Results: The mean plasma Kl concentrations were 551.0±177.8 in the ND , 400.3±140.7 in the HD and 577.3±243.6 pg/ml in the PD patients, and it was significantly lower in the HD than in the ND and PD patients. There were significant differences in serum FGF-23 levels among the ND, HD and PD patients (p<0.05), and the serum FGF-23 levels were highest in the PD patients and lowest in the ND patients. In the ND patients, plasma Kl showed significantly negative correlations with Cr (r =-0.244, p=0.043), P (r=-0.273, p=0.023) and Alb (r=-0.266, p=0.027), while serum FGF-23 showed significantly positive correlations with Cr (r=0.498, p=0.001), P (r=0.398, p=0.010) and i PTH (r=0.397, p=0.010). In the HD patients, plasma Kl significantly positively correlated with Cr (r=0.474. p=0.017), while serum FGF-23 significantly positively correlated with Ca (r=0.543, p=0.009) and P (r=0.478, p=0.024) In the PD patients, plasma Kl significantly positively correlated with Ca (r=0.569, p=0.021), but serum FGF-23 did not. Serum FGF-23 negatively correlated with Alb in both the HD (r=-0.464, p=0.030) and the PD (r= -0.530, p=0.035) patients, but plasma Kl did not. Plasma Kl did not correlate with either serum FGF-23 or i PTH among any groups.

Conclusions: In conclusion, the contributing factors to plasma Kl concentration are different from those to serum FGF-23 level in patients with CRF.

FR-PO1210

Effects of Frequent Hemodialysis on Measures of Chronic Kidney Disease Mineral and Bone Disorder (CKD-MBD): The Frequent Hemodialysis Network Daily and Nocturnal Trials John T. Daugirdas,[1] Glenn M. Chertow,[2] Andreas Pierratos,[3] Juan Carlos Ayus,[4] Tom H. Greene,[5] Brent W. Miller,[6] Sam H. James,[7] Gerald Schulman,[8] Alan S. Kliger,[9] Cynthia A. Kendrick,[10] The FHN Trial Group.[11] *[1]U Illinois Chicago; [2]Stanford U; [3]U Toronto; [4]Renal Consultants of Houston; [5]U Utah; [6]Washington U St. Louis; [7]U California San Francisco; [8]Vanderbilt U; [9]Yale U; [10]Cleveland Clinic; [11]NIDDK, NIH.*

Background: Phosphorus is believed to be better controlled with more frequent hemodialysis.

Methods: In the Frequent Hemodialysis Network (FHN) Daily and Nocturnal Trials, we examined the effects (month 12 vs. baseline) of treatment assignment to 6/week dialysis on predialysis serum phosphorus (P) and on prescribed dose of phosphorus binder expressed as an equivalent phosphorus binder dose (EPBD, g/day) where phosphorus-binding equivalence was calculated on a weight basis relative to calcium carbonate.

Results: In the Daily Trial (n=245), where the prescribed 6/week session length was 1.5-2.75 hours, assignment to frequent hemodialysis was associated with a 0.55 mg/dL decrease in mean serum P relative to the conventional hemodialysis arm (95% CI -0.86 to -0.23) while EPBD was reduced by 1.60 g/day (95% CI -2.73 to -0.48). In the Nocturnal Trial (n=87), where the prescribed 6/week session length was 6-8 hours, assignment to frequent dialysis was associated with a 1.23 mg/dL decrease in mean serum P vs. control (95% CI -1.77 to -0.68), and with an EPBD reduction of 3.78 g/day (95% CI -4.96 to -2.60). Only 20% of subjects (3/15) adherent to 6/week nocturnal treatment (weekly time > 35 hrs) required phosphorus binders, and 60% (9/15) of these subjects required addition of phosphorus to the dialysate. The length of the preceding interdialytic interval was related to higher predialysis serum P, averaging +0.47±0.18 (SE) and +0.64±0.17 mg/dL per 48 h in the Daily and Nocturnal Trials, respectively.

Conclusions: Our results confirm findings in prior observational and nonrandomized studies of improved control of hyperphosphatemia with 6/week dialysis. The improvement was greater when prescribed 6/week treatments were of longer duration.

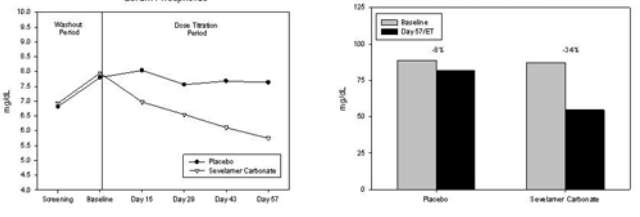
A Randomized, Double-Blind, Placebo-Controlled, Dose-Titration Study of Sevelamer Carbonate in Hemodialysis Patients Nan Chen. *Shanghai Ruijin Hospital, Shanghai, China.*

Background: While clinical practice guidelines advocate that hyperphosphatemic CKD patients should be treated with phosphate binders, there is little information on how these patients respond when not treated and how the pattern of hyperphosphatemia changes over time.

Methods: This randomized, double-blind, dose-titration study compared placebo and sevelamer carbonate in HD patients. Patients on calcium-based binders prior to the study were randomized to either placebo (n=70) or sevelamer carbonate (n=135) for an 8-wk treatment period. Starting dose was 800 mg TID with meals for both groups. If serum phosphorus was >5.5 mg/dL, blinded study drug was increased by 800 mg per meal.

Results: The maximum prescribed daily dose was 8.8 ± 1.6 g/day for placebo and 7.1 ± 2.5 g/day for sevelamer carbonate.

Mean serum phosphorus decreased significantly with sevelamer carbonate (p<0.0001) but remained persistently elevated with placebo throughout the study. The sevelamer carbonate group achieved better phosphorus control compared to pre-study calcium-based binder. There were also statistically significant mean decreases from baseline in serum total and LDL-cholesterol with sevelamer carbonate (p<0.0001), but not placebo. The magnitude of LDL-cholesterol reduction found in the current study is similar to the reduction found in SHARP.



Sevelamer carbonate was well-tolerated. Overall, the AEs experienced by the patients in the sevelamer carbonate and placebo groups were similar and consistent with the patients' underlying renal disease.

Conclusions: This study demonstrates that hyperphosphatemia develops quickly following the cessation of phosphate binders and remains persistently elevated when not treated. This study also demonstrates that sevelamer carbonate is an effective phosphate binder that also decreases LDL-cholesterol which is important given the increased cardiovascular risk profile of many dialysis patients.

FR-PO1212

Comparison between PA21, a New Iron-Based Non-Calcium Phosphate Binder and Lanthanum and Sevelamer Carbonate in Uremic Rats

Olivier Phan,[1] Marc P. Maillard,[1] Hartmut H. Malluche,[2] Felix W. Funk,[3] Michel Burnier.[1] *[1]University of Lausanne CHUV; [2]University of Kentucky Chandler Medical Center; [3]Vifor (International) Inc.*

Background: In a previous study, we demonstrated that PA21, a new calcium-free, iron based phosphate binder effectively controlled hyperphosphatemia and iPTH levels, and was superior to calcium carbonate in preventing the development of vascular calcifications in rats with chronic renal failure (CRF). This ongoing study expands on our previous findings and compares the efficacy of PA21 with lanthanum (La) and sevelamer carbonate (Se) on hyperphosphatemia, and secondary hyperparathyroidism.

Methods: CRF was induced in rats using 0.75% adenine-enriched high phosphorus 1.3 % diet for 4 weeks. Then, rats were randomized to receive the same % of active ingredient of each binder in the diet without adenine for another 4 week period. The concentration (%) of each binder was chosen to deliver the same amount of active pharmaceutical ingredient to each rat: PA21 5%, La 2%, Se 1.5%. N=6/group.

Results: At randomization, no difference was observed for serum calcium (Ca), phosphorus (P), or creatinine (creat) concentration between the 4 groups. Food intake was comparable in all groups during the study. At sacrifice, the following results were found:

	Body weight g	Creatinine µmol/l	P mmol/l	Ca mmol/l	iPTH pg/ml	U. P/creat
CRF placebo	311±8.6	157±14	4.2±0.6	2.4±0.5	3704±868	21±4.6
CRF PA21	300±6.3	136±14	2.1±0.1 ***	2.5±0.03 *	1277±411**	4.6±1.0**
CRF La	306±5.8	144±21	2.5±0.1 ***	2.5±0.5 *	1109±355**	10±1.1***
CRF Se	305±5.7	130±8	2.4±0.1 ***	2.6±0.01 *	1000±212**	7.3±1.1*[/sup]

***p<0.001, **p<0.01, *p<0.05 vs CRF placebo

Conclusions: These experimental data show that the iron based, calcium-free phosphate binder PA21, is at least as effective as La and Se in controlling P and iPTH in rats with CRF.

FR-PO1213

Serum Phosphorous (Phos) as a Predictor of Macrovascular Events and Mortality within a Large Ethnically Diverse Population with and without CKD

John J. Sim,[1] Antoine C. Abcar,[1] Ning Smith,[2] Joanie Chung,[2] Dean A. Kujubu,[1] Simran K. Bhandari,[1] Scott A. Rasgon,[1] Kamyar Kalantar-Zadeh.[3] *[1]Nephrology & Hypertension, KPSC LAMC, Los Angeles, CA; [2]Research & Evaluation, KPSC, Pasadena, CA; [3]Nephrology, Harbor UCLA, Torrance, CA.*

Background: We sought to determine whether higher serum Phos was a risk for ischemic heart disease (IHD), congestive heart failure (CHF), cerebrovascular events (CVE), and mortality outcomes.

Methods: Retrospective cohort study 1/1/1999 -12/31/2009 persons ≥18yrs with Phos ≥ 1 and min 1 yr continuous followup. Subjects were categorized into population based quartiles using time dependent average Phos. The association btwn Phos quartiles and the primary outcome (composite of new hospitalization diagnoses of IHD, CHF, and CVD, and mortality) was examined using Kaplan Meier analysis and multivariate Cox Proportional Hazard model adjusting for age, gender, hypertension, diabetes, estimated glomerular filtration rate (eGFR), and charlson comorbidity index.

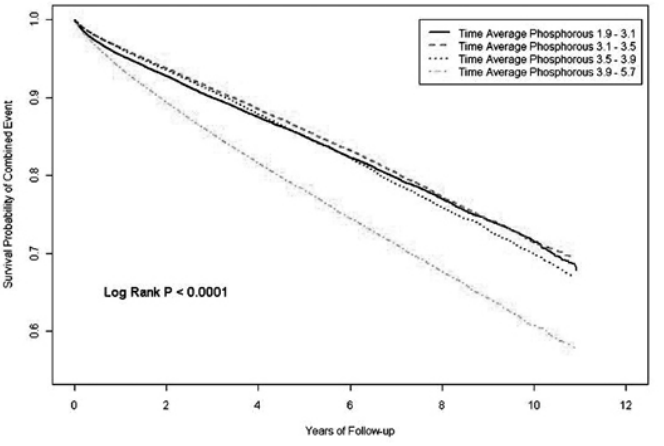
Results: Total 209,865 persons included in cohort with mean age 54 yrs, 61% females, and 41% whites. Median followup was 3.1yrs. 13% had eGFR<60ml/min. Time dependent average Phos were categorized into 4 quartiles (mg/dl); 1.9-3.0, 3.1-3.4, 3.5-3.8, and 3.9-5.7. Compared to lowest Phos quartile, adjusted HR were increased with higher Phos.

Adjusted HR for Outcomes

Phos Quartile	Composite (95%CI)	IHD	CHF	CVE	Mortality
1.9-3.0	-	-	-	-	-
3.1-3.4	0.92 (0.89-0.95)	0.94	1.07	1.20	0.90
3.5-3.8	0.98 (0.95-1.02	1.02	1.19*	1.06	0.94
3.9-5.7	1.46 (1.41-1.50)	1.29*	1.78*	1.23*	1.16*

* p<0.05

Linearity was demonstrated for combined outcomes with HR 1.25 for 0.5 mg/dl increase in Phos. Survival curves demonstrated lower event free rates with higher Phos.



Conclusions: Higher serum Phos demonstrated greater risk for IHD, CHF, CVE, and mortality outcomes within a large population primarily without CKD.

FR-PO1214

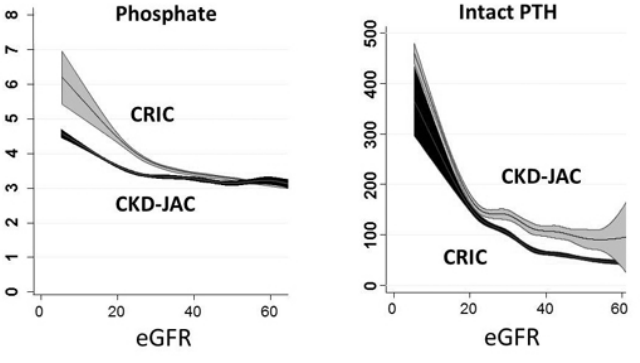
Serum Calcium Phosphate, and PTH Levels: A Comparison of American and Japanese CKD Patients

Takayuki Hamano,[1] Naohiko Fujii,[2] Tadao Akizawa,[2] Tsuyoshi Watanabe,[2] Seiichi Matsuo,[2] Satoshi Iimuro,[2] Yasuo Ohashi,[2] Arnold B. Alper,[3] Anna C. Porter,[3] Lisa C. Nessel,[3] Myles S. Wolf,[3] Harold I. Feldman.[3] *[1]Center For Clinical Epidemiology and Biostatistics, University of Pennsylvania, Philadelphia, PA; [2]CKD-JAC Investigators; [3]CRIC Investigators.*

Background: The DOPPS revealed that American hemodialysis patients have two times higher PTH levels compared to their Japanese counterparts despite comparable levels of serum calcium (Ca) and phosphate (P). There are no comparative data in predialysis patients with CKD.

Methods: We compared baseline levels of serum Ca, P, PTH, urinary phosphate (a proxy for net absorbed phosphate), urinary calcium, and use of phosphate binders and vitamin D preparations among participants of the CRIC (Chronic Renal Insufficiency Cohort) and CKD-JAC (Japanese Cohort) studies. Since PTH was measured by different assays, we calibrated the PTH levels using a range of samples from a set of 108 patients with CKD not enrolled in either study.

Results: CRIC and JAC enrolled 3939 and 2977 patients, respectively. Serum P and urinary P/creatinine (P/Cr) (0.62 vs.0.43) were significantly higher in CRIC participants regardless of eGFR and despite their significantly greater likelihood of receiving phosphate binders (7.7 vs.4.4%). However, PTH levels were significantly higher in JAC even after extensive adjustment. Serum Ca levels were also significantly higher in CRIC, while Urinary Ca/Cr were comparable.



Conclusions: Higher phosphorus intake reflected by urine P/Cr possibly could explain the higher serum P levels in American patients. Higher PTH in the Japanese might be explained by the absence of vitamin D-fortified food in Japan. Future cross-national comparisons of serum vitamin D and FGF23 levels, and dietary history will help define these differences.

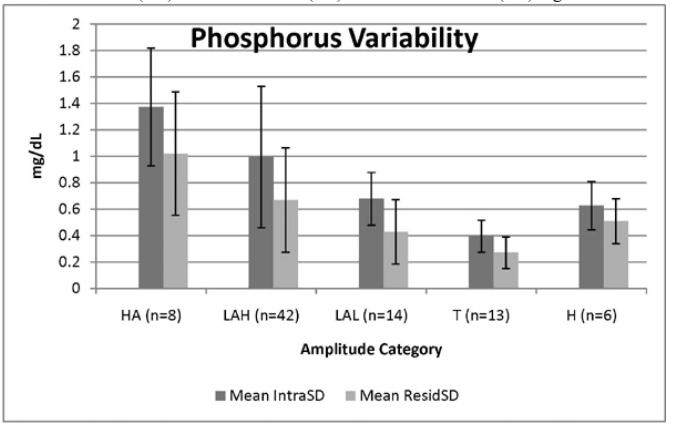
FR-PO1215

Methods Quantifying Variations in Serum Phosphorus Concentrations in Hemodialysis (HD) Patients Katie E. Cardone,[1,2] Alissa Lynn Phillips,[1] Rachid Daoui,[3] Christopher D. Hoy,[3] Shari A. Meola,[3] George R. Bailie.[1,2] *[1]Albany College of Pharmacy and Health Sciences, Albany, NY; [2]Albany Nephrology Pharmacy Group (ANephRx), Albany, NY; [3]Hortense and Louis Rubin Dialysis Center, Clifton Park, NY.*

Background: Medication & diet are used to manage CKD-MBD. Fluctuations may lead to frequent regimen changes and contribute to poor adherence. However, limited data exist regarding [phosphorus (P)] variability in HD pts. Methods to quantify variations in serum hemoglobin have been defined, but have not been used to assess [P] variability. The purposes of this study were to 1)determine extent & magnitude of [P] fluctuation in HD patients using various methods, 2)define typical ranges of fluctuation for each method.

Methods: Retrospective chart review of [P] was conducted at 3 HD centers. All adult HD patients who received treatment in the first quarter of 2009 (between 1/1/2009 and 3/31/2009), who had >2 [P] lab value were included. Patients were censored at death, transfer, hospitalization or HD discontinuation. [P] fluctuation was determined using 3 methods of variability: intrapatient standard deviation (intraSD), residual SD (residSD) and amplitude of variation (high amplitude (HA), low amplitude high (LAH), low amplitude low (LAL), high values only (H), low only (L), or target range only (T). Patients were divided by amplitude classification. Mean(SD) intraSD and residSD were determined for each amplitude group.

Results: Eighty-three patients met study criteria. Half of all patients had LAH fluctuation. Mean(SD) intraSD was 0.86(0.5) & residSD was 0.59(0.4) mg/dL.



Conclusions: [P] variability is significant among HD patients, and may be measured in various ways. It is unclear which method of variability best correlates with clinical outcomes, and warrants further study.

FR-PO1216

Effect of Lanthanum Carbonate Compared with Calcium Carbonate on CAPD Patients in Korea: A Randomized Prospective Study Yong Kyu Lee,[1] Sug Kyun Shin,[1] Ho Yung Lee.[2] *[1]Nephrology, NHIC Ilsan Hospital, Goyang, Geongido, Korea; [2]Nephrology, Severance Hospital, College of Medicine, Seoul, Korea.*

Background: Hyperphosphatemia can result in hyperparathyroidism, metabolic bone disease, cardiovascular calcification, and mortality. But, controlling hyperphosphatemia with calcium-based phosphate binders can lead to hypercalcemia, hypoparathyroidism, arterial calcification, low bone turnover.

Methods: This study is a randomized prospective study designed to compare effect of lanthanum carbonate with calcium carbonate in controlling serum calcium, phosphate, iPTH levels on CAPD patients. Patients who were on CAPD for at least 6 months were screened for 4 weeks. Within those patients, patients whose serum phosphate were over 5.6mg/dL at 0 week were randomly assigned to either lanthanum carbonate or calcium carbonate.Serum calcium, phosphate, iPTH level and other biochemical parameters were examined every 4 weeks for 24 weeks.

Results: A total of 44 patients were enrolled in this study. Out of 44 patients, 11 patients were dropped out due to adverse effect of each drug. After 24 weeks of treatment, both lanthanum carbonate and calcium carbonate reduced serum phosphate level significantly, from 6.59 ± 0.76 to 4.61 ± 0.63 mg/dL and from 6.55 ± 0.54 to 4.91 ± 0.75 mg/dL, respectively. Calcium X phosphate product was reduced in both groups, from 59.66 ± 9.00 to 42.55 ± 8.63 mg2/dL2 and from 60.01 ± 7.18 to 46.21 ± 6.38 mg2/dL2, respectively. Serum iPTH level in Lanthanum Carbonate group was not significantly different, but in calcium carbonate group, the level decreased significantly, from 221.96 ± 223.94 to 151.17 ± 176.09 pg/dL. Serum calcium level was not elevated significantly in both groups.

Conclusions: Lanthanum carbonate is as effective as calcium carbonate in reducing serum phosphate level, and serum iPTH level tends to be steadier in lanthanum carbonate group compared to calcium carbonate group in CAPD patients as in HD patients. Though it was not significantly different, lanthanum carbonate tends not to elevate calcium level in CAPD patients compared to calcium carbonate. But high incidence of G-I adverse effect in lanthanum carbonate group needs to be further evaluated.

FR-PO1217

Role of Sodium-Dependent Phosphate (Pi) Transporter (Npt2b) on Salivary Pi Secretion Hiroko Segawa,[1] Tomo Mukai,[1] Saori Ohnishi,[1] Shohei Sasaki,[1] Akiko Ohi,[1] Shoji Kuwahara,[1] Shinsuke Kido,[1] Sawako Tatsumi,[1] Yasuko Ishikawa,[2] Otoya Ueda,[3] Naoshi Horiba,[3] Kou-Ichi Jishage,[3] Naoshi Fukushima,[3] Ken-Ichi Miyamoto.[1] *[1]Department of Molecular Nutrition, Institution of Health Bioscience, University of Tokushima Graduate School, Tokushima, Japan; [2]Department of Medical Pharmacology, Institution of Health Bioscience, University of Tokushima Graduate School, Tokushima, Japan; [3]Pharmaceutical Research Department 1, Chugai Pharmaceutical Co., Ltd., Gotenba, Shizuoka, Japan; [4]Genome Antibody Product Research Department, Chugai Research Institute for Medical Science Inc., Gotenba, Shizuoka, Japan.*

Background: Hyperphosphatemia is recognized as a contributor to vascular calcification in patients with chronic kidney disease (CKD) and hemodialysis (HD) patients and is independently associated with cardiac mortality. Dietary phosphate (Pi) restriction, and the Pi binders are important therapy for dialysis patients with hyperphosphatemia. Recently, Savica et al reported the salivary secretion of Pi to be an important determinant of hyperphosphatemia in patients with CKD and in those with ERSD under chronic dialysis (JASN 20:639,2009, J Renal Nutrition 21, 39, 2011). In the present study, we investigated the role of type IIb sodium-dependent Pi transporter (Npt2b) on salivary Pi excretion in mice.

Methods: Pilocarpine was injected intravenously into wild-type mice (Wt mice, C57BL6/J) and Npt2b-null mice (Npt2b+/+, and Npt2b+/-). During the 5 min after administration, saliva was collected by pipette.

Results: In Wt mice fed a high Pi diet, the levels of plasma and salivary Pi are significantly higher than those in Wt mice fed a low Pi diet. The expression of Npt2b protein was detected at the apical side of duct cells in the salivary glands, suggesting that ductal cells appears to be able to reabsorb Pi, thereby modifying the Pi concentration in the final saliva. The levels of Npt2b protein were decreased about 50% in the salivary glands of Npt2b+/- mice. The salivary Pi concentrations were significantly increased in Npt2b+/- mice compared with those in Npt2b+/+ mice.

Conclusions: These data suggest that Npt2b is involved in Pi secretion by salivary glands.

Funding: Government Support - Non-U.S.

FR-PO1218

FGF23 Is Expressed in Coronary Arteries of Patients Undergoing Heart Transplantation Natalie A. van Venrooij,[1] R.C. Pereira,[1] Yin Tintut,[2] Linda Demer,[2] Michael C. Fishbein,[3] Katherine Wesseling-Perry,[1] Isidro B. Salusky.[1] *[1]Pediatric Nephrology, UCLA; [2]Cardiology, UCLA; [3]Pathology, UCLA, Los Angeles, CA.*

Background: Elevated levels of FGF23 have been associated with left ventricular hypertrophy, vascular calcification, and mortality in patients with chronic kidney disease (CKD). Vascular calcification in patients with advanced CKD is an active process, with vascular smooth muscle cells (VSMC) acquiring osteogenic properties; however, the stage of kidney disease at which this transformation occurs and the contribution of FGF23 to this process are undefined.

Methods: To evaluate the relationship between renal function, vascular calcification, and vascular FGF23 expression, immunohistochemistry for FGF23, DMP1, and osteopontin and Von Kossa staining was performed in coronary arteries from 27 patients who underwent cardiac transplantation between February 2008 and 2010. 24 hr CrCl, HgA1c, and HSCRP values were obtained pre-transplantation.

Results: 53% of subjects had positive staining for FGF23. Table 1 describes the characteristics of patients with FGF23-positive and FGF23-negative staining. * indicates $p<0.05$.

Variable	FGF-23 positive (n=14)	FGF-23 negative (n=13)
Age (years)	65.4 ± 1.6*	53.8 ± 3.2
Gender (Male)	87%	92%
Ethnicity		
White	62%	50%
Black		25%
Hispanic	8%	8
Other	31%	17%
Diabetics	29%	33%
Prior smokers	62%	50%
Hypertensive history	50%	50%
S-Calcium (mg/dL)	9.0 ± 0.2	8.9 ± 0.2
S-Phosphorus (mg/dL)	3.6 ± 0.2	3.9 ± 0.4
Alkaline Phosphatase (IU/L)	83 (73, 102)	83 (62, 102)
Creatinine Clearance (ml/min/1.73m^2)		
CKD (%)		
none	45 (34, 97)≠	89 (57, 105)
Stage 2	36%	46%
Stage 3	0%	23%
Stage 4	57%*	31%
	7%*	0%
CRP (mg/dL)	8.0 (2.7, 35.5)*	32.0 (18.7, 88.6)
HgA1C (%)	6.4 ± 0.2	6.1 ± 0.1

Patients with positive FGF23 staining were older, had lower CRP levels, and were more likely to have a CrCl<60 ml/min/1.73m² than those with no vascular FGF23 expression. 36% of patients with positive FGF23 staining had normal renal function. FGF23 colocalized with DMP1 and FGF23 expression correlated directly with vascular calcification score and DMP1 expression.

Conclusions: Osteogenic transformation of VSMC occurs in individuals with very early and no CKD and progresses with worsening kidney function; whether FGF23 plays a role in the development of cardiovascular calcification or is solely a marker of the disease process remains to be determined.

FR-PO1219

Intact Fibroblast Growth Factor 23 Levels Predict Cardiovascular Death and Events before Dialysis Inception but Not after the Start of Dialysis
Chikako Nakano,[1] Takayuki Hamano,[1] Naohiko Fujii,[2] Isao Matsui,[1] Kodo Tomida,[1] Kazunori Inoue,[1] Akihiro Shimomura,[1] Yoshitsugu Obi,[1] Noriyuki Okada,[3] Yoshiharu Tsubakihara,[3] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Internal Medicine, Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Osaka, Japan; [3]Nephrology and Hypertension, Osaka General Medical Center, Osaka, Japan.*

Background: High fibroblast growth factor23 (FGF23) levels were reported to be risk factors for mortality in incident and maintenance hemodialysis patients. The association of FGF23 levels with cardiovascular diseases (CVD) among predialysis chronic kidney disease (CKD) patients remains unclear.

Methods: In this prospective cohort study, we enrolled 738 CKD outpatients of 2 nephrology units (mean estimated glomerular filtration rate (eGFR), 35mL/min/1.73m²). The endpoint was composite of any CVD event with hospitalization and cardiovascular death.

Results: For a median duration of 4.4 years, 86 patients developed the outcomes including 62 events before dialysis initiation. Cox proportional hazards analyses revealed that high FGF23 levels predicted the outcomes preceding dialysis therapy (hazard ratio [HR] per SD of lnFGF23, 1.93; 95% confidence interval [CI], 1.17-3.21). If we did not censor the cases at dialysis inception and followed those after that, FGF23 did not predict the outcomes (HR, 1.26; 95%CI, 0.85-1.87). Interactions between FGF23 and prior CVD or diabetes mellitus (DM) were not significant. Multiple imputation of missing values did not change the results. Adding FGF23 to the base model of age, sex, DM, prior CVD, pulse pressure, and eGFR led to a net reclassification improvement of 6.87% (P=0.04) due to better identification of the patients not developing CVD (specificity gain).

Conclusions: Intact FGF23 levels among predialysis CKD patients predicted CVD events and death before dialysis inception, but did not predict the outcomes during the entire follow-up including the period after the start of dialysis.

FR-PO1220

Klotho Plasma Levels in CKD Patients: Relation to Renal Function, FGF-23 and Parathyroid Hormone Levels
Sarah Seiler, Franziska Flügge, Esther Herath, Anja Weihrauch, Danilo Fliser, Gunnar H. Heine. *Internal Medicine IV, Saarland University Hospital, Homburg, Saar, Germany.*

Background: The single-pass transmembrane protein Klotho acts as co-receptor for the phosphaturic hormone FGF-23. It has been hypothesized that soluble Klotho, which results from cleavage of the extracellular domain of Klotho by a membrane-standing protease, might exert systemic effects on calcium phosphate metabolism. CKD patients have diminished renal expression of the Klotho gene, and lower renal excretion of the Klotho protein. However, data on plasma levels of circulating Klotho in CKD patients are not available.

Methods: We studied 312 CKD stage 2-4 patients in our ongoing CARE FOR HOMe study. We measured plasma levels of intact parathyroid hormone (iPTH), Klotho and FGF-23, and assessed urinary fractional phosphate excretion (FePi). We estimated glomerular filtration rate (eGFR) using the Modification of Diet in Renal Disease study equation 4.

Results: Our patients had a mean eGFR of 44.2±15.7 ml/min/1.73 m², and were 65±12 years of age. Median FGF-23 level was 99.0 rU/ml (IQR 60.3-158.6 rU/ml), median Klotho level 537.9 pg/ml (IQR 450.1-665.7 pg/ml). With progressive impairment of renal function, FGF-23 and iPTH levels, and FePi increased (all p<0.001), while Klotho plasma levels did not (p=0.37). FGF-23 and iPTH levels were correlated with serum calcium and phosphate as well as with FePi, while Klotho was not correlated with any of these parameters:

Table 1

	Klotho (pg/ml)	FGF-23 (rU/ml)	iPTH (pg/ml)
Klotho (pg/ml)	-	r=-0.06; p=0.22	r=0.06; p=0.25
FGF-23 (rU/ml)	r=-0.06; p=0.22	-	r=0.17; p=0.002
iPTH (pg/ml)	r=0.06; p=0.25	r=0.17; p=0.002	-
Calcium (mmol/l)	r=0.01; p=0.88	r=-0.01; p=0.89	r=-0.20; p<0.001
Phosphate (mg/dl)	r=-0.07; p=0.21	r=0.18; p=0.001	r=0.17; p=0.002
FePi (%)	r=0.03; p=0.63	r=0.18; p=0.001	r=-0.20; p<0.001

Conclusions: In our cohort of CKD stage 2-4 patients we confirmed a gradual increase of FGF-23 and iPTH levels with declining renal function. In contrast, Klotho plasma levels were neither associated with renal function, nor with parameters of calcium phosphate metabolism. In the long-term follow-up of our study we will assess the predictive power of Klotho plasma levels for future cardiovascular or renal events in CKD patients.

FR-PO1221

A Randomized Cross-Over Trial Evaluating FGF23 and PTH in the Treatment of CKD Stage 3b
Inger Hjørdis Bleskestad,[1] Anders Hartmann,[2] Harald Bergrem,[1] Lasse G. Goransson.[1] *[1]Stavanger University Hospital, Norway; [2]Oslo University Hospital, Norway.*

Background: FGF23, a phosphaturic hormone is secreted from bone and the level increases as renal function declines. The level of FGF23 is associated with increased mortality in haemodialysis-patients. The use of active vitamin D and phosphate binders as recommended in international guidelines, may affect the level of FGF23 and thereby clinical outcome. We investigated the effects of a phosphate binder and active vitamin D on the serum levels of FGF23 and PTH in patients with CKD stage 3b (30-45 ml/min/1.73m²).

Methods: Seven women and 14 men where included, mean age 65.6 ± 12.2 years. They were randomized in a 1:1 ratio to receive one of two treatment sequences. Group 1: alphacalcidol 0.25 µg once daily for two weeks followed by sevelamer carbonate 800 mg TID with meals for two weeks after a two-week washout period. Group 2: vice versa. Nineteen patients completed the study. The 25(OH) vitamin D level at baseline was 97.6 ± 25.0 mmol/l.

Results: There were no significant period or "carry-over" effects for FGF23 or PTH. There were no significant treatment effects on FGF23 or PTH (p=0.604 and p=0.243 respectively). The period-difference for FGF23 was however unexpectedly positive for both groups.

In group 1 the FGF23 level was higher after treatment with alphacalcidol compared to sevelamer carbonate (mean 105.8 ± 41.6 vs. 79.1 ± 36.5 pg/ml, p=0.047 (CI: 0.4-52.9), for PTH lower (median: 26.5, range: 14.6-55.2 vs. median 36.1, range 13.4-106.9 pg/ml, p=0.011 (CI: 3.5-13.8). In group 2 the FGF23 level increased after treatment with sevelamer carbonate and throughout the washout period non-significantly.

Conclusions: In this cross-over trial with alphacalcidol and sevelamer carbonate in patients with CKD stage 3b, the response on the FGF23 level seems to depend on whether alphacalcidol or sevelamer carbonate is initiated as the first line of therapy. Initiating therapy with sevelamer carbonate increases FGF23 levels while this response is mitigated in the group of patients given alphacalcidol followed by sevelamer carbonate. This observation needs to be confirmed in larger studies.

FR-PO1222

KAI-4169, a Novel Peptide Agonist of the Calcium Sensing Receptor, Suppresses Parathyroid Hormone, Parathyroid Gland Hyperplasia, and Ectopic Calcification in a Rodent Model of Chronic Renal Dysfunction
Sarah Walter, James Tomlinson, Amos Baruch, Shawn Alexander, Jin Dong, Kevin Q. Yin, Dirk B. Mendel, Derek Maclean, Felix D. Karim, Randolph M. Johnson. *Research, KAI Pharmaceuticals, South San Francisco, CA.*

Background: Chronic Kidney Disease-Mineral and Bone Disorder (CKD-MBD) is a frequent and serious complication of CKD that is linked to bone abnormalities and increased risk for cardiovascular disease. KAI-4169 is a novel peptide agonist of the calcium sensing receptor (CaSR). The efficacy of KAI-4169 was evaluated in the 5/6 nephrectomy model, a preclinical rat model of chronic renal dysfunction.

Methods: Three separate studies were done using this model. In the first study, animals were randomly assigned to receive daily doses of placebo, KAI-4169 (1 mg/kg) by IV bolus or cinacalcet (10 mg/kg by oral gavage) for 4 weeks. In the second two studies, KAI-4169 was administered for ~6 weeks as a thrice weekly subcutaneous bolus (3 mg/kg) Control animals were either treated with vehicle or left un-treated.

Results: In the first study, parathyroid hormone (PTH) was the primary endpoint examined. 48 hours after the last dose, animals treated with KAI-4169 had significantly reduced levels of PTH compared with placebo-treated rats. In contrast, PTH had returned to baseline or to above baseline values for the cinacalcet-treated rats by 16 hours after the last dose. Control rats in the second and third studies developed elevated PTH (~1500 pg/mL), parathyroid gland hyperplasia (as measured by gland weight and BrdU staining), elevated serum creatinine and significant vascular and soft tissue calcification. Repeat-dose administration of KAI-4169 reduced PTH levels, attenuated parathyroid gland hyperplasia, significantly reduced aortic and renal calcification and was associated with a significant reduction in serum creatinine compared with baseline values.

Conclusions: KAI-4169 is a novel peptide agonist of the human CaSR that reduces PTH levels and improves markers of CKD-MBD. KAI-4169 is currently in clinical development as an IV treatment for CKD-MBD/SHPT in hemodialysis patients.

FR-PO1223

The Impact of Parathyroidectomy on Circulating FGF23 Levels and Renal Phosphate Handling
Liesbeth Viaene, Bjorn K.I. Meijers, Kathleen Claes, Pieter Evenepoel. *Nephrology, University Hospital, Leuven, Belgium.*

Background: The full relationship between fibroblast growth factor 23 (FGF23) and parathyroid hormone (PTH) remains incompletely understood, with regard to the reciprocal regulation of their transcription and secretion as well as with regard to their phosphaturic actions. Recent experimental evidence suggests PTH directly affects FGF23 secretion.

Methods: We performed a prospective observational study in 24 renal transplant recipients (14 male; age 51±12y) with persistent hyperparathyroidism and hypercalcemia referred for parathyroidectomy (PTX). Parameters of mineral metabolism (including fasting calcitriol, and biointact FGF23 and PTH) and renal phosphate handling (fasting fractional phosphorus excretion, FE_{phos}) were assessed immediately before PTX and at discharge (day 11±8). Twenty healthy volunteers (8 male, age 34±10 years) served as controls.

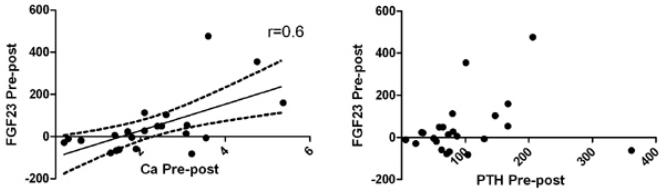
Results: PTX was successful in all patients.

Evolution of parameters of mineral metabolism before and after PTX

	Pre-PTX	Post-PTX	Controls	p ANOVA
eGFR	45*	41*	94	<0.0001
Calcium	10.9*	8.7$	9.2	<0.0001
Phosphate	2.1*	3.3$	3.5	<0.0001
PTH (ng/L)	99*	10$	17	<0.0001
FGF23 (ng/L)	90*	71*	27	<0.0001
Fe Phosphate	44*	22*$	12	<0.0001

Median values are shown; *p<0.05 vs controls; $ p<0.05 vs post-PTX

Overall, FGF23 levels did not decline after PTX. Delta calcium (p= 0.01), but not delta PTH (p =0.3) correlated with delta FGF23 (figure).



The FE_{phos} significantly decreased after PTX, but remained significantly higher as compared to controls (12±7%; p=0.01) despite similar phosphorus concentrations (3.5±0.3 mg/dL).

Conclusions: Our data suggest that calcium rather than PTH directly affects the efflux of FGF23 from bone. PTH and FGF23 act synergistically to increase phosphaturia.

FR-PO1224

Phosphate Restriction Extends the Life of Uremic Rats with Extensive Vascular Calcification Eduardo Slatopolsky, Duk H. Lee, Jane L. Finch. *Medicine/Renal Division, Washington University School of Medicine, St. Louis, MO.*

Background: Numerous studies have demonstrated the role of hyperphosphatemia in the pathogenesis of secondary hyperparathyroidism, cardio-vascular disease and the progression of renal failure. The purpose of this study was to determine if, in rats with chronic kidney disease (CKD) and severe vascular calcification, a significant reduction in phosphate intake could prolong the life of these animals.

Methods: CKD was induced by 5/6th nephrectomy. A group of normal rats served as control (NC). All rats were fed a high-phosphate diet containing 1.4% phosphorus (P) and 0.8% calcium (Ca). After 3 months some rats from both groups were sacrificed. The remaining uremic rats were divided into the following 3 groups: uremic rats +1.4% P diet (UHP), uremic + 1.4% P diet + sevelamer (4%) (UHP+S) and uremic + a very low P diet, 0.1%, (ULP). These rats were sacrificed after 10 weeks.

Results: After the first 3 months, the serum P in uremic rats increased from 5.9 ± 0.34, in normal rats, to 10.3 ± 0.76 mg/dl. The Ca x P increased from 56.7 in normal rats to 94.3 mg2/dl2. Aortic calcium content was also increased (NC: 0.5 ± 0.06 vs. uremic: 46.2 ± 14.2 mg/mg dry wt). Uremic rats also exhibited positive aortic staining for von Kossa, RUNX2 and osteopontin. After the study was continued for an additional 10 weeks, the serum P in the UHP group was 14.8 ± 5.14 mg/dl vs. UHP+S rats (9.8% ± 2.87), ULP rats (3.7 ± 0.02) and NC rats (3.9 ± 0.03). Mortality in the UHP group was 78%. Mortality was reduced to 30% by treatment with sevelamer (UHP+S)and further reduced by the 0.1 % P diet to just 8% (ULP). Positive staining for aortic von Kossa, RUNX2 and osteopontin was increased in UHP rats. Phosphorus restriction inhibited this.

Conclusions: These studies clearly demonstrate that a significant reduction in mortality in uremic rats with severe vascular calcification can be achieved by intensive control of P restriction.

FR-PO1225

Changes in Fibroblast Growth Factor 23 during Treatment with Vitamin D Analogs. Comparison of Alfacalcidol and Paricalcitol in CKD5D Patients, with Secondary Hyperparathyroidism, in a Randomised Controlled Trial Ditte Hansen,[1] Knud Rasmussen,[1] Lars Rasmussen,[2] Susanne Møller Pedersen,[2] Lisbet Brandi.[1] *[1]Medical Department, Roskilde Hospital, Denmark; [2]Clinical Biochemistry and Pharmacology, Odense University Hospital, Denmark.*

Background: Fibroblast growth factor 23 increases renal phosphate excretion and decreases levels of circulating 1,25 dihydroxyvitamin D. In patients with chronic kidney disease, fibroblast growth factor 23 levels are markedly elevated by unknown mechanisms. Treatment with vitamin D analogs may influence on the level of fibroblast growth factor 23 in hemodialysis patients. Furthermore, the level of fibroblast growth factor 23 may predict the response to treatment of secondary hyperparathyroidism

Methods: In a Danish multicenter study, intravenous alfacalcidol and paricalcitol were compared in hemodialysis patients with secondary hyperparathyroidism in a randomised 2 x 16 week cross-over study, with 6 weeks wash-out period preceding treatment and between treatment periods. In 57 of the enrolled patients, blood samples were frozen before and after each treatment period, and available for measurement of fibroblast growth factor 23.

Results: Alfacalcidol and paricalcitol increased fibroblast growth factor equally (period 1: 223% versus 314%; P=0.384 and period 2: 174% versus 227%; P=0.510) and the levels returned to pre-treatment levels during the six week wash out period. Independent predictors of rise in fibroblast growth factor 23 were baseline levels of fibroblast growth factor (P<0.01), changes in ionised calcium (P<0.01) and phosphate (P<0.01) and cumulative dose of vitamin D analogues (P=0.024). Pre-treatment levels of fibroblast growth factor 23 were independently associated with the level of parathyroid hormone after 16 weeks of treatment with vitamin D analogs (P=0.016).

Conclusions: Alfacalcidol and paricalcitol increase levels of fibroblast growth factor 23 significantly in hemodialysis patients. However, the impact of such increase is not known. Baseline FGF23 levels predicts PTH response to treatment

FR-PO1226

Parathyroid Hormone (PTH) Levels and Mortality among Hemodialysis (HD) Patients Not Receiving Treatment for Secondary Hyperparathyroidism (SHPT): Results from the Dialysis Outcomes and Practice Patterns Study (DOPPS) Francesca Tentori,[1] Mary K. Guidinger,[1] William G. Goodman,[2] Ronald L. Pisoni,[1] Yun Li,[1,3] Ryan D. Kilpatrick,[2] Juergen Bommer,[4] Masafumi Fukagawa,[5] Brian Bieber,[1] Bruce M. Robinson.[1,3] *[1]Arbor Research Collaborative for Health; [2]Amgen, Inc.; [3]U of Michigan; [4]Dialysezentrum Heidelberg; [5]Tokai University School of Medicine.*

Background: Very high PTH levels have been associated with mortality in HD patients. Agents prescribed for SHPT, namely vitamin D analogs and calcimimetics, may have impacted those results. To add insight into whether PTH levels per se are associated with mortality we tested this association among DOPPS participants not receiving treatment for SHPT.

Methods: Of 17,476 DOPPS participants from 12 countries in 1996-2008, 5,728 (30.2%) were categorized as "untreated", i.e. had no evidence of vitamin D (oral or IV) or cinacalcet prescription for 12 months following study entry. Using the most recent PTH value at the end of the 12-month period, the association between PTH levels and mortality over study follow-up was evaluated in Cox models with different levels of adjustment.

Results: Compared to those receiving SHPT therapy, untreated patients had shorter duration of HD and lower serum PTH (mean 217.0 ± 314.8 vs. 306.9 ± 384.0 pg/ml for treated group). Among untreated patients, age was inversely associated with PTH. The association between PTH and mortality in untreated patients is shown.

			Model A	Model B	Model C	Model D
			Unadjusted	Adjusted for demographics + co morbidities*	Model B + serum albumin, Kt/V and hemoglobin	Model C + serum calcium and phosphorus
PTH (pg/mL)	% of patients	Mean age, years	HR (CI)	HR (CI)	HR (CI)	HR (CI)
<50	19.0	63.4	1.30 (1.11, 1.53)***	1.27 (1.07, 1.52)***	1.24 (1.04, 1.49)**	1.29 (1.08, 1.55)***
50-149	35.9	64.3	1.20 (1.04, 1.39)**	1.10 (0.94, 1.28)	1.09 (0.94, 1.27)	1.11 (0.96, 1.30)
150-299	25.5	62.9	1	1	1	1
300-499	10.7	61.0	0.99 (0.79, 1.24)	1.15 (0.92, 1.44)	1.18 (0.94, 1.48)	1.16 (0.93, 1.46)
≥500	8.9	56.4	0.99 (0.78, 1.24)	1.35 (1.08, 1.69)***	1.36 (1.07, 1.73)**	1.33 (1.05, 1.67)**

*Age, sex, black race, years on dialysis, body mass index, and 13 summary co morbid conditions. Models were stratified by phase & country and Accounted for facility level clustering. **P≤0.05. ***P≤0.01.

Conclusions: In an international cohort of HD patients without evidence of SHPT treatment for 12 months, PTH levels < 50 and ≥500 pg/ml were associated with elevated mortality (p<0.05), with the possibility of lowest mortality risk in the KDOQI target range of 150-300 pg/ml. Our results indicate an opportunity for improvement in clinical practice, since a high % of untreated patients had PTH levels above the lowest risk range.

FR-PO1227

The Association of Dietary Phosphorus Intake with Serum Fibroblast Growth Factor-23 and Vitamin D Metabolites in Chronic Kidney Disease: The Seattle Kidney Study Kalani T. Yamamoto, Alina Kostina, Bryan R. Kestenbaum. *Kidney Research Institute, University of Washington, Seattle, WA.*

Background: Phosphorus is excreted through the kidneys by phosphaturic hormones fibroblast growth factor-23 (FGF-23) and parathyroid hormone (PTH) and impairs activation of vitamin D. The impact of dietary phosphorus on mineral metabolism hormones in the setting of chronic kidney disease (CKD) is unclear. We tested the hypothesis that dietary phosphorus, measured using prospective food diaries, would be associated with key mineral metabolism biomarkers among CKD patients.

Methods: We studied 60 patients from the Seattle Kidney Study, a prospective study of CKD, who were not taking activated vitamin D or phosphorus binders and agreed to complete food diaries. We assessed mean dietary phosphorus intake using 5-day

prospective food records and 24-hour recall, with data entered into the Nutrition Data System for Research software system. We measured serum intact FGF-23 and PTH using immunoassays and vitamin D metabolites using mass-spectroscopy.

Results: Mean 5-day phosphorus intake by food diary was 1231 ±355 mg/day in men and 1033 ±327 mg/day in women. Correlation of 5-day prospective dietary phosphorus with 24-hour dietary recall phosphorus was low (r2 = 0.10). Dietary phosphorus, assessed by either method, was not associated with any of the measured mineral metabolism biomarkers.

Association of dietary phosphorus intake with FGF23, PTH, and vitamin D metabolites

		Per 200 mg increase in dietary phosphorus (95% CI)*	
Mineral	N	Diary	FFQ
1,25-vitamin D†	59	-1.65 (-5.48, 2.19)	1.00 (-0.62, 2.62)
Vitamin D24,25†	59	0.31 (-0.09, 0.72)	-0.15 (-0.32, 0.02)
PTH	59	-12.5 (-28.9, 4.01)	-0.59 (-8.02, 6.85)
FGF-23	59	3.24 (-7.9, 14.4)	-1.24 (-6.16, 3.69)

*Models adjusted for age, race, gender, BMI, eGFR , and total kcal. †Additionally adjusted for 25-OH vitamin D

Conclusions: Despite large variation in dietary phosphorus intake across individuals with CKD, dietary phosphorus was not associated with FGF-23, PTH, or vitamin D metabolites.

FR-PO1228

Comparison among Different Dialysate Calcium Concentrations in Bicarbonato Hemodialysis Carlo Basile, Pasquale Libutti, Francesco Casucci, Piero Lisi, Carlo Lomonte. *Division of Nephrology, Miulli General Hospital, Acquaviva delle Fonti, Italy.*

Background: A correct net calcium (Ca) mass balance during hemodialysis (HD) is crucial in the treatment of renal osteodystrophy.

Methods: Twenty-two stable anuric uremic patients underwent three 4h-bicarbonate HD sessions, each with a different dialysate total Ca (tCa) concentration (1.25, 1.375 and 1.50 mmol/l). Hourly measurements of plasma water ionized Ca (pw iCa), of inlet and outlet dialysate iCa and plasma parathyroid hormone (PTH) concentrations were effected. iCa and tCa mass balances (iCaMBs and tCaMBs) were measured from the dialysate side (Genius batch dialysis system, FMC, Germany).

Results: Mean hourly pw iCa concentrations were statistically significantly higher with a dialysate tCa concentration of 1.50 mmol/l. Mean tCaMBs were positive (diffusion gradient from the dialysate to the patient), being more and more higher by increasing dialysate tCa concentrations (+ 75 ± 122 mg, + 182 ± 125 mg, + 293 ± 228 mg, respectively) ($P < 0.0009$). Only 6 out of the 66 tCaMBs were negative (exclusively with 1.25). Mean tCaMBs were less positive than mean iCaMBs for each of the dialysate tCa concentration studied, even though the mean difference between tCaMBs and iCaMBs (9.8%) did not reach the level of statistical significance. The scatter plot of tCaMBs during every HD session (y axis) vs. the area under the curve of the hourly inlet dialyzer diffusion concentration gradients (dialysate iCa concentration - pw iCa concentration) was: $y = 4.667x - 140.24$ ($R2 - 0.155$, $P < 0.001$). It means that when the measured diffusion concentration gradient is 0, the tCaMB is - 140.2 mg, which represents about 3 l of ultrafiltrate. Mean Δ values of plasma PTH of each treatment (i.e. the mean differences between post- and pre-HD levels) were statistically significantly different among the three treatments ($P < 0.021$), being positive with a dialysate tCa concentration of 1.25 mmol/l and negative with both a dialysate tCa concentration of 1.375 and 1.50 mmol/l.

Conclusions: A dialysate tCa concentration of 1.375 mmol/l should be preferred being able to keep the patient in a mild positive tCaMB, to avoid HD hypercalcemia and not to stimulate PTH secretion.

FR-PO1229

The Interaction of Secondary Hyperparathyroidism(SHPT) and Fibroblast Growth Factor 23(FGF23) Changying Xing, Rui Wang, Huijuan Mao. *Dept. of Nephrology, First Affiliated Hospital of Nanjing Medical University, Nanjing, Jiangsu Province, China.*

Background: To investigate the FGF23 before and after parathyroidectomy (PTX) with forearm autotransplantation in patients with advanced SHPT and the cause of resistance of SHPT to FGF23 in hemodialysis patients.

Methods: 1. Serum iFGF23 was detected from 21 patients with advanced SHPT patients before PTX day 3. To further observe immediate changes of FGF23 after PTX, serum iFGF23 was detected before and in 20 minutes, third, fifth, seventh day after PTX. Furthermore, the 25(OH) D3, iPTH, calcium, phosphorus, calcium and phosphorus product changes were observed before and after PTX. 2. The specimens of parathyroid tissue were taken from 8 patients with PTX and were divided into two types: diffuse type (D- type) and nodular type (N-type). The expression of Klotho and FGFR1 were detected by Western blot. 3. Parathyroid cells gotten from patients with SHPT were randomly divided into four groups in vitro as follows: blank-control group, FGF23 stimulation: FGF23 (0.1μg/ml) stimulation group, FGFR3 antibody + FGF23 stimulation group: According to the recommended concentration of FGFR3,0.5μg/ml and1.0μg/ml FGFR3 and FGF23 (0.1μg/ml) co-stimulated for 0h, 2h, 6h, 12h, 24h, 36h.

Results: 1.FGF23 was significantly elevated in SHPT patients. In 21 PTX patients, postoperative FGF23 were significantly decreased compared with preoperative levels, and this was followed by a reduction in iPTH levels. Calcium levels, phosphorus levels, and calcium-phosphorus product levels were significantly decreased after PTX, and this was followed by a reduction in plasma FGF-23 levels in time-course study. 2.Nodular type of parathyroid tissue exhibited lower Klotho and FGFR1 expression than diffuse type of parathyroid tissue. 3.The administration of recombinant FGF23 0.1μg/ml and FGFR3 antibody 1.0μg/ml together, the level of PTH was decreased at 2h.

Conclusions: Parathyroid glands regulate circulating FGF23 levels in SHPT. Nodular type of parathyroid tissue exhibited lower Klotho and FGFR1 suggestes the depressed expression of the Klotho–FGFR1 complex in hyperplastic glands. FGF23 and FGFR3 antibody together, downregulate the level of PTH at 2h.

FR-PO1230

Maxacalcitol Ameliorates Tubulointerstitial Fibrosis in the Obstructed Kidney by Abrogating Smad3-Dependent TGF-β1 Production, without Affecting the Renal Renin Expression Kazunori Inoue,[1] Isao Matsui,[1] Takayuki Hamano,[2] Akihiro Shimomura,[1] Chikako Nakano,[1] Atsushi Takahashi,[1] Yoshiyasu Ueda,[1] Yoshitsugu Takabatake,[1] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Center for Clinical Epidemiology and Biostatistics, University of Pennsylvania School of Medicine, PA.*

Background: Active vitamin D (aVD) is one of the candidates protecting the kidney from tubulointerstitial fibrosis(TIF) because aVD negatively regulates renin in renal diseases with high local renin. However, the therapeutic effects of aVD under low renin condition are not well-established.

Methods: Six-week-old male Sprague-Dawley rats were randomly divided into four groups; sham + vehicle (S+V), sham + maxacalcitol (22-oxacalcitriol (OCT))(S+O), unilateral ureteral obstructed (UUO) + vehicle (U+V), or UUO + OCT (U+O). Vehicle or OCT at a dose of 0.5 μg/kg BW was administrated subcutaneously twice a day. All animals were sacrificed 3 days after UUO because renal renin was temporary down-regulated in UUO kidney on day 3.

Results: Fibrotic parameters (such as tubular injury index, interstitial volume index, and collagen I positive area) and mRNA expression levels of collagen I, collagen III, and fibronectin 1 were elevated in group U+V in comparison with two sham groups. OCT significantly ameliorated these fibrotic changes. Because mRNA and protein levels of renal renin in Group U+O were comparable to those of group U+V, the amelioration of TIF by OCT seemed not to be mediated through suppression of renal renin. Neither renal angiotensin II levels nor plasma renin activities were affected by OCT. OCT significantly suppressed TGF-β1/Smad pathway both in the obstructed kidney and in cultured NRK52E cells. We found that TGF-β1 up-regulates mRNA of TGF-β1 itself in NRK52E cells. Because a selective inhibitor of TGF-β1 type I receptor or a Smad3 inhibitor abrogated the TGF-β1-induced TGF-β1 production, this vicious circle seemed to be Smad3-dependnent. OCT suppressed this vicious circle.

Conclusions: Our findings provide a new rationale for aVD therapy in fibrotic kidney diseases even without renin up-regulation.

FR-PO1231

Combinational Usage of Vitamin D Status and the Earliest Marker Fibroblast Growth Factor 23 Improves Risk Stratification for Renal Outcome Chikako Nakano,[1] Takayuki Hamano,[1] Naohiko Fujii,[2] Isao Matsui,[1] Kodo Tomida,[1] Kazunori Inoue,[1] Akihiro Shimomura,[1] Yoshitsugu Obi,[1] Noriyuki Okada,[3] Yoshiharu Tsubakihara,[3] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Internal Medicine, Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Hyogo, Japan; [3]Nephrology and Hypertension, Osaka General Medical Center, Osaka, Japan.*

Background: High serum phosphate, parathyroid hormone (PTH) and fibroblast growth factor 23 (FGF23) levels and vitamin D deficiency, when studied separately, were found to predict the progression of chronic kidney disease (CKD). However, not all mineral bone disease (MBD)-related factors have been measured simultaneously.

Methods: This prospective cohort consisted of 738 predialysis outpatients (mean estimated glomerular filtration rate (eGFR), 35 mL/min/1.73m^2) in 2 nephrology units. The endpoint was doubling of serum creatinine or dialysis initiation.

Results: At baseline, the increase in intact FGF23 levels with eGFR decline was earlier than changes in the other MBD-related factors. For a median duration of 4.4 years, 213 patients reached the endpoint. In Cox proportional hazards model, high FGF23 and low 25-hydroxyvitamin D (25D) levels predicted CKD progression (interaction P=0.11), while 1,25-dihydroxyvitamin D, PTH, phosphate levels, or active vitamin D therapy did not. Adding FGF23 and 25D to the base model of age, sex, diabetes, proteinuria, eGFR, prior cardiovascular disease, systolic blood pressure, hemoglobin, and albumin led to a net reclassification improvement of 9.05% (P=0.001). Dividing patients into 4 groups by the median of 25D and FGF23, adjusted hazard ratios for the outcome of High FGF23-Low 25D, High FGF23-High 25D, and Low FGF23-Low 25D groups were 2.52 (95%CI 1.13-5.62), 1.96 (0.88-4.36), and 1.47 (0.63-3.43), respectively, compared to Low FGF23-High 25D group (P for trend=0.01). Treating death as a competing risk did not change the results.

Conclusions: Combinational use of two markers improved risk stratification.

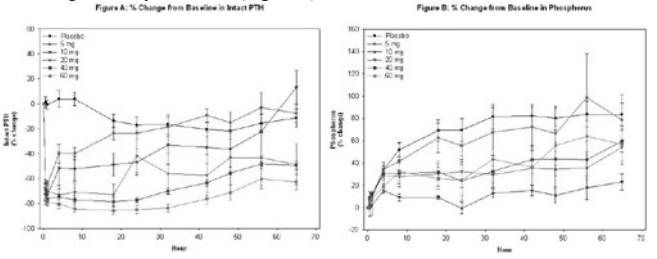
FR-PO1232

The Effect of KAI-4169, a Novel Treatment for Chronic Kidney Disease-Mineral and Bone Disorder, on Serum Phosphorus Kinetics Post-Hemodialysis Kevin J. Martin,[1] Gregory Bell,[2] Saling Huang,[2] Karen Pickthorn,[2] Marwan O. Kaskas,[3] Marializa Bernardo,[4] Peter F. Mount,[5] David A. Power,[5] Geoffrey A. Block.[6] *[1]Saint Louis University; [2]KAI Pharmaceuticals; [3]Northwest Louisiana Nephrology; [4]Southwest Houston Research; [5]Austin Hospital; [6]Denver Nephrology.*

Background: KAI 4169 is a novel, long-acting, peptide agonist of the calcium sensing receptor under development for the treatment of Chronic Kidney Disease-Mineral and Bone Disorder (CKD-MBD) in ESRD.

Methods: Twenty-eight subjects on hemodialysis were given a single dose of KAI 4169 or placebo. The 5, 10 and 20 mg cohorts were studied in a 2-period cross-over design while the 40 and 60 mg cohorts were randomized to KAI-4169 or placebo with 8 subjects per cohort. Immediately following hemodialysis, subjects were admitted to a Phase 1 unit and observed for 3 days. Baseline laboratory testing was performed 2 hours post hemodialysis.

Results: Following injection of KAI 4169 post dialysis, there is a rapid 60-80% decrease in the levels of intact PTH followed by a dose dependent return towards baseline over the following ~70 hours (Figure A). Phosphorus values which were decreased by dialysis, rose rapidly over the first 8 hours to a plateau and then increased more slowly during the remaining interdialytic interval (Figure B).



Interestingly, the rate of return to the plateau level of phosphorus was markedly modified by KAI-4169. The 5 mg dose had minimal effect but higher doses markedly decreased the rise of serum phosphorus towards pre-dialysis values.

Conclusions: These observations suggest that the marked reduction in PTH sustained over 72 hours appears to alter serum phosphorus kinetics post dialysis such that phosphorus efflux, presumably from bone, is markedly attenuated. This would suggest that phosphorus efflux from bone is a significant contributor to the generation and maintenance of hyperphosphatemia in patients with secondary hyperparathyroidism on hemodialysis.

FR-PO1233

Vitamin D Deficiency in Acute Kidney Injury David E. Leaf,[1] Myles S. Wolf,[2] Leonard Stern.[1] *[1]Department of Medicine, Division of Nephrology, Columbia University Medical Center, New York, NY; [2]Division of Nephrology, University of Miami, FL.*

Background: Chronic kidney disease and end-stage renal disease are associated with high rates of vitamin D deficiency. In contrast, little is known about vitamin D homeostasis in acute kidney injury (AKI).

Methods: We recruited 28 participants with AKI and 30 controls from the medical intensive care unit and general hospital wards of Columbia University Medical Center. The following serum values were measured at baseline and repeated 5 days later: 25-hydroxyvitamin D (25(OH)D), 1,25-dihydroxyvitamin D_3 ($1,25(OH)_2D_3$), 24R,25-dihydroxyvitamin D_3 ($24R,25(OH)_2D_3$), Vitamin D Binding Protein (VDBP), Fibroblast Growth Factor 23 (FGF-23), and Parathyroid Hormone (PTH).

Results: Compared with controls, participants with AKI had lower baseline levels of 25(OH)D, 1,25(OH)2D3, 24R,25(OH)2D3), and VDBP, and higher levels of FGF-23 and PTH. Among participants with AKI, there was a significant inverse correlation between FGF-23 and 25(OH)D (p=0.018), however, no significant correlations were found between FGF-23 and 1,25(OH)2D3, nor between FGF-23 and 24R,25(OH)2D3.

Baseline serum values in control vs. AKI, median (IQR)

	Control	AKI	p-value
25(OH)D (ng/ml)	14 (8-21)	8 (5-15)	0.049
1,25(OH)2D3 (pg/ml)	25 (15-35)	15 (10-22)	0.013
24R,25(OH)2D3 (ng/ml)	1.5 (0.6-2.6)	0.9 (0.3-1.2)	0.009
VDBP (mg/dl)	29 (25-36)	23 (14-31)	0.009
FGF-23 (RU/ml)	263 (87-577)	1546 (253-2988)	0.003
PTH (pg/ml)	40 (30-80)	74 (50-148)	0.013
Ca (mg/dl)	9.6 (9.3-9.8)	9.1 (9.0-9.4)	0.001
PO4 (mg/dl)	3.4 (2.9-4.0)	4.7 (3.6-5.8)	0.001

Conclusions: AKI is associated with vitamin D deficiency and elevation of FGF-23. While elevated FGF-23 may contribute to vitamin D deficiency in AKI, the mechanism does not appear to be mediated by CYP24 and enhanced catabolism of 25(OH)D, given our findings of a decreased $24R,25(OH)_2D_3$. The mechanism may be related to alterations of vitamin D distribution or to diminished substrate delivery, as the VDBP levels were also decreased. The significance of these preliminary findings is unclear and will require future investigation. Vitamin D deficiency in AKI may have important physiologic consequences such as impaired host immunity, and may be a marker of poor outcomes.

No Change in Methylation Pattern of Parathyroid *VDR* and *CaR* Genes in Secondary Hyperparathyroidism in the Rat Jacob Hofman-Bang,[1] Eva Graversen,[1] Ewa Lewin.[1, 2] *[1]Department of Nephrology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; [2]Department of Nephrology, Herlev Hospital, University of Copenhagen, Copenhagen, Denmark.*

Background: Secondary hyperparathyroidism (sHPT) due to uremia is characterized by decreased expression of the vitamin D receptor (*VDR*) and the calcium sensing receptor (*CaR*) in the parathyroids. Previous results from our lab showed a resistance towards normalization of the gene expression of *VDR* and *CaR* after an isogenic kidney transplantation in rats. In parathyroid tissue cultures CaR expression is also significantly reduced. Methylation of cytosine nucleotides in CpG islands - CpG being the DNA di-nucleotide - is often detected during epigenetic down-regulation of gene expression.

The possibility of a change in the parathyroid promoter methylation was therefore examined in uremic rats on a high phosphate diet for 8 weeks (n=9) as compared to sham operated rats. Furthermore, the methylation pattern was examined in 24 h parathyroid tissue cultures(n=7).

Methods: Utilizing melting temperature profiling of the PCR products after bisulfite treatment of genomic DNA from rat parathyroids, we assessed the methylation pattern of gene promoter regions harbouring CpG islands in the *CaR* and *VDR* genes. Gene expression was assessed by real time PCR.

Results: The parathyroids of uremic rats and the parathyroid cultures all showed the same low methylation pattern, as seen in sham rats. Verifying the low expression of CaR in vitro, we also observed a low expression of VDR, PTH and Klotho at 24 hours.

Conclusions: In the rat model of sHPT due to uremia and in tissue cultures of normal parathyroid glands no aberrant methylation pattern was detected in the promoter regions of the parathyroid *CaR* and *VDR* genes. As such, a change in the methylation of the promoters in the parathyroids could not explain the decreased expression of *CaR* and *VDR* genes in experimental uremia. Furthermore, the low *CaR* and *VDR* gene expressions *in vitro* after 24 h could not be attributed to promoter methylation.

FR-PO1235

The Fasting Fractional Excretion of Phosphate Is Correlated with FGF23 Levels in CKD Patients Not on Dialysis Patricia Quadros Branco,[1] Ricardo Vizinho,[1] Teresa Adragao,[1] Andre L. Weigert,[1] Maria Augusta Cabrita Silva Gaspar,[1] Rita Birne,[1] Cristina Jorge,[1] Artur P. Mendes,[1] Jorge Dickson,[1] Joao Faro-Viana,[2] Jose Matias Barata.[1] *[1]Nephrology Department, HSC, Carnaxide, Lisboa, Portugal; [2]Pathology Department, CHLO.*

Background: In CKD patients (pts) increase of FGF23 levels precedes PTH and phosphate (P) increase; 24h-phosphaturia is reduced in advanced CKD stages and 24h-fractional excretion of P (FEP) is not consistently correlated with FGF23. This study aimed to analyze, in a group of CKD not on dialysis pts the correlation of fasting FEP and FGF23 levels.

Methods: We studied 86 CKD (74% male; 21% diabetic; age 65±13 years; CKD stages 3: 48%, 4: 43%, 5: 9%). FGF23 (C-Terminal, Immutopics) was evaluated by ELISA. FEP (%) calculated using formula (UPO4 x PCr):(PPO4 x UCr) x 100**.** Blood and urine samples were taken simultaneously in a fasting steady state, after discarding overnight urine. Glomerular filtration rate (eGFR) was estimated by the MDRD4 equation.

Results: P>4.5 mg/dL was found in 17% pts, iPTH>normal in 85%, FEP>20% in 88% and FGF23>100 rU/mL in 87%. 43% pts had 25-OH-vitD deficiency (<15 ng/ml) and 42% insufficiency (15-30 ng/ml). In univariable analysis, logFGF23 was inversely correlated with eGFR (p<0.001) and albumin (p<0.022) and directly correlated with P levels (p<0.001), iPTH (p=0.001) and with FEP (p=0.001); FEP was inversely correlated with eGFR (p<0.001) and directly with PTH (p<0.001). Patients with P>4.5 mg/dL showed higher FGF23 levels (p<0.001) and FEP values (p=0.010).

In multivariable analysis, adjusting for age, eGFR and PTH levels, logFGF23 was directly correlated with P levels (p<0.001) and FEP (p=0.008) and inversely with albumin levels (p=0.01); FEP was inversely correlated with eGFR (p<0.001) and P levels (p=0.001) and directly with logFGF23 (p=0.008).

Conclusions: In summary, in this group of CKD pts, P levels were increased only in 17% of pts; while FEP>20% was detected in 88% of pts. Fasting FEP was inversely associated with eGFR and positively associated with FGF23 levels. FEP evaluated by this simple method may be a useful tool in the assessment of the altered mineral metabolism of CKD pts.

FR-PO1236

Safety and Efficacy of Cholecalciferol (D3) Treatment in Hemodialysis Patients: Effects on Bone and Mineral Metabolism Maria Krassilnikova, Peter S. Heeger, Brian D. Radbill, Anita Mehrotra. *Medicine, Mount Sinai School of Medicine, New York, NY.*

Background: 25OH vitamin D (25OHD) deficiency is common in hemodialysis patients, and uncontrolled studies show that repletion may be associated with a decline in PTH. To determine the safety and efficacy of D3 repletion and its effect on bone and mineral metabolism, we carried out a randomized controlled study of D3 repletion in a cohort of dialysis outpatients.

Methods: We screened 97 patients for 25OHD deficiency. 79 patients with 25OHD levels <25ng/mL were randomized to treatment with D3 (50,000 IU/week to goal >35 followed by 10,000 IU/week) or control (no therapy) in a 2:1 ratio. After 6 weeks, 3, and 6 months, patients were assessed for any side effects, medications and monthly parameters of bone and mineral metabolism were reviewed, and 25OHD levels were measured.

Results: In the D3 treatment arm, baseline median 25OHD increased from 13.5ng/mL to 40.5 at 6 weeks (n=51/p<0.001), 43.4 at 3 months (n=38/p<0.001) and 38.5 at 6 months (n=20/p<0.001). Baseline median serum Ca was 9.3mg/dL and remained unchanged at 6 weeks (9.2/p=0.785), 3 months (9.4/p=0.984), and 6 months (9.4/p=0.852). Median PTH was 360pg/mL at baseline, 381 at 6 weeks (p=0.212), 372 at 3 months (p=0.757), and 292 at 6 months (p=0.97).

At our dialysis center, therapy with activated Vit D is dose-adjusted to serum PTH level. Intriguingly, normalization of 25OHD with oral D3 resulted in a significant decrease in dose of activated Vit D from 4mcg 3x/week at baseline to 2mcg 3x/week at 6 months (n = 20/p=0.026).

In contrast, in the control arm (n=28), we did not observe changes in median 25OHD (13.1ng/mL at baseline vs. 10.4 at 6 months, n=13, p=0.944). There were no changes in Ca (9.1mg/dL at baseline vs. 8.8 at 6 months, p=0.158) or PTH (293pg/mL at baseline vs. 329 at 6 months, p=0.158). Moreover, activated Vit D requirements were unchanged.

Conclusions: The early results of this randomized trial indicate that D3 repletion is safe and effective in hemodialysis patients and suggest that repletion lowers dose of activated Vit D required to maintain optimal bone mineralization. Because oral D3 is inexpensive, these findings could have important economic implications.

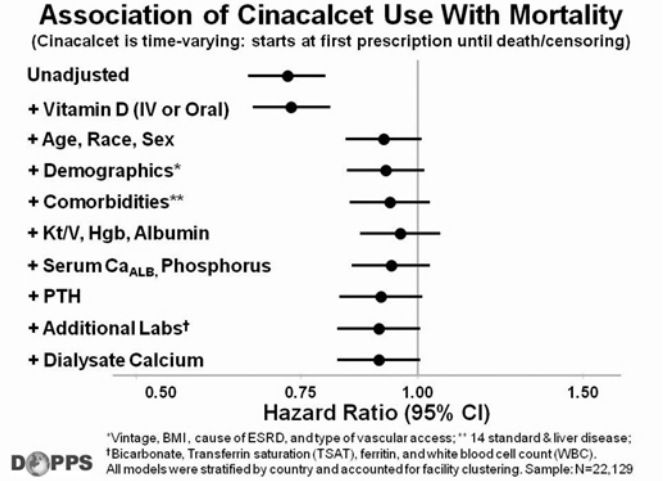
Cinacalcet Therapy & Mortality among Hemodialysis (HD) Patients: International Results from the Dialysis Outcomes & Practice Patterns Study (DOPPS) Francesca Tentori,[1] Diane Steffick,[1] Ronald L. Pisoni,[1] Brenda W. Gillespie,[1,2] Peter G. Kerr,[3] Stefan H. Jacobson,[4] Takashi Akiba,[5] Bruce M. Robinson.[1,2] *[1]Arbor Research Collab for Health, Ann Arbor, MI; [2]Univ of Michigan, Ann Arbor; [3]Monash Medical Centre & Univ, Australia; [4]Danderyd Hospital, Stockholm, Sweden; [5]Tokyo Women's Medical Univ, Japan.*

Background: Elevated parathyroid hormone (PTH) is associated with poor outcomes in dialysis patients. By acting on parathyroid calcium-sensing receptors, calcimimetics (cinacalcet) may provide better PTH control than vitamin D (VitD) alone. Among VitD-treated patients from a US dialysis provider, those also using cinacalcet had lower mortality. We studied cinacalcet use & mortality in a HD cohort from 12 countries with wide variation in clinical practices.

Methods: 22,129 patients in DOPPS3 & 4 (2005-2010) were analyzed; 4,534 (20%) used cinacalcet. Cox models were used to predict survival with a time-varying cinacalcet indicator set at first reported prescription.

Results: Cinacalcet use rose over time from 8% (2005) to 19% (2010) & varied across facilities in each country (e.g. 0 to 90% in US). Patients on cinacalcet were younger (Δmean=5.8 yrs), had been on dialysis longer & had fewer comorbidities than those not on cinacalcet. At study entry, VitD (IV/oral) use was 71% for cinacalcet patients & 58% for non-cinacalcet patients. Mortality risk was lower for cinacalcet users in unadjusted models (HR=0.73, p<.001); this association was explained mostly by adjustments for demographics (HR=0.92, p=.08) & slightly by other factors (HR=0.91, p=.08).



Conclusions: Cinacalcet use varies widely between facilities, likely due to differences in policies & provider preferences. In this international HD cohort, mortality risk is slightly lower with cinacalcet use. Whether this finding is due entirely to patient health status or to a drug effect requires additional investigation.

Characterization of KAI-4169, a Novel Peptide for the Treatment of Chronic Kidney Disease – Mineral and Bone Disorder, in a Phase I Study in Healthy Males Kevin J. Martin,[1] Gregory Bell,[2] Karen Pickthorn,[2] Saling Huang,[2] Peter Hodsman,[3] Munro Peacock.[4] *[1]Saint Louis University School of Medicine; [2]KAI Pharmaceuticals; [3]Nucleus Network; [4]Indiana University.*

Background: KAI-4169 is a novel peptide agonist of the CaSR that is being developed as a therapy for patients with chronic kidney disease-mineral and bone disorder (CKD-MBD). This 'first-in-man' study was conducted to evaluate the safety, tolerability, pharmacokinetics and pharmacodynamics of KAI-4169 in healthy males.

Methods: KAI-4169, administered as an IV bolus, was evaluated in a single-center, randomized, double-blind, placebo-controlled, single-dose, dose escalation Phase 1 study. Eight subjects were enrolled in each of 4 cohorts (0.5, 2, 5, 10 mg) and were randomized 6:2 to KAI-4169 or placebo. Serum for routine chemistries and PTH were obtained prior to dosing and every 2-6 hours following dosing for 48 hours. Plasma for KAI-4169 analysis were collected at regular intervals following dosing. Urine was collected 24 hours prior to dosing and for 48 hours following dosing.

Results: The plasma terminal half-life of KAI-4169 was ~20 hours and KAI-4169 exposure was dose-dependent. KAI-4169 resulted in dose-dependent reductions in iPTH with a mean percent change from baseline at 30 minutes folowing dosing of -3.5, -21.7, -55.4, -69.0 and -72.6% for placebo, 0.5, 2, 5 and 10 mg groups, respectively. Dose-dependent reductions in serum calcium were observed with a mean maximal reduction of ~16% at the highest dose. There was no significant change in the urine Ca/Cr ratio but tubular reabsorption of Ca tended to decrease with dose in the period immediately following dosing. Mean serum phosphorus (Pi) changes were similar to placebo except in the 10 mg cohort where it increased; however, apparent dose-dependent reductions in the Pi/Cr ratio and dose-dependent increases in tubular reabsorption of Pi were observed.

Conclusions: KAI-4169, a novel peptide agonist of the CaSR, was well tolerated at single doses up to 10 mg in healthy men and resulted in sustained dose-dependent reductions in PTH and calcium. KAI-4169 may represent a novel therapeutic approach for the treatment of CKD-MBD.

FR-PO1239

Evidence for Increased Catabolism of 25(OH)D in CKD Hala Alshayeb,[1] Barry M. Wall,[2] Arif Showkat,[1] Geeta G. Gyamlani,[2] Valentin David,[1] Bing Dai,[1] Leigh Darryl Quarles.[1] *[1]Nephrology, UTHSC, Memphis, TN; [2]Nephrology, VAMC, Memphis, TN.*

Background: Low circulating 25(OH)D, a marker of vitamin D deficiency, is prevalent in CKD. 1,25$(OH)_2$D is synthesized from 25(OH)D by CYP 27b1 and both D metabolites are catabolized via Cyp24-mediated hydroxylation. Complex derangements in vitamin D metabolism occur in CKD, including PTH stimulation of Cyp27b1 and FGF23 and active vitamin D analogue stimulation of Cyp24. The contribution of Cyp24-mediated catabolism to the lower serum 25(OH)D in CKD is not clear.

Methods: We examined serum FGF23 and 25(OH)D levels and kidney Cyp24 mRNA expression in a nutritionally replete Col4a3$^{-/-}$ mouse CKD model. In addition, we assessed the ability of cholecalciferol po 10,000 IU/week for 8 weeks to increase serum 25OHD level in CKD (n=14) and non-CKD (n=14) patients with 25(OH)D levels ≤ 20 ng/ml. We assessed the effects of concomitant treatment with activate vitamin D analogues on cholecalciferol-induced changes in serum 25(OH)D in patients with ESRD (n=14).

Results: The Col4a3-/- mice exhibited reductions in renal function that were associated with progressive increments in serum FGF23 levels and elevations of Cyp24 message expression in the kidney. Serum FGF23 concentrations were negatively correlated with serum 25(OH)D levels in Col4a3-/- mice (Pearson r=-0.65, p<0.00001). CKD and non-CKD patients had similar baseline 25(OH)D and 1,25(OH)2D concentrations, but the CKD group had significantly higher baseline PTH levels(167±117 vs 60± 27). The change in 25OHD and 1,25(OH)2D levels were lower in CKD vs non-CKD (12±9 vs 19±8, p=0.05) and (4±24 vs 16±32, p =0.1). Serum iPTH levels decreased significantly after treatment in CKD (-42±68, p=0.04) but not in non-CKD (-10±25, p=0.16). In the ESRD group co-treatment with doxercalciferol resulted in significantly lower cholelcalciferal induced increments in 25(OH)D (11±6) compared to the non-doxercalciferol treated group (22±12) (p=0.04).

Conclusions: Experimental CKD in mice have FGF23-associated reductions in 25(OH) D and patients with impaired renal function are resistant to cholecalciferol treatment possibly due to FGF23 and/or doxercalciferol-mediated Cyp24 catabolism of 25(OH)D.

Funding: NIDDK Support

FR-PO1240

Vitamin D Deficiency in Fabry Disease Christiane Drechsler,[1] Stefan Pilz,[3] Christoph Wanner.[1] *[1]Dept of Medicine 1, Div of Nephrology, University of Wuerzburg, Germany; [2]Dept of Endocrinology, University of Graz, Austria.*

Background: Patients with Fabry disease frequently develop left ventricular (LV) hypertrophy and renal fibrosis. Due to heat intolerance and inability to sweat, patients tend to avoid sunlight exposure. We hypothesized that subsequent vitamin D deficiency may contribute to hypertrophic cardiomyopathy (HCM). This study investigated the vitamin D status and its association with LV mass, HCM and adverse clinical symptoms in patients with Fabry disease.

Methods: 25-hydroxyvitamin D (25[OH]D) was measured in 111 patients with genetically proven Fabry disease. LV mass and HCM were assessed by echocardiography and magnetic resonance imaging. In cross-sectional analyses, associations with adverse

clinical outcomes were determined by linear and binary logistic regression analyses, respectively, and adjusted for age and sex.

Results: Patients had a mean age of 40±13 years (42% male), and mean 25(OH)D of 23.5±11.4 ng/ml. Those with severe vitamin D deficiency (25[OH]D ≤ 10ng/ml) had an adjusted 10fold higher risk of HCM compared to those with sufficient 25(OH)D levels >30ng/ml (p=0.005). The mean LV mass was meaningfully different with 170±75 g in severely deficient, 154±60 g in deficient and 128±58 g in Vitamin D sufficient patients, respectively (p=0.013). With the severity of vitamin D deficiency, the median levels of proteinuria increased, as did the prevalences of depression, edema, cornea verticillata and the need for medical pain therapy.

Conclusions: Vitamin D deficiency was strongly associated with HCM and higher LV mass in patients with Fabry disease as well as adverse clinical symptoms. Whether vitamin D supplementation improves complications of Fabry disease, requires randomized controlled trials.

FR-PO1241

Regulators of Bone Mineral Disorder and Vascular Function in Patients with Chronic Kidney Disease Doris T. Chan,[1,2] Ashley B. Irish,[3] Gursharan K. Dogra.[1] *[1]Renal Unit, Sir Charles Gairdner Hospital, Nedlands, Western Australia, Australia; [2]School of Medicine and Pharmacology, University of Western Australia, Perth, Western Australia, Australia; [3]Department of Nephrology, Royal Perth Hospital, Perth, Western Australia, Australia.*

Background: In light of the known association between hyperphosphatemia and mortality, regulators of bone mineral disorder (BMD) such as fibroblast growth factor-23 (FGF-23), 25-hydroxyvitamin D (25OHD) and fetuin-A may contribute to excess cardiovascular risk in patients with chronic kidney disease (CKD) by mechanisms which involve alteration in vascular function.

Methods: In this cross-sectional study of patients with stage 3-5 CKD (n=125) and 40 healthy controls (HC), regulators and markers of BMD [FGF-23, fetuin-A, 25OHD, calcium, phosphate (PO4), intact parathyroid hormone (iPTH)] and measures of vascular function [endothelium-dependent flow mediated dilatation (FMD) and systemic arterial compliance (SAC)] were evaluated.

Results: Compared with HC, CKD subjects had lower 25OHD, higher PO4, fetuin-A and FGF-23 levels (all p<0.05) but had no difference in serum calcium levels. CKD subjects with lower FMD (median cut-off <4.19%) had higher FGF 23 (P=0.05) and fetuin (p=0.02) levels while those with impaired large artery compliance (median cut-off <14.58ml/mmHgx10) had lower 25OHD level (p=0.05) but with no difference in serum calcium, PO4 and iPTH. In a stepwise multiple regression analysis, higher FGF-23 was independently associated with reduced FMD (beta=-0.28, p=0.001) while low 25OHD was independently associated with impaired large artery compliance (beta=0.19, p=0.01).

Conclusions: Increased serum FGF-23 level in CKD is independently associated with endothelial dysfunction, whereas low 25OH was independently associated with impaired large artery compliance. These data support a link between regulators of BMD and vascular dysfunction in CKD.

FR-PO1242

Comparison of Alfacalcidol and Paricalcitol for Treatment of Secondary Hyperparathyroidism in Hemodialysis Patients: A Randomised Cross-Over Study Ditte Hansen,[1] Knud Rasmussen,[1] Henning B. Danielsen,[8] Helmut Meyer-Hofmann,[2] Egidijus Bacevicius,[2] Jens K. Madsen,[9] Birgitte Godskesen Tougaard,[9] Peter Marckmann,[4] Jorgen Nielsen,[6] Svend Kreiner,[7] Peter Thye-Rønn,[5] Thomas G. Lauridsen,[3] Lisbet Brandi.[1] *[1]Roskilde University Hospital; [2]Aalborg University Hospital; [3]Region Hospital Holstebro; [4]Odense University Hospital; [5]Esbjerg Hospital of Southwest Denmark; [6]Holbaek Hospital; [7]Department of Biostatistics, University of Copenhagen; [8]Viborg Hospital; [9]Århus Universityhospital Skejby, Denmark.*

Background: Alfacalcidol and Paricalcitol are vitamin D analogs used for secondary hyperparathyroidism in CKD patients. Their ability to suppress secondary hyperparathyroidism, without elevating phosphate and calcium outside the accepted range, have never been compared in a randomised clinical trial before.

Methods: In a Danish multicenter randomised 2 x 16 weeks cross-over study, intravenous alfacalcidol and paricalcitol were compared in chronic hemodialysis patients with secondary hyperparathyroidism. Doses were increased every second week until parathyroid hormone were sufficiently suppressed or phosphate or ionised calcium were increased above accepted range.

Results: A total of 86 hemodialysis patients were randomised. Due to the presence of a period effect only data from the first treatment period (n=80) were available for statistical tests. The proportion of patients reaching a 30% decrease in parathyroid hormone during the last four weeks of the treatment period were similar in the two groups (alfacalcidol 82% and paricalcitol 93% (P=0.180)). There was no difference in the incidence of hypercalcemia or hyperphosphatemia between the treatment groups. A significant interaction effect between baseline parathyroid hormone and treatment was found (P=0.012), suggesting that alfacalcidol suppressed parathyroid hormone irrespective of baseline level, whereas suppression by paricalcitol depended on baseline level.

Conclusions: We found no over-all difference between alfacalcidol and paricalcitol with respect to suppression of secondary hyperparathyroidism and induction of hypercalcemia and hyperphosphatemia in hemodialysis patients.

Funding: Pharmaceutical Company Support, Private Foundation Support, Government Support - Non-U.S.

Lack of Signalling through Vitamin D Receptor Leads to Stress-Induced Premature Senescence in Vascular Smooth Muscle Cells Petya Valcheva, Noelia Torremade, Milica Bozic, Elvira Fernandez, Jose M. Valdivielso. *Experimental Nephrology, IRBLLEIDA, Lleida, Spain.*

Background: Vitamin D has been associated with cardiovascular health in a number of epidemiological studies. In vascular smooth muscle cells (VSMC), vitamin D regulates proliferation and calcification. In the artery wall, angiotensin II (Ang II) is a potent mediator of oxidative stress and provokes premature senescence in VSMC. Ang II levels are controlled by renin expression, which promoter is regulated by vitamin D. Thus, a defect of vitamin D signalling in the artery wall could lead to an increase in Ang II levels and its adverse effects.

Methods: Proliferation of VSMC of VDRKO and WT mice was tested in vitro and in vivo. The expression of the cell cycle regulators involved in the G1/S transition checkpoint were analyzed. The local production of Ang II and of Ang II-induced free radicals, and its involvement in the phenotype of VDRKO cells was tested.

Results: Proliferation rates of VSMC from VDR null mice (VDRKO) are lower than wild type (WT) both, in vitro and in vivo, together with an increased expression of p19Arf, p27Kip1, p21Cip1 and p57Kip2, and lower levels phosphorylated pRb and cyclins D and E. Furthermore, VDRKO cells showed an increase in the expression of cathepsin D and Ang II type 1 (AT1) receptor, together with an increased production of Ang II. Also, superoxide anion production was higher in the mutant cells, and was inhibited with both losartan and DPI. Thus, VDRKO cells showed premature senescence together with an increase in free radicals produced by NADPH oxidase.

Conclusions: Absence of VDR signalling in VSMC leads to premature senescence due to the increased local production of AngII, and an increase in free radicals, which suggests a possible role of the vitamin D system in vascular diseases associated with hyperproliferation of VSMC.

FR-PO1244

Effects of Cinacalcet Treatment on Serum Soluble Klotho Levels in Hemodialysis Patients with Secondary Hyperparathyroidism Hirotaka Komaba, Hisae Tanaka, Masahiro Koizumi, Hiroo Takahashi, Kaichiro Sawada, Takatoshi Kakuta, Masafumi Fukagawa. *Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan.*

Background: Klotho is a transmembrane protein and acts as a cofactor for fibroblast growth factor 23 (FGF23). In patients with end-stage renal disease, parathyroid expression of Klotho and FGF receptor 1 is decreased, which may contribute to the pathogenesis of secondary hyperparathyroidism (SHPT) by causing parathyroid resistance to FGF23 to inhibit parathyroid hormone (PTH) secretion. Klotho also exists as a soluble circulating protein, which is generated by cleavage of the extracellular domain of the molecule. However, the role of soluble Klotho in patients with SHPT is largely unknown.

Methods: This was a *post hoc* analysis of data from a 52-week, multicenter, open-label, single-arm trial that examined the effect of cinacalcet on SHPT in patients undergoing hemodialysis. Soluble Klotho and full-length FGF23 levels were measured at baseline and study weeks 12, 24, and 52, using serum samples of 51 patients who participated and completed the study.

Results: At baseline, median soluble Klotho was 398 pg/ml (interquartile range, 268 to 588 pg/ml), which was slightly lower than the reported values in healthy subjects. After 12 weeks of cinacalcet treatment, soluble Klotho decreased significantly but only slightly (median, 378 pg/ml; interquartile range, 266 to 568 pg/ml), and returned to the baseline values thereafter. There were no significant associations between changes in soluble Klotho and changes in any other parameters of mineral metabolism, including serum calcium, phosphorus, intact PTH, and FGF23.

Conclusions: Despite significant alterations in mineral and bone metabolism during treatment with cinacalcet, there were only slight and transient reductions in soluble Klotho levels. Further studies are needed to determine the role of soluble Klotho in altered mineral metabolism in patients with SHPT.

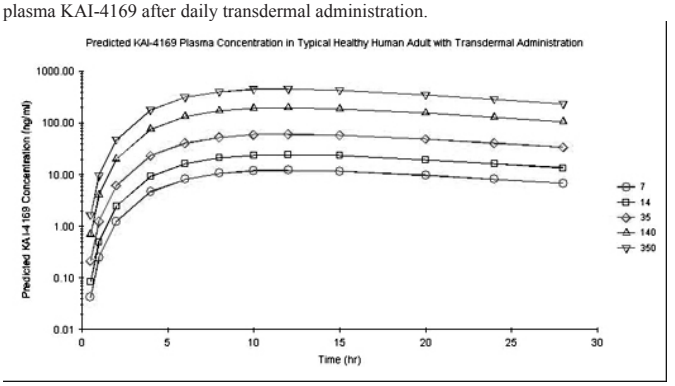
FR-PO1245

PK/PD Modeling of Transdermal Delivery of a Novel Peptide, KAI-4169, for the Treatment of Chronic Kidney Disease-Mineral and Bone Disorder Karen Pickthorn,[1] Jun Shen,[2] Andrew M. Vick,[2] Sarah Walter,[1] Saling Huang,[1] Gregory Bell,[1] Randolph M. Johnson.[1] *[1]KAI Pharmaceuticals, South San Francisco, CA; [2]Seventh Wave, Chesterfield, MO.*

Background: KAI-4169, a novel peptide agonist of the calcium sensing receptor that inhibits PTH secretion, is in development for the treatment of CKD-MBD. Microporation of the stratum corneum is a painless method of enabling transdermal delivery of peptide compounds. Systemic delivery of KAI-4169 using transdermal microporation patch technologies was evaluated in animals and was used with clinical Phase 1 PK and PTH data obtained following IV KAI-4169 to healthy volunteers (HV) and hemodialysis patients (HD) to develop a quantitative PK/PD model for daily dosing with a KAI-4169 patch.

Methods: KAI-4169 disposition parameters were directly extracted from Phase 1 data. From preclinical data, bioavailability was estimated and a transit absorption model constructed to estimate the number of compartments and mean transit time for drug to

pass through these compartments to reach the central circulation. Using these parameters, a 1-compartment distribution with transit absorption model was constructed to simulate plasma KAI-4169 after daily transdermal administration.



Phase 1 PK/PD data were then leveraged to simulate PTH response with KAI-4169 patch administration in Stage 4 CKD patients.

Results: The novel peptide KAI-4169 can be delivered systemically by patch technologies. In HV and HD subjects, KAI-4169 demonstrated low PK variability and a predictable exposure-response relationship. Simulations performed with the integrated PK/PD model indicate that daily dosing with KAI-4169 patch will result in dose-dependent sustained exposure to KAI-4169 with corresponding reductions in PTH.

Conclusions: Daily transdermal patch administration of KAI-4169 is predicted to provide sustained PTH control in Stage 4 patients with CKD-MBD.

Calcidiol Is Less Effective Than Calcitriol in Regulating VDR Target Gene Expression in Human Coronary Artery Smooth Muscle Cells J. Ruth Wu-Wong,[1] Myles S. Wolf,[2] Masaki Nakane.[1] *[1]Renal Research, VidaGene, Chicago, IL; [2]Miller School of Medicine, University of Miami, FL.*

Background: Vitamin D receptor (VDR) activation by agonists such as calcitriol, paricalcitol and doxercalciferol is associated with cardiovascular benefits in chronic kidney disease patients, but whether VDR's hormone, calcitriol, and prehormone, calcidiol, exhibit similar effects requires more studies.

Methods: Primary culture of human coronary artery smooth muscle cells (HCASMCs) were treated with the VDR agonist calcitriol or the prehormone calcidiol in the presence of normal (0.9 mM) or elevated (2.06 mM) phosphate (Pi). The expression of VDR target genes were determined by real-time PCR and proteins detected by Western blotting. The expression and activity of CYP27B1 (the enzyme responsible for converting calcidiol to calcitriol) was also measured.

Results: Treating HCASMCs with 2.06 mM Pi for 24 -48 hr significantly elevated the VDR mRNA (233%) and protein levels (181%). Calcitriol and calcidiol induced CYP24A1 expression with EC50 values at 70 and 662 nM, respectively; the effects of both compounds were not affected by high Pi. Calcitriol and calcidiol stimulated the expression of thrombomodulin with EC50 at 61 and 156 nM at 0.9 mM Pi, respectively. When the Pi concentration was increased to 2.06 mM, the EC50 of calcitriol on stimulating thrombomodulin was at 31 nM, but the EC50 of calcidiol was increased to 780 nM. At either 0.9 or 2.06 mM Pi, calcitriol suppressed the expression of thrombospondin-1 with IC50 at 9-12 nM, while calcidiol had no significant effect. Mechanistic analysis demonstrated that HCASMCs expressed the CYP27B1 mRNA and protein, which was not significantly affected by elevated Pi. HCASMCs converted calcidiol to calcitriol at a low rate (about 20% in 24 h).

Conclusions: HCASMCs express CYP27B1 and are capable of converting calcidiol to calcitriol, but the conversion rate is low, which may explain why the prehormone calcidiol is less effective than calcitriol in regulating VDR target gene expression.

FR-PO1247

Relationship between Parathyroid Hormone(PTH)and Serum Phosphorus (P) Levels before and during Treatment with Cinacalcet among Hemodialysis (HD) Patients with Secondary Hyperparathyroidism (SHPT) Kerry Cooper, Yumi Kubo, Holly Tomlin, William G. Goodman. *Amgen Inc.*

Background: Efforts to control hyperphosphatemia in patients on HD focus mainly on reducing gastrointestinal P absorption with dietary P restriction and P binders. Much less attention is given to SHPT as a cause of hyperphosphatemia despite the known effect of PTH to mobilize both P and calcium from bone.

Methods: We thus evaluated the relationship between PTH and P levels before and during 26 weeks of treatment with Sensipar®/Mimpara® (cinacalcet) using pooled data from Phase III studies. All subjects had a PTH>300pg/mL and calcium≥8.4mg/L at study entry. Per criteria, all subjects were on constant doses of vitamin D sterols and P binders at baseline and mean doses did not change during follow-up. The severity of SHPT at baseline was categorized by PTH levels: 300-500pg/mL; 500-800pg/mL; and >800pg/mL. Among cinacalcet-treated subjects (N=656), the median (Q1,Q3) of all PTH and P levels between study weeks 12 and 26 were compared with median PTH and P values at baseline.

Results: The median serum P at baseline was incrementally higher by category of disease severity, being highest in those with PTH>800 pg/mL. Serum P decreased during treatment with cinacalcet regardless of baseline disease severity. Both the absolute change and percentage decrease in serum P were incrementally greater with increasing disease severity. In fact, the largest reductions in serum P were seen in cinacalcet-treated subjects with baseline PTH>800 pg/mL. For all cinacalcet-treated subjects, the reductions in PTH and serum P were positively associated.

	PTH (pg/mL) 300-500 (N=242)	500-800 (N=228)	>800 (N=186)
Baseline P (mg/dL), median (Q1, Q3)	5.82 (4.81, 6.73)	5.88 (4.89, 7.10)	6.55 (5.45, 7.67)
P after Cinacalcet Therapy [median, (Q1, Q3)]			
Mean P During Therapy (mg/dL)	5.21 (4.30, 6.31)	5.28 (4.35, 6.28)	5.64 (4.74, 6.77)
Absolute Change from Baseline (mg/dL)	-0.48 (-1.29, 0.26)	-0.62 (-1.58, 0.41)	-0.86 (-1.73, 0.10)
Percent Change from Baseline (%)	-7.95 (-21.94, 5.28)	-10.11 (-26.27, 6.81)	-12.46 (-26.51, 2.22)
PTH after Cinacalcet Therapy [median (Q1, Q3)]			
Mean PTH During Therapy (pg/mL)	191.10 (135.00, 298.49)	281.10 (1 72.29, 426.00)	703.10 (384.12, 1134.00)
Absolute Change from Baseline (pg/mL)	-197.56 (-263.09, -74.81)	-345.31 (-453.30, -201.95)	-464 (-733.80, -105.60)
Percent Change from Baseline (%)	-51.07 (-66.45,20.85)	-54.99 (-72.46, -30.87)	-39.60 (-65.02, -8.62)

Conclusions: Hyperphosphatemia worsens in subjects with advanced SHPT and serum P levels decrease when PTH levels are lowered during treatment with cinacalcet. Inadequately controlled SHPT contributes substantially to the hyperphosphatemia that characterizes patients undergoing HD.

FR-PO1248

25-Hydroxyvitamin D3 Levels Are Predictors of Morbidity and Mortality in Hemodialysis Patients Patrícia Matias,[1,2,3] Cristina Jorge,[1,2,3] Carina Ferreira,[1,2,3] Marília Borges,[4] Inês Aires,[1,2,3] Tiago Amaral,[1,2,3] Marco Mendes,[1,2,3] Célia Gil,[1,2,3] José Cortez,[4] Aníbal Ferreira.[1,2,3] *[1]Dialysis Clinic, Hemodial, Vila Franca de Xira, Portugal; [2]Dialysis Clinic, Dialverca, Alverca, Portugal; [3]NIDAN, Lisboa, Portugal; [4]Laboratório Dr. Fernando Teixeira, Lisboa, Portugal.*

Background: Vitamin D deficiency has been associated with the development of cardiovascular (CV) disease and mortality in the general population.

The aim of this prospective study was to evaluate the relationship between 25-hydroxyvitamin D3 [25(OH)D3] and 1,25-dihydroxyvitamin D3 [1,25(OH)2D3] levels and mortality in chronic hemodialysis (HD) patients.

Methods: With this purpose, we measured [25(OH)D3] and [1,25(OH)2D3] serum levels twice (end of Winter and of Summer) and correlated them with hospitalizations and overall and CV mortality for the following 48-month period. All patients were submitted to oral cholecalciferol supplementation according to baseline calcidiol levels during the studied period.

We studied 223 HD patients with mean age (± SD) of 62.7±15.3 years, 48% female, 27% diabetics, with mean HD time of 42.9±39.3 months. Univariate and multivariate analysis were performed and a $p<0.05$ was considered significant.

Results: During the study, 44% of the patients were hospitalized at least once and 29% of the patients died (mainly from CV causes). [25(OH)D3] levels were significantly lower in the patients that died from all causes (16.6±8.2 vs. 23.7±13.1 ng/mL, $p< 0.001$) and in patients that died from CV causes (16.4±8.7 vs. 22.6±12.6 ng/mL, p=0.006). [25(OH)D3] levels were also lower in patients hospitalized during the study (18.5±9.3 vs. 23.9±11.7 ng/mL, p=0.001). [1,25(OH)2D3] levels were similar in all groups.

In multivariate analysis, lower levels of [25(OH)D3] were predictors of hospitalization (p=0.01), death from all causes (p=0.001) and death from CV causes (p=0.02). Patients with [25(OH)D3] deficiency (< 15 ng/mL) had a significantly lower survival at the end of the 48-month studied period ($p<0.001$).

Conclusions: In conclusion, [25(OH)D3] serum levels seem to be a good marker of morbidity (according to hospitalizations) and mortality (overall and CV) in HD patients.

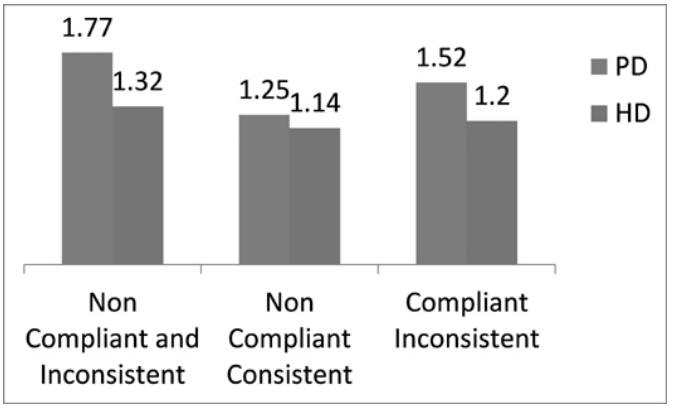
FR-PO1249

Serum Phosphorous Variability Is Associated with Elevated Mortality Risk in Hemodialysis and Peritoneal Dialysis Patients Stefanos Zenios,[1,3] Hector J. Rodriguez,[2] Constantia Petrou.[3] *[1]Graduate School of Business, Stanford University; [2]DaVita Inc; [3]Culmini Inc.*

Background: To determine the association between serum phosphorous levels and variability, and mortality in ESRD patients.

Methods: Data on all ESRD patients from a major dialysis chain from 1/1/2006 to 12/1/2009 were divided into six-month intervals generating a total of 119,191 patients and 852,239 six-moth windows. For each patient-interval we obtained treatment modality (PD vs HD), average and standard deviation of serum phosphorous levels, age, gender and race, comorbidity indicators, Charlson index, ICD-9-CM codes, medical tests, dialysis adequacy, pre and post dialysis weight and blood pressure, medication doses and compliance. Patients were classified: compliant when average serum phosphorous was below the K/DOQI guidelines standard of 5.5 mg/dl, non-compliant otherwise, consistent when standard deviation of serum phosphorous was below the all-patient average of the standard deviations, inconsistent otherwise. Time dependent proportional hazards regression for time to death was performed seperately for HD and for PD.

Results: 57% of patients were compliant, 56% were consistent, 40% were compliant and consistent. After adjusting for comorbidities, other lab tests, and medication dosing and compliance, higher serum phosphorous levels and variability were associated with higher mortality in both HD and PD patients. The Figure presents relative mortality risk (compliant/consistent is the baseline) - all values were significantly higher than 1 (p-value < 0.001)



Conclusions: Serum phosphorous variability was found to be an independent predictor of mortality in both PD and HD patients. Optimal medical management should focus on managing both serum phosphorous levels and their variability. Unmeasured variables may account for patients with higher and more variable phosphorous levels having higher mortality.

FR-PO1250

Vitamin D Catabolism in Chronic Kidney Disease Cortney R. Bosworth, Gregory Levin, Cassianne Robinson-Cohen, Bryan R. Kestenbaum, Jonathan Himmelfarb, Bessie A. Young, Ian H. de Boer. *University of Washington, Seattle, WA.*

Background: The current paradigm of decreased 1,25-dihydroxyvitamin D [1,25$(OH)_2$D] activation in chronic kidney disease (CKD) is incomplete because it overlooks the role of vitamin D catabolism. 24,25-dihydroxyvitamin D [24,25$(OH)_2$D], the first product in the metabolism of 25-hydroxyvitamin D [25(OH)D] by CYP24A1, is a biomarker of vitamin D catabolism. We developed a novel assay to quantify serum 24,25$(OH)_2$D and studied its determinants, functional significance, and health outcomes in CKD.

Methods: We performed a case-cohort study in the Nephrology clinic-based Seattle Kidney Study. We randomly sampled 277 of 531 participants for inclusion in descriptive analyses and added 34 cases for mortality analyses (total N=90 cases of death). Vitamin D metabolites were measured from frozen baseline serum using HPLC-tandem mass spectrometry. The Barlow method was used for assigning case-cohort sampling weights in survival analyses.

Results: At baseline, participants had a mean eGFR of 46ml/min/1.73m2 and a mean age of 61 years. 83% were men and 69% were white. 24,25(OH)2D concentration declined with kidney function. For eGFR ≥60, 45-59, 30-44, 15-29, and <15 ml/min/1.73m2, mean serum 24,25(OH)2D concentrations were 3.6, 3.2, 2.6, 2.6, and 1.7ng/ml, respectively (p trend <0.001). Black race, diabetes, and acidosis were also associated with lower 24,25(OH)2D concentration. 24,25(OH)2D concentration was more strongly correlated with parathyroid hormone (PTH) concentration (r=-.37, p<0.001) than 25(OH)D (r=-.24) or 1,25(OH)2D (r=-.16). 24,25(OH)2D concentration below the cohort median (2.4ng/mL) was associated with an estimated 87% greater risk of death (95% CI 3%, 240%), p=0.04, after adjustment for age, sex, race, diabetes, coronary artery disease, eGFR, albuminuria, bicarbonate, and 25(OH)D. This association was not attenuated by further adjustment for 1,25(OH)2D, PTH, or fibroblast growth factor-23.

Conclusions: CKD is a state of stagnant vitamin D metabolism characterized by both decreased 1,25$(OH)_2$D production and decreased vitamin D catabolism. Low 24,25$(OH)_2$D, a novel marker of vitamin D catabolism, is associated with increased risk of death.

The Vitamin D Analog Eldecalcitol (ED-71) Is a Potent Inducer of Intestinal Phosphate Absorption and Sodium-Phosphate Cotransporter IIb Alex J. Brown, Cynthia S. Ritter. *Renal Division, Washington University School of Medicine, St. Louis, MO.*

Background: The vitamin D analog eldecalcitol (ED-71) has been developed for treatment of osteoporosis. We have previously reported that this analog has greater potency than calcitriol, the natural vitamin D hormone, on intestinal calcium and phosphate (Pi) absorption. In the present study, we further investigated the actions of eldecalcitol on Pi absorption and induction of the sodium/phosphate cotransporters.

Methods: Vitamin D-deficient rats were treated orally with 0, 20, 50 or 150 pmol of eldecalcitol or calcitriol q.o.d. for 12 days. Duodenal Pi absorption was measured by the duodenal loop method. Phosphate transporter mRNAs were quantified by RT-qPCR. In a second experiment, normal rats were gavaged with vehicle, eldecalcitol (50 pmol) or calctriol (50 or 1000 pmol) at 72 and again at 24 h prior to sacrifice, and phophate transporters expression was determined in the duodenum, jejunum, ileum, kidney and lung.

Results: Duodenal Pi absorption was maximally increased by 8-fold with the 20 pmol dose of eldecalcitol, while none of the doses of calcitriol were effective. This action of eldecalcitol was attributable to a dramatic 24-fold induction of NaPi-IIb (SLC34A2) mRNA in the duodenum. Other duodenal sodium-phosphate cotransporters, Pit-1 (SLC20A1) and Pit-2 (SLC20A2) were not increased. In normal rats, eldecalcitol increased NaPi-IIb 8- and 3-fold in the duodenum and jejunum, respectively, but had no effect in ileum or lung, despite the presence of the VDR and induction of 24-hydroxylase mRNA. Calcitriol had no effects in any of the tissues. Renal NaPi-IIa and NaPi-IIc were not regulated by either vitamin D compound under these conditions.

Conclusions: These studies indicated that the vitamin D analog eldecalcitol is a unique potent stimulator of intestinal Pi absorption via induction of NaPi-IIb. The mechanisms responsible are under investigation.

FR-PO1252

Vitamin D Suppresses High Glucose-Induced GLUT1 Expression in Mesangial Cells by Targeting NF-κB Dilip K. Deb, Youli Wang, Yunzi Chen, Yan Chun Li. *Department of Medicine, University of Chicago, IL.*

Background: Glucose transporter 1 (GLUT1) is a facilitative glucose transporter that is up-regulated by high glucose (HG). In diabetes GLUT1 overexpression in mesangial cells stimulates glucose uptake and the synthesis of extracellular matrix, leading to glomerular injury. Glomerular GLUT1 overexpression in transgenic mice causes glomerulosclerosis even in non-diabetic conditions. Our previous studies showed that vitamin D reduces glomerulosclerosis in diabetic nephropathy.

Methods: We used mesangial cell cultures to explore the molecular mechanism underlying vitamin D inhibition of glomerulosclerosis

Results: Exposure of primary mesangial cells to HG media (30 mM) markedly stimulated GLUT1 expression at mRNA and protein levels, and the stimulation was blocked by 1,25-dihydroxyvitamin D (1,25-VD). Consistently 1,25-VD also inhibited HG-induced glucose influx in mesangial cells. The HG-stimulation was blocked by NF-κB inhibitor BAY 11-7082, suggesting the involvement of NF-κB in HG induction of GLUT1. A putative cis-κB site was identified in the GLUT1 enhancer-2 at + 17282 by in silico analysis. EMSA showed that this κB site could be bound by p65. ChIP assays with anti-p65 antibodies confirmed the interaction of p65 with this κB site in mesangial cells. HG increased p65 binding to the κB site, which was blocked by 1,25-VD. Luciferase reporter assays using pEn-GLUT1-Luc plasmid showed that HG induced luciferase activity in the wild-type plasmid, but not in a mutant plasmid in which this κB site was mutated. The HG-induced luciferase activity was inhibited by 1,25-VD treatment.

Conclusions: Taken together these data suggest that 1,25-VD suppresses HG-induced GLUT1 expression by targeting the κB-mediated pathway. Suppression of GLUT1 may contribute to the reno-protective activity of vitamin D against glomerulosclerosis in diabetes.

FR-PO1253

Serum 25-Hydroxyvitamin D Levels and Vascular Calcification in Predialysis and Dialysis Patients with Chronic Kidney Disease Dong Ho Yang,[1] So-Young Lee,[1] Yoon Hee Lee,[2] Hoon Jung.[3] *[1]Internal Medicine, Bundang CHA General Hospital, CHA University, Seongnam, Geonggi-do, Republic of Korea; [2]Pathology, Gangnam CHA Hospital, CHA University, Seoul, Republic of Korea; [3]Internal Medicine, Seoul Bukbu Geriatic Hospital, Seoul, Republic of Korea.*

Background: The role of vitamin D in the process of vascular calcification is controversial in patients with chronic kidney disease. We investigated whether serum 25-hydroxyvitamin D associates with vascular calcification in predialysis and dialysis patients.

Methods: We included 209 patients. Vascular calcification was evaluated by examining plain X-rays of pelvis and hands as previously described. The augmentation index (AIx) was assessed with a commercially available device (VP-2000, Colin Corporation).

Results: We found a high prevalence of vitamin D deficiency in our population (77.0%). Vascular calcification was present in 36.4% of all patients. The presence of vascular calcifications was significantly associated with lower 25(OH)D levels in predialysis, dialysis and all patients. Multivariate analysis showed that 25(OH)D levels were inversely associated with simple vascular calcification score ≥ 1 (OR; -0.037, 95% CI; 0.86 - 0.99, P = 0.037). Lower 25(OH)D levels were associated with higher AIx in predialysis and all patients, but this inverse relationship was abolished in multivariate analysis.

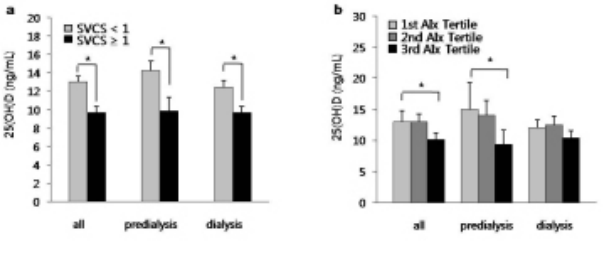

Figure. 1. (A) Mean 25(OH)D levels according to SVCS. (B) Mean 25(OH)D levels by tertiles of the augmentation index. *P < 0.05

Conclusions: We showed an independent relationship between low serum 25(OH)D levels and vascular calcification in both predialysis and dialysis patients.

FR-PO1254

Long-Term Effect of Cinacalcet Hydrochloride Treatment on the Parathyroid Gland Volume in Patients with Advanced Secondary Hyperparathyroidism

Shunsuke Yamada,[1] Masatomo Taniguchi,[1] Masanori Tokumoto,[3] Kazuhiko Tsuruya,[2] Satoru Fujimi.[4] *[1]Deparatment of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Department of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [3]Division of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [4]Department of Nephrology, Fukuoka Renal Clinic, Fukuoka, Japan.*

Background: Cinacalcet hydrochloride has been shown to lower serum PTH and to improve achievement rate of the guidelines for secondary hyperparathyroidism (SHPT). However, long-term effect of cinacalcet hydrochloride treatment with intravenous vitamin D therapy on the parathyroid gland (PTG) volume has not been fully elucidated.

Methods: The present study comprised of 60 hemodialysis patients from 10 dialysis centers in Japan, who received more than two years of cinacalcet treatment for advanced SHPT, resistant to intravenous vitamin D therapy (intact PTH; 568 ± 268 pg/mL). The serial changes in the biochemical parameters and maximum PTG volume were determined. We also investigated the factors that determined "marked PTG reduction", and the achievement rate of the guideline recommended by the Japanese Society of Dialysis Therapy (JSDT); 8.4 ≤ calcium ≤ 10.0 mg/dL, 3.5 ≤ phosphorus (P) ≤ 6.0 mg/dL, 60 ≤ intact PTH ≤ 180 pg/mL. "Marked PTG reduction" was defined as more than 30% reduction in maximum PTG volume after two years of treatment, and was used as the endpoint in the following analysis.

Results: Cinacalcet treatment with a mean dose of 47.5 mg/day for two years achieved approximately 25% reduction in PTG volume overall. A total of 33 patients showed "marked PTG reduction". The achievement rate of the JSDT guideline increased from 5% to 48%. Multivariate logistic regression analysis revealed that lower serum P level, less number of detected PTG, and PTG volume < 500 mm3 at baseline were significantly associated with "marked PTG reduction".

Conclusions: Cinacalcet treatment with intravenous vitamin D therapy for two years effectively reduced maximum PTG volume even in patients with advanced 2HPT, leading to the increased achievement rate of the JSDT guideline.

FR-PO1255

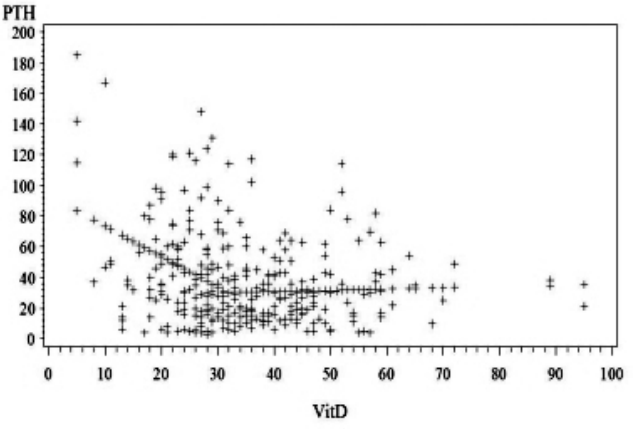
Serum 25-Vitamin D Level in Children: Do We Need To Change the Reference Range Based on 2011 Institute of Medicine (IOM) Report?

Tarak Srivastava, Uttam Garg, Melanie Ruiz, Hongying Dai, Uri S. Alon. *Bone and Mineral Disorders Clinic, Children's Mercy Hospital, Univ. of Missouri, Kansas City, MO.*

Background: The 2011 IOM Report recommends serum 25-Vitamin D (S-VitD) of ≥20 ng/ml as normal value. The traditional reference range (RR) of S-VitD for children in our clinical lab has been ≥30 ng/ml. Characteristically, in subjects with normal kidney function the onset of Vit D insufficiency is indicated by a rise in serum PTH (S-PTH). Considering the new IOM report, the aim of this study was to re-examine our RR for S-VitD based on S-PTH.

Methods: The database of clinical lab of our tertiary children's hospital from Jul 09 to Jan 11 was analyzed for S-VitD, S-PTH and serum creatinine (S-Cr). Data were included only of the child's initial sample and if all measurements done on same blood sample. S-VitD was measured by Tandem Mass Spectrometry on AB4000 QTrap, S-PTH by immunoassay (Immulite™) and S-Cr on Vitros autoanalyzer. To exclude patients with kidney failure, primary hyperpara and pseudohypopara we included only children with S-Cr ≤0.6 mg/dL and S-PTH ≤200 pg/ml.

Results: There were 304 samples with S-Cr ≤0.6 mg/dL and S-PTH ≤200 pg/ml. Using S-VitD <30, 39% were insufficent/ deficient compared to 10% for S-VitD <20 ng/ml. The inflection point by Gaussian-Newton method for S-VitD (Figure) was at 31.7 ng/ml (95%CI 26.4-37.0). S-PTH ≥75 pg/ml was recorded in 23 children (19.3%) with S-VitD <30 ng/ml compared with only 12 (6.5%) with S-VitD ≥30 ng/ml (χ2-test p=0.0006). OR for S-PTH ≥75 for S-VitD ≥30 was 0.29 (95%CI 0.14-0.61). Similar analysis in 553 children with S-Cr ≤1.0 mg/dL yielded identical results with inflection at 30.1 ng/ml (95%CI 24.1-36.1).



Conclusions: Based on both the inflection point for S-VitD and incidence of elevated S-PTH, and in contrast to the IOM recommendation, we suggest to maintain in children a cut-off value of ≥30 ng/ml.

FR-PO1256

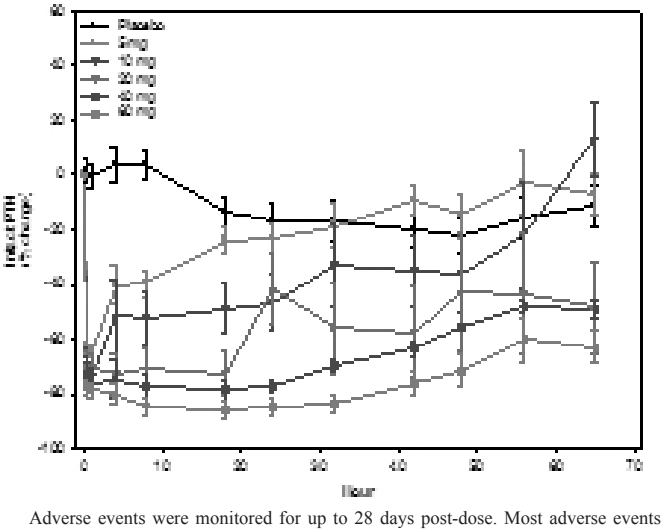
Characterization of KAI-4169, a Novel Peptide for the Treatment of Chronic Kidney Disease – Mineral and Bone Disorder, in a Single-Dose Study in Hemodialysis Subjects

Kevin J. Martin,[1] Gregory Bell,[2] Karen Pickthorn,[2] Saling Huang,[2] Marwan O. Kaskas,[3] Marializa Bernardo,[4] Peter F. Mount,[5] David A. Power.[5] *[1]Saint Louis University; [2]KAI Pharmaceuticals; [3]Northwest Louisiana Nephrology; [4]Southwest Houston Research; [5]Austin Hospital.*

Background: KAI-4169, a novel peptide agonist of the calcium sensing receptor (CaSR), is being evaluated in hemodialysis subjects as a treatment for CKD-MBD. This randomized, double-blind, placebo-controlled, single-dose, dose-escalation study was designed to evaluate the safety, tolerability, pharmacokinetics and pharmacodynamics of KAI-4169 administered as an IV bolus.

Methods: Twenty-eight subjects were enrolled in one of five cohorts (5, 10, 20, 40, 60mg). Cohorts 1-3 were treated in a 2-period crossover design with 4 subjects/cohort. In Cohorts 4 and 5, 8 subjects were randomized 1:1 to KAI-4169 or placebo. Major inclusion criteria included hemodialysis for at least 3 months, serum iPTH >300 pg/mL, serum cCa ≥ 9.0 mg/dL and the dose of vitamin D or analogs had to be stable for at least 3 weeks prior to screening. Subjects were admitted to a clinical research unit following hemodialysis and were observed for 3 days prior to discharge for hemodialysis.

Results: Treatment with KAI-4169 resulted in rapid suppression of iPTH with mean maximal reduction from baseline of 64, 73, 75, 84 and 86 % at the 5, 10, 20, 40 and 60 mg dose levels, respectively.



Adverse events were monitored for up to 28 days post-dose. Most adverse events were mild or moderate and resolved without sequelae. No drug-related GI adverse events were reported.

Conclusions: KAI-4169, a novel peptide agonist of the CaSR, administered as an IV bolus resulted in sustained, dose-dependent reductions in serum PTH and was well tolerated at single doses up to 60 mg. KAI-4169 represents a novel therapeutic approach for the treatment of CKD-MBD.

Are Current KDOQI/JSDT Guidelines Sufficient for Preventing the Progression of Secondary Hyperparathyroidism? Sato Megumi,[1] Masanor Jotoku,[2] Yuzuru Sato,[2] Ryota Ikee,[3] Masataka Tsunoda,[4] Naomi Sasaki,[5] Nobuo Hashimoto.[5] *[1]Department of Nephrology, Sato Junkankikanaika, Matsuyama, Ehime, Japan; [2]Department of Internal Medicine, Sato Junkankikanaika, Matsuyama, Ehime, Japan; [3]Department of Nephrology and Dialysis, H.N.Medic Kitahiroshima, Kitahiroshima, Hokkaido, Japan; [4]Department of Nephrology and Dialysis, H.N.Medic Spporo-Higashi, Sapporo, Hokkaido, Japan; [5]Department of Nephrology and Dialysis, H.N.Medic, Sapporo, Hokkaido, Japan.*

Background: There are several guidelines for secondary hyperparathyroidism(2°HPT) in the world, and each guideline has each standard values for Ca, P and PTH. In this study we compared the incidence of refractory 2°HPT between the dialysis patients who had been categorized by the current guidelines from the Kidney Disease Outcomes Quality Initiative(KDOQI) and Japanese Society for Dialysis Therapy (JSDT).

Methods: 180 chronic hemodialysis patients were enrolled into the study protcol. The patients were divided into the next 3 groups based on the averaged cCa and P. Group A: cCa and P met KDOQI guideline (n=107), Group B: gap area between JSDT and KDOQI (n=47), Group C: the rest patients (n=26). Refractory 2°HPT was identified as the administration of Cinacalcet hydrochloride(CH) or receiving of parathyroidectomy (PTx). The incident rates of refractory 2°HPT in each group were evaluated after 3-year-followup period.

Results: The mean values in cCa, P, i-PTH were shouwn in table 1. The incident rate in each group was significantly different from each other; 1/107 (0.9%) in Group A, 12/47 (25.5%) in Group B and 14/26 (53.9%) in Group C(Table 1).

Parameters of each group

	Group A(n=107)	Group B(n=47)	Group C(n=26)
cCa(mg/dL)	9.1±0.3	9.6±0.3	9.9±0.8
P(mg/dL)	4.9±0.4	5.4±0.5	6.1±1.1
i-PTH(pg/mL)	174.4±62.2	168.4±102.1	299.3±240.9
PTx. or CH	1/107	12/47	14/26
rate of incidence	0.9%	25.5%	53.9%

Conclusions: The JSDT guideline is not sufficient to prevent the onset of refractory 2°HPT because the incidence in Group B was significantly higher than that in Group A. In conclusion, ideal standard values in cCa and P should be stricter than the current values in both JSDT and KDOQI guidelines for preventing refractory 2°HPT.

FR-PO1258

Proteinuria Modifies Response to Cholecalciferol in CKD Amay Parikh,[1] Herbert S. Chase,[2] Linda Vernocchi,[1] Leonard Stern.[1] *[1]Columbia University, New York, NY; [2]Biomedical Informatics, Columbia University, New York, NY.*

Background: We previously showed that the response to cholecalciferol replacement therapy in CKD, assessed by the 25-OH Vitamin D (25VitD) level, was associated with eGFR: Non-responders displayed a worsening eGFR over time compared to Responders. The mechanism of the observation was unknown. The aim of this study was to test whether the effect on eGFR by the cholecalciferol response was modified by proteinuria.

Methods: 309 pts (Stages 2-5) were identified from 2001-2010 at the CKD Clinic at Columbia University. Demographics, creatinine, proteinuria (24 hr urine protein or protein/creatinine ratio), and VitD were extracted from the Columbia CKD Program database. Pts received cholecalciferol 10,000 IU capsules weekly as initial therapy. We repleted VitD to a target level of 40-60 ng/ml. When levels above 40 were not achieved, doses were titrated up to a maximum of 50,000 IU weekly. Pts reaching a level of 40 ng/ml were designated Responders. Pts not reaching a level of 40 ng/ml were designated Non-responders. The MDRD eGFR was calculated.

Results: 147/309 pts had proteinuria data and 93/147 pts with a mean follow up of 1.5 years had a concurrent creatinine. The initial mean 25VitD level was lower in the NON-RESPONDERS (19 vs. 23 ng/ml, p=0.02). The initial mean proteinuria in NON-RESPONDER (1.47 g/d) was higher than RESPONDER (0.89 g/d) (p<0.004). During 50 months of follow-up, proteinuria levels remained lower in the RESPONDERS (p=0.04). No difference was observed in microalbuminuria between the two groups. With similar initial eGFR (NON-RESPONDERS 27 vs. RESPONDERS 30 ml/min/1.72m^2, p=0.09) and elevated proteinuria, the eGFR declined faster in the NON-RESPONDERS. Regression modeling showed that proteinuria modifies the effect of cholecalciferol response on the change in eGFR (p=0.02).

Conclusions: Response to treatment with VitD is associated with lower initial levels of proteinuria, better preservation of eGFR, and a reduction in proteinuria over time. The mechanism of the observation is unknown but may be related to alterations of VitD metabolism or binding protein characteristics in CKD. Future research is planned to address these issues.

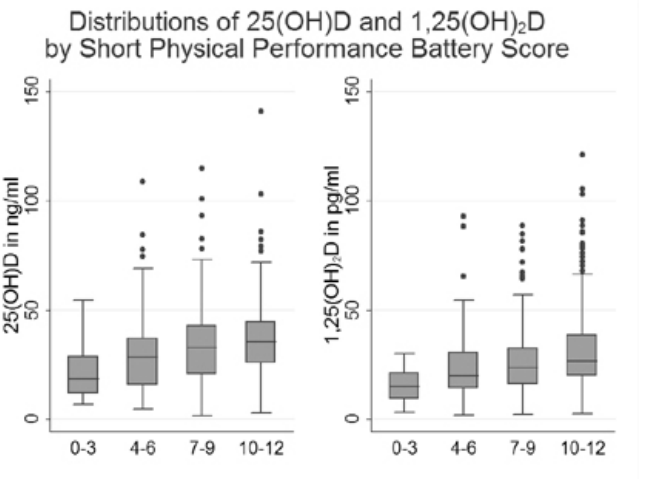
FR-PO1259

Vitamin D Levels and Physical Performance in Chronic Kidney Disease: A CRIC Study Peter P. Reese,[1] Mat Davis,[1] Harold I. Feldman,[1] Anne Cappola,[1] Mary B. Leonard.[2] *[1]University of Pennsylvania, Philadelphia, PA; [2]Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Risk factors for poor physical function in CKD have not been established. CKD is associated with low vitamin D levels, and vitamin D deficiency may impair muscle strength.

Methods: Physical performance was assessed using the Short Physical Performance Battery (SPPB) in 1056 Chronic Renal Insufficiency Cohort (CRIC) participants, median (interquartile range) age 64 (57-70) years, eGFR 45 (34-55) ml/min/1.73m^2; 54% male; 58% white, and 35% black race. The SPPB score (0-12) summarizes tests of gait speed, timed chair-raises and standing balance, and is a validated predictor of death and disability that was developed among elderly persons. Serum 25(OH)D and 1,25$(OH)_2$D concentrations were quantified by HPLC tandem mass-spectrometry and I^{125} RIA, respectively.

Results: Median SPPB score was 9 (IQR 7-10). 42% of black and 11% of whites were 25(OH)D deficient [<20 ng/ml]. Median 1,25(OH)2D was 24 pg/ml. In univariate analyses, 25(OH)D and 1,25(OH)2D were positively associated with SBBP scores.



In multivariable linear regression, lower SPPB was significantly associated with older age, female sex, black race, greater BMI, cardiovascular morbidities, lower eGFR, 25(OH) D deficiency, and lower 1,25$(OH)_2$D levels.

Linear Regression Model of SPPB Score

Predictor	Beta	p
Age, vs <50 yr		
50-59	-0.41	0.07
60-69	-0.67	0.001
≥70	-1.53	<0.001
Female	-0.44	<0.001
Black Race	-0.56	0.001
Congestive heart failure	-0.49	0.03
Stroke	-0.19	0.001
Diabetes	-0.23	0.09
Anemia	-0.30	0.03
BMI, vs <25 kg/m²		
25-29	-0.10	0.57
30-34	-0.50	0.009
≥35	-0.98	<0.001
Income, vs <$20,000		
20,000-49,999	0.61	0.004
50,000-99,999	0.86	<0.001
≥100,000	1.33	<0.001
eGFR, vs <15 ml/min/1.73m²		
15-29	0.96	<0.01
30-59	1.04	0.001
≥60	1.22	0.001
25(OH)D >20 ng/mL	0.38	0.02
Log 1,25$(OH)_2$D	0.32	0.008

Conclusions: eGFR, and levels of 25(OH)D and 1,25$(OH)_2$D were independently associated with selected physical performance measures.

Funding: NIDDK Support

FR-PO1260

Vitamin D Deficiency (VDD) Is Associated with Increased Frequency of Vascular Access Dysfunction (VAD) in Chronic Hemodialysis Patients (HDPs) Reuben Valentin,[1] Jose A. Velez,[1] Khaldoun Soudan,[1] Christine L. Gear,[1] Jonathan A. Gelfond,[1] Wajeh Y. Qunibi.[1] *[1]Division of Nephrology, University of Texas Health Science Center at San Antonio, TX; [2]Epidemiology and Biostatistics, University of Texas Health Science Center at San Antonio, TX.*

Background: VDD is prevalent worldwide and is associated with obesity, diabetes, hypertension and other cardiovascular risks. Vitamin D receptors are present in vascular smooth muscle and endothelial cells. Vascular access complications in HDPs are a major source of morbidity and increased health costs. In this study we sought to examine the relationship between 25OHD levels and dialysis access interventions for thrombosis, failure to mature, pseudoaneurysm, steal syndrome, stenosis within 1 year of initial 25OHD level.

Methods: We reviewed medical records of 256 HDPs who had 25OHD level and arteriovenous fistula or arteriovenous graft. We performed univariate Poisson regression with the number of access interventions regressed onto pre-specified demographic and laboratory variables and then included significant variables as covariates in a multiple logistic regression of the odds of having one or more intervention.

Results: Mean age was 55±12.5 years. 48% were female. Mean 25OHD level was 19.1±11 ng/ml. Serum calcium, 25OH, hemoglobin, platelets, albumin were significantly associated with access interventions (p<0.05). The per-unit change in intervention risk associated with 25OHD level remained significant (p=0.0246; 95%CI [0.94, 1.00]) after adjusting for these variables.

Multiple Logistic Regression of Risk of Access Intervention

Variable	Log Odds	Std_Err	OR	95% CI	P-Value
Calcium	-0.136	0.17	0.87	(0.62, 1.22)	0.4276
25OHD	-0.033	0.01	0.97	(0.94, 1)	0.0246
Hemoglobin	0.011	0.09	1.01	(0.85, 1.2)	0.9005
Platelet	2.632	1.76	13.9	(0.44, 441.98)	0.1359
Albumin	-0.531	0.38	0.59	(0.28, 1.25)	0.1659

The adjusted OR of the risk of access intervention for patients with 25OHD deficiency (<15 ng/mL) was 1.98 (p=0.0142: 95%CI [1.15, 3.41]) compared to those with 25OH ≥15 ng/mL.

Conclusions: VDD is associated with the development of VAD. Treatment of VDD for the purpose of preventing VAD must await randomized, controlled studies.

FR-PO1261

Parathyroid Hormone, Calcium, and Phosphorus Metabolism in Children Undergoing Chronic Peritoneal Dialysis Yoon Jung Lee, Joo Hoon Lee, Young Seo Park. *Pediatrics, University of Ulsan College of Medicine, Seoul, Korea.*

Background: Chronic kidney disease-mineral and bone disorder (CKD-MBD) remains a significant problem in children on dialysis. Parathyroid hormone (PTH), calcium and phosphorus metabolism is a key component of CKD-MBD and PTH is at the center of the mineral imbalance, consequent skeletal disease and growth failure. However, the optimal PTH target in CKD patients is a matter of long-standing controversy.

Methods: We assessed the status of CKD-MBD in children on peritoneal dialysis for more than 1 year at Asan Medical Center between May 2001 and July 2010 and compared biochemical profile with recommendations of KDOQI guidelines. We also analyzed the relationship between PTH and growth.

Results: Twenty-five boys and 16 girls with median age of 16 years (3-22 years) were included. The median age at initiation of peritoneal dialysis was 10 years (0-17 years) and mean±SD duration of peritoneal dialysis was 39.9±22.0 months. Mean±SD values of serum PTH, Ca, P and CaXP during the period of peritoneal dialysis were 466.2±539.5 pg/mL, 9.7±1.1 mg/dL, 6.1±1.8mg/dL and 58.9±17.0 mg2/dL2,, respectively. More than 50 percent of patients had mean values of Ca, P, CaXP and PTH above the range recommended in the KDOQI guideline. Six patients (14.6%) showed clinical symptoms and/or radiological signs of CKD-MBD including rickets, bone pain, bone deformities and tissue calcifications. These patients exhibited more severe secondary hyperparathyroidism than those without bone disease (830.9±364.8 vs 378.0±261.0 pg/mL, P<0.005). Mean±SD HtSDS at initiation of peritoneal dialysis was -1.60±1.34. Mean ΔHtSDS was not different between patient with mean PTH >;300 pg/mL and <300 pg/mL (-1.04±1.66 vs -1.31±1.36, P=0.415) and annual ΔHtSDS was not correlated with time-averaged PTH levels regardless of growth hormone therapy.

Conclusions: Biochemical profile was outside the guideline targets in more than 50% percent of patients despite effort to control Ca, P and PTH. Signs and symptoms of CKD-MBD were observed in 15 percent of patients whose PTH level was significantly higher. There were no relationships between growth and time-averaged PTH concentrations regardless of growth hormone therapy.

FR-PO1262

Cinacalcet Treatment Decreases Parathyroid Gland Volume in Hemodialysis Patients with Secondary Hyperparathyroidism – A Long-Term Follow-Up Study Mitsuru Ichii,[1] Eiji Ishimura,[1] Senji Okuno,[2] Naoki Tsuboniwa,[2] Shinya Nakatani,[1] Kyouko Norimine,[2] Kenjirou Yamakawa,[2] Shigeichi Shoji,[2] Tomoyuki Yamakawa,[2] Yoshiki Nishizawa,[1] Masaaki Inaba.[1] *[1]Metabolism, Endcrinology, and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan; [2]Shirasagi Hospital, Osaka, Japan.*

Background: We and others have recently reported that cinacalcet treatment significantly decreases parathyroid gland volume (PTV) in hemodialysis patients with secondary hyperparathyroidism (SHPT) in 6 months (Ichii, et al. Nephron Clin Pract;115:c195, 2010) and in 12 months (Komaba, et al. Clin J Amer Soc Nephrol 5:2305, 2010). However, further long-term effect of cinacalcet on PTV is unknown. In the present study, we examined changes in PTV after cinacalcet treatment for longer term.

Methods: Cinacalcet was administered in patients with SHPT in whom active vitamin D and phosphate binders could not sufficiently reduce PTH levels. Dosage of cinalcalcet was adjusted according to the Japanese guideline for the treatment of SHPT (Ther Apher Dial 12:514, 2008). PTV was measured four times by ultrasonography before (- 12.3±3.8 months), at the start of ,at 7.0±2.9 months and at18.6±2.8 months after cianalcet treatment in 49 patients with SHPT (61±9 years, hemodialysis duration 166±85 months).

Results: Intact-PTH was significantly increased from 500±279 pg/ml 12 months before, to 607±288 pg/ml at the start of cinacalcet treatment (p<0.01). It was decreased to 244±132pg/ml at 7.0 months (p<0.0001), and to 202 ± 116pg/ml at 18.6 months (p<0.0001). PTV was significantly increased from 681±638 mm3 12 months before, to 994±754 mm3 at the start (p<0.0001). PTV was significantly decreased to 737±553 mm3 (p<0.001) at 7.0 months, and was continuously decreased to 643±552 mm3 (p<0.001) at 18.6 months. Although, out of 49 patients, there were 12 patients in whom PTV was increased during the period, intact-PTH in these patients was significantly decreased (p<0.0001).

Conclusions: In the present study, cinacalcet treatment was demonstrated to decrease PTV, along with decreasing intact PTH, for longer periods. This study suggests that cinacalcet treatment may postpone parathyroidectomy and/or reduce its cases.

FR-PO1263

Serum 25-Hydroxyvitamin D Concentration and Risk of Clinical Disease Events in a Community-Based Population of Older Adults Gregory Levin,[1] Cassianne Robinson-Cohen,[1] Bryan R. Kestenbaum,[1,2] Ian H. de Boer.[1,2] *[1]University of Washington; [2]Kidney Research Institute.*

Background: Circulating concentrations of 25-hydroxyvitamin D [25(OH)D] are used to define vitamin D deficiency. While not optimal, threshold 25(OH)D concentrations for populations with chronic kidney disease have largely been extrapolated from the general population. Current clinical 25(OH)D targets are based on associations with markers of bone and mineral metabolism. These targets may not reflect optimal levels for other chronic diseases that are potentially affected by vitamin D and do not account for seasonal 25(OH) D variation. The goal of this study was to evaluate the relationship of serum 25(OH)D concentration with the incidence of major disease outcomes that are pathophysiologically relevant to vitamin D.

Methods: We studied 1,662 Caucasian older adults from the community-based Cardiovascular Health Study. We measured baseline serum 25(OH)D concentration using a high performance liquid chromatography-tandem mass spectrometry assay that conforms to National Institute of Standards and Technology reference standards. We defined the primary outcome measure as the time to a composite outcome of incident hip fracture, myocardial infarction, cancer, or death from any cause.

Results: Over 11 years median follow-up, the composite outcome occurred in 1,041 participants (63%). The association of 25(OH)D < 20 ng/ml with the composite clinical outcome varied by season (p=0.03). Serum 25(OH)D concentration below the lowest season-specific 22nd percentile (< 14 ng/mL in winter, < 18 ng/mL in spring, < 22 ng/mL in summer, and < 19 ng/mL in fall) was associated with an 18% greater adjusted risk of the composite outcome (95% confidence interval 1%, 38%). Compared with a static 25(OH) D threshold of 20 ng/mL, season-specific thresholds reclassified 8% of participants and improved risk prediction (net reclassification index 2.8%, p=0.047).

Conclusions: These findings suggest that threshold concentrations of 25(OH)D associated with increased risk of relevant clinical health events center near 20 ng/mL. In addition, season-specific targets for 25(OH)D concentration may be more appropriate than static targets when evaluating health risk.

FR-PO1264

VS-110: A Novel Vitamin D Receptor Modulator with Cardiovascular Protective Effects in 5/6 Nephrectomized Uremic Rats J. Ruth Wu-Wong, Megumi Kawai, Yung-Wu Chen, Masaki Nakane. *Renal Research, Vidasym, Chicago, IL.*

Background: Vitamin D receptor modulators (VDRMs) such as calcitriol, paricalcitol and doxercalciferol are commonly used to manage hyperparathyroidism secondary to chronic kidney disease (CKD). A majority of CKD patients die from cardiovascular complications. Clinical observations demonstrate that VDRM therapy may provide cardiovascular and survival benefit for CKD patients. However, current on-market VDRMs have a narrow therapeutic index (TI) at 1-4-fold (estimated from the hypercalcemic toxicity and PTH suppressing efficacy). Hypercalcemia remains a serious concern, which leads to the need for frequent drug dose titration and serum calcium monitoring. Significant clinical benefit can be derived from a VDRM with expanded TI and cardiovascular protective effects.

Methods: The 5/6 nephrectomized (NX) male Sprague-Dawley rats at Week 6 after the surgery exhibited established uremia, elevated parathyroid hormone (PTH), endothelial dysfunction and left ventricular hypertrophy.

Results: Treatment of 5/6 NX rats by VS-110, a novel VDRM, at 0.01 - 1.0 μg/kg (oral gavage, once daily, for two weeks) suppressed serum PTH effectively without raising serum calcium, demonstrating a >50-fold TI. Similar results were obtained when VS-110 was given to 5/6 NX rats by i.p., 3x/week for two weeks. When the 5/6 NX uremic rats were treated with VS-110 (0.01 - 1 μg/kg) for two weeks, VS-110 improved endothelium-dependent aortic relaxation, reduced left ventricular (LV) fibrosis and attenuated LV hypertrophy in a dose-dependent manner without affecting serum calcium. Real-Time PCR showed that VS-110 induced CYP24A1 and CD14 expression in HL-60 cells with EC50 values at 6.8 and 0.4 nM, respectively. VS-110 induced HL-60 differentiation with an EC50 value at 1.7 nM (vs. calcitriol at 13.9 nM) and inhibited the proliferation of primary human keratinocytes with an IC50 value at 1.4 nM (vs. calcitriol at 10 nM).

Conclusions: These studies demonstrate that VS-110 is a novel VDRM with greatly expanded TI and an overall therapeutic product profile that supports clinical development for expanded use in pre-dialysis CKD patients to realize the cardiovascular protective effects of VDR activation.

FR-PO1265

Rise in Uncontrolled Secondary Hyperparathyroidism (SHPT) among Blacks after Implementation of the US Prospective Payment System (PPS): Results from the DOPPS Practice Monitor (DPM) Francesca Tentori,[1] Douglas S. Fuller,[1] Ronald L. Pisoni,[1] Justin M. Albert,[1] Marc Turenne,[1] Bruce M. Robinson.[1,2] *[1]Arbor Res Collab for Hlth, Ann Arbor, MI; [2]Univ of MI, Ann Arbor, MI.*

Background: Increased financial constraints may lead to lower utilization of intravenous (IV) vitamin D analogs under the new bundled prospective payment system (PPS), leading to poorer control of secondary hyperparathyroidism (SHPT). Because Black patients require higher vitamin D doses (Wolf JASN 2008) on average, they may be particularly susceptible to this change.

Methods: The DOPPS Practice Monitor (DPM) provides timely, public reporting of trends in dialysis care as the new PPS and QIP are implemented (www.dopps.org/dpm). The DPM follows a nationally representative sample of ~140 US dialysis units with ≥20 chronic hemodialysis patients. We studied trends in parathyroid hormone (PTH) values and SHPT therapies from July 2010 to February 2011.

Results: The % of patients with PTH measured over 3 months did not change (93-96%). The median PTH value rose among Blacks from 296 (interquartile range [IR]: 214-469) to 379 pg/ml (IR: 236-606), and among non-Blacks from 244 (IR: 173-354) to 283 pg/ml (IR: 192-435). The prevalence of severe uncontrolled SHPT (defined as PTH >600 pg/ml) rose sharply among Blacks (from 16 to 26%) and slightly among non-Blacks (from 9 to 11%). Preliminarily, these changes do not appear to be due to decreased overall use of SHPT treatments (% prescribed IV vitamin D rose slightly in both race groups, cinacalcet use rose slightly in blacks) or to changes in serum calcium or phosphorus.

Distribution of PTH values by race group in US-DOPPS

	Month	N	Mean (pg/ml)	Median (pg/ml)	< 150 pg/ml	150-300 pg/ml	301-600 pg/ml	> 600 pg/ml
Black	10-Jul	685	420	296	12%	39%	33%	16%
	10-Aug	915	419	299	10%	40%	35%	15%
	10-Sep	880	412	301	11%	39%	35%	15%
	10-Oct	881	437	321	10%	37%	35%	19%
	10-Nov	910	469	338	11%	30%	37%	23%
	10-Dec	970	493	374	9%	29%	37%	25%
	11-Jan	908	498	375	9%	28%	39%	24%
	11-Feb	866	484	379	10%	29%	35%	26%
Non-black	10-Jul	1,652	326	244	18%	48%	25%	9%
	10-Aug	2,096	316	238	19%	48%	23%	9%
	10-Sep	2,003	305	236	18%	50%	24%	8%
	10-Oct	1,956	314	245	20%	46%	26%	9%
	10-Nov	2,097	325	256	18%	44%	28%	10%
	10-Dec	2,069	338	268	17%	41%	32%	10%
	11-Jan	1,879	358	281	16%	38%	33%	13%
	11-Feb	1,816	371	283	14%	40%	35%	11%

Conclusions: Our results indicate a notable increase in PTH levels overall, and in severe uncontrolled SHPT (>600 pg/ml) among Blacks, over the early PPS transition period. Additional evaluation of the causes of this trend and its potential consequences are warranted.

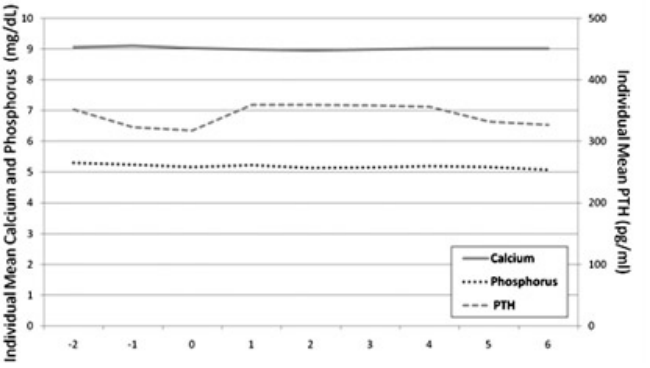
FR-PO1266

Effects of Switching from Intravenous Paricalcitol to Doxercalciferol on Dialysis Patient Bone and Mineral Outcomes T. Christopher Bond, Steven M. Wilson, Mahesh Krishnan, Tracy Jack Mayne. *DaVita Clinical Research, Minneapolis, MN.*

Background: The relative effectiveness of various forms of intravenous vitamin D among hemodialysis (HD) patients is still in question. We assessed outcomes before and after a planned switch of dialysis patients from paricalcitol to doxercalciferol.

Methods: This single-arm, prospective study measured pre/post levels of phosphorus, corrected calcium and parathyroid hormone (PTH) to assess non-inferiority of clinical outcomes in dialysis facilities that switched all of their patients from paricalcitol to doxercalciferol. Patient (n=828) lab values for the 2 months before the switch were compared to the 6 months following the switch at the patient level using mixed models. Similar facility (n=7) comparisons compared the 6 months before the switch to the 6 months following the switch. Pre-set criteria for inferiority were a rise in phosphorus or calcium ≥ 0.5 mg/dL or a rise of PTH of ≥ 100 pg/mL.

Results: The individual-level analysis showed no meaningful differences in mean laboratory values before and after the switch (Figure). All confidence intervals for repeated measures mixed model analyses excluded the pre-set criteria, indicating non-inferiority of doxercalciferol versus paricalcitol. Patient-time within range for all 3 laboratory measures was constant or increased across the time frame of the study. The facility-level analysis of laboratory values showed results similar to those seen in the individual-level analysis. There was no change in hospitalizations or hospitalized days per patient-year.



Conclusions: All individual-level and facility-level assessments support the conclusion that doxercalciferol is non-inferior to paricalcitol on bone and mineral outcomes in HD patients. The small increase in PTH coincides with the increase in the KDIGO upper limit from 300 to 600 pg/mL.

Cinacalcet Hydrochloride Induces Apoptosis of Parathyroid Cells in Humans and In Vitro: Histological and Cytological Analyses Ryoko Tatsumi, Takatoshi Kakuta, Kaichiro Sawada, Genta Kanai, Hirotaka Komaba, Masafumi Fukagawa. *Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan.*

Background: Secondary hyperparathyroidism develops during the long course of chronic kidney disease. Recently, cinacalcet hydrochloride has been available as one of the treatment options for secondary hyperparathyroidism. There have been a number of reports on the effects of cinacalcet on biochemical parameters of secondary hyperparathyroidism. In this study, we examined histological and cytological changes of parathyroid glands removed from patients with severe secondary hyperparathyroidism, particularly focusing on apoptosis in parathyroid cells.

Methods: The study subjects were 16 dialysis patients who underwent parathyroidectomy for severe secondary hyperparathyroidism in our hospital from April 1, 2007 to March 31, 2010, in whom 8 patients had been treated with cinacalcet hydrochloride and the others had not. We compared the number of TUNEL-positive cells between cinacalcet group and non-cinacalcet group. We also examined the effects of cinacalcet on parathyroid cell death in vitro cell culture with the TUNEL staining, using parathyroid cells from patients with severe secondary hyperparathyroidism.

Results: The number of TUNEL-positive cells in cinacalcet group was significantly higher than that of non-cinacalcet group (12.7 ± 4.3 versus 3.2 ± 2.4 per 1000 cells, P <0.001). In vitro examination also showed significant increases of apoptotic cells with the addition of 10 μM cinacalcet hydrochloride into the culture medium, further supporting the apoptotic effect of cinacalcet on parathyroid gland cells.

Conclusions: These results suggest that treatment with cinacalcet induces apoptosis in hyperplastic parathyroid cells in patients with secondary hyperparathyroidism.

FR-PO1268

Differential Effects of Active Vitamin D Compounds on Secondary Hyperparathyroidism and Vascular Calcification W. Charles O'Neill,[1] Xiaonan H. Wang,[1] Hartmut H. Malluche.[2] *[1]Emory University; [2]University of Kentucky; [3]Amgen, Inc.*

Background: Active vitamin D compounds suppress secondary hyperparathyroidism but can also produce vascular calcification. Whether PTH can be suppressed at doses that do not augment vascular calcification is unclear. Since phosphate also affects PTH secretion and vascular calcification, we reasoned that the differential effects on PTH and vascular calcification depend on phosphate intake.

Methods: Renal failure was produced in rats by feeding adenine, and calcitriol or paricalcitol was given 3 times per week at varying doses. After 28 days, aortic calcium was measured by the cresopthalein method after extraction in HCl. PTH was measured by immunoassay using an antibody against rat PTH 1-34.

Results: Plasma calcitriol, measured by radioimmunoassay 48 hours after dosing, was 6.3 ± 1.8, 7.5 ± 1.0, 24.6 ± 4.1, and 79.6 ± 6.1 pg/ml at 0, 10, 40, and 100 ng/kg calcitriol, indicating that the higher doses resulted in persistent elevations. With 1.06% dietary phosphorus, suppression of PTH (348 ± 66 vs. 719 ± 85 pg/ml, p<0.001) required 100 ng/kg calcitriol, while 40 ng/kg increased aortic calcium (3695 ± 733 vs. 1077 ± 865 nmol/mg, p<0.005; normal: <25). Similarly, with 0.73 % phosphorus intake, 40 ng/kg calcitriol increased aortic calcium (5091 ± 1055 vs. 367 ± 217 nmol/mg, p<0.005) without suppression of PTH (304 ± 138 vs. 276 ± 55 pg/ml). Paricalcitol increased aortic calcification at 160 ng/kg (2623 ± 562 vs. 1586 ± 388 nmol/mg, p=0.007) while 320 ng/kg was required to suppress PTH (197 ± 77 vs. 636 ± 56 pg/ml, p <0.001). However, with a 0.4% phosphorus diet (normal rat chow), PTH was suppressed at 40 ng/kg calcitriol (29 ± 16 vs. 570 ± 109 pg/ml, p=0.002) without significantly increasing aortic calcification (558 ± 551 vs. 88 ±

47 nmol/mg). Aortic calcium content correlated weakly with plasma phosphate (r=0.28, p <0.001) but not with PTH or calcium. A significant increase in plasma calcium occurred only with paricalcitol.

Conclusions: Suppression of secondary hyperparathyroidism by calcitriol without promoting vascular calcification is dependent on phosphate intake. There was no advantage of paricalcitol over calcitriol.

Chronic Exposure to Laminar Shear Stress Induces an Anti-Coagulant, Anti-Inflammatory Phenotype in Glomerular Endothelial Cells and Results in Communication with Podocytes Sadie Slater, Gavin Iain Welsh, Moin Saleem, Peter W. Mathieson, Simon C. Satchell. *Academic Renal Unit, University of Bristol, Bristol, United Kingdom.*

Background: The importance of podocyte to glomerular endothelial cell (GEnC) communication in the glomerulus is widely recognised. In systemic circulations chronic laminar shear stress (LSS) plays a crucial role in determining EnC behavior and regulating EnC communication with smooth muscle cells. Here we investigate signaling pathways activated by LSS in GEnC and the effect on co-cultured podocytes.

Methods: Conditionally immortalised human GEnC and podocytes were utilised. GEnC were cultured under static conditions, or on an orbital shaker set to generate 10dynes/cm2 LSS, for 24, 48, 72 or 96h. Western blotting examined changes in protein expression. A nitrate assay measured nitric oxide (NO) production. Changes in GEnC barrier properties in response to LSS were measured using an ECIS (Electric Cell Impedance Sensing) system. Changes in podocyte protein expression and barrier properties in response to GEnC LSS were investigated using a GEnC-podocyte co-culture model, or by placing conditioned media from static or LSS GEnC on podocytes.

Results: LSS in GEnC increased expression of KLF2 ($p<0.0001$), thrombomodulin ($p<0.003$), eNOS ($p<0.003$), and NO ($p<0.005$). These changes are associated with ERK5 phosphorylation and were prevented by addition of a MAPK kinase inhibitor, OU126. ECIS demonstrated GEnC monolayer resistance decreased in response to LSS. Podocytes exposed to spermine, a nitric oxide donor, showed decreased monolayer resistance and increased phosphorylation of a key protein in actin regulation, VASP. Similarly, GEnC LSS media decreased podocyte monolayer resistance and increased VASP phosphorylation, compared to static media.

Conclusions: We have demonstrated chronic LSS in GEnC results in an anti-inflammatory, anti-coagulant phenotype, mediated via the MEK5 pathway, leads to an increase in NO. Mediators (possibly NO) produced by GEnC during LSS decrease podocyte barrier properties and increase VASP phosphorylation. This is the first data to directly demonstrate GEnC to podocyte communication and suggests an important role in glomerular homeostasis.

Interferon Beta Modulates Glomerular Endothelial Cell(GEnC) Barrier Properties through Activation of the Small GTPase Rap1 Georgina Cope,[1] Candida Tasman,[3] Peter W. Mathieson,[1] David O. Bates,[2] Gavin Iain Welsh,[1] Simon C. Satchell.[1] *[1]Academic Renal Unit, University of Bristol, Bristol, United Kingdom; [2]Microvascular Research Laboratories, University of Bristol, Bristol, United Kingdom; [3]Dementia Research Group, University of Bristol, Bristol, United Kingdom.*

Background: We have previously shown that IFNβ protects rats from albuminuria in experimental glomerulonephritis. In-vitro exposure of glomerular endothelial cell (GEnC) monolayers to 1000 units/ml of IFNβ reduced their permeability, suggesting that IFNβ may act directly on cells of the glomerular filtration barrier to maintain its permselectivity. Others have shown that endothelial barrier properties are enhanced by activation of the small GTPase Rap1. We therefore tested the hypothesis that IFNβ acts via Rap1.

Methods: Pull down assays were used to detect activated Rap1 post IFNβ. An ECIS (electric cell-substrate impedance sensor) system was used to monitor GEnC monolayer resistance in the presence of IFNβ with or without GGTI-298 (Rap1 inhibitor)or siRNA to Rap1a. Immunoprecipitation and immunofluorescence were used to determine the effects of IFNβ on Rap1 association with actin and Rap1-GTP-interacting adaptor molecule (RIAM) and its subcellular location.

Results: IFNβ induced Rap1 activation at a level comparable to 8'me cAMP, an activator of Rap1a. Co-incubation with GGTI-298 significantly reduced the tightening of the GEnC barrier provoked via IFNβ. To determine the isoform of Rap1 responsible we used targeted siRNA to Rap1a. This resulted in Rap1a knockdown and attenuated the increase in resistance caused by IFNβ for 6 hours, while GGTI-298 mediated a sustained inhibition. Activation of Rap1 in GEnC via IFNβ induced its association with actin and RIAM. This interaction was reduced by co-incubation of GGTI-298 and IFNβ. IFNβ induction of the Rap1a: actin association did not cause cytoskeletal rearrangement or changes in cell shape suggesting it is not a cytoarchitectural regulator.

Conclusions: IFNβ mediated tightening of GEnC monolayers is partially dependent on Rap1 activation. Modulation of this pathway in glomerular cells may have therapeutic potential in proteinuric renal disease.

FR-PO1271

α-Actinins Suppress Podocyte Contractility Fangfang He,[1] Hui Chen,[1] Philip A. Bondzie,[1] Julie A. Tomolonis,[1] Daniel J. Becker,[2] Martin R. Pollak,[3] Joel M. Henderson.[1] *[1]Department of Pathology and Laboratory Medicine, Boston University School of Medicine, Boston, MA; [2]Division of Nephrology, Brigham and Women's Hospital, Boston, MA; [3]Division of Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Mutations in the gene encoding α-actinin-4, an actin-filament crosslinking protein, cause an autosomal dominant form of focal segmental glomerulosclerosis. α-actinins may modulate actomyosin contractility through actin binding and crosslinking, or through other mechanisms. Changes in podocyte actomyosin contractility associated with altered α-actinin function may compromise glomerular structural integrity, thereby leading to glomerular damage. The aim of this study is to define the role of α-actinins in modulation of podocyte contractility.

Methods: α-actinin-1 and α-actinin-4, two isoforms significantly expressed in cultured murine podocytes, were independently ablated in these cells using lentiviral RNA interference. Ablated and control cells were plated on glass and polyacrylamide elastic substrates. Immunostaining was performed to characterize α-actinin and filamentous actin distribution, and traction force microscopy was used to measure cell traction.

Results: Highly efficient ablation of both α-actinin-1 and α-actinin-4 was achieved at the protein level using the lentiviral system. Both α-actinin-1 and α-actinin-4 ablation were associated with disorganization of actin stress fibers. α-actinin-1 and α-actinin-4 ablation increased cell traction by 68% and 35%, respectively, relative to controls.

Conclusions: Both α-actinin-1 and α-actinin-4 participate in cytoskeletal organization and traction modulation in murine podocytes. Our results indicate that α-actinins tend to suppress podocyte contractility. These findings suggest that altered α-actinin function (e.g., gain of function mutations) could cause glomerular damage by altering podocyte contractility.

Endocytic Proteins in Podocytes Affect the Stability of Foot Processes in Kidney Glomeruli Keita Soda, Xuefei Tian, Rena Zheng, Shuta Ishibe. *Internal Medicine, Section of Nephrology, Yale University, School of Medicine, New Haven, CT.*

Background: Membrane trafficking linking actin regulation plays a pivotal role in maintaining cell homeostasis. However, membrane dynamics in podocytes remain unclear. We show that endocytic proteins, Dynamins (Dyn1 and Dyn2) and Synaptojanin 1(SJ1) affect the stability of glomerular filtration barrier in the kidney.

Methods: Podocyte specific double knockouts of Dyn1 and Dyn2 were generated using the Cre-LoxP system (Dyn dKO). Kidney sections were analyzed with H and E, PAS, trichrome staining and electron microscopy (EM). Albuminuria and urine creatinine were measured by ELISA. Endocytosis assays were performed on primary wild type (WT) and mutant podocytes.

Results: Dyn dKO mice were born at the expected Mendelian frequency. However, these mice failed to gain weight by 4 weeks (1.3±0.1 vs. 1.4 ±0.1, 10.5±0.4 vs. 8.5±0.3, 21.8±1.8 vs. 13.3±0.8 (wild vs. Dyn dKO;p1, 4 and 8weeks)(g)), developed severe albuminuria normalized to urine creatinin(16.3±0.9 vs. 716.7± 37.0, 15.4±0.8 vs. 1246.7±43(wild vs. Dyn dKO;4 and 8 weeks) (μg/mg)), and creatinine measurements demonstrated progressive renal failure (0.35±0.06 vs. 0.78±0.09, 0.34±0.06 vs. 1.3±0.04, 0.32±0.05 vs. 1.47±0.06 (wild vs. Dyn dKO;4,8 and 10 weeks)(mg/dL)) with the majority of Dyn dKO mice dying by 10 weeks. Histological examination resulted in lesions characteristic of focal segemental glomerulosclerosis that progressed to global sclerosis and interstitial fibrosis, while EM demonstrated severe foot process effacement. To further explore the role of the endocytic pathway, Dyn binding partner SJ1 was examined. SJ1 null mice had severe albuminuria at birth (25±5 vs 890±67 (wild vs. SJ1 KO)(μg/mg)) and foot process effacement. Compared to wild type podocytes, Dyn dKO or SJ1 null podocytes had robust Arp2/3 accumulation at clathrin coated pits as well as endocytic defects characterized by significantly decreased Nephrin uptake compared to wild type (Dyn dKO; <4%, SJ1 KO; <70%, $p<0.05$ respectively).

Conclusions: These findings provide insight into Dynamins and Synaptojanin 1 playing a fundamental role regulating endocytosis and actin dynamics within the glomerular filtration barrier.

FR-PO1273

Calprotectin, an Endogenous Toll-Like Receptor 4 Ligand (TLR4), Is Critical for Induction of Glomerulonephritis Ruth J. Pepper,[1] Phoebe E.H. Sharp,[2] Gurjeet Bhangal,[2] Hsu-Han Wang,[1] Ruth M. Tarzi,[2] Charles D. Pusey,[2] H. Terence Cook,[2] Alan D. Salama.[1] *[1]Centre for Nephrology, UCL; [2]Imperial College London.*

Background: Calprotectin an endogenous TLR4 agonist, expressed in neutrophils, monocytes and infiltrating macrophages. We investigate disease induction using the murine nephrotoxic nephritis (NTN) model in calprotectin deficient mice, as well as potential amplification of human monocyte calprotectin expression by MPO-ANCA and PR3-ANCA, investigation of serum levels and cell surface expression in patients.

Methods: Accelerated NTN experiments performed on wild-type (WT) and calprotectin deficient mice (Cal-/-), with day 7 sacrifice. Renal histology was scored for thrombosis and macrophage infiltration, and serum measurement of urea and creatinine. In human

studies, healthy control monocytes and patients in remission were stimulated with ANCA, and calprotectin expression determined by flow cytometry (FACS). Serum levels measured by ELISA. Calprotectin surface expression of neutrophil and monocytes in patients and controls determined by FACS.

Results: Cal-/- mice were protected from glomerulonephritis with significantly lower serum urea than WT ($p<0.05$), less thrombosis and proteinuria and significantly less macrophage and T cell glomerular infiltration ($p<0.001$, $p<0.005$). In human studies, monocytes isolated from remission vasculitis patients significantly upregulate calprotectin expression following MPO-ANCA stimulation ($p<0.01$), control IgG or PR3-ANCA did not induce a significant increase. AAV patients (non-renal involvement) who subsequently relapse have higher serum calprotectin at 1 and 6 months after treatment compared to non-relapsers. Patients demonstrate significantly higher calprotectin surface expression in neutrophils and monocytes compared to controls ($p<0.05$).

Conclusions: Mice deficient in calprotectin are protected from renal injury, demonstrating calprotectin has a critical role in the initiation of glomerulonephritis. We demonstrate significantly higher serum levels in those who subsequently relapse. MPO-ANCA can promote further upregulation of monocyte calprotectin levels. Patients have increased surface expression of calprotectin on neutrophils and monocytes.

FR-PO1274

Substrate Elasticity and Geometry Affect Podocyte Cell Mechanics Eric Schordan,[1] Sandra Schordan,[1] Rudolf Merkel,[2] Bernd Hoffmann,[2] Nicole Endlich,[1] Karlhans Endlich.[1] *[1]Anatomy and Cell Biology, University Medicine Greifswald, Greifswald, Germany; [2]Institute of Complex Systems (ICS-7), Forschungszentrum Juelich GmbH, Juelich, Germany.*

Background: Podocyte foot processes cover the outer aspect of the capillaries in the renal glomerulus. They are important determinants of the permeability of the glomerular filtration barrier. In addition, podocytes stabilize the capillary wall with a contractile actin cytoskeleton counteracting the high hydrostatic capillary pressure. Chronic kidney disease is predominantly caused by damage and failure of podocytes, e.g. by increased capillary pressure.

Methods: In the present study we investigate the cytoskeleton and cell mechanics of podocytes in response to different elasticities and geometries of the substrate.

Results: We find that soft substrates (8 to 56 kPa mimicking basement membrane elasticity) as compared to stiff substrates (490 kPa or rigid plastic) modify cell morphology by inducing cell orientation, actin cytoskeleton reorganization and formation of longer processes. Directed cell migration in a wounding assay is impaired on soft substrates, whereas cell spreading remains unaffected. The geometry of non-planar soft substrates, mimicking the curvature of the capillary wall, is sensed by podocytes and leads to morphological changes. Traction forces of podocytes, measured on soft substrates with embedded displacement markers, increase with increasing substrate stiffness. Recently, we have shown that stress fibers are elongated at focal adhesions and move centripetally over time. Here we show that elongation rate correlates with traction force.

Conclusions: Our data demonstrate that elasticity and geometry affect podocyte cell mechanics. Moreover, there is a coupling between substrate elasticity, traction force and stress fiber formation.

FR-PO1275

Nephrin Regulates Lamellipodia Formation by Assembling a Protein Complex That Includes Ship2, Filamin and Lamellipodin Puneet Garg, Leslie Cook, Madhusudan M. Venkatareddy, Rakesh Verma. *Internal Medicine/ Renal, University of Michigan, Ann Arbor, MI.*

Background: Actin dynamics has emerged at the forefront of podocyte biology. Identification of human disease with mutations in actin associated proteins presenting with proteinuria and chronic kidney disease supports the importance of actin dynamics in podocytes. Numerous mouse knock out models of actin associated proteins further demonstrates its importance in not only development but maintenance and repair of the podocytes. Podocyte intercellular junction receptor Nephrin plays a vital role in regulating actin dynamics.

Methods: To identify the proteins that interact with Nephrin we generated a library of His-tagged SH2 domains of SH3-SH3 domain containing proteins.

Results: Here we report recruitment and regulation by Nephrin of a protein complex that includes ship2 (SH2 domain containing 5'inositol phosphatase), Filamin (FLN) and lamellipodin (LPD). These proteins are important in regulation of actin dynamics, lamellipodia formation and focal adhesion dynamics. Nephrin activation resulted in phosphorylation of actin crosslinking protein FLN in a p21 activated kinase dependent manner. FLN exists in a complex with Ship2 in the cytoplasm. This leads to ship2 enrichment at the sites of actin polymerization. Ship2 dephosphorylates PIP3 to generate PI (3,4) P2. This further leads to recruitment of scaffold protein LPD which binds specifically to PI (3,4)P2 via its PH domain. Nephrin activation in cell culture results in formation of lamellipodia, a process that requires specialized actin dynamics at the leading edge along with focal adhesion turnover. Using the previously described CD16-Nephrin clustering system, Nephrin ligation resulted in abnormal morphology of actin tails in human podocytes where ship2, FLN and LPD was knocked down. We also observed decreased efficiency of lamellipodia formation and cell migration in these knock down cells.

Conclusions: We propose that Nephrin-Neph1 complex not only initiates actin polymerization but is also able to regulate and assemble a protein complex that is necessary to regulate the architecture of the generated actin filament as well as focal adhesion dynamics.

FR-PO1276

Indomethacin Blocks the Fluid Flow Shear Stress (FFSS)-Induced Increase in Glomerular Albumin Permeability (P_{alb}) *In Vitro* Tarak Srivastava,[1] Ellen T. McCarthy,[2] Ram Sharma,[3] Mukut Sharma.[3] *[1]Nephrology, CMH, UMKC, Kansas City, MO; [2]Nephrology, KUMC, Kansas City, KS; [3]Nephrology, KC VA Med Ctr, Kansas City, MO.*

Background: FFSS, the force tangential to the podocyte surface that results from flow of ultrafiltrate, increases with SNGFR. Increased SNGFR occurs in congenital or acquired solitary kidneys and in early diabetic nephropathy, conditions that result in microalbuminuria and CKD. We have shown that FFSS: alters the actin cytoskeleton in podocyte monolayers and increases COX-2 expression and prostaglandin E_2 (PGE_2) levels. We have also shown that PGE_2, increases albumin permeability (P_{alb}) in isolated glomeruli and that increased P_{alb} precedes proteinuria in models of diabetes and hypertension. We hypothesized that increased FFSS alters filtration barrier through COX2 metabolites.

