant kidney rats and CRF patients. The incidence of arterial calcification is high in CRF patients; the arterial expression of Runx2 and Col II is an early sign of calcification.

SA-PO2268

No Modifications in Clinical Outcomes after Availability of Guidelines for Mineral Metabolism in Dialysis Patients Walter Guillermo Douthat,[1,2] Carlos R. Chiurchiu,[1,2] Javier De Arteaga,[1,2] Jorge Luis De la Fuente,[1,2] Pablo U. Massari.[1,2] *[1]Renal Service, Hospital Privado-Centro Medico de Cordoba, Cordoba, Argentina; [2]Posgraduate School of Nephrology, Catholic University of Cordoba, Cordoba, Argentina.*

Background: In recent years new guidelines for bone and mineral metabolism (BM) management for patients with ESRD were published, but unfortunately their availability not necessarily guarantees better outcomes.

Methods: We performed a survey that included 1210 patients belonging to 25 dialysis centers, to analyzed witch guide was used, percentage of patients that achieve major BM outcomes and treatment used. Results were compared with a similar survey performed during pre-guide K/DIGO era (2001).

Results: Guidelines used were Local (Argentinian) 68,1%, K/DOQI 33,9%, K/DIGO 21,6%, and in 6,1% cases not guide was used. Comparing results between 2001 to 2010, no difference was found in serum phosphate levels, but an increase in iPTH ($p<0.0001$), and a decrease in mean s.calcium ($p<0.0001$), and CaxP product ($p<0.02$) were observed. Percentage of patients that reach K/DOQI outcomes in 2010 compared to 2001 were: phosphorous 52 vs 51%, calcium 52 vs 43%, CaxP product 77 vs 73%, and iPTH 21 vs 28% respectively. For K/DIGO (iPTH 2 to 9 times up normal levels) 47,3% vs 58% in 2010 vs 2001 respectively. Percentage of patients who achieve any of 4 outcomes of K/DOQI were 9,5% vs 8,4%, and reach all 4 outcomes 5,9 vs 6,6% for 2010 vs 2001.

Treatment of hyperparathyroidism used in 2010 vs 2001 were: parathyroidectomy 8,6 vs 6,1%; oral calcitriol 40,8 vs 71,3%, e.v.calcitriol 5,2 vs 3,3%; paricalcitol 2,1 vs 0%, and doxercalciferol 0,9 vs 0%.Oral phosphate chelators were: calcium salts 86,6 vs 94,8%, aluminium salts 4,0 vs 4,4% and sevelamer 5,6 vs 0% respectively.

Conclusions: In our population during the last decade, no changes were observed in outcomes and procedures despite availability of new BM guidelines.

SA-PO2269

The Impact of Daily Activity and Muscle Strength on Fractures in CKD Sarah West,[1,3] Sophie Jamal,[1,3] A. M. Cheung,[1,2] Charmaine E. Lok.[2,3] *[1]University of Toronto, ON, Canada; [2]Toronto General Hospital, Toronto, ON, Canada; [3]Women's College Hospital, Toronto, ON, Canada.*

Background: Fractures are common in patients with CKD. Tests of neuromuscular function (NMT) discriminate well among fractured and non-fractured patients on dialysis. The ability of daily activity and NMT to discriminate among fracture status in patients with CKDIII-V(non-dialysis) is unknown.

Methods: Baseline data from an ongoing prospective study of adult patients with CKDIII-V were used to determine if NMT (the timed up and go test [TUG] and 6 minute walk test [6MW]), and/or daily activity (sedentary, light, or moderate/vigorous activity measured by triaxial accelerometry [StayHealthy, RT3]) could discriminate among those with and without fractures (self-reported low trauma fractures >40 yrs and/or prevalent vertebral fractures identified by morphometry). Results are expressed as areas under the receiver operating characteristic curves (AUROC) with 95% confidence intervals (CI), adjusted for age and weight.

Results: Of 128 men and 86 women studied, 32 completed accelerometry. Compared to non-fractured patients (n=143), those with fractures (n=70) were older (59±16 vs. 69±14 yrs, $p<0.001$), had a reduced 6MW distance (335.5±87.1 vs. 289.9±142.2 m, $p=0.04$), were more sedentary with light daily activity (min/day, $p<0.05$). No other demographic factors distinguished those with and without fractures. The mean weight of patients was 79.9±19.8 kg, most were Caucasian (70.0%), > 40% had diabetes, and 74% patients were CKD stage 4 or 5. The mean duration of CKD was 8.0±10.3 yrs, and 30.2% reported a fall in the past 12 mos. The TUG (mean 12.3±5.7 sec) was able to discriminate among those with and without fractures (AUROC: 0.70 [95% CI: 0.61-0.80]), as was the 6MW test with an AUROC: 0.69 (95% CI: 0.59-0.80). By accelerometry, sedentary activity (min/day) was able to discriminate fracture status (AUROC: 0.71 [95% CI: 0.51-0.93]), as was light activity (min/day), with an AUROC of 0.76 (95% CI: 0.56-0.95).

Conclusions: NMT and accelerometry are simple, practical measures that can discriminate among CKD patients with and without fractures. Their ability to predict future fractures require further study.

SA-PO2270

Bone and Mineral Metabolism in the Course of Secondary Hyperparathyroidism Therapy with Cinacalcet Zbigniew Nowak, Daniel Baczynski, Grzegorz Kade, Zofia Wakowicz, Stanislaw Niemczyk. *Department of Nephrology, Military Institute of Medicine, Warsaw, Poland.*

Background: The evaluation of secondary hyperparathyroidism (sHPT) in everyday practice is based on non-invasive measurements of bone markers such as iPTH, calcium, phosphate. Tartrate-resistant acid phosphatase-TRAP5b is expressed in bone resorbing osteoclasts and has been considered as a useful marker of bone resorption in uremic patients. There are no date related to the usefulness of this marker in the monitoring of sHPT therapy with calcimimetics.

The purpose of our study was to determine the influence of cinacalcet on markers such as TRAP5b, iPTH, Ca, P.

Methods: We studied group of 32 patients with sHPT with PTH> 500 pg/ml(mean 757+/-264pg/ml) (F=14, M=18; peritoneal dialysis 6 patients and HD 26 patients; mean age 66±17). We planned 6 month cinacalcet therapy and 6 month observation without cinacalcet therapy. There were 2 subgroups of patients with sHPT: groupA (n=18) treated with cinacalcet and group B (n=14) trated with traditional methods. The following parameters were determined in serum: iPTH, Ca, P, and tartrate resistant acid phosphatase TRACP5b as a marker of bone resorption. TRACP 5b activity was measured using assay Bone TRAP™ (SBA Finland). These parameters were measured before start of cinacalcet therapy and after 3rd and 6 st month of therapy and after 3rd and 6 st month without cinacalcet therapy.

Results: Patients treated with cinacalcet (group A) had significant lower values of iPTH and TRAP 5b after 3rd and 6st month of therapy in comparison to group B . We observed 66% reduction of iPTH level (from 816±295pg/ml to 278±149pg/ml at 6st month) and 76% reduction of TRAP 5b level(5.6±2,8 to 1,3± 0,5U/L). After stooping cinacalcet therapy we observed significant increase of iPTH (from 266±142pg/ml to 683±292pg/ml) and TRACP 5b (1,3± 0,5U/L to 4,9±1,8U/L). We did not found any significant difference Ca and P values in both groups.

Conclusions: Treatment of sHPT with Cinacalcet in dialysed patients was effective and allowed the significant reductions of iPTH and TRACP 5b levels. Monitoring of TRACP5b might be useful in assessment of bone resorption in the course of cinacalcet treatment.

SA-PO2271

Changes in Serum Phosphorus and Calcium Predict Parathyroid Hormone (PTH) Over-Suppression in Hemodialysis (HD) Patients (pts) Neal Mittman, Swapna Vemulapalli, Brinda Desiraju, Morrell M. Avram. *Avram Division of Nephrology, S.U.N.Y. Downstate University Hospital at L.I.C.H., Brooklyn, NY.*

Background: Secondary hyperparathyroidism is associated with significant morbidity in HD pts. K/DOQI guidelines recommend a therapeutic target for intact PTH (iPTH) between 150-300 pg/ml. Over-aggressive treatment, especially with vitamin D analogs, risks PTH over-suppression and adynamic bone disease (ABD), a low bone turnover state associated with hypercalcemia which has become the most prevalent bone histology. ABD has been associated with increased risk of fractures, cardiovascular calcification and mortality, and requires prompt modification of treatment regimen. iPTH levels are most commonly tested quarterly, potentially delaying identification of ABD.

Methods: Over a period of two years in our urban dialysis center, we found 93 HD pts with quarterly iPTH values both above and below 150 pg/ml on stable doses of paricalcitol (mean dose 5.7±3.5 µg TIW, range 1-20), on whom we collected demographic and biochemical data.

Results: Mean age was 65 yr (range, 22-90). Fifty-four percent were men, and the majority were of African descent (80%). Sixty-one percent were diabetic. Dialysis vintage was 55 months. The results are shown in the Table.

	First sample	Second sample	p
Intact PTH (pg/ml)	327±177	90±40	<0.0001
Calcium (mg/dl)	9.29±0.65	9.93±0.66	<0.0001
Phosphorus (mg/dl)	5.28±1.46	4.60±1.60	<0.0001
CaxP product	49.4±14	45.8±16.8	0.012
Alkaline Phosphatase (U/l)	95.9±68	85.7±45	0.039

PTH=Parathyroid hormone; Calcium was corrected for albumin

PTH over-suppression (327 ± 177 pg/mL to 90 ± 39.6; p<0.0001) was associated with significant elevations in corrected serum calcium (9.29 ± 0.65 mg/dL to 9.93 ± 0.66; p<0.0001) and reductions in alkaline phosphatase (95.9 ± 68 µg/L to 85.7± 45; p= 0.039), as expected. In addition, we found highly significant reductions in serum phosphorus (5.28 ± 1.46 mg/dL to 4.60 ± 1.60; p<0.0001) and in calcium-phosphorus product (49.4 ± 14 to 45.8 ± 16.8, p= 0.012).

Conclusions: In conclusion, falling monthly values of serum phosphorus associated with rising serum calcium may portend the onset of PTH over-suppression, leading to earlier recognition and intervention for ABD.

Funding: Private Foundation Support

SA-PO2272

Normal Serum Phosphate Levels Associated to Carotid Atheromatosis in Chronic Kidney Disease Stages 2-5 Secundino Cigarran,[1] Emilio E. Gonzalez-Parra,[2] Guillermina Barril,[3] Juan J. Carrero.[4] *[1]Nephrology, Hospital Da Costa, Burela, Lugo, Spain; [2]Nephrology, Fundación Jimenez Díaz, Madrid, Spain; [3]Nephrology, Hospital Universitario de la Princesa, Madrid, Spain; [4]Division of Renal Medicine, Karolinska Institutet, Stockholm, Stockholm, Sweden.*

Background: Atherosclerotic cardiovascular disease is a significant cause of morbidity and mortality in patients with chronic kidney disease (CKD). Phosphate (P) levels are consistently linked with cardiiovascular events and death in chronic kidney disease (CKD) patients and in general population. Fibroblast growth factor 23 (FGF23) is involved in P homeostasis at early stages of CKD and in atheromatosis process.

Methods: We analyze, in cross-sectional study, the role between P levels and carotid atheromatosis in CKD patients stage 2-5. 426 pts with CKD stage 2-5 (mean age 68.08 ± 12.5 yr, 31.1% women, 27.7% diabetic status, GFR-MDRD 51.62± 23.69 ml/min/1.73m^2) were included. Carotid atheromatosis diagnosed by high-resolution B-mode ultrasonography (USBM) and body composition assessment was performed by whole tetrapolar bioelectrical vectorial impedance analysis (BIVA) (EFG, Akern Firenza Italy). Biochemical nutrition, inflammation & mineral bone disease markers were analyzed. ABI test was performed to 56 pts.

Results: 313 (74.4%) had CA and compared with non CA were older (68.66±10.1vs 54.34 ±10.5 years, P<0.001), male gender (65% vs 49% p<0.05).

T paired Test

Variable	Non CA (N=113)	CA (N=313)	P
Na-k Exchange	.96±.13	1.05±.18	.000
ECW (%)	47.47±4.45	49.59±4.82	.000
Phase Angle (º)	5.70±.87	5.30±.91	.000
C Reactive Protein (mg/dl)	.52±.50	.68±1.13	.020
Serum P (mg/dl)	3.35±.55	3.47±.57	.000
P excrertion Index	.79±.34	.94±.39	.000
ABI	.86±.09	1.03±.23	.000

CA=Carotid Atheromatosis; Non CA =Non Carotid Atheromatosis

Conclusions: CA pts are older, lower GFR , diabetic and cellular damage expresed by increased Na-K exchange, lower PA, increased ECW, C reactive protein, serum P and P excretion index. The latter indirectly assess the FGF23 activation, and both of them are directly involved in vascular calcification process. Further studies are required to clarify if P levels and P excretion index may be useful markers for cardiovascular risk in CKD and nonCKD populations.

Funding: Other NIH Support - SERGAS

Ionized Calcium and Mortality in Chronic Hemodialysis Jean-Christophe Szelag, Walid Arkouche, Ignace Mpio, Alejandra Lenz, Carlos Cardozo, Elias Abdullah, Nouredine Boumendjel, Denis Fouque, Maurice Laville. *AURAL Lyon.*

Background: Previous studies have emphasized the noxious effects of high serum calcium and its variations on HD-subjects risk of death. Ionized calcium (Ca++) variations are independent of inflammatory, nutritional and hydratation statuses which are other prognosis factors.

Methods: The studied population consisted in 197 subjects (76 women, 121 men, median age 61,2,diabetes=50)on hemodialysis for more than 3 months. The mean follow-up was 30 months (2-39 months). Ca++ was measured in optimal conditions two hours after sampling. We used a single concentration value in 35 subjects and a three month averaged-concentration (3 to 5 samplings) in 162 subjects. The data are expressed as mean+/-SD, median.

Results: Forty patients died during the follow-up. A survival benefit was observed with concentration under 1,14 mol/L (ph 7,40)(low Ca++ group: 65 subjects, 1,08+/- 0,08, 1,10 mol/L , total calcium concentration 2,11+/-0,20, 2,125 mol/L vs. higher Ca++ group: 132 subjects, 1,21+/-0,05, 1,20 mmol/L, (p=0,03), total calcium concentration 2,24+/-0,14, 2,225 mmol/L, (p=0,004)) (log rank test, p=0,0082). Serum phosphorus (1,66+/-0,54, 1,59 mmol/L vs 1,65+/-0,77, 1,53 mmol/L, p=0,48), albuminemia (39,5+/-3, 39,55 vs 40,1+/-2,9, 40,1 g/L), inflammatory status (usCRP, 11,09+/-15,3, 5,35 vs 10,7+/-13,5, 5,23 mg/L) were the same in both groups. iPTH was significantly higher in low Ca++ group (622,4+/-616, 409 pg/ml vs 396+/-369, 285 pg/ml, p=0,01. Active vitamin D prescription was the same in both groups (Low Ca++ 60%, Higher 49,2%, p=0,07), whereas subjects with low Ca++ were more often treated with cinacalcet (27,6 vs 16,6%, p=0,03). Ionized calcium above 1,14 mmol/L was an independent risk factor for death in univariate Cox model (p=0,015, HR=2,9, 95%CI 1,2-7), case-mix (diabetes, dialysis vintage, age and sexe) (p=0,0308, HR=2,6, 95%CI 1-6,37) and multivariate model (inflammatory status, albuminemia, serum phosphorus and iPTH) (p=0,0227, HR=3 , 95% CI 1,17-8,2)

Conclusions: Our small scale, retrospective and non time-dependent study found a survival benefit with Ca++ under 1,14mmol/L in HD-subjects with higher PTH level and cinacalcet treatment.

SA-PO2274

The Relationship between Prevalent Cardiovascular Events, Hip Fractures and Dialysate Calcium Concentration, Stratified by Predialysis Serum Calcium Concentration in Japanese Hemodialysis Patients Shinichi Sueta,[1] Seiji Hashimoto,[2] Satoshi Ogata,[2] Miho Tagawa.[1] *[1]Nephrology, Kyoto Katsura Hospital, Kyoto, Japan; [2]Patient Registration Committee, Japanese Society for Dialysis Therapy, Tokyo, Japan.*

Background: Previous studies showed that higher dialysate calcium (Ca) concentration is associated with higher mortality. However, it is not known whether predialysis serum Ca concentration has effects on the association.

Methods: This is a cross sectional study using the database of the Japan Renal Data Registry in 2008. Predictor variable was dialysate Ca concentration (dialysate Ca ≤ 2.5 mEq/L, dialysate Ca ≥ 3.0 mEq/L). Outcome variables were prevalence of myocardial infarction (MI), cerebral hemorrhage (CH), cerebral infarction (CI), amputation, and hip fracture. Multivariable logistic regression model was employed adjusting for 15 covariates. Stratified analysis was performed by tertiles of predialysis serum corrected Ca (corrected Ca: 8.9mg/dl, 9.0-9.5, 9.6mg/dl).

Results: Of total 271,510 patients in 2008, we used complete data set of 91,533 patients.

Odds ratios (95 % CI) for higher dialysate Ca user of having prevalent cardiovascular events or hip fractureAssociation of higher dialysate Ca and prevalence of cardiovascular events or hip fracture compared with lower dialysate Ca user as a reference.

Tertiles of predialysis corrected Ca	≤8.9	9.0-9.5	≥9.6
MI	0.917(0.844-0.997)	1.063(0.967-1.168)	0.902(0.820-0.993)
CH	0.881(0.785-0.989)	1.003(0.890-1.130)	0.898(0.805-1.003)
CI	0.878(0.822-0.937)	1.008(0.939-1.081)	0.987(0.921-1.059)
Amputation	0.879(0.760-1.017)	0.920(0.783-1.080)	0.921(0.791-1.072)
Hip fracture	0.773(0.668-0.895)	0.935(0.801-1.092)	0.804(0.695-0.930)

Data shown as odds ratio

Conclusions: Higher dialysate Ca concentration was significantly associated with lower prevalence of MI and hip fracture in lowest and highest tertiles of predialysis corrected Ca concentration. It was also significantly associated with lower prevalence of CH and CI in lowest tertile of predialysis albumin corrected Ca concentration. Longitudinal studies of incident hard outcomes are required to delineate the appropriate choice of dialysate Ca concentration based on predialysis serum calcium levels.

SA-PO2275

Increased Risk of Hip Fracture among Hemodialysis Patients Masks the Influence of Ethnic Difference Minako Wakasugi,[1] Junichiro J. Kazama,[1, 2] Masatomo Taniguchi,[2] Atsushi Wada,[2] Kunitoshi Iseki,[2] Yoshiharu Tsubakihara,[2] Ichiei Narita.[1] *[1]Division of Clinical Nephrology and Rheumatology, Niigata University, Niigata, Japan; [2]Renal Data Registry Committee, Japanese Society for Dialysis Therapy, Bunkyo, Tokyo, Japan.*

Background: Patients with end-stage renal disease have an approximately four-fold greater risk of hip fracture than that of the general population in the United States. However, this finding was based on the observation of Caucasians, who have significantly greater risk for hip fracture than Asians in general.

Methods: We conducted a retrospective cohort study using panel data from the Japanese Society for Dialysis Therapy registry. Data from the hemodialysis patients receiving 3 times/week therapy who had no history of hip fracture as of December 31of 2007 was extracted. The observed number of hip fractures was compared to the expected number based on a Japanese national survey. The standardized incidence ratios (SIRs) were calculated as the ratios of observed to expected number of cases.

Results: During the one-year study period, 1,437 hip fractures out of 128,141 hemodialysis patients (61.9% male) were recorded. The overall incidences of hip fracture were 7.57 and 17.43 per 1000 person years in males and females, respectively. The SIRs for male and female patients were 6.2 (95% confidence interval (CI), 5.7 to 6.8) and 4.9 (95% CI, 4.6 to 5.3), respectively, compared to those in the general population. In diabetic patients, the SIRs continuously rose with increasing dialysis vintage (duration after the initiation of dialysis), whereas the SIRs remained nearly constant until 16 years vintage in non-diabetic patients, but steeply increased thereafter.

Conclusions: Japanese hemodialysis patients have an approximately five-fold greater risk of hip fracture than that of the general population. Although the bone fracture in the Caucasians is twice as much as that in the Asians, the overall incidences of hip fracture were comparable among dialysis patients. Since the influence of uremia on fracture risk was so critical, the effect of ethnic difference seemed to have been masked.

SA-PO2276

Fibroblast Growth Factor 23 and Bone Metabolism in Elderly Chronic Kidney Disease Patients Eiichiro Kanda,[1] Sei Sasaki.[2] *[1]Tokyo Kyosai Hospital, Tokyo, Japan; [2]Tokyo Medical and Dental University, Tokyo, Japan.*

Background: Osteoporosis is commonly observed among elderly persons. We investigated the relationship between lumbar fracture and bone metabolism markers in elderly chronic kidney disease (CKD) patients.

Methods: 105 elderly CKD patients who had never used calcium or vitamin D supplements were enrolled in this cross sectional study in Tokyo, Japan. We investigated the prevalence of lumbar fracture and measured serum calcium, phosphate, $1,25(OH)_2$ vitamin D (1,25-VD), intact parathyroid hormone (iPTH), fibroblast growth factor 23 (FGF23), serum N-terminal telopeptide (NTX) and urinary NTX. Factors associated with lumbar fracture and FGF23 levels were assessed by regression or multivariate logistic model adjusted for age and gender.

Results: The following results were obtained: female, 32.4%; diabetics, 30.5%; average age (SD), 73.2(7.7) years; estimated glomerular filtration rate (eGFR), 45.7(24.1) ml/min; calcium 9.4 (0.5) mg/dl; phosphate 3.5(0.7) mg/dl; intact PTH 3.5(0.7) pg/ml; 1,25-VD 47.2(21.0) pg/ml; FGF23 78.0(101.7) pg/ml; serum NTX 20.5 (17.4) nmol BCE/L; urinary NTX 35.8 (24.3) nmol BCE/mmol.Cr. Univariate analysis revealed that FGF23 level significantly correlated with eGFR, calcium, phosphate, 1,25-VD, intact PTH, and serum NTX levels (P<0.0001), but not with urinary NTX level. Lumbar fracture was associated with age and High FGF23 levels: more than 81 years group (referred to 61-70 years) odds ratio (OR) 4.00 (95% confidence interval 1.05-15.30); high FGF23 levels (>71.0), adjusted OR 4.37 (1.06-17.97). High FGF23 levels were closely associated with bone mineral factors: increased phosphate level (>4.3), adjusted OR 4.18 (1.13-15.40); decreased 1,25-VD level (<20), 19.38 (3.71-101.29); increased serum NTX level (>16.5), 15.08 (4.72-48.15); increased urinary NTX level (male>66.2, female >89.0), 9.15 (1.37-60.99). None of the patients showed both high intact PTH and low FGF23 levels.

Conclusions: Increased FGF23 level was observed with the progression of CKD before intact PTH level increased, and was associated with lumbar fracture and osteoporosis markers. FGF23 is a valuable marker to detect and prevent abnormality of bone metabolism at an early stage of CKD.

SA-PO2277

Tests of Bone Density and Structure Are Associated with Fractures in Stage 3-5 Chronic Kidney Disease Sophie Jamal,[1,3] Sarah West,[1,3] A. M. Cheung,[1,2] Charmaine E. Lok.[1,2] *[1]University of Toronto, ON, Canada; [2]Toronto General Hospital, Toronto, ON, Canada; [3]Women's College Hospital, Toronto, ON, Canada.*

Background: Fractures are common in CKD patients. Bone mineral density (BMD) by dual x-ray absorptiometry (DXA) does not discriminate well (hip BMD AUROC: 0.56) among fractured and non-fractured dialysis patients. However, the ability of BMD by DXA and bone structure by high-resolution peripheral quantitated computed tomography (HR-pQCT) to discriminate fracture status among patients with stages 3-5 CKD (CKD:III-V) is unestablished.

Methods: Baseline data from our ongoing study in adult CKD:III-V patients,was used to determine if BMD by DXA (Hologic) at the lumbar spine (LS), total hip (TH), ultradistal radius (UDR); and/or cortical area, density & thickness, trabecular area, density & separation by HR-pQCT (XtremeCT) at the radius could discriminate fracture status (fracture=self-reported low trauma fractures occurring after 40 yrs and/or prevalent vertebral fractures identified by morphometry). Results are expressed as areas under the receiver operating characteristic curves (AUROC) with 95% confidence intervals (CI), adjusted for age and weight.

Results: Data from 128 men and 86 women showed that compared to those without fractures (n=143), those with fractures (n=70) were older (59±16 vs. 69±14 yrs, p<0.001). The mean weight was 79.9±19.8 kg, most were Caucasian (70.0%), > 40% had diabetes, and most (74%) patients were CKD stage 4 or 5. The mean duration of CKD was 8.0±10.3 yrs, and 30.2% reported a fall in the last 12 mos. BMD by DXA discriminated among those with and without fractures (AUROC for LS: 0.70 [95% CI: 0.62-0.78]; TH: 0.69 [95% CI: 0.61-0.77]; UDR: 0.71 [95% CI: 0.63-0.78]). HR-pQCT also performed well for cortical measures (AUROC for area: 0.67 [95% CI: 0.59-0.76]; density: 0.70 [95% CI: 0.63-0.78] and thickness: 0.70 [95% CI: 0.62-0.78]) and trabecular measures (AUROC for area: 0.70 [95% CI: 0.62-0.78]; density: 0.70 [95% CI: 0.63-0.78]; and separation: 0.70 [0.63-0.78]).

Conclusions: BMD by DXA and HR-pQCT can discriminate fracture status in CKD:III-V patients. Prospective studies are needed to evaluate the fracture predictive ability of BMD and HR-pQCT.

SA-PO2278

Dialysis as a Treatment Option for Primary Tumoral Calcinosis in a Patient with a New FGF Mutation Patricia T. Goldenstein,[1] Manuel C. Castro,[1] Rodrigo B. Oliveira,[1] Hugo Abensur,[1] Claudio Luders,[1] Rosilene M. Elias,[1] Harald Jueppner,[2] Alexandre Costa Pereira,[3] Vanda Jorgetti,[1] Rosa M.A. Moyses.[1] *[1]Nephrology, Hospital das Clínicas da Faculdade de Medicina da USP, Sao Paulo, Brazil; [2]Nephrology, Massachussets General Hospital, Boston, MA; [3]Cardiology, Hospital das Clínicas da Faculdade de Medicina da USP, Sao Paulo, Brazil.*

Background: Primary tumoral calcinosis (TC) is a rare autosomal recessive metabolic disorder characterized by ectopic calcified tumoral masses and dental abnormalities, as well as soft tissue periarticular and vascular calcifications. Until now, mutations in three genes were ascribed to be responsible for the human disorder.

Methods: Here we describe a case of a 24-yr-old male with TC, with a new mutation in FGF23 and an unusual treatment option in an attempt to effectively control his phosphate and reduce his calcified lesions.

Results: The patient presented subcutaneous nodules, as well as periarticular and vascular calcifications. Biochemical analysis disclosed hyperphosphatemia (9.0 mg/dL), normocalcemia (4.8 mg/dL) with a normal renal function and FeP = 3%. PTH was suppressed (15 pg/mL), associated with a low-normal 25-OH-vitamin D (26 ng/mL). Serum intact FGF-23 was undetectable. As for FGF23, a heterozygous state was observed defined by p.Q67H (exon 1) and p.Q156stop (exon 3). Despite of four surgeries for tumoral resection and medical treatments with aluminum hydroxide, sevelamer and acetazolamide, lesions continued to progress. Due to lack of other treatment options, patient was included in a daily dialysis program, leading to a better phosphorus control. After 24 months of therapy, TC lesions decreased in size and he recovered most of his mobility. This is the first report of a new mutation in FGF gene and the first case in which dialysis was described as an effective treatment option for TC with normal renal function.

Conclusions: This patient, with his rare genetic disease, gave us the opportunity to test in vivo the role of phosphate in extra-osseous calcification and emphasizes the need of its control in the context of CKD.

SA-PO2279

The Value of DXA Versus QCT for Diagnosis of Osteoporosis in Patients with CKD Hartmut H. Malluche,[1] Hanna W. Mawad,[1] James N. Wise,[2] Stephanie Fugate,[1] Kimberly McLaughlin,[1] Anthony Wolbarst,[2] Daniel Davenport,[3] Marie-Claude M. Faugere.[1] *[1]Division of Nephrology, University of Kentucky; [2]Department of Radiology, University of Kentucky; [3]Department of Surgery, University of Kentucky.*

Background: Bone mineral density (BMD) of the lumbar spine and hip was measured by dual-energy x-ray absorptiometry (DXA) and quantitative computed tomography (QCT) in 82 patients with CKD-5D.

Methods: There were 42 men (age 52.0 ± 2.13 yrs) and 40 women (age 56.2 ± 2.18 yrs). Mean dialysis duration was 59.1 ± 6.30 mos. Thirty seven % of the patients were diabetics. Iliac crest bone biopsies were done for histomorphometry at time of BMD measurements in a subgroup of 23 patients. Diagnosis of osteoporosis by DXA or QCT was made when t-scores were < -2.5 and by histomorphometry when cancellous bone volume and/or cortical thickness were below normal and/or cortical porosity was above normal values.

Results: Osteoporosis was found in the spine by DXA in 10% and by QCT in 14%; osteoporosis in the hip was found by DXA in 26% and by QCT in 16% (p=0.008). Absolute scores of the hip obtained from DXA and QCT were not different and correlated. T-scores of the hip from DXA and QCT also correlated but were lower with DXA than QCT (-1.3 ± 0.20 vs. -0.12 ± 0.22, p <0.001). This suggests that the differences observed in recognition of osteoporosis were not due to absolute test results, but related to differences in normative databases used to calculate t-scores. Bone histology identified presence of osteoporosis in 90% of the patients.

Sensitivity, specificity, positive and negative predictive values of DXA versus QCT for osteoporosis diagnosed by histology are shown below.

	DXA Hip	QCT Hip	DXA Spine	QCT Spine
Sensitivity (%)	43	29	5	29
Specificity (%)	50	100	100	100
Positive Predictive Value (%)	90	100	100	100
Negative Predictive Value (%)	8	12	10	12

Conclusions: In conclusion, for prediction of histologically documented osteoporosis DXA and QCT are equally specific (100%) for the spine while for the hip QCT had superior specificity. Sensitivity is poor with both DXA and QCT of spine and hip. For diagnosis, specificity and sensitivity of at least 80% is required, thus neither DXA nor QCT is reliable.

Funding: NIDDK Support, Private Foundation Support

SA-PO2280

Evaluation of Bone Mineral Density in Long-Standing Type 1 Diabetic Patients with or without Diabetic Nephropathy Maria Lajer,[1] Simone Theilade,[1] Christel Joergensen,[1] Frederik I. Persson,[1] Gudbjörg Andrésdóttir,[1] Henrik Reinhard,[1] Hans-Henrik Parving,[2] Lise Tarnow,[1] Peter Rossing.[1] *[1]Steno Diabetes Center; [2]University Hospital of Copenhagen.*

Background: Patients with chronic kidney disease including diabetic nephropathy are suggested to have reduced bone mineral density (BMD).

Methods: Cross-sectional evaluation of 293 prospectively followed long-standing, type 1 diabetic patients. 115 patients with diabetic nephropathy (54% men; age [mean±SD] 54±9 years, 42±8 years of diabetes, duration of nephropathy 22±6 years) and 178 patients with persistent normoalbuminuria (49% men, age 59±10 years, 41±10 years of diabetes) were included. BMD (g/cm^2) in femoral neck, total femoral bone and lumbar spine was measured by dual energy x-ray absorptiometry (DXA). Osteopenia and osteoporosis were defined by any sex matched T-score from -2.5 to -1.0 and <-2.5, respectively. The difference between BMD and age-sex matched average defines the Z-score. GFR was measured by ^{51}Cr-EDTA clearance in patients with nephropathy.

Results: Among patients with diabetic nephropathy, 58 (50%) and 31(27%) had osteopenia and osteoporosis, respectively compared to 106 (60%) and 22 (12%) of the normoalbuminuric patients; p=0.006. Among male patients with nephropathy, the prevalence of osteoporosis was 37% *vs.* 9% with normoalbuminuria (p<0.001), whereas no difference was seen among women. Similarly, men with nephropathy had significantly lower age-sex matched spinal, femoral neck and total femoral bone Z-scores compared to normoalbuminuric patients; p≤0.002. There was no statistically difference in woman.

Finally, among patients with diabetic nephropathy, baseline GFR levels did not differ between men and women; 94(29) *vs.* 95(30), respectively but correlated positively with femoral neck and total femoral BMD (r=0.36 and r=0.38; p<0.001, respectively).

Conclusions: The risk of osteoporosis was highest among male patients with type 1 diabetes and long-standing diabetic nephropathy and femoral BMD correlated with renal function. Hence screening, prevention and treatment of osteoporosis in patients with impaired renal function should be considered.

SA-PO2281

Low-Dose Calcifediol Supplementation Augments Serum PTH Levels in Hemodialysis Patients at Risk for Adynamic Bone Disease Francesco Iannuzzella, Silvia Mattei, Fabio Carlini, Alfredo Stefani, Sonia Pasquali. *Division of Nephrology, Arcispedale Santa Maria Nuova, Reggio Emilia, Italy.*

Background: Adynamic bone disease (ABD) is a common form of renal osteodystrophy. In hemodialysis (HD) patients, the use of active vitamin D analogs may favor the development of ABD by means of the suppression of PTH secretion. By contrast, treatment of low 25-hydroxyvitamin D (calcifediol) levels may exert a stimulatory effect on bone formation. We undertook this study to assess the effect of low-dose calcifediol supplementation on mineral metabolism and serum PTH levels in long-term HD patients considered at risk for ABD because of low serum PTH levels.

Methods: This was a 3-month follow-up, prospective study of a cohort of prevalent HD patients from a single center. Eligible subjects were on HD for ≥3 months with PTH levels <150 pg/mL. All patients were included in the study, except for those who were taking cinacalcet or any active vitamin D analog and those who had undergone parathyroidectomy. Calcium based-phosphate binders dose remained unchanged during the study. Serum levels of 25-hydroxyvitamin D, PTH, Ca, P and alkaline phosphatase were measured before and after supplementation. All patients received 20 drops of oral calcifediol (1.5 mg/10 mL) once a week after the first HD session of the week for 3 months. Statistical analysis was performed using paired Wilcoxon test.

Results: The study included 18 patients: 8 men and 10 women with mean age of 57.8±19.5 years. Mean HD vintage was 24.3±32.4 months. Calcifediol serum levels were <30 ng/ml in all our patients at baseline and significantly increased at the end of the study (8.1±4.9 vs. 23.8±10.1, P<0.001). Serum PTH increased significantly (79.6±34.2 vs. 118.9±59.0, P<0.05). Serum phosphate showed a slight but significant increase with supplementation (4.3±1.3 vs. 4.8±1.0, P<0.05), whereas no change was reported for both serum calcium (9.2±0.8 vs. 8.8±0.5, P>0.05) and alkaline phosphatase levels (175.6±58.3 vs. 179.8±61.1, P>0.05).

Conclusions: The parathyroid glands of vitamin D deficient HD patients with relative hypoparathyroidism or ABD responded to a low-dose 25-OH-vitamin D supplementation with a significant increase in serum PTH levels.

SA-PO2282

DXA and HRpQCT Detect Minimal Bone Loss after Kidney Transplantation with Early Corticosteroid Withdrawal Lucas Nikkel, Chiyuan Amy Zhang, Sumit Mohan, Bekir Tanriover, David J. Cohen, Lloyd Ratner, Geoffrey K. Dube, Stephanie Boutroy, Xiaowei Sherry Liu, Donald J. McMahon, Elizabeth Shane, Thomas L. Nickolas. *Columbia University.*

Background: With corticosteroid (CS)-based immunosuppression (CSBI), areal bone mineral density (aBMD) declines 2-10% during the first 6 months (m) after kidney transplant (KTx), particularly at trabecular (Tb) rich sites, such as the lumbar spine (LS); fracture rates are high at both spine and hip. Early corticosteroid withdrawal (ECSW) protocols, based on calcineurin inhibitors (CNI) are increasingly used after KTx. We hypothesized that KTx recipients managed with ECSW would not experience significant bone loss.

Methods: We included KTx recipients ≥18 yrs managed with ECSW. At baseline, 3m and 6m post-KTx, we measured aBMD by dual energy X-ray absorptiometry (DXA) at predominantly Tb sites: LS and ultradistal radius (UDR); and cortical (Ct) sites: total hip (TH); femoral neck (FN); 1/3 radius (1/3R). High resolution peripheral QCT (HRpQCT; Scanco Medical, AG, voxel size~82µm) was used to measure total, Ct and Tb volumetric BMD (vBMD); Ct thickness (CtTh); and Tb number (TbN), thickness (TbTh) and separation (TbSp) at the distal radius (DR) and tibia (DT). Comparisons were made using paired T-tests; results are expressed as Means±SD.

Results: Of 48 subjects enrolled, 29 and 24 completed 3m and 6m of observation respectively. Age was 51±13 years; 27% were women; 73% were white. BMI was 29±4 Kg/m2. Mean baseline T-Scores were > -2.5 at all sites. At 6m, aBMD declined significantly only at the 1/3R (-1.8%; p=0.02) and UDR (-2.7%; p=.04). By HR-pQCT at 6m, DR total vBMD decreased by -2.6% (p=0.01), Tb vBMD decreased by -2.5% (p<0.001), and there was a non-significant 1.3% decrease in DT total vBMD (p=0.08). TbN, TbTh, and TbSp were unchanged at both DR and DT at 6m.

Conclusions: After KTx, ECSW was associated with less bone loss at the LS, FN, and TH than previously reported with CSBI. Significant bone loss occurred at the 1/3R and UDR which HR-pQCT suggested is primarily Tb; the mechanism of bone loss at the DT and DR was unclear. Larger and longer studies are needed to assess ECSW effects on fracture rates after KTx.

Funding: Private Foundation Support

SA-PO2283

Does Simultaneous Pancreas-Kidney Transplantation Reduce Fracture Risk? An Analysis of the USRDS Lucas Nikkel,[1] Sumit Mohan,[1] Bekir Tanriover,[1] Lloyd Ratner,[1] Chiyuan Amy Zhang,[1] Donald J. McMahon,[1] Mary B. Leonard,[3] Christopher S. Hollenbeak,[2] Elizabeth Shane,[1] Thomas L. Nickolas.[1] *[1]Columbia University; [2]Penn State Hershey; [3]Childen's Hospital of Pennsylvania.*

Background: Simultaneous pancreas-kidney transplant (SPK) is treatment of choice for patients with Type 1 Diabetes Mellitus (DM1) and end stage renal disease (ESRD). Both DM1 and ESRD increase fracture (Fx) risk due to metabolic abnormalities that negatively impact bone quality and strength. SPK improves metabolic disarray due to both DM1 and ESRD and may decrease Fx risk. We hypothesized that in patients with DM1, SPK would reduce Fx associated with hospitalizations compared to patients with DM1 who received a kidney transplant (KTx) alone.

Methods: Adults age≥18 yrs with DM1 undergoing either SPK or KTx between January 1, 2000 and December 31, 2006, were identified from USRDS. First Fx events were identified from hospital discharge ICD9 codes after Tx. Continuous covariates (age, BMI, HLA mismatches) were compared with Students t tests and categorical covariates were compared by Chi-square. Time to first post-Tx Fx was modeled by Kaplan-Meier and Cox methods. Propensity score adjustment was used to balance differences in age, gender, race, BMI, prior dialysis, HLA mismatches, and immunosuppression between Tx groups.

Results: Of 11,237 patients with DM1, 4,987 and 6,250 underwent SPK and KTx, respectively. There were 221 and 378 Fxs in the SPK (4.4%) and KTx (6.1%) cohorts respectively (p<0.0001). In univariate analysis, SPK had 27% lower Fx risk than KTx (p<0.001). After adjustment for age, gender, race, BMI, prior dialysis, HLA mismatches, and immunosuppression by propensity score, SPK had 23% lower Fx risk (Hazard Ratio [HR]: 0.77; p=0.009) and 40% lower hip Fx risk (HR: 0.60; p=0.04) versus KTx. Older age, white race, prior dialysis, and pre-Tx Fx were also associated with increased risk.

Conclusions: SPK results in 23% reduced risk for all Fx types requiring hospitalization and 40% reduced risk for hip Fx in comparison to KTx alone in adults with DM1. Prospective studies are needed to elucidate the mechanisms that account for the differential effects of SPK and KTx on bone quality and propensity for Fx.

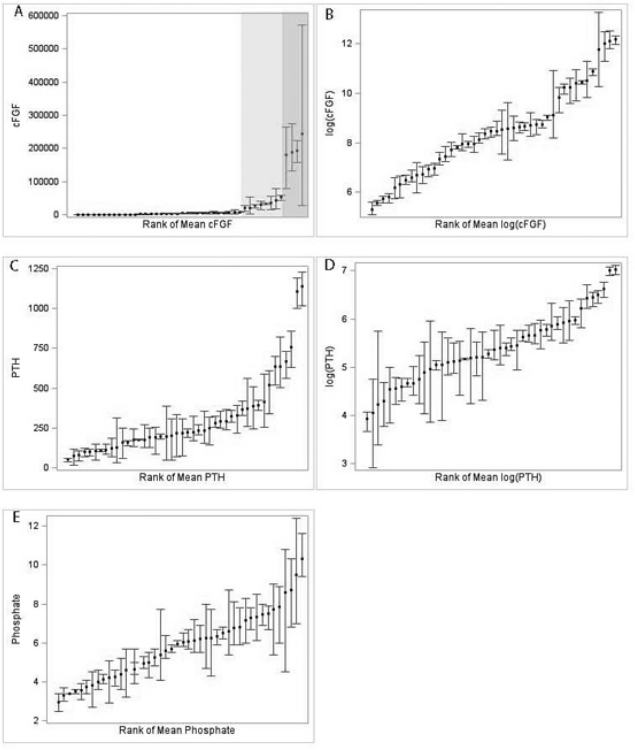
Fibroblast Growth Factor 23 in Patients Undergoing Peritoneal Dialysis Tamara Isakova,[1] Huiliang Xie,[1] Allison Barchi-Chung,[1] Gabriela S. Vargas,[1] Nicole Sowden,[1] Jessica Houston,[1] Patricia R. Wahl Pristau,[1] Andrew L. Lundquist,[2] Michael Epstein,[2] Kelsey T. Smith,[1] Luis M. Ortega,[1] Gabriel Contreras,[1] Oliver Lenz,[1] Talat Alp Ikizler,[3] Harald Jueppner,[2] Myles S. Wolf.[1] *[1]University of Miami Miller School of Medicine; [2]Massachusetts General Hospital; [3]Vanderbilt University.*

Background: Fibroblast growth factor 23 (FGF23) is an independent risk factor for mortality in patients with end-stage renal disease (ESRD). Before FGF23 testing can be integrated into clinical practice of ESRD, further understanding of its determinants is needed.

Methods: In a study of 67 adults undergoing peritoneal dialysis, we tested the hypothesis that longer dialysis vintage and lower residual renal function and renal phosphate clearance associate with higher FGF23. We also compared the monthly variability of FGF23 versus parathyroid hormone (PTH) and serum phosphate.

Results: In unadjusted analyses, FGF23 correlated with serum phosphate (r = 0.66, P <0.001), residual renal function (r = – 0.37, P = 0.002), dialysis vintage (r = 0.31, P = 0.01), and renal phosphate clearance (r = – 0.38, P = 0.008). In adjusted analyses, absence of residual renal function and greater dialysis vintage associated with higher FGF23, independent of demographics, laboratory values, peritoneal dialysis modality and adequacy, and treatment with vitamin D analogs and phosphate binders. Urinary and dialysate FGF23

clearance was minimal. In three serial monthly measurements, within-subject variability accounted for only 10% of total FGF23 variability compared with 50% for PTH and 60% for serum phosphate.



Conclusions: Increased serum phosphate, loss of residual renal function, longer dialysis vintage and lower renal phosphate clearance associate with elevated FGF23 levels in ESRD patients undergoing peritoneal dialysis. FGF23 may be a more stable marker of phosphate metabolism in ESRD than PTH or serum phosphate.

SA-PO2285

Impact of Lanthanum Carbonate on FGF23 in Chronic Kidney Disese Stages 3-5

Neenoo Khosla, Stuart M. Sprague. *Nephrology, Northshore University Healthsystem, Evanston, IL.*

Background: FGF23 plays an important role in the regulation of phosphate as well as vitamin D and parathyroid hormone (PTH) metabolism. As CKD progress, phosphate retention with hyperparathyroidism develops. Serum phosphate levels are not a good early marker of phosphate retention, whereas increases in FGF23 which help maintain normal phosphate balance may be a better indicator of phosphate retention and subsequent development of hyperparathyroidism. The purpose of this study was to determine if reducing FGF23 levels with lanthanum could prevent or reverse the development of hyperparathyroidism.

Methods: A randomized double blinded placebo controlled study was performed in subjects with CKD stages 3-5 to determine if treatment with lanthanum carbonate 500 mg or placebo given with meals could reduce FGF23 and PTH. Subjects were treated for 60 days and doses increased to 1000 mg pc for phosphorous > 5.5 mg/ dl. We report interim data on first 14 patients randomized. One way ANOVA was used to assess significance

Results: Fourteen patients were randomized to placebo versus treatment. Two patients in treatment group and 1 in placebo group dropped out secondary to GI side effects. Data from 5 patients on Lanthanum and 6 patients in placebo are presented. There was no change in serum FGF23, calcium, phosphorus, 25 vitamin D and change in PTH (%) levels in patients treated for 60 days with placebo. There were significant declines in FGF23 levels and change in PTH in patients treated with lanthanum for 60 days.

Impact of Lanthanum Carbonate versus Placebo on Markers of Mineral Metabolism

	PLACEBO GROUP			LANTHANUM GROUP		
Values (mean ±SD)	Time 0	60 Days	P value	Time 0	60 Days	P value
FGF23 (RU/ml)	123.4±35	105.6±55	0.51	150.6±56	39.9±17	**0.003**
Calcium (mg/dl)	9.5±0.3	9.6±0.4	0.61	9.6±0.4	9.5±0.3	0.79
Phosphorus(mg/dl)	3.65±0.4	4±0.8	0.37	4.2±0.6	4.26±0.7	0.88
% Change PTH	100	88±41	0.49	100	57.2±40	**0.04**
25Vit D(ng/ml)	47.8±9	50.7±11	0.67	39.4±17	37.8±14	0.89

Conclusions: Lanthanum carbonate given with meals significantly reduces FGF23 and PTH levels with no changes in calcium, phosphorus and 25 D levels.

SA-PO2286

Disordered Mineral Metabolism in the CKiD Children: Role of FGF23

Anthony A. Portale,[1] Myles S. Wolf,[2] Isidro B. Salusky,[3] Harald Jueppner,[4] Juhi Kumar,[5] Susan L. Furth,[6] Bradley A. Warady.[7] *[1]Pediatrics, UCSF, San Francisco, CA; [2]Medicine, University of Miami, FL; [3]Pediatrics, UCLA, Los Angeles, CA; [4]Pediatrics, Massachusetts General Hospital, Boston, MA; [5]Pediatrics, Weill Cornell Medical College, NY, NY; [6]Pediatrics, Children's Hospital of Philadelphia, PA; [7]Pediatrics, Children's Mercy Hospital, Kansas City, MO.*

Background: FGF23 is an important regulator of phosphorus (Pi) and vitamin D metabolism. However, little is known about the prevalence and determinants of FGF23 excess across the spectrum of CKD in children.

Methods: We measured plasma C-terminal FGF23 (Immutopics 2nd gen) in 426 children, ages 1-16 yrs, with CKD stages 2-4 enrolled in the observational Chronic Kidney Disease in Children (CKiD) study. GFR was measured by plasma clearance of iohexol (n=286) or estimated using the CKiD estimating equation.

Results: Mean age of subjects was 11.5 ± 4.3 (SD) yrs. CKD was due to glomerular disease in 21% and non-glomerular disease in 79%. Mean GFR was 46 ± 18 ml/min/1.73 m2; 18% of subjects had CKD stage 2, 59% stage 3, and 21% stage 4. Overall, median serum Pi and PTH levels were within the normal range, but median FGF23 was 132 RU/ml (IQR: 88-223), 2.3-fold higher than that in healthy children. 66% of subjects met criterion for FGF23 excess (>100 RU/ml), but only 12% had hyperphosphatemia. FGF23 was strongly associated with GFR (r=-0.44), age-adjusted Pi (r=0.30), and PTH (r=0.36) (P<0.001 for each). In stage 2 CKD, mean age-adjusted Pi was below the normal mean (P<0.01), PTH was >65 pg/ml in only 15%, whereas FGF23 was >100 RU/ml in 44% of subjects. As GFR declined further, the prevalence of FGF23 excess increased (stage 3, 66%; stage 4, 91%). FGF23 was higher in children with glomerular than with non-glomerular disease (P<0.001), after adjusting for age, GFR, and Pi.

Conclusions: Plasma FGF23 concentrations are increased early in the course of CKD in children, before increases in serum Pi or PTH. Thus, increased FGF23 may be an early biomarker of disordered Pi homeostasis and an initiating mechanism of abnormal mineral metabolism in children with progressive CKD.

SA-PO2287

Evaluation of the Relationship between Vitamin D Analogs and FGF23: Is There a Difference between Agents?

Magdalene M. Assimon, Darius Mason. *Albany College of Pharmacy & Health Sciences, Albany, NY.*

Background: Fibroblast growth factor (FGF23), a key regulator of mineral metabolism, has been associated mortality in the dialysis population. Activated vitamin D administration increases FGF23 levels. Observational studies have shown that the beneficial effects of vitamin D analogs (VDAs) on survival are reduced at higher doses. The aim of this study was to explore the relationship between FGF23, VDA selection and VDA dosage among hemodialysis (HD) patients.

Methods: Adults on HD for ≥ 3 months were included in this cross-sectional study. Patient demographics, laboratory values and current medication regimens were obtained. Weekly VDA doses were converted to doxercalciferol equivalents (4.6 µg of paricalcitol = 3.1 µg doxercalciferiol) for uniformity. Pre-dialysis levels of intact FGF23 were measured via ELISA. Stepwise linear regression was used to identify factors associated with FGF23.

Results: A total of 127 patients (57% male, 46% diabetic etiology, 64% on doxercalciferol therapy) with a mean age = 62.4±14.9 years, HD vintage = 3.5±2.9 years and log FGF23 = 2.57±0.37 pg/ml were included in this analysis. Log FGF23 levels positively correlated with HD vintage (r=0.24, p=0.0065), calcium (r=0.26, p=0.0036), phosphorus (r=0.57, p < 0.0001), PTH (r=0.25, p = 0.0054), VDA dose (r=0.21, p=0.0181) and negatively correlated with age (r=-0.18, p=0.0388). Log FGF23 was lower in those on doxercalciferol compared to patients on paricalcitiol (2.50±0.33 pg/ml versus 2.70±0.42 pg/ml, p=0.002). Use of paricalcitol (β=0.15, p=0.0032), VDA dose (β=0.007, p=0.0258), calcium (β=0.21, p<0.0001), phosphorus (β =0.15, p<0.0001) and HD vintage β=0.02, p=0.028) were independently associated with log FGF23.

Conclusions: The positive independent association between VDA dose and FGF23 are indicative of a dose response relationship between VDAs and FGF23. Furthermore, paricalcitol therapy was independently associated with higher FGF23 concentrations, compared to doxercalciferol therapy. These results suggest that individual VDAs may have differential effects on FGF23 regulation in HD patients and warrants further investigation.

SA-PO2288

FGF-23 Levels Are Modified by Loop Diuretic Treatment in CKD Patients

Sarah Seiler, Esther Herath, Franziska Flügge, Anja Weihrauch, Danilo Fliser, Gunnar H. Heine. *Internal Medicine IV, Saarland University Hospital, Homburg, Saar, Germany.*

Background: FGF-23 is a central regulator of calcium phosphate metabolism. Similar to parathyroid hormone (iPTH), FGF-23 stimulates renal phosphate excretion. While plasma levels of both iPTH and FGF-23 increase in advanced CKD in order to combat phosphate retention, an elevation of FGF-23 may precede the decline of estimated glomerular filtration rate (eGFR) in very early CKD for unknown reasons. In CKD patients, use of loop diuretics is a known stimulus for increased renal calcium loss and consecutively increased iPTH levels. To date it is unclear whether the use of loop diuretics results in a concomitant increase of FGF-23.

Methods: We studied 343 CKD stage 2-4 patients in our ongoing CARE FOR HOMe study. In all patients we measured plasma levels of iPTH, FGF-23 and urinary fractional calcium excretion (FeCa) , and recorded the intake of diuretic medication (loop diuretics: LD; thiazide diuretics: TD). In addition, we assessed left ventricular function using echocardiography and eGFR using the MDRD study equation 4.

Results: Study participants had a mean eGFR of 44.2±15.7 ml/min/1.73 m², and were 65±12 years of age. Median FGF-23 level was 99.0 rU/ml (IQR 60.3-158. rU/ml), mean iPTH level was 70.2±57.9 pg/ml. 281 patients (81.9 %) were on diuretic medication, comprising 161 patients (46.9 %) receiving LD, and 174 patients (50.7%) receiving TD. Intake of thiazides was associated with lower FeCa (TD: 0.52±0.51%; no TD: 0.89±0.98%; p<0.001), LD were associated with higher FeCa (LD: 0.88±1.01%; no LD: 0.54±0.48%; p=0.010). Moreover, the intake of LD was associated with higher iPTH (LD: 90.6±72.2 pg/ml; no LD: 52.3±32.7 pg/ml; p<0.001) and FGF-23 levels (LD: 125.4 rU/ml [IQR 78.0-187.3 rU/ml]; no LD: 76.4 rU/ml [IQR 50.5-116.3 rU/ml]; p<0.001), while the intake of thiazides was not. This association remained significant after correction for eGFR and left ventricular function in a linear regression analysis.

Conclusions: The results from our study complements earlier data on the impact of LD on secondary hyperparathyroidism, reporting for the first time an association between choice of diuretic medication and FGF-23 levels in CKD patients.

SA-PO2289

24,25 Dihydroxyvitamin D Levels Are Elevated in Dialysis Patients and Correlate with FGF23 Levels Marta Christov,[1, 2] Nigel Clarke,[3] Julia Beth Wenger,[2] Richard E. Reitz,[3] Ravi I. Thadhani,[2] Harald Jueppner.[2] *[1]Medicine, Beth Israel Deaconess Medical Center, Boston, MA; [2]Medicine, Massachusetts General Hospital, Boston, MA; [3]Quest Diagnostics Nichols Institute, San Juan Capistrano, CA.*

Background: 25(OH) vitamin D (25D) deficiency is common in patients treated with dialysis and may contribute to the adverse outcomes observed in this cohort. In these patients increased FGF23 levels are thought to inhibit the renal 1-alpha hydroxylase and stimulate the 24-hydroxylase thus contributing to diminished 1,25(OH)2 vitamin D (1,25D) levels and to the development of secondary hyperparathyroidism. Recent data suggest the presence of increased amounts of the 24-hydroxylase protein in the kidneys of rodents and humans with CKD, which may contribute to both 25D deficiency (by metabolism into inactive analogs) as well as 1,25D deficiency (by "siphoning off" of the precursor 25D).

Methods: Using a novel mass spectrometry approach, we measured 24,25D levels in the circulation of 120 individuals with no known renal dysfunction and 60 patients initiating hemodialysis.

Results: In the reference group, 24,25D levels were positively correlated with 25D status. Specifically, the mean 24,25D level in individuals with 25D levels <20 ng/mL was 1.27±0.3 ng/mL (mean±SEM), while in those with 25D levels >30 ng/mL it was 6.1±0.56 ng/mL. In the dialysis population 24,25D levels were significantly elevated; patients with baseline 25D levels <20 ng/mL had a 24,25D level of 9.0±1.26 ng/mL (mean±SEM), at times rising above the absolute 25D level in individual patients. 24,25D levels correlated positively with 25D, calcium and albumin. Treatment with an active vitamin D analog did not increase 24,25D levels and neither did the dialysis procedure itself. FGF23 levels measured in a subset of patients correlated positively with 24,25D levels (N=23, R=0.42, p<0.05).

Conclusions: In summary, 24,25D levels in dialysis patients are increased compared with those in a reference population and correlate with FGF23 levels. This correlation is consistent with the FGF23-mediated increase in 24-hydroxylase expression in renal and possibly extra-renal tissues.

Association of Fibroblast Growth Factor 23 on Pulse Wave Velocity in Chronic Kidney Disease Stage 3-5 Patients with 2 Years Follow-Up Annet Bouma-de Krijger,[1] Arjan D. Van Zuilen,[2] Marc G. Vervloet,[1] Frans J. van Ittersum,[1] Pieter M. Ter Wee,[1] Jack F. Wetzels,[3] Peter J. Blankestijn.[2] *[1]Nephrology, VU University Medical Centre, Amsterdam, Netherlands; [2]Nephrology, University Medical Centre Utrecht, Utrecht, Netherlands; [3]Nephrology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Background: FGF23 is independently associated with cardiovascular outcome in CKD. However, the mechanism of this association is not known. To investigate the influence of FGF23 on vascular function we evaluated the association between baseline FGF23 and PWV and changes in FGF23 and PWV during two years.

Methods: We performed a post-hoc analysis of PWV in a subset of 188 CKD patients (132 male, ,mean age 56,5 years +/-12,7) included in the multicenter Masterplan-trial. Multiple logistic regression was used to evaluate the association between of FGF23 and PWV at baseline; generalized estimating equations were applied to evaluate this relationship in the entire 2 years study period.

Results: At baseline, mean arterial pressure (MAP), age and HbA1c were associated with PWV (all p < 0,05). In a model adjusted for these covariates, FGF23 was not associated with PWV. In the entire 2 years study period, FGF23 had a significant effect on PWV (p <0.001). In addition, PWV increased significantly over time (p=0.019).

table1

	Regression coefficient	p-value	Explained variance (model)
PWV baseline (m/s)			0.338
FGF23 baseline (U/ml)	0.001	0.405	
Age baseline (year)	0.103	0.000	
MAP baseline (mmHg)	0.058	0.000	
Hba1c baseline (%)	0.574	0.017	
PWV change (m/s) Baseline to 2 years			0.3980
Male gender	0,269	0.111	
Diabetes	0.396	0.335	
FGF23 (U/ml)	0.001	0.000	
Age (year)	0.110	0.000	
MAP (mmHg)	0.69	0.000	
HbA1c (%)	0.526	0.12	
Time (2 years vs baseline)	0.745	0.19	

Conclusions: Baseline FGF23 was not associated with baseline PWV. In two year follow-up FGF23 is significantly associated with PWV. This association is modest and clinical meaning remains to be determined.

SA-PO2291

Correction of Hyperphosphatemia Suppresses Cardiac Remodeling in Uremic Rats Masahide Mizobuchi,[1] Hiroaki Ogata,[2] Chiaki Kumata,[1] Ai Nakazawa,[1] Fumiko Kondo,[1] Eriko Kinugasa,[2] Tadao Akizawa.[1] *[1]Division of Nephrology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan; [2]Department of Internal Medicine, Showa University Northern Yokohama Hospital, Yokohama, Japan.*

Background: Hyperphosphatemia is associated with cardiovascular disease in patients with CKD. Correction of hyperphosphatemia is imperative from a perspective of the progression of cardiovascular disease. We investigated the association between phosphate metabolism and cardiac remodeling in 5/6th nephrectomized rats.

Methods: Adult Sprague-Dawley rats underwent subtotal nephrectomy (Nx) by the ligation method. Four groups were studied for 8 wk: 1) control (sham), 2) Nx rats fed a normal phosphate (0.9%) diet (Nx+NP), 3) Nx rats fed a high phosphate (2%) diet (Nx+HP), and 4) Nx rats fed a high phosphate diet containing 2% lanthanum (Nx+HP+La).

Results: Subtotal nephrectomy caused blood pressure elevation, and renal dysfunction as evidenced by a gradual increase in proteinuria and elevation in serum creatinine levels. Nx+HP rats showed a significant increase in serum phosphate and PTH levels compared with Nx+NP rats while Nx+HP+La rats showed slight decrease in these levels. Not only Nx+HP rats, but also Nx+HP+La rats showed a significant increase in serum FGF23 levels compared with Nx+NP rats. Urinary phosphate excretion showed a similar trend as serum FGF23 levels. Both Nx+NP rats and Nx+HP rats showed a significant increase in the left ventricle weight compared with sham rats while the increase was significantly suppressed in Nx+HP+La rats. Nx+HP rats showed a significant increase in matrix deposition of the cardiac tissue compared with the Nx+NP rats while the increase was significantly suppressed in Nx+HP+La rats.

Conclusions: Correction of hyperphosphatemia could suppress the cardiac remodeling, which was independent of serum FGF23 levels.

SA-PO2292

Effects of the Correction of 25-hydroxyvitamin D Deficiency on Hyperparathyroidism and Malnutrition-Inflammation Status in Hemodialysis Patients Raquel Ojeda, Sagrario Soriano, Maria Luisa Agüera, Maria Antonia Alvárez-Lara, Alejandro Martin-Malo, Pedro Aljama-Garcia. *Nephrology, Hospital Universitario Reina Sofia, Cordoba, Spain.*

Background: It has been reported that 85% of hemodialysis (HD) patients have decreased vitamin D (25-OH-D) levels (< 30 ng/ml). The aim of this study was to analyze the effect of the correction of 25-OH-D deficiency on the control of hyperparathyroidism (HPT) and the malnutrition-inflammation status in patients on HD.

Methods: Twenty seven stable patients on HD with low levels of 25-OH-D (< 20 ng/ml) were included in this study. They were 65.2 ± 16.8 years old and 48% were men. All patients were prospectively treated with calcifediol (mean dose 266 mcg/ week) for an average of 3 months. Calcium, phosphorus, alkaline phosphatase, PTH, albumin, hemoglobin, TAST, cholesterol, tryglicerides, eKt/V, URR and darbepoetin and paricalcitol doses were analyzed before and after the correction the deficiency of 25-OH-D.

Results: After treatment with calcifediol all patients normalized the levels of 25-OH-D (> 30 ng/ml), and decreased PTH with a reduction of paricalcitol requirements (before/ after correction n=11/3) and an improvement in their malnutrition-inflammation status (increased albumin and decreased CRP).

	Pre-Calcifediol	Post-Calcifediol	p
PTH (pg/ml)/LnPTH	318.78/5.26	229.61/4.72	0.001/0.000
Calcium (mg/dl)	8.72±0.61	9.2±0.56	0.000
Phosphorus (mg/dl)	3.98±0.99	4.41±1.28	0.057
Ln Alkaline phosphatase	4.83±0.56	4.54±0.5	0.000
Paricalcitol (mcg/week)	1.78±2.62	0.52±1.52	0.026
LnCRP	2.15±1.32	1.52±0.96	0.000
Albumin (g/dl)	3.2±0.38	3.43±0.42	0.000
Hemoglobin (g/dl)	11.45±0.94	11.92±0.93	0.140

Table 1. Main biochemical and pharmacological parameters determined before and after correction the deficiency of 25-OH-D.

With this protocol there were no episodes of severe hypercalcemia or hyperphosphatemia. The dose of phosphate binders remained stable along the study.

Conclusions: Our results strongly suggest that an adequate dose of calcifediol may correct the deficiency of 25-OH-D in HD patients without relevant side-effects. The normalization of 25-OH-D levels (>30 ng/ml) improved the malnutrition-inflammation status and allows a better control of HPT with a reduction of paricalcitol requirement.

SA-PO2293

Update on the PACE Study: Randomized Controlled Trial of Paricalcitol and Calcitriol Endpoints Seth Goldberg,[1] Stuart M. Sprague,[2] Mark D. Faber.[3] *[1]Washington University, St Louis, MO; [2]North Shore University Health System, Evanston, IL; [3]Henry Ford Hospital, Detroit, MI.*

Background: Exogenous activated vitamin D can reduce parathyroid hormone (PTH) levels and reverse bone disease in secondary hyperparathyroidism (SHPT). In preclinical studies, paricalcitol causes a smaller increase in serum calcium and phosphorus levels than calcitriol, possibly due to less activation of the intestinal and bone vitamin D receptors. The aim of this study is to compare the safety and efficacy of these active vitamin D analogs in patients with CKD stages 3 and 4.

Methods: Randomized, open label, active comparator, multicenter, phase 4 study of paricalcitol vs calcitriol in patients with CKD stages 3 and 4 with SHPT (PTH >120 pg/mL), albumin-corrected calcium >8.5 mg/dL and <10.0 mg/dL, and phosphorus <4.6 mg/dL. Goal enrollment is 110 patients among the four participating sites.

Results: To date, 103 patients have been randomized (72 completed, 17 early termination). Data from 53 patients have been evaluated, 27 on paricalcitol and 26 on calcitriol. Baseline lab values are shown in the table.

Baseline Values

	Paricalcitol	Calcitriol
Ca (mg/dL)	9.34 +/- 0.35	9.34 +/- 0.35
PO4 (mg/dL)	3.72 +/- 0.51	3.79 +/- 0.48
eGFR (mL/min)	26.1 +/- 6.5	26.3 +/- 9.6
iPTH (pg/mL)	172.5 (137-219)	246 (190-320)

iPTH expressed as median (interquartile range)

At least one adverse event was reported in 64% of patients. Of these, only hypercalcemia was deemed likely to have been caused by the study drug. None of the serious adverse events are classified as being likely secondary to study drug. The final data are expected in January 2012.

Conclusions: Baseline characteristics are similar between the groups in the 53 patients analyzed. The median baseline iPTH values did differ between the two groups but as drug dose titration is dependent on the percentage of reduction from baseline, this difference is not anticipated to affect the secondary efficacy endpoints. Patients reporting adverse events that were possibly or likely to be related to the study drugs were few in number.

Normal DXA Scans Predicts Low Fracture Risk in Hemodialysis Patients Scott A. Rasgon, Richard M. Dell, John J. Sim. *Nephrology, Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA.*

Background: Hip fracture rates in dialysis patients have been reported to be 4.4 times higher than the general population. KDIGO makes the following recommendations for Bone Mineral Density (BMD) testing "**3.2.2 In patients with CKD stages 3-5D with evidence of CKD-MBD, we suggest that BMD testing not be performed routinely, because BMD does not predict fracture risk as it does in the general population, and BMD does not predict the type of renal osteodystrophy (2B).**" This is based on thirteen studies with the most subjects in any of the studies was 242. Five of the studies showed no correlation with fracture rates and 8 showed some correlation with low BMD and increased fracture rate.

Methods: We reviewed the BMD data from DXA scans in our population of hemodialysis patients at Kaiser Permanente Southern California to see if there was any correlation between BMD testing and hip fracture rates in dialysis patients greater than 60 years of age. In our 60+ population there was 607,000 DXA scans done of which 1883 were done on hemodialysis patients during the time period of 01/01/1998-03/04/2011.

Results: We found the following results. 288 hemodialysis patients had a normal DXAscan and had only one hip fracture for a rate of .3 %.

Hemodialysis Hip Fracture and DXA Results

DXA score	Age 60-64	Age 65-69	Age70-74	Age 75-79	Age 80-84	Age 85 +	Total
	N (Fracture)						
Normal	40 (1)	45	75	70	35	23	288 (1)
-1 to -2	53 (1)	88 (1)	118 (2)	116 (1)	60	29	464 (5)
-2 to -2.49	32	48 (1)	82 (1)	61 (2)	51 (4)	32 (3)	306 (11)
Osteoperosis	68 (1)	114 (2)	198 (4)	193 (5)	143 (4)	107 (2)	823 (18)
No DXA	466 (1)	287 (1)	133 (2)	67 (0)	49 (2)	38	1040 (6)

Comparing a DXA score of <-2 vs >=-2 the relative risk of hip fractures was 3.22 p<.005.

Conclusions: We conclude that a normal DXA scan in a hemodialysis patient may be predictive of low fracture risk and patients with a DXA score >2 has a higher relative risk of hip fracture. We have more subjects in our study than other previous studies combined. Our study shows that in hemodialysis patients with a normal DXA scan the rate of hip fracture is very low. We should concentrate our fall reduction and treatment options for patients who are at high risk who do not have normal DXA scans.

SA-PO2295

Oral Paricalcitol Versus Oral Calcitriol for the Treatment of Secondary Hyperparathyroidism in ESRD Patients on CAPD Ema Juliaty Jamaluddin,[1] Abdul Halim Abdul Gafor,[1] Norella C.T. Kong,[1] Rizna Cader,[1] Rozita Mohd,[1] Vincent Chui Wei Wong,[1] Shamsul Azhar Shah.[2] *[1]Medical Department, University Kebangsaan Malaysia, Cheras, Kuala Lumpur, Malaysia; [2]Public Health Department, University Kebangsaan Malaysia, Cheras, Kuala Lumpur, Malaysia.*

Background: Few studies have reported on the use of oral paricalcitol for the treatment of SHPTH in ESRD patients on CAPD.

Objective: We evaluated the efficacy of oral paricalcitol versus oral calcitriol on serum iPTH and parameters of bone mineral metabolism in CAPD patients with SHPTH.

Methods: Patients randomized to receive oral paricalcitol or oral calcitriol for 12 weeks. Serum iPTH, Ca/PO_4 and ALP were measured at baseline and 3-weekly. Serum hsCRP and peritoneal membrane function tests (Kt/V_{urea} & PFT) were also recorded

Results: Results are presented in the table.

	Drug	Baseline	Week 3	Week 6	Week 9	Week 12	Intra group p-value
Serum iPTH (pmol/L)(1.5-7.6)	Paricalcitol	85.65 (46.6)	44.25 (24.4)	49.15 (24.4)	43.00 (30.3)	37.2 (30.9)	<0.001
Serum iPTH (pmol/L)(1.5-7.6)	Calcitriol	98.9 (70.5)	69.75 (105.3)	61.55 (110.0)	22.70 (16.8)	16.8 (88.6)	<0.001

Serum calcium(mmol/L) (2.14-2.58)	Paricalcitol	2.24 (0.49)	2.36 (0.30)	2.47 (0.27)	2.48 (0.43)	2.42 (0.48)	0.004
Serum calcium(mmol/L) (2.14-2.58)	Calcitriol	2.25 (0.34)	2.20 (0.23)	2.41 (0.21)	2.41 90.21)	2.41 (0.50)	0.002
Inter group p-value		0.758	0.150	0.410	0.440	0.777	
Serum phosphorus (mmol/L)(0.71-1.36)	Paricalcitol	1.65 (0.65)	1.48 (0.55)	1.49 (0.64)	1.65 (0.73)	1.77 (0.64)	0.504
Serum phosphorus(mmol/L)(0.71-1.36)	Calcitriol	2.02 (0.71)	1.74 (0.75)	1.93 (0.97)	1.88 (0.80)	2.41 (0.50)	0.201
Inter group p-value		0.095	0.315	0.258	0.085	0.554	
CaxPO4 product (mmol2/L2)(<4.4)	Paricalcitol	3.83 (1.83)	3.61 (1.50)	3.82 91.67)	4.00 (1.82)	4.29 (1.20)	0.025
CaxPO4 product (mmol2/L2)(<4.4	Calcitriol	4.67 (1.49)	4.55 (2.06)	4.45 (2.24)	4.51 (1.68)	4.78 (1.68)	0.010
Inter group p-value		0.900	0.537	0.382	0.198	0.425	

Both vitamin D analogues were equally efficacious. The number of hypercalcemic events were similar. Pre-and post-treatment serum hsCRP and peritoneal membrane function were also not different.

Conclusions: Oral paricalcitol was as efficacious as oral calcitriol in reducing serum iPTH in CAPD patients with SHPTH.

Ergocalciferol (ergo) Therapy in Calcidiol Deficient Hemodialysis (HD) Patients on Therapeutic Doses of Paricalcitol Does Not Decrease Inflammation Vidya M. Raj Krishnamurthy,[2] Christi M. Terry,[1,2] Tom H. Greene,[1,2] Guo Wei,[2] Alfred K. Cheung,[1,2] Srinivasan Beddhu.[1,2] *[1]VA; [2]Univ Utah.*

Background: Even though, most HD patients receive active vitamin D, it is unclear whether additional therapy with ergo in those with calcidiol deficiency would be beneficial.

Methods: We conducted a randomized double blind cross-over trial of ergo (50,000 U/wk) vs placebo in 24 HD patients with plasma 25(OH)vitamin D levels <30 ng/ml and high sensitivity C-reactive protein (hs-CRP) > 3mg/L and who are on paricalcitol with iPTH range between 150-600 pg/ml. The primary outcome was serum IL6 and secondary end points were plasma hs-CRP and TNFα as well as peripheral blood monocyte production of IL-6 and TNFα (presented as a separate abstract). The study was 80% powered to detect 40% reduction in the geometric mean IL6.

Participants were randomly assigned to ergo vs placebo for 12 wks, followed by 4 wk washout and cross-over for 12 wks. Pre-HD blood samples were collected at baseline and wks 12, 16 and 28. The samples were stored at -80°C freezer before analyses. Plasma IL6 and TNFα levels were measured using a DuoSet ELISA development system. Mixed effects model for a 2-period 2-treatment cross-over design was used.

Results: The mean age was 59 ± 13 yrs. 42% were men and 80% were white. 67% had DM. Average duration of ESRD was 3.7±4.6 yrs. Mean serum 25 OH vitamin D levels were 15.6±5.2 ng/ml and median hsCRP levels were 8.8 (IQR 4.2- 19.1) mg/L. The main effects (post vs. pre in active group vs. post vs. pre in placebo group) are summarized in Table.

Difference of plasma biomarkers in the pre and post ergo vs placebo treatment

Biomarkers	mean(95%CI)	p
Plasma 25(OH)D ng/ml	17.5(9.3-25.7)	<0.001
Serum IL6pg/ml*	0.84(0.55-1.29)	0.26
Serum TNFαpg/ml*	1.06(0.54-2.11)	0.75
Serum hs-CRP mg/L*	1.16(0.63-2.14)	0.76

*log transformation of IL-6, TNFα and hs-CRP

Even though active therapy increased serum vitamin D levels, active therapy did not decrease serum levels of IL-6, hsCRP or TNFα.

Conclusions: Ergo Rx ↑ plasma 25(OH)D levels but did not ↓ inflammation in calcidiol deficient HD patients on therapeutic doses of paricalcitol.

SA-PO2297

Effects of Paricalcitol or Cinacalcet Treatment on CKD-BMD Markers in Subjects with Secondary Hyperparathyroidism (SHPT): Results from IMPACT-SHPT

Kevin J. Martin,[1] Markus Ketteler,[2] Mario Cozzolino,[3] David J. Goldsmith,[4] Amit Sharma,[5] Michael Amdahl,[6] Samina Khan.[6] *[1]Saint Louis U; [2]Klinikum Coburg; [3]Paolo Hosp; [4]Guy's Hosp; [5]Boise Kidney and Hypertension Inst; [6]Abbott.*

Background: Managing SHPT is vital for the prevention of CKD-BMD in subjects on hemodialysis (HD). IMPACT compared SHPT treatment effects of the selective vitamin D receptor (VDR) activator, paricalcitol, with the calcimimetic, cinacalcet. Here we report effects on markers of CKD-BMD.

Methods: IMPACT was a randomized 28 wk, phase 4, international, open-label study of HD subjects receiving IV (IV Stratum) or oral paricalcitol (Oral Stratum) with supplemental cinacalcet for hypercalcemia, compared to subjects treated with cinacalcet with low dose vitamin D. Mean reductions in CKD-BMD markers from baseline to end of study were determined.

Results: In the IV Stratum, there were 62 paricalcitol and 64 cinacalcet subjects (60% male, mean age:61±12 years, mean duration of dialysis:4.1±4.0 years). For the Oral Stratum, there were 72 paricalcitol subjects and 70 cinacalcet subjects (65% male, mean age:65±13 years, mean duration of dialysis:3.9±3.2 years). In the IV Stratum, paricalcitol had significantly greater reductions in iPTH, compared to cinacalcet. In the Oral Stratum paricalcitol demonstrated numerically, but not statistically, greater reductions in iPTH. In both strata paricalcitol reduced alkaline phosphatase (AP) and bone-specific alkaline phosphatase (BAP) while cinacalcet increased AP and BAP.

Conclusions: In contrast to cinacalcet treatment, therapy with paricalcitol was associated with decreases in AP and BAP. There were minimal changes in calcium in both groups. However, long term effects on bone markers of CKD-MBD remain to be determined.

Alienating Effect of Cinacalcet on PTH Secretion from Parathyroid Growth in Patients with Secondary Hyperparathyroidism

Tatsuo Tsukamoto, Eri Muso. *Division of Nephrology and Dialysis, Department of Medicine, Tazuke Medical Research Institute, Kitano Hospital, Osaka, Japan.*

Background: Cinacalcet with various doses and derivatives of vitamine D is effective in controlling secondary hyperparathyroidism (SHPT) complicated with chronic kidney disease. We had conducted a clinical trial to confirm the suppressive effect of the combination therapy of cinacalcet with maxacalcitol, a vitamin D derivatives, on moderate to severe SHPT whose intact parathyroid hormones (iPTH) were ranged from 300 to 1000pg/ml for one year (UMIN 000001793). We demonstrated the combination therapy could be useful to keep the suppression of PTH secretion (43rd ASN Annual Meeting, SA-PO2164, 2010). However, little is known whether this suppression would last for long time. In this extensive study, we shows the follow-up data of SHPT and parathyroid gland size for another two years in this cohort.

Methods: 53 patients with 157 of enlarged parathyroid glands were enrolled at the initiation. The biochemical data and gland size was measured every 6 months.

Results: The average dose of cinacalcet and maxacalcitol were 39mg daily and 14μg per week at the end of the study, respectively. PTH decreased significantly from 565.5±32.0pg/ml (mean±SE) to 164.3±20.1pg/ml after one-year treatment, 134.0±14.2 after another one-year (n=29), and 178.7±22.5 after another two-year (n=18). Half of the enlarged parathyroid glands showed significant volume reduction after the one-year treatment. On the other hand, the growth rate of expanding glands even under the treatment was similar to that of maxacalcitol alone. Thus, the total volume of glands did not change throughout this study periods. The cystic change that was observed in 10% of glands at the first year could be mostly undetectable by a high-resolution color Doppler ultrasonography after that. The major causes of drop-out were intolerance, ineffectiveness, caidio-vascular event, and hemorrhagic gastric ulcer.

Conclusions: Our findings indicate that the combination of cinacalcet with maxacalcitol might have a differential effect on parathyroid growth and PTH secretion in patients with SHPT. Further study would be required to clarify the limitation of this therapy.

Modification of Human Artery Inflammation by Paricalcitol Is Altered in CKD

Guerman Molostvov,[1] Rosemary Bland,[2] Daniel Zehnder.[1] *[1]Clinical Sciences Research Institute, University of Warwick, Coventry, West Midlands, United Kingdom; [2]BioMedical Research Institute, University of Warwick, Coventry, West Midlands, United Kingdom.*

Background: Arterial inflammation in patients with CKD is associated with vascular calcification. We investigated the role of vitamin D receptor activators (VDRa), paricalcitol and calcitriol on inflammatory responses of arterial wall.

Methods: Arterial explants from CKD patients undergoing renal transplant (n=18) and healthy donors (n=7) were incubated for 48 hours with TNF (20ng/ml), calcitriol (100nM) or paricalcitol (300nM) with/without TNFα. Expression of target gene mRNA was quantified by real-time PCR.

Results: Cbfa1 and osteocalcin (osteoblast markers) were significantly higher in CKD arteries (2.5 fold, $p<0.05$) and both VDRa inhibited Cbfa1 ($p<0.05$) but not osteocalcin. Matrix metabolizing enzymes were quantified. Basal expression of MMP2 was similar, but MMP9 was significantly lower in CKD arteries. Both were unaltered by VDRa.

Components of the vascular vitamin D system (VDR, CYP27B1 and CYP24A1) were analyzed. Basal VDR expression was suppressed by 60% in CKD explants ($p<0.05$) and increased in both groups by VDRa ($p<0.05$). Basal CYP24A1 expression was similar in both groups and was induced by VDRa. The response was much greater in CKD group (20 fold in control; $p<0.05$ vs 300-900 fold in CKD; $p<0.01$). Basal CYP27B1 was 2 fold higher in CKD and was unaltered by VDRa.

To assess inflammatory responses, explants were treated with TNFα and changes in osteoblastic genes, MMPs and VDR measured. Paricalcitol attenuated TNFα induction of these genes in control group, but did not modify the muted response in CKD group. In control arteries CYP27B1 and CYP24A1 were induced by TNFα but not modified by paricalcitol. Both enzymes were induced by TNFα in CKD arteries. Interestingly TNFα attenuated paricalcitol mediated CYP24A1 upregulation, whereas paricalcitol attenuated TNFα induction of CYP27B1.

Conclusions: Our findings indicate that arteries from patients with advanced CKD have undergone phenotypic transformation with reduced VDR expression and enhanced CYP24A1 responsiveness. There was a differential VDRa effect in healthy arteries compared to CKD.

Safe and Effective Treatment of Vitamin D Deficiency in Pediatric Dialysis Patients

Poyyapakkam Srivaths, Eileen D. Brewer. *Pediatrics, Renal Section, Baylor College of Medicine, Houston, TX.*

Background: We and others have shown that vitamin D deficiency (vit D def) is highly prevalent in Pediatric (ped) dialysis pts. However, no treatment (tmt) guidelines exist for ped dialysis pts. Purpose of this study was to establish an safe and effective tmt regimen for vit D def in ped dialysis pts and assess effects of tmt on biochemical mineral parameters**.**

Methods: 10 month prospective study of 58 ped pts (median age 15y; range 1-24y; 28 Hispanic, 16 Black, 13 White, 1 Asian; 31 HD/25 PD /2 home HD). Vit D def was diagnosed by serum 25-hydroxy vitamin (25vitD) <30 ng/dL. KDOQI guidelines for tmt of vit D def in adults with chronic kidney disease (CKD) were followed: if serum 25vitD level <15 ng/mL, oral ergocalciferol 50,000 units weekly x 4 followed by monthly doses x 6 or 4000 units daily x 12 weeks; if 25vitD level 16-29, 50,000 units monthly x 6 or 2000 units daily for 12 weeks. 28/31 HD pts were treated in-center with either weekly or monthly ergocalciferol. Serum 1,25-dihydroxy vit D (1,25vitD) was assessed in 55 pts pre- and end tmt.

Results: 54/58 pts (93%) had vit D def with 13/58 (23%) severe (serum 25vitD <7 ng/mL). 54/58 pts were taking IV or oral calcitriol; 4/58 received IV paracalcitol. Ergocalciferol tmt improved mean serum 25vitD from 15.5 to 30.1 ng/mL ($p=0.0001$, Table). Tmt response did not differ by modality or pt ethnicity. Serum Ca, P, PTH & 1,25vitD were not different at end of tmt compared with pre-tmt.

Effects of Oral Ergocalciferol Treatment of Vitamin D Deficiency

	25vitD(ng/ml)*	1,25vitD(pg/ml)	Ca(mg/dL)	P(mg/dL)	PTH(ng/L)
Pre-ergocalciferol	15.5(8.8)	31.3(20.4)	10.1(0.7)	5.7(1.6)	385(402.5)
End ergocalciferol	30.1(15.4)	30.6(19.1)	10.1(1)	6.2(1.9)	355(313.9)

Values expressed as mean(SD) *p=0.0001

Conclusions: 1) Vit D def can be treated safely and effectively with oral ergocalciferol in ped dialysis pts as young as 1 y old using adult CKD KDOQI guidelines. 2) If pt adherence is a concern, in-center tmt with weekly or monthly doses is safe and not associated with hypercalcemia. 3) Serum PTH was not different at end ergocalciferol tmt, so oral ergocalciferol improves vit D def in ped dialysis pts, but does not by itself correct high serum PTH.

Comparison of Paricalcitol and Cinacalcet for the Treatment of Secondary Hyperparathyroidism (SHPT) in Subjects on Hemodialysis: Secondary Analyses from IMPACT Study

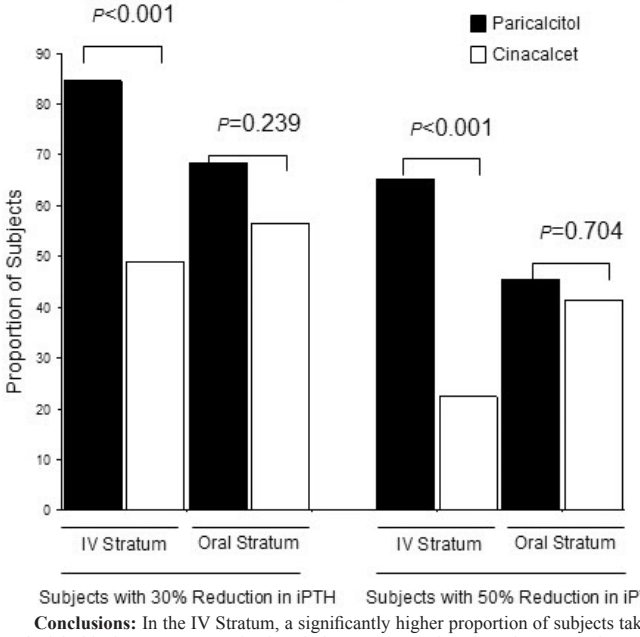
Markus Ketteler,[1] Kevin J. Martin,[2] Mario Cozzolino,[3] David J. Goldsmith,[4] Amit Sharma,[5] Michael Amdahl,[6] Samina Khan.[6] *[1]Klinikum Coburg; [2]Saint Louis U; [3]Paolo Hosp; [4]Guy's Hosp; [5]Boise Kidney and Hypertension Inst; [6]Abbott.*

Background: Optimal management of SHPT is important for the prevention of CKD-BMD in patients undergoing hemodialysis (HD). IMPACT-SHPT compared the reduction of iPTH levels in HD subjects treated with the selective vitamin D receptor (VDR) activator, paricalcitol, or the calcimimetic, cinacalcet. Here we report the secondary endpoint results on iPTH suppression.

Methods: IMPACT was a randomized 28 wk, phase 4, international, open-label study of subjects undergoing hemodialysis receiving IV (IV Stratum) or oral paricalcitol (Oral Stratum) with supplementary cinacalcet for hypercalcemia, compared with subjects receiving cinacalcet with low-dose vitamin D. The proportion of subjects with at least 30% and 50% reduction from baseline to mean iPTH during weeks 21-28 were determined as secondary analyses.

Results: In the IV Stratum there were 62 paricalcitol subjects and 64 cinacalcet subjects (60% male, mean age:61±12 years, mean duration of dialysis:4.1±4.0 years). In Oral Stratum there were 72 paricalcitol subjects and 71 cinacalcet subjects (65% male, mean age:65±13 years, mean duration of dialysis:3.9±3.2 years.

Figure: Proportion of Subjects with at Least 30% or 50% Reduction from BL to Mean iPTH During Weeks 21-28



Conclusions: In the IV Stratum, a significantly higher proportion of subjects taking paricalcitol had 30% or 50% reductions in iPTH compared to cinacalcet. In Oral Stratum subjects taking paricalcitol had numerically greater but not statistically significant reductions in iPTH compared with subjects taking cinacalcet. However, the beneficial effect of iPTH reduction on long-term outcomes from observational studies needs to be determined in clinical trials.

SA-PO2302

Prevalence and Risk Factors for 25OH Vitamin D Deficiency in Hemodialysis Patients

Maria Krassilnikova, Peter S. Heeger, Brian D. Radbill, Anita Mehrotra. *Medicine, Mount Sinai School of Medicine, New York, NY.*

Background: Despite routine administration of 1,25OH Vit D, 25OH Vit D (25OHD) deficiency is common in dialysis patients, and the reasons for this deficiency remain poorly understood.

Methods: We performed 25OHD testing and analyzed demographic data and medication histories in 97 hemodialysis outpatients. A subset of 41 patients participated in dietary and lifestyle surveys to assess their sun exposure and average intake of Vit D containing foods.

Results: The prevalence of Vit D deficiency was 90.8% (25OHD level <30ng/mL), and 24.5% of patients had severe Vit D deficiency with level <10ng/mL. Median Vit D level was 14.8ng/mL (IQR=11.2). We found no association between Vit D level and age, gender, race, dialysis vintage, smoking status, serum albumin or URR. Vit D levels negatively correlated with BMI (Spearman's ρ=-0.271/p=0.010).

Lifestyle surveys revealed that in summer, patients spent a median number of 7 days/week outside with daily >15 min sun exposure; while in winter they spent a median number of 3 days. 26.8% of patients reported sunscreen use.

Dietary surveys showed a median weekly vitamin D intake of 1113 IU (IQR=748, Table 1), which was significantly below FDA recommendation of 2800-5600 IU/week.

Nutritional guidelines for dialysis patients suggest a limited intake of Vit D-containing dairy products because they are also phosphate-rich. Since many patients struggle to adhere to phosphate binder regimen, they reported being counseled against dairy product consumption.

Conclusions: Our study demonstrates a higher than previously reported prevalence of Vit D deficiency among hemodialysis patients despite seemingly adequate sun exposure and a low rate of sunscreen use. Based on the findings indicative of a physician-initiated bias against intake of Vit D-containing foods, we recommend oral D3 as a safe and inexpensive approach to correct this abnormality.

Table 1: Median intake of vit D-containing foods

Item	Vit D (IU) per serving	Amount per serving	Median number of servings/week (IQR)	Total vit D/week (IU)
Fish	100-654	3oz	2 (2)	754
Milk	100	8oz	0.5 (2)	50
Yogurt	80	6oz	0 (0.75)	0
Cheese	6-12	1oz	6 (5)	54
Cereal	40	1cup	2 (4)	80
Eggs	25	1 egg	5 (5)	125
				Total~1063 IU/ week

Predictors of Vitamin D Status in Incident Chronic Kidney Disease Patients: A Cross-Sectional Analysis in a High UV Climate

Amit Nigam,[1] William G. Petchey,[1,2] David W. Johnson,[1,2] Carmel M. Hawley,[1,2] Nicole M. Isbel.[1,2] *[1]Nephrology, Princess Alexandra Hospital, Brisbane, Queensland, Australia; [2]Centre for Clinical Research Excellence – CardiovasculaDisease and Metabolic Disorders, School of Medicine, University of Queensland, Brisbane, Queensland, Australia.*

Background: Hypovitaminosis D is a significant problem in Chronic Kidney Disease (CKD) and is associated with adverse outcomes. Whether high ambient UV exposure can mitigate this problem is unknown. Our aim was to determine vitamin D status in a sub-tropical climate amongst an unselected incident CKD population; assess risks and correlates, and review whether higher 25-hydroxyvitamin D (25-OHD) can abate the decrement in 1,25-dihydroxyvitamin D (1,25-OHD) normally encountered with advancing CKD.

Methods: Prospective cross-sectional study of 593 consecutive CKD patients stage 1-5 referred to Princess Alexandra Hospital, Brisbane, Australia (27°28'S). The main outcome measure was 25-OHD sufficiency (≥30ng/mL), and bone-mineral parameters including 1,25-OHD, calcium, and phosphate.

Results: In spite of potentially higher environmental UV exposure, only 48% of patients with CKD were 25-OHD sufficient. Traditional risks for hypovitaminosis D were maintained, and sufficiency was independently predicted by testing in the Summer/Autumn period (OR 3.17, 95%CI: 2.07-4.86, p<0.001), male gender (OR 2.61, 95%CI: 1.68-4.05, p<0.001), Caucasian race (OR 2.19, 95%CI: 1.25-3.84, p<0.001), normal albumin (OR 0.46, 95%CI: 0.23-0.90, p=0.02), and normal BMI (OR 1.80, 95%CI: 1.08-3.00, p=0.02). Vitamin D sufficiency was also associated with higher corrected calcium (0.4 mg/dL increments; OR 1.42, 95%CI: 1.16-1.74, p=0.001) and higher 1,25-OHD (OR 1.01, 95%CI: 1.01-1.02, p<0.001). Whilst circulating 25-OHD concentrations were relatively maintained across the range of renal function observed, 1,25-OHD concentrations fell with advancing CKD.

Conclusions: 25-OHD insufficiency is mitigated but still highly prevalent in patients with CKD in a high ambient UV environment. Despite the maintenance of relatively higher 25-OHD concentrations with advancing CKD, substrate availability does not appear to be a major determinant of circulating 1, 25-OHD.

SA-PO2304

Thyroid Hormones Decrease the Plasma 1alpha, 25-dihydroxyvitamin D_3 Levels through Transcriptional Repression of the Renal 25-hydroxyvitamin D_3 1alpha-hydroxylase (CYP27B1) Gene

Mina Kozai, Hironori Yamamoto, Ayako Otani, Shoko Ikeda, Otoki Nakahashi, Yutaka Taketani, Eiji Takeda. *Depertment of Clinical Nutrition, University of Tokushima, Japan.*

Background: The renal 25-hydroxyvitamin $D_3$1α-hydroxylase enzyme (CYP27B1), is implicated in the control of plasma 1,25-dihydroxyvitamin D ($1,25(OH)_2D$) levels. Previously, it has been demonstrated that the low levels of plasma $1,25(OH)_2D$ in hyperthyroidism patients and the decrease of $1,25(OH)_2D$ synthesis in perfused kidneys treated with 3, 5, 3'-tri-iodothyronine (T_3). However, the regulation mechanism of renal vitamin D metabolism by thyroid hormones is still not clear.

Methods: To address effects of T_3 on the plasma $1,25(OH)_2D$ levels and renal CYP27B1 gene expression, C57BL6 mice were rendered pharmacologically hypo- and hyperthyroid by administration of propyl-thiouracil or T_3. Western blots, real-time PCR and in situ hybridization analysis were used to elucidate the CYP27B1 gene expression in kidney. CYP27B1 gene promoter activity was measured using luciferase reporter assay system. DNA-protein interaction for cis-elemets of CYP27B1 gene were assessed by gel shift assay.

Results: Hyperthyroid mice showed low levels of plasma $1,25(OH)_2D$ and marked decrease in renal CYP27B1 expression levels. In addition, T_3 inhibited the renal CYP27B1 mRNA expression highly induced in mice given low-phosphorus diet or low-calcium diet, vitamin D receptor-knockout mice and alpha klotho mutant mice. The CYP27B1 promoter activity in renal proximal tubular cells were inhibited by T_3 in thyroid hormone receptor

β1 (TRβ1)-dependent manner. We also found the transrepression of CYP27B1 gene by T_3 involves a negative vitamin D response element (1αnVDRE) and VDR interacting repressor (VDIR). The gel shift analysis demonstrated that the binding of VDIR to 1αnVDRE was reduced by TRβ1/retinoid X receptor α. Furtheremore, the inhibitors of histone deacetylase and DNA metyltransferase completely abrogated T_3-dependent repression of CYP27B1 gene premoter.

Conclusions: These results suggest that thyroid hormones decrease the plasma $1,25(OH)_2D$ levels through transcriptional repression of the renal CYP27B1 gene by TRβ1.

Web-Based Evaluation of Clinical Benefit of Cinacalcet in End-Stage Renal Disease – The WELCOME Study Jaroslav Rosenberger,[1] Piotr Mierzicki,[2] Alexander Selyutin,[3] Frantisek Svara,[4] Kinga Jedynasty.[5] *[1]FMC, SNP c.1., Kosice, Slovakia (Slovak Republic); [2]SP Wojewodzki Szpital Specjalistyczny, Chelm, Poland; [3]Regional Clinical Hospital #1 (Orenburg city), Moscow, Russian Federation; [4]Department of Medicine, Strahov General University Hospital, Prague, Czech Republic; [5]Amgen GmbH-CEE HO, Vienna, Austria.*

Background: Mimpara® (MIM) modulates calcium-sensing receptors and is approved for treatment of secondary hyperparathyroidism (sHPT) in End-Stage Renal Disease (ESRD). WELCOME is a multicenter, noninterventional observational study in patients with ESRD from Central and Eastern Europe (CEE) receiving MIM for sHPT.

Objective: Describe attainment of sHPT targets during MIM treatment, before (BGI) and after (AGI) release of KDIGO guidelines in 2009.

	BGI [2006 to Jun2009] N=704		AGI [Jul2009 to Sep2010] N=357	
Treatment Target (Completers)	Enroll	6-mo	Enroll	6-mo
PTH ≤300 pg/mL (%)	2.7	31.8	2.3	28.3
PTH (pg/mL) Mean (SD)	807 (436)	609 (465)	897 (521)	704 (521)
Ca 8.4-9.5 mg/dL (%)	46.4	60.8	47.3	55.5
P 3.5-5.5 mg/dL (%)	22.4	34.5	30.3	41.5
CaXP <55 mg2/dL2 (%)	37.5	66.6	45.7	66.7
PB use (%)	83.5	67.9	86.3	72.0
VitD use (%)	59.2	44.6	61.3	48.5

Methods: Patients on peritoneal dialysis (PD) or hemodialysis (HD) starting MIM ≤1 month prior to the study were eligible. Patient data were collected through a web-based case report form. Primary endpoint: % achieving PTH ≤300 pg/mL after 6 months. Secondary endpoints: % at target for Ca, P, or Ca´P at enrolment and 6 months; MIM dose; vitamin D sterol (VitD) and phosphate binder (PB) use; safety.

Results: 1061 patients completed ≥144 days of MIM (≥80% of planned). Initial MIM dose was 31.1±6.0 (BGI), 31.7±7.4 mg (AGI); mean daily dose at 6 months was 37.6±11.6 (BGI) and 37.5±11.3 mg/day (AGI); treatment results for completers are shown below. Among all enrolled (1230), adverse drug reactions (ADR) reported by 4.9% BGI and 4.4% AGI included gastrointestinal complaints and paresthesia. One serious ADR was reported; all-cause mortality was 2.8%.

Conclusions: MIM therapy increased % of patients meeting some therapeutic targets; mean PTH was not changed AGI. Reduced PB and VitD use was observed after 6 months of MIM therapy.

Vitamin D Deficiency in Chronic Renal Failure Patients: A Screening Survey and Clinical Feature Analysis from a Single Hemodialysis Center in China Ping Wen, Chunsun Dai, Junwei Yang. *Center for Kidney Disease, 2nd Affiliated hospital, Nanjing Medical University, Nanjing, Jiangsu, China.*

Background: Vitamin D deficiency has been reported to be closely associated with many clinical complications such as cardiovascular events and osteodystrophy in chronic renal failure patients. The aims of this study are to screen serum Vitamin D level in chronic renal failure patients from our hemodialysis center in china and analyze their clinical features.

Methods: In this study, 278 chronic renal failure patients were included and serum 25-hydroxyvitamin-D level was detected by using a commercial available ELISA kit. The correlation of patients' clinical features including age, gender, body mass index (BMI), blood pressure, medicine, primary kidney disease, duration of dialysis, complications and biochemical indexes with their serum 25(OH)D level were analyzed by using multiple logic regression analysis method

Results: Among the 278 patients, 175 were male. The patients' age was ranged from 23 to 89 years (average was 57.4 years) and the average duration of their dialysis was 62.3 months. Serum 25(OH)D deficiency (<15ng/ml) and insufficiency (15ng/ml≤25(OH)D<30ng/ml) were present in 55% and 37% of the dialysis patients respectively. Only 8% of the patients showed normal serum 25(OH)D level. Further analysis of their clinical features revealed that Vitamin D deficiency was more prevalent in female or patients with cardiovascular complications($P<0.05$), while less Vitamin D deficiency could be found in male or patients received RAAS inhibitors or a-blockers($P<0.05$). Diabetic patients showed a low 25(OH)D level compared to the other patients. No close correlation was found as to the other clinical features including age, BMI, serum calcium and iPTH levels with Vitamin D deficiency.

Conclusions: The prevalence of hypovitaminosis D is high in chronic renal failure patients in china. Female, cardiovascular complications and diabetes are correlated with Vitamin D deficiency and taking RAAS inhibitors or a-blockers may benefit the patients with such deficiency.

The Cardiovascular Effects of Cinacalcet in Hemodialysis Patients with Secondary Hyperparathyroidism Sun Ryoung Choi, Hoon Suk Park, In O Sun, Byung Ha Chung, Bumsoon Choi, Chul Woo Yang, Yong-Soo Kim, Cheol Whee Park. *Division of Nephrology, Department of Internal Medicine, Catholic University of Korea, Seoul, Republic of Korea.*

Background: Recently, it has been suggested that cinacalcet significantly improves cardiovascular survival in hemodialysis patients and up-regulation of the calcium-sensing receptor may be involved in the improved outcome. The calcium-sensing receptor has been identified in heart endocardial epithelium, microvasculature of the myocardium, aortic endothelium and the vascular smooth muscle.Thus, we evaluated the effects of cinacalcet on the cardiovascular system in hemodialysis patients with secondary hyperparathyroidism.

Methods: We studied 14 patients with ESRD who had high levels of intact PTH (iPTH,>300pg/mL) and corrected serum calcium (cCa,>9.0mg/dL) with cinacalcet over 20-week period. After treatment, we performed flow-mediated dilation (FMD), cadio-ankle vascular index (CAVI) and echocardiographic analyses.

Results: Twenty weeks cinaclacet treatment significantly decreased blood levels of iPTH (666.8±257.8 vs. 277.1±266.7pg/mL; $p<0.01$),calcium (9.4±0.50vs.8.7±0.50mg/dL; $P<0.01$),phosphorus(6.9±1.38vs.5.0±1.49mg/dL;$P<0.01$),calcium x phosphorus product (65.9±15.7vs.44.5±15.3; $P<0.01$)and 25(OH) vitamin D(8.5±2.8vs.7.6±2.7ng/mL; $P<0.05$). But the level of C-reactive protein was not affected by treatment.There were no differences in systolic(134.5±22.1vs.128.0±21.0mmHg;$P=0.2$) and diastolic blood pressures(75.2 ±14.6vs.72.7±14.2mmHg;$P=0.45$).There were notable reduction trends in the LV mass (244.6±94.0vs.212.9±63.9gm),the LV mass index (158.6±63.8vs.138.3±45.7g/m^2) and E/E'(15.2±6.8vs.13.5±5.6),although they did not achieve statistical significance.There were no significant changes in the ejection fraction and fractional shortening. In contrast, of great interest, cinacalcet significantly improved FMD(8.6±2.9vs.14.3±2.83%; $P<0.01$) and enhanced CAVI (8.8±2.3vs.7.6±2.4; $P<0.05$) as markers of endothelial-dependent arterial dilation and arterial compliance, respectively.

Conclusions: Cinacalcet treatment in hemodialysis patients with secondary hyperparathyroidism ameliorates aortic stiffness, arterial compliance and seems to improve cardiac hypertrophy

SA-PO2308

Nutritional Vitamin D Use in Chronic Kidney Disease: A Survey of Pediatric Nephrologists Lindsay M. Griffin,[1] Susan L. Furth,[1] Michelle Denburg,[1] Isidro B. Salusky,[2] Mary B. Leonard.[1] *[1]Children's Hospital of Philadelphia, Philadelphia, PA; [2]University of California - Los Angeles, Los Angeles, CA.*

Background: Controversy abounds regarding use of vitamin D (cholecalciferol and ergocalciferol) in CKD. Our aims are to describe vitamin D supplementation by pediatric nephrologists and to identify physician and patient characteristics that influence the choice to supplement.

Methods: We surveyed 1,176 International Pediatric Nephrology Association physician members. The questionnaire included 8 vignettes comprised of potential determinants of supplementation (starred in Table). Vignettes were stratified by vitamin D level and randomly assigned to IPNA members. Nephrologists were asked if they would recommend supplementation in each case. Multivariate logistic regression was used to assess odds of supplementation.

Results: The response rate was 45% (479/1074; 50 members do not see pediatric CKD patients and 52 emails were invalid); 64% in the US (200/311) and 37% (281/763) in other countries. These preliminary data are limited to US respondents. The proportions recommending supplementation for vitamin D levels of < 10, 10-19, 20-29 and > 30 ng/mL were 96, 95, 70%, and 29%, respectively. Low vitamin D levels were the most influential factor in increasing odds of supplementation (Table) but elevated PTH, time since training, and CKD severity were also associated with supplementation.

Table. Logistic Regression Model of Recommending Supplementation Amongst US Respondents

Characteristic	Group	Adjusted Odds Ratio (95% CI)	p-value
CKD Stage*	CKD 2-3	Reference	
	CKD 4-5	1.5 (1.1 - 2.1)	<0.05
	Dialysis	1.2 (0.8 - 1.8)	0.38
PTH Level*	At target for stage	Reference	
	Above target for stage	1.4 (1.01 - 1.9)	<0.05
Skin Pigmentation*	Light	Reference	
	Dark	1.0 (0.8 - 1.4)	0.88
CKD cause*	CAKUT	Reference	
	FSGS, Normal Albumin	1.01 (0.7 - 1.4)	0.95
	FSGS, Low Albumin	0.9 (0.6 - 1.2)	0.41
Vitamin D Level (ng/mL)*	≥30	Reference	
	20-29	6.5 (4.5 - 9.4)	<0.0001
	10-19	51.8 (32.1 – 83.8)	<0.0001
	<10	60.0 (33.0 – 109.2)	<0.0001
Year Completed Training, Quartiles	2004 - 2011	Reference	
	1995 - 2003	1.8 (1.2 - 2.8)	<0.01
	1988 - 1994	1.6 (1.02 - 2.4)	<0.05
	1969 - 1987	1.7 (1.1 - 2.6)	<0.01

* Variables included in case vignettes

Conclusions: These data suggest that recommending nutritional vitamin D is common and associated with lower vitamin D levels, elevated PTH, and more time since completed training. Further analyses will assess geographical differences in supplementation. Future studies are needed to validate this questionnaire, documenting actual practices.

Vitamin D Supplementation Is Increasing in the Chronic Renal Insufficiency Cohort (CRIC) and Is Associated with Greater Vitamin D Levels Laura H. Mariani,[1] Justine Shults,[1] Matthew T. White,[1] Cheryl A. Anderson,[2] Harold I. Feldman,[1] Mary B. Leonard.[1] *[1]University of Pennsylvania; [2]Johns Hopkins.*

Background: The recent Institute of Medicine Report on Vitamin D noted a significant increase in use of vitamin D supplements in the population.

Methods: We examined vitamin D supplement use at annual visits for the 3939 subjects in CRIC and used generalized estimating equations (GEE) to describe changes and determinants of supplementation.

Results: The proportion of subjects reporting use of a calciferol increased significantly, largely due to products containing only ergocalciferol or cholecalciferol (Figure 1). Active vitamin D sterol use was stable at 2-3%. In a multivariate logistic GEE model, supplement use was greater in older, female, non-black, married subjects with higher education and lower BMI (Table 1). Nephrology care, CKD cause, degree of proteinuria, exercise, smoking and eGFR were not independent predictors. Serum 25(OH)D levels were measured in 1529 participants at year 1. Reported use of vitamin D supplementation was associated with an 8.3 ng/mL greater (95% C.I. 6.3, 10.3, $p < 0.0001$) level adjusting for race, age, season, BMI, physical activity, proteinuria, and dietary vitamin D intake.

Conclusions: Vitamin D supplementation rates rose significantly among CRIC participants and was associated with greater levels. Studies of vitamin D deficiency and outcomes in CKD should consider changing supplementation practices.

Safety of Oral 25 Hydroxy Vitamin D (cholecalciferol) in Treatment of Symptomatic Vitamin D Deficiency in Renal Transplant Recipients-Cinacalcet May Also Be Needed Nihil Chitalia, David Goldsmith. *Nephrology and Transplantation, Guy's and St Thomas' NHS foundation trust, London, United Kingdom.*

Background: Bone mineral disorders (CKD-MBD) are common post transplantation, particularly with an increasing age and longevity of transplant recipients and grafts. Not only is the treatment of CKD-MBD is less well defined in the kidney transplant population, but 'substrate' vitamin D deficiency is also common post kidney transplant in part due to avoidance of sunlight. The safety data on oral native vitamin D supplementation in transplant recipients is not available.

Methods: We present the safety data on use of oral Cholecalciferol (Dekristol®) 20,000 IU fortnightly for 6 months, up to a total of 240,000 IU, given to eight symptomatic kidney transplant recipients; symptoms ranging from muscle aches to lethargy. All patients were confirmed to be 25 hydroxy vitamin D deficient [25(OH)D<37.5 nmol/L] and other potential causes were excluded. One patient had secondary hyperparathyroidism (serum PTH=133 pmol/L) and two patients were on preceding 1α calcidol therapy.

Results: The mean age of the group was 55±16 years with eGFR 52±22 ml/min/1.73m2.

Table 1: Pre and 6 month post vitamin D supplementation biochemical parameters

Variable	Pre supplementation	Post Supplementation	P value
Serum Calcium *(mmol/L)*	2.43±0.15	2.47±0.12	0.56
Serum Phosphate *(mmol/L)*	1.07±0.32	1.12±0.26	0.58
Serum PTH *(pmol/L)*	107±80	74±35	0.26
Serum Alkaline Phosphatase *(U/L)*	156±211	98±58	0.12[¥]
eGFR ml/min/1.73m^2	52±23	50±18	0.45
Serum 25 (OH)D *(nmol/L)*	20.4±8.6	73±18.2	<0.001*

[¥] Wilcoxson Rank sum test, *P<0.05

Two patients suffered hypercalcemia (defined as atleast one serum calcium>2.60 mmol/L) whilst on vitamin D. Both of these patients were borderline hypercalcemic due to prior secondary hyperparathyroidism pre vitamin D supplementation. Both these patients required addition of Cinacalcet to allow for successful sustained oral vitamin D administration.

Conclusions: We have found oral cholecalciferol in the dose of 40,000 IU monthly to be a safe and effective therapy for symptomatic hypovitaminosis D in kidney transplant patients. Concomitant hyperparathyroidism and preexisting hypercalcemia may warrant simultaneous administration of a calcimimetic to allow for continued vitamin D administration.

Low 25-hydroxyvitamin D Levels Are Associated with an Increased Risk of Community Acquired Pneumonia Anna Jeanette Jovanovich,[1] Michel B. Chonchol,[1] Shailendra Sharma,[1] Kim McFann,[1] Sidney N. Thornton,[2] Jessica B. Kendrick,[1] John R. Holmen. *[1]Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]Intermountain Healthcare, Salt Lake City, UT.*

Background: 25-hydroxyvitamin D (25(OH) D) levels are inversely associated with the development of upper respiratory tract and influenza infections. However, the relationship between 25(OH) D levels and the risk of developing community-acquired pneumonia (CAP) has not been evaluated.

Methods: We performed a population-based cohort study of adult patients diagnosed with community-acquired pneumonia (CAP) who had 25(OH)D levels measured 3 to

15 months prior to admission. Vitamin D was evaluated as a continuous variable and a categorical predictor (< 15 ng/mL vs. higher). The primary outcome of interest was CAP admissions identified through ICD9 codes and confirmed with a chest X-ray. Patients with CAP were matched 1:1 with controls on age, sex, race and season. Conditional logistic regression was used to evaluate if vitamin D levels were associated with an increased risk of CAP.

Results: We identified 66 patients with CAP and 66 matched controls. The mean (SD) age of the participants was 60 ± 17 years, 71% were female and 86% were Caucasian. There was a higher prevalence of chronic kidney disease in patients with CAP compared to controls (31.8% vs. 10.6%, p=0.003). There was no significant difference in mean 25(OH) D levels between patients with CAP and controls (31.7 ± 16 and 34.9 ± 16 ng/mL, p=0.33, respectively). After adjustment for diabetes, renal disease and peripheral vascular disease, when evaluated as a categorical predictor, vitamin D levels < 15 ng/mL vs. higher (adjusted OR 2.57, 95% CI 1.08-6.08; p=0.03) were strongly associated with an increased odds of admission for CAP. When 25(OH)D levels were evaluated as a continuous variable, there was no association between increasing vitamin D levels and lower risk of CAP (adjusted OR 0.92, 95% CI 0.81-1.03; p=0.14).

Conclusions: Vitamin D deficiency (< 15 ng/mL) is associated with an increased risk of CAP. Prospective randomized studies examining the effects of vitamin D_3 supplementation on the risk of infection are needed.

SA-PO2312

Arterial Calcification and Its Association with Clinical Variables and Biochemical Markers in Incident Peritoneal Dialysis Patients

Marcela Avila,[1] Carmen Josefina Mora,[1] Carmen María del Prado,[1] Elizabeth G. Hernandez-Infante,[1] Dolores Noriega,[2] Diana Villanueva,[3] Hector Hinojosa Heredia.[4] *[1]UIMEN, CMN SXXI IMSS, Mexico; [2]CLINICA 32, IMSS, Mexico; [3]CLINICA 25, IMSS, Mexico; [4]CLINICA 47, IMSS, Mexico.*

Background: There is not sufficient information available to permit relating arterial calcification with clinical variables and biochemical markers. Our aim was to know the association of arterial calcification with biochemical markers and clinical variables in incident patients on peritoneal dialysis

Methods: We included 178 incident patients on peritoneal dialysis, of which 80% were on CAPD and 20% on APD. Demographic and clinical data were recorded. Arterial calcification (AC) was evaluated in the abdominal aorta and pelvic vessels with simple phase using 4-cut computerized multidetector tomography (MCST), Philips Mx 8000, in the abdominal aorta and pelvis. We measured total Ca, phosphorus, albumin, glucose (GLU), cholesterol, and creatinine in serum with immunoturbidimetric assay (Roche/ Hitachi 902 Germany); Osteocalcin (OT) Osteoprotegerin (OPG), iPTH and IL8 were measured by Milliplex Kit.

Results: The mean age was 49±11, BMI 24±4, 65% male, 65% with diabetic nephropathy as a cause of disease, 49% with diabetes mellitus**;** time on dialysis was 1.5 ±1.2months.

Conclusions: The patients with AC =58% were older (53±7 vs 44±13 years; p<0.05), had significantly higher mean GLU (140±74vs 106±50 mg/dL, p< 0.001); COL (200±48vs180±39mg/dL p<0.005), OPG (1374±1000vs930±600 ng/mLp<0.013), and IL8 (12±5vs9±4ng/mLp<0.013). Lower CREA (10.1±3.1 vs 13±5.3; p<0.05) and ALB(3.28±.5vs3.51±5 g/dL). Diabetes and diabetic nephropathy as a cause of disease were more frequent. At the lumbar and ilialiac levels 52 and 57% respectively of the patients showed calcification, total Score Agaston was 285 (3-9158). After controlling for potential confounding variables, there was significant interaction effect between AC and age (hazard ratio 95% CI) 1.2 (1.03- 1.2) had an increased risk of AC.

Age was the factor most associated with arterial calcification measurements through tomography in incident peritoneal dialysis patients.

SA-PO2313

Cinacalcet Loading Test Predicts the Effect of Long-Term Cinacalcet Treatment in Hemodialysis Patients with Secondary Hyperparathyroidism

Hitoshi Yokoyama. *Division of Nephrology, Kanazawa Medical University, Uchinada, Ishikawa, Japan.*

Background: Secondary hyperparathyroidism (SHPT) is the most important complication of mineral-bone disease (MBD) in hemodialysis (HD) patients. We prospectively evaluate the effects of cinacalcet on MBD markers using the response of intact parathyroid hormone (iPTH) to cinacalcet loading test.

Methods: Fifty-three HD patients with SHPT were included based on serum iPTH≥180 pg/mL and/or adjusted total serum calcium (sCa) ≥ 10.5mg/dL. sCa, serum albumin, serum phosphate (P) and iPTH were measured before and 3 hours after oral intake of cinacalcet 25mg tablet. After loading test, 48 HD patients started on a single daily dose of 25mg of cinacalcet, and were followed serum markers (sCa, P, iPTH, bone alkaline phosphatase (BAP), intact osteocalcin (iOC) and NTx) at 12, 24 and 48 weeks after therapy. The daily dose of cinacalcet was adjusted between 25 and 75mg according to the control of SHPT.

Results: iPTH (mean +/- SD) decreased from 721 +/- 499 pg/mL to 381 +/- 280 pg/mL after loading test in 48 patients (p<0.001). Serum mean iPTH kept lower levels at 12, 24 and 48 weeks (n=46, 352 +/- 331 pg/mL, n=42, 275 +/- 210 pg/mL, n=42, 225 +/- 147 pg/mL, respectively; p<0.001). Then, mean levels of serum Ca, BAP, iOC and NTx also significantly decreased from 10.0 mg/dL, 33 U/L, 147 ng/mL, 266 nmol BCE/L to 9.6mg/dL, 20 U/L, 70 ng/mL, 140 nmol BCE/L at 48 weeks, respectively. iPTH 316 mg/d at 3hrs (odds ratio (OR) 13.4, 95%CI 2.2–81.2, p = 0.005), increased BAP (>/= 34.0µg/L in male, >/= 35.5µg/L in female; OR 11.4, 95%CI 1.7-77.7, p = 0.013), and increased NTx (>/= 102.3nmol BCE/ L; OR 0.05, 95%CI 0.003-0.908, p = 0.043) were selected by multiple logistic analysis as predictive factors for achieving iPTH </= 180 pg/mL after 48 weeks cinacalcet therapy. Finally, the cut off point of iPTH at 3hrs was 245 pg/mL (sensitivity 0.72, specificity 0.80 by ROC curve) in patients who achieved the JSDT guidelines (intact PTH </= 180 pg/mL and corrected Ca </= 10.0 mg/dL and phosphorus </= 6.0 mg/dL) at 48 weeks.

Conclusions: iPTH levels at 3hrs of cinacalcet loading test predicted the effect of long-term cinacalcet treatment for SHPT in HD patients.

SA-PO2314

Prescription Patterns and Mineral Metabolism Abnormalities in the Cinacalcet Era: Results from the MBD-5D Study

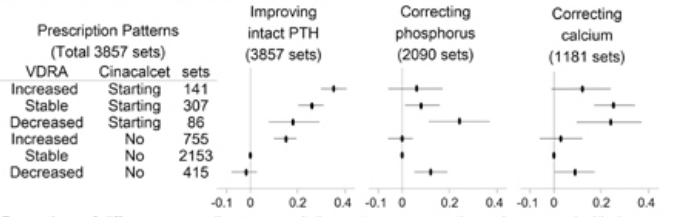
Masafumi Fukagawa,[1] Shingo Fukuma,[2] Tadao Akizawa,[3] Yoshihiro Onishi,[2] Shunichi Fukuhara,[4] Kiyoshi Kurokawa.[5] *[1]Tokai University; [2]iHope International; [3]Showa University; [4]Kyoto University; [5]National Graduate Institute for Policy Studies.*

Background: Prescription patterns for hemodialysis patients with secondary hyperparathyroidism have begun to vary widely after market introduction of cinacalcet.

Methods: Using data from the MBD-5D study in Japan (January 2008 to July 2009), we conducted a cohort study involving 1725 hemodialysis patients (3857 sets for repeated measures) with intact PTH level exceeding 180 pg/ml who used intravenous Vitamin D receptor activator (VDRA) without cinacalcet at baseline. We defined 6 prescription patterns based on combination of cinacalcet (starting or not starting) and VDRA dose (decreased, stable, or increased). The main outcome measure was proportion of difference in improving intact PTH levels by at least 1 category (<180, 180-299, 300-499, and ≥500 pg/mL) adjusting for age, gender, dialysis duration, phosphate binder, dialysate calcium concentration, Kt/V and levels of phosphorus, and intact PTH. The secondary outcome measures were proportion of difference in correcting phosphorus (3.5-6.0 mg/dL) and calcium levels (8.4-10.0 mg/dL).

Results: Adjusted proportions of difference are summarized in the figure. The patterns of "starting cinacalcet" and "increased VDRA" were independently associated with improving intact PTH levels and showed an additive effect. Among patients with high phosphorus or calcium levels, the patterns involving starting cinacalcet and decreased VDRA were independently associated with correcting phosphorus or calcium levels.

Figure| Adjusted proportion of difference for improving intact PTH, correcting phosphorus and calcium levels according to prescription patterns



Proportions of difference according to prescription patterns were estimated compared with the category of stable VDRA without cinacalcet.
Increased VDRA: >25% increased dose, Stable VDRA: between -25% to 25% dose, Decreased VDRA: >25% decreased dose

Conclusions: Our results showed association between prescription patterns of cinacalcet and VDRA and subsequent levels of intact PTH, phosphorus, and calcium. These findings may subsequently be used to determine clinically effective prescription patterns.

Genetic Variants in the Vitamin D Receptor Gene and Individual Response to IV 1,25-Vitamin D in Hemodialysis Patients

Chunmei Huang,[1] Jose C. Florez,[2] Julia Beth Wenger,[1] Elizabeth D. Ankers,[1] Ravi I. Thadhani.[1] *[1]Renal Division, Massachusetts General Hospital, Boston, MA; [2]Endocrinology Division, Massachusetts General Hospital, Boston, MA.*

Background: Changes in PTH, Ca and PO4 in response to intravenous 1,25-vitamin D (IV vitD) treatment differ in individual hemodialysis (HD) patients. Genetic factors may influence response to treatment. We investigated whether HD patients with different BsmI genotypes in the vitamin D receptor (*VDR*) gene have differential responses to IV vitD.

Methods: ArMORR is a nationally representative prospective cohort study of incidental HD patients in dialysis centers operated by Fresenius in 2004-2005. 890 random patients in this cohort who had DNA available, PTH levels >150pg/ml and who received IV vitD treatment during the first 90 days of HD were defined as the treatment group. 315 patients who did not receive IV vitD during first 90 days of HD were defined as the untreated group. DNA was extracted and genotyping for the *VDR* BsmI polymorphism (rs1544410, alleles A/G) was performed using the Sequenom platform. The primary outcome was the change in PTH; secondary outcomes were changes in Ca, PO4 and CaxPO4 product after IV vit D treatment. These outcomes were compared among the three genotypes (BB *vs* Bb *vs* bb, corresponding to AA *vs* AG *vs* GG alleles) using ANOVA.

Results: In the IV vitD treatment group, there were no significant differences in PTH, Ca, PO4 and CaxPO4 product at baseline among three genotype groups (P>0.05). The dosages of IV vitD among the three genotype groups were not significantly different (P>*0.05*). The PTH percent reduction relative to baseline PTH after IV vitD treatment was significantly larger in BB homozygotes at the *VDR* BsmI polymorphism than that observed in bb homozygotes (38±38% *vs* 27±51%, P=0.03). No significant differences were observed in PTH change in the untreated group (P>0.05).

Conclusions: Carriers of the *VDR* BsmI BB genotype (A allele homozygotes) may have better response in PTH reduction than those with the bb genotype (G allele homozygotes) after IV vitD treatment. Randomized controlled trials are needed to further test the association between this variant and response to IV vitD treatment.

A Detrimental Role for Ubiquitin C-Terminal Hydrolase L1 (UCH-L1) in ACTN4-Associated FSGS Naomi C. Read,[1,2] Josee Coulombe,[1] Doug A. Gray,[1] Chris R. Kennedy.[1] *[1]Ottawa Hospital Research Institute, ON, Canada; [2]Cellular & Molecular Medicine, University of Ottawa.*

Background: Podocyte UCH-L1 expression increases in many glomerular diseases including FSGS. In a familial form of FSGS, mutations in the ACTN4 gene lead to podocyte α-actinin-4 aggregation and impairment of the ubiquitin-proteasome pathway (UPP). We hypothesized that UCH-L1 contributes to podocyte injury in ACTN4-associated FSGS.

Methods: UCH-L1$^{+/-}$ mice were developed and bred to mice with podocyte-specific K256E-ACTN4 overexpression (K256E-ACTN4^{pod+}) to obtain K256E-ACTN4^{pod+}/UCH-L1$^{-/-}$ mice - followed to 10 weeks of age for albuminuria (spot urine albumin:creatinine). Immunohistochemistry (IHC) determined renal expression of UCH-L1. For *in vitro* studies, podocytes were infected with adenovirus containing wild type (WT) or K256E α-actinin-4. Effect of UPP inhibition (MG132, 50μM, 16h) on WT or K256E α-actinin-4 expression was determined by western blot (WB) and apoptosis estimated by counting of DAPI stained condensed nuclei.

Results: IHC revealed elevated podocyte UCH-L1 in K256E-ACTN4^{pod+} mice. Gene deletion in UCH-L1$^{-/-}$ mice was confirmed by RT-PCR of tail snip DNA and by WB of brain lysates. UCH-L1$^{-/-}$ mice are viable but succumb to neurodegenerative effects by 15 weeks of age. ACTN4^{pod+} mice exhibited progressively elevated albuminuria at 4 and 10 weeks (1568 and 2391μg/mg) as compared to WT (153 and 186μg/mg) and UCH-L1$^{-/-}$ littermates (142 and 111μg/mg). In contrast, while K256E-ACTN4^{pod+}/UCH-L1$^{-/-}$ mice exhibited elevated albuminuria at 4 weeks (2465μg/mg), this was significantly reduced by 10 weeks (731μg/mg). Lastly, UPP inhibition induced a 2-fold increase in apoptosis in WT α-actinin-4 expressing podocytes (21% of cells), while K256E α-actinin-4 expressing cells exhibited a 3.5-fold induction (37% of cells). UPP inhibition reduced K256E α-actinin-4 levels in the triton-soluble fraction of lysates, suggesting increased levels in the triton-insoluble cytoskeletal fraction, consistent with aggregation.

Conclusions: K256E α-actinin-4 aggregates are toxic and lead to podocyte apoptosis. Deletion of UCH-L1 in mice may enhance UPP activity, reduce K256E α-actinin-4 levels and thereby reverse podocyte injury in this model of FSGS.

Activation of Multiple Signaling Pathways in Podocytes by Cardiotrophin-Like Cytokine-1 May Lead to Glomerular Injury of FSGS Virginia J. Savin,[1] Mukut Sharma,[1] Jianping Zhou,[1] Ellen T. McCarthy,[2] Shuhua Wang,[2] Ram Sharma.[1] *[1]Nephrology, Kansas City VA Medical Center, Kansas City, MO; [2]Kidney Institute, University of Kansas Medical Center, Kansas City, MO.*

Background: Focal segmental glomerulosclerosis (FSGS) is associated with circulating factor(s) that cause proteinuria, increase glomerular albumin permeability (P_{alb}) in *in vitro* assays and result in transplant recurrence and graft loss. We have used proteomics (LC-MS) to identify cardiotrophin-like cytokine-1 (CLC-1), a member of the IL-6 family, as a candidate for this activity. Podocytes express all 3 CLC-1 receptor components, gp 130, IL6R and CNTFR. CLC-1 incubation increases P_{alb} of normal glomeruli while CLC-1 injection causes proteinuria in rats and mice. We studied activation of JAK/STAT, PI3K/AKT and MAPK/ERK pathways to determine whether CLC-1 affected them.

Methods: Differentiated podocytes were incubated with CLC-1 (10 ng/mL) or control medium for 15 minutes at 37° C. Phosphorylated proteins were detected in cell lysates after electrophoresis and immunoblotting using monoclonal antibodies to phospho-JAK2, phospho-STAT 3, phospho-AKT or phospho-ERK1/2 (Cell Signaling Technology, Boston, MA).

Results: Differentiated murine podocytes expressed JAK 1, 2, 3 and STAT 1, 3, 5, 6; JAK2 and STAT3 were the predominant isoforms. Podocytes also expressed AKT, and ERK1/2. These proteins represent 3 distinct signaling pathways. Incubation with CLC-1 dramatically increased phosphorylation of JAK 2 and STAT3 and decreased phosphorylation of both AKT and ERK1/2 by more than 50%. These results confirm that, in immortalized podocytes, CLC-1 activates the JAK/STAT pathway associated with IL-6 family cytokines and also alters signaling by PI3K/AKT and MAPK/ERK pathways.

Conclusions: Results support the hypothesis that CLC-1 has direct effects on the podocyte that may alter its function and also its survival. These signals may contribute both to the early onset of proteinuria after transplantation in recurrent FSGS and to glomerular scarring that results in progression and kidney loss in both native kidneys and allografts. Further understanding of these pathways may lead to specific therapy to protect the kidney in FSGS.

The Effect of Recurrent FSGS Plasma on Podocyte Cytoskeleton Is Reversed by Blocking TNFalpha Elena Torban,[1] Sima Babayeva,[1] Anil Vasudevan,[3] Martin M. Bitzan,[2] Paul R. Goodyer.[2] *[1]McGill Univeristy, Montreal, Canada; [2]Montreal Children's Hospital, McGill University, Montreal, Canada; [3]St. John's Hospital, Bangalore, India.*

Background: Patients with steroid-unresponsive FSGS, in whom the known slit diaphragm genes are normal, develop inexorable renal failure. 50% rapidly develop proteinuria in their renal allograft, reflecting a circulating factor that disrupts podocyte biology. Plasma from these patients rapidly disturbs the cytoskeleton of human podocytes *in vitro*, disperses MYH9 from actin stress fibers and nephrin from the slit diaphragm. In 2009, Leroy reported a boy with recurrent FSGS who responded to infusion of tumor necrosis factor-alpha (TNFα) antibody. We hypothesized that TNFα is responsible for the rapid cytoskeletal changes induced by FSGS plasma.

Methods: In a patient with recurrent FSGS undergoing plasmapheresis we collected plasma effluent (PPE) at the beginning and end of treatment, adding it to confluent monolayer cultures of differentiated human podocytes. In some experiments, hPod were treated with recombinant TNFα or pretreated with blocking antibodies against TNFα or TNFα receptors prior to PPE. Cytoskeletal changes were assessed by immunofluorescent microscopy and immunoblotting.

Results: Proteiuria (Uprot/creat >10g/g) was responsive (Uprot/creat <0.5g/g) to plasmapheresis. FSGS-PPE from the beginning (but not the end) of PPE, disrupted arrangement of stress fiber (phalloidin and MYH9 staining) and dispersed adhesion complexes (vimentin staining) in hPod. TNFα alone recapitulated the effect of early FSGS-PPE. Pretreatment of hPod with anti-TNFα prevented the FSGS-PPE effect in a dose-dependent manner. Likewise, pretreatment of hPod with blocking TNFα receptor I and/or II averted the FSGS-PPE-induced changes in cytoskeleton and adhesion complexes. When the patient was treated with weekly infusions of etanercept, Uprot/creat was now maintained <0.5g/g without plasmapheresis.

Conclusions: The rapid effects of FSGS plasma on the cytoskeleton of cultured podocytes are largely attributable to TNFα in this patient. Etanercept resulted in a significant sustained reduction in proteinuria.

miR-143 Contributes to Podocyte Injury Induced by TGF-beta1 Toru Sakairi,[1] Yoshifusa Abe,[2] Keiju Hiromura,[1] Satoshi Takahashi,[1] Hiroko Hamatani,[1] Yoshihisa Nojima,[1] Jeffrey B. Kopp.[3] *[1]Medicine and Clinical Science, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan; [2]Department of Pediatrics, Showa University School of Medicine, Tokyo, Japan; [3]Kidney Disease Section, NIDDK/NIH, Bethesda, MD.*

Background: Transforming growth factor (TGF)-beta contributes to podocyte injury in FSGS and diabetic nephropathy. Micro(mi)RNAs are small non-coding RNAs that regulate expression of target mRNAs by reducing translational efficiency. Certain miRNAs have been shown to contribute to progression of kidney diseases. We sought to identify miRNAs involved in podocyte injury induced by TGF-beta.

Methods: We used a human podocyte cell line treated with TGF-beta1 and TGF-beta1 transgenic mice that develop severe global glomerulosclerosis.

Results: For discovery, we performed miRNA profiling of the cultured human podocytes treated with TGF-beta1 at 5 ng/ml or vehicle control for 24 hours, using a miRNA microarray. Among miRNAs significantly increased by TGF-beta1 were miR-143, miR-31, miR-181a and miR-181b and these were confirmed by quantitative RT-PCR, which showed that miR-143 had the largest increase (2.93 ± 1.18 fold over control). We next assessed the function of miR-143, using lentiviral expression. Incubation of cultured podocytes with TGF-beta1 increased expression of COL1A1 mRNA (1.98 ± 0.15 fold), and decreased that of Wilms tumor suppressor gene (WT1) mRNA (0.25 ± 0.05 fold) and protein. Ectopic expression of miR-143 (without TGF-beta1 exposure) also increased expression of COL1A1 mRNA (1.65 ± 0.11 fold) and decreased expression of WT1 mRNA (0.60 ± 0.13 fold compared to control) and protein. The combination of TGF-beta1 and miR-143 had an additive effect for both genes. Finally, we found that miR-143 was up-regulated in the TGF-beta1 transgenic glomeruli compared to wild-type glomeruli (1.98 ± 0.4 fold) at three weeks of age prior to developing glomerulosclerosis.

Conclusions: In conclusion, TGF-beta1 induced miR-143 expression in cultured human podocytes and mouse glomeruli, and up-regulated miR-143 may mediate the induction of COL1A1 and the repression of WT1 by TGF-beta1. Up-regulation of miR-143 may be a biomarker for TGF-beta1 induced podocyte injury.

SA-PO2320

Molecular Mechanism for Angiotensin II Induced Proteinuria Eva Koenigshausen, Martin Rütze, Ulf Zierhut, Sebastian Alexander Potthoff, Magdalena Woznowski, Ivo Quack, Johannes Stegbauer, Lars C. Rump, Lorenz Sellin. *Nephrology, Heinrich Heine University, Duesseldorf, Germany.*

Background: Microalbuminuria serves as an early marker for glomerular injury in hypertensive and diabetic patients. Inhibitors of the renin-angiotensin-aldosterone system but not calcium chanel blockers reduce albuminuria in these patients. Albuminuria results from a defect in the glomerular filter and its slit diaphragms. A major component of the glomerular slit diaphragm is nephrin, that is endocytosed upon binding to the adaptor protein β-arrestin2.

Methods: Cells expressing the AT1-receptor or its mutant D125AR126L, nephrin and β-arrestin2 were stimulated with Ang II. After cell lysis, co-immunoprecipitation with subsequent western blot analysis was performed. For the inhibitor studies, cells were pretreated with the inhibitor before stimulation with Ang II. For siRNA experiments cells were transfected with Gαq siRNA and lysed three days thereafter. The effect of Ang II on the β-arrestin2 binding motif was studied by using two nephrin mutants. For the endocytosis assay, cells were stimulated with Ang II and incubated with biotin before cell lysis.

Results: Ang II stimulation increases the protein interaction between nephrin and β-arrestin2. This Ang II effect is dependent on the AT1-receptor and can be inhibited by AT1-receptor blockers. The G-protein signalling is essential for the Ang II effect, as the AT1-receptor mutant D125AR126L abolishes all G-protein signalling. SiRNA against the Gαq subunit and a phospholipase C inhibitor block the Ang II effect. Phosphorylation of T1120 and T1125 of nephrin are essential for the binding of β-arrestin2. Phosphorylation of nephrin S1146 mediates the Ang II effect. Stimulation with Ang II increases endocytosis of nephrin, which can be inhibited by AT1-receptor and PLC-blockers. The Ang II effect on nephrin-β-arrestin2 binding is also shown in isolated glomeruli.

Conclusions: Ang II weakens the integrity of the slit diaphragm through increase of nephrin endocytosis and is perceived to promote proteinuria. This previously unknown molecular effect of Ang II could help to understand the molecular mechanisms of Ang II induced proteinuria beyond hemodynamic effects.

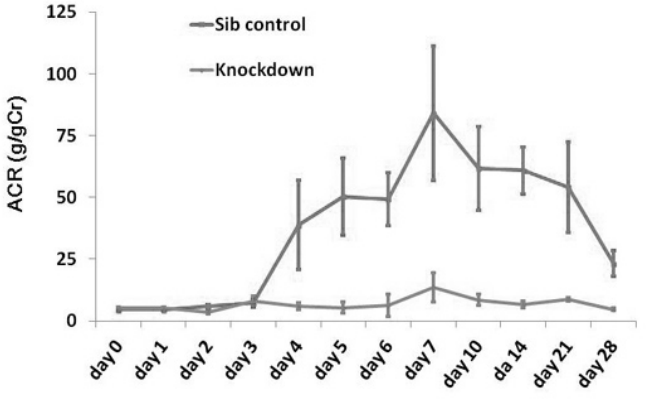
GPC5 Predispose FGF Signaling Related Podocyte Injury Koji Okamoto, Kenjiro Honda, Kent Doi, Toshiro Fujita, Eisei Noiri. *Departments of Nephrology & Endocrinology, Hemodialysis & Apheresis, University Hospital, The University of Tokyo, Japan.*

Background: Genome-wide association study for nephrotic syndrome revealed glypican 5 (*GPC5*) as risk gene (*Nature Genetics 2011*). However, the relationships between podocyte injury and GPC5 was not fully elucidated.

Methods: Podocyte specific GPC5 knock down mice and their sib control mice were studied in mice model. We created two models of heavy proteinuria; Fatal model with puromycin aminonucleoside (PAN) 300mg s.c. and bFGF 5 μg 4 days and moderate model with Fatal model with PAN 300mg s.c. and bFGF 5 μg 2 days.

Results: Massive albuminuria occurred in sibling control mice and lasted for more than 10 days to 28 days. In contrast, mild albuminuria occurred in the podocyte-specific Gpc5 knockdown mice.



Even In fatal model, the proteinuria in the podocyte-specific Gpc5 knockdown mice was relatively low compared with that of sib control mice. Electron microscopic changes was found 7 days after PAN injection, whereas light microscopic changes was found 14 days after PAN injection. Approximately 25% of glomeruli showed global sclerosis; 50% of glomeruli showed segmental sclerosis at day 28 in sibling control mice. In contrast, 90% of glomeruli showed virtually no changes in conditional knockdown mice.

Conclusions: Our in vivo data strongly suggest a role of the GPC5-FGF2 pathway in nephrotic syndrome pathogenesis.

Heterogenous Changes in Podocyte Morphology and Function in Adriamycin Nephropathy in Mice Matthias Hackl,[1] Katalin Susztak,[2] Janos Peti-Peterdi.[1] *[1]Physiology & Biophysics, University of Southern California, Los Angeles, CA; [2]Albert Einstein School of Medicine, Yeshiva University, Bronx, NY.*

Background: Adriamycin nephropathy is a well-characterized model of focal segmental glomerulosclerosis (FSGS) in mice, however proteinuria, glomerular hyalinosis/sclerosis and tubular atrophy have been studied mainly by histology. The purpose of this study was to directly and quantitatively visualize the early changes in FSGS in vivo using advanced techniques of multiphoton microscopy (MPM).

Methods: 4 week old C57BL6 male mice were injected with 25mg/kg adriamycin iv. After 7 days proteinuria increased 20 to 50 fold and the animals were surgically instrumented for kidney MPM. The vasculature was labeled with albumin-Atto565. Injection of Lucifer Yellow (LY), a molecule which is freely filtered into the Bowman's space, identified podocytes by negative labeling. A new transgenic mouse model was developed (Pod:EGFP-tomato) featuring specific expression of the intensely green fluorescent protein EGFP in podocytes targeted to the cell membrane while other cell types express the red fluorescent protein tomato. Measurements of the glomerular sieving coefficient (GSC) for albumin were obtained to assess the local permeability of the glomerular filter.

Results: MPM of the glomeruli identified several, but not all podocytes with hypertrophy and intense LY uptake. Intense leaking of red plasma fluorescence into the Bowman's space was observed around these injured podocytes, but other glomerular regions appeared normal. GSC measurements in damaged and intact areas of the glomerular filtration barrier confirmed that the leakage of albumin was restricted to the focal regions of podocyte injury. All changes were absent in control animals injected with normal saline.

Conclusions: In vivo multiphoton imaging of the adriamycin model of FSGS in mice is technically feasible and useful for the study of the molecular players in the development of proteinuria in transgenic mice. In the early stages of adriamycin GS, podocyte damage/dysfunction appears to be limited to a few podocytes, where intense, focal leakage of albumin may be the cause of proteinuria.

Vitronectin-Binding Exogenous Plasminogen Activator Inhibitor-1 (PAI-1) Protects Podocytes Against Injury *In Vivo* and *In Vitro* Haichun Yang,[1] Jianyong Zhong,[2] Ji Ma,[2] Bridgette Corsa,[1] Agnes B. Fogo.[1] *[1]Pathology, Vanderbilt University Medical Center, Nashville, TN; [2]Pediatric Nephrology, Vanderbilt University Medical Center, Nashville, TN.*

Background: We previously found that genetic PAI-1 deficiency protects podocytes against injury both *in vivo* and *in vitro*. To determine whether this PAI-1 protective effect on podocytes is plasmin dependent or due to vitronectin (Vn) interactions, we assessed effects of mutant forms of recombinant human PAI-1 variants on podocyte function.

Methods: Uninephrectomized (UNx) mice were fed high salt diet and infused with angiotensin II (Ang II) for 8 weeks. Different human stable PAI-1 variants, including PAI-1-K (retaining protease inhibitor effects of native PAI-1 but not binding to Vn), or PAI-1-R (competitive blocker of Vn), or 14-1b (control PAI-1, retaining all known functions of native PAI-1), or PBS were injected daily. Primary cultured podocytes were injured by puromycin aminonucleoside (PAN) and various PAI-1 variants were added.

Results: Systolic blood pressure was significantly increased in mice with UNx/Ang II, and none of the PAI-1 variants changed SBP. However, the albuminuria caused by UNx/Ang II was significantly reduced by 14-1b and PAI-1-R (14-1b 1587.4±377.8, PAI-1-R 1165.8±324.16 *vs.* AngII 2348.1±920.96 ug/mg, $p<0.05$) while there was no change by PAI-1-K. Only vitronectin-binding PAI-1 variants resulted in PAI-1 deposition along glomerular basement membranes. In parallel, 14-1b and PAI-1-R maintained synaptopodin and decreased desmin on podocytes, while PAI-1-K and PBS did not. *In vitro*, Vn-binding human PAI-1, 14-1b and PAI-1-R maintained synaptopodin and α-actinin-4 expression after PAN treatment, and also decreased pro-apoprotic Bax expression in wild type podocytes (14-1b 0.69±0.03, PAI-1-R 0.56±0.03 *vs.* PAN 0.99±0.02, $p<0.05$). Previous data showed lack of protection against PAN by Vn-binding human PAI-1 in *PAI-1*$^{-/-}$ podocytes, which also expressed less uPAR compared to wild type.

Conclusions: Our data suggest that vitronectin-binding PAI-1 protects podocytes against injury. Collectively, these studies suggest the protective effect of vitronectin-binding PAI-1 may be related to uPAR.

SA-PO2324

Novel Therapeutics in Diabetic Nephropathy: Sialic Acid Precursors Reduce Proteinuria in Experimental Diabetic Nephropathy Camille E. Mace, Lionel C. Clement, Sumant S. Chugh. *Medicine/Nephrology, University of Alabama at Birmingham, AL.*

Background: We have recently shown that the expression of sialic acid deficient (hyposialylated) Angptl4 is increased in podocytes in minimal change disease (MCD) (Clement Nature Medicine 2011), and that improving sialylation with sialic acid precursors like N-acetyl D-mannosamine (ManNAc) reduces proteinuria significantly. Proteinuria in diabetic nephropathy is a complex, multidimensional process, so we investigated whether hyposialylated Angptl4 is a significant contributor towards proteinuria in this disease.

Results: Confocal imaging for Angptl4 in human kidney biopsies from patients with diabetic nephropathy reveal increased glomerular Angptl4 expression. We isolated glomeruli from hyperglycemic animals and normoglycemic controls from two rodent models of Type 2 diabetes, the db/db mouse and Zucker Diabetic Fatty (ZDF) rat. 2D gel electrophoresis and Western Blot of glomeruli revealed an overall increase in Angptl4 expression, including the high isoelectric point (pI) hyposialylated form, in both models. Treatment of proteinuric hyperglycemic ZDF rats with ManNAc in tap water (treatment group, n=5 rats/group) or plain tap water (control group) caused very significant reduction in proteinuria ($P<0.01$ on Day 3, $P<0.05$ on Day 7). Proteinuria was assessed on weekly intervals for 5 weeks. By the end of 5 weeks of therapy, fold increase in proteinuria over baseline was 2.96 ± 0.32 (control group) and 2.12 ± 0.27 (study group); $P<0.05$. Further studies with different ManNAc regimens are in progress.

Conclusions: In summary, glomerular Angptl4 expression is increased in human and rodent diabetic nephropathy, and treatment with sialic acid precursors significantly reduces proteinuria in a rat model of diabetic nephropathy.

Filtration Barrier Dysfunction in Diabetic CLIC5A Deficient Mice Yimin Zhang, Laiji Li, Abass Almomany, Barbara J. Ballermann. *Medicine, University of Alberta, Edmonton, AB, Canada.*

Background: The Chloride Intracellular Channel 5A (CLIC5A), one of two CLIC5 isoforms, is a glomerulus-predominant protein that co-localizes with Ezrin and podocalyxin in podocytes. In CLIC5 (jbg/jbg) deficient mice, podocyte Ezrin and phospho-Ezrin levels are reduced, podocyte architecture is abnormal and adriamycin-induced injury is more severe than in wild-type (+/+) mice. In human patients with diabetic nephropathy glomerular CLIC5A mRNA expression is reduced. Here, we sought to determine whether CLIC5A deficiency is a susceptibility factor for diabetic nephropathy in mice.

Methods: Heterozygous (+/jbg) mice were bred to generate jbg/jbg, +/jbg and +/+ littermates. Diabetes was induced at 8 weeks of age with intraperitoneal (50μg/g) streptozotocin for 5 consecutive days. Non-diabetic controls were similarly injected with buffer alone. The day of the first injection was defined as day 1, week 1. Mice with fasting blood glucose levels >12.6 mmol/L on day 14 were considered diabetic. Blood glucose and western blots for urine albumin were obtained every two weeks, and mice were euthanized during weeks 6 and 14 for tissue analysis.

Results: Light microscopy of PAS and H&E stained renal tissue was normal for control and diabetic mice of all genotypes at 6 and 14 weeks. There was increased deposition of extracellular matrix and mild mesangial expansion in all diabetic mice compared to non-diabetic mice, but no differences between the three genotypes were observed. By immunoblot analysis of kidney tissue, podocalyxin migrated as a single band in non-diabetic +/+ mice. An additional, more slowly migrating band suggesting reduced podocalyxin glycosylation was observed in diabetic +/+ mice and in both, diabetic and non-diabetic jbg/jbg mice. In +/+ and +/- mice, CLIC5A abundance did not change with induction of diabetes. Finally, diabetic jbg/jbg and +/jbg mice, had higher urine albumin levels than non-diabetic jbg/jbg or +/jbg controls, whereas no difference in urine albumin was observed between diabetic and non-diabetic +/+ mice.

Conclusions: The findings lead us to postulate that CLIC5A deficiency may change podocalyxin glycosylation in glomerular podocytes, increasing filtration barrier dysfunction in diabetes.

Differential Modification of Enalapril in the Kidneys of Lean and 'Programmed' Obese Male Young Rats Hyung Eun Yim, Kee Hwan Yoo, Cheol Park, In Sun Bae, Joo Won Lee. *Pediatrics, Korea University Medical Center, Republic of Korea.*

Background: The acquired reset of the renin-angiotensin system (RAS) has been suggested to cause lifelong functional and structural alterations. We aimed to investigate the role of the RAS block in the renal pathophysiological changes in the rat model of 'programmed' obesity.

Methods: Three or 10 male pups per mother were assigned to either the small litter (Obese group) or normal litter (Lean group) rats during the first 21 days of life. With this, all pups were randomized into 4 groups, and treated with enalapril (Obese enalapril, OE; Lean enalapril, LE) or vehicle (Obese control, OC; Lean control, LC) between the ages of 2 and 4 weeks postnatally. All pups had body weight, blood pressure (BP) and renal alterations determined at 28 days of age.

Results: Pups in the OC group weighed more than rats in the LC group between 7 days and 28 days of age ($P < 0.05$). Enalapril decreased body weights in the Obese and Lean groups at 28 days ($P < 0.05$). Mean BP levels in the OC and OE groups were higher than those of the LC and LE groups ($P < 0.05$). Enalapril increased renal cell apoptosis and proliferation, glomerulosclerosis, and tubulointerstitial fibrosis compared to both Lean and Obese controls, respectively ($P < 0.05$). Pups in the OE group particularly showed the highest increases in renal cell apoptosis, glomerulosclerosis and tubulointerstitial fibrosis compared to the other groups ($P < 0.05$). Immunoblotting and immunohistochemistry showed that enalapril increased renin, angiotensin II receptor type (AT) 2, and matrix metalloproteinase (MMP)-9 and decreased AT 1, tissue inhibitor of MMP (TIMP)-1, and osteopontin expression in the kidneys of Lean group. In contrast, enalapril decreased AT2 and MMP-9 and increased TIMP-1, osteopontin, and plasminogen activator inhibitor-1 expression in the kidneys of Obese group ($P < 0.05$).

Conclusions: These data indicates that renal changes following early postnatal overfeeding may be fundamentally different to those of normal postnatal growth after exposure to the RAS inhibition. Angiotensin II can be a key player in the developmental renal programming of obesity.

SA-PO2327

Impairment of Podocyte Function in Mice with Gsα Deletion in Juxtaglomerular Cells Lanping Jiang,[1] Christoph Eisner,[2] Yuning Huang,[2] Diane Mizel,[2] Jurgen Schnermann,[2] Limeng Chen.[1] *[1]Department of Nephrology, Peking Union Medical College Hospital, Beijing, China; [2]NIDDK, NIH, Bethesda, MD.*

Background: Mice with deletion of Gsa in renin-producing cells (RC/FF mice) have been shown to have greatly reduced renin production and responsiveness of renin secretion to acute stimuli. In addition, long-term experiments documented that renal function and pathology deteriorated progressively in RC/FF mice. In the present study we have determined a possible role of podocyte abnormalities in this low renin mouse model and the effects of ACE inhibition (ACEI).

Methods: Experiments were performed in 7-8 weeks old RC/FF mice and age-matched control mice kept on a standard diet. In addition mutant and control mice were studied after being fed a low-salt diet (0.03% NaCl w/w) for 7 days, and receiving enalapril in the drinking water (about 10 mg/kg per day). Efficacy of the prolonged treatment with ACEI was examined in anesthetized mice by determining the blood pressure (BP) response to angiotensin I. After the treatment blood were collected for plasma renin measurements and mice were sacrificed. Kidneys were fixed for histological examination. Wilms tumor protein (WT1) as a selective podocyte marker was determined by immunohistochemistry.

Results: Urinary albumin excretion was higher in RC/FF mice when adjusted by GFR. Focal segmental glomerular sclerosis was observed in older RC/FF mice. Compared with the control mice, WT1 positive podocyte counts as well as the glomerular area were significantly decreased in RC/FF mice. When stimulated by low salt and ACEI, WT1 positive podocyte area per glomerulus had markedly increased in both RC/FF and control mice. Although there were no significant changes of PRA by the chronic low salt/ACEI treatment, WT1 positive podocyte area per glomerulus was much higher in RC/FF mice than control mice.

Conclusions: Chronic Gsa deletion in JG cells leading to greatly reduced renin production may impair podocyte function resulting in increased albumin excretion and FSGS in the older age. This process may be partly improved by ACEI through currently unknown pathways.

MicroRNA Profile Determines Progression of HIV-Associated Nephropathy Partab Rai, Dileep Kumar, Pravin C. Singhal, Ashwani Malhotra. *Medicine, NSLIJ, Great Neck, NY.*

Background: Micro RNAs with dual function to act as inducers or repressors of gene activity have been reported to be differentially expressed in various pathological and physiological states. However, the precise role of microRNAs, endogenous RNA oligonucleotides which specifically target mRNA and regulate gene expression in HIV –associated nephropathy (HIVAN) is not functionally known. Our laboratory had shown the activation of mTOR pathway in HIVAN and rapamycin, an inhibitor of mTOR pathway, which has been used to attenuate polycystic kidney disease in animal experimental models. We asked whether microRNAs regulate this process in this model.

Methods: Kidneys were harvested from FVB/N and Tg26 mice at 8wks of age (n=3). In another group,mice were given rapamycin®(5mg/kg ,ip, alternate day) for 4 weeks. In brief, total RNA from renal tissue (n=3) was isolated from FVB/N (controls), Tg26 and Tg+R by Triozol reagent (Invitrogen). A complete miRNA microarray was performed in these groups and a data analysis was generated. cDNA was synthesized using SuperScript Enzyme Mix (Invitrogen).Real-Time qPCR was performed to confirm the miRNA microarray data by using SYBR Green Universal Kit (Invitrogen) using forward primers and universal qPCR primers (Invitrogen).

Results: TG26 mice showed altered expressions of mir- 145(C=18793±2273, Tg=8454±1255, and R=13910±3232,Arbitrary Units; AU ; p<.04), mir-16(C=11594±1393, Tg=5758±1898, and R=10373±3484 AU; p<.05), mir-30c (C=22517±2908, Tg=15486±1992, and R=19537±4178 AU; p<.07), mir-466 (C=8274±1038, Tg=12856±1754, and R=9623±3237 AU; p<.09) in Tg26 mice which were reversed by rapamycin. These results were confirmed by qRT-PCR.

Conclusions: These microRNAs have been considered to play key roles in many cellular processes such as proliferation, differentiation and apoptosis by inhibiting target gene expression. Our results demonstrate that the above selective bioregulators could have a functional impact in HIVAN.

SA-PO2329

TWEAK and FN14 in Proteinuric Podocyte Injury Maria D. Sanchez-Niño,[1] Ana Belen Sanz,[1] Sergio A. Mezzano,[2] Rafael Selgas,[1] Marta Ruiz-Ortega,[3] Jesus Egido,[3] Alberto Ortiz.[3] *[1]IdiPAZ, Madrid, Spain; [2]Universidad de Valdivia, Chile; [3]IIS-Fundacion Jimenez Diaz, Madrid, Spain.*

Background: Tumor necrosis factor-like weak inducer of apoptosis (TWEAK) is a TNF superfamily cytokine that activates the Fibroblast growth factor-inducible 14 (Fn14) receptor. Cultured podocytes have been shown to express Fn14. However, there is scarce information on TWEAK actions on podocytes and on in vivo Fn14 in podocytes.

Methods: Biopsies from human nephrotic syndrome were studied. Studies in mice and rats were done: TWEAK administration to mice, BSA for protein overload-induced proteinuria and puromycin aminonucleoside to rats. In vitro studies were done in murine podocytes.

Results: Kidney Fn14 mRNA and protein was increased following puromycin aminonucleoside administration to rats. The increased Fn14 at day 2 preceded the onset of proteinuria and the increment in kidney MCP-1. Total kidney Fn14 mRNA (1.5-fold) increased at day 7 in murine protein overload-induced proteinuria and was associated with increased glomerular macrophage infiltrates. Immunohistochemistry and co-staining with WT-1 localized the increased Fn14 expression to podocytes in both rat PAN nephrosis and in protein overload-induced proteinuria. In human nephrotic syndrome, Fn14-expressing podocytes displayed NFkB activation and expressed MCP-1. TWEAK administration to mice increased podocyte RelA translocation to nuclei and MCP-1 expression. In cultured podocytes stressors such as PAN and inflammatory cytokines, increased Fn14 mRNA (2.2-fold) and protein (2.2-fold) levels in a dose- and time-dependent manner with peak protein expression at 6 hours. TWEAK activated NFkB and increased MCP-1 mRNA and protein in cultured podocytes, an effect prevented by parthenolide. Indeed, anti-TWEAK neutralizing antibodies prevented PAN induction of MCP-1 mRNA in cultured podocytes.

Conclusions: In conclusion, Fn14 is upregulated in podocytes in different forms of proteinuric kidney disease and by diverse stressors. TWEAK has NFkB-mediated pro-inflammatory effects on podocytes that may be relevant for the pathogenesis of proteinuric kidney disease. Thus, TWEAK or Fn14 targeting should be explored in proteinuric diseases.

Podocyte Specific GLUT4 Deletion Protects from the Development of Lipopolysaccharide (LPS) Induced Albuminuria Johanna Guzman,[1] Britta Sylvia Walter,[1] Cristina Muresan,[1] Mary Donnelly,[1] Kirk N. Campbell,[3] Peter H. Mundel,[4] Jochen Reiser,[1] Sandra M. Merscher-Gomez,[1] Alessia Fornoni.[1] *[1]Medicine/Nephrology, University of Miami Miller School of Medicine, FL; [2]Medicine/Nephrology, Mount Sinai Medical Center, New York, NY; [3]Medicine, Massachusetts General Hospital, Boston, MA.*

Background: Insulin resistance correlates with albuminuria in patients with diabetes as well as in normal individuals. Mice with a podocyte-specific insulin receptor deletion develop glomerular lesions resembling diabetic nephropathy (DN), suggesting an important role of insulin signaling in podocyte function.

Methods: We investigated how GLUT4 is modulated in human DN and how GLUT4 affects podocyte function.

Results: Using RT-PCR, we show that GLUT4 is downregulated in glomeruli from patients with DN when compared to controls (N=6 each, $p<0.05$). Mice with a podocyte-specific deletion of Glut4 (Glut4 KO) were generated by crossing Glut4 floxed mice with Podocin-Cre mice. Glut4 KO mice did not show an increased urinary albumin to creatinine ratio up to 19 weeks of age. However, when challenged by two daily consecutive injections of LPS (200µg each), Glut4 KO mice had an albumin/creatinine ratio of 139 ± 131 versus 1059 ± 449 µg/mg in wildtype mice ($p<0.001$). Western blot analysis of glomeruli demonstrated that Glut4 KO mice were protected from LPS induced degradation of synaptopodin and nephrin. In order to further characterize the role of GLUT4 in podocyte function, we performed GLUT4 siRNA experiments in differentiated mouse podocytes. GLUT4 siRNA podocytes showed an increased in synaptopodin and RhoA expression ($p<0.01$), associated with cell blebbing ($p<0.05$) and increased cell migration. These changes were conserved when the experiments were repeated in glucose free medium, suggesting that Glut4 may affect podocyte function in a glucose independent manner.

Conclusions: In conclusion, Glut4 is directly involved in the regulation of the podocyte actin cytoskeleton and targeting GLUT4 may represent a new strategy for certain glomerular diseases.

SA-PO2331

The Role of the Protein Kinases MK2 and MK3 in a Mouse Model of Acute Proliferative Glomerulonephritis Rose M. Ayoob,[1] Melinda Chanley,[1] Adam J. Guess,[1] Ruma Pengal,[1] Brian Becknell,[1] Jeffrey B. Kopp,[2] Rainer Benndorf,[1] William E. Smoyer.[1] *[1]Center for Clinical and Translational Research, Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Kidney Disease Section, NIDDK, Bethesda, MD.*

Background: Signaling by various MAPK kinases, including p38 MAPK, has been implicated in both renal function and disease, although their exact role is not understood. Increased p38 MAPK activity has been observed in podocytes in patients with glomerulonephritis (GN). Two of the major substrates of p38 MAPK, MK2 and MK3, have been suspected to play a role in this injury. The goal of this study was to determine the role of both MK2 and MK3 in the development of glomerular injury using a model of acute proliferative GN in mice with disrupted MK2 and MK3 genes.

Methods: Four groups of age-and sex-matched mice (n=13/group) with different MK2 and MK3 genotypes received anti-mesangial cell serum i.v. on Days 1-4. Kidney function was assessed by serum blood urea nitrogen (BUN) and urine protein:creatinine ratios (Up:Ucr) on Days 0, 4, 8 and 12. Renal histology was analyzed at Days 8 and 16.

Results: Significant differences were found in BUN ($P<0.05$) and Up:cr ($P<0.01$) values on Day 4, and in survival to Day 28 ($P<0.01$). Survival rates for $MK2^{++}/MK3^{++}$ and $MK2^{-}/MK3^{++}$ mice were 68% vs. 52% for $MK2^{++}/MK3^{-}$ vs. 19% for $MK2^{-}/MK3^{-}$ mice. Histological analysis revealed thickening of glomerular capillary walls due to reduplication of basement membranes as well as subendothelial and mesangial deposits in each group. Glomeruli examined on Day 16 revealed 4% had crescents in $MK2^{-}/MK3^{++}$ mice vs. 15% in $MK2^{++}/MK3^{++}$ and 22% in $MK2^{-}/MK3^{-}$ mice, while crescents were absent in $MK2^{++}/MK3^{-}$ mice.

Conclusions: MK2 and MK3 both contribute to glomerular structure and function in murine proliferative GN, yet they have distinguishable effects on survival.

Galectin-9 Inhibits Cell-Mediated Immune Response in Mice Anti-GBM Glomerulonephritis Qian Zhang, Jin Yuan, Hong Luan, Yongman Lv. *Nephrology, Tongji Hospital, Tongji Medical College of HUST, wuhan, Hubei, China.*

Background: Tim-3 is a cell surface molecule expressed mostly on Th1 cells, besides Th17 cells, macrophages, DCs and NK cells. Galectin-9 identified as the ligand of Tim-3 functions in diverse biological processes, including cell adhesion, cell proliferation and apoptosis. Because Th1 and Th17 cells are the major immune factors in anti-GBM glomerulonephritis, the function of which is regulated by galectin-9 via Tim-3-galectin-9 pathway, we hypothesized that galectin-9 could regulate the immune response in mice anti-GBM glomerulonephritis, and ameliorate the pathologic damage.

Methods: For inducing anti-GBM glomerulonephritis in C57BL/6 mice, we immunized mice with rabbit IgG and complete Freund's adjuvant, 10 days later injected rabbit anti-GBM serum and then administrated galectin-9 intraperitoneally 100ug daily from day1 to day 7 and PBS as control. All mice were seperately sacrificed at day 7, day 14, day 21, day 28 and day 56. Splenic lymphocytes were isolated and employed for FACS, cytokines were detected by ELISA, and the kidneys were utilized to determine the extent of influx of $CD4^{+}$ cells and glomerular damage.

Results: Administration of galectin-9 improved histologic damage significantly, including glomerular mesangial cell and matrix proliferation, crescent formation and mouse IgG deposition. Then, we analysed the distribution of immunologic cells in immune organs and kidneys. The results showed that in spleen, the rates of $CD4^{+}CD69^{+}$ T cells, $CD8^{+}CD69^{+}$ T cells and $CD19^{+}CD69^{+}$ B cells decreased significantly from day 7, and the similar tendency was observed in Th1 and Th17 cells from day 14, but not in Th2 cells. And in kidneys, administration of galectin-9 inhibits the filtration of $CD4^{+}$T cells.The suppression of Th1 and Th17 caused the decreased secretion of specific cytokines(IL-2, IL-10, IL-12, IL-17, IFN-γ and TGF-β1) in peripheral blood. In addition, we found that the kidneys from galectin-9 treated mice expressed lower level of α-SMA, collagenIand collagen III.

Conclusions: These results demonstrate that galectin-9 inhibits Th1 and Th17 cell-mediated immune response in anti-GBM glomerulonephritis, and interferes with the progress of fibrosis.

SA-PO2333

Estrogen Receptor Alpha Knockout Mice Develop Podocyte Damage and Increased Glomerular Collagen IV Deposition Sebastian Kummer,[1] Lara Vanessa Wegerich,[1] Stefanie Jeruschke,[1] Petra Lehmann,[2] Nadezda Koleganova,[2] Marie-Luise Gross-Weissmann,[2] Jun Oh.[1,3] *[1]Dep. of General Pediatrics, University Children's Hospital, Duesseldorf, Germany; [2]Inst. of Pathology, University Hospital, Heidelberg, Germany; [3]Dep. of Pediatric Nephrology, University Medical Center, Hamburg, Germany.*

Background: Epidemiological studies have demonstrated that outcome of chronic kidney diseases can be positively influenced by female gender. This suggests critical influences of gender hormones on glomerular structure and function. We examined estrogen receptor alpha (ERα) knockout mice for podocyte/glomerular damage as well as ERα expression and protective effects of estrogens on podocytes in vitro.

Methods: ERα knock out mice were examined for podocyte and mesangial cell number, volume, expression of TGFβ1/collagen IV and glomerular sclerosis. Expression of ERα was investigated in podocytes in vitro and in vivo. Antiapoptotic action of 17β-estradiol was analyzed in puromycin-treated podocytes using Annexin-FITC flow cytometry and Hoechst nuclear staining for apoptosis detection. Destabilization of mitochondrial membrane potential, an early indicator of apoptosis, was visualized with tetramethyl rhodamine methylester staining.

Results: In ERα knockout mice, podocyte number was reduced compared to wild-type controls in female/male animals (80/86 vs. 132/135 per glomerulus, $p<0.05$). Podocyte cell volume was enhanced in ERα knockout mice (429/371µm3 vs. 264/223µm3, $p<0.05$). TGFβ1 and collagen IV expression were significantly enhanced in knockout mice, indicating glomerular damage.

ERα is expressed in human and murine podocytes on mRNA and protein level. 17β-estradiol reduced PAN-induced apoptosis in vitro by 26.5% or 56.6% (FACS and Hoechst staining, $p<0.05$). Podocyte apoptosis is associated with mitochondrial membrane potential depolarization, which could be significantly restored by 17β-estradiol.

Conclusions: ERα deficient mice develop a loss of podocytes and cellular hypertrophy, indicating cellular stress. Correspondingly, podocytes express ERα in vitro and in vivo, mediating significant protection against apoptotic stimuli. These findings may explain in part the gender differences in glomerular diseases.

SA-PO2334

Heparan Sulfate Deficient Zebrafish Show Glomerular Malfunction and Ineffective Filtration Ramzi Khalil, Danielle Cohen, Malgorzata Wiweger, Wietske Van der Ent, Emile De Heer, Jan A. Bruijn, Pancras C.W. Hogendoorn, Hans J. Baelde. *Pathology, Leiden University Medical Center, Netherlands.*

Background: There has been a longstanding discussion on whether heparan sulfate proteoglycans (HSPG) serve as a charge selective filtration medium in the glomerular filtration barrier. A recent mouse model showed that a lack of podocyte specific HSPG does not lead to glomerular dysfunction. This project aims to investigate whether a biallelic knockout of the homologue of human EXT2 in zebrafish, leading to shortenened and functionally impaired HSPGs, results in abnormal glomerular filtration.

Methods: Zebrafish (*Danio rerio H*) *dackel* (*dak*) mutants have a premature stop codon in the *ext2* gene. The *ext1* and *ext2* gene products encoding subunits of heparan sulfate co-polymerase are essential components in the heparan sulfate chain elongation. Wild type (WT) larvae and homozygous *dak* mutants were injected intravenously with a mixture of FITC labeled lysine fixable 70kD dextran and TRITC labeled 3kD dextran at 4 days post fertilization, fixed with formalin at 5 or 60 minutes after injection, imbedded in TissueTec® for oriented sectioning and studied by immunofluorescent microscopy.

Results: Neither TRITC nor FITC fluorescent absorption droplets were found in the *dak*'s renal tubules at both timeframes. Only TRITC and no FITC droplets were found in the renal tubules of the WT zebrafish at both 5 and 60 minutes.

Conclusions: These results show that the WT glomerulus can filtrate small particles, but not the 70kD FITC. As none of the injected dyes are detected in *dak* mutants, these larvae either have an impaired tubular uptake or an inefficient glomerular filtration. Data from our previous studies have shown that homozygous *dak* mutants display structural changes of the glomerular basement membrane and podocyte foot process effacement. Therefore, a glomerular cause is most likely. Whether the impairment in glomerular filtration is caused by a developmental imperfection or a loss of function in the glomerular filtration barrier remains to be studied. Taken together, these results show that in this model, HSPGs are essential for effective glomerular filtration.

SA-PO2335

Crk1/2 Signaling Is Necessary for Foot Process Spreading in Mice and Is Activated in Human Proteinuric Kidney Disease Britta George,[1] Rakesh Verma,[2] Abdul A. Soofi,[2] Maria Pia Rastaldi,[3] Lawrence B. Holzman.[1] *[1]Renal-Electrolyte and Hypertension Division, University of Pennsylvania, Philadelphia, PA; [2]Division of Nephrology, University of Michigan, Ann Arbor, MI; [3]Renal Research Laboratory, Fondazione IRCCS Ospedale Maggiore Policlinico & Fondazione D'Amico, Milano, Italy.*

Background: The slit diaphragm protein Nephrin is necessary for establishing the morphology of the podocyte in development by transducing from the podocyte intercellular junction phosphorylation-mediated signals that regulate cytoskeletal dynamics.

Methods: Podocyte culture, podocyte-specific knockout mice and human kidney tissue immunofluorescence were employed to understand Crk biology.

Results: We found that activation of Nephrin induced lamellipodia formation in podocyte culture. Following Nephrin activation in cell culture, a FAK/Cas/Crk protein complex was recruited to Nephrin in a pI3- and Src kinase-dependent fashion. Crk1/2 and Cas were necessary for Nephrin-induced lamellipodia formation since cell spreading was attenuated in podocytes with RNAi-mediated knockdown of Crk1/2 or in Cas-null mouse embryonic fibroblasts. We found that proteins of the FAK/Cas/Crk complex were present at the intercellular junction of developing podocyte precursors *in vivo* in their activated phosphorylated state. To test the relevance of Crk1/2 signaling, mice deleted of Crk1/2 in a podocyte-specific fashion were bred and found to develop and age normally. Surprisingly, podocytes in these mice were protected from protamine sulfate (PS)-induced foot process spreading. In human proteinuric kidney disease, the FAK/Cas/Crk signaling axis was activated as p-Cas and p-FAK staining was increased in podocytes of minimal change and membranous nephropathy patients compared to healthy controls.

Conclusions: We conclude that Nephrin induces cell spreading in culture via a FAK/Cas/Crk protein complex. In mice the FAK/Cas/Crk complex is necessary for foot process spreading following podocyte injury; our additional findings in human tissue lead us to speculate that this might be true in some forms of human glomerular disease. Altogether, the Crk protein complex represents a promising therapeutic target in human podocytopathy.

Transgenic Mice with Disrupted ABIN1 Function Develop Diffuse Proliferative Lupus Nephritis Dawn J. Caster,[1] Sambit Kumar Nanda,[2] Kenneth R. McLeish,[1,3] Philip Cohen,[2] David W. Powell.[1] *[1]Medicine, University of Louisville School of Medicine, KY; [2]Medical Research Council Protein Phosphorylation Unit, Dundee, Scotland, United Kingdom; [3]VMAC, .*

Background: Lupus nephritis (LN) occurs in 50% to 60% of patients with systemic lupus erythematosus (SLE), and 60% of these patients are classified as focal (Class III) or diffuse (Class IV) proliferative LN. Recent genome wide association studies of patients with SLE identified mutations in a number of NF-κB signal components, including ABIN1. We have recently published the characterization of a knock-in ABIN1 mouse expressing a mutated form of ABIN1 that is unable to bind to polyubiquitin chains (Nanda et al, 2011. J. Exp. Med. 20102177). These mice demonstrated enhanced NF-κB activity and developed lupus-like autoimmune disease with enlarged spleens and lymph nodes, hypergammaglobulinemia, and anti-nuclear antibodies. The present study was performed to define the renal involvement in this novel model of murine SLE.

Methods: Histology and serology analysis was performed for 3 and 5 month old ABIN1 transgenic mice.

Results: Kidneys from 3 month old transgenic mice showed mild focal or diffuse mesangial proliferation without expansion of the mesangial matrix, loss of glomerular capillaries, or interstitial changes. At 5 months transgenic mice demonstrated advanced proliferative glomerulonephritis with mesangial expansion and lobulation, occlusion of capillary lumens, thickening of capillary walls, and focal interstitial cellular infiltrates. Electron microscopy showed discrete mesangial and subendothelial electron dense deposits, and immunohistochemistry showed deposition of C3, C1q, IgG, IgM, and IgA for both ages. At 5 months transgenic mice demonstrated significantly reduced serum C3 and C4 and had elevated serum cystatin C.

Conclusions: This novel mouse model of SLE demonstrates progressive glomerulonephritis with histologic features similar to Class III and IV LN. We conclude that loss of ABIN1 regulation of NF-κB results in production of autoimmune glomerulonephritis.

SA-PO2337

Glomerular Macrophage Heterogeneity in Murine Cryoglobulinemia-Associated Membranoproliferative Glomerulonephritis Progression Yujiro Kida, Kelly L. Hudkins, Charles E. Alpers, Jeremy S. Duffield. *Medicine & Pathology, University of Washington, Seattle, WA.*

Background: Inflammatory macrophages (Mφ) are known to play dual roles in tissue repair and regeneration or in amplification of tissue injury and scarring. Many studies in kidney diseases suggest that Mφ amplify injury and fibrosis, but recent studies in AKI show the same cells are beneficial in tissue repair.

Methods: We used mice expressing Lck-Tslp and Cd11b-DTR transgenes to explore the overall function of glomerular Mφs in cryoglobulinemia and MPGN. Lck-Tslp generates overactive B lymphocytes that produce cryoglobulins, and CD11b-DTR permits specific conditional ablation of Mφs when diphtheria toxin (DT) is injected.

Results: To study the function of inflammatory Mφs in this MPGN model we achieved glomerular Mφ ablation of 80% compared with controls, from d30-d50 with alternate day DT injections. IgG deposition was unaffected, but ablation lead to a 40% reduction in mesangial matrix expansion detected by silver stain or Coll-IV stain. Mesangial cell area was also reduced by 40% and proteinuria reduced by 60%. The overall function of Mφs is deleterious, promoting mesangial proliferation and sclerosis. To understand the phenotype of MPGN glomerular Mφs we phenotyped them using established markers of activation and differentiation. All MPGN Mφs showed evidence of activation but are highly heterogeneous, expressing both M1 (CD11a, Ly6C, CD40) & M2 (CD206, Mac2, ITGβ5) markers, suggesting that either glomerular Mφs have dual functions or that the established markers are poor discriminators of function. A minority (25%) specifically express the reparative function marker Gpnmb, and the expression of FcγRs is also heterogeneous.

Conclusions: This study indicates a key and predominately deleterious role for Mφ in the progression of kidney injury in MPGN. Glomerular Mφ activation is universal and the majority express markers of M1 & M2 functions but a minority of glomerular Mφ express markers suggestive of reparative functions.

SA-PO2338

Lymphocyte Connective Tissue Growth Factor Mediates Cryoglobulin Production and Induces Cryoglobulinaemic Glomerulonephritis Alan D. Salama,[2] H. Terence Cook,[1] Charles D. Pusey,[1] Ruth M. Tarzi,[1] Ruth J. Pepper,[2] Nadia Wahab,[1] Roger M. Mason,[1] Maria Fragiadaki.[1] *[1]Renal Section, Imperial College London, London, United Kingdom; [2]UCL Centre for Nephrology, Royal Free Hospital, London, United Kingdom.*

Background: Cryoglobulins are immunoglobulins that precipitate at temperatures below 37 degrees and may be idiopathic, termed mixed essential cryoglobulinaemia (MEC) or associated with haematological malignancies and hepatitis C. Cryoglobulins stimulate small vessel vasculitis and renal involvement with mesangiocapillary glomerulonephritis. However, the aetiology of cryoglobulinaemia remains poorly defined and in viral associated cases therapy is often restricted by potential viral replication.

Methods: We have investigated the role of connective tissue growth factor(CTGF, CCN2)a pleiotropic growth factor upregulated in hepatocytes following hepatitis C infection and in lymphocytes during certain haematological malignancies.

We investigated CTGF expression in lymphocytes from patients with MEC, its effect on immunoglobulin production and the impact of lymphocyte overexpression of CTGF in a murine model.

Results: CTGF was significantly elevated in the serum and peripheral blood mononuclear cells (PBMC) of patients with MEC compared to controls (p=0.016). Addition of CTGF to lymphocytes stimulated lymphocyte proliferation, immunoglobulin G and M production and induced cryoglobulins. Patient's PBMC expressed altered CTGF mRNA moieties compared to controls, with excess exon 1 and 2 expression. 75% of mice that overexpressed CTGF in lymphoid cells developed a time-dependent cryoglobulinaemic glomerulonephritis, manifesting from 7 months. Bone marrow transfer from CTGF transgenic mice into irradiated wild type recipients confirmed that glomerulonephritis was transferable by haemopoetic cells.

Conclusions: Lymphocyte expression of CTGF is a critical requirement for cryoglobulin production in human cells in vitro and in an in vivo murine model which results in cryoglobulinaemic glomerulonephritis. Targeting CTGF may provide a rational non-immunosuppressive therapeutic approach for treating cryoglobulinaemia, which is most appealing in those cases associated with viral infections.

SA-PO2339

Immunostaining of Urinary Sediments for Claudin1, Neutrophil Elastase and CD68 for the Evaluation of Disease Activity of Glomerulonephritis Kojiro Yamamoto,[1] Takashi Oda,[1] Takahiro Uchida,[1] Atsushi Watanabe,[1] Taketoshi Kushiyama,[1] Keishi Higashi,[1] Naoki Oshima,[1] Yutaka Sakurai,[2] Soichiro Miura,[1] Hiroo Kumagai.[1] *[1]Department of Nephrology, National Defense Medical Collage, Tokorozawa, Saitama, Japan; [2]Department of Preventive Medicine and Public Health, National Defense Medical Collage, Tokorozawa, Saitama, Japan.*

Background: Urinary sediments of the patients who underwent kidney biopsy in our hospital were immunocytochemically analyzed in relation to renal histology.

Methods: We collected morning urine samples from 196 patients hospitalized for kidney biopsy from 2008 to 2011. Sediments of their urine were deposited onto the slide,

and indirect immunofluorescent staining was performed with anti-neutrophil elastase (NE) (neutrophil), CD68 (MØ), CD3 (T cell), synaptopodin (podocyte), cytokeratin (tubular epithelial cell), and claudin1 (CL1). CL1 is one of the tight junction proteins that are specifically expressed on epithelial cells of Bowman's capsule. The relationship between the positive cell number for various markers and the crescent formation rate (<30%: low, >30%: high) or global sclerosis rate (<10%: low, >10%: high) was evaluated.

Results: The numbers of CL1+ and NE+ cells were significantly increased in those patients with high crescent formation (p=0.04 and 0.001, respectively). However, no significant differences in CL1+ or NE+ cells were found in relation to the global sclerosis rate. We also evaluated the data from the state of crescents (cellular, fibro-cellular, fibrous, or no crescent). The numbers of CL1+ and NE+ cells were significantly increased in the patients with cellular crescent but was unchanged in those with fibro-cellular or fibrous crescents. The number of CD68+ cells was significantly increased in patients with cellular and fibro-cellular crescents but was unchanged in those with fibrous crescents. No other markers showed any significant difference in relation to crescent formation rate, glomerular sclerosis rate or state of crescents.

Conclusions: These data suggest that the immunostaining for CL1, NE and CD68 of urinary sediment is useful for the evaluation of glomerulonephritis, which may help for the decision of steroid and immunosuppressants.

SA-PO2340

Histopathological Classification of Primary Renal Vasculitis: What's New? Ana Pinho,[1] Ana Cabrita,[1] Anabela Malho,[1] André Fragoso,[1] Sandra Sampaio,[1] Elsa Morgado,[1] Ana Paula Silva,[1] Isabel Pinto,[1] Idalecio Bernardo,[1] Pedro Neves,[1] Helena Carreira.[2] *[1]Nephrology Department, Faro Hospital, Faro, Portugal; [2]Public Health Institute of Oporto Universtity, Oporto.*

Background: Current histopathological classifications for renal vasculitis are not consensual. A new classification for ANCA-associated glomerulonephritis based on chronic damage extension has been recently described (focal, crescentic, mixed and sclerotic). Our aim was to determine the predictive value for renal outcome according to chronic and active glomeruli damage extension observed on kidney biopsy samples from patients with primary vasculitis.

Methods: We performed a 25 years retrospective study of 66 patients (56% female) with clinical vasculitis (45 had Systemic Lupus Erythematosus and 21 had ANCA-associated glomerulonephritis). Demographic and laboratory data were recorded at the time of biopsy. Biopsy samples were classified as active (≥33% glomeruli combining cellular proliferation, leukocyte infiltration or fibrinoid necrosis-G1); sclerotic (≥33% sclerotic glomeruli-G2); mixed (≥33% combining crescentic and sclerotic glomeruli- G3); crescentic (≥33% glomeruli with cellular crescents-G4) and as focal (≥66% not affected glomeruli-G5). Survival analysis was used to assess differences in renal outcomes according to pathologic groups.

Results: The median of observed glomeruli was 10(49.3% of samples). At 5 years follow-up, the actuarial renal survival was 64.8% in G1, 55.6% in G2, 66.7% in G3, 36.4% in G4 and 93.5% in G5. The Cox regression revealed that hemoglobin (Hazard Ratio(HR)=0.70;p=0.004) and serum creatinine levels (HR=1.22; p=0.046) had a statistically significant effect on renal survival. Compared to G5, the HR for G1 was 5.3 fold higher (p=0.012) and the overall G2, G3 and G4 HR was 4.5 fold higher (p=0.006) .The type of vasculitis had no influence in this Cox model.

Conclusions: Extension damage in excess of one third on renal histologic analysis, in patients with primary vasculitis, emerged as an independent risk factor for progression to renal failure.

SA-PO2341

Misdiagnosed Cases of C3 Glomerulopathy among Children with Post Infectious Glomerulonephritis Badria M. AlGhaithi,[1] Paul S. Thorner,[2,3] Christoph Licht.[1,3] *[1]Nephrology, The Hospital for Sick Children; [2]Pathology, The Hospital for Sick Children; [3]U of Toronto.*

Background: C3 glomerulopathy (C3G) is a disease entity that has been recently introduced. C3G has been linked to dysregulation of the alternative complement pathway, and is characterized by isolated C3 glomerular deposits in the absence of immunoglobulins (Ig). There are a number of diseases that together with C3G form a phenotypic spectrum including dense deposit disease (DDD), atypical hemolytic uremic syndrome, and more recently, CFHR5 nephropathy. Clinically, C3G varies from mild degrees of hematuria, proteinuria, and renal impairment to end stage renal disease. We postulate that cases of C3G have been misrepresented in the past, possibly as post infectious glomerulonephritis (PIGN).

Methods: Based on this rationale, 33 patients who clinically presented with PIGN at our center from 1985 to 2010 having undergone renal biopsy were retrospectively reviewed for possible re-classification. Clinical characteristics including renal function, complements, urine profile and blood pressure data was captured from first presentation to last available follow up, which ranged from one month to 10 years.

Results: Serum C3 was low for all patients at first presentation. From re-review of the original renal biopsies, 25 patients (76%) were confirmed as PIGN based on the presence of subepithelial hump-like deposits and C3 depositions with or without Ig. Four patients (12%) were categorized as 'possible C3G' based on the absence of subepithelial humps in the presence of C3 but with Ig, while two (6%) had 'probable C3G' based on the presence of C3 only without subepithelial humps. Two patients (6%) demonstrated intermediate features suggesting both DDD and C3G. Five cases in the 'probable' and 'possible' C3G categories had a mild disease course initially resembling PIGN, however due to persistent low C3 and mild proteinuria, a renal biopsy was performed. Of these, 67% (4/6) continued to have proteinuria at last follow-up.

Conclusions: These results support our hypothesis that cases of C3G may have been categorized in the past as PIGN. Genetic testing for complement pathway abnormalities is warranted to further support this hypothesis.

SA-PO2342

Eculizumab as Life Saving Treatment in Complement Mediated MPGN Seetha Radhakrishnan, Fred G. Pluthero, Christoph Licht. *Division of Nephrology, The Hospital for Sick Children, Toronto, ON, Canada.*

Background: Membranoproliferative glomerulonephritis (MPGN) is a rare glomerulopathy with risk of progression to ESRD and post transplant recurrence. Pathogenetically, there is increasing evidence for dysregulation of the alternative complement pathway (AP). Eculizumab is a monoclonal C5 antibody that prevents terminal complement pathway activation. We present a treatment resistant case of MPGN where eculizumab served as an organ and life sustaining measure.

Methods: A 16 year old healthy female presented with nephrotic range proteinuria, peripheral edema and anemia (LDH and haptoglobin normal; occasional schistocytes). Renal biopsy showed mesangial interposition, wire loops, subendothelial and mesangial deposits and full house IF. In light of negative ANA and dsDNA a diagnosis of MPGN I was made and treatment with steroids and MMF commenced.

At 8 weeks, work up for fever and pancytopenia revealed group A strep, pseudomonas bacteremia, and CMV viremia, which was treated. Bone marrow showed signs of possible macrophage activation syndrome. MMF was held, steroid pulses and IVIG x3 were provided. Patient had persistent thrombocytopenia and anemia, increasing creatinine, and anuria eventually requiring hemodialysis (HD). Complement analysis revealed strong AP activation (undetectable C3; high C5b-9; low CH50; positive C3NeF). While no complement mutation was found, CFHR1/3 was absent on western blot. CFH antibodies were not detected.

Results: To regain complement control, plasma therapy (infusion x5 followed by pheresis x7) was commenced. While there was subtle treatment response (improvement in creatinine and C3) anuria persisted and clinical status deteriorated with respiratory compromise, GI bleeding and seizures. With eculizumab (900 mg/wk x4), treatment response was dramatic: following 1st dose neurologic complications ceased, urine output normalized and HD was discontinued. Thrombocytopenia and anemia recovered after 2nd dose.

Conclusions: Recovery of this patient from life threatening conditions in response to eculizumab strongly suggests (i) a role for AP dysregulation in MPGN pathogenesis and (ii) future AP controlling treatment strategies for MPGN – a remarkable breakthrough for this condition.

SA-PO2343

Platelets Serve as Source of Complement Factor H (CFH) Activity in a Modified Fluid-Phase Alternative Complement Pathway Cofactor Activity Assay Jiawei Zhao, Fred G. Pluthero, Antony Jeganathan, Christoph Licht. *Division of Nephrology, The Hospital for Sick Children, Toronto, ON, Canada.*

Background: We have recently shown that that the alternative complement pathway regulator complement factor H (CFH) is present in a non-granular compartment in human blood platelets and that platelets are capable of taking up and releasing CFH (Licht et al, Blood 2009). The physiological role of platelet CFH remains to be determined, given the high concentrations of this protein (up to 600 μg/ml) normally present in plasma.

Methods: In order to assess the potential physiological relevance of platelet CFH, washed normal platelets were used as the sole source of CFH in a modified fluid-phase alternative complement pathway cofactor activity assay. This assay allows for testing the potential of a protein to serve as cofactor to complement factor I (CFI) in cleaving C3b, the active form of complement C3, by observing the appearance of C3b cleavage products.

Results: Varying platelet concentrations ranging from 600 to 30/nL were incubated with 2 μg/mL C3b and 6 μg/mL CFI at 37°C for 60 min, and supernatants assayed via immunoblotting for the presence of C3b cleavage products. CFH cofactor activity was observed to increase with platelet concentration, while platelets remained in a resting state. A time course analysis with a platelet concentration of 300/nL (within the normal range of blood platelet concentration) gave results similar to those observed with plasma and purified CFH.

Conclusions: These results show that like endothelial cells, platelets can serve as a cellular source of CFH cofactor activity *in vitro*. This provides support for the emerging hypothesis that in addition to their established roles in the blood coagulation, inflammatory and immune systems, platelets may actively participate in the regulation of the complement system, particularly the constitutively-active alternative pathway that is involved in several complement-related diseases.

The Podocyte Is the Initial Target in the Renal Pathogenesis of Diarrhoea-Associated Haemolytic Uraemic Syndrome Lindsay S. Keir,[1] Gavin Iain Welsh,[1] Richard Coward,[1] Anna Richards,[2] Robert A. Spooner,[3] Moin Saleem.[1] *[1]Academic Renal Unit, University of Bristol, Bristol, United Kingdom; [2]Centre for Inflammation Research, Queens Medical Research Institute, Edinburgh, United Kingdom; [3]School of Life Sciences, University of Warwick, Coventry, United Kingdom.*

Background: D+HUS is the leading cause of pediatric acute renal failure. It occurs after infection by shigatoxin (stx) producing bacteria. Stx binds Gb3 cellular receptors. It was considered an endothelial disease until the report of an inducible podocyte-specific VEGF-A knockdown mouse that developed glomerular thrombotic microangiopathy- the hallmark of HUS. Furthermore, familial HUS is caused by dysregulation of the alternative complement pathway with mutations identified in complement regulators. Eculizumab, a drug that blocks the complement cascade, is being trialed in atypical HUS and used experimentally in D+HUS. We hypothesize that podocytes, VEGF-A and complement regulators play a co-ordinated role in the renal pathogenesis of D+HUS.

Methods: Immunofluorescence of human and mouse immortalized glomerular cell lines detected Gb3. Cellular stx1 sensitivity was determined using a radio-labeled protein synthesis assay. An ELISA measured VEGF-A produced by stx treated podocytes. Human cells were treated with VEGF-A and western blotting determined complement regulator expression. A factor H re-synthesis assay was devised to remove bound factor H. Cells were fixed or treated with serum free media +/- VEGF-A. Factor H was detected by immunofluorescence.

Results: Human glomerular cells express Gb3 and are stx1 sensitive. Human podocytes are more sensitive than endothelial cells. Mouse podocytes lack Gb3 and are stx1 insensitive. Stx stimulation of human, but not mouse, podocytes reduced VEGF-A production. VEGF-A up regulates human glomerular cells complement regulator expression. Both glomerular cells synthesize factor H in vitro and VEGF-A regulates this effect.

Conclusions: Podocytes are a sensitive stx1 target. Reduced podocyte VEGF-A down-regulates complement regulator expression and production in the glomerular endothelium, making it vulnerable to attack. This is further evidence indicating a central role for the podocyte in D+HUS.

Small Molecule Disruptors of Interactions between Protein Kinase A and A-kinase Anchoring Proteins Inhibit AVP-Mediated water Reabsorption – Implications for Treatment of Cardiovascular Diseases Kerstin Zuehlke,[1,2] Jelena Milic,[1] Walter Rosenthal,[2] Enno Klussmann.[2] *[1]Department of Signal Transduction, Leibniz Institute for Molecular Pharmacology (FMP), Berlin, Germany; [2]Anchored Signalling, Max Delbrück Center for Molecular Medicine (MDC, Berlin, Germany.*

Background: Stimulation of the vasopressin V2 receptor by Arginine-vasopressin (AVP) is followed by an increase in cAMP and activation of protein kinase A (PKA). PKA phosphorylates the water channel aquaporin-2 (AQP2). This leads to a redistribution of AQP2 into the plasma membrane and facilitates water reabsorption from primary urine, depending on interaction of PKA with A-kinase anchoring proteins (AKAPs), which position PKA at defined cellular sites and thereby coordinate PKA signaling.

Methods: 20,064 drug-like small molecules were screened among others using surface plasmon resonance (SPR) measurements.

Live cells are incubated with compound of interest and AKAP150 was immunoprecipitated. Co-precipitated PKA was determined using the PepTag-Assay (fluorescent peptide substrate).

PKA-dependent phosphorylation of substrate proteins was measured in vivo by Western blotting.

The effects of small molecules on the development of SIADH and chronic heart failure were investigated using immunohistochemical and echocardiographic methods.

Results: Elevated secretion of AVP as it occurs in the syndrome of inappropriate secretion of antidiuretic hormone (SIADH) is the most frequent cause of hyponatremia. Moreover, elevated levels of AVP are associated with chronic heart failure. In both SIADH and chronic heart failure the elevated AVP levels cause a predominant localization of AQP2 in the plasma membrane and lead to excessive water retention. Here we present small molecules disrupting AKAP-PKA interactions in renal principal cells in culture and in animal models. The molecules prevent the AVP-induced redistribution of AQP2 suggesting that AKAP-PKA interactions are novel drug target for the treatment of diseases associated with exessive water.

Conclusions: Small molecules interrupting AKAP-PKA interactions may pave the way to new strategies for the treatment of diseases associated with excessive water, such as SIADH and chronic heart failure.

Differential Polarity of AQP2 Membrane Insertion by Vasopressin and Forskolin in a 3D MDCK Cyst Culture Model – Role of cAMP Levels William Rice, Hua Ann Jenny Lu, Dennis Brown. *Program in Membrane Biology, Massachusetts General Hospital and Harvard Medical School, Boston, MA.*

Background: In renal collecting duct principal cells Vasopressin (VP) acts through its receptor, V2R, to increase intracellular cAMP leading to the activation of PKA and subsequent phosphorylation and apical trafficking of the water channel Aquaporin 2 (AQP2). Recent studies have shown that VP modulates the phosphorylation of the AQP2 C-terminal serines, S256, S261, S264, S269 and have demonstrated that phosphorylation at S256 by PKA is the dominant signal for trafficking of AQP2 from intracellular vesicles to the apical membrane. However, the roles of the other C-terminal serines have yet to be determined.

Methods: In this study, we used AQP2 phosphorylation specific antibodies to visualize the intracellular location of phospho- AQP2 in an in vitro MDCK 3D cyst model.

Results: We found that the cyst model is well polarized, with tissue architecture that resembles that of the collecting duct in animals. As observed in vivo and in tissue slice cultures, VP, low dose forskolin (0.1μM) or (<5μM) CTP-cAMP stimulation led to apical localization of total AQP2, AQP2- pS256, pS264 and pS269. Inhibition of PKA by H89 or mPKI blocked translocation of AQP2 to the apical membrane as well as the phosphorylation at S269. Interestingly, high dose FK (50μM) or CTP-cAMP (50μM), but not VP (1μM) led to strong basolateral localization of total AQP2, AQP2-pS256 and pS269. As VP stimulation of cAMP levels is limited by V2R signaling, these data suggest that the differential polarity of AQP2 insertion is mediated by the intracellular level of cAMP.

Conclusions: This study describes the successful use of phosphorylation specific AQP2 antibodies to visualize the intracellular location of specific phosphorylation isoforms of AQP2 in an in vitro culture system. This 3D culture system will enable efficient screening of conditions that modulate AQP2 trafficking and serve as a tool for elucidating the role of AQP2 phosphorylation at each of the C-terminal serines. The relevance of our findings to the observed segment-specific apical and/or basolateral insertion of AQP2 in vivo is now under investigation.

SA-PO2347

Endothelial Aquaporin-1 Water Channels Are Positively Regulated by Protein Kinase C and Glucose-Degradation Products Wei Zhang, Sandra Muller-Krebs, Martin G. Zeier, Vedat Schwenger. *Dept. of Nephrology, University of Heidelberg, Germany.*

Background: Aquaporin-1(AQP1) is expressed widely in microvascular endothelia including the peritoneum. AQP1, a so-called water-specific “ultrasmall pore” in the peritoneal membrane, plays a key role for ultrafiltration (UF) in peritoneal dialysis (PD).

Little has been known for the functional AQP1 regulation in endothelia. Our previous findings demonstrated that AQP1 expressed in Xenopus oocytes is strongly regulated by protein kinase C (PKC). Additionally, it was found that glucose degradation products (GDPs) generated during heat sterilization in dialysis fluids involve the activation of PKC. The aim of the study is to investigate the molecular mechanisms of the regulation of AQP1 by PKC and GDPs in endothelial cells.

Methods: AQP1 expression in HUVEC cells was studied with rt-PCR and immunocytochemistry. AQP1-regulated water permeability in Xenopus oocytes and HUVECs was measured through microscopic recordings of hypo-osmotic challenges and digital volume quantification.

Results: Aquaporin-1 is highly expressed in HUVEC cells and can be knocked down effectively with a siRNA-approach. Water permeability of HUVEC cells is strongly increased after pharmacologic activation of PKC. This effect is completely abolished after either co-application of PKC inhibitors or knock-down of AQP1.

The water permeability both in oocytes and HUVECs is markedly increased by GDPs (methylglyoxal or 3.4-dideoxyglucosone-3-ene). This effect is completely blocked in AQP1ΔPKC channels lacking PKC phosphorylation sites in oocytes, and not present in HUVECs transfected with AQP1-siRNA.

Conclusions: This is the first study to show that in endothelial cells PKC positively regulates the AQP1-mediated water permeability, and that GDPs modulate the AQP1-related water permeability via PKC. These findings may contribute insights about AQP1-mediated endothelial permeability, as well as provide new clues for AQP1 modulation in the peritoneal membrane during PD.

SA-PO2348

Regulation of ENaC by Phosphoinositide 3-Kinase and AMP-Activated Protein Kinase: Studies with Resveratrol John P. Johnson,[1] Kelly Weixel,[2] Kenneth R. Hallows,[1] Allison L. Marciszyn,[1] Robert S. Edinger.[1] *[1]Renal-Electrolyte Division, University of Pittsburgh School of Medicine, PA; [2]Biology, Chatham University, Pittsburgh, PA.*

Background: Several studies indicate the multiple effects of resveratrol on cellular function are due to its inhibition of class 1A phosphoinositide 3-kinase (PI3K) mediated signaling pathways but it also activates (AMPK). Sodium transport in the kidney via the Epithelial Na+ Channel (ENaC) is highly sensitive to changes in phosphoinositide signaling

in the membrane and AMPK. Therefore we employed resveratrol to probe the relative effects of phosphatidylinositol species in the plasma membrane and AMPK activity and their impact on ENaC activity in a native cell culture model.

Methods: A combination of biophysical and biochemical assays were used to identify the effect of resveratrol on ENaC activity in CCD cells. Knockdown of AMPK and inhibitor studies were used to confirm the function of AMPK in mediating the effects of resveratrol on ENaC. In addition, live cell microscopy techniques were used to assess the time course and acute effects of resveratrol on phosphatidylinositol species in the plasma membrane of mpkCCDc14.

Results: We found that resveratrol acutely reduces amiloride-sensitive current in CCD cells. The time course and dose dependency of this inhibition paralleled plasma membrane depletion of a PI(3,4,5)P3 reporter in live-cell microscopy, indicating that this early inhibitory process is likely mediated by resveratrol's known effects on PI3K activity. Additionally, resveratrol induced a late inhibitory effect (3-24 hr) that appears to be mediated via AMPK activation. Resveratrol induces a significant activation of AMPK compared with vehicle controls after 3 hours which persisted through 24 hours. Knockdown of AMPK or treatment with the AMPK inhibitor, Compound C,reduced the late inhibition of ENaC but had no effect on the early inhibitory response to resveratrol.

Conclusions: Collectively, these data demonstrate that resveratrol inhibits ENaC activity by two mechanisms: an early effect seen within 5 minutes related to depletion of membrane PIP3, and a sustained late (3-18 hour) effect secondary to activation of AMPK.

Purinergic Cascade Contributes to the Activation of Ca^{2+}-Permeable TRPV4 Channels by Mechanical Forces in the Aldosterone-Sensitive Distal Nephron Mykola Mamenko, Oleg L. Zaika, Roger G. O'Neil, Oleh Pochynyuk. *Integrative Biology and Pharmacology, University of Texas Health Science Center at Houston, Medical School, Houston, TX.*

Background: Epithelial cells in the aldosterone-sensitive distal nephron (ASDN) respond to changes in flow/composition of the ultrafiltrate by elevating $[Ca^{2+}]_i$. It is thought that this is critical for adaptation of water-electrolyte transport at this site. At the same time, environmental changes are known to trigger paracrine ATP release in the ASDN.

Methods: In this study, we probed a role for purinergic signaling in mediating mechano-sensitive responses by directly monitoring changes in $[Ca^{2+}]_i$ in individual cells within split-opened ASDN of mice.

Results: Purinergic stimulation caused a similar transient Ca^{2+} peak followed by a sustained plateau in both principal and intercalated cells. Genetic deletion of P2Y2 receptors compromised purinergic signaling and, importantly, attenuated Ca^{2+}-responses to hypotonic media and elevated flow. Furthermore, we show here that activation of mechano-sensitive TRPV4 channel plays a major role in the sustained $[Ca^{2+}]_i$ elevation during purinergic stimulation. Genetic deletion of TRPV4 channel disrupted ATP-induced Ca^{2+}-plateau.

Conclusions: We concluded that paracrine release of ATP in response to mechanical stimulations reciprocally modulates cellular responses by activating mechano-sensitive TRPV4 channel in ASDN cells.

Identification of CNK3 as an Important Component of the Aldosterone-Controlled ENaC Regulatory Complex Rama Soundararajan, Tim Ziera, Jian Wang, David Pearce. *Medicine (Nephrology), University of California San Francisco, San Francisco, CA.*

Background: Members of the Connector Enhancer of KSR (CNK) family of proteins possess multiple protein interaction domains, and have been proposed to function as scaffolds possibly assisting various interactions in a multiple signaling cascade. Mammalian CNK3 is an aldosterone-induced protein that is essential for the activity of the epithelial sodium channel (ENaC). In the present study, we examine its role in ENaC stimulation.

Methods: We used biotinylation assays in transiently transfected HEK293T kidney epithelial cells to study the effect of CNK3 on ENaC surface expression. We also used these cells to test protein-protein interactions in co-immunoprecipitation assays. We used polarized mpkCCD kidney epithelial cells grown on Transwell filters to study effects on ENaC activity.

Results: We show that CNK3 is associated with ENaC at the cell surface and that it interacts with the components of the previously described ENaC regulatory complex (ERC). The PDZ domain in CNK3 appears to be crucial for its association with SGK1 and GILZ1, and for its stimulation of ENaC cell surface expression in HEK293T cells. We further demonstrate that the PDZ domain in CNK3 is required for aldosterone-controlled ENaC-mediated Na+ transport in mpkCCD cells.

Conclusions: These results strongly suggest that CNK3 is essential for the proper assembly of ENaC-regulatory factors thus facilitating appropriate aldosterone signaling to stimulate Na+ reabsorption via ENaC (Funding Sources: NIH Grants DK078679, DK056695 and DK085101).

SA-PO2351

Oxidative Stress in Regulation of Renal Na/K-ATPase Signaling and Distribution Yanling Yan,[1] Deepak K. Malhotra,[1] Zi-Jian Xie,[2,1] Nader Abraham,[2] Joseph I. Shapiro,[1,2] Jiang Liu.[1] *[1]Medicine, University of Toledo College of Medicine, OH; [2]Pharmacology and Physiology, University of Toledo College of Medicine, OH.*

Background: In Dahl salt-resistant (R) and -sensitive (S) rats, we found that impaired renal proximal tubular Na/K-ATPase/c-Src signaling contributes to salt-sensitive hypertension, but the underlying mechanism is not clear. Interestingly, the S rats have significantly higher heme oxygenase-1 (HO-1) expression level, both before and after high salt diet (2% NaCl for 7 days, compared to 0.3% NaCl), than the R rats in renal proximal tubules (n=8 per group per strain, $p<0.01$). We investigated the role of oxidative stress in regulation of renal proximal tubular Na/K-ATPase signaling and distribution.

Methods: c-Src phosphorylation, cellular fractionation.

Results: In pig LLC-PK1 cells, ouabain stimulated c-Src activation, ROS generation, protein carbonylation,and Na/K-ATPase endocytosis. These ouabain effects were significantly attenuated by pretreatment with ROS-scavenging NAC. Increases in oxidative stress by glucose oxidase (GO, 1 and 3mU/ml) also activated c-Src and stimulated Na/K-ATPase endocytosis in LLC-PK1 cells. Induction of HO-1 by CoPP or knockdown of Na/K-ATPase α1 subunit by siRNA significantly attenuated ouabain-induced c-Src activation. These data suggest that Na/K-ATPase is required in ouabain-induced ROS generation and this increase in ROS is a downstream effector of Na/K-ATPase/c-Src that is critical in ouabain-induced Na/K-ATPase endocytosis. The data also suggest that oxidative stress may affect Na/K-ATPase/c-Src signaling and redistribution.

Considering that HO-1 is one of the most potent antioxidant enzyme, we further speculate that the HO-1 is capable of neutralizing high salt diet- and/or ouabain-stimulated elevation of ROS in the S rats, either as a stimulator or as a downstream effector of Na/K-ATPase/c-Src signaling. This leads to the impairment of Na/K-ATPase/c-Src signaling and redistribution of the Na/K-ATPase and NHE3 in the S rats, thus the salt-sensitive hypertension.

Conclusions: Oxidative stress, including ouabain-induced ROS generation, is capable of regulating Na/K-ATPase/c-Src signaling and redistribution.

SA-PO2352

AS160: A New Na,K-ATPase Partner That Regulates the Trafficking of the Sodium Pump in Response to Energy Depletion Daiane Santana Alves,[1] Glen A. Farr,[1] Michael Kashgarian,[1] Johannes Loffing,[2] Michael J. Caplan.[1] *[1]Molecular and Cellular Physiology, Yale University, New Haven, CT; [2]Institute of Anatomy, University of Zurich, Switzerland.*

Background: The Na,K-ATPase is the major active transport protein found in the plasma membranes of most epithelial cell types. The Na,K-ATPase appears to be located in two different cellular pools. The major sodium pump pool is located at the plasma membrane, while the other pool resides in cytoplasmic vesicular compartments which can translocate to the plasma membrane in response to physiological stimuli. We have identified AS160 as a new Na,K-ATPase partner. AS160 is a Rab GAP that regulates the trafficking of the GLUT4 and the ENaC in response to insulin/muscle contraction and aldosterone, respectively.

Methods: We characterized the interaction between AS160 and Na,K-ATPase by co-immunoprecipitation and co-localization assays. We characterized the physiological role of the AS160 interaction with sodium pump by using RNAi techniques to knockdown AS160 expression in cultured MDCK renal epithelial cells. Finally, we examined the regulation of this interaction in mice subjected to renal ischemia followed by reperfusion.

Results: In COS cells, coexpression of AS160 and Na,K-ATPase led to the intracellular retention of the sodium pump, suggesting that AS160 may participate in mediating the accumulation of an intracellular pool of Na,K-ATPase. We also demonstrated that knockdown of AS160 increased the total cellular levels of Na,K-ATPase activity, suggesting that AS160 modulates the size of the active pool of the pump. We characterized the physiological role of the interaction between AS160 and Na,K-ATPase. We found that AS160 is required for the intracellular accumulation of the Na,K-ATPase following energy depletion in cultured epithelial cells. Finally, we performed in vivo experiments that suggest that the phosphorylation state of AS160 correlates with the subcellular distribution of the Na,K-ATPase following renal ischemia and reperfusion.

Conclusions: We conclude that AS160 is a new sodium pump partner that regulates Na,K-ATPase retention in the cytoplasm and its trafficking to the plasma membrane following energy depletion.

SA-PO2353

Coordinated Action by Tsg101 and USP2-45 in the Negative Feedback Loop of the Mineralocorticoid Receptor Olivier Staub, Nourdine Faresse. *University of Lausanne.*

Background: In order to avoid prolonged response and consequently tissue damages, desensitization mechanisms often take place in order to downregulate stimulated pathways. In the context of aldosterone/mineralocorticoid receptor (MR) signalling, it was shown that prolonged exposure to aldosterone decreased MR expression via the proteasome, but the mechanisms of this feedback regulation remain unclear. We were interested into pathways involving MR signalling termination in response to aldosterone.

Methods: These questions were studied either in transfected M1 or in mCCD cells by applying immunoprecipitations, immunoblotting, luciferase assays and measurements of transepithelial Na transport.

Results: We first observed that MR was ubiquitylated at the basal state and that this modification was removed after aldosterone treatment. As for other nuclear receptor, we found that MR interacted with Tsg101 at the basal state and this association was disrupted after aldosterone treatment. We found that Tsg101 can stabilize MR probably by maintaining its ubiquitylation. Because USP2-45 is an aldosterone induced deubiquitylating enzyme, we wondered if USP2-45 was involved in the deubiquitylation of the receptor. We found that USP2-45 interacted with MR, removed its ubiquitylation and decreased its expression via the proteasome.

Our data imply a mechanism in which MR is ubiquitylated at the basal state and protected by Tsg101. Aldosterone treatment stimulates USP2-45 expression, which interacts with MR and deubiquitylates the receptor. The removal of the ubiquitin destabilizes the MR/Tsg101 interaction and induces MR degradation via the proteasome by a so far unknown mechanism.

Conclusions: These results reveal the existence of a functional network involving USP2-45 and Tsg101 into a negative feedback loop of the MR pathway that mediates the degradation of MR in response to aldosterone.

Funding: Government Support - Non-U.S.

SA-PO2354

Sensory Renal Innervation: Does a Kidney-Specific Expression Pattern of Voltage-Activated Sodium Channels Lead to a Specific Firing Activity and Higher Excitability? Wolfgang Freisinger, Tilmann Ditting, Sonja Heinlein, Johannes Schatz, Roland Veelken. *Medical Clinic 4, Nephrology and Hypertension, Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany.*

Background: Thermal ablation of renal innervation has been effective in trating hypertensive patients. However, especially afferent renalinnervation is poorly understood. We recently found that renal afferent neurons exhibited predominantly tonic firing patterns, i.e. sustained action potential (AP) firing throughout depolarizing current injection (DCI), pointing to a higher excitability. Non-renal neurons responded mostly with a phasic response, i.e. <4 APs. We now tested the hypothesis that different voltage-gated sodium-channels, which initiate the action potential generation, are responsible for these differences.

Methods: Dorsal root ganglion neurons from Sprague Dawley rats (Th11-L2) were recorded in current clamp technique and characterized as tonic or phasic according to their response to DCI. Then, single cells were switched to voltage-clamp, potassium and calcium channel blockers were added to the external solution. The application of the sodium channel blocker Tetrodotoxin (TTX) then allowed to further characterize voltage-gated sodium currents.

Results: 66 DRG neurons were investigated (n=40 phasic, n=26 tonic). Tonically firing cells showed significantly a lower firing threshold (-21,75 ± 1,43 mV vs.-29,33 ± 1,63 mV*), a lower overshoot (46,79 mV [38,63 - 54,75] vs. 56,74 mV [53,6 – 60,96]) and longer action potential duration (4,61 ms[4,15 – 5,85] vs. 3,35 ms[2,12 – 5,67]). Tonic cells showed a significantly smaller fraction of TTX-sensitive Na+- currents (60,45 ± 12,94pA/pF vs. 140,44 ± 30,88pA/pF), whereas activation did not reveal a significant change (*p<0,05).

Conclusions: We could show for the first time that a smaller TTX-sensitive channel expression is very likely linked to electrophysiological differences observed between renal versus non-renal petidergic afferent nerve fibers. This finding points to an organ-specific expression pattern of sodium channels concerning renal innervation. Sodium channel expression and consequently excitability is likely to be altered in hypertension and inflammation.

SA-PO2355

Identification of Two Novel Renal Olfactory Receptors Ryan J. Protzko, Jennifer L. Pluznick. *Physiology, Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: ORs are chemosensory GPCRs which comprise the largest gene family in the mammalian genome. We previously found that the OR signaling pathway plays a functional role in the kidney (Pluznick, PNAS 2009) and identified six renal ORs. In this study, we identify two additional novel renal ORs and examine their tissue distribution and ligand specificity.

Methods: An RT-PCR screen using primers to ORs with known or predicted ligands was performed on murine kidney cDNA. Primers for ORs found in kidney were also tested on cortex, medulla, and 8 non-renal tissue cDNAs. Trafficking to the cell surface was assayed by immunofluorescence (IF); one OR was screened for responses to various ligands using a dual-luciferase ligand screen.

Results: An RT-PCR screen for 27 ORs with known ligands revealed 2 novel renal ORs: Olfr691 (cortex and medulla, 2/8 non-renal tissues) and Olfr545 (medulla, 6/8 non-renal tissues). Olfr691 and Olfr545 were cloned and expressed in HEK293T cells. Because the luciferase ligand screen requires surface expression, surface delivery was assayed by IF. Olfr691 reaches the cell surface when co-expressed with RTP1L (receptor transporting protein 1, long); Olfr545 does not reach the cell surface under any condition tested. Olfr691 was reported to respond to valeric and isovaleric acid (Saito, Cell 2004); we screened Olfr691 for responses to chemically related compounds, and also performed an unbiased screen against a chemical library. Olfr691 responds only to short and medium chain fatty acids (FAs; C3-8, including isomers): chiefly propionoic, isobutryic, butyric, isovaleric and valeric acids.

Conclusions: We have previously shown that the OR signaling pathway plays important functional roles in the kidney. Here, we identify two additional renal ORs. Olfr691, found in the cortex and medulla, responds to short- and medium-chain FAs. The primary biological source of short chain FAs is intestinal bacterial metabolism, indicating that Olfr691 may signal in response to gut flora activity. Further studies will focus on localizing Olfr545 and Olfr691, identifying Olfr545 ligands, and examining the potential roles of these receptors in vivo.

SA-PO2356

Advanced Glycation End-Products, Glomerular Endothelial Cells, Tight junction, Renin Angiotensin System Zengchun Ye, Canming Li, Cheng Wang, Tan-Qi Lou. *Department of Nephrology, Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China.*

Background: To investigate whether advanced glycation end-products (AGEs) influence the permeability and tight junction proteins of cultured rat glomerular endothelial cells (rGEnCs) *in vitro*, and the underlying role of renin angiotensin system activation in this process.

Methods: The GEnCs permeability was detected by measuring the transendothelial electrical resistance and flux of FITC-BSA across the GEnCs monolayers. Angiotensin II was detected by ELISA, and ZO-1, Occludin , Claudin-5 and JAM-A were detected by immunofluorescence and Western blotting.

Results: The results show that AGEs increased the permeability of glomerular endothelial cells monolayers in a concentration- and time-dependent manner. This effect of AGEs was accompanied by a redistribution of tight junction proteins, including ZO-1, occludin, JAM-A and claudin-5, from the cell–cell borders of glomerular endothelial cells. AGEs also down-regulated the expression of the tight junction proteins, occludin, JAM-A and claudin-5. In addition, a significant finding in this study was that AGEs could increase the permeability of rGEnC monolayers by activating the intracellular renin angiotesin system (RAS) in a RAGE–dependent signaling pathway. This was supported by the finding that AGEs were able to stimulate the activity of angiotensin converting enzyme (ACE), and up-regulate the expression of angiotensin II and angiotensin II type 1 receptor (AT1R) in rGEnCs. This activation was blocked by a neutralizing antibody to RAGE, and by pharmacologic inhibitors of RAS.

Conclusions: The results collectively indicate that the induction of increased permeability of rGEnCs by AGEs may be predominantly via a RAGE-angiotensin II-AT1 pathway. This effect on glomerular endothelial cells illustrates a novel action of ACEI/ARB for use in diabetic nephropathy.

SA-PO2357

Diabetic Nephropathy-Associated IHG-1 Is a Novel Regulator of Mitochondrial Fusion Fionnuala B. Hickey, James B. Corcoran, Brenda Griffin, Una Bhreathnach, Catherine Godson, Madeline Murphy. *Conway Institute, University College Dublin, Dublin, Ireland.*

Background: *Induced in high glucose-1* (IHG-1) is a highly conserved, glucose-regulated transcript associated with diabetic kidney disease. In addition, we have detected increased IHG-1 expression in a murine model of renal fibrosis [rat unilateral ureteral obstruction]. A mitochondrial localization sequence is the only predicted functional domain identified in IHG-1. We have confirmed the mitochondrial localization of IHG-1 and further investigated a potential role in mitochondrial dynamics. Mitochondria are plastic organelles that frequently change shape and size and these dynamic fusion and fission events are important for the bioenergetic function of mitochondria.

Methods: The subcellular localization of IHG-1 has been determined by immunofluorescence, electron microscopy and biochemical methods. Mitochondrial morphology has been examined by live cell imaging following labelling of mitochondria with GFP. Mitochondrial fusion/fission was analysed using fluorescence recovery after photobleaching (FRAP) and other live cell imaging techniques. Binding of IHG-1 to mediators of mitochondrial fission and fusion has been examined by co-immunoprecipitation.

Results: IHG-1 is predominantly localised to the mitochondrial matrix and is associated with the inner mitochondrial membrane. To date there is little information on mitochondrial dynamics in kidney. This study demonstrates that inhibition of endogenous IHG-1 expression results in fragmented mitochondrial morphology and leads to decreased mitochondrial fusion. Conversely, overexpression of IHG-1 leads to increased mitochondrial fusion. The effect of IHG-1 on mitochondrial dynamics is dependent on its mitochondrial localization. We have also demonstrated that IHG-1 binds to known mediators of mitochondrial fusion – mitofusin 1(Mfn1) and Mfn2. This provides a possible mechanism of action through which IHG-1 affects mitochondrial dynamics.

Conclusions: Mitochondrial dysfunction is a major contributor to hyperglycemic-induced kidney damage and also has a well documented role in fibrosis. Therefore, IHG-1 may have a critical function in both diabetic nephropathy and other fibrotic conditions.

The Role of Toll-Like Receptor Proteins (TLR) 2/4 in Human Proximal Tubular Cells In Vitro – A Potential Mediator of Diabetic Nephropathy?
Harshini Mudaliar,[1] Katherine Jane Pegg,[1] Steven J. Chadban,[2] Huiling Wu,[2] Carol A. Pollock,[1] Usha Panchapakesan.[1] *[1]Renal Group, Kolling Institute, University of Sydney, Sydney, St Leonards, New South Wales, Australia; [2]Renal Medicine, Royal Prince Alfred Hospital, University of Sydney, Sydney, Camperdown, New South Wales, Australia.*

Background: Inflammatory responses are crucial in the pathogenesis of diabetic nephropathy (DN). TLRs are ligand activated membrane-bound receptors which activate nuclear factor-kappaB (NF-κB). TLR 2/4 are present in proximal tubular cells (PTC) and are activated by ligands pathological in DN (i.e. HMGB1, fibronectin and heat shock proteins). We have previously shown that 30mM glucose increases HMGB1 expression in PTCs. Here, we explored the effect of varying glucose levels and HMGB1 on TLR 2/4 signalling to help understand the inflammatory pathway activation in DN.

Methods: HK2 cells (a human kidney PTC line) were exposed to control (5mM), 30mM glucose, fluctuating glucose (5mM /30mM) and 11.25mM glucose for 72h. Cells were harvested for nuclear extract and protein. TLR2/4 expression and NF-κB binding were measured. The role of HMGB1 in TLR2/4-regulated NF-κB activation was assessed with silencing TLR2/4. The effect of glucose on TLR2/4 expression was examined by restricting glucose uptake with a sodium-glucose co-transporter2 (SGLT2) inhibitor.

Results: TLR2/4 expression and downstream NF-κB binding increased drastically with 11.25mM glucose compared to 30mM glucose and fluctuating glucose. Blocking glucose uptake with an SGLT2 inhibitor prevented any increase in TLR2/4 expression. Recombinant HMGB1 increased NF-κB binding at 2h and this was prevented by TLR2 silencing.

Conclusions: Increase in TLR2/4 expression stimulated by 11.25mM glucose may occur through intracellular hyperglycemia within PTCs as this effect was blocked by SGLT2 inhibitor. NF-κB activation was also induced at high glucose levels, and by recombinant HMGB1, suggesting a role for TLR2/4. Furthermore, TLR2 may function as the predominant receptor in mediating HMGB1-induced NF-κB activation.

Transcription Regulation of Cell Matrix Proteins in Proximal Tubular Cells Treated with High Glucose
Mukesh Yadav,[UTHSCSA] Anamika Yadav,[UTHSCSA] Samy L. Habib.[UTHSCSA] *; [2]Cellular and Structural Biology and Geriatric Research, Education and Clinical Center, South Texas Veterans Healthcare System, University of Texas Health Science Center, San Antonio, TX.*

Background: The rate of deterioration of kidney function correlates best with the degree of tubular fibrosis and accumulation of cell matrix proteins. The mechanisms of renal cell matrix expansion as well as the signal transduction pathways activated in the diabetic milieu are incompletely characterized.

Methods: Phosphorylation of two effector molecules of downstream target of mTOR, p70 ribosomal protein S6 kinase (S6K) and 4E-BP1 was measured in proximal tubular cells treated with high glucose. Cell matrix proteins (Collagen IV and fibronectin) expression was also measured in cells treated with high glucose (25mM) for 0-24hrs. Transcription factors expression of cAMP-responsive element binding protein (CREB) and yin-yang 1 (YY1) was evaluated in cells treated with high glucose.

Results: Exposure of cells to high glucose (0-24hrs) resulted in increase mTOR activity through increasing the phosphorylation 4E-BP1 and p70S6K that lead to increased the protein expression of fibronectin and collagen IV. Pretreatment the cells with rapamycin blocked fibronectin and collagen IV accumulation induced by high glucose at 12 and 24hrs. In addition, blocking mTOR by rapmaycin leads to decreased the expression of CREB that involve in transcription regulation of fibronectin and collagen IV. Our data also show that rapamycin treatment resulted in increase the cytoplasmic expression of YY1 and lead to deceased the accumulation of fibronectin and collagen IV.

Conclusions: Our data show that treatment with rapamycin resulted in decease the phosphorylation of 4E-BP1 and p70S6K and lead to decreased the accumulation of cell matrix proteins through CREB in cells treated with high glucose. These data provide a novel role of TOR inhibitor as therapeutic agent that transcriptionally regulates the cell matrix proteins in diabetes.

mTORC2 Knockdown Slows the Progression of Cysts in Type I MDCK Cells
Kameswaran Ravichandran, Iram Zafar, Zhibin He, Charles L. Edelstein. *Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO.*

Background: mTOR exists in association with two different complexes, mTOR complex 1 (mTORC1) and mTOR complex 2 (mTORC2). mTORC1 consists of mTOR and Raptor while mTORC2 consists of mTOR and Rictor. Recent studies on rapalogues (rapamycin or everolimus) in humans with ADPKD were very unimpressive. While there are multiple reasons for the unimpressive effect of rapalogues in human PKD, one possible reason is that while rapamycin inhibits mTORC1 it does not have an effect on pro-proliferative mTORC2.

Methods: The downstream substrates of mTORC2 (pAktSer^{473}, pPKC-alpha Ser^{657}, pSGK Ser^{422}) were analyzed by immunoblot in 8 wk old Han:SPRD (Cy/+) rats. The effect of specific mTORC2 knockdown on cyst formation was determined in an *in vitro* model of Type 1 MDCK cells that form cysts in collagen. Rictor, the functional component of mTORC2 was silenced using a plasmid-based shRNA vector system (pTRIPZ) expressing RNAs under the Tet-On inducible promoter. pAktSer^{473} expression was 90% reduced in Rictor knockdown cells (MDCK-puro+dox) compared to puromycin-treated controls (MDCK-puro). Cysts diameters were measured using Image J software.

Results: On immunoblot the downstream targets of mTORC2 (pAktSer^{473}, pPKC-alpha Ser^{657}, pSGK Ser^{422}) were upregulated in Cy/+ rats compared to wild type littermate controls (+/+). In Cy/+ compared to +/+, pAktSer^{473} was three fold increased (P<0.001,N=4), pPKC-alpha Ser^{657} was twofold increased (P<0.05, N=3) and pSGK Ser^{422} was twofold increased (P<0.05, N=3). The diameter of the cysts was significantly decreased in Rictor knockdown MDCK-puro+dox cells.

Diameter of cysts in microns

EXPERIMENTAL GROUPS	Day4	Day8	Day12	Day16
MDCK Control	57.36±0.46	106.7± 0.50	239.7 ±1.32	393.3 ±1.76
MDCK-puro	51.37± 0.37	104.6± 0.65	239 ± 2.09	360.4 ±5.43
MDCK-puro+dox	45.63± 0.60*	81.56± 0.96*	189.6 ±2.45*	240.3 ±2.90*

*P<0.05 vs MDCK Control and MDCK-puro

Conclusions: 1) There is increased mTORC2 signaling in 8wk old Cy/+ kidneys with PKD, 2) Silencing of mTORC2 in an *in vitro* model reduces cyst size. In conclusion, mTORC2 merits further study in PKD.

Hyperactive TORC1 and TORC2 Launch Hif1alpha-Dependent Expression of PTEN To Regulate Phosphorylation of Akt in Tuberous Sclerosis Complex (TSC)
Falguni Das,[1] Nirmalya Dey,[1] Nandini Ghosh-Choudhury,[2] B. S. Kasinath,[1] Hanna E. Abboud,[1] Goutam Ghosh-Choudhury.[1] *[1]Medicine, UTHSCSA, San Antonio, TX; [2]Pathology, UTHSCSA, San Antonio, TX.*

Background: TSC results from mutations in one of two genes, TSC1 and TSC2. TSC2 mutations contribute more to the pathology of the disease, including renal angiomyolipomas. TSC2 acts as a signaling hub in the PI 3 kinase/Akt/mTOR node. Of the two mTOR complexes, TORC1 and TORC2, TSC2 deficiency results in constitutive activation of TORC1.We have reported recently that human renal angiomyolipomas and TSC2 null murine embryonic fibroblasts (MEFs) display high levels of the tumor suppressor protein PTEN with reduced phosphorylation of Akt. The mechanism of PTEN upregulation is not known. Use of rapamycin and constitutively active mTOR (engineered to block TORC1 only) in TSC2 null MEFs and in 293 cells showed that TORC1 increases PTEN mRNA and protein levels. Also, kinase dead mutant of mTOR (mTOR KD), which blocks both TORC1 and TORC2, inhibited expression of PTEN via transcriptional mechanism in TSC2 null MEFs and in 293 cells. Moreover, mTOR KD enhanced and suppressed phosphorylation of Akt at the catalytic loop site Thr-308 and hydrophobic motif site Ser-473, respectively. Furthermore, the inhibition of deregulated mTOR in TSC2 null MEFs and in 293 cells by shRNA-mediated downregulation of raptor, an exclusive component of TORC1, inhibited expression of Hif1alpha, resulting in attenuation of PTEN protein and mRNA expression and transcription, concomitant with enhanced phosphorylation of Akt at Thr-308 and Ser-473. Knockdown of rictor, a sole component of TORC2, reduced expression of Hif1alpha and PTEN but significantly decreased the Akt phosphorylation at both sites. Importantly, rescue of Hif1alpha prevented rictor-downregulated PTEN expression. In contrast, overexpression of rictor increased Hif1alpha and PTEN protein levels. Thus we provide evidence for a novel cell autonomous function of both TORC1 and TORC2 in Hif1alpha-mediated upregulation of PTEN, thereby decreasing phosphorylation of Akt and contributing to the nonmalignant nature of tumors in TSC patients.

Ca^{2+} Influx through Reverse-Mode Na^+/Ca^{2+} Exchange Is Critical for Vascular Endothelial Growth Factor (VEGF) Mediated – ERK1/2 Activation and Angiogenic Functions of Human Endothelial Cells
Petros Andrikopoulos,[1,2] Magdi Yaqoob,[2] Suzanne Eccles.[1] *[1]CR-UK Cancer Therapeutics Unit, The Institute of Cancer Research, London, United Kingdom; [2]Translational Medicine and Therapeutics, William Harvey Research Institute, London, United Kingdom.*

Background: Cardiovascular complications are a major cause of morbidity/mortality in CKD. Deregulated Ca^{2+} levels are universal in CKD patients. However, the effect(s) of altered Ca^{2+} signalling on the vascular endothelium remains largely unknown. Here, by using VEGF, as a paradigm, we investigated the effect of extracellular Ca^{2+} on endothelial cell signalling.

Methods: Human umbilical vein endothelial cells (HUVECs) were serum starved in a physiological buffer and preincubated with reverse-mode (Ca^{2+} in - Na^+ out) Na^+/Ca^{2+} exchanger (NCX). ERK1/2 activation was determined by western blot. PKC and B-Raf activities were determined by scintilation counting. $[Ca^{2+}]_i$ was measured in HUVECs loaded with the fluorescent Ca^{2+} indicator Fluo-4NW.

Results: Here, we report that extracellular Ca^{2+} is required for VEGF-induced ERK1/2 activation and that release of Ca^{2+} from intracellular stores alone, in the absence of extracellular Ca^{2+}, is not sufficient to activate ERK1/2. Furthermore, inhibitors or reverse-mode NCX suppressed the VEGF-induced activation of ERK1/2 in a time- and dose-dependent manner and attenuated VEGF-induced Ca^{2+} transients. Knock-down of NCX1 (the main NCX isoform in HUVECs) by siRNA confirmed the pharmacological data. A panel of NCX inhibitors also significantly reduced VEGF-induced B-Raf activity

and inhibited $PKC_{[sup]\alpha[/sup]}$ translocation to the plasma membrane and total PKC activity *in situ*. Finally, application of NCX inhibitors reduced VEGF-induced HUVEC proliferation, migration and tubular differentiation in surrogate angiogenesis functional assays *in vitro*.

Conclusions: We propose that Ca^{2+} influx through reverse-mode NCX is required for the activation and the targeting of PKCα to the plasma membrane, an essential step for VEGF-induced ERK1/2 phosphorylation and downstream EC functions. Thus, in CKD, deregulated Ca^{2+} may affect endothelial signalling and potentially contribute to endothelial dysfunction.

SA-PO2363

FTI-277 – A Novel Inhibitor of Vascular Calcification Arvind Ponnusamy,[1,2,3] Smeeta Sinha,[1,2] Gareth D. Hyde,[2] Philip A. Kalra,[1] Ann E. Canfield.[2,3] *[1]Renal, Salford Royal NHS Trust Foundation; [2]University of Manchester; [3]NIHR BRC Manchester, United Kingdom.*

Background: Patients with chronic kidney disease have poor cardiovascular outcomes due to increased vascular calcification and atherosclerosis. Vascular calcification is a highly-regulated process involving the loss of calcification-inhibitory molecules, osteogenic differentiation of VSMC, and VSMC apoptosis. This study aims to determine whether vascular calcification is regulated by protein farnesylation

Methods: Bovine and human vascular smooth muscle cells were used in mineralisation and apoptosis experiments. Mineralisation and apoptosis were induced using 5 mM β-glycerophosphate or 2.6 mM phosphate in serum-free medium, respectively. Akt phosphorylation and active caspase 3 were assessed by western blotting. Gene expression was analysed using qRT-PCR.

Results: The farnesyl transferase inhibitor, FTI-277, significantly inhibits calcification of VSMC in a dose-dependent manner ($p<0.001$). Pre-incubation of VSMCs with FTI-277 (10 μM) inhibits Ras activation and markedly enhances serum-induced Akt phosphorylation. Wortmannin inhibits PI3K/Akt signalling. Therefore, VSMCs were induced to mineralise in the presence of wortmannin (100 nM), FTI-277, wortmannin and FTI-277, or vehicle. Wortmannin significantly promotes VSMC mineral deposition ($p<0.001$). Some mineralisation was detected in cells incubated in the presence of both reagents, demonstrating that the effects of FTI-277 can be partially negated by preventing downstream PI3K signalling. FTI-277 also reduces caspase 3 activation and significantly inhibits phosphate-induced VSMC apoptosis ($p<0.05$). To determine whether FTI-277 also regulates the osteogenic differentiation of VSMC, RNA was collected from cells cultured +/- FTI-277 for 9-10 days. Results show that FTI-277 inhibits Runx2, Msx 2 and alkaline phosphatase mRNA expression ($p<0.05$), promotes matrix Gla protein mRNA expression ($P<0.05$), and maintains α-smooth muscle actin expression.

Conclusions: These studies demonstrate that FTI-277 inhibits VSMC mineralisation by activating downstream PI3K/Akt signalling and preventing apoptosis, and by regulating the osteogenic differentiation of VSMC.

Microstructured Platform Systems To Study *Tunneling Nanotube* (TNT) Related Processes in Human Peritoneal Mesothelial Cells (HPMCs) Julia Ranzinger,[1] Amin Rustom,[2] Marcus Abel,[2] Julia Leyh,[1] Lars Kihm,[1] Martin G. Zeier,[1] Vedat Schwenger.[1] *[1]Nephrology, University of Heidelberg, Germany; [2]New Materials and Biosystems, Max Planck Institute for Intelligent Systems, Stuttgart, Germany.*

Background: Efficacy of peritoneal dialysis (PD) depends on the integrity of the peritoneal membrane. Anew discovered membrane channels, TNTs, mediate intercellular communication between cells of different cellular systems and therefore attain physiological and pathological relevance. Due to the sensitivity of TNTs and the dependence on density of respective cells, quantitative investigations of TNT-related processes are difficult. We developed micropatterned gold dot surfaces as platform systems to study cell-cell interactions in HPMCs.

Methods: Microstructured surfaces were prepared by means of photolithography. The size and the distance of the gold dots were set to match with the average diameter of HPMCs and to prevent cell clustering. For biofunctionalization, IKVAV peptide representing the cell-binding domain of the α-chain of laminin was coupled covalently on the gold dots. Mesothelial cells from i) omentum of healthy donors and ii) effluents in dialysis fluid from patients undergoing PD were isolated and cultured on the platforms. 3D fluorescence and scanning electron microscopy were applied to detect TNTs.

Results: HPMCs selectively adhere to the functionalized gold dots when cultured on the platforms. No unspecific association to the glass on the surfaces occurred. When we investigated the number of TNTs connecting HPMCs cultured on these platform systems, we found that TNT- formation was hindered almost completely. Compared to the number of TNTs detected between cells plated on glass cover slides, only a negligible number of TNTs could be visualized when cells were cultured on biofunctionalized microstructures.

Conclusions: The existence of TNTs connecting HPMCs *in vitro* points to a distinctive communication among these cells at least under cell-culture conditions and is presumably crucial for the integrity of the peritoneal membrane. We show that the spatial separation of HPMCs by culturing the cells on biofunctionalized microstructures leads to an inhibition of the TNT-formation.

SA-PO2365

Renal Kinome Scan in Lupus Nephritis Chun Xie,[1,2] Tianfu Wu,[2] Chandra Mohan.[2] *[1]Division of Nephrology/Internal Medicine, UT Southwestern Medical Center, Dallas, TX; [2]Division of Rheumatology/Internal Medicine, UT Southwestern Medical Center, Dallas, TX.*

Background: Protein kinases are key regulators of a wide variety of biological processes. Several protein kinases have been elucidated to play important roles in the pathogenesis of systemic lupus erythematosus (SLE) and glomerulonephritis. However, almost all of these investigations focused only on single molecules or pathways. The human genome contains more than 500 protein kinase genes. Most of these kinases have not been investigated in regard to their roles in SLE or glomerulonephritis. In the current study, we performed a systemic kinome scan in kidneys of spontaneous lupus mouse strains

Methods: Protein extracts from renal cortices of 6-8 months old NZB/NZW F1, and MRL.lpr mice as well as C57BL/6 controls were subjected to kinome profiling, using Kinex Antibody Microarray. Some of the differentially expressed kinases were then validated by Western blot or immunohistochemistry.

Results: We were able to detect 193 protein kinases, 24 protein phosphatases and 150 regulatory subunits of these enzymes by using this platform. 87 of these molecules were found to be differentially expressed in lupus kidneys, compared to the controls. Using the Ingenuity Pathway Analysis (IPA), we identified several biological networks, functions and pathways, including cell growth and proliferation, gene expression, posttranslational modification, immune response, and inflammation, etc., that are involved in lupus nephritis. In addition, some of these molecules have been validated by Western blot or immunohistochemistry. The role of tyrosine hydroxylase, one of the molecules that are highly expressed in lupus kidneys, in the pathogenesis of lupus nephritis, is being tested in animal models.

Conclusions: We have identified several molecules that have altered expression in lupus nephritis, by systemic kinome profiling. We also revealed several disease pathways that are involved in lupus nephritis. The functional studies of these molecules and pathways are in progress.

SA-PO2366

Uremia Decreases the IL-6 Response to Exercise of Skeletal Muscle: Alteration in JAK2/STAT3 and AMPK Signaling Natalia H. Dünner, Fabiola Venegas, Juan P. Peña, Francisco G. Coronado, Enrique Jaimovich, Luis F. Michea. *Facultad de Medicina, Universidad de Chile, Santiago, Chile.*

Background: Chronic renal failure (CRF) induces muscular weakness and decreased exercise endurance. Interleukin-6 (IL-6) is a cytokine upregulated by exercise in skeletal muscle, with autocrine effects on skeletal muscle metabolism. The AMP-activated protein kinase (AMPK) is a fuel sensing enzyme activated by changes in the energy state of the cell, and recent findings indicate that IL-6 can activate AMPK *in vivo*. Several studies show that IL-6 mRNA is altered in CRF, but it is unknown if CRF affects the response to exercise. We hypothesized that the regulation of muscular IL-6 expression and AMPK in response to exercise is impaired in CRF.

Methods: Male Sprague-Dawley rats were given 5/6 nephrectomy (NPX) or sham surgery and pair-fed. The response to exercise was measured in *extensor digitorum longus* (EDL) fatigued by *in situ* electrical stimulation through the sciatic nerve, or after swimming. At the end of the exercise protocols, EDL was dissected for mRNA and protein evaluation.

Results: We found no significant differences in the abundance of IL-6 mRNA of EDL at rest. After *in situ* stimulation we observed 85±8 fold induction of IL-6 mRNA in the EDL of Sham rats; however, IL-6 mRNA in EDL from NPX rats increased only 22±7 fold ($n=6$, $P<0.01$). Since IL-6 exerts a positive feedback in muscle, we analyzed IL-6 signaling pathway. NPX did not affect mRNA of IL-6 receptors, IL-6Ra and gp130. The Janus Kinase 2 (JAK2) protein decreased to 63±4.5% of control levels in EDL of NPX rats ($n=5$, $P<0.01$). We observed reduced activation of Stat3 and reduced induction of Suppressor of cytokine signalling-3 (SOCS-3) mRNA in EDL of NPX rats after exercise ($n=3$-4, $P<0.05$). Basal P-AMPK levels were reduced in NPX (54±14% of control, $n=6$, $P<0.05$) and this difference was maintained after exercise (61±10%, $n=6$, $P<0.05$).

Conclusions: The data show reduced activation of IL-6 pathway in EDL of NPX rat in response to exercise. The decrease of AMPK phosphorylation could contribute to low endurance to exercise in CRF.

SA-PO2367

Stimulation of RANKL and Bone Resorption by Metabolic Acidosis Requires Gβγ Signaling Nancy Krieger, Christopher D. Culbertson, David A. Bushinsky. *Medicine, University of Rochester, NY.*

Background: Chronic metabolic acidosis (Met) stimulates cell-mediated net calcium (Ca) efflux from bone, mediated primarily through increased osteoblastic prostaglandin E_2-induced stimulation of RANKL and osteoclastic bone resorption. Osteoblasts express OGR1, a proton (H^+)- sensing G-protein coupled receptor (GPCR), and we demonstrated that H^+ activation of OGR1 increases intracellular Ca in osteoblasts and the OGR1 inhibitor, $CuCl_2$, blocks H^+-induced bone resorption. Our results suggest that OGR1, coupled to Gq, is the sensor that detects increased [H^+] during Met and initiates osteoblastic signaling leading to increased osteoclastic bone resorption.

Methods: To explore regulation of G-protein coupled signaling by Met, neonatal mouse calvariae were incubated for 48 h in physiologically neutral (Ntl, pH=7.50, Pco_2=34 mmHg, $[HCO_3^-]$=28 mM) or acid (Met, pH=7.17, Pco_2=33 mmHg, $[HCO_3^-]$=13 mM) medium ± 20 μM gallein (Gal), a selective inhibitor of Gβγ signaling, and net Ca efflux measured. To determine RANKL mRNA expression, primary osteoblasts were isolated from calvariae and incubated in Ntl (pH=7.43, Pco_2=39 mmHg, $[HCO_3^-]$=25 mM,) or Met (pH=7.10, Pco_2=39 mmHg, $[HCO_3^-]$=15 mM) medium ± 20 μM gal for 48h. Cells were collected and RANKL mRNA levels measured by real time PCR.

Results: Compared to incubation in Ntl (442±80 nmol/bone/24h), Met induced net Ca efflux (1339±92, $p<0.05$); Gal did not alter Ca efflux in Ntl (218±62) but blocked the increase with Met (264±138, $p<0.05$ vs Met alone) (n=8/group, mean ± SE). Compared to incubation of primary osteoblasts in Ntl (0.85±0.11), Met induced an increase in RANKL mRNA (1.29±11, $p<0.05$); Gal did not alter RANKL in Ntl (0.69±0.06) but blocked the increase with Met (0.91±0.05, $p<0.05$ vs Met alone) (n=6/group). OPG mRNA levels were not altered by Met either in the absence or presence of Gal.

Conclusions: Thus gallein inhibited Met stimulation of osteoblastic RANKL production and acid-induced bone resorption. These results, together with our previous finding of acid inhibition of RGS16, which can limit G protein signaling, suggest that regulation of Gβγ is important for modulating the OGR1-mediated response of the osteoblast to metabolic acidosis.

Exposure to Uremic Serum Induces a Pro-Calcific Phenotype in Human Mesenchymal Stem Cells Rafael Kramann,[1] Rebekka K. Schneider,[2] Uta Kunter,[1] Jurgen Floege.[1] *[1]Department of Nephrology and Clinical Immunology, RWTH University, Aachen, Germany; [2]Institute of Pathology, RWTH University, Aachen, Germany.*

Background: Arterial media calcification in chronic kidney disease (CKD) patients involves osteoblast-induced calcification of the collagen extracellular matrix (ECM) resulting in intramural ossification. The current study is based on the hypothesis that mesenchymal stem cells (MSC) constitute critical cells for pro-calcific ECM remodelling in CKD patients.

Methods: Human MSC were cultured in media supplemented with pooled sera from either healthy or uremic patients (20%). Results were compared to MSC cultured in growth medium as well as osteogenic differentiation medium. Calcification and matrix remodelling were further analysed in a three-dimensional in-vitro collagen scaffold recapitulating the vascular collagen I/III environment.

Results: In two-dimensional culture, exposure to uremic serum enhanced the proliferation of MSC (cell counting, BrdU incorporation), whereas apoptosis and necrosis were not affected (annexin V and 7-AAD staining). Uremic serum-exposed MSC recapitulated osteogenesis by calcification of their ECM (von Kossa staining, calcium quantification) and expression of bone-related genes (BMP-2 receptor, ALP, osteopontin, Runx2, collagen I) over a period of 35 days. The uremic serum-induced osteogenesis was completely blocked by a BMP-2/4 neutralizing antibody. In the three-dimensional system, uremic serum-induced calcification was shown to occur along collagen fibers (SEM, energy-dispersive X-ray spectroscopy) and was accompanied by extensive matrix remodelling. Uremic serum exposed MSC acquired a myofibroblast phenotype as shown by a significant contraction of the ECM and by *de novo* expression of α-smooth muscle actin. The procalcific ECM remodelling was accompanied by increased expression of collagen I, osteopontin, laminin and fibronectin (immunohistochemistry) and exhibited parallels to the ECM remodelling observed in arteries of CKD-patients (n=8) (with arteries from children serving as control).

Conclusions: Uremic serum induced in a BMP-2/4-dependent manner an osteoblast-like phenotype in MSC accompanied by matrix remodelling and calcification.

SA-PO2369

Hypoxia-Inducible Factors in Glomerular Endothelial Cells Alexander Weidemann, Susanne Olbrich, Margarete Goppelt-Struebe, Kai-Uwe Eckardt. *Nephrology and Hypertension, University of Erlangen-Nuremberg, Erlangen, Germany.*

Background: Hypoxia-inducible factors (HIFs) regulate genes which are central for the adaptation to low oxygen conditions. In normoxia HIF is degraded and inactive. Pharmacological activation of HIF in normoxia is protective in kidney injury. The cellular compartment which exerts the protective effects upon HIF activation is still elusive but endothelial HIF might be one of the effectors. To dissect the molecular mechanisms of how HIFs affect endothelial cell function we established an in vitro model of glomerular endothelial cells (glEnd) with stable HIF-knockdown.

Methods: glEnds with stable knockdown of both HIFα isoforms were generated by lentiviral transfection with shRNA producing constructs. Molecular analyses were performed by real-time PCR and westernblotting. HIF was stabilized by DMOG which inhibits HIF-prolyl hydroxlases (PHD). Proliferation was analysed by MTT assays.

Results: glEnds express both HIFα proteins, however HIF-2α levels is much lower. Deletion of HIF-1α does not affect expression of HIF-2α and vice versa. Of the taget genes investigated, most of them are regulated by HIF-1α only. HIF-2α only contributes to a limited extend (e.g. to VEGF regulation). HIFα deficiency does not affect cell proliferation under normoxic conditions. However, HIF-1α deletion significantly impares proliferation in hypoxia, whereas deletion of HIF-2α has no effect. Treatment with the PHD-inhibitor DMOG significantly slows proliferation in normoxia. This antiproliferative effect was rescued by deletion of HIF-1α.

Conclusions: Surprisingly the functional relevance of HIF-2α in glEnd cells in vitro is limited whereas HIF-1α is the dominant HIF-isoform. Hypoxic proliferation is critically dependent on HIF-1 for metabolic adaptation. In contrast, reduction of proliferation by PHD-inhibition is also mediated by HIF-1. This indicates that although most target genes are regulated similarly by both stimuli, the functional consequences of HIFα stabilization are diverse. Given the increasing interest in using HIF-activation as therapeutical approach to renal disease, these cells are a valuable tool to investigate the functional roles of HIFα in the renal endothelium in vitro.

Reduction of Na/K-ATPase in Marinobufagenin-Induced Cardiac Myocyte Apoptosis Changxuan Liu,[1,2] Yan Bai,[2] Yu Wang,[1] Lijun Liu,[2] Deepak K. Malhotra,[3] Christopher J. Cooper,[3] Joseph I. Shapiro,[2,3] Zi-Jian Xie,[2,3] Jiang Tian.[3] *[1]Renal Division and Institute of Nephrology, Peking University First Hospital, Beijing, China; [2]Department of Physiology and Pharmacology, University of Toledo, OH; [3]Medicine, University of Toledo, OH.*

Background: Na/K-ATPase functions as a receptor for cardiotonic steroids (CTS) such as ouabain, marinobufagenin (MBG), and digoxin. Decreases in cardiac Na/K-ATPase have been documented in patients with heart failure and other disease states. Our previous studies demonstrate that reduction of Na/K-ATPase attenuates CTS-induced Src signaling, resulting in increased cell death in renal epithelial cells.

Methods: We employed a Na/K-ATPase α1 heterozygote knockout mouse model (α1+/-), in which, the expression of heart tissue Na/K-ATPase α1subunit is reduced by about 30% in comparison to its wild type (a1+/+) littermate. Experimental mice were subject to marinobufagenin (MBG) infusion using osmotic mini pumps and the echocardiography was performed. Cardiac myocytes were also isolated from these mice for in vitro experiments.

Results: The results showed that MBG infusion increases myocyte apoptosis and induces left ventricle dilation in the heterozygote mice, but not in the wild type mice. Moreover, MBG significantly reduced the contractile function in these heterozygote mice. Mechanistically, we demonstrated that MBG activates Akt and the mammalian target of rapamycin (mTOR) in wild type mice. Activation of mTOR further increases the phosphorylation of ribosome S6 kinase and Bcl-2-associated death promoter (BAD) and protects cells from apoptosis. However, this survival signaling induced by MBG was abolished in the heterozygote mice. Instead, MBG activates caspase 9 in heterozygote mice, which may account for the cardiac myocyte apoptosis. Using rat neonatal cardiac myocytes, we further demonstrate that directly inhibiting the mTOR pathway by rapamycin also enable MBG to activate caspase 9 and induce myocyte apoptosis.

Conclusions: Reduction of cardiac Na/K-ATPase attenuates MBG-induced activation of survival signaling while making cardiac myocytes susceptible to MBG-induced apoptosis.

Albumin Overload Leads to Low Molecular Weight Proteinuria in Normal Mice, While a Compensatory Proteolytic Pathway Develops in Limp-2 Null Mice Darren H.K. Lee,[1] Scott Andrew Fraser,[1] Marina Katerelos,[1] Kurt Gleich,[1] Paul Saftig,[2] David A. Power.[1] *[1]Depts of Nephrology and Medicine, Austin Health, VIC, Australia; [2]Institut für Biochemie, Christian-Albrechts-Universität zu Kiel, Kiel, Germany.*

Background: Mutations of the lysosomal protein Limp-2 cause low molecular weight (LMW) proteinuria and albuminuria due to reduced proteolysis in the proximal convoluted tubule (PCT).

Methods: To determine how Limp-2 affects the response to protein overload, WT and Limp-$2^{-/-}$ mice received daily bovine serum albumin (BSA) injections i.p. for 10 days.

Results: Urinary albumin/creatinine ratio did not increase significantly in BSA-treated Limp-$2^{-/-}$ mice (Day 0: 134±104; Day 10: 211±210 mg/mmol), whereas levels in WT mice increased to those seen in Limp-$2^{-/-}$ mice (Day 0: 30±52; Day 10: 246±299 mg/mmol; $p<0.05$). BSA treated Limp-$2^{-/-}$ mice showed no increase in LMW proteinuria (retinol-binding protein (RBP), vitamin D-binding protein and α1-microglobulin), while WT mice developed LMW proteinuria. There was no difference in megalin or cubilin mRNA expression.

Quantitative immunofluorescence microscopy showed that RBP and LAMP-1 labelled vesicles in the PCT were distributed more basally in the untreated Limp$2^{-/-}$ mice compared with WT ($p<0.001$), confirming delayed proteolysis. Surprisingly, RBP was distributed more basally in BSA-treated mice in both groups ($p<0.01$), also suggesting delayed protein degradation. Western blots showed that cathepsin B and L expression was increased in BSA-treated Limp-$2^{-/-}$ mice ($p<0.05$) while cathepsin L but not cathepsin B was up-regulated in BSA-treated WT mice ($p<0.001$). Similarly, the proportion of RBP vesicles co-localising with cathepsin B increased in BSA-treated Limp-$2^{-/-}$ mice (Mander's coefficients: 0.18±0.07 vs 0.13±0.09; $p<0.05$) whereas it did not change in BSA-treated WT mice (0.30±0.10 vs 0.30±0.09).

Conclusions: In response to BSA overload, WT mice develop tubular proteinuria and delayed proteolysis of reabsorbed proteins. In contrast, Limp-$2^{-/-}$ mice show no significant increase in pre-existing tubular proteinuria, apparently due to the presence of increased cathepsin B. This data suggests considerable plasticity in the response of the PCT to protein overload.

TGFβ Modulates Mitochondrial Bioenergetics and Morphology in Podocytes Gabriella Casalena, Ilse S. Daehn, Erwin P. Bottinger. *Medicine, Mount Sinai School of Medicine, New York, NY.*

Background: TGFβ regulates differentiation, growth, and apoptosis of podocytes and mediates podocyte depletion in glomerulosclerosis. In patients with progressive glomerular diseases the increased expression of TGFβ in podocytes can be one of the causes of damage induction and perpetuation in glomerular tufts. Mitochondrial dysfunction and oxidative stress emerged recently as potential therapeutic targets in glomerular injury. Whether TGFβ regulates mitochondrial dysfunction/oxidative stress in podocytes is not known.

Methods: Mitochondrial function in WT, CD2AP-deficient and Smad2-Smad3-deficient murine immortalized podocytes grown in non-permissive conditions was analyzed upon treatment with 5 ng/ml of TGFβ for 6, 24 and 48 hr.

Results: TGFβ treatment induced a significant Smad-dependent increase of podocyte oxygen consumption rate starting at 24 hr. Increased oxygen consumption was associated with mitochondrial membrane depolarization, mitochondrial network fragmentation, and increased cellular reactive oxygen species (ROS). TGFβ-induced ROS production was reverted by NADPH oxidase inhibitor apocynin. In contrast, TGFβ did not alter mitochondrial superoxide level (MitoSox). ATP content was not different from untreated podocytes and increased respiration was not associated with increase mitochondrial mass as shown by citrate synthase activity. At early time points, TGFβ treatment partially inhibited the expression of nuclear and mitochondrial genes encoding subunits of Complex I of respiratory chain. In contrast, expression of SOD2 increased with TGFβ treatment.

Conclusions: Our results suggest that TGFβ-Smad activation increases OCR as part of a secondary metabolic response to preserve cellular energy (ATP) homeostasis during TGFβ-induced cellular phenotype responses. Compensatory stimulation of anti-oxidant mitochondrial gene expression (SOD2) may prevent increase of mitochondrial superoxide levels. In a context of oxygen deprivation, often observed in chronic and acute kidney diseases, the lack of adaptive changes in mitochondria could promote apoptosis commitment in podocytes. We conclude that canonical TGFβ-Smad pathways regulate adaptive modifications of mitochondrial metabolism in podocytes.

Glomerulotubular Disconnection Is Rescued by the Antiapoptotic Effect of Ouabain in Rats with Passive Heymann Nephritis Ulla B. Holtback,[1] Xiao Liu,[1] Ann-Christine Eklof,[1] Agnes B. Fogo,[2] Anita Aperia.[1] *[1]Women´s and Children´s Health, Karolinska Institutet, Stockholm, Sweden; [2]Pathology, Vanderbilt University.*

Background: Glomerulotubular disconnection and formation of atubular glomeruli, which is a common feature in both tubular and glomerular disorders, contribute to the progression of chronic renal disease. Apoptosis of proximal tubular cells is considered as a main cause of the disconnection. Our group has shown that a cardiotonic steroid, ouabain, protects kidney cells from apoptosis by triggering a Ca^{2+}-NF-kB signal (JASN 2006, Nature Com 2010).

Here we have examined whether ouabain may protect from apoptosis and glomerulotubular disconnections in rats with passive Heymann nephritis (PHN), a model of human membranous nephropathy.

Methods: PHN and control rats were followed for 4 months. One PHN group (n=7) received ouabain (15 mg/kg/day) and the other received vehicle via intraperitonal mini pumps.

Results: S-Cr was significantly increased in PHN rats compared to control and PHN/ouabain rats. Significant proteinuria was recorded in both PHN groups, but was somewhat less pronounced in PHN/ouabain rats. Morphometric analysis of the kidneys revealed glomerular fibrosis and basement membrane damage in both PHN groups, but significantly less pronounced in PHN/ouabain rats. For assessment of apoptosis, kidney sections were TUNEL stained and counterstained with hematoxylin. The number of apoptotic cells at the glomerulotubular disconnection was significantly, 3.2 fold, higher in PHN than in PHN/ouabain rats. To assess the level of glomerulotubular disconnections, kidneys were serially sectioned and an average of 75 sections/kidney were analyzed. In control rats 95% of glomeruli were normally connected. In PHN 64% were normally connected, 19 % were connected to atrophic tubules and 17% to atubular glomeruli. In PHN/ouabain rats 84% of glomeruli were normally connected, 10 % were connected to atrophic tubules and 6 % to atubular glomeruli

Conclusions: The results support the notion that glomerulotubular disconnection is triggered by local apoptosis and imply that formation of atubular glomeruli can be alleviated by the antiapoptotic effects of ouabain.

SA-PO2374

Identifying P2X7 Receptor as a Key Regulator of Deleterious Renal Epithelial-Fibroblast Cross Talk Murugavel Ponnusamy,[1] Shougang Zhuang.[1,2] *[1]Department of Medicine, Alpert Medical School, Brown University, Providence, RI; [2]Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China.*

Background: P2X7 is an extracellular ATP dependent membrane receptor, which can acts as a mediator of cell death. Despite P2X7 receptor protein is barely expressed or not detectable in normal kidney, its expression is increased in some kidney disease models or human kidney diseases. Currently, the potential pathological role of P2X7 receptor and the signaling cascades leading to its expression in the kidney are largely understood. As a reduced number of peritubular fibroblast is observed in the interstitium adjacent to damaged tubular epithelium in the early phase of AKI, we examined whether damaged renal epithelial cells would directly induce renal interstitial fibroblast death via activation of purinergic signaling in vitro.

Methods: Renal proximal tublular cells (RPTC) and rat renal interstitial fibroblast cell line (NRK-49F) were used.

Results: Exposure of cultured NRK-49F cells to necrotic RPTC lysate or supernatant induced expression of $P2X_7$ receptor and cell death in NRK-49F. Inhibition of P2X7 with A438079, a highly selective $P2X_7$ receptor inhibitor, or knockdown of $P2X_7$ receptor with siRNA blocked the deleterious effect of necrotic RPTC supernatant. In response to necrotic RPTC, multiple signaling pathways including ERK1/2, p38, JNKs and AKT are activated in NRK-49F, pharmacological inhibition of ERK1/2, but not p38, JNK and AKT pathways blocked RPTC supernatant-induced P2X7 expression and cell death. Similar results were also obtained in NRK-49F with knockdown of ERK1/2 or MEK1, a direct upstream activator of ERK1/2. Conversely, over-expression of MEK1 enhanced these responses. Further, siRNA mediated knockdown of Elk1, a transcriptional factor targeted by ERK1/2, also reduced necrotic RPTC-induced P2X7 expression and renal fibroblast death.

Conclusions: These data indicate that necrotic RPTC supernatant can directly induce death of renal interstitial fibroblasts via up-regulation of P2X7 receptor through an ERK signaling-dependant mechanism.

Apoptotic Cells Alter Proximal Tubular Cell (PTC) Viability Via Multiple Complex Signaling Pathways Vimal Patel,[1] Lanfei Feng,[1] Donald Massenburg,[1] Angelika Antoni,[2] Joyce Rauch,[3] Wilfred Lieberthal,[4] Jerrold S. Levine.[1] *[1]Medicine, University of Illinois at Chicago, IL; [2]Medicine, Kutztown University, Kutztown, PA; [3]Medicine, McGill University, Montreal, QC, Canada; [4]Medicine, SUNY, Stoney Brook, NY.*

Background: Cells undergoing apoptosis acquire new activities that modulate the fate and function of neighboring live cells. We have previously shown that apoptotic target cells decrease the viability of live kidney PTC responder cells. Here, we elucidate the signaling pathways responsible for decreased viability of PTC responders following their receptor-mediated interaction with apoptotic targets.

Methods: We used BU.MPT cells, a conditionally immortalized PTC line, as responder cells. BU.MPT cells, induced to undergo apoptosis in several ways, were used as apoptotic targets.

Results: Apoptotic targets induced apoptotic death in ~80% live PTC responders by 48 hrs. Modulation of PTC viability occurred through at least 3 distinct pathways. First, inhibition of Akt promoted apoptosis via activation of Bad and decreased cellular abundance of β-catenin. However, a constitutively active Akt construct (mAkt) reduced target-induced PTC apoptosis to ~40%, indicating a role for Akt-independent pathways. Second, combined use of mAkt and the caspase-8 inhibitor Z-IETD-FMK reduced PTC apoptosis to <20%, indicating that activation of caspase-8 contributes to target-induced PTC death. Finally, activation of p38 served a counter-regulatory role and protected PTC from target-induced death by increasing β-catenin abundance. Inhibition of p38 by SB203580 increased target-induced PTC death to ~100% by 48 hrs.

Conclusions: Together, these data emphasize the complexity and robustness of the signaling events induced in viable PTC responders following interaction with apoptotic targets. By acting as sentinels of environmental change, apoptotic targets may allow neighboring viable cells, especially non-migratory epithelial cells, to monitor and potentially adapt to local stresses.

Attenuating Effect of Angiotensin-(1-7) on Angiotensin II-Mediated Reactive Oxygen Species Induced Apoptosis through Regulation of Mitochondrial NOX4 Su-Mi Kim,[1] Yang Gyun Kim,[1] Sul-Ra Lee,[2] Jay-Sung Gim,[1] Kyung-Hwan Jeong,[2] Sang-Ho Lee,[1] Eun Young Kim,[1] Tae Won Lee,[2] Chun-Gyoo Ihm,[2] Ju-Young Moon.[1] *[1]Internal Medicine, Kyung Hee University Hospital, Seoul, Sangil-Dong, Gangdong-Gu, Korea; [2]Internal Medicine, Kyung Hee University Medical Center, Seoul, Hoegi-dong, Dongdaemun-gu, Korea.*

Background: Angiotensin II (Ang II)-mediated reactive oxygen species (ROS) are important second messengers for the transcriptional effects of Ang II, and NOX4 is the central enzyme of Ang II-induced ROS. Recent evidence suggests mitochondrial NOX4 has a remarkable role. In this study, we examined the hypothesis that angiotensin-(1-7) (Ang-(1-7)) attenuates Ang II-induced mitochondrial NOX4 mediated ROS injury in proximal tubular epithelial cells.

Methods: The normal rat kidney tubular epithelial cells (NRK-52E) were cultured, and then stimulated with Ang II (10^{-6}M) with or without pre-incubation with 10^{-6}M of Ang-(1-7). The mitochondrial NOX4 activation was determined to isolation of subcellular fraction by Western blotting. Intracellular ROS generation was measured using DCF-DA and MitoSOX. Mitochondrial membrane potential ($\Delta\Psi$) was detected using JC-1 by flow cytometry and confocal microscopy. Apoptosis was measured using a TUNEL assay and FITC-Annexin V staining.

Results: The mitochondrial and membrane NOX4 were activated in response to Ang II stimuli for 24 hours, however, pre-incubation of Ang-(1-7) inhibited both activation of NOX4. Pre-incubation with Ang-(1-7) in addition to Ang II significantly inhibited the Ang II-induced ROS production as the level of control. Ang-(1-7) attenuated the Ang II induced depolarization of mitochondrial membrane potential, and release of AIF and

cytochrome C from mitochondria to cytosol. Ang II -induced apoptotic cell death was attenuated by Ang-(1-7).

Conclusions: Ang-(1-7) attenuated the Ang II-stimulated activation of NOX4 in both mitochondria and membrane. These findings ware related to improved mitochondrial dysfunction and apoptosis in response to Ang II and suggest that Ang-(1-7) may attenuate Ang II-stimulated ROS-mediated apoptosis NRK-52E cells.

High Glucose Levels Induce Apoptosis through Endoplasmic Reticulum Stress in Peritoneal Mesothelial Cells Junichi Nakamata,[1] Hiroyuki Morimoto,[2] Ryoko Baba,[2] Tetsu Miyamoto,[1] Kaori Kanegae,[3] Ryota Serino,[1] Narutoshi Kabashima,[3] Yutaka Otsuji,[1] Yoshiaki Doi,[2] Masahito Tamura.[3] *[1]2nd Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyusyu, Japan; [2]Department of Anatomy, University of Occupational and Environmental Health, Kitakyusyu, Japan; [3]Kidney center, University of Occupational and Environmental Health, Kitakyusyu, Japan.*

Background: To maintain adequate peritoneal function is important for long-term peritoneal dialysis (PD) therapy. Peritoneal dialysate, containing non-physiological materials such as glucose, is implicated in long-term damage of the peritoneal membrane. Endoplasmic reticulum (ER) stress is associated with the progression of Diabetes mellitus, hyperglycemia-associated atherosclerosis and kidney diseases. However, the involvement of ER stress in PD has yet to be elucidated. We investigated whether high glucose levels induce apoptosis through ER stress pathway in rat peritoneal mesothelial cells (PMCs).

Results: The primary PMCs were obtained from the peritoneal parietal wall of Wistar rats. Serum-starved PMCs were incubated with 2% glucose in culture medium for 0 - 72 hours. High glucose concentrations significantly increased both the expression and phosphorylation levels of eIF2α, a key signaling molecule that attenuates general protein translation and induces apoptosis in the PERK-eIF2α pathway, in a time-dependent manner. The ratio of phosphorylation to total eIF2α was also increased in the same manner. After a 24 hour incubation of PMCs with 0.1% - 4% glucose, the relative phosphorylation levels of eIF2α were increased in a dose-dependent manner. At concentrations greater than 3%, glucose suppressed cell viability examined by WST-1 assay and increased DNA fragmentation examined by DNA ladder formation assay. These results demonstrate that high glucose concentrations promote eIF2α-mediated ER stress and apoptosis in PMCs.

Conclusions: In PMCs, it was assumed the high concentration of glucose induced the cell death by apoptosis through the ER stress pathway. Thus, we consider at present that the ER stress is likely to be involved in peritoneal damage in patients under PD therapy.

SA-PO2378

Advanced Oxidation Protein Products Induce Podocyte Apoptosis Via a RAGE-Mediated Signaling Pathway Li Li Zhou, Jing Nie, Fan Fan Hou. *Nephrology, Nanfang Hospital, Guangzhou, Guangdong, China.*

Background: The accumulating of advanced oxidation protein products (AOPPs) was found in diabetes, metabolism syndrome and chronic renal disease. We previously reported that accumulated AOPPs could induce the apoptosis and depletion of podocytes through activation of NADPH activity. The aim of the present study is to identify the receptor on the surface of podocyte which mediated the effect of AOPPs on podocytes.

Methods: The binding activity of AOPPs-MSA to RAGE in cultured podocytes was determined by co-immunoprecipitation and co-immunolocalization fluorescence analysis. Assessment of podocyte apoptosis was determined by Annexin V-labeling and TUNEL Assay. Expression of apoptosis related molecules and activation of NADPH oxidase were analyzed by western blotting, immunoprecipitation and lucigenin-enhanced chemiluminescence. The sequences of custom small interfering RNA (siRNA) duplex for mouse RAGE and scrambled siRNA were also used for detection the aboved objectives .

Results: By immunoprecipitaion assay, we found that AOPPs interacted with RAGE receptor in conditionally immortalized podocyte cells. Immunofluorescence staining demonstrated that AOPPs colocalized with RAGE at the cell membrane. The apoptosis of podocyte induced by AOPPs was inhibited by a RAGE neutralizing antibody in a dose-dependent manner. However, the neutralizing antibodies against other scavenger receptors such as CD36, SR-A, LOX1, AGE-R3 and inflammation related receptor TLR4 had no effect. Knockdown RAGE expression by siRNA interference significantly inhibited AOPPs-induced the upregulation of apoptotic proteins such as p53, Bax, caspase 3 and PARP-1, and the activation of NADPH oxidase, in podocyte.

Conclusions: These data suggest AOPPs induce podocyte apoptosis and activation of NADPH oxidase-dependent p53-Bax apoptotic pathway via a RAGE-mediated signaling pathway.

SA-PO2379

Aldehyde-Mediated Accumulation of ROS Accounts for Cellular Apoptosis in HK-2 Cells Eun Hui Bae,[1] Sunghee Cho,[2] Soo Yeon Joo,[2] Seong Kwon Ma,[1] Suhn Hee Kim,[3] Jongun Lee,[2] Soo Wan Kim.[1] *[1]Department of Internal Medicine, Chonnam National University Medical School, Gwangju, Korea; [2]Department of Physiology, Chonnam National University Medical School, Gwangju, Korea; [3]Department of Physiology, Chonbuk National University Medical School, Jeonju, Korea.*

Background: Aldehyde products of lipid peroxidation such as 4-hydroxy-2-hexenal (HHE) may in part be responsible for the pathogenesis of various kidney injuries. The present study was aimed at investigating the effects of HHE on cellular apoptosis in renal tubular epithelial cells.

Methods: Human proximal tubular epithelial (HK-2) cells were treated with HHE. Cell viability was examined by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. The fluorescent probe 2',7'-dichlorofluorescein diacetate was used to measure intracellular levels of reactive oxygen species (ROS). The expression of NF-kB, mitogen activated protein kinase (MAPK), pro-apoptoic Bax, and anti-apoptotic Bcl-2 proteins was determined by semiquantitative immunoblotting. Apoptosis was assessed by flow-cytometry after the cells were stained by fluorescein isothiocyanate-conjugated annexin V protein and propidium iodine.

Results: HHE caused dose-dependent decreases of cell viability along with increases of ROS. Flow-cytometry confirmed HHE-induced apoptosis. HHE increased the expression of p38 MAPK, extracellular signal regulated kinase (ERK), and c-Jun N-terminal kinase (JNK). HHE also induced an activation of NF-kB and degradation of IkB-a. The NF-kB activation was prevented by inhibitors of ERK (PD98059) or JNK (SP600125), but was not affected by inhibitors of p38 MAPK (SB203580). HHE decreased the expression of Bcl-2, while it increased that of Bax; of which magnitudes were attenuated by NF-kB inhibitors (Bay 117082). The inhibition of NF-kB also prevented HHE-induced apoptosis.

Conclusions: HHE-induced tubular cell apoptosis is mediated by ROS generation and modulation of Bax and Bcl-2 in HK-2 cells; in which ROS may play a role inducing redox-sensitive transcription factors, NF-kB, through activation of ERK and JNK.

SA-PO2380

Role of Extracellular Matrix Renal Tubulo-Interstitial Nephritis Antigen in Cell Survival Ping Xie,[1] Lin Sun,[2] Yashpal S. Kanwar.[1] *[1]Pathology, Northwestern University, FSM, Chicago, IL; [2]Department of Nephrology, Central South University, Changsha, Hunan, China; [3]Pathology, Northwestern University, FSM, Chicago, IL.*

Background: Tubulo-interstitial nephritis antigen (TINag) is an ECM protein expressed in tubular basement membranes (TBMs). Since some of the ECM proteins are known to modulate cell survival, studies were initiated in Lewis rats lacking TINag expression to see if they are relatively susceptible to cisplatin induced-injury. Cisplatin administration caused relatively high degree of tubular cell damage and apoptosis, exclusively in regions where TINag is normally expressed in the parental Wistar strain. This was accompanied with an accentuated increase in serum creatinine and renal Kim-1 RNA, and protein expression of Bax, p53 and of its phosphorylated form and nuclear accumulation, high molecular weight mitochondrial DNA fragmentation, and a reciprocal decrease of Bcl-2. Inclusion of cisplatin in the culture medium led to a fulminant apoptosis of HK-2 cells with increased Caspase activity, mtDNA fragmentation and reduced cell survival. These adverse effects were partially reversed in cells maintained on a TINag substratum. Far-Western assays established TINag binding with integrin receptors αvβ3 and α3β1. Gene disruption with αv-siRNA accentuated cisplatin-induced apoptosis, translocation of mitochondrial cytochrome-C, cytoplasmic Bax and reduced cell survival, while having a marginal effect with α3-siRNA. Gene disruption of αv also decreased the expression of integrin recruited focal adhesion kinase (FAK) with marked dephosphorylation, while there was an increased p53 expression and phosphorylation. These adverse effects were reduced when cells were grown on TINag substratum. In vivo as well a higher degree of decrease in the expression and phosphorylation of FAK was observed in Lewis rats following cisplatin treatment. These studies demonstrate an essential contribution of TINag towards cell survival to maintain tubular homeostasis via interacting with αvβ3, as a result the FAK is recruited to suppress p53 and events that lead to apoptosis.

Receptor Interacting Protein 1-Mediated Necroptosis Essentially Contributes to Renal Ischemia/Reperfusion Injury Andreas Linkermann,[1] Jan H. Bräsen,[2] Nina Himmerkus,[3] Ulrich Kunzendorf,[1] Stefan Krautwald.[1] *[1]Clinic for Nephrology and Hypertension, Christian-Albrechts-University, Kiel, Germany; [2]Institute for Pathology, Christian-Albrechts-University, Kiel, Germany; [3]Institute for Physiology, Christian-Albrechts-University, Kiel, Germany.*

Background: Loss of kidney function in renal ischemia/reperfusion injury (IRI) is caused by programmed cell death (PCD) but the contribution of necroptosis, a recently discovered form of programmed necrosis, has not been investigated.

Methods: We employ murine renal tubular cells and freshly isolated proximal tubules for analysis of the sensitivity to undergo Fas- or TNF-induced tubular cell PCD. By the addition of caspase-inhibitors or the specific RIP1-inhibitor Necrostatin-1 (Nec-1) we inhibit apoptosis and necroptosis, respectively. In vivo, both sublethal and lethal renal ischemia/

reperfusion injury (IRI) was performed in the presence and absence of PCD-inhibitors. Electron microscopy, immunohistochemistry, conventional PAS-staining, western blotting and FACS analysis were employed to quantify apoptosis and necroptosis ex vivo.

Results: We identify death receptor-mediated caspase-independent cell death in murine tubular cells and characterize it as necroptosis by addition of Nec-1. The necroptotic key players RIP1 and RIP3 were detected in whole kidney lysates and freshly isolated murine proximal tubules. In vivo, Nec-1 reduces organ damage and renal failure, even if administrated after reperfusion and resulted in a significant survival benefit in a model of lethal renal IRI. We functionally compared these results with the contribution of apoptosis to renal IRI. Unexpectedly, the specific blockade of apoptosis by zVAD neither prevented organ damage nor the increase of retention parameters in renal IRI.

Conclusions: Our results demonstrate the presence and functional relevance of necroptosis in the pathophysiologic course of ischemic kidney injury and a functional predominance of necroptosis over apoptosis in this setting. Above that we identify the therapeutical potential of Nec-1 as a drug for the prevention and treatment of renal IRI.

Renin Induces Podocyte Apoptosis through Renin Receptor and p38 MAPK Pathway Independent of Ang II Generation Hai Yuan, Zhilong Ren, Fengqi Hu, Wei Liang, Guohua Ding. *Division of Nephrology, Renmin Hospital of Wuhan University, Wuhan, Hubei, China.*

Background: Podocyte plays an important role in the pathogenesis and progression of glomerulosclerosis. Various elements of renin-angiotensin-aldosterone system (RAAS), such as angiotensin II and aldosterone, can induce podocyte apoptosis. However, little is known about the direct effect of renin on podocytes through renin receptor. In the present study, we evaluated the effect of renin on cultured podocyte apoptosis and the role of p38 MAPK pathway.

Methods: Expression of renin receptor was detected by fluorescent staining and RT-PCR. Podocytes were incubated in media containing either buffer or renin for variable time periods. The cells were also treated with either inhibitor of p38 MAPK or buffer. At the end of the incubation period, apoptosis was evaluated by cell nucleus staining, and caspase 3, p38, phospho-p38 MAPK were measured by Western blotting.

Results: We demonstrated that both renin receptor mRNA and protein were expressed in cultured podocytes. Exposure of podocytes to renin induced podocyte apoptosis in a time-dependent manner, which was accompanied by up-regulation of active caspase-3 and increased expression of p38MAPK. Renin-induced podocyte apoptosis and p38 MAPK phosphorylation were inhibited when the cells were pretreated with p38 MAPK inhibitor. Transfection of renin receptor siRNA ameliorated the above changes induced by renin. Furthermore, these effects of renin were not altered by blocking of angiotensin II using either enalapril or losartan.

Conclusions: These data suggest that renin induces podocyte apoptosis, which is mediated through renin receptor and p38 MAPK pathway independent of Ang II generation.

SA-PO2383

Connexin43 Contributes to Puromycin-Elicited Podocyte Injury Qiaojing Yan, Yuan Chi, Ying Zhu, Masanori Kitamura, Jian Yao. *Department of Molecular Signaling, University of Yamanashi, Chuo, Yamanashi, Japan.*

Background: Gap junctions (GJs), formed by specific protein termed connexin (Cx), play important roles in regulation of cell phenotype and in the control of cell survival. Podocyte injury is one of the major factors contributing to the initiation and development of proteinuria and glomerulosclerosis. In our previous study, we demonstrated that puromycin-induced podocyte injury *in vivo* is preceded by a markedly increased Cx43 level *(Am J Pathol, 2002, 161:1597-1606).* However, the mechanisms involved in the elevation of Cx43 and the functional roles of Cx43 in podocyte injury have not been elucidated. The purpose of this study was to tackle these questions.

Methods: Podocyte viability was evaluated by MTT assay, caspase-3 cleavage and Hoechst staining. The levels of Cx43, P38 and caspase-3 were evaluated by Western blot analysis. Cx43 distribution and function were assayed by immunofluorescent staining and dye-transfer assay, respectively.

Results: 1) Exposure of cultured podocytes to puromycin caused a time- and concentration-dependent podocyte injury. This effect could be significantly blocked by antioxidants, indicating a critical role of oxidative stress in cell injury. 2) Puromycin-induced podocyte injury was preceded by an obviously increased Cx43 protein level. Pretreatment of cells with antioxidants also largely abolished the Cx-43 elevating effect, indicating an involvement of oxidative stress in induction of Cx43. 3) Consistent with a critical role of oxidative stress in Cx43 expression and podocyte injury, agents that induce intracellular superoxide anion formation were found to be able to mimic the effect of puromycin on Cx43 levels and cell injury. In addition, puromycin, indeed, elevated intracellular superoxide. 4) Suppression or inhibition of GJs with the GJ inhibitors significantly abrogated the cytotoxic effect of puromycin and inhibited activation of P38 MAP kinase and cleavage of caspase 3.

Conclusions: Our study thus revealed an important role of GJ protein Cx43 in mediation of oxidative stress-induced podocyte injury. Cx43 could be used as a marker of oxidative stress in podocytes and a therapeutic target for prevention and treatment of podocyte injury.

SSeCKS Sequesters Cyclin D1 in Glomerular Parietal Epithelial Cells Bettina Burnworth, Jeffrey W. Pippin, Ron D. Krofft, Kelly L. Hudkins, Charles E. Alpers, Kelly D. Smith, Stuart J. Shankland, Peter J. Nelson. *University of Washington, Seattle, WA.*

Background: Glomerular parietal epithelial cells (PECs) are precursors for podocytes in mature glomeruli, however, as progenitors, the distinct mechanisms that allow for repeated periods of cell-cycle arrest and re-entry of PECs after glomerulogenesis are unknown. Here, we show that the Src-suppressed protein kinase C substrate, SSeCKS, a multivalent scaffolding A kinase anchoring protein, sequesters cyclin D1 in the cytoplasm of quiescent PECs.

Methods: The expression and interaction of SSeCKS and cyclin D1 was studied in PECs in tissue culture, during glomerulogenesis, and in post-natal glomeruli of $SSeCKS^{+/+}$ and $SSeCKS^{-/-}$ mice.

Results: SSeCKS expression is induced in embryonic PECs but not in embryonic podocytes starting at the S-phase of glomerulogenesis, and is constituitively expressed post-natally by PECs, but not podocytes, in normal glomeruli. Cyclin D1 immunoprecipitated with SSeCKS from capsulated glomeruli containing PECs, whereas decapsulated glomeruli without PECs lacked SSeCKS and cyclin D1. Cell-cell contact inhibition of proliferation in cultured PECs induced SSeCKS expression and binding of cyclin D1 by SSeCKS in the cytoplasm, whereas phosphorylation of SSeCKS by activated PKC disrupted binding, resulting in nuclear translocation of cyclin D1. $SSeCKS^{-/-}$ mice showed hyperplasia of PECs in otherwise normal glomeruli and developed significantly worse proteinuric glomerular disease, marked by increased PEC proliferation and expression of nuclear cyclin D1, from nephrotoxic nephritis.

Conclusions: These results suggest that SSeCKS controls the localization and activity of cyclin D1 in PECs.

SA-PO2385

HIV-Nef Induces Detachment, Migration and Proliferation of Human Podocytes by Compromising Cytoskeletal Integrity Hitesh Patni, Divya Salhan, Ashwani Malhotra, Mohammad Husain, Pravin C. Singhal. *Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY.*

Background: HIV-1 gene Nef has been considered to play an important role in the development of HIV-1 associated nephropathy (HIVAN). We hypothesized that Nef decreases adhesion and enhances detachment, migration, and proliferation of podocytes by compromising their cytoskeletal integrity.

Methods: We developed stable colonies of conditionally immortalized human podocytes expressing either Nef (Nef/CIHP) or empty vector (EV/CIHP). To identify Nef-linked proteins, GST pull down assay followed by mass spectrometry was carried on EV/CIHP and Nef/CIHP. To identify Nef interacting proteins, yeast two hybrid assay was carried out. To determine mRNA expression of relevant proteins, microarray array analysis of RNA from EV/CIHP and Nef/CIHP was carried out. To identify co-localization of Nef with interacting proteins, imaging studies were performed. To determine alteration in Nef-induced functionality of podocytes, adhesion, detachment, migration, proliferative and apoptotic studies were done.

Results: GST pull down assay in Nef/CIHPs displayed a band at 45 kD, which was identified to be actin by mass spectrometry; whereas, yeast two hybrid assay identified the following nef-interacting proteins: syntrophin, filamin B, syntaxin, translational elongation factor 1, and zyxin. Microarray analysis of RNAs from Nef/CIHP revealed enhanced expression of Rac1 and syndecan-4 and attenuated expression of syndecan-3 and syntenin when compared with EV/CIHPs. Imaging studies displayed co-localization of Nef with actin and zyxin in Nef/CIHPs. Nef /CIHP displayed scant number of actin filaments and enhanced number of lamellipodia. Since Nef/CIHPs displayed enhanced expression of Rac1, it appears that Nef-induced Rac1 expression may be contributing to increased number of lamellipodia in Nef/CIHPs.Nef/CIHP displayed decreased adhesion, enhanced detachment and migration. Moreover, Nef/CIHPS displayed proliferative phenotype.

Conclusions: We conclude that interaction of Nef with actin compromises cytoskelatel integrity of human podocytes and make them prone to detach, migrate and proliferate.

A Novel, Dual Role of CCN3 in Experimental Glomerulonephritis: Pro-Angiogenic and Anti-Mesangioproliferative Effects Claudia R.C. van Roeyen,[1] Peter Boor,[1] Uta Kunter,[1] Ina V. Martin,[1] Ana Kaitovic,[1] Erawan Borkham-Kamphorst,[2] Bernard Perbal,[3] Ralf Weiskirchen,[2] Tammo Ostendorf,[1] Jurgen Floege.[1] *[1]Nephrology, RWTH Aachen University, Aachen, Germany; [2]Clinical Chemistry and Pathobiochemistry, RWTH Aachen University, Aachen, Germany; [3]L´oreal R&D, Clark, NJ.*

Background: In contrast to factors promoting mesangial cell proliferation, little is known about their endogenous regulators. During experimental mesangioproliferative nephritis glomerular CCN3 (nephroblastoma overexpressed gene) expression is reduced prior to the proliferative phase and overexpressed both in glomeruli and serum when mesangial cell proliferation subsides.

Methods: To further elucidate its role in mesangioproliferative glomerulonephritis (GN), CCN3 was systemically overexpressed by muscle electroporation in healthy or nephritic rats. This increased CCN3 serum concentrations more than 3-fold for up to 35 days after electroporation.

Results: At day 5 after induction of mesangioproliferative GN, CCN3 transfected rats exhibited an increase in glomerular endothelial area and in glomerular mRNA levels of the pro-angiogenic factors VEGF and PDGF-C. *In vitro* CCN3 induced proliferation of glomerular endothelial cells. In the mesangioproliferative phase (day 7), CCN3 overexpression decreased albuminuria, the α-smooth-muscle actin (αSMA) positive mesangial area, the number of proliferating mesangial cells and glomerular accumulation of fibronectin and type IV collagen. In progressive nephritis at day 56, systemic overexpression of CCN3 resulted in decreased albuminuria, glomerulosclerosis and reduced cortical collagen type I accumulation. In healthy rat kidneys, overexpression of CCN3 induced no morphological changes but regulated glomerular gene transcripts (reduced transcription of PDGF-B, PDGF-D, PDGFR-ß, fibronectin, and αSMA and increased PDGFR-α and PDGF-C).

Conclusions: Our data identify a dual role of CCN3 in experimental glomerulonephritis with both pro-angiogenic and anti-mesangioproliferative effects, both of which serve to reconstitute the normal glomerular architecture. Manipulation of CCN3 could represent a novel approach to help repair glomerular endothelial damage and mesangioproliferative changes.

Profiling of Inflammatory Mediators Produced by Primary Human Mesangial Cells *In Vitro*

Margaret M. O'Neill, Steven S. Pullen. *CardioMetabolic Diseases Research, Boehringer Ingelheim Pharmaceutical Inc., Ridgefield CT.*

Background: The study of fibrotic changes occurring in the development of chronic kidney disease has shown the importance of inflammatory products in initiating and perpetuating the local environment in the diseased kidney during the progression towards end stage renal disease.

Methods: Normal primary human mesangial cells were stimulated with AngII, IL-1β, IL-6 or TGFβ1, factors known to be dysregulated in renal disease. To determine which cytokines or chemokines were produced, an initial screen of supernatants was performed using multi-analyte arrays. A 12 cytokine array including TNFα, IL1β, IL6, IL12, IL17A, IL8, MCP-1, RANTES, MIP-1a, MIP-1b, MDC and Eotaxin was selected based on preliminary experiments. Subsequent determinations for dose and time studies were done using single analyte ELISA kits.

Results: Production of inflammatory mediators IL6, IL8 and MCP-1 was induced by AngII, IL1β, IL6 and TGFβ1. IL1β stimulation also increased production of RANTES and MIP-1a. TGFβ1, an important modulator in kidney disease, was quantified in separate experiments. AngII, IL1β and IL6 all increased production of TGFβ1. Stimulation of cells with TGFβ1 induced an autocrine increase in TGFβ1 production. The production of IL6, IL8, MCP-1 and TGFβ1 was found to be both dose and time dependent. IL1β was the only factor to induce GM-CSF and ICAM-1 surface expression whereas IL1β and IL6 induced a modest increase in TSP-1. Fibronectin and collagen I deposition were detected 4-7 days after stimulation.

Conclusions: This data provides an *in vitro* kidney specific cellular assay with the potential to triage inhibitors of inflammatory pathways participating in kidney disease.

Up4A, Elevated in Patients with End-Stage Renal Disease, Induced a Phenotype Switch of Vascular Smooth Muscle Cells Via P2Y Activation

Mirjam Schuchardt, Jasmin Pruefer, Markus van der Giet, Markus Tolle. *Med. Klinik mit SP Nephrologie, Charite - Campus Benjamin Franklin, Berlin, Germany.*

Background: Vascular mineralization is a major risk factor in patients with chronic kidney disease (CKD) and contributes to the increased cardiovascular mortality. Vascular calcification is an actively induced process Smooth muscle cells differentiate twoard osteoblast-like phenotype. The dinucleoside polyphosphate uridine adenosine tetraphosphate (Up4A) has been previously shown to be a potent calcification inducing substance. Now we searched for the involved mechanism.

Methods: In vitro and ex vivo calcification in rat VSMCs and aortic rings was measured. Calcium deposition was monitored. Expression of cbfa1 was measured in rat VSMCs after stimulation with Up4A.

Results: Up4A induced calcification of rat VSMCs in vitro and ex vivo in rat aortic rings, visualized by Alizarin Red Staining and quantified. The non-selective P2Y inhibitors suramin, PPADS, and RB-2 as well as MRS2578, which antagonizes P2Y6, have a significant inhibitory effect on the Up4A-induced mineralization in VSMCs. For mineralization of VSMCs a trans-differentiation of VSMCs in osteoblast-like cells could be detected. Investigating the gene expression in rat VSMCs Up4A is able to induce the initial transcription factor cbfa1. To proof the antagonistic potential of the mentioned antagonists, these were also investigated on their inhibitory potential on Up4A-induced cbfa1 expression. Suramin, PPADS, RB-2 and MRS2578 co-incubation is able to significantly diminish the Up4A-induced cbfa1 expression. P2Y2/4/6 receptor activation might be responsible for this effect. ATPγS, a selective P2Y2 agonist could mimic the effect to induce the cbfa1 expression. To further verify the P2Y2 activation, we used P2Y2-/- mice for ex vivo mineralization assay. In P2Y2-/- mice, Up4A is not able to potentiate the effect of CM, compared to wild-type mice.

Conclusions: Up4A-mediated mineralization depends on the activation of P2Y2 to stimulate trans-differentiation in VSMCs. Up4A has influence on vascular mineralization and therefore, the purinergic signaling might be involved in arteriosclerotic processes.

SA-PO2389

4-Phenylbutyrate Inhibits Transforming Growth Factor-β1-Induced Apoptosis Via a Caspase-Mediated Mechanism in Human Renal Proximal Tubule Epithelial Cells

Elise Brimble, Richard Austin, Jeffrey G. Dickhout. *Nephrology, McMaster University and St. Joseph's Healthcare Hamilton, Canada.*

Background: TGF-β1 signaling is an important inducer of apoptosis in tubular epithelium during renal injury, however, the precise mechanism is unknown. Smad3 may mediate TGF-β1-induced renal tubular epithelial cell (RTEC) apoptosis, as shown by a reduction in its incidence in the $Smad3^{-/-}$ mouse in a model of obstructive nephropathy. Histone deacetylase (HDAC) inhibition reduced TGF-β1-induced apoptosis in cultured RTECs. However, it is unclear how HDAC inhibitors interfere with this apoptotic response. We hypothesize that HDAC inhibitors reduce RTEC apoptosis by disrupting TGF-β1 signaling.

Methods: We used human primary RTECs and HK-2 cells treated with human recombinant TGF-β1 to determine the effects of pan-HDAC inhibitors, 4-Phenylbutyrate (4-PBA) and vorinostat, on the incidence of apoptosis. Tauroursodeoxycholic acid (TUDCA), a low molecular weight chemical chaperone, was used as a control, as 4-PBA has chemical chaperone properties. LDH release and TUNEL assays were used to assess cytotoxicity and apoptosis. Western blotting was used to monitor TGF-β1 signaling and the endoplasmic reticulum (ER) stress response. Z-VAD FMK, a pan-caspase inhibitor, was used to determine the dependence of TGF-β1-induced apoptosis on caspase activity.

Results: We found that TGF-β1 treatment induced cytotoxicity and apoptosis in RTECs. This effect was significantly inhibited by treatment with 4-PBA and vorinostat, but not with TUDCA. TGF-β1 was not found to induce apoptosis through the ER stress-inducible protein CHOP/GADD153; however, 4-PBA induced XBP1 splicing, a cytoprotective response to ER stress. TGF-β1-induced apoptosis was found to be dependent on caspase activity, as was the ability of 4-PBA to inhibit cell death. 4-PBA, vorinostat, and TUDCA were not found to have an effect on TGF-β1-induced Smad3 phosphorylation or expression.

Conclusions: TGF-β1-induced apoptosis contributes to the deterioration of tubule function in chronic kidney disease. Thus, HDAC inhibitors may be an effective treatment to maintain renal function by preserving tubule integrity via inhibition of caspase mediated TGF-β1-induced apoptosis.

Loss of the β Isoform of Calcineurin A (CAβ) Reduces Hypertrophy, Suppresses Protein Synthesis, and Activates AMP Dependent Kinase (AMPK)

Harold A. Franch,[1,2] Changlin Ding,[2] Sara Zoromsky,[2] Jennifer L. Gooch.[1,2] *[1]Renal Division, Atlanta VAMC, Decatur, GA; [2]Emory University, Atlanta, GA.*

Background: Transgenic mice with CAβ knocked out (CAβ-/-) have normal renal development and function, but do not exhibit renal hypertrophy when diabetic (Reddy RN et. al. 2009). Because calcineurin regulates protein synthesis and breakdown in cardiac hypertrophy, we examined its role in protein metabolism and in phosphatidylinositol 3 kinase (PI3K) mitogen associated kinase (MAPK), and AMPK signaling in proximal tubule cells.

Methods: C^{14} phenylalanine pulse/chase was used for protein synthesis and breakdown in NRK-52E renal epithelial cells and SV40 immortalized cell lines created from CAβ-/- and wildtype litter mate proximal tubules. Signaling intermediates were examined by Western blotting comparing the ratio of phospho-specific to whole protein antibodies. Inhibitors of CA (8 μM cyclosporine A (CYA) or 200 nM tacrolimus), of PI3K (25 μM LY249002) and of MAPK (50 μM U0126) were used. All results are $p<0.05\%$.

Results: CYA decreased protein content/well (48h) by 14±2% and protein synthesis (20h) 51±2% of control in NRK-52E cells. In contrast, protein degradation (0h-28h) was decreased by 10±1%. Tacrolimus gve similar results on protein content and degradation. Inhibitors of MAPK or PI3K pathways reduced protein synthesis by 48±3% or 56±2% in these cells. However, CYA or tacrolimus increased both basal and EGF-induced MAPK and AKT (downstream of PI3K) phosphorylation (1h) by 50% to 3-fold. Downstream of MAPK and AKT, AMPK (which acts to inhibit the mammalian target of rapamycin) phosphorylation was ~6 fold higher with CYA compared to control. CAβ-/- tubular cells had lower protein per well (48h, 20±2%) and protein synthesis (20h, 16±1) than CAβ+/+ cells. In CAβ -/- cells, CYA treatment (20h) did not decrease protein synthesis further, while it reduced it 20±2% in CAβ +/+ cells. AMPK phosphorylation was >10 fold higher in CAβ -/- compared with CAβ+/+ cells.

Conclusions: The inhibition of calcineurin or knockout of CAβ reduces protein accumulation in renal tubular cells via reduced protein synthesis possibly through activation of AMPK. Activation of AMPK may explain decreased renal hypertrophy in CAβ mice.

SA-PO2391

Consideration of Protein Expression Changing with Pitavastatin or Edaravone Therapy in Chronic Puromaycin Aminonucreoside Nephropaty

Tokushi Nakajima, Koichi Kanozawa, Tetsuya Mitarai. *Nephrology and Hypertension, Saitama Medical Center, Kawagoe, Saitama, Japan.*

Background: In puromaycin aminonucreoside nephrosis rats which is one of human nephritic syndrome animal model. Excessive oxidants, especially oxidative LDL play roles in the pathogenesis of glomerular injury. To clarify the protective effects of anti-

oxidative therapy, we investigated changes in chemical markers of lipid peroxidation and renal histology, and protein array in rats with chronic puromycin aminonucleoside (PAN) nephrosis (C-PAN).

Methods: C-PAN was induced by intraperitoneal injections of PAN (130 mg/kg on day 1 and 60 mg/kg on day 14). Rats administered normal saline served as controls (n=5). C- PAN rats were divided into four groups (each group: n=4, positive control, negative control, pitavastatin treatment , edaravone treatment). Blood and urinary samples were collected every week. Animals were sacrificed at the end of experiment for histological and protein array analysis.

Results: In C-PAN+Pit and C-PAN+Eda rats, urinary excretion of albumin and 8-isoPGF2α and thiobarbituric acid-reactive substances (TBARS) were significantly decreased compared with that in C-PAN rats ($p<0.01$). On histological examination, glomerular injury score, 4-HNE positive area, Infiltration of macrophages and tunnel positive cell counts were significantly lower in both groups than in C-PAN rats ($p<0.05$). All of these results shows their features. In protein microarray, Plk-2 (Polo-like protein kinase) and IkBa (Inhibitor of NF-kappa-B alpha) were upregulated [Plk-2; Pit/Eda: 118 /114 folds, IkBa; Pit/Eda: 39 /122 folds]. And edaravone treatment group showed Mn-SOD upregulation (Eda: 32 folds).

Conclusions: These findings showed anti-oxidative treatment to C-PAN ameriolated glomerular injury. And these effects correlated with anti-apoptotic protein and cell signaling protein upregulation. In edaravone treatment, anti-oxidant protein also upregulated. But both treatment changing thses molecules, finding from other results, pitavastatin has not only protective effects but regeneration of constituent cells. Because edaravone changed anti-oxidative protein, this effects would useful for renal protection as an anti-oxidative treatement.

SA-PO2392

Overexpression of GFP-GABARAP Causes Deterioration of Proteinuria and Glomeruloscrelosis in Adriamycin-Induced Nephropathy Mice Katsuhiko Asanuma,[1] Miyuki Takagi,[1] Kanae Nonaka,[1] Etsuko Asanuma,[1] Takashi Ueno,[4] Yasuhiko Tomino.[1] *[1]Division of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Department of Biochemistry and Cell Biology, National Institute of Infectious Diseases, Tokyo, Japan; [3]Research Institute for Diseases of Old Age, Juntendo University Faculty of Mediine, Tokyo, Japan; [4]Department of Biochemistry, Juntendo University Faculty of Mediine, Tokyo, Japan.*

Background: We previously reported that LC3, a promising marker of autophagy, played an important role in recovery from podocyte damage in an experimental nephrosis model. GABARAP is a γ-aminobutyric acid A receptor associated protein and has recently been characterized as another homolog of LC3, although its precise role in autophagy remains unclear.

Methods: We recently generated GFP-GABARAP transgenic mice, in which GFP-GABARAP is abundantly expressed in glomerular podocytes.

Results: We observed that aged transgenic mice showed slight albuminuria and showed low levels of foot-process effacement. Surprisingly, a single injection of adriamycin caused a more significant increase in proteinuria and sclerotic glomeruli in transgenic mice compared with wild type mice. Under these conditions, neither GFP-GABARAP nor endogenous GABARAP appeared to be recruited by autophagosomes and remained in the cytosol. Moreover, cytosolic GFP-GABARAP was significantly colocalized with p62 to form aggregates.

Conclusions: It appears that the GFP-GABARAP/p62 complex is responsible for impairment of glomerular function, and that it retards recovery from the effects of adriamycin.

SA-PO2393

Anti-Proliferative Effect of Asymmetric Dimethylarginine (ADMA) – A Clue to Renal Fibrosis? James Alexander Tomlinson,[1] Ben Caplin,[2] Jill T. Norman,[2] David C. Wheeler,[2] James M. Leiper.[1] *[1]Nitric Oxide Signalling Group, MRC Clinical Sciences Centre, London, United Kingdom; [2]Renal Department, UCL/ Royal Free, London, United Kingdom.*

Background: The endogenous nitric oxide synthase (NOS) inhibitor, asymmetric dimethylarginine (ADMA), has been implicated in a wide variety of diseases including chronic kidney disease (CKD) although a true cause and effect remains to be established. CKD is characterised by progressive functional decline histologically manifest as progressive tubulointerstitial fibrosis. Renal tubular epithelial cells play a key role in fibrosis and are known to express components of the NO system. We hypothesised that ADMA may contribute to fibrosis by impairing the ability of renal epithelial cells to repair following injury.

Methods: Confluent conditionally-immortalised human proximal tubular epithelial cells were made quiescent and a wound was scratched across the monolayer. Cells were incubated in the presence or absence of 10% foetal calf serum (FCS) and ADMA [3 and 10uM] for 24 hours. The extent of repair (in-filling) of the wound was measured. Proliferation was distinguished from migration using the cytostatic drug Mitomycin C and subsequently confirmed using a BrdU incorporation assay to measure DNA synthesis.

Results: FCS (10%) markedly stimulated epithelial repair of the scratch (48% ±7 vs 11% ±2; $p<0.0001$). Mitomycin C significantly retarded repair (18% ±0 vs 48% ±7; $p<0.0001$), suggesting that wound repair was largely due to epithelial cell proliferation. ADMA significantly inhibited serum-induced wound repair (32% ± 3 vs 48% ±7; $p<0.05$) and BrdU incorporation (0.96 ±0.23 vs 1.67 ±0.45 arbitrary units (AU); $p<0.0001$) when compared with FCS treatment alone, suggesting a potent anti-proliferative effect. Inhibition of NOS with two other inhibitors, PBITU and L-NAME also suppressed cell proliferation (0.36 ±0.11 vs 1.67 ±0.45 AU; $p<0.0001$ and 1.14 ±0.32 vs 1.67 ±0.45 AU; $p<0.05$ respectively).

Conclusions: ADMA exerts an anti-proliferative effect on renal epithelial cells, most likely due to reduced NO availability. This suggests a potential mechanism for impaired renal repair and fibrosis.

SA-PO2394

Fucosylation Influences Extracellular Matrix Accumulation in TGF-β1-Stimulated HK-2 Cells Hong Li Lin, Zheng Mei Jie, Fang Ming, Ke Ping Wang. *Department of Nephrology, First Affiliated Hospital of Dalian Medical University, Dalian, Liaoning, China.*

Background: TGF-β1 plays an key role in the development of renal fibrosis.Our previous work found that core fucosylation which catalized by its specific transferase Fut8 was essential for TGF-β receptors to fulfill their functions, however, it remains unclear whether fucosylation exerts effects on ECM accumulation and tubular epithelial cell apoptosis.

Methods: A fibrosis HK-2 cell model was established with 10ng/ml TGF-β1. Fut8 siRNA was transfected into HK-2 cells with Lipo2000 at the concentration of 30nM. The changes of Fut8 expression were examined by western blot, and the apoptosis were determined by flow cytometry. Also, expression levels of protein MMP-2,3,9 and TIMP-1 were detected by western blot. Additionally, ECM proteins, including collagen type I,III,IV, were examined by immunofluorescence. Besides, fibronectin and laminin were examined by Real time-PCR.

Results: The expression of Fut8 protein increased after stimulated by TGF-β1, and Fut8-siRNA transfection reversed the significant up-regulation of Fut8 protein and inhibited the apoptosis of HK-2 cells. Moreover, TGF-β1 enhanced the expression of MMP-2, 3 as well as TIMP-1, but had no effect on MMP-9; Furthermore, Fut8-siRNA up-regulated the expression of MMP-2,3,9 , and decreased the expression of TIMP-1. Collagen typeI, III, IV, fibronectin and laminin,were excessive synthesis after stimulated by TGF-β1, while they had no obvious change when treated by TGF-β1 together with Fut8-siRNA.

Conclusions: Bolocking fucosylation may suppress ECM accumulation and apoptosis in HK-2 cells stimulated by TGF-β1, then suppress interstitial fibrosis.

SA-PO2395

Aristolochic Acid Enhances Invasion and Migration of Human Urothelial Cancer TSGH Cells In Vitro and In Vivo Horng-Rong Chang,[1,2] Hui-Pei Huang,[3] Jen-Pi Tsai,[1] Jong-Da Lian,[2] Chau-Jong Wang.[3] *[1]Chung Shan Medical University, Institute of Medicine, Taichung, Taiwan; [2]Division of Nephrology, Department of Medicine, Chung Shan Medical University Hospital, Taichung, Taiwan; [3]Chung Shan Medical University, Institute of Biochemistry and Biotechnology, Taichung, Taiwan.*

Background: Aristolochic acid I (AAI) had been implicated in urothelial carcinoma (UC) in humans. However, whether AAI promotes invasion/migration of UC has not been established.

Methods: A study of human UC TSGH cells cultured with AAI was conducted. Cell viability, the effects of AAI on the activity of MMP-9, the abilities of invasion/migration and the migration-related proteins (Ras, RhoA, ROCK1, PI-3K, p-Akt and NF-κB) of the TSGH cells were assessed. The TSGH cells were subcategorized to one-day or 30-day AAI exposure. An *in vivo* study using a nude mice xenograft model was employed to test the anti-tumor effects of Rho kinase inhibitor or Y27632.

Results: A time- and dose-dependent increase in both activity and mRNA level of MMP-9 were demonstrated. The mRNA level of uPA was increased and of TIMP1 was decreased in the cells with 30-day but not one-day AAI exposure. A dose-dependent enhancement in wound healing rate and cell migration was demonstrated, especially in the 30-day AAI-exposed cells. Expressions of Ras/RhoA and other migration-related proteins were increased after AAI treatment which could be inhibited by Y-27632. The *in vivo* results demonstrated that Y27632 was able to attenuate the speed of growth of the inoculated tumors in nude mice.

Conclusions: Our results provided *in vitro* and *in vivo* evidence that prolonged AAI exposure enhances invasion and migration of human TSGH cells.

SA-PO2396

Runx3 Mediates Suppression of Tumor Growth and Metastasis of Human CCRCC by Regulating Cyclin Related Proteins and TIMP-1 Hanmin Wang, Shiren Sun, Lijie He.

Background: Although our previous studies indicated that Runx3 has been implicated in tumor suppression in several tumors, the precise molecular mechanisms in renal cancer remained unclear.

Methods: Here we tested Runx3 in clear cell renal cell carcinoma (CCRCC) in vivo and in vitro.

Results: We presented that the expression of Runx3 was absent or significantly decreased in 75 cases of CCRCC tissues ($p<0.05$, table1,figure1,a is cancer, b is non-cancerous). Enforced Runx3 expression mediated 786-O CCRCC-derived cells to exhibit significant inhibition of growth, G1 cell cycle arrest and metastasis in vitro, and to lost 786-O tumorigenicity in nude mouse model. Runx3-induced growth suppression was found

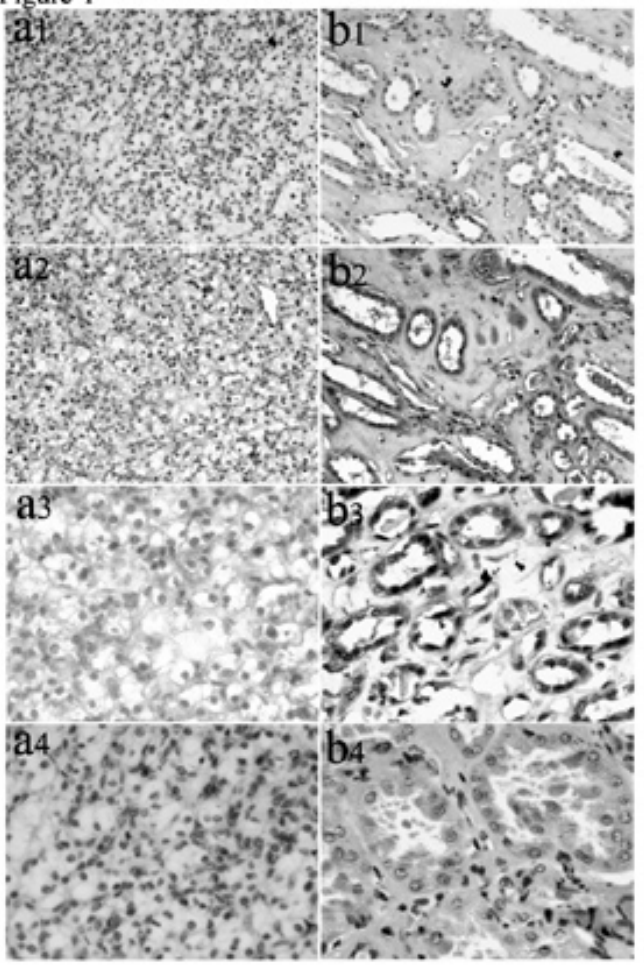
partially to regulate various proteins, including inhibition of cyclinD1, cyclinE, cdk2, cdk4 and p-Rb, but up-regulation of $p27^{Kip1}$ and Rb. Simultaneously, overexpression of Runx3 led to significant induction of TIMP-1 expression.

Clinicopathological associations of Runx3 expression in CCRCC patients

Category	Total number of cases	Runx3 expression -	Runx3 expression +	Runx3 expression ++	Positive case	P value
Adjacent tissue of CCRCC	77	12(15.58%)	16 (20.78%)	49 (63.64%)	65 (84.42%)	
CCRCC tissues	75	52 (69.33%)	12 (16%)	11 (14.67%)	23 (30.67%)	<0.001**

Runx3 staining was graded as negative (-; score: 0–1), weak (+; score:2–4), and strong (++; score:5–8). Pearson's X2 Test, **P<0.001 vs non-cancerous tissues.

Figure-1



Conclusions: Therefore, Runx3 has the proliferative and metastatic abilities of CCRCC cells, which was mediated, at least partially by regulating cyclins and TIMP1.

SA-PO2397

Age Associated Loss in Tubular Epithelial Proliferation Reserve Is Intrinsically Determined Nathan D. Susnik, Inna V. Kuznetsova, Birgit Berkenkamp, Christoph Jacobi, Inga Soerensen, Hermann G. Haller, Anette Melk, Roland Schmitt. *Department of Nephrology, Hannover Medical School, Hannover, Germany.*

Background: Data from kidney injury models suggests that the loss of renal repair capacity with aging is largely due to a decreased tubular epithelial proliferative reserve. This concept has been challenged because age dependent factors might lead to different damage loads in experimental kidney injury, this may cause changes in the reparative proliferation response.

Methods: In order to test for age-dependent changes in the renal epithelial proliferative reserve without inducing cellular injury, we used lead acetate, a potent direct mitogen, to stimulate tubular cell proliferation. Lead acetate was used in old (22 months) and young (4 months) mice in vivo and in old and young primary tubular epithelial cells (PTEC). Differences in cell cycling, cell damage and markers of senescence were quantified by histology, immunoblot and qPCR.

Results: Lead acetate significantly increased the rate of tubular epithelial proliferation without causing cell damage as shown by unchanged levels of injury markers Ngal and Kim-1. The increase in proliferation was significantly smaller in old mice. Cyclin D1 positive tubular cells increased only in young kidneys, but not in old kidneys. Kidneys from old mice expressed significantly more of the senescence markers p16INK4a, senescence associated β-galactocidase, and phospho-γH2AX, regardless of lead acetate stimulation. Only young isolated PTEC showed increased proliferation after lead acetate stimulation but to a lesser extent than in vivo. This may have been due to a dramatic increase of p16INK4a and p21 in both age groups, resulting in almost identical levels of senescence markers in PTEC from young and old mice after 6 days of culture.

Conclusions: These data indicate that the aged kidney has an intrinsically reduced proliferative capacity. This is in agreement with a higher load of senescence markers from both the stress- and telomere-induced pathway. Age-dependent differences in tubular cell proliferation quickly diminish in vitro because cultured PTEC from young kidneys undergo accelerated aging with rapid induction of cellular senescence.

SA-PO2398

Inactivation of Mxi1 Regulates IFT20 Expression in Polycystic Kidney Jong Hoon Park, Je Yeong Ko, Kyung Hyun Ryu. *Department of Biological Science, Sookmyung Women's University, Seoul, Republic of Korea.*

Background: Most cell types have primary cilium, which consists of protruding structures that sense mechanical and chemical signals from the extracellular environment. Cilia are assembled via a process known as intraflagellar transport (IFT) and a variety molecules, including IFT20, IFT88 and Kif3a, participate in the assembly of cilia. It is critical that the size control system of cilia be elucidated to enable a through understanding of ciliary diseases such as autosomal dominant polycystic kidney disease (ADPKD), which involves abnormally short cilia. ADPKD is a human genetic disease that is rooted in defects in cilia formation, maintenance or function.

Methods: To confirm the effect of Mxi1 on cilia, we performed immuno assay in Mxi1-deficient MEFs and Mxi1-deficient mice. Also, IFT genes were screened *in vitro* and *in vivo* using real-time PCR to select candidate gene. Furthermore, we performed promoter assay to check the effect of Mxi1 on candidate gene regulation.

Results: Previously, multiple tubular cysts were observed in the kidneys of Mxi1-deficient mice aged six months or more. Here, we clarify the relationship between inactivated Mxi1-induced cyst formation and cilia assembly. In Mxi1-deficient MEFs, the length of structurally normal cilium decreased, but we still confirmed the presence of cilia in cysts of Mxi1-deficient mice. To elucidate the cilia regulatory mechanism related to Mxi1, IFT genes are validated in Mxi1 MEFs and Mxi1 mice using real-time PCR. IFT20, IFT88, Kif3a genes are decreased in Mxi1-deficient model and IFT20 is selected for candidate gene. We observed that cilia length and IFT20 expression are regulated by Mxi1 level *in vitro*. Also IFT20 promoter activities are regulated by Mxi1 level in mIMCD.

Conclusions: These results indicate that inactivation of Mxi1 plays an important role in the down-regulation of IFT20 expression in polycystic kidneys.

Funding: Government Support - Non-U.S.

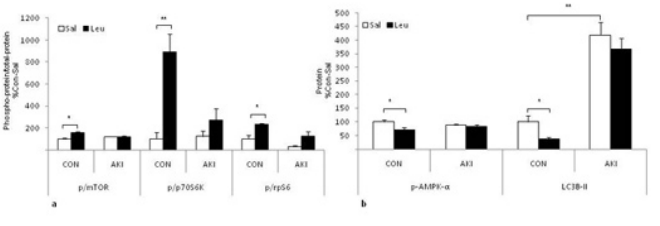
SA-PO2399

Resistance to Leucine Induced Signal Transduction and Regulation of Autophagy in Acute Kidney Injury Kevin L. McIntire,[1,2] Yu Chen,[1,2] Sumita Sood,[1,2] Ralph Rabkin.[1,2] *[1]Research Services, VA Palo Alto HCS, Palo Alto, CA; [2]Medicine/Renal Division, Stanford University, Palo Alto, CA.*

Background: Adequate nutrient intake in acute kidney injury (AKI) is a key part of patient management. Of particular interest are the branched chain amino acids(BCAA) especially leucine(LEU). LEU serves as a substrate, stimulates insulin release and directly activates the mTOR anabolic signaling pathway, stimulating protein synthesis via phosphorylation(p-) of p70 ribosomal S6 kinase-1(p70S6K), S6 ribosomal protein(rpS6) and eukaryotic 4E-binding protein1(4E-BP1). LEU also inhibits proteolysis in part by suppressing autophagy which is increased in AKI. Of note, LEU activation of mTOR is regulated in part by p-AMPK which inhibits mTOR activation. Since LEU resistance develops in other acute catabolic conditions and signaling defects are common in uremia, we set out to determine whether LEU is effective in stimulating skeletal muscle mTOR anabolic signaling and inhibiting autophagy, in AKI.

Methods: Rats with post-renal AKI(ureters ligated)and sham operated controls(CON) were gavaged with LEU or saline(Sal)and sacrificed 60 mins later.

Results: BCAA levels post-LEU were similar.Western blots show that LEU significantly stimulated p-mTOR, p-P70S6K and p-rpS6 in CON but not AKI rats(Fig 1a).LEU suppressed LC3B-II protein levels(an autophagy marker) in CON, but had no effect on the elevated levels in AKI and also suppressed p-AMPK in CON, but not AKI rats(Fig 1b).



Conclusions: Together, failure of LEU to stimulate phosphorylation of the mTOR anabolic pathway, and failure to suppress both p-AMPK and autophagy strikingly demonstrates that AKI induces a leucine resistant state. We suggest that this AA resistance may contribute to protein energy wasting that often persists in AKI patients despite nutritional supplementation.

Snail Destabilizes Cell Surface Localization of the Apical Polarity Protein Crumbs3a Jennifer L. Harder, Eileen L. Whiteman, Jay Pieczynski, Benjamin L. Margolis. *Internal Medicine, University of Michigan, Ann Arbor.*

Background: During Epithelial to Mesenchymal Transition (EMT), cells modulate expression of proteins resulting in loss of apical-basal polarity. Mechanisms involved in this switch target the polarity protein Crumbs3, a small transmembrane protein that is essential for generation of the apical membrane and tight junctions of epithelial cells. The Crumbs3 gene is a direct target of transcriptional regulation by Snail, a potent inducer of EMT. However, Snail has also been shown to have multiple non-transcriptional roles, including regulation of cell adhesion and movement as well as cell proliferation and survival. In this set of experiments, we defined the normal kinetics of Crumbs3a in polarized epithelial cells and then explored Snail's post-translational effects on Crumbs3a (Crb3a).

Methods: We used MDCKs, a tissue culture model, stably expressing epitope-tagged versions of Crb3a and Snail in an inducible or constitutive manner to study the dynamics of Crb3a.

Results: Using fluorescently-tagged Crb3a in combination with fluorescence recovery after photobleaching (FRAP), we found that Crb3a normally has a half-life of under 6 hours and is highly mobile at the cell surface. We then used covalently modifiable SNAP epitope-tagged Crb3a to examine kinetics of Crb3a at the cell surface. We showed that Crb3a is rapidly turned-over in the presence of Snail, decreasing the half-life of Crb3a on the cell surface from 2 to 1 hour. In contrast, cell surface stability of Crb3a is unaffected by disruption of cell polarity following dissolution of cell-cell contacts under low calcium conditions. We further observed that Crb3a's mobility on gel electrophoresis is altered in the presence of Snail, in part due to alterations in both N- and O-glycosylation.

Conclusions: Taken together, these results suggest that Snail induces post-translational modifications that alter Crb3a's trafficking and stability at the epithelial cell surface. Moreover, our results support the concept of discernable transcriptional and post-translational effects of Snail on cell polarity and that these post-translational effects involve post-translational modulation of the polarity protein Crb3a.

Analysis of Williams-Beuren Syndrome-Related Genes; by Using a Caenorhabditis Elegans as a Model Organism Tomoko Uehara, Eriko Kage-Nakadai, Shohei Mitani. *Physiology, Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan.*

Background: Williams-Beuren syndrome (WBS) is a contiguous gene syndrome with an autosomal dominant inheritance pattern and that is caused by microdeletion at 7q11.23 and haploinsufficiency of this region. Approximately 50% of patients with WBS have morphological or functional anomalies of kidney or urinary tract. There is insufficient knowledge of candidate genes of these anomalies. In this study, we analyzed genes that are located on the deletion area by use of a model organism, Caenorhabditis elegans.

Methods: At least twelve genes in WBS deletion region are expressed in kidney. Firstly, we searched six C. elegans gene homologs with the human genomic DNA database. Secondly, we identified that each gene expression pattern using its own promoter mediated expression of green fluorescent protein (GFP). We also analyzed phenotypes using RNA interference (RNAi). Furthermore, we isolated a deletion mutant of the C28H8.1 gene, the homologue of human BCL7B gene, because of showing the significant effect of RNAi and assayed the phenotype more extensively.

Results: Expression patterns of these six genes were as follows. C28H8.1, a BCL7B gene homologue, was expressed ubiquitously. C27F2.4, a WBSCR22 gene homologue and the gene product may have metylation-associated function, was expressed in motor neurons and intestine cells. dnj-16, F46C5.9 and F32B4.6, a homologue of a DNAJC30 gene, a TBL2 gene and an ABHD11 gene, respectively, were expressed in intestine cells particularly during in larvae stage. Downregulation of C28H8.1 function by feeding RNAi induced reproductive defect and morphological deformation. The phenotype of C28H8.1 deletion mutant was also the failure of reproduction and developmental anomaly.

Conclusions: To summarize this study, we analyzed six gene homologs of human genes associated with WBS and expressed in kidney. C28H8.1, the homolog of BCL7B, appears to be involved in early embryonic development, in particular, cell cycle system. The other five of them did not show any specific expression-pattern or specific phenotype. We are planning to analyze these genes in more detail.

SA-PO2402

Molecular Mediators of Endoplasmic Reticulum Stress-Induced Cytotoxicity in Human Proximal Tubular Epithelial Cells Rachel Carlisle, Elise Brimble, Alana Heffernan, Richard Austin, Jeffrey G. Dickhout. *Nephrology, St Joseph's Healthcare Hamilton and McMaster University, Hamilton, ON, Canada.*

Background: Various drugs, including gentamicin, cisplatin, the acetaminophen metabolite p-aminophenol, and cyclosporine A, induce endoplasmic reticulum (ER) stress causing acute renal injury in proximal tubular epithelial cells (PTEC). This injury may be mediated by the expression of CHOP/GADD153, an ER stress-inducible proapoptotic gene. However, direct evidence of CHOP/GADD153-induced PTEC cell death is lacking.

Methods: In this study, cytotoxicity was measured by LDH release assay and apoptosis was measured by TUNEL assay. CHOP/GADD153 and TDAG51 protein levels were measured by Western blotting. CHOP/GADD153 knockdown was achieved using siRNA transfection, while CHOP/GADD153 and TDAG51 overexpression was performed by transient transfection.

Results: Using HK-2 cells, we demonstrated that the nucleoside antibiotic tunicamycin (Tm, 1 g/mL) induces ER stress and causes substantial upregulation of CHOP/GADD153 in PTEC at 18 h, followed by a significant increase in apoptotic cell death at 48 h. This effect was inhibited by siRNA-mediated CHOP knockdown. The SERCA inhibitor thapsigargin (Tg, 200 nM) induces ER stress, but unlike Tm, produced little or no CHOP/GADD153 expression at 18 h. However, Tg did induce expression of the novel proapoptotic gene TDAG51 at 18 h leading to similar cytotoxicity as Tm at 48 h. To directly determine if CHOP/GADD153 overexpression induced apoptosis in PTEC, overexpression of CHOP/GADD153 was achieved and increased the incidence of apoptosis to 26.6+8.6% (from 3.8+0.9% in pcDNA3.1 transfected controls). Transient transfection of TDAG51 in an eGFP vector resulted in increased apoptosis in the HK-2 model of PTEC (vector, 0.5+0.4% vs. TDAG51, 26.0+3.4%) and in primary human PTEC (vector, 5.2+1.3% vs. TDAG51, 30.0+4.6%).

Conclusions: ER stress is a common pathological pathway that leads to acute renal injury from numerous drugs; however, the molecular mediators of PTEC death appear to differ depending on the mechanism of action of the specific ER stress inducer, as shown, in this case, by Tm and Tg treatment.

SA-PO2403

Phagocytosis of Apoptotic HIV-1- Infected CD4+/PD-1+ T Cells Is Critical for Establishment of HIV-1 Reservoirs in Tubular Cells Hersh Goel,[1] Mohammad Husain,[1] Nirupama Chandel,[1] Joanna Mikulak,[2] Ashwani Malhotra,[1] Helena Schmidtmayerova,[1] Pravin C. Singhal.[1] *[1]Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY; [2]Immunology, Istituto Clinico Humanitas, Rozzano (Milano), Italy.*

Background: HIV-1 infection of Kidney cells has been suggested to be a key factor which contributed to the pathogenesis of HIV-associated nephropathy (HIVAN). In the present study, we evaluated the potential of tubular cells to serve as an HIV-1 reservoir.

Methods: Human renal proximal tubular cells (HRPTECs and HK2s) were pulsed with HIV-1 (X4 HIV-$1_{92HT599}$) and then evaluated for HIV infection. To rescue HIV from tubular cells, HK2s were intubated with lymhocytes (LY) and followed by evaluation of LY for HIV replication. To determine viral transfer from HIV infected lymphocytes (HIV-LY) to tubualr cells, HIV-LYs were co-cultivated with HIK2/HRPTECs. To determine the role of apopotosis, LYs and HIV-LYs were pre-treated with anti-PDL-1 antibody and then evaluated for apoptosis by FACS analysis. To determine the role of apoptosis and phagocytosis of LYs in HIV transmission to HK2s, HIV-LYs were pretreated with either anti-PDL-1 antibody, cyotchalasin B, or a caspase-3 inhibitor followed by co-culitvation with HK2s for 24 hours and then evaluation of tubular cells for HIV expression.

Results: Both, HK2s and HRPTECs endocytosed viral particles; however, it was non-productive infection; nonetheless, HK2s transmitted viral particles to T cells. Co-cultivation of HIV-LYs with HK2s/HRPTECs triggered apoptosis of CD4+/T cells via PD-1/ PD-L1 interactions. Subsequent phagocytosis of PD-1+/CD4 T cells by HK2s facilitated activation of tubular cells and HIV expression. Both anti-PD-L1 antibody and cytochalasin-B inhibited uptake of HIV-LY by HK2s, their activation, and HIV expression. These findings identify a novel pathway that enables tubular cells to serve as an HIV-1 reservoir.

Conclusions: Our results indicate that tubular cells not only facilitated apoptosis of HIV-1 infected T cells but also showed capability of phagocytosing them. It appears that phagocytosed apoptosed T cells provided a suitable milieu for productive HIV-1 infection in tubular cells.

SA-PO2404

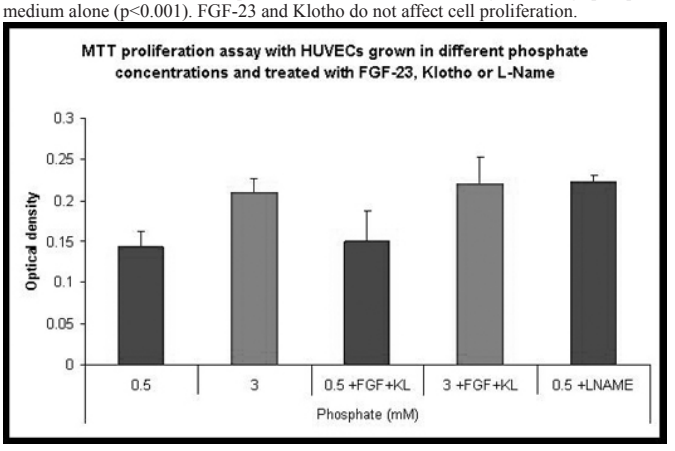
Hyperphosphataemia Increases Endothelial Cell Size, Granularity and Rate of Proliferation Kathryn K. Stevens, William A. Sands, Rajan Kantilal Patel, Christian Delles, Alan G. Jardine. *Renal Research Group, ICAMS, University of Glasgow, United Kingdom.*

Background: The mechanism of action of elevated serum phosphate as a risk factor for cardiovascular disease is unclear. We studied the effect of phosphate on the growth and proliferation of human umbilical vein endothelial cells (HUVECs).

Methods: HUVECs were cultured in standard (0.5mM) or high phosphate media (3mM). Cells were counted and then photographed and cell length and area measured. Cell proliferation was measured using the MTT assay in the presence of standard and high phosphate media alone or in combination with FGF-23, Klotho and L-NAME (eNOS

inhibitor). Western blot was performed for phospho and total eNOS. FACscan was used to assess granularity of the cells. Differences between groups were calculated in SPSS using a Student's t test or ANOVA with post hoc analysis as appropriate.

Results: HUVECs grown in high phosphate medium are more granular ($p=0.007$) and proliferate more rapidly than cells in standard medium ($p<0.001$). The morphology of the cells is different with a bigger cell area. MTT assays in cells grown in standard phosphate medium, treated with L-NAME proliferate at a similar rate to cells grown in high phosphate medium alone ($p<0.001$). FGF-23 and Klotho do not affect cell proliferation.



Expression of Phospho and total eNOS is reduced in HUVECs grown in high phosphate medium ($p=0.037$).

Conclusions: Nitric oxide inhibits cell growth. HUVECS, grown in high phosphate medium, are bigger, more granular and proliferate more rapidly. This may be secondary to increased oxidative stress with reduced nitric oxide production and thus removal of growth inhibition. Western blot confirms reduced eNOS expression in cells grown in high phosphate medium. These experiments mimic a uraemic state and may offer an explanation for elevated serum phosphate as a cardiovascular risk factor.

SA-PO2405

Renal Epithelial Cells Repress Calreticulin Expression To Increase Free Calcium and Adaptation to Osmotic Stress Asima Bibi, Gry Helene Dihazi, Marwa Youssef Eltoweissy, Gerhard A. Mueller, Hassan Dihazi. *Georg-August-University, University Medical Centre Goettingen.*

Background: ER resident calcium binding proteins play an important role in different stress balance mechanisms. The thick ascending limb of Henle's loop (TALH) is normally exposed to variable and often very high osmotic stress and involves different mechanisms to counteract this stress. The alteration of ER stress proteins is a part of TALH cells reaction to osmotic stress. The aim of the present study was to investigate the role of calreticulin (CALR) in adaptation and survival of TALH epithelial cells under osmotic stress.

Methods: Two-dimensional difference in-gel electrophoresis (2D-DIGE) combined with mass spectrometry, Western blot and RT-PCR analyses were done to analyze the protein expression in TALH cell line exposed to hyperosmotic stress. MTT assay was performed to check the percent viability of cells. Free intracellular calcium concentration was monitored with fura 2/AM fluorescent dye.

Results: 2D-DIGE and Western blot analyses demonstrated that TALH cells showed a significant down-regulation of CALR as a part of their reaction to variable osmotic stress. However, primary renal inner medullary collecting duct cells and interstitial cells showed no significant changes in CALR expression. Furthermore, RT PCR analysis of TALH cells exposed to osmotic stress showed a time dependent downregulation of CALR accompanied with continuous change in the level of free intracellular calcium. Inhibition of the calcium release by the IP3R antagonist, prevented CALR expression alteration under hyperosmotic stress, whereas the cell viability was significantly impaired. Overexpression of wild type CALR in TALH cells resulted in significant decrease in cell viability under hyperosmotic stress. In contrast, the hyperosmotic stress did not have any effect on cells overexpressing the CALR mutant, lacking the calcium-binding domain. MTT cell viability test showed that silencing CALR with siRNA significantly improved the cell survival under osmotic stress conditions.

Conclusions: Thus we conclude that CALR due to its calcium binding property plays a crucial role in osmotic stress adaptation and survival of TALH cells.

SA-PO2406

Discovery of a Splice Variant and Endogenous Inhibitor of Chk1 That Regulates Cell Cycle and DNA Damage Checkpoints Navjotsingh P. Pabla, Zheng Dong. *Georgia Health Sciences University and Charlie Norwood VA Medical Center.*

Background: The DNA damage response (DDR) and cell cycle checkpoints are essential regulatory mechanism for maintaining genomic stability. Checkpoint Kinase 1 (Chk1) is a key regulator of checkpoint signaling in both unperturbed cell cycle and DNA damage response. Under these conditions, Chk1 becomes active to prevent CDK1 activation and mitotic entry till DNA is properly replicated or repaired. It is unclear how Chk1 activity is controlled in unperturbed cell cycle. During DNA damage, Chk1 is activated by ATR mediated phosphorylation; however it is not entirely clear how the phosphorylation activates Chk1.

Methods: Here we report an N-terminally truncated alternative splice variant of Chk1, Chk1-S.

Results: This splice variant lacks the ATP binding domain and hence is kinase-inactive. Its expression is regulated in a cell-cycle dependent manner with highest expression seen in G2 phase. Importantly, we show that Chk1-S is an endogenous repressor and regulator of Chk1. In unperturbed cell cycle, Chk1-S interacts with and antagonizes Chk1 to promote S to G2/M phase transition. Overexpression of Chk1-S induces premature mitotic entry, resulting in mitotic catastrophe. In DNA damage, Chk1 is phosphorylated and the phosphorylation disrupts the Chk1/Chk1-S interaction, resulting in free, active Chk1 to arrest cell cycle to facilitate DNA repair. Chk1-S is widely expressed in multiple cell types with higher expression observed in fetal and cancer tissues than normal tissues. In tumor xenografts, forced overexpression of Chk1-S induces mitotic catastrophe and reduces tumor growth.

Conclusions: The identification of Chk1-S as a novel splice variant and key regulator of Chk1 provides new insights into cell cycle regulation, DNA damage response, and cancer therapy.

Na+-Sensitive Chronic Kidney Disease in Mice Lacking Renal Principal Cell Histone H3 K79 Methyltransferase Dot1 Hongyu Wu,[1] Lihe Chen,[1] Qiaoling Zhou,[2] Stefan Berger,[3] Günther Schütz,[3] Yang Xia,[1] Wenzheng Zhang.[1] *[1]University of Texas Medical School at Houston; [2]Central South University; [3]German Cancer Research Center.*

Background: Little is known regarding the epigenetic programs regulating the pathogenesis of chronic kidney disease (CKD), possibly due to a lack of rodent models in which epigenetic modifiers are specifically disrupted. We have previously reported that histone H3 K79 methyltransferase Dot1 is highly expressed in mouse kidney and regulates ENaC-mediated Na+ transport in IMCD3 cells.

Methods: To identify new functions of Dot1 in kidney, we used LoxP-Cre system to inactivate Dot1 in AQP2-expressing cells (Dot1f/f AQP2Cre or mutants) and applied histological, immunochemical, TUNEL and metabolic analyses to characterize the phenotype.

Results: We found that on a normal Na+ diet, the mutants decreased principal cells (PC) by 20% and increased urine volume by 40% (2011 ASN abstract 21278). Here we report that the CKD phenotype of the mutants after chronic Na+ loading (3.1% dietary Na+ for 32 days). The control mice were capable of handling the chronic Na+ loading to maintain the body weight (BW), renal physiology, blood pressure and apparent normal cortex and medullar structure. The mutants progressively became very sick, and eventually lost BW by 12.4% vs. the initial BW, and had over 4-fold higher urine volume, 56% lower urine osmolarity, and 20 mmHg lower systolic BP vs. control. Multifocal cortex-like lesions, inflammatory infiltration, protein casts, dilated distal tubes with detached cells, fibrosis, apoptosis and epithelial-to-mesenchymal transition (EMT) as evidenced by loss of epithelial marker E-cadherin expression and gain of myofibroblast marker α- smooth muscle actin expression was also readily detected in the mutants, but hardly found in controls. These changes were accompanied by ~40-58% decrease in PC, 23-30% increase in IC and 13-28% increase in cells lacking expression of both PC and IC markers vs. controls.

Conclusions: In summary, Dot1f/f AQP2Cre mice may represent a new mouse CKD model, linking dietary Na+ intake and H3 K79 methylation to cell differentiation and pathogenesis of the disease.

Aldosterone Promotes Proliferation of Cultured Renal Fibroblasts Via Activation of Mineralocorticoid/PDGF/EGF Receptors and MAPK/PI3K Signaling David J. Nikolic-Paterson,[1,2] Louis L. Huang,[1,2] Frank Yuanfang Ma,[1,2] Gregory H. Tesch.[1,2] *[1]Nephrology, Monash Medical Center, Clayton, Victoria, Australia; [2]Medicine, Monash University, Clayton, Victoria, Australia.*

Background: The development of tubulo-interstitial fibrosis (TIF) is critical for the progression of renal injury to end-stage renal disease. The severity of TIF is dependent on the accumulation of interstitial fibroblasts, which results from increased fibroblast recruitment and proliferation. Aldosterone, a mineralocorticoid hormone, has pro-fibrotic properties and can induce renal or cardiac fibrosis. However it is not known whether aldosterone can stimulate renal fibroblast proliferation. Therefore, we examined the effects of aldosterone on the proliferation of cultured kidney fibroblasts and identified the intracellular signaling mechanisms involved.

Methods: Uptake of ^{3}H-Thymidine was used to determine the dose-dependent effects of aldosterone on the proliferation of rat renal fibroblasts (NRK49F cells) cultured in serum-free media. Specific kinase inhibitors were used to identify the importance of growth factor receptor and mitogenic signaling pathways in aldosterone-induced proliferation.

Results: Aldosterone at physiologic concentrations (1-10nM) increased NRK49F proliferation by 2-fold after 24 hours ($p<0.0001$). This effect was inhibited by pretreatment with mineralocorticoid receptor (MR) antagonist eplerenone. Further characterization identified that the proliferative effects of aldosterone could also be blocked by inhibition of PDGFR (STI-571), EGFR (AG1478), ERK (UO126), JNK (SP600125), and PI3-K (LY294002) at doses that were not cytotoxic. In comparison, treatment with inhibitors of TGF-βR1/ALK5 (SB431542) and p38MAPK (SB202190) had no effect on the aldosterone-induced proliferation of NRK49F cells.

Conclusions: Aldosterone induces renal fibroblast proliferation via ligation of MR and subsequent activation of growth factor receptors (PDGFR/EGFR) and specific intracellular signaling pathways (ERK, JNK, PI3-K). These findings suggest that increased levels of aldosterone in diseased kidneys may promote renal fibrosis by inducing proliferation of kidney fibroblasts.

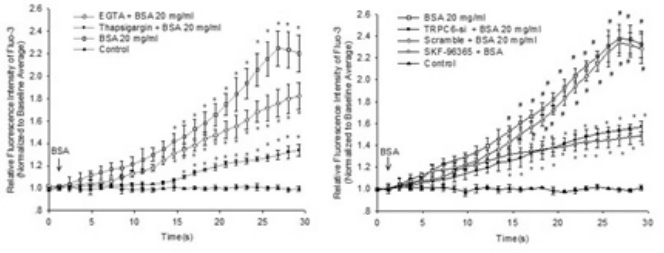
Calcium Entry Via TRPC6 Mediates Albumin Overload-Induced Endoplasmic Reticulum Stress and Apoptosis in Podocytes Shan Chen, Hui Wang, Chun Zhang. *Department of Nephrology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, Hubei, China.*

Background: Albumin, the most abundant component of urine proteins, exerts injurious effects on podocytes. In the current study, we tested the hypothesis that albumin overload may induce functional and structural changes in podocytes via TRPC6-mediated Ca^{2+} entry.

Methods: Cultured podocytes were divided into several groups: control; vehicle; EGTA (extracellular Ca^{2+} chelater), Tapsigargin (intracellular Ca^{2+} store inhibitor), scramble siRNA; TRPC6 siRNA; SKF-96365 (TRPC channel blocker). Fluo 3-AM was used as a calcium indicator and the calcium-dependent fluorescence was monitored using confocal microscope upon albumin stimuli. Western blot was used to detect TRPC6, endoplasmic reticulum (ER) stress proteins GRP 78 and caspase-12. Rhodamine-labeled phalloidin was used to stain the F-actin. Annexin V-FITC and PI double staining was used to detect the apoptosis rate.

Results: High concentration of albumin (BSA 20 mg/ml) triggered intracellular calcium ($[Ca^{2+}]_i$) increase through mechanisms involving the intracellular calcium store release and extracellular calcium influx in podocytes. Albumin-induced increase in $[Ca^{2+}]_i$ was blocked by TRPC6 siRNA or SKF-96365.



Long-term albumin exposure caused an up-regulation of TRPC6, which was inhibited by TRPC6 siRNA. Additionally, the inhibition of TRPC6 prevented the F-actin cytoskeleton disruption that is induced by albumin overload. Moreover, albumin overload induced expression of GRP78, led to caspase-12 activation and ultimately podocyte apoptosis, all of which were abolished by the knockdown of TRPC6 using siRNA.

Conclusions: The amelioration of podocyte injury in albumin-overloaded podocytes by TRPC6 blockade further strengthened the critical role of this calcium channel. TRPC6 may be an therapeutic target in treating proteinuric kidney diseases.

Funding: Government Support - Non-U.S.

SA-PO2410

Protein Kinase B: A Multifaceted Protein in Albumin Endocytosis Elif Erkan. *Pediatrics, University of Pittsburgh, PA.*

Background: Orchestrated efforts of clathrin and clathrin associated proteins (CLASPs) regulate albumin endocytosis in the proximal tubule. In glomerulonephritis high concentrations of albumin passing through the altered glomerular filtration barrier results in proximal tubule cell apoptosis. The purpose of this study is to investigate a possible link between albumin endocytosis and survival pathways.

Methods: Co-immunoprecipitation and GST pull-down experiments were utilized to examine protein-protein interactions. Genetic manipulations were accomplished by transfection of human kidney proximal tubule cells with plasmid DNA and small interfering RNA. Albumin endocytosis was evaluated by FITC labeled albumin uptake.

Results: Co-imunoprecipitation showed an interaction between protein kinase B (Akt) and clathrin heavy chain, Ap2μ2 and adaptor protein disabled-2 (Dab2). GST pull down experiments utilizing Dab2 PTB domain (1-206), 1-368, 335-610 (M15) and proline rich domain (PRD, 600-730) identified PRD as the Akt interacting domain. In order to narrow down the interaction site, shorter constructs of PRD were created. Disabled-2 600-638 was found to be the binding domain of Akt. Overexpression of Akt by constitutively active and wild type plasmids increased albumin uptake where as dominant negative Akt caused a decrease in albumin internalization. Silencing Dab2 abolished Akt induced albumin uptake demonstrating physiological relevance of Akt-Dab2 interaction. Albumin overload resulted in attenuation of this interaction as a result of downregulation of both Dab2 and Akt expression in association with apoptosis.

Conclusions: We concluded that Akt is involved in albumin endocytosis via its interactions with CLASPs. We postulate that inhibition of Akt and Dab2 and attenuation Akt-Dab2 interaction with albumin overload may represent a defense mechanism of proximal tubule to limit albumin endocytosis. This mechanism may induce apoptosis by release of mitochondrial proapoptotic proteins that stay in phosphorylated form under the control of Akt in physiological conditions. Further delineation of interactions of Akt with upstream proteins and receptors will enhance our understanding of protein-protein interactions that regulate albumin endocytosis.

Growth Arrest Specific Protein 1 (GAS1) Is a Novel Secreted, Endogenous, and PDGF-Regulated Inhibitor of Mesangial Cell Proliferation Claudia R.C. van Roeyen,[1] Stephanie Zok,[1] Peter Boor,[1] Jessica Pruessmeyer,[2] Tammo Ostendorf,[1] Andreas Ludwig,[2] Jurgen Floege.[1] *[1]Nephrology, RWTH Aachen, Aachen, Germany; [2]Pharmacology&Toxicology, RWTH Aachen, Aachen, Germany.*

Background: GAS1 is a glycosyl-phosphatidyl-inositol (GPI)-anchored protein which is highly expressed in embryonal mouse fibroblasts (NIH3T3) and inhibits their proliferation.

Methods: In a cDNA-array analysis we identified GAS1 as one of the most potently suppressed genes following PDGF-BB or –DD stimulation of mesangial cells (MC).

Results: *In vitro* MC released soluble GAS1-protein into the cell culture supernatant. Growth-arrest led to GAS1 overexpression and an increased release. The secretion process was also enhanced by stimulation with phorbolester or ionomycin and involved the activity of the disintegrins and metalloproteinases (ADAM) 10 and 17 as indicated by inhibition experiments. In addition recombinant soluble GAS1 protein markedly inhibited the growth of proliferating MC. *Vice versa* induction of MC proliferation by PDGF-BB or -DD led to downregulation of GAS1 mRNA while specific ligands of the PDGF α-receptor PDGF-AA and –CC had no effect. In healthy rat kidneys we localized GAS1 protein to podocytes. During mesangioproliferative glomerulonephritis (GN) in rats glomerular GAS1 mRNA expression decreased prior to the onset of MC proliferation and increased at later stages when the glomeruli recovered.

A soluble GAS1 tagged with an Fc-fragment (GAS1/Fc) was systemically overexpressed by muscle electroporation in rats with mesangioproliferative GN at day 3 after induction. This resulted in 3-fold increased GAS1 serum concentrations. At day 9 overexpressed Gas1/Fc ameliorated renal damage as indicated by decreased albuminuria and serum-creatinine. GAS1/Fc-transfected rats exhibited a reduction of the glomerular α-smooth-muscle actin positive mesangial area and glomerular mRNA expression and a decreased number of proliferating glomerular cells. The number of infiltrating glomerular $ED1^+$-macrophages and mRNA expression of CCL2 were also reduced.

Conclusions: In summary we identify GAS1 as a novel endogenous growth inhibitor of MC. Gas1 presents a potentially novel therapeutic target in mesangioproliferative glomerular diseases.

Identification & Characterization of a Novel Oncogenic HIF-1 Target Involved in Renal Cell Carcinoma Kumi Shoji,[1] Imari Mimura,[1,2] Takamoto Ohse,[1] Takashi Murayama,[3] Reiko Inagi,[1] Takehiko Wada,[1] Tetsuhiro Tanaka,[1] Haruki Kume,[4] Akiteru Goto,[5] Toshiro Fujita,[1] Hiroyuki Aburatani,[2] Tatsuhiko Kodama,[2] Masaomi Nangaku.[1] *[1]Nephrol Endocrinol, Univ Tokyo Sch Med, Tokyo, Japan; [2]Lab Syst Biol Medi, RCAST, Univ of Tokyo, Tokyo, Japan; [3]Pharmacology, Juntendo Univ Sch Med, Tokyo, Japan; [4]Urol, Univ Tokyo Sch Med, Tokyo, Japan; [5]Pathol, Univ of Tokyo, Tokyo, Japan.*

Background: Hypoxia inducible factor (HIF) is upregulated under hypoxia and regulates coordinated transcriptional response, playing a key role in many pathological conditions such as tumorigenesis.

Methods: We performed genome-wide analysis of HIF targets utilizing microarray analysis in combination with ChIP-Sequencing. We focused one of the new targets, sperm associated antigen 4 (SPAG4), which is expressed in a limited number of normal tissues.

In order to elucidate a role of SPAG4 in renal cell carcinoma (RCC), we analyzed SPAG4 expression by immunohistochemistry on tissue microarray (TMA) containing 208 RCC specimens.

We also performed cell biological studies of cells with overexpression or knockdown of SPAG4, utilizing immunofluorescence, immunoprecipitation, and live cell imaging using SPAG4-EGFP, dynein-mCherry, and calnexin-mCherry.

Results: We identified 26 new targets of HIF-1, and SPAG4 was selected for a further analysis, of which function remains unknown. In cultured cells, SPAG4 was up-regulated under hypoxia, and luciferase assays demonstrated that hypoxia response element in the intron of SPAG4 is essential for the response.

RCC TMA analysis showed expression of SPAG4 in more than 80% RCC. High expression of SPAG4 correlated with poor prognosis in early stage cancer and increased risk for metastasis. The intensity of SPAG4 expression was associated with vein invasion and nuclear grading, suggesting a role of SPAG4 in tumor development and metastasis.

We localized SPAG4 in the nuclear membrane and the cytoplasm. SPAG4 was co-localized with dynein and was involved in cytokinesis.

Conclusions: In conclusion, we identified a novel HIF target, SPAG4, by the genome-wide system biological method. Our functional analysis showed a potential role of SPAG4 in cytokinesis and RCC.

SA-PO2413

Perspectives of an Interaction between Caveolae and Notch Signalling on the Pathogenesis of Renal Fibrosis Yuliya Sharkovska,[1] Carsten Dittmayer,[1] Markus Schuelke,[2] Michael S. Goligorsky,[3] Sebastian C. Bachmann.[1] *[1]Institut für Vegetative Anatomie, Charité Universitätsmedizin, Berlin, Germany; [2]Department of Neuropediatrics, Charité Universitätsmedizin, Berlin, Germany; [3]Departments of Medicine, Pharmacology, and Pathology, Renal Research Institute, New York Medical College, Valhalla.*

Background: As a common pathological alteration in progressive chronic kidney disease, renal fibrosis is associated with tubular atrophy and deposition of extracellular matrix. TGFβ is considered as a central mediator in fibrosis. The mechanistic roles of caveolae and Notch signalling have further been implicated in its pathogenesis, and caveolin-1 (Cav-1) may affect TGFβ signalling and as well as gamma-secretase activity. The molecular detail of this hypothetical cascade and its impact on renal fibrosis is not yet clear.

Methods: To elucidate this, we have used Cav-1-deficient mice (Cav-1 -/-) and human fibroblasts from patients with congenital generalized lipodystrophy (CGL4), lacking caveolae due to mutations of polymerase I and transcript release factor (PTRF), an essential protein for caveolae biogenesis (Rajab A, PLoS Genet 6/1/2010).

Results: Ultrastructural analysis demonstrated the near-complete absence of caveolae in both models. In Cav-1 -/- mice, the degree of fibrosis upon induction of tubulointerstitial scarring was substantially enhanced as compared to wildtype mice (Park HC, AJP 298/F357/2010). Human fibroblasts displayed enhanced Notch signalling in the absence of PTRF as revealed by expressional analysis and immunohistochemistry of its components, Jagg-1, Notch-1, Notch intracellular domain, and HES1. Increases in Notch signalling were more pronounced in control, than in PTRF-deficient fibroblasts upon stimulation with TGFß. Changes in Notch were paralleled by alpha-smooth muscle actin and collagen I expression.

Conclusions: These data indicate that caveolae and the components of Notch signalling are involved in the pathogenesis of fibrosis. We further conclude that the profibrotic effect of caveolar malformation is likely to be mediated by Notch activation.

SA-PO2414

VEGF Receptor 2 Direct Interaction with Nephrin Links VEGF-A Signals to Actin in Kidney Podocytes Claudia A. Bertuccio,[1] Delma Veron,[1] Pardeep Kumar Aggarwal,[1] Lawrence B. Holzman,[2] Alda Tufro.[1] *[1]Yale University School of Medicine, New Haven, CT; [2]University of Pennsylvania, Philadelphia, PA.*

Background: The transmembrane protein nephrin is an essential component of slit-diaphragms, the specialized cell junctions that link podocyte foot processes. Podocytes are epithelial cells that surround the glomerular capillaries in the kidney and are necessary for the organ filtering function. Nephrin signaling complex transduces extracellular cues to the podocyte cytoskeleton and regulates podocyte shape and function. Vascular endothelial growth factor A (VEGF-A) is a required growth factor produced and secreted by podocytes. Accumulating evidence suggests a crosstalk between VEGF-A and nephrin signaling pathways. Our previous studies have shown that nephrin associates with VEGF receptor-2 (VEGFR2) tyrosine kinase, the signaling receptor for VEGF-A in vivo.

Methods: In the present study we characterized the interaction between nephrin and VEGFR2 in vitro and in cultured cells (podocytes and COS cells transfected with the corresponding expression plasmids), using mass spectrometry, co-immunoprecipitation, GST-binding assays and blot overlay experiments.

Results: We demonstrate that nephrin-VEGFR2 interaction is direct. This interaction occurs through VEGFR2 and nephrin cytoplasmic domains. Nephrin-VEGFR2 interaction is modulated by tyrosine phosphorylation of both cytoplasmic domains. Furthermore, our results indicate that the nephrin-VEGFR2 complex involves Nck and actin. We provide evidence that this multi-protein interaction occurs in cultured podocytes.

Conclusions: We propose that nephrin-VEGFR2 complex acts as a key mediator to transduce local VEGF-A signals to the podocyte actin cytoskeleton, thereby regulating the normal foot process structure and glomerular filter integrity.

Simvastatin Inhibits Angiopoietin-2 Release and Production – A Novel Pleiotropic Effect? Sascha David,[1,2] Chandra C. Ghosh,[1] Aditi Mukherjee,[1] Stephen G. John,[3] Chris W. McIntyre,[3] Samir M. Parikh.[1] *[1]Division of Medicine and Center for Vascular Biology Research, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA; [2]Nephrology, Medical School Hannover; [3]University of Nottingham.*

Background: We recently found that circulating levels of Angiopoietin-2 (Anpt-2) increase with the extent of chronic kidney disease (CKD) and correlate with prevalent atherosclerotic burden. Angpt-2 is a growth factor, stored in endothelial cells (ECs), that sensitizes ECs to diverse inflammatory stimuli thereby potentially contributing to the accelerated atherogenesis in CKD. Anti-inflammatory effects of statins are well-known, yet the mechanisms of these pleiotropic properties remain incompletely understood. We hypothesized that statins may directly inhibit Angpt-2 action and test in vivo and in vitro.

Methods: Angpt-2 was measured in EC media, lysates, as well as sera from 128 CKD patients by commercial ELISA (R&D Systems). Different EC lines were treated with simvastatin (10-100 μM) or vehicle. Immunofluorescence (IF) was performed using antibodies against 'Angpt-2' and 'von Willebrand Factor' (vWF). Total RNA was amplified with a commercial TaqMan qPCR assay (Applied Biosystems).

Results: CKD stage 4-5 patients on statins (n=48) had significantly lower circulating levels of Angpt-2 compared to CKD patients without statin treatment (n=80) (statin: 1.87 ± 0.68 vs. no statin: 2.43 ± 1.18 ng/mL; p=0.0002).

In vitro, a high amount of Angpt-2 accumulated in the media of all three EC types. Simvastatin dose-dependently reduced not only the release of Angpt-2 (64% reduction at a dose of 100 μM after 24 h, $p<0.05$), but also the intracellular Angpt-2 protein concentration (66% reduction, $p<0.05$) and transcript abundance (10-fold decrease, $p<0.05$). Furthermore, IF experiments demonstrated that other contents of endothelial Weibel-Palade bodies (e.g. vWF) were virtually unaffected by simvastatin.

Conclusions: CKD patients on maintenance statin therapy had lower circulating Angpt-2 levels than their CKD controls. Simvastatin markedly reduced Angpt-2 release and production by ECs in vitro. The mechanism for this effect and its downstream consequences merit further investigation.

SA-PO2416

In Vivo Erythropoietic Activity of Peginesatide Correlates with Erythropoietin Receptor Residence Time and Plasma Half Life Jennifer M. Green, Karen Leu, Qing Fan, Brian T. Frederick, Richard B. Mortensen, Peter R. Young, Peter J. Schatz, Kathryn W. Woodburn, Christopher P. Holmes. *Affymax, Inc., Palo Alto, CA.*

Background: Peginesatide is a PEGylated, investigational, peptide-based erythropoiesis stimulating agent that was designed and engineered to stimulate the erythropoietin receptor (EPOR). Peginesatide has a unique structure that consists of a synthetic peptide dimer (with no sequence similarity to erythropoietin) conjugated to a 40 kDa PEG moiety.

Methods: To determine the effects of PEGylation on the biological activity of peginesatide, a series of compounds were synthesized where the peginesatide peptide dimer was conjugated to PEG moieties ranging in molecular weight from 2 kDa up to 60 kDa. Each of these compounds was evaluated for kinetics of binding to the EPOR, the ability to stimulate the proliferation and differentiation of $CD34^+$ bone marrow cells into erythroid precursors, and the ability to stimulate erythropoiesis in vivo.

Results: As PEG size increased, progressively slower association and dissociation rates were observed resulting in an overall lower affinity for EPOR (KD = 24 to 2400 pM, from 2 kDa to 60 kDa, respectively) and reduced potency for stimulating differentiation of $CD34^+$ cells into erythroid precursors (EC_{50} = 22 to 781 pM, respectively). Interestingly, the progressively slower dissociation rates resulted in an increase in EPOR occupancy time ($t_{1/2}$ = 260 to 1300 min, respectively), which contributed to an extended activation of EPOR signaling. This extended EPOR activation, in combination with a prolonged plasma half-life due to increased PEG size, led to the opposite trend in vivo with peptides conjugated to larger PEGs exhibiting increased erythropoietic potency. Peptides conjugated to PEG moieties larger than 20 kDa induced a robust production of red blood cells whereas those linked to PEGs smaller than 10 kDa were not efficient in driving erythropoiesis.

Conclusions: These results suggest that the extended erythropoietic activity of peginesatide in vivo results from both prolonged peptide-receptor residence time and plasma half life which may contribute to maintenance of hemoglobin levels with monthly dosing.

Peginesatide Stimulation Allows for a Longer Lifespan of the Activated Erythropoietin Receptor Jennifer M. Green,[1] Karen Leu,[1] Peter J. Schatz,[1] Don Wojchowski.[2] *[1]Affymax, Inc., Palo Alto, CA; [2]Maine Medical Center Research Institute, Scarborough, ME.*

Background: Peginesatide (Hematide™) is a PEGylated, investigational, peptide-based erythropoiesis stimulating agent (ESA) that is designed to specifically stimulate the erythropoietin receptor (EPOR).

Methods: To investigate the regulation of EPOR trafficking after peginesatide vs. recombinant human erythropoietin (rHuEPO, epoetin alfa) dosing, we have developed a novel panel of specific rabbit monoclonal anti-EPOR antibodies, and have used these tools together with Western blotting and flow cytometry to study EPOR cell surface expression, internalization, and degradation.

Results: In exponentially growing erythropoietin-dependent UT-7/EPO cells maintained in rHuEPO, cell surface EPORs were detected at low levels, and EPOR turnover/degradation appeared to predominate. In contrast, cell surface EPOR levels were increased significantly (~ 5.9 fold) in cells maintained in functionally equivalent levels of peginesatide, suggesting that EPOR turnover was lessened. After culture of cells for 18 hours in the absence of EPOR stimulation, subsequent treatment with rHuEPO led to the rapid tyrosine-phosphorylation of the EPOR, subsequent receptor internalization, and the rapid appearance of the major 42 kDa and 30 kDa EPOR degradation fragments observable within 15 minutes of treatment. In contrast, EPOR phosphorylation occurred at reduced magnitude following peginesatide treatment, but was sustained and correlated with an observed 30 minute delay in EPOR fragmentation. Since the ubiquitin/proteasome system plays a major role in EPOR internalization and down-modulation, we investigated EPOR ubiquitination after peginesatide vs. rHuEPO treatment. Each ESA induced EPOR ubiquitination, but peginesatide did so at significantly lower levels (~ 50% less).

Conclusions: These studies provide new mechanistic insights into the molecular basis for the extended erythropoietic activity of peginesatide.

SA-PO2418

Blockade of p38 MAPK Pathway Ameliorates Aldosterone-Induced Renal Injury in Guanylyl Cyclase-A Deficient Mice Yukiko Kato, Masashi Mukoyama, Hideki Yokoi, Yoshihisa Ogawa, Kiyoshi Mori, Masato Kasahara, Takashige Kuwabara, Hirotaka Imamaki, Tomoko Kawanishi, Akira Ishii, Kenichi Koga, Keita P. Mori, Akira Sugawara, Kazuwa Nakao. *Department of Medicine and Clinical Scinence, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: Recent clinical and experimental studies have shown that aldosterone plays an important role in the pathogenesis of renal injury. We have already reported that natriuretic peptide/guanylyl cyclase-A (GC-A) signaling exerts renoprotective effects in 5/6 nephrectomized, anti-GBM glomerulonephritis and streptozotocin-induced diabetic mice. Furthermore, we demonstrated that uninephrectomized GC-A knockout (KO) mice with four-week administration of aldosterone and sodium overload exhibited accelerated hypertension with marked nephrotic-range proteinuria (~300-fold urinary albumin excretion from baseline) compared to wild-type mice. Administration of aldosterone also increased phosphorylation of ERK and p38 MAP kinase (MAPK) mainly in podocytes of GC-A KO mice.

Methods: To determine the interaction between p38 MAPK and GC-A, we examined the effect of p38 MAPK inhibitor on renal findings. Two weeks after uninephrectomy, mice were administered with aldosterone (0.2 μg/kg/min) subcutaneously using an osmotic minipump, with 6% sodium diet and with hydralazine or p38 MAPK inhibitor (FR 167653, 33mg/kg/day) by drinking water. We examined systolic blood pressure, urinary albumin to creatinine ratio, and histological findings.

Results: Although a hydralazine treatment significantly reduced systolic blood pressure, urinary albumin excretion did not change compared with aldosterone-infused GC-A KO mice. Interestingly, urinary albumin excretion was dramatically decreased by 90% in aldosterone-infused GC-A KO mice with FR treatment. Glomerular hypertrophy and mesangial expansion was decreased in FR-treated aldosterone-given GC-A KO mice.

Conclusions: These results suggest that p38 MAPK acts as an important molecule connecting aldosterone and GC-A pathways, and could be a potential target against aldosterone-induced glomerular injury.

SA-PO2419

Mutation of Endocytic Motifs in the Cytoplasmic Loop of AT_{1a} Receptors Impairs Angiotensin II Uptake and Activation of MAP Kinases ERK1/2 and Sodium and Hydrogen Exchanger-3 in Proximal Tubule Cells Xiao C. Li,[1] Ulrich Hopfer,[2] Jia L. Zhuo.[1] *[1]Department of Pharmacology and Toxicology, University of Mississippi Medical Center, Jackson, MS; [2]Department of Physiology and Biophysics, Case Western Reserve University, Cleveland, OH.*

Background: The present study tested the hypothesis that the motif Leu^{316} to Tyr^{319} in the cytoplasmic loop of the AT_{1a} receptor is required for AT_{1a}-mediated Ang II uptake and activation of ERK1/2 (p-ERK1/2) and the sodium and hydrogen exchanger-3 (p-NHE-3) in mouse proximal tubule cells.

Methods: GFP-tagged wild-type (AT_{1a}R/GFP) or mutant AT_{1a} receptors with deletion of the motif Leu^{316} to Tyr^{319} in the cytoplasmic loop (AT_{1a}R/GFP[ΔL316-Y319]) were expressed in AT_{1a}-knockout (AT_{1a}-KO) mouse proximal tubule cells. The transfected cells were stimulated with Ang II (10 nM) in the presence or absence of the AT_1 antagonist losartan (10 μM) or the MEK1/MEK2 inhibitor UO126 (10 μM).

Results: AT_{1a}R/GFP was endocytosed into the cytoplasm and nuclei in a time-dependent manner. Ang II-induced AT_{1a}R/GFP endocytosis was associated with a twofold increase in p-ERK1/2 (control: 0.25 ± 0.03 vs. Ang II: 0.56 ± 0.06 p-ERK1/2/t-ERK1/2 ratio, $p<0.01$) and a 70% increase in p-NHE-3 proteins (control: 0.22 ± 0.02 vs. Ang II: 0.38 ± 0.03 p-NHE-3/actin ratio, $p<0.01$). Co-expression of AT_{1a}R/GFP with an intracellularly expressed cyan fluorescent Ang II fusion protein (ECFP/AII) in AT_{1a}-KO cells also induced similar activation of ERK1/2 (control: 0.26 ± 0.03 vs. ECFP/AII: 0.48 ± 0.07 p-ERK1/2/t-ERK1/2 ratio, $p<0.01$) and NHE-3 (control: 0.23 ± 0.02 vs. ECFP/AII: 0.46 ± 0.03 p-NHE-3/actin ratio, $p<0.01$). Losartan and UO126 blocked the p-ERK1/2 and p-NHE-3 responses to Ang II or ECFP/AII. By comparison, the endocytosis of the mutant AT_{1a}R/GFP(ΔL316-Y319) receptor was impaired, while Ang II- or ECFP/AII-induced activation of p-ERK1/2 and p-NHE-3 was markedly attenuated.

Conclusions: We conclude that the endocytic motif Leu^{316} to Tyr^{319} in the cytoplasmic loop of the AT_{1a} receptor may play an important role in AT_{1a} receptor-mediated Ang II uptake, and in extracellular or intracellular Ang II-induced activation of ERK1/2 and NHE-3 in mouse proximal tubule cells.

SA-PO2420

Angiotensin-Converting Enzyme 2 (ACE2) Is Shed from Proximal Tubular Cells Via ADAM-17 Joe A. Zimpelmann, Fengxia Xiao, Renisha Padmini Nadarajah, Chris R. Kennedy, Kevin D. Burns. *Kidney Research Centre, Division of Nephrology, Dept. of Medicine, Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada.*

Background: Angiotensin-converting enzyme 2 (ACE2) is highly expressed in the proximal tubule where it converts angiotensin (Ang) II to Ang-(1-7). As an integral membrane protein, ACE2 may cleaved by a disintegrin and metalloproteinase (ADAM)-17, resulting in extracellular shedding. We determined if ACE2 is shed from proximal tubule, and studied potential stimuli for shedding.

Methods: In primary cultures of mouse proximal tubular cells and in urine samples, ACE2 activity was measured using a fluorogenic ACE2 substrate.

Results: A time-dependent and significant increase in ACE2 activity was observed in the media from cultured proximal tubular cells. After 6 days in culture, ACE2 activity was 10-fold higher in media than in the membrane fraction (media: 3,103 ± 219 vs. membrane: 266 ± 29 ng-eq/dish; n=8, $p<0.001$). Incubation of cells in high D-glucose (25 mM), but not L-glucose, for 72 h significantly increased ACE2 activity in the media, an effect blocked by the ADAM-17 antagonist, TAPI-1 ($p<0.001$, n=11). Similarly, incubation of cells for 48-72 h with Ang II (10^{-7} M) enhanced ACE2 activity in the media ($p<0.001$, n=11), an effect that was blocked by the AT_1 receptor antagonist losartan, or TAPI-1. In cells transiently transfected with a human ACE2 cDNA expression plasmid, ACE2 activity was significantly increased in supernatant fractions ($p<0.001$ vs cells transfected with empty vector; n=3). In streptozotocin (STZ)-diabetic mice, and in mice infused with Ang II (1000 ng/kg/d) and fed a high salt diet, a progressive increase in urinary ACE2 activity occurred, compared to baseline levels (STZ-diabetes: $p<0.001$ vs non-diabetic mice; n=15). Renal tubular immunostaining for ADAM-17 was increased in diabetic mice and mice infused with Ang II.

Conclusions: These data suggest that ACE2 is shed from proximal tubular cells into the urinary space. Shedding is stimulated by high glucose or Ang II, via an ADAM-17-mediated pathway. Loss of membrane-bound ACE2 might alter the peritubular levels of Ang II and Ang-(1-7) and thereby affect kidney disease progression.

Regulation of AngII-Induced Pro-TGFalpha Cleavage in CKD Progression Andreas Herrlich. *Renal Division, Brigham and Women's Hospital, Boston, MA.*

Background: Low-level Angiotensin II (AngII)-stimulation in mice induces CKD lesions similar to human CKD in normotensive ACE/ARB treated patients with partially suppressed AngII; this depends on AngII-mediated cleavage of pro-TGF-alpha in tubular cells. Lesions were strongly reduced with metalloprotease inhibition, in pro-TGFalpha knockout mice, or mice expressing a defective EGF receptor in tubular cells. We have identified regulators of pro-TGFalpha cleavage: PKCalpha and the PKC-regulated protein phosphatase 1 (PP1) inhibitor PPP1R14D.

We provide evidence that the AngII-TGFalpha signaling pathway is relevant in humans and show that AngII-induced TGFalpha cleavage in kidney cells depends on the action of PKCalpha and PPP1R14D.

Methods: Kidney microarray data
Western blot and FACS
shRNA knockdown
Immunoprecipitation

Results: pro-EGF expression in diabetic nephropathy is highest in CKD stage I-II and decreases strongly with disease progression. pro-TGFalpha levels are very low in CKD I + IV-V, but significantly elevated in the earlier stages, CKD stage II-III. This observation mirrors the situation in the AngII-TGFalpha mouse model. Genetic CKD susceptibility loci in mice, rats and humans contain the pro-TGFalpha gene.

In kidneys of hypertensive mice, PKCalpha and PPP1R14D are significantly upregulated as compared to normotensive mice.

AngII- and TPA-induced TGFalpha cleavage in human embryonic kidney cells can be blocked with a PKC inhibitor (BIM1) or specific knockdown of PKCalpha or PPP1R14D.

Only TPA-treated PPP1R14D samples co-precipitate other proteins not present in the control (silver gel). PP1alpha co-immunoprecipitates only with AngII- or TPA-induced PPP1R14D-signaling complexes (western blot).