Methods: Glomeruli from Sprague-Dawley rats (200-225 g) were subjected to 0.3 dynes/cm^2 FFSS for 30, 60 or 120 mins followed by a recovery for 120 mins at 37°C. Indomethacin (2.5μM) was included in the medium in some experiments. Changes in glomerular P_{alb} were determined using an *in vitro* assay. Untreated baseline and time matched glomeruli were used as controls. Murine podocytes were subjected to FFSS for 120 minutes and analyzed for changes in gene expression using Affymetrix GeneChipMouse Exon 1.0 ST Array.

Results: Results show that FFSS increased Palb at 30, 60 and 120 minutes. The effect of FFSS on Palb persisted after 120 minutes of recovery. Partial results presented in the Table below show that indomethacin significantly blocked the effect of FFSS on Palb

Group	P_{alb}±SEM	*P* value
Control	0.02±0.04	
FFSS [120 min]	0.77±0.06	0.001*vs.* Control
FFSS [120 min] + Recovery [120 min]	0.62±0.06	0.001*vs.* Control
Indomethacin+FFSS+Recovery	0.16±0.11	0.001 *vs.* FFSS

n=20 glomeruli/group

Initial analysis of the gene array results has shown a >3 fold upregulation of COX-2 expression in FFSS-treated compared to control podocytes (data not shown here).

Conclusions: These results suggest that flow-induced increase in FFSS increases P_{alb} through PGE_2, an arachidonic acid metabolite of the COX pathway. We postulate that changes in the glomerular filtration barrier secondary to FFSS may explain the microalbuminuria in CKD.

FR-PO1277

The Podocyte Slit-Diaphragm Molecule MAGI-1 Is Required for Nephrin Localization and Function Justin Vadaparampil, Lewis Kaufman. *Nephrology, Mount Sinai School of Medicine, New York, NY.*

Background: In podocytes, MAGUK with inverted domain structure-1 (MAGI-1) is specifically expressed at the slit-diaphragm and functions as a linker protein that directly interacts with several other critical proteins including nephrin, α-actininin-4, and synaptopodin. Previously, the function of MAGI-1 and its roles in podocyte dynamics in proteinuric diseases were entirely unknown.

Methods: To study the mechanisms of MAGI-1 function in greater detail, we generated stable MAG-I deficient podocytes using targeted shRNA lentiviral infections of an established human cell line.

Results: MAGI-1 deficient podocytes have significant abnormalities in cellular morphology characterized by a simplified and overall smaller cell size, less intricate cytoskeletal architecture, and less complex projections and llamelopodia. Podocytes lacking MAGI-1 also divide at a dramatically lower rate and adhere abnormally to many components of the glomerular basement membrane including collagen type IV and laminin.

To begin to investigate MAGI-1 function, we examined the impact of MAGI-1 deficiency on the localization of its known interacting partners. In MAGI-1 deficient podocytes transfected with a FLAG-nephrin expression construct, membrane expression of nephrin was almost completely lost with significant accumulation in the cytoplasm. These results were confirmed when analyzing endogenous nephrin in fully differentiated podocytes. Ongoing work is focused on dissecting involved mechanisms.

Conclusions: Our data suggests that MAGI-1 deficiency has a signficant impact on podocyte architecture in culture. These effects may be mediated by the loss of nephrin surface expression in the setting of MAGI-1 deficiency. We speculate that loss of MAGI-1 results in destabilization of the protein complex associated with nephrin's cytoplasmic domain resulting in increased nephrin endocytosis.

Funding: NIDDK Support

FR-PO1278

Sumoylation Determines Localization and Stability of Nephrin at the Plasma Membrane Irini Schaefer, Erik Himmelseher, Hermann G. Haller, Mario Schiffer. *Nephrology, Medical School Hannover, Hannover, Germany.*

Background: The podocyte slit diaphragm is a delicate extracellular protein structure that has to withstand bloodpressure associated changes in glomerular perfusion pressure and thus requires constant renewal. A disordered endocytosis of nephrin could cause a misplaced localization and could therefore lead to destabilization of the slit diaphragm. Sumo (small ubiquitin-like modifier) is a ubiquitin-like protein with 20% identity to ubiquitin. In vertebrates the Sumo-family has at least four members: Sumo-1, -2, -3 and a recently reported member Sumo-4. Sumoylation of proteins on lysine residues can block

ubiquitination of the same site thus lead to stabilization. The aim of our studies was to analyze the role of Sumoylation in regulating localization and stability of nephrin.

Methods: First we analyzed sumoylation of nephrin by in vitro Sumoylation. For mapping the potential sites that can be modified by Sumoylation we used Sumosp 2.0. We found one predicted Sumoylation sequence at the cytoplasmic tail of nephrin that is conserved in mouse and human. To explore if this predicted site is modified by Sumoylation we created nephrin-mutants in which lysine was converted to arginine. To show that Sumoylation may regulate stability of nephrin we examined the steady-state level by treatment with cycloheximide. Furthermore we performed endocytosis-assays, subcellular fractionization and confocal microscopy.

Results: We could show that nephrin is sumoylated by Sumo-1, -2 and -3. By immunoprecipitation and in vitro Sumoylation we could verify that the lysine-mutant can not be sumoylated. Cycloheximide-experiments showed that the lysine-mutant has a lower steady-state level compared to WT-nephrin. Furthermore endocytosis of the lysine-mutant is enhanced and subcellular fractionization and confocal microscopy showed that the lysine mutant accumulated at the perinuclear region and cytosol.

Conclusions: These data suggest that Sumoylation determines localization and enhances stability of nephrin. Next to glycosylation and phosphorylation, Sumoylation is a posttranslational modification that may play a role in the tight regulation of nephrin trafficking and turnover at the slit diaphragm.

Role of Guanine Nucleotide Exchange Factor-H1 in Complement-Mediated RhoA Activation in Glomerular Epithelial Cells Flaviana Mouawad, Lamine Aoudjit, Ruihua Jiang, Tomoko Takano. *Medicine, McGill University, Montreal, QC, Canada.*

Background: In the rat model of membranous nephropathy (passive Heymann nephritis), complement C5-9 causes visceral glomerular epithelial cell (GEC) injury. We reported previously that complement activates the small GTPase, RhoA, in GEC *in vitro* and *in vivo*. The present study addresses the role of guanine nucleotide exchange factor (GEF)-H1, an activator of RhoA, in complement-mediated RhoA activation in GEC.

Methods: Rat GEC and immortalized mouse podocytes were used. Complement stimulation was done by serially exposing cells to antibody and normal human serum (NS) or de-complemented serum (control). Affinity precipitation by RhoG17A, which binds to active GEF, followed by immunoblotting was used to quantify GEF-H1 activity. RhoA activity in live cells was visualized by fluorescence resonance energy transfer. Passive Heymann nephritis was induced by an intravenous injection of anti-Fx1A antiserum in male Sprague-Dawley rats.

Results: GEF-H1 protein was expressed in mouse podocytes, rat GEC, and rat glomeruli. In vitro, NS, but not control serum, activated GEF-H1 activity, starting at 15 min, which continued to increase up to 40 min. Complement-mediated GEF-H1 activation was absent when C8-deficient serum was used but was restored when C8 was added back, indicating that it is dependent on C5b-9. RhoA activity was also increased by complement in a time course similar to GEF-H1. RhoA activation was most distinct in the sub-membrane area of cellular protrusions and was followed by retraction of the protruded area. Complement-mediated GEF-H1 activation was reduced by the inhibitors of the Extracellular-signal Regulated Kinase (ERK) pathway (U0126 and PD98057). In vivo, GEF-H1 and RhoA were activated in the glomeruli from rats with passive Heymann nephritis at 14 days after disease induction.

Conclusions: Complement C5b-9 activated GEF-H1 in GEC in a time course similar to RhoA. GEF-H1 activation is likely to contribute to complement-mediated RhoA activation in GEC, which may lead to morphological changes of GEC and proteinuria in a rat model of membranous nephropathy.

Funding: Government Support - Non-U.S.

FR-PO1280

The Novel Podocyte Protein 4.1O Interacts with Slit Diaphragm Proteins Nephrin, and Glepp1, and Ameliorates Nephrin Endocytosis Eva Koenigshausen,[1] Sinja Ohlsson,[1] Marcus G. Pezzolesi,[2] Magdalena Woznowski,[1] Ivo Quack,[1] Sebastian Alexander Potthoff,[1] Andrzej S. Krolewski,[2] Lars C. Rump,[1] Lorenz Sellin.[1] *[1]Nephrology, Heinrich Heine University, Duesseldorf, Germany; [2]Section on Genetics and Epidemiology, Joslin Diabetes Center - Harvard Medical School, Boston, MA.*

Background: Microalbuminuria is as an early marker for diabetic nephropathy. A GWAS for diabetic nephropathy revealed FRMD3 as a candidate gene in type 1 diabetics. FRMD3 encodes for the protein 4.1O. 4.1 proteins serve as adaptors between plasma membrane proteins and the actin cytoskeleton. The 4.1O orthologue in zebrafish is required for prevention of proteinuria. Nephrin is endocytosed upon binding to the adaptor protein β-arrestin2. The expression and molecular function of 4.1O in human podocytes is unknown so far.

Methods: Human podocytes were differentiated over 14 days. RNA and protein were isolated and followed by RT-PCR or western blot respectively for 4.1 family members. Cells expressed 4.1O and nephrin or GLEPP1 or truncations of the indicated proteins. After cell lysis co-immunoprecipitation was performed. Using monoclonal and polyclonal antisera immunofluorescence for 4.1O was done.

Results: 4.1 family members 4.1O, 4.1G, 4.1B and 4.1N are expressed in human podocytes. 4.1O shows a punctated cytoplasmic distribution with staining of the plasma membrane. 4.1O interacts with nephrin and GLEPP1 but not with Neph1. The interaction domain of 4.1O within the nephrin C-terminus. 4.1O binds to nephrin within its very c-terminal domain. In addition protein 4.1O forms homodimers. 4.1O reduces the interaction of nephrin with β-arrestin2 and .

Conclusions: FRMD3 (4.1O) has been shown to be a candidate gene for diabetic nephropathy in type 1 diabetics. In zebrafish, its deletion leads to proteinuria. 4.1O is a novel human podocyte protein that interacts with nephrin and GLEPP1. Binding of 4.1O to nephrin prevents β-arrestin2 binding to nephrin. It is therefore conceivable that 4.1O is a relevant adaptor to slit diaphragm proteins and the actin cytoskeleton. Furthermore it is postulated that 4.1O plays an important role in the protection for progression of proteinuric kidney disease by inhibition of nephrin endocytosis.

FR-PO1281

RhoA Regulates the Expression of Fibronectin Via Nuclear Factor of Activated-T Cells in Podocytes Lei Zhu, Ruihua Jiang, Lamine Aoudjit, Tomoko Takano. *Medicine, McGill University, Montreal, QC, Canada.*

Background: RhoA is a small GTPase which regulates the actin cytoskeleton. We reported previously that high level expression of active RhoA in podocytes in mice induces glomerulosclerosis, accompanied by fibronectin upregulation. The aim of this study was to investigate the mechanism by which RhoA upregulates fibronectin expression in podocytes. Role of nuclear factor of activated-T cells (NFAT) was investigated.

Methods: Differentiated mouse podocytes or cultured rat podocytes were used for studies with cultured cells. Double luciferase assay was used to study the activation of the fibronectin promoter and the NFAT pathway. $[Ca^{2+}]i$ was determined using Fluo-4. RhoA activity was monitored by fluorescence resonance energy transfer in live cells. Nuclear extracts from glomeruli were used to study NFAT activation *in vivo* by electromobility shift assay (EMSA).

Results: Constitutively active (CA)-RhoA activated the fibronectin promoter, which was inhibited by BAPTA (Ca2+ chelater), W7 (calmodulin inhibitor), FK506 (calcineurin inhibitor), and VIVIT (NFAT inhibitor). Angiotensin II, which is known to activate RhoA in podocytes, also transactivated the fibronectin promoter, which was inhibited by the same set of inhibitors. CA-RhoA activated the NFAT-responsive promoter and CA-NFAT in turn activated the fibronectin promoter, which was further augmented by an activator of protein kinase C, phorbol 12-myristate 13-acetate. RhoA-mediated NFAT activation was inhibited by BAPTA and W7. Calpeptin, an activator of RhoA, increased [Ca2+]i in a time course similar to RhoA activation. Induction of CA-RhoA expression also increased [Ca2+]i significantly. NFAT activation, studied by EMSA, was detected in glomerular nuclear extracts from rats with puromycin aminonucleoside nephrosis and from mice which express constitutively active RhoA in podocytes.

Conclusions: RhoA activates the $[Ca^{2+}]i$ -NFAT pathway in podocytes. RhoA-induced fibronectin upregulation is, at least in part, mediated by gene transactivation via NFAT. Thus, the RhoA-NFAT pathway may contribute to the development of certain forms of glomerulosclerosis.

Albumin Exposure Induces an Inflammatory Response and Reduces VEGF Expression in Cultured Podocytes Kayo Okamura,[1] Patrick Daniel Dummer,[2] Jeffrey B. Kopp,[2] Judith Blaine.[1] *[1]Medicine, University of Colorado Denver, Aurora, CO; [2]National Institute of Diabetes and Digestive and Kidney Disease, Bethesda, MD.*

Background: Albuminuria exposure induces an injury response in cultured proximal tubular cells, but the effects of albumin on cultured podocytes have not been as well investigated. *In vivo*, podocytes express multi-ligand receptors that facilitate albumin uptake, including low-density lipoprotein-related protein 2 or megalin and neonatal Fc receptor.

Methods: We studied human urine-derived podocyte-like cells, transformed with human telomerase reverse transcriptase and temperature-sensitive SV40 T antigen (Sakairi, Am J Physiol 2010). Podocytes were cultured under non-permissive conditions (37°C) at which they express differentiation markers including WT1, synaptopodin, and nestin. Podocytes were exposed to medium supplemented with 10% heat-inactivated fetal bovine serum (final albumin concentration ~ 2 mg/ml), supplemented with either 5 mg/ml recombinant human serum albumin or dextran of a similar molecular mass as an oncotic control. Cytokine mRNA levels were assessed by quantitative RT-PCR over an 8 hour time course and cytokine medium levels were assessed over a 48 hour time course. Results are expressed as fold-change compared to oncotic control.

Results: Albumin exposure increased expression of interleukin-1beta (IL-1b) expression (peak mRNA increase ~ 8 fold at 3 hours)), increased tumor necrosis factor alpha (TNFa) expression (peak mRNA increase ~3 fold at 3 hours, peak protein increase ~15 fold at 6 hours), increased interleukin-6 expression (peak mRNA increase ~ 7 fold and peak protein increase ~8 fold at 48 hours). In addition, vascular endothelial growth factor (VEGF) mRNA expression was reduced by ~3 fold at 6 hours compared to dextran treated controls.

Conclusions: These results suggest that exposure of cultured podocytes to albumin concentrations similar to those present in nephrotic urine induce an inflammatory factor cascade, with increased expression of IL-1b and TNFa followed by IL-6, and reduce VEGF mRNA expression. Together these may contribute to dysfunction of podocytes and glomerular endothelial cells in nephrotic syndrome.

Podocyte Failure Caused by Hypertrophic Stress in Rats Expressing a Podocyte-Specific Dominant Negative 4E-BP1 Transgene of the mTOR Pathway. Acceleration of Proteinuria, FSGS and Progression to ESKD by Conditions Causing Glomerular Growth, and Prevention by Calorie Restriction

Akihiro Fukuda,[1] Mahboob A. Chowdhury,[1] Madhusudan M. Venkatareddy,[1] Su Qing Wang,[1] Jocelyn E. Wiggins,[1] Ken Inoki,[2] Roger C. Wiggins.[1] *[1]Division of Nephrology, Departments of Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Life Sciences Institute, University of Michigan, Ann Arbor, MI.*

Background: Progressive podocyte depletion drives progressive glomerulosclerosis. Podocyte depletion could result from reduction in podocyte number, size and/or function.

Methods: To test the hypothesis that reduced capacity of podocytes to respond to hypertrophic stress would lead to glomerulosclerosis we developed Fischer 344 rats expressing a human AA-4E-BP1 dominant negative transgene driven by the podocyte-specific podocin promoter. 4E-BP1 (in the mTOR pathway) controls CAP-dependent translation and plays a role in determining cell size.

Results: Tg rat podocytes uniformly expressed the transgene, were born with the expected ratios without increased proteinuria and normal kidney histology. At 100g homozygous (but not heterozygous) rats had reduced podocyte and glomerulular tuft volume. Both hetero and homozygous tg rats developed proteinuria, FSGS and reached ESKD by 12 months. Accelerated glomerular hypertrophy was induced by uninephrectomy (NX). Wt rats with NX develop minor proteinuria and few FSGS lesions by 14 weeks. In contrast NX of heterozygous tg rats caused proteinuria after 3 weeks, FSGS by 8 weeks and ESKD by 14 weeks. NX of homozygous tg rats caused rapid development of high level proteinuria, glomerulosclerosis and ESKD by 9 weeks. Proteinuria occurred in direct proportion to body weight gain. Morphometry showed development of a mismatch between glomerular size and total podocyte volume in hetero and homozygous rats. Both proteinuria and FSGS were completely prevented by calorie restriction.

Conclusions: Reduced capacity of podocytes to respond to hypertrophic stress in response to growth signaling through the mTOR pathway can trigger proteinuria, FSGS and progression to ESKD. Calorie restriction could be a useful adjunctive therapy to slow and/or prevent progression to ESKD.

Motor Protein Myo1c Is a Critical Component of the Glomerular Filtration System

Ehtesham Arif,[1] Babita Kumari,[1] Matthew J. Lazzara,[2] Deepak Nihalani.[1] *[1]Medicine, Philadelphia, PA; [2]Chemical and Biomedical Engineering, Philadelphia, PA.*

Background: Podocyte cells along with their specialized junctions "slit diaphragm" form the key components of glomerular filtration assembly. These structures are critical for the glomerular filtration function including the selective passage of low molecular weight waste products and the retention of blood plasma proteins. Our recent study identifies Myo1c as a novel Nephrin and Neph1 interacting motor protein that transports these proteins from cytoplasm to podocyte cell membrane.

Methods: This study investigates the role of Myo1c in maintaining the glomerular filtration function using zebrafish as a model system.

Results: Knockdown of Myo1c gene in zebrafish using antisense morpholino resulted in abnormal developmental phenotype.

In addition, the knockdown also induced pericardial edema and whole body edema at 72hpf (arrows) which suggests impairment of pronephric osmoregulatory function. Histological analysis of mutant fish revealed dilated nephric tubules consistent with loss of slit diaphragm proteins Nephrin and Neph1 in zebrafish. Further investigation to determine changes in the podocyte foot processes using electron microscopy and loss of filtration barrier using transgenic fish is under progress.

Conclusions: In conclusion, Myo1c is a component of Nephrin and Neph1 signaling pathway and plays a role in maintaining glomerular function.

Septin-7, a Novel Interaction Partner of CD2AP, Negatively Regulates Glucose Uptake

Anita A. Wasik,[1] Meng-Qiu Dong,[2] Marilyn G. Farquhar,[3] Sanna H. Lehtonen.[1] *[1]Haartman Institute, University of Helsinki, Finland; [2]Scripps Research Institute, La Jolla, CA; [3]University of California San Diego, La Jolla, CA.*

Background: Podocytes are insulin sensitive and take up glucose in response to insulin using glucose transporters GLUT4 and GLUT1. Glucose uptake depends on nephrin, which interacts with VAMP2 residing on GLUT4 storage vesicles (GSVs) and facilitates the fusion of the vesicles with the plasma membrane. CD2AP, an adaptor protein essential for the glomerular filtration barrier, interacts with nephrin and a number of proteins involved in various signaling and vesicular trafficking pathways.

Methods: Here we describe the identification of the small GTPase septin-7 as a novel interaction partner of CD2AP by pull-down assay and mass spectrometry and show by 2-deoxy-D-glucose uptake assay that septin-7 regulates glucose uptake.

Results: Septin-7 partially co-localizes with CD2AP in rat glomeruli and pull-down assay on rat glomerular lysate indicates that their interaction is mediated by the 3rd SH3 domain of CD2AP and the C-terminus of septin-7. Further, co-immunoprecipitation assays show that both CD2AP and nephrin interact with septin-7. Septins are filament-forming proteins and also septin-7 is expressed in cultured human podocytes in a filamentous pattern that depends on the intact actin cytoskeleton. In addition to regulating cytokinesis, mammalian septins function in exocytosis. We found that septin-7 interacts with regulators of vesicular trafficking both on GSVs and plasma membrane suggesting that septin-7 could regulate the exocytic transport of GSVs. In line with this, knockdown of septin-7 in HIRc cells, rat fibroblasts that stably express human insulin receptor, increased the glucose uptake activity of the cells. Further, the interaction of VAMP2 and ectopically expressed nephrin increased in septin-7 depleted HIRc cells.

Conclusions: The data indicate that septin-7 may form a filamentous barrier and thus hinder vesicle trafficking, and consequently, depletion of septin-7 facilitates the fusion of the vesicles with the plasma membrane. Involvement of nephrin suggests that septin-7 may participate in the regulation of glucose transport also in podocytes.

FR-PO1286

Ang II Induces Nephrin Dephosporylation and Podocyte Injury through Caveolin 1-Dependent Mechanism Zhilong Ren,[1] Wei Liang,[1] Cheng Chen,[1] Pravin C. Singhal,[2] Guohua Ding.[1] *[1]Division of Nephrology, Renmin Hospital of Wuhan University, Wuhan, Hubei, China; [2]Medicine, North Shore-Long Island Jewish Health System, Manhasset, NY.*

Background: It has been suggested that nephrin contributes to the mechanism of Ang II- induced podocyte injury. Caveolin-1 has been demonstrated to play a crucial role in signaling transduction. In the present study, we evaluated the effect of AngIIon nephrin phosphorylation in podocytes and whether caveolin-1 was involved in this process.

Methods: Cultured podocytes were exposed to Ang II(10^{-6}mol/L) and pretreated with or without losartan(10^{-5}mol/L) for variable time periods. Nephrin and caveolin-1 expression and their phosphorylation were evaluated by Western-blotting and immunofluorescence. Caveolar membrane fractions were isolated by sucrose density gradient centrifugation, then the distribution and interactions between ATI, nephrin, Csk and caveolin-1 were analyzed using Western-blotting and co-immunoprecipitation. Podocyte apoptosis was evaluated by cell nucleus staining with Hochest-33342.

Results: Caveolin-1 was expressed in podocytes and had a low level of phosphorylation in control condition. After Ang II stimulation, caveolin-1 phosphorylation was increased, but its total protein expression had no significant change. Nephrin and caveolin-1 were found to be co-localized in caveolae fractions. AT1 and Csk moved in caveolae fractions and had a interaction with caveolin-1 after the stimulation of AngIIfor 3-hour. Transfection of caveolin-1 plasmid(pEGFPC3-cav-1) significantly increased AngII-induced nephrin dephosphorylation and podocyte apoptosis. Furthermore, knockdown caveolin-1 protein using siRNA inhibited nephrin dephosphorylation and ameliorated Ang II-induced podocyte apoptosis.

Conclusions: In conclusion, these data indicate that AngIIinduces nephrin dephosphorylation and podocyte injury through a caveolin-1-dependent mechanism.

FR-PO1287

Role of Scribble for Podocyte Function and Cell Polarity Eugen Widmeier,[1] Bjorn Hartleben,[1] Nicola Wanner,[1] Sung Tae Kim,[2] Jeffrey H. Miner,[2] Dontscho Kerjaschki,[3] Gerd Walz,[1] Tobias B. Huber.[1] *[1]Renal Division, University Hospital Freiburg, Germany; [2]Nephrology Department, Washington University St. Louis; [3]Pathology, Medical University Vienna, Austria.*

Background: The kidney filter represents a unique assembly of podocyte epithelial cells that tightly enwrap the glomerular capillaries with their foot processes and the interposed slit diaphragm. So far, very little is known about the guidance cues and polarity signals required to regulate proper development and maintenance of the glomerular filtration barrier. We recently demonstrated that the evolutionarily conserved apical Par3-Par6-aPKC complex, a fundamental regulator of cell polarity proteins interact with Neph1 and Nephrin at the slit diaphragm of the glomerular filtration barrier and that podocyte-specific deletion of aPKCiota in mice results in severe proteinuria, nephrotic syndrome, progressive glomerulosclerosis and death at 3-4 weeks after birth. The cell polarity protein Scribble, a large, multidomain scaffold protein, is known to be essential for 3-dimensional tissue morphogenesis. Here we report, that Scribble translocates from the lateral side of polygonal shaped immature podocytes to the basal cell membrane during podocyte differentiation. Immunogold electron microscopy reveals membrane associated localisation of Scribble predominantly basal of the slit diaphragm and partially at the slit diaphragm. To further study the role of Scribble for podocyte differentiation Scribble flox/flox mice were generated by introducing lox-p-sites into the Scribble introns 1 and 8 and these mice were crossed to Cre deleter mice and Podocin-Cre mice. Constitutive Scribble knockout animals die during embryonic development around E14. Kidney culture experiments of constitutive Scribble knockout mice reveal unaffected foot process development and slit diaphragm formation. Podocyte specific Scribble knockout mice develop normally and show no histological, ultrastructural or clinical abnormalities for up to 12 months of age. Ongoing research evaluates the role of Scribble under glomerular pathophysiological conditions.

FR-PO1288

Functional and Spatial Analysis of *C. elegans* SYG-1 and SYG-2, Orthologs of the Neph/Nephrin Cell Adhesion Module Directing Selective Synaptogenesis Elke Neumann-Haefelin,[1] Nicola Wanner,[1, 2] Gerd Walz,[1, 3] Tobias B. Huber.[1, 2, 3] *[1]Renal Division, University Hospital, Freiburg, Germany; [2]Spemann Graduate School of Biology and Medicine, Albert-Ludwigs-Universität, Freiburg, Germany; [3]Centre for Biological Signalling Studies (bioss), Albert-Ludwigs-Universität, Freiburg, Germany.*

Background: The assembly of specific synaptic connections represents a prime example of cellular recognition. Members of the immunoglobulin superfamily are ancient proteins in both mammals and invertebrates, where they constitute a trans-synaptic adhesion system. The correct connectivity patterns of the IgSF proteins nephrin and Neph1 are crucial for the assembly of functional neuronal circuits and the formation of the kidney slit diaphragm, a synapse-like structure forming the filtration barrier.

Methods: Here, we utilize the nematode *C. elegans* model for studying the requirements of synaptic specificity mediated by nephrin-Neph proteins.

Results: In C. elegans, the nephrin/Neph1 orthologs SYG-2 and SYG-1 form intercellular contacts strictly in trans between epithelial guidepost cells and neurons specifying the localization of synapses. We demonstrate a functional conservation between mammalian nephrin and SYG-2. Expression of nephrin effectively compensated loss of syg-2 function in C. elegans and restored defective synaptic connectivity further establishing the C. elegans system as a valuable model for slit diaphragm proteins. Next, we investigated the effect of SYG-1 and SYG-2 trans homodimerization respectively. Strikingly, synapse assembly could be induced by homophilic SYG-1 but not SYG-2 binding indicating a critical role of SYG-1 intracellular signalling for morphogenetic events and pointing towards the dynamic and stochastic nature of extra- and intracellular nephrin-Neph interactions to generate reproducible patterns of synaptic connectivity.

Conclusions: In summary, our findings corroborate that *C. elegans* is a useful tool for investigating fundamental nephrin/Neph protein functions. Furthermore, we present novel insights into the mechanisms of SYG-1 and SYG-2 homotypic adhesion properties and intracellular functions.

FR-PO1289

Effect of Amyloidogenic Immunoglobulin Light Chains on the Contractile Cytoskeleton of Human Podocytes In Vitro Laura Econimo,[1] Julie A. Tomolonis,[1] Laura M. Dember,[2] David C. Seldin,[2] Lawreen H. Connors,[2] Joel M. Henderson.[1] *[1]Pathology and Laboratory Medicine, Boston University Medical Center, Boston, MA; [2]Amyloid Treatment & Research Center, Boston University Medical Center, Boston, MA.*

Background: Podocyte injury and proteinuria are hallmarks of renal involvement in light-chain (AL) amyloidosis, but the mechanisms underlying these effects are not well established. Recent work suggests that amyloidogenic light chains (LC) may have direct toxic effects on cells. Given the importance of the cytoskeleton to podocyte barrier function, we hypothesized that amyloidogenic LC may elicit a toxic effect on podocytes, characterized by derangement of cytoskeletal structure and function. In this study, we investigated the effect of amyloidogenic LC on human podocyte cytoskeletal structure and contractile function in vitro.

Methods: Human LC were isolated from urine of patients with: renal amyloidosis and severe proteinuria; amyloidosis without renal involvement; and multiple myeloma. Human podocytes were plated on glass and polyacrylamide elastic substrates, and exposed to soluble LC, control protein (recombinant transthyretin, rTTR) or vehicle for 24 hr. After protein exposure, immunostaining was performed to characterize filamentous actin distribution and soluble protein endocytosis, and traction force microscopy was used to measure cell traction.

Results: All of the proteins to which podocytes were exposed (LC or TTR) were confirmed to be endocytosed by the cells. Cells exposed to amyloidogenic LC appeared small and exhibited cytoskeletal disorganization, as compared to cells receiving other treatments. Cells exposed to amyloidogenic LC showed a significant decrease (up to 62%) in traction force magnitude compared to vehicle control; cells exposed to other LC or rTTR exhibited less marked decreases (20 to 31%) in traction force relative to control.

Conclusions: The results suggest that amyloidogenic LC have a direct toxic effect on podocytes, manifest as contractile cytoskeleton dysfunction.

Complement Modulates the Ubiquitin-Proteasome System and Endoplasmic Reticulum-Associated Degradation in Glomerular Epithelial Cells Thomas M. Kitzler, Joan Papillon, Julie Guillemette, Simon S. Wing, Andrey V. Cybulsky. *Department of Medicine, McGill University, Montreal, QC, Canada.*

Background: In experimental membranous nephropathy, complement C5b-9 induces sublethal glomerular epithelial cell (GEC) injury and proteinuria. C5b-9 also activates mechanisms that restrict injury or facilitate recovery. The actions of C5b-9 are mediated by pathways, including mitogen-activated protein kinases and protein kinase C (PKC). Recently, we showed that in GECs, C5b-9 augmented the function of the ubiquitin-proteasome system (UPS); moreover, proteasomal inhibition exacerbated complement-mediated cytotoxicity. This study addresses mechanisms by which complement modulates the UPS.

Methods: We monitored UPS function by transfection of a UPS reporter, GFP^u (CL1 degron fused with green fluorescent protein). By analogy, CD3δ-yellow fluorescent protein (YFP) was employed as a reporter of endoplasmic reticulum-associated degradation (ERAD). Ubiquitin mRNA was quantified by RTq-PCR.

Results: In GECs, sublytic C5b-9 decreased GFPu due to proteasomal degradation. This reduction in GFPu was attenuated by the c-jun N-terminal kinase (JNK)-directed inhibitor, SP203580, or by expression of a dominant-negative JNK mutant, whereas inhibitors of the extracellular signal-regulated kinase and p38 pathways were ineffective. Complement-induced GFPu degradation was also blocked by the PKC-directed inhibitor, GF109203X, or by depletion of PKC (prolonged pretreatment with phorbol myristate acetate). Complement increased the level of CD3δ-YFP in GECs. The overall ubiquitination of proteins was enhanced in complement-treated GECs and in glomeruli of rats with experimental membranous nephropathy, although ubiquitin mRNA was unchanged in GECs.

Conclusions: In GECs, complement increased ubiquitination of proteins, consistent with increased protein misfolding, and augmented overall UPS function, which was at least in part dependent on JNK and PKC. In parallel, ERAD was impaired, perhaps

due to an overabundance of misfolded proteins in the ER, and/or reduced capacity for retrotranslocation to the proteasome. Therapeutic modulation of UPS function may be a novel strategy to limit complement-mediated GEC injury.

FR-PO1291

Cell Surface Heparan Sulfate Glycosaminoglycans Regulate Podocyte Cell-Cell Recognition Kevin J. McCarthy, Deborah J. McCarthy. *Pathology, LSU Health Sciences Center, Shreveport, LA.*

Background: Studies from our laboratory showed that heparan sulfate glycosaminoglycans (HS) on cell surface proteoglycan (PG) core proteins serve as podocyte adhesion co-receptors. HS-null podocytes have decreased ability to attach, spread, and migrate compared to control cells. In this present report, we investigated if cell surface HS mediates cell-cell interactions in podocytes.

Methods: Immortalized Ext1 $^{fl/fl}$ podocytes were used for the study, deletion of the floxed Ext1 allele was done via adenoviral delivery of a Cre recombinase construct (HS-null podocytes). Control podocytes were infected with the same adenovirus construct but lacking the Cre recombinase cassette (HS+ podocytes). Differentiated, non-replicating HS+ and HS- podocytes were labeled in vitro using cell permeant fluorescent dyes CMFDA or CMAC for identification during co-culture experiments. For co-culture experiments, equal numbers of differentially labeled HS+ and HS- were admixed and added to microwell slides. Fluorescent images were digitized at 0, 4, 12, 24, 48, hours and 1 week post-seeding. Short term (<24hrs) interactions were also explored by time lapse microscopy. Controls for cell monolayer development consisted of seeding equivalent numbers of HS+ and HS- cells in separate wells.

Results: At T=0, fluorescent imaging of mixed cultures showed that both HS+ and HS- podocytes were dispersed in a random suspension. At T=2 hours, podocytes from both groups had attached and spread to the substrate in a random pattern. Between 6-12 hrs, HS+ podocytes had begun to aggregate into clusters, whereas the HS- podocytes remained oriented into cords. At longer intervals, (24hrs-48hrs), the HS+ cells remained as clusters, the HS-cells consistently excluded-at no time were heterotypic aggregates (HS+: HS-) seen. Exogenous addition of heparin had no effect on sorting.

Conclusions: The data show that cell surface HS mediates cell-cell interactions in a homophilic manner and that heterophilic interactions, i.e. HS+:HS- aggregates do not occur. Thus, besides playing a role in cell-matrix interactions in podocytes, cell surface HS also plays a previously uncharacterized role in mediating cell-cell interactions in podocytes.

FR-PO1292

Regulation of Inflammatory Response in Renal Glomeruli Depends on the State of Podocytes Sahithi Josna Panchagnula,[1] Simon C. Satchell,[2] Moin Saleem,[2] Lorraine Harper,[1] Julie M. Williams,[4] Helen M. McGettrick,[1] Samantha Tull,[1] Edward Rainger,[1] Caroline O.S. Savage.[3] *[1]University of Birmingham, Birmingham, United Kingdom; [2]University of Bristol, Bristol, United Kingdom; [3]Glasko Smith Kline, Stevanage, United Kingdom; [4]Wellcome Trust Clinical Research Facility, Birmingham, United Kingdom.*

Background: We have hypothesized that podocytes modulate inflammatory responses cooperatively with glomerular endothelial cells (GEnC) in both health and disease.

Methods: Using an *in vitro* static co-culture system, the effects of podocytes on GEnCs to recruit neutrophils was studied in the absence and presence of ANCA. The effect was also studied by injuring the podocytes with puromycin aminonucleoside (PAN).

Results: Co-culture of GEnC and podocytes stimulated with higher concentrations of TNF-α (100U/ml), demonstrated significant reduction in neutrophil recruitment by up to 50% when compared to GEnC mono-cultures. Neutrophil recruitment in co-cultures vs monocultures was 18.83 ± 4.8% and 31.48 ± 5.5%, n=4, using primary cells and 22.3 ± 1.9% and 45.16 ± 4.5%, n=31, using immortalised cell lines. IL-6 was found to be key mediator involved in the inhibition of neutrophil recruitment. The neutrophil interactions in co-cultures were dependent on CXCR2 and ENA-78. The ability of ANCA to enhance neutrophil recruitment by GEnC mono-cultures with TNF-α (2U/ml), was mitigated in co-cultures and the effect was reversed with increasing TNF-α. Co-cultures did not show inhibition in neutrophil recruitment following podocyte injury by PAN.

Conclusions: Healthy podocytes modulate GEnC responses to cytokine stimuli via IL-6. Modulation can occur with ANCA activation of neutrophils to a certain level but is lost with increased endothelial activation or when podocytes are injured. Collectively, we demonstrate importance of podocytes in modulating endothelial responses to injury.

FR-PO1293

Transforming Growth Factor (TGF)-β1 Induced DNA Methylation of Wilms' Tumor Suppressor Gene (WT1) Promoter in Human Podocytes Hiroko Hamatani, Keiju Hiromura, Toru Sakairi, Satoshi Takahashi, Hidekazu Ikeuchi, Akito Maeshima, Yoshihisa Nojima. *Department of Medicine and Clinical Science, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan.*

Background: WT1, firstly identified as a tumor suppressor gene, is essential for normal podocyte function. Previous reports have shown that WT1 promoter is often methylated in cancers, leading to transcriptional silencing. Recently, it was reported that TGF-β1 downregulates WT1 expression in podocytes. We investigated the possibility that the reduction of WT1 expression is caused by its promoter methylation.

Methods: A conditional immortalized human podocyte cell line was treated with 3 ng/ml of TGF-β1. A human renal tubular epithelial cell line (HK-2), which does not express WT1, was used as the positive control for the methylated WT-1 promoter. The degree of DNA methylation was determined by quantitative methylation-specific PCR (Q-MSP) and bisulfate sequence.

Results: We first determined the effect of TGF-β1 on WT1 expression. Both WT1 mRNA and protein expression were reduced by the treatment of TGF-β1. We next examined the degree of methylation of WT1 promoter by Q-MSP. The level of DNA methylation was low in untreated podocytes (2.9±4.5%). In contrast, increased methylation was detected in podocytes treated with TGF-β1 for 11 days (14.3%±10.6%). Untreated HK2 showed hypermethylation (99.1±0.96%). Bisulfite sequencing also revealed some methylation of CpG sites at WT1 promoter in TGF-β1-treated podocytes, whereas almost no methylation was observed in untreated podocytes. Finally, pretreatment with demethylation agent, 5-aza-2'-deoxycytidine (5-aza-dC), partially prevented the reduction of WT1 mRNA (37.1±11.3% vs 65.9±26.2% of untreated cells, TGF-β1 alone vs TGF-β1 + 5-aza-dC, determined by real time PCR).

Conclusions: Our data showed that TGF-β1 induces DNA methylation of WT1 promoter in human cultured podocytes. The reduction of WT1 expression by TGF-β1 is considered to be partly caused by the DNA methylation of WT1 promoter.

FR-PO1294

Insulin Stimulates the Production of VEGF-A in the Podocyte Dependent on the Insulin Receptor Lorna J. Hale, Peter W. Mathieson, Moin Saleem, Gavin Iain Welsh, Richard Coward. *Academic Renal Unit, Bristol University, Bristol, United Kingdom.*

Background: VEGF-A is a pro-survival factor abundantly produced by the podocyte, that is critical for glomerular function. Diabetic nephropathy is the leading cause of end stage renal failure in the developed world; however in this condition the role VEGF-A is unclear. Using transgenic mice with podocyte specific deletion of the insulin receptor (IR) (podIRKO) we have recently shown that insulin sensitivity of the podocyte is critical for normal glomerular function (Welsh et al Cell Metabolism 2010). One of the features we observed was increased podocyte apoptosis over time. We therefore set out to investigate if podocyte VEGF-A is controlled by insulin.

Methods: We used conditionally immortalised human podocytes in vitro and murine in vivo models to study the role insulin in the production of VEGF-A. We knocked out the podocyte specific IR by 75% in human cells using ShsiRNA and by at least 90% in mice using cre-lox technology.

Results: In vitro - Insulin rapidly increased the level of mRNA production in human podocytes within 30 minutes of insulin stimulation (increase of 115%. * $p<0.05$. $N\geq5$ experiments) and this was detectable at the protein level (30% increased VEGF-A protein production within 24 hours [$p<0.01$ n=9 experiments]). This was reduced in podocytes with IR knockdown by 30% ($p<0.001$ n=7).

In vivo- VEGF-A was studied both pre and post the development of albuminuria (which occurs at 5 weeks in the podIRKO model). At 4 weeks the production of VEGF-A was diminished by 40% by measuring quantitative PCR of a single cell podocyte suspension and this continued and was reflected by decreased in-situ VEGF-A hybridisation signal after albuminuria has developed in podIRKO animals, when measured at 8 weeks.

Conclusions: VEGF-A is insulin inducible in the podocyte. Our results suggest that when podocyte insulin resistance is present then VEGF-A production is reduced. This occurs prior to the development of albuminuria. Reduced insulin stimulated VEGF-A production could explain the development of podocyte induced apoptosis observed in our transgenic models and also that commonly observed in human diabetic nephropathy.

Podocyte Membrane Traffic Modulates HIV Accumulation Via DC-SIGN Dileep Kumar,[1] Joanna Mikulak,[2] Partab Rai,[1] Rungwasee Rattanavich,[1] Mohammad Husain,[1] Ashwani Malhotra,[1] Pravin C. Singhal.[1] *[1]Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY; [2]Immunology, Istituto Clinico Humanitas, Rozzano (Milano), Italy.*

Background: HIV infection of podocytes has been considered to play a critical role in development of HIV-associated nephropathy. Podocytes display a dysregulated growth and proliferative phenotype. We recently reported that DC-SIGN facilitates HIV-1 entry into conditionally immortalized human podocytes (CIHPs) (Am J Physiol 299:F664-F673, 2010). In the present study, we examined the role of DC-SIGN in membrane traffic-modulated podocyte viral accumulation.

Methods: CIHPs were pulsed with primary R5 and X4 strains for two hours and then thoroughly washed. Subsequenlty, CIHPs were assayed for viral accumulation by RT-PCR at different time periods. To determine the role of DC-SIGN for HIV-1 sequestration in CIHPs, control, anti-DC-SIGN-antibody treated CIHPs and siRNA/DC-SIGN transfected CIHPs were pulsed with HIV. To study the effect of membrane traffic, CIHPs were pretreated with either buffer, cytochalasin-B (an inhibitor of actin filament), colchicine (an inhibitor of microbules), Brefeldin A (an inhibitor of Golgi-ER pathway) and then pulsed with HIV. Cells treated under these conditions were evaluated for HIV accumulation and DC-SIGN expression.

Results: CIHPs rapidly internalized R5 and X4 HIV-1 primary strains via endocytosis. Both anti-DC-SIGN antibody and siRNA/DC-SIGN attenuated HIV accumulation in CIHPs. Pretreatment of CIHPs with both colchicine and cytochalasin B increased podocyte HIV-1 accumulation and thus, showed the role of actin and microtubules in the podocyte viral trafficking. Since Brefeldin A also enhanced podocyte HIV-1 accumulation, it seemed that

Golgi-ER pathway might be linked to podocyte viral sorting. Interestingly, CIHPs treated with colchicine, cytochalasin B, and Brefedin A showed a two-fold increase in DC-SIGN expression. Thus, it appears that in addition to the blockade of the membrane traffic and enhanced expression of DC-SIGN has contributed to HIV entry into CIHPs.

Conclusions: These findings indicated that alteration of membrane traffic promoted podocyte HIV-1 accumulation by enhancing podocyte expression of DC-SIGN.

Funding: NIDDK Support

FR-PO1296

aPKC lambda/iota and zeta Are Required for Podocyte Process Development

Bjorn Hartleben,[1] Eugen Widmeier,[1] Mario Schiffer,[2] Tobias B. Huber.[1] *[1]Renal Division, University Hospital Freiburg, Germany; [2]Renal Division, Medizinische Hochschule Hannover, Germany.*

Background: The kidney filter represents a unique assembly of podocyte epithelial cells that tightly enwrap the glomerular capillaries with their foot processes and the interposed slit diaphragm. Previously, we identified the Par3, Par6, aPKC polarity complex as novel interactors of Nephrin and Neph1 at the slit diaphragm. Podocytes express both isoforms of aPKC, lambda/iota and zeta. Genetic deletion of aPKC lambda/iota in podocytes results in severe proteinuria, nephrotic syndrome, progressive glomerulosclerosis and death at 3-4 weeks after birth. Interestingly, while podocyte-specific aPKC lambda/iota KO mice develop such a severe glomerular phenotype they still born with a podocyte footprocess network. We speculated that the aPKC zeta isoform might act as functional backup compensating for the loss of aPKC lambda/iota during glomerular development. Here we report that podocyte-specific double knockout of both aPKC isoforms lambda/iota and zeta results in a dramatic phenotype of podocytes that fail to form correct primary and secondary processes. This severe phenotype leads to a glomerular developmental arrest, mesangiolysis, incomplete capillary network and perinatal death.

These results suggest that aPKC signaling is the essential step in formation of the podocyte process network identifying a fundamental signaling program for the regulation of the complex three-dimensional podocyte network.

The Reno-Protective Effect of Ethyl Pyruvate in Streptozotocin-Induced Diabetic Nephropathy Model

Kyung Don Ju, Eun Jin Cho, Kook-Hwan Oh, Eun Kyoung Shin. *Division of Nephrology, Department of Internal Medicine, Seoul National University, Republic of Korea.*

Background: Pyruvate is an endogenous anti-oxidant and anti-inflammatory substance. The present study was implemented to investigate the protective effect of pyruvate against the development and progression of diabetic nephropathy in an *in-vitro* and *in-vivo* model.

Methods: Diabetic condition was induced by injecting streptozotocin(STZ, 65mg/kg) intraperitoneally from the S-D rats. Those that developed diabetes after 48 h were treated with ethyl pyruvate (40mg/kg) intraperitoneally every other day. Rat mesangial cells cultured primarily from the S-D rat were treated in high glucose (HG, 50mM) or normal glucose (NG, 5 mM) conditions.

Results: HG increased mRNA and protein expression levels of MCP-1, TGF-b1, laminin, fibronectin and type IV collagen in a time dependent manner. And NADPH oxidase-dependent reactive oxygen species (ROS) generation was increased in HG-stimulated cultured mesangial cells. Ethyl pyruvate (EP) decreased NADPH-dependent ROS generation and reduced mRNA and protein levels of MCP-1, TGF-b1, laminin, fibronectin and type IV collagen in a dose dependent manner. Diabetic rats without pyruvate treatment and nondiabetic rats were used for control. Pyruvate-treated diabetic rats exhibited decreased albuminuria, and NADPH-dependent ROS generation. Immunohistoche-mistry showed reduced laminin, type IV collagen and fibronectin deposition in the glomeruli compared with nontreated diabetic rat. Parallel changes were shown in the tissue mRNA and protein expression level of MCP-1, TGF-b1, laminin, fibronectin and type IV collagen in the kidney.

Conclusions: These findings suggest that pyruvate protects against kidney injury via NADPH oxidase inhibition.

Distribution of the Hindiii Restriction Fragment Length Polymorphism and CR1 Expression on Blood Leukocytes of Patients with Primary Glomerulonephritides and Lupus Nephritis

Aleksandra Rochowiak,[1] Zofia I. Niemir,[1] Magdalena Lebkowska,[2] Grzegorz Dworacki.[2] *[1]Department of Nephrology, Univ. of Medical Sciences, Poznan, Poland; [2]Department of Clinical Immunology, Univ. of Medical Sciences, Poznan, Poland.*

Background: CR1 is a membrane receptor for C3b and C4b expressed on blood cells. Being involved in the processing and clearance of immune complexes (IC) and regulation of B-cell function, it protects from the development of IC diseases. CR1 expression on erythrocytes was supposed to be linked to high (H) and low (L) expression alleles identified by HINDIII restriction fragment length polymorphism (RFLP). Intriguingly, there are no studies that would have examined the influence of this polymorphism on the level of CR1 expression on blood leukocytes (BL) in patients with primary and secondary glomerulonephritides (GN).

Methods: The surface expression of CD35 was determined by flow cytometry analysis of whole blood samples from 65 patients with primary GN (PGN), 31 with lupus nephritis (LN) and 44 healthy controls (C), with back gating on monocytes (M, CD14), neutrophils (N, CD15) and B-lymphocytes (CD19). DNA was isolated from BL, amplified using primers specific for intron 27 of CR1 gene and HINDIII RLFP analysis was performed thereafter.

Results: Among 140 examined individuals, the HH allele was found in 65%, HL in 29.9% and LL in 5.71% of them. Unexpectedly, the highest expression of CR1 on all cell types was associated with the LL allele. In this respect, significant differences were found between individuals having the LL vs. HH alleles ($p<0.001$) and LL vs. HL alleles ($p<0.05$). The comparison of subjects having the HL and HH alleles revealed that those with the HL allele displayed significantly higher CR1 expression on B-cells ($p<0.01$) and N ($p<0.05$), but this could not be demonstrated on M. The prevalence of the HH allele was the highest in the examined groups (PGN, 60%; LN, 64.5%; C, 72.7%), followed by HL (30.8%, 32.3% and 25%) and LL allele (9.2%, 3.2% and 2.3%, respectively).

Conclusions: We found a genetic link between the HINDIII RLFP and CR1 expression on BL in Polish population. However, no impact of this polymorphism on the development of IC diseases could be confirmed.

Toward the Practical Use of Nephrin Peptides as a TRPC6 Inhibitor

Shoichiro Kanda,[1,2] Yutaka Harita,[1,2,3] Takashi Sekine,[2] Takashi Igarashi,[2] Takafumi Inoue,[4] Seisuke Hattori.[5] *[1]Div. of Cellular Proteomics (BML), Institute of Medical Science, Tokyo University, Tokyo, Japan; [2]Dept. of Pediatrics, Tokyo University, Tokyo, Japan; [3]Dept. of Molecular Biology, Yokohama City University, Yokohama, Japan; [4]Dept. of Life Science and Medical Bioscience, Waseda University, Tokyo, Japan; [5]Dept. of Biochemistry, Kitasato University, Tokyo, Japan.*

Background: There are lines of evidence that overactivation of TRPC6, is involved in the podocyte pathophysiology (Winn M, Science. 2005) (Reiser J, Nat. Genet. 2005) (Moller C C, JASN. 2007). However, regulatory mechanism of TRPC6 remains unclear. We reported phosphorylation of TRPC6 Y284 is necessary for the binding with PLC-γ1, which promotes the membrane expression. Nephrin also binds to pY284 and interferes the phospho-dependent activation of TRPC6 by disrupting the PLC-γ1-TRPC6 interaction. (Kanda S, MoBC. 2011). Here we analyzed the phosphorylation status of Y284 in glomeruli, and examined whether Nephrin peptide has an inhibitory effect on TRPC6 activity.

Methods: We raised a phospho-specific anti-TRPC6 antibody against pY284. We introduced four kinds of Nephrin peptides, each of which consist of 12 amino acids, into the cytoplasm of cultured cells by a peptide delivery system and assessed the TRPC6 activity by biotinylation assay and calcium assay using Fura-2 loaded cells.

Results: In isolated rat glomeruli, Y284 phosphorylation was observed weakly, and augmented by a phosphatase inhibitor. We identified Nephrin cytoplasmic region (1216-1227) is necessary for its binding with phospho-TRPC6. Two different Nephrin peptides around this region inhibited phospho-dependent TRPC6 membrane trafficking. Toward an in vivo application of Nephrin peptides, we conjugated a motif of 11 consecutive arginines to the most effective Nephrin peptide and delivered it into cultured podocytes. The peptides were delivered into almost all the cells. This Nephrin peptide reduced the membrane expression of phospho-TRPC6 to 57.1±2.8 % and the phospho-dependent Ca uptake to 79.9±6.7 % as compared to a control peptide.

Conclusions: Nephrin peptides inhibits phospho-dependent TRPC6 activation, and have a potential as a therapeutic reagent with appropriate delivery in vivo.

FR-PO1300

Nephrin Missense Mutations Alter Cellular Trafficking and Induce Endoplasmic Reticulum Stress

Tatiana Drozdova, Andrey V. Cybulsky. *Medicine, McGill University, Montreal, Canada.*

Background: Nephrin, a key component of the filtration slit diaphragm, undergoes post-translational modifications in the endoplasmic reticulum (ER). Mutations in nephrin lead to proteinuria. We examined the effects of missense mutations in nephrin on protein folding in the ER, cellular trafficking, and induction of the unfolded protein response (UPR).

Methods: Wild type (WT) nephrin, and the I171N, G270C, S366R, S724C and R743C mutant cDNAs were expressed in 293T cells or glomerular epithelial cells (GECs) by transient transfection. Association of nephrin with the ER chaperone, calnexin, was studied by co-immunoprecipitation. Activation of the UPR was assessed by monitoring expression of the ER chaperone, Grp94, phosphorylation of eukaryotic translation initiation factor-2α subunit (eIF2α), and induction of C/EBP homologous protein-10 (CHOP), as well as activating transcription factor-6 (ATF6)-luciferase reporter activity.

Results: All nephrin mutants showed increased association with calnexin, compared with WT nephrin. The I171N and G270C mutants increased expression of Grp94 in 293T cells, and stimulated ATF6-luciferase activity in both 293T cells and GECs. Nephrin S366R and S724C tended to induce the UPR, but changes in Grp94 and ATF6-luciferase activity were less consistent. The R743C mutant did not enhance Grp94 expression, nor ATF6-luciferase activity. All nephrin mutants did not increase eIF2α phosphorylation, nor CHOP expression. Immunofluorescence microscopy showed WT nephrin at the plasma membrane, while the I171N and S366R mutants were perinuclear, colocalized with calnexin. Morever, the two nephrin mutants induced aggregation of the ER chaperone, calreticulin, compared with WT. Treatment of cells with castanospermine (which reduces the interaction of nephrin with calnexin) resulted in a portion of nephrin I171N and S366R appearing at the plasma membrane.

Conclusions: Certain nephrin mutants show impaired folding in the ER, and activate the ATF6 branch of the UPR. Induction of ER chaperones may represent a cytoprotective response, allowing cells to withstand proteotoxic injury. Blocking the interaction of nephrin with calnexin results in a partial rescue of certain nephrin mutants to the plasma membrane.

Cyclin-Dependent Kinase Cdk5 Regulates TRPC6 Function at the Slit Diaphragm Henning Hagmann,[1] Bernhard Schermer,[1] Jeffrey W. Pippin,[2] Thomas Benzing,[1] Stuart J. Shankland,[2] Paul T. Brinkkoetter.[1] *[1]Department of Nephrology, University of Cologne, Germany; [2]Department of Nephrology, University of Washington, Seattle, WA.*

Background: The slit diaphragm (SD) bridges the 30-40nm wide intercellular gap in between neighbouring podocyte foot processes. It not only displays a structural component of the glomerular filter but it is also a site of highly active signalling to ascertain podocyte function and survival. Among the proteins involved are the Nephrin-Neph signalling complex as well as the non-selective cation channel TRPC6. Hyperactive TRPC6 channel activity has been shown to cause podocyte demise and glomerular disease (FSGS) [1].

Results: Here, we provide evidence that the atypical cyclin dependent kinase Cdk5 is a key regulator of TRPC6 activity in podocytes. Cdk5 and its activator p35 interacted and co-localized with SD-proteins in detergent resistant membrane fractions in vitro and phosphorylated the non-selective cation channel TRPC6 directly. In contrast, no effect was observed for Cdk5-Cyclin I, another activator present in podocytes. We further investigated the physiological impact of phosphorylation on TRPC6 protein stability and membrane localization. Phosphorylation of TRPC6 led to enhanced translo-cation of the channel protein to the plasma membrane and increased TRPC6-channel activity, as assessed in whole cell voltage clamp experiments in Xenopus oocytes and fluorometric Ca2+-measurements in cultured podocytes.

Conclusions: Our data suggests that Cdk5, a kinase involved in synaptogenesis and synaptic plasticity of neurons, plays a crucial role at the slit diaphragm. It acts directly on slit diaphragm proteins and regulates TRPC6 signalling by direct phosphorylation. This new regulatory role of Cdk5 at the podocytes intercellular junction makes it tempting to speculate that the podocyte slit diaphragm and the neuronal synapse, indeed, share great similarities and raises an array of questions concerning slit-diaphragm turnover and remodelling.

FR-PO1302

Protein Kinase G Negatively Regulates Angiotensin II-Induced Transient Receptor Potential Cation Channel-6 Activity in Cultured Podocytes Gentzon Hall, Peter J. Lavin, Rasheed A. Gbadegesin, Guanghong Wu, Alison Byrd, Alison Homstad, Michelle P. Winn. *Medicine/Nephrology, Duke University Medical Center, Durham, NC.*

Background: The transient receptor potential cation channel, type 6 (TRPC6) is a non-selective, Ca^{2+}-permeable cation channel that causes hereditary FSGS. Despite mounting evidence for the role of TRPC6 in various glomerular pathologies, the development of selective TRPC6 inhibitors has been complicated by the high degree of sequence homology between TRPC family members. Recent insights into the functional regulation of TRPC6 have revealed protein kinase G (PKG) as a key negative modulator of TRPC6 activity through phosphorylation of 2 highly conserved residues, threonine 69 (T69; T70 in humans) and serine 321 (S321; S322 in humans). In an effort to characterize the role of PKG-mediated inhibition of TRPC6 activity in podocytes, we evaluated TRPC6 phosphorylation at threonine 69 (T69) in mouse podocytes.

Methods: Using a combination of immunoblotting, siRNA-mediated gene knockdown, adenoviral gene expression, and scratch wound healing assays in conditionally immortalized and primary murine podocyte cultures, we examined the role of PKG-mediated TRPC6 phosphorylation.

Results: In unstimulated podocytes, TRPC6 is heavily phosphorylated at T69. This basal phosphorylation is attenuated 4 fold with siRNA-mediated gene knockdown of PKG and 2 fold with Angiotensin II (Ang II) stimulation. Pretreatment of podocytes with the PKG signaling agonists SNAP and 8-br-cGMP and the soluble guanylate cyclase agonists YC-1 and Bay 41-2272, completely attenuated Ang II-induced T69 dephosphorylation. Additionally, pharmacologic agonism of PKG pathway signaling attenuated TRPC6-dependent podocyte migration by 30%-50%. Similarly, in Ang II-stimulated podocytes overexpressing a phosphomimetic mutant of human TRPC6 (TRPC6 T70E/S322E), podocyte migration was significantly reduced by 30%.

Conclusions: Taken together, these data provide evidence for the role of PKG in the modulation of TRPC6 activity in podocytes and highlight the potential therapeutic value of NO/cGMP/PKG agonism in the treatment of TRPC6-associated podocytopathies.

PKCε Is the Upstream Regulator of Dynamin in Podocytes Beina Teng,[1] Sanja Sever,[2] Changkyu Gu,[2] Hermann G. Haller,[1] Mario Schiffer.[1] *[1]Division of Nephrology, Department of Medicine, Medical School Hannover, Hannover, Germany; [2]Nephrology Division, Department of Medicine, Massachusetts General Hospital, Charlestown, MA.*

Background: We have previously demonstrated that the novel PKC isoform (PKCε) participated in signaling pathways controlling actin filament dynamics. PKCε deficiency in podocytes resulted in defective actin arrangement including cell adhesion, migration, spreading and motility, which led to a progressive reduction of podocytes and a spontaneous glomerulosclerosis phenotype in PKCε-/- mice in vivo.

Methods: Wildtype or mutant PKCε (dominant negative), wildtype or mutant dynamin (deletion or dominant negative) were re-expressed in PKCε-/- podocytes via adenoviral infection to further confirm the role of PKCε in podocyte deregulation.

Results: Re-expression of wildtype PKCε but not the mutant resulted in increased formation of stress fibres, focal adhesion complexes, lamellipodia and filopodia in PKCε-/- podocytes. Loss of PKCε in podocytes dramatically reduced the activities of Rho family small GTPases that are key upstream regulators of actin-cytoskeleton rearrangement, which could be reversed by re-expression of wildtype PKCε.

Dynamin, a large GTPase known to regulate either actin or actin-binding proteins to modulate the actin reorganization, was detected to be a binding partner of PKCε in vitro. The expression level of dynamin was not significantly changed in PKCε-/- podocytes compared to wildtype podocytes. Overexpression of constitutively active dynamin(dynE/K) construct via adenoviral infection in PKCε deficient podocytes but not the dominant negative dynamin (dynK/A, dynK/E) or deletion mutant dynamin (dynΔPRD) significantly enhanced the formation of stress fibers, focal adhesion complexes and lamellipodia. Overexpression of dynamin also alters the signaling of Rho family small GTPases especially the Rac1 activity and its localization. All the disordered actin-cytoskeletal phenotypes due to PKCε deficiency could be partically rescued by overexpression of constitutively active dynamin.

Conclusions: PKCε might be an upstream regulator of dynamin in the signaling processes that modulate the dynamics of actin cytoskeleton in podocytes.

FR-PO1304

CLIC5A Enhances Ezrin Phosphorylation and Association with the Actin Cytoskeleton Abass Almomany, Laiji Li, Barbara J. Ballermann. *Medicine, University of Alberta, Edmonton, AB, Canada.*

Background: CLIC5A is a glomerulus-predominant protein that co-localizes with podocalyxin and Ezrin in podocyte foot processes. Ezrin couples transmembrane proteins like podocalxin to cortical actin when it is phosphorylated on T567(P-Ezrin). In CLIC5A deficient mice, podocyte P-Ezrin and total Ezrin are reduced, podocyte structure is abnormal, and adriamycin-induced injury is more severe than in wild-type mice. Here, we explored whether Ezrin phosphorylation is regulated by CLIC5A.

Methods: Wild-type CLIC5A was cloned into pCDNA3.1. Cos-7 cells, lacking endogenous CLIC5A, were transfected with CLIC5A or vector. Total cell lysates, and soluble and cytoskeletal fractions were prepared using Triton X-100 lysis buffer.

Results: Immunoblots of total cell lysates showed that total Ezrin abundance was similar in CLIC5A and vector transfected cells. However, a much greater proportion of Ezrin was phosphophorylated at T567 in the CLIC5A-transfected, compared to vector transfected cells. Furthermore, in CLIC5A-transfected cells there was a dramatic, 8-10 fold greater association of Ezrin with the cytoskeletal fraction than in vector-transfected cells, and most of this Ezrin was phosphorylated. The PKC inhibitor staurosporine (100 nM 30 min) strongly inhibited Ezrin phosphorylation and its association with the cytoskeletal fraction, while the RhoA kinase inhibitor Y-27632 (15 μM 30 min) had no effect on Ezrin phosphorylation. Akt activation was similar in CLIC5A- and vector-transfected cells. The phosphatase inhibitor calyculin A increased P-Ezrin abundance in the total cell lysates and Ezrin association with the cytoskeletal fraction. The rate of Ezrin de-phosphorylation, quantified by determining P-Ezrin abundance as a function of time after addition of staurosporine, did not differ in CLIC5A- and vector-transfected cells.

Conclusions: Hence, CLIC5A promotes Ezrin phosphorylation and its association with the cytoskeletal fraction in transfected Cos-7 cells. Enhanced Ezrin phosphorylation is likely PKC- (not RhoA or AKT) mediated, and is not due to inhibition of phosphatase activity. We propose that in podocytes, CLIC5A may maintain the association of Ezrin with actin by regulating Ezrin phosphorylation.

FR-PO1305

Glomerular Endothelial Cells Express Glutamate Receptors: Implication for Glomerular Filter Permeability Min Li,[1] Silvia Armelloni,[1] Laura Giardino,[1] Alessandro Corbelli,[1] Masami Ikehata,[1] Deborah Mattinzoli,[1] Piergiorgio Messa,[2] Maria Pia Rastaldi.[1] *[1]Renal Research Laboratory, Fondazione IRCCS Policlinico & Fondazione D'Amico, Milan, Italy; [2]Nephrology and Dialysis, Fondazione IRCCS Policlinico, Milan, Italy.*

Background: We have previously shown that podocytes express glutamate receptors (NMDR and Grm1), and that changes of glomerular glutamate signaling cause podocyte damage and proteinuria. Aim of this study was to start uncovering molecular mechanisms linking dysregulated glutamate signaling to proteinuria.

Methods: In-vitro filter permeability was measured by a novel 3D co-culture system with podocytes and endothelial cells grown on the opposite sides of a membrane. BSA passage from the endothelial to the podocyte supernatant was assessed by spectrometry.

Immunostainings (IF, immunoEM), western blot (WB) and in-cell ELISA served to evaluate NMDR and Grm1 expression and MAPKinase activation.

Results: IF, WB and immunoEM showed that glomerular endothelial cells express NMDAR and Grm1, as it occurs in brain capillaries.

In the 3D co-culture system, BSA permeability was increased not only by podocyte damage but also by incubation of endothelial cells with a neurotoxic dose of glutamate (1 mM).

Application to podocytes of alpha-latrotoxin (a-LTX), a neurotoxin causing bulk glutamate release from synaptic vesicles, induced as well a marked increase in BSA permeability, that was prevented by endothelial cell incubation with the NMDAR antagonist MK-801, but not with the Grm1 antagonist CPCCOEt.

In-cell ELISA demonstrated that glutamate exposure (either direct on endothelial cells, or indirect by a-LTX applied to podocytes) causes endothelial activation of the MAPKinase pathway. The effect is exclusively depending on endothelial NMDAR activation because it is abrogated by endothelial pre-incubation with MK-801, but not with CPCCOEt.

Conclusions: Our data provide a first molecular link between podocyte glutamatergic signaling and increased filter permeability. From our experiments we can hypothesize that leakage of albumin is caused by excessive entry of calcium through the NMDAR into endothelial cells and leads to endothelial dysfunction through activation of the MAPKinase pathway.

FR-PO1306

A Novel Function of the MYPT Family Member TIMAP in Endothelial Cells (EC)

Marya Obeidat, Laiji Li, Barbara J. Ballermann. *Medicine, University of Alberta, Edmonton, AB, Canada.*

Background: TIMAP is a prenylated EC-predominant protein phosphatase 1 (PP1c) regulatory subunit in the myosin phosphatase (MYPT) family, first identified by us in glomerular EC. MYPTs control PP1c activity toward myosin light chains (MLC). Whether TIMAP shares this MYPT function is unknown. Here we explored whether TIMAP regulates phosphorylation of MLC2 (P-MLC2)in EC.

Methods: Two point mutations were introduced in the PP1c binding site of TIMAP, producing TIMAP(PP1c-). Immunoprecipitates of EC-expressed wild-type TIMAP (TIMAP(WT)), but not TIMAP(PP1c-) contained PP1c protein and phosphatase activity. We reasoned that TIMAP(PP1c-) might inhibit de-phosphorylation of P-MLC2 by the TIMAP/PP1c holoenzyme in a dominant negative fashion and therefore increase P-MLC2 abundance.

Results: Endogenous TIMAP and MLC2 co-immunoprecipitated from EC lysates, and in migrating EC, stably expressed TIMAP(PP1c-) exquisitely co-localized with MLC2 at the tip of trailing projections. Contrary to expections, expression of TIMAP(PP1c-) in EC was associated with markedly reduced P-MLC2 in cellular projections, compared to EC transfected with vector or TIMAP(WT) (n=3). By western blot, the proportion of MLC2 phosphorylated on T18/S19 was also lower in EC expressing TIMAP(PP1c-) compared to TIMAP(WT). Upon Rho kinase inhibition with Y27632, P-MLC2 was rapidly dephosphorylated, but the dephosphorylation rate in EC expressing TIMAP(WT) and TIMAP(PP1c-) was identical (n=3). Expression of TIMAP(PP1c-), but not TIMAP(WT) induced formation of long projections in EC, similar to those observed when myosin activity was inhibited. Finally, free MLC2 could be phosphorylated on T18/S19 by myosin light chain kinase (MLCK) in vitro. Also, MLC2 bound directly to TIMAP in vitro. However, the MLCK-mediated phosphorylation of MLC2 bound to immobilized TIMAP(WT) was almost completely blocked, even when PP1c was absent.

Conclusions: The findings that TIMAP interacts with MLC2, that TIMAP devoid of PP1c inhibits MLC2 phosphorylation in EC and in vitro, and mimics myosin inhibitors functionally in EC, lead us to propose the novel mechanism that the T18/S19 phosphorylation site of MLC2 becomes inaccessible to kinases when MLC2 is bound to TIMAP.

The Impact of Interplay between c-mip and WT1 Activity in the Pathophysiology of Podocyte Diseases

Qingfeng Fan,[1] Andreas Schedl.[2] *[1]Inserm U955, Eq21, Creteil, France; [2]INSERM U636, Nice, France.*

Background: C-maf inducing protein, c-mip, was identified in our lab as a key component in the molecular pathogenesis of acquired nephrotic syndromes (NS). The Wilm's tumor suppressor gene *WT1* is expressed constitutively in podocytes and is essential for the functional integrity of glomerular filtration barrier. Mutations of *WT1* gene are associated with NS but the mechanisms of proteinuria are unclear. Because WT1 may act as transactivator or transrepressor, it is not known whether the podocyte dysfunction mainly results from downregulation or overexpression of target genes or both. We report here a functional antagonism between c-mip and WT1 may play a critical role in the pathophysiology of podocyte diseases.

Methods: All adult patients analyzed in this study suffered from idiopathic NS. IHC was performed for WT1 in human biopsy and mouse kidney sections. Chromatin immunoprecipitation, EMSA, WT1 decoy oligonucleotide transfection and luciferase activity assays were performed in M15 and podocyte cell lines. Ubiquitin E3 ligase activity detection kit was used to evaluate the E3 activity of c-mip. siRNA was performed to knockdown c-mip in vivo.

Results: Under physiological conditions, WT1 binds to c-mip promoter via WT1 responsive elements and inhibits its transcriptional induction in podocytes. Conversely, the abundance of c-mip in podocytes was strongly increased in patients presenting with Denys-Drash syndrome. We showed that the induction of c-mip in mouse model for Frasier syndrome precedes the development of the massive albuminuria. In acquired idiopathic NS, c-mip was upregulated in podocytes, while WT1 protein level was reduced. We demonstrated that c-mip interferes with the constitutive transactivation of WT1 mediated by NF-kB. Moreover, we showed that c-mip interacts with WT1 and exhibits an E3 ligase activity, which targets WT1 to proteasome degradation. Intravenous injection of c-mip-siRNA specifically prevented the repression of WT1 in LPS-induced proteinuria in mice.

Conclusions: The negative cross-talk between WT1 and c-mip is required for glomerular integrity and might be a critical determinant in the pathophysiology of podocyte diseases.

EphB4 Forward Signaling Maintains Podocyte Homeostasis during Thy1.1 Nephritis

Monika Lucyna Wnuk,[1, 2] Ruslan Hlushchuk,[3] Gerald Tuffin,[1, 4] Georg Martiny-Baron,[5] Philipp Holzer,[5] Patricia A. Imbach,[5] Valentin Djonov,[3] Uyen Huynh-Do.[1] *[1]Department of Nephrology and Hypertension, Inselspital, University of Bern Medical School, Bern, Switzerland; [2]Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, ON, Canada; [3]Institute of Anatomy, University of Bern, Bern, Switzerland; [4]Glycart Biotechnology, Schlieren, Switzerland; [5]Novartis Institutes for BioMedical Research, Basel, Switzerland.*

Background: Glomerular diseases starting with mesangiolysis have a high potential for recovery, the molecular mechanisms remain however to be defined. Eph receptor tyrosine kinases and their ligands (ephrins) play a pivotal role in the homeostasis of many adult organs and are also widely expressed in the kidney. The aim of our study was thus to assess their role in the glomerular recovery from Thy1.1 nephritis, a rat model of reversible mesangioproliferative glomerulonephritis (GN).

Methods: Western blotting and immunohistochemical methods were used to follow the expression and activation status of Eph/ephrins in healthy and nephritic glomeruli. Next, NPV-BHG712, a novel inhibitor of EphB4 phosphorylation, was applied to control or nephritic rats.

Results: EphB4 and ephrinBs were expressed in healthy glomeruli and upregulated during Thy1.1 nephritis. EphB4 was mostly expressed at the apical membranes of podocytes, whereas ephrinBs were located at the foot processes. Importantly, EphB4 was strongly phosphorylated around day 9 of nephritis. NPV-BHG712 induced no glomerular changes in controls. Nephritic animals treated with vehicle showed neither morphological evidence of podocyte injury nor loss of podocytes. In contrast, NPV-BHG712 application to nephritic rats induced glomerular microaneurysms, podocyte damage and loss. Prolonged NPV-BHG712 treatment resulted in increased albuminuria and substantially disregulated mesangial recovery. Additionally, NPV-BHG712 inhibited capillary repair by intussusceptive angiogenesis, suggesting a previously unrecognized role of podocytes in regulating intussusceptive vessel splitting.

Conclusions: In aggregate, our results identify EphB4 signalling as a novel pathway allowing podocytes to adapt to transient capillary collapse and thus survive.

FR-PO1309

Divergent Mechanisms of Proteinuria and Fibrogenesis in a Mouse Model of Adriamycin Nephrosis

Gal Finer, H. William Schnaper, Yashpal S. Kanwar, Xiaoyan Liang, Tomoko Hayashida. *Pediatrics, Northwestern University.*

Background: Transforming growth factor (TGF-β) is an important mediator of renal fibrogenesis. We initially showed that PI3K and TGF-β contribute to collagen I expression in vitro. Extending these findings, we presented at ASN 2010 a modified mouse model of adriamycin (ADR) nephropathy manifesting proteinuria and FSGS-like histology. Here, we evaluated the role of the p110γ isoform of PI3K in this model.

Methods: A single intravenous injection of ADR to 8 week-old 129Sv/j mice induced glomerulopathy. Kidney tissue and cultured mouse podocytes were evaluated by using standard immunohistochemistry and qPCR.

Results: In-vivo administration of soluble TGF-β receptor II protected against glomerular disease, but did not change ADR-induced proteinuria or tubular injury. Akt phosphorylation was detected by immunostaining of ADR-treated mouse kidneys, suggesting PI3K activation. mRNA encoding p110γ, but not other PI3K isoforms, was selectively up-regulated in ADR-kidneys. Though p110γ is highly enriched in leukocytes, we found that cultured podocytes express p110γ and that p110γ staining colocalizes with nephrin in ADR-kidney glomeruli. In-vivo blockade of p110γ by AS605240 prevented both proteinuria and glomerulosclerosis in ADR-treated mice. In cultured podocytes, AS605240 prevented ADR-induced podocyte damage, protecting against cytoskeletal disorganization and apoptosis. These data suggest that p110γ mediates podocyte injury at the initiation of the disease process. In ADR-kidneys, AS605240 treatment prevented TGF-β expression. In cultured human kidney epithelial cells, AS605240 did not affect collagen induction by TGF-β, whereas pan-PI3K inhibition by LY294002 blocked collagen induction. These data suggest that PI3K p110γ contributes to disease initiation and podocytes injury, whereas other PI3K isoforms play a role in subsequent, TGF-β-mediated collagen expression.

Conclusions: We suggest that PI3K p110γ mediates podocyte injury, resulting in proteinuria, through cell signaling that is not directly dependent on TGF-β/Smad3 pathway activation. Conversely, TGF-β/Smad3 signaling is not involved in proteinuria, but instead has a significant role fibrogenesis.

Hypoxia-Inducible Factor 1α Expression Is Upregulated and Accerelates Fibrosis in Adriamycin-Induced Murine Glomerulonephropathy Tomoko Hayashida, Xiaoyan Liang, Susan C. Hubchak, H. William Schnaper. *Pediatrics, Northwestern University, Chicago, IL.*

Background: Hypoxia-inducible factor (HIF)-1α has been associated wtih ischemic renal injury, but its fibrogenic role in normoxia is less characterized. We recently reported that transforming growth factor (TGF)-β upregulates HIF-1α expression in normoxic cultured human kidney cells. Transcriptional inhibition of HIF-1α blocked TGF-β1-induced type I collagen expression (Basu, JASN 2011). Here, we tested a possible role for HIF-1α in a mouse model of kidney fibrosis.

Methods: Glomerulonephropathy was induced in male 129x1/Svj mice by a single injection of adriamycin (ADR, 15 mg/kg, iv). Some mice were transferred to a hypoxia chamber (10% oxygen) the day after the ADR administration. On day 10, mice were sacrificed 1 hr after Hypoxyprobe administration (60 mg/kg, iv), which accumulates under hypoxia ($pO2 < 10$ mmHg) and is detectable by immunochemistry post mortem. Kidneys were harvested to evaluate histology and mRNA expression by real-time PCR.

Results: As described, ADR-treated mice in normoxia develop proteinuria and TGF-β-mediated histopathological changes consistent with FSGS, associated with increased ECM mRNA expression starting at day 7 and plateaus by day 14. (Finer and Hayashida, ASN2010). Hypoxyprobe adducts were minimally detected in control mouse kidney cortex, whereas they strongly decorated proximal tubules of the ADR-treated mouse kidneys. HIF-1α mRNA expression, determined in whole kidney lysates, was increased 4.3x by ADR compared to control. Glomeruli of the ADR-treated mice showed mesangial expansion and fibrosis but no Hypoxyprobe staining, suggesting a non-hypoxic mechanism for glomerular changes. The kidneys of ADR mice housed in hypoxia showed greater histopathological changes. COL1A2 mRNA expression in whole kidney lysates was not affected in control mice in hypoxia, whereas hypoxia exacerbated COL1A2 mRNA expression in ADR-treated mice (1.89x vs. 5.47x, respectively, compared to normoxic control). Hypoxia did not increase whole-kidney HIF-1α expression greater than that seen with ADR alone.

Conclusions: These results suggest a synergestic role for HIF-1α in both hypoxic and normoxic kidney fibrosis.

Renoprotective Effect and Mechanism of Bortezomib in Adriamycin-Induced Nephropathy Rats Qiao Zhou, Ying Lu, Fang Zhong, Xu Hao, Cong Li, Shanmai Guo, Weiming Wang, Nan Chen. *Nephrology, Ruijin hospital, Shanghai, China.*

Background: Many studies indicate that the proteasome inhibitor could exert potent anti-fibrosis/inflammatory effects . Bortezomib demonstrates a potent antitumor activity against several human cancers and has been clinically used in patients with refractory multiple myeloma.

Methods: Adriamycin nephropathy was induced in Sprague-Dawley rat by a intravenous injection of adriamycin. 4 weeks after injection, bortezomib was given intraperitoneally (30μg/kg or 60μg/kg, twice in week) for 4 weeks. At the end of study, the biochemical indicators were measured and the pathological changes of the renal tissue were evaluated by light microscope. Transmission electron microscopy was used to observe the ultrastructure change of rat kidney. Immunohistochemistry and mRNA expression was applied to observe the expression levels of FSP-1, α-SMA, ColI, Col III, TGF-β, Smad2, Smad3 and the macrophage infiltration in rat kidney.

Results: During the course of nephrotic syndrome, serum creatinine(Scr) and blood urea nitrogen (BUN) were significantly elevated ($p<0.05$). Histological examinations of kidney tissue demonstrated evident tubulo-interstitial inflammation and fibrosis ($p<0.05$). Compared with untreated adriamycin nephrotic group, bortezomib treatment could significantly reduce the level of urine protein, the Scr and BUN, which was accompanied by the attenuation of the macrophage infiltration, pathological changes and ultrastructure change in rat kidney. Immunohistochemistry results showed that the expression of FSP-1, α-SMA, ColI, Col III, TGF-β and Smad3 significantly increased in adriamycin-induced nephritic group($p<0.05$), but no significant difference in Smad2 ($p>0.05$) was found. Compared with the untreated adriamycin-induced nephrotic group, bortezomib treatment could significantly decreased the expression of FSP-1, α-SMA, ColI, Col III, TGF-β and Smad3 ($p<0.05$), but Smad2 was increased ($p<0.05$).

Conclusions: The results demonstrated that bortezomib could significantly ameliorate nephrotic syndrome in adriamycin-induced nephropathy rats and progression of renal fibrosis through a TGF-β/Smad-dependent pathway.

FR-PO1312

Podocyte Damage in Fabry Disease Max C. Liebau,[1,2] Fabian Braun,[1] Claudia Larissa Weitbrecht,[1] Roman-Ulrich Mueller,[1,3] Moin Saleem,[4] Bernhard Schermer,[1,3] Thomas Benzing,[1,3] Markus Cybulla,[5] Christine E. Kurschat.[1,3] *[1]Department of Nephrology, University Hospital Cologne, Cologne, Germany; [2]Department of Pediatrics, University Hospital Cologne, Cologne, Germany; [3]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases, University of Cologne, Germany; [4]Children's Renal Unit, Bristol Royal Hospital for Children, Bristol, United Kingdom; [5]Department of Medicine IV, University Hospital Freiburg, Freiburg, Germany.*

Background: Fabry disease is an X-linked lysosomal storage disorder resulting from an inborn deficiency of lysosomal α-galactosidase A (α-gal A). This deficiency leads to accumulation of neutral glycosphingolipids, mostly globotriaosylceramide (Gb3), in various tissues including kidney, heart, vessels and brain. End-stage renal disease is very common in hemizygous males and limits life expectancy in these patients but renal involvement leading to proteinuria, hematuria, and renal insufficiency is not well understood. Histological studies suggest that the accumulation of Gb3 in podocytes plays an important role in the pathogenesis of glomerular damage. However, the pathophysiological role of Gb3 in podocytes is difficult to study due to the lack of an appropriate animal or cell culture model.

Methods: We have established a human cell culture model of podocyte damage in Fabry disease by using RNA interference technology in combination with lentiviral gene transfer. An established human podocyte cell line was transduced with various short hairpin RNA (shRNA) constructs against human α-gal A. Reduction of α-gal A mRNA levels and α-gal A activity were confirmed by qPCR and by a photometric assay.

Results: Lipid chromotography revealed Gb3 accumulation in α-gal A knockdown cells. We observed a decrease of AKT phosphorylation as well as reduced levels of phospho-mTOR in α-gal A knockdown cells, associated with an increase in autophagy.

Conclusions: Our data suggest that podocyte disease in Fabry patients is linked to a dysregulation of autophagy.

This novel cell line will serve as a promising tool for further studies on the pathophysiological mechanisms responsible for glomerular dysfunction in Fabry disease.

FR-PO1313

Inverted Formin 2 Is Essential for Maintenance of Podocyte Morphology and Signaling Hua Sun, Martin R. Pollak, Johannes S. Schlondorff. *Nephrology, Beth-Israel Deaconess Medical Center, Boston, MA.*

Background: Podocytes are terminally differentiated cells whose morphology and function depend on the fine regulation of actin skeleton dynamics. Mutations in inverted formin 2 (INF2), an actin regulating protein, can cause familial focal segmental glomerulosclerosis (FSGS). INF2 serves as a potential regulator of actin dynamics through its dual polymerization/depolymerization activity and by interference with diaphanous-related formin (mDia) mediated actin polymerization. Here we investigated the role of INF2 in the maintenance of actin-based morphology and signaling in podocytes to gain insight into the mechanism of this form of disease.

Methods: In cultured human podocytes, slit diaphragm (SD) signaling was initiated by nephrin clustering and phosphorylation. The distribution pattern of SD proteins and the nephrin signalsome was compared with/without INF2 knockdown by siRNA sequences targeting INF2. The translocation of SD proteins and signalsome components were observed by immunofluorescent stain.

Results: In cultured podocytes, nephrin and podocin localized along the ruffles of the cells, at the tip of actin filaments. The phosphorylated nephrin recruited adaptor protein NCK/actin serving protein mDia to the signalsome, and induced local actin tail formation. With INF2 knockdown, the de novo expressed nephrin or podocin was stuck in the cytoplasmic endosomes rather than being transported to the ruffles of the cells. The recruitment of mDia and the formation of actin tails were disrupted.

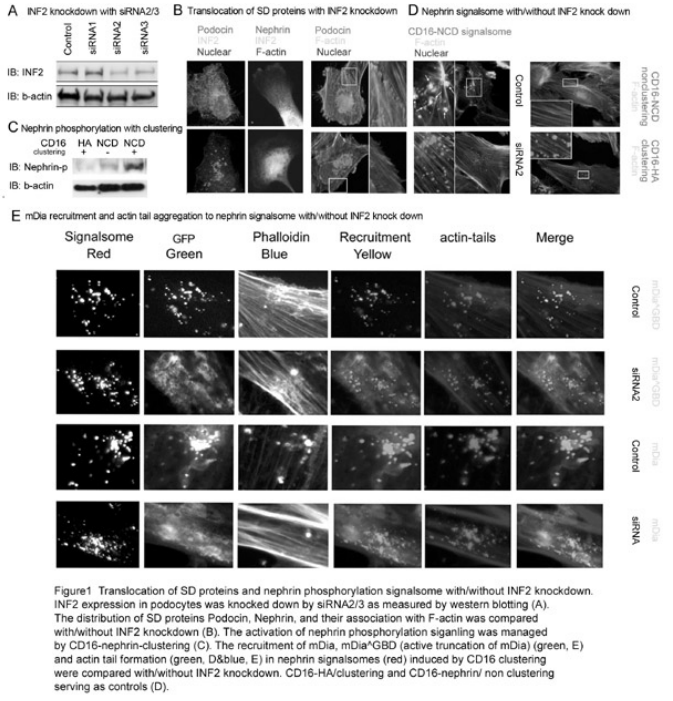

Figure1 Translocation of SD proteins and nephrin phosphorylation signalsome with/without INF2 knockdown. INF2 expression in podocytes was knocked down by siRNA2/3 as measured by western blotting (A). The distribution of SD proteins Podocin, Nephrin, and their association with F-actin was compared with/without INF2 knockdown (B). The activation of nephrin phosphorylation siganling was managed by CD16-nephrin-clustering (C). The recruitment of mDia, mDia^GBD (active truncation of mDia) (green, E) and actin tail formation (green, D&blue, E) in nephrin signalsomes (red) induced by CD16 clustering were compared with/without INF2 knockdown. CD16-HA/clustering and CD16-nephrin/ non clustering serving as controls (D).

Conclusions: INF2 is an essential protein in maintaining the actin cytoskeleton-dependent morphology of podocyte, distribution of SD proteins, and the response of actin-regulating signal transduction initiated by nephrin phosphorylation. The decomposition of foot process integrity may be associated with the deficiency of INF2 in the SD complex-cytoskeleton pathway.

FR-PO1314

Role of Calcium-Indepent Phospholipase A_2-γ in Complement-Mediated Glomerular Epithelial Cell Injury Hanan Elimam, Tomoko Takano, Joan Papillon, Andrey V. Cybulsky. *Nephrology, McGill University, Montreal, QC, Canada.*

Background: In experimental membranous nephropathy, complement C5b-9-induces glomerular epithelial cell (GEC) injury and proteinuria. The effects of C5b-9 are mediated via signaling pathways, including calcium-independent phospholipase A_2γ (iPLA$_2$γ), protein kinase C (PKC), and mitogen-activated protein kinases (MAPKs), that is extracellular signal-regulated kinase (ERK), c-Jun N-terminal kinase (JNK) and p38. The iPLA$_2$γ pathway is cytoprotective. The present study addresses the mechanisms of iPLA$_2$γ activation.

Methods: Cultured GEC were stably transfected with iPLA$_2$γ cDNA. GEC were incubated with antibody and normal serum (to assemble complement C5b-9) or heat-inactivated serum (control). To study MAPKs in iPLA$_2$γ activation, COS-1 cells were transfected with iPLA$_2$γ and cyclooxygenase-1 (COX-1). PLA$_2$γ activity was monitored by quantifying prostaglandin E_2 (PGE_2) production. Mutations in two putative ERK phosphorylation sites in iPLA$_2$γ (S168, S271A) were created by PCR-based mutagenesis.

Results: Complement-mediated production of PGE2 was amplified in GEC that overexpress iPLA2γ, compared with control cells, and the effect of iPLA2was blocked by the iPLA2γ inhibitor, bromoenol lactone (BEL). In GEC that overexpress iPLA2γ, complement-mediated PGE2 production was reduced significantly by depletion of PKC, as well as by chemical inhibitors of MAPK/ERK kinase-1 (MEK1) and p38, but not JNK. PKC activation did not, however, stimulate PGE2. In COS-1 cells that overexpress iPLA2γ and COX-1, PGE2 production and ERK activation were induced by expression of constitutively active MEK1 or by stimulation with epidermal growth factor (EGF)+ionomycin, and the effect of EGF+ionomycin was inhibited by BEL. Activation of S168A, S271A and S168A/S271A iPLA2γ mutants was comparable to the wild type enzyme.

Conclusions: Complement-mediated activation of iPLA$_2$γ is mediated via PKC and ERK. PKC is necessary, but is insufficient for iPLA$_2$γ activation. ERK is necessary and sufficient, but appears not to act directly on iPLA$_2$γ. Defining the mechanisms by which complement contributes to GEC injury and proteinuria will provide opportunities for development of novel therapeutic approaches.

Serum Albumin-Induced Podocyte Cox-2 Expression Is Inhibited by Glucocorticoids and MAPK Inhibitors Shipra Agrawal,[1] Adam J. Guess,[1] Ruma Pengal,[1] Rainer Benndorf,[1,2] William E. Smoyer.[1,2] *[1]Center for Clinical and Translational Research, Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Department of Pediatrics, Ohio State University, Columbus, OH.*

Background: Proteinuria is a hallmark of glomerular disease, the third leading cause of ESRD in the US. Proteinuria is also a known risk factor for progressive glomerular disease, and results in increased podocyte exposure to serum albumin (SA). Additionally, oxidized forms of SA have been found in patients with glomerular disease. Based on this, we analyzed the ability of SA and oxidized SA to induce Cox-2 in podocytes, and whether glucocorticoids (GC), thiazolidinediones (TZDs) or selected MAPK inhibitors could block this induction.

Methods: Cultured murine podocytes were treated with SA and oxidized SA at physiological concentrations and cell viability and Cox-2 expression were quantified. In addition, since GC, TZDs and MAPK inhibitors have all been reported to reduce both proteinuria and direct podocyte injury, we also analyzed their ability to regulate SA-induced Cox-2 expression.

Results: SA increased Cox-2 mRNA and protein expression in podocytes in a dose-dependent manner. Moreover, SA-induced Cox-2 expression was reduced by inhibitors of ERK1/2, p38 MAPK, and MK2, but not SAPK/JNK, although all of these were activated by SA exposure. In addition, GC, but not TZDs, inhibited SA-induced Cox-2 expression. Notably, treatment with oxidized SA led to a greater induction of Cox-2 protein than un-treated SA. Lastly, increasing doses of SA led to progressive reductions in podocyte viability.

Conclusions: Physiologic concentrations of SA induce podocyte Cox-2 expression, which can be inhibited by both GC and selected MAP inhibitors. Since GC and MAPK inhibitors are now known to directly protect podocytes against injury, our results suggest that Cox-2 may be a molecular mediator of SA-induced podocyte injury.

15-Deoxy-$D^{12,14}$-Prostaglandin J_2 Inhibits the Expression of Chemokines by Blocking NF-κB Nuclear Translocation Via PPARg-Independent Mechanism in Lipopolysaccharide-Stimulated Renal Tubular Epithelial Cells Ying Lu, Qiao Zhou, Fang Zhong, Xu Hao, Cong Li, Weiming Wang, Nan Chen. *Nephrology, Ruijin Hospital, Shanghai, China.*

Background: 15d-PGJ_2 is a high-affinity ligand for peroxisome proliferator-activated receptorg (PPARg), and has been suggested to exert anti-inflammatory effects in vivo. The aim of the study was to investigate the effect and mechanism of 15d-PGJ_2 on the expression of chemokines in Lipopolysaccharide–stimulated renal tubular epithelial cells.

Methods: Confluent renal tubular epithelial cells (HK-2 cells) were separated into four groups: control group, LPS-stimulated group, 15d-PGJ_2 alone group and 15d-PGJ_2-pre-treated LPS group. Chemokines including interleukin-8 (IL-8) and chemoattractant protein-1 (MCP-1) were determined by Real-time PCR and ELISA. The location of nuclear factor-κB (NF-κB) was detected by immunofluorescence analysis. The phosphorylated IκBα (p-IκBα) in cytoplasm and NF-κB in nucleus were analyzed by western blot. To evaluate the inhibitory effects of 15d-PGJ_2 were PPARg-dependent or independent, PPARg was knocked down by RNA interference (RNAi) .

Results: The results showed that, compared with the control group, IL-8 and MCP-1 were significantly increased at both transcription and post-transcription level in LPS-simulated group. Accordingly, p-IκBα in cytoplasm as well as NF-κB in nucleus was significantly increased in LPS-stimulated HK-2 cells compared with the control group. Pre-treatment HK-2 cells with 15d-PGJ2 abolished LPS-induced IL-8 and MCP-1 overproduction. Knockdown of PPARg by RNAi in HK-2 cells shows that 15d-PGJ2 also inhibited LPS-induced IL-8 and MCP-1 overexpression in these cells. And nuclear translocation of p65 and phosphorylation of IκBα induced by LPS were restored by 15d-PGJ2 in both HK-2 cells and PPARg-knockdown HK-2 cells.

Conclusions: In the study, we demonstrated that 15d-PGJ_2 could inhibit the expression of chemokines by blocking NF-κB translocation into nucleus via a PPARg-independent mechanism in LPS–stimulated renal tubular epithelial cells.

FR-PO1317

Regulation of Fatty Acid Oxidation Profoundly Affects Palmitic Acid Induced Podocyte Cell Death Kapil Dev Kampe,[1] Jonas Sieber,[1] Peter H. Mundel,[2] Andreas Werner Jehle.[1,3] *[1]Department of Biomedicine, Molecular Nephrology, University Hospital, Basel, Switzerland; [2]Division of Nephrology, Massachusetts General Hospital, Boston; [3]Department of Internal Medicine, Kantonsspital Bruderholz, University of Basel, Basel, Switzerland.*

Background: Diabetes mellitus type 2 is associated with altered lipid metabolism leading to elevated levels of free fatty acids (FFAs). Recently, we have reported the antagonistic effects of palmitic acid versus monounsaturated FFAs (MUFAs) on podocyte survival (Am J Physiol Renal Physiol. 2010 Oct;299(4):F821-9). The objectives of this study were to elucidate whether inhibition or stimulation of fatty acid oxidation (FAO) may affect palmitic acid induced podocyte cell death.

Methods: Conditionally immortalized murine podocytes were differentiated for at least 11 days and palmitic acid or oleic acid were complexed to BSA. Apoptosis and necrosis

were quantified by annexin V and propidium iodide labeling. We used etomoxir, a carnitine-palmitoyltransferase 1 (CPT1) inhibitor, to reduce FAO. Contrariwise, 5-aminoimidazole-4-carboxamide ribonucleoside (AICAR) was used to stimulate FAO. Levels of pAMPK, pACC, AMPK and ACC were measured by immunoblotting. We used tritiated palmitic acid and measured tritiated water to assess oxidation of palmitic acid.

Results: Etomoxir (10-200μM) dose-dependently increases palmitic acid induced cell death up to 200%. Contrariwise, we show that AICAR significantly decreases palmitic acid induced apoptosis and necrosis by 49.5±1.5%, (p=0.004), and 55.7±4.0% (p=0.01) respectively. AICAR upregulated the phosphorylation of both AMPK and ACC. Functionally, AICAR significantly increases oxidation of palmitic acid by 124.0±4.9% (p<0.001) as assessed by the metabolism of tritiated palmitic acid. Similarly, oleic acid increases oxidation of palmitic acid by 51.3±9.6% (p=0.001).

Conclusions: Our results unveil that the regulation of FAO via the AMPK-ACC-CPT1 pathway profoundly affects palmitic acid induced podocyte cell death. Although oleic acid significantly increases FAO of palmitic acid this effect can only partially explain the protective effect of MUFAs for palmitic acid induced podocyte cell death.

FR-PO1318

DNase I Induces Other Endonucleases, DNA Damage and Apoptosis Pathways in Kidney Tubular Epithelial Cells by Its DNA Cleavage Activity Tariq Fahmi,[1] Xiaoying Wang,[1] Eugene Apostolov,[1] Alexei G. Basnakian.[1,2] *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]Central Arkansas Veterans Healthcare System, Little Rock, AR.*

Background: Every mammalian cell has cytotoxic endonucleases which degrade host DNA prior and after cell death. The endonucleases have similar mode of action and often simultaneously induced to cleave DNA after cell injury. The mechanism for the simultaneous induction of endonucleases is unknown. Induction of DNase I, the most active kidney endonuclease, has been observed in kidney ischemia-reperfusion (IR), and its inactivation was protective against toxic or ischemic kidney injuries suggesting that DNase I is responsible for kidney cell death. We hypothesized that DNase I may be a universal regulator of other endonucleases, as well as some apoptosis and DNA damage pathways.

Methods: To test this, rat kidney tubular epithelial NRK52E cells were transfected with rat DNase I gene or its inactive mutant in pECFP expression vector for 6, 12 and 24 hrs, while control cells were transfected with "empty" pECFP. DNase I-CFP expression was monitored by fluorescence. RNA was analyzed for all known cytotoxic endonucleases and ~200 markers of DNA damage and apoptosis pathways using real-time RT-PCR.

Results: The measurements showed certain endonucleases, DNA damage and apoptosis pathways were induced by active DNase I, including: (1) several cytotoxic endonucleases except DNase II, with the maximal effect for DNase gamma and DNase X; (2) beta-actin, the only known endogenous inhibitor of DNase I; (3) Fas, previously described being transcriptionally regulated by DNase I, and its inhibitor FAIM; (4) caspases 3, 7, 8 and 12; (5) DNA polymerase beta (indicative of single-stranded DNA breaks); (6) p53 and Tp53bp2 (likely a result of DNA damage); and (7) Apaf 1 (likely a result of p53 activation). Immunohistochemical analysis of rat kidneys subjected to IR injury showed that DNase I and some of these markers are induced at 16 hrs after ischemia.

Conclusions: These results suggest for the first time that DNase I activity may induce other endonucleases and several key regulators of DNA damage and apoptosis pathways during kidney injury.

FR-PO1319

Ethanol Causes Oxidative Stress, Alters Actin Cytoskeleton and Decreases Expression of Cytochrome P450 Isoforms in Murine Podocytes Ellen T. McCarthy,[1] Jianping Zhou,[2] Ryan G. Eckert,[1] Shuhua Wang,[1] Tarak Srivastava,[3] Ram Sharma,[2] Mukut Sharma.[2] *[1]University of Kansas Medical Center, Kansas City, KS; [2]Kansas City VA Medical Center, Kansas City, MO; [3]Children's Mercy Hospital, Kansas City, MO.*

Background: The contribution of ethanol (EtOH) to progression of chronic kidney disease is controversial, although EtOH is associated with hypertension. Effects of EtOH on podocytes are unknown. We have shown that EtOH alters podocyte expression of cytochrome P450 (CYP450) isoforms involved in 20-hydroxyeicosatetraenoic acid (20-HETE) synthesis and that 20-HETE is protective in several models. We hypothesized that EtOH causes oxidative stress and alters podocyte structure and that 20-HETE provides protection from injury.

Methods: Immortalized podocytes were incubated with EtOH (1 to 20 μL/mL) for 1 to 24 hr. These concentrations correspond to blood alcohol levels seen in humans. We examined podocyte superoxide generation using the fluorescent probe hydroethidine (HE), visualized podocyte actin cytoskeleton using confocal microscopy and measured expression of CYP4a12a and CYP4a12b using quantitative RT-PCR. 20-HETE (100 nM) was included in the incubation medium in some groups.

Results: Incubation with EtOH increased superoxide levels, indicated by increased HE fluorescence. Furthermore, EtOH caused disruption of actin filaments. These effects were dose- and time-dependent. Inclusion of 20-HETE abrogated the increase in superoxide and prevented actin cytoskeletal disruption. EtOH (20 μl/ml) decreased expression of CYP4a12a and CYP4a12b at 24 hr (P<0.02 and P<0.001 vs control, respectively) while lower concentrations increased the expression of these isoforms.

Conclusions: EtOH in meaningful concentrations increased oxidative stress and altered actin cytoskeleton in podocytes, effects reversed by 20-HETE. We posit that excessive EtOH consumption may alter glomerular structure and function by mechanisms that include increased oxidative stress and decreased synthesis of protective eicosanoids. Such changes may exacerbate underlying glomerular pathological conditions and contribute to progressive renal injury. In contrast, moderate EtOH intake may provide protection by increasing 20-HETE.

FR-PO1320

Role of Podocytes´ Collagen Receptors in Renal Fibrosis of COL4A3 Knockout Mice Diana Rubel, Rainer Girgert, Gerhard A. Mueller, Oliver Gross. *Dep. of Nephrology and Rheumatology, University Medicine Goettingen, Goettingen, Germany.*

Background: Podocytes sense the composition of glomerular basement membrane by collagen receptors such as DDR1 (discoidin domain receptor 1) and ITGA2 (Integrin α2). Therefore, collagen receptors might play an important role in maintenance normal composition of the glomerular basement membrane and in type IV collagen diseases such as Alport syndrome. In the present study, we compared renal signaling of DDR1/ITGA2 and COL4A3 (Alport) knockout mice with wildtype controls.

Methods: Phosphorylation of Akt/PKB and STAT1 was analyzed by Western Blotting. Quantification of protein bands was carried out by ImageJ and the ratio of phosphorylated to unphosphorylated protein was calculated. Matrix accumulation and fibrosis was analyzed by immuno-histochemistry.

Results: Kidney lysates of wildtype mice showed an age-dependent (50d, 100d, 150d) increase of phosphorylated Akt/PKB. Even the lowest level of activated Akt in 50 d wildtype mice was higher than in COL4A3 knockouts of any age. Mice without ITGA2- and DDR1-expression exhibited the same expression profile, but have a higher level of phosphorylated Akt (paralleled by less matrix accumulation) compared to COL4A3 knockout mice. Phosphorylated STAT1 also increases with age in wildtype mice. In contrast to Akt/PKB, activation of STAT1 is at its maximum at 4.5 weeks of age and slightly decreases until week 9 in COL4A3 knockout mice. The fraction of phosphorylated STAT1 in Alport mice is lower than in wildtype mice.

Conclusions: Akt1 is involved in cellular survival pathways. Therefore, decreased activation of STAT1 by the DDR1 pathway in mutant mice indicates a role of DDR1 in podocyte injury during renal fibrosis. A lower activation of ITGA2 pathway in COL4A3 knockout mice results in decreased levels of phosphorylated STAT1 causing less cdc42 activity and decreased actin polymerization. Further studies will focus on the role of actin polymerization in the various genotypes, downstream signaling pathways and the cross-talk of ITGA2/DDR1-signaling in podocytes.

FR-PO1321

Expression of NIPP1 in AGE-BSA Treated Podocytes Marita Liebisch, Gunter B. Wolf. *Internal Medicine III, University of Jena, Jena, Germany.*

Background: Patients with diabetes mellitus have increased level of advanced glycation end products (AGEs) accumulating in different tissues including the kidney. The formation of AGEs causes in molecular dysfunctions of molecules and is finally followed by organ damage leading to podocyte damage, a typical feature of diabetic nephropathy.

The nuclear inhibitor of PP1 (NIPP1) inhibits the phosphatase activity of PP1, which is involved in the regulation of numerous cellular processes such as intracellular transport or metabolism. Moreover, NIPP1 is important in spliceosome assembly and pre-mRNA splicing. By performing differential display analysis we have recently found out that NIPP1 gene expression was differentially regulated in Co-BSA and AGE-BSA treated differentiated podocytes. The aim of this study was to address the NIPP1 expression in podocytes.

Methods: The NIPP1 mRNA expression in cultured differentiated podocytes was analyzed by Real Time PCR, the protein concentration in corresponding samples by Western Blot analyses and immunofluorescence staining. In addition, it was analyzed whether the reduced NIPP1 expression correlates with changes in cell cycle or cell proliferation.

Results: Real Time PCR and Western Blot analyses exhibited a significantly reduced NIPP1 expression in AGE-BSA treated podocytes compared with Co-BSA treated cells. Immunofluorescence showed a NIPP1 translocation from the cytoplasma to the nucleus compared to the control cells. NIPP1 siRNA transfection of podocytes reduced NIPP1 expression in podocytes and induced p27Kip1 a cell-cycle inhibitor, previously shown to be induced by AGE-Bsa in podocytes. Moreover, Podocytes revealed a lesser proliferation rate when NIPP1 expression is reduced either by AGE-BSA or NIPP1 siRNA.

Conclusions: AGE-BSA treated podocytes demonstrated a reduced NIPP1 expression compared to control cells. This decreased NIPP1 expression may explain several pathophysiological alterations of podocytes in diabetic nephropathy such as hypertrophy, cell-cycle arrest, and apoptosis.

Role of Connective Tissue Growth Factor in High Glucose-Induced Epithelial-Mesenchymal Transition of Podocytes Hou-Yong Dai, Rining Tang, Min Zheng, Jie Ni, Linli Lv, Kun Ling Ma, Bi-Cheng Liu. *Institute of Nephrology, Zhongda Hospital, Southeast University School of Medicine, Nanjing, Jiangsu Province, China.*

Background: Our previous studies demonstrated that connective tissue growth factor (CTGF) plays an important role in the early kidney hypertrophy and fibrosis of diabetic nephropathy, while the potential mechanism is still unclear. This study was to investigate the role of CTGF in high glucose-induced epithelial–mesenchymal transition in podocytes.

Methods: The differentiated podocytes cultured under different conditions for 24 hours at 37°C were divided into four groups as follows: Control (5 mM GS), 5 mM

GS supplemented with 50 ng/ml CTGF, high glucose (30 mM GS) and high glucose supplemented with CTGF(50 ng/ml). The morphology of cultured podocytes was performed by phase contrast microscopy. To study the relative marker of epithelial–mesenchymal transition (EMT), the mRNA and protein expression were analyzed by real-time RT-PCR and western blotting, respectively. In addition, the effect of inhibition CTGF with anti-CTGF antibody on high glucose-induced EMT of podocytes was investigated.

Results: High glucose induced phenotypic transition of podocytes from an arborized morphology to a cobblestone morphology. After addition of CTGF to high glucose, podocytes developed a feature of spindle. In high glucose conditions, podocytes underwent EMT, demonstrating that the epithelial marker of nephrin was decreased, in contrast, the mesenchymal marker of desmin was increased. Of note, exogenous CTGF in synergy with high glucose promoted EMT, moreover, high glucose-induced EMT of podocytes was prevented by CTGF inhibition with anti-CTGF antibody.

Conclusions: This study demonstrated that CTGF was involved in high glucose-induced EMT of podocytes, which suggested inhibition of CTGF might be a potential target for prevention of diabetic nephropathy.

FR-PO1323

Connective Tissue Growth Factor Binds to Epidermal Growth Factor Receptor To Modulate Renal Inflammation Sandra Rayego-Mateos,[1] Raquel Rodrigues-Diez,[1] Raúl R. Rodrigues Díez,[1] Carolina Lavoz,[1] Janos Pato,[2] Gyorgy Keri,[2] Alberto Ortiz,[3] Jesus Egido,[3] Marta Ruiz-Ortega.[1] *[1]Nephrology, Universidad Autónoma, Madrid, Spain; [2]Vichem Chemie Ltd., Budapest, Hungary; [3]ISCFJD-UAM, Madrid, Spain.*

Background: Connective tissue growth factor (CTGF) has suggested as a risk marker for chronic kidney diseases. CTGF inhibition ameliorates experimental renal damage. Some authors hypothesize that CTGF is an antifibrotic therapeutic target, but is important first to understand its renal effects and molecular effectors. In vivo, CTGF induces renal recruitment of inflammatory cells via upregulation of cytokines and chemokines. There is no described a known specific CTGF receptor. Our aim was to investigate whether CTGF interact with epidermal growth factor receptor (EGFR) in the kidney, evaluating the signalling pathways and cellular responses.

Methods: Systemic administration of CTGF (2.5ng/g BW) to mice was done, a group was also treated with the EGFR kinase inhibitor Erlotinib (40mg/Kg). In vitro studies were done in tubular epithelial cells.

Results: In vivo, CTGF caused EGFR phosphorylation in the kidney, mainly located in tubuloepithelial cells. Treatment with Erlotinib inhibited CTGF-induced renal changes observed at 24 hours, including ERK activation (a downstream EGFR signalling), up-regulation of proinflammatory factors and interstitial inflammatory cell infiltration. In cultured tubular epithelial cells, CTGF increased EGFR phosphorylation. This process was not due to EGFR transactivation, as shown by the lack of effect of matrix metalloproteases inhibitors (GM6001 and TAPI-2). Direct binding was demonstrated by cross-linking and immunoprecipitation studies, that leads to CTGF-EGFR heterodimers formation. EGFR activation is regulated by integrins, as shown by different approaches: RGD peptides, neutralizing antibody and RNA silencer of αV and β3 integrin. Moreover, erlotinib inhibited CTGF-induced proinflammatory mediators and ERK activation in tubular cells.

Conclusions: Our results suggest that CTGF directly binds to EGFR and activates its signalling pathway, leading to modulation of downstream mechanisms, such as ERK activation, and cellular responses, including renal inflammation.

In Vivo Manipulation of Glutathione S-Transferase A4 Prevents 4-hydroxynonenal-Induced Renal Tubular Cell Damage Anlin Liang, Yun Wang, Lauren Elizabeth Woodard, Matthew H. Wilson, Jie Du, William E. Mitch, Jizhong Cheng. *Nephrology Division, Baylor College of Medicine, Houston, TX.*

Background: Lipid peroxidation yields toxic products that can damage cell membranes, including aldehyde 4-hydroxynonenal (4-HNE). Since glutathione S-transferase, GSTA4, can eliminate 4-HNE, we studied a mouse model of unilateral ureteral obstruction (UUO) to determine if changing GSTA4 expression influences UUUO-induced fibrosis.

Methods: Hydrodynamic injection or an inducible, piggyBac transposon gene delivery system were used to study if GSTA4 protects against tubule cell damage and fibrosis in mice with UUO or after release of UUO (RUUO). WT and GSTA4 KO mice were studied.

Results: At 3 days of UUO, 4-HNE and its protein adducts increased while GSTA4 decreased. UUO in GSTA4 KO mice increased the interstitial expression of fibroblast markers (SMA-α, FSP-1 and TGF-β) vs results in WT mice. Tubular cell damage was also more severe vs results in WT mice. To raise GSTA4 activity, we hydrodynamically injected GSTA4 into the renal vein. This reduced 4-HNE levels and the interstitial fibrosis studied by UUO. To determine if long-term activation of GSTA4 would restore the tubule architectures damaged by UUO, we studied mice bearing an inducible GSTA4 expression accomplished using a PiggyBac transponson system. In these mice GSTA4 was expressed in response to doxycyline. After 3 days of UUO, we released UUO (i.e., RUUO) and 3 weeks later, we found GSTA4 was overexpressed. This decreased SMA-α and collagen I staining in the interstitium.

Om GSTA4 KO mice, UUO increased autophagy in tubule cells. In NRK52E cells, GSTA4 overexpression blocked 4-HNE-induced expression of LC3-II, consistent with reduced autophagy. GSTA4 expression also inhibited 4-HNE-mediated tubule cell damage with downregulation of Occludin and E-cadherin. The mechanism involved an UUO-induced increase in the Snail transcription factor plus GSK-3β phosphorylation. These responses were blocked by GSTA4 overexpression.

Conclusions: Thus, the UUO-induced fibrosis and tubule cell damage involves 4-HNE and is blocked by GSTA4.

Cdc42-Interacting-Protein-4 Promotes the Translocation of β-catenin to Nucleus in TGF-β1- Induced Renal Tubular Epithelial-to-Mesenchymal Transdifferentiation Chuou Xu, Qiaodan Zhou, Rui Zeng, Lily Liu, Gang Xu. *Division of Nephrology, Department of Internal Medicine, Tongji Hospital Medical College, HUST, Wuhan, Hubei, China.*

Background: Epithelial-to-mesenchymal transdifferentiation (EMT) in kidney is the transition of tubular epithelial cells into myofibroblasts, it is considered as one of the most important events underlying chronic renal diseases. During the process of EMT, epithelial cells lose the expression of E-cadherin. Snail family members are E-cadherin transcriptional repressors which have been implicated in promoting EMT. Evidence demonstrates that translocation and accumulation of β-catenin in the nucleus lead to enhanced binding to members of the T cell factor (TCF) family and lymphoid enhancer factor (LEF) family, in turn, β-catenin/TCF/LEF complexes activate target genes such as Snail family. Thus, it is essential to investigate what effects translocation of β-catenin to nucleus. Cdc42-interacting protein 4 (CIP4), a Cdc42 effector protein involved in cytoskeletal organization and actin polymerization, is suggested to associated with β-catenin and paly a role in EMT. We investigated this potential role of CIP4 in TGF-β1-induced renal tubular EMT.

Methods: Expression,interaction and colocalization of proteins were detedced by western blotting,immunoprecipitation and confocal iamging respectively.

Results: Expression of CIP4 was upregulated in rat proximal tubule cell line (NRK52E) stimulated by TGF-β1 accompanied by reduced expression of E-cadherin and increased expression of mesenchymal marker α-SMA. The interaction between CIP4 and β-catenin was detected by immunoprecipitation, CIP4 colocalized with β-catenin in cell membrane/cell nucleus before/after TGF-β1 stimulation by confocal images. In normal condition, overexpression of CIP4 promoted translocation of β-catenin to nucleus accompanied by the reduced expression of E-cadherin. Furthermore, to knockdown CIP4 by using siRNA, we found that β-catenin translocated to nucleus was decreased, expression of E-cadherin was reversed.

Conclusions: In conclusion, CIP4 promotes translocation and accumulation of β-catenin to nucleus in TGF-β1-induced renal tubular EMT ,which is accompanied by reduced expression of E-cadherin.

Mechanisms of Proteinuria Induced by Rho A GTPases Liming Wang,[1] Matthew Jay Ellis,[1] David Howell,[2] Robert F. Spurney.[1] *[1]Department of Medicine, Duke University and Durham VA Medical Centers, Durham, NC; [2]Department of Pathology, Duke University and Durham VA Medical Centers, Durham, NC.*

Background: Podocytes play a pivotal role in maintaining the integrity of the glomerular filtration barrier. A growing literature suggests that this function is regulated by small GTPases belonging to the Rho GTPase family.

Methods: A constitutively active Rho A (V14Rho) or a dominant negative Rho A (N19Rho) were introduced into cultured podocytes using protein transduction by tagging the proteins with the TAT human immunodeficiency virus (HIV) protein sequence [V14Rho(+) or N19Rho(+)]. Cell impermeable proteins lacking the TAT sequence were used as controls [V14Rho(-) or N19Rho(-)]. To investigate the role of Rho A in podocyte biology in vivo, we created transgenic (TG) mice that expressed either V14Rho or N19Rho specifically in podocytes using a doxycycline inducible strategy.

Results: V14Rho(+) enhanced both stress fiber formation and podocyte apoptosis, and the apoptotic effect was blocked by the Rho kinase inhibitor Y27632. In contrast, N19Rho(+) had no significant effect on podocyte apoptosis but decreased stress fiber formation and promoted the formation of monomeric actin (G actin). In TG mice, induction of either V14Rho or N19Rho caused a significant increase in albuminuria and foot process effacement. The mechanisms of these adverse effects, however, appeared to be different. Induction of V14Rho caused a reduction in expression of nephrin at both the mRNA and protein levels without affecting expression of the actin-associated, cytoskeletal protein synaptopodin. In contrast, induction of N19Rho had no effect on nephrin mRNA or protein levels but decreased synaptopodin expression.

Conclusions: These data suggest that basal Rho A activity has beneficial effects in podocytes, perhaps by stabilizing the glomerular architecture. In contrast, high levels of Rho A activity also promote podocyte injury by mechanisms that appear to be different from the mechanisms that alter glomerular filtration barrier function following Rho A inhibition.

Complete Differentiation of Rab3A-KO Podocytes Induced by GABAA-R Agonists Silvia Armelloni, Min Li, Laura Giardino, Alessandro Corbelli, Masami Ikehata, Deborah Mattinzoli, Piergiorgio Messa, Maria Pia Rastaldi. *Renal Research Laboratory, Fondazione IRCCS Policlinico & Fondazione D'Amico, Milan, Italy.*

Background: We have previously shown that Rab3A-KO mice have spontaneous macroalbuminuria with podocyte cytoskeletal changes and decreased expression of specific molecules. Aim of this study was the identification of intracellular pathways possibly linking Rab3A absence to podocyte damage.

Methods: RealTime-RTPCR-arrays were used to quantify differential gene expression. Cell proliferation was evaluated by FACS analysis of BrdU incorporation and by "FUCCI assay", based on cell transfection of Cdt1 and geminin, fused to fluorescent markers. Activation of the MAPKinase pathway, and expression of GABA Receptors and cytoskeletal molecules were investigated by Western Blot and immunostaining.

Results: Rab3A-KO podocytes showed increased mRNA expression of Ntrk2, Fgf2, Tro, NpY, and NpYr1 and a decreased expression of Nrg1 than WT cells. All overexpressed molecules are involved in proliferation and maturation of neuronal precursors and act by activating the MAPKinase pathway. Nrg1 instead regulates neuronal differentiation and synapse development.

FACS analysis showed increased BrdU incorporation in KO podocytes and the FUCCI method detected more KO than WT cells in the G2 phase of the cell cycle.

KO cells also displayed higher p-MAPK/MAPK ratio than WT podocytes.

Further, mRNA and protein of GABAA-Receptors (GABAA-R) were higher in KO than WT podocytes. Incubation of KO-cells with GABAA-R antagonists induced further p-MAPK increase, while incubation with a GABAA-R agonist, not with a GABAB-R agonist, caused p-MAPK reduction, increased the expression of the cytoskeletal molecules Arg and synaptopodin, and improved alpha-actinin-4 distribution.

Conclusions: Our results show that Rab3A null podocytes are less differentiated and, as it occurs in neuronal cells, a series of early genes induce proliferation through activation of the ERK/MAPK pathway.

Our data also show the potential involvement of GABAA-Receptors in these processes; ionotropic GABAA-R activity decreases MAPK activity and can be modulated by specific agonists, which improve cell differentiation by cytoskeletal regulation.

Gα12 Activation Leads to Upregulation of IL-8 (CXCL-8) Ilene Boucher,[1,2,3] Wanfeng Yu,[2,3] Tianqing Kong,[1,3] Bradley M. Denker.[1,2,3] *[1]Medicine, Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Medicine, Renal DIvision, Beth Israel Deaconess Hospital, Boston, MA; [3]Harvard University Medical School, Boston, MA.*

Background: Injury activates numerous signaling pathways, several of which can stimulate GPCRs. Angiotensin II, LPA, and thrombin receptors couple to Gα12 (Gα12/Gα13 is one of four Gα families) and are activated with injury. Gα12 can be activated by reactive oxygen species (ROS) and regulates cell junctions, migration, proliferation and apoptosis. Preliminary in vivo studies suggest an important role for Gα12 in the renal response to ischemia/reperfusion injury (IRI), but the mechanisms are unknown. Inflammation mediated by secreted cytokines such as IL-6, IL-8 are important components of the injury response, but a role for Gα12 regulating inflammation with injury has not been identified.

Methods: To determine if Gα12 regulates inflammatory cytokines, previously characterized tet-off inducible (-dox) MDCK cells expressing constitutively active Gα12 (Q229L; QLα12) were analyzed in triplicate using Affymetrix microarrays and compared with non-induced cells (+dox). Cell supernatants were analyzed in triplicate for IL-8 secretion by ELISA.

Results: Relative message levels for the IL-6 and IL-8 showed no significant change (defined as 2-fold with $p<0.05$), but IL-8 was significantly upregulated (34 fold). We confirmed increased IL-8 secretion by ELISA. There was 1020± 155 pg/mL of baseline IL-8 secreted in the controls (+dox) and with QLα12 expression (-dox) the amount increased 5-fold to 5820±167pg/mL.

Conclusions: Preliminary studies with IRI in Gα12-/- mice reveal a less severe injury phenotype and studies are in progress to quantify the inflammatory response and determine if the putative IL-8 orthologue (CXCL-15) is inhibited with injury. Taken together, we hypothesize that Gα12-stimulated cytokines may be a novel therapeutic target to prevent inflammation in acute kidney injury.

The Role of Rho Kinase in the Regulation of K-Cadherin Expression in Tubule Epithelial Cells Nileshkumar Shah,[1] Iain Macphee,[2] Mysore Keshavmurthy Phanish,[1] Mark Edward Dockrell.[1] *[1]SWT Institute for Renal Research, London, United Kingdom; [2]St George's University of London, London, United Kingdom.*

Background: Regulation of cadherin expression if of critical importance for maintaining cell contact and epithelial integrity but it can also regulate various signaling cascades important in determining cell proliferation and phenotype. In the kidney TGFβ1-mediated reduction in E-cadherin (Cdh1) is associated with epithelial mesenchymal transition. However, our group demonstrated that unlike rodent models K-cadherin (Cdh6) is expressed in human proximal tubule, not Cdh1, and that diabetic nephropathy is associated with its loss. Hence, we have investigates the regulation of Cdh6 by TGFβ1 in human proximal tubule epithelial cells (PTEC).

Methods: Human primary PTEC were grown in supplemented media; 0.25% serum: experiments were carried out at passage 3. Cadherin expression was monitored by Western Blotting and qPCR. Cells were grown to 75% confluence and treated with TGFβ1 1.25-5.0 ng/ml for 1-48 h.

Results: Previously our group and others have demonstrated that TGFβ1 causes a rapid and sustained reduction in Cdh1 expression at concentrations as low as 1 ng/ml. In primary human PTEC TGFβ1 only caused a significant reduction in Cdh6 mRNA at 5 ng/ml; this reduction was rapid but transient returning to control levels by 24h. TGFβ1-induced reduction in Cdh6 protein also required 5ng/ml but was only statistically significant at 48h. We subsequently investigated the signaling cascades underlying this reduction in protein. Previously we have published that complete abrogation of TGFβ1-induced reduction in Cdh1 required knock-down of Smads2 & 3; however the k/d of Smad2, Smad3 or both, by RNAi did not change the affect of TGFβ1 on Cdh6. We also investigated the affect of inhibiting a range of kinases, including Alk5, Erk1/2, p38, Jnk, PI3-kinase and Rho kinase (Rock). Only inhibition of the TGFβ type1 receptor, Alk5 and Rock limited the effect of TGFβ on Cdh6 expression.

Conclusions: We conclude that the regulation of Cdh6 (K-cadherin), the native cadherin of the human proximal tubule, is more resistant to TGFβ1 than Cdh1 (E-cadherin) and occurs through distinct mechanisms.

Endothelin(ET)-1, Via ET_AR, Activates β-Arrestin-Mediated Signaling Pathways and Promotes Podocyte Migration: Implications for Proliferative Lesions in Chronic Kidney Disease Simona Buelli,[1] Elena Gagliardini,[1] Laura Rosano,[2] Anna Pezzotta,[1] Anna Bagnato,[2] Giuseppe Remuzzi,[1,3] Ariela Benigni.[1] *[1]Mario Negri Institute, Bergamo, Italy; [2]Regina Elena National Cancer Institute, Roma, Italy; [3]Ospedali Riuniti, Bergamo, Italy.*

Background: Podocytes acquire a migratory phenotype and form bridges named synechiae between the glomerular tuft and the Bowman's capsule, contributing to hyperplastic lesion formation in crescentic glomerulonephritis and podocytopathies (JASN 20:2593,2009). The stimulus enabling podocyte migration is unknown. Previous evidence showed a role of ET-1 in podocyte cytoskeletal rearrangement in vitro (Am J Pathol 169:1965,2006) and podocyte loss in experimental diabetes (Am J Physiol Renal 297:F1448,2009). Cancer cell invasiveness is driven by ET-1-mediated recruitment of β-arrestin -a signal transducer and adapter protein of G protein coupled receptors- to ET_AR resulting in β-catenin signaling activation, essential for motility (PNAS 106:2806,2009). Here we study if this mechanism operates in proliferative kidney disorders, and whether ET-1 triggers podocyte migration via β-arrestin-mediated signaling.

Methods: Migration of differentiated mouse podocytes and β-arrestin signaling pathway were assessed by wound healing assay and immunoprecipitation/immunoblotting.

Results: ET-1 (100nM) promotes podocyte migration via ETAR as selective antagonist BQ123 significantly prevents cell motility. ET-1 upregulates podocyte constitutive expression of β-arrestin mRNA and protein and induces the formation of ETAR/β-arrestin/Src signaling complex. By inducing Src activation, ET-1 promotes EGFR transactivation and Akt phosphorylation associated with active β-catenin accumulated in the cytoplasm, events preceding transcription of pro-migratory genes. Mice with adriamycin-induced nephropathy unexpectedly exhibit glomerular synechiae and few crescents at 4wk. Podocytes forming synechiae express high β-arrestin-1 levels.

Conclusions: These results indicate that, as in cancer cells, ET-1 promotes podocyte migration and activates ET_AR/β-arrestin/β-catenin pathways providing new clues for therapies based on ET receptor antagonists in podocytopathies associated with crescentic lesions.

Characterization of a β_2 Adrenoceptor Pharmacophore That Predicts Mitochondrial Biogenesis Lauren P. Wills, Richard Trager, Christopher C. Lindsey, Yuri K. Peterson, Craig Cano Beeson, Rick G. Schnellmann. *Pharmaceutical and Biomedical Sciences, Medical University of South Carolina, Charleston, SC.*

Background: The renal tubular epithelia have capacity for repair and regeneration after insults, which can be improved by compounds that promote mitochondrial biogenesis.

Methods: To examine the impact of the β-adrenergic signaling pathway on mitochondrial biogenesis, primary renal proximal tubule cells (RPTC) and adult feline cardiomyocytes (AFC) were exposed for 24 hr to multiple β-adrenoceptor (β-AR) agonists: isoproterenol (non-selective β-AR agonist), BRL 37344 (selective β_3-AR agonist), and formoterol (selective β_2-AR agonist). The Seahorse Biosciences analyzer was used to quantify FCCP-uncoupled oxygen consumption rate (OCR), a marker of maximal electron transport chain activity and mitochondrial biogenesis.

Results: Isoproterenol and BRL 37244 did not alter mitochondrial respiration at any of the concentrations examined (10-1000 nM). Formoterol exposure (30 nM) resulted in increased FCCP-uncoupled OCR and mitochondrial DNA (mtDNA) copy number. The effect of formoterol on OCR in RPTC was inhibited by the β2-AR antagonist propanolol. To examine the effects in vivo, C57BL/6 mice were exposed to 100 μg/kg of formoterol for 24 or 72 hr. Formoterol exposure increased kidney and heart mtDNA copy number, induced the mitochondrial regulator PGC-1α (peroxisome proliferator-activated receptor gamma coactivator 1-α), and induced multiple genes coding for electron transport chain

proteins (ATP6, ATP synthase β, COX1 and ND6). Pharmacophore evaluation of formoterol identified two chemically similar compounds from the Sigma Library of Pharmacologically Active Compounds (tomoxetine and nisoxetine), and two from the ChemBridge DIVERSet that caused significant increases in mitochondrial respiratory capacity.

Conclusions: These data have been utilized to develop a discrete pharmacophore model capable of predicting novel compounds with mitochondrial biogenic properties. This project was funded through grant number: GM084147.

FR-PO1332

A Role for PI3-kinase in Regulating the EMT-Antagonist Protein, SARA

Constance Runyan, H. William Schnaper. *Pediatrics, Northwestern University, Chicago, IL.*

Background: TGF-β1 promotes renal fibrosis, in part by promoting epithelial to mesenchymal transition (EMT). We have previously shown that the Smad anchor for receptor activation (SARA) helps maintain an epithelial cell phenotype, and that reduction of SARA by TGF-β1 or other means stimulates events associated with EMT. Investigation of signaling pathways that might regulate SARA expression demonstrated a role for PI3-kinase signaling, as evidenced by the fact that, like TGF-β1, the PI3-kinase inhibitor LY294002, caused a reduction in SARA expression and a concomitant increase in the expression of the EMT marker αSMA. However, our data suggested that the mechanism by which PI3-kinase inhibition depletes SARA differs from the mechanism that results from prolonged TGF-β1 treatment.

Methods: Standard protein, transfection, qPCR, and immunocytochemical techniques were employed.

Results: To confirm the effects of chemical PI3-kinase inhibition, we established an HKC proximal tubule cell line that stably expresses an shRNA for the p85α-regulatory subunit of PI3-kinase. The activity of Akt, a downstream target of PI3-kinase, is inhibited by LY294002, but was enhanced in p85α knock-down cells. However, knock-down cells still have depleted SARA expression and increased αSMA expression. These data suggest that maintenance of SARA expression likely is mediated by PI3-kinase but independent of pAkt. It is known that SARA associates with early endosomal subcellular compartments. While, LY294002 treatment did not interfere with SARA localization, it did cause alterations in endosome size and number. Potassium depletion, used to block internalization to the early endosome, inhibited the LY294002-induced SARA depletion. Further, co-immunoprecipitation studies demonstrated a SARA-p85α interaction that was reduced by LY294002 under control conditions, but was enhanced under conditions of inhibited internalization.

Conclusions: Our data therefore suggest that SARA is protected from degradation via its interaction with PI3-kinase at the cell membrane, but that the separation of this complex upon internalization to altered endosomal compartments leads to reduced SARA expression.

FR-PO1333

PI3K, but Not Smad3, Is Required for Normoxic Induction of HIF-1αexpression by TGF-β

Susan C. Hubchak, H. William Schnaper. *Pediatrics, Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: The transforming growth factor (TGF)-β pathway, acting through the Smad signaling proteins, has been shown to interact with hypoxia-inducible factor (HIF)-1α in models of hypoxic kidney injury. Previously, we showed that TGF-β1 increases HIF-1α transcriptional activity and protein expression in a human proximal tubule cell (HKC) line under normoxia (21% O_2) in a receptor-dependent manner. Blockade of the Smad3 signaling pathway with the dominant-negative Smad3A construct reduced normoxic TGF-β1-stimulated HIF-1α transcriptional activity. Interestingly, a dominant-negative HIF-1α construct reduced normoxic basal and TGF-β1-stimulated Smad3 transcriptional activity, including the activation of the COL1A2 gene promoter. However it was not clear from these studies if Smad3 was required for normoxic induction of HIF-1α expression by TGF-β1 or if phosphoinositide-3 kinase (PI3K), a mediator of Smad3-independent TGF-β effects, might play a role.

Methods: Smad3 wild type (wt) and null mouse embryo fibroblasts (MEF) were stimulated with 1 ng/ml TGF-β1 for 6 hrs in 21% O_2-5%CO_2 before harvest for Western analysis. In select experiments, Smad3 null MEF were pretreated with 20 μM of the PI3K inhibitor LY294002 (LY) before stimulation with 1 ng/ml TGF-β1 and Western analysis.

Results: Smad3-wt MEF treated with TGF-β1 exhibited a 6.8 ± 3.3-fold increase in HIF-1α protein expression over vehicle treated cells. Although levels were reduced, HIF-1α was still expressed in Smad3-null MEF and TGF-β1 stimulated a 1.9 ± 0.6-fold increase. In Smad3-null MEF, LY reduced normoxic basal HIF-1α protein levels and abrogated TGF-β1-stimulated HIF-1α expression. Thus, TGF-β-stimulated HIF-1α expression was enhanced by, but not dependent upon, Smad3.

Conclusions: Together, our data suggest that PI3K mediates normoxic TGF-β-stimulated HIF-1α expression in a Smad3-independent manner, and raise the possibility that PI3K/HIF-1α and TGF-β/Smad3 participate in parallel pathways to promote fibrogenesis in normoxia or hypoxia.

Mammalian Diaphanous 1 (mDia1) Plays a Central Role in RAGE Induced Redox Signaling

Fatouma Toure,[1] Guenter Fritz,[2] Qing Li,[1] Yushan Zou,[1] Rosa Rosario,[1] Art Alberts,[3] Ravichandran Ramasamy,[1] Philippe Rieu,[4] Shi Fang Yan,[1] Ann Marie Schmidt.[1] *[1]Medicine, NYU medical center, New York, NY; [2]Department of Neuropathology, University of Freiburg, Germany; [3]Laboratory of Cell Structure & Signal Integration, Van Andel Research Institute, Grand Rapids, MI; [4]Nephrology, Hospital University of Reims, Reims, France.*

Background: RAGE (Receptor for Advanced Glycation end Products) is a multiligand receptor of the immunoglobulin superfamily involved in fundamental disease processes characterized by vascular pathology. Vascular stress leads to up-regulation of RAGE ligands in the vessel wall, thereby facilitating their engagement and activation of RAGE to induce pro-inflammatory and tissue-damaging responses. We previously reported that the cytoplasmic domain of RAGE interacts with mDia-1, a member of the formin family involved in actin and microtubule reorganization.

Methods: In the present study, we tested the role of mDia1 in RAGE induced oxidative stress generation and redox signaling pathways. We established primary cultures of murine aortic smooth muscle cells (SMCs) from wild-type, RAGE null and mDia-1 null mice. Recombinant S100B was used as a prototypic RAGE ligand.

Results: We found that: 1/ RAGE activation leads to the translocation of cSRC kinase to the membrane, followed by Rac1 and Nox1 activation. Nox4 was not affected. 2/ RAGE induced superoxide production and consequent phosphorylation of GSK3β were required for WT SMCs migration. 3/ Presence of mDia1 was critical for RAGE induced cSRC translocation at the membrane, Rac1 and Nox1 activation, AKT/GSK3 β phosphorylation and VSMC migration. Finally, in vivo, in a mouse model of guidewire induced femoral artery denudation, we found that mice devoid of mDia-1 had less neointimal expansion. Furthermore, NADPH oxidase activity, and phosphorylation of AKT/GSK3beta were lower in arteries of animals devoid of mDia1.

Conclusions: We conclude that mDia1 integrates oxidative and signal transduction pathways triggered at least in part by RAGE ligands, therefore acting as a regulator of pathological neointimal expansion.

A Novel Role of Tuberin in the Regulation of Cell Matrix Proteins in Proximal Tubular Cells

Samy L. Habib,[UTHSCSA] Mukesh Yadav,[UTHSCSA] Anamika Yadav. [UTHSCSA] *[1]Cellular and Structural Biology and Geriatric Research, Education and Clinical Center, South Texas Veterans Healthcare System, UTHSCSA, San Antonio, TX; [2]Cellular and Structural Biology, UTHSCSA, San Antonio, TX; [3]Cellular and Structural Biology, UTHSCSA, San Antonio, TX.*

Background: Matrix protein accumulation is major pathological features of diabetic nephropathy that eventuate in renal failure. PI3-K/Akt pathway phosphorylates tuberin on specific residues result in its inactivation. Tuberin inactivation leads to activate mTOR pathway, which increases protein translation and cell growth. Hyperglycemia increases cell matrix proteins but the pathogenic mechanisms are not fully understood.

Methods: Inactivation of tuberin and activation of downstream signal of mTOR, collagen IV and fibronectin expression were measured in kidney cortical tissue of control and type 1 diabetic animals and in primary proximal tubular cells (PPT) incubated with normal or high glucose. In addition, promoter transcription activity of fibronectin was measured in PPT cells treated with high glucose (HG) using luciferase assay.

Results: Our data show that inactivation of tuberin resulting activation of the mTOR pathway enhances matrix proteins accumulation in PPT cells exposed to HG and in kidney cortex of rats with type1 diabetes. We find also that high glucose enhances phosphorylation/inactivation of tuberin and results in increased phosphorylation of S6 Kinase, a major downstream target of mTOR. This is associated with increased fibronectin and collagen IV protein expression in cultured PPT cells. Our data show that the increase in fibronectin and collagen IV protein expression in tuberin-null cells is reversed upon the introduction of tuberin cDNA. In addition, our data show that blockade of mTOR with rapamycin prevents HG-induced increase in fibronectin promoter transcriptional activity in PPT cells.

Conclusions: In conclusions, we show for the first time a novel role of tuberin in the regulation of cell matrix proteins in proximal tubular cells. Our data provide an evidence that diabetes enhances tuberin phosphorylation/inactivation and results in an increase cell matrix proteins accumulation in kidney cortex.

FR-PO1336

Curcumin Blocks Ang II Induced TNFα Secretion by Inhibiting Phosphorylation of TNFα Converting Enzyme (TACE)

Siddhartha S. Ghosh, George Bassam Saffouri, Shobha Ghosh, Domenic A. Sica, Todd W. Gehr. *Int Medicine/Nephrology, VCU, Richmond, VA.*

Background: Angiotensin II (Ang II) by increasing TNFα secretion, can secondarily induce inflammation and aggravate renal failure. We showed that curcumin (CUR) ameliorates renal failure in rats by blocking TNFα secretion. However, the mechanism by which TNF secretion relates to Ang II/CUR is poorly elucidated. Phosphorylation of TNFαconverting enzyme(TACE)facilitates release of the active form of TNFα. Various signaling pathways including the MEK/ERK pathway mediate the phosphorylation of TACE. We theorized that Ang II, by activating the ERK pathway, can induce TACE

phosphorylation and CUR, which is known to block ERK phosphorylation, can prevent TACE activation and reduce TNFα secretion.

Methods: Thioglycolate elicited peritoneal macrophages (MO) from Sprague Dawley rats were plated for cell culture. The MO were treated with Ang II in the presence and absence of 10 μM CUR and/or 10 μM of ERK inhibitor PD 98059 (PD) for 24 hours; control MO were exposed to ethanol. TNFα was measured by ELISA. MO lysates were made with phosphatase and protease inhibitors (n= 4-6).

Results: Ang II treated MO had a 65% increase in TNFα secretion (p[let]0.01), CUR and PD blunted it by 40±3.9% ($p<0.01$) and 17±4.2% ($p<0.05$) respectively. Western blot analysis of macrophage lysates showed that Ang II increased ERK phosphorylation by 3 fold, which was effectively reduced by PD ($p<0.01$) and CUR ($p<0.05$). TACE was immunoprecipitated from MO lysate and immunoblotted with phosphoserine and phosphothreonine antibodies. Compared to controls total phosphorylation of TACE following Ang II treatment was increased by 41±5.1% ($p<0.01$) and only by 20±6.5 % ($p<0.01$) and 34 + 5.0 % ($p<0.05$) respectively, with CUR and PD pre-treatment [CUR vs PD $p \leq 0.05$].

Conclusions: Ang II increases TNFα secretion by phosphorylating TACE, a process effectively blocked by CUR. Although CUR was less effective than PD in blocking ERK phosphorylation it was more effective in blocking TNFα secretion and TACE phosphorylation. The superiority of CUR to PD may be a function of Ang II activating other phosphorylation pathways such as PKC, inhibitable by CUR but not by the MEK inhibitor PD.

FR-PO1337

High Glucose Induced Classically Activated Macrophage Facilitates Process of Epithelial Mesenchymal Tansition in Renal Proximal Tubular Epithelial Cells

Yansheng Jin, Xiaoliang Zhang, Kun Ling Ma, Linli Lv, Bi-Cheng Liu. *Institute of Nephrology, Zhongda Hospital, Southeast University School of Medicine, Nanjing, Jiangsu Province, China.*

Background: It is the status of macrophage activation rather than infiltrated number in kidney tissue plays the key role in determining the outcome of kidney diseases. There are two types of macrophage activation including classical (M1) and alternative (M2) types. M1 induces inflammation and tissue injury while M2 may provide anti-inflammatory effect and promote tissue repair. Our previous study had demonstrated that macrophage-renal tubular cell binding could drive TGF-β1 expression by tubular cells. This study was to investigate the effect of high glucose (HG) on macrophage activation type and consequent effect on epithelial mesenchymal tansition (EMT) in renal proximal tubular epithelial cells (PTEC).

Methods: U937 and HK-2 cells were used in all experiments. High glucose (30mM) was used to stimulate U937 and M1 marker iNOS, TNF-α and IL-12 were detected by ELISA. Stimulated U937 were co-cultured with HK2 cells followed by measurement of EMT marker α-SMA,fibronectin and E-cadherin by western immunoblotting.

Results: Treatment of U937 cells with HG significantly increased the expression of iNOS mRNA ($P<0.05$) and the activity of iNOS ($P<0.05$), with the maximal iNOS activity achieved at hour 9 ($P<0.01$). Incubation of 30mM of HG with U937 cells for 24 hours increased expression of TNF-α ($P<0.01$) and IL-12 ($P<0.01$), with the peak level up to 15 times higher than control. In addition, co-culture of HG treated U937 with HK-2 cells for 24 hours decreased expression of E-cadherin mRNA ($P<0.05$) and protein ($P<0.05$), whereas α-SMA and fibronectin were significantly increased ($P<0.05$). The mRNA expression of α-SMA and fibronectin in HK2 cells were also increased after incubation with HG treated U937 ($P<0.05$). This change was similar with the positive control with IFNγ+LPS treatment to U937, which represents M1 activation, while it was not observed in the osmotic control (treatment with mannitol).

Conclusions: High glucose shifts macrophage differentiation into classically activated (M1) macrophage, which could facilitate the process of EMT in HK2 cells.

Erbin Inhibits TGF-β1-Induced Epithelial-to-Mesenchymal Transition in Renal Tubular Epithelial Cells through an ERK Dependent Pathway

Qiaodan Zhou,[1] Rui Zeng,[1] Chuou Xu,[1] Lily Liu,[1] Lin Chen,[2] Min Han,[1] Gang Xu.[1] *[1]Division of Nephrology, Department of Internal Medicine, Tongji Hospital, Tongji Medical College, HUST, Wuhan, Hubei, China; [2]Department of Hepatic Surgery, Tongji Hospital, Tongji Medical College, HUST, Wuhan, Hubei, China.*

Background: Epithelial-to-mesenchymal transition (EMT) plays a crucial role in the progression of renal interstitial fibrosis, which ultimately leads to end-stage renal failure. Erbin, a member of LAP family, is recently reported to inhibit Smads and ERK pathway which are two important intracellular signaling involved in TGF-β1-induced EMT.However, the role of Erbin in the regulation of EMT and the underlying mechanisms remain to be fully understood. To that end, we aimed to evaluate the expression of Erbin in renal interstitial fibrosis (RIF) and the potential role of Erbin in tubular EMT stimulated by TGF-β1.

Methods: Western blotting anaysis for Erbin, E-cadherin and α-SMA; RT-PCR for Erbin; Immunohistochemistry for Erbin expression in Rat renal tissue;

Masson staining for rat renal tissue;

Immunofluorescence test for E-cadherin and α-SMA.

Results: In this study we demonstrated that the expression of Erbin was up-regulated in the tubular epithelia of 5/6-nephrectomized rats. We also showed here that TGF-β1 induced Erbin expression both in mRNA and protein level in NRK52E cells during their acquisition of an EMT phenotype. Importantly, elevated expression of Erbin inhibited ERK signaling and partial reversed EMT stimulated by TGF-β1. In the mean time, reducing Erbin expression by specific siRNA enhanced ERK phosphorylation with no effect on smads signaling, promoted the E-cadherin suppression and induced α-SMA in response to TGF-β1, which could be rescued if cells were treated with the inhibitor of MEK1/2 U0126. However, in the absence of TGF-β1, Erbin failed to affect ERK activation and EMT process.

Conclusions: These results demonstrate that Erbin is a negative feedback molecule induced by TGF-β1 and inhibits TGF-β1-induced EMT via ERK signaling pathway.

FR-PO1339

Differential SMAD3 Linker Region (LR) Phosphorylation Is Specific for Different Cell Tissue-Types and Phenotypes

James Alexander Browne, Tomoko Hayashida, H. William Schnaper. *Division of Kidney Diseases, Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Regulation of TGF-β/Smad3-mediated fibrogenesis involves complex interaction among canonical and non-canonical signaling pathways. Here, we report the specificity of phosphorylation at several sites (Thr179, Ser204, Ser208, and Ser213) within the Smad3 LR. Previously we showed that ERK is required for collagen reporter activity; and that intact phosphoacceptor sites at Ser204 or Ser208 are required for collagen promoter activation by Smad3, whereas the remaining Thr179 and Ser213 may have opposing effects.

Methods: To further investigate a role for ERK in LR phosphorylation we pre-treated serum-starved murine embryonic fibroblasts (MEFs) with the MEK inhibitor, PD98059 (PD), prior to TGF-β1 stimulation (2ng/ml, 1h). Smad3 LR phosphorylation at Thr179, Ser204, Ser208, and Ser213 was assessed by western blotting. LR phosphorylation was also examined in human renal tubule epithelial cells (HKC), human mesangial cells and mouse podocytes.

Results: Phosphorylation at Thr179, Ser204, Ser208, and Ser213 of the Smad3LR by TGF-β1 was confirmed in wild type MEFs. In HKC, both Thr179 and Ser208 were phosphorylated while in mesangial cells, Ser208 and Ser213 were phosphorylated, none of which were affected by PD. In podocytes, phosphorylation at Thr179, Ser208 and Ser213 were detected (effect of PD not tested). In embryonic fibroblasts, PD inhibited Ser204 phosphorylation but did not affect the remaining sites (Thr179, Ser208 or Ser213). This is consistent with the notion that Ser204 is a primary ERK target and the remaining sites (Thr179, Ser208 or Ser213) are phosphorylated by other mediators.

Conclusions: The ability of TGF-β1 to stimulate, and of PD to inhibit, Ser204 phosphorylation in embryonic fibroblasts but not in HKC is consistent with previous findings that show PD to inhibit TGF-β1-stimulated collagen reporter activity in embryonic fibroblasts and mesangial cells but not in HKC. Further investigation of the role of the Smad3 LR in renal cell function may offer new approaches to selectively modifying TGF-β1-stimulated responses in progressive kidney disease.

Connective Tissue Growth Factor (CTGF) Antagonizes BMP Signalling in Renal Cells with Pathogenic Consequences for Cellular Behaviour and Function

Marie B. Browne,[1] Helen O'Donovan,[1] David Walsh,[1] Noelynn Oliver,[4] Catherine Godson,[2] John Crean,[1] Derek Brazil.[3] *[1]UCD Diabetes Research Centre, University College Dublin, Dublin, Ireland; [2]UCD School of Medicine and Medical Science, UCD Conway Institute, University College Dublin, Dublin 4, Ireland; [3]Centre for Vision and Vascular Science, Queen's University Belfast, United Kingdom; [4]Fibrogen Inc, San Francisco, CA.*

Background: Initiation and progression of Diabetic Nephropathy (DN) is characterized by alterations in TGF β superfamily signalling, while there is increasing evidence for regulation of BMP signalling activity by extracellular BMP antagonists including CTGF. It has recently been shown that CTGF inhibits BMP-7 activity in experimental DN and in cultured renal cells however the relationship between BMP-2/4 signalling and CTGF has not been investigated in renal cells.

Methods: Biotinylated BMP-4 allowed measuring of changes in receptor binding.We used structural comparison modeling to predict changes in the binding energy between the wild-type CTGF VWC substituted for the equivalent domain of CV-2 by in silico mutagenesis.

Results: Analysis of complex structures of the TGF β1 superfamily member BMP-2 and Crossveinless-2 (CV-2) is informative: The VWC domain of CTGF shares significant homology with SD-1 of CV-2 and is structurally highly conserved.Mutagenesis studies identified key amino acids within the VWC domain that mediate the antagonism of BMP-2. We have shown in mesangial cells that CTGF antagonizes BMP-2/4 induced phospho smad 1/5/8. This effect was reversed by pre treatment of cells with anti-domain 2, a humanized monoclonal antibody directed against the VWC domain of CTGF. CTGF also inhibited BMP-4 receptor binding and BMP-4 induced alkaline phosphatase. CTGF mRNA and protein levels are significantly increased in the STZ-type 1 diabetic mice, concurrent with decreased levels of phosphorylated smad 1/5/8. Injection of wildtype Zebrafish Danio Rerio with in vitro transcribed CTGF mRNA also induces an anti-BMP phenotype.

Conclusions: Although previously undescribed inhibition of BMP-2/4 activity by CTGF may play a crucial role in the progression of DN with anti-CTGF therapies proving promising.

HIF1 Modulates Chromatin Conformational Change by Recruiting KDM3A and Enhances Regulation of Glucose Transporter 3 in Endothelial Cells
Imari Mimura,[1,2] Tsuyoshi Inoue,[1] Youichiro Wada,[2] Yasuharu Kanki,[2] Toshiro Fujita,[1] Hiroyuki Aburatani,[2] Tatsuhiko Kodama,[2] Masaomi Nangaku.[1] *[1]Division of Nephrology and Endocrinology, University of Tokyo, Japan; [2]Research Center for Advanced Science and Technology, University of Tokyo, Japan.*

Background: Hypoxia plays a crucial role in both acute and chronic kidney injury. Hypoxia inducible factor 1 (HIF1) is a master regulator of the gene expressions especially to organize glycolysis, cell proliferation and cell survival under hypoxia. Recently HIF1 was reported to regulate subsets of histone demethylases, which modify the chromatin structures. However, its role in epigenetic regulation remains unknown. We aimed at clarifying a new epigenetic mechanism via HIF1, which serve as the first-line defense against hypoxic milieu in various organs including the kidney.

Methods: We performed chromatin immunoprecipitation with deep sequencing (ChIP-Seq) to identify the genome-wide binding sites of HIF1 and clarified the histone modifications in human umbilical venous endothelial cells. We also examined chromatin conformation capture assay to identify the chromatin structural change under hypoxia.

Results: We identified that HIF1 binds to the distal regions from the transcriptional starting sites and plays an important role as an enhancer of glucose transporter 3 (SLC2A3). The reporter assay confirmed that the distal regions of SLC2A3 up-regulate the luc activity under hypoxia and overexpression of HIF1. We clarified the distal region enhances SLC2A3 expression by changing chromatin conformational structure via HIF1. Furthermore KDM3A (JMJD1a; jumonji-domain containing 1a) is a member of histone demethylases and up-regulated by HIF1 under hypoxia. We demonstrated that KDM3A is recruited to the enhancer regions of SLC2A3 by HIF1 and demethylates dimethyl-H3K9 to up-regulate the expression under hypoxia, while KDM3A is not recruited to those enhancer regions when HIF1 is knocked down. These results demonstrate that HIF1 is essential to change the chromatin conformation and recruit KDM3A under hypoxia.

Conclusions: Our findings provide new insights into the regulatory mechanism of HIF1 and epigenetic modifications of KDM3A in HUVEC under hypoxia.

Interferon Gamma Promotes Starvation-Induced Autophagy by Activating the GCN2-ATF4 Pathway
Sophie Fougeray,[1] Eric Thervet,[2] Nicolas Palllet.[1] *[1]U775, INSERM, Paris, France; [2]Nephrology Department, Georges Pompidou European Hospital, Paris, France.*

Background: The aim of this study is to characterize the mechanisms and the consequences of IFNγ-induced autophagy in human epithelial cells.

Methods: Human Renal Cortical Cells (HRCCs) were exposed to 10 ng/ml IFNγ for 24 to 72 hours. Mechanisms and consequences of autophagy were evaluated by western blotting, real time PCR, immunofluorescence and small interfering RNA. An immunohistological study was performed from biopsies of human renal allograft affected by acute rejection and BK virus nephropathy to evaluate autophagy in these situations.

Results: IFNγ increased autophagic flux in HRCCs. Autophagy inhibition by RNA interference directed toward Beclin1 significantly reduced cell viability, suggesting that autophagy promotes cell survival during IFNγ-induced stress.

Indoleamine Dioxygenase (IDO) was strongly upregulated in HRCCs during IFNγ exposure and tryptophan was metabolized in the culture medium. Tryptophan supplementation reduced autophagic flux, suggesting that IFNγ-induced autophagy is a consequence of IDO-mediated tryptophan depletion.

GCN2, an eIF2α kinase activated during amino acid depletion, is phosphorylated following IFNγ treatment. GCN2 activates the eIF2α-ATF4-CHOP pathway leading to autophagy. IFNγ-induced autophagy is significantly reduced by RNA interference directed toward GCN2, suggesting that IFNγ-induced autophagy depends on an intact GCN2 pathway.

Finally, we demonstrate that the tubular expression of the autophagic marker LC3a is strongly upregulated during acute cellular rejection and BK virus nephropathy, conditions which are associated with IFNγ expression, in human renal allograft biopsies, compared to controls.

Conclusions: We report that IFNγ induces autophagy in human tubular cells and promotes cell survival. IDO-induced tryptophan depletion promotes autophagy. IFNγ-induced autophagy is dependant on an intact GCN2-eIF2α pathway leading to the upregulation of the autophagy inducers ATF4 and CHOP. Our results also suggest that autophagy is triggered during acute cellular rejection and BK virus nephropathy in human.

A Circadian Oscillator Kid-1, Whose Transcription Is Directly Regulated by c-Myc, Participates in the Transcriptional Mechanism of Per2 through Intervening in the Network of c-Myc and Tif1β
Masaya Yamato,[1] Keiko Yasuda,[1] Koichi Sasaki,[1] Hiromi Rakugi,[2] Yoshitaka Isaka.[2] *[1]Department of Nephrology, Rinku General Medical Center, Izumisano, Osaka, Japan; [2]Department of Geriatrics and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Discerning the role of the intrinsic kidney clock has important implications for cell cycle of renal tubular epithelial cells and renal function. We reported that a Zinc-finger transcriptional repressor Kid-1 is controlled by the kidney clock, but the mechanism of rhythmic Kid-1 mRNA expression remained to be determined.

Methods: There is no canonical E-box element in the promoter of Kid-1 gene. To determine whether Kid-1 is directly regulated by CLOCK, we knocked down CLOCK in NIH3T3 cells by siRNA. Predictably, Kid-1 mRNA expression level unchanged. Intriguingly, when the expression level of c-Myc was knocked down by siRNA, the level of Kid-1 mRNA was upregulated. c-Myc is a critical repressor for circadian Cyclin D1 transcription through its initiator element. Therefore, we searched Kid-1 gene for analogous sequences.

Results: We found a putative initiator element ACATTTC in Kid-1 promoter region, whose sequence is conserved among mice, rats and human. Luciferase assay and Chromatin immunoprecipitation (ChIP) assay in NIH3T3 cells confirmed that c-Myc negatively regulated Kid-1 transcription through its initiator element. Western blot analysis confirmed that transient overexpression of Kid-1 in NRK52E cells resulted in downregulation of c-Myc and silencing of Kid-1 by siRNA in NRK52E cells resulted in upregulation of c-Myc. Moreover, when Kid-1 was knocked down, the expression levels of Per2 mRNA and its protein product markedly decreased. ChIP assay confirmed that the more amount of lysine9 trimethyl histone H3 interacted with Per2 promoter region when Kid-1 was knocked down. Moreover, the association of c-Myc with Tif1β which is a transcriptional repressor appeared in Per2 promoter region when Kid-1 was knocked down.

Conclusions: These results suggest that Kid-1, whose transcription is negatively regulated by c-Myc, participates in the transcriptional mechanism of *Per2* through intervening in the network of c-Myc and Tif1β.

FR-PO1344

An HIF-1α-Independent Neoangiogenic Pathway Regulated by the Unfolded Protein Response during Renal Ischemia
Nicolas Bouvier,[1] Eric Thervet,[2] Nicolas Palllet.[1] *[1]U775, INSERM, Paris, France; [2]Nephrology Department, Georges Pompidou European Hospital, Paris, France.*

Background: Ischemic injuries stress kidney tissue and challenge cell viability. Adaptive responses to ischemia are mostly mediated by the activation of the transcriptional factor HIF-1α. Emerging evidence suggest that other adaptive pathways promoting neoangiogenesis may be implicated.

Ischemia promotes glucose deprivation, ATP deprivation, hypoxia that triggers Endoplasmic Reticulum (ER) Stress followed by the adaptive response termed Unfolded Protein Response (UPR). The aim of this study was to test whether the UPR would promote neoangiogenesis independently of HIF-1α pathway during ischemic stress.

Methods: qPCR, immunoblots and ELISA were performed on human kidney tubular cell lines (HK2) exposed to glucose deprivation and/or hypoxia to evaluate the expression of the UPR markers BiP, CHOP and ATF4 and the expression of neoangiogenic inducers Vascular Endothelial Growth Factor (VEGF) basic Fibroblast Growth Factor (bFGF), Angiopoietin 1, Angiogenin and Platelet Derived Growth Factor. ARN interference directed against the three transducers of the UPR, ATF6, PERK and IRE1 was performed to test which UPR axis is involved in mediating VEGF and bFGF expression.

Results: Glucose deprivation and hypoxia significantly increased the expression of VEGF, bFGF both at the mRNA and protein levels. Glucose deprivation did not alter HIF-1α protein or mRNA levels suggesting that this pathway is not involved, whereas HIF-1α is upregulated during hypoxia.

Glucose deprivation, not hypoxia, increases the expression level of the UPR markers BiP, CHOP, ATF4, and the spliced form of XBP1 mRNA, suggesting that glucose deprivation, not hypoxia, promotes ER stress and triggers the UPR.

RNA interference directed against PERK decreased VEGF and bFGF secretion whereas RNA interference against Ire1α and ATF6 do not decrease these markers.

Conclusions: This work demonstrates that ischemia increases the expression of neoangiogenesis inducers VEGF and bFGF independently of the HIF-1α pathway in human kidney tubular cells and that the Perk arm of the UPR could play a role in neoangiogenesis during kidney ischemia.

FR-PO1345

Hypercritical Role of mRNA Regulation for Hypoxia Inducible Factor 1 alpha (HIF-1alpha) Expression Ralf Mrowka,[1] Anja Bondke Persson,[2] Andreas Steege,[3] Andreas Patzak,[2] Pontus Persson,[2] Michael Fähling.[2] *[1]KIM III, Experimental Nephrology, Universitätsklinikum Jena, FSU, Jena, Germany; [2]Physiology, Charité - Universitätsmedizin Berlin, Berlin, Germany; [3]Nephrology, Universität Regensburg, Regensburg, Germany.*

Background: Genes are regulated at multiple levels such as transcriptional as well post-transcriptional level. The expression of hypoxia-inducible factor 1 (HIF-1) is critical for many processes such as erythropoesis, vascular growth, anaerobic metabolism, and iron transport mechanisms. Beside the oxygen-dependent hydroxylation of the regulative HIF-1alpha subunit, there is increasing evidence for non-oxygen dependent pathways affecting HIF-1 regulation. In this study we addressed the question as to whether the HIF-1alpha mRNA is important for the regulation of the transcription factor complex and whether there are trans-acting factors that might act as regulators for HIF-1 activity.

Methods: We quantify the impact of transcriptional as well as post-transcriptional gene regulation for the factor HIF-1alpha. Further, we present a computational and experimental approach to identify RNA-binding proteins (RNA-BPs) that modulate mRNA stability of selected genes. For this purpose, we used gene expression data of a large set of microarray experiments available from the Stanford microarray database. We also applied modelling techniques to gain insight into the signalling dynamics of HIF-1.

Results: Based on large-scale expression data, we show that HIF-1alpha mRNA turnover is crucial for the activity of HIF-1 and expression of its downstream targets. We identify a hypercritical requirement in the HIF-1alpha mRNA level which highly impacts the activity of HIF-1 as a transcription factor. Further, we show, both computationally and experimentally, that the gene expression levels of a number of RNA-binding proteins is directly correlated with that of HIF-1 target genes.

Conclusions: Our integrated modelling and experimental approach highlights the importance of mRNA regulation especially under conditions that affect HIF-1alpha protein turnover. We identify a number of RNA binding proteins that modulate HIF-1alpha expression level and subsequently HIF-1 function.

FR-PO1346

Regulation of HuR Expression in Renal Ischemia Suman Govindaraju, Beth S. Lee. *Physiology and Cell Biology, Ohio State University Medical Center, Columbus, OH.*

Background: HuR is a ubiquitously expressed RNA-binding protein that is increasingly shown to be a master regulator of genes associated with growth,cell division and stress response.We have demonstrated that renal HuR is specifically upregulated in proximal tubule (PT) cells following an ischemic event, where it protects these cells from subsequent apoptosis. The purpose of this study is to evaluate the transcriptional control of HuR in PT cells.

Methods: Cultured proximal tubule (PT) cell lines were grown under normal conditions or ATP depletion to mimic ischemic stress.Levels of HuR mRNA transcripts were determined by competitive RT-PCR and ribonuclease protection assays.Levels of HuR protein were determined by Western blotting.Gel mobility shift assays were used to detect binding of transcription factors to the 5' UTR of the HuR gene.

Results: We demonstrate that HuR mRNA is expressed in two forms with alternate 5' untranslated regions that are differentially expressed during normal growth and stress. We are exploring why PT cells express these forms under different cellular conditions, as insights into regulation of HuR will elucidate mechanisms controlling expression of genes promoting growth and cell survival.We are currently characterizing the mechanisms that regulate transcription of the alternate transcript, which is efficiently transcribed during normal growth, but down-regulated following cellular stress. Studies so far reveal that transcription factors Sp1 and NF-κB play a critical role in regulating this form of HuR mRNA. Further, we found that NF-κB stimulation of HuR expression results in its participation in a positive feedback loop that promotes expression of Akt, a protein kinase well-established as a mediator of cell survival.

Conclusions: HuR mRNA exists in two alternate forms which differ in the length of their 5'UTR and are differentially expressed during normal growth and cell stress. Elucidating these mechanisms will help us understand its protective role in ischemia-reperfusion injury, ischemic pre-conditioning and other models of renal cellular stress.

FR-PO1347

5-Hydroxytryptamine-Class 2 Receptor-Mediated Mitochondrial Biogenesis as a Potential Therapeutic Strategy for Treatment of Acute Kidney Injury Jennifer L. Blakely, Sara M. Garrett, Craig Cano Beeson, Rick G. Schnellmann. *Department of Pharmaceutical and Biomedical Sciences, South Carolina College of Pharmacy, Medical University of South Carolina, Charleston, SC.*

Background: Renal proximal tubule cells (RPTC) exposed to acute oxidant injury exhibit mitochondrial dysfunction; recovery of cellular function in these cells is temporally related to recovery of mitochondrial function, indicating that the mitochondria are a potential novel target for the treatment of AKI. Previous work in our laboratory demonstrated that DOI, a 5-hydroxytryptamine 2 receptor ($5HT_2$) pan-agonist, stimulates mitochondrial biogenesis in vitro by increasing the expression of peroxisome-proliferator-receptor-γ-coactivator-1α (PGC-1α), the "master regulator" of mitochondrial biogenesis. Additionally, it was demonstrated that DOI accelerates the recovery of mitochondrial function after exposure of RPTC to acute oxidant injury, suggesting that 5-HT receptor agonists may represent a novel therapeutic strategy for the treatment of mitochondrial and cell injury.

Methods: The goal of these studies was to further explore the role of $5HT_2$ receptors as targets for induction of mitochondrial biogenesis using the Seahorse Biosciences analyzer as a respirometric screen in primary cultures of rabbit RPTC. Concentration-response experiments were conducted using six $5HT_2$ receptor agonists and six $5HT_2$ receptor antagonists.

Results: Four compounds increased maximal FCCP-uncoupled respiration, a test for mitochondrial biogenesis. CP-809101, a highly selective 5HT2c agonist, yielded a maximal biogenic response at 100 nM whereas three 5HT2A antagonists, SB-242084, ketanserin and MDL-100907, yielded a maximal biogenic response at 100 nM, 100 nM and 1 nM, respectively.

Conclusions: Based on these results, we postulate that $5HT_{2c}$ agonism is responsible for the mitochondrial biogenic effect of DOI on cells exposed to oxidant injury. Furthermore, we suggest that $5HT_{2A}$ receptor antagonism signals mitochondrial biogenesis through a novel pathway.

FR-PO1348

FoxO1 Is the Dominant Mediator of the Skeletal Muscle Atrophy Due to CKD and FoxO1 Can Be Inhibited *In Vivo* by miR-486 Jing Xu,[1] Zhaoyong Hu,[2] Yanlan Dong,[2] William E. Mitch.[2] *[1]Department of Nephrology, Changhai Hospital, Shanghai, China; [2]Nephrology Division, Baylor College of Medicine, Houston, TX.*

Background: The loss of muscle protein induced by chronic kidney disease (CKD) occurs via the ubiquitin-proteasome system (UPS). A pathway that activates the UPS in muscle includes an upregulation of the expression of atrophy-related E3 ligases, Atrogin-1 and MuRF-1. It is generally accepted that forkhead transcription factors (FoxOs) can stimulate expression these E3 ligases, it is not known which isoform (Foxo1, Foxo3 or FoxO4) activates muscle proteolysis *in vivo*. Identifying which FoxO is required could lead to therapeutic strategies.

Methods: We studied mice with muscle-specific deletion of FoxO1(MFKO) and examined how CKD (subtotal nephrectomy) affects muscle protein degradation. We also investigated if blocking FoxO1 expression by a micro RNA strategy changes muscle wasting.

Results: MFKO did not alter the expression of FoxO3a or FoxO4 in muscle and CKD did not cause significant muscle atrophy in MFKO mice. The expression of Atrogin-1/MuRF-1 in muscle and the rate of muscle protein degradation were blocked by ~70% ($p<0.01$). Since miR-486 can damp FoxO1 translation, we examined if miR-486 influences protein metabolism in muscle cells. After transfecting a miR-486 mimic into primary cultures of mouse myotubes, the FoxO1 protein level decreased and its phosphorylation increased. Control myotubes treated with dexamethasone (Dex) had increased Atrogin-1/MuRF-1 expression and protein degradation and these responses were largely blocked by expression of miR-486. In mice, we electroporated the miR-486 mimic into the mixed fiber, tibialis anterior (TA) muscles of CKD or Dex-treated mice. Muscle mass (the ratio of TA muscle weight to tibia length) in CKD mice significantly improved after electroporation of the miR-486 mimic and there was significant depression of FoxO1 protein and Atrogin-1/MurF-1 expression.

Conclusions: Our results demonstrate that FoxO1 is a dominant mediator of the CKD-induced activation of Atrogin-1/MuRF-1, and their contribution to muscle protein degradation. Manipulation of miR-486 could potentially blunt catabolic responses in muscle.

FR-PO1349

FGF23 Is Independently Associated with Vascular Calcification but Not Bone Mineral Density in Patients at Various CKD Stages Sophie Liabeuf,[1,2] Lucie Desjardins,[1,2] Cédric Renard,[4] Aurélie Lenglet,[1,2] Horst-Dieter Lemke,[5] Gabriel Choukroun,[2,3] Tilman B. Drueke,[2] Ziad Massy.[1,2,3] *[1]Pharmacology Department - Clinical Research Center, Amiens University Hospital, Amiens, France; [2]INSERM ERI 12, University of Picardie Jules Verne, Amiens, France; [3]Nephrology Department, Amiens University Hospital, Amiens, France; [4]Radiology Department, Amiens University Hospital, Amiens, France; [5]EXcorLab GmbH, Obemburg, Germany.*

Background: The hormone fibroblast growth factor 23 (FGF23) is involved in mineral homeostasis but may also have a role in vascular calcification and bone mineralization. Previous studies related to FGF23 and vascular and bone outcomes have been restricted to dialysis patients. The aim of the present study was to establish whether or not plasma FGF23 levels are associated with aortic and coronary calcification, arterial stiffness and bone mineral density in patients with early as well as late stages of CKD.

Methods: One hundred and fifty-three patients with CKD stages 2-5D were included in a cross-sectional study. In addition to routine biochemistry and intact FGF23 determinations, aortic and coronary calcification and stiffness and bone mineral density (BMD) were assessed by multislice spiral computed tomography and automated pulse wave velocity (PWV).

Results: Plasma intact FGF23 levels were elevated in CKD patients; the elevation preceded that of serum phosphate in early-stage CKD. Patients with elevated FGF23 levels had higher aortic and coronary calcification scores than patients with lower FGF23

levels. Multivariate linear regression analysis indicated that only age ($p<0.001$) and FGF23 ($p=0.008$) were independently associated with aortic calcification score. Plasma FGF23 was neither associated with PWV nor with BMD.

Conclusions: Our data suggest that plasma FGF23 is an independent biomarker of vascular calcification in patients with various CKD stages including early stages. The association between vascular calcification and FGF23 levels appears to be independent of BMD. It remains to be seen whether this association is independent of bone turnover and bone mass.

FR-PO1350

microRNA-29 Is a Regulator of TGFβ-Dependent Fibrogenesis Phillip Kantharidis, Bo Wang, Rosemarie Carew, Chris Tikellis, Merlin C. Thomas, Mark E. Cooper. *JDRF Danielle Alberti Memorial Centre for Diabetes Complications, Baker IDI Heart & Diabetes Institute, Melbourne, Victoria, Australia.*

Background: Glomerular and interstitial fibrosis is a common pathogenic pathway for progressive kidney disease. The renal accumulation of extracellular matrix (ECM) is primarily driven by increased levels of pro-fibrotic mediators, including TGF-β1. Recent data have suggested an important role for specific microRNAs in enhancing fibrogenic signalling and sustaining pro-fibrotic phenotypes. In particular, the 3'UTR of most collagens contains target sites for miR-29 mediated translational repression. This study examines the potential functions of the microRNA-29 in TGF-dependent fibrogenesis.