Conclusions: 1. TGFalpha expression in human kidney correlates with disease activity in diabetic nephropathy and is contained in several genetic loci associated with CKD progression shared between human, mouse and rat.

3. PKCalpha and PPP1R14D are
a) upregulated in the kidneys of hypertensive mice.
b) required for AngII-induced TGFalpha cleavage in kidney cells.

6. PP1alpha specifically regulates AngII-induced TGFalpha cleavage.

5. Targeting TGFalpha cleavage downstream of the receptor could provide new drug targets for human CKD progression.

Activation of the Retinoid X Receptor Modulates Angiotensin II Induced Inflammation and Hypertrophy in Vascular Smooth Muscle Cells Seth B. Furgeson, Vicki J. Van Putten, Peter Simpson, Mary C.M. Weiser-Evans, Raphael A. Nemenoff. *Medicine/Division of Renal Diseases and Hypertension, University of Colorado-Anschutz Medical Campus, Aurora, CO.*

Background: PPARγ agonists have been shown to interfere with the biological effects of angiotensin II (AII) and decrease blood pressure in animal models. PPARγ forms a heterodimer with the retinoid X receptor (RXR) to activate target genes. Rexinoids represent a class of RXR agonists that have been shown to activate a subset of RXR heterodimers, including PPARγ, PPARα, PPARδ, LXR, and FXR. In vascular smooth muscle cells (VSMCs), AII increases expression of pro-inflammatory cytokines and smooth muscle contractile proteins and induces cellular hypertrophy. The purpose of this study was to examine the effects of the rexinoid bexarotene (Bex) on VSMC responses to AII.

Results: In cultured rat aortic VSMCs, using a PPAR-RE luciferase construct, Bex (1 μM) increased PPARγ activity by 80% while pioglitazone (Pio; 10 μM), a PPARγ agonist, led to a 60% increase. Bex also increased LXR activity 3 fold while Pio had little effect. AII (1 μM) significantly increased IL-6 and MCP-1 mRNA and protein. Both Bex and Pio blocked cytokine induction by AII, but Bex was more effective (decrease in IL-6 mRNA: 96% vs. 68%, decrease in IL-6 protein secreted: 77% vs. 54%; decrease in MCP-1 mRNA: 94% vs. 57%, and decrease in MCP-1 protein: 71% vs. 43%). AII also significantly increased calponin (a smooth muscle cell marker) as measured by both immunoblotting and qRT-PCR; Bex, but not Pio, prevented this increase. Bex completely inhibited the pro-hypertrophic effects of AII, as determined by 3H-leucine incorporation into protein, while Pio had no effect. Effects on signaling pathways were also examined. Bex inhibited activity of p38, ERK, and JNK at 15 and 30 minutes following AII stimulation.

Conclusions: Bexarotene, an RXR agonist, inhibits pathological effects of AII in the vasculature. Given the stronger responses to bexarotene compared to pioglitazone, the effects of bexarotene likely involve other nuclear receptors. Rexinoids may be useful agents in treating vascular disease.

Influence of Angiotensin II (ANG II) on Morg1 Expression in Renal Cells

Tzvetanka Bondeva, Gunter B. Wolf. *Internal Medicine III, University of Jena, Jena, Germany.*

Background: The mitogen-activated protein kinase organizer 1 (Morg1) serves as a scaffold molecule for a number of proteins involved in the MAPK signalling complex. In addition it is involved in the regulation of the HIF-1α activity via PHD3 stabilization. Morg1 is expressed in kidney. The purpose of this study was to analyze the influence of ANG II on Morg1 expression and its correlation with PHD3 activity and HIF-1 alpha promoter activity in MMCs, MTCs and differentiated podocytes.

Methods: Morg1 expression was investigated in MMC (mouse mesangial cells), MTC (mouse tubular cells) and in differentiated podocytes by real-time PCR. HIF-1α transcriptional activity was tested using Luciferase reporter-gene assay. PHD3 activity was tested based on a HIF-1α peptide assay.

Results: MMCs, MTCs and differentiated podocytes were stimulated with ANG II for different time points. We observed a biphasic effect of ANG II on Morg1 mRNA expression which was time dependent and differentially regulated by the ANG II-receptor (ATR) 2 subtype. While 9 h ANG II incubation inhibited Morg1 expression in MMCs via AT1 and AT2 subtypes based on ATR2 blockers studies, it enhanced Morg1 mRNA expression after 24 h mainly through ATR1 subtype. In MTCs 9 h stimulatory effect of ANG II on Morg1 expression was reduced to basal at the presence of PD 123319, an AT2 blocker, while the suppression of Morg1 after 24 h ANG II was reversed by addition of losartan, an AT1 inhibitor. Podocytes demonstrated an elevated Morg1 expression after 3 h ANG II treatment, which was partially suppressed by both PD 123319 and losartan. On the other hand, 24 h ANG II treatment inhibited Morg1 expression in differentiated podocytes through AT2 receptor subtype. We also found that ANG II effects on Morg1 mRNA expression in renal cells are independent of MAPK activity. In correlation with Morg1 expression pattern was the measured PHD3 activity. Reporter-gene assays have shown possible negative regulation of HIF-1α activity via Morg1 and PHD3 in MTCs.

Conclusions: Our study indicates that ANG II regulates Morg1 expression and HIF-1α transcriptional activation through cell type specific complex mechanisms in renal cells.

Interactions between Adiponectin and Angiotensin II in Human Renal Tubular Cells

Fei Fang, George Chu Liu, Xiaohua Zhou, James W. Scholey. *Institute of Medical Science, University of Toronto, ON, Canada.*

Background: Chronic kidney disease (CKD) is a major risk factor for all-cause mortality, and its incidence is on the rise. The mechanism responsible for the progression of CKD is not completely understood, and epidemiology studies suggest that obesity can contribute to this process. One way that obesity may exacerbate CKD is by dysregulation of the adipokines. Adiponectin is a 30kDa hormone secreted by adipose tissue, and its circulating level decreases with obesity. Previous studies indicated that adiponectin could protect the heart and vasculature from various insults, which may be partially due to its inhibitory effect on the generation of reactive oxygen species. However the effect of adiponectin on kidney has not been fully elucidated. We hypothesized that adiponectin also plays a protective role in the kidney. To test our hypothesis, we studied the interaction of adiponectin and angiotensin II (AngII), which is well known to contribute to kidney injury, in human renal tubular cells.

Methods: Primary human renal proximal tubule epithelial cells (RPTECs) of passage 4 -7 were used for all experiments. NADPH oxidase activity was measured by lucigenin-enhanced chemiluminescence assay. NFκB activity was measured with commercial kits.

Results: Both the AdipoR1 and AdipoR2 were expressed in RPTEC and were present on cell membrane. AngII treatment didn't alter the expression level of neither the receptors. Adiponectin inhibited the activation of NADPH oxidase by AngII in RPTECs, which can be mimicked by the AMPK agonist AICAR and stable cAMP analogues pCPT-cAMP and db-cAMP. The effect of adiponectin was blocked by the AMPK antagonist compound C, adenylate cyclase inhibitor SQ22536 and PKA inhibitor H89. The AngII-induced increase in NFκB activity was also reduced by adiponectin.

Conclusions: Adiponectin attenuated the AngII-induced superoxide generation by NADPH oxidase in RPTEC, which was dependent on AMPK and cAMP/PKA pathways. NFκB activation caused by AngII in renal tubular cells was also attenuated by adiponectin. Our results suggest that decreasing adiponectin levels associated with obesity may be one of the mechanisms by which obesity contributes to the progression of CKD.

FXR or TGR5 Agonists Prevent High Glucose Mediated Glucolipotoxicity in Human Podocytes

Michal Herman-Edelstein,[1] Renana Eshet-Leon,[1] Moshe Levi,[2] Uzi Gafter.[1] *[1]Nephrology and Hypertension, Medical Center Tel-Aviv university, Petah Tikva, Israel; [2]Department of Medicine Division of Nephrology and Hypertension, University of Colorado, Denver, CO.*

Background: Diabetic nephropathy has been associated with abnormal lipid metabolism and lipotoxicity. Accumulation of lipid droplets (LDs) in podocytes is a frequently observed phenotype in the diabetic kidney. Bile acid activated nuclear hormone receptor the farnesoid X receptor (FXR) and the G protein-coupled receptor (TGR5) regulates bile acid, glucose, and lipid metabolism and inflammation. Activation of FXR by synthetic ligands GW4064 or INT-747 attenuates renal fibrosis in animal models of diabetic nephropathy. The aim of this work was to study the mechanism of the adipogenic program and LD accumulation in human podocytes and the effect of FXR and TGR5 agonists.

Methods: Podocytes were treated with high glucose to induce de-novo lipogenesis. Lipid content was assessed by Oil Red O as well as Nile Red staining. Expression of mRNA and protein of molecules controlling lipid homeostasis was examined by real-time quantitative PCR, LDs were determined using FACS method and by confocal microscopy.

Results: Administration of high glucose increased the number of LDs and the LD-associated protein adipocyte differentiation-related protein (ADRP). Selective FXR agonist (GW4064) and TGR5 agonist (INT-777) significantly inhibited high glucose induced increase of lipogenic genes including sterol regulatory element binding protein-1 (SREBP-1), which is a transcription factor regulating the synthesis of fatty acid and triglycerides, and its target gene an acetyl-CoA carboxylase (ACC) . We also found that GW4064 attenuates podocyte lipid accumulation.

Conclusions: FXR or TGR5 selective agonists may attenuate glucose induced podocyte glucolipotoxicity by inhibiting podocyte lipid droplet accumulation and transdifferentiation into adipocyte-like cells.

MCP-1/CCR2 System Is Involved in Epithelial-Mesenchymal Transition of Peritoneal Mesothelial Cells

Sun Ha Lee, Jisun Paeng, Seung Hyeok Han, Tae-Hyun Yoo, Shin-Wook Kang. *Dept. of Int. Medicine, College of Medicine, BK21, SBSI, Yonsei Univ., Seoul, Korea.*

Background: MCP-1 and its receptor, CCR2, have been known to be directly involved in extracellular matrix synthesis. In addition, the MCP-1/CCR2 system was present in peritoneal mesothelial cells(PMCs), and MCP-1 production was increased in PMCs under high glucose(HG) conditions. Therefore, we presumed that the MCP-1/CCR2 system may play an important role in the pathogenesis of peritoneal fibrosis(PF) and conducted this study to investigate the functional role of the MCP-1/CCR2 system in epithelial-mesenchymal transition(EMT) of PMCs and PF.

Methods: In vitro, human PMCs(HPMCs) were incubated in M199 media containing 5.6 mM glucose(NG), NG+MCP-1, or 100 mM glucose(HG) with or without mutant MCP-1(mMCP-1) for 72 hours. In vivo, peritoneal catheter was inserted into Sprague-Dawley rats, and saline(control, C) or 4.25% PD solution(PD) was infused. In the PD group, rats were treated either with empty lentivirus vector or lentivirus vector containing mMCP-1 intraperitoneally, once a week. After 4 weeks, peritoneum was removed. Western blot analysis was performed to evaluate fibronectin(FN), E-cadherin, and α-smooth muscle actin(α-SMA) protein expression. PF was determined by Masson's trichrome(MT) staining.

Results: FN and α-SMA protein expression were significantly increased, and E-cadherin protein expression was significantly decreased in HPMCs exposed to NG+MCP-1 and HG compared to NG cells($p<0.05$). These changes in FN, α-SMA, and E-cadherin expression in NG+MCP-1 and HG cells were significantly abrogated by mMCP-1($p<0.05$). In rats infused with PD solution, the expression of FN protein and the ratios of α-SMA/E-cadherin protein expression of peritoneum were significantly higher compared to C rats($p<0.05$). In addition, the thickness of PMC layer and the intensity of MT staining in the peritoneum of PD rats were significantly increased compared to C rats($p<0.05$). These changes in PD rats were significantly ameliorated by the treatment with lentivirus containing mMCP-1.

Conclusions: These findings suggest that the MCP-1/CCR2 system is involved in peritoneal EMT and its inhibition may be a potential therapeutic target for PF.

SA-PO2427

Adenosine 1 Receptor-Mediated Effects on Energy Balance and Body Weight Lingli Li,[1] Robert Faulhaber-Walter,[2] Christoph Eisner,[3] Yuning George Huang,[1] Jurgen B. Schnermann.[1] *[1]National Institute of Diabetes and Digestive and Kidney Diseases, NIH, Bethesda, MD; [2]üGMP, Standort Rinteln, Germany; [3]Department of Anesthesiology, UMM, Mannheim, Germany.*

Background: Adenosine 1 receptors (A1AR) presumably by activation of the tubuloglomerular feedback pathway exert an important role in limiting glomerular hyperfiltration in the Akita mouse model of type I diabetes mellitus. In addition, A1AR-/- mice develop insulin resistance suggesting that A1AR mediate direct anti-diabetogenic effects.

Methods: Body weight, food intake, urinary osmolarity and Cl- concentration were measured by standard methods. The body fat fraction was determined by Echo MRI 3-in-1™ . Plasma adenosine was measured by HPLC. Serum leptin was measured by ELISA (Tatyana Chanturiya, NIDDK, NIH, Bethesda, MD).

Results: A1AR-/- mice have a 13% greater body weight than age matched wild type (WT) mice. Body fat fraction was 15±4% in A1AR-/-, significantly higher than 10.8±2% in WT. Food intake measured over 10 days (g/mouse/day) averaged 3.85 ± 0.1 in WT (n=10) and 4.12 ± 0.06 in A1AR-/- (n=12; $p<0.05$). Water intake was also significantly higher in A1AR-/- than WT (+12.5%) accompanied by a decrease in urinary osmolarity (-29.5%) and Cl- concentration (-30.8%). Despite the higher fat content serum leptin levels (ng/ml) were significantly lower in A1AR-/- than WT mice (2.14±0.05 vs. 3.75±0.36; $p<0.01$). Mice with a deletion of the equilibrative nucleoside transporter (ENT1-/-) have an elevated plasma adenosine concentration (1173±78 vs. 178±24 nM; $p<0.01$). Body weight (g) of 14 wk old ENT1-/- averaged 24.4±0.37 (n=5), significantly less than that of age-matched WT mice (28.5±0.76; n=5; $p<0.05$), and this was associated with a decreased food intake (g/day) in ENT1-/- mice compared to WT (3.6±0.1 vs. 4.14±0.19; $p<0.05$).

Conclusions: We conclude that adenosine through tonic activation of A1AR in fat tissue stimulates the release of leptin and that this suppresses food intake and prevents the development of insulin resistance. A1AR-mediated effects of adenosine contribute to the maintenance of a normal energy balance and to the prevention of obesity.

Prostaglandin E2 (PGE2), a Mediator of Proliferation and Cl- Secretion in Polycystin-1 Deficient Cells Yu Liu,[1] Madhumitha Rajagopal,[3,4] Daniel Armando Flores,[1] Lorenzo Battini,[1] G. Luca Gusella,[1] Alan C. Pao,[3,4] Rajeev Rohatgi.[1,2] *[1]Medicine, Mount Sinai School of Medicine, New York, NY; [2]Medicine, James J. Peters VAMC, Bronx, NY; [3]Medicine, Stanford University, Palo Alto, CA; [4]Medicine, VA Palo Alto Health Care System, Palo Alto, CA.*

Background: PGE2 and calcium activated Cl- channels (CaCCs), specifically bestrophin-1, are implicated in proliferation of epithelial cells. Thus, we hypothesized that PGE2 mediated signaling may activate dysregulated CaCCs which contribute to the proliferative and secretory phenotype of ADPKD epithelia.

Methods: Utilizing wildtype IMDC3, control transfected (siLuc) IMCD3, and IMCD3 cells transfected with siRNA against PKD1 (siPKD1), we measured PGE2 mediated proliferation (cyquant[Invitrogen]), PGE2 induced Cl- secretion, and mRNA abundance of CaCCs.

Results: Proliferation was presented as a ratio of the fluorescence at each time point (18-96 hrs) to the fluorescence measured at 18 hrs. siPKD1 cells proliferated faster than wildtype and siLuc cells (n=6 wells for each group, $p<0.05$) at 72 and 96 hrs after plating. Next, cyclooxygenase(COX)-1 (SC560), COX-2 (CAY10404) and COX-1/2 (indomethacin) inhibitors were incubated with siPKD1 cells, and proliferation compared to untreated siPKD1(n=6 for each group) cells. COX inhibition reduced proliferation at all time points compared to untreated cells. On the other hand, incubation with 50 nM PGE2 enhanced siPKD1 cellular proliferation (n=6, $p<0.05$), but reduced wildtype cellular proliferation(n=6, $p<0.05$), suggesting that PGE2 has dichotomous effects. Moreover, PGE2 induced Cl- secretion was 5 fold greater in siPKD1 ($p<0.05$) than in wildtype cells. 45% of the Cl- current was inhibited by a CFTR inhibitor ($P<0.05$) and ~30-40% was inhibited by FFA ($P<0.05$), a non-selective CaCC inhibitor. Quantitative RT-PCR showed ~3 and ~6 fold increase in TMEM16a and bestrophin-1 (CaCCs), respectively, compared to control cells.

Conclusions: PGE2 induces proliferation and CFTR-, CaCC-dependent Cl- secretion in siPKD1 cells. We speculate that the over-expression of CaCCs, contribute to PGE2 mediated Cl- secretion and proliferation seen in siPKD1 cells.

Rosuvastatin Reduces Pressure-Induced Fibrotic Signals through PGI_2-PPARγ Pathway in Renal Tubular Cells Tso Hsiao Chen, Cheng-Hsien Chen. *Department of Nephrology, Taipei Medical University-Wan Fang Hospital, Taipei, Taiwan.*

Background: Statins have been reported to alleviate renal fibrosis in the animal model with unilateral ureteral obstruction. However, the molecular mechanism of this anti-fibrotic effect is still a mist. Pressure force is an important mechanisms contributing to the induction and progression of tubulo-interstitial fibrogenesis in ureteric obstruction.

Methods: We established an *in vitro* pressure culture system to study the influence of statins on renal tubular cell fibrosis. Fibrosis-associated molecules, such as COX-2, connective tissue growth factor (CTGF), fibronectin, were monitored by Western blotting. TGF-b, PGE2 and PGI2 generated from pressure-treated cells were identified using ELISA kits. We also used PGIS siRNA transfection to block the expression of PGI2 in rat renal tubular cell NRK-52E.

Results: When NRK-52E cells were cultured in the pressure culture system, 60-mmHg pressure induced the expression of connective tissue growth factor (CTGF), transforming growth factor beta (TGF-b), fibronectin and phospho-Smad3. These pressure-induced fibrotic signals were reduced by rosuvastatin in a dose-dependent manner. Rosuvastatin also reduced the TGF-b-induced expression of fibronectin and CTGF in NRK-52E cells. The pretreatment of rosuvastatin significantly induced prostacyclin (PGI_2) generation, but reduced pressure-induced prostaglandin E2 (PGE_2). The trasfection of PGI_2 synthase siRNA decreased the inhibitory effect of rosuvastatin on pressure-induced CTGF, TGF-β and fibronectin. On the other hand, the specific inhibitor for cyclooxygenase-2, NS398, diminished pressure-induced PGE_2 generation, and partially reduced pressure-induced fibrotic signals. Additional PGE_2 decreased the anti-fibrotic effect of rosuvastatin. When we monitored the influence of the nuclear receptors for PGI_2 on the anti-fibrotic effect of rosuvastatin using siRNA transfection, the blockage of PPARγ reduced the inhibitory effect of rosuvastatin on pressure-induced fibrotic signals.

Conclusions: We conclude that rosuvastatin prevents renal tubular cells from pressure-induced fibrosis by enhancing PGI_2-PPARγ pathway and reducing PGE_2 generation.

Effects of Wnt-7a on Aristolchic Acid Induced Renal Tubular Epithelial-Mesenchymal Transition Guo-Qin Wang, Hong-Liang Rui, Yan-Yan Wang, Hong Cheng, Yi-Pu Chen. *Division of Nephrology, Beijing Anzhen Hospital, Capital Medical University, Beijing, China.*

Background: The Wnt family controls both ureteric bud development and signaling, but it also serves as inductive factor to regulate nephrogenesis in the mesenchymal. It was reported that Wnt protein is expressed in the nephron precursor cells, bing important for their development to nephrons. This study was to observe whether Wnt7 reverses epithelial-to-mesenchymal transition (EMT) and induces mesenchymal-epihtelial transition (MET) on aristolchic acid-induced renal tubular epithelial cell.

Methods: Human proximal renal tubular epithelial cell line HK-2 cells were cultured in different conditions: (1) serum free as control, (2) cultured with AA (30mg/l) for 24h, (3) treated with Wnt7a (20ng/ml) for 48h after stimulated with AA (30mg/l), (4) treated with Wnt7a(20ng/ml) plus LiCl (Wnt's blocker, 1ug/ml) for 48h after stimulated with AA(30mg/l). Expression of cytokeratin, E-cadherin, a-smooth muscle actin (a-SMA) and vimentin was assessed by immunofluorescence and western-blot.

Results: After incubation with AA, Levels of a-SMA (698.1±20.7 vs 66.5±9.8, $P<0.05$) and vimentin (496.3±19.7 vs 187.3±20.5, $P<0.05$) expressions increased significantly, but levels of cytokeratin (211.3±16.1 vs 624.7±19.4, $P<0.05$) and E-cadherin (168.7±11.3 vs 426.5±21.9, $P<0.05$) expressions decreased in comparison to control group. Treatment of HK2 cells stimulated by AA with Wnt7 resulted in down-regulation of a-SMA (151.5±14.3 vs 698.1±20.7, $P<0.05$) and vimentin (214.5±20.2 vs 496.3±19.7, $P<0.05$) expression, but up-regulation of cytokeratin (516.8±14.2 vs 211.3±16.1, $P<0.05$) and E-cadherin (310.7±10.5 vs 168.7±11.3, $P<0.05$) expressions. Compared to HK2 cells treatment with Wnt7a, the expression of a-SMA (411.2±18.5 vs 151.5±14.3, $P<0.05$) and vimentin (472.7±23.1 vs 214.5±20.2, $P<0.05$) enhanced while cytokeration (239.6±13.2 vs 516.8±14.2, $P<0.05$) and E-cadherin (199.7±17.1 vs 310.7±10.5, $P<0.05$) expression reduced markedly on HK2 cells treatment with Wnt7a and Licl.

Conclusions: Wnt7a is able to reverse EMT induced by AA, which represents a potential therapeutic approach to aristolchic acid nephropathy prevention.

Reciprocal Expression of microRNA-214 (miR-214) and Insulin-Like Growth Factor-1 Receptor (IGF-1R) Dictates Renal Carcinoma Cell (RCC) Proliferation Via Akt/TORC1 Circuit Nirmalya Dey,[1] Falguni Das,[1] Nandini Ghosh-Choudhury,[2] B. S. Kasinath,[1] Hanna E. Abboud,[1] Goutam Ghosh-Choudhury.[1] *[1]Medicine, UTHSCSA, San Antonio, TX; [2]Pathology, UTHSCSA, San Antonio, TX.*

Background: IGF-1R signal transduction significantly contributes to development of the renal cancer irrespective of the VHL status of the tumors. We found increased levels of IGF-1R in the VHL-deficient 786-O and in VHL positive ACHN RCCs as compared to normal human proximal tubular epithelial cells (HK2). Rate of proliferation of the RCCs and mitogenic effect of IGF-1 were significantly elevated. The mechanism by which the expression of IGF-1R in these RCCs is increased is not known. We considered a miRNA-mediated posttranscriptional mechanism. We detected decreased expression of mature, pre- and pri-miR-214 in the ACHN and 786-O RCCs compared to HK2 cells. Molecular cloning of the human promoter for miR-214 and reporter assay showed a significant transcriptional silencing of miR-214 in the RCCs compared to HK2 cells. We identified miR-214 recognition elements in the 3'UTR of IGF-1R mRNA and established their responsiveness to miR-214. miR-214 inhibited expression of IGF-1R, resulting in attenuation of IGF-1-stimulated Akt phosphorylation in RCCs. Furthermore, IGF-1 increased PRAS40 phosphorylation at Thr-246, which was necessary for RCC proliferation. Moreover, the inactivating phosphorylation of PRAS40 by IGF-1R stimulation enhanced TORC1 activity, resulting in S6 kinase and 4EBP-1 phosphorylation. Phosphorylation-deficient mutant of 4EBP-1 inhibited IGF-1R-provoked proliferation of RCC. Expression of miR-214 significantly inhibited IGF-1R-forced phosphorylation of PRAS40, S6 kinase and 4EBP-1. Finally, miR-214 prevented proliferation of RCCs in response to IGF-1 but

without causing apoptosis of the cells. Together our results identify a reciprocity between miR-214 and IGF-1R levels in RCCs independent of the VHL status of the cells. Our data provide evidence for a previously unrecognized mechanism of RCC proliferation involving miR-214 and TORC1.

Target Genes of Endogenous Retinoic Acid and Retinoic Acid Receptors in Collecting Duct Cells: A Pan-Genomic View Qihe Xu,[1] Yuen Fei Wong,[1] Patricia D. Wilson,[2] Robert J. Unwin,[2] Jill T. Norman,[2] Bruce M. Hendry.[1] *[1]Department of Renal Medicine, King's College London, London, United Kingdom; [2]Centre for Nephrology, University College London, London, United Kingdom.*

Background: Gestational vitamin A deficiency (VAD) impairs renal development and post-natal VAD causes polyuria, urolithiasis, renal inflammation and fibrosis. Vitamin A is converted into retinoic acid (RA) to activate RA receptors (RAR). We previously showed that endogenous RA/RAR signaling was confined to the ureteric bud (UB)/collecting duct (CD) cell lineage in mouse kidneys, including the mIMCD-3 mouse inner medullary cell line. We hypothesized that endogenous RA/RAR interactions in CD cells regulate genes that may mediate VAD-associated renal anomalies.

Methods: Affymetrix GeneChip Mouse Gene 1.0 ST Arrays and RT-qPCR were used to shortlist and validate RA/RAR target genes in mIMCD-3 cells treated for 24h with 2 distinct RA/RAR inhibitors, 1 μM AGN193109 (RAR pan-antagonist) or 25 μM DEAB (RA synthesis inhibitor), ± 0.01-0.2 μM RA (n=3). Target genes of endogenous RA/RAR were defined as those: (i) significantly regulated by both inhibitors and reversed by RA ($P \leq 0.05$); (ii) changed ≥2-fold by either inhibitor.

Results: Microarray analysis showed that inhibitors induced 22 and suppressed 105 genes. While changes of all induced genes were <2-fold and not further investigated, RT-qPCR validated 18 of 19 genes suppressed ≥2-fold as target genes of endogenous RA/RAR. Dhrs3, which encodes an enzyme converting RA precursors to vitamin A, was most highly suppressed (25-100-fold) by inhibitors. Ten other validated genes have potential roles in kidney injury/repair (Tns1, Lcn2, Itga2, Muc20, Galns), renal/epithelial development (Sprr1a, Ppbp, Muc20) and water/solute homeostasis (Npr3, Clca4, Slc37a1). Seven remaining validated genes have unknown functions in the kidney (9930023K05Rik, Cpm, Klhdc7a, Sorcs2, 2310007B03Rik, Upk3b, Ebf1).

Conclusions: Endogenous RA/RAR in CD cells regulate a broad profile of genes involved in renal development, repair and homoestasis. Further investigation should provide valuable insights into the complex role of RA/RAR in normal and diseased kidneys, including the pathogenesis of VAD-associated anomalies.

ATP Secretion by Rat Loops of Henle *In Vivo* Sara Damiano,[1] Robert J. Unwin,[2] David G. Shirley.[2] *[1]Chair of Nephrology, Department of Internal Medicine, Seconda Universita degli Studi di Napoli, Napoli, Italy; [2]Centre for Nephrology, University College London, London, United Kingdom.*

Background: Recent evidence from *in vitro* studies indicates that the cells of the thick ascending limb of the loop of Henle can secrete nucleotides into the lumen and that this secretion is stimulated by increases in intraluminal pressure (Praetorius & Leipziger 2010, Ann Rev Physiol 72: 377). Further *in vitro* studies suggest that ATP inhibits sodium reabsorption in the thick ascending limb (Garvin et al 2011, Ann Rev Physiol 73: 359). The purpose of the present investigation was to assess, *in vivo*, whether significant amounts of ATP are secreted by the loop of Henle and whether this is affected by flow rate.

Methods: Rats were anaesthetised and prepared surgically for micropuncture studies. Loops of Henle of superficial nephrons were functionally isolated by the introduction of intraluminal oil columns and perfused from late proximal convoluted tubules for 5-7 min using artificial proximal tubular fluid containing no ATP; the fluid emerging from the loop was collected at the early distal tubule. Each loop was perfused twice: with and without the ATPase inhibitor ARL 67156, or at 20 *vs* 40 nl/min. The collectates from each category of perfusion were pooled (n = 8-13 loops) and the ATP concentration of the pooled sample was measured using the luciferin-luciferase reaction.

Results: When loops were perfused at 20 nl/min, in the absence or presence of intraluminal ARL 67156 (100 μM), the ATP concentrations in the collected fluid were 162 ± 22 nmol/l and 275 ± 41 nmol/l, respectively (n = 5 pairs of pooled collections, P<0.05, paired t). When loops were perfused at 20 nl/min or 40 nl/min (in the absence of ARL 67156), the ATP concentrations in the collected fluid were 177 ± 42 nmol/l and 334 ± 92 nmol/l, respectively (n = 5 pairs of pooled collections, P<0.05, paired t); in the latter experiments, the rates of ATP collection were 2.1 ± 0.5 fmol/min and 5.8 ± 1.4 fmol/min, respectively (P<0.01).

Conclusions: These data indicate that physiologically significant amounts of ATP are secreted by loops of Henle in *vivo*. Furthermore, the amount secreted is profoundly affected by changes in tubular flow rate.

Nephron Segment-Specific Gene Deletion Using a Cre-Adenovirus Pablo D. Cabral, Marcela Herrera, Pablo A. Ortiz, Jeffrey L. Garvin. *Hypertension and Vascular Research, Department of Internal Medicine, Henry Ford Hospital, Detroit, MI.*

Background: Most pharmacological tools used to study renal physiology have limited specificity. This has led to the development of methods to manipulate gene expression to study protein function. However, current methods to delete genes of interest are limited. Non-selective knockout from birth may result in compensation by other genes and eliminate the ability to study the function of a specific protein in a specific tissue. Development of transgenic mice using a Cre/loxP strategy requires two strains, being expensive and time-consuming. We have previously shown that injection of adenoviral vectors in the renal outer medulla resulted in efficient and specific transduction of thick ascending limbs. The development of the Cre/loxP system selectively allows gene disruption. We hypothesized that in vivo injection of adenoviruses expressing Cre recombinase under the control of the promoter for the NaK2Cl cotransporter (NKCC2) in the renal outer medulla results in selective transduction of medullary thick ascending limbs.

Methods: A double fluorescent Cre reporter mouse strain that expresses td tomato, a red fluorescent protein, before Cre-mediated excision and green fluorescent protein (GFP) after excision was used. Adenoviruses containing Cre recombinase driven by the NKCC2 promoter (Ad-NKCC2Cre), which is specific for thick ascending limbs, were injected in the renal outer medulla.

Results: Western blots showed GFP expression in outer medullary lysates 7 days after Ad-NKCC2Cre injections. Immunofluorescence of kidney sections transduced with Ad-NKCC2Cre showed expression of GFP in outer medullary thick ascending limbs, identified by positive Tamm-Horsfall labeling. Neither renal cortex nor inner medulla were positive for GFP. Immunofluorescence microscopy showed that 82 ± 5 % and 82 ± 1 % of the outer medullary thick ascending limbs expressed GFP at 7 and 14 days respectively.

Conclusions: We concluded that combining Cre/loxP technology and efficient adenovirus-mediated transduction of thick ascending limbs could be a useful tool to study gene function in adult mice preventing compensation.

Relaxin Signals through the Nitric Oxide Pathway To Promote Matrix Metalloproteinase Activity in the Kidney Bryna Chow,[1] Timothy Hewitson,[2] Chrishan S. Samuel.[1] *[1]Neuropeptides/Relaxin Division, Howard Florey Institute, Parkville, Victoria, Australia; [2]Nephrology, Royal Melbourne Hospital, Parkville, Victoria, Australia.*

Background: The inevitable consequence of end-stage kidney disease is the excessive accumulation of extracellular matrix, primarily collagen which drives the pathological setting of renal fibrosis. Pre-clinical and signal transduction studies have shown that the anti-fibrotic hormone relaxin can inhibit TGF-β1 activity by binding to Relaxin Family Peptide Receptor 1 (RXFP1) and activating a neuronal nitric oxide (NO) synthase (nNOS)-NO-cyclic guanosine monophosphate (cGMP)-dependent pathway to abrogate Smad2 phosphorylation; thereby inhibiting TGF-β1-induced myofibroblast differentiation and collagen synthesis. Thus, this study sought to determine if relaxin's well-documented additional ability to induce collagen degradation by matrix metalloproteinases (MMPs) was by a similar mechanism.

Methods: Primary myofibroblasts (propagated from rat kidneys 3 days after unilateral ureteric obstruction) were treated with relaxin (100ng/ml) in the absence or presence of the general NO inhibitor L-NAME (75 μM), the nNOS inhibitor NPLA (2 μM), the inducible NOS (iNOS) inhibitor 1400W (0.5 μM) or cGMP inhibitor ODQ (5 μM) over a 72 hour culture period. Media samples were collected and assessed for changes in MMP-2 and MMP-9 activity (by gelatin zymography), while cell layer protein was assessed for changes in MMP-13 levels (by Western blotting).

Results: Relaxin significantly up-regulated MMP-2, MMP-9 and MMP-13 expression and activity when administered over a 72 hour culture period to renal myofibroblasts by 128%, 115% and 91%, respectively (all p<0.01 vs untreated cells). This relaxin-induced up-regulation of MMPs was significantly blocked by L-NAME, NPLA, 1400W and cGMP (by ~50–90%) (all p<0.05 vs relaxin alone-treated levels), while neither of these inhibitors affected basal MMP levels.

Conclusions: These findings suggest that relaxin signals through a RXFP1-nNOS/iNOS-NO-cGMP pathway to promote renal MMP activity; and that the NO-cGMP pathway is central to relaxin's anti-fibrotic actions.

Attenuation of Systolic Hypertension and Angiotensinogen Gene Expression in Diabetic Akita Transgenic Mice Overexpressing Heterogenous Nuclear Ribonucleoprotein F in the Kidney Chao-Sheng Lo,[1] Shiao-Ying Chang,[1] Yixuan Shi,[1] Isabelle Chenier,[1] Shao-Ling Zhang,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] John S.D. Chan.[1] *[1]Res. Ctr., CHUM-Hotel Dieu Hospital, Montreal, QC, Canada; [2]Res. Ctr., Maisonneuve-Rosemont Hospital, Montreal, QC, Canada; [3]Pediatr Nephrol Unit, Mass Gen Hosp, Boston, MA.*

Background: Heterogeneous nuclear ribonucleoprotein F (hnRNP F) binds to the insulin-responsive element in the rat angiotensinogen (Agt) gene promoter and inhibits Agt gene transcription *in vitro*. We now investigate whether overexpression of hnRNP F

can modulate renal Agt gene expression and subsequently attenuate systolic hypertension (sHTN) in Akita mice with type 1 diabetes.

Methods: Akita transgenic (Tg) mice specifically overexpressing hnRNP F solely in their renal proximal tubular cells (RPTCs) were created by cross-breeding of Akita mice with hnRNP F-Tg mice that specifically overexpress hnRNP F in their RPTCs by employing kidney specific androgen-regulated protein promoter. Non-Akita littermates served as controls. Blood glucose, systolic blood pressure (SBP) and albuminuria were monitored weekly from 10 to 20 weeks of age. Kidneys were processed for histology studies. Renal proximal tubular Agt mRNA and protein expression were quantified by respective real time-qPCR and Western blotting. Urinary angiotensin II (Ang II) levels were quantified by ELISA.

Results: Our results demonstrate that Akita mice develop sHTN (~136 ± 3.8 mm Hg) and display renal hypertrophy and hydronephrosis as compared to non-Akita controls (~108 ± 0.7 mm Hg). HnRNP F overexpression markedly decreased sHTN, kidney/body weight ratio and renal hypertrophy without affecting blood glucose level and the urinary albumin/creatinine ratio in Akita hnRNP-F Tg mice as compared to Akita mice. Furthermore, Agt mRNA and protein expression as well as urinary Ang II levels are significantly increased in Akita mice but normalized in Akita hnRNP F-Tg mice.

Conclusions: Our data suggest that hnRNP F plays a protective role by attenuating sHTN and preventing RPTC injury in diabetes, and indicate that these actions are mediated, at least in part, through attenuating intrarenal Agt gene expression and RAS activation *in vivo*.

SA-PO2437

Stimulatory Effect of Insulin on Renal Proximal Na Transport Is Preserved in Obesity-Induced Insulin Resistant Rats Motonobu Nakamura, Osamu Yamazaki, Hideomi Yamada, Masashi Suzuki, Shoko Horita, George Seki, Toshiro Fujita. *Internal Medicine, Tokyo University, Tokyo, Japan.*

Background: The role of hyperinsulinemia in the pathogenesis of obesity-induced hypertension remains to be established. We have shown that the stimulatory effect of insulin on renal proximal tubule transport is preserved in the insulin resistant IRS2 KO mice (JASN 16:2288,2005).

Methods: In the present study, we tried to examine whether the renal tubular actions of insulin are preserved in the more generalized forms of insulin resistance. We determined the activity of Na-HCO_3 cotransporter NBCe1 in isolated renal proximal tubules by cell pH measurements with a fluorescence dye BCECF. Glucose uptake into adipocytes obtained from periepididymal fat tissues was also measured to estimate the degree of insulin resistance. Akt phosphorylation was analyzed by Western blotting.

Results: We first confirmed that a PI3-kinase inhibitor wortmannin completely inhibited the stimulatory effect of insulin on NBCe1 activity in Wistar rats. We next compared the effects of insulin in the hyperphagic Otsuka Long-Evans Tokushima Fatty (OLETF) rats and the control LETO rats. By 22 weeks of age, OLETF rats developed obesity (Body weight: 534 ± 13 vs 426 ± 9g), hyperinsulinemia (3.5 ± 0.2 vs 1.7 ± 0.3 ng/ml), and insulin resistance as evidenced by the increased homeostasis model assessment of insulin resistance (28 ± 1 vs 10 ± 2). The stimulation of glucose uptake into adipocytes by 10^{-8} M insulin was severely reduced in OLETF rats (57 ± 27%) compared to that in LETO rats (269 ± 26%). By sharp contrast, the stimulation of NBCe1 activity by 10^{-8} M insulin was comparable in OLETF (70 ± 11%) and LETO rats (74 ± 15%). In OLETF rats, the insulin-induced Akt phosphorylation was preserved in renal cortex tissues, but severely blunted in adipocytes.

Conclusions: These results indicate that the stimulatory effect of insulin on NBCe1 activity in proximal tubules was dependent on PI3-kinase/Akt pathway, and that this stimulation was completely preserved in obesity-induced insulin resistance. Hyperinsulinemia associated with obesity may contribute to the occurrence of hypertension by facilitating renal Na absorption.

SA-PO2438

TIF2/SRC2 Expression in Blood Leukocytes Is a Determinant of Steroid Response in Pediatric Idiopathic Nephrotic Syndrome: A Midwest Pediatric Nephrology Consortium Study Danica Petrovic-Djergovic,[1] Seetharamaiah Chittiprol,[1] Phylip Chen,[1] Tad Eichler,[1] Richard F. Ransom,[1] The MWPNC.[2] *[1]Nationwide Children's Hospital; [2]Midwest Pediatric Nephrology Consortium.*

Background: Resistance to glucocorticoid (GC) therapy in nephrotic syndrome (NS) is considered a poor prognostic sign, since the 8-10% of steroid-resistant NS (SR) account for ~15% of all end-stage renal diseases in children. Defects in the anti-inflammatory effect of GC, rather than its effects on metabolic or endocrine pathways, are thought to be the basis of GC insensitivity in NS. TIF-2 (GRIP1/SRC2) is a member of the mammalian p160 nuclear cofactor family with a critical role in the anti-inflammatory effects of GC. We hypothesized that TIF2 (encoded by NCOA2) is essential for the therapeutic action of GC in NS.

Methods: Samples were obtained from steroid-sensitive (SS) and SR pediatric patients at both presentation (PS) and after the first 6-8 week course of GC therapy (TS). Relative mRNA expression was measured in peripheral blood RNA by qRT-PCR, and flow cytometry (geometric means) was used to measure relative protein expression.

Results: The expression of NCOA2 but not the two other p160-family members (NCOA1,3) increased after GC therapy in SS ($P<0.01$) but not SR patients. NCOA2 expression correlated, as expected, with DUSP1 expression ($P<0.0001$), since TIF2 is known to be essential for GC induction of DUSP1 mRNA. Flow cytometry confirmed that more TIF2 protein was present in the CD19+ leukocyte sub-population ($P<0.05$) in TS samples from SS vs. SR patients. There was also an increase in the amount of TIF2 (ratio of TS:PS) in CD4+ leukocytes from SS patients but not from SR patients ($P<0.05$). Finally, we found that GC treatment of cultured PS leukocytes from SS but not SR patients resulted in significant increases in TIF2 protein in CD4+ ($P<0.05$), CD8+ ($P<0.01$), and CD19+ ($P<0.05$) but not CD16+ sub-populations.

Conclusions: Together these results suggest that GC induction of the TIF2 nuclear receptor cofactor is essential for proper steroid responsiveness in NS, and that GC-induced TIF2 expression in leukocytes is a biomarker of patient steroid response in NS.

Funding: NIDDK Support

SA-PO2439

Temporal Effects of Calcimimetics on Parathyroid Gland Gene Expression in Rats with Early Secondary Hyperparathyroidism Victoria Shalhoub,[1] Edward Shatzen,[1] Sabrina Ward,[1] Michael J. Boedigheimer,[1] Mara Campbell,[1] Michael A. Damore,[1] Zheng Pan,[2] James R. Davis,[1] Charles M. Henley III,[1] William G. Richards.[1] *[1]Amgen, Inc, Thousand Oaks, CA; [2]Amgen, Inc, San Francisco, CA.*

Background: Secondary hyperparathyroidism (SHPT) is a complication of chronic kidney disease (CKD). Calcimimetics (CM), modulators of the calcium-sensing receptor (CaSR), lower serum PTH and calcium (Ca) in CKD patients and rodent models. Although much is known about CaSR signaling pathways, the precise events are not well defined. Here, changes in gene expression were examined after CM treatment, in thyroparathyroid glands (TPG) of a rat model of CKD with SHPT.

Methods: Two-month-old 5/6 nephrectomized (Nx) SD rats, fed a standard diet (1.17%Ca/1.0%Pi), developed renal insufficiency and SHPT over 6 weeks. Rats (13/group) were then dosed p.o. daily with vehicle (veh) or the research CM R-641 (10 mg/kg). Blood and TPG were harvested at 4, 48, 72 and 96 hours.

Results: Six weeks post 5/6Nx, rats had higher serum PTH (1153±124 vs 435±30pg/ml, mean±SEM), BUN (50±3 vs 18±0mg/dL) and creatinine (0.65±0.02 vs 0.24±0mg/dL) than sham-veh rats. Gene profiles and the number of dividing cells (Ki67+) in PG, were no different comparing sham and 5/6Nx rats, reflecting the slow progression of PG cell hypertrophy/hyperplasia in rats fed a standard diet. Calcimimetic treated 5/6Nx rats had lower serum PTH levels than veh-treated 5/6Nx rats (52±8 vs 1153±124pg/ml). Gene expression changes occurred in pathways that included CaSR, proliferation, apoptosis and lipid (fold change <-1.5 or >1.5; $P<0.001$). Two major categories of gene expression changes were observed: Those that occurred early (by 4 hours) included cyclin dependent kinases and inhibitors, G proteins, FOS, TNF and other apoptosis family members; and, those that occurred after 48-hours of treatment, which included genes involved in G protein, prostaglandin, arachidonate, lipoxygenase and cytoskeletal pathways.

Conclusions: This study extends knowledge of molecular events elicited in TPG within hours to one week after a single CM dose in an early rat CKD model. Confirmation of these findings in PGs may lead to novel therapeutic targets for SHPT.

Parathyroid Hormone Related Protein Dissociates Increased cAMP from Renin Secretion in Mouse Juxtaglomerular Cells Douglas K. Atchison,[1,2] Pamela Harding,[2] William H. Beierwaltes.[1,2] *[1]Department of Physiology, Wayne State University School of Medicine, Detroit, MI; [2]Hypertension and Vascular Research Division, Department of Internal Medicine, Henry Ford Health System, Detroit, MI.*

Background: cAMP is the stimulatory second messenger for renin secretion. Primary signals that stimulate renin do so by increasing the production of cAMP via the calcium-inhibitable adenylyl cyclase-V (AC-V) in the juxtaglomerular (JG) cell. Parathyroid hormone related protein (PTHrP) stimulates renin secretion in the isolated perfused kidney, but it is unknown if this is due to a direct effect on the JG cell. We hypothesized that JG cells would express the receptor for PTHrP (PTH1R), and that PTHrP would increase cAMP and renin secretion.

Methods: Experiments used primary cultures of isolated mouse JG cells.

Results: RT-PCR showed that JG cells express PTH1R. 10 nM and 1 μM PTHrP increased JG cell cAMP levels from 1.60±0.27 to 7.14±0.87 and 23.0±11.5 pmol/mg protein, respectively ($p<0.05$). However, neither 10 nM nor 1 μM PTHrP increased renin release from a basal level of 301.0±56.0 ng Ang I/ml/hr mg protein (10 nM PTHrP: 314.3±62.9; 1 μM PTHrP: 342.5±65.1 ng Ang I/ml/hr/mg protein, respectively). Since renin secretion is enhanced by low extracellular Ca, we repeated the experiments in either low or high calcium media with 1 μM PTHrP. PTHrP increased cAMP in the low-calcium medium from 4.76±2.17 to 20.51±11.93 pmol/mg protein ($p<0.05$) and in the high-calcium medium from 5.14±2.57 to 14.85±8.33 pmol/mg protein ($p<0.05$). However, basal renin release did not increase in either low- or high-calcium media with the addition of PTHrP (low-calcium basal: 432.0±127.5; low-calcium PTHrP: 497.2±165.4; high-calcium basal: 214.5±81.3; high-calcium PTHrP: 209.4±53.6 ng Ang I/ml/hr/mg protein).

Conclusions: Our data demonstrate that PTHrP increases cAMP by acting on PTH1R without stimulating renin release in primary cultures of mouse juxtaglomerular cells. The implication of this is that PTHrP dissociates cAMP formation from renin secretion in the JG cell by stimulating an adenylyl cyclase besides AC-V, or that adenylyl cyclase signaling in the JG cell may be compartmentalized.

Relationships between Physical Activity and Nutrition with Quality of Life in CKD Patients Robert G. Fassett,[1,3] Iain Robertson,[2] Madeline J. Ball,[2] Dominic P. Geraghty,[2] Jeff S. Coombes.[3] *[1]Renal Medicine, University of Queensland, Brisbane, Queensland, Australia; [2]Human Life Sciences, University of Tasmania, Launceston, Tasmania, Australia; [3]Human Movement Studies, University of Queensland, Brisbane, Queensland, Australia.*

Background: The Lipid lowering and Onset of Renal Disease (LORD) trial was a three-year randomised, double-blind, placebo-controlled trial investigating the effects of atorvastatin on kidney function in CKD patients. The study design included measures of physical activity and nutrition every nine months. The aim of this sub-study was to investigate the relationships between physical activity and nutrition with quality of life (QoL).

Methods: 132 patients with serum creatinine levels >120µmol/l, not taking lipid-lowering therapy and at all levels of proteinuria and serum cholesterol were enrolled. For this sub-study data was available for 120 patients and they were followed for a mean of 2.9 years. Every nine months physical activity, nutrition and QoL were assessed using the Active Australia questionnaire, 4-day diet diaries analysed with Foodworks software and the SF-36 questionnaire respectively. The association (Odds Ratio) between a number of predictors and 10 SF-36 QoL measurement scales were estimated using repeated measures ordinal logistic regression. An OR >1.00 indicates a positive association, and an OR <1.00 indicates a negative association.

Results: Weekly physical activity (METmins) was strongly associated with all measures on the SF-36 including the mental component score (MCS), (OR 1.3, 95% CI 1.1-1.6, P=0.01) and the physical component score (PCS), (OR 1.6, 95% CI 1.1-2.2, P=0.008). Dietary phosphate intake was strongly positively associated with improved PCS (OR 1.6, 95% CI 1.1-2.2, P=0.02) and dietary zinc was associated in a milder but consistent manner with poorer physical QoL and a lower MCS (OR 0.7, 95% CI 0.4-1.0, P=0.048). Dietary calcium and iron were both associated with poorer physical quality of life and better mental QoL.

Conclusions: Greater levels of physical activity are strongly associated with improved QoL in CKD patients. Micronutrients such as dietary phosphate, zinc, calcium and iron are also related to QoL.

High Levels of Adiponectin in End Stage Renal Disease May Be Due to Increased Production in Visceral Fat Maria P. Martinez Cantarin,[3] Cataldo Doria,[2] Adam Mathias Frank,[2] Warren R. Maley,[2] Carlo B. Ramirez,[2] Bonita E. Falkner.[1] *[1]Medicine, Thomas Jefferson University Hospital; [2]Surgery, Thomas Jefferson University Hospital; [3]Pharmacology, Thomas Jefferson University.*

Background: Plasma adiponectin is elevated in End Stage Renal Disease (ESRD) but the cause of abnormally increased adiponectin is unclear. Possible mechanisms include augmented production secondary to chronic inflammation, decreased clearance from the failed kidneys, or increased adiponectin resistance. The purpose of this study was to determine if there is increased adipose tissue production of adiponectin in ESRD. We compared plasma levels of adipokines and expression of adiponectin and adiponectin receptors in fat and muscle of ESRD patients and controls.

Methods: The study sample included 16 ESRD patients and 9 kidney donors (controls). Blood and tissue samples were obtained at the time of kidney transplantation and kidney donation. Adiponectin, hrCRP, IL-6, TNF-α and PAI-1 were measured in plasma samples by ELISA. Adiponectin protein and adiponectin receptor-1/2 mRNA expression analysis (by TaqMan Assays) was performed in subcutaneous, visceral fat and muscle.

Results: Mean plasma adiponectin in ESRD was 14 9.1 µg/ml and 85.4 µg/ml in controls (p=0.14). Plasma TNF-α (13 ± 5 pg/ml) and CRP (4.2 ±3.1 mg/L) values were significantly higher in ESRD compared to controls (8 ± 0.9 pg/ml; and 0.9 ± 0.9 mg/L; p<0.05). There were no differences in plasma levels of IL-6 and PAI-1 between the groups. Adiponectin protein expression in visceral fat was 1.5 fold higher in ESRD than controls (p<0.001). Adiponectin receptor 1 was 1.4 times higher in muscle and 1.2 times higher in visceral fat of ESRD compared to controls (p<0.05). There were no significant group differences in the expression of adiponectin protein or adiponecin receptor in subcutaneous fat.

Conclusions: In ESRD there is greater expression of adiponectin protein and adiponectin receptor 1 in visceral adipose tissue compared with controls. These results represent the first evidence of increased adiponectin expression in human adipose tissue in ESRD; and could explain at least one of the mechanisms by which this hormone is elevated in kidney disease.

SA-PO2443

Executive Functioning May Vary with GFR in Children with Mild to Moderate CKD Susan R. Mendley,[1] Stephen R. Hooper,[2] Matthew Matheson,[3] S. Shinnar,[4] Arlene C. Gerson,[3] Alison G. Abraham,[3] Marjolaine M. Limbos,[5] Robert W. Butler,[6] Marc Lande,[7] Susan L. Furth,[8] Bradley A. Warady.[9] *[1]U Maryland; [2]U North Carolina; [3]Johns Hopkins U; [4]Albert Einstein Coll of Med; [5]British Columbia Children's Hosp; [6]Ohio State U; [7]U Rochester; [8]U Pennsylvania; [9]Children's Mercy Hosp.*

Background: Neurocognitive dysfunction, with selective defects in executive function (EF), complicates advanced CKD and ESRD. In children, performance improves with renal transplantation. It is unknown whether EF is also impaired by moderate CKD; this would inform educational intervention during rapid neurocognitive development in childhood.

Methods: Tests of problem solving, inhibitory control and working memory were incorporated into the prospective, observational NIH-sponsored CKiD cohort study of children with mild to moderate CKD. Cross-sectional analysis of baseline test performance was by linear regression, stratified by estimated GFR: <30, 30 to<40, 40 to<50, ≥50 ml/min/1.73 m^2; blood pressure; renal diagnosis; and duration of CKD.

Results: 340 subjects, age 10-17 y (median 13) were tested. 26% had BP >90th %ile for age and height; 18% had glomerular disease; CKD duration was 6-13 y (median 10).

Performance on the Delis-Kaplan Tower Test, an EF task of planning and problem solving, was lowest in the group with GFR<30 and was progressively less affected in each higher GFR strata when compared to those >50. Mean values all fell within normal ranges and between-GFR differences did not reach significance in this cross-sectional comparison. By contrast, neither working memory (Wechsler Intelligence Scale Reverse Digit Span) nor inhibitory control (Errors of Commission subscale of the Connors Continuous Performance Test) varied with GFR at baseline. Likewise, neither high BP nor cause or duration of CKD affected performance of any test.

Conclusions: Cross-sectional analysis suggests tests of planning and problem solving may vary inversely with GFR in children with mild-moderate CKD. Large inter-individual variation in these measures of subtle cognitive impairment will require repeated observations and within-subject comparisons over time to discern an effect of progressive CKD.

SA-PO2444

Effects of Low-Protein Diet Supplemented with Ketoacid on Decreasing the Proteinuria in Primary Glomerular Diseases: An Additive Renoprotection Apart from Glucocorticoid and Immunosuppressant Hong Li Lin,[1] Wei Sun,[2] Hua Xie,[3] Yan Ling Sun.[4] *[1]Department of Nephrology, First Affiliated Hospital of Dalian Medical University, Dalian, Liaoning, China; [2]Department of Nephrology, First Affiliated Hospital of Dalian Medical University, Dalian, Liaoning, China; [3]Department of Nephrology, First Affiliated Hospital of Dalian Medical University, Dalian, Liaoning, China; [4]Department of Nephrology, First Affiliated Hospital of Dalian Medical University, Dalian, Liaoning, China.*

Background: We designed a prospective, randomized and controlled study to evaluate the effects of low-protein diet (LPD) supplemented with ketoacid on decreasing proteinuria and protecting renal function in primary glomerular disease patients.

Methods: 60 early-stage primary glomerular disease patients (eGFR≥60ml·min^{-1}·1.73m^{-2}) with predominant proteinuria(≥2g/24h)were randomly enrolled to LPD group(diet protein intake 0.6g·kg^{-1}·d^{-1} and ketoacid 1890mg·d^{-1})or normal-protien diet (NPD) group (diet protein intake 1.0g·kg^{-1}·d^{-1}) . All patients received the same treating protocols of glucocorticoid and immunosuppressant and were followed up for 12 months. Urinary excretion of urea nitrogen, proteinuria, creatinine, eGFR, serum prealbumin, albumin, anthropometric parameters, and blood pressure were measured or calculated monthly. The compliance and therapeutic effects were evaluated.

Results: 22 patients in LPD group and 19 in NPD group achieved the 12-month follow-up. Proteinuria decreased significantly in LPD group compared with NPD group from the 3rd to 12th month(p<0.05). Serum creatinine decreased and eGFR increased in LPD group(p<0.05). Serum albumin and prealbumin increased obviously in LPD group, and a significant difference was observed between two groups(p<0.05). After follow-up, there were 10 and 9 patients achieving complete remission and partial remission in LPD group, respectively, while 4 and 7 in NPD group.

Conclusions: LPD supplemented with ketoacid has beneficial effects on decreasing proteinuria, protecting renal function and maintains nutritional status in early-stage primary glomerular disease patients. The additive renoprotective effects exist apart from glucocorticoid and immunosuppressant.

SA-PO2445

A Cross-Sectional Study of Serum Potassium Abnormalities Associated with Prescribed Medication in a CKD Population Darren Green, David I. New, Philip A. Kalra. *Vascular Research Group, Manchester Academic Health Sciences Centre, University of Manchester, Salford Royal Hospital, United Kingdom.*

Background: Hyper- and hypokalemia are associated with cardiac arrhythmia. They may be caused by drugs such as anti-hypertensives which are prescribed with particular frequency in renal clinics. We sought to understand which drugs were most frequently associated with abnormal serum potassium in this setting.

Methods: We undertook a cross-sectional analysis of the serum potassium and concomitant medication history of 1208 patients visiting a tertiary renal out-patient clinic over 5 years. We examined the effect of drugs which are known to alter potassium distribution and excretion, whilst accounting for co-morbidities and age.

Results: The mean age was 57.9 years, eGFR 32.4mL/min/1.73m2, 63% were male, 37% diabetic. 10.5% of serum potassium results were >5.5mmol/L, 5.0% were ≥6.0mmol/L and 1.1% were <3.5mmol/L. ACE inhibitors, angiotensin II receptor blockers and beta-blockers were associated with hyperkalemia, but digoxin and spironolactone were not. This latter effect may be because 92% of spironolactone users (45 of 49) were also on a loop or thiazide diuretic. These two diuretics were associated with a lower mean serum potassium but prednisolone, nebulised β2 agonists and insulin were not. Multivariate logistic regression showed that only ACE inhibitors (odds ratio 2.1), eGFR (k+ ≥6.0 vs. k+ <6.0 = 22.3 vs. 32.9 mL/min/1.73m2), and male gender (OR 1.8) were independent predictors of a serum potassium ≥6.0mmol/L. Only thiazide use was an independent predictor of potassium <3.5mmol/L (OR 5.7). Of the 60 episodes of k+ ≥6.0mmol/L, 10 blood samples were repeated within 12 hours. In 4 serum potassium remained elevated. These were all CKD stage 5, and only 1 was taking an ACE inhibitor. The mean eGFR of those with a repeat potassium <6.0mmol/L was 23.6mL/min/1.73m2.

Conclusions: Beta-blockers should not be ignored as a potential cause of hyperkalemia. However, ACE inhibitors were the only drug predictive of potassium ≥6.0mmol/L. The effect was less significant than that of eGFR, and unrelated to episodes of persistent hyperkalemia. Hypokalaemia was almost exclusively an association of thiazide diuretics.

SA-PO2446

Endogenous Testosterone as a Determinant of Muscle Mass and Strength in Nondialyzed Men with Chronic Kidney Disease Secundino Cigarran,[1] Guillermina Barril,[2] Francisco Coronel,[3] Juan J. Carrero.[4] *[1]Nephrology, Hospital Da Costa, Burela, Lugo, Spain; [2]Nephrology, Hospital Universitario de la Princesa, Madrid, Spain; [3]Nephrology, Hospital Clinico Universitario San Carlos, Madrid, Spain; [4]Division of Renal Medicine, Karolinska Institutet, Stockholm, Stockholm, Sweden.*

Background: Testosterone deficiency is a common finding in men with chronic kidney disease (CKD). Testosterone also plays an important anabolic role in muscle synthesis. Muscle wasting is an important and deleterious feature of protein-energy wasting (PEW) in CKD. It is currently unknown if endogenous testosterone associates with features of muscle wasting in men with CKD.

Methods: We cross-sectionally studied 267 nondialyzed men (mean±SD age 67±13 years) with manifest CKD (stages 1-5, eGFR 42.9 [interquartile range 30.2-56.7] ml/min/1.73m²). Endogenous testosterone and markers of PEW such as albumin, prealbumin, CRP or nPNA were analyzed. Muscle mass was estimated by whole tetrapolar bioelectrical vectorial impedance (BIVA) and muscle strength by handgrip dynamometry.

Results: Across decreasing tertiles of testosterone distribution, patients were incrementally older and CRP levels rose significantly. Prealbumin, hemoglobin, nPNA, handgrip strength (both dominant and nondominant hands) and BIVA-estimated surrogates of muscle mass (lean body mass, body cell mass and phase angle) were progressively reduced (P<0.05 for all). In hypothesis-driven multivariate regression analyses, testosterone significantly and independently contributed to explain the variance of handgrip strength and lean body mass. Through stepwise forward exclusion, the variance of endogenous testosterone in this patient population was best explained by handgrip strength, lean body mass, hemoglobin, eGFR, CRP and cardiovascular comorbidity (P<0.05 for all).

Conclusions: Endogenous testosterone is an independent and important determinant of both muscle mass and strength in nondialyzed men with CKD. Because preceding evidence indicates that these relationships are likely causal, we speculate that by targeting changes in circulating testosterone we may improve muscle mass and function in these patients.

SA-PO2447

Impact of Subclinical Bacterial Infection on Epigenetic DNA Methylation in Japanese CKD Stage 5 Patients Sawako Kato,[1] Yoshinari Yasuda,[1] Bengt Lindholm,[2] Peter Stenvinkel,[2] Karin Luttropp,[5] Tomas J. Ekström,[6] Yukio Yuzawa,[3] Yoshinari Tsuruta,[4] Shoichi Maruyama,[1] Seiichi Matsuo.[1] *[1]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan; [2]Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden; [3]Fujita Health University school of Medicine, Aichi, Japan; [4]Meiyo Clinic, Aichi, Japan; [5]Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden; [6]Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden.*

Background: Inflammation is mortality risk factor in chronic kidney disease (CKD) stage 5 pts. Although a report from 2007 showed that inflamed uremic pts had signs of global DNA hyper-methylation, the impact of subclinical bacterial infections on systemic inflammation and on DNA methylation status is not known.

Methods: In 44 consecutive incident dialysis patients (27 males, mean age 59±12 years) without clinical signs of infections, global DNA methylation in peripheral blood DNA was evaluated using HpaII/MspI ratio by the luminometric methylation assay method. Lower ratio of HpaII/MspI indicates global DNA hypermethylation. Procalcitonin (PCT), a marker of inflammation and bacterial infections, was measured using immuno-chromatography assay.

Results: HpaII/MspI ratio was 0.31 (0.26-0.61) and sPCT was 0.08 (0-0.87) ng/mL. The pts were divided into hyper- and lower-methylation groups by the median value. The pts in hyper-methylation group had higher ferritin levels (201.6(15.0-879.0) vs. 92.9(20.0-346.0) ng/mL; p=0.047), but there was no significant difference in age, gender, prevalence of diabetes, smoking habit, anemia or serum albumin levels between the two groups. However, HpaII/MspI ratio showed significant negative correlations to PCT (ρ=-0.32 P=0.035), and ferritin (ρ=-0.33 P=0.027), and CRP correlated to ferritin (ρ=0.37 P=0.014). In a multiple linear regression analysis, PCT and ferritin, but not CRP, were associated with lower HpaII/MspI ratio (R2=0.24, p=0.0131).

Conclusions: Global DNA hyper-methylation was associated with elevated PCT and ferritin, which could suggest that subclinical bacterial infection leads to DNA hyper-methylation.

SA-PO2448

Gender Differences in Body Composition in Chronic Kidney Disease Patients at the Different Functional Stages Carlo Donadio. *Internal Medicine, Nephrology, University of Pisa, Italy.*

Background: Malnutrition is frequent in end-stage renal disease patients treated by dialysis. Few data are available on the evaluation of nutritional status in chronic kidney disease (CKD) patients at different renal functional stage. The measurement of body electrical impedance (BIA) is a simple, inexpensive, and validated method to analyze body composition and measure body fluids in CKD patients.

The aim of this study was to evaluate the effect of the decreased renal function on body composition of CKD patients.

Methods: One thousand two hundred and eighty-nine and sixteen adult patients (617 f, 672 m), aged 15-85 years, mean 51.3; body weight 36.6-160.0 kg, mean 72.4; BMI 15.8-67.5 kg/m2, mean 26.4, affected by different kidney disease with different degree of functional impairment (serum creatinine 0.4-14.4, mean 1.77) participated in this study.

Glomerular filtration rate (GFR) was measured as the renal clearance of 99mTc-DTPA. Body composition was evaluated by means of single-frequency bioimpedance analysis. Values of fat mass (FM), fat-free mass (FFM), body cell mass (BCM) and extra-cellular water (ECW) were indexed to squared height of patients, similarly to BMI.

Results: BMI e FMI significantly increased with the reduction of GFR in females, while were unchanged in males. FFMI was unmodified independently from the gender. BCMI significantly decreased only in males, while was unmodified in females. Finally, ECWI significantly increased in all patients. These results indicate significant differences between male and female CKD patients, and in particular a different effect of decreased GFR on body mass and body composition in male and female patients.

Conclusions: Traits of malnutrition are present in chronic kidney disease patients, before starting renal replacement therapy. Significant differences in body composition have been found according to gender. In particular, the decrease in GFR was accompanied by the reduction in body cell mass only in male CKD patients. It is possible that the higher fat mass plays a protective role in females.

Plasma Adiponectin Concentration and Estimated Glomerular Filtration Rate (eGFR) in the Elderly. Polish Population Study "PolSenior" Marcin Adamczak, Magdalena Szotowska, Jerzy Chudek, Andrzej Wiecek. *Department of Nephrology, Endocrinology and Metabolic Diseases, Medical University of Silesia, Katowice, Poland.*

Background: The consequence of impairment kidney function and aging on the endocrine function of adipose tissue is not fully elucidated. Adiponectin is an adipokine with antiatherosclerotic, cardioprotective and antidiabetic properties. The aim of present study was to estimate plasma adiponectin concentration and their relationship with estimated glomerular filtration rate (eGFR) in representative samples of the elderly population in Poland.

Methods: The study was carried out as a part of the nationwide PolSenior project in the population of randomly selected 4979 (2412 females and 2567 males) aged 65-101 years. In 3692 subjects (1762 females and 1930 males) plasma adiponectin concentration was assessed by an ELISA method and eGFR was estimated using the CKD-EPI formula.

Results: If compared with males, females aged 65-90 years were characterized by significantly higher plasma adiponectin concentration (11.0±5.9 vs 13.3±6.8; p<0.001). Analysis of variance, between groups stratified according to eGFR with respect of plasma adiponectin concentration showed significant (p<0.001) differences with increase with the degree of the impairment kidney function [in subject with eGFR 90-120 ml/min (n=304) – 11.2±6.3; eGFR 60-90 ml/min (n=2273) – 11.9±6.3; eGFR 45-60 ml/min (n=723) – 12.4±6.6; eGFR < 45 ml/min (n=392) – 13.1±6.6 μg/ml]. A significant negative correlations were found between plasma adiponectin concentration and eGFR (r=-0.082, p<0.001). Multiple regression analysis with gender, age and eGFR as independent factors showed that only age has significant influence on plasma adiponectin concentration in the elderly Polish population (β=-0.08; p=0.035).

Conclusions: 1/ Among the subjects older than 65 years, plasma adiponectin concentration was increased with the degree of the kidney function impairment. 2/ Such an increase of plasma adiponectin concentrations may be secondary to the age-related decline of the kidney function.

SA-PO2450

Insulin Resistance in Children with Primary Nephrotic Syndrome and Normal Renal Function Aihua Zhang, Songming Huang, Guixia Ding, Yanggang Yuan, Chunhua Zhu. *Nephrology, Nanjing Children's Hospital, Nanjing Medical University, Nanjing, China.*

Background: Clinical research has demonstrated that children with ESRD on hemodialysis have IR and hyperinsulinism. The present study was to investigate whether the children with **early stage primary nephritic syndrome (PNS)** have IR, and IR in this group is associated with renal pathology, therapeutic response to glucocorticoids, and clinical outcome.

Methods: One-hundred and nineteen PNS patients with normal renal function and 125 normal controls were studied. Fasting blood glucose (FBG), fasting serum insulin (FISN) and fasting serum C-peptide (FCP) were measured. The Homa index of insulin resistance (HOMA-IR), islet B cell function (HOMA-islet) and insulin sensitive index (ISI) were calculated. The correlations were assessed between HOMA-IR, FCP, blood pressure (BP), blood lipids, renal function, blood coagulation, clinical disease type, pathology, and the early therapeutic effectiveness of high-dose glucocorticoid.

Results: There was no evidence of IR in the early stage of PNS. Although levels of FBG, FISN and FCP were all within the normal range, FCP was significantly higher than in the control group. Spearman's correlation analysis revealed a significant correlation between FCP and age, BP, SCr, TG and FISN. FCP was positively correlated with BMI and negatively with GFR. Pearson's correlation analysis showed that $\log_{10}$ (FCP) positively correlated with age, SCr, TG, FBG and FISN. There was a positive correlation between $\log_{10}$ (FCP) and BMI and a negative correlation with GFR and FBG. Furthermore, multivariate stepwise regression analysis revealed TG as an independent risk factor for $\log_{10}$ (FCP).

Conclusions: Although IR was not detected, a significant increase in BP, uric acid (UA), blood lipids and blood coagulability was observed in the PNS group. A correlation observed between HOMA-IR, age, BP, serum creatinine (SCr) and TG may suggest that insulin sensitivity will emerge as renal disease progresses. FCP levels were increased in the PNS group, suggesting that FCP may be a protective factor.

Validation of Predictive Equations for Resting Energy Expenditure in Chronic Kidney Disease Enric Vilar,[1,2] Ashwini Machado,[1] Andrew Garrett,[2] David Wellsted,[2] Ken Farrington.[1,2] *[1]Lister Renal Unit, Stevenage, United Kingdom; [2]University of Hertfordshire, Hatfield, United Kingdom.*

Background: The effect of the uremia on metabolic rate is poorly understood and knowledge of metabolic rate in CKD is important for provision of accurate dietary advice. Validated predictive equations for energy expenditure are needed in CKD.We studied the effect of physical activity and GFR on resting energy expenditure(REE) in CKD. We evaluated algorithms for REE, including one recently developed at our unit.

Methods: We performed a metabolic analysis of subjects on dialysis and with CKD. All subjects had a metabolic analysis including measurement of body size parameters and REE by indirect calorimetry. Physical activity was measured with Metabolic Equivalent of Task (MET) using the Stanford 7 day recall questionnaire. Physical activity and REE were compared between the dialysis and CKD groups. Predictive equations for REE were evaluated using the Bland-Altman method.

Results: 400 subjects were recruited, 200 on dialysis and 200 with CKD. Weight, serum albumin and body mass index was lower in patients on HD ($p<0.001$ for each). Physical activity was lower in patients on dialysis compared to those with CKD (mean MET 1.44 v 1.50 for males, 1.42 v 1.56 for females, overall $p<0.001$).There was no significant difference in REE between subjects with CKD and those on dialysis ($p=0.14$ for females, $p=0.26$ for males). In a regression model, eGFR did not predict REE after correcting confounding variables. In a separate model, eGFR significantly predicted estimated Total Energy Expenditure (REE*Mean MET). Equations for REE (Schofield, Mifflin-St Jeor and Harris-Benedict) underestimated REE in the CKD group (bias +138 to +193kCal/day). A novel equation developed at our unit had lower bias (-36kCal/day). All equations had similar limits of agreement(424-484kCal/day).

Conclusions: Patients on dialysis are less active than those with CKD, but REE does not differ. Equations for REE derived in normal individuals tend to underestimate in CKD. A recently described equation improves bias with similar level of agreement. Considerable variance in REE is unexplained by such equations and results should be interpreted with caution.

Metabolomic Profiling of Uremic Solutes in CKD Patients Takehiro Suzuki,[1] Yasutoshi Akiyama,[1] Takafumi Toyohara,[1] Hiroshi Sato,[2] Yoichi Takeuchi,[1] Sadayoshi Ito,[1] Tomoyoshi Soga,[3] Takaaki Abe.[1] *[1]Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Graduate School of pharmaceutical Sciences, Tohoku University, Sendai, Japan; [3]Institute for Advanced Biosciences, Keio University, Tsuruoka, Japan.*

Background: Chronic kidney disease (CKD) is strongly associated with cardiovascular events and prognosis. Early detection and accurate monitoring of patients with CKD is likely to improve care and decrease the risk of cardiovascular and cerebrovascular disease. As a new diagnostic tool, we examined the retention of uremic solutes as a simpler, more accurate method to assess renal function.

Methods: Comprehensive metabolome analysis of 41 CKD patients by capillary electrophoresis mass spectrometry (CE-MS) of blood samples were performed (Toyohara T. JASN 2009).

Results: By CE-MS, we found 22 cations and 30 anions that accumulated significantly as the estimated GFR decreased. These compounds included 9 cations and 27 anions that were newly identified in our study. In contrast, we also found 7 cations (2 new) and 5 anions (all new),that decrease significantly as eGFR declines. We next evaluated each substance for its suitability to detect early CKD stage. Compounds highly correlated with eGFR and whose plasma concentration changed in a manner approximated by the first-degree equation are excellent candidates for detecting CKD and identifying uremic toxins that might aggravate kidney function in the early stage of CKD compared with 2nd -degree model such as creatinine (1-methyladenosine rs= -0.772, N-acetylglucosamine rs= -0.751, γ-butyrobetaine rs= -0.734, sebacate rs= -0.751, cis-aconitate rs= -0.719, and homovanillate rs= -0.711).

Conclusions: These results identify a number of uremic compounds. Many of them are novel, and increase in a manner approximated by the first-degree equation, that predict worsening renal function in early stage of CKD. Thus these compounds provide early diagnostic information. In addition CE-MS should be useful tools for exploring the uremic toxins (Toyohara T. Hypertens Res 2010).

SA-PO2453

Analysis of Urinary Proteomic Profiles between Progressive and Non-Progressive IgA Nephropathy by 2D-DIGE and MALDI -TOF-MS Ling Wang,[1] Zhaohui Ni,[1] Liou Cao,[1] Fuquan Yang,[2] Qin Wang,[1] Shan Mou,[1] Minfang Zhang.[1] *[1]Renal Division, Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China; [2]Institute of Biophysics, China Academy of Science, Beijing, China.*

Background: IgA nephropathy (IgAN) is the most common glomerular disease in adults. Searching for prognostic markers which could identify those who will progress to renal failure is highly necessary.

Methods: Urine samples were obtained from non-progressive and progressive IgAN patients.2D-DIGE and MALDI/TOF/MS was used. Biological variations of the protein expression level among gels were analyzed with DeCyder software and evaluated for statistical significance. The deferentially regulated spots were picked out and were identified by MALDI/TOF MS or LC MS.

Results: 36 spots were significantly differentially expressed. We had identified 23 proteins significantly expressed with 19 up-regulated and 4 down-regulated.

No	Protein	Up or Down
1	zinc-alpha-2-glycoprotein, chain B	down
2	plasma retinol-biding protein; RBP precursor	down
3	histone H2B	down
4	carbamoyl-phosphate synthetase 1, mitochondrial	down
5	zinc-alpha-2-glycoprotein chain A	up
6	alpha-1-microglobulin/bikunin precursor	up
7	Transthyretin Chain A	up
8	ATP synthase, H+ transporting, mitochondrial F1 complex, beta subunit	up
9	T-cell antigen receptor VJ junction beta chain	up
10	immunoglobulin heavy chain	up
11	lectin, galactoside-binding, soluble, 2	up
12	Interferon-induced protein with tetratricopeptide repeats 2	up
13	T-cell receptor beta chain	up
14	serum transferin n-terminal lobe,chain A	up
15	Chain A, Solution Structure Of Domain 3 From Human Serum Albumin Complexed To An Anti-Apoptotic Ligand Directed Against Bcl- Xl And Bcl-2	up
16	transferrin	up
17	RNA polymerase II subunit	up
18	ubiquitin-conjugating enzyme E2 variant 1	up
19	suppression of tumorigenicity 7	up
20	MAP3K12 binding inhibitory protein 1,	up
21	transcription factor HFK3	up
22	T cell receptor beta chain	up
23	hypothetical protein	up

Conclusions: We have established a proteomic method to discover urinary biomarkers of IgAN and identified several urinary proteins or peptide which could be further studied. These findings could be helpful in early diagnosis of the progressive IgAN.

SA-PO2454

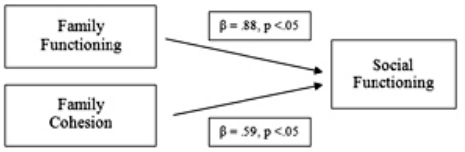
The Disability-Distress-Coping Mode – One Way To Conceptualize Adjustment in Adolescents with Chronic Kidney Disease Nicole M. Fenton,[1] Kristi Bickford,[2] Maria E. Ferris.[2] *[1]Psychology, University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Kidney Center, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Studies suggest that among individuals with CKD, illness severity may not adequately predict an adolescent's adjustment. Rather, psychosocial factors may be one key to understanding adjustment. The current study utilized the Disability-Distress-Coping Model. Our aims were to:Examine if 1) family functioning and 2) overall coping efficacy significantly influences adjustment (social functioning, depressive symptoms, and ER visits).

Methods: Participants were recruited from the UNC Kidney Center's outpatient clinic and included 50 adolescents age 13-18 with a diagnosis of CKD stage ≥2. De-identified web-based measures were administered including: the FRI, KidCope, PedsQL, and the CDI.

Results: Data analysis consisted of a series of regressions where age and disease severity were controlled for. Results indicated that family functioning and family cohesion were significant positive predictors of the adolescent's social functioning.

Figure 1: Significant Findings - Aim 1:
Family functioning and family cohesion are both significant predictors of the adolescent's social functioning



Overall coping efficacy was not a significant predictor of the adolescent's social or psychosocial functioning, however; the efficacies of two specific coping strategies were: emotion regulation and seeking social support. Finally, neither family functioning nor coping efficacy were significant predictors of depressive symptoms or ER visits.

Conclusions: These findings suggest that adolescents with CKD are able to adjust well to having a chronic illness and that family functioning and the coping efficacy strategies of emotion regulation and seeking social support play an important role in facilitating this positive adjustment.

SA-PO2455

Clinical Presentation of Sleep Apnea in Patients with Chronic Kidney Disease David Donald McTavish Nicholl, Sofia B. Ahmed, Andrea H. Loewen, Brenda Hemmelgarn, Darlene Y. Sola, Jamie M. Beecroft, Tanvir Chowdhury Turin, Patrick Hanly. *Medicine, University of Calgary, Calgary, AB, Canada.*

Background: Sleep apnea is an important and common co-morbidity in patients with chronic kidney disease (CKD). However, few studies have addressed how sleep apnea presents in this patient population and whether it is clinically apparent. The objective of this study was to compare the prevalence and severity of sleep-related symptoms in CKD patients with and without sleep apnea.

Methods: One hundred twenty-four patients were recruited from out-patient nephrology clinics. All patients completed a questionnaire examining symptoms of sleep apnea (snoring, witnessed apneas, nocturnal choking), the Epworth Sleepiness Scale (ESS>10=daytime sleepiness), Pittsburgh Sleep Quality Index (PSQI>5=poor sleep quality), and overnight cardio-pulmonary monitoring for determination of sleep apnea (respiratory disturbance index >15). Patients with sleep apnea (n=51) were compared to patients without apnea (n=73).

Results: CKD patients with sleep apnea did not differ from those without sleep apnea in the prevalence of snoring (76% vs. 74%, p=0.8), witnessed apneas (35% vs. 19%, p=0.060), and nocturnal choking (33% vs. 23%, p=0.2). There was a higher prevalence of daytime sleepiness in CKD patients with sleep apnea compared to non-apneic patients (39% vs. 20%, p=0.024) and there was a non-significant increase in ESS scores in CKD patients with apnea (median (range), 9 (2-24) vs. 6 (0-17), p=0.055). There were no differences in the prevalence of poor sleep quality between apneic and non-apneic patients (47% vs. 43%, p=0.7; median (range), 5 (0-15) vs. 5 (0-16), p=0.6).

Conclusions: Sleep apnea is highly prevalent in patients with CKD but is not clinically apparent. Consequently, objective cardio-pulmonary monitoring during sleep is required to reliably identify this co-morbidity.

SA-PO2456

Validity of the Berlin Questionnaire and Adjusted Neck Circumference in Identifying Sleep Apnea in Patients with Chronic Kidney Disease David Donald McTavish Nicholl, Sofia B. Ahmed, Andrea H. Loewen, Brenda Hemmelgarn, Darlene Y. Sola, Jamie M. Beecroft, Tanvir Chowdhury Turin, Patrick Hanly. *Medicine, University of Calgary, Calgary, AB, Canada.*

Background: Given the reported high prevalence of sleep apnea in patients with chronic kidney disease (CKD) and end-stage renal disease (ESRD), a clinical instrument to assess the prevalence of sleep apnea in these populations would be useful. The Berlin Questionnaire (BQ) and Adjusted Neck Circumference (ANC) are 2 such instruments that have been validated in patients with normal kidney function. The objective of this study was to determine the validity of the BQ and ANC in patients with CKD and ESRD, using overnight cardio-pulmonary monitoring to diagnose sleep apnea.

Methods: Two hundred fifty-four patients were recruited from nephrology clinics and hemodialysis units. All patients completed the BQ, ANC, and overnight cardio-pulmonary monitoring for diagnosis of sleep apnea (respiratory disturbance index (RDI)>15). Patients were stratified into 3 groups based on estimated glomerular filtration rate (eGFR): eGFR≥60 mL/min/1.73m^2 (n=55); CKD (eGFR<60 mL/min/1.73m^2, n=124); and ESRD (on hemodialysis, n=75). Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated for the BQ and the ANC (Table 1) and the association between the BQ and ANC and a diagnosis of sleep apnea (RDI>15) was determined using logistic regression (Table 2).

Results:

Table 1		eGFR>60	CKD	ESRD		
BQ	Sensitivity	86.7%	78.7%	60.5%		
	Specificity	60.0%	37.7%	43.8%		
	PPV	44.8%	46.3%	59.1%		
	NPV	92.3%	72.2%	45.2%		
ANC	Sensitivity	73.3%	69.4%	54.8%		
	Specificity	84.2%	67.1%	71.0%		
	PPV	64.7%	58.6%	71.9%		
	NPV	88.9%	76.6%	53.7%		
Table 2		Univariate			Multivariate	
eGFR>60	OR	95% CI	P-value	OR	95% CI	P-value
BQ	9.75	1.93-49.15	0.006	5.40	0.92-31.68	0.062
ANC	14.67	3.48-61.82	<0.001	9.46	2.08-43.04	0.004
CKD						
BQ	2.24	0.96-5.24	0.062	1.55	0.60-4.03	0.369
ANC	4.63	2.12-10.09	<0.001	3.89	1.68-8.99	0.001
ESRD						
BQ	1.19	0.47-3.01	0.714	0.87	0.32-2.35	0.784
ANC	2.96	1.11-7.93	0.031	3.04	1.11-8.28	0.030

Conclusions: The BQ and the ANC were less accurate in patients with CKD and ESRD than in patients with eGFR>60. However, the ANC was consistently better than the BQ.

SA-PO2457

Intestinal Microbial Flora Is Altered by Uremia Nosratola D. Vaziri,[1] Jakk Wong,[2] Madeleine V. Pahl,[1] Jun Yuan,[1] Todd Z. Desantis,[2] Yvette M. Piceno,[2] Gary L. Andersen.[2] *[1]Med/Neph, UC Irvine, Irvine, CA; [2]Molecular Microbial Ecology Group, LBNL, Berkeley, CA.*

Background: The community of microbes residing in the intestinal tract (microbiome) constitutes a symbiotic ecosystem which confers trophic and protective functions and contributes to micronutrient homeostasis. Alteration in microbiome contributes to diverse illnesses including inflammatory bowel disease, diabetes, cancer, cardiovascular disease, obesity, etc. Selection pressures on part of the host and microbes shape the structure-function of microbiome. We believe that influx of urea (and its hydrolysis to ammonia), urate and oxalate, dietary restrictions, phosphate binders and antibiotics change the milieu of intestine in ESRD. This can, in turn, alter the microbiome and cause production of toxic, pro-inflammatory and pro-oxidant metabolites. We tested the hypothesis that uremia may change the composition and function of microbiome.

Methods: Microbial DNA was isolated from the stools of 24 ESRD patients and 12 controls. A phylogenetic microarray was used for comprehensive identification of microbial populations.

Results: While large inter-individual variations were observed in the microbiome composition, significant differences were found in the abundance of 183 bacterial taxonomic units between the ESRD patients and the control groups. Microbial families showing the largest increase in ESRD patients were Brachybacterium, Catenibacterium, Enterobacteriaceae, Halomonadaceae, Micromonosporaceae, Moraxellaceae, Nesterenkonia, Polyangiaceae, Pseudomonadaecea, and Thiothrix including several families possessing *urease* and *uricase* genes (P<0.015). Overall, a number of species from Clostridia, Bacteroidetes, and Betaproteobacteria were less abundant while species from Actinobacteria and Gammaproteobacteria were most abundant in ESRD patients compared to controls.

Conclusions: ESRD significantly alters the abundance of several microbial families which appears to be in part driven by overabundance of urea and urate in the intestine. Studies are planned to focus on individual members of these families and their contribution to complications of ESRD.

SA-PO2458

Asymmetric Dimethylarginine, Oxidative Stress, and Tubular Dysfunction in Patients with Chronic Kidney Disease Stages 3 and 4 – A One Year Follow-Up Study Jaromir Eiselt,[1] Daniel Rajdl,[2] Kamila Rulcova,[1] Jan Wirth,[1] Jaroslav Racek.[2] *[1]Internal Dept. 1, Charles Univ., Plzen, Czech Republic; [2]Dept. of Biochemistry, Charles Univ., Plzen, Czech Republic.*

Background: Asymmetric dimethylarginine (ADMA) is a mediator of endothelial dysfunction and a prognostic factor in patients with chronic kidney disease (CKD). Production and eliminaton of ADMA may be affected by oxidative stress and metabolic function of the kidneys.

Results: In a one year follow-up study (examinations in months 0, 6 and 12) we measured plasma levels of ADMA, markers of oxidative stress (advanced oxidation protein products (AOPP), advanced glycation end-products (AGE)) and tubular dysfunction (the ratio of cystatin-C to creatinine in urine, U_CysC/Cr) in 95 patients with CKD stages 3 and 4. All of the patients measured parameters were compared with 41 healthy controls.

Methods: During the one year follow-up, we observed a gradual decrease of glomerular filtration rate (GFR) and an increase of AGE and AOPP. We did not document changes of ADMA and U_CysC/Cr. All tested markers were clearly elevated in CKD patients as compared to healthy controls. Results are summarized in the table.

	Controls (n=41)	Pts (n=95) Mo 0	Pts Mo 6	Pts Mo 12	ANOVA on Ranks
GFR (mL/min)	111.3 (90.7-130.5)[a]	26.7 (20.3-37.6)	25.3 (19-38.7)	21.1 (14.1-38)[b]	p=0.021
ADMA (µmol/L)	0.78 (0.68-0.86)[a]	0.86(0.76-0.93)	0.80(0.70-0.93)	0.87(0.73-1.01)	p=0.064
AOPP (µmol/L)	109 (101-121)[a]	142 (121-171)	137 (121-153)	146 (126-174) [c]	p=0.037
AGE (FU/g of protein)	1.39 (1.3-1,52)[a]	1.55 (1.38-1.84)	1.72 (1.52-2.2)	1.76 (1.52-2.18)[b]	p<0.001
U_CysC/Cr (µg/mmol)	9.7(8.2-16)[a]	21.7 (9-87.8)	20.3 (10-153)	13.0(5.8-93.4)	p=0.095

Data is median (interq. range); comparisons using Mann-Whitney test or Kruskal-Wallis ANOVA on Ranks followed by Tukey or Dunn's Method as appropriate; [a]p<0.01 vs. Mo 0, [b]p<0.01 vs. Mo 0, [c]p<0.05 vs. Mo 6

Conclusions: Despite a decline in GFR and increase of markers of oxidative stress, the levels of ADMA remained unchanged during the one year follow-up. Stable tubular function documented by U_CysC/Cr supports the hypothesis that metabolic function of the kidneys in CKD stages 3 or 4 can partially compensate the efect of oxidative stress and prevent the increase of ADMA.

Funding: Government Support - Non-U.S.

SA-PO2459

Treatment Needs of Patients with Chronic Kidney Disease Stage 3 in Primary Care Natasha J. McIntyre,[1] Richard J. Fluck,[1] Chris W. McIntyre,[1,2] Maarten W. Taal.[1] *[1]Department of Renal Medicine, Royal Derby Hospital, Derby, Derbyshire, United Kingdom; [2]Department of Vascular Medicine, University of Nottingham, United Kingdom.*

Background: Since 2006, English GP practices have been required to keep a register of patients with CKD stage 3-5. NICE guidelines recommend regular follow-up, but these patients are often perceived to be low risk, not requiring active management. We aimed to assess treatment needs of CKD stage 3 patients in primary care as well as their level of awareness of CKD.

Methods: We studied 1741 patients on GP registers with CKD stage 3. Each subject underwent clinical assessment as well as urine and blood tests. At screening, participants were asked if they had been aware of their CKD diagnosis. Results were reviewed by a Nephrologist and a letter recommending a treatment plan in accordance with NICE guidelines was sent to the GP.

Results: The mean age was 73±9yrs and 60% (n=1052) were female. Diabetes mellitus was present in 17%. 41% were unaware of their CKD diagnosis. Multivariable logistic regression analysis identified subjects with fewer educational qualifications, aged <75yrs, eGFR 30-44mL/min/1.73m^2 and significantly albuminuric as more likely to be aware of their diagnosis. Advice given are shown in the table.

Table 1. Advice given

	n	%
Continue routine follow up	576	33.1
Specific advice regarding BP control	576	33.1
Refer to Nephrology	103	5.9
Investigations for anaemia	142	8.2
Statin therapy for dyslipidaemia	69	4.0
Advice to stop potentially nephrotoxic drugs	120	7.5

Reasons for recommending nephrology referral include GFR decline>10mL/min/1.73m^2 over 5yrs (67%), GFR decline >5mL/min/1.73m^2 in 1yr (15%), proteinuria (13%), compications of CKD (1%), progression to CKD 4/5 (4%). Of subjects with a GFR decline of >10mL/min/1.73m^2 over 5yrs, 8% had significant proteinuria with 8% having progressed to stage 4.

Conclusions: A large proportion of patients were unaware of their CKD diagnosis. Our data indicate increasing engagement with patients to become active partners in their management will require improved communication targeted at specific groups. Our data support the use of primary care CKD registers to identify patients with CKD stage 3 to facilitate evaluation and follow up.

SA-PO2460

Current Practice in Diagnosis and Treatment of Anemia in Stage 3 or 4 Chronic Kidney Disease Francesco Locatelli,[1] Peter F. Barany,[2] Carlo A. Gaillard,[3] Walter Hoerl,[5] Daniell Mitchell,[4] Claudio Mori.[4] *[1]Ospedale A. Manzoni, Lecco, Italy; [2]Karolinska Institutet, Stockholm, Sweden; [3]VU University Medical Center, Amsterdam, Netherlands; [4]Vifor Pharma, Glattbrugg, Switzerland; [5]Medical University Vienna, Vienna, Austria.*

Background: In chronic kidney disease (CKD), anemia is often associated with iron deficiency (ID). Thus, repletion of iron stores is recommended before treatment with erythropoiesis-stimulating agents (ESAs). This study evaluated current practice in diagnosis and treatment of CKD-associated anemia and ID in non-dialysis (ND) patients.

Methods: From Aug-Nov 2010, randomly selected nephrologists in Austria, Italy, Netherlands and Sweden spending >50% of working time on patient-care and managing >10 CKD patients monthly were surveyed for patient demographics, tests for anemia and ID, and therapies of 5 CKD patients (stage 3-4) most recently treated for anemia within 6 months prior to the survey. Randomly selected questionnaires (10%) were returned to physicians for validation. Results are presented as median [range] amongst countries.

Results: 125 physicians (119 hospital-, 6 office based) reported 623 cases (57% [54-71] male; 40% [29-60] >70 years old). Tests performed by nephrologists to confirm anemia and ID were hemoglobin (Hb) in 85% [59-87] and/or hematocrit in 89% [83-94] of patients and ferritin (63% [52-69]) and/or transferrin saturation (TSAT, 28% [16-54]). Median Hb at diagnosis was 97g/L [96-102]; 54% [44-60] presented with Hb <100g/L and 3% [0-16] with Hb <80g/L. Median ferritin and TSAT at diagnosis were 91µg/L [40-121] and 20% [14-23]. Absolute ID (defined as ferritin <100µg/L) was found in 53% [34-67] and TSAT was <20% in 53% [13-58] of those tested. 54% [15-66] received ESA treatment combined with iron, 41% [24-54] ESA alone and 9% [5-31] iron alone. Except for Sweden (46%), only a small minority of iron-treated patients received intravenous (IV) iron (7-11%).

Conclusions: High rates of severe anemia and ID indicate suboptimal monitoring and treatment of anemia in ND-CKD patients. Awareness of the prevalence of ID in ND-CKD patients and the importance of an integrated (iron in combination with ESA) treatment approach, needs to be increased.

SA-PO2461

Relationship between Kidney Damage and Mortality among a Community-Based Chinese Population Fukun Niu,[1,2] Luxia Zhang,[1] Xingyu Wang,[3] Lisheng Liu,[3] Haiyan Wang.[1] *[1]Institute of Nephrology and Division of Nephrology, Peking University First Hospital, Beijing, China; [2]Nephrology and Rheumatology, First Affiliated Hospital of Zhengzhou University, Zheng Zhou, Henan, China; [3]Beijing Hypertension League, Beijing, China.*

Background: Previous studies indicate that indicators of kidney damage are associated with adverse outcome, while studies among community-based population are limited, especially among developing countries.

Methods: This prospective cohort study included 1189 community-based participants in Beijing, China. Estimated glomerular filtration rate (eGFR) and urinary albumin-to-creatinine ratio (ACR) were assessed at baseline, and all participants had eGFR above 30mL/min/1.73m2. All deaths were confirmed by medical record review. Multivariable Logistic regression models were used to explore the association between kidney damage and mortality.

Results: The average age was 60.1±9.4 years; and male accounted for 49.5%. During a median of 6 year's follow-up, 87 participants(7.3%) died, among whom 38 died of cardiovascular disease (3.2%) and 29 died of cancer (2.4%). After adjusting for potential confounders including eGFR, albuminuria was independently associated with increased risk of cardiovascular mortality and all-cause mortality. For every 10 mg/g increase of ACR, the odds ratio(OR) of cardiovascular mortality and all-cause mortality was 1.05 [95%CI, 1.01–1.10]and 1.06[95%CI,1.02-1.10]. eGFR were not independently associated with mortality, and both baseline albuminuria and eGFR were not significantly associated with cancer mortality . Receiver operating characteristic (ROC) curve showed the cut-off values with both maximal sensitivity and specificity of ACR for the prediction of cardiovascular and all-cause mortality was 3.89 mg/g creatinine and 3.76mg/g creatinine.

Conclusions: Increased urinary ACR is independently associated with increased risk of both cardiovascular mortality and all-cause mortality, even at levels markedly lower than the current definition of "albuminuria".

SA-PO2462

Safety, Immunogenicity, and Efficacy of Subcutaneous Biosimilar Epoetin Alfa (HX575) in Non-Dialysis Patients with Renal Anemia: A Multi-Center, Randomized, Double-Blind Study Karsten Roth,[1] Kai-Uwe Eckardt,[2] Simon D. Roger.[3] *[1]Sandoz Biopharmaceuticals, Holzkirchen, Germany; [2]Universitätsklinikum Erlangen, Erlangen, Germany; [3]Renal Research, Gosford Hospital, Gosford, New South Wales, Australia.*

Background: HX575 is a biosimilar version of epoetin alfa that is approved in Europe and Australia for the treatment of anemia associated with chronic kidney disease (CKD) using the intravenous route of administration. HX575 is not authorized for use in the USA. Here we report data from a study of anemic pre-dialysis patients to assess the safety, immunogenicity and efficacy of subcutaneous (SC) administration of HX575 versus Erypo®/Eprex®.

Methods: This was a randomized, double-blind study in adult patients (n=337) with stage III–V CKD and a hemoglobin (Hb) level of 7.5–11.0 g/dL. Eligible patients were randomized to 52 weeks of treatment with HX575 or Erypo®/Eprex® at a starting dose of 25 IU/kg body weight three times weekly or 75 IU/kg body weight once weekly during weeks 1 to 5. This could be adjusted after 5 weeks to maintain Hb levels between 10 and 12 g/dL. The primary objective was to assess the safety and immunogenicity of HX575 compared with Erypo®/Eprex®. Efficacy endpoints were mean absolute change in Hb from baseline to end of week 13 and mean weekly epoetin dosage in weeks 11–13.

Results: SC HX575 was comparable to Erypo®/Eprex® in terms of maintaining Hb levels and epoetin dose requirements. Two patients in the HX575 group developed neutralizing antibodies (NAbs) to erythropoietin, which resulted in the study being terminated prematurely. Aside from these two events, reported adverse events were as expected for patients with stage III–V CKD and similar in both treatment groups.

Conclusions: In this study, SC HX575 demonstrated efficacy and comparability with the reference epoetin alfa, but two patients developed NAbs during treatment with SC HX575 in this study. Results of a thorough root-cause analysis reported elsewhere indicate that increased tungsten exposure in pre-filled syringes precipitated immunogenic reactions.

SA-PO2463

Chronic Kidney Disease Prevention and Management in Community Health Centers Cynthia R. Christiano, Paul Bolin, Melanie I. Hames, Karen R. Parker, Rachel Ward, Courtland Winborne, Lacy Dean. *East Carolina University, Greenville, NC.*

Background: Chronic Kidney Disease (CKD) leads to high rates of morbidity and mortality. Early detection and management may prevent progression to kidney failure. Primary care providers (PCPs) in Community Health Centers (CHCs) are strategic agents for detection of early CKD.CHCs primarily serve low-income and AA patients who are at high risk for CKD. However, PCP management of CKD is sub-optimal. We aimed to improve CKD detection, prevention and management among PCPs in CHCs. We anticipate that an educational collaboration with nephrologists and PCPs working in a CHC will result in improved clinical practices related to CKD care. We hypothesized that decreases in BP and improved anti-hypertensive filling practices would result from the intervention.

Methods: Nephrologists conducted lectures based on KDOQI and JNC-7 guidelines with the CHCs' providers. Site visits occurred weekly for 6 months (intervention) then gradually decreased. Electronic pharmacy records were queried for data on antihypertensive prescriptions pre-and post-intervention in the initial clinic. A random sample of hypertensive, adult patients were stratified by their respective PCPs. Provider management of BP was evaluated by comparing multiple BP data points from the patient sample pre-and post-intervention. Changes were assessed using paired sample t-tests. This program was repeated in an additional CHC where BPs were analyzed.

Results: The initial clinic demonstrated a statistically significant increase (27%) in prescriptions for antihypertensives pre-and post-intervention. When comparing individual provider management pre-and post- intervention, significant decreases in SBP were observed for all three providers ($p<.05$). Decreases in DBP were significant for two providers ($p<.05$). Interim data from an additional CHC is currently insignificant.

Conclusions: Intervention in the initial CHC demonstrated improved provider practices and patient outcomes. Although when repeated, in a different CHC, similar success was not achieved. The recent growth of and unique challenges in CHCs may require flexible interventions to be effective.

Imbalance of Growth Factors Favouring Anti-Angiogenesis in Children with Chronic Kidney Disease David A. Long,[1] Karen Price,[1] Maria Kolatsi-Joannou,[1] Richard J. Johnson,[2] Adrian S. Woolf,[3] Lesley Rees,[1] Rukshana C. Shroff.[1] *[1]UCL Institute of Child Health, United Kingdom; [2]University of Colorado; [3]University of Manchester, United Kingdom.*

Background: Cardiovascular disease (CVD) is a cause of morbidity and mortality in childhood chronic kidney disease (CKD). Endothelial damage and dysfunction is one of the earliest events in CVD development and may result from disturbances in vascular growth factors. Angiopoietin (Ang)-1 promotes endothelial survival and stabilisation, whereas Ang-2 is an endogenous Ang-1 antagonist causing endothelial death and vessel regression when ambient VEGF-A is low, pro-inflammatory responses and is induced by acute stimulation with uric acid.

Methods: We measured circulating Ang levels in pre-dialysis CKD 4-5 and dialysis children and correlated these with clinical, biochemical and vascular measures. We also examined local Ang and VEGF expression in arterial biopsy samples.

Results: Ang-2 levels were markedly elevated in dialysis compared to pre-dialysis CKD4-5 patients (10.5±1.3 vs 2.6±0.2 ng/ml, $p<0.001$). Using paired samples Ang-2 was not cleared by haemodialysis itself. There was no correlation between time in pre-dialysis CKD 4-5 and Ang-2, but time on dialysis showed a significant positive correlation ($p=0.0023$, $r=0.54$). Amongst dialysis patients Ang-2 positvely correlated with mean time-averaged systolic blood pressure ($p=0.0003$, $r=0.64$), serum urate levels ($p=0.0038$, $r=0.52$), carotid intima media thickness ($p= 0.0053$, $r=0.58$) and aortic augmentation index ($p=0.04$, $r=0.47$). On multiple regression analysis, strongest relationships were found between Ang-2 and systolic blood pressure ($\beta=2.73$, $p<0.001$) and serum urate ($\beta=0.12$, $p=0.03$). Ang-1 and VEGF-A were downregulated in patients' peripheral arterial smooth muscle, whereas Ang-2 was unchanged.

Conclusions: Children on dialysis have an anti-angiogenic and inflammatory milieu evidenced by depletion of Ang-1 and VEGF-A in their vessels and increased circulating Ang-2 which may lead to elevated blood pressure through changes in serum urate. Vascular growth factors could constitute important biomarkers and possible future therapeutic targets in children with CKD.

SA-PO2465

Effectiveness and Safety of MIRCERA® for Anemia Treatment in Chronic Kidney Disease (3-5) Patients on Hemodialysis or Not on Dialysis, in Routine Clinical Practice – The Atenea Study J.M. Portolés,[1] N.J. Vega,[2] G. Fernández-Fresnedo,[3] Alejandro Pérez,[4] S. Bea,[5] M.J. Camba.[6] *[1]Hospital Puerta de Hierro, Spain; [2]Hospital Doctor Negrin, Spain; [3]Hospital Marqués de Valdecilla, Spain; [4]Clinica Souto Boo, Spain; [5]Centro de Diálisis Gamapal, Spain; [6]Complejo Hospitalario de Ourense, Spain.*

Background: MIRCERA® has strongly demonstrated its efficacy and safety in anemia control of adult CKD patients, in clinical trials.

Methods: This observational cross-sectional study involving 20 Spanish centers examined these benefits when administered up to 6 months for correction (naïve patients) or maintenance (converted patients) in CKD patients in Hemodialysis (HD) or not on dialysis (ND), in a real clinical setting. Final results are presented.

Results: Of the 201 patients evaluated, 6.5% were naïve-ND, 25.4% converted-ND and 68.2% converted-HD. Overall baseline data: Mean age: 66.9±14.3 years. Male: 66.2%. CKD 3/4/5: 8%/19.4%/72.6%. Predominant etiologies: 22% vascular and 21% diabetes. The most frequent previous ESAs were darbepoetin alfa in 51% of ND patients and epoetin beta in 58.4% of HD. Hb levels significantly increased from 10.2±0.7g/dL at the start of MIRCERA® to 11.6±1.3g/dL at month 6 ($p<0.005$) in naïve-ND patients. Those converted showed stable Hb values after 6 months of MIRCERA® in both ND (12.1±1.3 g/dL *vs* 12.3±1.2 g/dL) and HD group (11.6±1.3 g/dL *vs* 11.4±1.2 g/dL). Starting doses of MIRCERA® resulted lower than recommended on SPC: from darbepoetin alfa<40µg/w and epoetin<8,000IU/w to MIRCERA® 94.6±35.7µg/m (n=120); from darbepoetin alfa 40-80µg/w and epoetin 8,000-16,000IU/w to MIRCERA® 138.2±34µg/m (n=51); from darbepoetin alfa >80µg/w and epoetin>16,000IU/w to MIRCERA® 301.5±129.4µg/m (n=17). Throughout the study, mean MIRCERA® dose adjustments were 1.1±0.4 in naïve-ND, 1.5±0.7 in converted-ND and 1.7±0.9 in converted-HD, and no dose adjustment was required in 38.5%, 54.9% and 23.4%, respectively. No MIRCERA®-related AEs were reported.

Conclusions: MIRCERA® successfully provides anemia control with doses bellow to those described in the SPC and few dose adjustments. MIRCERA® is safe and simplifies anemia treatment in CKD in routine clinical practice.

SA-PO2466

Understanding Transition Readiness: How To Facilitate High Transition Readiness and What Are the Implications of Low Transition Readiness? Nicole M. Fenton,[2] Mary Hunter Benton,[1] Stephen R. Hooper,[2] Kristi Bickford,[1] William A. Primack,[1] Maria E. Ferris.[1] *[1]School of Medicine - Kidney Center, University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Psychology, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: The transition from pediatric to adult-focused health care is a critical time yet, little is known about how to facilitate transition readiness or the implications of low transition readiness. Utilizing the Disability-Distress-Coping Model we examined psychosocial function and transition readiness. Our aims were to:

1) Examine if psychosocial functioning (family functioning, coping efficacy, and quality of life) and disease characteristics (disease severity/burden and age at diagnosis) would predict transition readiness.

2) Determine if transition readiness would be a predictor of emergency room (ER) visits and non-adherence.

Methods: Thirty adolescents age 13-18 with a diagnosis of CKD stage ≥2 were included. De-identified web-based measures were administered including: the Family Relationship Index, KidCope, PedsQL, and the UNC TR$_x$ANSITION Scale. Adherence and ER visits were documented based on chart review and self-report.

Results: Hierarchical regressions were performed. Family cohesion was a significant positive predictor of both overall transition readiness and adherence ($p<.05$). However, none of the other variables (quality of life, coping efficacy, and disease characteristics) were significant predictors of transition readiness. Higher transition readiness was a significant predictor of higher medication adherence and fewer ER visits ($p<.05$).

Conclusions: In our cohort, family cohesion appears to facilitate transition readiness. Healthcare providers may want to encourage the family unit to provide support when adolescents are preparing for transition. Additionally, this study also suggests that low transition readiness may predict non-adherence to medications and ER utilization. This highlights the importance of preparing adolescents for the transition from pediatric to adult-focused health services and suggests a significant influence on low adherence on healthcare utilization.

SA-PO2467

Serum Vitamin B_{12} and Folic Acid Concentrations and Estimated Glomerular Filtration Rate (eGFR) in the Elderly. Preliminary Results of the Polish Population Study "PolSenior" Andrzej Wiecek, Magdalena Szotowska, Marcin Adamczak, Jerzy Chudek. *Department of Nephrology, Endocrinology and Metabolic Diseases, Medical University of Silesia, Katowice, Poland.*

Background: During the last years increasing prevalence of vitamin B_{12} and folic acid deficiency is observed in different groups of patients. Taking into consideration important role of vitamin B_{12} and folate in hematopoesis, skin and brain function, such deficiency seems to be one of the crucial issues of the public health. The aim of this study was to examine serum vitamin B_{12} and folic acid concentrations and their relationship with eGFR in representative samples of the elderly population in Poland.

Methods: In 1193 subjects (609 males; 584 females) aged over 65 years (mean age 79±9) from the "Polsenior" study the relationship between vitamin B_{12} or folate serum concentrations and eGFR was calculated. Serum vitamin B_{12} and folate concentration was measured by RIA method. eGFR was estimated using the CKD-EPI formula.

Results: Analysis of variance, between groups stratified according to eGFR with respect of both vitamin B_{12} and folic acid, have showed significant ($p<0.05$) differences [in subject with eGFR 90-120 ml/min (n=199) - 334±769 and 5.63±7.44; eGFR 60-90 ml/min (n=659) - 312±220 and 4.90±4.34; eGFR < 60 ml/min (n=278) - 285±142 pmol/l and 4.59±4.70 nmol/l, respectively]. However no significant correlation was found between age or eGFR and serum vitamin B_{12} or folate concentrations.

Conclusions: 1. Both vitamin B_{12} and folate concentrations decrease with worsening of kidney function in elderly patients. 2. These results suggest a particular need for increased vigilance for deficiency of vitamin B_{12} and folic acid in elderly patients with chronic kidney disease.

Clinical Characteristics of Chronic Kidney Disease Patients with Hyperkalemia Due to Angiotensin II Receptor Blocker

Hideki Fujii, Keiji Kono, Kentaro Nakai, Shunsuke Goto, Shinichi Nishi. *Division of Nephrology and Kidney Center, Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Angiotensin II receptor blocker (ARB) is often used in the clinical settings. Most patients with chronic kidney disease (CKD) take ARB for renal and cardiovascular protection. Though hyperkalemia is a life-threatening complication resulting from use of ARB especially in CKD patients, an available way of predicting hyperkalemia remains unknown.

The purpose of our study is to elucidate the characteristics of CKD patients with hyperkalemia due to ARB.

Methods: Twelve consecutive CKD patients with hyperkalemia (≥5.5mEq/l) due to ARB were included in this study. Patients with rennin angiotensin system inhibitor, loop diuretics, thiazide, spironolactone or eprelenone were excluded from the present study. Patients with rapidly progressive glomerulonephritis, acute kidney injury, congestive heart failure and acute coronary syndrome were also excluded. We measured serum potassium levels, serum creatinine levels, blood urea nitrate levels, urinary protein excretion, urinary β_2-microglobrin (U-β_2MG) levels, and urinary N-acetylglucosamine (U-NAG) levels before and after taking ARB. In addition, we calculated fractional excretion of potassium (FEK) and transtublar potassium gradient (TTKG) before taking ARB. In 3 of the 12 patients, we investigated the change of serum potassium levels, FEK and TTKG depending on the dose of ARB. Case-note review enabled us to assess other clinical characteristics of the study patients.

Results: Averaged serum creatinine levels were 2.59±1.37 mg/dl and averaged maximum serum potassium levels were 6.94±1.04 mEq/l. The presence of diabetes and hypertension was 33% and 100%, respectively. Regardless of renal function, U-β_2MG and U-NAG were high in most study patients. Furthermore, FEK and TTKG were relatively low in these patients. They were lowering with increasing the dose of ARB.

Conclusions: In CKD patients with hyperkalemia, TTKG and FEK were low and urinary tubular injury markers were elevated before taking ARB. It is suggested that TTKG and FEK are available as a predictive marker of hyperkalemia due to ARB in CKD patients.

SA-PO2469

Characteristics of Patients with CKD and Anemia Treated with Darbopoetin Who Failed To Maintain Hemoglobin Levels at 4-Week Dosing Intervals

Grace Snyder,[3] James F. Simon,[1] Jesse D. Schold,[1] Susana Arrigain,[2] Celeste Jindra,[1] Joseph Hrehov,[1] Anil K. Jain,[3] Stacey Jolly,[3] Martin J. Schreiber,[1] Joseph V. Nally.[1] *[1]Nephrology and Hypertension, Cleveland Clinic; [2]Quantitative Health Science, Cleveland Clinic; [3]Internal Medicine, Cleveland Clinic.*

Background: Resistance to erythropoietin-stimulating agents (ESA) is associated with increased CV risk in renal anemia patients. Darbopoetin alpha therapy may be dosed at 2- or 4-week (wk) intervals based on convenience and other factors. Some patients require a higher monthly dose at 4-wk intervals. We investigated whether characteristics differ between anemic CKD patients requiring ESA dosing at 2- vs. 4-wk intervals.

Methods: Patients who initiated darbopoetin therapy in our renal anemia clinic at 2-wk intervals then switched to 4-wk intervals after Hb stabilized in target range between Sep 2007 and Nov 2009 were included. Patients were considered a failure of 4-wk therapy if their Hb dropped or monthly ESA requirement increased after the switch and were returned to 2-wk dosing. Patients who failed 4-wk dosing were compared to those who did not. We evaluated factors associated with time to failure of 4-wk dosing using Kaplan-Meier survival estimates and Log-rank tests for categorical variables and Cox proportional hazards model for continuous variables.

Results: 186 patients started ESA therapy at 2-wk intervals during the study period. 81 (44%) switched to a 4-wk interval and had continued follow-up (median 5 months). 28 (35%) switched back to 2-wk intervals because of failure to maintain their Hb. At 6 months, fewer kidney transplant patients (25% vs. 76%, p=0.03) and patients on corticosteroids (36% vs. 77%, p=0.01) were at 4-wk intervals. Higher Hb (p=0.003) and eGFR (p=0.003) at switch to 4-wk intervals were associated with lower risk of failing 4-wk interval therapy.

Conclusions: Lower Hb level and eGFR at the time of switch to 4-wk intervals, kidney transplant status and corticosteroid use were significantly associated with failing 4-wk interval ESA therapy. Patients at risk for failure on 4-wk interval therapy should be monitored and considered for dosing interval change if failure occurs.

Iron Replacement Therapy for CKD Patients Not on Dialysis

Peter Juergensen,[1] Fredric O. Finkelstein.[2] *[1]Medicine, Hospital of St. Raphael, New Haven, CT; [2]Medicine, Yale University School of Medicine, New Haven, CT.*

Background: Standardized protocols have been developed for iron replacement therapy for patients with chronic kidney disease patients (CKDP) maintained on dialysis; the vast majority of hemodialysis patients (pts) receive intravenous (IV) iron. The iron utilization requirements for CKDP-not on dialysis (NOD) have not been well defined. The present study was designed to examine the percent of CKDP-NOD who require iron replacement to maintain their ferritin levels > 100 ng/ml and TSat > 20%.

Methods: 1065 CKDP-NOD who were followed in our clinic for 12 months between 1/08 and 5/11 and had hemoglobin levels and iron studies checked were included. The 12 month follow-up included the first 12 months after 1/08 or the initial 12 mths after initiation of ESA therapy or referral to the CKD clinic. 567 of these pts received ESAs; these pts had Hgb levels checked monthly and iron studies checked every 3 months; iron was prescribed if TSats were below 20% and/or ferritin levels were below 100 ng/ml at any time during the study period. The decision to give IV or po iron was left up to the discretion of the nephrologist but IV iron was prescribed if pts could not tolerate po iron or if the degree of iron deficiency was felt to be severe (TSat < 15% and/or ferritin <70 ng/ml). The 498 pts not receiving ESAs had iron studies checked if Hgb levels fell below 10 gm%

Results: 14.3% of pts who were receiving ESAs were prescribed IV iron. 63% of pts were prescribed oral iron. Of pts not receiving ESAs, 9.1% received IV iron and 22.2% were prescribed oral iron.

Conclusions: In conclusion, iron supplementation is frequently needed in CKDP-NOD receiving ESAs to maintain adequate iron stores. Those pts not receiving ESAs require iron supplementation less often to maintain iron stores and Hgb levels > 10 gm%.

SA-PO2471

Functional Health Literacy in the Chronic Renal Insufficiency Cohort Study

Ana C. Ricardo,[1,2] Wei Yang,[2] Elisa J. Gordon,[1] Claudia M. Lora,[1,2] John W. Kusek,[2] Amada Lopez,[1,2] Eva Lustigova,[2] Lisa C. Nessel,[2] Sylvia E. Rosas,[2] Susan P. Steigerwalt,[2] Xiaoming Zhang,[2] Michael J. Fischer,[1,2] James P. Lash.[1,2] *[1]University of Illinois at Chicago; [2]Chronic Renal Insufficiency Cohort (CRIC) Study Group.*

Background: Low health literacy is associated with increased risk of death, yet the health literacy of individuals with chronic kidney disease (CKD) is rarely assessed.

Methods: We evaluated the prevalence and correlates of low health literacy in a cross-section of 2872 CRIC Study participants. Low health literacy was defined as a Short Test of Functional Health Literacy in Adults (STOFHLA) score ≤16.

Results: Table 1 shows significant differences in demographic and clinical characteristics between participants with low v. adequate health literacy (p<0.05).

Table 1. Demographic and Clinical Characteristics*

	Health Literacy	
	Low	Adequate
	n=640 (22)	n=2232 (77)
Age, yrs, Mean (SD)	64.2 (9)	61 (11)
Male gender	384 (60)	1193 (53)
Income <$20,000/year	393 (61)	451 (20)
Education ≤6th grade	163 (26)	23 (1)
Hispanic Ethnicity	245 (38)	185 (8)
eGFR, ml/min/1.73m2, Mean (SD)	34.4 (16.4)	42.1 (17.7)
Urine Protein g/24 hr, Median (IQR)	0.8 (0.2-2.6)	0.3 (0.1-1.3)
Diabetes	460 (72)	1012 (45)
Self-reported CVD	318 (50)	805 (36)
Left Ventricular Hypertrophy**	171 (75)	181 (47)
Blood Pressure >130/80	358 (56)	949 (43)
Hemoglobin A1C (HbA1C) >7%	202 (33)	377 (18)

*Results are presented as n (%), unless otherwise noted. **Echocardiogram obtained within one year of the STOFHLA. SD, standard deviation; IQR, interquartile range; eGFR, estimated glomerular filtration rate; CVD, cardiovascular disease.

In adjusted analyses, low health literacy was a significant predictor of lower eGFR (β coefficient, 2.01 ml/min/1.73m2), HbA1C >7% [odds ratio (OR) 1.6, 95% confidence interval (CI) 1.2-2.2], and higher prevalence of self-reported CVD (OR 1.4, 95% CI 1.1-1.8). Significant predictors of low health literacy were: older age, male gender, Hispanic ethnicity, low educational attainment, and diabetes (p<0.05).

Conclusions: In the CRIC cohort, low health literacy was prevalent and associated with a greater burden of chronic illness. Health literacy interventions may have the potential to improve clinical outcomes in patients with CKD.

SA-PO2472

The Validity of Current CKD Staging Paradigms Revisited and Disputed: A 2-Year Snap Shot of Stage IV CKD Patients in a Mayo Clinic Laboratory Database: A Call for Process Reengineering in Nephrology Practice

Macaulay A. Onuigbo.[1,2] *[1]College of Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, WI.*

Background: It is generally believed that there is a predictable, linear and time-dependent progressive decline in eGFR, ultimately in some patients, ending inexorably in ESRD and the need for RRT. It is on this premise that the current CKD staging protocols

popularized by the NKF are based. Furthermore, several attempts have been made to fabricate mathematical formulas to accurately predict CKD progression. This author's hypothesis is that all these assumptions remain unproven and factually flawed, and that indeed eGFR in CKD patients, is mostly stable and that often, CKD progression to ESRD follows a staccato and unpredictable pattern precipitated and triggered by acute kidney injury (AKI).

We set out to prove this by analyzing a two-year snap shot of patients with eGFR 15.0-29.9 ml/min/1.73 sq m BSA in a Mayo Clinic electronic laboratory database.

Methods: We pulled by IT reporting, all patients with eGFR in the 15.0-29.9 ml/min/1.73 sq m BSA range in a Mayo Clinic electronic laboratory database, reported between April 19, 2009 and April 19, 2011. All patients who had received RRT for AKI or ESRD were excluded from analysis. We included for analysis, all patients with at least three recorded eGFR values, and with a minimum of 6 months between the first and the last reported eGFR estimations.

Results: After excluding 62 ESRD patients, and all who received RRT for AKI, 241 patients qualified for this analysis. There were 102 males and 139 females. In over 95% of the patients, eGFR remained very stable and did not vary by as much as 5 eGFR points (<25% from baseline) over the two-year study period.

Conclusions: We submit that eGFR in the majority of CKD stage IV patients remains stable even after two years. Current CKD staging paradigms are flawed. Formulas attempting to estimate CKD progression by assuming a steady state decline in eGFR in ml/min/year are likely misguided. Further studies are warranted to properly inform and educate both the medical profession and the general population on these very critical knowledge deficiencies.

SA-PO2473

Effect of Conversion from Other ESAs to CERA Once Monthly for Maintaining Hemoglobin (Hb) Concentration in Pre-Dialysis CKD Patients Ji-Young Choi,[1] Chul Woo Yang,[2] Yeong Hoon Kim,[3] Kwon Wook Joo,[4] Tae-Hyun Yoo,[5] Kang Wook Lee,[6] Sang-Ho Lee,[7] Sug Kyun Shin,[8] Wooseong Huh,[9] Sun-Hee Park,[1] Chan-Duck Kim,[1] Yong-Lim Kim.[1] *[1]Kyungpook National University; [2]Catholic University of Korea; [3]Inje University; [4]Seoul National University; [5]Yonsei University; [6]Chungnam National University; [7]Kyung Hee University; [8]National Health Insurance Corporation Ilsan Hospital; [9]Sungkyunkwan University.*

Background: The purpose of this study was to identify whether Hb concentrations can be maintained stably when switching from other ESAs to CERA.

Methods: Pre-dialysis CKD patients (n=191) maintained Hb level of 10.0-12.0 g/dL through epoetin-α, β or darbepoetin-α were enrolled. Conversion ratio from other ESAs to CERA was represented in Table 1.

Table 1. Conversion ratio from other ESAs to CERA

Previous weekly dose of ESA		Starting dose
Epoetin (IU)	Darbepoetin-α (μg)	CERA (μg/month)
<8,000	<40	120
8,000~16,000	40~80	200
>16,000	>80	360

The dose of CERA was titrated to maintain the Hb within a range of ± 1.0 g/dL of the reference Hb and target Hb levels of 10.0-12.0 g/dL. Hb level and the proportion of patients maintaining average Hb concentration were assessed.

Results: The mean Hb level was 10.86 ± 0.71, 11.87 ± 0.93 and 11.16 ± 0.94 g/dL at baseline, 3 and 6 month, respectively. One hundred eight patients (74.5%) maintained target Hb levels (10.0-12.0 g/dL). The mean monthly dose of CERA was 121.2 ± 9.8, 72.7 ± 46.6, and 66.2 ± 47.1 μg at 1st, 4th, and 6th month, respectively. Patients who received decreased dose of CERA because of higher Hb level than 12.0 g/dL were 119 (82.1%), whereas only 6 patients (4.1%) received increased dose because of Hb values < 10.0 g/dL. Patients with Hb overshoot (Hb > 13.0 g/dL and had to stop CERA until Hb level decreased to < 12.0 g/dL) were 59 (40.7%).

Conclusions: Conversion from other ESAs to CERA in pre-dialysis CKD patients can efficaciously maintain Hb concentration and the dose requirement of CERA had significantly decreased compared with those at conversion. It may be needed to adjust the conversion ratio than recommendation for switching from other ESAs to CERA.

Pedometer Determined Physical Activity in Children and Adolescents with Chronic Kidney Disease, End Stage Renal Disease and Kidney Transplant Recipients and Association with Physical Performance and Physical Functioning Aalia Akber,[1] Kirsten L. Johansen,[2] Anthony A. Portale.[1] *[1]Pediatrics, UCSF; [2]VAMC, San Francisco, CA.*

Background: Data and recommendations on physical activity (PA) are limited in children with CKD. The objectives of this study were to: 1) measure the level of PA in children with all stages of CKD and compare these with the recommendations for healthy children; 2) to determine patient characteristics associated with PA; and; 3) to determine the association of PA with physical performance (PP)and physical functioning (PF).

Methods: Participants were enrolled from the Pediatric Nephrology and Transplant Clinics at UCSF. PA was measured for 7 days using the Yamax Digi-Walker SW-200 pedometer and expressed as daily step counts; PP was measured by the 6 minute walk test (6MWD), and PF with the self-report PedsQL 4.0. Univariate and multivariable linear regression analyses were used.

Results: We studied 44 participants aged 7-20 years with CKD Stages 1-4 (n=12), with ESRD on hemodialysis or peritoneal dialysis (n=7), and kidney transplant recipients (n=25). As a group, participants were very sedentary, walking 6218 (3637, 9828) steps/d and thus falling short of levels recommended for healthy children, 15,000 steps/d for boys and 12,000 steps/d for girls. There was no difference in PA between the 3 groups. Girls were less active than boys ($p < 0.01$) and PA was 44% lower among young adults (18-20 years) compared with younger age groups ($p<0.05$). PA was associated positively with maternal education and hemoglobin concentration but inversely with BMI. PP in boys and girls were -2 and -4 standard deviations below the expected 6MWD, respectively, with worse performance in older subjects. Low levels of PA were associated with poor PP and PF, after adjusting for age, sex, and BMI.

Conclusions: In most participants with CKD, PA levels were considerably below levels recommended for healthy children, without apparent improvement after transplantation. The associations of decreased PA with BMI, decreased PP, and PF suggest negative consequences to the limited activity of these children. Studies to determine if interventions to increase PA can improve PP and PF are needed.

Polymorphisms of UCP2 Gene Are Associated with Carbohydrate and Lipid Metabolic Disorders in Chinese Peritoneal Dialysis Patient Tongying Zhu, Lihua Zhang, Yun Li, Lin Tang, Chuan-Ming Hao. *Department of Nephrology, Huashan Hospital of Fudan University, Shanghai, China.*

Background: We investigated the association of three functional variants of UCP2 polymorphism with metabolic disorder and low-grade inflammation in prevalent Chinese peritoneal dialysis patients.

Methods: 116 prevalent PD patients were enrolled, who were genotyped for the UCP2 variants -866G>A, Ala55Val and 45bp ins/del. HOMA-IR, plasma lipid profile, CRP, ferritin, peritoneal glucose absorption, and adipocytokines were examined and compared in different genotypes.

Results: The patients with GG genotype in -866 G/A gene had a higher serum triglyceride than those with A allele(P=0.011).Patients with VV genotype in Ala55Val gene, have a higher level of serum triglyceride (P=0.005), HOMA-IR (P=0.028), ferritin (P=0.045) and peritoneal glucose absorption (P=0.007), and a lower adiponectin level (P=0.014). GG and VV genotype were also found to be significant predictors of hypertriglyceridemia even after adjusted for glucose absorption (GG:OR=2.441, P=0.031, VV: OR=2.40, P=0.03) by logistic regression analysis. While DD genotype in 45bp ins/del polymorphism had higher triglyceride (P =0.021) and HOMA-IR (P =0.001) than DI/II genotype.

Compared to those with only one or none above inferior genotypes, patients who carrying GG- VV-DD simultaneously showed a significant higher degree of de novo diabetes (6/27 vs. 2/45, P=0.02), higher HOMA-IR (3.93 vs. 2.43,P=0.00) , triglyceride (2.68 vs.1.4mmol/L,P=0.00), cholesterol (5.36 vs. 4.65mmol/L,P=0.01), CRP(5.77 vs1.72mg/L, P=0.018), ferritin (270 vs. 209ug/L, P=0.019), leptin (2.85 vs. 2.05ng/ml, P=0.011), and higher glucose absorption (108.99 vs. 83.67g/day, P=0.00). Logistical regression analysis showed that GG- VV- DD genotype had a significant tendency to become hypertriglyceridemia (OR=5.97, P=0.002) and insulin resistance(OR=3.084, P=0.031) even adjusted for glucose absorption.

Conclusions: PD patients with UCP2 -866G/G, Ala55Val V/V, and 45bp DD genotype demonstrated a significant critical metabolic disorder , suggesting a possible role of UCP2 gene polymorphism in the liability of metabolic disturbance under a high glucose environment.

Predictors of Total Sleep Time in Advanced Chronic Kidney Disease Patients Nadeem R. Kolia, Bahar Laderian, Cynthia D. Grady, Mahlet Nega, Enyinna L. Nwachuku, Sarah Ramer, Mark L. Unruh. *University of Pittsburgh School of Medicine.*

Background: Sleep is an important daily activity that aids the body in maintaining homeostatic balance. Sleep deprivation has been linked to increased risk of cardiovascular disease as well as an overall diminished quality of life. This study examined the total sleep time of advanced chronic kidney disease (CKD) and end-stage renal disease (ESRD) patients to determine if modifiable risk factors are associated with reduced total sleep time.

Methods: 88 patients with advanced CKD (stages 4-5) and 93 patients with ESRD on dialysis were compared with 224 controls form the Sleep Strategies-Concentrating on Risk Evaluations study of sleep and cardiovascular risk. All participants underwent home polysomnography. Patient demographics; blood pressure; hypertension, diabetes, and depression status; and anti-hypertensive and anti-depressant medications were also assessed.

Results: The sample (median age 58 years) was 56.3% male and 62.1% white. Total sleep time in minutes differed significantly between controls (365.80±83.19), CKD patients (362.93±100.1), and ESRD patients (318.98±117.46), p=0.001. The percent of the sample with less than 5 hours of sleep also differed significantly between controls (20.1%), CKD patients (27.3%), and ESRD patients (43.2%), p<0.001. In a multivariable linear regression model adjusted for race and hypertension, a 1-year increase in age (-1.44, 95% CI -2.29 to -0.62), female sex (20.75, 95% CI 1.40 to 40.1), presence of sleep-disordered breathing (-0.62, 95% CI -1.08 to -0.16), periodic limb movements index (-2.88, 95% CI -4.52 to -1.23), and ESRD (vs. control) (-45.96, 95% CI -69.7 to -22.3) were all independently associated with total sleep time. The presence of CKD (vs. control) (-10.95, 95% CI -36.4 to 14.5) was not independently associated with total sleep time.

Conclusions: ESRD patients sleep significantly less (on average 46 minutes) compared to controls, possibly contributing to increased risk of cardiovascular disease and reduced quality of life. Addressing sleep-disordered breathing and restless legs, common complaints in ESRD, might lead to increases in total sleep time for these patients.

SA-PO2477

Increased Intrarenal Angiotensin II Activity and Risk of Chronic Kidney Disease Katherine T. Mills, Hiroyuki Kobori, L. Lee Hamm, Arnold B. Alper, Islam Enver Khan, Md Mahfuzur Rahman, Myra A. Kleinpeter, L. Gabriel Navar, Grace Browne, Chung-Shiuan Chen, Yanxi Liu, Ji Hua Xu, Nishant B. Jalandhara, Kanwaljit K. Chouhan, Vecihi Batuman, Jiang He, Jing Chen. *Tulane University.*

Background: Urinary angiotensinogen (UAGT) is a stable biomarker and strongly associated with intrarenal angiotensin II activity. However, less is known about UAGT levels and risk of chronic kidney disease (CKD).

Methods: We investigated urinary and plasma angiotensinogen (PAGT) with risk of CKD in 201 CKD cases and 201 controls without CKD. CKD was defined as estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m² or presence of albuminuria.

Results: Compared to controls, median 24 hour UAGT (44.4 vs. 7.4 ug/24 hr, p<0.0001) and UAGT/creatinine ratio (UCr) (26.3 vs. 4.4 ug/g, p<0.0001) were significantly higher in CKD cases. PAGT was similar between cases and controls (23.3 vs. 22.4 ug/mL, p=0.14). The 24 hour UAGT per 1.73 m² body surface area was highly correlated with the UAGT/UCr ratio (r=0.90, p<0.0001) but not PAGT. Both 24-hour UAGT and the UAGT/UCr ratio were significantly correlated with eGFR and 24-hour urine albumin (p<0.0001). After adjusting for age, gender, race, smoking, drinking, education, physical activity, systolic blood pressure, glucose, LDL cholesterol, and body mass index, the odds ratio (OR) for CKD comparing the highest to the lowest tertile of UAGT was 5.8 (95% CI, 3.0, 11.4). Similar results were seen for tertiles of the UAGT/UCR ratio (OR: 5.8, 95% CI, 3.1, 10.7). Weaker associations were observed for PAGT (ug/ml) with an odds ratio of 3.3 (95% CI, 1.7, 6.3) for the highest compared to the lowest tertile. The results did not change substantially after further adjustment for history of CVD, diabetes, hypertension, and use of angiotensin-converting enzyme inhibitor and angiotensin receptor blocker medications.

Conclusions: These data indicate that UAGT level is associated with an increased risk of CKD and may be a useful biomarker for the prediction of CKD risk. The UAGR/UCr ratio could be used to evaluate 24 hour UAGT. The predictive value of UAGT for the risk and progression of CKD should be examined in a prospective cohort study.

NGAL and Progression of ADPKD Patients in Stage II-III CKD Grazia Maria Virzì,[1,3] Valentina Corradi,[1,3] Fiorella Gastaldon,[1] Massimo de Cal,[1] Dinna N. Cruz,[1,3] Maurizio Clementi,[2] Claudio Ronco.[1,3] *[1]Nephrology, S Bortolo Hosp; [2]Pediatrics-Clinical Genetics, Padua; [3]IRRIV, .*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a genetically heterogeneous inherited condition with a variable rate of progression.

In addition to NKF-KDOQI guidelines regarding routine screening, recent studies suggest a possible role for NGAL in assessing CKD progression; it could be a good marker also for ADPKD progression.The aim of the study was to evaluate whether NGAL could predict loss of function in ADPKD patients in stage II-IIICKD.

Methods: Pts with ADPKD, based on ultrasound criteria, were enrolled and followed prospectively. Creat and NGAL values were measured at baseline and followed up.

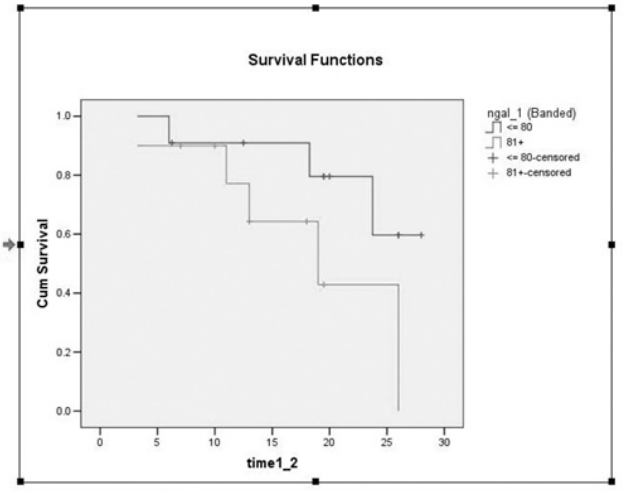
eGFR was calculated with 4-variable standardized-MDRD equations. NGAL was measured in plasma by the Triage®NGALDevice.

Survival data were analyzed by the Kaplan-Meier curve using the median NGAL (80pg/ml) as a cut-off value.

Results: We enrolled 21 ADPKD pts (12M/9F; mean age39±9yrs); mean creat was 1.3±0.7mg/dl and mean eGFR was 67.8±23.3mL/min/1.73m². After a median follow-up of 16.5mo, 8pts (38%) progressed to a worse stage of CKD and 62% were stable.

Kaplan-Meier curves are presented in Fig1.

Fig.1: Kaplan-Meier survival curves in patients with NGAL level above and below the cut-off of 80 pg/ml (median values)



NGAL values inversely correlated with eGFR; eGFR was higher in pts with NGAL values<80pg/ml.

Although, no statistically significant relationship between higher NGAL and decreasing eGFR was observed, a positive trend was evident.

Pts with NGAL values<80pg/ml were followed for a longer period of time-18.7mo versus 14mo for NGAL above the cut off.

Conclusions: We observed a positive trend, but no significant relationship between NGAL and progression of CKD in ADPKD patients in stage II-IIICKD. The present study has limitations: it was a single-center study and the cohort of patients was small. It is necessary to increase the sample size of ADPKD pts enrolled to validate our hypothesis.

SA-PO2479

Urinary Neutrophil Gelatinase-Associated Lipocalin Does Not Correlate with Renal Dysfunction in Polycystic Kidney Disease Graham D. Smith,[1] Caroline M. Robinson,[1] Keith A. Burling,[2] Anthony G. Norden,[2] Richard N. Sandford,[1] Fiona E. Karet.[1,3] *[1]Medical Genetics, University of Cambridge, United Kingdom; [2]Core Biomedical Assay Lab, NIHR Cambridge Medical Research Centre, United Kingdom; [3]Renal Medicine, University of Cambridge, United Kingdom.*

Background: Neutrophil gelatinase-associated lipocalin (NGAL) was first identified as a component of neutrophil granules and has since been found in the majority of tissues. It is implicated in a variety of cellular processes e.g. inflammation and cell survival. It is a 25kDa protein that exists in mono-, homo- and heterodi-meric forms, the latter in association with matrix metalloproteinase 9 (MMP-9).

NGAL has been implicated in pathological conditions and its presence in urine is proposed as a biomarker for various kidney diseases, including Polycystic Kidney Disease (PKD) (1).

Methods: We used commercially available ELISA kits to assess levels of urinary NGAL (uNGAL) or uMMP9/NGAL in adult PKD patients (n=41, mean age 43±10.5 y); creatinine 70-627 µmol/l) compared to matched healthy controls with normal renal function.

Results: We found no differences in uNGAL levels between PKD patients and controls: median 12.5 ng/ml (range 0-60) vs 4.16 ng/ml (0.2-60), p=0.12. In contrast, a cohort of AKI patients had median 234 ng/ml (138-310). Correction of uNGAL for urinary creatinine resulted in a statistically but clinically insignificant difference between PKD and control groups: median 2.1 (0.1-26) and 1.1 (0.02-11) ng/ml, (p=0.013), with AKI patients' median being 20.3 (2.7-51.7) ng/ml.

For uMMP9/NGAL, only negligible amounts were detectable in either patients or controls, with median 0 ng/ml for both groups, range 0-0.203 (patients) and 0-0.395 (controls), p=0.31. We saw no correlation between levels of adjusted uNGAL (r^2=-0.27) or uMMP9/NGAL (r^2=0.13) and degree of kidney dysfunction in the patient population.

Conclusions: The similar ranges of uNGAL or uNGAL/MMP-9 found in patient and normal urine samples, and the lack of change with altered renal function, indicate that neither would be a reliable biomarker for disease progression in PKD, and their utility in a clinic setting are not supportable.

Angiotensinogen Is Filtered through the Glomerulus and Reabsorbed by the Proximal Tubule in Both Mice and Humans Fumio Niimura,[1] Taiji Matsusaka,[2] Takeshi Matsuyama,[3] Shojiro Okamoto,[1] Masuhiro Shimoda,[5] Tomohiro Udagawa,[6] Tae Omori,[7] Iekuni Ichikawa.[4] *[1]Pediatrics, Tokai University School of Medicine, Kanagawa, Japan; [2]Nephrology, Tokai University School of Medicine, Kanagawa, Japan; [3]Pediatrics, Fussa Hospital, Tokyo, Japan; [4]Pediatric Nephrology, Vanderbilt University, Nashville, TN; [5]Pediatrics, Musashino Red Cross Hospital, Tokyo, Japan; [6]Pediatrics, Tokyo Medical and Dental University, Tokyo, Japan; [7]Pediatrics, Tokyo Metropolitan Bokutoh Hospital, Tokyo, Japan.*

Background: Recently, in liver- or kidney-specific Angiotensinogen (Agt) knockout mice, we demonstrated that circulating Agt of liver origin is filtered through the glomerulus, and reabsorbed by the proximal tubule. This is in contrast to the notion that Agt cannot be filtered through the glomerulus and that Agt in the urine is produced by the proximal tubule (PT).

Methods: To clarify whether Agt is reabsorbed by PT in human subjects, urinary Agt was measured in 12 patients with Dent disease, Lowe syndrome, and idiopathic low molecular weight proteinuria, using human Agt ELISA kit (IBL), developed by Kobori et al. These patients are characterized by inability to reabsorb filtered low molecular weight proteins, resulting in massive urinary excretion of β2 microglobulin (MG) and α1 MG.

Results: In these patients, urinary Agt was markedly elevated, ranging from 1,446 to 33,410 μg/gCr (median, 11,312). These values are far above the published values. Urinary β2 MG in these patients was 18,600 to 173,000 μg /L. Urinary Agt correlated well with urinary β2 MG (r=0.82), α1 MG (r=0.98). In control subjects without proteinuria, urinary Agt, measured concurrently using the same kit, ranged from 11.0 to 108.7 μg/gCr (median, 25.9), values comparable to previously published values, verifying that the assay method was appropriate.

Conclusions: Observed markedly augmented urinary excretion of Agt in patients with PT dysfunction indicates that, in human subjects, Agt is filtered through the glomerular filtration barrier, and reabsorbed by the proximal tubule. Thus, abnormal elevation in urinary Agt excretion reflects either or both disrupted glomerular sieving function and/or defective tubule reabsorptive capacity.

Renal Uptake of Technetium-99m DMSA Is Mediated by the Megalin/Cubilin Receptor Complex Kathrin Weyer,[1] Rikke Nielsen,[1] Michael Rehling,[2] Henrik Birn.[1] *[1]Department of Anatomy, Aarhus University, Aarhus, Denmark; [2]Department of Clinical Physiology and Nuclear Medicine, Aarhus University Hospital Skejby, Aarhus, Denmark.*

Background: Dimercaptosuccinic acid (DMSA) labeled with technetium-99m (Tc-99m) is the major renal imaging agent used in diagnosis of renal parenchymal disorders. Tc-99m DMSA is highly accumulated in the kidney cortex, but despite the extensive clinical use, the mechanism for renal targeting of the tracer remains elusive. In this study we have tested the role of the proximal tubule endocytic receptor complex megalin/cubilin in the uptake of Tc-99m DMSA.

Methods: Control mice or conditional megalin/cubilin-deficient mice were i.v. injected with the tracers Tc-99m DMSA or Tc-99m MAG3 (mercaptoacetyltriglycine). Six hours post-injection, samples of plasma, urine, and kidneys were collected and analysed using a gamma counter. Whole-body autoradiographies of the mice were made with a gamma-camera.

Results: The renal uptake of Tc-99m DMSA was reduced to 11.4% (+/- 2.5%, n=7) in the megalin/cubilin-deficient mice compared to controls, and a corresponding increase in the urinary excretion of Tc-99m DMSA could be detected. This was further confirmed by whole-body autoradiographies of the mice, where no Tc-99m DMSA activity could be detected in the kidneys of the megalin/cubilin-deficient mice. In contrast, urinary excretion of Tc-99m MAG3 by the megalin/cubilin-deficient mice was similar to control mice, suggesting that the basolateral uptake of the proximal tubule cells is not disturbed by the megalin/cubilin-deficiency.

Conclusions: Our data show that Tc-99m DMSA is taken up by tubular luminal reabsorption mediated by the megalin/cubilin receptor complex and further demonstrate that the tracer distribution is an index of renal proximal tubule endocytic function.

SA-PO2482

Complement (C) Activation in Renal Ischemia/Reperfusion (I/R) Injury Is Mediated by Pentraxin 3 (PTX3): A Species-Specific Difference G. Castellano,[1] C. Divella,[1] Antonia Loverre,[1] Claudia Curci,[1] Alessandra Stasi,[1] M. Rossini,[1] P. Ditonno,[1] M. Battaglia,[1] Mohamed R. Daha,[2] Pieter van der Pol,[2] Cees van Kooten,[2] G. Pertosa,[1] Loreto Gesualdo,[1] G. Grandaliano,[3] Francesco Paolo Schena.[1] *[1]Dept. of Emergency and Organ Transplantation, Univ. of Bari, Italy; [2]Dept. of Nephrology, Univ. of Leiden, Netherlands; [3]Dept. of Biomedical Sciences, Univ. of Foggia, Italy.*

Background: Next to the short pentraxin CRP and SAP, the long pentraxin PTX3 is characterized by a different gene organization and cellular source. PTX3 has been recently implicated in the priming of vascular inflammation via C activation. Aim of this work was to investigate the possible involvement of PTX3 in renal I/R injury.

Methods: Two experimental models of I/R were used: 6 rats and 5 pigs underwent 45' (rat) and 30' (pig) of renal warm I by clamping renal artery. Renal tissues were analyzed at different time points.

Results: In the pig model, confocal microscopy demonstrated PTX3 deposits already at 15' of R, localized at peritubular (T0 .1±.05, T15 7.7±1.1; p=.005) and glomerular (T0 .5±.2, T15 8.2±2.5; p=.01) capillary levels, showing a specific co-localization with CD31, an endothelial cell marker. We observed a significant increase in infiltrating interstitial leucocytes, including $CD163^{+}/PTX3^{+}$monocyte-macrophages (T0 .01±.02, T15 6.2±2.1; p=.01) and $SWC3a^{+}/PTX3^{+}$dendritic cells (T0 .5±.3, T15 3.7±.5 p=.04). Finally, we identified interstitial $FSP1^{+}/PTX3^{+}$myofibroblast (T0 .3±.2, T15 4.1±1.3; p=.03). Co-localization between C5b-9 and PTX3 on renal endothelial cells clearly demonstrated the C activation in the presence of PTX3 deposits. On the contrary, the analysis of rat kidneys showed that PTX3 was not modulated by I/R injury. Rat PTX3 specifically co-localized only with alpha-SMA positive cells at the vascular level without any association with infiltrating leukocytes and C activation

Conclusions: This study first demonstrates a significant difference in PTX3-mediated C activation between pig and rat kidney. Since PTX3 can activate the Classical and Lectin pathways of C via specific binding with C1q and MBL, we hypothesize that PTX3 might be a new therapeutic target to prevent C-induced renal I/R injury

Funding: Government Support - Non-U.S.

Coagulation and Complement Cascade Priming Induces NOX4 Activation in Renal Ischemia-Reperfusion (I/R) Injury S. Simone,[1] F. Rascio,[1] Antonia Loverre,[1] G. Castellano,[1] C. Cosola,[1] P. Ditonno,[1] Francesco Paolo Schena,[1] Loreto Gesualdo,[1] G. Pertosa,[1] G. Grandaliano.[2] *[1]Dept of Emergency and Organ Transplantation, University of Bari, Bari, Italy; [2]Dept of Biomedical Sciences, University of Foggia, Italy.*

Background: Renal I/R plays a key role in the pathogenesis of delayed graft function after renal transplantation and is characterized by a cascade of inflammatory events, including an increased reactive oxygen species generation. The complement and coagulation cascades has been suggested to play a pathogenic role in I/R-induced renal damage. Aim of the study was to investigate the activation of NADPH oxidases in a pig model of renal I/R injury focusing on the coagulation and complement systems.

Methods: Renal I/R was induced in 5 pigs by arterial clamping. The NADPH oxidase activity was assessed by chemiluminescence on renal tissue taken before ischemia (T0) and a different time after reperfusion (T15', 30', 60'). NOX4 protein expression and fibrin deposition were evaluated by immunohistochemistry. In vitro, NOX4 protein expression was assessed by immunoblotting in human proximal tubular epithelial cells (HK2) treated with thrombin (5*10-3U/μl) or C3a (5*10-7M) for different time periods.

Results: NADPH-oxidase activity was significantly increased during reperfusion in a time-dependent manner with a peak at T60 (T0 1.3±.4, T60 5.3±2.0 ΔURL/Dt, p=.03). We observed a significant increase in tubular NOX-4 expression (T0 5.1±.8, T30' 18.6±.5, pixels/total area, p=.03) and interstitial fibrin (T0 2.2±.7, T30' 10.3±.3 pixels/total area, p=.03) and C5b9 deposition (p=.03), all with a peak at T30'. NOX4 expression and fibrin or C5b9 deposits co-localized at the different time points. In addition we observed a significant and direct correlation between fibrin or C5b9 deposition and NOX4 protein expression (r=.86, p<.001; r=.58,p=.01). In vitro, thrombin and C3a induced NOX4 expression in HK2 cells in a time-dependent manner with a peak at T15'(p=.02).

Conclusions: NOX4 is activated during I/R; coagulation and complement cascades may play a role in NOX4 activation. Coagulation, complement and NADPH oxidase may represent a pharmacological target to prevent oxidative damage during I/R injury.

Funding: Government Support - Non-U.S.

SA-PO2484

Role of the Uremic Solute Indoxyl Sulfate on Tissue Factor Production Via Aryl Hydrocarbon Receptor Pathway Bertrand Gondouin,[1,2] Claire Cerini,[1] Laetitia Dou,[1] Ariane Duval-Sabatier,[1,2] Philippe Brunet,[1,2] Stephane Burtey.[1,2] *[1]INSERM U608, Université Aix-Marseille - UFR Pharmacie, Marseille, France; [2]Centre de Nephrologie et Transplantation Renale, Hôpital La Conception, Marseille, France.*

Background: Endothelial dysfunction is implicated in the high cardiovascular mortality seen in CKD patients. The uremic solute indoxyl sulfate (IS) is particularly deleterious for the endothelium and IS levels are correlated with cardiovascular mortality. Tissue factor (TF) is a key initiator of coagulation and an actor in atherogenesis. TF plasma levels are elevated in CKD patients, but the mechanisms involved are unknown. Therefore, we have performed a clinical and in vitro study to assess the potential role of IS on TF production and the cellular pathways involved notably the AHR pathway.

Methods: Plasma IS and soluble TF (sTF) levels were measured in 72 hemodialysis (HD) patients, 50 undialyzed CKD patients (CKD) and 37 control subjects (controls).

We studied in vitro the effect of IS at uremic concentrations on TF production and procoagulant activity in cultured endothelial cells (HUVEC) and leukocytes (PBMC). Finally, we studied the involvement of aryl hydrocarbon receptor (AHR) in this TF production using siRNA experiments.

Results: sTF levels were respectively 142±48 pg/mL in HD, 77±66 pg/mL in CKD and 36±14 pg/mL in controls, with significant differences between all groups. In CKD patients, sTF levels were negatively correlated with eGFR (r= - 0,333, p < 0,05) and positively correlated with IS (r= - 0,333, p < 0,05).

In vitro, IS increased TF protein levels and TF-dependent procoagulant activity in HUVEC and PBMC.

This increased TF production is preceded by increased mRNA levels suggesting an elevated transcriptional activity. siRNA directed against AHR abolished the increase in TF induced by IS.

Conclusions: The increase in sTF in CKD patients is related to renal function and levels of IS. In vitro, IS induces TF production in HUVEC and PBMC, which involves the transcription factor AhR.

As AHR and TF have a demonstrated role in atherogenesis, IS could thereby contribute to the high cardiovascular risk observed in uremic patients.

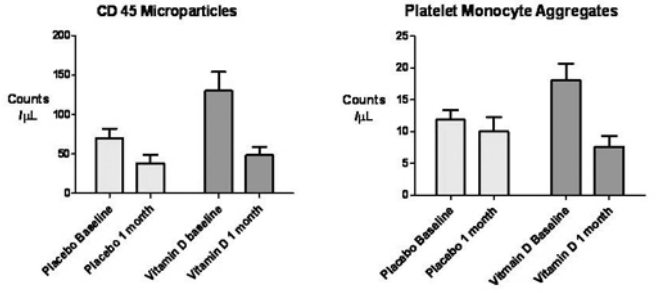
SA-PO2485

Ergocalciferol Significantly Reduces Markers of Vascular Inflammation in Patients with Chronic Kidney Disease Stage 3-4 Gavin Dreyer,[1] Marion Macey,[2] Martin J. Raftery,[1] Magdi Yaqoob.[1] *[1]Renal Unit, Royal London Hospital, United Kingdom; [2]Haemtology Unit, Royal London Hospital, United Kingdom.*

Background: Chronic kidney disease (CKD) causes vascular inflammation and endothelial dysfunction leading to cardiovascular disease (CVD). Newer vitamin D analogues may reduce the burden of CVD in CKD but are expensive and the mechanism of action is incompletely understood. We conducted a pilot, randomised, placebo controlled trial evaluating the effect of ergocalciferol, an inexpensive vitamin D compound, on known markers of vascular inflammation in CKD 3-4.

Methods: Patients with CKD stage 3-4 (n=13) were enrolled. Baseline samples for flow cytometry quantified platelet monocyte aggregates (PMA) and CD 45 microparticles (CD45MP), both markers of vascular inflammation. Patients were randomised to ergocalciferol (n=7) 50,000iu weekly for 4 weeks or placebo (n=6). Patients with diabetes mellitus were excluded to remove the confounding effect of diabetes on the endothelium. Samples were taken at baseline and repeated after 1 month.

Results: The mean age, eGFR, blood pressure, ethnicity and tobacco use did not differ between treatment groups with CKD. PMA and CD45MP were similar between placebo and ergocalciferol treated CKD patients at baseline (PMA - p=0.056, CD45MP - p=0.41). At 1 month, PMA and CD45MP were significantly lower in the ergocalciferol group (p=0.002 and p=0.007) but unchanged in the placebo group.



Conclusions: Ergocalciferol reduces markers of vascular inflammation in CKD 3-4. These findings may explain the reduction in CVS disease in previous studies of patients with CKD treated with vitamin D compounds but could also reflect the unique effect of ergocalciferol itself. Multi centre clinical studies are required to further evaluate the role of ergocalciferol therapy to reduce CVD in CKD and to better understand its precise mechanism of action.

SA-PO2486

The Correlation between Albumin to Creatinine Ratio and Total Protein to Creatinine Ratio in Patients with Chronic Kidney Disease Chun Soo Lim,[1, 2] Yon Su Kim.[2] *[1]Department of Internal Medicine, Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [2]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: The quantification of urinary protein excretion is important for monitoring of chronic kidney disease (CKD). Random urine total protein-to-creatinine ratio and albumin-to-creatinine ratio have been supposed as alternatives to 24 h urine measurements.

Methods: A total of 808 patients were prospectively enrolled from renal out-patient clinics. We measured albumin-to-creatinine ratio, protein-to-creatinine ratio and urine dipstick test simultaneously in random urines, and we investigated the relation between albuminuria and proteinuria in random urine samples in CKD patients.

Results: Albuminuria was well correlated with proteinuria [$\beta = 1.114$ (95% CI 1.061 to 1.166), $P < 0.001$, $R2 = 73.6\%$]. The correlation between albuminuria and proteinuria was significantly better in patients with dipstick albumin positive than those with negative ($P < 0.001$ for interaction), in patients with urine creatinine level ≥ 60 mg/dL than those with < 60 mg/dL ($P = 0.024$ for interaction), and in patients with estimated GFR < 60 mL/min/1.73m2 than those with ≥ 60 mL/min/1.73m2 ($P = 0.040$ for interaction). However, the correlation between albuminuria and proteinuria was not different according to the sex ($P = 0.941$), status of diabetes mellitus ($P = 0.820$), and age (≥ 60 years vs < 60 years) ($P = 0.706$).

Conclusions: The determination of proteinuria or albuminuria in random urine samples, when properly interpreted by taking into consideration the urine concentration, the amount of proteinuria and renal function, could be acceptable for the measure of monitoring of proteinuria or albuminuria.

SA-PO2487

Polyclonal Immunoglobulin Free Light Chains and hs-CRP Kinetics in Inflammatory and Renal Scenarios Anne Bevins,[1] Lakhvir Assi,[1] Paul Cockwell,[2] Richard Hughes,[1] Colin A. Hutchison.[2] *[1]The Binding Site Group Ltd, Birmingham, United Kingdom; [2]Renal Unit, University Hospital Birmingham, United Kingdom.*

Background: Chronic kidney disease (CKD) patients are at increased risk of infection & cardiovascular disease (CVD). Currently patients can be risk stratified with high sensitivity C-reactive protein (CRP), a robust marker of innate immunity. We hypothesized that if a marker of adaptive immunity was also studied, further prognostic information could be gained. The purpose of this study was to determine the relationship between CRP and a potential marker of the adaptive immune response (polyclonal free light chains (FLC)).

Methods: Four cross-sectional renal cohorts were studied; CKD (n=871) diabetes (n=736), vasculitis (n=68) and renal transplant recipients (n=399). Serum CRP levels were correlated to polyclonal FLC levels (κ+λ, Freelite™) and FLC production rates ([κ+λ]/GFR), these compared to a healthy control group (n=108). This was further explored longitudinally in an intensive care case series (n=11).

Results: The correlations between CRP and both total FLC and FLC production rates were weak across all renal cohorts: CKD 0.328 & 0.299; diabetes 0.185 & 0.162; vasculitis 0.273 & 0.260; and renal transplant recipients 0.152 & 0.151, respectively. These correlations were weaker in the diabetics and transplant recipients than the CKD population (all p<0.01). There were no significant differences in correlation of CRP with total FLCs between the control population and all renal cohorts, however correlation with FLC production was significantly stronger in the CKD population (p=0.016). Serial samples collected from ICU patients displayed elevated CRP levels at presentation, and a delayed increase in FLC concentration (8/11 patients). The three patients that did not display increased FLC were admitted to ICU for non-inflammatory diagnoses, including respiratory failure, asthma, and acute kidney injury.

Conclusions: These results demonstrate clear differences in response kinetics of CRP and FLCs to inflammatory insult and disease. Potentially use of CRP and FLCs, as markers of innate and adaptive immunity, can provide a novel insight into inflammation and allow risk stratification.

SA-PO2488

Immunohistochemical Analysis of Vasohibin-1 Using Renal Biopsy Specimens of Patients with Renal Disorders Norikazu Hinamoto,[1] Yohei Maeshima,[1] Daisuke Saito,[1] Hiroko Yamasaki,[1] Hiroyuki Watatani,[1] Haruyo Ujike,[1] Shinji Kitamura,[1] Hitoshi Sugiyama,[1] Naoki Kanomata,[2] Hikaru Sonoda,[3] Yasufumi Sato,[4] Hirofumi Makino.[1] *[1]Medicine and Clinical Science, Okayama Univ. Graduate School of Medicine, Okayama, Japan; [2]Pathology, Kawasaki Medical School, Kurashiki, Okayama, Japan; [3]Discovery Research Laboratories, Shionogi, Settsu, Osaka, Japan; [4]Vascular Biology, Tohoku Univ., Sendai, Miyagi, Japan.*

Background: Glomerulosclerosis and tubulointerstitial injuries are involved in the progression of renal disorders. Vasohibin (VASH)-1 serves as a negative feedback regulator of angiogenesis and we recently reported the therapeutic efficacy of VASH-1 in mouse diabetic nephropathy models (Diabetes, 2009, AmJPhys-Renal, 2011). The aim of the current study is to examine the renal levels of VASH-1 in patients with renal disorders and to evaluate its clinical usefulness.

Methods: We performed immunohistochemistry for VASH-1 and CD31 using renal biopsy sections obtained from 54 patients (glomerulonephritis, glomerulosclerosis, diabetic nephropathy etc.) and 6 renal sections obtained from normal portions of surgically nephrectomized kidneys (renal cell carcinoma). Correlation between histological parameters and the number of VASH-1$^+$ cells was examined.

Results: VASH-1 was observed in renal endothelial cells of normal subjects and additionally in mesangial cells, crescent, and in interstitial inflammatory cells in subjects with renal diseases. Significant positive correlation was observed between the number of VASH-1$^+$ cells in each renal compartment and plasma levels of VASH-1. Significant positive correlation was observed between 1) crescent formation and the number of VASH-1$^+$ cells in glomerulus (r=0.48, P=0.001) or cortex (r=0.64, P<0.0001), and 2) interstitial cell infiltration and the number of VASH-1$^+$ cells in cortex (r=0.34, P=0.02). The number of VASH-1$^+$ cells in glomerulus did not correlate with glomerular CD31$^+$ endothelial area.

Conclusions: These results suggest that Vasohibin-1 may be associated with crescentic lesion and interstitial inflammatory cell infiltration in renal disorders, thus implicating its potential to serve as a novel renal biomarker.

SA-PO2489

Clinical Utility of Tests for Hepatitis C Surveillance David B. Van Wyck, Nancy Culkin, Marc Eckhert, Eileen J. Peacock, Kathy Holland, Timothy Sherrill. *DaVita Inc, Denver, CO.*

Background: KDIGO, KDOQI and CDC recommendations specify retesting seronegative patients every 6-12 months for the surveillance of hepatitis C (HCV) infection in hemodialysis (HD) facilities. However, the clinical utility of recommended tests has not been examined in large populations.

Methods: We initiated baseline and annual surveillance in 104,129 in-center HD patients for the presence of antibodies to HCV using a screening chemiluminescent immunoassay. Consistent with guidelines, we considered patient specimen signal/cutoff ratios of <0.8 to be nonreactive (presumed negative), ratios ≥11 to be reactive without recommendation for supplemental testing (presumed positive), and ratios of 0.8 to < 11.0 equivocal (0.8 to <1.0) or reactive (1.0 to <11) with a recommendation for supplemental testing using recombinant immunoblot assay (RIBA) for confirmation of HCV antibody. RIBA results were reported as positive (confirmatory), negative or indeterminate. From 11/2009 to 4/2011, we tested new patients and those previously found to be HCV negative.

Results: Overall HCV prevalence by screening was 7.4%. Among patients previously nonreactive for HCV, 0.099% showed reactive results ≥11 on follow-up surveillance testing. 1.4% underwent supplemental testing for RIBA: of these, 22.2% were confirmed positive; 41.7% were found to be negative; and, 36.1% returned indeterminate results. No previously nonreactive patient was found to be positive by RIBA supplemental testing. Among patients previously reactive ≥11, 0.078% were nonreactive on follow-up, and 0.223% showed results in the 1.0 to <11 range.

Conclusions: Among HCV-positive patients, we found evidence that reactivity in HCV screening antibody assays wanes or fluctuates. Since the resulting pre-test probability of new-negative results in previously seropositive patients approaches that of new-positive results in previously seronegative patients, our findings suggest that HCV surveillance in seronegative patients should be conducted no more frequently than annually, and that new positive results in HD patients should be interpreted with caution and case-by-case clinical adjudication.

Correlation between the Renal Resistive Index and Histology Steven Grange,[1] Fabien Soulis,[1] Dominique Guerrot,[1] Arnaud Francois,[2] Caroline Freguin,[1] Michel R. Godin,[1] Bruno Legallicier.[1] *[1]Nephrology, Rouen University Hospital, Rouen, France; [2]Pathology, Rouen University Hospital, Rouen, France.*

Background: Renal interstitial fibrosis (IF) and arteriosclerosis are determinants of CKD progression. Intra-renal arterial resistance index (RI), a simple non-invasive and reproductive ultrasonographic tool, has become increasingly used in CKD patients. Studies evaluating associations of RI with robust histological variables and renal prognosis are lacking. The objective of this prospective study was to analyze correlations between RI and renal histomorphological measurements, and predictive value for CKD progression.

Methods: Patients hospitalized for renal investigation (n = 47) underwent RI measurement (3.5 MHz) in interlobar arteries and own kidney biopsy. Arteriosclerosis, interstitial surface and IF were assessed by standardized morphometric analyses of blinded Sirius Red (SR) stained slides, under normal and polarized light. MDRD eGFR was measured at M0, M12, M24 and M36. CKD progression combined endpoint was defined as ≥ 10% decrease in eGFR, dialysis requirement or death.

Results: Mean RI was 0.65 ± 0.08. RI was positively correlated with interstitial surface and negatively with eGFR at M0, M12, M24, and M36 (all p<0.05). Interlobar RI was moderately associated with interlobular arteriosclerosis (p<0.09), suggesting that thickening of distal arteries may influence RI. At M36, 14 patients reached the progression endpoint (eGFR decrease: n=5, dialysis: n=5, death: n=4). Compared to stable patients, subjects with CKD progression presented significantly higher RI and interstitial surface but reduced IF (all p<0.05), suggesting that increased RI could be related in this population to interstitial infiltration and active extracellular matrix production (type IV collagen, proteoglycans and laminins), and not to chronic accumulation of type I and III collagen (SR +).

Conclusions: In CKD patients, resistance index is associated with renal interstitial and arterial lesions. Active interstitial lesions rather than chronic interstitial fibrosis, seems to be a major determinant of high RI in patients with CKD progression, and further suggest the RI predictive potential in this setting.

SA-PO2491

Correlation between the Renal Resistive Index and Graft Histology Steven Grange,[1] Fabien Soulis,[1] Dominique Guerrot,[1] Arnaud Francois,[2] Caroline Freguin,[1] Michel R. Godin,[1] Bruno Legallicier.[1] *[1]Nephrology, Rouen University Hospital, Rouen, France; [2]Pathology, Rouen University Hospital, Rouen, France.*

Background: The progressive loss of renal allograft function is related to interstitial fibrosis (IF) and arteriosclerosis. Intra-renal arterial resistance index (RI) has become increasingly used in kidney transplantation. Large studies evaluating associations of RI with robust histological variables and the evolution of graft function are lacking. The objective of this prospective study was to analyze correlations between RI and renal histomorphological measurements, and their predictive value for graft function.

Methods: At inclusion 105 kidney transplant patients underwent RI measurement (3.5 MHz) in interlobar arteries, and renal graft biopsy. Arteriosclerosis, interstitial surface and IF were assessed by standardized morphometric analyses of blinded Sirius Red (SR) stained slides, under normal and polarized light respectively. MDRD eGFR was measured at M0, M12, M24 and M36. Progression combined endpoint was defined as ≥ 10% or ≥ 20% decrease in eGFR at M12 or M24 respectively, dialysis requirement or death.

Results: Patients were included 23±36 months post-transplantation. Mean RI was 0.68±0.08. RI was negatively correlated with eGFR at M0, M12, M24, and M36 (all p<0.05). At M24, 30 patients reached the progression endpoint (eGFR decrease: n=10, dialysis: n=18, death: n=2). After exclusion of patients with acute graft failure and/or rejection (conditions associated with interstitial edema), RI was positively correlated with interlobular arteriosclerosis, and subjects with progressive loss of graft function presented higher RI and interstitial surface (including cells and type IV collagen, laminins and proteoglycans) but reduced IF evaluated by the only detection of type I and III collagens (SR+) (all p<0.05).

Conclusions: In kidney transplant patients, resistance index is associated with interstitial and arterial lesions and predicts progressive loss of allograft function. Our results suggest that interstitial infiltration and active extracellular matrix production, rather than chronic interstitial deposition of fibrillar collagens, are a major determinant of high RI in this setting.

SA-PO2492

Vascular Sclerosis in Tumor Nephrectomy Specimens Has Prognostic Significance Steven P. Salvatore,[1] Eugene K. Cha,[2] James S. Rosoff,[2] Surya V. Seshan.[1] *[1]Pathology, Weill Cornell Medical College, New York City; [2]Urology, Weill Cornell Medical College, New York City.*

Background: Evaluating non-tumor portions of tumor nephrectomies is useful to diagnose non-neoplastic renal disease. The purpose of this study is to determine the medical renal disease frequency and to assess the prognostic significance of the degree of vascular sclerosis in long term follow-up of tumor nephrectomy patients.

Methods: We reviewed non-neoplastic kidney sections of 465 cases from 1998 to 2008. Sixty-four cases were excluded (18 tumor compression, 25 no non-neoplastic, 21 embolized). PAS staining, immunofluorescence, and/or electron microscopy was performed where appropriate. Vascular sclerosis was scored from mild to severe. Follow-up of at least 1 year was evaluated in 178 cases. The degree of vascular sclerosis was compared to the change in pre-op creatinine to follow-up.

Results: Of 401 cases, 59 had additional medical renal disease (15%): diabetic nephropathy 29, hypertensive nephropathy 13, FSGS 7, collapsing glomerulopathy 2, granulomatous tubulointerstitial nephritis 2, acute pyelonephritis, TMA, atheroembolic disease, reflux nephropathy, proliferative glomerulonephritis, and membranous glomerulonephritis 1 each. 80% of the cases with additional non-neoplastic diagnoses and follow-up showed severe arteriolosclerosis. Higher corresponding global glomerulosclerosis (GS) was seen in the more affected vascular cases, mean 3.6% GS for mild versus 15% GS for severe. Three patients progressed to end stage renal disease from 1 to 4 years after nephrectomy, all with diabetic nephropathy.

Degree of vascular sclerosis compared with mean change in creatinine

Arterioles	N	mean Cr difference (mg/dL)	p value	mean f/u (yrs)
mild	89	0.2	0.002	3.6
moderate	55	0.4	0.019	3.7
severe	34	0.8	n/a	3.9
Arteries				
mild	88	0.3	0.04	4.0
moderate	60	0.4	0.09	3.1
severe	30	0.7	n/a	3.6

Conclusions: Medical renal disease was identified in 15% of tumor nephrectomy specimens in our center. The degree of vascular sclerosis is highly predictive of elevated creatinine levels and decline in renal function in post-nephrectomy patients. The prognostic implications of the non-tumor pathology are therefore important in patients with reduced renal mass.

SA-PO2493

Plasma Cell-Rich Acute Rejection Has a Higher Graft Failure Rate Compared to Antibody Mediated Rejection of Renal Allografts Sharad Sathyan, Thangamani Muthukumar, Marie Matignon, Manikkam Suthanthiran, Surya V. Seshan.

Background: Acute rejection (AR) is classified as T cell or antibody mediated. Rarely, interstitial infiltrates during AR are enriched with plasma cells. Graft outcome following an episode of such plasma cell-rich acute rejection (PCR-AR) has not been well defined.

Methods: We reviewed charts of kidney recipients with biopsies classified as PCR-AR (plasma cells >20% of the interstitial infiltrates), from 1999-2010. Primary outcome was graft loss. Patients who did not reach the primary outcome were censored at their last follow up. We compared their graft survival with a cohort of kidney recipients with acute antibody mediated rejection (AMR).

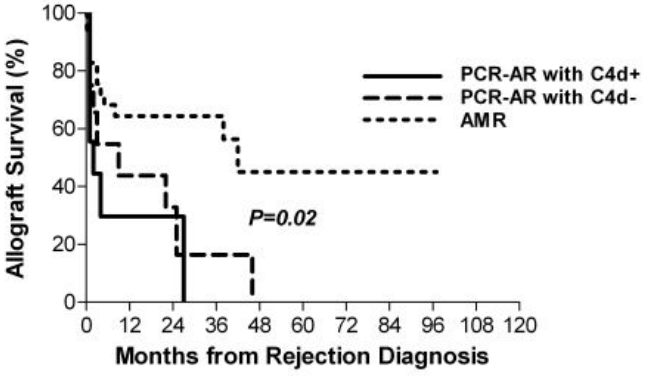
Results: 26 kidney recipients had PCR-AR (mean age: 41±16 years, 14 females, 13 Blacks, 10 deceased donors). Immunosuppression was CNI/steroid based in 14, steroid free in 9, and sirolimus based in 3. None had BKV or CMV infection. 11 (42%) had prior rejections.

PCR-AR occurred 39 months median (range: 1-144) after transplant. At rejection, creatinine was 4.21 (2.0-35.6) and Prograf trough was 3.4 (2.0-16.6). Prograf was 5.2 (2.0-9.5) 3-months prior.

Biopsies showed both lymphocytic and plasma cell tubulitis (moderate-10 (38%) and severe-13 (50%)). Interstitial fibrosis was mild in 6 (23%), moderate in 13 (50%) and severe in 5 (19%). C4d was available in 21 (81%) of which 9 (43%) were positive.

Ten (38%) were treated with steroids alone, 11 (42%) with IVIG/plasmapheresis, and 11 (42%) with antibody based therapy. 2 did not receive specific therapy.

21 lost their graft. Median graft survival was 5 months after PCR-AR.



Compared to a cohort of 29 kidney recipients with AMR (all C4d+ and matched for time to rejection), allograft survival in PCR-AR was significantly worse whether they were C4d positive or not.

Conclusions: Plasma cell rich AR has an inferior allograft outcome compared to AMR.

SA-PO2494

Potential Role of Alternatively Activated Macrophages in Chronic Allograft Nephropathy Yohei Ikezumi,[1] Toshiaki Suzuki,[1] Tamaki Karasawa,[1] Hiroya Hasegawa,[1] Masanori Hara,[2] Toshio Yanagihara,[2] David J. Nikolic-Paterson,[3] Makoto Uchiyama.[1] *[1]Department of Pediatrics, Niigata University Medical and Dental Hopital; [2]Department of Pediatrics, Yoshida Hospital, Niigata-City, Japan; [3]Monash University Department of Medicine, Monash Medical Centre, Clayton, Victoria, Australia.*

Background: Interstitial fibrosis is an important mechanism in chronic allograft nephropathy (CAN). Macrophages with an alternatively activated phenotype (M2) have been implicated in promoting fibrosis in non-inflammatory kidney diseases, including cyclosporine toxicity. This study examined the possible involvement of M2-type macrophages in CAN.

Methods: A total of 30 biopsy sections from 14 children who underwent kidney transplantation were stained for α-smooth muscle actin (αSMA), CD68 (total macrophages), CD163 (M2 marker) and CD3 (T cells). Urinary CD163 excretion was assessed by ELISA.

Results: None of the patients examined had a history of clinical symptoms of rejection. At the time of biopsy, all patients were on maintenance immunosuppression therapy, including methylprednisolone, mycophenolate mofetil, cyclosporine and/or tacrolimus. Immunostaining identified a significant increase in interstitial fibrosis with accumulation of CD68+ macrophages. Dual immunofluorescence staining showed that most interstitial CD68+ macrophages also expressed CD163, indicating an M2 phenotype. CD163+ cells were frequently localized to areas of interstitial fibrosis and there was a significant correlation between the number of interstitial CD163+ cells and the degree of interstitial fibrosis ($r=0.71$, $p<0.0001$), and between interstitial fibrosis and estimated GFR ($r=-0.79$, $p<0.0001$). There was also a significant correlation between interstitial fibrosis and the time from transplantation to biopsy. Although CD3+ T cell infiltration was also observed in some patients, there was no relationship with macrophage accumulation or fibrosis. Urine CD163 levels correlated with the number of interstitial CD163+ cells ($r=0.51$, $p<0.01$).

Conclusions: Our findings identify a major population of M2-type macrophages in patients with CAN, and suggest that these M2-type macrophages may promote the development of interstitial fibrosis in CAN.

SA-PO2495

Peritubular Capillaritis in Renal Biopsies of Early Acute Rejection Episodes Hanneke De Kort,[1] Marian C. Van Groningen,[1] Marko J. Mallat,[1] Natascha Goemaere,[2] Johan W. De Fijter,[1] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Leiden University Medical Center; [2]Pathan Foundation Rotterdam.*

Background: A consensus for the ptc-score was reached at the Banff Conference in '07, although it was emphasized that it did not equate with any specific diagnosis, and ongoing reproducibility and diagnostic studies were required. The ptc-score involves the scoring of cortical peritubular capillaries for capillaritis (defined as luminal inflammation by neutrophils, monocytes/macrophages, and lymphocytes). We assessed clinical relevance and inter-observer agreement of the ptc-score.

Methods: We reviewed all 723 patients who received a renal transplant in our center from '95-'06. 122 patients who had a histologically proven first acute rejection episode within 6 mo after transplantation according to the Banff '08 working proposal for classification were included. Mean follow-up was 7.3 yrs (+/-3.9). In Kaplan-Meier survival analyses, time to graft failure and patient death were assessed for the combined ptc grades 0&1 versus 2&3 and for mononuclear versus mixed ptc-infiltrate. All Banff components were scored by 2 pathologists. Ptc-score was according to the Banff '07 report and scored by 2 pathologists independently.

Results: The inter-observer agreement on several aspects of the ptc-score gave poor to fair κ results. The dichotomized ptc-score gave a fair κ of 0.231 ($p=0.004$). Difficulties in identifying peritubular capillaries, especially in areas with vast infiltrates, probably lie at the basis of the inter-observer discrepancy. Ptc-grading was associated with interstitial infiltrate (OR 2.9 [CI 1.1-7.6], $p=0.029$) and the total inflammation-score (OR 7.5 [CI 2.7-20.3], $p=0.001$). Ptc grading did not correlate with C4d staining (performed on frozen tissue samples). Ptc grading did not predict for graft outcome. However, both ptc grades 2&3 and a mixed composition of the infiltrate were associated with worse patient survival.

Conclusions: In this study, ptc correlates with interstitial and total inflammation scores, and in itself, correlates with worse patient survival. To improve the applicability in clinical pathological analyses, we propose a reduction in the components of the ptc grading scheme.

SA-PO2496

Morphometric Quantitation of Interstitial Fibrosis and Peritubular Capillary Density in Renal Allograft Biopsies with Transplant Glomerulopathy Kuang-Yu Jen, Sindhu Chandran, Flavio G. Vincenti, Zoltan G. Laszik. *University of California San Francisco, San Francisco, CA.*

Background: Loss of peritubular capillaries (PTCs) is considered to play an important role in chronic antibody-mediated rejection (AMR) of renal allografts. However, the precise relationship between the severity of interstitial fibrosis (IF) and the degree of PTC loss has not been well-established. The objective of our study is to evaluate the relationship of PTC density and the degree of IF in C4d-positive and C4d-negative renal allograft biopsies with chronic AMR in the form of transplant glomerulopathy (TxGP).

Methods: C4d-positive (n=12) and C4d-negative (n=21) renal allograft biopsies with TxGP were examined in this study. Paraffin sections were stained with a mixture of anti-CD34 and anti-collagen type III primary antibodies followed by incubation with a mixture of fluorescein isothiocyanate (FITC)-labeled and Texas Red-labeled secondary antibodies. Digital images of multiple cortical fields were taken from each double-stained slide at 10x magnification under immunofluorescence microscopy. The images were processed using the ImageJ software to calculate the cortical fractional area of collagen and CD34 positivity. Glomeruli and large vessels were excluded from the analysis.

Results: Strong and specific staining for CD34-positive PTCs and interstitial collagen was achieved. Comparing cortical fractional area of collagen positivity to CD34 positivity for C4d-negative and C4d-positive cases indicated a correlation coefficient of -0.84 and -0.67, linear regression slope of -0.58 and -0.39, and R-squared values of 0.70 and 0.45, respectively. A few C4d-positive biopsies show disproportionately low PTC density, which contributed to a less steep slope by linear regression and a lower correlation coefficient and R-squared value.

Conclusions: Morphometric analysis using immunofluorescence staining for collagen type III and CD34 provides precise quantitative measurements of IF and PTC density, respectively. In allograft biopsies with TxGP, there is an inverse relationship between IF and PTC density independent of C4d status.

SA-PO2497

Histologic Assessment of Renal Transplant Biopsies Using Whole Slide Digital Images Kuang-Yu Jen,[1] Jean L. Olson,[1] Tibor Nadasdy,[2] Zoltan G. Laszik.[1] *[1]Pathology, University of California San Francisco, San Francisco, CA; [2]Pathology, Ohio State University, Columbus, OH.*

Background: Whole slide digital image technology allows histologic evaluation of pathologic specimens on digitally scanned slides for diagnostic purposes. However, there are no data documenting the feasibility of such technology in the field of renal transplant (Tx) pathology. The purpose of our study was to assess the diagnostic accuracy of evaluating digital whole slide scans of kidney Tx biopsies as compared to conventional microscopic evaluation of glass slides.

Methods: Twenty-five kidney Tx biopsies demonstrating a spectrum of pathologic changes were evaluated by four well-trained renal pathologists. Each case included one H&E and one PAS-stained section, which were scanned using the Aperio ScanScope Scanner. Each pathologist evaluated each case twice, on separate occasions: once using a microscope to view the glass slides and once using the digital scans viewed on a computer monitor. The cases were coded to minimize bias. Thirty-one pre-specified features, most of which are Banff scores, were categorically scored by each pathologist for both the conventional slides and the digital scans. Intra-observer reliability was assessed using linearly-weighted Cohen kappa coefficient. Inter-observer reliability for conventional glass slides was evaluated using linearly-weighted Fleiss kappa coefficient.

Results: Mean intra-observer kappa coefficients (range from 0.59 to 0.94) were generally higher than inter-observer kappa coefficients (range from 0.16 to 0.66) for thirty features evaluated. This finding indicates that intra-observer reliability in scoring morphologic features is higher than inter-observer reliability. Detection of oxalate crystals was suboptimal on digital slides. The average time spent on examining digital scans was approximately 1.5 times greater than that spent on conventional glass slides.

Conclusions: Digital scans of histologic sections for the evaluation of renal Tx biopsies appear to be a reliable approach for diagnostic purposes. One significant drawback of digital scans is that they are more time-consuming for pathologists to fully evaluate.

SA-PO2498

Pediatric Kidney Transplantation into Adults; a Biopsy Review Hae Yoon Grace Choung,[1] Suzanne Meleg-Smith.[2] *[1]Debakey Scholars Program, Tulane University School of Medicine, New Orleans, LA; [2]Pathology, Tulane University School of Medicine, New Orleans, LA.*

Background: Although the good clinical outcome of single pediatric-donor-graft (PedDG) renal transplantation has been shown at several institutions, including Tulane (*Zhang et al, Clin J Am Soc Nephrol, 2009*), there are only scant descriptions of the post-transplantation graft biopsy (bx) in these recipients.

Methods: During a period of 11 years (1998-2009), single kidneys from donors aged 1 to 9 years were transplanted into 105 recipients.

Results: To investigate the graft pathology in PedDG , we studied the 54 PedDG recipients who had 101 "for cause" graft bx , obtained between 3 and 5840 post transplant days. As control, we randomly selected 50 adult-donor graft (ADG) recipients with 79 "for cause" bx during the same period. Immunohistochemistry (IF) had been performed in 39 PedDG and in 47 ADG bx.

Results:

Table 1 - Diagnosis	PedDG bx n=101		ADG bx n=79	
Acute tubular necrosis	12	12%	15	19%
Acute T-cell mediated rejection	32	32%	19	24%
Transplant glomerulopathy	7	7%	4	5%
Calcineurin inhibitor toxicity	5	5%	2	2.5%
TMA	10	10%	3	4%
Infectious interstitial nephritis	8	8%	5	6%
BKV nephritis	2	2%	3	4%
Vascular event	1	1%	2	2.5%

Table 2 – IF	PedDG recipients		ADG recipients	
Acute antibody mediated rejection	5/30	17%	10/47	21%
Immune complex (IC) mediated GN *	9/39	23%	1/32	3%
* p value is < 0.05				

Table 3 - Post tx interstitial fibrosis	< 3 months		3 to12 months		> 12 months	
	PedDG	ADG	PedDG	ADG	PedDG	ADG
Mild: < 25%	1/36	4/31	2/31	4/24	4/43	8/25
Moderate: 25-49%	0	1/31	3/31	8/24	7/43	3/25
Severe: >50%	0	1/31	3/31	3/24	9/43	11/25

Table 4 - Diagnosis	PedDG recipients n=54		ADG recipients n=50	
Focal Segmental Glomerulosclerosis	12	22%	12	24%
Diabetic nephropathy	2	4%	1	2%

Conclusions: Detailed study of a series of 180 "for cause" post transplantation renal bx shows a statistically significant increased incidence of IC mediated GN in recipients of single PedDG as compared to ADG.

SA-PO2499

Extracapillary Proliferation as an Independent Predictive Factor in IgAN Konstantinos Giannakakis,[1] Rosaria Polci,[2] Ilaria Serriello,[3] Antonietta Gigante,[3] Margherita Rosa,[5] Sandro Feriozzi,[2] Marco Galliani,[4] Massimo Morosetti,[6] Francesco Pugliese,[3] Tommasangelo Petitti,[8] Andrea Onetti-Muda.[7] *[1]Pathology, S, Rome, Italy; [2]Nephrology, Bellcole Hospital, Virerbo, Italy; [3]Clinical Medicine, Rome, Italy; [4]Nephrology, Pertini Hospital, Rome, Italy; [5]Nephrology, San Camillo Hospital, Rome, Italy; [6]Nephrology, G.B. Grassi Hospital, Ostia, Italy; [7]Pathology, Campus Biomedico University, Rome, Italy; [8]Data Analysis, Campus Biomedico University, Rome, Italy.*

Background: The predictive value of the Oxford calssification histological lesions in IgAN has been validated; attention has been placed on its predictive value of the decline of renal function. The aim of our work was to correlate active glomerular lesions at biopsy and progression of renal damage.

Methods: We have studied 473 renal biopsies with diagnosis of IgAN; of these, 184 had availability of clinical data at follow-up (sCr and eGFR by CKD-EPI formula) up to a maximum of 25 years. The median age at diagnosis was 36.7 years; 70% of patients were males. Histological parameters were from the Oxford classification (mesangial and endocapillary proliferation, segmental glomerulosclerosis, tubular atrophy, extracapillary proliferation, interstitial fibrosis) and in addition glomerular fibrinoid necrosis. Data were analyzed by univariate and multivariate investigation, according to linear regression of longitudinal data, taking into account the distance between time of biopsy and time points of acquisition of clinical data.

Results: Statistical analysis showed a correlation between progression of renal damage (eGFR) and segmental glomerulosclerosis (p=0.001), cellular crescents (p=0.01), fibrous crescents (p=0.02), fibrinoid necrosis (p=0.04) and interstitial fibrosis (p=0.03); no correlation was evident with fibrocellular crescents and endocapillary proliferation.

Conclusions: Our preliminary results suggest that active glomerular lesions, such as cellular crescents and fibrinoid necrosis, correlate with decline of renal function, differently from the Oxford classification. These histological parameters should therefore be taken into account to classify histologically cases of IgAN, and for the appropriate treatment.

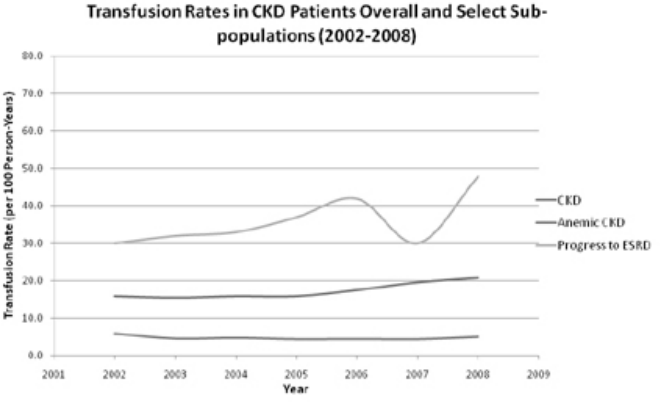
SA-PO2500

Red Blood Cell (RBC) Transfusion Rates among Young, Commercially Insured Chronic Kidney Disease (CKD) Patients Karminder S. Gill,[1] Jeffrey Petersen,[1] Paul Muntner,[2] Richard A. Lafayette,[3] Sai Ram Reddy Keithi Reddy,[1] Jeffrey C. Fink,[4] David T. Gilbertson,[5] Brian D. Bradbury.[1] *[1]Amgen, Inc., Thousand Oaks, CA; [2]Dept of Epidemiology, U. of Alabama, Birmingham, AL; [3]Div of Nephrology, Stanford U. School of Medicine, Palo Alto, CA; [4]Dept of Medicine, U Maryland, Baltimore, MD; [5]Chronic Disease Research Group, Minneapolis, MN.*

Background: The rate of RBC transfusions among older CKD patients not on dialysis has been estimated at 15-25%, but there is scant data among younger CKD patients.

Methods: We used data from the Ingenix medical claims database, a large, geographically diverse database of ~40 million commercially insured US individuals (2002-2008). We identified yearly cohorts of patients 18-64 years of age diagnosed with CKD; we required patients to have 1 yr of data available before diagnosis to characterize each cohort. We followed each cohort for 1 yr to estimate the RBC transfusion rates, using Poisson regression.

Results: We identified 144,100 CKD patients (range: 15,565 in 2002 up to 28,013 in 2008); 57% were 50-64 years of age; 46% were female. Comorbidities were common: hypertension (54%), diabetes (33%), hyperlipidemia (31%), and coronary artery disease (18%), and 23% were diagnosed with anemia. Overall, the transfusion rate was 4.0/100 person-years (PYs) (95% CI: 3.9-4.1). Rates were noticeably higher among those with diagnosed anemia (14.1/ 100 PYs[95% CI: 13.6-14.5]) and were highest among those who progressed to end stage renal disease (ESRD) (30/100 PYs [95% CI: 26-35]).



Conclusions: RBC transfusions are not uncommon among young, commercially insured anemic CKD patients, particularly those transitioning to ESRD. The risk of allosensitization and its effects on renal transplantation needs to be considered in patients who are likely to transition to ESRD.

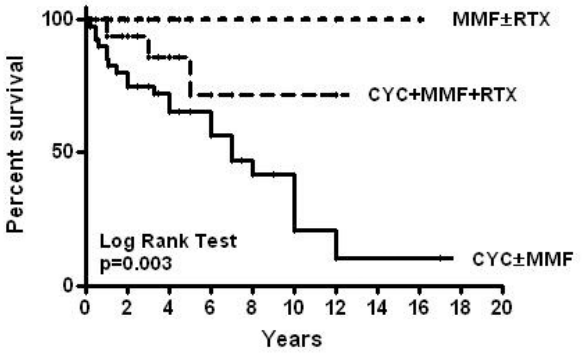
SA-PO2501

Rituximab Use in Childhood Onset Lupus Nephritis: "Early Versus Late" Tanya E. Pereira, Carolyn L. Abitbol, Chryso P. Katsoufis, Wacharee Seeherunvong, Jayanthi Chandar, Michael Freundlich, Gaston E. Zilleruelo. *Pediatric Nephrology, University of Miami/Holtz Children's Hospital, FL.*

Background: Rituximab, a monoclonal anti-B cell antibody, is increasingly used as adjuvant treatment of rheumatoid arthritis and sporadic cases of systemic lupus nephritis (LN). No large experience in children has been reported. The aim of our study was to examine renal survival in a cohort of patients with childhood onset LN treated with sequential treatment regimens of intravenous Cyclophosphamide (CYC), mycophenolate mofetil (MMF) and Rituximab (RTX).

Methods: A retrospective analysis was performed on 78 patients with childhood onset severe LN (≥WHO Class 3) over 25 years. This largely non-white (56% African American, 29% Hispanic) cohort was stratified into 3 "Eras" according to the introduction of RTX as a new adjuvant medication: Baseline Era1 (N=41): CYC±MMF; Era2 (N=16): CYC+MMF+RTX; Era3 (N=21): MMF±RTX. Histological biopsy classification was similar across all groups.

Results: Average period of follow-up was 6±4 years. Median renal survival for the cohort was 10 years. In Era1, the median renal survival was 7 years. Renal survival improved with the addition of RTX in Era2 as "salvage therapy" in 16 refractory patients. Era3 marked the early use of RTX with MMF as induction therapy. None of these patients has experienced renal demise with a median follow-up of 3.3 years (range 1 to 16 years). Three patients in the entire cohort expired, 1 in Era1 and 2 in Era2. The overall five year patient survival was 96% for the entire cohort. One patient who received RTX expired but her death was not attributed to the medication.



Conclusions: Our data suggest that the early use of RTX as adjuvant induction therapy may improve short term renal survival. Confirmation of its efficacy and safety in children will require controlled treatment trials.

SA-PO2502

Clinical Impact of LDL-C to HDL-C Ratio in Association with CKD Yoshinari Yasuda,[1] Kiyoshi Shibata,[1] Sadao Suzuki,[2] Sawako Kato,[1] Shoichi Maruyama,[1] Enyu Imai,[1] Seiichi Matsuo.[1] *[1]Nephrology/CKD Initiatives, Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Nagoya City University, Nagoya, Japan.*

Background: Chronic kidney disease (CKD) has been increasingly highlighted as a serious risk factor for cardiovascular diseases (CVD). Dyslipidemia plays important role in both CKD and CVD onset and progression through atherogenesis. Low-density lipoprotein cholesterol (LDL-C) to high-density lipoprotein cholesterol cholesterol (HDL-C) ratio (LHR) was reported as a promising predictor for CVD and mortality, but it has not been fully elucidated in association with CKD. In this study, we analyzed the relationship between the LHR and CKD.

Methods: The study subjects were 3,983 men and 3,742 women, who underwent health check in Kasugai City Medical Care Center in 2008. Patients under treatment for dyslipidemia were excluded from the study. Estimated GFR (eGFR) was calculated by the Japanese eGFR equation, and cases with eGFR less than 60 mL/min/1.73m² and/or with proteinuria were diagnosed as CKD. LDL-C and HDL-C were measured directly by enzymatic method and LDL-C was divided by HDL-C for LHR. Multivariate odds ratios of LHR (> 1.5), LDL-C (≥ 140 mg/dL) and HDL-C (≤ 40 mg/dL) were calculated for CKD using logistic regression adjusted for age and sex. Average eGFR values were compared in the quartile for LHR, LDL-C and HDL-C.

Results: Among CKD subjects, LHR and LDL-C were significantly higher and HDL-C was significantly lower compared to non-CKD. Odds ratios for CKD increased significantly as LHR category advanced.

Odds ratio for CKD

LHR	OR	95% CI
1.5≥	1.00	reference
1.51 - 2.50	1.42	1.21 - 1.68
2.51 - 3.50	1.64	1.36 - 1.97
3.51≤	2.15	1.67 - 3.05

Multivariate analysis revealed that LHR but LDL-C or HDL-C was a significant risk factor for CKD. In quartile analysis, average eGFR values (mL/min/1.73m²) decreased in order in LHR (Q1: 76.83, Q2: 73.56, Q3: 72.58, Q4: 70.94), LDL-C (Q1: 76.01, Q2: 73.78, Q3: 72.43, Q4: 71.79) and HDL-C (Q1: 74.85, Q2: 74.76, Q3: 73.20, Q4: 71.17), but the best difference was observed in LHR.

Conclusions: LHR revealed stronger association with CKD than LDL-C or HDL-C, suggesting the importance of well-balance of LDL-C and HDL-C to prevent arteriosclerosis.

Increased Risk of Kidney Cancer in Young Men with Moderately Impaired Renal Function after a Long Follow-Up in a Large, Population-Based Cohort Anders G. Christensson. *Nephrology and Transplantation, Clinical Sciences, Malmö, Sweden.*

Background: There are reports that impaired renal function increases the risk of cancer. We evaluated whether moderately impaired renal function influenced risk of developing cancer in a large, population-based cohort.

Methods: We used data from Malmoe Preventative Medicine Project, a large, population-based cohort (74% participation) containing demographic data and blood samples collected from 33,346 persons aged 33-50 during 1974-86 in Malmoe, Sweden. Incident cancers were identified from the Swedish Cancer Registry, updated to 12/31/2006. Median follow-up time was 28 years. Glomerular filtration rate (GFR) was estimated using the Modified Diet and Renal Disease formula. Patients were classified as having normal kidney function and mild kidney disease (GFR >90 and ≥60-90 mL/min/1.73m2) or moderate kidney dysfunction (GFR<60 mL/min/1.73m2). Males and women were divided into older men (age 60), younger men (age 40-52), older women (age 47-57) and younger women (age 35-43). We calculated the risk of developing cancer using the competing risks regression to account for the competing risk of death from other causes after a follow-up of 20 years. Adjustment for age was conducted. We also evaluated the risk of cardiovascular events.

Results: The representativeness of the study population was seen in the significantly increased risk of cardiovascular events among persons with GFR <60 mL/min/1.73m2 for both males and females. 6,595 participants were diagnosed with cancer. The median age at baseline was 47 (IQR 40, 49). 22,183 (69%) participants were male; prostate cancer was the most common cancer diagnosis (n=1,579). Most subjects had mild kidney disease (n=22,336; 70%), 27% (n=8,621) had normal renal function and 1242 subjects GFR <60 mL/min/1.73m2 . We found no significant increase in cancer incidence among those with GFR <60 vs ≥60 mL/min/1.73m2. There was an increased risk for kidney cancer in young men with <60 vs ≥60 mL/min/1.73m2 (SHR: 2.38; 95% CI: 1.05, 5.44; p=0.039).

Conclusions: Among young men we found an increased risk of kidney cancer in those with moderately impaired renal function after a long follow-up.

SA-PO2504

Cost-Effectiveness of Statins for Primary Cardiovascular Prevention in Chronic Kidney Disease Kevin F. Erickson,[1,2] Sohan Japa,[2] Arjun S. Adhikari,[2] Joshua Glucoft,[2] Glenn M. Chertow,[1] Alan M. Garber.[2] *[1]Nephrology, Stanford University School of Medicine, Palo Alto, CA; [2]Center for Primary Care and Outcomes Research, Stanford University, Stanford, CA.*

Background: Patients with chronic kidney disease (CKD) have a high risk of myocardial infarction (MI) and stroke compared to the general population. Although statins are effective at preventing cardiovascular (CV) disease in patients with CKD, guidelines give conflicting recommendations about statin use in CKD. This study assesses the cost-effectiveness of statins for primary prevention of cardiovascular disease in patients with hypertension and CKD.

Methods: A decision analytic model was constructed to evaluate the costs and benefits of statin use in preventing MI and stroke in patients with CKD, without CKD, and with varying assumptions about CKD progression. An increased absolute risk reduction from statins in CKD was modeled along with higher costs, increased morbidity and mortality, increased incidence of adverse events, and varying treatment effects associated with CKD. A separate micro-simulation model determined progression between CKD stages. The primary outcome was the incremental cost-effectiveness ratio (ICER) associated with statin therapy.

Results: In the base case, a 65 year old male with hypertension and stage 3 CKD, statin therapy increased costs by about $5,000 and led to a gain of 0.10 QALYs. The ICER from statins was about $50,000/QALY in the base case, similar in magnitude to the cost-effectiveness estimated from an identical cohort without CKD. Statins were more cost-effective in patients whose CKD did not increase in severity.

Conclusions: Statins can lead to large absolute reductions in CV disease in CKD patients, due to their high underlying risk of cardiac events. These gains are partially offset by an elevated risk of adverse events and decreased length and quality of life CKD patients can expect, independent of CV disease. The cost-effectiveness of Statins in CKD is sensitive to CKD progression, suggesting Statins would be cost-effective at a willingness to pay threshold of $50,000/QALY in a wide range of patients with stable (i.e., non-progressive) CKD.

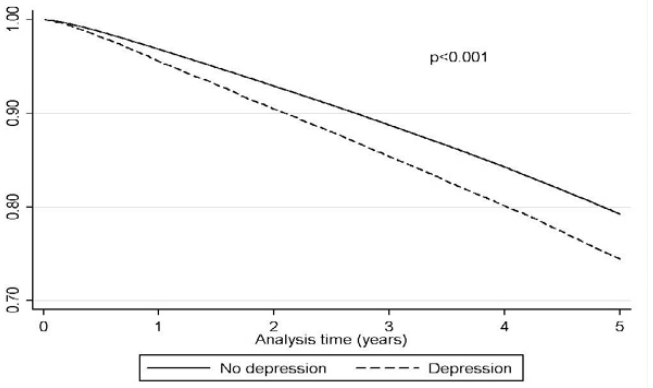
SA-PO2505

Association of Depression, Severity of Non-Dialysis Dependent CKD and Mortality in US Veterans Rasheed A. Balogun,[1] Emaad M. Abdel-Rahman,[1] Seki A. Balogun,[1] Evan H. Lott,[3] Jun Ling Lu,[3] Sandra M. Malakauskas,[2] Jennie Z. Ma,[1] Mark D. Okusa,[1] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[1,2] *[1]U of Virginia; [2]Salem VAMC; [3]VA Inf&Com; [4]Harbour-UCLA.*

Background: Depression (D) is known to be associated with higher mortality in ESRD patients. Less information is available in earlier stages of CKD

Methods: We examined association of D with all-cause mortality in 657,614 US veterans with CKD stages 1-5. Associations of D with all-cause mortality and stratified by CKD stages were examined with Kaplan Meier method,in fixed effect and time-dependent Cox models. Models were adjusted for sociodemographics, comorbidities, blood pressure and laboratory variables

Results: Patients were 73.9±9.8 yrs, 97% male and 71% white. There were 37,032 patients (5.6%) with D (67.1±11.3 years, 93% males and 71% white, with eGFR 54±17 ml/min) in 2005-2006. D was more common in patients with CKD 1 (13%) than in patients with CKD 2 (9%), 3A (6%), 3B (5%), 4 (4%) and 5 (4%). Patients with D were younger, more likely to be female, not married, lack insurance and had higher prevalence of comorbidities. During a median follow-up of 4.8 yrs, 189,561 patients died (mortality rate, 95% CI: 67.3/1000 patient yrs, 67.0-67.6). D was associated with higher age-adjusted mortality (Haz.ratio (95%CI): 1.31 (1.30-1.32) p<0.001, which was, however, attenuated after multivariable adjustments (1.00, 0.97-1.03 p=0.9).



Associations between D and mortality were similar in patients with different stages of CKD except those with CKD 1, in whom D remained significantly associated with mortality after multivariable adjustments (1.18, 1.02-1.36; p=0.02)

Conclusions: Patients with CKD 1 had higher prevalence of depression and showed a significant association with mortality than those with more advanced CKD. Screening, diagnosing and treating depression may have the maximum impact if done in earlier stages of CKD.

SA-PO2506

Abnormal Nitric Oxide Metabolism, Prothrombic State, Impaired Angiogenesis and Risk of Chronic Kidney Disease Jing Chen, L. Lee Hamm, Myra A. Kleinpeter, Fred E. Husserl, Islam Enver Khan, Federico Teran, Grace Browne, Chung-Shiuan Chen, Yanxi Liu, Katherine T. Mills, Eva Lustigova, Ji Hua Xu, Stephanie E. Rogers, Joseph Tarsia, Kamal Ramesh Shah, Chuan He, Arnold B. Alper, Eric E. Simon, Jiang He. *Tulane University.*

Background: Endothelial dysfunction is frequently observed in patients with chronic kidney disease (CKD). The underlying mechanism is not fully understood.

Methods: We investigated the association of endothelial dysfunction biomarkers in the nitric oxide pathway [asymmetric dimethylarginine (ADMA), and L-arginine], thrombosis [von Willebrand factor (vWF)], and angiogenesis (endostatin) with the risk of CKD in 201 CKD patients and 201 controls without CKD.

Results: Compared to those without CKD, patients with CKD were older (56 vs. 53 yrs), more likely to be male (55% vs. 45%), less likely to have high school education (59% vs. 82%), or consume alcohol (28% vs. 59%). Race and cigarette smoking were comparable between CKD patients and controls. Mean systolic blood pressure (132 vs. 122 mmHg), body mass index (32 vs. 29 kg/m^2), fasting glucose (120 vs. 103 mg/dL), history of hypertension (88% vs. 24%), history of diabetes (49% vs. 6%), and CVD (44% vs. 7%) were higher while LDL cholesterol (102 vs.118 mg/dL) was lower in CKD patients than in controls. After adjustment for above risk factors, the median [inter-quartile range(IQR)] of ADMA [0.58 µmol/L (IQR, 0.55-0.62) vs. 0.27 µmol/L (IRQ, 0.27-0.30), p<0.0001], L-arginine [71.39 µmol/L (IQR, 67.06-75.73) vs. 33.08 µmol/L (IRQ, 28.77-37.38), p<0.0001], vWF [1321.29 mU/mL (IQR, 1244.02-1398.57) vs. 1157.54 mU/mL (IRQ, 1080.53-1234.55), p=0.01], and endostatin [277.15 ng/mL (IQR, 259.55-294.76) vs. 142.18 ng/mL (IRQ, 124.63-159.73), p<0.0001] were higher in CKD patients than in controls.

Conclusions: These data indicate that abnormal nitric oxide metabolism, prothrombic state, and impaired angiogenesis are associated with risk of CKD.

SA-PO2507

Untreated Bacteriuria, Cardiovascular Events, and Death among Female Patients with CKD Susmitha Dhanyamraju,[1] Michael Foltzer,[2] Xiaoqin Tang,[3] H. Lester Kirchner,[3] Robert M. Perkins.[1,3] *[1]Nephrology, Geisinger Medical Center; [2]Infectious Diseases, Geisinger Medical Center; [3]Center for Health Research, Geisinger Medical Center.*

Background: Untreated bacteriuria may trigger local and systemic inflammatory responses. This study examined the relationship between untreated UTI and *de novo* CV events and death among female patients with CKD.

Methods: A retrospective cohort of female patients receiving care between 2004 and 2010 at a tertiary health care system in Central Pennsylvania and with stages 1-4 CKD was established. Patients with a prior history of MI, CHF, or stroke were excluded. Study exposure was a positive urine culture (bacterial growth of ≥ 100,000 CFU/ml) without an antibiotic prescription within 90 days of culture order. Adjusted Cox models were developed to estimate the association between infection (treated and untreated) and time to first CV event (composite of MI, CHF, and stroke), and time to death. Models account for cumulative episodes of UTI during follow up.

Results: 6807 patients (81.8% without UTI, 7.9% with only treated UTI(s), 7.6% with only untreated UTI(s), and 2.7% with both treated and untreated UTIs) met criteria. Median (IQR) follow up was 5.2 (3.4, 5.9) years. Mortality rates were 22.8, 29.9, and 44.3 deaths/1000 PY in the no-UTI, treated-UTI, and untreated-UTI groups, respectively.

Cox PH models for time to death and first CV event, by treatment status

Death			
		HR (95% CI)*	**p-value**
Unadjusted	Treated UTI(s)	1.31 (1.03, 1.66)	0.03
	Untreated UTI(s)	1.94 (1.57, 2.38)	<0.001
Fully Adjusted**	Treated UTI(s)	0.81 (0.63, 1.05)	0.1
	Untreated UTI(s)	1.42 (1.15, 1.76)	<0.001
CV Event (MI, CHF, Stroke)			
		HR (95% CI)*	**p-value**
Unadjusted	Treated UTI(s)	3.68 (2.95, 4.59)	<0.001
	Untreated UTI(s)	3.56 (2.53, 4.78)	<0.001
Fully Adjusted**	Treated UTI(s)	2.11 (1.66, 2.69)	<0.001
	Untreated UTI(s)	2.01 (1.58, 2.57)	<0.001

*Reference group: no UTI (n = 5559). **Model adjusted for age, race, CKD stage at baseline, Charlson score, hyperlipidemia, diabetes, hypertension, peripheral vascular disease, history of cancer, COPD, connective tissue disease, and hospitalization during follow up

Conclusions: Untreated UTIs among female patients with CKD may increase the risk of CV events and death.

SA-PO2508

Serum Creatinine Is Associated with Carotid Intima-Media Thickness in Males: Results of a Population-Based Study (SHIP) Sylvia Stracke,[1] Friedlinde Ernst,[1] Daniel Robinson,[2] Christian Schwahn,[3] Ulrich John,[3] Stephan Felix,[2] Henry Voelzke.[3] *[1]University Medicine Greifswald, Nephrology, Germany; [2]University Medicine Greifswald, Cardiology, Germany; [3]University Medicine Greifswald, Institute of Epidemiology and Social Medicine, Germany.*

Background: Chronic kidney disease (CKD) remains asymptomatic until its late stage. There is only little information on the association of renal function with subclinical atherosclerosis as depicted by carotid intima media thickness (cIMT). The aim of the present study was to examine the association of cIMT with various serum markers of renal function in a large population based study.

Methods: The Study of Health in Pomerania (SHIP) is a cross-sectional, population based study in the North East of Germany. Data from 2367 individuals (1199 males) aged 45 years or older were available for analysis. Creatinine clearance was calculated by the Cockroft-Gault, Jelliffe, Wright and the abbreviated Modification of Diet in Renal Disease formulae. Women and men were analyzed separately.

Results: 240 males (20.0%) and 244 females (20.9%) showed serum creatinine values above the normal range. Males and females with high serum creatinine had higher serum HbA_1C levels, pulse pressure, BMI, and serum uric acid levels. After adjusting for confounding factors, multivariable analysis revealed that in males, raised serum creatinine levels were independently associated with carotid IMT (non-standardised ß-coefficient 0.0274, 95% CI 0.005-0.050, p= 0.018). However, we could not find an association for raised serum creatinine levels in women nor for reduced values of calculated creatinine clearances in either sex.

Conclusions: We found a gender-specific relation between impaired renal function measured by serum creatinine and cIMT. With rising serum creatinine, the exponential relationship between creatinine and eGFR leads to relatively higher increases in serum creatinine for each mL loss of GFR and thus creatinine in already established renal failure may be more sensitive biomarker for renal function than eGFR.

SA-PO2509

The Association of Stage of CKD and Hemoglobin A1C in a Diabetic Primary Care Population Bessie A. Young,[1,2,3] Margaret K. Yu,[2] Courtney R. Lyles.[3] *[1]Division of Nephrology, VA Puget Sound Health Care System, Seattle, WA; [2]Division of Nephrology, University of Washington, Seattle, WA; [3]Health Services, University of Washington, Seattle, WA; [4]Kidney Research Institute, University of Washington, Seattle, WA.*

Background: Hemoglobin A1C (A1C) levels decrease as estimated glomerular filtration rate (eGFR) declines. Few studies have detailed the decline in glycemic control as a function of chronic kidney disease (CKD) stage. We determined differences in baseline A1C values as a function of CKD stage.

Methods: The Pathways Study is a prospective cohort study of diabetic patients at a large managed care health maintenance organization. Baseline laboratory data were extracted from linked automated records. EGFR was determined using the modified equation by Levy. Stage of CKD as defined by the Kidney Disease Outcomes Quality Initiative (KDOQI) guidelines. Cross-sectional associations of A1C and stage of CKD were determined by student t-test and linear regression. Association of A1C <6.5% with stage of CKD was determined by multivariable logistic regression.

Results: Of the 4842 subjects enrolled in the study, 3999 had baseline laboratory data sufficient to be included. By stage of CKD, 14% were stage 1, 35.7% stage 2, 20.0% stage 3, 10.9% stage 4, and 1.5% were stage 5. Those with late stage CKD were more likely to be older, married, African American, and to have been hospitalized in the prior year. Mean A1C levels were 7.6±1.6, 7.9±1.6, 7.8±1.5, 7.8±1.5, 7.5±1.4, and 6.4±1.4, for stages 0, 1, 2, 3, 4, and 5 respectively. Differences were significant between stages 0 to 1, 1 to 2, and 4 to 5 (p<0.02). A1C levels increased in stages 1 (β=0.31, 95% CI=0.17, 0.45) and 2 (β=0.27, 95% CI=0.10, 0.42), while they decreased in stages 4 (β=-0.40, 95% CI=0-.78, -0.02) and 5 (β=-1.80, 95% CI=-2.57, -1.03). Stage 5 CKD was associated with a 17-fold odds of A1C <6.5 (OR=17.74, 95% CI=5.54-56.76).

Conclusions: Among subjects with diabetes, A1C decreased after stage 3 CKD and was significantly below recommended guidelines by stage 5 CKD. CKD influences level of glycemic control and may increase the risk of hypoglycemic reactions among diabetic patients with CKD.

SA-PO2510

Accuracy of Race Imputation Using the BISG Method and Applicability for CKD Stephen F. Derose, Richard Contreras. *Research & Evaluation, Kaiser Permanente Southern California, Pasadena, CA.*

Background: The use of existing health plan data for studies on racial and ethnic differences is often limited by missing race data. Methods of imputation using have recently improved: the Bayesian Improved Surname Geocoding (BISG) uses US Census block group and surname to predict race, and can be modified for use of additional inputs. We tested the accuracy of BISG imputation against existing administrative health plan data and compared actual and imputed race for predicting differences in serum creatinine, which is useful for estimating GFR in CKD epidemiology.

Methods: Participants were adult members of Southern California Kaiser Permanente with an outpatient serum creatinine test from 1998-2006 (N = 1,585,983). Race data was available in 70.6% of participants. The accuracy of individual race imputation was tested using AROC. Racial differences in the first available serum creatinine were assessed using linear regression on log(serum creatinine) with adjustment for age and gender (Table 1).

Results: Race group AROC (prevalence %) were: White 0.90 (34); Hispanic 0.93 (22); Black 0.94 (9); Asian & Pac. Isl. 0.90 (5.5); Native Amer. 0.6 (0.1); Multiple 0.62 (0.1). Regression results showed very similar estimates of racial differences in serum creatinine (discrepancies ranged from 1-16%), although 95% CIs rarely overlapped.

Percent Difference in Serum Creatine vs. Whites (95% CI)

Race	Actual (Administrative)	BISG
Black	8.25 (8.13, 8.37)	8.86 (8.71-9.00)
Hispanic	-8.41 (-8.50, -8.32)	-8.49 (-8.58, -8.40)
Asian & Pac. Isl.	-7.32 (-7.47, -7.17)	-8.49 (-8.66, -8.32)
Native Amer.	-3.42 (-4.65, -2.18)	-3.30 (-5.69, -0.90)
Multiple	-1.40 (-2.46, -0.34)	-4.20 (-5.16, -3.24)
Other	-1.29 (-1.95, -0.62)	-
Unknown	-2.40 (-2.48, -2.31)	-

Conclusions: The BISG method was accurate for higher prevalence race groups. The imputation of black race was very good in our settings, which is especially helpful for estimating GFR. Missing data can be eliminated, which helps determine complete population disparities. While not a substitute for measured race, BISG is a promising method for obtaining information on racial differences in CKD from existing health plan datasets.

SA-PO2511

Obesity Is a Risk Factor for End-Stage Renal Disease and Mortality in Pre-Dialysis Patients Ellen K. Hoogeveen,[1] Nynke Halbesma,[2] Moniek C.M. de Goeij,[2] Elisabeth W. Boeschoten,[3] Friedo W. Dekker.[2] *[1]Nephrology, Jeroen Bosch Hospital, Den Bosch, Netherlands; [2]Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands; [3]Hans Mak Institute, Naarden, Netherlands.*

Background: Obesity is associated with increased mortality and decline in renal function in the general population. In contrast, obese dialysis patients may have an improved survival, the so called "obesity paradox". The aim of this study was to assess whether obesity is a risk factor for end-stage renal disease (ESRD) and mortality in chronic kidney disease stage 4-5 pre-dialysis patients with an estimated GFR <30 ml/min/1.73 m^2 not yet on dialysis.

Methods: In a prospective multi-center cohort study incident pre-dialysis patients (>18y) were included when referred to a specialized pre-dialysis outpatient clinic between 2004 and 2011 and followed until start of dialysis, transplantation, death or January 2011. We used body mass index (BMI) measured at baseline as an index of adiposity. Patients were stratified into four categories of baseline BMI: <20, 20-25 (reference), 25-30, and ≥30 (obesity) kg/m^2.

Results: A total of 473 patients were included (mean (SD): age 65y (14), men 68%, BMI 27 (6) kg/m^2, median follow-up time 1.15 years, 365 patients completed the study: 9% died and 64% started dialysis). The combined endpoint was defined as ESRD for which dialysis was needed or death on pre-dialysis care. The combined endpoint rates (95%-CI)/100py per BMI category were: 29.6 (17.4-45.4), 29.6 (24.41-35.3), 42.6 (64.6-76.2) and 46.4 (38.8-54.3). The combined endpoint rate was 1.6 times higher in patients with obesity than with a normal BMI, which corresponded with an excess rate of 16.8 ESRD-deaths/100 py. After adjustment for age, sex, smoking and history of cardiovascular disease the hazard ratios (95%-CI) for the combined endpoint by category of increasing BMI were 1.13 (0.61-2.08), 1 (reference), 1.46 (1.08-1.97), 1.52 (1.10-2.10).

Conclusions: In conclusion, pre-dialysis patients with obesity compared with patients with a normal BMI, have a 50% higher risk of ESRD or death on pre-dialysis care.

SA-PO2512

Predictive Role of Serum Cystatin C on Survival in Cardio-Surgery Patients Roberto Palumbo,[1] Annalisa Noce,[2] Michele Ferrannini,[1] Mariarita Dessì,[3] Simone Manca di Villahermosa,[2] Olga Durante,[2] Mariapaola Canale,[2] Nicola Di Daniele.[2] *[1]Nephrology and Dialysis, S. Eugenio Hospital, Rome, Italy; [2]Department of Internal Medicine, University of Tor Vergata, Rome, Italy; [3]Department of Laboratory Medicine, University Tor Vergata, Rome, Italy.*

Background: Pre-operative renal dysfunction is a known risk factor for morbidity and mortality in cardio-surgery patients. Serum Cystatin C (sCysC) is a well recognized marker of early renal dysfunction, and previous studies suggest a sCysC predictive role for cardiovascular events in the general population. To assess predictive value of pre-operative sCysC on long-term mortality in adult cardio-surgery patients.

Methods: Between November 2005 and March 2007 421 consecutive patients aged 67,72±10,76 years were admitted in our cardio-surgery department. (217 for coronary artery bypass graft, 150 for valvular prosthetic surgery, 54 for other surgical procedures). We conducted a prospective observational study evaluating all causes of long-term mortality till December 2009. At admission sCys C was dosed in all patients (normal 0.5-0.92mg/L). Patients were stratified in quartiles according to sCysC: Q1 sCys C<0,81mg/L (29 patients), Q2 sCysC 0,81-0,92mg/L (81), Q3 sCysC 0,93-1.10mg/L (29) and Q4 sCys C>1.10mg/L (282 patients). Kaplan–Meier cumulative survival curves were plotted for sCysC quartiles. Patients' cardiovascular mortality was the primary endpoint of the study.

Results: One-hundred twenty four patients (29,4%) reached the study end-point. Q3 and Q4 patients (67 and 66% 2-year actuarial survival) showed a significantly higher cumulative mortality compared to Q1 and Q2 patients (100 and 85%, respectively) (p=0,0007).

Conclusions: Serum Cystatin C may be considered a good predictor of long-term cardiovascular mortality in cardio-surgery patients.

SA-PO2513

Estimated GFR, Albuminuria, and Risk of Fracture Hospitalization in the Atherosclerosis Risk in Communities (ARIC) Study Emma K. Williams, Yingying Sang, Kunihiro Matsushita, Elizabeth Selvin, Brad C. Astor, Josef Coresh. *Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Background: Few studies have examined the association between the full range of kidney function and bone fractures. We examined the relationship of estimated glomerular filtration rate (eGFR) based on plasma cystatin C (eGFRCys) and albuminuria with incident fracture hospitalizations in the ARIC Study. The eGFR estimate based on cystatin C was used because it has a linear relationship with other adverse outcomes.

Methods: Plasma cystatin C and urine albumin:creatinine ratio (ACR) were measured in samples collected during 1996-98 (ARIC visit 4). Hospital record surveillance ascertained incident fracture hospitalizations through 2008. Cox proportional hazards models were used to estimate the linear associations of eGFRCys and ACR with fracture hospitalization.

Results: The median ACR was 3.73 (IQR 5-95 percentile 0.59-63.9) mg/g and the mean eGFRCys was 80 mL/min/1.73m2 (SD 20). During a median of 11 years of follow-up, 572 fracture hospitalizations occurred among 11,138 study participants who were aged 53-75 at visit 4. Each eightfold higher ACR was associated with a hazard ratio (HR) of 1.30 (95% CI 1.16-1.46), after adjusting for age, sex, race, cholesterol level, diabetes, history of cardiovascular disease, smoking status and systolic blood pressure.

	HR	95% CI
Higher ACR, 8-fold	1.30***	1.15 - 1.46
Lower eGFR, 30 ml/min/1.73m2	1.25***	1.09 - 1.43
Age, 10 years	2.10***	1.79 - 2.47
Female Sex	1.64***	1.36 - 1.97
Black Race	0.73*	0.58 - 0.93
Total cholesterol level, mmol/L	1.02	0.94 - 1.11
Diabetes	1.10	0.88 - 1.38
History of CVD	1.24	0.98 - 1.55
Smoking status	1.18	0.99-1.40
Systolic blood pressure	1.00	1.00-1.00

*** p<0.001, ** p<0.01, * p<0.05

In the same model, every 30 mL/min/1.73m2 lower eGFRCys was associated with an HR of 1.25 (95% CI 1.09-1.44). Both risk factors showed a linear association with no clear threshold.

Conclusions: Kidney damage, as reflected by microalbuminuria or moderately decreased GFR, is associated with increased risk of fracture in this community-based cohort.

SA-PO2514

Baseline Characteristics and Therapeutic Projects of Patients Older Than 75 Years with MDRD below 20. PSPA Investigator Group Olivier Moranne,[1] Cécile Couchoud,[2] Vincent L.M. Esnault.[1,3,4,5] *[1]Nephrology & Public Health, Hospital, Nice, France, Metropolitan; [2]REIN Registry, Biomedecine Agency, Saint Denis La Plaine, France; [3]University of Nice Sophia-Antipolis, France; [4]VIGNEAU C Service de néphrologie, CHU Rennes, France; [5]CNRS/UMR 6061Université Université de Rennes 1, France.*

Background: The Incidence of End Stage Renal Disease (ESRD) is growing in patients older than 75 years. Pre-ESRD clinical characteristics, care pathways nor outcome are well described in this population. Therefore, we set up a cohort study in this population and report the baseline characteristics.

Methods: PSPA is a multicenter prospective cohort study including patients older than 75 years with MDRD below 20 without renal replacement therapy (RRT) followed by nephrologists. 586 patients were included in 23 nephrology departments in France. Socio-demographic data, comorbidities, mobility, laboratory tests, medical treatments and therapeutic projects were collected for each patient.

Results: Baseline characteristics were as follow: mean age 82 ± 5 y/o, MDRD: 13 ± 4 mL/min/1.73m^2, 58% men, 36% diabetes, BMI 26 ± 5 kg/m^2, SBP 145 ± 22, DBP 74 ± 11 mmHg, prot/creatUratio 1 [0.1-2.0] g/g. Other comorbidities were: 31% congestive heart failure, 22% peripheral vascular disease, 10% active malignancy and 5% dementia. Most of the population was home resident (85%) and 80% could walk without help. Treatments included a median of 11 oral daily drug intakes including ACE inhibitors (44%), ESA (32%). Mean hemoglobin level was 12 ± 7 g/dL. The therapeutic projects were distributed as follows: 17% were under discussion, 43% had no planned RRT because of stable kidney function, 24% had planned RRT and 16% were not considered for RRT (half of the time by the nephrologist). The most frequent criteria for no indication for RRT by the nephrologist were dementia or cognitive dysfunction, active malignancy or denutrition and for patients older age and women.

Conclusions: In this population few patients are planned for RRT and many are considered as having a stable kidney function. Patient characteristics are different when RRT is not considered by patients or nephrologists. This cohort will be followed for 4 years.

Evaluation of a Public Health Campaign To Increase Kidney Health Awareness in a Canadian Province Krista S. Ryz,[1] Mauro Verrelli,[1] Jan Schneider,[2] Amie C. Lesyk,[2] Manish M. Sood,[1] Claudio Rigatto,[1] Paul Komenda.[1] *[1]Dept . of Medicine, University of Manitoba, Winnipeg, MB, Canada; [2]Manitoba Renal Program, Winnipeg, MB, Canada.*

Background: To evaluate the effectiveness of a Canadian province wide public health campaign in raising awareness of risk factors that can lead to kidney disease and the ability of the campaign to encourage behaviours that lead to early detection.

Methods: A multi-faceted public health campaign was undertaken in urban and rural/remote Manitoba, Canada in March, 2011. The March 2011 campaign was built on a similar advertising platform that had been executed the previous year. A variety of media were employed to reach the target audience including radio, television, newspaper, web based efforts, postcards with prescriptions, and advertising on the side of buses. We performed a pre and post campaign telephone interview omnibus survey of Manitobans 18 years of age and over in February and April 2011 respectively. Respondents were selected by random digit dialling and each respondent was asked a question to determine awareness of the campaign, and if aware, their understanding of the message. Weighting was applied to data correcting for differences between the demographics of the sample and the 2006 census data on Manitoba's population.

Results: In pre-campaign sampling, there were a total of 3,751 co-operative contacts, of which 804 completed interviews. In post-campaign sampling a total of 3,231 co-operative contacts were established of which 802 completed interviews. Overall, percentage of respondents that were familiar with the campaign increased from 7% to 25%. 30% of urban respondents were aware of the message versus 18% of those in rural/remote Manitoba. In those that recalled the campaign, there was no difference in the pre and post campaign surveys in knowledge gain including: awareness of kidney disease, risk factors that lead to kidney disease or the need for follow-up to have kidney function evaluated.

Conclusions: A public health awareness campaign increased familiarity but not knowledge gain regarding kidney disease. Further research will focus on improving knowledge gain in the general population regarding the importance of kidney health.

SA-PO2516

High Dietary Salt Intake Is Associated with a Lower Risk of Chronic Kidney Disease in US Adults Shailendra Sharma,[1] Anna Jeanette Jovanovich,[1] Kim McFann,[1] Michel B. Chonchol,[1] Jessica B. Kendrick.[1,2] *[1]Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]Denver Health Medical Center, Denver, CO.*

Background: Extrapolations from observational studies and intervention trials suggest that population-wide moderation of salt intake might reduce cardiovascular events, however, it is unclear whether dietary sodium intake is associated with chronic kidney disease (CKD).

Methods: The cross-sectional association between sodium intake and CKD was examined in 13,917 adults 18 years of age or older who participated in the National Health and Nutrition Examination Survey (NHANES 2001-2006). Dietary sodium intake was calculated from 24-hour dietary recall obtained by trained interviewers. Dietary sodium intake was evaluated in quartiles 1 through 4 (≤ 2116, 2117-3061, 3062-4267, > 4267 mg/day). The primary outcome was chronic kidney disease (CKD) defined as an estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73m^2 or eGFR > 60 mL/min with albuminuria (>30 mg/g). Multivariate logistic regression analysis was used to examine the association between dietary sodium intake and CKD.

Results: The mean (SE) age of the participants was 45(0.4) years, 73% were white, 28% had a history of elevated blood pressure and 7% had a history of diabetes. The mean (SE) dietary sodium intake and mean eGFR were 3520 ± 26 mg/day and 88.0 ± 0.60 mL/min/1.73m^2, respectively. In this cohort, 14.2% had CKD (7.3% had an eGFR <60 mL/min and 8.4% had albuminuria > 30 mg/g). After adjustment for age, sex, race, diabetes, hypertension and diuretic usage there was a significant association between higher quartiles of sodium intake and decrease odds of CKD, with adjusted odds ratios of 1.0, 0.85 (95% confidence interval [CI], 0.71 to 1.01;p=0.06), 0.77 (95% CI, 0.64 to 0.91; p=0.003), and 0.66 (95% CI, 0.54 to 0.82; p=0.0001) for quartiles 1 through 4, respectively.

Conclusions: In this population-based cohort study, higher dietary salt intake is associated with a lower risk of CKD. Clinical trials are needed to evaluate if dietary salt intake is a modifiable risk factor for CKD or kidney disease progression.

SA-PO2517

Low Dietary Potassium Intake Is Associated with an Increased Risk of Chronic Kidney Disease in US Adults Shailendra Sharma,[1] Kim McFann,[1] Anna Jeanette Jovanovich,[1] Michel B. Chonchol,[1] Jessica B. Kendrick.[1,2] *[1]Division of Renal Disease and Hypertension, University of Colorado Denver, Aurora, CO; [2]Denver Health Medical Center, Denver, CO.*

Background: Potassium intake is inversely related to blood pressure levels but the relationship between potassium intake and chronic kidney disease (CKD) has not been examined.

Methods: We performed a cross-sectional study using the National Health and Nutrition Examination Survey (2001-2006). 13,917 adult participants with dietary data were included in the analysis. Dietary potassium intake was calculated from 24-hour dietary recall. Potassium intake was examined in clinically significant categories [Low <2000, normal: 2000-4000 and high >4000 mg/day) and in quartiles 1-4 (≤ 1737, 1738-2455, 2456-3341, > 3342 mg/day). The primary outcome was CKD defined as a eGFR <60 mL/min or eGFR >60mL/min with albuminuria (>30mg/g). Multivariate logistic regression models were used to examine the association between potassium intake and CKD.

Results: The mean age and eGFR (SE) of participants was 45 ± (0.4) years and 88.00 ± 0.56 mL/min/1.73m^2. The mean (SE) potassium intake was 2760 ± 22 mg/day. After adjustment for age, sex, race, diabetes and hypertension, low potassium intake (<2000 mg/day) was associated with an increased risk of CKD (OR= 1.35,95% 1.14-1.59; p=0.0005) when compared to normal intake group. High potassium intake (>4000 mg/day) was nearly significantly inversely related to CKD (OR = 0.78, 95% 0.61-1.00, p = 0.05). When potassium intake was evaluated in quartiles, subjects in the first quartile had a 55% increased odds of CKD compared to subjects in the 4th quartile (OR= 1.55, 95% CI 1.25-1.93; p<0.0001). We also examined the relationship of combinations of potassium and sodium intake with CKD. Median intake of potassium and sodium were used to determine high and low potassium and sodium intake. Subjects with high potassium and high sodium intake had a decreased odds of CKD compared to subjects with low potassium and low sodium intake (OR=0.66, 95% CI 0.57-0.78; p<0.0001).

Conclusions: Low dietary potassium intake is associated with an increased risk of CKD. Studies are needed to examine effects of potassium on kidney disease.

SA-PO2518

Association of Common GFR-Associated SNPs with Albuminuria in Individuals of European Descent Conall M. O'Seaghdha,[1] Ming-Huei Chen,[2] Meredith C. Foster,[1] Carsten A. Böger,[3] Ian H. de Boer,[4] Anna Kottgen,[5] Afshin Parsa,[6] Murielle Bochud,[7] Wen Hong Linda Kao,[8] Caroline S. Fox.[1] *[1]NHLBI's Framingham Heart Study; [2]Boston University; [3]Regensburg University Medical Center, Germany; [4]University of Washington, USA; [5]Freiburg University, Germany; [6]University of Maryland; [7]Centre Hospitalier Vaudois, Switzerland; [8]Johns Hopkins University.*

Background: Albuminuria is an important marker of prognosis in chronic kidney disease (CKD). The presence of albuminuria predicts CKD progression and the development of end-stage renal disease. We hypothesized that single nucleotide polymorphisms (SNPs) recently identified as associated with estimated glomerular filtration rate (eGFR) and CKD might also be associated with albuminuria.

Methods: We investigated 16 eGFR/CKD-associated SNPs in a cohort of 32,324 individuals of European ancestry for their association with the urinary albumin-to-creatinine ratio (UACR) using regression analyses, adjusting for age and sex. We performed meta-analysis of results from 13 contributing cohorts using an inverse variance weighted method. We accounted for multiple testing using a false discovery rate adjustment.

Results: The minor allele of rs17319721 in the SHROOM3 gene, which is associated with lower GFR, was associated with lower UACR levels (β-coefficient for UACR -0.034, p-value 0.0002). While several additional eGFR/CKD SNPs demonstrated nominal statistical association with UACR at DAB2, UBE2Q2, STC1 and GCKR, none were significantly associated after false discovery rate adjustment (q-value range for association with UACR 0.06 – 0.30). Furthermore, alleles associated with lower eGFR tended to be associated with lower UACR levels (DAB2, UBE2Q2, and STC1) and an allele associated with higher GFR was nominally associated with higher UACR levels (GCKR).

Conclusions: Apart from the SHROOM3 locus, we observed no robust associations between eGFR-associated SNPs and UACR. These findings suggest distinct genetic components to these traits.

Health Literacy and Blood Pressure Control among Hispanic Americans with Chronic Kidney Disease: A Report from the Paso del Norte Kidney Disease Study (PNKDS) Jimena A. Blandon, Jinyi Ling, Tarek Alhamad, German T. Hernandez. *Divisions of Nephrology & Hypertension and Biostatistics & Epidemiology, Paul L Foster School of Medicine, Texas Tech University Health Sciences Center at El Paso, TX.*

Background: Health literacy (HL) refers to a patient's ability to comprehend medical instructions. Adequate HL may be important in achieving blood pressure control in CKD patients. We assessed HL levels among Hispanic patients with CKD stages 2-4. We evaluated the cross-sectional relationship between adequate levels of HL and BP control.

Methods: We enrolled patients with CKD stages 2-4 attending our nephrology clinic in El Paso, TX. Patients underwent an interview & exam. The patients' HL was measured using the short-form Test of Functional Health Literacy in Adults (s-TOFHLA) in either English or Spanish. HL was classified as inadequate for s-TOFHLA scores 0-16, marginal for 17-22, and adequate for 23-36. BP control was defined as <130/80 mmHg.

We performed logistic regression with BP control as the outcome, comparing subjects with adequate HL to subjects with inadequate/marginal HL. Analyses were stratified by gender & diabetic status and were adjusted for age, language, health insurance, income & eGFR.

Results: 245 patients were enrolled, 51% female, 91% self-identified as Hispanic, 73% had an annual income <$20,000, 61% had diabetes, the mean eGFR was 44 ml/min, the mean BP was 135/75 mmHg. 36% had a BP <130/80 mmHg. The mean HL score was 22; 52% had adequate HL & 46% had inadequate/marginal HL (8% missing).

After adjusting for age, language, insurance, income & eGFR, there was no relationship between HL adequacy & BP control among diabetic men, non-diabetic men, and non-diabetic women. Among women with diabetes (n=69), the adjusted odds ratio for BP control was 3.33 (95% CI: 1.01-11.01; p=0.048) for women with adequate HL compared to those with marginal/inadequate HL.

Conclusions: Among Hispanics with CKD, there is a high prevalence of inadequate or marginal HL and poor BP control. Among diabetic females with CKD, adequate HL is associated with a higher odds of BP control. Treating providers should be aware of patients with poor HL as they may be at risk for uncontrolled BP.

SA-PO2520

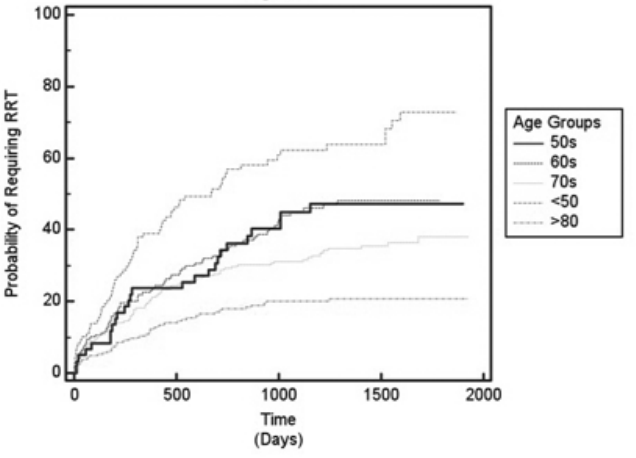
Outcome of Patients Attending Low Clearance Clinics in Northern Ireland Anil Kumar Xavier, Ying C. Kuan. *Renal Unit, Altnagelvin Hospital, Londonderry, United Kingdom.*

Background: Low clearance clinics (LCC) are designed to focus multidisciplinary care on patients with advanced renal disease, particularly in preparation for renal replacement therapy (RRT). Although studies have highlighted the high mortality in this cohort, few studies have specifically looked at the outcomes of patients entered into LCC. This retrospective study looks at the outcome of patients, specifically at RRT or death, in LCC in Northern Ireland.

Methods: Patients who entered LCC between 2006-10 were included, and followed up until 1st April 2011. Duration for RRT commencement or death was calculated. Analysis of likelihood of either outcome, depending on age category was then analysed using Kaplan-Meier method and Cox proportional hazards model.

Results: Data of 910 patients (478 males, 432 females) were analysed. The age range was 18-98 years (median age - 75). At the end of the follow up period, 324 (36%) patients had commenced RRT and 170 (18%) patients had died without receiving RRT. Using Coxs hazard analysis, the risk of death increased with age (p<0.0001), and conversely, likelihood of RRT requirement correlated negatively with age (p<0.0001). Kaplan Meier survival chart of outcome related to probability of requiring RRT is as below.

Figure 1



Conclusions: 1. The risk of dialysis requirement was highest amongst those in the youngest age group, and decreased with advancing age.

2. Conversely, the risk of death without initiation of RRT is highest amongst those in the oldest age group.

3. LCC's are beneficial for overall care of this vulnerable population group, and identified many patients at high risk of requiring RRT. Further studies in this population may allow for better targeting of therapy and resources to optimise outcome.

SA-PO2521

Fluid Balance and Patient Outcomes in AKI: Analysis of the Renal Study Participants Martin P. Gallagher,[1] Rinaldo Bellomo,[2] Alan Cass,[1] Louise Cole,[3] Joanne Y. Lee,[1] Serigne N. Lo,[1] Shay McGuinness,[4] John A. Myburgh.[1,5] *[1]The George Institute for Global Health, Sydney, Australia; [2]Austin Hospital, Heidelberg, Australia; [3]University of Sydney, Kingswood, Australia; [4]Auckland City Hospital, Auckland, New Zealand; [5]St George Hospital, Kogarah, Australia.*

Background: Fluid resuscitation is considered beneficial in critically ill patients with AKI, but there is little evidence to support it. Some evidence from observational studies suggests liberal fluid administration may be harmful. Using data from the RENAL Study we sought to examine the relationship between fluid balance (FB) and clinical outcomes in critically ill patients with acute kidney injury (AKI) requiring dialysis.

Methods: Fluid balance and clinical outcomes data from all participants in the study, a randomised trial of dialysis dose intensity in the setting of AKI in intensive care patients, was analysed using multivariable logistic regression, Cox proportional hazards, time dependent analysis and repeated measure analysis models.

Results: Data on 1464 participants was analysed. During study treatment, mean daily FB among survivors was -201 ml/day compared with +476 ml/day among non-survivors (P<0.001). Mean cumulative FB over the same period was -1294 vs. 311 ml (p<0.001). A negative mean daily FB during study treatment was independently associated with a decreased risk of death at 90 days (OR: 0.32, 95%CI: 0.24-0.43; p<0.001) and with increased survival time (P<0.001). In addition, a negative mean daily FB was associated with significantly increased renal replacement (RRT) free days (p=0.002), ICU free days (p<0.001) and hospital free days (p=0.01). These findings included adjustment for co-morbidities and patient acuity, and were unaltered after the application of different statistical models.

Conclusions: In RENAL Study participants, a negative fluid balance was consistently associated with improved clinical outcomes. Future interventional studies targeting fluid replacement may be one means of improving the poor outcomes of patients with AKI.

Funding: Government Support - Non-U.S.

SA-PO2522

Distribution of CKD and Albuminuria in Shropshire, U.K R. Diwakar,[1] Katherine Richmond,[2] Kevin Eardley.[1] *[1]Department of Nephrology, Royal Shrewsbury Hospital, Shrewsbury, England, United Kingdom; [2]Department of Biochemistry, Royal Shrewsbury Hospital, Shrewsbury, England, United Kingdom.*

Background: In the elderly (> 65 years) non-diabetic population there is on going debate about using eGFR as a screening tool for diagnosing Chronic Kidney Disease (CKD). CKD in Shropshire involve predominantly this age group. The Department of Health Quality and Outcomes Framework (QOF) recommends annual assessment including testing of Urine Albumin Creatinine ratio (UACR) to be performed. This is an expensive strategy the benefits of which is unclear in elderly non-diabetics with CKD Stage 3A without albuminuria. Hence we decided to analyse what proportion of nondiabetic CKD patients in Shropshire is above 65, has CKD stage 3A with no albuminuria.

Methods: Shropshire is a county of about 500, 000 people. All samples sent by general practitioners are analysed in one of 2 laboratories. Data was collected retrospectively from the computer systems of these laboratories of nondiabetic adult patients (age> 18) who had eGFR of < 60 ml/min (Stage 3 CKD or above) between October 2009 to September 2010.

Results: 9333 patients were found to have a GFR of < 60 ml/min (Stage 3a 6582, Stage 3b-2256, Stage 4- 454 and stage 5- 41). Among these 9333 patients UCR data was missing in 142 patients. Data from the remaining 9191 patients (1372 < /= 65, 7819 > 65 years of age) were analysed further. ACR analysis revealed normalbuminuria (UACR < 3 mg/mmol) in 7131 patients (5984 in the over 65), microalbuminuria (UACR 3-30) in 1753 patients (1581 > 65 years), overt proteinuria (UACR > 30) in 307 patients (254 > 65 years). In those > 65 years 4377 patients had CKD stage 3a and normalbuminuria, 1409 patients had stage 3b CKD and normalbuminuria.

Conclusions: Of the 9191 patients with CKD stage 3 - 5 in Shropshire (in whom UACR data was available), 47.6 % were elderly patients with CKD Stage 3A with no albuminuria. Yearly assessment including UACR in this group is probably not beneficial as it neither predicts progression of renal failure nor is it predictive of increased cardiac risk compared to general population. Recognising this in future QOF guidelines to General Practitioners in the UK could represent considerable savings.

SA-PO2523

Effects of Age and Case Definitions of Periodontitis on Associations with Albuminuria and CKD Afshin Parsa,[1] Nawi Ng,[2] Shabnam Salimi.[1] *[1]Nephrology, University of Maryland School of Medicine, Baltimore; [2]Umeå University, Sweden.*

Background: A wide variety of definitions of periodontitis have been employed, many focusing on acute periodontal disease activity. Since the development of renal disease is more likely due to chronic periodontal disease, we hypothesized that markers of chronic periodontal disease burden, including edentulous state, would be favorably associated with renal dysfunction. We also explore whether age, which can be correlated with both periodontal disease duration and susceptibility to chronic kidney disease (CKD), modifies these associations.

Methods: A total of 13,958 adult participants from NHANES III were included in this study. We used an adapted CDC definition to define periodontitis severity and also look at the effect of case definitions on our renal measures. The association between periodontitis and edentulous state with macroalbuminuria (ACR ≥ 300 mg/g), glomerular filtration rate (GFR) and CKD (GFR ≤ 60 ml/min/1.73.m2) was analyzed using multivariate logistic regression to adjust for related clinical and socioeconomic factors. We also looked for differential association between periodontal disease and renal function measures by age groups (age ≥ or < 40years).

Results: We found strong associations between severe periodontitis and both macroalbuminuria and CKD (OR: 1.89, CI:1.18-3.03; OR: 1.60, CI:1.28-2.00, respectively). There was also a strong association between edentulous state and macroalbuminuria (OR: 1.96, CI 1.21-3.16) and CKD (OR: 1.77, CI 1.38-.2.28). Further adjustment for inflammatory markers only slightly attenuated these associations. Edentulous state was a more robust predictor of CKD than periodontitis in the younger group, while periodontitis was a better predictor in those older than 40. We also find novel significant additive interactions between age, periodontitis and CKD (p<0.001).

Conclusions: In addition to case definition, age group strongly affects the association between periodontal disease and renal function measures. These findings not only further argue for the standardization of periodontal case definitions, but also suggest that age is a critical determinator of the association between periodontal and renal disease.

SA-PO2524

Is There a Lower Competing Risk of Death Than Risk of ESRD To Account for the High Incidence of ESRD in Taiwan Wu-Chang Yang,[1] Yee-Yung Ng,[1] Chih-Ching Lin,[1] Shang-Jyh Hwang.[2] *[1]Division of Nephrology, Taipei Veterans General Hospital and National Yang-Ming U., Taipei, Taiwan; [2]KMU, Kaohsiung, Taiwan.*

Background: Chronic kidney disease (CKD) is a disease of medical progress. A better healthcare for cardiovascular disease (CVD) prolong the life span of diabetic and elderly patients, who are very high risk group of CKD. Thus, the longer these patients survive, the higher chance they will develop CKD and the consequent end-stage renal disease (ESRD). A recent study shows that Asian CKD patients had faster CKD progression but lower mortality rate than Caucasian patients. Moreover, the incidence of of CVD in general population is much less in Asians than Caucasians. It is therefore reasonable to hypothesize that a lower risk of death competing for risk of ESRD is one of rationales to account for the high incidence of ESRD in Taiwan.

Methods: Two groups of study cohort were collected for comparison. One is hospital-based CKD registry which include 8,404 patients from 89 medical centers, collected from Jan 2007 to Dec 2009 and folllowed up to Jun 2010. The second one is a population-based sero-epidemiologic survey including 6,600 cases conducted for TW3H (Hypertension, Hyperglycemia, and Hyperlipidemia) Project in year 2002. A post hoc survival analysis was conducted in 2008.

Results: In a 2.5 years follow-up, the hospital-based CKD registry does show a 5.4 times lower competing risk of death than risk of ESRD in CKD patients. However, The population-based TW3H project showed a 18.4 times higher competing risk of death during 7 years' follow-up. The ratio of risk of death vs. risk of ESRD were 49.7, 11.4, 4.5 and 1.0 for patients with eGFR 60~89, 30~59, 15~29, and ≤15 ml/min, respectively. Subjects with lower eGFR have a higher CVD, cerebrovascular, and all-cause mortality.

Conclusions: The risk of death in CKD patients is much higher than risk of ESRD in stage 2-4 CKD patients. Thus, a lower competing risk of death is unlikely a rationale for the high incidence of ESRD in Taiwan. However, a better optimized CKD care in medical centers can reduce the metabolic burden of CKD and leads to a lower competing risk of death, further emphasizing the importance of multi-disciplined renal care.

SA-PO2525

Aortic Valve Calcification Predicts Coronary Artery Disease in Patients with Chronic Kidney Disease Soo Bong Lee, Il Young Kim, Bo Kyung Choi, Dong Won Lee, Harin Rhee, Eun Young Seong, Sang Heon Song, Ihm Soo Kwak. *Department of Internal Medicine, Pusan National University School of Medicine, Yangsan, Republic of Korea.*

Background: Aortic valve calcification (AVC) is common in chronic kidney disease (CKD) patients and the prevalence of coronary artery disease (CAD) in CKD patients is higher than other disease populations. But little is known about the association between AVC and CAD in CKD patients

Methods: We retrospectively reviewed the medical records of 408 patients who underwent both transthoracic echocardiography (TTE) and coronary angiography in our university hospitals. The patients were divided into 2 groups according to their estimated glomerular filtration rate (eGFR), CKD group (n=131, eGFR 15-59 mL/min/1.73m^2) and non-CKD group (n=277, eGFR ≥ 60 mL/min1.73m^2). TTE reports were reviewed to evaluate the AVC and the Gensini score was used to evaluate the severity of CAD.

Results: The CKD group showed higher prevalence of AVC (32% vs. 11%, p<0.001), CAD (61% vs. 24%, p<0.001) and more severe CAD (Gensini score, 25.86 ± 30.76 vs 15.83 ± 27.39, P<0.001) than non-CKD group. In multivariate logistic regression analysis, AVC was the predictor of CAD only in CKD group (OR=11.079, P<0.001), whereas there was no statistical significance in non-CKD group (OR=1.658, P=0.228).

Conclusions: The severity and prevalence of CAD were higher in CKD group compared to non-CKD group. AVC seemed to predict the CAD only in CKD group. Identifying the presence of AVC by non-invasive TTE could be useful in predicting the CAD in patients with CKD.

SA-PO2526

Prevalence and Predictors of Fatigue in CKD and ESRD Manisha Jhamb,[1] Kelly V. Liang,[1] Khaleelah Glover,[2] Nirav A. Shah,[1] Mark L. Unruh.[1] *[1]Renal-Electrolyte Division, Department of Medicine, University of Pittsburgh, PA; [2]Department of Psychiatry, University of Pittsburgh, PA.*

Background: Fatigue is a common debilitating symptom in patients with advanced chronic kidney disease (CKD), but there are no studies comparing the severity of fatigue using validated measures among non-dialysis dependent CKD and end-stage renal disease (ESRD) patients. The Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) is a 13-item fatigue scale, which has been shown to be reliable and responsive to interventions. The aim of this study is to examine the prevalence and severity of fatigue; and identify predictors of fatigue in a cross-sectional survey of 173 CKD and ESRD patients.

Methods: We examined fatigue in 87 CKD stage 4-5 patients and 86 ESRD patients using the FACIT-F and SF-36 scales. The participants were divided into two groups (FACIT-F scores >24 versus <=24) based on the mean score among anemic cancer patients. Predictors of worse fatigue at baseline were determined using linear regression model.

Results: The mean FACIT-F score among all participants was 34.5±11.0 and was similar among the CKD and ESRD groups (p=0.73). The FACIT-F score correlated closely with the SF-36 vitality score (Pearson correlation coefficient 0.81). After adjusting for age, race, gender, group (CKD versus ESRD), and medication use (benzodiazepine, antidepressant), the presence of cardiovascular disease, low serum albumin, depression, poor subjective sleep quality, and excessive daytime sleepiness were found to be independent predictors of worse fatigue at baseline.

Characteristic	Beta	Standard Error	p-value
Cardiovascular disease	-4.75	2.19	0.032
Albumin	24.78	7.68	0.002
Depression	-1.63	0.16	<0.0001
Sleep quality	-0.67	0.22	0.003
Daytime sleepiness	-4.57	1.10	<0.0001

Conclusions: Patients with CKD stage 4-5 and ESRD experience profound fatigue. Interestingly, the severity of fatigue is similar in these two groups. The FACIT-F is a useful scale to assess the severity of fatigue in this population and correlates highly with the SF-36 vitality scores. Depression, poor sleep and low albumin levels may be targets for interventions to improve fatigue in patients with advanced CKD.

SA-PO2527

A Comparison between Patients Referred and Not Referred to an Inner:city Nephrology Clinic Anjali Acharya,[1] Sophie Kwok,[1] Venu Gopal Kankani,[1] Rakesh Malhotra.[1] *[1]Nephrology, Jacobi Medical Center, Bronx, NY; [2]Scarsdale, NY; [3]Scarsdale, NY.*

Background: The prevalence of chronic kidney disease (CKD) is increasing. Ethnic minorities are at high risk, constituting a majority of the population in Bronx inner-city hospitals. There is a high prevalence of diabetes mellitus (DM) and hypertension in this population, which places them at a high risk for CKD. Early detection of CKD and renoprotection are crucial in this group.

Objective: To compare the baseline characteristics, comorbid conditions and stage of CKD of patients at referral to a nephrology clinic to those not referred.

Methods: We conducted a retrospective chart review of all patients seen in the primary care clinic from July 1, 2009 to December 31, 2009 who had a serum creatinine (SCr) of 1.5mg/dl or greater. Data was collected on demographics, comorbid conditions and stage of CKD for those referred to nephrology as well as for those not referred.

Results

	Nephrology Consults n (%)	No – Consults n (%)	P value
Number	71	253	
Demographics			
Gender			
Male	42 (59.2)	161 (63.6)	.490
Female	29 (40.8)	92 (36.4)	
Age	59.77±10.72	60.71±11.74	
BMI	30.1±6.5	31.4±10.3	
Smoker, n(%)	13 (18.3)	79 (31.3)	.09
Insurance, n (%)	68 (95.8)	245 (97.2)	.17
Comorbidity			
DM, n (%)	34 (47.9)	149 (58.9)	.002
Hypertension, n (%)	60 (84.5)	212 (83.8)	.885

CKD			
Stage 3	52 (80)	222 (87.7)	
Stage 4	10 (15.4)	27 (10.7)	
Stage 5	3 (4.6)	1 (0.4)	

*Coronary artery disease (CAD); Congestive heart failure (CHF); Human immunodeficiency virus (HIV)

Results: Only 21% (71 of 324) of patients with an SCr of greater than 1.5mg/dl were referred to the renal clinic.

58.9% of those with an SCr greater than 1.5mg/dl and not referred for nephrology consultation had DM.

Despite early stage of CKD in 80% of those referred, CAD was present in almost 48% of patients.

10.7% of the patients in the non-referral group were in stage 4 CKD.

Conclusions: Education of primary care physicians for early nephrology referral of a high-risk population for progression of CKD should be a priority.

SA-PO2528

Effect of Imputing Non-Ignorable Missing Data on Serial Measures of Renal Function: The Strong Heart Study Nawar M. Shara,[1,2] Hong Wang,[1,2] Barbara V. Howard,[1,2] Jason G. Umans.[1,2] *[1]MedStar Health Res Inst; [2]Georgetown-Howard Universities Clin & Translational Sci Ctr.*

Background: Kidney and cardiovascular disease (CVD) co-progress over time. However, it is challenging to simultaneously study interactions between progressive CKD and CVD in longitudinal studies because their morbidity and mortality lead to missing data which are likely not missing at random (NMAR). We have previously assessed the choice of imputation methods to best account for MAR renal function data in prediction of CVD (Kidney Int, 2007). We now explore approaches for cases in which data are NMAR and when exclusion of the missing data would likely bias relationships.

Methods: A cohort of 4549 American Indians from the Strong Heart Study with complete serial measures of serum creatinine data was considered. This cohort has a high burden of obesity, DM, CKD, and CVD. We used 4 different approaches to derive renal data subsets with MAR or NMAR data using the following algorithms: 1. missing completely at random 2, autoregressive MAR data 3. autoregressive MAR augmented with age and sex 4. and empirical non-ignorable missing data. These four subsets with missing data were used to examine the performance of five imputation methods: 1. listwise deletion (LD) 2. mean of serial measures 3. adjacent value (AV) 4. multiple imputation (MI) and 5. pattern-mixture (PM). One-hundred bootstrap samples were obtained with replacement to ascertain the accuracy of the point estimates.

Results: The hazard ratios (HRs) from each of the imputed sets were contrasted with HRs obtained from complete data set and compared across the different models. HRs generated by the PM method were closest to those using complete data. For NMAR data, the mean Scr imputed by PM differed less from that in the full dataset than did mean Scr using any of the of the imputation methods. The PM and AV imputation methods provided HRs for CVD risk which were similar to those using the complete data. By contrast, the PM method overestimated the mean of Scr and underestimated the hazard ratio for CVD risk when data were MAR.

Conclusions: Pattern-mixture imputation best accounted for non-random missing renal function data in a large study of progressive CKD and CVD.

Lack of Specialised Renal Care in Patients with Chronic Kidney Disease: The Implicate Study Patrick Saudan, Marangon Nicola, Chantal Martinez, Catherine Stoermann, Belen Ponte, Sophie M. De Seigneux, Pierre-Yves F. Martin. *Nephrology, Geneva University Hospitals, Geneva City, Geneva, Switzerland.*

Background: We undertook a prospective randomised trial to determine the impact of specialised care by nephrologists compared to guidelines-directed management by primary care physicians (PCP) on prognosis, planning of RRT and patient satisfaction in CKD patients.

Methods: Single center prospective randomised study. *Inclusion criteria:* CKD patients with an eGFR< 45 ml/min, aged 18-80 years old and enrolled during a hospitalization. *Exclusion criteria:* AKI or ESRD, estimated life expectancy < 2 yrs, refusal or inability to sign writing consent and patients previously known by nephrologists. The primary composite endpoint is death and/or hospitalisation during the 24 months after inclusion. The secondary endpoints are initiation of urgent RRT, decline of renal function and quality of life. *Study design:* Patients are randomised in two arms: -Combined management PCP and nephrologists (4 nephrology visits/year) -Management by PCPs with the help of written instructions and consultations being provided by our unit if requested by PCPs. Quality of life will be assessed every year with

Results: At the end of May 2011, 289 patients have been eligible, of whom 69 patients refused to participate and 70 (24%) were already followed by a nephrologist. One hundred and fifty patients have been randomised. Mean age is 66 ± 9 yrs, mean baseline eGFR is 31 ± 9 ml/min and mean Charlson comorbidity score is 4.7. Out of the 289 patients, 219 had either diabetes or nephrosclerosis, 19 had chronic glomerulonephritis (CGN) and 51 other diagnoses of CKD. Follow-up for patients with CGN rises to 89% and falls to 17% in patients with CKD due to diabetes or nephrosclerosis.

Conclusions: These preliminary results indicate that there is a lack of renal care for patients with CKD, especially for those whose renal impairment is due to diabetes or nephrosclerosis. The Implicate study may demonstrate whether regular renal care in these patients brings substantial benefits in terms of survival, hospitalisation rate and decline of renal function. ClinicalTrials.gov**:** NCT00929760

SA-PO2530

Chronic Kidney Disease Is a Risk Factor for Complications of Peripheral Artery Disease Ojas A. Naik, Jose Jesus Perez, Sreedhar A. Mandayam, Venkataraman Ramanathan. *Department of Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Peripheral artery disease (PAD) coexists in patients with chronic kidney disease (CKD) and is often associated with significant morbidity and mortality. During the 1-year follow up period after diagnosis of PAD, we identified risk factors associated with composite end point of gangrene, death, or re-hospitalization for PAD.

Methods: In this retrospective study, we obtained data from veterans who were evaluated for PAD and who had abnormal ankle-brachial index (0.9> ABI > 1.3), digital pressure (<50) or abnormal qualitative waveform. Veterans who had prior history of PAD were excluded. MDRD GFR was estimated. Veterans were followed for one year after index vascular evaluation. Primary end point was composite of gangrene, ischemic ulcer, death or re-hospitalization for PAD symptoms.

Results: A total of 597 veterans underwent vascular evaluation and after excluding normal studies and veterans with prior history of PAD, our study group included 346 veterans. During the 1-yr follow up, 27 veterans (group A) reached composite endpoint and 319 did not (group B). On comparing the two groups, patient characteristics including history of diabetes (56% vs. 50%), hypertension (89% vs 92%), smoking (70% vs 67%), hyperlipidemia (70% vs 80%, ischemic heart disease (30% vs 39%) were statistically similar.

Risk Factor	Group A (n=27)	Group B (n=319)	P value
Age	70 +/- 10	66 +/-10	0.03
Vascular Imaging Study	12 (46%)	146 (46%)	> 0.05
Severe PAD ((ABI < 0.7)	20 (73%)	153 (48%)	0.013
Revascularization	3 (11%)	56 (18%)	> 0.05
CKD (eGFR < 60ml/ min)	14 (52%)	90 (28%)	0.01

As shown, risk factors for veterans reaching composite endpoint include older age, severe PAD and stage III or worse CKD.

Conclusions: Chronic kidney disease appears to be associated with an increased risk of PAD-related complications and death. Further study is needed to see if earlier screening for PAD in patients with CKD can lead to earlier diagnosis and management and reduce these complications.

SA-PO2531

Effect of Angiotensin Receptor Blockers on Serum Phosphate and Calcium and Its Association with Renal and CV Outcomes Paul Smink,[1] Stephan J.L. Bakker,[1] William F. Keane,[2] John N. Harvey,[3] Dick de Zeeuw,[1] Hiddo Jan Lambers Heerspink.[1] *[1]Kidney Center, University Medical Center, Groningen, Netherlands; [2]Dept. Medicine, University of Minnesota, Minneapolis; [3]Dept of Endocrinology, Maelor Hospital, Wrexham, United Kingdom.*

Background: Previous studies have shown that high serum phosphate and low calcium are associated with increased risk of renal and cardiovascular outcomes. Angiotensin Receptor Blockers (ARB) delay the progression of renal disease and provide cardiovascular (CV) protection. We assessed the effects of ARB treatment on phosphate and calcium and investigated to what extent short-term effects of ARBs on these parameters translate into long-term renal and CV outcomes.

Methods: In a combined analysis of the Reduction of Endpoints in non insulin dependent diabetes mellitus with the Angiotensin II Antagonist Losartan (RENAAL) and Irbesartan Diabetic Nephropathy (IDNT) trials, we first determined the effect of ARB therapy on phosphate and calcium by testing the one year change versus placebo, secondly determined the association of these changes with long-term outcomes and finally adjusted the effect of ARB treatment on long-term outcomes for change in calcium and phosphate in Cox regression analyses.

Results: Compared to placebo, ARB treatment increased calcium levels with 0.07 mg/dL (95%CI 0.03 to 0.11; p<0.001) at year 1, but did not change phosphate (-0.01 mg/dL (95%CI -0.05 to 0.08; p=0.64). Each 0.1 mg/dL increment in calcium in the first 12 months resulted in a reduction of long term renal risk of 7% (95%CI 5 to 8; p=<0.001). No association was observed between the one year change in calcium and cardiovascular outcome. Adjustment of the renoprotective effect of ARBs for the observed one year change in calcium attenuated the effect of ARB treatment from 21% (95%CI 9 to 31) to 7% (95%CI -7 to 19), suggesting that part of the renoprotective effect is attributable to its effect on serum calcium. Essentially similar results were obtained when the analyses were repeated in the trials separately.

Conclusions: ARB treatment induces an increase in serum calcium, which explains part of its long-term renoprotective effect in diabetic patients with nephropathy.

Patterns of Progression in Chronic Kidney Disease (PoPe) Study: Baseline Data Craig L. Nelson,[1,4] Robert G. Fassett,[2,4] Neil Boudville,[3,4] Anna Kemp,[3] Eugenia Pedagogos,[4] Helen G. Healy,[4] George Jack Mangos,[4] Henry R. Moody,[4] Geoffrey S. Kirkland,[4] Troy D. Kay,[4] David A. Waugh.[4] *[1]Nephrology, Western Health, Melbourne, Victoria, Australia; [2]University of Queensland, Australia; [3]University of Western Australia, Australia; [4]electronic Kidney Disease National Audit Alliance, Australia (eKiDNAA), Australia.*

Background: The factors influencing the rate of CKD progression remain unclear. eKiDNAA is a National collaborative CKD research group assessing CKD patients referred to nephrology practices in Australia. We present baseline data from the first 3105 patients entered into the study. We aim to assess referred Australian CKD patients longitudinally for rates of progression of CKD, and to explore factors that may influence it such as demographics, biochemistry, therapies and co-morbidities.

Methods: This is an observational cohort study. Data were collected on referred CKD patients attending nephrology practices in Australia using Audit 4 software. The data collected included demographics, diagnosis and stage of CKD.

Results: The data on the first 3105 patients seen and entered into the Audit 4 database are presented. The study is ongoing. The average age of the cohort was (mean/SD) (68/14.9) years. CKD Stages were represented as follows: 1-2: 11%, 3: 39%, 4:21%, 5: 27%. Males had greater representation at all stages of CKD most marked in Stage 5, M:F 62:38%. Diagnoses recorded for all stages of CKD were: Hypertension 51%, Diabetic Nephropathy 27%, Glomerulonephritis 14%, APCKD 4%, Reflux Nephropathy 3%, Other 25%. Hypertension may be over represented as it is recorded as a co-morbidity and may not be the primary cause of the CKD.

Conclusions: We have initiated a CKD research group of Audit 4 users investigating CKD longitudinally in Australia. Baseline data shows a large number of stage 3 CKD patients with mainly hypertension and diabetic nephropathy. Longitudinal data will enable assessment of factors determining the rate of CKD progression, adequacy of CKD therapies, models of CKD care and resource utilization.

SA-PO2533

Use of Coenzyme Q10-Depleting Medications by Chronic Kidney Disease Status in the U.S. Vanessa Grubbs,[1,2] Laura C. Plantinga,[1] Delphine S. Tuot,[1] Neil R. Powe.[1,2] *[1]University of California, San Francisco; [2]San Francisco General Hospital.*

Background: Many commonly used medications deplete body stores of coenzyme Q10 (CoQ), which is believed to have antioxidant effects. This depletion may contribute to oxidative stress and subsequent renal dysfunction. The use of CoQ-depleting medications in the U.S. by CKD status is unknown.

Methods: Using 1999-2008 National Health and Nutrition Examination Survey data, we examined reported use of CoQ-depleting medications among 21,169 non-pregnant adults (age 20+ years). CoQ-depleting medications included: beta blockers, clonidine, gemfibrozil, statins, hydralazine, thiazide diuretics, sulfonylureas, tricyclic antidepressants, and phenothiazine derivatives. CKD stage 1/2 was defined by urinary albumin:creatinine ratio of ≥30 mg/g with eGFR ≥60 ml/min/1.73 m2 and CKD stage 3/4 by eGFR 15-59 ml/min/1.73 m2. The prevalence and odds of taking a CoQ-depleting medication by CKD status were estimated via multivariable logistic regression, weighted to the U.S. population.

Results: Overall, an estimated 20.7% of participants reported taking at least one CoQ-depleting medication, but prevalent use was significantly higher among those with greater CKD severity: 16.3%, 33.2%, and 53.0% of those with no CKD, CKD stage 1/2, and CKD stage 3/4, respectively (p<0.001). Among 10,388 participants without diabetes (self-reported or glycosylated hemoglobin >6.5) or hypertension (self-reported or blood pressure >140/90), conditions for which most CoQ-depleting medications are indicated, prevalent use followed a similar pattern: 5.4%, 8.4%, and 24.8% of those with no CKD, CKD stage 1/2, and CKD stage 3/4, respectively (p<0.001). After adjustment for demographics, co-morbid disease, and healthcare visits, those with advanced CKD were 1.5-fold more likely to be taking a CoQ-depleting medication than those without CKD (stage 1/2: OR 1.10, 0.93-1.29; stage 3/4: OR 1.53, 1.30-1.80, vs. no CKD).

Conclusions: Greater CKD severity is associated with higher use of CoQ-depleting medications. The extent to which CoQ–depleting medications contribute to CKD development and progression and whether CoQ dietary supplementation may ameliorate this effect is worthy of investigation.

SA-PO2534

Referral Patterns for CKD to Nephrology; the Implications in the Management of the Renal Patient in an Academic Internal Medicine Practice Alejandro Solano Bayardo, Tiffanie M. Lowy, Leela M. Mathew. *Internal Medicine Department, Unity Health System, Rochester, NY.*

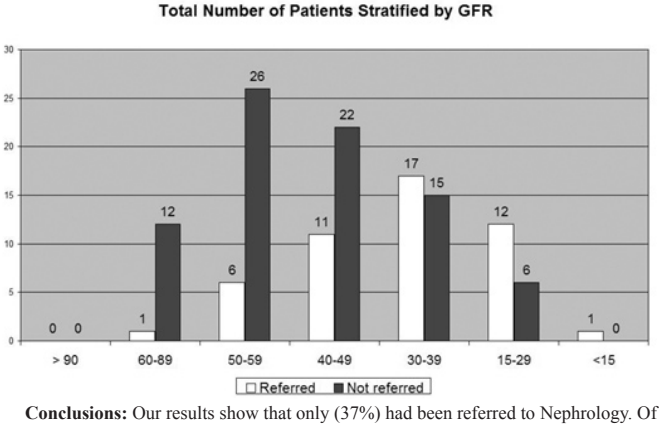
Background: Our objective was to determine the rate of referral and primary care physician patterns of referral to nephrologists in patients with CKD.

Methods: We conducted a retrospective review through NextGen EMR and Unity Faculty Partners, an academic ambulatory Internal Medicine clinic in Rochester, NY. We analyzed all patients with an ICD-9 code for CKD from 2007-2010, encompassing a total of 166. Out of this, 37 were excluded based on ESRD, those who had expired or lost to follow-up. Data was collected from the remaining 129 patients and graphed based on GFR, age and attending physician.

Results:

CKD Referral to Nephrology

	CKD I	CKD II	CKD III	CKD IV	CKD V	Total
Referred	0	1	34	12	1	48
Not Referred	0	12	63	6	0	81
			Mean Age			
Referred	0	62	63	79	82	67.1
Not Referred	0	68	76	86	0	75.2



Conclusions: Our results show that only (37%) had been referred to Nephrology. Of those with stage IV, most had been referred (66%). However, those with stage III, only (35%) had been referred. Stage III showed a wide variation, thus we further subdivided GFR into 3 groups from 30-39, 40-49 and 50-59. We were able to demonstrate an inverse relationship between a decline in GFR and an increase in referral with the majority of them being referred when the GFR fell to < 40.

Many of the patients that were not referred had advanced age, reflecting the decline of GFR to be age-related. Also some of them had shortened life expectancy from other causes. Additionally, we determined the patterns of referral according to attending physicians and found variable results demonstrating a non referral rate from 29-79%.

Acknowledging the current state of increasing co-morbidities in the U.S., both hypertension and diabetes mellitus are on the incline creating enormous potential for renal complications, optimal management of CKD is fundamental.

SA-PO2535

Analysis of Cause of Death and Level of Active Medical Management in a Conservative Care Programme for End Stage Renal Disease Linda H. Bisset,[1] Maria Fish,[1] Vicky Hinton,[1] Linda Evans,[1] Christine Porter,[1] Mark A.J. Devonald.[1,2] *[1]Renal and Transplant Unit, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom; [2]School of Clinical Sciences, University of Nottingham, United Kingdom.*

Background: In end stage renal disease (ESRD), renal replacement therapy (RRT) does not always improve quality or duration of life. Nottingham Renal Unit has an established conservative care (CC) programme which advises on symptom control and management of complications of CKD. We analyzed our 10 year prospective database to determine impact of the CC team on patients who have died. We determined the proportion of deaths attributed to ESRD and the proportion where bone disease or anaemia were being actively managed.

Methods: We analyzed data from patients who died on the CC programme, assessing demographics, CKD stage, changes in eGFR and laboratory parameters from start of CC to death. Aetiology of CKD and cause of death were coded by EDTA-ERA classification.

Results: At analysis 269 patients had died on the programme. 53% male, 93% Caucasian and median age 81. 37% had diabetes mellitus. Aetiology of CKD was uncertain in 42%. 43% were CKD stage 5 at start compared with 70% at death. Median number of days to death was 315. Table 1 illustrates median age, eGFR and laboratory parameters. Serum albumin and bicarbonate were lower at death. At start 7% pts were prescribed erythropoietin (EPO) therapy compared with 54% at death. Most common documented cause of death was therapy ceased at 38%, respiratory 17% and cardiac disease in 16%.

	Age	eGFR	Hb	Ca	P	Bic	Alb
Baseline	81	16	10.6	2.4	1.3	24	35
Death	82	11	10.2	2.4	1.4	21	29

Conclusions: Classification of 'therapy ceased' in this cohort is likely to mean death from ESRD, though there might be some exceptions to this (currently under analysis). The majority of patients did not die of renal failure. Median eGFR at start of programme is higher than expected from published data due to the inclusion of CKD stage 3 and 4. The CC programme at Nottingham Renal Unit offers patients an important alternative to RRT. Active medical management from the CC team appears to be important, regardless of whether patients subsequently die of renal failure or another pathology.

SA-PO2536

Evaluation of Chronic Kidney Disease Detection among High Risk Populations Using Automated Estimated Glomerular Filtration Rate Reporting M. Ahinee Amamoo,[2] Maria E. Ferris,[1] Keisha L. Gibson,[1] M. Alan Brookhart,[2] Abhijit V. Kshirsagar.[1] *[1]UNC Kidney Center, University of NC- Chapel Hill, Chapel Hill, NC; [2]Epidemiology, University of NC- Chapel Hill, Chapel Hill, NC.*

Background: Automatic eGFR reporting occurs in several US healthcare organizations but its impact remains debated. In April 2005, the University of North Carolina Healthcare System(UNCHS) voluntarily implemented automatic reporting of eGFR, calculated using the Modification of Diet in Renal Disease(MDRD) equation on all serum creatinine(SCr) tests. This study evaluates whether automatic eGFR reporting results in higher CKD detection among high-risk populations.

Methods: We compared the detection of CKD using ICD9 codes in the periods before and after the implementation of eGFR reporting, using linear risk regression. Hypertensive and diabetic adults, age 18-70 seen in the UNCHS between January 1, 2004 and August 31, 2009 with two SCr measurements, at least six months apart were included in the study.

Results: We identified 2077 hypertensive and 1042 diabetic patients. Patient characteristics were comparable before and after eGFR reporting. Mean age was 58±9 years, 60% females, and 55% Caucasian. The one year cumulative incidence of CKD detection was 0.09 for hypertensive patients and 0.12 for diabetics. Hypertensive and diabetic patients seen after eGFR reporting had a higher 1-year risk of CKD detection than before eGFR reporting,(Relative risk(RR:1.66, 95% confidence interval (CI):1.01,2.73) and (RR=1.2;95%CI:0.75,2.16), respectively. After adjusting for age, race, and gender, the 1-year risk of CKD detection among those who were seen after automatic eGFR reporting was 77% higher among hypertensive patients (RR:1.77;95%CI:1.03,2.77) and 25% higher among diabetics (RR=1.25;95%CI 0.75,2.10), than the 1-year risk of CKD detection among those seen before automatic eGFR reporting.

Conclusions: Increased detection of CKD occurred after eGFR reporting among high risk populations. These data suggest that automatic eGFR reporting promotes earlier detection of CKD among high risk populations. Future studies should examine whether earlier detection leads to changes in management of CKD.

Funding: NIDDK Support

SA-PO2537

Comparing eGFR Equations in the Elderly Natalie R. Ebert,[1] Olga Jakob,[2] Jens Gaedeke,[1] Martin K. Kuhlmann,[3] Peter Martus,[2] Markus van der Giet,[1] Elke Schaeffner.[1] *[1]Nephrology, Charité, Berlin, Germany; [2]Clinical Epidemiology and Biostatistics, Charité, Berlin, Germany; [3]Nephrology, Krankenhaus Friedrichshain, Berlin, Germany.*

Background: Although chronic kidney disease (CKD) is disproportionately affecting the elderly, these are underrepresented in most studies. We used the Berlin Initiative Study (BIS) population to compare present eGFR formulas.

Methods: The BIS is an ongoing prospective population-based cohort studying CKD in people ≥70. Sampling was done stratified for age and gender. Confirmatory analysis was done with t-test and chi^2-test. Agreement between formulas was assessed using Bland Altman and kappa statistics.

Results: The characteristics of the study population and subpopulations ($eGFR_{CKD\text{-}Epi}$ ≥ and <60 ml/min/1.73m^2) are shown in Table 1.

Table 1

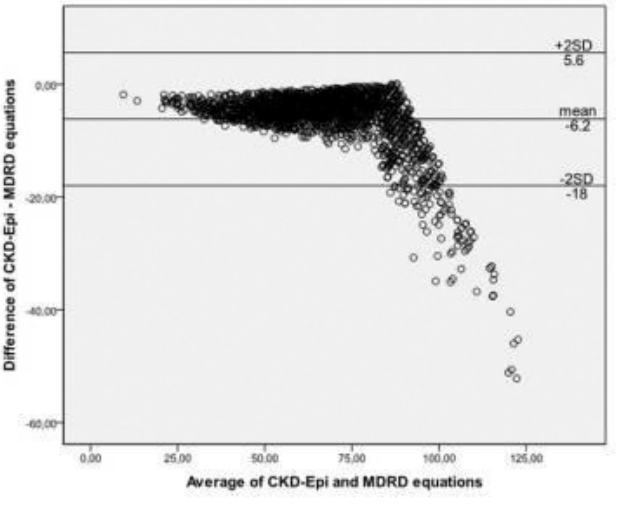
Characteristics	Total	$eGFR_{CKD\text{-}Epi}$≥60	$eGFR_{CKD\text{-}Epi}$<60	p-value
n	1967	1240	727	
Age (yrs)[1]	80	78	83	<0.001
Women[2]	52	53	50	n.s.
BMI[1]	27	26	28	n.s.
Art. Hypertension[2]	77	71	88	<0.001
Diabetes mel.[2]	23	21	27	0.004
MI[2]	14	11	19	<0.001
Stroke[2]	8	7	10	0.02
Cancer[2]	23	22	24	n.s.
Creatinine (mg/dl)[1]	1.0	0.8	1.3	<0.001
Cystatin C (mg/l)[1]	1.22	1.04	1.54	<0.001
$eGFR_{CKD\text{-}Epi}$(ml/min/1.73m^2) [1]	65	76	46	<0.001
ACR >30[2]	26	20	36	<0.001

Data are presented as [1] mean and [2] percentage

Paired t-test of eGFR equations showed sign. difference (p<0.001) of eGFR calculated with MDRD (71 ml/min/1.73m^2) or Cystatin C (60 ml/min/1.73m^2) compared to CKD-Epi for the total cohort.

Agreement between CKD-Epi and Cystatin C equations as well as CKD-Epi and MDRD for diagnosis of CKD with weighted kappa statistic was 0.58 and 0.85, respectively.

Bland Altman analysis between CKD-Epi and MDRD showed better agreement in lower but not in higher eGFR levels corresponding to the structure of the CKD-Epi formula (Figure 1).



Conclusions: Significant discrepancies of eGFR can be observed when using different estimating equations in the elderly. Comparison to GFR measurement is needed in people ≥ 70.

Funding: Private Foundation Support

SA-PO2538

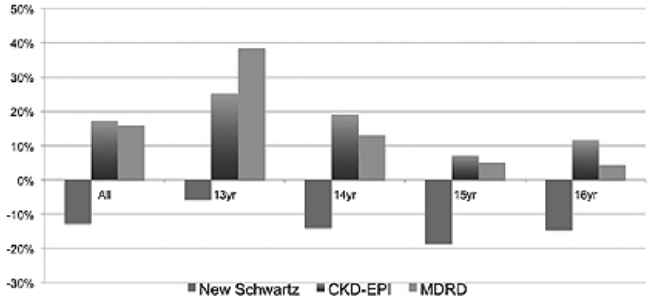
Which Is the Best Estimating Equation for GFR in Adolescents? John Brandt,[1] Craig S. Wong,[1] Antonia M. Harford,[1] Amy Staples.[1] *[1]Department of Pediatrics, University of New Mexico, Albuquerque, NM; [2]Albuquerque, NM; [3]Albuquerque, NM.*

Background: In 2009, Schwartz, et al. via the CKiD study revised a commonly used equation (eqn) to estimate GFR (eGFR) for children. The CKiD bedside (bCKiD) eqn tends to underestimate measured GFR (mGFR) in children over the age of 4 years(yrs) especially in adolescents (adol). Adol patients(pts) may be closer to adult body size and physiology than to younger pts. We investigate whether the adult derived eGFR eqns or the new bCKiD eqn are more accurate to estimate mGFR in adol pts.

Methods: Retrospective analysis of 140 pts 13 to 17 yrs with mGFR by iothalamate steady-state methodology at a tertiary care pediatric hospital. Diagnoses (Dx) include solid tumor pts both pre and post chemotherapy (chemo), children with chronic kidney disease (CKD) and with renal transplants(txp). Serum creatinine (sCr) was determined by enzymatic assay.

Results: Age range 13 to 17 yrs, mean age 14.9 (SD1.1). 49% male. The mean sCr for all pts was 0.76 mg/dl (SD 0.4). By Dx group, 15% were done pre-chemo, 56% were post-chemo, 16% had CKD and 13% were txp pts.

The bCKiD eqn underestimated mGFR by 13%, while CKDEPI overestimates by 17% and MDRD by 16%. The bCKiD eqn was most accurate in the youngest subjects and increasingly underestimated mGFR as age increased.



All three equations where more accurate for girls compared to boys.

Conclusions: The bCKiD eqn is reliable in younger pts, but less reliable in older adols, particularly boys. The MDRD and CKDEPI eqns accuracy are similar to bCKiD eqn, but overestimating mGFR in the opposite direction. Stratifying by age and gender, both CKDEPI and MDRD have an advantage over the bCKiD eqn in pts over 14 yrs of age. Overall, the bCKiD eqn may benefit from an adjustment in adols for gender, similar to what is seen in the adult-based eqs. and the original Schwartz eqn.

SA-PO2539

Comparison of Creatinine-Based and Cystatin C-Based GFR Estimating Equations in Chinese Children Xuemei Li,[1] Mengchun Gong,[2] Xuewang Li,[1] Hongmei Song,[3] Yan Qin,[1] Ke Zheng.[1] *[1]Nephrology, Peking Union Medical College Hospital, Beijing, China; [2]Internal Medicine, Peking Union Medical College Hospital, Beijing, China; [3]Pediatrics, Peking Union Medical College Hospital, Beijing, China.*

Background: There is no data about glomerular filtration rate, measured through plasma or renal clearance of the exogenous markers, in the Chinese children. The objective of this study is to measure GFR and validate the GFR estimating equations in the Chinese children, aiming at selecting the equations with best performance in GFR estimation and CKD staging.

Methods: 85 children were enrolled in the study. Single-compartment plasma clearance of ^{99m}Tc-DTPA was measured using the radioactive counts of the two plasmas sampled after a bolus injection and transformed into two-compartment plasma clearance (mGFR). mGFR was normalized (nGFR) by body surface area. eGFR was calculated using 9 different equations, based on Creatinine (3), Cystatin C (3) or their combination (3). Creatinine and cystatin C were measured using kinetic Jaffe method and immunoturbidimetry, respectively. Correlation and agreement between eGFR and nGFR and the accuracy of GFR estimation was compared to validate and selet GFR estimating equations.

Results: Compared with the other six equations, original Schwartz equation, Filler equation and CKiD equation produced the eGFR with better correlation with nGFR ($\gamma_{Pearson}$ was 0.78, 0.73 and 0.75, respectively), stronger explanation capacity of variance in nGFR (R^2 was 0.612, 0.716 and 0.730), smaller bias (bias was 0.2, -4.2 and 3.5), narrower 95% LOA ([-61,61], [-50,42] and [-37,44]), better performance in Bland-Altman analysis , higher intraclass correlation coefficient (0.594, 0.724 and 0.741), higher CCC (0.592, 0.722 and 0.735), higher ratio of eGFR within nGFR±10% (30.6%, 33.8% and 37.7%) and within nGFR±30% (81.2%, 76.6% and 77.9%), higher ratio of correct CKD staging (65.9%, 68.8% and 75.3%) and better agreement in CKD staging between eGFR and nGFR (Kappa value was 0.60, 0.61 and 0.65).

Conclusions: The selected equations used to estimate GFR in Chinese children were original Schwartz equation, Filler equation and CKiD equation, while CKiD equation has the best performance.

Estimating GFR in Renal Transplantation: A Multicentric Evaluation of Cystatin C Performance Ingrid Masson,[1] Nicolas Maillard,[1] Eric Alamartine,[1] Etienne Cavalier,[3] Pierre Delanaye,[2] Christopher R. Mariat.[1] *[1]Nephrology, University Hospital of St-Etienne, St-Etienne, France, Metropolitan; [2]Nephrology, University Hospital of Liege, Liege, Belgium; [3]Biology, University of Liege, Belgium.*

Background: Serum cystatin C (SCy) might be a better GFR marker than serum creatinine (SCr) in renal transplant patients. The aim of our study was 1- to confirm or not the superiority of SCy in estimating renal graft function and 2- to determine the influence of confounding bio-clinical variables susceptible to explain SCy concentration independently of GFR in renal transplant patients.

Methods: 826 renal inulin clearances (true GFR) performed in 423 renal transplant patients from 3 different European transplant centres were analysed. SCy and SCr were measured by nephelemetry calibrated on IFCC material and enzymatic method traceable to IDMS , respectively. GFR was estimated according to SCr-based equations (MDRD study equation and CKD-EPI(SCr) equation), SCy-based equation (CKD-EPI(SCy) equation) and both SCr and SCy-based equation (CKD-EPI(mix) equation). Primary endpoint was defined as the accuracy 30% (P30). The following co-variables were assessed : Weight, Gender, Age, Time post-tx, Stages of CKD, Diabetic status, Proteinuria, IS regimen, usCRP and Albuminemia.

Results: Mean (+/-SD) inulin clearance, SCr and SCy were 50.6 (+/-19) mL/min/1.73m2, 129 (+/-52) µmol/l and 1.64 (+/-0.61) mg/l, respectively. P30 was 75%, 77%, 81% and 84% for the CKD-EPI(SCr) equation, the MDRD Study equation, the CKD-EPI(Scy) equation and the CKD-EPI(mix) equation, respectively ($p<0.05$ for the comparison between SCr-based and SCy-based equations). Aera under ROC for a GFR threshold of 60 ml/min/1.73m2 was 0.832 and 0.901 for SCr and SCy, respectively ($p<0.0001$). After adjustments for the different non-GFR determinants tested, SCy remained significantly superior to SCr in predicting renal graft function.

Conclusions: Our data, obtained in a large population of transplant patients and with a standardized method of SCy dosage, confirm the superiority of SCy over SCr. Whether this better predictive performance may clinically translate into a better management of the transplant patient remains to be determined.

GFR Estimation in the Morbidly Obese Pre and Post Bariatric Surgery: One Size Does Not Fit All Samra Abouchacra,[1] Ahmed Chaaban,[1] Nicole Gebran,[1] Qutaiba Abdulatif Daoud,[1] Bassam O. Bernieh,[1] Hanan Luay Al Omary,[2] Mohamed Ahmed,[1] Said Abuhasna.[1] *[1]Tawam Hospital, United Arab Emirates; [2]Baghdad University, Iraq.*

Background: Hyperfiltration with increased glomerular filtration rate (GFR) is commonly associated with obesity. This is expected to improve post bariatric surgery. However formula-based GFR estimation in the obese is limited by body size confounders necessitating use of modified equations, the reliability of which remains uncertain.

Our aim was to compare GFR- estimating formulae in morbidly obese patients at baseline & post bariatric surgery.

Methods: Retrospective review of 220 patients (145 females), mean age 34.7± 10 yrs with post-op followup over 6 months.

GFR was calculated using: MDRD4, CKD-epi: Usual & Body Surface Area (BSA)-adjusted; Cockroft Gault (CG) & Lean Body Weight-corrected (CG-LBW) formulae.

Results: Significant reduction in weight & BP was achieved with data as shown.

	Baseline	Postop
Weight (kg)	128.6±26	97.6±22*
BMI (Kg/m2)	47.0 ± 9	36.12±7*
SBP (mmHg)	132.75±12	121.64±11*
DBP (mmHg)	78.7±9	71.31±9*
Serum Creatinine (µmol/L)	63.05±14	58.01±13*
GFR estimation (ml/min):		
CG	227.05±76	172±65*
CG-LBW	128.67±44	109.6±43*
MDRD4	107.8 ±36	110.7±47†
CKD-Epi	108.7 ±27	107.1±37†
Adjusted MDRD	139.49 ±66	112.41±73*
Adjusted CKD-Epi	127.28 ±59	110.59 ±64*

* p <0.05 vs baseline † p NS

GFR estimation by different formulae showed marked variation. The expected supranormal GFR was apparent in estimators which took into account body size descriptors. This was grossly overestimated by CG but attenuated with adjustment for LBW. Conversely, MDRD and CKD-epi underestimated GFR which increased with BSA –correction. Post-operatively, significant decrease in GFR was seen in adjusted BSA- versions and CG-LBW. This became apparent when BMI decreased by 4.35 kg/m2.

Conclusions: Though clinicians must be critical in application of GFR estimates to patient care, CG-LBW appears to be a practical solution in the obese. This is because LBW can be more reliably assessed compared to BSA. However since adjusted MDRD & CKD-epi correlated well with it, these can be alternatives given their less cumbersome calculation. Future comparisons are needed with a "gold standard" for GFR.

SA-PO2542

Renal Effects of Bariatric Surgery in Patients with Chronic Kidney Disease Samra Abouchacra,[1] Ahmed Chaaban,[1] Nicole Gebran,[1] Qutaiba Abdulatif Daoud,[1] Hanan Luay Al Omary.[2] *[1]Tawam Hospital, Al-Ain, United Arab Emirates; [2]Baghdad University, Iraq.*

Background: Obesity is known to be associated with hyperfilteration state which improves with weight reduction. However, the impact of bariatric surgery on glomerular filtration rate (GFR) of patients with already compromised renal function is not yet established.

Methods: Patients with kidney disease (CKD I-II) who underwent bariatric surgery were retrospectively reviewed. Their eGFR was calculated using Cockroft Gault- lean body weight adjusted formula (GC-LBW). This was also estimated by both CKD-Epi and BSA- adjusted version pre and post operatively.

Results: From 220 patients, 41 were found to have pre- op e*GFR* 60- 90ml/min. M:F 1: 40, mean age 45.15± 8 yrs. 7 patients had diabetes and another 7 were hypertensive. After mean follow up of 7.2 ±3 months, significant decrease in weight, BMI and BP was achieved. Baseline and post op data are shown.

	Pre	Post
Weight (kg)	110.54±18	86.33±17*
BMI (kg/m2)	43.83±8.1	34.04±6.7*
sBP (mmHg)	132.55±13	120.8±11*
dBP (mmHg)	78.71±9.2	72.15±8*
Serum Creatinine (µmol/l)	80.32±14	69.6±13*
eGFR CG-LBW (ml/min)	76.26±9	86.63±18*
eGFR CKD-Epi (ml/min)	80.99±18	103.6±19*
eGFR adjusted CKD-Epi (ml/min/BSA in m2)	102.25±50	98.02±45
BSA (m2)	1.87±0.8	1.65±0.7

* p value < 0.05

Conclusions: Despite the small sample size and short follow up, using CG-LBW formula, a significant increase in GFR was seen in obese patients with early CKD after bariatric surgery. This was in contrast to the decrease reported previously in those with hyperfilteration preoperatively. Improvement in BP and overall metabolic profile may be partly responsible.

Though similar changes were seen with CKD-Epi eGFR, this is clearly unreliable without BSA correction. When adjusted, an overestimation of GFR was observed pre, with no sig change post op.

In the absence of gold standard for eGFR measurement, CG-LBW appears to be a more reliable estimator with possible role in CKD staging.

Whether the renal benefits from bariatric surgery are sustained or seen in more advanced CKD stages is uncertain. Long term studies are needed to explore this further.

SA-PO2543

Relationship between Glomerular Filtration Rate, Body Surface Area and Gender Belen Redal-Baigorri,[1] James G. Heaf,[2] Knud Rasmussen.[1] *[1]Nephrology, Roskilde Hospital, University of Copenhagen, Roskilde, Denmark; [2]Nephrology, Copenhagen University Hospital at Herlev, Herlev, Denmark.*

Background: Normalisation of GFR with BSA with extreme body sizes might be misleading and this can have consequences in drug dosing and living donor kidney assessment.

Methods: Cross sectional study of 895 cancer patients, to investigate whether GFR indexed for BSA is reliable in extreme body sizes and whether this relationship is influenced by gender. GFR was investigated with (^{51}Cr-EDTA), the results were expressed as absolute values (GFR ml/min) or normalised for BSA by Du Bois and Du Bois formula (GFR ml/min per 1.73m^2,GFR bsa), and extracellular volume, ECV (GFRecv).

Results: A useful normalization index (NI) should have a high correlation to GFR, no residual correlation after correction, give similar values for both genders, and be robust over the entire range of values. The overall correlation between GFR and BSA was high (r=0.52), but was low for BSA <1.6 kg/m^2 (0.13) in both sexes. In males BSA was correlated to GFRbsa if BSA >1.8 (r=0.28). GFR correlation to ECV was high (0.49), and robust over the entire range of ECV values. However GFR correlated to GFRecv in women (r=-0.15). There were no significant differences between genders for GFRbsa or GFRecv.

BSA and ECV correlation with GFR

BSA correlation to GFR and GFR ml/min per 1.73m² . R values						
		Men		Women

*:p<0.05; **p<0,01; ***:p<0,001;

Conclusions: Neither NI performed optimally. BSA was inappropriate when BSA<1.6 for both sexes. ECV performed better particularly in males.

SA-PO2544

Cystatin C- vs Creatinine-Based Equations Compared to 99m TcDTPA Scintigraphy for the Assessment of Glomerular Filtration Rate in Chronic Kidney Disease Hernan Trimarchi. *Nephrology, Hospital Britanico, Buenos Aires, Argentina.*

Background: In Chronic kidney disease (CKD) accurate estimation of the glomerular filtration rate (GFR) is essential. Gold standards are expensive and labourious. Different equations based on creatinine have been proposed to estimate GFR. However,creatinine levels are frequently far from reflecting real GFR. We compared creatinine- with cystatin C-based formulae, using ^{99m}TcDTPA scintigraphy as gold standard, and propose the best equation for each stage of CKD.

Methods: Prospective, cross-sectional, observational enrolling 300 subjects in 1 year. CKD and stages were defined as to K/DOQI guidelines and stratified into its 5 stages using ^{99m}TCDTPA. Group (G) 1n=26; G2n=52; G3n=90; G4n=37; G5n=60; Control Gn=35. Creatinine equations: Creatinine clearance, Crockoft-Gault, MDRD-4, CKDEPI. Cystatin C equations: Larsson, Larsson modified, Grubb, Hoek.

Results: Age and body mass index were different among groups; proteinuria, hypertension, diabetes and primary glomerulopathies significantly increased as kidney disease worsened. In the global assessment, CKDEPI and Hoek gave the highest significantly correlations with DTPA: ρ=0.826,p<0.001 and ρ=0.704,p<0.001. Lineal regression analyses: CKDEPI vs DTPA, r0.826, r^{2}0.682; Hoek vs DTPA, r0.704, r^{2}0.496; CKD EPI vs Hoek: r0.811; r^{2}0.658. Hoek kappa constant: 0.585, p<0.001; CKDEPI kappa constant: 0.505, p<0.001. However, important differences emerged when each group was studied separately. Most significant correlations with ^{99m}TcDTPA: Control G, creatinine clearance ρ=0.421, p=0.012; G1, Crockoft-Gault ρ=0.588, p=0.003; CKDEPI ρ=0.460, p<0.05; G2, CKDEPI ρ=0.462, p< 0.05; G3, CKDEPI ρ=0.508, p<0.001; MDRD-4 ρ=0.506, p<0.001; Hoek ρ=0.475, p<0.001; G4, Hoek ρ =0.618, p<0.001; creatinine clearance ρ =0.507, p=0.04; CKDEPI ρ=0.463, p=0.02; G5, CKDEPI ρ=0.604, p<0.001; Hoek ρ=0.592, p<0.001

Conclusions: If GFR<60 ml/min (stages 3 and 4), CKDEPI and Hoek equations appear to best correlate with ^{99m}TcDTPA. In stage 5, all formulae significantly coincide. However, in controls and in early stages of CKD creatinine-based methods or equations may correlate better with ^{99m}TcDTPA.

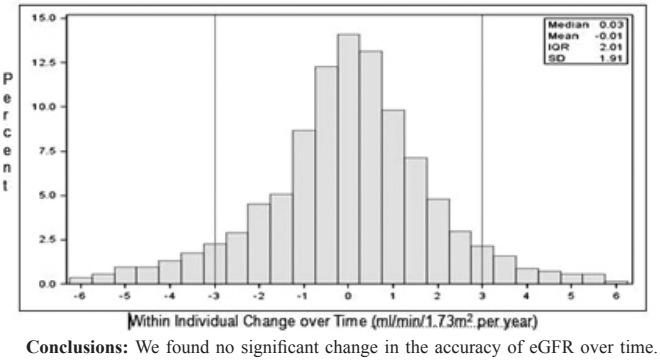
SA-PO2545

Accuracy of a Glomerular Filtration Rate Estimating Equation over Time in People with a Wide Range of Kidney Function Smita Padala,[1] Hocine Tighiouart,[1] Lesley Stevens Inker,[1] Gabriel Contreras,[2] Julia Lewis,[3] Michael Steffes,[4] Roger A. Rodby,[5] Christopher H. Schmid,[1] Andrew S. Levey.[1] *[1]Tufts Medical Center; [2]University of Miami; [3]Vanderbilt University Medical Center; [4]University of Minnesota; [5]Rush University Medical Center.*

Background: The accuracy of GFR estimated from serum creatinine (Scr) over time is not well known. We examined the rate of change in measured GFR (mGFR), estimated (eGFR) and the difference between mGFR and eGFR (error) over time in a large dataset with a wide range of kidney function.

Methods: GFR was measured using urinary clearance of ^{125}I-iothalamate (reference test) in subjects with and without kidney disease and diabetes. GFR was estimated using the Chronic Kidney Disease Epidemiology Collaboration equation (index test). The change over time was modeled using mixed models. We considered a change in error larger than ±3 ml/min/1.73 m^2 per year as clinically significant.

Results: There were 13,708 GFR measurements in 3635 subjects over a mean follow up of 3.6 years. The mean mGFR, eGFR and error at baseline were 76, 76, and -0.3 ml/min/1.73 m^2. The mean (standard error) change in mGFR, eGFR and error were -2.3 (0.12), -2.2 (0.09) and -0.1 (0.10) ml/min/1.73 m^2 per year (P <.0001, <.0001 and 0.6 respectively). The variability (SD) among subjects in changes in mGFR, eGFR and error was 2.24, 1.59, and 1.91 ml/min/1.73m^2 per year, respectively. Only 16% of subjects had changes in error larger than ± 3 ml/min/1.73 m^2 per year (Figure 1).



Conclusions: We found no significant change in the accuracy of eGFR over time. Changes in eGFR over time in most individuals were due to changes in mGFR rather than changes in non-GFR determinants of Scr. In the absence of recognized changes in non-GFR determinants of Scr, clinicians should interpret changes in eGFR as reflecting changes in mGFR.

SA-PO2546

Simple Cystatin C Formula Compared to Sophisticated CKD-EPI Creatinine & Cistatin C-Based Formula for Estimation of Glomerular Filtration Rate in Elderly Patients with Mild to Moderate Impaired Kidney Function Sebastjan Bevc, Radovan Hojs, Robert Ekart, Maksimiljan Gorenjak, Ludvik Puklavec. *Dept. of Nephrology, Nuclear Medicine, Clinical Chemistry, UKC Maribor, Slovenia.*

Background: Serum creatinine (Screa) concentration and Screa-based formulas are the most commonly used markers to estimate glomerular filtration rate (GFR). Recently, serum cystatin C (Scys)-based formulas and the newer creatinine & cystatin C-based formula (The Chronic Kidney Disease Epidemiology Collaboration formula (CKD-EPI creatinine & cystatin formula)) were proposed as new GFR markers. The aim of our study

was to compare CKD-EPI creatinine & cystatin formula and simple Scys formula (100/Scys) against 51CrEDTA clearance in eledrly patients with mild to moderate (GFR 89-30 ml/min/1.73m2)impaired kidney function.

Methods: 106 adult Caucasians patients older than 65 years (58 women, 48 men; mean age 72.5 years) were included. In each patient 51CrEDTA clearance, Screa (Jaffe – IDMS traceable method) and Scys (immunonephelometric method) were determined. GFR was calculated using the CKD-EPI creatinine & cystatin formula and simple Scys formula.

Results: The mean 51CrEDTA clearance was 52.2 ± 15.9 ml/min/1.73m2, mean Screa 1.6 ± 0.47 mg/dl, mean Scys 1.79 ± 0.6 mg/l. Statistically significant correlations between 51CrEDTA clearance and both formulas were found (P<0.0001). In the ROC curve analysis (cut-off for GFR 60 ml/min/1.73m2) no significant difference of diagnostic accuracy between CKD-EPI creatinine & cystatin formula and simple Scys formula was found (P=0.395). Bland and Altman analysis for the same cut-off value showed that CKD-EPI creatinine & cystatin formula (bias: -21.2 ml/min/1.73m2) underestimated and simple Scys formula (bias: 4.1 ml/min/1.73m2) overestimated measured GFR. All equations lacked precision. It was 8.7 ml/min/1.73m2 for CKD-EPI creatinine & cystatin formula and 9.8 ml/min/1.73m2 for simple Scys formula.

Conclusions: Our results indicate that simple Scys formula which requires just one variable (Scys concentration) is reliable marker of GFR in elderly patients with mild to moderate impaired kidney function and comparable to sophisticated CKD-EPI creatinine & cystatin formula.

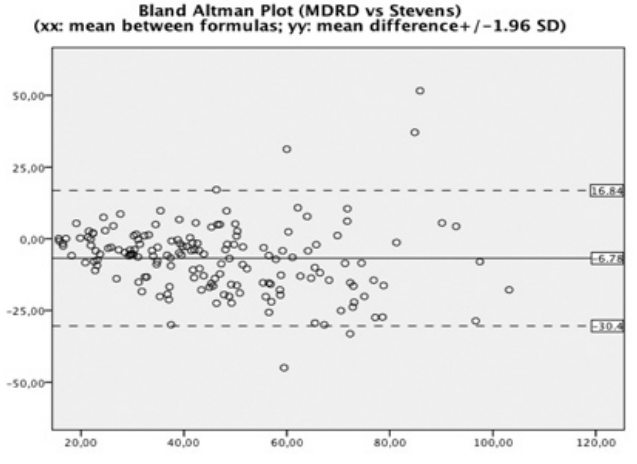
SA-PO2547

Creatinine and Cystatin C: Different Performance in Staging Chronic Kidney Disease in the Elderly Ana Rocha, Jorge Malheiro, Pedro V.A. Aguiar, António Manuel Nunes Cabrita. *Centro Hospitalar do Porto, Portugal.*

Background: An older population with chronic kidney disease (CKD) has frequently a high cardiovascular (CV) comorbidity and a pro-inflammatory status. Several clinical and analytical variables in this context may interfere with serum creatinine (sCr) and cystatin C (sCys).

Methods: We proposed to analyse in a stage 1-4 CKD and over 60 years population the agreement between glomerular filtration rate (GFR) formulas based on sCr (MDRD) and sCys (Stevens) through Kappa statistics and Bland-Altman plot. The degree of difference between formulas and their association with clinical variables was analysed by spearman correlation. A multivariate linear regression model was used to determine the influence on sCr and sCys of prevalent clinical and analytic variables.

Results: We studied 163 subjects, mean age 74 years, 53.4% females and with 2 or more CV risk factors (hypertension, diabetes mellitus (DM), dyslipidemia) in over 80%. The prevalence of CKD stages 3-4 was 81% by MDRD and 70% by Stevens formulas with a poor agreement between them (K=0.55).



The mean difference was -6.78 ml/min/1.73 m2, being significantly higher in younger age, male gender, milder CKD, in proteinuric and hyperuricemic patients. A multivariate adjusted model for age, gender, log-body mass index, DM, high ferritin status, albumin and HDL-cholesterol revealed a higher correlation with log-sCys (r=0.53) than log-sCr (r=0.38). DM and high ferritin were significant predictors of increased log-sCys and log-sCr. Higher log-sCys was also independently predicted by older age (p=0.005), female gender (p=0.02), lower albumin (p=0.005) and HDL-cholesterol (p=0.001).

Conclusions: In the elderly, a stronger association of sCys with nonrenal factors may limit its accuracy as determinant of GFR, but a higher correlation with these prevalent clinical and analytical variables can add clinical pertinence to it.

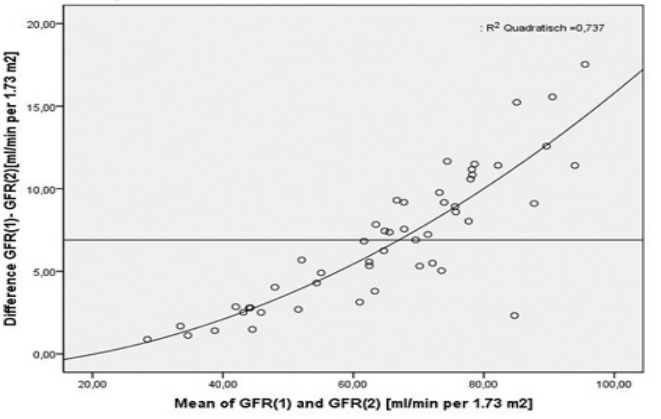
SA-PO2548

Glomerular Filtration Rate Via Plasma Iohexol in the Elderly – A Comparison of Slow and Fast Component Peter Martus,[1] Markus van der Giet,[2] Natalie R. Ebert,[3] Jens Gaedeke,[3] Olga Jakob,[1] Martin K. Kuhlmann,[4] Elke Schaeffner.[3] *[1]Dpt. Biostatistics and Clinical Epidemiology, Charité, Berlin, Germany; [2]Dpt. of Nephrology, CBF, Charité, Berlin, Germany; [3]Dpt. of Nephrology, CVK, Charité; [4]Vivantes, Berlin, Germany.*

Background: GFR measurement can be done using the clearance of Iohexol. We compare the modeling of Iohexol clearance using one or two components in a half logarithmic model.

Methods: We use a subsample (n=50) of the Berlin Initiative Study (BIS) with 10 measurement points of Iohexol concentration in the plasma at 10-300 min after infusion. The analysis of the slow and fast component of Iohexol clearance follows Schwarz et al.(2006); fast component: 10 to 90 min, slow component: 120 to 300 min. GFR was calculated from the area under the curve using the slow (GFR(1)) or both components (GFR(2)). We assess bias and agreement using the method of Bland and Altman.

Results: Median age was 76 ys (IQR 73-83 ys), 27 males, 23 females. Median body surface area was 1,81 m2(IQR 1,71-1,94). The area of the slow component (median 44,2 mg min/ml; IQR: 37,6 to 57,9) did not correlate with the additional area of the fast (median 4,9; IQR 3,7-5,9; r = -0.16). GFR (1) (median 71,4; 54,4-82,4) was about 10-15 % larger as compared to GFR (2) (median 62,6; 50,0-72,7). The correlation between GFR (1) and GFR (2) was 0.992. Bland Altman Plot shows moderate agreement (average difference 6.9 ml/min +- 8.1 (2SD) per 1.73 m2) and larger differences for larger GFR values. After removal of systematic differences we could predict GFR(2) from GFR(1) with a precision of +- 3.7 ml/min per 1.73 m2.



Conclusions: In elderly subjects agreement between both approaches (slow vs. slow+fast component) was less compared to Schwarz et al (2006) probably due to smaller Iohexol measurements at 10 and 20 min after infusion in our sample. After including a bias correction the slow component was sufficient.

SA-PO2549

Glomerular Filtration Rates in a Healthy, Multi-Ethnic Asian Population Boon Wee Teo, Evan J.C. Lee. *Medicine, Yong Loo Liin School of Medicine, National University of Singapore, Singapore.*

Background: Measured glomerular filtration rates (GFR) in healthy Asians without chronic kidney disease (CKD) (Indians, Nephron physiol 2005 Barai et al; Chinese, AJKD 2010 Zuo et al) have reportedly been lower than in European populations. We assess the normal distribution of GFR in a multi-ethnic Asian population without kidney disease and the GFR estimated with the CKD-EPI equation.

Methods: We prospectively recruited 103 healthy participants (49.5% male, Chinese 34%, Malay 24.3%, Indian 23.2%, and others 19.4 %). We measured Scr by an enzymatic method, and measured GFR (all GFR; in mL/min/1.73m^2) using 3-sample plasma clearance of ^{99m}Tc-DTPA, normalized to body surface area (du Bois). We use linear regression to assess the association of demography with mGFR, and to develop a GFR prediction equation. We use demographic data (mean age) from previously published studies to predict the GFR of those populations. We estimate GFR (eGFR) using the CKD-EPI equation, and assess its performance using the bias (median difference of eGFR-mGFR), precision (IQR), root mean square error (RMSE), and the percentage accuracy of eGFR to within 15%, 30% and 50% of mGFR.

Results: Population means: age 42.5±14.3years, body mass index 24.9±4kg/m^2, body surface area 1.7±0.2m^2, serum creatinine 0.8±0.2 mg/dL, mGFR 101±15.8, and eGFR 104±15.2. By linear regression, predicted GFR = 124.6 – 0.565(Age). In the full multivariate model (age, gender, race), GFR was lower in males (-2.58, P=0.04) and in Indians (-9.3, P<0.001). Predicting mean GFR using data from previously published studies, the GFR for Chinese was similar: GFR 99 (male, mean age 41.6); GFR 98 (female, mean age 46.4). But is higher in our Indians: predicted GFR 97 (mean age 31.2). For eGFR, the bias is 4, precision 17.7, RMSE 14.8. Percentage accuracy of eGFR to within 15%, 30% and 50% of mGFR are 70.9, 93.2, and 99, respectively.

Conclusions: Healthy Indians have significantly lower GFR compared to other ethnic groups. When adjusted for age, the mean measured GFR in Chinese participants was similar to Chinese in China, but our Indians had higher GFR than those in India. The CKD-EPI equation estimates GFR accurately in a multi-ethnic Asian population without CKD.

The Significance of Cystatin C in Different Stages of Chronic Kidney Disease Zilong Li, Yanhui Lv, Juan Wang, Hua Zhou, Lining Wang, Jun Wang. *Department of Nephrology, First Affiliated Hospital of China Medical University, Shenyang, Liaoning, China.*

Background: To analyze the sensibility of cystatin C in reflecting glomerular filtration rate (GFR) of chronic kidney diseases (CKD), estimate the scope of cystatin C in different CKD stages and different total GFR (TGFR) groups, assess the relevance of cystatin C with proteinuria and anemia.

Methods: 70 CKD patients were divided into five stages based on estimated GFR (eGFR), and four groups based on TGFR. 20 healthy persons were selected as control group. Scr, cystatin C, the quantity of 24-hours urinary protein, hemoglobin were measured, and TGFR was measured by kidney ECT, eGFR was calculated through Cockroff-Gault formula.

Results: There is statistical difference in the levels of serum cystatin C between the patients in CKD2-5 stages and control group ($P < 0.05$), as well as in different stages of the CKD2-5patients.The concentration range of cystatin C in five stages of CKD are as follows: stage 1 is ≤1.07 mg/L, stage 2 is between 1.07 and 1.62 mg/L, stage 3 between 1.62 and 2.31 mg/L, stage 4 between 2.31 and 3.58 mg/L, and stage 5 is over 3.58 mg/L. The range of cystatin C in four TGFR groups are: in normal group cystatin C ≤1.11 mg/L, in slight injury group between 1.11~1.52mg/L, in moderate injury group 1.52~2.58 mg/L, and in severe injury group >2.58 mg/L. Significant correlation coefficient exist in the cystatin C and the quantity of urinary protein in CKD 3 stage ($R = 0.481$, $P < 0.05$).There is correlation coefficient between cystatin C and the hemoglobin of 33 patients with anemia(R=–0.688, P<0.01).

Conclusions: Cystatin C is more sensitive than serum creatinine in reflecting renal function.The quantity of urine protein have positive correlation with the level of cystatin C. And there is correlation between the concentration of cystatin C and the degree of anemia.

SA-PO2551

SCreening for Occult REnal Disease (SCORED) Is Useful tool To Identify Individuals at High-Risk for Chronic Kidney Disease Itágores Hoffman II Coutinho,[1] Manuel C. Castro,[2] José Gerley Diaz Castro,[1] Joao Egidio Romao.[2] *[1]Department of Medicine, Federal University of Tocantins, Palmas, Tocantins, Brazil; [2]Nephrology Division, Hospital das Clínicas – São Paulo University Medical School, São Paulo, Brazil.*

Background: The health burden of renal disease is high for patients and health services worldwide, and screening for chronic kidney disease (CKD) has been increasingly advocated. Population-based studies relating to the prevalence of CKD in the community are limited. We prospective studied whether stratification by SCORED values could be useful to identify subjects who are at high-risk for having CKD in a general population-based sampling.

Methods: The frequency of individuals at high-risk for CKD was determined using a cross-sectional study of 873 adult households in Palmas, Brazil, randomly selected using a stratified, cluster method. Age, gender, and race were similar to the entire Palmas´ urban population.

Results: An estimated GFR <60 ml/min/1.73 m2 was present in 46 (5.3%) of participants studied, and the risk for having CKD was greater in women than in men, and it increased with age from 2.7% in the 18 to 44 yr age group to 19.0% in those 65 yr of age older. The frequencies of CKD Stage 3, 4 and 5 were 4.8%, 0.5% and 0%, respectively. SCORED values included 224 (25.7%) patients with high SCORED values (≥4), and 649 (74.3%) subjects with low SCORED values. Subjects with higher SCORED values were at a significantly higher risk of having CKD compared with those who had lower SCORED values (12.9% vs 2.6%, $\chi 2 = 35.58$; $p < 0.001$). The sensivity for predicting CKD by SCORED model was 63% and the specificity was 76%; the positive predictive value was 13%, whereas the negative predictive value was 76%.

Conclusions: High SCORED values were associated with a higher risk for having CKD in a general population-based sampling. This simple screening tool was a useful tool to identify individuals at high-risk for CKD.

SA-PO2552

Comparison of Anticancer Drugs Dosing Recommendations for Chronic Kidney Disease Patients Based on Three Methods for Assessing Kidney Function Elerson Costalonga,[1] Veronica T. Costa e Silva,[1] Henrique Palomba,[1] James Hung,[1] Emmanuel A. Burdmann,[1,2] Luis Yu.[1,2] *[1]Nephrology Department, Cancer Institute of Sao Paulo, Brazil; [2]Nephrology Department, University of Sao Paulo School of Medicine, Brazil.*

Background: The aim of this study was to determine whether a difference exists when making anticancer drug dosage adjustments in patients with CKD and cancer based on estimation of GFR using the Chronic Kidney Disease Epidemiology Collaboration, Modification of Diet in Renal Disease(MDRD) simplified and Cockcroft-Gault(CG) equations.

Methods: eGFR was calculated using CG, MDRD simplified and CKD-EPI equation for 131 adult outpatients with cancer submitted to nephrology consultation. Equations were compared using Bland-Altman methodology. Dosage discordance rates of the antineoplasics were determined on the basis of manufacturer renal dose recommendations.

Results: On avarege patients had 66 ± 12 years and 68% were male. Median (IQR) eGFRs (ml/min) for all patients using the CG, MDRD and CKD-EPI equations were 37.7 (5 - 53), 38.8 (24 - 51) and 39.4 (24 - 52) respectively (pns). Comparisons between the three equations are shown on Table 1. A significant discordance rate of 3 - 16% ($p < 0.01$) was demonstrated among the recommended dosing adjustments of the selected anticancer drugs except for fludarabine, etoposide and bleomycin when CKD EPI was compared to MDRD. Sixty two patients (47.3%) had at least one dosage discordance.

eGFR results and anticancer drugs discordance rates

	CCG vs. MDRD	CCG vs. CKD EPI	MDRD vs. CKD EPI	
Correlation Coefficient	0.93	0.95	0.99	p < 0.01
Bland-Altman plot limits of agreement	-14.7 and 16.3	-15.1 and 15.7	-8.6 and 7.6	
Discordance Rates				
Cisplatin	16.0%	16.0%	6.1%	
Etoposide	10.6%	9.1%	3.0%	
Methotrexate	15.9%	15.3%	6.9%	
Topotecan	16.0%	13.7%	6.1%	
Fludarabine	10.7%	9.9%	3.8%	
Bleomycin	10.6%	9.1%	3.0%	

Conclusions: This analysis demonstrated significant different dosing anticancer recommendations for CKD patients according to CG, MDRD and CKD EPI equations. These results have important potential clinical implications since different outcomes may occur as a result of the discordant doses.

SA-PO2553

Influence of Thyroid Function on Different Kidney Function Tests Martin Kimmel, Niko Braun, Mark Dominik Alscher. *Department of Internal Medicine, Division of General Internal Medicine and Nephrology, Robert-Bosch Hospital, Stuttgart, Germany.*

Background: The commonly used kidney function tests (KFT) have limitations, especially in thyroid dysfunction. Therefore we studied the most commonly used KFT in patients with hypo- and hyperthyroidism and after reaching euthyroidism.

Methods: Prospective case series in 16 patients with thyroid dysfunction. Serum creatinine, 24-hour creatinine-clearance, calculated GFR by Cockroft-Gault, estimated GFR (eGFR) by CKD-EPI equation, serum cystatin C (CysC), eGFR based on CysC, eGFR based on a combined (CysC and creatinine) formula and plasma NGAL were measured in hypo- and hyperthyroidism and after gaining euthyroidism.

Results: When fT4 normalized in hypothyroid patients, creatinine decreased significantly (P<0,001) from 1,2±0,2 to 0,9±0,1 mg/dl and creatinine based eGFR increased significantly: 24 hour creatinine clearance (P<0,001), Cockroft-Gault (P<0,001) and CKD-EPI equation (P<0,001). The combined (CysC and creatinine) GFR formula increased significantly (P=0,01). In contrast CysC increased significantly (P=0,02) and eGFR based on CysC decreased significantly (P=0,02) . There was no significant change in NGAL levels (P=0,9).

When fT4 normalized in patients with hyperthyroidism creatinine increased significantly (P<0,001) from 0,63±0,10 to 0,77±0,13 mg/dl and creatinine based eGFR decreased significantly: 24 hour creatinine clearance (P=0,03), Cockroft-Gault (P=0,01) and CKD-EPI equation (P=0,02). There was no significant change (P=0,76) for the combined (CysC and creatinine) GFR equation. In contrast CysC decreased significantly (P=0,01) and CysC based GFR increased significantly (P<0,001). There was no significant change in NGAL levels (P=0,61).

Conclusions: Thyroid function has a major influence on the vast majority of KFTs. CysC is strongly influenced by the thyroid function and should be avoided in thyroid disorders, but there was no effect of the thyroid function on the low NGAL levels.

The recommended KFT in thyroid dysfunction is a creatinine based GFR estimation. Furthermore kidney and thyroid function should always be used together to avoid misleading interpretations.

SA-PO2554

Vitamin D Insufficiency and Incident Chronic Kidney Disease in Australia: The Australian Diabetes, Obesity and Lifestyle (AusDiab) Study Matthew J. Damasiewicz,[1] Dianna J. Magliano,[2] Robin M. Daly,[3] Claudia Gagnon,[4] Zhong X. Lu,[5] Peter R. Ebeling,[6] Steven J. Chadban,[7] Robert C. Atkins,[2] Peter G. Kerr,[1] Jonathan E. Shaw,[2] Kevan R. Polkinghorne.[1] *[1]Monash University, Australia; [2]Baker IDI, Australia; [3]Deakin University, Australia; [4]Laval University, Canada; [5]Melbourne Pathology, Australia; [6]Melbourne University, Australia; [7]Sydney University, Australia.*

Background: 25-OH vitamin D (25D) insufficiency has been associated with CKD (albuminuria and impaired GFR) in cross-sectional studies, however this association is less clear in prospective studies. We aim to measure the 5-yr incidence of CKD in subjects with 25D insufficiency and assess 25D insufficiency as a risk factor for CKD.

Methods: The prospective AusDiab Study followed subjects over 5 years. Incident CKD was defined as subjects negative at baseline but positive after 5 years for (1) eGFR <60 ml/min/1.72m2 using the CKD-EPI equation (impaired GFR), n=6285; or (2) spot urine

albumin to creatinine ratio of ≥2.5 mg/mmol for males and ≥3.5 for females (albuminuria), n=6096. 25D levels of <50nmol/L were considered insufficient. The incidence of CKD in 25D insufficient subjects was standardised to the 1998 Australian population. Logistic regression was used to assess 25D insufficiency as a risk factor for CKD.

Results: The annual age-standardized incidence of an eGFR<60 in subjects with and without 25D insufficiency was 0.86% (95% CI 0.65-1.07) and 0.47% (0.38–0.55), respectively; for albuminuria the incidence was 1.14% (0.89–1.38) and 0.61% (0.50–0.71), respectively. 25D insufficiency was not associated with development of an eGFR<60 (univariate OR 1.35, p=0.076, multivariate OR 0.93, p=0.725). 25D insufficiency was significantly associated with an increased likelihood of new albuminuria in both the univariate (OR 1.55,p=0.0002) and multivariate models (OR 1.42,p=0.02).

Conclusions: 25D insufficiency was significantly associated with the 5-year incidence of albuminuria, but not impaired GFR. Given this association and potential mechanistic links between 25D insufficiency and kidney damage, including modification of inflammation, cell proliferation and apoptosis, further research in this area is warranted.

SA-PO2555

Vitamin D Insufficiency and Chronic Kidney Disease in Australia: AusDiab Study Matthew J. Damasiewicz,[1] Dianna J. Magliano,[2] Robin M. Daly,[3] Claudia Gagnon,[4] Zhong X. Lu,[5] Peter R. Ebeling,[6] Steven J. Chadban,[7] Robert C. Atkins,[2] Peter G. Kerr,[1] Jonathan E. Shaw,[2] Kevan R. Polkinghorne.[1] *[1]Monash University, Australia; [2]BakerIDI, Australia; [3]Deakin University, Australia; [4]Laval University, Canada; [5]Melbourne Pathology, Australia; [6]Melbourne University, Australia; [7]Sydney University, Australia.*

Background: Low 25D levels have been associated with albuminuria, however the association with GFR is less clear. We aim to determine the associations between 25-hydroxy vitamin D levels (25D), and albuminuria and an impaired glomerular filtration rate (GFR) in a population-representative cohort of Australian adults.

Methods: The study population was the baseline Australian Diabetes, Obesity and Lifestyle (AusDiab) Study cohort, surveyed from 1999–2000 (n=10732). Estimated GFR (eGFR) was calculated using the CKD-EPI equation using enzymatic creatinine measurements, with CKD defined as <60ml/min/1.73 m2. Albuminuria was defined as a spot urine albumin to creatinine ratio of ≥2.5 mg/mmol for males and ≥3.5 for females. 25D insufficiency was defined as levels <50 nmol/L. Logistic regression models accounting for survey design were used to assess the effect of 25D insufficiency on albuminuria and CKD, adjusted for gender and age (model 1), and adjusted for multiple variables including age, gender, diabetic status, body mass index, cholesterol and triglyceride levels, smoking status, time of blood test (season), ethnicity, cardiovascular disease and systolic blood pressure, as well as eGFR or albuminuria, respectively (model 2).

Results: 30.6% of the study population had 25D level <50 nmol/L (95% CI 25.6-35.8). 25D insufficiency was significantly associated with albuminuria in the unadjusted model (OR 2.05, p<0.0001), model 1 (OR 1.78, p<0.0001), and model 2 (OR 1.56, p=0.003). While 25D insufficiency was significantly associated with an eGFR<60 in the unadjusted model (OR 1.52, p=0.02), the association was not significant in the adjusted models (model 1: OR 0.95, p=0.78; model 2: OR 0.85, p=0.31).

Conclusions: 25D insufficiency was common in this population and levels of <50 nmol/L were independently associated with albuminuria, but not with impaired eGFR.

SA-PO2556

Uric Acid Is Associated with Chronic Kidney Disease and Hypertension in the Genetics of Coronary Artery Disease in Alaska Natives (GOCADAN) Study Stacey Jolly,[1] Mihriye Mete,[2] Hong Wang,[2] Jianhui Zhu,[2] Sven O.E. Ebbesson,[3] V. Saroja Voruganti,[4] Anthony Comuzzie,[4] Jason G. Umans,[2,5] Barbara V. Howard.[2,5] *[1]Cleveland Clinic; [2]MedStar Health Research Institute; [3]Norton Sound Health Corporation; [4]Texas Biomedical Research Institute; [5]Georgetown-Howard Universities Center for Clinical and Translational Science.*

Background: Uric acid has been associated with both prevalent and incident HTN and CKD, perhaps contributing to cardiovascular disease (CVD). No studies have explored these associations in Alaska Eskimos, a population with high rates of CVD but low prevalence of DM and CKD.

Methods: Cross-sectional analysis of 89% (n=1078) of GOCADAN study participants with available lab data at baseline (2000-2004). CKD was defined by an eGFR <60ml/min/1.73m^2. Albuminuria was defined as a urine albumin/creatinine ratio 30 mg/g. Using logistic regression models, we sequentially adjusted for age, sex, smoking, BMI, DM, trigylcerides, systolic BP (or eGFR), and hsCRP to separately determine independent associations of uric acid with CKD and with HTN.

Results: The 7% (n=75) of GOCADAN participants with prevalent CKD were more likely to be older (63 v 41 y), have DM (9% v 3%), albuminuria (20% v 6%), or HTN (63% v 18%). Likewise, the 21% (n=230) with prevalent HTN were more likely to be older (57 v 39y), have DM (13% v 1%), or albuminuria (17% v 4%) (All p<0.05). Uric acid was independently associated with prevalent CKD and with prevalent HTN (Table).

Table. Associations of Uric Acid and CKD in GOCADAN

	CKD (n=1078)	HTN (n=1077)
Models	Odds Ratio (95% CI)	Odds Ratio (95% CI)
1-univariate	1.8 (1.6-2.1)	1.7 (1.5-1.9)
2-age, sex, smoking	1.8 (1.5-2.1)	1.5 (1.3-1.8)
3-above + BMI, diabetes, trigylcerides	2.0 (1.6-2.5)	1.3 (1.1-1.5)
4-above + systolic BP (or eGFR for the HTN model)	2.0 (1.6-2.5)	1.2 (1.1-1.5)
5-above + hsCRP	2.0 (1.6-2.6)	1.2 (1.1-1.5)

Conclusions: Among Alaska Eskimos, uric acid is independently associated both with prevalent CKD and with prevalent HTN. Future studies are needed to determine whether uric acid contributes to increasing CVD in this population.

SA-PO2557

Gout Risk Factors and Treatment among Chronic Kidney Disease Patients: A Hospital Based Cross Sectional Study Erdal Sarac. *Internal Medicine, Saint Elizabeth Health Center, Youngstown, OH.*

Background: Gout has doubled in prevalence in the United States. Recent studies have proposed hyperuricemia and gout as a risk factor for progression of chronic kidney disease (CKD). This study investigated the prevalence gout in patients with CKD and compared the current practice patterns to recommendations and guidelines put forward by European League Against Rheumatism (EULAR).

Methods: A total of 1,827 patients admitted between 2009 and 2010 at St. Elizabeth Health Center with a diagnosis of chronic kidney disease were included by database search using ICD-9 codes. Patients were divided into two groups: CKD with gout and CKD without gout. Data collection included age, sex, and comorbid diagnoses. A subset of 50 patients was randomly selected to compare the treatment they received with EULAR guidelines.

Results: The prevalence of gout in the hospitalized patients with CKD was 251/1827 (13.7%: 95% CI 12-15%). Males exhibited higher rates of gout: 150/814 (18.4%) vs. 101/762 (13.3%), respectively (X^2=5.40, p=0.02). Gout prevalence increased with age - highest prevalence was observed among patients age 71 to 80 years of age, with elderly males exhibiting even higher rates of disorder (17% in female and 26% in male). CKD patients with and without gout has a prevalence rate of CAD of 41.8% vs. 36.3% (X^2=2.62, p=0.11). Diabetes mellitus was higher in the CKD patients without gout, 29.8% versus 36.3% (X^2=3.99, p=0.04). Both hyperlipidemia and hypertension were higher in the CKD patients with gout: 46.2% versus 38.7% (X^2=3.99, p=0.004), and 82.5% versus 78.1%, respectively (X^2=2.20, p=0.14). Only 65% of CKD patients with gout were treated following EULAR guidelines.

Conclusions: This study reveals a high prevalence of gout in patients with CKD. Male sex, advanced age, CAD, hypertension, and hyperlipidemia were significantly associated with gout among CKD patients. In contrast, the prevalence of diabetes was higher in CKD patients without gout. Treatment for gout was sub-optimal in the subset of examined CKD patients. Newer treatment modalities for gout may change these findings in the future. Greater awareness is needed to improve the management strategies for gout in CKD patients

SA-PO2558

Association of Simple Renal Cysts by Computed Tomography (CT) with Kidney Function and Chronic Kidney Disease (CKD) Risk Factors Mira T. Keddis,[1] Terri J. Vrtiska,[2] Vicente E. Torres,[1] Andrew D. Rule.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Radiology, Mayo Clinic, Rochester, MN.*

Background: Simple renal cysts are common and can be better detected by CT scan than ultrasound, but the clinical relevance is not clear. The objective of this study was to determine if kidney function and CKD risk factors associate with cysts.

Methods: Contrast enhanced CT images of potential kidney donors between 2000 and 2008 at Mayo Clinic were reviewed to characterize renal cysts. Clinical and laboratory data was abstracted from the medical record. Hypertension was defined by use of anti-hypertensive medications or blood pressure (BP) >140/90 mmHg. The association of kidney function and CKD risk factors with renal cysts was assessed with nominal logistic, ordinal logistic, and linear regression adjusting for age and sex.

Results: There were 1946 potential kidney donors, of which, 28% had at least one renal cyst ≥ 5 mm in diameter, 42% were male, and 15% had hypertension. Mean ± SD age was 43 ± 12 years, body surface area (BSA) was 1.98 ± 0.25 m², diastolic BP 74 ± 10 mmHg, 24-h urine albumin excretion was 8.2 ± 18 mg, measured glomerular filtration rate (GFR) was 102 ± 19 ml/min/1.73 m², and serum creatinine was 0.87 ± 0.17 mg/dL.

Odds ratios or % difference for cyst findings

Kidney function or CKD risk factor	Any cyst ≥5mm	Number of cysts ≥ 5mm among persons with any cyst ≥5mm	Any cyst ≥10mm	Any cyst ≥20mm	Any cortical cyst ≥5mm	Largest cortical cyst diameter (% difference)
Age per 10 years	1.6*	1.6*	1.8*	2.3*	1.9*	11*
Male	1.5*	2.1*	2.5*	3.1*	1.9*	26*
BSA per 0.25 m²	1.0	1.2	1.3*	1.5*	1.1	12*
Hypertension	1.0	1.7*	1.4*	1.2	1.1	18
Diastolic BP per 10mmHg	1.0	1.2*	1.1	1.2	1.0	7.1*
24-h urine albumin excretion per doubling	1.1*	1.2*	1.2*	1.2*	1.1*	4.9*
Measured GFR per 19 ml/min/1.73 m²	1.1*	1.1	1.1	1.0	1.1	-0.8
Serum creatinine per 0.17 mg/dL	0.9	0.7*	0.8*	1.2	0.9	0.0

*P<0.05

Conclusions: Increased number and size of renal cysts showed some association with older age, male gender, larger BSA, diastolic BP, hypertension, increased albumin excretion, and hyperfiltration. These findings suggest simple cysts may be a marker of early kidney injury in relatively healthy adults.

Funding: NIDDK Support

SA-PO2559

Diabetic Nephropathy: Prevalence and Progression (DNP²) Study Ping Tyug Loh,[1] Matthias Paul Han Sim Toh,[2] Christine Xia Wu,[2] Valerie Ma,[1] Vathsala Anantharaman.[1] *[1]National University of Singapore, Singapore; [2]National Healthcare Group, Singapore.*

Background: Diabetes is the leading cause of End Stage Renal Failure (ESRF) worldwide with Asia contributing the largest burden; nevertheless, there is little data on prevalence and progression of Diabetic Nephropathy (DN) from Asian countries. In Singapore, population prevalence of diabetes of 11.3% and incidence of ESRF due to DN of 134 per million population are both very high. As majority of diabetics are managed in primary care setting, this retrospective study aimed to assess the burden of DN in a community healthcare cluster (National Health Care Group; NHG) by describing its prevalence and progression.

Methods: From the Chronic Disease Management Registry 2006-2009, 76,641 prevalent patients within NHG with Type 2 Diabetes Mellitus [Chinese: 69%; Female: 52%, Mean (Age: 62 years; Duration of diagnosis: 7 years; HbA1c: 7.6%; BMI: 26.4), 81% Hypertensive, 75% on Angiotensin-Converting-Enzyme-Inhibitor (ACEI) or Angiotensin-Receptor-Blocker (ARB)] were identified. These patients, were studied for prevalence of normo-(NA), micro-(MI) and macro-albuminuria (MA) as defined by ADA and for renal impairment as defined by eGFR< 60 ml/min (estimated Glomerular Filtration Rate with MDRD equation). Annualized progression from NA to MI, MI to MA and MA to renal impairment was calculated.

Results: As there were 49.2% with NA and no renal impairment, the prevalence of DN was as 50.8%; 19.1% had MI, 4.6% had MA while 27.1% had renal impairment. Progression from NA to MI occurred at 9.9% per year, from MI to MA at 7.5% per year, and from MA to renal impairment at 10.2% per year. Those who progressed were older, hypertensive with longer duration of diagnosis. HbA1c was not observed to be significantly associated with DN progression. Of note, only 13.5% of those with MI at baseline were on maximal dose of ACEI/ARB.

Conclusions: The observed rates of progression from stage to stage were very high despite relatively good glycemic control. While hypertension control could not be evaluated here, the majority of patients were on less than maximal doses of ACEI/ARB. Strategies to optimize ACEI/ARB dosage could potentially reduce the rates of DN progression.

SA-PO2560

Progression in Diabetic Nephropathy: Is Ethnicity an Independent Risk Factor? Syed Atif Mohiuddin, Rohini Mathur, Omer H. Ali, Gavin Dreyer, Sally Hull, Magdi Yaqoob. *Barts and the London NHS Trust, United Kingdom.*

Background: Higher prevalence of ESRD in south Asian and Black populations compared to Caucasians is not fully accounted for by higher prevalence of diabetes mellitus (DM). Our renal unit serves an ethnically diverse population and we analysed the progression of diabetic nephropathy (DN) in these subsets of population.

Methods: In this prospective study we analysed the progression of DN in ethnic subgroups. All patients with biopsy proven or clinical diagnosis of DN attending nephrology outpatient clinics were included in the study. 4 variable MDRD equation was used to estimate GFR (eGFR).

Results: A total of 329 patients (105 Caucasians, 75 Black and 149 south Asians, mean age 60 years ± 11.9, 121 women and 208 men) were analysed. Mean duration of follow up was over 6 years and similar in all 3 cohorts. Baseline eGFR was significantly higher in south Asians (44±21 ml/min) compared with Caucasians (38±19 ml/min, p value 0.02) but was similar to Blacks. Baseline systolic BP was significantly higher in Black (158±26mmHg) and Caucasians (146±23 mmHg) compared with south Asians (136±24 mmHg p value<0.001). Baseline diastolic BP was also higher in Black (83±15 mmHg) compared with Caucasians (76±11mmHg) and south Asians (75±11mmHg p value 0.002). ACE inhibitor or ARB use, baseline HBA1C and baseline proteinuria was not statistically different. Unadjusted analysis showed significantly higher rate of GFR decline in Black (5.38 ± SEM 0.77 ml/min/year) and south Asians (4.42±SEM 0.43) compared with Caucasians population (2.67±SEM 0.33, p 0.002 and 0.01 respectively). After adjustment for BP, glycaemic control, medication and proteinuria, there was no difference in progression between Black and Caucasians but difference persisted in south Asians (p 0.04). Systolic BP (p value <0.001) and baseline proteinuria (p value 0.02) were the other predictors of DN progression. Mortality or incidence of ESRD was not different.

Conclusions: Black and south Asians have higher rate of DN progression. This is explained by higher BP in Black but south Asians have higher rate of progression despite low BP. Further studies are needed to determine optimal target BP in this ethnic group.

SA-PO2561

Role of Asymmetric Dimethyl Arginine and Endothelial Dysfunction Associated Gene Polymorphisms in Early Stage CKD Development in Obese Patients Marat G. Gallyamov,[1] Evgeniya Saginova,[1] Maria M. Severova,[2] Marietta Lianidis.[1] *[1]Faculty of Fundamental Medicine, Lomonosov Moscow State University, Moscow, Russian Federation; [2]First Moscow State Medical University, Moscow, Russian Federation.*

Background: Endothelial dysfunction associated with obesity is one of the main mechanisms in damage such target organs as heart, vessels and kidney. Asymmetric dimethyl arginine (ADMA) is an endogenous inhibitor all types of NO-synthases (NOS) and novel marker. ADMA is tightly associated with methylen tetrahydrofolate reductase (MTHFR) and NADPH-oxidize. The aim of our study was to define role of ADMA and endothelial NOS (eNOS), MTHFR, and NADPH-oxidize gene polymorphism in early stage CKD development in obese patients.

Methods: We investigated 66 patients (17f) with BMI over 25 (mean 33.9+/-6.8) and age 18-60 yrs (44+/-11). They did not have eGFR less 45 ml/min/1.73 m^2, hematuria, albuminuria over 2.0 g/l, proved kidney diseases, coronary heart disease, brain insult. All patients were tested on leptin, insulin, C-peptide, ADMA. We detected polymorphism of C242T allele p22 subunit NADPH-oxidize gene (p22-NADPH), G894T allele eNOS gene, and C677T allele MTHFR gene. Intima-media thickness (IMT) of common carotid artery was assessed by duplex ultrasonography.

Results: 36% patients had CKD. Leptin, insulin, C-peptide levels, HOMA-index and waist circumference were higher in patients with CKD. CKD was associated with higher prevalence of increased IMT (52% vs. 30%). In CKD ADMA was significantly correlated with IMT and leptinemia. Although prevalence of pathological alleles in the genes was comparable in patients with and without CKD, homozygous p22-NADPH and MTHFR mutation carriers had the highest level of insulinemia (19.1+/-5.8 uUnits/ml) and HOMA-index (4.7+/-1.3). Combined C242T- and C677T- carriage aggravated insulin resistance and leptinemia. Patients with homozygous G894T-eNOS had lower eGFR (73+/-11).

Conclusions: In obese subjects development of CKD was tightly associated with vascular remodeling. We suggested that ADMA and C242T- p22-NADPH and C677T-MTHFR gene polymorphism can cause early stage CKD mainly via aggravation of insulin resistance and leptinemia.

Urinary F2-Isoprostanes Fail To Predict Cardiovascular Disease in a Population with High Prevalence of Diabetes, Obesity and CKD: The Strong Heart Study Nawar M. Shara,[1,2] Hong Wang,[1] Mihriye Mete,[1,2] Ginger Milne,[3] Barbara V. Howard,[1,2] Jason G. Umans.[1,2] *[1]MedStar Health Research Inst; [2]Georgetown-Howard Universities Ctr for Clin & Translational Sci; [3]Vanderbilt U.*

Background: Oxidative stress (OS) may contribute to progressive atherosclerosis and to CVD risk. Among OS biomarkers, urinary F2 isoprostanes, including 8-iso-prostaglandin F2α (8-iso), nonenzymatic products of arachidonate peroxidation, appear to provide superior and stable estimates of integrated OS, responsive to known oxidants and to antioxidants. We tested the association between urinary 8-iso and subsequent CVD events in a population with high prevalence of DM, obesity and CKD.

Methods: A nested case-control study within the Strong Heart Study (SHS) of 4,549 American Indians, aged 45-75y at baseline, with high prevalence of DM (44.8%), obesity (50.7%), and CKD (11.3%). During a median of 15y follow-up from 1989 to 2007, there were 1329 total fatal and non-fatal incident CVD events. From this population, 336 cases of incident CVD and 343 controls free from CVD at last follow-up were randomly selected and included in this analysis. Urinary 8-iso was measured by GC/MS and indexed to urinary creatinine. Samples had been stored at -80C.

Results: Compared with controls, cases developing CVD were older; had higher baseline SBP, DBP, LDL-C, fasting plasma glucose, HbA1c; had lower HDL-C; and had higher prevalence of hypertension, diabetes, microalbuminuria, and macroalbuminuria (all p<.05). Sex and BMI did not differ significantly between groups (all P>.05). Urinary 8-iso was not elevated in cases with incident CVD (p=.16). The multivariate-adjusted odds ratios (ORs) (95% confidence interval [CI]) of incident CVD across the increasing quartiles of urinary 8-iso/creatinine were 1(referent), 0.59(0.31, 1.12), 0.59(0.31, 1.14), and 0.57(0.30, 1.09); the OR (95% CI) for log (8-iso/creatinine) was 0.88(0.65, 1.19). Similar results were observed after excluding those with 8-iso >10 ng/mg creatinine.

Conclusions: There was no prospective association between baseline urinary 8-iso PGF2α and incident CVD events over a median 15y follow-up in a population with high prevalence of DM, obesity and CKD and high risk of CVD.

Factors Associated with Serum NGAL (neutrophil Gelatinase-Associated Lipocalin) in Patients with Chronic Kidney Disease Hidekazu Moriya, Kunihiro Ishioka, Machiko Oka, Sumi Hidaka, Takayasu Ohtake, Shuzo Kobayashi. *Department of Nephrology, Immunology and Vascular Medicine, Shonan Kamakura General Hospital, Kamakura, Kanagawa, Japan.*

Background: It is well known that serum or urinary levels of NGAL increases earlier than that of serum creatinine (Cr) in acute kidney injury (AKI), and that NGAL has been identified to be a useful biomarker of AKI. In addition, it has been reported that NGAL also increases in chronic kidney disease (CKD) with the property of inhibition of human erythropoiesis by stopping differentiation or apoptosis of erythroid precursors. The present study investigated the factors associated with serum levels of NGAL in patients with CKD.

Methods: We measured serum NGAL, using a ELIZA Kit (Triage® NGAL, Biosite Incorporated, USA), in 103 patients with CKD stage 1-4 who are stable for more than three months. We also measured hemoglobin, hematocrit, serum creatinine and blood pressure. We also investigated the existence of comorbidity (hypertension, chronic heart failure, urinary protein, diabetes mellitus).

Results: Thirty three patients showed that serum NGAL levels were below 60ng/ml, which was upper limit of measurement. Mean levels of remaining seventy patients were 148.4±62.7ng/m. NGAL levels are significantly positively correlated with age and negatively correlated with hemoglobin and 1/Cr, respectively. In patients with chronic heart failure, Serum levels of NGAL were significantly increased, compared with those without it (200.4±63.4 vs 138.8±58.1ng/ml, respectively). Serum levels of Cr are only an independent factor related with NGAL in a multivariate analysis.

Conclusions: NGAL increases in correlation with residual renal function in CKD patients. Moreover, chronic heart failure is an important factor to increase serum levels of NGAL.

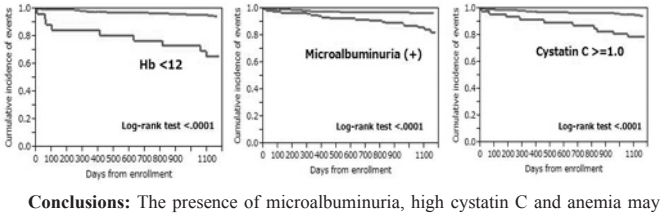
SA-PO2564

Cumulative Impact of Anemia, Albuminuria and Cystatin C on Adverse Prognosis in HIV-Infected Men Minoru Ando,[1] Naoki Yanagisawa,[1] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Department of Nephrology, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; [2]Department IV of Internal Medicine, Tokyo Women's Medical University, Tokyo, Japan.*

Background: The heightened risk for cancer and cardiovascular disease (CVD) in well-treated HIV-infected patients may be due to residual immunodeficiency and inflammation. The presence of anemia and chronic kidney disease (CKD) likely accelerates such ill linkage. We examined cumulative impact of anemia and CKD on prognosis in HIV-infected subjects.

Methods: A 3-year prospective cohort study was conducted in 520 HIV-infected men with undetectable HIV-RNA level. All-cause death and incident cancer and CVD were considered critical events. Cumulative incidence of such events was analyzed by the Kaplan Meier method, stratified by presence or absence of microalbuminuria (ACR ≥30mg/g), high cystatin C (serum level ≥1.0 mg/L) or anemia (Hb <12 g/dL). Multivariate Cox proportional hazards analysis was used to calculate the HR of developing critical events for the combined impact of 3 variables. 'Score 1' was assigned to each variable, and the maximum score is a total of 3 points. The model was adjusted for age, CD4 counts and presence of comorbidites including viral hepatitis, hypertension and diabetes at baseline.

Results: The prevalence of microalbuminuria, high cystatin C, and anemia at baseline was 23.7%, 9.0%, and 5.0%, respectively. During the follow-up period, critical events developed in 34 subjects (6.5%). The cumulative incidence of events was significantly higher in the group with microalbuminuria, high cystatin C, or anemia than in each opposite. The HR for critical events increased 2.0-fold per one-point increase in the number of risk factors (95% CI; 1.72-3.25, P=0.0002).



Conclusions: The presence of microalbuminuria, high cystatin C and anemia may have a great synergistic impact on the incidence of critical events in well-treated HIV-infected men.

SA-PO2565

Renal Endogenous Angiotensin II as a Principal Source of Urinary Angiotensin II in Chronic Kidney Disease Patients Xiaoyan Zhang, Xiaoqiang Ding, Jie Teng, Yi Fang, Jianzhou Zou. *Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China.*

Background: It has been demonstrated that there was a significant relationship between UAGT and kidney Ang II content and renal Ang II immunostaining intensities. These results provide further evidence that UAGT may be a useful index of renal endogenous Ang II activity. This study analyzed the relationship of UAng II with circulating and intrarenal RAS activity in chronic kidney disease (CKD) patients to investigate the origin of UAng II in human.

Methods: 128 CKD patients who had not received ACEI or ARB during last 2 months were included in the study. Urinary and plasma renin activity, AGT, Ang II, aldosterone and type IV collagen were measured by RIA or ELISA. Urinary AGT, Ang II, aldosterone, and type IV collagen levels were expressed per 1 mg of urinary creatinine (mg Cr). Common logarithmic transformation for RAS components and urinary type IV collagen were performed because these variables did not exhibit normal distribution.

Results: Average UAng II in 128 CKD patients was 4.92 +/- 0.70 pg/(mg Cr). 54 (42.2%) patients were male, which was negatively correlated with UAng II (r =-0.36, P<0.01). Average proteinuria was 2.03 +/- 2.66 g/24h, which was negatively correlated with UAng II (r=-0.20, P<0.05). Average plasma renin activity(PRA) was 162.10+/-81.94, 6.80+/- 1.30 pg/ml/h , which was negatively correlated with UAng II(g=-0.20, P<0.05). Average urinary angiotensinogen (UAGT) was 4.64 +/- 1.27 ng/(mg Cr), which was positively correlated with UAng II (g=0.29, P<0.01). Average urinary type IV collagen(UCol IV) was 5.19 +/- 1.39 ng/(mg Cr) , which was positively correlated with UAng II (g=0.31, P<0.01). Multiple regression analysis indicated that male (P<0.01), low proteinuria (P<0.01) and high UAGT (P<0.01) were correlated significantly with high UAng II. There was no correlation of UAng II with plasma angiotensin II.

Conclusions: Renal endogenous angiotensin II maybe the principal source of urinary angiotensin II and plasma angiotensin II doesn't play an important role in the formation of urinary angiotensin II in chronic kidney disease patients.

SA-PO2566

Body Mass Index Predictive Performance of Estimated Glomerular Filtration Rate: A cystatinC- Versus Creatinine-Based Formulas Comparison Jorge Malheiro, Isabel Fonseca, Maria Joao Carvalho Azevedo Rocha, Josefina Santos Lascasas, António Manuel Nunes Cabrita. *Nephrology Unit, Centro Hospitalar do Porto, Porto, Portugal.*

Background: Higher than normal body mass index (BMI) is a risk factor for incident chronic kidney disease (CKD). Serum creatinine and cystatin C are the two main endogenous markers of kidney function. The relations of high BMI (≥25Kg/m^2) with CKD as estimated by creatinine- and cystatinC-based estimating equations were analyzed.

Methods: Stage 1-3 CKD patients from our ambulatory clinic with stable kidney function and simultaneous measurement of serum creatinine and cystatin C were randomly selected (n=179). Skewed data was log_transformed. CKD was defined as an estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73m^2, using creatinine- or cystatinC- based formulas. Regression models evaluated the relationship between high BMI, CKD status (logistic) and eGFR (linear), adjusted for age, gender and cardiovascular risk factors (diabetes, hypertension, dyslipidemia).

Results: Patients sampled were mainly old (median age, 65 years), with a high prevalence of CKD (by creatinine- and cystatinC-based formulas 59.8% and 51.4% respectively) and cardiovascular risk factors.

Clinical comparison between patients with normal versus high BMI

	Normal BMI (n=67)	High BMI (n= 112)
Age in years, median*	58	67.5
Male gender, %	67.2	55.4
Diabetes, %*	19.4	41.1
Hypertension, %*	74.1	89.3
Dyslipidemia, %*	59.7	75
CKD prevalence by creatinine-based eGFR, %	50.7	65.2
CKD prevalence by cystatin-based eGFR, %*	34.3	61.6

* P <0.05

High BMI was not associated with CKD by creatinine-based eGFR (*P*=0.48). In contrast, high BMI was associated with CKD when defined using cystatinC-based equation in a multivariate-adjusted model (OR=2.20, *P*=0.03). In linear regression, BMI was also a predictor of eGFR by cystatinC with an estimated decrease of 0.9 ml/min/1.73m^2 per 1 Kg/m^2 increase in BMI (*P*=0.04). Linear regression between BMI and eGFR by creatinine was not significant (*P*=0.23).

Conclusions: High BMI status was associated with CKD when cystatinC-based eGFR was used, but not with creatinine-based eGFR. Influences of adiposity associated factors on serum cystatin C merit further investigation.

SA-PO2567

Iron Chelation with Deferiprone for Diabetic Nephropathy in the db/db Mouse Ahmad Bilal Malik,[1] Robert Camferdam,[1] R. Stafford Justus,[2] Songthip Ounpraseuth.[1] *[1]University of Arkansas for Medical Sciences; [2]Central Arkansas Veterans Healthcare System, Little Rock, AR.*

Background: Catalytic iron (CatFe), by participating in redox cycling generates powerful reactive oxidant species and chelation may reduce progression of diabetic nephropathy (DN) and stabilize clinical parameters.

Methods: We tested the efficacy of the oral iron chelator deferiprone in a prototypical mouse model of human diabetes mellitus type 2 ($Lepr^{db}$/ $Lepr^{db}$). Using male mice from two batches of 6 animals for the control and treatment groups each, the latter received deferiprone dissolved in drinking water (125mg/kg body weight) starting at age 4.5 weeks till euthanasia at 28 weeks.

Results: Compared with baseline (25.92 ± 0.49g vs. 30.75 ± 0.53g), weight was better preserved in the treatment group (59.2 ± 2.29g vs. 54.15 ± 8.81g) at euthanasia. Mean blood glucose deteriorated with age in both groups (160.56 ± 10.74 vs. 345.69 ± 31.98mg/dL at 6 weeks) with lower final values in the treatment group (569.38 ± 98.49 vs. 685.04 ± 31.31mg/dL at euthanasia). The linear trend in the mean 24-h urinary CatFe excretion (CatFe/Cr ratio) values was evaluated using a repeated measures analysis of variance (ANOVA) as a function of treatment, batch, weeks, and their two-way interactions. Chelation was significantly better at week 6 (p= 0.0163) and despite a considerable reduction in CatFe excretion by the end of the study in the treatment group, this did not reach statistical significance with least squares means (LSM) giving values of 50.10 ± 233.25 vs. 942.75 ± 233.01µmol/mmol in the treatment and control groups respectively. 24-h urinary protein excretion (albumin/cr ratio) at weeks 6 and 24, using repeated measures ANOVA and determining the effect of treatment with deferiprone using LSM for the main treatment effect gave values of 529.02 ± 259.7 vs. 942.08 ± 257.38µg/mg, a statistically significant reduction (p= 0.0316). Serum Creatinine was slightly better, albeit not significantly different in the treatment group (0.541 ± 0.03 vs. 0.556 ± 0.03mg/dL by LSM).

Conclusions: CatFe chelation using deferiprone in a non-iron overload prototypical DN mouse model resulted in a significant reduction in proteinuria over a 6 month period.

The Effects of Antagonism of Toll-Like Receptors by GIT27 on Lpid Metabolism and Diabetic Nephropathy in High Fat-Fed Mice Jin Joo Cha,[1] Hyunwook Kim,[2] Mihwa Lee,[1] Hye Kyung Song,[1] Deok Hwa Nam,[1] Jung Eun Kim,[1] Young Youl Hyun,[1] Ji Eun Lee,[2] Sang Youb Han,[3] Kum Hyun Han,[3] Young Sun Kang,[1] Dae R. Cha.[1] *[1]Division of Nephrology, Department of Internal Medicine, Korea University College of Medicine Ansan Hospital, Ansan-si, Gyeonggi-do, Korea; [2]Division of Nephrology, Department of Internal Medicine, Wonkwang University College of Medicine Sanbon Hospital, Gunpo-si, Gyeonggi-do, Korea; [3]Division of Nephrology, Department of Internal Medicine, Inje University College of Medicine Ilsan Baik Hospital, Goyang-si, Gyeonggi-do, Korea.*

Background: Numerous studies have demonstrated that obesity is a state of a systemic inflammatory condition. However, the underlying mechanism for linking metabolic and inflammatory pathway remains elucidated. Toll-like receptors (TLRs) have been recognized as proinflammatory and pattern-recognition receptors that play a key role in the innate immune system mainly against microbial pathogens. But recently it has been demonstrated that TLRs are also involved in sterile inflammation such as atherosclerosis and insulin resistance. Therefore, we asked whether GIT27, an immunomodulatory agent interfering TLR 4 and TLR2/6 signaling pathway, has beneficial effects on lipid metabolism and progression of kidney disease in obese high fat-fed mice.

Methods: Eight-week old male C57BL/6 mice were used and divided into 3 groups. Mice on normal chow, mice on high fat diet, and mice on high fat diet administered with 12-week intraperitoneal GIT27 treatment.

Results: With 3-month treatment of GIT 27, treated animals showed significantly improved serum cholesterol and triglyceride levels as well as gained less cholesterol and triglyceride accumulation in both kidney and liver. In addition, lipid hydroperoxide levels in the kidney, adipose tissue, and liver were significantly suppressed and urinary levels of inflammatory cytokines such as IL-2 and TNF-α and 8-isoprostane were also reduced. Moreover, treatment with GIT27 markedly decreased urinary albumin excretion and improved renal histologic changes.

Conclusions: Collectively, TLR antagonism by GIT27 might protect against obesity-related kidney disease by anti-inflammatory properties mainly affecting lipid metabolism.

SA-PO2569

Losartan Reverts Glomerular Sclerosis Induced by Type 2 Diabetes by Reducing Mesangial Cell Transdifferentiation Mirian A. Boim, Carine Prisco Arnoni, Edgar Maquigussa, Luciana G. Pereira. *Medicine - Renal Division, Federal University of Sao Paulo, Sao Paulo, Brazil.*

Background: Myofibroblastic transition (MFT) contributes to the pathogenesis of the diabetic nephropathy (DN). Ang II may have a role in this phenomenon. The present study evaluated the presence of MFT markers in a model of type 2 diabetes in rats and the capacity of the AT1 receptor inhibition by losartan to induce the regression of MFT-induced glomerulosclerosis. The MFT induction and reversion was also evaluated in cultured mesangial cells (MC), stimulated with high glucose concentration and with AngII.

Methods: Type 2 diabetes was induced by a high fat diet (55%) and low dose of streptozotocin (30mg/kg). After 12 weeks animals were divided into two groups untreated and treated with losartan (50mg/Kg/day,p.o.) for another 8 weeks. Results were compared with an age-control group (CT). Immortalized mouse MC were stimulated with 30mM glucose or AngII (10^{-7}M) during 4 days. Then cells were treated with growing doses of losartan (10^{-4}M-10^{-6}M) for 48 hr. The expression levels of fibronectin, type 4 collagen, TGF-β1 and the transdifferentiation markers including α-smooth muscle actin (α-SMA), desmin and fibroblast-specific protein 1 (FSP1) were estimated by real time PCR, Western blot and immunohistochemistry. MC transdifferentiation was confirmed by migration assay.

Results: Diabetic animals presented hypertension, hypercholesterolemia, hyperglicemia and severe proteinuria characterizing type 2 DN. Collagen accumulation, macrophages infiltration, expression of MFT markers and TGF-β1 were observed in 12 weeks diabetic kidneys. MC presented high migration capacity (more than 100% vs control cells), and increased expression levels of α-SMA according to the miofibroblast phenotype. Losartan treatment initiated after the nephropathy onset was able to significantly reduce these pre existent fibrotic manifestations and reversed the MFT displayed by MC.

Conclusions: Losartan can be a potential strategy, not only to minimaze the progression of the diabetic nephropathy, but also to reverse the fibrogenic processes by bringing cells back to their original phenotype .

SA-PO2570

Insulin and Angiotensin Converting Enzyme 2 in Podocytes: A Protective Mechanism Against Albuminuria in Diabetic Nephropathy? Eva Marquez, Marta Riera, Judit Rigol-Giner, Julio Pascual, Maria Jose Soler. *Kidney Disease Research Group, Nephrology Department, Hospital del Mar - IMIM, Barcelona, Spain.*

Background: Diabetic nephropathy (DN) is the leading cause of end-stage renal disease in our environment. Renin-Angiotensin System (RAS) blockade has been shown to delay the progression of chronic kidney disease. Angiotensin-converting enzyme 2 (ACE2) is an element of RAS that cleaves angiotensin II to angiotensin 1-7, a vasodilator and anti-proliferative peptide. ACE2 is present in glomerulus, mainly in the podocytes. ACE2 inhibition in experimental DN increases albuminuria and worsens glomerular injury. The podocyte is a key cell involved in the development of albuminuria since early stages of DN and presents a functionally active local RAS and insulin receptors in its cell surface. It is known that insulin resistance is related with the severity of albuminuria.Our hypothesis is that insulin increases ACE2 expression in podocytes as a renoprotective mechanism against albuminuria.

Methods: A conditionally immortalized mouse podocyte cell line proliferated in permissive conditions with mouse γ-interferon at 32ºC. After that cells were induced to differentiate in nonpermissive conditions at 37ºC without γ-interferon for 14 days. Cells were then incubated without or with insulin (200nM) for 24 hours and collected for gene expression studies (qPCR), immunofluorescence staining, and protein studies (WB).

Results: ACE2 protein expression was significantly increased in podocytes incubated with insulin (n=6) as compared to controls (n=6) (1.27±0.2 vs 0.67±0.1 ACE2/β-actin p=0.03). In concordance, ACE2 gene expression was significantly increased in podocytes incubated with insulin (n=6) as compared to controls (n=6) (1.83±0.21 vs 1.16±0.03 ACE2/GAPDH, p=0.004). By immunoflurescence, ACE2 staining was increased in podocytes incubated with insulin as compared to controls.

Conclusions: In the podocyte, a cell that expresses a functional intrinsic RAS, insulin incubation increases ACE2 expression. This finding may suggest a specific role of insulin in maintaining intraglomerular RAS balance and protect against the progression of diabetic kidney disease.

SA-PO2571

A2B Adenosine Receptor as Novel Therapeutic Target during Diabetic Nephropathy Douglas Ridyard, Alexander Badulak, Holger Eltzschig, Almut Grenz. *Dept. of Anesthesiology, UC Denver, Denver, CO.*

Background: More than half of patients suffering from juvenile diabetes go on to develop diabetic nephropathy (DN). Only limited therapeutic approaches are available, including dialysis or kidney transplantation. Therefore, novel therapeutic approaches to prevent or at least treat DN are presently an area of intense investigation. Adenosine represents an endogenous signaling molecule to balance inflammatory reactions under different pathophysiological conditions. Extracellular adenosine is derived mainly via phosphohydrolysis of adenosine 5'-monophosphate (AMP) by the ecto-5'-nucleotidase (CD73) and can activate four individual adenosine receptors. At present, the role of adenosine generation and signaling in DN is unknown.

Methods: At 8 weeks of age, mice received daily streptozotocin injections intraperitoneally (50 mg/kg in 0.1 M citrate buffer, pH 4.5) for 5 consecutive days. The mice were considered diabetic if the blood glucose concentration (BGC) was above 500 mg/dl.

Results: Sixteen weeks after induction of STZ-induced diabetes histological evaluation by PAS staining showed significantly more glomerular sclerosis in CD73-/- compared to WT controls. Furthermore we could show a selective induction of the renal A2B adenosine receptor transcript and protein 16 weeks following STZ-induced diabetes. After 4 months of diabetes A2BAR-/- mice showed more apoptosis in the glomeruli compared to wild type STZ-induced diabetic mice. Treatment with an A2BAR agonist (BAY60-6583)

via Alzet pumps in wild type STZ-induced mice ameliorated the severity of apoptosis thereby indicating a protective role of extracellular adenosine by stimulating the A2BAR. Interestingly we could show an increase of the A2BAR in renal vessels during STZ-induced diabetes mellitus in an A2BAR reporter mouse by utilizing XGal staining.

Conclusions: In summary we show that adenosine generation by CD73 and stimulation of the endothelial A2BAR ameliorates renal damage occurring during diabetic nephropathy. We hope these studies will lay the groundwork for novel and specific therapeutic approaches in the treatment of DN, which are urgently needed for improving the outcome of Type 1 diabetic patients.

SA-PO2572

Defective Autophagy Promotes Podocyte Injury and Diabetic Nephropathy Li Fang, Chunsun Dai, Junwei Yang. *Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical University, Nanjing, Jiangsu, China.*

Background: Podocyte injury is one of the prominent features in the progression of chronic kidney diseases as well as in the condition of diabetic nephropathy. As terminally differentiated cell, the podocyte has the ability to maintain homeostasis under certain pathophysiological stress. Autophagy, a highly regulated lysosomal pathway in the recycling of cytosol portions and the removal of superfluous or damaged organelles, is essential for cell homeostasis. However, the role and mechanisms of autophagy in podocyte dysfunction under diabetic state remain largely unknown.

Results: In this study, we found that a progressive albuminuria and podocyte injury was accompanied by defective autophagy manifested as decreased volume and numerical densities of autophagosome, along with, the downregulated expression of autophagy-related proteins including beclin-1, Atg12-Atg5, and LC3II/LC3I in kidneys from STZ-induced diabetic mice. Autophagy could be triggered in conditionally immortalized mouse podocytes in vitro with high glucose, advanced glycation end-products (AGEs), TGF-b1, AngII or bovine serum albumin (BSA) respectively. Blockade of autophagy with 3-Methylamphetamine (3-MA) or Beclin-1 siRNA promoted podocyte injury under both basal and autophagy-stimulating conditions. To investigate the correlation of ER stress with podocyte autophagy, we detected the abundance of CHOP, a sensor of severe ER stress, in podocytes treated with 3-MA or Beclin-1 siRNA. CHOP abundance was remarkably increased. Downregulation of CHOP with siRNA transfection protected podocytes from 3-MA or Beclin-1 siRNA-induced damage.

Conclusions: Taken together, these observations indicate that autophagy protects podocytes against damage through interfering ER stress and the defective autophagy may promote podocyte injury and proteinuria in diabetic nephropathy.

Nicorandil Ameliorates Podocyte Injury through the Activation of ATP-Dependent K^+ Channel in Diabetic Nephropathy Katsuyuki Tanabe, Miguel A. Lanaspa, Wataru Kitagawa, Christopher J. Rivard, Richard J. Johnson, Takahiko Nakagawa. *Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO.*

Background: Diabetic nephropathy is the leading cause for ESRD and it is urgent to find a therapeutic strategy. Unfortunately, RAS blockades are occasionally unsatisfactory, especially in patients with endothelial dysfunction. In the last ASN meeting, we reported that nicorandil ameliorated podocyte injury and reduced oxidative stress in diabetic endothelial nitric oxide synthase (eNOS) knockout (KO) mice. However, precise mechanism remains unclear. This reagent has dual actions; one is to release NO and the other is to open ATP-dependent K^+ channel. Here, we further examined a mechanism by which nicorandil prevented podocyte injury.

Methods: Podocyte injury was morphologically examined in eight week-old male eNOS-KO mice in which diabetes was induced by 50mg/kg of streptozotocin (ip) for 5 consecutive days, and nicorandil (30mg/kg/day) was administered for 8 weeks. To study direct effects of nicorandil on the differentiated podocytes, cells were stimulated by normal or high glucose with/without 10^{-5}M nicorandil for 72 hours.

Results: In diabetic eNOSKO mice, an increase in urinary microalbuminuria and urinary 8-OHdG excretion, both of which caused by diabetic condition, was significantly reduced by nicorandil. In the podocyte, podocin expression as well as number of WT-1 positive cells was less while oxidative stress was higher. However, nicorandil significantly blocked such podocyte injury. Interestingly, we found the expression of sulfonylurea receptor-2 (SUR-2), which is the component of ATP-dependent K^+ channel and importantly a binding site for nicorandil, in glomeruli, especially in podocytes. These data suggest that nicorandil could directly protect podocyte. Likewise, this assumption was proven by our in vitro evidence that high glucose caused an increase in ROS, as evidenced by the conversion from H_2DCFDA to DCF, in cultured human podocytes whereas nicorandil significantly reduced ROS production.

Conclusions: These results suggest that nicorandil has protective effects by reducing ROS on podocytes through opening ATP-dependent K^+ channel.

Serum and Urinary ACE2 Is Increased in NOD Diabetic Mice Marta Riera,[1] Eva Marquez,[1] Heleia Roca-Ho,[1] Daniel Batlle,[2] Julio Pascual,[1] Maria Jose Soler.[1] [1]*Kidney Disease Research Group, Nephrology Department, Hospital del Mar- IMIM, Barcelona, Spain;* [2]*Nephrology, Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: ACE2 is a homologue of ACE that plays a counter-regulatory role. Renal cortex ACE2 activity is increased in some diabetic mouse models. However, little is known about ACE2 and the effect of insulin in NOD(non-obese diabetic).

Methods: Serum, urinary and renal cortical ACE2 was studied in NOD mice at 20 and 40 days after onset diabetes and compared with NOR controls and with insulin-treated NOD.

Results: Blood glucose and UAE increased in NOD as compared to NOR (21d; BG:571.1±20.3 vs 112.0±4.9mg/dL. UAE: 91.4±27.1 vs 8.6±3.0µgAlb/mgCrea/40d; BG; 550.6±32.7 vs 138.7±4.3. UAE: 492.2±310.9 vs 22.0±4.4, $p<0.05$). Insulin administration decreased BG and UAE (21d; BG: 113,4±5,4. UAE: 20.5±4.6 / 40d: BG: 88,4±12,2. UAE: 50.4±15.7, $p<0.05$).

Serum and urine ACE2 enzyme activity was increased in NOD mice compared to NOR.Insulin administration decreased serum and urine ACE2 activity.

	Serum ACE2 activity(RFU/µl/hr)	Urine ACE2 activity(RFU/µgCrea/hr)
NOR21d	71.5±4.3	1.6±0.1
NOD21d	249.8±39.0*	7.8±1.6*
NODins21d	126.7±14.8#	3.7±1.3
NOR40d	60.9±2.5	2.4±0.7
NOD40d	543.5±145.0*	37.5±10.3*
NODins40d	106.6±15.6#	4.2±1.7#
p	p<0,05(NOD vs*NOR or#NODins)	p<0,05(NOD vs*NOR or#NODins)

In tubules from NOD, ACE2 protein expression by WB was increased compared to NOR mice at 40 days of diabetes (21d; 0.38±0.1 vs 0.3±0.1 ACE2/β-actin / 40d; 1.2±0.2 vs 0.4±0.1, $p<0.05$). Insulin administration increased protein expression in 40d NOD mice(2.3±0.6, $p<0.05$).