Methods: The ectopic expression of pre-miR-29a/b/c or pre-miR-Control (miR-C) was induced in rat proximal tubular cells, primary messangial cells and immortalised human podocytes using Oligofectamine. Cells were then exposed to TGF-β1 (1-10ng/mL) for 3-10 days and the expression of collagen assessed using RT-PCR and immunoblotting.

Results: Treatment of renal cells with TGF-β1 reduced the expression of the miR-29a/b/c and increased fibrogenesis. By contrast, ectopic expression of miR-29 repressed the expression of collagen I and IV, at an mRNA and protein level, and attenuated TGF-dependent fibrogenesis in both renal cell lines. Luciferase-reporter constructs incorporating the 3'UTR of collagen I and IV demonstrated that TGF-β1 increased luciferase activity (collagen expression) and that miR-29 was able to prevent this increase.

Conclusions: miR-29 potentially plays an important role in TGF-β1-mediated collagen synthesis in renal cells. These miRNAs potentially represent a new target for the development of anti-fibrotic therapies for the treatment of chronic kidney disease.

Increased Zinc-α2-glycoprotein White Adipose Tissue Synthesis in Chronic Kidney Disease: Nutritional and Metabolic Impacts Caroline Pelletier,[1 2 3] Laetitia Koppe,[1 2 3 4] Emilie M. Kalbacher,[1 2 3 4] Denis Fouque,[2 4] Christophe O. Soulage.[1 3] *[1]CarMeN u1060, INSERM, France; [2]Univ Lyon 1, France; [3]INSA, Lyon, France; [4]HCL, Lyon, France.*

Background: Chronic kidney disease (CKD) is frequently associated with protein energy wasting which has been recognized as a predictive factor of mortality. Zinc-α2-glycoprotein (ZAG) has been proposed as a new adipokine involved in body weight control through its lipid mobilizing activity.We hypothesized that the uremic environment in CKD may interact with the adipose tissue, resulting in an over-production of ZAG and therefore contributing to metabolic disturbances observed in CKD patients.

Methods: ZAG level was quantified in mouse 3T3-L1 adipocytes after incubation in culture medium containing either urea (30mM), plasma from healthy volunteers, CKD or haemodialysis (HD) patients (20%,v/v). ZAG was also measured in white adipose tissue (WAT) from 5/6 nephrectomized or controls rats. Plasmas from 8 healthy volunteers, 8 CKD and 8 HD patients and subcutaneous adipose tissue (SAT) biopsies from 5 CKD patients and 9 non uremic individuals were collected. ZAG protein content was quantified in plasma, white adipose tissue or 3T3-L1 adipose cells by Western blotting.

Results: Uremic plasma but not urea or control sera, induced a significant increase of ZAG protein content (+224%,$p<0.001$) in 3T3-L1 adipocyte associated with an increase in basal lipolysis (+153%,$p<0,005$). 5/6 nephrectomized rats exhibited a significant decrease in WAT accretion (-44%,$p=0,006$) and a higher content of ZAG in WAT (+598%,$p<0,02$). ZAG protein level in WAT was negatively correlated with adipose tissue mass ($p=0,006$). Human plasma concentration of ZAG was increased in CKD patients as compared with healthy volunteers (+279%,$p=0,001$). Human SAT from CKD patients showed a higher content of ZAG protein level (+234%,$p=0,042$).

Conclusions: Undefined circulating factors in CKD, but not urea itself, increase ZAG production in adipocytes. These results suggest that the increase of ZAG serum levels reported in CKD patients could be due to an overproduction of ZAG by adipose tissue. The increase in ZAG could be a major contributor of fat mass loss and PEW in CKD patients.

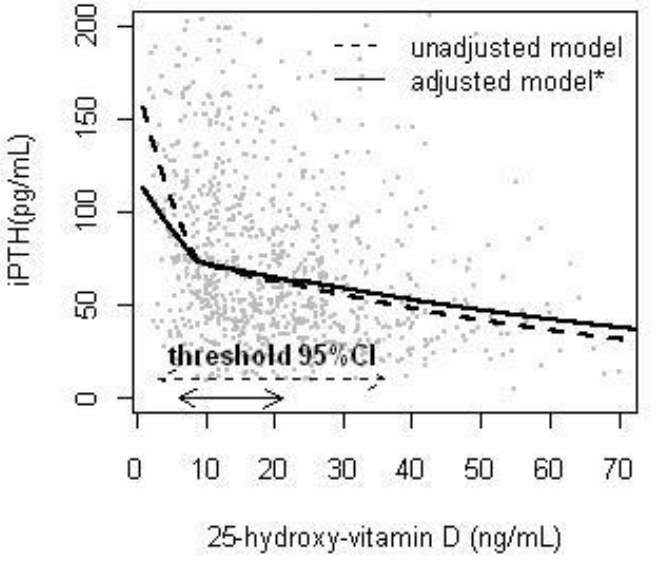
FR-PO1352

The Relationship between Vitamin D and Parathyroid Hormone in Chronic Kidney Disease: Is There a Threshold ? Marie Metzger,[1] Pascal Houillier,[2] Martin Flamant,[3] Jean-Philippe Haymann,[4] Marc Froissart,[2] Benedicte Stengel,[1] Pablo A. Urena.[5] *[1]Inserm U1018, Villejuif, France; [2]Paris Descartes University, Paris, France; [3]Bichat Hospital, Paris, France; [4]Tenon Hospital, Paris, France; [5]Clinique du Landy, St Ouen, France.*

Background: Vitamin D is essential for the regulation of parathyroid hormone (PTH) synthesis. According to the last KDIGO guidelines, serum 25(OH)D concentration might be measured in CKD patients and vitamin D deficiency corrected using treatment strategies recommended for the general population. However, there is no consensus on what define the adequate 25(OH)D values in CKD patients regarding to the level of PTH.

Methods: We used data from the NephroTest cohort including 916 adult patients with ND-CKD stages 1 to 5 and free from vitamin D supplementation to assess the relationship between PTH and 25(OH)D, and to test the existence of a threshold.

Results: Median values (IQR): measured GFR by 51Cr-EDTA: 38(28-52) mL/min/1.73m²; 25(OH)D: 17(11-27) ng/mL; PTH: 64(40-107) pg/mL. Mean ionized calcium (sd): 1.21 (0.07) mmol/L. PTH values were better predicted by a linear piecewise regression model of log(PTH) on 25(OH)D with a threshold of 9 ng/mL than by a linear regression model ($p=0.01$). Adjusting for ionized calcium and measured GFR significantly improved model predictions ($r^2=0.38$ vs 0.10 for the model without adjustment) and reduced the 95%CI around the 9 ng/mL threshold = [6-21 ng/mL]. Estimated slopes were significantly negative before and after the threshold.



*estimated for mGFR of 30-45 ml/min/1.73m² and mean ionized calcium

Conclusions: As in general population, the relation between serum PTH and 25(OH)D is non linear. The rise in serum PTH concentration markedly accelerates when serum 25(OH)D levels fall below 9 ng/mL with an upper 95%CI around 20 ng/mL. This result suggests maintaining serum 25(OH)D concentration above 20 ng/mL to improve the management of secondary hyperparathyroidism in CKD patients.

Regulation of Hematopoeitic Growth Factor-Inducible Neurokinin, a Tubular Injury and Repair Marker, by Glucose in Mouse Distal Convoluted Tubule Cells and Patients with Diabetic Nephropathy Ying Wang, Anuja P. Shah, Lili Tong, Janine A. La Page, Sharon G. Adler. *Internal Medicine, LABiomedical Research Institute at Harbor-UCLA, Torrance, CA.*

Background: Microalbuminuria (MACR) is less sensitive/specific for diabetic nephropathy (DN) than previously thought, but is used to indicate disease activity/treatment response. Implicit is that therapy predominantly (but not exclusively) targets the glomerulus, but progression correlates better with tubulointerstitial change. We reported urine HGFIN/creatinine (uHGFIN/cr) as a sensitive/specific CKD biomarker in animals/patients, including some with DN (Patel-Chamberlin et a: KI 79:1138, 2011). De novo co-expression of HGFIN with LC3 II in injured distal nephron cortical tubule cells indicated expression in tubules undergoing autophagy. Others reported that HGFIN (aka Gpnmb) mediates autophagy/repair in injured tubules (Li et al: FASEBJ 24:4767, 2010). The regulation of HGFIN expression in diabetes has not been studied.

Methods: We: 1) Measured HGFIN mRNA/protein in mDCT cells cultured with varying glucose (Glu) concentrations; and 2) Assessed uHGFIN/cr values in DN patients randomized to placebo or minocycline (posited anti-apoptotic).

Results: 1) HGFIN/18s mRNA increased linearly in mDCT cells incubated with Glu at 10, 20* and 25* mM (*p<0.05 vs 5.5 mM), but trended down at 30 mM. HGFIN protein increased linearly at 10* and 20* mM Glu (*p<0.05 vs 5.5 mM) but trended down at 25 and 30 mM. 2) In a subset of clinical trial patients, with the randomization blind intact, MACR and uHGFIN/cr decrements were strongly associated; MACR stability/worsening was associated with higher uHGFIN/cr excretion.

Conclusions: 1) HGFIN mRNA/protein levels in mDCT cells are regulated at least in part by medium Glu content. Moderately high Glu increased, but extremely high Glu attenuated, HGFIN expression. 2) uHGFIN/cr correlated with treatment responses in DN. Taken together, these data suggest that HGFIN, which influences autophagy by regulating phagosomal-lysosomal trafficking, is regulated at least in part by Glu exposure, reflects tubular injury in vivo, is modifiable in DN, and may be a target for novel DN therapies and a measure of therapeutic success or failure.

Osteoprotegerin Is Associated with Inflammation, Atherosclerosis and Mortality in CKD Patients Stage 3-5

Marcelo M. Nascimento,[1] Shirley Yumi Hayashi,[1,2] Astrid Seeberger,[1] Tae Yamamoto,[1] Abdul Rashid Tony Qureshi,[1] Britta Lind,[2] Miguel C. Riella,[3] Lars-åke Brodin,[2] Bengt Lindholm.[1] *[1]Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden; [2]Dept of Med Eng, School of Technol and Health, Royal Institute of Technology, Stockholm, Sweden; [3]Pro Renal Foundation, Curitiba, Brazil.*

Background: Osteoprotegerin (OPG) regulates bone mass by inhibiting osteoclast differentiation and activation, and also plays a role in vascular calcification. Recent research has implicated OPG in atherogenesis, but epidemiological confirmation of this is sparse. In this study we evaluated the relationships between OPG levels and inflammatory and oxidative stress (OS) markers, atherosclerosis and mortality in CKD patients stage 3-5.

Methods: 162 patients (median age 61 years, 62% males; 50 hemodialysis (HD), 57 peritoneal dialysis (PD) and 50 CKD stages 3-4) were studied. All survivors completed 36 months of follow-up. Clinical characteristics were documented, and markers of mineral metabolism (including fibroblast growth factor-23; FGF-23), inflammation (high-sensitivity C-reactive protein; hsCRP, and interleukin-6; IL-6) and OS (8-OH-deoxyguanosine; 8-OHdG) as well as intima-media thickness (IMT; expressed as mean IMT) in common carotid arteries through B-mode ultrasonography were measured at baseline.

Results: After 36-months follow-up, 38 patients (23 PD, 17 HD and 3 CKD stage 3-4) had died. The survival rate by Kaplan–Meier analysis was significantly different according to OPG levels ($\chi 2 = 14.33$; P = 0.002). Increased OPG levels were positively associated with IL-6 (r= 0.38, p<0.001), FGF-23 (r= 0.26, p<0.001), hsCRP (r= 0.0.24, p=0.003), and 8-OHdG (r= 0.44, p<0.0001). In addition, OPG was positively associated with troponin I (r= 0.54, p<0.001) and IMT (r= 0.39, p<0.0001). Moreover, in Cox analysis, only OPG (HR=1.07(95% confidence interval (95% CI) 1.02-1.13) and hsCRP (HR= 1.02 (95% CI 1.01-1.04) were independently associated with increased risk of death.

Conclusions: Although the role of OPG in the vascular biology is poorly understood, these results suggest that elevated levels of serum OPG are associated with atherosclerosis and all-cause mortality in CKD patients stage 3-5.

Protein-Energy Wasting Abolishes the Association between Fat Mass and Bone Mineral Density in End-Stage Renal Disease Patients

Ting Jia,[1] Sun-Hee Park,[1,2] Abdul Rashid Tony Qureshi,[1] Peter F. Barany,[1] Olof Heimburger,[1] Tobias Larsson,[1] Jonas Axelsson,[1] Bengt Lindholm,[1] Peter Stenvinkel.[1] *[1]Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden; [2]Div of Nephrol, Dept of Internal Medicine, Kyungpook National University Hospital, Daegu, Korea.*

Background: Low bone mineral density (BMD) is common in end-stage renal disease (ESRD) patients and leads to worse outcome. Many studies have demonstrated a positive association between fat mass and BMD. However, it is not known if protein-energy wasting (PEW) affects this association in ESRD.

Methods: 332 ESRD patients from an ongoing prospective cohort study including incident patients who were close to beginning dialysis replacement therapy were included. Total BMD was measured by dual energy X-ray absorptiometry (DXA) and expressed as T-score, indicating the number of standard deviations from the mean scores for 30-year old normal men and women separately. Fat mass (total fat mass, truncal fat mass and non-truncal fat mass) distribution was measured by DXA also. Subjective global assessment (SGA) was used as a surrogate of PEW. Spearman rank correlation analysis was used to determine the association between T-score and selected parameters.

Results: 100 patients had signs of PEW (SGA≥2), and these patients had lower BMD t-score compared to the non-wasting group (-1.09±1.18 vs -0.26± 1.31, p<0.0001,). BMD t-score positively correlated with truncal fat mass (r=0.2775, p<0.0001), non-truncal fat mass (r=0.2381, p<0.0001) and total fat mass (r=0.3017, p<0.0001) in non-wasted ESRD patients. However, in wasted patients these associations did not attain statistical significance (truncal fat mass, r=0.1604, ns; non-truncal fat mass, r=0.1538, ns; total fat mass, r=0.1564, ns).

Conclusions: Whereas BMD t-score positively correlated with truncal fat mass, non-truncal fat mass and total fat mass in non-wasted ESRD patients, no such associations were found in wasted ESRD patients. Our findings suggest that presence of PEW abolishes the normal and expected association between fat mass and BMD.

FR-PO1356

Proteinuria in Injection Drug Users Associated with Vitamin D Deficiency

Michelle M. Estrella, Gregory Kirk, Shruti H. Mehta, Todd Brown, Mohamed G. Atta, Derek M. Fine, Gregory Lucas. *Johns Hopkins University.*

Background: Proteinuria is common in injection drug users and HIV-infected persons. Vitamin D deficiency may contribute to proteinuria.

Methods: To study whether vitamin D deficiency is associated with higher risk of proteinuria (urine protein/creatinine ≥200 mg/g on 2 occasions) in this patient population at risk for kidney disease, we conducted a cross-sectional study in 277 HIV-infected and 647 HIV-uninfected individuals in the AIDS Linked to the Intravenous Experience Cohort.

Results: Most participants (73%) had 25-OH vitamin D levels<20 ng/mL. Deficient persons were likely to be black and less likely to be HIV or hepatitis C-infected versus vitamin D-replete persons (Table 1).

Table 1. Participant characteristics by vitamin D status

Characteristic	≥20 ng/mL	<20 ng/mL	P-value
Mean age, y (SD)	48.5 (8.9)	49.1 (7.6)	0.35
Male, %	67	65	0.59
Black, %	86	93	0.001
Injection drug use within 6 months,%	37	36	0.80
HIV-infected,%	37	28	0.008
Median CD4+ count, cells/mm^3 (IQR)	332 (189-584)	269 (154-449)	0.05
Median HIV RNA, copies/mL (IQR)	65.5 (<40-21800)	1570 (<40-218000)	0.06
AIDS history,%	6	4	0.20
ART within 6 months, %	62	50	0.06
Hepatitis C positive,%	91	83	0.003
Diabetic, %	11	10	0.70
Hypertensive,%	47	53	0.06
Mean proteinuria, mg/g (SD)	236 (382)	286 (751)	0.33
Median eGFR,mL/min|1.73m^2 (IQR)	98.2 (80.4-114.7)	102.5 (85.5-114.6)	0.20

Abbreviations: SD, standard deviation; IQR, interquartile range; ART, antiretroviral therapy; eGFR, estimated glomerular filtration rate

In univariate analysis, vitamin D was not associated with proteinuria (OR≡1.36 per log-1ng/mL lower, p≡ 0.40). After adjustment for age, race, HIV and hepatitis C serostatus, diabetes, hypertension, and CKD, lower vitamin D levels were associated with over a 2-fold higher risk of proteinuria (OR≡2.27 per log-1ng/mL lower, p≡0.04).

Conclusions: Vitamin D deficiency is prevalent in injection drug users, though fewer HIV-infected persons have low vitamin D levels. After accounting for CKD and CKD risk factors, lower vitamin D levels are associated with a higher risk of proteinuria. Studies are needed to determine predictors of vitamin D deficiency and whether vitamin D repletion ameliorates proteinuria in this patient population.

Plasma 25-Vitamin D, 1,25-Vitamin D, Parathyroid Hormone (iPTH), and Fibroblast Growth Factor 23 (FGF23) Levels Do Not Predict Cognitive Function in Patients with Advanced Chronic Kidney Disease (CKD)

Anna Jeanette Jovanovich,[1] Michel B. Chonchol,[1] Christopher B. Brady,[2] James S. Kaufman,[2] Alfred K. Cheung,[3] Jessica B. Kendrick.[1] *[1]University of Colorado Denver Health Sciences Center; [2]VA Boston Healthcare System; [3]VASLCHCS.*

Background: Little is known about the relationship of abnormalities of mineral metabolism with cognitive impairment in CKD patients.

Methods: We investigate the longitudinal association between 25-vitamin D, 1,25-vitamin D, iPTH and FGF23 levels and cognitive function in 605 patients with advanced CKD not requiring dialysis (n=247) and ESRD (n=358), aged, 67± 12 years who participated in a randomized clinical trial evaluating the effects of folic acid and B vitamins on death in subjects with advanced CKD. Cognitive function was measured with the telephone interview for cognitive status – modified, a brief telephone cognitive assessment similar to the mini-mental state exam. We used linear regression analyses to examine the association between abnormalities of mineral metabolism levels with impairment of cognitive function.

Results: Initial cognitive function was impaired in approximately 20% of patients regardless of treatment assignment (vitamin or placebo) or kidney disease status (advanced CKD or ESRD). Increasing log 1,25D levels were protective of cognitive impairment (β= 1.96±0.87; p=0.02) and increasing log iPTH ((β= -1.40±0.57; p=0.04) and log FGF23 levels (β= -1.04±0.29; p=0.004) were associated with worsening cognitive status in unadjusted analyses. In multivariate analyses including all predictor variables, age, gender, race, smoking, years of education, body mass index, treatment assignment, hypertension, diabetes and serum calcium and phosphate levels the associations between log 1,25-vitamin D, log iPTH, and log FGF23 were no longer significant (p>0.05 for each). Increasing log 25-vitamin D level was not associated with cognitive function in unadjusted and adjusted analyses.

Conclusions: In this study of patients with advanced CKD, plasma levels of 25-vitamin D, 1,25-vitamin D, iPTH and FGF23 were not independently associated with cognitive outcomes in patients with advanced CKD.

FR-PO1358

Mineral Metabolism and Physical Function in Patients Undergoing Hemodialysis Ranjani N. Moorthi,[1] Sharon M. Moe,[1] Joline L.T. Chen,[2] Carmen Castaneda-Sceppa.[4] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Boston University School of Medicine, Boston, MA; [3]Tufts Medical Center, Boston, MA; [4]Northeastern University, Boston, MA.*

Background: Chronic kidney disease patients have a phenotype of premature aging, inclusive of poor physical function. Declining eGFR is related to poor physical performance using both objective and subjective measures. Abnormalities of parathyroid hormone (PTH), Phosphorus (Pi), Calcium (Ca) as well as 25-hydroxy Vitamin D (25OHD) deficiency are widespread in dialysis patients and may play a role in poor physical / muscle function in these patients. In this analysis, we explore this potential relationship.

Methods: We examined the cross-sectional relationship of 25(OH)D, PTH, Pi, Ca and physical performance in the baseline population of a published RCT of low intensity exercise in 44 hemodialysis patients, using stored serum samples. Outcomes of interest were the Short Physical Performance Battery (SPPB), which includes measures of strength, endurance and balance and measures of lean body mass by Dual-energy X-ray absorpiometry (DXA). Leisure time physical activity was assessed by self report using the Physical Activity Scale for the Elderly (PASE).

Results: Serum samples were analyzed in 41 patients with median dialysis vintage of 2 years. 25OHD levels were less than 10 ng/ml in 38% of patients. A 10 pg/ml increase in PTH was associated with a 0.05 kg decrease in whole body lean mass (p=0.02) after adjusting for age, gender, randomization group, 25OHD, Ca and Pi. No relationship was noted between 25OHD, Ca or Pi and lean muscle mass. Also, no baseline mineral metabolism parameters were associated with SPPB or PASE scores.

Conclusions: We found a relationship between high PTH and low muscle mass by DXA. High PTH increases intracellular Ca in muscle, and therefore likely plays a role in muscle metabolism. Loss of muscle mass can be debilitating for CKD patients. We found no associations between 25OHD levels, Ca or Pi and muscle mass/ function or on measures of self report. This analysis provides further grounds for conducting interventional studies of agents to lower PTH in CKD patients to prevent loss of muscle mass.

FR-PO1359

Cholecalciferol Supplementation Does Not Affect Insulin Sensitivity in Non-Diabetic Patients with Moderate Impairment of Renal Function Hamid R. Dezfoolian, Ellen Christoffersen, Maria Svensson. *Kidney Diseases, Sahlgrenska University, Gothenburg, Sweden.*

Background: Reduced insulin sensitivity is a well-known phenomenon in end-stage renal disease (ESRD), but is also present at other manifestations of kidney diseases such as micro albuminuria, nephrotic syndrome and mild-moderate reduced renal function. Alterations in vitamin D metabolism have been suggested to influence the insulin resistance.

The aim of this study was to evaluate the potentially effect of 10 weeks high dosage vitamin D3 (cholecalciferol) supplementation in non-diabetic patients with moderate chronic kidney disease (CKD).

Methods: 24 patients with non-diabetic CKD stages 3-4 (Glomerular filtration rate (GFR) measured using Iohexol® clearance 15-60 ml/min/1.73m^2), low serum 25-OH-vitamin D levels (< 75 nmol/L) and elevated fasting serum insulin levels (>10 mU/L) were included in a randomized, placebo-controlled, two-way cross-over study to receive daily either 3200 IU (80 µg) vitamin D3 (cholecalciferol; TillVal D®) or placebo in 10 weeks. Insulin sensitivity was assessed at the end of each treatment period as M-value, i.e. glucose infusion rate divided by lean body mass (estimated with bio impedance) during the assumed steady state (60-120 min) using a hyperinsulinemic (40 mU/m^2/min) euglycemic (5.6 mmol/L) clamp.

Results: 19 (79%) patients (M/F 13/6, age 65.8±13.7 years, BMI 28.8±4.7 kg/m2, GFR 35±10.7 ml/min/1.73m2 , serum 25-vitamin D 51±15 nmol/L and fasting insulin 15±7 mU/L; mean±sd) completed both treatment and placebo periods. No significant difference in insulin sensitivity (mean M-values) was found between cholecalciferol supplementation and placebo (8.0±3.5 vs. 8.1±3.3 mg/kg lean body mass/min, p=0.89) despite significantly difference in mean serum 25-OH-vitamin D between the placebo and vitamin D3 periods (52±14 vs. 85±17 nmol/L, p <0001).

Conclusions: Preliminary analyses reveal that supplementation with high dosage vitamin D3 (cholecalciferol) does not alter insulin sensitivity (M-value) in patients with non-diabetic moderate impaired kidney function (CKD 3-4).

FR-PO1360

Hypomagnesemia and Glomerular Hyperfiltration in Diabetes Mellitus Type 2 P.C. T. Pham,[1] P.M. T. Pham,[2] P.T. T. Pham.[3] *[1]Nephrology, UCLA-OVMC, Sylmar, CA; [2]Medicine, GLA VA Medical Center, Sepulveda, CA; [3]Kidney and Pancreas Transplant, UCLA, Los Angeles, CA.*

Background: Glomerular hyperfiltration (GlomHyper) and hypomagnesemia are commonly observed in diabetes mellitus type 2 (DM2). We examine the relationship between DM2 GlomHyper and hypomagnesemia.

Methods: DM2 patients without known kidney disease evaluated at UCLA-OVMC during January-March 2001 were included. Data retrieved include serum creatinine, hemoglobin, hemoglobin A1C (HbA1C), routine electrolytes, lipid profiles, urinalyses, history of hypertension, and pharmacy profiles. Estimations of the presenting glomerular filtration rate (eGFR) were determined by the CKD-epi formula. Multivariate analyses were performed to determine if any clinical factors were associated with GlomHyper, defined as eGFR greater than 120 mL/min/1.73 m^2.

Results: There were 550 patients (54% females); mean age 57.5±11.0 years; eGFR 95.7±14.8 mL/min/1.73 m2. Twenty-nine patients had GlomHyper. GlomHyper had significant negative correlations with age, hypertension, serum calcium, and the use of aspirin, RAS inhibitors, and diuretics, and a positive correlation with HbA1C. Although the correlation between serum magnesium and GlomHyper did not reach statistical significance, it had a significant negative correlation with eGFR. Analysis of the interaction between magnesium and calcium levels (calcium x magnesium) revealed a more significant correlation with GlomHyper than either calcium or magnesium level alone, Pearson coefficients: -0.13 (p=0.008),-0.11 (p=0.03), and -0.08 (p=0.07), respectively. Another multivariate analysis revealed a significant correlation with lower magnesium levels and GlomHyper in the stratum with calcium levels below median, but not in the higher calcium stratum (coefficient: -0.27, p=0.0001).

Conclusions: The interaction factor (magnesium x calcium) revealed the strongest correlation with GlomHyper compared to either factor alone. We speculate that the DM2 GlomHyper induces urinary loss of both cations, but while hypocalcemia directly exacerbates GlomHyper *via* hypocalcemia-associated afferent arteriolar vasodilation, hypomagnesemia exerts an indirect effect *via* hypoparathryoidism-induced hypocalcemia.

FR-PO1361

Fibroblast Growth Factor 23 and Chronic Kidney Disease Progression Madhumathi Rao,[1] Joachim H. Ix,[2] Priyanka Jain,[1] Temitope Ojo,[1] Andrew G. Bostom,[3] Vaidyanathapura S. Balakrishnan.[1] *[1]Nephrology, Tufts Medical Center, Boston, MA; [2]Nephrology, University of California- San Diego, CA; [3]Renal Diseases, Rhode Island Hospital, Providence, RI.*

Background: Recent reports have suggested that fibroblast growth factor 23 (FGF-23) may be a risk factor for CKD progression. We assessed the relationship between circulating levels of intact FGF-23 and other mineral metabolism related factors (parathyroid hormone (PTH), serum calcium (Ca) and phosphate (P)) and their relationship to progression to end stage renal disease (ESRD).

Methods: We followed 196 clinically stable adult CKD (eGFR>15 ml/min/1.73m2) patients prospectively for a median of 35 months. Plasma levels of intact FGF-23 were measured by ELISA (Immutopics, San Clemente, CA).

Results: FGF-23 levels were above reference ranges in 6% with median (P25-P75) of 17 (11-29) pg/mL. The mean±SD age of the study population was 61±15 years, 57% were male, 19% African American and 32% diabetic; 19% of subjects were CKD KDOQI stage 1 and 2, 52% stage 3 and 29% stage 4. Hyperphosphatemia (P>4.5 mg/dL) was present in 9% and elevated PTH (PTH>65 pg/mL) in 58%. FGF-23 and PTH levels correlated inversely with eGFR and were positively correlated with each other (p<0.001). PTH levels were inversely related to serum Ca (r=-0.24, p=0.002) and FGF-23 levels to serum P levels (r=0.17, p=0.02). ESRD occurred in 35 participants, who had significantly lower eGFR and higher PTH and FGF-23 levels at baseline (all p<0.001). In a multivariate Cox model, the strongest predictors of CKD progression were eGFR, level of proteinuria and PTH at baseline (HR , 95% CI for doubling: 1.8, 1.2-1.8). FGF-23 levels were not related to outcome (HR 1.1, 95%CI: 0.7-1.8).

Conclusions: FGF-23 levels are inversely correlated with eGFR and contribute to abnormal mineral metabolism in CKD, but do not predict CKD progression. PTH may have a role in predicting CKD progression apart from its role as a risk factor for cardiovascular disease.

FR-PO1362

Differences between Hospitals in Attainment of Parathyroid Hormone Treatment Targets in Chronic Kidney Disease Do Not Reflect Differences in Quality of Care Mieke J. Peeters,[1,2] Arjan D. Van Zuilen,[3] Jan A.J.G. van den Brand,[1] Peter J. Blankestijn,[3] Marc A.G.J. Ten Dam,[2] Jack F. Wetzels.[1] *[1]Radboud University Nijmegen Medical Center, Nijmegen; [2]Canisius Wilhelmina Hospital, Nijmegen; [3]University Medical Center Utrecht, Netherlands.*

Background: Transparency in quality of care (QoC) is stimulated and hospitals are compared and judged on the basis of their performance on specific treatment targets. In patients with chronic kidney disease (CKD), QoC differed significantly between hospitals. [NDT 2010;25:3647-3654] This was not explained by available patient characteristics. In this analysis we explored additional parameters to explain differences between centers in attainment of PTH treatment targets.

Methods: Using baseline data of the MASTERPLAN study, we selected one of the worst (center A) and one of the best (center B) performing hospitals. Differences between the two treatment centers were analyzed from the year prior to start of the MASTERPLAN study until the baseline evaluation and determinants of PTH were assessed.

Results: 101 patients from center A (median PTH 9.9 pmol/L, 63 patients above target) and 100 patients from center B (median PTH 6.5 pmol/L, 32 patients above target), were included. In multivariate analysis kidney transplant status, MDRD-4, and treatment center were independent predictors of PTH. However, when MDRD-6 (which accounts for serum urea and albumin) was used instead of MDRD-4, the center effect was reduced. Moreover, after calibration of the serum creatinine assays treatment center no longer influenced PTH. Analysis of clinical practice did not reveal differences in PTH management between the centers. Notably, hyperparathyroidism resulted in a change in therapy in less than 25% of patients.

Conclusions: Results of hospital performance comparisons should be interpreted with great care. We show that differences in PTH control between center A and B are not explained by differences in treatment, but depend on incomparable patient populations and laboratory techniques. We propose the use of the MDRD-6 formula to estimate GFR in analyses in which kidney function plays a central role.

FR-PO1363

An Analysis of the Presence of Pathogens in Hemodialysis Subjects Using Ibis Technology: Results from the IMPACT Study Comparing Paricalcitol and Cinacalcet for the Treatment of Secondary Hyperparathyroidism (SHPT) Markus Ketteler,[1] Kevin J. Martin,[2] Mario Cozzolino,[3] David J. Goldsmith,[4] Amit Sharma,[5] Michael Amdahl,[6] Samina Khan.[6] *[1]Klinikum Coburg; [2]Saint Louis U; [3]Paolo Hosp; [4]Guy's Hosp; [5]Boise Kidney and Hypertension Inst; [6]Abbott.*

Background: Hemodialysis patients have an increased risk of acquiring infections due to immunocompromised state and repeated venipuncture. In a significant number of dialysis patients, the nature of infection remains obscure, leading to suboptimal treatment. Timely and accurate diagnosis of pathogens causing clinical or subclinical infections is essential to optimize care in this patient population.

Methods: IMPACT was a randomized 28 wk, phase 4, international, open-label study of subjects undergoing hemodialysis receiving IV (IV Stratum) or oral paricalcitol (Oral Stratum) with supplementary cinacalcet for hypercalcemia, or cinacalcet with low-dose vitamin D. Ibis, a technology combining PCR and electrospray ionization mass spectrometry, can detect a broad range of pathogens. Baseline and final samples were tested using Ibis. Ibis is currently an investigational research tool; the clinical implications and interpretations of these results are not established.

Results: In IV Stratum there were 62 paricalcitol subjects and 64 cinacalcet subjects (60% male, mean age:61±12 years, mean duration of dialysis:4.1±4.0 years). In Oral Stratum there were 72 paricalcitol subjects and 70 cinacalcet subjects (65% male, mean age:65±13 years, mean duration of dialysis:3.9±3.2 years). Ibis results are shown below.

	IV Stratum		Oral Stratum	
	Paricalcitol N=62	Cinacalcet N=64	Paricalcitol N=72	Cinacalcet N=70
Bacterial or Fungal infections, n				
Baseline	0	2	9	7
Final	6	6	8	4
Viral infections, n				
Baseline	1	1	3	5
Final	1	0	4	2

Conclusions: Overall, a variety of bacterial, fungal, and viral species were detected using Ibis. This is the first report of Ibis results in hemodialysis subjects. Once widely available, Ibis technology may help aid in the timely identification of pathogens leading to optimal treatment of infections.

Circulating Klotho Is Decreased in Pediatric Hemodialysis Patients Daniel Ranch,[1] Mazen Y. Arar,[1] Farzana Perwad.[2] *[1]Dept. of Pediatrics, University of Texas Health Science Center, San Antonio, TX; [2]Dept. of Pediatrics, University of California, San Francisco, CA.*

Background: Klotho is both a membrane-bound and circulating protein produced by the kidney. Membrane-bound klotho is a critical cofactor for the hormone fibroblast growth factor-23 to regulate phosphorus and vitamin D homeostasis. Circulating klotho protein has been detected in blood and urine in humans; however its functions are unknown. In mice, klotho deficiency induces vascular calcifications, osteopenia, and premature aging, a phenotype similar to chronic kidney disease (CKD). Wild-type mice with CKD have decreased plasma and urinary klotho compared to controls. Over-expression of klotho in these mice decreases soft tissue calcification, preserves renal function and delays progression of CKD. Recent studies in adult CKD patients showed a progressive decrease in urinary klotho with worsening kidney function, but whether serum klotho levels are affected by CKD is unknown in both adult and pediatric patients. In this study we hypothesized that circulating klotho is decreased in pediatric patients with CKD.

Methods: Twelve pediatric patients on chronic hemodialysis (4 males and 8 females, 2-17 yrs of age) and 9 healthy controls (1 male and 8 females, 3-12 yrs of age) were recruited.

Results: Serum klotho levels ranged from 1263 to 5265 pg/ml in healthy controls, and from 378 to 5389 pg/ml in hemodialysis patients. Mean serum klotho levels were lower in hemodialysis patients compared to controls (1542 ± 1569 vs 2741 ± 1355 pg/ml, $p<0.05$). In hemodialysis patients, serum klotho levels inversely correlated with age ($r=0.74$, $p<0.01$) and directly with serum calcium concentrations ($r=0.62$, $p<0.05$). No significant correlation was found between serum klotho and serum phosphorus ($r=0.33$), calcium-phosphate product ($r=0.23$), serum intact parathyroid hormone ($r=0.2$), serum 25(OH)D ($r=0.12$), or serum 1,25(OH)2D ($r=0.26$). No correlation between serum klotho levels and age or serum calcium was found in the control group.

Conclusions: These results prove our hypothesis that circulating klotho is decreased in pediatric CKD patients. Further studies are needed to determine the role of klotho in CKD pathophysiology.

FR-PO1365

Obesity-Related Glomerulopathy: Mast Cells Infiltration and Tubulointerstitial Lesion Xufang Wang, Ming-Chao Zhang, Chun-Xia Zheng, Honglang Xie, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.*

Background: Tubular atrophy and interstitial fibrosis are the most valuable predictors of renal function in obesity related glomerulopathy (ORG). However, the studies of ORG have been mainly focused on glomerular injury, and we know little about the mechanism of tubulointerstitial injury. Mast cells have been implicated in tubular injury in multiple kidney diseases, including diabetic nephropathy. To investigate if mast cells are also involved in tubulointerstitial injury of ORG, we examined mast cell infiltration and its correlation with tubular injury and renal function.

Methods: 39 patients with biopsy-proven ORG and 10 non-obese donors as control were included in this study. Tryptase and CD68 were used for detecting mast cells and macrophages by immunohistochemistry.

Results: Mast cells were detected in fibrotic interstitial areas mostly, but not within glomeruli. The density of mast cells was significantly increased in ORG compared with the control group, and it was well correlated with body mass index (BMI) ($r=0.364$, $P=0.023$), systolic blood pressure ($r=0.459$, $P=0.003$), serum creatinine ($r=0.637$, $P<0.001$), tubular atrophy ($r=0.47$, $P=0.003$) and interstitial fibrosis ($r=0.669$, $P<0.001$), in contrast, it was negatively correlated with eGFR ($r=-0.559$, $P<0.001$). Macrophages accumulated focally in the tubular interstitium with other infiltrated cells, and their density was positively correlated with the number of interstitial infiltrating cells ($r=0.476$, $P=0.002$). No correlation was found between the numbers of mast cells and macrophages. Multivariate regression modeling showed that the number of mast cells was the critical factor for eGFR ($R2=0.44$, $P=0.036$).

Conclusions: Our data show that patients with ORG have an increase in the number of interstitial mast cells, which was correlated positively with BMI, blood pressure, serum creatinine, and tubular injury, but negatively with eGFR, suggesting a role for mast cells in tubulo interstitial lesion. Further functional studies are required to determine the role for mast cells in tubular injury of ORG.

FR-PO1366

Fibroblast Growth Factor-23 Predicts Renal Failure Progression in Children with Chronic Kidney Disease Elke Wuehl,[1,2] Gianluigi Ardissino,[1] Tomasz F. Urasinski,[1] Salim Caliskan,[1] Franz S. Schaefer.[1,2] *[1]ESCAPE Trial Group; [2]Pediatric Nephrology, Center for Pediatrics and Adolescent Medicine, University of Heidelberg, Heidelberg, Germany.*

Background: Fibroblast growth factor-23 (FGF-23), a phosphaturic hormone involved in calcium phosphate homeostasis, appears to predict renal disease progression in adults with non-diabetic CKD (Fliser, JASN 2007).

Methods: To determine renal survival according to FGF-23 serum levels in children with CKD stage II-IV, 232 children participating in the ESCAPE trial (age 11.5±4 yrs, GFR 45±18 ml/min/1.73m²; underlying renal disease: hypo/dysplasia (N=164), glomerulopathies (N=28), hereditary or other (N=40)) were analyzed. All patients received fixed dose ACE inhibition and were followed prospectively by 2-monthly examinations for up to 5 years. The study endpoint was defined by eGFR loss >50% from baseline, GFR <10ml or start of renal replacement therapy. FGF-23 levels were determined at baseline (C-terminal human FGF-23 ELISA (Immutopics, San Clemente, CA, USA)).

Results: Serum FGF-23 levels (mean 52±81 RU/ml) were correlated with estimated GFR ($r=-0.47$, $p<0.0001$), the annualized change of eGFR at baseline (-0.21, $p=0.002$), the urinary protein-creatinine ratio (0.24, $p=0.0007$) and serum phosphate levels (0.20, $p=0.004$). The risk of attaining the renal endpoint was 59.5% in patients with serum FGF-23 in the upper distribution quartile, as compared to 26.9% in patients with lower levels ($p<0.0001$). The relative risk of attaining the endpoint was increased by FGF-23 independently of age, eGFR, proteinuria, serum phosphate and the underlying renal diagnosis. Each increase of FGF-23 by 50 RU/ml was associated with an increase in the relative risk by 19% (Hazard ratio 1.19, CI 1.035-1.367, $p=0.01$).

Conclusions: Serum FGF-23 is an independent predictor of progressive renal failure in children with CKD undergoing ACE inhibition. Further studies are needed to evaluate the interplay between FGF-23, parathyroid hormone, Vitamin D, calcium and phosphate levels on renal disease progression and cardiovascular morbidity and mortality.

Changes in Serum Uric Acid Have Reciprocal Effect on eGFR Change: A 10-Year Follow-Up Study of Community-Based Screening in Okinawa, Japan Kunitoshi Iseki. *Dialysis Unit, University Hospital of the Ryukyus, Nishihara, Okinawa, Japan.*

Background: Hyperuricemia is common among hypertension and metabolic syndrome therefore it could be a cause and result of these comorbid conditions. Few studies, however, have examined the relationship between the presence/absence of hyperuricemia and the changes in eGFR among the large cohort of general population.

Methods: We examined the participants who visited twice at 1993 and 2003 screening in Okinawa, Japan, and have data serum creatinine and uric acid. Total number was 16,796. Serum creatinine was measured by Jaffe method in 1993 and the enzymatic method in 2003 Serum creatinine was measured by the enzymatic method (converted to the value of measured by enzymatic method) and the estimated GFR (eGFR, ml/min/1.73m²) was

calculated by the Japanese Society of Nephrology (Matsuo S et al. Am J Kidney Dis 2009). Hyperuricemia (H) was defined as serum uric acid 7.0mg/dl and over in both sexes, and others were Normouricemia (N). Based on the absence or presence of H in 1993 and 2003 screening, we categorized into 4 groups as: Group 1 to 4 of N/N, H/N, N/H, and H/H. UA, serum uric acid (mg/dl). Trends were analyzed by analysis of variance.

Results: In all categories, ΔUA was significantly associated withΔeGFR, suggesting that increase (decrease) in serum uric acid was associated with decrease (increase) in eGFR. Subjects with persistent hyperuricemia (H/H) and developed hyperuricemia (N/H) showed higher decline in eGFR, whereas those with persistent normouricemia (N/N) and returned to normouricemia (H/N) showed slower decline in eGFR.

Relation between change in eGFR & UA

	Group 1	Group 2	Group 3	Group 4
Number	12794	1007	1453	1376
UA, '93/'03	4.9/5.1	7.9/6.1	6.1/7.8	8.0/8.2
eGFR, '93/'03	81.3/71.8	74.0/70.0	78.9/64.4	76.6/66.7
eGFRin '93	90 and over	60-89	45-59	<45
Number	4551	9970	2126	146
ΔeGFR/ΔUA	-3.0**	-3.0**	-2.6**	-1.5#

**P<0.0001, #P=0.020 by ANOVA

ΔeGFR/ΔUA* were calculated after adjusting for age, sex, and baseline eGFR.

Conclusions: Results suggest that maintaining normal range of serum uric acid is important to maintain eGFR.

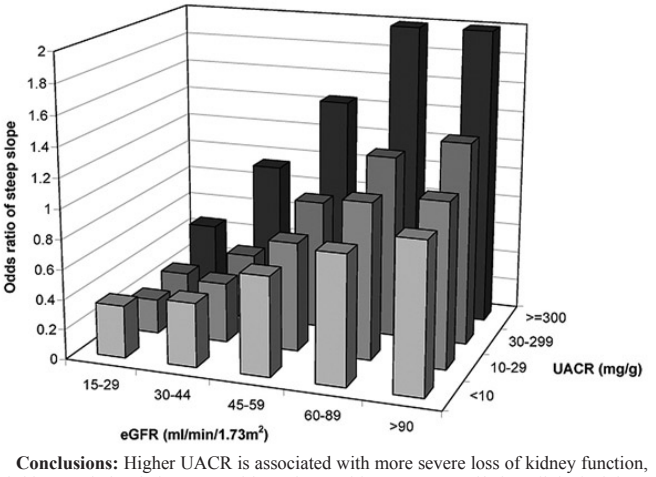
CKD Stage Modifies the Association of Urine Microalbumin-Creatinine Ratio (UACR) with Loss of Kidney Function in a Large Cohort of US Veterans

Csaba P. Kovesdy,[1,2] Evan H. Lott,[3] Jun Ling Lu,[4] Sandra M. Malakauskas,[1,2] Jennie Z. Ma,[2] Mark D. Okusa,[2] Kamyar Kalantar-Zadeh.[5] *[1]Salem VA Medical Center; [2]University of Virginia; [3]VA Informatics and Computing Infrastructure; [4]Salem Research Institute; [5]Harbor UCLA.*

Background: The association of albuminuria with the progression of CKD in patients with various stages of CKD is not well characterized.

Methods: We examined the association of UACR with the slopes or eGFR in a nationally representative cohort of 275,479 US veterans with at least 3 eGFR values recorded after 2005. Slopes were calculated using a median (interquartile range) of 8 (5-13) eGFR values over up to 5 years of follow-up. Associations of UACR with slopes overall and stratified by baseline CKD stage were examined in linear and logistic regression models. Models were adjusted for sociodemographics, comorbidities, blood pressure and laboratory variables.

Results: The median (interquartile range) of eGFR slopes was -1.25 ml/min/1.73m2/year (-3.85, 0.92). A 1-unit increment in UACR on natural-log scale was associated with -0.37 ml/min/1.73m2/year steeper slopes (95%CI: -0.38, -0.36; p<0.001) in unadjusted analyses and with -0.25 ml/min/1.73m2/year steeper slopes (-0.26, -0.23; p<0.001) after multivariable adjustments. A linear association of UACR with steeper slopes (defined as slopes <-4 ml/min/1.73m2/year) was seen in patients with eGFR ≥45 ml/min/1.73m2. In patients with eGFR 30-44 only UACR >300 was associated with steeper slopes, and in patients with eGFR 15-29 the association appeared U-shaped, with UACR <10 mg/g also showing an association with steeper slopes (Figure).



Conclusions: Higher UACR is associated with more severe loss of kidney function, and this association is incremental in patients with eGFR >45 ml/min. Clinical trials to examine the effect of lowering UACR to improve renal outcomes in early CKD stages are indicated.

Aristolactam-DNA Adducts in the Renal Cortex: Biomarkers of Internal (Environmental) Exposure to Aristolochic Acid

Kathleen G. Dickman,[1] Sandra Karanovic,[2] Ivana Vukovic-Lela,[2] Karla Tomic,[3] Damir Dittrich,[3] Zelimir Stipancic,[4] Robert Turesky,[5] Arthur P. Grollman,[1] Jovan Nikolic,[6] Bojan Jelakovic.[2] *[1]Stony Brook Univ., Stony Brook, NY; [2]Univ. of Zagreb, Zagreb, Croatia; [3]General Hospital Dr. Josip Bencevic, Slavonski Brod, Croatia; [4]General Hospital, Ozdak, Bosnia and Herzegowina; [5]NY State Dept. of Health, Albany, NY; [6]Clinical Center Serbia, Belgrade, Serbia.*

Background: Endemic (Balkan) nephropathy (EN) is a chronic tubulointerstitial disease that is highly associated with urothelial cell carcinomas (UUC) of the upper urinary tract. Both diseases have been linked to exposure to aristolochic acid (AA), a nephrotoxin and carcinogen produced by Aristolochia plants that grow in wheat fields in endemic sites and contaminate flour used to prepare bread. AA reacts with DNA to form aristolactam-DNA (AL-DNA) adducts that lead to A:T transversions in the tumor suppressor gene TP53. Due to inefficient repair, adducts persist for years in the renal cortex and thus serve as an exposure biomarker. Here, we present evidence linking AA exposure to UUC in endemic regions of Bosnia, Croatia and Serbia that harbor EN.

Methods: DNA was extracted from renal cortex and tumors obtained from 67 patients from endemic sites who underwent nephroureterectomy for UUC. Ten subjects from nonendemic sites served as controls. Renal cortical AL-DNA adducts were quantified by a ^{32}P-postlabelling assay. TP53 mutations in UUC were identified by chip-sequencing technology.

Results: Most endemic subjects had observed Aristolochia plants in their wheat fields in the past, and were therefore likely to have ingested AA-contaminated bread. We detected renal cortical AL-DNA adducts in 70% of the endemic cohort, and the chemical identity of these lesions was verified by mass spectroscopy. A:T mutations in TP53 were present in 25% of the endemic cases, and AL-DNA adducts were also found in 94% in these cases, emphasizing the close association of these two biomarkers. In contrast, neither AL-DNA adducts nor TP53 mutations were detected in nonendemic subjects.

Conclusions: Aristolochic acid is the primary causative agent of urothelial carcinomas of the renal pelvis and ureter in EN subjects.

Sustained-Release Tablets of Orally-Active Prostacyclin Analogue, Beraprost Sodium, for Patients with Non-Diabetic Chronic Renal Failure

Toshiro Fujita,[1] Akio Koyama,[2] Fumitake Gejyo,[3] Hideki Origasa,[4] Masanao Isono,[5] Takashi Kiriyama.[6] *[1]Nephrology and Endocrinology, University of Tokyo; [2]University of Tsukuba; [3]Niigata University; [4]Biostatistics and Clinical Epidemiology, University of Toyama; [5]Toray Industries, Inc.; [6]Astellas Pharma, Inc.*

Background: Increasing evidence points to the protective effects of prostacyclin on kidney in pathophysiological conditions. Several nonclinical studies have suggested beraprost sodium (BPS), an orally active prostacyclin analogue, prevents progression of chronic renal failure (CRF) by maintaining renal blood flow and attenuating tubulointerstitial hypoxia.

Methods: This study was designed as a randomized double-blind placebo-controlled comparative study in CRF patients [serum creatinine (SCr) 1.5 to 4.5 mg/dL (male), 1.3 to 4.0 mg/dL (female)] to evaluate the effect of sustained-release tablets of BPS (TRK-100STP) on the progression of non-diabetic CRF in patients. The patients were treated with TRK-100STP twice daily at 120 μg/day (n=36), 240 μg/day (n=41) or placebo (n=35) for 28 weeks after a 22-week run-in period in which the patients were treated with the placebo.

Results: The primary endpoint (difference in 1/SCr slope between the run-in period and treatment period for the 240 μg group) showed no statistically significant difference, however, a significant change was observed in the 120 μg group. Sub-population analysis of patients with a SCr of 2.0 mg/dL or higher showed a significant amelioration of the 1/SCr slope in the 240 μg group, and improvement of the eGFR in both active groups. The main ADRs observed in the 112 patients were headache and hot flush, which were expected from BPS's vasodilative effects, in addition to diarrhea and vomiting. However, none of the ADRs was clinically significant.

Conclusions: The results indicate that TRK-100STP has a beneficial effect on the progression of non-diabetic CRF, especially in patients with SCr of 2.0 mg/dL or higher. An international P-IIb/III study using a renal composite endpoint has already started in Japan, China, Hong Kong, South Korea, Taiwan, Malaysia, Thailand and Philippines.

FR-PO1371

Risk Factors for Renal Disease Progression after Orthotopic Liver Transplantation

Joseph Craig Longenecker,[1,2] Michelle M. Estrella,[2] Richard M. Ugarte,[2] Mohamed G. Atta.[2] *[1]Kuwait University Faculty of Medicine, Kuwait; [2]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Chronic kidney disease (CKD) is an important long-term complication in orthotopic liver transplantation (OLTx) patients. Few studies have assessed risk factors for CKD progression in post-Tx patients in the era of the Model for End-Stage Liver Disease (MELD).

Methods: Using medical record and UNOS registry data from May 1995 to April 2009, this non-concurrent prospective cohort study followed 419 primary OLTx adults at a tertiary hospital for up to 2 years. Pre-Tx and 3-, 6-, 12-, and 24-month post-Tx glomerular filtration rates were estimated (eGFR, using the CKD-Epi formula), along with other baseline clinical parameters. The pre-MELD era was defined as time until February 2002.

Results: The mean age was 51 years, 67% of the cohort was male, and 39% received OLTx in the pre-MELD era. The median pre-transplant and 12-month post-Tx eGFRs were 82 and 63 ml/min/1.73m2, respectively, representing a 20% decline in eGFR. After 24 months, the median eGFR was 59. Over 12 months, eGFR declined >33% in 31% of participants; and for those followed for 24 months, 42% declined >33%. Among those with pre-Tx eGFR ≥90, 60-89, and 30-59 ml/min/1.73m2, 70%, 52%, and 9% declined to a lower eGFR category over 12 months, respectively. Decline in eGFR primarily occurred in the first three months post-Tx. Progression to a lower eGFR category was associated with age>55 (versus age<45 years; adjusted odds ratio, AOR=8.0, p<0.001), and marginally associated with hemodialysis in the post-Tx period (AOR=4.8, p=0.08), and diabetes (AOR=1.9, p=0.09). No association was present with gender, race, hepatorenal syndrome, hypertension, or hepatitis C virus. After 24 months, eGFR decline >33% was lower in the MELD era compared to the pre-MELD era (AOR=0.5, p=0.03).

Conclusions: Renal function declined substantially after OLTx, and was associated with older age, post-Tx hemodialysis requirement, diabetes, pre-MELD era, and higher pre-Tx eGFR.

FR-PO1372

Fibroblast Growth Factor 23 Is a Risk Factor for Rapid Progression of Chronic Kidney Disease in Elderly Patients Eiichiro Kanda,[1] Sei Sasaki.[2] *[1]Tokyo Kyosai Hospital, Tokyo, Japan; [2]Tokyo Medical and Dental University, Tokyo, Japan.*

Background: The level of fibroblast growth factor 23 (FGF23) is increased at later stages of chronic kidney disease (CKD). FGF23 as a risk factor for the progression of CKD in elderly CKD patients has not been fully established.

Methods: 105 elderly CKD patients who had never used calcium or vitamin D supplements were enrolled in this study in Tokyo, Japan. We compared estimated glomerular filtration rate (eGFR) at the start of the study with that two months later and evaluated whether the decrease in eGFR was more than 5%. Urinary protein, serum calcium, phosphate, 1,25$(OH)_2$ vitamin D (1,25-VD), intact parathyroid hormone (iPTH), and FGF23 levels were measured at the start of the study. Factors were assessed using multivariate logistic model and regression analysis adjusted for age and gender.

Results: The following results were obtained: average age (SD), 73.2 (7.7) years; eGFR, 45.7 (24.1) ml/min; median urinary protein, 201.1 mg/day (IQR 61.9-700.6); median FGF23, 49.0 pg/ml (IQR 34.0-71.0); female, 32.4%. A decreased eGFR was observed in 22.9% of the patients. The percentages of patients with high FGF23 levels (>71.0 pg/ml) were as follows: Stage 3, 50%; Stage 4, 50%; Stage 5,100%. Univariate analysis showed that FGF23 level correlated with eGFR, urinary protein, serum calcium, phosphate, 1,25-VD, and iPTH levels (P<0.0001). Multivariate analysis showed that FGF23 level was associated negatively with eGFR (P<0.0001) and positively with urinary protein level (P=0.005).

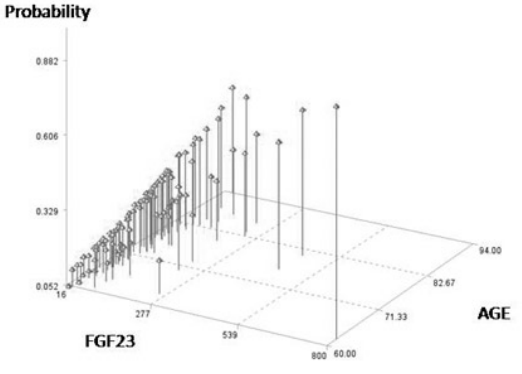

Figure Probability of the decrease in GFR increases according to FGF23 levels and age.

High FGF23 levels were associated with the decrease in GFR adjusted odds ratio, 4.35 (95% confidence interval 1.54-12.23).

Conclusions: In CKD patients, our findings suggest suggested that FGF23 level is associated with the progression of CKD. To detect and prevent the progression of CKD, FGF23 level should be monitored from an early CKD stage.

FR-PO1373

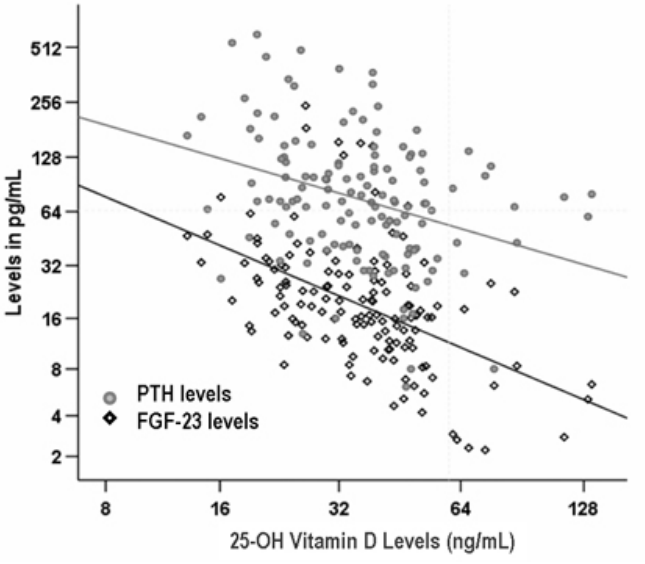
Vitamin D Deficiency in Chronic Kidney Disease and Its Role in Disease Progression Priyanka Jain,[1] Temitope Ojo,[1] Carmen Castaneda-Sceppa,[2] Vaidyanathapura S. Balakrishnan,[1] Madhumathi Rao.[1] *[1]Nephrology, Tufts Medical Center, Boston, MA; [2]Health Sciences, Northeastern University, Boston, MA.*

Background: 25-OH Vitamin D (VitD) deficiency is common in chronic kidney disease (CKD) and is associated with increased morbidity and mortality. We examined risk factors for VitD deficiency and its association with mineral metabolism parameters and CKD progression.

Methods: 196 clinically stable adult CKD (eGFR >15 ml/min/1.73m2) patients were followed for a median of 35 months. VitD levels were measured by liquid chromatography and tandem mass spectroscopy. Intact parathyroid hormone (PTH) in serum was measured by non-competitive chemiluminescent immunoassay and intact fibroblast growth factor 23 (FGF-23) in plasma by ELISA (Immutopics, San Clemente, CA).

Results: The mean±SD age of the study population was 61±15 years; 57% were male, 19% African American and 32% diabetic; 19% of subjects were CKD KDOQI stage 1 and 2, 52% stage 3 and 29% stage 4; 34% were VitD insufficient and 25% VitD deficient. VitD levels did not vary by age, gender, race or severity of CKD, but showed a significant inverse correlation with PTH and FGF-23 levels (r, p-value: -0.24, 0.002; -0.22, 0.002). A 10 ng/mL increase in VitD levels was associated with 0.9 (95% CI 0.8-1.0) pg/mL lower PTH levels (p=0.007) and 0.9 (95% CI 0.8-1.0) pg/mL lower FGF-23 levels (p=0.004). Low VitD levels appeared to be associated with a greater risk of CKD progression (HR, 95%CI per 10 ng/mL increase: 0.5, 0.4-0.8; p=0.002) on univariate analysis but not after adjustment for baseline kidney function and PTH levels.

Conclusions: In summary, low VitD levels are common in patients with CKD and appear to have an impact on regulatory factors involved in mineral metabolism. The implications for longer term outcomes need further study.



Funding: NIDDK Support

FR-PO1374

Comparison between the Steroid Pulse Mono-Therapy and the Combination Therapy of Steroid Pulse and Tonsillectomy for IgA Nephropathy Ayami Ochi, Takahito Moriyama, Kayu Nakayama, Kosaku Nitta. *Medicine, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Steroid pulse therapy reported by Pozzi C *et al.*has been recognized as long-term effective therapy for IgA nephropathy (IgAN). In this decade, the combination of tonsillectomy and steroid pulse therapy has been widely performed in Japan. However there is no report to compare those two therapies.

Methods: In this prospective cohort analysis, we compared clinical findings at renal biopsy, histological findings according to the Oxford classification, and the ratio of complete remission rate (RR) of urinary protein excretion (U-Prot) and urinary red blood cells (U-RBC) at one year after treatment between 26 newly diagnosed IgAN patients received tonsillectomy and steroid pulse therapy (TaSP group), and 15 newly diagnosed IgAN patients received steroid pulse mono-therapy (SP-group).We defined clinical remission as U-Prot< 0.5 g/gCr and U-RBC <5 counts/HF.

Results: Clinical and histological characteristics at baseline between both groups did not differ (TaSP vs. SP group; mean eGFR: 68.2 vs. 68.4 ml/min, mean U-Prot: 0.63 vs. 0.51 g/day, and mean U-RBC 25 vs. 20 counts/HF). RR of U-Prot analyzed by the Kaplan-Meier method did not differ between both groups (76.9 vs. 60.0 %). However RR of U-RBC was significantly higher in TaSP group than in SP group (80.0 vs. 33.0 %, Log rank test; P=0.0053). Moreover, RR of both U-Prot and U-RBC was significantly higher in TaSP group than in SP group (65.0 % vs. 13.3 %, Log-rank test; P=0.0029). The cox regression analysis showed that combination therapy was associated with clinical remission (HR:12.07, 95%CI: 2.80-90.91, P= 0.0003).

Conclusions: Combination therapy of tonsillectomy and steroid pulse therapy showed higher clinical remission rate of urinary findings at one year after treatment in comparison to the steroid pulse mono-therapy in patients with IgAN. Long term observation for renal survival should be analyzed in the future.

FR-PO1375

von Willebrand Factor Synthesis and Circulating Half Life and Osteoprotegerin Levels Are Progressively Elevated in Stage 3-5 CKD Patients Cynthia M. Pruss,[1] Spencer Barr,[1] Julie Grabell,[2] Angie Tuttle,[2] Michael A. Adams,[1] Jocelyn S. Garland,[2] Paula James,[2] Rachel M. Holden.[2] *[1]Biomedical and Molecular Sciences, Queen's University, Kingston, ON, Canada; [2]Medicine, Queen's University, Kingston, ON, Canada.*

Background: Von Willebrand Factor (VWF) and osteoprotegerin (OPG) are co-secreted by the endothelium and remain associated in the circulation. VWF and OPG are biomarkers for endothelial dysfunction and have been linked to cardiovascular disease but have not been evaluated longitudinally in individuals with CKD.

Methods: VWF antigen (VWF:Ag), VWF propeptide (VWFpp), OPG, and IL-6 levels were measured at baseline and at 4 years in a cohort of individuals with stage 3-5 CKD (N=54, mean age 62 years, 44% female) and were compared to age matched controls (N=38, 67.2 years, 58% female). The VWFpp to VWF:Ag ratio (VWFpp/VWF:Ag) was used to evaluate VWF circulating time, with ratios <1 representing increased VWF half life.

Results: At baseline, VWF:Ag, OPG and IL-6 were significantly higher than age-matched controls. Within the CKD cohort, there were significant increases in VWF:Ag, VWF:pp, VWFpp/Ag, and OPG between baseline and 4 years. The VWFpp/VWF:Ag ratio was significantly lower in CKD patients indicating an increase in VWF circulating half life. OPG levels correlated positively with the VWF:Ag ($p<0.001$), VWFpp ($p<0.001$), and negatively with GFR ($p<0.05$) when all CKD measurements were pooled.

Average Values for CKD Patients and Normal Controls

	CKD, Initial	CKD, 4 years	Normal Controls
VWF:Ag (U/ml)	1.67 ± 0.65	1.93 ± 0.72	1.32 ± 0.47
VWFpp (U/ml)	1.30 ± 0.43	1.75 ± 0.46	1.38 ± 0.29
VWFpp/VWF:Ag	0.83 ± 0.22	0.98 ± 0.30	1.17 ± 0.18
OPG (ng/ml)	2.91 ± 1.59	7.89 ± 4.23	1.13 ± 1.54
IL-6 (pg/ml)	7.38 ± 13.1	8.77 ± 17.41	2.42 ± 3.33
GFR (ml/min)	27.9 ± 10.6	23.0 ± 10.0	(-)

Values presented are average ± SD.

Conclusions: The role of endothelial dysfunction is emerging as a key contributor to cardiovascular disease. This study demonstrates that there is a significant increase in VWF synthesis in the earlier stages of CKD that is progressive over time. The relationship between endothelial dysfunction, VWF synthesis and OPG requires further study.

Genetic Variant of the Renin-Angiotensin-Aldosterone System (RAAS) and Renal Survival in Japanease Patients with Chronic Kidney Desease (CKD) Yasukazu Makino, Tadashi Konoshita. *Third Department of Internal Medicine, Fukui University School of Medicine, Eiheiji, Fukui, Japan.*

Background: Chronic kidney disease (CKD) is a public health problem, and inhibiting progression of CKD patients is a major task for the nephrology.The renin-angiotensin-aldosteron system (RAAS) may play pivotal role in the progression of CKD. And genetic polymorphism of RAAS has been reported to be associated with the development of some type of renal disease. However there has been few investigation of RAAS genetic variation and CKD.progression in a large population-based study.

Methods: We enrolled 1055 CKD patients who consulted nephrologist in our hospital between January, 1995, and December, 2010. All patients were Japanease. 486 (48.2%) reached end stage renal disease (ERSD) at an average age of 55.1±22.3 years. We estimeted the association between cumultive renal survival and five polymorphism of RAAS. The investigated genetic polymorphism are renin enhancer region (REN) C-5312T, angiotenogen (AGT) M235T, angiotensin converting enzyme ACE insertion/deletion, angiotensinIItypeIrecptor (ATR1) A1166C, and aldosterone synthase CYP 11B2 C-344T. For statistical analysis of the time course to ESRD,a cumulative survival analysis using the Kaplan-Meiyer method with log-rank test.

Results: Cumulative renal survival in CKD was significantly less in those with TT genotype in (REN C-5312T) [log-rank,P=0.0071 X2=7.380].There was no association between cumulative survival and M235T, ACEI/D,A1166C,and C-344T polymorphism.

Conclusions: REN C-5314T polymorphism may play a role CKD progression. And this polymorphism affect prognosis in CKD patient.

FR-PO1377

Circulating Bone Morphogenetic Protein-1 (BMP7) and Transforming Growth Factor-β1 (TGFβ1) as Potential Biomarkers for Renal Endpoint in Patients with Type 2 Diabetes Mellitus Muh Geot Wong,[1] Min Jun,[2] Usha Panchapakesan,[1] Mark Woodward,[2] Xinming Chen,[1] John P. Chalmers,[2] Vlado Perkovic,[2] Carol A. Pollock.[1] *[1]Kolling Institute of Medical Research, University of Sydney, NSW, Australia; [2]George Institute for Global Health, University of Sydney, Camperdown, NSW, Australia.*

Background: Albuminuria and reduced estimated glomerular filtration rate (eGFR) are known predictors of decline in kidney function for patients with diabetes mellitus. There is an increasing need for additional biomarkers which can predict renal outcome in the earlier stages of diabetes. Aims: To assess the baseline circulating value of TGFβ1 and BMP7 in patients with type 2 diabetes mellitus, and to establish the relationship of these markers with the risk of progressive diabetic nephropathy.

Methods: Serum samples from 124 participants of the ADVANCE Collaborative Group study, were studied. Cases were defined as those who developed a renal endpoint; ie. doubling of serum creatinine to at least 200umol/l, the need for renal replacement therapy, or death due to renal disease. Using propensity score methodology, controls were matched for age, sex, race, baseline estimated glomerular filtration rate (eGFR) (<60 vs. >60), urinary albumin:creatinine ratio (UACR), baseline blood pressure, baseline HbA1c, known macrovascular disease, history of retinopathy and treatment allocation. Enzyme linked immunosorbent assays were used to analyse total and active circulating TGFβ1 and BMP7 at baseline.

Results: Individuals with type 2 diabetes who developed renal endpoints (n=52) had a significantly higher circulating total TGFβ1, 12684.7 pg/ml vs. 7501.6 pg/ml, ($p<0.01$) and lower circulating BMP7 levels 6.89 pg/ml vs. 19.33 pg/ml ($p<0.0001$), compared to controls (n=72) respectively. Adjusted sensitivity analyses revealed TGFβ1 is a positive predictor (OR=1.9, 95% CI 1.30-2.30, p= 0.0002) and BMP7 is a negative predictor (OR=0.37, 95% CI 0.25-0.62 $p<0.0001$) for renal endpoints, independent of other conventional risk factors such as UACR and eGFR and each other.

Conclusions: Circulating BMP7 and TGFβ1 have prognostic potential in predicting poor renal outcomes in type 2 diabetes mellitus.

FR-PO1378

Aging and Progression of Chronic Kidney Disease Rachel Bregman, Renata De Souza Mendes, Carla C.S. Lemos, Frances Silva, Maria Ines Barreto Silva. *Nephrology, State University of Rio de Janeiro, Rio de Janeiro, Brazil.*

Background: Aging is a reality in the modern world and is pointed as a risk factor for Chronic Kidney Disease (CKD). The aim of this study was to analyze the progression of CKD in elderly.

Methods: We evaluated 236 patients (group1) with 60-74 years (y) and 72 patients with 75 years or more (group 2). Mean age (y) (±SD) was 68±4 and 80±4; time on treatment (y) was 3.8±3 and 3.6±3 respectively. Group 1 presented as baseline diseases hypertension (H) in 37% and diabetes mellitus (DM) in 41%; and group 2 H:53% and DM:30%. Patients were under treatment with a multidisciplinary team. Glomerular filtration rate was estimated (eGFR) by MDRD.

Results: At the time of referral MDRD (ml/min) was 32±12 (group1) and 36±13 (group 2). The rate of progression of CKD was -1.2±5 ml/min/y and -1.2±4 ml/min/y respectively. Proteinuria (mg/g creatinine) expressed as median (interquatile interval) was: all patients 281(125-961); group1: 288 (127-1088), group 2: 273 (95-890). Laboratory data showed all the parameters within the normal range. SBP was higher than 130mmHg in 22% and 46% in group1 and group 2 respectively. Analysing patients together SBP correlated ($p=0.033$) with the decrease of eGFR and proteinuria ($p=0.006$).

Population profile

	glucose mg/dl	SBP mmHg	DBP mmHg	albumin g/dL	cholesterol mg/dl	hemoglobin g/dl
60-74 years	108±24	136±17	79±7	4.3±0.3	191±38	12.3±1.8
75 years<	110±32	134±14	78±8	4.3±0.3	188±41	12.2±1.4

SBP:systolic blood pressure, DBP:diastolic

Conclusions: DM was less prevalent in older patients. High values of SBP suggest a decrease of arterial stiffness, and the correlation of high SBP with the decrease of eGFR and proteinuria, suggest endothelial dysfunction. The rate of decline of eGFR was below 4ml/min/y in 81% of the patients. We suggest that elderly respond well to CKD treatment implemented by a multidisciplinary team. Early referral (stage 3/4) was probably another point corroborating to retard progression of CKD. Therefore, we postulate that old people are likely to have a good prognosis of CKD, implicating in quality of life since the need of renal substitutive therapy is postponed.

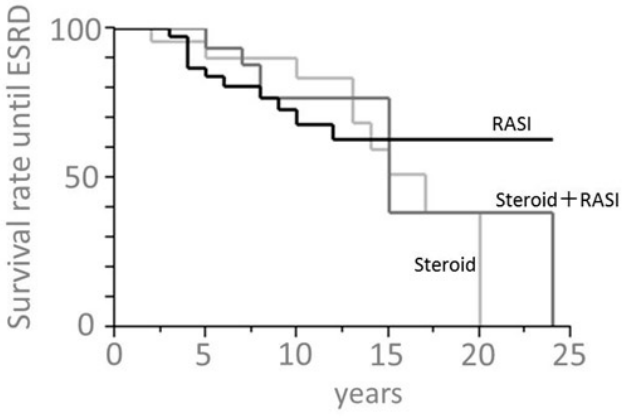
FR-PO1379

The Long-Term Beneficial Effect of Inhibitors of Renin-Angiotensin Aldosterone System (RASI) for Advanced IgA Nephropathy with Impaired Renal Function Takahito Moriyama, Ayami Ochi, Kayu Nakayama, Kosaku Nitta. *Medicine, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan.*

Background: The adaptation for steroid therapy and the effect of RASI for advanced IgA nephropathy (IgAN) patients with impaired renal function is still controversial.

Methods: In this retrospective cohort analysis, we divided 91 IgAN patients with an estimated glomerular filtration rate (eGFR) of less than 60 ml/min and proteinuria greater than 0.5 g/day and lower than 3.5 g/day into three groups: the RASI group (RASI: n=39), the steroid group (STEROID: n=22), and combination of RASI and steroid therapy group (COMBI: n=30). We analyzed the clinical and histological background, renal survival rate until progression to end stage renal disease, and the risk factors for progression.

Results: The clinical and histological backgrounds were not significantly different among the three groups (eGFR (ml/min) and proteinuria (g/day): RASI; 46.4 and 1.37, STEROID; 48.5 and 1.52, and COMBI; 46.2 and 1.58). Until 2 years after treatment, proteinuria and U-RBC decreased from baseline in the three groups ($P<0.001$), and the decline of reduction of proteinuria was highest in COMBI (RASI 21.6%, STEROID 23.7%, and COMBI 53.0% decrease from baseline U-Prot). However, the renal survival rate until ESRD was not significantly different among the three groups.



Proteinuria at 2 years after treatment was an independent risk factor for progression by Cox multivariate analysis (HR 1.38, 95%CI 1.06-1.79, P=0.0173), however treatment of steroid and combination therapy was not.

Conclusions: The beneficial effect of RASI on renal survival of advanced IgAN with impaired renal function is equal to that with steroids and combination of steroid and RASI. RASI may be a sufficient therapy for advanced IgAN with impaired renal function and the adaptation of steroid therapy should be considered carefully.

FR-PO1380

The Relationship of Urine Proteinuria to Outpatient "AKI" and Renal Progression Steven J. Rosansky,[1,2] James W. Hardin,[2] Frankie Richards,[1] Kathlyn Sue Haddock,[1] Ann M. O'Hare,[4] William F. Clark.[3] *[1]Dorn Research Institute, WJBD VA Hospital, Columbia, SC; [2]Dept of Biostatistics, School of Public Health University of SC, Columbia, SC; [3]London Health Sciences Center, University of S Ontario, London, ON, Canada; [4]Nephrology, VA Seattle, Seattle, WA.*

Background: Outpatient "AKI" and change of renal function per year as measured by MDRD e GFR may be important parameters in the management of CKD patients. Proteinuria has been reported to be associated with a higher frequency of inpatient ICD coded AKI. The current study examines the relationship of urine proteinuria, renal function decline and outpatient AKI

Methods: All outpatient creatinine and urinalysis data from through December 31, 2008, were obtained for patients with an initial serum creatinine of ≥ 1.3 mg/dl during 1989-2003. Lab data was utilized from 3776 patients who had at least one urinalysis and ≥3 creatinine values over ≥3 years. Each subject's creatinine values (same methodology throuhout study)were separated into 90-day consecutive windows. "AKI "was defined by sequential outpatient serum creatinine values where a second creatinine was ≥ 50 percent higher than a prior serum creatinine in a 90-day window. The change in outpatient 4 variable MDRD e GFR (ml/min/1.73m^2/year) was calculated using the average of the first and last creatinine values and was examined according to three urinalysis categories, using all urinalysis data per patient, no proteinuria; < 2plus proteinuria; and ≥ 2plus proteinuria. Growth curve analysis was utilized to examine the relationship of all covariates to renal function change.

Results: Patients had an average of 23 creatinine and 9.4 urinalysis measures during an average follow-up of 9.6 years. AKI occurred in 10.4% of the overall population,9.1 percent of whites and 14.3 percent of blacks(p<.001).

	Proteinuria		
	None	< 2+	≥ 2+
Urinalysis Group (n)	1995	1357	424
AKI Episodes (% of population)	5.4	13	26
Decline in MDRD eGFR (ml/min/1.73^2/yr)	0.71	1.37	2.18

for all results, p<.001

Conclusions: In conclusion, outpatient "AKI" occured more frequently in blacks than whites.Higher urinalysis protein levels were associated with more AKI episodes and faster decline in e GFR..

FR-PO1381

Determinants of Arterial Stiffness in Patients with Chronic Kidney Disease Stage 3 Natasha J. McIntyre,[1] Richard J. Fluck,[1] Chris W. McIntyre,[1,2] Maarten W. Taal.[1] *[1]Department of Renal Medicine, Royal Derby Hospital, Derby, Derbyshire, United Kingdom; [2]Department of Vascular Medicine, University of Nottingham, United Kingdom.*

Background: Early stage CKD is associated with increased cardiovascular (CV) risk but the underlying mechanisms remain uncertain. Arterial stiffness (AS) is associated with increased CV risk in advanced stages of CKD, but it is unknown whether AS is relevant to CV disease in early CKD. We therefore investigated AS in subjects with CKD stage 3 in a primary care setting.

Methods: 1741 patients with eGFR 59-30ml/min/1.73m^2; mean age 73±9 yrs, were recruited from Primary Care Practices for the Renal Risk In Derby (R^{2}ID) Study. A detailed medical history and clinical assessment was obtained as well urine and serum biochemistry testing. Carotid to femoral pulse wave velocity (PWV) was measured, as a marker of AS, using a Vicorder™ device (Skidmore Medical Ltd,UK).

Results: Univariate analysis revealed significant correlations between PWV and previously identified risk factors for CV disease such as age (r=0.443), systolic BP (r=0.330), Body Mass Index (r=-0.134), Log urinary Protein to Creatinine ratio(r=0.128), Waist to Hip ratio (r=0.122), Diastolic BP(r=0.083), eGFR (r=-0.067), Log High sensitivity CRP(r=0.066) and HDL Cholesterol (r=-0.058). PWV was significantly higher in males (9.6m/sec vs.10.3m/sec), diabetics (9.8m/sec vs.10.3m/sec), and those with a history of CV events (9.8m/s vs.10.3 m/sec). Multivariable liner regression analysis identified independent determinants of higher PWV (Table; R2=0.29)

Independent determinants of higher PWV

	β	p value
Age	0.407	<0.0001
Systolic BP	0.184	<0.0001
Body Mass Index	-0.120	<0.0001
Diabetes Mellitus	0.110	<0.0001
Diastolic BP	0.097	<0.0001
eGFR	0.060	0.008
HS CRP	0.049	0.028
Female Gender	-0.048	0.039
HDL Cholesterol	-0.049	0.041
Albumin to creatinine ratio	0.045	0.044

Conclusions: Age was the dominant determinant of AS in this cohort of elderly patients with CKD stage 3. Nevertheless, reduced eGFR, albuminuria and several factors associated with CKD (including hypertension, inflammation, and dyslipidaemia) were all also identified as independent determinants. Long term follow-up will investigate the importance of AS as an independent risk factor for CV events in this cohort.

FR-PO1382

Neutrophil/Lymphocyte Ratio Independently Predicts Cardiovascular Events in Patients with Moderate To Severe Chronic Kidney Disease Yalcin Solak,[1] Mahmut Ilker Yilmaz,[2] Alper Sonmez,[3] Mutlu Saglam,[4] Erdinc Cakir,[5] Hilmi Umut Unal,[2] Kayser Caglar,[2] Murat Karaman,[6] Seyid Ahmet Ay,[6] Mujdat Yenicesu.[2] *[1]Nephrology, Selcuk Uni., Konya, Turkey; [2]Nephrology, GATA, Ankara, Turkey; [3]Endocrinology, GATA, Ankara, Turkey; [4]Radiology, GATA, Ankara, Turkey; [5]Biochemistry, GATA, Ankara, Turkey; [6]Internal Medicine, GATA, Ankara, Turkey.*

Background: Cardiovascular (CV) diseases are leading cause of death in patients with chronic kidney disease(CKD).Neutrophil/Lymphocyte ratio(NLR) has been shown independently predict mortality and poor outcomes in patients with myocardial infarction, heart failure and advanced malignancy.We aimed to evaluate value of NLR in predicting fatal and nonfatal CV events in patients with stage 3-5 CKD.

Methods: Stage 3-5 CKD patients were followed-up for time-to-event analysis until occurrence of fatal or nonfatal CV events.Endothelium-dependent vaso-dilatation (FMD) and endothelium-independent vasodilatation(NMD) compared with NLR, CRP and routine laboratory data at baseline. Associations of NLR and endothelial dysfunction and other laboratory parameters were determined.Prevalence of fatal and nonfatal events according to NLR was calculated.Estimate survival time for each category are calculated.

Results: 225 patients included in the study (70 patients with stage 3,74 stage 4 and 81 stage 5 CKD).There was an inverse association between NLR and eGFR.Notably, while total WBC and neutrophil counts did not show significant difference across CKD stages, lymphocyte counts significantly decreased from stage 3 to stage 5 CKD. Multivariate analysis showed that associates of FMD only included NLR, diabetes, NMD, serum albumin and eGFR. During a mean follow-up period of 39 (2-42) months, 14 CV deaths, 52 non-fatal cardiovascular events were registered. Univariate and multivariate COX analyses showed that NLR was a significant independent predictor of fatal and nonfatal CV events (hazard ratio 1.58, p=0.001). When entire cohort divided by median NLR (2.81), 63 out of composit CV events occurred in patients with NLR above 2.81. Survival time was significantly longer in patients with lower NLR compared with patients with higher NLR.

FR-PO1383

Relationships between Physical Activity and Nutrition with Kidney Function in CKD Patients Robert G. Fassett,[1,3] Iain Robertson,[2] Madeline J. Ball,[2] Dominic P. Geraghty,[2] Jeff S. Coombes.[3] *[1]Renal Medicine, University of Queensland, Brisbane, Queensland, Australia; [2]Human Life Sciences, University of Tasmania, Launceston, Tasmania, Australia; [3]Human Movement Studies, University of Queensland, Brisbane, Queensland, Australia.*

Background: The Lipid lowering and Onset of Renal Disease (LORD) trial was a three-year randomised, double-blind, placebo-controlled trial investigating the effects of atorvastatin on kidney function in CKD patients. The study design included measures of physical activity and nutrition every nine months. The aim of this sub-study was to investigate the relationships between physical activity and nutrition with kidney function.

Methods: 132 patients with serum creatinine levels >120µmol/l, not taking lipid-lowering therapy and at all levels of proteinuria and serum cholesterol were enrolled. For this sub-study data was available for 120 patients and they were followed for a mean of 2.9 years. Physical activity and nutrition were assessed every nine months using the Active Australia questionnaire and 4-day diet diaries analysed with Foodworks software respectively. eGFR was calculated using the MDRD formula. The association (Odds Ratio) between a number of predictors and eGFR were estimated using repeated measures ordinal

logistic regression. An OR >1.00 indicates a positive association, and an OR <1.00 indicates a negative association. General linear modelling was used to determine relationships between physical activity and nutrition with the change in eGFR.

Results: eGFR was positively associated with phosphate intake (OR 2.3, 95% CI 1.5-3.4, P<0.001), and negatively with folate (OR 0.6, 95% CI 0.4-1.0, P<0.03). They were no significant associations between physical activity and kidney function. Weekly physical activity was not associated with changes in kidney function and there were no group differences (placebo = slope 0.19 (SD 3.51), atorvastatin = 0.41 (2.73)). There was a significant group difference (P=0.009) between time in high intensity physical activity and eGFR (placebo = -0.24 (2.52), atorvastatin = 0.72 (2.07)).

Conclusions: Atorvastatin improves kidney function in patients with chronic kidney disease undertaking high intensity physical activity.

FR-PO1384

Malnutrition-Inflammation Score Is Associated with Handgrip Strength in Non-Dialysis-Dependent Chronic Kidney Disease Patients Fernanda C. Amparo,[1, 2] Antonio C. Cordeiro,[1, 3] Juan J. Carrero,[3] Lilian Cuppari,[2] Bengt Lindholm,[3] Celso Amodeo,[1] Amanda G.M.R. Sousa,[1] Maria A. Kamimura.[2] *[1]Dante Pazzanese Institute of Cardiology, São Paulo, Brazil; [2]Nutrition Program, Federal University of São Paulo, São Paulo, Brazil; [3]Baxter Novum and Renal Medicine, Karolinska Institute, Stockholm, Sweden.*

Background: Handgrip strength (HGS), a marker of muscle function, predicts mortality in earlier stages of chronic kidney disease (CKD). Protein-energy malnutrition and inflammation are coexisting deleterious conditions commonly shared by CKD patients (pts) that affect muscle function. We investigated whether the Malnutrition-Inflammation Score (MIS), developed for dialysis pts, is associated with HGS in non-dialysis-dependent (NDD) CKD pts.

Methods: We cross-sectionally evaluated 166 pts with NDD-CKD stages 2-5 (59 [51-67] years; 63% men). MIS was calculated as previously described, excluding the count for dialysis vintage. HGS was assessed in the dominant arm. Anthropometric parameters, laboratory data and bioelectrical impedance analysis were recorded.

Results: HGS correlated positively with lean body mass index [LBMI] (r=0.40; P<0.01), body cell mass [BCM] (r=0.63; P<0.01) and 24h urinary creatinine clearance [24hCrCl] (r=0.42; P<0.01), and negatively with age (r = -0.18; P=0.02) and MIS (r=-0.42; P<0.01). Pts were divided into two groups according to the sex-specific HGS median, (low [n=80] and high [n=86] HGS). Those with lower HGS were older (63[55 – 69] vs. 57 [50 – 64] years; P < 0.01), had lower LBMI (19.8 ± 3.3 vs. 21.0 ± 3.3 kg/m2; P=0.02), lower BCM (23.5 ± 6.4 vs. 28.1 ± 6.3 kg; P<0.01), lower 24hCrCl (15.3 [10.3 – 25.6] vs. 24.4 [12.1 – 36.4] ml/min/1.73m2; P<0.01), and higher MIS (8 [5-10] vs. 5 [3-7]; P<0.01). Linear regression analyses showed an association between MIS and HGS in both, crude and adjusted models (Table).

Model	Covariates	Coefficients	95% CI	P	R^2
1	MIS	-1.36	-1.82 to -0.90	<0.01	0.17
2	1+ age, gender	-1.15	-1.54 to -0.76	<0.01	0.43
3	2+ diabetes, 24hCrCl	-0.92	-1.31 to -0.53	<0.01	0.48
4	3+ BCM, C-reactive protein	-0.55	-0.99 to -0.11	0.02	0.53

Conclusions: The MIS score was associated with HGS in our population, indicating that MIS may be used to predict muscle function in NDD-CKD pts.

Funding: Government Support - Non-U.S.

FR-PO1385

Recent Status of Vitamins B1, B2, and C in Japanese Patients with End-Stage Renal Disease Toshikazu Wada, Hideaki Iwasawa, Ami Hayashi, Yoshitaka Miyaoka, Toshiyuki Nakao. *Nephrology, Tokyo Medical University, Tokyo, Japan.*

Background: Water-soluble vitamin deficiencies have been recognized in end-stage renal disease (ESRD) patients. Recently, the numbers of ESRD elderly patients in Japan have been increasing. We investigated the status of vitamins B1 (VB1), B2 (VB2), and C (VC) in Japanese ESRD patients not receiving renal replacement therapy (RRT) and those receiving maintenance hemodialysis (HD), and determined the kinetics of these vitamins in HD patients. We also investigated the status of these vitamins in ESRD elderly patients.

Methods: Plasma VB1, VB2, and VC levels were obtained in 46 non-RRT ESRD patients (age: 63.0 ± 14.0 years). In 82 HD patients (66.2 ± 12.5 years), the plasma vitamin levels were obtained before and after a single HD session and at the start of the next HD session. Dialysis clearance of these vitamins was assessed.

Results: The proportions of patients whose plasma VB1, VB2, and VC levels were under the normal range were as follows - non-RRT patients: 13.0%, 13.0%, 41.3%; HD patients: 12.2%, 12.2%, 51.2%; those above the normal range were as follows - non-RRT patients: 15.2%, 30.4%, 19.6%; HD patients: 11.0%, 24.4%, 19.5%, respectively. The patients who were prescribed vitamins showed high plasma vitamin levels. The plasma VC level significantly decreased after a single HD session (P < 0.05), and significantly increased at the start of the next HD session (P < 0.05); the plasma VB1 and VB2 levels did not significantly change in patients without vitamin supplements. The mean dialysis clearance of VC was significantly higher than those of VB1 and VB2 (both P < 0.05). In the elderly patients without vitamin supplements, non-RRT patients had significantly lower plasma VB1 levels than non-elderly patients (P = 0.006), and HD patients had significantly lower plasma VC levels than non-elderly patients (P = 0.001).

Conclusions: Low plasma VB1, VB2, and VC levels were commonly found in ESRD patients, especially in elderly patients. Control of the balance between vitamin intake and loss based on individual requirements is essential for ESRD patients.

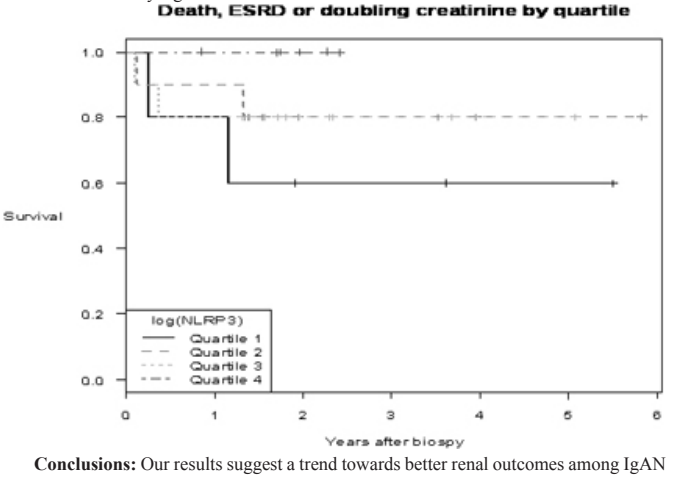
FR-PO1386

Association of NLRP3 Gene Expression with Human IgA Nephropathy Progression Xiangyu (Wendy) Wang, Justin Chun, Andrea Soo, Sofia B. Ahmed, Kiril Trpkov, Brenda Hemmelgarn, Daniel A. Muruve. *University of Calgary, Canada.*

Background: IgA nephropathy (IgAN) is characterized by variable clinical features and outcomes. The identification of reliable disease biomarkers will help define prognosis and therapeutic outcomes. Inflammation mediated by NOD-like receptors may be involved in the pathogenesis of IgAN. The increased expression of NLRP3 mRNA has been demonstrated in IgAN. However the association of NLRP3 gene expression with IgAN progression is an unexplored area.

Methods: Biopsies of 39 patients with IgAN from September 2003 to December 2007 were randomly chosen for analysis of NLRP3 mRNA expression by quantitative real-time PCR. Patients with advanced kidney disease(creatinine, Cr>300umol/L; n=3) and missing Cr (n=5) were excluded. A total of 31 cases of IgAN were analyzed. NLRP3 gene expression was analyzed as a logarithmic variable due to its non-normal distribution, and categorized into quartiles. The outcome was kidney failure, defined as a composite of doubling of serum Cr, ESRD or death. Subjects were followed from the time of their kidney biopsy to March 31, 2009 for the outcome of kidney failure.

Results: The mean age of the 31 subjects was 47 years, of whom 58% were male. The composite renal outcome was reached in 6 (19%) of the patients. The association between log NLRPs quartiles and survival is shown in Figure 1. There was an inverse and graded association between NLRP3 gene expression and kidney failure -- subjects with the highest NLRP3 gene expression were least likely to develop kidney failure, although the results were not statistically significant.



Conclusions: Our results suggest a trend towards better renal outcomes among IgAN subjeicts with higher NLRP3 mRNA expression. The presence of NLRP3 in IgAN may indicate reversible or treatment responsive inflammation although larger studies are required to confirm these findings.

FR-PO1387

Insulin Resistance and Type 2 Diabetes Patients in Difference Stage of Nephropathy Bancha Satirapoj, Ouppatham Supasyndh, Rattanawan Dispan, Prajej Ruangkanchanasetr, Panbubpa Choovichian. *Internal Medicine, Phramongkutklao Hospital, Bangkok, Thailand.*

Background: Diabetic nephropathy (DN) is one of the most serious complications of diabetes mellitus due to its high morbidity and mortality. In type 2 diabetic patients resistance to the action of insulin has been documented, but only a few studies have evaluated the risk of diabetic subjects with insulin resistance for developing DN. In this study we assessed insulin resistance in different stage of DN.

Methods: This is a cross-sectional study of 230 patients with type 2 diabetes. Patients were divided into three groups according to levels of urinary albumin-to-creatinine ratio (ACR) and urine protein: normoalbuminuria (ACR < 30 mg/g), incipient nephropathy (ACR 30-299 mg/g), and overt nephropathy (ACR ≥ 300 mg/g and/or persistent proteinuria). Insulin resistance was evaluated by homeostasis model assessment (HOMA-IR).

Results: There was a trend toward a higher HOMA-IR in overt and incipient nephropathy, but failed to reach statistic significance. Compared with the first quartile of HOMA-IR, the fourth quartile of HOMA-IR was associated with a significantly higher risk of overt nephropathy: crude odds ratio (OR) 4.14; 95% CI 1.69-10.11 and adjusted OR 5.79; 95% CI 1.72-19.52. In contrast, HOMA-IR quartiles were not significantly associated with the development of incipient nephropathy. Known duration of diabetes (adjusted OR 1.09; 95% CI 1.05-1.14), history of hypertension (adjusted OR 2.83; 95% CI 1.24-6.47), diabetic retinopathy (adjusted OR 6.48; 95% CI 3.01-13.96), and urinary albumin-to-creatinine ratio (adjusted OR 1.29; 95% CI 1.14-1.47), were also associated with development of diabetic nephropathy.

Conclusions: In addition to known risk factors of DN, high insulin resistance was independently associated with development of overt nephropathy in type 2 diabetes, but not incipient nephropathy.

FR-PO1388

Left Ventricular Hypertrophy, Endothelial Dysfunction & Inflammation in CKD Dimitrios J. Poulikakos, Ana Sofia Rocha, Nihil Chitalia, Juan Carlos Kaski, Debasish Banerjee. *Renal and Cardiology Units, St Georges Hospital, London, United Kingdom.*

Background: Left ventricular hypertrophy [LVH] is common in CKD patients; however the mechanism is not clear. Inflammation and associated endothelial dysfunction [ED] are present in CKD and predict adverse cardiovascular outcomes. The relationships of inflammation, ED and LVH in different stages of CKD; predialysis, dialysis and post kidney transplantation [KT] are unclear.

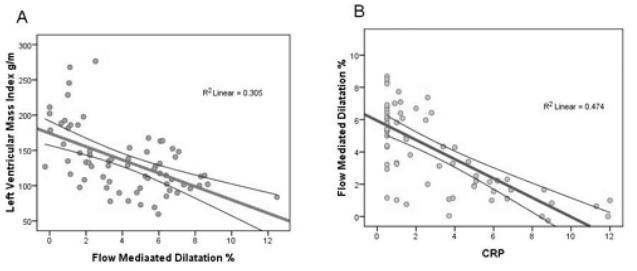
This study examined the relationship of inflammation, ED and LV mass in predialysis, dialysis and KT patients.

Methods: This study included 39 patients with different stages of CKD. Patients with heart failure, recent MI, infection and cancer were excluded. ED was measured using the brachial artery flow mediated dilatation [FMD]. Echocardiogram was used to estimate LV mass. LV mass index (LVMI) was calculated using Penn formula and indexed by height. Inflammation was measured using high sensitivity CRP.

Results: The clinical characteristics in 17 pre-dialysis, 9 haemodialysis and 13 KT patients were: age 56±12 [mean±SD] yrs, 33% female, 20% diabetes, 10% smokers, BMI 26±4 kg/m2, SBP 139±19mmHg, DBP 81±11mmHg, cholesterol 4.3±1.3mmol/L and Hb 12.7±1.6 g/L.

LVMI was high 157±45g/m and FMD was 2.6±2.1%. The hsCRP was 4.5±3.4mg/L. With increasing CRP the FMD decreased (r=-0.70,p<0.001) and with decreasing FMD, LVMI increased (r=-0.55, p<0.001), see figure 1. Increasing LVMI was associated with increasing CRP (r=0.51, p<0.001). In multivariate analysis the relationship between LVMI and FMD remained significant after adjusting for age, gender, diabetes, and hypertension (Adj. beta =-0.507, p=0.01).

Figure 1 Relationship of LV hypertrophy, endothelial dysfunction and inflammation



LVMI increases with worsening endothelial function in A; and FMD worsens with increasing CRP in B

Conclusions: The study demonstrates an association of inflammation, endothelial dysfunction and LV mass in all CKD patients.. This suggests Inflammation may have a role in the development of LV hypertrophy due to endothelial dysfunction.

FR-PO1389

A Multicenter Assessment of Depressive Symptoms in Patients Undergoing Hemodialysis: Women over 60 Years Should Receive the Attention and Monitoring Carmen B. Tzanno-Martins,[3] Fernanda Ribeiro Nisihara,[2] Geison Stein Meirelles Ramos,[1] João Paulo L.B. Martins,[1] Elzo R. Junior.[1] *[1]Home Dyalisis Center, São Paulo, Brazil; [2]Renal Class, São Paulo, Brazil; [3]Cine Integrado de Nefrologia, Guarulhos, Brazil.*

Background: Recent studies report that 10% to 25% of the general population has depressive symptoms. These symptoms are more frequent in women (15 to 20%) and elderly individuals (2 to 14%). These values can reach 30% in elderly nursing home residents.

Depressive symptoms can arise from psychosocial problems, or associated medical conditions such as cancer, chronic pain and chronic degenerative diseases, including Chronic Kidney Disease.

Recently, it has been shown that the prevalence of depression in patients with chronic kidney disease undergoing hemodialysis varies from 5% to 22%, with frequent occurrence of depressive symptoms with the onset of treatment.

Objective: To assess the prevalence of depressive symptoms using the Beck Inventory (screening test for diagnosis of depression) in chronic hemodialysis patients in 3 centers in the state of Sao Paulo, Brazil (n = 567) and correlate with demographics.

Methods: The Beck Depression Inventory was administered to a random sample of 70% of patients in three clinics (n = 397/567). We use statistical tests as chi-square with Fischer's post-test.

Results:

Final results of the Beck Depression Inventory applied to female patients

	under 60 years	over 60 years	Total
No depressive symptoms	80 (74.1%)	36 (54.5%)	116 (66.7%)
Depressive symptoms	28 (25.9%)	30 (45.5%)	58 (33.3%)
Total	108 (100.0%)	66 (100.0%)	174 (100.0%)

We conclude that the percentage of patients on chronic hemodialysis with depressive symptoms is higher than the general population (28.71%).

Conclusions: The data suggest that female patients had higher frequency of depressive symptoms compared to males regardless of age (25.9% X 21.7% under 60 years old, and 45.5% vs. 30.6% over 60 years old) (p <0.05). However, we found a greater number of female patients with depressive symptoms over the age of 60 years (25.9 X 45.5%) (p <0.05). Our data suggest that these patients should be accompanied with measures of psychological support during treatment.

Incidental Imaging Is Enough To Screen for Acquired Cystic Kidney Disease Laura J. Maursetter, Hemender Singh Vats, Micah R. Chan. *Department of Nephrology, University of Wisconsin-Madison, Madison, WI.*

Background: Acquired cystic kidney disease (ACKD) is a known complication of End Stage Renal Disease (ESRD). The pathophysiology is unknown but uremia seems to be a common factor. There is the potential for these cysts to turn malignant adding increased mortality to the ESRD population. The rate of ACKD increases with time on hemodialysis (incidence 50% at 3 years and 90% at 5-8 years) and it has been suggested that screening patients after they have received hemodialysis for three years is an ideal time to avoid complications and reduce mortality. The prevalence of renal cell carcinoma in ESRD patients has been debated (1.6 to 4%) but has been consistently shown to be higher than the general population.

Currently no official screening guidelines have been established to assess transplant or ESRD patients for ACKD. Given the complexity of ESRD patients and the comorbidities that are associated with this disease, we predict sufficient renal imaging may be incidentally done through work up of other medical issues to make additional screening unnecessary.

Methods: 80 ESRD patients from Wisconsin Dialysis Incorporated, located in Madison, Wisconsin, were randomly identified as having been on dialysis for more than 3 years. The electronic medical record of each patient was reviewed for the time period after the patient had reached 3 or more years on dialysis. All imaging studies were reviewed for any ultrasound, CT scan or MRI images that could have incidentally found suspicious renal cysts. Any images that did not report findings of the renal system were disregarded.

Results: There was a total of 670.2 dialysis years reported in the 80 ESRD patient charts that were reviewed. Evaluation of each electronic medical record determined that 57.5% of ESRD patients have imaging performed randomly that could incidentally diagnose renal disease. None of the indications listed for the imaging tests was for ACKD screening.

Conclusions: Although the prevalence of renal cell carcinoma is much greater in the ESRD population, when taking into account the incidental screening, cost of the screening test and rate of disease occurrence, it is not cost effective to implement a screening system.

FR-PO1391

Responsiveness to Erythropoiesis Stimulating Agents (ESA-R) Predicts ESRD in Non Dialysis CKD Patients Roberto Minutolo,[1] Bruno Cianciaruso,[2] Vincenzo Bellizzi,[3] Giuseppe Conte,[1] Luca De Nicola.[1] *[1]Nephrology, Second Univ. of Naples; [2]Nephrology, Univ. Federico II, Naples; [3]Nephrology, Univ. Hospital, Salerno, Italy.*

Background: RCTs on complete normalization of anemia in CKD show that lower ESA-R predicts poor cardiovascular (CV) outcome. It is unknown whether this association persists in clinical practice where the target of partial anemia correction is pursued.

Methods: We verified the prognostic role of ESA-R in 194 consecutive CKD patients, regularly seen in outpatient nephrology clinics, that started ESA in the 2002-06 period. Exclusion criteria were causes of anemia other than CKD or recent transfusion. ESA-R was calculated as $(Hb_1\text{-}Hb_0)$/time/ESA dose (g/dL/mo per 1000 U/wk of ESA). Renal death (ESRD or death) was recorded from the 1st control after starting ESA to Apr 2011.

Results: Age was 64±16 y, 48% were males, 34% had diabetes and 32% CV disease. At baseline, BMI was 27±5 kg/m2, BP 140±21/77±11 mmHg, phosphate [/A]4.3±0.9 mg/dL, TSAT 23±9%, ferritin 158±139 ng/mL, CRP 0.8±0.9 mg/dL. These variables were similar across tertiles of ESA-R while, from lower to higher tertile of ESA-R, GFR increased (22±12, 22±14, 28±13 mL/min/1.73m2 , P=0.01) and proteinuria decreased (1.1 [0.3-2.2], 0.6 [0.2-1.8], 0.5 [0.1-1.3] g/d P=0.04). First control occurred after 1.4±0.5 mo.

	ESA-R<0.08 (n=65)	ESA-R 0.08-0.24 (n=64)	ESA-R>0.24 (n=65)	P
Basal Hb (g/dL)	10.1±0.7	9.9±0.8	9.7±0.9	0.006
Hb 1st control (g/dL)	10.2±0.8	11.0±0.9	11.8±1.2	0.0001
First ESA dose (IU/wk)	4738±2041	5141±2525	4397±1937	0.16
During initial 6 months				
Months with Hb<11	4.0 [2.2-5.5]	1.5 [0.8-3.8]	0.8 [0.5-1.4]	0.0001
Mean ESA dose (IU/wk)	4761±2207	4719±1844	3482±1582	0.0001

During follow-up (median 2.9 yrs), 99 patients reached ESRD and 35 died. At Cox analysis (adjusted for age, gender, BMI, diabetes, CV disease, BP, GFR, proteinuria, Hb, CRP, phosphate), lowest tertile of ESA-R predicted renal death (HR 2.61, 95%CI 1.46-4.64) and ESRD (2.46, 1.27-4.78).

Conclusions: ESA-R predicts renal prognosis in CKD patients followed in nephrology clinics, where ESRD is the predominant outcome and ESA is commonly used at low dose. A potential role for persistent hypoxia in patients with more advanced renal damage is suggested.

FR-PO1392

AKB-6548, a New Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitor Increases Hemoglobin While Decreasing Ferritin in a 28-Day, Phase 2a Dose Escalation Study in Stage 3 and 4 Chronic Kidney Disease Patients with Anemia Charlotte Hartman,[1] Mark T. Smith,[2] Cindy Flinn,[1] Isaiah Shalwitz,[1] Kevin G. Peters,[1] Robert Shalwitz,[1] Volker H. Haase.[3] *[1]Akebia Therapeutics, Inc., Cincinnati, OH; [2]Kidney Care Associates, LLC, Augusta, GA; [3]Vanderbilt University Medical Center, Nashville, TN.*

Background: Current treatment of anemia associated with chronic kidney disease (CKD) with erythropoiesis-stimulating agents (ESAs) can lead to supraphysiological levels of circulating erythropoietin (EPO) that persist for days, a profile that may be associated with increased cardiovascular side effects. Therefore, a drug that provides moderate increases and reestablishes the diurnal variation in EPO may be a better treatment for patients with CKD. AKB-6548, a new short-acting hypoxia-inducible factor prolyl hydroxylase inhibitor, was selected to induce controlled daily rises in EPO that closely simulate physiologic responses to changes in altitude.

Methods: In a Phase 2a dose escalation study, 10 CKD patients received AKB-6548 once daily for 28 days. Dosing began at 400mg in CKD Stage 3 patients and 300mg in CKD Stage 4 patients. It increased by 100mg for each week that absolute reticulocyte count (ARC) did not increase by 18,000 above the baseline (BL) average.

Results: Dosing was generally well tolerated. Results, including both Stage 3 and 4 CKD patients, demonstrated that hemoglobin rose from 9.91g/dL at BL to 10.54g/dL by Day 29. Ferritin decreased from 334.10ng/mL at BL to 271.70ng/mL by Day 29. We conclude that AKB-6548 is well-tolerated and increases hemoglobin while decreasing ferritin in a dose-dependent manner in patients with Stage 3 or 4 CKD.

Conclusions: The consistent rise in hemoglobin and the concurrent fall in ferritin over the course of the study suggest an efficacious daily dose of AKB-6548 begins between 300 and 400mg.

	Baseline	Day 29	Paired t-test
Hemoglobin (g/dL)	9.91±0.63	10.54±0.89	p=0.0019
Ferritin (ng/mL)	334.10±209.82	271.70±181.31	p=0.0016

FR-PO1393

Hemoglobin Variability in Chronic Kidney Disease and Type 2 Diabetes in TREAT Julie Lin,[1] Marc A. Pfeffer,[1] Ajay K. Singh,[1] Nairne William Scott-Douglas,[2] Chao-Yin Chen,[3] Jerome A. Rossert,[3] Peter Ivanovich,[4] Giuseppe Remuzzi, Mark E. Cooper. *[1]Medicine, Brigham and Women's Hospital, Boston, MA; [2]Baker IDI Heart & Diabetes Institute, Melbourne, Victoria, Australia; [3]Amgen, Thousand Oaks, CA; [4]Nephrology, Northwestern University, Chicago, IL.*

Background: Sparse data are available on the natural history of hemoglobin (Hb) change in contemporary patients with CKD, anemia, and type 2 DM.

Methods: TREAT placebo arm patients (n=2,026) with type 2 DM, eGFR 20-60 ml/min/1.73 m^2, and Hb≤11 g/dL received "rescue" ESA therapy with darbopoetin at 0.45 mcg/kg/month (1/4 of active therapy start dose) only when Hb<9 g/dL.

Results: During mean f/u of 2.4 yrs, 1,113 (55%) did not have a Hb <9 g/dL nor received ESA. 913 (45%) had at least one Hb<9 g/dL and received "rescue", 321 (16%) received a single ESA dose while 334 (16%) got >4 monthly doses. Median Hb in non-"rescue" group was 10.7 g/dL at baseline (BL), 11.1 g/dL at 12 mos (n=829), and 11.2 g/dL at 24 mos (n=537). In the "rescue" group, median Hb was 10.0 g/dL at BL, 10.0 g/dL at 12 mos (n=684), and 10.1 g/dL at 24 mos (n=422). Besides lower baseline Hb (p<0.001), "rescue" group had lower eGFR (30 vs. 35 ml/min/1.73 m2), higher proteinuria (0.8 vs. 0.3 g/g Cr), ferritin (162 vs. 118 ug/L) and TSAT (23% vs. 22%) (all p≤0.001). Previous ESA use (13% vs 8%, p<0.001) and blood tx (11% vs 8%, p=0.02) were more frequent in the "rescue" group. During the trial, the rescue group was more likely to receive IV iron (25% v. 17%, p<0.001) and blood tx (35% v. 16%, p<0.001).

Conclusions: In the TREAT placebo arm, Hb remained stable with no or minimal ESA over 2.4 years follow-up, demonstrating that most patients with moderate anemia, eGFR 20-60 ml/min/1.73 m^2, and type 2 DM have stable Hb without implementing chronic ESA therapy.

FR-PO1394

Comparison of High Dose Ferric Carboxymaltose to Oral or IV Iron in Subjects with Iron Deficiency Anemia (IDA) Not Suitable for Oral Iron Lynda A. Szczech,[1] David B. Bregman,[2] David Morris,[3] Angelia Butcher,[2] Todd Koch,[2] Lawrence Tim Goodnough,[4] Jane E. Onken.[1] *[1]Duke Clinical Research Inst, NC; [2]Luitpold Pharmaceuticals, PA; [3]Webbwrites, NC; [4]Stanford Univ, CA.*

Background: Ferric carboxymaltose (FCM) is a non-dextran IV iron that permits larger infusions compared to other IV irons marketed in the US. This trial randomized patients with IDA to FCM or other intravenous iron products to evaluate effect on hemoglobin as well as hemodynamics and other safety parameters.

Methods: Patients eligible for this randomized controlled trial had IDA due to any etiology (menorrhagia, GI, or CKD) with hemoglobin (Hb) ≤ 11.0 g/dL at screening. Subjects in Cohort I underwent a 14 day (run-in) course of oral iron. Subjects with an increase in Hb ≥ 1 g/dL were not randomized. All other subjects were randomized to FCM (2 injections of 750 mg @ 100 mg/minute on Days 0 and 7) or oral iron for 14 more days. The primary efficacy endpoint was the change in Hb from baseline to highest value between baseline and Day 35. Subjects with a history of severe intolerance to oral, considered too anemic for oral, or were intolerant of oral iron during the run-in were assigned to Cohort II and randomized to FCM as above or another IV iron (IV standard of care [IVSOC]). IVSOC was iron sucrose for 90% of subjects. For both cohorts, safety was assessed for 120 days, including an adjudicated composite endpoint (death, myocardial infarction, stroke, unstable angina, congestive heart failure, arrhythmia, hypertension, or hypotension).

Results: In Cohort I, the change in Hb (g/dL) from baseline to highest value between baseline and Day 35 was 1.57 for FCM (N=244) vs. 0.80 for oral iron (N=251)(p = 0.001). In Cohort II, the change in Hb (g/dL) was 2.90 for FCM (N=245) vs. 2.16 for IVSOC (N=237)(p = 0.001). FCM was well tolerated. Results were consistent regardless of etiology or Hb status at baseline. There was no significant difference between FCM and comparator with respect to the composite safety endpoint

Conclusions: In this head to head trial, FCM was safe and effective for the treatment of IDA in subjects unsuitable for oral iron regardless of etiology or Hb status at baseline.

FR-PO1395

Red Blood Cell Survival in Patients on Maintenance Dialysis Frederiek E. Vos, John B.W. Schollum, Carolyn V. Coulter, Terence C. Doyle, Stephen Duffull, Robert J. Walker. *Medicine, University of Otago, Dunedin, New Zealand.*

Background: Shortening of red blood cell (RBC) survival contributes to the anemia of chronic kidney disease. The toxic uremic environment accounts for the reduced RBC life span. The impact of mechanical damage caused by hemodialysis to the shortened life span remains unclear. Reductions up to 70% in RBC survival have been reported in uremic patients. To date, no accurate, well-controlled RBC survival data exists in dialysis patients on different dialysis modalities and under erythropoiesis stimulating agent (ESA) therapy. Aim of this study was to determine RBC survival in hemodialysis (HD) and peritoneal dialysis (PD) patients compared to healthy subjects.

Methods: In this observational study, 14 HD patients and 5 PD patients were recruited. In addition, 14 healthy subjects matched according to age and gender to the HD patients were included to assess the normal range of RBC survival. All dialysis patients were either on ESA therapy or received regular iron supplementations. RBC survival was determined by radioactive chromium labeling and included correction for potential losses due to elution and vesiculation.

Results: Over 85% of dialysis patients were anemic (Hb 12.0 g/dL ± 1.1), hemoglobin concentrations were not significantly different among HD and PD subjects. The median RBC survival was significantly reduced by 20% in hemodialysis patients compared to healthy subjects (58.1 (54.6 – 71.2) vs 72.9 (63.4 – 87.8) days, p < 0.05). No difference was shown among the PD and HD group (55.3 (49.0 – 60.2) vs (58.1 (54.6 – 71.2) days, p = ns).

Conclusions: Despite current ESA therapy, reduced RBC survival contributes to CKD-related anemia, but the reduction is less than previously reported. Mechanical damage related to HD does not appear to contribute to the reduced RBC life span.

Funding: Government Support - Non-U.S.

FR-PO1396

Serum Hepcidin Levels Predict the Progression of Renal Anemia in Patients with Non-Dialysis Chronic Kidney Disease Kakuya Niihata,[1] Naohisa Tomosugi,[2] Takuya Uehata,[3] Tatsuya Shoji,[1] Yusuke Sakaguchi,[1] Akira Suzuki,[1] Terumasa Hayashi,[1] Noriyuki Okada,[4] Yoshiharu Tsubakihara.[1] *[1]Department of Kidney disease and Hypertension, Osaka General Medical Center, Osaka, Japan; [2]Medical Research Institute, Kanazawa Medical University, Kahoku, Japan; [3]Department of Nephrology, Osaka University Graduate School of Medicine, Suita, Japan; [4]Department of Clinical Laboratory, Osaka General Medical Center, Osaka, Japan.*

Background: We reported that hemoglobin (Hb) levels in patients with non-dialysis chronic kidney disease (CKD) were correlated with serum hepcidin (Hep-25) in the cross-sectional study. In this study, we examined whether Hep-25 levels predict the progression of renal anemia in patients with non-dialysis CKD.

Methods: Study design: Prospective observational cohort study. Materials: 355 ambulatory patients with CKD (stage1-5) in Osaka General Medical Center between

February 1, 2007, and June 30, 2007. Exclusion criteria: Those who had received renal replacement therapy, or those who had received erythropoiesis-stimulating agent (ESA) therapy within 6 months before the baseline evaluation. Outcome: Starting ESA therapy by the study end date, i.e., December 31, 2010. Predictor: Hep-25 levels. Statistics: Restricted cubic spline curve analysis. Hazard ratios were obtained using Cox proportional hazard models adjusted for age, sex, estimated glomerular filtration rate (eGFR) and Hb. We divided the patients by the median of ferritin levels and did the same analysis for each group.

Results: The mean age (standard deviation [SD]) was 61.8 (14.9) years;56.6% of the patients were men. The mean (SD) eGFR and Hb were 47.5 (25.0) mL/min/1.73m2 and 12.7 (1.8) g/dL.The total number of events was 80. The Cox proportional regression analysis showed that Hep-25 was a significant predictor of progression of renal anemia (p=0.04, Linearity p=0.09), In high ferritin group, Hep-25 was also a significant predictor (p=0.01, Linearity p=0.02) , whereas not in low ferritin group (p=0.09, Linearity p=0.04).

Conclusions: The Hep-25 levels significantly predict the progression of anemia in patients with non-dialysis CKD. Relationship between Hep-25 and progression of anemia varies according to ferritin levels.

FR-PO1397

Procalcitonin vs. C-reactive Protein for Predicting Infection in Chronic Kidney Disease Patients Ji Hyeon Park, Seung Tae Han, Jaeyoung Yoon, Hye Ryoun Jang, Jung Eun Lee, Wooseong Huh, Dae Joong Kim, Yoon-Goo Kim, Ha Young Oh. *Department of Medicine, Samsung Medical Center, Seoul, Korea.*

Background: Recently, procalcitonin (PCT) is used widely as a surrogate marker for predicting infection in chronic kidney disease (CKD) patients because nonspecific elevation of C-reactive protein (CRP) caused from chronic inflammation was reported in these patients. However, it is uncertain whether PCT is more accurate or cost effective for detecting infection compared to CRP in CKD patients. We investigated the clinical usefulness of PCT and CRP in patients with CKD stage 3-5.

Methods: Two hundred patients with CKD were included. In the group I, all 159 patients had culture-proven infection. Patients had CKD stage 3, 4, or 5 (n=30, 30, and 99). The 98 CKD stage 5 patients in group I were divided into three subgroups: no dialysis (n=31), hemodialysis (HD) (n=34) and peritoneal dialysis (PD) (n=34). A total of 41 patients (group II) were CKD stage 5 without infection. Group II were divided into two subgroups: HD (n=27) and PD (n=14). Simultaneously measured serum PCT and CRP levels were analyzed in each group.

Results: Both serum PCT and CRP levels were significantly higher in infection group compared to noninfection group.

Procalcitonin(PCT) and C-reactive protein(CRP) levels in each group

	Infection+		Infection-	
	CRP(mg/dl)	PCT(ng/ml)	CRP(mg/dl)	PCT(ng/ml)
CKD 5 with HD	9.80 (22.47)*	4.50 (42.01)†	1.29 (2.35)	0.48 (0.80)
CKD 5 with PD	3.30 (9.78)*	1.32 (10.74)*	0.50 (1.41)	0.41 (0.46)

Data represent median values (interquartile range).*P<0.001 versus infection-, †P=0.01 versus infection-.

Serum PCT and CRP showed distinct positive correlation in group I (r= 0.568, p<0.01) and weak positive correlation in grop II (r=0.357, p=0.012). PCT showed a sensitivity of 95.1% and a specificity of 19.5% predicting infection, whereas the sensitivity and specificity of CRP were 96.7% and 29.3%, respectively.

Conclusions: Our study demonstrates that measuring CRP is still accurate and cost effective for predicting infection in CKD patients. PCT may not be superior to CRP in regard to both diagnosis and cost benefit in CKD patients.

FR-PO1398

C.E.R.A. Once-Monthly (QM) Maintains Stable Hemoglobin (Hb) Levels in High-Risk (HR) Patients (pts) with Chronic Kidney Disease (CKD) Not on Dialysis: An Analysis of 4 European Trials Jean-Philippe Ryckelynck,[1] Bruno Cianciaruso,[2] Peter F. Barany,[3] Carlo A. Gaillard.[4] *[1]CHU Clemenceau, Caen, France; [2]University Federico II, Naples, Italy; [3]Clintec, Karolinska Institutet, Stockholm, Sweden; [4]University Medical Center, Amsterdam, Netherlands.*

Background: To explore Hb stability with C.E.R.A. QM in different types of HR pts with CKD not on dialysis converted from shorter-acting erythropoiesis-stimulating agents (ESAs).

Methods: Adult CKD pts not on dialysis were converted to C.E.R.A. QM to achieve target Hb values of 10.0-12.0 or 10.5-12.5 g/dL. 4 HR subgroups were defined based on epoetin or darbepoetin alfa dose (≥8000 IU or 40 μg weekly, respectively) before switching, median Hb fluctuations (≥0.31 g/dL) during screening, pre-existing cardiovascular (CV) risk factors (diabetes or cardiac), or median baseline NT-proBNP (≥670 pg/mL). Hb parameters were evaluated over 8 weeks after a 16-week titration period.

Results: Pts (n=245), median age 70 (range 24-93) years, were classified into subgroups as shown.

Subgroup criteria	Pts (n)
ESA dose	
High	74
Low	171
Hb fluctuations*	
≥0.31 g/dL	122
<0.31 g/dL	122
Pre-existing CV risk factors	
No	98
Yes	147 (diabetes 101, cardiac 89)
Baseline NT-proBNP**	
≥670 pg/mL	63
<670 pg/mL	71

*Data missing for 1 pt; **unavailable for 1 trial

Mean Hb in the HR subgroups was: 11.5 g/dL (high dose), 11.5 g/dL (Hb fluctuations ≥0.31 g/dL), 11.6 g/dL (CV risk factors), 11.4 g/dL (NT-ProBNP ≥670 pg/mL). The corresponding Hb fluctuations were: 0.41, 0.46, 0.45, and 0.47 g/dL. Hb stability (mean Hb within target or change from baseline ≤1 g/dL) was maintained by 82%, 75%, 73%, and 84% of pts, respectively. There were no significant differences in any of these parameters between the HR and low-risk groups. HR pts required higher C.E.R.A. doses. Cardiac and vascular adverse events (AEs) were more frequent in HR pts; differences in the frequency of serious AEs were non-significant.

Conclusions: C.E.R.A. QM maintains Hb stability across different types of HR pts not on dialysis.

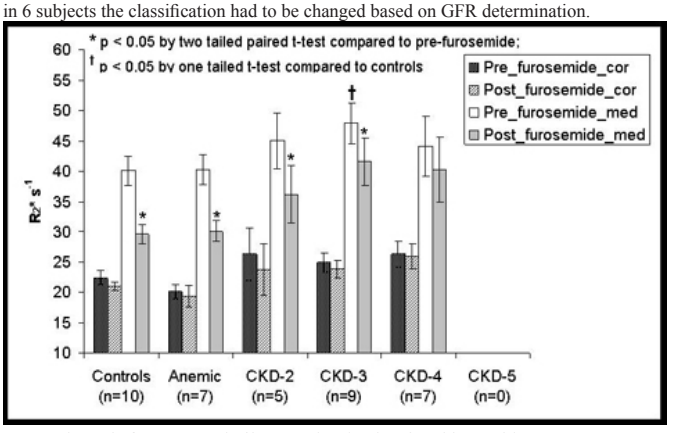
FR-PO1399

Blood Oxygenation Level Dependent MRI in Chronic Kidney Disease: A Preliminary Cross-Sectional Study Pottumarthi V. Prasad,[1] Muhammad Haque,[1] Luping Li,[1] Ujala Bokhary,[1] Rajiv Agarwal,[2] Stuart M. Sprague.[3] *[1]Radiology, NorthShore University HealthSystem, Evanson, IL; [2]Medicine, Indiana University, Indianapolis, IN; [3]Medicine, NorthShore University HealthSystem, Evanston, IL.*

Background: There is growing evidence for increased renal hypoxia in CKD and to support BOLD MRI as a useful tool for monitoring intra-renal oxygenation status. Here, a study was performed to compare BOLD MRI measurements in subjects at different stages of CKD.

Methods: A total of 38 subjects participated to-date: healthy control (n=10), anemic (n=7), CKD stage 2 (n=5), 3 (n=8), 4 (n=6), and 5 (n=3) based on eGFR. All subjects came to the study after an overnight fast and BOLD MRI studies were performed using a 3.0 T scanner and mGRE sequence before and after administration of 20 mg of furosemide (i.v.). R2* was used as BOLD parameter and is a reflection of the level of hypoxia. On a separate day, GFR was measured by iothalamate for accurate staging.

Results: Even though GFR by iothalamate and eGFR values were correlated (R2=0.7), in 6 subjects the classification had to be changed based on GFR determination.



As shown in figure, a trend of increased R2* values in subjects with CKD was apparent. Medullary R2* decreased significantly post-furosemide in all the groups (except CKD-4) and there was progressive reduction in magnitude of response in subjects with CKD.

Conclusions: Our preliminary experience with BOLD MRI measurements in patients with CKD suggest increasing levels of hypoxia both in cortex and medulla and lower medullary response to furosemide. This may suggest that increased hypoxia is probably related to reduced oxygen supply consistent with present understanding of the pathophysiology. Future studies should ask subjects to not take ACEi or ARBs prior to the BOLD MRI (Manotham K, ASN 2006 PO188) to observe potentially higher level of hypoxia.

Patients with CKD Have Reduced Levels of Circulating MicroRNA 145 and 155 Kraiwiporn Kiattisunthorn,[1] Neal X. Chen,[2] Kalisha O'Neill,[2] Xianming Chen,[2] Sharon M. Moe.[2,3] *[1]Medicine, Faculty of Siriraj Medical School, Mahidol University, Bangkok, Thailand; [2]Medicine, Indiana University School of Medicine, Indianapolis, IN; [3]Roudebush Veterans Affairs Medical Center, Indianapolis, IN.*

Background: Atherosclerotic cardiovascular disease is highly prevalent across the spectrum of CKD, especially in dialysis patients. MicroRNAs (miRNAs) can modulate cellular proliferation, differentiation and apoptosis and are shown to be associated with cancer and cardiovascular disease. A recent study has demonstrated that circulating hsa-miR-145 and hsa-miR-155 expression decreased in non CKD patients with cardiovascular disease (CAD). The objective of the current study is to determine the miRNA profile in normal and CKD patients with or without CAD.

Methods: miRNAs were isolated from 5 different pooled serum collections from healthy volunteers and 5 different pooled samples from hemodialysis patients by QIAzol Lysis Reagent and miRNeasy Mini Kit (Qiagen). Quantitative real-time PCR was performed to determine the expression of miR-145 and miR-155 using specific primers and normalized by U6 SnRNA.

Results: The results demonstrated that compared to healthy controls, miR-155 was down-regulated by 68% in hemodialysis patients. We also collected serum from CKD patients and found there is 23% decrease for miR-145 and 49% decreased for miR-155 ($p=0.04$) in the serum of stage 4 CKD patients with CAD compared to those of sex and age-matched stage 4 CKD patients without CAD. There was no difference in age, diabetes, albumin, calcium or phosphorus, but PTH was higher in those with CAD.

Conclusions: Circulating miR-155 levels were significantly lower in dialysis patients than that in healthy controls. Furthermore, CKD patients with CAD had decreased miR-145 and miR-155 compared to those without CAD. These results suggest that miR-145 and miR-155 may be novel biomarkers of CKD and CAD. Further studies are needed to validate these results.

Urinary Excretion of Hepcidin 20, 22, and 25 Is Dependent on Iron Storage but Not on Each Serum Level Takahiro Kuragano, Hiroshi Nonoguchi, Takeshi Nakanishi. *Division of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.*

Background: We have already demonstrated that serum hepcidin-25 is dependent on iron storage but not inflammatory cytokines in hemodialysis patients without apparent inflammation. Recently, enhanced urinary hepcidin 25 excretion in patients with acute kidney injury has been suspected as an index of the tubular damage. To clarify the kinetic of hepcidin isoform in predialysis patients and the renal handling of hepcidin, we evaluated serum and urinary hepcidin isoform levels in patients with various stages of chronic kidney disease (CKD).

Methods: We measured serum and urinary levels of hepcidin 20, 22, and 25 in 46 predialysis CKD patients and 10 healthy controls by LC-MS/MS methods. Serum levels of iron, TIBC, transferrin, ferritin, creatinine (Cr), urea nitrogen (UN), IL-6 and TNF-α levels were measured. Urinary levels of β2-microglobulin (MG), N-acetyl-β-D-glucosaminidase (NAG), Liver type fatty acid binding protein (L-FABP), and albumin were also measured. Urinary level of each hepcidin isoform was normalized by Cr.

Results: There were no significant differences in serum hepcidin isoform or urinary levels between control and CKD patients. Serum levels of hepcidin 20, 22, and 25 were significantly correlated each other. However, there was no significant correlation between serum and urinary levels of each hepcidin isoform. Serum hepcidin 20 ($p<0.01$,$R=0.67$), 22 ($p<0.01$, $R=0.60$), and 25 ($p<0.01$, $R=0.62$) levels were significantly correlated with serum ferritin levels, but not with serum levels of creatinine, UN, IL-6, and TNF-α. Urinary hepcidin 20 ($p<0.01$, $R=0.67$), 22 ($p<0.01$, $R=0.60$) and 25 ($p<0.01$, $R=0.62$) levels were also significantly correlated with serum levels of ferritin, but not with urinary β2MG, NAG, FABP and albumin.

Conclusions: In CKD patients, there was no significant correlation between serum and urinary hepcidin isoform levels. Furthermore, each hepcidin isoform in serum as well as urine was faithfully correlated with iron storage but not with renal function, tubular damage, or inflammatory conditions. Further clarification regarding renal handling of hepcidin needs to be determined.

FR-PO1402

The Effect of Dietary Magnesium on Vascular Calcification and Erectile Dysfunction in a Rat Model of Chronic Kidney Disease Alexis Jozefacki,[1] Maria Tina Maio,[1] Kristin M. McCabe,[1] Navid Shobeiri,[1] Mason Curtis,[1] Spencer Barr,[1] Rachel M. Holden,[1,2] Michael A. Adams.[1] *[1]Department of Biomedical and Molecular Sciences, Queen's University, Kingston, ON, Canada; [2]Department of Medicine, Queen's University, Kingston, ON, Canada.*

Background: Erectile dysfunction (ED) is highly prevalent in patients with chronic kidney disease (CKD). We have previously shown that the pudendal artery (PA) is critical to the vasculogenic erectile response and that this artery is prone to vascular calcification (VC). Magnesium (Mg) has been shown to inhibit VC in vitro. We determined the effect of high dietary Mg on VC in the PA and on the associated erectile response in a rodent model of CKD.

Methods: Male Sprague-Dawley rats (375-400g) received a 0.25% adenine diet containing either control Mg (0.05%; n=8) or high Mg (0.2%; n=8) for 5 weeks. The o-cresolphthalein complexone method was used to assess the Ca content in the PA. Erectile response (average # of erections per 30 minute period) was assessed at weeks 1 and 5 using an apomorphine bioassay.

Results: The mean (SD) creatinine was 378(85) uM. Animals receiving the high Mg CKD diet had significantly higher ($p<.05$) levels of serum Mg compared to the control Mg diet. The Ca content in the PA was significantly lower in the high Mg group (23.75±14.6 nmoles Ca/mg tissue; $p<0.05$) than in the control Mg group (107.4±95.8 nmoles Ca/mg tissue). The Mg:Ca ratio in the PA decreased as Ca content in the PA increased and a plateau was attained as calcification progressed. Erectile responses were normal (>2.5 erections/30 mins) at week 1. At 5 weeks, the control Mg group had a significant decline in erectile response compared to both week 1 ($p<0.05$) and the high Mg group ($p<0.05$). The inverse correlation between PA Ca content and erectile response ($r=-0.7$) was close to attaining significance ($p=0.06$).

Conclusions: These results demonstrate that high dietary Mg inhibits VC in the PA and attenuates the decline in erectile responses observed in this rodent CKD model that may be due, in part, to the reduction in Ca content. Further studies are necessary to determine the mechanism by which Mg inhibits PA calcification and attenuates the progression of ED.

FR-PO1403

Uremic Toxins May Hange the Pharmacokinetics of Erythromycin in Healthy Volunteers, Chronic Kidney Disease and End-Stage Renal Disease Lynda A. Frassetto, Sam H. James, Hong Sun, Maribel Reyes, Leslie Benet. *UC San Francisco.*

Background: Elimination of non-renally excreted drugs is altered in chronic kidney diease (CKD); non-renal (hepatic) clearance (CLh) increases for some drugs and decreases for others. We hypothesize that drugs that require transporters for uptake or excretion may be affected by circulating uremic toxins thereby changing pharmacokinetic (PK) parameters. We studied the PK of E in healthy controls (HC), CKD and ESRD patients on hemodialysis (HD). We previously demonstrated that the uremic toxin carboxy methylpropylfuranpropanoic acid (CMPF) inhibits the transport of both E and its metabolite N-demethyl E and indoxyl sulfate (IS) inhibits the metabolism to the metabolite. CMPF and IS correlated significantly and inversely with CLh of E; CMPF $r= -0.46$, IS $r= -0.44$, both $p<0.05$.

Methods: We studied 12 CKD, 12 ESRD, and 12 HC subjects. eGFR was calculated using the MDRD equation. HD patients were studied on non-dialysis days. Each subject took 1 oral dose of E (250mg for HC and ESRD, 125mg for CKD; all data was dose adjusted). PK blood samples were drawn at 0, 0.5,1, 1.5, 2, 4, 6, 8, 10, 12, 14, and 24 hours (h). Urine samples were collected at 4 h intervals for 24 h. Plasma and urine concentration for E and N-demethyl E were determined by LC-MS/MS. Values expressed as mean ± SD.

Results: eGFR (mL/min/1.73m2): HC 86±11; CKD 28±7; ESRD ~0.

table1

	E			N-demethyl E		
	HC	CKD	ESRD	HC	CKD	ESRD
Cmax, ng/mL	473±297	568±370	764±529	38±26	35±21	*#65±51
T1/2, h	3.7±2.5	*7.8±5.3	*#5.5±2.7	3.6±1.9	4.8±2.2	*5.6±3.6
AUC0-∞, ng/mL*h	1173±789	*2230±1696	*2309±1805	120±71	192±136	*298±241
CLr, L/h/kg	0.04±0.01	*0.01±0.01	—	—	—	—
V/F, L/kg	22±12	*30±27	18±12	—	—	—
CL/F, L/h/kg	5.59±5.32	3.28±3.45	3.18±2.99	—	—	—

Apparent volume of distribution, V/F; * $p<0.05$ vs HC; # $p<0.05$ vs CKD

The metabolite/parent AUC was significantly greater in the ESRD than the CKD group (0.13±0.08 vs. 0.08±0.03, $p=0.04$).

Conclusions: Oral CL (CL/F) for the CKD and ESRD patients is the same suggesting the effect of uremic toxins on hepatic elimination is similar in both CKD and ESRD. In only the CKD patients the uremic toxins have a further effect increasing V/F, prolonging T1/2 and decreasing production of the metabolite.

Comparative Analysis of CKD-EPI, MDRD, and AASK-MDRD Estimations of Glomerular Filtration Rate in a HIV-Infected Population Tahira P. Alves,[1] Pingsheng Wu,[2] Talat Alp Ikizler,[3] Timothy Sterling,[4] Samuel Stinnette,[4] Peter Rebeiro,[4] Suvro Ghosh,[1] Todd Hulgan.[4] *[1]Medicine, Nephrology, University of Texas Health Science Center and Audie L. Murphy VA Hospital, San Antonio, TX; [2]Medicine and Biostatistics, Vanderbilt University Medical Center, Nashville, TN; [3]Medicine, Nephrology, Vanderbilt University Medical Center, Nashville, TN; [4]Medicine, Infectious Diseases, Vanderbilt University Medical Center, Nashville, TN.*

Background: Chronic kidney disease (CKD) is common among HIV-infected persons (HIV+) and very few studies have compared creatinine-based estimates of glomerular filtration rates (eGFR) in HIV+ persons.

Methods: We compared the MDRD, CKD-EPI, and AASK-MDRD (sub analysis of HIV+ blacks) equations in calculating eGFR level and the subsequent categorization into CKD stages 1-5. Wilcox signed rank test, Intra-class correlation coefficient (ICC), and Bland-Altman plots were used to compare the agreement of CKD-EPI vs. MDRD vs. AASK-MDRD (subanalysis of HIV+ blacks).

Results: Among the 2468 individuals included in this cross-sectional observational cohort study, 21% were female and 33% were black. Median CD4 count 327 cells/mm^3, VL 8,055 copies/mL, BMI 25kg/m^2, and albumin measured 4.3g/dL. CKD-EPI calculations

of eGFR resulted in a higher eGFR compared with the MDRD equation (median: 103 vs. 98, P<.01). The ICC of the two equations was 0.56 (95% confidence interval [CI]: 0.53,0.59). The ICCs of the three equations were: 0.96 (95%CI 0.95,0.96) between CKD-EPI and AASK-MDRD; 0.76 (95%CI: 0.73,0.78) between AASK-MDRD and MDRD; and 0.72 (95%CI: 0.68,0.75) between CKD-EPI and MDRD. Among HIV+ blacks, the AASK-MDRD equation resulted, on average, in the highest eGFR value (median: 109.3), with CKD-EPI the second (median: 107.1), and the MDRD with the lowest value (median: 104.8).

Conclusions: In conclusion, the results of all three equations closely agreed, but the CKD-EPI generated a higher eGFR than the MDRD. The AASK-MDRD equation generated the highest eGFR among blacks. Further studies are needed to determine the predictive value of these creatinine based eGFR on the risk of CKD progression, ESRD and mortality in the HIV+ population.

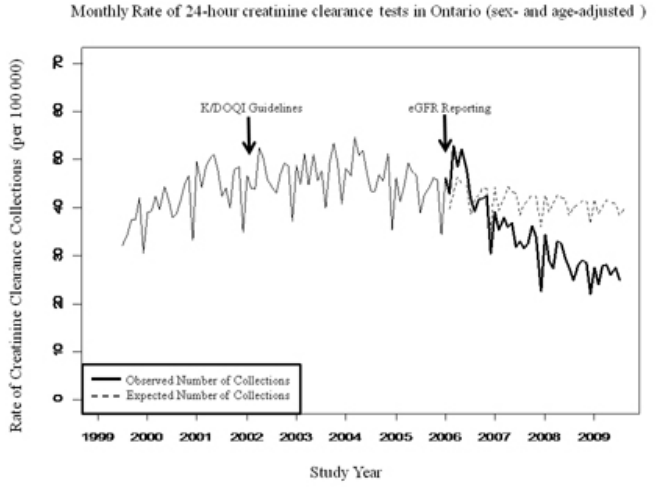
FR-PO1405

The Effects of Clinical Practice Guidelines and Estimated Glomerular Filtration Rate Reporting on Creatinine Clearance Testing Yoan K. Kagoma,[1] Amit X. Garg,[1,2,3,4] Lihua Li,[2] Arsh Jain.[1,2] *[1]Schulich School of Medicine and Dentistry, London, ON, Canada; [2]Division of Nephrology, University of Western Ontario, London, ON, Canada; [3]Department of Epidemiology and Biostatistics, University of Western Ontario, London, ON, Canada; [4]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada.*

Background: In 2002, the Kidney Disease Outcomes Quality Initiative (K/DOQI) suggested that renal function should be assessed using the estimated glomerular filtration rate (eGFR) and that the use of timed urine collection (creatinine clearance, CrCl) should be minimized. We sought to determine the effect of the K/DOQI guidelines and the province-wide introduction of eGFR reporting on requests for CrCl collection.

Methods: Time-series models with intervention analyses were used to model the impact of the following interventions on the rate of CrCl collection: 1)the publishing of K/DOQI guidelines and 2)the province-wide introduction of eGFR reporting. We collected sex- and age-adjusted CrCl collection rates and patient demographics monthly. Patients <25 years or on dialysis were excluded.

Results: The study period spanned August 1999 to July 2009. Data from 8.4 million patients per month were available.



The K/DOQI guidelines were not associated with a significant change in the sex- and age-adjusted rate of CrCl tests performed (p=0.82). eGFR reporting was associated with a significant decline (23.5% absolute change) in the sex- and age-adjusted rate of CrCl tests performed (p<0.0001).

Conclusions: In this setting, practice guidelines did not influence CrCl tests. Rather, the direct introduction of eGFR reporting into physician workflow resulted in a sudden and dramatic decrease in CrCl collection. These data suggest that changing physician practice patterns requires more than guidelines, rather it is more likely to occur through educational and structural changes to practice.

FR-PO1406

Clinical Phenotypes Associate with Outcome in ARVD James Ritchie, Constantina Chrysochou, Philip A. Kalra. *Vascular Research Group, MAHSC, University of Manchester, Salford Royal Hospital, United Kingdom.*

Background: ASTRAL showed unselected revascularization for atherosclerotic renovascular disease (ARVD) did not reduce mortality or cardiovascular events vs. medical therapy. Revascularization is still undertaken for some clinical presentations: flash pulmonary edema (FPE), refractory hypertension (RH) and rapidly declining renal function (RDF), though randomized data is lacking. By analyzing prospective data (1995-2010) on our ARVD cohort (n=819) we aimed to quantify effects of revascularization in these clinical settings.

Methods: Patients were categorized as receiving medical therapy (n=668) / revascularization (n=145). These groups were divided by presence / absence of indications to revascularize. Indications were divided by phenotype: FPE (identified from clinical records); RH (SBP >160mmHg despite ≥3 anti-hypertensives); RDF (creatinine at diagnosis >1.2x or 100µmol/L higher than result in previous 6 months). Effects of phenotype on death and dialysis events were assessed using Cox proportional hazards corrected for age, sex, BP, eGFR, vessel patency, proteinuria and angiotensin blockade. In the medical group patients with each indication were compared vs. those without. In the revascularization group each indication was compared for revascularized vs. medically treated patients.

Results: In the medical therapy group presence of an indication was associated with significant increases in hazards for both endpoints (p<0.005). This was not seen in the revascularized group.

In the medical group FPE had the greatest hazard for death and RDF for dialysis. Revascularization reduced hazard for death in patients with FPE but did not reduce hazard for dialysis for any phenotye.

		DEATH		DIALYSIS	
	n	HR (95%ci)	p	HR (95%ci)	p
	MEDICAL				
Indication	274	1.6 (1.2-2.2)	0.004	3.1 (1.7-5.7)	<0.001
FPE	44	2.4 (1.2-4.6)	0.01	2.7 (0.9-7.8)	0.08
RDF	146	1.5 (1.1-2.1)	0.02	3.5 (1.8-6.6)	<0.001
RH	124	1.2 (0.8-1.9)	0.47	2.6 (1.1-5.9)	0.02
	REVASCULARIZED				
Indication	71	0.7 (0.4-1.3)	0.27	1.2 (0.5-2.8)	0.76
FPE	15	0.08 (0.01-0.6)	0.01	*Insufficient events*	
RDF	33	1.3 (0.6-2.6)	0.49	1.9 (0.7-5.3)	0.19
RH	37	0.3 (0.1-1)	0.054	0.35 (0.06-2.2)	0.26

Conclusions: These findings emphasize the importance of the clinical presentation of the ARVD patient in deciding management.

FR-PO1407

Hepatitis C Virus Infection Increases Risk for End-Stage Renal Disease in Patients with Chronic Kidney Diseases Shang-Jyh Hwang,[1,2] Jia-Jung Lee,[1] Ming-Yen Lin,[1,3] H.C. Chen.[1,2] *[1]Division of Nephrology, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [2]Department of Renal Care, Kaohsiung Medical University, Kaohsiung, Taiwan; [3]Institute of Occupational Safety and Health, Kaohsiung Medical University, Kaohsiung, Taiwan.*

Background: Current evidence regarding the relationship between hepatitis C virus infection and outcome of chronic kidney disease is controversial. We aim to explore whether hepatitis C virus infection increases risk for end stage renal disease in patient with chronic kidney disease.

Methods: Our study cohort was patients received multidisciplinary chronic kidney disease care in one medical center, southern Taiwan from 2002 through 5/31/2008. Subjects were traced until starting dialysis, death or end of 2008. Subjects with adequate register data and follow up for at least 90 days were included in our analysis. Survival analyses including Kaplan Meier and Cox proportional model were used to estimate the cumulative incident rate and risk of end stage renal disease and p-value <0.05 was considered as significant.

Results: A total of 2021 patients in our chronic kidney disease cohort were included in the final analysis.After adjusted age, sex, primary diseases, educational status, herb use, stage of chronic kidney diseases, body mass index, blood pressure, and hemoglobin, hepatitis C virus infection shows significantly increasing risk for end stage renal disease.

Table 1. The Cox-regression analysis of Hepatitis C virus infection to dialysis in patients with CKD

	Hazard Ratio	95% CI	p-value
Age	0.97	0.96-0.98	<0.001
Sex			
male	1.00	-	-
Female	0.46	0.34-0.61	<0.001
Primary diseases			
CGN	1.10	0.81-1.48	<0.001
Diabetes mellitus	2.23	1.66-3.00	<0.001
Others	1.00	-	-
Hepatitis C infection			
None	1.00	-	-
Yes	1.45	1.03-2.05	0.03

Model was adjusted by age, sex, primary diseases, educational status, herb use, stage of chronic kidney diseases, body mass index, blood pressure, hemoglobin.

Conclusions: Hepatitis C virus infection increased risk for end-stage renal disease in chronic kidney disease cohort in a hepatitis C endemic area. Our results encouraged further research to evaluate effect of antivirus drug on risk reduction for end stage renal disease in patient with chronic kidney disease.

Urinary Level of Ngal Is Superior to Urinary Protein in Prediction of Chronic Kidney Disease Progression

Tomoko Kawanishi,[1] Kiyoshi Mori,[1] Masashi Mukoyama,[1] Masato Kasahara,[1] Hideki Yokoi,[1] Takashige Kuwabara,[1] Hirotaka Imamaki,[1] Akira Ishii,[1] Kenichi Koga,[1] Yukiko Kato,[1] Keita P. Mori,[1] Kenji Ueshima,[2] Sachiko Tanaka,[2] Akira Sugawara,[3] Kazuwa Nakao.[1]
[1]Department of Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]EBM Research Center, Kyoto University Graduate School of Medicine, Kyoto, Japan; [3]Division of Nephrology, Osaka Red Cross Hospital, Osaka, Japan.

Background: Urinary neutrophil gelatinase-associated lipocalin (uNgal) level is a biomarker which enables early diagnosis of acute kidney injury. In this study, we evaluated the association of uNgal levels with clinical parameters in chronic kidney disease (CKD) patients, their changes by treatment, and the predictive ability of uNgal for the progression of CKD in comparison with urinary protein.

Methods: Urine samples were collected from 98 CKD patients admitted to our department of Kyoto University Hospital, and they were followed for a mean period of 12 months. uNgal levels were measured by chemiluminescence immunoassay and normalized to urine creatinine. We defined renal events as >50% increase in serum creatinine levels or progression to end-stage renal disease.

Results: uNgal levels were significantly correlated to serum creatinine and urinary protein levels, respectively. uNgal level was decreased by steroid therapy in IgAN or FSGS, and by percutaneous nephrostomy in hydronephrosis. uNgal levels on entry of patients who later developed renal events were significantly higher compared with those of patients without it. As to prediction of renal events, areas under the ROC curves for uNgal and urinary protein were 0.94 and 0.82, respectively (difference, p=0.06). Kaplan-Meier curves of renal event-free survival indicated that subjects with uNgal values above the optimal ROC cut-off level (112 μg/gCr) experienced much faster occurrence of renal events than ones below the cut-off ($P < 0.0001$).

Conclusions: uNgal was shown to be a useful biomarker of disease severity and treatment efficacy of CKD, and uNgal appears to be more powerful than urinary protein in anticipating deterioration of CKD.

FR-PO1409

Combined Association of Cystatin C-Based and Creatinine-Based Estimated Glomerular Filtration Rate with Mortality: The Atherosclerosis Risk in Communities (ARIC) Study

Salman Waheed,[1] Brad C. Astor,[2] Kunihiro Matsushita,[2] Josef Coresh.[2] *[1]Medicine, Johns Hopkins University, Baltimore, MD; [2]Epidemiology, Johns Hopkins University, Baltimore, MD.*

Background: Estimates of GFR based on serum creatinine ($eGFR_{cr}$) can be biased by several non-GFR determinants, including muscle mass, resulting in misclassification of risk categories. Cystatin C-based GFR estimates ($eGFR_{cys}$) have a stronger and more linear association with mortality than $eGFR_{cr}$. More needs to be known about the combined association of these two markers with mortality.

Methods: We followed 10440 adults enrolled in the ARIC study for a median of 10.2 years. Participants were categorized as <30, 30-59, 60-89, 90-104 (reference) or ≥105 mL/min/1.73 m^2 determined by $eGFR_{cr}$ or $eGFR_{cys}$. We compared the association of $eGFR_{cr}$ and $eGFR_{cys}$ with mortality, individually as well as combined. Cox proportional hazards models were used with adjustment for demographics, diabetes, hypertension, cardiovascular disease, smoking, BMI and C-reactive protein.

Results: Mean age was 63 years with 22% blacks and 56 % women. 10.2% and 9.8% had eGFRcys and eGFRcr <60 mL/min/1.73 m2, respectively. Both reduced eGFRcys and eGFRcr were independently associated with mortality with a stronger association with eGFRcys than eGFRcr. Approximately half of the participants with eGFRcr 30-59 were reclassified up to >60 by eGFRcys. Participants reclassified to a higher GFR category by eGFRcys than eGFRcr had lower mortality risk and those reclassified to a lower category had higher mortality compared to those with concordant classification.

$eGFR_{cys}$	$eGFR_{cr}$ (ml/min/1.73 m^2)					
(ml/min/1.73m^2)	≥105	90 - 104	60 - 89	30 - 59	<30	Overall
≥105	1.2 (0.8, 1.8)	0.8 (0.5, 1.2)	0.5 (0.3, 0.8)	a	a	0.9 (0.7, 1.1)
N	[194]	[405]	[282]	[6]	[0]	[887]
90 - 104	1.3 (0.8, 2.1)	Reference	0.8 (0.6, 1.1)	0.3 (0.003, 1.9)	a	Reference
N	[139]	[848]	[1187]	[33]	[0]	[2207]
60 - 89	1.2 (0.7, 2.0)	1.2 (0.9, 1.5)	1.0 (0.8, 1.3)	1.0 (0.7, 1.4)	a	**1.2 (1.0, 1.4)**
N	[110]	[1219]	[4454]	[495]	[0]	**[6278]**
30 - 59	a	1.4 (0.7, 3.0)	**1.8 (1.3, 2.4)**	**1.9 (1.4, 2.5)**	a	**2.1 (1.8, 2.6)**

<30	a	a	**2.0 (1.2, 3.6)**	**4.7 (2.8, 8.1)**	**6.9 (4.1, 11.6)**	**4.1 (3.5, 5.0)**
N	[2]	[19]	**[69]**	**[28]**	**[27]**	**[145]**
Overall	1.2 (0.9, 1.6)	Reference	0.9 (0.8, 1.1)	**1.3 (1.1, 1.6)**	**5.8 (3.8, 8.8)**	
N	[448]	[2542]	[6423]	**[989]**	**[38]**	
Reclassified Up	NA	16%	22.90%	54%	28.90%	
Reclassified Down	56.70%	50.70%	7.80%	2.80%	NA	

N=sample size; a= sample size<25; **statistically significant results in bold**

Conclusions: Combining serum creatinine and cystatin C can improve mortality prediction replicating the results in the REGARDS cohorts suggesting this may provide a useful strategy when finer risk stratification is useful.

Cost-Effectiveness of Chronic Kidney Disease Mass Screening Test in Japan

Kunihiro Yamagata,[1,3] Masahide Kondo,[2,3] Chie Saito,[1] Koichi Asahi,[3] Toshiki Moriyama,[3] Kazuhiko Tsuruya,[3] Hideaki Yoshida,[3] Kunitoshi Iseki,[3] Tsuyoshi Watanabe.[3] *[1]Nephrology, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan; [2]Health Care Policy and Management, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan; [3]Japanese Society of Nephrology Task Force for the Validation of Urine Examination as a Universal Screening, Tokyo, Japan.*

Background: AlthoughCKD is a significant public health problem, strategy for its early detection is still a matter of controversy.

Methods: To assess the cost-effectiveness of mass screening for CKD, we performed cost-effectiveness analysis using a decision tree and Markov model to compare test modalities (dipstick test to check proteinuria only, serum creatinine (Cr) assay only, and both) in the context of the reform of Japan's mandatory annual health check-up for adults. In modelling, we carry out a deliberate literature survey to find out the best available evidence from Japan, while reports from other countries are excluded.

Results: Incremental cost-effectiveness ratios (ICERs) of mass screening compared to do-nothing are $12,660/QALY for urine dipstick test only, $90,250/QALY for serum Cr assay only, and $91,505/QALY for both, respectively. And ICERs associated with the reform are $103,618/QALY for mandating serum Cr assay in addition to currently mandatory dipstick test, and $100,016/QALY for mandating serum Cr assay and making dipstick test discretionary, respectively.

Conclusions: Taking a threshold to judge cost-effectiveness according to a World Health Organisation's recommendation, three times of Gross Domestic Product per capita, U.S.$128 thousand /QALY, a policy for reform that making serum Cr assay mandatory is cost-effective. And a choice of continuing current policy that keeping dipstick test mandatory is also cost-effective. Our results suggests that population strategy for CKD detection such as mass screening using dipstick test and/or serum Cr assay can be justified as an efficient use of health care resources in a population with high prevalence of the disease like Japan and Asian countries.

Epidemiology of Pulmonary Hypertension in Different Stages of Chronic Kidney Disease Zhilian Li, Wei Shi, Shuangxin Liu, Xinling Liang, Wenjian Wang, Zhiming Ye, Yuan Han Chen, Lixia Xu. *Nephrology, Guangdong General Hospital.*

Background: Pulmonary hypertension(PH) has been reported to occur in a considerable proportion of patients with ESRD and has been regarded as an independent predictor of mortality in hemodialysis patients. However, the epidemiology of PH in non-ESRD patients remains unclear. The aim of this study is to evaluate the incidence of PH in different stages of chronic kidney disease (CKD) and the association of PH with cardiovascular status in this population.

Methods: We retrospectively evaluated the records of 1,600 in-patients between 2008 and 2010. Patients were divided into 6 groups: Group 1-4 for CKD stage 1-4; Group 5 for those were in stage 5 but still not or initiated dialysis <3 months; Group 6 for maintenance hemodialysis(MHD) patients(hemodialysis≥3 months). Systolic pulmonary artery pressure(SPAP) was evaluated using Doppler echocardiography and calculated using Bernoulli equation, a value of >40mmHg was defined as PH. History of cardivascluar events was recorded. Patients with chronic obstructive pulmonary disease(COPD), connective tissue disease, history of pulmonary embolism or chest wall or parenchymal lung disease, rheumatic heart disease, congenital heart disease and acute heart failure were excluded.

Results: PH was detected in 214(13.4%) of the total 1,600 CKD patients. Prevalence of PH in Group 1-6 was 0.5%, 3.17%, 3.77%, 6.92%, 12.84% and 30.70%, respectively. Chi-Square Test (linear-by-linear association) showed with renal function progressively declined, the incidence of PH (R2=0.772, P=0.000)and cardiovascular events (R2=0.959, P=0.000) increased. Patients with history of cardiovascular events had a higher incidence of PH than those without history of cardiovascular events (25.8% v.s 8.0%, P=0.000).

Conclusions: These results showed that incidence of PH was low in Stage 1-4 of CKD patients but elevated in ESRD especially in MHD patients. PH may be a risk factor of cardiovascular events in CKD patients.

Is Doubling of Serum Creatinine the Right Endpoint in Nephrology Trials? Hiddo Jan Lambers Heerspink,[1] Ron T. Gansevoort,[1] Vlado Perkovic,[2] Giuseppe Remuzzi,[3] Julia Lewis,[4] Dick de Zeeuw.[1] *[1]UMCG, Groningen, Netherlands; [2]George Institute, Sydney, Australia; [3]Mario Negri Institute, Bergamo, Italy; [4]VanderBilt University, Nashville.*

Background: Doubling of serum creatinine (DSCR) is frequently used as an endpoint in nephrology trials. However, DSCR is reached by only few patients during trials. We aimed to assess whether adopting smaller increases in serum creatinine as endpoint may yield more endpoints while maintaining similar precision of treatment effects. If true, this would potentially allow fewer patients to be included in nephrology trials.

Methods: In a post-hoc analysis of the RENAAL and IDNT trial, the effects of Angiotensin Receptor Blockers (ARB) were estimated on the renal endpoint defined by different percentages increase in serum creatinine by means of Cox proportional hazard analysis. A post-hoc power calculation was performed to determine the minimal number of patients needed to obtain a significant treatment effect. The percentage increase in serum creatinine was assessed from month 3, thus excluding the initial hemodynamic effect.

Results: The effect of the ARB irbesartan decreased when smaller percentages increases in serum creatinine were used as endpoint (figure 1). However, the confidence interval of the treatment effect also decreased at smaller increases in serum creatinine as endpoint so that the least number of patients were required to detect a significant treatment effect at a 100% increase (doubling) in serum creatinine. Similar results were obtained in the RENAAL trial, or when the change in serum creatinine was calculated from baseline in both studies.

Conclusions: For drug trials in nephrology enrolling patients with type 2 diabetes and nephropathy, DSCR is an appropriate endpoint. Using smaller increases in serum creatinine as endpoint does not lead to fewer patients needed to detect a significant treatment effect.

Decreased Kidney Function and Risk of Venous Thrombosis Gurbey Ocak,[1] Carla Y. Vossen,[1,2] Marion Verduijn,[1] Friedo W. Dekker,[1] Willem Lijfering,[1,3] Frits R. Rosendaal.[1,3] *[1]Department of Clinical Epidemiology, Leiden University Medical Center; [2]Department of Medical Genetics, University Medical Center Utrecht; [3]Department of Thrombosis and Haemostasis, Leiden University Medical Center, Netherlands.*

Background: Whether decreased kidney function is associated with venous thrombosis (VT) is unknown. We investigated whether decreased kidney function, assessed by estimated glomerular filtration rates (eGFR), is associated with an increased risk of VT. In addition, we investigated whether an increased risk of VT is a result of increased levels of hemostatic factors. Furthermore, we assessed the effect of decreased kidney function on VT in combination with other risk factors to identify high-risk groups.

Methods: MDRD based eGFR and hemostatic factors were determined in 2469 patients with VT and 2931 control participants enrolled in the MEGA case-control study. Odds ratios were calculated and adjusted for age, sex, and body mass index.

Results: Mildly decreased kidney function (eGFR 60-90 ml/min; n=3098) increased the risk of VT 1.1-fold (95%CI 1.0-1.2), moderately decreased kidney function (eGFR 30-60; n=235) 2.5-fold (95% CI 1.9-3.4), and severely decreased kidney function (eGFR <30; n=15) 5.8-fold (95% CI 1.6-21.0) as compared to persons with a normal kidney function (eGFR >90; n=2052). Nearly all hemostatic factors that we studied showed a shift to a procoagulant state with decreasing kidney function, most notably FVIII, with levels that compared with normal kidney function, were on average 6.4 IU/dL (95% CI 2.9-9.9), 34.5 (95% CI 24.5-44.4), and 135.7 (95% CI 90.0-181.4) higher for mildly, moderately, and severely decreased kidney function, respectively. The odds ratios for VT attenuated after adjustment for FVIII. The risk of VT was highly increased (odds ratios > 9) for moderately to severely decreased kidney function in combination with surgery, hospitalization, or non-O blood group.

Conclusions: Decreased kidney function was associated with VT and with a procoagulant state. The increased risk of VT was mediated by FVIII. The risk of VT was highly increased in CKD in the presence of other risk factors of VT.

FR-PO1414

Low GFR after Kidney Donation Is Not CKD Laura V. de Vries,[1] H. Tent,[1] Johannes S. Sanders,[1] Hendrik Sijbrand Hofker,[2] Stephan J.L. Bakker,[1] Gerjan Navis.[1] *[1]Department of Nephrology, University Medical Center Groningen, Netherlands; [2]Department of Surgery, University Medical Center Groningen, Netherlands.*

Background: CKD staging is based on prognostic impact of GFR with/without proteinuria. Many kidney donors have an estimated (e)GFR<60 mL/min/1.73m² post-donation and thus meet with criteria of CKD stage 3 (CKD3). However, prognostic impact of a given GFR in two diseased kidneys may not be equivalent to the same GFR in one healthy kidney. To test this assumption, we compared renal function course in former kidney donors to CKD patients matched for GFR, age and gender.

Methods: We included 57 (63% male) kidney donors (baseline values 3 months after donation) and 57 CKD patients. All had repeated GFR (^{125}I-iothalamate) and ERPF (^{131}I-hippuran) measurements after 4.7±1.5 years.

Results: At baseline, 25% of donors met criteria for CKD3. In all donors GFR increased over time, with a slight fall in ERPF, while GFR and ERPF fell in all CKD patients. CKD stage improved to CKD 0-2 in 13 donors with CKD3 at baseline, whereas it worsened in 21 CKD patients. Change in GFR significantly differed between donors and CKD patients (see table), both for CKD with (n=31; -2.1±3.3) and CKD without (-1.1±3.2 ml/min/yr) proteinuria.

Conclusions: Thus, despite similar baseline GFR and CKD stage, renal prognosis is substantially different for donors and CKD patients. Although many donors initially meet criteria of CKD3 they should not be regarded as CKD patients. CKD staging is not applicable to kidney donors.

		Donors	CKD patients	P-value

Chronic Kidney Disease (CKD), Hypertension Control, and Risk of Obstructive Sleep Apnea (OSA) Brian J. Mussio,[1,2] Loretta Simbartl,[2] Ralph Panos,[1,2] Charuhas V. Thakar.[1,2] *[1]Internal Medicine, University of Cincinnati, OH; [2]Medical Service, Cincinnati VA, Cincinnati, OH.*

Background: Hypertension is an important modifiable risk factor in patients with CKD. OSA is a known cause of secondary hypertension, however, there are limited studies examining its prevalence in CKD, and its effect on hypertension control

Methods: We conducted a prospective study in 211 patients at the Cincinnati Veteran's Administration Medical Center's CKD & Hypertension Clinic. All enrolled patients completed a Berlin Questionnaire and an Epworth Sleepiness Scale, validated screening tools for OSA and daytime sleepiness, respectively. Baseline demographics, comorbidities, laboratory data, and anti-hypertensive medications were recorded at the time of survey, whereas outpatient blood pressure readings were averaged for a time-period of one-year prior to the survey date. Univariate analyses were conducted using t-test, Wilcoxon test, and Chi-square tests.

Results: 99% of participants were male with a mean age of 63.7 (± 10.7), and mean creatinine of 2 mg/dl (± 1.3). Only 29% of patients had an average BP of < 130 or < 80 mm of Hg, and 80% of patients were taking ≥ 3 medications for hypertension. Based on the Berlin score, 142 (67%) participants were in the "high-risk" group for OSA, and 69 (33%) were in the "low-risk" group. Based on the 29 patients with a confirmed diagnosis of OSA, the sensitivity of the Berlin Questionnaire was 93%. Compared with the low-risk group, patients in high-risk group were younger (62.5±10.1 vs. 66.2±11.6, p = 0.02), had a higher prevalence of diabetes (51% vs. 36%, p = 0.04), and had higher Epworth scores (11±6 vs. 6±5, p < 0.001). Average blood pressures were similar in both groups, but the number of blood pressure medications required to achieve the blood pressures was higher in the high-risk group (3.2±1.3 vs. 2.7±1.2, p = 0.01).

Conclusions: OSA in veterans attending CKD/hypertension clinics may be under-recognized. Although blood pressure control was comparable, patients at high-risk for OSA required more antihypertensive medicines. Whether OSA is a modifiable risk factor in hypertension management in CKD needs prospective investigation.

FR-PO1416

Development and Validation of a Model To Predict ESRD in Elderly Patients with Advanced CKD Puja Goswami,[1] Paul E. Drawz,[2,3] Denise C. Babineau,[4] Mahboob Rahman.[1,2,3] *[1]Medicine, University Hospitals Case Medical Center, Cleveland, OH; [2]Nephrology & Hypertension, Case Western Reserve University, Cleveland, OH; [3]Medicine, Louis Stokes Cleveland VAMC, Cleveland, OH; [4]Center for Clinical Investigation, Case Western Reserve University, Cleveland, OH.*

Background: KDOQI guidelines recommend preparation for renal replacement therapy (RRT) in all patients with a GFR<30. However, elderly patients are at increased risk for all-cause mortality and have a lower risk for ESRD. The goal of this study was to develop and validate a model to predict the 12 month risk for ESRD in elderly subjects with advanced CKD. Additionally, we assessed the ability of the model recently published by Tangri et al to predict ESRD in our elderly cohort.

Methods: We performed a retrospective cohort study at the Louis Stokes Cleveland VAMC. Eligible subjects were 65 years of age and older, had an outpatient GFR<30, and had not received RRT. The primary outcome was the need for RRT within 1 year of the index GFR. A Cox proportional hazards regression model was developed using backward step-down variable selection and boostrap sampling. The accuracy of the model to predict ESRD was assessed using Harrell's C index.

Results: Of the 1,866 patients included in the study, 77 patients developed ESRD. Risk factors for ESRD in the model were age (HR 0.47 (75th vs 25th quantile for continuous variables)), CHF (HR 4.72), elevated BP (HR 1.55), index GFR (HR 0.24), potassium (HR 0.67), and albumin (HR 0.69). There were significant interactions between GFR and CHF and between GFR and age. The bootstrap corrected C-index for the model was 0.85, indicating excellent predictive ability. The C-index for the Tangri model was 0.78, indicating good predictive ability.

Conclusions: A model using commonly available clinical measures showed excellent predictive ability for ESRD at 12 months in elderly subjects with advanced CKD. Additionally, we validated the ability of the Tangri model to predict ESRD in an external cohort. These risk prediction models can be utilized by patients and physicians to make more informed decisions regarding the need for preparation for ESRD, such as vascular access placement.

FR-PO1417

Risk Factors for Progression in DM and Non DM CKD Patients after CKD Integrated Program Mei-Chuan Kuo,[1,2] Chi-Chih Hung,[1] Shang-Jyh Hwang,[1,2] H.C. Chen.[1,2] *[1]Nephrology, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [2]Faculty of Renal Care, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan.*

Background: Taiwan has the highest incidence of end stage renal disease in the world. For decreasing the incidence of end stage renal disease and better care of chronic kidney disease patients, team of chronic kidney disease (CKD) was set up in our hospital since Dec 31, 2002. Despite of intensive intervention including education and diet modification, rapid progression was still found in many patients. This aim of this study is to evaluate the difference potential risk factors to influence the progression of DM and non DM CKD.

Methods: Patients that ever joined this program from Dec 31, 2002 to Dec 31, 2008 were enrolled. Those patients followed up for more than one year with at least 3 data of serum creatinine after joining this program were enrolled. After calculate estimated glomerular filtration rate (eGFR), we can further calculate the slope decline in each patient. The slope declines more than -1ml/min/1.73m^2/year was defined as progression group and -5ml/min/1.73m^2/year was defined as rapid progression (RP) group. By comparison with the demographic and laboratory data, we can get the potential risk factors for the progression of CKD. The statistic methods we used include chi-square test, student's t test and logistic regression.

Results: 1018 patients(female: 445, male: 573, age: 63±14 y/o) were enrolled in this study. 335 were DM patients. 211 patients were rapid progression and 100 were DM patients. The follow up days in rapid progression groups is shorter than others . The frequency for CKD nurse education and dietician education are higher in RP groups. By single variant analysis, older age, severity of proteinuria, lower hematocrit, higher serum cholesterol and phosphate level, rapid progression before CKD program and diabetes mellitus (DM) were risk factors for progression. After multivariant analysis, only severity of proteinuria are significant risk factors for CKD progression.

Conclusions: Severity of proteinuria is still the most significant risk factors for CKD progression despite of intensive CKD education program.

FR-PO1418

Therapeutic Plasma Exchange for Renal Indications in the Elderly: Ten Years Experience in One Center Emaad M. Abdel-Rahman, John S. Hayes, Jamison W. Chang, Rasheed A. Balogun. *Division of Nephrology, University of Virginia, Charlottesville, VA.*

Background: Elderly, above age 65 years, are growing in number. The structural and functional changes associated with aging place elderly at risk when challenged by extra corporal therapies as therapeutic plasma exchange (TPE). **Aim:** To compare renal indications and mortality associated with the use of TPE in elder versus younger patients.

Methods: We retrospectively analyzed data on all patients who underwent TPE for renal indications at the UVA between January 1 2000 and June 30, 2010. Beside demographic and comorbidity data, we collected therapy specific data; procedure access, indications, side effects and mortality data.

Results: During this period, 621 patients underwent 4722 sessions of TPE. Of them 191 patients were elderly (30.7%) and they underwent 1289 sessions (27.3%) of TPE. Total of 101 patients (16.3%) underwent 593 sessions of TPE because of renal- indications; 24 patients (92.3% white and 54% males) in the elderly group and 77 (90 % white, 58.1% males) in the younger. No statistical differences were observed in laboratory parameters, technique or comorbidies. Side effects of dyspnea and hypotension were documented in only two patients, both in the elderly cohort. Main indications of TPE in the elderly were glomerulonephritis (GN) followed by multiple myeloma (MM), with a trend towards more death in the elderly (p=0.07). The multivariable regression model which included age category, serum albumin and entrance serum creatinine was unable to predict mortality in this group of patients.

	Age (yrs)	# of treatment (Mean/pt)	GN	MM/Cast	Kidney TX rejection	HUS/TTP	Mortality
Elder (n=24)	73.5 +/- 6.2	109 (6.7)	70.8%	12.5%	8.3%	8.3%	42.3%
Young (n=77)	43.8+/-14.4	484 (6.2)	24.7%	6.5%	62.3%	6.5%	23.1%

Indications and Mortality Associated with TP in Elderly

Conclusions: In our experience, renal indications for TPE in elderly are different than for younger patients, with GN being the main indication .TPE used for renal indications in the elderly is relatively safe, with an increased occurrence of adverse events compared to younger patients. Trends towards death in the elderly may be multi factorial and not related to TPE alone.