Renal cortex ACE2 activity in NOD at 40 days increased compared with NOR (ACE2 activity: 2552.1±730.6 vs 1576.0±576.6 RFU/µg/hr, $p<0.05$). Insulin administration restored control values (1785.0±519.6, $p<0.05$).

Correlations: serum and urinary ACE2 activity with BG ($r=0.57, p<0.05$; $r=0.76, p<0.05$) and serum and cortical ACE2 activity with UAE ($r=0.83, p<0.05$; $r=0.54, p<0.05$).

Conclusions: NOD mice show increased serum and urinary ACE2 activity in an early stage of diabetic kidney disease and it remains elevated after 40 days of diabetes. Serum and urinary ACE2 may be an early marker of diabetic kidney disease.

The Change of β-Catenin in Experimental Diabetic Nephropathy Tae-Sun Ha. *Pediatrics, Chungbuk National University College of Medicine, Cheongju-si, Chungbuk, Korea.*

Background: Proteinuria is a cardinal feature of glomerular disease including diabetic nephropathy, and glomerular filtration barrier is considered as a filter restricting protein excretion in urine. We tested whether the expression of β-catenin, a molecule known to be located at the silt diaphragm, would be altered by high glucose in the cultured podocyte *in vitro* and by diabetes *in vivo*.

Methods: To investigate whether diabetic conditions including high glucose and advanced glycosylation endproducts (AGE) induce podocyte β-catenin changes, we observed renal tissues of diabetic rat obtained at 48 hrs, 4 weeks and 10 weeks after the induction of diabetes. And, we cultured rat glomerular epithelial cells (GEpC) and mouse podocytes under normal (5 mM) or high glucose (30 mM, HG) and AGE- or BSA-added conditions and examined the distribution of β-catenin by confocal microscope and measured the change of β-catenin expression by Western blotting and RT-PCR.

Results: Immunofluorescence of rat tissues stained with α-actinin and β-catenin showed their co-localization and decrease in intensities at podocyte around capillary loops. We also found that β-catenin relocalized from peripheral cytoplasm to inner actin filaments and its decrease in intensities by both AGE-added and HG condition in GEpC and mouse podocytes. In Western blotting, HG or AGE-added condition decreased β-catenin expression by 20.5% ($p<0.05$) and 16.0% ($p<0.05$), respectively, compared to the normal glucose condition. HG plus AGE-added condition further decreased β-catenin protein expression to statistically significant level (31.5%, $p<0.05$). No significant change was seen in osmotic control. In RT-PCR, HG plus AGE-added condition significantly decreased the expression of β-catenin mRNA by 14% ($p<0.05$) compared to normal glucose condition.

Conclusions: These results suggested that the exposure of podocytes to HG and AGE *in vitro* and diabetes *in vivo* reduced β-catenin mRNA and protein expression. These findings suggest that the decrease in β-catenin expression is connected to the early changes of diabetic nephropathy and thus may contribute to the development of proteinuria.

Short Duration of Diabetes Alters Renal Endothelial Cell Function Christine M. Sorenson, Cathy Grutzmacher. *Department of Pediatrics, University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: Diabetic nephropathy is the most common cause of end stage renal disease and is a major risk factor for cardiovascular disease. In the United States, microvascular complications during diabetic nephropathy contribute to high morbidity and mortality rates. However, the identity of the underlying molecular and cellular mechanisms remains elusive.

Methods: Male Akita/+ (autosomal dominant mutation in the insulin II gene (Ins2)) mice, which reproducibly develop diabetes by 4 weeks of age were used. The impact of short duration of diabetes on renal endothelial cell (EC) function, as well as ex vivo aortic sprouting, was determined. Capillary morphogenesis of renal EC was evaluated in Matrigel. The migration of EC was evaluated using a transwell and scratch wound assay. The changes in eNOS expression and phosphorylation, as well as production of various extracellular matrix proteins, were determined by Western blotting. The rate of EC proliferation and apoptosis was determined using Clik-it EdU and TUNEL-labeling, respectively.

Results: Renal EC from Akita/+ mice following 4 weeks of diabetes demonstrated decreased migration and capillary morphogenesis. These studies were consistent with our aortic *ex vivo* angiogenesis assays, which showed a significant decrease in the number of sprouting outgrowths in aortas from Akita/+ mice. We also observed increased total and phosphorylated eNOS expression in renal EC from diabetic mice, which in turn corresponded with a 4-fold increase in NO level. In contrast, to renal tubule cells during diabetes, renal EC demonstrated decreased osteopontin expression along with increased fibronectin expression, potentially contributing to EC dysfunction. The levels of proliferation and apoptosis were similar.

Conclusions: These studies demonstrate that aberrant EC function with short duration of diabetes may set the stage for vascular dysfunction and rarefaction at later stages of diabetes.

Progressive Renal Failure, Proteinuria and Glomerulosclerosis in a Murine Model of Diabetic Nephropathy Is Associated with Mitochondrial Oxidative Stress Sharma S. Prabhakar. *Medicine, Texas Tech Medical Center, Lubbock, TX.*

Background: Animal models of diabetic nephropathy (DN) hitherto described do not confirm to human disease since they do not exhibit the progression of proteinuria or renal failure characteristic of human disease. We previously characterized and published the phenotypic features of ZSF1 rats at 20 weeks which develop histological and functional changes that mimic early human DN (*Prabhakar et al JASN 2007*). We studied ZSF rats for much longer period with the goal of examining the progression of nephropathy and seeking correlations with human DN.

Methods: ZSF rats were obtained at 8 weeks of age and fed on high calorie diet till 40th week to maintain hyperglycemia. The body weights and blood pressures were monitored weekly while blood samples were obtained at the 8th, 12th 24th and 40th week. A 24 hour urine sample was obtained at the same time points for the measurement of creatinine clearance and protein excretion rates. Since 8-OHdG (8- hydroxy-deoxyguanosine), a measure of mitochondrial oxidative stress correlates better with total body oxidant stress and urinary excretion of 8-OHdG parallels the renal oxidative stress, urinary 8-OHdG levels were measured at the same time points. At 40 weeks the rats were euthenized and kidneys harvested to examine the histopathology.

Results: ZSF rats developed obesity hypertension, hyperlipidemia by 12th week as well as nephropathy with progressive proteinuria and renal failure that reached end stage by 40th week. Renal histology at this stage showed advanced diffuse glomerulosclerosis. The results of the functional parameters measured are shown below.

Functional characteristics of ZSF rats at different ages

Age in weeks	8	12	24	40
Uprot (mg/G creat)	165±37	459±84	1254±148	3658±542*
CCr (L/Kg/BW/d)	5.3 ± 1.2	4.2 ± 0.9	3.1 ± 0.7	2.1±0.6*
Ur 8-OHdG (ng/ Kg/BW)	387±89	2468 ±307	5429± 453	7658±566*

n=6, *p<0.001 vs. at 8 weeks age.

Conclusions: We conclude ZSF1 rats develop obesity, diabetes and nephropathy which progresses to advanced renal failure along with nephrotic syndrome, profound mitochondrial oxidative stress and diffuse severe glomerulosclerosis. Thus ZSF rats represent an ideal murine model to study human DN.

The Absence of Collagen Type VIII Leads to Inhibition of Epithelial-Mesenchymal Transition (EMT) in Induced Diabetic Nephropathy Ivonne Loeffler, Gunter B. Wolf. *Internal Medicine III, Universiyt of Jena, Jena, Germany.*

Background: The epithelial-mesenchymal transition (EMT) is a mechanism of renal tubulointerstitial fibrosis in diabetic nephropathy (DN) that leads to an accumulation of smooth muscle α-actin (α-SMA)-positive myofibroblasts. The process of the EMT is characterized by the progressive loss of E-Cadherin, zonula occludens 1 (ZO1) and cytokeratine (CK) of tubular epithelial cells, which is associated with increased expression of mesenchymal markers (α-SMA, fibroblast-specific protein 1 FSP1 and vimentin). It has been reported, that up to 36 % of matrix-producing cells in the tubulointerstitium are of epithelial origin and may develop from tubular epithelial cells by EMT. We have previously found that the non-fibrillar short-chain collagen VIII (genes: COL8A1 and COL8A2) expression is enhanced in renal cells of diabetic mice and in biopsies of patients with DN, COL8A1 and COL8A2 expression was also inducible in mesangial cells by stimulation with TGF-β1 in vitro. Furthermore, we have shown that the characteristic features of DN in STZ-induced diabetic Col8A1/A2 knockout (KO) mice were significantly lower compared to the wildtype. The present study investigates whether EMT plays a role in these effects.

Methods: Kidneys from healthy and STZ-induced diabetic wildtype and Col8A1/A2-KO mice were harvested and analyzed. We investigated the expression of miscellaneous EMT markers with immunohistological as well as PCR array technology.

Results: In contrast to diabetic wildtyp mice, showing Col8A1/A2 expression, no evidence on development of EMT was found in diabetic Col8A1/A2-KO mice. Both, the significant increase of renal interstitial myofibroblasts and the inhibition of the expression of epithelial markers respectively the enhanced expression of typical mesenchymal markers in tubular cells were missing in kidneys of diabetic Col8A1/A2-KO mice.

Conclusions: The results suggest that either collagen type VIII may be one of the major inducer of EMT in kidneys of diabetic wildtyp mice or at least the lack of Col8A1/A2 disrupts the process of TGF-β1-induced EMT.

Phenotypical Changes of Podocyte CD2AP in Experimental Diabetic Nephropathy Via PI3-K/Akt Signaling Tae-Sun Ha. *Pediatrics, Chungbuk National University College of Medicine, Cheongju-si, Chungbuk, Korea.*

Background: Proteinuric conditions demonstrate ultrastructural changes in podocytes with retraction and effacement of the highly specialized interdigitating foot processes, resulting in hyperpermeability.

Methods: To investigate podocyte phenotypical changes, including quantitative and distributional changes of CD2AP protein in diabetic conditions, we prepared diabetic renal tissues and cultured podocytes in diabetic conditions. According to diabetic duration, density of CD2AP in renal tissue of experimental diabetic nephropathy became conglomerulated and diminished. To investigate how high-glucose (HG) and advanced glycosylation end products (AGE) induce podocyte phenotypical changes, including quantitative and distributional changes of CD2AP protein and search for the signaling mechanisms, we cultured rat glomerular epithelial cells (GEpC) and mouse podocytes under: (1) normal glucose (5mM, = control); (2) HG (30 mM); (3) AGE-added; or (4) HG plus AGE-added conditions. We also examined the *in vivo* changes of CD2AP in streptozotocin-induced diabetic tissues.

Results: HG plus HG and AGE induced the re-localization of CD2AP into inner actin filaments complexes by confocal imaging. In Western blotting, administration of high glucose or AGE decreased the CD2AP productions by 36.9% ($p<0.05$) and 16.0% ($p<0.05$), respectively. Furthermore, both high glucose and AGE decreased the amount of CD2AP more significantly by 64.6% compared to those of control ($p<0.01$). In RT-PCR, administration of high glucose, AGE or both high glucose and AGE decreased the expression of CD2AP mRNA by 44.9%, 27.9%, and 29.3% ($p<0.05$), respectively, compared to that of control. In addition, LY294002, a PI3-K inhibitor, could prevent the quantitative and distributional changes of CD2AP induced by HG and AGE.

Conclusions: These findings suggest that diabetic conditions induce the phenotypical changes of podocyte CD2AP via PI3-K/Akt signaling.

The Role of MORG1 in Early-Stage Diabetic Nephropathy (DN) Carola Ruhe, Gunter B. Wolf. *Internal Medicine III, University of Jena, Germany.*

Background: DN is a progressive kidney disease resulting and is characterized by excessive deposition of extracellular matrix proteins, increasing intrarenal inflammation and chronic hypoxia. The mitogen-activated protein kinase organizer 1 (MORG1) has been identified as a novel WD-repeat protein that interact with the prolyl hydroxylase 3 (PHD3), an important enzyme involved in the regulation of the hypoxia-inducible factor (Hif). The purpose of this study was to assess the role of MORG1 in the development of early-stage diabetic nephropathy in diabetic heterozygous MORG1+/- mice.

Methods: Diabetes mellitus was induced in wildtype MORG1+/+ and heterozygous MORG1+/- mice with an intraperitonal injection of streptozotocin (STZ, 5 x 50mg/kg). Immunohistochemistry and molecular biology techniques were used to estimate the expression of extracellular matrix proteins (collagen I, collagen IV and fibronectin), proinflammatory mediators (e.g. MCP-1 – monocyte chemotactic protein-1) and the transcription factors Hif1α and Hif2α in the kidney of non-diabetic and diabetic mice.

Results: The expression of collagen I in the glomeruli of diabetic heterozygous MORG1+/- mice was significantly less compared with the diabetic wildtype MORG1+/+ mice. On the other hand, downregulation of MORG1 did not show a significant impact on glomerular deposition of both collagen IV and fibronectin The proinflammatory mediator MCP-1 was significantly increased in the diabetic group compared with the non-diabetic group, but there were no significant differences in the expression of MCP-1 between diabetic wildtype and diabetic heterozygous mice.

Conclusions: Downregulation of MORG1 reduces the deposition of extracellular matrix proteins and attenuates the progression of DN. However, the expression of proinflammatory markers seems to be independent from MORG1.

SA-PO2581

The Inflammatory Genotype of Diabetic Nephropathy Katherine J. Kelly,[1] Jesus H. Dominguez.[1,2] *[1]Nephrology, Indiana U, Indianapolis, IN; [2]VAMC, Indianapolis, IN.*

Background: Obese, diabetic ZS (F1 hybrids of Zucker and SHHR) rats develop progressive renal fibrosis and inflammation on a high fat diet. Nephropathy is markedly accelerated after a single episode of renal ischemia.

Methods: Whole transcriptosome RNA sequencing was performed to fully characterize transcript expression in obese-diabetic/postischemia (OI) as compared to obese-diabetic/sham surgery (OS) and lean (L) rat kidneys.

Results: WBC (cells/hpf) are markedly increased in OI rats: 0.3±0.2 in L, 8±1 in OS, 12±1 in OI, p<0.01, with the majority being macrophages (MP). MP were also prominent in biopsies of diabetic nephropathy (30±2 vs 10±3 in membranous or hypertensive renal disease). A wide variety of genes encoding pro-inflammatory mediators were markedly upregulated (for example, 83 and 19 fold increase in IL24; 5.0 and 3.3 fold increase in the chemokine Ccl6 in OI and OS vs L). Upregulated transcripts included MP antigens (for example CD 68 was increased 2.5 and 2.2 fold in OI and OS vs L). mRNAs for chemokines associated with pro-inflammatory M1 MP polarization (Ccl19, 4.3 and 2.9 fold; Ccl7, 7.8 and 3.1 fold; Cxcl11, 2.2 and 1.7 fold) were significantly increased. Although mRNAs for M2 polarization antigens (mannose receptor, 6.0 and 3.1 fold) were also increased, the M2 genotype was not fully expressed. IL4 and IL13, mediators of M2 activation, were undetectable in OI and OS kidneys. mRNAs for MP scavenger receptors (CD163 increased 20 and 16 fold; MSR1 4.3 and 2.8 fold), MP elastase (8.3 and 5.3 fold) and Trem2 (triggering receptor expressed on macrophages; 23 and 15 fold) were among the transcripts most markedly altered in the obese-diabetic/postichemic kidneys. The increases in pro-inflammatory mediator gene expression are consistent with recruitment of multiple types of inflammatory cells to the kidney, amplification of the inflammatory response and tissue injury.

Conclusions: RNAseq data on mRNA encoded proteins are tremendously valuable for they offer a comprehensive and integrated view of the massive inflammatory response in diabetic nephropathy. This analysis shows a broad immunological dysfunction in the diabetic kidney and at the same time reveals a multitude of potential targets for therapy.

SA-PO2582

High Glucose Upregulates Nucleoporin62 (Nup62) in Human Mesangial Cells Rekha Singh. *Research, Hines VA Medical Center, Hines, IL.*

Background: Malfunction of nuclear pore complex (NPC) proteins such as nucleoporin62 (Nup62) could alter nuclear import of transcription factors resulting in abnormal gene transcription. Our preliminary studies in Streptozotocin (STZ)-induced diabetic rats (type 1 diabetes) and Zucker diabetic fatty rats (ZDF, type 2 diabetes) showed increased protein expression of Nup62 in glomerular extracts suggesting that high glucose milieu in diabetes might affect NPC functions. In this study, we further examined the effect of high glucose on Nup62 in glomerular mesangial cells.

Methods: Primary human mesangial cells (HMC; ScienCell, CA) were cultured and incubated with media (without serum and growth factors) containing 5 mM glucose (NG) or 25 mM glucose (HG) for a period of 1-10 days. At termination of experiments, cytoplasmic and nuclear extracts were prepared and protein expression of Nup62 was determined by Western blotting. Also, HMC were seeded in Lab-Tek cell culture slides and Nup62 localization was examined by immunofluorescence. Since high glucose-induced stimulation of mesangial matrix is mediated by angiotensin II (Ang II), we tested the effect of Ang II (1 μM) on Nup62 protein expression and localization in HMC. Additionally, HMC treated with HG or Ang II were also analyzed for protein expression and localization of nuclear transport factor2 (NTF2) which is functionally associated with Nup62.

Results: Exposure of HMC to high glucose caused upregulation of Nup62 protein expression in nuclear extracts and an increase in Nup62 localization on the nuclear membrane. In addition, protein expression and nuclear accumulation of NTF2 was found to be greater in HG-treated cells compared to NG-treated cells. Incubation of HMC with Ang II resulted in increased Nup62 and NTF2 protein expression accompanied by increased co-localization of AT1 receptor with Nup62 in the nucleus. Similar to Ang II, HG also enhanced nuclear co-localization of AT1 receptor with Nup62 in HMC.

Conclusions: These results suggest that both high glucose and Ang II increase protein expression and nuclear localization of Nup62 and NTF2 in HMC which could affect nuclear import of transcription factors and gene transcription of matrix proteins.

Funding: Veterans Administration Support

SA-PO2583

Nephrinuria vs. Podocyturia: Which Is a Better Early Marker for Diabetic Nephropathy? Shuchita Sharma,[1] Andi Qipo,[1] Kwanghee Kim,[2] Pu Zong,[1] Swati Mehta,[1] Dennis Michael Bonal,[3] Belinda Bun Jim.[1] *[1]Jacobi Med Ctr, NY; [2]Trinity Health Ctr, ND; [3]Columbia Med Ctr, NY.*

Background: There is interest in using urinary podocyte (podocyturia) as a marker to assess glomerular disease activity in diabetic nephropathy (DN), as its pathogenesis is related to podocyte loss. However, technical issues and lack of validation still prevent its clinical application. Nephrin, a podocyte protein, is also found in the urine of diabetic patients (nephrinuria). With the advent of an enzyme-linked immunosorbent assay (ELISA) for nephrin (Exocell, Inc. Philadelphia, PA), we are able to accurately measure nephrinuria. Which marker offers superior correlation with clinical disease is unclear.

Methods: We compared these two markers by quantifying podocyturia and nephrinuria in 24 diabetic patients and 10 healthy controls and correlated with clinical parameters. For podocyturia, a cell pellet was obtained via centrifugation from fresh urine and fixed for immunofluorescence. Podocytes were identified by colocalization of podocyte markers podocin and synaptopodin and counted by 2 investigators. For nephrinuria, ELISA was performed on urine supernatant. The Wilcoxon rank test compared differences between study and control groups, while the Spearman rank correlation coefficients associated clinical parameters with urine podocyte-to-creatinine ratio (UPodCR) and urine nephrin-to-creatinine (UNCR).

Results: UPodCr and UNCR were both significantly higher in the study than control groups (p=0.005 and p=0.01 respectively). UNCR correlated significantly with urine albumin-to-creatinine ratio (UACR) (rho=0.92,p<0.0001), BUN (rho=0.47, p=0.02), serum creatinine (rho=0.48, p=0.01), systolic BP (rho=.75, p<.0001), while UPodCR did not: UACR (rho= -0.46,p=0.02), BUN (rho= -0.34, p=0.09), serum creatinine (rho= -0.50, p=0.01), systolic BP (rho= -0.45,p=0.02). Other variables such as serum albumin, presence of diabetic retinopathy, HB_{A1C}, use of ACEI/ARB did not show significant correlation with either method.

Conclusions: As nephrinuria correlates better than podocyturia with most clinical parameters in DN, we conclude that nephrinuria is a superior marker and avoids the technical pitfalls of counting podocytes.

SA-PO2584

High Glucose Promotes Renal Tubular CTGF Expression Via the Activation of Protease-Activated Receptors Wai Han Yiu,[1] Joseph C.K. Leung,[1] Loretta Y.Y. Chan,[1] Hui Y. Lan,[2] Kar Neng Lai,[1] Sydney C.W. Tang.[1] *[1]Department of Medicine, University of Hong Kong, Queen Mary Hospital, Hong Kong; [2]Department of Medicine and Therapeutics, and Li Ka Shing Institute of Health Sciences, Chinese University of Hong Kong, Hong Kong.*

Background: Protease-Activated Receptors (PARs) are potent mediators of inflammation and fibrosis after being cleaved and activated by serine proteases. Overexpression of PARs in several kidney diseases suggests a possible role in the progression of kidney damage. Based on our previous study in which high glucose stimulates pro-inflammatory and pro-fibrotic signals in cultured human proximal tubular epithelial cells (PTEC), we here investigate the role of PARs in high glucose induced expression of connective tissue growth factor (CTGF), the pro-fibrotic mediator for the accumulation of extracellular matrix protein and the pathogenesis of diabetic nephropathy.

Methods: Human PTEC were cultured in medium with normal glucose (5mM), high glucose (30mM) or high glucose with specific PAR antagonist (SCH79797 for PAR-1, ENMD-1068 for PAR-2 and trans-Cinnamoyl-YPGKF-NH2 for PAR-4) added 1h before stimulation. RNA were isolated after 6h incubation for gene expression analysis by quantitative real time PCR and culture supernatant were collected after 24h incubation for protein expression analysis by ELISA.

Results: We demonstrated the expression of PARs in PTEC. PAR-2 was the most abundant receptor in PTEC compared to PAR-1 and PAR-4, whereas PAR-4 had the lowest expression among the receptor family. However, high glucose (30mM) selectively enhanced PAR-4, but not PAR-1 and PAR-2 mRNA expression in PTEC. In addition, high glucose stimulated a time-dependent increase in CTGF mRNA and protein levels, and the expression was significantly inhibited by pre-incubation with PAR-1, PAR-2 and PAR-4 antagonists.

Conclusions: These results suggest that PARs mediate the modulation of CTGF expression in renal tubular cells and the up-regulation of PAR-4 may further contribute to the progression of fibrosis in the diabetic kidney.

This study is supported by the General Research Fund of the Research Grants Council of Hong Kong (project number 7796/11M)

SA-PO2585

The Role of FXR in Renal Diseases and Associated Metabolic Disorders Affecting Offspring Impacted by Maternal Obesity Sonia Saad,[1] Hui Chen,[2] Katherine Jane Pegg,[1] Carol A. Pollock,[1] Muh Geot Wong.[1] *[1]Medicine, Kolling, Sydney, NSW, Australia; [2]Science, UTS, Sydney, NSW, Australia.*

Background: Children of obese mothers have increased risk of developing obesity, dyslipidemia, glucose intolerance and chronic kidney disease. The link between dysregulated lipid metabolism and pathogenesis of nephropathy is increasing. The underlying mechanisms are unclear. Obesity leads to increased plasma free fatty acids. The nuclear receptor farnesoid X receptor (FXR) regulates fatty acid metabolism and abnormal FXR expression or function plays an important role in nephropathy associated with substrate metabolic disorders. The aim of this study is to investigate if disordered FXR contributes to the link between lipid metabolic disorders in obese mother and the adverse renal outcomes in their offspring in vivo.

Methods: Renal proximal tubule epithelial cells (HK2) were exposed to high glucose (HG) for 24 and 72 hrs. FXR and SREBP-1c mRNA expression was determined by real time PCR. siRNA was used to silence FXR. Collagen IV (CIV) and Fibronectin (FN) levels were determined by Western blot. FXR levels in the kidney of patients with diabetic nephropathy (DN) vs non-diabetic patients was determined by immunohistochemistry. Female Sprague Dawley rats were fed either HFD (20kJ/g) or chow (14kJ/g) before mating and for the experimental period (9 weeks). Abdominal fat, plasma and liver triglyceride, blood glucose change during glucose tolerance test in chow and HFD-fed offspring from obese mothers were measured. Renal structure and FXR expression were determined by immunohistochemistry.

Results: HK2 cells exposed to HG have reduced FXR but increased SREBP-1c mRNA expression. FXR silencing augments high glucose induced FN and CIV expression in

these cells. FXR is expressed in renal human tubule and its level is reduced in patients with DN. Renal structural changes were present in offspring from obese mothers with features of dysregulated glucose and lipid metabolism in association with reduced FXR expression in the tubule.

Conclusions: Our results suggest a role for FXR in adverse renal outcomes in offsprings from obese rats with metabolic derangement which may be of considerable therapeutic value.

Clinical and Molecular-Pathological Effects of Chronic Hypoxia on Diabetic Nephropathy in db/db Mice Naoki Takahashi,[1] Hideki Kimura,[1] Kazuko Kamiyama,[1] Tomomi Kurose,[2] Hidehiro Sugimoto,[2] Toshio Imura,[2] Daisuke Mikami,[1] Kenji Kasuno,[1] Haruyoshi Yoshida.[3] *[1]Division of Nephrology, University of Fukui, Japan; [2]Division of Clinical Laboratories, Fukui University Hospital, Fukui, Japan; [3]Department of Internal Medicine, Sugita Genpaku Memorial Obama Municipal Hospital, Obama, Japan.*

Background: Hypertension, angiogenetic cytokines and eNOS-VEGF imbalance, which may be affected by chronic hypoxia, reportedly accelerate progression of diabetic nephropathy. However, no detailed information has been known about the clinical and molecular-pathological effects of chronic hypoxia on diabetic nephropathy in db/db mice.

Methods: 8 w.o. male db/db mice were bred in a normobaric hypoxic chamber (12%O_2). The hypoxic group (H-group) was kept in this chamber for 16 weeks (n=11) and the control group (N-group) was bred in room air (n=12). Mice were sacrificed at 12 and 24 w.o. in order to evaluate histological changes and mRNA amounts (VEGF-A, PAI-1, MCP-1, TGF-β1, CTGF, eNOS, CD34 and Angiopoetin1 and 2) extracted from whole kidney.

Results: H-group showed severer erythrocytosis, greater albuminuria and higher serum LDL levels than N-group, while the two groups did not differ in levels of blood pressure, serum Cr, Ccr or urinary VEGF-A antigen. As for histological aspects, H-group had greater glomerular swelling (1.3-fold), lower number of podocyte and CD34-positive endothelium per glomerular area and higher rates of microaneurysm formation, glomerulosclerosis and glomerular macrophage infiltration than N-group. Glomerular VEGF-A positive area levels were, however, similar in H and N-groups. Concerning molecular analyses, in H-group, mRNA levels of MCP-1 and PAI-1 were significantly increased by 1.6-fold at 4W and1.9-fold at 16W and by 2.1-fold at 16W, respectively as compared with N-group, whereas mRNA levels of VEGF-A, TGF-β1, CTGF, Angiopoetin1 and 2, CD34 and eNOS were very similar.

Conclusions: Hypoxia-specific glomerular injury may result from the decreased number of endothelium and podocyte per glomerular area and the increased macrophage infiltration via MCP-1 and PAI-1 induction, but not from hypertension or hyperfiltration.

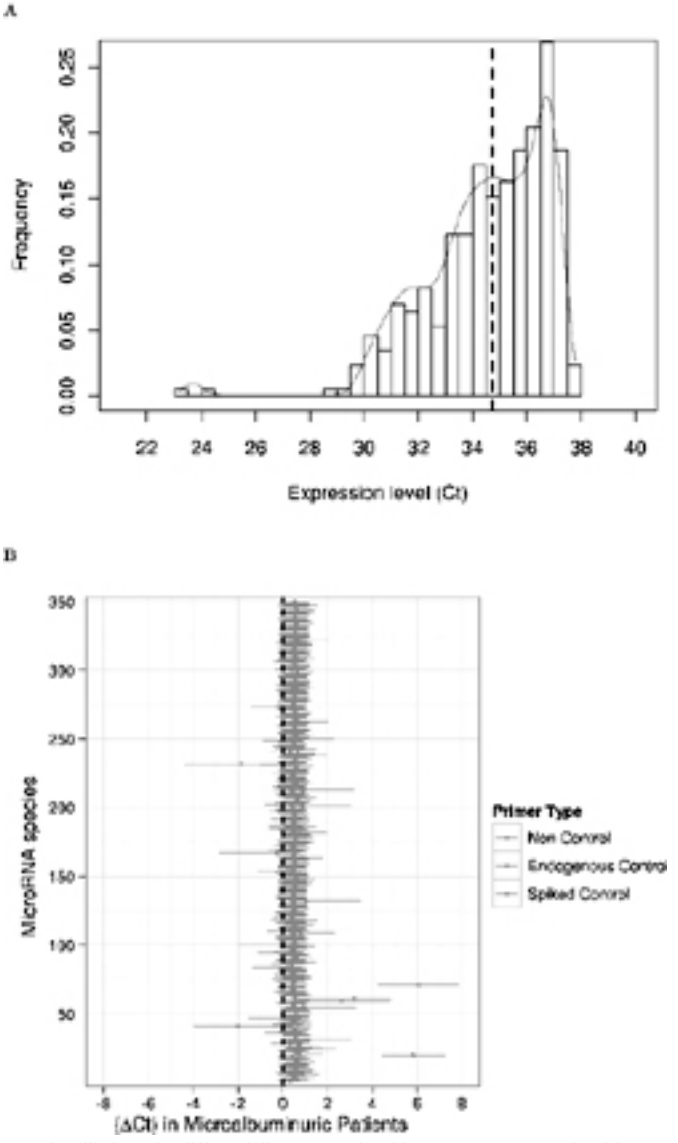
SA-PO2587

Urine microRNA Profiling in Nephropathy of Type 1 Diabetes Christos Argyropoulos,[1] Kai Wang,[2] Jose F. Bernardo,[1] David Galas,[2] John P. Johnson.[1] *[1]University of Pittsburgh, PA; [2]Institute for Systems Biology, Seattle, WA.*

Background: Diabetic Nephropathy (DN) is the leading cause of Chronic Kidney Disease (CKD) in the US, affecting 1/4 of patients with Type 1 Diabetes (T1D). We examined urine profiles of microRNA (miR), endogenous RNA negative regulators of gene expression, as biomarkers for the development of DN.

Methods: Patients (pts) with T1D from the Pittsburgh Epidemiology of Diabetes Complications (EDC),a historical prospective cohort, free from DN (N,n=10), or with microalbuminuria (MA,n=20) during follow up (f/u). We profiled miR spectrum in urine from the last f/u visit (N) or the last non-albuminuric visit (MA) pts, with qPCR panels. The PCR cycle (Ct) at which fluorescence exceeded the background was used to quantify miR abundance. We analyzed Cts with a Bayesian mixed model under a Dirichlet Process Mixture prior. This model groups miRs in clusters of similar expression, while controlling the number of false discoveries. Model estimates for the differences between MA and N (ΔCt), corresponding to log-fold changes in specific miR levels, were sequentially normalized to endogenous and spiked-in controls.

Results: Patient characteristics were similar though MA patients tended to be younger (28.4±5.7 vs 42.9±5.1). Un-normalized Cts of the N group clustered in 4 peaks (FigA,histogram/red line), around the mean (dashed line).The majority of un-normalized ΔCt clustered with the controls indicating no difference in expression between N and MA pts (FigB).



miRs likely to be differentially expressed (odds > 99:1): Downregulated in MA (miR-495: 131 fold, miR-548o: 162 fold), upregulated in MA (miR-122: 20 fold, miR-589: 16 fold).

Conclusions: Urine miR expression differs in T1D pts who develop MA compared to pts who never develop DN. Future studies should verify the utility of these miRs as early biomarkers of DN.

SA-PO2588

Podocyte-Specific JAK2 Overexpression Augments Albuminuria and Glomerular Size but Not Mesangial Matrix Expansion in 129S6 Mice Hongyu Zhang, Frank C. Brosius. *Internal Medicine/Nephrology and Physiology, University of Michigan.*

Background: JAK2 has been implicated in the pathogenesis of diabetic nephropathy (DN). Humans with type 2 diabetes express higher JAK2 levels in podocytes early in DN and in proximal tubular epithelia in progressive DN (Berthier, et. al. Diabetes, 2009;58:469).

Methods: In order to test the role of increased JAK2 expression in podocytes in early DN we knocked in a STOP/FLOX JAK2 construct to the ROSA26 locus in 129S6 mice and generated podocyte-specific enhanced JAK2 expression by crossing the mice with tissue specific Nphs2 Cre 129S6 mice allowing *JAK2* transcription driven by the ubiquitously expressed ROSA26 promoter. We subsequently crossed in the Akita insulin 2 mutation which produces type 1 diabetes in mice to test the effects of podocyte specific JAK2 overexpression in type 1 diabetes.

Results: The podocyte specific JAK2 heterozygote mice have a ~80% increase in total glomerular JAK2 mRNA similar to the increase seen in humans with progressive DN. With this relatively modest increase in JAK2 expression, there were no differences in nodiabetic JAK2 animals compared to nondiabetic animals with normal JAK2 levels, but there was a 66% increase in albuminuria in diabetic podocyte JAK2 mice at 12 wks of age ($p<0.01$) compared to diabetic littermates with normal JAK2 levels. However, the difference in albuminuria disappeared by 24 weeks and was also not present at 32 weeks. Mesangial

expansion was also not greater in the podocyte JAK2 diabetic mice than in the diabetic mice with normal JAK2 levels at 32 weeks of age compared to nondiabetic controls. However, there was a greater increase in glomerular volume in the diabetic JAK2 mice compared with the diabetics with normal JAK2 levels (2.52-fold vs. 1.67-fold; $p<0.05$).

Conclusions: These data suggest that increased expression of podocyte JAK2 may play a role in early DN by increasing glomerular growth more than podocyte foot process changes or in glomerular fibrosis.

Aberrant Activation of the Canonical Wnt Pathway in the Renal Tubular Cells in Diabetic Nephropathy Jian-Xing Ma, Ti Zhou, Rui Cheng, Xuemin He, Ying Chen. *Physiology, Univerwsity of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: The Wnt pathway mediates multiple physiological and pathological processes such as inflammation, angiogenesis and fibrosis. The present study is to investigate whether the canonical Wnt signaling plays a role in the pathogenesis of diabetic nephropathy (DN).

Methods: Expression of Wnt ligands and Frizzled receptors in the canonical Wnt pathway in the kidney was compared at the mRNA levels using real-time RT-PCR between Akita mice, streptozotocin (STZ)-induced diabetic rats and db/db mice and their respective non-diabetic controls. Renal function was evaluated by measuring the urine albumin excretion. Primary human renal proximal tubular epithelial cells were treated with high glucose and 4-hydroxynonenal (HNE). Levels of β-catenin, connective tissue growth factor and fibronectin were determined by Western blot analysis.

Results: Some of the Wnt ligands and Frizzled receptors showed increased mRNA levels in the kidneys of Akita mice, STZ-induced diabetic rats and db/db mice, compared to their non-diabetic controls. Renal levels of β-catenin and Wnt proteins were up-regulated in these diabetic models. Lowering the blood glucose levels by insulin attenuated the activation of Wnt singling in the kidney of Akita mice. In cultured primary human renal proximal tubular cells, high glucose and HNE both activated Wnt signaling. Inhibition of Wnt signaling with a monoclonal antibody blocking low-density lipoprotein receptor-related protein 6 (LRP6) ameliorated renal inflammation, fibrosis and reduced proteinuria.

Conclusions: The Wnt pathway is activated by hyperglycemia in the kidney of both types 1 and 2 diabetic models. The Wnt pathway dysregulation in diabetes represents a new pathogenic mechanism of DN and renders a new therapeutic target.

Relationships between Serum MCP-1 and Subclinical Kidney Disease: African American-Diabetes Heart Study Mariana Murea,[1] Thomas Costin Register,[7] Jasmin Divers,[2] Donald W. Bowden,[3] John Jeffrey Carr,[6] Richarlette Caresse Hightower,[6] Susan Carrie Smith,[3] Keith A. Hruska,[5] Carl D. Langefeld,[2] Barry I. Freedman.[1] *[1]Nephrology, Wake Forest Baptist Health, Winston-Salem, NC; [2]Public Health Sciences, Wake Forest Baptist Health, Winston-Salem, NC; [3]Biochemistry, Wake Forest Baptist Health, Winston-Salem, NC; [4]Center for Diabetes Research, Wake Forest Baptist Health, Winston-Salem, NC; [5]Pediatric Nephrology, Washington University in St. Louis, St Louis, MO; [6]Radiology, Wake Forest Baptist Health, Winston-Salem, NC; [7]Pathology, Wake Forest Baptist Health, Winston-Salem, NC.*

Background: Monocyte chemoattractant protein-1 (MCP-1) plays key roles in nephropathy and atherogenesis. Relationships between serum MCP-1 concentration and kidney and cardiovascular disease (CVD) were assessed in African American (AA) population.

Methods: Serum MCP-1 was measured in 479 AAs with type 2 diabetes (T2D). Urine albumin: creatinine ratio (ACR), eGFR, and calcified atherosclerotic plaque (CP) in the coronaries, carotid arteries, and infra-renal aorta were measured. Generalized linear models were fitted to test for associations between MCP-1 and ACR, eGFR, and CP.

Results: Participants were 57% female; mean (SD) median age 55.6 (9.5) 55.0 years, diabetes duration 10.3 (8.2) 8.0 years, urine ACR 151 (569) 14.0 mg/g, MDRD eGFR 95.2 (27.2) 93.3 ml/min/1.73m^2, MCP-1 262.9 (239.1) 224.4 pg/ml, coronary artery CP 280 (634) 13.5, carotid artery CP 47 (132.9) 0, and aorta CP 1616 (2864) 319. Adjusting for age, sex, smoking, BMI, blood pressure, diabetes duration, hemoglobin A_{1c}, cholesterol, and medications, serum MCP-1 levels had direct correlation with ACR (parameter estimate 0.002, p=0.043) and inverse correlation with eGFR (parameter estimate -0.0005, p=0.007). Significant associations were not detected with the extent of CP in any vascular bed.

Conclusions: Serum MCP-1 levels are significantly associated with cross-sectional measures of kidney function and albuminuria in AAs with T2D. In this racial group, MCP-1 levels are not associated with the vascular CP, surrogate of subclinical CVD.

SA-PO2591

Altered Wnt/β-catenin Pathway and Association of β-catenin with CHOP in Tubules of Diabetic Mice Michelle T. Barati, Susan M. Isaacs, David W. Powell, Michael Merchant, Jon B. Klein. *Nephrology, University of Louisville, KY.*

Background: The presence of endoplasmic reticulum (ER) stress response and apoptosis in diabetic nephropathy (DN) is evident, yet the role of ER stress in tubule cell dysfunction during DN is unclear. The goal of this study was to characterize novel effectors of ER stress response signaling in renal tubules that may play a role in DN pathogenesis.

Methods: We first identified proteins co-immunoprecipitating with ER stress-induced pro-apoptotic transcription factor CHOP in tubules of mice, using mass spectrometry (MS). Cell extract from isolated cortical tubules of OVE26 diabetic and FVB control mice were used. Immunoprecipitated proteins were trypsinized, subjected to LC-MALDI-TOF/TOF MS and LC-ESI-MS/MS. Identified proteins were analyzed for network associations using Ingenuity Pathways Analysis (IPA). Association of MS-identified proteins in complex with CHOP was validated by immunoprecipitation of CHOP from tubule extract followed by immunoblot analysis for specific proteins.

Results: IPA identified a protein network related to Wnt/β-catenin signaling including, Frizzled related protein, Wnt, casein kinase1γ, APC, dikkopf1 homolog, zo-1, jagged1, polycystin1, myosin7A, tp73, and Jade1. CHOP/β-catenin association was increased in tubules of 3 month old diabetic mice, and decreased in 7 month old diabetic mice. Casein kinase1γ and Jade1 expression (proteins that regulate β-catenin) was increased in tubules of diabetic mice. CHOP/β-catenin interaction was studied in proximal tubule cells (HK-2) during Thapsigargin (TG)-induced ER stress conditions, by confocal microscopy. TG increased total CHOP expression, decreased membrane β-catenin localization, and increased nuclear co-localization of both proteins. Additionally, exposure of HK-2 cells to high albumin concentrations increased β-catenin nuclear localization.

Conclusions: Together, these findings demonstrate altered interaction of β-catenin and CHOP in a protein complex during the course of diabetes in renal tubules. An alternate role for CHOP action and a novel molecular mechanism of ER stress response signaling in tubule cell pathogenesis during diabetes are suggested by these findings.

The Study of Inhibitory Effects by Aprotinin on the Mannan-Binding Lectin Pathway Activation in the Kidney of Diabetic Rats Xiaoyong Yan,[1] Songmin Huang,[1] Yuxi Yang.[1] *[1]Department of Nephrology, The West China Hospital of Sichuan University.*

Background: Our previous work has proved that the levels of Mannan-binding lectin (MBL-A and MBL-C),C3 and Membrane-attack complex(MAC) expression were increased in the kidney of diabetic Rats.The lectin pathway may contribute to the development of early stage DN.It can be beneficial for kidney protection of a therapy of MBL complement pathway inhibitors.Aprotinin can inhibit the lectin pathway through its ability to inactivate irreversibly the MBL-associated serine protease (MASP).In the present studies,we would evaluate the inhibitory effects of aprotinin on the lectin pathway activation in the kidney of diabetic Rats.

Background: SD male rats were randomly divided into three groups: normal control group(group N),DN group (group DN) and DN treated with aprotinin(group DN-A).Rats of the group DN were treated by streptozotocin(50mg/kg).After modeling,Rats of the group DN-A were injected intraperitoneally with aprotinin(40000 KIU/kg.d,Bayer,German) for four weeks (3-week to 7-week).The 6 rats of the three groups were sacrificed at week 4 and 8 respectively,meanwhile blood sugar, serum creatinine(Scr),body weight, kidney weight and 24-hours urinary protein were monitored.The expression of MBL-A,MBL-C,C3 and MAC in renal tissue were detected by immunohisochemistry and western blot.

Results: In the group DN-A,a significant reduction of urinary protein,body weight /kidney weight(KI),glomerular tuft volume(GV),mesangial matrix expansion index (MMEI) and plasma glucose levels(not to normal levels) were observed as compared with group DN at 4-week and 8-week.However the levels of Scr was not markedly increased. In group DN-A, the renal expression of MBL-A,MBL-C,C3 and MAC were obviously decreased as compared with group DN at 4-week and 8-week by immunohisochemistry and western blot.

Conclusions: The present studies suggest that a beneficial effect of aprotinin treatment on the process of glomerular damage in the diabetic Rats.Its effects may attribute to inhibition of the lectin pathway activation.

Urinary Biomarkers Are Increased in Experimental Diabetes Franklin E. Fuenmayor-Cardozo, Ganesan Ramesh, David M. Pollock, John White. *Medicine, Georgia Health Sciences University, Augusta, GA.*

Background: Recent studies suggest an increased role of tubulointerstial injury in diabetic kidney disease. However, there are no validated biomarkers of tubulointerstitial injury in diabetes. We hypothesized that tubular injury biomarkers useful for studying acute kidney injury would be elevated early in experimental diabetes.

Methods: SD rats were made diabetic using i.v. streptozotocin (STZ) (n = 7). Controls (CTL) received normal saline (n = 9). Rats were placed in metabolic cages at baseline, 4 weeks, and 10 weeks. Urinary kidney injury molecule-1 (KIM-1) and N-acetyl-b-D-glucosaminidase (NAG) were measured by ELISA. For a positive control known to develop tubulointerstitial injury, we used the DOCA salt model. SD rats underwent uninephrectomy and were implanted with a 200 mg time-released DOCA pellet and given normal saline as drinking water (n = 7) x 4 weeks.

Results: As expected, blood glucoses were increased in STZ rats (485 ± 22 mg/dL, $P < 0.05$ vs. CTL, DOCA) and blood pressures were markedly increased in DOCA rats (190 ± 4 mmHg, $P < 0.05$ vs CTL, STZ). Urinary protein excretion was not different between STZ and CTL at 4 wks, but was increased in DOCA rats (29 ± 7.6 vs. 25.1 ± 7.7 vs. 315.3 ± 51.8 mg/24h, $P < 0.05$) suggesting worse damage in the DOCA group. By 10 weeks, urinary protein had increased in STZ vs. CTL (77.5 ± 13.4 vs. 32.3 ± 6.4 mg/24h, $P < 0.05$). At 4 wks, urinary KIM-1 excretion was increased in DOCA rats, but not in STZ compared to CTL (90.6 ± 8.8 vs. 15.8 ± 2.3 vs. 14.2 ± 8.1 ng/24h, $P < 0.05$). At 10 wks KIM-1

excretion was increased in STZ (17.9 ± 1.7 vs. 12.9 ± 0.3 ng/24h, $P < 0.05$). Conversely, NAG excretion was increased in STZ and DOCA compared to CTL at 4 wks (3167 ± 473 and 2298 ± 210 vs. 337 ± 25 IU/24h, $P < 0.05$). Likewise, NAG excretion was increased at 10 wks in STZ vs. CTL (4042 ± 353 vs. 366 ± 27 IU/24h, $P < 0.05$).

Conclusions: Urinary tubular biomarkers are increased early in experimental diabetes. In the case of NAG, the increase occurs prior to the development of significant proteinuria. Our data suggests these biomarkers may be useful surrogates for therapies targeting tubulointerstitial injury in diabetes and chronic kidney diseases.

SA-PO2594

N-Acetylcysteine and Oxidative Stress in the Kidney of Uninephrectomized Rats with Diabetes Mellitus Elisa M.S Higa,[1,2] Guilherme Baia Nogueira,[1] Adelson Marçal Rodrigues,[1] Giovana Rita Punaro,[1] Margaret Gori Mouro,[1,2] Fabiane Maciel.[1] *[1]Medicine - Nephrology Division, UNIFESP; [2]Medicine - Emergency Division, UNIFESP, Sao Paulo, Brazil.*

Background: Diabetes mellitus (DM) induces intra and extracellular changes, with a substantial increase in reactive oxygen species (ROS). ROS cause damage in systemic and renal microvasculature, which could be one of the mechanisms involved in the pathophysiology of diabetic nephropathy. ROS also modulate other substances, like the nitric oxide (NO), a powerful vasodilator with important role on kidney function. N-acetylcysteine (NAC) is an antioxidant largely used to prevent contrast induced renal lesion.

The aim of this study was to evaluate the effect of NAC and oxidative stress in the kidney of uninephrectomized rats with DM.

Methods: Adult male Wistar rats were unilaterally nephrectomized (UNx). Control groups (CTL) were sham operated. DM was induced with streptozotocin (60mg/kg, iv), in half of UNx animals (DM+UNx) and the others received its vehicle (CTL+UNx). Half of the CTL+UNx and DM+UNx animals received NAC (600mg/L in water, ad libitum). Groups (N=4 each): CTL, CTL+UNx, CTL+UNx+NAC, DM+UNx and DM+UNx+NAC. Before and after 8 weeks with NAC, we collected the 24 hour urine and a blood sample. Data = mean±SEM, analyzed by one-way ANOVA, with Tukey post-test; significant for P<0.05.

Results: DM+UNx compared with CTL+UNx showed increased levels of glycemia (427±31 vs 189±25) and altered renal function, with increased plasmatic creatinine (2.0±.1 vs 1.2±.1), urea (71±5 vs 38±8) and proteinuria (40±10 vs 15±1). DM+UNx presented increased TBARS (8.9±1.3 vs 3.2±.1 and 517±44 vs 95±6) and reduced NO (55±9 vs 62±4 and 7.5±.2 vs 10.5±1.6), both in plasma and urine respectively. NAC in DM rats reduced proteinuria (16±4), plasmatic creatinine (1.5±.1) and urea (60.7±2.3) and attenuated TBARS's levels, in plasma and urine (3±.4 and 352±27), as well as increased plasma NO (82.6±9.2), all P<0.05.

Conclusions: In DM+UNx rats, NAC protected against kidney injury, probably due to the control of oxidative stress and/or increase of NO bioavailability, suggesting that NAC could be useful in the treatment of diabetic patients.

SA-PO2595

The Role of Chymase in the Renal Lesion of the Diabetic Rats Mei Zhang, Jing Bai, Xiaodong Nie, Wen Huang. *Nephrology, Beijing Tongren Hospital, Capital Medical University, Beijing, China.*

Background: Diabetic nephropathy is a leading cause of end-stage renal disease, which characterized by renal fibrosis.The objective of the study is to investigate the role of chymase in the development of renal fibrosis of diabetic rats

Methods: 24 male SD rats were randomly divided into three groups including control , DM and DM+ Chy-Inhibitor (Chy-I)groups . Diabetes was induced by intraperitoneal injection of Streptozotocin (60mg/kg).The rats in the Chy-I group were injected with chymase inhibitor $(Oph)_2$ 1mg/kg/d for 12 weeks.Kidney weight, level of blood glucose, 24-hour urinary protein, creatinine clearance, serum lipid level, and blood pressure were measured. The renal pathologic lesion were observed by light microscope and electron microscrope, the expression of fibronectin, type IV Collagen, α-SMA and TGF-β1 were observed by immunohistochemistry and RT-PCR

Results: Diabetic rats were presented with characteristics of increasing creatinine clearance, KW/BW, level of serum cholesterol, 24-hour urinary albumin and urinary albumin /creatinin (P<0.05, P<0.01, P<0.01, P<0.05 and P<0.01), and decreasing level of serum albumin and total protein (P<0.05) respectively. Compared with DM group, level of serum cholesterol and urinary albumin /creatinin were decreased for15.58%and 75.40% in Chy-I group(P<0.05). There were no significant difference with DM group and Chy-I group in KW/BW, 24-hour urinary albumin, blood pressure, level of serum lipid, albumin and protein and creatinine clearance.

Diabetic rats had increasing deposition of extracellular matrix in glomerular area followed by elevated expression of FN, ColIV, alpha-smooth muscle actin (α-SMA) and TGF-β1. Compared with model group, the admission of chymase inhibitor could decrease expression of FN, ColIV , alpha-smooth muscle actin (α-SMA) and TGF-β1 for 25.35% ,17.24%, 26.30% and 19.98%.(p<0.05,). The lesion of foot processes of podocytes was ameliorated in Chy-I group

Conclusions: In diabetic rats, chymase promoted the secretion of urinary protein, the injury of foot processes of podocyte and deposition of extracellular matrix. Inhibition of chymase could preserve the progression of renal lesion.

SA-PO2596

Involvement of Adiponectin and Adiponectin Receptor 1 in the Albuminuria Appearance of Diabetic Nephropathy Koichi Kanozawa, Juko Asakura, Hajime Hasegawa, Taisuke Shimizu, Kaori Takayanagi, Takatsugu Iwashita, Yosuke Tayama, Tokushi Nakajima, Tetsuya Mitarai. *Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Saitama, Japan.*

Background: We reported that a decline of microalbuminuria(MA) was related to increase of adiponectin(APN) by administrating various kinds of PPARγ agonists for human diabetic nephropathy(DN). Recently, it has been reported that APN-knockout mice exhibited increased albuminuria and fusion of podocyte foot processes. On the other hand, among ligands of APN, it is revealed that APN receptor(AdipoR) 1 and T cadherin(TCd) express in the kidney. The aim of this study is to clarify participation in the appearance of MA and the formation of DN with the APN/AdiopR/TCd system.

Methods: The male Otsuka Long Evans Tokushima Fatty(OLETF) rats which were known as type 2 diabetes, and Long Evans Tokushima Otsuka(LETO) rats which were control, were used. These rats were derived into three groups, such as the OLETF received low-dose (2.5 mg/kg) pioglitazone for six weeks (PGZ-OLT), the OLETF not received PGZ (OLT), and LETO (LET). To 34 weeks of age, APN, creatinine clearance, and urinary albumin excretion rate(UAE) were measured, and the kidneys were extracted. We examined local existence of the APN, AdiopR1, and TCd in the kidney tissue of each group, using indirect immunofluorescent method.

Results: APN in 34 weeks decreased to 1.3±0.2 μg/ml in the OLT, and rose with 2.6±0.3 μg/ml in the PGZ-OLT, compared with 1.8±0.1 μg/ml in the LET. On the other hand, UAE rose significantly with 3720.5±1394.3 mg/mgCr in OLT whereas it was 8.8±5.1mg/mgCr in LET, and was controlled in 2221.7±1155.4 mg/mgCr in the PGZ-OLT. In the kidney histologic examination, APN accorded for local existence of AdiopR1 in the glomerulus, it was dyed by podocytes, mesangial cells, and endothelial cells, but APN did not accord with the local existence of TCd. Interestingly, the stainability of APN aggravated it in OLT in comparison with the LET, and improved it in PGZ-OLT, and these ware the relations that were reverse to serum APN each.

Conclusions: It was suggested that APN/AdiopR1 system in the glomerulus involved in an appearance of the MA in DN.

SA-PO2597

Involvement of Renal Cytochromes P450 and Arachidonic Acid Metabolites in Diabetic Nephropathy Assaad Antoine Eid,[1,4] Rita Maalouf,[3,4] Linda Roman,[5] Fuad N. Ziyadeh.[2] *[1]Anatomy, Cell Biology and Physiology, Faculty of Medicine, American University of Beirut, Beirut, Lebanon; [2]Internal Medicine, Faculty of Medicine, American University of Beirut, Beirut, Lebanon; [3]Chemistry, Faculty of Sciences, Lebanese University, Beirut, Lebanon; [4]Medicine, University of Texas Health Science Center at San Antonio, TX; [5]Biochemistry, University of Texas Health Science Center at San Antonio, TX.*

Background: Diabetic nephropathy is characterized by early hyperfiltration, hypertrophy, extracellular matrix accumulation, and later by proteinuria, fibrosis and loss of renal function. In hypertrophy, tubules increase in cell size and accumulate extracellular matrix and are associated with alterations in renal sodium handling as well as hypertension; both are processes linked by involvement of the arachidonic acid (AA) metabolites 20-HETE and EETs. It is known that AA is metabolized by several cytochrome 450 (CYP) isoforms to produce 20-HETE and EETs.

Methods: The levels of CYPs 2B, 2C, and 4F were assessed in a rat model of type1 diabetes.

Results: There was significant induction of expression and activity of these CYPs in the cortex of the diabetic animals, and this was greatly prevented by insulin therapy. Immunoblot analysis of microsomes derived from cultured rat proximal tubular cells, grown in normal or high glucose (HG), confirmed this observation. As a functional measure of cellular hypertrophy, the incorporation of S^{35}-methionine into a primary culture of rat renal cortical cells was monitored. Growing cells in HG resulted in methionine incorporation increase. When cultured in HG and in the presence of 0016HETE, a specific inhibitor of 20-HETE production, methionine incorporation is decreased to control levels. Thus, inhibition of CYPs in these renal cells attenuates the cellular hypertrophy caused by HG.

Conclusions: Our results indicate that hyperglycemia in diabetes has a significant effect on the expression level of AA-metabolizing CYPs, which is manifest as increased AA metabolism, and might thus be expected to alter kidney function through alteration of type and amount of AA metabolites produced.

SA-PO2598

Sphingosine Kinase 1 (SK1) Inhibition Plays a Role in TGFbeta-Induced Epithelial-Mesenchymal Transition (EMT) and Inflammation In-Vitro and In-Vivo Model of Diabetic Nephropathy Dania Yaghobian,[1] Sonia Saad,[1] Xinming Chen,[1] Anthony Don,[2] Carol A. Pollock.[1] *[1]Medicine, Kolling Institute, Sydney, NSW, Australia; [2]Medicine, UNSW, Sydney, NSW, Australia.*

Background: Sphingosine 1- phosphate (S1P), a pleiotropic lipid mediator, is produced by phosphrylation of sphingosine by SK1 and SK2. EMT is a major contributor to the development of renal fibrosis as about 35% active fibroblasts are derived from EMT in kidney disease, contributing to the production of extracellular matrix (ECM), cytokines,

chemokines and growth factors, resulting in enhanced inflammatory and fibrotic responses. We aim to determine the role of SK1 on TGFβ induced EMT, inflammation and fibrosis an in-vitro and in-vivo model of diabetic nephropathy

Methods: HK2 cells were incubated with SKI-II (2μM) an inhibitor of SKs for 3 hours then exposed to TGFβ-1, -2 or-3 isoforms (2ng/mL) for 72 hours. Morphological changes of cells were monitored, mRNA and protein expression of SK1, E-cadherin, TNFα and MCP-1 were determined by PCR, western blot and ELISA. C57BL/6 wild-type and SK1$^{-/-}$ knockout mice were rendered diabetic with Streptozotocin for 16 weeks. Body weight, blood pressure, blood glucose, creatinine clearance and albuminuria were recorded. Levels of SK1, SK2, S1P, ceramide as well as MCP-1, E-cadherine and FN were determined in the kidney using RT-PCR and western blotting. Serum changes in SK1, SK2, S1P and ceramide is determined using mass spectroscopy.

Results: TGFβ-1, -2 and -3 isoforms equally induced phenotypic changes of EMT in HK2 cells. This was reversed with SKI-II. SK1 mRNA was significantly increased by exposure to TGFβ-1, -2 and -3 isoforms (p=<0.01). This was also reversed to basal levels with SKI-II. E-cadherin mRNA expression was suppressed by TGFβ-1, -2 and -3 compared to control (p<0.05) and partially reversed by SKI-II (P<0.05). mRNA and protein expression of MCP-1 was significantly induced by TGFβ-1, -2 and -3 and TNFα (p<0.01) and reduced to almost undetectable levels in the presence of SKI-II. In-vivo work is currently in progress and will be reported.

Conclusions: SK1 plays an important role in TGFβ-induced EMT and inflammatory responses in fibrosis and may direct future therapeutic strategies

Early Microvascular Damage in Pigs with Diabetic Nephropathy Coincides with Angiopoetin Dysbalance in the Kidney Meriem Khairoun,[1] Mieke Vd Heuvel,[3] Bernard Van Den Berg,[1] Oana Sorop,[3] Rients De Boer,[1] Ingeborg M. Bajema,[4] Ton J. Rabelink,[1,2] Marlies E.J. Reinders,[1] Wim J. Van der Giessen,[3] Joris I. Rotmans.[1,2] *[1]Department of Nephrology, LUMC; [2]Einthoven Laboratory for Experimental Vascular Research, LUMC; [3]Experimental Cardiology, EMC Rotterdam; [4]Department of Pathology, LUMC.*

Background: Diabetes mellitus (DM) is associated with a range of microvascular complications including diabetic nephropathy (DN). Microvascular abnormalities in the kidneys are common histopathologic findings in DN. These abnormalities may represent one manifestation of ongoing systemic microvascular damage. Recently, Sidestream dark-field (SDF) imaging has emerged as a noninvasive tool to visualize the microcirculation. In this study, we investigated the early effects of diabetes on renal and systemic microvasculature in pigs.

Methods: DM was induced by streptozotocin (80 mg/kg body weight). Mean capillary density (MCD) and microvascular morphology were visualized using SDF imaging and compared among pigs with DN on atherogenic diet (N=8), nondiabetic pigs (AT) on atherogenic diet (N=7) and control pigs (N=7). Both AT and DN pigs were on a restricted atherogenic diet for 14 months. Kidneys were harvested and sections were stained with markers for microvascular integrity, Angiopoietin-1 (Ang-1), and Angiopoietin-2 (Ang-2).

Results: Kidney biopsies showed marked glomerular lesions consisting of mesangial expansion and podocyte lesions as well as tubular changes with foamy cytoplasm and hyalin droplets, which coincided with hyperfiltration. Analysis of capillaroscopic images revealed more capillary tortuosity in DN pigs (mean 2.31 ± 0.17 SEM compared to the control groups (0.89 ± 0.08 and AT 1.55± 0.11, p<0.05). Immunohistochemistry of kidney biopsies showed a disturbed Ang-2/ Ang-1 balance, with increased expression of Ang-2 in DN pigs as compared to controls.

Conclusions: Diabetic pigs showed rapid development of diabetic nephropathy, which is associated with an increase in capillary tortuosity and a dysbalance in angiopoietins. Thus, systemic microvascular damage induced by diabetes might be an important contributor to local perturbations in vital organs such as the kidney.

SA-PO2600

FGF-23 and Vitamin D Levels: New Risk Factors of Left Ventricular Hypertrophy in Diabetic Patients Ana Paula Silva, Ana Pinho, Ana Cabrita, André Fragoso, Nelson Almeida Tavares, Nélio Santos, Marilia Faisca, Pedro Neves. *Serviço de Nefrologia, Hospital Faro, Faro, Portugal.*

Background: Left ventricular hypertrophy is a well known independent risk factor of morbidity and mortality in both the general population and in those with chronic kidney disease (CKD).

Several experimental studies showed that vitamin D and FGF23 play a role in normal physiology of cardiomyocytes and vasculature. Furthermore, low vitamin D and higher FGF 323 levels are associated with several CVD outcomes such as myocardial infarction, congestive heart failure, and cardiovascular mortality.The aim of this study was to evaluate in a group of type 2 diabetic CKD (stages 3 and 4) patients the risk factors of left ventricular hypertrophy (LVH).

Methods: We evaluated 50 type 2 diabetic patients (f = 18, m = 32), with a mean age of 60.35 years and a mean estimated GFR (MDRD) of 50 ml / min.

Exclusion criteria were uncontrolled hypertension, prior known cardiovascular disease, neoplasic or infectious disease, anti-inflammatory, phosphorus binders and vitamin D therapies. We analyzed several biological and laboratorial parameters, including those related with inflammation and the mineral metabolism. The left ventricular mass index (LVMI) was calculated using the Penn convention criteria.

Results: In a multiple regression model, we found that Interleukin-6 (r=0,265 p=0,004), FGF23 (r=0,230 p=0,004), PTH (r=0,361 p=0,016) and t25(OH) D (r= - 0,263 p=0,005) levels independently influenced the LVMI.

Conclusions: In a small but very homogeneous group of type 2 CKD diabetic patients, we found that inflammation and the mineral metabolism disturbances are related with left ventricular hypertrophy. Further studies are needed to ascertain if the correction of these parameters (including vitamin D and FGF-23) are associated with better outcomes of our kidney patients.

Identification of Novel Glomerular Molecules Implicated in Albuminuria David A. Long,[1] Karen Price,[1] Maria Kolatsi-Joannou,[1] Cecile Dessapt-Baradez,[2] Jennifer L. Huang,[1] Jenny Papakrivopoulou,[1] Ron Korstanje,[3] Luigi Gnudi,[2] Adrian S. Woolf.[4] *[1]Nephro-Urology Unit, UCL Institute of Child Health, United Kingdom; [2]King's College London, United Kingdom; [3]The Jackson Laboratory; [4]University of Manchester, United Kingdom.*

Background: Albuminuria is an early warning sign for several chronic glomerular diseases. In diabetes mellitus, small increases of albumin excretion precede, and may predict progression to, overt nephropathy. Therefore, the discovery of molecules deregulated in "leaky" glomeruli may suggest novel biomarkers and therapeutic targets in early kidney disease.

Methods: To identify such genes, we utilised male and female mice of two widely-used wild-type (i.e. "normal") strains of laboratory mice, C57Bl/6 and FVB. We isolated whole glomerular tufts using Dynabeads in 18 week old animals and performed RNA microarray analyses to examine all glomerular transcripts. These results were compared to studies pinpointing genetic loci associated with albuminuria in mouse strains.

Results: Overtly healthy animals at 13 and 18 weeks of age demonstrated increasing albumin excretion as follows: C57Bl/6 females < C57Bl/6 males < FVB females < FVB males providing a unique model to track down albuminuria genes. Thirty nine genes in isolated glomeruli were significantly altered by both strain and gender, with expression levels following the degree of albuminuria (34 genes upregulated and five downregulated with increasing albuminuria). Comparing this expression data with genetic loci associated with albuminuria in mice implicated *Cyp4a12a* (a member of the cytochrome P450 family), *Hsd3b2* (essential for steroid production) and *Acy3* (aspartoacylase-3) as strong candidates for further study. We found that all three genes were expressed by isolated mouse podocytes induced to differentiate in culture.

Conclusions: Deregulated glomerular expression of *Cyp4a12a*, *Hsd3b2* and *Acy3* is associated with albuminuria between genders and different strains of mice. Further studies are required to unravel the precise glomerular roles of these genes, and we suggest that polymorphisms of these genes may determine the susceptibility of an individual to progressive renal disease.

SA-PO2602

Heart Rate Variability Changes Induced by Reduction of Fluid Overload Manuela Ferrario,[1] Ulrich Moissl,[2] Francesco Garzotto,[3] Maria Gabriella Signorini,[1] Dinna N. Cruz,[3] Alessandra Brendolan,[3] Anna Clementi,[3] Matteo Floris,[3] Ciro Tetta,[2] Sergio Cerutti,[1] Claudio Ronco.[3] *[1]Politecnico di Milano, Milano, Italy; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]San Bortolo Hospital, Vicenza, Italy.*

Background: Fluid overload (FO) is an important and independent predictor of mortality in chronic hemodialysis (HD) patients (pts). We showed previously differences in heart rate variability (HRV), a measure of the autonomic nervous system (ANS), among fluid overloaded and normohydrated HD pts. The aim of this pilot study was to investigate whether reduction of FO can modify HRV in HD patients.

Methods: We studied 5chronic HD patients with a pre-HD FO consistently >3 L. FO was estimated before every HD using a spectroscopy device (BCM, Fresenius Medical Care, Germany). Fluid removal during HD was adjusted during every HD to obtain a target average FO (average of pre- & post-HD FO) of 0.8L within 1 month. ECG Holter recordings were performed (starting before the HD session) at baseline (BL) and after 1month (1M). HRV was analyzed with parameters, such as mean HR (bpm), pNN50%, i.e. the percentage of adjacent NN intervals differing by more than 50ms. Spectral analysis was performed; we computed power in the low (LF), high frequency bands (HF), LF/HF ratio, LF% and HF% . LF relates to sympathetic activity, and HF to parasympathetic ANS activity and were calculated for different HD period.

Results: Pre-HD FO was successfully reduced within 1 month (BL: 3.45±0.99 L; 1M: 2.48±0.48L). In 4/5 pts, we observed a decrease of pNN50%, LF and LF%, indicating a decrease in sympathetic overactivity.

Table 1- Median values (interquantile ranges) of HRV indices

		HD	first30'HD	last30'HD	1hr after HD
pNN50%	BL	10.7(6.9,26.1)	12.7(5.8,25.0)	8.5(2.5,27.7)	5.7(3.4,12.3)
	1M	2.7(1.4,20.5)	16.6(2.2,19.4)	0.8(0.7,24.9)	0.9(0.8, 8.6)
LF(ms^2)	BL	955(115,1510)	931(267,1513)	1026(534,2276)	306(162,462)
	1M	271(207,743)	235(134,710)	250(157,922)	157(102,318)
LF%	BL	51(22,59)	53(31,68)	57(49,68)	27(18,36)
	1M	44(39,49)	40(31,48)	41(36,52)	27(14,31)
HF%	BL	8(1,21)	10(3,27)	15(9,32)	14(8,27)
	1M	17(7,27)	18(6,31)	18(16,27)	12(4,26)
LF/HF	BL	2(1,17)	3(2,36)	4(2,16)	2(1, 2)
	1M	3(2,7)	2(1,5)	3(1,4)	1(1,2)

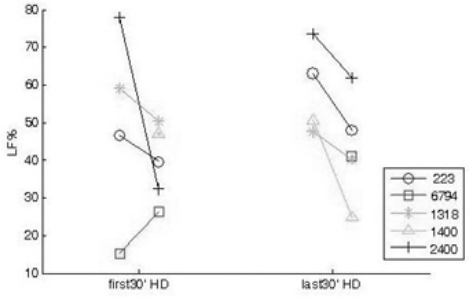

Figure 1: LF% values for each patients enrolled in the study

Conclusions: In this pilot study, we demonstrate for the first time that reduction of FO has an effect on sympathetic ANS activity and HRV. Further studies in a larger population are needed to verify this finding and to determine whether these changes persist in the long-term.

SA-PO2603

Relationship between Visceral Fat Area, Percentage of Body Fat and Prevalence of Cardiovascular Disease in Chronic Dialysis Patients Yukie Kitajima,[1] Yuzuru Sato.[2] *[1]Tokyo Healthcare University, Tokyo, Japan; [2]Sato Junkanki Hospital, Matsuyama, Ehime, Japan.*

Background: The risk of cardiovascular disease is substantially high in hemodialysis patients. The risk factors for cardiovascular disease in hemodialysis patients include age, duration of hemodialysis, diabetes mellitus and hyperphosphatemia. However it is not clear cardiovascular disease is associated with visceral fat area and percentage of body fat in hemodialysis patients. We investigated the relationship among visceral fat area, percentage of body fat, several clinical and biochemical parameters and anamnesis of cardiovascular complication in chronic hemodialysis patients.

Methods: Area of visceral fat was measured using computed tomographic scanning (CT) in 84 non-diabetic patients. Using a body composition analyzer, we measured total body fat,and percentage of body fat after completion of dialysis on the last day of the week. Patients were divided into two groups according to visceral fat area; those with visceral fat area < $100cm^2$ (Group A) and with > $100cm^2$ (Group B). Blood chemistry of lipid and complication of cardiovascular disease were evaluated in these patients. Body mass index (BMI) was calculated with body weight and height.

Results: Compared to Group A, Group B showed, significantly higher serum levels of triglyceride ($p<0.001$) and significantly lower, high-density lipoprotein-cholesterol levels ($p<0.001$). Group B also showed higher rate of cardiovascular complication, especially ischemic heart disease ($p<0.01$). Visceral fat area correlated with BMI ($R^2=0.5233$), total body fat ($R^2=0.544$), percentage of body fat ($R^2=0.283$). BMI correlate with total body fat ($R^2=0.792$), percentage of body fat ($R^2=0.491$). Furthermore, Patients with ischemic heart disease showed higher percentage of body fat ($p<0.05$).

Conclusions: In this study, higher visceral fat area was found to have the high rate of cardiovascular disease. Higher visceral fat area can be a contributing risk factor to cardiovascular disease, especially ischemic heart disease in chronic dialysis patients. In addition, BMI and percentage of body fat can be measured more easily than CT. Those assesments will evade the risk of cardiovascular disease.

SA-PO2604

Osteoprotegerin as a Prognostic Marker of Mortality in Hemodialysis Patients with Cardiovascular Disease Simon Winther,[1] Kaj A. Jørgensen,[1] Erik Berg Schmidt,[2] My Svensson.[1] *[1]Department of Nephrology, Aarhus University Hospital, Aarhus, Denmark; [2]Department of Cardiology, Aalborg Hospital, Aalborg, Denmark.*

Background: Patients with end-stage renal disease, treated with hemodialysis (HD) have an increased mortality, mainly caused by cardiovascular disease (CVD). Osteoprotegerin (OPG) is a glycoprotein involved in the regulation of the vascular calcification proces. Previous studies have demonstrated that OPG is incorporated in atherosclerotic plaques and that elevated OPG in plasma is related both to severity and progression of vascular calcification. Furthermore, elevated OPG has been shown as a prognostic marker of mortality, in several high-risk populations. The aim of this study was to investigate if OPG was a prognostic marker of mortality in patients with end-stage renal disease and previously documented CVD.

Methods: We prospectively followed 206 HD patients with documented CVD. CVD was defined as previously documented myocardial infarction, angina pectoris, angiographically documented coronary arteriosclerosis, stroke, transient ischemic attack, or peripheral vascular disease. Plasma levels of OPG were measured at baseline and the patients were followed for 2 years or until reaching the primary endpoint, all-cause mortality.

Results: All-cause mortality during follow-up was 44% (90/206) and median follow-up to the primary endpoint was 314 days. Levels of OPG were divided into tertiles (first: 1.35-4.12, second: 4.12-6.04, third: 6.04-31.32 pg/ml). High OPG levels were associated with increased mortality, using the first tertile as reference, with a HR of 1.83 (CI 1.05-3.20) for the second tertile and HR of 1.72 (CI 0.95-3.09) for the third tertile. In survival analysis this was not statistically significant with an adjusted p-value of 0.08 and an adjusted p-value for trend of 0.07. In multivariate Cox-regression analysis only age and OPG in the second tertile were associated with increased mortality.

Conclusions: In contrast to previous studies, we were not able to demonstrate that high levels of OPG, in a cohort of HD patients with documented CVD, were associated with an increased mortality.

Effect of Body Composition Moniter-Guided Volume Control on Inflammation and Adipokines in Hemodialysis Patients: A Prospective 16-Week Interventional Study Sejoong Kim,[1] Hayne C. Park,[2] Hajeong Lee,[2] Ho Jun Chin,[2] Dong Ki Kim,[2] Yon Su Kim,[2] Jin Suk Han,[2] Kwon Wook Joo.[2] *[1]Internal Medicine, Gachon University of Medicine and Science, Incheon, Korea; [2]Internal Medicine, Seoul National University College of Medicine, Seoul, Korea.*

Background: Inappropriate volume control can be linked to an increased cardiovascular morbidity in hemodialysis (HD) patients, although there is no accurate method to moniter patients' water contents. Also, inflammation and adipokines are related to cardiovascular outcome in HD patients. We evaluated the effect of body composition moniter (BCM)-guided volume control on inflammation and adipokines in hemodialysis patients.

Methods: We enrolled 120 patients who received more than 3-month hemodialysis in major 3 dialysis centers. According to the amount of fluid overload, which was provided by BCM (Fresenius Medical Care Korea), we divided into 3 groups: overhydrated group (OH; fluid overload ≥ 1.1L), normohydrated group (NH; -1.1L ≤ fluid overload < 1.1L), and dehydrated group (DH; fluid overload < -1.1L) and optimized body weight towards an objective target for normohydration for 16 weeks.

Results: The proportion of OH group was 36.6% (44/120), and that of DH group was 15% (18/120). Intervention failure rate was 16% (10/62). In OH group, serum levels of IL6 and MCP1 were significantly decreased after 8-week intervention period (IL6: 1.17 ± 1.34 at week 0 vs. 0.06 ± 1.18 log [pg/mL] at week 8, $p<0.001$; MCP1: 5.66 ± 0.77 at week 0 vs. 5.33 ± 0.39 log [pg/mL] at week 8, $p=0.019$). After 8-week intervention period, serum leptin levels were decreased, while serum adiponectin levels were increased in OH group. Those changes were persistent until another 8-week observation. In DH group, serum adiponectin levels were significantly increased every 8 weeks.

Conclusions: This results showed that inflammatory markers and adipokines improved after the correction of patients' overhydrated status and adiponectin levels increased after the optimization of patients' dehydrated status in hemodialysis patients.

SA-PO2606

Vascular Calcification Inhibitors Are Promising Markers of Subclinical Cardiovascular Disease in Incident Hemodialysis Patients: The Predictors of Arrhythmic and Cardiovascular Risk in ESRD (PACE) Study Stephen M. Sozio,[1] Rulan S. Parekh,[1,2] Julia J. Scialla,[1] Tariq Shafi,[1] Bernard G. Jaar,[1] Miguel Santaularia-Tomas,[1] Lucy A. Meoni,[1] Wen Hong Linda Kao.[1] *[1]Johns Hopkins University; [2]University of Toronto.*

Background: Vascular calcification is common in ESRD and likely contributes to clinical cardiovascular disease (CVD) events. The effect of circulating regulators of this dynamic process on subclinical CVD is unknown.

Methods: We investigated the association of the calcification inhibitors osteopontin (OPN), osteoprotegerin (OPG), bone morphogenetic protein-7 (BMP-7), and fetuin-A with simultaneously measured coronary artery calcium score (CAC), pulse pressure (PP), carotid-femoral pulse wave velocity (PWV), aortic augmentation index (AIX), and ankle-brachial index (ABI) in an incident hemodialysis cohort of 82 PACE participants. Laboratory and clinical tests were performed on a non-dialysis day at the baseline visit. Linear regression was used to assess the association of each inhibitor and subclinical CVD process.

Results: Mean age was 53 with 59% male, 67% African-American, 54% diabetic, and 50% with prior ASCVD. Mean±SD level of each calcification inhibitor was: OPN 313±113 ng/ml, OPG 9.7±3.4 pmol/l, BMP-7 9.3±2.8 pg/ml, fetuin-A 0.49±0.13 g/L. OPN, OPG, and fetuin-A were associated with several of the CVD processes.

	Circulating Vascular Calcification Inhibitor*			
Subclinical CVD	**OPN**	**OPG**	**BMP-7**	**Fetuin-A**
Cardiac Disease				
CAC§	**0.77 (0.07, 1.48)†**	**0.99 (0.22, 1.76)†**	-0.46 (-1.28, 0.36)	**-1.00 (-1.71, -0.29)†**
Arterial Stiffness				
PP (mmHg)	1.56 (-2.65, 5.77)	**6.50 (2.47, 10.5)†**	-0.14 (-4.28, 4.01)	-0.67 (-4.77, 3.42)
PWV (m/s)	0.18 (-0.69, 1.05)	**1.40 (0.54, 2.27)†**	-0.38 (-1.24, 0.48)	0.07 (-0.76, 0.89)
AIX (%)	**5.86 (2.26, 9.45)†**	**4.46 (0.70, 8.21)†**	2.84 (-0.54, 6.22)	1.90 (-1.87, 5.67)
Peripheral Vascular Disease				
ABI	0.00 (-0.08, 0.07)	-0.06 (-0.32, 0.02)	0.03 (-0.07, 0.13)	0.02 (-0.05, 0.10)

*Coefficient (95% CI) from unadjusted linear regression per SD increase in each calcification marker §per log(CAC+1) †p<0.05

Conclusions: OPN and OPG are promising markers of subclinical CVD. If validated prospectively, individual vascular calcification marker profiles have the potential to identify patients at highest risk of potential CVD outcomes.

Coronary Artery Calcifications and Cardiovascular Mortality in Hemodialysis Patients Roberto Palumbo,[5] Annalisa Noce,[1] Olga Durante,[1] Simone Manca di Villahermosa,[1] Michele Ferrannini,[5] Efstathia Athanasopoulou,[1] Sandro De Angelis,[3] Mariarita Dessì,[2] Pietro Sfregola,[4] Giorgio Splendiani,[3] Nicola Di Daniele.[1] *[1]Department of Internal Medicine, Tor Vergata University, Rome, Italy; [2]Department of Laboratory Medicine, Tor Vergata University, Rome, Italy; [3]Regional Agency for Transplantations and Related Pathologies, Rome, Italy; [4]Nephrology and Dialysis Service, Madonna delle Grazie, Velletri, Rome, Italy; [5]Nephrology and Dialysis Unit, S.Eugenio Hospital, Rome, Italy.*

Background: Coronary artery calcifications and long term overall cardiovascular mortality were investigated in maintenance hemodialysis (mHD) patients.

Methods: Between June and December 2002 two-hundred and five patients with no history of major acute cardiovascular event (MACE), aged 59.85±12.77 years, on mHD since 62.30±55.00 months were enrolled. All patients underwent a single cardiac Multi-layer spiral computed tomography (MSCT). Coronary calcium load was quantified according to the Agatston score (AS). According to AS patients were stratified into groups 1 (AS=0), 2 (AS 1 to 400), 3 (AS 401-1000) and 4 (AS>1000). All patients were followed up between January 2003 and January 2011. Primary endpoint of the study was mortality for MACE. Seven-year actuarial survival was calculated for patients of the four groups separately by Kaplan-Meyer equation. Patients who died for causes other than cardiovascular disease and transplanted patients were censored. The log rank test was employed to compare survival curves.

Results: One-hundred two patients (49.7%) died for cardiovascular disease during the follow up Seven-year actuarial survival was more than 90% for patients of groups 1 and 2, but failed to about 50% in patients of group 3 and to <10% in patients of group 4. Patients with AS>400 thus showed a significantly higher cardiovascular mortality compared to patients of with AS<400 (p<0.0001).

Conclusions: In mHD patients The presence of extended coronary artery calcifications detected with cardiac MSCT may be predictable of an elevated risk of cardiovascular mortality.

SA-PO2608

Correlation of Breast Arterial Calcification with Cardiovascular Disease in End Stage Renal Disease Na'Da Abouhassan, W. Charles O'Neill. *Renal Division, Emory University School of Medicine, Atlanta, GA.*

Background: Vascular calcification is common in end-stage renal disease (ESRD) and correlates with cardiovascular disease. However, since the imaging used to date cannot distinguish between medial and intimal (atherosclerotic) calcification, the clinical significance of medial calcification in ESRD is unknown. We have previously shown that breast arterial calcification (BAC) is exclusively medial and that BAC on mammography is a marker of generalized medial calcification

Methods: We obtained mammograms performed on women with ESRD at this institution. Age, race, cardiovascular disease, presence of diabetes mellitus (DM), and duration of renal replacement therapy were determined by review of the medical records. DM was defined as diabetic medication or diagnosis of DM. Coronary artery disease (CAD) was defined as a history of myocardial infarction, or coronary stenosis >50% on angiography. Peripheral artery disease (PAD) was defined as a history of bypass surgery or amputation, evidence of occlusion on imaging, or history of claudication. BAC was scored as present or absent by visual inspection of mammograms. Univariate analyses were performed using t-tests for continuous variables and the chi-squared test for categorical variables. Multivariate logistic regression analysis was performed with SPSS 17.0 software.

Results: We identified 91 women with ESRD and screening mammograms, all but 3 of whom were undergoing hemodialysis. BAC was detected on 57 mammograms (63 %). The prevalence of PAD in patients with BAC was 36.8 % as compared to 8.5% in patients without BAC (p = 0.003). The prevalence of CAD was 24.6 % in patients with BAC and 22.9% in patients without BAC. In a multivariate logistic model including age, diabetes, and duration of ESRD, only BAC (p = 0.006) and ESRD duration (p=0.031) were independent determinants of BAC.

Conclusions: BAC is strongly and independently correlated with peripheral arterial disease in ESRD. This indicates that medial arterial calcification is a risk factor for peripheral arterial disease and may have a pathophysiologic role.

SA-PO2609

Use of Warfarin for Atrial Fibrillation (AF) in Patients on Hemodialysis (HD) Salina Juma,[1] Charmaine E. Lok,[2] Catherine M. Clase,[3] Peter G. Blake,[1] Benjamin Ka Thomson,[1] Louise M. Moist.[1] *[1]University of Western Ontario, London, ON; [2]University Health Network, Toronto, ON; [3]McMaster University, Hamilton, ON.*

Background: The risk/benefit ratio for warfarin use in AF among patients on HD is unclear. The objectives of this study are to: 1) measure Nephrologists' certainty about warfarin use and 2) determine the patient variables influencing warfarin use in AF among Canadian Nephrologists.

Methods: Nephrologists at Victoria Hospital, London reviewed their patients with AF on HD. Using a 7 point scale, they documented their certainty regarding the use or nonuse of warfarin pre and post a 10 min presentation on risk and benefits of warfarin based on current literature. A survey was then developed consisting of 6 cases of patients with AF with a gradient of thromboembolic and bleeding risk and sent to a random sample of Nephrologists selected from the Canadian Society of Nephrology (CSN).

Results: Warfarin was used in 52.5 % of patients with AF. Nephrologists expressed uncertainty regarding both the use and nonuse of warfarin and this did not change with an update of the available literature. The survey response rate was 62.2 % (56/90).

CSN Survey Responses

Case	CHADS2	HD	GI Bleed	Risk for Falls	Very likely to start/ continue warfarin (%)	Very unlikely to start/ continue warfarin (%)	Uncertain (%)
1	2	No	No	No	80.4	3.6	16.1
2	2	Yes	No	No	50	14.3	35.7
3	5	Yes	No	No	76.7	3.6	19.6
4	5	Yes	No	Yes	23.2	28.6	48.2
5	5	Yes	Yes	No	48.2	8.9	42.9
6	5	Yes	Yes	Yes	3.6	67.9	28.6

Cases 1-3: A 65 year old Caucasian male, with untreated sustained AF, HTN and NIDDM. Cases 4-6: A 79 year old Caucasian female, on warfarin therapy, with sustained AF, previous stroke, HTN, NIDDM, PVD. She is on chronic HD secondary to glomerulonephritis.

The presence of renal failure and HD, previous GI bleed, and risk for falls all increased uncertainty about warfarin use. 73.2% of nephrologists agreed to be at clinical equipoise and 83.9% would enroll their patients with AF on HD in a RCT on oral anticoagulation.

Conclusions: Nephrologists have significant uncertainty about the use and non use of warfarin for AF among patients on HD. A RCT on the use of oral anticoagulation in patients with AF on HD is needed.

SA-PO2610

Left Ventricular Diastolic Dysfunction in Dialysis Patients Assessed by Novel Speckle Tracking Strain Rate Analysis: Prevalence and Determinants Mihaly K. De Bie,[1] Nina Ajmone Marsan,[1] Arien Gaasbeek,[1] Victoria Delgado,[1] Bas A. Gabreels,[3] Jan H. Groeneveld,[2] Jeroen J. Bax,[1] Martin J. Schalij,[1] Ton J. Rabelink,[1] J. Wouter Jukema.[1] *[1]Leiden University Medical Center; [2]Medisch Centrum Haaglanden; [3]Rijnland Ziekenhuis.*

Background: Diastolic dysfunction is common among dialysis patients and is associated with increased morbidity and mortality. Novel echocardiographic speckle tracking strain analysis permits accurate assessment of left ventricular (LV) diastolic function, with higher sensitivity and specificity as compared to more conventional measurements. The aim of the study was to evaluate the prevalence of diastolic dysfunction in chronic dialysis patients using this novel technique, and to identify its determinants among clinical and echocardiographic variables.

Methods: Patients currently enrolled in the ICD2 study protocol were included for this analysis. Next to conventional echo measurements diastolic function was also assessed by global diastolic strain rate during isovolumic relaxation (SRIVR). The presence of diastolic dysfunction was assessed using a previously defined cut-of: E/SRIVR ≥ 236. Following the determinants of diastolic dysfunction were identified among the baseline clinical parameters.

Results: A total of 77 patients were included (age 67±8 years, 74% male). When defined as E/SRIVR ≥ 236, the prevalence of diastolic dysfunction was higher compared to more conventional measurements (48% vs. 39%). Multiple regression analysis demonstrated that left ventricular mass (OR 1.02, 95% CI 1.01 - 1.04, p=0.01) and pulse wave velocity (OR 1.31, 95% CI 1.05-1.79) were independent determinants of diastolic dysfunction.

Conclusions: Diastolic dysfunction is highly prevalent among dialysis patients with preserved ejection fraction and might be underestimated using conventional measurements. Among baseline clinical and echocardiographic parameters left ventricular mass and pulse wave velocity were the only determinants of diastolic dysfunction in these patients.

Statin Exposure over Time in Chronic Dialysis: An Observational, National Study of Dually Eligible Patients James B. Wetmore, Theresa I. Shireman, Jonathan D. Mahnken, Qingjiang Hou, Purna Mukhopadhyay, Sally K. Rigler, Edward F. Ellerbeck. *University of Kansas School of Medicine, Kansas City, KS.*

Background: Although HMG CoA reductase inhibitors (statins) effectively lower cholesterol levels in patients on chronic dialysis, randomized trials have not consistently demonstrated a survival benefit. Statins are still widely prescribed in this population.

Methods: We examined factors associated with statin use over time in a large, national cohort of dually eligible, chronic dialysis patients from 2000-2005. Medication exposure was tracked through Medicaid prescription claims using the proportion of days covered (PDC) adjusted for inpatient and skilled nursing home stays. PDC was computed across the entire window of observation for each cohort member, reflecting medication exposure rather than adherence. Baseline characteristics and comorbidities were taken from linked USRDS Core Data.

Results: There were 18,757 dually-eligible, chronic dialysis patients taking statins during this period of observation (41.6% of the available cohort). The mean PDC for statin users was 0.57 (SD = 0.32). Statin PDCs increased with advancing age (10 year increments) but were lower among non-Caucasians ($p < 0.0001$). Persons with diabetes, CAD, or CVA at baseline also had higher PDCs ($p < 0.0001$). Cholesterol levels were not available for these study subjects, however, persons with higher BMIs had higher statin PDCs ($p < 0.0001$).

Conclusions: Even with their high potential for adverse cardiac outcomes, patients on chronic dialysis have inconsistent exposure to statins. In part, this may reflect the clinical equipoise during a period where clinical trials had not yet been completed. It may also reflect poor long-term adherence to statin therapy as has been demonstrated in other populations. Further examination of the effectiveness of statins in chronic dialysis is needed.

Funding: NIDDK Support

SA-PO2612

The Role of Statins and Cholesterol on Clinical Outcome of Continuous Ambulatory Peritoneal Dialysis Patients: A Retrospective Study Yong Kyu Lee, Tae Ik Chang, Sug Kyun Shin. *Nephrology Division, NHIC Ilsan hospital, Goyang, Geongido, Korea.*

Background: Patients who are on CAPD (Continuous Ambulatory Peritoneal Dialysis) show higher serum LDL cholesterol and Triglyceride compared to patients who are on hemodialysis. But higher cholesterol level does not seem to effect on raising mortality or cardiovascular morbidity and CAPD failure. On the contrary, lower serum cholesterol level in CAPD patients tends to raise mortality and morbidity due to poor nutritional status.

Methods: This study is a retrospective study designed to evaluate the effect of cholesterol level, statin on CAPD outcome and mortality. Patients who were on peritoneal dialysis for at least 6 months since March 1st, 2000 were included. A total of 467 patients were enrolled in this study. Patients' biological parameter, biochemical parameter and morbidity/mortality during CAPD maintenance period were collected.

Results: Patients whose initial cholesterol level were above 240 mg/dL shows significantly low CAPD failure rate compared to patients whose initial cholesterol level were below 200 mg/dL (OR= 0.469, p=0.049). Patients whose average LDL-cholesterol during CAPD period were over 100mg/dL showed significantly higher mortality compared to patients whose initial LDL-cholesterol level were below 100mg/dL (OR=1.848, p=0.024). Patients whose compliance to statin during CAPD period was over 80% showed significantly low mortality compared to patients who did not take statin during CAPD period (OD=0.556, p=0.020). Patients showed no significant difference in motality due to total cholesterol, HDL cholesterol levels and patients showed no significant difference in CAPD failure due to HDL/LDL cholesterol, statin usage.

Conclusions: In CAPD patients, serum total cholesterol level should be targeted higher than HD or CKD patients. On the contrary, similar to HD or CKD patients, Statin should be administered and LDL cholesterol should be lowered during CAPD period to lower mortality. To identify the difference in cholesterol mechanism of CAPD patients further, in depth study over adequate cholesterol level in CAPD patients needs to be proceeded.

SA-PO2613

***SIRT1 G*ene Polymorphisms Are Associated with Cholesterol Metabolism and Coronary Artery Calcification in Japanese Hemodialysis Patients** Toshimitsu Niwa,[1] Yasuhiko Shimoyama,[1] Hidehisa Shimizu.[1] *[1]Nagoya University Graduate School of Medicine; [2]Meiyo Clinic.*

Background: *Sirtuin 1 (SIRT1*), a longevity gene, protects cells against oxidative and genotoxic stress. This study aimed to investigate the association of *SIRT1* gene single nucleotide polymorphisms (SNPs), rs7895833, rs7069102 and rs2273773, with various laboratory data in 219 Japanese hemodialysis (HD) patients.

Methods: Genotyping of these polymorphisms was performed using polymerase chain reaction with confronting two-pair primers (PCR-CTPP) assay.

Results: The A allele frequency of rs7895833 and G allele frequency of rs7069102 were significantly lower in HD patients (0.228 and 0.131, respectively) than those in 803 control subjects (0.289 and 0.181, respectively) (p=0.010 and p=0.012, respectively). However, the allele frequency of rs2273773 was not significantly different from that in the control subjects. Multivariate analysis adjusted for age and duration on HD demonstrated that the serum levels of total and low-density lipoprotein (LDL) cholesterol were significantly high in G allele carriers of rs7069102 compared with CC genotype in male HD patients. Coronary artery calcification score was significantly high in C allele carriers of rs2273773 in all and male HD patients.

Conclusions: This study first demonstrates that *SIRT1* polymorphisms, rs7069102 and rs2273773, are associated with cholesterol metabolism and coronary artery calcification, respectively, in Japanese HD patients, especially in males.

SA-PO2614

Divert to Ultra: Differences in Infused Volumes and Clearance in Two Treatments HDF On-Line (Conventional vs Ultra) Antonino Sidoti. *Italian Cooperative Study on High Volume On-Line HDF, Italy.*

Background: A consolidate evidence exists about the higher removal capabilities of HDF therapies with respect to conventional HD. It is also well known that postdilution HDF improves the removal rate of mid to high molecular weight uremic toxins leading to some clinical benefits, like less dialysis related amyloidosis, better control of patient's phosphatemia and likely better response to ESA. The aim of this study was to compare two different post-dilution On-Line HDF in regards to exchanged volumes (EV) and middle molecules dialysis efficiency: standard On-Line (sOL) and ULTRAcontrol (UC).

Methods: Thirty ESRD patients (pts, 6/24 F/M) were enrolled in this prospective sequential study from 8 centres. The pts underwent a 3-month sOL (fixed exchanged volume) followed by 3-month UC. AK200 ULTRA has been employed in all treatments. In sOL, the EV were set according to a filtration fraction greater than or equal to 25%. In UC the EV was driven by a biofeedback system controlling in a double loop the transmembrane pressure (TMP) and its set point. In both HDF, pts mantained the treatment time, the dialyzer, the blood flow rate and anticoagulant regimen unchanged. Primary response variables were: EV, ß2-microglobulin (ß2m) clearance (Kß2m) measured at 60 and 120 min. Secondary response variables were: ß2m in pre and post dialysis and phosphate clearance (Kp).

Results: A greater EV was infused in UC than in sOL (20.8±3.7 l vs 16.9±4.4 Liters; $p<0.001$). The average Kß2m values were higher in UC than in sOL (111.5±22 vs 123.3±24 ml/min, $p<0.002$), while the average Kp did not achieve a statistical significant difference (150.8±33.9 vs 156.2±38.9 ml/min, p=NS) despite they were higher in UC than sOL. The estimated ß2m concentrations at the beginning of dialysis were similar in both HDF (23.0±11.8 vs 22.1±15.0 mg/l, p=NS), while they significantly differed in the post dialysis (7.8±5.8 vs 5.8±4.2 mg/l, $p<0.019$).

Conclusions: This study shows that the biofeedback module, applied to the automatic control of TMP in On-Line HDF (ULTRAcontrol), allows higher EV and correspondingly higher Kß2m. This results were obtained by reducing both the technical complexity of HDF and staff workload.

SA-PO2615

Has the Introduction of Clinical Practice Guidelines Improved Dialysis Care? Helga K. Mogensen,[1] Runolfur Palsson,[1,2] Olafur S. Indridason.[2] *[1]University of Iceland, Reykjavik, Iceland; [2]Divison of Nephrology, Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland.*

Background: Several clinical practice guidelines for dialysis care have been issued over the past decade. In this study we examined if the introduction of the KDOQI and ERBP guidelines resulted in improvement of the quality of dialysis therapy at the University Hospital in Reykjavik.

Methods: This was a retrospective study of all patients receiving dialysis at the University Hospital's Dialysis Unit for >3 months from 2003 to 2008. Data were obtained from electronic medical records. The study period was divided in two 3-year intervals, 2003-2005 and 2006-2008. Chi-square test was used to compare the proportion of patients reaching therapeutic targets in each interval and to compare hemodialysis and peritoneal dialysis patients.

Results: A total of 177 patients underwent dialysis treatment during the study period. The target level for URR (>65%) was achieved in 80.4% of hemodialysis patients during the first interval and 72.6% during the second interval (p=0.80). In the first interval, 65% of patients reached the target for hemoglobin (110-130 g/L) and 67.5% during the second interval (p=0.68). The target for serum calcium (2.20-2.60 mmol/L) was achieved in 72.1% of patients during the first and 70.7% during the second interval. Only 53.0% of patients reached the target for serum phosphate (1.13-1.78 mmol/L) during the first interval and 55.7% during the second interval (p=0.67). The target for PTH (150-300 ng/L) was achieved in only 23.9% of patients during the first and 33.0% during the second interval (p=0.30). The target for serum bicarbonate (>21 mmol/L) was achieved in 94.9% of peritoneal dialysis patients and 65.6% of hemodialysis patients ($p<0.001$); otherwise no significant difference existed between the two dialysis modalities.

Conclusions: Introduction of clinical guidelines has not been associated with substantial improvement in the care of dialysis patients in Iceland, as measured by selected quality indicators. The use of well defined clinical pathways may be needed to facilitate the implementation of clinical practice guidelines and to improve the quality of dialysis care.

SA-PO2616

Outcomes of Enhanced Systematic Screening for Transient Ischemic Attack in Hemodialysis Albert J. Power, Dima Dahdaleh, Claire Edwards, Jan Sawyer, Harri Jenkins, David Taube, Neill Duncan. *Imperial College Healthcare NHS Trust, London, United Kingdom.*

Background: Rapid recognition and management of transient ischemic attack [TIA] has been shown to reduce incident stroke in the general population but similar data are lacking in dialysis patients who form a high-risk group for cerebrovascular events. We hypothesised that systematic screening would reveal the true prevalence of TIA in hemodialysis [HD] and drive reductions in stroke incidence.

Methods: All patients on maintenance HD at one unit at our center were given verbal and written information about stroke symptoms [UK Dept of Health], staff attended an educational session and posters were distributed through the patient areas prior to study start. Prospective screening was performed once weekly using a dedicated questionnaire comprising all elements of the FAST test [UK Dept of Health], screening for sensory & visual symptoms and a record of any emergency attendances in an attempt to maximise yield.

Results: 304 patients were screened over 12 months from Nov 2009 [mean age 65.7±14.0yrs, 60% male, 53% Indo-Asian] with 2594 patient months follow-up. 44% were diabetic, 14% had prior cerebrovascular disease [stroke +/- TIA]. Mean HD length was 4.3±0.4hrs, single-pool Kt/V 2.0±0.3. Mean blood pressure was 140/78mmHg pre- & 135/75mmHg postdialysis. Mean hemoglobin was 12.2±0.9g/dL, mean weekly darbepoietin dose 0.56±0.37mcg/kg.

9504 questionnaires [mean 32±14/patient] were administered. 6 strokes occurred, 5 ischemic- an incidence rate of 23.1/1000 pt years. No patients screened positive for TIA despite a predicted rate of 4.2/1000 pt years [95% CI 1.4-9.7/1000 pt years]. One ischemic stroke was preceded by symptoms compatible with a TIA ascertained in retrospect alone.

Conclusions: In the first study of its kind to date systematic screening for TIA in HD patients cannot be relied on alone as a method of identifying HD patients at higher risk of stroke events. The confounding presence of symptoms attributable to uremia, neuropathy, dialysis hypotension and dysglycemia could reduce the sensitivity of established screening tests with significant implications for the detection and treatment of TIA in dialysis patients.

SA-PO2617

Improvement in Cardiac Strain Rate in Children on Chronic Hemodialysis after Carntine Supplementation Kristen Sgambat, Lowell Frank, Ahmad Ellini, Craig Sable, Asha Moudgil. *Nephrology, Childrens National, Washington, DC.*

Background: Carnitine is essential for transport of fatty acids into mitochondria and plays a key role in energy production in the myocardium. Carnitine deficiency may occur in patients on chronic hemodialysis (HD) due to removal by dialysis and inadequate intake and may contribute to cardiomyopathy. We prospectively assessed cardiac response to IV carnitine supplementation by standard echocardiographic (echo) and more sensitive parameters including left ventricular (LV) strain rate.

Methods: Carnitine levels (total,free,acyl,and acyl:free ratio) and cardiac function of 9 children on chronic HD were assessed before and after carnitine infusion (20mg/kg given 3 times a week for 6 months). Standard echo measures of LV size and systolic and diastolic function as well as circumferential and longitudinal strain rate analysis using speckle tracking were performed. Changes in echo parameters of a retrospective control group of 8 children on chronic HD not treated with carnitine were assessed for comparison.

Results: The study group had mean age of 12.7±1.9(range 9-16 years) and dialysis vintage 9.3±6.5 months,which did not differ from controls. After carnitine supplementation, total and free carnitine levels increased (48.9±1.67 vs. 260.3±13.1 µmol/l and 29.0 ± 1.19 vs.156.6 ± 8.44 µmol/l (p<0.001), whereas acyl:free ratio remained unchanged (0.73±0.04 vs. 0.69±0.05). There were no significant changes in standard echo measures of LV function including end diastolic dimension, mass index, ejection fraction, and shortening fraction after carnitine supplementation. However, there was a significant improvement in longitudinal strain rate (-1.48 ± 0.11 vs. -1.91 ± 0.12, p=0.01)after supplementation. There were no changes in blood pressure, interdialytic weight gain, or hemoglobin of study patients pre vs post treatment. No improvements in LV strain rate occurred in control subjects.

Conclusions: Carnitine supplementation improved total and free carnitine levels in children on chronic HD without impacting acyl:free ratio. LV performance improved after carnitine supplementation as assessed by strain rate analysis that was not obvious by standard echo measures.

SA-PO2618

Aspirin Resistance: Prevalence, Affecting Factors and Effects on Cardiovascular Complication and Vascular Access Failure in Hemodialysis Patients Jong-Woo Yoon, Myung Jin Choi, Youngki Lee, Ja-Ryong Koo, Jung-Woo Noh. *Internal Medicine, Hallym University Hospital, Kidney Research Institute, Chuncheon, Gangwon, Korea.*

Background: Even though aspirin has been effectively used for prevention of cardiovascular(CV) complication, some patients experience CV events during aspirin use. Association of aspirin resistance(AR) and CV events have been reported in many CV disease and kidney transplant patients. The prevalence and effects of AR on CV complication and vascular access failure of hemodialysis(HD) patients is not known.

Methods: 119 HD patients from two hospital who took 100-200mg of aspirin more than 1 month were enrolled. Patients who used NSAIDs or anti-platelet agents and thrombocytopenia were excluded. To define AR, measurement of anti-platelet effects was assessed by VerifyNow® assay device. AR was defined as aspirin resistance unit (ARU)>550.

Results: Among 119 patients, female was 68(58.1%), mean age was 57, mean dialysis duration was 51.5 month and 68(57.5%) were diabetes. AR was observed in 19 of 119 patients(15.9%) and showed higher hsCRP(14.24±7.91 vs 5.04±0.90, *p=0.02*) and higher prevalence of CV complication(43.8% vs 30.6%, *p=0.02*), including cerebrovascular complication(25.8% vs 19.8%, *p=0.01*). But vascular access failure incidence was not different. It also showed positive correlation with serum 25(OH) Vitamin D, total level(*r=0.305, p=0.001*), negative correlation with calcium(*r=-0.271*, *p=0.003*), phosphate(*r=-0.177, p=0.05*) and Kt/V urea(*r=-0.196, p=0.036*). Multivariety analysis showed vitamin D level(OR 1.117, 95% CI 1.025-1.117, *p=0.01*), phosphate(OR 0.618, 95% CI 0.395-0.968, *p=0.04*), HDL(OR 1.065, 95% CI 1.010-1.124, *p=0.02*) as a independent factor. There were no relationship between AR with age, sex, dialysis duration, diabetes, BMI, smoking, aortic calcification.

Conclusions: AR was observed 15.9% in HD patients and was associated with higher incidence of CV disease but vascular access failure was not. Relative lower Kt/V urea and higher hsCRP suggest the possible influence of dialysis adequacy and inflammation. Correlation with some factors affecting vascular remodeling mechanisms such as Vit D, HDL, phosphate, and calcium need further investigations.

SA-PO2619

Randomized Controlled Trial on the Cardiovascular Efficacy of Active Vitamin D in Hemodialysis Patients (J-DAVID): Rationale and Study Design Tetsuo Shoji.[1,2] *[1]Department of Metabolism, Endocrinology and Molecular Midecine, Osaka City University Graduate School of Medicine, Osaka, Japan; [2]J-DAVID Research Group.*

Background: Patients with stage 5 chronic kidney disease on maintenance hemodialysis are at an increased risk for cardiovascular disease. Observational cohort studies showed that use of active vitamin D sterols was associated with better survival and better cardiovascular outcome among dialysis patients. Since these patients have deficiency of active vitamin D which potentially plays protective roles in the cardiovascular system, we hypothesized that administration of active vitamin D would reduce the incidence of cardiovascular outcomes.

Methods: The Japan Dialysis Active Vitamin D Study (J-DAVID) is a prospective, randomized, open-labeled, blinded-endpoint (PROBE) trial. The intervention is oral alfacalcidol (starting dose of 0.5 micro g/day) versus no active vitamin D sterol (1:1 allocation). The main inclusion criteria were serum calcium ≤ 10.0 mg/dL, phosphate ≤ 6.0 mg/dL, intact PTH ≤ 180 pg/mL without use of active vitamin D sterol. The target number of subjects is 972, and the follow-up period is 4 years. The primary end-point is the composite of incident myocardial infarction, coronary revascularization, stroke, revascularization for PAD, amputation of ischemic legs, and congestive heart failure requiring hospitalization. The results will be analyzed on intention-to-treat principle.

Results: Between July 2008 and January 2011, a total of 976 subjects on maintenance hemodialysis were enrolled at approximately 100 dialysis centers in Japan, and they were randomly assigned to the two treatment arms.

Conclusions: The results of this study will provide important information on the cardiovascular protection of active vitamin D sterol in hemodialysis patients without increased intact parathyroid hormone level.

Funding: Private Foundation Support

SA-PO2620

The Effect of Intradialytic Vasopressin Infusion on Chronic Blood Pressure Control in Hypertensive Patients with ESRD: A Program To Develop a Decisive Randomized Controlled Trial Anjali Ganda,[1] John L.P. Thompson,[2] Joseph Schwartz,[3] Anthony M. Valeri,[1] Juan A. Oliver,[1] Alexandra Sanford,[2] Richard Buchsbaum,[2] John T. Bigger,[1] Bruce Levin,[2] Donald W. Landry.[1] *[1]Medicine, College of Physicians&Surgeons, Columbia University, New York, NY; [2]Biostatistics, Mailman School of Public Health, Columbia University, New York, NY; [3]Psychiatry & Behavioral Science, Stony Brook University, New York, NY.*

Background: Volume expansion is the central cause of interdialytic hypertension in patients with ESRD; ironically, hemodynamic instability during hemodialysis (HD) prevents adequate fluid removal and patients remain hypertensive between treatments. Non-pressor doses of exogenous arginine vasopressin (AVP) stabilize blood pressure (BP) and allow greater fluid removal during a single HD. We now hypothesize that chronic intradialytic AVP will lead to better chronic interdialytic BP control due to enhanced control of volume.

Methods: To demonstrate feasibility, we conducted a randomized, double-blinded, placebo-controlled 12-subject pilot study with 2-week follow-up, using the same randomization process, treatment groups, medication administration system, and outcome recording procedures that will be used in a 72-subject 12-week Phase II dose selection trial. The primary outcome was change in mean interdialytic 44-hour ambulatory systolic blood pressure (ABP). Dry weight was assessed via relative plasma volume monitoring.

Results: 12 hypertensive ESRD HD patients were randomized to 3 treatment groups. Mean age 73±8.1 years, 50% male, 60% Hispanic/Latino, 75% diabetic. Mean baseline (BL) interdialytic 44-hour systolic ABP 137.5 ±15.0 mmHg. Mean BL number of ABP observations 87.8±37.1. 10 patients completed all 6 study visits. There were no serious adverse events. Excluding 2 patients who lacked outcome data, mean change in systolic

ABP was -0.4±11.8 in the placebo group (N=4); -1.5±8.6 in the 0.15 mU/kg/min AVP group (N=3); and -3.7± 27.0 in the 0.30 mU/kg/min AVP group (N=3).

Conclusions: The pilot study shows that the study design and procedures are viable, and that the randomization, treatment administration, and data management systems function appropriately.

Magnesium: A Cardiovascular Risk Marker in Hemodialysis Patients Patrícia Matias,[1,2,3] Tiago Amaral,[1,2,3] Carina Ferreira,[1,2,3] Cristina Jorge,[1,2,3] Inês Aires,[1,2,3] Marco Mendes,[1,2,3] Célia Gil,[1,2,3] Aníbal Ferreira.[1,2,3] *[1]Dialysis Clinic, Hemodial, Vila Franca de Xira, Portugal; [2]Dialysis Clinic, Dialverca, Alverca, Portugal; [3]NIDAN, Lisboa, Portugal.*

Background: Hypomagnesemia seems to play a role in the pathogenesis of arterial hypertension, endothelial dysfunction and inflammation in the general population.

The aim of this cross-sectional study was to evaluate the relationship between pre dialysis magnesium (Mg) levels and inflammation, bone metabolism and cardiovascular risk markers, including pulse pressure (PP), left ventricular mass index (LVMI) and vascular calcifications (VC), in chronic hemodialysis (HD) patients.

Methods: We studied 206 HD patients with mean age (± SD) of 63.6±14.3 years, 45% female, 26% diabetics, with mean HD time of 42.3±38.6 months. All patients were under pre dilution hemodiafiltration with a dialysate Mg concentration of 1 mmol/L. Univariate and multivariate analysis were performed and a $p<0.05$ was considered significant.

Results: Mean serum Mg was 1.36±0.18 mmol/L and none of the patients presented hypomagnesemia (Mg < 0.6 mmol/L). Mg levels were negatively correlated with age (r= -0.44; p=0.006), diabetes mellitus (r= -0.42; p=0.007), iPTH (r= -0.33; p=0.02), PP (r= -0.36; p=0.01), LVMI (r= -0.37; p=0.01) and VC (r= -0.40; p=0.008). Mg was positively correlated with albumin (r= 0.57; p<0.001) and 25-hydroxyvitamin D3 (r= 0.45; p=0.004).

In multivariate analysis, lower Mg concentrations were predictors of an increased PP (> 65 mmHg) (p=0.002) and LVMI (> 140 g/m2) (p=0.03) and of a higher VC score (> 3) (p=0.01).

Conclusions: Pre dialysis Mg serum levels were associated with inflammation, bone disease and CV risk markers in HD patients.

SA-PO2622

Mechanical Circulatory Support in Dialysis Patients as a Bridge to Transplantation Jeffrey D. Wallach,[1] Gregory V. Warren,[1] Michael E. Anigbogu,[2] Krishna Nagendran,[2] T. Edward Hastings,[2] Nasir Z. Sulemanjee,[2] Andrew J. Boyle.[2] *[1]Division of Nephrology, Aurora St. Lukes Medical Center, Milwaukee, WI; [2]Division of Cardiology, Aurora St. Lukes Medical Center, Milwaukee, WI.*

Background: Advanced chronic kidney disease has generally been an exclusion criterion for cardiac transplant using standard listing criteria. Selected patients with end stage renal disease (ESRD) have undergone successful combined heart and kidney transplantation. However, the use of mechanical circulatory support as a bridge to transplantation has not previously been reported in patients with ESRD. We report the experience of a single transplant center where ESRD patients received continuous flow ventricular assist devices (VAD) as a bridge to transplant, and continued to receive dialysis in their usual outpatient setting.

Methods: 5 prevalent ESRD patients (3 in-center HD, 2 home PD, mean vintage 433 days) underwent VAD placement at our center between Nov 2009 and Oct 2010 as a bridge to transplantation. No ESRD patients were selected for destination therapy. Patients were observed from VAD placement until transplant or to 5/31/2011. Outcomes were length of stay (LOS) post-VAD placement, readmission days, and duration of circulatory support.

Results: Following VAD implantation initial LOS was 22 ±8 days. 2 patients were successfully weaned from dialysis post-VAD and did not require renal transplantation. Patients remained on VAD support for 202 ±72 days. No dialysis modality changes were made pre-transplant. There were 4 readmissions in 3 patients with diagnoses of peritonitis, ventricular tachycardia, driveline infection, and weakness. Following initial discharge post-VAD implantation, patients remained as outpatients for 98% of observed days. 4 patients received transplants and 1 patient remains listed.

Conclusions: 1)ESRD patients on HD or PD can successfully receive mechanical circulatory support with VAD as a bridge to transplantation. 2)Outpatient HD and PD can be safely performed in patients with VAD. 3)Clinical outcomes, LOS and readmissions in ESRD patients are similar to VAD patients without ESRD. 4)Following VAD implantation, an average of 98% of follow-up days were spent as outpatients.

SA-PO2623

Characteristics of the Dipper and Non-Dipper Type of Hemodialysis Patients -24-Hours ABPM Monitoring and Cardiovascular Complications over 10 Years Yuzuru Sato, Megumi Sato, Masanor Jotoku. *Internal Medecine, Sato Junkanki Hospital, Matsuyama, Ehime, Japan.*

Background: 24-hour blood pressure monitoring (ABPM) is useful to determine whether the patient is a dipper or non-dipper. But characteristics of dipper and non-dipper on hemodialysis patients, the relationship between the two types, and the cardiovascular complications on a long-term, are still unknown. In our study, ABPM was performed on 45 hemodialysis patients over 10 years.

Methods: 24-hour blood pressure monitoring (ABPM) was performed on 51 hemodialysis patients from 2000. Four patients were moved, two were transplanted and the other forty-five patients were followed for 10 years. ABPM started at the end of hemodialysis and BP was measured every 15 minutes at the daytime (defined from 6 AM to 9 PM) and every 1 hour at the nighttime (9 PM to 6 AM). Dipper status was defined on the changes between the average SBP from daytime and nighttime. We considered two groups, dippers (BP nocturnal fall superior to *10mmHg)* and non-dippers (BP nocturnal fall less than 10mmHg).

Results: The ABPM on 45 patients showed distinct groups, as 11 patients (24.4% of the whole patients) were dipper type (group A) and 34 patients (75.6%) were non-dipper type (group B). SBP of group A in the daytime was significantly higher than group B (163.7±16.8 vs. 150.2±19.4mmHg, $p<0.05$), but both group's SBP were similar in the nighttime (138.3±17.0 vs. 146.8±22.8mmHg). The aortic calcification scores (ACS) were the same according to computed tomography of the abdomen. Nine patients in group A and 13 in group B had cardiovascular complications for 10 years and the cumulative events-free rate of group B was significantly higher than group A's one (Kaplan-Meier methods p=0.016, Log-rank test). ACS of the patients in group B with cardiovascular complications were significantly higher than without them (63.9±24.0 vs. 34.6±25.4, $p<0.01$).

Conclusions: In this study, two types of hemodialysis patients were characterized over 10 years. Higher SBP in the daytime for dipper type patients and pre-existing severe aortic calcification for non-dipper type patients suggested several risk factors of cardiovascular complications in hemodialysis patients.

Methods: SA-PO2624

Early Interdialytic Fluid Retention Is Associated with Cardiovascular Outcomes in Incident Hemodialysis Patients Ji Yong Jung, Jae Hyun Chang, Sejoong Kim, Hyun Hee Lee, Wookyung Chung. *Department of Internal Medicine, Gachon University of Medicine and Science, Incheon, Republic of Korea.*

Background: Fluid retention is a major clinical problem in patients undergoing hemodialysis (HD) and is associated with cardiovascular outcomes. Patient with end stage renal disease have similarities to heart failure. Volume overload in heart failure is associated with worse outcome. Removal of fluid during the HD is the cornerstone of volume management in this population. Therefore, we hypothesized that greater inter-dialytic fluid retention (IDFR) is associated with poor cardiovascular event and survival in incident HD patients.

Methods: We analyzed the 174 patients who newly started and maintained the HD over 6-month in Gachon University Gil Hospital between January 1, 2003 and December 31, 2008. We did not take the first 3 month IDFR into account by reason of stabilized period in incident HD patients. According to the average IDFR of 4~6 month, we divided into 2 groups by the median value: Lower IDFR (< 2.17 kg), Higher IDFR (Fluid retention ≥ 2.17 kg). The associations of IDFR with cardiovascular outcomes were evaluated with the use of Cox proportional regression analysis.

Results: Higher IDFR showed higher prevalence of diabetes, better nutritional status (higher phosphorus and nPNA level). In univariate analysis, higher IDFR, hemoglobin (Hb), total cholesterol and LDL cholesterol level were associated with cardiovascular events. After multivariate adjustment, higher IDFR, low Hb, and high LDL cholesterol were associated with increased risk of cardiovascular events. The odds ratio (95% confidence interval) of cardiovascular events 2.213 (1.011 – 4.846, P = 0.047) in the higher IDFR, 0.557 (0.355-0.876, P = 0.011) in Hb level, and 1.106 (1.003 – 1.028, P = 0.014) in LDL cholesterol level, respectively. However, all-cause and cardiovascular mortalities were not significantly different between two groups.

Conclusions: In incident HD patients, early greater IDFR is associated with higher risk of cardiovascular events. Further research with large subjects needed to elucidate the pathophysiological mechanisms that link fluid retention to increased cardiovascular events.

SA-PO2625

Pre-Procedural Serum Albumin and C-reactive Protein Levels Predict Clinical Outcome after Endovascular Therapy in Hemodialysis Patients with Peripheral Artery Disease Fumiyo Kobayashi,[1] Hirotake Kasuga,[2] Keiko Kimura,[2] Chieko Matsubara,[2] Rei Okada,[2] Seiichi Matsuo.[3] *[1]Nephrology, Toyota Kyoritsu Clinic; [2]Nephrology, Nagoya Kyoritsu Hospital; [3]Nephrology, Nagoya University Hospital.*

Background: Although endovascular therapy (EVT) has become widely performed for peripheral artery disease (PAD), adverse events such as high restenosis rate or premature death after EVT remain major clinical problems in patients on hemodialysis (HD). On the other hand, malnutrition and chronic inflammation status are frequently observed, and linked to poor cardiovascular outcome in such population. We evaluated the possible prognostic values of serum albumin and C-reactive protein (CRP) levels on clinical outcomes after EVT in patients on HD.

Methods: A total of 450 HD patients successfully undergoing EVT for PAD were enrolled and were followed-up for up to 8 years. Serum albumin and CRP levels were measured prior to EVT. They were divided into tertiles according to serum albumin and CRP levels; the lowest tertile (T1), the middle tertile (T2) and the highest tertile (T3), respectively. We analyzed the incidence of major adverse cardiovascular events (MACE) as a composite endpoint including target lesion revascularization (TLR), amputation and all-cause death.

Results: During follow-up period (mean 36±31months), 206 MACE (46%) including 67 TLRs, 45 amputations and 94 deaths occurred. Event-free survival rate from MACE for 8 years was 23.1%, 25.9%, and 50.0% in T1, T2 and T3 of albumin ($p<0.0001$), and 41.2%,

36.3% and 18.9% in T1, T2 and T3 of CRP (p=0.0004), respectively. After adjustment, lower albumin (HR 2.00, 95%CI 1.29-3.10, p=0.0071 for T1 vs. T3) and elevated CRP (HR 1.93, 95%CI 1.29-2.90, p=0.0061 for T3 vs. T1) were independent predictors for MACE, respectively. In the combined setting of albumin and CRP, the risk of MACE was 5.22-fold (95%CI 2.34-11.64, p=0.0011) higher in the T1 of albumin with T3 of CRP compared to the T3 of albumin with T1 of CRP even after adjustment.

Conclusions: Lower albumin and elevated CRP levels could predict MACE after EVT in patients on HD. However, the combination of these variables is more markedly related to increased MACE than either variable alone.

SA-PO2626

Risk Factors of Progression of Aortic Arch Calcification in Patients with Maintenance Hemodialysis and Peritoneal Dialysis Hyun Gyung Kim, Young Ok Kim. *Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea.*

Background: Vascular calcification is accelerated during the dialysis and known as an important risk factor for cardiovascular disease. Progression of AoAC can be simply estimated with an AoAC score (AoACS) on chest radiography. The objective of this study was to evaluate the risk factors of the progression of AoAC.

Methods: The enrolled subjects were 125 hemodialysis and 59 peritoneal dialysis patients, newly treated at the dialysis unit. In the patients who had undergone chest radiographies before initial dialysis therapy and every year, we estimated AoACS and then divided into two groups by the presence or absence of the AoAC progression. We also compared the baseline clinical and biochemical profiles in two groups.

Results: Eighty-five (46.2%) were men and the mean age was 58.6 ± 12.7 years. 76 patients (41.3%) had AoAC before initial dialysis with the mean AoACS of 13.0 ± 20.4%. The mean duration of follow-up of AoACS was 2.7 ± 1.0 years. The half of the patients (50%) had the progression and the others non-progression of AoAC. Old age more than 65 years (p=0.003), dialysis duration (p=0.004), diabetes (p=0.015) and the presence of AoAC at baseline (p=0.001) were related to the progression of AoAC. No significant association was detected between the AoAC progression and baseline clinical parameters including gender, obesity, hypertension and dialysis modality. In multivariate analysis, the duration of dialysis (p=0.004) and the presence of AoAC at baseline (p=0.001) were independent risk factors of the progression of AoAC in dialysis patients.

Conclusions: The duration of dialysis and the presence of AoAC before initial dialysis were significantly related to the progression of AoAC in dialysis patients. We suggest that we should focus on the through management from pre-dialysis stage to prevent the progression of AoAC and reduce cardiovascular morbidity in chronic dialysis patients.

SA-PO2627

Reduction of Nurse Intervention Using Blood Volume Tracking (BVT) System Maria Doria,[1] Simonetta Genovesi,[2] Antonio Santoro.[3] *[1]Policlinico S.Donato I.R.C.C.S., San Donato, Italy; [2]San Gerardo Hospital, Monza, Italy; [3]Sant'Orsola Malpighi Hospital, Bologna, Italy.*

Background: Intradialytic hypotension (IDH) still represents the most common acute complication of hemodialysis (HD) therapy accounting for up to 30% of HD sessions. BVT system is a tool capable of reducing the occurrence of IDH by avoiding sudden drop of BV below hazard values during HD by adjusting both UF rate and the dialysate sodium content. The present study was aimed to understand if BVT system is able to reduce the staff workload and job complexity associated to a reduction of IDH.

Methods: Ten HD patients (M/F: 5/5; age: 76.7±8.3 yrs) prone to IDH were selected for the study. The presence of cancer, mental illness, pregnant, residual diuresis greater than 500 ml/d, poor vascular access were considered an exclusion criterion. Each patient was treated with 39 conventional HD for 3 months and then was switched to 39 HD+BVT for further 3 months. The variables monitored were: number of session requiring nurse interventions (NI), effective treatment time (ETT), body weight loss (BWL), end-treatment BV, pre/post dialysis systolic arterial pressure and heart rate, number of sessions complicated by IDH and type of staff interventions.

Results: Throughout the HD and the HD+BVT period all episodes of IDH, the number of NI, the total volume of fluid infusions for therapeutic purposes, the infusions of 11.7% NaCl and all possible preterm disconnection of patients were reported on the dialysis records. There was no statistically significant differences between the two treatments with regard to the actual treatment time, the BWL achieved and the corresponding average UF rate. The number of HD sessions requiring intervention by the medical staff was approximately halved when the patient underwent HD+BVT (102 vs. 57, p<0.001). Using as parameter the ETT, the HD sessions were interrupted before the prescribed time in a percentage significantly greater than the HD+BVT (15 vs. 2, p<0.001).

Conclusions: This study confirms the usefulness of the BVT during HD to reduce the frequency of IDH episodes in hemodynamically unstable patients, reducing the staff workload with less nurse interventions and higher dialysis efficiency.

SA-PO2628

Renalase Was Not Related to Blood Pressure, but to Residual Renal Function in Haemodialysis and Peritoneal Dialysis Patients Edyta Zbroch, Jolanta Malyszko, Jacek S. Malyszko, Ewa Koc-Zorawska, Michal Mysliwiec. *Nephrology, Medical University, Bialystok, Poland.*

Background: Recently the new flavin-adenine dinucleotide containing hormone, secreted by the kidney and circulates in blood, named renalase was investigated. It degrades catecholamines and may play a role in the regulation of sympathetic tone and blood pressure.

Methods: The aim of the study was to assess the serum renalase concentration (RNLS) in a cohort of 104 treated with haemodialysis (HD group) and 26 treated with peritoneal dialysis (PD group) patients and its relationship to the blood pressure control, type of antihypertensive therapy and the presence of residual renal function (RRF).

Results: Abnormal blood pressure control was observed in 67% patients of the HD group and in 57,69% of the PD group. The main antihypertensive drugs were beta-blockers and calcium-channel blockers. RRF was present in 50% of HD and in 61,5% of PD patients. RNLS in the study cohort was 25,86µg/ml and it was significantly higher than in the control group 3,86µg/ml (p<0,001). There was the significantly higher RNLS in the HD group comparing to the PD group (27,53 vs. 19,24µg/ml). The results indicated a significant correlation between the duration of dialysis and RNLS (r=0.3175, p=0.002). It was higher in those patients who were maintained dialysis longer. The relationship between the presence of RRF and RNLS was found in whole study cohort (24,21 vs. 27,83µg/ml, p=0,006) and in HD patients (25,65 with vs. 30,11µg/ml, p<0,002). The significant inverse correlation between RNLS and RRF was also indicated: HD group r=(-0,327, p =0,001); PD group r=(-0.4286, p=0.02). No correlation between RNLS and blood pressure rate was found. RNLS was higher in male than female only in HD patients.

Conclusions: The elevated RNLS in dialysis patients may be rather related to kidney function (as time on dialysis passes, the residual renal function is lower) and due to the sympathetic nervous system hyperactivity found in this population and it may have an impact on the development of cardiovascular complications. Further studies are needed to prove or disprove the possible role of renalase in the pathogenesis of hypertension in patients with kidney diseases.

Funding: Government Support - Non-U.S.

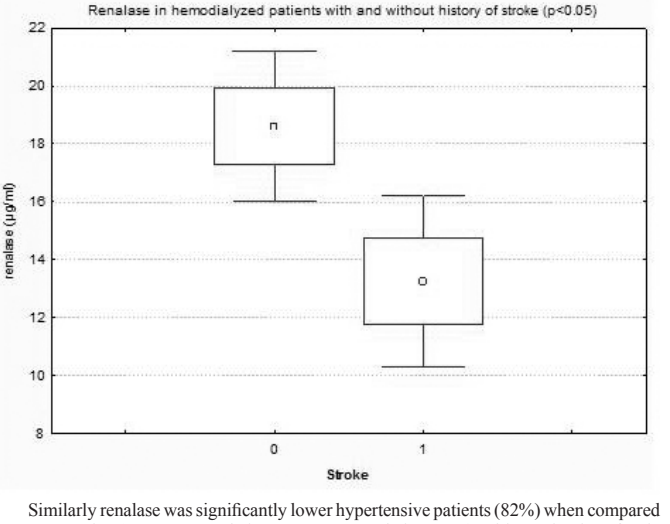
SA-PO2629

Renalase as a Possible Risk Factor of Cardiovascular Complications in HD Jolanta Malyszko,[1] Jacek S. Malyszko,[1] Ewa Koc-Zorawska,[1] Edyta Zbroch,[1] Michal Mysliwiec.[1] *[1]Nephrology, Medical University, Bialystok, Poland; [2]Dialysis Unit, NZOZ Centum, Mlawa, Poland.*

Background: Renalase, newly discovered hormone, is secreted by the kidney and circulates in blood. It was shown that renalase degrades catecholamines and may play the role in the regulation of sympathetic tone and blood pressure. Cardiac renalase deficiency may contribute to the increased susceptibility to myocardial injury due to ischemia and rhythm disturbances frequently found in CKD. The aim of the study was to assess the renalase relationship to cardiovascular status in hemodialyzed patients.

Methods: Renalase was assessed using commercially available assay from uscn. Life Sci, China. Echocardiography was performed in each patient.

Results: Serum renalase was significantly lower in patients with a history of stroke (21%) (13.25±3.97µg/ml vs. 18.61±6.91µg/ml, p<0.05), than in patients without it.



Similarly renalase was significantly lower hypertensive patients (82%) when compared to normotensive (16.47±5.86µg/ml vs. 22.34±8.91µg/ml, p<0.05), with proximal a-v fistula (29%) vs distal a-v fistula (16.55±6.39µg/ml vs. 24.61±5.14µg/ml, p<0.05), and higher in patients with glomerulonephritis (26%) vs other etiologies of ESRD (21.93±5.52µg/ml vs. 15.91±6.49µg/ml, p<0.05). Serum renalase correlated with creatinine, residual renal function, TSAT, and dysfunction of mitral valve. No correlation between serum renalase concentration, and blood pressure rate or haemodialysis vintage was found.

Conclusions: Our preliminary results suggest that renalase, due to the sympathetic nervous system hyperactivity could be associated with cardiovascular complications in hemodialzyed patients. However, further studies are needed to prove or disprove the possible role of renalase in the pathogenesis of these complications.

SA-PO2630

Age May Explain the Association of an Early Dialysis Start with Poor Survival

Maria Jose Soler,[1] Nuria Montero,[1] Maria Jose Pascual,[1] Clara Barrios,[1] Eva Marquez,[1] Maria Antonia Orfila,[1] Eva Rodriguez,[1] Higini Cao,[1] Emma Arcos Fuster,[2] Jordi Comas Farnes,[2] Julio Pascual.[1] *[1]Nephrology, Hospital del Mar, Barcelona, Spain; [2]Resgistre dels Malalts Renals de Catalunya, Barcelona, Spain.*

Background: Some studies postulated that early dialysis start may increase mortality. To examine this issue we measured survival associated with eGFR and age at dialysis initiation in our centre.

Methods: We studied the following variables at dialysis initiation: eGFR, age, gender, diabetes mellitus, serum albumin, hemoglobin, date of dialysis initiation, history of ischemic heart disease and stroke.

Results: Over the last 15 years 428 patients initiated dialysis therapy in our reference area. Mean age at dialysis start 63±13 years and 65% male. The three years survival rate was increasing within the different periods 63% 1995-99, 69% 2000-2004, 77% 2005-2009(p=0.003). Causes of death: heart disease(25%), infections(25%), neoplasms(11%), and stroke(9%). Mean eGFR dialysis start 8.16 mL/min. In the univariate analisis, increased eGFR, age, dialysis initiation 1995-99/2000-2004, diabetes and history of ischemic heart disease were associated with increased mortality in end-stage renal disease patients(ESRD) ($p<0.05$). Patients that started dialysis program with eGFR >8.16 were older than with eGFR<8.16 (66 vs 61y, $p<0.001$). In the multivariate Cox model(without age), eGFR, dialysis initiation period, serum albumin and history of ischemic heart disease were associated with mortality. The association between mortality and eGFR was lost when the model was adjusted by age.

Model without AGE included			Adjusted by age		
Variables included in the model	Relative risk	p	*Variables included in the model*	Relative risk	p
eGFR (ml/min/1.73)	1.05	0.004	eGFR (ml/min/1.73)	1.12	0.364
Period 1995-1999 (2005-2009=1)	2.16	<0.001	Period 1995-1999 (2005-2009=1)	2.39	<0.001
Period 2000-2004 (2005-2009=1)	1.63	0.029	Period 2000-2004 (2005-2009=1)	1.67	0.024
Albumin (g/l)	0.76	0.022	Albumin (g/l)	0.65	0.001
Ischemic heart disease	1.92	<0.001	Ischemic heart disease	1.58	0.005
			Age (years)	1.07	<0.001

Conclusions: History of ischemic heart disease, serum albumin and dialysis start before 2005 were risk factors for mortality in ESRD. Older age is usually associated with early dialysis initiation, so age adjustment is needed to perform studies aimed to calculate the effect of eGFR at dialysis initiation on survival.

SA-PO2631

Alteration of Autonomic Control during Hemodialysis in Peripheral Vascular Disease Patients

Jasmine Ion Titapiccolo,[1] Manuela Ferrario,[1] Ulrich Moissl,[2] Francesco Garzotto,[3] Maria Gabriella Signorini,[1] Dinna N. Cruz,[3] Flavio Basso,[3] Federico Nalesso,[3] Monica Zanella,[3] Ciro Tetta,[2] Sergio Cerutti,[1] Claudio Ronco.[3] *[1]Politecnico di Milano, Milano, Italy; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]San Bortolo Hospital, Vicenza, Italy.*

Background: An association between the pulse pressure (PP) decrease induced by HD treatment and improved outcomes was recently described. Chronic HD patients with peripheral vascular disease (PVD) may be unable to decrease PP because of vascular stiffness and altered autonomic nervous system. Our aim is to compare PP and heart variability parameters in HD patients with and without PVD.

Methods: We studied 7 HD patients (pts) with PVD and 8 without PVD. Continuous blood pressure (BP) was recorded with a Finometer (FMS) in the first and last half-hour of a single HD session (HD_{begin} and HD_{end}). Beat-by-beat series SBP, DBP, PP were extracted from BP signals and subjected to a spectral analysis. Power in the very-low, low and high frequency bands (VLF, LF, HF) was computed, as well as total power, LF/HF ratio, LF% and HF%. VLF relates to local control, e.g. nitric oxide, LF to sympathetic activity, and HF to the mechanical coupling with respiratory activity. DBP is considered related to afterload.

Results: As expected, PVD pts were significantly older (70±9 vs 48±15 yrs). At HD_{end}, PP was higher and HR was lower in PVD pts compared to no-PVD pts. PP increased during HD in PVD pts (ΔPP: +16.2±14.5 mmHg), while this remained stable or decreased in no-PVD. Table 1 reports the significant results.

Table 1
Mean Values of Time and Frequency Domain Indices

	PVD pts		no PVD pts	
	Begin	End	Begin	End
PP (mmHg)	*81± 19*[a]	***97±28***[*]	*73±12*	***70±16***
DBP (mmHg)	51.0± 7.0	**60.9±9.3**[**]	*55.9± 12.1*[a]	***77.9± 11.4***
HR (bpm)	*58±7*	***58±11***[*]	*68±14*	***73±14***
VLF_{DBP} ($mmHg^2$)	***1060±821***[*]	*1249±2031*	***380±215***	*604±571*
$LF\%_{DBP}$	***32± 13***[*,a]	*55±8*	***58± 19***	*54± 15*
$LF\%_{SBP}$	***22±8***[*,a]	*47±16*	***44± 22***	*47± 16*
$LF\%_{RR}$	***19± 12***[**,a]	*42±18*	***65± 14***	*57± 23*

T-test: * P-value<0.05, ** P-value<0.01
Paired t-test: [a] P-value<0.05 (HD_{begin} vs HD_{end})

Conclusions: In this pilot study, chronic HD patients with PVD have an altered autonomic peripheral control system with a prevalence of local control (VLF_{DBP} higher in PVD pts). PVD induces a chronic elevation of afterload and is associated with both a PP increase during HD and a reduced sympathetic activity on the heart (lower $LF\%_{RR}$).

SA-PO2632

Adverse Effect of Chronic Fluid Overload on Left Ventricular Mass Index in Pediatric Patients Maintained with Chronic Peritoneal Dialysis

Kimberly A. Burrows,[1,2] Heather A. Dickerson,[1,2] Poyyapakkam Srivaths,[1,2] Eileen D. Brewer.[1,2] *[1]Pediatric Renal & Cardiology Sections, Baylor College of Medicine, Houston, TX; [2]Texas Children's Hospital, Houston, TX.*

Background: Pediatric (ped) patients (pts) with end-stage renal disease have increased cardiovascular mortality. Risk factors include chronic fluid overload (CFO), hypertension, no residual renal function, anemia and inflammation, which all contribute to abnormal cardiac remodelling, increased left ventricular mass index/left ventricular hypertrophy (LVMI/LVH) and subsequent diastolic dysfunction. Few ped studies have assessed the relationship between CFO and cardiac remodeling and function, and no ped study has assessed CFO prevalence in ped pts maintained on chronic peritoneal dialysis (CPD). This study aimed to determine the prevalence of CFO and its association with LVMI in ped CPD pts.

Methods: This study is a prospective monthly follow-up study of ped pts 6-25 years old with no underlying primary cardiac disease, who have been treated with home cycler CPD for >3 months. Fluid status was assessed by bioimpedence, weight (wt) and BP at each monthly visit. BP indices were calculated to normalize BP for age and height for statistical analysis. Annual ECHOcardiograms done. CFO was defined as >4% target dry wt for at least 3 months per 6 month period or median value >4% for the entire 6 month period.

Results: 11 pts have been enrolled to date with 5/11 followed at least 6 months. 3/11 (27%) had CFO; all 3 had increased LVMI. CFO was associated significantly with increased LVMI and BP indices, but not other ECHOcardiogram parameters.

	Age in years	Dialysis months	LVMI g/m^2.7	FS%	EF%	95%ile SBP index	95%ile DBP index
No CFO	13(4)	15(21)	42.6(16.02)	36.5(6.4)	58(11)	0.84(0.11)	0.78(0.14)
CFO	16(8)	37(40)	68.6(17.17)	33(13.2)	50(13)	1.11(0.25)	1.04(0.16)
p value	NS	NS	0.04	NS	NS	0.02	0.01

Values mean(SD)

Conclusions: CFO may occur frequently in ped CPD pts and when present, appears to be associated with high BP indices and abnormal cardiac remodeling. CFO per se is likely an important risk factor for cardiovascular disease in ped CPD pts.

SA-PO2633

Bedside Cardiovascular Testing as a Prognostic Tool in Dialysis Patients

Darren Green, Paul Dunne, David I. New, Philip A. Kalra. *Vascular Research Group, Manchester Academic Health Sciences Centre, University of Manchester, Salford Royal Hospital, United Kingdom.*

Background: Cardiovascular disease and sudden death are a barrier to better survival in dialysis patients. However, the underlying pathology is poorly understood, and seems to be different to the general population. We used bedside cardiovascular tests to identify possible pathological processes responsible for the high rate of mortality in dialysis patients.

Methods: A longitudinal assessment of outcome in a cohort of stage 5 CKD patients starting dialysis was undertaken. We analyzed baseline 12 lead ECG and trans-thoracic echocardiogram performed as part of transplant, pre-operative, or routine out-patient cardiology assessment. A sub-group had also undergone pulse wave analysis. Multivariate logistic regression was used to identify independent predictors of all-cause mortality, whilst accommodating clinical co-variates.

Results: There were 208 patients (mean age 67 years, BMI 26kg/m2, BP 141/77 mmHg, 42% male, 33% diabetes, 39% ischemic heart disease). The mean time from starting dialysis to investigations was 4.7 months. Mean follow up was 47 months. There were 93 deaths at a rate of 113 per 1000 patient years. The following ECG parameters were independent predictors of death when $\alpha=0.05$: QRS/T-wave axis discordance >60°(Odds ratio=1.6); resting tachycardia (OR=2.0); strain pattern repolarization in left ventricular hypertrophy (LVH) (OR=1.9); abnormal R wave progression (OR=2.3). Atrial fibrillation, QRS duration, and QTc were not. On echocardiogram, M-mode ejection fraction (EF) was predictive of

death (OR=1.6 per 10% fall in EF) but qualitative assessment of function was not. Mass-indexed LVH was predictive (OR=2.1); LVH was concentric in 74% of cases. Diastolic function, annular calcification, and PWA were not predictive.

Conclusions: LVH is important in the high mortality of dialysis patients. The higher risk of strain pattern shows the potential value of using ECG and echocardiography together in risk assessment tools. Strain indicates abnormal repolarization, as does axis discordance. This may suggest that aberrant repolarization is a precursor to fatal arrhythmia in dialysis patients.

SA-PO2634

Do Current Guidelines for Implantable Cardioverter Defibrillator Therapy Apply to Hemodialysis Patients? A Single-Centre Experience Michelle M. O'Shaughnessy, Sinead Kinsella, Emer Joyce, Donal N. Reddan, Matthew D. Griffin, David Lappin. *Departments of Nephrology and Cardiology, Galway University Hospitals, Galway, Ireland.*

Background: One in four dialysis patients will succumb to sudden cardiac death (SCD). Carefully selected non-dialysis patients at high risk for ventricular arrhythmia can derive mortality benefit from implantable cardioverter defibrillator (ICD) therapy. The benefit of this intervention in end-stage kidney disease is less clear and data from randomised controlled trials (RCTs) are lacking. We studied the utility of conventional ICD guidelines as applied to a hemodialysis (HD) population.

Methods: A single-centre prospective observational study. American College of Cardiology/American Heart Association/Heart Rhythm Society (ACC/AHA/HRS) ICD eligibility criteria were applied to prevalent HD patients. Patients were grouped according to ICD eligibility status: potential candidates for secondary preventative ICD (group 1); potential candidates for primary preventative ICD (group 2); non-candidates (group 3). Cause-specific mortality for each group was determined.

Results: Sixty-two patients (66.1% male, 62.1±15.6 years) were followed for 29 months. Outcomes were as follows:

Group 1 (n=2): 1 patient (EF 15%) received an ICD and died of heart failure 20 months later; 1 (EF 55%) declined an ICD and died of a fatal arrhythmia 7 months later.

Group 2 (n=4): No patient received an ICD. 3 had multiple contraindications to ICD therapy (reduced life expectancy, sub-optimal medical management, recurrent infection) and died from non-SCD causes; 1 is alive and continues to receive hemodialysis.

Group 3 (n=56): 3 patients experienced sudden cardiac arrests (2 of which were fatal).

Conclusions: Conventional guidelines which stratify eligibility for primary preventative ICD therapy according to systolic cardiac function should be interpreted with caution in dialysis populations. Dialysis patients have multiple non-traditional risk factors for SCD and may consequently benefit from ICD therapy despite having an EF >35%. Dialysis patients with an EF ≤35% have a high burden of competing risk. RCTs examining the utility of ICD therapy in this unique population are required.

SA-PO2635

CKD-MBD as the Risk Factors of Incident Cardiovascular Disease (CVD) and Fatality after CVD in a Nationwide Registry of Japanese Hemodialysis Patients Tetsuo Shoji,[1,6] Seiji Marubayashi,[2,6] Takashi Shigematsu,[3,6] Kunitoshi Iseki,[4,6] Yoshiharu Tsubakihara.[5,6] *[1]Osaka City University Graduate School of Medicine, Osaka, Japan; [2]Ajina Tsuchiya Hospital, Hatsukaichi, Japan; [3]Wakayama Medical University, Wakayama, Japan; [4]University Hospital of The Ryukyus, Okinawa, Japan; [5]Osaka General Medical Center, Osaka, Japan; [6]Committee of Renal Data Registry, Japanese Society for Dialysis Therapy (JSDT-CRDR), Tokyo, Japan.*

Background: Although chronic kidney disease mineral and bone disorder (CKD-MBD) is a systemic disease affecting cardiovascular mortality, it is unknown whether it affects the risk of incident cardiovascular disease (CVD) or the risk of fatality after CVD. We examined the associations of some components of CKD-MBD and related medications with the risk of incident CVD and the risk of death after CVD in dialysis patients.

Methods: This is an observational cohort study using a standard analysis file provided by JSDT-CRDR (JRDR-09102) including 216612 dialysis patients at the end of 2004. We extracted subjects without previous history of CVD (myocaridal infarction, cerebral infarction, and/or cerebral bleeding) and with key variables including use of vitamin D receptor activator (VDRA) and outcomes at the end of 2005.

Results: A total of 49659 hemodialysis patients (59% men, 28% diabetes) were extracted. At baseline, the median age, serum corrected calcium, phosphate, and intact PTH levels were 63 years, 9.3 mg/dL, 5.4 mg/dL, and 136 pg/mL, respectively. VDRAs and phosphate binders were used in 57% and 85% of the cohort, respectively. Incident CVD events were recorded in 3134 patients, and 373 died after such events. In multivariate logistic regression models, a higher risk of incident CVD was associated with higher intact PTH, non-use of VDRA, and non-use of phosphate binders. A higher risk of death after CVD was associated with higher corrected calcium and non-use of phosphate binders.

Conclusions: Some components of CKD-MBD and related medications were independent predictors of incident CVD, death after CVD, or both in this large cohort of hemodialysis patients.

SA-PO2636

Associations between Serum Progesterone and Mortality in Hemodialysis Patients John Kyriazis,[1] Kostas Stylianou,[2] Ioannis P. Tzanakis,[3] George Lamprinoudis,[1] Eugene Daphnis.[2] *[1]Nephrology, General Hospital of Chios, Chios, Greece; [2]Nephrology, University Hospital of Heraklion, Heraklion, Crete, Greece; [3]Nephrology, General Hospital of Chania, Chania, Crete, Greece.*

Background: Recent epidemiologic data show that men and women with increased progesterone (PRG) levels are at a higher risk of cardiovascular disease (CVD) mortality (Gend Med 2009; 6: 433-443). In this study, we examined the possible associations of PRG levels with cardiovascular risk markers and subsequent mortality in hemodialysis (HD) patients.

Methods: One hundred and seventy-three HD patients (65±12 years, 111 men) after completion of baseline assessment, including sex hormones, were followed up for CVD and all-cause mortality.

Results: The median PRG concentrations in men 0.53 (0.25-1.20) ng/ml and women 0.43 (0.12-2.12) ng/ml did not differ from reported reference values for each sex. In the whole group, PRG levels were inversely related to HD vintage and positively related to prevalence of diabetes mellitus, diastolic blood pressure and serum phosphorus. Age and estradiol were inversely and positively associated with PRG in men and women, respectively. During a median follow up period of 49 months, 79 deaths occurred, 47 (59 %) of which were caused by CVD. Patients with PRG levels in the sex-specific highest tertile had increased CVD and all-cause mortality (crude hazard ratio: 2.94 [95% CI, 1.65 to 5.23] and 2.52 [95% CI, 1.62 to 3.93], respectively. Likewise, the risk for CVD and all-cause mortality increased by 51 % (1.51 [1.16-1.96]) and 45% (1.45 [1.18-1.78]), respectively, for each I SD increment in log PRG. The high serum PRG - mortality association remained essentially unchanged (in both analyses) after adjustment for age, sex, mass body index, serum albumin and c-reactive protein, clinical history of CVD at baseline, presence of diabetes and HD vintage. Addition of estradiol also failed to influence the results. Similar results were observed when looking at each sex separately.

Conclusions: Our results indicate that in HD patients, PRG levels positively correlate with all-cause and CVD mortality, as well as with cardiovascular risk markers. The clinical relevance for these findings needs further elucidation.

SA-PO2637

Involuntary Discharge from Dialysis Units (IVD): Who, Why, Where Abey K. Thomas,[1] Senthil P. Ramaiyah,[1] Brian T. Chu,[2] Carol Lyden,[3] George N. Coritsidis,[2] Chaim Charytan.[1] *[1]New York Hospital Medical Center of Queens, Flushing, NY; [2]Elmhurst Hospital Center, Elmhurst, NY; [3]IPRO ESRD Network of New York, Lake Success, NY.*

Background: Patients with behavioral, psychological or financial issues place an extra burden on the stretched resources of dialysis providers and may be at risk for IVD. IVD is a significant problem for patients, providers and payers and affects the quality of care. There is concern that the bundling policy may further increase IVD. There is a paucity of data about causes of IVD and their impact on ESRD care.

Methods: Data on IVD reported to ESRD Network 2(EN2) between July 2006 and March 2011 was analyzed for patient and facility characteristics and compared to the general EN2 population. Statistical analysis was performed by calculating IVD incidence rate in each group using average denominators. Comparison of proportions were carried out using the Fisher's exact test. p-values were calculated across all groups in each category.

Results:

Conclusions: Our study in EN2 reveals an increased incidence of IVD among younger, male, AA patients treated at larger, for-profit and LDO facilities predominantly for behavioral and financial reasons. These observations may have important consequences for developing interventions to deal with IVD, particularly given the growth of minority ESRD population and LDO facilities. These observations need to be compared to the national experience and trends monitored in an ongoing manner.

SA-PO2638

MORRIS: Model for Optimising Renal Replacement Investment and Services; an Interactive Tool Predicting Future Patient Numbers and Associated Costs Mark Brady,[1] Daisy Wild,[2] Beverley Matthews,[3] Donal O'Donoghue.[2] *[1]Cumberland Infirmary, NHS, Carlisle, United Kingdom; [2]Department of Health, London, United Kingdom; [3]NHS Kidney Care, London, United Kingdom.*

Background: Predicting the future needs for a renal replacement therapy (RRT) programme, on a national or local level is essential to maximise efficiency and quality of care. This freely available interactive tool combines UK national census data with UK renal registry data to forecast annual RRT at both national and local levels until 2018, with the ability to use local data or alter proportions of patients on different modalities to examine the effect of investment in such switches.

Methods: MORRIS model uses 2008 UK Renal Registry data, Office of National Statistics (2001) census data incorporating age and ethnicity with expert advice from UK nephrologists. It is a dynamic simulation model for patients survival and movement between modalities over time. Interactive element allows projections based on local data, plans or needs with treatment costs based on tariff or reference costs.

Results: Figure 1 shows one possible output from the model, making national level projections for various scenarios, predicting the cost of RRT provision in the UK will exceed 1 billion pounds in 2018 and demonstrating the cost benefits of altering the proportion of patients on various modalities. Improving transplantation rates and home therapies uptake together could save 24-28 million pounds per annum on RRT costs alone in the medium and long-term (scenario 1 vs 3). Numbers of in-centre dialysis patients could be 9000 lower by 2018 in this projection.

Scenario	Take-on rate	Tx rates	Home Dx rates	Number of patients in 2018					Costs in year (£ millions)	
				CHD	HHD	PD	Tx	Total	2013	2018
1	High	Fixed	Fixed	24700	500	5700	30200	61100	868	1,040
2	High	Growth	Fixed	21860	466	4310	35329	61965	849	1,045
3	High	Growth	Growth	15981	2664	7991	35329	61965	821	1,012
4	Mod	Fixed	Fixed	22800	500	5300	29900	58500	849	983
5	Mod	Growth	Fixed	19300	400	4300	35300	59300	866	987
6	Mod	Growth	Growth	14400	2400	7200	35300	59300	840	959
7	Low	Fixed	Fixed	22073	514	4478	29756	56820	812	951
8	Low	Growth	Fixed	18408	374	3576	35317	57675	829	956
9	Low	Growth	Growth	13400	2200	6700	35300	57600	829	927

Figure 1. MORRIS model national UK level predictions for patient numbers on various modalities and associated costs for year end 2013 and 2018, with variations in take-on, transplant or home dialysis rates indicated (CHD centre HD = satellite or hospital, HHD home haemodialysis). The scenarios described 1-9 are based on: Fixed referring to 2008 levels, transplant growth = 50% increase in 5 years, home therapies growth = 10% HHD & 30% PD. High take-on rate represents 2.8% average growth reported by UK RR from 2001-2008. Moderate take-on rate represents 1.6% growth, including demographics + risk factors. Low take-on rate of 0.8% growth represents demographics alone (age and ethnicity).

Conclusions: The MORRIS model is a powerful interactive tool for predicting future RRT requirements in the UK, demonstrating the benefits of investment in transplantation and home dialysis for example, with the ability to use the model at both national and renal unit level.

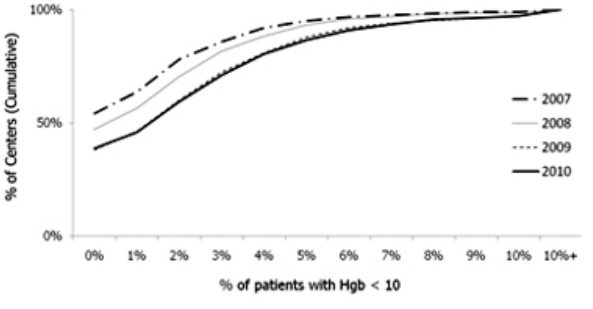
SA-PO2639

Impact of Baseline Year on PPS Payments under the Quality Improvement Program Andrew Barba, Randy Smith, Joe Weldon, LeAnne Zumwalt, Mahesh Krishnan. *DaVita Inc, Denver, CO.*

Background: In 2011, the CMS issued a final rule creating a Quality Incentive Program (QIP). Beginning in 2012, QIP penalizes dialysis facilities for underperformance by reducing payments up to 2%. QIP uses 3 weighted quality measures to generate a Total Performance Score (TPS): % of patients (pts) with hemoglobin (Hb) >12 g/dL, Hb <10 g/dL and urea reduction ratio (URR) ≥65%. The TPS compares a center's 2010 quality measures to the least stringent benchmark of either (i) the center's performance in 2007 (base year) or (ii) the 2008 national average. To assess the validity of the TPS, we determined the relative 2012 revenue impact of the QIP using the 2007 base year, and compared results to those using either 2008 or 2009 as the base year.

Methods: To model payments under QIP effective January 1, 2011, we estimated relative QIP impact per treatment for 1,682 centers using fiscal year (FY)10 claims from the DaVita database and current TPS calculations for Hb and URR. To reflect the CMS projected FY12 market basket update, we increased resulting estimates by 1.4%. We assessed QIP penalties for each facility according to their respective TPS. Facilities with insufficient clinical data were assigned an average TPS of 24 out of 30 possible points.

Results: The proportion of facilities that underperform using the <10 g/dL QIP measure is sizeable and differs by year (Figure). Between-year differences were due mainly to differences in Hb performance.



Conclusions: Lack of year-to-year consistency, particularly in anemia outcomes, throws into question the validity of the use of prospective payment quality measures that are calculated on temporally distant base years. Our results illustrate the need to modify QIP to use a baseline period as close as possible to the measurement period.

The End-Stage Renal Disease (ESRD) Prospective Payment System (PPS) and Access to Care: Incremental Distance Traveled by Displaced Patients

John J. Kochevar,[1] Samuel Brotherton,[1] Stephan C. Dunning,[2] Larry C. Emerson,[3] David T. Gilbertson,[2] David J. Harrison,[4] Ann C. McClellan,[5] William M. McClellan,[5] John Mark Stephens,[1] Shaowei Wan,[4] Matthew Gitlin.[4] *[1]KRA; [2]CDRG; [3]Dialysis Center of Lincoln; [4]Amgen; [5]Emory.*

Background: The ESRD PPS will reduce payments to some dialysis facilities by more than the 2% as predicted by CMS and could lead to facility closures. Our objective is to estimate incremental distances patients may need to travel in the event of reduced access to dialysis care.

Methods: We estimated facility risk of closure/consolidation due to financial stress based on payment reduction under the PPS using the CMS flat file of PPS payment changes and a 10-point scale of ability to respond incorporating financial (e.g. payer mix), patient (e.g. case mix) and facility factors (e.g. ownership type). We categorized 5114 facilities in the 48 contiguous US as high, medium or low risk based on their combined scores. We estimated effects assuming a random sample of 10% of the high-risk group closes/consolidate from 2011-2013 (N=156). We assumed patients would migrate to the next-nearest facility and calculated incremental road miles and travel times.

Results: The incremental distance and time due to closure/consolidation of a small random sample of high-risk facilities could cumulate to 20,828,330 miles and 387,130 hours over a three-year period. By 2013, mean incremental travel distance would be 1084 miles per-patient-per-year (PPPY), nearly double for those in non-urban areas.

Incremental Distances Traveled if 10% of At-Risk Facilities Close/Consolidate 2011-2013

	2011	2012	2013	Total
Facility Closures % (N)	3% (48)	3% (48)	4% (60)	10% (156)
Displaced Patients				
Total	3453	6801	10,251	11,994
Rural/Suburban	1384	3081	4,376	5,135
Urban	2069	3720	5875	6859
Mean Incremental Miles Traveled Per Treatment (Round-trip)				
Total	10.7	12.0	11.8	11.7
Rural/Suburban	17.0	19.7	20.9	20.0
Urban	6.4	5.4	4.5	5.1
Mean Incremental Miles PPPY				
Total	754	1047	1084	961
Rural/Suburban	1219	1741	2008	1656
Urban	443	471	395	436

Conclusions: Prior research by DOPPS showed that reduced access as a result of increased driving distances may be associated with increased mortality and morbidity. Increased travel could have significant implications for clinicians and policy makers especially in rural/suburban areas.

SA-PO2641

Urban Emergency Department (ED) Visits and Costs for Patients with End-Stage Renal Disease (ESRD), 2005-2009

Sara Mathew,[1] Aaron Truchil,[2] Ernest M. Post,[1] Barry Milcarek,[1] Krystal Hunter,[1] Jeffrey Brenner,[1,2] Lawrence S. Weisberg.[1] *[1]Department of Nephrology, Cooper University Hospital, Camden, NJ; [2]Camconnect, Camden, NJ.*

Background: Hospitalization of ESRD patients cost Medicare $35 billion in 2004-2008, not counting ED costs. Very little is known about the cost and utilization patterns of ED services by patients with ESRD.

Methods: We explored ED use and costs in a poor city, Camden, NJ, using a database of all ED contacts citywide, 2005-2009. We included only ED visits that did not result in hospitalization. We defined ESRD by ICD-9 code 585.6. We excluded patients less than 18 years old.

Results: Patients with ESRD accounted for 0.6% of the total patients in the study. The results are shown in Table 1 below.

Table 1

	Non ESRD	ESRD	P value
Unique patients	78219	488	
Total visits	289764	2876	
visits/patient	2(1-4)	4 (2-7)	<.001
charges/visit	$3539 ($1581-$7792)	$8980 ($3442- $17573)	<.001
receipts/visit	$372 ($0-$1130)	$1082 ($458-$2348)	<.001

*Mann-Whitney U test; Median [inter-quartile range]

We were also able to identify a subpopulation among the ESRD group as "super utilizers". We arbitrarily defined "super-utilizers" as patients with at least 10 ED visits in the 4 years. There were 71 such ESRD patients (14.5% of ESRD patients). They accounted for 1,475 (51%) of visits. Their median charge per visit was $36,899, 5.9 times that of the other ESRD patients. These super utilizers accounted for about 49.3% of the total charges and 46.5% of the total receipts. Acute dyspnea was the modal primary diagnosis for super-utilizers; the remaining patients did not have any one modal primary diagnosis in significant counts. Primary payers for "super-utilizers" were Medicare 47%, Medicaid 36%. For other ESRD patients, Medicare was the primary payer for 58%, Medicaid for 26%.

Conclusions: Thus, in this poor city, ESRD patients are disproportionate users of ED services, and their visits are costlier. A small minority account for the majority of visits and costs. Future interventions will target "super-utilizers" to diminish ED use by meeting their needs more cost effectively.

SA-PO2642

Healthcare Utilization and Costs in Patients with End-Stage Renal Disease Beginning Renal Replacement Therapy with Peritoneal Dialysis Versus Hemodialysis

Gary W. Inglese,[3] Charu Taneja,[1] Ariel Berger,[1] Lois Lamerato,[2] James A. Sloand,[3] Greg Abbott,[3] Greg G. Wolff,[2] Gerry Oster.[1] *[1]Policy Analysis Inc. (PAI), Brookline, MA; [2]Henry Ford Health System, Detroit, MI; [3]Baxter Healthcare Corporation, McGaw Park, IL.*

Background: To compare healthcare utilization and costs over 1 year between patients beginning renal replacement therapy with peritoneal dialysis (PD) versus hemodialysis (HD).

Methods: This retrospective study was conducted at a large US urban integrated health plan that maintains comprehensive records on the use of healthcare services by all of its members. Study subjects consisted of all persons aged 18-63 years who initiated PD or HD for end-stage renal disease (ESRD) between January 1, 2005 and December 31, 2008 ("study period"). Each patient's earliest noted date of receipt of dialysis was designated his/her "index date", and all patients were followed for 1 year thereafter. Each PD patient was matched to 2 HD patients using propensity scoring to control for differences in baseline characteristics, including age, gender, race, and pretreatment healthcare utilization. Healthcare utilization and costs were then compared over 1 year between matched PD and HD patients, using methods appropriate for matched samples.

Results: We identified a total of 162 patients who began dialysis during the study period (PD, n=26; HD, n=136). After matching, the final study sample included 26 PD patients and 52 HD patients. PD and HD patients were well-matched. Mean age of study subjects was 55 years, 58% were men, and 74% were African American. During the 1 year follow-up, HD patients were more likely to be hospitalized (67.3% vs 42.3% for PD; p=0.03). HD patients also averaged more physician office visits (17.2 vs 12.4, respectively; p=0.01) and emergency room visits (2.1 vs 1.1; p=0.04) over this period. Mean total healthcare costs over 12 months were significantly higher among HD than PD patients ($188,340 vs $127,981; p=0.01).

Conclusions: In patients initiating renal replacement therapy for ESRD, healthcare utilization and costs over 1 year may be lower in those receiving PD.

SA-PO2643

Key Performance Indicators (KPIs) for Peritoneal Dialysis in Thailand: A Nationwide Survey

Talerngsak Kanjanabuch,[1,2,3] Somchai Eiam-Ong,[1] Kriang Tungsanga,[1] Dusit Lumlertkul.[3] *[1]Medicine, Chulalongkorn University, Bangkok, Thailand; [2]Kidney&Metabolic Disorders Research Center, Chulalongkorn University, Bangkok, Thailand; [3]Nephrology Society of Thailand, Thailand.*

Background: Implementation of the "Peritoneal Dialysis-first (PD first)" policy, mandating PD as a first modality of RRT for ESRD patients under universal health coverage since year 2008, leads to rapid growing of PD cases and centers in Thailand. To ensure quality of PD service paralleling the burst of PD cases, nationwide survey of key performance indicators (KPIs) was performed.

Methods: All PD centers in Thailand were invited to participate in the present study. PD nurse case managers in each center were asked to review medical records of all patients undergoing PD during October 1, 2009 to September 30, 2010 and submitted data to the main investigators

Results: About three-fourths of all PD-centers in Thailand (88 out of 121) participated in the present study. One hundred five nephrologists and 154 PD nurse specialists served 7,339 PD (279 APD and 7,060 CAPD) patients in these centers. Overall annual dropout rate was 24.8% and mortality rate was 17.1%. Nephrologist/patient ratio was 1:58, and certified PD nurse/patient (N/P) ratio was 1:85. Of these, 33.7% had N/P ratio > 1:60, while 66.5% and 41.9% had no dietitian and no nephrologist, respectively in their center. Overall exit-site infection rate was 1 episode/ 40.7 pt-mo (0.30 episodes/pt-yr) while overall peritonitis rate was 1 episode/ 25.8 pt-mo (0.47 episode/pt-yr). Of interest, larger (>100 cases), community-based, PD nurse-overloading, non-nephrologist coverage centers had higher peritonitis (0.56 *vs.* 0.39; 0.67 *vs.* 0.46; 0.53 *vs.* 0.37; 0.46 *vs.* 0.35 episodes/pt-yr, respectively). Culture negative was 32.1%. Almost patients (90.4%) received pre-dialysis education and the home visit rate was 37.82%.

Conclusions: Despite of the rapid growth of PD cases under the limited resource, the PD-related infection rates in Thailand are only small degree behind the goal of Asia-Pacific Key Performance Indicators (KPIs) Task Force.

SA-PO2644

Association between Mode of Renal Replacement Therapy and Employment Status

Patrik Finne,[1] Ilkka Helanterä,[2] Mikko Haapio,[2] Petri K. Koskinen,[2] Carola Gronhagen-Riska.[2] *[1]Finnish Registry for Kidney Diseases, Helsinki, Finland; [2]Department of Nephrology, Helsinki University Central Hospital, Helsinki, Finland.*

Background: It is poorly known how mode of renal replacement therapy affects probability of being employed. We analyzed the association of treatment modality with employment status among patients on dialysis and after transplantation in a cross-sectional study.

Methods: The employment status of all prevalent 15–64-year-old dialysis and kidney transplantation patients in Finland at end of 2007 (N=2637) was analyzed by combining the data from Finnish Registry for Kidney Diseases with the official individual-level

employment statistics of the Finnish government. Association between treatment modality and employment status was studied using multivariate logistic regression with adjustment for age, gender, cause of ESRD, duration of ESRD, and comorbidities.

Results: Altogether 19% of hemodialysis patients, 31% of peritoneal dialysis patients, and 40% of patients with a functioning transplant were employed. In adjusted analysis, patients on home hemodialysis (odds ratio 2.41), automated peritoneal dialysis (OR 3.48) or those with a kidney transplant (OR 3.14) were more likely employed than in-center hemodialysis patients. Patients with type 1 or type 2 diabetes or amylodosis as the cause of end-stage renal disease had the lowest probability of employment (OR 0.26–0.32 as compared to glomerulonephritis). Patients aged 25–54 years were more frequently employed than those younger than 25 or older than 54. Gender did not predict employment. Among transplant recipients, a longer time since transplantation associated with higher employment in addition to the aforementioned factors.

Conclusions: Home dialysis modalities predicted higher employment of ESRD patients, also after transplantation. Diabetes patients were less likely to be employed.

SA-PO2645

Costs of Care and Major Clinical Events among Chronic Dialysis Patients with and without Treatment for sHPT: A Descriptive Study of Claims Data

Andrew Lee,[1] Xue Song,[2] Vasily Belozeroff,[1] David R. Diakun,[2] William G. Goodman.[1] *[1]Amgen Inc; [2]Thomson Reuters.*

Background: Secondary hyperparathyroidism (sHPT) is highly prevalent in chronic dialysis (CD) patients, yet little data describing costs of care for sHPT exists.

Methods: We examined direct medical costs in US CD patients covered by commercial or Medicare insurance with and without treatment for sHPT in a retrospective cohort study of 6-years-CD patient data from MarketScan. All patients were ≥ 18 years old with ≥ 2 CD claims ≥ 30 days apart. sHPT patients were identified as ≥ 3 claims within 2 weeks for therapeutic doses of vitamin D analog(s) and/or ≥ 1 claim for cinacalcet. Patients were followed up from first claim (sHPT patients) or from comparable dialysis vintage (non sHPT patients) to inpatient (IP) death, end of continuous insurance enrollment, parathyroidectomy (PTX) or end of study period. We summarized mean (SD) per patient (PP) annual total (TL), IP, outpatient dialysis (OPD), outpatient other (OPO), outpatient pharmacy (MED) cost categories, and the mean (SD) PP cost per hospitalization.

Results: A total of 26,371 non sHPT and 15,556 sHPT patients met study criteria. Based on 6 months of data prior to first claim, sHPT patients were younger (mean age 61.4 (SD 14.3) vs 66.2 (SD 14.1)) and had higher percentage of black patients (20.3 vs 16.8) than non sHPT patients. PP sHPT TL costs were 20.8% higher than non sHPT PP TL costs. Higher OPD and MED costs contributes to the higher TL costs for sHPT patients. For all CD patents, cost per fracture ranged from $16,990 for non-hip non-vertebral to $23,339 for hip fractures and cost per cardiovascular (CV) event ranged from $13,481 for heart failure to $25,484 for peripheral artery disease.

	Mean (SD) Annualized PP Costs					Mean (SD) PP Cost per Hospitalization		
N=41,927	IP	OPD	OPO	MED	TL	CV	Fracture	PTX
Non sHPT (n=26,371)	$25,117 (458)	$60,040 (531)	$20,455 (204)	$4,659 (46)	$110,271 (820)	$21,914 (40,092)	$18,991 (24,929)	N/A
sHPT (n=15,556)	$24,816 (523)	$83,142 (770)	$17,815 (228)	$7,431 (50)	$133,204 (1,053)	$23,906 (41,027)	$22,332 (27,837)	$18,010 (14,742)

Conclusions: The observed higher TL costs for sHPT patients may be an important consideration for reimbursement policy decisions.

Funding: Pharmaceutical Company Support

SA-PO2646

Cost-Effectiveness of Treating Chronic Anemia with Epoetin Alfa among Hemodialysis (HD) Patients in the United States (US)

Christopher S. Hollenbeak,[1] Sumit Mohan,[2] Greg De Lissovoy,[3] Peter L. Quon,[4] Matthew Gitlin,[5] Jill Javier,[4] John J. Isitt,[5] William M. McClellan.[6] *[1]Penn State College of Medicine; [2]Columbia University; [3]Amgen Consultant; [4]United BioSource Corp.; [5]Amgen, Inc.; [6]Emory University School of Medicine.*

Background: Economic constraints have introduced uncertainty regarding the value of partial correction of anemia using Epoetin alfa. We assessed the value of targeting hemoglobin (Hb) of 10 or 11g/dL vs. 9g/dL among Medicare patients on HD.

Methods: A Markov model was developed with 1-year cycles over a 5-year period. Model inputs included clinical (e.g. morbidity, mortality) and economic (e.g. drugs, outpatient, inpatient) factors adjusted to 2010 $USD and discounted 3.5% annually. Model assumptions were determined by previously published data and included no difference in mortality based on TREAT ESRD patients, a differential in hospitalization and health utility based on past clinical trials and observational data, and a dose-response curve constructed from 7 randomized trials. Outcomes included incremental cost per: quality-adjusted life year (QALY) gained and hospitalizations avoided. Sensitivity analyses (SA) were conducted to test assumptions of differential mortality and hospitalization rates by Hb level to assess uncertainty of the assumptions and outcomes.

Results: Compared to Hb targets of 10 or 11g/dL vs. 9g/dL the model results were cost saving in Hb targets of 10 or 11g/dL compared to higher costs and lower effectiveness in the Hb target of 9 g/dL. Over a 5-year period hospitalizations avoided were 0.89 resulting in cost offsets of $23,593 for 11 vs. 9g/dL and 0.51 resulting in cost offsets of $15,340 for 10 vs. 9g/dL. In SA, the cost-effectiveness for 11 vs. 9g/dL ($27,294 per QALY gained) and 10 vs. 9g/dL ($22,764 per QALY gained) persisted with equal rates of hospitalization.

Conclusions: Treating HD patients with Epoetin alfa for partial correction of anemia to Hb targets of 11 or 10 vs. 9g/dL may be cost-effective when taking into account new research. Further SA's are needed to confirm the robustness of the results when varying assumptions pertaining to mortality, hospitalization, and health-related quality of life.

SA-PO2647

Physician Reaction to Spontaneous Rises in Transferrin Saturation and Serum Ferritin Levels in End Stage Renal Disease Patients

T. Christopher Bond,[1] Jaime Rubin,[1] Steven Wang,[1] Robert M. Niecestro,[2] Enrique Poradosu,[2] Tracy Jack Mayne.[1] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Keryx Biopharmaceuticals, New York, NY.*

Background: Ferric citrate is an investigational phosphate binder (PB) to treat hyperphosphatemia in dialysis patients (pts). A Phase II randomized placebo-controlled trial demonstrated a significant increase in both transferrin saturation (TSAT) and ferritin (FN) levels in treated pts. We sought to determine how physicians titrate epoetin alfa (ESA) and intravenous iron (Fe) in response to the changes observed in this trial.

Methods: We analyzed data from DaVita pts experiencing rises in TSAT (>10%) and FN (15-25%) (6/1/08-12/31/10). Pts were: ≥18 years old; prescribed a PB; on dialysis ≥120 d; without significant change in Fe or ESA dose (-30% to 10%) from the prior mo; and without change in PB type. Per session ESA and Fe use was compared for 60 d before and after index date and stratified by baseline use.

Baseline Fe			Baseline ESA (U)			All
		1-<2000	2000-<4500	4500-<9000	≥9000	
0 to <16.0 mg	ESA	+772.1 (1,484.0)	+660.5 (2,456.6)	+51.8 (2,662.9)	-818.2 (4,811.6)	+360.9 (2,751.4)
	Fe	-0.92 (5.75)	-0.98 (4.66)	-0.07 (6.68)	-0.23 (8.81)	-0.67 (6.13)
16 to <32.0 mg	ESA	+542.0 (1,485.4)	-51.0 (1,884.7)	-1,081.8 (2,675.0)	-1,328.6 (4,079.2)	-387.7 (2,635.9)
	Fe	-4.23 (8.53)	-3.76 (9.50)	-3.38 (8.78)	-4.54 (11.01)	-3.92 (9.37)
≥ 32.0 mg	ESA	+226.7 (1,197.6)	-274.0 (1,659.6)	-1,332.8 (3,174.6)	-3,080.7 (5,583.8)	-1,715.7 (4,288.3)
	Fe	-15.19 (16.05)	-13.16 (17.93)	-11.32 (17.36)	-17.33 (22.05)	-14.66 (19.65)
All	ESA	+616.1 (1,463.9)	+181.6 (2,121.5)	-812.8 (2,883.7)	-2,146.7 (5,124.8)	-500.2 (3,316.5)
	Fe	-3.87 (9.57)	-4.60 (11.43)	-4.75 (12.42)	-10.30 (18.85)	-5.79 (13.62)

Results: 2,037 concurrent rises in FN and TSAT were found. Over the 2 mo after index date, decreases in ESA (-500 U) and Fe (-5.79 mg) use were observed. ESA reductions were greater for pts at higher baseline ESA and Fe doses (-3080 U), indicating an interaction effect. No such effect was seen for Fe.

Conclusions: Physicians may respond to rises in TSAT and FN by reducing ESA and Fe doses, particularly in pts with high baseline use. If approved, ferric citrate may reduce medication usage and have incremental economic value within the 2014 Medicare bundle.

Erythropoiesis-Stimulating Agents (ESAs) and Mortality in Hemodialysis Patients. Relationship among ESAs Dose, Hemoglobin, and C-reactive Protein Concentrations. A 36 Months Observational Study

Ezio Movilli, Corrado Camerini, Paola Gaggia, Roberto Zubani, Giovanni Cancarini. *Division of Nephrology, Spedali Civili and Section of Nephrology, University of Brescia, Brescia, Italy.*

Background: ESAs responsiveness and inflammationis are associated, leading to increase ESAs dosage (ESAdose) in order to reach hemoglobin (Hb) targets. While the relationship between inflammation, evaluated by C-reactive protein (CRP), and mortality is known, the relationship between ESAdose and mortality is not. Aim of the study: prospective evaluation, over a period of 36 months, of the role of CRP, ESAdose, and Hb on mortality in chronic hemodialysis (HD) pts.

Methods: 100/116 prevalent HD pts (mean age 68±13 years, 58 men, dialysis vintage 12-408 months) on ESA therapy, were enrolled and followed-up for 36 months. Demographic, co-morbidity, laboratory data, and causes of death were recorded. ESAdose (U/Kg/W), Hb (g/dL), serum ferritin (F) (ng/mL), %TSAT, CRP (mg/L) were measured at the start, and at the end of the study, or at death (on average 15±9 days before the event). Data are expressed as mean±SD, Linear and multiple regression analysis were employed. Survival was evaluated according to Kaplan-Meier analysis and Cox regression analysis. $p < 0.05$.was considered significant.

Results: CRP was 8.3±6.1 mg/L, Hb 11.2±0.6 g/dL, %TSAT 32±16%, F, 578±404 ng/mL, ESAdose 131±36 U/Kg/sett. 39 pts died during follow-up. The causes were: 51% cardiovascular, 30% infective, 19% neoplastic. Mortality was directly correlated either with CRP ($p<0.0001$), or with ESAdose ($p< 0.0001$). Kaplan-Meier survival analysis by dividing pts according to CRP quartiles (< 3.3; 3.3-6.5; 6.6-12.3; >12.3 mg/L) and ESAdose quartiles (< 104; 104-130; 131-157; > 157 U/Kg/W) showed that the higher values of CRP and ESAdose were associated with the higher mortality risk ($p <0.001$ for both variables). Cox regression analysis showed that CRP and ESAdose were independent significant factors associated with increased risk of desth(CRP: $p<0.0001$; ESA dose: $p< 0.001$).

Conclusions: High CRP levels and high ESAdoses, but not Hb concentrations, are the parameters that independently are associated with an increased mortality risk in HD pts.

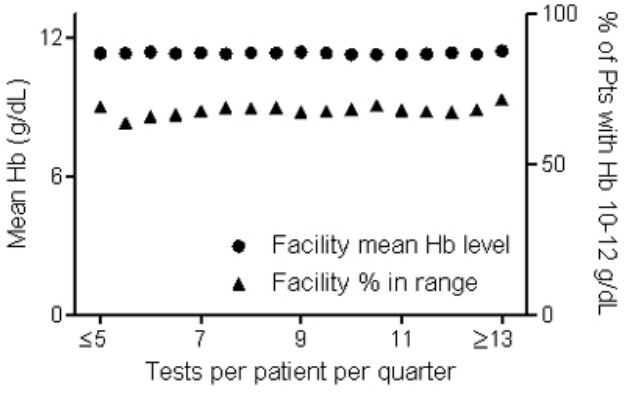
SA-PO2649

Association of Frequency of Hb Testing on Anemia Outcomes Irina Goykhman, Carey Colson, Steven M. Wilson, David B. Van Wyck. *DaVita Inc, Denver, CO.*

Background: A paucity of information about the optimal hemoglobin (Hb) testing frequency required to achieve target anemia outcomes likely contributes to wide practice variation in the frequency of orders for lab tests within the health care community. However, the medical resource consumption that arises from frequent lab testing has gained increasing consideration with the recently implemented US end-stage renal disease (ESRD) prospective payment system. We assessed facility-level Hb testing patterns and their impact on anemia outcomes.

Methods: We reviewed 2010 data from a large US dialysis provider's database to categorize dialysis facility Hb testing patterns as well as the percentage of patients with Hb levels in range (between 10 and 12 mg/dL). We categorized facilities by the mean number of reported Hb lab tests per patient dialyzing in that facility per quarter. We used patient-weighted Generalized Linear Models (GLM) to predict the percent of patients in range and mean Hb levels from number of Hb tests.

Results: The frequency of Hb testing based on physician ordering preference varied from 2.5 to 19.5 tests/quarter. Most (96%) facilities tested Hb 6-12 times per quarter, accounting for 97% of patients. Despite this, mean Hb levels did not vary significantly with greater Hb testing frequency (p=0.28; Figure).



Conclusions: When examined over a range from weekly to monthly, Hb test frequency shows no discernable relationship to Hb outcomes. This finding bears directly on the design and evaluation of anemia management protocols.

SA-PO2650

Association of Erythropoietin Dosing and Mortality in the Maintenance Pediatric Dialysis Population Rachel M. Lestz,[1] Barbara A. Fivush,[2] Meredith A. Atkinson.[2] *[1]Pediatric Nephrology, Children's Hospital of Los Angeles, Los Angeles, CA; [2]Pediatric Nephrology, Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Treatment with exogenous erythropoietin (EPO) has transformed the management of anemia in patients undergoing maintenance dialysis therapy. In recent years, the effort to normalize hemoglobin levels with increasing does of EPO has revealed an association of higher EPO doses with adverse events and increased mortality in the adult CKD and dialysis populations. However, this relationship has not yet been documented in pediatric patients.

Methods: Retrospective study of prevalent pediatric (age≤ 18 years) dialysis patients receiving maintenance EPO, using the Centers for Medicare & Medicaid ESRD Clinical Performance Measures Project 2005 linked with the USRDS mortality records for the following year. Four EPO categories were created based upon the distribution of EPO dosing (unit/kg/week): 0-25th %: 0-<92 u/kg/wk), 25-50th:92-<192 u/kg/wk(reference group), 50-75th%:192-<356 u/kg/wk , >75th %: ≥ 356 u/kg/wk. Cox-proportional hazards regression was performed to determine if EPO dose category was associated with an increased risk death over 12 months. The adjusted model controlled for race, age, gender, diagnosis, hemoglobin ≥11, albumin ≥3.5 (BCG)/3.2 (BCP), dialysis modality and access type, Kt/V and time on dialysis.

Results: Of the 1014 children included in the analysis, 35 died during the 12 month observation period. In the adjusted analysis, pts in the highest EPO category had a 4.2 times higher risk of death compared to those receiving 92-<192 units/kg/wk (25th-50th%) EPO dosing.

Adjusted Risk of Mortality

EPO Category	Hazard Ratio	95% CI	p-value
0-25th%: 25th-50th%	1.26	0.25-6.36	0.78
50-75th : 25th-50th%	3.07	0.85-11.12	0.09
>75th : 25th-50th%	4.21	1.12-15.10	0.03

Conclusions: Although mortality in general is a relatively rare outcome among children compared to adults on dialysis, we have shown that pediatric dialysis pts. who received the highest EPO doses demonstrated an increased risk of death. Further study, including prospective analyses, are required to determine whether the higher EPO doses have an independent causal affect in dialyzed children.

SA-PO2651

Evaluation of the Predictive Value of Commonly Used Anemia Management Indicators in Incident Hemodialysis Patients Jochen G. Raimann,[1,2] Len A. Usvyat,[1,2] Stephan Thijssen,[1,2] Peter Kotanko,[1,2] Nathan W. Levin.[1,2] *[1]Renal Research Institute; [2]Beth Israel Medical Center.*

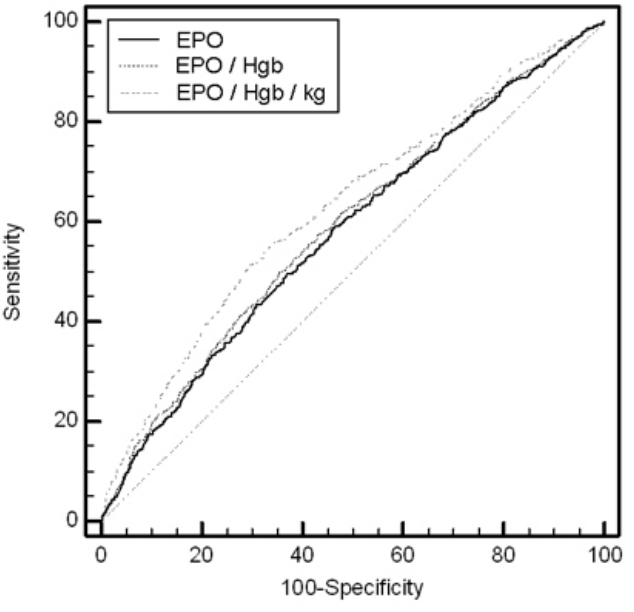
Background: Adequate anemia management improves survival and hospitalization rates (Locatelli 2004) in hemodialysis (HD) patients (pts). Erythropoietin (EPO) resistance, reflected by the ratio of EPO dose per hemoglobin (Hgb) concentration, was associated with inflammation (Stenvinkel 2002) and survival (Kilpatrick 2008). The best predictor of survival in terms of anemia management is controversial. This analysis aims to compare the predictive performance of different indicators.