FR-PO1419

Clinicopatholgical Manifestation in Japanese Patients of idiopathic Membranous Nephropathy with Each Era Shinji Kitajima,[1] Tadashi Toyama,[1] Kiyoki Kitagawa,[1] Kengo Furuichi,[1] Hitoshi Yokoyama,[2] Shuichi Kaneko,[3] Takashi Wada.[1] *[1]Division of Nephrology, Kanazawa University Hospital, Kanazawa, Ishikawa, Japan; [2]Division of Nephrology, Kanazawa Medical University Hospital, Uchinada, Ishikawa, Japan; [3]Department of Disease Control and Homeostasis, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa, Ishikawa, Japan.*

Background: The 20-year renal survival of idiopathic membranous nephropathy (IMN) in Japanese adults with nephrotic syndrome was reported around 60%. In this study, we evaluated the predisposing clinicopathological factors of patient survival with each era in Japan.

Methods: One hundred forty six Japanese patients (85 males and 61 females; mean age 46.2 years) with biopsy proven IMN from 1965 to 2007 in Kanazawa University Hospital were evaluated in this study. The patients were followed for more than three years, or until renal or patient death. The patients were divided into three groups with each era; group 1 (1963-1979, 74 cases), group 2 (1980-1989, 44 cases), and group 3 (1990-2007, 28 cases). Clinicopathological features were evaluated for rate of remission, renal death, and patient death.

Results: Age of onset was higher in group 3 (group 1; 37.7 years, group 2; 52.5 years, group 3; 58.6 years). The rate of nephrotic syndrome was higher in group 3 (group 1; 66.2%, group 2; 72.7%, group 3; 85.7%). Major immunosuppressive therapy at onset with each era were cyclophoshamide in group 1 (38.8%), immunoglobuline in group2

(59.3%), cyclosporine A in group 3 (60.7%) in addition to steroids. The remission rate at 100 months (group 1; 69.4%, group 2; 50.0%, group 3; 62.5%), the renal death rate at 100 months (group 1; 4.1%, group 2; 6.8%, group 3; 7.1%), and the patient death rate at 100 months (group 1; 4.1%, group 2; 9.1%, group 3; 7.1%) had no statistical difference. Based on the electron microscopic findings, the patients were assigned to two distinct groups, homogeneous type and heterogeneous type based on our previous report (Yoshimoto , et al. KI 2004). The rate of homogeneous type was high in group 3 (group 1; 57.8%, group 2; 50.0%, group 3; 82.1%).

Conclusions: Age, rate of nephrotic syndrome, and homogeneous type were higher in recent era.

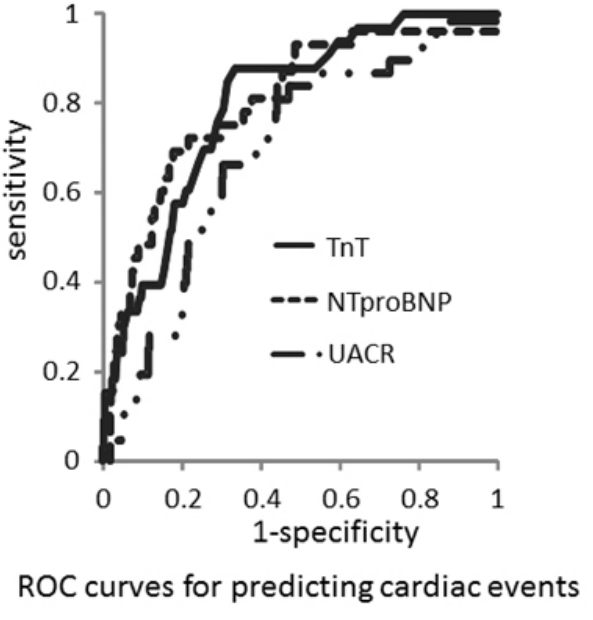
FR-PO1420

Cardiac Biomarkers in Patients with Chronic Kidney Disease Not on Dialysis Midori Hasegawa, Kyoko Kanayama, Yukio Yuzawa. *Nephrology, Fujita Health University School of Medicine, Toyoake, Aichi, Japan.*

Background: The purpose of this study is to assess N-terminal pro-brain natriuretic peptide(NT-proBNP), high sensitivity troponin T(hsTnT), and urinary albumin creatinine ratio (UACR) as predictors of cardiac events in patients with chronic kidney disease (CKD) not on dialysis.

Methods: The levels of serum NT-proBNP, hsTnT and UACR were measured in 413 ambulatory CKD patients not on dialysis whose estimated glomerular filtration rate was <60 ml/min/1.73 m^2. The patients underwent clinical follow-up for a median period of 17 months. Cardiac events were defined as cardiac death or hospitalization for acute coronary syndrome or for worsening heart failure.

Results: There were 33 cardiac events. The levels of NT-proBNP, hsTnT, and UACR were each divided into tertiles. Kaplan-Meier curves for cardiac events were clearly separated by the tertile of hsTnT, NT-proBNP, and UACR levels. Tertiles of NT-proBNP(HR4.79, 95%CI2.31-9.97), hsTnT (HR2.98, 95%CI 1.66-5.38), and UACR(HR2.71, 95%CI 1.64-4.48) were predictors of cardiac events by Cox regression analysis adjusted by age, gender, the presence of diabetes mellitus, and eGFR. Figure shows ROC curves for NT-proBNP (AUC 0.844; 95%CI, 0.782 to 0.907), hsTnT (AUC 0.795; 95% CI, 0.725 to 0.865), and UACR(AUC 0.714; 95%CI, 0.629 to 0.800) in predicting cardiac events. The best cut-off values were NT-proBNP of 1217pg/mL(sensitivity 72.7%, specificity 83.2%), hsTnTof 25.5 pg/mL (sensitivity 84.8%, specificity 68.2%), and UACR of 0.91g/gCr(sensitivity 66.7%, specificity 71.6%), respectively.



ROC curves for predicting cardiac events

Conclusions: NT-proBNP, hsTnT, and UACR are useful for risk stratification of cardiac events in CKD patients not on dialysis.

FR-PO1421

Risk Factors for Progression to CKD 3 in IgA Nephropathy Chung-Hoon Yu,[1,2] Jang-Hee Cho,[1,2] Mi-Kyung Jin,[1,2] Owen Kwon,[1,2] Kyung-Deuk Hong,[1,2] Ji-Young Choi,[1,2] Se-Hee Yoon,[1,2] Chan-Duck Kim,[1,2] Yong-Lim Kim,[1,2] Sun-Hee Park.[1,2] *[1]Department of Internal Medicine, Kyungpook National University Hospital, Daegu, Republic of Korea; [2]Clinical Research Center for End Stage Renal Disease, Republic of Korea.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis in Korea. To investigate the risk factors for progression, we retrospectively analyzed the data of IgAN from a single center in Korea.

Methods: Three hundred and twenty nine patients (M: F 173:156, mean age 34 ± 12) with biopsy-proven IgAN (January 2002 ~ December 2009) were available for analysis. Progression was defined as an development of CKD stage 3 (eGFR<60 mL/min/1.73m2 by MDRD) or start of renal replacement treatment (RRT) due to ESRD. Cox regression analysis was used and presented as odd ratio (OR; 95% CI).

Results: Number of patients with episodic gross hematuria, microscopic hematuria with proteinuria, nephritic syndrome and hypertension as an initial clinical presentation was 42 (12.8%), 203 (61.7%), 5 (1.5%) and 60 (18%), respectively. At presentation, mean creatinine and protein-creatinine ratio (PCR) by spot urine was 0.99±0.98 mg/dl and 970±130 mg/g. Number of patients with glomerulosclerosis on pathology was 151 (45%). During mean follow-up of 43 months (range 12~101), 14 (4.3%) patients had begun RRT and 28 (8.2%) patients were diagnosed as CKD stage 3 and above. With univariate analysis, age at diagnosis (p=0.014, OR=1.05 (CI 1.01-1.09)), glomerulosclerosis(p=0.02, OR= 7.89;(2.07-29.98)) and PCR > 500mg/g (p=0.013, OR=6.67 (1.508-29.67)) were associated with development of CKD stage 3. Glomerulosclerosis (p=0.01, OR=1.55 (1.07-2.26)) and hypertension (p=0.025, OR=3.55 (0.43-1.13)) were associated with start of RRT. With multivariate analysis, age at diagnosis, glomerulosclerosis and PCR ≥ 500mg/g were independent risk factors for development of CKD stage 3 and above.

Conclusions: This study suggests that age at diagnosis, hypertension, proteinuria more than 500mg/g and glomerulosclerosis on pathology are major risk factors for progression to CKD 3 and above in Korean patients with IgA nephropathy.

Lower Estimated Glomerular Filtration Is Associated with Trajectories of Life-Space Mobility among Older Adults C. Barrett Bowling,[1] Patricia Sawyer,[2] Paul Muntner,[2] Paul W. Sanders,[2] Richard M. Allman.[1] *[1]Birmingham VAMC; [2]University of Alabama at Birmingham.*

Background: While reduced estimated glomerular filtration rate (eGFR) is associated with decline in activities of daily living, less is known about the association of eGFR and mobility.

Methods: This analysis includes prospective, observational data from 400 community-dwelling Medicare beneficiaries (age >69) who had serum creatinine measured during an in-home assessment in 2004. eGFR was calculated using the CKD-EPI equation and categorized as ≥ 60, 45-59 and <45 ml/min/1.73 m^2. Life-space mobility was evaluated by telephone interviews every six months for up to 54 months. The Life-Space Assessment (LSA) reflects mobility and social participation by measuring where a person goes, how frequently they go there, and the degree of assistance needed. LSA scores range from 0-120 with higher scores indicating greater mobility.

Results: Participants had a mean age of 77.6 (SD=5.8, range 69-98), 42% were African American, 50% were female, and 29% and 20% had eGFR 45-59 and <45 ml/min/1.73 m2, respectively. Baseline life-space scores were 66.8, 64.6, and 53.7 for participants with eGFR levels of ≥ 60, 45-59 and <45 ml/min/1.73 m2, respectively (p<0.05 for those with eGFR < 45 versus ≥ 60 ml/min/1.73 m2). After adjustment for age, race, and sex, eGFR < 45 ml/min/1.73 m2 was associated with life-space trajectory (p=0.001; figure).

Conclusions: Among community-dwelling older adults, eGFR <45 ml/min/1.73 m^2 is associated with a lower baseline life-space mobility and longitudinal life-space mobility trajectory.

Figure. Trajectories of Life-Space Mobility among participants of the UAB Study of Aging by baseline level of estimated glomerular filtrate rate (eGFR) adjusted for age, sex, and race

Factors Associated with Impaired Urinary Albumin Excretion in Chinese Rural Population Xiaohong Fan, Jianfang Cai, Bixia Gao, Hang Li, Xuemei Li, Xue-Wang Li. *Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: Obesity may be measured by five anthropometric indicators such as waist circumference(WC), waist-to-hip ratio(WHR), waist-to-height ratio(WSR), and so on . We assess to investigate the relative factors associated with UAE in Chinese rural population, especially obesity and uric acid.

Methods: The investigated subpopulation derived from an epidemiological study in Pinggu district, Beijing(n=992, 51.7±10.8 years old) was analyzed in this

study. Measurements included overnight urine collection for UAE, blood pressure, anthropometric indicators, lipids, fasting glucose, uric acid, and hypersensitive C-reactive protein(hsCRP).

Results: In multiple logistic regression analysis, male, hypertension, diabetes, increased level of uric acid and hsCRP were significantly associated with albuminuria(UAE≥20ug/min); but five anthropometric indicators were not independently related to albuminuria. If stratified by gender, hyperuricemia and hsCRP were significantly potential risk factors for albuminuria in females, whereas the significant associations were not detected in males. And abdominal obesity measured by WC(OR=2.59 95%CI:1.26-5.33, P=0.03), WHR(OR=2.38, 95%CI:1.14-4.94, P=0.04) and WSR(OR=2.52, 95%CI:1.21-5.29, P<0.05) was significantly related to albuminuria in females after adjusted for age, diabetes and hypertension, but the association was not detected in males.

Logistic regression for relative factors associated with UAE

Population	relative factors	OR value (95%CI)	P value
Overall	male	1.68(1.15-2.47)	<0.01
	hypertension	2.29 (1.54-3.42)	<0.01
	diabetes	4.30 (2.75-6.73)	<0.01
	hyperuricemia	2.31 (1.15-4.68)	0.02
	elevated hsCRP	1.83(1.11-2.99)	0.02
Women(N=529)	diabetes	4.36 (2.34-8.15)	<0.01
	hyperuricemia	7.13(2.12-23.94)	<0.01
	elevated hsCRP	2.49 (1.24-5.00)	0.01
Men(N=463)	hypertension	3.20(1.86-5.51)	<0.01
	diabetes	4.83(2.50-9.35)	<0.01
	hyperuricemia	1.27 (0.52-3.14)	0.60
	elevated hsCRP	1.38 (0.68-2.82)	0.38

Conclusions: As the potential risk factors, hyperuricemia and elevated hsCRP had the genetic-specific effect on UAE, especially in females, abdominal obesity was also significantly related to impaired UAE in females.

Self-Reported Chronic Kidney Disease Prevalence – Results from the 2009 Michigan Behavioral Risk Factor Surveillance System Lori Corteville,[1] Chris Fussman,[1] Elizabeth Hedgeman,[2] Jerry Yee,[3] Rajiv Saran.[2] *[1]Michigan Department of Community Health, Lansing, MI; [2]University of Michigan, Ann Arbor, MI; [3]Henry Ford Hospital, Detroit, MI.*

Background: The incidence of kidney failure in Michigan is among the highest in the nation. However, state-specific prevalence estimates for the earlier stages of chronic kidney disease (CKD) are lacking. We sought to estimate the prevalence of CKD as well as the frequency of testing for CKD in the Michigan population using the Michigan Behavioral Risk Factor Surveillance System (MiBRFSS).

Methods: The MiBRFSS is an annual, state-level, random-digit-dialed telephone survey of adults who are 18 years of age and older conducted in cooperation with the Centers for Disease Control and Prevention; goals include providing population-level estimates of health behaviors, knowledge and awareness. In 2009, >6,000 Michigan adults were asked four questions regarding their current kidney function and whether they had undergone a serum creatinine and/or urine albumin test in the past three years. Final survey results were weighted to adjust for selection probability and to approximate the Michigan population.

Results: Initial results of this first MiBRFSS CKD module suggest that testing-for and awareness-of CKD is low within the Michigan adult population. Overall, 3.5% of Michigan adults were aware they had been diagnosed with CKD, and fewer than half (38.6%) were aware of having been tested in the past three years. Among individuals with diabetes (the leading cause of ESRD in Michigan), 8.6% were aware of a CKD diagnosis and 63.3% reported having been tested. Similarly, adults with other known risk factors had higher odds of awareness of CKD and testing for CKD than the general population.

Conclusions: We report the first measurement of state-level CKD prevalence using the MiBRFSS. Our results indicate that self-reported prevalence and testing is low within the general population. We contend that state efforts to raise the levels of detection and awareness of CKD are warranted to reduce the number of adults in Michigan living with CKD-associated complications and kidney failure.

FR-PO1425

Soluble RAGE, Glycated Hemoglobin and C-reactive Protein as Risk Factors for Incident Chronic Kidney Disease: The Atherosclerosis Risk in Communities (ARIC) Study Brad C. Astor,[1] Marc Halushka,[1] Ron C. Hoogeveen,[2] Christie Ballantyne,[2] Josef Coresh,[1] Elizabeth Selvin.[1] *[1]Johns Hopkins University; [2]Baylor College of Medicine.*

Background: Advanced glycation end products (AGEs) and their cell-bound receptors (RAGE) have been implicated in the pathogenesis of atherosclerosis and progression of chronic kidney disease (CKD). Circulating soluble RAGE (sRAGE) may act as a decoy to prevent the inflammatory processes initiated by RAGE activation. Alternatively, sRAGE level may be a marker of higher AGE levels, indicating increased risk of complications.

Methods: We conducted a case-control study to determine whether levels of sRAGE, glycated hemoglobin (HbA1c) and high-sensitivity CRP (hsCRP) are risk factors for incident CKD over 6 years. GFR was estimated by cystatin C ($eGFR_{Cystatin}$) and serum creatinine ($eGFR_{CKD-Epi}$) in ARIC Study participants (ages 47-68 years; 55% female; 19% black). A total of 1,942 participants with $eGFR_{CKD-Epi}$ and $eGFR_{Cystatin}$≥60 mL/min/1.73m^2 at baseline were included. CKD cases had a decline in eGFR≥25% over 6 years and a final eGFR<60 mL/min/1.73m^2.

Results: Higher HbA1c and CRP were significantly associated with incident CKD defined by eGFRCKD-Epi and eGFRCystatin. Higher sRAGE was associated with incident CKD by eGFRCKD-Epi only. Each of these associations was stronger in blacks (n=365) than whites (n=1,577).

Adjusted* Odds Ratio (95%CI) for Incident CKD, defined by:

	$eGFR_{CKD-Epi}$ (n=156)	$eGFR_{Cystatin}$ (n=433)
HbA1c category		
<5.7%	1.0 (Reference)	1.0 (Reference)
5.7-6.5%	1.1 (0.7-1.7)	1.1 (0.8-1.4)
>6.5% or diabetes†	2.1 (1.3-3.4)	1.9 (1.4-2.7)
sRAGE quartile		
<705 pg/mL	1.0 (Reference)	1.0 (Reference)
705-961 pg/mL	1.4 (0.8-2.3)	1.1 (0.8-1.5)
962-1266 pg/mL	1.8 (1.0-3.0)	0.9 (0.7-1.4)
>1267 pg/mL	1.9 (1.2-3.3)	1.1 (0.8-1.6)
8-fold higher hsCRP	1.8 (1.3-2.6)	1.4 (1.1-1.8)

***** Adjusted for age, sex, race, baseline eGFR, systolic blood pessure, anytihypertensive medication use, current smoking, BMI, LDL, HDL, triglycerides. †Self-reported diagnosis or medication use.

Conclusions: Higher HbA1c and CRP are risk factors for incident CKD in the general population. It remains uncertain whether sRAGE is an independent risk factor for CKD.

Funding: NIDDK Support

FR-PO1426

Solube RAGE, Glycated Hemoglobin,and hsCRP as Predictors of End-Stage Renal Disease: A Case-Control Analysis in the Atherosclerosis Risk in Communities (ARIC) Study Brad C. Astor,[1] Marc Halushka,[1] Ron C. Hoogeveen,[2] Christie Ballantyne,[2] Elizabeth Selvin,[1] Josef Coresh.[1] *[1]Johns Hopkins University; [2]Baylor College of Medicine.*

Background: Advanced glycation end products (AGEs) and their cell-bound receptors (RAGE) have been implicated in the pathogenesis of atherosclerosis and chronic kidney disease (CKD). Circulating soluble RAGE (sRAGE) may act as a decoy to prevent the inflammatory processes initiated by RAGE activation. Alternatively, sRAGE level may be a marker of higher AGE levels, indicating increased risk of these complications.

Methods: We conducted a case-control study nested within the ARIC Study to determine whether levels of sRAGE, glycated hemoglobin (HbA1c), and hsCRP predict incident ESRD over 18 years of follow-up. A total of 161 ESRD cases were frequency matched on sex, race, diabetes status and baseline eGFR (10 mL/min/1.73m^2) to 141 controls.

Results: Median (IQR) eGFR was 65.7 (47.4-92.3) mL/min/1.73m2. Cases had higher mean systolic blood pressure (138 vs. 130 mmHg; p=0.01), were more likely to be using antihypertensive medication (64 vs. 52%; p=0.03), and had higher mean sRAGE (1240 vs. 1030 pg/mL; p=0.02) than controls. Higher sRAGE was significantly associated with odds of ESRD in minimally adjusted analyses. Higher sRAGE and HbA1c were strongly associated with ESRD after full adjustment.

Odds Ratio (95% CI) of ESRD

	Minimally Adjusted*	Fully Adjusted†
HbA1c category		
<5.7%	1.0 (Reference)	1.0 (Reference)
5.7-6.5%	2.9 (1.1-7.2)	4.6 (1.6-13.2)
≥6.5% or diabetes‡	1.8 (0.3-12.4)	11.6 (4.5-30.0)
sRAGE quartile		
<620pg/mL	1.0 (Reference)	1.0 (Reference)
620-880 pgmL	1.9 (0.8-4.5)	1.4 (0.5-4.0)
880-1170 pgmL	1.4 (0.6-3.2)	1.6 (0.6-4.4)
≥1170pg/mL	3.2 (1.3-7.8)	4.8 (1.6-14.0)
8-fold higher hsCRP	1.2 (0.7-2.2)	1.1 (0.5-2.3)

*Adjusted for Matching criteria. †Adjusted for age, sex, race, baseline eGFR, systolic blood pressure, anytihypertensive medication use, current smoking, BMI, LDL, HDL, triglycerides and variables in the table. ‡Self-reported diagnosis or medication use.

Conclusions: Higher sRAGE and HbA1c are independent risk factors for ESRD.

Association of Serum Levels of and Genetic Variation in Inflammatory Genes with Decline in Renal Function: Results from the Chronic Renal Insufficiency Cohort (CRIC) Study Jayanta Gupta,[1] Peter A. Kanetsky,[1] Nandita Mitra,[1] Marshall M. Joffe,[1] Harold I. Feldman,[1] Muredach Reilly,[1] Nicolas Jose Guzman,[2] Maria R. Wing,[2] Vaidyanathapura S. Balakrishnan,[3] Vallabh O. Shah,[4] John W. Kusek,[5] Dominic S. Raj.[2] *[1]University of Pennsylvania; [2]George Washington University; [3]Tufts Medical Center; [4]University of New Mexico; [5]NIDDK.*

Background: Serum levels of inflammatory biomarkers and inherited variation in genes encoding these biomarkers previously have been associated with adverse renal outcomes. We investigated the association of serum levels of interleukin (IL) 6, IL1β, IL1 receptor antagonist (IL1RA), transforming growth factor (TGF) β, high sensitivity C-reactive protein (hsCRP) and fibrinogen and underlying genetic variation with progressive deterioration of renal function in CRIC study participants.

Methods: Biomarkers were determined in baseline serum samples. Genotypes for 266 corresponding SNPs were available from the ITMAT/Broad/CARE chip. For each participant, up to five measures of eGFR were available across study visits. Estimates were determined separately among 1,638 white and 1,651 African-American subjects

using a linear mixed effects model. Analyses were conducted with log-transformed measures. We adjusted for age, gender, and baseline eGFR in genetic models, and also for proteinuria, diabetic status, blood pressure and smoking status in addition to other covariates in biomarker models.

Results: Serum level of hsCRP was significantly associated with decline in eGFR in the African-American population after correction for the false discovery rate (FDR; p=0.04). We noted no other associations with baseline serum measures among either the white or African-American group. Although several variants in various genes were nominally associated with temporal decline in eGFR (p<0.05), none retained significance after FDR adjustment.

Conclusions: hsCRP predicts deterioration of renal function in the African-American subgroup of the CRIC cohort. Individual sequence variants in selected inflammatory pathway genes were not associated with progression of kidney disease; however, these findings need to be further investigated using pathway-based analysis.

Funding: NIDDK Support

FR-PO1428

Even Mild Chronic Kidney Disease Increases the Risk of Adverse Events after Elective Cholecystectomy: Analysis of National Data from the American College of Surgeons Sreedhar A. Mandayam,[1] Linda W. Moore,[2] Stephen L. Jones,[2] Edward Graviss,[2] Barbara Lee Bass,[2] William E. Mitch,[1] A. Osama Gaber.[2] *[1]Nephrology, Baylor College of Medicine, Houston, TX; [2]Weill Cornell Medical College, The Methodist Hospital, Houston, TX.*

Background: Cardiovascular risks from CKD are well described but whether CKD Stage 3 (CKD3) increases the risk of unanticipated adverse events in adults undergoing elective surgery is unknown. We assessed whether CKD3 increases unanticipated adverse events after elective cholecystectomy

Methods: We evaluated the ACS-NSQIP 2005-2007 database (a nationally representative dataset of surgical procedures and outcomes) for 30-day mortality and major complications following elective surgery. Pre-operative serum creatinine (SCr) and estimated GFR (CKD-Epi formula) were used to stratify patients into CKD3 (eGFR, 30-59) or NoCKD (eGFR>90)

Results: Non-emergency cholecystectomy occurred in 18,260 cases: median age was 47 (18-89years), 66.9% were white, 71% were women, 11.7% diabetic and 35.2% hypertensive. CKD3 was present in 5,542 (30.4%) with median SCr 1.2mg/dL; 0.9 to 2.5 compared to NoCKD (median Scr 0.7mg/dL, 0.4 to 1.3). Only 62 patients died but 638 had major complications. 30 day mortality occurred in 42 CKD3 pts vs 20 with NoCKD (p<0.0001) Major complications occurred in 5.9% of CKD3 and 2.5% of the NoCKD group (p<0.0001). Length of stay was also longer (2.2±0.4days vs 1.2±0.2days; p<0.0001). By multivariate nominal logistic regression, CKD3 was significant risk factor for major complications (p=0.0007). The proportional hazard for mortality was 2.6 (95% CI, 1.5-4.6; p=0.0007) with CKD3 of all pre-surgery risk factors.

The presence of CKD3 carries a significant risk of mortality and major complications plus a longer hospitalization even when the surgical procedure (e.g., cholecystectomy) is "low risk". Since the median serum Cr was only 1.2, most patients & surgeons are likely be unaware of preexisting kidney disease.

Conclusions: The presence of even mild renal insufficiency increases the risk(>2.5 fold) of major adverse outcomes following elective surgery. This raises the potential for more intensive evaluation in patients with CKD3.

FR-PO1429

Progression of Risk Factors for Chronic Kidney Disease in Zuni Indians Antonia M. Harford,[1] Arlene Bobelu,[2] Vallabh O. Shah,[1] Donica M. Ghahate,[1] Jeanette Bobelu,[1] S. Paine,[1,2] Philip Zager.[1,2] *[1]Internal Medicine, UNMHSC, Albuquerque, NM; [2]Dialysis Clinic, Inc., Albuquerque, NM.*

Background: The Zuni Kidney Project (ZKP) has described the epidemic of kidney disease in the Zuni Indians in a population based cross-sectional study identifying high prevalence of incipient and overt albuminuria in both diabetic and non-diabetic subjects. The subsequent investigation of Genetics of Kidney Disease in Zuni Indians (GKDZI) described the heritability of kidney disease and its intermediate phenotypes in a study of extended Zuni families.

Methods: In order to test the hypothesis that the risk factors for CKD would progress over time, we performed an analysis of a subset of GKDZI subjects who participated in both ZKP and GKDZI.

Results: Five hundred and twenty nine individuals who participated in GKDZI were studied at 2 time points at a mean interval of 6.7 years (range 2.5-9.9 years). Forty eight percent of this cohort was female, mean age at the 1st study point was 30.8 years. The table shows the progression of CKD and its risk factors over time.

CKD RISK FACTOR PROGRESSION IN ZUNI INDIANS

	Time Point 1	Time point 2
ESRD	0	4
% w eGFR <60	1.7%	3.2%*
Mean BMI	27.3	29.0*
% Diabetic	12.6	19.3*

529 participants (* statistically significant p<0.05)

The development of ESRD in 4 individuals in this cohort underscores the high incidence of renal disease previously described by our group in this population. In addition decreased renal function was noted in 9 (1.7%) individuals at the time point I and 17 (3.2%)at time point II. 105 participants were teenagers at the first study point and young adults at the second time point. This group had particularly high rates of progression of obesity, 42.9% were overweight or obese at time point I, 63.7% at time point II.

Conclusions: This analysis of a cohort of individuals from the ZKP/GKDZI studied at 2 time points over up to 9 years shows a progression of CKD and its risk factors including diabetes and obesity. These findings reinforce the need for interventions to modify these risk factors for CKD progression in this high risk population, particularly amongst the young adult Zuni.

FR-PO1430

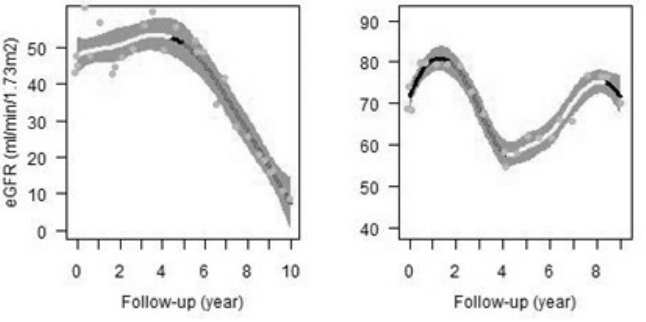
A Novel Within-Person Design To Study the Relationship between Concurrent Risk Factors and CKD Progression Liang Li,[1] Bo Hu,[1] Lawrence J. Appel,[2] Brad C. Astor,[2] Julia Lewis,[3] Michael S. Lipkowitz,[4] Robert D. Toto,[5] Xuelei Wang,[6] Jackson T. Wright,[6] Tom H. Greene.[7] *[1]Cleveland Clinic; [2]Johns Hopkins; [3]Vanderbilt; [4]Georgetown; [5]University of Texas Southwestern; [6]CWRU; [7]U Utah.*

Background: GFR decline in CKD is often assumed linear over time. We recently showed that over 9-12 yrs follow-up, a substantial portion of 1094 African American Study of Kidney Disease (AASK) pts had nonlinear eGFR patterns, which may include periods of rapid GFR decline or stable/improving GFR. Concurrent risk factors from the two periods on the same patient can be compared to study their relationship with CKD progression, removing confounding from baseline characteristics.

Methods: Penalized splines were used to estimate nonlinear eGFR trajectories. For each patient, we define a stable/improving period to be at least 3 yrs with eGFR slope no steeper than 3ml/min/1.73m^2/yr and total decline<4.5 ml/min/1.73m^2(red segment in figure) and a rapid decline period with slope steeper than 3 and total decline>12(yellow). Concurrent factors, measured every 6-12 months, are compared between the two periods with ANOVA.

Results: 105 AASK pts had both a stable/improving period and a rapid decline period. Rapid GFR decline was associated with higher serum sodium (p=0.021), serum CO2 (p=0.012), creatinine (p<0.001), urine protein/creatinine ratio (p<0.001), hospitalization rate (p=0.032), and lower urine urea nitrogen (p=0.0014), but not with urine sodium (p=0.69) and serum glucose (p=0.67).

Conclusions: This design is a new way to study relationship between concurrent risk factors and CKD progression, which avoids confounding from patient specific factors. It may yield useful insight into the pathophysiology of biomarkers and other concurrent risk factors with the acceleration/deceleration of CKD progression.



Funding: NIDDK Support

FR-PO1431

Hypoalbuminemia, Mortality and Chronic Kidney Disease (CKD) among Participants of the REGARDS Study Rebecca J. Schmidt,[1] Bethany S. Pellegrino,[1] Suzanne E. Judd,[2] Paul Muntner,[2] David G. Warnock,[2] Brian D. Bradbury,[3] Orlando M. Gutierrez,[2] William M. McClellan.[2] *[1]West Virginia University, Morgantown, WV; [2]University of Alabama, Birmingham, AL; [3]Amgen, Thousand Oaks, CA.*

Background: The predictive value of hypoalbuminemia in patients with end stage renal disease (ESRD) is well known. The prevalence and prognostic implications of low serum albumin (SA) in the general population and in patients with earlier stages of CKD are less clear.

Methods: The association between SA, CKD and income was examined among 20,106 subjects from REGARDS, a population-based study designed to identify factors leading to stroke in the Southeastern US.

Results: Hypoalbuminemia, defined as SA < 3.8 g/dl (10th percentile), was found in 10.2% of females (8.2% of males), 12.4% of blacks (7.3% of whites), 15.1% of diabetics and 10.9% of hypertensives. Mean (SD) SA was 4.17 g/dl (0.33).

Females were 28% more likely to have low SA than males, blacks 89% more likely than whites; diabetics 75% and hypertensives 23% more likely than those without either diagnosis. Low SA was 28% and 26% more likely in subjects without a high school education or with an annual income <$20,000, respectively. In both racial groups, the likelihood of having a low SA was >30% higher in those with low income or education. The prevalence of low SA rose with age reaching 17.3% for age >75.

Abnormal renal function associated with low SA; subjects with GFR <45 ml/min were twice as likely to have low SA; urine albumin-creatinine ratio (ACR) ≥ 30 mg/g posed

76% greater odds of having low SA. The association between low SA and both GFR and ACR persisted after adjusting for age, race, sex, comorbid illness and income. Low SA was associated with a mortality rate of 13.8% vs 5% among those with higher SA, HR (95% CI)=2.18 (1.90, 2.50). Higher mortality persisted after controlling for age, race, sex, hypertension, diabetes and income, adjusted HR (95% CI)=2.03 (1.77, 2.33).

Conclusions: Our findings suggest that hypoalbuminemia is associated with the presence of CKD and survival in patients with CKD. Hypoalbuminemia is worthy of further study as a biomarker of nutritional and socioeconomic status, as well as of inflammation in progressive CKD.

Funding: Pharmaceutical Company Support

FR-PO1432

Comparison of Two-Stage and One-Stage Meta-Analyses: An Example of eGFR-Mortality Association (for CKD-PC Collaborators) Yingying Sang, Kunihiro Matsushita, B. Khan Mahmoodi, Brad C. Astor, Josef Coresh, Mark Woodward. *Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Background: Individual participant data (IPD) meta-analysis provides precise statistical estimates. Two approaches to meta-analyze IPD are currently used. The 1-stage approach fits a regression model to a pooled dataset including all studies. The 2-stage approach fits models in individual studies and meta-analyzes the estimates. However, their comparability is not well described. We compare these methods for eGFR-mortality association in the CKD Prognosis Consortium (CKD-PC).

Methods: For the 1-stage method, we fitted a Cox stratified model, allowing each study to have a unique baseline hazard but assuming a common hazard ratio (HR) for eGFR across studies. For the 2-stage method, we first fitted a Cox model in each study, and then meta-analyzed HRs using a fixed-effect (assuming one true HR for eGFR across studies) and a random-effects (allowing some variance of true HR) model. eGFR was fitted as linear splines in all models.

Results: In a sample of 10 of 46 cohorts joining CKD-PC (58,790 participants and 8,369 deaths), these methods gave nearly identical estimates except for eGFR <30 (figure). The difference in eGFR <30 for the random-effects 2-stage method results from relatively high weights to studies with unreliable estimates in this range. The 95% CIs were wider as methods made fewer assumptions – narrowest for 1-stage method, slightly wider for the fixed-effect 2-stage and wider for the random-effects 2-stage method.

Conclusions: The two-stage and one-stage meta-analyses provided nearly identical estimates for the eGFR-mortality relationship. The random-effects 2-stage method will provide conservative estimates with wider 95% CIs but this is necessary in the presence of heterogeneity.

FR-PO1433

Kidney Function and Mortality in Octogenarians Shani Shastri, Ronit Katz, Dena E. Rifkin, Carmen A. Peralta, Michelle Odden, Michel B. Chonchol, Linda F. Fried, Michael Shlipak, Anne B. Newman, Mark J. Sarnak. *Nephrology, Tufts Medical Center, Boston, MA.*

Background: The clinical significance of chronic kidney disease has been questioned in elderly, particularly in the oldest old. We examined the association of kidney function with all-cause mortality among octogenarians in Cardiovascular Health Study (CHS) All Stars participants.

Methods: Kidney function was assessed using serum cystatin C and creatinine-based estimated glomerular filtration rate (eGFRCr) using the CKD-Epi equation in 1053 CHS All Stars participants. The association of kidney function with all-cause mortality was analyzed using unadjusted and adjusted Cox proportional hazards models in continuous and quintile-based analyses.

Results: Mean age was 86 years, 64% were females, 66% had hypertension, 14% had diabetes and 38.5% had prevalent cardiovascular disease. There were 154 deaths over median follow up of 2.63 years. After multivariable adjustment, the highest quintile of cystatin C as well as highest and lowest quintiles of eGFRCr were significantly associated with all-cause mortality.

Association of Mortality with Kidney Function

	Mortality Rate per 100 person yrs	Unadjusted Hazard Ratio (95% CI)	Adjusted* Hazard Ratio (95% CI)
Cystatin C Quintiles (mg/L)			
≤0.89	3.6	1.00 (ref)	1.00 (ref)
0.90 -1.02	4.8	1.37 (0.76, 2.49)	1.31 (0.72, 2.40)
1.03 - 1.15	4.8	1.33 (0.72, 2.45)	1.06 (0.57, 1.98)
1.16 - 1.39	5.5	1.44 (0.80, 2.59)	1.14 (0.62, 2.07)
≥ 1.40	11.1	3.12 (1.83, 5.30)	1.92 (1.09, 3.38)
CKD Epi eGFR Quintiles (ml/min/1.73 m2)			
≥75	6.9	2.32 (1.28, 4.20)	2.49 (1.36, 4.55)
64-75	3.1	1.00 (ref)	1.00 (ref)
55-63	4.1	1.25 (0.64, 2.43)	1.23 (0.63, 2.41)
44-54	6.4	1.99 (1.09, 3.66)	1.68 (0.91, 3.09)
≤ 43	9.0	2.86 (1.60, 5.09)	2.28 (1.26, 4.10)

*Adjusted for age, gender, race, hypertension, diabetes, smoking, body mass index, prevalent cardiovascular disease, prevalent heart failure, low density and high density lipoprotein, and C-reactive protein.

Conclusions: Decreased kidney function assessed using either cystatin C or eGFR based on creatinine is a risk factor for all-cause mortality in octogenarians. In adjusted analyses the relationships do no appear linear for either measure.

The Association of *klotho* Polymorphism with Disease Progression and Mortality in IgA Nephropathy Gang Jee Ko,[1] Eunah Lee,[1] Un Sil Jeon,[1] Heui Jung Pyo,[1] Ho Jun Chin,[2] Suhnggwon Kim,[2] Young-Joo Kwon.[1] *[1]Department of Internal Medicine, Korea University School of Medicine, Seoul, Korea; [2]Department of Internal Medicine, Seoul National University Bundang Hospital, Bundang, Gyeonggi-do, Korea; [3]Progressive Renal disease and Medical Informatics and gEnomics Research (PREMIER) members, .*

Background: IgA nephropathy is most common in primary glomerulonephritis causing end stage renal disease (ESRD), and vasculopathy is known to involve disease progression. *Klotho*, a gene related to aging, has been reported to play a role in atherosclerosis and endothelial dysfunction. We investigated whether *klotho* gene polymorphism affect clinical course of IgA nephropathy.

Methods: The data registered for the Progressive Renal disease and Medical Informatics and gEnomics Research (PREMIER) study which enrolled the patients with biopsy proven IgA nephropathy from 34 hospitals and clinics were analyzed. Two single nucleotide polymorphisms for *klotho* gene, G395A of promoter region and C1818T of exon 4, were examined using Taqman PCR assay, and investigated the association of genotypes of *klotho* with the progression of IgA nephropathy and patients survival.

Results: Among 1078 patients, clinical data from 978 patients confirmed whether alive or dead were analyzed. The allele frequency was 0.174 for A allele of G395A and 0.184 for T allele of C1818T complied with Hardy-Weinberg equilibrium. Death was observed more frequently in A allele carrier of G395A polymorphism (0.7 vs 2.6 % in GG vs GA+AA , p=0.04). Proportion of patients who were progressed to ESRD treated with dialysis also tended to be higher in A allele carrier of G395A polymorphisms (p=0.07), and renal survival was worse in same group (p=0.04). In subgroup analysis of CKD stage I to III patients at enrollment, more patients progressed to CKD stage IV and V in T allele carrier of C1818T polymorphism (6.5 vs 11.1% in CC vs CT+TT, p=0.04)

Conclusions: *Klotho* gene polymorphism was associated with patients' survival and disease progression of IgA nephropathy. The exact role and mechanism of Klotho protein in IgA nephropathy should be studied further in the future.

FR-PO1435

Factors Contributing to Suboptimal Initiation of Dialysis Despite Early Nephrologist Referral Stephanie A. Hughes,[4] Sheldon W. Tobe,[1] Philip McFarlane,[2] David C. Mendelssohn.[3] *[1]Medicine, Sunnybrook Health Sciences Centre, North York, ON, Canada; [2]Medicine, St. Michael's Hospital, Toronto, ON, Canada; [3]Medicine, Humber River Regional Hospital, Weston, ON, Canada; [4]Queen's University, Kingston, ON, Canada.*

Background: Early referral to a nephrologist improves dialysis outcomes. The STARRT study recently demonstrated that many patients still experience suboptimal dialysis starts, even when followed by nephrology for more than 12 months (NDT 2011). However, STARRT did not identify the factors associated with this, nor is there much information about this problem in the literature. The objectives of this study were to extend the results of the STARRT study by ascertaining the factors leading to suboptimal initiation of dialysis in patients who were referred to a nephrologist at least 12 months prior to commencement of RRT.

Methods: The methodology is a retrospective chart review. At each of three Toronto centers, charts of consecutive incident RRT patients were identified from January 1st to December 31st 2010. Information was collected from initial referral to a nephrologist until initiation of RRT. Preliminary data from a single center is presented.

Results: 88 incident RRT patients were studied. 52.2% were followed by a nephrologist for more than 12 months prior to initiation of dialysis. Of this group, 47.8% started dialysis with a central venous catheter, 37% with an arteriovenous fistula and 15.2% with a peritoneal catheter. Suboptimal starts occurred in 52.5% of patients receiving more than 12 months of

predialysis care. Factors contributing to suboptimal starts included patient-related delays (45.8%), acute-on-chronic kidney disease (29.2%), surgical delays (8.3%), late decision-making (8.3%), and other factors (8.3%).

Conclusions: The rate of suboptimal starts despite early referral remains high. This is due primarily to patient-related delays and urgent RRT initiation following an acute on chronic event. Especially the former would seem to be modifiable, and reducing the frequency of this occurrence would be expected to improve the quality of dialysis initiation and subsequent outcomes.

FR-PO1436

Use of an Electronic Medical Record, To Examine the Factors Associated with the Progression of Chronic Kidney Disease in Referred Patients in Australia Neil Boudville,[1, 2] Henry R. Moody,[2] Anna Kemp,[1] Robert G. Fassett,[2] Craig L. Nelson,[2] Eugenia Pedagogos,[2] Helen G. Healy,[2] George Jack Mangos,[2] Geoffrey S. Kirkland,[2] Troy D. Kay,[2] David A. Waugh.[2] *[1]University of Western Australia, Australia; [2]electronic Kidney Disease National Audit Alliance, Australia (eKiDNAA), Australia.*

Background: Despite the implementation of best practice guidelines, patients with chronic kidney disease (CKD) still progress. The aim of this study was to examine the utility of an electronic medical record (EMR), used by a number of Nephrology practices throughout Australia, to explore the factors that are associated with progression of CKD.

Methods: This was a retrospective study utilising *Audit4* (Software 4 Specialists, Australia), which is used by over 40 nephrology practices around Australia. Patients were included if they had a minimum of 2 serum creatinine measurements at least 90 days apart. Baseline was the time of the first entry of the patient into *Audit4*. Patients on renal replacement therapy at baseline were excluded. Rate of change in estimated Glomerular filtration rate (eGFR) was the primary outcome.

Results: 1327 patients were included, mean eGFR at baseline was 37.4±0.7mL/min/1.73m2 with a follow-up of 17.7months (range 7 to 26months). The change in eGFR was -0.84 ± 0.26mL/min/1.73m2/year. Univariate analysis demonstrated that women, smoking, erythropoeisis stimulating agent (ESA) use and high serum phosphate were associated with a greater decline in eGFR. Multivariate analysis showed that the factors associated with a more rapid decline in eGFR included: gender, age, ESA use, use of phosphate binders, and baseline eGFR (r2=0.11). Additional modelling demonstrated that hypertension (n=597, r2=0.15) and albuminuria (n=311, r2=0.22) were not predictors of progression in the Nephrologist-care setting, though inclusion of additional variables reduced the number of participants considerably due to missing data.

Conclusions: Our results demonstrate that the retrospective use of this EMR may result in inadequate data quality that could potentially bias the results. Mechanisms to increase the rigor of prospective data collection are required to enable EMRs to perform adequately for research.

FR-PO1437

Moderate Renal Dysfunction as an Independent Predictor of Impaired Preference-Based Health-Related Quality of Life: The 3rd Korean National Health and Nutrition Examination Survey Yun Jung Oh,[1] Chun Soo Lim,[2] Yon Su Kim,[1] Dong Ki Kim.[1] *[1]Internal Medicine, Seoul National University Hospital, Seoul, Korea; [2]Internal Medicine, Seoul National University Boramae Hospital, Seoul, Korea.*

Background: Only a few large-scale studies have investigated the association between health-related quality of life (HRQOL) and renal function. This study aimed to assess the impact of renal function on the HRQOL of the general population.

Methods: We analyzed data for 5,555 adults, aged 19 years or older, from the Korean National Health and Nutritional Examination Survey 2005. The EuroQol-5D (EQ-5D) score was used to evaluate HRQOL. The population was stratified into 3 groups according to the estimated glomerular filtration rate (eGFR): group 1, eGFR ≥ 90; group 2, 90 > eGFR ≥ 60; group 3, 60 > eGFR ≥ 30 mL/min/1.73 m^2. Individuals with more advanced renal dysfunction were excluded from the analysis.

Results: In this study population, parameters concerning the subjects' socioeconomic status (marital status, educational status, occupation, income and residential space) and psychological status (degree of stress, and quality of sleep) were all deteriorated with declining eGFRs. Moreover, the score of EQ-5D in patients with eGFR less than 60 mL/min/1.73 m2 was significantly lower compared to the other groups. On multivariate analysis, eGFR less than 60 mL/min/1.73 m2 was an independent determinant of impaired HRQOL after adjustment for age, gender, health-related behaviors (smoking and alcohol intake), socioeconomic and psychological variables, and other medical comorbidities including diabetes, hypertension, metabolic syndrome, ischemic heart disease, and cerebrovascular disease (odds ratio, 1.455; 95% CI, 1.020-2.074 ; p = 0.038). In subgroup analysis for patients with eGFR less than 60 mL/min/1.73 m2, eGFR was indepedent determinants for reporting problems in the mobility dimension of EQ-5D questionnaire (odds ratio, 3.583; 95% CI, 1.579-8.131 ; p = 0.022).

Conclusions: This study strengthens evidence that moderate renal dysfunction is an important predictor of HRQOL and also suggests that even the patients with moderately decreased eGFR should be managed to improve its global health outcome.

FR-PO1438

Visit to Visit Blood Pressure (BP) Variability and Cardiovascular Risk in CKD Patients Francesca Mallamaci, Daniela Leonardis, Giovanni Tripepi, Filippo Catalano, Anna Pisano, Giuseppe Enia, Maurizio. Postorino, Carmine Zoccali. *CNR-IBIM, Clin. Epid. and Physiopath. of Renal Dis. and Hypert., Reggio Calabria, Italy.*

Background: Blood pressure (BP) variability as measured by 24 ABPM is an independent risk factor for cardiovascular (CV) events in the general and in the hypertensive population. Recent observations in essential hypertensives indicate that also BP variability during consecutive visits predicts a high CV risk. No study investigated the relationship between visit to visit BP variability and the risk of CV events in CKD patients.

Methods: We investigated the relationship between visit to visit BP variability [expressed in terms of standard deviation (SD)] during consecutive visits (from 2 to 7 visits at 6-months intervals) in 792 patients with stage 3-4 CKD ($eGFR_{MDRD175}$:29±15 ml/min/1.73 m^2) over a an average follow-up of 31 months.

Results: During the follow-up, BP was on average 131/76 mmHg with a SD of 11±5/7±3 mmHg. The SDs of systolic BP (SBP) were directly related to the corresponding average values of SBP during the follow-up (r=0.31, P<0.001) and closely associated to the presence of CV comorbidities(P<0.001). During the follow-up, 104 patients had CV events. On univariate Cox regression analyses, the SD of SBP predicted a high risk of CV events [HR (5 mmHg increase): 1.34, 95% CI: 1.10-1.2.37, P<0.001] while no relationship was found between the SD of diastolic BP and the same outcome. In a multiple Cox model including the SDs [HR (5 mmHg): 1.22, 95% CI: 1.05-1.1.47, P=0.03] and the corresponding average values of SBP [HR (5 mmHg): 1.10, 95% CI: 1.05-1.16, P=0.03] both variables significantly predicted CV events. Data adjustment for Framingham risk factors did not modify the association between the SD of SBP and CV outcomes [HR (5 mmHg): 1.22, 95% CI: 1.02-1.47, P=0.03] while the average value of SBP lost its prediction power for these outcomes after multivariate data adjustment (P=NS).

Conclusions: Visit to visit variability of systolic BP is a stronger risk factor for CV events than average SBP in CKD patients. Assessment of visit to visit SBP variability may be useful for risk stratification in CKD patients.

FR-PO1439

Five-Year Review of Disease Pattern Observed in Native Renal Biopsies in Children from a Single Center in Korea Byoung-Soo Cho, Jin-Soon Suh. *Department of Pediatrics, Kyung Hee University Hospital, Seoul, Korea.*

Background: In the absence of a national renal biopsy registry for children, there is a paucity of information on the pattern of renal disease observed in native renal biopsies in pediatric patients in Korea.

Methods: A retrospective review of native renal biopsies performed in pediatric patients was undertaken at the Kyung Hee University Hospital from January 2005 to December 2009. Renal biopsies were studied by light, immunoflourescence and electron microscopy. And renal biopsy diagnoses were divided into the following groups: primary glomerulonephronephritis(GN), secondary glomerulonephritis, tubulointerstitial disease (TID) and hereditary disease (HD).

Results: A total of 617 pediatric patients were included in the study. The mean age was 12.4 years old and a male predominance (1.3:1) was observed. The most common clinical syndrome leading to renal biopsy was asymptomatic urinary abnormalities (64.3%), followed by macroscopic hematuria (16.1%), systemic disease (8.9%) and nephrotic syndrome (4.7%). Among the histologic diagnoses, primary GN was the most commonest diagnosis representing 76.7%, followed by secondary GN representing 6.6%. Among primary GN, mesangial proliferative GN, IgA nephropathy, membranous GN and focal segmental glomerulosclerosis accounted for most. Among secondary GN, Henoch-Scholein purpura nephritis was the most commonest, followed by lupus nephritis. TID and HD comprised 4.1% and 0.5% of all renal biopsy diagnoses, respectively.

Conclusions: The pattern of biopsied renal pathology is somewhat different from that of reported recently from other parts of the world. This study provides valuable information for epidemiological information for childhood renal disease, and it can be the initial step for follow-up and prospective studies.

FR-PO1440

Serum 25-hydroxyvitamin D Level Was Associated with Albuminuria in Korean Adults: A Population-Based Study Youngki Lee, Young Rim Song, Jong-Woo Yoon, Ja-Ryong Koo, Jung-Woo Noh. *Department of Internal Medicine, Hallym Kidney Research Institute, Hallym University, Seoul, Republic of Korea.*

Background: Several observational studies and trials have suggested that vitamin D deficiency was associated with cardiovascular diseases. However, studies have included primarily white populations and a recent systemic review showed the association between vitamin D status and cardiometabolic outcome was uncertain. The present study was undertaken to analyze the serum levels of 25-hydroxyvitamin D and cardiovascular risk factors in the Korean populations.

Methods: Data for this study was obtained from the Fourth Korea National Health and Nutritional Examination Surveys (KNHANES IV) conducted by the Division of Chronic Disease Surveillance, Korea Centers for Disease Control and prevention from 2007 to 2009. We examined interview and laboratory data including 25-hydroxyvitamin D levels from 13,022 participants aged 20 years and older.

Results: In the whole population, the mean 25-hydroxyvitamin D concentration was 18.9 ng/mL. The serum levels of 25-hydroxyvitamin D were lower in women (male 20.6 ng/mL, female 17.6 ng/mL). The serum level was lowest at the age range of 20-39, and then increased, reaching its peak at the age of >60 years. Serum 25-hydroxyvitamin D level was lower in participants with albuminuria and higher in persons with obesity (BMI >25 kg/m2). But vitamin D status was not associated with hypertension, diabetes mellitus, eGFR and history of cardiovascular diseases. After adjustment for age, gender, BMI, hypertension, diabetes mellitus, dyslipidemia, participants with vitamin D deficiency had an increased risk of albuminuria (odds ratio 1.66 [95% confidence interval (CI) 1.36-2.02; p<0.001]).

Conclusions: A lower 25-hydroxyvitamin D level may be associated with higher risk of albuminuria, but cardiovascular diseases or eGFR was not associated with vitamin D status.

FR-PO1441

Development of Diagnostic Panel for Diabetic Kidney Disease Mysore Keshavmurthy Phanish,[1] Nileshkumar Shah,[1] Sarah Yates,[1] Paul J. Roderick,[2] Scott Harris,[2] Marta Lapsley,[1] Mark Edward Dockrell.[1] *[1]SWT Institute for Renal Research, London, United Kingdom; [2]Public Health, Southampton Unversity, Southampton, United Kingdom.*

Background: Albuminuria and eGFR are used to detect and monitor progression of diabetic kidney disease. A proportion of diabetic patients with CKD do not have albuminuria and progression may or may not occur with worsening albuminuria. In this work, we investigated urinary biomarkers in 400 patients with diabetes and correlated their levels with stages of CKD.

Methods: Urine samples were collected from 400 diabetic patients, 388 were analysed. eGFR<60= 204 patients, eGFR>60= 184; ACR (Albumin/Creatinine ratio) <3 =186 and ACR >3=202 patients. We measured markers and mediators of renal injury: inflammatory cytokines (IL6, IL1β, TNFα and MCP1), markers of proximal tubular injury (RBP and NAG) and matrix protein Fibronectin (Fn) using Luminex and ELISA.

Results: Urinary RBP and IL6 correlated (Kruskal-Wallis test, p<0.001, JT test for trend in the ordinal eGFR categories, p<0.001) with CKD stages but not NAG, IL1β, TNFα and MCP1. MCP1 showed significant correlation with CKD stages when albuminuria was included in the analysis. In a subset urinary Fn, cadherin 2 & 6 (proximal tubule markers) and TGF β 1, 2 & 3 were measured. Compared to the healthy controls (n=20, Fn 5.39±1.37 ng/ml), urinary Fn levels were elevated in diabetic patients without CKD (eGFR >60, ACR <3): 9.55± 2.6 ng/ml. There was progressive increase in excretion of Fn with increasing stages of CKD. TGFβ isoforms or cadherin 2 did not correlate with disease; however cadherin 6 was associated with severity of CKD. Cadherin 6 was undetectable in healthy controls (n=12) and was detected in the urine of all patients with progressive CKD.

Conclusions: Urinary levels of IL 6 and RBP correlate with CKD stages in diabetic patients both in the presence and absence of albuminuria. Urinary Fn excretion is elevated in diabetic patients without any other evidence of kidney disease suggesting that it could be an early marker of diabetic kidney disease. Cadherin 6 appears to be a sensitive marker to detect and monitor progression of kidney disease in diabetic patients. Further analysis is in progress.

Funding: Pharmaceutical Company Support

FR-PO1442

Prevalence of Comorbidities among Veteran Chronic Kidney Disease Patients Neha Nainani,[1] Nilang G. Patel,[1] James W. Lohr,[1,2] Pradeep Arora.[1,2] *[1]Department of Medicine, SUNY, Buffalo, NY; [2]Nephrology, VAMC, Buffalo, NY.*

Background: Understanding the relationship between CKD and other chronic diseases is important to develop a public health policy to improve outcomes. In this study, we sought to describe prevalence of comorbid conditions in a cohort of veteran patients.

Methods: We conducted a retrospective cohort study of 97,451 patients seen in primary care clinic in VISN 2 network over 7 years to determine the prevalence of CKD using the MDRD study equation and the CKD-EPI study equation based on single serum creatinine value (MDRD-I, CKD-EPI-I) . Prevalence comorbidities were calculated by both equations. We compared the prevalence of comorbidities in VA vs other data bases like NHANES, KEEP and Medicare

Results: Veterans have a much higher burden of coexisting comorbidities with CKD. On further analysis of patients above age of 65, Veterans have much higher prevalence of CKD and peripheral vascular disease compared to the KEEP and NHANES dataset. Among patients below 65 years of age, only 10.6 % of patients had CKD. 36% patients had vascular disease in the CKD group as compared to 13.88% in the non CKD group. The prevalence of myocardial infarction, coronary artery disease, heart failure and peripheral vascular disease was much higher in the patients with CKD vs the non CKD group.

Prevalence of Comorbidities among CKD patients >65 years

	VAMC CKD	VAMC Non-CKD	KEEP CKD	KEEP Non-CKD	NHANES CKD	NHANES non-CKD
Number of Patients	74.7%	25.3%	43.6%	56.4%	44.2%	55.8%
CAD	26.9%	18%	21%	14.6%	26.7%	16.8%
CHF	12.1%	3.4%	7.5%	4.2%	13.5%	4.2%
PVD	16.9%	9.7%	1.3%	1%	8.5%	4%
CVA	13.6%	8.7%	11.1%	7.8%	12.4%	5.7%
HTN	76.6%	64.7%	94.9%	84.9%	91.6%	69%
Cancer	22.4%	20%	20.3%	18.6%	13.2%	4%
DM	34%	22.6%	45.1%	37.4%	21.4%	12.1%
Dyslipedemia	62%	59.5%	38.8%	42.1%	50.5%	56%

Conclusions: Prevalence of comorbidities including cardiovascular disease is very high among Veterans. This is also true for patients who were younger than 65 years. Higher prevalence of CKD among Veterans can be partially explained by a higher load of vascular comorbidities.

FR-PO1443

Reversible Acute Kidney Injury Is Associated with Improved Survival Compared to Persistent or No Acute Kidney Injury in Septic Shock Manish M. Sood, Claudio Rigatto, Leigh Anne Shafer, Joe A. Bueti, Paul Komenda, Anand Kumar. *Medicine, University of Manitoba, Winnipeg, MB, Canada.*

Background: AKI is common in septic shock being present in greater then 50% of cases. We set out to determine if reversible AKI alters survival compared to those with persistent AKI or no AKI.

Methods: Data was obtained from the Cooperative Antimicrobial Therapy of Septic Shock (CATSS) database comprising 28 centres in Canada, USA and Saudi Arabia. 7,390 individual case of septic shock occurring between Jan. 1996 and Dec. 2008 had baseline creatinine measurements. Cases with pre-existing chronic kidney disease (N=566), previous dialysis or dialysis during the current ICU admission (N=1,033) were excluded leaving 5,791 cases in the final analysis. Reversible AKI was defined by the presence then reversal of AKI according to RIFLE criteria during the first 24 hours of ICU admission. Persistent AKI was AKI over any two time points that did not reverse within the first 24 hours. Cox proportional hazards accounting for repeat creatinine measurements at baseline, 6 and 24 hours were used to determine the association between AKI status and in-hospital mortality.

Results: During the first 24 hours, AKI occurred in 79.3% of whom 11.8% recovered (reversible AKI). A total of 2,774 (47.9%) died in hospital, 49.6% of those with AKI (1,913) and 44.5% of those without AKI (861). Reversible AKI was associated with improved survival (HR 0.58 95%CI 0.48-0.71) compared to NO AKI (referent) and persistent AKI (HR 1.88, 95% CI 1.70-2.08). The improvement in survival in reversible AKI remained after adjustment for demographics, co-morbidities, illness severity (APACHE, number of failed organs, type of infection) and interventions (intubation, blood pressure support agents, appropriate antibiotics) with HR 0.61 (95%CI 0.50-0.74).

Conclusions: In septic shock, reversible AKI within the first 24 hours of admission confers a survival benefit compared to persistent or no AKI.

FR-PO1444

Site of Infection Impacts Presence and Severity of Septic Acute Kidney Injury Manish M. Sood, Keren Mandelzweig, Claudio Rigatto, Paul Komenda, Joe A. Bueti, Anand Kumar. *Medicine, University of Manitoba, Winnipeg, MB, Canada.*

Background: Sepsis is a common cause of acute kidney injury (AKI) in the Intensive Care Unit (ICU) and its presence is an independent marker of adverse outcomes. We set out to determine if the site of infection in septic shock impacted the presence and severity of AKI.

Methods: Using a large multi-centre database that included ICUs from 28 ICU's in Canada, the United States and Saudi Arabia, we analyzed data from cases of septic shock between 1996 to 2008. AKI was classified by the RIFLE criteria. Multivariate logistic regression was used to determine the association between infection site and the outcomes of presence and severity of AKI. Further the association of site of infection stratified by the presence/absence of AKI and in-hospital mortality was investigated. Analyses were adjusted for demographics, illness severity, co-morbidities and ICU interventions.

Results: A total of 7,587 patients had available baseline creatinine values of which 1,115 (15%) patients were excluded due to pre-existing CKD or being on chronic dialysis. The remaining 6,482 (85%) patients were included in the study. Those with AKI were sicker (higher APACHE score; p<0.0001), had more organ failure (p<0.0001), and had more lab and hemodynamic abnormalities. There was considerable variability in both the presence and severity of AKI based on the site of infection. AKI most commonly occurring in GI pseudomembranous (81.2%) and ischemic colitis (79.2%) and UTI (78.8%). Severe AKI (those with RIFLE class fail) was most common in GI pseudomembranous colitis (26.7%) and UTI (22.1%). After multivariate adjustment, ischemic colitis (OR 1.44, CI 1.02-2.02), urinary tract infection (UTI) (OR 1.84, CI 1.38-2.47), and necrotizing fasciitis (OR 1.76, CI 1.19-2.59) were associated with the presence of AKI. In an adjusted analysis looking the site of infection and in-hospital mortality, stratified by AKI the presence of AKI made no impact on mortality in UTI, and most GI infections (biliary, pseudomembranous colitis, perforation, abscess).

Conclusions: This study demonstrates that the presence and severity of septic AKI varies significantly based on the site of infection.

FR-PO1445

Estimated Glomerular Filtration Rate Using Standardized Serum Creatinine, Proteinuria, and Mortality Risk for All Causes and Cardiovascular Diseases Sewon Oh,[1] Su Mi Lee,[2] Ki Young Na,[1,2] Suhnggwon Kim,[2] Ho Jun Chin.[1,2] *[1]Seoul National University Bundang Hospital; [2]Seoul National University College of Medicine, Republic of Korea.*

Background: Lower eGFR and proteinuria (PU) are associated with adverse outcomes. However, it has not been determined which level of eGFR increase the risk of adverse outcomes using standardized serum creatinine. In addition, PU is not used to refine risk estimation of adverse events in the current staging system.

Methods: Based on the data from routine health check-ups in tertiary university hospitals during 2003-2009, 112,115 adult subjects were identified. Serum creatinine levels were calibrated to an assay traceable to isotope-dilution mass spectrometry . The eGFR was calculated using MDRD equation. PU was determined by urine dipstick test and defined as being trace or more.

Results: The majority of subjects (96.9%) had an eGFR of 60mL/min/1.73m2 or greater and 79.7% of subjects were under 60 years of age. Over 39.9±20.7 months, 498 (0.4%) subjects died and 72 (0.1%) died for cardiovascular cause. Compared with those with eGFR of ≥105mL/min/1.73m2, subjects with eGFR 90-104 mL/min/1.73m2 did not have increased risk for all-cause mortality after adjusting for confounders. However, the hazard ratio (HR) for death was 1.67 for subjects with eGFR 75-89 (95%CI, 1.17-2.38); 1.98 for those with eGFR 60-74 (95%CI, 1.36-2.88); 3.65 for those with eGFR<60 (95%CI, 2.31-5.77). In addition, PU revealed as an independent factor for death (HR, 1.25; 95%CI 1.01-1.54). For cardiovascular death (CVD), subjects with eGFR 75-104 did not show increased risk compared with those with eGFR of ≥105. The HR for CVD was 6.04 for those with eGFR 60-74 (95% CI, 1.39-26.37), 17.01 for those with eGFR<60 (95%CI, 3.63-79.77). Also, PU was associated with CVD (HR, 1.81; 95%CI, 1.07-3.05).

Conclusions: By using MDRD equation with standardized serum creatinine, the adjusted rate of all-cause mortality was higher in subjects with eGFR 75-89 mL/min/1.73m^2 compared with those with eGFR of ≥105 mL/min/1.73m^2 and the adjusted risk of CVD was higher in subjects with eGFR 60-74 mL/min/1.73m^2. In addition, PU more than trace was an independent risk factor for death from all-cause and CVD.

FR-PO1446

GFR Variability and Death among Patients with Stage 3 CKD

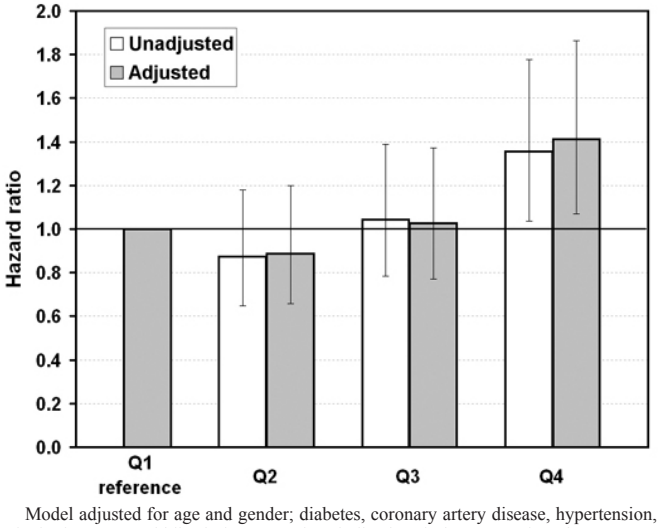
Robert M. Perkins,[1,2] Amanda C. Bengier,[1] Ion D. Bucaloiu,[2] H. Lester Kirchner.[1] *[1]Center for Health Research, Geisinger Health System, Danville, PA; [2]Nephrology, Geisinger Health System, Danville, PA.*

Background: Fluctuations in kidney function may herald hemodynamic compromise. We hypothesized that GFR variability predicts death among those with CKD.

Methods: All adults receiving primary care at Geisinger Health System between 2005 and 2007 who had stage 3 CKD and a minimum of 4 outpatient eGFR values within 24 months were enrolled. Subjects were excluded for any prior ESRD, CHF, metastatic cancer, or immunosuppressive therapy. The slope of eGFR change over time was calculated. Mean absolute residual value was calculated, where residual was the the difference between observed and predicted eGFRs. Quartiles of the mean absolute residual were used for stratification criteria. Subjects were followed until death or study end (March 31, 2011). An adjusted Cox proportional hazard model was developed to estimate the association between eGFR variability and death, the primary study outcome, while controlling for potential confounders.

Results: 3355 patients met entry criteria. Median (IQR) follow-up was 3.9 (3.5-4.1) years. Those patients with the highest (Q4) eGFR residual, relative to those with the lowest (Q1) were more likely to be younger and have diabetes, and to have been hospitalized in the prior 6 months; they were also more likely to have higher HDL and baseline eGFR levels. Unadjusted mortality rates (Q4 vs. Q1) were 40.8 vs. 30.0 deaths/1000 PY.

Figure. Multivariable adjusted Cox proportional hazard ratios for death by quartile of eGFR variability among patients with baseline stage 3 CKD



Model adjusted for age and gender; diabetes, coronary artery disease, hypertension, and Charlson co-morbidity index score; hospitalization during 6 months prior to entry; baseline eGFR, HDL, and serum albumin levels.

Conclusions: EGFR variability independently predicts death among patients with stage 3 CKD.

FR-PO1447

Clinical Impact of the Examination of the Ocular Fundus for CKD Patients without Atherosclerosis Risk Factors

Yoshinari Yasuda,[1] Kiyoshi Shibata,[1] Sadao Suzuki,[2] Sawako Kato,[1] Shoichi Maruyama,[1] Enyu Imai,[1] Seiichi Matsuo.[1] *[1]Nephrology/CKD Initiatives, Nagoya University Post Graduate School of Medicine, Nagoya, Japan; [2]Nagoya City University, Nagoya, Japan.*

Background: In recent years, chronic kidney disease (CKD) has been increasingly highlighted as a risk factor for dialysis and cardiovascular diseases. Although arteriosclerosis plays an important role for CKD onset and progression, clinical significance of the examination ocular fundus (EOF), a marker for arteriosclerosis, has not elucidated yet. Thus we analyzed relationship between EOF and CKD, especially among CKD without arteriosclerosis risks.

Methods: The study subjects were 3,464 men and 3,251 women, who underwent health check including the EOF in Kasugai City Medical Care Center in 2008. Estimated GFR (eGFR) was calculated by the Japanese eGFR equation, and cases with eGFR less than 60 mL/min/1.73m² and/or with proteinuria were diagnosed as CKD. EOF abnormality was diagnosed by abnormal findings by Keith-Wagner and/or Scheie classifications. Multivariate odds ratios for CKD were calculated using logistic regression adjusted for age, sex. In 3,470 subjects without arteriosclerosis risks of hypertension, dyslipidemia or hyperglycemia, multivariate odds ratios and specificity for CKD were also calculated.

Results: EOF abnormalities were observed in 602 cases (8.97%), whose eGFR was significantly lower than those without. Multivariate analysis revealed that age, male, obese, dyslipidemia and EOF abnormality were significant factors for CKD. Among subjects without arteriosclerosis risks, EOF abnormalities were found in 138 cases (4.00%), and EOF was significant risk factor for CKD by multivariate analysis.

Multiple logistic regression analysis of the risk factor for CKD

Risk factors	OR	95% CI	p value
Age	1.07	1.06 - 1.08	< 0.01
Male	1.53	1.28 - 1.82	< 0.01
Obese	1.32	1.02 - 1.70	< 0.05
EOF	1.52	1.05 - 2.20	< 0.05

Specificity of EOF abnormality against CKD was 92.7%.

Conclusions: EOF abnormality would be useful screening tool for CKD, especially among patients without arteriosclerosis risks. EOF might predict subclinical nephrosclerosis by reflecting the sum total of various arteriosclerosis risks for life.

Mortality Risk Factors as a Function of CKD Cohort Definition: Implications for Outcomes Analyses

Robert M. Perkins,[1,2] Jennifer Sartorius,[1] Walter Stewart.[1] *[1]Center for Health Research, Geisinger Medical Center; [2]Nephrology, Geisinger Medical Center.*

Background: Most retrospective cohort studies examining associations between CKD co-morbidities and mortality have enrolled mixed prevalent and incident populations. The influence of differential length-biased sampling on estimates of mortality risk associated with various covariates is unknown.

Methods: We analyzed all adults receiving primary care in an integrated healthcare system in central Pennsylvania with at least one outpatient estimated GFR value between January 1, 2004 and December 31, 2009, and stratified them non-exclusively by incident (at least two CKD-EPI eGFR values < 60 ml/min/1.73m^2, separated in time by at least 90 but no more than 730 days, with at least one prior value >= 60 ml/min/1.73m^2); prevalent (at least two CKD-EPI eGFR values < 60 ml/min/1.73m^2, separated in time by at least 90 but no more than 730 days, with no prior values >= 60 ml/min/1.73m^2); and mixed incident-prevalent categories. Patients with AKI at baseline, ESRD, or metastatic malignancy were excluded. Separate adjusted Cox proportional hazard models for each cohort were developed to identify factors independently associated with death.

Results: 32,596 subjects met study criteria. 12,578 were unclassifiable, largely due to having only a single eGFR value. Median follow-up across stratified groups ranged from 3.5-5.2 years. Mortality rates in the incident, prevalent, and mixed groups was 30.4, 49.9, and 42.4 deaths per 1000 PY, respectively. No covariates demonstrated discrepant risk directionality; many (age, gender, smoking status, ACEI/ARB use, CHF, AKI, proteinuria, and serum albumin) demonstrated consistent and significant hazard estimates across all cohorts. While a history of diabetes and myocardial infarction each independently predicted death among the prevalent population, these covariates were not independently associated with an increased risk of death in the incident cohort. Uniquely in the incident cohort, baseline BMI and eGFR did not independently predict death.

Conclusions: CKD cohort definitions influence mortality rates and mortality risk estimates for traditional covariates, with implications for risk modeling and prognostication.

Association between Hepatitis B Virus Infection with High Alanine Aminotransferase Levels and Low Renal Function: A Cross-Sectional Study in a Representative Sample of Chinese Jianfang Cai, Xiaohong Fan, Bixia Gao, Xuejiao Liu, Lili Liu, Hang Li, Xuemei Li, Xuewang Li. *Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China.*

Background: Population-based studies failed to ascertain the association between hepatitis B virus (HBV) infection and renal disease, which is clinically observed. Our study aimed to re-test this association by considering alanine aminotransferase levels (ALT).

Methods: We tested a representative sample of 6925 Chinese adults aged 30 to 75 years for levels of serum hepatitis B surface antigen, ALT, creatinine, urinary albumin-creatinine ratio, and potential risk factors for chronic renal dysfunction. Elevated ALT was defined as an ALT ≥ 1.25 times upper limit of normal proposed by AASLD.The participants were divided into HBV carriers with elevated ALT (HBV+/ALT+), HBV carriers with normal ALT (HBV+/ALT-), and non-carriers (HBV-/ALT±), then were reorganized into HBV+/ALT+, non-carriers with elevated ALT (HBV-/ALT+), and persons with normal ALT (HBV±/ALT-). General linear model was used to calculate and compare mean eGFR in different groups and odds ratios were estimated by using logistic regression.

Results: With Bonferroni correction for multiple comparisons (α = 0.017), group HBV+/ALT+ had a multivariate-adjusted estimated glomerular filtration rate (eGFR, mL/min/1.73 m2) that was 4.4 lower than that of HBV-/ALT± (95% CI, -7.6 to -1.1; P = 0.004), 4.8 lower than that of HBV-/ALT+ (95% CI, -8.1 to -1.4; P = 0.002), and 4.2 lower than that of HBV±/ALT- (95% CI, -7.5 to -1.0; P = 0.005). Estimated GFR didn't differ between HBV+/ALT- and HBV-/ALT±. Neither did that between HBV-/ALT+ and HBV±/ALT-. An eGFR less than 60 was 3.75 (95% CI, 1.11 to 12.73, P = 0.032) times as likely to occur in carriers with elevated ALT as non-carriers. HBV+/ALT+, HBV+/ALT-, and HBV-/ALT± didn't differ in the probability having albuminuria (10.9% vs. 7.5% vs. 10.8%, P = 0.39).

Conclusions: HBV carriage with elevated ALT levels was associated with reduced renal function. HBV infection may impair renal function paralleling liver injury and preceding HBV-associated nephropathy.

FR-PO1450

Total Serum Free Light Chains Independently Predict Survival in Patients with Stage 3 Chronic Kidney Disease Lakhvir Assi,[1] Natasha J. McIntyre,[2] Colin A. Hutchison,[3] Richard Hughes,[1] Stephanie J. Stringer,[3] Richard J. Fluck,[2] Chris W. McIntyre,[2] Paul Cockwell,[3] Maarten W. Taal.[2] *[1]The Binding Site Group Ltd; [2]Royal Derby Hospital; [3]Renal Institute of Birmingham.*

Background: Approximately 50% of all chronic kidney disease (CKD) patients have moderate renal impairment (Stage 3, GFR 30-59ml/min/1.73m^2) and are generally managed in primary care practices. Tools which allow appropriate risk stratification of this population are required to identify those individuals at risk of progressive renal failure or cardiac events. This study evaluated the prognostic value of polyclonal free light chains (FLCs) in CKD stage 3 patients.

Methods: Patients were recruited from primary care practices, as part of the Renal Risk in Derby study. FLCs were measured with the Freelite™ assay and established normal ranges were used (κ: median 7.3mg/L, range 3.3-19.4mg/L, λ: median 12.7mg/L, range 5.71-26.3mg/L). Total FLCs and κ/λ ratios were also calculated. Time to death was assessed using Kaplan Meier and Cox regression analysis.

Results: At baseline, total FLCs were elevated in 383/1741 (23%) patients (>50mg/L). To date, 52 patients had died. Of these deaths, 23/52 (44%) had abnormally elevated FLCs (median: 46.65mg/L, IQR: 26.24) vs alive patients (median: 36.02, IQR: 19.12). Total FLCs were significantly associated with early mortality (p<0.001). Patients with FLCs >50mg/L had shorter overall survival compared to patients with <50mg/L (p<0.001). In a univariate analysis, the following markers were associated with death: FLCs >50mg/L, gender, CRP, age, calcium, and HDL. Multivariate analysis identified FLCs >50mg/L, age and CRP, to be associated with reduced time to death. Interestingly, eGFR and urinary albumin/creatinine ratio, two factors widely reported as predictors of death, were not associated suggesting FLCs may be a more sensitive predictor of death.

Conclusions: To conclude, total FLCs provide independent prognostic information on the survival of patients with CKD stage 3. Further work will determine how FLCs can be prognostically used to manage these patients.

Are Chinese Herbs a Risk Factor for Progression to End-Stage Renal Diseases in Patients of Newly Diagnosed Chronic Kidney Disease?-- A Population-Based Study Ming-Yen Lin,[1,2] Yi-Wen Chiu,[1,3] H.C. Chen,[1,3] Shang-Jyh Hwang.[1,3] *[1]Division of Nephrology, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [2]Institute of Occupational Safety and Health, Kaohsiung Medical University, Kaohsiung, Taiwan; [3]Department of Renal Care, Kaohsiung Medical University, Kaohsiung, Taiwan.*

Background: The impact of Chinese herbs on renal function in patients of chronic kidney disease remains controversial. We searched claimed data of National Health Insurance (NHI) to study the ESRD outcome in newly diagnosed CKD patients in Taiwan.

Methods: Newly diagnosed CKD patients, based on sets of ICD-9 codes were screened from 1997 to 2008. Patients, who took Chinese hers for over 90 days after first diagnosed of CKD were categorized as Herb-used group and else as Control group. Time period from diagnosed as CKD to first dialysis, date of withdraw from NHI or to the end of 2008 was traced in each patient. Patients who started dialysis were considered as event and else as censored. Survival analyses were used, and p <0.05 was considered as statistically significant.

Results: There were 39,620 newly diagnosed CKD patients in Herb-used group and 66,795 patients in Control group. After adjusted by age, sex, diabetes mellitus, index year, Charlson Index, and urbanization of residence, the Herb-used group significantly had a reduced risk to end-stage renal disease than Control group.

Table 1. Risk for ESRD in newly diagnosed CKD patients by Cox regression analysis(n=105,725)

	Hazard Ratio	95% CI	p-value
Age			
<45	1.00	-	-
45-64	2.52	2.29-2.78	<0.0001
≥65	2.19	1.97-2.43	<0.0001
Sex			
male	1.00	-	-
female	1.22	1.14-1.30	<0.0001
Chinese herb used			
control	1.00	-	-
used	0.56	0.52-0.61	<0.0001

All variables (age, sex, diabetes mellitus, index year, Chinese herb used, Chalson index, and urbanization of residence) was including in the model

Conclusions: The preliminary results of this study show a beneficial effect of Chinese herbs use for the outcome of ESRD, which is contrary to the detrimental effect of herbs containing Aristolochic acid. Since one-third of newly diagnosed CKD patients in Taiwan still took Chinese herbs, thus the research on the therapeutic effect of Chinese herbs on kidney disease is encouraged.

FR-PO1452

Long-Term Antiproteinuric Effect of Spironolactone Translates into Slowing in the Progression of Renal Failure Enrique Morales, Ana Huerta, Victor Gutierrez-Millet, Eduardo Gutierrez, Elena Gutierrez-Solis, Natalia I. Polanco Fernandez, Esther Gonzalez Monte, Manuel Praga. *Nephrology, H.12 de Octubre, Madrid, Spain.*

Background: The efficacy of spironolactone (SL) to reduce proteinuria has been confirmed in several studies. However, information about whether this effect is persistent or transient and its possible repercusions on renal outcomes is lacking. Aims of the study were 1) to analyze the influence of long-term treatment with SL on the slope of GFR in patients who maintain proteinuria >1g/d in spite of renin-angiotensin blockade with angiotensin-converting enzyme inhibitors (ACEI), angiotensin receptor blockers (ARB) or ACEI+ARB combination, 2) to analyze if the short-term antiproteinuric effect of SL is sustained over time and 3) safety and side effects of long-term SL treatment.

Methods: Prospective observational single-center study was performed. 87 patients (59 m/28 f, mean age 58.4 ± 15.3 yr, 62% with GFR <60 ml/m) who maintain proteinuria > 1 g/d in spite of ACEI (16 p, 19.5%), ARB (49 p, 56.3%) or ACEI+ARB (21 p, 24.1%) were included. SL 25 mg/d (12.5-25) was added to previous treatment. Mean follow up was 24.5 ± 15.7 months (1-84).

Results: Baseline proteinuria (2.9 g/d, 1-10.4) significantly decreased by 41% (23-52) 1 mo after SL and 63% (39-79) at 12 months. At the end of follow-up proteinuria had decreased 61% from baseline (43-77), and 69% p had a proteinuria reduction >50%. GFR slope was -0.3 ml/m/mo in the 12 mo prior to SL treatment. In the first mo after SL, GFR significantly decreased (-4.7 ml/m), likely because of the diuretic effect of SL, but it tended to stabilize or improve thereafter. GFR slope after the first mo of therapy was 0.1 ml/m/mo, p 0.047 (in comparison with pre-SL period). Blood pressure showed a significant decrease and serum potassium increased from 4.6 ± 0.4 to 4.9 ± 0.6, p 0.00). 10 p (11.5%) discontinued SL because of hyperkalemia. Nine of them had GFR <60 ml/m at baseline.

Conclusions: SL induces an important and sustained antiproteinuric effect in patients with chronic proteinuric diseases. The incidence of hyperkalemia was low among patients with GFR>60 ml/m. GRF slope significantly improved after the introduction of SL.

FR-PO1453

Screening for CKD in Mexico. Targeting High-Risk Populations Guillermo G. Garcia,[1] Alfonso Gutierrez Padilla,[1] Alberto Barajas,[1] Martha Mendoza,[1] Ma del Mar Gonzalez,[1] Marcello Tonelli.[2] *[1]Nephrology, Hospital Civil de Guadalajara, Guadalajara, Mexico; [2]U of Alberta, Canada.*

Background: Chronic non-communicable diseases, such as obesity, diabetes mellitus, hypertension, and CKD, have become a major public health problem in Mexico. Since 2006, we pioneered screening people at risk for the presence of CKD using mobile units that travel to rural and urban communities of Jalisco.

Methods: Participants were informed of risk factors for CKD, but all consenting adults without known CKD were included. Trained personnel collected demographic and clinical data, and obtained blood and urine for serum chemistry and dipstick urinalysis. GFR was estimated with the MDRD formula. CKD was defined as per KDOQI guidelines. Between September 2006 and December 2009, 9,619 adults were screened in the mobile units. Results are compared with those of Mexico's National Health and Nutrition Survey (NHNS) 2006.

Results:

	Jalisco n=9619	NHNS 2006 n=33366	p
Age (y)	55.5±0.14	42.5±0.25	<0.000
Male, %	28.7	44.4	<0.000
Self-Reported DM, %	41.9	7.34	<0.000
DM2, %	56.1	14.42	<0.000
Self-Reported HTN, %	51.6	16.5	<0.000
% with SBP≥140 or DBP≥90	70.9	43.2	<0.000
BMI≥30, %	42.8	29.3	<0.000
S Chol≥200 mg⁄dl, %	54.7	43.6	<0.000
S Trig≥150⁄dl, %	58.5	31.5	<0.000
Waist >88 or >102 cm, %	61.2	43	<0.000
CKD, %	31.3	N⁄A	

Conclusions: We conclude that: 1) Our program has successfully targeted high risk populations for CKD; 2) the prevalence of CKD and its risk factors is higher in screenees served by these units as compared to the general Mexican population; 3) a program to use mobile units to deliver a protocol-driven care for this high-risk population will start shortly.

A Simple Estimation of Serum Bicarbonate Concentration in CKD Stage 5 Patients Tetsuya Makiishi, Shinya Yamamoto, Sayako Maeda. *Internal Medicine, Otsu Red Cross Hospital, Otsu, Shiga, Japan.*

Background: To evaluate bicarbonate concentration is essential in daily clinical practice for CKD patients. Blood gas analysis is usually used in Japanese medical facilities for this pourpose, where to measure CO2 content of serum sample is uncommon. However, routine use of a blood gas analyzer at outpatient clinic bears some difficulties because it requires additional techniques and costs. Recently, Hirose et al. founded a linear correlation between values of anion gap (AG) and those of serum phosphate (iP) levels in maintenance hemodialysis (MHD) patients, and reported a simple estimation equation for MHD patients (J Jpn soc Dial Ther 2010;43:919-23). The purpose of the present study is to create a simple estimation equation of bicarbonate for CKD stage 5 (Pre-dialysis) patients.

Methods: Among total of 71 patients who started dialysis therapy at our institution between April 2008 and November 2010, 51 data sets which were simultaneously measured both with a blood gas analyzer and a central laboratory analyzer at their first day of dialysis therapy were collected and examined for a relationship between values of serum anion gap (AG) (mEq/L) and inorganic phosphate (iP) levels (mg/dL) to yield a regression equation. By substituting this into the equation of the definition of AG (AG=Na–Cl–bicarbonate), an estimation equation for bicarbonate was obtained. A relationship between values of estimated bicarbonate (eHCO3-) calculated with the equation and those from the blood gas analyzer was examined. Effects of serum albumin and iP levels on the relationship was also tested.

Results: AGs were well correlated with iP levels (AG=2.08xiP+2.04, r=0.88, p<0.001). With a simplified form of the equation, a new simple estimation equation for bicarbonate, eHCO3- = Na–Cl–2iP–2, was then obtained. Values of eHCO3- were well correlated with those measured with the blood gas analyzer (r=0.84, p<0.001). In either of the low and the high albumin group, and in either of the good (iP < 6) and the high (iP > 6) phosphate group, eHCO3- were well correlated with those from the blood gas analyzer.

Conclusions: This simple equation could be a useful tool to assess serum bicarbonate concentration in CKD 5patients.

FR-PO1455

How Reliable Is Estimation of Glomerular Filtration Rate in Type 2 Diabetes? Xun Liu, Cheng Wang, Tan-Qi Lou. *Division of Nephrology, Department of Internal Medicine, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China.*

Background: Type 2 diabetes is a recognized public health problem worldwide. We compared both estimates with standard glomerular filtration rate (sGFR), measured by the ^{99m}Tc-DTPA method, in Chinese patients with type 2 diabetes.

Methods: A total of 207 type 2 diabetic patients were recruited. Serum creatinine (SC) level was measured by the enzymatic method. Average sGFR was 47.8 ± 26.3 ml/min per 1.73 m^2. In this study, GFR was predicted by Cockcroft-Gault-equation, 6-variable MDRD equation, 4-variable MDRD equation and MCQ equation.

Results: The agreement limits of all the equations exceeded the prior acceptable tolerances defined as 60 ml/min per 1.73 m2. Accuracies with a deviation less than 30% of all the equations were less than the prior acceptable tolerances defined as 70%. When compared the precision, bias as well as accuracy of estimated GFR (eGFR) with sGFR, GFR estimated by Cockcroft-Gault-equation showed better results. Detailed performances are listed in the table.

Overall performance between eGFR and sGFR

	Median of difference	Accuracy within 30%	Accuracy within 50%	Precision	slope of regression line with the X-axis	intercept of regression line with the Y-axis
Cockcroft-Gault equation	-1.0	52.7	72.0	99.8	0.44	-18.8
6-variable MDRD equation	-2.7*	45.9*	68.1*	91.7	0.47	-19.7
4-variable MDRD equation	0.5	45.9*	65.7*	90.8	0.53*	-20.8
MCQ equation	3.5*	34.3*	59.9*	102.8	0.54*	-16.7

*P<0.05 comparing with Cockcroft-Gault-GFR

Conclusions: When SC was measured by the enzymatic method, the performances of GFR estimation equations in Chinese type 2 diabetic patients were disappointing. At present, the Cockcroft–Gault equation may be more suitable in Chinese patients with type 2 diabetes.

FR-PO1456

Performance of GFR Estimation Equations in a South Asian Population Saleem Jessani,[1] Andrew S. Levey,[2] Lesley Stevens Inker,[1] Rasool Bux,[1] Christopher R. Mariat,[3] Christopher H. Schmid,[2] Tazeen H. Jafar.[1] *[1]Aga Khan University, Karachi, Pakistan; [2]Tufts Medical Center, Boston, MA; [3]University de Saint-Etienne, France.*

Background: Ethnic differences in the performance of glomerular filtration rate (GFR) estimation equations have been observed, perhaps in part from non GFR determinants of serum creatinine. However, the existing equations have not been evaluated in people of South Asian descent.

Methods: We measured GFR (mGFR) using the gold standard of urinary clearance of inulin in 581 South Asian men and women in the communities of Karachi, Pakistan, including 40 patients from renal clinics. Standardized creatinine assay was used. The performance of the MDRD Study and CKD-EPI equations was assessed as bias (median difference between measured and estimated GFR), precision (interquartile range of the differences, IQR), accuracy (percent of estimated GFR values that are within 30% of measured values, P30), and the root mean square error (RSME) on the log scale. 95% CI were computed via the bootstrap method using 1000 replications.

Results: The mean (SD) age of subjects was 51 (10) years. The mean (SD) mGFR was 90 (33) ml/min/1.73 m2. The performance of the equations is presented in table.

Metrics (95% CI)	CKD-EPI Equation	MDRD Study Equation
Bias, ml/min/1.73 m2	-6.8 (-9.4, -6.0)	-8.5 (-9.8, -6.5)
IQR, ml/min/1.73 m2	-15.0 (-19.1, -10.4)	-19.9 (-25.1, -15.2)
P30 %	76.1 (72.2, 79.0)	68.0 (63.6, 71.5)
RMSE	0.265 (0.240, 0.291)	0.295 (0.268, 0.322)

Conclusions: The CKD-EPI has significantly greater accuracy (P30) than the MDRD Study equation in this largely unselected South Asian population in Karachi. The overall fit of the equations is similar to reports in the US and European populations, however both equations over-estimate measured GFR at the high levels observed in this Pakistani population. The difference in bias between the Pakistani and US and European populations may be secondary to differences in GFR measurement methods, calibration of the creatinine assay, or non GFR determinants of serum creatinine. Possibly GFR estimation may be improved by modification of existing equations, development of new equations, or use of other endogenous filtration markers.

FR-PO1457

CKD-EPI without Adjustment for Black Race Is the Best Method for Estimating Glomerular Filtration Rate in Adult Patients with Sickle Cell Disease Marie Courbebaisse,[1] Jean-Antine Ribeil,[2] Gilles Chatellier,[5] Dominique Prie,[3] Dominique Eladari,[3] Jacques Pouchot,[4] Gerard Friedlander,[3] Jean-Benoit Arlet.[4] *[1]Néphrologie et Dialyses, Hopital Tenon, APHP, Paris, France; [2]Biothérapie, Hopital Necker, APHP, Paris, France; [3]Explorations Fonctionnelles, Hopital Necker, APHP, Paris, France; [4]Médecine Interne, Hôpital Européen Georges Pompidou, Paris, France; [5]Informatique Hospitalière, Hôpital Européen Georges Pompidou, Paris, France.*

Background: The aim of our study was to determine the best equation to estimate glomerular filtration rate (GFR) in adult sickle cell disease (SCD) patients.

Methods: Since 2007, all adult SCD patients on a steady state had GFR measurement by iohexol plasma clearance. Five equations were tested to estimate GFR: Cockcroft and Gault, MDRD-v4 and CKP-EPI equations with and without adjustment for black race. Measured GFR and estimated GFRs were compared according to Bland and Altman method.

Results: Sixty-four adult SCD patients (16 men, median age 27.5 (18-67.5), 41SS and 23 non SS) were evaluated.They were lean (median body mass index (BMI): 22 kg/m2 (16-33)) and mainly native of Sub-Saharan Africa and of French West Indies. Hyperfiltration (defined as GFR above110 ml/min/1.73m2) was detected in 53% of our patients and chronic

renal failure (CRF) in 18.8%. Micro or macroalbuminuria were detected in 65%, 50% and 28% of patients with hyperfiltration, CRF and normal GFR, respectively (p=0.04). Among the 5 equations tested, the CKD-EPI equation without adjustment for racial group had both the lowest biais and the greatest precision and the difference with the gold standard decreased with increasing GFR values, whereas it increased with the Cockcroft and Gault and MDRD-v4 equations.

Conclusions: SCD adult patients have a high rate of true glomerular hyperfiltration which is frequently associated with albuminuria. In this population, CKD-EPI equation without adjustment for black race is the best method for estimating GFR. The validity of this equation in black people of non American origin and in Black-Americans with low BMI should be evaluated.

FR-PO1458

Performance of GFR Estimating Equations in an HIV Population Lesley Stevens Inker,[1] Zipporah Krishnasami,[2] Hiba Graham,[4] James Hellinger,[1] Maia Leppo,[1] Andrew S. Levey,[1] Aghogho A. Okparavero,[1] Christopher H. Schmid,[1] Hocine Tighiouart,[1] Christina M. Wyatt.[3] *[1]Tufts Medical Center; [2]University of Alabama at Birmingham; [3]Mt Sinai Hospital; [4]Gilead Sciences Inc.*

Background: The performance of GFR estimating equations using serum creatinine (cr) or cystatin C (cys) has not been extensively tested in people with HIV.

Methods: We evaluated the performance of CKD-EPI cr, cys, and cr-cys GFR estimating equations compared to measure GFR (mGFR) using plasma clearance of iohexol in 200 HIV- positive patients on stable antiretroviral therapy. Assays for cr and cys are standardized to certified high-level reference materials. Performance was evaluated by bias (median difference between measured and estimated GFR), precision (interquartile range, IQR, of the difference), and accuracy (percentage of estimated GFR that are greater than 30% of the mGFR, 1-P_{30}).

Results: Of the 200 patients, 125 were on tenofovir disoproxil fumerate (TDF) and 75 were not. Mean age was ± 8 and 73% were male. Mean CD4 cell count was 583 ± 352 cells/mm3 and mean mGFR was 87 ± 26 (range 23-175) ml/min per 1.73 m2. There was no difference in clinical characteristics between patients on or off TDF. There was no difference in bias, precision and accuracy between patients on and off TDF for cr and cr-cys based equations, but a large difference in precision and accuracy for the cys equation.

Performance of GFR Estimating Equations, Overall and by Tenofovir Status

		Overall	Tenofavir	
			Y	N
Creatinine	Median Difference	5.4	5.1	6.6
	IQR	22.7	22.5	22.8
	1-P30	15	13,6	17.3
Cystatin C	Median Difference	4.3	3.2	5.1
	IQR	25.7	28.7*	17.09*
	1-P30	17.5	21.6*	10.7*
Creatinine-Cystatin C	Median Difference	6.4	6.3	6.5
	IQR	21.7	24.1	18.0
	1-P30	10	9.6	10.7

*p-value < 0.05. Units for median difference and IQR are ml/min/1.73m²

Conclusions: The CKD-EPI cr and the cr-cys estimating equations are reasonably accurate and can be used in patients with HIV. Cys based estimating equations are less accurate in patients on TDF due to some people having large under and overestimates of mGFR. It is not known whether this is due to differences in cys generation, kidney handling, or extra-renal elimination.

FR-PO1459

Combination Biomarkers for Glomerular Filtration Rate Estimating Equations May Obviate Ethnicity Adjustments in a Multi-Ethnic Asian Population Boon Wee Teo, Evan J.C. Lee. *Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore.*

Background: Estimates of glomerular filtration rates (eGFR) are improved using serum creatinine (Scr), serum cystatin C (CysC) and/or beta-trace protein (BTP) in combination with demographic data. We hypothesize that ethnicity is not a significant factor when multiple biomarkers are used for eGFR prediction. We assess eGFR using standardized Scr, CysC, and BTP in different combinations with demographics in a multi-ethnic Asian population of healthy and chronic kidney disease (CKD) patients.

Methods: We prospectively recruited 232 CKD patients and 103 healthy participants (52% male, Chinese 38.5%, Malay 29.6%, Indian and others 31.9%). We measured Scr by an enzymatic method, and cysC and BTP by nephelometry. We measured glomerular filtration rate (mGFR) using 3-sample plasma clearance of ^{99m}Tc-DTPA, calculated by the slope-intercept method, with body surface area normalization (du Bois) and Brochner-Mortensen correction. We fitted models developed using linear regressions of combinations of Scr, CysC, BTP and demographics. We use Akaike Information Criterion (AIC) and Bayesian Information Criteria (BIC) to select the best models. We assess the equations by considering the median bias between eGFR minus mGFR, precision (inter-quartile range) root mean square error (RMSE), and percentage accuracy (P15) to within 15% mGFR.

Results: Population means: age 53.5±15years, Scr 1.44±0.97mg/dL, CysC 1.26±0.66mg/L, BTP 1.34±0.86 mg/L, mGFR 66.7±33.3mL/min/1.73m2. In all models, ethnicity is not significant.

Models

Model	Criteria for model selection		
	R2	AIC	BIC
CysC, Scr, Age, Gender	0.893	-126.9	-104.0
BTP, Scr, Age, Gender	0.889	-114.5	-91.7
BTP, CysC, Age, Gender	0.874	-70.3	-47.5
BTP, CysC, Scr, Age, Gender	0.899	-143.8	-117.1
BTP, CysC, Scr, Age, Gender, Interaction*	0.902	-151.1	-120.6

*Interaction of age and cystatin C

The best equation included all biomarkers with demographics. The bias is -0.8, precision is 12.2, and RMSE is 12.3 (all mL/min/1.73m²). The P15 is 64.2%.

Conclusions: Using a combination of biomarkers with demographics may eliminate ethnicity as a significant factor in GFR prediction equations.

FR-PO1460

Estimation of Glomerular Filtration Rate in Lupus Nephritis: Which Formula More Accurately Reflects Actual GFR? Duangrutai Jitprawat,[1] Pongpija Tuchinda,[2] Thonnapong Thongpraparn,[2] Somkiat Vasuvattakul.[1] *[1]Division of Nephrology, Department of Medicine, Faculty of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand; [2]Division of Nuclear Medicine, Department of Radiology, Siriraj Hospital, Mahidol University, Bangkok, Thailand.*

Background: Estimation of glomerular filtration rate (GFR) is widely used in clinical practice. Creatinine is hypersecreted by injured tubules of lupus nephritis (LN). Routine measurement of creatinine clearance may over estimate GFR. We, therefore, assessed the performance of the formulas for GFR estimation: Modification of Diet in Renal Disease (4-v MDRD); 4-v MDRD with the ethnicity factor as established for Chinese population [4-v MDRD (Chinese)]; Cockcroft–Gault (CG); and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formulas, to determine the best formula reflecting actual GFR of LN patients.

Methods: In this cross-sectional study,we enrolled sixty-two LN patients at our renal clinic. 99mTc-DTPA renogram was used as a gold standard to measure GFR. Estimated GFR calculated by the 4-v MDRD, 4-v MDRD (Chinese), CG, and CKD-EPI formulas were compared with the measured GFR using 3 modalities: the intraclass correlation coefficient, bias, and proportion of estimated GFR within 30 % of measured GFR (P30).

Results: The intraclass correlation coefficients between measured GFR and estimated GFR were 0.88 for 4-v MDRD, 0.81 for CG, 0.87 for CKD-EPI, and 0.77 for 4-v MDRD (Chinese) formula. All of the estimated GFR formula overestimated measured GFR by 3.4, 9.6, 11.9, and 17.7 mL/min/1.73 m², for 4-v MDRD, CG, CKD-EPI, and 4-v MDRD (Chinese) formulas respectively). There were statistically significant difference of bias between the 4-v MDRD formula and the others. The 4-v MDRD formula also had the most accuracy (P30 = 93.5%). All formulas lacked precision in estimating GFR in the patients with measured GFR more than 60 mL/min/1.73 m².

Conclusions: The 4-v MDRD, 4-v MDRD (Chinese), CG, and CKD-EPI formulas can be used for estimating GFR in lupus nephritis, especially among patients with the GFR less than 60 mL/min/1.73 m². The 4-v MDRD formula is the most reliable and accurate method to reflect actual GFR.

FR-PO1461

Prevalence of Chronic Kidney Disease in England: Findings from the 2009 Health Survey Paul J. Roderick,[1] Jenny Mindell,[1] Marilyn Roth,[1] Beverley Matthews,[2] Donal O'Donoghue.[3] *[1]University of Southampton, United Kingdom; [2]NHS Kidney Care; [3]Salford Royal Foundation NHS Trust.*

Background: Chronic kidney disease is a global public health problem because it is common and associated with cardiovascular risk. Prevalence estimates from national health or research surveys have been obtained from several developed countries but no such survey undertaken in the UK. This paper presents nationally-representative general population data from the Health Survey for England 2009 on the prevalence of CKD in adults in England.

Methods: The HSE 2009 was one of an annual series of national cross sectional surveys which uses multistage probability sampling to obtain nationally representative estimates. Sampling was stratified by region, and used postcode sectors and postcode address file to sample households. 4680 households were invited and 2832 (61%) participated; in these all adults (age 16+) were invited and 4645 individuals took part and were interviewed. 3261 (71%) had a nurse visit, 2446 (75% of nurse visit) had a single blood test and 2864 (86% of nurse visit) provided a single urine sample. Serum creatinine was measured in one laboratory by an enzymatic method calibrated to IDMS. eGFR was calculated by the MDRD equation. Albuminuria was any albumin in the urine >2.5 mg/mmol in males and > 3.5mg/mmol in females.

Results: The prevalence of CKD stage 3-5 was 6% (7% in females, 5% in males). It varied with age ranging from 1% of males and 2% of females aged 16-54 to 31% of males and 36% of females aged 75 and over. It was commoner in females and there was an inverse socio-economic gradient. CKD stage 4 -5 was rare. Prevalence of albuminuria was 9%, higher in males (10% vs 8%) and with a strong inverse socio-economic in males. The overall prevalence of CKD stages 1-5 was 14% in males and 13% in females. Only 1.5% of males and 1.3% of females reported being told by a doctor they had CKD); 7.6% males and 7.9% females reported they had been tested for CKD.

Conclusions: These are the first nationally representative, population-based data on the prevalence of CKD in England. CKD is common, though heavily age–related. Like other vascular conditions, it has an inverse socio-economic gradient.

FR-PO1462

Comparison of Creatinine- and Cystatin C-Based GFR Estimating Equations in Children with the Diagnosis of Systemic Lupus Erythematosus

Mengchun Gong,[2] Xuemei Li,[1] Xuewang Li,[1] Hongmei Song,[3] Yan Qin,[1] Ke Zheng.[1] *[1]Nephrology, Peking Union Medical College Hospital, Beijing, China; [2]Internal Medicine, Peking Union Medical College Hospital, Beijing, China; [3]Pediatrics, Peking Union Medical College Hospital, Beijing, China.*

Background: There is no data about glomerular filtration rate, measured through plasma clearance of the exogenous markers, in the systemic lupus erythematosus (SLE) children. The objective of this study was to measure GFR and validate of the GFR estimating equations in the SLE children.

Methods: Children diagnosed as SLE were enrolled. Single-compartment plasma clearance of ^{99m}Tc-DTPA was measured and transformed into two-compartment clearance (mGFR). mGFR was normalized (nGFR) by BSA. eGFR was calculated using 9 different equations. Creatinine and cystatin C were measured using kinetic Jaffe method and immunoturbidimetry, respectively. Correlation and agreement between eGFR and nGFR and the accuracy of GFR estimation were compared.

Results: 23 children diagnosed as SLE were enrolled. The original Schwartz equation and CKiD equation, compared with the other seven equations, produced eGFR with better correlation with nGFR (γPearson was 0.567 and 549, respectively), smaller bias (1.8 and 4.12 ml/min×1.73m2), narrower 95% LOA ([-61, 64] and [-40,47]), better performance in Bland-Altman analysis, higher intraclass correlation coefficient (0.56 and 0.52) and concordance correlation coefficient (0.55 and 0.51), higher ratio of eGFR within nGFR±10% (30.4% and 40%) and within nGFR±30% (82.6% and 80%), higher ratio of correct CKD staging (56% and 70%) and better agreement in CKD staging between eGFR and nGFR (Kappa value was 0.44 and 0.46).

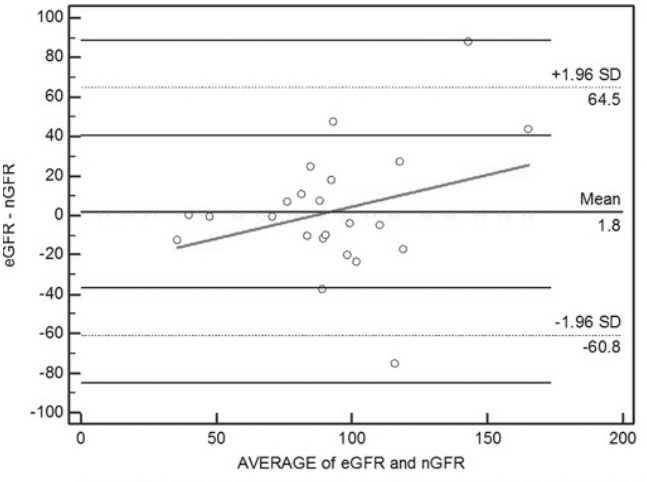

Figure 1 Bland-Altman Analysis of the original Schwartz equation in SLE children

Conclusions: Though the equations with better performance of GFR estimation in SLE children were the original Schwartz equation and the CKiD equation, neither equation is validated to be used for GFR estimation in SLE children.

Accurate Assessment of Kidney Function in Indigenous Australians: The eGFR Study

Louise J. Maple-Brown,[1,2] Jaquelyne T. Hughes,[1,2] Paul D. Lawton,[2] Graham Ross Dallas Jones,[3] Andrew G. Ellis,[4] Katrina Drabsch,[1] Alan Cass,[5] Wendy E. Hoy,[6] Richard J. Macisaac,[4] Kerin O'Dea,[7] George Jerums.[4] *[1]Menzies School of Health Research; [2]Royal Darwin Hospital; [3]St Vincents Hospital; [4]Melbourne University; [5]The George Institute; [6]University of Queensland; [7]University of South Australia, Australia.*

Background: Differences in body builds and compositions raise the possibility that creatinine-based estimates of glomerular filtration rate (GFR) derived for use in European populations may not be appropriate for Indigenous Australians. The aim of this study was to develop a validated and practical measure of GFR suitable for Indigenous Australians.

Methods: We measured GFR (mGFR) by plasma disappearance of iohexol over 4 hours and estimated GFR (eGFR) using the 4 variable modification of diet in renal disease (MDRD) equation.

Results: In 539 Indigenous Australians aged 44±15years, 37%males, 39% with diabetes (DM), BMI 30±7kg/m2, participants were classified by DM status and kidney function (eGFR, ml/min/1.73m2) into 5 strata: healthy, DM or albuminuria with eGFR >90, eGFR 60-89, eGFR 30-59, eGFR<30.

Indigenous Australians

	Healthy	DM or albuminuria with eGFR >90	eGFR 60-89	eGFR 30-59	eGFR<30
n	175	130	165	47	22
Mean eGFR	110	108	78	45	18
Mean mGFR	115	116	95	52	23
Bias (mGFR-eGFR, ml/min/1.73m²)	7.4	8.6	17.8	8.4	4.6
Precision (interquartile range of bias, ml/min/1.73m²)	24.8	28.5	24.7	14.0	7.8
Accuracy (% eGFR within 30% of mGFR)	99%	94%	82%	81%	77%

Data are geometric mean or median (bias). Units of eGFR, mGFR are ml/min/1.73m²

Bias did not differ by DM status. When compared to 42 Caucasian participants: bias and accuracy were not significantly different when eGFR<60mls/min/1.73m²; however bias (mls/min/1.73m²) was higher in Indigenous than Caucasian participants when eGFR≥60mls/min/1.73m² (11.7 vs 2.6, p=0.044), but improved with the Chronic Kidney Disease Epidemiology Collaboration equation (4.0 vs -6.8, p=0.1).

Conclusions: In summary, eGFR using the MDRD equation provides a reasonably unbiased and accurate estimation of GFR in Indigenous Australians. Detailed assessment of fat free mass may enhance accuracy of eGFR and is in progress.

FR-PO1464

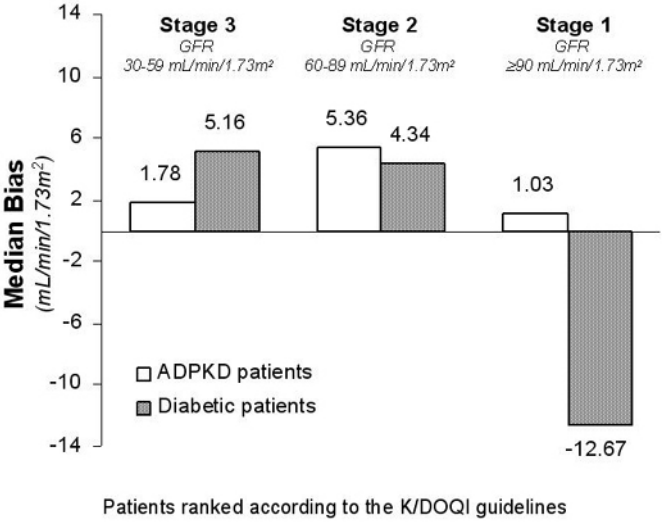
Performance of GFR Prediction Formulas in ADPKD and Type 2 Diabetes Patients: Role of Kidney Function and Demographic, Anthropometric and Clinical Patient Characteristics

Flavio Gaspari,[1] Antonio Cannata,[1] Fabiola Carrara,[1] Claudia Cella,[1] Silvia Ferrari,[1] Norberto Perico,[1] Nadia Stucchi,[1] Giuseppe Remuzzi,[1,2] Piero Ruggenenti.[1,2] *[1]Mario Negri Institute for Pharmacological Research, Bergamo, Italy; [2]Azienda Ospedaliera Ospedali Riuniti, Bergamo, Italy.*

Background: Prediction formulas have been developed for glomerular filtration rate estimation (eGFR) in subjects with reduced renal function. Whether and to which extent their performance is affected by kidney function, underlying renal disease and patient demographic, anthropometric and biochemical characteristics is poorly understood.

Methods: We evaluated the precision of GFR estimations by 14 formulas versus GFR measured by iohexol plasma clearance technique (mGFR) in 2 cohorts of ADPKD and type 2 diabetic patients matched by gender and GFR (difference between matched patients <±1 mL/min/1.73m²). Performance was assessed considering bias, mean percent error (MPE) and accuracy.

Results: In 97 ADPKD and 97 matched diabetic patients, mGFR (81.4±26.4 vs. 81.7±26.2 mL/min/1.73m²) and serum creatinine (1.15±0.43 vs. 1.04±0.40 mg/dL) were similar. Compared to ADPKD patients, however, diabetics were significantly (p<0.05) shorter, heavier, older, more dyslipidemic and hypertensive. In the whole study group accuracy within ±10% error of all formulas ranged from 14.4 to 49.5%. In diabetics with GFR ≥90mL/min/1.73m² median accuracy was as low as 31%. Both bias (see Figure) and MPE showed a large and systematic GFR underestimation in this subgroup.



Conclusions: Performance of prediction formulas was similarly poor in ADPKD patients independent of kidney function and in diabetic patients with GFR <90mL/min/1.73m². In diabetics with higher GFR all formulas were fully unreliable, possibly because of the confounding effect of demographic, anthropometric and clinical parameters in this population.

Funding: Private Foundation Support

FR-PO1465

Epidemiologic Investigation of Chronic Kidney Disease in the District of Hulunbeir of Inner Mongolia Autonomous Region Xiao-Yi Xu,[1] Jing-Hua Duo,[3] Yang Luo,[2] Hong-Liang Rui,[1] Guo-Bing Xu,[4] Hong Cheng,[1] Yi-Pu Chen.[1] *[1]Division of Nephrology, Beijing Anzhen Hospital, Capital Medical University, Beijing, China; [2]Division of Nephrology, Tiantan Hospital Affiliated to Capital Medical University, Beijing, China; [3]Division of Nephrology, People's Hospital of Hulunbeier, Inner Mongolia Autonomous Region, China; [4]Department of Clinical Laboratory, Peking University First Hospital, Beijing, China.*

Background: To investigate the prevalence and risk factors of chronic kidney disease (CKD) in the general adult population in the Hulunbeir Prefecture, Inner Mongolia Autonomous Region where many minorities of north China live.

Methods: Sampling survey was performed in the residents aged 20 years and older in the Hulunbeir Prefecture. All investigated subjects were tested for urinary albumin to creatinine ratio (ACR); hematuria by microscopy of urinary sediment; and GFR estimated by modified MDRD equation for Chinese adults (eGFR). The related risk factors of CKD were also investigated.

Results: Total 4522 subjects were enrolled in the study. The prevalence of albuminuria was 7.11%; hematouria was 2.64% and reduced eGFR [<60ml.min-1.(1.73m2)-1] was 2.75%. The prevalence of hypertension was 38.90%; hyperglycemia 6.61%; hyperlipidemia 2.72%; increased waist 24.79% and metabolic syndrome 15.02%. After the subjects with combined microalbuminuria, hematuria and reduced eGFR were excluded, the prevalence of CKD was 12.95%. Logistic regression analysis and stratified analysis showed, increased waist, elevated systolic pressure, hyperglycemia, hypertriglyceridemia and metabolic syndrome were independent risk factors associated with albuminuria; increased age, elevated systolic pressure and hyperglycemia were independently associated with reduced eGFR; increased age was independently associated with hematuria.

Conclusions: The prevalence of CKD is 12.95% in the Hulunbeir Prefecture, Inner Mongolia Autonomous Region. Independent risk factors of CKD include increased age, increased waist, hypertension, abnormal blood glucose or lipid, and metabolic syndrome.

FR-PO1466

Does Hemi-Nephrectomy Aggravate Residual Renal Function? Shohei Ishida,[1] Yoshinari Yasuda.[2] *[1]Department of Urology, Chukyo Hospital, Nagoya, Japan; [2]Department of Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Partial nephrectomy has been reported overseas to keep renal function better than hemi-nephrectomy. In japan, the influence of hemi-nephrectomy is unclear. The aim of this study is to assess of hemi-nephrectomy on long term postoperative renal function.

Methods: Among patients who underwent hemi-nephrectomy from January 2004 to December 2005, 66 patients could be followed at least five years and their pre-operative estimated glomerular filtration rate (eGFR) were more than 30ml/min/1.73m^2. For these 66 patients, the changes in eGFR were retrospectively analyzed over five years after the expiration of six months from hemi-nephrectomy.

Results: 49 cases of men and women in 17 cases, mean age at hemi-nephrectomy was 57.6 (30-79) years old. eGFR (mean±SD) before hemi-nephrectomy was 75.3±18.7ml/min/1.73m2, at six months after hemi-nephrectomy 49.7±12.4ml/min/1.73m2, at five years and six months after hemi-nephrectomy 51.9±11.4 ml/min/1.73m2. The rate of decrease in eGFR for five years is -0.4±1.7 ml/min/1.73m2/year (-0.7±4.5%/year), and renal function was slightly increased . Of these five years the rate of decrease in eGFR 50% or more (10%/year or more) patients were only two. These two patients showed proteinuria with qualitative analysis before and sx months after hemi-nephrectomy, and their eGFR at six months after hemi-nephrectomy were less than 30ml/min/1.73m2.

Conclusions: Preoperative view of the overall eGFR than patients 30ml/min/1.73m^2 (CKD stage 1-3), the hemi-nephrectomy specimen and should not cause deterioration of renal function. On the other hand, in some cases worsening renal function after hemi-nephrectomy, suggesting its potential as an indicator of the presence or absence of proteinuria before and after hemi-nephrectomy.

FR-PO1467

A Comparison of Equations To Estimate Glomerular Filtration Rate in Living Kidney Donor Candidates Nishant Fozdar, Charmaine E. Lok, Olusegun Famure, Joseph Kim. *Medicine (Nephrology), Toronto General Hospital, University Health Network, Toronto, ON, Canada.*

Background: Glomerular filtration rate is routinely estimated by equations. This study aims to validate and compare the performance of the Cockcroft-Gault (CG), Modification of Diet in Renal Disease (MDRD), Mayo Clinic (MC), and CKD-EPI equations for calculating estimated GFR (eGFR) in Canadian living kidney donor candidates.

Methods: A total of 440 individuals assessed for kidney donation at the Toronto General Hospital from 2006 to 2010 were included. Measured GFR (mGFR) from 99mTc-DTPA scans were compared to each equation using measures of bias (median difference between mGFR and eGFR), precision (interquartile range), accuracy (% of eGFR within 30% of mGFR), and classification (sensitivity and specificity) at mGFR cutoffs relevant for living kidney donation.

Results: The CKD-EPI equation performed well overall (see table). While CG had the lowest bias, it had relatively low precision and accuracy. MC and CG performed well at higher mGFR while CKD-EPI and MDRD performed well at lower mGFR. CKD-EPI had the most favorable operating characteristics at an mGFR cutoff of 90 ml/min (correctly identifying an mGFR below the cut-off as "positive") while MDRD performed well at mGFR cutoffs of 80 and 85 ml/min. MC had the greatest specificity in detecting GFRs below the cut-off values.

Conclusions: The CKD-EPI equation generally performed well, especially in terms of precision, accuracy, and clinically relevant classification but MC may be the most useful equation in correctly identifying living kidney donor candidates with inappropriately low GFR.Performance of GFR Equations in Living Kidney Donor Candidates

Characteristic	MDRD	MC	CG	CKD-EPI
Bias (95% CI)	13.4 (11.4, 15.4)	-5.5 (-7.7, -3.2)	0.5 (-2.9, 3.8)	8.9 (7.3, 10.5)
% Bias (95% CI)	13.1 (11.2, 15.0)	-5.6 (-7.8, -3.4)	0.5 (-3.0, 3.9)	8.6 (7.1, 10.1)
Precision (95% CI)	22.5 (10.9, 25.2)	21.9 (20.2, 23.6)	34.1 (30.5, 37.7)	20.3 (17.7, 22.9)
Accuracy (95% CI)	89.1 (85.8, 91.8)	89.1 (85.8, 91.8)	77.1 (72.8, 80.9)	92.1 (89.1, 94.4)
Sens/Spec at 80 ml/min	72%/75%	8%/99%	44%/87%	64%/84%
Sens/Spec at 85 ml/min	78%/70%	10%/98%	51%/82%	71%/78%
Sens/Spec at 90 ml/min	86%/59%	18%/97%	50%/75%	76%/73%

FR-PO1468

Assessment of Renal Function in African Americans (AAs) after Kidney Donation by Cystatin C and Creatinine Based Formulas Compared to ^{125}I iothalamate Clearance Sunil Kumar Jain,[1] John M. Arthur,[1] Milos Budisavljevic.[1] *[1]Division of Nephrology, Dept of Medicine, Medical University of South Carolina, Charleston, SC; [2]Division of Biostatistics and Epidemiology, Medical University of South Carolina, Charleston, SC; [3]Division of Biostatistics and Epidemiology, Medical University of South Carolina, Charleston, SC; [4]Division of Nephrology, Dept of Medicine, Medical University of South Carolina, Charleston, SC; [5]Division of Nephrology, Dept of Medicine, Medical University of South Carolina, Charleston, SC.*

Background: AAs have 4 times higher prevalence of ESRD than Caucasians. Therefore, assessment of kidney function is of considerable importance in this patient population. Kidney function is currently assessed most commonly by estimated glomerular filtration rate (eGFR) using creatinine based equation. Some studies indicate that measuring Cystatin C levels provide better estimate of GFR. We compared cystatin C (Cys C) and creatinine based formulas for GFR estimation with measured GFR in 33 AAs who donated their kidneys 5-27 years (mean=11.1 years) previously.

Methods: GFR was measured by ^{125}I iothalamate clearance. Cystatin C was measured by Bio Vendor Human Cystatin C ELISA Kit. Pearson correlation was used for statistical analyses.

Results: The mean measured GFR was 76.18 ml/min/1.73m2. The correlation between measured GFR and cystatin C and creatinine based equations is presented in Table 1.
Table 1

Variable	GFR ml/min	SD	Pearson correlation	p-value
Iothalamate GFR	76.18	13.11		
eGFR Cys C				
EPI unadjusted	85.3	19.3	0.4838	0.0058
EPI adjusted*	90.04	18.03	0.5718	0.0008
eGFR Creatinine				
MDRD	86.56	16.11	0.6370	<0.0001
AASK Study	92.19	16.88	0.6409	0.0003
Cockcroft - Gault	115.08	33.55	0.4990	0.0677

SD- Standard Deviation, *Adusted for age, gender and race

Conclusions: In AAs with a single kidney, both creatinine and cystatin C based equations overestimate GFR compared to measured GFR. The correlation of estimated GFR with measured GFR was statistically significant but not strong. Creatinine based formulas appear to be more accurate than cystatin C based formulas. As reported for subjects with two kidneys the MDRD equation estimated GFR better than Cockcroft-Gault.

FR-PO1469

Idiopathic Hypercreatininemia; Limitation of Creatinine Based eGFR and Utility of Cystatin C Based eGFR Masahiko Nagahama, Yasuhiro Komatsu. *Nephrology, St. Luke's international hospital, Tokyo, Japan.*

Background: The number of nephrology referral has increased as CKD classification by serum Cr based eGFR is accepted globally. However, some populations show disproportionally higher level of Cr compared to true GFR without apparent causes such as large muscle mass, rhabdomyolysis, excessive protein intake or medications which affects urinary Cr excretion such as Bactrim or Cimetidine. Those who exhibit higher serum Cr without any particular reason can be defined as "Idiopathic hypercreatininemia (IHC)". The aim of the present study is to clarify the prevalence and diagnostic test to prevent overdiagnosis of CKD leading to unnecessary diagnostic procedure and psychological burden of the patients.

Methods: Among 1,482 patients who were consulted to our nephrology clinic between 2005 and 2010, 103 patients (Group A, n=103) had their true GFR determined by 24hr urine collection (the average of Cr and urea clearance). Patients with Cr-based e GFR < 60 ml/min/1.73m^2 are categorized as IHC if they have; 1) true GFR > 60 ml/min/1.73m^2, 2) absence of large muscle mass (24hr urine Cr/Wt > 30), 3) CPK > 100mg/dl, and 4) no particular medications changing urinary Cr secretion. Fifteen patients out of 103 (14.5%) were diagnosed with IHC (IHC, n=15).

Results: Cystatin C based eGFR is normal, greater than 60ml/min/1.73m2, in majority of IHC (normal ratio 0.31 vs. 0.93, Group A vs. IHC, p<0.05), so as to urinary protein excretion (24hr urinary protein excretion 1904+/-2378mg vs. 38+/- 23mg Group A vs. IHC, P<0.05). The female ratio in IHC was significantly higher (female ratio 0.30 vs 0.60, Group A vs. IHC, P<0.05) and BSA tends to be smaller (BSA 1.68+/-0.2m2 vs. 1.64+/- 0.2 m2, Group A vs. IHC, p=0.16).

Conclusions: In conclusion, prevalence of IHC is high (14.5%) among patients referred to renal clinic. Cystatin C based eGFR can effectively rule out IHC. Higher female ratio and relatively smaller BSA imply that Cr metabolism rather than Cr production is related to this condition.

FR-PO1470

Prevalence of Chronic Kidney Disease in the Adult Population of Lausanne-Switzerland Belen Ponte,[1] Menno Pruijm,[2] Pierre-Yves F. Martin,[1] Michel Burnier,[2] Vincent E. Mooser,[3] Gerard Waeber,[2] Murielle Bochud.[2] *[1]University Hospital of Geneva; [2]Centre Hospitalier Universitaire Vaudois; [3]GlaxoSmithKline.*

Background: Chronic kidney disease (CKD) represents an important burden in the general population with increased cardiovascular morbidity and mortality. Population-based data are available in US and some countries of Europe but are lacking in Switzerland. We aimed to determine the risk factors and prevalence of CKD in the population of Lausanne, Switzerland.

Methods: This population-based study included 6184 Caucasians aged 35-75 years old between 2003 and 2006, of whom 2821 men and 3158 women had data for the present analysis. CKD was defined using KDOQI stages 1-5 according to estimated glomerular filtration rate (eGFR) and microalbuminuria. We compared CKD-EPI and MDRD equations to calculate eGFR and classify CKD.

Results: The prevalence of CKD using MDRD was 2.1%, 3.5%, 4.7% and 0.17% for stages 1, 2, 3 and 4-5, respectively. The corresponding prevalence using CKD-EPI was 2.3%, 3.2%, 4.5% and 0.17%. The prevalence of CKD (stages 1-5) was 10.4% using MDRD and 10.2% using CKD-EPI. Overlap between the two equations was 91% for stage 3 and 100% for stages 4-5. The prevalence of CKD (CKD-EPI) was 8.7% in non-diabetic and 28.9% in diabetic, 5.9% in normotensive and 17.4% in hypertensive subjects. It was 4.9%, 5.6%, 11.3% and 25.1% in persons aged 35-45, 45-55, 55-65 and 65-75 years, respectively. According to the Body Mass Index (BMI) prevalence was 7%, 10.7% and 17.2% for BMI<25, BMI 25-30 and BMI≥30kg/m2 respectively.

In multiregression analysis, determinants of CKD were age per year (OR 1.06; 95% CI 1.05-1.07), female sex (OR 1.22; 95% CI 1.02-1.47), hypertension (OR 1.78; 95% CI 1.45-2.18), diabetes (OR 2.32; 95% CI 1.78-3.03) and BMI≥30kg/m^2 (OR 1.33; 95% CI 1.03-1.72).

Conclusions: The prevalence of CKD in the adult population of Lausanne is substantial, although lower than in US. CKD prevalence sharply increases after 55 years of age and is particularly high in diabetic, hypertensive and obese subjects. Our results suggest that screening strategies aiming at detecting CKD should focus on higher risk patients such as elderly, diabetic, obese and hypertensive ones.

FR-PO1471

Annual Incidence of Kidney Damage in General Population Kei Nagai, Chie Saito, Kunihiro Yamagata. *Nephrology, Clinical medicine, University of Tsukuba, Tsukuba, Ibaraki, Japan.*

Background: Several reported studies on the prevalence of proteinuria in mass screening were based on single-screening data. Therefore, we investigated consecutive screening results to determine the annual incidence of kidney damage in the general population.

Methods: The subjects were participants in an annual health examination held in Ibaraki, Japan, between 1993 and 2003. 314,354 males and 649,533 females, who underwent serial urine studies for 3 years and were confirmed as negative for proteinuria in the initial year, were enrolled. Those subjects whose eGFR (estimated glomerular filtration rate) was less than 60 ml/min/1.73 m^2 were excluded. We calculated the incidences of proteinuria in the 2nd year and sustained proteinuria in the 3rd year, with separation by clinical condition and categorization by age. In addition, we evaluated risk factors and the effects of co-morbid conditions on the incidence of kidney damage.

Results: The positive rate of proteinuria was 2.51% in diabetic men, 1.81% in hypertensive men, and 0.89% in non-diabetic and non-hypertensive men. Among them, the population with sustained proteinuria in the 3rd year was 1,608/314,354 (0.51%) in all men, and 1,290/649,533 (0.20%) in all women. In non-diabetic and non-hypertensive subjects, the values were 351/145,256 (0.24%) in men and 337/380,743 (0.09%) in women. Age distribution of the positive rate of proteinuria and kidney damage in the diabetic population showed almost constant in all age groups, whereas those in non-diabetic populations increased with age. For the risk factor of newly developed kidney damage, severe hypertension was a significant positive correlation with the incidence of proteinuria.

Conclusions: Annual incidence of CKD stage I and stage II was 0.30% in the Japanese general population in both sexes. That of non-hypertensive non-diabetic subjects were 0.24% in men and 0.09% in women among Japanese adults aged 40 and over. These subjects would be missed without universal urinalysis screening in Japan.

FR-PO1472

Estimation of Glomerular Filtration Rate in Chinese Patients with Chronic Kidney Disease Xun Liu, Zhujiang Chen, Cheng Wang, Tan-Qi Lou. *Division of Nephrology, Department of Internal Medicine, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China.*

Background: Glomerular filtration rate (GFR) is the best index for the assessment of renal function. The applicability of formulas based on serum creatinine (SC) levels in Chinese patients with chronic kidney disease (CKD) is, however, less well studied.

Methods: 831 CKD patients were enrolled. SC was measured by the enzymatic method. Average sGFR measured by ^{99m}Tc-DTPA GFR estimation was 45.4±27.3 (3.3-137.7) ml/min/1.73 m^2. The patients' GFRs were estimated by Cockcroft-Gault-equation, MDRD1-equation, abbreviated MDRD-equation, reexpressed 6-variable MDRD equation, reexpressed 4-variable MDRD equation, CKD-EPI-equation, Chinese-equation, previously Japanese equation and new Japanese equation, and the results were analyzed.

Results: Bland-Altman analysis showed that previously Japanese equation, new Japanese equation and reexpressed 6-variable MDRD equation were better than the other equations. However, the precisions of all the equations exceeded the prior acceptable tolerances defined as 60 ml/min/1.73 m2. Linear regressions demonstrated that the slopes of previously Japanese equation, new Japanese equation and reexpressed 6-variable MDRD equation were closer to the identical line. The median of difference of Cockcroft-Gault-equation, abbreviated MDRD-equation and reexpressed 6-variable MDRD equation were smaller. The median % absolute difference of Cockcroft-Gault-equation, reexpressed 6-variable MDRD equation and Chinese-equation were smaller. Accuracy of Cockcroft-Gault-equation, reexpressed 6-variable MDRD equation and MDRD1-equation were higher than those of the other equations. However, accuracies with a deviation less than 30% of all the equations were less than 70%. When compared the performance between eGFR and sGFR in different stages of CKD, GFR estimated by Cockcroft-Gault-equation, reexpressed 6-variable MDRD equation, MDRD1-equation and reexpressed 4-variable MDRD equation showed better results.

Conclusions: When SC was measured by the enzymatic method, this study highlights a limitation in the use of GFR estimation equations in Chinese CKD patients.

FR-PO1473

Prevalence of Chronic Kidney Disease in China Luxia Zhang,[1] Li Wang,[2] Wenke Wang,[3] Bicheng Liu,[4] Jian Liu,[5] Menghua Chen,[6] Qiang He,[7] Yunhua Liao,[8] Xueqing Yu,[9] Nan Chen,[10] Jianer Zhang,[11] Zhao Hu,[12] Fuyou Liu,[13] Haiyan Wang.[1] *[1]Peking University First Hospital; [2]Sichuan Provincial People's Hospital; [3]Chifeng Second Hospital; [4]Zhongda Hospital; [5]First Hospital of Xinjiang Medical University; [6]Affiliated Hospital, Ningxia Medical University; [7]First Affiliated Hospital, Zhejiang University; [8]First Affiliated Hospital, Guangxi Medical University; [9]First Affiliated Hospital, Sun Yat-sen University; [10]Ruijin Hospital; [11]Taihe Hospital; [12]Qilu Hospital; [13]Second Xiangya Hospital.*

Background: Previous studies revealed a high prevalence of CKD among developing countries. However, there is no national survey of CKD incorporating both estimated glomerular filtration rate (eGFR) and albuminuria in a developing country with marked heterogeneity like China.

Methods: The present study is a cross-sectional survey among a representative sample of 47 204 participants in China. Participants were interviewed and were tested for albuminuria and reduced renal function. The crude and adjusted prevalence of indicators of kidney damage were reported.

Results: The adjusted prevalence of eGFR<60mL/min/1.73m2 and albuminuria was 1.7% (95% CI 1.5%-1.9%) and 9.3% (95% CI 8.7%-9.8%), respectively. The overall prevalence of CKD was 10.6% (95% CI 10.1%-11.2); therefore the number of patients with CKD in China is estimated to be 117.3 million. In rural area, the prevalence of eGFR<60mL/min/1.73m2 did not vary markedly with levels of economic development, while higher prevalence of albuminuria was observed in higher tertiles of GDP per capita. In urban area, lower prevalence of both eGFR<60 mL/min/1.73m2 and albuminuria was observed in sites with higher level of economic development.

Conclusions: Our study revealed that China is going to experience an enormous increase in the prevalence of CKD, especially for the rural residents, who comprised more than half of the population in China. The rapid surge in diabetes and hypertension, both of which are predicted to drive epidemics in CKD, will have profound socioeconomic and public health consequences in developing countries such as China.

FR-PO1474

Frequency of Mild Kidney Disease and Associated Risk Factors in Apparently Healthy Mexican Subjects Carlos Kornhauser. *Department of Medical Sciences, Universisty of Guanajuato, Leon, Guanajuato, Mexico.*

Background: Chronic kidney disease (CKD) associates with a wide rank of complications leading to a decreased quality of life. Mild kidney disease comprise the first three stages of CKD, being over 50 times more frequent than terminal kidney disease.

Objective: We evaluated the frequency of CKD in stages 1, 2, and 3, by assessing GFR according to the MDRD equation, and the presence of microalbuminuria in apparently healthy people.

Methods: We did an epidemiological, cross-sectional study in 1160 apparently healthy adult subjects of both sexes, in the city of Leon, Mexico. Subjects were randomly selected. Clinical and anthropometric data were collected. Glucose, creatinine, uric acid,

total cholesterol, triglycerides, and HDL, LDL cholesterol fractions were measured in serum. Urinary creatinine and albumin were also assessed. Descriptive statistics, Anova, Kruskal Wallis, multiple regression and logistic regression test were performed. p< 0.05 was considered significant.

Results: Male and female genders were evenly distributed. Male's average age was 40.5±8.9 years and 45±11 for women. 38.9% of the total population had overweight (BMI = 26-29.9), 31.5% were obese (BMI >; 30). 25% of the subjects were active cigarette smokers, 53% of the total population had high serum cholesterol and triglycerides levels. 9.4% of the total population was found with CKD: stage 1: 0.8%, stage 2: 3.8%, stage 3: 4.7%, and stage 5: 0.08%. Factors associated with CKD found were: Serum uric acid (> 5.0 mg/dl) with an OR of 1.9 (CI 95% 1.1-1.6, p= 0.009). Serum cholesterol (> 200 mg/dl), OR 1.5 (CI 95% 1.25–1.7, p= 0.01), serum triglycerides (> 150 mg/dl) OR 1.1 (CI 95% 0.93–1.3, p = 0.01), and obesity (BMI ≥ 30), OR 1.3 (CI 95% 1.1–1.6, p = 0.009).

Conclusions: The frequency of kidney disease stages in our population studied was similar to the frequency observed in other countries. eGFR and microalbuminuria have a negative association with age, female sex, hyperuricemia, hypertriglyceridemia, hypercholesterolemia and amount of body fat mass. High levels of uric acid, triglycerides, cholesterol, and obesity constitute factors associated with CKD.

FR-PO1475

The Prevalence of Chronic Kidney Disease in the ARV-Naive HIV-Infected Adults in Mainland China: Data from a National Multicenter Prospective Study

Mengchun Gong,[1] Taisheng Li,[2] Xuemei Li.[3] *[1]Department of Internal Medicine, Peking Union Medical College Hospital, Beijing, China; [2]Department of Infectious Disease, Peking Union Medical College Hospital, Beijing, China; [3]Department of Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: The prevalence of both chronic kidney disease and HIV infection are increasing in China, yet no data existed describing the epidemiologic characteristics of CKD in HIV infected adults in mainland China. The objective of this study is to determine the prevalence of CKD in the antiretroviral therapy-naïve HIV infected adults in mainland China.

Methods: This prospective study was conducted in 12 clinical trial units that geographically and socioeconomically covered major areas of mainland China. Demographic variables, medical information was recorded at the entry of the study. Spot urine tests and creatinine measurement (Jaffe method) were performed in local laboratories. Plasma HIV-1 RNA was evaluated using theAmplicor system (RocheDiagnostics and Abbott). eGFR was calculated using the MDRD equation. Patients with abnormal urine test or a decreased eGFR lower than 90ml/min*1.73m^2 were followed and spot urine test and creatinine test were repeated 12 weeks after the screening to confirm the diagnosis of CKD.

Results: 541 patients were enrolled and most of them were male (74.2%), with a mean age of 37.3 years (Table 1) . All of the patients were ARV-naive and the mean time since HIV diagnosis was 1.93 years. Baseline mean CD4 cell counts were 172, with a majority (99.6%) below 350 cells/mm3. The log value of viral load was on average 4·58 ± 0·04, with 58% under 50copies/uL.The prevalence of CKD in the Chinese ARV-naive HIV-infected patients was (16.0 ±1.7) %. Among the CKD patients, the majority were in CKD1 or CKD2.

Table 1 Prevalance of impaired renal function and kidney injury markers at baseline and 12-week follow-up

	Baseline	12-week
Proteinuria	9.4%	4.2%
Hematuria	10.7%	11.4%
Mean eGFR	109.9 ±1.1	111.7 ±1.2
eGFR≤90*	20.4%	20.5%
eGFR≤60*	0.4%	0.6%

* unit: mL/min×1.73m2

Conclusions: CKD is prevalent in the Chinese ARV-naive HIV-infected adults and the majority of CKD patients have mildly impaired renal function.

FR-PO1476

Chronic Kidney Disease in Patients on Lithium Therapy in Iceland

Davíð Arnar Sverrisson,[1] Olafur S. Indridason,[2] Engilbert Sigurdsson,[3] Gunnar Sigurdsson,[4] Runolfur Palsson.[1,2] *[1]University of Iceland; [2]Division of Nephrology; [3]Division of Endocrinology; [4]Department of Psychiatry, Landspitali - The National University of Iceland, Reykjavik, Iceland.*

Background: Long-term lithium treatment may lead to chronic kidney disease (CKD) but the magnitude of this risk has not been well characterized. The purpose of this study was to examine CKD associated with lithium therapy in Iceland.

Methods: In this retrospective study, we obtained information on all adult subjects taking lithium during the years 2003-2010 by examining records of serum lithium measurements performed at the Univeristy Hospital in Reykjavik and prescriptions for lithium in the National Drug Prescription Database. IDMS-standardized serum creatinine (SCr) was obtained from medical records and eGFR calculated from the lowest SCr value in the last year of measurement for each subject using the MDRD equation. CKD was defined as eGFR <60 mL/min/1.73m^2. A group of randomly selected community-dwelling adults was used as controls.

Results: A total of 1577 subjects received at least one lithium prescription during the study period, 628 (39.8%) of whom had no recorded measurements of serum lithium or SCr at the University Hospital. The remaining 949 subjects had a median (range) age of 50 (19-98) years, and 558 were female (58.8%). The control group comprised 1630 subjects with a median age of 60 (29-87) years, 1039 (63.7%) were female. The prevalence of CKD was 13.6% in the lithium group and 5.3% in the control group.

Prevalence of CKD in the lithium and control groups, by age

Agegroups	Lithium group	Control group	P-value	OR (95% CI)
18-30	0%	0%	-	-
30-40	2.6%	0%	0.3	-
40-50	3.5%	0.6%	0.016	6.1 (1.2-29.5)
50-60	14.4%	0.3%	<0.001	54.7 (7.4-405.2)
60-70	21.1%	2.3%	<0.001	11.5 (5.1-25.8)
>70	44%	15.5%	<0.001	4.4 (2.9-6.7

The duration of lithium treatment was independently associated with CKD with OR = 1.34 (95% CI, 1.28-1.41) for each year of therapy.

Conclusions: Lithium markedly increases the risk of CKD, particularly in the younger age groups. This may eventually lead to kidney failure but more importantly places these patients at increased risk of cardiovascular disaease.

FR-PO1477

A Prospective Population Screening Study of Prevalence of CKD and Its Risk Factors: The Texas CKD Study

John F. Moeller, Ronnie R. Orozco, Sharma S. Prabhakar. *Internal Medicine, Texas Tech University Health Sciences Center, Lubbock.*

Background: Recent reports indicate a high prevalence of CKD in general population in the US (16.8%, NHANES 2006). However most such reports are based on retrospective sampling and the true prevalence of CKD remains unclear. Texas is estimated to have disproportionately high prevalence of CKD and ESRD and related healthcare costs. The Texas CKD study is an initiative funded by the Texas Department of Health to address the same.

Methods: The study was organized by Texas Tech University and conducted in the West Texas population with a goal to screen a total of 1000 adult subjects (age >21 yrs). The subjects were recruited by a random digit dialing (RDD) methodology with phone interviews and scheduling administered by the University of North Texas Survery Research Center. Appriopriate approvals were obtained to comply with IRB and HIPAA regulations. The sample was adjusted to conform to rural urban mix, as well as age, race and sex ratios in the Texas adult population. Risk factors for CKD were noted by personal questionnaire while GFR was estimated using both MDRD and CKD-EPI formulae from serum creatinine values. Urine microalbumin and urine prot/creat ratio were also determined. CKD was defined using KDOQI guidelines. Individual results were discussed with the subjects to be relayed to their primary physicians for follow up as needed.

Results: Of a total of 931 subjects who completed evaluation, 172 met the critera for CKD using the MDRD formula giving an overall prevalence of 18.5%. Of them, 108 had stage 3 or worse CKD (11.6%). Only 21 of the 172 (12.2%) were aware that they had CKD. Hypertension was present in 389 subjects(41.8%), while diabetes was present in 155 (16.7%) and smoking in 17.4%. Furthermore 729 (78%) were overweight (BMI>25 Kg/m2) with 437(49%) being clearly obese (BMI>30 Kg/m2). Using the CKD-EPI formula the prevalence was slightly lower (155 or 16.7%).

Conclusions: CKD is very common in West Texas with a prevalence of 18.5% with a high prevalence of risk factors for CKD especially obesity. Awareness of the condition is dismally low underscoring the need for widespread screening and prevention by addressing the risk factors.

Funding: Government Support - Non-U.S.

Pre-Dialytic Chronic Kidney Disease in Children: A Nationwide Epidemiologic Survey in Japan

Kenji Ishikura, Osamu Uemura, Shuichi Ito, Naohiro Wada, Motoshi Hattori, Yasuo Ohashi, Yuko Hamasaki, Masataka Honda, Ryojiro Tanaka, Tetsuji Kaneko, Koichi Nakanishi. *The Pediatric-CKD Study Group in Japan, Tokyo, Japan.*

Background: Chronic kidney disease (CKD) in children is a progressive and intractable condition that may severely impair patients' growth, development, and quality of life; however, there is little epidemiologic information available on the disease, particularly in Asian children.

Methods: We performed a nationwide epidemiologic survey of children (3 months to 15 years old) with pre-dialytic CKD. CKD staging was classified as stages 3 to 5 according to new criteria we developed on the basis of new reference levels for serum creatinine (S-Cr) according to age and sex of Japanese children (Uemura O et al. Clin Exp Nephrol 2011 [Epub ahead of print]). CKD stages 3 to 5 were defined as follows: CKD stage 3, S-Cr more than twice the median level; CKD stage 4, S-Cr more than 4 times the median level; and CKD stage 5, S-Cr more than 8 times the median level. Questionnaires were then sent to 1190 institutions, which treat most of the children with pre-dialytic CKD in Japan.

Results: A total of 925 institutions (77.7%) responded. Information on 440 children with CKD in 112 institutions was collected as of April 1, 2010: 331 in stage 3, 103 in stage 4, and 26 in stage 5. The median age was 8.7 years, and 265 (60.2%) were male. The total number of children with CKD stage 3 to 5 in Japan was estimated to be 528.5 (95% confidential interval, 486.1-570.9). The prevalence was estimated to be 29.0 per 1,000,000 children aged 15 years or younger. Of the total number of patients, 90.7% had non-glomerular diseases. Among the children with non-glomerular diseases, 68.4% had congenital anomalies of the kidney and the urinary tract (CAKUT). Only 2.0% and 1.8% of all children had focal segmental glomerulosclerosis and chronic glomerulonephritis, respectively.

Conclusions: In conclusion, this first nationwide survey of children with CKD stage 3 to 5 in Japan indicated that most of the children had non-glomerular underlying diseases, mainly CAKUT. Improved management of CAKUT, including renoprotective treatment and urological interventions, is required.

Endocrine-Metabolic Disorders in Patients with Chronic Kidney Disease

Jung-Ho Shin, Min-Jee Han, Youn-Su Park, Woojin Nam, Su Hyun Kim, Dong-Jin Oh, Suk-Hee Yu. *Department of Internal Medicine, Chung-Ang University College of Medicine, Seoul, Korea.*

Background: Endocrine-metabolic disorders are common in patients with chronic kidney disease. Several studies showed that the prevalence of endocrine-metabolic disorders is increased in patients with chronic kidney disease, and that could have important role in the prognosis of chronic kidney disease. In this study, we investigated the prevalence of endocrine-metabolic disorders in healthy personS according to the renal function.

Methods: We retrospectively reviewed 948 adults selected from the Health Promotion Center at Chung-Ang University Hospital. Age, sex, height, weight, waist circumference, blood pressure, fasting glucose, lipid profile, serum creatinine and bone mineral density were evaluated. The glomerular filtration rate (GFR) was estimated by the Modification of Diet in Renal Disease (MDRD) formula. Decreased renal function was defined as an estimated GFR under 60 ml/min/1.73m^2 and metabolic syndrome was defined as per the International Diabetes Federation (IDF) 2006 criteria.

Results: The mean age was 47.7±9.3 years in men (276, 29.1%) and 50.8±9.7 years in women (672, 70.9%). There were 918 persons with normal renal function and 30 persons with decreased renal function. The prevalences of metabolic syndrome and osteoporosis were 13.8% (10.1% in men, 11.1% in premenopausal women and 27.0% in postmenopausal women) and 14.2% (9.8% in men, 11.1% in premenopausal women and 29.8% in postmenopausal women), respectively. The percentages of persons with metabolic syndrome and osteoporosis were increased in persons with decreased renal function (p=0.002 and 0.0048). Subgroup analysis was conducted for men, premenopausal women and postmenopausal women groups. In premenopausal women, we found similar results, but in men and postmenopausal women, we found no difference of prevalence between persons with normal renal function and persons with decreased renal function.

Conclusions: Metabolic syndrome and osteoporosis were increased in persons with a decreased renal function in premenopausal women. However, there was no association between endocrine-metabolic disorders and decreased renal function in men and postmenopausal women.

FR-PO1480

Estimated Glomerular Filtration Rate Does Not Progressively Decline in the Healthy Elderly, Particularly in Females and Those with High Cholesterol Levels

Fumihiko Hinoshita, Eri Imai, Asami Kato, Emi Sasaki, Naoto Hamano, Takashi Katsuki, Maki Shibata, Manami Tada. *Department of Nephrology, National Center for Global Health and Medicine, Tokyo, Japan.*

Background: Estimated GFR (eGFR) seems to be inappropriately underevaluated in the healthy elderly. Consequently, in a sweeping assumption, many of the elderly have been grouped as CKD stage 3 and considered as would-be candidates for HD in the future. Therefore, this study was performed to discern whether or not eGFR does progressively decline in the elderly with aging.

Methods: A total of 574 elderly people (286 males, 288 females) at the age of 60 or older (60 to 94 years old) without serious diseases were enrolled. They were living in one local community in central Tokyo. Clinical data including eGFR, BP, BUN, total cholesterol (TC), triglyceride, uric acid and urinalysis between 2008 and 2010 were annually collected and analyzed. The presence of DM, hypertension, hyperuricemia, past history for coronary events and apoplexy as well as the use of anti-hypertensives were examined. Those who had serum creatinine level of 1.5 mg/dL or more, and had been diagnosed as CGN, hemodialyzed or hospitalized during the study period were excluded from the study.

Results: eGFR did not markedly change for 2 years (ΔeGFR/2 yrs: -0.39 ± 7.86 mL/min). However, eGFR was slightly decreased in men (ΔeGFR/2 yrs: -1.98 ± 7.91 mL/min, P<0.001) and slightly increased in women (ΔeGFR/2 yrs: 1.18 ± 7.49 mL/min, P=0.027). It was confirmed by a multiple regression analysis that male sex, higher BUN (>21 mg/dL) and lower TC (<220 mg/dL) significantly contributes to the decline of eGFR. Past history for coronary events, hyperuricemia, proteinuria and higher BUN levels were also confirmed to be significant risk factors for an eGFR of lower than 50 mL/min in the elderly.

Conclusions: In contrast to the previous assumption, eGFR did not greatly decline year by year in the healthy elderly. Interestingly, female sex and relatively high TC levels might be the favorable factors to slow the decline of eGFR. Further study will be necessary to precisely comprehend the meaning of these results and to confirm the validity of the MDRD equation for calculating eGFR.

FR-PO1481

Validation of MDRD and Japanese eGFR Equation among Taiwanese and Korean: Approach To Set the Fundamental Scheme for eGFR Evaluation in Asia

Yoshinari Yasuda,[1] Masaru Horio,[2] H.C. Chen,[3] Ho Yung Lee,[4] Enyu Imai,[1] Seiichi Matsuo.[1] *[1]Nephrology/CKD Initiatives, Nagoya University Graduate School of Medicine, Nagioya, Japan; [2]Osaka University Graduate School of Medicine, Osaka, Japan; [3]Nephrology, Kaohsiung Medical University, Kaohsiung, Taiwan; [4]Nephrology, Yonsei Medical University, Seoul, Korea.*

Background: Glomerular filtration rate (GFR) is essential for CKD diagnosis and staging. The Modification of Diet in Renal Disease (MDRD) Study equation is globally well used, however ethnicity coefficient is not available for Asians. Japanese society of nephrology develop Japanese coefficient of 0.808 for MDRD equation, whereas Chinese and Korean coefficients were reported to be 1.233 and 1.09285, regardless of similar genetic and cultural background among Asians, probably due to different GFR measurement methods and lack of creatinine (Cr) standardization. Thus we validate MDRD and Japanese eGFR equations among Taiwanese and Koreans by inulin clearance (Cin), a gold standard for GFR, under the same protocol as in Japan and accurate sCr values.

Methods: Cin was evaluated among198 Taiwanese and 157 Koreans. All samples were measured in a single center, and sCr values were IDMS-traceable. This study was a part of Asian Collaborative Study for Creation of GFR Estimation Equation (ACOS-CG-FREE). Urinary Cr excretion rate divided by body weight was compared to that of Japanese.

Results: Performance of MDRD and Japanese equations are shown in table.

Performance of Japanese and MDRD GFR equations for Taiwanese and Korean

	Japanese equation	MDRD equation	Japanese equation	MDRD equation
	Taiwanese	Taiwanese	Korean	Korean
20% accuracy	40 %	57 %	44 %	42 %
30% accuracy	64 %	75 %	64 %	54 %
R	0.922	0.922	0.872	0.861
RMSE	17.85	16.51	22.3	26.0
Bias	-10.2±14.7	1.3±16.5	-2.4±22.2	10.3±23.9

Taiwanese and Korean coefficient for IDMS-MDRD equation were 1.054 and 0.916, respectively. Creatinine excretion was high among Taiwanese than Japanese or Korean.

Conclusions: Better accuracy was demonstrated in Japanese eGFR equation for Korean but not for Taiwanese, probably due to different body muscle mass.

Funding: Other U.S. Government Support

FR-PO1482

Risk Factor Profiles Based on Estimated Glomerular Filtration Rate and Dipstick Proteinuria among Participants of the Specific Health Check and Guidance System in Japan 2008

Kunitoshi Iseki,[1] Tsuyoshi Watanabe.[2] *[1]Dialysis Unit, University Hospital of the Ryukyus, Nishihara, Okinawa, Japan; [2]Division of Nephrology, Fukushima Medical School, Fukushoma, Japan.*

Background: Both estimated glomerular filtration rate (eGFR) and albuminuria (proteinuria) are important determinants of the risk of cardiovascular disease (CVD), end-stage renal disease (ESRD), and mortality. Few studies, however, have examined the risk factor profiles based on eGFR and proteinuria among the general population.

Methods: Data of the newly developed nationwide screening program of the Specific Health Checkups and Guidance System (Tokutei-Kensin) initiated in 2008 were used in this study. The aim of this screening, targeting people 40 to 74 years of age, was to detect those with metabolic syndrome and to offer those services regarding lifestyle modifications that will lead to the reduction of diabetes mellitus (DM) and DM-related ESRD. Individual records of 580,000 participants in 69 cities and towns and 3 unions' cohorts throughout Japan were anonymously provided and included in the present study.

Results: Details of 332,174 (57.3% of the total) participants with both serum creatinine and dipstick urine test data were analyzed. Mean (SD) age was 63.6 (8.3) years and 40.6% were men. The mean (SD) eGFR was 67.2 (17.7) ml/min/1.73m2 and 5.4% had proteinuria. The prevalence of CKD stage 3, 4, and 5 was 34.5%, 0.5%, and 0.1%, respectively. The prevalence of DM, hypertension, and history of stroke and heart disease was correlated with the combination of eGFR and degree of proteinuria.

Conclusions: The findings of the present study indicate that CKD and risk factors for CVD are quite common among middle-aged Japanese. CKD classification based on eGFR and proteinuria may be useful for predicting CVD, mortality rate, and ESRD in the Japanese.

FR-PO1483

The Choice of the CKD Definition and the Impact on the Chronic Kidney Disease Prevalence

Pierre Delanaye,[1] Etienne Cavalier,[2] Christopher R. Mariat,[3] Jean-Marie H. Krzesinski.[1] *[1]Nephrology, Dialysis, Transplantation, University of Liege, Belgium; [2]Clinical Chemistry, University of Liege, Belgium; [3]Nephrology, Dialysis, Transplantation, University Jean Monet, Saint Etienne, France.*

Background: CKD definition is notably based on an estimated GFR fixed cut-off at 60 mL/min/1.73 m². Such a fixed knot has already been criticized in the literature because GFR physiologically decreases with aging. In this work, we will illustrate the consequences of this fixed reference value on the CKD epidemiology.

Methods: Over a two years period, we tested 4208 voluntary subject aged of more than 50 years old for CKD with the measurement of an IDMS traceable creatinine. GFR was estimated with the MDRD study equation. CKD was defined by two ways: either with a reference range fixed at 60 mL/min/1.73 m² or according to age as defined in the Nijmegen

epidemiologic study (which also used the MDRD study equation)(Wetzels JF, Kidney Int, 2007). Vast majority of subjects were Caucasian. Subjects were classified according to their age, in 5 years-lengths categories. Older than 85 years subjects were excluded (n=4).

Results: Using the fixed definition, CKD was found in 13% of our subjects. Using the Nijmegen criteria, the CKD prevalence decreased to 5.9%. Therefore, according to the CKD definition used, the CKD prevalence can vary from simple to double. Among subject with discordant results, 73% were women. As expected, the discrepancies increased according to age (0.9% of subjects with discrepant results in the 50-55 years old bracket and up to 19% in the 75-79 years old one).

Conclusions: More than half of subjects with CKD as defined by estimated GFR under 60 mL/min/1.73 m² will become "healthy" if the CKD definition is modified according to age. This is particularly relevant in women and older population. This seems logical because both populations have physiologically lower GFR values. Not considering age in the CKD definition will overestimate the number of CKD patients, especially in women and older subjects.

FR-PO1484

The Effects of Ethnicity on C-reactive Protein Level in Patients with Diabetic Nephropathy Satyesh K. Sinha, Susanne B. Nicholas, Magda Shaheen, Deyu Pan. *Research, Charles R Drew University of Medicine and Science, Los Angeles, CA.*

Background: Studies show that ethnic differences alter the rate of progression of diabetic nephropathy (DN) and that African Americans (AA) have a more rapid course than Whites. We postulated that elevated indicators of inflammation in AA may potentially explain this disparity possibly reflected by levels of inflammatory marker C-reactive protein (CRP). We examined CRP and other clinical indicators of DN in different ethnic groups in the data from the National Health and Nutrition Examination Surveys (NHANES) 1999-2004.

Methods: We analyzed data for 1,637 adults aged =>20 years who were told had diabetes or had fasting blood sugar >125mg/dl. Descriptive statistics characterized the subjects. We use Chi-square for categorical variables and t-test or ANOVA for continuous variables to test the statistical differences between the groups.

Results: The data indicate that CRP, urinary albumin, serum creatinine, HbA1c and fasting glucose were significantly higher in diabetic patients with albuminuria compared to patients without albuminuria (0.75±0.06mg/dl, 455±48ug/ml, 1.04±0.04mg/dl, 7.83±0.11% and 187±5mg/dl, and 0.62±0.04, 9.60±0.31, 0.86±0.01, 7.24±0.09, 156±3.57 respectively; p≤0.05). Estimated GFR was significantly reduced in diabetic patients with albuminuria (75±1ml/min/1.73m2) compared to those without it (79±1ml/min/1.73m2) (p=0.004). There was no ethnic difference in the level of CRP and urinary albumin in patients aged 20-44 and ≥65, except among those without albuminuria, where AA had higher CRP compared to Whites (1.05±0.14 and 0.46±0.08 respectively) (p<0.01). However, in age group 45-64, for those without albuminuria, CRP and urinary albumin were significantly elevated in AA compared to Whites (p<0.01) but for those with albuminuria, only urinary albumin was significantly higher in AA compared to Whites (p<0.01). However, CRP was trended higher in AA compared to Whites (p=0.05).

Conclusions: Concentration of CRP is higher in AA compared to Whites aged 45-64. The results suggest that more advanced inflammatory processes might explain the more rapid progression of type 2 DN in AA patients in this age group and should be further examined.

FR-PO1485

Chronic Kidney Disease: Still an Unrecognized Health Issue? Claudia Friedl,[1] Alexander R. Rosenkranz,[1] Astrid Fahrleitner-Pammer.[2] *[1]Department of Internal Medicine, Division of Nephrology and Hemodialysis, Graz, Austria; [2]Department of Internal Medicine, Division of Endocrinology and Metabolism, Graz, Austria.*

Background: Chronic kidney disease (CKD), especially end stage renal disease (ESRD), is not only associated with a higher morbidity and mortality but also with extremely high cost for the healthcare system. Early diagnosis and therapy of CKD could slow down the progression of the disease and minimize the prevalence of cost-intensive ESRD. Aim of this present study was to determine the prevalence of CKD in inpatients at a general internal ward and to evaluate the frequency of documented CKD according to ICD-10 classification at discharge.

Methods: Over a period of 4 months the data of 238 patients admitted to a general internal ward of the Department of Internal Medicine, Medical University Graz, Austria, were collected. We analyzed the prevalence of CKD, defined as eGFR<60ml/min/1.73m². eGFR was derived from the four-variable MDRD. Furthermore discharge letters were reviewed and the frequency of documented ICD-10 CKD was analyzed. Patients on dialysis (n=7) and those with acute renal failure (n=3) were excluded from analysis. Continuous variables are presented as median (range).

Results: We included 228 patients, 110 (48%) female and 118 (52%) male, in the present analysis. Median age of the study population was 76 years [20-99], whereby with a median of 80 [20-99] women were significantly older (men: 70 [25-97] (p<0.001). eGFR was the same for both sexes with a median of 54,5 [15.8-149.0] in women and 63.6 [10.4-171.9] in men (n.s.). Nearly half of the study population at least had a eGFR<60 ml/min/1.73m². According to CKD stages the prevalence was 39.9% for stage 3, 7.9% for stage 4 and 1.3% for stage 5. The analysis of the related discharge letters showed a documentation of ICD-10 CKD diagnosis of 21% (n=48) in the total study population. Of those with an eGFR < 60ml/min/1,73m² just 38% were diagnosed as patients with CKD.

Conclusions: The present analysis shows a high rate of undiagnosed CKD in hospital setting even at an internal ward. This could have dramatic implications on the care, treatment and prevention of CKD and associated complications.

FR-PO1486

Survival in Patients Entering Renal Replacement Therapy in Their First Month of Life – A World-Wide Collaborative Study Karlijn J. Van Stralen,[1] Dagmara Borzych-Duzalka,[6] Kitty J. Jager,[1] Enrico Verrina,[2] Sean E. Kennedy,[5] Franz S. Schaefer,[3] Pierre Cochat.[4] *[1]ESPN/ERA-EDTA registry, Netherlands; [2]Gaslini Children's Hospital, Italy; [3]University of Heidelberg Childrens Hospital, Germany; [4]Université de Lyon, France; [5]Sidneys Childrens Hospital, Australia; [6]Medical University of Gdansk, Poland.*

Background: End-stage renal disease requiring RRT from the neonatal period is a very rare condition. Hence, little information is available regarding long-term treatment outcomes in these challenging patients.

Methods: Neonates who started RRT in their first month of life were included in the present study. patients starting RRT since 2000 who were registered prospectively in the ESPN/ERA-EDTA (122 patients), IPPN registry (42 patients) or ANZdata (4 patients) were considered, 8 patients were included in multiple registries. Patients were censored after 2 years of follow-up. Survival was estimated using the Kaplan-Meier method.

Results: A total of 161 patients from 30 countries started RRT during the first month of life. They were followed for a median of 31 (IQR 8-47) months. Nearly all children started on PD (90%), while 15 started on HD and one patient with a transplant. Half of them started in their first week of life. The most important causes of renal failure were congenital anomalies of the kidney and urinary tract (62%), followed by cystic kidneys (14%) and tubular necrosis (9%). Within the first 2 years after start of RRT, there were 99 changes in treatment modality among 75 children, including 26 transitions from PD to HD, 19 from HD to PD, 22 transplants, and 3 recoveries of renal function, of whom 2 were only temporary. Sixteen children died after a median of 6 months, resulting in an estimated two-year survival of 86%.

Conclusions: While we cannot exclude potential selection bias from excluding patients in whom RRT was electively not initiated, this study demonstrates that with current RRT technology remarkably good medium-term patient survival is achieved in those neonates in whom a decision for RRT is made. In addition to neurodevelopmental issues, this study might help physicians in deciding whether RRT is an option in neonates with severe renal failure.

FR-PO1487

Foxd1 Is an Upstream Regulator of the Renin-Angiotensin System (RAS) during Metanephric Kidney Development Renfang Song,[1] Graeme James Preston,[1] Maria Luisa S. Sequeira Lopez,[2] Ihor V. Yosypiv.[1] *[1]Pediatrics, Tulane University, New Orleans, LA; [2]Pediatrics, University of Virginia, Charlottesville, VA.*

Background: The RAS is critical in ureteric bud (UB) branching and metanephric kidney development. Mutations in the RAS genes in mice or humans cause a spectrum of congenital anomalies of the kidney and urinary tract (CAKUT). However, the mechanisms by which RAS gene mutations result in CAKUT are poorly understood. In this study, we tested the hypothesis that Foxd1, a forkhead box transcription factor essential for normal kidney development, is an upstream regulator of the RAS during UB morphogenesis.

Methods: The effect of genetic inactivation of Foxd1 on UB branching and RAS gene and protein expression was examined in embryonic (E) day E13.5 Foxd1+/+ and -/- kidneys in vivo and in mesenchymal (MK4) cells transfected or not with Foxd1 expression vector (1.0 μg plasmid DNA) in vitro. Angiotensinogen (AGT), renin, angiotensin I-converting enzyme (ACE), angiotensin (Ang) II receptor type 1 (AT1R) mRNA levels were determined by real-time qRT-PCR. Cellular distribution of AGT and renin proteins was examined by immunohistochemistry.

Results: The number of UB tips was decreased in Foxd1-/- (n=4) compared with Foxd1+/+ (n=6) metanephroi (14±2.1 vs. 28±1.3, p<0.05). Renin, ACE, AT1R mRNA levels as well as AGT and renin protein expression was decreased in Foxd1-/- compared with Foxd1+/+ E14.5 metanephroi (mRNA: renin: 0.23±0.01 vs. 1.0±0.02, p<0.01, ACE: 0.37±0.02 vs. 1.0±0.01, p<0.01, AT1R: 0.41±0.06 vs. 1.0±0.02, p<0.01), whereas AGT mRNA levels did not change. Foxd1 overexpression in MK4 cells increased renin, ACE, AT1R and did not alter AGT mRNA levels. Treatment of E13.5 Foxd1-/- kidneys with exogenous Ang II (10-5 M) for 24 hours increased the number of UB tips compared with media (control) (42±2.0 vs. 33±2.5, p<0.05).

Conclusions: In summary, RAS gene expression during metanephric development is differentially regulated by Foxd1 at the transcriptional level. We conclude that the cross-talk between the RAS and Foxd1 plays an important role in UB morphogenesis and pathophysiology of CAKUT.

FR-PO1488

Association between Genetic Variation at FOXP3 Gene Locus and Renal Transplant Outcomes Jennifer A. McCaughan,[1,2] Aisling E. Courtney,[1] A.J. McKnight,[2] Alexander P. Maxwell.[1,2] *[1]Department of Nephrology, Belfast City Hospital, Belfast, United Kingdom; [2]Nephrology Research Group, Queen's University, Belfast, United Kingdom.*

Background: T regulatory cells have emerged as key coordinators of immune tolerance. A unique feature of these cells is the stable expression of the forkhead box transcription factor gene *FOXP3* (Xp11.23). It is reported that transplant recipients with longterm graft survival demonstrate significantly higher *FOXP3* expression than those with graft loss from chronic immunological injury. This study is the first to investigate whether genetic variation at the *FOXP3* locus is associated with allograft or transplant recipient survival.

Methods: Genomic DNA was prospectively collected from recipient and donor pairs in first deceased donor kidney transplants. A total of 575 recipients and 516 donors were included with 354 (61%) recipients and 301 (58%) donors being male. Over 99% of both populations were White.

Genotyping data for *FOXP3* single nucleotide polymorphisms (SNPs) with a minor allele frequency > 5% were downloaded from the International HapMap Project for a White population. Five SNPs met the criteria for a Hardy Weinberg cutoff 0.001 and genotype rate > 95%. Four Tag SNPs were chosen using the pair-wise approach implemented in Haploview. Five potentially functional SNPs were downloaded from the Ensembl Genome Browser.

Eight SNPs were genotyped using Sequenom iPLEX and called using MassARRAY TYPER. A single SNP was genotyped using Taqman technology. Genotypes and allele frequencies were analysed on a gender-specific basis using SPSS.

Results: One FOXP3 SNP within the donor genome was significantly associated with allograft survival [rs2280883, p=0.038] and one with recipient survival [rs2294021, p=0.031]. FOXP3 gene variants in the recipient genome were not significantly associated with either allograft or recipient survival.

Conclusions: Recipient *FOXP3* expression post transplantation appears to be associated with long term allograft survival. It was an unexpected finding that *FOXP3* variants in the donor genome were associated with recipient and allograft outcomes. Replication of this study in another cohort of donor-recipient pairs will establish if this association is robust.

FR-PO1489

Genetic Variation at Caveolin-2 Locus and Renal Transplant Outcomes Jennifer A. McCaughan,[1,2] Aisling E. Courtney,[1] A.J. McKnight,[2] Alexander P. Maxwell.[1,2] *[1]Dept. of Nephrology, Belfast City Hospital; [2]Nephrology Research Group, Queen's University, Belfast.*

Background: Caveolae are invaginations of the plasma membrane which are formed from a stable complex of proteins caveolin-1 and caveolin-2. Caveolae have a key role in intracellular drug transport, cell growth, transmembrane signalling, and apoptosis. Single nucleotide polymorphisms (SNPs) within the caveolin-1 gene are significantly associated with renal allograft fibrosis and survival. The caveolin-2 gene (*CAV2*), located at 7q31.1, is also a plausible candidate gene implicated in renal allograft survival.

Methods: We performed SNP analysis on genomic DNA from 575 recipients and 516 donors in paired, first deceased kidney transplants. Prospective clinical data has been recorded from 1986 on all recipients. Over 99% of both populations were White.

Genotyping data for *CAV2* SNPs with a minor allele frequency > 5% were downloaded from the International HapMap Project for a White population. Thirteen SNPs met the criteria for Hardy Weinberg cutoff 0.001 and genotype rate >95%. Seven Tag SNPs were chosen using the pair-wise approach implemented in Haploview. Three potentially functional SNPs were downloaded from the Ensembl Genome Browser.

Eight SNPs were genotyped using Sequenom iPLEX and called using MassARRAY TYPER. Two SNPs were genotyped using Taqman technology. Genotypes and allele frequencies were analysed using SPSS.

Results: Investigating all common variants in CAV2 revealed statistically significant associations between two recipient SNPs and allograft survival [rs11980719, p = 0.017 and rs 13221869, p = 0.015]. rs13221869 is a potentially functional SNP resulting in an amino acid change: NP_937855.1:p.Phe13Leu.

Conclusions: This study provides further evidence that genetic variation in caveolin genes may play a role in renal allograft fibrosis and survival.

FR-PO1490

Genome Wide Methylation Analysis of 485,577 Features in a Renal Transplant Population Jennifer A. McCaughan,[1,2] Aisling E. Courtney,[1] Alexander P. Maxwell,[1,2] A.J. McKnight.[2] *[1]Regional Nephrology Unit, Belfast City Hospital, Belfast, NI, United Kingdom; [2]Centre for Public Health, Queen's University of Belfast, NI, United Kingdom.*

Background: Studies have highlighted that renal (dys)function is influenced by differential methylation at several loci. We investigated the DNA methylome by conducting an epigenome-wide association study in peripheral blood leukocytes.

Methods: Ninety-six individuals (recipients vs. donors) were matched for age and gender. Comparisons were performed for end stage kidney disease (ESKD), IgA nephropathy, chronic allograft nephropathy and survival outcomes.

Methylation status was profiled in individuals by hybridisation to 450K Infinium methylation beadchips (Illumina Inc, USA). 90 samples and arrays passed stringent quality control; raw data were normalised and beta values calculated. Significantly up and down regulated genes for each comparison (adjusted p<0.0001) were considered for biological relevance by functional enrichment analysis using KEGG pathways.

Results: Quantitative methylation values were obtained at a single-CpG site level for 485,577 features, encompassing coverage of all designable RefSeq genes, including promoter, 5', and 3' regions, CpG islands outside coding regions, and miRNA promoter regions. Experimentally defined genders matched each individual submitted for analysis and >99% duplicate concordance was observed.

Significant association ($P<10^{-10}$) was observed for ESKD, including multiple hits in biological candidate genes such as *NOSIP*, *JAG2*, *SMAD3*, *TBCD*, and *AFF3*. Genome-wide significance was not observed for IgA nephropathy or chronic allograft nephropathy; top ranked genes include *CALM2*. Multiple genes reached $P<10^{-8}$ for survival outcomes, top ranked members include the ADAM family. WNT, Jak-STAT signalling, tight junction and apoptotic pathways were highlighted by all comparisons.

Conclusions: We have identified differences in methylation profiles both globally, and at individual CpG sites, which are associated with ESKD and renal transplant outcomes.

FR-PO1491

Comprehensive Genetic and Epigenetic Investigations for Association of the Major Histocompatibility Complex Region in a Renal Transplant Population A.J. McKnight,[1] Jennifer A. McCaughan,[1,2] Aisling E. Courtney,[2] Alexander P. Maxwell.[1,2] *[1]Centre for Public Health, Queen's University of Belfast, NI, United Kingdom; [2]Regional Nephrology Unit, Belfast City Hospital, Belfast, NI, United Kingdom.*

Background: The prevalence of end-stage kidney disease (ESKD) continues to rise so that strategies to delay the onset of ESKD and improve long-term survival of renal grafts and transplant recipients are important goals. Genetic variation within the major histocompatibility complex (MHC) results in phenotypic variation in expressed human leukocyte antigens (HLA) that, along with non-HLA targets, affect renal function and transplant outcomes. We have previously reported association of MHC-related genes with diabetic nephropathy.

Methods: We have genotyped >3,000 maximally informative SNPs in the MHC region and MHC-related genes in 900 matched, White European, kidney transplant donors and recipients (maximum follow-up 238 months; median 69 months) using a combination of dedicated MHC panels (Illumina Inc, USA) and Sequenom-based genotyping. Complementary to this approach, next generation sequencing technology (Illumina) was performed to individually fine-map the entire MHC region for 10 participants. Association of variants with ESKD was evaluated using PLINK while short and long-term graft and recipient survival was evaluated using Kaplan-Meier plots and Cox regression models. Methylation status of CpG islands within 6p21 was available for 90 of the individuals genotyped.

Results: Greater than 97.5% completion was observed with >99% duplicate concordance. Genome-wide significant association (adjusted P<10-8) was identified for several loci. We also provide detailed coverage of the technically challenging 5 Mb region that includes HLA-A, B, C, DMA, DMB, DOA, DOB, DPA1, DPB*, DQA*, DQB*, DRA, DRB* E, F G, H, J, K, L, U and HLA-W genes.

Conclusions: Our comprehensive study highlights the complexity of the MHC region and provides important information for genes that are primarily involved in innate and adaptive immune systems. While we have identified several key loci that influence renal function, these need validated in larger cohorts followed by functional experiments to elucidate the mechanisms.

FR-PO1492

APOL1 Risk Genotypes Are Enriched in African American Study of Kidney Disease and Hypertension (AASK) Participants, Particularly among Those with Kidney Disease Progression Cheryl Ann Winkler,[1] Barry I. Freedman,[2] Wen Hong Linda Kao,[3] Carl D. Langefeld,[2] Brad C. Astor,[3] George W. Nelson,[1] Mary E. Comeau,[2] Donald W. Bowden,[2] Jeffrey B. Kopp,[4] Michael S. Lipkowitz.[5] *[1]SAIC, NCI, Frederick, MD; [2]Wake Forest University, Winston-Salem, NC; [3]Johns Hopkins University, Baltimore, MD; [4]NIDDK, Bethesda, MD; [5]Georgetown University Medical Center, Washington, DC.*

Background: Chromosome 22 variation explains much of the increased kidney disease risk in African descent individuals. The AASK study enrolled 1094 subjects with hypertension and reduced glomerular filtration rate and examined the effect of blood pressure control on nephropathy progression, defined as serum creatinine >3 mg/dL (61 events) or ESKD (158 events).

Methods: We compared APOL1 and MYH9 genotypes in 675 AASK subjects and 618 African American population controls. The control group, of whom 43% had hypertension, was recruited in southeastern USA and lacked a personal or family history of kidney disease. Mean African admixture was 0.89 in both cases and controls.

Results: APOL1 risk allele frequencies (G1 and G2) were 23.2% in cases compared to 11.6% in controls, OR 2.31, P= 7.1X10E-8. After adjusting for age and gender, the OR associated with having two risk alleles were as follows: for hypertensive kidney disease (all AASK cases) versus all controls, 2.3 (95% CI 1.7, 3.1), P = 6 X10E-8); for hypertensive kidney disease (all AASK cases) versus hypertensive controls, 2.2 (1.4, 3.7), P<0.002; for AASK cases with baseline urine protein/creatinine ratio >0.2 g/g vs controls, 4.3 (3.0, 6.2), P=1X10E-14; and for AASK cases with progression versus controls, 4.1 (2.9, 5.9), P= 1.8X10E-14. After adjusting for APOL1, the presence of two MYH9 E1 haplotype copies

was associated with OR 1.7 (1.1, 2.4), P=0.01 for progression. There was no interaction between APOL1 risk allele status and ACE inhibitor use with regard to progression.

Conclusions: APOL1 risk allele prevalence is elevated among AASK participants with hypertension-attributed kidney disease. Two APOL1 risk alleles markedly increase the risk of kidney disease progression.

FR-PO1493

The Use of Homozygosity Mapping To Identify the Responsible Gene for Diffuse Mesangial Sclerosis, an Entity with Genetic Heterogeneity Yaacov Frishberg, Efrat Ben Shalom, Rachel Becker-Cohen, Choni Rinat, Sofia Feinstein, Ruth Belostotsky. *Pediatric Nephrology, Shaare Zedek Medical Center, Jerusalem, Israel.*

Background: Many hereditary kidney diseases display genetic heterogeneity manifesting as a common phenotype derived from mutations in a number of different genes. Diffuse mesangial sclerosis (DMS), a histologic variant of steroid-resistant nephrotic syndrome (SRNS) in the pediatric age group represents an example of this phenomenon, with 4 genes (NPHS1, NPHS2, PLCE1 and WT1) responsible for a third of all cases. Given that these 4 genes contain together 79 exons, diagnostic sequencing is expensive, and remains ineffective in about 70% of all cases.

Methods: Detecting the genetic basis of the disease in patients from consanguineous or ethnically-related families can be accomplished by the implementation of homozygosity mapping based on SNP microarray analysis. Localization of homozygous genomic loci "identical-by-descent" allows to restrict the number of known genes which may be associated with the disease in particular cases.

Results: We performed homozygosity mapping in an attempt to study a consanguineous Arab family with 6 offspring affected with SRNS, 4 of whom succumbed to the disease. In one child, the histologic diagnosis of DMS was made when he already had ESRD. Homozygosity mapping revealed 8 homozygous regions of 10 to 2 Mbp in length, each. The only gene that has previously been associated with DMS or SRNS within these regions was PLCE1. Direct sequencing revealed the novel homozygous deletion c.4977_4982delCAGA leading to a frame shift p.Q1660LfsX9. The same mutation was later detected in an unrelated family of the same ethnic background with two affected children, pointing to a founder effect.

Conclusions: This approach is economically sound when the total number of exons of the potentially relevant genes exceeds 40-50. We recommend the implementation of homozygosity mapping in complex consanguineous families affected by diseases characterized by genetic heterogeneity.

FR-PO1494

Glucocorticoid Receptor Sensitivity in Patients with Focal Segmental Glomerulosclerosis Nataliya Chorny,[1] Steven Ghanny,[3] Shella Mongia,[2] Amrit Bhangoo,[3] Anil K. Mongia.[1] *[1]Peds Nephrology, SUNY, Brooklyn, NY; [2]Peds Endocrinology, SUNY, Brooklyn, NY; [3]Pathology, SUNY, Brooklyn, NY.*

Background: Glucocorticoids are the primary therapy used to treat FSGS though neither the target cell nor their mechanism of action in FSGS are known.

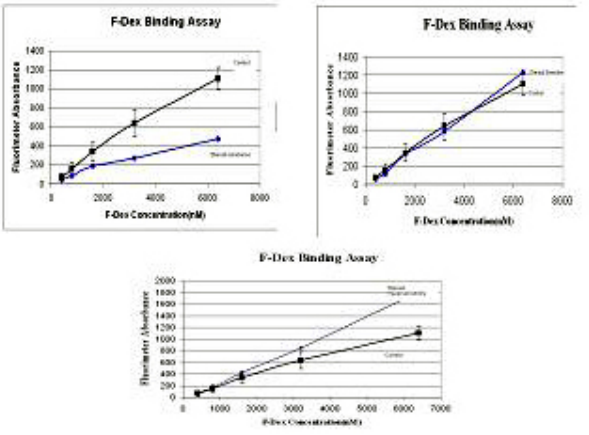
The aim of this study was to compile the clinical data, NPHS2 genes mutation and Glucocorticoid Receptor sensitivity in our patients with FSGS.

Methods: We evaluated 14 patients with FSGS. There were 4 Hispanics and 10 African Americans. 4 had ESRD. 11 patients were evaluated for NPHS2 mutations. Monocytes Glucocorticoid receptors sensitivity was studied in 5 patients. For monocytes testing cell suspension was centrifuged, resuspended and incubated. The next day the cells were reincubated at 37oC for 1 hour with F-Dex in concentration range from 400 to 6400nm. After washing, the absorbance was detected by Microplate Fluorometer Series 7600. Clinical data were compared with GR sensitivity results. NPHS2 mutation sequencing is in progress. IRB approved the study.

Results: 2 patients with no responce to Steroids and Immunosupression, who progressed to ESRD had Hypersensitive GR response. One patient who is steroid dependent had normal GR sensitivity.

Clinical features and GR sensitivity

Patient Ethnicity	Immune deposits	Response to Steroid	Response to Prograf/ Cellcept	ACE Tx	ESRD	GR sensitivity
Hisp	+	Steroid dependent	+	+	-	Normal
Hisp	+	-	-	-	+	Hyper
AA	+	-	-	no	+	Hyper
AA	+	never Tx	never Tx	+	-	Normal
AA	+	never Tx	never Tx	+	-	Resistant



Conclusions: We conclude that GR sensitivity testing may provide predictive value prior to deciding on starting steroid treatment and dose of steroids.

Replication and Validation of MYH9/APOL1 Chronic Kidney Disease Risk Alleles in an Urban Tertiary Care Center: Implications for Personalized Medicine Omri Gottesman, Marie Teil, Vaneet Lotay, Rajiv Nadukuru, Bernadette Liggayu, Kash Patel, Stephen B. Ellis, Erwin P. Bottinger. *Charles R. Bronfman Institute for Personalized Medicine, Mount Sinai School of Medicine, New York, NY.*

Background: Genetic variants in a region of chromosome 22 have consistently associated with nephropathy in African Americans and have been replicated in other populations. These have potential utility for genomic prediction of CKD risk. The Institute for Personalized Medicine Biobank is an electronic medical record-linked biorepository with up to 20,000 participants. Self-reported populations include ~40% Hispanic Americans (HA), ~30% African Americans (AA) and ~25% European Americans (EA). The prevalence of CKD stage 3 or higher (KDOQI definition) is ~15%.

Purpose: To replicate previous genotype-phenotype associations and validate risk loci in our heterogeneous local population prior to potential clinical decision support implementation.

Methods: We are directly genotyping all Biobank participants for 12 SNPs in the APOL1/MYH9 region that have been associated with CKD. Preliminary genotyping was undertaken on 2052 participants (900 cases (≥CKD3), 1152 controls). Logistic regression analysis was performed in each population for CKD and CKD +/- diabetes using age, sex, age^2 and the first two principal components (from genome-wide data) as covariates. Levels of statistical significance were determined by the Bonferroni correction or at $p<0.05$ for previously replicated loci.

Results: We have demonstrated that previously validated risk variants can be replicated within our local populations. In particular, the G1 alleles of APOL1 (rs60910145, rs73885319) are strongly associated with non-diabetic CKD in our AA population (OR's 2.6 and 3.8 respectively, $p<0.01$) with a recessive model of inheritance, consistent with previous reports. We also replicated a previous association of an MYH9 E1 allele (rs4821480) with non-diabetic CKD in our HA (OR 2.43, $p<0.05$).

Conclusions: We anticipate that extended results from ~5000 AA and ~7000 HA patients will provide a compelling rationale for future studies to evaluate the impact of genomic prediction tools in the management of modifiable CKD risk factors.

FR-PO1496

A Combined Deletion of CFHR1 and CFHR3 Conveys Protection Against IgA Nephropathy Jingyuan Xie,[1,2] Krzysztof Kiryluk,[2] Yifu Li,[2] Ping Hou,[3] Simone Sanna-Cherchi,[2] Zhaohui Wang,[1] Weiming Wang,[1] Hong Zhang,[3] Nan Chen,[1] Ali G. Gharavi.[2] *[1]Renal Department, Shanghai Ruijin Hospital, Shanghai Jiaotong University, Shanghai, China; [2]Division of Nephrology, Columbia University, New York City, NY; [3]Renal Division, Peiking University First Hospital, Institute of Nephrology, Peiking, China.*

Background: In a recent GWAS, we detected a major susceptibility locus for IgAN within the complement factor H (CFH) gene cluster on chr.1q32. The top SNP, rs6677604, tags a common deletion of CFHR1 and CFHR3 genes (CFHR1,3Δ). The goal of this study was (1) to directly type CFHR1,3Δ to determine whether it accounts for the association a the CFH locus, and (2) to identify additional rare CNVs in this region.

Methods: We studied a total of 1,929 biopsy-diagnosed primary IgAN cases and 1,652 healthy controls of Chinese ancestry. The CFHR1 and CFHR3 region was screened with multiplex ligation-dependent probe amplification (MLPA) and quantitative PCR. Association analyses were performed with PLINK v1.07 and UNPHASED 3.1.3.

Results: The CFHR1,3Δ and rs6677604 variants were in strong LD (r2=0.90, D'=0.98) and both had a strongly protective effect on IgAN (rs6677604 OR=0.61, p=1*10-6; CFHR1,3Δ OR=0.58, p=2*10-7). After conditioning on rs6677604, CFHR1,3Δ had an independent protective effect (OR=0.51, 95%CI: 0.26-1.00, p=0.05). In contrast, after conditioning on CFHR1,3Δ, rs6677604 was no longer significant (95%CI: 0.59-2.17, P=0.7). We also identified 3 rare single-gene CNVs (CFHR3Δ, CFHR1Δ and CFHR1 duplication, freq=0.8-2%), but these CNV's were not associated with risk of IgAN.

Conclusions: The CFHR1,3Δ variant explains the rs6677604 association signal, strongly suggesting that this deletion is the functional allele at the CFH locus. The absence of association of single-gene CNV's suggests a synergistic effect of the CFHR1 & CFHR3 deletions on the alternative complement pathway.

FR-PO1497

Genome-Wide Linkage Scan of Japanese Families with IgA Nephropathy

Shin Goto,[1] Hiroyasu Tsukaguchi,[2] Masakazu Wada,[1] Ichiei Narita.[1] *[1]Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Second Department of Internal Medicine, Kansai Medical University, Osaka, Japan.*

Background: A genetic predisposition of IgA nephropathy (IgAN) has been suggested by the familial clustering of the disease. Previously, genome-wide linkage analysis of IgAN have revealed several susceptibility loci including 6q22-23 (IGAN1), 4q26-31, 17q12-22, and 2q36. However, no causative gene mutations underlying these linkage loci has been identified. From the point of view of genetic heterogeneity of familial IgAN, oligo/polygenic and multiple susceptibility gene model for the disease are proposed.

Methods: In this study, we investigated 10 Japanese multiplex families in which multiple members are affected by biopsy proven IgAN. A total of 62 subjects (24 affected) were genotyped using Genome-Wide Human SNP Array 6.0. Multipoint linkage analysis was performed using SNP HitLink, which is a program providing a useful pipeline to directly connect SNP data and linkage analysis program, enabling a high-throughput analysis.

Results: The genotypes of each sample were determined with a high overall call rate of over 99.5%. Parametric analysis with assumption of an autosomal dominant mode of inheritance, with estimated penetrance of 75%, yielded maximum heterogeneity LOD score of 1.84 on 1p36. By nonparametric analysis, eight regions of potentially interesting level of nonparametric LOD (NPL > 3.0) were identified including 1p36 (NPL score 3.88).

Conclusions: These results provide a support for genetic heterogeneity among families with IgAN, and novel candidate loci responsible for familial IgAN in Japan.

FR-PO1498

Coding Polymorphisms of Interleukin-22 Receptor Alpha-1 Contributing to the Development of Childhood IgA Nephropathy in Korean Population

Jin-Soon Suh, Byoung-Soo Cho. *Department of Pediatrics, East West Kidney Diseases Research Institute, Kyung Hee University Hospital, Seoul, Korea.*

Background: Interleukin (IL)-22 is a member of the IL-10 cytokine family and represents an important effector molecule of activated immune cells. It mediates its effects via two receptors, IL-22R1 and IL-10R2 and subsequent Janus kinase-signal transducers and activators of transcription (JAK-STAT) pathways. Because of the restricted expression of IL-22R1, the main receptor of IL-22, its target cells are not immune cells but certain tissue cells including kidney. In the present study, we investigated the associations between polymorphisms of *IL-22R1 and IL-10R2* and childhood IgA nephropathy in Korean children.

Methods: We evaluated 194 pediatric patients with biopsy-proven IgAN and 287 healthy controls. Two single nucleotide polymorphisms (SNPs) in the coding region of the IL-22R1 gene [rs rs3795299 (missense, Arg518Gly) and rs10903022 (synonymous, Pro45Pro)], and one SNP in the IL-10R2 gene [rs2834167 (missense, Lys47Glu)] were selected and genotyped by direct sequencing methods.

Results: Our case-control analysis showed that genotypes of rs3795299 were associated with childhood IgAN in the codominant model [p=0.0028, OR(95% CI)=1.33 (0.91-1.95)] and in the recessive model [p=0.002, OR(95% CI)=0.28(0.11-0.69)]. After Bonferroni correction, this association of rs3795299 with IgAN risk remained significant.

Conclusions: Polymorphisms in IL22R1 may be associated with the development of childhood IgAN. Replication and functional studies are involved to better understand themechanism by which these polymorphisms may contribute to the pathogenesis of IgAN.

FR-PO1499

APOL1 Genetic Variants Significantly Increase Susceptibility to Focal Segmental Glomerulosclerosis and HIV-1 Associated Nephropathy but Not IgA Nephropathy in African Americans

Natalia Papeta,[1] Krzysztof Kiryluk,[1] Ami Patel,[1] Roel Sterken,[1] Nilgun Kacak,[1] Holly J. Snyder,[1] Philip Imus,[1] Anand Nilkanth Mhatre,[3] Bruce A. Julian,[2] Robert J. Wyatt,[4] Jan Novak,[2] Christina M. Wyatt,[5] Michael J. Ross,[5] Jonathan A. Winston,[5] David J. Cohen,[1] Gerald B. Appel,[1] Vivette D. D'Agati,[6] Ali G. Gharavi.[1] *[1]Medicine, Columbia University, New York, NY; [2]Microbiology and Medicine, University of Alabama, Birmingham, AL; [3]Otolaryngology, New York University, New York, NY; [4]Pediatric Nephrology, University of Tennessee, Memphis, TN; [5]Medicine, Mount Sinai School of Medicine, New York, NY; [6]Pathology, Columbia University, New York, NY.*

Background: A chromosome 22q13 locus, encompassing the MYH9 and APOL1 genes, has been strongly associated with increased risk of idiopathic focal segmental glomerulosclerosis (FSGS), HIV-1-associated nephropathy (HIVAN) and hypertensive end-stage kidney failure among individuals of African descent.

Methods: In this replication study, we examined the six top-most associated variants in *APOL1* and *MYH9* in an independent cohort of African-Americans with various nephropathies [FSGS (N=44), HIVAN (N=21), IgA nephropathy, (IgAN, N=32), vs. healthy controls (N=74)].To assess the role of MYH9 deficiency in nephropathy, we examined M*yh9* haploinsufficient mice (*Myh9*$^{+/-}$) and crossbred them with HIV-1 transgenic mice.

Results: All six variants were associated with FSGS and HIVAN (additive ORs 1.8-3.0, P-values 3 x 10-2 – 5 x 10-5), but not with IgAN. In conditional and haplotype analyses, two APOL1 haplotypes (tagged by rs60910145 and rs71785313) accounted for virtually all the association with FSGS and HIVAN on Chr. 22q13 (haplotype P-value = 5.6 x 10-8). Myh9+/- mice are healthy and devoid of proteinuria or nephropathy, irrespective of the presence of the HIV-1 transgene.

Conclusions: These data further support the strong association of genetic variants in *APOL1* with susceptibility to FSGS and HIVAN among African-Americans.

FR-PO1500

Genome-Wide Association Study Identified Multiple Susceptibility Loci for IgA Nephropathy in Chinese Population

Xueqing Yu,[1] Ming Li,[1] Hong Zhang.[2] *[1]Department of Nephrology, First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [2]Renal Division, Peking University First Hospital, Beijing, China.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis among patients undergoing renal biopsy and has a higher prevalence in Asian than western countries. There are multiple lines of evidence for the involvement of genetic risk factors, but only a few susceptibility genes have been identified.

Methods: Two-stage genome-wide association study (GWAS) was performed in the Chinese population, where the genome-wide discovery analysis was done in 1434 cases and 4270 controls by using the Illumina 660K SNP chips, and the replication analysis of the top 60 SNPs from GWAS was done in an additional 2703 cases and 3464 controls by using the iPLEX system and TaqMan assay.

Results: We found the most significant signal is in the MHC region on Chr.6 (P=4.92×10-21, OR=1.35), where several HLA alleles and haplotypes were implicated. Also, we discovered other two independent loci with genome-wide significance associated with IgAN, where multiple genes within these loci involved in the immune response. Furthermore, we confirmed the locus 22q12 of previous study (P=1.17×10-11, OR=0.78). Our study did not yield any supporting evidence for the association on 1q32 locus reported by the previous study (rs6677604, P=0.52, OR=0.94), although our discovery sample has sufficient power for detecting the association (power=0.86 at a significance of 0.01).

Conclusions: By identifying several susceptibility loci, our study may reveal the new insight into the biological variability in the development of IgAN.

FR-PO1501

APOL1 and MYH9 Genetic Variants Are Independently Associated with Kidney Disease Risk in African Americans

Jeffrey B. Kopp,[1] Barry I. Freedman,[2] Cheryl Ann Winkler,[3] George W. Nelson,[3] Donald W. Bowden,[2] Mary E. Comeau,[2] Carl D. Langefeld.[2] *[1]NIDDK, NIH, Bethesda, MD; [2]Wake Forest School of Medicine, Winston-Salem, NC; [3]NCI, NIH, Frederick, MD.*

Background: Admixture mapping identified a locus centered on MYH9 as a risk locus for focal segmental glomerulosclerosis (FSGS), HIV-associated nephropathy (HIVAN), and non-diabetic hypertension-attributed kidney disease in African Americans (AAs). Although MYH9, encoding myosin heavy chain 9, was a plausible candidate gene, a subsequent GWAS for FSGS, and results of the 1000 Genome project, revealed that coding variants of APOL1 accounted for the chromosome 22 kidney disease susceptibility; regression analysis suggested that all of the increased risk was due to two APOL1 mutations.

Methods: We re-examined this question using additional AA cases and controls. First, 271 FSGS and HIVAN cases and 939 controls were studied to determine the effect of MYH9 in each of six possible APOL1 genotype combinations in a stratified analysis. Second, 885 non-diabetic ESRD cases and 1259 population controls recruited at Wake Forest were evaluated, adjusting for APOL1 G1/G2 alleles.

Results: In the FSGS/HIVAN cohort, the risk-associated MYH9 SNP rs2413396 was tested by Fisher exact test and reached significance for two APOL1 genotypes (G1 = AA, G2 = DI, p = 0.006; G1 = AG, G2 = DI, p = 0.04). Considering all AA subjects in an analysis stratified on the APOL1 genotype, the MYH9 SNP was associated with renal disease (p=0.006, odds ratio 2.0, 95% confidence interval 1.4, 3.1). In the hypertension-attributed ESKD cohort, residual MYH9 effects were detected for three E1 haplotype SNPs under a recessive model: rs4821480 (P=0.029, OR=1.26), rs2032487 (P=0.036, OR=1.32), and rs4821481 (P=.012, OR=1.40).

Conclusions: These results suggest that additional independent loci within the MYH9/APOL1 extended linkage disequilibrium region on chromosome 22 are associated with renal disease.

FR-PO1502

Global Histone 3 Lysine 27 Trimethylation Status of Neutrophils and RUNX3 Expression in Anti-Neutrophil Cytoplasmic Autoantibody Vasculitis Kerry R. Colby, Meghan E. Free, Jia Jin Yang, Donna O. Bunch, Gloria A. Preston, J. Charles Jennette, Ronald J. Falk, Dominic J. Ciavatta. *UNC Kidney Center, University of North Carolina at Chapel Hill, NC.*

Background: The genes encoding two anti-neutrophil cytoplasmic autoantibody (ANCA) autoantigens, proteinase 3 (PR3) and myeloperoxidase (MPO), are aberrantly expressed in neutrophils of patients with ANCA disease. We have shown that both *PR3* and *MPO* genes in neutrophils of patients with ANCA disease, as compared to healthy controls, have decreased levels of histone H3 lysine 27 trimethylation (H3K27me3), a histone modification associated with epigenetic gene silencing at the *MPO* and *PR3* loci. This epigenetic difference may be a consequence of active demethylation via a H3K27me3 specific demethylase. Differences in H3K27me3 levels could also result from a failure to recruit the H3K27 methyltransferase. We have described a mechanism whereby RUNX3 recruits the H3K27 methyltransferase to *MPO* and *PR3* loci, and we have shown a decrease in the amount of *RUNX3* mRNA expression in total blood leukocytes of ANCA patients as compared to controls.

Methods: Total blood leukocytes were labeled with cell surface markers. Cells were incubated with primary antibodies recognizing either UTX, H3K27me3, or RUNX3. Levels of H3K27me3 and amount and distribution of UTX and RUNX3 among leukocytes were determined by flow cytometric analysis.

Results: Preliminary data show global H3K27me3 levels are reduced in patients with ANCA disease as compared to controls. We identified some patients with active ANCA disease that have increased UTX protein in subset of cells. Finally, our preliminary results show RUNX3 protein is decreased in monocytes of patients with ANCA disease as compared to healthy controls.

Conclusions: The global deficit in H3K27me3 may underlie altered expression of multiple neutrophil genes. This deficit could be due to both active demethylation in patients and the failure to recruit methyltransferases. These fundamental analyses to identify the molecular differences in peripheral blood cells between ANCA patients and healthy controls are crucial to understanding disease mechanisms of ANCA vasculitis.

FR-PO1503

Common Serum Urate – Associated Genetic Variants in over 100,000 Individuals Are Associated with Gout and Renal Urate Excretion Anna Kottgen,[1,10] Eva Albrecht,[2] Alexander Teumer,[3] Veronique I. Vitart,[4] Claudia Hundertmark,[1] Giorgio Pistis,[5] Daniela Ruggiero,[6] Toomas Haller,[12] Toshiko Tanaka,[7] Qiong Yang,[8] Murielle Bochud,[9] Wen Hong Linda Kao,[10] Caroline S. Fox,[11] Christian Gieger.[2] *[1]Freiburg University; [2]Helmhotz Center Munich, ; [3]Greifswald University, ; [4]MRC Human Genetics Unit, Edinburgh; [5]San Raffaele Scientific Institute; [6]IGB-ABT, CNR, Naples; [7]National Institute on Aging, Baltimore; [8]Boston University; [9]Lausanne University; [10]Johns Hopkins University; [11]National Heart, Lung, and Blood Institute; [12]University of Tartu.*

Background: Using genome-wide association studies and meta-analysis among 110,238 population-based European ancestry study participants, we identified 26 independent genomic loci, 16 of them novel, associated with serum urate concentrations ($p<5*10-8$).

Methods: To quantify associations with gout risk and highlight physiological mechanisms underlying the serum urate association, the single nucleotide polymorphism (SNP) with the strongest association at each genomic locus was related to gout among 73,236 participants (2,942 cases). Urate excretion was assessed as fractional excretion of urate (FEUA, n=3087), calculated from serum and urinary urate and creatinine.

Results: The urate-increasing allele at each of the 26 SNPs also associated with increased gout risk. The odds ratios for 15 SNPs associated at $p<0.05$ with gout ranged from 1.08 (rs675209 near RREB1, p=0.04) to 1.71 (rs2231142, ABCG2, p=10-32) per copy of the allele associated with higher urate levels, including novel loci such as near NFAT5 (OR=1.10). Association with FEUA ($p<0.05$) was observed for 7 SNPs, with the strongest association for rs12498742 in SLC2A9 (lowering the median FEUA of ~4% by 0.2% per urate increasing allele, p=10-7). For each of these SNPs including the one near NFAT5, the urate increasing allele was associated with lower FEUA, consistent with lower renal urate excretion.

Conclusions: Genome-wide association studies of serum urate identify novel genomic risk loci for gout. Association with FEUA suggest that some, but not all, SNPs may be associated with higher serum urate levels by altering renal urate excretion.

FR-PO1504

Association of SLC2A9 with Serum Uric Acid and Renal Phenotypes in Zuni Indians V. Saroja Voruganti,[1] Sandra L. Laston,[1] Karin Haack,[1] Jean W. Maccluer,[1] Shelley A. Cole,[1] Vallabh O. Shah,[2] Arlene Bobelu,[2] Jeanette Bobelu,[2] Antonia M. Harford,[2] S. Paine,[3] Philip Zager,[2,3] Anthony Comuzzie.[1] *[1]Genetics, Texas Biomedical Research Institute, San Antonio, TX; [2]University of New Mexico, Albuquerque, NM; [3]Dialysis Clinic Inc, Albuquerque, NM.*

Background: Elevated serum uric acid (UA) levels are associated with gout, metabolic syndrome, heart and renal disease. UA levels are heritable in Caucasian, African American and Asian populations. Genome-wide association studies (GWAS) have demonstrated an association of SNPs in the solute carrier protein 2 family, member 9 (SLC2A9) gene with UA. The Zuni Indians are a small, relatively endogamous, tribe in NM.

Methods: We studied 1016 members of extended families who participated in the NIH funded, Genetics of Kidney Disease in Zuni Indians (GKDZI) study. The GKDZI seeks to identify genetic factors, which modulate susceptibility to renal disease and intermediate phenotypes. We conducted a GWAS using the Illumina Human1M-Duo v3.0 BeadChips, read on the Illumina BeadStation 500GX and analyzed with Genome Studio software. We used a linear regression-based association test under an additive model of allelic effect. We accounted for the non-independence of family members using a kinship variance component. Analyses were done in SOLAR.

Results: There was strong heritability of UA levels ($h2 = 0.32 \pm 0.07$) ($p <0.001$) and strong association of UA levels with solute carrier family 2 (facilitated glucose transporter), member 9 (SLC2A9) SNPs, rs6449213, rs938555, rs16890979, rs12499857, rs734553 and rs6832439 ($p < 10-08$). SLC2A9 encodes a UA transporter that mediates renal urate flux from proximal tubules. Minor allele frequencies of SNPs ranged from 32 to 49% and the mean effect sizes ranged from 3.6 to 4.3%. All SNPs except rs6449213 and rs12499857 were associated with higher UA levels. There were associations of SLC2A9 SNPs with urine albumin-creatinine ratio, serum creatinine and glomerular filtration rate (eGFR) ($p < 0.05$).

Conclusions: The strong associations of SLC2A9 variants with UA in Zuni Indians replicate findings in other populations. The association of SLC2A9 with renal phenotypes is a novel finding.

FR-PO1505

Genetic Correlation between Urinary Calcium and Heritable Mandibular/Maxillary Hypoplasia in a Congenic Rat Line Krista L. Lewandowski,[1] Guy M.L. Perry,[1] Robert J. Reid,[1] Jyotirmoy Nandi,[1] David A. Bushinsky,[2] Steven J. Scheinman.[1] *[1]Medicine, SUNY Upstate Medical University, Syracuse, NY; [2]Medicine, University of Rochester, NY.*

Background: In a hypercalciuric congenic rat line derived from Genetic Hypercalciuric Stone-forming rat, we detected a de novo mutation (*pug*) with marked facial abnormalities (Figure 1), including: i) fusion of the coronal and sagittal sutures and ii) hypoplasia of the mandible, premaxilla and maxilla. These features have sometimes been associated with craniosynostosis and elements of calcium physiology in humans. We investigated possible genetic associations between the penetrance of this new mutation and urinary calcium excretion in our pedigree.

Figure 1. Facial abnormalities seen in *pug* (below), versus normal (above) rats

Methods: The rat pedigree consisted of 1589 rats over 14 generations, including 170 F_2 *pug*-normal heterozygotes to test possible bias from assortative breeding. Weight at 8 weeks was measured, followed by 4 days of urine collection. The *pug* phenotype was scored as a binary trait by multiple observers.

Results: Heritability for all three traits was high and pug was highly genetically correlated with calcium excretion (Table 1). There was no difference in the correlation of urinary calcium with pug in F2 pug-normal hets compared to the complete population (ß = 0.25±0.0039; P<0.05).

Table 1. Additive and dominant heritabilities (diagonal), and genetic correlations (above diagonal) for pug, calcium excretion, and 8-week weight (95% CI).

Additive	***pug***	**8-wk. wt.**	**Ca**
pug	0.63 (0.04)	-0.10 (0.03)	0.96 (0.04)
Ca		0.61 (0.04)	0.17 (0.04)
8-wk. wt.			0.31 (0.05)
Dominant	***pug***	**8-wk. wt.**	**Ca**
pug	0.23 (0.02)	0.37 (0.01)	0.50 (0.01)
Ca		0.34 (0.02)	-0.21 (0.04)
8-wk. wt.			0.15 (0.02)

Conclusions: Our results suggest the genetic association or linkage of calcium excretion with *pug*. Such a link could be clinically important for the genetic basis of craniosynostosis, and for renal complications of this and related disorders.

FR-PO1506

Next Generation Resequencing of 40 Candidate Genes for Calcium-Based Kidney Stones in 810 Subjects Identifies Novel Allelic Variants and Shows Association of Urinary Calcium Excretion with Claudin14

Hakan R. Toka,[1,2] David B. Mount,[1] Martin R. Pollak,[2] Gary C. Curhan.[1] *[1]Nephrology, Brigham and Women's Hospital, Boston, MA; [2]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Nephrolithiasis is a major cause of morbidity and a complex, multi-factorial condition involving multiple genes along with environmental influences determining the likelihood of stone formation. Higher urinary calcium excretion is associated with increased risk and can be considered as a strong risk factor.

Methods: This study was designed to investigate the role of rare, functionally significant allelic variants affecting urinary calcium excretion and other relevant urinary solutes. N = 40 known candidate genes were sequenced in 810 participants recruited from the Nurses Health Study (NHS) and the Health Professionals Follow-up Study (HPFS). Subjects were selected based on availability of validated phenotypical data and 24-hour urine collection data. Novel approaches were utilized which included barcoding and pooling strategies, target gene enrichment with RainDance technology and next generation sequencing.

Results: Most samples showed excellent sequencing data with deep coverage of 20x or more. Over 1600 potential SNPs were detected. Several strategies were applied to remove false positive variants. None of the novel variants showed statistically significant association between the high and the low urinary calcium group and were observed mostly in single subjects only. Analysis of more common, known variants suggested an association of Claudin14 (CLDN14) with low urinary calcium excretion. Although, this effect of CLDN14 was previously not observed in our GWAS study using samples from both, NHS and HPFS (unpublished data), an Icelandic study has previously shown association of CLDN14 with kidney stones.

Conclusions: Validation studies in larger sample sets will be necessary to confirm the association of CLDN14 with urinary calcium excretion. Further phenotypical analysis and functional studies of selected novel allelic variants identified in this study may shed light on molecular mechanisms leading to nephrolithiasis in a subset of patients in the general population.

FR-PO1507

A Single Nucleotide Polymorphism in the Aqp11 Gene Is Associated with an Increased Risk for Chronic Kidney Disease in Patients with Diabetes

David Peter Choma, Eric G. Neilson, Raymond C. Harris, Elena E. Tchekneva. *Nephrology and Hypertension, Vanderbilt University School of Medicine, Nashville, TN.*

Background: Aquaporin-11 is a novel aquaporin family member. Disruption of the murine Aqp11 gene causes severe proximal tubular injury and renal failure. A G662A single nucleotide polymorphism (SNP) in the human Aqp11 gene results in Gly102Ser substitution in a functionally important domain. The purpose of this study was to determine if individuals carrying the Aqp11 G662A SNP are at higher risk for developing chronic kidney disease (CKD).

Methods: This was a retrospective case control study. Patient data and DNA samples were obtained from the Vanderbilt DNA Databank (BioVU) and associated de-identified medical record. Caucasian patients greater than 18 years of age with exposure to intravenous hyperosmolar contrast by either ICD9 or CPT code were identified as potential study patients. Cases were defined as having AKI by creatinine elevation or ICD9 code. Control patients were those not having an AKI event. Covariates included age, gender and diabetes. Patients were defined as having CKD if the patient had at least 2 creatinine values separated by at least 90 days that were greater than or equal to 1.5mg/dl. Risk for either AKI or CKD was assessed as an odds ratio.

Results: Patients with diabetes carrying the SNP were at increased risk for any AKI event (OR 1.834; 95% CI 1.047-3.212; chi2 4.507; p=0.034) and for AKI within 7 days following contrast exposure (OR 1.412; 95% CI 0.599-3.329; chi2 0.623; p=0.435). An increased risk for any AKI was not observed in patients without diabetes (OR 1.087; 95% CI 0.836-1.414; chi2 1.081; p=0.582). There was a strongly significantly increased risk for CKD in patients with diabetes associated with the SNP (OR 2.778; 95% CI 1.254-6.152; chi2 6.620; p<0.02) that was not seen in non-diabetes CKD and control subpopulations.

Conclusions: Patients with diabetes and whom carry the Aqp11 SNP are at higher risk for an AKI event and for developing CKD. These data suggest the Gly102Ser substitution in the Aqp11 protein results in altered function and susceptibility to chronic renal injury in stress-induced conditions present in diabetes.

FR-PO1508

Modeling Study of Human Chloride Channel 5 Mutations in Japanese Families with Dent's Disease Suggests a Structure-Function Relationship

Akira Ashida,[1] Daisuke Yamamoto,[2] Takashi Sekine,[3] Takashi Igarashi,[4] Motoshi Hattori,[5] Hiroshi Tamai.[1] *[1]Department of Pediatrics, Osaka Medical College, Takatsuki, Japan; [2]Biomedical Computation Center, Osaka Medical College, Takatsuki, Japan; [3]Department of Pediatrics, Ohashi Medical Center, Toho University, Tokyo, Japan; [4]Department of Pediatrics, Graduate School of Medicine and Faculty of Medicine, The University of Tokyo, Tokyo, Japan; [5]Department of Pediatric Nephrology, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Dent's disease, an X-linked renal tubular disorder characterized by low molecular weight proteinuria, hypercalcinuria, and nephrolithiasis is caused mainly by inactivating mutations in the human chloride channel 5 (hCLC-5) gene. Molecular models of the extracytoplasmic domain and transmembrane domain of the protein have been deduced from the crystal structures of two bacterial chloride channels. Additionally, the X-ray crystal structure of the cytoplasmic domain of hCLC-5 has been established, thereby allowing us to construct a model of this domain and examine the role of its mutations.

Methods: We examined 114 Japanese cases of Dent's disease and identified hCLC-5 mutations in 69 cases, among which 26 missense mutations were subjected to molecular modeling analysis.

Results: The locations of the mutated residues were distributed around the three structural sites: 1) around the chloride or proton conduction pathway (12 mutated residues), 2) the subunit interface that would be buried during dimer formation (7 mutations), 3) the cytoplasmic domain that would regulate transport by binding to ATP (4 mutations).

Conclusions: The missense mutations identified in Japanese families can be classified into three clusters according to the structural sites at which they occur, each playing an important role in the Cl^-/H^+ activity of CLC-5.

FR-PO1509

Sickle Cell Trait Is Not Associated with ESRD Susceptibility in African Americans Barry I. Freedman,[1] Pamela J. Hicks,[2] Carl D. Langefeld,[3] Lingyi Lu,[3] Anthony J. Bleyer,[1] Jasmin Divers,[2] Patrick H. Nachman,[4] Vimal K. Derebail,[4] Donald W. Bowden.[2] *[1]Department of Internal Medicine-Nephrology, Wake Forest School of Medicine; [2]Department of Bioochemistry, Wake Forest School of Medicine; [3]Department of Public Health Sciences, Wake Forest School of Medicine; [4]Department of Internal Medicine-Nephrology, University of North Carolina at Chapel Hill.*

Background: Conflicting reports exist as to whether sickle cell trait (HbAS) is a risk factor for development and progression of nephropathy. To determine whether African Americans with HbAS are at increased risk for nephropathy, genetic association was assessed between HbAS and end-stage renal disease (ESRD).

Methods: Hemoglobin S (HbS), non-muscle myosin heavy chain 9 (*MYH9*) and apolipoprotein L1 (*APOL1*) nephropathy risk variants were genotyped in 3258 unrelated African Americans; 1085 with non-diabetic ESRD, 996 with type 2 diabetes (T2D)-associated ESRD, and 1177 non-nephropathy controls. Interactions between *APOL1* and *MYH9* risk variants and HbS were assessed using case-only and case-control centered two-way logistic regression interaction analyses.

Results: HbS genotypes met Hardy Weinberg Equilibrium expectations in both cases and controls. HbAS genotype frequencies were 8.7% in non-diabetic ESRD cases, 7.1% in T2D-ESRD cases, and 7.2% in non-nephropathy controls. Age-, gender- and admixture-adjusted p-values for HbAS association with non-diabetic ESRD were p=0.34 (odds ratio [OR] 1.16; 95% confidence interval [CI] 0.85-1.60, dominant); p=0.96 for T2D-ESRD (OR 1.01; 95% CI 0.70-1.50, dominant); and p=0.74 for all-cause ESRD (combined non-diabetic and T2D-ESRD cases versus controls; OR 1.05; 95% CI 0.79-1.40, dominant). No evidence of APOL1 or MYH9 interactions with HbAS was detected.

Conclusions: Sickle cell trait was not associated with diabetic or non-diabetic etiologies of ESRD in a large sample of African American residing in the southeastern U.S. Sickle cell trait does not appear to predispose to progressive nephropathy.

FR-PO1510

Association of Caveolin-1 Single Nucleotide Polymorphism on Clinical Outcomes in Vasculits Sourabh Chand,[1] Peter Hewins,[2] Matthew David Morgan,[1] Lorraine Harper,[1] Richard Borrows.[2] *[1]Centre for Translational Inflammation Research, University of Birmingham Research Laboratories, Birmingham, West Midlands, United Kingdom; [2]Renal Department, University Hospital Birmingham NHS Foundation Trust, Birmingham, West Midlands, United Kingdom.*

Background: Caveolin-1 (CAV1) is an essential structural component of caveolae and has been implicated in the pathogenesis of fibrosis, cancer, vascular disease, and the response to sepsis; these phenomena are important in systemic vasculitis.

Our group have identified a single nucleotide polymorphism (SNP) within the CAV1 gene (rs4730751) to be associated with renal allograft failure and fibrosis (Moore et al. JAMA 2010). The purpose of this study was to investigate the role of this gene variant in systemic vasculitis.

Methods: DNA from a prevalent cohort of 195 Caucasian patients with ANCA associated vasculitis, was genotyped for SNP rs4730751 of CAV1 using the Taqman® method.

The primary composite endpoint of time to all-cause mortality/renal replacement therapy (RRT) was chosen. Secondary endpoints were time to RRT, all-cause mortality, infective death and cancer incidence. The association between genotype and outcomes was assessed by survival and regression analyses.

Results: Genotype distribution across the cohort met with the Hardy-Weinberg law. Patients with genotype AA (24), AC (74) and CC (97) were identified.

For the primary composite endpoint, survival analysis suggested a protective effect of the CC from non-CC genotype (p=0.004). A protective effect of CC was also seen for all-cause mortality and for infective death (p=0.05 and p=0.013 respectively), but not time to RRT (p=0.112).

A regression model (adjusted for gender, age at presentation, creatinine at presentation, type of ANCA and diagnosis) revealed an independent protective effect of CC genotype for RRT/all-cause mortality, infective death and cancer incidence.

Conclusions: *CAV1* SNP rs4730751 genotype CC appears to be protective in vasculitis for the composite endpoint of time to all-cause mortality and RRT, with some suggestion that it also influences death due to sepsis as well as cancer incidence. Further work is warranted to identify the underlying mechanism for these findings.

FR-PO1511

The Influence of Some Polymorphisms on Development of AA Amyloidosis Zuzana Potysova,[1] Romana Rysava,[1] Jitka Stekrova,[2] Vladimir Tesar.[1] *[1]Department of Nephrology, Charles University in Prague, First Faculty of Medicine and General Teaching Hospital, Prague, Czech Republic; [2]Department of Genetics, Charles University in Prague, First Faculty of Medicine and General Teaching Hospital, Prague, Czech Republic.*

Background: Available data suggest an association between presence of AA (secondary) amyloidosis and MCP-1 (monocyte chemoatracttant protein-1) and MIP-1α (macrophage inflammatory protein-1 alpha) genes polymorphisms and an impact of polymorphisms in exon 3 of SAA 1 (serum amyloid A 1) gene on the incidence of AA amyloidosis in different populations.

Methods: DNA and serum specimens of patients with AA amyloidosis (43), rheumatoid arthritis (RA) without amyloidosis and healthy control group (100) were investigated by using PCR, RFLP and ELISA methods. Kruskal-Wallis and χ-square tests were used for statistical data evaluation.

Results: Significantly more frequent occurrence of 1.1/1.1 genotype in SAA 1 was recorded in AA amyloidosis group compared to RA group as well as in control group ($p<0.001$). Distribution of neither 1.1/1.1 genotype nor another ones did not vary among RA and control group. No significant difference in distribution of another genes was recorded among all three groups. Serum concentration of SAA was statistically significantly higher in AA amyloidosis group and also in RA group compared to healthy controls ($p<0.001$). Serum concentration of MCP-1 was statistically significantly higher in AA amyloidosis group compared to RA group ($p<0.05$). Concentrations of MIP-1α were markedly higher in both groups of patients compared to healthy controls (borderline to statistical significance).

Conclusions: Homozygosity of the 1.1 haplotype in SAA1 gene could be a risk factor for development of AA amyloidosis in Caucasian population. Our unique findings of higher serum concentration of MCP-1 in the AA amyloidosis group compared to RA group could advert to riskiness of another factors. This could have therapeutic consequence – earlier and more assertive therapy of underlying diseases in patients with appropriate genotype in order to prevent or interfere with occurrence of AA amyloidosis.

FR-PO1512

Clinical Characteristics of *PKD2* Gene-Linked Families Characterized by the Same Germ-Line Mutation Valentina Corradi,[1,3] Fiorella Gastaldon,[1] Grazia Maria Virzi,[1,3] Armando Vazquez,[3] Manish Kaushik,[3] Dinna N. Cruz,[1,3] Maurizio Clementi,[2] Claudio Ronco.[1,3] *[1]Nephrology, St Bortolo Hosp, Italy; [2]Clinical Genetics and Pediatrics, University of Padova, Italy; [3]International Renal Research Institute Vicenza, Italy.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the most common inherited renal cystic disease. It is genetically heterogeneous (*PKD1* and *PKD2*) with a significant intra-familial variability. ADPKD is characterized by "private mutations": it is rare to identify the same germ-line mutation in different families. The aim of the study was to evaluate the clinical characteristics of *PKD2*gene-linked families characterized by the same germ-line mutation.

Methods: Patients (pts) with ADPKD, by ultrasound criteria, were enrolled and followed prospectively. Complete clinical details were recorded, including family history and time of ADPKD diagnosis (t0). We applied linkage analysis to identify the gene involved. We used microsatellite markers (STR) flanking the 2 genes. Furthermore, we performed sequencing to identify mutations in PKD2 families. The eGFR was calculated with the 4-variable standardized-MDRD equation. The progression of CKD was determined by the change in eGFR per year. Data were shown as median (min;max).

Results: We identified 8 PKD2gene-linked families characterized by the same disease haplotype and the same germ-line mutation (2533C>T) in all affected individuals (16 pts). At t0 their age was 33.5 (19;53) yrs and eGFR 78.5 (32;94) mL/min/1.73 m². After a median follow-up of 10.73 (0.86;32.25) yrs, eGFR was 70 (14;94) mL/min/1.73 m² . Hypertension was present in 87.5% of pts, DM in 6.25%, kidney stones in 37.5%, and hepatic cysts in 62.5%. The change in eGFR per year was -0.70 (-7.01;+2.15) mL/min/1.73m².

Conclusions: The identification of the same germ-line mutation in 16 pts belonging to 8 families indicate the presence of a common ancestral founder in our geografical area. We observed a considerable variability in CKD progression, within the same mutation. This could be explained by other clinical or genetic factors. We plan to analyze for other possible candidate genes that may be contributing to the observed variability in the ADPKD progression.

FR-PO1513

Gender-Based Randomization in Renal Phenotype Guy M.L. Perry,[1] Steven J. Scheinman,[1] John R. Asplin.[2] *[1]SUNY Upstate Medical University, Syracuse, NY; [2]Litholink Corporation, Inc., Chicago, IL.*

Background: Models of mean effects on renal physiology may not account for inherent residual variance. Our work in a rodent model of heritable hypercalciuria indicates the existence of sex-linked loci for residual variation in urinary calcium. Inherent residual variation would be of great significance, potentially assorting individuals randomly among diagnostic and prognostic categories and contributing type II error to medical genetic assays of renal disease.

Methods: Since sex is a common element in this phenomenon, we hypothesized the existence of gender differences in coefficients of variation (CV) for paired 24-hour creatinine (Cr)-corrected measurements of urinary calcium (Ca), oxalate (Ox), citrate (Cit), uric acid (UA), sodium (Na), potassium (K), magnesium (Mg), phosphorus (P), ammonium (NH), chloride (Cl), urea nitrogen (UN) in 6,830 females and 9,135 males collected by the Litholink Corporation, Inc.

Results: Females had significantly ($P<0.05$) higher CVs than males for Na, Mg, P, Cl, K and NH post-Bonferroni correction (Tab. 1).

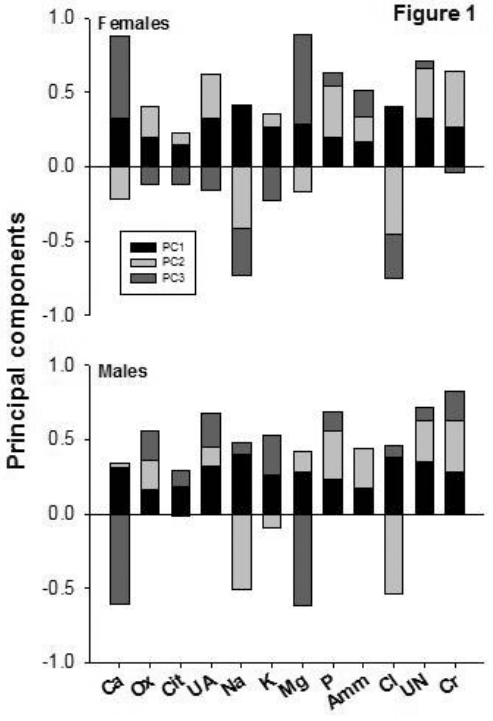
Table 1. Gender differences in mean coefficients of variation (CV) from paired 24-h urines in 6,830 females and 9,135 males.

Product	CV male (SE)	CV female (SE)	P
Na	0.19 (0.004)	0.18 (0.003)	0.001
Mg	0.16 (0.003)	0.15 (0.003)	0.001
P	0.14 (0.003)	0.13 (0.002)	0.001
Cl	0.19 (0.004)	0.18 (0.003)	0.001
K	0.13 (0.003)	0.13 (0.002)	0.008
NH	0.19 (0.004)	0.18 (0.003)	0.037

SE = standard error

There was no univariate effect of sex on Ca CV ($P>0.2$). Male and female loadings were similar over the first principal component ($\lambda_1=2.94$), but diverged over PC2 ($\lambda_2=1.55$) and PC3 ($\lambda_3=1.33$) largely for Ca, Mg, Na and Cl (Fig. 1)

Figure 1



Conclusions: Our findings support the hypothesis of sexual differences in residual variability in human renal phenotype. A full understanding of the genetics of urinary physiology needs to account for sexual and inherited variability and the factors underlying them.

Role for Mammalian Target of Rapamycin in Mediating Expression and Activity of a Disintegrin and Metalloproteinase 17 in Diabetic Kidney Disease

Bridget M. Ford,[1] Assaad Antoine Eid,[1] Yves C. Gorin,[1] Jeffrey L. Barnes,[1, 2] Hanna E. Abboud.[1, 2] *[1]Medicine/Nephrology, UT Health Science Center at San Antonio, San Antonio, TX; [2]South Texas Veterans Administration, San Antonio, TX.*

Background: Diabetic kidney disease (DKD) is characterized by extracellular matrix (ECM) accumulation. However, the mechanisms involved have not been completely identified. A disintegrin and metalloproteinase 17 (ADAM 17) cleaves growth factors involved in matrix accumulation. This study examined the role of ADAM 17 in matrix accumulation in the kidney cortex (KC) of a type 1 diabetic rat model.

Methods: Diabetes was induced in Sprague Dawley rats with streptozotocin and tissue was isolated at six weeks after the induction of diabetes for western blot analysis, immunoperoxidase staining, and a fluorometric-based assay for ADAM 17 activity . A subgroup of diabetic rats was treated with 1.0mg/kg of the mTORC1 inhibitor rapamycin, administered by intraperitoneal injection three times per week.

Results: MTOR phosphorylation on serine residue 2448 was enhanced in the KC of diabetic rats. ADAM 17 protein expression was significantly increased in the KC of type 1 diabetic rats by immunoperoxidase staining and western blot analyses. ADAM 17 enzyme activity in the KC and in proximal tubules (PT) isolated from the KC of the diabetic animals was also significantly increased suggesting a role for ADAM 17 in DKD. Collagen type IV expression was enhanced in the KC of diabetic animals. ADAM 17 protein expression, enzymatic activity, mTOR phosphorylation and collagen IV expression in the KC and in isolated PT were abolished with rapamycin treatment. In contrast to the findings in KC and in PT, the enzymatic activity of ADAM 17 was significantly decreased in isolated glomeruli of diabetic animals and was not affected by rapamycin treatment.

Conclusions: Collectively these data suggest a mechanism whereby mTORC1 mediates the activity and expression of ADAM 17 and collagen IV accumulation in the kidney cortex/proximal tubular kidney compartment. Moreover, the data suggest a differential role for ADAM 17 activity in kidney cortex and in proximal tubules as compared to the glomerular compartment.

Reversibility of Microvascular Tortuosity after Simultanous Pancreas-Kidney Transplantation

Meriem Khairoun,[1] Bernard Van Den Berg,[1] Ellen Lievers,[1] Joris I. Rotmans,[1,2] Eelco de Koning,[1] Anton Jan Van Zonneveld,[1,2] Johan W. De Fijter,[1] Ton J. Rabelink,[1,2] Marlies E.J. Reinders.[1] *[1]Department of Nephrology, Leiden University Medical Center; [2]Einthoven Laboratory for Experimental Vascular Research, Leiden University Medical Center, Netherlands.*

Background: Simultaneous pancreas-kidney transplantation (SPK) has been an advanced treatment option for type I diabetes patients with extensive microvascular (MV) disease and nephropathy. However, whether or not this treatment results in stabilization or even reversal of systemic diabetic MV disease is unknown, while such an effect may be relevant to the risk for future diabetic complications.

Methods: Mean capillary density and microvascular morphology were visualized using sidestream dark-field (SDF) imaging of the oral mucosa of diabetic nephropathy (DN; N=26) and SPK patients (N=38) and compared with healthy controls (N=20). In addition, 10 patients were studied longitudinally before (DN), 1 and 6 months after SPK. Furthermore circulating levels of growth factors that control MV structure, such as Angiopoietin-1 (Ang-1), Angiopoietin-2 (Ang-2) and Thrombomodulin (TM) were measured using ELISA.

Results: Both the cross-sectional as well as the longitudinal study showed no difference in capillary density. However, we found more capillary tortuosity in the DN group (mean 1.83 ±0.42 SEM vs 1,15 ±0.18 in controls) and normalization after SPK both in the cross-sectional study (1.31± 0.32, $p<0.05$) and after 6 months in the longitudinal study (1.53± 0.08, $p<0.05$). In line with these findings, markers of endothelial destabilization including Ang-2 and TM, were significantly increased in DN patients as compared to the SPK recipients in both studies and controls, while the Ang-1/Ang-2 ratio was normalized after SPK (from 0.16 ±0.04 to 0.08 ±0.02, $p<0.05$, controls 0.10 ±0.02).

Conclusions: SPK is effective in reversing the systemic MV derangements of type I diabetes patients with nephropathy.

FR-PO1516

Netrin-1 a Promising Diagnostic Biomarker of Chronic Kidney Diseases Is Increased in Diabetic and Hypertensive Rats

Riyaz Mohamed,[1] John White,[2] William Brian Reeves,[3] Ganesan Ramesh.[1] *[1]Vascular Biology Center, Georgia Health Sciences University, Augusta, GA; [2]Medicine, Georgia Health Sciences University, Augusta, GA; [3]Medicine, Pennsylvania State University College of Medicine, Augusta, GA.*

Background: Currently there are no validated early diagnostic biomarkers available for chronic kidney diseases (CKD). Microalbuminuria is insensitive and inaccurate for the diagnosis of CKD. Netrin-1 was recently identified as an early diagnostic biomarker of acute kidney injury. However, its usefulness for early diagnosis of CKD is unknown.

Methods: The current study evaluated whether netrin-1 is increased in urine from diabetic and salt sensitive hypertensive rats and correlated netrin-1 with development of nephropathy. Type 1 diabetes was induced using streptozotocin and salt sensitive hypertension was induced in uninephrectomized rats by implantation of a DOCA pellet with normal saline in drinking water. Netrin-1 and albumin concentrations in urine were measured by ELISA.

Results: Urinary protein excretion was not different between diabetic and control rats at 4 wks, but was increased in hypertensive rats (29 ± 7.6 vs. 25.1 ± 7.7 vs. 315.3 ± 51.8 mg/24h). By 10 weeks, urinary protein had increased in diabetic rats as compared to control rats (77.5 ± 13.4 vs. 32.3 ± 6.4 mg/24h). The urinary netrin-1 levels were significantly ($p<0.001$) higher in diabetic group at 4 (184±32 ng/24h urine) and 10 weeks (260±46 ng/24h urine) as compared to control group (15±1 ng/24h urine). Similarly, netrin-1 was increased significantly ($p<0.001$) in hypertensive Rat urine (141±20 ng/24h urine) at 4 weeks as compared to controls. To translate our animal findings into human disease, we analyzed urine samples from patients with different stages of diabetic nephropathy (normoalbuminuria, microalbuminuria, macroalbuminuria and renal dysfunction). Netrin-1 levels increased in a stage-dependent manner and were highest in patients with microalbuminuria and renal dysfunction.

Conclusions: In conclusion, netrin-1 can be detected in urine from diabetic and hypertensive rats and human diabetic patients and may serve as a useful diagnostic biomarker for CKD.

FR-PO1517

Nephronectin Is a Novel Protein Associated with Diabetic Nephropathy --Proteome Analysis of Isolated Glomeruli from Autopsy and Immunochemical Study Shinya Nakatani,[1] Eiji Ishimura,[1] Min Wei,[2] Katsuhito Mori,[1] Masaaki Inaba,[1] Hideki Wanibuchi.[2] *[1]Nephrology, Osaka City University Graduate School of Medicine, Osaka, Japan; [2]Metabolism, Endocrinology, and Molecular, Osaka City University Graduate School of Medicine, Osaka, Japan.*

Background: Proteome analysis of glomeruli of renal biopsy is difficult, since sufficient quantities of glomeruli are usually unavailable. Formalin-fixed paraffin-embedded (FFPE) kidney tissues of autopsies contain enough amounts of glomeuruli for proteome analysis. In order to identify a novel protein expression reflecting diabetic glomeruli, proteome analysis was performed, using FFPE kidney tissues of autopsy.

Methods: We conducted proteome analysis of lasermicrodissected glomeruli from FFPE kidney tissues of patients with diabetic nephropathy (n=10) and those of non-diabetic patients (n=10), using the isobaric tagging reagent iTRAQ, QSTAR Elite LC-MS/MS system, and Ingenuity Pathway Analysis (IPA). To validate the results of proteome analysis, we performed immunohistochemistry of 93 autopsies of type 2 diabetic patients.

Results: There were a total of 100 proteins that were differently expressed in glomeruli of diabetic patients, compared to those of non-diabetic patients. Based on the results of IPA, 31 renal and urological disease-related proteins were detected. Among them, nephronectin, an integrin α8β1 ligand which functions as assembly of extracellular matrix, was up-regulated in diabetic glomeruli (1.25 folds increase). Immunohistochemical analysis revealed that nephronectin was highly expressed in mesangial expansion and nodular glomerulosclerosis of diabetic patients, but not in glomeruli of non-diabetic patients. There was a significant positive correlation between glomerular sclerosis index and the percentages of nephronectin-positive glomeruli of diabetic patients ($r=0.89$, $p<0.0001$, $n=93$).

Conclusions: The present study demonstrated, for the first time, increased nephronectin expression in diabtic glomeruli, suggesting an important role of nephronectin in the development of diabtic glomerulosclerosis. Our study also showed that proteome analysis with FFPE kidney tissues is a useful tool for investigating glomerular disease.

FR-PO1518

Advanced Glycation End Products (AGEs) Activating Endoplasmic Reticulum Stress (ERS) Induces Renal Tubuloepithelial Cell Senescence Yani He, Jun Liu, Wei-Wei Zhang, Jurong Yang, BenGang Huo, Lirong Lin, Jun Zhan. *Department of Nephrology, Daping Hospital, the Third Military Medical University, Chongqing, China.*

Background: Renal tubuloepithelial cell (RTEC) senescence plays a critical role in the development of diabetic nephropathy(DN). Our study focuses on the role of ERS in RTEC senescence induced by AGEs in DN.

Methods: In vivo: Eighteen diabetic patients(60 to 75 yr)were classified into two groups:Early clinical DN(n=8) and advanced clinical DN (n=10), and renal carcinoma as normal control (n=10). All samples were subjected to examining SA-β-Gal of RTECs, also to immunohistochemical staining to analyze the expression of GRP78, ATF4, p16, p21. Double immunofluorescent staining was performed to study the expression of ATF4 and p16 or p21.

In vitro: RTECs were stimulated by AGE-BSA or ERS inducers tunicamycin(TM) or thapsigargin (TG) to stuy their influence on ERS and cell senescence. We assayed the ratio of SA-β-Gal and senescence-associated heterochromatic foci(SAHF).Cell proliferation and cell cycle were also examined by flow cytometry. The protein expression of GRP78, ATF4, p16, p21 was evaluated by western blot. Furthermore, the expression of p16 and GRP78 or ATF4 was assayed by double immunofluorescent staining.

Results: In vivo: We found GRP78, ATF4, p16, p21 and SA-β-Gal staining were significantly up-regulated in patients with DN ($P<0.01$). Immunofluorescent study showed that most ATF4 nuclear positive RTECs were co-stained with p16 or p21.

In vitro: The ratio of SA-β-Gal and SAHF, and the expression of GRP78, ATF4, p16, p21 were up-regulated by AGE-BSA with dose- and time-dependent manner, which associated with cell cycle arrest. Immunofluorescent staining showed that positive of SAHF in RTEC associated with elevated GRP78 or ATF4 expression. The ratio of SA-β-Gal and SAHF, and the expression of GRP78, ATF4, p16, p21 were also up-regulated by TM or TG with time- dependent manner. Furthermore, we found that GRP78 cytoplasm positive or ATF4 nuclear positive in RTECs were co-stained with p16.

Conclusions: Our study demonstrated that activation of ERS by AGEs could be a new pathophysiology mechanism of RTEC senescence in diabetic nephropathy.

FR-PO1519

Aggravation of Diabetic Nephropathy by Hyperlipidemia Is Mediated by MRP8/TLR4 Signaling in Macrophages Takashige Kuwabara,[1] Kiyoshi Mori,[1] Masashi Mukoyama,[1] Masato Kasahara,[1] Hideki Yokoi,[1] Yoko Saito,[1] Hirotaka Imamaki,[1] Tomoko Kawanishi,[1] Akira Ishii,[1] Kenichi Koga,[1] Keita P. Mori,[1] Yukiko Kato,[1] Akira Sugawara,[2] Kazuwa Nakao.[1] *[1]Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Nephrology, Osaka Red Cross Hospital, Osaka, Japan.*

Background: We have identified toll-like receptor 4 (TLR4) and myeloid-related protein 8 (MRP8) as commonly upregulated genes in glomeruli of insulin-dependent and -resistant diabetic mice using cDNA microarray. MRP8 is a high-affinity ligand for TLR4 that plays a key role in acceleration of inflammation mediated by TLR4. Since we have observed that high-fat diet (HFD) further enhanced glomerular expressions of these genes in streptozotocin (STZ)-induced diabetic mice along with doubling of albuminuria, we performed this study to clarify the role of MRP8/TLR4 signaling in worsening of diabetic nephropathy by hyperlipidemia (HL).

Methods: Diabetes was induced in wild-type (WT) and TLR4 knockout (KO) mice by ip injection of STZ. Normal diet was substituted with HFD at 2 weeks and all analyses were performed at 9 weeks after STZ.

Results: In diabetic WT and KO mice, addition of HFD similarly enhanced hypertriglyceridemia and renal lipid accumulation. Although HFD aggravated diabetic nephropathy in STZ WT mice, as indicated by marked increase in albuminuria, mesangial expansion, infiltration of macrophages (Mø) and upregulation of pro-inflammatory and pro-fibrotic genes in glomeruli and renal interstitium, and by decrease in glomerular podocin expression, synergistic effects of HFD upon renal lesions were almost completely abolished in STZ KO mice. MRP8 positive cells abundantly found in glomeruli of STZ-HFD-treated WT mice were mostly colocalized with Mø marker Mac2. In cultured bone marrow-derived Mø of WT mice, fatty acid enhanced MRP8 expression only under high-glucose conditions. Furthermore, phosphorylation of renal IRF3 in WT STZ mice was enhanced by HFD, suggesting the activation of TLR4-downstream, TRIF-dependent pathway.

Conclusions: These findings suggest that HL complicated with diabetes activates TLR4 on Mø, induces TLR4 ligand MRP8, enhances Mø infiltration and deteriorates glomerular lesions.

FR-PO1520

Deletion of *p47^{phox}* Reduces Progression of Diabetic Nephropathy in the Akita Mouse George Chu Liu,[1] Fei Fang,[1] Xiaohua Zhou,[1] Stuart Yang,[2] Heather N. Reich,[2] Rohan John,[3] Gavin Oudit,[4] James W. Scholey.[1] *[1]Institute of Medical Science, University of Toronto, ON, Canada; [2]Division of Nephrology, University of Toronto, ON, Canada; [3]Department of Pathology, University of Toronto, ON, Canada; [4]Division of Cardiology, University of Alberta, Edmonton, AB, Canada.*

Background: The role of NADPH oxidase-dependent superoxide generation in diabetic nephropathy has not been fully elucidated. Accordingly we examined the effect of deletion of the gene for the NADPH oxidase subunit, *p47^{phox}* on the progression of diabetic kidney injury in the Akita mouse ($Ins2^{WT/C96Y}$).

Methods: Four groups of mice were studied: non-diabetic *$Ins2^{WT/WT}$/p47$^{phox+/+}$* mice, non-diabetic *$Ins2^{WT/WT}$/p47phox$^{-/-}$* mice, diabetic *$Ins2^{WT/C96Y}$/p47$^{phox+/+}$* mice, and diabetic *$Ins2^{WT/C96Y}$/p47$^{phox-/-}$*. NADPH oxidase activity and gene expression levels were measured in isolated glomeruli at 8 weeks. Albumin excretion rates and kidney histomorphometry measures were assessed at 16 weeks of age. NADPH oxidase activity was examined in primary mesangial cell (MC), derived from $p47^{phox+/+}$ and $p47^{phox-/-}$ mice, and treated with 5.6mM glucose and 30mM glucose. The relationship between $p47^{phox}$ and collagen Iα1 mRNA expression was determined in kidney biopsies from normal and diabetic subjects.

Results: Deletion of the gene for p47phox reduced NADPH oxidase activity, superoxide generation, oxidative stress, and profibrotic gene expression in glomeruli from diabetic mice and led to a reduction in urinary albumin excretion, renal and glomerular hypertrophy, and mesangial matrix expansion in the diabetic mice. High glucose-induced NADPH oxidase activity and pro-fibrotic gene expression was attenuated in primary MC from mice with a deletion in the p47phox gene. There was a positive correlation between p47phox and collagen Iα1 mRNA levels in renal biopsy samples from control subjects and subjects with diabetic nephropathy.

Conclusions: Deletion of the gene for $p47^{phox}$ attenuates diabetic nephropathy in the Akita mouse, due in part to an effect on the mesangial cell response to high glucose.

FR-PO1521

Aliskiren in Combination with Valsartan Improve Type 1 Diabetic Nephropathy in Mice Weidong Wang, Xiaoxin Wang, Nathaniel L. Solis, Liru Qiu, Hannah Danielle Santamaria, Moshe Levi. *School of Medicine, University of Colorado Denver, Aurora, CO.*

Background: The current study was undertaken to investigate if combination therapy with aliskiren, a direct renin inhibitor, with valsartan, an angiotensin type 2 receptor blocker, provides additive protective effects in 1 diabetic nephropathy in mice.

Methods: Insulin deficiency and hyperglycemia were induced with streptozotocin (STZ, 40mg/kg/day) injection in DBA/2J mice for five days. The mice were treated with either aliskiren (25 mg/kg/day), valsartan (8 mg/kg/day), or combined aliskiren and valsartan, for 4 weeks. Western blots, immunofluoresence and qPCR was used to examine protective effects of the treatment against diabetic nephropathy.

Results: Combined treatment with aliskiren and valsartan significantly attenuated albuminuria (125 ± 10 in controls, 209 ± 29 in diabetes, and 128 ± 20ug/mg in combination, $p<0.05$) and urine nephrin excretion (81 ± 16 in controls, 189 ± 23 in diabetes, and 112 ± 30ng/mg in combination, $p<0.05$). This was associated with prevention of the reduced protein abundance of podocyte markers nephrin, WT1, podocin, and synaptopodin in glomeruli of diabetic mice. The combination also markedly decreased 1) profibrotic growth factors: renal transforming growth factor-beta and PAI-1 expression, 2) proinflammatory cytokines: tumor necrosis factor-alpha, MCP-1, and CD68), and 3) neutral lipid (oil red o) accumulation. Single treatment with either aliskiren or valsartan provided marked, but less beneficial effects on all the above-mentioned parameters than combination.

Conclusions: The combination of aliskiren and valsartan therefore protects against diabetic kidney disease through multiple mechanisms, and seems to be a promising therapeutic strategy for diabetic nephropathy.

FR-PO1522

Amelioration of Albuminuria and Tubulointerstitial Inflammation in STZ-Induced Diabetic TLR4-Deficient Mice Miao Lin, Wai Han Yiu, Hao-Jia Wu, Loretta Y.Y. Chan, Joseph C.K. Leung, Kar Neng Lai, Sydney C.W. Tang. *Medicine, Hong Kong University, Hong Kong, China.*

Background: We recently showed that tubular Toll-like receptor 4 (TLR4) expression was elevated in renal biopsies of histologically proven diabetic nephropathy (DN) and correlated with interstitial macrophage infiltration and HbA1c level. But the role of TLR4 in DN remains speculative. This study aims to study the role of TLR4 by using STZ-induced diabetic TLR4-deficient mice.

Methods: TLR4-/- mice and their wild type littermates (TLR4+/+) on C57BL6 background at 10-12 weeks old underwent uninephrectomy (Unx) or sham operation, and were then rendered diabetic by intraperitoneal injections of STZ. In vitro, the effect of an anti-TLR4 neutralizing antibody on high glucose (HG)-induced human proximal tubular epithelial cell (PTEC) inflammation was examined.

Results: At 12 weeks of diabetes, TLR4-/- mice demonstrated significantly ameliorated albuminuria and serum creatinine independent of blood glucose levels. This functional improvement was accompanied by substantially decreased F4/80+ macrophage infiltration into the tubulointerstitium and downregulation of cortical CCL-2, ICAM-1, and IL-1beta expression. At the signaling level, tubulointerstitial phosphorylated NF-κB/p65 activation was reduced in diabetic TLR4 -/- vs WT mice. The role of tubular TLR4 was confirmed in vitro. Pretreatment of PTEC with an anti-TLR4 neutralizing antibody significantly attenuated HG-induced NF-κB nuclear translocation and the downstream CCL-2 over-expression.

Conclusions: Our data suggest a pathogenic role of TLR4 in tubulointerstitial inflammation of diabetic kidney injury, and TLR4 may be a promising therapeutic target for further investigation.

Podocyte Specific Inducible Overexpression of Angiopoietin-1 Ameliorates Albuminuria in Diabetic Tansgenic Mice Luigi Gnudi,[1] Cecile Dessapt-Baradez,[1] Kathryn E. White,[2] Anthea Elaine Hayward,[1] Adrian S. Woolf,[4] David A. Long.[3] *[1]Cardiovascular Division, Kings College London, London, United Kingdom; [2]Biomedical Electron Microscopy Unit, Medical School, University of Newcastle upon Tyne, Newcastle upon Tyne, United Kingdom; [3]Nephro Urology Unit, Institute of Child Health, University College London, London, United Kingdom; [4]Biomedical Research Centre, Medical School, Manchester University, Manchester, United Kingdom.*

Background: Diabetic glomerulopathy is characterised by increased glomerular angiopoietin (Ang)-2 and reduced Ang-1 levels. Moreover, we showed that targeted glomerular Ang-2 overexpression increases albuminuria in non-diabetic mice. Ang-2 is a natural antagonist of Ang-1 by competitively inhibiting its binding to the Tie-2 receptor. We hypothesised that increasing Ang-1/Ang-2 balance *via* podocyte-specific Ang-1 overexpression would ameliorate diabetic glomerulopathy.

Methods: We generated transgenic mice with inducible overexpression of Ang-1 specifically in podocytes (*Tet-on*). 5 week-old transgenic and control mice were rendered diabetic by daily intraperitoneal streptozotocin injections for 5 days. Eight weeks old mice with glycemia >22 mmol/l were randomised to receive either doxycycline (DOX; 2 mg/ml) or vehicle (VEH) in drinking water. 24 hour urine collections were performed at baseline, during 10 weeks of DOX or VEH administration and immediately before sacrifice. Tissue was collected for molecular determinations and electron microscopy. Urine albumin was measured by ELISA, and plasma and urine creatinine measured by mass spectrometry.

Results: Diabetes caused significant increases in albuminuria at 10 weeks compared with non-diabetic animals ($p<0.05$). Experimental Ang-1 induction significantly reduced but did not normalise diabetic albuminuria ($p<0.05$). Mesangial expansion and glomerular basement membrane (GBM) thickening was increased in diabetic mice compared with non-diabetic animals but was not ameliorated by Ang-1 overexpression.

Conclusions: Podocyte-specific Ang-1 treatment ameliorates albuminuria in experimental diabetes without affecting mesangial and GBM dysmorphology.

FR-PO1524

An In-Vitro Model of Hepatic Insulin Resistance in Uremia Via 11 beta Hydroxy-Steroid Dehydrogenase 1 (11HSD1) Ananda Chapagain, Julius Edward Kieswich, Steven Michael Harwood, Martin J. Raftery, Magdi Yaqoob. *Translational medicine and Therapeutics, WHRI, London, United Kingdom.*

Background: Insulin resistance (IR) is a major contributor to cardiovascular morbidity and mortality in uremic patients. The enzyme 11b-hydroxysteroid dehydrogenase type 1 (11bHSD1) catalyses intracellular conversion of the inactive glucocorticoid cortisone to active cortisol and promotes gluconeogenesis in the liver. We investigated the role of 11bHSD1in development of IR in uremia using an *in vitro* model of IR using H4IIEC3 cells.

Methods: Confluent cells were starved overnight,washed with warm PBS , then treated with 1.Earl's balanced salt solution (EBSS) 2.EBSS with 15% control serum (EBSS+SS) 3.EBSS with 15 % uremic serum (EBSS+US) and 4.EBSS with uremic serum treated with 10-5 M carbenoloxone (CBX,Sigma). (EBSS+US+CBX).All results were expressed as mM glucose produced by the cells. To assess gluconeogenesis, phosphoenolpyruvate carboxykinase (PCK1) and HSD1 mRNA was measured and PCK1 activity was measured using an in-house flurometric method.All experiments and measurements were performed in triplicate.

Results: H4IIEC3s showed a significantly high glucose production in EBSS+SS and EBSS+US, compared to EBSS alone or EBSS+US+CBX groups (Glucose production , EBSS alone, 0.0033 ± 0.0009 mM vs 0.018 ±0.02 for EBSS+SS , 0.0275 ± 0.008 mM for EBSS+US and 0.028 ±0.0013 mM, $p<0.001$ RM ANOVA). This was associated with an up-regulation of mRNA transcription for 11bHSD1 (10-fold) and PCK1 (20-fold), which normalized in response to CBX treatment. Furthermore, there was no difference in supernatant lactate measured in any of the treatment groups (mean 20 ± 2.10, P=NS). Incubation with IL-1b at 10,20,30 ng/ml and corticosterone at 0.1 and 0.5 micromolar concentrations yielded a dose-dependent increase in PCK1 activity and glucose production.

Conclusions: These results suggest that IR in uremia occurs partly through abnormally elevated GC-directed gluconeogenesis as a result of increased 11HSD. We also demonstrate a novel and easily reproducible *in vitro* model of IR in uremia.

FR-PO1525

Intervention with JNK Blockade in the Early Phase of Type 1 Diabetic Nephropathy David J. Nikolic-Paterson,[1,2] Andy Lim,[1] Frank Yuanfang Ma,[1,2] Elyce Ozols,[1] Morag Young,[3] Brydon Bennett,[4] Glenn Friedman,[4] Gregory H. Tesch.[1,2] *[1]Nephrology, Monash Mediacl Centre, Clayton, Victoria, Australia; [2]Medicine, Monash University, Clayton, Victoria, Australia; [3]Prince Henry's Institute of Medical Research, Clayton, Victoria, Australia; [4]Celgene, San Diego, CA.*

Background: The c-Jun amino-terminal kinase (JNK) signalling pathway is activated in human kidney diseases, including diabetic nephropathy. Recent studies in animal models have shown that blockade of JNK signaling can suppress the development of renal injury in experimental glomerulonephritis and acutely reduce mean arterial pressure and vascular resistance in normal rats. The aim of this study was to determine whether JNK signalling plays a role in the development of diabetic nephropathy and in regulating hypertension, which exacerbates diabetic renal injury.

Methods: Diabetes was induced in spontaneously hypertensive rats (SHR) using streptozotocin. After 16 weeks of diabetes, rats with equivalent hyperglycaemia and albuminuria were randomised into groups which received no treatment, vehicle alone or a selective JNK inhibitor (CC-930, 60mg/kg/bid) for 10 weeks. These rats were assessed for hypertension and progression of renal damage.

Results: At week 16, diabetic rats showed increased kidney JNK activation compared with non-diabetic controls. Effective JNK inhibition was demonstrated at week 26 by reductions in c-Jun phosphorylation. CC-930 did not affect blood pressure, kidney hypertrophy, glomerular hyperfiltration, podocyte loss, glomerular fibrosis or tubulointerstitial injury in diabetic SHR. However, CC-930 reduced macrophages and ccl2 mRNA levels in diabetic kidneys. In contrast, CC-930 exacerbated albuminuria at week 26, which was associated with reduced glomerular mRNA levels of the podocyte-specific molecules, nephrin and podocin.

Conclusions: JNK inhibition does not prevent the progression of early diabetic renal injury in hypertensive rats, which contrasts with the ability of JNK inhibition to suppress albuminuria and injury in experimental glomerulonephritis.

Serum and Urine Metabonomic Profiling Reveals the Metabolic Feature of db/db Mice with Diabetic Nephropathy Yongchun Ge,[1] Mengjie Li,[2] Jiye A,[2] Xufang Wang,[1] Guangji Wang,[2] Zhi-Hong Liu.[1] *[1]Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China; [2]Laboratory of Metabolomics, Key Laboratory of Drug Metabolism and Pharmacokinetics, China Pharmaceutical University, Nanjing, China.*

Background: Metabonomics is a systematic tool for quantitative measurement of metabolites and has the potential to identify novel markers that characterize the development of diabetic nephropathy (DN) and are involved in metabolic perturbation.

Methods: We utilized diabetic db/db mice (n=14) as a DN model and non-diabetic db/m mice (n=14) as normal control, and profiled their serum and urinary metabolites using GC/TOF-MS based metabonomic platform. Principal component analyses of the GC/TOFMS data revealed distinct metabonomic profiles of db/db mice and db/m controls.

Results: The identified discriminatory metabolites between db/db and db/m suggested a perturbed TCA cycle (malate, citrate, succinate, aconitate), lipid metabolism, glycolysis, urea cycle (urea, creatinine, glycine, alanine) and amino acids turn over. During the development of diabetes and DN (i.e., 6, 8, 10, 12 and 16 weeks of age), db/db showed clearly trajectory metabolic pattern of their scores plotsting away from the controls. The db/db mice were characterized with extremely high level of TCA intermediates at 6 weeks, followed by a sharp decline, and prominent elevation of free fatty acids in serum from 8 to16 weeks of age. The drop of TCA intermediate level in serum at 8 weeks of age (compared with 6 weeks) indicated insulin resistance and a marked down-regulation of glycolysis; In contrast, TCA intermediates in urine did not change accordingly. We have also found

serum lysine, and, to less extent, several other amino acids, were increased significantly at 8 weeks of age, in parallel with urinary albumin excretion.

Conclusions: In conclusion, diabetic db/db mice manifested a significant decrease of TCA intermediate and a significant increase of Lysine in serum at 8 weeks of age. Further studies would be important to determine if these changes also occur in DN patients.

FR-PO1527

Comparison of Renoprotective Effects of Alternative Medication Versus Enalapril Sudha Chennasamudram,[1] Shashi Kudugunti,[2] Majid Moridani,[2] Tetyana L. Vasylyeva.[1] *[1]Dept of Pediatrics, Texas Tech University Health Science Center, Amarillo, TX; [2]Dept of Pharmaceutical Sciences, Texas Tech Unviersity Health Sciences Center, Amarillo, TX.*

Background: To investigate the renoprotective effects of alternative medication, (+)-catechin (C) using *in vivo* and *in vitro* models of diabetes.

Methods: ***In vivo:*** Five groups of rats were used in the study that lasted 12 weeks. Group 1 and 2 were the non-diabetic rats (n=12/group) treated with and without C respectively. Group 3 and 4 (n=12/group) were diabetic rats treated with and without C respectively. Group 5 (n=5) were diabetic rats treated with ACEi, enalapril. The dose of C was 30 mg/day and ACEi was 10 mg/kg. Urine was collected and analyzed for albumin and endothelin-1 (ET-1). Plasma was collected and analyzed for creatinine. Protein expression of fibronectin in kidney was examined by western blotting. ***In vitro***: Effects of C in the formation of reactive oxygen species (ROS) in mesangial cells and apoptosis in endothelial cells were investigated under normal (5 mM) and high glucose (25 mM) by flow cytometry.

Results: ***In vivo:*** After 12 weeks of C treatment, urinary albumin excretion was reduced by 36% and the plasma creatinine by 40% compared to values in diabetic rats with no treatment. ET-1 in urine was also decreased by 56% with C treatment. Similar results were achieved using ACEi in albumin and ET-1 excretion. But the plasma creatinine was 26% more in ACEi treated rats compared to rats treated with C. In kidney, the protein expression of fibronectin was decreased by two-fold in diabetic rats treated with C compared to the diabetic rats with no treatment. In vitro: High glucose increased ROS in mesangial cells compared to cells in low glucose. Treatment with 50 μM C significantly reduced high glucose induced ROS. Also, in endothelial cells, C treatment significantly reduced high glucose induced apoptosis.

Conclusions: Our findings suggest that C has strong renoprotective properties in diabetic nephropathy. *In vivo* studies show that C decrease albumin and ET-1 excretion in diabetic rats. *In vitro* studies show that the mechanisms of C action might be related to antioxidant properties leading to reduced ROS and apoptosis.

FR-PO1528

ONO-1301, a Sustained-Release Prostacyclin Analog, Ameliorates Renal Alterations in a Mouse Type 2 Diabetes Model through Its Direct Protective Effects on Mesangial Cells Hiroko Yamasaki, Yohei Maeshima, Daisuke Saito, Norikazu Hinamoto, Hiroyuki Watatani, Haruyo Ujike, Hitoshi Sugiyama, Hirofumi Makino. *Okayama Univ. Med. School., Okayama, Japan.*

Background: Diabetic nephropathy is the most common pathological disorder predisposing ESRD, and novel therapeutic approaches are required. ONO-1301 is a novel sustained-release prostacyclin analog possessing thromboxane A2 synthase inhibitory activity. Therapeutic efficacies of ONO-1301 in experimental models of pulmonary hypertension, pulmonary fibrosis and myocardial ischemia has been reported, and we recently reported the therapeutic efficacies of slow-release ONO-1301(SR-ONO) in experimental rat type 1 diabetic nephropathy model. Here, we examined the therapeutic effects of intermittent administration of SR-ONO on diabetic nephropathy in the obese type 2 diabetes mouse as well as its direct effects on mesangial cells.

Methods: Db/db mice, a model of obese type 2 diabetes, received subcutaneous injections of either SR-ONO(3mg/kg) or vehicle buffer every 3 weeks. Animals were sacrificed at 16 weeks of age. Cultured mouse mesangial cells(Mes13) were stimulated with high ambient glucose(HG; 25 mM) in the presence of ONO-1301(1-100 nM) for 6hrs or 24 hrs. Clinical parameters, kidney weight, glomerular volume and mesangial matrix index were examined, and immunohistochemistry, immunoblot and real-time PCR was performed.

Results: SR-ONO treatment did not affect obesity or hyperglycemia, but significantly ameliorated albuminuria, glomerular hypertrophy, the increase of mesangial matrix index, glomerular accumulation of type IV collagen, F4/80+ monocyte/macrophage, TGF-beta1, alpha-SMA and MCP-1 in db/db mice compared with vehicle treatment. SR-ONO treatment reduced the increase of oxidative stress(nitrotyrosine and MDA) in db/db mice. In Mes13 cells, ONO-1301 suppressed the increase of TGF-beta, type IV collagen, alpha-SMA, MCP-1 and fibronectin induced by HG(immunoblot and real-time PCR).

Conclusions: Taken together, these results suggest the potential therapeutic efficacy of intermittent administration of SR-ONO in diabetic nephropathy through its direct protective effects on mesangial cells.

FR-PO1529

Effects of VEGFR-1 or VEGFR-2 or Both VEGFR-1 and VEGFR-2 Inhibition on Diabetic Nephropathy in db/db Mice Sungjin Chung, Ji Hee Lim, Min-Young Kim, Hyun Wha Chung, Hyung Wook Kim, Yong-Soo Kim, Yoon-Sik Chang, Cheol Whee Park. *Division of Nephrology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea.*

Background: Interventions to manipulate vascular endothelial growth factor (VEGF)-VEGF receptors axis may be therapeutic tools in diabetic nephropathy. In this study, we examined the renal effects of anti-flt 1 hexamer (GNQWFI; VEGFR-1 inhibitor) or anti-flk 1 heptamer (ATWLPPR; A7R, VEGFR-2 inhibitor) or both of them in *db/db* mice.

Methods: The *db/m* and *db/db* mice were treated with GNQWFI or A7R peptide or both of them for 12 weeks.

Results: There were no differences in FBSand HbA1c levels in all db/db groups. Diabetes significantly suppressed the VEGFR-1 and increased VEGFR-2 expressions in the kidneys. VEGFR-1 and VEGFR-2 expressions were completely inhibited by GNQWF1 and A7R, respectively. In the db/db mice treated with GNQWF1 or A7R, albuminuria, glomerular mesangial matrix expansion and inflammatory cell infiltration, and profibrotic growth factors' expressions were more prominent than those of diabetic control db/db mice. They also exhibited increases in the number of apoptotic glomerular cells with no change in Ki-67 positive cells. Urinary 8-isoprostane and 8-OH-deoxyguanosine concentrations increased in the db/db mice treated with GNQWF1 or A7R compared with those in diabetic control db/db mice. More severe albuminuria and renal lesions were noted in the db/db mice treated with both of them compared with those of db/db mice treated with either GNQWFI or A7R. These changes were associated with inactivation of PI3K-Akt-eNOS pathway. In contrast, GNQWFI- and A7R-induced albuminuria and histopathological changes were not observed in any db/m groups. In HUVECs, high glucose media containing VEGFRs inhibitors induced more apoptotic cell death than did high-glucose media without VEGFRs inhibitors, in association with inactivation of PI3K-Akt-eNOS pathway.

Conclusions: The blockade of VEGFR-1 or VEGFR-2 or both using GNQWF1 or A7R peptide caused glomerular injury related to the inactivation of PI3K-Akt-eNOS pathway resulting in the oxidative stress-induced apoptosis in type 2 diabetic nephropathy.

FR-PO1530

Metabolic Syndrome Due to Deletion of the Gene Encoding Canonical Transient Receptor Potential 1 (TRPC1) Channel: A Novel Model Induced by Hyperphagia & Associated with Key Organ Dysfunctions Bonnie Eby,[1] Richard Matthew Atkins,[1] Chris Skaggs,[1] Jian Xu,[1] E-Ching Ong,[2] Joel Abramowitz,[3] Leonidas Tsiokas,[2] Lutz Birnbaumer,[3] Kai Lau.[1] *[1]Medicine, University of Oklahoma, Oklahoma City, OK; [2]Cell Biology, NIEHS University of Oklahoma, Oklahoma City, OK; [3]Intramural Research, NIEHS, Research Triangle Park, NC.*

Background: TRPC superfamily of cation channels includes certain members implicated in obesity & diabetes. TRPC1 expression is reduced in diabetes, but the relationship is unclear. Since null mice are fatter, we asked if TRPC1 deficiency produces insulin resistance & glucose intolerance & if hyperphagia is vital.

Methods: Metabolic studies were done on male mice at 2 mon & 4-22 mon, using glucometer, insulin ELISA, & lipids enzymatic assays.

Results: At 2 mon, null mice were 20% fatter, non-fasting glucose (171 vs 98 mg%) higher, & liver 36% heavier. At 7 mon, liver echo was 50% denser, suggesting steatosis. Random glucose (135 vs 100 mg%) at 9 mon & fasting glucose (109 vs 72 mg%) at 10 mon were higher. Null mice ate more food (3.3 vs 1.4 g/d) & calorie (19 vs 12 kcal/d). By 1 yr, they stayed 20% fatter as hyperglycemia & liver hyperdensity persisted. Glucose tolerance test (IP 2 mg/g) showed sustained hyperglycemia, 2-fold higher for 3 h & 65% higher by the 6th. Plasma insulin was 2.5-fold higher throughout. Fasting insulin (23 vs 7 μU/ml) & glucose (7 vs 4 mM) were elevated, due to severe insulin resistance (IR) (8 vs 1) by homeostatic model assessment (HOMA). HOMA beta cell function (β) (90 vs 99%) was normal. Null mice had elevated fasting total (153 vs 118 mg%) & LDL cholesterol (94 vs 59 mg%) & triglyceride (111 vs 36 mg%). At 13 mon, HOMA IR (5 vs 1) stayed high & HOMA β (84 vs 105%) normal. Hypertension was absent from 6 to 20 mon by tailcuff or intraarterial readings. Present were cardiomopathy, renal failure & endothelial dysfunction. Caloric restriction corrected excess weight, elevated glucose & cholesterols, implicating hyperphagia.

Conclusions: 1. TRPC1 deficiency produces all the features of metabolic syndrome except hypertension. 2. Hyperphagia is pathogenic. 3. The null mice are useful in studying the associated complications.

FR-PO1531

Glomerular Immunoglobulin Deposition Is a Feature of Human Diabetic Glomerular Injury and Immunoglobulin Deficient Mice Are Protected from Diabetic Albuminuria David J. Nikolic-Paterson,[1,2] Andy Lim,[1] Frank Yuanfang Ma,[1,2] Yingjie Han,[1] A. Richard Kitching,[2] Peter G. Kerr,[1,2] Gregory H. Tesch.[1,2] *[1]Nephrology, Monash Medical Center, Clayton, Victoria, Australia; [2]Medicine, Monash University, Clayton, Victoria, Australia.*

Background: Glomerular immunoglobulin (Ig) deposition is observed in many animal models of diabetic nephropathy; however, its significance and relevance to human disease is unknown. This study aims to establish whether glomerular Ig deposition is a feature of human diabetic glomerulopathy and if it has a role in diabetic renal injury in mice.

Methods: Biopsy reports with assessment of Ig and complement deposition were examined from 82 patients diagnosed with diabetic glomerulosclerosis (90% type 2 diabetes) at the Monash Medical Centre (1996-2009). These diabetic patients had abnormal albuminuria but showed no signs of other glomerular diseases on biopsy. In addition, we established a model of streptozotocin-induced diabetes in wild type and B-lymphocyte deficient (mu-chain-/-) mice and compared the development of albuminuria (weeks 12-24) and renal injury (week 24).

Results: Immunostaining identified that >90% of patient biopsies had glomerular deposition of IgM, C1q and C3, being seen in the mesangium, arterioles, capillary loops and some nodules. In comparison, IgG showed a similar pattern, but with weaker intensity, and was detected in 61% of cases. All diabetic wild type mice displayed glomerular deposits of Ig and C3, which were absent in the diabetic mu-chain-/- mice. Compared to non-diabetics, diabetic wild type mice had a 5 to 6 fold increase in albuminuria at 18-24 weeks of diabetes, which was reduced by 50% in diabetic mu-chain-/- mice ($p<0.01$). Histological analysis showed no difference in the glomerular matrix fraction or tubular damage between diabetic groups; however, mRNA levels of TGF-β1 and PAI-1 were reduced ($p<0.001$) in the diabetic kidneys of mu-chain-/- mice compared to wild type.

Conclusions: Glomerular deposition of Ig is a feature of patients with diabetic glomerulosclerosis and severe albuminuria. Our findings in Ig-deficient mice suggest a pathologic role for Ig in diabetic albuminuria.

FR-PO1532

Bis-Halpoinsufficiency Aggravates Diabetic Nephropathy by Increasing Oxidative Stress Sungjin Chung, Ji Hee Lim, Sun Ryoung Choi, Hoon Suk Park, In O Sun, Min-Young Kim, Yong-Soo Kim, Yoon-Sik Chang, Cheol Whee Park. *Division of Nephrology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea.*

Background: *Bis* gene is ubiquitously expressed in cells and has anti-stress and anti-apoptotic activity by enhancing Bcl-2 activity in a synergistic manner. Total Bis-insufficient mice showed early lethality associated with malnutrition. Notably, oxidative stress-induced apoptosis contributes the pathogenesis of diabetic nephropathy. We investigated the role of Bis expression on the diabetic nephropathy using Bis haploinsufficiency (Bis-HT) mice after 20 weeks of diabetes induced by streptozotocin.

Methods: We treated anti-oxidant tempol starting after 12 weeks of diabetes for 8 weeks to see the anti-oxidant effect on the retardation of the progress of renal damage and restoration of the renal phenotypes associated with Bis expression.

Results: After 20 weeks of diabetes, there was an increase in Bis levels in diabetic Bis-wild type (Bis-WT DM) mice compared to Bis-WT mice in the kidneys. In contrast, there was a significant decrease in Bis expression in diabetic Bis-HT (Bis-HT DM) mice compared to Bis-WT DM mice even under the same degree of hyperglycemia. Serum creatinine and albuminuria were increased in the Bis-HT DM mice compared to those of Bis-WT DM mice. More glomerular matrix expansion, TGF-β1 and HIF-1α expression, and tubulointersitial fibrosis were also noted in the Bis-HT DM mice related to increases in apoptotic glomerular and tubular epithelial cells, accompanying with decreases in Bis and Bcl-2 expressions. SOD1 and SOD2 expressions were significantly decreased in the Bis-HT DM mice compared to those of Bis-WT DM mice, resulting in increased oxidative stress. Interestingly, anti-oxidant tempol treatment starting after 12 weeks of diabetes for 8 weeks reversed renal damages in the Bis-HT DM animals associated with increasing Bis and Bcl-2 expressions and decreasing oxidative stress.

Conclusions: Our results demonstrated that Bis protein has a protective effect on diabetic nephropathy and that its effect may be explained, at least in part, by preserving of anti-oxidative function.

FR-PO1533

Toll Like Receptor 4 Activation Mediates Injury in the Early Diabetic Kidney Jin Ma,[1,3] Huiling Wu,[1,3] Usha Panchapakesan,[2,3] Carol A. Pollock,[2,3] Steven J. Chadban.[1,3] *[1]Renal Medicine RPAH and Collaborative Transplant Research Group; [2]Kolling Institute and Royal North Shore Hospital; [3]University of Sydney, Australia.*

Background: We have reported that high glucose promotes release of endogenous TLR ligands, which activate TLR4 resulting in inflammation in early DN. Here we tested the hypothesis that TLR4 signalling is required for the development of DN.

Methods: DN was induced in WT and TLR4$^{-/-}$ mice by intraperitoneal injection of STZ. Samples were harvested at week 6, 12 or 24 post-induction. Renal tubular epithelial cells (TEC) exposed to 25mM glucose for 12-hours *in vitro* were also examined.

Results: WT and TLR4-/- mice developed equivalent diabetes. WT diabetic mice developed significant albuminuria versus normals (ACR:182.3±80.1 vs 34.1±9.2mg/mmol (wk6), 402.4±145.9 vs 37.1±8.8mg/mmol (wk12), 377.5±118.8 vs 41.3±10.2mg/mmol (wk24), $p<0.01$), which was reduced in TLR4-/- diabetic mice (117.0±33.4mg/mmol (wk6), 323.5±102.2mg/mmol (wk12), 224.9±99.3mg/mmol (wk24), $p<0.01$). WT diabetic mice developed progressive glomerular hypertrophy versus TLR4-/- diabetic mice [glomerular volume 99.3±9.5 vs 80.3±8.7μm3x103 (wk6), 74.3±6.4 vs 52.6±6.4μm3x103 (wk12), 102.1±16.4 vs 56.1±5.6μm3x103 (wk24). $p<0.001$]. Deposition of collagen was evident in WT diabetic kidney from wk12 versus TLR4-/- diabetic and non-diabetic kidneys. Macrophage accumulation was evident in WT diabetic kidneys, though not in TLR4-/- diabetic mice, as compared to age-matched normals [19.4±3 vs 5.7±0.8 vs 5.7±1.5 cells/HPF (wk6), 16.2±0.7 vs 6.4±1.0 vs 5.8±0.5cells/HPF (wk12), 13.4±1.8 vs 4.6±0.7 vs 5.5±1.5cells/HPF (wk24), $p<0.0001$). mRNA expression of TLR4-downstream cytokine, chemokine and fibrotic-genes was up-regulated in WT diabetic kidney versus control, with significant attenuation in TLR4-/- diabetic kidneys. In vitro, gene expression of key pathogenic cytokines, chemokines and fibrotic-genes was increased after high-glucose exposure, while increases were attenuated in TLR4-/- TECs.

Conclusions: TLR4$^{-/-}$ mice were protected from injury in DN, suggesting a pathogenic role for TLR4.

Funding: Government Support - Non-U.S.

FR-PO1534

Toll like Receptor 2 Activation Mediates Injury in the Early Diabetic Kidney Jin Ma,[1,3] Steven J. Chadban,[1,3] Usha Panchapakesan,[2,3] Carol A. Pollock,[2,3] Huiling Wu.[1,3] *[1]Renal Medicine RPAH and Collaborative Transplant Research Group; [2]Kolling Institute and Royal North Shore Hospital; [3]University of Sydney, Australia.*

Background: We have reported that high glucose promotes release of endogenous TLR ligands, which activate TLR2 resulting in inflammation in early DN. Here we hypothesize that TLR2 signalling is integral to the development of DN.

Methods: DN was induced in WT and TLR2$^{-/-}$ mice by intraperitoneal injection of STZ. Samples were harvested at week 6, 12 and 24 post-induction. Renal tubular epithelial cells (TEC) exposed to 25mM glucose for 12 hours in culture were also examined.

Results: WT and TLR2-/- mice developed equivalent diabetes. WT diabetic mice developed significant albuminuria from week 6 versus controls (ACR: 182.3±80.1vs34.1±9.2mg/mmol at 6wk, 402.4±145.9vs37.1±8.8mg/mmol at 12wk, 377.5±118.8vs41.3±10.2mg/mmol at 24wk, $p<0.01$), which was reduced in TLR2-/- diabetic mice (ACR: 43.3±7.8vs182.3±80.1mg/mmol at 6wk, 181.6±73.3vs402.4±145.9mg/mmol at 12wk & 124.3±35.2vs377.5±118.8mg/mmol at 24wk, $p< 0.01$). WT diabetic mice developed histological damage including glomerular hypertrophy from week 6 ($p<0.001$), interstitial collagen deposition from 12 weeks ($p<0.01$) and macrophage accumulation from week 6 ($p<0.0001$). These findings were significantly attenuated in TLR2-/- diabetic mice. Pathogenic cytokine (TNFa), chemokine (MCP1) and pro-fibrotic (TGFb&fibronectin) mRNA expression was significantly up-regulated in WT diabetic kidney compared to normals but was decreased in TLR2-/- diabetic kidneys. In vitro, WT TEC produced key cytokines, chemokines and fibrotic-genes after high-glucose exposure, which was attenuated in TLR2-/- TECs.

Conclusions: TLR2$^{-/-}$ mice were protected from injury in DN, suggesting TLR2 contributes to the development of DN.

Histopathologic Changes of Diabetic Nephropathy in the db/db Mouse Following Iron Chelation with Deferiprone Ahmad Bilal Malik,[1] Syed M. Ali,[1] R. Stafford Justus,[2] Songthip Ounpraseuth,[1] Neriman Gokden.[1] *[1]University of Arkansas for Medical Sciences; [2]Central Arkansas Veterans Healthcare System, Little Rock, AR.*

Background: Catalytic iron (CatFe) participates in the generation of powerful reactive oxidant species that propagate diabetic nephropathy (DN). Chelation may stabilize these histopathologic lesions.

Methods: Using a prototypical mouse model of human diabetes mellitus type 2 (Lepr^{db}/Lepr^{db}), we tested the efficacy of the iron chelator deferiprone in stabilizing mesangial matrix expansion and glomerular basement membrane (GBM) thickening. Using male mice from two batches of 6 animals for the control and treatment groups each, the latter received deferiprone dissolved in drinking water (125mg/kg body weight) starting at age 4.5 weeks till euthanasia at 28 weeks.

Results: While the mean blood glucose was lower in the treatment compared with the control group (569.38 ± 98.49 vs. 685.04 ± 31.31mg/dL) at euthanasia, body weight was better preserved (59.2 ± 2.29g vs. 54.15 ± 8.81g). Deferiprone predictably decreased the 24-h urinary CatFe excretion (CatFe/Creatinine ratio) which after adjustment for treatment group, batch, time, and their two-way interactions in a repeated measures analysis of variance (ANOVA), using Least Squares Means (LSM) gave values of 50.10 ± 233.25 vs. 942.75 ± 233.01μmol/mmol in the treatment and control groups respectively ($p= 0.0163$ at week 6). By 28 weeks excretion remained considerably less in the treatment group but became non-significant. A nephropathologist who was blinded to the treatment adjudication interpreted the light (LM) and electron microscopy (EM) findings. Using 2- way ANOVA, and determining the effect of treatment with deferiprone, time and batch by LSM, the area of the glomerular tuft occupied by the mesangial matrix was 26.25 ± 3.38% vs. 27.5 ± 3.05% in the treatment and control groups respectively. By EM, the mean GBM thickness was 0.099 ± 0.01μm vs. 0.14 ± 0.02μm with a representative area of absolute mesangial thickness of 11.2μm vs. 12.6μm in the treatment and the control groups respectively.

Conclusions: CatFe chelation with deferiprone in the db/db mouse model resulted in stabilization of the classic histopathologic lesions of DN.

Ets-1 Acetylation Maintains Persistent Expression of microRNA-192 in Kidney Glomerular Mesangial Cells after Transforming Growth Factor-beta1 Treatment Mitsuo Kato, Mei Wang, Jung Tak Park, Sumanth Putta, Linda L. Lanting, Rama Natarajan. *Diabetes, Beckman Research Institute of City of Hope, Duarte, CA.*

Background: microRNAs (miRNAs) are involved in accumulation of extracellular matrix proteins in diabetic kidney glomerular mesangium. microRNA-192 (miR-192) is upregulated by Transforming Growth Factor beta1 (TGF-b) in a Smad3 and p53 dependent manner in early stages and plays a role in renal fibrosis. Although potential Ets-1 binding sequences are found in the promoter region of miR-192 and Ets-1 is an important factor in kidney injury, the role of Ets-1 has not been fully studied.

Methods: RNA levels were examined by Realtime PCR, protein, phosphorylation or acetylation levels by Western blotting, staining of phospho-p300 in mouse glomerui by immunohistochemistry, promoter activities by luciferase reporter assay, binding of Ets-1 and acetylation of histone H3 on the miR-192 promoter by Chromatin-immunoprecipitation assay.

Results: TGF-b activated Akt kinase which phosphorylates p300 (phospho-p300S1834) that acetylates Ets-1 and Histone H3K9/14 to regulate miR-192 expression through Ets-1 binding sites. This lead to persistent expression (>24hr) of miR-192 in mouse kidney glomerular mesangial cells. Luciferase reporter assays with miR-192 promoter constructs showed that the Ets-1 site is critical for the TGF-b response. Significant increase of phospho-p300S1834 levels were detected in glomeruli from the type 2 diabetes mice (db/db). Interestingly, in glomerular mesangial cells derived from Ets-1 knockout mice, basal miR-192 levels were higher and the persistent increase in TGF-b-induced miR-192 was lost. Furthermore, Ets-1 siRNA treatments increased miR-192 levels and inhibited the TGF-b-induced persistent increase of miR-192.

Conclusions: These results demonstrate a novel negative regulatory role for Ets-1 in miR-192 expression and demonstrate that the dissociation of acetylated Ets-1 (via TGF-b activated Akt/p300 pathway) from the miR-192 promoter region may allow a sustained and persistent expression of miR-192 in glomerular fibrosis. Thus Ets-1 may be a key regulator of fibrosis associated with diabetic nephropathy by controlling the expression of miR-192.

Insulin Modulates TRPC6 Channels in Podocytes: Possible Role in Stabilizing the Glomerular Filtration Barrier Stuart E. Dryer,[1] Jochen Reiser,[2] Alessia Fornoni.[2] *[1]University of Houston, Houston, TX; [2]University of Miami, FL.*

Background: Insulin signaling to podocytes is essential for normal function of the glomerular filtration barrier, but the effects of insulin on podocyte physiology are not well understood. TRPC6 channels are expressed in podocyte foot processes, and mutant forms of these channels can lead to glomerular disease.

Methods: Insulin modulation of TRPC6 channels was assessed by whole-cell recordings and cell-surface biotinylation assays in immortalized podocyte cell lines. Reactive oxygen species (ROS) were measured using fluorometric assays. Urinary albumin/creatinine ratios and glycemia were measured following tail-vein injections of glucose.

Results: Insulin caused a robust increase in macroscopic SKF96365- and La3+-sensitive cationic currents in podocyte cell lines. Insulin also increased steady-state surface expression of TRPC6 channels. These effects occurred in less than 15 min but were maximal after 24 hr. The effects of insulin on TRPC6 trafficking were blocked by siRNA against the NADPH oxidase NOX4 or by NADPH oxidase inhibitors. Insulin increased the generation of ROS in podocytes, and the effects of insulin on TRPC6 trafficking were blocked by manganese (III) tetrakis (4-benzoic acid) porphyrin chloride, a membrane-permeable scavenger of ROS. We also examined urinary albumin excretion following intravenous glucose in wild-type and TRPC6-knockout mice sufficient to produce a peak glycemia of 550 mg/dl. Glucose-induced albuminuria was greater in TRPC6 knockout mice compared to control, but glycemic control was not different.

Conclusions: Insulin modulates TRPC6 channels in podocytes, in part by increasing their steady-state surface expression. This effect requires generation of ROS, which appear to act as a type of second messenger for this effect. Modulation of podocyte TRPC6 channels, by increasing calcium influx and thereby stiffening the capillary wall, may be part of a mechanism to maintain stability of the glomerular filter in the face of stimuli that increase glomerular filtration rate (GFR). Insulin modulation of TRPC6 channels in particular may prepare podocytes to cope with the increased GFR evoked by a glucose load.

FR-PO1538

Increased Accumulation of Iron in Lysosomes of Proximal Tubule Cells of Hp 2-2 Diabetic Mice Farid M. Nakhoul,[1,3] Rachel Miller-Lotan,[3] Nakhoul Nakhoul,[3] Hoda Awad,[3] Andy P. Levy.[3] *[1]Nephrology, Poria Med Ctr, Lower Galilee; [2]Vascular Med.Lab, Technion-Faculty of Medicine, Haifa, Israel.*

Background: 30% of Patients with diabetes mellitus (DM) will develop ESRD. Its well know that diabetic patients with the Haptoglobin 1-1 (Hp 1-1) are more protected than Hp 2-2 in developing diabetic nephropathy(DN). Iron is a metal oxidant capable of generating ROS and has been postulated to contribute to progression of DN.Iron accumulates within proximal tubular (PCT) lysosomes in several models of renal disease. Vit.E may play a protective role in DN.

Methods: Samples of kidney tissue from the diabetic mice(Hp 1-1 DM, Hp 2-2 DM) with and without treatment with vit. E, were prepared for transmission electron microscopy. Areas showing positive Perls' stain were considered as containing more iron compounds and were ultra-thin cut and viewed through a JEOL 100SX EM. At least 4 glomeruli per sample plus the adjacent tubuli were examined. Clusters of iron-containing lysosomes (siderosomes) were seen in the PCT. The siderosomes were identified by the presence of typical electron-dense ferritin and hemosiderin within single-membrane bound bodies. To confirm the presence of iron in these organelles, Energy dispersive x-ray spectroscopy was used.

Results: LM examinations of glomeruli and PCT, disclosed increased in glomerular area in in Hp2-2 DM vs Hp1-1 DM, $p<0.05$), which decreased significantly by Vit.E in Hp2-2DM. Oxidative stress was measured by 4HNE immunostaining in glomeruli and PCT and was significantly increase in Hp 2-2 DM vs Hp1-1 DM and decreased by Vit. E in Hp2-2 DM. There was increase in ferritin in Lysosome of PCT cells of Hp2-2DM vs Hp1-1DM(0.194±0.01vs 0.116±005% area, $P<0.05$) and decreased by vit.E in Hp2-2DM(0.194 ±0.01 vs 0.13±0.007,$p<0.05$). Total iron content in the kidneys was increased in the Hp 2-2 DM vs Hp 1-1 DM (11.4 ±0.7 vs 9.4± 1.3 mg Fe/mg kidney) as measured by atomic absorption spectroscopy.

Conclusions: Increased iron accumulation within lysosomes of PCT cells of diabetic Hp 2-2 mice.

Increased iron accumulated as ferritin in Hp 2-2 DM, is associated with increased oxidative stress and Tubulo glomerular damage.

Funding: Other NIH Support - Israel Science Foundation (ISF), Government Support - Non-U.S.

Implications of Oxidative Stress Derived from Endothelial NAD(P)H Oxidase in the Development of Diabetic Nephropathy Hajime Nagasu, Minoru Satoh, Atsunori Kuwabara, Kengo Kidokoro, Naruya Tomita, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Matsushima Kurashiki, Okayama, Japan.*

Background: Increased generation of reactive oxygen species (ROS) is a common pathogenic mechanism underlying vascular and renal complications in diabetes. Endothelial NAD(P)H oxidase is a major source of vascular ROS and plays important role in endothelial dysfunction. We hypothesize that activation of endothelial NAD(P)H oxidase would initiate and accelerate diabetic nephropathy, especially development of albuminuria, in diabetic milieu.

Methods: We used endothelial specific NOX2 transgenic (NOX2TG) mice, AKITA type1 diabetic (AKITA) mice, NOX2Tg crossbred with AKITA mice, and wild type (WT) mice. NOXTG was generated in which NOX2, gp91 phox of NAD(P)H oxidase, under the control of Tie2 promoter, was overexpressed in the endothelium. All mice were back-crossed into C57BL/6J. These mice were sacrificed at 6 and 12-week-old of ages for molecular and histological analysis. We applied the in vivo live imaging techniques with multi-photon laser microscopy and various sizes of FITC labeled dextrans to analyze alterations in permeability of glomerular capillary walls in disease conditions.

Results: Urinary albumin excretion was increased only in NOXTG-AKITA but not in WT and AKITA at 6-week-old. At 12-weeks-old, serum creatinine level was significantly elevated only in NOXTG-AKITA but not AKITA and WT. No significant morphological changes were detected in glomeruli from all groups by light microscopic examinations. But slight degree of structural changes in podocytes and mesangial cells were observed only in NOXTG-AKITA under the electron microscope. The in vivo live imaging techniques revealed increased filtration of 40kDa dextran in glomeruli in AKITA and NOXTG-AKITA, but not in WT. Moreover, increased permeability of larger molecules, 70KDa dextran, were detected in NOXTG-AKITA. Lectin staining was decreased along glomerular endothelium in NOXTG-AKITA.

Conclusions: Activation of endothelial NAD(P)H oxidase in hyperglycemic milieu initiated and accelerated diabetic nephropathy characterized by development of albuminuria and hyperfiltration of macromolecules.

FR-PO1540

Maxacalcitol Prevents Progression of Endothelial Dysfunction in Rats with Diabetic Nephropathy Michinori Hirata,[1] Ken Aizawa,[1] Ken-Ichi Serizawa,[1] Kenji Yogo,[1] Yoshihito Tashiro,[1] Yoshiyuki Moriguchi,[1] Masafumi Fukagawa.[2] *[1]Product Research Laboratory, Chugai Pharmaceutical Co., Ltd., Gotemba, Shizuoka, Japan; [2]Division of Nephrology, Endocrinology and Metabolism, Tokai Unicersity School of Medicine, Isehara, Kanagawa, Japan.*

Background: Endothelial function is a powerful surrogate marker of cardiovascular risk in patients with end-stage renal disease (ESRD) or diabetic nephropathy, and can be evaluated by flow-mediated dilatation (FMD). FMD is reportedly correlated with serum 25-hydroxyvitamin D levels in ESRD patients, and restored by nutritional vitamin D in patients with type 2 diabetes. There is evidence that vitamin D receptor activators (VDRAs) might protect against cardiovascular event directly or through protecting against endothelial dysfunction, but the mechanisms remain unclear.

Methods: This study aimed to assess whether the VDRA maxacalcitol (MXA) could prevent decrease of FMD in spontaneously diabetic Torii (SDT) rats, a non-obese, type II diabetes rat model with hyperglycemia and proteinuria (from 20 weeks of age). FMD was measured in rats as changes in femoral arterial diameter after 5 min ischemia.

Results: FMD was lower in SDT rats than in Sprague-Dawley (SD) rats (% diameter change [mean±S.E.]: SD, 12.8±2.1%; SDT, 8.3±1.2%; n=6). Treatment with MXA (0.2 or 0.6 μg/kg/day, i.p. 3 times/week for 10 weeks) significantly prevented the decline of FMD without hypercalcemia or decreased blood glucose level (MXA0.2, 15.4±2.4%; MXA0.6, 16.7±2.4%; n=4 or 6); with insulin, FMD also returned to normal level (17.6±3.4%; n=6) but with decreased glucose level.

To clarify the mechanism of MXA, we evaluated the effects of anti-reactive oxygen species (ROS) on human coronary artery endothelial cells (HCAECs). High glucose significantly increased ROS generation in HCAECs, and MXA significantly inhibited ROS generation by suppressing $p22^{phox}$ expression. Supporting such a mechanism, $p22^{phox}$ subunit of NADPH oxidase, related to oxidative stress, were increased in femoral arteries of SDT rats.

Conclusions: In conclusion, in rats with diabetic nephropathy, MXA prevented endothelial dysfunction without hypercalcemia or decreased blood glucose by ameliorating oxidative stress.

FR-PO1541

Low Nitric Oxide Bioavailability Upregulates HB-EGF Expression in eNOS Knockout Diabetic Mouse Kidney Fenghua Zeng, Tomoki Miyazawa, Suwan Wang, Xiaofeng Fan, Huifang Cheng, Raymond C. Harris. *Department of Medicine, Vanderbilt University, Nashville, TN.*

Background: There is strong evidence that decreased Nitric oxide (NO) bioavailability in the diabetic state plays a central role in endothelial dysfunction. Studies also indicate that factors contributing to low NO bioavailability, such as hyperglycemia, AGEs and oxidative stress, also cause endothelial cell (EC) damage directly or indirectly through the actions of HB-EGF, suggesting that HB-EGF expression may also being regulated by NO levels and serve as a mediator of EC dysfunction in diabetes.

Methods: eNOS knockout diabetic mouse (*eNOSKO db/db*) was used in this study. Renal HB-EGF expression was measured by western blot and immunostaining. Heparin-binding assay was used to test urinary HB-EGF excretion. NOS inhibitor, L-NAME, was used in both *in vitro* and *in vivo* studies of the interaction of NO and HB-EGF level.

Results: We found that increased kidney HB-EGF expression can be detected as early as 8 weeks of age, and is further elevated to parallel the progression of glomerulopathy in eNOSKO db/db mice. Strong HB-EGF expression was seen in both EC and podocytes of glomeruli, EC and smooth muscle cells of the blood vessels as well as in tubular epithelial cells of thick ascending limb and collecting ducts in both eNOSKO and eNOSKO db/db mouse kidney. Even though HB-EGF expression levels in the kidney were increased in both eNOSKO and eNOSKO db/db mice at 8 weeks, dramatically increased HB-EGF levels were seen at later time points in eNOSKO db/db mice, and urinary HB-EGF excretion was detected exclusively in eNOSKO db/db mice. In cultured glomerular endothelial cells, administration of the NOS inhibitors L-NAME or L-NIO increased HB-EGF mRNA and protein expression. Furthermore, in vivo administration of L-NAME dramatically increased renal HB-EGF expression and urinary HB-EGF excretion in db/db mice, but not in non-diabetic control mice.

Conclusions: In conclusion, our results suggest that decreased NO bioavailability in *eNOSKO db/db* mice leads to increased HB-EGF expression, which may be an important mediator of the resulting glomerular damage in the progressive diabetic nephropathy in this model.

Funding: NIDDK Support

FR-PO1542

RAGE-Dependent Apoptosis of Podocytes in a Model of Diabetes and/or High Protein Diet Rick L. Meek,[1] Sandeep Ajoy Saha,[1,2] Sheryl K. Cooney,[1] Robert J. Anderberg,[1] Katherine R. Tuttle.[1,2] *[1]Providence Medical Research Center, Sacred Heart Medical Center; [2]University of Washington School of Medicine, Spokane, WA.*

Background: Albuminuria is an early manifestation of diabetic kidney disease (DKD). Podocyte loss is a central mechanism for albuminuria. The study aim was to determine if metabolic stressors characteristic of diabetes and/or high protein diet, specifically high levels of glucose (HG), amino acids (AA), and/or advanced glycation end products (AGE), promote podocyte loss through apoptosis mediated by the receptor for AGE (RAGE).

Methods: Immortalized mouse podocytes were exposed to metabolic stressors: 1) hyperglycemia (HG, 30.5 mM glucose); 2) an amino acid mixture designed to mimic high protein diet (AA); 3) the combination (AA/HG); 4) AGE-bovine serum albumin (AGE). Anti-serum to RAGE and non-immune control serum were added to determine RAGE-dependent responses. Both early (caspase 3/7 activity, day 1) and later (TUNEL staining, day 2) markers of apoptosis were measured in podocytes. Expression of RAGE protein was assessed (immunocytochemistry, day 2), and levels of carboxymethyllysine (CML), an AGE biomarker, were determined in conditioned media (ELISA).

Results: Caspase 3/7 activity and TUNEL-positive podocyte number strikingly increased after exposure to metabolic stressors of HG, AA, AA/HG, and AGE (150-300 %). RAGE immunostaining on podocytes and CML in conditioned media also increased after exposure to these metabolic stressors. Anti-RAGE antiserum effectively reduced caspase 3/7 activity and TUNEL-positive podocytes numbers to control levels in response to HG, AA, AA/HG, and AGE.

Conclusions: Metabolic stressors characteristic of diabetes and/or high protein diet promote apoptosis in podocytes by RAGE-dependent mechanisms. In addition, increased AGE ligands produced in response to these conditions may augment RAGE binding, and thereby, perpetuate podocyte apoptosis.

FR-PO1543

Exacerbated Diabetic Renal Alterations in Mice Lacking Vasohibin-1 Norikazu Hinamoto,[1] Yohei Maeshima,[1] Daisuke Saito,[1] Hiroko Yamasaki,[1] Hiroyuki Watatani,[1] Haruyo Ujike,[1] Hitoshi Sugiyama,[1] Hikaru Sonoda,[2] Yasufumi Sato,[3] Hirofumi Makino.[1] *[1]Medicine and Clinical Science, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [2]Discovery Research Laboratories, Shionogi, Settsu, Osaka, Japan; [3]Vascular Biology, Development, Aging, and Cancer, Tohoku Univ., Sendai, Miyagi, Japan.*

Background: Diabetic nephropathy is the leading cause of end-stage renal disease, and the involvement of proangiogenic factors such as VEGF-A had been reported. We previously reported the renoprotective role of exogenous Vasohibin (VASH)-1, a negative feedback regulator of angiogenesis and vascular maturation factor, in mouse models of diabetic nephropathy (Diabetes, 2009, AJPhys-Renal, 2011). VEGF-A and decreased angiopoietin (Ang)-1/2 ratio are associated with inflammation. In the present study, we aimed to evaluate the potential role of endogenous VASH-1 to regulate diabetic renal alterations.

Methods: Type 1 diabetes was induced in male VASH-1 heterozygous knockout mice (VASH1+/-) or wild-type (VASH1+/+) littermates (C57/BL6J) by intraperitoneal injections of streptozotocin (STZ, 50 mg/kg) for 5 consecutive days. Mice were sacrificed on week 16 after inducing diabetes.

Results: Renal histological alterations were not observed in non-diabetic VASH1+/- mice. Although hyperglycemia, blood pressure or glomerular hyperfiltration were not altered, renal hypertrophy, glomerular hypertrophy, albuminuria, glomerular accumulation of type IV collagen and mesangial matrix, and glomerular monocyte/macrophage infiltration, were significantly exacerbated in the diabetic VASH1+/- mice compared with diabetic VASH1+/+ mice. Renal levels of transforming growth factor (TGF)-beta1, VEGF-A and Ang-2 (immunoblot) were significantly increased, and the levels of Ang-1 was reduced in the diabetic VASH1+/- mice compared with the diabetic wild-type mice.

Conclusions: These results suggest that endogenous VASH-1 may exert renoprotective effects in type 1 diabetes, via suppressing inflammation and fibrosis partly through regulating VEGF-A and Ang-1/2 ratio, thus implicating its potential to serve as a novel therapeutic reagent for diabetic nephropathy.

FR-PO1544

Sepiapterin Improves eNOS Function and Attenuates Renal Injury in db/db Mice Huifang Cheng, Xiaofeng Fan, Raymond C. Harris. *Nephrology/Medicine, Vanderbilt University Medical School, Nashville, TN.*

Background: Our previous studies have demonstrated a role for impaired eNOS activity in the development of diabetic nephropathy (DN).

Methods: To investigate the effect of sepiapterin (Sep), a cofactor for endothelial nitric oxide synthase and a stable precursor of tetrahydrobiopterin (BH4), on DN, we administrated Sep (10 mg/kg/day by gavage) or the NO precursor, L-arginine (L-arg) (100 mg/kg/day) in a type II diabetic model, db/db (BKS) mice for 8 weeks (from 26 to 34 weeks).

Results: Neither Sep nor L-arg significantly affected the hyperfiltration (GFR: 290±20 μl/min. in control; 394±92 in untreated db/db; 431±52 in Sep and 394±19 in L-arg respectively), but both of the treatments reduced urine albuminuria (alb/cre:untreated: 759±281, Sep: 40±7 and L-arg: 163±37 μg alb /mg Cr respectively, n=6-8, $p<0.05$). Mesangial expansion was not affected by treatment, but Sep or L-arg decreased GBM thickness (control: 154±6; db/db: 335±23; Sep: 180±13; L-arg: 219±13 nm, n=3). After Sep or L-arg, urinary isoprostanes, a marker of oxidative stress, were significantly less (2.6±0.2 and 3.4±0.2 ng 8-iso-PGF2α /mg Cr), compared with untreated db/db (5.6±0.05), although they were still higher than control (1.4±0.1).

Neither immunohistochemistry nor immunoblotting indicated any significant alteration of glomerular eNOS monomer expression, but impaired eNOS dimerization was partially reversed by either Sep or L-arg (dimer/monomer ratio (wild type: 0.53±0.14; db/db: 0.23±0.08; Sep: 0.47±0.07 and L-arg: 0.40±0.13 respectively), indicating recovery of eNOS uncoupling after treatment. In addition, there was decreased phosphorylation of eNOS at Ser 1179 in db/db mice, which was partially restored by Sep or L-arg.

Conclusions: In summary, the current study further supports the important role of BH4 deficiency in eNOS dysfunction and suggests that sepiapterin supplementation might have therapeutic potential in diabetic nephropathy.

FR-PO1545

CTGF Is Overexpressed in BTBR *ob/ob* Mutant Mice and Inhibited upon Reversal of Diabetic Nephropathy Tri Q. Nguyen,[1,2] Tomasz A. Wietecha,[1] Roel Goldschmeding,[2] Kelly L. Hudkins,[1] Charles E. Alpers.[1] *[1]Dept of Pathology, University of Washington, Seattle, WA; [2]Dept of Pathology, University Medical Center Utrecht, Netherlands.*

Background: BTBR mice with the *ob/ob* leptin deficiency mutation develop progressive diabetic nephropathy (DN) that resembles its human counterpart (JASN 2010;1533-42). Connective tissue growth factor (CTGF; CCN2) is strongly upregulated in renal fibrosis and is an important factor in the progression of DN. It is not known if renal CTGF expression is dependent on the diabetic state or if it is regulated by other factors. We investigated CTGF expression in BTBR *ob/ob* mice both during progression of DN and during reversal of diabetes and DN.

Methods: Cohorts of female diabetic BTBR *ob/ob* mice (n=6) and normoglycemic BTBR wild-type (WT) mice (n=6) were followed for 24 wks. In a third cohort, leptin was administered by osmotic minipumps for 6 wks, starting at age 18 wks (n=6). In a fourth cohort, enalapril was given orally for the same period (n=6). CTGF expression was assessed by immunostaining and quantified by digital image analysis.

Results: In the kidneys of BTBR WT mice, CTGF was only focally present in podocytes and mesangial cells (mean positive glomerular area 1.7% ± 1.2). In BTBR ob/ob mice, glomerular CTGF was strongly increased (18.8%±4.6; P<0.001) and localized in podocytes, endothelial cells, mesangial cells and - matrix, and parietal cells. Treatment with leptin resulted in remission of diabetes and reversal of DN as reported previously (ASN abstract 2010) with corresponding decrease of CTGF (7.4%±1.9; P<0.05). Treatment with enalapril did not produce reversal of DN or decreased CTGF (20.5%±10.4; P=0.71). No significant CTGF staining was observed in the tubulointerstitium of BTBR WT or BTBR ob/ob mice.

Conclusions: CTGF is upregulated in glomeruli of BTBR *ob/ob* mice with DN. Treatment with leptin, but not enalapril, inhibits CTGF in association with reversal of the functional and structural kidney damage of DN. These data indicate that the expression of CTGF in DN may be closely linked or even dependent on the presence of a diabetic milieu, and that achieving normoglycemia may prevent the deleterious fibrosis mediated by CTGF.

Mechano-Growth Factor Induces the Mesangial Cell GLUT1 Glucose Transport System Minghui Xiang,[1] Kathleen O. Heilig,[1] Leighton R. James,[1] Joana Panni,[2] N. Stanley Nahman,[3] Charles W. Heilig.[1] *[1]Medicine, University of Florida College of Medicine-Jacksonville, FL; [2]Anesthesiology, University of Florida College of Medicine-Jacksonville, FL; [3]Medicine, Georgia Health Sciences University, Augusta, GA.*

Background: Recently we reported in preliminary form the expression of Mechano-Growth Factor (MGF) in mouse glomeruli and primary culture mesangial cells (MC). Glomerular MGF was increased in the glomerular mesangium of both Type 1- and Type 2 diabetic mice. Here we describe responses of cultured mouse MC to MGF-overexpression and to 20mM high glucose, including GLUT1 glucose transporter expression, GLUT1 transcription, glucose uptake rates, and extracellular matrix (ECM) protein expression.

Methods: MGF overexpression in primary culture mouse MC via a MoMuLV retroviral vector; 3H2-Deoxyglucose (3H2-DOG) uptake rates; Western analyses for GLUT1 and ECM proteins; MC exposure to 8 vs 20mM high glucose x 5d; GLUT1-luciferase reporter assays for transcription.

Results: MGF was detectable in control MC (MC-EV) transduced with the empty MoMuLV vector. Multiple clones of MGF-sense transduced MC (MGF-S) were obtained with overexpression of MGF protein at 3-fold control, P < .0005. In comparison, 20mM high glucose treatment of MC-EV increased MGF protein 2.6-fold . In 8mM glucose, immunolabelling of cells revealed diffuse expression of MGF in MGF-S, as opposed to perinuclear localization of MGF in MC-EV. GLUT1 transcription via the promoter + Enhancer-2 was increased 2.3-fold in MGF-S, with 2.3-fold increased GLUT1 protein (P < .05), and 3-fold increased glucose uptake (P < .o5). Fibronectin (FN) protein was increased 1.6-fold in MGF-S.

Conclusions: 1.MGF-overexpression in MC induced GLUT1 transcription, GLUT1 protein, glucose uptake, and FN ECM protein. 2.High glucose similarly increased MC MGF protein. 3. MGF is a MC protein induced by high glucose and diabetes, and may play a role in diabetic glomerulosclerosis in vivo.

Lowering Serum Uric Acid Attenuated NLRP3 Inflammasome-Induced Renal Inflammation in High Fructose Fed OLETF Rat Ju-Young Moon, Su-Mi Kim, Eun Young Kim, Yang Gyun Kim, Sul-Ra Lee, Kyung-Hwan Jeong, Sang-Ho Lee, Tae Won Lee, Chun-Gyoo Ihm. *Division of Nephrology, Department of Internal Medicine, Kyung Hee University, Seoul, Korea.*

Background: The NLRP3 inflammasome is a molecular platform activated upon signs of cellular danger to trigger innate immune defences though the maturation of pro-inflammatory cytokines such as interleukin-1β (IL-1β). Uric acid crystals have recently gained widespread attention due to their role as a natural endogenous adjuvant. In this study, we examined the hypothesis that soluble uric acid activates NLRP3 inflammasome-induced renal inflammation in type 2 diabetic rat.

Methods: The LETO and OLETF rats were divided into four groups: (1) LETO group; (2) OLETF group; (3) OLETF + high fructose diet (HFD) group; (4) high fructose fed OLETF with allopurinol treatment (HFD + allopurinol) group. Human renal proximal tubular epithelial cells (HK-2) and THP-1 cells were also cultured and stimulated with 15mg/dL of uric acid with or without allopurinol.

Results: HFD group showed a higher serum uric acid and urinary albumin creatinine ratio than OLETF group. HFD group showed marked increase of NLRP3 and IL-1β in kidney cortex. Immunohistochemical staining of ED-1 showed significant increase in HFD group compared to OLETF group. Allopurinol attenuated HFD induced hyperuricemia and NLRP3 activation-related renal inflammation. Uric acid also stimulated NLRP3 by reactive oxygen species (ROS) production in HK-2 and THP-1 cell.

Conclusions: The soluble uric acid could stimulate NLRP3 and IL-1β by ROS production in diabetic kidney. It may be related with hyperuricemia induced inflammation and progression of diabetic nephropathy.

FR-PO1548

Regulation of Stress Granule Formation through Diabetes and RACK1 Expression Michael Merchant, Michelle T. Barati. *Medicine-Nephrology, University of Louisville, KY.*

Background: Stress granules are transient cytoplasmic aggregations of protein and RNA, formed following stressors including heat, osmotic, and oxidant stress. They represent a compensatory attempt of the cell to triage and sequester important proteins and messenger RNA during stress but preceding ERAD. Previous studies indicated alteration to stress granule metabolism in parenchyma of patients with early diabetic nephropathy (DN). This current study addressed the hypothesis that elevated urinary glucose and/or protein may alter stress granule proteome.

Methods: Cultured immortalized human proximal tubules (HK2) cells were exposed to high glucose and/or albumin concentrations, then fractionated to enrich stress granules. Differentially abundant proteins were identified using electrophoresis and mass spectrometry. Soluble and granule-enriched HK2 lysate fractions, human renal biopsies, and isolated mouse tubules were subjected to immunoblot or confocal analysis for constituitive and conditionaly associating stress granule proteins. HK2 cells were treated with thapsigargin, a pharmacologic inducer of ER stress, to characterize the recruitment of proteins into stress granule structures.

Results: The receptor for activated protein C kinase-1 (RACK1) was recruited into stress granule containing fractions by diabetic stressors. Expression of RACK1 in renal biopsies from diabetic patients transiently increase with early DN and then decreased with advanced DN. RACK1 expression in isolated mouse tubules of non-diabetic and diabetic mice decreased with diabetes and with age. Treatment of HK2 cells with the ER stress inducer, thapsigargin, resulted in 1) constitutive TIA-1 and G3BP co-localization to granular structures and also a transient and significant re-localization of RACK1 to granule structures.

Conclusions: Sequestration of RACK1 into stress granules has been shown to inhibit cell apoptosis, by scaffolding key signaling proteins (eg protein kinase C). Stress granule triage of RACK1 by HK2 cells in diabetic conditions suggests an early attempt of the cell to survive the diabetic stressors. Data from human biopsy and isolated mouse tubules suggests this role of RACK1 may be lost with disease progression and/or age.

FR-PO1549

Impact of CD45+/Col1+ Cells through CCR2 Signaling on the Pathogenesis of Diabetic Nephropathy Akinori Hara,[1] Norihiko Sakai,[1] Kiyoki Kitagawa,[1] Kengo Furuichi,[1] Shuichi Kaneko,[1] Takashi Wada.[2] *[1]Disease Control and Homeostasis, Kanazawa University, Kanazawa, Ishikawa, Japan; [2]Department of Laboratory Medicine, Kanazawa University, Kanazawa, Ishikawa, Japan.*

Background: Recent evidence has revealed that migration and infiltration of bone marrow-derived cells, via the chemokine/chemokine receptor system, have been implicated in the pathogenesis of kidney fibrosis. In this study, the involvement of CD45 and type 1 collagen (Col1) dual-positive (CD45+/Col1+) cells through monocyte chemoattractant protein (MCP)-1/CCL2/CC chemokine receptor 2 (CCR2) signaling was examined in the pathogenesis of diabetic nephropathy.

Methods: Eight-week-old male db/db mice and db/+ control mice were fed with propagermanium (PG), a CCR2 inhibitor, or vehicle for 16 weeks. Human CD45+/Col1+ cells were isolated from healthy volunteers and incubated with normal or high concentrations of glucose.

Results: In flow cytometric and immunohistochemical analysis, CD45+/Col1+ cells were detected in the diabetic kidneys, especially in the interstitium, and the number of the

cells was reduced in PG-treated mice. Blockade of CCR2 signaling by PG reduced the extent of glomerulosclerosis and interstitial fibrosis accompanied with the decreased renal mRNA expression of transforming growth factor (TGF)-beta1, pro-alpha1 chain of Col1 (COL1A1), and MCP-1 in PG-treated mice. Urinary albumin excretion was reduced in PG-treated mice compared with that in vehicle-treated mice. In vitro experiments revealed that high glucose enhanced the synthesis of TGF-beta1, COL1A1 and MCP-1 in human isolated CD45+/Col1+ cells, and up-regulated expression of these molecules was blocked by PG treatment.

Conclusions: These findings suggest that CD45+/Col1+ cells may be involved in the progression of diabetic nephropathy through MCP-1/CCR2 signaling.

FR-PO1550

Functional Analysis of miR-30c, miR-26a and miR-379 in Podocytes and Their Potential Roles in Diabetic Nephropathy Kenichi Koga,[1] Hideki Yokoi,[1] Masashi Mukoyama,[1] Kiyoshi Mori,[1] Masato Kasahara,[1] Takashige Kuwabara,[1] Hirotaka Imamaki,[1] Tomoko Kawanishi,[1] Akira Ishii,[1] Keita P. Mori,[1] Yukiko Kato,[1] Moin Saleem,[2] Akira Sugawara,[1] Kazuwa Nakao.[1] *[1]Department of Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Academic and Children's Renal Unit, University of Bristol, Bristol, United Kingdom.*

Background: MicroRNAs (miRNAs) are small non-coding RNAs that downregulate mRNA levels. We have reported that connective tissue growth factor (CTGF) is involved in the progression of diabetic nephropathy, and that the natriuretic peptide/guanylyl cyclase-A (GC-A) pathway has a protective role against diabetic nephropathy. Recently, we showed that 48 miRNAs are changed with the stimulation of TGFβ1 on immortalized human podocytes by microarray analysis. Among them, we focused on miRNAs targeting CTGF (i.e., miR-30c and miR-26a) and GC-A (i.e., miR-379).

Methods: We transfected their mimics or inhibitors into podocytes by using nucleofection and examined target mRNA expression. We studied the role of miR-26a using its mimics in inhibiting TGFβ-CTGF pathway on podocytes with the stimulation of TGFβ1. Finally we examined expression of these miRNAs in glomeruli in type 2 diabetic db/db mice.

Results: Transfection of miR-30c mimic into podocytes tended to inhibit CTGF mRNA. miR-26a inhibitor upregulated CTGF mRNA by 1.3-fold. miR-379 mimic downregulated GC-A mRNA by 47%. TGFβ1 stimulation significantly increased col1a1 and col4a3 mRNA 2.5- and 1.8- fold in control group, respectively and transfection of miR-26a mimic significantly suppressed expression of col1a1 and col4a3 mRNA by 33% and 43% in TGFβ1-stimulated podocytes, respectively ($p < 0.05$). In glomeruli of db/db mice, miR-30c, miR-26a and miR-379 were significantly increased by 9.2-, 20.8- and 10.6-fold compared with those of db/m mice, respectively ($p < 0.05$).

Conclusions: These results indicate that miR-30c, miR-26a and miR-379 can be negative regulators of CTGF or GC-A in human podocytes, and suggest that these miRNAs may be involved in the progression of diabetic nephropathy.

FR-PO1551

Activated Local Renin-Angiotensin System Plays a Role in Albumin Permeability in Glomerular Endothelial Cells under High Glucose Conditions Jisun Paeng, Sun Ha Lee, Seung Hyeok Han, Tae-Hyun Yoo, Shin-Wook Kang. *Dept. of Int. Medicine, Collge of Medicine, BK21, SBSI, Yonsei Univ., Seoul, Korea.*

Background: Local renin-angiotensin system(RAS) is present in mesangial cells and podocytes, and their activation has been demonstrated to play an important role in the pathogenesis of diabetic nephropathy. However, little is known on local RAS within glomerular endothelial cells(GEC). This study was undertaken to investigate the existence of RAS components in GEC, their changes under high glucose conditions, and the role of local RAS in morphological and functional changes in high glucose-stimulated GEC.

Methods: GEC were exposed to 5.6 mM glucose(NG) or 30 mM glucose(HG) with or without 10^{-7} M losartan for 24 hours. Real-time PCR and Western blot analysis were performed for all components of RAS. Angiotensin I(AI) and AII concentrations in conditioned media were measured by ELISA. Renin activities were defined as the formation of AI in the presence of porcine angiotensinogen(AGT). Morphological changes were examined by scanning electron microscopy(SEM) and a Transwell assay was performed to determine FITC-tagged albumin permeability.

Results: AGT mRNA and protein expression were significantly increased in HG-stimulated GEC compared to NG cells. AI and AII concentrations were also significantly higher in HG-conditioned media. In contrast, there were no differences in renin activities, and angiotensin converting enzyme and AII type 1 and type 2 receptor expression among the groups. On SEM examination, the diameter of fenestrae in HG-stimulated GEC was significantly greater compared to NG cells. The number of fenestrae tended to be increased in GEC exposed to HG, but did not reach statistical significance. A Transwell assay revealed that FITC uptakes in filtered media through HG-stimulated GEC were 3.3-fold higher compared to NG cells($p<0.05$). The increase in fenestrae diameter and enhanced albumin permeability through GEC under HG conditions were significantly abrogated by losartan pretreatment.

Conclusions: These findings suggest that local RAS is activated in GEC under HG conditions and this activated RAS may play an important role in the development of albuminuria in diabetic nephropathy.

FR-PO1552

miR-200b Prevents TGFβ Induced Epithelial To Mesenchymal Transition and Represses Fibronectin by Targeting Its 3'UTR Owen Tang, Xinming Chen, Michael A. Hahn, Sylvie Shen, Carol A. Pollock. *Kolling Institute of Medical Research, St Leonards, NSW, Australia.*

Background: Data suggest that miR-200b suppressed the fibronectin by binding to its 3'UTR and we have also confirmed the site using site directed mutagenesis. Given this, miR-200b may have future therapeutic potential in progressive kidney fibrosis. MicroRNAs comprise a novel class of endogenous small noncoding RNA that control the expression of target genes. Our previous work had indicated miR-200b prevented transforming growth factor β1 induced epithelial to mesenchymal transition in human proximal tubular cells. Fibronectin which is a main constituent of extracellular matrix in renal fibrosis was also significantly reduced at transcription, translation level as well as secreted form when transfected with miR-200b. Hence this study was designed to explore the molecular mechanism in which miR-200b regulates fibronectin expression.

Methods: Potential miR-200b binding site on fibronectin 3' untranslated region was identified and cloned into downstream of luciferase gene in pMIR luciferase reporter plasmid. Another identical plasmid containing 4bp mutation in potential binding site was made using site directed mutagenesis. miR-200b was co-transfected with these reporter plasmids respectively into immortalised human proximal tubular cells. A non-specific miR was also used to serve as a negative control. Luciferase activity was measured 48hr post transfection.

Results: miR-200b reduced luciferase activity ($p<0.001$) by at least 2.5fold when co-transfected with reporter plasmid containing non-mutated fibronectin 3'UTR comparing to negative control. On the other hand, cells co-transfected with miR-200b and mutated fibronectin 3'UTR maintained high luciferase activity. Lentiviral construct had also been developed to achieve sustained over expression of miR-200b in fibrotic kidney mice model.

Conclusions: Data suggest that miR-200b suppressed the fibronectin by binding to its 3'UTR and we have also confirmed the site using site directed mutagenesis. Given this, miR-200b may have future therapeutic potential in progressive kidney fibrosis.

FR-PO1553

Protein Kinase DLK Is Necessary for Cell Autonomous Regulation of Insulin Sensitivity Hetty N. Wong,[1] Nathan Qi,[2] Deepak Nihalani,[1] Lawrence B. Holzman.[1] *[1]Medicine/Renal, Univ of Penn, Philadelphia, PA; [2]Medicine, Univ of Michigan, Ann Arbor, MI.*

Background: The protein kinase DLK (MAP3K12) is a component of a JIP1-JNK signaling module. Because we had previously observed that the DLK-JIP1-JNK1 complex is activated by insulin in cultured cells and because proximal components of the JNK1-JIP1-IRS negative feedback loop that in part determine insulin sensitivity and energy expenditure remain incompletely defined, we investigated the hypothesis that DLK is the MAP3K that functions proximal to JNK1 in determining cell autonomous insulin sensitivity in peripheral tissues and in regulating whole animal energy expenditure.

Methods: We generated a mouse line that carries a hypomorphic allele of Dlk (Dlk neo/neo). These mice were evaluated by indirect calorimetry and activity monitoring to determine their energy expenditure and hyperinsulinemic euglycemic clamp to determine whole body insulin sensitivity. Furthermore, we used ex vivo muscle strips, adipocytes and mouse embryonic fibroblast to study the cell autonomous role of DLK in regulation of insulin sensitivity.

Results: Dlk neo/neo mice are protected from age- and diet-induced obesity primarily because they expend more energy than control mice. This increased energy expenditure appears to result from increased resting metabolic rate and from increased energy consumption associated with increased motor activity. Relative to control mice, the Dlk neo/neo mice exhibit increased insulin sensitivity independently of obesity. Indeed, DLK regulates insulin sensitivity in peripheral tissues including white adipose and skeletal muscle in a cell autonomous fashion via a JNK-dependent pathway.

Conclusions: 1) DLK hypomorphic mice are protected from diet- and age-induced obesity.

2) DLK hypomorphic mice exhibit higher energy expenditure and increased motor activities.

3) Independent of fat mass, by using fat mass percentage matched young mice, we showed that DLK hypomorphic mice have altered glucose homeostasis and improved insulin sensitivity.

4) Using isolated muscle strips, white adipocytes and MEF, we showed that DLK has a cell autonomous role in insulin sensitivity regulation.

Renoprotection with Sodium Glucose Cotransporter 2 Inhibition Amanda J. Mather, Katherine Jane Pegg, Harshini Mudaliar, Carol A. Pollock, Usha Panchapakesan. *Renal Laboratory, Kolling Institute, Sydney, NSW, Australia.*

Background: This paper aims to examine the renoprotective effects of sodium glucose cotransporter 2 inhibitors (SGLT2i) using an in vitro model of proximal tubular cells (PTC). SGLT2i are oral hypoglycaemic agents used to treat patients with diabetes mellitus. SGLT2i block the reuptake of filtered glucose by inhibiting SGLT2, the primary glucose transporter in the PTC, leading to glycosuria and reductions in serum glucose. As a third of patients with

diabetes have diabetic nephropathy (DN), oral hypoglycaemic agents that have additional renoprotective effects beyond glucose lowering would be highly desirable

Methods: HK2 cells (a human kidney PTC line) were exposed to control (5mM) or high glucose (30mM), 0.5 ng/ml transforming growth factor beta (TGFβ) +/- the SGLT2i BI10773 for up to 72h. Cells were harvested for nuclear extract, RNA/protein and supernatants were collected. SGLT2, SGLT1 as well as various inflammatory/fibrotic markers relevant to DN were measured.

Results: TGFβ but not HG increased SGLT2 expression. SGLT2 inhibition with BI10773 reduced HG induced toll like receptor 2 and 4 as well as the transcription factors nuclear factor kappa B and activator protein 1 which promote inflammation and fibrosis in DN. Furthermore, BI10773 lowered HG induced collagen IV, an extracellular matrix protein as well as interleukin 6.

Conclusions: The SGLT2 inhibitor BI10773 reduces high glucose induced inflammatory and fibrotic markers by blocking glucose transport into the PTC. SGLT2 inhibition didn't increase compensatory glucose transport through SGLT1. Although HG did not regulate the expression of SGLT2, the presence of TGFβ, a cytokine intrinsic to the development of diabetic nephropathy, may potentiate the ill effects of HG through upregulating SGLT2.

Effects of Probiotic Ingestion on Renal Function and Oxidative Stress in Diabetic Rats Elisa M.S Higa,[1,4] Giovana Rita Punaro,[1] Fabiane Maciel,[1] Adelson Marçal Rodrigues,[1] Cristina S.B. Bogsan,[2] Marice Oliveira,[2] Marcelo Rogero.[3] *[1]Nephrology, UNIFESP, Brazil; [2]Biochemical Pharmaceutical Technology, USP, Brazil; [3]Nutrition Department, USP, Brazil; [4]Emergency Division, UNIFESP- EPM, Sao Paulo, Brazil.*

Background: Probiotics are defined as live microorganisms which could confer a health benefit, perhaps by interacting with the antioxidant system. Previous study in our Laboratory showed that after 8 weeks of DM induction in rats, the treatment with probiotic reduced oxidative stress and increased nitric oxide (NO), without significant changes in renal function.

The aim of this study is to assess the effects of early probiotic ingestion on the renal function and oxidative stress in diabetic rats.

Methods: DM was induced in male Wistar rats, with streptozotocin (45mg/kg, iv). The animals received probiotic (P) or its vehicle at 1.8 mL/d by gavage, in the 5th day of DM, during 8 weeks, being distributed in 4 groups (n=4 each): CTL; CTLP; DM; DMP. Before and after the treatment, 24 hour urine was collected to determine thiobarbituric acid reactive substances (TBARS) (nmol/24h), NO (µmol/24h) and proteinuria (mg/24h); plasma was obtained for urea (mg/dL). The results are presented as mean ±SEM, analyzed by one way ANOVA with Newman-Keuls post-test; significant for $P<0.05$.

Results: DM x CTL presented increased TBARS (293±19 x 81±2) and proteinuria (32 ±8 x 9±.7) and decreased NO (4±3 x 23±2); plasmatic urea was higher in DM (61±8 x 32±2). All P<0.05. After probiotic treatment in DM group there was a reduction of TBARS (247±17), proteinuria (16±2) and plasmatic urea (47±3) with increased NO (32±5), all P<0.05.

Some studies suggest the oxidative stress as well as the NO in the pathophysiology of diabetic nephropathy.

In fact, in this study, TBARS, an indicator of lipid peroxidation, was increased and NO was reduced in DM group. The use of probiotic attenuated these effects and, at the same time, reduced plasmatic urea in these animals.

Conclusions: Our study suggests that the early utilization of probiotic can protect against the DM deleterious effects on kidneys, by controlling the oxidative stress and recovering NO levels.

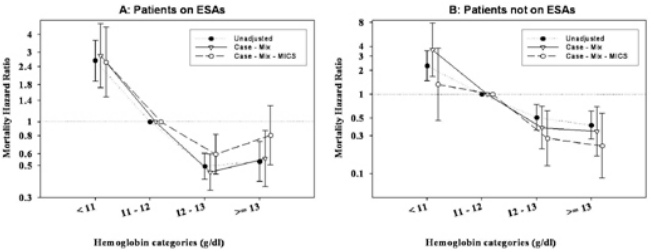
FR-PO1556

Hemoglobin Level and Survival in Hemodialysis Patients with and without Polycystic Kidney Disease: The Role of Administered Erythropoietin Anuja P. Shah,[1] Miklos Z. Molnar,[1,2] Lilia R. Lukowsky,[1] Joshua Zaritsky,[3] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh.[1,3] *[1]Harold Simmons Center, Torrance, CA; [2]Semmelweis University, Budapest, Hungary; [3]David Geffen School of Medicine at UCLA, Los Angeles, CA; [4]Salem VA Medical Center, Salem, VA.*

Background: Interventional trials indicate adverse outcomes when hemoglobin >13 g/dL is targeted in CKD patients who receive erythropoiesis stimulating agents (ESAs). It is not clear whether high achieved hemoglobin with minimal to no ESA such as in some polycystic kidney disease (PKD) patients (pts) is also associated with poor outcomes.

Methods: Survival models were examined to assess the hemoglobin-mortality association in a 6-year cohort of 110875 non-PKD and 2402 PKD hemodialysis pts across infrequent versus regular ESA therapy defined as ESA <25% of cohort time vs. otherwise, respectively.

Results: PKD and non-PKD pts were 58±13 & 62±15 years old & included 46% & 45% women. PKD pts had lower mortality than non-PKD within each hemoglobin level above 12 g/dL. In PKD pts, fully adjusted death HRs (95% confidence interval) of time-averaged hemoglobin increments <11.0, 12.0-<13.0, & ≥13.0 g/dL (reference: 11.0-<12.0 g/dL) for regular ESA therapy were 2.57 (1.48-4.48), 0.60 (0.43-0.82) & 0.81 (0.50-1.29); & for infrequent ESA therapy were 1.33 (0.47-3.78), 0.28 (0.13-0.61) & 0.22 (0.09-0.57), respectively.



In non-PKD pts, a similar trend towards higher death with hemoglobin>13g/dl was noticed with regular ESA dosing, although infrequent ESA therapy level did not modify the U-shaped Hb-death associations.

Conclusions: Achieved hemoglobin >13.0 g/dL exhibits a trend towards higher mortality in hemodialysis pts, which is not observed in PKD patient subgroup with infrequent ESA therapy. Whether ESA therapy leads to mortality of high hemoglobin warrants additional studies.

FR-PO1557

Sustained Erythropoiesis (6-30 Months) by the EPODURE Biopump in Patients with Chronic Kidney Disease: Further Results of Phase I/II Proof of Concept Trial Anatole Besarab,[1] Michal Elhalel,[2] Doron Schwartz,[3] Ehud Shoshani,[4] Andrew L. Pearlman,[4] Baruch Stern,[4] Philip Ng,[5] Allen R. Nissenson.[6] *[1]Henry Ford Hospital, Detroit, MI; [2]Hadassah Hospital, Jerusalem, Israel; [3]Sourasky Medical Center, Tel Aviv, Israel; [4]Medgenics, Inc, Misgav, Israel; [5]Baylor College of Medicine, Houston, TX; [6]DaVita, El Segundo, CA.*

Background: Sustained delivery of EPO maintaining levels 1-5 fold of normal could reduce risks of hemoglobin variability yet achieve recommended Hb targets, avoid supraphysiologic EPO concentrations, and increase patient compliance. The goal of EPODURE is to provide > 6 months of sustained EPO delivery from a single treatment using autologous 30mm x 2mm dermis core biopsies excised from the patient's skin under local anesthetic and converted in days into "biopump" EPO production units by introducing the EPO gene into cells of the intact explant. We reported (ASN 2010) the results in 12 patients treated up to 12 months with EPODURE Biopumps.

Methods: We now report results in 16 (8 EPO-naïve , 8 EPO-dependent) of a planned 18 CKD patients treated 6-30 months by 20, 40, or 60 IU/kg/day EPODURE implanted dose in an open label, dose ranging Phase I-II study in anemic CKD patients.

Results: SAFETY: No related SAEs were reported, EPO serum levels never exceeded 70 mU/ml, and all tests for anti-EPO antibodies were negative. Clinical feasibility was demonstrated, the brief procedure well tolerated.

EFFICACY: A single EPODURE administration elevated Hb levels for >3 mo in 14/16 and >6 mo in 10 /16, maintained Hb between 10-12 g/dl in 14/16 for >3 mo and 9/16 for >6mo, with longest >30 mo.

Where Hb declined it correlated with decreasing EPO levels, which peaked at 3 days post implantation. We suspect possible decline in EPO output in some biopumps, possibly due to suboptimal implantation. Improved implantation methods are now under study.

Conclusions: EPODURE is safe at doses up to 65 IU/kg/day is safe, a single administration in most patients can elevate Hb levels for 3-30 months and in appropriate dose maintain Hb in 10-12 g/dl range for up to 30 months. Further refinement in implantation methods to further increase average duration are underway.

FR-PO1558

Effect of Vitamin B12 and Folic Acid Supplementation on Erythropoietin Requirements To Maintain Hemoglobin Concentrations – Clinical and Economic Outcomes at 2 Years John P. Killen. *Department of Renal Medicine, Cairns Base Hospital, Cairns, Queensland, Australia.*

Background: The deficiency of vitamin B12 is known to cause erythropoietin resistance in hemodialysis (HD) patients. B12 is a middle molecule that is effectively removed by modern dialysis membranes, leading to an increased risk of B12 deficiency in HD patients. The aim of this prospective observational study was to assess the effect of intramuscular B12 and oral folic acid supplementation on hemoglobin concentrations and erythropoietin requirements in HD patients over 2 years.

Methods: All HD patients were assessed during the study period of January 2009 to January 2011 for erythropoietin requirement. Hemoglobin, B12, red cell folate and ferritin concentrations and transferrin saturation were also assessed. From January 2009 to January 2010 all HD patients with a plasma concentration of vitamin B12 less than 300 pmol/L were offered weekly injections of hydroxocobalamin 1000 micrograms (Neo-B12®, Hospira Australia) intramuscularly for 3 weeks and oral folic acid supplementation 0.5 mg daily for the course of the study. The B12 treatment was repeated if levels again fell below 300 pmol/L during the study period. No change in intravenous iron protocols occured during the study. Exclusion criteria included transplantation, change to peritoneal dialysis, death and loss to follow up during the study period.

Results: 48 HD patients were eligible. Average B12 concentration rose from 216 to 487 pmol/L (p<0.0001) and red cell folate from 928 nmol/L to 1669 nmol/L (p<0.0001). Average erythropoietin usage reduced from 11300 IU/week to 6300 IU/week (p<0.0005) to maintain an average haemoglobin of 116 g/L. The average transferrin saturation did not change during the study. The average ferritin rose from 670 to 880 microg/L.

Conclusions: In this 2 year observational study, intramuscular vitamin B12 with oral folic acid supplementation reduced the average erythopoitin requirements in HD patients with a serum B12 concentration less than 300 pmol/L by 44% during the study period without a significant change in the average hemoglobin concentration. This translates to an annual cost saving of approximately $AUD4600 per HD patient in this group.

FR-PO1559

An Open, Randomized, Parallel Group, Multi-Center Study on the Prognosis of Hemodialysis Patients in Anemia Treatment by Combination Therapy with Iron and Vitamin C and Erythropoietin (ACTIVE Study)
Takahiro Kuragano, Takeshi Nakanishi. *Hyogo College of Medicine, Department of Internal Medicine, Division of Kidney and Dialysis, Nishinomiya, Hyogo, Japan.*

Background: Clinical trials demonstrated that higher levels of hemoglobin (Hb) do not necessarily translate into improved mortality patients with chronic kidney disease. As such, there has been an increasing focus on individualized therapy in the renal anemia treatment. We evaluated the effect of newly proposed protocol for anemia therapy on adverse events in patients undergoing maintenance hemodialysis (MHD).

Methods: Study design: Randomized parallel group multi-center study. Study period: 3 years. Patients: 266 MHD patients. Intervention group: For obtaining target Hb (10≤Hb<12) and ferritin (300>), doses of erythropoietin (EPO), iron and vitamin C (VC) were changed every month based on ferritin and Hb levels according to the ACTIVE protocol. Non-intervention group: Attending physician determined the doses of EPO and iron. Primary outcomes: Survival rate, hospitalization rate, infection and cardiovascular disease (CVD). Secondary outcomes: Comparison of Hb, ferritin, TSAT, and dose of EPO between the groups.

Results: A total of 45 composite events occurred (4 deaths, 31 hospitalizations, 3 infections, 7 CVD) during the period. There was no significant difference between the groups in the frequency of adverse events. The percentage of the patients who could maintain target Hb (78±6% vs. 57±13%, p<0.001) and ferritin (72±12% vs. 59±14%, p=0.048) levels was significantly higher in the intervention group than in the non-intervention group. The frequency of adverse events was significantly lower (p=0.023, Hazard risk: 0.296) in patients maintaining the target Hb (≥75%) during the period. In the intervention group, Hb, TSAT levels, and dose of EPO of the intervention group were significantly higher, and ferritin level was lower than that of the non-intervention group.

Conclusions: The ACTIVE protocol modifying the doses of EPO, iron and VC according to monthly Hb and ferritin levels of individual MHD patient could stabilize Hb and ferritin levels within the target range, which in turn could contribute to the lower frequency of adverse events.

FR-PO1560

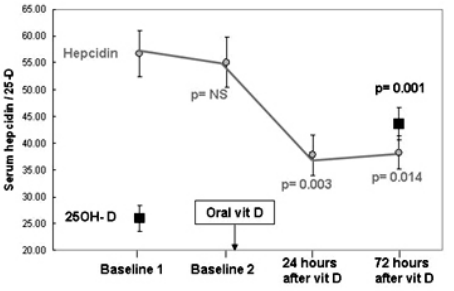
Vitamin D as a New Regulator of Iron Metabolism: Vitamin D Suppresses Hepcidin In Vitro and In Vivo
Justine Bacchetta,[1] Joshua Zaritsky,[1] Thomas S. Lisse,[1] Jessica L. Sea,[1] Rene Chun,[1] Elizabeta Nemeth,[1] Tomas Ganz,[1] Mark E. Westerman,[2] Isidro B. Salusky,[1] Martin Hewison.[1] *[1]David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Intrinsic LifeSciences, La Jolla, CA.*

Background: Recent reports have shown improved hemoglobin levels and decreased ESA doses with vitamin D repletion in CKD patients. We examined the effects of vitamin D on hepcidin (Hep), the iron-regulatory peptide hormone responsible for iron sequestration and anemia by posttranslational downregulation of ferroportin (Fp), the sole known exporter of iron from cells to the systemic circulation. In CKD, decreased renal clearance and inflammation increase Hep levels.

Methods: We utilized rtPCR techniques to assess Hep mRNA production and immunohistochemistry to stain for FP in peripheral blood mononuclear cells (PBMC) isolated from healthy donors and in monocytes (PDM) isolated from the dialysate of patients undergoing peritoneal dialysis.

Results: When treated with active 1,25-vitamin D (5 nM) or with precursor 25OH-vitamin D (100 nM) for 6 hours, PBMC and PDM showed decreased expression of Hep (fig). Chromatin immunoprecipitation revealed decreased recruitment of the RNA polymerase II within the promoter of the human Hep gene after treatment with 1,25D, pointing to direct effects of 1,25D on Hep transcription. Immunohistochemistry showed that PBMC and PDM expressed Fp, with membrane enhancement after treatment with 1,25D. Finally we observed a 50% decrease in serum hepcidin (ELISA) which persisted for 72 hours in 7 healthy human subjects after a single oral dose of vitamin D (100,000 IU).

Studied cells	Treatment	Fold-change hepcidin mRNA	P compared to vehicle
PBMC	25-D; 100 nM	0.87	NS
PBMC	1-25 D; 0.5 nM	0.42	< 0.05
PBMC	1-25 D; 5 nM	0.19	< 0.05
PD cells	25-D; 100 nM	0.57	< 0.05
PD cells	1-25 D; 5 nM	0.52	< 0.05



Conclusions: For the first time, these results in vitro and in vivo indicate that vitamin D is a potent suppressor of Hep in humans. These findings provide a clinically relevant mechanism by which vitamin D supplementation can improve anemia management in CKD.

Funding: NIDDK Support, Private Foundation Support

FR-PO1561

Early L-Carnitine Treatment in Incident Hemodialysis Patients: Randomized, Double Blind, Placebo-Controlled Trial. CARNIDIAL NCT 00322322
Lucile Mercadal,[1] Mathieu Coudert,[2] Anne Vassault,[3] Laurence Pieroni,[3] Messaoud Ouziala,[4] Hélène De Préneuf,[5] Aude Servais,[6] Nader Bassilios,[7] Ubald Assogba,[8] Gilbert Deray.[1] *[1]Nephrology, AP-HP, Pitie Salpetriere, Paris, France; [2]Biostatistics, AP-HP; [3]Biology, AP-HP; [4]CMC Pantin; [5]AURA, Paris; [6]Nephrology, AP-HP, Necker; [7]Clinique de Turin; [8]Clinique des Mousseaux.*

Background: Carnitine level prematurely decreases with hemodialysis vintage. A supplementation has been recommended in hemodialysis patients with carnitine deficiency and erythropoietin (rHuEPO) hypo responsiveness. Our hypothesis was that an early L-carnitine (LC) supplementation before the occurrence of a carnitine deficiency, could improve rHuEPO responsiveness.

Methods: Patients hemodialyzed for less than 6-months were randomized to receive either placebo or 1 gr LC after each dialysis session for a 1 year inclusion period. Primary outcome compared rHuEPO resistance index (RI) defined as weekly rHuEPO (UI/kg body weight) / hemoglobin level (g/dL) between groups. Study was double blinded for treatment and carnitine level.

Results: 92 patients hemodialyzed since 39 ± 27 days were randomized. At baseline, LC group had a higher RI partly explained by a higher CRP and a lower albuminemia in this group. Total plasmatic carnitine levels rose from 79 ± 51 to 258 ± 137 µmol/L at month 12 in the LC group whereas it fell from 68 ± 25 to 53 ± 24 µmol/L in the placebo group (x 0.77 placebo group, x 3.01 LC group; p<0.0001). Difference reached statistical significance at month 3. Free/total carnitine ratio was similar between groups and didn't vary during the study period(0.78 ± 0.09 to 0.77 ± 0.09 placebo group; 0.76 ± 0.10 to 0.73 ± 0.08 LC group). RI steadily improved in both groups from 15.8 ± 11.3 to 9.5 ± 5.8 UI/kg per g/dL in placebo group, and from 20.6 ± 12.8 to 15.6 ± 15.6 UI/kg per g/dL in the LC group (baseline-month12 difference between groups, ns). After adjustment for baseline characteristics, both groups had similar RI during the study period.

Conclusions: We confirm a 30% decline of carnitine level during the first dialysis year. An early treatment by L-carnitine does not improve rHuEPO responsiveness.

Novel Approaches To Treat Anemia in Chronic Kidney Disease
Jodie L. Babitt,[1] Qifang Wu,[1] Chia Chi Sun,[1] Valentina Vaja,[1] Delphine Meynard,[1] Igor Theurl,[2] Guenter Weiss,[2] Herbert Y. Lin.[1] *[1]Program in Membrane Biology, Nephrology Division and Center for Systems Biology, Massachusetts General Hospital, Harvard Medical School, Boston, MA; [2]Department of Internal Medicine, Clinical Immunology and Infectious Diseases, Medical University, Innsbruck, Austria.*

Background: Anemia is prevalent in patients with chronic kidney disease (CKD). An excess of the iron regulatory hormone hepcidin may contribute to the anemia of CKD by limiting iron availability for red blood cell production. Hepcidin decreases iron absorption from the diet and promotes iron sequestration in macrophage stores by downregulating the iron exporter ferroportin. Hepcidin is thought to accumulate in CKD patients due to reduced renal clearance and inflammation.

We have demonstrated a central role for the bone morphogenetic protein (BMP) signaling pathway, via the ligand BMP6 and the co-receptor hemojuvelin (HJV), in regulating hepcidin expression and systemic iron balance. While cell-surface HJV acts as a BMP co-receptor to increase hepcidin, soluble HJV (sHJV) inhibits BMP signaling

and hepcidin expression, presumably by sequestering BMP ligands. Importantly, proinflammatory cytokines require BMP signaling to upregulate hepcidin expression, suggesting that BMP inhibitors may be promising candidates as hepcidin lowering agents to treat anemia of inflammation, including anemia of CKD.

Methods: Here, we investigate the selectivity of sHJV as a BMP inhibitor by quantitating its binding affinity for various BMP ligands using Surface Plasmon Resonance, and we test the effects of BMP inhibitors in 3 rodent anemia models.

Results: We show that sHJV has the highest binding affinity for BMP6, while it has lower affinity for BMP7 and does not bind BMP9. sHJV and the small molecule BMP inhibitor LDN-193189 lower hepcidin expression, mobilize macrophage iron stores, and improve anemia in a PG-APS rat model of anemia of inflammation and a genetic model of anemia due to hepcidin excess (Tmprss6-/- mice). Finally, we investigate the use of these BMP inhibitors in an adenine rat model of anemia of CKD.