Methods: Pts starting HD between 1/1/2001 and 7/30/2008 in RRI clinics were included. Average EPO dose per treatment was computed over the first 3 months of HD and survival monitored over one year. Predictive power of 1) EPO dose per treatment, 2) EPO dose per treatment per g/dL Hgb and 3) EPO dose per treatment per g/dL Hgb per kg of body weight (BW) was assessed as the area under the curves (AUC) of the respective receiver operating characteristics (ROC) curves. Youden index was employed to compute optimal discriminatory thresholds; positive and negative likelihood rations (LR+; LR-) were calculated.

Results: 6580 incident HD patients (56% males, 44% black, 47% white, 50% diabetic, age 61.5±15.4 years) were studied. Mortality rate was 92.6 per 1000 pts per year. AUC differed between the respective ROC curves (P<0.0001; **Figure 1**): (1) EPO dose per treatment: 0.58 (95% CI 0.57 to 0.59); (2) EPO dose normalized to Hgb: 0.59 (95% CI 0.58 to 0.60); (3) EPO dose normalized to Hgb and BW: 0.63 (95% CI 0.62 to 0.64).

Average EPO per g/dL per kg of BW was 11.4 (95% CI 11.2 to 11.6); a threshold of 12.9 allowed to predict mortality (LR+ 1.7; LR- 0.7).

Conclusions: These data suggests that the normalization of EPO doses to Hgb and BW has the most predictive power. This result supports the use of ERI analyses of survival and anemia management.



SA-PO2652

Outpatient (OP) Red Blood Cell (RBC) Transfusion Payments among Patients on Chronic Dialysis Matthew Gitlin, Shaowei Wan, Xue Song, Jeffrey L. Carson, David M. Spiegel, Brian Custer, Akhtar Ashfaq, Helen V. Varker, Katherine A. Cappell.

Background: Estimate OP RBC transfusion payments among chronic dialysis patients.

Methods: This retrospective economic analysis is based on a conceptual model of transfusion associated resource use to estimate OP RBC transfusion payments in dialysis patients using MarketScan data (1/1/02-10/30/10). All patients had ≥ 2 chronic dialysis claims ≥ 30 days apart and ≤ 1 year (1st claim defined as index date), ≥ 6 months pre-index data to measure comorbidities, and ≥1 OP RBC transfusion and ≥30 days post-transfusion follow-up. Total payments per RBC transfusion episode included pre/post screening/monitoring (+/- 3 days), blood acquisition/administration (within 2 days) and associated complications (acute within 3 days, e.g., circulatory overload, acute lung injury and hyperkalemia; 45 days for chronic, e.g., hemolytic reaction).

OP RBC Transfusion Payments:

	Mean (SD)	Median (25%, 75%)
Per Episode per Patient ($) (N=7049)		
Screening/Monitoring	191 (616)	34 (0, 179)
Blood Acquisition/Administration	615 (1237)	289 (11, 801)
Complications	175 (4790)	0 (0, 0)
Total	951 (5038)	427 (54, 1074)
Per Unit ($) per Episode (N=340)		
Screening/Monitoring	244 (425)	117 (0,341)
Blood Acquisition/Administration	433 (495)	374 (0, 608)
Complications	156 (1918)	0 (0, 0)
Total	827(2127)	551 (163, 999)

Results: A total of 3283 patients were included in this preliminary analysis, with a mean age of 60.9 (SD 15.0), 56.4% men, and 40.9% with Medicare supplemental insurance. Mean Charlson comorbidity index was 4.3 (SD 2.5). During a mean length of follow up of 552 days (SD 503), a patient on average had 3.1 (SD 4.3) OP RBC transfusion episodes. In the subgroup who had specific procedure claims for RBC unit level data of blood acquisition/administration, the mean (median) number of units per transfusion episode was 1.1 (1).

Conclusions: Preliminary results show payments for OP RBC transfusions are driven by blood acquisition/administration, followed by screening/monitoring. Although infrequent, transfusion complications increase costs substantially when they occur.

SA-PO2653

A Comparison of Projected ESRD Incidence and Prevalence with Recent Data David T. Gilbertson,[1] Craig Solid,[1] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN.*

Background: The USRDS published projections of the ESRD population to 2015 in 2005, and updated these projections to 2020 in the 2009 Annual Data Report (ADR). A primary message of those projections was that while incident rates of ESRD were slowing in many age and race groups, counts continued to increase. Here we compared actual incidence and prevalence numbers with those projected in the 2009 ADR that used information available through 2007.

Methods: A non-stationary Markov model was used, incorporating census projections and expected changes in both demographics and diabetes prevalence, to project ESRD incidence and prevalence through 2020. USRDS data through 2007 were used to obtain transition probabilities as well as past incident and prevalent counts.

Results: Incident counts were virtually constant from 2006-2008, but increased 3.3% in 2009, somewhat larger than projected. Prevalent counts have been consistently increasing approximately 4% per year, and are also ahead of projected numbers. Using data through 2007 and assuming relatively constant incidence rates based on recent trends, the model consistently projected increasing incident/prevalent counts through 2020.

ESRD Projected and Actual Incidence/Prevalence

	Incidence		Prevalence	
	Projection	Actual	Projection	Actual
2006		111,110		508,461
2007		111,193		528,666
2008	113,198	112,664	545,128	549,265
2009	115,295	116,395	563,173	571,414
2010	117,425		581,352	
2015	129,555		676,343	
2020	142,858		774,386	

Conclusions: Modeling assumptions were generally conservative, assuming flattening or even decreasing incident rates in some age/race groups. However, the post WWII population bulge is beginning to move into age groups with increasing chronic disease and increasing numbers of patients requiring RRT are inevitable. If incident rates increase in some groups and ESRD death rates continue to decline, the total number of patients requiring RRT will exceed these projections. This increasing population, along with changing incentives under the Medicare payment bundle implemented in Jan 2011, may increase the use of home therapies in the dialysis population.

SA-PO2654

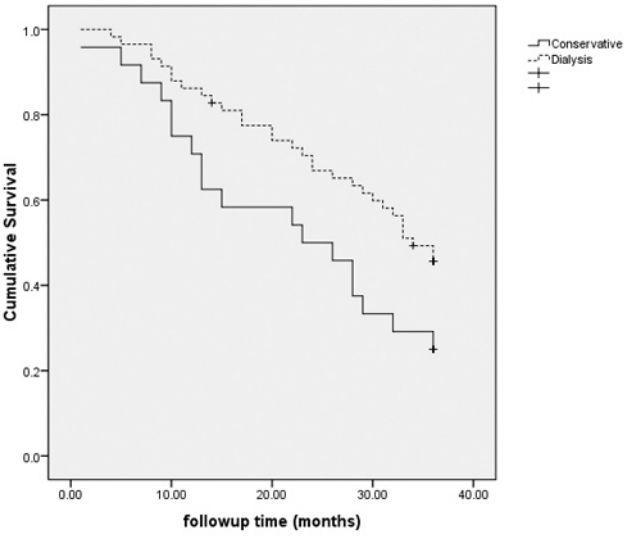
Does Dialysis Improve Survival in Elderly Patients? Darren Green, Philip A. Kalra. *Vascular Research Group, Manchester Academic Health Sciences Centre, University of Manchester, Salford Royal Hospital, United Kingdom.*

Background: It is unclear whether dialysis provides significant survival benefit to elderly CKD patients. Dialysis planning begins when patients reaches stage 5 CKD. It would be of benefit to be able to give prognostic information from this point.

Methods: We undertook a prospective observational study of outcome in patients who reached CKD stage 5 aged >75 years. Patients were sorted by whether they had chosen dialysis or conservative care, and were followed for 3 years. Patients were excluded if they suffered from malignancy, end-stage heart failure, or dementia.

Results: 82 patients were included (24 conservative care, 44 hemodialysis, 14 peritoneal dialysis). Dialysis patients were younger (79.4 vs. 83.4 years, p=0.000) and less likely to have coronary artery disease (21.6% vs. 45.5%, p=0.016). There was no difference in blood pressure, diabetes, heart failure, COPD, Karnofsky performance score, weight, smoking or alcohol intake. Patients who chose conservative care tended to be those who were widowed (40.0% vs. 10.4%, p=0.40) or lived alone (45.5% vs. 11.9%, p=0.36). 3 year survival was 45.6% for dialysis patients versus 25.0% for conservative care.

Figure 1. Survival in stage 5 CKD: dialysis versus conservative care.



This survival difference was independent of age. Patients who chose hemodialysis spent more time in hospital and underwent more operations that peritoneal dialysis or conservative care patients.

Table 1. Days spent in hospital per year by dialysis modality choice.

	Conservative	Hemodialysis	Peritoneal
Inpatient	15	27	19
Outpatient	8	64	20
Operations	0.0	1.4	0.7

Outpatient days include hemodialysis sessions. Operations included all dialysis access. Values are annual mean over the 3 years.

Conclusions: This study shows that there may be a survival benefit to choosing dialysis over conservative care in elderly patients with stage 5 CKD. Choosing dialysis appeared to be as strongly dependent on social factors as medical ones.

SA-PO2655

Exploring Preventable Hospitalizations of Dialysis Patients John R.C. Wheeler,[1] Richard Hirth,[1] Kathryn Meyer,[2] Joseph M. Messana.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Hospitalization rates are high (1.9 per pt yr) among ESRD pts. We investigated whether some types of hospitalization could be prevented by high quality dialysis care.

Methods: To identify causes of hospitalizations that may be candidate quality measures, we identified the most frequent diagnoses (dx) among ESRD pts and the frequency of dx deemed potentially preventable by AHRQ, i.e., Prevention Quality Indicators (PQIs). Medicare inpatient claims data for admissions in 2008 among ESRD pts were used. Admissions and time at risk were counted during time when the pt had Medicare as their primary payer (n=316,066 pts, with 238,266 yrs at risk and 447,972 admits).

Results: The most common discharge dx among ESRD pts were: (1) comp of device, implant or graft; (2) congestive heart failure (CHF); and (3) hypertension (HTN). The most common PQI dx were: (1) CHF; (2) DM long term complications; and (3) lower extremity amputation. AHRQ potentially preventable admissions comprised over 18% of all hospitalizations for ESRD pts, compared to 15% for all Medicare beneficiaries. Further, some non-PQI dx common among ESRD pts, such as comp of device, graft, or implant, may reflect preventable hospitalizations among ESRD pts. Finally, there is a high degree of variation across facilities in hospitalization rates for PQI dx (CHF inter-quartile range is 4% to 17%).

PQI Hospitalizations Among ESRD Medicare Primary ESRD Pts in 2008

Potentially Preventable Admission Indicator	N	% of Admits	Admits per 1,000 Enrollees
CHF	28,158	6.67	89.1
DM long term comp	17,650	4.18	55.8
Bacterial pneumonia	15,225	3.60	48.2
Lower extremity amputation	7,081	1.68	22.4
UTI	4,174	0.99	13.2
COPD	3,213	0.76	10.2
Dehydration	2,293	0.54	7.3
DM short term comp	2,071	0.49	6.6
Adult asthma	1,236	0.29	3.9
Angina	571	0.14	1.8
HTN	431	0.10	1.4
DM uncontrolled	355	0.08	1.1
Perforated appendix	153	0.04	0.5

Conclusions: PQI Hospitalizations account for more than 18% of admissions among ESRD pts. Further research may identify those potentially preventable hospitalizations that may reflect specific practice patterns in the dialysis setting, not currently identified using the AHRQ-PQI preventable hospitalization methodology.

Funding: Other U.S. Government Support

SA-PO2656

Hospital 30 Day Readmission Rates in Spanish Versus English Speaking End Stage Renal Disease Patients in a Medical Practice That Has Implemented An Ambulatory Care Language Concordance Program Mateo Levine Ledezma, Kwun-Yee T. Poon, Scott A. Rasgon. *Division of Nephrology and Hypertension, Kaiser Permanente, Los Angeles, CA.*

Background: Nationally there is a disparity in health outcomes in Hispanic compared with non-Hispanic patients with end-stage-renal-disease (ESRD)

Objective: To determine whether there is a difference in 30 day hospitalization readmission rates in Spanish vs English speaking ESRD patients in a medical group that has implemented a language concordance program.

Methods: We conducted a retrospective analysis of automated medical record database for admissions in Kaiser Permanente, Southern California hospitals in 2010 (n 366,225). Kaiser Permanente provides health care for more than 3.4 million patients, implemented an ambulatory care language concordance program in 2008. Non-English speaking patients where assigned primary care physicians fluent in preferred language (concordance 91.3%. The study cohort was adults (mean age 64.3) with a non obstetric admission (n 88,502); diagnosis ESRD (n 3,166), and Spanish (n 5,012). The demographics: gender (54% female), BMI (mean 29), diabetes (29%), and ethnicity (white 52%, black 15%, Hispanic 22%, and Asian 5%.

Results: Among study cohort patients who had an inpatient hospitalization in the measurement year (n 88,502), 9.8% had a second hospitalization within thirty days (n 8,617). Patients appeared older (mean 67), likely white (55%) or African American (17%), and tended to be English (vs Spanish) speaking (95.1%, $p<0.0014$). Patients with a diagnosis of ESRD (n 3,166), who had a 30 day readmission (n 679), tended to be white (35%) vs Hispanic (27%), male (56%), and older (67). The multivariate analysis of the independent variable in association with the outcome using logistic regression demonstrated Spanish versus English (OR 0.791, $p<0.0001$), gender female versus male (OR 0.914, $p<0.0001$), history of diabetes (OR 1.44, $p<0.0001$) and ESRD (OR 2.292, $p<0.0001$).

Conclusions: In a medical practice that has an ambulatory care language concordance program, Spanish speaking patients are 21% less likely to have a 30 day hospital readmission compared to English speaking patients, after adjusting for gender and history of ESRD.

SA-PO2657

Rehospitalizations in Prevalent 2009 Hemodialysis Patients Tricia L. Roberts,[1] David T. Gilbertson,[1] Craig Solid,[1] Allan J. Collins.[1, 2] *[1]USRDS Coordinating Center, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN.*

Background: Rehospitalizations contribute to the Medicare cost burden and indicate need for improved quality of care. Recent literature reported 30-day rehospitalization rates of nearly 20% among general Medicare patients; however, current rates among the dialysis population remain unknown.

Methods: We calculated rehospitalization rates in adult Medicare prevalent hemodialysis patients in 2009. Live hospital discharges were included from January 1 to December 1. We excluded rehabilitation claims, transfers, and discharges with a same-day admission to long-term care and critical access hospitals. Events were first rehospitalization and the combined endpoint of rehospitalization or death (rehos/death). Rates showed the percent of live discharges with an event within 30 days after discharge. Rates were computed by cause-specific groups for the discharge and rehospitalization. Rates from 1998 to 2009 were adjusted for age, gender, race, and primary diagnosis with direct adjustment.

Results: Results included 365,348 discharges from January 1 to December 1 in 2009. Overall, 36 and 39% of all-cause discharges were followed by an all-cause 30-day rehospitalization and rehos/death, respectively. The highest all-cause rehospitalization and rehos/death rates were among the youngest patients (age 20-44, 43 and 44%) and African Americans (38 and 40%). All-cause rehospitalization rates were highest after discharge from a cardiovascular hospitalization (37%), compared to infection (34%) and vascular access infection (31%). Among patients age 20-44, rehospitalization occurred after nearly half (47%) of discharges from a cardiovascular hospitalization. Cause-specific rehospitalizations were highest after a discharge with the same cause. Adjusted rehospitalization rates were stable from 1998 to 2009 and ranged from 35 to 36%.

Conclusions: Rehospitalization rates among hemodialysis patients were strikingly high: greater than one third of discharges were followed by at least one 30-day rehospitalization. Rates have not improved in the last decade, and identification of high risk groups, such as young patients and African Americans, could focus efforts to reduce rehospitalizations.

Long Term Renal Outcomes Following Autologous Stem Cell Transplant for Multiple Myeloma Siobhan Glavey,[1] Nelson Leung.[1] *[1]Nephrology, Mayo Clinic Rochester, Rochester, MN; [2]Hematology, Mayo Clinic Rochester, Rochester, MN.*

Background: Autologous Stem Cell Transplant (SCT) following high dose chemotherapy (HDC) has been established as optimal therapy for patients with multiple myeloma (MM) for over a decade. At our institution 19% of patients have a serum creatinine over 2g/dL at time of presentation with MM. The current literature pertaining to the outcome in terms of renal recovery following SCT is conflicting, particularly with regard to gaining independence from dialysis.

Methods: We conducted a retrospective analysis of the medical records of all patients undergoing SCT for MM between 2000 and 2010 at our institution. Inclusion criteria: Patients who had an elevation in serum creatinine (SCr) over 3mg/dLor were dialysis dependent at the time of SCT were selected. Exclusion criteria: Patients who had known chronic kidney disease preceeding the onset of MM were excluded.

Results: Fifteen patients (15/30) were found to have a serum creatinine over 3mg/dL in the pre-SCT period but were not dialysis dependent.Median SCr prior to SCT in this group was 3.5mg/dL. One month following SCT this increased to 6.1mg/dL.Four patients (26.6%) had progression to ESKD in the long term requiring dialysis. None of these patients regained independence from dialysis by time of death or last clinical review. Fifteen patients (15/30) were dialysis dependent at the time of SCT.Of these only one was able to attain independence from dialysis post SCT. This patient had improving renal function prior to SCT with an iothalamate clearance of 19ml/min and went on to discontinue dialysis 17 days after SCT.

Conclusions: Previous studies have indicated that SCT may have a favourable impact on renal outcome in MM.

We have not found this to be the case and on retrospective analysis of our experience in SCT for treatment of MM over ten years we found no benefit in terms of freedom from RRT or progression of renal pathology and impairment. Furthermore we found for patients who were close to commencing dialysis prior to SCT there was a 26.6% progression to ESKD requiring RRT in the long term. We propose caution prior to SCT in advising patients that there is likely to be an improvement in renal function.

SA-PO2659

Factors Affecting the Decision To Start Renal Replacement Therapy: Results of a Survey among European Nephrologists Moniek Van de Luijtgaarden, Marlies Noordzij, Wim Van Biesen, Christoph Wanner, Charles Tomson, Kitty J. Jager. *ERA-EDTA Registry Investigators, AMC, Amsterdam, The Netherlands.*

Background: The level of residual renal function is likely to determine the timing of start of renal replacement therapy (RRT).The patient's clinical status is suggested to play an *at least as* important role in this decision, but the importance of specific factors is unknown.We evaluated current opinions of European nephrologists on the decision making process on when to start RRT and whether opinions differed by nephrologist or facility characteristics

Methods: We distributed a web-based survey among nephrologists in 11 European countries with questions on the target level of renal function related to the start of RRT,factors bringing forward/postponing RRT,and nephrologist/facility characteristics.We used chi-square tests and multivariate linear regression to study associations and determinants of estimated glomerular filtration rate (eGFR)

Results: We received 433 completed surveys. Overall, renal function was not considered as the most important factor in the decision to start RRT, but for uncomplicated patients,54% of respondents did regard eGFR as the most important factor.The majority (88%) believed that a start at eGFR>10.5 mL/min/1.73m^2 was only beneficial if symptoms are present.Factors bringing forward the start of RRT were hyperkalemia (100%), pericarditis (98%) and fluid overload (97%). Patient preference (69%) and vascular dementia (66%) postponed the start.The median eGFR on which respondents aimed to start RRT in uncomplicated patients was 10.0 ml/min/1.73m^2 (IQR 8.0-10.0).We found higher target levels adjusted for confounders for respondents from countries with high vs low RRT incidence (eGFR 10.3 [9.8-10.8] vs 9.1) and from for-profit vs non-profit centers (eGFR 10.0 [9.4-10.7] vs 9.4;$p<0.05$)

Conclusions: Signs and symptoms rather than eGFR are important in the decision on when to start RRT. Nephrologists from countries with high RRT incidence and from for-profit centres aim to start at slightly higher eGFR levels. Although we gained insight in the decision making process, prospective studies are needed to further study current practice and its association with patient outcomes

SA-PO2660

The Rate of Wearing a Mask among HD Outpatients, Seroconversion Rates for Novel Influenza HA and Seasonal Influenza Vaccines, and Infection Status in the Pandemic between 2009 and 2010 Toru Hyodo,[1] Naoyuki Sato,[2] Daisuke Ishii,[1] Kazunari Yoshida,[1] Shiro Baba.[1] *[1]Urology, Kitasato University, Sagamihara, Kanagawa, Japan; [2]Nursing, Atsugi Clinic, Atsugi, Kanagawa, Japan.*

Background: To determine the rate of wearing a mask, seroconversion rates for novel and seasonal influenza vaccines, and rate of influenza infection in the pandemic of novel influenza (pandemic A[H1N1] 2009).

Methods: The rates of wearing a mask and the seroconversion status for A/Brisbane/59/2007(H1N1), A/Uruguay/716/2007(H3N2), and B/Brisbane/60/2008, which were used for inoculation in October 2009, and A/California/7/2009(H1N1) used for inoculation in December 2009 was compared before inoculation, and one month and six months after inoculation in 103 dialysis patients (average age: 64.0±13.4, mean dialysis history: 6.9±6.0 years, 75 men, 28 women, 42 diabetic patients, and 61 non-diabetic patients). Titers of at least 1:40 were within the safe range. The rate of influenza infection among HD patients was evaluated based on whether titers six months after inoculation were at least four times those one month after inoculation.

Results: Among the subjects, only 3.1±1.3% did not wear a mask between October 2009 and the end of April 2010. The proportion of subjects with titers of at least 1:40 for A/California was 8% before inoculation, 35% one month after inoculation, and 18% six months after inoculation, for A/Brisbane was 36% before inoculation, 45% one month after inoculation, and 38% six months after inoculation, for A/Uruguay was 24% before inoculation, 43% one month after inoculation, and 26% six months after inoculation, and for B/Brisbane was 25% before inoculation, 35% one month after inoculation, and 36% six months after inoculation. The rate of influenza infection was 1% (1 in 103 subjects, positive for type B).

Conclusions: It was suggested that the seroconversion rate for A/California used for inoculation between 2009 and 2010 was slightly lower than that for A/Uruguay or A/Brisbane. Given the seroconversion rates for vaccines among HD patients, wearing a mask appeared to be very effective because the number of infected subjects was extremely small.

SA-PO2661

Low Prevalence of Occult Hepatitis B Virus Infection in Chronic Hemodialysis and Kidney Transplant Patients Seema Baid-Agrawal,[1] Ralf Schindler,[1] Petra Reinke,[1] Ulrich Frei,[1] Thomas Berg.[2] *[1]Dept of Nephrology and Medical Intensive Care, Campus Virchow Clinic, Charite Medical University, Berlin, Germany; [2]Division of Hepatology, University Clinic Leipzig, Leipzig, Germany.*

Background: Occult hepatitis B virus (HBV) infection is defined as presence of HBV DNA in serum, liver or peripheral blood mononuclear cells (PBMC) in patients whose sera test negative for HBsAg. It may be a potential source of nosocomial transmission in chronic hemodialysis (CHD) patients and kidney transplant recipients (KTxR). This is the first study to date investigating its prevalence in large cohorts of these patients.

Methods: In this cross-sectional study, 391 patients undergoing CHD (Group 1), 417 NTxR (Group 2), and 20 HBsAg-positive non-HD non-KTx patients (positive controls, Group 3) and 40 HBsAg-negative healthy subjects (negative controls, Group 4) were enrolled.HBV DNA was determined in both serum and PBMC using Cobas TaqMan™ (Roche Diagnostics).

Results: Group 1 (CHD): 387/391 patients were HBsAg-negative (Group 1a), 4 were HBsAg-positive (Group 1b). The overall prevalence of HBsAg-positive infection was 1% (4/391). Occult HBV infection was found only in 1/387 (0.2%) HBsAg-negative patients and that also in serum and not in PBMC (HBV DNA-positive in serum). Group 2 (KTxR): 400/417 KTxR were HBsAg-negative (Group 2a), remaining 17 (4.1%) were HBsAg-positive (Group 2b). Occult HBV infection was found in 2/400 (0.5%) HBsAg-negative KTx recipients only in serum. Of note, HBV DNA was not detected in PBMC in any of CHD and KTx patients.

	HBV DNA positive in		
	serum only	both serum and PBMC	PBMC only
Group 1a (N=387)	1 (0.2%)	0	0
Group 1b (N=4)	1* (25%)	0	0
Group 2a (N=40)	2 (0.5%)	0	0
Group 2b (N=17)	4* (23.5%)	0	0
Group 3 (N=20)	5* (25%)	11(55%)	0
Group 4 (N=40)	0	0	0

* Most of the HBsAg+ patients were receiving anti-HBV therapy

Conclusions: We found a low prevalence (<1%) of occult HBV infection in CHD and KTx patients suggesting that laborious and expensive testing of HBV DNA in PBMC is not required for screening and diagnosis in these populations in our region. However, our results may not be generalizable to other populations with a higher prevalence of HBV where the role of occult HBV infection needs to be clarified.

SA-PO2662

Antibodies to Hepatitis B Virus Surface Antigen and Interleukin 12b Gene Polymorphism in Hemodialysis Patients Alicja E. Grzegorzewska,[1] Piotr M. Wobszal,[1,2] Pawel P. Jagodzinski.[2] *[1]Department of Nephrology, Transplantology and Internal Diseases, University of Medical Sciences, Poznan, Poland; [2]Department of Biochemistry and Molecular Biology, University of Medical Sciences, Poznan, Poland.*

Background: In hemodialysis (HD) patients, interleukin (*IL*) *18* -1297CC rs360719 genotype is associated with development of antibodies to surface antigen (anti-HBs) of hepatitis B virus (HBV). IL18 shares biological properties with IL12 in promoting Th1 system. A predominant Th1 response may inversely affect the Th2 humoral response. Our aim was to check the association between *IL12B* 3' untranslated (UTR) region polymorphism and anti-HBs development in HD patients with respect to *IL18* promoter polymorphism.

Methods: Polymerase chain reaction restriction fragment length polymorphism was used to detect *IL12B* rs3212227 3'UTR A/C and IL18 -1297C/T rs360719 polymorphisms in 364 HD patients and 242 controls. HD patients were categorized by *IL12B* genotypes (AA n = 226 AC n = 126, CC n = 12). Anti-HBs development in response to HBV transmission or anti-HBV vaccination was compared in these groups.

Results: There were no differences in genotype frequencies of *IL12B* or *IL18* and a gene-gene interaction in all HD patients and controls, and in *IL18* genotype frequencies in HD patients categorized by *IL12B* genotypes. Positive antibodies to HBV core antigen (anti-HBc) without developed anti-HBs were the most frequent in *IL12B* CC carriers (62.5%), and this frequency was higher than that in AC (12.9%, p = 0.009) or AA/AC (24.7%, p = 0.036) carriers. Positive anti-HBc without anti-HBs could be predicted by *IL12B* CC genotype (OR 3.00, 95%CI 1.86-4.84, p = 0.039) or *IL12B* AC genotype (OR 3.60, 95%CI 1.11-11.7, p = 0.033). A gene-gene interaction between *IL12B* and *IL18* was of borderline significance in anti-HBc positive patients categorized by anti-HBs development (p = 0.09) or "isolated" pattern (p = 0.08). Anti-HBs development in vaccinated patients was not *IL12B* genotype dependent.

Conclusions: *IL-12B* CC genotype, occurring in 3.3% of HD patients, seems to be related to impaired development of anti-HBs in response to HBV infection, but not in response to anti-HBV vaccination.

SA-PO2663

Use of Hepatitis C Nucleic Acid Testing Improves Surveillance in a United Kingdom Prevalent Haemodialysis Population Virginia L. Prout, Richard W. Corbett, Alison D. Cox, Mark Atkins, Neill Duncan. *West London Renal and Transplant Centre and Department of Virology, Imperial College Healthcare NHS Trust, London, United Kingdom.*

Background: The prevalence of Hepatitis C virus (HCV) infection is significantly higher in haemodialysis patients, with a wide disparity between countries. Though previous work supports the use of nucleic acid testing by polymerase chain reaction (PCR) for surveillance of infection in prevalent haemodialysis patients in areas with high levels of carriage, the evidence for its use in units with a lower prevalence is less clear.

Methods: Prospective data was collected over a twelve month period on all patients receiving maintenance haemodialysis across our satellite dialysis centres. In addition to monthly HCV antibody (3rd generation enzyme immunoassay- EIA) testing, four-monthly pooled samples from each unit were submitted for nucleic acid testing (HCV-RNA PCR). Each pool contained five patients, who were then re-tested individually in the presence of a positive pool result. Individuals known to carry HCV were not excluded.

Results: 1352 patients were tested on more than one occasion, in total 51 individuals (3.8%) were found to be either HCV-positive by PCR or EIA testing.

Prevalence of HCV antibodies and HCV-RNA in a prevalent haemodialysis population

	HCV-RNA (+) by PCR	HCV-RNA (-) by PCR
Anti-HCV (+) by EIA	42	7
Anti-HCV (-) by EIA	2	1307

All 7 patients who proved to be EIA+ / PCR- had at least two non-pooled negative HCV PCR results, separated by six months. All 44 patients found to be PCR+ have had non-pooled confirmatory testing and viral genotyping. The pooled screening program successfully identified the 42 EIA+ / PCR+ patients known to be viraemic prior to commencement of the study. The two EIA- /PCR+ patients had not been previously identified prior nor had had abnormal ALT levels and appeared to have longstanding infection with moderate viral loads.

Conclusions: Occult HCV infection is a problem even in low prevalence haemodialysis populations within the United Kingdom. Pooled HCV-RNA PCR surveillance allows efficient, robust and accurate identification of viraemic patients within a dialysis program.

SA-PO2664

Cessation of Renal Replacement Therapies with Improved Kidney Function in the ESRD Medicare Program Edwin D. Huff, Marianne Neumann, The FFBI Data Committee. *Fistula First Breakthrough Initiative, IPRO ESRD Network of NY, Lake Success, NY.*

Background: ESRD has meant "Loss of kidney function, with need for kidney replacement treatments", however, as evidence will show, some patients may not actually be afflicted with ESRD in the first place, and may instead be individuals suffering from types of acute kidney injury.

Methods: A total of 205,399 incident ESRD hemodialysis patients from 2008 & 2009 were tracked over two years in the CMS SIMs registry. Start dates were initialized with incident dialysis. Recovery, if reported, was marked from dialysis facility updates transmitted through ESRD Networks and entered into the SIMs central repository on a daily basis.

Results: The rate of renal recovery over two years was 6.67%, with median time to recovery 74 days (3.3% recovery rate). Approximately 75% recover within 120 days (4.9%). The rates of renal recovery in those years were 6.62% in 2008 and 6.69% in 2009. Significantly fewer patients were noted to have permanent accesses placed at incident dialysis, with over 94% utilizing catheters. The origin of their kidney diseases are similar, though more have Acute Tubular Necrosis. Patients who recover kidney function are half as likely (27% vs. 56%) to have had pre-dialysis nephrology consultations. Of those patients who were able to discontinue renal replacement therapies, 14% restart treatment within 2 years.

Conclusions: 13,673 patients over two years were reported to have regained adequate kidney function within 74 days on average. While many aspects of clinical presentation appear similar, there are noted differences suspected in disease onset and early treatment that

are consistent with many of these patients having acute kidney diseases. Fewer nephrology referrals and higher catheter rates are consistent with these cases having a shorter time horizon in their onset, not like those with chronic CKD patients.

Workload Demand and Caseload Disparities of Dialysis Social Workers in the United States Joseph R. Merighi,[1] Teri Browne.[2] [1]*School of Social Work, Boston University, Boston, MA;* [2]*College of Social Work, University of South Carolina, Columbia, SC.*

Background: Every dialysis unit in the United States must have a Master's level social worker as part of its patient care team. This study examines regional variations in perceived workload demands and patient caseloads of these dialysis social workers. Studies indicate that high social worker caseloads are associated with decreased ability to provide psychosocial interventions that can help improve patient outcomes (Merighi & Ehlebracht, 2005).

Methods: A 130-item online survey was conducted to assess renal social workers' caseloads, job-related resources, and workload demands. 1,055 full-time social workers completed the surveys from all five National Kidney Foundation (NKF) regions: 1 (Northeast), 2 (Southeast), 3 (Midwest), 4 (South), and 5 (West and Southwest). Respondents were recruited between 3/31/10 and 6/21/10 using the Council of Nephrology Social Worker listserv.

Results: One-way ANOVA was used to examine mean workload demands and caseloads across all five NKF regions. Findings yielded significant main effects for caseload, $F(4, 1035) = 5.46$, $p = .001$, and workload demands, $F(4, 939) = 3.06$, $p = .016$. Post hoc tests revealed significantly higher mean workload demands in Region 1 (21.3) compared to Region 3 (20.1) and Region 5 (19.9), and Region 4 had a significantly higher mean caseload (125) than Region 3 (112). Geographic Information Systems (GIS) technology was used to map workload demands and caseloads using respondents' unique zip code boundary. The GIS maps display a distinctive pattern at the state level of high workload demands in Region 1 (esp. NH, MA, and CT) and high caseloads in Region 4 (esp. AR and MS).

Conclusions: This study represents an important national effort to assess dialysis social workers' workload demands and caseloads and document regional disparities. High caseloads may prevent social workers from helping patients ameliorate psychosocial barriers to optimal kidney disease outcomes. These findings also have implications for all dialysis units because high social work caseloads may lead to facility citations for failure to comply with the Medicare's Conditions for Coverage.

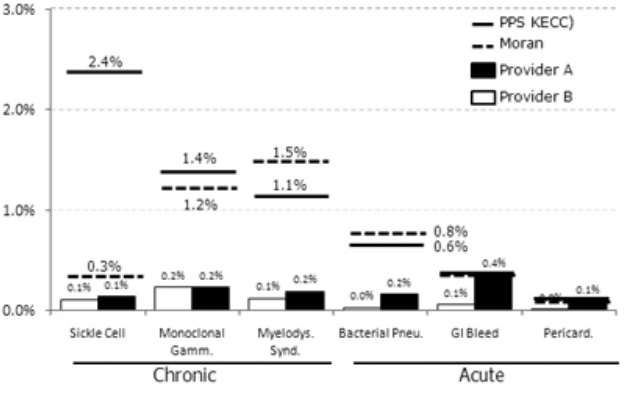
Case Mix Adjusters Continue To Be Difficult To Detect Tracy Jack Mayne, Jeremy Jonckheere, LeAnne Zumwalt, Mahesh Krishnan. *DaVita Inc, Denver, CO.*

Background: Beginning in 2011, the ESRD prospective payment system (PPS) increased the number of case mix adjusters (CMA) from 3 to 11, including 6 for co-morbid conditions. The additional CMAs were based on an analysis by the University of Michigan Kidney Epidemiology and Cost Center (KECC). Our objective was to replicate the prevalence reported by KECC in other currently available data sources.

Methods: The Moran Group (Moran) analyzed the 2008 5% Medicare Standard Analytic Files (SAFs) for the 6 CMA comorbidities in US dialysis patients. We searched for the ICD-9 codes for each adjustor as identified in the final rule, including non-nephrologist physician and hospital claims. In acute conditions, we added 4th quarter 2007 ESRD, physician, and hospital claims. In chronic conditions, we added all of 2007 ESRD, physician, and hospital claims. We then searched all available paper and electronic records at each of the two large dialysis organizations (Provider A and B) for documentable diagnoses of these 6 conditions.

Results: The prevalence of the 6 co-morbid case mix adjusters detected in the medical records of the two dialysis organizations was significantly lower than the prevalence reported by KECC (Figure). The Moran analysis of the Medicare 5% SAF found significantly less sickle cell disease, somewhat less monoclonal gammopathy, slightly more myelodysplastic syndrome and bacterial pneumonia, and equivalent GI bleed with hemorrhage and pericarditis.



Conclusions: The results demonstrate the difficulty for dialysis providers to document CMA prevalence at the level used to estimate the 2011 bundled rate. Were CMS to provide dialysis organizations with the prevalence of these conditions from the SAFs, this would correct the inequity in all areas except sickle cell disease.

Funding: Clinical Revenue Support

SA-PO2667

Actual Cost of Dialysis Drugs: A Step towards the Final Bundle Payment System in 2014 Megha Shah,[2] Michelle Malabanan,[2] Wajid M. Choudhry,[1] Vijay K. Jain.[1] [1]*Nephrology, Unity Health/University of Rochester, Rochester, NY;* [2]*Medicine, Unity Health System, Rochester, NY.*

Background: CMS have implemented the new ESRD bundled payment system on January 1, 2011. Medicare provides a single bundled payment of $229.63 per dialysis inclusive of the following:

1. Composite rate including labor to deliver dialysis and routine supplies
2. Part B ESRD injectable drugs and their oral Part D equivalent
3. ESRD lab. tests ordered by a nephrologist

The CMS however have delayed including Part D oral-only ESRD medications to the bundle base rate until 2014. There is insufficient data at a local and national level about the cost of these oral drugs.

Methods: We conducted a cross-sectional chart review of all patients in 2 hemodialysis units, one suburban (N=133) and one inner city (N=95) and the associated peritoneal dialysis program (N=35) in Rochester, NY. Our main objectives are to determine the actual cost of: 1) Part D ESRD prescribed oral-only drugs 2) injectable drugs and their oral equivalent. Data was collected over a 31- day period at these 2 hospital-owned dialysis units staffed by a single nephrology group. We determined average calcium and phosphorus levels, quarterly PTH levels and the last hemoglobin of the month to evaluate the effectiveness of current prescribing practices.

Results: The average patient age (66.6 years) is similar in all groups. Inner city unit had substantially higher black patients compared to the suburban unit (70.5% vs 23.3%). The calcium, phosphorus, PTH and hemoglobin control were similar in the three groups and were within the acceptable range (8.4-8.5 mg/dl, 4.8-5.1 mg/dl, 380-384 pg/ml, 11-11.3g/dl, respectively).

Cost per patient per dialysis	Suburban Unit	Inner City Unit	PD
Oral-Only Drugs ($)	47.4	44.2	39.7
Injectables + Vit D* ($)	50.5	50.5	18.8

*Included in the current bundle

Conclusions: Our data suggests that the average cost of ESRD oral drugs ranges between $39-$47 today. Data like ours at a local level will hopefully enable Medicare to make appropriate adjustments to the final bundle payment rule in 2014. This will help avoid any unintentional consequences on quality of care, such as alteration of prescribing practice based on economic reasons.

SA-PO2668

Poor Representation in the Medical Evidence Report (CMS-2728) of the Nephrology Care Received by Patients Approaching End-Stage Renal Disease: A Validation Study Jane Paik, Manisha Desai, Glenn M. Chertow, Wolfgang C. Winkelmayer. *Medicine, Stanford University, Stanford, CA.*

Background: In 2005, the Centers for Medicare and Medicaid Services added a new item to the Medical Evidence Report querying providers on the timing of the patient's first nephrologist consultation prior to initiation of renal replacement therapy (RRT). This item is also being used for monitoring disease-specific goals in the Healthy People 2020 initiative. The accuracy of the reported information, however, is unknown.

Methods: We defined a cohort of 41,455 patients initiating RRT between 7/2005 and 12/2006, who were ≥67 years old; among those, 28,778 had 2 years of uninterrupted Medicare (primary payer) coverage prior to RRT. We report accuracy of medical reporting using claims data as the gold standard. Using linear and Cox regression, we assessed the associations between the magnitude of discrepant reporting and patient characteristics as well as patient survival.

Results: Agreement between the two sources of ascertainment regarding timing of visit was present in only 32.9%, where the Kappa statistic was 0.13 when timing was defined as a 4-category variable and 0.30 when it was dichotomized as having had a visit over 6 months ago vs within 6 months. With an overall accuracy of 65%, accuracy was associated with race (p-value=0.001) and underlying cause of disease (p-value<0.001). In particular, whites had higher levels of accuracy at 67% compared to Asians and Native Americans, whose levels were at 62% and 61% respectively; among the underlying causes, cystic kidney was higher at 72% compared to hypertension and diabetes at 65%. Compared with patients receiving accurate reporting of their pre-dialysis nephrology care, inaccurate reporting was associated with a 22% increase in 1-year mortality.

Conclusions: We found substantial disagreement between information from the Medical Evidence Report form and Medicare physician claims on the timing of earliest pre-dialysis nephrologist care. In addition, inaccurate reporting contained prognostic information about these patients. This work casts doubt on the utility of the Medical Evidence Report for research and public health surveillance.

SA-PO2669

Adaptated Exercice Training Program for Dialysis Patients Philippe Chauveau,[1] Tomas Labat,[1] Stanislas Trolonge,[1] Christian Combe,[2] Catherine Deforges-Lasseur.[1] *[1]Aurad-Aquitaine, Bordeaux, France; [2]Hopital Pellegrin, CHU de Bordeaux, Bordeaux, France.*

Background: A sedentary lifestyle is frequent in hemodialysis (HD) patient and is associated with an increased relative risk for death. Evidence exists that increased physical activity (PA) is associated with better quality of life, better nutritional and inflammatory status and rehabilitation.

If an increased of PA should be one of the goals of care management several barriers prevent implementation of PA in dialysis units, related to patients but also to dialysis staff, notably lack of time, of knowledge or competence.

Methods: Since, march 2010, all 150 pts in AURAD Aquitaine have been informed about the opportunity to participate in an individualized program of PA (IPA) carried out by an Adapted Physical Activity Coach (APAC). After an Initial screening (consultation with the APAC, PA questionnaire (GPAQ), 6-minute walk test, balance test, handgrip strength, measure of quality of life (KDQOL36), assessment of body composition using the Body Composition Monitor® (BCM), biological nutritional parameters) and a 8-days period of observation with podometer and walkbook, an home-based individualized exercise program is determined for each patient and group-activity sessions were proposed. Supervision and support were provided according to patient's request.

Same complete screening is performed every 6 months.

Results: 32 patients (22%) enter the program (45±15 years, BMI 24±5 kg/m2) and only 2 stop at one year. At start, 6-min walk test was 541±110 m (320-885), mean steps per day using 8-days podometers was 5674 ± 2123steps/d: only 2 of them had a recommended PA according to age. 6-months evaluation is available for the 15 first patients (7 men , aged 41±15 years (20-65 years), and demonstrate a 37% increase of PA.

Conclusions: An individualized home-based PA program could be easily and safely initiated in dialysis unit using a trained qualified PA-health care professional. A combination of individual support and activity group maintain the adherence to the program. Preliminary results demonstrate an increase in physical activity and well-being.

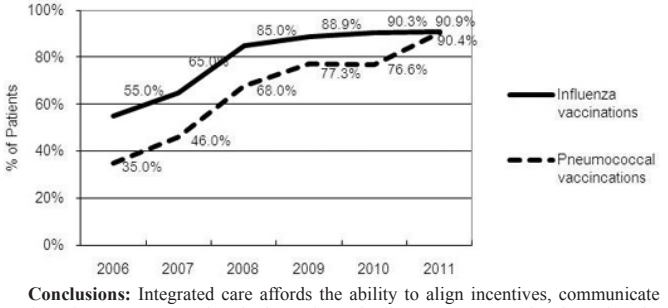
SA-PO2670

Effect of an Integrated Care Delivery System on Improving Immunization Outcomes Susan Rizkalla, Steve Mitchener, Barrett J. Johnson, David B. Van Wyck, Mahesh Krishnan, Allen R. Nissenson. *DaVita Inc, Denver, CO.*

Background: Pneumococcal vaccination and seasonal influenza vaccination each lower the risk of hospitalization and death in dialysis patients (pts). Those pts who receive both vaccines show the lowest risk. Using an integrated care intervention model similar to that proposed for accountable care organizations under healthcare reform, we undertook a systematic effort over the past 3 years to improve vaccination rates among in-center hemodialysis (HD) pts.

Methods: At the onset, clinical leadership recommended a goal of 90% of pts to receive pneumococcal vaccination (1x in past 5 years or 2x in lifetime), and 90% to receive seasonal influenza (annually). Operational leadership assigned a high priority to the effort, coordinated communications and management, provided implementation resources, applied process engineering approaches to identifying barriers and best practices, and assured adequate vaccine supply. IT systems were developed to report facility performance and identify unvaccinated pts in real time. Facility interdisciplinary care teams used teaching tools and daily exception reports during the flu vaccination season.

Results: Vaccination rates in the population of ~120,000 pts improved progressively during the period of intervention. By March 31, 2011, the goal of 90% seasonal and pneumococcal vaccination rate was achieved (Figure). The percentage of pts who declined influenza vaccination for allergy was very low (0.6%) in 2010.



Conclusions: Integrated care affords the ability to align incentives, communicate consistently, report comprehensively, and standardize care. Our results show that the integrated care model can be dramatically successful in improving vaccination rates within a large population of HD pts, and that care processes within large dialysis providers are well-suited to serve as potential accountable care organizations.

SA-PO2671

Regular Screening for Staphylococcus Aureus Colonisation in a Satellite Haemodialysis Population: Lessons Learnt from a One-Year Single Centre Study David Makanjuola,[1] Glynn Richardson,[1] Jonathan Dick,[1] Angela Wright,[1] Maggi Steele,[1] Ginny Quan,[1] John Clark.[2] *[1]Renal Unit, St. Helier Hospital, Surrey, United Kingdom; [2]Microbiology Department, St. Helier Hospital, Surrey, United Kingdom.*

Background: Methicillin resistant Staphylococcus aureus (MRSA) is an important pathogen in the haemodialysis (HD) population and clinically significant infection is strongly associated with skin colonisation. In a bid to reduce MRSA bacteraemias, the UK department of health advocates screening for MRSA in all HD patients; however, the cost implications and utility of this strategy are unknown.

Methods: 76 patients on HD at a satellite unit were screened at 0,1,2,3,6 and 9 months for staphylococcus aureus (SA) carriage. Universal hygiene precautions were observed. Due to limited availability, SA positive patients could not always be isolated during HD sessions. SA eradication was attempted using 4% Chlorhexidine solution on a maximum of two separate occasions for any single patient.

Results: 66 patients completed the study. 4% were MRSA positive at baseline and 9% were positive on at least one occasion during the study. Transitory, rather than persistent carriage was observed. 5 different strains of MRSA were detected. 2 patients were colonised with a similar strain, but they dialysed on different days, making direct spread unlikely. In the MRSA positive patients who responded to decolonisation therapy, upon becoming re-colonised with MRSA, it was found to be with the same strain as they originally had.

34% were methicillin sensitive SA positive on at least one occasion during the study. Of these, 4 were consistently positive through the study in spite of eradication therapy.

Conclusions: The limited spread of MRSA in our cohort suggests that even where there is a dearth of isolation rooms, barrier nursing and universal hygiene precautions are sufficient to prevent spread of MRSA.

The differing variety of MRSA strains suggests that patients are acquiring MRSA from diverse sources in the community or other healthcare settings, rather than from the dialysis unit. MSSA decolonisation was of limited benefit.

SA-PO2672

Comparison of Life Participation Outcomes between Renal Replacement Therapy Modalities: A Systematic Review Tanjala S. Purnell,[1] Priscilla Auguste,[1] Deidra C. Crews,[1] Julio Lamprea,[1] Temitope Olufade,[1] Raquel Greer,[1] Patti Ephraim,[1] Johanna Sheu,[1] Neil R. Powe,[2] Hamid Rabb,[1] L. Ebony Boulware.[1] *[1]Johns Hopkins University; [2]University of California San Francisco.*

Background: The effect of renal replacement therapy (RRT) modality on patients' limitations in life participation (physical function, travel, recreation, freedom, work) has been poorly explored.

Methods: We performed a systematic review to explore the association of RRT (hemodialysis-HD, peritoneal dialysis-PD, kidney transplant-TX) with patients' life participation. We searched PubMed (English language, after 1980) and hand-searched bibliographies to identify studies that compared relevant outcomes by RRT. Independent reviewers used standard criteria to evaluate the quality of studies' research design and methods (internal and external validity), and we calculated the Cohen's d effect size estimate to assess the magnitude and direction of differences. We considered non-statistically significant results to indicate that neither treatment was favored for that comparison.

Results: Of 270 potential studies, 42 studies met our inclusion criteria, ranging from low to moderate quality (Table 1). These studies included 81 relevant comparisons by RRT (28 HD-PD; 28 HD-TX; 20 PD-TX; 5 Dialysis-TX). Studies were conducted in diverse racial/ethnic groups and included 2 cohort, 39 cross-sectional, and 1 pre-post study designs. Patients who received a TX consistently reported more favorable outcomes than patients on HD or PD.

Table 1. Summary of Published Evidence Comparing Life Participation Outcomes by RRT Modality

RRT Modalities Compared	HD vs. PD			HD vs. TX			PD vs. TX			Dialysis* vs. TX		
Life Participation Outcome Domains	# of outcomes that			# of outcomes that			# of outcomes that			# of outcomes that		
Study Design (Total Published Studies)	Favors HD	Favors Neither	Favors PD	Favors HD	Favors Neither	Favors TX	Favors PD	Favors Neither	Favors TX	Favors Dialysis	Favors Neither	Favors TX
Physical Function												
Randomized Trial (0)												
Longitudinal Cohort (2)		2										
Cross-Sectional (15)	1	5			4	9		2	6			3
Pre-Post Transplant (1)						1						
Travel												
Randomized Trial (0)												
Longitudinal Cohort (1)		1										
Cross-Sectional (0)												
Recreation												
Randomized Trial (0)												
Longitudinal Cohort (1)		1										
Cross-Sectional (7)		5			2	2			3			1
Freedom												
Randomized Trial (0)												
Longitudinal Cohort (1)		1										
Cross-Sectional (5)		4				4			4			1
Work												
Randomized Trial (0)												
Longitudinal Cohort (1)		1										
Cross-Sectional (8)	2	4	1			6		1	4			
Total Published Study Comparisons Favoring Each RRT Modality	3	24	1	0	6	22	0	3	17	0	0	5

Note: *Dialysis includes both HD and PD patients.

Conclusions: Evidence suggests patients who receive a TX report fewer limitations in life participation outcomes than dialysis patients, and there are no significant differences between HD and PD patients. However, the overall quality of evidence is low. Rigorously performed studies are needed to better inform patients about the effect of RRT on these important patient reported outcomes.

Effects of Antioxidant Therapy in CKD: Systematic Review & Meta-Analysis Min Jun,[1] Vinod Venkataraman,[2] Mona Razavian,[1] Sophia Zoungas,[1,4] Angela C. Webster,[3] Bruce A. Cooper,[2] Toshiharu Ninomiya,[1] Vlado Perkovic.[1] *[1]George Institute for Global Health, Uni of Sydney, Australia; [2]Royal North Shore Hospital, Australia; [3]School of Public Health, Uni of Sydney, Australia; [4]School of Public Health & Preventive Med, Monash Uni, Australia.*

Background: Trials of antioxidants show inconsistent effects on cardiovascular (CV) risk in chronic kidney disease (CKD) so we performed a systematic review and meta-analysis to synthesize the available evidence.

Methods: We systematically searched MEDLINE, EMBASE, and Cochrane Library for prospective RCTs (1950-March 2011) assessing antioxidant therapy compared to placebo for CV outcomes. Summary RRs and 95% CIs were calculated using a random effects model. Study quality was judged based on specific variables. Outcomes analysed were CV death, CV events, coronary events, cerebrovascular events, peripheral vascular disease (PVD), end-stage kidney disease (ESKD), and adverse events.

Results: We identified 4 trials with 1500 participants (327 CV events, 209 coronary events, 298 deaths). Studies were of mixed quality with some studies lacking information regarding randomization process, allocation concealment, and intention-to-treat analyses. Compared to placebo, antioxidant therapy had no overall effect on risk of CV death (RR 0.95; 95% CI: 0.70-1.27, p=0.712), cerebrovascular events (0.91;0.63-1.32, p=0.632), PVD (0.55;0.27-1.21, p=0.099), or ESKD (0.57;0.31-1.06, p=0.075). Data for adverse outcomes were sparse and reported no difference between the antioxidant and placebo arms. There was significant heterogeneity in the magnitude of the effect across studies for CV events (I^2=76.4%, p=0.01) with no effect in the early CKD population (1.04;0.83-1.32) but a beneficial effect in dialysis patients (0.57;0.41-0.80, p=0.001). Similar heterogeneity was identified for coronary events (I^2=64.1%, p=0.062).

Conclusions: Overall, there is no evidence that antioxidant therapy reduces risk of CV death, all-cause death, or major CV events but it is possible there is benefit for patients undergoing dialysis. Sufficiently sized trials in patients with advanced CKD are needed to better understand the effects of antioxidant therapy.

SA-PO2674

Impact of a Low-Glucose Peritoneal Dialysis Regimen on Inflammatory and Fibrotic Mediators in Effluent Dialysate Susan Yung, Chris Ng, Andy Yim, Maggie Ma, Sing-Leung Lui, Daniel Tak Mao Chan. *Department of Medicine, University of Hong Kong, Hong Kong SAR, Hong Kong.*

Background: Constant exposure of the peritoneum to bio-incompatible peritoneal dialysis fluids (PDF) results in deleterious changes to the peritoneal structure and function, which leads to technique failure and unfavorable clinical outcomes. While low-glucose PDF may have improved biocompatibility compared with conventional glucose based dialysates, their impact on biomarkers of inflammation, fibrosis and peritoneal membrane integrity remains to be investigated.

Methods: New PD patients who had entered the PD programme within 1 month were randomized to receive either a low-glucose regimen (1 exchange of Nutrineal®, 2-3 exchanges of Physioneal® and 1 overnight exchange of Extraneal®) for 12 months and then Dianeal® for 6 months (PEN Group, n=43), or 3 to 4 exchanges of Dianeal® for 18 months (Control Group, n=37). Overnight PDF was collected from all patients for the assessment of CA125, and inflammatory and fibrotic markers.

Results: Patients in the PEN Group showed a progressive increase in dialysate CA125 level, which was significantly higher than that in Controls after 12 months treatment [mean (range): 56.50 (16.00-166.00) IU/ml vs 20.50 (1.00-84.00) IU/ml, PEN vs Control, P<0.01)], and which reverted after switching back to Dianeal®. Similarly, dialysate levels of decorin, MMP-9, adiponectin, ICAM and VCAM were 1.35-, 2.52-, 1.79-, 1.93- and 1.59-folds respectively higher in the PEN Group compared to Controls after 12 months, but the two groups showed similar levels after the PEN Group changed back to Dianeal®. In contrast, dialysate MIF level was significantly lower in the PEN Group during the first 12 months [0.46 (0.06-1.22) pg/ml vs 0.77 (0.00-1.95) pg/ml, P<0.05], but was comparable between the two groups at 18 months.

Conclusions: Our data demonstrate that the low-glucose dialysis regimen is associated with reduced intra-peritoneal inflammatory and fibrotic response, and thus potentially result in better preservation of the structural and functional property of the peritoneum during long-term peritoneal dialysis.

SA-PO2675

Relationship between Truncal Fat Mass and Serum High-Sensitivity C-Reactive Protein in Hemodialysis Patients — Metabolic Syndrome and Inflammation Eiji Ishimura,[1] Senji Okuno,[2] Naoki Tsuboniwa,[2] Shinya Nakatani,[1] Mitsuru Ichii,[1] Tomoyuki Yamakawa,[2] Shigeichi Shoji,[2] Yoshiki Nishizawa,[1] Masaaki Inaba.[1] *[1]Osaka City University Graduate School of Medicine, Osaka, Japan; [2]Shirasagi Hospital, Osaka, Japan.*

Background: The relationship between fat mass distribution and chronic inflammation in dialysis patients is unknown, although chronic inflammation is related to central obesity in general population.

Methods: The fat mass and lean mass (total, truncal, and non-truncal) of 452 maintenance hemodialysis patients (age: 64±11 years; hemodialysis vintage: 89±77 months; 37% diabetics) without significant infection were measured by dual X-ray absorptiometry, and their association with high sensitivity C-reactive protein (hsCRP) was examined.

Results: Total fat mass and truncal fat mass of the high hsCRP group (n=346) were significantly higher than those of the normal hsCRP group (n=106) (p<0.05, respectively); while there were no significant differences in non-truncal fat mass or in lean mass between the two groups. In all patients, there were significant positive correlations between serum hsCRP and total fat mass (r = 0.186, p < 0.0001), and between serum hsCRP and truncal fat mass (r = 0.202, p < 0.0001), although there was none between serum hsCRP and lean mass. In a multiple regression analysis, truncal fat mass was significantly and independently associated with serum hsCRP levels after adjustment for several confounders, whereas non-truncal fat mass was not.

Factors affecting serum hsCRP levels (multiple regression analysis)

	β	p-value
Age (per 1 year)	0.102	0.034
Gender (male 0, female 1)	0.152	0.001
Hemodialysis duration (months)	0.018	0.693
Diabetes (absent 0, present 1)	- 0.048	0.312
Albumin (per 1 g/dL)	- 0.278	< 0.001
Truncal fat mass (per 1 kg)	0.227	0.003
Non-truncal fat mass (per 1 kg)	- 0.007	0.926
R^2	0.137	< 0.001

Conclusions: Fat mass, particularly truncal fat mass, but not lean body mass, was significantly associated with serum hsCRP levels. The results indicate that truncal fat mass exhibits a distinct effect on chronic inflammation in hemodialysis patients, suggesting the effect of metabolic syndrome on chronic inflammation in dialysis patients.

SA-PO2676

Elevated Serum Concentrations of Maillard Amino Acid Amides Can Be Reduced by Hemodialysis with HCO1100 Dialyzer Membranes Matthias Girndt,[1] Roman Fiedler,[1] Christian Henning,[2] Christof Ulrich,[1] Felix Neugebauer,[1] Eric Seibert,[1] Marcus A. Glomb.[2] *[1]Department of Internal Medicine II, Martin-Luther-University Halle, Halle, Germany; [2]Institute of Chemistry - Food Chemistry, Martin-Luther-University Halle, Halle, Germany.*

Background: Protein glycation by Maillard reactions leads to advanced glycation end products (AGE). In plasma of hemodialysis (HD) patients AGEs are found at high concentrations. We studied plasma concentrations of a novel group of free amino acids with amid structure in HD patients and put emphasis on the ability of different dialysis techniques to remove them.

Methods: Amid-AGEs were quantified by mass spectrometry (LC/MS/MS) in plasma of HD patients obtained prior to a dialysis session. The patients studied were included in a randomized double blind cross over study testing efficacy and safety of a high cut-off dialyzer membrane (Gambro HCO1100™) compared to a high-flux membrane (Gambro Polyflux H™) in 17 patients (age 68.1±10.9 years). Treatment was performed over 2 weeks (6 consecutive dialysis sessions). Healthy individuals of two age ranges (young=27.2±6.2 years, elderly=65.1±4.3 years) were tested as controls.

Results: In healthy controls the plasma concentrations of the amino acid adducts *N*-formyllysin, *N*-acetyllysin, *N*-lactoyllysin, and *N*-glycerinyllysin increased with age. In HD patients the adducts showed higher plasma concentrations than in both healthy groups (formyllysin in pmol/ml, young=125±43; elderly=172±112; dialysis=309±113; p<0.0001 by Kruskal-Wallis test). Predialysis concentrations of formyllysin und acetyllysin could significantly be reduced by 2 weeks of high cut-off dialysis (formyllysin, polyamid 309±113; HCO 245±75; p=0.014 by Wilcoxon test).

Conclusions: Free amino acids with amid modifications are an important novel group of Maillard AGEs that are renally excreted in the healthy. HD dialysis patients have elevated plasma levels reminding of earlier findings of AGE proteins in these patients. High cut-off dialysis is the first intervention that proves to reduce these substances significantly from patient's plasma. This clears the way to interventional trials to better understand the relevance of free amino acid adducts in CKD.

Enhanced Suppressive Function of Tregs from ESKD Patients Using a New a High Cutoff HD Technique Pascal Meier. *Division of Nephrology, RSV - Hôpital du Valais, Sion, Switzerland.*

Background: Considering the effect of oxLDL accumulation on Tregs viability and function in chronic HD patients, a new generation of dialyzers, with very large pores (HCO 1100 Gambro), could be useful to clear oxLDL and thus improve Tregs survival and function. The aims of this study were to make *in vivo* assessments of several hemodialyzers (i.e. Polyflux 21 L – Polyflux 210 H [regular membranes: RM] *vs.* HCO [high cutoff] 1100) in plasma oxLDL clearing, and to analyze the Tregs suppressive function in ESKD patients.

Methods: Thirty ESKD patients on chronic HD (3 x 4 hours weekly) were studied in three equal groups during three months. Plasma and dialysate oxLDL concentrations were measured using a mAb-4E6–based ELISA. To determine the frequencies and phenotypes of Tregs, multicolor flow cytometry was performed. Apoptosis was indirectly assessed by Fas staining and flow cytometry and then confirmed by DNA fragmentation determination.

Results: Patients on RM exhibited elevated plasma level of oxLDL compared with HCO 1100 at three months (P = 0.002, ANOVA). In parallel, Tregs from patients on RM represented 1.34 to 1.73% of $CD4^+$ T cells whereas the frequency of Tregs in patients on HCO 1100 was 3.42±0.19%; P < 0.01. After PHA stimulation, increment in Tregs response was much more substantial in patients on HCO 1100 than in patients on RM. In

all experimental conditions, the apoptotic DNA fragmentation significantly increased in FAS-sorted Tregs from patients on RM compared with those on HCO 1100 (P = 0.005), in accordance with the decline in cell viability. Finally, Tregs from patients on RM did not efficiently suppress the proliferation of the co-cultured $CD4^+$/CD25- T cells (1:1; 21153±2045 cpm). In striking contrast, Tregs from patients on HCO 1100 were able to strongly inhibit the proliferation of $CD4^+$/CD25- responder T cells (1:1; 4172±382 cpm; P < 0.001). Unlike RM, the suppressive capacity of Tregs after one HCO 1100 HD session was significantly increased compared with that of Tregs before session.

Conclusions: In ESKD patients on chronic HD using HCO 1100, Tregs number, viability and suppression capacity were significantly improved compared with RM without significant side effects.

Monocyte Transcriptome Analysis in Hemodialysis Patients: Identification of a Role for a $CD16^+$ and $CX3CR1^+$ Subpopulation Eva Schepers, Annemieke Dhondt, Raymond C. Vanholder, Griet L.R.L. Glorieux. *Internal Medicine/Renal Division, University Hospital Gent, Gent, Belgium.*

Background: The risk for cardiovascular morbidity and mortality is increased in chronic kidney disease patients, whereby micro-inflammation plays an essential role. Numerous culprits have not yet been identified. In this study transcriptome analysis of monocytes was used to identify in an unbiased manner discriminative factors in hemodialysis (HD) patients.

Methods: Forty gender- and age-matched, non-diabetic, non-smoking subjects with a CRP<2mg/L were recruited, 9 healthy controls, 10 patients with GFR > 60 mL/min/1.73m^2 and a prevalent cardiovascular event (CVE), 11 patients on HD without prevalent cardiovascular event (HD) and 10 HD patients with prevalent cardiovascular event (HD/CVE). Monocytes were isolated, by a positive selection using MACS and submitted to transcriptome analysis using an in house-array containing ca. 700 genes associated with macrophage activation (Van den Berghe R et al: Retrovirol.7:53,2010)

Results: A significant differential expression was observed for FCGR3A (CD16;fold-change HD/CVE vs CVE; 2.73;p=0.005), CYTH1 (cytohesin 1;2.05;p=0.006), BMP2K (bmp2 inducible kinase;1.67;p=0.01) and CX3CR1 (chemokine receptor;1.53;p=0.049). For CD16 and for CX3CR1, this finding could be confirmed by qRT-PCR (HD and HD/CVE vs control and vs. CVE,p<0.05 and p<0.01,resp). Both CD16 and CX3CR1 relative expression correlated with CRP (r^2=0.1179;p<0.05 and r^2=0.3387;p<0.0001,resp). Flow cytometric analysis revealed a significant increase in the percentage CD16 positive monocytes both in the HD and HD/CVE group vs control and vs. CVE (p<0.01). No discrimination, based on CD16 expression, could be made between HD patients with or without cardiovascular disease.

Conclusions: The present study indicates the importance of pro-inflammatory $CD16^+$ monocyte subpopulation in HD patients who also have elevated CRP. The co-expressed chemokine receptor, CX3CR1, is involved in monocyte recruitment and survival in atherosclerotic plaques. For future, discriminative factors should be explored in well defined and purified monocyte subpopulations which play an important role in the inflammatory status of HD patients.

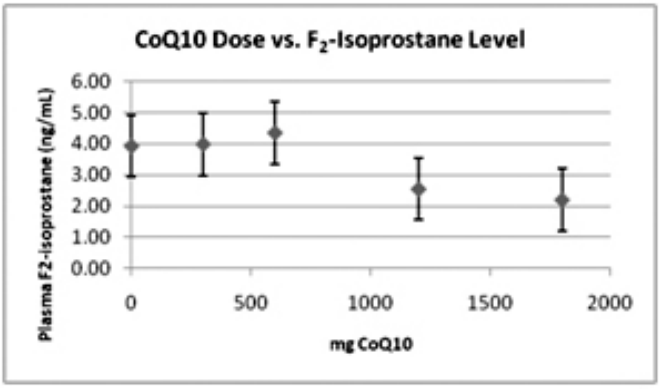
SA-PO2679

Safety, Tolerability, and Efficacy of the Dietary Supplement Coenzyme Q10 in Hemodialyisis Patients Catherine K. Yeung,[1] Adam Claessens,[1] Lori Linke,[2] Crystalyn Austin Clark,[2] Talat Alp Ikizler,[3] Danny D. Shen,[1] Jonathan Himmelfarb.[2] *[1]Department of Pharmacy, University of Washington, Seattle, WA; [2]Kidney Research Institute, University of Washington, Seattle, WA; [3]Division of Nephrology, Vanderbilt University, Nashville, TN.*

Background: Administration of coenzyme Q10 (CoQ10) has been shown to improve mitochondrial coupling of respiration to oxidative phosphorylation, improve oxidative stress, and may be associated with clinical cardiovascular benefits in diverse patient populations. To date, there are no studies evaluating the pharmacokinetics, safety tolerability and efficacy of CoQ10 administration in the hemodialysis population.

Methods: We performed a multiple ascending dose study in 20 hemodialysis patients. CoQ10 supplement (Vitaline) was successively administered at doses of 300 mg, 600 mg, 1200 mg, and 1800 mg for 14 days each. Safety and tolerability were assessed. Plasma CoQ10 concentrations were measured by LC/MS. Plasma F2-isoprostane concentration was measured by GC/MS to assess systemic oxidative stress.

Results: 15 of 20 subjects (75%) completed the entire sequence. CoQ10 supplementation was generally well tolerated and no severe adverse events were attributed to CoQ10. All laboratory values were within normal limits. CoQ10 was not significantly removed from circulation by hemodialysis. Mean Plasma F2-isoprostane concentration decreased following the 1200 and 1800 mg CoQ10 administration.



Conclusions: CoQ10 up to 1800 mg daily was shown to be safe and well tolerated in most subjects. The observed decrease in plasma levels of F2-isoprostanes suggests that CoQ10 is a promising antioxidant in dialysis patients. A double-blinded, randomized, placebo-controlled pilot study to assess the efficacy of CoQ10 in hemodialysis patients is warranted.

SA-PO2680

IL-17: A Novel Player in Peritoneal Dialysis Treatment Marta Ruiz-Ortega,[1] Raquel Rodrigues-Diez,[1] Luiz S. Aroeira,[2] José A. Jimenez,[2] Raúl R. Rodrigues Díez,[1] Sandra Rayego-Mateos,[1] Guadalupe González- Mateo,[2] Manuel Lopez-Cabrera,[2] Jesus Egido,[3] Alberto Ortiz,[3] Rafael Selgas.[2] *[1]Universidad Autonoma; [2]IDIPAZ; [3]ISCFJD, Madrid, Spain.*

Background: The classical view of the immune response regulation has been enlarged by the recent discovery of IL-17-producing T helper (Th) cells, named Th17 cells. Growing evidence suggests that IL-17, besides participating in immune-mediated diseases, is also involved in chronic inflammatory diseases. In peritoneal dialysis (PD) patients, a chronic inflammatory response and an imbalanced Th1/Th2 response have been described, but there is no data about the Th17 response.

Methods: Human peritoneal biopsies of PD patients were analyzed by immunohistochemistry. To study the regulation of Th17 responses in the peritoneal membrane an experimental PD model in mice, that resembles human situation, was done.

Results: In human peritoneal biopsies of PD patients, IL-17 expression associated to T lymphocyte infiltration was found. In the mice model, exposure of the peritoneum to PD fluid (PDF) for 7 days resulted in an inflammatory response, characterized by infiltrating T lymphocytes, including CD4+/IL-17 expressing cells in the submesothelial zone. Elevated gene and protein levels of IL-17 were found in the peritoneum of PDF-treated mice compared to untreated mice. In contrast, tissue levels of INF-γ and IL-4 (Th1 and Th2 hallmark cytokines, respectively) were not changed between groups. Th17 cell differentiation in mice is regulated by a combination of cytokines (IL-6 and TGF-β) and by several transcription factors (RORγt and STAT3). PDF-treated mice presented upregulation of TGF-β and IL-6, and activation of RORγt and STAT3 in peritoneum compared to controls. These data show an activation of the Th17 response in the peritoneum exposure to PDF. After 30 days of daily PDF instillation increased peritoneal thickness, angiogenesis and functional alterations were observed. At this time point, IL-17 levels remained elevated, both in the peritoneum and in the peritoneal lavage, correlated with peritoneal thickness.

Conclusions: These data suggest that local Th17 response could participate in dialysis-fluid induced damage to the peritoneal membrane.

SA-PO2681

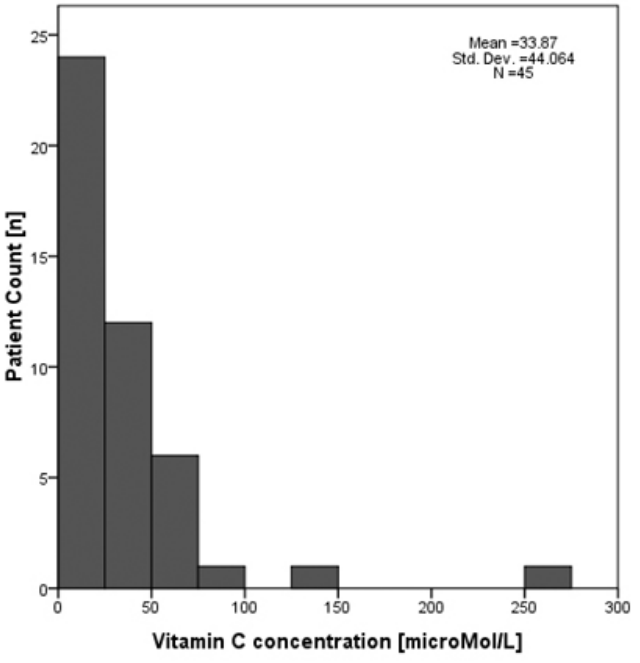
Ancillary Study to the Frequent Hemodialysis Network (FHN) Trial: Cross-Sectional Assessment of Vitamin C Concentrations in Chronic Hemodialysis Patients at Baseline Jochen G. Raimann,[1,2] Li Liu,[1,2] Samer Rateb Abbas,[1,2] Len A. Usvyat,[1] Stephan Thijssen,[1,2] Garry J. Handelman,[3] Peter Kotanko,[1,2] Nathan W. Levin,[1,2] And FHN Trial.[4] *[1]Renal Research Institute; [2]Beth Israel Medical Center; [3]University of Massachusetts; [4]NIDDK.*

Background: Vitamin C status in hemodialysis (HD) patients may be low because potassium-rich foods are restricted and potentially also because vitamin C is removed during dialysis. In the non HD population vitamin C levels are between 20-80 μmol/L and fatigue, as a first symptom of acute deficiency occurs below 20 μmol/L. Vitamin C deficiency has been associated with elevated oxidative stress, anemia and secondary hyperparathyroidism.

Methods: This analysis examined cross-sectional vitamin C levels in HD patients at baseline. Samples were taken prior to HD, processed with metaphosphoric acid as a preservative and immediately frozen at -70°C. Measurements were performed using HPLC. The Shapiro Wilk Test was used to test for normality.

Results: 45 chronic HD patients (age 49±12 years, 27 males, 31 blacks, body mass index 28.9±7.0 kg/m^2) were studied. The mean vitamin C concentration was 33.9±44.1 μmol/L, data was not normally distributed (**Figure 1**) and 22 patients (48.9 %) were below the level of 20 μmol/L where symptoms can be expected.

Conclusions: Vitamin C deficiency is frequent in HD patients. Almost 50% of the enrolled patients showed vitamin C levels below the symptom level. Associations with clinical parameters of anemia management, mineral and bone metabolism and inflammation require additional analyses.



SA-PO2682

Incidence and Mortality Risk Factors Associated with Non-Occlusive Mesenteric Ischaemia in Patients Undergoing Haemodialysis Borja Quiroga, Eduardo Verde, Soraya Abad, Almudena Vega, Marian Goicoechea, Javier Reque, Juan Manuel Lopez Gomez, Jose Luno. *Nephrology, Hospital Gregorio Marañón.*

Background: Non-occlusive mesenteric ischaemia (NOMI) is an emergent pathology in haemodialysis (HD) patients. Although it is associated with a poor outcome, it has not been studied enough.

Methods: A retrospective study was conducted between 2003 and 2011 in HD patients. During follow-up time, all cases of NOMI were registered, and demographic, clinical, biochemical and HD parameters were collected. Then, analysis was performed between this group and a control one (n=100). Risk factors associated with the NOMI development and prognosis were studied and survival curves were established between both groups.

Results: There were fifty-seven episodes of NOMI in 44 patients (mean age 72.9±8.9 years; 56% male). Thirty percent were diabetic. The incidence of NOMI was 2.29 episodes/100-patients/year. Cardiovascular risk factors were present in 72% of the patients. The patients with NOMI had leukocytosis (16945±4672/μL), mild acidosis (bicarbonate 22.6±4.3 mEq/L), even though the episodes were posthaemodialysis, and serum lactate (2.6±1.8 mg/dL), LDH (441±649 UI/L) and CPR (21.4±15.5 mg/dL) increase. The caecum was the most frequently (42%) affected segment, followed by diffuse bowel involvement. Nineteen patients (33%) were surgically treated. Twenty six patients (59%) did not survive the acute episode of NOMI.

Caecum damage was the only protective factor related with mortality in the univariate and multivariate analysis (RR 0.16; p=0.009). The incidence of NOMI was related to age (RR 1,11; p<0,001), diabetes mellitus (RR 2,61; p=0,037) and duration of dialysis (RR 1,01; p=0,006), when compared with the control group. Those patients who survived the acute episode (41%) were compared with the control group (47%), showing a higher mortality at 5-year follow-up (Log Rank 26.48; p<0.001).

Conclusions: NOMI is associated with age, diabetes mellitus and long time undergoing haemodialysis. Caecum damage is the most frequent location, but is related with better prognosis. Mortality is very high both in the acute episode and long-term.

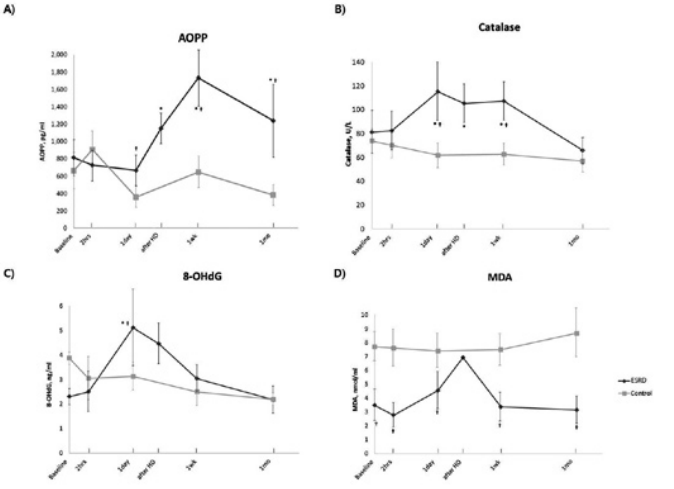
SA-PO2683

Iodinated Contrast Media Can Induce Long-Lasting Oxidative Stress in Hemodialysis Patients Soo Young Yoon, Seun Deuk Hwang, Yoon Ji Kim, Sang Heun Lee, Deok Kyu Cho, Yun Hyeong Cho, Sung Jin Moon, Sang Choel Lee. *Internal Medicine, Kwandong University, Goyang, Republic of Korea.*

Background: Due to their comorbidities, dialysis patients have many chances to undergo diagnostic and therapeutic procedures using iodinated contrast media. Iodinated contrast has been regarded as a safe agent in these patients who have little risk of contrast-induced nephropathy. Oxidative stress plays a major role in toxicity of contrast media. We hypothesized that contrast induces more severe systemic oxidative stress in hemodialysis (HD) patients than in non-dialysis population. We assessed time-sequenced blood oxidative stress level after contrast media exposure in anuric HD patients compared to those in the controls.

Methods: We included 21 anuric HD patients (ESRD group) and 23 controls (Control group) scheduled for coronary angiography (CAG) and assessed 4 oxidative stress markers (AOPP, advanced oxidation protein products; catalase; 8-OHdG, 8-hydroxydeoxyguanosine and MDA, malondialdehyde) before and after CAG, and subsequently up to 28 days.

Results: In the Control group, only AOPP increased immediately after CAG and returned to baseline within one day. However, in the ESRD group, AOPP, catalase and 8-OHdG significantly increased from one day after CAG, and remained elevated longer than in the Control group.



Changes in oxidative stress markers after coronary angiogram
* p<0.05 vs. baseline; † p<0.05 vs. Control

Conclusions: Our study showed that iodinated contrast media induces severe and prolonged oxidative stress in HD patients. Further studies are needed to determine the effectiveness of the preventive measures using antioxidants such as N-acetylcysteine.

SA-PO2684

Elevated Serum Osteoprotegerin Levels Are Associated with Inflammation, Malnutrition, and New-Onset Cardiovascular Events in Peritoneal Dialysis Patients Shin-Wook Kang, Mi Jung Lee, Dong Ho Shin, Seung Jun Kim, Dong Eun Yoo, Hyung Jung Oh, Seung Hyeok Han, Tae-Hyun Yoo. *Dept. of Int. Medicine, College of Medicine, BK21, SBSI, Yonsei Univ, Seoul, Korea.*

Background: Osteoprotegerin(OPG) has been known to be associated with cardiovascular events(CVE) and malnutrition in non-dialysis chronic kidney disease patients. Malnutrition-inflammation-atherosclerosis(MIA) syndrome is commonly found in dialysis patients, but the association between OPG levels and MIA syndrome has been largely unexplored in these patients. This cross-sectional study was undertaken to investigate the association between OPG levels and malnutrition, inflammation, and CVE in prevalent peritoneal dialysis(PD) patients.

Methods: A total of 176 prevalent PD patients were included. At baseline, OPG, hs-CRP, and albumin concentrations were measured. In addition, percent lean body mass(%LBM) was determined by creatinine kinetics. Subjective global assessment(SGA) was also performed. Based on the median levels of OPG, patients were divided into 2 groups, and CVE and patient survival were compared by Kaplan-Meier analysis. Moreover, Cox regression analysis was conducted to determine risk factors for CVE.

Results: Age, hs-CRP, and Charlson comorbidity indiex were significantly higher, while serum albumin levels, %LBM, and SGA score were significantly lower in patients with high OPG levels(H group) compared to patients with low OPG levels(L group). The rates of newly developed CVE were significantly higher in the H group compared to the L group(40.9 vs. 17%, P<0.01). Overall mortality rates were also higher in H group compared to L group, without statistical significance. Univariate Cox regression analysis revealed OPG as a risk factor for new-onset CVE(per an increase by 1 in log OPG; HR, 2.34; 95% CI, 1.35-4.04; P=0.002), which remained significant after adjustment for age, sex, diabetes, and PD duration(HR, 2.00; 95% CI, 1.13-3.89; P=0.02).

Conclusions: Serum OPG levels were significantly correlated with markers of systemic inflammation and malnutrition and was revealed as a significant predictor of new-onset CVE in PD patients, suggesting OPG might be a prognostic indicator of MIA syndrome in PD patients.

SA-PO2685

Circulating S100A12 (EN-RAGE) Levels Predict Cardiac Dysfunction by Tissue Doppler Echocardiography in Peritoneal Dialysis Patients Tae Yamamoto,[1] Shirley Yumi Hayashi,[1,2] Abdul Rashid Tony Qureshi,[1] Marcelo M. Nascimento,[1] Ayumu Nakashima,[1] Lars-åke Brodin,[2] Björn Anderstam,[1] Britta Lind,[2] Miguel C. Riella,[3] Astrid Seeberger,[1] Bengt Lindholm.[1] *[1]Renal Medicine and Baxter Novum, Karolinska Institute, Stockholm, Sweden; [2]Med Eng, School of Technol and Health, Royal Institute of Technology, Stockholm, Sweden; [3]Pro-Renal Foundation, Curitiba, Brazil.*

Background: Cardiovascular disease is common in patients (pts) on peritoneal dialysis (PD), and Tissue Doppler imaging (TDI) is a useful tool for assessing cardiac function. In PD pts, dialysis solutions may lead to formation of advanced glycation end-products (AGEs), which may result in cardiovascular toxicity. Therefore, we examined the possible link between circulating AGEs and cardiac function in PD pts.

Methods: Plasma concentrations of soluble form of receptor for AGEs (sRAGE), its ligand S100A12, and other biomarkers were measured in 51 pts undergoing PD. The myocardial systolic (PSV, peak systolic velocity) and diastolic (E', early diastolic velocities) velocities were assessed by TDI. M-mode echocardiography was also performed. Pts were divided into two groups by E' value.

Results: Among 51 pts, 95% (n=48) had diastolic dysfunction (E' <8.0 cm/s). The medium plasma levels of S100A12 and sRAGE were 64 ng/ml and 2594 pg/ml. S100A12 levels correlated with PSV and E', both of which were negatively associated with troponin-1 and left ventricular mass index. High E' group had lower S100A12 and higher sRAGE levels compared to low E' group, while other inflammatory and oxidative stress markers such as CRP, IL-6, TNF and 8OHdG did not differ. Stepwise multiple regression analysis identified S100A12 (β=-0.38, p=0.002) and age (β=-0.52, p<0.001) as independent determinants of E' in a model (r^2=0.40).

Predictors of early diastolic velocities (E', cm/s)

	Unadjusted (β, P) (r2=0.09)	Model 1 (β, P) (r2=0.38)	Model 2 (β, P) (r2=0.39)	Model 3 (β, P) (r2=0.40)
logS100A12	-0.33 (0.017)	-0.38 (0.001)	-0.41 (0.001)	-0.38 (0.002)
Age (years)		-0.55 (<0.001)	-0.53 (<0.001)	-0.52 (<0.001)
Albumin (g/dl)			0.16 (0.167)	0.15 (0.200)
Troponin-I				-0.12 (0.29)

Conclusions: Circulating S100A12 is an independent predictor for cardiac dysfunction in PD pts, suggesting an important role of AGEs.

Monocyte Chemoattractant Protein-1 Production Is Diminished by Mycophenolic Acid Mirjam Schuchardt,[1] Jasmin Pruefer,[1] Matthias Höhne,[2] Markus van der Giet,[1] Markus Tolle.[1] *[1]Med. Klinik mit SP Nephrologie, Charite - Campus Benajmin Franklin, Berlin, Germany; [2]Novartis Pharma AG, Nürnberg, Germany.*

Background: For the initiation and maintenance of atherogenesis or in transplant vasculopathy, the production of monocyte chemoattractant protein-1 (MCP-1) is crucial. There is evidence that the immunosuppressive regime influences vascular alterations. In the last years there is increasing evidence that mycophenolic acid (MPA), routinely used after kidney transplantation, is more than just an immunosuppressant. In this study we wanted to investigate the influence of MPA on the thrombin-induced MCP-1 production in vascular smooth muscle cells (VSMCs).

Methods: MCP-1 formation was measured via real-time PCR and Luminex™ technology. Superoxide production was detected in dihydroethidium (DHE)-labeled cells via fluorescence microscopy and quantified in a multimode-reader. H2O2 production was measured in 5,6-chloromethyl-2',7'-dichlorodihydrofluorescein diacetate acetyl ester (CM-H2DCFDA)-labeled cells via flow cytometry. Rac1 activation was detected via ELISA. NADPH consumption rate was measured photometrically.

Results: Thrombin induced MCP-1 expression and secretion in VSMCs. Costimulation with MPA dose-dependently and significantly decreased the thrombin-induced MCP-1 production. Next, we investigated the production of superoxide in DHE-labeled cells treated with thrombin ± MPA. MPA significantly diminished the superoxide production as well as the H2O2 production in H2DCFDA-labeled VSMCs. The NADPH oxidase is a dominant source of reactive oxygen species in the vasculature. Therefore, we measured the NADPH consumption. MPA significantly reduced the thrombin-induced NADPH consumption rate in VSMCs. To gain further evidence pointing to NADPH oxidase as target, we measured Rac1 activation. MPA significantly diminished the thrombin-induced Rac1 activation significant.

Conclusions: MPA attenuates the production of the pro-inflammatory chemokine MCP-1 in VSMCs, directing an anti-inflammatory effect of MPA in a redox-sensitive manner. In summary, MPA is not only an immunosuppressant substance, but might also play a relevant role in anti-inflammatory response.

SA-PO2687

Combined High Serum Ferritin and Low Iron Saturation Predicts Infection in Hemodialysis Patients André Fragoso, Ana Pinho, Anabela Malho, Ana Paula Silva, Elsa Morgado, Pedro Neves. *Nephrology, Hospital de Faro EPE, Faro, Portugal.*

Background: Serum ferritin is a classical marker of iron status and chronic inflammation. More recently, the combination of high serum ferritin and low iron saturation has been associated with inflammation. The aim of our paper was to study the relationship between these inflammatory markers and infection events.

Methods: We included all patients of a dialysis unit on treatment for more than 3 months by the 31st of January 2009. Patients were prospectively followed for 12 months and divided in two groups (G1: patients with infection events; G2: without infection events).

Results: We followed 169 patients (63,3% males) with a mean age of 61,87±16,32 years in hemodialysis for 73,26±112,14 months. G-1 patients showed lower serum iron (63,56±22,21 vs 75,70±29,01 mcg/dl; p<0,05), serum ferritin (527,42±246,65 vs 673,56±349,79 ng/ml; p<0,05) and iron saturation ratio (25,53±8,31 vs 34,06±23,13%; p<0,05). No differences were found between the two groups regarding CRP, albumin, BMI, KT/V and IV iron dose. In a logistic regression model, after adjustment for Diabetes, BMI, serum albumin and CRP, patients with combined high serum ferritin (>600ng/ml) and low iron saturation ratio (<25%) presented a 5-fold risk for an infection event (p=0,023).

Conclusions: In our population, known markers of chronic inflammation independently predicted infection events. To our knowledge this relationship has only been demonstrated in peritoneal dialysis patients. Further studies are needed to better understand the mechanisms that link inflammation to classical infection in the hemodialysis setting.

SA-PO2688

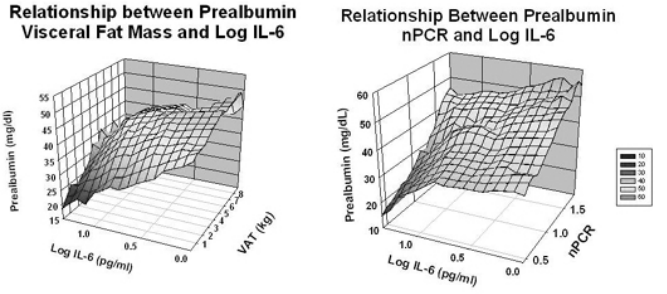
Prealbumin Is Associated with Visceral Fat Mass in Hemodialysis Patients George A. Kaysen,[1,4] Alessio Molfino,[1,2] Steven B. Heymsfield,[3] Fansan Zhu,[4] Peter Kotanko,[4] Nathan W. Levin.[4] *[1]Medicine, UC Davis, Davis, CA; [2]University of Rome, Italy; [3]PBRC, Baton Rouge, LA; [4]RRI, NY, NY.*

Background: Both Albumin (ALB) and Prealbumin (PreAlb) are associated with malnutrition and inflammation. Each have a residual effect on mortality outcomes when included in regression models that include the other. PreAlb, but not ALB is inversely associated with infectious and directly associated with vascular access hospitalizations. PreAlb has been reported to be increased in the obese mouse model as a consequence of stabilization of PreAlb by Retinol Binding Protein 4 (RTB4), secreted by adipocytes. We questioned if PreAlb was associated with adiposity in dialysis patients, independent of the effects of inflammation or nutrition.

Methods: We evaluated body composition in 48 prevalent hemodialysis (HD) patients by MRI, measuring total skeletal muscle mass (SM), visceral and subcutaneous adipose tissue (VAT and SAT), and serum ALB, PreAlb, RTB4, interleukin -6 (IL-6) concentrations. We used normalized protein catabolic rate (nPCR) to report nutrition and separately analyzed the determinants of ALB and then of PreAlb by multiple stepwise regression.

Results: 32 subjects were women, 16 were diabetic, median age 54.5, range 40-69, 10th 90th percentile). Median BMI 27.3, range 22.5-37.2 10th 90th percentile), Median TAT 24.3 kg range 11.5-40.1 kg 10th-90th percentile), Median VAT 3.25 kg range 0.5 5.8 kg 10th-90th percentile). PreAlb was positively associated with VAT (P = 0.002), and nPCR (P=0.0001) and RTB4 P = 0.05, and negatively associated with IL-6 (P<0.003) and white race (P< 0.001). r^2 for the model was 0.66.

Prealbumin is Independently Associated with Inflammation, Visceral Adiposity and nPCR



By contrast ALB was positively associated only with nPCR and negatively with Log IL=6. r^2 for the model was 0.18.

Conclusions: PreAlb, like ALB, is associated with markers of nutrition (nPCR) and inflammation (IL-6), but unlike ALB, PreAlb is strongly associated with adiposity.

SA-PO2689

Increase in Lymphocyte β-catenin, IL-10 and Cortisol Serum Levels May Play a Role in the Protection of the Central Nervous System Against the Inflammation in Hemodialysis Patients with Cognitive Impairment Sabrina Degaspari,[1] Geison Stein Meirelles Ramos,[2] João Paulo L.B. Martins,[2] Elzo R. Junior,[2] Carmen B. Tzanno-Martins,[2] Carolina D. Munhoz,[1] Cristoforo Scavone,[1] Elisa M. Kawamoto.[1,3] *[1]Pharmacology-ICB, USP, Brazil; [2]Cine; [3]Laboratory of Neurosciences, NIA, NIH; [4]Nephrology, URGS, Porto Alegre, Rio Grande do Sul, Brazil.*

Background: A high prevalence of cognitive impairment (CI) in hemodialysis patients (HD-P) is well established. Inflammatory process has been shown to be associated with chronic kidney disease and may play a role in the development of CI. WNT signaling has been described in pathological conditions, such as neuroinflammation, and recent data have suggested that WNT signaling could participate in anti-inflammatory response. The purpose of this study is to evaluate the role of cytokines and the WNT signaling in HD-P with or without CI.

Methods: Thirty six HD-P were submitted to cognition test through Modified Mini Exam of Mental State and Kidney Disease Quality of Life. Blood was collected before and after hemodialysis (HD) procedure. Serum was used to analyze IL-6, IL-10, TNF and cortisol levels by ELISA test. Lymphocytes were isolated to verify the WNT proteins by Western Blotting analysis.

Results: Forty percent of patients showed CI. We observed that IL-6 (control=7.1±0.4 pg/ml) and TNF (control=14.4±4.8 pg/ml) levels were increased in HD-P (IL-6=227.8±92.1 pg/ml*; TNF=53.7±9.4 pg/ml*) without CI before HD, whereas IL-10 (control=7.4±2.4 pg/ml) and cortisol (control=0.16±0.03 mg/dl) levels were increased in HD-P-CI before (IL-10=22.6±8.5 pg/ml*; cortisol=0.32±0.03 mg/dl*) and after (IL-10=32.4±9.1 pg/ml*; cortisol= 0.28±0.04 mg/dl*) HD (*p<0,05). We also observed an increase of β-catenin in lymphocytes of HD-P-CI compared with control and HD-P groups.

Conclusions: HD-P without CI show an increase in proinflammatory cytokines levels and the increase of IL-10 and cortisol in HD-P-CI could be an organic response against an inflammatory state. The increase of β-catenin in HD-P-CI demonstrates the activation of the canonical WNT signaling that may play a role in the protection of the central nervous system against the neuroinflammation.

SA-PO2690

Variations in the Prevalence of HIT Antibodies during the Period 2004-2011. Relevance to Heparin Contaminants Vinod K. Bansal,[1] Debra Hoppensteadt,[2] Jawed Fareed.[2] *[1]Nephrology, Loyola University Medical Center; [2]Pathology, Loyola University Medical Center; [3]Thoracic and Cardiovascular Surgery, Loyola University Medical Center.*

Background: During the period of November 2007 - April 2008 several batches of unfractionated heparin were recalled due to the unexpected adverse reactions. These heparins were characterized to contain such contaminants as oversulfated chondroitin sulfate and high molecular weight dermatan sulfate. Several centers also reported a high prevalence of heparin induced thrombocytopenia (HIT) during this time. In order to compare the prevalence of HIT antibodies in ESRD patients, plasma samples from different time periods were analyzed.

Methods: In conjunction with an ongoing program to investigate the prevalence of HIT antibody (HIT Ab) in ESRD, blood samples were collected from patients (n=53-89) on maintenance dialysis and retrospectively analyzed for the presence of these antibodies during the period February-April 2004-2011.Specified cut off levels were used to determine the positive and negative results. An ELISA method (GTI. Brookfield, WI) was used to quantitate the HIT antibodies.

Results: The prevalence of the HIT Ab during the period 2004-2011 was < 15% with the exception of 2007 where it was 35% and in 2008 it was 30%. A decreased prevalence was noted during the period 2009-2011 (13-15%). The antibody titers as quantified by optical density measurement were relatively higher during the year 2007 and 2008. Moreover, the subtyping of these antibodies in 2007 and 2008 showed a higher proportion of IgG subtype. Similar trends were noted in the prevalence of HIT antibodies when other methods to detect HIT antibodies were used.

Conclusions: The oversulfated glycosaminoglycans such as oversulfated chondroitin sulfate and other non-heparin glycosaminoglycan derivatives are most likely to contribute to this increased prevalence and seroconversion of HIT antibodies. These observations suggest that heparin contaminants have contributed to the higher prevalence of HIT antibodies during the period 2007-2008. The improved quality measures resulting in more purified heparins after this recall have resulted in a decreased prevalence of these antibodies.

SA-PO2691

Characteristics of T Cell Mediated Immunity in Patients with End-Stage Renal Disease Byung Ha Chung, In O Sun, Hoon Suk Park, Sun Ryoung Choi, Bumsoon Choi, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang. *Department of Internal Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea.*

Background: Patients with end-stage renal disease (ESRD) exhibit immune dysregulation, but the precise immunological profile has not been investigated fully. We evaluated T cell-associated immune characteristics in ESRD patients.

Methods: Thirty-eight ESRD patients (22 on hemodialysis (HD) and 16 in predialysis) and 24 healthy volunteers were included. We compared the laboratory findings and immune profiles associated with T cells in these patients.

Results: Among the effector T cell subset, the percentages of Th2 cells and Th17 cells were significantly higher in the ESRD group than in the healthy controls ($P<0.05$). The frequencies of Th1 cells did not differ significantly between these groups. The percentages of Th1, Th2 and Th17 cells did not differ significantly ($P>0.05$) between the two subgroups within the ESRD group. The $CCR4^{-}CCR6^{+}$ /$CD4^{+}$T cell percentage was also significantly higher in the ESRD group. The naïve T cell ($T_{naïve}$) percentage was significantly lower in the ESRD group, and the difference between patients and controls was greater in the predialysis patients than in the HD patients ($P<0.05$, for each comparison). By contrast, the percentages of central memory T cells (T_{CM}) and effector memory T (T_{EM}) cells were significantly higher in the ESRD group. Interleukin-17 production by T_{EM} cells was significantly higher in the ESRD group. The severity of uremia was related negatively to the $T_{naïve}$ cell percentage but positively to the T_{CM} and T_{EM} cell percentages. The percentages of T_{EM} and $CD45RA^{+}$ T effector memory subsets of $CD8^{+}$ T cells were significantly higher in the ESRD group ($P<0.05$).

Conclusions: The result of this study showed significantly altered T cell-associated immunity and that it could not be corrected with hemodialysis.

SA-PO2692

Insulin Resistance in Non-Diabetic, Non-Obese Patients on Peritoneal Dialysis Dong Eun Yoo, Seung Jun Kim, Hyung Jung Oh, Seung Hyeok Han, Tae-Hyun Yoo, Shin-Wook Kang, Dae-Suk Han. *Dept. of Int. Medicine, College of Medicine, BK21, SBSI, Yonsei Univ., Seoul, Korea.*

Background: Adipose tissue produces adipokines, which are closely associated with insulin resistance(IR). However, in patients with end-stage renal disease(ESRD), even though they are not obese, IR is commonly observed and is known to be attributed to uremia-associated factors, such as chronic inflammation and oxidative stress. This study was conducted to elucidate which factor, between adipokines or chronic inflammation, is more important in the pathogenesis of IR in non-diabetic, non-obese ESRD patients on peritoneal dialysis(PD).

Methods: This cross-sectional study included 55 non-diabetic, non-obese PD patients. Homeostatic model assessment-insulin resistance(HOMA-IR) was calculated, and leptin, adiponectin, high-sensitivity C-reactive protein(hsCRP), and IL-6 levels were measured. The patients were divided into 2 groups according to the median value of HOMA-IR, and clinical findings and laboratory data were compared between groups. Pearson's correlation analysis was performed to determine the relationship of clinical and laboratory data with HOMA-IR, and multiple linear regression analysis was used to identify independent factors associated with HOMA-IR.

Results: The mean age was 47.3 years, 50.9% were male, and the mean PD duration was 83.1 months. Male gender was significantly more prevalent, and hsCRP and IL-6 concentrations were significantly higher in patients with high HOMA-IR($p<0.05$). In addition, correlation analysis revealed that HOMA-IR was positively related to log hsCRP($r=0.499$, $p<0.001$), log IL-6($r=0.367$, $p=0.006$), and age($r=0.370$, $p=0.005$), whereas it was negatively correlated with Kt/Vurea($r=-0.296$, $p=0.031$). However, there was no correlation between HOMA-IR and adipokines, such as leptin and adiponectin. In multiple linear regression analysis, log hsCRP was the only significant independent factor associated with HOMA-IR(β±SE, 1.402±0.619; $p<0.05$).

Conclusions: This study shows that chronic inflammation rather than adipokines plays a major role in the pathogenesis of IR in non-diabetic, non-obese ESRD patients on PD, suggesting attenuating chronic inflammation may improve IR in these patients.

SA-PO2693

Kidney Failure Is Associated with an Imbalance between Pro- and Anti-Oxidant Agents Bertrand Gondouin,[1,2] Laetitia Dou,[2] Claire Cerini,[2] Stephane Burtey,[1,2] Philippe Brunet,[1,2] Regis Guieu,[3] Bertrand Dussol.[1] *[1]Service de Nephrologie et Transplantation Renale, Hôpital Conception, Marseille, France; [2]INSERM U 608, Faculté de Pharmacie, Marseille, France; [3]Service de Biochimie et Biologie Moleculaire, Hôpital la Timone, Marseille, France.*

Background: Patients with kidney failure display an accelerated atherosclerosis related to non-classical cardiovascular risk factors, including oxydative stress. Numerous studies have shown elevated levels of pro-oxidant agents whereas few studies have evaluated levels of antioxidant agents. This study evaluated the main parameters of oxidative stress in hemodialysis patients (HD).

Methods: Fifty non diabetic clinically stable HD, and thirty healthy subjects (HS) were included. HD were 30 male and 20 female, 66±15 years old with a dialysis vintage of 9±6 years. HS were 8 male and 22 females, 62±9 years old. We performed dosages of (i) anti-oxidant agents: super oxide dismutase (SOD), vitamins C, A, E, zinc (Zn), copper (Cu) and selenium (Se), (ii) pro-oxidant agents: malondialdehyde (MDA), ischemia modified albumin (IMA), and (iii) enzymes: xanthine oxidase (XO), red blood cells glutathione reductase (RBC-GR), and plasmatic glutathione reductase (P-GR). Results are expressed in mean +/- SD.

Results: Plasma levels of vitamin C (5.6±3.9 mg/L vs 16.7±7.1, $p<0.0001$), SOD (350±100 vs 416±65 U/g of Hb, $p<0.01$), Zn (69±14 vs 95±15 µg/dl, $p< 0.0001$), and Se (47±15 vs 73±17µg/L, $p <0.0001$) were lower in HD. Vitamin A levels were higher in HD (1.35±0.57 vs 0.73±0.17 mg/L, $p<0.0001$). Vitamin E and Cu were not statistically different.

Activities of RBC-GR (19.4±7.4 vs 10.2±3.3 U/g of Hb, p <0.0001), and XO (6.2±1.7 vs 5.0±1.3 µM/min, p<0.01) were higher in HD but not P-GR activity. MDA (256±72 vs 140±30 nmol/L, p<0.0001), and IMA (104±13 vs 90±9UI/L, p<0.0001) were higher in HD.

Conclusions: These results evidenced an imbalance in favour of oxidative stress in HD patients. The increased activity of xanthine oxidase led to the formation of numerous free radicals and its inhibition by allopurinol could be a therapeutic option to reduce oxidative stress in HD patients. A 2-years prospective follow-up is in progress to link those biological abnormalities to clinical events.

Funding: Government Support - Non-U.S.

SA-PO2694

Plasma Gelsolin Correlates with All Cause Hospitalization in Hemodialysis Patients Laura Rosales,[1] Yanna Dou,[1,2] Len A. Usvyat,[1] Georges Ouellet,[3] Stephan Thijssen,[1,2] Viktoriya Kuntsevich,[1,2] Mary Carter,[1] Nathan W. Levin,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, NY; [2]Beth Israel Medical Center, NY; [3]Maisonneuve-Rosemont Hospital, Montreal, Canada.*

Background: Plasma Gelsolin (pGNS) is a circulating protein that has been implicated in acute and chronic inflammation and tissue injury. Low pGNS may reflect the occurrence of clinical adverse events since its protective action at removing circulating actin declines. This prospective study explored the relationship between pGNS and hospitalizations (hosp) from all cause in hemodialysis (HD) patients (pat) over a 12 month period.

Methods: pGSN levels were determined with the 2C4 pGSN ELISA kit (Critical Biologics, Cambridge, MA) in maintenance HD pat from 2 HD centers; demographics (age, HD vintage, race, gender, BMI), co-morbidities: diabetes (DM), cardiovascular disease (CVD), HIV, and hepatitis C were recorded. Hosp and cause of admission were documented for 1 year. Cox proportional and Anderson Gill hazard models adjusted for age, gender, height, BMI, DM, vintage, HIV and hepatitis C status were used to compute hazard ratios (HR) for mortality, first and multiple hosp, and cause of admission such as CVD, infection and vascular access events.

Results: 104 stable HD pat followed for 1 year (mean±SD; age 61±15 years; HD vintage range 0.3-17.5 years; 52% female; 49% Blacks, 53% DM). pGSN was 195 mg/L ± 52.6 mg/L. pGSN quartiles were: Q1: <153.7 mg/L; Q2: 154.8-190.3 mg/L, Q3: 190.4 to 225.3 mg/L; Q4: > 225.4 mg/L.

In multivariate Cox analysis, Q1 of pGNS was associated with a high risk for all cause first hosp (HR 2.2, 95%CI 1.14 to 4.32, p<0.05).

Hazard ratio of pGNS for first hospitalization

Quartiles	HR	95% CI	P value
1	2.21	1.14 to 4.32	<0.05
2	1.19	0.59 to 2.39	0.62
3	1.00	0.49 to 2.05	0.99
4	1	reference	

In Anderson Gill analysis for multiple hosp the HR was not significant. Low pGNS did not show a significant relationship with mortality or cause of hosp.

Conclusions: Low pGNS levels in stable chronic HD pat were associated with time to first hosp from all causes; no relationship was found with recurrent hosp, cause of hosp, and mortality. In chronic HD pat pGNS may have a predicting value in the short term.

SA-PO2695

Influence of HCO1100™ – Dialysis Membrane on Monocyte Subpopulations and Soluble Inflammatory Parameters in Hemodialysis Patients with Elevated CRP Levels Roman Fiedler, Christof Ulrich, Felix Neugebauer, Eric Seibert, Matthias Girndt. *Department of Internal Medicine II, Martin-Luther-University Halle, Halle, Germany.*

Background: Chronically elevated CRP levels are a negative predictor for survival in hemodialysis (HD) patients because they indicate inflammation, atherosclerosis, and malnutrition. Inflammation-inducing cytokines are only insufficiently dialyzed due to their middle molecular weight (15-45 kD). As a result, cellular activation with enhanced levels of proinflammatory monocytes (CD14+CD16+, Mo3) and elevated ACE-expression (CD143) on this cells go along with high cardiovascular mortality in HD.

Methods: In a double-blind randomized crossover study we tested the impact of the High-cut-off (HCO)- Membrane 1100™ (Membrane B, Gambro, Hechingen, Germany) on removal of different cytokines (IL-1, IL-6, IL-10, TNFα) as well as on changes of the inflammatory monocyte subpopulation compared to the conventional high-flux membrane Polyflux 11S (Membrane A, Gambro, Hechingen, Germany). 17 patients (11 male, 6 female), aged 68.1 ± 10.9 years and on HD since 3.7 ± 2.8 years, were investigated over a study period of 2 weeks (6 HD consecutive sessions) on each membrane type. After normalisation data were analyzed by a one-way analysis of variance (ANOVA) for repeated measurements.

Results: Treatment with membrane B resulted in a non-significant decrease of Mo3 from 18.7 ± 7.4 to 17.7 ± 7.1 % (membrane A: 16.2 ± 7.7 to 17.9 ± 9.0 %, p=0.31) and in an increase of CD143-expression (MFI) from 11.2 ± 3.8 to 12.1 ± 5.5 (membrane A: 12.5 ± 5.1 to 12.0 ± 5.4 %, p=0.23). All other examined parameters were not different between both groups.

Conclusions: HCO 1100™ short-time dialysis treatment seems to be without effect on inflammatory parameters, at least regarding different important cytokines and pro-inflammatory monocyte subpopulations. Since trends indicate that the treatment intensity and duration might have been too low, additional studies with larger sample sizes and longer treatment duration are justified.

Funding: Government Support - Non-U.S.

SA-PO2696

Vitamin D Deficiency Is a Predictor of Inflammatory State in Hemodialysis Patients Syed Atif Mohiuddin, Omer H. Ali, Ravindra Rajakariar, Mark Blunden, Magdi Yaqoob. *Royal London Hospital.*

Background: High inflammatory burden is associated with morbidity and mortality in dialysis patients. Recent studies have indicated that vitamin D deficiency in dialysis patients may be associated with increased inflammatory markers which may be potentially reversed by vitamin D supplementation. In this cross sectional study we analysed the impact of vitamin D deficiency on inflammatory markers in a large multi ethnic cohort of haemodialysis patient in East London.

Methods: All patients admitted to the hospital or acute infections were excluded from the analysis. Vitamin D deficiency was defined as total 25 hydroxy vitamin D level less than 30 nmol/L, level between 30 and 79 defined insufficiency and level ≥80 was regarded as normal.

Results: 704 patients (32% Caucasian, 30% black,28% south Asian) were analysed. Results are shown in the table.

table1

	Normal	Insufficiency	Deficiency	Significance(p Value)
No (%)	115(16)	372(53)	217(31)	
Age±SD	58 ±16	60±14	56±15	0.27
Sex (male%)	58	64	53	0.04
Weight Kg±SD	70±18	73±18	70±19	0.9
Dialysis VintageYears±SD	3.2±2.7	3.1±2.6	3.8±2.6	<0.001
Dialysis catheter(%)	34	41	42	0.63
Mean Total Vitamin D nmol/l ±SD	118±31	47±13	21±5	<0.001
Mean PTH ±SD	43±42	47±42	53±60	0.09
Mean Calcium mmol/l±SD	2.34±0.18	2.29±0.19	2.29±0.2	0.01
Mean Phosphate mmol/l±SD	1.49±0.46	1.62±0.5	1.64±0.55	0.01
CRP>5 (%)	48	61	63	0.02
Albumin<35 g/l(%)	3	7	7	0.26
Mean KT/V±SD	1.55±0.26	1.5±0.32	1.55±0.35	0.9

Although there was no difference in albumin levels in different groups due to low prevalence of albumin deficiency, a strong association was found between low vitamin D levels and low albumin in regression analysis(p value <0.001). Vitamin D levels less than 80 nmol/l were also associated with high CRP levels (OR 1.75, p value 0.005). This association persisted after adjustment for comorbidity. A trend towards high PTH, low calcium and high phosphate was also seen with low vitamin D levels.

Conclusions: Vitamin D deficiency in haemodialysis population is associated with raised inflammatory markers. A multi-centre intervention study to look at the effect of vitamin D replacement on the inflammatory markers, morbidity and mortality is warranted.

SA-PO2697

Oral L-Carnitine Administration Could Lower Plasma Levels of Total Homocysteine in Patients on Hemodialysis Masataka Tsunoda,[1] Ryota Ikee,[2] Naomi Sasaki,[3] Megumi Sato,[4] Nobuo Hashimoto.[3] *[1]H. N. Medic Sapporo-Higashi, Sapporo, Japan; [2]H. N. Medic Kitahiroshima, Kitahiroshima, Japan; [3]H. N. Medic, Sapporo, Japan; [4]Jinzonaika Megumi Clinic, Sapporo, Japan.*

Background: Hyperhomocysteinemia has been consistently demonstrated in patients with renal failure. Recent studies suggested that increased levels of total homocysteine (tHcy) may result in both atherosclerosis and osteoporosis in HD- and non-HD patients through increased oxidant stress. On the other hand, there are some reports suggesting that L-carnitine may have antioxidant and anti-inflammatory properties. In this retrospective cohort study, we investigated effect of L-carnitine administration on clinical parameters including tHcy in HD patients.

Methods: We enrolled 10 males and 7 females treated with HD for at least 1 year (age 65 ± 11 years, HD duration 166 ± 137 months) to this study. L-carnitine was orally administered at 300 mg before each dialysis session. Plasma levels of tHcy, white blood cell (WBC) count, hemoglobin (Hb), albumin (Alb), high sensitivity C-reactive protein (hsCRP), and lipid profile (total cholesterol [TC], triglyceride [TG], and high-density lipoprotein cholesterol [HDL-C]) were evaluated every 3 months for 6 months.

Results: The mean value of tHcy at baseline was 61.8 ± 40.8 nmol/mL. After L-carnitine administration, plasma levels of tHcy significantly decreased. The mean reduction of tHcy at month 6 was 21.3 ± 20.0%, and the maximum reduction was 70.9%. Other parameters did not change during this follow-up period (Table 1).

Table 1. Effects of L-carnitine administration in HD patients.

	Baseline	Month 3	Month 6
tHcy (nmol/mL)	61.8 ± 40.8	56.8 ± 34.5*	47.7 ± 24.7*
WBC count (/µL)	5538 ± 1696	6581 ± 4420	5639 ± 1859
Hb (g/dL)	11.4 ± 0.92	11.3 ± 1.05	11.2 ± 0.58
Alb (g/dL)	3.86 ± 0.38	3.79 ± 0.37	3.76 ± 0.31
hsCRP (mg/dL)	0.09 ± 0.16	0.38 ± 0.94	0.18 ± 0.34
TC (mg/dL)	138 ± 31	140 ± 30	138 ± 34
TG (mg/dL)	108 ± 49	112 ± 40	115 ± 41
HDL-C (mg/dL)	46 ± 12	47 ± 13	46 ± 13

*p<0.05 compared with baseline.

Conclusions: We found a significant reduction of plasma tHcy levels after L-carnitine administration in HD patients. L-carnitine may prevent atherosclerosis and bone fracture by reducing plasma tHcy.

SA-PO2698

Electronegative LDL and Its Autoantibodies Correlated with Inflammatory Markers in Hemodialysed Patients Julie Lobo,[1] Milena Barcza Stockler-Pinto,[1] Najla Elias Farage,[2] Tanize Do Espirito Santo Faulin,[4] Dulcinéia Saes Parra Abdalla,[4] João Paulo Torres,[1] Denis Fouque,[5] Denise Mafra.[3] *[1]Federal Univ. of Rio de Janeiro, Brazil; [2]RenalCor Clinic, Brazil; [3]Federal Univ. Fluminense, Brazil; [4]Université Claude Bernard, Lyon, France; [5]University of São Paulo, Brazil.*

Background: A modified circulating electronegative LDL subfraction [LDL (-)], which has chemotactic, cytotoxic and immunogenic properties, is increased in hemodialysis (HD) patients and has been implicated in inflammation and atherosclerosis. However, antibody against LDL(-) may play a protect role, although the mechanisms involved have not yet been elucidated. Our aim was to investigate the association between LDL(-) and anti LDL(-) autoantibodies with inflammatory markers in HD patients.

Methods: Forth seven HD patients (29M/18F; 54.3 ± 12.6 yr, body mass index (BMI) 24.4 ± 4.1 Kg/m^2, average dialysis time 57.5 ± 50.1 months) from a private Clinic in Rio de Janeiro, Brazil, were studied and compared to 20 healthy subjects (9M/11F, 51.6 ± 15.6 yr, BMI 25.5 ± 3.9 Kg/m^2). LDL(-) and Anti LDL(-) IgG autoantibodies were determined by ELISA. TNF-α, IL-6, VCAM-1 and ICAM-1 were measured by a multiplex assay kit manufacture by R&D Systems®. The SPSS (version 11.0) was used as statistical program.

Results: HD patients present higher levels of inflammation and LDL(-) and lower levels of anti LDL(-) IgG autoantibodies when compared with health subjects (Table 1). There was a positive correlation between LDL(-) and IL-6 (r=0.25, p=0.004) and ICAM-1 (r=0.36; p=0.003) and a negative correlation between anti-LDL(-) autoantibodies and TNF-α (r=-0.37; p=0.003) and VCAM-1 (r=-0.50; p= 0.0001).

Table 1: Biochemical characteristics of the HD patients and healthy individuals

Parameters	HD Patients	Healthy individuals
LDL(-) (U/L)	0.32 ± 0.30*	0.09 ± 0.10
Anti LDL(-) (mg/L)	0.02 ± 0.01*	0.05 ±0.03
TNF-α (pg/ml)	5.5 ± 2.1*	2.4 ± 1.1
IL-6 (pg/ml)	4.1 ± 1.6*	2.6 ± 0.2
VCAM-1 (ng/mL)	48.5 ± 8.5*	23.8 ± 5.5
ICAM-1 (ng/mL)	20.5 ± 15.9*	7.2 ± 1.2

* p<0.04.

Conclusions: Our data seem to suggest that the association between LDL(-) and inflammation and the lower levels of anti-LDL(-) autoantibodies are important risk factors related to atherosclerosis in CKD.

Novel Anti-Inflammatory Natural Products: Potential Agents for Reducing Inflammatory Signaling during Hemodialysis (HD) Thomas A. Vander Jagt, Lucy A. Hunsaker, David L. Vander Jagt, Vallabh O. Shah. *Uni of New Mexico.*

Background: The process of hemodialysis produces oxidative stress and secretion of pro-inflammatory agents, resulting in chronic low-grade inflammation in patients undergoing hemodialysis. Chronic inflammation can lead to downstream risks of CVD which are linked to increased patient mortality. Bacterial contamination of dialysis media and/or equipment or physical progression of blood leukocytes past artificial surfaces can initiate proinflammatory reactions. Several factors may contribute to the inflammatory response during HD, such as activation of the pro-inflammatory transcription factor NF-κB in leukocytes. Recently, we used lipopolysaccharide (LPS) stimulation of blood leukocytes to screen a natural product library (TimTec480) in order to identify novel anti-inflammatory agents ideally for use in dialysis media (Shah et al. 2010; Shah et al. 2011). These initial studies identified cardiac glycosides (strophanthidin, oubain, proscillaridin A, digoxin, digitoxin and lanatoside C) as inhibitors of the activation of NF-kB that also prevent expression of TNFα and other pro-inflammatory cytokines in whole blood in response to LPS.

Methods: In the current study a natural product library from Green Pharma (GPNCL240) was initially screened for inhibition of LPS-induced TNFα secretion in whole blood at 4 μg/ml. Agents that significantly prevented TNFα secretion were then screened using a luciferase reporter assay to determine whether these natural products also inhibited the activation of NF-κB.

Results: Two natural products (taspine and 10- hydroxy-camptothecin) were identified from this library. Both taspine and 10-hydroxy-camptothecin, similar to the cardiac glycosides, demonstrate low micro-molar IC50 values for inhibition of TNFα secretion in whole blood in response to LPS and for inhibition of NF-κB activation in reporter assays.

Conclusions: The mechanism appears mainly to involve inhibition of the activation of pro-inflammatory NF-kB. It appears reasonable to propose that a safe natural product can be identified that can be added to dialysis media to protect blood leukocytes and reduce chronic inflammatory signaling during hemodialysis.

SA-PO2700

Vascular Calcification: Is There a Role for Ferritin? André Fragoso, Ana Pinho, Anabela Malho, Ana Paula Silva, Elsa Morgado, Pedro Neves. *Nephrology Department, Hospital de Faro, Epe, Faro, Portugal.*

Background: Vascular calcification predicts cardiovascular events and death in ESRD patients. The aim of our study was to identify predictors of vascular calcification in our hemodialysis population.

Methods: We included all patients of a dialysis unit on treatment for more than 3 months by the 31st of January 2009. Patients were prospectively followed for 12 months. Vascular calcification was assessed and the population divided in two groups according to the Adragão score (G-1: score < 2; G-2: score ≥ 2.

Results: We followed 169 patients (63,3% males) with a mean age of 61,87±16,32 years in hemodialysis for 73,26 ±112,14 months. G-2 patients were older (65,60 ±13,86 vs 56,89±18,23 years, p = 0,001) and showed higher levels of ferritin (723,50±340,90 vs 569,31± 313,94 ng/ml, p= 0,003) despite lower IV iron doses (39,80±36,78 vs 53,64±40,69 mg/week, p= 0,023). The number of received RBC units was also higher (5,37± 10,23 vs 2,63 ± 3,43 units, p= 0,033) in the G-2. Additionally, these patients showed lower levels of serum Pi (4,14 ±1,06 vs 4,61 ±1,44 mg/dl, p= 0,019) and albumin (4,16±0,29 vs 4,33±0,33 g/dl; p= 0,001). Furthermore, the number of hospital admissions (0,93±1,20 vs 0,50±0,82 adm/patient, p=0,011) and mean in-hospital stay (5,19±8,9 vs 1,49±3,30 days, p = 0,001) were higher in the G-2 group. In a logistic regression model each ferritin quartile represented a 1.4-fold risk for a vascular calcification score ≥ 2 (p = 0,014; 95% CI: 1,079-1,957), which in turn represented a 1.3-fold risk for cardiovascular events (p=0,012, 95% CI: 1,062-1,640).

Conclusions: Vascular calcification is a known risk factor for cardiovascular events in the renal population. The encountered relationship between ferritin and vascular calcification puts inflammation and oxidative stress as central players in the genesis of cardiovascular disease.

SA-PO2701

Low Free Triiodothyronine and Hospitalization in Chronic Hemodialysis Patients Yanna Dou,[1,2] Laura Rosales,[1] Len A. Usvyat,[1] Georges Ouellet,[1,2,3] Stephan Thijssen,[1,2] Mary Carter,[1] Nathan W. Levin,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York; [2]Beth Israel Medical Center, New York; [3]Maisonneuve-Rosemont Hospital, Canada.*

Background: Low levels of free triiodothyronine (fT3) are associated with inflammation, cardiovascular disease and mortality in hemodialysis (HD) patients. This study investigates the relationship between fT3 and multiple hospitalizations (hosp), first hosp and the cause of first hosp (cardiovascular events, infection) in HD patients.

Methods: In this prospective study chronic HD patients were recruited from two HD centers. fT3 was measured pre-HD at baseline by direct chemiluminescense (ADVIA Centaur, Deer field, IL). Mortality, time to first hosp, the cause of first hosp and multiple hosp were analyzed by Cox proportional and Andersen-Gill hazard models adjusted for age, gender, height, BMI, diabetes, dialysis vintage, HIV and hepatitis C status.

Results: 104 chronic HD patients were studied (54 females; 51 blacks; 55 diabetes; mean age 61±15 years). Mean level of fT3 was 2.4±0.4 pg/ml (normal range 2.27 to 4.22 pg/ml). During one-year follow up, 9 patients died and 191 hosp events occurred. In multivariate hazards model analysis, only Q1 of fT3 was associated with an increased risk of both time to first hosp and multiple hosp.

Hazard Ratio (HR) of fT3 for hospitalization

Quartiles of fT3 [pg/mL]	HR for first hosp	95% CI	P value	HR for multiple hosp	P value
Q1: <2.2	3.03	1.47 - 6.27	<0.01	2.4	0.02
Q2: 2.2-2.4	1.55	0.72 - 3.34	0.26	1.4	0.32
Q3: 2.4-2.6	2.20	0.93 - 5.17	0.07	2.56	0.02
Q4: >2.6	reference				

Q1 of fT3 did not show a significant relationship with mortality or cause of hospitalization.

Conclusions: Low fT3 level is an independent predictor of all-cause hospitalization in chronic HD patients.

SA-PO2702

The Immunosuppressivum 6-mercaptopurine Increases Calcification of Vascular Smooth Muscle Cells Jasmin Pruefer,[1] Mirjam Schuchardt,[1] Markus Tolle,[1] Matthias Höhne,[2] Markus van der Giet.[1] *[1]Med. Klinik mit SP Nephrologie, Charite - Campus Benjamin Franklin, Berlin, Germany; [2]Novartis Pharma AG, Nürnberg, Germany.*

Background: The cardiovascular mortality is dramatically increased in patients with chronic kidney disease and kidney transplanted patients. Vascular alterations like arteriosclerosis contribute to the increased cardiovascular risk. The mineralization process in the vascular wall is characterized by an transformation of vascular smooth muscle cells in the media to osteochondrocyte-like cells. There is evidence that different immunosuppressive therapy affect the development of arteriosclerosis. In this study we investigated the influence of 6-mercaptopurine on the mineralization process of rat vascular smooth muscle cells (VSMCs).

Methods: In vitro calcification in rat VSMCs were induced with calcification medium (CM). Calcium deposition was monitored by Alizarin staining and quantified by O-cresolphthalein complexone method. ALP gene expression was measured by real-time PCR.

Results: Cultivation of VSMCs in CM in vitro induced mineralization of VSMCs visualized by Alizarin Red staining quantified by measuring the extracellular calcium content. This process could be time-dependently and significantly increased in the presence of 6-MP [100 μmol/L]. To verify this effect, we used aortic rings and stimulated it for 14 days in CM±6-MP ex vivo. 6-MP could significantly increase the calcium content of the aortic rings compared to CM alone. For the precipitation of calcium phosphate, the activation of alkaline phosphate (ALP) is necessary. CM led to a significant increase in ALP enzyme activity, which is enhanced by pretreatment with 6-MP. Besides ALP activity, ALP expression was investigated. The 6-MP-induced ALP expression is significantly and dose-dependently increased in VSMCs after 48 h.

Conclusions: 6-MP treatment increases the mineralization of VSMCs in vitro and ex vivo. The data let suggest that 6-MP treatment may contribute to the high cardiovascular risk by enhancing vascular mineralization and arterial stiffening.

SA-PO2703

Eosinophilia after an Initiation of Dialysis Is Associated with Cardiovascular Morbidity and Mortality Jung-Hwa Ryu, Kyungjin Kim, Mina Yu, Dong-Ryeol Ryu, Seung-Jung Kim, Kyu Bok Choi, Duk-Hee Kang. *Division of Nephrology, Department of Internal Medicine, Ewha Womans University School of Medicine, Seoul, Republic of Korea.*

Background: Dialysis-associated eosinophilia(DAE) has been reported frequently with incidence of 19~57%, however the clinical significance of DAE is not determined, especially in terms of the association of DAE with morbidity or mortality. In this study, we investigated the incidence of DAE, factors determining the development of DAE and an association of DAE with cardiovascular disease(CVD).

Methods: One hundred sixty seven patients on dialysis(HD or PD) more than 3M at Ewha Medical Center with available data on eosinophil count before and after 3 and 12M from an initiation of dialysis were enrolled(M:F=72:85, age 60.3 years, dialysis duration 50.8M). Eosinophilia is defined as a presence of eosinophil>5% of peripheral leukocytes or eosinophil count>350/mm^3. Definition of DAE was new development of eosinophilia after an initiation of dialysis at 3M(DAE3), 12M(DAE12), and both initial 3 and 12M(DAE3+12).

Results: DAE was observed in 50 patients(29.9%) with a comparable incidence in HD(30.2%) and PD(28.8%). There was no association of eosinophil count with age, gender, underlying renal disease, history of allergy or asthma or any specific medication. Subject with DAE had higher prevalence of CVD compared to DAE(-) subject. In subgroup analysis, both all-cause and cardiovascular mortality was higher in DAE12 compared to DAE(-) subject(all-cause: 58.8% vs. 24.3%, p=0.006, cardiovascular: 35.3% vs. 7.1%, p=0.006). Interestingly, all-cause and cardiovascular mortality of subject with DAE12 was significantly higher than subject with DAE3 or DAE3+12. In multiple regression analysis adjusted by age, gender, diabetes, and hypertension, DAE12 was an independent risk factor for both overall and cardiovascular mortality(overall: OR4.577, 95%CI; 1.284-16.311, cardiovascular: OR5.255, 95%CI 1.405-19.657). Kaplan-Meier survival analysis also revealed a lower survival rate in subject with DAE12(p=0.025) compared to other groups.

Conclusions: These results suggest that the development of late-onset eosinophilia may be associated with cardiovascular morbidity and mortality.

SA-PO2704

Genotype/Phenotype Correlation in FHHNC Caused by Mutations in Either CLDN16 or CLDN19: Long-Term Follow-Up in 125 Patients Lea Haisch,[1] Karl P. Schlingmann,[1] Bodo B. Beck,[2] Pierre Cochat,[3] Martin Konrad.[1] *[1]University Children's Hospital, Muenster, Germany; [2]University Children's Hospital, Cologne, Germany; [3]Edouard-Herriot Hospital, Lyon, France.*

Background: Familial hypomagnesemia with hypercalciuria and nephrocalcinosis (FHHNC) is a tubular disorder caused by mutations in genes coding for the tight junction proteins Claudin-16 and Claudin-19. Both proteins play a pivotal role for the paracellular reabsorption of cations in the thick ascending limb. Interestingly, FHHNC leads to chronic renal failure and may be associated with extrarenal symptoms. This study compared the clinical course of FHHNC caused by mutations in CLDN16 or CLDN19.

Methods: We investigated 125 patients with FHHNC (CLDN16, n=100; CLDN19, n=25). We identified 20 different mutations in CLDN16 and 7 in CLDN19 including 6 novel mutations. We developed a standardized questionnaire to assess the long-term clinical course. Heterologous expression studies were carried out to investigate the cellular localization of the novel mutations.

Results: Immunohistostainings showed that most of the new mutants were retained in subcellular compartments. The decline in renal function showed no significant difference between the two cohorts, with a tendency toward a slower progression in CLDN19 patients (0.35 ml GFR loss/year vs 3,8 ml in CLDN16). Polyuria/polydipsia, an additional symptom in FHHNC, was reported by 85% of all patients, but salt craving (CLDN19: 57%; CLDN16: 8%; $p < 0.01$) and bedtime drinking (CLDN19: 75%; CLDN16: 45%; $p < 0,05$) significantly differed between the groups. 63% of all patients reported urinary tract infections without a difference between the two cohorts or gender. Most patients with CLDN19 defects seeked medical assistance for eye involvement which was the first symptom of FHHNC in this group. Moreover, 11/13 patients with CLDN19 defects showed retinal abnormalities compared to 0/19 of CLDN16 patients with documented fundoscopy.

Conclusions: Clinical course of FHHNC depends on the genotype. FHHNC due to defects in CLDN19 differs from CLDN16 not only by the ocular involvement but also by a more pronounced renal salt loss and a slower progression of chronic renal failure.

SA-PO2705

Significance of Henle's Loop as a Responsible Nephron Segment of Impaired Mg Reabsorption in Renal Interstitial Damages Taisuke Shimizu, Hajime Hasegawa, Kaori Takayanagi, Yosuke Tayama, Juko Asakura, Takatsugu Iwashita, Koichi Kanozawa, Yuta Kogure, Tota Kiba, Shimpei Okazaki, Minoru Hatano, Tetsuya Mitarai. *Dept of Nephrol & Hypertens, Saitama Med Center, Saitama Med Univ, Kawagoe, saitama, Japan.*

Background: Hypermagnesiuria-induced hypomagnesemia is known to be occasionally developed in renal interstitial disorders (RID), and has been demonstrated to be correlated with severity of interstitial damages, suggesting that evaluation of hypermagnesiuria might be a clinical parameter of RID which frequently lacks significant urine abnormalities. In kidney, it is known that Mg is reabsorbed in mTAL by 70% of filtered Mg and in DCT by 10%. The aim of this study is to elucidate the responsible tubular segment for impaired Mg reabsorption in RID by use of unilateral ureter obstruction (UUO) model.

Methods: Kidneys were sampled 1 week after ligation of left ureter of male SD rats. Interstitial damages and changes in expression of Mg transporting molecules were assessed by histological analysis, immunohistochemistry and RT-PCR in control (C) and obstructed (O) groups.

Results: In results, studies of ratio of interstitial area (C: 0.19, O: 0.32), number of ED-1 positive cells (C: 32.5, O: 235.8/field), expression of MCP-1 (C: 105.0, O: 302.6%), and expression of TGF-beta (C: 101.1, O: 338.9%) revealed development of significant RID in O group in addition to an increase in FEMg (C: 2.1, O: 12.7%). The expression of Mg transporting molecules in mTAL showed significant decrease (C:100.3, O:59.3% in paracellin-1, C:103.1, O: 8.38% in NKCC2), whereas those in DCT, including TRP6, 7 and NCC, were not changed. Those results of gene expression were agreed with immunohistochemistry.

Conclusions: In conclusion, obtained results may suggest that the responsible tubular segment of impaired Mg reabsorption in RID would be mTAL, not DCT. Decreased expression of paracellin-1 in tight junction of mTAL, resulting in the decreased trans-tubular Mg permeability, might be implicated in the impaired Mg reabsorption associated with diminished driving force of Mg transport by suppression of lumen-positive charge due to decreased NKCC2 expression.

SA-PO2706

Genome-Wide Association Study Identifies Multiple Novel Common Variants Associated with Serum Calcium Concentration Conall M. O'Seaghdha,[1] Karen Kapur,[2] Qiong Yang,[3] Ian Deary,[4] Caroline Hayward,[6] Anna Kottgen,[7] Lorna Lopez,[4] David Siscovick,[9] Toshiko Tanaka,[10] Alexander Teumer,[11] Veronique I. Vitart,[6] Caroline S. Fox,[1] Murielle Bochud.[2] *[1]NHLBI's Framingham Heart Study; [2]University of Lausanne, Switzerland; [3]Boston University; [4]University of Edinburgh, United Kingdom; [5]University of Rotterdam, Netherlands; [6]MRCHGU, Edinburgh, United Kingdom; [7]Freiburg University, Germany; [8]Inst. Pop. Genetics, Italy; [9]Cardiovascular Health Research Unit, Seattle; [10]National Institute on Aging, Baltimore; [11]University of Greifswald, Germany.*

Background: Serum calcium levels are highly heritable. Genome-wide association studies (GWAS) have recently demonstrated association of SNPs within the calcium-sensing receptor gene (CASR) with serum calcium levels. However, the role of common genetic variation in calcium homeostasis is largely undetermined.

Methods: We performed GWAS in 17 population-based studies (n=47718) to identify common genetic variation associated with serum calcium level. The analysis was performed in 39400 individuals of European ancestry and 8318 of Asian ancestry for ~2.5 million genotyped and imputed single-nucleotide polymorphisms, adjusted for age, sex and study center.

Results: We confirmed the previously identified association of rs1801725 in the CASR gene; serum calcium levels were 0.07 mg/dL higher per copy of the minor allele. We also identified 7 new loci (p-value range 4.80 x10-08 to 2.53 x 10-12), at 2q37.1, 2p23.3, 6q13, 7q11.21, 10p14, 11p15.4 and 20q13.2. These SNPs identify several potential loci of interest, including genes related to the metabolism of vitamins D (CYP24A1) and K (VKORC1-L1). Results were similar for albumin-corrected calcium and were reproducible between European and Asian populations.

Conclusions: We have identified several common novel loci that are associated with calcium concentration in European and Asian adult populations. While preliminary and in need of independent replication, these findings highlight known pathways and suggest several novel pathways in association with calcium homeostasis.

SA-PO2707

Post-Hepatectomy Hypophosphatemia in Rats Kengo Nomura, Sawako Tatsumi, Yuji Shiozaki, Seiichi Yamaguchi, Tatsuya Kamatani, Hiroko Segawa, Shinsuke Kido, Ken-Ichi Miyamoto. *Molecular Nutrition, University of Tokushima, Tokushima, Japan.*

Background: Significant hypophosphatemia is common after major hepatic resection. Recently, the increase of renal fractional excretion of phosphate (FE Pi) has been reported to implicate in post-hepatectomy hypophosphatemia. In order to clarify the mechanism of hypophosphatemia caused by hepatectomy, we investigated rats received a partial hepatectomy (PH; about 70%).

Methods: We used male Wistar rats (9 wk old) for experiments. Thyroparathyroidectomy (TPTX) surgery was performed on male Wistar rats (6 wk old), which were purchased from SLC (Shizuoka, Japan). The blood and urine biochemical marker were measured before and on postoperative hours 6, 12, 24 in PH and sham rats. The expression of NaPi-IIa and NaPi-IIc in renal proximal tubules were analyzed by western blotting and immunohistochemistry.

Results: Within 24 hours after PH, serum phosphate levels were significantly decreased in PH rats. Urine Pi/creatinine ratio and FE Pi levels markedly increased. These results are consistent with hepatectomy patients. The Na+ -dependent phosphate uptake in renal brush border membrane vesicle declined about 40-50% at 6 hours after PH. Indeed, the amounts of NaPi-IIa and NaPi-IIc protein were significantly decreased in the PH rats.

The levels of serum fibroblast growth factor 23 (FGF23) were decreased about 50%, but the intact parathyroid hormone (PTH) concentration significantly increased in 6 hours after PH. To verify whether elevation of plasma PTH after PH causes hypophosphatemia, we analyzed the effects of PH on thyroparathyroidectomy (TPTX) rats. The present study showed that PH-TPTX rats still exhibited hypophosphatemia with down-regulation of NaPi-IIa and NaPi-IIc transporters.

Conclusions: These results imply that other factors rather than FGF23 and PTH, may contribute hypophosphatemia in PH rats.

Funding: Government Support - Non-U.S.

SA-PO2708

Estrogen Causes Phosphaturia through Specific Downregulation of NaPi-IIa and Via the Activation of Both Estrogen Receptors ERα and ERβ Faraaz Siddiqui,[1] Moshe Levi,[2] Hassane Amlal.[1] *[1]Internal Medicine, University of Cincinnati, OH; [2]Internal Medicine, University of Colorado Health Sciences Center, Denver, CO.*

Background: We have previously demonstrated that estrogen (E2) treatment of ovariectomized (OVX) rats caused a significant urinary Pi wasting and hypophosphatemia. This effect resulted from downregulation of apical sodium-dependent phosphate cotransporter (NaPi-IIa). However, the effects of E2 on other Pi transporters and the respective roles of estrogen receptors ERα and ERβ in this effect remain unknown.

Methods: To address these issues, we first examined whether ERα and ERβ are expressed in the kidney proximal tubule using RT-PCR and immunoblotting. Next, and because of the anorexic effect of E2 or the activation of ERα vs. ERβ, we performed two experiments. First, 3 groups of OVX rats were treated with either E2, 4,4',4''-(4-Propyl-[1*H*]-pyrazole-1,3,5-triyl) *tris*phenol (PPT), a selective ERα agonist, or vehicle in pair feeding protocol. In a second experiment, OVX rats were injected with 2,3-*bis*(4-Hydroxyphenyl)-propionitrile (DPN), a highly potent ERβ agonist, or its vehicle, and the expression of NaPi-IIa and other Pi transporters was examined by Northern hybridization and immunoblotting.

Results: Molecular studies demonstrated both ERα and ERβ are expressed in the kidney PT cells, and while NaPi-IIa mRNA and protein were significantly reduced (-62% and -58% vs. vehicle, P<0.03), as expected, the expression levels of NaPi-IIc (P>0.05), Pit1 (P>0.05) and Pit2 (P>0.05) were unchanged in E2, as compared to pair-fed vehicle rats. Further, PPT caused a significant decrease in NaPi-IIa mRNA (-31%, P<0.003) but did not significantly alter its protein abundance, as compared to pair- fed vehicle. Interestingly, DPN treatment caused a significant decrease in the protein abundance of NaPi-IIa (-61%, P<0.007), however, its mRNA expression levels was not significantly decreased, as compared to vehicle (P>0.05).

Conclusions: These studies demonstrate that the phosphaturic effect of E2 is mediated solely and specifically through downregulation of NaPi-IIa and that this effect involves a complex mechanism involving the activation of both receptors ERα and ERβ.

Renalase Regulates Renal Phosphate Excretion Daria Sizova, Gary V. Desir. *Medicine Nephrology, Yale School of Med & VACHS, New Haven, CT.*

Background: Renalase, a FAD/NADH dependent amine oxidase that metabolizes catecholamines, including dopamine (DA), plays an important role in the regulation of blood pressure and cardiac function. It is expressed in kidney, heart, liver, and skeletal muscle, and the highest levels are detected in proximal tubules. The protein is secreted plasma and urine. In the renalase KO mouse, plasma and urinary DA are markedly elevated. Furthermore, changes in dietary phosphate (Pi) modulate expression and activity of renalase in WT kidney, along with MAO-A and MAO-B, suggesting that these enzymes participate in renal Pi metabolism by regulating renal and urinary DA levels. The KO mouse was studied to determine the contribution of renalase to renal Pi handling.

Methods: KO and WT mice were maintained either on a low Pi diet (0.02% Pi) for 4 days or on a high Pi diet (1.25%). Serum Pi were determined at baseline and prior to sacrifice. Kidney were harvested and gene expression was measured by quantitative PCR.

Results: Figure 1a shows that serum phosphate is significantly lower in KO mice maintained on a low Pi diet. On a high Pi diet, serum phosphate is also significantly lower in KO mice. These data suggest that KO mice excrete Pi at a higher rate than WT, and are unable to conserve Pi on a low Pi diet in spite of significant fall in serum Pi. Gene expression analysis using qPCR revealed that low Pi intake was associated with increased COMT (27%, n=5, p<0.01, fig 1b) and MAO-B (45%, n=5, p<0.05) in KO compared to WT.

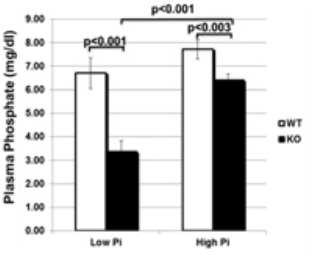

Figure 1a: Diet induced hypophosphatemia in renalase KO mice (n=5) maitained on low Pi for 4 days

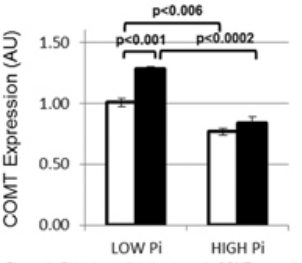

Figure 1b: Pi intake mediated changes in COMT expression in WT (n=5, clear box) and KO (n=5, filled box) mice.

Conclusions: In the absence of renalase, a low Pi diet fails to decrease urinary DA even though both COMT and MAO-B are upregulated, suggesting that renalase is the key factor that regulates urinary DA levels. Elevated urinary DA in the renalase KO drives urinary Pi excretion and leads to low serum Pi. These data support the notion that renalase plays a critical role in renal phosphate metabolism by regulating urinary DA.

Adverse Effects of Simulated Hyper- and Hypo-Phosphatemia on Endothelail Cell Function and Viability Ai Peng,[1,4] Tianfu Wu,[2] Cai-Hong Zeng,[3] Dinesh Rakheja,[4] Zhi-Hong Liu,[3] Jiankun Zhu,[2] Nosratola D. Vaziri,[5] Chandra Mohan,[2] Xin J. Zhou.[4] *[1]Medicine, Shanghai Tenth Hospital of Tongji University, Shanghai, China; [2]Medicine, UT Southwestern Medical Center, Dallas, TX; [3]Research Institute of Nephrology, Nanjing University School of Medicine, Nanjing, China; [4]Pathology, UT Southwestern Medical Center, Dallas, TX; [5]Medicine, UC Irvine, Irvine, CA.*

Background: Dysregulaiton of phosphate homeostasis as occurs in chronic kidney disease is associated with cardiovascular complications. It has been suggested that both hyper- and hypo-phosphatemia can cause cardiovascular disease. The molecular mechanisms by which high or low serum phosphate levels adversely affect cardiovascular function are poorly understood. The purpose of this study was to explore the mechanisms of endothelial dysfunction in the presence of non-physiologic phosphate levels.

Methods: We studied the effects of simulated hyper- and hypophosphatemia in human umbilical vein endothelial cells in vitro. The effects of inorganic phosphate on cell proliferation and apoptosis were measured by flow cytometry. Nitric oxide (NO) production and endothelial NO synthase were determined. The effects of inorganic phosphate on cell signaling protein expressions were determined using reverse-phase protein microarry.

Results: We found both simulated hyperphosphatemia and hypophosphatemia decrease eNOS expression and NO production. This was associated with reduced intracellular calcium, increased protein kinase C β2 (PKCβ2), reduced cell viability, and increased apoptosis. While simulated hyperphosphatemia was associated with decreased Akt/p-Akt, Bcl-xl/Bax ratios, NFkB and p-Erk abundance, simulated hypophosphatemia was associated with increased Akt/p-Akt and Bcl-xl/Bax ratios and p-Mek, p38, and p-p38 abundance. This is the first demonstration of endothelial dysfunction with hypophosphatemia.

Conclusions: Our data provides the basis for further studies to elucidate the relationship between altered phosphate homeostasis and cardiovascular disease. As a corollary, our data suggests that the level of phosphate in the culture media, if not in the physiologic range, may inadvertently affect experimental results.

Association of 24-Hour Urine Dopamine with Serum and Urine Phosphorus in Persons with Coronary Heart Disease: The Heart and Soul Study Nisha Bansal,[1] Chi-Yuan Hsu,[1] Mary Whooley,[1] Joachim H. Ix.[2] *[1]UCSF; [2]UCSD.*

Background: Urine dopamine (DA) is produced in the proximal tubule and has been found to increase in response to dietary phosphorus (Pi) intake, and to contribute to greater urinary Pi excretion in animal models. Whether urine DA is associated with Pi homeostasis in humans is uncertain.

Methods: Urine DA and Pi were measured in 24 hour urine collections among 963 outpatients with stable coronary heart disease (CHD). Fasting morning serum was used to measure Pi and kidney function. We examined cross-sectional associations between urine DA and serum Pi, 24-hour urine Pi, (as an indicator of dietary Pi intake), and fractional excretion of phosphorus (FePi) using linear regression. Models were adjusted for age, sex, race, eGFR by cystatin C, albuminuria, hypertension, heart failure, tobacco use, body mass index and diuretic use.

Results: Mean age was 67±11 years, 83% were men, and mean eGFR was 71±23 ml/min/1.73m^2. Mean urine DA was 192.8±85.1 µg/day, mean serum Pi was 3.7 ± 0.6 mg/dL, mean 24-hour urine Pi was 46.8 ± 25.1 mg/day, and mean FePi was 7.3 ± 8.6%. Higher urine DA was associated with younger age, male sex, black race, higher eGFR, and lower albuminuria (all P< 0.05). In adjusted models, each standard deviation higher DA was associated with higher serum Pi, higher urine Pi, and lower FePi (Table 1).

Conclusions: These data suggest that higher dietary Pi intake is associated with higher urine dopamine in persons with CHD, consistent with animal models. However, these changes were not associated with higher fractional excretion of phosphorus, suggesting that urine DA increases in parallel with phosphorus intake, but may not be responsible for greater urinary Pi excretion.

Table 1. Association of Urine DA (per SD) with Serum Pi, 24-Hr Urine Pi and FePi

	Unadjusted	Adjusted*
Serum Pi (mg/dL)	0.02 (95% CI: -0.02, 0.06), p=0.3	0.04 (95% CI: 0.003, 0.09), p=0.04
24-Hour Urine Pi (mg/day)	4.8 (95% CI: 3.2, 6.4), p<0.001	3.6 (95% CI: 1.7, 5.6), p<0.001
FePi (%)	-2.3 (95% CI: -2.9, -1.8), p<0.001	-0.8 (95% CI: -1.5, -0.2), p=0.007

Dietary Phosphate Modifies Life Span in Drosophila Clemens Bergwitz,[1] Joanne Huang,[1] Mark J. Wee,[1] Harald Jueppner.[3] *[1]Endocrine Unit, Massachusetts General Hospital, Boston; [2]Dept. of Genetics, Harvard Medical School, Boston; [3]Dept. of Pediatrics, Massachusetts General Hospital, Boston.*

Background: Drosophila, owing to the large number of genetic tools and its short life span, has been used as model organism to study the effects of the insulin/IGF-1 signaling, reactive oxygen species, and autophagy pathways on longevity.

Methods: To test the hypothesis that dietary phosphate modifies life span in Drosophila just like in higher organism and humans, we supplemented Standard medium (yeast/corn/malt/sucrose/agar)(SM), with 30 mM sodium-phosphate (pH 6.0)(Pi30), 30 mM sodium-sulfate (pH 6.0)(Si30), or 1% sevelamer (Sev1%).

Results: Median lifespan of male yellow white flies (wild-type) at 25 degrees C was 45±2.5, 36±3.9, 44±2.9, and 51±3.4 days in SM, Pi30, Si30, and Sev1%, respectively (n>100 flies per condition). Findings were similar for females and for different fly strains, including W1118, Canton S, and Oregon R. Hemolymph phosphate concentration was 21±0.3, 23±1.7, and 23±1.6 mg/dl in SM, Pi30, and Sev1%, respectively. Excretion of phosphate was 2.5±0.4, 9.0±2.5, and 0.6±0.05, and ng/fly/60 min., and whole fly phosphate content was 285±7, 273±28, and 285±5 ng/fly, respectively. We next prepared a defined medium supplemented with 1.5 mM potassium-phosphate (pH 6.0), 27 mM Pi and 53 mM Pi, in which total osmolarity was kept constant using potassium sulfate. Survival of yellow white males was 22±0.3, 20±0.3, and 17±0.9 days in these media, respectively. All media supported larval development and eclosion of adult flies after 11 days, except for Sev1%, which caused developmental delay.

Conclusions: Our findings suggest that the effects of dietary phosphate on life-span are conserved between fly and man. Life-span in flies is extended by 40% in Sev1% when compared to Pi30 medium, and by 10% when compared to SM. By adjusting phosphate excretion under different dietary conditions, homeostatic mechanisms appear to be present in fly intended to maintain stable hemolymph and whole fly phosphate concentrations. Drosophila may therefore be a suitable model organism to understand the molecular basis of dietary phosphate toxicity in vivo.

SA-PO2713

OSR1 in the Regulation of Proximal Tubuluar Phosphate Transport Michael Föller,[1] Ganesh Pathare,[1] Kerim Mutig,[2] Jakob Völkl,[1] Sebastian C. Bachmann,[2] Florian C. Lang.[1] *[1]Institute of Physiology, University of Tuebingen, Germany; [2]Insitute of Anatomy, Charité, Berlin, Germany.*

Background: Gain of function mutations of WNK1 and WNK4 kinases lead to Gordon's syndrome resulting in hypertension and hyperkalemia. WNK kinases phosphorylate and thereby activate the serine/threonine oxidative stress kinase 1 (OSR1) and the closely-related STE20/SPS1-related proline/alanine-rich kinase (SPAK). Both, OSR1 and SPAK have been shown to participate in the regulation of renal salt excretion and blood pressure by stimulating the $Na^+/K^+/2Cl^-$ cotransporter (NKCC2) and the Na^+/Cl^- cotransporter (NCC). The present study explored whether OSR1 is expressed in proximal renal tubules and influences proximal tubular phosphate transport.

Methods: Immunohistochemical analysis showed OSR1 expression in murine proximal tubular epithelial cells. To elicit the in vivo significance of OSR1-sensitive phosphate transport, knock-in mice carrying WNK kinase-resistant OSR1 ($OSR185A/^+$) were compared to wild type mice ($OSR^+/^+$).

Results: Despite a significantly lower serum phosphate concentration the urinary phosphate excretion was significantly larger in $OSR185A/^+$ mice than in $OSR^+/^+$ mice. The serum calcium concentration was not significantly different between the genotypes whereas the urinary calcium excretion tended to be lower in $OSR185A/^+$ mice compared to $OSR^+/^+$ mice. Under a low phosphate diet, the serum phosphate concentration was again significantly lower and the urinary phosphate excretion significantly higher in $OSR185A/^+$ mice compared to $OSR^+/^+$ mice. Neither plasma PTH nor serum calcitriol levels were significantly different between the genotypes.

Conclusions: In conclusion, OSR1 is expressed in proximal tubular epithelial cells and participates in the regulation of Napi-IIa-dependent renal phosphate reabsorption.

SA-PO2714

Regulation of the Type IIa Sodium Phosphate Cotransporter by AMP Activated Protein Kinase Eleanor D. Lederer,[1,2] Francesca Pribble,[2] Syed J. Khundmiri.[2] *[1]Medical Service, Robley Rex VA Medical Center, Louisville, KY; [2]Medicine, University of Louisville School of Medicine, KY.*

Background: The physiologic functions of AMP activated protein kinase (AMPK), a kinase implicated in cell polarity and energy metabolism, in proximal tubule are not known. Based on the critical role of phosphate in cell metabolism and the documented role of AMPK in regulation of sodium pump expression, we hypothesized that AMPK regulated apical membrane trafficking of the type IIa sodium phosphate cotransporter (Npt2a).

Methods: OK (opossum kidney) cells, a model for renal proximal tubule, were grown in monolayers. Total and activated (phospho) AMPK were detected by Western blot in whole cell lysates and membrane preparations. Npt2a expression was detected by Western blot. Phosphate transport was measured by uptake of radiolabeled phosphate in transport medium.

Results: Treatment of cells with 1 mM AICAR, an AMPK activator, resulted in a progressive increase in pAMPK expression detectable at 2h and rising by 75% at 24 hours, analyzed as pAMPK to total AMPK. Exposure of cells to medium containing no phosphate had no effect on AMPK activity in membrane or cytosol fractions, measured by pAMPK to total AMPK. Treatment with phosphate-free medium or with AICAR for two hours had no effect on AMPK activation in brush border membrane (BBM). AICAR alone had no significant effect on Npt2a expression or phosphate uptake. Phosphate-free medium increased Npt2a expression by 44% at 2 hours. However, treatment of cells with phosphate-free medium in the presence of AICAR blocked the ability of phosphate-free medium to increase BBM expression of Npt2a. Despite the increase in Npt2a expression in the presence of phosphate-free medium, phosphate uptake did not change.

Conclusions: We conclude that 1) OK cells express AMPK, 2) ambient phosphate does not regulate AMPK activation, and 3) activated AMPK has no effect on basal Npt2a expression but inhibits Npt2a apical membrane trafficking stimulated by low ambient phosphate. The dissociation of Npt2a expression and function in phosphate-free medium suggests differential regulation of these properties by as yet unknown mechanisms.

Secondary Hyperparathyroidism and Hyperphosphaturia in Mice Lacking Adenylyl Cyclase 6 Timo M. Rieg,[1,3] Tong Tang,[3] H. Kirk Hammond,[1,3] Volker Vallon.[1,2,3] *[1]Dept. of Medicine, University of California San Diego, CA; [2]Dept. of Pharmacology, University of California San Diego, CA; [3]VA San Diego Healthcare System, San Diego, CA.*

Background: Adenylyl cyclase isoform 6 (AC6) is expressed in all renal tubular segments and catalyzes the synthesis of cAMP. Parathyroid hormone (PTH) is coupled to a Gs protein-coupled receptor and upon activation Na+/phosphate cotransporters are retrieved from the membrane of the proximal tubules resulting in increased phosphate excretion. Fibroblast growth factor 23 (FGF23) was identified as novel phosphaturic hormone. To define the role of AC6 in Pi and Ca2+ homeostasis, we studied AC6 wild-type (WT, n=10) and knockout (AC6-/-, n=10-13) mice.

Methods: Twentyfour hour metabolic cage studies were performed with free access to food (2% Ca2+, 1% Pi) and water. Blood was taken from the retrobulbar plexus. Plasma and urine were analyzed for Pi and Ca2+. A separate plasma sample was analyzed for PTH, FGF23, and 1,25-Dihydroxy Vitamin D. To test for primary hyperparathyroidism we applied the calcimimetic (NS568, 30 mg/kg by oral gavage) to activate Ca2+ sensing receptors and study suppression of endogenous PTH after 30 min.

Results: Metabolic cage studies identified greater urinary Pi excretion in AC6-/- (32±5 vs. 4±1 µmol/day, P<0.001) which was associated with, and likely secondary to, higher plasma levels of PTH (255±60 vs. 39±6 pg/ml, P<0.005) and FGF23 (466±36 vs. 275±13 pg/ml, P<0.001), which may have suppressed 1,25-Dihydroxy Vitamin D levels in AC6-/- (141±17 vs. 215±16 pmol/l, P<0.01). Urinary Ca2+ excretion (2.5±0.2 vs. 2.6±0.2 µmol/day), plasma Pi (WT: 1.5±0.1 vs. 1.5±0.1 mmol/l in AC6-/-) and Ca2+ (WT: 2.7±0.1 vs. 2.7±0.1 mmol/l in AC6-/-) were not different. NS568 suppressed endogenous PTH to similar levels in both genotypes (WT: 14±1 and AC6-/-: 14±2 pg/ml).

Conclusions: Our results imply AC6 in the regulation of Pi homeostasis and exclude primary hyperparathyroidism as the cause for phosphaturia. PTH- and/or FGF23 induced inhibition of renal Pi reabsorption do not require AC6. Further studies are needed to determine the cause of secondary hyperparathyroidism including primary alterations in Ca2+ homeostasis or intestinal phosphate uptake.

Calcium Sensitive Dicarboxylate Transport in Mouse Proximal Tubule Cells Kathleen S. Hering-Smith,[1,2,3] Glenn T. Nagami,[4] L. Lee Hamm.[1,2,3] *[1]Medicine, Tulane University, New Orleans, LA; [2]Physiology, Tulane University, New Orleans, LA; [3]THRCE, Tulane University, New Orleans, LA; [4]Nephrology Section, VA Greater Los Angeles Health Care System, Los Angeles, CA.*

Background: Urinary citrate is the most important endogenous inhibitor of calcium nephrolithiasis and is regulated by proximal tubule reabsorption. Urinary citrate increases with alkalosis and with increased urinary calcium. We recently reported a novel calcium sensitive dicarboxylate citrate transport process (AJP 2010) in the OK (opossum proximal tubule) cell line. This transport differed from that found with NaDC1, the known apical citrate transporter.

Methods: To determine whether this calcium sensitive process is also found in other species, ^{14}C-citrate uptake was measured in the proximal tubule specific cell lines S1 and S2 derived from large T-antigen transgenic mice. Cell were grown on permeable supports with uptake measured from the apical aspect only.

Results: In both S1 and S2 cells, lowering extracellular calcium stimulated citrate uptake (0.70 ± 0.16 to 1.35 ± 0.33 pmole/well in S1, and 0.075 ± 0.01 to 0.10 ± 0.02 pmole/well in S2, $p< 0.05$ for both). Succinate uptake (which occurs via NaDC1 also) was not affected by calcium. Uptake was not sensitive to 2,3-dimethylsuccinate, an inhibitor of basolateral type dicarboxylate transporters. NaDC1 was present in both cell types by Westerns in equivalent amounts despite the nearly 10 fold difference in citrate uptake.

Conclusions: Mouse proximal tubule cells contain an apical calcium sensitive citrate transporter demonstrating that this novel citrate transport process is present in a variety of mammalian species. Despite the presence of NaDC1, this process is unlikely to be NaDC1 since we have previously demonstrated that NaDC1 is not calcium sensitive. The proximal tubule likely contains several citrate transporters reflecting regulation of reabsorption by several pathways.

L-WNK1 Controls ARH-Dependent ROMK Endocytosis by Phosphorylation

Liang Fang, Paul A. Welling. *Department of Physiology, University of Maryland School of Medicine, Baltimore, MD.*

Background: In states of dietary potassium deficiency, ROMK renal potassium channel is marked for endocytosis by a clathrin adaptor protein, ARH, and regulated by a kinase mutated in a familial disease of hyperkalemia and hypertension, WNK1 (Fang et al, Journal of Clinical Investigation '09). In the present study, we explore the mechanism by which ARH is regulated by L-WNK1. In the absence of L-WNK1, ARH is polyubiquitinated and highly liable, decaying in very short time frame by the proteasome. Co-expression of L-WNK1 rendered ARH insensitive to degradation, and increased ARH phosphorylation. In vitro studies with purified proteins revealed ARH is substrate of L-WNK1 phosphorylation, but a signaling intermediate was found to be required for maximal activity. The primary phosphorylation site was mapped a serine at the N-terminal region, which is important for protein stability. In conclusion, L-WNK1 phosphorylates ARH and blocks proteasomal degradation of ARH. This mechanism provides a likely explanation for how ARH protein abundance is augmented in states of dietary potassium deprivation to stimulate ROMK endocytosis and reduce urinary potassium loss.

High Potassium Intake Upregulates Transepithelial Potential Difference and Potassium Secretion in Mouse Cortical Collecting Duct

Chih-Jen Cheng, Michel G. Baum, Chou-Long Huang. *Department of Medicine and Pediatrics, UT Southwestern Medical Center, Dallas, TX.*

Background: K^+ secretion via constitutively active ROMK and flow-stimulated maxi-K channels in aldosterone-sensitive distal nephron including late DCT, CNT and CCD are important for K^+ homeostasis. Patch-clamp and immunological studies showed that a high K^+ diet increased the density of ROMK and ENaC in rat CCD. In vitro microperfusion study of rabbit CCD showed that flow-stimulated K^+ excretion presumably via maxi-K is upregulated by high K^+ intake. In the study in rabbit CCD, baseline K^+ excretion presumably via ROMK was not increased by a high K^+ diet, raising the possibility of species differences of K^+ secretion in CCDs. Genetic mouse models are invaluable for studying K^+ handling in renal tubules, yet little information is available for dietary regulation of K^+ secretion in the mouse CCD.

Methods: C57BL/6 mice were fed either a control K (CK) (1% K^+) or high K (HK) diet (5.25% K^+) for 3 weeks. CCDs dissected from CK and HK mouse kidneys were microperfused in vitro under no transepithelial osmotic gradients. Tubular fluid samples were collected at a low physiological flow rate (1-2 $nl_{[sup]*[/sup]}min^{-1}$,$mm^{-1}$). The lengths of perfused segments ranged from 0.4 to 0.6 mm (mean 0.5 mm) in both CK and HK mice. K^+ and Na^+ concentrations in perfusate and collected fluids were analyzed using ion selective electrodes (ISE).

Results: Lumen-negative transepithelial PD were increased in HK versus CK CCDs (-20.1 ± 3.3 vs. -0.4 ± 0.1 mV, $p < 0.01$). High K^+ diet greatly increased secretory K^+ fluxes (J_k: 28.1 ± 8.8 $pmol_{[sup]*[/sup]}min^{-1}$,$mm^{-1}$ in HK mice versus 1.0 ± 0.5 pmol,min^{-1},mm^{-1} in CK). The increase in J_k was completely abolished by amiloride (100 μM).

Conclusions: A high K^+ diet increases transepithelial PD and enhances K^+ excretion in the mouse CCD. The mechanism for the increase in PD and whether an increased abundance of ROMK contributes to the increased K^+ secretion remain to be determined. Future studies will include investigation of regulation of K^+ secretion in CCDs by WNK kinases using genetic mouse models. Finally, ISE is a reliable method for measuring K^+ and Na^+ in small volume of fluid collection in microperfusion.

SA-PO2719

Inhibition of Src-family Protein Tyrosine Kinase (SFK) and Serine/threonine Phosphatase Stimulates ROMK Channels in the Rat Cortical Collecting Duct (CCD)

WenHui Wang. *Pharmacology, New York Medical College, Valhalla, NY.*

Background: Previous studies have demonstrated that low Na intake or aldosterone infusion did not increase ROMK channel activity in the CCD despite of a high aldosterone level. The aim of the present study is to test the hypothesis that a high SFK activity may be responsible for suppressing the effect of aldosterone on ROMK channels.

Methods: We used the Western blot to examine the effect of low Na intake and a high K intake (HK) on the expression of WNK4, c-Src and phosphorylated-c-Src^{Y416} (P-c-Src^{Y416}) in the rat kidney. Also, we used the patch-clamp technique to examine the effect of inhibiting SFK and serine/threonine phosphatase on ROMK channels in the CCD of rats on a low Na diet or a HK diet.

Results: A HK intake significantly decreased c-Src expression and P-c-Src^{Y416} level but had no effect on WNK4 expression in the kidney. In contrast, low Na intake had no effect on c-Src expression and P-c-Src^{Y416} level in comparison to the control animals, suggesting that SFK activity is higher in the kidney of rats on a low Na diet than those on a HK diet. Patch-clamp experiments demonstrated that inhibition of SFK activated ROMK channels in 7 patches of total 10 experiments and increased channel activity, defined by NP_o from 0.9±0.2 to 3.0±0.5. In contrast, inhibition of SFK had no effect on ROMK channels in the CCD of rats on a HK diet. Also, patch-clamp experiments showed that inhibition of phosphatases with calyculin A (5 nM) increased ROMK channel activity (NP_o= 1.9±0.3) in the CCD of rats fed low Na diet but not in rats on a HK diet. This suggests the role of serine/threonine phosphatases in suppressing ROMK channel activity in rats on a low Na diet.

Conclusions: We conclude that SFK and serine/threonine phosphatases play a role in suppressing ROMK channels in the CCD of rats on a low Na diet.

Funding: NIDDK Support

SA-PO2720

Protein Phosphatase 1 (PP1) Binds to With-no-Lysine Kinase 4 (WNK4) and Regulates the Effect of WNK4 on ROMK Channels

WenHui Wang. *Pharmacology, New york Medical College, Valhalla, NY.*

Background: WNK4 inhibited ROMK channels and the inhibitory effect of WNK4 was abolished by SGK1 but restored by c-Src. The aim of this study is to explore the role of serine/threonine protein phosphatases in modulating the interaction among SGK1, c-Src and WNK4.

Results: Immunoprecipitation experiments demonstrated that serine/threonine phosphatase, PP1, binds to WNK4 at amino acid (aa) residues 695-699 ($PP1^{\#1}$) and at aa1211-1215 ($PP1^{\#2}$) in HEK cells transfected with flag-tagged WNK4 constructs. Coexpression of c-Src decreased the association of PP1 to WNK4 at $PP1^{\#1}$ but increased the association at $PP1^{\#2}$. Expression of WNK4 mutants, $WNK4^{-PP1\#1}$, $WNK4^{-PP1\#2}$ or $WNK4^{-PP1\#1+2}$ in which the $PP1^{\#1}$, $PP1^{\#2}$ or both $PP1^{\#1}$ and $PP1^{\#2}$ binding sites were deleted or mutated, inhibited ROMK channels as potent as WNK4. However, inhibition of phosphatases with calyculin A enhanced WNK4's inhibition of ROMK channels in the cells transfected with $WNK4^{-PP1\#1}$ but diminished the WNK4-induced inhibition in the cells transfected with $WNK4^{-PP1\#2}$. In contrast, neither the basal activity of ROMK channels nor WNK4's inhibition of the K channel was affected by calyculin A treatment in HEK cells transfected with wt WNK4. Moreover, c-Src restored the inhibitory effect of WNK4 but not $WNK4^{-PP1\#1}$ on ROMK channels in the presence of SGK1. Expression of c-Src inhibited SGK1-induced phosphorylation of WNK4 but not $WNK4^{-PP1\#1}$ at Ser^{1196}. In contrast, coexpression of c-Src restored the inhibitory effect of $WNK4^{-PP1\#2}$ on ROMK in the presence of SGK1 and inhibited SGK1-induced WNK4 phosphorylation at Ser^{1196} in cells transfected with $WNK4^{-PP1\#2}$.

Conclusions: We conclude that WNK4 is associated with PP1 at two sites and that PP1 binding to aa 695-9 is directly responsible for removal of SGK1-mediated phosphorylation of WNK4 while PP1 at aa1211-5 is responsible for removal the phosphorylation of WNK4 whose phosphorylation enhanced WNK4's inhibition of ROMK channels.

SA-PO2721

A-kinase Anchoring Protein (AKAP) Regulates BK Channel-Mediated K^+secretion (JK) in the Cortical Collecting Duct (CCD)

Wen Liu, Carlos Schreck, Lisa M. Satlin. *Department of Pediatrics, Mount Sinai School of Medicine, NY, NY.*

Background: The apical BK channel in CCD principal cells (PC) is tonically inhibited by PKA under low flow conditions (Liu et al, AJP Renal 297:F904, 2009), an observation that led us to speculate that BK channel-mediated flow-induced net K secretion (FIKS) requires release of channel inhibition by this kinase. Emerging evidence suggests that interactions between integral membrane proteins (e.g., ENaC) and protein kinases are stabilized at the plasma membrane by anchoring proteins, including AKAP.

Methods: To examine whether AKAP contributes to the tonic inhibition of the BK channel under basal conditions, we measured JK and net Na absorption (JNa; each in pmol/min.mm) in NZW rabbit CCDs microperfused in vitro at slow (~1) and fast (~5 nl/min.mm) flow rates in the presence of St-Ht31 (25 μM), a cell permeant AKAP inhibitor peptide that disrupts PKA anchoring on AKAP, added to bath and lumen. Control studies were performed using a control peptide (CP; 25 mM) of similar sequence which does not inhibit the interaction between PKA and AKAP.

Results: We found that JK was higher in CCDs treated with Ht31 (-19.0±1.9; n=8) than CP (-7.3±2.9; n=3; p<0.01) when perfused at slow flow rates; JNa in these same Ht31 and CP treated CCDs did not differ (21.7±3.1 vs. 13.3±1.9; p=0.13). A 5-fold increase in luminal flow rate did not further increase JK in 3 Ht31-treated tubules (-17.6 ±0.2 to -21.5±0.2; p=NS).

Conclusions: Our observation that the BK channel blocker iberiotoxin (50 nM) inhibited the Ht31-induced stimulation of JK in 5 CCDs perfused at slow flow rates (-19.8±2.9 to -10.1±1.7; p<0.05), without significant effect on JNa (19.5±3.7 vs. 16.6±4.6; p=NS), suggests that AKAP contributes to suppression of BK channel activity under low flow conditions, perhaps by anchoring PKA to the ion channel at the apical membrane.

The Kir4.1 Knock-Out Mouse Shows Decreased Na^+/Cl^- Cotransporter Expression Daniel A. Gray, Michael W. Cypress, Talia Holtzman. *Nephrology Unit, University of Rochester, NY.*

Background: Mutations in the Kir4.1 potassium channel underlie the SeSAME/EAST syndrome, an autosomal recessive condition characterized by seizures, sensorineural deafness, ataxia, developmental abnormalities and a hypokalemic hypomagnesemic metabolic alkalosis. To better understand the pathophysiology of this syndrome, we have been investigating the renal phenotype of a generalized Kir4.1 knock out mouse.

Methods: Serum and spot urine electrolytes were measured in 3-6 day old pups and paraformaldehyde-fixed kidney sections were probed with antibodies to distal nephron transporters.

Results: Our previous work showed that the Kir4.1 knock out mouse displays a reduced serum [K^+] associated with an elevated transtubular K^+ gradient and decreased urine osmolality. We now show that serum [Mg^{+2}] is also significantly reduced from 2.9 ± 0.3 mEq/L in WT to 2.3 ± 0.1 mEq/L in the knock out (n=6-7, p < 0.05) and is associated with an inappropriately elevated urine [Mg^{+2}]. Serum [Ca^{+2}] was normal. Light microscopy did not demonstrate any structural abnormalities of the distal nephron in the knock out. However, decreased Na^+/Cl^- cotransporter (NCCT) expression was observed by immunofluorescence in kidney sections probed with an NCCT antibody. No increase in aquaporin-2 immunofluorescence was seen to account for the decreased osmolality observed in the knock out.

Conclusions: Our results suggest that the renal phenotype of the SeSAME/EAST syndrome is largely recapitulated in the Kir4.1 knock out mouse. In addition, the decreased NCCT expression observed suggests a means by which loss of basolateral Kir4.1 function results in failure to reabsorb Na^+ and Cl^- apically.

SA-PO2723

A Case of EAST/Sesame Syndrome with Tubulopathy as First Manifestation Rosa Vargas-Poussou,[1] Djamal Djeddi,[2] Xavier Jeunemaitre.[1] *[1]Genetics, AP-HP Hôpital Européen Georges Pompidou, Paris, France; [2]Pediatrics, CHU d'Amiens, Amiens, France.*

Background: EAST (epilepsy, ataxia, sensorineural deafness,tubulopathy) or SeSAME (Seizures, sensorineural deafness, ataxia, mental retardation, electrolyte imbalance)is a rare autosomal recessive disease caused by mutations at the KCNJ10 gene coding for potassium channel kir 4.1. First manifestations of index cases of the 7 families described to date are neurological, in particular generalized seizures in the first months of life.

Methods: We describe clinical and genetic characterization of a French patient with this disease, in whom the first manifestations were linked to tubulopathy.

Results: Patient was the first child of a consanguineous union, born at term of an uncomplicated pregnancy. At 6 months of age, she was hospitalized for failure to thrive and a profound hypokalemia (2.2 mmol/L) was detected. Enteral nutrition and oral potassium were instituted. During a new hospitalization 1 month later for persistent hypokalemia, clinical and biological data were: weight 4.6 kg, size 60 cm, blood pressure: 99/49 mmHg, axial hypotonia and psychomotor retardation. Blood analysis: pH 7.52, electrolytes (mmol/L): Na 140, K 3.1, HCO3 26, Cl 98, Ca 2.65 and Mg 0.97. Urine electrolytes (mmol/L): Na 59, K 82, and Cl 102. Calcium/creatinine 0.03 mmol/mmol. Plasma renin and aldosterone: 480 and 284 pg/mL. Renal ultrasound was normal. The diagnosis of Bartter/Gitelman syndrome was suggested, haplotype analysis showed homozygosity at CLCNKB locus but sequencing and MLPA were negative. Neurological evaluation at 9 months showed a rotatory nystagmus and a mild ataxia; cerebral tomography and visual evoked potential were normal; hearing evaluation showed bilateral absence of otoacoustic emission. At age 1 year she had generalized seizures with recurrence 2 weeks later. During last hospitalization auditory evoked potential showed mixed hearing loss.KCNJ10 sequencing showed a known homozygous missense mutation (p.Arg175Gln), for which in vitro expression showed an impaired channel function (Reichold M et al. PNAS 2010).

Conclusions: EAST/SeSAME syndrome can be first presented as a salt wasting tubulopathy followed by severe neurological manifestations.

PAR2 Promotes Potassium Sparring and Controls Plasma Potassium Concentration Luciana Morla, Gaëlle Brideau, Lydie Cheval, Gilles Crambert, Suresh Krishna Ramakrishnan, Alain Doucet. *UMRS 872, team 3, UPMC Univ Paris 06 and INSERM and CNRS, Paris, France.*

Background: We previously showed that activation of PAR2 by trypsin or an agonist peptide increases sodium reabsorption in isolated rat cortical collecting duct (CCD) without promoting potassium secretion. We therefore evaluated the role of PAR2 in maintaining potassium balance *in vivo* and in controlling the activity of the potassium-secreting channel ROMK in CCD.

Methods: For this purpose, we compared plasma potassium level and potassium handling in $PAR2^{-/-}$ and wild type (WT) mice under basal state and potassium depletion *in vivo* and in *in vitro* microperfused CCDs.

Results: Under basal state, $PAR2^{-/-}$ mice displayed normal potassium excretion and blood concentration. Within two days of potassium depletion, $PAR2^{-/-}$ mice showed a blunted ability to maximally decrease their urinary excretion of potassium, as compared to WT mice. This inappropriate ability to conserve potassium was associated with decreased plasma potassium concentration in $PAR2^{-/-}$ mice (in mM ± SE; WT, 3.9 ± 0.2; $PAR2^{-/-}$, 3.2 ± 0.1; p<0.025). To evaluate the effect of PAR2 on ROMK activity, we compared the effect of trypsin on AVP-stimulated potassium secretion in isolated CCDs. In absence of AVP, rat CCDs neither reabsorbed sodium nor secreted potassium. AVP treatment induced sodium reabsorption and potassium secretion. Pre-treatment with trypsin did not alter AVP-stimulated sodium reabsorption but abolished potassium secretion, suggesting an inhibitory effect on ROMK. This inhibition was further supported by the finding that trypsin induced the phosphorylation of ERK in CCD, a pathway known to induce the endocytosis of ROMK.

Conclusions: In conclusion, we showed that activation of PAR2 inhibits potassium secretion in CCD and thereby participates in potassium sparing during potassium restriction.

Progesterone Is Required for Efficient Renal Adaptation to Chronic Dietary K+ Restriction in Male by Stimulating H,K-ATPase Type 2 Expression Gilles Crambert, Amel Salhi, Aurelie Edwards. *UMRS872 Team 3, INSERM/UPMC/CNRS, Paris, France.*

Background: Modern dietary habits are characterized by high-Na and low-K intakes, each of which has been correlated with a higher risk for hypertension. In this study, we examined whether long-term variations in the intake of Na+ and K induce lasting changes in the plasma concentration of circulating steroids.

Methods: We developed a mathematical model of adrenal steroidogenesis in mice that permits to predict concentration of all steroids based on the level of expression of the steroidogenic genes. These predictions were then confirmed by experimental measurements using RIA. The investigations of the renal effects of progesterone in the context of a dietary K restriction has been done in mice and using a cell line (mCCD).

Results: Our mathematical model predicted that male mice increase their plasma progesterone levels in response to K+ depletion. This prediction was confirmed by experimental measurements showing a 3-time increase of progesterone after 8 days of K restriction. Our results indicated a relationship between the ability to produce progesterone and the efficiency of the renal retention of K. Moreover, adrenalectomized mice exhinited a 2-time higher loss of potassium when placed under low-K diets and have an increase mortality rate after 10 days of this treatment.

The mechanism by which progesterone stimulates renal K retention involved an increased expression and activity of HKA2. This effect was proved by using HKA2 null mice that turned to be "resistant" to the anti-kaliuretic effect of progesterone whereas wild-type mice reduced their K excretion by 15-20% after progesterone injection.

Finally, we determine that the progesterone-dependent ability to retain K+ efficiently is RU486-sensitive , indicating the involvement of the nuclear progesterone receptor in this process.

Conclusions: Our results suggest the existence of a hereto unknown regulatory process involving progesterone, its nuclear receptor, the HKA2 and renal K+ retention.This effect of progesterone, in male as in female, is mineralcorticoid-independent (aldosterone is low in the K-depleted state) and may represent a "hidden" regulatory pathway in hypokalemic states.

Claudin-16 Knock Down Mice Modulate Pendrin and vH-ATPase Abundance in Distal Nephron To Prevent Volume Depletion Nina Himmerkus,[1] Jan E. Behrends,[1] Magdalena A. Gutowska,[1] Paul S. Steels,[2] Markus Bleich.[1] *[1]Institute of Physiology, Christian-Albrechts-University, Kiel, Germany; [2]Biomed, University Hasselt, Diepenbeek, Belgium.*

Background: Mutations in Claudin-16 are associated with the hereditary disease Familial Hypomagnesemia with Hypercalciuria and Nephrocalcinosis (FHHNC). In Claudin-16 knock down mice (KD) we have previously shown that young KD mice compensate for NaCl loss in the TAL by enhanced downstream reabsorption in the cortical collecting duct (AJP,2008; 295(6):F1641-7).

Methods: We now investigated a cohort of aged (1.5-2 years) mice to assess long term compensation. We examined the expression pattern and membrane representation of chloride bicarbonate exchangers (Pendrin and AE1) and the vH^+-ATPase by confocal immunofluorescence (IF). IF data are given as % intensity of IF in the membrane area compared to the cytosolic signal.

Results: KD showed the key symptoms of FHHNC and were 15% lighter, 10% shorter and showed a slightly increased hematocrit. Urine osmolality was 1.5-fold higher and the ratio of urinary Na^+ to K^+ concentrations was 30% decreased, indicating an increased sodium and water reabsorption in the distal nephron. The urine of KD as well as WT was acidic (pH 5.8 +/- 0.2 vs. pH 5.8 +/- 0.1). In kidney slices of KD 64% of the Pendrin IF was localized in the luminal membrane of cortical intercalated cells compared to 46% in WT. Freshly isolated cortical collecting ducts showed a similar pattern and, in addition, basolateral membrane expression of vH^+-ATPase was increased in KD with 41% compared to 21%, respectively. In the medulla 58% of vH^+-ATPase IF intensity was localized in the luminal membrane of KD intercalated cells compared to 42% in WT. We did not find any difference in the distribution of the IF signal for AE1.

Conclusions: We conclude that aged KD suffer from long term volume depletion. Functional upregulation of Pendrin serves compensatory NaCl reabsorption downstream of the TAL. The increased cortical bicarbonate secretion is counterbalanced by an activation of H^+ secretion in the medulla.

The Leaky Epithelial Cell Culture Model, OK Cells, Express Claudin-4, Whose Gene Dosage Dictates Transepithelial Resistance R. Todd Alexander, Jelena Borovac, Reid S. Barker, Emmanuelle Cordat. *University of Alberta, Edmonton, AB, Canada.*

Background: The study of paracellular flux across leaky epithelial, such as the proximal tubule, has been limited by the lack of a properly characterized cell culture model. We therefore set out to determine the molecular and electrophysiological properties of the leaky epithelial cell culture model, opossum kidney (OK) cells.

Methods: The electrophysiological properties of OK cells were assessed on confluent monolayers grown on semi-permeable filters, mounted in Ussing chambers, by measuring transepithelial resistance (TER) and dilution potentials. To determine the molecules mediating the electrophysiological properties we identified, cloned and then measured the relative expression, by quantitative PCR, of the claudins (a family of tight junction proteins, which dictate paracellular permeability characteristics). To validate the model system we over-expressed claudin-4 (identified as being endogenously present) and then repeated the expression and electrophysiological studies.

Results: OK cells demonstrate a low transepithelial resistance (TER = 10.2 ± 1.4 Ωcm^2), slight cation selectivity (pNa/pCl = 1.07 ± 0.002), a Eisenman sequence for cations of $K^+ > Cs^+ > Rb^+ > Na^+ > Li^+$ and for anions of $Cl^- > I^- > Br^-$. This mirrors the published electrophysiological properties of the proximal tubule *in vivo*. At the molecular level OK cells express claudin 4 > 1 > 6 > 20 > 9 > 12 > 11 > 15. We were surprised that claudin-4, a barrier forming claudin, was significantly expressed in this model system of a leaky epithelia. We therefore generated stable cell lines over-expressing claudin-4. Immunofluorescence microscopy confirmed that claudin-4 appropriately localized to the tight junction when over-expressed. All the clones stably expressing claudin-4 demonstrated significantly increased TER, without an alteration in pNa/pCl. They also displayed significantly increased claudin-1, -6 and -9 expression.

Conclusions: Together these results establish OK cells as a leaky epithelial model system to study claudin function. They also implicate claudin-4 in forming a paracellular barrier, whether directly or via affects on other claudin expression remains to be elucidated.

Differential Effects of Extracellular ATP on Chloride Transport Via Calcium Activated Chloride Channels in Kidney Cortical Collecting Duct CELLS Madhumitha Rajagopal,[1,2] Alan C. Pao,[1,2] Jonathan Widdicombe.[3] *[1]Nephrology/ Medicine, Stanford University, Stanford, CA; [2]Veterans Affairs Palo Alto Health Care System, Palo Alto, CA; [3]Physiology and Membrane Biology, University of California, Davis, Davis, CA.*

Background: The cortical collecting duct (CCD) of the kidney plays a critical role in fine-tuning sodium chloride (NaCl) balance and is subject to extensive regulation by hormones such as aldosterone. Recent studies have demonstrated that extracellular nucleotides are also important in regulating the epithelial Na^+ channel (ENaC) in the CCD, thereby contributing to NaCl balance and blood pressure regulation under high dietary salt conditions. Extracellular nucleotides also regulate Cl^- transport through Ca^{2+} activated chloride channel (CACC) in CCD cells, although the relationship between CACC and ENaC activity is not clearly defined.

Methods: We studied a CCD ($mpkCCD_{cl4}$) cell line in Ussing chambers to determine the effects of ATP on CACC-mediated Cl^- transport under varying levels of ENaC activity.

Results: To simulate conditions associated with salt overload, we clamped transepithelial voltage (V_{te}) to 0 mV and then treated $mpkCCD_{cl4}$ cells with amiloride to inhibit ENaC. The addition of ATP caused a robust and transient increase in Cl^- secretion, which could be inhibited by flufenamic acid (FFA, a CACC inhibitor) or BAPTA-AM (a Ca^{2+} chelator). The V_{te} of aldosterone-stimulated $mpkCCD_{cl4}$ cells was ~ -50 mV. Therefore, to mimic conditions of the DOCA-salt model of hypertension, where both aldosterone and ATP are elevated, we treated $mpkCCD_{cl4}$ cells with aldosterone, clamped the V_{te} at -50 mV, and then treated cells with ATP. We found that ATP induced a robust and transient increase in transcellular Cl^- absorption, which could be inhibited by FFA or BAPTA-AM.