Conclusions: Together, our data suggest the possible utility of BMP inhibitors as hepcidin lowering agents to treat anemia of CKD.

Impact of Cholecalciferol Repletion on Erythropoietin Requirements in Vitamin D-Deficient Hemodialysis Patients: Pilot Data from a Randomized Controlled Trial Anita Mehrotra, Maria Krassilnikova, Brian D. Radbill, Peter S. Heeger. *Medicine, Mount Sinai School of Medicine, New York, NY.*

Background: Vitamin D deficiency is common in hemodialysis patients. Uncontrolled studies suggest that correction of Vit D deficiency with ergocalciferol (D2), cholecalciferol (D3), and calcitriol is associated with decreased erythropoietin (EPO) requirements.

Methods: To better characterize the relationship between Vit D deficiency/repletion and EPO requirements, we examined the impact of D3 repletion on EPO requirements in 79 Vit D-deficient (25OH-D <25 ng/mL) hemodialysis patients randomized to receive D3 (n=51) or standard of care (no repletion, n=28) in a 2:1 ratio. Patients randomized to treatment with D3 received 50,000 IU/wk to a goal 25OH-D of >35ng/mL, followed by 10,000 IU/wk. Changes in 25OH-D, hemoglobin (Hb), and EPO requirements were assessed at 3 months. EPO (Darbepoetin) doses were adjusted by the nursing staff as per the dialysis unit protocol (for target Hb 10-12 g/dL) independent of D3 administration.

Results: Baseline demographic characteristics (age, race, sex) were similar between both groups, as were baseline Vit D levels (median 13.5 in treatment group vs 13.1 in control group, p=0.623), baseline Hb (mean Hb 11.8 g/dL in treatment group vs 11.4 g/dL in control group, p=0.155), and baseline EPO requirements (median Darbepoetin dose 40 units/wk in treatment group vs 50 units/wk in control group, p=0.262). 45 patients had 3 month follow-up data available. Patients randomized to D3 treatment had a rise in 25OH-D at 3 months (11.9 to 44.1 ng/mL, p<0.001, n=30), with a corresponding fall in EPO requirements (50.00 to 40.32 units/wk, p=0.029, n=30) despite no change in Hb (11.9 to 11.5 g/dL, p=0.180, n=30). No change in Vit D level, Hb, or EPO dose was observed in control patients at 3 months (n=15). Patients randomized to D3 did not experience hypercalcemia or other adverse events.

Conclusions: Our preliminary data from this ongoing randomized controlled trial suggest that treatment of Vit D deficient dialysis patients with D3 is safe, effective, and may result in lower EPO requirements. If these results are confirmed, the cost-savings may be significant.

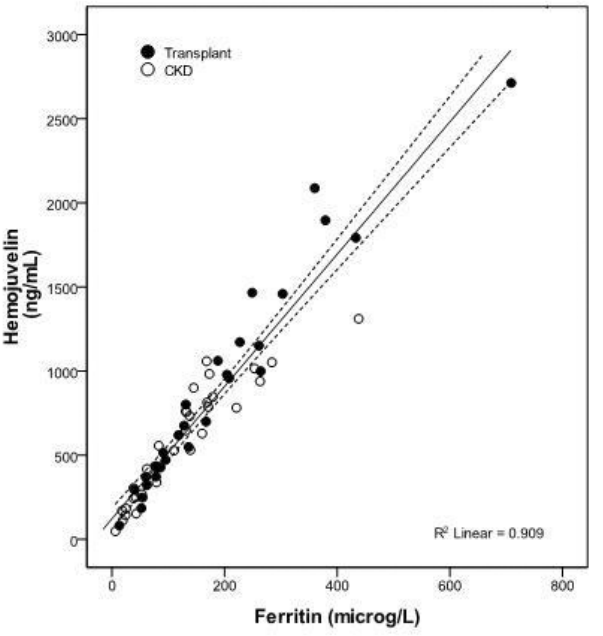
FR-PO1564

Serum Hemojuvelin and Ferritin Levels Are Tightly Correlated in CKD Patients Adam Rumjon,[1] Pantelis Sarafidis,[1] Jolanta Malyszko,[2] Iain C. Macdougall.[1] *[1]King's College Hospital; [2]Medical Academy, Bialystok.*

Background: Hemojuvelin (HJV) is a recently discovered protein involved in the cellular regulation of hepcidin. Both HJV and hepcidin are emerging as crucial players in the complex biology of iron homeostasis. It is known that membrane-bound and soluble forms of HJV exist, but their exact actions remain uncertain. Hepcidin levels are known to be elevated in CKD and dialysis patients, but this is the first report of serum HJV levels in a renal population.

Methods: 93 patients were studied (31 HD, 31 transplant, and 31 CKD; age- and gender-matched). Blood samples were taken for measurement of serum HJV, hepcidin, ferritin, IL-6, CRP, and standard hematological parameters. HJV levels were measured using an ELISA (USCN Life Science Inc, Wuhan, China) by an operator blinded to the clinical details. Hepcidin levels were determined by mass spectrometry, using hepcidin-25 as an internal standard.

Results: HJV levels (ng/ml) were highest in HD (2619±1445) followed by transplant (870±638), and then CKD patients (590±344). HJV and hepcidin were moderately correlated in CKD (r=0.641, p<0.001) and transplant (r=0.569, p=0.001), but not in HD patients (r=0.112, p=0.570). The correlation of HJV with ferritin was very tight in all 3 groups; CKD (r=0.918, p<0.001), transplant (r=0.969, p<0.001), HD (r=0.794, p<0.001). A correlation between HJV and Hb was seen only in transplant patients (r=-0.407, p=0.028); HJV did not correlate with IL-6 or CRP.



Conclusions: This is the first time that serum hemojuvelin levels have been examined in a CKD population. The tight correlation between HJV and ferritin was unexpected, but consistent across all 3 sub-populations studied. Although a role for HJV in the cellular regulation of hepcidin has been established, clinical data are lacking. The results presented here suggest that this is worthy of further study.

FR-PO1565

Similar Mortality in Hemodialysis Patients with Hemoglobin 9 to 9.9 Versus 10 to 10.9 A. Gul,[1] O. Myers,[1] Bruce L. Horowitz,[1] Edward J. Bedrick,[1] Antonia M. Harford,[1] Philip Zager.[1,2] *[1]Internal Medicine, UNMHSC, Albuquerque, NM; [2]Dialysis Clinic, Inc., Albuquerque, NM.*

Background: High epoetin (EPO) doses have been associated with increased mortality in hemodialysis (HD) patients. This finding, in conjunction, with the 'bundle', have led opinion leaders to recommend reducing the target hemoglobin (Hb) from 10-12 to 9-11. However, prior to implementing a randomized controlled trial to assess the safety and efficacy of the proposed change, a preliminary comparative effectiveness study comparing outcomes in patients with Hb of 9-9.9 versus 10-10.9 is needed. The present study explored the hypothesis that all-cause mortality is similar in patients with Hb levels of 9-9.9 versus 10-10.9.

Methods: We studied an incident cohort of 8365 patients, who began HD in DCI facilities between 2006-2009 and survived ≥150 days. We used Cox models to assess the relationship between the most recent Hb value, excluding a 30-day lag, and mortality. Baseline covariates included age, sex, race, cause of ESRD and vintage. Time-varying covariates included pre-dialysis systolic blood pressure, albumin, creatinine, Kt/V, TSAT, ferritin, BMI, vascular access and iron dose.

Results: There were 1867 deaths. Mortality in patients with Hb 9.0–9.9 (HR = 0.97; 95% CI 0.79-1.19) was similar to the referent group (Hb 10.0-10.9). Mortality was lower among patients with Hb ≥ 11-11.9 (HR 0.76; 95% CI 0.67-0.87) versus the referent group. Conversely, mortality tended to be higher in patients with Hb <9.0 versus the referent group (HR = 1.20; 95% CI 0.92-1.57). In a sensitivity analysis, addition of EPO dose to the model did not significantly change the hazard ratios. EPO doses were highest in patients with Hb values < 9.0. EPO doses ≥20,000 units/week, were associated with increased mortality versus the EPO referent group (8,000- 12,499 units/week) (HR = 1.18 95% CI 1.02 – 1.36).

Conclusions: Mortality among patients with Hb 9-9.9 was similar to that in the referent group (Hb 10-10.9). These observational data suggest that it may be safe and feasible to conduct a pilot study comparing Hb targets 9-11 versus 10-12. EPO resistance may be a significant risk factor for mortality.

FR-PO1566

TSAT and Serum Ferritin Increases Observed in Ferric Citrate Clinical Trials May Lead to Dialysis Cost Savings Jaime Rubin,[1] T. Christopher Bond,[1] Steven Wang,[1] Robert M. Niecestro,[2] Enrique Poradosu,[2] Tracy Jack Mayne.[1] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Keryx Biopharmaceuticals, New York, NY.*

Background: Ferric citrate, a novel, investigational phosphate binder for the treatment of hyperphosphatemia in dialysis patients (pts), has been shown in clinical trials to increase serum ferritin (SF) and saturated transferrin (TSAT) and reduce erythropoietin stimulating agents (ESAs) and intravenous (IV) iron (Fe) use. We developed a cost-offset model

quantifying potential cost-savings associated with ESA and Fe reductions observed in moderate (M)/high (H) ESA use-pts experiencing equivalent increases in Fe markers.

Methods: We constructed a cost-offset model of M(4500 to <9000U/session) and H(≥9000U/session) ESA users over a 2 mo time horizon from a payor perspective. Unit costs for phosphate binders (lanthanum carbonate, sevelamer, calcium acetate), ESAs and IV Fe were derived from 2011 published sources. Monthly ESA (M=10,400U; H=27,480U) and Fe (M=132mg; H=61mg) dose reductions resulting from concurrent TSAT (≥ 10%) and SF (15-25%) increases were derived from a DaVita database. We assumed equal phosphorus outcomes and price for ferric citrate and comparator binders.

Results: Given equivalent phosphorus outcomes and price, ferric citrate would potentially generate monthly cost savings of M:$123 and H:$315 due to reductions in ESA (M:$102; H:$268) and IV Fe (M$22; H:$47); reducing ESA costs by 15% and 21% per mo, respectively. Ferric citrate would potentially save $630/high-use pt/2 mo. For the average dialysis clinic with 80 pts and 50% M/H ESA users, the monthly savings would be $17,500 for these pts. When the expected per-session reduction in ESA and IV Fe dose was reduced by half, the expected cost savings would be reduced proportionally.

Conclusions: These results indicate that the rises in TSAT and SF observed with the investigational drug ferric citrate in clinical trials may produce significant reductions in monthly ESA and IV Fe costs, generating meaningful savings under the Medicare bundled dialysis payment. Sustained rises in TSAT and SF over a longer duration would potentially lead to considerable annual cost-savings.

The Impact of Frequent In-Center Versus Conventional Hemodialysis on Anemia: The Frequent Hemodialysis Network Trial

Daniel B. Ornt,[1] Alan S. Kliger,[2] Rita Suri,[3] Mohamad Akram Rashid,[4] Anjay Rastogi,[4] Manjula Kurella Tamura,[6] Brett Larive,[7] John T. Daugirdas,[8] Tom H. Greene,[9] Nathan W. Levin,[10] The FHN Trial Group.[11] *[1]CaseWestern Reserve U.; [2]St. Raphael and Yale U.; [3]U. of Western Ontario; [4]UCLA; [5]UCLA; [6]Stanford U.; [7]Cleveland Clinic; [8]U. of Illinois; [9]U. Utah; [10]Renal Research In.; [11]NIDDK.*

Background: Management of anemia in hemodialysis (HD) patients remains complex and costly. The Frequent HD Network (FHN) Daily prospective, randomized trial demonstrated significantly reduced left ventricular hypertrophy and improved physical-health composite scores for patients receiving 1 year of 6 times/week HD (6X) compared to 3 times (3X). We also hypothesized that 6X HD would improve management by reducing use of erythropoietin-stimulating agents (ESA) (pre-specified main secondary outcome) and/or improving hemoglobin (Hb) levels.

Methods: Hb was measured monthly and other anemia related measures (iron (Fe), transferrin saturation, and ferritin), were obtained at baseline (B) and follow-up months 4, 8 and 12. ESA and IV Fe administered were reported as total 4-week dose. We report treatment comparisons of changes from B to month 12 obtained using mixed effects models, with log transformations applied to ESA and IV Fe.

Results: Hb increased slightly in the 6X (n=125) group vs. 3X (n=120) (0.3; CI 0.0 to 0.6, p=.02), but both groups had mean Hb levels in the appropriate clinical range at month 12 (11.7 to 12.0 mg/dL). Geometric mean ESA-equivalent dose declined 16% more in the 6X group vs. 3X, but this difference was not statistically significant (95% CI: 35% decrease to 8% increase, p = 0.18). The change in mean ESA/Hb also did not differ significantly between the 6X and 3X groups (19% greater decrease in 6x, 95% CI: 38% decrease to 6% increase, p = 0.12). There were no significant differences in IV Fe or Fe stores between the groups.

Conclusions: In the FHN Daily trial, the frequent HD intervention had no significant effect on either ESA or ESA/Hb. Consistent with some observational studies; the 6X intervention did lead to a small increase in Hb level. The implications of this finding remain under investigation.

FR-PO1568

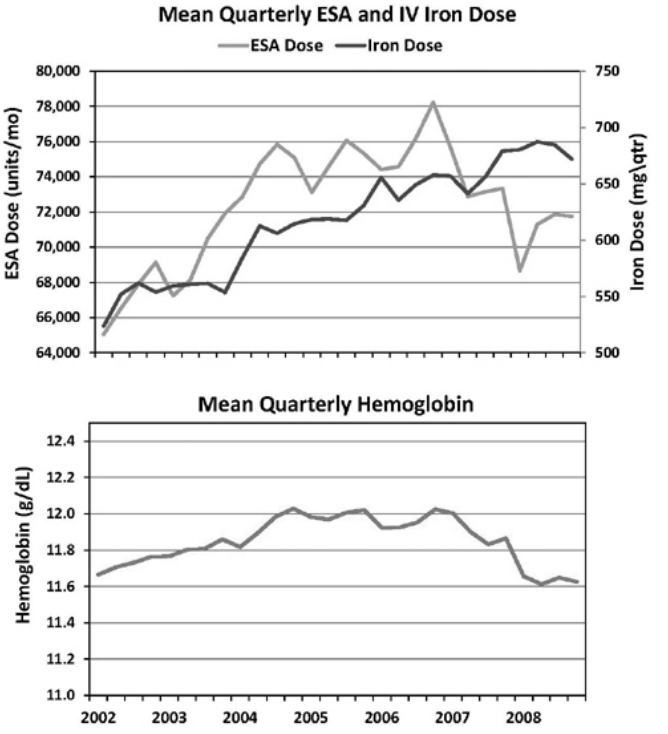
Patterns of Anemia Management in U.S. Hemodialysis Patients (2002-2008)

Janet K. Freburger,[1] Leslie J. Ng,[2] Brian D. Bradbury,[2] Abhijit V. Kshirsagar,[1] M. Alan Brookhart.[1] *[1]University of North Carolina, Chapel Hill, NC; [2]Observational Research, Amgen, Inc., Thousand Oaks, CA.*

Background: Current data on patterns of anemia management, particularly in regard to iron use, are lacking in the hemodialysis (HD) population. Such information will further our understanding of changes in anemia management in response to changing clinical guidelines and safety concerns raised from high hemoglobin (Hb) target studies using erythropoiesis-stimulating agent (ESA) therapy; and will provide baseline data for future studies examining the effect of the new dialysis bundled payment system on anemia management.

Methods: USRDS data (2002-2008) on prevalent, Medicare HD patients receiving ESA therapy were examined. For each patient, receipt of intravenous (IV) iron, total IV iron dose, total ESA dose/month, and Hb values were determined. These data were then summarized by calendar quarter (percentage or mean) and plotted for the entire sample and by demographic (sex, age, race) and clinical (cause of ESRD, dialysis vintage) subgroups.

Results: Among ~250,000 HD patients/year, quarterly iron use increased from approximately 65% in 2002 (Q1) to 78% in the 2008 (Q4). Mean quarterly iron dose increased from approximately 525 mg in 2002 to 675 mg in 2008. Mean quarterly ESA dose/month increased from 2002 to 2006 and then began to decline. Similar patterns were observed for Hb values.



The same patterns in iron and ESA doses and Hb were observed across demographic and clinical subgroups, but there were important differences between subgroups in the amount of iron and ESA received. These differences were most notable among black versus white and shorter versus longer dialysis vintage subgroups.

Conclusions: Anemia management patterns have changed markedly between 2002-2008 with a steady increase in IV iron use even after declines in ESA dose and Hb. The clinical impact of these changes need further study.

Funding: Pharmaceutical Company Support

FR-PO1569

Treatment with Hemodiafiltration (HDF) Improves ESA Responsiveness over 12 Months in Patients with High ESA Resistance without a Concomitant Reduction in Predialysis Hepcidin-25 (Hep25) Levels

Neelke C. Van Der Weerd,[1] Muriel Grooteman,[1] Peter J. Blankestijn,[2] Michiel Bots,[2] Marinus A. Van Den Dorpel,[3] Claire H. Den Hoedt,[3] Albert H. Mazairac,[2] Menso Nube,[1] Erik L. Penne,[2] Jack F. Wetzels,[4] Dorine W. Swinkels,[4] Pieter M. Ter Wee.[1] *[1]VU Medical Center, Amsterdam, Netherlands; [2]University Medical Center, Utrecht, Netherlands; [3]Maasstad Hospital, Rotterdam, Netherlands; [4]Radboud University Medical Center, Nijmegen, Netherlands.*

Background: In chronic Hemodialysis (HD) patients with high resistance to erythropoiesis stimulating agents (ESA; expressed as an ESA index [ESA dose/weight/Hct/wk]), treatment with online HDF may improve ESA responsiveness. One of the possible mechanisms is lowering of Hep25 by HDF. The aim of this analysis was to investigate whether the decreased ESA resistance in ESA resistant patients treated with online HDF is correlated with a change in predialysis Hep25 levels, as compared to those treated with conventional low-flux HD.

Methods: Baseline and 12 months' data from 82 prevalent HD patients in the highest tertile of ESA resistance who were included in the randomized controlled CONvective TRAnsport STudy (CONTRAST; NCT00205556), were analyzed (50% male, age 63.2±13.7 [mean±SD]). Predialysis levels of Hep25 were measured with mass spectrometry.

Results: In the HDF group (n=40), both the ESA index (-0.27 DDD/kg/Hct/wk [-0.38 to -0.15]; mean [95%CI]) and the soluble transferrin receptor (sTfR, -0.33 mg/L [-0.56 to -0.10]) decreased significantly over 12 months, with no changes in the HD group. Cumulative doses of iron supplements and ferritin were similar in both groups. In the HDF group, the transferrin saturation ratio increased over time with 0.43 (0.06 to 0.80). Hep25 increased non-significantly in both groups (HDF: 4.3 mg/L [-0.1 to 8.7]); HD: 1.4 [-3.9 to 6.6]; p=0.40). The Hep25/sTfR ratio increased in the HDF group (p=0.02) and remained unaltered in HD patients.

Conclusions: These data suggest either that ESA resistance is not primarily mediated by Hep25, or that treatment with HDF results in a temporarily decrease in Hep25 levels resulting in improved iron availability, ultimately leading to a new balance between Hep25 and sTfR .

FR-PO1570

Rate of Hemoglobin (Hb) Decline Following Peginesatide Dose Interruption

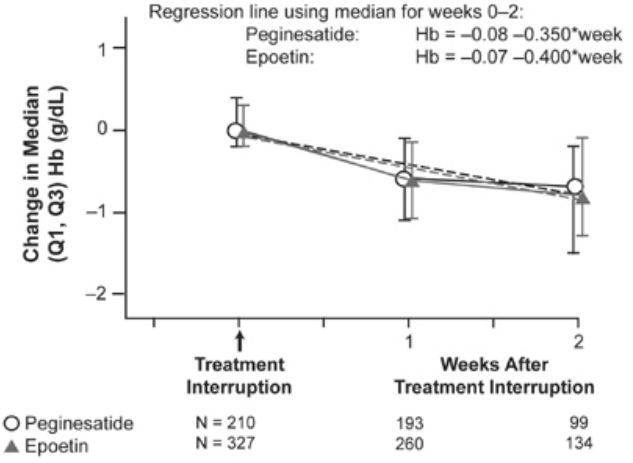
Anatole Besarab,[1] Francesco Locatelli,[1] Steven Fishbane,[1] Nathan W. Levin,[1] Carol Francisco,[2] Hong-Ye Gao,[2] Vandana S. Mathur,[2] Alex Yang,[2] Anne-Marie Duliege,[2] Krishna R. Polu.[2] *[1]AFX-01-12 and -14 Peginesatide Study Groups; [2]Affymax, Inc., Palo Alto, CA.*

Background: The rate of Hb decline after ESA dose interruption is likely due to intrinsic factors such as RBC lifespan rather than the effect of the ESA used on erythropoiesis (Locatelli, 2001). Similar rates of Hb decline are reported for various ESAs (Barany, 2007), despite differences in pharmacokinetics. Peginesatide (Hematide™) is a synthetic, PEGylated, investigational, peptide-based ESA that is designed to specifically stimulate the erythropoietin receptor. This analysis characterizes Hb decline after ESA dose interruption in patients on dialysis.

Methods: Data were pooled from two phase 3, randomized, active-controlled, open-label trials (N=1608) assessing safety and efficacy of peginesatide (once monthly) compared with epoetin alfa/beta (epoetin; 1-3 times weekly) in hemodialysis patients (EMERALD 1 and 2). Doses were titrated to Hb levels of 10-12 g/dL. Protocol-specified thresholds for dose interruption (delay by ≥1 week) due to elevated Hb levels were: Hb ≥13.0 g/dL for peginesatide and ≥12.5 g/dL for epoetin. The rate of Hb decline was estimated from linear regression after a dose interruption occurred.

Results: This analysis included 210 of 1066 patients on peginesatide and 327 of 542 patients on epoetin who had ≥1 protocol-specified dose interruption (median Hb = 13.3 g/dL vs 12.9 g/dL at time of dose hold, respectively). The rate of median Hb change was -0.35 g/dL/wk for peginesatide and -0.40 g/dL/wk for epoetin (Figure). Mean time from dose interruption until resumed dosing was ~3 wks for both groups (>75% of patients reinitiated the ESA within 4 wks).

Figure. Change in Median Hb After First Dose Interruption



Conclusions: Rates of Hb decline after dose interruption were similar for peginesatide and epoetin.

Funding: Pharmaceutical Company Support

FR-PO1571

Safety Results from Two Phase 3 Studies of Peginesatide Treatment for Anemia in Hemodialysis (HD) Patients

Francesco Locatelli,[1] Steven Fishbane,[1] Iain C. Macdougall,[1] Andrzej Wiecek,[1] Adrian Constantin Covic,[1] Hina Patel,[2] Daniel S. Cooper,[2] Helen Tang,[2] Minjia Chen,[2] Anne-Marie Duliege,[2] Martha Mayo,[2] Krishna R. Polu.[2] *[1]AFX-01-12 and -14 Peginesatide Study Groups; [2]Affymax, Inc, Palo Alto, CA.*

Background: Peginesatide (Hematide™) is a synthetic, PEGylated, investigational, peptide-based erythropoiesis-stimulating agent (ESA) that acts via stimulation of the erythropoietin receptor. Key adverse events (AEs) including those associated with the ESA class in HD patients are reported here.

Methods: Data were pooled from two phase 3, randomized, active-controlled, open-label trials evaluating the safety and efficacy of peginesatide (once monthly) compared with epoetin alfa/beta (epoetin; 1-3 times weekly) in HD patients (EMERALD 1 and 2). A primary analysis of cardiovascular (CV) events adjudicated by an independent Event Review Committee showed similar rates in the peginesatide and epoetin groups; here nonadjudicated CV events and ESA class AEs were evaluated.

Results: A similar number of patients in the peginesatide and epoetin groups had AEs (94.6% vs 93.0%), serious AEs (53.7% vs 57.0%), nonadjudicated CV AEs, and ESA class AEs (Table). Adjusted on-study mortality rates were also similar for the two groups (8.7 vs 9.5 deaths per 100 patient follow-up years). No clinically relevant differences in laboratory parameters, including platelet counts, or blood pressure levels were observed between treatment groups.

Event, n (%)	Peginesatide (n = 1066)	Epoetin (n = 542)
Cerebrovascular Disorders	45 (4.2%)	40 (7.4%)
Cardiac Failure	229 (21.5%)	116 (21.4%)
Cardiac Arrhythmias	210 (19.7%)	123 (22.7%)
Ischemic Heart Disease*	118 (11.1%)	67 (12.4%)
Hypertension	208 (19.5%)	101 (18.6%)
Thromboembolic Events		
Arterial	71 (6.7%)	48 (8.9%)
Venous	21 (2.0%)	9 (1.7%)
Vascular access complications	193 (18.1%)	107 (19.7%)
Convulsions	23 (2.2%)	11 (2.0%)
Infusion/Injection-related Reactions	32 (3.0%)	11 (2.0%)
Gastrointestinal Hemorrhage	71 (6.7%)	47 (8.7%)
Malignancy	41 (3.8%)	23 (4.2%)

*Includes myocardial infarction and unstable angina.

Conclusions: Once-monthly peginesatide had similar frequencies of AEs including CV and ESA class AEs compared to epoetin in HD patients.

FR-PO1572

Greater Rise in Percent Hemoglobin < 10 g/dL among Black Patients with Implementation of the New US Bundled Dialysis Payment System: Initial Results from the DOPPS Practice Monitor

Ronald L. Pisoni,[1] Douglas S. Fuller,[1] Justin M. Albert,[1] Brian Bieber,[1] Brenda W. Gillespie,[2] Hal Morgenstern,[2] Friedrich K. Port,[1] Francesca Tentori,[1] Marc Turenne,[1] Bruce M. Robinson.[1,2] *[1]Arbor Res Collab for Hlth, Ann Arbor, MI; [2]Univ of MI, Ann Arbor, MI.*

Background: A new bundled Medicare ESRD prospective payment system (PPS) for dialysis services was implemented in the U.S. in Jan 2011. The US Government Accountability Office (GAO) urged prompt monitoring of the PPS, cautioning that some patients may be adversely affected by provider responses to the PPS. We report initial trends in anemia management in blacks vs. non-black with PPS implementation.

Methods: The Dialysis Outcomes and Practice Patterns Study (DOPPS) launched the nationally representative DOPPS Practice Monitor (DPM; www.dopps.org/dpm) for timely, public reporting of US hemodialysis (HD) practice trends during implementation of the PPS and quality incentive program (QIP). Linear regression analyses were based on monthly cross-sectional data from US dialysis units between July 2010 to Feb 2011.

Results: During the 8 months, mean Hgb level fell by 0.4 g/dL in blacks vs 0.1 g/dL in other patients (p=0.01). The proportion of patients with Hgb <10 g/dL rose from 6.6% to 11.3% in blacks vs little change in other patients (p=0.02). Mean EPO dose declined similarly among black vs other patients (-204 vs -164 U/mo; p=0.76). The proportion of patients prescribed IV iron use rose 1.3-1.5%/mo in both groups; mean IV iron dose remained steady and did not differ by race. >98% of EPO was given by IV during each month.

Distribution of monthly anemia measurements in US-DOPPS

Month	Mean Hgb (g/dL)		Hgb <10 g/dL (%)		IV iron use (%)		IV epoetin (U/wk)	
	Black	Non-Black	Black	Non-Black	Black	Non-Black	Black	Non-Black
Mean N	854	1,849	854	1,849	642	1,373	691	1,393
Jul 2010	11.66	11.46	6.6	9.2	73.8	72.9	18,815	16,495
Aug 2010	11.61	11.46	8.0	8.5	75.1	73.5	18,802	16,841
Sep 2010	11.46	11.51	9.0	8.2	72.4	74.8	19,133	17,651
Oct 2010	11.48	11.47	10.1	9.0	74.1	74.4	17,946	16,204
Nov 2010	11.45	11.44	8.5	8.4	79.5	77.5	17,719	15,372
Dec 2010	11.35	11.44	9.2	9.4	78.0	78.9	17,285	15,320
Jan 2011	11.28	11.37	10.1	8.3	80.3	82.1	17,828	16,034
Feb 2011	11.22	11.36	11.3	8.4	83.0	83.1	17,805	16,207

Hgb=based on single measurement during month; IV iron use=any IV iron use during the 3-month period ending with the month shown; IV epoetin=actual EPO administered over the prior 30 day period expressed as a weekly average. Trend for "Mean Hgb (g/dL)" in blacks=-0.047/mo (95% CI: -0.071, -0.024); in non-Blacks=-0.018/mo (95% CI: -0.03, -0.005). Trend for "Hgb <10 g/dL (%)" in blacks=0.49/mo (95% CI: 0.07, 0.91); in non-Blacks=-0.04/mo (95% CI: -0.33, 0.25).

Conclusions: During this PPS transition period, changes in anemia management have led to a greater rise in % of patients with Hgb <10 g/dL and larger decline in mean Hgb in black vs other patients. Continued monitoring of these practice trends and effect on transfusion rates and other clinical outcomes is warranted.

The Safety of Feraheme® (ferumoxytol) in Hemodialysis Patients at Three Dialysis Chains over a One Year Period

Brigitte Schiller,[1] Premila Bhat,[2] Amit Sharma,[3] William Strauss,[4] Zhu Li,[4] Justin Mclaughlin,[4] Annamaria T. Kausz.[4] *[1]Satellite Healthcare, San Jose, CA; [2]Atlantic Dialysis Management Services, LLC, Ridgewood, NY; [3]Boise Kidney and Hypertension Institute, Boise, ID; [4]AMAG Pharmaceuticals, Lexington, MA.*

Background: Feraheme® (ferumoxytol) is an IV iron approved in June 2009 for the treatment of iron deficiency anemia (IDA) in adult patients with chronic kidney disease (CKD). The aim of this study was to characterize the safety profile of ferumoxytol as administered in a real-world setting.

Methods: Adverse events (AE) following treatment were tracked by the medical staff at each of the sites across the three dialysis chains. Any patient who received any dose of ferumoxytol from January through December 2010 was included in this analysis. To standardize the reported AE terms, AEs were coded using a standard drug safety coding

convention (MedDRA Version 13). All AEs were cross-checked against post-marketing safety reports received by AMAG to ensure all AEs were captured.

Results: Overall, 8,666 CKD patients were administered a total of 33,358 doses of ferumoxytol at these three dialysis chains. The table below displays the rates of three AE categories calculated on a per-patient and on an event-per-exposure basis.

	Total Subjects (N=8,666)	Total Exposures (N=33,358)
	Subjects (%)	Events (%)
AEs	108 (1.25)	330 (0.99)
Serious AEs	18 (0.21)	45 (0.13)
AEs leading to drug discontinuation	49 (0.57)	NA

The overall rates of AEs, SAEs, and AEs leading to ferumoxytol discontinuation were low. The most common SAEs (>2 subjects) were hypotension (0.12%), hypersensitivity (0.06%), dyspnea (0.05%), and loss of consciousness (0.03%). The frequency or severity of AEs did not increase among patients receiving two or more courses of ferumoxytol.

Conclusions: Based on a one year observation period across three dialysis chains involving 8,666 patients treated with 33,358 doses of ferumoxytol, the AE profile was consistent in frequency and severity with data from clinical trials. These long-term data with repeat dosing in a large number of hemodialysis patients confirm the safety for the treatment of IDA in patients with CKD on hemodialysis.

FR-PO1574

Hepcidin-25 (Hep25) Is a Biomarker of Iron Stores and Erythropoiesis in Chronic Hemodialysis (HD) Patients, with an Important Role of Residual Kidney Function Neelke C. Van Der Weerd,[1] Muriel Grooteman,[1] Peter J. Blankestijn,[2] Michiel Bots,[2] Marinus A. Van Den Dorpel,[3] Claire H. Den Hoedt,[3] Albert H. Mazairac,[2] Menso Nube,[1] Erik L. Penne,[2] Jack F. Wetzels,[4] Dorine W. Swinkels,[4] Pieter M. Ter Wee.[1] *[1]VU Medical Center, Amsterdam, Netherlands; [2]University Medical Center, Utrecht, Netherlands; [3]Maasstad Hospital, Rotterdam, Netherlands; [4]Radboud University Medical Center, Nijmegen, Netherlands.*

Background: Hep25, the active form of hepcidin, is a key regulator of iron homeostasis and is increased in chronic HD patients. Little is known about patient-, laboratory- and treatment related factors that influence Hep25 levels. Therefore, in the current study, potential determinants of Hep25 were assessed in a large cohort of stable, chronic HD patients.

Methods: Baseline data were studied from 405 patients (62% male; age 63.7 ± 13.9 [mean ± SD]) enrolled in the CONvective TRAnsport STudy (CONTRAST; NCT00205556), from whom additional blood samples were available. Hep25 was measured with mass spectrometry. Patient- (gender, age, dialysis vintage, diabetes, body mass index, residual kidney function [eGFR]), laboratory- (hemoglobin, ferritin, transferrin saturation, soluble transferrin receptor [sTfR], albumin) and treatment related characteristics (spKt/V, dose of erythropoiesis stimulating agents [ESA], use of iron therapy) were entered in a multivariable linear regression model if they showed a univariable relation ($p<0.15$) with log-transformed Hep25. All models were adjusted for participating center.

Results: Hep25 levels were independently positively associated with ferritin (per 10 ng/mL; B=0.02; $p<0.001$) and negatively with eGFR (per ml/min/1.73m2; B=-0.04; p=0.003) and sTfR (per mg/L; B=-0.33; $p<0.001$). An inverse relation with ESA dose was present only in the univariable analysis (p=0.05).

Conclusions: These findings confirm the vital role of hepcidin in the iron mobilization in chronic HD patients and underscore the importance of residual kidney function in these patients.

FR-PO1575

Treatment of Confirmed B12 Deficiency in Hemodialysis Patients Improves Epogen Requirements Norbert Shtaynberg, Majed Samarneh, Morton J. Kleiner, Suzanne E. El Sayegh. *Nephrology, Staten Island University Hospital, Staten Island, NY.*

Background: Vitamin B12 deficiency may have deleterious effects on end stage renal disease (ESRD) patients on maintenance hemodialysis, and may increase erythropoietin stimulating agent (ESA) resistance, yet little is known about its' prevalence in this population.

Methods: Serum Vitamin B12 and MMA levels were drawn from ESRD patients prior to hemodialysis. All patients with MMA levels greater than 800nmol/L had peripheral smears evaluated for B12 deficiency. Those with confirmatory smears were considered to be deficient and received intramuscular vitamin B12 injections for four months. Post treatment MMA levels and smears were obtained. Erythropoietin dosages were monitored throughout the treatment period.

Results: There was a 58% (60/103) prevalence of vitamin B12 deficiency as defined by a positive MMA level and a positive blood smear. Out of 52 patients with positive smears, 36 (69.2%) were negative on repeat analysis after B12 treatment.

Mean epogen (EPO) dosages significantly decreased by 16,572 ± 41,902 units per month from baseline to the post-B12 treatment period (p=.0082, Wilcoxon Signed Rank test). Three months prior to treatment, the mean monthly EPO dose was 82,067 ± 47,906 and post, the mean EPO usage was 65,495 ± 39,691. Post treatment hemoglobin levels were not significantly different from baseline. Supplementation was also noted to improve social function (p=0.047).

Conclusions: Vitamin B12 supplementation was associated with a decrease in the mean dose of ESA administration while maintaining a stable hemoglobin level. Maintaining serum vitamin B12 levels improves functionality, and may allow a decrease in the use of ESA's, avoiding their toxicities and significant costs.

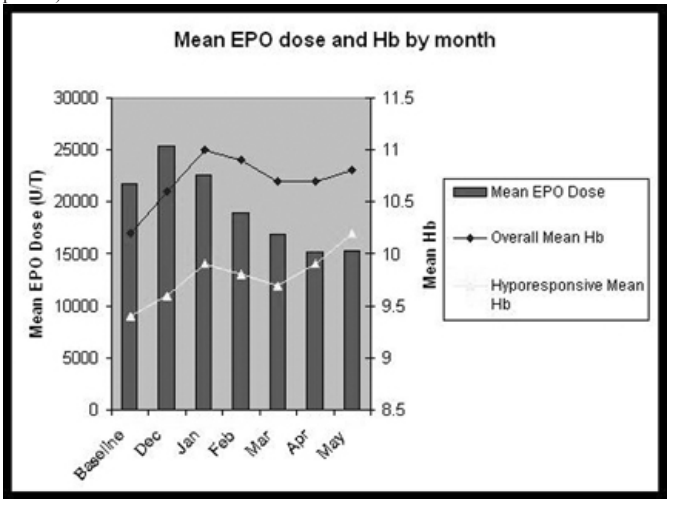
FR-PO1576

Erythropoietin Maximum Dose Reduction Protocol for Hemodialysis Amret T. Hawfield, Gregory B. Russell, John M. Burkart, Vidhya Chandramohan. *Wake Forest School of Medicine, Winston-Salem, NC.*

Background: Clinical trials using erythropoietin stimulating agents (ESAs) failed to demonstrate benefit from high hemoglobin targets in ESRD and CKD. The CHOIR trial demonstrated higher mortality and cardiovascular events in those unable to meet hemoglobin targets on high dose erythropoietin (EPO).

Methods: A protocol to reduce the maximum EPO dose at 17 dialysis facilities was initiated in December 2010. EPO dose was tapered from 28,500 Units/Treatment (U/T) to 20,000 U/T for patients on thrice weekly in-center hemodialysis. Hemoglobin (Hb) was checked twice monthly. Iron deficiency and hyperparathyroidism were managed per standardized protocols. Fifty six of 1223 prevalent hemodialysis patients were on EPO >20,000 U/T in December 2010 and 43 of them had 6 month data in May 2011. Seven were considered EPO hyporesponsive (Hb < 11 mg/dL for the prior 3 months despite maximum dose EPO). Baseline values were obtained from the mean EPO dose and Hb value for the 3 months prior to the protocol change. Monthly frequencies and means for EPO dose and Hb were calculated monthly for 6 months following the protocol change. A paired t-test was used to calculate significant changes.

Results: Mean baseline EPO dose and Hb were 21,714 U/T and 10.2 mg/dL, respectively. The mean EPO dose was reduced to 15,188 U/T over 6 months and mean Hb remained stable at 10.8 mg/dL. Among the 43 patients with 6 month paired data, the mean EPO dose reduction was 10,256 U/T (SD=5605; $p<0.0001$), while the mean Hb increased by 0.2 mg/dL (SD=1.6, p=0.41). Among EPO hyporesponsive patients a 7875 U/T EPO decrease (SD= 2023; p=0.0002) and with a 0.6 mg/dL Hb increase (SD= 1.0; p=0.20) were observed.



Conclusions: These data suggest that protocols gradually reducing maximum EPO doses in patients on hemodialysis can be safely implemented without significant short-term worsening of anemia.

Abstract Withdrawn

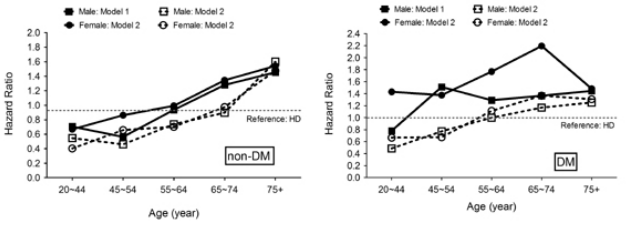
FR-PO1578

Nutrition and Anemia Status Affect the Survival of Older and Diabetic Peritoneal Dialysis Patients Wu-Chang Yang,[1] Yee-Yung Ng,[1] Shang-Jyh Hwang.[2] *[1]Division of Nephrology, Taipei Veterans General Hospital, National Yang-Ming University, Taipei, Taiwan; [2]Kaohsiung Medical University, Kaohsiung, Taiwan.*

Background: While the prevalent and incident ESRD patients are increasing worldwide, the penetration rate of peritoneal dialysis (PD) is decreasing in many countries. One of major reasons for this trend is a concern for a reduced survival in older and diabetic PD patients, especially in the females.

Methods: A nation-based comparison of survival between hemodialysis (HD) and PD incident patients, collected from Jan 1998 through Jun 2007 and followed up to Dec 2007, which included 66,678 HD and 4,680 PD patients who did not have a switch in dialysis mode during the follow-up period.

Results: PD utilization tends to be lower in older or diabetic patients (p= 0.055). As compared with HD patients at each age-specific group, Log-Rank and Cox analysis adjusted by sex, age, and diabetes (Model 1) did show a significantly unfavorable outcome for non-DM PD patients if age ≥65, and for diabetic PD patients if age ≥45, respectively.



The averaged levels of albumin and hematocrit during their follow-up period were significantly lower in patients who were diabetic, older or doing PD. If these averaged values of albumin and hematocrit were included in Cox analysis (Model 2), however, the survival of PD patients became comparable in non-DM patients until age of ≥75, and in diabetic patients until age of ≥65.

Conclusions: One of the major obstacles for PD utilization in older or diabetic ESRD patients is a relatively reduced survival than HD. Significantly lower levels of albumin and hematocrit are prevalent in these PD subgroups due to their co-mobilities, which could jeopardize and therefore, partly account for their reduced survival on dialysis. Thus, disorders in nutrition and anemia should be aggressively corrected in these patients doing peritoneal dialysis.

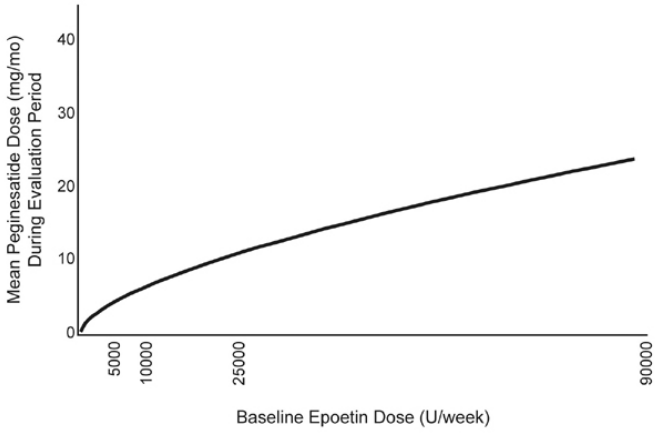
Relationship between Peginesatide and Epoetin Doses in Hemodialysis (HD) Patients Steven Fishbane,[1] Robert Provenzano,[1] Mark Kaplan,[1] Brigitte Schiller,[1] Anatole Besarab,[1] Carol Francisco,[2] Hong-Ye Gao,[2] Richard Daley,[2] Sandra Tong,[2] Martha Mayo,[2] Alex Yang,[2] Krishna R. Polu.[2] *[1]AFX-01-12 and -14 Peginesatide Study Groups; [2]Affymax, Inc., Palo Alto, CA.*

Background: Use of higher erythropoiesis-stimulating agent (ESA) doses may be associated with higher cardiovascular-related mortality (Regidor 2006), a risk likely confounded by patient factors such as health status (Besarab 2009). Peginesatide (Hematide™) is a synthetic, PEGylated, investigational, peptide-based ESA that is designed to specifically stimulate the erythropoietin receptor.

Methods: Data were pooled from two phase 3, randomized, active-controlled, open-label trials assessing safety and efficacy of peginesatide (once monthly; N=1066) compared with epoetin alfa/beta (epoetin; 1-3 times weekly; N=542) in HD patients previously on stable epoetin doses (EMERALD 1 and 2). The relationship between baseline (BL) epoetin dose and mean evaluation period (EP; wks 29-36) ESA dose was evaluated. The dose ratio (BL epoetin [U/wk]: EP peginesatide [mg/mo] or EP epoetin [U/wk] dose) was calculated for each patient and tabulated by quartile.

Results: The relationship between epoetin and peginesatide dose was nonlinear (Figure). Median dose ratios by quartile for patients on peginesatide compared with BL epoetin doses ranged from 1040:1 in the first quartile (BL epoetin ≤4800 U/wk) to 2150:1 in the fourth quartile (BL epoetin ≥16,400 U/wk). Median dose ratios for patients who remained on epoetin were ~1:1 for all quartiles. The treatment groups were similar with respect to iron use, ferritin, TSAT, CRP, and hemoglobin levels at BL and during the EP.

Figure. Dose Relationship



Conclusions: The relationship between epoetin and peginesatide dose was nonlinear, suggesting that HD patients requiring more epoetin at baseline tend to require relatively less peginesatide to achieve similar hemoglobin levels.

FR-PO1580

Efficacy of Oral Iron Supplementation in ESA-Treated Patients on Hemodialysis Whose Serum Hepcidin Levels Are Not Elevated Shinichi Suga,[1] Hironobu Kawai,[2] Keiju Hiromura,[3] Yoshihisa Nojima,[3] Naohisa Tomosugi.[4] *[1]Saiseikai Maebashi Hosp, Maebashi, Gunma, Japan; [2]Fujioka General Hospital, Fujioka, Gunma, Japan; [3]Gunma University, Graduate School of Medicine, Maebashi, Gunma, Japan; [4]Medical Research Institute, Kanazawa Medical University, Kahoku, Ishikawa, Japan.*

Background: Several factors including increased body's iron storage, decreased erythropoiesis and chronic inflammation result in an elevation of serum hepcidin levels in hemodialysis (HD) patients, which may prevent intestinal iron absorption. We hypothesized that hepcidin is not elevated in iron-deficient maintenance HD patients treated with ESA, and that oral iron supplementation can save ESA doses.

Methods: HD patients (serum ferritin < 100 ng/mL and transferrin saturation (TSAT) < 30%, n=25) treated with darbepoetin α, received 105 mg oral ferrous sulfate once a day for 24 weeks. The dose of darbepoetin was adjusted to maintain a Hgb level of 10 to12g/dL. We used mass spectrometry assay to measure serum hepcidin-25 (Hep-25).

Results: Before the iron administration, mean serum Hep-25 in the HD patients was comparable with that of healthy controls (22±12 ng/mL). Hep-25 positively correlated with serum ferritin (ρ=0.71, $p<0.01$), but not with TSAT. Oral iron administration resulted in the elevation of serum ferritin, TSAT and Hep-25. Although mean Hgb remained relatively constant throughout the study period, mean darbepoetin α dose decreased by 17% at week 12 and by 37% at week 24. In patients whose darbepoetin α dose was unchanged during the first 4 weeks, elevation of Hgb in the 4 weeks negatively correlated with Hep-25 at week 0 (ρ= -0.48, P = 0.048), but not with ferritin or TSAT.

	week 0	week 12	week 24
Hgb g/dL	10.5 ± 0.3	11.8 ± 0.2*	10.6 ± 0.2
Hep-25 ng/mL	12.3 ± 3.5	29.7 ± 5.5*	43.5 ± 5.3*
ferritin ng/mL	31.4 ± 3.4	54.2 ± 6.2*	97.5 ± 10.2*
TSAT %	20.4 ± 1.9	34.0 ± 2.4*	35.1 ± 3.3*
DA µg/week	21.1 ± 3.6	17.5 ± 1.9*	13.3 ± 1.8*

Values are mean ± SE. *p<0.05 vs week 0

Conclusions: We found that oral iron administration could effectively stimulate erythropoiesis in iron-deficient HD patients with ESA, if their serum Hep-25 levels are not elevated. Hep-25 may be a useful biomarker for the response to oral iron supplementation.

FR-PO1581

Effects of the ESRD Medicare Bundling Rule on Anemia Management in Private Dialysis Units Katie E. Cardone,[1,2] Brian Brian Fox,[1] Shari A. Meola,[3] Christopher D. Hoy,[3] Amy B. Pai.[1,2] *[1]Albany College of Pharmacy and Health Sciences, Albany, NY; [2]ANephRx, Albany, NY; [3]H&L Rubin Dialysis Center, Troy, NY.*

Background: Reform of the CMS ESRD payment policy in Jan 2011 required bundled payments for previously separately billable drugs. Given the cost difference between erythropoiesis stimulating agents & IV iron, this study evaluated implications of the new bundling rule on anemia management.

Methods: This was a retrospective cohort study of in-center hemodialysis (IHD), home hemodialysis (HHD) & peritoneal dialysis (PD) patients at 2 private, nonprofit dialysis centers in Upstate New York. Medical record & laboratory data were pooled and evaluated for time periods Jan 2010 - April 2010 (pre-bundle) and from Jan 2011 - April 2011 (post-bundle). All patients with available anemia medication use data were included. Monthly epoetin alfa (EPO) and intravenous iron sucrose (IVFe) doses were analyzed pre- and post-bundling. All available monthly [hemoglobin] for study patients were collected.

Results: A total of 1470 patient-months were evaluated, IHD=1061 mo, HHD=288 mo, PD=121 mo. Among IHD patients receiving EPO, mean(SD) monthly doses significantly decreased after the bundle was imposed, 62,758 (69,034) vs. 44,140 (45,454) units respectively ($p<0.001$). For those on IVFe, mean monthly doses significantly increased from 306 (221) to 453 (290) mg ($p<0.001$). Mean hemoglobin concentrations were significantly lower after implementation of the bundle 11.1(1.4) compared to 11.6(1.4) g/dL pre-bundle ($p<0.001$). Similar drug use shifts were observed in both the HHD and PD patients. Both the HHD and PD groups had a 0.5 g/dL reduction in Hb concentrations in the post-bundle observation period ($p<0.001$ for both groups).

Conclusions: Since revision of the ESRD Conditions for Coverage, we observed significant decreases in EPO and increases in IVFe doses. Hemoglobin concentrations were significantly reduced, but remained within the target range. Given long-term safety concerns with EPO and IV iron, practice pattern changes related to the bundled drug coverage policy should continue to be closely evaluated with regard to patient outcomes.

FR-PO1582

Four-Year Follow-Up of the Recombinant Human Erythropoietin (rHuEPO) Bundling Policy in Japan: Results from the Japan Dialysis Outcomes and Practice Patterns Study (DOPPS) Takeshi Hasegawa,[1] Jinyao Zhang,[2] Yun Li,[3] Ronald L. Pisoni,[2] Tadao Akizawa,[4] Bruce M. Robinson.[2,3] *[1]Showa University Fujigaoka Hospital; [2]Arbor Research Collaborative for Health; [3]University of Michigan; [4]Showa University.*

Background: A recombinant human erythropoietin (rHuEPO) bundling policy for hemodialysis (HD) patients in the Japanese health insurance system was implemented in April 2006. We previously reported short-term changes in anemia management following this policy change [Hasegawa, KI 2010]. Understanding longer term changes is important for understanding the possible impact of bundled payment policy in other health care systems.

Methods: Anemia management variables were determined in four cross-sections of chronic HD patients in Japan-DOPPS. One cross-section (Jan 2006) was prior to the rHuEPO bundling policy, with the others in 2007, 2009, and 2010.

Results: Since policy implementation, mean ESA dose has declined but % ESA use has increased slightly. Both IV iron use and dose over a 4 month period has increased (Table). There was little change in % with transferrin saturation (TSAT) <20% but a substantial decline in the % with serum ferritin <100 ng/mL. Hemoglobin (Hgb) levels increased modestly.

Conclusions: This 4-year follow-up after the rHuEPO bundling policy in Japan indicates an initial rise then stable IV iron use, an initial drop then stable ESA dose, plus a small rise in Hgb levels. Hemoglobin levels, average ESA doses, and IV iron use remain lower in Japan than in the US, and this may limit inference from these Japanese findings about the likely impact of ESA bundling in the US.

	Cross-sections			
	Before bundling	After bundling		
	Jan 2006	Jan 2007	Sep 2009	Sep 2010
Number of patients	1584	1622	1684	1631
Number of facilities	53	53	59	57
ESA use (%)	81.9	82.2	83.8	84.1
Darbepoetin use (as % of ESA)	0	0	46.4	48.5
Mean ESA dose (units/week)*	5266	4645	4681	4707
IV iron use (%)**	31.8	41.2	36.1	39.7
Mean IV iron dose (mg/month)**	105	111	134	125
Hemoglobin (g/dL), median	10.40	10.40	10.45	10.50
Hgb <10 g/dL, %	34.9	34.9	32.1	29.4
Hgb ≥12 g/dL, %	8.9	10.1	6.3	7.1
Transferrin saturation (%), mean	26.0	27.9	27.0	26.3
TSAT <20%, %	36.0	28.8	29.8	30.5
TSAT ≥40%, %	12.6	17.3	10.7	10.3
Serum Ferritin (ng/mL), mean	222	224	288	288
Ferritin <100 ng/mL, %	34.6	23.9	8.8	7.3
Ferritin ≥500 ng/mL, %	9.9	9.3	14.9	15.0

Data are from Japan-DOPPS phases 3 and 4; *ESA use was any use during the past month; ESA dose was the mean weekly dose during the past month; Aranesp dose was converted to estimated erythropoietin dose using a conversion factor of 1:200 (aranesp [mcg/week] : erythropoietin [units/week]); **IV iron use was any use during prior 4 months; IV iron dose was the mean monthly dose during the prior 4 month period among patients prescribed IV iron.

Validation of an Intelligent Decision Support Tool for Anemia Management Adam E. Gaweda,[1,2] Michael E. Brier,[1,2,3] George R. Aronoff.[1,2] *[1]University of Louisville, KY; [2]Pharos Medicine, Inc., Louisville, KY; [3]Robley Rex VA Medical Center, Louisville, KY.*

Background: Erythropoiesis Stimulating Agents (ESA) are dosed by protocols derived from NKF/KDOQI guidelines and ESA package information. We developed an intelligent decision support system for individualized ESA dosing based on model predictive control called Smart Anemia Manager™ (SAM). We benchmark this tool against two standard protocols through in silico simulation.

Methods: We represented ESRD patients with a mathematical model of erythropoiesis relating weekly Hgb to weekly ESA dose received. To account for inter-patient variation in ESA response, we created a pool of models with different (fixed) parameters including ESA sensitivity from 0.1 to 0.9 g/dL per 1,000 ESA Units per week, RBC lifespan between 60 and 120 days, body mass 50 to 150 kg, and baseline Hgb 7 to 9 g/dL. We represented intra-patient Hgb variability by normally distributed random noise with zero mean and standard deviation 0.0 to 1.0 g/dL. All the simulation parameters other than Hgb, ESA dose and body mass were not "visible" to SAM nor the benchmark protocols. We simulated Hgb response over 12 months and used the following performance metrics: percent Hgb levels within target range (10-12 g/dL), and mean ESA dose per patient-week.

Results: Results of the comparison are shown in the table for three different levels of intra-patient variability. SAM outperforms Protocols 1 and 2 in terms of percent Hgb within target range. As expected, increasing intra-patient variability decreases percent Hgb within target. Anemia management with SAM results in a 36% relative decrease in ESA dose compared to Protocol 1 and 2. Intra-patient variability does not significantly affect ESA utilization.

Performance comparison between SAM and standard protocols

	Protocol 1		Protocol 2		SAM	
Intrapatient variability (g/dL)	% Hgb 10-12	Mean Epo per Pt-wk	% Hgb 10-12	Mean Epo per Pt-wk	% Hgb 10-12	Mean Epo per Pt-wk
0.0	68	11,200	50	11,500	74	7,300
0.5	54	10,400	44	12,000	67	7,300
1.0	40	9,800	33	13,000	48	7,100

Conclusions: In-silico validation supports that Smart Anemia Manager™ improves cost-effectiveness of anemia management compared to standard ESA dosing protocols.

Red Blood Cell Life Span and Erythropoietin Resistance Index in Hemodialysis Patients Yanna Dou,[1,2] Anja Kruse,[1,2,3] Georges Ouellet,[1,2,4] Stephan Thijssen,[1,2] Nathan W. Levin,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York; [2]Beth Israel Medical Center, New York; [3]Bern University Hospital, Switzerland; [4]Maisonneuve-Rosemont Hospital, Canada.*

Background: Anemia is a common complication in hemodialysis (HD) patients. Poor response to erythropoiesis-stimulating agent therapy is an adverse prognostic factor with inflammation and reduced iron availability as leading causes. This study investigated the relationship between red blood cell life span (RBCLS) and the clinically used erythropoietin resistance index (ERI).

Methods: In chronic HD patients, hemoglobin (Hgb), high-sensitivity CRP (hsCRP), RBCLS, serum iron, ferritin and TSAT were measured. RBCLS was estimated from endogenous alveolar carbon monoxide concentration (determined by gas chromatography) and hemoglobin concentration (Strocchi, 1992). Demographics and weekly Epoetin alfa (EPO) dose were recorded. ERI was defined as weekly EPO dose per kilogram of body weight divided by Hgb level in g/dL. We performed logistic regression of ERI (categorized as above or below the median) on age, diabetes status, hsCRP (>5 or ≤5 mg/L), RBCLS (<60 or ≥ 60 days), TSAT, ferritin, and serum iron.

Results: Thirty-six HD patients (24 males, age 59±15 years, dialysis vintage 59±51 months, 17 patients with diabetes) were studied. Bivariate correlation analysis showed borderline significance for patients with lower RBCLS having higher ERI (Spearman rho = –0.32; P=0.057). Median ERI was 10.5 (U*dL)/(week*kg*g). Among all variables analyzed, elevated ERI was associated only with RBCLS below 60 days (OR 5.2; 95% CI 1.3 to 21.6, P<0.05), but not with age, diabetes, hsCRP>5 mg/dL, TSAT, ferritin, and serum iron.

Conclusions: RBCLS is inversely related to ERI, a parameter commonly used to assess HD patients' responsiveness to EPO. Both EPO dose and Hgb level enter the calculation of the ERI, and both are closely intertwined with RBCLS, a fact that is often neglected or underappreciated in clinical practice. A consideration of RBCLS is vital for any interpretation of ERI, particularly in populations with notably variable RBCLS, such as dialysis patients. Research to reveal the causes of reduced RBCLS in HD patients is needed.

FR-PO1585

Smart Anemia Manager Results in Better Hemoglobin Control and Cost Savings over a Traditional Algorithmic Approach Michael E. Brier,[1,2,3] George R. Aronoff,[2,3] Alfred A. Jacobs,[2] Adam E. Gaweda.[2,3] *[1]Robley Rex Veterans Medical Center, Louisville, KY; [2]University of Louisville, KY; [3]Pharos Medicine, Louisville, KY.*

Background: Erythropoietin (EPO) is dosed by protocols derived from NKF/KDOQI guidelines and EPO package information. We developed an intelligent decision support system for individualized EPO dosing based on model predictive control called Smart Anemia Manager (SAM). We tested the hypothesis that SAM will better control Hb response to EPO and use less EPO than a traditional algorithmic approach (TAP).

Methods: In a retrospective controlled clinical trial of SAM (n=68) vs. TAP (n=66) we compared anemia management in our dialysis facility for 6 months prior to the introduction of SAM to the 6 months after SAM and between TAP and SAM. The SAM program is implemented as a stand alone program that reads EPO dose and hemoglobin data from an electronic medical record. It then determines the best patient-specific future dose of EPO based on a model predictive control algorithm. The TAP is developed as an expert system based on the EPO package insert and KDOQI guidelines. The target Hb was 11.0 g/dl in both groups. We measured the mean Hb and weekly EPO dose.

Results: Shown below are the mean and SD for Hb and mean weekly EPO dose for the period 6 months prior to and 6 months after the implementation of SAM.

	Hb Before	Hb After	EPO Before	EPO After
TAP	11.5±0.93	11.3±1.00	10,777	8,734
SAM	11.3±0.9	11.0±0.9	9,029	5,902

SAM was able to achieve the target Hb within the time course of the study while TAP was not. Decreasing the population mean Hb resulted in EPO sparing in both groups but SAM resulted in an additional EPO sparing of about 2,800 units per week. SAM also resulted in a 10% decrease in Hb variability as measured by Hb standard deviation.

Conclusions: Prospective prediction of Hb response to EPO dosing with SAM is superior to an expert rule based technique used in the management of the anemia of end-stage renal disease. SAM exposes patients to less EPO, better achieves the target Hb, and results in cost savings to dialysis units in the range of $1,100-$3,800/patient/year, depending on current EPO usage.

Red Blood Cell Life Span Is Associated with Hemoglobin Variability in Chronic Hemodialysis Patients Yanna Dou,[1,2] Anja Kruse,[1,2,3] Georges Ouellet,[1,2,4] Stephan Thijssen,[1,2] Nathan W. Levin,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York; [2]Beth Israel Medical Center, New York; [3]Bern University Hospital, Switzerland; [4]Maisonneuve-Rosemont Hospital, Canada.*

Background: Increased hemoglobin (Hgb) variability is associated with higher mortality in chronic hemodialysis (HD) patients. Erythropoiesis-stimulating agent dose, iron deficiency, infections and intercurrent events can influence Hgb variability. The relationship between red blood cell life span (RBCLS) and Hgb variability has not previously been investigated.

Methods: Chronic HD patients from a single center were enrolled. Hgb, high-sensitivity CRP (hsCRP), iron status, reticulocyte production index (RPI) and RBCLS were assessed. RBCLS was estimated from endogenous alveolar carbon monoxide level (determined by gas chromatography) and Hgb concentration (Strocchi, 1992). Intra-individual standard deviation (SD) of subsequent Hgb levels indicated Hgb variability. Patients were stratified into high (SD>1 g/dL) or low (SD≤1 g/dL) Hgb variability groups. We performed logistic regression of Hgb variability on RBCLS (<40 or ≥40 days), mean weekly Epoetin alfa (EPO) dose, and mean RPI.

Results: 33 HD patients (22 males, age 59±16 years, dialysis vintage 52±53 months, 15 diabetics) were enrolled. Patients with high Hgb variability (N=12) showed a shorter RBCLS (56±16 vs. 73±23 days, P<0.05), a higher hospitalization rate (3.03 vs. 0.18 hospitalizations per patient-year, P<0.05), higher EPO doses, and higher variability of RPI; indicators of iron status and inflammation did not differ between the two groups. In logistic regression, RBCLS<40 days was associated with increased risk of high Hgb variability (OR 6.0; 95%CI 1.2-29.0; P<0.05).

Conclusions: This study reveals short RBCLS is a novel risk factor for Hgb variability. Short RBCLS in this context is presumably not causally linked to higher Hgb variability *per se*. Rather, the association may be a reflection of intercurrent events that effect both shorter RBCLS and reduced Hgb levels (e.g., via oxidative stress or other mechanisms). The fluctuating nature of such states may explain higher Hgb variability and shorter average RBCLS in the affected patients.

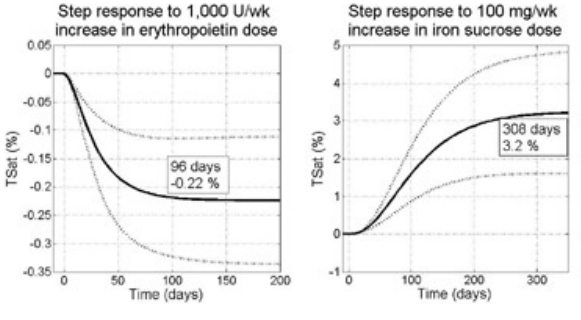
FR-PO1587

Mathematical Modeling of Erythropoietin and Iron Dosing in Anemia Management Adam E. Gaweda,[1] Yossi Chait,[2] Michael E. Brier,[1,3] George R. Aronoff.[1] *[1]University of Louisville, KY; [2]University of Massachussets, Amherst, MA; [3]Robley Rex VA Medical Center, Louisville, KY.*

Background: Sufficient iron is required for the optimum response to erythropoietin. To help guide parenteral iron supplementation, we derived a mathematical model which quantifies the effect of parenteral iron and erythropoietin on transferrin saturation (TSat), a frequently used marker of iron stores in anemia management.

Methods: We prospectively collected Hemoglobin (Hgb), TSat, erythropoietin and iron sucrose dose weekly for one year in a cohort of 56 hemodialysis patients at the University of Louisville dialysis facility. Using these data, we estimated the response of TSat (output) to changes in erythropoietin and iron sucrose dose (inputs) using a population-based additive second-order model. This model has two physiologic parameters for each input: steady-state gain (sensitivity) and time constant (dynamics). Model estimation was performed in Matlab®.

Results: The left hand side plot below shows the predicted response to a 1,000 U increase in weekly erythropoietin dose with constant iron sucrose dose. TSat decreases by about 0.22% at a steady-state achieved after approximately 96 days. The right hand side plot below shows the predicted response to a 100 mg iron sucrose dose increase with constant erythropoietin dose. A 100 mg increase in weekly iron sucrose dose increases TSat by 3.2% at a steady-state achieved after about 308 days.



Conclusions: Our proposed mathematical model quantitatively describes the interaction of erythropoietin and iron during anemia management in dialysis patients. Using this model, we can estimate how much iron supplementation is required to maintain iron repletion that maximizes the response to erythropoietin.

Defining Erythropoiesis Stimulating Agent (ESA) Hyporesponsiveness David T. Gilbertson, Yi Peng, Tom Arneson, Stephan C. Dunning, Allan J. Collins. *CDRG, Minneapolis, MN.*

Background: 'ESA hyporesponsiveness' in hemodialysis (HD) patients refers to high doses of ESAs to treat anemia. It is generally the result of functional iron deficiency, bone marrow fibrosis and/or inflammation. There does not appear to be a standardized definition of ESA hyporesponsiveness, and dose cutoffs used as a definition have changed over time as ESAs have been used at higher doses. We investigated 3 definitions of hyporesponsiveness in 2008 prevalent Medicare HD patients.

Methods: 3 definitions of hyporesponsiveness (90th percentile of each: EPO Total Dose, EPO Total Dose/kg, and EPO Total Dose/Hb) were applied to the cohort of HD patients. Each of five observed months was defined as hyporesponsive or not, for each patient. Patients with ≥1 month of hyporesponsiveness were classified as such. Further classifications included chronic (hyporesponsive 4+ consecutive months) and acute hyporesponsiveness (≤3 consecutive months of hyporesponsiveness with at least one month not hyporesponsive before and after the hyporesponsive month(s).

Results: The 3 definitions produced similar proportions in hyporesponsiveness categories. 20-21% were hyporesponsive: 5-6% acute, 4-5% chronic, and 10-11% meeting neither the acute nor the chronic definition. Factors associated with all hyporesponsive patients (any, acute, or chronic) were similar across the 3 definitions. The strongest factors associated with any hyporesponsiveness included: Low Hb, decreasing trend of Hb, younger age, non-diabetic cause of renal failure, increased dialysis vintage, cancer, GI bleeding, congestive heart failure, IV antibiotic use, increased months with iron use, hospital admissions, for-profit dialysis provider, and large dialysis organizations.

Conclusions: The three definitions of hyporesponsiveness produced similar estimates of prevalence and associations with patient characteristics. Thus for the sake of clinical simplicity, Total ESA Dose may be most appropriate measurement of hyporesponsiveness. With the bundled reimbursement system implemented in Jan 2011, ESA dosing patterns may change significantly, and these associations should be reassessed.

FR-PO1589

Intra-Individual Variability of Serum Hepcidin-25 in Hemodialysis Patients Hilde P. Peters,[1] Coby M.M. Laarakkers,[2] Jan A.J.G. van den Brand,[1] Dorine W. Swinkels,[2] Jack F. Wetzels.[1] *[1]Nephrology, Radboud University Nijmegen Medical Center, Nijmegen, Gelderland, Netherlands; [2]Laboratory of Genetic, Endocrine and Metabolic Diseases, Radboud University Nijmegen Medical Center, Nijmegen, Gelderland, Netherlands.*

Background: Hepcidin-25 regulates iron metabolism by integrating input from erythropoietic, inflammatory and iron signaling pathways. Serum hepcidin levels are increased in patients with CKD and may contribute to deficient erythropoiesis. Thus, (changes in) hepcidin-25 levels could become a tool to guide treatment with iron and erythropoiesis stimulating agents. For meaningful interpretation of data, it is essential to know the intra-individual variability of serum hepcidin levels. We aimed to assess the intra-individual variability of serum hepcidin-25 in hemodialysis patients and to identify significant determinants.

Methods: We included hemodialysis patients (n=43, 56% male, age 62±15 yrs) who attended our hospital for regular dialysis. Blood samples were drawn prior to dialysis once weekly during 6 weeks. The majority was treated with iron and epoetin beta. Hepcidin-25 was determined by mass spectrometry and the mean coefficient of variance (CV_1; standard deviation/mean) was calculated for each patient.

Results: At baseline, median hemoglobin was 11.4 (IQR 10.5-11.9) g/dl and serum hepcidin-25 was 46.7 (26.2-73.4) ng/ml. Median CV1 of hepcidin-25 was 26% (IQR 17-48). CV1 was higher in patients with low hepcidin and ferritin. CV1s of CRP and ferritin were 41% (IQR 8-63) and 12% (IQR 11-26), respectively. By multivariate regression analysis we found baseline ferritin and CV1 of transferrin saturation (TSAT) , but not CRP, to be independent predictors of intra-individual hepcidin-25 variability. In the majority of patients there was no correlation between hepcidin-25 and ferritin, iron, TSAT, CRP, or hemoglobin. Changes in serum hepcidin-25 could not be predicted from changes in ferritin or CRP.

Conclusions: Our results indicate that there is significant intra-individual variability of serum hepcidin-25 levels in hemodialysis patients. We found no correlation between variability of hepcidin-25 and CRP levels, thus excluding the inflammatory status as an important determinant of hepcidin variability.

FR-PO1590

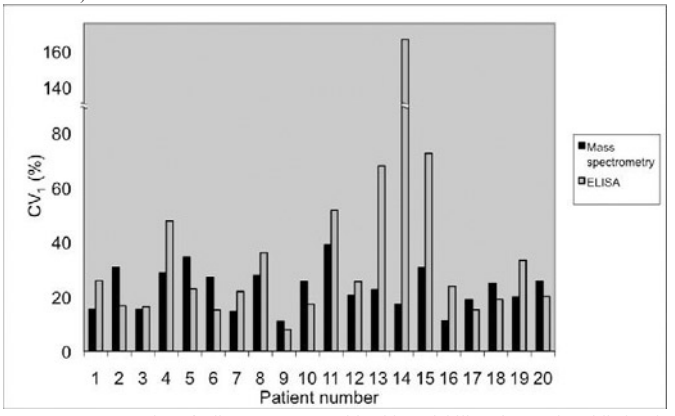
Intra-Individual Variability of Hepcidin in Haemodialysis Patients Using Mass Spectrometry and ELISA Adam Rumjon,[1] Sukhvinder Singh Bansal,[2] Jolanta Malyszko,[3] Iain C. Macdougall.[1] *[1]King's College Hospital; [2]King's College London; [3]Medical Academy, Bialystok.*

Background: Measurement of serum hepcidin levels may provide a useful alternative to the current methods of determining iron status in chronic hemodialysis patients. However, the biological variability of this pivotal regulator of iron homeostasis is unclear, and the impact of dialysis clearance and iron therapy on hepcidin variability has not been established.

Methods: Serum hepcidin levels were measured in 20 stable, chronic hemodialysis patients at the start of 9 consecutive dialysis sessions. Liquid chromatography mass spectrometry (employing hepcidin-25 as an internal standard) and a competitive ELISA

were both used to calculate the coefficient of variance (CV_1) in this population. Potential factors affecting CV_1 were also examined.

Results: The median CV1 was 23.7% (16.8, 27.9) and 23.3% (17.1, 38.9), with the MS and cELISA assays respectively. The median CV1 was similar in patients receiving and not receiving regular IV iron (p=0.77). High sensitivity CRP levels were also determined at each timepoint in all patients, and its correlation with serum hepcidin levels was weak (r=0.154, p=0.043). Hepcidin levels appeared to be higher following an inter-dialytic period of 3 days versus 2 days (p=0.02). No relationship was found between serum hepcidin and dialysis quantity, hemoglobin levels, erythropoietin dosage, or serum ferritin levels (data not shown).



Conclusions: These findings suggest considerable variability of serum hepcidin levels in hemodialysis patients. Inflammation and the use of IV iron therapy did not impact on the degree of variability. Hepcidin levels were higher after an inter-dialytic period of 3 days versus 2 days. These findings need to be taken into account in any future studies assessing the utility of serum hepcidin as a guide to the use of IV iron or ESA therapy.

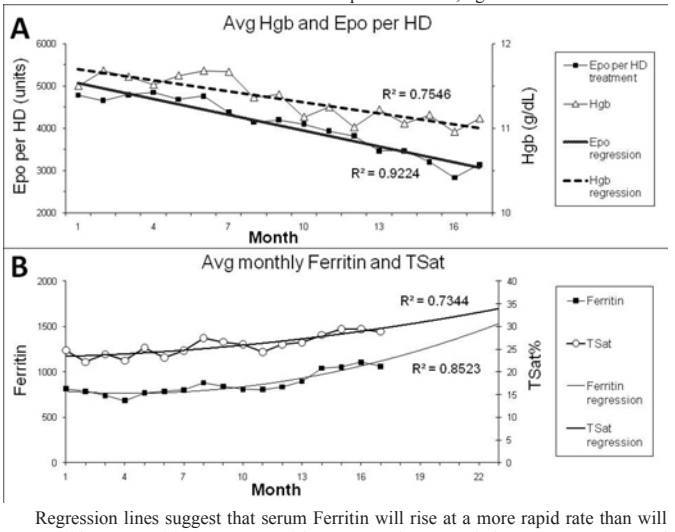
FR-PO1591

Increasing Iron and Decreasing Erythropoietin Use in Hemodialysis Patients: How High Will Serum Ferritins Become? Preeti R. Nargund, Andrew I. Chin. *Division of Nephrology, University of California, Davis School of Medicine, Sacramento, CA.*

Background: With curtailed use of erythropoietin (EPO) in anemia management of patients on HD, many centers are utilizing automated iron protocols. We describe the changes in mean serum Ferritin and Transferrin saturation (TSat) in HD patients with these new protocols in effect. By extrapolation of these data, we provide a glimpse of how high Ferritin levels may become with common iron targets.

Methods: Retrospective analysis of mean monthly serum Ferritin, TSat, Hgb, Albumin, EPO dose per HD, and administered iron from a 16 month period in which iron protocols were implemented and EPO protocols were adjusted. CQI data from 4 hemodialysis clinics affilitated with an urban academic medical center. Best fit regression was performed to provide trend lines for the parameters of interest.

Results: Mean Hgb and units of EPO per HD treatment are shown in figure A. There is a clear reduction in the amount of EPO being given, driven not only by a change in the target Hgb levels (from 11-12 g/dL to 10-12 g/dL), but also by an increased use of intravenous iron replacement for deficiency based on new protocols. As a result, mean serum Ferritin and TSat levels have increased over this same period of time, figure B.



Regression lines suggest that serum Ferritin will rise at a more rapid rate than will TSat within a TSat-driven, automated iron protocol. Extrapolating to a mean TSat of 35% (a common lower-limit TSat target range), mean serum Ferritins may go well over 1600 µg/L.

Conclusions: There has been a significant reduction in EPO use and an increase in iron use in anemia management of HD patients. With iron protocols targeting a higher range of TSat, serum Ferritins will necessarily rise. Our data suggests that Ferritin will rise at a more rapid rate than will TSat, perhaps up to levels that may cause concern for many nephrologists.

Dose of Erythropoiesis-Stimulating Agents (ESAs) and Adverse Outcomes in Chronic Kidney Disease (CKD): A Meta-Regression Ioannis Koulouridis,[1,2] Mansour Alfayez,[1] Thomas Trikalinos,[3] Ethan M. Balk,[3] Bertrand L. Jaber.[1,2] *[1]Department of Medicine, Division of Nephrology, St. Elizabeth's Medical Center, Boston, MA; [2]Department of Medicine, Tufts University School of Medicine, Boston, MA; [3]Center for Clinical Evidence Synthesis, Tufts Clinical and Translational Science Institute, Boston, MA.*

Background: Higher target hemoglobin (Hb) during ESA therapy for anemia of CKD is associated with increased cardiovascular morbidity. We conducted a meta-regression to examine whether the ESA dose is associated with adverse outcomes independent of Hb.

Methods: We searched MEDLINE and prior meta-analyses for randomized controlled trials of ESAs for anemia of CKD. We extracted data on ESA dose, Hb level, and outcomes. Using study arm (or cohort) as the unit of analysis, mixed effects generalized linear meta-regression was performed to examine the association between ESA dose and all-cause and cardiovascular mortality.

Results: We identified 31 trials (12,956 patients). Higher first 3-month and total study-period mean ESA dose was associated with higher unadjusted odds for all-cause (but not cardiovascular) mortality, which remained significant after adjustment for first 3-month mean Hb and target Hb, respectively (Table). Total study-period mean ESA dose was also associated with higher unadjusted odds for several secondary outcomes (Figure).

Conclusions: Higher ESA dose for anemia of CKD may be associated with higher all-cause mortality.

Predictor	No. cohorts	Relative OR (95% CI)	P value
First 3-month mean ESA dose*			
Unadjusted	11	1.42 (1.10, 1.83)	0.007

FR-PO1593

Use of Crit-Line Hematocrit Monitoring To Assist with Anemia Management in Chronic Hemodialysis Frank Jiann-Gang Luo,[1,2] Steven R. Fast,[1] Amul K. Jobalia.[1,2] *[1]Division of Nephrology, Santa Clara Valley Medical Center, San Jose, CA; [2]Stanford University School of Medicine, Stanford, CA.*

Background: Hemodialysis patients receiving erythropoiesis-stimulating agent (ESA) require frequent monitoring to keep hemoglobin (Hb) levels within target. Frequent blood draws are impractical, costly, and do not provide point-of-care decision making on ESA administration. Crit-Line (Hema Metrics, Utah, USA) is a non invasive, photometric device which measures the percent change in blood volume during dialysis based on changes in the hematocrit (Hct). We present our experience of incorporating the Hct reading from Crit-Line in an anemia protocol to aid ESA administration.

Methods: We amended our existing anemia protocol with a 'hold' parameter - the prescribed dose of ESA was held for the dialysis session if the Crit-Line Hct at the start of treatment was greater than 36%. No other aspect of the protocol was changed. We analyzed Hb/Hct levels, ESA dose, ferritin/transferrin saturation and intravenous iron usage for 6 months before and after protocol amendment.

Results: Data from 136 patients receiving dialysis during the trial period was analyzed. Crit-Line Hct at the start of dialysis correlated well with laboratory measured predialysis Hct (r2=0.85). Mean Hb, Hct and Epoetin alfa (Epo) dose for two 3-month periods before (Q2-Pre, Q1-Pre) and after (Q1-Post, Q2-Post) protocol amendment were:

	Q2-Pre	Q1-Pre	Q1-Post	Q2-Post
Hb (g/dl)	12.0±1.1	12.1±1.1	11.7±1.0 *†	11.8±1.1 *†
Hct (%)	36±4	36±3	35±3 *†	35±3 *†
Epo (units/month/patient)	63434±51421	59269±44573	47924±38746 *†	44069±37110 *†

mean±SD

Quarter (Q)

∗ p<0.05 vs Q1-Pre

† p<0.05 vs Q2-Pre

Mean Hb and Hct improved to within target range (Hb 10-12g/dl; Hct 30-36%). Epo usage decreased 19% in the first quarter after protocol amendment. No difference was seen in intravenous iron usage. On average, 2.32 million units of Epo per month were held because of Crit-Line Hct > 36%.

Conclusions: Crit-Line Hct readings can be used to guide ESA administration at each dialysis treatment. This may result in improved anemia management without the need for more frequent blood draws and prevent ESA overuse which could translate to significant cost savings.

FR-PO1594

Clinical and Laboratory Features of Hemodialysis Patients with Adequate Control of Renal Anemia without Erythropoietin Stimulating Agents Remus Aurel Orasan,[1] Stefan H. Jacobson,[2] Bjorn Englund,[3] Ljubisa M. Veljancic,[4] Andrzej Jan Swiderski,[5] Andre L. Weigert.[6] *[1]Nefromed Dialysis Centers, Cluj-Napoca, Romania; [2]Dept Nephrol., Karolinska Institutet, Danderyd Hospital, Stockholm, Sweden; [3]Euromedic International; [4]Clinic of Nephrology MMA, Belgrade, Serbia; [5]IDC Leszno, Poland; [6]Eurodial Obidos, Portugal.*

Background: There is little data in literature comparing clinical and laboratory features of hemodialysis (HD) patients who were prescribed erythropoietin stimulating agents (ESA) with patients who, for medical and/or socio-economical reasons, were not.

Methods: We followed 12,873 HD patients from 7 countries (Bosnia Herzegovina, Croatia, Poland, Portugal, Romania, Russia and Turkey) for 3 years, divided in 2 subgroups: subgroup A – patients without ESA for at least 6 consecutive months (n=1,314;10.2%) and subgroup B – patients receiving ESA (n=11,559;89.8%). In both subgroups we assessed body mass index (BMI), dialysis vintage (DV), Charlson comorbidity index (CI)(range 0-6), hemoglobin (Hb), ferritin (Fer), transferrin saturation (TSAT), albumin, Kt/V, blood flow rate (QB), calcium (Ca), phosphorus (P), intact PTH and systolic blood pressure (SBP).

Results: In subgroup A, age (56.3±13.2 vs 60±15 years, p<0.0001), CI (3.5±1.3 vs 3.8±1.5, p<0.0001), Fer (486.5±574.7 vs 735.9±622.7 ng/mL, p<0.0001), Kt/V (1.5±0.3 vs 1.5±0.9, p<0.0001), SBP (128.3±21.8 vs 134.5±21.9 mmHg, p<0.0001) and TSAT (32.8±22.6 vs 34.8±32.2 %, p<0.0001) were lower than in subgroup B, while Hb (12.7±1.6 vs 10.7±1.3 g/dL, p<0.0001), albumin (40.9±4 vs 39.6±4.8 g/L, p<0.0001), BMI (25.5±4.7 vs 25.1±5.1 kg/m2, p<0.0001), Ca (9±1 vs 8.8±1.4 mg/dL, p<0.0001), PTH (521.4±633.5 vs 398.7±568.8 pg/mL, p<0.0001), P (5.4±1.7 vs 5.2±1.7 mg/dL, p<0.0001), QB (345.4±42.3 vs 327.4±44.7 mL/min, p<0.0001) and DV (93.7±68 vs 65.3±56.6 months, p<0.0001) were higher.

Conclusions: HD patients not receiving ESA for at least 6 consecutive months maintained a higher Hb, they were younger, better nourished, longer DV, and they had a lower CI, SBP and Fer than patients treated with ESA. HD patients with no ESA treatment had adequate dialysis, fairly well controlled mineral bone disease markers and TSAT>30%.

FR-PO1595

Standardized vs. Patient-Specific Computer-Assisted Erythropoietin Dosing: A Randomized Controlled Trial Kevin Ho,[1] John McMichael,[2] Christos Argyropoulos,[1] Vladimir Ladik,[3] Laurie Zickgraf,[3] Alice A. Martin,[4] Klemens B. Meyer,[4] Dana C. Miskulin.[4] *[1]Univ of Pittsburgh, Pittsburgh, PA; [2]Dimensional Dosing Sys Inc, Wexford, PA; [3]Dialysis Clinic Inc, Nashville, TN; [4]Tufts Medical Center, Boston, MA.*

Background: EPO (epoetin) is the largest modifiable factor determining incenter hemodialysis (HD) treatment cost highlighted by the CMS Bundled Payment/QI programs.

Methods: We performed a double blind randomized control trial to compare two computer-assisted algorithms in dosing iv EPO 3x weekly: patient-specific (Intelligent Dosing System, IDS) vs. non-individualized (DCI). Incenter HD patients (n=48) were randomized to either algorithm for 6 months (intervention). Biweekly Hb values electronically triggered dose adjustments. EPO usage, Hb, EPO Resistance Index (ERI=EPO/weight/Hb) data were aggregated monthly on a patient basis. Observed Hb (g/dL) was classified as: at target 10-12, >12, or <10. Run-in and intervention measurements were analyzed with mixed linear models (continuous outcomes) or mixed logistic regression (discrete outcomes) to account for repeated assessments of the same individuals.

Results: From intervention mos. 1 to 6, the % patients at target increased 52.1% to 61.9%; 59.4% of IDS vs. 54.6% of DCI patients were at target Hb on average. During run-in, IDS patients had more variable Hb levels (variance ratio 1.23, 95%CI 1-1.52), higher EPO use (p=0.004), and higher ERI (p=0.028) than DCI patients. However with intervention, IDS patients were more likely to achieve target Hb each mo. (OR=2.1, 95% CI 1.02-4.28, p=0.043), less likely to overshoot (Hb>12: OR 0.35, 95% CI: 0.17-0.73, p=0.005), and no more likely to undershoot (Hb<12: OR 2.6, 95% CI 0.69-11.3, p=0.21). The no. of dose adjustments by IDS vs. DCI algorithms leading to Hb values at target were 107 vs. 111; for Hb<10, 20 vs. 9; for Hb>12, 125 vs. 152. Average EPO use declined in both arms, but the decline was larger in the IDS arm (p=0.0006).

Conclusions: Unlike 'one-size fits all' EPO protocols, a patient-specific algorithm may account for non-linear Hb-EPO dose relationships and yield comparable anemia outcomes without increasing dose requirements. Further testing in a larger population is indicated.

Funding: Clinical Revenue Support

FR-PO1596

Anemia Day: Simultaneous, Once Every Two Weeks (Q2W) Administrations of Darbepoetin Alfa (DA) and Iron (V), Improve Anemia Management in Hemodialysis (HD) Patients Jacques B. Rottembourg, Alain P. Guerin, Diaconita Mirela. *Hemodialysis Unit, Diaverum Group, Paris, France.*

Background: Most HD patients (Pts) require erythropoietin-stimulating-agents (ESA) and iron to control anemia in the long run. In HD Pts, several studies show that IV iron reduces ESA doses, Q2W DA IV dose requirements are similar to every week (QW) DA IV one's and less-frequent ESA administration might result in decreased in-centre nursing time and potentially reduce costs. The aim of the "Anemia Day" was to explore the potential add-on benefit of a simultaneous Q2W injection of both ESA (DA) and iron sucrose (V) during the same dialysis session.

Methods: By September 2010, all stable HD Pts treated in the unit by IV DA Q2W and IV V QW were prospectively switched to simultaneous Q2W IV DA and V dose regimen. Hb level (target 11.5-12 g/dl), ESA and iron parameters were assessed for an 8 months period. Hb was measured every two weeks and iron parameters (ferritin [F]and TSAT) every 2 months. Data at Baseline (BL) defined by the month before inclusion, month 4 (M4) and month 8 (M8) were analyzed and paired Student's t-tests were performed.

Results: 110 HD Pts were included : male 57%, mean age (SD) 60.5 (15.7) years, mean time on dialysis of 52.7(45.7) months, with 30% of Pts with diabetes as primary renal disease.

	BL	M4	M8	p M8 vs BL
Hb g/dl: mean (SD)	11.43(1.08)	11.61(1.33)	11.73(0.96)	0.02
Ferritin µg/l: mean (SD)	608 (375)	684 (349)	911 (509)	0.001
TSAT %: mean (SD)	37.0 (16.3)	36.0 (14.6)	48.7 (20.1)	0.001
DA µg/kg/week: mean (SD)	0.58 (0.42)	0.56 (0.46)	0.48 (0.44)	0.005
V mg/Q2W: mean (SD)	124 (59)	111 (61)	100 (68)	0.001

Hb level was maintained within the targets, with a significant dose decrease in ESA (17.3%) and V (18.5%). Iron parameters should be more carefully monitored in order to decrease V use, and avoid any iron overload. Such a strategy is advantageous for the entire anemia management team, with additional benefits for nurses in terms of convenience, reduced risk of omission and traceability.

Conclusions: Synchronized administration of DA and iron sucrose may result in erythropoïesis optimisation in HD Pts. These findings, which may have important implications for economic reasons, need to be confirmed by further controlled trials.

FR-PO1597

Metoxipolietilenglicol-Epoetina Beta (MIRCERA): An Efficient Treatment for Anaemia in Peritoneal Dialysis Patients. Final Results. CAPRI STUDY

Rosa Ramos,[1] Teresa Maria Gonzalez,[2] Manuel Vera,[3] Isabel García,[4] Francesc Barbosa,[5] Josep Teixido,[6] Carmen García,[7] Marc Cuxart,[8] Carlota Gonzalez,[2] Juan José De la Cruz.[9] *[1]Nephrology, Vall d'Hebron Hospital, Barcelona, Spain; [2]Nephrology, Bellvitge Hospital, Hospitalet de Llobregat, Barcelona, Spain; [3]Nephrology, Clinic Hospital, Barcelona, Spain; [4]Nephrology, Josep Trueta Hospital, Girona, Spain; [5]Nephrology, del Mar Hospital, Barcelona, Spain; [6]Nephrology, Germans Trias i Pujol Hospital, Badalona, Barcelona, Spain; [7]Nephrology, Joan XXIII Hospital, Tarragona, Spain; [8]Nephrology, Figueres Hospital, Figueres, Girona, Spain; [9]Statistical, Autonoma University, Madrid, Spain.*

Background: MIRCERA is a new eritrophoietic stimulating agent (ESA) with the longest half life. It is a good condition to indicate Mircera for treatment of anaemia in predialysis and peritoneal dialysis (PD). The aim is to follow the evolution of hematological parameters in PD patients in Catalonia. This is the first study on PD patients.

Methods: We included 113 PD patients that initiated MIRCERA as the first treatment of anaemia or as a change from previous ESAs.

Results: 83 patients completed follow-up at 12 months. Mean age was 57,8±16y. 59% were men. 71% of patients began PD as first treatment of CRF, 12(14,5%) were transferred from HD and 12(14,5%) returned to PD after kidney transplant failure. 10(12%) patients were naïve, 52(62%) previously treated with darbepoetin-alpha, 19(22,9%) with Epo-beta and 2(2,4%) with Epo-alpha. Mean dose of Mircera was 115,4±56,2µg/month at the beginning, 117,2±58,5µg/month at 6 months, 126±65,9µg/month at 12 months. Hb levels remained stable all through the measurements(11,9±1,4g/dl;11,8±1,4g/dl;11,8±1,5g/dl). No relation was observed between dose of dialysis administered(weekly Kt/V) and Mircera dose or Hb levels. At baseline, 36.7% of patients showed good blood pressure control(SBP/DBP <140/90 mmHg) and 51.0% at 6 months($p<0.05$). Mild adverse events were registered not directly related to Mircera.

Conclusions: Mircera once a month is safe and effective in correcting and maintaining the Hb levels. This pivotal study suggests that MIRCERA is an efficient treatment for PD patients.

FR-PO1598

Once Monthly C.E.R.A. Therapy Stabilizes Hemoglobin Levels in Peritoneal-Dialysis-Patients: Results from the BEAM-Study

Michael Koch,[1] Wolfgang Treiber,[2] Danilo Fliser.[3] *[1]Dialysis Center, Mettmann, Germany; [2]Dialysis Center, Neuwied, Germany; [3]Clinic for Internal Medicine IV, University of Saarland, Homburg, Germany.*

Background: The continuous erythropoietin receptor agonist (C.E.R.A.) has been approved for once monthly (QM) treatment of renal anemia. Therefore, it might be useful in peritoneal dialysis (PD) patients (pts). The BEAM study was the first study in Germany which was designed to investigate the efficacy and safety of C.E.R.A. in this pts.

Methods: In this non-interventional study 223 PD pts fulfilled the inclusion criteria and had been enrolled in the study. On average, the pts were 3.0 years exposed to PD. 61.4% of pts underwent CAPD (continuous ambulatory PD), 29,6% received APD (apparative PD) and 8,6% were treated in-centre at least three times a week with apparative PD. 48,2% of pts started with QM C.E.R.A. coming from shorter acting ESA, 27,7% were already on C.E.R.A. and 24,1% started de novo with C.E.R.A..Data about C.E.R.A treatment were analysed about a time period of up to 9 months (mt) in a descriptive way.

Results: 220 pts (98,7%) formed the safety population (SP). For 80.5% of pts Hb measurements were available over a time period of 2 mt beyond 6 mt of treatment (modified efficacy set, MES). Mean age of the study population was 59,6 years (48,6% female). 40,9% of pts exhibited cardiac disorders like coronary artery disease and 18,2% type II diabetes mellitus. C.E.R.A. administration modus was as follows: 38.6% of pts at the study centers, 35.5% of pts excl. at home and 25.9% of pts at both locations. In the MES-population the Hb increased from 11.1 to 11.4 g/dL at the end of the study. During the evaluation period (mt 7-9) 14.9, 37.9, and 39.8% of pts displayed Hb values in the target range of 11-12, 10-12, and 11-13 g/dL, respectively. The average dose of C.E.R.A.changed from 110 to 103 µg at the end of the study. In total, 37,3% of the SP population didn´t need any C.E.R.A.dose modifications during the 9-mt. Overall there were no specific drug related adverse events during the study.

Conclusions: QM treatment with C.E.R.A. is associated with a high degree of Hb-stability and tolerability within PD pts.

Secular Trends in Anemia Management in Hemodialysis 2004-2010

Navdeep Tangri,[1] Dana C. Miskulin,[1] Jing Zhou,[2] Courtney Cook,[2] Karen J. Bandeen-Roche,[2] L. Ebony Boulware.[2] *[1]Tufts Medical Center; [2]Johns Hopkins University; [3]DEcIDE Network Patient Outcomes in ESRD Study Investigators.*

Background: Several factors may have influenced anemia management in US hemodialysis patients, including: clinical trials showing increased adverse events and mortality with targeting higher hemoglobin (Hb), a FDA black box warning advising clinicians to avoid Hb >13 g/dl, a trial showing Hb responds to IV iron with serum ferritin up to 1000 ng/ml, and Medicare payment bundling of erythropoietin stimulating agents in Jan 2011.

Methods: We describe quarterly changes in median Hb, serum ferritin, transferrin saturation (TSat), and erythropoietin and IV iron use from 2004-2010 among patients treated with HD for ≥3 months in Dialysis Clinic Inc.

Results: As shown in the figures below, among 27798 patients, the median Hb increased between 2004 and 2006, peaking at 12.1 g/dl in 2006, declined in 2007, and gradually declined to its lowest point of 11.5 g/dLin 2010. Iron use declined from 2004-2005 and increased sharply in 2010. The median erythropoietin dose per treatment decreased steadily from 2004 (4200 units) to 2007 (3000 units), and slowly declined through 2010, at 2300 units by year end. The median serum ferritin was 429 ng/ml in early 2004 and steadily increased to 835 ng/ml in late 2010. Transferrin saturation (TSat) started to increase only in late 2010.

Conclusions: Hb and Epogen use declined and IV iron use increased from 2004-2010, with the largest changes occurring in 2010. Concurrently, serum ferritin increased from 2004 but median TSat and IV iron use per quarter increased only since 2010. Trends in utilization may reflect the influence of recent research findings and policy changes. Further investigation is warranted of reasons for stable TSat in the setting of rising ferritins, as well as of the safety of IV iron administration in the setting of higher ferritin levels.

FR-PO1600

Hyporesponsiveness to Erythropoiesis Stimulating Agents Is Associated with Increased Mortality among Hemodialysis Patients

Bed P. Chhatkuli, Kambiz Kalantarinia. *Division of Nephrology, University of Virginia Health System, Charlottesville, VA.*

Background: Higher hemoglobin concentrations are associated with higher mortality in CKD. We investigated if this increased mortality is related to higher degree of hyporesponsiveness to erythropoiesis stimulating agents (ESA).

Methods: Retrospective cohort study of all prevalent UVA ESRD patients on chronic hemodialysis for at least 3 months in 2008. Data on patient demographics, comorbidities and 3 consecutive monthly values for body weight, hemoglobin, ESA dose and other lab values was collected. Responsiveness to ESA was determined by dividing the ESA dose per kilogram of body weight by the Hb concentration. The association between tertiles of ESA responsiveness (EResp) and mortality was investigated in a multivariate model including patient demographics, diabetes status, albumin, Kt/V, PTH, iron status and use of renin angiotensin blockers.

Results:

Patient Characteristics

	All (n = 702)	Tertile 1 (n = 234)	Tertile 2 (n= 234)	Tertile 3 (n = 234)	p value
Age (SD)	62.5 (13.9)	61.9 (12.7)	63.6 (14.0)	62 (15)	0.98
Gender (%) F	45.2	39.7	46.2	49.6	0.09
Race (%) AA/C/O	(57/41/2)	(54/44/2)	(55/42/3)	(62/37/1)	0.25
RAAS blocker (%)	42	58	62	54	0.24
Diabetes (%)	57.8	55.1	59.8	58.5	0.57
Albumin (g/dL)	3.9 (0.5)	4.0 (0.4)	4.0 (0.5)	3.8 (0.6)	<0.0001
PTH (pg/mL)	336 (302)	297 (309)	341 (241)	372 (343)	0.008
Ferritin (ng/mL)	608 (634)	572 (367)	598(378)	654 (959)	0.18
Transferrin sat (%)	24.1 (9.5)	25.8 (8.9)	24.1 (8.1)	22.4 (11)	0.0001
Hemoglobin (g/dL)	11.5 (1.1)	12.0 (0.8)	11.6 (0.8)	11 (1.3)	<0.0001
Aranesp dose (mcg)	174.2 (105 – 327)	83.3 (58.3 – 108.3)	174.2 (141.7 – 226.7)	402.1 (300.0 – 620.0)	<0.0001
EResp (mcg/ kg/g Hb)	0.32 (0.32)	0.09 (0.03)	0.22 (0.05)	0.65 (0.38)	<0.0001
Alive (%)	64.4	73.9	62.8	56.4	0.0003

In multivariate analysis, age (p<0.0001), race (p =0.047) and EResp (p <0.001) were associated with mortality. In comparison to the lowest quartile of EResp, tertiles 2 and 3 had OR of 1.80 and 2.7 for mortality. In a different model where Hb and ESA dose were entered separately, ESA dose and not Hb was associated with mortaliy.

Conclusions: Hyporesonsiveness to ESA and higher doses of ESA are associated with higher all cause mortality among HD patients.

FR-PO1601

IV Versus SC ESA Dosing Requirements in US and Non-US Hemodialysis (HD) Patients Brigitte Schiller,[1] Iain C. Macdougall,[1] Francesco Locatelli,[1] Andrzej Wiecek,[1] Adrian Constantin Covic,[1] Carol Francisco,[2] Helen Tang,[2] Sandra Tong,[2] Minjia Chen,[2] Anne-Marie Duliege,[2] Krishna R. Polu,[2] Martha Mayo.[2] *[1]AFX-01-12 and -14 Peginesatide Study Groups; [2]Affymax, Inc, Palo Alto, CA.*

Background: Peginesatide (Hematide™) is a synthetic, PEGylated, investigational, peptide-based erythropoiesis-stimulating agent (ESA) that acts via stimulation of the erythropoietin receptor.

Methods: Data were pooled from two phase 3, randomized, active-controlled, open-label trials assessing the safety and efficacy of peginesatide (once monthly) compared with epoetin alfa/beta (epoetin; 1-3 times weekly) in HD patients previously on stable epoetin doses (EMERALD 1 and 2). Patients received study drug via the same administration route used at the time of screening. This analysis compares hemoglobin (Hb) levels and intravenous (IV) versus subcutaneous (SC) dosing requirements in US and non-US HD patients.

Results: The median epoetin dose during the evaluation period (weeks 29-36) tended to be lower for the SC than IV route across regions, whereas this was not observed for peginesatide (Table). For both routes, ESA doses were higher in US than non-US patients. Mean Hb levels were similar for US and non-US patients regardless of administration route (Table). Mean total IV iron administered was 2246 mg for US and 2613 mg for non-US patients during weeks 0-52.

	SC		IV	
Evaluation Period	**Peginesatide**	**Epoetin**	**Peginesatide**	**Epoetin**
US Patients				
Mean Hb level (SE), g/dL	11.3 (0.1) [n = 34]	11.2 (0.2) [n = 15]	11.1 (0.04) [n = 698]	11.2 (0.05) [n = 380]
Median dose (Q1-Q3), mg/mo or U/wk	6.8 (3.5-11.8) [n = 33]	7,200 (3,800-13,800) [n = 15]	5.6 (3.4-10.2) [n = 683]	9,800 (5,400-18,700) [n = 374]
Non-US Patients				
Mean Hb level (SE), g/dL	10.9 (0.1) [n = 62]	10.8 (0.1) [n = 27)	11.2 (0.09) [n = 139]	10.9 (0.1) [n = 63]
Median dose (Q1-Q3), mg/mo or U/wk	3.9 (2.5-6.8) [n = 62]	4,100 (2,300-6,100) [n = 27]	3.5 (2.2-5.7) [n = 138]	5,000 (2,700-8,000) [n = 61]

Conclusions: For peginesatide, the SC route was not associated with reduced doses compared with IV. Despite similar Hb values in the range of 10-12 g/dL, ESA doses in US patients were higher than in non-US patients.

FR-PO1602

Nutrition and Erythropoietin Resistance Index in Hemodialysis Patients. CARNIDIAL Trial [NCT 00322322] Lucile Mercadal,[1] Mathieu Coudert,[2] Anne Vassault,[3] Laurence Pieroni,[3] Messaoud Ouziala,[4] Hélène De Préneuf,[5] Aude Servais,[6] Nader Bassilios,[7] Ubald Assogba,[8] Gilbert Deray.[1] *[1]Nephrology, AP-HP, Pitie Salpetriere Hospital, Paris, France; [2]Biostatistics, AP-HP; [3]Biology, AP-HP; [4]CMC Pantin; [5]AURA; [6]AP-HP, Necker hospital; [7]Clinique de Turin; [8]Institut Mutualiste Montsouris.*

Background: Nutrition influences anaemia correction in hemodialysis by several pathways, such as nutrient deficiencies and a decrease of anti-oxidative capacity leading to a pro-inflammatory effect. We described herein the relation between nutrition markers and rHuEPO responsiveness.

Methods: The data of 92 incident hemodialysis patients randomized to receive in double blind placebo or intravenous L-carnitine for a 1 year period were considered for analysis. Primary outcome was presented elsewhere. Determinant factors of rHuEPO resistance index (RI) defined as weekly rHuEPO (UI/kg body weight) / hemoglobin level (g/dL) were studied on 1144 observations taking into account patient effect and using a Box-Cox transformation. Albuminemia dosage was centralized and done by a turbidimetry method. Relations between RI and nutritional markers and supply were studied in multivariate analysis adjusted for iron status, CRP, dialysis vintage, renin angiotensin system inhibitors, dietary supplement, and carnitine group.

Results: Mean caloric supply was 1691 ± 460 kcal/day. Albuminemia increased during the study period from 34.0 ± 6.4 to 36.8 ± 5.2 g/L (p=0.0045). Albuminemia, lymphocytes count were negatively associated with RI whereas serum bicarbonates were positively associated with it. After adjustment,the nutrition marker being either albuminemia or lymphocytes count or serum bicarbonates remained strongly associated with RI (β -0.12 ± 0.02 per g/L albuminemia, p<0.0001; β -0.03±0.01 per % increase in lymphocytes, p=0.01; β 0.08 ± 0.03 per mmol/L bicarbonates, p=0.005). Oral dietary supplement remained associated with a higher RI (β 2.9±0.7 for patients taking supplement, p=0.0003).

Conclusions: Nutrition status independently of iron and inflammation status and carnitine supply is a potent determinant factor of rHuEPO resistance index.

The Effects of Feraheme® (ferumoxytol) Administration on Target Hemoglobin Levels in Hemodialysis Patients across Three Dialysis Chains Amit Sharma,[1] Premila Bhat,[2] Brigitte Schiller,[3] Justin Mclaughlin,[4] Zhu Li,[4] Annamaria T. Kausz,[4] William Strauss.[4] *[1]Boise Kidney and Hypertension Institute, Boise, ID; [2]Atlantic Dialysis Management Services, Ridgewood, NY; [3]Satellite Healthcare, San Jose, CA; [4]AMAG Pharmaceuticals, Lexington, MA.*

Background: Dialysis clinics typically aim to maintain their IDA patients' hemoglobin (Hgb) level between 10-12 g/dL. The IV iron ferumoxytol (Feraheme®) was approved by the FDA in 2009, with a recommended dose of 2x510 mg 3 to 8 days apart. The intent of this study was to examine the success of maintaining Hgb levels within the target range using ferumoxytol across a range of real-world administration practices and patient characteristics.

Methods: Three separate US-based dialysis chains provided laboratory and dosing data from all patients treated with ferumoxytol throughout 2010. Throughout this period, all available values for Hgb, TSAT, and ferritin were obtained for each patient from electronic laboratory databases, while all ferumoxytol doses were obtained from billing records. Monthly Hgb values were based on the last available measurement within the calendar month. Across the three chains, different IV iron treatment paradigms were employed: Chains A and B primarily dosed ferumoxytol in courses of 2 x 510 mg administered within 3 to 8 days, while Chain C primarily gave single 510 mg doses monthly as needed. All 3 chains targeted Hgb between 10 to 12 g/dL.

Results: Over the one-year period across the three chains, 8,666 patients were treated with 33,358 doses of ferumoxytol. Following conversion to ferumoxytol, all three chains were able to maintain a majority of their patients within the target Hgb range over the following 12 months despite variations in IV iron administration practices and patient characteristics (Chain A = 55 to 66%; Chain B = 63 to 78%; and Chain C = 52 to 72%).

Conclusions: Across the 3 dialysis chains, the use of ferumoxytol either by period course or by monthly dosing allowed for the majority of patients to be maintained within the target Hgb range of 10-12 g/dL.

FR-PO1604

Reduction in Erythropoeitin Usage Following Change in Iron Therapy to Ferumoxytol Roger J. Haley. *KDHCD, Visalia, CA.*

Background: Based upon a favorable reimbursement model, the two hemodialysis facilities operated by Kaweah Delta Health Care District, a California Hospital District, changed parenteral iron preparation from ferrous sucrose [V] to ferumoxytol [F].

Due to looming "bundling" of dialysis related charges, which would nullify the favorable reimbursement, a retrospective study was carried out to ascertain overall financial performance of continued use of [F] versus [V]. The change-over for all patients occurred in the same calendar month.

Methods: The patient cohort consisted of all patients who underwent hemodialysis in one of the facilities in the six months prior to the change over and the 7 months following the changeover. Patients were censored if: no [V] was given in the 6 month [V]-phase, were hospitalized at any point in the 13 months, received a blood transfusion as any point in the 13 months, or missed more than 2 dialysis treatments during any calendar month. 92 patients met these criteria. Data was analyzed for this study group (n=92).

Administration of EPO and Iron was determined by a renal pharmacist acting under a protocol for Epo and Iron administration, that remained unchanged during the study time frame, other than iron preparation.

The "change-over month" was excluded from analysis due to the fact both EPO and F were administered based upon laboratory determinations at the beginning of the changeover month, which reflected response to [V].

Results: Values in table are means ± SD. The 6 months preceding change-over was compared to the 6 months following the change-over month in this stable patient group.

Results

Group	Hgb	Ferritin	Iron Sat	Epo u/dialysis	Iron mg/month
[V]	11.7±0.8	670±427	28±12	3679±3255	172±275
[F]	11.7±0.8	782±352	31±13	2846±3762	137±265
p value	0.74	<0.0001	<0.05	<0.0001	<0.01

The data shows controlled Hgb, improved iron studies, and lower iron and EPO usage.

Conclusions: Based upon current population and acquisition and administration costs, progressive bundling of reimbursement (to 100% cost borne by the facilities for all EPO and Iron) the use of [F] should result in $986 savings per patient annually, with overall savings exceeding $300,000 annually.

FR-PO1605

C.E.R.A. Once-Monthly (QM) Maintains Stable Hemoglobin (Hb) Values in Patients (pts) with Chronic Kidney Disease (CKD) on Dialysis: A Pooled Analysis of Nine Trials Conducted in a Real-World Setting Frank Dellanna,[1] Michael Dickenmann,[2] Ricardo Correa-Rotter,[3] Christos E. Iatrou,[4] Valeriy Y. Shilo,[5] Sylvie Sulkova,[6] Joan Fort,[7] Neval Duman,[8] Francesco Locatelli.[9] *[1]Dialysezentrum Karlstrasse, Düsseldorf, Germany; [2]University Hospital, Basel, Switzerland; [3]Instituto Nacional de la Nutrición, Salvador Zubirán, Mexico; [4]General Hospital of Nikea Piraeus, Athens, Greece; [5]Moscow University of Medicine and Dentistry, Moscow, Russian Federation; [6]Institute of Clinical and Experimental Medicine, Prague, Czech Republic; [7]University Hospital Vall d'Hebron, Barcelona, Spain; [8]Ankara University School of Medicine, Ankara, Turkey; [9]Alessandro Manzoni Hospital, Lecco, Italy.*

Background: To investigate the impact of different Hb targets on Hb levels, Hb stability and C.E.R.A. dose in pts with CKD on dialysis switched from maintenance therapy with shorter-acting erythropoiesis-stimulating agents (ESAs) to C.E.R.A. QM.

Methods: Data were pooled from nine 24-week trials in adult pts with CKD on dialysis converted to C.E.R.A. QM. Clinical endpoints during the final 8-week period (evaluation period [EP]) were analysed according to the target Hb range: 10-12 g/dL (4 trials), 10.5-12.5 g/dL (3 trials), or 11-13 g/dL (2 trials).

Results: Pts (n=1473) had a median age of 63 (range 19-93) years. The table shows: mean Hb; mean Hb fluctuation; the percentage of pts with stable Hb (average Hb within the target range or a change from baseline ≤1 g/dL); and the mean dose of C.E.R.A. QM for the 3 groups during the EP.

Target range (n)	Mean Hb (g/dL)	Mean Hb fluctuation (g/dL)	Pts maintaining stable Hb levels (%)	Mean C.E.R.A. dose (µg)
Overall (n=1473)	11.4±1.02	0.48±0.30	77	134±86
10-12 g/dL (n=603)	11.2±0.94	0.47±0.28	82	128±92
10.5-12 5g/dL(n=459)	11.6±1.11	0.53±0.34	74	136±91
11-13 g/dL (n=411)	11.5±0.96	0.44±0.28	75	143±62

On average there were 2.0 dose changes per pt over 24 weeks of treatment. Tolerability of C.E.R.A. QM was similar to that of prior ESA therapy.

Conclusions: These pooled data in pt on dialysis show homogenous results with C.E.R.A. QM across all study endpoints, irrespective of the target Hb.

FR-PO1606

Characteristics of Patients with Acute vs. Chronic Erythropoiesis Stimulating Agent (ESA) Hyporesponsiveness David T. Gilbertson, Yi Peng, Tom Arneson, Stephan C. Dunning, Allan J. Collins. *CDRG, Minneapolis, MN.*

Background: 'ESA hyporesponsiveness' in hemodialysis (HD) patients refers to high doses of ESAs to treat anemia. A presumed need for high-dose ESA is often the result of functional iron deficiency, bone marrow fibrosis and inflammation. Episodes of hyporesponsiveness may resolve quickly, or may persist. We assessed unadjusted associations of patient characteristics with acute vs. chronic hyporesponsiveness.

Methods: We used point prevalent HD patients on May 1, 2008 with Medicare coverage, surviving through Dec 2008. The 90th percentile of total EPO dose each of 5 months (Aug-Dec) was used to define monthly hyporesponsiveness for each patient. Further classifications included chronic (hyporesponsive in 4+ consecutive months) and acute hyporesponsiveness (≤3 consecutive months of hyporesponsiveness with at least one month not hyporesponsive before and after the hyporesponsive month(s)). Comorbidity was defined using Medicare Part A & B claims during May-Jun (antecedent), and separately, Aug-Dec (concurrent).

Results: 4.5%, and 5.2% of patients were classified as chronic, and acute, respectively. There were no differences by gender or race between patients with acute vs. chronic hyporesponsiveness. However, patients who were younger, with diabetes as cause of renal failure, lower BMI, and of shorter dialysis vintage had proportionally greater acute hyporesponsiveness. Most comorbidities, whether antecedent to the study period or concurrent, were more prevalent in patients who had episodes of acute versus chronic hyporesponsiveness. The largest differences between the two groups were for cerebrovascular accident/transient ischemic attack, ASHD, and infectious and all-cause hospitalizations.

Conclusions: Episodes of acute and chronic hyporesponsiveness are not uncommon, and early identification of patients at risk for such episodes may lead to improved anemia management in these patients. The impact of the bundled reimbursement system, implemented in Jan 2011, on the management of anemia in these patients is unknown, and should be assessed.

FR-PO1607

Hemoglobin (Hb) Stability during Peginesatide Versus Epoetin Treatment in Hemodialysis (HD) Patients Robert Provenzano,[1] Brigitte Schiller,[1] Mark Kaplan,[1] Bruce S. Spinowitz,[1] Carol Francisco,[2] Anne-Marie Duliege,[2] Alex Yang,[2] Krishna R. Polu,[2] Martha Mayo.[2] *[1]AFX-01-12 and -14 Peginesatide Study Groups; [2]Affymax, Inc., Palo Alto, CA.*

Background: Hb variability is associated with an increased risk of mortality in HD patients (Pisoni 2011). Limiting it is desirable and important for reimbursement metrics like the quality incentive program (QIP). Peginesatide (Hematide™) is a synthetic, PEGylated, investigational, peptide-based erythropoiesis-stimulating agent (ESA) that is designed to specifically stimulate the erythropoietin receptor.

Methods: Data were pooled from two phase 3, randomized, active-controlled, open-label studies assessing safety and efficacy of peginesatide (once monthly; N = 1066) compared with epoetin alfa/beta (epoetin; 1-3 times wkly; N = 542) in HD patients (EMERALD 1 and 2). Hb variability during the evaluation period (EP; wks 29-36) was measured using the standard deviation (SD) of Hb levels within patients and median of the absolute deviation (MAD) from the within-patient Hb level. An Hb analysis similar to the QIP determined the proportion of patients with average monthly Hb levels over 1 yr within the 10-12 g/dL target range (wks 29-80). A composite safety endpoint (CSE) was evaluated that consisted of 6 events: all causes of death, stroke, myocardial infarction, and serious adverse events (AEs) of congestive heart failure, unstable angina, and arrhythmia.

Results: Hb variability was similar for the peginesatide and epoetin groups using the SD (median = 0.51 vs 0.48) and MAD (median = 0.44 for both) methods. In the QIP analysis, most patients in the peginesatide and epoetin groups had average monthly Hb levels within the target range (91% vs 95%). Fewer patients in the peginesatide than epoetin group had dose adjustments (>20% change from previous dose) during the EP (47% vs 68%). The frequency of CSE events during the studies was similar for both groups (23% vs 24%).

Conclusions: Hb stability and the proportion of patients within the target range were similar for peginesatide and epoetin; fewer patients in the peginesatide group had dose adjustments. Similar rates of cardiovascular AEs were reported for peginesatide and epoetin.

FR-PO1608

Prescribing EPO to Chronic HD Patients: A Physiologic Approach Implemented with Continuous Quality Improvement Leads to Decreased EPO Dose Changes and Decreased Hemoglobin Variability Jonathan Lorch,[1] Victor E. Pollak.[2] *[1]New York Presbyterian Hospital-Weill Medical College of Cornell University, New York, NY; [2]University of Colorado HSC, Denver, CO; [3].*

Background: Prescribing EPO has been influenced by widely used guidelines whose validity in practice has never been tested rigorously. Physicians have been urged to maintain patient Hb in the 100-120 g/L range, and to adjust EPO dosage to meet this target range. Allowing Hb to exceed 120 g/L has been thought to have an adverse effect on survival despite compelling contrary evidence.

Methods: Starting in February 2010, we tested an approach using patient-specific data collected during daily care and stored in a commercially available electronic medical record (EMR) in one dialysis unit (the protocol unit, 260 patients). Repleting iron insufficiency, ensuring iron sufficiency, and reducing EPO stepwise were key elements, while changing dose every 6-8 weeks rather than every 2-4 weeks.

Year	2004-2005	2006-2007	2008	2009	2010-1	2010-2	2011
Protocol Unit	12.6	14.9	10.6	8.4	4.8	3.8	2.1
Comparator Unit 1	18.9	20.1	20.0	20.5	21.2	17.0	8.5
Comparator Unit 2	8.8	19.8	19.3	15.2	17.6	14.3	8.5

Results: This was associated with an increase in Hb to 123.6 g/L and a low mortality (11.7 deaths per 100 patient years). Two other units (210, 186 patients respectively) served as comparators. In each unit, using data stored in the EMR, we counted and report in the Table new and discontinued orders for EPO and analyzed duration of treatment by HD per patient year from 2004 to May 2011. Data for 2010 are shown in two 6-month periods because the protocol, with its EPO prescribing changes, was instituted in 2010.

Conclusions: In the protocol unit. changes for new and discontinued EPO orders decreased by 78% and 87% per patient year respectively. In 2004-2009 there was an average of 15.8 EPO dose changes per year in the 3 units, a rate 4.2 and 7.5 times that in the protocol unit in the last two time periods. Also, the median coefficient of variation (CV) of individual patient Hb decreased 49% from 11.3% to 5.7% in the protocol unit. Hb CV was 49%, 30%, and 29% greater in the 3 units in 2004-2009 when KDOQI prescribing guidelines were in use.

FR-PO1609

Prescribing EPO to Chronic Maintenance HD Patients: A Physiologic Approach Implemented with Continuous Quality Improvement Leads to Decreased EPO Use and Increased Hemoglobin Jonathan Lorch,[1] Victor E. Pollak.[2] *[1]Medicine, New York Presbyterian Hospital-Weill Medical College of Cornell University, New York, NY; [2]Medicine, University of Colorado HSC, Denver, CO; [3].*

Background: EPO mitigates severity of anemia in chronic HD patients. Data from the US, Australia/New Zealand, and 8 European countries found that the per country weekly EPO dose varied from 9,500 to >21,300 units, with no relationship between dose and achieved Hb which ranged from 116 to 121 g/L (McFarlane PA, et al. Kidney Int 78:215, 2010). The therapeutic approach has been influenced by widely used guidelines whose validity in practice has never been tested rigorously.

Methods: With the objectives of achieving optimal Hb with minimum required EPO and maintaining stable Hb and EPO, we designed and tested an approach using patient-specific data collected during daily care and stored in a commercially available electronic medical record (EMR). Patient specific data collected over 9.5 years informed the study which was implemented in 250 HD patients in a single dialysis unit receiving EP0 prior to February 1, 2010, and followed to April 30, 2011. Repleting iron insufficiency, ensuring iron sufficiency, and reducing EPO stepwise were key elements. Decision support tools were used that enabled relevant data display over prolonged periods in patient-centered reports. EPO dose, adjusted at 6-8 week intervals, was based on current clinical condition and past responses.

Results: In the study patients, IV iron administration and TSAT increased after protocol start. Hb increased by months 1-2; EPO decrease began from month 4 onward. By months 11-15, EPO had decreased 32% from 15,488 to 10,580 units/week while patient median Hb increased 8% from 114 to 123.6 g/L. Both Hb and EPO administered changed little from month 7 onward, and were stable in months 11-15. Comparable results were not observed in two comparator units that reduced EPO administration, but with neither a defined plan nor a CQI approach.

Conclusions: It is possible to reduce EPO administration and its cost while maintaining or improving patient Hb and maintaing a low patient mortality (11.7 deaths per 100 patient years).

FR-PO1610

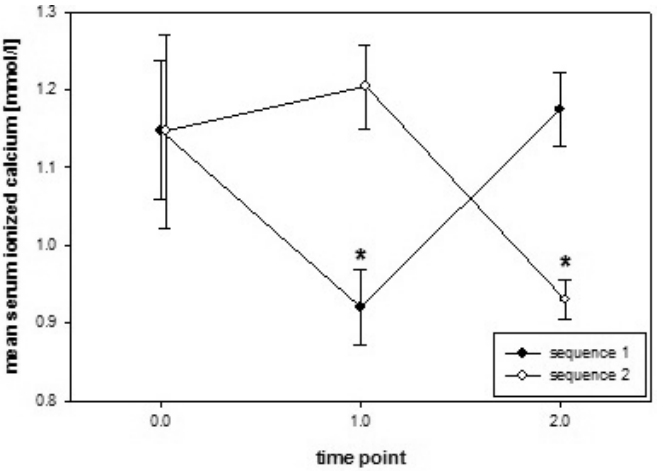
Serum Ionized Calcium Levels Determine Arterial Stiffness in Dialysis with Regional Citrate Anticoagulation Matthias B. Moor, Anja Kruse, Dominik E. Uehlinger, Ute Eisenberger. *Nephrology and Hypertension, University Hospital Bern, Bern, Switzerland.*

Background: Hemodynamic effects of changes in serum ionized calcium (iS_{Ca}) are difficult to determine during conventional hemodialysis (HD) using a fixed dialysate concentration of calcium. The model of regional citrate anticoagulation (RCA) using continuous calcium infusion allows to study the effects of predefined iS_{Ca} changes on arterial stiffness and blood pressure during HD.

Methods: In a cross-over study, 15 patients with chronic kidney failure underwent two HD sessions with RCA. Each session was divided into 2 study phases in which iS_{Ca} was titrated either to 0.8-1.0 mmol/l or to 1.1-1.4 mmol/l. Sequence of phases was randomly chosen and alternated for the second session. 30 minutes after reaching a stable iS_{Ca} level, pulse wave velocity (Pulse Trace PWV, Micro Medical Ltd, UK), arterial blood pressure and heart rate were measured. Statistical analysis was performed with SAS 9.2 for Windows on an X64_VSPRO platform.

Results: ISCa levels were modified during sequence 1 (iSCalow-high) from a predialysis baseline value of 1.15 ± 0.09 mmol/L, first to 0.92 ± 0.05 mmol/L (time point 1; *p< 0.001 vs baseline) and then to 1.18 ± 0.05 (time point 2; ns). During during sequence 2 (iSCahigh-low), iSCa levels were modified from 1.15 ± 0.12 mmol/L first to 1.20 ± 0.05 mmol/L (time point 1; ns vs baseline) and then to 0.93 ± 0.03 (time point 2; *p < 0.001), see figure.

Assuming a basic linear repeated measures model, PWV was positively related to iS_{Ca} levels ($p < 0.03$) independent of systolic or diastolic blood pressure, heart rate or ultrafiltration rate.



Conclusions: PWV, an indirect measure of arterial stiffness known to impact on long-term survival in chronic hemodialysis patients, is closely related to serum ionized calcium levels in HD patients using RCA as a study model.

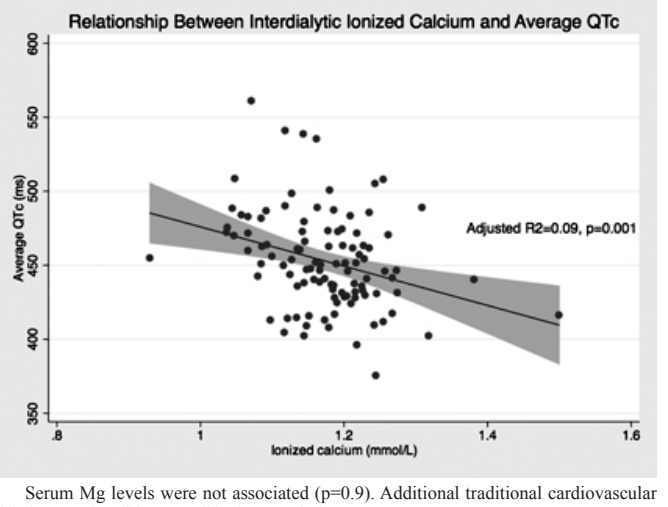
Interdialytic Ionized Calcium Is Associated with a Pro-Arrhythmic Phenotype in Incident Dialysis Patients: The Predictors of Arrhythmic and Cardiovascular Risk in ESRD (PACE) Study Danica Lam,[1] Wen Hong Linda Kao,[2] Stephen M. Sozio,[2] Lucy A. Meoni,[2] Tariq Shafi,[2] Bernard G. Jaar,[2] Julia J. Scialla,[2] Larisa Tereshchenko,[2] Rulan S. Parekh.[1,2] *[1]University of Toronto; [2]Johns Hopkins University.*

Background: Patients on hemodialysis are at high risk of malignant arrhythmias and sudden cardiac death (SCD). We hypothesize that low levels of interdialytic ionized calcium (iCa) and magnesium (Mg) are associated with arrhythmias.

Methods: We investigated the cross-sectional association of prolonged QT interval, a pro-arrhythmic electrocardiogram (ECG) metric, with levels of Mg and iCa in an incident hemodialysis cohort of 114 PACE participants. At the baseline visit on a non-dialysis day, iCa corrected for pH and Mg levels were measured. A 5-minute signal-averaged ECG was recorded in a quiet room. Corrected QT (QTc) intervals were calculated and prolonged QTc was defined as >460 ms in women and >440 ms in men.

Results: In the 114 participants studied, mean age was 55±15 years. 54% were male, and 74% African-American. 32% had self-reported coronary artery disease, 54% diabetes, 25% atrial fibrillation, and 22% congestive heart failure. Prevalence of a prolonged QTc was 58% in men and 46% in women. The mean iCa levels were 1.2±0.1 mmol/L and mean Mg levels were 1.8±0.2 meq/L. Linear regression showed that iCa has a significant effect on QTc (Figure).



Serum Mg levels were not associated (p=0.9). Additional traditional cardiovascular risk factors also did not modify the association.

Conclusions: Prevalence of prolonged QTc on non-dialysis days was very high among incident dialysis patients. Interdialytic iCa but not Mg is significantly inversely associated with length of the QTc. Additional work is needed to determine if clinical dialysis parameters lower iCa and increase the risk of long QTc, which ultimately may lead to SCD.

FR-PO1612

Association of Cardiac Valve Calcification and C-Reactive Protein (CRP) with Cardiovascular and All-Cause Mortality in End-Stage Renal Disease Patients – 10-Year Follow-Up Study from Induction of Hemodialysis Therapy

Yasuhiko Ito,[1] Hirotake Kasuga,[2] Masashi Mizuno,[1] Keiko Kimura,[2] Shoichi Maruyama,[1] Enyu Imai,[1] Seiichi Matsuo.[1] *[1]Nephrology, Nagoya University, Nagoya, Japan; [2]Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan.*

Background: Cardiac valve calcification is frequently seen in patients with end-stage renal disease (ESRD), and may potentially reflect systemic atherosclerosis. Serum CRP is also reported to predict future cardiovascular (CV) events. We investigated the association of cardiac valve calcification, CRP and their joint role with prediction of mortality in patients on hemodialysis (HD).

Methods: A total of 1,290 consecutive patients who started HD therapy were screened by echocardiography. Patients were divided into 3 groups; those without valve calcification (NC group, n=548), those with calcification in a single (aortic or mitral) valve (SC group, n=487) and those with calcification in both valves (BC group, n=255). They were also divided into tertiles according to serum CRP levels; T1: <0.9, T2: ≥0.9 to >4.9 and T3: ≥4.9 mg/l, respectively. They were followed up for up to 10 years.

Results: Serum CRP levels were 4.0±6.7, 6.8±9.9 and 7.2±9.8mg/l in the NC, SC and BC group, respectively (p<0.0001), and were independently associated to valve calcification (Odds ratio 1.13, 95%CI 1.06-1.21, p=0.0003). Adjusted hazard ratio (HR) of valve calcification was 2.64 (95%CI 1.53-4.56, p=0.0023 for group BC vs. NC) for CV mortality and 1.86 (95%CI 1.30-2.67, p<0.0001 for group BC vs. NC) for all-cause mortality, respectively. Similarly, adjusted HR of elevated CRP levels was 3.09 (95%CI 1.54-6.16, p=0.0050 for T3 vs. T1) for CV mortality and 2.44 (95%CI 1.64-3.64, p<0.0001 for T3 vs. T1) for all-cause mortality, respectively. In the joint setting of valve calcification and CRP, the risk of CV and all-cause mortality was 6.4-fold (p=0.0073) and 3.6-fold (p<0.0001) in the BC group with T3 of CRP compared with the NC group with T1 of CRP even after adjustment, respectively.

Conclusions: Cardiac valve calcification and elevated CRP levels were closely linked, and interactively increased risk of mortality in ESRD patients who started HD therapy.

FR-PO1613

Phosphate Plasma Level as Risk Factor for Cardiovascular Morbidity and Mortality and Association of Sevelamer with Outcomes in Hemodialysis Patients – Posthoc Analysis of the AURORA Trial

Bengt C. Fellstrom,[1] Mattias Tejde,[2] Hallvard Holdaas,[3] Alan G. Jardine,[4] Roland E. Schmieder,[5] Eva K.A. Johnsson,[6] Faiez Zannad.[7] *[1]Renal Unit, Uppsala, Sweden; [2]Renal, Falun; [3]Renal, Oslo; [4]CV Res, Glasgow; [5]Renal, Erlangen; [6]AZ, Gbg; [7]CIC, Nancy.*

Background: AURORA was a randomized trial in 2776 hemodialysis patients, studying the effect of rosuvastatin10 mg on major CV events. There was no effect on any CV endpoint, but the database provides an opportunity to explore risk factors for CV events and mortality.

Methods: Baseline plasma phosphate as risk factor for CV disease (CVD) in HD patients was examined for CV endpoints used in the study, including mortality. Cox proportional analysis was used for risk factor assessment, after adjustment for covariates and presented as hazard ratio (HR) per unit phosphate increase. Ranking of risk factors at baseline (age, diabetes, high-sensitivity C-reactive protein [hsCRP], albumin, phosphate, low-density lipoprotein cholesterol (LDL-C), previous CVD, smoking, medication, etc) was performed. Concomitant medication was analysed as as well. Sevelamer was used in 508 patients (18%) , and its association with outcome was analysed.

Results: Plasma phosphate at baseline was an independent and strong risk factor for Major CV events (HR=1.49; p<0.0001; Rank 3), death from any cause (HR=1.34; p<0.0001; Rank 5), CV death (HR=1.58; p<0.0001; Rank 3), Atherosclerotic event (HR=1.46; p<0.0001; Rank 3), Major CV event or death (HR=1.35; p<0.0001; Rank 5), Nonfatal MI (HR= 1.51; p<0.0013; Rank 4) but not for Non-CV death (HR=1.11; p= 0.24; Rank 11) . Sevelamer use at baseline was associated with reduced mortality (HR= 0.84 ; P<0.029). Thus, plasma phosphate was one of the strongest and highest ranking risk factors for CV events and mortality and the use of sevelamer was associated with a reduced mortality, basically because of influence on CV death.

Conclusions: Baseline plasma phosphate levels is one of the most important risk factor for CV events and mortality in hemodialysis patients in the AURORA trial. Sevelamer treatment seems to be associated with a better patient survival.

FR-PO1614

The German Calciphylaxis (Calcific Uremic Arteriolopathy) Registry

Vincent Brandenburg,[1] Paula Specht,[1] Jurgen Floege,[2] Markus Ketteler.[3] *[1]Cardiology, University Hospital Aachen, Aachen, Germany; [2]Nephrology, University Hospital Aachen, Aachen, Germany; [3]Nephrology, Klinikum Coburg, Coburg, Germany.*

Background: Calcific uremic arteriolopathy (CUA, calciphylaxis) is a rare condition associated with high morbidity and mortality. CUA is clinically characterised by painful, ischemic, skin ulcerations. Pathomorphologically, media calcification of cutaneous arterioles is the hallmark of the disease.

Methods: We established an internet-based registry (www.calciphylaxie.de) to allow online notification for all cases of established or suspected CUA. The registry is a comprehensive data base including various parameters (patient characteristics, laboratory data, clinical background and presentation as well as therapeutic strategies). Follow-up of the patients is planned by systematic queries of long-term outcome. We try to gain overview about current treatment strategies and link them to the clinical course.

Results: Altogether 127 CUA patients from 105 centers have been documented during 54 months: n = 76 (60 %) female; median age 69 yrs (range 21 - 89); 80% Caucasians; n = 99 (78%) dialysis patients; n= 57 (45%) diabetic patients.

Lab data from dialysis patients (median, interquartilen-range): Serum total calcium: 2.23 (2.08 - 2.39) mmol/L; serum phosphorus: 1.7 (1.3 - 2.1) mmol/L; PTH 156 (61 - 357) pg/mL. Oral anticoagulation with coumadins was common (46%). Cutaneous lesions were localized in more than 80% at the lower extremities or gluteal region. Among the most frequently recorded therapeutic procedures were: surgical necrosectomy, intensifying dialysis modality, i.v. sodium-thiosulfat application, lowering dialysate and oral calcium burden, systemic antibiotics, and stopping coumadins

Conclusions: CUA is associated with end-stage renal disease, female gender, diabetes and oral anticoagulation. PTH levels do not exceed current KDIGO target levels for ESRD in most cases. Decisions on therapeutic strategies vary significantly. The present internet based CUA registry is a valuable tool to collect data upon CUA cases and will serve as a basis for prospective studies.

FR-PO1615

The Calcium Content of Hard Coronary Plaques Is a Predictor of Mortality in Maintenance Hemodialysis Patients

Antonio Bellasi,[1] Emiliana Ferramosca,[2] Geoffrey A. Block,[3] Paolo Raggi.[4] *[1]Azienda Ospedaliera S.Anna, Italy; [2]Azienda Ospedaliera S.Orsola-Malpighi, Italy; [3]Denver Nephrology; [4]Emory University.*

Background: The prognostic value of coronary artery calcification (CAC) has been documented in CKD patients. Nonetheless, several investigators maintained in the past that calcified plaques are stable and not prone to cause events

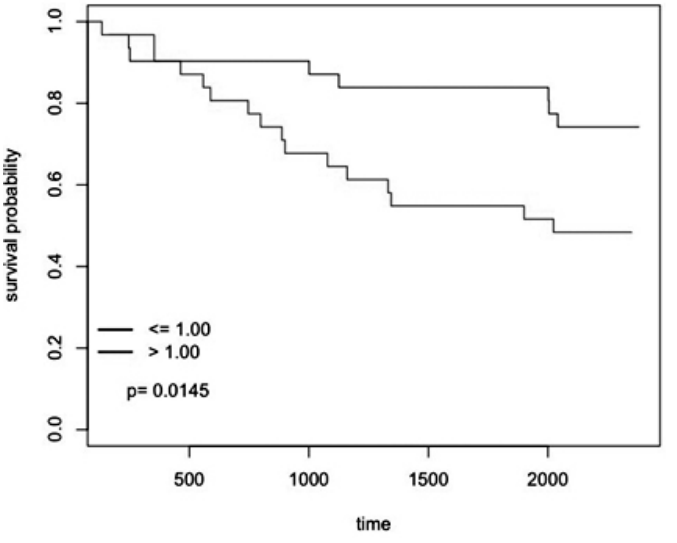
Methods: Between 2004 and 2005, 130 individuals underwent cardiac CT imaging for quantification of CAC via the Agatston and the Volume score. Since the Agatston score is derived by multiplying the density and the volume of calcified lesions, the ratio of the Agatston and the Volume score (AVR) standardizes the overall calcium content per plaque volume unit. Patients were classified as high AVR (>1) or low (≤1) AVR. Survival analyses tested the association between AVR and all-cause mortality during a median follow-up of 5 years

Results: Overall 63% of patients had a high AVR. The study cohort characteristics are summarized in the table.

Table 1

	Overall (n=130)	Low ratio (n=48)	High ratio (n=82)	p
Age (SD)	55(14)	50(13)	59(13)	0.005
%Men	52	64	49	0.29
Dialysis Vintage (SD)	4.2(4.2)	4.1(3.8)	4.4(2.9)	0.72
Hypertension (%)	95	96	96	0.66
Diabetes (%)	52	44	58	0.32
ASCVD (%)	38	28	48	0.11
Framingham (% risk)	12(10)	11(11)	14(11)	0.25
Congestive heart failure (%)	22	12	28	0.17

The mortality rate of patients with high AVR was higher than in those with low AVR calcification.



After adjustment for age, sex, race, diabetes and history of atherosclerotic disease (ASCVD) high AVR remained independently associated with all-cause mortality (HR: 2.24; 95% CI: 1.02 – 4.88, p=0.042)

Conclusions: Increased AVR is an independent predictor of all-cause mortality in hemodialysis patients. These results suggest that presence of calcium content in the coronary arteries in not an index of stability but rather a harbinger of adverse future events

FR-PO1616

Study on the Relationship of Serum 25-hydroxyvitamin D Levels with Vascular Calcification in Hemodialysis Patients Jae Hyun Chang, Sejoong Kim, Hyun Hee Lee, Wookyung Chung, Ji Yong Jung. *Department of Internal Medicine, Gachon University of Medicine and Science, Incheon, Korea.*

Background: Cardiovascular disease (CVD) is the main cause of mortality in chronic kidney disease patients. Vascular calcification is highly prevalent in this population and is an independent predictor of cardiovascular mortality. The role of vitamin D in this process remains controversial. The aim of this study was to determine the prevalence of vitamin D deficiency (25-hydroxyvitamin D [25D] ≤ 15 ng/ml), insufficiency (25D levels between 16 and 30 ng/ml), and moreover the relationship between vitamin D levels and vascular calcificationin hemodialysis patients.

Methods: We performed a cross-sectional study with 289 hemodialysis patients.Patients were 56.9 ± 14 years of age, 49.5% males,46.4% diabetics and 34.9% with a history of CVD. PlainX-ray images of lateral lumbar spinefrom all subjects were studied for calculation of semiquantitativevascular calcification scores as described by Kauppila.

Results: Only 3.1% of patients had adequate levels of25D (>30 ng/mL), 10.7% of them had insufficientlevels and 86.2% had deficient levels. Female gender and diabetes were associated with vitamin deficiency. We also found a high prevalence of vascular calcificationin this population. Kauppila scores revealed 180 patients (62.3%) with vascular calcification. In univariate analysis, 25D levels were inversely related to vascular calcification (r = – 0.170, P = 0.004). However, after correction for confounding factors, this relation lost statistical significance. Multivariate analysis showed that age, systolic blood pressure, andLDL-cholesterol were directly associated with higher vascular calcification scores (>7).

Multiple logistic regression analysis of factors associated with higher vascular calcification scores

Parameters	OR	95% CI	P
Dependent variable:Kaupilla> 7			
Age	1.068	1.041-1.095	< 0.001
SBP	1.014	1.002-1.026	0.021
LDL-C	1.012	1.001-1.023	0.031
25D	0.974	0.920-1.031	0.370

Conclusions: Vitamin D deficiency and insufficiency were highly prevalent in hemodialysis patients. However, low 25D levels could not be identified as an independent predictor of vascular calcification in thesepatients.

FR-PO1617

Septadian Variation in Cardiac Mortality in Haemodialysis (HD) but Not Peritoneal Dialysis (PD) Patients Rathika Krishnasamy,[1,2] Carmel M. Hawley,[1,2] Sunil V. Badve,[1,2] Brian E.R. Livingston,[1] Stephen P. McDonald,[1] Philip A. Clayton,[1] Fiona Brown,[1] Kevan R. Polkinghorne,[1] Kym M. Bannister,[1] Neil Boudville,[1] Kathryn J. Wiggins,[1] David W. Johnson.[1,2] *[1]Australia and New Zealand Dialysis and Transplant Registry, Adelaide, Australia; [2]Department of Nephrology, University of Queensland at Princess Alexandra Hospital, Brisbane, Australia.*

Background: Cardiovascular disease (CVD) represents the leading cause of death in dialysis patients. However there is limited evidence that dialysis modality may also influence mortality related to CVD. The aim of this study was to evaluate the effects of dialysis modality and HD frequency on the septadian pattern of cardiac and non-cardiac mortality in the Australian and New Zealand (ANZ) end-stage kidney failure (ESKF) cohorts, using data from the Australia and New Zealand Dialysis and Transplant (ANZDATA) Registry.

Methods: We analysed all adult ESKF patients (n=14594, HD n= 10338, PD n = 4256) receiving maintenance dialysis in ANZ who died between 1 January 1999 and 31 December 2008. The independent predictors of cardiac and non-cardiac death were determined by multivariable logistic regression.

Results: Cardiac deaths accounted for 40% of deaths. Cardiac death was significantly more likely to occur on Mondays and Tuesdays for HD patients receiving 3 or fewer dialysis sessions per week (n=9967), [Monday adjusted odds ratio(OR)1.42(95% CI 1.22-1.66), Tuesday OR 1.29(95% CI 1.10-1.51)].This pattern of increased deaths on Mondays and Tuesdays was not seen among PD patients, HD patients receiving more than 3 sessions per week (n =371) or home HD patients (n=573). Subgroup analyses showed sudden cardiac deaths also had a septadian pattern among HD patients.This pattern was not seen for non-cardiac deaths.

Conclusions: Our novel finding is that patients on PD, home HD and HD patients receiving more than 3 sessions per week did not demonstrate the usual septadian pattern of CV deaths on Mondays and Tuesdays. This data may provide insights into mechanisms of CV deaths in the dialysis cohort.

FR-PO1618

Carotid Artery Calcification at the Initiation of Hemodialysis Is a Risk Factor for Cardiovascular Events in Patients with End-Stage Renal Disease Yoriko Ura,[1] Hirofumi Ikeda,[1] Masaharu Nagata,[2] Masaru Nakayama.[1] *[1]Division of Nephrology and ClinicalResearch Institute, Department of Internal Medicine, National Kyushu Medical Center Hospital, Fukuoka, Japan; [2]Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

Background: Vascular calcification has been recognized as a risk factor for cardiovascular (CV) events in patients with end-stage renal disease (ESRD). However, the association of carotid artery calcification (CAAC) with CV events remains unknown. The aim of this study was to elucidate whether CAAC is associated with composite CV events in ESRD patients.

Methods: One-hundred thirty-three patients who had been started on hemodialysis between 2004 and 2008 were included in this retrospective cohort study. These patients received multi-detector computed tomography to assess CAAC at the initiation of hemodialysis. Composite CV events, including ischemic heart disease, heart failure, cerebrovascular diseases, and CV deaths after the initiation of hemodialysis, were examined in each patient.

Results: CAAC was found in 94 patients (71%). At the end of follow-up, composite CV events were seen in 47 patients: ischemic heart disease in 20, heart failure in 8, cerebrovascular disease in 12, and CV deaths in 7. The incidence of CAAC was 87% in patients with CV events, which was significantly higher than the rate (62%) in those without. Kaplan-Meier analysis showed a significant increase in composite CV events in patients with CAAC compared with those without CAAC (p=0.001, log-rank test). Univariate analysis using a Cox hazard model showed that age, smoking, common carotid artery intima-media thickness and CAAC were risk factors for composite CV events. In multivariate analysis, only CAAC was a significant risk factor for composite CV events (hazard ratio, 2.85; 95% confidence interval, 1.18-8.00; p=0.02).

Conclusions: CAAC is an independent risk factor for CV events in ESRD patients. The assessment of CAAC at the initiation of hemodialysis is useful for predicting the prognosis.

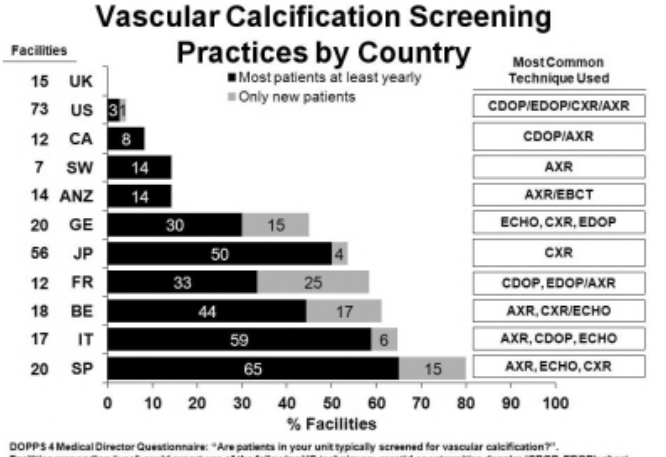
FR-PO1619

Dramatic International Variation in Vascular Calcification Screening Practices: Results from the DOPPS Bruce M. Robinson,[1,2] Douglas S. Fuller,[1] Brian Bieber,[1] Christian Combe,[3] Yun Li,[1,2] David C. Mendelssohn,[4] Francesca Tentori,[1] Shunichi Fukuhara.[5] *[1]Arbor Res Collab for Hlth, Ann Arbor; [2]Univ of MI, Ann Arbor; [3]CHU Bordeaux, France; [4]Humber River Reg Hosp, Canada; [5]Kyoto Univ, Japan.*

Background: The 2009 KDIGO MBD guidelines indicate CKD stage 3-5D patients with vascular/valvular calcification (VC) are at highest cardiovascular (CV) risk, but do not recommend for or against VC screening. We describe facility VC screening practices internationally and associations with clinical outcomes.

Methods: Data were from 7,703 chronic in-center hemodialysis (HD) patients in 266 DOPPS 4 facilities (2010). Medical directors were asked if they typically screen for VC. Among 6 countries with >45% of units screening for VC, clinical practices and laboratory measures were compared with generalized estimating equations adjusted for demographics, comorbidity, and intra-facility correlation. Rates of CV hospitalizations and mortality were compared with adjusted Cox models.

Results: Routine VC screening was reported by <5% of US and UK units but was common (45-80%) in Japan and most European DOPPS countries. Somewhat lower Ca-based phosphate binder (51.5% vs 58.5%, p=0.16) and dialysate Ca (<3 mEq/L; 25.5% vs 36.7%, p=0.14) use was seen in VC screening units. No notable differences in vitamin D use or serum calcium, phosphorus, and PTH levels were seen. VC screening units had similar CV hospitalizations (hazard ratio [HR]=0.86; 95% CI=0.61, 1.21) and all-cause mortality (HR=0.99; 95% CI=0.79, 1.25) as non VC-screening units.



DOPPS 4 Medical Director Questionnaire: "Are patients in your unit typically screened for vascular calcification?". Facilities responding "yes" could report use of the following VC techniques: carotid or extremities doppler (CDOP, EDOP); chest, abdominal, or hand X-ray (CXR, AXR, HXR); echocardiogram (ECHO); or electron-beam computed tomography (EBCT). Most common techniques listed in order of frequency.

Conclusions: Use of VC screening and preferred screening tests vary dramatically across DOPPS countries. VC screening units may choose practices that limit calcium exposure to a greater extent than other units. Whether tailoring therapy based on VC screening limits VC progression or improves clinical outcomes needs additional study.

Funding: Pharmaceutical Company Support

FR-PO1620

Association of Omega-3 Polyunsaturated Fatty Acids with Carotid Arteriosclerosis in Patients on Chronic Hemodialysis Hirotake Kasuga,[1] Ryo Takahashi,[1] Keiko Kimura,[1] Chieko Matsubara,[1] Rei Okada,[1] Seiichi Matsuo.[2] *[1]Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan; [2]Nephrology, Nagoya University Hospital, Nagoya, Japan.*

Background: Omega-3 polyunsaturated fatty acids (n-3 PUFAs) are widely recognized to have beneficial effects on cardiovascular disease. In hemodialysis (HD) patients, blood levels of n-3 PUFAs have been reported to be more suboptimal compared to general population. However, the association between n-3 PUFAs levels and cardiovascular risk is little known in this population. We investigated the association of n-3 PUFAs levels with carotid arteriosclerosis in HD patients.

Methods: Carotid ultra-sound was performed in a total of 461 patients (male 67%, age 67±12years, diabetes 46%) stably undergoing HD. Intima-media thickness (IMT) and plaque score (PS) in common carotid artery were measured. Carotid arteriosclerosis was defined as IMT >1.2mm and/or PS >5.0mm. The levels of n-6 PUFAs [dihomo-gamma-linolenic acid (DHLA) and arachidonic acid (AA)] and n-3 PUFAs [eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA)] were also measured prior to carotid ultra-sound.

Results: Carotid arteriosclerosis was seen in 94 patients (20.4%). Individual PUFAs were comparable between patients with and without carotid arteriosclerosis, however, the ratio of EPA / AA and the ratio of n-3 / n-6 PUFAs were significantly lower in patients with carotid arteriosclerosis than in those without (0.43±0.29 vs. 0.53±0.44, p = 0.027 and 0.94±0.43 vs. 1.07±0.55, p = 0.036, respectively). On multivariate logistic regression analysis, the ratio of EPA / AA [odds ratio (OR) 0.45, 95% confidential interval (CI) 0.22-0.93, p = 0.029] and the ratio of n-3 / n-6 PUFAs (OR 0.60, 95%CI 0.36-0.99, p = 0.046) were independently associated with carotid arteriosclerosis, respectively. Based on the cut-off level of 0.27 determined by ROC analysis (AUC = 0.63), the incidence rate of carotid arteriosclerosis was significantly higher in patients with low EPA / AA ratio than those with high EPA / AA ratio (27.9% vs. 17.5%, p = 0.012).

Conclusions: These data suggest that low levels of both EPA / AA ratio and n-3 / n-6 PUFAs ratio were closely associated with incidence of carotid arteriosclerosis in patients on HD.

FR-PO1621

Long-Term Outcomes of Cardiac Risk Stratification Using Gated Single Photon Emission Computed Tomography (SPECT) in Asymptomatic End-Stage Renal Disease Patients at the Start of Dialysis Jwa-Kyung Kim,[1] Ja-Ryong Koo,[2] Young Rim Song.[1] *[1]Department of Internal Medicine & Kidney Research Institute, Hallym University Medical Center, Anyang, Gyunggi-do, Korea; [2]Department of Internal Medicine & Kidney Research Institute, Hallym University Medical Center, Chuncheon, Gangwon-do, Korea; [3]Korea.*

Background: Screening for occult coronary artery disease (CAD) might permit early identification of subjects at increased risk of an adverse cardiac event. The aim of this study was to investigate the long-term effects of cardiac risk stratification using gated single photon emission computed tomography (SPECT) in ESRD patients at the start of dialysis.

Methods: This is an observational cohort study performed in Hallym University Hospital between January 2005 and April 2009. Baseline echocardiography were performed in all patients. For high risk patients who presented at least one cardiovascular risk factor, or decreased ejection fraction(<50%) or regional wall motion abnormality (RWMA) on echocardiography, SPECT was recommended. Cardiac events were defined as cardiac death and non-fatal acute coronary syndrome.

Results: Among 303 patients, 254 were high-risk patients. SPECT was performed in 143 of the patients and 66 showed reversible perfusion defects. During the mean follow-up of 59.0 months, overall cardiac event rate per person-year of follow-up was 6.0%; it was significantly higher in high-risk group compared to that of low-risk group (6.6 vs. 1.6%, HR3.43, 95% CI 1.61-7.24). Multivariate Cox analysis showed that old age, diabetes and RWMA were independent predictors of adverse cardiac events in total patients. Among high-risk patients who underwent SPECT, summed stress score ≥9 (HR 2.60 95%CI 1.32-5.13) and reversible perfusion defect (HR3.37 95% CI 1.86-6.10) was additionally associated with the increased risk of cardiac event. The subgroup analysis in patients with reversible perfusion defects showed that intensive revascularization therapies decreased the risk of cardiac events by 50% compared to patients who treated only medically.

Conclusions: In conclusion, intensive cardiac work-up with SPECT may provide important prognostic information, particularly in high-risk dialysis patients.

FR-PO1622

Temporal Evolution of Systolic and Diastolic Blood Pressure in the Frequent Hemodialysis Network (FHN) Trials Peter Kotanko,[1] John B. Stokes,[2] Amit X. Garg,[3] Thomas A. Depner,[4] Christopher T. Chan,[6] Andreas Pierratos,[7] Brett Larive,[5] Gerald J. Beck,[5] Tom H. Greene,[5] Nathan W. Levin,[1] Alan S. Kliger,[8] The FHN Trial Group.[5] *[1]Renal Research Institute, New York, NY; [2]Iowa U and VA Med. Center, Iowa City, IA; [3]Div of Nephrology, U Western Ontario, London, Canada; [4]UC Davis, Davis, CA; [5]NIDDK, NIH, Bethesda, MD; [6]Univ. Health Network, Toronto, Canada; [7]U Toronto, Toronto, Canada; [8]Yale U, Princeton, NJ.*

Background: As part of the FHN Trials we investigated the impact of 6x weekly in-center hemodialysis (HD; Daily Trial) and 6x weekly nocturnal home HD (Nocturnal Trial) over 12 months on systolic and diastolic blood pressure (SBP; DBP).

Methods: In the Daily Trial 245 patients (pts) were randomized to 6x or 3x weekly HD, in the Nocturnal Trial 87 pts were randomized to 6x weekly nocturnal HD or 3x weekly HD. Pre-HD SBP and DBP were measured at baseline and then monthly. Intradialytic weight loss (IWL) was used as a proxy of interdialytic weight gain.

Results: In the Daily Trial, compared to 3x weekly HD, 6x HD resulted in lower blood pressure at 1 month (SBP [mean±SE; mm Hg]: -5.9±1.8, P<0.001; DBP: -3.4±1.1, P<0.01) and at 12 months (SBP: -10.3±2.0; DBP: -5.5±1.2; all P<0.001). 6x HD led to a 0.4±0.2 kg (P=0.06) lower post-HD weight and a lower IWL of 1.0± 0.1 (P<0.001) at month 1; this difference was maintained through month 12.

In the Nocturnal Trial SBP and DBP did not differ between the 2 groups after 1 month; at 12 months both were lower in 6x HD pts (SBP: -8.3±3.3; DBP: -4.9±1.9; all P<0.05). Post-HD weight did not differ throughout the trial. IWL at month 1 was similar in the 2 arms; by 12 months 6x HD pts had a lower IWL by 0.5±0.2 (P<0.01).

Conclusions: Compared to 3x weekly HD, 6x HD produced a comparable fall in SBP and DBP in both the Daily and Nocturnal Trials; the difference became evident earlier in the Daily Trial. This indicates that frequent HD reduces blood pressure whether HD is given during the day or in longer nocturnal sessions. Potential mechanisms may be reduction of extracellular volume, as evidenced by reduced post-HD weight in the Daily Trial, and reduced IWL in both trials.

FR-PO1623

Absolute Values of Systolic Blood Pressure (SBP) Do Not Predict Second Year Survival in Incident Hemodialysis Patients with Stable SBP Jochen G. Raimann,[1,2] Len A. Usvyat,[1] Stephan Thijssen,[1,2] Peter Kotanko,[1,2] John Rogus,[3] Eduardo K. Lacson,[3] Nathan W. Levin.[1,2] *[1]RRI, NY; [2]BIMC, NY; [3]FMC NA.*

Background: The U-shaped relationship between systolic blood pressure (SBP) and mortality is recognized in incident and prevalent hemodialysis (HD) patients (Li 2006, Zager 1998). Incident HD patients whose pre-HD SBP increased or decreased by more than 1 mmHg per month over their 1st year had greater mortal risk compared to those with "stable" SBP (Usvyat, WCN 2011; ASN 2011). This analysis investigates the influence of absolute values of SBP on second year survival among patients with stable SBP (i.e. lacking linear trend of increase or decrease).

Methods: Patients who started HD in between Jan 1, 2001 to Feb 28, 2010 with at least 13 HD treatments in their second year of HD were stratified into 4 groups according to the SBP during the first month in Year 1: <120, 120-150, 151-180 and above 180 mmHg. Changes were quantified as the slope of a linear regression of SBP values per patient in the first year. Patients selected for survival studies showed SBP between -0.5 and +0.5 mmHg change per month. Cox Regression was used to analyze the hazard ratio (HR) of death by SBP group.

Results: Of 10245 eligible, incident HD patients (57% male, 38% black, 54% white, 54% diabetic and 62.1±15.6 years old), 1385 patients with stable SBP in Year 1 were included. HR for mortality adjusted for age, gender, black race, BMI, cardioprotective drugs (CPD), diabetes and various other co-morbidities did not differ between the SBP groups. Only age (HR 1.02; P<0.001) and race (HR 1.83, P<0.05) remained significant predictors. Use of CPD showed a trend of improved survival (HR 0.7, P=0.10).

Conclusions: The risk of death did not vary in different SBP groups, supporting prior findings that implicate change in SBP (compared to absolute levels) as the more significant factor impacting mortality risk in chronic HD patients. It cautions against the current practice whereby treatment targets are derived from epidemiologic studies, specifically that absolute thresholds should not be used in isolation for the development of guidelines and treatment strategies, because they do not reflect SBP changes.

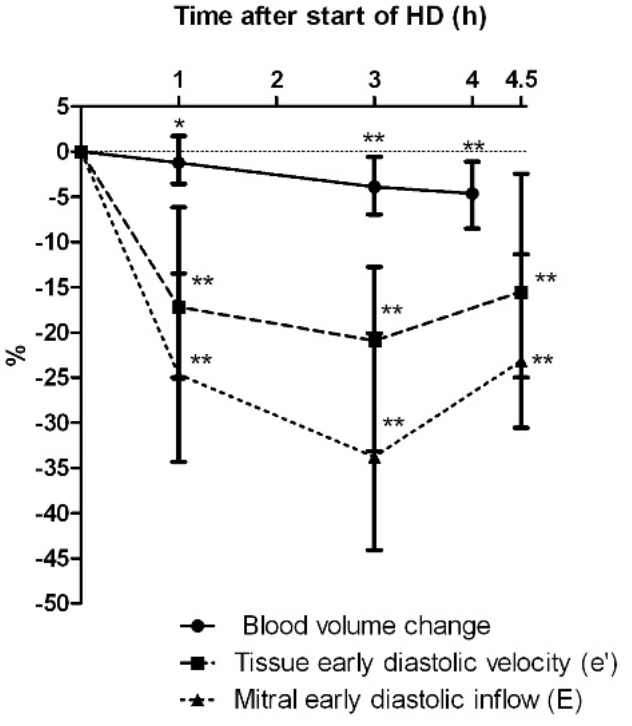
FR-PO1624

Hemodialysis-Induced Diastolic Dysfunction: It Is Not Only Volume! Solmaz Assa,[1] Yoran M. Hummel,[2] Adriaan A. Voors,[2] Johanna J. Kuipers,[3] Ralf Westerhuis,[3] Paul E. de Jong,[1] Casper F. Franssen.[1] *[1]Nephrology; [2]Cardiology, University Medical Center Groningen; [3]Dialysis Center Groningen, Netherlands.*

Background: Left ventricular (LV) diastolic dysfunction is common in hemodialysis (HD) patients. However, acute changes in diastolic function have been thus far studied before and after HD but not during HD. We evaluated in detail changes in LV diastolic function in relation to volume parameters during a single HD session.

Methods: Hundred and nine adult HD patients with a mean (±SD) age of 62.5 ± 15.6 year and median dialysis vintage of 2 (1-4) years participated in this study. Echocardiographic examination was performed 4 times: before HD, 60 min and 180 min after the start of HD and 30 min after the end of HD. Diastolic function was evaluated using mitral early inflow (E) and tissue-Doppler derived early diastolic velocity (e'). The change in blood volume (BV) during HD was calculated from the changes in hematocrit.

Results: Pre-HD median (IQR) E and mean (±SD) e' were 0.9 (0.8-1.1) m/s and 6.6 ± 2.1 cm/s, respectively. The figure describes the changes in LV diastolic function parameters during HD. E and e' decreased significantly at 60 min of HD by 24.7% (13.5-34.3%) and 17.2% (6.1-25.0%), respectively (both p<0.001), whereas BV had decreased by only 1.3% (-3.4-1.7%) (p<0.05, compared with pre-HD). There was no correlation between the change in BV or ultrafiltration (UF) volume and changes in E and e' at 60 min of HD, indicating that these changes were unrelated to changes in volume. At 180 min HD onwards the change in E correlates significantly with BV and UF volume. Such a correlation was not seen for the change in e'.



Conclusions: Diastolic function acutely deteriorates early during HD. This is not related to changes in BV or UF volume. Therefore, other factors than hypovolemia seem to cause an early impairment in diastolic function.

FR-PO1625

Predictors of Blood Pressure Variability Change over Time in Incident Hemodialysis Patients

Tariq Shafi,[1 2] Stephen M. Sozio,[1 2] Jing Zhou,[1 2] Courtney Cook,[1 2] Karen J. Bandeen-Roche,[1 2] L. Ebony Boulware.[1 2] *[1]Johns Hopkins University; [2]DEcIDE Network Patient Outcomes in End Stage Renal Disease Study Investigators.*

Background: Blood pressure variability (BPV) increases the risk of death in hemodialysis (HD) patients but the factors associated with BPV are not well described.

Methods: We assessed factors influencing within-patient variability in predialysis systolic BP (SBP) among 25,031 incident HD patients treated at Dialysis Clinic, Inc. (DCI). We assessed comorbidity using a previously validated index and fluid removal using change in weight during dialysis. We examined BPV in 3-month windows over the first year of HD using the residual-intercept ratio obtained from mixed-effects linear regression models estimating changes in SBP over time. This ratio reflects each individual's BPV over time with positive values reflecting greater BPV.

Results: Patients' mean age was 62 years; 35% were black and 44% were female. Patients who were older, female, black and had more comorbidity had consistently higher BPV during the first 6 months of dialysis. Greater fluid removal was associated with lower BPV in the first 6 months and calcium-phosphate product was associated with higher BPV after 6 months.

Predictors of Systolic BP Variability[1] in Incident Hemodialysis Patients

	0-3 months	4-6 month	7-9 months	10-12 months
N	25,031	21,190	18,729	16,665
Mean SBP±SD, mmHg	148±27	149±26	149±26	149±26
Predictors				
Age, years (Ref:18-44)				
45-64	**4.4**‡	**2.9**‡	**2.5**‡	**2.4**‡
>64	**3.6**‡	**1.7**†	1.1	**1.6**†
Female vs. Male	**4.6**‡	**4.9**‡	**5.0**‡	**5.2**‡
Black vs. White	**4.9**‡	**5.4**‡	**4.1**‡	**4.3**‡
Comorbidity (Ref:0-3)				
4-6	**1.2**†	**1.1**∗	**1.7**‡	**1.1**∗
7-9	**1.9**†	**1.5**∗	1.3	1.3
>9	**2.0**∗	1.6	0.02	0.7
Fluid Removal, per 10% weight	**-8.7**‡	**-4.3**‡	-2.4	-2.2
S. Albumin, per 1 g/dL increase	**-6.4**‡	**-7.3**‡	**-8.5**‡	**-9.3**‡
S.CaXPhos, per 10 higher	0.1	0.3	**0.7**‡	**0.7**‡

[1]Coefficients represent individual BPV in a 3 month period. Positive values represent higher BP variability. Coefficients are scaled by 10^{-1}. *p<0.05; †p<0.01; ‡p<0.001

Conclusions: In the first of year of HD, factors influencing within-patient BP variability can change significantly over time. Studies are needed to better understand these dynamic changes and their influence on clinical outcomes in HD patients.

FR-PO1626

Randomized Cross-Over Study of Daily Versus Conventional Hemodialysis To Explore Mechanisms of Blood Pressure Improvement

Deborah Lynn Zimmerman, Kevin D. Burns, Marcel Ruzicka. *Medicine, University of Ottawa, ON, Canada.*

Background: Hypertension (HTN) is poorly controlled in many end stage renal disease (ESRD) patients treated with conventional hemodialysis (CHD). Our study had 2 objectives: 1) To determine if short daily hemodialysis (SHD) is associated with improved systolic blood pressure (SBP) compared to CHD in hypertensive ESRD patients, and 2) To explore the potential mechanisms of BP improvement.

Methods: Randomized cross-over study of prevalent HD patients with a history of HTN (pre-dialysis SBP >140 and/or on 2 or more antihypertensive medications). After informed consent, patients underwent a 3 month run-in phase in which the dialysate Na was reduced to 138 mM, dry weight and antihypertensives were optimized to achieve a pre-dialysis SBP of <140mmHg. At the end of the run in phase, patients were then randomized to a further 3 months of CHD or SHD and then crossed over to the other treatment arm. SBP, ECFV via bioimpedance and catecholamines were measured after each phase, and intensity of antihypertensive therapy was estimated.

Results: 22 patients consented to participate in the study; 3 patient withdrew prior to randomization, 2 patients did not complete the SHD arm (included in the intent to treat analysis). There was a statistically significant decrease in SBP from study entry to the end of the run in phase (151 vs 138 mm Hg, p=0.004) without a change in dry weight (77.4 vs 77.1 kgs, p=0.63) or intensity of antihypertensive medications (p=0.57). There was no difference in SBP between CHD versus SHD (142 vs 139 mmHg, p=0.39) although more medication was required to control SBP in CHD (5.0 vs 3.7, p=0.02). These differences were not explained by plasma catecholamine levels (norepinephrine, p=0.33; epinephrine, p = 0.48), ECFV (p=0.77) or changes in dry weight (p=0.70).

Conclusions: A protocol-based approach to HTN management is associated with a significant reduction in SBP in ESRD patients treated with HD. Once target SBP has been achieved, both CHD and SHD are associated with maintenance of SBP but more antihypertensive medications are required in CHD. The mechanism(s) by which SHD improves SBP such that the number of medications can be reduced remains unclear.

Incidence, Prevalence and the Risks of Atrial Fibrillation in Dialysis Patients

Deborah Lynn Zimmerman,[1] Manish M. Sood,[2] Rachel M. Holden,[3] Swapnil Hiremath,[1] Claudio Rigatto,[2] Catherine M. Clase.[4] *[1]Medicine, University of Ottawa, ON, Canada; [2]Medicine, University of Manitoba, Winnipeg, MB, Canada; [3]Medicine, Queen's University, Kingston, ON, Canada; [4]Medicine, McMaster University, Hamilton, ON, Canada.*

Background: ESRD patients appear to be at high risk for atrial fibrillation (AF) but the risks and benefits of anticoagualtion for stroke prevention remain unclear. We undertook a systematic review to clarify the risks of mortality and stroke in patients with ESRD and AF.

Methods: A literature search using Medline and embase from 1990 to November 2010 was conducted that included ESRD patients treated with dialysis. Studies described incidence or prevalence and/or complications of AF with or without anticoagulation. Abstracts were reviewed and data abstracted by two investigators with conflicts resolved by a third investigator. Observational study quality was judged using the NewCastle Ottawa Scale. Event rates were calculated in patient-years and were combined using a random effects model.

Results: The average Ottawa New Castle Score was 6.1 (range 3-9) in the 21 studies that met our eligibilty criteria. The majority of patients were male (56%) with an mean age of 61 years. The overall prevalence of AF was 12.3% (range 4.5%-27%) and the overall incidence was 2.4/100 patient-years (range 0.97-5.9 events/100 patient-years). The risk of mortality was increased in ESRD patients with AF compared to ESRD patients without AF, 21.6/100 patient-years and 14.2/100 patient-years respectively. The risk of stroke was increased in patients with AF at 5.2/100 patient-years compared with 2.5/100 patient-years. The effects of anticoagulation on reducing the risk of stroke were heterogeneous.

Conclusions: The incidence and prevalence of AF in ESRD patients is high and is associated with an increased risk of mortality and stroke. Study variability was observed in design, population characteristics and method of AF documention. Given the limitations of the study designs and the equipoise about the risks and benefits of anticoagulation in patients with ESRD, a randomized controlled trial is required to clarify the optimal anticoagulation strategy in the ESRD population.

FR-PO1628

Determinants of Prolonged QTc Interval over 5 Years in Patients Undergoing Regular Hemodialysis Shigeru Oikawa,[1] Akihiko Kato,[2] Fumio Takayama,[1] Hisanori Azekura,[1] Narikazu Iijima,[1] Akira Shimomura.[1] *[1]Sanaru Sun Clinic, Hamamatsu, Shizuoka, Japan; [2]Blood Purification Unit, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan.*

Background: Prolongation of the corrected QT interval (QTc) on the surface electrocardiogram (ECG) is a predictor of total death and cardiac event in general population and patients with end-stage kidney disease. QTc prolongation is often observed in patients on chronic hemodialysis (HD), while it remains to be determined which factors are more associated with QTc prolongation over time.

Methods: In this study, we longitudinally measured QTc interval over 5 years, and examined the determinants of progression of QTc prolongation in stable 76 HD patients who had not taken any medication to prolong QTc interval (age: 63±12 [35-89] years, time on HD: 148±66 [63-387] months, male/female = 45/31, diabetes; n=12).

Results: Basal QTc was significantly and inversely correlated with albumin-corrected serum calcium (r=-0.36, p<0.01) and creatinine (r=-0.28, p=0.01). A longer QTc was also observed in female HD patients. During the 5-year observation, mean QTc was significantly increased from 421±18 to 428±21ms (p<0.01). The prevalence of borderline/abnormal QTc was increased from 18.4 to 36.8% (p<0.01). There was a significant and positive relationship between absolute changes in QTc and HD period (r=0.25, p<0.03). Older patients (≥65 years, n=34) disclosed a significant increase in QTc from 422±18 to 433±22ms during the follow-up (p<0.01). QTc interval was also prolonged more markedly in patients with serum albumin lower than 4.0 g/dL (420±20 vs. 434±22ms, p<0.05) (n=32) than those without (421±1 vs. 425±21ms). In contrast, diabetes and other co-morbid factors did not affect QTc prolongation.

Conclusions: These findings suggest that HD therapy increases QTc interval over time. In addition, prolongation of QTc is associated with ageing and hypoalbuminemia in stable patients on long-term HD.

FR-PO1629

Pulmonary Hypertension the Predictor of Mortality in HD and PD Patients: A Prospective Chinese Study Limeng Chen, Xuemei Li, Xiaohong Fan, Hong Xu, Jianling Tao, Xuewang Li. *Department of Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: Pulmonary hypertension (PH), a disease which carries substantial morbidity and mortality has been reported. No prospective evaluation of the prevalence or clinical significance of PH in ESRD patients in China has been undertaken. The objective of this study was to evaluate the impact of PHT and mortality among ESRD patients receiving chronic HD and PD therapy.

Methods: Echocardiograms were performed prospectively in chronic PD (n=73) and HD (n=89) patients at a single dialysis center. The patient's general clinical data were collected. The arterial stiffness was prospectively estimated by measure the Ankle-Brachial Index and brachial-ankle pulse wave velocity (baPWV). ABI and baPWV were remeasured , clinical outcome (death) were recovered at 36months.

Results: In these cohort patients, 44.9% of patients receiving HD, and in 34.2% of the patients receiving PD met the definition of PH (sPAP ≥ 35 mm Hg). Of those 30.3% HD patients and 16.4% PD patients met the definition of more severe PH (sPAP>45 mmHg). At 36 months, mortality was significantly higher in patients with PH (26.2%) compared with patients without PH(8.2%, p=0.002). And the PH was the independent risk factor of mortality in HD patients. Echocardiographic findings showing impaired left ventricular(LV) function and elevated diameter of inferior vena cava and left atrial were significantly associated with more severe PH. Anemia and lower body weight was also connected with PH. The other clinical features, such as dialysis time, nPCR, hypertension, CRP, P, PTH, Alb, TG, TC, HDL, Pwv and ABI had no significant difference between patients with or without PHT.

Conclusions: This prospective study of a single dialysis center suggests that PH may be present in nearly half of Chinese HD patients and 1/3 PD patients. When PH was present is associated with increased mortality. The Echocardiographic findings suggested that the PH may be secondary to diastolic dysfunction and compounded by volume overload.

FR-PO1630

Echocardiographic Determinants of an Abnormal Spatial QRS-T Angle in Chronic Dialysis Patients Mihaly K. De Bie,[1] Nina Ajmone Marsan,[1] Arien Gaasbeek,[2] Victoria Delgado,[1] Ton J. Rabelink,[2] Jeroen J. Bax,[1] Martin J. Schalij,[1] J. Wouter Jukema.[1] *[1]Cardiology, Leiden University Medical Center, Leiden, Netherlands; [2]Nephrology, Leiden University Medical Center, Leiden, Netherlands.*

Background: The spatial QRS-T angle, the angle between the mean QRS- and T-vector, describes the relation between ventricular depolarization and repolarization. Having a wide (abnormal) angle is considered a predictor of arrhythmic events in various patient groups, including dialyis patients. Given the high incidence of sudden cardiac death in dialysis patients, this parameter is of particular interest in this patient group. The objective of this study was to assess the association of (modifiable) echocardiographic parameters and an abnormal spatial QRS-T angle in dialysis patients.

Methods: A total of 93 consecutive dialysis patients (67.5 ± 7.5 yrs, 76% male) were included. In all patients a 12-lead electrocardiogram, a 2-dimensional echocardiogram and routine blood samples were obtained. Using a previously validated computer algorithm, the spatial QRS-T angle was then calculated from the 12-lead ECG. An abnormal spatial QRS-T angle was defined as ≥130° in males and ≥116° in females.

Results: An abnormal spatial QRS-T angle was present in 27 (29%) patients. Patients with an abnormal spatial angle had a higher serum phosphate (1.65 ± 0.43 mmol/L vs. 1.45 ± 0.32 mmol/L, p = 0.027). Furthermore, these patients had a lower left ventricular ejection fraction (LVEF) of 47 ± 7% vs. 55 ± 6% (p < 0.001) and had higher LV dyssynchrony as measured by tissue Doppler imaging, with a septal to lateral (S-L) delay of peak systolic velocity of 70 ± 42 ms vs. 40 ± 38 ms (p=0.001) respectively. Multivariate logistic regression analysis controlling for possible confounders demonstrated that LVEF (OR 0.82; 95%CI 0.73 -0.92, p=0.001) and S-L delay (OR 6.5; 95%CI 1.53 – 27.8, p=0.01) were independent determinants of an abnormal spatial QRS-T angle in this patient group.

Conclusions: Left ventricular ejection fraction and dyssynchrony are echocardiographic determinants of an abnormal spatial QRS-T angle in dialysis patients and might therefore represent a potential target for the prevention of sudden cardiac death in these patients.

FR-PO1631

Effect of Hemodialysis and Trimetazidine on QTc Prolongation in Patients with End-Stage Chronic Kidney Disease Ivica Premuzic Mestrovic,[1] Boris Kudumija,[2] Damir R. Rosic,[3] Mladen Knotek.[1] *[1]Department of Medicine, University of Zagreb Medical School, Clinical Hospital Merkur, Zagreb, Croatia; [2]Dialysis, Avitum, Zagreb, Croatia; [3]Department of Anatomy, University of Zagreb Medical School, Zagreb, Croatia.*

Background: Long QTc is an independent risk factor for sudden cardiac death in patients with end-stage renal disease. Patients on chronic hemodialysis (HD) have prolonged baseline QTc that is further extended by the HD.

This study examined whether the length of the baseline QTc and its changes in response to HD procedure depended on the HD days of the week and whether QTc duration may be reduced by trimetazidine, an antiishemia drug.

Methods: In a prospective, sequential trial 31 patients (age 57 ± 10 years, 23 men), treated by chronic HD, without any significant ischemic heart disease, were included. The study was conducted in two phases: a 14-day control phase (without trimetazidine) and the 28-day implementation phase of trimetazidine (at a dose of 35 mg bid). In the first week of the control phase and in the last week of the study, immediately before and after each HD session a 12-canal ECG was done and serum K, Na, Ca^{++} and troponin I were determined. The length of QT interval was determined manually, and was corrected for heart rate by the Bazzet formula.

Results: The pre-HD QTc during both phases was similar (p = n.s.). A significant prolongation of QTc occurred after the second (443.3±25.8 vs. 429.7±20.3 ms, p<0.01) and third HD session (441.6±25.9 vs. 430.1±25.3 ms, p<0.05) in the control phase. In the last week of the treatment phase this prolongation of the QTc after the first (437.2±27.5 vs. 430.4±22.4 ms, p= n.s.), the second (433.3±25.8 vs. 430.1±25.6 ms, p= n.s.) and the third (431.5±25.6 vs. 428.5±22.6 ms, p= n.s.) HD session disappeared. Serum K, Na, Ca++ and troponin I were not significantly associated with variability of the QTc. Trimetazidine was well tolerated, with no observed side effects.

Conclusions: The QTc after the HD procedure may depend on the day of the week, with the second and third HD day of the week being associated with prolongation of the QTc in response to HD. Prolongation of the QTc in response to HD can be significantly reduced by trimetazidine.

FR-PO1632

Ventricular Repolarization, Total Mortality and Sudden Death in a Population of Hemodialysis Patients Paolo Fabbrini,[1,2] Simonetta Genovesi,[1,2] Emanuela Rossi,[1] Andrea Stella.[1,2] *[1]Università degli Studi di Milano Bicocca, Monza, Italy; [2]Clinica Nefrologica AO S Gerardo, Monza, Italy.*

Background: A prolonged ventricular repolarization time (QT interval) is associated to an increased risk of total mortality and sudden death in the general population.

Among hemodialysis (HD) patients the prevalence of QT interval prolongation is high and the HD session can induce a further QT increase, but no data are available on QT length and mortality relationship in this population.

Methods: We studied 122 patients, recruited between 2005 and 2010 in a single HD center [age 71.3 years (38.5-89.2), HD duration 3.0 years (0.0-37.9), 64.8% male]. 37.7% of patients had ischemic cardiac disease, 42.6% dilated cardiomyopathy, 84.4% were hypertensive and 27.1% were diabetic. Ejection fraction (EF) was 60.0% (22-72) and cardiac mass index (CMI) was 147.3 gr/m2 (54.0-311.2). By ECG Holter and a dedicated algorhythm 24h QT length corrected for heart rate (QTc) was calculated. QTc length was considered prolonged when longer than 450 msec in men and 460 msec in women.

Results: 43 patients out of 122 (35.3%) had a prolonged QTc. Female gender (p<0.001), dilated cardiomyopathy (p=0.004) and amiodarone therapy (p=0.037) were significantly associated to a QTc prolongation, while EF% (p=0.004) was inversely correlated to the length of ventricular repolarization. Up today 37 deaths (10 sudden death) were observed. After stratification for age, QTc prolungation (p<0.001, HR=1.27 for 10 msec of increment) and the presence of dilated cardiomyopathy (p=0.052, HR=2.15) were independent predictors of mortality, while beta-blockers therapy was weakly protective (p=0.10, HR=0.53). Sudden death was associated to a prolonged QTc (p=0.010, HR=1.40 per 10 msec of increment), digoxin therapy (p=0.014, HR=22.44) and a greater CMI (p=0.037, HR=1.19 per 10 gr/m2 of increment).

Conclusions: In a population of HD patients, a prolongation of QTc interval is an independent predictor of total and sudden mortality

FR-PO1633

Prevalent and Incident Rates of Asymptomatic Electrocardiographic Abnormalities in Hemodialysis Patients Darren Green, Paul Dunne, David I. New, Philip A. Kalra. *Vascular Research Group, Manchester Academic Health Sciences Centre, University of Manchester, Salford Royal Hospital, United Kingdom.*

Background: Dialysis patients have a high rate of cardiovascular disease. Dialysis is itself associated with arrhythmia and myocardial ischemia. Routine ECG would be of potential benefit in detecting early signs of new cardiovascular changes as it is low cost, non-invasive, and repeatable.

Methods: We performed a pilot study of incidental ECG abnormalities in a cross-section of dialysis patients from one centre. Patients were selected who had an elective ECG as part of transplant, pre-operative, or routine out-patient cardiology assessment. In patients with 2 such ECGs, comparison was made between tracings. Patients were excluded who had suffered acute troponin rises between ECGs, so as to assess changes that occur independent of distinct acute cardiac events.

Results: 176 patients were included in the cross-sectional study. The mean age was 68 years, with mean time on dialysis 4.7 months. 29% of patients had 1st degree heart block, 12% had prolonged QRS (>100ms), 28% Sokolow-Lyon indexed LVH, 26% T-wave inversion, and 3% atrial fibrillation. 89 patients had follow up assessment with mean time between ECGs 18 months. New onset QRS ischemic changes in the absence of acute coronary events occurred at a rate of 50 per 1000 patient years. The rate of new T-wave abnormalities was 48 per 1000 patient years. QTc became prolonged only in female patients (female baseline mean 431ms vs. follow up 458ms p=0.000, male baseline 434ms vs. follow up 438ms p=0.486). The rates of new conduction defects were 50 and 36 per 1000 patient years for atrial fibrillation and 1st degree heart block, respectively.

Conclusions: The prevalent rate of conduction defects and rate of new onset changes was high. This may give insight into the source of the high rate of arrhythmic death suffered by dialysis patients. The rate of onset of new ischemic changes fits with previous reports of dialysis being associated with myocardial injury. This pilot study supports the need for future work to determine whether routine ECG can improve cardiovascular risk stratification for these patients.

FR-PO1634

Pre-Dialysis Factors and the Timing of Dialysis Initiation among Older Adults Deidra C. Crews,[1,3] Julia J. Scialla,[1,3] Haifeng Guo,[2,3] Jiannong Liu,[2,3] Bernard G. Jaar,[1,3] L. Ebony Boulware.[1,3] *[1]Johns Hopkins Medical Institutions, Baltimore, MD; [2]Chronic Disease Research Group, Minneapolis, MN; [3]DEcIDE Network Patient Outcomes in ESRD Study Investigators.*

Background: In recent years patients have been initiating dialysis at increasingly higher estimated glomerular filtration rates (eGFR), despite a lack of evidence of benefit and suggestions of harm in some studies. We examined pre-dialysis factors that might influence earlier initiation of dialysis by nephrologists treating older adults.

Methods: Using USRDS data, we identified patients initiating dialysis at age 67+ years from 2006-2008, with 2 years Medicare coverage prior to initiation, and at least one outpatient nephrology visit in the 6 months preceding initiation. Medicare claims and the Medical Evidence form were used to ascertain comorbidities, and 6 months of Medicare claims were reviewed for the frequency of nephrology visits and number of congestive heart failure (CHF) admissions immediately preceding dialysis initiation. Logistic regression assessed the relation between pre-dialysis patient characteristics (comorbidities and health care utilization patterns) and early (eGFR ≥10 ml/min/1.73m^2) versus later (eGFR <10) dialysis initiation. We adjusted for demographics, year of dialysis initiation, ESRD cause, albumin, hemoglobin, and erythropoiesis stimulating agents and/or intravenous iron use.

Results: Among 70,662 patients, median age was 77 [interquartile range (IQR) 72-82] years and median eGFR at dialysis initiation was 11.0 (IQR 8.2-14.4) ml/min/1.73m2. Early initiators comprised 58%. Greater burden of comorbidities, frequent nephrology visits and CHF admissions were associated with early dialysis initiation.

Adjusted Odds Ratios Comparing Early versus Later Dialysis Initiation

Pre-Dialysis Factor	N (%)	Categories	Odds Ratios (95% Confidence Interval)
Comorbidity score (greater=more comorbidities)	18,252 (26)	≤ 5	1.00 (referent)
	15,446 (22)	>5 to ≤ 8	1.38 (1.32-1.44)
	20,232 (29)	>8 to ≤ 11	1.67 (1.59-1.75)
	16,732 (24)	>11	2.12 (2.02-2.24)
Nephrology visits in the 6 months prior to dialysis initiation	29,066 (41)	>0 to ≤ 5 visits	1.00 (referent)
	19,412 (28)	>5 to ≤ 10 visits	1.12 (1.08-1.17)
	22,184 (31)	>10 visits	1.22 (1.17-1.26)
CHF admissions in the 6 months prior to dialysis initiation	36,699 (52)	None	1.00 (referent)
	18,489 (26)	>0 to ≤ 1 admissions	1.15 (1.11-1.20)
	8,413 (12)	>1 to ≤ 2 admissions	1.54 (1.46-1.63)
	7,061 (10)	>2 admissions	2.12 (1.99-2.27)

Conclusions: Multiple comorbid illnesses and intensive pre-dialysis health care utilization may influence nephrologists to initiate dialysis early among older adults.

FR-PO1635

Prospective Study on Clinical Effects of Dialysis in Treatment-Resistant Congestive Heart Failure Frank Van der Sande,[1] Trijntje T. Cnossen,[1] Jeroen Kooman,[1] Harmen P. Krepel,[2] Nicole Uszko-Lencer,[4] Karel M.L. Leunissen.[1] *[1]Nephrology, University Hospital Maastricht, Maastricht, Netherlands; [2]Nephrology, Franciscus Hospital, Roosendaal, Netherlands; [3]Nephrology, Catharina Hospital, Eindhoven, Netherlands; [4]Cardiology, University Hospital Maastricht, Maastricht, Netherlands.*

Background: The incidence of congestive heart failure (CHF) is still increasing and treatment of hypervolemic patients with treatment-resistant CHF complicated by progressive and permanent chronic renal insufficiency, known as cardiorenal syndrome (CRS) type 2, is notoriously difficult. Aim of the study was to investigate clinical outcome in CRS type 2 treated with dialysis.

Methods: Prospective observational non-randomized study. At start, after 4 and 8 months of dialysis, functional status, quality of life (QoL) using Minnesota Living with Heart failure Questionnaire and left ventricular ejection fraction (LVEF) were evaluated. Survival and hospitalization time were registered till April 1, 2011.

Results: Twenty-three patients with CRS type 2 (mean age 66±21 years, mean glomerular filtration rate 14.6±12.1 ml/min, 95% CI 0-28.5 ml/min, mean Charlson's comorbidity index 4.9±1.2) started with dialysis (12 (52%) patients started peritoneal dialysis (PD), 11 (48%) intermittent hemodialysis (IHD)). Seven patients (30%) died during the study period. Cumulative survival is shown in a Kaplan-Meier curve (figure 1). Median estimated survival time was 16 months. At the end of the follow-up period 5 patients were still treated for >20 months. Hospitalizations for cardiovascular causes were reduced (2.1±2.9 vs. 0.4±0.6 days/patient/month, p=0.000). NYHA class improved (3.8±0.4 at start vs. 2.4±0.7 after 4 months vs. 2.7±0.9 after 8 months; p=0.001) and QoL tended to improve (63±21 at start vs. 41±20 after 4 months vs. 51±25 after 8 months; p=0.056)). Left ventricular ejection fraction (LVEF) did not change.

Conclusions: After starting dialysis for CRS type 2, survival is highly variable, hospitalizations for cardiovascular causes were reduced, functional status improved and QoL tended to improve, but LVEF was not different. No differences were detected between IHD and PD.

FR-PO1636

Impact of Baseline Levels and Trimestral Variation of Triiodothyronine and Thyroxine on Mortality in Maintenance Hemodialysis Patients Christian L. Meuwese,[1] Friedo W. Dekker,[2] Bengt Lindholm,[1] Abdul Rashid Tony Qureshi,[1] Olof Heimburger,[1] Peter F. Barany,[1] Peter Stenvinkel,[1] Juan J. Carrero.[1] *[1]Renal Medicine and Baxter Novum, Karolinska Institutet, Sweden; [2]Clinical Epidemiology, Leiden University Medical Center, Netherlands.*

Background: Conflicting evidence exists with regards to the association of thyroid hormone levels and mortality risk in patients with end-stage renal disease (ESRD), which is limited to studies comprising single thyroid-hormone measurements. This study assesses the impact of basal and trimestral variation of thyroid stimulating hormone (TSH), triiodothyronine (T3) and thyroxine (T4) on cause-specific mortality in dialysis patients.

Methods: In 210 prevalent hemodialysis patients serum T3, T4, TSH and Interleukin-6 were measured three months apart. Cardiovascular and non-cardiovascular deaths were registered during follow-up. Based on fluctuations along tertiles of distribution, four trimestral patterns were defined for each thyroid hormone: persistently low, decrease, increase and persistently high. By means of Kaplan Meier survival curves and Cox proportional hazard models, the impact of baseline levels and trimestral variation on mortality was investigated.

Results: TSH levels did not associate with mortality. At baseline, patients with low T3 or T4 (≤66th percentile) had higher hazards of dying than patients with high levels. Longitudinally, patients with persistently low levels of T3 or T4 during the 3-month observational period had higher mortality hazards than those having persistently high levels. These associations were mainly attributable to cardiovascular-related mortality. The association between T4 and mortality was not altered after adjustment for T3.

Conclusions: Hemodialysis patients with reduced T3 or T4 levels bear an increased mortality risk, especially due to cardiovascular causes. This was true when considering both baseline measurements and trimestral variation patterns. This longitudinal design adds important observational evidence -although non-decisive- that the link may underlie a causal effect. Thus, this study supports the hypothesis that restoration of thyroid hormone alterations in ESRD may improve patient´s outcome.

Biofeedback Dialysis for Hypotension and Extracellular Volume Excess: A Systematic Review and Meta-Analysis Gihad E. Nesrallah,[1,2] Elie Akl,[2] Reem Mustafa,[2] Robert M. Lindsay,[1] Rita Suri.[1] *[1]Nephrology, University of Western Ontario, Canada; [2]Clinical Epidemiology and Biostatistics, McMaster University, Canada.*

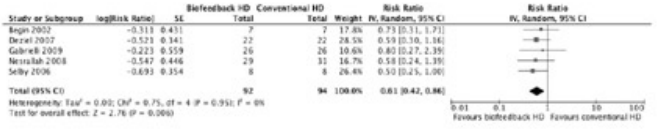
Background: Intradialytic hypotension (IDH) is associated with morbidity and mortality. Biofeedback (BF) devices which automate ultrafiltration and conductivity in response to changes in blood volume may reduce IDH and related complications. We conducted a systematic review to assess the benefits and harms of BF dialysis.

Methods: We adhered to a pre-specified protocol (PROSPERO ID: CRD42011001133). Data sources included CENTRAL (Issue 1,2011), MEDLINE (1966-2011), EMBASE (1980-2011), and ISI Web of Science (1976-2011). We included randomized parallel arm and crossover trials that randomized adults(>18 years) with symtomatic IDH or extracellular fluid volume expansion to receive HD with a BF device or usual care. All patients received 3 times weekly HD. Two authors assessed trial quality and independently extracted data in duplicate. We used a random effects model and expressed results as a risk ratio (RR) for dichotomous outcomes or mean difference (MD) for continuous data. We measured heterogeneity using the I^2 statistic.

Results: Seven studies met inclusion criteria. Two were parallel RCT's and 5 were cross-over studies. All studies were open-label. Studies were generally small (median N = 20), and not powered to assess survival or hospitalization. BF devices significantly reduced IDH (RR 0.61, 95% CI 0.42 to 0.86; I2=0%), but not predialysis systolic BP (MD 3, 95% CI -2 to 8 mmHg; I2=0%). Quality of life (QoL) data was reported in two studies, but the results could not be pooled; neither study demonstrated improved QoL. Potential harms were not assessed in any study.

Conclusions: BF dialysis reduces the frequency of IDH. Whether BF devices improve survival, hospitalization or QoL requires further study in adequately powered randomized trials.

Figure 1. Biofeedback HD vs. conventional HD with constant dialysate conductivity and ultrafiltration rate; outcome: intradialytic hypotension.



FR-PO1638

Role of Statins on C-Reactive Protein and the Kinetics of Erythrocyte Sodium Lithium Countertransport in Hemodialysis Patients Kriengsak Vareesangthip. *Renal Division, Department of Medicine, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand.*

Background: Cardiovascular disease as a result of accelerated atherogenesis is common in hemodialysis patients. Dyslipidemia may be a major contributor in this process and can be influenced by statins. Statins may exhibit additional inhibitory effects on the atherogenesis by a reduction of the inflammatory marker C-reactive protein (CRP). Erythrocyte sodium-lithium countertransport (Na/LiCT) is a sensitive membrane protein and has been reported to be abnormal (low Km) in hemodialysis patients. The activity of Na/LiCT has a positive correlation with the level of CRP in high cardiovascular risk patients. There is evidence suggesting that simvastatin can reduce the level of CRP and the other acute phase reactants in hemodialysis patients. We have hypothesized that simvastatin may decrease the CRP level and would improve the kinetics of Na/LiCT.

Methods: Twenty hemodialysed patients were divided into 2 groups. The study group 1 (n=10) has received simvastatin 10 mg daily for 4 months and the placebo group (n=10) has received placebo tablets for the same period as in the study group. We have measured serum CRP level, ESR, lipid profiles and the kinetics of Na/LiCT in all 20 patients before and after taking simvastatin.

Results: After 4 months, the CRP level was decreased in the study group more than in the placebo group (18.6% reduction in the study group vs 1.0% reduction in the placebo group). Before the treatment period, the Km for external sodium of erythrocyte of Na/LiCT was lower than that of normal controls in both groups of patients (56±3 vs 76±2 in group 1, P<0.01 and 50±2 vs 76±2 in group 2, P<0.01). After 4 months of simvastatin, the Km for external sodium was significantly improved (56±3 vs 69±5, P<0.01).

Conclusions: These results show those simvastatin exhibit comparable favorable effects on lipid profiles and the reduction of CRP level in hemodialysis patients. Moreover, the improvement of the kinetics of erythrocyte Na/LiCT as shown in this ESRD population, may indicate that these statins exhibit favorable effects on oxidative stress.

FR-PO1639

Predictors of Antihypertensive Medication Exposure over Time for Dually Eligible Dialysis Patients Theresa I. Shireman,[1] James B. Wetmore,[1] Jonathan D. Mahnken,[1] Qingjiang Hou,[1] Purna Mukhopadhyay,[1] Sally K. Rigler,[1] Edward F. Ellerbeck.[1] *[1]University of Kansas School of Medicine, Kansas City, KS; [2]St. Luke's Mid-America Heart Instiute/UMKC, Kansas City, MO.*

Background: Renin angiotensin system antagonists (RASAs), beta-blockers (β-blockers), and calcium channel blockers (CCBs) are widely prescribed for their antihypertensive and cardioprotective benefits in patients on chronic dialysis, yet we do not know about chronic dialysis patients' degree of exposure to these classes while on dialysis.

Methods: We examined exposure patterns for a retrospective cohort (2000-2005) to determine factors associated with varying levels of use. We created a Medicare-Medicaid eligible cohort of new dialysis patients and tracked their medication exposure until death, transplant, or end of observation. The proportion of days covered (PDC), adjusted for institutional stays, was computed for each drug class from Medicaid drug claims and USRDS core data. PDC was computed across the entire window of observation for each cohort member without regard to when treatment began, reflecting medication exposure rather than adherence.

Results: Of 45,127 subjects in the cohort, 61.6% used a RASA, 64.2% a CCB, and 33.6% a β-blocker. Among users in each class, PDCs were highest for CCBs (mean 0.55, SD 0.31) followed by RASAs (mean 0.52, SD 0.31) and β-blockers (mean 0.46, SD 0.32). Advancing age was associated with higher PDCs for all classes, and Caucasians had higher PDCs than other racial groups ($p < 0.0001$). Diabetes, hypertension, and CVA were associated with higher RASA PDC ($p < 0.0001$). β-blocker PDCs were higher in the presence of HF or CAD ($p < 0.01$). The absence of HF and CAD was associated with higher CCB PDCs ($p < 0.01$). The presence of hypertension and CVA was associated with higher CCB PDC ($p < 0.0001$).

Conclusions: Despite substantial cardiac comorbidity, just under 2/3 used a CCB or a RASA and 1/3 used a β-blocker. Their respective PDCs indicate that use was limited to approximately 50% of dialysis tenure time. While exposure levels were somewhat consistent with clinical indications, there was less use among non-Caucasians, a finding that deserves further investigation.

FR-PO1640

Predicting Mortality in Incident Hemodialysis Patients: Validation of a European Model in an International Cohort Martin Wagner, Christoph Wanner, Francesca Tentori, Brian Bieber, Ronald L. Pisoni, Damian G. Fogarty, Bruce M. Robinson, Navdeep Tangri. *Medicine, University of Wuerzberg, Wuerzberg, Germany.*

Background: The risk of death varies among patients on hemodialysis. We previously developed and internally validated a model to predict mortality in incident patients from the UK Renal Registry (UKRR). The model included a number of routinely collected variables and achieved adequate performance. Here, we present the external validation of the prediction model in an international cohort of incident patients from the Dialysis Outcomes and Practice Patterns Study (DOPPS)

Methods: We included all patients initiating hemodialysis treatment in 2002-2004 (DOPPS), who survived the first 90 days on treatment. The variables in the prediction model comprised age, gender, race, primary renal disease; diabetes, CVD, smoking, albumin, hemoglobin, calcium, and creatinine. Discrimination was evaluated with a time-dependent c-statistic. Calibration was evaluated using the Nam and D'Agostino chi square statistic.

Results: The DOPPS dataset consisted of 3612 patients, of whom 355 died. The prediction model achieved adequate discrimination (c-statistic 0.74) and good calibration (observed vs. predicted risk, p-value 0.24).

	Discrimination C-statistic	Calibration observed/predicted risk across quatiles				
		low	intermediate	high	very high	p-value
UKRR	0.80 ± 0.01	0.1/1.4%	3.6/4.1%	5.3/8.2%	21.1/17.2%	<0.05
DOPPS	0.74 ± 0.02	1.2/2.1%	6.6/5.9%	10.6/11.4%	22.1/23.0%	0.24
North America	0.69 ± 0.03	4.5/2.7%	8.0/7.1%	15.0/13.1%	28.6/24.3%	0.10
Europe	0.74 ± 0.02	0.1/1.8%	7.8/5.5%	11.6/9.0%	23.8/20.0%	0.08
Asia/Pacific Rim	0.85 ± 0.04	0.1/0.2%	2.2/0.5%	2.4/1.0%	15.8%/2.5%	<0.05

While discrimination was adequate in the UKRR and the European DOPPS cohort (c statistic 0.80 and 0.74), the model was less accurate in North American patients (c-statistic 0.69) and calibration was limited in Asian patients.

Conclusions: Basic patient characteristics and laboratory variables are sufficient to accurately predict one-year mortality in patients incepting hemodialysis. Our model, developed in the UKRR, is now externally validated in an international cohort. Further research is needed to establish an easy-to-use clinical score that may provide useful information at the bedside.

FR-PO1641

Factors Predicting Mortality of New Patients Commencing Dialysis Therapy after 5 and 10 Years Follow-Up Sunil Bhandari,[1] Oliver T. Browne.[2] *[1]Renal Medicine, Hull & East Yorkshire Hopsitals NHS Trust and Hull York Medical School, Hull, East Yorkshire, United Kingdom; [2]Medical School, Hull York Medical School, Hull, United Kingdom.*

Background: The natural history of patients commencing dialysis is not well characterised and there is little evidence regarding the impact of potential pre-dialysis factors predicting mortality.This study examined pre-dialysis and co-morbid risk factors for 10y mortality post start of dialysis therapy.

Methods: A prospective study: all new subjects commencing dialysis in 2001/02 in East Yorkshire were followed up for a mean of 11.8 years. Predictors of mortality (e.g predialysis factors - creatinine, albumin, haemoglobin etc) were determined by uni-variate, multi-variate analysis and survival via Kaplin-Meier analysis.

Results: 94 patients, mean age of 63±1y were analysised. Mortality rate at 106 months was 60%. 30% (29) of patients had been transplanted during the follow-up period. 20 transplant patients were still alive with a functioning transplant (67%), 7 experienced transplant failure and returned to dialysis. 2 transplants died (myocardial infarction and calciphylaxis). Low-eGFR and haemoglobin at dialysis commencement had a significant impact on early mortality on univariate analysis. At 5y vascular disease and sepsis accounted for 71% of mortality. This decreased to 46% by 10y for these causes. Cardiac disease was the commonest cause of death. In 17% of patients death was related to dialysis or its withdrawal.

From Kaplan-Meier survival, patients with vascular disease had a cumulative survival of 14% vs. 33% of those without vascular disease (p=0.05). Diabetic patients had a cumulative survival of 18% vs. 27% without diabetes (p=0.02). Contrary to the 5 year data, calcium phosphate was no longer predictive of mortality.

Conclusions: Diabetes and vascular disease remain strong predictors of mortality. Calcium-phosphate levels are more specific predictors of early cardiac mortality. Low-eGFR and low haemoglobin concentration at dialysis commencement had a significant impact on early mortality but were not predictive of mortality on survival analysis. Aggressive management of cardiac risk factors in addition to early transplantation is key to survival.

FR-PO1642

Clinical Characteristics and Coronary Plaque Morphology in Chronic Kidney Disease (CKD) Patients Keiji Kono,[1] Hideki Fujii,[1] Kentaro Nakai,[1] Shunsuke Goto,[1] Masafumi Fukagawa,[2] Shinichi Nishi.[1] *[1]Division of Nephrology and Kidney Center, Kobe University Graduate School of Medicine, Kobe, Japan; [2]Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan.*

Background: Coronary artery disease (CAD) is a major cause of death in patients with chronic kidney disease (CKD). However, the pathophysiology of CAD remains unclear. Virtual Histology- Intravascular Ultrasound (VH-IVUS) can provide four major plaque components (fibrous, fibro-fatty, dense calcium and necrotic core) in vivo with a high accuracy. The aim of this study is to evaluate the clinical characteristics and coronary plaque morphology by VH-IVUS analysis in CKD patients.

Methods: Seventy-eight patients (CKD stage 1-2, n=31; CKD stage 3, n=24; CKD stage 4-5, n=11; Hemodialysis (HD), n=12) with CAD, who underwent VH-IVUS between May 2005 and December 2009 at our institute, were included in this study. They were divided into 2 groups, ACS group and non-ACS group, according to the admission diagnosis. VH-IVUS analysis on culprit segments was performed for all the study patients. From these profiles, we calculated Necrotic core/Dense calcium (NC/DC) ratio, and compared the ratio in patients with or without ACS in all the study patients.

Results: The result of VH-IVUS analysis showed that the relative volume of dense calcium (% DC) and necrotic core (% NC) gradually increased with decreasing renal function. On the other hand, NC/DC ratio gradually decreased with the development of CKD (CKD stage1-2: 2.5±1.4, CKD stage3: 2.2±1.6, CKD stage4-5: 1.6±0.9, HD: 1.4±0.7, p=0.06). Moreover, NC/DC ratio was significantly higher in patients with ACS compared to those without ACS (ACS: 2.3±1.5, non-ACS: 1.5±0.8, p<0.05). In multiple variate analysis, % DC was significantly correlated with diabetes mellitus (β=0.214, p<0.05) and estimated glomerular filtration rate (GFR) (β=-0.313, p<0.05).

Conclusions: Our findings suggested that the compositional pattern of coronary plaque was transformed from necrotic core -rich plaque into calcium-rich plaque with the development of CKD, and NC/DC ratio was associated with incidence of ACS in CKD.

FR-PO1643

Hemodialysis-Induced Regional Left Ventricular Systolic Dysfunction Is Independently Associated with Increased Mortality Solmaz Assa,[1] Yoran M. Hummel,[2] Adriaan A. Voors,[2] Ralf Westerhuis,[3] Paul E. de Jong,[1] Casper F. Franssen,[1] Johanna J. Kuipers.[1] *[1]Nephrology; [2]Cardiology, University Medical Center Groningen; [3]Dialysis Center Groningen, Netherlands.*

Background: The hemodialysis (HD) procedure may acutely induce regional left ventricular (LV) systolic dysfunction. The time course of this entity, its relation with intra-HD volume changes and long-term consequences are unknown. Therefore, we studied the occurrence of regional LV dysfunction at different times during HD in relation to volume parameters and the impact on outcome.

Methods: In 109 HD patients with a mean (±SD) age of 62.5±15.6 and median (IQR) dialysis vintage of 2 (1-4) years, echocardiography was performed pre-HD, at 60 and 180 min intra-HD and 30 min post-HD. LV global and regional systolic function was evaluated by ejection fraction (EF) and wall motion score index (WMSI). HD-induced regional LV dysfunction was defined as an increase in WMSI in ≥2 segments at either 60 or 180 min intra-HD or 30 min post-HD compared with pre-HD. Mean follow-up was 1.5 years.

Results: HD-induced regional LV dysfunction was found in 29 (27%) patients. These patients had worse pre-HD WMSI and EF, more previous cardiovascular events and higher pre-HD CRP levels (all p <0.05). In 17 (59%) of these patients, HD-induced regional LV dysfunction was manifest already at 60 min intra-HD when blood volume was only -1.3% (-3.4-1.7) lower than pre-HD. The course of blood volume, ultrafiltration (UF) volume, blood pressure and heart rate did not differ between patients with and without HD-induced regional LV dysfunction. Patients with HD-induced regional LV dysfunction had a significantly higher mortality, also after correction for age, sex, dialysis vintage, diabetes, cardiovascular history, UF volume, baseline WMSI & EF, and CRP (HR: 5.4; CI: 1.3-23.4; P=0.024).

Conclusions: HD regularly induces significant regional wall motion abnormalities, and these changes are related to a strongly increased mortality. HD-induced regional LV dysfunction occurs independently of changes in BV, suggesting that other mechanisms than hypovolemia must be involved.

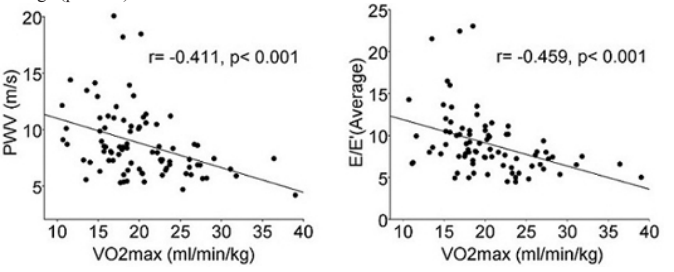
Increased Arterial and Left Ventricular Diastolic Stiffness Are Associated with Poor Cardiovascular Exercise Capacity in Advanced CKD Stephen M. Ting,[1,2] Hasan Iqbal,[1] Sudheer Koganti,[1] Prithwish Banerjee,[1] Robert Higgins,[1] Nicolas Aldridge,[1] Rosemary Bland,[2] Daniel Zehnder.[1,2] *[1]Univ. Hosp. Coventry & Warwickshire NHS Trust; [2]Warwick Medical School, United Kingdom.*

Background: Loss of large artery elasticity and LV diastolic dysfunction are notably prevalent in CKD patients. We sought to determine if LV diastolic compliance and aortic stiffness were associated with objective measure of cardiovascular functional reserve in CKD.

Methods: Patients waitlisted for kidney transplantation were prospectively assessed. Cycle ergometric exercise testing, TD echocardiography and carotid-femoral pulse wave velocity (PWV) were performed.

Results: 87 patients [age, 47 (37,59) years] were evaluated. Increased aortic stiffness (PWV: ≤8.15 vs. >8.15 m/s) was associated with reduced maximal exercise oxygen consumption [VO2max: 22.6 (18.1,26.2) vs. 18 (15.4,20.2) ml/min/kg, p< 0.001] and anaerobic threshold [VO2AT: 12.8 (10.9,14.1) vs. 11.6 (10.3,12.3) ml/min/kg, p= 0.03]. Patients with lower VO2max had a higher measure of LV filling pressure (E/E', p< 0.001). E/E' was calculated using the averaged of septal and lateral mitral annular lengthening velocities.

In univariate analysis, VO2max was inversely correlated with PWV (r= -0.411, p< 0.001) and E/E' (r= -0.459, p< 0.001). Similar correlations were observed for VO2AT with PWV (r= -0.295, p< 0.01) and E/E' (r= -0.258, p= 0.02). There were no clear associations between VO2max with LV ejection fraction (p= 0.07), LVMI (p= 0.33) and dialysis vintage (p= 0.39).



Conclusions: Arterial stiffness and abnormal LV diastolic filling pressure were strongly associated with poor cardiovascular functional reserve. This highlights the significance of ventriculo-arterial coupling in the complex mechanism of CKD mediated CHF. Further study with assessment following kidney transplantation may clarify the relationship between these prognostic factors.

The Effect of Hemodialysis Ultrafiltration on Hemoconcentration and Changes in Whole Blood Viscosity Shayan Shirazian,[1] James Drakakis,[1] Sudharani Dikkala,[1] Paula J. Dutka,[1] Marc E. Duey,[2] Daniel J. Cho,[3] Steven Fishbane.[1] *[1]Nephrology and Hypertension, Winthrop University Hospital, Mineola, NY; [2]ProMetrics Inc., King of Prussia, PA; [3]Rheovector LLC, Pennsauken, NJ.*

Background: Whole blood viscosity (WBV) is an important predictor of cardiovascular outcomes. Hemodialysis patients may experience hemoconcentration and increases in WBV from fluid ultrafiltration (UF). The objectives of this study were to determine 1) the effect of hemodialysis on hemoconcentration/WBV and 2) whether UF volume requirements influence hemoconcentration and increases in WBV.

Methods: This was an observational analysis of 59 hemodialysis patients maintained at target Hgb 11-12 g/dL using darbepoetin alfa. Demographic and clinical characteristics were recorded. Blood samples were analyzed at initiation, midway and at the end of

dialysis. A scanning capillary viscometer (Prometrics Inc.) was used to measure WBV at multiple shear rates.

Results: For analysis, patients were divided into low-normal vs. high UF groups (cutoff 2700 ml). At baseline, patients in the high UF group were younger and had a greater proportion of diabetics. Mean hematocrit increased during dialysis in both groups. The intradialytic increase in hematocrit was significantly greater in the high versus the low UF group (3.2% vs. 1.28%, p=0.01), with a significantly higher end-dialysis hematocrit in the high UF group (40.5% vs 38%, p=0.02). At the end of dialysis both systolic (low shear rate) WBV ($p<0.01$) and diastolic (high shear rate) WBV ($p<0.01$) were significantly higher in the high UF compared to the low UF group. There was an approximately two-fold increase in systolic ($p<0.01$) and diastolic (p=0.01) WBV during dialysis in high versus low UF groups. The increase in systolic blood viscosity during dialysis was significantly correlated with an increase in Hct ($R2=0.6526$, $p<0.01$).

Conclusions: Hemodialysis results in hemoconcentration and increased WBV. Among patients requiring greater UF volumes, there are greater increases in Hct, systolic and diastolic WBV. Because of the potential harmful cardiovascular effects of increased WBV, patients with greater UF requirements may need lower Hgb targets during erythropoietin treatment.

FR-PO1646

Serum Cystatin C as a Predictor for Cardiovascular Events in End-Stage Renal Disease Patients at the Initiation of Dialysis Sang Heon Song,[1,2] Ihm Soo Kwak,[1,2] Soo Bong Lee,[1] Eun Young Seong,[1,2] Il Young Kim,[1] Harin Rhee.[1,2] *[1]Department of Internal Medicine, Pusan National University School of Medicine, Busan, Korea; [2]Biomedical Research Institute, Pusan National University Hospital, Busan, Korea.*

Background: Cystatin C has been known to predict cardiovascular outcomes in elderly persons and stage 3 or 4 CKD patients. However, there has been no study to investigate whether cystatin C could predict the cardiovascular events in ESRD patients. Furthermore, recent studies argue that cystatin C-based eGFR level ($eGFR_{cysC}$) is a better predictor of cardiovascular disease than $eGFR_{Cr}$ because the non-GFR determinants of cystatin C also reflect cardiovascular risk. Current study was performed to delineate the role of serum cystatin C and $eGFR_{cysC}$ for prediction of the cardiovascular events and compare the other traditional variables with serum cystatin C in incident dialysis patients.

Methods: This study included 66 ESRD patients [mean age, 52.7±16.3 years; hemodialysis (HD), 46 pts; peritoneal dialysis (PD), 20 pts] who survived for more than 3 months after the start of dialysis, and serum cystain C levels were measured at the point of dialysis initiation. We conducted a retrospective charts review and median follow-up period was 14.9 months.

Results: Serum cystatin C was correlated with BUN ($r=0.537$, $p<0.001$), serum creatinine ($r=0.480$, $p<0.001$) and smoking ($r=0.284$, p=0.021). Cystatin C was inversely correlated with age ($r=-0.316$, p=0.01) and eGFRCr by MDRD ($r=-0.533$, $p<0.001$). The incidence of cardiovascular events was 16.7% (11/66). Kaplan-Meier analysis for cardiovascular events revealed that patients with lower cystatin C level (< 4.14 mg/L) had a better event-free survival rate compared with higher cystatin C group (≥4.14 mg/L) (p=0.039). In univariate analysis, serum cystatin C (HR, 2.62; 95% CI, 1.24-5.53; p=0.011), eGFRcysC (HR, 0.64; 95% CI, 0.47-0.87; p=0.004) were significant factors for the prediction of cardiovascular events. After multivariate adjustment, eGFRcysC was only an independent determinant of cardiovascular events (HR, 0.60; 95% CI, 0.39-0.95; p=0.029).

Conclusions: Our study suggested that $eGFR_{cysC}$ independently predicted cardiovascular events in incident dialysis patients

FR-PO1647

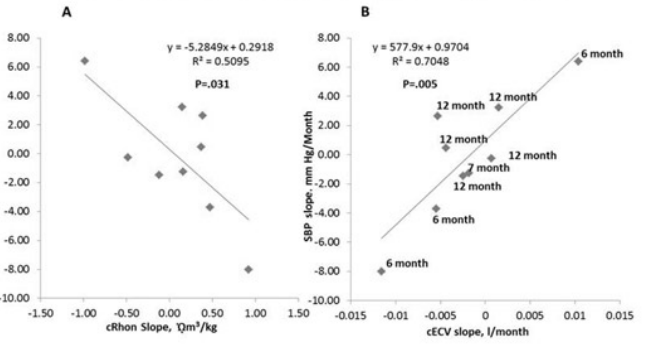
Correlation between Extracellular Volume as Assessed by Calf Bioimpedance Spectroscopy (cBIS) and Blood Pressure Changes in Hemodialysis (HD) Patients Rakesh Malhotra,[1] Olynka Vega,[1] Erik L. Penne,[2] Penny Faith Palmiero,[1] Samer Rateb Abbas,[1] Stephan Thijssen,[1] Nathan W. Levin,[1] Peter Kotanko,[1] Fansan Zhu.[1] *[1]RRI, NYC; [2]VUMC, Amsterdam.*

Background: Chronic fluid overload is associated with hypertension in HD patients. cBIS is a noninvasive technique to determine volume and distribution of body fluids (F Zhu;2008). The aim of the study is to investigate whether changes in fluid volume as assessed by cBIS correlate with changes in systolic blood pressure (SBP).

Methods: Chronic HD patients who were enrolled as part of a sodium intervention trial were followed for one year. In each subject, cBIS was done monthly pre-HD and post-HD to assess normalized calf resistivity ($\rho N,5, 10^{-2} W\ m^3/kg$) and extracellular volume (cECV) using a Hydra 4200 device (Xitron technologies, San Diego, CA). SBP and diastolic blood pressure (DBP) were recorded pre-HD and post-HD. Only patients with at least 6 month of follow-up were included. Temporal changes of pre-HD SBP, ncRho, and cECV were computed by simple linear regression.

Results: We studied 9 HD patients (6 men; age 45.8 ± 16.8 yrs). Temporal changes of SBP were significantly correlated with those of ncRho ($R2=0.50$, P=0.031; Fig.1A) and cECV ($R2 = 0.70$; P=0.005; Fig.1B)

Figure1: Correlation between SBP and ncRhon (A) and cECV (B) in HD patients



Conclusions: cBIS is a simple and non-invasive low cost means to objectively measure body fluid content in HD patients. Our study shows that cBIS derived measures (ncRho; cECV) are clinically meaningful. The use of cBIS for diagnosis and treatment guidance of fluid overload can facilitate blood pressure control.

Results of Follow-up Measurements

	Baseline	Month 3	Month 6	Month 9	Month 12
# patients	9	9	9	5	5
cECV	0.20±0.04	0.19±0.03	0.20±0.03	0.18±0.01	0.18±0.01
ρN,5,10-2Ω m3/kg	13.5±3.0	13.6±6.5	13.7±3.0	14.1±2.2	14.9±1.46

Mortality Due to Pulmonary Embolism, Myocardial Infarction, and Stroke among Patients Starting Dialysis Gurbey Ocak,[1] Karlijn J. Van Stralen,[2] Marion Verduijn,[1] Friedo W. Dekker,[1] Kitty J. Jager.[2] *[1]Department of Clinical Epidemiology, Leiden University Medical Center, Leiden; [2]ERA-EDTA Registry, Department of Medical Informatics, Academic Medical Center, Amsterdam, Netherlands.*

Background: Dialysis patients have an increased cardiovascular mortality risk as compared to the general population. However, there is limited information on how specific cardiovascular causes contribute to this increased risk.

Methods: Age-and sex-standardized mortality rate ratios (SMRs) for cardiovascular causes were calculated for 130 439 adults starting dialysis and registered in the ERA-EDTA Registry as compared with the European general population. Furthermore, we calculated hazard ratios (HRs) with 95% confidence intervals (CIs) to investigate the association between potential risk factors and specific causes of cardiovascular death.

Results: The overall age- and sex-standardized mortality rate of cardiovascular causes was 8.9 (95% CI 8.7-9.1) times higher in dialysis patients than in the general population. The SMRs in dialysis patients as compared to the general population were 12.2 (95% CI 10.2-14.6) for pulmonary embolism, 11.0 (95% CI 10.6-11.4) for myocardial infarction, 8.4 (95% CI 8.0-8.8) for stroke, and 8.3 (95%CI 8.0-8.5) for other cardiovascular diseases. Primary kidney diseases due to diabetes and multi-system disease were associated with an increased mortality risk due to pulmonary embolism (HR 1.9; 95% CI 1.0-3.8 and HR 3.2; 95% CI 1.6-6.4, respectively), myocardial infarction (HR 4.1; 95% CI 3.4-4.9 and HR 2.2; 95% CI 1.7-2.7, respectively), stroke (HR 3.5; 95% CI 2.8-4.4 and HR 2.8; 95% CI 2.1-3.6, respectively), and other cardiovascular causes of death (HR 3.4; 95% CI 2.9-3.9 and HR 3.4; 95% CI 2.9-4.0, respectively) as compared to patients with polycystic kidney disease after adjustment for age, sex, calendar year, and country.

Conclusions: Compared to the general population, dialysis patients have an highly increased mortality risk due to myocardial infarction, stroke, and pulmonary embolism.

FR-PO1649

Obesity Paradox in Japanese Hemodialysis (HD) Patients Jyunichiro Hashiguchi,[1] Satoshi Funakoshi,[1] Takashi Harada,[1] Junko Kubo,[1] Rica Etoh,[1] Yoshiaki Lee,[1] Kazunori Utsunomiya,[3] Mineaki Kitamura,[2] Tomoya Nishino,[2] Shigeru Kohno.[2] *[1]Divisionof Blood Purification, Nagasaki Renal Center, Nagasaki, Japan; [2]Department of Internal Medicine, Nagasaki University Graduate School of Medicine, Nagasaki, Japan; [3]Department of Diabetes, Jikei University, Tokyo, Japan.*

Background: Dialysis Outcome and Practice Patterns Study (DOPPS) had suggested that nutritional indicator, including higher body mass index (BMI), has an important factor on the survival of HD patients. On the other hand, obesity is considered to be independent risk factors for the development of cardiac risks in the general population (obesity paradox). We hereby assess the impact of BMI on cardiac function of Japanese HD patients in long term.

Methods: From April of 2005 to March of 2010, 94 HD patients in our facility with stable BMI and normal protein catabolic rate (nPCR) over 5 years were enrolled in this study after appropriate informed consent. Ultrasound cardiography including ejection fraction (EF) or left ventricle diameter (LVDd) were evaluated before and after the period of > 5 years. The objects were divided into three groups, one for the patients with BMI

< 20 (underweight), one for BMI 20-25 (optimal) and BMI > 20 (overweight), and then analyzed the correlation between BMI and cardiac function.

Results: As shown in the table, EF in underweight group did not change after 5 years, whereas EF had significantly decreased in overweight group from 0.658±0.33 to 0.617±0.25 (p<0.05).

Change in Cardiac Parameters during 5 years

	underweight	optimal	overweight
	before / after	before / after	before / after
No. of patients	44	34	19
DM / non-DM	12 / 32	10 / 24	7 / 12
average EF	0.688 / 0.707	0.679 / 0.699	0.658 / 0.617*
average LVDd (mm)	51.3 / 55.2*	54.5 / 55.8	52.5 / 50.8

* p<0.05

The increase in LVDd was observed in underweight group from 51.3±18.6 to 55.6±10.9, wheras there were no change in optimal or overweight group. Nutritional factors including nPCR stayed the same in all groups.

Conclusions: In Japanese HD patients population where the average body weight is 53-56 Kg in adults, higher BMI indicating obesity may increase cardiac risks presumably associated with various baseline health status including cardiac load.

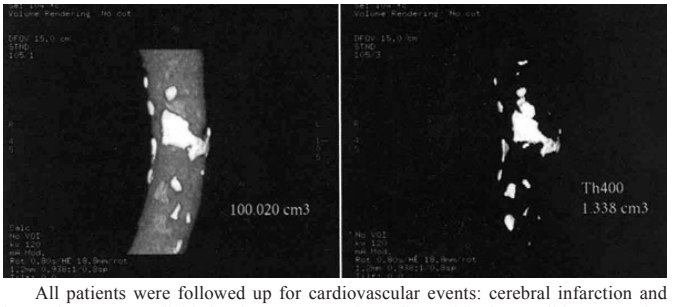
Calcification of the Thoracic Aorta Determined by Three-Dimensional Computed Tomography Predicts Cardiovascular Complications in Hemodialysis Patients Nozomu Kamiura,[1] Kiyoko Yamamoto,[2] Shioko Okada,[2] Makoto Sakai,[1] Akira Fujimori.[2] *[1]Department of Internal Medicine, Konan Hospital; [2]Blood Purification and Kidney Center, Konan Hospital.*

Background: The most common cause of death in dialysis patients is cardiovascular disease, and this may be due in part to the presence of excessive vascular calcification.

Methods: Computed tomography using contrast medium was performed in 49 hemodialysis patients (29 males and 20 females; 17 diabetics, 32 nondiabetics; average age 68.9 ± 11.0 years). Calcification score (CS) was defined as the ratio of the volume of the vascular calcification to the volume of the thoracic aorta, 10 cm caudal part from the bifurcation of the trachea.



All patients were followed up for cardiovascular events: cerebral infarction and hemorrhage, myocardial infarction, ECG or echocardiographic abnormalities suggestive of myocardial ischemia, cardiac surgery, leg amputation, and death and hospitalization due to heart failure.

Results: After 3 years of follow-up, 12 patients reached the end point. Mann-Whitney U test showed that both high CS (P = 0.007) and male gender (P = 0.009) were significantly associated with cardiovascular outcome which did not correlate with age, dialysis duration, diabetes mellitus, smoking status, LDL cholesterol, pulse-wave velocity, maximum intima-media thickness of the carotid artery wall, systolic blood pressure, left ventricular hypertrophy. Multiple logistic regression analysis revealed that high baseline CS was a singificant predictor of the cardiovascular events (P < 0.05), independent of age, gender, dialysis duration, diabetes, smoking status, and LDL cholesterol.

Conclusions: Calcification of the thoracic aorta determined by three-dimensional computed tomography predicts cardiovascular events in hemodialysis population.

FR-PO1651

C-Reactive Protein Is a Strong and Independent Risk Factor for Cardiovascular Morbidity and Mortality in Hemodialysis Patients – Post Hoc Results from the AURORA Trial Inga Soveri,[1] Eva Carlsson,[1] Ingar Holme,[2] Hallvard Holdaas,[3] Alan G. Jardine,[4, 5] Roland E. Schmieder,[6] Eva K.A. Johnsson,[7] Faiez Zannad,[8] Bengt C. Fellstrom.[1] *[1]Nephrology, Uppsala University, Sweden; [2]Preventive Medicine, Clinical Research, Oslo University Hospital, Ullevål, Norway; [3]Nephrology, Oslo University Hospital, Rikshospitalet, Norway; [4]Renal Unit, British Heart Foundation Glasgow Cardiovascular Research Centre, United Kingdom; [5]Medicine and Therapeutics, Western Infirmary, Glasgow, United Kingdom; [6]University Hospital Erlangen-Nürnberg, Erlangen, Germany; [7]AstraZeneca, Mölndal, Sweden; [8]Inserm CIC9501 and U961, CHU Nancy, Nancy Université, France.*

Background: The AURORA trial was a controlled, randomized trial in 2,776 hemodialysis patients, studying the effect of rosuvastatin 10 mg on major cardiovascular (CV) events. There was no significant effect on any CV endpoint in the overall study; however, the data provide an opportunity to explore risk factors for CV events and mortality in hemodialysis patients.

Methods: High-sensitivity C-reactive protein (hsCRP) as a risk factor for CV disease (CVD) in hemodialysis patients was examined for the CV endpoints used in the study, including mortality. Cox proportional analysis was used for risk factor assessment, presented as hazard ratio (HR) per unit hsCRP increase. Ranking of risk factors at baseline (age, diabetes, hsCRP, albumin, phosphate, low-density lipoprotein cholesterol, previous CVD, smoking, medication, etc) was performed using a Random Forest Model.

Results: The model showed that baseline hsCRP was an independent and strong risk factor for all endpoints.

hsCRP at baseline as risk factor for endpoints in AURORA

	HR	p-value
Major CV events	1.112	0.0011
Death from any cause	1.167	<0.0001
CV death	1.151	<0.0001
Atherosclerotic event	1.128	0.0026
Major CV event or death	1.148	<0.0001
Non-fatal myocardial infarction	1.14	0.041
Non-CV death	1.207	<0.0001

Ranking of risk factors captured in the study showed that hsCRP as a risk factor was surpassed only by age and diabetes for all endpoints.

Conclusions: In this post-hoc analysis, baseline hsCRP was the 3rd-6th strongest risk factor for CV events and patient mortality among hemodialysis patients in the AURORA trial.

FR-PO1652

The Survival Impact of Cardiac Output on Access Blood Flow in Chronic Hemodialysis Patients --A Nine-Year Cohort Study Cheng-Kai Tsai. *Division of Nephrology, St. Martin De Porres Hospital, Chia-yi, Taiwan.*

Background: Access surveillance program becomes clinical routine to maintain the adequate performance of dialysis. The previous study postulated that the Qa may serve as a maker to predict clinical outcomes of dialysis patients. We know the Qa is potentially affected by many factors, including systemic hemodynamics, the size and endothelial function of vessels supplying and draining the access, and the presence of intravascular lesions, but the role of the performance of cardiac contractivity in access blood flow has not been discussed.

Methods: The purpose of our study was to evaluate the impact of cardiac performance on access blood flow. Thus, we had conducted a nine-year prospective cohort study of 434 patients, aged from 18 to 80, who received hemodialysis treatment in our medical center from January 2002 to December 2010.The surveillance program initiated the evaluation of all eligible patients, including cardiac function assessment and the Qa measurement by the saline dilution method using Transonic HD01/02 devices twice yearly.

Results: The cardiac index (CI) was classified into three categories (<2.5, 2.5 to 4.5, >4.5), and access blood flow (Qa) into five categories (<500, 501 to 999, 1000 to 1499, 1500 to 1999, >2000 ml/min).

A big difference of access blood flow (788±396 ml/min vs 1062±524 ml/min, p<0.001) and cardiac index (3.18±0.97 vs 3.65±1.01, p<0.001) was found between diabetic and non-diabetic patients.

Patient's cardiac index between 2.5 to 4.5 and the Qa between 1500 to 2000ml/min acquired the best survival rate, and the hazard ratio after adjustment for demographic characteristics, comorbidity, and the access type was still high in patients with lowest cardiac index and Qa.

Conclusions: The patients with diabetes whose access blood flow and the cardiac index are lower lead to greater risk of death and their vulnerability.

Funding: Private Foundation Support

FR-PO1653

Outcomes of Cardiovascular Implantable Electronic Device Infections in Patients on Chronic Hemodialysis Therapy LaTonya J. Hickson,[1] Katherine Y. Le,[2] Larry M. Baddour,[3] David L. Hayes,[4] Walter R. Wilson,[3] James Steckelberg,[3] Muhammad Rizwan Sohail.[3] *[1]Nephrology and Hypertension, Mayo Clinic; [2]Internal Medicine, Mayo Clinic; [3]Infectious Diseases, Mayo Clinic; [4]Cardiovascular Diseases, Mayo Clinic, Rochester, MN.*

Background: Infection is a serious complication of cardiovascular implantable electronic device (CIED) implantation. Hemodialysis (HD) dependent patients have multiple co-morbid conditions with an impaired immune system. Thus, they may be at higher risk of complicated CIED infection with poorer outcomes than non-HD patients.

Objective: To compare clinical presentations and outcomes in patients with CIED infection based on whether they are HD-dependent or not.

Methods: We reviewed all cases of CIED infections treated at our center between 1991 and 2008 and analyzed their pertinent clinical features.

Results: Among the 415 patients with CIED infection, mean age was 69±15 years and 75% were male. Seventeen (4%) had received HD therapy prior to CIED infection. HD patients were more likely to be female (59% vs 24%, p=0.001). Both localized signs at the generator pocket and systemic manifestations of infection were less frequent in HD as compared to the non-HD group. Although HD patients were more likely to be bacteremic (100% vs. 44%, p<.0001), endocarditis rates were similar (50% vs 34%, p=0.2). There were no differences in device removal complication rates between the two groups. However, HD patients were relatively less likely to undergo device removal (82% vs. 95%, p=0.02) or undergo implantation of a new device (43% vs 67%, p=0.04). Although mortality rates at 30- and 60-day were similar between HD and non-HD groups, 90-day mortality was significantly higher (24% vs 8%, p=0.02) among HD patients.

Conclusions: HD-dependent patients are more likely to present with bacteremia complicating CIED infection and have a higher 90-day mortality rate as compared to non-HD dependent patients.

FR-PO1654

Efficacy of Low-Dose Bisoprolol in Maintenance Hemodialysis Patients with Asymptomatic Left Ventricular Remolding and Diastolic Dysfunction
Yiwen Li, Qiu Jin, Ling Sun. *Kidney Disease Center, First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China.*

Background: Left ventricular hypertrophy and diastolic dysfunction are the most frequent cardiac alteration in ESRD. The aim of this study was to determine whether β-blockers, bisoprolol, had beneficial effects in maintenance hemodialysis patients with asymptomatic left ventricular diastolic dysfunction.

Methods: In this study we enrolled 30 patients with chronic kidney disease (CKD) undergoing maintenance hemodialysis accompanying left ventricular diastolic dysfunction more than six months. Bisoprolol was started with 1.25 mg once daily orally 30 minutes after breakfast and increased every 1 week by 1.25 mg increments up to the maximum tolerated dose. Echocardiographic examination was used to measurement of left ventricular diastolic function.

Results: 27 patients finished 6 months study. After 6 months treatment, compared with the baseline, the cardiothoracic ratio was significant decreased. Echocardiographic examination showed that there was no significant change in EF, but LVDd , LVDs, PWT were significant decreased . E/A ratio significantly increased.

Conclusions: Our study demonstrate bisoprolol efficacy in improving left ventricular remolding and diastolic dysfunction in HD patient with normal blood pressure.

FR-PO1655

Potassium-Binding Sodium-Based Resins: Associations with Serum Chemistries and Interdialytic Weight Gain
Michel Y. Jadoul,[1] Angelo Karaboyas,[2] Francesca Tentori,[2] David A. Goodkin,[2] Yun Li,[2,3] Laura Labriola,[1] Bruce M. Robinson.[2,3] *[1]Cliniques univ. St Luc, Université Catholique de Louvain, Brussels, Belgium; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]University of Michigan, Ann Arbor.*

Background: Na-based resins increase phosphaturia and plasma bicarbonate levels in non-uremic dogs, due to calcium binding in the gut, favoring phosphorus and bicarbonate absorption. Relevance to hemodialysis (HD) patients is unknown.

Methods: Data were from 10,487 HD patients in the Dialysis Outcomes and Practice Patterns Study (DOPPS) phases 2-4 (2002-2011) in countries with >5% Na-based K resin use: Belgium (12%), Canada (7%), France (49%), Italy (19%), and Sweden (25%). Linear mixed models were used to determine associations at baseline between K resin use and interdialytic weight gain (IDWG), serum concentrations of bicarb, P, K, Ca, and Na. Instrumental variable (IV) analyses were conducted because they can limit treatment-by-indication bias due to unmeasured confounders.

Results: Overall K resin use was 20%, with notable facility variation. The 95th percentile of facility % K resin use was 58%; 22% of facilities did not prescribe any K resins. Patients prescribed a K resin had a greater IDWG (in line with the Na load of K resins), and higher serum bicarb, P, and Na (but not Ca) than patients without a K resin Rx (Table 1). While the magnitudes of the bicarb and Na effects are small, the P effect could impact P-binder dose. Findings were directionally consistent in the IV analysis for bicarb, P, Na, and IDWG (i.e., possibly causal) but not K (treatment-by-indication bias).

Conclusions: As hypothesized, Na-based K resin use in HD patients is associated with higher serum bicarbonate, phosphorus, and sodium concentrations and greater IDWG. Additional studies are warranted to assess the impact of K resins on vascular calcification, CV events, and mortality.

Table 1: Effect of Na-based K Resin Prescription (Estimate*, 95% CI)

Outcome	Unadjusted	Adjusted	IV approach (adjusted)
Serum Bicarbonate (mEq/L)	0.09 (-0.10,0.28)	0.32 (0.14,0.51)	0.10 (-1.26,1.46)
Serum Phosphorus (mg/dL)	0.37 (0.28,0.46)	0.20 (0.11,0.28)	0.32 (-0.05,0.69)
Serum Potassium (mEq/L)	0.34 (0.30,0.38)	0.20 (0.16,0.24)	-0.16 (-0.35,0.03)
Serum Sodium (mEq/L)	0.38 (0.20,0.56)	0.35 (0.16,0.53)	0.96 (-0.02,1.93)
IDWG (kg)	0.44 (0.36,0.51)	0.26 (0.19,0.33)	0.24 (-0.07,0.55)

*Estimate is the difference in the outcome for patients with baseline K resin use compared to non-use

Adjustments: age, gender, black race, vintage, BMI, residual kidney function, vascular access, ferritin, hemoglobin, white blood cell count, serum albumin, serum creatinine, and 14 comorbid conditions
Note: All models adjusted for DOPPS phase and country and accounted for facility clustering effects

FR-PO1656

Multiple Biomarkers Improve the Prediction of Cardiovascular Mortality in Patients on Chronic Hemodialysis
Rei Okada,[1] Hirotake Kasuga,[1] Ryo Takahashi,[1] Keiko Kimura,[1] Chieko Matsubara,[1] Seiichi Matsuo.[2] *[1]Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan; [2]Nephrology, Nagoya University Hospital, Nagoya, Japan.*

Background: Patients on chronic hemodialysis (HD) are widely recognized to be at high risk for cardiovascular (CV) mortality, thus the more accurate prediction of CV mortality is clinically important. Three biomarkers,Serum brain natriuretic peptide (BNP), Troponin T (TnT) and C-reactive protein (CRP) ,are individually established to be predictive biomarkers for CV mortality in this population.

Methods: A total of 500 consecutive HD patients were examined by the measurement of three biomarkers for 10 years. The cut-off values were based on the tertiles of the individual biomarkers, and a multivariate Cox analysis including three biomarkers for CV mortality was performed. From the analyzed model, a simplified score was obtained by putting weight to individual biomarkers based on the adjusted hazard ratio (HR). Finally, the multi-marker score(MMS) was defined as the sum of these points, with higher points indicating a higher mortality risk.

Results: During follow-up period (80±41 months), 204 patients died including 95 CV deaths. Three biomarkers were individually independent predictors for CV mortality ($p<0.01$ for all). However, by receiver operating characteristic (ROC) analysis, area under curve (AUC) for CV mortality was larger in the multi-marker score (0.76) compared to BNP (0.64), TnT (0.70) and CRP (0.65) alone. Similarly, AUC for all-cause mortality was 0.80, 0.68, 0.74 and 0.73 in MMS. Among low-risk group (MMS< 3), middle-risk group (MMS=4-6) and high-risk group (MMS> 7), 10-year survival rate was 93.5%, 73.3% and 54.0% for CV mortality and 83.1%, 52.6% and 26.6% for all-cause mortality ($p<0.0001$ for both), respectively. Even after adjustment, MMS had strongly predictive power.

	Cardiovascular mortality		All-cause mortality	
Multi-marker score	HR (95%CI)	P value	HR (95%CI)	P value
<3	Reference		Reference	
4-6	4.00 (1.70-9.40)	0.0015	2.88 (1.68-4.94)	0.0001
>7	7.80 (3.25-18.73)	<0.0001	5.93 (3.39-10.37)	<0.0001

Conclusions: Multiple biomarkers could more accurately predict the mortality than these biomarkers alone in patients on HD.

FR-PO1657

NT-ProBNP Has No Diagnostic Value in End Stage Renal Disease Patients Presenting with Dyspnea
Jose Albert Avila, Richard K. Kasama, Shaffer R.S. Mok. *Medicine, Nephrology, Cooper University Hospital, Camden, NJ.*

Background: NT-ProBNP/BNP although used to differentiate acute dyspnea states, has not been validated in End Stage Renal Disease(ESRD) patients. We examine hemodialysis(HD) patients presenting with dyspnea.

Methods: Retrospectively, 250 HD subjects admitted to Cooper Hospital from 07/2010 to 03/2011, with acute dyspnea were broken into a high group (NT-ProBNP >=70,000) and a low group (NT-ProBNP <2,600) based on a rough cut off of 2,500 reported for chronic kidney disease patients. Analysis used Chi-square to assess differences between low and high NT-ProBNP levels in relation to performing hemodialysis, number of cardiology consults and echocardiograms ordered corrected for the continuous data set. Standard t-test analysis evaluated the difference in creatinine, volume removed, weights, weight change, and ejection fraction(EF) between groups.

Results: Out of 250 subjects, 235 had NT-ProBNP levels performed. No statistically significant difference was found in the frequency of hemodialysis, obtaining cardiology consults and echocardiograms between ESRD patients with high and low NT-ProBNP.
Chi-square analysis

Procedure	Chi-Square	P-value	Continuity correction	P-value
Hemodialysis	4.581	0.032	2.633	0.105
Cardiology consult	1.904	0.168	1.233	0.267
Echocardiogram	0.807	0.369	0.413	0.521

No statistically significant difference in creatinine, volume removed, weight change, and EF between groups with low and high NT-ProBNP was noted. There was a statistically significant difference in weight pre and post HD between the groups.

	Group (Low vs High NT-ProBNP)	Mean (N, SD)	t-test	P-value
Creatinine (mg/dL)	Low	7.24 (30, 5.25)	-0.585	0.561
	High	7.92 (31, 3.75)		
Volume removed (liters)	Low	2.14 (29, 1.19)	-0.455	0.651
	High	2.28 (31, 1.13)		
Weight pre-HD (kg)	Low	89.76 (29, 28.53)	2.180	0.033
	High	77.50 (31, 12.50)		
Weight post-HD (kg)	Low	87.53 (29, 28.86)	2.201	0.032
	High	74.97 (31, 12.85)		
Weight change (kg)	Low	2.23 (29, 2.08)	0.642	0.523
	High	2.53 (31, 1.49)		
EF (%)	Low	57.20 (30, 16.13)	1.540	0.129

Conclusions: There is no difference in the initial management strategies of HD patients presenting with NT-ProBNP levels in both extremes. In ESRD, the NT-ProBNP has no clinical value for discriminating between primary pulmonary processes and volume overload states and, therefore, should not be ordered as part of an emergency room evaluation.

FR-PO1658

Threshold Value of Serum b-Type Natriuretic Peptide (BNP) Level in Predicting Cardiovascular Disease (CVD) Risk in Hemodialyzed Patients Yusuke Tsukamoto,[1] Michio Kuwahara,[2] Sei Sasaki.[3] *[1]Department of Nephrology, Itabashi Chuo Medical Center, Itabashi-ku, Tokyo, Japan; [2]Department of Nephrology, Shuwa General Hospital, Kasukabe-shi, Saitama, Japan; [3]Department of Nephrology, Tokyo Medical and Dental University, Bunkyo-ku, Tokyo, Japan.*

Background: BNP has been reported to be a useful marker for CVD risk both in non-CKD and CKD patients. However, peptides accumulate in patients with decreased kidney function and threshold value in non-CKD cannot be applied in dialyzed patients.

Methods: Total of 463 patients (median HD vintage=87 months, age=60 yrs/o, male 68%, diabetic 39%) were studied from Jan. 2009 to Dec. 2010. Serum BNP level and ultrasonic cardiography was measured at the end of the first dialysis session of the week. Other serum laboratory tests were done at the beginning of dialysis.

Results: One hundred and seven CVD events (include 44 CVD deaths) were recorded during this study period. Cox-hazard revealed that BNP had a significant power to predict CVD events (hazard ratio=1.0002, p=0.0026 adjusted by age, sex, diabetes, dialysis vintage). ROC analysis demonstrated that threshold BNP level was higher than 503 pg/ml (specificity 81.2%, sensitivity 37.7%, P=0.0008) for CVD events and 708 pg/ml (specificity 87.4%, sensitivity 34.1%, P<0.05) for CVD death. Multiple regression analysis showed that BNP was correlated with ejection fraction (negatively, P=0.0002), left atrial diameter (P=0.019) but not with left ventricular mass index or average dialysis ultrafiltrate volume (n=287). In this cohort, higher ultrafiltrate volume was also associated with high risk of CVD event (hazard ratio=1.62, P<0.05 adjusted by demographics, n=362).

Conclusions: 1. Serum BNP level reflected a volume status of hemodialyzed patients and suggested to be a good marker to decide an adequate body weight. 2. Serum BNP level is a good marker to predict CVD risk not only in non-CKD but also in hemodialyzed patients. However, the threshold value for risk should be set much higher than one for non-CKD.

FR-PO1659

High Cardiac Troponin T Levels Predicts High Mortality in Hemodialysis Patients with Preserved Left Ventricular Ejection Fraction Chi-Ting Su,[1,3] Kuan-Yu Hung,[2] Jenq-Wen Huang.[2] *[1]Nephrology, Internal Medecine, Nation Taiwan University Hospital, Yun-Lin Branch, Douliou, Taiwan; [2]Nephrology, Internal Medecine, Nation Taiwan University Hospital, Taipei, Taiwan; [3]Human Genetic, Graduate School of Public Health, University of Pittsburgh, PA.*

Background: The implication of cardiac troponin-T (cTnT) to evaluate of cardiac functions in heomdialysis patients with preserved left ventricular ejection fraction (LVEF) remains unclear. We conduct this study to illustrate the potential value of cTnT to predict systolic function and patient survival.

Methods: There were one hundred and nine hemodialysis patients enrolled. Patients with severe valvular heart disease, atrial fibrillation, pulmonary edema or acute coronary syndrome were excluded. Study participants received echocardiography with tissue Doppler imaging analysis, and 2-dimensional speckle-tracking echocardiography with strain analysis. Patients were stratified by level of cTnT ≥0.05 ng/ml and cTnT < 0.05 ng/ml.

Results: Between two groups, there was no significant difference of gender, age, LVEF, systolic myocardial velocity, and the level of high sensitivity C-reactive protein (hsCRP). Patients, with high level of cTnT (≥0.05 ng/ml), presented with lower serum albumin level (3.13 ± 0.33 g/dL vs. 3.38 ± 0.41 g/dL, p=0.008) than those in the other group. By strain analysis, among patients with high cTnT level, reduced global LV peak systolic longitudinal strain (GSl; high level cTnT vs. low level cTnT group:-16.8 ± 3.3% vs. -19.0 ± 3.6%, p=0.02) developed. There was a correlation between GSl and level of cTnT (r=0.36, p < 0.001). One and half year mortality rate was lower in the group with low cTnT level (high level cTnT group vs. low level cTnT group: 40% v.s. 9.8%, p= 0.003).

Conclusions: Deterioration of LV systolic function, GSl, developed along with the increasing level of cTnT. In maintenance hemodialysis patients with level of cTnT ≥0.05 ng/ml presented with worse LV systolic function and lower albumin level than others with level of cTnT<0.05 ng/ml. The lower survival rate was associated with the higher level of cTnT.

FR-PO1660

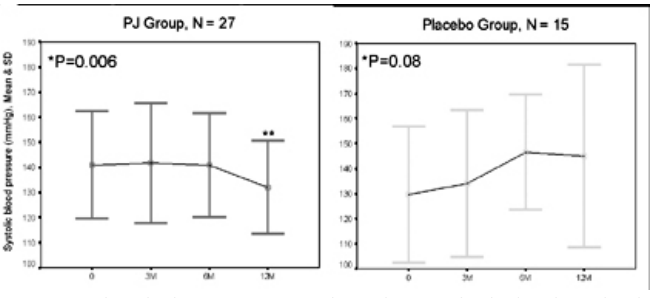
Pomegranate Juice Intake Attenuates Traditional Cardiovascular Risk Factors in Hemodialysis Patients: A Randomized Placebo Controlled Trial Lilach Shema,[1] Liora Ore,[2] Shifra Sela,[3] Ronit Geron,[1] Galina Shapiro,[3] Batya Kristal.[1] *[1]Nephrology Department, Western Galilee Hospital, Nahariya, Israel; [2]School of Public Health, University of Haifa, Israel; [3]Clinical Microbiology Lab and Eliachar Research Lab, Western Galilee Hospital, Nahariya, Israel.*

Background: The aim of the present study was to investigate the long term effects of Pomegranate juice (PJ) consumption, rich in polyphenols, on traditional cardiovascular (CV) risk factors: lipid profile, hypertension and on the progression of the atherosclerotic process.

Methods: 101 HD patients were randomized to receive 100 cc of PJ (0.7mM polyphenols) or matching placebo, three times a week for one year. The primary endpoints were systolic and diastolic blood pressure, number of antihypertensive drugs, level of triglycerides (TG), total cholesterol, HDL and LDL. Secondary endpoint was a composite of variables: Intima Media Thickness (IMT), number and structure of atherosclerotic plaques of the Carotid arteries.

Results: After one year of intervention the change in the number of antihypertensive drugs was significantly different between the two groups (P.V = 0.05). The number of antihypertensive drugs decreased in 22% of patients in the PJ group compared to 7.7% in the placebo group, while an increase was documented in 12.2% of patients in the PJ compared to 34.6% in the placebo group. Furthermore, a significant time response improvement in systolic blood pressure, triglycerides and HDL was observed in the PJ group.

Conclusions:



Among patients in the PJ group attenuation and aggravation in the atherosclerotic process was detected in 25% and 5% respectively, while more than 50% of patients in the Placebo showed progression and none showed improvement.

Conclusions: PJ consumption attenuates traditional CV risk factors. Hence, it may favor the high incidence of morbidity and mortality in HD patients.

FR-PO1661

Treatment of Chronic Low Back Pain in Hemodialysis Patients: A Randomized Controlled Trial Ricardo Sesso, Tatiana Cristofolini, Jamil Natour. *Nephrology, Federal University of São Paulo, Brazil.*

Background: Low back pain is a very common and disabling symptom that has not been properly studied in hemodialysis patients. The aim of this study was to evaluate the effectiveness of a physiotherapy approach to chronic low back pain.

Methods: 104 patients with chronic low back pain (lasting more than 3 months) not related to infection, tumor or fractures, and undergoing chronic hemodialysis in two hemodialysis units were prospectively randomized to one of two intervention groups: 1. Physiotherapy (N=53) with the McKenzie method consisting of repetitive and sustained flexion/extension exercises of the lumbar spine. Four movements were selected: flexion in standing, extension in standing, flexion in lying and extension in lying position; repeated twenty times per session (30 min. total) three times a week for eight weeks. Group 2 (N=51): received transcutaneous electrical nerve stimulation (TENS) for 20 min at 50-100 Hz frequencies for the same time frame. Outcome measures: lumbar pain visual analogue scale (VAS, ranging from 0-10[worse]), and the functional lumbar spine status measured by the Roland Morris (RM) disability questionnaire (with 24 items and scores ranging from 0 to 24[worse]) reported by the patients 1 week after the end of treatment.

Results: Mean patients' age was 58 yr.; median time on dialysis was 3.9 yr. Baseline sociodemographic, laboratory and clinical patients' characteristics were similar in both groups. Mean±SD scores of the VAS pre- and post-treatment were 6.9±1.6 and 1.4±1.4, respectively, in group 1, and 7.1±1.6 and 6.4±1.6, respectively in group 2. Mean change from baseline to after treatment was 5.5±1.8 and 0.8±0.6 for groups 1 and 2, respectively, P<0.001. Baseline RM scores were 20.0±2.6 and 20.8±2.4, for groups 1 and 2, respectively. Mean change from baseline to after treatment was 16.0±2.6 and 1.1±1.0 for groups 1 and 2, respectively, P<0.001. The effectiveness of the physiotherapy intervention was observed in all strata of the sociodemographic, laboratory and clinical variables.

Conclusions: Physiotherapy with the McKenzie method is effective in decreasing chronic low back pain and improving disability in chronic hemodialysis patients.

Hemodialysis Time of Day and Restless Legs Complaint: USRDS Special Study Data

Nancy G. Kutner,[1] Donald L. Bliwise,[1] Rebecca H. Zhang,[1] Kirsten L. Johansen,[1,2] Lynda A. Szczech.[3] *[1]USRDS Rehabilitation/QoL Special Studies Center, Emory University, Atlanta, GA; [2]Nephrology Section, San Francisco VA Medical Center, San Francisco, CA; [3]Nephrology, Duke University Medical Center, Durham, NC.*

Background: Restless legs is a prevalent complaint among patients on dialysis, but contributors are not well specified. Worsening of symptoms later in the day is a defining characteristic of restless legs syndrome (RLS). Data from the Comprehensive Dialysis Study (CDS) allowed us to explore variation in patients' restless legs complaint by HD treatment time, a factor that has received little study.

Methods: The CDS surveyed incident dialysis patients aged >18 from 296 randomly selected clinics throughout the US. Participants included 1,174 patients whose HD started before 2 pm (early shift) and 270 patients whose HD started 2 pm or later (late shift). RLS was defined by positive response to the three NIH workshop criteria: unpleasant sensations plus urge to move legs, sensations occur mainly at rest and improve with movement, and symptoms worse in evening/night than in morning. Patient characteristics potentially associated with RLS were compared by HD shift using t-test and chi-square analysis, and logistic regression was used to predict RLS.

Results: RLS was reported more often by late shift patients than by early shift patients (35% vs 28%; p = 0.008). Race/ethnicity, gender, educational level, and mean hemoglobin level were similar for early and late shift patients, while early shift patients were more likely to have diabetes and to be older. With adjustment for diabetes and age, the odds ratio for RLS among late shift patients compared to early shift patients was 1.37 (CI 1.05-1.79); p = 0.02.

Conclusions: RLS is time-of-day and activity dependent. For patients at risk for RLS, undergoing HD later in the day may increase distress and could contribute to patients' shortening treatment; it has been shown that RLS has negative implications for patient survival. CDS data suggest the value in clinical practice of early screening for restless legs complaint and avoiding late shift HD in at-risk patients.

FR-PO1663

A Prospective Trial Assessing the Longitudinal Stability of CKD-MBD Parameters in Hemodialysis Patients

Theresa Gross,[1] Thilo Krueger,[1] Markus Ketteler,[2] Vincent Brandenburg.[3] *[1]Nephrology, RWTH Aachen, Aachen, Germany; [2]Nephrology, Klinikum Coburg, Coburg, Germany; [3]Cardiology, RWTH Aachen, Aachen, Germany.*

Background: PTH is known to exhibit significant intraindividual variability in hemodialysis (HD) patients. Fibroblast growth factor 23 (FGF23) is an independent risk factor of mortality in dialysis. The variability of FGF23 in serial measurements has not yet been determined.

Methods: In this prospective, monocentric study over 32 weeks 56 chronic HD pts. (63% male, mean age 65±13 yrs, 35% diabetics) were investigated . 49 pts. underwent three to six serial measurements of FGF23 and other routine CKD-MBD parameters. We calculated the intraclass correlation (ICC) from estimates of between-subject variance ($\sigma 2b$) and within-subject variance ($\sigma 2w$) derived from mixed linear models. We applied the following formula: $\sigma 2b / (\sigma 2b + \sigma 2w)$. FGF23 was measured by c-terminal assay.

Results: During the study period the within-subject variability of FGF23 accounted for 15 % of the total variability compared to 30% in PTH, 50% in Ca, 27% in PO4, 30% in CaxPO4 and for 5.5% in bone alkaline phosphatase (BAP).

According to serial serum FGF23 measurements HD pts could be grouped into categories: group 1 (n=13): constantly low values <2000 RU/ml, group 2 (n=14): medium values 2000-10.000 RU/ml, group 3 (n=10): constantly high values >10.000 RU/ml and group 4 (n=12): changing values. These groups were sign. different in classical CKD-MBD parameters. Pts. with high FGF23 (group 3) had sign. higher time averaged values for Ca [2.53±0.12 vs 2.36±0.08 mmol/l], ion.Ca [1.32±0.07 vs 1.25±0.04 mmol/l], PO4 [2.41±0.38 vs 1.65±0.27 mmol/l] and CaxPO4- [6.08±0.85 vs 3.89±0.6 $mmol^2/l^2$] then pts. in group 1 (all $p< 0.01$).

Conclusions: FGF23 and BAP were characterized by lower within-subject variability compared to PTH, Ca and PO4 in HD pts.. About 75% of the pts. showed stable values in different ranges in this cohort. These data may help establishing FGF23 as diagnostic marker in HD pts.

FR-PO1664

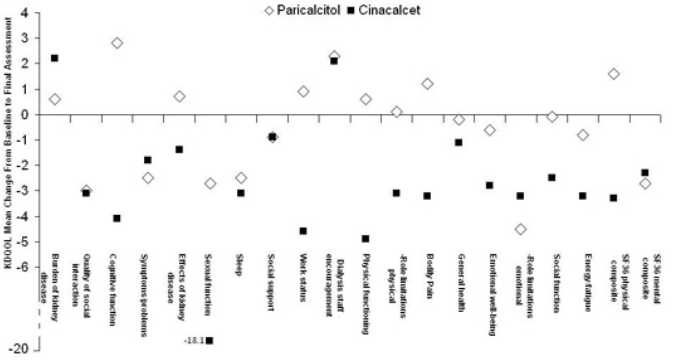
IMPACT-SHPT Study: Comparative Quality of Life Analysis of the Treatment of Secondary Hyperparathyroidism

David J. Goldsmith,[1] Markus Ketteler,[2] Kevin J. Martin,[3] Mario Cozzolino,[4] Myles S. Wolf,[5] Amit Sharma,[6] Michael Amdahl,[7] Samina Khan,[7] Steven E. Marx.[7] *[1]Guy's Hosp; [2]Klinikum Coburg; [3]Saint Louis U; [4]University of Milan; [5]U of Miami; [6]Boise Kidney and Hypertension Inst; [7]Abbott.*

Background: The IMPACT-SHPT is a randomized, open-label, 28-week, multicenter trial to compare paricalcitol and cinacalcet to determine the most effective therapy for the treatment of SHPT in subjects undergoing hemodialysis. The objective of this analysis is to assess patient reported outcomes using the KDQOL-SF in subjects receiving paricalcitol (IV Stratum-US) compared with cinacalcet plus low dose vitamin D.

Methods: 268 Subjects were randomly assigned to IV paricalcitol or cinacalcet treatment groups and received at least one dose for up to 28 weeks. The cinacalcet group received a fixed dose of doxercalciferol. If serum calcium was >10.5 mg/dL on two consecutive levels cinacalcet was administered in the paricalcitol arm. The treatment goal was to achieve a iPTH between150 to 300 pg/mL during weeks 21–28. KDQOL-SF questionnaire was self administered. The baseline and final KDQOL-SF measurement were compared between US treatment arms.

Results: KDQOL Mean Change From Baseline to Final Measurement



Conclusions: Paricalcitol treated patients experienced a 5 point mean difference in change from baseline to final measurement in cognitive function, sexual function, work status, and physical function compared with cinacalcet plus low dose vitamin D. Paricalcitol treated patient's mean difference in change from baseline to final measurement were higher in15 out 20 domains compared with cinacalcet plus low dose vitamin D. Higher scores represent a better health state. Clinicians and healthcare decision makers may consider these findings when evaluating treatment options for secondary hyperparathyroidism.

Achievement of KDOQI Guidelines for Bone Metabolism and Mortality in Incident Hemodialysis Patients in Relationship to Age

Olynka Vega,[1, 2] Len A. Usvyat,[1] Rakesh Malhotra,[1, 2] Stephan Thijssen,[1, 2] Nathan W. Levin,[1, 2] Peter Kotanko.[1, 2] *[1]Renal Research Institute, New York; [2]Beth Israel Medical Center, New York.*

Background: The National Kidney Foundation Kidney Disease Outcomes Quality Initiative (NKF-KDOQI) guidelines for bone and mineral metabolism (BMM) do not take patient's age into account. This study aims to investigate the effect of age on the achievement of BMM NKF-KDOQI goals during the first three months in HD and the impact of this achievement on all-cause mortality at 24 moths.

Methods: The study included all incident patients aged >18 years that received HD at the facilities of the Renal Research Institute from 2001 to 2008. Patients were divided into four age groups at start of dialysis: 1: 18-60, 2: 61-70, 3: 71- 80, and 4: >80 years old. Demographic data, etiology of ESRD, the average levels during the first 3 months on HD of total calcium (Ca), phosphorus (P) and parathyroid hormone (PTH) were collected by chart review. Multivariate Cox regression models were used to calculate HR and 95% CI.

Results: We included 3456 patients, 56.6% male, 51% Diabetics and 48.1% whites.

HR for all cause Mortality. At target groups were used as reference.

	18- 60 years, N= 1612	61-70 years, N= 808	71-80 years, N= 697	>80 years, N= 339

Phosphorus				
< target	1.7 (0.8-3.4)	2.45 (1.1-5.0)†	1.2 (0.6-2.5)	0.9 (0.5-1.7)
> target	0.6 (0.4-0.9)	0.9 (0.5-1.5)	0.9 (0.5-1.1)	1.2 (0.6-2.5)

*P=0.02, † P=0.01, ‡P= 0.002

All-cause mortality risk increased with hypocalcemia in all age groups bellow 80 years. Hypophosphatemia increased mortality in age group 61-70. PTH levels did not impact survival.

Conclusions: Hypocalcemia increased all cause mortality risk in patients bellow 80 year old. The reasons for this association are unclear, but may be related to arrhythmias. Hypophosphatemia, a likely reflection of poor nutrition, was associated with increased all cause mortality risk in the age group 61-70 years.

FR-PO1666

Influence of Age on Bone Mineral Metabolism Parameters: Differences and Commonalities between Two Countries Olynka Vega,[1, 2] Gero D. von Gersdorff,[3] Mathias Schaller,[3] Len A. Usvyat,[1] Nathan W. Levin,[1, 2] Peter Kotanko,[1, 2] Claudia Barth.[4] *[1]Renal Research Institute, New York; [2]Beth Israel Medical Center, New York; [3]Nephrology, University of Cologne Medical Center, Germany; [4]Kuratorium fur Heimdialyse, Neu-Isenburg, Germany.*

Background: The KDOQI guidelines for bone and mineral metabolism (BMM) do not take patient's age into account. This study aims to investigate the effect of age on the achievement of BMM KDOQI goals using two cohorts of HD patients from the US and Germany.

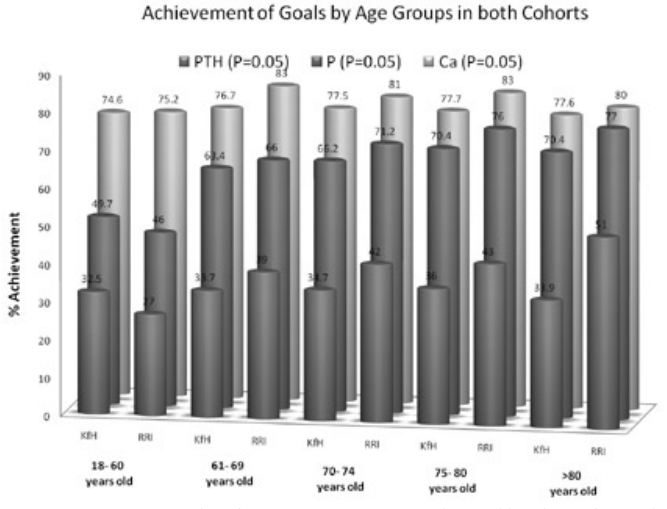
Methods: We included all patients aged >18 years who received in 2009 HD at the facilities of the German Kuratorium für Heimdialyse (KfH), and the Renal Research Institute (RRI), USA. Patients were stratified by age: 18-59; 60-69; 70-75; 75-80, and >80 years. Etiology of ESRD, levels of total calcium (Ca), phosphorus (P), and parathyroid hormone (PTH) were collected from the databases. ANOVA was used.

Results: There were 8638 patients in the KfH-cohort and 2446 in the RRI-Cohort. Diabetes was the most common cause of ESRD in both cohorts (KfH=26% and RRI 33%). HR for all cause Mortality. At target groups were used as reference.

Table 1. Ca, P and PTH levels by age groups. Values are in mean ± SD

	18-60 years		75-80 years		>80 years		
	Kfh	RRI	Kfh	RRI	Kfh	RRI	P
No.	3520	787	1106	283	389	421	
P (mg/dL)	5.5±1.3	5.6±1.2	4.7±1	4.7±0.9	4.7±1	4.5±0.8	<0.001
Ca (mg/dL)	8.9 ± 0.6	8.9±0.7	8.9±0.5	9±0.5	8.9±0.5	8.9±0.5	<0.001
PTH (ng/mL)	278±258	536±563	211±183	356±257	205±191	304±221	<0.001
% Patients with PTH <150 ng/mL	32.5	9	44	12	46	16	<0.001

Ca, P, CaxP product levels, and the % of patients achieving BMM KDOQI goals did not differ between the countries. The % of patients achieving BMM KDOQI goals increased with the age in both cohorts. Noteworthy, PTH <150 ng/mL was >3 times more frequent in the KfH cohort.



Conclusions: Irrespective of country, BMM KDOQI goals are achieved more frequently with increasing age. Older patients may increase susceptibility to low PTH levels

FR-PO1667

Long-Term Treatment of Bixalomer in Chronic Kidney Disease Patients on Hemodialysis with Hyperphosphatemia Tadao Akizawa,[1] Chisato Kameoka.[2] *[1]Department of Nephrology, Showa University School of Medicine, Tokyo, Japan; [2]Astellas Pharma Inc., Tokyo, Japan.*

Background: Bixalomer is a new phosphate-binding polymer in development for the treatment of hyperphosphatemia. In this study, the long-term safety and efficacy of bixalomer in Japanese Chronic Kidney Disease (CKD)-Hemodialysis (HD) patients were assessed.

Methods: This was a multicenter, open-label study in CKD-HD patients with hyperphosphatemia. Main efficacy endpoints were time course of serum phosphorus (Pi) level and achievement rate of the target Pi range in Japanese guideline (3.5 to 6.0mg/dL). For safety assessment, the incidence of adverse drug reactions (ADRs) was tabulated. The starting dose was 1.5g/day and then the dose was titrated up to 7.5g/day depending on the serum Pi levels. Treatment period was up to 48 weeks.

Results: A total of 248 subjects were investigated and 179 subjects completed the study. The mean serum Pi level decreased over time and remained around 5.5 mg/dL until Week 48. The results of the main efficacy endpoints are summarized in the following table.

	Week 0	Week 48	End of Treatment
Serum Pi level (mg/dL)	7.71	5.47	5.77
The achievement rate of the target Pi range (%)	7.0	70.8	62.6

The incidence of AEs and ADRs was 94.4% and 29.4%, respectively. Serious adverse events which were assessed by investigators as related to the study drug were colitis ischaemic, diverticulum intestinal haemorrhagic, oesophageal ulcer, and cholecystitis acute (n=1 each). The most common ADR was constipation (21.0%). The majority of ADRs occurred in the early treatment period up to Week 12 and the incidence did not tend to increase with long-term treatment. Furthermore, bixalomer did not decrease HCO_3 levels.

Conclusions: Bixalomer was able to control serum Pi levels for a long period and would not raise any major safety concerns when administered for a long period. Therefore, bixalomer could be a clinically effective drug that can be administered for a long period to treat hyperphosphatemia.

IMPACT-SHPT Study: Comparative Economic Analysis of the Treatment of Secondary Hyperparathyroidism Amit Sharma,[1] Markus Ketteler,[2] Kevin J. Martin,[3] Myles S. Wolf,[4] Mario Cozzolino,[5] David J. Goldsmith,[6] Michael Amdahl,[7] Samina Khan,[7] Steven E. Marx.[7] *[1]Boise Kidney and Hypertension Inst; [2]Klinikum Coburg; [3]Saint Louis U; [4]U of Miami; [5]University of Milan; [6]Guy's Hosp; [7]Abbott.*

Background: The IMPACT-SHPT is a randomized, open-label, 28-week, multicenter trial that compared paricalcitol and cinacalcet to determine the most effective therapy for the treatment of SHPT in subjects undergoing hemodialysis. The objective of this analysis is to assess the cumulative dose and cost of paricalcitol and cinacalcet treatment during the study period.

Methods: Subjects were randomly assigned to receive paricalcitol or cinacalcet and fixed IV doxercalciferol or oral alfacalcidol for 28 weeks. Cinacalcet was administered if serum calcium is ≥ 10.5 mg/dL on two consecutive levels in the paricalcitol arm. The treatment goal was to achieve a mean iPTH value between150 to 300 pg/mL during weeks 21–28. Data were collected from 268 subjects who received at least one dose of randomized study drug. Using a US perspective, costs were estimated by utilizing average whole price minus fifteen percent.

Results: The 28 week treatment dose in the paricalcitol arm was: paricalcitol 56,668 mcg, and cinacalcet 20,850 mg, compared to the cinacalcet arm: cinacalcet 895,200 mg, doxercalciferol 4,087 mcg, and alfacalcidol 2,780 mcg. The treatment cost was $184,279 in the paricalcitol arm compared to $490,611 in the cinacalcet arm over 28 weeks.

Conclusions: These results suggest the annual treatment cost of targeting the same iPTH control is 62% ($612,663) lower with paricalcitol compared with cinacalcet plus low-dose vitamin D in this study. There is an estimated savings of about $229,462 per 100 patients per year from a US perspective. Paricalcitol therapy costs are much lower than cinacalcet plus low dose vitamin D for the same target iPTH control. This is a conservative estimate since oral doses were not included if subjects did not return their study drug bottles for the determination of doses taken, as instructed per protocol. Healthcare decision makers should consider these findings when assessing therapies for the treatment for secondary hyperparathyroidism.

FR-PO1669

A Phase III, Sevelamer HCl-Controlled Study of Bixalomer in Chronic Kidney Disease Patients on Hemodialysis with Hyperphosphatemia Tadao Akizawa,[1] Hideki Origasa,[2] Chisato Kameoka.[3] *[1]Department of Nephrology, Showa University School of Medicine, Tokyo, Japan; [2]Division of Biostatistics and Clinical Epidemiology, University of Toyama School of Medicine, Japan; [3]Astellas Pharma Inc., Tokyo, Japan.*

Background: Bixalomer is a new phosphate-binding polymer in development for the treatment of hyperphosphatemia in Chronic Kidney Disease(CKD)-Hemodialysis(HD) patients in Japan. In this study, the non-inferiority of bixalomer to Sevelamer HCl(SH) in efficacy was assessed and the safety of bixalomer was also compared with that of SH.

Methods: This was a multicenter, randomized, SH-controlled, open-label study in CKD-HD patients with hyperphosphatemia. Primary endpoint was serum phosphorus(Pi) levels at the end of treatment. The starting dose was 1.5g/day(bixalomer) and 3g/day or 6g/day(SH, based on the serum Pi level before treatment period). Depending on serum Pi levels, the dose of bixalomer or SH was titrated up to 7.5g/day and 9g/day, respectively. Subjects received the study drug for 12 weeks.

Results: Overall 110 subjects were randomized to either bixalomer group or SH group(n=55 each). The adjusted mean serum Pi level at the end of treatment was 5.87mg/dL and 5.55mg/dL, respectively. The upper limit of the 95%CI for the difference between the adjusted mean for bixalomer group and SH group (bixalomer-SH) was below 1.0mg/dL(non-inferiority margin in this study). Thus the non-inferiority of bixalomer to SH was confirmed. The incidence of common gastrointestinal adverse drug reactions(GI ADRs) which were assessed by investigators as related to the study drug is summarized in the following table with the final mean daily dose. No serious or severe GI AEs were reported. In addition, bixalomer did not decrease HCO3 levels, which were measured to assess the metabolic acidosis risk.

	Bixalomer	SH
GI-ADRs	29.1%	47.3%
-Constipation	18.2%	29.1%
-Abdominal distension	1.8%	12.7%
Mean Daily Dose (Week11 to 12)	4.78g/day	5.00g/day

Conclusions: Bixalomer was as effective as SH in decreasing serum Pi level. Bixalomer caused fewer GI ADRs and showed no deterioration of metabolic acidosis. These results indicated the clinical benefits of bixalomer as a treatment for hyperphosphatemia.

N-DEPTH – Nephrology DVT and Pulmonary Embolism Prophylaxis STudy in Hospitalized Patients Christine M. Ribic, Andrew M. Burke, Sarah Karkhanechi, Catherine M. Clase, Azim S. Gangji. *Medicine, McMaster University, Hamilton, ON, Canada.*

Background: In hospitalized patients, the risk of venous thromboembolism (VTE) has been reported to be higher in patients with chronic kidney disease. Prophylaxis prescription practices, and the risk of VTE and bleeding in hospitalized patients treated with dialysis are unknown.

Methods: This single centre, retrospective chart review was designed to determine the rate of VTE pharmacological prophylaxis in adult patients treated with chronic dialysis (≥ 3 months) on index admission during Sept 2008 to Sept 2009. Exclusion criteria included admission ≤ 24 hours, for suspected VTE, bleed or renal transplant. We defined VTE prophylaxis as administration of prophylactic doses of heparin within 48 hours of admission. We collected data on VTE risk factors as per the ACCP guidelines, VTE events defined objectively with imaging and major bleeding events.

Results: We screened 329 patient admissions: 143 met eligibility criteria. Of these, 23(16.1%) patients were on full dose anticoagulation (coumadin with INR > 2.0, or heparin) and were ineligible for VTE prophylaxis. Of the 120 eligible patients, 31(25.8%) received VTE prophylaxis. The number of baseline VTE risk factors (range 1 to 7) and anticoagulant or antiplatelet use did not predict the use of VTE prophylaxis (p=0.86). There was a trend towards less use of prophylaxis in patients receiving clopidogrel at baseline (p=0.05). VTE events (1 pulmonary embolism; 1 deep vein thrombosis) occurred in 2(2.2%) eligible patients not receiving prophylaxis and no events occurred in those receiving prophylaxis (p=0.55). There was no difference in minor or major bleeds between those that did (n=3) and did not receive prophylaxis (n=6; p=0.66). The majority of bleeding events were gastrointestinal (n=7).

Conclusions: To our knowledge this is the first account of use of prophylaxis in this population. Three-quarters of apparently eligible patients on dialysis admitted to a tertiary care centre under 13 different nephrologists were not prescribed prophylaxis, and baseline VTE risk factors did not predict for whom it was prescribed. Bleeding risk was not increased in patients receiving prophylaxis. This issue deserves wider study.

FR-PO1671

Retrospective Analysis of Etiology and Management of Pneumonia in End Stage Renal Disease Rupam Ruchi,[1] Matthew Whitbeck,[1] Sanjeev Kumar,[2] Milagros Zegarra.[1] *[1]Internal Medicine, Wayne State University; [2]Anesthesiology, Wayne State University, Detroit.*

Background: The American Thoracic Society guidelines for management of pneumonia recommends that pneumonia in ESRD should empirically be treated as health care associated pneumonia(HCAP). We conducted this study to investigate if patients who are initially treated as HCAP do better vs patients who are empirically treated as community acquired pneumonia(CAP).

Methods: It is a retrospective cohort study including patients 18-89 yrs with ESRD on hemodialysis for ≥3 months, admitted with pneumonia. According to initial antibiotic used, patients were divided into group A (treated empirically as HCAP) and group B (treated empirically as CAP). Data was collected regarding demographic profile, severity of pneumonia (as assessed by PSI and CURB-65), co-morbidities, microbiology, length of hospital stay, in-hospital mortality. The chi-square statistics & multiple linear regression were used.

Results: 103 patients were included. Group A (n=51) and group B (n=52) were comparable with respect to all parameters except number of patients with COPD (p=0.03), nursing home residents (p=0.02), PSI (96.1 ± 22.4 in group A vs in 116.5 ± 34.8 in group B, p≤0.01), CURB-65 (45.1% patients in group A had CURB-65 of 2 and above, vs 57.6% in group B, p≤0.01). Length of hospital stay was significantly lower in group A, 6.4 ± 6.9 days as compared to 9.5 ± 6.9 days in group B, p=0.02. This difference persisted even after adjusting for age, race, PSI, hypertension, COPD, and being nursing home residents. No patient died in group A whereas 13.5% patients died in group B, p≤0.01. However, after adjusting for PSI, this difference was not found to be significant (p=0.09). A microbiological diagnosis was established in 31 patients, identifying a total of 44 organisms. In group B, 27.1% patients grew MRSA and 11.5% grew Pseudomonas, vs none of those in group A.

Conclusions: Empiric treatment of pneumonia in ESRD patients on hemodialysis as CAP reduces the length of hospital stay without any significant difference in mortality. We suggest stratification of these patients according to the severity of their pneumonia and treating less severe pneumonia as CAP, rather than HCAP.

FR-PO1672

High Prevalence of Incidental Findings in Chest Computed Tomography in Incident Hemodialysis Patients: The Predictors of Arrhythmic and Cardiovascular Events in End-Stage Renal Disease (PACE) Study Bernard G. Jaar,[1] Svetlana V. Chembrovich,[1] Stephen M. Sozio,[1] Julia J. Scialla,[1] Tariq Shafi,[1] Joao A.C. Lima,[1] Wen Hong Linda Kao,[1] Rulan S. Parekh,[1 and 2] Lucy A. Meoni.[1] *[1]Johns Hopkins University; [2]University of Toronto.*

Background: Routine evaluation of research images by radiologists can result in identification of incidental findings. To our knowledge no studies have reported on the prevalence of these findings in research chest computed tomography (CT) of incident hemodialysis (HD) patients (pts) and its association with clinical characteristics.

Methods: We performed a cross-sectional analysis of the first 205 pts who underwent a research cardiac imaging protocol with a 320 slice multidector CT scan (Toshiba Aqulion) with under 5 msv of radiation.

Results: Of the 205 pts, 25% were ≥ 65 years, 57% male, 28% white race, 61% smoker, 33% had body mass index (BMI) of ≥ 30 and 45% had existing cardiovascular disease (CVD). Overall, 44% had at least one and 15% had 2 or more incidental findings with 11% of the pts requiring follow-up to rule out malignancy. Among the 205 pts, lung nodules represented the most frequent findings (25%). The likelihood of any incidental findings was 3 times higher in pts ≥ 65 years, Odds Ratio (OR) [95% Confidence Interval] 2.96 [1.41-6.20] and 1.8 times higher in pts with existing CVD (OR 1.79 [1.01-3.19]); whereas a BMI of ≥ 30 was associated with lower odds (OR 0.49 [0.27-0.89]). Both older age and existing CVD, but not lower BMI, were also associated with higher odds of lung nodule. After adjustment, age ≥ 65 years remain associated with a higher likelihood of any incidental findings and pulmonary nodule; (OR 2.58 [1.20-5.55]) and (OR 3.94 [1.93-8.01]) respectively; while a BMI of ≥ 30 was associated with lower odds of any incidental findings (OR 0.46 [0.25-0.86]). Neither pulmonary nodules nor any incidental findings were associated with smoking, chronic lung disease or history of cancer.

Conclusions: The high occurrence of these incidental findings in incident HD pts requiring further investigations raises important practical, ethical and medico-legal issues that need to be carefully considered in research projects using chest CT scanning.

FR-PO1673

Prevalence of Oral Lesions in Hemodialysis Patients: A Multinational Cohort Study Giovanni F.M. Strippoli. *Diaverum Medical Scientific Office, Lund, Sweden.*

Background: Oral diseases are common in the general population and particularly in underprivileged portions of society. It is plausible that prevalence would be high in people with end stage kidney disease receiving hemodialysis but this has not been formally established. We globally surveyed the prevalence of any oral lesion in people on hemodialysis.

Methods: In this ongoing multinational cross-sectional and prospective cohort study, we enrolled people receiving hemodialysis in 30 outpatient clinics selected randomly from a collaborative network. Prevalence of dental, periodontal, mucosal and salivary lesions was assessed based upon standard dental practice methodology. Analysis was with descriptive statistics.

Results: Of 1744 hemodialysis patients in the participating clinics, 1308 (75%) received a complete oral visit (mean age 66.81 (13.85) years). 323 (27%) were edentulous, 371 (40%) reported attrition and dental erosion (bruxism), 21 (2%) had enamel hypoplasia. DMFT score was 23.94 (8.58). Salivary pH was 7.39 (0.85). Buffer capacity was high in most patients (868, 69% high capacity; 96 patients (8%) low capacity). The salivary flow rate before dialysis was 0.69 (0.64), versus 0.76 (0.74) post dialysis. 469 patients (36%) had mucosal lesions (any), 172 candidiasis (15%), 46 unrecognized neoformations (4%), 17 gingival overgrowth (2%), among others. 538 patients (45%) reported dryness of mouth, 72 (6%) burning and 57 (5%) pain in their mouth. Finally, periodontitis was present in 496 (58%) of 873 dentate patients undergoing periodontal evaluation.

Conclusions: In conclusion, we found oral lesions to be highly prevalent in people receiving hemodialysis. This ongoing study will be completed in 2012 and prospectively analyzed the relationship between exposure to any oral lesions and the risk of major patient level endpoints including mortality and cardiovascular events. Focus on oral health could be an essential component of managing people with end stage kidney disease.

ORAL-D steering committee/participants: Stroumza P, Frantzen L, Leal M, Torok M, Bednarek A, Dulawa J, Gelfman R, Celia E, Craig JC, Johnsohn D, Ruospo M, Palmer S, Hegbrant J, Wollheim C, Strippoli GF.

FR-PO1674

Thirst and Oral Symptoms in Hemodialysis Patients: A Multinational Cohort Study Giovanni F.M. Strippoli. *Diaverum Medical Scientific Office, Lund, Sweden.*

Background: Thirst and xerostomia, the subjective complaint of dry mouth due to a lack of saliva, are common side-effects of various medications, and it is plausible that their prevalence would be high in people with end stage kidney disease receiving hemodialysis as well as dialysis treatment itself being a major determinant. In this cohort study, we globally survey the prevalence of any oral symptoms in hemodialysis.

Methods: In this ongoing multinational cross-sectional and prospective cohort study, we enrolled consenting people receiving hemodialysis in 30 outpatient clinics selected

randomly from a collaborative dialysis network. Xerostomia inventory and dialysis thirst inventory were assessed based upon validated methodology. Analysis was with descriptive statistics.

Results: Of 1733 hemodialysis patients in the participating clinics, 1308 (75%) received a self administered questionnaire on oral symptoms. 557 patients (43%) reported occasional use of candies for dry mouth sensation, 313 (24%) had difficulties to swallow and 635 (49%) needed to sip to swallow, 693 (54%) wake up during the night to drink, 479 (37%) had dry mouth and 642 (50%) had dry lips, for a total xerostomia inventory score of 21.14 (5.47). Thirst as a symptom was problem for 823 patients (64%), 1028 (79%) were thirsty during the day and 667 (51%) during the night, 425 (33%) patients felt that thirst influenced their social life. The final dialysis thirst inventory score is 18.42 (5.61).

Conclusions: In conclusion, we found oral symptoms to be highly prevalent and heavily affecting people receiving hemodialysis. This ongoing study will be completed in 2012 and prospectively evaluate the relationship between these symptoms and major patient level endpoints including mortality and cardiovascular events. ORAL-D steering committee/participants: Stroumza P, Frantzen L, Leal M, Torok M, Bednarek A, Dulawa J, Gelfman R, Celia E, Craig JC, Johnsohn D, Ruospo M, Palmer S, Hegbrant J, Wollheim C, Strippoli GF.

FR-PO1675

Oral Hygiene Habits in Hemodialysis Patients: A Multinational Cohort Study Giovanni F.M. Strippoli. *Diaverum Medical Scientific Office, Lund, Sweden.*

Background: Oral hygiene habits in people with end stage renal disease receiving hemodialysis has never been formally studied. In this study we globally survey oral hygiene habits in a large hemodialysis population.

Methods: ORAL-D is an ongoing multinational cross-sectional and prospective cohort study of oral diseases in people on hemodialysis. We enrolled consenting people receiving hemodialysis in 30 outpatient clinics selected randomly from a collaborative dialysis network. Oral hygiene habits were assessed based upon standard patient questionnaire methodology. Analysis was with descriptive statistics.

Results: Of 1733 hemodialysis patients in the participating clinics, 1308 (75%) responded to a self administered oral hygiene questionnaire. Of these, 723 (56%) did not remember when they had the latest visit, or never had one, 372 (29%) had the first dental visit after they were 30 years old, 259 (19%) never brushed their teeth, 426 (33%) used mouthwash and only 67 (5%) used dental floss, 524 (44%) changed the toothbrush as needed, and only 378 (30%) spent more than 2 minutes for the daily oral hygiene.

Conclusions: In conclusion, according to existing validated instruments for evaluation of oral hygiene, people receiving hemodialysis display very poor oral hygiene patterns. This ongoing study will be completed in 2012 and explore the association of such patterns with major patient level endpoints including mortality and cardiovascular events.

ORAL-D steering committee/participants: Stroumza P, Frantzen L, Leal M, Torok M, Bednarek A, Dulawa J, Gelfman R, Celia E, Craig JC, Johnsohn D, Ruospo M, Palmer S, Hegbrant J, Wollheim C, Strippoli GF.

FR-PO1676

The Use of External Carotene Cream (CC) Can Inhibit Hypertrophic Scars Caused by Needle Injury in Hemodialysis (HD) Patients Satoshi Funakoshi,[1] Jyunichiro Hashiguchi,[1] Rica Etoh,[1] Junko Kubo,[1] Yoshiaki Lee,[1] Takashi Harada,[1] Kazunori Utsunomiya,[3] Mineaki Kitamura,[2] Tomoya Nishino,[2] Shigeru Kohno.[2] *[1]Division of Blood Purification, Nagasaki Renal Center, Nagasaki, Japan; [2]Department of Internal Medicine, Nagasaki University Graduate School of Medicine, Nagasaki, Japan; [3]Department of Diabetes, Jikei University, Tokyo, Japan.*

Background: Hypertrophic scars and keloids both represent fibrotic skin conditions which is difficult to treat with a high recurrence rate. Since upper arms are most susceptible to developing these types of conditions, HD patients are under high risks as they receive needle injuries repeatedly in HD session on the brachial arteriovenous fistula.

Carotene, an antioxidant, is also known to reduce squamous metaplasia in skin tissues. We herein evaluate the effects of CC on prevention of developing keloids and hypertrophic scars on the brachial skin in HD patients.

Methods: Fourteen HD outpatients with moderate – severe scars and keloids on their forearms were enrolled in this study after appropriate IC. After every HD session CC or control creams was put on the needle injuries of their skin, and the skin color and thickness of skin in scar area were monitored using photometer (Spectrophotometer NF333, SOUKEN, Tokyo) and superficial ultrasound study (LOGIQ E9, GE Yokokawa, Tokyo) for 4 weeks (the period of skin turn over).

Results: As shown in the table, there was significant difference between CC and control creams in both the skin color and the thickness of skin after 4 weeks.

Effects of carotene cream (CC) on skin color and thickness in arteriovenous fistula area

		pre	4 weeks	p-value
Skin color	control	55.81±0.99	57.38±2.9	0.23
	CC	56.78±2.06	59.92±4.38	0.044*
Skin thickness (mm)	control	0.69±0.06	0.56±0.05	0.085
	CC	0.79±0.11	0.53±0.05	0.0038*

Adverse effects including skin rash or erosion were not observed.

Conclusions: Our results strongly indicate the potential effects of CC on protecting the formation of keloids and hypertrophic scars, and eventually improving QOL of HD patients.

FR-PO1677

Prevalence of Nephrogenic Systemic Fibrosis (NSF) in Dialysis Patients: The Pro-FINEST Study Sabine Amet,[1] Vincent Launay-Vacher,[1] Benedicte Stengel,[2] Anne Castot,[3] Camille Frances,[4] Nicolas Grenier,[5] Jean-Yves Gauvrit,[6] Genevieve M. Reinhardt,[7] Olivier Clement,[8] Nicolas Janus,[1] Carmen Kreft-Jais,[3] Gabriel Choukroun,[9] Maurice Laville,[10] Gilbert Deray.[11] *[1]ICAR Department, Nephrology, Pitie-Salpetriere Hospital, Paris, France; [2]INSERM U1018, Paul Brousse Hospital, Villejuif, France; [3]Drug Monitoring, Afssaps, Saint-Denis, France; [4]Dermatology, Tenon Hospital, Paris, France; [5]Radiology, Pellegrin Hospital, Bordeaux, France; [6]Radiology, Pontchaillou Hospital, Rennes, France; [7]Radiology, Haguenau Hospital, Haguenau, France; [8]Radiology, G. Pompidou Hospital, Paris, France; [9]Nephrology, South Hospital, Amiens, France; [10]Nephrology, Edouard Herriot Hospital, Lyon, France; [11]Nephrology, Pitie-Salpetriere Hospital, Paris, France.*

Background: NSF is a cutaneous and systemic disorder characterized by widespread tissue fibrosis. It has been linked with gadolinium-based contrast agents (GBCA), especially in dialysis patients. The Pro-FINEST study is a national prospective study endorsed by the French Drug Agency (Afssaps), and the French Societies of Nephrology, Dermatology, and Radiology. It aims at determining the prevalence of NSF after a Magnetic Resonance Imaging (MRI) examination, +/- GBCA, in dialysis patients.

Methods: The study is based on a 3-section patient form. Section 1: demographics and dialysis; Section 2: MRI examination; Section 3: any dermatological event (DE). Further investigations are planned in case of DE. When a NSF diagnosis is confirmed, an ancillary study is scheduled, with random selection of 4 patients (same gender, dialysis technique, centre, GBCA and without any DE after MRI).

Results: Since 01/2009, 571 patients have been included (247 centres): mean age 63.3 years, 58.5% males, 368 forms received: 58.7% received GBCA, 90.7% Gadoterate. 14 patients reported a DE. Dermatological diagnoses did not report any evidence of NSF.

Conclusions: So far thus, no case of NSF has been reported in 571 dialysis patients among whom the majority received a GBCA. Most patients received a macrocyclic gadolinium chelate for which no unconfounded case of NSF has been observed yet worldwide (Gadoterate).Final results will be available at the time of the congress.

FR-PO1678

Skin Pathologies and Associated Mortality in a Cohort of End-Stage Renal Disease Undergoing Chronic Hemodialysis Therapy Stefan Walter, Andreas Kribben, Oliver Witzke, Thorsten Feldkamp, Stefan Becker. *Department of Nephrology, University Hospital Essen, Essen, NRW, Germany.*

Background: Pathologies and symptoms of the skin are frequently encountered in end-stage renal disease patients undergoing chronic hemodialysis therapy. Uremic pruritus, pigmentary disorders or further skin-diseases like calciphylaxia are often described in the literature.

Aim of the study was to detect skin pathologies of such patients, to identify risk factors and to test for associated mortality.

Methods: 508 patients undergoing chronic hemodialysis therapy (8 centres in North Rhine-Westphalia, Germany) were included into the study. Patients were interviewed and further data was taken from their medical records. Physical examination included upper and lower extremities and focused on xerosis, edema, papules, pustula, hardening, hyperpigmentation, and tethering of the skin.

To identify risk factors, we performed a multivariate analysis. 6 month after the visit the mortality-status was checked.

Results: 86.8 % (441/508) of the patients presented at least one of the respected skin pathologies. Frequently were found: xeroderma (71.9%, 365/508), itching (39.0%, 198/508) and edematous (17.5%, 89/508) skin, as well as hyperpigmentation (14.8%, 73/508), induration (1.6%, 8/508) and tethering of the skin (0.4%, 2/508).

Risk factors for hyperpigmentation, induration or tethering of the skin were simultaneous presence of coronary heart disease ($p<0.005$), warfarin therapy ($p<0.001$), peripheral arterial disease ($p<0.002$) or a previous thrombosis ($p<0.003$).

Patients with this skin lesions had a significantly higher mortality ($p<0.002$, OR=2.6) than patients without these lesions.

Conclusions: Skin lesions are a frequent finding in end-stage renal disease patients undergoing chronic hemodialysis therapy. One may assume that certain findings are associated with certain comorbidities and hence increased mortality.

FR-PO1679

Efficacy of Glycerol-Paraffin in Uremic Xerosis: A Randomized, Double-Blind, Comparative Study Jacek Szepietowski,[1] Elias V. Balaskas,[2] Didier Bessis,[3] Dimitrios Ioannides,[2] Claudio Ponticelli,[4] Corinne Ghienne,[5] Patrick Dupuy.[5] *[1]Department of Dermatology, Venereology and Allergology, University of Medicine, Wroclaw, Poland; [2]Department of Nephrology, Ahepa University Hospital, Thessaloniki, Greece; [3]Department of Dermatology, Hospital Saint Eloi, Montpellier, France; [4]Department of Nephrology, Scientific Institute Humanitas, Rozzano, Italy; [5]Division of Research and Development, Orfagen, Toulouse, France.*

Background: Uremic xerosis is a bothersome condition that is poorly responsive to moisturizing and emollient therapy. It is associated with cutaneous deficiency in glycerol and exacerbated pruritus (uremic pruritus).

Methods: A randomized, double-blind, intra-individual (left vs right comparison), multicentric clinical study was performed on 100 patients with moderate to severe uremic xerosis for 7 days, during which the patients applied twice daily an emulsion combining glycerol and paraffin (test product) on one allocated lower leg, and the emulsion alone (comparator) on the other lower leg. This was followed by an open-labeled use of the test product on all the xerotic areas for 49 days. The main efficacy parameter was treatment response on each lower leg, as defined by a reduction from baseline of at least 2 grades in a pre-defined 5-point clinical score, on day 7.

Results: Among the ninety-nine (99) patients analyzed, the test product was highly effective with a treatment response in 72 patients (73%), whereas 44 patients (44%) responded to the comparator ($p<0.0001$, inter-group analysis). This was associated with an objective reduction in the density and thickness of the scales using D-squames on day 7 ($p<0.0001$ compared to the comparator), and a substantial improvement of the uremic pruritus (75%) and quality of life at study end ($p<0.001$, intra-group analysis). The test product was very well tolerated, product-related local intolerance (exacerbated pruritus, local burning, erythema) occurring in only 5 patients (5%).

Conclusions: In conclusion, uremic xerosis and pruritus can be managed successfully when an appropriate skin protectant is used.

Funding: Pharmaceutical Company Support

FR-PO1680

Quality of Life in Patients with Uremic Xerosis Patrick Dupuy,[1] Jacek Szepietowski,[2] Elias V. Balaskas,[3] K.M. Taube.[4] *[1]Division of Research and Development, Orfagen, Toulouse, France; [2]Department of Dermatology, Venereology and Allergology, University of Medicine, Wroclaw, Poland; [3]Department of Nephrology, Ahepa University Hospital, Thessaloniki, Greece; [4]Department of Dermatology, Martin Luther University, Halle, Germany.*

Background: Although uremic xerosis (rough and scaly skin affecting patients with end-stage renal disease, ESRD) is a neglected disease, it is a prominent feature that aggravates uremic pruritus and may have some psychological and social consequences.

Methods: Three hundred and thirty four (334) ESRD patients with moderate-to-severe uremic xerosis were surveyed for quality of life (QoL) assessment, using the generic Short-Form (SF-12) scale and the Dermatology Life Quality Index (DLQI). In parallel, the intensity of xerosis on 4 sites (the two lower legs, chest, forearm without arterio-venous shunt) was assessed, using a 5-point lesional intensity score. Pruritus was auto-assessed by the patients, using a 100-mm visual analogue scale (VAS).

Results: Uremic xerosis patients had a marked deterioration of the Physical Component Summary (PCS) of SF-12 (mean ± SD: 34.92 ± 9.98) and DLQI (5.06 ± 4.73). Younger age ($r = - 0.20$), xerosis intensity ($r = 0.14$), and the presence of pruritus ($p < 0.0001$) and its intensity ($r = 0.50$) were shown to be significant worsening factors of DLQI. Because a weak but significant correlation between the intensity of xerosis and pruritus was also demonstrated ($r = 0.18$, $p = 0.001$), the direct contribution of age, xerosis and pruritus on DLQI was analysed in a multiple linear regression model. Age and pruritus intensity, but not xerosis intensity, were found to be independent contributors to DLQI deterioration ($p < 0.0005$). On the other hand, uremic xerosis without associated pruritus still resulted in DLQI alteration (3.24 ± 3.99).

Conclusions: It was concluded that young age and intensity of uremic pruritus compromise QoL in uremic xerosis patients. Some characteristics of uremic xerosis other than xerosis intensity may also be involved in QoL alteration.

Sexual Dysfunction in Women Requiring Hemodialysis: A Multinational Cross-Sectional Study Suetonia Palmer,[1] Giovanni F.M. Strippoli.[2,3] *[1]University of Otago, Christchurch, New Zealand; [2]Diaverum Medical Scientific Office, Lund, Sweden; [3]Mario Negri Sud Consortium, S Maria Imbaro, CH, Italy.*

Background: Existing data for the prevalence and correlates of sexual dysfunction, including depression, in women on hemodialysis are limited by suboptimal study design.

Methods: Using a multinational cross-sectional study, we studied women receiving hemodialysis between January and June 2008 within a collaborative network in Europe and South America. Sexual dysfunction (SD) was identified using the 19-item Female Sexual Function index questionnaire based on self-reported sexual experiences in the four weeks before questionnaire. Depression was measured using the Center for Epidemiological Studies-Depression (CES-D) questionnaire. Correlates of self-reported SD were identified by multiple regression analyses. We used recursive partitioning and amalgamation analysis to group clinical characteristics associated with SD.

Results: 659 of the 1472 eligible women (45%) completed the questionnaires. Over half (386 [56%]) lived with a partner and 232 (35%) were sexually active. Overall, 555 (84%) of respondents reported SD. Women with a partner were less likely to experience SD (78% versus 92% without a partner). In multivariate analysis, age was a strong correlate of SD; for each 1 year increase in age, sexual dysfunction increased by 8% (adjusted odds ratio [AOR] 1.08 [95% CI, 1.06-1.11]). SD was also independently associated by depressive symptoms, lower educational attainment, menopause, diabetes, and diuretic therapy. Nearly all women who were not wait-listed for a kidney transplant and not living with a partner (249/260 [96%]) reported SD. Over half (55%) of sexually active women reported SD which was associated with age, depressive symptoms, menopause, low serum albumin, and diuretic therapy. Analyses were limited by the response rate and residual confounding.

Conclusions: This descriptive study suggests most women on hemodialysis may experience sexual problems. Additional research on the relevance of SD to the quality of life, well-being, and outcomes in these women is now required.

FR-PO1682

Effect of Hypnosis on Anxiety, Depression, Fatigue and Sleepiness in People Undergoing Hemodialysis Philippe Chauveau,[1] Aurelie Untas,[2] Catherine Dupre,[4] Anne Kolko-Labadens,[3] Nicolas Cazenave.[4] *[1]Aurad-Aquitaine, Bordeaux, France; [2]Universite Paris Descartes, Paris, France; [3]Hopital Foch, Paris, France; [4]CHU de Toulouse, Toulouse, France.*

Background: Hypnosis has shown positive effects in stress related disorders (e.g., cancer, surgery, burns), but has not been studied in chronic renal disease. We investigated the effects of a hypnosis session on anxiety, depression, fatigue and sleepiness in patients undergoing hemodialysis.

Methods: The sample consisted in 29 patients (mean age 62.6 years, SD=16.8, 52% of men). Patients assigned to take part to a hypnosis session during a hemodialysis session. Anxiety, depression, fatigue and sleepiness were measured weekly with validated scales (Hospital Anxiety and Depression Scale, Multidimensional Fatigue Inventory, Epworth Sleepiness Scale). Fatigue was also measured daily using a numeric scale. Study participation lasted fifteen days. Hypnosis session took place on the eighth day.

Results: Depression was significantly associated to anxiety, fatigue and sleepiness. Fatigue was strongly correlated to sleepiness. Anxiety, depression and sleepiness significantly decreased after hypnosis, whereas fatigue remained constant.

Conclusions: This preliminary study shows encouraging results which suggest that hypnosis is an effective intervention to help hemodialysis patients face treatment consequences, such as feelings of negative emotions. Future studies should investigate the effect of a longer intervention getting people to do self-hypnosis.

FR-PO1683

Subjective Sleep Quality in Kidney Disease Patients Sameer Shakir, Gabrielle R. Paoletti, Elizabeth K. Lee, Dahlia Raymond, Brett A. Tomlin, Sarah Ramer, Mark L. Unruh. *University of Pittsburgh School of Medicine, PA.*

Background: Sleep affects one's quality of life. Patients' subjective ratings of their sleep, however, do not correlate well with objective measures. This study examined predictors of subjective sleep quality in patients with CKD and ESRD compared to controls.

Methods: The cross-sectional sample consisted of 75 CKD and 77 ESRD patients as well as 224 controls from the Sleep-Strategies Concentrating on Risk Evaluations study. The outcome measure, the Pittsburgh Sleep Quality Index (PSQI), is a 19-item scale with a total score of 0-21. Lower scores indicate higher sleep quality. Patients underwent home polysomnography (PSG), filled out the Perceived Stress Scale-4 (PSS-4), a measure of life stress, and the Life Orientation Test-Revised (LOT-R), a scale of optimism. Other variables included demographics; anthropometrics; hypertension, diabetes, depression status; and medications.

Results: Mean age was 56.8±11.5 years. Males made up 56.3% and non-African-Americans 62.5% of the sample. The mean PSQI score for CKD patients was 6.5±3.7; for ESRD patients, 8.5±4.6; and for controls, 6.4±3.4 ($p=0.002$). CKD patients, ESRD patients, and controls differed significantly in age, sex, race, PSS-4 score, sleep apnea status, sleep efficiency, sleep latency, and total sleep time. In a multivariate linear regression controlling for age and race, female sex (1.40, 95% CI 0.62, 2.17), ESRD (vs. control) (1.81, 95% CI 0.82, 2.81), and sleep efficiency (-0.03, 95% CI -0.06, -0.005) significantly predicted higher PSQI score. In another multivariate linear regression controlling for the above covariates and adding PSS-4 and LOT-R scores, PSS-4 score became a significant predictor (0.26, 95% CI 0.12, 0.41) in addition to female sex and ESRD (vs. control). Sleep efficiency became non-significant.

Conclusions: ESRD patients experience significantly worse subjective sleep quality, as measured by the PSQI, than controls, but female sex and higher stress level are stronger predictors of worse sleep quality than any objective measure obtained from PSG. A full assessment of sleep quality must therefore include subjective and objective ratings.

FR-PO1684

The Prevalence of Sleep Disturbances (SD) in Pediatric Chronic Kidney Disease (CKD): A Report of the Midwest Pediatric Nephrology Consortium

Ira D. Davis,[1] Laurence A. Greenbaum,[2] Debbie S. Gipson,[3] Lieling Wu,[1] John D. Mahan.[4] *[1]Medical Products, Baxter Healthcare Corporation, McGaw Park, IL; [2]Pediatrics, Emory University and Children's Healthcare of Atlanta, Atlanta, GA; [3]Pediatrics, University of Michigan, Ann Arbor, MI; [4]Pediatrics, Ohio State University, Columbus, OH.*

Background: Although SD are common in adults with CKD, little is known about the prevalence of SD in pediatric CKD.

Methods: Between May 1, 2006 and July 1, 2008, a clinic-based survey of sleep habits and common symptoms (sx) of SD was conducted in 159 school-aged CKD patients (pts) and/or parent-proxy. Three pt study groups of CKD were assessed: 1) not on dialysis, not transplanted (n=68); 2) dialysis (n=30); 3) functioning transplant (n=61). Four sx domains for SD were assessed: 1) Excessive daytime sleepiness (EDS) using pediatric modification of the Epworth Sleepiness Scale; 2) Sleep disordered breathing (SDB) sx using Pediatric Sleep Questionnaire; 3) Restless Legs Syndrome sx using a standard questionnaire; and 4) Insufficient Sleep duration based on normative data for age, gender. Pts and parent-proxy completed the Pediatric Quality of Life Inventory Version 4.0 Generic Core Scales questionnaire (PedsQL) to assess health-related quality of life (HRQOL).

Results: The overall characteristics of these pts were: mean (SD) age=13.8 (3.6) years, 50.9% male, 30.2% non-Caucasian, 50.9% congenital CKD; no significant difference between CKD study groups were noted ($p > 0.05$). Overall, 93 pts (58.5%) had sx of a SD in at least one sleep domain, the most common being EDS (n=73) and SDB (n=37). Multivariate-adjusted logistic regression of associations (age, gender, CKD study group, CKD diagnosis, BMI z-score, PedsQL Total Score, and steroid use) with SD revealed that lower PedsQL Total Scores were associated with a higher likelihood of any SD ($p < 0.001$), SDB ($p< 0.001$), or EDS ($p = 0.003$). The association of a SD and a decrease in HRQOL scores was independent of the CKD pt study group.

Conclusions: SD are common throughout the spectrum of pediatric CKD and are associated with diminished HRQOL scores independent of the CKD pt study group.

Sudden Discontinuance of On-Line HDF Clearly Proved the Clinical Advantage of Itself in Relieving Dialysis Related Symptoms

Ikuto Masakane. *Dialaysis Center, Yabuki Shima Clinic, Yamagata, Japan.*

Background: On 11th march 2011, a terrible disaster smashed the north east part of Japan. Our facility is just next to the smashed area and we experienced 3 days of electric power failure. We had been treated many dialysis patients by on-line HDF; however, just after the disaster we were not able to continue on-line HDF for 18 days because we could not validate the quality of dialysis fluid as safe as enough for on-line HDF. In the current study we reviewed the changes in dialysis related symptoms through the discontinuance of on-line HDF.

Methods: In our facility 94 out of 159 chronic dialysis patients (59%) had been treated by on-line HDF for relieving their itchiness, restless leg syndrome and insomnia and so on. On-line HDF was stopped on 11th March 2011 and restarted on 28th March. The changes in their subjective symptoms were retrospectively monitored 2 or 3 weeks after the disaster and followed up 1 and 2 months later. Ninety one out of 94 patients admitted to be monitored about their symptoms.

Results: Forty-three out of 91 patients (47%) recognized recurrence of their symptoms or new onset dialysis related symptoms. The recurrence of the same symptom for that on-line HDF was introduced was observed in 37% of the patients. The frequent symptoms were itchiness (29%), irritable state (15%), fatigue (15%) and insomnia (7%), and its degree was different in each patient. These symptoms gradually disappeared as at 51% by 2 weeks later the restart of on-line HDF, at 68% by 1 month, and at 99% by 2months.

Conclusions: We have proposed that on-line pre-dilution HDF is effective to relieve the dialysis patients of their dialysis related symptoms such as itchiness, irritability, insomnia and skin pigmentation. (NDT plus 3 (suppl)28-35, 2010) However, this proposal is not based on any prospective controlled studies, and actually it is hard to build randomized control study to prove the benefit of on-line HDF. Our patients don't accept for the enrollment to this kind of study because they don't want to be treated by any other than on-line HDF. The disaster gave us the opportunity to reconsider what is a good dialysis modality and a natural evidence for the clinical advantage of on-line HDF.

FR-PO1686

Trends in the Occurrence and Outcomes of Acute Non-Variceal Upper Gastrointestinal Bleeding in U.S. Patients with End-Stage Renal Disease (1998-2007)

Juyeh Yang,[1,2] Tsung-Chun Lee,[4] Maria E. Montez-Rath,[1] Manisha Desai,[3] Jane Paik,[3] Glenn M. Chertow,[1] Wolfgang C. Winkelmayer.[1] *[1]Divisions of Nephrology, Stanford University School of Medicine, Palo Alto, CA; [2]Division of Nephrology, Far Eastern Memorial Hospital, New Taipei, Taiwan; [3]General Medical Disciplines, Stanford University School of Medicine, Palo Alto, CA; [4]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan.*

Background: Renal failure is a risk factor for acute nonvariceal upper gastrointestinal bleeding (ANVUGIB) and associated with poor outcomes. We examed the burden of ANVUGIB and its outcomes on dialysis patients.

Methods: Using the United States Renal Data System, we quantified the occurrence rate and 30-day mortality of ANVUGIB (2 criteria) in dialysis patients. We used Poisson and logistic regression to estimate occurrence rates of ANVUGIB and 30-day mortality from 1998-2007, respectively.

Results: 958533 patients contributed 2403545 patient-years for study. The occurrence rates for ANVUGIB were 56 and 318 episodes per 1000 person-years for stringent and lenient criterion respectively. Crude occurrence rates remained flat (stringent) or increased (lenient) over the decade; only adjustment for socio-demographics and comorbidities resulted in significant declining trends. Patients had higher hematocrits prior to and were more likely to receive blood transfusions during their ANVUGIB episodes in later years. Overall 30-day mortality was 11.7% and declined over time.

Annual changes in the occurrence of and 30-day mortality rate after ANVUGIB

		change of an increment of one year (%)	95% Confidence interval (%)	
Stringent algorithm				
Occurrence rate ratio	Unadjusted	-0.2	-0.4	0.04
	Adjusted	-2.7	-2.9	-2.5
Mortality odds ratio	Uadjusted	-2.3	-2.7	-1.8
	Adjusted	-3.3	-3.8	-2.8
Lenient algorithm				
Occurrence rate ratio	Unadjusted	3.2	3.1	3.3
	Adjusted	-1.5	-1.6	-1.4
Mortality odds ratio	Unadjusted	-2.8	-3.0	-2.5
	Adjusted	-3.6	-3.8	-3.4

Conclusions: Despite declining trends worldwide, crude rates of ANVUGIB among dialysis patients did not decrease over the decade. Though 30-day mortality from ANVUGIB declined, ANVUGIB remains a significant burden in dialysis patients.

FR-PO1687

Exercise Interventions in Chronic Kidney Disease: A Systemic Review and Meta-Analysis

Sankar D. Navaneethan,[1] George Thomas,[1] Edgard I. Wehbe,[1] John P. Kirwan.[2] *[1]Nephrology & Hypertension, Cleveland Clinic, Cleveland, OH; [2]Pathobiology, Lerner College of Medicine of Cleveland Clinic, Cleveland, OH.*

Background: Exercise interventions improve physical performance and cardiovascular risk factors in the general population. Their beneficial effects are unclear in various stages of chronic kidney disease (CKD). We systematically reviewed the effects of exercise interventions in CKD.

Methods: We searched MEDLINE (1966- September 2010) and SCOPUS (September 2010) for relevant randomized trials comparing exercise interventions (aerobic, resistance or combination of aerobic and resistance regimen) in non-dialysis dependent CKD, dialysis and renal transplant recipients. Two reviewers independently extracted data on relevant outcomes from included studies. Results were summarized as mean difference (MD) with 95% confidence intervals (CI) using a random effects model.

Results: Thirty-three trials (3 non-dialysis dependent CKD, 25 dialysis and 5 renal transplant studies) were included; most were small and of short duration. When compared with control group, exercise interventions significantly improved peak oxygen consumption (11 trials, 467 patients; MD 4.79 ml/kg/min; 95% CI 3.31 to 6.26) and lowered systolic blood pressure (MD -4.76 mmHg; 95% CI -8.89 to -0.62), and diastolic blood pressure (MD -3.43 mmHg; 95% CI -5.76 to -1.10) at the end of treatment period among dialysis patients. There were no significant differences in the 6 minute walk time between exercise and control groups in the dialysis population. No significant heterogeneity was noted in these analyses. Few studies reported better health related quality of life with exercise using different scales. Studies that included renal transplant recipients and non-dialysis dependent CKD patients did not report outcomes consistently and was not pooled.

Conclusions: Short-term exercise interventions improve physical performance and blood pressure and with possible beneficial effects on health-related quality of life in dialysis patients. Data among non-dialysis dependent CKD and renal transplant recipients are sparse. Larger, long-term and better quality studies exploring various exercise interventions are warranted.

FR-PO1688

Open Dissection Versus Laparoscopic Peritoneal Dialysis Catheter insertion: A Randomized Prospective Comparison on Outcome and Economical Evaluation

Zi Li, Ping Fu. *Department of Medicine-Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

Background: Peritoneal dialysis (PD) catheter malfunction owing to displacement is another important complication lead to technique failure besides peritonitis. Previous study indicated the success of PD depended more on placement technique than on catheter design. Currently available methods for catheter placement are principally including open dissection and laparoscopic insertion. The best method is still controversial while the laparoscopy is much expensive. In this study, we compared the outcome and economical expense between the two methods.

Methods: We conducted a prospective randomized study in which patients underwent PD catheter placement by either the open dissection or the laparoscopic technique . Open dissection was performed under local anesthesia and laparoscopic insertion was performed by one general surgeon under general anesthesia. Tenckhoff direct PD catheters were placed

in all patients and continuous ambulatory peritoneal dialysis was started at the third day of the procedure.

Results: Seventy-four patients were enrolled from January 2011 to April 2011. The mean hospital stay time was 13.2 days and 8.66 days in open dissection group and laparoscopic group respectively ($P < 0.05$). The mean operative cost was CNY 400.00 and CNY 5000.00 ($P < 0.001$) and the mean hospital expense was CNY 15356.25 and CNY 15768.70 in open dissection group and laparoscopic group respectively ($P > 0.05$). Fluid leakage was observed in 1 patient in open dissection group, but in no patients in laparoscopic group ($P > 0.05$). Bleeding occurred in 2 patients in open dissection group and in 1 patient in laparoscopic group ($P > 0.05$). Catheter displacement occurred in 5 patients in open dissection group and in 3 patients in laparoscopic group ($P > 0.05$). Neither group had exit site infection, peritonitis or death during the follow-up.

Conclusions: Compared to open dissection, although the operative cost is higher, laparoscopic placement does not increase the total hospital expense maybe due to the shortened hospital stay. Current study did not find which method could lower the perioperative complications and catheter displacement.

FR-PO1689

Sarpogrelate Hydrochloride Improves Skin Perfusion Pressure of Lower-Extremity in the Hemodialysis Patients with Peripheral Arterial Disease

Sumi Hidaka, Kunihiro Ishioka, Machiko Oka, Hidekazu Moriya, Takayasu Ohtake, Shuzo Kobayashi. *Department of Nephrology, Immunology and Vascular Medicine, Shonan Kamakura General Hospital, Kamakura, Kanagawa, Japan.*

Background: Peripheral arterial disease (PAD) is more prevalent in patients on hemodialysis (HD), however, little is known about the effectiveness of drugs in HD patients. This study aimed to clarify the effects of sarpogrelate hydrochloride, a selective 5-HT2A antagonist,on HD patients with PAD comparing with cilostazol.

Methods: We conducted prospective, randomized, open-label, multicenter trial for 6 months on HD patients with PAD. PAD was diagnosed by the clinical symptoms (Fontaine classification: I or II) and positive sign of the following test; 1) ultrasonography, multidetector-row CT or angiography for arteries of lower legs, 2) ankle-brachial pressure index of either foot below 1.0 or skin perfusion pressure (SPP) below 50mmHg. All eligible patients (n=35) were divided into age-, and HD duration-matched two groups, with medication given sarpogrelate of 300mg/day (n=17) or cilostazol of 200mg/day (n=18) followed by 6 months. We measured SPP before and 6 months after with serum levels of hsCRP, MDA-LDL, plasma levels of fibrinogen and pentosidine.

Results: There was no significant difference in the patient's characteristics. At 6 months, SPP was increased in both groups (sarpogrelate: 43±17 to 55±15 mmHg, cilostazol: 49±21 to 66±29 mmHg, $p<0.05$) and there was no difference in both groups before and after 6 months. The levels of hsCRP and fibrinogen showed no differences between both groups before and after 6 months. Plasma pentosidine levels were decreased in both groups (0.65±0.24 to 0.48±0.12 μg/ml, 0.58±0.22 to 0.47±0.17 μg/ml, respectively: $p<0.05$) and there was no difference in both groups. Serum MDA-LDL level was not increased in sarpogrelate group, while significantly increased from 60.5±25.5 to 87.0±56.5 U/l in cilostazol group ($p<0.05$) . Heart rate was significantly increased in cilostazol group from 77±13 to 83±16 bpm ($p<0.05$), but not in sarpogrelate group.

Conclusions: Sarpogrelate clearly improved SPP without increases in heart rate and serum MDA-LDL level in HD patients with PAD.

FR-PO1690

Predictors of Intradialytic Blood Pressure Drops in Hospitalized Hemodialysis Patients

Theresa Gross,[1] Abdul Hamid Ismail,[3] Nadine Danielle Trué,[1] Christina Fitzner,[2] Benjamin Eilebrecht,[3] Jurgen Floege,[1] Steffen Leonhardt,[3] Frank Eitner.[1] *[1]Nephrology, RWTH Aachen, Aachen, Germany; [2]Medical Statistics, RWTH Aachen, Aachen, Germany; [3]Medical Information Technology, RWTH Aachen, Aachen, Germany.*

Background: Estimation of the hydration status of hospitalized and multimorbid hemodialysis (HD) patients by clinical examination only is often imprecise and can result in severe drops in blood pressure (BP). We analyzed whether a combination of bioimpedance spectroscopy (BIS), blood gas analysis (BGA), electrocardiogram (ECG) and clinical evaluation could predict BP instability during the course of HD treatments.

Methods: Prospective, non-interventional study in 72 hospitalized HD patients (38% female, age 65±15 yrs, BMI 25.5 ± 5.2; 38% diabetics), examined by BIS (hand-to-foot), ECG, BGA, BP and clinical evaluation every 30 min during a 4 hrs HD; 3 groups were separated: A: n=30, stable BP, no hypotensive symptoms (symptoms defined as dizziness, vomiting, nausea, numbness or an intervention like: Trendelenburg maneuver, stop ultrafiltration, fluid infusion); B: n= 25, drop in BP > 25 mmHg, no symptoms; C: n=17, drop in BP > 25mmHg plus symptoms.

Results: Based on the clinical evaluation 40% of group C patients were considered to be hypervolemic and 50% to be euvolemic prior to the dialysis session. Clinical evaluation did not correlate with BIS measurements. The three groups differed significantly in the measured parameters:

groups	A	B	C
Extracellular resistance (Re[Ω])	534±79 [1]	535±101 [2]	625±95
Extracellular water (ECW [ml])	19.4±2.6 [1]	19.5±2.8 [2]	6.5±3.3
Intracellular water (ICW [ml])	25.4± 4.5 [1]	26.6±4.8 [2]	21.7±6.7
Potassium [mmol/l]	3.93±0.04 [1]	4.07±0.05	4.16± 0.06
Hematocrit [%]	31±0.5 [1]	33±0.5	34±0.7
pH	7.43±0.05 [1]	7.42±0.05	7.40±0.07

[1] $p<0.05$ between group A and C; [2] $p<0.05$ between group B and C

A measured ECW <18ml early in the course of the HD session identified patients with subsequent symptomatic BP drops (and so belonging to group C) with a sensitivity of 67% and a specificity of 66%.

Conclusions: HD patients who develop symptomatic intradialytic BP drops reveal different BIS and BGA profiles prior to the BP drops. BIS and BGA monitoring might help preventing BP drops in hospitalized HD patients.

FR-PO1691

Comparison of the Efficacy of Senna Glycoside Versus Lactulose in the Treatment of Chronic Constipation in Maintenance Hemodialysis Patients

Naetirat Kittiyanpanya,[1] Bussabong Noola,[2] Bancha Satirapoj,[1] Wanich Piyanirun,[3] Ouppatham Supasyndh.[1] *[1]Nephrology, Phramongkutklao Hospital; [2]Radiology, Phramongkutklao Hospital; [3]Gastroenterology, Phramongkutklao Hospital, Bangkok, Thailand.*

Background: Chronic constipation is one of the frequent gastrointestinal symptoms in patients with maintenance hemodialysis (MHD). There are several inevitable factors contributed to the symptom and often the patients are more likely to use laxatives. We aimed to compare the effecacy of senna glycoside and lactulose in treating chronic constipation in MHD patients and to demonstrate the colonic transit time among those.

Methods: The randomized, double blind, cross-over study in MHD patients at Phramongkutklao Hospital was conducted during July to December 2010. The MHD patients with chronic constipation matched to ROME III criteria were eligible and randomized to 2 arms; the senna glycoside (S) and the lactulose (L). The colonic transit time was performed by using radio-opaque marker before and after the study periods. The stool daily charts defined by ROME III criteria were evaluated as the tool during the study.

Results: Twenty-nine of patients per protocol were studied. Sixteen were male (55%) with average age 58.17±12.26 years. Median colonic transit time was 38.4(16.8-52.8) hours. Only 3 patients were reported having prolonged colonic transit time over 72 hours. There was no difference between the cathartic effect of senna glycoside and lactulose (58.6% vs. 75.9%, p=0.403). The S-group had higher abdominal cramp than the L-group (65.5% vs. 13.8%, $p<0.001$), while the L- group had higher abdominal bloating than the S- group (93.1% vs. 6.9%, $p<0.001$). The average doses related with adverse effect was 4.00±1.76 tablets for senna glycoside and 22.8±12 mL for lactulose. No serious drug adverse events were reported.

Conclusions: The present study shows that both laxative agents are effective in treatment of constipation in MHD patient. However, each of them may have different gastrointestinal adverse effects.

FR-PO1692

Dialyzability and Pharmacokinetics of Oral Levofloxacin in Infected Hemodialysis Patients

Shuichi Tsuruoka,[1] Noritsugu Yokota,[2] Kunihiro Yamagata.[1] *[1]Nephrology, University of Tsukuba, Ibaraki, Japan; [2]Hemodialysis Unit, Moka Hospital, Moka, Tochigi, Japan.*

Background: Pharmacokinetic parameters of the drugs are altered by infection, because increase of systemic cytokines during the infection changes metabolism and excretion of the drug in the body. This study was performed to evaluate the dialyzability and pharmacokinetics of oral levofloxacin simultaneously in infected hemodialysis patients, which has not been reported previously.

Methods: Seven infected maintenance hemodialysis patients due to pyelonephritis lacking residual renal function were enrolled. Levofloxacin (500 mg after hemodialysis session for the first day and 250 mg for the 4 hours before scheduled hemodialysis session on the 3rd day) was orally administered. On the 3rd day, blood was taken from arterial and venous sides before and 2 and 4 hours after session initiation. Another sampling was performed on the 5th day of the study. Drug concentration, hematocrit, and urea nitrogen concentration were measured. Dialyzability and pharmacokinetic parameters of levofloxacin were evaluated by arterio-venous difference method.

Results: All patients exhibited improved symptoms without major problems. Drug concentrations in all arterial samples were above MIC of targeted bacteria. Dialyzer clearance and elimination fraction were 57.8±3.9 ml/min/m2 and 64.1±1.6%, respectively. Apparent half-lives during and after dialysis session were 4.6±0.5 and 27.1±3.8 hours, respectively. Dialyzer clearance was positively correlated with urea reduction ratio and negatively correlated with serum albumin concentration. About 1/3 of the drug was removed by dialysis when administered 4 hours before the session.

Conclusions: Oral dosing of this drug at 500 mg on the 1st day, followed by 250 mg on the 3rd day, in infected maintenance hemodialysis patients provides safe drug concentration compatible with that of healthy subjects orally receiving 500 mg daily. Because a significant amount of the drug was removed, administration might be undertaken after the dialysis session.

FR-PO1693

An Efficacy Study of Combined Hepatitis A and B Vaccine(TWINRIX®) in Non-Responders to Double Dose Hepatitis B Vaccination in Dialysis Patients

Narothama Reddy Aeddula,[1] Robert Mark Black,[1,2,4] George M. Abraham,[1,3,4] Elizabeth Ann Normand.[2] *[1]Dept of Medicine, St Vincent Hospital, Worcester, MA; [2]Division of Renal Medicine, St Vincent Hospital, Worcester, MA; [3]Division of Infectious Diseases and Geographic Medicine, St Vincent Hospital, Worcester, MA; [4]Dept of Medicine, Univ. of Massachusetts Medical School, Worcester, MA.*

Background: Dialysis is an established route of transmission for Hepatitis B virus(HBV).The Centers for Disease Control and Prevention recommends routine immunization in dialysis patients against HBV.An average of 64% of dialysis patients develops seroprotective antibodies with immunization when compared to 90-95% of healthy, immunocompetent adults.Recent reports indicate that combined hepatitis B and hepatitis A vaccine(Twinrix®,GSK,UK) may improve immunogenicity in healthy non-responders to hepatitis B vaccine.The purpose of our study is to determine whether Twinrix® results in increased hepatitis B surface antibody titers(anti-HBs) in dialysis patients who are non-responders to a primary course of double dose monovalent hepatitis-B vaccine.

Methods: This pilot study was designed as a randomized controlled trial.Twenty three subjects (15 male) who were non-responders to an initial double dose monovalent hepatitis-B vaccine were recruited.Twelve patients were randomized to receive a double dose of Twinrix®at 0,1 and 6 months(treatment arm) and 11 patients received repeat double dose monovalent hepatitis B vaccine at 0,1 and 6 months(control arm).The anti-HBs titers were determined before vaccination and 4 weeks after each dose.

Results: Of the 18 patients who completed the study,7 of 9 (77.8%) in treatment arm and 5 of 9 (55.5%) in control arm had antibody titers >10 mIU/ml (Relative Risk[RR]=1.4 (95%CI 0.71-2.77).There was no difference in adverse events in either group.

Conclusions: Vaccination of non-responders to monovalent hepatitis B vaccine with combined hepatitis B and hepatitis A vaccine produced improved hepatitis B seroconversion rates in dialysis patients compared to monovalent hepatitis B vaccine.This is the first evaluation in a US population and merits larger studies to better evaluate this potential benefit.

FR-PO1694

Proteinase-Activated Receptor-2, a Novel Mechanism of Uremic Pruritus: A Pilot Study

Sung Jin Moon,[1] Sang Choel Lee,[1] Soo Young Yoon,[1] Sung-Kyu Ha.[2] *[1]Department of Internal Medicine, Myongji Hospital, Kwandong University College of Medicine, Goyang, Korea; [2]Department of Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea.*

Background: Pruritus is a common problem in ESRD patients. The underlying mechanisms are not yet fully understood. We examined the relationship of the proteolytic activity, expression of PAR2, and pruritus in the skin of ESRD patients.

Methods: The Skin of ESRD patients with pruritus (n=12) and without pruritus (n=4) were compared about activity of serine protease and expression of PAR2. The skin biopsy was conducted on the abdomen. In addition, the effect of soybean extracts treatment for 4 weeks, containing protease inhibitor was examined in ESRD patients with pruritus (n=6). The status of pruritus was examined by pruritus score and VAS scale.

Results: Proteolytic activity and PAR2 expression was increased in ESRD patients with pruritus compared with those without pruritus. Soybean extracts treatment decreased the activity of proteolytic activity and expression of PAR2, and the severity of pruritus.

Conclusions: We suggested that the soybean extracts containing protease inhibitor is a new candidate for the treatment of uremic pruritus and the new pathogenesis based on the relationship of PAR2 and uremic pruritus.

FR-PO1695

Clinicopathological Study on 11 Patients with End-Stage Renal Disease Showing Intestinal Perforation Due to Cation-Exchange Resin Against Hyperkalemia

Akira Kurosu,[1] Keiko Kanemoto,[2] Kensuke Joh.[3] *[1]Department of Legal Medicine, Dokkyo Medical University, Japan; [2]Department of Nephrology, Kanto Rosai Hospital, Japan; [3]Division of Pathology, Sendai Shakaihoken Hospital, Japan.*

Background: The administration of cation-exchange resin (CER) of potassium absorbing agent such as sodium polystyrene sulfonate (Kayexalate) or calcium polystyrene sulfonate (Kalimate) is used extensively for treatment against hyperkalemia, especially in the patients with end-stage renal disease (ESRD). The purpose of this study to survey a rare side effect of CER.

Methods: The 11 patients with ESRD, who experienced intestinal perforation after oral administration of CER, were selected . Evidence of CER administration was documented by identifying basophilic polygonal crystals, which are characteristic of both Kayexalate and Kalimate.

Results: Median age of the patients (male 7, female 4) was 72.5 years old (43-90 years). The site of perforation was sigmoid colon in 9 patients and rectum in 2 patients. Underlining diseases consisted of CGN in 8 patients and diabetic glomerulosclerosis in 3 patients. Regardless of underlining diseases, all patients showed the event of intestinal perforation during CKD stage 4 to 5D. The 8 patients and 3 patients were orally administrated with Kayexalate (without sorbitol) and with Kalimate, respectively. Total dose of both CER was 30g/day. After emergent events, all patients were treated by Hartmann's operation. Resected intestine was examined. Microscopically, all patients revealed scattered basophilic and polygonal crystals at necrotic perforating site. Diverticulitis was confirmed in all patients. Besides necrotic lesion, remaining intact mucosa penetrated between discontinuous muscularis propria suggesting underlying diverticulum.

Conclusions: Patients with ESRD have a common physiological background to generate a diverticulum. Even though the patients were treated only with CER without sorbitol, which can be one of the causes of colonic necrosis, an intestinal perforation occurred on the basis of diverticulum. The present study proposes that the clinicians can decrease the risk of intestinal perforation by avoiding administration of CER in the ESRD patients with diverticulum.

The Incidence of Intestinal Perforation in U.S. Dialysis Patients Remained Unchanged after Approval and Subsequent Widespread Adoption of Sevelamer Hydrochloride

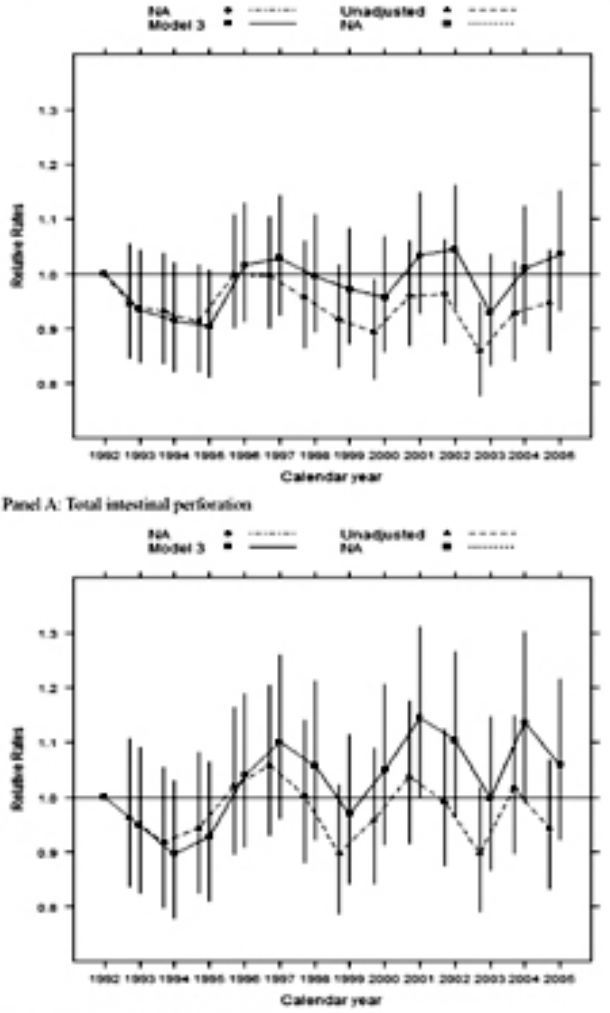
Juyeh Yang,[#1#2] Tsung-Chun Lee,[#3] Maria E. Montez-Rath,[#2] Manisha Desai,[#4] Wolfgang C. Winkelmayer.[#2] *[1]Division of Nephrology, Far Eastern Memorial Hospital, New Taipei, Taiwan; [2]Division of Nephrology, Stanford University School of Medicine, Palo Alto, CA; [3]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; [4]General Medical Disciplines, Stanford University School of Medicine, Palo Alto, CA.*

Background: Concerns have been raised that sevelamer hydrochloride may increase the risk of intestinal perforation. We examined temporal trends of the incidenc of intestinal perforation among U.S. dialysis patients between 1992 and 2005.

Methods: In the United States Renal Data System database, we studied dialysis patients between 1992 and 2005. We used ICD-9 diagnosis code 569.83 to ascertain events of intestinal perforation. We defined as spontaneous perforations those events that had no identifiable leading disease or no potential iatrogenic procedures. We used Poisson regression to model the annual number of intestinal perforations, and interrupted time-series analysis was used to test for any changes of incidence rates before versus after 1999.

Results: Overall, 1068594 patients contributed 2.85 Million patient-years. We observed 12518 events of intestinal perforation of which 7928 were considered spontaneous perforations. Annual incidence rates before and after adjustment for demographic and comorbid factors over time are shown in the figure.

Figure 1 Relative incidence rates of intestinal perforation (1992-2005)



Legend: Rate ratios and corresponding 95% confidence intervals
Model 1: adjusted for age, gender and race
Model 2: additionally adjusted for Medicaid coverage, dialysis vintage and modality
Model 3: additionally adjusted for history of past kidney transplantation and 11 comorbidities.

Formal tests for any changes in the level or slope of incidence comparing time periods before and after 1999 indicated no evidence for any changes. (p-values for changes in level/trend: 0.35/0.63 and 0.39/0.22, for total and spontaneous episodes).

Conclusions: In this population-based study, we did not find any significant changes in the incidence of intestinal perforation before versus after approval of Sevelamer in 1998.

Venous Needle Dislodgement Prevention in Hospital Based Hemodialysis

Martin E. Lascano, Michael Bradley Andersen. *Nephrology & Hypertension, Cleveland Clinic, Cleveland, OH.*

Background: Venous needle dislodgement (VND) is a serious complication of hemodialysis (HD) and, if undetected, can cause serious morbimortality. VND is not a reportable statistic so precise incidence is unavailable. Prior reports of ~414 episodes/year in USA are likely an underestimate.

Our hospital HD unit cares for high-acuity patients, frequently with altered mental status, with a higher than average risk for VND.

In February 2010, we introduced a quality improvement project aiming to reduce VND rates, with a goal of zero undetected VND episodes.

Internal data showed 3 undetected VND episodes during the prior 3 months (2 class IV hemorrhages), incidence of 1 VND per 538 HD treatments.

Methods: Components of the project were: 1) standardizing cleaning and disinfection procedure of the arteriovenous (AV) access and surrounding skin; 2) implementing a unique anchoring needle taping (silk or plastic) technique, and a standard protocol for anchoring the blood lines to the patient; 3) setting the lower limit of the venous pressure alarm as close as possible to the current venous pressure; 4) ensuring that AV access and needles were visible at all times; 5) using a fiber optic blood detection device for all patients with AV access. The device has a single-use sensor patch placed over the venous needle site where it will absorb blood if VND occurs and emitting an audible alarm; 6) modifying staffing levels with the addition of a quality control nurse, and ensuring adequate staff-to-patient ratios to allow routine AV access monitoring during HD.

Results: All staff were trained in a 1-month time frame and required to demonstrate proficiency in the above. These included physicians, nurses, HD technicians, risk management personnel, development of educational materials and technical support.

Between 2/15 and 12/31/2010 there have been zero undetected VND episodes and the overall occurrence dropped from 13 in 2009 to 4 in 2010 (incidence 1 VND per 1750 treatments).

Conclusions: In conclusion, prevention of VND in high-risk hospitalized HD patients is achievable with effective education, protocol standardization and ongoing monitoring. Minimization of undetected VND episodes can be aided by blood loss detection devices use.

FR-PO1698

Lymphangiogenesis Develops during Peritoneal Fibrosis in Peritoneal Dialysis Patients and Rat Peritonitis Model

Hiroshi Kinashi,[1] Yasuhiko Ito,[1] Masashi Mizuno,[1] Yasuhiro Suzuki,[1] Fumiko Nagura,[1] Waichi Sato,[1] Naotake Tsuboi,[1] Shoichi Maruyama,[1] Enyu Imai,[1] Yoshifumi Takei,[2] Seiichi Matsuo.[1] *[1]Nephrology and Renal Replacement Therapy, Nagoya University, Nagoya, Japan; [2]Biochemistry, Nagoya University, Nagoya, Japan.*

Background: Peritoneal fibrosis/sclerosis (PF) causes ultrafiltration failure (UFF) and is an important complication in long-term peritoneal dialysis (PD). We studied the roles of lymphangiogenesis and vascular endothelial growth factor-C (VEGF-C), which is a potentially important mediator of lymphangiogenesis, in the relationship between PF and UFF.

Methods: VEGF-C contents in human dialysate effluent (n=124) and VEGF-C tissue expression (n=69) were investigated by ELISA, real-time PCR and immunohistochemistry. VEGF-C production with TGF-β1 in Met-5A mesothelial cells and human mesothelial cells (HPMC) from the spent patient peritoneal dialysate (n=28) were studied. Expression of lymphatic vessels was examined by immunohistochemistry. We developed a rat model of PF induced by intraperitoneal injection of chlorhexidine gluconate (CG) every other day. Rats were treated with TGF-β Type I receptor inhibitor (TGFβRI). Lymphatic vessels and VEGF-C were evaluated by immunohistochemistry and real-time PCR.

Results: The dialysate-to-plasma ratio for creatinine (D/P Cr) was positively correlated with dialysate VEGF-C concentration. VEGF-C mRNA expression was 4.3-fold higher in peritoneal membranes with UFF than in pre-PD renal failure peritoneum. Lymphatic vessels and VEGF-C, which was detected in the mesothelial cells and some macrophages, were higher in the advanced fibrotic peritoneum. VEGF-C expression was upregulated by TGF-β1 in cultured Met-5A cells, which was specifically suppressed by TGFβRI. In cultured HPMC, TGF-β1 upregulated VEGF-C mRNA expression at 12 hours, and was correlated with D/P Cr ($R=0.64$, $p<0.001$). In the rat CG model, lymphatic vessels and VEGF-C expression were high, and significantly suppressed by TGFβRI.

Conclusions: Our results suggest that high peritoneal transport is associated with lymphangiogenesis and fibrosis via the TGF-β-VEGF-C pathway.

FR-PO1699

Effects of Icodextrin on Inter-Cellular Adhesion Molecule-1 Expression Via Protein Kinase C in Human Endothelial Cells

Masahito Tamura,[1] Narutoshi Kabashima,[1] Ryota Serino,[2] Tetsu Miyamoto,[2] Kaori Kanegae,[1] Yumi Furuno,[2] Junichi Nakamata,[2] Nana Ishimatsu,[2] Akihiro Kuma,[2] Yutaka Otsuji.[2] *[1]Kidney Center, University of Occupational and Environmental Health, Kitakyushu, Fukuoka, Japan; [2]Department of Cardiology and Nephrology, University of Occupational and Environmental Health, Kitakyushu, Fukuoka, Japan.*

Background: Intracellular adhesion molecule (ICAM)-1, which is one of the adhesion molecules, plays an important role in inflammatory processes of peritoneal damages in patients on peritoneal dialysis (PD) by mediating leukocyte-endothelial cell adhesion, leukocyte migration, and T cell-antigen-presenting cell interactions. We compared the effects of glucose and icodextrin on ICAM-1 expression in human endothelial cells.

Methods: We used icodextrin powder-dissolved culture medium to exclude the effects of ingredients of the PD fluid. Quiescent cultured human umbilical vein endothelial cells (HUVECs) were exposed to either glucose or icodextrin, and the expression levels of ICAM-1 were analyzed by flow cytometry using FACScan. Phosphorylation of protein kinase C (PKC) was analyzed by western blotting using antibodies against phosphorylated forms of PKC.

Results: High glucose levels induced ICAM-1 expression on cell surface of HUVEC in time- and concentration-dependent manners, while icodextrin did not influence the expression levels of ICAM-1. Glucose increased phosphorylation levels of PKC, and calphostin C, which is a specific inhibitor of PKC, completely suppressed glucose-induced PKC phosphorylation and ICAM-1 expression. Icodextrin had no effects on phosphorylation levels of PKC.

Conclusions: Our results indicate that glucose induces ICAM-1 by activating PKC, while icodextrin has no effects on PKC activation and ICAM-1 expression; hence, icodextrin-containing PDF has superior biocompatibility and does not influence leukocyte-endothelial cell adhesion in the peritoneum of patients on PD.

FR-PO1700

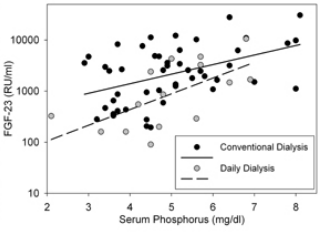
Effects of Short Daily Versus Conventional Hemodialysis on Serum FGF-23 Levels Joshua Zaritsky,[1] Anjay Rastogi,[2] George E. Fischmann,[2] Kenneth S. Kleinman,[2] Georgina Chow,[1] Barbara Gales,[1] Isidro B. Salusky,[1] Katherine Wesseling-Perry.[1] *[1]Department of Pediatrics, UCLA, Los Angeles, CA; [2]Department of Medicine, UCLA, Los Angeles, CA.*

Background: Increased FGF-23 levels have been associated with cardiac abnormalities, vascular calcifications and mortality in hemodialysis (HD) patients. However, it remains unknown whether the frequency and type of HD influence FGF-23 levels.

Methods: We therefore compared FGF-23 levels as well as other biochemical variables between 15 patients (pts) undergoing short daily home HD (DHD) using the NxStage System® and 48 pts undergoing conventional in-center HD (CHD) (table). FGF-23 levels were measured using the 2nd generation Immutopics® C-terminal assay.