Conclusions: These findings illustrate that the direction of CACC-mediated Cl^- transport in CCD cells, which is dependent on V_{te} and ENaC activity, and suggest that extracellular ATP, in combination with aldosterone, differentially regulates CACC activity under conditions that reflect varying states of NaCl balance.

Chemical Library Screening for Drugs To Correct Intracellular Mislocalization of R8L Mutant Barttin Naohiro Nomura, Shotaro Naito, Eisei Sohara, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Department of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental Universtiy, Bunkyo-ku, Tokyo, Japan.*

Background: Barttin, a gene product of *BSND*, is one of four genes responsible for Bartter syndrome. Previously, we showed that one of the disease-causing mutant barttin, R8L, was mis-localized to cytoplasm and could not reach to plasma membranes in MDCK cells and R8L knockin mouse. In addition, we reported that curcumin and 17-allylamino-17-demethoxygeldanamycin (17-AAG) could rescue the mis-localization of R8L barttin and partially corrected the phenotypes in the R8L barttin knockin mice. These results suggested that the aberrant intracellular localization of R8L barttin is a major cause of this disease, and to find more potent drugs to correct the mislocalization could be a promising strategy to treat this disease. For this purpose, we screened a chemical library consisting of about 20,000 chemical compounds in our university.

Methods: The screening was performed using MDCK cells stably expressing GFP-tagged R8L barttin. Cellular localization of the GFP signal after treatment with the compounds was assessed by using ArrayScan (Thermo Scientific), an automated fluorescence microscopic imaging system designed for high throughput screening.

Results: As a result of this screening, we identified four candidates. We confirmed the effects of these compounds by cell surface specific biotinylation assay. Furthermore, we injected one of these compounds to R8L knockin mice intraperitonealy, and could observe the improvement of plasma membrane signal of R8L barttin in the kidney.

Conclusions: We expect that these chemical compounds can be seeds for drugs to treat Bartter syndrome type IV caused by R8L barttin mutation, and that they can also be effective for treating diseases caused by mislocalization of mutant proteins, such as CFTR-ΔF508.

Chloride Channels CLIC1 and CLIC4 Function in Proximal Tubule Endocytosis John C. Edwards, Yao-Wen Cheng. *UNC Kidney Center and Department of Medicine, University of North Carolina, Chapel Hill, NC.*

Background: CLIC proteins can function as chloride channels but their normal physiologic role remains uncertain. CLIC4 has been implicated in intracellular membrane traffic in tubulating endothelial cells. Whether CLICs are important in other intracellular membrane pathways is unknown. CLIC1 and CLIC4 are both highly expressed in the apical region of kidney proximal tubule cells and a role in proximal tubule endocytosis has been proposed. We examined mice carrying targeted disruption of either CLIC1 or CLIC4 for alterations in levels of proteinuria which could be a reflection of proximal tubule endocytosis.

Methods: Urine and blood was collected from groups of *Clic1*$^{(-/-)}$ or Clic4$^{(-/-)}$ mice and matched WT controls. Plasma albumin, plasma and urine creatinine, and urine total protein were determined by commercially available clinical testing. Urine albumin concentration was determined by western blotting. Plasma and urine β-2 microglobulin (β2M) were determined by ELISA assay. Values are reported as mean ± SEM. P values determined by T-test.

Results: Creatinine, albumin, and β2M values in plasma were not different among the groups.

	Clic1 WT(n=5)	Clic1(-/-) (n=5)	P value	Clic4 WT (n=5)	Clic4 (-/-) (n=5)	P value
Urine pro/ creat (mg/ mg)	0.265±0.048	0.279±0.011	(NS)	0.172±0.028	1.332±0.615	0.096
Urine alb/creat (normalized arbitrary units)	1.00±0.029	1.42±0.086	0.0016	1.00±0.047	1.39±0.14	0.025
Frac Exc β2M (%)	1.44±0.4	6.71±2.1	0.04	(nd)	(nd)	

nd: not determined

Mice lacking either CLIC1 or CLIC4 showed changes in urinary protein. *Clic1*$^{(-/-)}$ mice had no significant change in total urine protein but have significantly increased albuminuria and β2microglobunuria. *Clic4*$^{(-/-)}$ mice had a tendency to increased urine pro/creat ratio that did not reach significance have significantly increased albuminuria.

Conclusions: Both CLIC1 and CLIC4 appear to contribute to clearance of protein from the glomerular filtrate. In particular the increased fractional excretion of β2M in the *Clic1*$^{(-/-)}$ mice indicate decreased endocytic uptake from the proximal tubule lumen. The data are consistent with the hypothesis that CLICs 1 and 4 function as chloride channels in vesicles along the endocytic pathway.

A Novel Conditional Knockout Mouse Model of the Proximal Tubule Endocytic Receptors Megalin and Cubilin Kathrin Weyer,[1] Tina Storm,[1] Jingdong Shan,[2] Seppo J. Vainio,[2] Erik I. Christensen,[1] Pierre J. Verroust,[1] Rikke Nielsen.[1] *[1]Department of Anatomy, Aarhus University, Aarhus, Denmark; [2]Department of Medical Biochemistry and Molecular Biology, University of Oulu, Finland.*

Background: The megalin and cubilin receptors are highly expressed in the kidney proximal tubules. Previous studies using animal models have demonstrated their synergistic and important role for normal proximal tubule endocytic recovery of filtered proteins in vivo. Studies using mouse models are however restricted by the fact that cubilin-deficient mice die in utero and most megalin-deficient mice die perinatally.

Methods: Using the *Cre/loxP* gene knockout system, we have developed a viable megalin and/or cubilin knockout mouse model, where the Cre gene is driven by the Wnt4 promoter which is expressed in the embryonic kidney. Kidney tissue was analysed using immunohistology and Western blotting. Urine samples were analysed for excreted proteins by SDS-PAGE, ELISA and Western blotting.

Results: The $Meg^{lox/lox}$;Wnt4-Cre, $Cub^{lox/lox}$;Wnt4-Cre, and combined $Meg^{lox/lox}$,$Cub^{lox/lox}$; Wnt4-Cre transgenic mice were all viable, fertile, and transmitted the transgenes in a Mendelian fashion. Kidney tissue analysis by immunohistology and Western blotting demonstrated a highly reproducible and efficient (≥88%) knockdown of megalin and cubilin in proximal tubule cells. Consistent with the loss of megalin and cubilin expression in the kidneys, the mice were found to excrete increased amounts of low molecular weight proteins in the urine. Because this model allows the production of a large number of mice we were further able to statistically analyse groups of mice for urinary albumin excretion.

Conclusions: We anticipate that these mice will be a valuable tool to study the role of megalin/cubilin-defects in the pathogenesis of proximal tubulopathies.

SA-PO2732

Altered Prostanoid Receptor Signaling, but Not Decreased PGE2 Production, Explains the Significant Resistance of $P2Y_2$ Null Mice to Li-Induced Polyuria Ioana L. Pop,[1] Yue Zhang,[1] Noel G. Carlson,[2] Bellamkonda K. Kishore.[1] *[1]Medicine, Nephrology, VAMC & Univ of Utah; [2]Neurovirology & GRECC, VAMC & Univ of Utah, Salt Lake City, UT.*

Background: Previously we showed that genetic deletion of $P2Y_2$ receptor results in significant resistance to Li-induced polyuria, without altering blood or renal medullary Li levels. Here we document that this resistance is not due to decreased production of PGE2, which is widely regarded as a causative factor in Li-induced polyuria, but instead due to altered prostanoid receptor (EP-R) signaling.

Methods: Groups of wild type (WT) and $P2Y_2$-R KO mice were fed normal (ND) or Li-added (LD) diets (40 mmol/kg food) for 14 days with free access to water and euthanized.

Results: Li-induced polydipsia, polyuria, and decreases in urine osmolalities and AQP2 protein abundance in renal medulla were significantly less in KO mice vs. WT mice ($P < 0.05$). Interestingly, genetic deletion of $P2Y_2$-R did not suppress Li-induced increased urinary excretion of PGE2 ($P < 0.05$). Since PGE2 induced effects are mediated through EP-Rs, using semi-quantitative immonoblotting, we determined the protein abundances of EP1, EP2, EP3 and EP4 receptors in the inner medulla (EP2-R not detectable). EP3-R protein abundance in ND fed KO mice was markedly low as compared to the ND fed WT mice (29%; $P < 0.001$), while levels of EP1-R and EP4-R were not altered across the groups (EP2-R not detectable). Li-feeding caused a modest decrease in EP3-R protein in WT (67%; $P > 0.05$), and KO mice (82%). Furthermore, *ex vivo* stimulation of medullary collecting ducts (mCD) with PGE2 generated significantly more cAMP in LD-fed KO mice vs. LD-fed WT mice (130%; $P < 0.03$), while no such differences were seen when the mCD from these groups of mice were stimulated by dDAVP.

Conclusions: Taken together these data suggest that genetic deletion of $P2Y_2$-R offers significant resistance for the development of Li-induced polyuria by alteration of EP-R signaling, but not by decreasing the production of PGE2. Incidentally, this study reveals that the decreased protein abundance of EP3-R in P2Y2-R KO mice may also contribute to the increased urinary concentrating ability reported in these mice.

SA-PO2733

Acute Lithium Administration Increases Water Excretion through Activation of MAP Kinases Francesco Trepiccione,[1] Trairak Pisitkun,[2] Jason D. Hoffert,[2] Robert A. Fenton,[1] Soren Nielsen,[1] Mark A. Knepper,[2] Birgitte M. Christensen.[1] *[1]Department of Biomedicine, Water and Salt Research Center, Aarhus University, Aarhus, Denmark; [2]Epithelial Systems Biology Laboratory, NHLBI, NIH, Bethesda, MD.*

Background: Acute lithium (Li^+) treatment impairs the water permeability of the kidney collecting duct. Changes in phosphorylation status are a fast way of regulating protein function. Here we used a phosphoproteomic approach to detect the early molecular targets of Li^+ in inner medullary collecting duct (IMCD).

Methods: Rats were treated with a gavage of either LiCl or NaCl (2.4 mmol/Kg of BW). After 4 or 9 hours rats were euthanized and IMCD suspensions were prepared. Phosphopeptides from IMCD isolated after 9 hours of Li^+-treatment were enriched by immobilized-metal affinity chromatography (IMAC) and then analysed on a LTQ-orbitrap LC-MS/MS system. Label-free relative quantification of MS1 peak integration was carried out by QUOIL software.

Results: Nine hours after LiCl gavage, rats showed a significantly increased urine volume and decreased urine osmolality ($p<0.01$ n=8). A total of 1222 unique phosphopeptides were identified in 578 proteins. DAVID analysis of the obtained phosphopeptide database highlighted a MAPK cluster of proteins. In addition, phosphopeptides in the Li^+-treated group with ≥ 1.5 fold increased abundance shared a common "proline-directed" kinase motif as determined by Motif-X analysis, further evidence that MAP kinases may be regulated by acute Li^+. The phosphopeptides in this group included AQP2 phosphorylated at S261, a potential MAPK target.Western blot analysis of IMCD isolated 4 hours after LiCl gavage showed increased phosphorylation of p38 and ERK1/2. No changes were observed in pS261-AQP2 and pJNK1/2 at 4 hours. After 9 hours of LiCl gavage pS261-AQP2 and pS256-261-AQP2 were significantly increased, while no changes in pS256-AQP2 or phosphorylated MAPKs were observed.

Conclusions: We conclude that MAPK pathways are an early target of Li^+ action in IMCD and the Li^+-related polyuric effect may involve the associated increase in pS261-AQP2.

SA-PO2734

Thiazide Attenuates Lithium-Induced Nephrogenic Diabetes Insipidus Independently of the Sodium-Chloride Co-Transporter Anne P. Sinke,[1] Marleen L.A. Kortenoeven,[2] Peter M.T. Deen.[1] *[1]Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Anatomy, University of Aarhus, Aarhus, Denmark.*

Background: Thiazide diuretics are commonly used to reduce urine output in patients with lithium-induced nephrogenic diabetes insipidus (Li-NDI). As thiazides block NaCl-cotransporter (NCC) mediated sodium uptake, it is generally thought that the observed AQP2 expression levels with treatment are due to hypovolemia-induced increases in vasopressin release. As Li-NDI is already anticipated to go with increased vasopressin levels, we investigated the role of NCC in this paradoxical anti-diuretic effect.

Methods: Polarized mouse cortical collecting duct (mpkCCD) cells show deamino-8 D-arginine vasopressin (dDAVP)-induced expression of endogenous AQP2, which is reduced upon treatment with clinically-relevant (1 mM) levels of ltihium for 24-48 hours. Interestingly, this lithium-induced reduction in AQP2 levels was reversed by thiazide treatment for 48 hours. Moreover, while lithium inactivated Gsk-3β, mainly by increasing its S9-phosphorylation, thiazide treatment reduced intracellular levels of lithium and led to increased total levels of Gsk-3β, while Gsk-3β phosphorylation was not changed, indicating that thiazide treatment partly impairs lithium influx resulting in more active Gsk-3β. Interestingly, however, NCC expression was not observed at protein or mRNA level, suggesting that the thiazide effect was NCC independent.

Results: To test the physiological relevance of these data in vivo, we examined the effects of thiazide on Li-NDI in NCC knockout mice and found that thiazide still reduced urine volume, and increased urine osmolality and AQP2 abundance in NCC knockout mice as compared to lithium-treated NCC knockout mice.

Conclusions: Our in vitro and in vivo data reveal that at least part of the antidiuretic effect of thiazide in Li-NDI is NCC independent.

SA-PO2735

Pharmacological Blockade of $P2Y_{12}$ Receptor Increases Urinary Concentration in Rats Yue Zhang,[1] Ioana L. Pop,[1] Noel G. Carlson,[2] Bellamkonda K. Kishore.[1] *[1]Medicine, Nephrology, VAMC & Univ of Utah; [2]Neurovirology & GRECC, VAMC & Univ of Utah, Salt Lake City, UT.*

Background: $P2Y_{12}$ receptor, a G protein-coupled ADP receptor, is expressed predominantly in blood platelets, and the brain (microglia and astrocytes). Apart from Rap1b and Akt-mediated effects that contribute to platelet aggregation, signaling through $P2Y_{12}$-R also inhibits adenylyl cyclase. Hence, we investigated the expression and activity of $P2Y_{12}$-R in rat kidney.

Methods: Real-time RT-PCR and Western blotting (antibody and blocking peptide from AnaSpec) were used to detected the expression of $P2Y_{12}$-R. Groups of rats were administered clopidogrel bisulfate (Plavix®; 20 mg/kg bw/day) in drinking water for 2 weeks and euthanized. Water intake and urine output were monitored and kidney tissue analyzed.

Results: $P2Y_{12}$-R mRNA and protein are expressed in all regions of normal rat kidney, albeit at a much lower level (10-12-fold) than in the brain. Administration of Plavix® resulted in a significant increase in urine osmolality ($P < 0.02$), associated with significant decreases in urine output ($P < 0.05$) and water consumption ($P < 0.04$), and a modest increase in solute-free water absorption (24%; $P = 0.06$) as compared to the control group of rats. These changes in whole body water metabolism were matched with significant increases in the protein abundance of AQP2 water channel in the inner medulla (1.9-fold; $P < 0.002$), and cortex (2.7-fold; $P < 0.02$), but not in the outer medulla. Plavix® did not alter the protein abundances of AQP1 water channel or $P2Y_{12}$-R in the kidney. Interestingly, Plavix® administration significantly increased the urinary excretion of AVP (2-fold; $P < 0.01$) and decreased urinary PGE2 (~40%; $P < 0.02$). Finally, Plavix® administration (80 mg/kg/day for 2 weeks) resulted in significant increase in urinary concentration in $P2Y_2$ receptor null mice also, thus ruling out the possible contribution of $P2Y_2$ receptor blockade in mediating the observed effects.

Conclusions: Further studies are needed to delineate the renal and extra-renal actions of $P2Y_{12}$-R in urinary concentration and its potential as a target to treat water-losing conditions, such as nephrogenic diabetes insipidus.

Molecular Mechanisms of Proton Permeation across Membranes: Differential Effects of Cholesterol Mark L. Zeidel,[1] Aaron Carrithers,[2] John Mathai.[1] *[1]Medicine, Beth Israel Deaconess Medical Center, Boston, MA; [2]Transylvania University, Lexington, KY.*

Background: Despite years of study the mechanisms by which H+ permeate lipid membranes remains unclear (1, 2). H+ flux differs from that of other ions in that H+ conductance is not dependent on the actual [H+] in the solution.

Methods: Combining careful proton permeability measurements with structural analyses of lipid bilayers using X-ray diffraction, we have developed models of water, solute and H+ permeation across membranes, comprising various headgroups, chain lengths and extent of unsaturation(3). We compared H+ permeability with physical parameters of the lipids, such as area/lipid, hydrocarbon thickness, bending modulus and compressibility modulus.

Results: Like water and solutes, in membranes composed of a single phospholipid, H+ permeability varied linearly with area/lipid, and was unrelated to other physical parameters. On this basis, in single component lipid systems, the rate limiting step for H+ permeation is penetration of the proton from the aqueous medium into the lipid bilayer. When cholesterol is a component of the bilayer, water permeability decreases (15.8 ±0.58 x 10-3 cm/s and 6.8 ± 0.57 x 10-3 cm/s in absence and presence of cholesterol respectively) , but H+ permeability increases as the proportion of cholesterol increases and as area/lipid decreases (0.056 ± 0.006 cm/s in absence and in presence of cholesterol 0.113 ± 0.005 cm/s).

Conclusions: We conclude that mechanisms of H+ permeability differ markedly from those of water and solutes. We have developed and are testing a new model for H+ permeation, which defines how cholesterol enhances H+ flux, while impeding water and solute fluxes.

Gas Permeability of the Urothelium Mark L. Zeidel,[1] Florian Zocher,[2] Peter Pohl,[2] Tung-Tien Sun,[3] John Mathai.[1] *[1]Medicine, Beth Israel Deaconess Medical Center, Boston, MA; [2]Biophysics, Johannes Kepler University Linz, Linz, Austria; [3]Cell Biology, New York University School of Medicine, New York, NY.*

Background: Mammalian urinary bladder, which maintains enormous chemical gradients between blood and urine exhibits extremely low permeability (P) to water and solutes like urea and other metabolites in the urine. The bladder permeability barrier resides in the umbrella cell (UC) apical membrane (AM) with its specialized lipid composition and dense array of uroplakin complexes. Umbrella cell's of uroplakin II/III knockout mice showed a marked diminution of plaque surface area and significantly enhanced water and urea P which suggested that uroplakins represent a significant component of the AM barrier to water and solute flux across the bladder. Under many conditions PCO2 of urine reaches 80 – 100 mm Hg, 3 – 4 fold higher than the blood PCO2. This high urinary PCO2 suggests that bladder P to CO2 must be very low. We have shown that gases such as CO2 and H2S are freely permeable across the lipid membrane and are limited only by the unstirred layer adjacent to the membrane. Since the umbrella cell apical membrane forms a barrier to water and solute flux, we hypothesized that this specialized membrane may also act as a barrier to CO2 flux.

Results: We measured the CO2 flux across normal urothelium and urothelium in which apical membrane barrier function was disrupted. We found that disrupting apical membrane barrier function gave water and urea P's that were 7 to 8 fold higher than in wild type mice with intact urothelium. However these interventions had no impact on CO2 P's across the bladder (P, 0.0115 cm/s). To test if the observed permeability was due to an unstirred layer effect or due to kinetics of CO2 hydration, we measured the CO2 permeability in MDCK cells in presence (P, 0.035 cm/s) and absence of carbonic anhydrase inhibitor (P, 0.366 cm/s).

Conclusions: Our studies show that the lowered permeability of CO2 across the bladder is mainly due to a lack of carbonic anhydrase in the urothelium and the large unstirred layer created by the 4-5 cell layers of the urothelium.

Functional Implications of Inner Medullary Vascular and Loop-of-Henle Architecture Thomas Pannabecker,[1] William H. Dantzler,[1] Anita T. Layton.[2] *[1]Physiology, University of Arizona, Tucson, AZ; [2]Mathematics, Duke University, Durham, NC.*

Background: A region-based mathematical model of the medullary concentrating mechanism was extended to represent new anatomic findings on vascular architecture in rat inner medulla (IM). We also hypothesize that the terminal aquaporin-1 null segment of the descending thin limb may express a urea-Na+/Cl- co-transporter.

Methods: Radial organization of outer medullary (OM) and IM nephrons and vessels is represented by 4 or 3 interconnected concentric regions, respectively. Water and solute conservation equations incorporate medullary blood flow. Equations embody mass conservation of solute and water, and represent transport of solutes and water by single-barrier equations that represent double-barrier transepithelial or transendothelial transport. Transmural solute diffusion is characterized by solute permeabilities; active transport is represented by saturable Michaelis-Menten kinetics. Water flux is osmotically-driven, or, for ascending vasa recta, is pressure-driven advection.

Results: Model results suggest that, despite compartmentalization, IM interstitial fluid composition is substantially more homogeneous compared to OM. Despite a reduction in IM collecting duct (CD) water permeability, more water is reabsorbed along the IM CD in diuresis, resulting in larger IM blood flow, owing to a much larger transepithelial osmolality gradient. In antidiuresis, as urea diffuses from urea-rich papillary interstitium into descending thin limb lumen, NaCl is secreted via hypothetical urea-NaCl co-transport against its concentration gradient. NaCl is reabsorbed near the loop bend, raising interstitial fluid osmolality and promoting water reabsorption from CDs.

Conclusions: Marked radial organization of the upper IM, centered on the CD clusters, results in sequestration of urea in and near CD clusters. Indirect effects of vasopressin on CDs have much smaller impact on medullary blood flow than direct vasoconstrictive actions. The model predicts that the urea-Na+ or urea-Cl- co-transporter improves the concentrating ability by facilitating cycling of NaCl within the IM, and yields a loop-bend fluid composition consistent with experimental data.

Vasopressin-Induced Phosphorylation at Ser261 in AQP2-P262L May Underlie Nephrogenic Diabetes Insipidus Christiane Trimpert,[1] Enno Klussmann,[2] Peter M.T. Deen.[1] *[1]Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Max Delbrueck Center for Molecular Medicine Berlin, Berlin, Germany.*

Background: Vasopressin regulates water homeostasis through insertion of aquaporin-2 (AQP2) water channels in the apical plasma membrane of collecting duct principal cells. AQP2 mutations cause nephrogenic diabetes insipidus (NDI), a disease in which the antidiuretic response is lacking, resulting in polyuria. While most AQP2 mutants in recessive NDI are misfolded, retained in the endoplasmatic reticulum and unable to interact with wild-type (wt)-AQP2, cell culture studies suggest that AQP2-P262L in recessive NDI folds properly and interacts when co-expressed with wt-AQP2, but is impaired in its vasopressin-induced translocation from vesicles to the apical membrane when co-expressed with other recessive NDI mutants. It was recently shown that besides S256, vasopressin-induced translocation of AQP2 also coincides with AQP2 phosphorylation at S264 and S269 and dephosphorylation at S261. Since P262 lies adjacent to S261, we tested vasopressin-induced phosphorylation of AQP-P262L.

Results: In MDKC and mpkccd cells, wt-AQP2 only shows an unglycosylated 29kDa band, while AQP2-P262L is expressed as a double 29/30kDa band. Using AQP2 antibodies insensitive to phosphorylation, dDAVP increased the presence of the 30kDa band. This band felt back to 29kDa upon treatment with phosphatases, indicating that phosphorylation of AQP2-P262L underlies the appearance of the 30kDa band. Using phospo-specific antibodies, it appeared that, similar to wt-AQP2, dDAVP increased pS256 and pT269 in human AQP2-P262L. However, in contrast to wt-AQP2, pS261 was hardly detectable with control AQP2-P262L and was extensively increased with dDAVP. Moreover, compared to the 29kDa band, 30kDa AQP2-P262L was strongly phosphorylated at S256 and S261.

Conclusions: Our data reveal that vasopressin induces phosphorylation at S261 in AQP2-P262L and that this difference from wt-AQP2 may underlie its inability to sort to the plasma membrane and to cause NDI in the patients.

Collecting Duct-Specific Knockout of Adenylyl Cyclase Type VI Causes Urinary Concentration Defect in Mice Karl P. Roos,[1] Kevin A. Strait,[1] Mitsi A. Blount,[2] Donald E. Kohan.[1] *[1]Department of Medicine, Division of Nephrology, Univeristy of Utah School of Medicine, Salt Lake City, UT; [2]Department of Medicine, Renal Division, Emory University School of Medicine, Atlanta, GA.*

Background: Adenylyl cyclase VI (AC6) has been implicated in arginine vasopressin (AVP)-stimulated renal water reabsorption. To evaluate the role of AC6, we generated mice with collecting duct (CD)-specific KO of AC6 using the Cre/lox system.

Methods: Renal papillary AC6 mRNA was determined. Inner medulla aquaporin (AQP2), urea transporter A1 (UT-A1), and urea transporter A3 (UT-A3) protein expression was analyzed. Inner medullary CD (IMCD) were acutely isolated to evaluate AVP-stimulated cAMP accumulation. KO and floxed controls were studied on normal, high and low water intake, as well as a DDAVP clamp (25 ng/hr). KO and control mice were fed a standardized gel diet containing all daily food and water. All data is expressed as % reduction of KO from control and are all significant ($p<0.05$).

Results: There was a 43% reduction in AC6 mRNA expression in renal papilla (sample contains non-CD cell types). There was a reduction in inner medulla AQP2, UT-A1, and UT-A3, (44%, 21% and 44% respectively), and 66% reduction of AQP2 expression in outer medulla. In acutely isolated IMCD, AVP-stimulated cAMP accumulation was reduced by 44%. Baseline (normal Na diet and free access to water) urine osmolality (Uosm) was reduced 26%. After 18 hr water deprivation, Uosm was reduced by 18%. There was no change in Uosm with chronic water loading. With DDAVP infusion, there was no difference in Uosm under any of the conditions. There was no difference in urine

volume or fluid intake under any of the conditions. After being fed standardized gel diet, plasma AVP levels were unchanged. There was no difference in urine urea excretion on the baseline water intake diet.

Conclusions: In summary, CD-specific KO of AC6 leads to a urinary concentration defect in mice. This is associated with decreased AVP-stimulated cAMP accumulation and reduced expression of AQP2, UT-A1, and UT-A3. These data indicate that AC6 in the CD mediates, at least in part, AVP regulation of water and urea transport pathways.

Familial Azotemia Is Caused by a Duplication of Urea Transporter-B Gene

Arend Bokenkamp,[1] Jeff M. Sands,[2] Lonneke Wigman,[3] Rob Van Zwieten,[3] Arthur J. Verhoeven,[4] Janet D. Klein,[2] Tiffany L. Thai,[2] Lia A.C. Knegt,[4] Jaap Willem Groothoff,[4] Gabor E. Linthorst.[4] *[1]Pediatric Nephrology, VU University Medical Center, Amsterdam, Netherlands; [2]Department of Medicine, Emory University, Atlanta; [3]Sanquin Blood Transfusion Service, Amsterdam, Netherlands; [4]Medical Biochemistry/Clinical Genetics/Pediatrics/Internal Medicine, Academic Medical Center, Amsterdam, Netherlands.*

Background: Facilitated urea transport in the kidney is regulated by urea transporters UT-A and UT-B. UT-A is expressed in different nephron segments, UT-B in the descending vasa recta and on erythrocytes. Autosomal dominant familial azotemia has been reported in two kindreds. It is characterized by high plasma urea due to an isolated impairment of urea excretion. Here, we report a family with autosomal-dominant azotemia segregating with a duplication of the UT-B gene.

Methods: Case report: The index patient, her brother and her son have isolated azotemia (plasma urea 46 mmol/l) due to strongly diminished fractional excretion of urea of 1.4% (normal 30%). Creatinine clearance and other tubular functions are normal.

Results: CGH array analysis revealed a duplication on chromosome 18q12.3-21.1, which includes the gene coding for UT-B. A kidney biopsy revealed isolated UT-B staining in the vasa recta in the affected child and a control biopsy indicating orthotopic expression. UT-B content by Western-blot in biopsy material was twice that of a control. This coincided with increased UT-B expression on erythrocytes (142% of controls) and a threefold acceleration of urea-induced hemolysis.

Conclusions: Impaired fractional excretion of urea segregates with a duplication in the UT-B gene. This leads to increased expression of UT-B in kidney and on erythrocytes. Functional studies demonstrate increased urea transport in erythrocytes. This is suggestive of an increased urea transport in the descending vasa recta, while ectopic UT-B expression was ruled out. We hypothesize that increased delivery of urea to the inner medulla exceeds UT-A mediated excretion in Henle's loop causing backflow to the systemic circulation via the ascending vasa recta.

SA-PO2742

Demeclocyclin Attenuates Hyponatremia by Reducing Adenylate Cyclase and Aquaporin-2 Expression

Anne P. Sinke,[1] Marleen L.A. Kortenoeven,[2] Peter M.T. Deen.[1] *[1]Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Anatomy, University of Aarhus, Aarhus, Denmark.*

Background: Demeclocycline is a bacteriostatic antibiotic of the tetracycline group, which has been shown to cause water diuresis and nephrogenic diabetes insipidus and is used to treat hyponatremia. Although demeclocycline is thought to act in the distal part of the renal nephron, the exact mechanism is not known.

Methods: Mouse cortical collecting duct (mpkCCD) cells were treated with deamino-8 D-arginine vasopressin (dDAVP) to induce endogenous AQP2 expression, and treated with demeclocycline for the last 24 hours. Demeclocycline reduced AQP2 abundance in mpkCCD cells in a time and dose dependent manner. This effect was abolished by inhibiting protein synthesis, implying that a decrease in AQP2 production explains the AQP2 down-regulation. Using a AQP2-promoter-luciferase construct, it was shown that demeclocycline decreases AQP2 transcription. Further analysis revealed that demeclocycline decreased adenylate cyclase III and V/VI expression and inhibited vasopressin induced cAMP production.

Results: To test the physiological relevance of these data, rats receiving liquid diet in combination with dDAVP and with or without demeclocyclin were examined. In these hyponatremic rats, demeclocyclin increased urine volume (44.8 ± 9.3 vs 91.3 ± 15.9 ml/kg/24 hours; $p<0.05$), decreased urine osmolality (1374 ± 117 vs 820 ± 148; $p<0.05$), and reduced hyponatremia (117.3 ± 4.5 vs 98.7 ± 0.8 mmol/l; $p<0.05$). Immunoblotting revealed reduced AQP2 and adenylate cyclases in the inner medulla only.

Conclusions: Our in vitro and in vivo data reveal that demeclocycline causes diuresis and reduces hyponatremia by affecting adenylate cyclases III or V/VI expression resulting in reduced cAMP and AQP2 expression in the inner medullary collecting duct.

The AVP-Stimulated NaCl Absorption in Mouse Medullary Thick Ascending Limb Is Abolished by the V2 Receptor Antagonist Satavaptan

Rita D. Marques,[1] Pauline De Bruijn,[1] Markus Bleich,[2] Helle A. Praetorius,[1] Jens G. Leipziger.[1] *[1]Physiology and Biophysics, Aarhus University, Aarhus, Denmark; [2]Physiology, Christian Albrechts University, Kiel, Germany.*

Background: Arginin-vasopressin (AVP) activates water and electrolyte absorption in the collecting duct as well as electrolyte absorption in the thick ascending limb (TAL). In all renal tubules, which respond to AVP the hormone causes increases of cAMP and intracellular Ca^{2+}. The V2 receptor is critical for most renal tubular actions of AVP. However, other AVP receptors (V1) are known to be expressed in TAL of certain mammalian species.

Objective: Investigate the effect of the highly specific V2 receptor antagonist satavaptan on AVP-stimulated NaCl transport in mouse thick ascending limb.

Methods: We used isolated, perfused mouse mTAL to electrically measure Na^+ absorption. By electrodes we determined the transepithelial voltage (V_{te}) and the transepithelial resistance (R_{te}) and via these the transepithelial Na^+ absorption (equivalent short circuit current, I_{sc}).

Results: Non-stimulated mTALs showed a lumen-positive transepithelial voltage (V_{te}) of +6.26±1.02 mV and a transepithelial resistance (R_{te}) of 3.05±0.45 Ω cm^2 resulting in an equivalent short circuit current (I_{sc}) of 2196±356 μA/cm^2 (n=5). Within 5-10 minutes basolateral AVP (10 nM) triggered a pronounced and ongoing activation of transport as seen by an increase of V_{te} to +11±0.71 mV and I_{sc} to 3460±475 μA/cm^2. R_{te} remained unaltered. In paired experiments satavaptan (1 μM) completely abolished the AVP-induced increase in V_{te} and I_{sc} (n=5). Satavaptan did not influence baseline mTAL transport.

Conclusions: These are the first functional data in isolated perfused mTAL to quantify the effect of specific V2 antagonists on NaCl transport. They indicate that V2 receptor blockage is sufficient to suppress the entire AVP-activated NaCl absorption in mouse mTAL. Other vasopressin receptors appear not to be involved. Thus, the critical role of the V2 receptor for AVP-mediated transport activation is confirmed.

Cold-Induced AQP2 Basolateral Membrane Accumulation in Polarized MDCK Cells

Naofumi Yui, Dennis Brown. *Program in Membrane Biology, Massachusetts General Hospital and Harvard Medical School, Boston, MA.*

Background: AQP2 accumulates in the apical plasma membrane of collecting duct principal cells upon stimulation by vasopressin (VP). However, basolateral AQP2 has been reported in vivo, and forskolin (FK) or VP-induced AQP2 plasma membrane distribution is different among cultured cell lines. Here, we report experimental conditions that affect the polarized expression of AQP2 in MDCK cells.

Methods: We initially performed domain-specific biotinylation assays and immunofluorescence (IF) on filter-grown MDCK cells before and after stimulation with FK.

Results: By surface biotinylation, AQP2 was clearly detected in the basolateral membrane under basal conditions, and this expression was not increased by FK. However, by IF, AQP2 was not detected in the basolateral membrane, but instead accumulated only in the apical membrane after FK. This discrepancy, together with a previous finding that basolateral AQP2 appeared after cold incubation (4°C for 4 h) in rat kidney slices, led us to hypothesize that cold exposure (4°C), necessary for biotinylation, might induce basolateral AQP2 accumulation. Indeed, by IF, AQP2 was clearly accumulated in MDCK cell basolateral membranes after 15 min at 4oC, even in the absence of VP or FK. After rewarming to 37°C, AQP2 was internalized into vesicles, suggesting that MDCK cells were not irreversibly damaged, but had been temporarily modified by the low temperature. This cold-induced AQP2 basolateral membrane accumulation was not seen in transfected LLC-PK1 cells, suggesting that the effect is cell-specific. Furthermore, the effect was not reproduced at 37°C after microtubule disruption by colchicine, ruling out one possible explanation for our data (MT are depolymerized at 4°C).

Conclusions: These results suggest that a basolateral targeting pathway for AQP2 is present in MDCK cells and can be revealed by cold treatment. This system may be useful in the further understanding of this targeting process, which also occurs in some renal tubule segments. In addition, our results raise a note of caution for interpretation of basolateral signals in domain-specific biotinylation assays.

SA-PO2745

Membrane Fusion Protein SNAP23 Mediates Constitutive NKCC2 Trafficking in Thick Ascending Limbs

Paulo S. Caceres,[1,2] Pablo A. Ortiz.[1,2] *[1]Hypertension & Vascular Res, Henry Ford Hospital; [2]Physiology, Wayne State Univ, Detroit, MI.*

Background: Vasopressin stimulates NaCl reabsorption and NKCC2 in the thick ascending limb (TAL) by enhancing cAMP. Trafficking of NKCC2 to the apical surface is required for ion transport and this is stimulated by cAMP. In all cells, vesicle fusion is mediated by proteins of the SNARE family. Vesicle Associated Membrane Proteins (VAMPs) recognize two other SNAREs in the target membrane: a SNAP (Synaptosome Associated Protein) and a syntaxin. We previously found that VAMP3 mediates constitutive delivery of NKCC2 to the surface while VAMP2 mediates cAMP-stimulated NKCC2 trafficking. The target membrane SNAREs involved in NKCC2 trafficking are unknown. Four SNAP isoforms (23,25,29 and 47) have been described. SNAP23 is present in the kidney and binds VAMP2 and VAMP3 in other cells. We hypothesized that SNAP23 colocalizes with NKCC2 and mediates constitutive and cAMP-stimulated NKCC2 trafficking in TALs.

Methods: TALs were transduced in vivo with adenoviruses coding for a dominant-negative SNAP23 (SNAP23ΔC8) injected into the outer medulla. TAL suspensions were obtained from the left kidney (SNAP23ΔC8-transduced) and the control right kidney (GFP-transduced), and incubated with vehicle or forskolin+IBMX to increase intracellular cAMP. Surface NKCC2 was measured by surface biotinylation of TAL suspensions obtained from transduced kidneys. Immunolabeling of SNAP23 and NKCC2 was performed in isolated, perfused TALs.

Results: SNAP23 colocalized with NKCC2 in the apical membrane and subapical space. Expression of dominant negative SNAP23ΔC8 decreased constitutive surface NKCC2 by 36±6% ($p<0.01$). However, cAMP increased surface NKCC2 to similar extent

in control and SNAP23ΔC8-transduced TALs (GFP: 91±23%, SNAP23ΔC8: 140±20% increase from baseline, n=5). SNAP23ΔC8 did not affect total NKCC2 levels (5±13% of control). A Western blot screening in TALs revealed expression of SNAP23, 29 and 47 but not SNAP25.

Conclusions: We conclude that SNAP23 is involved in constitutive (biosynthetic) but not in cAMP-stimulated NKCC2 trafficking in the TAL, most likely by pairing with VAMP3. Other SNAP isoforms are expressed and may be responsible for cAMP-stimulated NKCC2 trafficking.

Decreased Abundance of Urinary Exosomal Aquaporin-2 after Renal Ischemia-Reperfusion in Rats and Humans Hiroko Sonoda,[1] Naoko Yokota-Ikeda,[2] Shigehiro Uezono,[2] Sayaka Oshikawa,[1] Masahiro Ikeda.[1] *[1]Veterinary Pharmacology, University of Miyazaki, Japan; [2]Nephrology, Miyazaki Prefectural Miyazaki Hospital, Miyazaki, Japan.*

Background: Urinary exosomes are small vesicles secreted by all tubular epithelial cells and are known to contain membrane proteins. Several studies have shown that urinary exosomal proteins have potential to be used as biomarkers for renal diseases. So far, we have reported that urinary exosomal aquaporin-2 (AQP2) is continuously decreased in cisplatin-induced acute kidney injury (AKI) in rats. However, it has not been examined whether urinary exosomal AQP2 levels are affected by renal ischemia-reperfusion (I/R) that is also known to cause AKI. In this study, we examined the abundance of urinary exosomal AQP2 following renal I/R in a rat model and in kidney transplantation patients.

Methods: Rats were subjected to unilateral renal I/R (I/R-rats) or sham operation (sham-rats). Urinary exosomes were isolated by differential ultracentrifugation.

Results: In I/R-rats, plasma creatinine concentration was slightly but significantly higher than in sham-rats. As judged by immunoblot analysis, urinary exosomal AQP2 level was significantly lower in the urine collected at 0-6 h after renal I/R, in comparison with the sham-rats. However, this reduction was not further observed in the urine collected at later times. Renal AQP2 protein level was significantly decreased at 6 h after I/R in the cortex but not in the outer and the inner medulla. In 9 human recipient patients, all exosomal AQP2 levels in urine collected within 2 days after kidney transplantation through the urinary catheter for 30 min were less than 4% of the mean value for 3 healthy volunteers. On the other hand, such reduction in urinary exosomal AQP2 was only observed in 4 out of 49 patients with various renal diseases (IgA nephritis, minimal change diseases, and etc.) other than AKI and end-stage renal disease.

Conclusions: These results indicate that urinary exosomal AQP2 abundance decreases at an early time after renal I/R along with decrease in renal cortex AQP2 content, suggesting urinary exosomal AQP2 as a biomarker for the early detection of renal I/R-induced AKI.

SA-PO2747

PPARγ Controls Urine Concentrating Ability Independently of Vasopressin Tianxin Yang,[1,2] Alexandra Panasiuk,[1] Maicy Downton,[1] Li Zhou,[1,2] Zhanjun Jia.[1,2] *[1]Internal Medicine, University of Utah; [2]VA Medical Center.*

Background: The synthetic PPARγ agonists, thiazolidinediones (TZDs), are highly effective in managing type 2 diabetes but are limited by a major side effect of fluid retension. Despite intensive investigation, the role and mechanism of PPARγ regulation of fluid metabolism is still incompletely understood. The present study was undertaken to investigate the integrative role of PPARγ in regulation of fluid homeostasis.

Methods: The inducible whole-body PPARγ knockout mice were created by crossing floxed PPARγ mice with β-actin-Cre/ESR mice, followed by tamoxifen treatment. The phenotype in these mice was analyzed.

Results: The KO mice had grossly normal phenotype except a modestly increased food intake (WT: 5.26±0.439g vs. KO: 4.46±0.152g, $p<0.05$). Strikingly, the KO mice developed severe urine concentrating defect as evidenced by marked increases in water intake (WT: 5.3±0.72 mL vs. KO: 7.2±1.28 mL, $p<0.05$) and urine volume (WT: 1.45±0.216 mL vs. KO: 2.52±0.497 mL, $p<0.01$) accompanied with reduced urine osmolality (WT: 2796.7±439.72 mOsm/kg H_20 vs KO: 1488.0±282.79 mOsm/kg H_20, $p<0.01$). The urine concentrating defect persisted after pair-feeding or in combination with pair-drinking. Surprisingly, plasma vasopressin concentration assessed by ELISA was not different between the genotypes. After 24-h water deprivation, urine osmolality increased 27% in WT mice but failed to rise in the KO mice. However, the responsiveness to acute (0.06 ng/kg i.p.) and chronic (1μg/kg/day) deamino-8-D-arginine vasopressin (dd-AVP) treatment remained intact in these mice.

Conclusions: Together, we identified PPARγ as an essential regulator of urine concentrating ability that appears to be independent of vasopressin.

SA-PO2748

Quantitative Phosphoproteomics of Bilateral Ureteral Obstruction Induced Nephrogenic Diabetes Insipidus Sookkasem Khositseth,[1] Panapat Uawithya,[2] Poorichaya Somparn.[3] *[1]Department of Pediatrics, Faculty of Medicine, Thammasat University, Pathumthani, Thailand; [2]Department of Physiology, Faculty of Medicine, Siriraj Hospital, Mahidol University, Thailand; [3]Biomedical Science, Graduate School, Chulalongkorn University, Thailand.*

Background: Nephrogenic diabetes insipidus (NDI) is a common complication in patients with obstructive uropathy.

Methods: We employed phosphoproteomics of rat inner medullary collecting duct (IMCD) to investigate the mechanism of bilateral ureteral obstruction (BUO)-induced NDI. IMCD isolated from 7 12-hr BUO rats and 7 sham-operated rats were compared (n=3). The samples were enriched for phosphopeptides using Ga^{3+}immobilized metal affinity chromatography, and analyzed by liquid chromatography-tandem mass spectrometry using an LTQ-OrbitrapVelos machine. Phosphopeptide identification was performed using SEQUEST algorithm and label-free quantification was executed using QUOIL software (NHLBI Proteomics Core Facility).

Results: We identified 30 increased phosphorylation sites and 84 decreased phosphorylation sites in the BUO. The increased phosphorylation sites present in proteins involved in cytoskeletal reorganization (Lima1, Plec, Pxn, Twf1, Sept2), vesicle trafficking (Ebag9), transcriptional regulation (Ebag9, Eif4b), and nucleotide binding (Hnrnpk, Pds5b, Rbm39, Top2a). The decreased phosphorylation sites present in channel proteins (Aqp2 and Slc14a2), cytoskeletal proteins (Add1, Cnn3, Ctnna1, Ctnna2, Cttn, Myh9), nucleotide binding proteins (Hdgf, Hnrnpc, Hnrpd, Nucks1, Psip1), small G protein (Fgd2), and steroid binding protein (Pgrmc2). Down-regulation of aquaporin-2(Aqp2) phosphorylation at S256, S261, and S264 (by 33.5%), and urea transporter (Slc14a2) phosphorylation at S62, and S63 (by 17.4%) were observed. Immunoblotting showed a significant reduction in total Aqp2 (82%, $P<0.001$), pS256-Aqp2 (95%, $P<0.01$), and total UT-A1 (68.2%, $P<0.001$) in BUO IMCD compared to the sham control.

Conclusions: Two key proteins in urine concentrating mechanism, Aqp2 and Slc14a2, were found decreased in both total and phosphorylated forms in BUO-induced NDI model in rat. Other signaling molecules that might play important role in this disease process were also identified.

SA-PO2749

Impaired Renal Water Reabsorbtion Mediated by Vascular Disrupting Agent Anja Bille Bohn,[1,2] Rikke Norregaard,[3] Yan Wang,[3] Lotte Bonde Bertelsen,[2] Michael R. Horsman,[1] Hans Stødkilde-Jørgensen,[2] Jorgen Frokiaer.[3] *[1]Department of Experimental Clinical Oncology, Aarhus University Hospital, Denmark; [2]MR-Research Centre, Aarhus University Hospital, Denmark; [3]Institute of Clinical Medicine, Aarhus University, Denmark.*

Background: Combretastatin A-4 phosphate (CA4P) is a vascular disrupting agent shown to mediate its effect primarily on tumor blood vessels. We have previously shown that CA4P results in a significant increase in hematocrit and in mean arterial blood pressure in non-tumour bearing mice. Based on this we now want to examine whether this is associated with molecular changes in renal water handling.

Methods: Non-tumour bearing male Wistar rats were injected intraperitoneally with CA4P (30 mg/kg) or saline (controls). Blood samples and urine was collected and analyzed. Tissue water content was assesed using DCE-MRI. Renal tissue was examined for AQP2, the active phosphorylated AQP2 (pAQP2) and vasopressin V2 receptor (V2R) expression in inner medulla (IM). Furthermore, medullary osmolality and cAMP was determined.

Results: Total hemoglobin increased 1h after CA4P treatment (11.1±0.3 vs. 9.2±0.3 mmol/l, $p<0.01$). Tissue water content in muscle, brain, or renal tissue following CA4P administration did not change significantly. Urinary water and salt excretion in the CA4P treated rats increased significantly during the first hour after treatment (200.1±20.6 vs. 90.0±12.1 μl/min/kg, $p<0.01$ and 16.9±3.8 vs. 3.9±0.9 μmol/min/kg, $p<0.01$, respectively). Urine and medullary osmolality decreased 2h after CA4P. AQP2 mRNA level in IM did not change in response to CA4P treatment. However, immunohistochemistry showed an apical localization of pAQP2 in control rats compared to a more diffuse pAQP2 distribution within the IM principal cells in the CA4P treated rats. V2R expression and medullary cAMP concentration did not change 1h after CA4P. Three hours after CA4P treatment the AQP2 mRNA level and the pAQP2 protein level was significantly increased compared to controls.

Conclusions: The data are compatible with the notion that CA4P affects the urine concentrating ability through a local renal effect on colleting duct water permeability due to changed AQP2 trafficking.

SA-PO2750

Urine Concentration Defect in the Absence of Urea Transpoters-A1/A3 May Involve an Inability to Phosphorylate Aquaporin2 at Serine 256 Titilayo O. Ilori, Jeff M. Sands, Janet D. Klein. *Medicine, Emory University School of Medicine, Atlanta, GA.*

Background: Polyuria is a significant clinical manifestation of diabetes mellitus yet diabetics rarely go into hypovolemic shock. Upregulation of aquaporin 2 (AQP2) and urea transporters increase water and solute reabsorption. In the absence of the urea transporters UT-A1 and UT-A3, AQP2 cannot stimulate increased urine osmolality even with vasopressin. In this study we looked for changed in phosphorylated AQP2 in response to diabetes in wild type (WT) and UT-A1/A3 knockout (KO) mice.

Methods: WT and A1/A3 KO mice were injected 2 times with 100mg/kg streptozotocin. After 24 h hyperglycemia was verified. Metabolic cages were used to collect 24 h urines for osmolalities. Mice were sacrificed at 7 days or when humane end points were reached. Lysates of inner medullas were analyzed by western blot probing for total AQP2 and pser256- and pser261-AQP2. Thereafter, WT and A1/A3 KO were treated with vasopressin for 7 days via minipump. Aquaporin 2 levels were then measured by western blot.

Results: There was a 40% survival of UT-A1/A3 KO 7d post-STZ injection compared to 70% in WT. AQP2 levels are decreased 30% in UTA1/A3 KO mice compared to WT mice and did not increase in the diabetic A1/A3 KO mice, compared to a 133% increase in WT diabetic mice. Vasopressin treatment (7-days) up-regulated AQP2 abundance in the UT-A1/A3 KO mice, but did not correct the KO's polyuria. Pser256 AQP2 was lower in the

UT-A1/A3 KO vs WT mice and did not increase in either WT or KO mice with diabetes. Pser261-AQP2 tended to be decreased with diabetes in both KO and WT mice consistent with increased vasopressin levels in diabetic animals.

Conclusions: We conclude that despite increased AQP2 in response to vasopressin, in the absence of UT-A1 and UT-A3 the diabetic animal is unable to optimally activate AQP2 consistent with decreased pser256-AQP2 in both normal and diabetic KO vs WT mice. An inability to activate AQP2 despite increased protein may explain the lack of vasopressin-mediated urine concentration in the absence of UTA1/A3.

Urinary Exosomal Aquaporin-2 Excretion Is Altered by the Treatment with Furosemide or Acetazolimide, in Association with Vasopressin Yoshiki Higashijima, Hiroaki Kondo, Kanako Shigemura, Saki Takahashi, Hiroko Sonoda, Masahiro Ikeda. *Veterinary Pharmacology, University of Miyazaki, Japan.*

Background: Aquaporin-2 (AQP2) is the only AQP regulated by vasopressin. In response to vasopressin, AQP2 traffics to the apical plasma membrane to increase water permeability in collecting ducts. Exosomes are membranous vesicles delivered to the urine from all renal epithelial cell types and this urinary exosomes are known to contain membrane proteins including AQP2. So far, we reported that urinary exosomal AQP2 level was continuously decreased in rats treated with cisplatin, suggesting urinary exosomal AQP2 as a biomarker for the detection of cisplatin-induced acute kidney injury (2010 ASN). However, at present the mechanisms underlying the excretion of urinary exosomal AQP2 are largely unknown. In order to elucidate the mechanism, this study examined the effects of diuretics on the excretion of urinary exosomal AQP2.

Methods: A 2-h urine was collected from rats treated with saline (control), furosemide (20 mg/kg), acetazolamide (50 mg/kg), or OPC-31260 (10 mg/kg, a V2 receptor antagonist). Urinary exosomes were isolated from the collected urine by differential ultracentrifugation.

Results: Western blot analysis revealed that urinary exosomal AQP2 abundance was dramatically increased in the furosemide and the acetazolamide groups, in comparison with the control group, while OPC-31260 had no significant effect on the urinary exosomal AQP2 excretion. In the furosemide and acetazolamide groups, renal AQP2 protein level was significantly decreased in the cortex but not in the outer and the inner medulla, and this decrease was accompanied with the enhancement of the apical expression of AQP2. Co-administration of OPC-31260 with furosemide or acetazolamide completely inhibited the increased excretion of urinary exosomal AQP2 in response to furosemide or acetazolamide.

Conclusions: Our results indicate that basal excretion of urinary exosomal AQP2 is independent of vasopressin, but its increased excretion by a decrease in body fluid volume through treatments with diuretics is initiated by vasopressin.

SA-PO2752

Decreased Aquaporin 2 and Urea Transporters in a Rat Model of Nephrotic Syndrome Raed Bou Matar,[2] Jeff M. Sands,[1] Janet D. Klein.[1] [1]*Renal Division, Emory University, Atlanta, GA;* [2]*Department of Pediatrics, Emory University, Atlanta, GA.*

Background: Urea transporters and aquaporins play an important role in the regulation of water homeostasis. Nephrotic syndrome is associated with significant primary renal salt and water retention. This study investigates the role of urea transporters and aquaporins in nephrotic syndrome associated water retention. We tested the effect of doxorubicin-induced nephrotic syndrome on the abundance of urea transporters UT-A1, UT-A3, aquaporin-2 (AQP2), and Na-K-Cl Cotransporter 2 (NKCC2) in the rat kidney tissue.

Methods: Three cohorts of male Sprague Dawley rats (total n = 18 treatment, 13 control) were injected intravenously with doxorubicin and urinary protein excretion was monitored. Upon confirmation of high grade proteinuria using spot urine protein to creatinine ratios (Pr/Cr), we determined urine osmolality, serum cholesterol, and serum creatinine by specific chemical assays. A Pr/Cr of 80 was used as the endpoint indicator. Kidney tissue was dissected and analyzed for the abundances of UT-A1, UT-A3, AQP2, and NKCC2 using western blot.

Results: Within 2 weeks following doxorubicin injection, all treated rats developed features of nephrotic syndrome, with an average 9-fold increase in urine Pr/Cr ratio (from 15 ± 2 to 130 ± 10; $p < 0.001$) and significant hypercholesterolemia (from 103 ± 2 mg/dl to 276 ± 19 mg/dl). Urine osmolalities were reduced by 38 ± 5% in the doxorubicin treated group (983 ± 84, treatment vs. 1570 ± 134, control). UT-A1 and UT-A3 protein abundances in IM tip tissue were significantly decreased (44 ± 8% and 31 ± 5% respectively; $p < 0.001$) in nephrotic rats. AQP2 protein abundance was also significantly reduced (65 ± 7%, $p < 0.001$) in the nephrotic group as compared to control rats. A 72 ± 5% reduction in the abundance of the NKCC2 was noticed in outer medullary tissue of nephrotic rats as compared to controls.

Conclusions: AQP2, UT-A1, UT-A3, and NKCC2 are decreased in doxorubicin-induced nephrotic syndrome and may represent a response to avid reabsorption of sodium at the level of the cortical collecting duct, coupled with a general disruption of the normal corticomedullary osmotic gradient.

SA-PO2753

Enhanced Renal Expression of *SGLT2* Gene in Response to Diabetes Niloofar Moeini Tabatabai, Rajendra Kishore Kothinti. *Medicine, Medical College of Wisconsin, Milwaukee, WI.*

Background: SGLT2 is the major glucose transporter in the kidney and is expressed on the apical side of the proximal tubule cells. It has been suggested that SGLT2 expression may be enhanced in type 2 diabetic patients. The goal of this study was to examine temporal changes in renal expression of *SGLT2* gene in response to diabetes.

Methods: Zucker Diabetic Fatty (ZDF) (*fa/fa*) rats, a model of type 2 diabetes, and non-diabetic *fa/+* controls were obtained. Five male 5 weeks (wk) old controls and 5, 8, 12, 15, and 19 wk old *fa/fa* were used. Overnight urine was collected from fasting rats. Rat was anesthetized, blood was collected from the heart, and left kidney was removed. Serum and urine concentrations of glucose and serum insulin levels were measured. To examine *SGLT2* gene expression, total RNA from kidney tissues were prepared, reverse transcribed, and cDNA samples were used in real time polymerase chain reaction with SYBR Green reagents. Amplification of small subunit ribosomal protein 15 (S15) cDNA was used as endogenous control and fold difference between *fa/fa* groups and controls were determined.

Results: Fasting serum glucose in 5 wk old control and *fa/fa* were 109 and 195 mg/dL, respectively. In *fa/fa*, serum glucose increased to 221 mg/dL by 8 wk of age, it reached 301 mg/dL in 12 wk old rats and remained as high in 15 and 19 wk old *fa/fa*. Glucose excretion was only ~0.018 g/day in 5 wk old control and *fa/fa*; however, 8 wk old *fa/fa* were glucosuric and excreted 9 g of glucose/day. Glucose excretion almost doubled by 12 wk, reached 21 g/day by 15 wk, and then declined. In 5 wk old *fa/fa*, serum insulin was 1.5 ng/ml, reached maximum of 11 ng/ml at 8 wk of age, and declined to ~2 ng/ml in older rats. Relative expression of *SGLT2* mRNA in the kidneys of 5 wk old *fa/fa* was 1.6 (arbitrary unit, A.U.) and it increased 1.6 folds to maximum of 2.5 A.U. by 8 wk of age. *SGLT2* expression in 12 and 15 wk old *fa/fa* were 1.53 and 1.76 A.U., respectively, and decreased to 0.82 A.U. by 19 wk of age.

Conclusions: Results of this study show that renal expression of *SGLT2* gene was enhanced in the early stages of the development of type 2 diabetes in ZDF *fa/fa* model. Increased expression of SGLT2 may augment symptom of hyperglycemia.

SA-PO2754

Hypertonicity Increased Glutathione Content in MDCK Cells and Had Protective Effect Against H_2O_2 Induced Cell Damage Masaru Horio. *Functional Diagnostic Science, Osaka University Graduate School of Medicine, Suita, Japan.*

Background: Oxidative stress in renal tubular cell is a possible factor inducing the cell damage. Hypertonicity is one of the main causes of the oxidative stress. Glutathione (GSH) is an important antioxidant, but the content after hypertonic exposure has not been well studied. GSH content after hypertonic exposure and effect of preincubation with hypertonic medium on oxidative stress were evaluated.

Methods: ROS generation was detected using carboxy-H_2DCFDA**.** GSH content, activity of glutamate-cysteine ligase (GCL), the rate-limiting enzyme of GSH synthesis, and contents of amino acids, which included primary sources of GSH, were measured. Cell damage was assessed by LDH activity in culture medium.

Results: Hypertonicity increased reactive oxygen species (ROS) in an osmolality dependent manner. Hypertonicity of 400 and 450 mOsm significantly increased GSH content up to 1.5 fold the value of isotonic cells after 8h. Higher osmolality (500 and 600mOsm) did not show further increase of GSH, but decrease the GSH content. Significant increase of GCL activity was not observed after 8h of hypertonicity of 350, 400 and 450 mOsm. Contents of glutamate, glycine and cysteine which were precursors of GSH, were significantly increased 7, 3 and 2 fold the value of isotonic cells after 8h of hypertonicity, respectively. This might be a mechanism of inducing GSH content by hypertonicity. H_2O_2 showed cell damage in MDCK cells in dose dependent manner assessed by LDH activity in culture medium. 24h-preincubation of 400mOsm significantly protected the H_2O_2-induced cell damage.

Conclusions: Preincubation of mild hypertonicity has a protective effect on H_2O_2 induced cell damage in MDCK cells. Increase of GSH content by hypertonicity may contribute to the protective effect.

Removal of Indoxyl Sulfate by Hybrid Kidney with Human Organic Anion Transporter-3 Over-Expressing Cells Hisashi Yamamoto,[1] Shuichi Tsuruoka,[1 2 3] Takashi Ioka,[1] Yoshikatsu Kanai,[4] Hitoshi Endou,[5] Akio Fujimura,[2] Eiji Kusano.[1] [1]*Nephrology, Jichi Medical University, Tochigi, Japan;* [2]*Clinical Pharmacology, Jichi Medical University, Tochigi, Japan;* [3]*Nephrology, University of Tsukuba, Ibaraki, Japan;* [4]*Pharmacology, Osaka University, Osaka, Japan;* [5]*Pharmacology and Toxicology, Kyorin University School of Medicine, Tokyo, Japan.*

Background: Indoxyl sulfate (IS), one of the protein-bound uremic toxins and a substrate of organic anion transporter (OAT)-3, is cleared poorly by conventional hemodialysis. One of the reasons for the high incidence of cardiovascular disease in dialysis patients is accumulation in the body of uremic toxins. We have previously

reported a hybrid-type artificial kidney by introducing drug transporter gene and succeeded experimental treatment of drug intoxication. We evaluated the efficacy of a hybrid kidney with introducing OAT-3 gene for IS removal in vitro and in vivo.

Methods: The proximal tubule cell line over-expressing human OAT-3 (S2-hOAT3) and control gene (S2-DNA) were cultured onto the hollow fiber module. Transport of IS from the capillary to pericapillary side were evaluated in vitro. The hybrid kidney system was further connected to 7/8-nephrectomized uremic dogs and blood was circulated for 4-hour through the system. Arterial and venous blood concentrations of IS were monitored during the treatment.

Results: In vitro clearance of IS in hollow fiber module with S2-hOAT3 (45 ± 3.6 ml/min) was significantly higher than in S2-DNA (7.1 ± 1.6 ml/min) and no cells (12.6 ± 1.4 ml/min), respectively. When we applied this module to 7/8-nephrectomized uremic dogs, the arterial IS levels decreased from 0.53 ± 0.06 to 0.16 ± 0.02 mg/dl by 4-hour treatment of S2-hOAT3. In vivo clearance of IS was significantly higher in S2-hOAT3 (46.4 ± 3.0 ml/min) than in S2-DNA (0.8 ± 0.5 ml/min) and no cells (6.17 ± 1.8 ml/min), respectively.

Conclusions: These results demonstrated that our hybrid kidney with S2-hOAT3 can selectively remove IS in uremic dog. This might be useful for the treatment of chronic renal failure patients to avoid cardiovascular complications.

SA-PO2756

Inhibitory Effect of Overexpression of Aquaporin-11 on Intracellular Ca^{2+} Release in Transfected Mammalian Cells Ryuji Nishimura, Kanako Muta, Saki Takahashi, Hiroko Sonoda, Masahiro Ikeda. *Veterinary Pharmacology, University of Miyazaki, Japan.*

Background: The aquaporins (AQPs) are a family of membrane protein that are selectively permeable to water and glycerol. So far, thirteen AQPs (AQP0 - AQP12) have been identified in mammals, and among them the recently identified molecule AQP11 is known to be localized in the endoplasmic reticulum (ER), an intracellular Ca^{2+} store. Furthermore, AQP11-null mice die in the neonatal period due to renal failure with progressive renal cyst formation. However, the molecular function of AQP11 is largely unknown. In this study, we examined whether AQP11 affected intracellular Ca^{2+} response in transfected mammalian cells.

Methods: Intracellular Ca^{2+} concentration was monitored with Fluo4 in CHO-K1 cells transfected with each expression plasmid. Cultured cells were observed 24 h post-transfection using a confocal microscope.

Results: The elevation of intracellular Ca^{2+} concentration in response to ATP was completely inhibited in both the presence and absence of extracellular Ca^{2+} in cells expressing N-terminal DsRed monomer-tagged AQP11 (DsRM-AQP11). Similar inhibition was also observed in cells expressing myc-AQP11 or AQP11-DsRM. On the other hand, no inhibition of ATP-induced Ca^{2+} increase was observed in cells expressing DsRM-AQP1. Under extracellular Ca^{2+}-free condition, ionomycin is known to mobilize Ca^{2+} from intracellular Ca^{2+} stores, depending on Ca^{2+} content of the stores. When cells expressing DsRM-AQP11 was treated with ionomycin in the absence of extracellular Ca^{2+}, ionomycin-induced Ca^{2+} response was also significantly inhibited. In order to identify the amino acid region involved in inhibiting the Ca^{2+} response, we examined the effect of the overexpression of deletion mutant (DsRM-AQP11-E230X, -L196X, -V161X, -G111X, -H74X, -E50X) on ATP-induced Ca^{2+} increase. As a result, reduced inhibition of ATP-induced Ca^{2+} -increase was observed only in cells expressing DsRM-AQP11-E50X.

Conclusions: These data indicate that AQP11 inhibits ATP-induced Ca^{2+} release via the depletion of intracellular Ca^{2+} stores, suggesting the importance of AQP11 in the regulation of intarcellular Ca^{2+} concentration.

Aquaporin-11 Expression in the Brain: Choroid Plexus and Capillaries with Blood-Brain Barrier Function Shin Koike,[1] Yasuko Tanaka,[1] Yoshiyuki Morishita,[2] Kenichi Ishibashi.[1] *[1]Meiji Pharmaceutical University, Japan; [2]Jichi Midical School, Japan.*

Results: We found that AQP11 was expressed in the cytosol of choroid plexus epithelia and at endothelia of brain capillaries by immunohistochemistry selectively as absent in other capillaries outside the brain. AQP1 was also expressed at choroid plexuses and capillaries while AQP4 was expressed at astrocytes around capillaries. AQP11 was initially expressed at pia mater and little at capillaries in newborns (P1), and the former expression shifted to the latter with growth, which was quantified by a capillary deletion method: the ratios of capillary to parenchymal fractions increased by 2.5 folds from P1 to P28. AQP1and 11 were highest at P1 and decreased at P7 to P28 by one-eighth in AQP1 and by one-third in AQP11in the brain, while AQP4 increased 6 folds from P1 to P7. The brain of AQP11-null mice revealed numerous intracellular vacuoles in the choroid plexus but the other area of the brain appeared normal. The water contents of the brain were similar (78.61% vs. 78.96%). The two-dimentional protein electrophoresis analysis also revealed no obvious changes of protein expression patterns. Blood-brain-barrier (BBB) function examined by biotin injected into the heart appeared to be normal with no leakage in AQP11-null mice even with a lipopolysaccharide pre-administration. Interestingly, the expression of AQP4 was decreased by half in the brain of AQP11-null mice by real-time PCR with normal AQP1 expression. When osmotically challenged by addition of sodium (serum Na199 mEq/l) or water (Na123), the decreased AQP4 mRNA in AQP11-null mice was restored to normal levels. Hypotonia (Na123) enhanced the expansion of perivascular Virchow-Robin spaces in AQP11-null mice. In wild mice, mannitol administration (Na156) decreased AQP1,4,11 mRNAs in the brain. Both hyponatremia (Na121) and hypernatremia (Na154) significantly decreased AQP11 mRNA with stable AQP4 mRNA.

Conclusions: As AQP4 plays an important role in the regulation of brain edema, these findings suggest that both AQP4 and AQP11 may function in concert at BBB in response to osmotic changes. AQP11 can be a target for drugs to modulate brain edema as well as BBB function.

Inhibitors of the Uric Acid Transporter URAT1 Require URAT1 Phenylalanine 365 for High Affinity Interaction Philip K. Tan, David L. Hyndman, Jeffrey N. Miner. *Ardea Biosciences, San Diego, CA.*

Background: URAT1 is the target of many uricosuric agents that block uric acid reabsorption. Ardea Biosciences has recently identified a class of next generation inhibitors that specifically inhibit URAT1 at nanomolar potency. Here we report on a residue in URAT1 that is required for this high affinity interaction.

Methods: Human URAT1 has a 74% protein sequence identity with the ortholog rat uric acid transporter rRST, yet the compounds inhibit rRST with a 1000-fold lower affinity. We focused on residues that differ between these transporters and systematically converted residues within URAT1 into the corresponding RST residues, and vice versa, and measured the activity and sensitivity of these mutants to URAT1 inhibitors. We also developed a binding assay to URAT1 membranes using a radiolabeled next generation Ardea compound.

Results: Conversion of a single residue in URAT1 at position 365, from phenylalanine to the RST residue tyrosine, results in a mutant URAT1 uric acid transporter that is 100-fold less sensitive to inhibition. Conversely, conversion of RST residue tyrosine-365 to the URAT1 phenylalanine produces an RST mutant that is 10-fold more sensitive to inhibition. For the binding assay, binding of the radiolabeled compound is specific and saturable to URAT1 and occurs at a nanomolar affinity, showing that the compound directly binds with high affinity to URAT1. Xenopus Oocyte microinjection experiments were also conducted demonstrating that the binding site is available from both the inside of the cell and the outside.

Conclusions: URAT1 phenylalanine-365 is both necessary and sufficient for the high affinity inhibition by inhibitors, and this inhibition is perturbed by the addition of a tyrosine hydroxyl group. URAT1 phenylalanine-365 is either involved in a direct hydrophobic interaction with these molecules that is blocked by the tyrosine hydroxyl group, or it is important to maintain a particular structure within URAT1 that is required for high affinity binding. We suggest that URAT1 phenylalanine-365 is within a substrate binding pocket that also interacts with Ardea's compound inhibitors.

SA-PO2759

Protective Effects of N-acetylcysteine (NAC) in Renal and Lung Function in Old Rats Maria Heloisa M. Shimizu, Rildo A. Volpini, Ana C. de Bragança, Lucia Andrade, Antonio C. Seguro. *Nephrology, School of Medicine - University of Sao Paulo, Sao Paulo, Brazil.*

Background: Oxidative stress increases with age and is associated with alterations in kidney and lung functions. Previous studies demonstrated that NAC, an antioxidant drug, protects animals from kidney and lung injury.

Methods: The aim of this study was to evaluate the effects of NAC on sodium and water transporters in kidney and lung of old rats. Normal 8-month-old male Wistar rats were treated (n=6) or not (n=6) with NAC (600 mg/L in drinking water) and followed for 16 months. At the end of follow-up we measured thiobarbituric acid reactive substances (TBARS, a lipid peroxidation marker), urine volume (UV) and inulin clearance (In Cl). In addition we performed immunoblotting for renal proteins (NKCC2, αENaC and AQP2) and for lung proteins (αENaC , NKCC1 and AQP5).

Results: Mean NAC ingestion was 24±2 mg/day. As we can see in table 1, NAC decreased serum TBARS and ameliorate inulin clerance in old rats.

	In Cl (ml/min/100 g BW)	U V(µl/min)	FE H2O (%)	TBARS (nmol/ml)
Old Rat	0.308±0.012	23.1±8.0	0.63±0.09	10.6±0.7
Old Rat +NAC	0.459±0.041 *	7.6±0.4 **	0.29±0.02**	8.4±0.3 *

* $p<0.01$; ** $p<0.05$ vs. Old Rat

NKCC2 and AQP2 renal expression was significantly 69% and 42% higher in old+NAC rats than in old rats. There was no change in αENaC renal expression. In old+NAC rats, lung expression of αENaC and AQP5 was 32% and 30% higher than in old rats, whereas the NKCC1 was lower in 46% than the old rats.

Conclusions: NAC treatment in old rats ameliorated renal function and upregulated NKCC2 and AQP2 renal expression. These effects may increase urine concentration and dilution capacity in old rats and consequently decrease the incidence of hypo or hyperosmolar states in this population. In addition, we found that NAC profoundly influences the sodium and water transport in alveolar epithelial cells and these effects may decrease the incidence of lung edema in old population.

Sodium Myoinositol Cotransporter-1 Knockout Mice Are Not at Increased Risk for Osmotic Renal Injury Ajay Kher, S. Ananth Karumanchi, Samir M. Parikh. *Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Previous studies have shown that (1) loss of the tonicity-responsive transcription factor NFAT5/TonEBP results in renal atrophy, (2) NFAT5 is a critical positive regulator of the tonicity-responsive sodium-myoinositol co-transporter-1 (SMIT-1), and (3) injection of a small-molecular SMIT inhibitor into rodents induces acute kidney injury. We therefore hypothesized that SMIT-1 knockout mice (KO) would have increased susceptibility to the osmotic stress of dehydration.

Methods: 10-12 week KO, heterozygotes and wild-type male mice were evaluated at baseline and after 48hours of dehydration for serum electrolytes, BUN and creatinine by iSTAT analyzer and urine osmolarity. Mice also underwent radiocontrast injury by intraperitoneal injection of LNAME and Indomethacin (each 10mg/kg) followed 1 hour later by an intravenous injection of iohexol 10ml/kg.

Results: Baseline renal function was indistinguishable between KOs, heterozygotes, and wild-type male littermates. After 48 hours of dehydration, mice of all three genotypes had similar percent weight loss (WT 14.2 +/- 0.8, Het 15.9 +/- 1.8, KO 15.9 +/-1.3), serum sodium (WT 152+/-1.6, Het 153+/-4.6, KO 152+/-4.0 meq/L) and BUN (WT 46+/-5.6, Het 48+/-5.0, KO 54+/-11.9 mg/dl). SMIT1 KO mice were also able to increase their urine osmolarity to a similar extent (WT n=4, 3975 mosm/L, Het n=6, 3925 mosm/L, KO n=2, 4170 mosm/L). After mouse radiocontrast renal injury, male wildtype (n=13), heterozygote (n=9) and knockout (n=8) mice developed similar BUN elevation (WT 73+/-30, Het 73+/-29, KO 74+/-32).

Conclusions: We conclude that loss of SMIT-1 does not lead to renal atrophy and that SMIT-1 knockout mice do not appear to be at increased risk of osmotic renal injury. Our results suggest the importance of other NFAT5 transcriptional targets either singly or, more likely, in combination.

The Effect of Hyperosmolality on the Proliferation and Cell Cycle Regulation of Gastrointestinal and Bladder Epithelial Cell Lines Bradley P. Dixon, Brian J. Siroky, John J. Bissler. *Division of Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Children with complex urogenital abnormalities require surgical reconstruction of their urinary tract, and the gastrointestinal tissues often utilized in such reconstructions are at increased risk for cancer. We have previously shown that the hyperosmolal bladder microenvironment may attenuate the DNA damage response in gastrointestinal, but not bladder, cells. Hyperosmolal conditions in the bladder may also induce alterations in cellular proliferation and cell cycle regulation in susceptible tissues, which combined with a faulty DNA damage response could, in part, explain the tissue-specific susceptibility to cancer in the augmented bladder. We sought to characterize the cellular proliferation and cell cycle regulation of gastrointestinal and bladder epithelial cells adapted to a hyperosmolal microenvironment.

Methods: Conditionally immortalized colon (YAMC) and bladder (ULTI) epithelial cells were gradually adapted to either isoosmolal or hyperosmolal conditions. Cellular proliferation was measured by detachment and counting on a hemocytometer, as well as crystal violet DNA binding assay. Cell cycle analysis was performed by propidium iodide staining and flow cytometry.

Results: The YAMC colon cells demonstrated continued cellular proliferation from 450mOsm/kg to 600mOsm/kg, whereas in ULTI bladder cells, cellular proliferation plateaued after 450mOsm/kg. Additionally, YAMC cells adapted to hyperosmolal sodium chloride had marked abnormalities in cell cycle distribution by 450mOsm/kg and especially 600mOsm/kg, whereas the cell cycle distribution of ULTI cells was preserved to 600mOsm/kg.

Conclusions: Gastrointestinal cells under hyperosmolal conditions were less likely to reduce cellular proliferation despite, and perhaps due to, dysregulation of the cell cycle, whereas these processes remained intact in bladder cells. These findings, coupled with an attenuated DNA damage response under such conditions, could ultimately explain the susceptibility to carcinogenesis experienced by gastrointestinal tissues in the augmented bladder.

High Throughput Quantification of Apical Versus Basolateral Trafficking Javier E. Mazzaferri,[1] Stephane Lefrancois,[1,2] Santiago Costantino.[1,3] *[1]Centre de Recherche, Hôpital Maisonneuve-Rosemont, Montréal, Canada; [2]Département de Médicine, U. de Montréal; [3]Département d'Ophtalmologie et Institut de Génie Biomédicale, U. de Montréal.*

Background: Aquaporins (AQP) 2, 3 and 4 are water permeable membrane channels expressed in principal cells of the collecting duct of the kidney. AQP2 localizes to the apical membrane (in response to vasopressin secretion caused by dehydration) allowing water reabsorption from urine. Mutations in AQP2 have been implicated in Nephrogenic Diabetes Insipidus. AQP3 and AQP4 are localized to the basolateral membrane constituting potential water exit pathways from the cell. The complex protein trafficking machinery that maintains these segregated distributions of biomolecules in the apical and basolateral membranes is still not completely understood. Studies that have attempted to characterize the molecular mechanisms implicated in AQP trafficking have often relied on observations made with single or time-lapse fluorescence microscopy images. However, the lack of adequate image analysis techniques makes many of these observations potentially biased and not statistically significant.

Methods: We propose to address this by accurately quantifying the dynamics of AQPs trafficking vesicles using video-rate optically-sectioned in-vivo images. The commercially available optical sectioning techniques do not meet these requirements; therefore we proposed to use an approach that takes advantage of typical features of vesicles. In fact, cargo vesicles are near diffraction limited, belonging to the high-frequency range of the images' spatial spectrum, and are naturally axially localized. High-frequency filtering provides optically-sectioned images of cargo vesicles at frame rates near 10 times faster than confocal microscopy.

Results: We present in-vivo images of MDCK cells transfected with various GFP-tagged AQPs, obtained with the proposed approach.

Conclusions: We have obtained high-resolution, axially-resolved video-rate images of GFP-AQP trafficking vesicles. This will enable us to perform quantitative studies to further elucidate the molecular mechanisms required to sort AQPs to either the apical or basolateral membranes of polarized renal epithelial cells.

Trends in Hyponatremia Management & Outcomes in Hospital: Interim Results from a Prospective, Observational, Multi-Center, Global Registry Arthur Greenberg,[1] Joseph G. Verbalis,[2] Alpesh Amin,[3] Joseph Dasta,[4] Sandra Chase.[5] *[1]Division of Nephrology, Duke University Medical Center, Durham, NC; [2]Georgetown University Medical Center, Washington, DC; [3]University of California, Irvine, CA; [4]University of Texas, Austin, TX; [5]Otsuka America Pharmaceutical, Inc, Princeton, NJ.*

Background: Hyponatremia (HN) is the leading electrolyte abnormality of hospitalized patients (pts), and an independent predictor of increased mortality. This registry is designed to observe currently utilized management modalities for HN, characterize their relative efficacy, and assess their impact on hospital resource utilization.

Methods: After informed consent or waiver, medical records of pts meeting the registry entry criteria, principally age ≥18 years and euvolemic or hypervolemic HN (serum sodium ([Na]) ≤130 mmol/L) were abstracted. Accrual to date is approximately 40% of the projected US enrollment; data are summarized by sample size (n) and percentage (%) for categorical data, and mean and standard deviation for continuous data.

Results: A total of 483 of the 634 pts enrolled at 96 US sites between study initiation in Sept 2010 and May 2011 had sufficient data for analysis. The mean entry and discharge [Na] values were 125±4.8 mmol/L and 131.3±7.6 mmol/L, respectively. The average length of stay was 9.8±8.7 days.

Demographics, Etiologies, Chronicity and Outcomes	
Baseline Characteristics (n=483)	**%**
Male	49%
White	75%
Age ≥ 65 years	49%
Etiology of HN (n=483)	
SIADH	25%
Heart Failure	28%
Cirrhosis	12%
Nephrotic Syndrome	4%
More than One Hypervolemia Dx	31%
Onset/Duration of HN (n=483)	
Chronic HN	42%
HN as Admitting Dx	19%
HN Developed during Admission	29%
HN on a Prior Admission	29%
Pts treated and discharged with [Na] <130 mmol/L (n=118)	
Any Drug	43%
Fluid Restriction	57%

A total of 116 pts received drug therapy, and 122 fluid restriction alone. A drug was added in 36% of pts initially receiving fluid restriction alone, while only 12% of pts initially receiving drug therapy were treated with a second drug.

Conclusions: These interim data suggest that HN is often chronic or recurrent, fluid restriction alone is frequently not adequate, and pts are often discharged without resolution of HN particularly when the HN is not drug treated. Additional data will be forthcoming as enrollment and analysis continue.

Renoprotective Mechanisms for AII Blockade in CKD Involve AMPK and Autophagy Joseph Satriano, Aihua Deng, Roland C. Blantz. *UC San Diego, VASDHS, San Diego, CA.*

Background: In the subtotal nephrectomy (STN) model of chronic kidney disease (CKD) we previously observed similar physiologic, metabolic and histologic renal protection with administration of ACE inhibitor + AII receptor blockers (AII-b), or via induction of hypoxia inducing factor-1 (HIF-1) with cobalt chloride (Co) or dimethyloxalyglycine

(DMOG) (Deng, et al, AJP:Renal 2010). Here we further investigate the molecular mechanisms involved in this protection.

Methods: Physiologic and protein expression (Western blotting) changes were evaluated in the rat STN model at 1-week post 5/6 nephrectomy.

Results: Our studies reveal a reduction of renoprotective AMPK activity in STN (>3 fold*). AMPK inhibition of mTOR promotes autophagy, a mechanism required for defense against proteotoxicity and metabolic stress. In accord with a decrease in AMPK in STN we observe an increase in mTOR activity, reflected by the increase of p70S6K expression (>40 fold*), and a reduction of autophagy, via the LC3-II/LC3-I ratio (>7 fold*) and the accumulation of the autophagy linker protein p62 (1.5 fold*). Importantly, the administration of either AII-b or DMOG effectively normalizes AMPK activity, p70S6K, autophagy and p62 levels in STN animals (*). Interestingly, Co, although a HIF-1 inducer like DMOG, did not affect AMPK activity, autophagy or p62 levels, but did provide beneficial kidney effects. Co does, however, induce HO-1 levels (45 fold*), unlike AII-b or DMOG that do not increase HO-1.

Fibrosis and apoptosis are observed in CKD. We see a marked increase in profibrotic PAI-1 expression in STN (>8 fold*). All three agents prevent this response (*). The expression of the execution caspase-3 of apoptosis also increases with STN (1.6 fold*), an event normalized with Co or DMOG administration (*). AII-b tends to decrease caspase-3 from STN alone levels, but is not statistically significant.

(* = $p<0.05$)

Conclusions: Normalization of AMPK/autophagy in STN animals by AII-b and DMOG correlates with beneficial physiologic changes in GFR, RBF and renal metabolic efficiency (QO2/TNa). Thus, preventing the decrease in the renoprotective AMPK pathway network could afford kidney protection and normalization of function in CKD.

Angiotensin II Generates Oxidative Stress in the Kidney Proximal Tubule Via EGFR-ERK Pathway Vinayak Ramanath, Ravi Nistala, Adam Whaley-Connell, James R. Sowers. *Internal Medicine/Nephrology, University of Missouri-Columbia, Columbia, MO.*

Background: Oxidative stress is a major contributor to both short term and long term kidney function decline that ultimately leads to chronic kidney disease and its attendent problems. Proximal tubule oxidative stress is increasingly recognized as a major player in the early stages of kidney damage. Activation of NADPH oxidase enyzme and mitochondria contribute towards generation of oxidative stress in the proximal tubule. Several moieties have been implicated in the causation of oxidative stress. The role of the renin-angiotensin-aldosterone system has been well documented in the generation of kidney oxidative stress. However, the mechanisms for linking Angiotensin II (Ang II) to the generation of the superoxide free radical are not well known. **Hypothesis**: Ang II generated oxidative stress via transactivation of the EGFR-ERK pathway.

Methods: A opossum proximal tubule cell line (OKP) was used as a model system to study the signaling mechanisms activated by Angiotensin II. 24-hour starved OKP cells were treated over a time-course of 5min to 24hrs. The 30min and 24hr timepoints were chosen to look at the acute and chronic effects of Ang II. Superoxide generation was measured by lucigenin assays while NADPH oxidase activity was measured via Cayman radical assay. Protein measurements were via Western blots and immunoprecipitation. siRNA assays were performed according to the manufacturer (SABiosciences).

Results: Ang II stimulated superoxide production in a biphasic manner with 2 peaks at 30min and 24hrs. This was primarily via activation of NADPH oxidase enzyme. Ang II transctivated the EGF receptor and led to further activation of ERK. Blockade of EGFR with AG1478 and siRNA reversed Ang II-mediated activation of oxidative stress. Furthermore, blockade of Ang II-mediated oxidative stress improves albumin endocytosis via improvement in megalin function.

Conclusions: Ang II mediates oxidative stress in the kidney proximal tubule primarily via transactivation of the EGFR. Generation of oxidative stress and alteration in megalin function via Ang II may explain Ang II-mediated proteinuria at the proximal tubule level.

Deletion of the Ace2 Gene Exacerbates Kidney Injury in Mice after Unilateral Ureteral Obstruction Fei Fang,[1] James W. Scholey,[1] George Chu Liu,[1] Xiaohua Zhou,[1] Gavin Oudit,[3] Rohan John.[2] *[1]Institute of Medical Science, University of Toronto, ON, Canada; [2]Department of Pathology, University of Toronto, ON, Canada; [3]Division of Cardiology, University of Alberta, Edmonton, AB, Canada.*

Background: Activation of the renin-angiotensin system (RAS) is a well-established risk factor for chronic kidney disease, and blockade of the RAS has proven beneficial in this regard. ACE2 is a homologue of ACE that is highly expressed in the kidney, and can degrade angiotensin II (AngII) to produce the vasodilating peptide angiotensin-(1-7). Deletion of the Ace2 gene in male mice has been associated with an age-dependent development of glomerulosclerosis, which was prevented with AT1R blocker irbesartan. ACE2 has also shown to be a protective factor in diabetic glomerular injury. However the role of ACE2 in modulating tubulointerstitial kidney injury is not as well defined. Unilateral ureteral obstruction (UUO) is an accelerated model of chronic kidney disease associated with the rapid development of inflammation and fibrosis in the tubulointerstitium of the kidney, in part due to activation of the RAS. Accordingly we sought to determine whether deletion of the Ace2 gene would exacerbate kidney injury in mice subjected to UUO.

Methods: Two groups of male mice were studied: 8 week old wild-type C57BL/6J mice and mice with a deletion in the gene for Ace2. Mice from each group were subjected to sham operation or UUO of the left kidney, and gene expression measured by real time PCR in the renal cortex after 7 days.

Results: As expected, UUO was associated with an increased expression of pro-inflammatory genes (IL6, TNFα, and MCP-1), pro-fibrotic genes (collagen 1α1, TGFβ1, PAI-1, and αSMA) seven days after surgery. Deletion of the Ace2 gene did not affect expression in sham-operated mice, but exacerbated the increase in expression levels for both the inflammatory and fibrotic genes following UUO.

Conclusions: Deletion of the ACE2 gene promotes inflammation and fibrosis in the kidneys of mice after UUO, suggesting that ACE2 is also protective in the kidney tubulointerstitium.

Effect of Combination Therapy with Low Dose Darbepoetin and High Dose ARB on Established Glomerulosclerosis in 5/6 Nephrectomized Mice Keizo Matsushita, Haichun Yang, Agnes B. Fogo. *Department of Pathology, Vanderbilt University Medical Center, Nashville, TN.*

Background: Very early intervention with low dose erythropoietin, independently of effects on anemia, may attenuate progressive kidney failure. We now assessed effects of combination therapy with low dose darbepoetin and high dose ARB on established glomerulosclerosis.

Methods: 129/Sv male mice underwent 5/6 nephrectomy (5/6Nx). Body weight (BW), systolic blood pressure (SBP), urinary albumin creatinine ratio (ACR) and hematocrit (Hct) were measured. At wk8 mice underwent renal biopsy and were randomized to groups with equal starting moderate glomerulosclerosis (GS), and treated with darbepoetin alpha (0.1 μg/kg sc once a week, DAR; n=9), losartan (200 mg/L DW; ARB; n=10), DAR+ARB (n=8), or vehicle (VEH; n=9) for 4 wks until sacrifice.

Results: At wk8 after 5/6Nx, BW, SBP, ACR, Hct and GS were similar among groups by study design. Survival at wk12 was higher in all treatment groups compared to VEH (DAR+ARB 100%, ARB 90%, DAR 80%, vs VEH 67%). SBP at wk12 was reduced in ARB and DAR+ARB (94±9 and 114±8 mmHg), but increased in DAR (191±10 mmHg) compared to VEH (172±11 mmHg). Hct was significantly decreased in VEH and DAR (34.5±3.3 and 30.1±2.5%), but ARB (37.2±0.8%) and combination (40.6±1.5%) prevented anemia. ARB and DAR+ARB reduced proteinuria (ACR 28.6±9.8 and 29.9±13.8 mg/g), compared to VEH and DAR (1014±440 and 812±263 mg/g). GS showed progression in untreated VEH (0-4 scale, mean 1.3±0.3 at wk12, 91±55% increase from biopsy). DAR alone had no effect on progression (90±38% increase GS). In contrast, ARB showed significantly less sclerosis (30±25% increase, with regression of sclerosis in 3 mice at wk12 vs wk8), and DAR enhanced this effect (0±23% increase, regression in 5 mice). Podocyte number (WT-1/glomerulus) in VEH was 4.7±0.6 with no benefit of DAR alone (5.7±0.4). In contrast, ARB and DAR+ARB increased podocyte number (6.5±0.5, 6.6±0.6; $p<0.05$ vs VEH).

Conclusions: Low dose darbepoetin per se has no effect on progression, but in combination with high dose ARB halts progressive renal anemia and enhances regression of glomerulosclerosis.

Combined Losartan (L) and Hydrochlorothiazide (H) Therapy Arrests Renal Injury and Reverses Cell Events in the Remnant Kidney Model (Nx) Simone R. Costa, Carla P. Valente, Cristiene Okabe, Flavia G. Machado, Camilla Fanelli, Claudia R. Sena, Grasiela P. Barlette, Vivian L. Viana, Denise M. Malheiros, Roberto Zatz, Clarice K. Fujihara. *Univ Sao Paulo, Brazil.*

Background: We showed previously that L+H treatment arrests renal injury and reverses tubulointerstitial proliferation in Nx even when started at very late phases. Here we investigated further the mechanisms of this protection, focusing on 1) the role of hypertension (HTN). 2) the nephron segments involved in the antiproliferative action. 3) the possible role of myofibroblasts.

Methods: Adult male Munich-Wistar rats underwent Nx and received no treatment for 4 mo. At this time, tail-cuff pressure (TCP, mmHg), serum creatinine (Scr, mg/dL), glomerulosclerosis (%GS), % cortical interstitium (%INT), % interstitial smooth muscle actin (%α-SMA_{int}), tubular PCNA+ cells ($PCNA_{tub}$, cells/mm^2) and distal tubule PCNA+ cells ($PCNA_{dist}$, cells/mm^2) were assessed in 15 pretreatment controls (Nx_{pre}). The remaining rats were divided in: $\mathbf{Nx_V}$ (untreated); $\mathbf{Nx_{LH}}$ (L, 50 mg/kg/d and H, 6 mg/kg/d); and $\mathbf{Nx_{AHHd}}$ (Amlodipine, 5 mg/kg/d, H, 6 mg/kg/d, Hydralazine, 12 mg/kg/d). Age-matched sham-operated rats (**S**) were also studied. Results (Mean±SE) after 3 mo of treatment (^{a,b,c,d}; $p<0.05$ vs. S, Nx_{pre}, Nx and Nx_{AHHd}, respectively)

Results:

	TCP	S_{Cr}	%GS	%INT	%αSMA_{int}	$PCNA_{tub}$	$PCNA_{dist}$
S	141±1	0.6±0.1	1±1	0.7±0.1	0.1±0.1	9±1	0.2±0.1
Nx_{pre}	207±3^{a}	1.4±0.1^{a}	26±3^{a}	4.2±0.4^{a}	6.4±0.9^{a}	68±6^{a}	3.9±0.9^{a}
Nx_V	212±4^{a}	2.4±0.1^{ab}	58±4^{ab}	6.9±0.4^{ab}	6.7±0.8^{a}	70±9^{a}	2.6±0.3^{a}
Nx_{AHHd}	172±9^{abc}	2.1±0.1^{abc}	47±7^{abc}	5.5±0.6^{ac}	7.8±1.2^{a}	55±6^{a}	2.1±0.4^{ab}
Nx_{LH}	164±3^{abc}	1.6±0.1^{acd}	25±3^{acd}	4.0±0.4^{ac}	4.5±0.7^{ad}	26±2^{abcd}	0.2±0.1^{bcd}

Nx_{pre} exhibited severe HTN, GS and INT expansion, marked tubular (partly distal) cell proliferation, and increased αSMA expression. Renal injury worsened in Nx_V. LH treatment arrested renal injury at pretreatment levels, and reversed both distal and total tubular cell proliferation. Despite similar TCP reduction, AHHd only slightly ameliorated renal injury and tubular hyperplasia.

Conclusions: Cell events predominate over HTN in the pathogenesis of advanced renal injury in Nx. Myofibroblast infiltration, likely originated in part from proximal tubular cells, may play a key role in this process.

SA-PO2769

Inhibitory Effect of Spironolactone (SPL) on Renal Injury and Intrarenal Angiotensinogen (AGT) Expression in Salt-Loaded, Nitric Oxide-Deficient Rat Takaichi Suehiro, Kazuhiko Tsuruya, Toshiaki Nakano, Masatomo Taniguchi. *Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

Background: Intrarenal renin-angiotensin system (RAS) may be involved in the pathogenesis of kidney injury, and AGT is thought to have an important role for the intrarenal RAS activation. The effect of RAS blockade for intrarenal RAS is evaluated in some animal models, but little is known about mineralocorticoid receptor (MR) blockade. The aim of this study is to investigate the effect of MR blocker for kidney injury and AGT in nitric oxide-deficient rats with salt loading, and to evaluate the relationship between kidney damage and AGT.

Methods: Male Wistar rats were divided into the following three groups; the control rats given vehicle (Cont), L-NAME rats given 50 mg/kg/day L-NAME in drinking water and 4% salt in chow (L-NAME), and SPL-treated L-NAME rats given 100 mg/kg/day SPL in chow in addition to L-NAME rats (SPL).

Results: Following treatment for 6 weeks, L-NAME rats developed hypertension, proteinuria and kidney injury. Without reduction of blood pressure (BP), SPL prevented proteinuria (14, 112, and 27 mg/day in Cont, L-NAME, and SPL, respectively; $p<0.05$), glomerulosclerosis, interstitial fibrosis (IF), osteopontin (OPN) expression determined by real time PCR and immunohistochemistry, and urinary excretion of 8-OHdG. Plasma angiotensin II and aldosterone (Ald) were comparable among the three groups, but urinary AGT excretion (208, 6697, and 1317 ng/day in Cont, L-NAME, and SPL, respectively; $p<0.05$) and AGT expression in the proximal tubules were increased in L-NAME rats, while these changes were inhibited by SPL. Urinary AGT was positively correlated with proteinuria, IF and OPN expression ($r = 0.87$, 0.69, and 0.73, respectively; $p<0.05$).

Conclusions: In conclusion, the present study demonstrated that SPL ameliorated kidney injury through reduction of AGT expression in the kidney independent of plasma Ald and BP, and intrarenal AGT was related to renal injury. These results suggest that intrarenal AGT may be activated through MR pathway and potentially involved in the kidney injury during nitric oxide deficiency and salt-loaded status.

SA-PO2770

Ghrelin Suppresses Angiotensin II-Induced Premature Renal Senescence by Reducing Oxidative Stress Keiko Fujimura, Shu Wakino, Koichi Hayashi. *Department of Medicine, Keio University, Tokyo, Japan.*

Background: Premature senescence is one of the main pathways towards the deterioration of renal function. Angiotensin II (AngII) induces renal premature senescence by multiple mechanisms including by increasing oxidative stress. Recent study revealed that GH secretagogue ghrelin exerts anti-senescence effects by reducing mitochondria-derived reactive oxygen spieces (ROS) levels. In this study, we examined whether ghrelin inhibits AngII-induced renal senescence and damages.

Methods: Renal senescence was induced by infusion of AngII in C57BL/6 mice with osmotic mini-pump. Ghrelin was administered by the daily intraperitoneal injection. 8 weeks after the treatment, kidneys were removed and utilized in the various experiments. In *in vitro* experiment, cultured human proximal cell line, HK-2 cells were incubated with 1 mM of AngII for 72 hrs and ghrelin were administered 30 mins prior to AngII stimulation.

Results: AngII infusion induces senescence and oxidative stress as accessed by senescence-associated (SA) b-Gal and 4-hydroxy-2-nonenal (4-HNE) staining, respectively. The expressions of markers for senescence, p21 , p53 as well as senescence-associated cytokines, TGF-b , PAI-1 in the kidney were increased by AngII. AngII infusion also induced renal damages as assayed by the urinary excretion of renal tubular marker, N-acetyl-glucosaminide (NAG) and neutrophil gelatinase-associated lipocalin (NGAL) as well as by urinary protein excretion. Finally, AngII infusion provoked interstitial fibrosis as evaluated by Masson-trichrome staining. These changes were attenuated by the treatment with Ghrelin. In HK-2 cells, the receptors for both Ghrelin and AngII were expressed. SA b-Gal assay revealed tubular cell senescence by AngII. AngII also increased the expression of p21 and p53 as well as TGF-b and PAI-1. These changes were attenuated by pretreatment with Ghrelin. In addition, AngII reduced the mitochondria number, which was restored by Ghrelin as measured by staining cells with mitochondria-specific fluorescent dye.

Conclusions: Our data indicated that ghrelin suppressed AngII-induced renal premature senescence and AngII-induced renal damages presumably through modulating the mitochondrial ROS production.

SA-PO2771

Endogenous Angiotensin-(1-7) Protects Against Tubulointerstitial Fibrosis in Mice with Unilateral Ureteral Obstruction Danielle L. Zimmerman, Alex Gutsol, Anthony Carter, Rhian Touyz, Kevin D. Burns. *Kidney Research Centre, Division of Nephrology, Dept. of Medicine, Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada.*

Background: Angiotensin-(1-7) [Ang-(1-7)] is a heptapeptide product of the renin angiotensin system that is generated by angiotensin-converting enzyme 2 (ACE2)-dependent degradation of Ang II. In proximal tubular cells, Ang-(1-7) inhibits Ang II-stimulated mitogen-activated protein kinase signaling, suggesting that it may counteract the profibrotic and proinflammatory effects of Ang II. We determined if endogenous Ang-(1-7) protects against tubulointerstitial injury in a mouse model of renal fibrosis.

Methods: Male C57BlK6/J mice underwent unilateral ureteral obstruction (UUO) and were treated with or without the Ang-(1-7) antagonist A779 (31 ug/kg/hr by osmotic mini-pump), starting at day 0 until sacrifice at day 10. Blood pressures were monitored by tail cuff plethysmography and tissues were harvested for histologic and immunoblot analyses.

Results: Blood pressure was not affected by UUO or treatment with A779. UUO caused a significant increase in tubulointerstitial injury scores compared to unobstructed kidneys, and this was exacerbated in mice treated with A779 (UUO: 1.38 ± 0.1 vs UUO+A779: 2.07 ± 0.2, $p<0.01$, $n=7$).). By immunoblots, expression of fibronectin, pro-collagen I, and transforming growth factor-ß (TGF-β) was increased in obstructed kidneys, compared to unobstructed kidneys, with a further significant increase in A779-treated mice (fibronectin: UUO: 1.17±0.09, vs UUO+A779: 2.80±0.30, $p < 0.001$; pro-collagen I: UUO: 0.84±0.06 vs UUO+A779: 1.16±0.14, $p < 0.05$; TGF-β: UUO: 0.9±0.2 vs UUO+A779: 1.8±0.2, $p <0.01$, $n=7$). Expression of α-smooth muscle actin was also increased in obstructed kidneys with A779 treatment ($p<0.05$, $n=7$). Protein expression of ACE2 and ACE was significantly decreased in obstructed kidneys ($p<0.001$, $n=7$), but A779 had no effect on expression.

Conclusions: These data indicate that the Ang-(1-7) antagonist A779 worsens renal fibrosis in mice with UUO. The results suggest that endogenous Ang-(1-7) protects against tubulointerstitial injury *in vivo*, perhaps via inhibition of profibrotic pathways stimulated by Ang II.

SA-PO2772

Dependence of Renal Fibrosis on a Cell Cycle Regulator Judit Megyesi, Adel Tarcsafalvi, Robert L. Safirstein, Peter M. Price. *Internal Medicine, UAMS, Little Rock, AR.*

Background: A major cause of progressive renal failure occurs during repair from kidney injury that results in the formation of fibrotic lesions rather than tissue replacement. The molecular causes of this maladaptive growth are not yet understood, but recent studies have suggested potential pathways.

Methods: We used several mouse models of renal fibrosis, either mimicking effects of acute kidney injury or effects of loss of renal mass.

Results: A mouse model of subtotal nephrectomy induced parameters of chronic kidney failure, i.e. systemic hypertension, glomerular sclerosis, interstitial fibrosis, and reduced glomerular filtration. Fibrosis was evident 6 weeks after nephrectomy and functional renal failure occurred 14-16 weeks after surgery. A cell cycle regulatory protein, $p21^{WAF1/Cip1}$, was induced in the remnant kidney, accompanied by hypertrophy in the tubular epithelial cells. In homogygous p21 knock-out mice, the filtration rate of the remaining nephrons did not decline, and sclerosis did not develop. We have since developed transgenic mice in which p21 expression could be induced in kidney proximal tubules. We hypothesized that p21 over-expression will induce more severe fibrosis and tested this in models of AKI in which renal fibrosis developed several weeks after injury. Comparing wild-type with transgenic mice 14 days after unilateral ureteral obstruction, more α-smooth muscle actin was seen around the kidney tubules of transgenic mice. Similarly, more macrophage infiltration was seen in the p21 these mice. We also used an *in vitro* model of fibrosis using 0.5 mg/ml aristolochic acid treatment of mouse proximal tubule cells (TKPTS) in which 6.3 mg collagen was secreted by the cells per ml of medium after 48 hours. p21 regulates the cell cycle by inhibiting progression into S and M phases, and the effect of p21 induction correlated with collagen production as evidenced by TKPTS cells being arrested in G2 phase preceding collagen induction.

Conclusions: We conclude that p21 induction is a causative mechanism for development of fibrosis and chronic renal failure, either from its activity to prevent cell cycle progression or from its activity to inhibit phosphorylation of pro-fibrotic substrates of cell cycle kinases.

Attenuated Glomerular Arginine Transport Provokes Renal Injury in the Pregnant Uremic Rat Doron Schwartz, Idit F. Schwartz. *Nephrology, Tel Aviv Sorasky Medical Center, Tel Aviv, Israel.*

Background: Pregnancy worsens renal function in females with renal failure (CRF) through an unknown mechanism. Reduced nitric oxide (NO) generation induces renal injury. Arginine transport by cationic amino acid transporter-1 (CAT-1), which governs endothelial NO generation, is reduced in both renal failure and pregnancy. We hypothesize that attenuated maternal glomerular arginine transport promotes renal damage in CRF pregnant rats.

Methods: Rats underwent a two stage 5/6 nephrectomy (interval of one week). All experiments were performed 6 weeks following the second operation.

Results: In uremic rats, pregnancy induced a significant decrease in glomerular arginine transport and c-GMP generation (a measure of NO production) compared to CRF or pregnancy alone and these effects were prevented by L-arginine. While CAT-1 abundance was unchanged in all experimental groups, PKCα and phosphorylated PKCα (CAT-1 inhibitor), were significantly augmented in CRF, pregnant, and pregnant CRF animals, phenomena which were prevented by co-administrating L-arginine. α-tocopherol (PKC inhibitor) significantly increased arginine transport in both pregnant and CRF pregnant rats, effects which were attenuated by ex vivo incubation of glomeruli with PMA (a PKC stimulant). Renal histology revealed no differences between all experimental groups. Creatinine clearance failed to augment and renal cortical expression of HIF-1α significantly increased in CRF pregnant rat, both phenomena were prevented by arginine.

Conclusions: These studies suggest that in CRF rats, pregnancy produces a profound decrease in glomerular arginine transport, through post translational regulation of CAT-1 by PKCα, resulting in attenuated NO generation. These events provoke renal damage manifested by upregulation of renal HIF-1α and loss of the ability to increase GFR during gestation and may be responsible for the accelerated deterioration in renal function during pregnancy in uremic females.

Periostin Is a Novel Marker of the Severity of Hypertensive Nephropathy Dominique Guerrot, Sandrine Placier, Mouna Mael-Ainin, Jean-Claude Dussaule, Christos Chatziantoniou. *INSERM UMR 702, Tenon Hospital, Paris, France.*

Background: The aim of our study was to identify novel determinants of progression and regression of chronic kidney disease.

Methods: Rats were treated with the NO synthase inhibitor L-NAME. When proteinuria exceeded 1 g/mmol creatinine (5-6 wk), a group of animals was used to estimate renal hemodynamics and morphology parameters just before the beginning of therapy (LN 6w group). The remaining animals were divided into two groups for an additional experimental period of 4 wk: in the first group L-NAME was given alone (LN 10w); in the other group L-NAME was co-administered with Losartan. At the end of Losartan treatment, some animals showed normal creatininemia (REGR), whereas other animals escaped therapy (creatininemia ≥70 µmol/l, ESC group).

Results: Differential transcriptomic analysis of renal cortex between REGR and LN 10w groups revealed that periostin, a gene non expressed in normal kidneys (but strongly involved in heart remodelling and fibrosis), was highly upregulated in the LN 10w group. Quantitative evaluation of periostin mRNA and protein expressions in the kidney indicated that periostin was continuously increasing during hypertensive nephropathy, it was significantly decreased in the REG group, whereas it remained increased in the ESC group in spite of 4 wk losartan treatment. Immunohistochemistry revealed that hypertensive nephropathy was characterized by a strong increase in periostin staining in the media and the adventitia of renal vessels. Interestingly periostin also exhibited a focal de novo interstitial expression in close vicinity to the most severe lesions.

To further evaluate the relevance of periostin as a marker of progression of renal disease, we performed regression analyses with classical functional and histological parameters of hypertensive nephropathy. We found a very strong positive association (r≥0.70) between periostin expression and creatininemia, proteinuria, renal blood flow decrease, and histological lesion scores.

Conclusions: Periostin expression in the kidney is associated to the development of hypertensive renal disease. We propose periostin as a novel marker determining progression/regression of chronic kidney disease.

Funding: Government Support - Non-U.S.

SA-PO2775

Epiphyseal Growth Plate Growth Hormone Receptor Signaling Is Impaired in a Rat Model of Chronic Kidney Disease Related Growth Retardation Yael Segev,[1] Ariel Troib,[1] Debbie Wiezel,[1] Ralph Rabkin,[2] Daniel Landau.[3] *[1]Shraga Segal Dept of Microbiology and Immunology, Ben Gurion University, Beer Sheva, Israel; [2]Medicine, Veterans Administration, Stanford University, Palo Alto, CA; [3]Pediatrics, Ben Gurion University, Beer Sheva, Israel.*

Background: Linear growth retardation with reduced muscle mass is a major problem in children and adults with chronic kidney disease (CKD) and is ascribed to insensitivity to GH. This resistance has largely been attributed to low IGF-I bioavailability and to a decrease in liver GH receptor (GHR) expression and signaling. No data is available on bone GHR expression and action in CKD. We investigated the role of local GH-IGF system in developing bones of young growth retarded CKD rats.

Methods: Twenty-day old rats underwent a 2 step 5/6 nephrectomy (CKD) or sham operation. Control rats (C) were pair-fed with CKD. Animals were sacrificed 2 weeks after second surgery.

Results: There was no difference in the amount of food consumed, yet there was a significant difference in weight gain and longitudinal growth between C and CKD rats. Serum creatinine (225±11% of C) and albuminuria were significantly higher in CKD rats. No change was observed in serum GH, yet serum IGF1 was decreased significantly in CKD. Epiphyseal growth plate (EGP) morphometry showed no change in the proliferative zone but a wider hypertrophic zone in CKD rats, with a disturbance in cell order (but not in cell count) in that zone. EGP type 10 collagen mRNA increased in CKD (375±56% of C, $p< 0.05$). EGP GH receptor (GHR) mRNA was unchanged, but JAK2 mRNA and phosphorylated (p-) STAT5 were decreased, while SOCS2 mRNA was increased in CKD. IGF1 mRNA levels were unchanged.

Conclusions: Young rats with moderate CKD develop significant growth retardation despite the enlargement of EGP hypertrophic zone, hinting for a chondrocyte maturation arrest. The decrease in JAK2 mRNA and p-STAT5 and the increase in SOCS2 mRNA in the EGP of CKD rats in spite of unchanged GHR mRNA suggest a bone GHR signaling impairment in CKD as an additional mechanism of CKD mediated growth retardation.

AZGP1 Inhibits the Development of Renal Fibrosis Inga Soerensen, Nathan D. Susnik, Hermann G. Haller, Roland Schmitt. *Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.*

Background: With age the kidney becomes more susceptible to acute and chronic injury and looses its regenerative potential. Additionally, old kidneys show more interstitial fibrosis and tubular atrophy. Zinc-α2-glycoprotein 1 (AZGP1) is a secreted glycoprotein whose function has not yet been fully elucidated. In vivo knockdown of AZGP1 in old mice was associated with increased epithelial proliferation and amplification of interstitial fibrosis. Therefore, our hypothesis was that AZGP1 has an antifibrotic effect.

Methods: UUO as a common fibrosis model was induced in AZGP1-/- and AZGP1 +/- mice. At different time-points kidneys were analyzed using histology, immunohistochemistry, qPCR and immunoblot. For in vitro studies we used different renal epithelial cell lines and rat renal fibroblasts. Epithelial cells were transiently transfected with an AZGP1 expression construct. The resulting conditioned medium was transferred to cultured rat renal fibroblasts. The expression of myofibroblast markers was analysed using immunoblot and qPCR.

Results: Renal fibrosis developed in both groups of mice but AZGP1 deficiency was associated with a significant attenuation of renal tubulointerstitial damage. We found that α-Smooth muscle actin, as a marker for fibrosis, was significantly higher in UUO kidneys of AZGP1 -/- mice. Additionally we found a significant reduction of the epithelial marker E-Cadherin in AZGP1 -/- UUO kidneys at one and two weeks, whereas Vimentin was highly upregulated on protein and mRNA level. The number of infiltrating inflammatory (CD45+) cells were elevated in AZGP1 -/- kidneys. In vitro we found that the conditioned medium obtained from AZGP1 overexpressing epithelial cells contains factors that inhibit TGFβ-dependent activation of fibroblasts .

Conclusions: In summary our data indicate that epithelial expression of AZGP1 attenuates the development of fibrosis in the UUO model. In vitro studies suggest that the secretome of AZGP1 overexpressing renal epithelial cells exhibits an inhibitory effect on the activation of renal fibroblasts.

The Role of Autophagy in Unilateral Ureteral Obstruction Rat Model Yong Kyun Kim,[1] Wan-Young Kim,[2] Sun-Ah Nam,[2] Ho Cheol Song,[1] Euy Jin Choi,[1] Jin Kim.[2] *[1]Internal Medicine, Catholic University of Korea, Seoul, Korea; [2]Department of Anatomy and MRC for Cell Death Disease Research Center, Catholic University of Korea, Seoul.*

Background: Autophagy is a cellular process of degradation of damaged cytoplasmic components and regulates cell death or proliferation. Unilatreral ureteral obstruction (UUO) is a model of progressive renal fibrosis in the obstructed kidney. And UUO is followed by compensatory cellular proliferation in the contralateral kidney. We investigate the role of autophagy in the obstructed kidney and contralateral kidney after UUO.

Methods: To obtain the evidence and the patterns of autophagy during UUO, the rats were sacrificed 3, 7 and 14 days after UUO. To examine the efficacy of the autophagy inhibitors, 3-MA , the rats were treated with 3-MA. The rats were divided into the four groups: (1) the rats that underwent sham operation and were treated with vehicle, (2) the rats that underwent sham operation and were treated with 3-MA (3) the rats that underwent UUO and were treated with vehicle and (4) the rats that underwent UUO and were treated with 3-MA. The rat were sacrificed 7 days after UUO.

Results: After UUO, autophagy was induced in the obstructed kidney in a time-dependent manner. Autophagy is induced in the obstructed kidney early after UUO and before tubular cell apoptosis and tubulointerstitial fibrosis and then it decreased toward the basal levels at day 14 after UUO. Inhibition of autophagy by 3-MA enhance tubular cell apoptosis and tubulointerstitial fibrosis in the obstructed kidney. In the contralateral kidney, autophagy was also induced and prolonged during UUO. Inhibition of autophagy by 3-MA increased the protein expression of proliferating cell nuclear antigen significantly in the contralateral kidney. The Akt-mammalian target of rapamycin (m-TOR) signaling pathway was involved in the induction of autophagy after UUO in both kidneys.

Conclusions: Taken together, our present results support that autophagy induced by UUO has a renoprotective role in the obstructed kidney and regulatory role of compensatory cellular proliferation in the contralateral kidney through Akt-mTOR signaling pathway.

SA-PO2778

Epithelial-to-Mesenchymal Transition of Tubular Epithelial Cells Associates with Deciliation and Loss of Claudin-2 Expression Punita Dhawan, Amar B. Singh. *Vanderbilt University.*

Background: After sustained injury, tubular epithelial cells undergo epithelial-to-mesenchymal transition (EMT), which plays critical role in the evolution of renal fibrosis. Loss of functional tight junction (TJ) and polarity characterizes EMT. Tight Junction helps maintain polarity, which also appears necessary for ciliogenesis. Importantly, proteins that regulate polarity and/or ciliogenesis are localized at the TJ. However, role of TJ integral protein, claudins, in renal injury and associated EMT is poorly understood.

Methods: MDCK-II cells were subjected to chronic hypoxia (1% Oxygen). To induce EMT MDCK-II cells were also subjected to chronic EGF receptor (EGFR) activation. To silence claudin-2 expression anti-claudin-2 shRNA was used.

Results: Exposure of MDCK-II cells to chronic hypoxia led to the EMT. Cells lost cilia and epithelial morphology. E-cadherin expression decreased while Vimentin expression increased. Membrane distribution of $Na\text{-}K^+$-ATPase was lost while apical permeability

increased (P<0.001) and thus suggested loss of polarity. However, the most profound decrease was observed in claudin-2 expression, a TJ protein, which decreased to undetectable levels and this decrease preceded the decrease in E-cadherin expression. We observed a similar decrease in claudin-2 expression to undetectable levels when EMT was induced in MDCK-II cells by chronic EGF receptor (EGFR) activation, either using exogenous EGF (100 ng/ml) or stable expression of soluble HB-EGF, an EGFR ligand. Re-expression of claudin-2 in MDCK-II cells expressing soluble HB-EGF rescued the epithelial phenotype including cilia growth. In contrast, stable silencing of claudin-2 expression in MDCK-II cells resulted in sharp decreases in cilia length (P<0.001) and delayed tight junction formation following Ca^{++}-switch. Furthermore, stable expression of claudin-2 in MDCK-I cells, a clonal variant of MDCK-II cells deficient in claudin-2 expression and cilia formation, resulted in cilia formation in these cells.

Conclusions: Our findings support an important role for claudin-2 in the regulation of renal tubular injury and associated EMT through its role in the regulation of epithelial cell morphogenesis including polarity and cilia formation.

Hypoxia-Induced Down-Regulation of MicroRNA-34a Promotes Epithelial-Mesenchymal Transition by Targeting Notch Signal in Tubular Epithelial Cells Rui Du, Shiren Sun. *Deparment of Nephrology, Xijing Hospital, FMMU, Xi'an, China.*

Background: Hypoxia-induced renal tubular cell Epithelial–mesenchymal transition (EMT) is an important reason for renal fibrosis. MicroRNAs (miRNA) are small non-coding RNA molecules which bind to their mRNA targets thereby leading to repression of translation. The role of miRNA in the hypoxia-induced EMT is largely unknown.

Methods: miRNA profiling was performed to identify differentially expressed miRNAs in HK2 cells under normal and low oxygen and the results were then verified by quantitative real time RT-PCR (qRT-PCR). Specific miRNA inhibitors and mimics transfection was performed to assess the function of miRNA in hypoxia-induced renal tubular cell EMT. Luciferase report gene assay and western blot was performed to validate the target genes of miR-34a. siRNA against Notch1 was designed to investigate the role of miR-34a-Notch pathway in hypoxia induced renal tubular cells EMT.

Results: miRNA-34a was identified as a down-regulated miRNA in hypoxic renal tubular epithelial cells. Inhibition of miR-34a expression in HK2 cells, which highly express endogenous miR-34a, promoted a mesenchymal phenotype accompanied by reduced expression of the epithelial marker E-cadherin and increased expression of the mesenchymal markers α-SMA and vimentin. Whereas, miR-34a mimic effectively reversed hypoxia-induced EMT. MiRNA-34a transfection in HK2 cells under hypoxia abolished hypoxia-induced expression of Notch1 and Jagged1 as well as Notch downstream signal, such as snail and slug. Western blot and luciferase report gene assay showed direct evidence for miR-34a targeting Notch1 and Jagged1. Notch1IC transfection could activate Notch signal and promote EMT phenotype, while siRNA against Notch1 effectively reversed hypoxia and miR-34a inhibitor-induced tubular epithelial cells EMT.

Conclusions: Our study provides evidence that hypoxia-induced decrease of miR-34a expression could promote renal tubular epithelial cells EMT by directly targeting Nothch1 and Jagged1, and subsequently activation of Notch downstream signal.

SA-PO2780

MicroRNA-324-3p Is a New Mediator of Kidney Fibrosis in Progressive Nephropathy and a Potential Target of ACE Inhibition-Induced Renoprotection Daniela Macconi,[1] Susanna Tomasoni,[1] Paola Romagnani,[3] Piera Trionfini,[1] Fabio Sangalli,[1] Benedetta Mazzinghi,[3] Paola Rizzo,[1] Giuseppe Remuzzi,[1,2] Ariela Benigni.[1] *[1]Mario Negri Institute, Bergamo, Italy; [2]Ospedali Riuniti, Bergamo, Italy; [3]University of Florence, Florence, Italy.*

Background: Munich Wistar Fromter (MWF) rats develop spontaneous proteinuria, glomerulosclerosis and tubulointerstitial fibrosis with age. So far efforts in finding candidate genes causing progressive renal damage have been inconclusive. Recent studies have suggested that post-transcriptional regulation of genes by microRNA (miRNA), may have a pathogenetic role in chronic kidney disease.

Methods: Untreated or lisinopril-treated MWF rats (40 to 60 weeks of age) were studied together with Wistar rats as controls. miRNA expression was assessed by microarray and real time RT-PCR in microdissected glomeruli and by in situ hybridization in the whole kidney. miRNA targets were predicted by in silico approach.

Results: Analysis of miRNA expression profiling showed miR-324-3p as the most up-regulated miRNA in glomeruli of MWF rats compared to Wistar. Expression of miR-324-3p was confined to podocytes and parietal cells of the Bowman's capsule in the glomerulus, but was also present at tubular level. Among predicted targets of miR-324-3p, we focused on prolyl endopeptidase (Prep) mRNA encoding a serine peptidase involved in the metabolism of angiotensins and in the synthesis of the anti-fibrotic peptide N-acetyl-seryl-aspartyl-lysyl-proline (Ac-SDKP). In MWF rats up-regulation of miR-324-3p was associated with marked reduction of Prep in both glomeruli and the tubular epithelium, loss of Ac-SDKP expression and enhanced collagen deposition. ACE-inhibition down-regulated miR-324-3p in Bowman's capsule and in cortical tubules with a parallel increase in renal Prep expression. Lisinopril-treated MWF rats also showed increased plasma levels of Ac-SDKP and reduced renal fibrosis.

Conclusions: Dysregulation of post-transcriptional events linked to miR-324-3p/Prep pathway contributes to kidney fibrosis in progressive nephropathy and suggests miR-324-3p as a potential therapeutic target of ACE inhibition.

MiR-30e Antagonizes TGFb1-Induced EMT by Targeting UCP2 in Kidney Tubular Epithelial Cells Lei Jiang, Chunsun Dai, Junwei Yang. *Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical University, Nanjing, Jiangsu, China.*

Background: MicroRNAs (miRNAs) are a class of non-coding RNAs that regulate target gene expression at the posttranscriptional level. The role and mechanisms of miRNAs in kidney tubular cell EMT and renal scar formation after injury remain unclear. Mitochondrial uncoupling protein 2 (UCP2) are members of mitochondrial anion carrier proteins (MACP). UCP2 separates ATP synthesis with energy dissipated as heat, also referred to as the mitochondrial proton leak. The role and mechanism of UCP2 in Epithelial-Mesenchymal Transition of tubular epithelial cells is also unknown.

Results: In this study, we found that miR-30e expression was declined and UCP2 protein expression was increased in unilateral ureter obstruction (UUO) kidneys. TGF-β1 could downregulate miR-30e and upregulate UCP2 expression in cultured NRK-52E cells. MiR-30e mimics largely abolished TGF-β1-induced UCP2 upregulation and tubular cell EMT, while miR-30e inhibits mimicked TGF-β1's effect. A mammalian expression vector in which the luciferase reporter cDNA linked to a 3'UTR segment of UCP2 was created. The miR-30e mimics significantly reduced TGF-β1-induced luciferase activity, which indicates that UCP2 is the direct target of miR-30e. We then explore the role of UCP2 in TGFb1-induced EMT and kidney fibrosis. UCP2 siRNA transfection could remarkably downregulate UCP2 expression and block TGF-β1-induced EMT in NRK-52E cells. In vivo, UCP2 knockout mice were more resistant to UUO-induced kidney fibrosis compared to its control littermates.

Conclusions: Taken together, it is concluded that miR-30e antagonizes TGFb1-induced EMT and fibrosis by targeting UCP2 in tubular epithelial cells.

The Relation between Renal Parameters and Urinary microRNAs in Patients with Renal Diseases Tsuneo Konta, Kazuko Suzuki, Ami Ikeda, Yusuke Mashima, Emiko Nishidate, Kazunobu Ichikawa, Isao Kubota. *Department of Cardiology, Pulmonology, and Nephrology, Yamagata University School of Medicine, Yamagata, Japan.*

Background: Renal microRNAs modulate the development and the progression of renal diseases by regulating various gene expressions in kidney. In this study we examined whether urinary microRNAs reflect renal changes in patients with renal diseases.

Methods: We extracted and quantified microRNAs in morning spot urine in 28 patients with renal diseases (16 IgA nephropathy, 6 crescentic glomerulonephritis and 6 diabetic nephropathy) and 5 healthy controls, and examined the relation between clinical and pathological parameters and urinary microRNAs including miR-133b, miR-192, miR-200 family and miR-30c. The localization of microRNAs expression was examined using in situ hybridization in renal biopsy specimens and urinary sediments.

Results: The urinary excretion of total microRNAs was significantly higher in the patients with renal diseases than controls (median 389 vs. 182 μg/gCr, P=0.014). Urinary protein excretion was related positively with urinary total microRNAs and miR-133b, and negatively with miR-192 and 200a, respectively. Glomerular proliferative changes were negatively related with urinary miR-192, miR-200 family and miR-30c. Glomerular sclerotic changes were positively related with urinary total microRNAs. There was no significant relation between GFR and interstitial fibrosis, and urinary microRNAs. In situ hybridization revealed that the expressions of microRNAs were detected mainly in glomerular cells, infiltrating cells and renal tubular epithelial cells in biopsy specimens and urinary sediments.

Conclusions: This study showed that urinary microRNAs were related with renal changes and might be utilized for the diagnosis and the evaluation of renal diseases.

SOCS-3 Protein Expression Correlates with Kidney Function In Vivo and Differentially Regulates Proliferation and Differentiation Via STAT1 and -3 in Human Proximal Tubule Cell Hannes Neuwirt, Michael Rudnicki. *Dept. of Internal Medicine IV, Innsbruck Medical University, Innsbruck, Tyrol, Austria.*

Background: Proliferation and epithelial-mesenchymal-epithelial (EME) cycling are the underlying mechanisms of kidney repair and fibrosis, respectively. Suppressor of cytokine signaling (SOCS-)3 is a negative regulator of STAT1 and -3 signaling pathway for which both pro- and antifibrotic as well as pro- and antiproliferative effects have been shown depending on the cellular context.

Methods: We have analysed the expression of SOCS-3 in two kidney cell lines (HK-2, LLC-PK1) and in human renal biopsies, and we studied its effects on STAT1/3 activation and upon cytokine stimulation. For this purpose we established cellular models with SOCS-3 overexpression and SOCS-3 knock-down.

Results: In renal biopsies from patients with glomerular diseases SOCS-3 expression was inversely correlated with creatinine at time of biopsy and follow up. In vitro modulation of SOCS-3 levels was sufficient to alter basal activity of STAT1 and -3. SOCS-3 knock-down in LLC-PK1 cells resulted in pSTAT1/3 upregulation. This was associated with epithelial differentiation and inhibition of proliferation. On the other hand SOCS-3 overexpression in human HK-2 cells inhibited pSTAT1 but not pSTAT3, which was associated with induction of epithelial differentiation and inhibition of proliferation.

Conclusions: Our data suggest that SOCS-3 regulates STAT1/3 phosphorylation in renal tubule cells and that pSTAT3 stimulates epithelial differentiation and proliferation while pSTAT1 might have a dominant role in inhibition of these cellular functions in HK-2 cells. Downregulation of SOCS-3 and following activation of STAT1 signalling may inhibit proliferation and epithelial differentiation leading to progressive decline of renal function.

SA-PO2784

Tubular Deficiency of von Hippel-Lindau Attenuates Renal Disease Progression in the Anti-GBM Glomerulonephritis Franziska Theilig,[1] Anne Enke,[1] Brigitte Scolari,[1] Sebastian C. Bachmann,[2] Robert Koesters.[3] *[1]Medicine, Anatomy, Fribourg, Switzerland; [2]Charite, Anatomy, Berlin, Germany; [3]INSERM/University Pierre et Marie Curie, Paris, France.*

Background: In many kidney diseases, the original insult primarily involves the glomerulus and may then pass onto the tubulointerstitium. Several hypothesis link the glomerular disease to tubular injury, one of the foremost is the chronic tubular hypoxia. The effects of hypoxia and consecutive stabilization of hypoxia-inducible factors (HIF) however, are discussed controversially. Hypoxia was shown to induce interstitial fibrosis but also to have beneficial effects on renal disease progression when HIF was activated pharmacologically.

Methods: To analyze the impact of HIF´s on the tubulointerstitial disease development in a primary glomerular affection transgenic von Hippel Lindau (VHL)-knockout mice were generated and induced before the onset of an anti-glomerular basement membrane glomerulonephritis (GN).

Results: Tubular VHL-knockout and therefore local HIF-a stabilization increased renal production of VEGF, TGF-b_1 and PDGF-B resulting in augmented formation of capillaries, interstitial matrix and conversion of fibroblasts into myofibroblasts. Within the glomerular disease VHL-knockout reduced the glomerular damage and attenuated tubulointerstitial injury albeit similar characteristics. Likewise, proteinuria, plasma urea concentration and tubulointerstitial matrix were decreased in VHL-knockout with GN.

Conclusions: These findings demonstrate that tubular HIF-a stabilisation in a glomerular disease is beneficial for the disease outcome. In comparison to VHL-knockout alone GN is a much stronger activator of fibrosis so that other stimuli than hypoxia may be considered for renal disease progression.

Aspirin Inhibits the Development of Vascular Calcification through Induction of Heat Shock Protein 72 in Human Aortic Smooth Muscle Cells Tzong-Shi Lu,[1] Kenneth Lim,[1,2] Guerman Molostvov,[2] Daniel Zehnder,[2] Li-Li Hsiao.[1] *[1]Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Clinical Sciences Research Institute, Warwick Medical School, Coventry, United Kingdom.*

Background: Vascular calcification (VC) is a significant contributor to cardiovascular mortality in patients with chronic kidney disease (CKD) and coronary artery disease (CAD). Acetylsalicylic acid (Aspirin, ASA) is a widely used medication in artery intima disease. However, the role of ASA in the development of VC is unknown. There is emerging evidence that ASA could function as an inducer of the cardio-protective factor, heat shock protein 72 (HSP72). It is possible that ASA may also exert cardio-protective effects through HSP72.

Methods: Human vascular smooth muscle cells were treated with control or calcification medium containing 5mM calcium chloride and 5mM β-glycerolphosphate with/without ASA (4mM) treatment for 21 days.

Results: We have shown for the first time that ASA can inhibit the development of VC through the induction of HSP72 in our long-term VC model, *in vitro*. Furthermore, heat shock treatment (HST), an established inducer of HSP72 significantly inhibited the development of VC. Anti-calcific effects of both ASA and HST were abolished by HSP72 SiRNA. We also found marked reduction of HSP72 expression in arteries from patients with CKD and CAD, compared to healthy controls, *in vivo*. This confirms the role of HSP72 as an endogenous calcification inhibitor. We next showed that ASA, through a HSP72-dependent pathway, suppressed major promoters (Cbfa1, Osteocalcin, and Alkaline Phosphatase) of VC and also stabilized the contractile smooth muscle cell phenotype through maintaining myocardin and serum response factor in our long-term VC model. Organ culture of arteries from CKD and CAD patients, confirmed that despite initially reduced expression, retained their ability to induce HSP72 by HST.

Conclusions: In conclusion, our study shows that ASA is a powerful inhibitor of VC and its anti-calcific effects function through a HSP72-dependent pathway. We suggest treatment strategies involving ASA or other inducers of HSP72 as a new approach to inhibit localized or diffuse VC.

SA-PO2786

AMPK Activity as a Biomarker of CKD Status and Its Association with Metformin's Effects on CKD Aihua Deng,[1,2] Joseph Satriano,[1,2] Roland C. Blantz.[1,2] *[1]Medicine, University of California at San Diego, San Diego, CA; [2]Nephrology/Hypertension, VA San Diego Healthcare System, San Diego, CA.*

Background: Our previous studies have shown that both Angiotensin II blockade (AIIB) and hypoxia inducible factor induction with DMOG can significantly correct renal metabolic deficiency and improve renal function in rat renal ablation&infarction (A/I) model of chronic kidney disease(CKD)[Deng & Blantz, AJP:Renal,2010]. In this study , we investigated the regulation of AMPK activity in the CKD model as well as the therapeutic effects of metformin, an activator of AMPK.

Methods: The rat A/I model of CKD was produced by removing the right kidney and ligating two branches of the left renal artery. AMPK activity (p-AMPK-α) was tested by Western blot. GFR, RBF, renal oxygen consumption (QO2) and sodium transport(TNa) were measured. An increase in QO2/TNa indicates renal metabolic deficiency.

Results: Untreated A/I rats showed reductions of GFR, RBF and renal metabolic efficiency, accompanied with a major decrease in AMPK activity, i.e. a reduction of p-AMPK-α(P<0.01). AIIB and DMOG both improved renal fuction, corrected renal metabolic deficiency and normalized AMPK activity (P<0.01). Metformin also normalized AMPK activity (P<0.01), while significantly correcting renal metabolic deficiency and improving kidney function.

The effects of 3 different treatments on renal function, renal metabolic efficiency in A/I rats

	GFR ml/min	RBF ml/min	QO2 ml/min	QO2/TNa ml/mmole
Normal n=6	1.05 ±0.11	6.72±0.47	0.15±0.01	1.08±0.11
A/I n=7	0.54±0.05*	3.39±0.44*	0.12±0.01	1.70±0.10*
A/I + AIIB n=8	0.84±0.04†	6.64±0.23†	0.11±0.01	0.98±0.07†
A/I + DMOG n=7	1.48±0.19†	7.2±0.55†	0.20±0.03†	1.03±0.12†
A/I + Metformin n=8	1.10±0.06†	6.26±0.24†	0.17±0.01	1.13±0.10†

* P<0.05 vs normal; †P<0.05 vs A/I

Conclusions: Untreated A/I kidney demonstrated reduced AMPK activity , associated with reductions in renal function and renal metabolic efficiency. The three agents (AIIB, DMOG and Metformin) produced similar beneficial effects associated with normalization of AMPK activity, suggesting that renal AMPK activity is an indicator of CKD status, regardless of their initial molecular pathways. Metformin may be an additional effective agent for CKD treatment.

NLRP3 Functions in Renal Tubular Epithelial-Mesenchymal Transition Independent of Cytokine Production Wenjie Wang,[1] Aylin Sar,[2] Akosua Vilaysane,[1] Sharon Ann Clark,[1] Kiril Trpkov,[2] Daniel A. Muruve.[1] *[1]Medicine, University of Calgary, Calgary, AB, Canada; [2]Pathology, University of Calgary, Calgary, AB, Canada.*

Background: Interstitial inflammation and fibrosis are strongly associated with the outcome of chronic kidney disease. We recently demonstrated that the NOD-like receptor containing a pyrin domain 3 (NLRP3) not only mediates renal inflammation but also potentially plays a direct role in fibrogenesis. We investigated whether NLRP3 plays a role in tubular epithelial-mesenchymal transition (EMT).

Methods: Human proximal and murine tubular epithelial cell were cultured in the presence or absence of transforming growth factor-β (TGF-β, 10ng/ml). Tubular EMT was determined by the expression of α-smooth muscle actin and matrix metalloproteinase. NLRP3 and MMP gene transcription and expression were assessed by semi-quantitative PCR or western blotting. NLRP3, apoptosis-associated speck-like protein containing a CARD domain (ASC), Caspase-1 and MyD88 knockout tubular epithelial cell was studied to determine the contribution of inflammasome formation and proinflammatory cytokine on MMP expression. In vivo progressive fibrosis model of unilateral ureteic obstruction was carried out in NLRP3$^{-/-}$ or littermate mice. After 14 days, renal MMP activity and histological change were analyzed.

Results: TGF-β induced tubular EMT and concomitant NLRP3 expression in a time-dependent fashion as evident by de novo expression of α-smooth muscle actin and upregulation of both MMP-2 and 9. The induction of MMP-9 was decreased in both NLRP3 and ASC knockout tubular epithelial cell, suggesting an essential role for NLRP3 in tubular EMT. The effect of NLRP3 and ASC on MMP-9 expression was inflammasome-independent as neither MyD88 or Caspase-1 knockout, nor adding IL-18 to NLRP3$^{-/-}$ tubular epithelial cell affected MMP-9 expression. Finally, NLRP3 knockout mice demonstrated decreased MMP-9 expression and developed less fibrosis compared to wild type controls after unilateral ureteric obstruction.

Conclusions: These data suggest a role for epithelial NLRP3 in promoting renal fibrosis independent of the inflammasome formation and also independent of subsequent pro-inflammatory cytokine production.

SA-PO2788

CKD Changes the Composition of Exhaled Gasses and Gaseous Products of the Gut Microbiome Simone Meinardi,[2] Kyu-Bok Jin,[1] Donald R. Blake,[2] Nosratola D. Vaziri.[2] *[1]Medicine, Inje Univ Haeundae Paik Hospital; [2]Medicine/Chemistry, UC Irvine, Irvine, CA; [3].*

Background: Few gases are produced by cellular metabolism and many by intestinal flora. While much is known about the effect of CKD on composition of body fluids little is known on its impact on the gases in exhaled breath or those produced by the gut microbiome. We showed that uremia significantly changes the structure-function of the gut microbiome. We hypothesized that uremia-induced changes in cellular metabolism and intestinal microbiome may modify gaseous metabolites found in the exhaled breath and generated by the intestinal flora.

Methods: SD rats were randomized to the CKD (5/6 nephrectomy) or control (sham operation) groups and observed for 6 wks. Exhaled breath was collected in evacuated stainless steel canisters at wks 0, 1, 2, 4, and 6. The animal was enclosed in a 10 L glass chamber flushed with clean air for 1 hr, the chamber was then sealed with animal inside for 45 min and 2 L of air were collected. At wk 6 feces were collected, dissolved in milliQ water, incubated at 37º C in glass reactor for 24 hr and the headspace air collected. The gases collected from exhaled breath and cultured feces were analyzed by a gaschromatographic system equipped with 6 different column/detector combinations.

Results: More than 50 gases were detected in the animals' exhaled breath and cultured feces ranging from pptv to ppmv of which 7 gases in exhaled breath and 8 collected from the cultured feces were significantly different between the 2 groups at week 6. Longitudinal studies revealed an early rise in isoprene and a late fall in concentration of linear aldehydes in the exhaled breath in the CKD rats. Numerous sulfur and oxygen containing gases were identified in both exhaled breath and cultured feces. Compared to controls cultured feces from the CKD animals released larger amounts of dimethyldisulfide and dimethyltrisulfide, and three thioesters which were absent in the controls.

Conclusions: CKD significantly changes the composition of exhaled breath and gaseous products of intestinal flora. Further studies are needed to determine the utility of these gases as biomarkers of CKD and its complications.

SA-PO2789

CKD Results in Depletion of H_2S, Accumulation of Homocysteine, and Downregulation of the Related Enzymes in the Kidney Mohammad A. Aminzadeh, Nosratola D. Vaziri. *Medicine/Nephrology, University of California, Irvine, CA.*

Background: Oxidative stress and inflammation are constant features and major mediators of progression of chronic kidney disease (CKD) and its cardiovascular complications. Hydrogen sulfide (H2S) is an endogenous signaling gas which has potent anti-hypertensive, anti-oxidant, and anti-inflammatory properties. In contrast, homocysteine has pro-oxidant and pro-inflammatory effects. H2S is produced by cystathionine β-synthase (CBS), cystathionine γ-lyase (CSE), and 3-mercaptopyruvate sulphurtransferase (MST) while homocysteine is removed by CBS and methylenetetrahydrofolate reductase (MTHFR). Plasma H2S is reduced in humans with hypertension, atherosclerosis, and end-stage renal disease and tissue H2S is diminished in experimental animals with atherosclerosis, hypertension, and acute kidney injury. The effect of CKD on intra-renal metabolism of H2S and homocysteine is unknown and was studied here.

Methods: SD rats were subjected to 5/6 nephrectomy or sham operation and observed for 6-12 weeks. Kidney tissue H2S-producting capacity, homocysteine content, and CBS, CSE, MST and MTHFR expressions were determined.

Results: The CKD group exhibited significant reduction in plasma H2S concentration (33.30±2.40 vs44.65±1.56, P<0.001) and oxidative stress in the remnant kidney. This was associated with marked elevation of homocysteine (0.19±0.02 vs 0.05±0.02 P<0.001), significant reductions in CBS (46%, P<0.006), CSE (76%, P<0.004), MST (60%, P<0.021 and MTHFR (86%, P<0.001) expressions and H2S-production capacity (28%, P<0.001) in the remnant kidney.

Conclusions: Progression of renal disease and oxidative stress in CKD are associated with depletion of H2S and accumulation of homocysteine in the remnant kidney which are due to down-regulation of H2S-producing and homocysteine-metabolizing enzymes. Given the potent anti-oxidant, anti-inflammatory and cytoprotective properties of H2S and pro-oxidant and pro-inflammatory effects of homocysteine, the observed abnormalities can contribute to progression of CKD.

Dabigatran, a Direct Thrombin Inhibitor, Demonstrates Antifibrotic Effects on Kidney Fibroblasts James W. Tanner, Danielle M. Fowler, Jorge L. Villalona, Glenn A. Reinhart, Joanne Van Ryn, Scott MacDonnell. *Cardiometabolic Diseases Research, Boehringer Ingelheim Pharmaceuticals, Ridgefield, CT.*

Background: Involvement of the coagulation cascade, via thrombin mediated activation of the PAR-1 receptor, has been shown to play a role in the activation and development of lung fibrosis, but is undocumented in the context of renal fibrosis. Objectives include, investigating the profibrotic activity of thrombin in renal fibroblasts by assessing myofibroblast formation and extracellular matrix (ECM) deposition and determine whether the direct thrombin inhibitor, dabigatran, interferes with these signaling events.

Methods: Rat kidney fibroblasts (NRK49F) were treated with thrombin at 0.5U/ml-2.5U/ml for 24, 48, and 72 hours. Functional parameters examined included kinetics (cell proliferation), differentiation (αSMA expression), and ECM deposition (collagen I and fibronectin expression). RT-PCR and immunohistochemistry was used to characterize expression of profibrotic genes and PAR-1 in both isolated fibrobalsts and rat kidney tissue.

Results: In fibroblasts, thrombin induced both αSMA and fibronectin expression, stimulated collagen synthesis (hydroxyproline and immunostaining) in a time and dose dependent manner (P<0.05), and had no significant proliferative effects. Thrombin induced collagen deposition was comparable to TGF-b (5ng/ml) stimulation at 72 hours despite a significantly lower expression of fibrotic genes. Dabigatran, at concentrations of 10 and 1000ng/ml inhibited thrombin induced myofibroblast activation and ECM accumulation in a dose dependent manner (P<0.05). The inhibitory effects of dabigatran were not observed when fibroblasts were stimulated with TGF-b (5ng/ml) while ALK5 inhibition failed to prevent thrombin induced collagen production. In a model of rat obstructive nephropathy (UUO), PAR-1 mRNA expression was increased 4-fold, in kidney tissue.

Conclusions: Dabigatran inhibited thrombin induced activation and ECM deposition in kidney fibroblasts. These effects were independent of TGF-b signaling. Thus direct thrombin inhibition with dabigatran may warrant study as an antifibrotic drug for the treatment of renal fibrosis.

Effects of the Receptor Tyrosine Kinases Inhibitor BIBF1000 on Renal Fibrosis in Rodents Steven M. Weldon,[1] Haichun Yang,[2] Yiqin Zuo,[2] Cheng-Kon Shih,[1] Susan Goldrick,[1] Hong Wang,[1] Xiaoyu Jiang,[1] Glenn A. Reinhart,[1] Agnes B. Fogo.[2] *[1]Cardiometabolic Disease, Boehringer Ingelheim Pharm. Inc., Ridgefield, CT; [2]Division of Renal Pathology, Vanderbilt University Medical Center, Nashville, TN.*

Background: Tubular interstitial fibrosis (TIF) is a major factor contributing to the progression of chronic kidney disease (CKD) and subsequent renal failure. Presently only ACE inhibitors and ARBs are approved CKD therapy. We used unilateral ureteral obstruction (UUO) in rodents to study mechanisms and potential modulation of TIF. Receptor tyrosine kinase inhibitors (RTKi) such as Gleevec (imatinib) exhibit anti-fibrotic activity in animal models including UUO. BIBF1000 (BIBF) is a novel RTKi that attenuates PDGF,VEGF and FGF signaling and fibrosis in the rat bleomycin lung fibrosis model but has not been evaluated in renal fibrosis. Therefore, we evaluated BIBF in the UUO model of renal fibrosis.

Methods: SD rats and C57BLKS mice were treated 1 day prior to ureter ligation with vehicle (VEH), enalapril (ENA, 30 mg/kg), Gleevec (GLE, 100 mg/kg) or BIBF (25 or 50 mg/kg) by gavage (5 days). TIF was assessed by sirius red morphometry (SRM) and a panel of fibrotic and inflammatory biomarkers (BMs) were evaluated by immunostaining (IHC) or qPCR (mRNA).

Results: In mice, BIBF attenuated TIF by 18.8 and 19.1% (*p<0.05) for the 25 and 50 mg/kg doses, respectively. By comparison, GLE exhibited 17%* inhibition while ENA showed only 7% inhibition. In rats, BIBF inhibited TIF in a dose-depend manner, 16% and 25%*, respectively. GLE reduced TIF by 21%* and ENA by 13%. BIBF, GLE and ENA showed differential effects on fibrotic and inflammatory BMs in mice and rats. Finally, plasma levels of GLE were nearly identical in both mice and rats; ENA exhibited nearly 3-fold higher levels in rats while BIBF showed ~ 10-fold higher exposure in mice.

Conclusions: In conclusion, these are the first data to show a novel RTKi such as BIBF1000 attenuates renal tubulointerstitial fibrosis assessed quantitatively using SR morphometry. As such, RTK's and downstream signaling pathways may offer a novel alternative for targeting fibrotic renal disease associated with CKD and subsequent renal failure.

Peritoneal Dialysate-Induced Down-Regulation of E-cadherin Is Mediated by Oxidative Stress Via an Activation of Mitochondrial Respiration, Independent of NAPDH Oxidase Duk-Hee Kang, Eun Sun Ryu, Mina Yu, Yang-Hee Jang. *Division of Nephrology, Ewha Womans University School of Medicine, Seoul, Korea.*

Background: Chronic exposure of the peritoneum to unphysiologic dialysate leads to peritoneal membrane dysfunction and fibrosis. Recent studies indicate phenotypic transition of peritoneal mesothelial cells as an early mechanism of peritoneal fibrosis. Especially, E-cadherin, which was formerly viewed exclusively as a structural protein mediating cell-cell adhesion, is now regarded as a key molecule to regulate the epithelial phenotype. Glucose-degradation product in conventional dialysate has been blamed for peritoneal dialysis-induced changes in peritoneum, and a use of low-GDP solution leads to rapid remesothelialization and less EMT.

Methods: In order to investigate the mechanism of peritoneal fibrosis after a prolonged use of high GDP dialysate, we examined an alteration in E-cadherin mRNA and protein expression in primarily isolated peritoneal mesothelial cells exposed to conventional high GDP or low GDP solution. We also investigated the effect of anti-oxidants on E-cadherin expression of MCs.

Results: Conventional dialysate (Perisis^{R}, Boryung Pharm, Korea) induced a down-regulation of E-cadherin with an enhanced generation of ROS assessed by DCF-DA staining. Interestingly, the exposure of MCs to low-GDP dialysate (PeriPlus^{R}, Boryung Pharm, Korea) resulted in a less decrease in E-cadherin expression both in mRNA and protein levels and less increase in ROS production compared to conventional dialysate. *N*-acetylcysteine or mitoQ, a novel mitochondria-specific antioxidant inhibited conventional dialysate-induced

down-regulation of E-cadherin, however apocynin, an inhibitor of NAPDH oxidase, showed no significant effect on E-cadherin expression. Treatment of MCs with H_2O_2 or glucose oxidase per se induced phenotypic transition with a decrease in E-cadherin expression.

Conclusions: Taken together, oxidative stress induced by GDP seems to be one of the mechanisms of peritoneal damage in PD patients, and novel mitochondrion-targeted antioxidant can be a therapeutic option for preserving mesothelial phenotype.

This study was supported by the grant from Seoul R & D Program (ST090834M0214881).

SA-PO2793

Renal Mass Reduction (RMR) Impairs Recovery from Acute Kidney Injury (AKI) and Promotes the Mechanisms of Chronic Kidney Disease (CKD) Progression Aaron Polichnowski,[1] Rongpei Lan,[2] Hui Geng,[2] Karen A. Griffin,[1] Anil K. Bidani,[1] Manjeri A. Venkatachalam.[2] *[1]Loyola U Med Ctr; [2]U TX.*

Background: Clinical studies suggest that AKI in CKD settings increases the risk for progression to end stage. Limited experiments testing this concept have been conflicting.

Methods: Sprague-Dawley rats were prepared for blood pressure radiotelemetry (BP) and normotensive RMR by uninephrectomy (UNx), UNx + excision of 2 poles from other kidney (3⁄4 Nx), or no Nx. Two wks later, AKI was induced by 40' ischemia/reperfusion (I/R) and rats followed for 4 wks post I/R.

Results: SCr and BP in Pre I/R 3⁄4 Nx rats were modestly increased. Without I/R, this effect of RMR was stable over 4 wks (not shown). Judged by SCr at 48h post I/R, AKI severity was similar in all groups. But, recovery was impaired in 3⁄4 Nx relative to other groups (SCr 7d).

Pre I/R				Post I/R (1st wk)		Post I/R (4th wk)	
Group	SCr mg/dl	BP mmHg	Uprot mg/24h	SCr 48h	SCr 7d	BP	Uprot mg/24h
No Nx (n=10)	0.44±0.03*	114±1.9	4.6±0.4	4.6±0.4	0.8±0.07	119±1.8	6.1±0.7
UNx (n=12)	0.60±0.04*	109±2.0	4.5±0.3	4.3±0.4	0.9±0.05	120±3.8	23.1±12.4
3/4 Nx (n=12)	0.85±0.04*	130±3.4*	8.6±1.2	4.5±0.3	1.8±0.2*	152±8.2*	57.6±14.5*

mean±SE; * $p < 0.05$ vs all other groups. BP and Uprot data 1st wk post I/R not shown

SCr remained significantly higher than pre I/R values over 4 wks in 3⁄4 Nx rats; this was mirrored by more extensive tubule atrophy and fibrosis 4 wks post I/R compared to other groups. BP was similar before I/R and 1 wk post I/R in 3/4 Nx rats, but showed large increases by 4 wks. This was accompanied by markedly increased Uprot. Overall, the severity of tubulo-interstitial fibrosis correlated better with BP and Uprot than with SCr. Data in UNx rats showed similar trends but exhibited much greater variability.

Conclusions: Repair is less complete and fibrosis more extensive after ischemic AKI in the setting of severe RMR. By reducing functional renal mass further, such tubulo-interstitial fibrosis after AKI accelerates the development of hypertension and augments proteinuria, setting the stage for CKD progression. Our data suggest that RMR models are useful to investigate the mechanisms responsible for incomplete repair, regeneration and fibrosis in CKD progression after AKI.

SA-PO2794

The Role of Erk Activation in the Subtotal Nephrectomy Model of Kidney Fibrosis Faith Hannah Nutter, John Haylor, Arif Khwaja. *Academic Unit of Nephrology, University of Sheffield, Shefffield, United Kingdom.*

Background: The Ras-Mek-Erk signalling pathyway plays a key role in many cellular pathways underpinning kidney fibrosis including cell proliferation, apoptosis, epithelial to mesenchymal transition and accumulation of extracellular cellular matrix. Phosph-Erk (p-Erk) is upregulated in fibrotic kidney disease and in vitro data suggests Erk activation amplifies TGF-β mediated pro-fibrotic effects. We hypothesised that Erk is a therapeutic target in fibrotic kidney disease and the MEK inhibitor CI-1040 would attenuate renal fibrosis in the subtotal nephrectomy (SNx) model.

Methods: Male Wistar rats were subjected to either 5/6 SNx or sham operation under isofluorane anaesthesia. SNx rats received intraperitoneal injections of either CI-1040 (100mg/kg/day) or vehicle alone from day 1. Animals were sacrificed 130 days later. Renal function was assessed by serum creatinine, creatinine clearance and urinary protein excretion. Fibrosis and myofibroblast number were assessed by Masson's Trichrome and α-SMA staining. Immunohistochemistry and western blotting for p-Erk was performed on lymphocyte and kidney homogenates. Cell proliferation was assessed by BrdU uptake.

Results: A 5-fold upregulation of p-Erk levels ($p<0.0001$) was observed in renal tissue and lymphocytes throughout the duration of the model with CI-1040 almost completely inhibiting p-Erk activity in the kidney (4.78 ± 0.8 vs. 0.14 ± 0.1 OD/mm2, $p<0.0001$) and in lymphocytes. Despite inhibition of p-Erk, CI-1040 had no effect on either the development of renal fibrosis (17.3 ± 3.6 vs. $24.6 \pm 4.6\%$) or the increase in α-SMA positive cells (17.1 ± 3.3 vs. $20.8 \pm 4.5\%$). Furthermore CI-1040 had no impact on creatinine clearance, proteinuria or on cell proliferation.

Conclusions: Erk activity is significantly upregulated following SNx yet complete inhibition of Erk activation by CI-1040 had no impact on kidney function, fibrosis or myofibroblast number. This suggests that kidney fibrosis in SNx is not dependent on Erk activation. It is possible that upregulation of other mitogen activated protein kinases (MAPKs) pathway may compensate for the loss of Erk activation and future work will examine activity of JNK and p38 MAPKs.

Renal Growth Hormone Receptor Signaling Is Impaired in a Rat Model of Chronic Kidney Disease Daniel Landau,[1] Debbie Wiezel,[2] Ariel Troib,[2] Ralph Rabkin,[3] Yael Segev.[2] *[1]Pediatrics, Ben Gurion University, Beer Sheva, Israel; [2]Shraga Segal Dept. of Microbiology and Immunology, Ben Gurion University, Beer Sheva, Israel; [3]Medicine, Veterans Administration Hospital and Stanford University, Palo Alto, CA.*

Background: Linear growth retardation with reduced muscle mass is a major problem in children and adults with chronic kidney disease (CKD) and is ascribed to insensitivity to GH. Treatment with exogenous GH has been accepted as standard therapy in children with CKD and short stature. However, concerns have been raised in the past on the potential fibrogenic effects of GH on the kidney since transgenic mice over-expressing bGH develop glomerulosclerosis. We have previously described the renal GH-IGF –I signaling in a whole animal model of diabetic kidney disease. No data is available on this renal pathway in CKD.

Methods: To investigate the renal GHR signaling pathway of growth retarded young CKD rats, 5/6 nephrectomized (CKD) and pair-fed control (C) 20 day old rats were sacrificed after 2 weeks of CKD. Bovine GH (IV 100μg/kg) was given 15 min prior to sacrifice.

Results: There was no difference in the amount of food consumed, yet there was a significant difference in weight gain and longitudinal growth between C and CKD. Serum creatinine increased to 225±11% of C and albumin excretion was significantly higher in CKD. Glomerular volume was higher in CKD vs. C (252±12.5 % of C, $p< 0.05$). No change was observed in serum GH, yet serum IGF-I was decreased significantly in CKD vs. C (60.4±5 % of C, $p < 0.05$). Kidney and liver IGF-I mRNA levels were unchanged.

A significant decrease was seen in kidney GHR mRNA and protein, as well as phosphorylated (p-)JAK2 and p-STAT5 in CKD vs. C. An increase in SOCS3 mRNA was seen in CKD vs. C.

Conclusions: Young rats with moderate CKD develop significant growth retardation. The decrease in GHR expression as well as the subsequent proteins of its signaling pathway in the kidney in association with the increase in the GHR inhibitor SOCS3 shows a GHR signaling impairment in the kidneys of CKD rats. This may explain the relative insensitivity of kidney tissue to the potential adverse effects of exogenous GH in CKD patients.

SA-PO2796

Renal Failure, Endothelial Dysfunction, Hypotension and Anemia in Mice with Homozygous Deletion of the Gene Encoding the Canonical Transient Receptor Potential 1 (TRPC1) Channel: Role of Hypoplasia Kai Lau,[1] Pedro Lozano,[1] Qilong Wang,[1] Bonnie Eby,[1] Becky Pennington,[1] Richard Matthew Atkins,[1] Meghan Pantalia,[1] Joel Abramowitz,[2] Lutz Birnbaumer,[2] Leonidas Tsiokas.[3] *[1]Medicine, University of Oklahoma, Oklahoma City, OK; [2]Intramural Research, NIEHS, Research Triangle Park, NC; [3]Cell Biology, University of Oklahoma, Oklahoma City, OK.*

Background: TRPC is a superfamily of cation channels implicated in many cell functions. A key role for TRPC1 was found in cardiac hypertrophic signaling, VSM proliferation & mesangial cell contraction. Its normal physiologic functions are unknown.

Methods: Male TRPC1 +/+ & -/- mice were studied by cardiac & renal ultrasound, clearance (C) of creatinine (cre) by HPLC & inulin, tailcuffs/intra-arterial blood pressure (BP) readings & chamber studies of aorta relaxation.

Results: At 2 mon, null mice had smaller heart (0.45 vs. 0.52% of body weight [BW]) & kidney (1.4 vs. 1.5%). At 7 mon, they had reduced left ventricle end-diastolic & end-systolic diameters & volumes. Stroke index (SI) & cardiac output (CO) (14 vs. 21 ml/min) were reduced. Systolic (in torr) (113 vs. 121), diastolic (77 vs. 86) & mean arterial (MA) BP (89 vs. 98) were lower. Arterial resistance [MABP/CO] was high. Arterial stiffness was elevated 2 fold & compliance down 50%. Heart was 20% smaller at 22 mon. Aortic relaxation were normal at 2 mon but reduced at 22 mon. Hematocrit was reduced by ~20% from 10-22 mon. At 7 mon, kidney volume (KV) by echo & KW:BW were reduced. From 11-20 mon, KV stayed lower by 18% & KW:BW ratio down by 28%. Renal echogenicity was similar at 7 & 11 mon but elevated by 37 % at 20 mon, consistent with scarring. Normal at 12 mon, serum cre (0.1 vs. 0.06 mg%) was elevated at 17 mon. Ccre (ml/min) was down by ~50% (0.7 vs. 1.1/mouse; 1.7 vs. 3.4/100g BW). Renal failure was confirmed by ~46% reduced Cinulin (μl/min) (214 vs. 384/mouse; 603 vs. 1,155/100g BW; 362 vs. 681/g KW).

Conclusions: 1. TRPC1 deficiency retards renal & heart growth, produces hypoplastic nephropathy, reduces CO & BP, increases arterial resistance & stiffness & causes endothelial dysfunctions & anemia. 2. Our data indicate its key roles in normal development.

SA-PO2797

DNA Methyltransferase 1, 3a, 3b and 3L Are Transiently Upregulated during the Development of Renal Fibrosis Benjamin Arthur Vervaet, Anne Soontjens, Anja Verhulst, Patrick C. D'Haese, Annelies De Beuf. *University of Antwerp.*

Background: The cell biological process underlying all chronic renal disorders is fibrosis. Crucial in this process is the activation of fibroblasts, resulting in their proliferation and excessive production of extracellular matrix. Recently, it has been shown that DNA methylation, performed by DNA methyltransferases (Dnmt's), plays an important role

in the perpetuation of this fibroblast activation. Little is known, however, on (i) which Dnmt's are involved and (ii) what their temporal expression is in the kidney during the development of fibrosis. Hereto, the present study aimed at a time course evaluation of the expression of the most prominent Dnmt's (Dnmt1, 3a and 3b) and the similar, but non-functional, Dnmt3L in two different mice models of fibrosis: aristolochic acid nephropathy and ischemia reperfusion (I/R) injury.

Methods: Mice (20-25g) received a single intraperitoneal injection of aristolochic acid I (AAI, 3.5 mg/kg) or PBS or underwent unilateral left ischemia during 30 minutes. Mice were sacrificed after 1, 3, 6 and 12 weeks. The expression level of Dnmt1, 3a, 3b and 3L was assessed by quantitative real-time PCR on total renal tissue mRNA.

Results: All Dnmt's were significantly upregulated during the development of renal fibrosis in both animal models from week 1 on, reaching maximum expression levels 3 weeks after AAI injection and 6 weeks after reperfusion. At week 12, when fibrosis was most prominent, the expression of the Dnmt's decreased towards control levels in both models.

Conclusions: Dnmt 1, 3a, 3b and 3L are all upregulated shortly, but not permanently, after AAI injection or I/R injury, supporting a transient role for these enzymes in the development of renal fibrosis following both an acute toxic and ischemic insult. Interestingly, these findings contrast the recently reported observation that only Dnmt1 (but not Dnmt3a and Dnmt3b) was upregulated in a folic acid induced mouse model of renal fibrosis (Bechtel et al. Nat. Med. 2010;16(5):544). Our data, therefore, indicate that the involvement of Dnmt's might depend on the stage of renal histopathology and/or the type of insult.

Indoxyl Sulfate Induces Cbp/p300-Interacting Transactivator, with Glu/Asp-Rich Carboxy-Terminal Domain, 2, and Impairs Hypoxia Response in Proximal Tubular Cells Tetsuhiro Tanaka,[1] Toshiro Fujita,[2] Masaomi Nangaku.[2] *[1]Division for Health Service Promotion, University of Tokyo, Japan; [2]Division of Nephrology and Endocrinology, University of Tokyo School of Medicine, Japan.*

Background: Hypoxia in the tubulointerstitium is common in progressive renal diseases. Hypoxia-inducible factor (HIF) is a heterodimeric transcription factor composed of α- and β- subunits and controls the expression of genes involved in glycolysis, angiogenesis and erythropoiesis in hypoxia. Results from recent studies suggest that HIF, while obviously expressed, may be insufficiently activated in experimental chronic kidney disease (CKD) models.

Methods: In this study, we investigated the effect of indoxyl sulfate (IS), a uremic toxin which accumulates in CKD patients and is responsible for renal pathology, on cellular response to hypoxia in cultured proximal tubular cells. Hypoxia response by HIF-1 was measured by luciferase reporter assay. Quantitative changes in HIF-1α, Cbp/p300-interacting transactivator, with Glu/Asp-rich carboxy-terminal domain, 2 (CITED2) and HIF-target genes were analyzed by real-time PCR and Western blotting. HIF-1 binding to the enhancer region was evaluated by chromatin immunoprecipitation (ChIP) assays. Protein interaction between HIF-1α and its coactivators was estimated by mammalian two-hybrid assays.

Results: Transient transfection with the hypoxia-responsive luciferase reporter (HREluc) revealed that IS impaired hypoxia response in HK-2 cells, which was associated with a decrease in the expression of HIF-1 target genes. Immunoblotting using whole cell lysates demonstrated no significant changes in HIF-1α expression, and ChIP assays revealed no effect of IS on HIF-1 binding to the promoter region. However, IS induced the expression of CITED2 via post-transcriptional mechanisms and impaired activity of the HIF-1α C-terminal transactivator domain (CTAD) by blocking the recruitment of its coactivator p300.

Conclusions: Results of the present study uncover a novel mechanism through which IS dampens hypoxia response mediated by HIF-1, and may provide an insight into clinical problems such as insufficient erythropoietin (EPO) production in uremic patients.

Role of HSP47 in Epithelial-Mesenchymal Transition of Renal Tubular Epithelial Cell and Extracellular Matrix Accumulation Huixin Bi,[1] Ruihong Liu,[1] Lin Sun,[1,2] You-Ming Peng,[1] Fu-You Liu.[1] *[1]Department of Nephrology, Second Xiangya Hospital, Central South University, Changsha, Hunan, China; [2]Departments of Pathology and Medicine, Northwestern University, Chicago, IL.*

Background: Epithelial-mesenchymal transition (EMT) and extracellular matrix (ECM) accumulation play an important role in renal tubulointerstitial fibrosis. Previous studies have showed the close relationship between the increased expression of HSP47 and the progression of tubulointerstitial fibrosis. However whether HSP47 plays a role in the process of EMT and ECM accumulation is unclear.

Methods: HSP47 antisense oligonucleotides(ODNs) was introduced in the kidney with an ultrasound microbubbles system by injecting it into a renal artery at the day of inducing UUO, sense ODNs served as a control. Rats were sacrificed at day 14 after UUO or sham operation. The expressions of HSP47, vimentin, ZO-1 and ColI were detected by immunohistochemical, Western blot and Real-time PCR, respectively. In vitro studies, HK-2 cells were exposed to 10ng/ml TGF-β1. Furthermore, HK-2 cells were transfected with HSP47 siRNA and siRNA negative control before exposing to TGF-β1. The expressions of HSP47, vimentin, ZO-1, ColI, Smad3 and p-Smad3 were examined by Western blot, Real-time PCR, and/or immunofluorescence, espectively.

Results: Compared to that in control, after treatment of HSP47 antisense ODNs resulting in an efficient and specific inhibition of HSP47 expression in the kidney of UUO model, the vimentin and ColI expression was significantly decreased and ZO-1 expression was significantly increased in the obstructed kidneys. Compared to the TGF-β1 group, inhibition of HSP47 expression in HK-2 cells up-regulated the expression of ZO-1 and down regulated the expressions of vimentin, ColI. Compared to the TGF-β1 group, inhibition of HSP47 expression down regulated the expression of p-Smad3/Smad3 in HK-2 cells.

Conclusions: HSP47 could promote the EMT of renal tubular epithelial cells in vivo and vitro via modulation the activation of Smad3, and suppression of HSP47 would be a possible therapeutic target against tubulointersitial fibrosis.

TGF-b1 Mediates Macrophage-Induced Tubular Epithelial-to-Mesenchymal Transition in Fibrotic Nephropathy Yang Zhou, Chunsun Dai, Junwei Yang. *Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical University, Nanjing, Jiangsu, China.*

Background: Macrophage infiltration is a common feature of chronic kidney disease, which suggests a pathologic function for macrophage in renal fibrosis. Tubular epithelial cell sparks renal fibrogenesis through epithelial-to-mesenchymal transition (EMT). Whether macrophage infiltration causes EMT and the exact underlying mechanisms remain to be determined.

Results: In this study, the effect of macrophage infiltration on kidney tubular EMT was investigated in unilateral ureteral obstruction (UUO) mice and cultured tubular cells. Macrophage infiltration was remarkably increased in the obstructive kidney. RT-PCR and ELISA analysis showed robust increased TGF-b1 mRNA expression and protein secretion in primary cultured macrophages isolated from UUO mice. Culture media from these activated macrophages could induce Smad signaling activation and EMT in tubular cells (NRK-52E), as demonstrated by loss of E-cadherin, de novo expression of a-SMA and upregulation of fibronectin, suggesting a critical role for activated macrophage in promoting EMT. Moreover, macrophage-induced Smad3 phosphorylation and tubular EMT were largely abolished by TGF-b1 neutralization antibody.

Conclusions: Hence, these results indicate that TGF-b1 plays an essential role in macrophage-induced tubular EMT in fibrotic nephropathy.

Funding: Government Support - Non-U.S.

SA-PO2801

Transforming Growth Factor-β Receptor Inhibition Preserves Renal Tubular Mass and Reduces Formation of Atubular Glomeruli Following Ureteral Obstruction Robert L. Chevalier,[1] Michael S. Forbes,[1] Barbara A. Thornhill,[1] Dae-Kee Kim.[2] *[1]Department of Pediatrics, University of Virginia, Charlottesville, VA; [2]College of Pharmacy, Ewha Womans University, Seoul, Korea.*

Background: Chronic kidney disease is characterized by parenchymal loss and interstitial fibrosis. Unilateral ureteral obstruction (UUO) is the most widely used model of chronic kidney disease, and we have recently reported that murine UUO results in rapid formation of atubular glomeruli (ATG) (March 2011, doi:10.1152/ajprenal.00022.2011). Transforming growth factor-β1 (TGF-β1) is a central regulator of renal cell death and collagen deposition following UUO.

Methods: Mice were subjected to UUO and placement of subcutaneous pellets for the continuous release of vehicle or IN-1130 (ALK5 TGF-β Type I receptor inhibitor), 30 mg/kg/day. Kidneys were harvested after 14 days, and proximal tubules, tubular atrophy and ATG were identified by *Lotus tetragonolobus* lectin. Collagen was identified by Sirius red. Relative distribution of renal parenchymal thickness, glomerular area, proximal tubular area, and interstitial collagen deposition were determined by quantitative histomorphometry.

Results: Weight and parenchymal thickness of the obstructed kidney were 42% and 51% greater in IN1130-treated than control mice, respectively ($p<0.05$). Glomerular area was 27% greater in IN1130 than in control mice ($p<0.05$). The fraction of intact glomeruli was 42±5% in IN1130-treated mice, but only 23±3% in controls ($p<0.05$); the volume fraction of proximal tubules was 30±5% with IN1130 vs. 18±2% in controls ($p<0.05$). Renal interstitial collagen accumulation was 2.9±0.3% with IN1130, but increased to 5.2±0.3% in controls ($p<0.05$).

Conclusions: We conclude that in addition to its role in interstitial fibrosis, TGF-β signaling mediates proximal renal tubular injury leading to the formation of ATG following UUO. ATG are formed in many renal disorders, including IgA and membranous nephropathy, cystinosis, diabetes, renovascular hypertension and renal allograft rejection (JASN 19:197, 2008). Inhibition of TGF-β type I receptor kinase may therefore prove clinically effective in the preservation of functional nephron number in chronic kidney disease.

Gremlin Is a Mediator of High Glucose and TGF-β-Induced Fibrosis in Renal Cells Sergio A. Mezzano,[1] Raquel Rodrigues-Diez,[2] Carolina Lavoz,[2] Sandra Rayego-Mateos,[2] Raúl R. Rodrigues Díez,[2] Alberto Ortiz,[2] Jesus Egido,[2] Marta Ruiz-Ortega.[2] *[1]Nephrology, Universidad Austral, Valdivia, Chile; [2]Universidad Autonoma Madrid, Spain.*

Background: Accumulation of extracellular matrix (ECM) is a hallmark of renal fibrosis. Fibroblasts are the main matrix-producing cells. Epithelial mesenchymal transition (EMT) is a source of activated fibroblasts. Gremlin is a developmental gene upregulated in diabetic nephropathy and in renal cells in response to high glucose and TGF-β1, but its role in renal fibrosis is unclear. We studied the role of gremlin in fibrogenic events in cultured renal cells.

Methods: Murine fibroblasts or human tubuloepithelial cells (HK2) were stimulated with recombinant gremlin, TGF-β or high glucose conditions. Changes in ECM or EMT proteins were evaluated by western blot and confocal microscopy. Endogenous gremlin was targeted with small interfering RNA (siRNA). The involvement of TGF-β in gremlin actions was assessed with a TGF-β neutralizing antibody.

Results: In murine fibroblasts stimulation with recombinant gremlin upregulated profibrotic genes, such as TGF-β1 and CTGF, and increased the production ECM proteins, including type I collagen. In human tubular epithelial cells gremlin also increased ECM-related proteins and induced EMT changes: phenotypic modulation to myofibroblast-like morphology, loss of epithelial markers (E-cadherin and cytokeratin) and induction of mesenchymal markers (vimentin and fsp-1). In both fibroblasts and tubular epithelial cells TGF-β1 induced gremlin production. We have tested whether gremlin is a downstream mediator of the profibrotic effects of TGF-β1 and high glucose. The blockade of endogenous gremlin with small interfering RNA inhibited TGF-β1 and High glucose-induced ECM upregulation and EMT.

Conclusions: Gremlin could participate in renal fibrosis, acting as a downstream mediator of high glucose and TGF-β1. Our data suggest that gremlin is a novel mediator of renal fibrosis and could be a target for anti-fibrotic therapies.

SA-PO2803

Marinobufagenin Induces CD40 Expression in Experimental Uremic Cardiomyopathy Steven T. Haller,[1] George Budny,[1] Jiang Liu,[1] Olga Fedorova,[2] Alexei Bagrov,[2] Deepak K. Malhotra,[1] Christopher J. Cooper,[1] Joseph I. Shapiro.[1] *[1]Medicine, University of Toledo Collage of Medicine, OH; [2]National Institute on Aging, Baltimore, MD.*

Background: We have shown that experimental uremic cardiomyopathy causes cardiac fibrosis, the generation of reactive oxygen species (ROS), and is associated with increased levels of the cardiotonic steroid marinobufagenin (MBG), a ligand of the Na/K-ATPase. CD40, a type I transmembrane receptor and member of the TNF receptor superfamily, is expressed by a variety of cells including endothelial cells and renal proximal tubular epithelial cells. CD40 receptor expression has been shown to play a vital role in inflammation. Recent evidence in renal transplant models suggests that activation of CD40, by its ligand (CD40L), results in activation of profibrotic signaling cascades. CD40 expression in the setting of experimental uremic cardiomyopathy has not been defined.

Methods: Male Sprague Dawley rats weighing between 250-300 gms were used for these studies. Western blot analysis was performed on kidney cortex tissue derived from partially nephrectomized (PNx) rats, and rats administered MBG at a dose of 10μg/kg/day by osmotic minipump infusion. In vitro experiments were performed using a pig renal proximal tubular cell line (LLC-PK1 cells).

Results: The PNx and MBG treated animals exhibited a substantial increase in CD40 expression compared to controls along with concurrent increases in collagen type-I expression. LLC-PK1 cells treated with MBG, ouabain, and glucose oxidase (a hydrogen peroxide inducer) showed a similar response. The increase in CD40 expression was mitigated by treatment with a monoclonal anti-MBG antibody (3E9).

Conclusions: MBG and ROS stimulate CD40 expression, which may contribute to the development of renal fibrosis in the setting of experimental uremic cardiomyopathy.

Carbamylated Proteins Accumulate in Tissues in Mice with Chronic Renal Failure Christine Pietrement,[1, 2] Laetitia Gorisse,[2] Philippe Rieu,[2, 3] Stephane Jaisson,[2, 4] Philippe Gillery.[2, 4] *[1]Department of Pediatrics, University Hospital, Reims, France; [2]UMR CNRS/URCA n°6237, Faculty of Medicine, Reims, France; [3]Department of Nephrology, University Hospital, Reims, France; [4]Laboratory of Pediatric Biology and Research, University Hospital, Reims, France.*

Background: Carbamylation is a late post-translational modification of proteins resulting from the nonenzymatic binding of isocyanic acid, a urea by-product, to specific free functional groups. This reaction alters protein structural and functional properties. Many studies have suggested the involvement of carbamylated proteins in chronic renal failure (CRF) and atherosclerosis but their *in vivo* accumulation or degradation is still incompletely known. We tested the hypothesis of the *in vivo* carbamylated proteins accumulation in a CRF animal model.

Methods: C57Bl/6J mice were subjected to a 75% reduction of total renal mass or to sham operation, and were sacrificed 10 weeks after surgery. Carbamylated proteins were evaluated in plasma and tissues by homocitrulline (Hcit) measurement with LC-MS/MS method after acid hydrolysis.

Results: In CRF mice group, mean serum urea concentration was 16.92 mmol/L and hematocrit 38% *vs* 8.24 mmol/L and 41% in control group. Hcit concentration was increased in CRF mice plasma *vs* control (0.97 and 2.07 mmol/mmol of amino acids respectively). Plasma urea and Hcit were positively correlated (r^2=0.8). Hcit content was increased in CRF mice *vs* controls in heart (x2.2), lung (x2.2), aorta (x2.1), brain (x2.0), spleen (x1.8), muscle (x1.7), liver (x1.6), skin (x1.5), kidney (x1.5), bone (x1.5). Blood urea concentration was positively correlated with Hcit content in muscle, lung, brain, spleen, heart, kidney, liver ($0.66 < r^2 < 0.91$). Hcit was increased in purified collagen from skin and tail tendons in CRF mice *vs* controls (x2.1 and x1.7, respectively) with a positive correlation to blood urea concentration (r^2=0.42 and 0.43).

Conclusions: These results indicate that carbamylated proteins in CRF increase in plasma and accumulate in tissues. The accumulation of these functionally and structurally altered proteins may contribute to the extra-renal consequences and progression of CRF.

SA-PO2805

Electroacupuncture and Moxibustion Hinder the Progression of Renal Disease by Modulating Systemic and Renal Renin-Angiotensin System (RAS) Josne Carla Paterno, Dulce Elena Casarini, Fernanda Fernandes Barrinha, Zaira Palomino Jara, Nestor Schor, Anaflávia De Oliveira Freire, Vicente de Paulo Castro Teixeira. *Medicine, UNIFESP, Sao Paulo, Brazil.*

Background: Systemic and renal RAS are pivotal for the development and maintenance of renal disease. Traditional Chinese Medicine (TCM) is increasingly recognized as an effective therapy in several fields of medicine. Among its therapeutic strategies are eletroacupuncture (EA) and moxibustion (MO). We investigate the effects of EA and MO on RAS in an experimental model of hypertensive and progressive renal disease (PRD).

Methods: Male wistar rats were submitted to 5/6 nephrectomy (5/6 nx) and studied along eight weeks. There were three groups: 5/6 nx (NX), 5/6 nx and EA-MO session in sham-points(NX-AS); and 5/6 nx and EA-MO session in three real acupuncture points (NX-AM). We evaluated 24h-proteinuria, tail-cuff blood pressure (TBP), mean arterial blood pressure (MAP), plasma and renal Ang I, Ang II and Ang^{1-7} and plasma renin activity.

Results:

Biochemical and Blood Pressure Studies

Parameters	NX	NX-AS	NX-AM
24h-proteinuria (mg/24h) initial	12.3 ± 3.1	11.9 ± 4.4	13.8 ± 3.7
24h-proteinuria (mg/24h) final	187.2 ± 25.1	179.5 ± 46.8	68.4 ± 15.1*
TBP (mmHg)	188.7 ± 15.2	176.7 ± 15.2	127.4 ± 9.4*
MAP (mmHg)	190.3 ± 12.8	182.7 ± 14.8	125.3 ± 19.8*
Plasma Ang I (ng/mL)	50.4 ± 13.5 Ψ	24.9 ± 6.6	88.1 ± 21.6 #
Plasma Ang II (ng/mL)	58.7 ± 19.9 Ψ	22.5 ± 6.2	32.3 ± 9.1 #
Plasma Ang 1-7 (ng/mL)	4.2 ± 2	5.9 ± 1.3	15.8 ± 7.2*
Renal Ang I (ng/g)	26.6 ± 9.2	20.1 ± 5.9	21.4 ± 4.7
Renal Ang II (ng/g)	8.8 ± 4.1 Ψ	19.1 ± 5.4	14.2 ± 4.7
Renal Ang 1-7 (ng/g) (ng/g)	12.4 ± 3.2	7.9 ± 2.1	43.3 ± 9.4*
Plasma Renin Activity (pmol/h)	22.9 ± 7.2	40.1 ± 0.9	29.8 ± 4.6*

(p=<0,05) vs NX and NX-AS; # (p=<0,05) vs NX-AS; Ψ(p=<0,05) vs NX-AS and NX-AM

Conclusions: The acupuncuture-treated group presented significant improvement in all measured functional parameters. EA and MO modulated RAS leading to higher production of systemic and renal Ang^{1-7}. Since A^{1-7} is protective against endothelial dysfunction and has vasodilatory and antifibrotic effects, our findings suggest that it could contribute to the improvement of the PDR in this model.

SA-PO2806

Antioxidant Inflammation Modulators (AIMs) Increase Glucose Metabolism in Muscle Cells Rhesa D. Stidham,[1] Thomas Palaia,[2] Ron Bumeister,[1] Deborah A. Ferguson,[1] Christian Wigley,[1] Louis Ragolia.[2] *[1]Reata Pharmaceuticals, Inc., Irving, TX; [2]Winthrop University Hospital, Mineola, NY.*

Background: Oxidative stress induced by chronic hyperglycemia is involved in the development of CKD and insulin resistance. The Antioxidant Inflammation Modulator (AIM) drug class potently induces Nrf2, a regulator of many antioxidant and cytoprotective genes.

Bardoxolone methyl is an AIM that recently completed a 52-week randomized, placebo-controlled trial for treatment of chronic kidney disease (CKD) in type 2 diabetics. In this trial, 54% of bardoxolone methyl-treated patients experienced muscle spasms, which were most frequent during the first two months of treatment and generally mild to moderate in severity. Muscle spasms were not associated with markers of muscle injury and improved while on drug. Similar muscle spasms have been reported with insulin treatment in diabetics, suggesting an association with muscle glucose metabolism.

Methods: To test whether a similar mechanism occurs in response to AIMs, we investigated their effect on glucose metabolism in cultured skeletal muscle cells. Uptake of 2-deoxyglucose (2-DG) and GLUT4 translocation to the plasma membrane were monitored in differentiated L6 muscle cells treated with RTA 405, a bardoxolone methyl analog. In differentiated C2C12 muscle cells, levels of the glycolytic products pyruvate and lactate were measured in response to both bardoxolone methyl and RTA 405 using biochemical assays. The extracellular acidification rate (ECAR) was also measured in response to RTA 405.

Results: RTA 405 increased 2-DG uptake in a dose-dependent manner. This effect correlated with translocation of GLUT4 to the plasma membrane. Pyruvate and lactate concentrations also increased in a dose-dependent manner following treatment with both bardoxolone methyl and RTA 405. RTA 405 also increased the extracellular acidification rate, further suggesting elevated glycolytic flux.

Conclusions: Taken together, these observations are consistent with treatment-induced increases in muscle glucose uptake and anaerobic glycolysis, which could result in enhanced acidification and correlate with muscle spasms, similar to that observed transiently following bouts of extreme exercise.

Progenitor Cell Secretory Products Exert Additive Renoprotective Effects When Combined with ACE Inhibitors in Experimental CKD Darren A. Yuen, Yanling Zhang, Kim Connelly, Andrew Advani, Richard E. Gilbert. *St. Michael's Hospital, Toronto, ON, Canada.*

Background: Bone marrow-derived early outgrowth cells (EOCs) and their secreted factors markedly attenuate the functional and structural manifestations of experimental CKD. However, with blockade of the renin-angiotensin system (RAS) as established therapy in progressive kidney disease, any new therapy would need to show incremental efficacy. Accordingly, we tested whether administration of EOC-derived factors provides additive renoprotective effects when used in combination with RAS blockade for the treatment of late-stage CKD.

Methods: Cell free conditioned medium (CFCM) was generated by incubating F344 rat EOCs with serum-free EBM-2 medium to collect their secreted factor(s). Subtotally nephrectomized (SNX) F344 rats were randomized at a late stage of disease (8 wks post-SNX) to receive enalapril 0.5 mg/L in drinking water or vehicle. 4 wks later, enalapril-treated rats were randomized to receive thrice weekly iv injections of CFCM or EBM-2 for 2 wks on top of continued enalapril administration. Three groups were thus studied: (1) No Therapy, (2) Enalapril and EBM-2, and (3) Enalapril and CFCM. GFR, urinary protein, and systolic BP were assessed serially.

Results: Compared to vehicle, 4 wks of enalapril treatment lead to a slight reduction in urinary protein at 12 wks post-SNX (vehicle vs enalapril: 117 ± 30 vs 89 ± 20 mg/d). Following treatment with EBM-2, the Enalapril and EBM-2 group experienced a further rise in proteinuria and decline in GFR to levels similar to those of the 'No Therapy Group'. In contrast, the 'Enalapril and CFCM Group' demonstrated a sustained reduction in proteinuria, and a higher GFR. No differences in systolic BP were noted between treatment groups (Table 1).

	No Therapy	Enalapril and EBM-2	Enalapril and EOC CM
GFR (µL/min/g body wt)	2.4 ± 0.3	2.5 ± 0.3	3.7 ± 0.5 *
Urinary protein (mg/d)	139 ± 25	101 ± 31	59 ± 14
Systolic BP (mm Hg)	158 ± 9	152 ± 9	163 ± 7

* p < 0.05 vs No Therapy

Conclusions: These data demonstrate that EOC-derived factors exert additive renoprotective effects on top of ACE inhibitor therapy in experimental CKD, providing the rationale for clinical trials of EOC-based therapies for CKD.

Abstract Withdrawn

SA-PO2809

Repeated Treatment with Progenitor Cell Secretory Products Maintains Long-Term Renoprotection in Experimental CKD Darren A. Yuen,[1] Yanling Zhang,[1] Kim Connelly,[1] Andrew Advani,[1] Richard E. Gilbert.[1] *[1]St. Michael's Hospital, Toronto, ON, Canada; [2]Toronto, ON, Canada; [3]Toronto, ON, Canada.*

Background: Bone marrow-derived early outgrowth cells (EOCs) are thought to mediate organ protection via paracrine effects. Given the dysfunction of autologous cells from patients with CKD and the uncertainties surrounding allogeneic cells, we considered whether repeated administration of a cell-free but EOC-derived product might provide a viable alternative strategy for kidney protection.

Methods: The secretory output of EOCs was harvested by incubation with serum-free EBM-2 medium to generate cell free conditioned medium (CFCM). Subtotally nephrectomized (SNX) F344 rats were randomized 4 wks post-SNX to receive 3x weekly iv injections of CFCM or EBM-2 over 2 wks. Rats were retreated if they showed signs of recurrence, as defined by a 4-fold rise in proteinuria above initial post-treatment values. Three groups were studied, according to whether they were administered CFCM: once (Initial Therapy Group), twice (Repeated Therapy Group) or not at all (No Therapy Group). GFR, urinary protein, and systolic BP were assessed serially.

Results: Proteinuria rose progressively in the 'No Therapy Group' (1740 ± 468 mg/d) but was lower in rats initially treated with CFCM (881 ± 138 mg/d) at 10 wks post-SNX. Following CFCM retreatment at this time point, the 'Repeated Therapy Group' showed sustained improvements in renal function, whereas the 'Initial Therapy Group' experienced a fall in GFR and rise in proteinuria to levels similar to those of the 'No Therapy Group' at 14 wks post-SNX (Table 1). Systolic BP did not differ between groups.

	No Therapy	Initial Therapy	Repeated Therapy
GFR (µL/min/g body wt)	1.41 ± 0.25	1.70 ± 0.15	2.14 ± 0.20 *
Urine protein:creatinine ratio (mg/mmol)	2674 ± 602	2536 ± 471	1912 ± 311
Systolic BP (mm Hg)	178 ± 20	183 ± 10	173 ± 10

* p < 0.05 vs No Therapy

Conclusions: EOC-derived factors, whilst reno-protective, have a limited duration of action. Repeated administration of these factors was, however, able to extend the duration of efficacy. These findings suggest that while CFCM may be a viable alternative to cell infusion, the need for their repeated administration seems likely.

A Protective Role for Type 1 Angiotensin Receptors on Macrophages in Renal Fibrosis Jiandong Zhang, Johannes Stegbauer, Young-Soo Song, Thomas M. Coffman, Steven D. Crowley. *Duke University.*

Background: In current studies, we examined the actions of type 1 angiotensin (AT_1) receptors specifically on macrophages during progressive renal fibrosis in the unilateral ureteral obstruction (UUO) model.

Methods: To this end, we intercrossed mice carrying a floxed gene for the AT_{1A} receptor (*Agtr1a*$^{flox/flox}$) with mice harboring *Cre recombinase* under the control of the LysM promoter to remove AT_{1A} receptor-mediated responses from macrophages alone (*Cre*$^{+}$ *Agtr1a*$^{flox/flox}$ = MKO). Compared to *Cre*$^{-}$ *Agtr1a*$^{flox/flox}$ littermates (WT), the MKOs had a ~75% reduction in AT_{1A} receptor mRNA expression in macrophages ($p<0.0001$) but had preserved AT_{1A} expression in B and T cells, kidney, and heart (p=NS).

Results: 7 days following UUO, staining of kidneys from MKO mice showed 80% more collagen-producing myofibroblasts (9.4±0.6% vs 5.2±0.4% a-SMA+; $p<0.001$) and 64% more interstitial fibrosis than UUO WT kidneys (4.1±0.4% vs 2.5±0.2% picrosirius red; p=0.003). Moreover, at day 7 UUO, renal mRNA expressions of Col I and TGF-β1 were enhanced by 129% (p=0.02) and 40% ($p<0.04$), respectively, in MKOs compared to WTs. Macrophage infiltration was slightly greater in obstructed MKO kidneys than WTs (10.7±1.3% vs. 7.8±0.8%;$p<0.07$). Early in the course of UUO (day 3), MKO kidneys compared with WTs had increased expression of pro-inflammatory M1 macrophage markers (IL-1β +92%,$p<0.02$;TNF-α +42%;p=0.01) but similar levels of anti-inflammatory M2 macrophage markers (YM-1, IL-1R2). Moreover, peritoneal macrophages cultured from MKO mice had enhanced IL-1β and TNF-α mRNA levels (+ >100%;$p\leq0.01$ for each) but similar M2 marker levels to WT controls, suggesting that AT_1 receptors on macrophages suppress their M1 differentiation during UUO and thereby protect the kidney from injury. Consistent with this possibility, in renal tubular cells (RTCs) co-cultured with MKO macrophage supernatants, TGF-β1 and PAI-1 mRNA levels were enhanced by 106% and 156%, respectively, compared to RTCs co-cultured with WTs ($p\leq0.006$ for each).

Conclusions: We conclude that AT_1 receptors on macrophages ameliorate fibrotic CKD by limiting their polarization toward the pro-inflammatory M1 phenotype.

Human Embryonic Mesenchymal Stem Cell Derived Conditioned Medium Rescues Kidney Function in Rats with Established Chronic Kidney Disease Arianne van Koppen,[1] Jaap A. Joles,[1] Bas W.M. Van Balkom,[1] Dominique De Kleijn,[2] Marianne Christina Verhaar.[1] *[1]Nephrology&Hypertension, University Medical Center, Utrecht; [2]Experimental Cardiology, University Medical Center, Netherlands.*

Background: Chronic kidney disease (CKD) is a major health care problem. New interventions to slow CKD progression are needed. Mesenchymal stem cell (MSC) derived conditioned medium (CM) plays a protective role in acute renal failure. In a model of acute myocardial infarction, both human MSC-derived CM and exosomes effectively decreased infarct size, suggesting exosome-mediated repair. We studied functional and structural effects of human MSC-derived CM and exosomes in a rat model of established CKD.

Methods: CKD was induced by 5/6 nephrectomy (SNX) in Lewis rats and progression was accelerated with L-NNA and 6% NaCl diet. Six wk after SNX, CKD rats received 250µl conditioned medium (CM) (N=13), 250µl non-CM (NCM) (N=13), 7µg exosomes in 250µl PBS (N=8) or 250µl PBS (vehicle) (N=8) IV twice daily for 4 consecutive days. Systolic blood pressure (SBP) and 24h-proteinuria were assessed fortnightly. Six wk after treatment, glomerular filtration rate (GFR; inulin clearance) and effective renal plasma flow (RPF; PAH clearance) were determined. Renal injury and inflammation were scored. CM, NCM, exosomes and PBS were also tested *in vitro* (angiogenesis and scratch-wound closure).

Results: At 5 wk after treatment, SBP was lower in CM- compared to both NCM- and PBS-treated rats: 145±17 vs. 163±21 and 172±15 mm Hg ($P<0.05$). Proteinuria tended to decrease after CM treatment. After 6 wk, CM was functionally effective vs. both NCM and PBS: GFR: 0.43±0.08 vs. 0.34±0.09 and 0.32±0.07 ml/min/100gr ($P<0.05$) and RPF: 1.48±0.22 vs. 1.25±0.62 and 0.99±0.34 ml/min/100gr ($P<0.05$). CM treatment decreased glomerulosclerosis and tubular damage ($P<0.05$). Exosomes influenced neither kidney function nor morphological damage. Both CM and exosomes stimulated angiogenesis and wound closure vs. respective controls *in vitro*.

Conclusions: Human MSC-derived CM decreases progression of CKD and hypertension, and ameliorates morphological injury in a rat model of established CKD. In this CKD model, these beneficial effects appear not to be due to exosomes.

SA-PO2812

Role of the Transcription Factor ETS-1 in the Regulation of Pro-Inflammatory and Pro-Fibrotic Mediators in Response to Ang II Wenguang Feng,[1] Phillip H. Chumley,[1] Ping Hua,[1] Gabriel Rezonzew,[1] Edgar A. Jaimes.[1,2] *[1]Department of Medicine, University of Alabama at Birmingham, AL; [2]VA Medical Center, Birmingham, AL.*

Background: The transcription factor ETS-1 is an important mediator of growth-related responses and inflammation in different models of injury. We previously demonstrated that ETS-1 mediates macrophage infiltration, cell proliferation, mesangial expansion and oxidative stress in response to Angiotensin II (Ang II) in vivo (AJP '08, ASN '10). Herein, we tested the hypothesis that ETS-1 mediates these effects by regulating the expression of pro-inflammatory and pro-fibrotic mediators upregulated by Ang II.

Methods: C57BL/6 mice (n=6/group) were infused with vehicle (Veh), Ang II (1.4mg/kg/day SQ), Ang II and an ETS-1 dominant negative peptide (DN, 10 mg/kg/day SQ) or Ang II and an ETS-1 mutant peptide (MU 10 mg/kg/day SQ) for 4 weeks. Kidneys were saved for immunofluorescence (IF), real time PCR and western blot (WB).

Results: Ang II increased the mRNA expression of the pro-inflammatory cytokines IL-4, IL-5, IL-6 and CCL3, the growth factors TGF-β and CTGF and the NADPH oxidase NOX4 (table). DN reduced the mRNA expression of these mediators ($p<0.05$ vs Ang II), except IL-6 while MU had no effect. Ang II resulted in a 15-fold increase in TGF-β protein expression (WB), which was reduced by 49% by DN ($p<0.01$) but not by MU. Ang II also increased CTGF expression (IF): Veh: 0.7±0.25, Ang II: 560±299 ARU ($p<0.05$), which was reduced by DN: 4.7±2.8 ARU ($p<0.01$) but not by MU: 149±98.7 ARU.

Table

	TGFβ	CTGF	NOX4	IL4	IL5	CCL3	IL6
Veh	1.0±0.06	1.0±0.14	1.0±0.27	1.0±0.22	1.0±0.05	1.0±0.12	1.0±0.30
Ang II	1.5±0.23*	2.6 ±0.38*	2.4 ±0.29*	2.1±0.19*	2.0±0.16*	1.5±0.22*	2.1±0.37*
Ang II+DN	0.8±0.18#	1.7±0.26#	1.6±0.31#	0.9±0.13#	0.8±0.14#	0.6±0.15#	3.0±0.90
Ang II+MU	1.3±0.02	1.9±0.15	1.9±0.24	1.9±0.26	2.1±0.16	0.8±0.30	4.2±1.52

Data are shown as mean±SE, mRNA expression was normalized by 18s RNA. * $P<0.05$ vs control; # $P<0.05$ vs Ang II

Conclusions: Our studies demonstrate that the transcription factor ETS-1 mediates the expression of several pro-inflammatory and pro-fibrotic mediators induced by Ang II making ETS-1 a potential novel target in the treatment and prevention of end-organ injury in hypertension.

Conditioned Medium Generated from Early Outgrowth Bone Marrow Cells Reveals Renoprotective Effects in Type 2 Diabetes Yanling Zhang, Darren A. Yuen, Andrew Advani, Kim Connelly, Richard E. Gilbert. *St. Michael's Hospital, Toronto, Canada.*

Background: Our previous study shows that early outgrowth cells (EOCs) cultured from the bone marrow preserve kidney structure and function in chronic kidney disease including diabetic nephropathy. The benefits of the cells appear not to be a consequence of engraftment into the kidney, but rather systemic antioxidant and antifibrotic effects. Accordingly, we postulated that EOCs might mediate their beneficial effects by secreting soluble renoprotective factor(s). To test the hypothesis in the *in vivo* setting we conducted proof of principle studies using a cell free preparation in which the EOCs had been grown.

Methods: EOCs were grown from donor db/m mice bone marrow and conditioned medium (CM) was generated by incubating EOCs with serum-free EBM-2 culture medium. db/db mice were randomized to receive thrice weekly tail vein injections of either 10 x concentrated EOC CM or EBM-2 for 2 weeks. Outcome parameters including mesangial expansion, glomerular hypertrophy and oxidative stress were assessed 4 weeks after the first injection. The *in vitro* antioxidant activity of EOC CM was assessed by DCFDA.

Results: EOC CM demonstrated robust antioxidant activity *in vitro*, reducing the accumulation of reactive oxygen species (ROS) within NRK cells cultured in 25 mM glucose ($p< 0.05$). EBM-2 treated db/db mice developed mesangial matrix expansion and collagen type IV accumulation and increased ROS ($p<0.05$). EOC CM treatment attenuated mesangial and peritubular matrix expansion and collagen type IV accumulation, as well as ROS accumulation.

Conclusions: Our data demonstrate that EOC conditioned medium can mimic the effects of cell infusion, possibly acting via antifibrotic and antioxidant mechanisms. These findings may be translatable to offer a new cell free therapeutic strategy for diabetic nephropathy.

Chronic Nicotine Exacerbates Sub Pressor Ang II (SP-AngII) Induced Hypertension (HTN) and Renal Injury Kiran B. Chandrashekar,[1] Arnaldo F. Lopez-Ruiz,[1] Andrea P. Soljancic,[1] Ruisheng Liu,[2] Istvan Arany,[3] Luis A. Juncos.[1,2] *[1]Division of Nephrology, University of Mississippi Medical Center, Jackson, MS; [2]Physiology, University of Mississippi Medical Center, Jackson, MS; [3]Pediatrics, University of Mississippi Medical Center, Jackson, MS.*

Background: Smoking, in tandem with HTN, are strong risk factors for the development and progression of renal disease. Nicotine (Nic) is one of the main contributing factors to the deleterious effects of smoking. To evaluate the interaction between Nic and HTN in the progression of chronic kidney disease, we hypothesized that long term Nic administration exacerbates the functional and parenchymal damage induced by SP-AngII-induced HTN, a clinically relevant model of essential HTN.

Methods: To test this, male SD rats were pretreated for 12 days with Nic [12.5μg/ml; dose needed to reach a steady state cotinine (a Nic metabolite) level similar to chronic human smokers) or vehicle (saccharine-Sac2%) in drinking water. We then randomized these animals into four groups: 1) Control-Sac, 2) Nic + Sac, 3) SP-AngII (200ng/kg/min) + Sac, 4) SP-AngII + Nic + Sac. Each of these groups received either vehicle (saline) or SP-AngII by SQ osmotic minipumps, for an additional 22 days. Systolic blood pressure (SBP) was measured by tail cuff throughout the duration of the study. At the end of the protocol, laser doppler probes were used to measure outer medullary renal blood flow and the resistance (OM-RVR) was calculated. Renal function was evaluated by plasma creatinine. The kidney tissue was then harvested to evaluate injury (KIM-1), inflammation (MCP-1, TGF-β1) and apoptosis (Cytochrome-C).

Results:

	SBP mmHg	OM-RVR TPU/mmHg	Creatinine mg/dl	KIM-1 pg/μg	Cyt-C ng/μg	MCP-1 pg/mg	TGF-β1 ng/μg
Sac	110±3	4.5±0.2	0.4±0.05	58±5	8±1	523±47	13±2
Nic	111±5	4.9±0.2	0.6±0.13	253±9*	12±3	996±103*	24±2.5*
SP-AngII	164±2*†	6.6±0.3*†	1.2±0.14*†	537±76*†	26±2*†	1518±147*†	23.9±2.8*
SP-AngII+Nic	175±3*‡†	9.5±0.5*‡†	1.8±0.1*‡†	874±68*‡†	71±7*‡†	2193±207*‡†	34.5±2.1*‡†

$p< 0.05$; * vs. Sac; ‡ vs. SP-AngII; † vs. Nic

Conclusions: Nicotine initiates a pro-inflammatory and pro-fibrotic state, which consequently exacerbates SP-AngII-induced HTN, renal dysfunction and damage.

Funding: Other NIH Support - NIH DK073401

Stromal Cell-Derived Factor-1 Preserves Renal Function in Chronic Kidney Disease Li-Hao Chen,[1] Darren A. Yuen,[1] Yanling Zhang,[1] Manish M. Sood,[2] Ian W. Gibson,[2] Michael Kuliszewski,[1] Howard Leong-Poi,[1] Kim Connelly,[1] Richard E. Gilbert,[1] Andrew Advani.[1] *[1]Keenan Research Centre, St. Michael's Hospital, Toronto, ON, Canada; [2]Health Sciences Centre, University of Manitoba, Winnipeg, ON, Canada.*

Background: While the homeostatic chemokine stromal cell-derived factor-1 (SDF-1) plays an essential role in renal vascular development, its function in the adult kidney and in chronic kidney disease (CKD) is unclear. In the present study, we hypothesized that the pro-angiogenic properties of SDF-1 would serve to promote microvascular health in both the normal and chronically ischemic kidney.

Methods: SDF-1 expression was determined in human biopsies, rat kidneys and cultured cells. Antagonism and augmentation of SDF-1/CXCR4 signaling were achieved with either AMD3100 or gene transfection.

Results: While SDF-1 was expressed by podocytes, fibroblasts, collecting ducts and also corticomedullary proximal tubular cells, its cognate receptor CXCR4 was primarily restricted to endothelial cells of glomerular and peritubular capillaries. Unlike in biopsies from patients with diabetic nephropathy, SDF-1 expression was not upregulated in kidneys from individuals with CKD due to secondary focal segmental glomerulosclerosis (FSGS). Moreover, SDF-1 expression was decreased in renal fibroblasts exposed to the pro-fibrotic growth factor transforming growth factor-β and in the kidney cortices of subtotally nephrectomized (SNx) rats, a rodent model of CKD reminiscent of FSGS. The CXCR4 antagonist AMD3100, which attenuated SDF-1 induced endothelial tube formation in vitro, increased proteinuria in normal rats and accelerated renal injury in SNx animals associated with a decline in capillary growth and an increase in matrix deposition. Conversely, increasing SDF-1 activity, achieved by ultrasound-guided gene transfection using plasmid-bearing microbubbles, attenuated proteinuria progression in SNx rats.

Conclusions: Collectively, these observations indicate that SDF-1 plays a homeostatic role in the adult kidney and in the setting of progressive, proteinuric kidney disease. Therapeutic strategies that augment SDF-1 signaling represent a novel approach to slow the decline of kidney function in patients with CKD.

SA-PO2816

Blood or Urine? A Systematic Comparison of Information Content and Analytical Practicality of Different Sample Types for Targeted Metabolomics Ulrika Lundin, Klaus M. Weinberger. *Biocrates Life Sciences AG, Innsbruck, Austria.*

Background: Right now there is a controversy going on since the majority of metabolomics studies are based on either only urine or only blood fluid (serum or plasma) samples. In nephrology, urine might seem like the obvious sample type of choice, because of the metabolic activity of the kidneys and the urine being excreted would show big changes in the composition of its metabolites. We intended to do a systematic review to see which sample type is really the most informative for targeted metabolomics, particularly in nephrology.

Methods: The comparisons between sample types were done in three different studies; on db/db mice, a rodent model of hyperphagia-associated type II diabetes with little kidney damage, puromycin-induced nephrotoxicity in Sprague-Dawley rats and a clinical study on the progression of chronic kidney disease in diabetic and non-diabetic patients. Targeted metabolomics was used to quantify metabolites from plasma and urine including the classes amino acids, biogenic amines, polyamines, acylcarnitines, phosphatidylcholines, sphingomyelins, eicosanoids, bile acids and energy metabolism intermediates in the presence of isotopically labeled internal standards and determined by flow injection analysis (FIA)-

and high performance liquid chromatography (HPLC)-tandem mass spectrometry with multiple reaction monitoring (MRM) using an AB Sciex 4000 QTRAP® with electrospray ionization. Additionally, free fatty acids were quantified by GC-MS.

Results: We performed a large a number of comparisons to assess sensitivity and specificity on the datasets of urine, blood and both combined. Because of the study design of the cohorts, we could look at the data both in a nephrology and non-nephrology aspect to be unbiased and remove any organ-specific information. With discriminant analysis and receiver operating characteristics analysis we assessed the information in the different datasets and summarized the outcomes.

Conclusions: We found that that blood is much more informative than urine, and almost as good as the combined dataset, the reason probably being that there is a strict homeostatic regulation in the blood, whereas urine does not possess this property.

Reduced Klotho Expression Level in Kidney Aggravates Renal Interstitial Fibrosis Hidekazu Sugiura,[1] Takumi Yoshida,[2] Junko Kohei,[1] Shunji Shiohira,[1] Michihiro Mitobe,[1] Ken Tsuchiya,[1] Kosaku Nitta.[1] *[1]Fourth Department of Internal Medicine, Tokyo Women's Medical University, Tokyo, Japan; [2]Yoshida Medical Clinic, Tokyo, Tokyo, Japan.*

Background: Klotho is associated with the suppression of several aging phenotypes. The renal expression of the *Klotho* gene is markedly suppressed in chronic renal disease patients. Renal fibrosis is a major risk factor of chronic kidney disease (CKD). We explored the relation between renal interstitial fibrosis and Klotho in mice and cultured renal cell lines. We previously reported The plasma urea nitrogen and phosphate concentrations were significantly elevated, the renal a-SMA level was significantly upregulated, and renal interstitial fibrosis was severer in Klotho-deficient mice (*kl/kl* mice). In addition, TGF-β1 reduced Klotho expression in a time-dependent manner in epithelial cells.

Methods: Expression of fibrotic factors was by Real time PCR, Western blotting, ELISA and immunohistochemical staining. To determine whether reduction in Klotho expression predisposes the kidney to renal fibrosis, we introduced renal fibrosis to *kl/+* mice by unilateral ureteral obstruction (UUO) and compared them with wild-type mice.

Results: The expression levels of a-SMA (1.6-fold, $p<0.05$), fibronectin (1.6-fold, $p<0.05$) and TGF-β1(1.4-fold, $p<0.05$) were higher and the renal interstitial fibrosis was severer in the *kl/+* mice than those in the wild-type mice. In cultured renal fibroblast cells (NRK49F cells), expression levels of a-SMA and PAI1 (0.5-fold, $p<0.05$) were significantly suppressed by addition of recombinant Klotho protein to the medium. The expressions of a-SMA and PAI-1 were significantly increased in NRK49F cells cultured in the presence of TGF-β1 for 24 hours, although these elevations in the a-SMA and PAI-1 levels (0.6-fold, $p<0.05$) were significantly blunted in NRK49F cells cultured in the presence of TGF-β1 with recombinant Klotho protein. These effects were also suppressed by a TGF-β1 receptor inhibitor (ALK5 inhibitor).

Conclusions: Klotho is downregulated by the progression of renal fibrosis and chronic kidney disease via TGF-β1. Reduced Klotho expression levels in the kidney aggravate renal interstitial fibrosis via TGF-β1.

SA-PO2818

Xeno-Klotho Administration Retards the Progression of Adriamycin Nephropathy Tsuneo Takenaka, Tsutomu Inoue, Hirokazu Okada, Yoichi Ohno, Takashi Miyazaki, Hiromichi Suzuki. *Saitama Medical University.*

Background: Recent data reveal that elevating free klotho in proximal tubular lumen reduces phosphate reuptake, and suggest that the gain-of-function in klotho gene slows the progression of chronic kidney diseases, at least partly through the inhibition of TGF signaling and fibrosis.

Methods: In the present study, effects of exogenous administration of recombinant human klotho protein on renal injury was assessed in two groups of rats (n=6 for each group); male Wister rats treated with intravenous adriamycin (5 mg/Kg) to induce focal segmental glomerulosclerosis through tail vein as a control (C), those treated with recombinant human klotho (10 μg/Kg/day) by osmotic pump (K). Saline was used as a vehicle. Four weeks later, rats were killed, and harvested kidney for analysis.

Results: Chronic administration of klotho increased serum free klotho (870±65 vs. 186±16 pg/ml, $p<0.01$). Albuminuria was lower in K (5.3±1.2 mg/day) than C group (15.2±3.1 mg/day, $p<0.01$). Creatinine clearance tended to be lower in C (1.6±0.2 ml/min) than K group (2.0±0.3 ml/min, $p=0.07$). Serum calcium was similar (9.9±0.2 vs. 10.0±0.2 mg/dl), but phosphate was reduced in K group (6.4±0.2 vs. 7.6±0.3 mg/dl, $p<0.05$). Phosphate excretion was also increased in K group (9.0±0.7 mg/day), compared to C group (5.8±0.5 mg/day, $p<0.05$). Although serum levels of fibroblast growth factor (FGF) 23 and parathyroid hormone were similar between two groups, 1,25-dihydroxy-vitamin D was lower in K than C group (164±9 vs. 201±10 pg/ml, $p<0.05$). However, western blotting demonstrated that exogenous klotho infusion failed to alter both renal klotho and 1-alpha-hydroxylase expression.

Conclusions: The present data demonstrate that adding-on circulating free klotho suppresses the production of 1,25-dihydroxy-vitamin D independently of parathyroid hormone, FGF23 and renal 1-alpha-hydroxylase expression. Our findings indicate that an elevated circulating klotho declines serum phosphate associated with increased phosphate excretion without affecting renal klotho expression. The current results have provided the evidence that free klotho reduces albumin excretion, showing renoprotective actions in adriamycin nephropathy.

Ronacaleret Retards Renal Injury with Preserving Klotho in 5/6-Nephrectomized Rats Tsuneo Takenaka, Tsutomu Inoue, Hirokazu Okada, Takashi Miyazaki, Hiromichi Suzuki. *Saitama Medical University, Iruma, Saitama, Japan.*

Background: We have previously reported that vitamin D increases renal expression of klotho in rats with normal kidney function, and that calcimimetics reduces it.

Methods: In the present study, effects of ronacaleret, a calcilytic agent, on renal injury was assessed in four groups of rats (n=6-10 for each group); 5/6-nephrectomized (uninephrectomy with ligation of 2 renal artery branches in contralateral kidney) Wister rats as a control (C), those treated with ronacaleret (150 mg/kg/day) (R), rats treated with calcitriol (30 ng/kg/day) (V), and rats treated with both ronacalcet and calcitriol (R+V). Three months later, rats were killed with over-anesthesia, and harvested remnant kidney for analysis.

Results: Albuminuria was lower in R (4.2±0.6 mg/day), V (3.8±0.5 mg/day) and R+V (4.2±0.6 mg/day) than C group (13.2±1.4 mg/day, $p<0.05$). Creatinine clearance (Ccr) was elevated in R (2.2±0.2 ml/min) and V (1.9±0.2 ml/min) than C group (1.5±0.2 ml/min, $p<0.05$). Serum calcium was increased in R+V (10.1±0.1 mg/dl) than C group (9.4±0.1mg/dl, $p<0.05$). Fractional phosphate excretion was increased in R (13±2 %), V (13±2 %) and R+V (16±2 %) compared to C group (7±1 %, $p<0.05$), and serum phosphate was reduced in R group (6.1±0.3 mg/dl vs 7.8±0.3 mg/dl (C)). FGF23 was lower in R (371±18 pg/ml) and higher in V (675±58 pg/ml) and R+V (671±54 pg/ml) than C group (500±33 pg/ml, $p<0.05$). However, parathyroid hormone did not significantly differ among 4 groups. RT-PCR and western blot analyses revealed that compared to C ($p<0.05$), renal klotho expression was elevated in R (1.8-2.1 fold) and V (1.7-2.0 fold) groups.

Conclusions: The present data indicate that ronacaleret preserved klotho expression and renal function with reduction in serum phosphate and albuminuria in 5/6-nephroctomized rats. Our findings demonstrate that vitamin D prevented declines in klotho expression and renal function, suppressing albuminuria. The current results provide the evidence that hypercalcemia decreases klotho expression, participating in the progression of renal dysfunction.

SA-PO2820

Renal Nrf2 Expression Is Decreased in Klotho Deficient Mouse Tetsuro Kusaba, Eiko Matsuoka, Yasukiyo Mori. *Department of Nephrology, Kyoto Prefectural University of Medicine, Kyoto, Japan.*

Background: Klotho is anti-aging humoral factor and abundantly expressed in the kidney and has an antioxidative effect. Nuclear factor erythroid-2-related factor (Nrf2) is a cytoplasmically localized transcription factor and also has an antioxidative effect. Nrf2 translocates to the nucleus in response to oxidative stress and regulates the expression of genes encoding antioxidant enzymes. Although both Klotho and Nrf2 have an antioxidative effect on kidney, the relationship between these molecules has not been well understood previously.

Methods: Tissue extract of kidney was obtained from Klotho deficient and wild-type mice and nuclear Nrf2 expression was assessed by Western blot analysis. The tubular epithelial cells were primarily cultured from these mice and assessed the Nrf2 expression. 300mM of H_2O_2 was added to these cells for 3hours and nuclear Nrf2 translocation was assessed by the immunofluorescence analysis. For investigating the association between Nrf2 and Klotho protein further, immunoprecipitation between these molecules were performed.

Results: Nrf2 expression in tissue lysates of kidney is significantly decreased in klotho deficient mouse compared with wild type mouse ($p < 0.05$). Nrf2 expression in primarily cultured epithelial cells is also significantly decreased in klotho deficient mouse. Nuclear Nrf2 translocation after H_2O_2 stimulation was remarkably decreased in primarily cultured epithelial cells from klotho deficient mouse compared with wild type mouse. In western blot analysis, the H_2O_2 stimulation did not affect the Nrf2 expression in klotho deficient mouse, whereas increased in those from wild type mouse. However, immunoprecipitation analysis revealed that klotho protein did not bind to Nrf2.

Conclusions: Our data suggested that anti-oxidative effect of klotho was partially and indirectly through Nrf2 expression and its nuclear translocation.

SA-PO2821

Serum Klotho Levels Are Associated with Kidney Function but Not with Calcium Phosphorus Metabolism in CKD Eric Seibert, Daniel Radler, Christof Ulrich, Sylvia Hanika, Roman Fiedler, Matthias Girndt. *Department of Internal Medicine II, Martin-Luther-University Halle, Halle, Germany.*

Background: Klotho protein which is expressed on renal distal tubular cells is an essential co-receptor for FGF-23 and a key regulator of phosphate excretion. Its disturbed expression in mice leads to a syndrome resembling premature human aging. Its secreted form modulates expression of ion-channels and the sensitivity of growth factors which may be key factors for its anti-aging properties. In chronic kidney disease (CKD), impaired renal klotho expression has been demonstrated by Western blot and immunohistochemic analyses. Therefore, soluble klotho is expected to be reduced as well and is likely to contribute to accelerated aging.

Methods: We performed a cross-sectional study of soluble klotho serum levels using a recently established ELISA in 156 subjects with a kidney function ranging from normal to end-stage renal disease.

Results: Klotho levels were significantly lower in HD patients than in healthy adults and those with moderate CKD (368.3±99.0 pg/ml vs. 468.1±205.8, p<0.01 and 368.3±99.0 pg/ml vs. 498.7±221.9, p<0.01). There was a significant correlation with eGFR (p=0.0005, r=0.31). In end stage renal disease there was a weak but significant correlation with bone alkaline phosphatase and 25-OH-Vitamin D levels. Correlations to age, calcium or phosphorus levels could not be established. Klotho levels were significantly higher in females (463.0±202.6 pg/ml vs. 387.6±132.0 pg/ml, p=0.02), and acute kidney injury (567.6±294.4 pg/ml, vs. 403.5±152.5 pg/ml, p<0,01).±

Conclusions: Serum klotho levels are associated with kidney function. In CKD, impaired klotho levels may contribute to accelerated aging and may be a measure of viable renal tubular cells mass.

Induction of Phosphaturia Accelerates Chronic Kidney Diseases in Mice

Chung-Yi Cheng,[1,2] Kazuhiro Shiizaki,[1] Johanne V. Pastor,[1] Lei Wang,[1] Joel Schwartz-Moretti,[1] Addie Dickson,[1] Ming Chang Hu,[1] Orson W. Moe,[1] Makoto Kuroo.[1] *[1]Pathology, University of Texas Southwestern Medical Center at Dallas, TX; [2]Internal Medicine, Taipei Medical University-Wan Fang Hospital, Taipei, Taiwan.*

Background: Lowering serum phosphate(Pi) levels by Pi binders improves clinical outcome of chronic kidney disease (CKD). Because serum Pi levels can be lowered also by promoting phosphaturia, we tested if induction of phosphaturia would delay CKD progression in mice. Klotho is expressed in the kidney where it functions as a co-receptor for fibroblast growth factor-23 (FGF23) and plays a critical role in Pi metabolism. The extracellular domain of Klotho is subject to ectodomain shedding and secreted into blood and urine. Secreted Klotho has phosphaturic activity independent of FGF23. Klotho injection ameliorates acute kidney injury (AKI), and transgenic overexpression of Klotho alleviates soft tissue calcification in CKD. This study is to test whether Klotho injection alleviates CKD in mice.

Methods: Eight weeks old mice (129S1/SvImJ males) had received uninephrectomy plus ischemic reperfusion injury in contralateral kidney followed by feeding with 2% Pi diet. Mice were treated with secreted Klotho (0.02mg/kg, i.p, every other day) or vehicle for 12 weeks.

Results: Mice given recombinant secreted Klotho exhibited more prominent renal damage than vehicle-treated mice in functional (higher serum creatinine (Cr) and lower Cr clearance), histological (more severe nephrocalcinosis, renal interstitial fibrosis), and molecular parameters (higher levels of TGF-β1, phosphorylated Smad2/3, α-smooth muscle actin, collagen-1 and p21). Previous animal studies have furnished a model that kidney damage induced by dietary Pi overload correlates better with Pi excretion per nephron than blood Pi. It is conceivable that Klotho injection further increases urinary Pi excretion that is already high due to dietary Pi overload; with increased CaPi crystal formation in the tubules and nephrocalcinosis.

Conclusions: Thus, we propose that a delicate balance between the beneficial effects of phosphaturia v.s. overloading kidney with phosphate should be considered in Pi-lowering therapies.

Myocardial Expression of Fibroblast Growth Factor Receptor-1 and Renin-Angiotensin System Genes in Hypertrophic Hearts of Uremic Rats

Michael Freundlich,[1] Yan Chun Li,[2] Jose R. Weisinger,[3] Yasmir Quiroz,[4] Janaury Bravo,[4] Bernardo Rodriguez-Iturbe.[4] *[1]Pediatric Nephrology, University of Miami, FL; [2]Medicine, University of Chicago, IL; [3]Nephrology, University of Miami, FL; [4]Renal Service and Hospital Universitario, Universidad del Zulia, Maracaibo, Venezuela.*

Background: Cardiac hypertrophy (CH), common in CKD, associates with increased mortality. CH causes are multifactorial including disturbances of the renin-angiotensin system (RAS) and fibroblast-growth factor (FGF)-23. However, expression of RAS components in myocardium (M) of uremic animals has not been studied; furthermore, the coreceptor Klotho, essential for FGF-23 action, is not expressed in M. Since the vitamin D analog paricalcitol (Pc) improves uremic CH, suppresses C-RAS in non-uremic animals and interacts with FGF23 in other tissues, we studied Pc effects on the M expression of these genes in uremic rats.

Methods: CH and left ventricular (LV) gene expression of RAS components and the FGF receptor 1 (r1) were evaluated in 5/6 nephrectomized rats treated 8 weeks with Pc 0.3 μg/kg 3x/week IP or enalapril (E) 5 mg/kg/day enterally vs. untreated uremic (U) and sham-operated animals (S).

Results: PC and E improved hypertension (U 204±18 mm Hg; Pc 156±8; E 144±9.5; p<0.0001) and renal insufficiency (creatinine, U 1.67±0.7 mg/dl; Pc 0.76±0.11; E 0.76±0.06; p<0.002). Cardiac weight↑in U was similarly↓by Pc and E (p<0.02). U↑mRNA expression of LV angiotensinogen by 30-fold (p<0.01 vs.S), attenuated by Pc and E (p<0.006); AT1R↑2.4-fold in U, was suppressed markedly by E and unmodified in Pc. ACE mRNA was similar in all groups. Renin mRNA expression and brain natriuretic peptide (BNP) protein in LV↑in U and suppressed similarly by Pc and E (p<0.05). FGFr1 mRNA was↑6-fold in U, and while Pc↓only mildly this gene, E↓values similar to S .

Conclusions: 1) CH is associated with increased LV renin and angiotensinogen gene expression and M upregulation of FGFr1 mRNA. 2) M renin mRNA and BNP were similarly suppressed by Pc and E. Evaluation of direct effects of PC and E, independent of those related to improvement of uremia and hypertension in this model, requires further studies.

Funding: Clinical Revenue Support, Government Support - Non-U.S.

SA-PO2824

Serum Levels of Soluble Secreted αKlotho Are Modulated by Renal Function, Age, FGF23, and May Play a Key Role in CKD-MBD in Chronic Kidney Disease Patients

Yoshiko Shimamura,[1] Koji Ogata,[1] Kosuke Inoue,[1] Toru Kagawa,[1] Masayuki Ishihara,[1] Toshihiro Takao,[1] Kenji Yuasa,[2] Yoshio Terada.[1] *[1]Endcrinology, Metabolism and Nephrology, Kochi Medical School, Nankoku, Japan; [2]Kochi-Takasu-Hospital, Kochi, Jordan.*

Background: αKlotho was first identified as an aging gene and was later shown to be a regulator of phosphate metabolism. Fibroblast growth factor 23 (FGF23) is the important regulator of phosphate. FGF23 was reported to markedly increase in patients of CKD. αKlotho protein is a co-receptor specific for FGF23. But serum level of soluble αKlotho in CKD patients is still undermined, especially in relationship to FGF23, creatinine, and phosphate levels. This study was designed to investigate whether serum αKlotho are modulated by renal function, age, FGF23, and study a potential role in CKD-MBD in CKD. This study is the first report on the utility of serum αKlotho in human CKD.

Methods: We made a continuously survey of CKD patient characteristics and outcomes in Kochi prefecture (Western Japan). Patients of CKD (N=101) were enrolled. Serum sample were collected and measured FGF23 and soluble αKlotho by using an ELISA kits. In addition, serum creatinine, hemoglobin, albumin, Ca and Pi were measured. This study was approved by Kochi University review board. All patients provided written informed consent.

Results: FGF23 correlated positively to age(P<0.01:r=0.296) and creatinine (P<0.0001:r=0.861)and negatively to hemoglobin(P<0.01:r=-0.340) and albumin(P<0.0001:r=0.861). FGF23 was clearly associated with CKD stage. αKlotho negatively correlated to age(P<0.001:r=-0.368)and positively correlated to hemoglobin (P<0.05:r=0.246). αKlotho had a tendency to associate negatively with serum creatinine. Interestingly, αKlotho levels significantly decreased early phase of CKD (stage 2) as compared with stage1. In addition, αKlotho dramatically decrease according to the progression of CKD, especially stage 4 and 5. However, αKlotho did not show statistically significant correlation with Pi, Ca and FGF23.

Conclusions: Our data indicate that serum αKlotho could be a new predictive marker in progression of CKD, especially in early stage, and αKlotho and FGF23 may play a key role in pathogenesis of CKD-MBD.

SA-PO2825

Atheromatous Disease and Resistance to the Phosphaturic Action of FGF23 Contribute to the Severiry of Vascular Calcification in Non-Dialyzed Kidney Disease Patients

Lourdes Craver,[1] Montserrat Martinez-Alonso,[2] Adriana S. Dusso,[3] Jose M. Valdivielso,[3] Elvira Fernandez.[1] *[1]Nephrology Dept., Arnau Vilanova Hospital, Lleida, Spain; [2]Estadistic Dept., IRB Lleida, Lleida, Spain; [3]Experimental Nephrology, IRB Lleida, Lleida, Spain.*

Background: Vascular calcification (VC) is an important contributor to the high mortality rates in chronic kidney disease (CKD), and hyperphosphatemia is a well recognized cause of enhanced VC in these patients. However, a recent study in hemodialysis patients has shown that not only hyperphosphatemia, but also atheromatous disease contributes to carotid calcification

Methods: This cross-sectional study analyzes the impact of abnormalities in phosphate (P) metabolism and atheromatous disease on abdominal aortic calcification (AAC) measured by the Kauppila index (KI) in 186 patients CKD stages 3, 4, and non–dialyzed stage 5.

Results: In multivariate analyses, both the presence of AAC and its severity (Moderate: KI≤5; Severe: KI>5) associated positively with age, a higher stage of CKD, and more significantly, with atheromatosis disease (higher carotid intima-media thickness and presence of carotid plaques), and negatively with female sex. Intriguingly, no association was found between either AAC or KI values with well recognized risk factors from abnormal mineral metabolism (serum levels of Ca, P, PTH, soluble a-Klotho, 25(OH)D and 1,25(OH)2D). Furthermore, serum FGF23 associated positively only with the severity but not with the presence of AAC, while the fractional excretion of P (FEP) associated negatively with both. The correlation between FEP and serum FGF23 showed that the highest FGF23 levels associated with KI > 5 only in a small group of patients in which FEP was far below the expected FEP for a given serum FGF23 in both non calcified and moderately calcified patients.

Conclusions: Atheromatous disease and an impaired phosphaturic response to high serum FGF23 contribute to the severity of VC at CKD stages 3, 4 and non-dialyzed stage 5.

SA-PO2826

Impaired Angiogenesis and Rarefied Peritbular Capillaries Participated in Renal Tubularintersitial Fibrosis in Experimental Chronic Renal Ischemic Rats Jiaming Zhu, Yi Fang, Xiaoqiang Ding. *Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China.*

Background: Chronic tissue hypoxia is regarded as a contributing factor in the progression of renal failure, impaired angiogenesis and loss of peritubular capillaries in the late phase of renal diseases gives evidence of renal hypoxia.

Methods: Unilateral clamping of the left renal artery to induce chronic ischemia of the kidney tissue was utilized in this study. The experimental rats and respective sham-operated controls were sacrificed at week 1 and 12, and the renal tissues were harvested for histological study.

Results: The results showed that the blood pressure and serum creatinine of the experimental rats was elevated at week 6 and keep a high level in late stages. The left renal tissue with artery stenosis showed proximal tubuler epithelium vacuole and granulation degeneration with inflammatory cells infiltration in tubulerinterstitium in week 1 group. Hypoxyprobe™-1 labelling showed significant staining in out medulla and cortex, while the hypoxic probe was only weak stained in outer medulla in the control rats. Interestingly, VEGF and both of its receptors Flk and Flt were markedly upregulated in one week ischemic renal cortex compared with the control($P<0.01$. But in advanced stage (week 12), the chronic ischemic renal tissue exhibited atrophic tubular epithelium, widened tubularinterstitium with obvious collagen I expresssion. The Hypoxyprobe™-1 labelling showed limited staining only in medulla while negative staining in cortex. Coincidence with Hypoxyprobe™-1, VEGF and its receptors staining in cortex weakened significantly compared with that of early stage(week 1)($P<0.01$). Further investigation revealed that the endothelial cell marker CD31 was markedly reduced and showed a significant loss of peritubular capillaries in cortex area, and also decreased endothelial progenitor cell marker CD34 expression with lack of vascular repair compared with that of One week group.

Conclusions: We concluded persistent ischemia would finally destroy the ability of angiogenesis in renal tissues, which accelerated ischemia extent of the kidney, led to interstitial fibrosis and attributed to renal failure in advanced stages.

SA-PO2827

Paradoxical Pro-Growth Gene Expression Patterns in Rat Kidney Endothelial Cells Characterized by Limited Growth Potential David P. Basile,[1] Pingyu Zeng,[2] Jessica Friedrich.[1] *[1]Cellular & Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN; [2]Pediatrics, Indiana University School of Medicine, Indianapolis, IN.*

Background: The renal vasculature is characterized by limited regenerative potential following both acute and chronic injuries, and peritubular capillary loss is a consistent feature in the setting of interstitial fibrosis leading to worsened hypoxia. The current study sought to investigate the growth properties of rat kidney endothelial cells and determine factors that may lead to their impaired regenerative capacity.

Methods: Rat kidney endothelial cells (KEC) were isolated by CD31 immuno-isolation techniques and maintained in long-term cultures.

Results: When compared with endothelial cells isolated from the pulmonary microvasculature (i.e., PMVEC), KECs did not respond to VEGF, had significantly slower growth rates and limited clonogenic capacity. The expression of 84 VEGF signaling pathway genes was compared in KEC and PMVEC by quantitative PCR arrays. Despite their low growth rates, KECs showed significant and dramatic enhancement in 18 VEGF pathway genes ($\log_2>2$ vs PMVEC), including Flt-1 (~50 fold), FLK-1/KDR (~60 fold) and NOS-3 (~200 fold). In contrast, only 5 genes were expressed at sigificantly lower levels in KEC vs. PMVEC, and these included VEGF-A and C. We further screened the expression of 384 rat microRNAs and compared KECs and PMVECs. The vast majority of miRNAs were either undetectable or showed no difference between KECs and PMVECs; However, 4 miRNAs were significantly greater in KECs including the pro-angiogenic miR126, which was expressed at ~ 10,000 fold greater levels in KEC vs. PMVEC. Moreover, the pro-apoptotic miR24 was highly expressed in PMVECs and was 3-fold lower KECs.

Conclusions: Taken together, rat KECs display a prominent enhancement of genes typically associated with endothelial proliferation and angiogenesis, despite their low growth rates, suggesting that unidentified factors may impose strong negative growth regulation in these cells.

SA-PO2828

Reduced γ-Carboxylase Activity in Uremia- A Possible Mechanism of Uremic Vascular Calcification Nadine Kaesler,[1] Thomas Schettgen,[2] Elke Magdeleyns,[3] Vincent Brandenburg,[4] Cees Vermeer,[3] Jurgen Floege,[1] Thilo Krueger.[1] *[1]Nephrology and Clinical Immunology, University Clinic of the RWTH Aachen, Aachen, Germany; [2]Institute and Outpatient Clinic of Occupational Medicine, University Clinic of the RWTH Aachen, Aachen, Germany; [3]VitaK BV, University Maastricht, Maastricht, Netherlands; [4]Cardiology, Pneumology, Angiology and Internal Medicine Intensive Care, University Clinic of the RWTH Aachen, Aachen, Germany.*

Background: Vascular Calcification (VC) is present in chronic kidney diseases. This can be inhibited by matrix gla protein (MGP), which achieves full activity by carboxylation by the vitamin K dependent γ-carboxylase. Its inhibition by warfarin leads to augmented vascular calcification. The vitamin K regeneration cycle is formed by DT-diaphorase, VKOR and γ-carboxylase. Vitamin K deficiency is present in dialysis patients and so we investigated whether uremia reduces enzyme activities.

Methods: 10 Wistar rats in each group were fed a) standard diet b) 100mg/kg vitamin K2 c) 0,75% adenine or d) 0,75% adenine + 100mg/kg vitamin K2. Finally, serum parameters, extent of VC, uncarboxylated (uc)MGP and in kidney an liver activities of diaphorase, VKOR and γ-carboxylase were measured.

Results: After 4 weeks of treatment, creatinine, urea (7-fold) and phosphate were higher in adenine groups (c+d) than in controls (a+b). Calcium was unchanged. Aortic calcium content was higher in c+d than in controls. Systolic blood pressure was unaltered in all groups. DT-diaphorase activity was significantly higher (70, 72%) in groups c+d. VKOR activity was unchanged; γ-Carboxylase was more active in groups c+d, significantly. This also led to significant higher levels of ucMGP (12.2 vs 8.6, 7.4 μM).

Conclusions: Experimental uremia inhibits the key enzyme of the vitamin K dependent carboxylation, γ-Carboxylase. This is accompanied by higher levels of ucMGP and calcium deposition in the aorta. Even though there is reduced enzyme activity, vascular calcification and ucMGP can be reduced by dietary vitamin K2 (group d). Our data identifies a new mechanism of uremic vascular calcification and supports the rationale of our vitamin K2 interventional study VitaVasK.

SA-PO2829

Low-Dose Erythropoietin Increases Superoxide Production in Normal Rat Aorta and Endothelial Cells Chieko Ihoriya, Minoru Satoh, Hiroyuki Kadoya, Yuko Nishi, Kengo Kidokoro, Hajime Nagasu, Naruya Tomita, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: High-dose erythropoietin (EPO) affords vascular and tissue protection with non-hematopoietic effects, but it is still controversial whether the therapeutic dosage of EPO is beneficial for cardiovascular protection. High-dose EPO has been reported to increase nitric oxide (NO) production via activation of the phosphatidylinositol-3-kinase/Akt pathway. However, the clinical dosage of EPO sometimes leads to an increase in blood pressure in humans. This study was designed to investigate whether the therapeutic dosage of EPO accentuates oxidative stress and modulate endothelial function.

Methods: In in vivo experiments, normal male Sprague-Dawley (SD) rats were treated with either EPO (20 IU/kg/week, subcutaneously) 3 times per week or darbepoietin (D-EPO; 0.1 μg/kg/week, subcutaneously) 1 time per week for 4 weeks. The endothelial-dependent vasodilatory response, NADPH oxidase activity, and gene expression of ICAM-1 and TNF-αwere assessed. To explore whether EPO is involved in superoxide production, in in vitro experiments, we stimulated human umbilical vein endothelial cells with EPO and assessed NADPH oxidase activity and NO production.

Results: The used doses of EPO and D-EPO had no effect on hemoglobin level. In the normal SD rats, the acetylcholine-dependent vasodilatory response decreased significantly in both the EPO and D-EPO treatment groups. NADPH oxidase activity as well as aortic gene expression of ICAM-1 and TNF-αincreased significantly, and to the same extent, in both groups.We confirmed EPO-mediated superoxide production in vitro. EPO increased NO levels as previously reported. However, because of parallel superoxide production, NO was consumed during the production of peroxynitrite associated with activation of NADPH oxidase.

Conclusions: Administration of EPO and D-EPO increased oxidative stress and impaired endothelial function in normal rats and in human endothelial cells.

SA-PO2830

Hyperphosphataemia Impairs Relaxation in Resistance Vessels; an Effect Which Is Partially Reversed in the Presence of a Phosphodiesterase Inhibitor Kathryn K. Stevens, Elisabeth C. Beattie, William A. Sands, Christian Delles, Alan G. Jardine. *Renal Research Group, ICAMS, University of Glasgow, United Kingdom.*

Background: The mechanism of action of phosphate as a risk factor for cardiovascular disease is unclear. This study looks at the effect of altered phosphate concentration on the function of rat resistance vessels

Methods: Resistance vessels were dissected from the mesentery of 12 week old male WKYs and incubated overnight in physiological saline solution (PSS) with normal (1.18mM) or high phosphate concentration (2.5mM). Vessels were mounted on a wire myograph. Vasoconstriction response to phenylepherine (PE) and vasorelaxation response to carbachol were measured. L-NAME was added and contractile response to PE measured again. In a separate experiment, following contraction with PE, vasorelaxation response to sodium nitroprusside (SNP) was measured. Experiments were repeated in the presence of zaprinast (phosphodiesterase 5 (PDE5) inhibitor). Concentration-response curves were constructed for each vessel for PE +/- L-NAME, carbachol and SNP.

Results: Vessels in high phosphate relax less well in response to both carbachol and SNP than those in normal phosphate PSS ($p<0.001$ and $p=0.029$). The contractile response to PE, in the absence of LNAME, between the 2 groups is similar. In normal phosphate PSS, with the addition of LNAME, a significant difference is seen in the concentration-response curve to PE ($p=0.05$). This difference is not seen in the vessels in high phosphate PSS. In the presence of zaprinest, there is improved relaxation in the vessels in high phosphate ($p=0.006$).

Conclusions: Elevated phosphate decreases endothelium dependent and independent vasorelaxation. This may be a marker of oxidative stress and endothelial dysfunction. The presence of a PDE5 inhibitor, which increases cyclic GMP, improves the relaxation response. Elevated phosphate may result in a combination of reduced production of basal nitric oxide within endothelial cells and cyclic GMP production or guanylate cyclase expression in vascular smooth muscle cells. These experiments mimic a uraemic state and may offer an explanation for elevated serum phosphate as a cardiovascular risk factor.

SA-PO2831

CD36-Na/K ATPase Signal Complex Mediates a Pro-Inflammatory Signaling Loop in Kidney David J. Kennedy,[1] Wenxin Huang,[1] Jiang Liu,[2] Zi-Jian Xie,[2] Joseph I. Shapiro,[2] Roy L. Silverstein.[1] *[1]Cell Biology, Cleveland Clinic, Cleveland, OH; [2]Medicine, University of Toledo, OH.*

Background: Pro-atherogenic, hyperlipidemic (HL) states are accompanied by increases in circulating ligands for scavenger receptor CD36 (e.g. oxLDL) and the signaling Na/K ATPase (e.g. ouabain-like cardiotonic steroids). These factors increase inflammation, oxidative stress, and progression of chronic kidney disease. We tested the hypothesis that ligands generated in HL accelerate renal inflammation through activation of a CD36-Na/K ATPase signaling complex, including potentiation of an inflammatory paracrine loop between proximal tubule (PT) cells and their associated macrophages (MΦ).

Methods: CD36$^-$ and CD36+(WT) mice on an apoE$^-$ background were fed a high-fat diet (HFD) for 32wks.

Results: Compared to WT, CD36$^-$ kidneys had less glomerular and tubulointerstitial Mφ accumulation, glomerular foam cell formation and mesangiolysis. CD36$^-$ Mφ also demonstrated decreased production of proinflammatory cytokines and ROS in response to oxLDL, ouabain, or plasma from HFD mice. Both oxLDL and ouabain increased attachment of WT but not CD36$^-$ Mφ to tissue culture plastic. In a modified Boyden chamber migration assay, WT Mφ showed increased migration to cell-free conditioned media from HK2 PT cells treated with either oxLDL or ouabain. OxLDL, ouabain, and HFD plasma stimulated ROS production in LLC-PK1 PT cells and this was inhibited by either N-acetyl-cysteine or apocynin. OxLDL induced ROS were also proportionally attenuated by RNAi-induced knock-down of the Na/K ATPase α-1 subunit in A411 cells (40% Na/Kα-1 knockdown) and PY17 (90% Na/Kα-1 knockdown). Cells transfected with control vector showed no effect. OxLDL and ouabain increased CD36 and Na/Kα-1 co-localization in both LLC-PK1 and Mφ as demonstrated by co-IP and a cell surface fluorescence proximity ligation assay. Finally, oxLDL and ouabain increased the content of both CD36 and Na/Kα-1 in HK2 PT early and late endosomes.

Conclusions: These data suggest that a CD36-Na/K ATPase signaling complex in both PT and Mφ facilitates the development of chronic inflammation that underlies the renal dysfunction common to HL states.

SA-PO2832

Selective Estrogen Receptor Modulator Inhibits Fatty Acid-Induced Inflammasome Activation and Attenuates Proteinuria-Induced Tubular Injury in Mice Yuko Nishi, Minoru Satoh, Naruya Tomita, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: Proteinuria is an independent risk factor for progressive renal diseases by initiating or aggravating tubulointerstitial injury. Albumin-bound free fatty acid (FFA) overloaded in proximal tubule evokes inflammatory responses. However, the mechanisms underlying the induction of inflammation have not yet been fully elucidated. Recent study showed that inflammasomes-dependent inflammatory responses were triggered by FFA and mitochondria-derived reactive oxygen species (ROS) were required for this response in adipose tissue. We hypothesized that albumin-bound FFA would trigger inflmmasomes activation through mitochondrial ROS production and raloxifene, selective estrogen receptor modulator, could ameliorate tubular injury by reducing inflammasomes-activation associated with mitochondrial oxidative stress.

Methods: Female ICR-driven glomerulonephritis (ICGN) mice, an inbred strain with hereditary nephrotic syndrome, underwent ovariectomy and treatment with raloxifene. Human renal proximal epithelial cells were cultured with human fatty acid-bearing human albumin (FA-HSA) or human fatty acid free human albumin (Free-HSA) for 24 h with or without raloxifene and antiestrogen, ICI 182,780.

Results: ICGN mice showed tubular activation of inflammasomes and elevated imflammasomes-dependent cytokines. Raloxifene attenuated these changes and ameliorated tubular damages. Moreover, raloxifene reduced mitochondrial ROS production, prevented morphological changes of mitochondria, and improved mitochondrial respiratory function. FA-HSA but not Free-HSA caused loss of mitochondrial membrane potential, increased oxidative stress, and inflammasomes activation. Pretreatment with raloxifene improved the FA-HSA-induced changes via amelioration of mitochondrial function. These beneficial effects of raloxifene were blocked by co-incubation with ICI 182,780.

Conclusions: Albumin bound FFA activates inflammasomes in tubular cells through induction of mitochondrial ROS production. Thus, Inflammasomes could be regarded as a novel and promising therapeutic target for proteinuria-induced renal injuries.

SA-PO2833

Disintegration of Colonic Mucosal Tight Junction in Uremia: A Likely Cause of CKD-Associated Inflammation Nosratola D. Vaziri, Ardeshir Rahimi, Jun Yuan, Hyder Said, Veedamali Subramanian. *Medicine/Nephrology, University of California, Irvine, CA.*

Background: Inflammation is a constant features and a key mediator of progression of CKD and its cardiovascular complications. Inflammation in CKD has been attributed to uremic toxins, co-morbid conditions, infections, dialysis procedure etc. However, little attention is paid to the potential role of the gut and its microbial flora in the CKD-induced inflammation. CKD patients frequently exhibit endotoxemia without detectable infection. Intestinal epithelium and its tight junction form a barrier which prevents entry of microbes and their byproducts in the internal milieu. We tested the hypothesis that uremia may impair structure and function of intestinal tight junction, facilitating leakage of toxic/pro-inflammatory byproducts of the microbial flora in the circulation.

Methods: SD rats were randomized to undergo 5/6 nephrectomy (CKD) or sham-operation (control) and observed for 8 weeks. In a separate experiment SD rats were rendered uremic by addition of 0.7% adenine to their food for 2 weeks and observed for 2 weeks. Rats consuming regular diet served as controls. The animals were euthanized and colon was harvested and processed for expression of the key constituents of the tight junction using RT-PCR, Western blot analysis and immunohistology.

Results: The animals with CKD exhibited azotemia, reduced creatinine clearance and marked reductions ($P<.001$) in protein expressions of claudin-1 (70-90%), occludin-1(50%-70%), ZO- 1 (80%-90%) and phosphorylated myosin light chain in ascending and descending colon. The reduction of the given proteins was confirmed by immunohistological examinations. In contrast, mRNA abundance of claudin-1, occludin-1 and ZO-1 were elevated or unchanged pointing to the possible post-transcriptional/post-translational modification as a cause of the observed tight junction protein depletion.

Conclusions: The study revealed for the first time that uremia results in disintegration of the colonic tight junction, a phenomenon which can contribute to the systemic inflammation and common occurrence of endotoxemia in advanced CKD.

SA-PO2834

Spironolactone (Sp) Prevents Chronic Kidney Disease (CKD) Induced by Acute Kidney Injury (AKI) Jonatan Barrera-Chimal, Rosalba Pérez-Villalva, Roxana Rodriguez, Juan Reyna, Norma Bobadilla. *Molecular Physiology Unit, Instituto de Investigaciones Biomédicas, UNAM and Instituto Nacional de Ciencias Médicas y Nutrición SZ, Mexico, Mexico.*

Background: AKI has been recognized as a risk factor to develop CKD, however the mechanisms involved have not been elucidated yet. We previously demonstrated that Sp prevents renal injury induced by ischemia/reperfusion (I/R). This study was designed to: 1) develop an experimental model that leads to CKD induced by AKI, 2) study the mechanisms by which AKI may lead to CKD and 3) determine if preventing AKI with Sp protects against CKD.

Methods: Forty Wistar rats were divided in: 1) Sham-operated, 2) Sp-treated group (20mg/Kg), 3) rats underwent to bilateral ischemia (45') and 4) rats receiving Sp before I/R (Sp+I/R). All groups were followed through 270 days. Proteinuria (UProtV) and urinary Kim-1 (UKim) were evaluated every 30 days. At the end, creatinine clearance (CrC) and renal blood flow were measured. Right kidney was used for molecular studies and the left for histopathological analysis.

Results: Rats underwent to I/R exhibited increased mortality rate by 57% and developed CKD characterized by a progressive increase in UProtV and UKim, together with a fall in CrC and RBF. Glomerular hypertrophy and focal sclerosis, extensive tubular dilation, tubular proliferation and tubule-interstitial fibrosis were also observed. These alterations were associated with an up-regulation of αSMA and TGFβ and its downstream effectors: p-Smad 3, collagen-I, and fibronectin. Also, an up-regulation of TGFα and inflammatory cytokines were observed. In Sp+I/R group mortality, Uprot, UKim, renal dysfunction and structural injure were prevented. Renal architecture preservation was associated with prevention of αSMA up-regulation, reduction of pro-inflammatory cytokines, profibrotic factors and its target genes.

Conclusions: Here we show a new model of CKD induced by AKI. In this model, the mechanisms responsible of CKD progression were mediated by up-regulation of αSMA, TGFα and TGFβ, together with a greater activation of TGFβ pathway and inflammatory response. Intriguingly, we show for the first time that Sp is a novel treatment to prevent CKD induced by AKI.

Clinical Implication of Tubulointerstitial Inflammatary Cell Infiltration in IgA Nephropathy Haifeng Ni, Linli Lv, Bi-Cheng Liu. *Institute of Nephrology, Zhongda Hospital, Southeast University School of Medicine, Nanjing, Jiangsu Province, China.*

Background: IgA nephropathy is the most common glomerular disease which could progressively progressed to end stage renal failure. While inflammatary cell infiltration in tubulointerstitium is commonly involved in IgA nephropathy (IgAN) , the importance of such involvement is not well defined. In the present study, we evaluated the infiltration of inflammatory cells in renal tubulointerstitium with IgAN and its clinical implication.

Methods: We have evaluated the infiltrating immune cells in renal biopsies from 33 patients with IgAN using immunohistochemical techniques with antibodies against T cells (CD3,CD4, CD8,), B cells (CD20), macrophages (CD68) and follicular dendritic

cells (CD21). Progression in renal disease was defined as an elevation of serum creatinine above the normal limit and over 20% from baseline.

Results: It was shown that positive rates in progressive disease were 100% for CD3,100% for CD4,89% for CD8, 33.33% for CD20, 11.11% for CD21. Those of CD3, CD4, CD8 and CD68 were significantly higher than in Stable disease. Clinical pathological analysis showed that a positive correlation between the number of interstitial CD3+T cell, CD68+ macrophages and the level of serum creatinine (p=0.09,p=0.005) and proteinuria (p=0.011,p=0.007) at the time of biopsy was found. Moreover, In the renal tubulointerstitium, the number of CD3+, CD4+, CD68+cells correlated with interstitial fibrosis (p=0.004,p=0.01,p=0.008) and the number of CD8+cells correlated with segmental glomerulosclerosis (p=0.03). In the multivariate analysis, the number of tubulointerstitial CD3+ and CD68+ cells were independently associated with progressive disease in IgAN.

Conclusions: Our study demonstrated that interstitial CD3+ and CD68+macrophages play an important role in causing the progression of IgAN. It might hold a great promise in predicting the prognosis of IgAN patients by evaluating inflammatary cells infiltration in renal tubulointerstitium.

Bardoxolone Methyl Transcriptionally Regulates Transaminase Levels and Increases Glutathione Levels Gregory A. Miller, Ron Bumeister, Jeffrey Laidlaw, Pritam Kambuj, Brandon Probst, Deborah A. Ferguson, W. Christian Wigley. *Reata Pharmaceuticals, Inc., Irving, TX.*

Background: Bardoxolone methyl is the lead molecule from the Antioxidant Inflammation Modulator (AIM) class that potently induces Nrf2, a transcriptional regulator of many antioxidant and cytoprotective genes. In a 52-week randomized, placebo-controlled clinical trial in patients with chronic kidney disease and type 2 diabetes, 98% of patients treated with bardoxolone methyl had transaminase elevations above baseline levels, while 71% had transaminase elevations ≥2X the upper limit of normal. The transaminase elevations were transient, peaking within 2 to 4 weeks of treatment initiation or dose escalation, and generally resolved without drug discontinuation. Transaminase elevations did not recur once resolved and were not associated with liver toxicity.

Methods: Studies were undertaken to investigate the molecular mechanism underlying these observations.

Results: Treatment with bardoxolone methyl and other AIMs increased transaminase mRNA and protein levels in hepatocytes, myocytes, renal cells, and macrophages in a dose- and time-dependent manner. Treatment of HuH-7 human hepatoma cells and AML-12 mouse hepatocytes with bardoxolone methyl resulted in time- and dose-dependent increases in glutathione (GSH) levels. Transaminase enzymatic reactions produce GSH, an essential antioxidant molecule. Consistent with this, microarray analysis of bardoxolone methyl-treated HepG2 hepatoma cells revealed induction of several genes involved in GSH production, as well as the production of GSH precursors. We observed that siRNA knockdown of ALT1 in AML-12 mouse hepatocytes resulted in reduced glutamate levels. Furthermore, siRNA knockdown of ALT2 in HuH-7 human hepatoma cells resulted in up to a 50% reduction in total GSH levels.

Conclusions: These data suggest that transcriptional elevation of transaminases may reflect increased demand for glutamate as a result of bardoxolone methyl-mediated increases in glutathione production.

CD11c Positive Cells Recruitment Is Critical for the HFD-Induced Kidney Injury Wenjian Wang,[1] Wei Shi,[1] Xinling Liang,[1] Farhad R. Danesh.[2] *[1]Division of Nephrology, Gaungdong Genral Hospital, Gaungzhou, Guangdong, China; [2]Division of Nephrology, Baylor College of Medicine, Houston, TX.*

Background: CD11c is a type I transmembrane protein found at high levels on most human dendritic cells, but also on monocytes macrophages, neutrophils, and some B cells that induces cellular activation. Recently, a specific subset of CD11c positive macrophages was shown to be recruited to obese adipose and muscle tissue. This subset expresses CD11c and produces high levels of proinflammatory cytokines that are linked to the adipose tissue injury. CD11c+ cell ablation leads to a marked decrease in inflammatory markers, both locally and systemically, as reflected by gene expression and protein levels.

Methods: With a method by which mice were subjected to unilateral nephrectomy and followed by either high-fat diet (HFD) or normal diet (ND) for 16 weeks, we successfully established a HFD-induced kidney injury model evidenced by significant deposition of lipid, fibronectin, collagen I, and collagen III in the kidneys.

Results: Those HFD-induced kidnry injury mice displayed markedly increased plasma levels of MCP-1, IL-6, and TNF-α and reactive oxygen species production in the kidneys compared with ND mice. Interestingly, a significantly increased recruitment of specific subset CD 11c positive cells were observed in the kidneys of HDF mice compared to the volume of ND mice. Importantly, when the HDF mice were pretreated with 500 rad of total body irradiation, a significantly decreased numbers of CD11c positive inflammatory cells as well as a markedly ameliorated kidney injury locally, and a marked decrease in proinflammatory cytokines systemically were observed compared to the no pretreated mice.

Conclusions: Our findings provide new insights into the role of CD11c positive cells in lipid-induced kidney injury, and offer a potential novel target in preventing the progression of chronic kidney disease elicited by HDF-induce hyperlipidemia.

SA-PO2838

Differentiating Profibrotic and Anti-Inflammatory Effects of TGF-β1 by Targeting β-Catenin Guoping Zheng,[1] Xinrui Tian,[2] Jianlin Zhang,[2] Thian Kui Tan,[1] So Ra Lee,[1] Tim Tzu-Ting Hsu,[1] Ya Wang,[1] Qi Cao,[1] Dong Zheng,[1] Yiping Wang,[1] Changqi Wang,[1] Vincent W.S. Lee,[1] David C. Harris.[1] *[1]Centre for Transplantation and Renal Research, University of Sydney, Sydney, NSW, Australia; [2]Shanxi Medical University, Taiyuan, Shanxi, China.*

Background: TGF-β1 is known to be both anti-inflammatory and profibrotic. Epithelial-mesenchymal transition (EMT) is an important mechanism for TGF-β1-mediated fibrosis, in which β-catenin plays a role. However, the dependence on β-catenin of TGF-β1-induced EMT has never been fully explained. Whether β-catenin plays a role in the anti-inflammatory effects of TGF-β1 is unknown.

Methods: A protein knockdown chimera (F-Trcp-Ecad) was used for specific degradation of cytosolic β-catenin in C1.1 renal tubular epithelial cells and J774 macrophages. TGF-β1-induced EMT in C1.1 cells, inhibition of J774 activation (by LPS/IFN-γ), β-catenin/p-Smad/LEF-1 interactions and β-catenin Topflash activity were analysed.

Results: TGF-β1-induced EMT, E-cadherin promoter repression, snail transcription and MMP-9 activity were reduced in C1.1 cells expressing F-TrCP-Ecad. F-TrCP-Ecad selectively degraded cytosolic β-catenin, and blocked TGF-β1-induced Smad3/β-catenin complex formation with no involvement of β-catenin/LEF-1 complex and Top/Fop flash activity. In contrast, the steady state level of β-catenin in J774 macrophages was low and was not changed when exposed to IFN-γ or LPS with or without TGF-β1. TGF-β1 inhibition of LPS-induced TNF-α and IFN-γ-stimulated iNOS mRNA expression was not affected in J774 cells expressing wild type β-catenin or F-TrCP-Ecad. Neither β-catenin/Smad3 or β-catenin/LEF-1 complex formation or β-catenin signaling was involved in the TGF-β1 inhibition of macrophage.

Conclusions: TGF-β1 induces EMT through a β-catenin/p-Smad3 dependent mechanism in C1.1 cells, but inhibits macrophage activation independently of β-catenin in J774 cells. Degradation of cytosolic β-catenin inhibits TGF-β1-induced EMT, but not anti-inflammatory effects of TGF-β1. β-catenin dependency of profibrotic but not anti-inflammatory actions of TGF-β1 expose β-catenin as a key therapeutic target.

Do Cytokines at Moderately Elevated Concentrations in CKD Really Induce Leukocyte Activity? Nathalie Neirynck, Griet L.R.L. Glorieux, Eva Schepers, Raymond C. Vanholder. *Internal Medicine, Nephrology, University Hospital Ghent, Ghent, Belgium.*

Background: Oxidative stress induced by uremic retention products is one of the mechanisms involved in the pro-inflammatory status and the cardiovascular morbidity and mortality of CKD. IL6, TNFα, IL1β and IL18 are moderately elevated in CKD. In observational studies, IL6 and TNFα were associated with increased cardiovascular mortality in CKD. Although extensively studied at high concentrations as in sepsis, low concentrations as observed in uremia have to the best of our knowledge rarely been evaluated. The present study investigated whether IL6, TNFα, IL1β and IL18, as occurring in CKD, induced oxidative burst in leukocytes.

Methods: Whole blood of healthy volunteers was incubated in vitro with different concentrations of cytokines, ranging from 5 to 102.8pg/ml for IL6, from 20 to 1400pg/ml for TNFα, from 20 to 400pg/ml for IL1β and from 75 to 1200pg/ml for IL18. Oxidative burst in leukocytes in basal conditions and after stimulation with fMLP, E.coli and PMA, was measured by flow cytometry.

Results: At baseline, TNFα and IL6 increase the percentage of ROS-producing monocytes and granulocytes from the lowest concentration on (P<0.05), while no effects were seen with IL1β and IL18. After stimulation with fMLP, TNFα increased the percentage of ROS-producing monocytes and granulocytes in uremic concentrations, while IL6 suppressed oxidative burst in granulocytes at various uremic concentrations (P<0.05). After stimulation with E.coli, IL18 increased the percentage of ROS-producing cells (P<0.05, all leukocyte cell types). After E.coli stimulation, the mean ROS-production per cell in monocytes increased with IL6 (P<0.05 at 21.9pg/ml and 95.4pg/ml), while it was suppressed by TNFα from 70pg/ml on (P<0.05). After stimulation with PMA there were no significant effects.

Conclusions: Our data indicate that although cytokines appear to influence inflammatory status, there is certainly no consistent evolution in uremic concentrations. First of all, in basal conditions only some cytokines (TNFα and IL6) are pro-inflammatory while others (IL1β and IL18) are not. In activated leukocytes, some cytokines appear to have stimulatory and inhibitory effect as well.

Protective Effect of Electrolyzed Water with High Dissolved Hydrogen (H_2) on the Development of Cardiorenal Syndrome by Aging in Dahl Salt Sensitive Rat Wan-Jun Zhu,[1,2] Masaaki Nakayama,[1,3] Shigeru Kabayama,[1,2] Sadayoshi Ito.[1] *[1]Center for Advanced and Integrated Renal Science, Tohoku University, Sendai, Japan; [2]Department of Blood Purification, Tohoku University Hospital, Sendai, Japan; [3]Fukushima Medical University, Fukushima, Japan.*

Background: Electrolyzed water (EW) exhibits high dissolved H_2 (DH). We recently reported that EW protects kidney and heart tissue from injury induced by ischemia reperfusion. Oxidative stress and inflammation play a crucial role for chronic kidney injury by aging. The present study aims to test the effect of EW drinking on the development of cardio-renal tissue injury by aging.

Methods: Dahl salt sensitive male rats (n=90) were divided into three groups: filter water (FW; DH 0.0mmol/L) (TI9000, Nihon Trim, Osaka), de-gass EW (DW; DH 0.35 mmol/L), and EW (DH 0.0 mmol/L) for *ad lib* drinking (n=30 each). They were fed with 0.5% salt diet during the study. Blood pressure (BP) were measured by tail cuff method every 4weeks. Echocardiography, and tissue samplings of kidney and heart, were performed at 16th, 24th, and 48th week.

Results: There were no differences during the study in body weight, water and food consumption among the groups, but the BP was the lowest in EW ($p<0.05$). Regarding the test parameters, no differences were found at 16th, 24th week, but the following parameter levels or changes (vs. 16th week) were significantly less in EW as compared to counterparts at 48th week ($p<0.05$); (Heart) left ventricle posterior wall thickness: FW 14.4%, DW 12.7%, EW 6.3%; cardiomyocyte size (μm): FW 43.2%, DW 14.0%, EW 0%; heart tissue fibrosis: FW 300.4%, DW 155.2%, EW 25.1%; ED1 staining (number/slice): FW 28.1±1.46, DW 20.5±1.29, EW 12.1±2.41; malondialdehyde (MDA) staining (%/field):FW 63.7±2.64, DW 70.0±3.94, EW 44.6±2.92, (Kidney): ED1 cells in cortex (number/slice): FW 113.5±13.11, DW 88.2±11.85, EW: 75.3±3.04; MDA staining in cortex (%/field): FW 60.5±1.18, DW 66.2±1.48, EW 57.2±1.20.

Conclusions: *Ad lib* drinking of high H_2 water could suppress the development of cardiorenal tissue injury of Dahl Salt sensitive rat by aging, at least partly, through the mechanism of attenuating inflammation and oxidative stress.

Uremic Toxins Inhibit Glucuronidation in Human Proximal Tubule Epithelial Cells Henricus A.M. Mutsaers,[1,2] Dorien Reijnders,[1] Martijn J. Wilmer,[1] Hanneke Wittgen,[1] Lambertus Vd Heuvel,[3] Joost G. Hoenderop,[2] Rosalinde Masereeuw.[1] *[1]Pharmacology & Toxicology, Radboud University Nijmegen Medical Centre, Netherlands; [2]Physiology, Radboud University Nijmegen Medical Centre, Netherlands; [3]Pediatrics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Background: Metabolic enzymes play a key role in the clearance and bioavailability of drugs. During chronic kidney disease (CKD), metabolism is affected leading to altered drug disposition. Furthermore, there is a progressive accumulation of uremic retention solutes due to impaired renal clearance. Here we investigated the impact of uremic toxins on the functionality of an important class of phase II enzymes, *viz.* UDP-glucuronosyltransferases (UGTs).

Methods: Gene expression of phase I and II enzymes in conditionally immortalized renal proximal tubule epithelial cells (ciPTEC) was studied via a qPCR array and UGT protein expression was investigated via Western blot. In addition, the glucuronidation activity of a subset of UGTs in ciPTEC, either untreated or exposed to uremic toxins for 48h, was studied by high performance liquid chromatography using 7-hydroxycoumarin (7-OCH) as a substrate.

Results: Our results showed that ciPTEC express a wide variety of metabolic enzymes, similar to primary proximal tubule epithelial cells, including cytochrome P450 enzymes and UGTs. Especially UGT1A1, 1A9, 2B7 and 2B28 are highly expressed in ciPTEC (Ct: 25, 17, 24 and 25, respectively; Ct GAPDH: 23) and UGTs were demonstrated to be functionally active (7-OCH-glucuronide Km: 12 ± 2 μM, Vmax: 242 ± 10 pmol/min.mg). Furthermore, exposure of ciPTEC to non-toxic concentrations of indoxyl sulfate, oxalate, putrescine, p-toluenesulfonic acid or a mix of these toxins significantly decreased the glucuronidation of 7-OHC with 20%, 14%, 18%, 16% and 41%, respectively. Moreover, UGT1A and 2B protein expressions remained unaltered following exposure to uremic toxins, suggesting that the observed inhibition occurs via a direct enzyme interaction.

Conclusions: In conclusion, uremic toxins inhibit UGT function in ciPTEC, thereby affecting the metabolic capacity of the kidney. This may have a clinically significant impact on pharmacokinetics in CKD patients.

Elevated Soluble Flt1 Mediates an Anti-Angiogenic State in Patients with ANCA-Associated Vasculitis Caroline Vercel,[1] Ruth J. Pepper,[2] H. Terence Cook,[3] Alan D. Salama,[2] Fadi Fakhouri.[1] *[1]Nephrology and Immunology, CHU de Nantes, Nantes, France; [2]Centre for Nephrology, University College London, London, United Kingdom; [3]Centre for Complement & Inflammation Research, Division of Immunology and Inflammation, Department of Medicine, Imperial College London, United Kingdom.*

Background: Anti-neutrophil cytoplasm antibody (ANCA)-associated vasculitis (AAV) are a group of necrotizing small vessel vasculitis. Little is known regarding endothelium survival and repair in these diseases.

This study aims to demonstrate that elevated levels of sFlt1 (soluble fms like tyrosine kinase1), an inhibitor of VEGF, induce an anti-angiogenic state that could impair vascular regeneration.

Methods: Circulating sFlt-1 levels were determined by ELISA, during active disease and remission, in plasma from patients with Proteinase 3 (PR3)-AAV(n=40), Myeloperoxydase(MPO)-AAV (n=23), and healthy controls (n=18).

To assess the anti-angiogenic activity of these plasma; we used the chick chorioallantoic membrane(CAM) model of angiogenesis. To determine the source of sFlt-1 in AAV patients, HUVEC and monocytes were incubated with: PR3 and MPO-AAV patients' plasma drawn during acute or remission phase and monoclonal anti-PR3 and anti-MPO antibodies. For each condition, sFlt-1 level was measured in cells supernatants.

Results: sFlt1 serum levels increased during active AAV in patients with PR3-ANCA(mean 7304 [321-47355] pg/ml; $p<0,001$ vs controls(mean 120 [82-168] pg/ml))and MPO-ANCA(mean 2242 [31-16851] pg/ml; $p<0,001$ vs controls). sFlt1 levels decreased during remission but remained higher than controls. Plasma from patients with acute AAV displayed an anti-angiogenic effect in the CAM model, an effect prevented by incubating serum with an excess of VEGF.

Monoclonal anti-PR3 antibodies and plasma from patients with acute PR3-AAV induced a significant and sustained sFlt1 release from monocytes. Anti-MPO antibodies and plasma from acute MPO-AAV had no effect.

Conclusions: Anti-PR3 antibodies mediate an increase in sFlt1 during acute ANCA-associated vasculitis that sustains an anti-angiogenic state.sFlt1 may be an optimal tool for the assessment of AAV prognosis and blocking sFlt1 may enhance renal recovery in AAV patients.

SA-PO2843

Cyclosporine A Treatment for idiopathic Membranous Nephropathy: A Systematic Review and Meta-Analysis Ge Xiao, Liya Yang, Bi-Cheng Liu. *Institute of Nephrology, Zhongda Hospital, Southeast University School of Medicine, Nanjing, Jiangsu Province, China.*

Background: Treatment of idiopathic membranous nephropathy (IMN) is still a challenge for nephrologists. Cyclosporine A (CSA) has recently been used as an commonly immunosuppressant in the treatment of IMN. However, its clinical effect has not been clear. In this study, a systematic review and meta-analysis were performed to evaluate the efficacy and adverse effect of CSA in treatment of IMN.

Methods: Publications in the English literature were searched with the keywords or text words: 'cyclosporine', 'glomerulonephritis', 'membranous', 'membranous nephropathy' , 'membranous glomerulopathy', 'membranous glomerulonephropathy', 'idiopathic membranous nephropathy', 'idiopathic membranous glomerulonephritis' for clinical trials in electronic databases. Primary outcome was relative risks (RRs) of complete and total renal remission at the end of study period. Secondary outcome included RRs of deterioration of renal function, relapse, development of end-stage renal disease (ESRD) and hypertension.

Results: Five randomized controlled trials (RCTs) and two clinical controlled trials (CCTs) involving 353 patients were included. CSA offers better efficacy in inducing complete renal remission rates than other regimens (RR 1.68, 95%CI 1.18 - 2.18, p=0.002). But CSA did not increase total renal remission rates compared with control group (RR 1.18, 95%CI 0.85 - 1.64, p=0.31). After removing the Kosmadakis trial whose follow-up was less than 1 year, the total renal remission rates was also higher in patients receiving CSA than those receiving other regimens(RR 1.46, 95%CI 1.20 - 1.77, p=0.0001). CSA tended to deteriorate renal function (RR 1.44, 95%CI 0.98 - 2.14, p=0.07) compared with control group. However, there's no significant difference between two groups in the risks of relapse (RR 1.26, 95%CI 0.35 - 4.49, p=0.72), hypertension(RR 1.50, 95%CI 0.80 - 2.81, p= 0.20)and ESRD (RR 0.63, 95%CI 0.25 - 1.56, p= 0.32).

Conclusions: This study suggested that CSA was effective in inducing complete remission in IMN than other regimens. However, CSA appears to cause a decline of renal function which recovers after dosage reduction or discontinuation.

New Retinoic Acid Receptor Agonists for Treatment of Kidney Disease Yifei Zhong,[2] Ruijie Liu,[1] Peter Y. Chuang,[1] John C. He.[1] *[1]Medicine, Mount Sinai School of Medicine, New York, NY; [2]Nephrology, Shanghai University of Traditional Chinese Medicine, Shanghai, China.*

Background: There is a lack of the treatment options for kidney glomerular disease including HIV-associated nephropathy (HIVAN). Podocyte injury is a major cause of glomerular disease. Thus, the strategy to develop effective drugs to protect podocytes

from injury is critical for treating patients with glomerular disease. Retinoic acid reduces proteinuria and glomerulosclerosis in multiple animal models of kidney disease. However, the clinical studies are limited because all-trans retinoic acid (ATRA) has significant side effects. Animal studies suggest that ATRA attenuates proteinuria likely through protection of podocytes from injury. The protective effects of ATRA are though binding to the retinoic acid receptor-alpha (RARa). We hypothesize that the RARa specific agonists might be potential drugs for treating patients with kidney disease with significantly less side effects than ATRA.

Methods: To test our hypothesis, we first designed a new lead compound (BD4), which can bind to RARa receptor specifically and has much lower toxicity based on the structure prediction and in vitro cell toxicity assay. We examined the effects of BD4 in podocyte differentiation in vitro. We tested the effects of BD4 in vivo by treating the animal model for HIVAN (Tg26) with either BD4 or vehicle from age of 4 weeks to 10 weeks. Then, we assessed proteinuria and kidney histology in these mice.

Results: BD 4 is a unique compound as this is the first retinoids containing boronic acid. We found that BD4 induces expression of podocyte differentiation markers including synaptopodin, nephrin, and WT-1 in podocytes similar to the effects of ATRA. We confirmed that BD4 reduces proteinuria and improves kidney injury in HIV-1 transgenic mice, a model for HIV-associated nephropathy. BD4 treated mice did not develop any obvious toxic or side effects.

Conclusions: Our data suggest that BD4 is a potential new RARa agonist with less toxicity for treatment of patients with kidney disease including HIVAN.

KLF15 Reduces the Threshold for Podocyte Injury Sandeep K. Mallipattu, Ruijie Liu, Peter Y. Chuang, Yan Dai, John C. He. *Nephrology, Mount Sinai School of Medicine, New York, NY.*

Background: Podocyte injury resulting from a loss of podocyte differentiation has been implicated in many glomerular diseases. It has been previously shown that Retinoic Acid (RA) induces podocyte differentiation via stimulation of cAMP/PKA/CREB pathway. Previous computation analysis revealed that Krupper-Like Factor 15 (KLF15), a kidney enriched CREB targeted nuclear transcription factor, is highly regulated in RA mediated podocyte differentiation and binds to the promoter region of many podocyte specific genes. RA was shown to increase KLF15 expression in cultured wild-type and HIV infected podocytes. KLF15 expression was suppressed in in vitro and in vivo models of HIV-associated nephropathy. KLF15 over-expression stimulated the expression of podocyte differentiation markers in wild-type and HIV-infected murine podocytes. KLF15 binds to the promoter region of slit diaphragm proteins in RA treated murine podocytes. Although, KLF15-/- mice have minimal podocyte injury at baseline, we hypothesize that KLF15 may reduce the threshold for podocyte injury.

Methods: We used two known murine models of podocyte injury to test our hypothesis. Initially, wild-type and KLF15-/- mice were administered low dose Lipopolysaccharide (LPS) (10ug/g) and urine was collected and mice were sacrificed at 48 hours. Similarly, wild-type and KLF15-/- mice were administered Adriamycin (20mg/kg) and urine was collected and mice were sacrificed at four weeks.

Results: Compared to the control group, we observed that LPS treated KLF15-/- mice had a 4-5X increase in albuminuria with significant increase in podocyte effacement. Similarly, the Adriamycin treated KLF15-/- mice had a 15-20X increase in albuminuria with significant podocyte effacement and glomerular basement membrane thinning.

Conclusions: Although a lack of KLF15 expression results in minimal podocyte injury, additional injury (LPS/Adriamycin) results in significant podocyte effacement and albuminuria. This indicates that KLF15 plays a vital role in reducing the threshold for podocyte injury.

Podocyturia in Patients Treated with Anti-VEGF Therapy for Cancer Correlates with the Level of Proteinuria Juan C. Calle,[1] Iasmina Craici,[1] Steven Wagner,[1] Aminah Jatoi,[2] Eddie L. Greene,[1] Joseph P. Grande,[3] Vesna D. Garovic.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Oncology, Mayo Clinic, Rochester, MN; [3]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN.*

Background: Proteinuria is a recognized side effect of anti-VEGF (Vascular Endothelial Growth Factor) medications. Similarly, podocyturia (excretion of viable podocytes in the urine) has been observed in various proteinuric diseases including patients treated with anti-VEGF therapy. In this study, we report the largest series to date analyzing podocyturia in patients undergoing anti-VEGF therapy with and without proteinuria.

Methods: The aim of the study was twofold: 1. to demonstrate the presence of podocyturia in patients developing proteinuria while undergoing anti-VEGF therapy and 2. quantitate the observed higher level of viable podocyte excretion in the urine of patients with greater than 500 mg of proteinuria/24 hours calculated by the protein to creatinine ratio.

For identification of viable podocytes, overnight cultures of urine sediment followed by staining with podocin antibodies and a secondary FITC–labeled antibody were performed.

Results:

	Proteinuria ≤500 mg/24 hours	Proteinuria ≥500 mg/24 hours
# of patients	28	12
Age range (mean)	34-79 (59) years	51-73 (63) years
Female n (%)	19 (68)	7 (58)
Type of cancer		
Lung cancer and pulmonary carcinoids	3	1
Ovarian cancer	3	3
Gastrointestinal system cancer and carcinoids	12	4
Hemangioendothelioma	2	0
Central nervous system	2	2
Breast cancer	2	0
Melanoma	1	0
Renal cell carcinoma	3	2
Type of anti-VEGF treatment		
Bevacizumab	23	11
Bevacizumab + Sunitinib	1	0
Bevacizumab + Sorafenib	3	0
Sunitinib	0	1
Sorafenib	1	0
Podocyturia (cells/mg of creatinine)		
Range	**0-1.64**	**0-14.55**
Mean*	**0.17**	**2.67**

***p value = 0.0068. 95% CI for proteinuria ≤500 mg/24 (0.06–0.17); ≥500 mg/24 hour (0.82–3.56)**

Conclusions: Our data demonstrate two major findings: 1. the presence of podocyturia accompanies proteinuria in patients undergoing anti-VEGF therapy regardless of the type of cancer and 2. levels of podocyturia are higher in patients with proteinuria ≥500 mg/24 hours when compared to patients excreting ≤500 mg/24 hours.

SA-PO2847

Serum Phosphate in the Nephrotic Syndrome Varies with Degree of Proteinuria but Is Independantly Associated with High Pulse Wave Velocity Donal John Sexton, Sinead Kinsella, Joseph A. Eustace. *Department of Renal Medicine, Cork University Hospital, Cork, Ireland.*

Background: The prevalence and determinants of abnormal vascular stiffness in the Nephrotic Syndrome is not well defined.

Methods: We conducted a cross-sectional study of 42 prevalent non-diabetic adult nephrotics, measuring carotid-femoral Pulse Wave Velocity (PWV) (MicroMedical Pulse Trace v2.12) at a median (intra quartile range (IQR)) of 23 (10 - 47) months of follow-up. PWV was dichotomized using age specific cutoffs (Eur Heart J, 2010). Relationship between variables from time of renal referral, at time of PWV testing and time averaged (Time Av) over the above interval were quantified by non-parametric (Spearman's) correlation and linear regression using SPSS v18.

Results: Mean age was 44(18) yrs, 74% were male, 38% had FSGS, 19% MN, 12% MCD; 40.5% had an early full remission, 28.6% never remitted and 31% relapsed. 48% were on current immunosupression.

At presentation median (IQR) CKD-EPI eGFR and spot urine protein creatinine ratio (urPCR) was 80 (56-90) ml/min and 4.4 g/g (2.9-7.1); mean (sd) serum phosphate (P), total cholesterol (TC) and albumin were 1.34 (0.23) mmol/L, 8.2 (3.3) mmol/L and 25 (9.8) g/dl; referral urPCR correlated with P, TC and albumin, all $p<0.01$. P was associated with urPCR on univariate analysis ($\beta=0.43$, $p=0.007$) and when adjusting for eGFR ($\beta=0.42$, $p<0.01$) but not with eGFR.

Median (IQR) PWV was 7.1(4-11) m/sec. PWV did not correlate with the serum TC, any lipoprotein subfraction, mean arterial pressure, eGFR, albumin or urPCR at referrral, follow-up or Time Av values. PWV only correlated with follow-up P ($r=0.49$, $P=0.001$) and Time Av P ($r=0.51$, $P=0.001$).

An elevated, age-specific, PWV was present in 52.4% (22/42) overall and in 65% (13/20) of those <40 year old. Time Av P was independantly associated with PWV ($\beta=1.58$, $p<0.001$) simultaneously adjusting for age, gender and eGFR and separately when adjusting for Time av {eGFR, TC and urPCR} ($\beta=1.72$, $p=0.002$)

Conclusions: PWV is elevated in nephrotics. Serum phosphate levels vary with the degree of proteinuria independantly of GFR and associate with high PWV independantly of blood pressure, dyslipidaemia, GFR or proteinuria.

SA-PO2848

Measurement of D-dimer Levels in the Nephrotic Syndrome Donal John Sexton, Marek J. Mazur, Joseph A. Eustace. *Department of Renal Medicine, Cork University Hospital, Cork, Ireland.*

Background: The Nephrotic Syndrome is associated with a significant increased risk of thromboembolism. D dimer is commonly used as a screening test for thrombosis in general practice, but prevalent D dimer levels -and its associations- in the nephrotic syndrome in the absence of overt thrombosis is poorly characterised.

Methods: We conducted a cross sectional study of 97 patients with the nephrotic syndrome. Ddimer were measured using either BIOPOOL MiniQuant or Siemens INNOVANCE assays. No patient had clinical evidence of thrombosis or was on anticoagulation. Univariate and multivariate linear regression models were used to examine associations with Ln-transformed D dimer (Ln- DDimer) levels, expressed as percentage of the assay specific reference range, using SPSS v18 and a type one error rate of 0.05.

The descriptive statistics are expressed as median (25-75th centile) unless otherwise stated.

Results: Study characteristics were (n=97) MDRD eGFR: 49 ml/min (30-90), protein:creatinine ratio (PCR) 2.0 g/g (0.8-4.4), , urate 434 umol/L (332-545), mean (sd) age 55yrs (20), mean (sd) serum albumin 34g/dl (8.4). 5% had a raised CRP. On separate univariate linear regression models the β (95% CI) for the association with Ln-DDimer was: age (decades) 0.54 (0.02-0.03), eGFR -0.34 (-0.02, -0.005), Ln PCR 0.59, (0.31, 0.55) and serum albumin -0.49 (-0.07, -0.03), all P<0.01. Ln-DDimer was not associated with wbc count, urate, gender, diagnosis of membranous nephropathy, or diabetes mellitus. On multivariate modeling using backward stepwise regression the final model β (95% CI) was age (decades) 0.36 (0.01, 0.03) p<0.001, Ln-PCR 0.33 (0.309, 0.39) p=0.002 and Serum Albumin -0.23 (-0.05, -0.004) p=0.02. Ln-D dimer was not independently associated with eGFR (p=0.3). When analysis was performed stratified by DDimer assay type, lnPCR correlation with DDimer in both separate analyses (P=0.0001).

Conclusions: The standard reference range of Ddimer for evaluation of thrombosis should not be used for patients with the nephrotic syndrome. Elevated Ddimer levels in the NS is associated with PCR rather than eGFR.

SA-PO2849

1,25-Dihydroxyvitamin D(3) Ameliorates Podocytes Injury Via Inhibiting CD80 Expression Jianchao Ma, Wei Shi, Wenjian Wang, Shuangxin Liu, Lixia Xu, Zhilian Li, Zhiming Ye, Yuan Han Chen, Xinling Liang. *Nephrological Department, Guangdong General Hospital, Guangzhou, Guangdong, China.*

Background: Accumulating studies have demonstrated that 1,25-Dihydroxyvitamin D(3) reduces podocytes loss and slows the decline of kidney function in chronic kidney disease. Recent evidences showed that CD80 expressed on injured podocytes and may play a critical role in proteinuria. In this study, we hypothesized that vitamin D protects podocytes via modulating CD80 expression.

Methods: SD rats were subjected to 5/6 nephrectomy, and then were randomly allocated into two groups: 5/6 nephrectomy and 5/6 nephrectomy + 1,25-Dihydroxyvitamin D(3) (0.3ug/kg.day) groups. Albuminuria was monitored at 2 weeks, 4weeks, 8weeks and 12weeks after treatment. *In vivo*, immortalized mouse podocytes were cultured and randomized into groups: control, PAN and PAN +1,25-Dihydroxyvitamin D(3) (10^{-9}ug/L) treated groups . CD80 ,VDR and synaptopodin were tested in both protein and mRNA level. The podocyte apoptosis was checked by immunofluorescence.

Results: A significant decrease of proteinuria and podocytes apoptosis were observed in 5/6 nephrectomy +1,25-Dihydroxyvitamin D(3) group compared to 5/6 nephrectomy rats. In vivo, 1,25-Dihydroxyvitamin D(3) also exhibited a decrease of apoptosis cell nuber in PAN-induced podocytes. Importantly, the expression of CD80 was markedly inhibited by 1,25-Dihydroxyvitamin D(3) in both protein level and mRNA level. Consistent with the results observed in vivo, the same effect of 1,25-Dihydroxyvitamin D(3) on the podocytes injury induced by PAN was also confirmed in vitro.

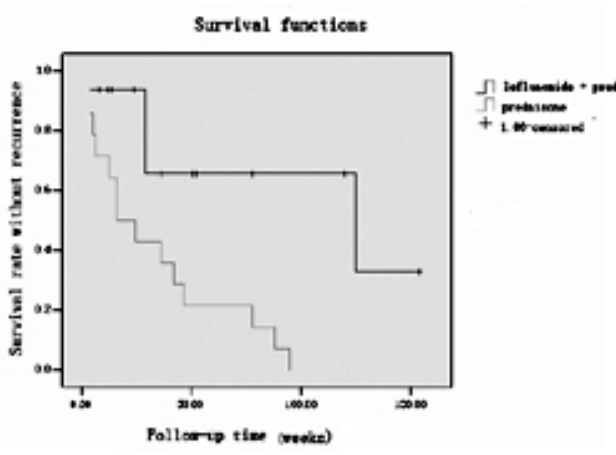
Conclusions: Our findings provided new insights of the renopretection role of 1,25-Dihydroxyvitamin D(3) in podocytes injury, and offer a potential target in prevent the progression of CKD by inhibiting CD80 expression.

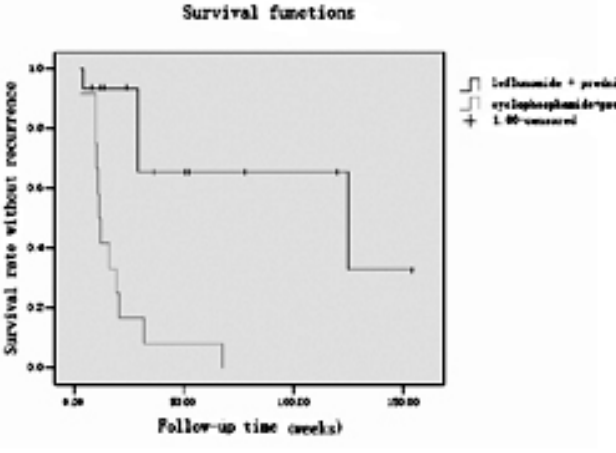
SA-PO2850

Efficacy and Safety of Leflunomide in the Treatment of Steroid Dependent or Resistant Minimal Change Disease: A Single-Centre Experience Jun-Hua Zhou, Yi-Miao Zhang, Gang Liu, Jun Li, Rong Xu, Jing Huang. *Renal Division, Peking University First Hospital, Beijing, China.*

Methods: Fourteen patients with steroid-dependent MCD (minimal change disease) and two patients with steroid-resistant MCD, who had been treated with leflunomide, were retrospectively analyzed.The initial dose of leflunomide was 10-20mg/d combined with prednisone of initial dose of 0.25-1.0mg/kg/d and gradually tapering after 8 weeks. Clinical data of baseline, 2nd, 4th, 8th, 12th, 24th, 48th week was analyzed comparing with previous prednisone monotherapy and prednisone combined with cyclophosphamide therapy.

Results: Total effective rate of the steroid-dependent patients was 100% (14/14), and complete remission rate was 92.8% (13/14).Besides,two steroid-resistant patients achieved complete remission by leflunomide combined with prednisone.During the treatment,eight patients had adverse effects which could be well tolerated.Comparing with prednisone monotherapy,the dose of prednisone to maintain remission was reduced dramatically (from median 22.5mg/d to median 7.5mg/d,P=0.041),relapse rate during follow-up time decreased from 100% to 31.3% (*P*=0.002), the median time before relapse increased from 20.3 weeks to 32.5 weeks.





Comparing with prednisone combined with cyclophosphamide,the dose of prednisone to maintain remission could be reduced significantly (from median 22.5mg/d to median 5.0mg/d, *P*=0.003), relapse rate during follow-up time decreased from 100% to 31.3% (*P*=0.001),the median time before relapse increased from 11.7 weeks to 32.5 weeks.

Conclusions: Leflunomide might be effective in steroid-resistant and steroid-dependent minimal change disease.It may reduce the amount of prednisone to maintain remission and reduce relapse rate comparing with prednisone monothrerapy and prednisone combined with cyclophosphamide therapy.This strategy might be usually well tolerated by the patients.

SA-PO2851

Synthetic ACTH Is Less Effective Than Cyclophosphamide in Patients with Idiopathic Membranous Nephropathy Julia M. Hofstra,[1] Hans S. Brink,[2] Jos J. Van de Kerkhof,[3] Jack F. Wetzels.[1] *[1]Nephrology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [2]Internal Medicine, Medisch Spectrum Twente, Enschede, Netherlands; [3]Internal Medicine, Bernhoven Hospital, Veghel, Netherlands.*

Background: Therapy with alkylating agents in idiopathic membranous nephropathy (iMN)is effective, but associated with serious side effects. Synthetic ACTH may be advantageous with reported remission rates up to 85% and no significant side effects.

Methods: We conducted a prospective cohort study in patients with iMN and high risk for renal failure (NCT00694863). Patients with iMN, a nephrotic syndrome, eGFR> 60 ml/min and high risk for progression (elevated urinary β2m levels) were treated with i.m. injections of synthetic ACTH during 9 months (m.). Maximal dose was 1 mg tetracosactide-hexacetate (Synacthen Depot®) twice a week. For comparison, we selected historical controls, treated with cyclophosphamide (CP 1.5 mg/kg/day for 12 m.) and steroids, matched for serum creatinine, proteinuria, age, sex and previous immunosuppressive treatment.

Results: We compared 16 patients (M/F 13/3, age 52 ±15yr, sCr 105 ±20 μmol/l, sAlb 23 ±7g/L, Prot./Cr.Ratio 8.3 ±3.5 g/10mmol) treated with ACTH and 16 patients treated with CP (M/F13/3, age 48 ±13 yr, sCr 102 ±23 μmol/l, sAlb 22 ±5 g/L, PCR 9.6 ±3.5 g/10mmol). At the end of treatment, 7 (44%) patients treated with ACTH developed a partial remission of proteinuria (PCR < 2.0g/10mmol) versus 15 (94%) patients treated with CP (p= 0.02). At the end of follow-up (20±6 m.in the ACTH group and 75±30 m. in the CP group), relapses had occurred in 3 of 7 patients (43%) in the ACTH group and 4 of 15 patients (27%) in the CP group (log rank p<0.01). Although all patients had side effects on ACTH, these were minor and necessitated dose reduction in only one patient compared with 5 patients treated with CP.

Conclusions: Treatment with synthetic ACTH is less effective than CP in inducing an initial remission of proteinuria in high risk patients with iMN. Sustained remission was induced in only a minority of patients. These data suggest that synthetical ACTH has limited value in the treatment of high risk patients with iMN.

SA-PO2852

Efficacy of Rituximab in Steroid Resistant & Dependent Nephrotic Syndrome Arvind Bagga,[1] Aditi Sinha,[1] Asha Moudgil,[2] Ashima Gulati,[1] Stanley C. Jordan.[3] *[1]All India Institute of Medical Sciences, New Delhi, India; [2]Children's National Medical Center, Washington; [3]Cedars Sinai Medical Center, Los Angeles.*

Background: To evaluate the efficacy of rituximab (RTX) in inducing & maintaining remission in difficult steroid resistant (SRNS) & steroid dependent nephrotic syndrome (SDNS)

Methods: Data on 74 patients receiving RTX (375 mg/m^2 IV weekly) for SRNS (4 doses) or SDNS (2 doses) & followed ≥6-months is presented. Therapy with prednisone & calcineurin inhibitors (CNI) was tapered. For SRNS, remission was defined as complete (CR), partial (PR) or non response (NR).

Results:

SRNS. Following onset at a mean age of 4 yr, 38 patients received RTX at 10 yr. Failure of IV steroids & failure (26) or toxicity (12) to CNI was present. Histology showed MCD (n=18) or FSGS (20). Four weeks post-RTX, 17 (45%) patients showed CR or PR, allowing CNI taper (100%) & discontinuation (61%). Remission rates were similar for initial (35%) or late (50%) steroid resistance & CNI failure (38%) or toxicity (44%). More patients with MCD (60%) than FSGS (24%) attained remission (P=0.04). At 2-yr, 47% had favorable outcome (CR/PR 7, steroid sensitive relapses 11); 24% had impaired GFR.

SDNS. Following onset at a mean age of 3-yr, 36 patients received RTX at 12-yr. Patients had failed therapy with levamisole, cyclophosphamide, MMF or CNI. Following therapy, there was decrease in relapses (difference 3.5 episodes/yr; P<0.001). The mean duration of remission was 13 (5-38) months; 3, 18, 7 cases relapsed at <6, 7-12 & ≥12 months respectively. Therapy with CNI or MMF was discontinued; steroids were withdrawn in 79%. At 19 months follow-up, 28% had sustained remission, 16% infrequent relapses & 56% frequent relapses. Relapse-free survival was 92%, 32% & 16% at 6, 12 & 18 months respectively. Repeat doses of RTX (n=11) had similar benefit.

CD19 depletion was found in all cases.

Conclusions: RTX effectively induced remission in patients with refractory SRNS & maintained 6-months remission in over 90% cases with SDNS. Since a high proportion of patients with SDNS relapsed after 6-months, studies should examine interventions that prevent relapses following RTX.

Urinary Exosomes May Represent a New Diagnostic Tool for Early Diagnosis of Renal Damage Anja Susanne Muhlfeld,[1] Silvia Spanu,[2] Bernd Denecke,[3] Jurgen Floege.[1] *[1]Department of Nephrology and Clinical Immunology, University Clinic of the RWTH Aachen University, Aachen, Germany; [2]Department of Nephrology, University of Medicine and Pharmacy, Cluj-Napoca, Romania; [3]IZKF, RWTH Aachen University, Aachen, Germany.*

Background: Exosomes are membrane vesicles, that are secreted from the surface of all cells types after fusion of the multivesicular body with the cell membrane. They contain proteins and mRNA of the cells of origin. Because of the surrounding cell membrane intraexosomal proteins and mRNA are well protected from digesting enzymes. In the present study we have evaluated the expression profile of intra-exosomal mRNAs as a non-invasive tool for the diagnosis of renal disease.

Methods: Toxic podocyte damage was induced by puromycin aminonucleoside in male Sprague Dawley rats. Urinary exosomes were isolated by differential centrifugation at time points 0 (before disease induction), at the onset of proteinuria (day 5) and during maximal disease activity (day 10). Exosomal mRNA was isolated, amplified, and the mRNA species were globally assessed by gene array analysis.

Results: Rats treated with puromycin aminonucleoside developed acute kidney damage, indicated by an increase in serum creatinine and BUN and the development of proteinuria. Messenger-RNA isolated from urinary exosomes revealed 887 differentially expressed genes with an at least 1.5-fold change and 77 genes with an at least 3-fold change in their level of expression on days 5 and 10 as compared to baseline expression on day 0. These genes were mainly involved in the maintenance and reorganization of the cytoskeleton, in the response to oxidative stress and in the control of the apoptotic pathway. Out of these genes we identified a number of genes that were regulated only in the initial phase of the disease (day 5), i.e. at the onset of proteinuria, and therefore bear the potential to act as early markers of glomerular damage.

Conclusions: The gene expression pattern in urinary exosomes of rats with puromycin aminoglycosid nephrosis may serve to identify early markers of renal disease that may lend themselves to both diagnostic and pathogenetic studies.

SA-PO2854

Superior Results with Tacrolimus Than Ciclosporine in Children with Steroid Resistant Nephrotic Syndrome Mara Medeiros, Yolanda Fuentes, Saul Valverde, Ana M. Hernández. *Hospital Infantil de México Federico Gomez, Mexico, DF, Mexico.*

Background: The aim of the study was to evaluate if Prednisone (PDN) and Tacrolimus (Tac) therapy administered during a 12 month period achieves a greater rate and prolonged remission of proteinuria in pediatric patients with sterioid resistant nephrotic syndrome SRNS, compared to those treated with the standard prednisone and Cyclosporine(CyA) regimen."

Methods: A comparative, randomized trial was conducted in children with SRNS; the protocol was approved by the IRB, parent and children consent/assent was obtained in all cases. They received prednisone (PDN) 60 mg/m2/day for 1 month and 30 mg/m2/day every 48 hours, for 5 months, group I received CyA 5 mg/kg/day, target levels 100 to 200 ng/ml. Group II received Tac 0.10 mg/kg/day,adjusted to target levels 5-10 ng/ml). Monthly visits were scheduled for clinical and laboratory evaluations (blood and urine).

Results: Twenty patients were included, ten in each group. Clinical an laboratory data is depicted in Table 1. All Tac treated patients had complete remission at 6 months of treatment, whereas only four patients in the CyA group.

Table 1. Clinical and Laboratory Data

	CyA (n=10)	Tac (n=10)	p value
Age (median years, range)	5.9 (2.2, 17)	7.2 (2.7, 15.8)	0.76
Baseline serum albumin (mg/dL)	2.9 (0.7,3.3)	1.6 (0.4,3.2)	0.51
6 months serum albumin (mg/dL)	3.6 (2.8,3.9)	3.7 (3.4,4.1)	0.62
New onset hypertension (n,%)	8 (80%)	1 (10%)	0.005
Partial or complete remission (n.%)	7 (70%)	10 (100%)	0.21
Complete remission (n,%)	4 (40%)	10 (100%)	0.01

CyA: Cyclosporin, Tac: Tacrolimus, NS: Nephrotic syndrome.P value obtained either by Fisher Exact test or Mann Whitney test.

No difference was found in serum creatinine and eGFR.

Conclusions: The rate of complete remission is higher with tacrolimus than with cyclosporine at six months of treatment in SRNS children.

Patients treated with cyclosporine had significantly higher rate of new onset hypertension.

Tacrolimus seems to be better theraputic option in SRNS than Cyclosporine.

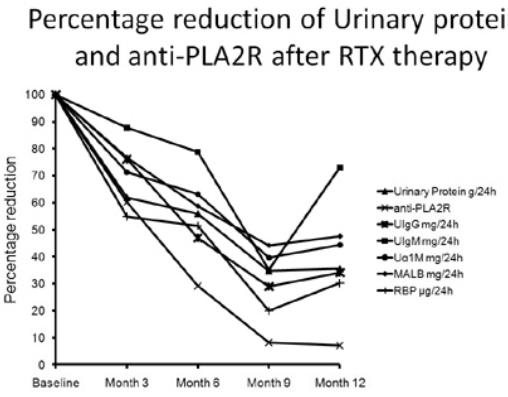
SA-PO2855

Urinary Biomarkers as Predictors of Response to Rituximab in Patients with Membranous Nephropathy Maria V. Irazabal,[1] Alfonso Eirin,[1] John C. Lieske,[1] Laurence H. Beck,[2] John J. Dillon,[1] Patrick H. Nachman,[3] Sanjeev Sethi,[1] Stephen B. Erickson,[1] Daniel C. Cattran,[4] Fernando C. Fervenza.[1] *[1]Division of Nephrology, Mayo Clinic, Rochester, MN; [2]Department of Medicine, Boston University School of Medicine, Boston, MA; [3]Division of Nephrology, University of North Carolina, Chapel Hill, NC; [4]Division of Nephrology, Toronto General Hospital, Toronto, ON, Canada.*

Background: Rituximab (RTX) reduces proteinuria (P) in membranous nephropathy (MN). However, given the cost and potential side-effects, it would be useful to limit treatment to patients likely to respond to RTX. Recent data suggest that urinary markers (e.g. IgG) predict prognosis in MN, but whether they can predict P response to RTX is unknown.

Methods: Urinary (U) excretion of retinol binding protein (RBP), alpha-1 microglobulin (α1M), albumin (alb), IgG, and IgM at baseline were correlated with P at 12 and 24 mo, in 20 MN patients treated with RTX (375mg/m^{2}x4) with retreatment at 6 mo. Anti-phospholipase A2 receptor antibody (anti-PLA2R) was also tested.

Results: At 24 mo, complete remission (CR=UP<0.3g/24h) occurred in 4 patients, partial remission (PR=UP<3.5g but >0.3g/24h) in 12, limited response (LR=>50% UP reduction but UP>3.5g) in 1, non-response (NR=<50% UP reduction) in 2, and 1 relapsed. Baseline UIgG (mg/24h), fractional excretion (FE) of IgG, Uα1M (mg/24h) and URBP (μg/24h), significantly correlated with change in P at 12 mo (p=0.04, 0.05, 0.04, and 0.03), but not at 24mo (p=0.55, 0.42, 0.29 and 0.20 respectively). Correlation between baseline UIgM, FEIgM, Ualb, FE alb and response at 12 or 24 mo was not significant. In the 16 patients in which the anti-PLA2R antibody were positive, the decline correlated with the reduction in these protein markers.



Conclusions: Quantification of low, medium and high molecular weight UP may predict short but not long-term response to RTX.

Cd2ap Regulates Actin Cytoskeleton in Podocytes by Regulating RhoA Activity Hani Suleiman,[1] Andrey S. Shaw.[1] *[1]Department of Pathology and Immunology, Washington University, Saint Louis, MO; [2]Institut für Anatomie und Zellbiologie, Universitätsmedizin Greifswald, Greifswald, Germany.*

Background: CD2-associated protein (CD2AP) is a scaffold protein which plays a critical role in the maintenance of the kidney filtration barrier. The integrity of the kidney filtration barrier is regulated through the fine organization of the actin cytoskeleton. Since CD2AP has been implicated in actin regulation, we were interested to determine whether CD2AP deficient podocytes exhibit any changes in actin-myosin machinery; and whether these changes in actin-myosin machinery could explain the kidney phenotype found in the Cd2ap (-/-) mice.

Methods: Imaging, FRET sensor based live imaging, Immunohistochemistry, Western blot, Immunoprecipitation.

Results: We find here that podocytes lacking Cd2ap (-/-) have less prominent actin stress fibers, and disorganized localization of Non-muscle myosin IIa. Consistent with the defect in Non-muscle myosin IIa, when we measured the actin-myosin cytoskeleton force across the cells, we found that podocytes lacking Cd2ap exhibit less cell tension. Biochemically, Cd2ap (-/-) cells had reduced myosin light chain phosphorylation (pMLC) on Ser19, a key regulator of non-muscle myosin II activity. We measured the RhoA activity RhoA using a FRET sensor and found that RhoA activity is being reduced, which could explain the pMLC defect. Potentially explaining the defect, the RhoGAP, p190, was found to be hyperphosphorylated in CD2ap deficient cells. Furthermore, we have evidence suggesting that Cd2ap and p190RhoGAP interact together, which could be responsible for proper activation/inhibition of p190RhoGAP.

Conclusions: We conclude that Cd2ap regulates the actin-myosin machinery by regulating RhoA activity.

SA-PO2857

The Occurrence of Cancer in Patients with Membranous Nephropathy Sophia Lionaki,[1,2] Sean Barbour,[3] Yichun Hu,[1] Susan L. Hogan,[1] Caroline E. Jennette,[1] Ronald J. Falk,[1] Daniel C. Cattran,[3] Patrick H. Nachman,[1,4] Heather N. Reich.[3,4] *[1]UNC Kidney Center, University of North Carolina; [2]Nephrology, Laiko Hospital, Greece; [3]University of Toronto, Canada; [4]Contributed equally, .*

Background: To describe the frequency and character of cancers (CA) in patients with biopsy proven membranous nephropathy (MN), in relation with clinical parameters, and long term outcomes.

Methods: We studied 898 patients with MN from the Glomerular Disease Collaborative Network (N=412) and the Toronto Glomerulonephritis Registry (N=486). Clinical and laboratory values at biopsy were included in the analysis. Smoking and immunosuppressive therapies for MN were studied as predisposing factors for cancer.

Results: Among 898 patients with MN, a total of 85 malignancies were recorded in 64 patients (7.1%) [56 patients (6.2%) excluding non-melanoma skin CA]. Of these, 39 (45.9%) occurred within 5 years of biopsy diagnosis. The most common cancers were of the skin (20), prostate (10), breast (9), lung (9), GI tract (6) and hematologic (6). Excluding non-melanoma skin CA, patients with CA were older.

Characteristic Total, N=898	Patients with CA, N=56	Patients without CA, N=842	P value
Age (years)	60.8±11.9	48.4±15.8	<0.0001
Caucasian, n(%)	42(80.8)	556(70.6)	0.25
Male, n(%)	33(58.9)	522(62)	0.67
24hr prot (g/day)	7.9±5.8	7.7±5.5	0.92
Serum albumin (g/dl)	25.49±7.51	25.96±7.58	0.81
Duration of proteinuria prior to Bx (months)	4.9±8.7	3.4±34.8	0.14
eGFR adjusted for age (ml/min/1.73m2)	77.2±31.3	72.8±31	0.31
Smoking, ever, n(%)	27(65.85)	330(60.44)	0.62
Patients treated with Immunosuppression, n (%)	30(53.7)	486(57.7)	0.58
Patients reaching ESRD, n(%)	8(14.3)	96(11.4)	0.52
Time to ESRD (months)	62.0±70.4	56.35±61.2	0.9

There were no statistical differences in serum albumin, eGFR adjusted for age, proteinuria or duration of proteinuria prior to biopsy between those with and without CA. Cancers occurred in 3.6% of patients <60 y.o. and 12.9% in those ≥ 60 y.o.

Conclusions: There is an increased frequency of cancers among patients with MN older than 60 years**.** We found no distinguishing clinical features at presentation between patients with and without cancer. Presence of cancer did not affect renal survival.

SA-PO2858

Performance of Anti-Phospholipase A2-Receptor Antibody Testing for Membranous Nephropathy in Routine Clinical Practice Ulf Schoenermarck,[1] Peter Eichhorn,[2] Thomas Sitter,[3] Thorsten Wendler,[1] Volker Vielhauer,[3] Stephan R. Lederer,[4] Kai Fechner,[5] Michael Fischereder.[1] *[1]Medical Clinic I, Nephrology Div., University Hospital Munich-Grosshadern, Munich, Germany; [2]Institute of Clin. Chemistry, University Hospital Munich, Munich, Germany; [3]Medical Policlinic, Dept. of Nephrology, University Hospital Munich-Innenstadt, Munich, Germany; [4]KfH Nierenzentrum Laim, Munich, Germany; [5]Institute of Experimental Immunology, Euroimmun AG, Luebeck, Germany.*

Background: Autoantibodies against the M-type phospholipase A2 receptor (anti-PLA2R) have been recently identified in patients with primary membranous nephropathy (MN). Aim of the study was to evaluate the measurement of anti-PLA2R-antibodies with a commercially available serologic test in routine clinical practice.

Methods: All patients with the diagnosis of bioptically proven MN seen between 10/2010 and 06/2011 were tested for the presence of anti-PLA2R-antibodies. As control group patients with secondary forms of MN and other proteinuric renal diseases were analysed. For detection of circulating anti-PLA2R-antibodies an indirect immunoflourescence assay was used (EUROIMMUN AG, Lübeck, Germany). A specific cytoplasmic fluorescence of transfected HEK 293-cells at a dilution of 1:10 or higher was considered to be positive.

Results: The anti-PLA2R-antibody test was negative in all patients (n=10) with secondary forms of MN (hepatitis B, n=1, tumor-assoc., n=1, assoc. with connective tissue disease and SLE, n=7, MPO-ANCA-assoc. MN, n=1) and patients with other proteinuric diseases (n=14). 11 of 16 patients with primary MN were positive for anti-PLA2R-antibodies. The antibody titer ranged from 1:10 to 1:3200 and was present up to 8 years after first diagnosis of MN. There was no correlation between the antibody level and proteinuria or renal function. Further 3 patients with primary MN tested at time or after kidney transplantation were also negative for anti-PLA2R-antibodies, although one patient presented with nephrotic proteinuria due to bioptically proven recurrent MN.

Conclusions: Anti-PLA2R-antibodies have a high sensitivity and 100% specificity for primary MN. The serologic test appears to be a useful tool in routine clinical testing.

SA-PO2859

The Role of Gene Polymorphisms of the Renin-Angiotensin-Aldosterone and Inflammation Pathways in the Progression of Glomerular Diseases: A Validation Study Isabelle Chapdelaine, Remi Goupil, Jean-Philippe Rioux, Stephanie Raymond-Carrier, Francois Madore, Stephan Troyanov. *Nephrology, Hôpital du Sacré-Coeur, University of Montreal, Montreal, QC, Canada.*

Background: Clinical risk factors of progression in glomerular diseases such as proteinuria and blood pressure predict outcome imperfectly. Previous studies have proposed various polymorphisms of genes implicated in the pathophysiology of glomerulopathies as clinical tools in risk assessment. We sought to validate their impact on the rate of renal function decline in a prospective cohort study receiving usual anti-hypertensive and anti-proteinuric therapies.

Methods: Using Medline, we identified 9 candidates polymorphisms of known genes, mostly of the renin-angiotensin-aldosterone and inflammation pathways: MCP-1 A2518G, TGF-ß1 T869C and C-509T, ACE I/D, AGT M235T, AT1R A1166C, TSC-22 A-396G, eNOS 4b/a C344T.

Results: We prospectively recruited 93 predominantly male (73%) and Caucasian (85%) patients with an age of 64 ± 13 years and eGFR of 34 ± 21 mL/min/1.73m2 at baseline. Patients were matched to 50 healthy controls of similar ethnic background. Sixty-one percent of patients had diabetic nephropathy, almost all received renin-angiotensin-aldosterone blockade (91%) and none immunosuppressive therapy. The average MAP during follow-up was 94 ± 7 mm Hg with a urinary protein to creatinine ratio of 0.15 (interquartile range from 0.05-0.30) g/mmol. The rate of renal function decline was -2.9 ± 4.5 mL/min/1.73m2/yr over a median 34 months period. Proteinuria and blood pressure strongly predicted progression.

However, none of the proposed polymorphism predicted renal function decline nor showed simple or partial correlations with proteinuria or MAP. A summation variable of the number of simultaneous polymorphisms also showed no predictive trend. Finally, the distribution of each allele was almost identical in the patients versus the control group.

Conclusions: This study does not validate an important role for these 9 candidate polymorphisms in the progression of glomerular diseases receiving standard therapy.

The Serum Cholestanol, a Marker of Cholesterol Absorption, Is Elevated in Patients with Nephrotic Syndrome Masao Kikuchi, Shouichi Fujimoto, Yuji Sato, Kazuo Kitamura. *University of Miyazaki Hospital, Faculty of Medicine, Miyazaki, Japan.*

Background: In generally, nephrotic syndrome-associated hypercholesterolemia is considered due to increased production of lipoprotein by the mechanism of compensation for hypoproteinemia. But, there have been reports that cholesterol synthesis was not increased in nephrotic animal or human. There is still no convincing evidence for this hypothesis, especially in human.

Methods: In the present work, we investigated the serum cholestanol, campesterol and sitosterol, as markers of cholesterol absorption, and lathosterol as a marker of cholesterol synthesis in nephrotic patients not treated with a cholesterol lowering drug. Furthermore, we did same examinations in patients inducing complete remission. We made a comparison those results in patients in the nephrotic state (NS, n=19) and those in patients in the complete remission state (CR, n=8).

Results: The serum lathosterol, a marker of cholesterol synthesis, was elevated in NS, compared to CR (NS vs. CR, 3.85±0.42 vs. 2.39±0.32 μg/ml, p=0.04). As for markers of cholesterol absorption, the serum campestanol and sitosterol were not significantly different in both state, but the serum cholestanol, which is less affected by diet, were significantly elevated in NS, compared to CR (NS vs. CR, 5.52±0.50 vs. 3.35±0.34 μg/ml, p=0.01). The serum lathosterol and cholestanol were not correlated with the severity of nephrotic syndrome (ie: serum total protein and albumin, urinary protein concentration, serum total and low-density lipoprotein cholesterol, etc.).

Conclusions: In nephrotic syndrome, not only synthesis but also absorption of cholesterol should contribute to hypercholesterolemia.

SA-PO2861

Development of Chronic Kidney Disease Was Not Predicted by Urinary Testing or Renal Biopsy at Liver Transplantation for Hepatitis C Virus-Induced Cirrhosis David Patrick Newton, Brendan M. McGuire, Bruce A. Julian. *Medicine, University of Alabama at Birmingham, AL.*

Background: We have shown that urinalysis and quantitative proteinuria are often normal despite biopsy-proven immune-complex glomerulonephritis at the time of liver transplantation for cirrhosis due to chronic infection with hepatitis C virus (HCV) (Ann Intern Med 2006;144:735). It is uncertain whether the renal outcome for such transplant recipients can be predicted based on urinalysis or renal histology at the time of engraftment.

Methods: We reviewed the long-term clinical follow-up of 30 patients who had undergone renal biopsy at time of liver transplantation for HCV cirrhosis in 2004-2005.

Results: Four patients died within 2 years of transplantation, including 1 on dialysis at engraftment. The second patient on dialysis at transplantation now has eGFR 65 mL/min/1.73 m2. Seven patients have developed stage 4 chronic kidney disease at last follow-up. The Table compares this subgroup to the 19 other surviving patients. Microscopic hematuria was defined as >4 rbc/hpf; proteinuria was defined as dipstick 1+ or urinary protein/creatinine ratio at least 0.30.

eGFR at last follow-up	> 30 mL/min/1.73 m2	< 30 mL/min/1.73 m2
n	19	7
AT LIVER TRANSPLANTATION		
Age, yr, mean	50.3	55.7
Gender, male, n (%)	17 (89)	2 (29)
Race, Causcasian, n %	16 (84)	6 (86)
eGFR, mL/min/1.73 m2 (±SD)	62 (25)	61 (31)
HCV viral load, copies/mL, mean	537,931	598,904
Proteinuria, n (%)	4 (21)	1 (14)
Hematuria	10 (53)	2 (29)
Renal histology, n (%)		
Membranoproliferative glomerulonephritis	9 (47)	2 (29)
IgA nephropathy	3 (16)	3 (43)
Mesangioproliferative glomerulonephritis	5 (26)	1 (14)
Minor glomerular changes	2 (11)	1 (14)
AT LAST FOLLOW-UP		
Interval post transplant, mo (±SD)	68 (20)	69 (17)
Proteinuria, n (%)	10 (53)	6 (86)
Change in eGFR, % (±SD)	27 (69)	-53 (20)

Conclusions: Development of chronic kidney kidney disease was common within a relatively short interval after liver transplantation for HCV cirrhosis. However, this complication was not predicted by severity of urinary abnormalities, eGFR, or renal histological features at the time of liver transplantation.

SA-PO2862

Antiproteinuric Action of Cinacalcet in Children with Steroid-Sensitive Nephrotic Syndrome Betti Schaefer,[1] Jun Oh,[2] Franz S. Schaefer,[1] Burkhard Toenshoff,[1] Claus P. Schmitt.[1] *[1]Center for Pediatric and Adolescent Medicine, Heidelberg; [2]University Children's Hospital, Hamburg.*

Background: CaSR is expressed in human podocytes. In vitro, exposure of podocytes to the calcimimetic R-568 stabilizes the actin cytoskeleton and reduces PAN induced apoptosis. In vivo it attenuates proteinuria, podocyte and GFR loss and glomerulosclerosis. Clinical data have not yet been obtained.

Methods: 4 children (3-9 years) with idiopathic nephrotic syndrome (NS), who showed up with initial manifestation (n=2) and second relapse (n=2), respectively, and who objected to steroid therapy, were treated with the calcimimetic Cinacalcet (Cin). Initial dose was 15 mg/m²BSA/d, gradually increased by 5 mg/m²BSA according to the antiproteinuric effect. Calcium was supplemented at an initial dose of 2x500 mg/m²BSA/d.

Results: The first patient received a single dose of Cin (5 mg/m²). Protein- and albuminuria were reduced (570 to 398 and 378 to 255 g/mol crea) within 24 hours (normal range <20 and <3). In the remaining 3 patients proteinuria was 1618, 821 and 763 g/mol crea and declined by 92, 71 and 73% to a nadir of 130, 235 and 209 within 8, 5 and 3 days. Albuminuria was 1347, 648 and 746 g/mol crea and declined by 96, 73, and 76% to a nadir of 58, 172 and 178. Serum albumin was 26.7, 26.9 and 29.1 g/l and increased to a maximum of 27.4, 28.6 and 31.8. Oedema disappeared in all 3 patients within 6-13 days. Ca^{++}- and phosphate excretion did not change; serum Ca^{++} remained in the normal range. The maximal doses of Cin were 26.1, 21 and 28.3 mg/m²BSA, the treatment was well tolerated. All 3 children experienced a relapse after 10, 23 and 19 days; which was associated with an upper airway infection in 2 patients. Cin was discontinued and prednisolone therapy initiated, which induced remission in all 3 patients within 7-9 days.

Conclusions: Cinacalcet markedly reduces proteinuria in children with idiopathic NS, albeit without inducing a complete and stable remission.

SA-PO2863

Correlation between Podocyte Loss and Albuminuria in a PAN-Induced Model of Glomerulonephropathy Stefan Wawersik, Stephen O'Brien, William Weber, John N. Vassiliadis, Steven R. Ledbetter, Susan Schiavi, Cynthia M. Arbeeny. *Endocrine and Renal Sciences, Genzyme, Framingham, MA.*

Background: Developing therapeutics for glomerular disease requires testing in pre-clinical models, often relying on albuminuria as an indicator of efficacy. Podocyte loss has recently been recognized as a critical step in glomerulopathy progression, and measurement of podocyte number has consequently emerged as an additional disease endpoint. However, the correlation between podocyte loss and albuminuria has not been carefully explored.

Methods: To better understand the relationship between these two endpoints, we carried out a time-course study in a puromycin aminonucleoside (PAN) rat model of glomerular injury. Uninephrectomized rats were dosed with PAN or with PBS as a control. Urine, serum, and kidneys were collected at weeks 1-5, 7, and 12.

Results: Average ACR in PAN-treated rats peaked at 4 weeks, after which ACRs declined but remained elevated relative to PBS controls. Podocyte loss is evident in PAN-treated rats over the course of the study, measured as number of WT-1 positive nuclei per glomerular area. A 42% reduction in podocyte density was observed at week 12 relative to controls or to PAN-treated rats at week 1. The largest drop in podocyte density was observed between weeks 2 and 3, slightly preceding the peak in average ACR. When all samples are analyzed together, ACR and podocyte number show a modest but statistically significant correlation (R^2=0.158, P<0.002). However, no correlation between ACR and podocyte number is observed when early PAN-treated samples (from weeks 1-5, peak proteinuria) are considered separately, and early PAN data are statistically distinct from late PAN- (weeks 7-12) and PBS-treated samples (P<0.01). Accordingly, the ACR/podocyte loss correlation improves when early PAN-treated samples are removed (R^2=0.472, P<0.001).

Conclusions: Taken together, these data suggest that the high levels of albuminuria seen in the early weeks of toxin-induced renal injury models may not reflect long term disease progression, and that care must therefore be taken in using such models to predict the efficacy of candidate therapeutics for renal disease.

SA-PO2864

Treatment of Resistant Glomerular Diseases with ACTH Gel: A Prospective Trial Andrew S. Bomback, Pietro A. Canetta, Jai Radhakrishnan, Gerald B. Appel. *Columbia University Medical Center, New York.*

Background: Adrenocorticotropic hormone (ACTH) has shown promising results as second- and third-line therapy for idiopathic glomerular diseases resistant to conventional therapies, but the data reported to date has solely been from retrospective, observational studies.

Methods: In this prospective, open-label, pilot study (NCT01129284), 15 patients with resistant glomerular diseases were treated with ACTH gel (80 units SC twice weekly) for 6 months. Resistant membranous nephropathy (MN) was defined as failure to achieve sustained remission with at least 2 immunosuppressive regimens, resistant MCD/FSGS was defined as failure to achieve sustained remission with corticosteroids and at least 1 other immunosuppressive regimen, and resistant IgA nephropathy was defined as ≥1 g/day proteinuria despite effective renin angiotensin system blockade. Complete remission was defined as stable or improved renal function with proteinuria falling <500 mg/day. Partial remission was defined as stable or improved renal function with ≥50% reduction in proteinuria and final proteinuria 500-3500 mg/day.

Results: The study included 5 patients with resistant MN, 5 patients with resistant MCD(n=2)/FSGS(n=3), and 5 patients with resistant IgA nephropathy. Two resistant MN patients were in partial remission at the end of 6 months of therapy, although 3 achieved immunologic remission of disease (PLA2R antibody disappeared by 4 months of therapy). One patient with resistant FSGS achieved complete remission at 6 months; one patient with resistant MCD achieved a partial remission at 6 months but relapsed within 4 weeks of stopping ACTH. Three of 5 patients with resistant IgA nephropathy demonstrated ≥50% reductions in proteinuria while on ACTH, with proteinuria consistently <1 g/day by 6 months. Three of 15 patients reported significant steroid-like adverse effects with ACTH, including weight gain and hyperglycemia, prompting early termination of therapy without any signs of clinical response.

Conclusions: ACTH gel is a promising treatment for resistant glomerular diseases. This therapeutic option should be studied further in randomized, controlled trials against currently available therapies for resistant disease.

SA-PO2865

Anti-Viral Therapy in Hepatitis B-Associated Membranous Nephropathy

In O Sun, Yu Ah Hong, Hyun Gyung Kim, Hoon Suk Park, Sun Ryoung Choi, Byung Ha Chung, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim, Bumsoon Choi. *Division of Nephrology, Department of Internal Medicine, Catholic University of Korea, Seoul, Republic of Korea.*

Background: Lamivudine is effective for treatment of hepatitis B-associated membranous nephropathy (HBV-MN), but prolonged use leads to the emergence of drug-resistant variants. Also, new drugs such as entecavir, adefovir or clevudine have been introduced to treat the chronic hepatitis B, but there are few data on its efficacy in HBV-MN. We describe our experiences about treatment of HBV-MN with various anti-viral drugs.

Methods: From 1996 to 2010, biopsy-proven MN was diagnosed in 89 patients, and 10 patients had HBsAg. We investigated the clinical courses and therapeutic responses, and prognoses of patients with HBV-MN.

Results: The incidence of HBV-MN was 10.1%. The mean age of the patients was 33 years (range, 19-55), and 8 patient (80%) were men. All patients had HBsAg, hepatitis B e antigen (HBeAg) and HBV DNA. Of the patients, 6 received anti-viral drugs, and 4 were treated by supportive care. One out of four patients who received supportive care had a spontaneous remission. Out of six patients who received anti-viral drugs, four were treated by lamivudine, and the other two by entecavir. Two of the four patients treated by lamivudine achieved complete remission with seroconversion to anti-HBeAg, whereas the other two patients experienced lamivudine-resistant strains with mutations at the at the tyrosine-methionine-aspartate-aspartate (YMDD) motif of DNA polymerase, which were detected at 22 and 23 months after lamivudine treatment, respectively. Therefore adefovir was added in one patient, and lamivudine was switched to clevudine in the other patient. Afterward two patients have been kept remission state of proteinuria. Two patients who received entecavir as an initial therapy went into complete remission, and resistance to entecavir didn't occur during follow-up period. No side-effects were seen in the patients who received anti-viral drugs.

Conclusions: New nucleoside analogues such as entecavir, adefovir or clevudine could be effective at treatment of HBV-MN including lamivudine resistant strains.

SA-PO2866

Factors Influencing Treatment Choice in Idiopathic Membranous Nephropathy (IMN)

Shannon L. Mahoney,[1] Vimal K. Derebail,[1] Andrea Biddle,[1] Yichun Hu,[1] Michelle A. Hladunewich,[2] Ronald J. Falk,[1] Daniel C. Cattran,[2] Heather N. Reich,[2,3] Patrick H. Nachman.[1,3] *[1]UNC Kidney Center, Chapel Hill, NC; [2]University of Toronto, ON, Canada; [3]Contributed Equally.*

Background: The treatment of patients with IMN may include immunomodulation in patients resistant to conservative therapy alone, or perceived at high risk of progression. This study assesses the factors influencing the decision to treat with immunomodulators and the choice of treatment between cyclophosphamide (CP) and calcineurin inhibitors (CNI).

Methods: An inception cohort of 720 adults with biopsy-proven IMN (from 1976-2005) was derived from the Glomerular Disease Collaborative Network (N=328) and the Toronto Glomerulonephritis Registry (N=392). Subjects were allocated to groups based on initial treatment: no immunotherapy, CP, CNI, glucocorticoids (GC) only, or other immunosuppressant. The second treatment was considered in patients who initially received GC alone. Factors influencing decision to treat were analyzed using logistic regression, and those influencing choice of treatment by multinomial logit.

Results: Changes in choice of first therapy were observed over time. GC alone was the predominant approach until about 1994, at which time CP became the predominant choice. CNI were used in a minority of patients. Serum albumin, proteinuria, and site were significantly different between those treated (66.3%) and those not treated (33.7%).

Factors affecting decision to treat IMN

	Adjusted Odds Ratio	p-value
Site	0.45	0.001
Female	0.73	0.18
Age at biopsy (per increasing year)	0.99	0.11
Race		
-White	1	
-Other	0.86	0.57
Serum albumin <2.5 mg/dL	1.88	0.007
24 hour proteinuria (per g/day)	1.12	<0.001
eGFR (per 10 mL/min/1.73m2)	0.97	0.45
MAP (per mmHg increase)	1.00	0.72

None of the factors analyzed with regards to choice of treatment was significant.

Conclusions: Serum albumin, proteinuria, and site were the only independent determinants of the decision to treat with immunomodulators. No factors were associated with the specific choice of therapy between CP and CNI; however, the sample size of those treated was most likely too small to detect differences.

Urinary Interleukin-6 (IL-6)and Epidermal Growth Factor (EGF) as Independent Risk Factors for the Progression of Primary Chronic Glomerulonephritis (CGN)

Ilona Idasiak-Piechocka,[1] Elzbieta Pawliczak,[1] Andrzej P. Oko.[1] *[1]Nephrology, University of Medical Sciences, Poznan, Poland; [2]Nephrology, University of Medical Sciences, Poznan, Poland; [3]Nephrology, University of Medical Sciences, Poznan, Poland; [4]Nephrology, University of Medical Sciences, Poznan, Poland.*

Background: The aim of the study was to estimate whether initial urinary IL-6 and EGF excretions in patients with newly diagnosed CGN are associated with clinical course and the outcome of the disease during 4-year follow-up.

Methods: 150 Caucasian patients (114 men and 36 women) with biopsy proven primary CGN were included into the study.One day before kidney biopsy urinary excretion of IL-6 (UIL6)and EGF (UEGF)were measured using the ELISA methods (R&D System.106 patients were treated with steroids alone and in 78 patients immunosuppressive therapy was included.

Results: UIL-6 excretion was significant higher (p<0.00001)than in healthy subjects. Significant negative correlation between initial U IL-6 and eGFR was found in patients with CGN (Sr = -0.40). UIL-6 was significantly higher but UEGF excretion was significantly lower in patients with eGFR <60 ml/min/1,73m2 when compared to patients with eGFR > 60 ml/min/1,73m2. After 4-year of follow-up, patients were divided into two groups: progressors (PG) - loss of eGFR > 5ml/min/1,73m2 /year and nonprogressors (NPG) with stable kidney function (loss of eGFR < 5ml/min/1,73m2/year). UIL-6 was significantly higher in PG when compared with the NPG (p<0,0005) and control subjects. On the contrary, UEGF excretion was significantly lower in PG in comparison to NPG patients (p<0,02).

Conclusions: Logistic regression analysis of the UIL-6 and UEGF excretions and traditional risk factors for the progression of the disease (eGFR< 60ml/min/1,73m2, male gender, age > 60 years, glomerulosclerosis > 30% and interstitial fibrosis 2+) showed that the most important independent risk factors for the deterioration of renal function are initial high (>11,8 pg/mgCr) UIL-6 excretion, initial low (<15.468 pg/mgCr) UEGF excretion and male gender. The initial value of IL-6/EGF> 0.46 increased the risk of progression of the disease 7,8 times in patients with newly diagnosed primary CGN.

Clinical Outcome of Renal Primary Systemic Amyloidosis after Stem Cell Transplantation

Claire Tinel,[1] Laurent Martin,[2] Denis Caillot,[3] Jean-Michel Rebibou.[1] *[1]Nephrology, University Hospital, Dijon, France; [2]Pathology, University Hospital, Dijon, France; [3]Hematology, University Hospital, Dijon, France.*

Background: Regarding the treatment strategy of primary amyloidosis, autologous stem cell transplantation after high dose melphalan shows similar patient survival than melphalan plus dexamethasone, but little is known on the renal outcome when complete remission is achieved.

Methods: Nine patients (sex-ratio F/M=3,7; age 60±9) with biopsy-proven AL amyloidosis and renal manifestations (defined by proteinuria ≥ 0,5 g/d or nephrotic syndrome, and/or a glomerular filtration rate (GFR) ≤ 30 ml/min) were treated in our center. 8 patients received high-dose melphalan and autologous stem cell transplantation.

Results: Renal manifestations included proteinuria (n=8) (median 10 g/d [range 1,5-47]), nephrotic syndrome (n=6) and GFR ≤ 30 ml/min (n=2). Multiple myeloma was associated in 6 patients (75%), at stage II (n=5) and III (n=1) according to the International Staging System. The mean follow-up was 62 ± 19 months; 2 patients died without any hematological or renal response. Among the 6 surviving patients, 4 achieved stringent complete remission (sCR), 1 reached partial remission (PR), and 1 relapsed after 4 years (digestive tract relapse without renal involvement). The patient showing PR, reached terminal renal failure after 33 months and initiated hemodialysis. Renal response defined as a proteinuria ≤ 0,5 g/d was achieved by the 5 other patients, in a mean time of 21 months. All renal responders experienced transitory renal impairment. By month 12, the lowest kidney function was noted with a mean GFR of 35 ml/min (n=5), as compared to 76 ml/min (n=5) on diagnosis. We observed a late improvement with a mean GFR of 54 ml/min (n=4) after 6 years.

Conclusions: In primary systemic amyloidosis treated with high-dose melphalan followed by autologous stem cell transplantation, achieving complete hematologic response is associated with an excellent renal response. Our unique patient with partial remission doesn't allow us to draw conclusions on the renal prognosis in this event. Interestingly we observed worsening renal function during the 1st year, followed by a late improvement.

SA-PO2869

Membranous Nephropathy Associated with Monoclonal Immunoglobulin-M
Stephane Burtey,[1] Laurent Daniel.[2] *[1]Centre de Néphrologie et Transplantation Rénale, AP-HM, Marseille, France; [2]Service d'Anatomopathologie, AP-HM, Marseille, France.*

Background: Membranous nephropathy (MN) is the most common cause of primitive nephrotic syndrome in adults. MN is characterized by IgG and C3 deposits on urinary side of glomerular basal membrane. Recently autoantibodies against PLA2R have been described associated with idiopathic MN in 70% of the cases. It remains 30% of MN without aetiology. The aim of our work is to study the association of monoclonal gammapathy with MN.

Methods: Retrospective study of all the MN diagnosed in an universitary hospital in France. The time lapse of the study was from January 2000 to July 2010. A monoclonal gammapathy, lupus biomarkers, hepatitis B and C, and HIV serology were systematicly searched for all the patients.

Results: We identified 94 patients with MN, 11 MN were associated with lupus. In the remaining 83 patients, 58 males and 25 females of mean age 53.5 years were studied. In 7 patients we found a monoclonal gammapathy. All the 7 were IgM. In two cases, Waldenström Disease (WD) was diagnosed, in the remain 5 cases, it was concluded to a IgM MGUS. The two patients with WD were treated with success and the MN is in full remission. One patient received a Ponticelli protocol with success on MN associated with a decrease in IgM level. One patient received only rituximab without effect on MN and IgM level. The last 3 patients received supportive care and experienced partial remission. On kidney biopsy we identified IgM deposits associated with IgG and C3 deposits in 5 cases.

Conclusions: Our data suggested that monoclonal IgM could be associated with MN. Full remission of nephrotic syndrome was obtained only when level of monoclonal IgM decreased and we identified IgM deposits in the kidney, thus suggesting a relationship between the hematological disease and nephropathy. The prevalence of MGUS IgM in our cohort of MN is 6% compared to 0,5% in general population in favor of a none fortutious association between monoclonal IgM and MN.

In conclusion, monoclonal IgM could play a role in pathogenesis of MN.

SA-PO2870

Renal Involvement in Patients with Primary Myelofibrosis: Fact or Fiction?
Sandra Herrmann,[1] Samih H. Nasr,[2] Samar M. Said,[2] Nelson Leung.[1] *[1]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Department of Laboratory Medicine and Pathology, Mayo Cinic, Rochester, MN.*

Background: Some small reports suggest that primary myelofibrosis (PMF) can be associated with renal dysfunction. However, the prevalence of renal disease including glomerulopathy in PMF remains poorly defined.

Methods: Retrospective cohort analysis of all patients with PMF listed in the Mayo Clinic Myelofibrosis Database. Patients without renal function data or those who underwent stem cell transplant were excluded.

Results: Among a total of 565 patients with PMF (mean age 65±12 years, 366 men), the mean serum creatinine (Scr) at referral was 1.16±0.36 mg/dL, eGFR was <60 mL/min/1.73 in 210 patients (37%). Follow-up data were available for 383 patients, and over a mean follow-up period of 34±36 months, the average Scr increased from 1.13±0.35 to 1.17±0.6 mg/dL ($p<0.05$). Only 22 (5.7%) had a Scr ≥2 mg/dl and 5 (1.3%) had ESRD requiring hemodialysis. A total of 241 patients had complete urine analysis at the end of the follow up, and the mean proteinuria was 866±213 mg/day. Proteinuria ≥1 gr/day and ≥3 gr/day was seen in 29 (12%) and 13 (5.3%) patients, respectively. Survival data were obtained by chart review for the follow-up patients. Mortality rates were not different for patients without and with an eGFR <60 mL/min/1.73m2 from the time of the initial visit (mean follow-up time 63±50 months). However, mortality rates from the time of their last follow-up visit (mean follow-up time 29±42 months) were significantly higher for patients who sustained a decrease in eGFR ≥30 mL/min/1.73m2 from the initial to the last follow-up visit (63 vs. 38%, $p<0.01$).

Five kidney biopsies were reviewed. Myeloproliferative-neoplasm (MPN)-related glomerulopathy was the most common finding in four. One biopsy showed ATN. In two patients, the biopsies also showed extramedullary hematopoiesis.

Conclusions: This is the largest study on renal function in patients with PMF and indicates that a decline in eGFR may predict mortality. Contrary to plasma cell dyscrasias, glomerulopathy is rare in PMF and the most common histologic findings are MPN-related glomerulopathy and extramedullary hematopoiesis.

SA-PO2871

Rituximab *vs.* Calcineurin Inhibitors in Steroid Dependent Nephrotic Syndrome
Aditi Sinha, Ashima Gulati, Arvind Bagga. *All India Institute of Medical Sciences, New Delhi, India.*

Background: There are no studies comparing the efficacy of calcineurin inhibitors (CNI, cyclosporine CsA, tacrolimus Tac) & rituximab (RTX) in maintaining remission in steroid dependent nephrotic syndrome (SDNS). We report a retrospective comparison of their efficacy in SDNS.

Methods: Patients, 1-18 yr-old, with SDNS, failing therapy with ≥2 alternative agents (levamisole, cyclophosphamide, MMF) were eligible. Those receiving subsequent therapy with RTX (375 mg/m^2 IV for 2 weekly doses) or CNI (CsA 4-6 mg/kg/d; Tac 0.1-0.2 mg/kg/d) & followed ≥12 months were included. Relapses were treated with prednisone (2 mg/kg/d until remission, then tapered).

Results: 27 patients received CNI (CsA 14, Tac 13) and 10 RTX. Baseline features were similar (Table).

	Calcineurin inhibitors, N=27	Rituximab, N=10
Baseline		
Age at onset, yr	2.5 (1-7)	4.3 (1-6)
Age at therapy, yr	10.1 (4-17)	12 (8-15)
Relapses/yr	3 (1-7)	3 (1-5)
Cumulative prednisone, mg/kg/6-mo	70 (7-138)	69 (16-127)
Body mass index (BMI) SDS	1.8 (-0.6-4.3)	2.0 (0.5-3.6)
Effect of therapy		
Sustained remission at 1-yr	15 (56%)	6 (60%)
Time to first relapse, months	11 (1-35)	7 (2-32)
Relapses		
At 1-yr	1 (0-5)	0 (0-3)
At last follow up	2 (0-10)	2 (0-3)
Off prednisolone at 1-yr[$]	8 (30%)	8 (80%)
Prednisone dose, mg/kg/6-mo		
0-6 months[$]	50 (24-83)	19 (11-69)
6-12 months*	22 (2-116)	8 (0-69)
BMI SDS	1.6 (-0.3-4.2)	1.4 (0.2-2.7)

*P<0.05; [$]P<0.01

The median follow up was 26 (range 12-50) months in CNI & 14 (12-36) months in RTX groups. Patients treated with RTX had a shorter duration of remission (P=0.3). Relapse rates & proportions of patients with sustained remission & frequent relapses were similar. Patients in the RTX group received significantly lower doses of steroids in the following year. Adverse effects were infusion reactions (4); nephrotoxicity (5) & cosmetic effects (11).

Conclusions: Therapy with RTX was as effective as CNI in reducing relapses in patients with difficult SDNS. Therapy with the former resulted in significant steroid sparing, but the duration of sustained remission was shorter. Prospective studies are required to compare the efficacy of these agents and examine interventions that sustain the effect of RTX therapy.

Novel Treatment of Steroid Resistant Nephrotic Syndrome in Children with Oral Galactose
Kristen Sgambat, Asha Moudgil. *Nephrology, Childrens National, Washington, DC.*

Background: Children with steroid resistant nephrotic syndrome(SRNS)typically have FSGS, but may rarely have minimal change histology. These patients are resistant to immunosuppressive(IS) drugs with poor long-term outcome. Immune mediated FSGS has been associated with the presence of a circulating permeability factor(FSPF), thought to increase glomerular permeability to albumin leading to proteinuria and focal sclerosis. Galactose binds to FSPF in vitro, but the effect in vivo is unknown. We prospectively investigated the effect of oral galactose on change in FSPF and clinical response in children with SRNS.

Methods: 52 children with primary SRNS or biopsy proven FSGS were screened. Children meeting inclusion criteria{nephrotic proteinuria(UPC above 2) despite IS therapy and ACE/ARB more than 12 weeks,stable Cr and estimated GFR above 60 ml/min/1.73m2} were tested for FSPF. Those with positive FSPF were treated with oral galactose(0.2g/kg/dose BID)for 16 weeks. Pre and post treatment FSPF levels, UPC, serum albumin(sAlb),and eGFR were assessed.

Results: FSPF was tested in 6 children(8.8±3.8 years old; 3 male,3 female). Of these,5 had FSGS (1 with post transplant recurrence) and 1 had minimal change. Patients with FSGS had positive FSPF, whereas patient with MCNS was negative for FSPF. Three children with baseline eGFR 93.9±26.7 completed 16 weeks of therapy without any side effects. These children were resistant to previous treatments with tacrolimus (3), ACE (2), rituximab(2), cyclosporine(1), and MMF(1). Time from onset of NS to FSPF was 31±8.7 months. Post-therapy, FSPF decreased from 0.74±0.16 to 0.35 + 0.21 and became negative in 2 of 3 children. UPC did not improve after therapy (12.6±9.4 pre and 27.4±31.9 post-therapy). Pre and post treatment eGFR (93.9±26.7 versus 89.4±50.7) and sAlb (2.4±1.3 versus 2.2±0.6) remained unchanged. One child with post-transplant recurrent FSGS entered chronic dialysis at the end of therapy.

Conclusions: Oral galactose was well tolerated in 3 children with SRNS and was able to decrease FSPF to negative range in 2 children. However, no clinical improvement was observed. It remains to be determined whether galactose will be clinically beneficial if used early in the course of SRNS.

Columbia FSGS Classification Predicts Renal Outcome
Aline Lázara Resende,[1] Silvia M. Titan,[1] Leonardo Abreu Testagrossa,[2] Vinícius Colares,[1] Denise Maria Avancini Costa Malheiros,[2] Rui Toledo Barros,[1] Viktoria Woronik.[1] *[1]Nephrology Division, Hospital das Clínicas, Sao Paulo University Medical School, Sao Paulo, Brazil; [2]Pathology Division, Hospital das Clínicas, Sao Paulo University Medical School, Sao Paulo, Brazil.*

Background: Columbia classification (CC)has been proposed as a predictor of worse renal outcome in FSGS. We have analyzed clinico-laboratorial features and renal survival of Brazilian patients according to CC.

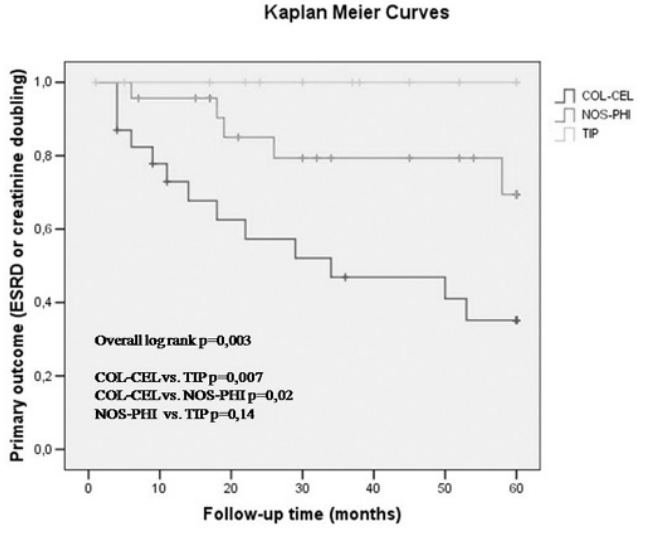
Methods: Inclusion criteria were primary FSGS from 99-09, no dialysis at presentation, and follow-up time >4m. Of 80 patients, 57 had available material for CC reclassification. Data was retrospectively collected. Primary outcome (PO) was defined as ESRD or creatinine doubling.

Results: Of 57 cases, 23 (40,3%) had collapsing or cellular (COL-CEL), 23 (40,3%) had peri-hilar or not otherwise specified (NOS-PHI) and 11 (19,4%) had tip lesion variants (TIP). Baseline variables were similar between groups. The PO was significantly related to age, renal fibrosis, non-response to treatment and to CC. Cox regression showed that CC was significantly associated with PO, even after adjustments for age and fibrosis.

Logistic regression models on the risk of ESRD or creatinine doubling.

	HR	Lower 95%CI	Upper 95%CI	p
Univariate				
Age	0,95	0,91	1,00	0,05
Renal fibrosis	2,54	1,08	5,93	0,03
Non-response at 4th month	5,10	1,66	15,66	0,004
CC (TIP vs. NOS-PHI vs. COL-CEL)	3,48	1,48	8,18	0,004
CC (COL-CEL vs. OTHER)	3,81	1,44	10,04	0,01
CC (non-TIP vs. TIP)	28,68	0,19	4260,27	0,19
Multivariate				
CC (TIP vs. NOS-PHI vs. COL-CEL)	3,20	1,36	7,54	0,01
Age	0,96	0,91	1,01	0,08
CC (TIP vs. NOS-PHI vs. COL-CEL)	3,00	1,25	7,24	0,01
Renal fibrosis	0,01	0,69	4,59	0,24
CC (TIP vs. NOS-PHI vs. COL-CEL)	2,64	1,07	6,52	0,04
Age	0,96	0,92	1,01	0,09
Renal fibrosis	1,79	0,67	4,78	0,25

Kaplan-Meier curves showed that the COL-CEL group had a worse outcome.



Conclusions: CC was an independent predictor of renal outcome in our study.

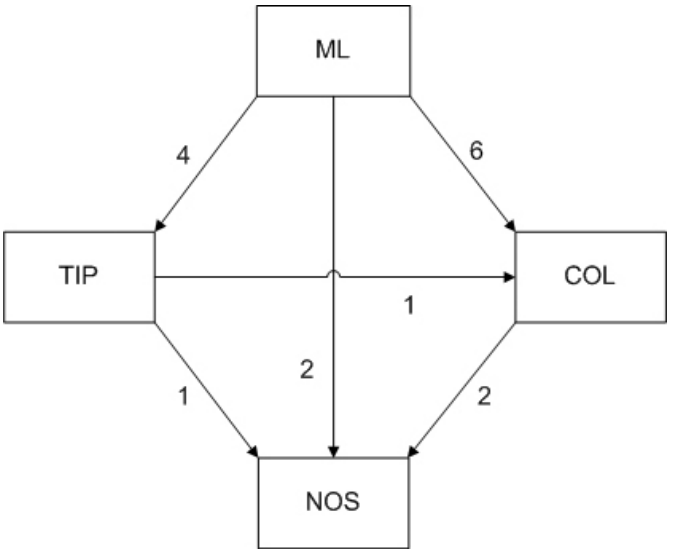
SA-PO2874

Evolution and Concordance of Focal Segmental Glomerulosclerosis Histologic Lesions in Native Kidney and Renal Allograft Biopsies Rutger J. Maas,[1] Eric Steenbergen,[2] Bart Smeets,[2] Elisabeth Cornelissen,[3] Jeroen Deegens,[1] Jack F. Wetzels.[1] *[1]Nephrology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [2]Pathology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [3]Pediatric Nephrology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.*

Background: The Columbia classification of FSGS defines five mutually exclusive histologic variants. It is unclear if these variants reflect pathogenetic differences. We questioned if the classification of FSGS remains unchanged in an individual patient. Therefore, we compared repeated biopsies, performed in the native kidney as well as in the allograft during recurrence after transplantation.

Methods: We identified 30 patients with a biopsy proven diagnosis of FSGS in the native kidney and FSGS recurrence in a renal graft. Twelve patients were excluded because slides from only one kidney biopsy were available. Biopsy specimens from native (n=22) and transplant kidneys (n=45) of 18 patients were reviewed according to the Columbia classification. Samples without FSGS lesions were classified as minimal lesions (ML).

Results: Median age at FSGS diagnosis of these patients was 15 (range 4-57) years. We evaluated 25 repeated biopsies (8 native kidney, 17 transplant kidney). A change in variant was observed in 16 (64%, figure1). Fourteen patients with known native kidney histology developed a recurrent FSGS in 18 transplants. In the majority of patients the first allograft biopsy showed a ML pattern. We did not find any correlation between the variant in the native kidney and the first or second allograft.



Conclusions: In the majority of patients, there was no concordance in FSGS variants between repeated biopsies or between native and transplant kidney biopsies. These data suggest that the morphological variants must reflect different stages in the evolution of lesions

SA-PO2875

Arterial Stiffness in Childhood Nephrotic Syndrome Christine Sethna, Michael Gottesman, Rachel Frank, Lulette Infante, Suzanne M. Vento, Howard Trachtman. *Division of Pediatric Nephrology, Cohen Children's Medical Center of New York, New Hyde Park, NY.*

Background: Nephrotic syndrome (NS) may place pediatric patients at increased risk for cardiovascular disease (CVD). Arterial stiffness is an independent risk factor for CVD and is associated with proteinuria and hyperlipidemia; however, the relationship between arterial stiffness and childhood NS has not been explored. The objective was to investigate arterial stiffness measured by pulse wave velocity (PWV) and to test the hypothesis that children with NS have higher PWV than healthy controls.

Methods: Carotid-radial PWV was measured using applanation tonometry (AtCor Medical) in 35 subjects with NS and 25 healthy controls. Variables associated with increased pulse wave velocity in subjects with NS were evaluated by Pearson correlation and multiple regression analysis.

Results: NS subjects included 9 F/26 M, age 13.1 ± 3.9 yr, range 6-18 yr. Control subjects consisted of 5 F/20 M, age 12.6 ± 4.0 yr, range 6-18 yr. Age and gender did not differ between groups. NS diagnoses included: 17 MCNS, 11 FSGS, 2 MPGN and 3 Membranous. Median (range) time since diagnosis of NS was 2.3 (0.1-16) yr. Fourteen subjects (40%) had urine protein/creatinine >0.2; the rest were in remission. NS subjects had greater BMI ($p < 0.01$), systolic BP ($p < 0.01$) and diastolic BP ($p < 0.01$) compared to controls. PWV did not significantly differ between NS and controls (7.86 ± 1.47 vs. 7.54 ± 1.62 ms, $p = 0.44$) with no alteration after adjustment for age, gender, race and BMI. PWV in NS subjects positively correlated with age ($r = 0.47$, $p < 0.01$), height ($r = 0.44$, $p < 0.01$), weight ($r = 0.49$, $p < 0.01$), BMI ($r = 0.37$, $p = 0.03$), systolic BP ($r = 0.56$, $p < 0.001$), diastolic BP ($r = 0.5$, $p < 0.01$), and diagnosis of FSGS vs other NS ($r = 0.37$, $p = 0.03$). Cholesterol, proteinuria, time since diagnosis and medications were not associated with PWV.

Conclusions: Contrary to expectation, pediatric patients with NS do not have increased arterial stiffness related to its key features (proteinuria, hypercholesterolemia, treatment). However, the diagnosis of FSGS is associated with higher PWV and may place these patients at increased risk for CVD.

SA-PO2876

Glucocorticoids Alone or with Cyclosporine Is Effective in Korean Patients with Idiopathic Membranous Nephropathy Shin-Wook Kang, Dong Ho Shin, Mi Jung Lee, Seung Jun Kim, Dong Eun Yoo, Hyung Jung Oh, Seung Hyeok Han, Tae-Hyun Yoo. *Dept. of Int. Medicine, College of Medicine, BK21, SBSI, Yonsei Univ., Seoul, Korea.*

Background: Idiopathic membranous nephropathy(IMN) is a frequent cause of nephrotic syndrome(NS) in adults. An accumulating evidence has suggested that combined regimen of glucocorticoids and alkylating agents is beneficial to treat IMN in Western patients. However, glucocorticoids alone or with cyclosporine(CsA) have been reported to be effective for treating IMN in some populations. This study was undertaken to investigate the effects of glucocorticoids alone or with CsA treatment on proteinuria and renal function in Korean IMN.

Methods: A total of 179 Korean NS patients with IMN were included. The primary endpoint was regarded as complete remission of proteinuria(CR), and the secondary endpoints as a decline in eGFR>50% or initiation of dialysis. Cox regression analysis was

conducted to identify the independent power of glucocorticoids alone or with CsA treatment in reaching the primary endpoint, and Kaplan-Meier curves were constructed to compare the difference in attaining the primary and secondary endpoints between groups.

Results: Among the patients, 122 patients(68.2%) were treated with glucocorticoids alone or with CsA, and 57(31.8%) did not receive immunosuppressant treatment. Serum albumin concentrations were significantly lower, while serum cholesterol levels were significantly higher in the treatment group(P<0.05). During the mean follow-up duration of 58 months, CR occurred more frequently in the treatment group compared to the non-treatment group(72.1 vs. 40.4%, P<0.01). In multivariate analysis adjusted for age, gender, blood pressure, initial proteinuria, and serum creatinine levels, the probability of reaching the primary endpoint was significantly higher in the treatment group(OR, 2.75; 95% CI, 1.68-4.49; P<0.01). Kaplan-Meier analysis also revealed that CR rates and event-free rates for the secondary endpoints were significantly higher in the treatment group(P<0.05).

Conclusions: This study shows that glucocorticoids alone or with CsA were effective in inducing CR and preserving renal function in Korean IMN patients.

A Steroid-Sparing Therapeutic Option for Minimal Change Disease in Adults: An Initial Report of Tacrolimus Combined with Low-Dose Corticosteroid Therapeutic Trial Yong Chul Kim,[1,2,3] Ho Seok Koo,[2,4] Hajeong Lee,[1,2] Suhnggwon Kim,[1,2] Taewoo Lee,[2,3,5] Ho Jun Chin.[1,2] *[1]Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [3]Biomedical Sciences, Seoul National University Graduate School, Seoul, Republic of Korea; [4]Internal Medicine, Inje University College of Medicine, Republic of Korea; [5]UNC Kidney Center, Unitversity of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Minimal change disease (MCD) in adults not only takes longer to remit compared to children, but the response to high-dose corticosteroid treatment also tends to be less predictable with frequent relapse and drug-dependency. Avoiding prolonged exposure to steroids is challenging in practice. We conducted a single-arm, prospective, interventional study to examine the efficacy and safety of tacrolimus plus low-dose corticosteroid regimen for adult MCD with steroid dependent (SD), frequent-relapsing (FR), and/or intolerance to steroids.

Methods: Eighteen patients (mean age ± SD, 39.1 ± 19.3) with renal biopsy-proven MCD (mean serum albumin, 2.25 g/dL; mean urine protein-creatinine ratio (UPCR), 10.46) were enrolled. Tacrolimus was given orally at a dose of 0.03 to 0.05 mg/kg/day (target trough level, 5-10 ng/dL) for 16 weeks. Oral prednisolone was also simultaneously prescribed at a dose of 0.3 to 0.5 mg/kg/day with slow tapering.

Results: Proteinuria was significantly and consecutively reduced starting from the first week (median [range] of UPCR; 10.45 [3.1-18.4] at baseline, 3.07 [0.03-13.82] at 1 week, 0.14 [0.02-8.28] at 2 weeks; *P*<0.01). Complete remissions (UPCR < 0.3) were attained in 16 out of 17 patients after 16 weeks of the treatment and mean time to complete remission was 3.5 weeks (range, 1 to 16 weeks). One patient dropped out of the study. No significant adverse events were observed.

Conclusions: The therapeutic effect of tacrolimus plus low-dose corticosteroid was shown early with an excellent response rate. This regimen can be considered as a therapeutic option for patients with MCD showing intolerance and/ or resistance to standard corticosteroid therapy.

SA-PO2878

Focal and Segmental Glomerulosclerosis: An Emerging Glomerulophaty in Jalisco, Mexico. Clinical and Histological Presentation Karina Renoirte, Xochitl Guerrero, Maria Concepcion Oseguera-Vizcaino, Guillermo G. Garcia. *Nephrology, Hospital Civil de Guadalajara, Guadalajara, Jalisco, Mexico.*

Background: Focal segmental glomerulosclerosis (FSGS) is found in 7-15% of patients undergoing evaluation for proteinuria, and is the 3rd cause of nephrotic syndrome wordlwide.There is scare data on this pathology in Mexico. We estimated its frequency, clinical and histological presentation, response to prednisone in patients from Jalisco, Mexico.

Methods: We reviewed 364 native kidney biopsies performed at Hospital Civil, a tertiary-care facility between Jan 2000 and March 2011. Age, gender, BP, degree of proteinuria, hematuria, eGFR, clinical and histological presentation, response to PDN and renal survival were recorded. Renal survive was defined as the doubling of Scr or the start of RRT. Complete remission (CR) was defined as urine proteine < 0.2 g/d; partial remission (PR) as < 3.4g/d but >0.2g/d or < 50% of initial value; steroid resistant (SR) those cases that didn't respond.

Results: FSGS was found in 164(45%) of the cases, followed by Lupus (16%) and membranous (11%) nephropaties. 111 record were available for review. Mean follow up was 27 months (range 1-90). Average glomeruli per biopsy for non-nephrotic patients was 12, range 5-47, and for nephrotic patients 9, range 3-26, p=0.004. No significant difference was observed between both groups for glomerular lesion (tip lesion, podocitopathy, nodular or collapsing type) nor chronicity index.

Clinical characteristics and and renal survival

N	No Nephrotic, N=55	Nephrotic, N= 56	p
Age(y)	25.2±9.3	271±3.7	0.04
Male	29(53%)	31(55%)	0.39
HTN	14(25%)	24(43%)	0.02
eGFR ml/min/1.73m2	74.49±32.1	74.12±41.0	0.95
Proteinuria(%)	1.44±0.75	6.38±3.88	0.0000001
Hematuria(%)	6(11%)	20(36%)	0.0003
Prednisone Rx (%)	46(84%)	56(100%)	0.03
CR(%)	21(41%)	15(28%)	0.08
PR(%)	13(25%)	19(35%)	0.13
SR(%)	14(27%)	17(31%)	0.3
Doubling Scr(%)	4(7%)	9(16%)	0.08

Conclusions: FSGS emergerged as the most most common lesion responsible of proteinuria in native kidney biopsies. Histological lesion, response to prednisone and renal survival did'nt differ among non-nephrotic and nephrotic patients, and is similar as reported in other series. HTN and hematuria were more common in nephrotic patients.

Urinary Excretion of Th1, Th2 and Th17 Cytokines in Idiopathic Focal Segmental Glomerulosclerosis. Preliminary Results from a Single Center Maria Stangou, Michael Spartalis, Aikaterini A. Papagianni, Dimitrios Moisiadis, Helen Rizopoulou, George Efstratiades, Demitrios Memmos. *Department of Nephrology, Aristotle University of Thessaloniki, Hippokration General Hospital, Thessaloniki, Greece.*

Background: Idiopathic Focal Segmental Glomerusclerosis (FSGS) usually leads to end stage renal disease. Cytokines excreted in the urine may represent immunological mechanisms and predict response to treatment.

Methods: First morning urine samples, collected at day of renal biopsy from 20 FSGS patients [M/F 15/5 age 43.4yrs (16-75)], and 10 healthy controls, were used to detect IL-1β, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12, IL-13, IL-17, INF-γ, G-CSF, GM-CSF, MCP-1, MIP-1B, TNF-β, by a multiplex cytokine assay. Histological findings evaluated were: percentage of global sclerosis, mesangial hypercellularity, interstitial infiltration and tubular atrophy. Renal function and degree of proteinuria were estimated at the day of renal biopsy and at the end of follow up.

Results: FSGS patients, comparing to controls had increased urinary levels of IL-1B (0.02±0.04 vs. 0.008±0.004fg/dl, p=0.05), IL-5 (0.02±0.02 vs. 0.01±0.004fg/dl, p=0.05) IL-12 (0.08±0.07 vs. 0.04±0.01fg/dl, p=0.05) GM-CSF (4.9±9 vs. 0.3±0.7ag/dl, p=0.03), and MCP-1 (1.2±0.9 vs. 0.2±0.2fg/dl, p<0.0001). During follow up, (68.4±40.5months), renal function deteriorated (Screat increased from 1.9±0.9 to 5±4.1mg/dl, p=0.009) and proteinuria reduced Ualb from 5±3.2 to 1.3±1.6g/24hr, p=0.01.

Cytokines which showed significant correlations with histology were mainly produced by Th2 cells. Global sclerosis correlated with: IL-10 (r=0.6, p=0.009), IL-13 (r=0.5, p=0.03) and TNF-beta (r=0.5, p=0.03). Degree of mesangial hypercelullarity had negative correlation with IL-4(r=-0.6, p=0.01), IL-5 (r=-0.6, p=0.03), IL-10 (r=-0.7, p=0.002) and GM-CSF(r=-0.5, 0.04). Patients who did not respond to treatment and progressed to ESRD had increased IL-6 (0.13±0.06 vs. 0.07±0.04fg/dl, p=0.05), MCP-1(1.7±0.9 vs. 0.9±0.8fg/dl, p=0.02) and reduced IL-17 0.03±0.03 vs. 0.05±0.1fg/dl).

Conclusions: Th2 cytokines seem to participate to the progression of histological lesions in FSGS and their urinary levels may predict disease outcome.

A Retrospective Study of Adult-Onset Minimal Change Nephrotic Syndrome Rutger J. Maas, Jeroen Deegens, Jack F. Wetzels. *Nephrology, Radboud University Nijmegen Medical Center (on behalf of the study group), Nijmegen, Netherlands.*

Background: Few studies have addressed the clinical course of adult-onset minimal change nephrotic syndrome (MCNS)

Methods: We retrospectively studied the clinical characteristics, treatment response and outcome of 89 patients with adult-onset MCNS treated since 1985 in eight Dutch hospitals. Median follow-up was 5.0 years (range 0.3-25.7 years)

Results: Baseline characteristics are shown in the table. Acute renal failure with need for dialysis occurred in five patients at presentation. Twelve patients (13%) achieved a complete remission without immunosuppressive therapy after a median of 126 days (range 15-748 days). Seventy-two patients (81%) received initial high-dose corticosteroids (CS), and five cyclophosphamide. In general, tapering of CS was started 2 weeks after attaining partial remission. Total treatment duration averaged 277 days. With initial CS treatment, 61 patients (85%) achieved a complete remission after a median of 42 days (range 7-393 days), 6 (8%) achieved a partial remission after 46 days (range 12-111 days), 4 (4%) did not achieve a remission and 1 died during acute renal failure. All four patients who did not reach a remission on initial CS, ultimately reached a complete remission after additional immunosuppression. Overall, 34% of CS treated patients had persistent remission, relapses

occurred in 66%, median number of treated relapses was 2 (range 1-14).

Conclusions: Acute renal failure is a serious complication of adult-onset MCNS. Long-term outcome is good. Spontaneous remission rate is high. CS treatment results in complete remission in the majority of patients.

Characteristics at onset (mean ± SD)

Clinical characteristics (n=89)	
Age (yr)	48.1 ± 17.5
Gender (male/female)	38/51
Serum creatinine (micromol/l)	101 ± 68
eGFR by modified MDRD (ml/min per 1.73 m2)	79 ± 31
Serum albumin (g/l) (n=88)	19.2 ± 6.6
Urine protein (g/d) (n=84)	10.4 ± 5.3

Comparative Response of inmunosuppresive Treatment on Proteinuria in Adults with Primary Focal and Segmental Glomeruloesclerosis Diana Elvia Ceja Villanueva. *Nephrology and Hemodialysis, IMSS, D.F., Mexico.*

Background: The objective was to determine the difference on proteinuria in patients with GSFS treated with cyclophosphamide, mycophenolate mofetil or cyclosporine at 12 and 24 weeks of tretament, reduction according to treatment response and improvement of serum albumin.

Methods: Retrospective clinical study conducted in the Nephrology departament of the Specialty Hospital Raza, IMSS. We analyzed 58 cases of patients registered with FSGS in a period of five years. The cases were divided into three different groups depending on the treatment received. Ciclophosphamide, mycophenolate mofetil or cyclosporine. Albumin and albuminuria were compared to 12 and 24 weeks of treatment, and response to treatment as partial, full or no response.

characteristics of the cases studied

feature	cyclophospamide	mycophenolate mofetil	cyclosporine	value P
Male	12	8	8	
female	12	10	8	
interstitial fibrosis, %	23	32	24	
Tubular atrophy, %	21	19	18	
serum albumin, mg/dl	3.8	3.2	3.6	0.031
serum creatinine, mg/dl	1.47	1.25	1.19	
baseline albuminuria g/L	6.31	7.13	5.43	
albuminuria 12 weeks, g/L	3.59	5.45	4.52	0.013
albuminuria 24 weeks, g/L	3.67	4.93	3.34	0.090
complete response 12 weeks, %	3/24 (12.5)	1/18 (5.5)	1/16 (6.2)	
complete response 24 weeks, %	5/24 (20.8)	0/18 (0.0)	1/16 (6.2)	

The data are presented in number,% and standard deviation,P value .05 with nonparametric Kruskal-Wallis

Results: Significant difference in the different groups of treatment on albuminuria at 12 weeks of treatment (p=031) y improvement of serum albumin (p=013). In the analysis between groups showed significant difference with a value of P= .005 in reducing albuminuria at 12 weeks and improvement of serum albumin, P=.009 in CFA group compared with MMF. Were not significant when compared with the CSA group.

Conclusions: CFA reduces albuminuria no statistical difference in the CsA group, improved both serum albumin, MMF group does not improve the amount of serum albumin compared with CFA and CsA. Mycophenolato mofetil group reported minimal partial response without achieving complete remission.

Interstitial Nephritis Is the Commonest Renal Pathology in HIV Infected Patients in West London Jeremy B. Levy,[1] Heather Isenman,[1] H. Terence Cook,[1] Rachael Jones.[2] *[1]Imperial College Renal & Transplant Centre, Imperial College NHS Trust, London, United Kingdom; [2]Dept of HIV, Chelsea & Westminster NHS Foundation Trust, United Kingdom.*

Background: The survival of patients with HIV has been transformed by highly active anti-retroviral therapy (HAART): patients survive longer, develop non-HIV related chronic disease, and are exposed to potentially toxic therapies.

Methods: We retrospectively reviewed the data on all patients with HIV in West London who had a renal biopsy over the last 12 years.

Results: 39 patients had a renal biopsy between 1998 & 2010 (10 female, 29 male; mean age 44). Mean creatinine at presentation was 3.4 mg/dL (sd 3.6). Mean time from diagnosis of HIV to renal biopsy was 8.6 years but 9 patients presented with renal disease as the indicator illness of HIV (diagnoses HIV associated nephropathy (HIVAN; 2), tubulo-interstitial nephritis (TIN; 4), immune complex nephritis (2), advanced scarring (1)). The most common diagnosis overall was acute TIN: 8 patients (21%) as primary diagnosis and 5 (13%) as a major but probably secondary feature. 92% of patients with TIN were taking either AZT or abacavir and mean creatinine was 3.4 mg/dL. 3/13 required dialysis but the remainder recovered renal function with steroids and change of ART. Acute tubular damage was the 2nd commonest finding (6 patients) 7-25 years after HIV diagnosis, all with controlled HIV on ART. Mean creatinine 6.4 mg/dL, 1 required acute dialysis and all recovered renal function. All were taking protease inhibitors and 3/6 tenofovir. HIVAN was uncommon and only seen in 5 patients (13%): all black, mean creatinine 4.5 mg/dL with heavy proteinuria, all uncontrolled HIV with viral loads > 50. None recovered renal function. Other renal diagnoses included IgA, immune complex GN, FSGS, membranous, advanced scarring, focal necrotising GN.

Conclusions: Renal biopsy findings in HIV are very variable with important prognostic features: in West London acute TIN and tubular damage are the commonest findings mostly related to drug toxicity and with a good outcome. There may be an association of AZT & abacavir with TIN, and PIs with ATN. HIVAN is rare in W London and has a poor outcome. Other glomerular diseases are uncommon.

Time-Average Proteinuria >2g/day as a Valid Predictor of Worse Renal Outcome in Idiopathic Membranous Nephropathy Masahiro Eriguchi, Toshiaki Nakano, Masatomo Taniguchi, Kazuhiko Tsuruya. *Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

Background: The benefit of achieving a partial remission of proteinuria has not been well described with idiopathic membranous nephropathy (IMN). To assess the partial remission associated with good renal prognosis and establish its prognostic value, we examined the effects of sustained exposure to proteinuria in patients with IMN.

Methods: We studied consecutive 61 patients with biopsy-proven IMN. Baseline data were collected at the time of renal biopsy, and follow-up data (blood pressure, proteinuria, serum creatinine (S-Cr) and total cholesterol) were collected every 6 months and used as time-averaged models. Linear regression analysis was used to determine independent predictors of the rate of glomerular filtration rate (GFR) decline. Cox proportional hazards model was used to evaluate the influence of the time-average proteinuria (TA-P) on the occurrence of renal end-points (EP; exceeding 1.5-fold of the baseline S-Cr level). The subjects were divided into 4 categories according to TA-P (<1 g/d; 1-2 g/d; 2-3.5 g/d; >3.5 g/d), and the rate of GFR decline and renal EP were analyzed among the 4 categories.

Results: With a mean observation period of 7.1 years, 47 patients (77%) achieved <1 g/d of proteinuria. At the last observation, GFR declined at -0.32 ± 0.52 mL/min/1.73m^2/mo overall, 13 patients (21%) had reached renal EP and 5 patients (8%) had reached renal death. Multivariate linear regression analysis and Cox proportional hazards model revealed that TA-P was the most important predictor of the rate of GFR decline and renal EP. When corrected for other parameters with analysis of covariance, the rate of GFR decline differed significantly among the 4 categories of TA-P, and the difference in rate of decline occurred between the 1-2 and 2-3.5 g/d of TA-P. Having <1 g/d of TA-P was similar to 1-2 g/d, but >2 g/d of TA-P was associated with worse renal outcome.

Conclusions: Sustained proteinuria >2 g/d was the strongest predictor of the progression of renal disease in IMN, and the treatment goal of proteinuria <2 g/d is considered to be valid as the partial remission.

The Treatment of Hepatitis B Virus-Associated Nephritis with Variation or Refratory to Lamivudine Yongze Zhuang, Xiaorong Zhong. *Dept of Nephrology, Fuzhou General Hospital of Nanjing Command of PLA, Fuzhou, Fujian, China.*

Background: Hepatitis B virus-Associated nephropathy(HBV-GN) is a common secondary glomerulonephritis in China. Lamivudine is often used to treat patients with HBV-GN, but the effect of lamivudine is not found in a few patients.The treantment of Hepatitis B virus-Associated nephropathy with variation or refractory to lamivudine is very difficult.

Methods: 9 cases with Hepatitis B virus-Associated nephropathy had variation or refractory to lamivudine and high level of serum HBV-DNA(≥1.0x10^{5}copy/ml).The quantitation of proteinuria was more than 1.5g/d after treatment of lamivudine.Those patients were treated with entecavir(0.5mg/d).The other drugs ,which were used during the treatment of lamivudine, were continuously used(ACEI or ARB) or stopped(Tripterygium wilfordii).The therapeutic effect of entecavir and the level of serum HBV-DNA were observed during the follow-up time.

Results: Nephrotic syndorme(NS) was found in 7 cases and proteinuria combined with microscopic heamaturia in 2 cases. Among 9 cases, membranous nephropathy was in 3 cases, mesangial proliferative nephritis in 3 cases, membranoproliferative nephritis, IgA nephropathy and focal segmental mesangial proliferative nephritis in 1 case respectively.The patients were treated with lamivudine for 14.1±10.3 months.The corticosteroids was used in 6 caess.After the treatment of lamivudine, partial remission(PR) appeared in 5 cases and no responsive(NR) in 4 cases(NS in the patients).But, after the patients were treated with entecavir for 12 months, complete remisson(CR) was found in 6 cases, PR in 2 cases and NR in 1 case.Among 7 cases whose serum HBV-DNA were detected, the level of serum HBV-DNA decreased apparently and was normal in 5 cases.After follow-up for between 19 months and 27 months, CR was found in 7 cases and NR in 2 cases.The side effects of entecavir were not found during the follow-up.

Conclusions: Entecavir combined with the other renal protection drugs is a safe and effective scheme for the treatmenr of Hepatitis B virus-Associated nephropathy with variation or refractory to lamivudine and may be used continuously for no less than 18 months.

SA-PO2885

Treatment with Mizoribine Followed by Low-Dose Prednisone Is Highly Effective in Patients with Idiopathic Membranous Nephropathy and Nephrotic Syndrome Yoshihiro Matsumoto, Yasushi Shimada, Youichi Nojima. *Nephrology and Dialysis, Shizuoka City Hospital, Shizuoka, Japan.*

Background: Idiopathic membranous nephropathy (IMN) patients with persistent high-grade proteinuria are at the highest risk of developing end-stage renal failure. We have previously reported the effects of treatment with mizoribine followed by low-dose prednisone in 4 IMN and nephrotic syndrome patients. The purpose of this study was to elucidate these results by using a larger study group consisting of patients who have been recently diagnosed with IMN and nephrotic syndrome.

Methods: We selected 12 consecutive patients who visited our hospital from 2005 to 2010 and were diagnosed with IMN and nephrotic syndrome. After 2 months of observation without any other treatment, mizoribine was started at a dose of 150 mg/day. After 2 months of mizoribine monotherapy, 20 mg/day prednisone was combined with 150 mg/day mizoribine. After that, the dosage of prednisone and/or mizoribine was tapered gradually according to the urinary protein-to-creatinine ratio (P/C), which is closely correlated to the daily protein excretion. After initiating combination therapy, the urinary P/C and the levels of serum albumin were measured on a monthly basis for 12 months.