Results: DHD pts were younger but there were no differences in the duration of end stage renal disease (ESRD). A greater number of DHD patients received vitamin D sterol therapy than CHD patients while there was no difference in calcimimetic therapy between groups. Overall serum calcium, phosphorus and intact parathyroid hormone (iPTH) levels were similar and phosphorus levels correlated with FGF-23 in both groups as expected; r=0.67 (p<0.005) and r=0.42 (p<0.003) in DHD and CHD respectively (figure). However, FGF-23 levels were lower in the DHD group despite greater use of vitamin D sterols.

	Daily Dialysis Mean±SD or Median (25-75%)	Conventional Dialysis Mean±SD or Median (25-75%)	p
Age (yrs)	45 ± 18	62 ± 19	<0.05
ESRD duration (yrs)	1.8 (1-18)	2.5 (1-5)	NS
Male/Female (N)	11/4	30/18	NS
Vitamin D use (%)	47 (25-70)	10 (5-20)	<0.05
Calcimimetic use (%)	33 (15-59)	40 (29-52)	NS
Hgb (mg/dl)	12 ± 1	12.1± 1.5	NS
Calcium (mg/dl)	8.8 ± 0.6	8.7 ± 0.7	NS
Phosphorus (mg/dl)	4.9 ± 1.3	5 ± 1.4	NS
iPTH (pg/ml)	198 (110-376)	237 (130-320)	NS
FGF-23 (RU/ml)	860 (222-3037)	2520 (909-5556)	<0.03



Conclusions: These findings suggest that FGF-23 levels may be a more sensitive biomarker of cumulative phosphate burden than single phosphate determinations. Future trials are needed to assess whether targeted reduction of FGF-23 by DHD will result in improved cardiovascular outcomes.

FR-PO1701

Effects of Toll-Like Receptor 2 on the Inflammatory Response and Cytokine Production from Intraperitoneal Polymer Catheters Michael F. Flessner,[1] Elise Peery Gomez-Sanchez,[2] Xiaorong Li.[2] *[1]KUH, NIDDK, Bethesda, MD; [2]Medicine, GV Montgomery VA Medical Center, Jackson, MS.*

Background: To test the hypothesis that inflammation from a sterile intraperitoneal (ip) foreign body is mediated by Toll-Like Receptor 2 (TLR2), we compared the responses of normal C57Bl mice (C, n=12) and TLR2-Knock-out mice (TKO, n=20) to polyethylene catheters.

Methods: Five 5Fr catheter rings were placed ip in each treated animal, while sham animals underwent a laparotomy only. After 1 or 2 weeks, the rings were aseptically recovered, and cells adhering to the catheters were separated using ultrasound and stained for immunochemical cell markers (ICC). Cells, catheter, and a swab from the abdomen were cultured for 96 hours to insure sterility. Abdominal wall tissues were collected after sacrifice and processed for CD31 (angiogenesis marker), Trichrome (peritoneal thickness), and immunohistochemistry for cytokines (IHC, 1=no stain to 4=heavy stain).

Results: While week number was not a significant factor, marked differences were noted between animals with catheters and those without for: peritoneal thickness (μm±SE): 74.4±3.5 vs 16.1±4.8; angiogenesis (vessels/mm±SE): 41.5±3.6 vs 6.5±5.0; IHC for: αSMA: 3.1±.1 vs 1.4±.2 and TGFβ: 2.7±.1 vs 1.3±.1 (p<10-5, ANOVA). Adherent cells showed ICC staining for macrophages, mesothelial cells, myofibroblasts and lymphocytes. Staining for macrophages increased from 1 to 2 weeks, but all other cells maintained the same degree of ICC stain. Comparison of TKO animals to the C demonstrated that deletion of TLR2 decreased inflammatory angiogenesis (vessels/mm±SE, p<.01): TKO, 31.7±3.1 vs C, 61.3±4.4, but increased peritoneal staining for αSmooth Muscle Actin (p<.05): 3.4±.1 vs 2.6±.2. No significant differences were noted in fibrotic thickness or in Transforming Growth Factor β staining.

Conclusions: From these observations, we conclude that deletion of TLR2 decreases angiogenesis in the inflammatory response to biomaterials. The fibrotic response appears to be more complex and likely involves other pathways.

FR-PO1702

Fibrinogen Enhances Inflammatory Cell Adherence to Intraperitoneal Polymer Catheters and Decreases Cytokine Production Michael F. Flessner,[1] Xiaorong Li,[2] Elise Peery Gomez-Sanchez.[2] *[1]KUH, NIDDK, NIH, Bethesda, MD; [2]Medicine, GV Montgomery VA Hospital, Jackson, MS.*

Background: Binding of fibrinogen has been shown to be a potential step of inflammatory cell adherence to foreign materials in the peritoneal cavity (Tang, 1993).

Methods: To test the hypothesis that pretreatment with fibrinogen alters cell adherence and cytokine appearance after peritoneal implantation, we incubated sterile 5Fr polyethylene catheter rings in solutions of saline (S), saline + 1.5 mg/ml fibrinogen (F), or saline + 5 mg/ml albumin (A) for 4 hours and placed 5 rings each into the peritoneal cavity of 18 C57Bl mice. After 1 week, the rings were aseptically recovered, and cells adhering to the catheters were separated using ultrasound and stained for immunochemical cell markers (ICC). Cells, catheter, and a swab from the abdomen were cultured for 96 hours to insure sterility. Abdominal wall tissues were collected after sacrifice and processed for CD31 (angiogenesis marker), Trichrome (peritoneal thickness), and immunochemistry for cytokines (IHC, 1=no stain to 4=heavy stain).

Results: Cell densities on the catheter material (10^3#cells/cm^2, mean±SE) were: (A), 138.2±21.0; (S), 177.2±23.0; (F), 273.3±21.0 (p<.002, 1-way ANOVA). ICC for macrophages (MAb F4/80) was lowest with (F), 2.0±.3; (S), 2.7±.3, and highest for (A), 3.6±0.3. Other ICC (CD3, CD8, cytokeratin, vimentin) were similar for adherent cells. Tissue CD31 staining, peritoneal thickness, and IHC for Fibroblast Growth Factor and Transforming Growth Factor β were not different among the treatments (1-way ANOVA). IHC for Vascular Endothelial Growth Factor (VEGF:A, 2.5±.2; S, 2.6±.2; F, 1.9±.2; p<0.004) and for α-Smooth Muscle Actin (αSMA: A, 3.4±.2; S, 3.3±.2; F, 2.8±.2; p<0.05) were significantly less for F than the other treatments.

Conclusions: We conclude that pretreatment of catheters with fibrinogen enhances overall cell adhesion, while decreasing the relative macrophage number when compared to saline or albumin solutions. F also leads to decreased appearance of VEGF and αSMA in the peritoneal response at 7 days. We conclude that the addition of fibrinogen affects the foreign body response to polyethylene in mice.

FR-PO1703

Interleukin-10 Prevents the Progression of Peritoneal Fibrosis Akira Onishi,[1/2] Yoshiyuki Morishita,[1] Masashi Urabe,[2] Ichiro Hirahara,[1] Shigeaki Muto,[1] Keiya Ozawa,[2] Eiji Kusano.[1] *[1]Division of Nephrology, Department of Medicine, Jichi Medical University, Shimotsuke, Tochigi, Japan; [2]Division of Genetic Therapeutics, Center for Molecular Medicine, Jichi Medical University, Shimotsuke, Tochigi, Japan.*

Background: Peritoneal fibrosis (PF) is an intractable complication of peritoneal dialysis (PD). Interleukin-10 (IL-10) was reported to have anti-fibrotic effects; however, little is known about its effects on PF. In the present study, we examined the effects of IL-10 on PF.

Methods: *In vitro* study: Rat peritoneal mesothelial cells (RPMCs) purified from Sprague-Dawley (SD) rats were incubated with IL-10 for 48 h. Then, 50 mM methylglyoxal (MGO); an inciting agent of PF was added. After 24 h, the phenotype and signal transduction in RPMCs were analyzed by qRT-PCR. *In vivo* study: Male SD rats aged 6 weeks were injected intramuscularly with an AAV type 1-based vector encoding IL-10 (AAV-IL-10). The rats injected with the vector encoding GFP (AAV-GFP) or PBS served as controls. From the 28th day after the injection, PD fluid containing 10 mM MGO was injected intraperitoneally every day for 3 weeks. Then, the parietal peritoneum was sampled for analyses.

Results: *In vitro study:* IL-10 mitigated a decrease in epithelial markers (E-cadherin and occludin), an increase in mesenchymal markers (fibronectin and vimentin) and up-regulation of TGF-β1 and Snail induced by MGO in RPMCs. *In vivo* study: Histological analysis revealed marked fibrous thickening of the peritoneum in AAV-GFP and PBS groups. In AAV-IL-10 group, the thickness of the peritoneum was reduced to less than one-half of those in the other groups. Immunohistochemistry showed that decreased epithelial markers and increased mesenchymal markers of the peritoneal cells were mitigated in AAV-IL-10 group compared to AAV-GFP or PBS group. qRT-PCR analysis revealed that TGF-β1 and Snail expression levels in the peritoneum in AAV-IL-10 group was less than 0.3-fold compared to those in AAV-GFP or PBS group.

Conclusions: The results of present study suggested that IL-10 inhibited the progression of PF through the suppression of TGF-β1 signaling. AAV vector-mediated systemic IL-10 delivery would be a potentially powerful option for treatment of PF.

FR-PO1704

Protective Effect of Icodextrin on Mesothelia-to-Mesenchymal Transition (MMT) of Mesothelial Cells (MCs) Induced by Peritoneal Dialysis (PD) Liquids Abelardo I. Aguilera,[2] Pilar Sandoval-Correa,[1] Rafael Selgas,[3] Maria Luisa Perez Lozano,[1] Manuel Lopez-Cabrera.[1] *[1]Biologia Molecular, Centro de Biologia Molecular Severo Ochoa, Madrid, Spain; [2]Servicio de Nefrología, Hospital Universitario de la Princesa, Madrid, Spain; [3]Servicio de Nefrología, Hospital Universitario de la Princesa, Madrid, Spain.*

Background: MMT of MCs is a key process in the initiation of peritoneal membrana (PM) damage in PD. MCs exposed to glucose degradation products (GDPs), low pH and pro-inflammatory cytokines undergo on MMT. Some clinical studies suggest that Icodextrine (Ico) can show better biocompatibility. This study analyzes the effects of Ico on MMT of CMs as triggering of PM damage.

Methods: On the last 10 years we periodically cultured MCs from PD effluents. In MCs lysate we determined E and N-cadherin, Snail and α-SMA as MMT markers. Fibronectin and collagen-I as extrecellular matrix-component (ECM) and VEGF as pro-angiogenic factor. These values were compared between the different PD liquids and clinical events. MCs from omentum (HPMO) were used to *in-vitro* experiments. In our PD mice model we are studying the effects of Ico on PM

Results: We included 157 PD patients of whom 137 were extracted. 63 cultures were from 23 patients using Ico, 23 were from 12 using Dianeal. 26 and 35 cultures

were from 9 and 13 patients using Physioneal 35 and 40, respectively. 66 cultures were classified as fibroblastoid phenotype, 59 as cobblestone and 12 as mixed or not growth. Transdifferentiated MCs showed higher levels of snail (PCR), fibronectin, VEGF, TGF-β and IL-8. High Cr-MTC and lower UF capacity were also found in patients who drained these cells. Although there were 2 more cases of peritonitis in the Ico group, the frequency of MMT was 50% compared to 75% of Dianeal. As expected, Ico group showed lower values of EMC, VEGF and TGF-β and similar frequency of MMT than physioneal. In HPMO, Ico partially inhibited the MMT induced by TGF-β and PD liquids but decreased ECM. Animal experiments are underway.

Conclusions: In PD Ico showed a protective effect on PM through a partial inhibition of MMT of MCs.

FR-PO1705

Are Matrix Metalloproteinase-2 and Plasminogen Activator Inhibitor-1 Determined by Peritoneal Transport or Local Production?

Deirisa Lopes Barreto, Dirk Gijsbert Struijk, Raymond T. Krediet. *Department of Internal Medicine, Division of Nephrology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands.*

Background: Solute transport in peritoneal dialysis occurs from the peritoneal microcirculation to the peritoneal cavity, and visa versa by diffusion and by hydrostatic, and osmotic pressure gradients. Peritoneal effluent contains clinical relevant substances derived from intraperitoneal production or transperitoneal transport or both. Matrix metalloproteinase-2 (MMP-2) is a glycoproteinase that cleaves denatured collagen, and complement other collagenases in the degradation of fibrillair collagens. Elevated intraperitoneal levels of plasminogen activator inhibitor-1 (PAI-1) have been demonstrated to be present in patients with intra-abdominal adhesions. Therefore, the aim of this study was to investigate the potential use of MMP-2 and PAI-1 in effluent as markers in the development of peritoneal alterations.

Methods: For this purpose the roles of peritoneal transport and local peritoneal production of these parameters was studied. This single centre cohort study included 86 incident PD patients. All patients were treated with biocompatible dialysis solutions and underwent a standard peritoneal permeability analysis (SPA). The presence of local production as well as correlations between MMP-2, PAI-1 and peritoneal transport parameters were studied.

Results: Median effluent levels of 22.1ng/mL for MMP-2 and 0.95ng/mL for PAI-1 were found. Local peritoneal production averaged 93% of effluent MMP-2 concentration and 77% for PAI-1. Also, when expressed as ratio, D/P_{MMP-2} or D/P_{PAI-1} over $D/P_{Albumin}$ exceeded 1 and therefore local production could be established on top of transport. Furthermore, correlations between $MTAC_{creatinine}$ and MMP-2 ($r=0.38$, $p<0.001$) or PAI-1 ($r=0.42$, $p<0.001$) were present.

Conclusions: In conclusion this study demonstrates that MMP-2 and PAI-1 pass the peritoneal membrane via peritoneal transport. However, the presence of local production was much more important. This data illustrates the potential of MMP-2 and PAI-1 as biomarkers of peritoneal modifications, but constituents of peritoneal transport and local production should be separated in every patient.

FR-PO1706

Indoxyl Sulfate and *p*-cresyl Sulfate Concentrations Increase in Incident Peritoneal Dialysis Patients along the Loss of Residual Renal Function

Liesbeth Viaene, Bjorn K.I. Meijers, Bert Bammens, Pieter Evenepoel. *Nephrology, University Hospital, Leuven, Belgium.*

Background: Residual renal function (RRF) is of critical importance for the clearances of p-cresyl sulfate (PCS) and indoxyl sulfate (Inds) in peritoneal dialysis (PD) patients. Besides other mechanisms, high serum PCS and IndS concentrations may contribute to the association between poor RRF and increased cardiovascular (CV) morbidity in PD patients. Studies evaluating the impact of RRF on serum levels of PCS and IndS have so far yielded conflicting results, probably related to small sample size and retrospective design.

Methods: We performed a prospective, observational cohort study in incident PD patients. Serum concentrations, mass removal and total, renal and dialytic clearances of creatinine, urea nitrogen, PCS and Inds were assessed 1, 6, 12 and 24 months after start of PD. Data from 35 patients (19 male, age 55±17 year) with a technique survival exceeding 2 years were analyzed.

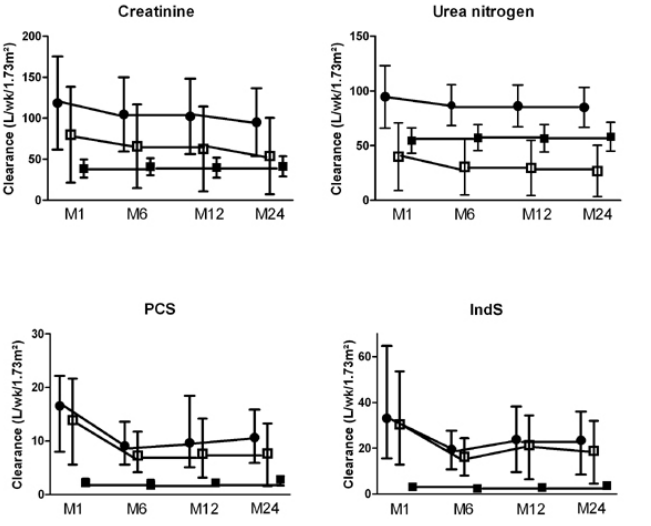
Results: Serum concentrations of PCS and IndS increased with dialysis vintage, along the decline in RRF. Conversely, mass removal of both toxins remained stable.

Evolution of serum concentrations and mass removal (MR) of PCS and IndS

	M1	M6	M12	M24	P
nPNA	1.8	1.8	1.9	1.9	0.9
PCS (μM)	84	99	107	122	0.01
IndS (μM)	43	57	60	69	0.0009
Urea nitrogen (mg/dL)	105	108	109	110	0.3
Total MR PCS (mg/week)	235	209	215	195	0.7
Total MR IndS (mg/week)	260	210	237	266)	0.6

Median values are shown.

Compared to urea nitrogen, total clearances of PCS and IndS showed a more prominent decline along the loss of RRF.



Time course of renal (open squares), peritoneal (closed squares) and total (closed circles) clearances of creatinine, urea nitrogen, PCS and IndS.

Conclusions: Contrary to previous reports, we demonstrate that serum PCS and IndS concentrations in incident PD patients increase along the loss of residual renal function.

FR-PO1707

Baroreceptor Function Is Similar in Chronic Peritoneal Dialysis and Hemodialysis Patients

Dvora Rubinger, Ilana Harel, Dan Sapoznikov. *Nephrology and Hypertension Services, Hadassah University Medical Center, Jerusalem, Israel.*

Background: The baroreflex function (BRS), a measure of the autonomic nervous system activity was not well characterized in patients with end-stage renal disease on chronic peritoneal dialysis treatment (CCPD/CAPD).

Methods: To assess BRS indices, continuous beat-to-beat intervals (IBI) and systolic blood pressure (SBP) were monitored using the Finometer equipment in a group of patients on chronic peritoneal dialysis treatment (CCPD/CAPD, n=10) as compared with age matched patients on chronic hemodialysis (HD, n=91), and control subjects (C, n=27).

Results: Mean SBP and IBI variability , BRS indices and BEI (baroreflex effectiveness index) were (median and interquartile range):Table 1.

	C	HD	p vs.C	CCPD/CAPD	p vs.C	p vs. HD
Age* (years)	56±7	56±12	NS	56±15	NS	NS
SBP (mm Hg)	126 (24)	137 (32)	NS	127 (43)	NS	NS
BEI (%)	11.8 (12.2)	3.0 (7.3)	0.005	2.3 (7.3)	0.001	NS
Slope (msec/mmHg)	6.34 (2.47)	4.88 (3.32)	0.005	4.35 (4.77)	0.001	NS
LF IBI ($msec^2$/Hz)	2285 (2166)	743 (1570)	0.001	876 (1633)	0.008	NS
HF IBI $msec^2$/Hz)	250 (222)	125 (157)	0.008	94 (78)	0.003	NS
LFα(msec/mmHg)	4.99 (2.66)	3.23 (2.51)	0.002	3.32 (1.73)	0.015	NS
HFα(msec/mmHg)	6.19 (5.17)	3.90 (2.47)	0.002	3.38 (1.90)	0.004	NS

* mean±SD; Slope: the slope of the regression line between IBI and SBP for at least 3 beats; % BEI: % of sequences out of the number of ramps; LF IBI and HF IBI: power spectrum of IBI in the low frequency (0.04-0.15 HZ, LF) and the high frequency (0.15-0.40 Hz, HF) bands.α: the square root of the ratio of average power spectral density of IBI and SBP in the low (LF) or high (HF) frequency bands.

Mean IBI, mean diastolic blood pressure (DBP) and the variablity of the blood pressure were in the same range in all groups.The proportion of diabetic patients was similar in HD and CCPD/CAPD groups.

Conclusions: These results show that heart rate variability and baroreceptor indices are markedly reduced in patients with end-stage renal disease on both maintenance hemodialysis and CCPD/CAPD, as compared with normal individuals. The dialysis modality, however, has no effect on the degree of suppression of the autonomic function. The prognostic significance of these findings remains to be defined.

FR-PO1708

Is the Sodium Restriction Harmful or Beneficial in the Long-Term Peritoneal Dialysis?

Jie Dong, Yanjun Li, Rong Xu. *Institute of Nephrology, Peking University, Beijing, China.*

Background: Sodium restriction is routinely recommended for patients on peritoneal dialysis (PD). However, a very low sodium intake was shown to be associated with protein-energy wasting and high mortality in patients on PD most recently. We aimed to determine whether a reduction in sodium intake in the early stage of PD is associated with a decline in dietary and nutritional parameters, and with a high risk for mortality.

Methods: A total of 305 incident patients were enrolled in our single-center cohort study. All patients were followed until death or censored. Demographic data was collected at baseline. Biochemical, dietary and nutrition data were examined at baseline and thereafter at regular intervals. Three groups of patients were defined according to the change of sodium intake over the first two quarters: one in which sodium intake decreased, one in which sodium intake remained stable, and a third group in which sodium intake increased.

Results: Participants with decreased sodium intake tended to be young, non-diabetic and less inflammatory status. There were no significant differences in the longitudinal change of dietary protein and energy intake, serum albumin and lean body mass during the long-term follow-up between groups. The decreased sodium intake significantly predicted a lower risk for cardiovascular mortality with HR of 0.57 (0.38~0.86) and for first cardiovascular event with HR of 0.68 (0.52~0.88) after adjusting for recognized confounders.

Conclusions: Our study revealed that decreased sodium intake in the early stage of PD was not associated with declined dietary and nutritional status in the long term. The decreased sodium intake independently predicts a lower risk for cardiovascular death and first cardiovascular event.

FR-PO1709

Sleep-Disordered Breathing, Restless Legs Syndrome and Daytime Sleepiness in Automated Peritoneal Dialysis

Maria-Eleni Roumelioti, Christos Argyropoulos, Filitsa H. Bender, Beth M. Piraino, Mark L. Unruh. *Renal and Electrolyte, University of Pittsburgh.*

Background: Sleep-Disordered Breathing (SDB), Restless Legs Syndrome (RLS), and excessive daytime sleepiness (EDS) are highly prevalent among hemodialysis (HD) patients (pts). The burden of these conditions remains poorly defined among Automated Peritoneal Dialysis (APD) pts.

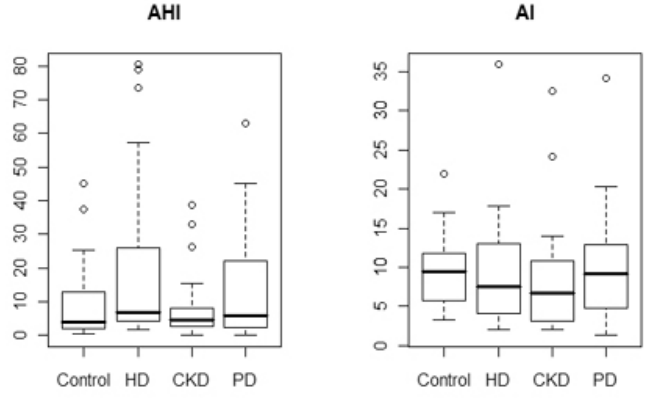
Methods: APD pts were matched to pts with CKD (MDRD eGFR<40 ml/min),on HD and healthy control participants from the Sleep-SCORE Study of sleep and cardiovascular risk with respect to age, gender and BMI. We used in-home unattended polysomnography to measure total sleep time (TST), sleep efficiency (SE) (TST as a proportion of the time spent in bed); Apnea/Hypopnea Index (AHI,apneas and hypopneas/hour)and Arousal Index (AI, microarousals/hour). EDS was defined by a score≥10 on the Epworth Sleepiness Scale (ESS). Presence of RLS was examined with the Hopkins RLS Diagnostics Questionnaire.

Results: A total of 88 pts were studied (22 in each group):

Patient Characteristics

	APD	CKD	HD	Controls
Age	42±14	47±12	50±6	52±6
Women	16(73%)	15(68%)	16(73%)	16(73%)
African Americans	11(50%)	9(40%)	11(50%)	11(50%)
BMI	26.2±6	30±7	28.8±6	31±7
Waist Circumference (cm)	98±17	107±21	104±18	96±18
Neck Circumference (cm)	36±4	37±6	40±6	37±3
SBP (mmHg)	134±15	147±22	148±32	127±15
DBP (mmHg)	87±28	85±16	82±14	80±11

HD pts had the lowest TST (302±114 min) and SE (69±17%) among the 4 groups. APD pts were similar to controls(TST: 355±113 min vs 366±102 min p=0.78 , SE: 72±19% vs 74±13% p=1). The prevalence of EDS was 45% and did not differ among the 3 groups $\chi 2$=0.32). AHI and AI (SBD) scores were not different among the groups.



RLS was present in 35% of the 3 groups, with no difference among them ($\chi 2$=0.93)

Conclusions: The burden of SBD, RLS and EDS is similar among pts on APD, HD and advanced CKD and should be discussed when opting for a dialysis modality.

FR-PO1710

Effluent Markers and Epithelial Mesenchymal Transition in CAPD

Sonoo Mizuiri,[1] Ken Sakai,[2] Yasushi Ohashi,[2] Yoshihide Tanaka,[2] Yasunori Suzuki,[2] Yoshinari Hattori,[2] Atsuhiko Mutou,[2] Yoshiko Nishizawa,[1] Kenichiro Shigemoto,[1] Atsushi Aikawa.[2] *[1]Division of Nephrology, Ichiyoukai Harada Hospital, Hiroshima, Japan; [2]Nephrology, Toho University School of Medicine, Tokyo, Japan.*

Background: Epithelial mesenchymal transion (EMT) of peritoneal mesothelial cells is important for peritoneal deterioration in CAPD. It is reported that hepatocyte growth factor (HGF) and bone morphogenic protein-7 (BMP-7) ameliorate EMT, but the clinical significance of effuluent HGF and BMP-7 levels remain unclear. It has also been reported that dialysate growth factor levels should be measured relative to the level of cancer antigen 125 (CA125).

Methods: We evaluated the association between peritoneal solute transport rate (PSTR) and effluent markers related to EMT with adjusted values for effluent cancer antigen 125 (CA125). One hundred five incident peritoneal dialysis (PD) patients on PD for 25 (12-68) months with biocomapatible solutions were included in the study. Fast peritoneal equilibration test was used to evaluate PSTR. Effluent hepatocyte growth factor (HGF), bone morphogenic protein-7 (BMP-7), vascular endothelial growth factor (VEGF), interleukin-6 (IL-6) and CA125 at 4h were measured.

Results: Clinical data are shown in the table.

Clinical data

Group	Patients with high transport rate	Others
n	14	91
Age	58 (44-68)	55 (46-64)
D/P creatine	0.90 (0.87-0.96)*	0.71 (0.60-0.75)
Diabetics	8/14	22/91
Duration of PD	10 (7-11)*	32 (15-75)
Urine volume	400 (176-624)	100 (0-875)
Serum albumin	2.70 (2.69-2.98)*	3.40 (3.03-3.78)

*P<0.001 compared with others

Patients with dialysate/plasma creatinine ≥0.82 showed significantly higher effluent HGF [240 (198-319) vs. 133 (107-216) pg/ml, P<0.001], VEGF [33 (29-34) vs 25 (20-31) pg/ml, p<0.01] and IL-6 [24 (14-35) vs 12 (7-24) pg/ml, p<0.05] levels than the others. Dialysate/plasma creatinine levels were significantly correlated with HGF (r=0.53, p<0.001), VEGF (r=0.35, p<0.001), IL-6 (r=0.35, p<0.001), IL6/CA125 (r=0.25, p<0.05) but not with BMP7, BMP7/CA125, HGF/CA125, VEGF/CA125.

Conclusions: Effluent HGF levels as a compensatory mechanism is a marker of peritoneal deterioration, but controversy remains regarding the adjustment of markers for CA125.

Biological Effects Research of Maltose Peritoneal Dialysis Solution

Zhanjun Shu,[1] You-Ming Peng,[1] Lin Sun,[1,2] Li Xiao,[1] Guanghui Ling,[1] Fu-You Liu.[1] *[1]Department of Nephrology, Second Xiangya Hospital, Central South University, Changsha; [2]Departments of Pathology and Medicine, Northwestern University, Chicago, IL.*

Background: Over the past 15 years, peritoneal dialysis (PD) has undergone considerable development from a technological point of view, and osmotic agent has played the essential role in peritoneal dialysis fluid.

Methods: We set up a method to quantitative the maltose by HPLC. Rabbits were enrolled as acute renal failure model to study transport capability in small molecule solute. Anew non-uremic rat model of long-term peritoneal dialysis were enrolled to research the influence of peritoneum structure in long-term peritoneal dialysis.

Results: The glucose and maltose concentrations can be determined with a recently established HPLC methods . The elution peak retention time of glucose and maltose are 5.485min and 4.112min respectively. In our study we select 2.5%and 4.25%maltose peritoneal dialysis solution as subject investigated. The osmotic pressure of maltose is lower than that of glucose but higher than that of Icodextrin. The PH of maltose is higher than that of glucose and icodextrin. The non-uremic rat model of long-term the peritoneal dialysis and the acute renal failure rabbit model have the certain usability. The net ultrafiltration of maltose peritoneal dialysis solution excelled equal concentration glucose peritoneal dialysis solution in 4h.Meanwhile the net ultra filtration of 4.25% maltose peritoneal dialysis solution excelled 7.5% Icodextrin. In 8h the net ultra filtration of maltose peritoneal dialysis solution still excelled equal concentration glucose peritoneal dialysis solution, but lower than that of 7.5% Icodextrin.

Conclusions: The net ultrafiltration of maltose peritoneal dialysis solution excelled equal concentration glucose peritoneal dialysis solution in 4h. The transport capability in small molecule solute of maltose peritoneal dialysis solution overmatches that of equal concentration glucose peritoneal dialysis solution.The biocompatibility of maltose peritoneal dialysis solution overmatches traditional glucose peritoneal dialysis solution.

The Definition of Histological Criteria for Encapsulating Peritoneal Sclerosis – A Standardized Approach Niko Braun,[1] Peter Fritz,[2] Christoph Ulmer,[3] Martin Kimmel,[1] Dagmar Biegger,[2] German Ott,[4] Fabian R. Reimold,[1] Klaus-Peter Thon,[3] Juergen Dippon,[5] Stephan Segerer,[6] Mark Dominik Alscher.[1] *[1]Department of Internal Medicine, Division of Nephrology, Robert-Bosch Hospital, Stuttgart, Germany; [2]Margarete-Fischer–Bosch Institute of Clinical Pharmacology, University of Tuebingen, Stuttgart, Germany; [3]Department of Surgery, Robert-Bosch Hospital, Stuttgart, Germany; [4]Department of Diagnostic Medicine, Division of Pathology, Robert-Bosch Hospital, Stuttgart, Germany; [5]Department of Mathematics, University of Stuttgart, Stuttgart, Germany; [6]Division of Nephrology, University Hospital Zurich, Switzerland.*

Background: The two most relevant pathologies of long-term peritoneal dialysis (PD) are simple sclerosis and encapsulating peritoneal sclerosis (EPS). Aim of the study was to define relevant and reproducible histological parameters in patients with EPS compared to patients on PD without EPS.

Methods: 31 EPS patients and 27 PD patients were analyzed. Two blinded investigators recorded the following histological characteristics: mesothelial denudation, fibrosis, acute and chronic inflammation, hemorrhage, cellularity, number of vessels, vasculopathy, iron content, number of fibroblast-like-cells (FLC), calcification, ossification and fibrin deposits and podoplanin.

Results: The following findings were significantly more common in EPS: FLC ($p<0.001$), meothelial denudation ($p<0.001$), decreased cellularity ($p=0.008$), fibrin deposits ($p<0.03$), positive iron staining ($p=0.05$) and IHC podoplanin vascular ($p<0.001$), podoplanin avascular ($p<0.001$). Multivariate analysis yielded mesothelial denudation ($p=0.04$), FLC ($p=0.04$), acute and chronic inflammation ($p=0.03$), fibrin deposits (0.04) and cellularity ($p=0.02$) as significant histological parameters. Inclusion of podoplanin resulted in different parameters according to binary logistic regression: podoplanin vascular ($p=0.008$), calcium deposits ($p=0.02$), cellularity ($p=0.02$) and chronic inflammation ($p=0.006$).

Conclusions: We demonstrated that a binary logistic regression model differentiates between histological findings in PD compared to EPS. Our next goal is to establish a scoring system with a larger cohort of patients.

FR-PO1713

Visceral Fat Thickness Is Associated with Carotid Atherosclerosis in Peritoneal Dialysis Patients Jisun Paeng,[1] Mi Jung Lee,[1] Dong Ho Shin,[1] Tae Ik Chang,[2] Seung Jun Kim,[1] Dong Eun Yoo,[1] Hyung Jung Oh,[1] Seung Hyeok Han,[1] Tae-Hyun Yoo,[1] Shin-Wook Kang.[1] *[1]Dept. of Int. Medicine, College of Medicine, BK21, SBSI, Yonsei Univ., Seoul, Korea; [2]Dept. of Int. Medicine, NHIC Ilsan Hospital, Goyang, Korea.*

Background: Visceral fat is known to be more metabolically active and to be associated with atherosclerosis, inflammation, and insulin resistance. However, the impact of visceral fat on cardiovascular disease in patients on peritoneal dialysis(PD) has never been elucidated. This study was conducted to investigate whether visceral fat thickness(VFT) has a predictive role in carotid atherosclerosis(CA) determined by carotid intima-media thickness(cIMT) in PD patients.

Methods: A cross-sectional study was undertaken in 88 prevalent PD patients. Body mass index(BMI) and waist circumference(WC) were measured as anthropometric indices of obesity. VFT and subcutaneous fat thickness(SFT) were determined by sonographic measurement of abdominal fat. CA was defined as increased cIMT(>1.0 mm) or presence of plaque. Logistic regression analysis(age and sex-adjusted, and multivariate-adjusted) was performed to confirm the independent association of obesity indices with CA. In addition, various biochemical markers for inflammation and insulin resistance according to VFT category were compared by ANOVA.

Results: Thirty-two patients(36.3%) had CA. Patients with CA had significantly higher VFT, BMI, and WC compared to patients without CA. In univariate logistic analysis, BMI, WC, and VFT, but not SFT, were significant risk factors for CA. However, multivariate analysis revealed VFT was an independent factor associated with CA after adjusting for demographic, biochemical parameters, and anthropometric indices(per 1mm increase; OR, 2.294; 95% CI, 1.048-5.021; P=0.038). When the patients were divided into three groups according to VFT, log high-sensitivity C-reactive protein levels, fibrinogen concentrations, and HOMA-IR were significantly higher in the 3rd tertile compared to the other tertiles.

Conclusions: VFT, not SFT, is independently associated with CA in PD patients. Therefore, sonographic measurement of VFT could be useful to stratify the risk of cardiovascular disease in these patients.

FR-PO1714

Oral Active Vitamin D and the Risk of Peritonitis: The Benefit of an Early Start Ana Pinho,[1] Helena Carreira,[2] Ana Cabrita,[1] André Fragoso,[1] Anabela Malho,[1] Isabel Pinto,[1] Idalecio Bernardo,[1] Pedro Neves.[1] *[1]Nephrology Department, Faro Hospital, Faro; [2]Public Health Institute of Oporto Universtity, Oporto.*

Background: Peritonitis is a major complication of peritoneal dialysis (PD), being associated with high hospitalization rate and increased mortality. Data on the relationship between medication and the incidence of peritonitis is scarce and inconsistent. It has been suggested that baseline treatment with vitamin D could be associated with a lower risk of peritonitis. The aim of our study was to clarify the role of active vitamin D exposure in our PD patients.

Methods: We included and followed prospectively all patients who were on PD for at least 3 months, since 2000. Comorbidities and laboratory parameters were assessed at baseline. Data regarding oral active vitamin D treatment (Alfacalcidol and Calcitriol) was recorded throughout the follow-up and in a low clearance clinic period (pre-PD).

Results: We evaluated 105 incident patients, 43% female, with a mean age of 53 years and a mean follow-up time of 31months. The incidence rate of peritonitis was 0.25episodes/patient-year. Peritonitis was the major cause both for hospitalization (36.1%) and death (22.4%), being associated with 2.8 increased risk for mortality ($p=0.029$). Of our population, 17 patients were treated with vitamin D (0.69±0.54mcg/week) for 115±46 weeks during the pre-PD. At the start of PD therapy, 11 patients began vitamin D and during follow-up period another 44 patients also initiated vitamin D treatment.

In the univariate analysis, the treatment with vitamin D in pre-PD was associated with a significantly lower risk of peritonitis ($p=0.012$). After adjustment for time on PD, age, diabetes, baseline serum albumin and CRP, pre-PD vitamin D therapy was associated with an 72% of reduction of peritonitis risk [OR: 0.28; IC95%: 0.08-0.93). The therapy with vitamin D after the beginning of PD wasn't associated with reduction of peritonitis risk.

Conclusions: Treatment with oral vitamin D in a pre-PD period is associated with a lower risk of peritonitis. Further studies are still needed to corroborate our results and to get a better understanding of how vitamin D exerts this protection capacity peritonitis.

FR-PO1715

Automated Cell Analysis Improves Diagnostic Accuracy in Peritoneal Dialysis Associated Peritonitis A.M. Van Alphen, Robert Jonge, Marjen W. Fieren. *Erasmus University Medical Center, Rotterdam, Netherlands.*

Background: According to current guidelines PD associated infectious peritonitis is recognised by elevated white blood cell (WBC) counts ($>100*10^6$ /L) in the effluent. Of these leukocytes >50% are required to be polymorphonuclear cells (PMN's). Microscopic analysis has been gold standard to determine differential WBC count. However, microscopic analysis is time consuming, requires skilled personnel, suffers from substantial variability and is seldom available 24 hours per day. Since immediate antibiotic treatment of peritonitis is warranted time to diagnosis should be as short as possible. Automated hemocytometric analysis may overcome these problems.

Methods: We report on our three year experience with automated hemocytometric analysis using the Sysmex® XE-5000 body fluids mode. Previously we showed that this method enables highly accurate WBC differential counting in body fluids including PD effluent, even at low WBC numbers. The system has been implemented in March 2008 in our hospital. Since implementation data on differential WBC is available within one hour after sampling. We evaluated 61 episodes of symptomatic effluent leukocytosis occurring from March 2008-March 2011. We excluded the first week after start training PD from our analysis.

Results: Six episodes were characterised by predominant monocytosis. All 6 episodes recovered without antibiotic treatment and cultures, evaluated using Bactec® technique, remained sterile. In 55 cases, patients presented with predominant neutrophilic leucocytosis in the effluent (1 episode/23 patient months). These patients were all treated with antibiotics. The average percentage of PMN's in the effluent was 79%. 39 (71%) episodes resolved, 6 (11%) episodes resulted in relapse peritonitis and 10 (18%) proved refractory to treatment. In 5 cases (9%) no pathogen could be identified on culture. Because PMN ratio was >50% in these 5 patients, they were treated with antibiotics. All five recovered readily.

Conclusions: Immediate availability of differential WBC counts in PD effluents, using automated hemocytometric analysis, prevents unnecessary treatment of PD associated peritonitis with antibiotics in 10% of presenting cases.

FR-PO1716

Low Calcium Dialysate as a Risk Factor for Decline in Bone Mineral Density in Female Patients on Peritoneal Dialysis: A Single-Centre Retrospective Observational Study Seokhui Kang, Jun-Young Do, Kyu-Hyang Cho, Jong-Won Park, Kyung-Woo Yoon. *Division of Nephrology, Department of Internal Medicine, Yeungnam University Hospital, Daegu, Korea.*

Background: Previous studies have showed that low calcium dialysate (LCD) induce an increase of serum intact-parathyroid hormone (i-PTH) in PD patients. There are few reports on the effects of LCD for decline in bone mineral density (BMD) in PD patients.

Methods: We reviewed the medical records at Yeungnam University Hospital in Korea and identified all the female patients who received PD between 2001 April and 2009 March. Among them, patients with < 2 years of follow-up were excluded. BMD measurement was performed yearly by the Hologic (Discovery Wi). One hundred ten patients were enrolled. The following data was documented from the patients' record: age at the initiation of PD, underlying disease, the time averaged laboratory findings, types of dialysate and changes in total body BMD during 2 years.

Results: Twenty four underwent LCD and 86 patients underwent standard calcium dialysate (SCD). The mean age was 49.8 ± 11.4 years old in low calcium dialysate group and 49.5 ± 13.7 years old in standard calcium dialysate group. Total BMD (g/cm^2) was 1.02 ± 0.13, 1.02 ± 0.13 and 1.00 ± 0.12 at baseline, 1 year and 2 years after the initiation of PD. There was a significant decrease in the BMD between 1 and 2 years after the initiation of PD. Time averaged intact-PTH was 249.4 ± 161.3 in LCD group and 141.3 ± 1189 in SCD group ($p = 0.000$). Time averaged alkaline phosphatase (ALP) was 215.4 ± 87.6 in LCD group and 186.4 ± 74.6 in SCD group ($p = 0.023$). On the univariate analysis, LCD, residual renal function, normalized protein equivalent of nitrogen appearance, weekly Kt/V, i-PTH, ALP and initial total body BMD were associated with decline of total body BMD. On the multivariate analysis, LCD, ALP and initial total body BMD were proved to be the independent risk factors for decline in total body BMD.

Conclusions: Low calcium dialysate is a risk factor for decline in BMD. LCD may be associated with increment of ALP and intact-PTH. Therefore, LCD should be carefully used for female PD patients with risk of decline in BMD.

FR-PO1717

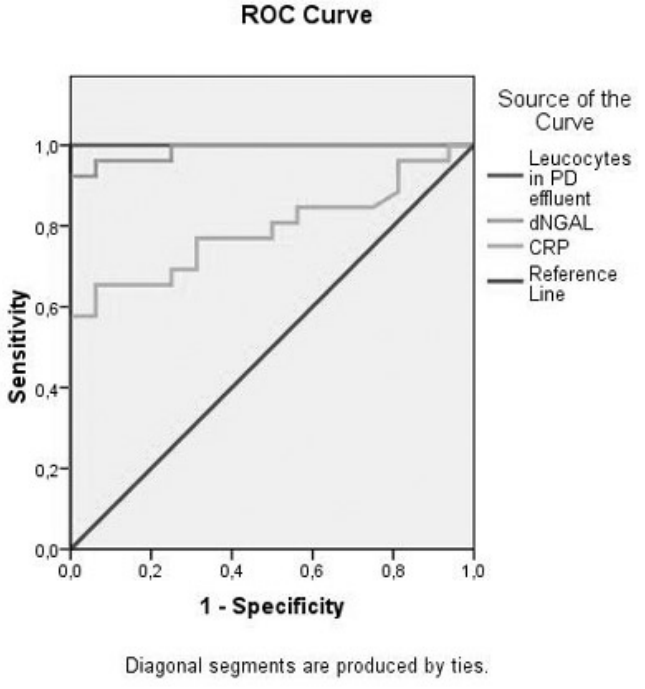
Neutrophil Gelatinase-Associated Lipocalin in Peritoneal Dialysate Effluent as a Marker of Acute Episode of Peritonitis Francesca K. Martino,[1] Pierluigi Di Loreto,[1] Ilenia Filippi,[2] Maria Pia Rodighiero,[1] Claudio Ronco.[1-2] *[1]Nephology, Dialysis and Kidney Transplant, San Bortolo Hospital, Vicenza, Italy; [2]IRRIV, Vicenza, Italy.*

Background: The major infective complication of peritoneal dialysis (PD) is the development of peritonitis. Serum neutrophil gelatinase-associated lipocalin (NGAL) was reported as biomarker of bacterial infection and a previous study of Leung showed its increase during the first days of peritonitis. The aim of study is to access the utility of NGAL in peritoneal dialysate effluent (dNGAL) for the diagnosis of peritonitis in PD patients.

Methods: In this cohort study dNGAL concentration (evaluated by Archictet NGAL assay Abbott) was measured in heterogeneous group of PD patients (n=57) with or without any suspect of peritonitis. Moreover we evaluated CRP, Procalcitonin in the blood and leucocytes in the blood and in PD effluent. The episodes of peritonitis are defined in agreement with the guidelines of the International Peritoneal Dialysis Society.

Continuous variables were presented as the median values and interquartile range (IQR). The Mann-Whitney U tests was used to compare continuous variables. Binary regression analysis was performed to study the ability of variables to predict peritonitis and ROC analysis was used to calculate area under curve (AUC) for biomarkers. All statistical analysis were performed with SPSS version 17.0.

Results: During 8 months of observation, we had 38 peritonitis. In univariable analysis CRP and dNGAL were significantly associated with peritonitis, with OR of 1,5 (p=0,02) and 1,008 (p<0,01), respectively. In multivariable analysis, only NGAL (p=0,042) in PD effluent was independent predictor of peritonitis (H.R. 1,007). AUC for dNGAL was 0,988 while AUC for CRP was 0,792.



Conclusions: In our analysis, dNGAL could be used as a potential biomarker of peritonitis in PD patients.

FR-PO1718

Non-Infectious Complications of Fistulas in Patients Receiving Frequent Hemodialysis Deborah Lynn Zimmerman,[1] Sarah Daisy Kosa,[2] Christopher T. Chan,[2] Charmaine E. Lok.[2] *[1]Ottawa Hospital, Ottawa, ON, Canada; [2]Toronto General Hospital, Toronto, ON, Canada.*

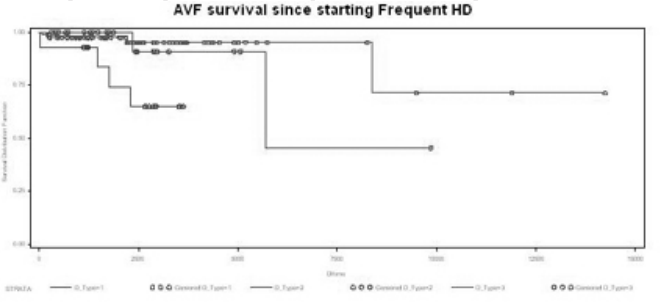
Background: Frequent hemodialysis includes short daily dialysis (SDH), frequent conventional hemodialysis (FHD) and nocturnal dialysis (NHD). FHD is associated with many beneficial clinical outcomes. There is a paucity of data directly comparing these modalities in terms of vascular access complications, interventions, and fistulas (AVF) survival.

Methods: Patients who received SDH (>5x/wk), FHD (4 days/wk; <4 hrs/session) and NHD (>3 x/week, >5 hrs/session) who were dialyzed with a catheter (CVC), AVF, or graft (AVG) were prospectively followed between Jan 2001-Dec 2010. The intervention rate for each type of vascular access between FHD, SD, and NHD were compared. AVF survival in SDH vs. NHD were compared by Kaplan Meier analysis (log rank test) using SAS, v 9.2.

Results: 193 accesses were studied.

	FHD (n=19)	SDH (n=46)	NHD (n=128)
Fistula	10 (53%)	32(70%)	68 (53%)
Graft	2 (11%)	1 (2%)	6 (5%)
Catheter	7 (36%)	13 (28%)	54 (42%)
AVF interventions (avg/pt)	1.28	0.93	1.45

On average, more AVF are attempted and used in NHD (0.51/pt) compared with SDH (0.20/pt); p<0.0001. Patients cannulating AVF with buttonhole technique needed more retraining than rotating site cannulation. On average there were more AVG interventions (for stenosis and thrombosis) in NHD than in SDH (p=0.04). However, the overall intervention rates and complication rates did not differ between NHD and SDH. There was longer AVF survival for NHD patients compared with both frequent FHD and SDH (p=0.004)



(d_type=3 is NHD; D_type=2 is SDH)

Conclusions: Patients on frequent dialysis have similar vascular access interventions. AVF in patients on NHD have greater patency compared with SDH and FHD. Further evaluation of the impact of patient characteristics and prior dialysis history on AVF outcomes in frequent dialysis is required.

FR-PO1719

Impact of Early Decline in Residual Renal Function on the Body Composition Changes and Clinical Outcomes during the First Year in the Continuous Ambulatory Peritoneal Dialysis Patients Kyu-Hyang Cho,[1] Jun-Young Do,[1] Seokhui Kang,[1] Jong-Won Park,[1] Kyung-Woo Yoon,[1] Tae Woo Kim.[2] *[1]Internal Medicine, Yeungnam University Hospital, Daegu, Republic of Korea; [2]Internal Medicine, Soonchunhyang University Gumi Hospital, Gumi, Republic of Korea.*

Background: Preservation of residual renal function in peritoneal dialysis patient is essential to improve clinical outcomes. Therefore, the authors investigated the effect of rapid decline of residual renal function in early period on clinical outcomes and body composition changes in CAPD patients.

Methods: Among new incident CAPD patients from May 2001 to December 2009 in our hospital, 200 patients who finished 12 month protocol (male: 103, mean age: 50.0 ± 13.2 years, DM: 94) were analyzed. Patients were assigned to high GDP group (n=103, Dianeal® and Stay-safe®) and low GDP group (n=97, Physioneal® and Balance®). We defined early RRF decline group (n=68) as more than 5 ml/min decline in RRF at the first month after initiation of PD from GFR just before initiation of PD. Clinical indices and UFV during the PET were measured at the first , 6th and 12th month. Body composition including LBM and fat mass were measured using BIA at the first and 12th month.

Results: 1) Baseline characteristics between early RRF decline group and non-early RRF decline group were not significantly different. 2) Incidence of early RRF decline group was 34%. There is significant positive correlation between RRF at the first month and RRF at the 12th month . 3) Early RRF decline group showed significant lower RRF at the 6th and 12th month, and also significant higher CRP and lower serum albumin at the 12th month than non-early RRF decline group. Early RRF decline group showed significant lower BW, TBW and LBM at the 12th month than non-early RRF decline group. There were no significant differences in RRF at the 12th month between the high GDP and the low GDP group.

Conclusions: Early decline of RRF in the first month could be associated with body composition changes and clinical outcomes during the first year in CAPD patients. It is suggested that preservation of RRF in early period of peritoneal dialysis is important to improve clinical outcomes and nutritional status.

FR-PO1720

Adequate Kt/V and Its Practical Data in Infants Receiving Peritoneal Dialysis Shojiro Okamoto, Tomoyuki Sakai, Riku Hamada, Yuko Hamasaki, Kenji Ishikura, Hiroshi Hataya, Masataka Honda. *Department of Nephrology, Tokyo Metropolitan Children's Medical Center.*

Background: In children who are receiving peritoneal dialysis (PD), the adequate Kt/V urea/week remains controversial. The K/DOQI Guidelines recommendation that an adequate Kt/V urea/week is above 1.8/week. The Japanese guidelines recommend a value above 2.5/week for children and above 3.0/week for infants.

Methods: In our institution, the target BUN level is below 70 mg/dl for children who are receiving PD and adequate nutrition. We studied infants who were receiving ambulatory PD treatment during the 1-year period from January 2009. In these patients, we analyzed the Kt/V urea/week and n-PNA (neutralized-protein equivalent of nitrogen appearance). Residual kidney function (RKF) was also evaluated.

Results: Nine patients were studied, including 4 with RKF. The median age was 5.0 years. Average Kt/V urea/week was 2.83 (2.66 in patients with RKF, 2.97 in anuric patients). Average n-PNA was 1.31 g/kg/day (1.34 g/kg/day in patients with RKF, 1.29 g/kg/day in anuric patients). Five patients received nightly intermittent PD (4 had RKF), 2 received continuous cyclic PD (both were anuric), and 2 received continuous cyclic PD + continuous ambulatory PD (both were anuric). The average BUN level in patients with RKF was 64.05 mg/dl, which was higher than that in anuric patients (61.4 mg/dl). The average ultrafiltration volume of PD was higher in anuric patients. The average rate of increase in the height standard deviation was 0.11. The average intraperitoneal volume was 895 ml/m^2. Only 1 patient had a complication of inguinal hernia.

Conclusions: In our series, the Kt/V urea/week of infants who were receiving PD was higher than the value recommended by the K/DOQI guidelines. Growth was satisfactory under appropriate nutrition, without complications. In anuric patients, the elevated level of Kt/V was in contrast to the lower level of BUN, suggesting that the Kt/V resulted from other determinants of the PD prescription, such as ultrafiltration volume. To perform PD appropriately in infants, not only the Kt/V, but also growth, nutrition, membrane permeability, and ultrafiltration volume should be comprehensively considered.

FR-PO1721

The Effect of Frequent Hemodialysis (HD) Therapies on Serum Beta2-Microglobulin (B2M) Levels in Patients Having Residual Renal Function (RRF) Alp Akonur, Baris U. Agar, Angelito A. Bernardo, J. Ken Leypoldt. *Renal, Baxter Healthcare Corporation, McGaw Park, IL.*

Background: Extracorporeal removal of B2M using high-flux hemodialyzers is largely hindered by the compartmentalization of its distribution volume. While the CONTRAST study has recently demonstrated that therapies using enhanced convective transport can reduce serum B2M levels in patients with and without RRF (Penne et al, CJASN 2010), an equivalent analysis is not yet available for frequent HD therapies.

Methods: We used a variable-volume, two-compartment kinetic model (Ward et al, KI 2006) to calculate weekly mean pretreatment serum B2M concentrations (MPC) with in-center (ICHD), short-daily (SDHD), and nocturnal (NHD) HD therapies in patients with increasing degrees of residual renal B2M clearance (RRC-B2M). The modeled B2M parameters were the intercompartmental mass transfer coefficient (40 ml/min), generation rate (0.17 mg/min), non-renal clearance (3 ml/min), and distribution volume (13.3 L) (Clark et al, JASN 1999). The RRC-B2M considered ranged from 0 to 4 ml/min. Dialysis frequency and duration were: 3 times/week and 4 hours/treatment (3X/4hr) (ICHD), 6X/3hr (SDHD), and 6X/8hr (NHD). A dialyzer clearance rate of 50 ml/min was assumed.

Results: Considerable reductions in MPC were achieved with both frequent therapies compared with ICHD. Similar, less pronounced, reductions were also found when RRC-B2M was gradually increased from 0 to 4 ml/min. NHD in patients without RRF and ICHD in patients with RRC-B2M of 4 ml/min resulted in comparable reductions.

	RRC-B2M (ml/min)	0	1	2	3	4
ICHD	MPC (mg/L) / Reduction (% a)	35.8 / NA	30.0 / 16.1	25.8 / 28.0	22.6 / 37.0	20.1 / 44.0
SDHD	MPC (mg/L) / Reduction (% b)	28.9 / 19.3	25.1 / 16.6	22.1 / 14.4	19.8 / 12.6	17.8 / 11.1
NHD	MPC (mg/L) / Reduction (% b)	19.6 / 45.3	17.9 / 40.4	16.5 / 36.2	15.2 / 32.6	14.2 / 29.4
a	Reduction in MPC calculated with respect to ICHD when RRC-B2M=0					
b	Reduction in MPC calculated with respect to ICHD at the corresponding value of RRC-B2M					

Conclusions: These simulations show that frequent HD therapies may help achieve considerable reductions in serum B2M levels in patients with and without RRF.

FR-PO1722

PD-Associated Peritonitis as a Risk Factor for the Development of Encapsulating Peritoneal Sclerosis (EPS): The Historical Cohort Study of Fifty Patients with EPS in Japanese Single Center Masatsugu Nakao, Keitaro Yokoyama, Yudo Tanno, Ichiro Ohkido, Hiroshi Hayakawa, Masato Ikeda, Hiroyasu Yamamoto, Tatsuo Hosoya. *Division of Nephrology and Hypertension, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan.*

Background: Encapsulating peritoneal sclerosis (EPS) is a serious complication that occurs in peritoneal dialysis (PD) patients. PD-associated peritonitis is speculated to be involved in the pathogenesis of EPS, however there have been very few statistical reports.

Methods: To evaluate PD-associated peritonitis as a risk factor for EPS, we compared a group of 50 PD patients who developed EPS with a group of 57 PD patients who did not develop EPS in the number of PD-associated peritonitis episodes, the causative organisms, and the duration of treatment.

Results: In this study, as we previous reported, a high permeability on peritoneal function testing and the β2MG level were examined as predictors of EPS. Comparison between the EPS and non-EPS groups yielded the following serum levels: 33.8 ± 8.54 vs. 29.2 ± 8.18 for β2 MG (P = 0.0062), 3.82 ± 5.38 vs. 0.20 ± 0.28 for CRP (P = 0.0000017), and 0.82 ± 0.10 vs. 0.67± 0.12 for D/PCr (P = 0.0000032). In addition, a past history of peritonitis was significantly more common (P = 0.0073) and the number of peritonitis episodes was significantly higher (1.80 ± 2.19 vs. 0.75 ± 1.07, P = 0.0019) in the EPS group. Moreover, the duration of treatment of peritonitis was significantly longer in the EPS group than in the non-EPS group (18.11 ± 15.3 vs. 10.2 ± 4.90, P = 0.002).On the other hand, *Streptococcus sp.* was more common causative organisms in the non-EPS group than in the EPS group. Oppositely *Staphylococcus aureus* was more common causative organisms in the EPS group. These results might indicate that the prevalence of antibiotic-resistant peritonitis is higher in the EPS group.

Conclusions: The number of peritonitis episodes and the prevalence of antibiotic-resistant peritonitis might be associated with the development of EPS.

FR-PO1723

Macrophage Infiltration and Factor V Expression in the Peritoneum through Peritoneal Dialysis Hideki Nosaka,[1] Michiko Bessho,[2] Toshiya Takeda,[3] Fumiaki Nogaki,[1] Yoshiaki Isogawa,[3] Tomomi Takeda,[3] Keiko Nomura,[3] Yoko Matsuo,[4] Noriko Mori,[4] Takahiko Ono.[1] *[1]Shimada Municipal Hospital, Shimada, Japan; [2]University of Shizuoka, Japan; [3]Kyoto Takeda Hospital, Kyoto, Japan; [4]Shizuoka General Hospital, Shizuoka, Japan.*

Background: Fibrin deposition was frequently observed in peritoneal fibrosis induced with long-term peritoneal dialysis (PD). Factor V in its active form (Va) serves as a membrane-bound cofactor to factor Xa, which facilitates activation of prothrombin to thrombin. Previously we have reported that expression of factor V in infiltrated macrophages, together with factor X deposition, progressed fibrosis in an experimental model (Perit Dial Int 29: 340-351, 2009). In the present study, we have conducted a clinicopathological study to examine factor V expression in the peritoneum through PD.

Methods: Peritoneal specimens were obtained at the opportunity of PD tube exchange, removal, or reinsertion in ten cases. Those included one case of encapsulating peritoneal sclerosis (EPS), one case of peritoneal fibrosis, three cases of peritonitis, three cases of reintroduction after each pause of PD, and two cases of tunnel infection. Specimens from ten cases at initiation of PD were evaluated as pre-PD controls, and compared with PD cases. Factor V was detected with a specific rabbit antibody, and macrophages were stained with a monoclonal anti-CD 68 antibody.

Results: In all pre-PD specimens, CD-68-positive cells infiltration was negatively or scarcely observed. CD-68-positive cells were moderate- or abundantly observed in the peritoneal specimens with EPS, peritoneal fibrosis, or peritonitis: spindle-shaped morphology in the EPS case, and rounded in the peritonitis cases. Accordingly, factor V-positive cells were also observed in the same manner as CD-68-positive cells. The frequency of CD-68-positive cells infiltration was significantly correlated with that of factor V-positive cells ($p < 0.01$).

Conclusions: Present data suggest that the factor V expression in macrophages may be induced in the peritoneum through inflammation during PD procedures, and that macrophages may change morphology from round to spindle-shape in the advanced phase.

FR-PO1724

Reduced Sodium Sieving on Chronic Peritoneal Dialysis: Clinical and Physiologic Correlates Javier De Arteaga,[1,2] Carlos R. Chiurchiu,[1,2] Walter Guillermo Douthat,[1,2] Jorge Luis De la Fuente.[1,2] *[1]Nephrology, Hospital Privado, Cordoba, Argentina; [2]Postgraduate Nephrology, Catholic University, Cordoba, Argentina.*

Background: A reduced sodium sieving (RNAS) during a hypertonic glucose dwell can be the consequence of aquaporin dysfunction or a reduced osmotic conductance to glucose. Also has been claimed that a high transport status associates to RNAS. Other clinical correlates that could be associated to this situation like pts age, gender , previous transplants or total dialysis time have not been extensively evaluated.**Objective**: to study these clinical and physiologic variables that could be linked to RNAS in our chronic PD pts.

Methods: Since 2001, modified PET (4.25%) tests have been done yearly with ultrafiltration measured every hour mannualy in 46 chronic PD pts. In PET, initial plasmatic and hourly dialysate NA were analysed by ISE (indirect ion selective electrode). A High transport state was defined as a D/P creat > 0.81 at 4hs and RNAS was defined as a delta NA (dialysate NA 60 min- dialysate NA time 0) < 4.5. In 3 RNAS pts osmotic conductance to glucose was evaluated by a UNIPET.(Lamilia ,2010). None of these patients has an ultrafiltration failure (UF < 400cc at 4 hs)

Results:

Gr 1: (Reduced NA sieving): vs Gr 2: (normal)

	Group1.	Group2:	P value
N	11	35	
OCG (n=3)*	4,45 ± 0,64	_	_
D/P Cr 4hs	0,87 ± 0,056	0,76 ± 0,10	0,0006
Age (ys)	52,81 ± 17,16	51,2 ± 13,43	0,82
Total DP (ms)	23,64 ± 17,16	29,77 ± 30,94	0,75
Total dialysis(ms)	31,27 ± 26,72	43,72 ± 37,14	0,26
Gender (Fem)	18%	54,28%	0,10
Transport High	90,99%	31,43%	0,0006
Transplant (yes)	36%	25,71%	0,37

* osmotic conductance for glucose (UNIPET)

Conclusions: 11 patients (23.9%) have a reduced sodium sieving (RNAS). There is a strong association with a high transport state (p <.0.0006). A reduced osmotic conductance for glucose was not associated to RNAS in the only 3 patients evaluated (unipet).Although not significant (p< 0.10), there seems to be a trend towards a male gender in the RNAS group of our population.

FR-PO1725

Risk Factors for Mortality in Stable Peritoneal Dialysis Patients Seokhui Kang, Jun-Young Do, Kyu-Hyang Cho, Jong-Won Park, Kyung-Woo Yoon. *Division of Nephrology, Departement of Internal Medicine, Yeungnam University Hospital, Daegu, Korea.*

Background: Peritoneal dialysis (PD) is an established treatment modality for patients with end stage renal disease (ESRD). The mortality rates of ESRD patients have significantly declined over the past decade. However, there are few reports on the risk factor for mortality in stable PD patients who survive for a considerable time.

Methods: We reviewed the medical records and we identified all the adult patients who received PD. Among these patients, those with <2 years of follow-up were excluded. Two hundred thirty-six patients were enrolled. The following data was documented from the patients' record: age at the initiation of PD, gender, the laboratory findings, the comorbidities (Davies index) and survival.

Results: The mean follow-up was 62.4 ± 24.2 months. The cumulative survival was 95.5% at 3 years and 80.3% at 5 years. On the univariate regression analysis, old age (>60-years-of-age), hypoalbuminemia, low residual renal function (RRF) (≤4 ml/min) and a high Davies index were associated with increased mortality for the stable PD patients. On the multivariate analysis, old age, low RRF and a high Davies index were proved to be the independent risk factors for mortality.

Table 1. Predictive factors affecting the mortality of long-term survivors on PD

Variables	Univariate analysis		Multivariate analysis	
	Odd ratio	p-value	Odd ratio	p-value
Age at the initiation of PD (≥60-years)	4.169 (2.350-7.395)	0.000	4.542 (2.446-8.436)	0.000
Gender (Female)	0.850 (0.505-1.429)	0.540		
TA-albumin (≤35g/L)	2.015 (1.198-3.391)	0.008	1.123 (0.627-2.010)	0.697
TA-CRP (≥5mg/L)	1.672 (0.975-2.868)	0.062	1.296 (0.725-2.318)	0.381
RRF (≤4ml/min) at 24 months	2.380 (1.021-5.548)	0.045	2.876 (1.178-7.021)	0.020
Davies index				
Low risk (reference)	1		1	
Intermediate risk	3.410 (1.703-6.828)	0.001	3.552 (1.727-7.307)	0.001
High risk	8.348 (3.147-22.143)	0.000	6.112 (2.132-17.516)	0.001

Abbreviations: CI, confidence interval; PD, peritoneal dialysis; TA, time-average; CRP, C-reactive protein; BMI, body mass index; RAS, rennin-angiotensin system; RRF, residual renal function.

Conclusions: The preservation of the RRF and proper management of the comorbidities may help to improve the survival of stable PD patients.

FR-PO1726

Efficacy of Lanthanum Carbonate in Patients on Peritoneal Dialysis: An Opportunity To Improve Nutrition? Rosamund Wilson,[1] Maggie Gill,[2] John Brian Copley.[3] *[1]Spica Consultants, Marlborough, United Kingdom; [2]Shire Pharmaceuticals, Basingstoke, United Kingdom; [3]Shire Pharmaceuticals, Wayne.*

Background: There may be an increase in the use of peritoneal dialysis (PD) in patients with chronic kidney disease (CKD) in the USA as a result of recent changes in dialysis reimbursement. Both PD and dietary phosphate restriction may have a negative effect on nutritional status so the use of an effective phosphate binder to control hyperphosphatemia may allow higher protein intake. This analysis assesses the efficacy of the non-calcium, non-resin phosphate binder lanthanum carbonate (LC) in reducing serum phosphorus (P) in patients on continuous ambulatory PD (CAPD).

Methods: This was a double-blind, placebo-controlled, parallel-group study, conducted in two parts. Part 1 involved dose titration up to 2250mg/day of LC over a 4-week period to achieve P<5.57mg/dL. In part 2 (a double-blind period), patients were randomized to receive their maintenance dose of LC or matching placebo for 4 weeks.

Results: Patients enrolled in this study had albumin levels of approximately 3.8g/dL (normal range=3.4–5.4g/dL) and these levels were maintained during LC treatment. Twenty-one patients receiving CAPD entered the double-blind phase; 10 were randomized to LC and 11 to placebo. At the end of treatment, 60% of patients treated with LC had controlled P (4.03–5.57mg/dL) vs. 10.0% in the placebo group. There was no difference in P levels between treatment groups at the start of the double blind phase (LC=4.87mg/dL, placebo=4.89mg/dL; *P*=0.96), but there was a significant difference at last visit (LC=4.83 mg/dL, placebo=6.96 mg/dL; *P*=0.0015). The most common adverse events during LC treatment were vomiting (26%) and nausea (23%) in part 1 and localized infection (20%, not considered related to LC) in part 2.

Conclusions: Patients on PD may require higher protein intake than those on hemodialysis, so it is important not to impair nutritional status while controlling serum P. Treatment with LC resulted in significantly reduced P levels in patients receiving CAPD at doses up to 2250mg. The more commonly used dose of 3000mg may be expected to give further reductions, possibly allowing greater protein intake.

FR-PO1727

Baseline Residual Renal Function and Female Sex Are Associated with Technique Survival in Incident Peritoneal Dialysis Patients Kai Lu,[1] Jason Jones,[2] David C. Selevan,[3] Peggy Balcius,[2] Victoria A. Kumar.[1] *[1]Nephrology, SCPMG, Los Angeles, CA; [2]Research and Evaluation, SCPMG, Pasadena, CA; [3]Renal Business Group, SCPMG, Pasadena, CA.*

Background: Previous studies have reported that technique survival for peritoneal dialysis (PD) patients is highest in our region (Network 18) compared to the rest of the nation. We therefore sought to examine predictors of technique survival in a cohort of PD patients at a large healthcare maintenance organization.

Methods: We identified all adult patients in our database who initiated PD at our institution between January 1, 2001 and December 31, 2010. We included only patients with a renal creatinine clearance ($rCrCl_0$) and a total creatinine clearance ($totCrCl_0$) at initiation of PD. Baseline peritoneal creatinine clearance ($pCrCl_0$) was obtained by subtraction of $rCrCl_0$ from $totCrCl_0$ Patients who received a renal transplant during the study period were censored from the analysis. A Cox proportional hazards model was used to individually evaluate the effect of $rCrCl_0$, $pCrCl_0$ and $totCrCl_0$ on technique survival after adjusting for age, sex and Charleson Comorbidity Index (CCI).

Results: Baseline patient demographics are shown in Table.

Patient demographics

Number of patients	647
Median age in years	56.8 (47.5-65.6*)
Number of females (%)	296 (45.7)
CCI	6 (3-7*)
Number of diabetics (%)	399 (61.7)
PD as first modality (%)	402 (62.1)

* 95% Confidence Interval (CI)

Median technique survival for our patients was 4.64 years (CI 3.57-5.68). For each 10L/week increment in $rCrCl_0$ and $totCrCl_0$, there was a 4% increase in technique survival (Hazard ratio [HR] 0.996 for both, CI 0.996-0.999, p=0.006 and 0.0996-0.999, p=0.007, respectively). The HR for $pCrCl_0$ was 1.0 (CI 0.995-1.003, p=0.947). Female sex predicted technique survival in all 3 models, most strongly in the $rCrCl_0$ model (HR 0.582, CI 0.441-0.769, p<0.001).

Conclusions: $rCrCl_0$ and $totCrCl_0$ are associated with PD technique survival, but $pCrCl_0$ is not. Baseline renal function and female sex appear to be the strongest predictors of technique survival in our patients.

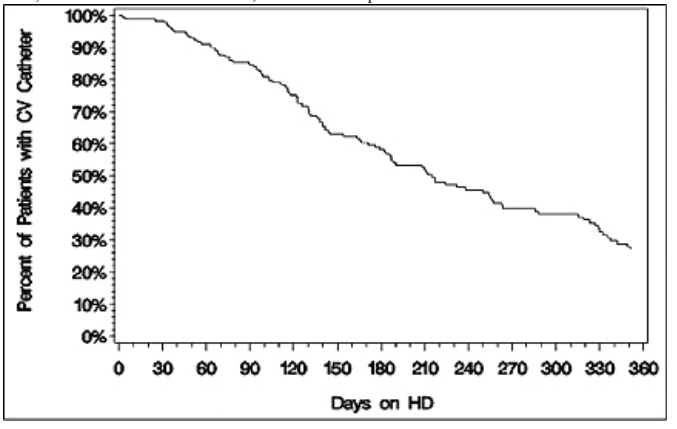
FR-PO1728

Vascular Access Use in Patients Who Transfer from Peritoneal Dialysis to Hemodialysis Leslie P. Wong, Sumi J. Sun, David Francis Nash. *Medical and Clinical Affairs, Satellite Healthcare, San Jose, CA.*

Background: PD dropout is common, with 45% of incident patients leaving PD by 2 years. Many patients transfer to HD and require vascular access. Unfortunately, there is little data describing access use and outcomes in these patients.

Methods: We analyzed the Satellite Healthcare database between January 1993 and May 2010 for patients who transferred from PD to HD. After excluding 432 records with insufficient data or multiple transfers, 439 patients were studied. One-year outcomes included probability of central venous catheter (CVC) use over time, rate of access or bacteremia-related hospitalization and subsequent modality status.

Results: Demographics were: mean age 63, 56% white, 55% male, 49% DM, 13% CHF, 95% Kt/V > 1.7, 85% high transporters, 31% with residual kidney function and 75% with albumin < 3.5. Median duration on PD was 358 days and 48% were incident PD patients. Leading reasons for transfer were peritonitis 15% and psychosocial 11% but only recorded for 42% of patients. Sixty-six percent of patients transferred to HD with a CVC. More incident PD patients started with a CVC (73%) compared to patients with prior HD (59%) p=0.003. Median number of CVC days was 215, with 84% of patients still using a CVC after 90 days (see figure). Forty percent of CVC patients switched to an AVF/AVG within 1 year. Access or bacteremia-related hospitalization rate was 49 admissions/1000 patient years and did not differ between groups. At 1 year 53% of patients remained on HD, 15% died, 21% transferred back to PD, 3% were transplanted and 8% moved.



Conclusions: CVC use predominates in patients who transferred from PD to HD. Though most patients stayed on HD, conversion to AVF/AVG was suboptimal. Hospitalization rate was not higher for CVC patients but may reflect underreporting. Vascular access planning for PD patients warrants further study.

FR-PO1729

Modeling Intraperitoneal Cefazolin and Cefepime for Nocturnal Intermittent Peritoneal Dialysis Pisut Katavetin, Talerngsak Kanjanabuch, Kriang Tungsanga, Somchai Eiam-Ong. *Divsion of Nephrology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand.*

Background: Nocturnal intermittent peritoneal dialysis (NIPD) has been increasingly. Cefazolin and cefepime are the principal drugs for treatment of peritoneal dialysis (PD)-related peritonitis. Current guideline suggested daily intraperitoneal (IP) administration of drugs in the additional long day dwell which is not always practical. We, therefore, developed a mathematical model to test whether intermittent IP drug delivery into the first bag (5 liter) of NIPD could yield an optimal antibiotics level both in serum and in peritoneal fluid in patients undergoing 10 liters (L) NIPD in 5 cycles over 12 hours.

Methods: Two-compartment, fixed volume model for pharmacokinetics of cefazolin and cefepime in PD patients were developed. Level of cefazolin and cefepime in serum and in dialysate were then calculated according to the model using the pharmacokinetic parameters derived from the literature. The concentration of antibiotics in the PD fluid of the second to fifth cycle were assume to be about 0.6 time of that in the previous cycle due to the dilution of antibiotics by adding 2 L of fresh PD fluid from the second bag into the remaining 3 L first antibiotics containing bag.

Results: In a 70 kilogram (kg) NIPD patient, adding 1.5 gram (g) of cefazolin in the first 5 L bag of NIPD could yield optimal serum and peritoneal antibiotics concentration during the on-cycler period but may yield marginal concentration in peritoneal fluid (6-7 µg/ml) despite adequate serum concentration during the off-cycler period. For cefepime, 1 g of cefepime in 70 kg patient could yield optimal serum and peritoneal antibiotics concentration during both on-cycler and off-cylcer period although there was a considerably delay in time to reach optimal serum concentration in the first day. Increasing dose of cefepime to 1.5 g could ameliorate this problem.

Conclusions: Intermittent intraperitoneal administration of cefazolin and cefepime in the first bag of NIPD is a reasonable option for treatment of NIPD-related peritonitis with favorably increasing dose by 1.5 time.

FR-PO1730

Periostin- A Matricellular Protein Involved in Peritoneal Injury during Peritoneal Dialysis Niko Braun,[1] Kontheari Sen,[2] Mark Dominik Alscher,[1] Peter Fritz,[3] Martin Kimmel,[1] Achim Joerres,[4] Clemens D. Cohen,[2] Stephan Segerer.[2] *[1]Department of Internal Medicine, Division of Nephrology, Robert-Bosch Hospital, Stuttgart, Germany; [2]Division of Nephrology, University Hospital Zurich, Switzerland; [3]Department of Diagnostic Medicine, Division of Pathology, Stuttgart, Germany; [4]Department of Nephrology and Medical Intensive Care, Charité-Universitätsmedizin, Campus Virchow-Klinikum, Berlin, Germany.*

Background: Periostin is a matricellular protein involved in tissue remodelling. We hypothesized that this protein might be expressed in the peritoneal cavity of patients on peritoneal dialysis (PD) and patients with signs of encapsulating peritoneal sclerosis (EPS).

Methods: We localized periostin in peritoneal biopsies from patients on PD with EPS (n=7), on PD without signs of EPS (n=10), and compared it with biopsies taken during hernia repair as controls (n=11).

Results: Periostin was found in the wall of larger arteries and focally in the submesothelial zone in control biopsies. Patients on PD demonstrated interstitial periostin in variable amounts depending on the severity of submesothelial fibrosis. In EPS there was a very prominent expression in the sclerosis layer. Commonly the superficial layer was periostin negative. A semiquantitative score was most prominently associated with the diagnosis of EPS, as well as with the thickness of the submesothelial fibrosis zone.

Conclusions: Periostin is expressed in EPS and to a lesser extend in simple peritoneal sclerosis. It might play a role in the progression of peritoneal injury.

FR-PO1731

Bone Mineral Density and Abdominal Aortic Calcifications Detected by Computed Tomography in Peritoneal Dialysis Patients Pierluigi Di Loreto, Francesca K. Martino, Claudio Ronco. *Nephrology Dialysis Transplantation, San Bortolo Hospital, Vicenza, Italy.*

Background: Bone mineral density (BMD) is negatively correlated with vascular calcification and cardiovascular risk in CKD pts. Aim of this study is to confirm these observations in Peritoneal Dialysis (PD) patients.

Methods: We studied 45 PD patients (mean age 61,9 ±14,5 years, 41,3% Women and 58,7% Man, mean age Man 65,7±11 Y, Women 56,2±17 Y p=0,031 for sex) mean duration of PD was 21,9±25,4 months. These patients underwent an abdominal computerized tomography scan. The severity score for Abdominal aortic Calcifications (AOC) was: 1=none, 2=mild, 3=moderate, 4=severe. For each patient we collected the following laboratory data: calcium corrected for albumin, PTH, phosphorus, alkaline phosphatase, haemoglobin, BMI, diuresis, KT/V, use of Vitamin D, Cinacalcet, phosphate binders, ESA, warfarin. Quantitative CT measurements of BMD (mg/ml) using fully automated software were obtained at the first, second, third and fourth lumbar vertebrae. Statistical analysis was performed with SPSS.

Results: We found a negative correlation between BMD and age (M p=<0,006, r =-0,516, W p=<0,001, r= -0,763) and between BMD and calcium in women (p=0,037, r = 0,481). 25 pts (55,6% Man and 42,1% Women with no statistically significant difference between sexes) were osteoporotic (BMD <160 mg/ml), and respectively 14 and 11 of them showed severe and mild AOC. After 2 years the overall prevalence of fracture was 15,5% (7 pts). 12 pts (26%) died. All the pts who died and those with fracture showed a low BMD and a severe AOC. No correlations was found between laboratory data, BMI, diuresis, KT/V, use of medications, lenght of dialisys and BMD-AOC.

Conclusions: Our data confirm that low BMD is correlated with age, vascular calcification and cardiovascular risk as in CKD pts. We could not confirm the findings of other Authors who suggested that low body weight and low KT/V were the most important risk factors for low BMD in PD pts

FR-PO1732

Effects of Spironolactone on Residual Renal Function in Patients Receiving Peritoneal Dialysis Berna Yelken,[1] Numan Gorgulu,[2] Meltem Gursu,[3] Yasar Caliskan,[4] Halil Yazici,[4] Ay?egül Telci,[5] Rumeyza Kazancioglu,[6] Tevfik Ecder,[4] Semra Bozfakioglu.[4] *[1]Division of Nephrology, Department of Internal Medicine, Gaziosmanpasa Faculty of Medicine, Gaziosmanpasa University, Tokat, Turkey; [2]Division of Nephrology, Memorial Hospital, Istanbul, Turkey; [3]Division of Nephrology, Department of Internal Medicine, Haseki Education and Research Hospital, Istanbul, Turkey; [4]Division of Nephrology, Department of Internal Medicine, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey; [5]Department of Biochemistry, Istanbul Faculty of Medicine, Istanbul University, Turkey; [6]Faculty of Medicine, Bezmialem vakif university, Istanbul, Turkey.*

Background: There is increasing evidence that long-term peritoneal dialysis (PD) is associated with structural changes in the peritoneal membrane. It is unknown whether spironolactone affects RRF in addition to the structural changes in the peritoneal membrane.

Methods: 23 (13 female) patients with RRF (>400 ml/day) receiving PD were evaluated.After measuring baseline serum high sensitive C-reactive protein (hs-CRP), vascular endothelial growth factor (VEGF), transforming growth factor beta (TGF-β), connective tissue growth factor (CTGF) and N- terminal pro-B-type natriuretic peptide (NT-proBNP) level, ultrafiltration (ml/day), RRF, creatinine clearance (CrCL), Kt/V, normalized protein catabolic rate (nPCR), peritoneal transport status and dialysate CA125 level and VEGF, spironolactone (25 mg daily) therapy was given for six months. At the end of six months all measurements were repeated.

Results: The mean age of the patients was 46±13 years. Duration of PD was 15±21 months (range; 2-88). After spironolactone therapy, the mean dialysate CA125 level significantly increased as compared to baseline (20.52±12.06 U/ml vs. 24.44±13.97 U/ml; p=0.028).Serum hs-CRP, VEGF, TGF-β, CTGF and NT-proBNP levels, dialysate VEGF levels, daily ultrafiltration, Kt/V, nPCR and peritoneal transport status of patients were similar between two study periods. There was no decrease in RRF and CrCL at the end of six months.

Conclusions: Spironolactone therapy for six months appears to preserve RRF and peritoneal structure in patients with PD.

FR-PO1733

Agreement between Peripheral Venous and Arterial Blood Gas Measurements in the Intensive Care Unit Ho Sik Shin, Jin Hee Park, Sung Bin Kim, Yeon Soon Jung, Hark Rim. *Internal Medicine, Kosin University College of Medicine, Busan, Korea.*

Background: Venous blood gas (VBG) analysis is safer than arterial blood gas (ABG) analysis and may be a suitable alternative for determining acid-base status. The objective of this study was to examine the agreement between ABG and peripheral VBG samples for all commonly used parameters in medical intensive care unit (ICU) patients.

Methods: We performed a single-center, prospective trial to assess the agreement between arterial and peripheral VBG measurements in a medical ICU. When an ABG was deemed necessary as part of ICU management, a peripheral venous sample was also obtained within 2 minutes to examine the agreements among the pH, PCO_2, bicarbonate and total CO_2 measurements. All of the samples were immediately analyzed using the same arterial blood gas analyzer. A maximum of 5 paired ABG-VBG samples were obtained per patient to prevent any single patient from dominating the data set.

Results: Regression equations were derived to predict arterial values from venous values as follows: Arterial pH = 0.763 X venous pH + 1.786, arterial bicarbonate = 0.822 X Venous bicarbonate + 2.815 and arterial HCO_3 = 0.639 X Venous total CO_2 + 5.360. The mean ABG minus peripheral VBG differences for pH, PCO_2, and bicarbonate were not clinically important.

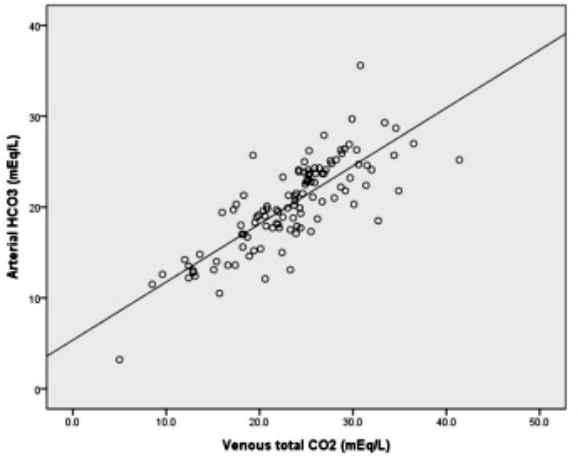


Figure 4. Correlation between peripheral VBG value for total CO_2 and ABG values for HCO_3 R = 0.802, Arterial HCO_3 = 0.639 X Venous total CO_2 + 5.360

Table 1. Patient characteristics

Characteristic	Value
Age (years; mean±SD)	65.5 ± 12.4
Gender (male/female; n %)	20 (58.8) / 14 (41.2)
Intubated (n/N %)	8/34 (23.5)
Hypotensive (n/N %)	30/34 (88.2)
Inotropic agent use (n/N %)	30/34 (88.2)
Primary diagnosis (%)	
Sepsis	14.7
Upper GI bleeding	2.9
Renal failure	67.6
Pneumonia	2.9
Pancreatitis	5.9
Respiratory failure of unknown cause	5.9

Conclusions: Peripheral venous pH, PCO_2, bicarbonate and total CO_2 can replace their arterial equivalents in many clinical contexts encountered in the ICU.

FR-PO1734

A Phase 1, Open-Label Study of Intravenous Conivaptan in Subjects with Renal Impairment Keith Erdman,[1] Michael Roy,[1] Anura Abeyratne,[1] Lisa Plumb,[1] Dennis Riff,[2] Jim Keirns.[1] *[1]Astellas Pharma Global Development, Inc., Deerfield, IL; [2]Advanced Clinical Research Institute, Anaheim, CA.*

Background: Conivaptan is a vasopressin $V_{1A/2}$ receptor antagonist approved for intravenous treatment of euvolemic and hypervolemic hyponatremia in hospitalized patients. This study assessed the pharmacokinetics, protein binding, and safety of conivaptan in subjects with normal renal function or with mild or moderate renal impairment.

Methods: Subjects with normal renal function (Cockroft-Gault formula, eGFR >80mL/min), or mild (50–80 mL/min) or moderate (30-49 mL/min) renal impairment were administered conivaptan as a loading dose of 20 mg intravenously over 30 minutes, followed by a 20 mg/23.5 hour continuous infusion on day 1 and a 20 mg/24 hour continuous infusion on day 2. Serial blood sampling for calculation of conivaptan pharmacokinetic parameters C_{LD}, C_{48}, and $AUC_{0-\infty}$ and urine collection to assess urinary conivaptan excretion began immediately before the start of the loading dose and continued for 96 hours.

Results: Mean pharmacokinetic parameters tended to be higher in the mild renal impairment group due to one subject with a low free fraction and one subject with a spurious conivaptan concentration at hour 24.

Conclusions: Renal Impairment

	Normal (n=8)	Mild (n=8)	Moderate (n=8)
C_{LD} (ng/mL)	548 (151)	794 (251)	592 (185)
C_{48} (ng/mL)	52 (15)	93 (66)	55 (38)
$AUC_{0-\infty}$ (hr•ng/mL)	2857(638)	5053 (2815)	3267(1649)
Fraction unbound	0.0073 (0.0015)	0.0067 (0.0028)	0.0077 (0.0028)
Ae_{last} %	1.5 (0.4)	1.5 (0.2)	1.0 (0.4)
CL_R (L/hr)	0.33 (0.10)	0.22 (0.09)	0.20 (0.08)

Data are mean (SD)

Conivaptan was minimally excreted in the urine and >99% protein bound. Ae_{last}%, renal clearance, and protein binding values were similar across groups. The most frequently reported AEs were associated with infusion site reactions. All events were mild in intensity, there were no serious AEs, and no subjects discontinued from the study.

Conclusions: Conivaptan was well tolerated in all subjects with no indication of safety issues. There were no significant differences in exposure between the 3 groups.

Aggressive and Unnecessary Treatment of Mild Hyperkalemia: Inappropriate Use of Kayexalate Gabriel El-kass, Farhanah Yousaf, Emily Yan, Bruce S. Spinowitz, Chaim Charytan. *Department of Nephrology, New York Hospital Queens, Flushing, NY.*

Background: Although hyperkalemia is potentially a lethal metabolic complication which may require emergent treatment, there is no consensus defining clinically significant hyperkalemia, nor the settings which require K^+ lowering therapy. The literature suggests that clinically significant hyperkalemia occurs at K^+ levels >;6.0 mEq/L with EKG changes or at K^+ >;6.5 mEq/L [Levinsky, 1966; Greenberg, 1998; AHA 2005]. A recent study suggested that even more severe hyperkalemia may not require aggressive therapy nor hospitalization [Charytan D, 2000]. By extrapolation, it may be assumed that lower levels of hyperkalemia might not require aggressive intervention. This becomes particularly important in view of concerns raised about the efficacy and safety of Kayexalate (SPS) [Sterns, 2010]. During an investigation on the efficacy and safety of SPS at our institution, we decided to explore how frequently clinically mild hyperkalemia, a serum K^+ ≤5.6 mEq/L, was treated with SPS with or without additional interventions.

Methods: Medical records of patients ≥18 years receiving SPS in emergency department or as in-patients between June 2010 and August 2010 were reviewed.

Results: 154 patients were prescribed SPS 249 times. Of these, 92 patients, 45 males and 47 females, aged 76.0±13.3 yrs, received 106 doses of SPS for a serum K^+ ≤5.6 mEq/L. SPS was administered as a 30 g dose in 99 cases and as a 15 g dose in 7 cases. 103 doses were given orally, 2 doses rectally, and 1 dose via PEG.

	Pre SPS K+	Post SPS K+	Delta Δ	p Value
Mean±SD	5.37±0.26	4.84±0.66	0.53±0.07	<0.001

31 available EKGs were unremarkable for hyperkalemia-associated changes. 7 patients required K^+ supplements due to subsequent development of hypokalemia.

Conclusions: The above experience suggests that mild clinically insignificant hyperkalemia is often treated aggressively and unnecessarily. Considering the infrequent but potentially serious adverse events associated with SPS, intestinal necrosis and perforation, cost of therapy, and possible unnecessary hospitalization or delayed discharge, it may be appropriate to redefine significant hyperkalemia and develop new therapeutic guidelines.

FR-PO1736

Hospital Pharmacy Guidelines for the Administration of 3% Sodium Chloride in Children Siddharth Shah,[3] Juan Carlos Ayus,[2] Michael L. Moritz.[1] *[1]Pediatrics, Chidlren's Hosptial of Pittsburgh of UPMC; [2]Renal Consultants of Houston; [3]Chidlren's Hospital of Pittsburgh of UPMC.*

Background: Hyponatremic encephalopathy is a medical emergency with the treatment of choice being 3% sodium chloride (NaCl). A 100 cc or 2 cc/kg bolus of 3% NaCl is the preferred therapy (NEJM 2005:353) that has now been accepted as the standard of care (NephSAP 2011:10). We suspect that children's hospital pharmacies may have policies that would restrict the administration of a 3% NaCl bolus due to concerns for overcorrection of hyponatremia.

Methods: An internet survey was distributed to the pharmacy directors of 43 children's hospitals participating in the Child Health Care Corporation of America (CHCA) network in order to assess their policies for administering 3% NaCl.

Results: The response rate was 65%. 71.4% of respondents had policies for the administration of 3% NaCl. The majority of respondents had policies restricting the volume dispensed (53.6%) and rate of administration allowed (67.9%). The majority of pharmacies (57.1%) also would not allow 3% NaCl to be used in a non-ICU setting or via a peripheral IV. Of those who allowed 3% NaCl through a peripheral IV, 57.1% had restrictions on its use. Only 24% of respondents had similar policies for the administration of hypertonic sodium bicarbonate or mannitol.

Conclusions: The majority of children's hospital pharmacies have restrictive policies for the rate, volume, route and setting of administration of 3% NaCl. These restrictive policies could prevent the timely use of a 3% NaCl bolus for the treatment hyponatremic encephalopathy in children.

FR-PO1737

Urine of Patients with Cerebral/Renal Salt-Wasting Syndrome Contains a Substance That Inhibits Reabsorptive Sodium Flux in LLC-PK1 Cells Steven J. Youmans,[1] John K. Maesaka.[2] *[1]Dept. of Biomedical Sciences, NY College of Osteopathic Medicine, NYIT, Old Westbury, NY; [2]Dept. of Medicine, Winthrop University Hospital, Mineola, NY.*

Background: We have proposed that the persistent elevation of fractional excretion (FE) of urate after correction of hyponatremia identifies patients with cerebral/renal salt-wasting syndrome (RSW), being most common in patients with neurosurgical (NS) diseases. Our study sought to demonstrate whether natriuretic activity, previously found in the plasma of NS patients with increased FEurate >10% and normonatremia, is also present in urine. The control population was made up of normonatremic NS patients with normal FEurate and SIADH.

Methods: Ammonium precipitates (ppts) of urine were dialyzed (10 kDa), lyophilized, and quantitated by protein content. Ppts were applied to monolayers of a pig proximal tubule cell line (LLC-PK1) cultured on commercial transwells and the transcellular movement of 22Na was determined over time.

Results: Ppts from 5 of 6 RSW patients inhibited the absorptive sodium flux by -30.5 ±2.9% at 5 µg protein/ml and -31.9±3.3% at 10 µg protein/ml versus 4 Controls

at the same concentrations. (Mean ± SEM, P=.002 and P=.003 at 5 and 10 µg protein/ml respectively; 3-5 repetitions per RSW and 2-4 per Control patient.) It was noted that means for Controls showed some stimulation of Na absorption versus vehicle, which did not reach significance (P=.18 and P=.14). In paired experiments in which different concentrations of RSW ppt were tested in the same run, a dose-response was seen, inhibition being greater for a change from 10 to 20 µg/ml than for a change from 5 to 10 µg/ml (-23.0±3.8% vs. -11.6±4.4% respectively; P=.045).

Conclusions: The results suggest that ammonium precipitable substance(s) in urine from NS patients with increased FEurate and normonatremia inhibits transcellular transport of Na as compared to ppts from normonatremic NS patients with normal FEurate and SIADH. The natriuretic substance may contribute to the renal Na loss seen in RSW. These studies support our proposal that normonatremia with increased FEurate might identify patients with RSW and that RSW is common in NS patients.

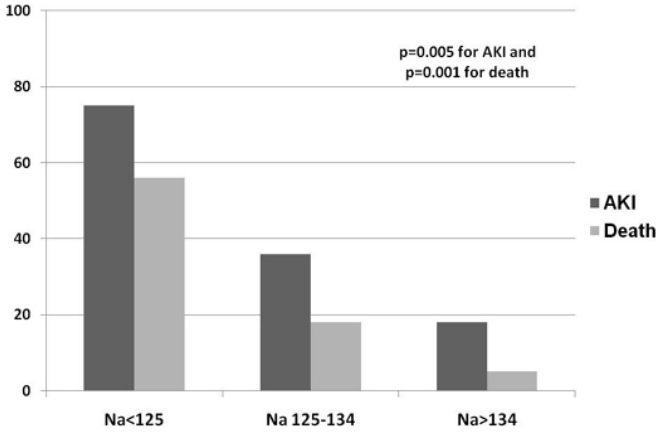
FR-PO1738

Hyponatremia and Acute Kidney Injury (AKI) Are Associated with Mortality in HIV Patients with Neurotoxoplasmosis Alexandre Braga Liborio,[1] Geraldo B. Silva,[1,2] Carolina Gaspar Cavalho Heil Silva,[2] Adalberto Studart Neto,[2] Francisco José Correia Lima Filho,[2] Elizabeth De Francesco Daher.[2] *[1]School of Medicine, University of Fortaleza, Fortaleza, Ceara, Brazil; [2]Department of Internal Medicine, School of Medicine, Federal University of Ceara, Fortaleza, Ceara, Brazil.*

Background: Toxoplasmosis a main cause of neurologic symptoms among HIV-infected patients. AKI has not been studied in this population. Hyponatremia is a potential complication of neurologic-related disorders. The objective of this study is to describe the occurrence of hyponatremia and its relationship with AKI and mortality in HIV-associated neurotoxoplasmosis.

Methods: Retrospective cohort of patients with HIV-related neurotoxoplasmosis. AKI was considered only if RIFLE criteria were achieved after hospital admission. Serum creatinine (Scr) at admission was considered baeline Scr.

Results: A total of 92 patients were included, with an average age of 36 +/- 9 years old; 73.9% were male. Hyponatremia at admission was observed in 40 (43.4%) patients and AKI developed in 25(27.1%) during hospital-stay. Sulfadiazine was the choice treatment in 81% of cases and SMZ-TMT in the remaining, with no difference in AKI-occurrence. Death occurred in 13 cases (14.1%). Sodium level was associated with AKI and mortality.



After adjusting for other clinical and laboratory variables, only male gender (OR 7.89, p=0.03) and hyponatremia at admission (OR 4.73, p=0.02) were predictors for AKI. Independent risk factors for death were AKI (OR 8.3, p<0.0001), hyponatremia (OR 9.9, p<0.0001) and diarrhea (OR 5.86, p<0.053).

Conclusions: Hyponatremia and AKI are common events in neurotoxoplasmosis and are associated with mortality. As patients presented hyponatremia at admisson and developed AKI during hospital-stay, we suggest hyponatremia is a primary event in this population and may have a causative role in AKI-development.

FR-PO1739

Association of Hyponatremia and Hypernatremia with Mortality in Burn Patients Molly A. Tilley,[1] Ian J. Stewart,[1] Benjamin D. Morrow,[1] Keith W. Kramer,[1] Chris A. Gisler,[2] James K. Aden,[3] Evan Renz,[3] Kevin Chung.[3] *[1]San Antonio Military Medical Center; [2]University Texas Health Sciences Center San Antonio; [3]Burn Center, US Army Institute of Surgical Research.*

Background: Dysnatremias are associated with mortality in many groups. However, this relationship has not been well described in burn patients. Our study seeks to determine if moderate to severe hyponatremia or hypernatremia are independently associated with mortality in this population.

Methods: We examined all admissions to our institution's burn center from January 2003 to December 2008. Patients were included if they were at least 18 years old and had a serum sodium obtained during their hospitalization. Exclusion criteria included end stage renal disease and death within 24 hours of admission. Independent variables included age, gender, percentage total body surface area burned (%TBSA), percentage of third degree burn, inhalation injury, injury severity score (ISS), Acute Kidney Injury Network (AKIN) stage, hypernatremia, and hyponatremia. These variables were examined via multiple logistic regression analysis against death. Moderate to severe hyponatremia and hypernatremia were defined as serum sodium less than 130mmol/l and greater than 150mmol/l, respectively.

Results: In 1973 subjects with a mean age of 36±16, average %TBSA of 16±18, and average ISS of 10±12, hypernatremia occurred in 9.8% (n=194) while hyponatremia occurred in 7.0 % (n=138) during their admission. Overall in-hospital mortality was 7.6% (n=150). Among those with hypernatremia and hyponatremia, mortality was 33.5% and 13.5% respectively which were both significantly higher than the mortality rate (4.5% and 6.8%) among those without these abnormalities (p<0.0001 and p=0.0027, respectively). On multiple logistic regression, however, only age, %TBSA, ISS, and AKIN stage were found to be significant predictors of mortality. Hypernatremia (OR 0.66, 95% CI 0.35-1.25, p=0.20) and hyponatremia (OR 0.46, 95% CI 0.21-1.03, p=0.06) were not.

Conclusions: In contradistinction to other groups, neither hyponatremia nor hypernatremia are independent predictors of mortality in the burn population.

Funding: Other U.S. Government Support

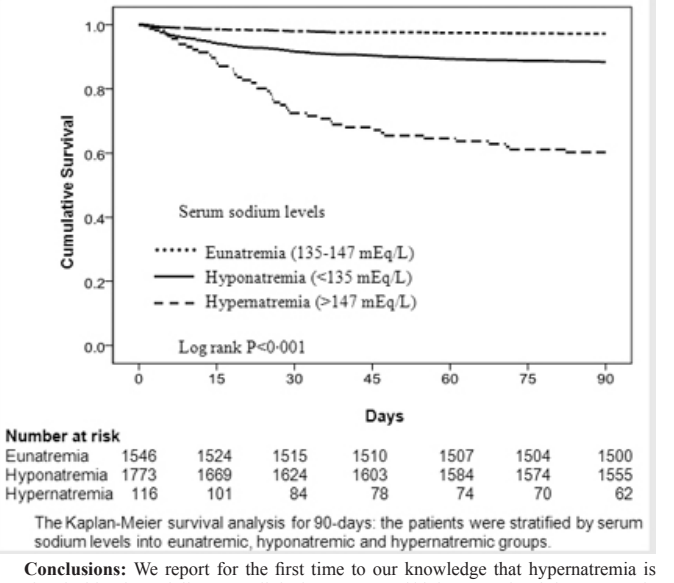
FR-PO1740

The Cost and Clinical Outcomes of Hypernatremia in Hospitalized Cancer Patients Elson Thomas,[1,2] Simit Doshi,[2] Amit Lahoti,[2] Abdulla K. Salahudeen.[2] *[1]Department of Internal Medicine, Division of Renal Disease & Hypertension, University of Texas Medical School at Houston, TX; [2]Division of Internal Medicine, UT MD Anderson Cancer Center, Houston, TX.*

Background: Disorders of sodium balance are the most common of the electrolyte abnormalities seen in clinical practice. However, unlike hyponatremia, little is known about hypernatremia, especially related to outcomes. The objective was to evaluate the frequency and severity of hypernatremia in patients admitted to the hospital and its associations with clinical outcomes and hospital costs.

Methods: We analyzed prospectively collected data on patients with cancer admitted to the UT MD Anderson Cancer Center over a 3-month period in 2006. Clinical outcomes and costs were compared among hypernatremics, eunatremics and hyponatremics (serum Na >147 mEq/L, 135-147 mEq/L and <135 mEq/L, respectively).

Results: Of 3886 patients admitted, 3%, 46% and 51% were respectively hypernatremic, eunatremic and hyponatremic. The length of hospital stay in hypernatremics was 4-fold higher than eunatremics (e.g., 27 ± 22 days vs. 6 ± 5 days, p < 0.001) and 2-fold higher than hyponatremics. Moreover, the multivariate hazard ratios (HR) for mortality of hypernatremics were significantly higher than eunatremics (in-hospital HR: 3.83, 95% CI: 2.10 - 6.95; p<0·001 and 90-day HR: 10.20, 95% CI: 6.50-15.99; p<0·001) or hyponatremics (in-hospital HR: 1.73, 95% CI: 1.20-2.50; p<0.005 and 90-day HR: 2.99, 95% CI: 2.14-4.20; p<0.001) (see figure: survival curve). The cost was higher for hypernatremics compared to rest of the groups (46% higher than eunatremics, 37% higher than hyponatremics; p<0.001 for both).



The Kaplan-Meier survival analysis for 90-days: the patients were stratified by serum sodium levels into eunatremic, hyponatremic and hypernatremic groups.

Conclusions: We report for the first time to our knowledge that hypernatremia is associated with substantially worse clinical outcomes and higher costs than is hyponatremia and eunatremia. These findings warrant similar studies in non-cancer patients.

FR-PO1741

Inverse Correlation of Serum Sodium Level with Body Temperature in Children with Common Febrile Diseases Hideki Matsumura,[#1] Akira Ashida,[#2] Akihiko Shirasu,[#2] Hyogo Nkakura,[#2] Motoshi Hattori,[#3] Hiroshi Tamai.[#2] *[1]Pediatrics, Hirakata City Hosptital, Osaka, Japan; [2]Pediatrics, Osaka Medical College, Osaka, Japan; [3]Pediatric Nephrology, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Hyponatremia is a common electrolyte abnormality in hospitalized patients. Routine use of hypotonic maintenance fluids can lead to potentially fatal hyponatremia in cases of excess antidiuretic hormone (ADH) production. Several studies have demonstrated that non-osmotic ADH activity contributes to the development or persistence of hyponatremia in children with common febrile diseases. However, as the relationship between hyponatremia and body temperature has remained unclear, we examined this relationship in children with common diseases.

Methods: In this retrospective case study based on chart review, 2,027 children (1,150 males and 877 females, 1,418 febrile and 609 non-febrile patients) presenting with acute illnesses at Hirakata City Hospital, between November 2008 and October 2009 and for whom blood test data were available, were enrolled. The median age of this cohort was 2.7 years and the mean serum sodium concentration was 136.5 mEq/L: 454 of the 2,027 patients showed hyponatremia, with a serum sodium level of <135 mEq/L. The patients were classified into four groups on the basis of body temperature: <37°C, 37°C (37.0 - 37.9), 38°C (38.0 - 38.9) and ≥39°C, and serum sodium concentration was compared among them.

Results: The mean sodium level was significantly lower in febrile than in non-febrile patients: 135.7 mEq/L (95%CI, 135.5 - 135.8) versus 138.4 mEq/L (138.2 - 138.6), respectively. The serum sodium levels in the temperature groups were in ascending order, 138.6mEq/L (138.4 - 138.8), 137.3 mEq/L (137.1 - 137.6), 136.1 mEq/L (135.8 - 136.3) and 134.6 mEq/L (134.4 - 134.9), respectively. The serum sodium level in each individual temperature range was significantly different from that in the others, and became lower as the body temperature increased.

Conclusions: Fever may play an important role in the development of hyponatremia in children with common febrile diseases. Care is necessary when administering intravenous fluid to febrile pediatric patients.

FR-PO1742

Severe Hyperkalemia Requiring Hospitalization; Predictors of Mortality and Improvement Jung Nam An,[1] Jung Pyo Lee,[1,2] Yun Kyu Oh,[1,2] Chun Soo Lim.[1,2] *[1]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea; [2]Department of Internal Medicine, Seoul National University Boramae Medical Center, Seoul, Korea.*

Background: Severe hyperkalemia (K≥6.5mEq/L) is a potentially life-threatening electrolyte disorder. To treat it promptly and effectively, it is essential to know its causes, risk factors, clinical manifestations, and predictors of mortality and improvement.

Methods: A total of 610 Korean patients over age 18 who were hospitalized with a diagnosis of severe hyperkalemia from August 2007 to July 2010 became the subject of this retrospective study. The medical records were reviewed.

Results: Hypertension was the most common underlying medical condition, followed by diabetes and chronic kidney disease (CKD). The most common precipitating factor was metabolic acidosis, followed by acute kidney injury (AKI), drugs such as angiotensin receptor blocker, K-sparing diuretics, beta blocker, and non-steroidal anti-inflammatory drugs (NSAIDs), and infection. The higher serum potassium levels were significantly associated with the use of NSAIDs, metabolic acidosis, and the history of recurrent severe hyperkalemia. Also, mortality was strongly correlated with the severity of hyperkalemia. Changes in electrocardiogram findings were associated with higher potassium levels, but didn't increase the mortality rate themselves. The mortality rate was higher in patients with underlying disease such as malignancy and severe medical conditions including infection and bleeding. In addition, AKI in patients with normal baseline renal function and metabolic acidosis were definite predictors of mortality. Whereas, mortality rate had a lowering tendency in patients with underlying disease such as hypertension, AKI on underlying CKD, and drug-induced hyperkalemia.

Conclusions: Severe hyperkalemia requiring hospitalization and prompt treatment occurred in various medical conditions. The precipitating factors were also diverse. The mortality rate was especially higher in patients with severe underlying diseases and with new-onset AKI rather than AKI on underlying CKD.

FR-PO1743

Role of Kidney-Specific WNK1 in the Regulation of NCC and ROMK by High Dietary Potassium Intake Zhen Liu, Chou-Long Huang. *Medicine, UT Southwestern Medical Center, Dallas, TX.*

Background: Upregulation of secretory K+ channels including ROMK in the distal nephron is an important adaptive response to high dietary K+ loading. Earlier studies in adrenalectomized animals suggest that the regulation is independent of aldosterone. Recent studies in rodents show that K+ loading also downregulates NCC, which would lead to increased Na+ reabsorption via ENaC and enhance K+ secretion via ROMK. The mechanism for inhibition of NCC by K+ loading remains elusive. An increase in the aldosterone by K+ loading should stimulate NCC. WNK1 is a ubiquitous protein kinase of which increased expression causes hypertension and hyperkalemia. KS-WNK1 is a kidney-specific splice variant of WNK1 and reportedly activates NCC and inhibits ROMK, respectively. High dietary K+ intake stimulates KS-WNK1, and in this study we examine the role of KS-WNK1 in the regulation of NCC and ROMK by K+ loading.

Methods: KS-WNK1-null mice were generated by homologous recombination to delete exon 4A, the unique coding exon of KS-WNK1.

Results: Previously, we reported that KS-WNK1-null mice have Na+ retention, increased surface expression of NCC and elevated blood pressure on a high-Na+ diet compared to WT littermates. Here, we reported that serum K+ levels were not significantly different between null and WT mice fed a normal K (1%) diet (4.4 ± 0.2 vs 4.2 ± 0.2 mM), but were significantly higher in KS-WNK1-null mice fed a high K (10%) diet for 10 days (5.0 ± 0.2 vs 4.2 ± 0.2 mM, $p<0.05$). Immunofluorescent staining using antibodies against NCC and p-T58-NCC showed that dietary K+ loading decreased the abundance of total NCC and phospho-NCC in WT but had lesser effect in KS-WNK1-null mice. Western blot analysis confirmed the differential effect of K+ loading on NCC in WT vs KS-WNK1-null mice. Immunofluorescent staining revealed that dietary K+ loading increased the apical abundance of ROMK in AQP2-positive tubules in WT mice, but had a much less effect on ROMK in KS-WNK1 mice.

Conclusions: These results support the hypothesis that increased expression of KS-WNK1 contributes to the downregulation of NCC and upregulation of ROMK by dietary K+ loading.

FR-PO1744

Characterisation of Mouse Models of Specific Inactivation of WNK1 in the Distal Nephron Cara J. Busst,[1] Xavier Jeunemaitre,[1,2] Juliette Hadchouel.[1] *[1]Paris Centre for Cardiovascular Research, INSERM U970 - Université Paris Descartes, Paris, France; [2]Genetic Department, Hopital Européen Georges Pompidou, Paris, France.*

Background: Identification of mutations in the WNK1 (With No Lysine (K) kinase 1) gene as responsible for the Mendelian disease Familial Hyperkalemic Hypertension (FHHt) led to the discovery of a new pathway for blood pressure regulation. To date, most studies have been conducted in vitro and have focused on the role played by the ubiquitously expressed long isoform and the kidney-specific isoform of WNK1 (L- and KS-WNK1 respectively) in the distal convoluted tubule (DCT). Recent research on a mouse model of KS-WNK1 inactivation suggests that this segment is not solely responsible for the development of hypertension observed in FHHt patients and that there are compensatory mechanisms acting in the connecting tubule (CNT) and/or collecting duct (CD).

Methods: To characterise the role of L-WNK1 in the late distal tubule, we generated a mouse model with specific inactivation of L-WNK1 in the collecting duct by crossing mice carrying a conditional allele of WNK1, containing LoxP sites encasing exons 4 and 4a, with mice expressing Cre-recombinase under the control of the Hoxb7 promoter. Control and mutant males were maintained in metabolic cages to measure blood and urine electrolytes.

Results: There were no differences in blood or urinary electrolytes when comparing mutant and control animals, nor was there a difference in urinary aldosterone levels. Western blot analysis of cortical membrane protein extracts did not reveal a difference in expression of the Na-Cl cotransporter, the epithelial sodium channel or pendrin between the two groups.

Conclusions: In summary, inactivation of WNK1 in the collecting duct does not appear to have a strong phenotype in terms of electrolyte transport in the kidney, likely due to compensatory mechanisms acting in other kidney segments, similar to what was observed in the mouse model of CD-specific inactivation of ENaC. To gain further insights in the role played by L-WNK1 in nephron segments downstream of the DCT, we are currently characterising a mouse model of L-WNK1 inactivation in Principal cells of the CNT and CD.

Alternatively Spliced PY Cassette Exons in WNK1 Decrease Stability by Enhancing Sensitivity to the E3 Ubiquitin Ligase Nedd4-2 Ankita Roy,[1] Avin C. Snyder,[1] Shaheen Khadem,[1,2] Rodrigo Alzamora,[1] Yen-Pei Christy Chang,[3] Arohan R. Subramanya.[1,2] *[1]Department of Medicine, University of Pittsburgh; [2]VA Pittsburgh Healthcare System, Pittsburgh, PA; [3]Department of Medicine, University of Maryland, Baltimore, MD.*

Background: With-No-Lysine kinase 1 (WNK1) is a large serine-threonine kinase that regulates Na+ and K+ handling in the aldosterone-sensitive distal nephron (ASDN). Two major functional isoforms of WNK1 are expressed in the kidney: full-length WNK1 (L-WNK1), and a truncated kidney-specific kinase-defective product (KS-WNK1). Alternative splicing of exons 11 and 12 of WNK1 has also been reported in kidney, but the significance of these events is unknown.

Methods: To clarify the role of exons 11 and 12 in WNK1 function, we assessed WNK1 mRNA expression in human kidney by RT-PCR. Exons 11 and 12 were cloned from rat kidney cDNA and integrated in-frame to a rat L-WNK1 splice variant lacking the two exons (Xu et al, JBC 2001). WNK1 cDNAs were then expressed in HEK293 cells for biochemical assessments of protein abundance, interaction, and stability.

Results: We detected a contingent of 16 renal L-WNK1 and KS-WNK1 mRNAs containing a complete assortment of exon 11 and 12 combinations. Bioinformatic analysis revealed that exons 11 and 12 each harbor a canonical PY motif ([L/P]PXY), which binds to WW domain proteins such as the E3 ligase Nedd4-2; remarkably, no other PY motifs are present in the WNK1 sequence. When expressed in cells bearing endogenous Nedd4-2, exons 11 and 12 decreased steady state L-WNK1 protein abundance by enhancing its proteasomal degradation. Conversely, ablation of both PY motifs by site-directed mutagenesis increased L-WNK1 abundance relative to wild type, suggesting that the exons decrease protein stability by promoting Nedd4-2 interaction.

Conclusions: These observations indicate that exons 11 and 12 function as alternatively spliced "PY cassettes" that enhance WNK1 sensitivity to Nedd4-2 mediated degradation. Since Nedd4-2 is inhibited by signaling intermediates downstream of aldosterone and vasopressin, we propose that hormonal stimuli for NaCl reabsorption in the ASDN augment WNK-dependent signaling through Nedd4-2 dependent control of WNK1 protein abundance.

Renal Phenotype of WNK3 Knockout Mouse Katsuyuki Oi,[1] Eisei Sohara,[1] Motoko Chiga,[1] Dario Alessi,[2] Sei Sasaki,[1] Shinichi Uchida.[1] *[1]Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan; [2]MRC Protein Phosphorylation Unit, University of Dundee, United Kingdom.*

Background: Mutations of WNK1 and WNK4 genes cause the human hereditary hypertensive disease, pseudohypoaldsteronism type II (PHAII). By analyzing the PHAII model mouse, we discovered the novel kinase cascade (WNK4-OSR1/SPAK) in kidney that regulates Na-Cl cotransporter (NCC). WNK3, another member of WNK kinase family, reportedly regulates Na-K-Cl cotransporter (NKCC) and NCC when co-expressed in Xenopus oocytes. However, it remains to be determined whether WNK3 is in fact involved in the regulation of these transporters in vivo. To investigate this issue, we generated and analyzed WNK3 knockout mice.

Methods: The construct was designed to result in the insertion of loxP sequences flanking exon 2 of Wnk3. Then, we mated WNK3 (flox/+) offspring with CAG Cre transgenic mouse and successfully obtained WNK3 knockout mouse. The knockout of WNK3 gene was confirmed by RT-PCR and immunoblot in various organs. To determine the transporters potentially regulated by WNK3 in kidney, we first determined WNK3 expression along nephron by laser capture microdissection and RT-PCR.

Results: We found that WNK3 is expressed in proximal tubules, thick ascending limb of Henle's loop, distal tubules and collecting ducts, where NHE3, NKCC2, NCC and ENaC are expressed, respectively. We then performed immunoblot of these transporters. Under normal diet and even under low salt diet, we could not see any significant difference in the protein abundance and the magnitude of phosphorylation of NKCC2 and NCC between WNK3 knockout and wild-type mice. There was also no remarkable difference in ENaC and NHE3 protein levels between the two genotypes.

Conclusions: Thus, it is unlikely that WNK3 has a major role in WNK-OSR1/SPAK kinase cascade in kidney.

FR-PO1747

NCC Modulation by WNK3 Requires WNK3-SPAK Interaction Diana Pacheco-Alvarez,[1] Norma Hilda Vázquez,[2] Norma Bobadilla,[2] Maria Castañeda-Bueno,[2] Gerardo Gamba.[2] *[1]Escuela de Medicina, Universidad Panamericana, Mexico City, Mexico; [2]INNSZ-IIB-UNAM, Mexico City, Mexico.*

Background: With-no-lysine kinase 3 (WNK3) is a powerful activator of NKCCs and NCC while it is an inhibitor of KCCs. It has been shown that WNKs lie upstream of the STE-20 kinases SPAK/OSR1 and that interaction with SPAK occurs through the SPAK-binding motif, RFx(V/I), three of which are present in WNK3. In a previous study we observed that NKCC2 activation by WNK3 is prevented by elimination of the WNK3 SPAK binding site F1337 (PNAS, 2008). Here we define the role of SPAK/OSR1 in the modulation of NCC and other members of the SLC12 family by WNK3.

Methods: The SPAK binding sites of WNK3 (F242A, F873A, or F1337A; one at a time), NCC (F19A), and NKCC2 (F17A) were eliminated. Basal activity, the effect of WNK3 or low chloride hypotonic stress was assessed by measuring the tracer $^{22}Na^+$ or $^{86}Rb^+$ uptake in *Xenopus* oocytes injected with combinations of transporters and kinases wild type or mutant cRNAs. Proteins extracted from oocytes were used to define the interaction between WNK3-SPAK-NCC by immunoprecipitation and NCC-T58 phosphorylation by using phosphoantibodies.

Results: Basal activity of NCC-F19A and NKCC2-F17A was reduced by 50%. However, the response to WNK3 and to low chloride hypotonic stress was still present. WNK3-F1337A no longer activates NKCC2, but the effect towards NCC, NKCC1 and KCC4 is preserved. In contrast, the effect of WNK3 towards these cotransporters, but not NKCC2, was prevented in WNK3-F242A. Elimination of F873 had no consequences in WNK3 effects. Catalytic activity is preserved in WNK3-F242A. Immunoprecipitation revealed that WNK3-SPAK-NCC forms a protein complex that is still present with NCC-F19A, but not with WNK3-F242A. WNK3 promoted NCC or NCC-F19A phosphorylation at T58. This effect was not observed with WNK3-F242A.

Conclusions: Our observations suggest that basal activity of NCC, but not activation by WNK3, requires the presence of the SPAK binding site on the cotransporter. However, modulation of NCC (and NKCC1 or KCC4) requires interaction between WNK3 and SPAK through the binding site F242 at WNK3. Interestingly, a different SPAK binding site on WNK3 is required for NKCC2 activation.

FR-PO1748

WNK4 Is a Novel Regulator of Thiazide Sensitive NaCl Transport in the Collecting Duct Cara J. Busst,[1] Dominique Eladari,[2] Francoise Leviel,[2] Christelle Soukaseum,[1] Richard P. Lifton,[4] Xavier Jeunemaitre,[1,3] Juliette Hadchouel,[1] Régine Chambrey.[2] *[1]Paris Centre for Cardiovascular Research (INSERM U970), Paris, France; [2]Cordeliers Research Centre (INSERM U872), Paris, France; [3]Hôpital Européen Georges Pompidou, Paris, France; [4]Yale University School of Medicine, New Haven, CT.*

Background: Mutations in the WNK1 and WNK4 (With no lysine (K)) kinases were found to cause Pseudohypoaldosteronism type II (PHAII), an autosomal dominant hypertension with hyperkalemia and hyperchloremic metabolic acidosis. Transgenic mice expressing WNK4 containing a PHAII mutation (TgWNK4PHAII) display all features of PHAII, thought to be due solely to increased Na-Cl cotransporter (NCC) activity in the distal convoluted tubule (DCT). However, recent research on mice lacking the kidney-specific isoform of WNK1 (expressed only in the DCT) showed that NCC overactivity is not sufficient to generate PHAII due to compensatory mechanisms in the cortical collecting duct (CCD).

Methods: To investigate CCD function, we performed isolated, perfused tubule studies on CCDs dissected from WT and TgWNK4PHAII mice.

Results: We observed increased Na+ and Cl- transport in TgWNK4PHAII mice while K+ and epithelial voltage were unchanged, suggesting that increased Na+ reabsorption in these mice is not mediated by the epithelial sodium channel (ENaC). We then examined ENaC activity in vivo by subjecting mice to amiloride injections while housed in metabolic cages and found that ENaC activity was indeed decreased in TgWNK4PHAII mice, as the natriuretic and anti-kaliuretic response was abolished. We recently showed that parallel action of the Na+-dependent Cl-/HCO3- exchanger NDCBE and the Cl-/HCO3- exchanger pendrin drives electroneutral thiazide-sensitive and amiloride-insensitive Na+ transport in the CCD. We thus repeated microperfusion experiments in the presence of hydrochlorothiazide and observed inhibited Na+ and Cl- transport in TgWNK4PHAII mice.

Conclusions: In conclusion, WNK4 appears to be an important regulator of NaCl transport in the CCD, modifying activity of the electroneutral NaCl transport system mediated by NDCBE and pendrin, and indicates that this system may play a key role in PHAII.

FR-PO1749

WNK4 Suppresses WNK3-Driven Phosphorylation of NCC in Mammalian Kidney Cells Chao-Ling Yang,[1,2] Shaunessy L. Rogers,[1,2] James A. McCormick,[1] David H. Ellison.[1,2] *[1]Nephrology & Hypertension, Oregon Health & Science University, Portland, OR; [2]Renal Section, VA Medical Center, Portland, OR.*

Background: WNK kinases regulate renal salt transport via the thiazide-sensitive Na-Cl cotransporter, NCC. Previous work has shown that WNK4 and KS-WNK1 inhibit NCC activity, acting in opposition to WNK1 and WNK3, both in vitro and in vivo. It has also shown that WNK3 is more potent as a kinase than WNK4. We reported that WNK3 is highly expressed along the distal nephron, where it is expressed with NCC. Based on their ability to form protein-protein complexes and on the functional attenuation data, we proposed that WNK kinases form a signaling complex to regulate NCC activity to maintain salt homeostasis (JCI 2007). NCC must traffic to the apical membrane of distal convoluted tubule cells, and be phosphorylated along its amino terminus, to be active.

Methods: Here, we compared effects of WNK3 and WNK4 in HEK293 cells, which express SPAK endogenously. We transfected the cells with NCC, WNK3, and WNK4, and performed immunoblotting and immunocytochemistry.

Results: We first showed that these cells glycosylate and phosphorylate NCC normally. Transfected WNK3 strongly promoted NCC phosphorylation at T53, one of the sites essential for NCC activation. This effect required SPAK, because knockdown of endogenous SPAK with siRNA, or co-expression of kinase-inactive SPAK T243A, prevented the increased phosphorylation. Unlike WNK3, WNK4 suppressed NCC protein expression, as well as NCC T53 phosphorylation. Furthermore, WNK4 could block WNK3-mediated NCC phosphorylation. This inhibition was independent of WNK4 kinase activity, because a WNK4 C-terminal fragment, without a kinase domain, had a similar effect as full-length WNK4.

Conclusions: In conclusion, WNK3 and WNK4 exert opposite effects on NCC phosphorylation in mammalian cells, and WNK4 inhibits the effect of WNK3 to activate SPAK and phosphorylate NCC. These effects appear to be additive to those of WNK4 on NCC protein trafficking to the plasma membrane, suggesting WNK kinases regulate transporter activity at several steps.

FR-PO1750

Upregulation of Thiazide-Sensitive and Furosemide-Sensitive Sodium Absorption, NCC, and NKCC2 Expression in PHAII Mutant Mice Qingshang Yan, Laxiang Wan, Junhui Zhang, Nanami Gotoh, Jesse Rinehart, Richard P. Lifton, Gerhard H. Giebisch, Tong Wang. *C. & M. Physiology, Yale University, School of Medicine, New Haven, CT.*

Background: WNK4 mutations cause pseudohypoaldosteronism type II (PHAII), a disease featuring increased renal NaCl reabsorption and impaired K^+ secretion. PHAII mutant mice exhibited phenotypes of higher blood pressure, hyperkalemia and hypercalciuria. We investigate the mechanism of increased NaCl absorption in PHAII mice.

Methods: The renal expression levels of NKCC2 (Na/2Cl/K-cotransporter), thiazide-sensitive Na^+-Cl^- cotransporter (NCC) and the ENaC (epithelia Na^+ channel) were examined by Q-PCR and their activities by measuring the effect of furosemide (Furo), hydrochlorothiazide (HCTZ) and benzamil (BEZ) on Na^+ and K^+ excretion by renal clearance. The urine volume (UV), GFR and absolute (ENa, EK) and fractional (FENa, FEK) Na^+ and K^+ excretion were measured before and after bolus iv of diuretics in wild-type (WT) and WNK4 mutant (PHAII) mice.

Results: All three diuretics produced significant diuretic and natriuretic effects in WT, but Furo and HCTZ produced stronger and benzamil produced smaller diuretic and natriuretic effects significantly in PHAII mice compared to the WT. The fractional increase of UV was 8.6- vs. 6.5-fold, 5.6- vs. 1.9-fold and 0.30- vs. 1.2-fold; ENa was 17.8- vs. 4.9-fold, 17.6- vs. 4.4-fold and 3.9- vs. 5.6-fold; and FENa was 34.6- vs. 10.1-fold, 19.4-vs. 5.4-fold and 2.85- vs. 4.4-fold with Furo, HCTZ and BEZ treatment in PHAII mice vs. WT, respectively. Furo and HCTZ increase and BEZ reduced both EK and FEK but there was no significant difference in the fractional changes in EK and FEK caused by the diuretics between WT and PHAII mice. Q-PCR data show NKCC2 and NCC expression levels were 25% and 61% higher in PHAII than in WT mice. NHE3, α, β and γ ENaC expression were not significantly changed but ROMK expression was reduced by 46% in PHAII vs. WT.

Conclusions: We conclude that 1) elevated NKCC2 and NCC activities contributes to increased NaCl absorption; 2) reduced ROMK expression limits ENaC activity; and 3) other K^+ secretion mechanisms may be upregulated when the ROMK channel is downregulated in PHAII mice.

FR-PO1751

Epithelial Ion Flux in the Fly Renal Tubule Occurs through NKCC, and Is Regulated by WNK and SPAK Aylin R. Rodan,[1] Michel G. Baum,[1,2] Chou-Long Huang.[1] *[1]Medicine, UTSW; [2]Pediatrics, UTSW, Dallas, TX.*

Background: NCC and NKCC play key roles in renal epithelial ion transport. Recent evidence suggests that the WNK and SPAK/OSR1 kinases regulate these transporters, but many questions remain. Analysis in mammalian systems is complicated by multiple NKCC, WNK, and SPAK/OSR1 family members.

Methods: We are using *Drosophila melanogaster*, which has sophisticated genetics, a rapid life cycle, and well-characterized renal tubular epithelial transport, to better understand these pathways. The fly homologs of NKCC, SPAK/OSR1 and WNK are *Ncc69*, *fray* and *wnk*, respectively. In the fly tubule, an apical H^+-ATPase generates a lumen-positive transepithelial potential difference (TEP), which drives K^+ secretion by K^+/H^+ exchange. To investigate the roles of *Ncc69* in basolateral K^+ uptake, and *wnk* and *fray* in K^+ transport regulation, we have measured TEP and K^+ flux in isolated fly renal tubules.

Results: 100 μM bumetanide, an NKCC inhibitor, reversibly decreased TEP from 42 mV to 21 mV when added basolaterally to perfused tubules. In *Ncc69* mutants, transepithelial K^+ flux was slightly decreased, from 59 pmol/min in wild-type to 48 pmol/min in mutants. Loss of *Ncc69* is compensated by other mechanisms, including upregulation of a cAMP-sensitive pathway: in mutant tubules, 1 mM cAMP increased K^+ flux 2.7-fold, compared to only 1.4-fold in wild-type. To isolate the role of *Ncc69*, K^+ flux through the Na-K-ATPase was inhibited with a submaximal dose of ouabain (100 μM). Under these conditions, K^+ flux decreased from 92 pmol/min in wild-type to 52 pmol/min in *Ncc69* mutants, and addition of 100 μM bumetanide decreased K^+ flux in wild-type to 52 pmol/min, but did not significantly decrease *Ncc69* mutant K^+ flux (45 pmol/min). Thus, *Ncc69* is the bumetanide-sensitive transporter in the fly tubule. Tubule knockdown of *wnk* decreased K^+ flux to 40 pmol/min, compared to 75 pmol/min in the control. Similarly, tubule knockdown of *fray* decreased K^+ flux to 58 pmol/min, compared to 76 pmol/min in the control.

Conclusions: WNK and SPAK play an evolutionarily conserved role in the regulation of renal epithelial ion flux, likely through the regulation of NKCC. Future studies will examine the mechanisms by which this occurs.

SPAK and OSR1 Act as Interdependent Kinases That Control Renal Salt Excretion and Blood Pressure Via Regulation of NCC Phosphorylation and Distal Convoluted Tubule Cell Mass Paul R. Grimm,[1] Tarvinder K. Taneja,[1] Jie Liu,[1] Richard A. Coleman,[1] Eric J. Delpire,[2] James B. Wade,[1] Paul A. Welling.[1] *[1]Department of Physiology, University of Maryland School of Medicine, Baltimore, MD; [2]Department of Anesthesiology, Vanderbilt University Medical Center, Nashville, TN.*

Background: The STE20/SPS-1-related proline-alanine-rich protein kinase (SPAK) and its homolog, Oxidative Stress Related Kinase (OSR1), co-localize at the apical membrane of the TAL and DCT and have the capacity to regulate NKCC2 and NCC, yet genetic ablation of SPAK in mice causes a salt-wasting nephropathy that is restricted to the DCT, reminiscent of Gitelman's syndrome. Here, we explore why proper DCT function is especially dependent on SPAK.

Results: In SPAK-/- mice, NKCC2 becomes hyper-phosphorylated, and this is paralleled by a concomitant increase in OSR1 expression, consistent with a compensatory mechanism in the TAL. By contrast, OSR1 is not augmented in the DCT. In fact, OSR1 becomes largely displaced from NCC and the apical membrane, redistributing to dense punctate structures within the cytoplasm. These changes are paralleled by a dramatic decrease in NCC abundance and phosphorylation; without SPAK and proper localization of OSR1, phosphorylation-dependent regulation of NCC by dietary sodium restriction is lost. As assessed by immunohistochemical and transcript analysis, SPAK-/- also exhibit a remarkable decrease in the distal convoluted tubule, exclusive to DCT1. As a result, SPAK-/- mice are highly sensitive to dietary salt-restriction, displaying prolonged negative sodium balance and hypotension.

Conclusions: In conclusion: 1) OSR1is compensatory to SPAK removal in the TAL; 2) In the DCT, SPAK and OSR1 act as interdependent kinases that are necessary for phospho-regulation of NCC and the control of DCT1 cell mass.

Funding: NIDDK Support

FR-PO1753

SPAK and OSR1 Kinases Modulate Luminal Trafficking and Cellular Abundance of NKCC2 Aljona Borschewski,[1] Kamel Laghmani,[2] Kerim Mutig,[1] Sylvie Demaretz,[2] Christin Dathe,[1] Alexander Paliege,[1] Nicholas R. Ferreri,[3] Eric J. Delpire,[4] Sebastian C. Bachmann.[1] *[1]Institut für Vegetative Anatomie, Charité Universitätsmedizin, Berlin, Germany; [2]INSERM, Centre de Recherche des Cordeliers, Paris, France; [3]Dept. of Pharmacology, New York Medical College, Valhalla, NY; [4]Dept. of Anesthesiology, Vanderbilt University School of Medicine, Nashville.*

Background: Na^+,K^+,$2Cl^-$-cotransporter (NKCC2) of the thick ascending limb (TAL) is essential for urinary concentration and volume regulation. Sterile 20/SPS1-related proline/alanine-rich kinase (SPAK) and oxidative-stress responsive kinase 1 (OSR1) regulate NKCC2 activity by phosphorylation of conserved N-terminal threonines. The aim of the present study was to evaluate the effects of SPAK and OSR1 on total abundance and surface expression of NKCC2.

Methods: Localization of SPAK and OSR1 in TAL was verified immunohistochemically. Effects of SPAK and OSR1 on NKCC2 phosphorylation (pT96 and pT101), surface expression, and total abundance were studied in cultured rat TAL cells and in opossum kidney (OPK) cells by means of knockdown or transient overexpression of the kinases and NKCC2.

Results: Confocal evaluation revealed co-localization of SPAK and OSR1 with NKCC2 in subapical compartment of mouse and rat TAL. The interactions between the kinases and NKCC2 were established by co-immunoprecipitation experiments using rat medullary kidney homogenates. In cultured TAL cells, the endogenous abundance of SPAK and NKCC2 was verified by immunoblotting. Knockdown of SPAK in cultured TAL cells resulted in significantly decreased total abundance (-75%) and phosphorylation of NKCC2 (-82%). In OPK cells, co-transfections of NKCC2 with SPAK or OSR1 produced significant increases of NKCC2 surface expression (+71% and +74%, respectively) and total abundance (+22% and +26%, respectively) as revealed by immunoblotting from total cell lysates and biotynylated fractions.

Conclusions: This study provides evidence that SPAK and OSR1 may regulate the activity of NKCC2 not only by phosphorylation of the conserved N-terminal threonines but also by modulation of the total abundance and surface expression of the transporter.

FR-PO1754

Cytoplasmic Hsp70/Hsp90 Multichaperone Complexes Regulate Thiazide-Sensitive NaCl Cotransporter Biogenesis and Degradation Arohan R. Subramanya,[1,3] Patrick G. Needham,[2] Shaheen Khadem,[1,3] Avin C. Snyder,[1] Jeffrey L. Brodsky.[2] *[1]Department of Medicine, University of Pittsburgh; [2]Department of Biological Sciences, University of Pittsburgh; [3]VA Pittsburgh Health Care System, Pittsburgh, PA.*

Background: The thiazide-sensitive NaCl cotransporter (NCC) is the primary mediator of sodium reabsorption in the distal convoluted tubule. Loss-of-function mutations of NCC cause Gitelman's syndrome, a hypotensive salt-wasting disorder. NCC is a complex polytopic membrane glycoprotein that is susceptible to misfolding and endoplasmic reticulum-associated degradation (ERAD). Most Gitelman's mutants are unable to escape ER quality control, but the molecular details of this process remain unknown.

Methods: To begin to define these mechanisms, we utilized yeast as a model system to compare mouse NCC processing in wild type strains and in strains with targeted mutations in individual chaperones. Findings were subsequently verified in MDCK epithelia. We employed a variety of methods to study NCC ERAD, including cell fractionation and pulse-chase assays, co-IPs, and MALDI-TOF Mass Spectrometry.

Results: NCC behaves as a bona fide ERAD substrate in yeast, as it is membrane-integrated, is predominantly ER localized, and undergoes ubiquitylation and proteasomal degradation. While the ER luminal chaperone Kar2/BiP is dispensible for NCC ERAD, the cytoplasmic Hsp70 Ssa1 is required. In MDCK cells, cytoplasmic mammalian Hsp70 (Hsp72) coexpression enhanced NCC ERAD, decreasing its half-life by ~50%. Proteomic analyses of NCC immunoprecipitates confirmed that the cotransporter was associated with a mammalian cytoplasmic chaperone complex consisting of Hsp70, Hsp90, and Hsp40. Modulation of the activity of this complex by pharmacological Hsp90 inhibition, or by the distal nephron-expressed Hsp70/Hsp90 co-chaperone CHIP, altered the rate of NCC turnover.

Conclusions: These findings demonstrate that cytoplasmic chaperones play a critical role in NCC ER quality control. We propose that cytoplasmic multichaperone complexes sense NCC folding status, and that disease-causing conformational variants of NCC may be predisposed to enhanced ERAD through altered interactions with this quality control machinery.

FR-PO1755

Acute Insulin Stimulation Induces Phosphorylation of the Na-Cl Cotransporter in Cultured Distal mpkDCT Cells and Mouse Kidney Eisei Sohara,[1] Tatemitsu Rai,[1] Sung-Sen Yang,[2] Akihito Ohta,[1] Shih-Hua P. Lin,[2] Alain Vandewalle,[3] Sei Sasaki,[1] Shinichi Uchida.[1] *[1]Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan; [2]Division of Nephrology, Department of Medicine, Tri-Service General Hospital, Taipei, Taiwan; [3]INSERM U773, Université Paris 7 -Deni Diderot, Paris, France.*

Background: The NaCl cotransporter (NCC) is essential for sodium reabsorption at the distal convoluted tubules (DCT), and its phosphorylation increases its transport activity and apical membrane localization. Although insulin has been reported to increase sodium reabsorption in the kidney, the linkage between insulin and NCC phosphorylation has not yet been investigated.

Methods: This study examined[ensp]whether insulin[ensp]regulates NCC phosphorylation in cultured cells and mouse.

Results: In cultured mpkDCT cells, insulin increased phosphorylation of STE20/SPS1-related proline-alanine-rich kinase (SPAK) and NCC in a dose-dependent manner. Ly294002, a PI3K inhibitor, decreased the insulin effect on SPAK and NCC phosphorylation, indicating that insulin phosphorylates SPAK and NCC through PI3K in mpkDCT cells. Moreover, acute insulin administration to mice increased phosphorylation of oxidative stress-responsive kinase-1 (OSR1)/SPAK and NCC in the kidney. Time-course experiments in mpkDCT cells and mice suggested that SPAK is upstream of NCC in this insulin-induced NCC phosphorylation mechanism, which was confirmed by the lack of insulin-induced NCC phosphorylation in SPAK knockout mice. Moreover, insulin administration to WNK4 hypomorphic mice did not increase OSR1/SPAK phosphorylation in the kidney, suggesting that WNK4 is also involved in the insulin-induced OSR1/SPAK phosphorylation mechanism.

Conclusions: The present results demonstrated that insulin is a potent regulator of NCC phosphorylation in the kidney, and that WNK4 and SPAK are involved in this mechanism of NCC phosphorylation by insulin.

FR-PO1756

Aldosterone Affects NCC Phosphorylation Involving MAPK ERK1/2 Signaling Pathway Xiuyan Feng,[1] Yanhui Wang,[1,4] Ping Wu,[1] Eric J. Delpire,[3] Hui Cai.[1,5] *[1]Renal Division, Emory University School of Medicine, Atlanta, GA; [2]Department of Nephrology, Second Affiliated Hospital, Wenzhou Medical College, Wenzhou, Zhejiang, China; [3]Department of Anesthesiology, Vanderbilt University Medical Center, Nashville, TN; [4]Department of Nephrology, First Affiliated Hospital, Wenzhou Medical College, Wenzhou, Zhejiang, China; [5]Renal Section, Atlanta VA Medical Center, Atlanta, GA.*

Background: The thiazide-sensitive Na^+-Cl^- cotransporter (NCC) is one of the key regulators in renal sodium handling. Chronic treatment with aldosterone increased NCC abundance *in vivo*. We have previously shown that knock-down of ERK 1/2 expression increased NCC protein expression in mouse distal convoluted tubule (mDCT) cells.

Methods: We used cell cutlure, western blot analysis and siRNA knock down technique to carry out the experiments.

Results: To determine whether acute aldosterone treatment affects NCC regulation involving MAPK ERK1/2 signal pathway, we treated the mDCT cells with aldosterone 1uM at different time point and found that the ERK1/2 phosphorylation increased at 15 minute of aldosterone treatment but deceased after 1 hour and lasted at least 24 hour. However, SPAK phosphorylation at S373 was not significantly altered. We then determined whether reduction of SPAK expression by siRNA affects ERK1/2 phosphorylation and NCC phosphorylation. Under knock-down of SPAK expression, we still observed the dynamic change of ERK1/2 phosphrylation in a similar fashion as before. We found that aldosterone increased NCC phosphoralation at T60 at 6 hour of aldosterone treatment. Knock-down of SPAK expression did not alter aldosterone-mediated increased NCC phosphorylation at T60.

Conclusions: These results suggest that ERK1/2 signaling pathway is involved in the acute aldosterone-mediated NCC phosphorylation and potential regulation of NCC function and protein expression.

Development of New Systems To Measure total and Phosphorylated Na-Cl Cotransporter(NCC) Protein in Human Urine Kiyoshi Isobe, Eisei Sohara, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Nephrology, Tokyo Medical and Dental University, Bunkyo-ku, Tokyo, Japan.*

Background: Thiazide-sensitive sodium chloride cotransporter (NCC) localizes to the apical membrane of the distal convoluted tubule (DCT) in kidney, and was responsible for reabsorbing 5-10% of the filtered load of sodium chloride. By analyzing the pathogenesis of pseudohypoaldosteronism type II (PHAII), we discovered that WNK-OSR1/SPAK kinase cascade is a powerful regulator of NCC. NCC phosphorylated by OSR1/SPAK kinases was shown to be functionally active and concentrated on the plasma membranes of DCT. Thiazide, an inhibitor of NCC, is one of the first-line drugs for treating hypertension. However, it is difficult to predict the thiazide sensitivity in each patient prior to the administration. Since NCC protein is known to be excreted in urine, we hypothesized that NCC excretion in urine could be a biomarker for predicting the thiazide sensitivity in hypertensive patients. In order to investigate this possibility, sensitive, efficient and reproducible methods measuring urine NCC are necessary.

Methods: In this study, we developed a sandwich ELISA method to measure NCC in human urine along with a conventional but improved Western blotting method.

Results: Sandwich ELISA and Western blotting are able to detect urinary NCC as low as 2.5 pmol/ml and 5.0 pmol/ml, respectively. Using these methods, we found that NCC concentration in spot urine samples remained constant within a day when they were corrected by respective creatinine concentration. This result suggests that single spot urine can be used to estimate total excretion of NCC for 24 hours. We also confirmed that urine NCC excretion varied according to different salt intake. Furthermore, we for the first time succeeded to detect phosphorylated NCC (pNCC) in human urine by using phospho-specific anti-human NCC antibodies. Since pNCC is an active form of NCC, pNCC in urine could be more sensitive marker for predicting in vivo activity of NCC than total NCC.

Conclusions: Thus, we established methods to measure NCC and pNCC in human urine samples. The relationship of thiazide sensitivity and urine NCC and pNCC will be efficiently investigated by these systems.

Urinary Excretion of Na-Cl Cotransporter in Exosomes Is Increased by High Salt Diet as Well as Low Salt Diet Muhammad Zakir Hossain Khan, Eisei Sohara, Akihito Ohta, Shotaro Naito, Motoko Chiga, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Nephrology, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: Na-Cl co-transporter, the key regulator of sodium reabsorption in the distal convoluted tubule (DCT) is responsible for reabsorption of 5-10% of filtered sodium in the kidney. We recently demonstrated that constitutive activation of the WNK kinase-OSR1/SPAK kinase-NaCl cotransporter (NCC) phosphorylation cascade is the molecular pathogenesis of salt-sensitive hypertension in pseudohypoaldosteronism type II. We also have reported that dietary salt intake regulates expression and phosphorylation of NCC.In order to establish a method to monitor the activity of NCC in kidney by urine examination; we sought to determine the correlation between NCC in kidney and NCC in urine exosomes.

Methods: After 6 days feeding with three different diets (normal, low and high salt), we collected urinary exosomes from wild-type C57/BL6 mice.

Results: Western blotting of these samples revealed total and phosphorylated NCC (S71 and T53) were increased in mice fed low salt diet than in mice fed normal diet, which is consistent with previous reports, and also well correlated with the increases of total and phosphorylated NCC in the kidney. However, we found that total and phosphorylated NCC in urine exosomes from mice fed high salt diet was also increased compared with those in mice fed normal diet.

Conclusions: Since urinary exosomal proteins are derived from multi-vesicular bodies, formed by endocytosis of plasma membranes, we speculate that, the increased excretion of NCC in exsosomes may be caused by the increased endocytosis of NCC from the apical plasma membranes in DCT. This result suggests that urinary NCC excretion in exosomes may not necessarily reflect NCC abundance in the apical plasma membranes of DCT, at least in mice.

Genotype and Phenotype Analysis in Taiwanese Patients with Gitelman's Syndrome Min-Hua Tseng,[1,2] Sung-Sen Yang,[2,3] Yu-Wei Fang,[2] Shih-Hua P. Lin.[2,3] *[1]Department of Pediatrics, Chang Gung Memorial Hospital, Taoyuan; [2]Graduate Institute of Medical Sciences, National Defense Medical Center., Taipei; [3]Department of Medicine, Tri-Service General Hospital, Taipei, Taiwan.*

Background: Phenotype and genotype analysis is rarely performed in a large number of patients with Gitelman's syndrome (GS) caused by mutations in *SLC12A3* encoding the thiazide-sensitive NaCl cotransporter of distal convoluted tubules .

Methods: 106 Taiwanese GS patients (M:F = 64:42, age 24 ± 10) with *SLC12A3* mutations belonging to 85 unrelated families were investigated. All had chronic hypokalemia with renal salt and potassium wasting, metabolic alkalosis, and normotension. Genomic DNA and/or cDNA from blood leukocytes were done for the detection of *SLC12A3* mutations and haplotype analysis with intra- and extra-genic markers for recurrent *SLC12A3* mutations. Clinical symptoms and biochemical studies on the first presentation and follow-up studies were recorded.

Results: 38 different *SLC12A3* mutations including 25 missense, 3 nonsense, 3 deletion, 3 splice site, 3 deep intronic, 1 insertion were identified with compound heterozygosity being the most common. Approximately 10 % and 15% of patients had triple and heterozygous *SLC12A3* mutations, respectively. 14 mutations including 8 missense, 2 nonsene, 2 deep intronic, 1 deletion and 1 insertion were recurrent with only one founder mutation (S710X). Typical hypocalciuria and hypomagnesemia were not found in 7 and 9 patients, respectively. In addition to male patients having an earlier age of onset, more severe hypokalemia and neuromuscular symptoms, patients with homozygous and deep intronic mutation in the intron 13 (c.1670-191C>T) also had severe hypokalemia. Seven and four patients had chronic kidney disease (CKD, stage III and IV) and type 2 diabetes mellitus at follow up, respectively.

Conclusions: GS patients with *SLC12A3* mutations may not always have hypocalciuria and hypomagnesemia. Screening of recurrent "hot spot" *SLC12A3* mutations may provide an early molecular diagnosis. Besides gender effect, the nature of homozygous and deep intronic mutations may influence the phenotype. GS patients have a significant risk for the development of CKD and abnormal glucose metabolism.

FR-PO1760

Diagnostic Value of Diuretics Loading Test in Gitelman Syndrome
Jeonghwan Lee,[1] Sejoong Kim,[2] Yun Kyu Oh,[3] Kwon Wook Joo,[1] Jin Suk Han.[1] *[1]Internal Medicine, Seoul National University Hospital, Seoul, Korea; [2]Internal Medicine, Gachon University Gil Medical Center, Seoul, Korea; [3]Internal Medicine, Seoul National University Boramae Hospital, Seoul, Korea.*

Background: We investigated the diagnostic significance of diuretics test in Gitelman syndrome (GS) and evaluated the superiority among various indices of renal clearance test.

Methods: Sixteen patients with clinically typical Gitelman syndrome were enrolled. One patient with factitious vomiting due to bulimia nervosa and 1 normal volunteer were also studied as controls. Mutation analysis of *SLC12A3* and *CLCNKB* gene was done in all the subjects. Diuretics tests were performed with thiazide (HCT) and furosemide (FUR). Clearance indices (CI) such as FE_{Na}, FE_{Cl}, C_{Cl} and DFCR (distal fraction of chloride reabsoprtion) were calculated. The ratio of clearance index (CI(HCT/FUR) which stands for CI(HCT)/CI(FUR)) and the ratio of delta CI (ΔCI(HCT/ FUR) which stands for ΔCI(HCT)/ΔCI(FUR)) were also calculated.

Results: All subjects had normotensive hypokalemic metabolic alkalosis, hyperreninemia and increased aldosterone level. *SLC12A3* mutation was detected in 11 patients (8 compound heterozygous, 3 homozygous mutations), but not in 5 patients. No *CLCNKB* mutation was detected in all the subjects. GS patients showed blunted response to thiazide administration (the range of FE_{Na}(HCT/Basal) was 0.75 ~ 5.74). The ranges of FE_{Na}(HCT/FUR), FE_{Cl}(HCT/FUR) and ΔFE_{Na}(HCT/FUR) of GS patients were 0.05 ~ 0.24, 0.05 ~ 0.30 and -0.05 ~ 0.14, and those of control group were 0.38 ~ 0.39, 0.31 ~ 0.38 and 0.34 ~ 0.36, which clearly discriminated patients from controls. Indices calculated from FE_{Cl}, C_{Cl}, and DFCR except FE_{Cl}(HCT/FUR) and ΔCCl(HCT/FUR) overlapped between GS patients and controls.

Conclusions: We suggest that the diagnosis of GS can be done with clinical characteristics and renal clearance test with diuretics instead of *SLC12A3* mutation analysis. FE_{Na} associated indices rather than absolute values were more reliable among various clearance indices in the diagnosis of GS.

FR-PO1761

Activation of the Bumetanide-Sensitive Na^+,K^+,2Cl^--Cotransporter NKCC2 Is Facilitated by Tamm-Horsfall Protein in a Chloride-Sensitive Manner
Kerim Mutig,[1] Thomas Kahl,[1] Turgay Saritas,[1] Michael Godes,[1] James M. Bates,[2] Maria Castañeda-Bueno,[3] Luca Rampoldi,[4] Shinichi Uchida,[5] Carsten Hille,[6] Carsten Dosche,[6] Hajamohideen S. Raffi,[2] Pontus Persson,[1] Gerardo Gamba,[3] Satish Kumar,[2] Sebastian C. Bachmann.[1] *[1]Charite Universitätsmedizin, Germany; [2]University of Oklahoma Health Sciences Center, OK; [3]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico; [4]San Raffaele Scientific Institute, Italy; [5]Tokyo Medical and Dental University, Japan; [6]University of Potsdam, Germany.*

Background: Active transport of NaCl in the thick ascending limb (TAL) is accomplished by Na^+,K^+,2Cl^--cotransporter (NKCC2). The activation of NKCC2 depends on intracellular chloride concentration ($C_{[i]}$) and includes its amino-terminal phosphorylation. We hypothesized that co-expressed Tamm Horsfall protein (THP) modulates NKCC2 activity in TAL.

Methods: Effects of THP on NKCC2 phosphorylation (T96/T101) and transport activity were studied in THP-deficient (THP-/-) and wild type (WT) mice, cultured TAL cells, and frog oocytes.

Results: THP-/- mice displayed decreased phosphorylation of NKCC2 (-49%, $p<0.05$) compared to WT mice. Cultured TAL cells with low endogenous THP levels displayed sharp increases in NKCC2 phosphorylation (+38%, $p<0.05$) along with a pronounced decrease of $C_{[i]}$ (-40.4%, $p<0.05$) upon transfection with THP. In NKCC2-expressing frog oocytes, co-injection with THP cRNA significantly enhanced the activation of NKCC2 under low chloride hypotonic stress (+112% vs. +235%, $p<0.05$). Stimulation of the vasopressin V2 receptor pathway by V2R agonist (dDAVP; 30 min) resulted in enhanced NKCC2 phosphorylation in WT mice and cultured TAL cells transfected with THP whereas in the absence of THP, NKCC2 phosphorylation upon dDAVP was blunted in both systems. Attenuated effects of furosemide along with functional and structural adaptation of the distal convoluted tubule in THP-/- mice further supported the notion that NaCl reabsorption was impaired in TAL lacking THP.

Conclusions: In summary, these results are compatible with a permissive role for THP in the modulation of NKCC2-dependent TAL salt reabsorptive function.

FR-PO1762

cAMP Stimulates NKCC2 Recycling in Thick Ascending Limbs (TALs) Via PKA: Role of Ser126 Phosphorylation
Gustavo R. Ares, Pablo A. Ortiz. *Hypertension & Vascular Research Division, Henry Ford Hospital, Detroit, MI.*

Background: The apical cotransporter NKCC2 mediates NaCl reabsorption by the thick ascending limb (TAL). Surface NKCC2 is maintained by constitutive trafficking into and out of the apical membrane that involves recycling of internalized transporters. cAMP, the second messenger of AVP and β-adrenergic agonists, stimulates apical membrane NKCC2 and NaCl reabsorption by increasing the rate of NKCC2 exocytosis via protein kinase A (PKA). However, it is not known whether cAMP stimulates NKCC2 exocytosis from a recycling compartment or the biosynthetic pool. cAMP also enhances NKCC2 phosphorylation at Ser126, Ser874, and Thr96, and 101. We hypothesized that cAMP stimulates NKCC2 recycling in TALs *via* PKA, and Ser126 phosphorylation is involved in this trafficking event.

Methods: We measured NKCC2 recycling and phosphorylation in rat TAL suspensions by a modified surface biotinylation protocol and Western blot.

Results: TALs were incubated in the absence or presence of forskolin/IBMX (F/I) to stimulate cAMP and recycling of internalized NKCC2 measured and expressed as a percent of the internalized pool. We found that internalized NKCC2 recycles back to the surface in a constitutive manner (7 min = 11.4±2.1%, 15 min = 17.2±3.0%, 30 min = 25.1±3.3%, n=6). cAMP enhanced the rate of NKCC2 recycling by up to 160% by 15 min (7 min = 22.8±3.6%, 15 min = 44.6±4.8 %, 30 min = 47.3±1.6%, n=6, $p<0.05$). The internalized pool did not loose the biotin label nor was degraded over 30 min. We found that the PKA inhibitor H-89 (10 μM) completely blocked cAMP-stimulated NKCC2 recycling by 30 min (Basal = 39.5±1.9, cAMP = 59.8±1.7, cAMP+H-89 = 27.3±4.3, n=5, $p<0.05$). cAMP enhanced phospho-Ser126 by 33±6-fold and H-89 blocked this effect by 82% ($p<0.05$), we did not detect Ser874 phosphorylation. cAMP also enhanced Thr96 and Thr101 phosphorylation by 1.7±0.4-fold ($p<0.05$), however this was not blocked by H-89 (1.8±0.4-fold).

Conclusions: We conclude that cAMP stimulates NKCC2 recycling in TALs *via* PKA. PKA inhibition blocked NKCC2 recycling and Ser126 phosphorylation. Our data suggest that Ser126 rather than Thr96,101 is involved in cAMP stimulated trafficking in TALs.

Renal Na^+-K^+-Cl^--Cotransporter Is Structurally and Functionally Associated with Lipid Rafts
Anna Daigeler,[1] Thomas Kahl,[1] Bridget S. Wilson,[2] Alexandra Boehlick,[1] Markus Bleich,[3] Sebastian C. Bachmann,[1] Kerim Mutig.[1] *[1]Department of Vegetative Anatomie, Charité Universitätsmedizin, Berlin, Germany; [2]Department of Pathology, University of New Mexico School of Medicine, Albuquerque; [3]Department of Physiology, Christian-Albrechts-University Kiel, Kiel, Germany.*

Background: Apical Na^+-K^+-2Cl^- cotransporter (NKCC2) is an integral membrane protein responsible for the reabsorption of NaCl in the thick ascending limb (TAL). NKCC2 activity is dependent on the phosphorylation of conserved N-terminal threonine residues. 40-70% of NKCC2 was identified in cholesterol-enriched lipid rafts (LR). This study addresses the distribution of NKCC2 in different types of LR and evaluates their role for NKCC2 function.

Methods: Distribution of NKCC2 was evaluated by colocalization of the transporter with the LR markers, ganglioside GM1 and GPI-anchored Tamm-Horsfall protein (THP) on native membrane sheets from cultured rat TAL cells. Short term effects of methyl-β-cyclodextrin (MβCD)- or sphingomyelinase (SM)-induced disruption of LR on steady state and vasopressin (AVP)-stimulated phosphorylation and transport activity of NKCC2 were evaluated.

Results: Immunogold labeling of luminal membrane sheets from rat TAL cells revealed an association of NKCC2 and phospho (p)-NKCC2 (pT96/pT101) with electron-dense membrane regions. There was little or no colocalization of NKCC2 with GM1 but significant colocalization of the transporter with THP (57% of NKCC2 signal) indicating that NKCC2 is participating in LR containing GPI-anchored proteins. SM-induced disruption of LR markedly decreased the amount of pNKCC2 in the membrane sheets (-70%, $p<0.05$) which was accompanied by redistribution of NKCC2 to membrane regions with lower electron density. SM-treatment also decreased pNKCC2 levels in isolated mouse TALs (-66%, $p<0.05$). AVP increased the phosphorylation of NKCC2 in TAL cells (+33%, $p<0.05$) and its transport activity in isolated perfused mouse TALs (+44%, $p<0.05$). The effects of AVP were significantly blunted after MβCD-induced LR disruption.

Conclusions: We conclude that LR play an important role for NKCC2 phosphorylation and activity.

FR-PO1764

Heterogeneity in the Processing of NKCC2 Mutants Related to Bartter Syndrome Type 1
Yingying Zhu, Sylvie Demaretz, Nadia Defontaine, Nancy Zaarour, Kamel Laghmani. *INSERM, UMRS 872 - Equipe 3- ERL7226, Universités Paris V, Paris VI, Paris, France.*

Background: Mutations in the apically located Na-K-2Cl co-transporter, NKCC2, lead to type I Bartter syndrome (BS1), a life-threatening kidney disease. Regulatory characterizations of NKCC2 mutants were essentially limited to Xenopus laevis oocytes. Consequently, our knowledge of the molecular mechanisms underlying membrane trafficking of NKCC2 mutants in mammalian cells is poor. Undeniably, only analysis of the expression of such NKCC2 mutants in renal cells would definitively establish their cellular fate. Here, we investigated the consequences of previously reported, pathogenic, missense mutations of NKCC2 in renal cells.

Methods: The effect of NKCC2 mutations on protein processing was examined in OKP and HEK cells, using immunoblot analysis and confocal imaging. NKCC2 transport activity was measured as bumetanide-sensitive NH4 influx.

Results: WT NKCC2 was detected as two protein bands representing the core glycosylated (120 kDa) and the complex glycosylated (160 kDa) forms of the protein, located at the endoplasmic reticulum (ER) and the plasma membrane, respectively. Immunocytochemistry analysis showed that WT NKCC2 staining co-localized with biotinylated cell-surface proteins indicating correct targeting of NKCC2 to the cell surface. Immunoblot analysis of three out of six NKCC2 mutants showed only the core glycosylated form of NKCC2. Co-immunolocalization assay revealed that these mutants were not detected at the cell surface due to retention in the ER. Accordingly, they were not functional. One NKCC2 mutant displayed partial loss of complex glycosylation at the

cell surface, which was associated with reduced transport activity. Finally, two NKCC2 mutants were correctly glycosylated and trafficked normally to the cell surface, but exhibited a significantly decreased transport activity.

Conclusions: In summary, our study revealed distinct cellular mechanisms accounting for NKCC2 loss of function in BS1. They are consistent with a model whereby the processing of NKCC2 mutant is determined by mutant specific mechanisms, suggesting that a mutant specific method would be required to rescue the functional expression of each NKCC2 mutant.

A Primary Culture System of Mouse Thick Ascending Limb Cells Established on Collagen-Coated Membranes Bob Glaudemans,[1] Olivier Devuyst,[1,2] Sara Terryn.[1,2] *[1]Institute of Physiology, University of Zurich, Zurich, Switzerland; [2]Nephrology, UCL Medical School, Brussels, Belgium.*

Background: The epithelial cells lining the thick ascending limb (TAL) of the loop of Henle play essential roles in the normal and diseased kidney.

Methods: We report a new method to develop primary cultures from TAL cells, obtained from microdissected tubules from the outer medulla of 1-month-old collagenase-treated mouse kidneys.

Results: The selected tubules specifically express uromodulin (Tamm-Horsfall protein) and the Na+,K+,2Cl- cotransporter NKCC2, whereas markers such as podocin (glomerulus), aquaporin-1 (proximal tubule) and aquaporin-2 (collecting duct) are negative. The TAL tubules were then cultured on permeable filter supports for 7-10 days, allowing the formation of well-polarized confluent monolayers with apical and basolateral domains. The TAL cells maintain a differentiated state, with expression of functional markers such as uromodulin, NKCC2 and the chloride channel ClC-Kb. Confocal microscopy confirmed the apical staining of both NKCC2 and uromodulin. The staining partly overlapped, as NKCC2 was located within the apical membrane, while GPI-anchor protein uromodulin showed additional staining at the extracellular compartment. Further analyses evidenced the typical filaments made of uromodulin in the apical extracellular compartment. In line with in vivo measurements, electrophysiological recordings of primary cultured TAL cells grown on filters show a high transepithelial resistance (1200 ± 175 ohm/cm2) and a lumen-positive transepithelial potential (Vte) (9.3 ± 1.2 mV/cm2) (n=9). The activity of NKCC2 and its role in maintaining the TAL lumen-positive Vte was confirmed by addition of apical bumetanide (100 µmol/L), which caused a sudden drop in Vte, with recovery after washing.

Conclusions: The establishment of this primary culture system will allow to investigate the role of TAL cells obtained from transgenic mouse models, providing insights for understanding the role of that segment in health and disease.

FR-PO1766

Regulation of the Epithelial Na+ Channel by Intracellular Na+ – Mechanism and Time Course Ankit B. Patel,[1,2] Lawrence G. Palmer.[1] *[1]Physiology and Biophysics, Weill Cornell Medical College, New York, NY; [2]Tri-Institutional MD-PhD Program, Weill Cornell/Rockefeller University/Sloan-Kettering Institute, New York, NY.*

Background: Feedback inhibition of the epithelial Na+ channel (ENaC) by intracellular Na+ is a homeostatic mechanism to regulate epithelial sodium transport. Decreases in cell surface expression and open probability of ENaC are thought to be responsible for this regulation.

Methods: We investigated the time course and mechanism of feedback inhibition using two-electrode voltage clamp (TEVC) to measure ENaC activity and biotin labeling to examine cell surface expression. Brefeldin A was used to inhibit insertion of newly ENaC subunits in the plasma membrane.

Results: Incubation of rENaC-expressing Xenopus oocytes in high-Na+ buffer decreased ENaC currents by 70% over 80 minutes but had little effect on oocytes expressing Liddle's mutant (βR564X). However, western blots showed little to no change in cell-surface γ ENaC of WT or βR564X with 1-1.5 hour high-Na+ incubation. Overnight incubation in high-Na+ caused a 92% and 75% decrease in ENaC currents in WT and βR564X-expressing oocytes, respectively with a concomitant decrease in cell-surface γ ENaC in both groups. There was no change in cell surface expression of β ENaC during 1-1.5 hour or overnight high Na+ incubation. In the presence of Brefeldin A, high-Na+ incubation compared to low-Na+ incubation decreased ENaC currents by 82% over 8 hours. We also observed decreased surface expression of cleaved γ ENaC but not total γ or β ENaC.

Conclusions: We show here that increases in intracellular Na+ can decrease ENaC activity independent of changes in cell surface γ ENaC. Retrieval of Liddle's mutant (βR564X) with overnight high-Na+ incubation suggests a Nedd-4 independent retrieval of cell surface γ ENaC. The lack of change in cell surface β ENaC with high Na+ incubation suggests that cell surface expression of the β and γ subunits of ENaC is differentially regulated. Lastly, we show with Brefeldin A that cleaved γ ENaC is preferentially retrieved with high-Na+ incubation suggesting a key role for the regulation of cleaved γ ENaC in the feedback inhibition of the channel.

FR-PO1767

Epithelial Na^+ Transport Regulation by AMP-Activated Protein Kinase in Kidney Collecting Duct and Its Role in Ischemia Hui Li, J. Darwin King, Rodrigo Alzamora, Jeffrey Lee, Nuria M. Pastor-Soler, Kenneth R. Hallows. *Medicine, University of Pittsburgh, PA.*

Background: The epithelial Na^+ channel (ENaC) in the kidney collecting duct regulates total body volume and blood pressure and is regulated by hormones and cellular signals, including metabolic stress induced by ischemia. The metabolic sensor AMP-activated protein kinase (AMPK) inhibits ENaC in kidney and lung epithelia, but the potential role of AMPK activation in the acute inhibition of ENaC following metabolic stress is unknown.

Methods: We used mouse polarized kidney cortical collecting duct ($mpkCCD_{c14}$) cells cultured on Transwells for surface biotinylation and Ussing chamber short-circuit current (I_{sc}) measurements of ENaC following AMPK activity modulation and chemical ischemia. We also used the ex vivo kidney slices method to examine treatment-dependent changes in ENaC immunolocalization by confocal microscopy.

Results: AMPK activation by 5-aminoimidazole-4-carboxamide riboside (AICAR) treatment (1 mM) inhibited both baseline and 10 nM desmopressin (dDAVP)-induced β-ENaC apical membrane expression in $mpkCCD_{c14}$ cells. Similarly, ex vivo AICAR treatment of kidney slices disrupted dDAVP-induced ENaC apical pole accumulation as assessed by immunolocalization in the CD. Treatment of $mpkCCD_{c14}$ cells with chemical ischemic agents, either an inhibitor of glycolytic metabolism (10 mM 2-deoxyglucose) or inhibitors of oxidative metabolism (0.1 µM antimycin A or 2-5 µM CCCP), elicited rapid reductions in amiloride-sensitive ENaC-dependent I_{sc}. These ENaC inhibition responses were blunted in the presence of the AMPK inhibitor Compound C (50 µM) or with inducible RNAi-mediated AMPK-α1 knockdown in $mpkCCD_{c14}$ cells, suggesting that AMPK activation plays a significant role in the ENaC inhibition response to ischemia.

Conclusions: AMPK inhibits ENaC activity and apical surface expression in kidney CCD cells and participates in the ischemia-induced down-regulation of ENaC activity. Inhibition of ENaC and other transport proteins by AMPK under conditions of metabolic stress may play an adaptive role by preventing the dissipation of ionic gradients generated by cellular pumps, thereby limiting cellular ATP consumption.

FR-PO1768

ENaC-Mediated Sodium Reabsorption in $P2X_4$ Null Mice Eilidh Craigie,[1] Robert J. Unwin,[1] Scott S.P. Wildman,[2] David G. Shirley.[1] *[1]Centre for Nephrology, University College London Medical School, London, United Kingdom; [2]Department of Veterinary Basic Sciences, Royal Veterinary College, London, United Kingdom.*

Background: There is now overwhelming evidence that extracellular nucleotides, acting via P2 receptors, can modify ENaC-mediated sodium reabsorption in collecting ducts (Bailey & Shirley 2009, Purinergic Signal. 5:473). However, the P2 receptor subtype(s) involved have not been clearly defined. Pharmacological profiling and the use of genetically engineered mice point to an important role for $P2Y_2$ receptors (Pochynyuk *et al* 2010,FASEB J 24: 2056), but a patch-clamp investigation of rat cortical collecting duct principal cells has provided evidence that apical $P2X_4$ and/or $P2X_{4/6}$ receptors may also modulate ENaC activity (Wildman *et al* 2008, JASN 19: 731).

Methods: The present study was designed to assess, in vivo, the possible role of the $P2X_4$ receptor subunit in the regulation of ENaC activity. $P2X_4$ null mice ($P2X_4^{-/-}$), and their wild-type littermate controls ($P2X_4^{+/+}$), were anaesthetised and surgically prepared for renal clearance studies. After control collections of urine and plasma, mice were given the ENaC inhibitor benzamil (1 mg/kg bolus, IV), and further collections were made. Data are presented as mean±SEM; statistical comparisons were made using ANOVA.

Results: In animals used as drug-vehicle controls, GFR and fractional sodium excretion (FE_{Na}) remained stable. Benzamil treatment did not affect GFR significantly in either $P2X_4^{+/+}$ or $P2X_4^{-/-}$ mice. In $P2X_4^{+/+}$ mice, benzamil caused an increase in FE_{Na} from 0.6 ± 0.2 % to 1.9 ± 0.3% (n = 8, P<0.001; ΔFE_{Na} = 1.3 ± 0.2 %). In $P2X_4^{-/-}$ mice, benzamil increased FE_{Na} from 0.8 ± 0.2 % to 1.8 ± 0.2 % (n = 8, P<0.001; ΔFE_{Na} = 1.0 ± 0.3 %). The benzamil-induced increase in FE_{Na} was not significantly different between the two groups.

Conclusions: These data provide no solid evidence for a role for $P2X_4$ receptors in the regulation of ENaC-mediated sodium reabsorption in mice on a normal sodium intake. It remains to be seen whether this is the case when ENaC expression and activity is up regulated under sodium-restricted conditions.

FR-PO1769

Extracellular ATP Directly Activates Ion Channels in a Mouse Collecting Duct Cell Line Toby S. Scott-Ward, Rebecca Birch, Claire M. Peppiatt-Wildman, Scott S.P. Wildman. *Urinary System Physiology Unit, Royal Veterinary College, London, United Kingdom.*

Background: Extracellular nucleotides have emerged as potent modulators of various renal functions. They exert their effects by binding to and activating cell-surface P2 receptors. These are subdivided into ionotropic P2X receptors (14 subtypes) and metabotropic P2Y receptors (8 subtypes). In the collecting duct, ENaC, AQP2, and ROMK activity and/or expression is altered by extracellular nucleotides. Due to a lack of selective agonists and antagonists, and notoriously unreliable antibodies, controversy exists over the

P2 receptor subtype(s) responsible. Arguably, P2X subtypes are largely overlooked when considering the receptor(s) responsible for extracellular nucleotide-evoked modulation of these key solute and water transport mechanisms.

Methods: Using a cell line (M1) derived from principal cells of the CCD, and perforated whole-cell and excised outside-out configurations of the patch-clamp technique, we have sought functional evidence for extracellular ATP-gated P2X receptor ion channel expression in the CD. The external (bath) solution contained 145 mM NaCl and the internal (pipette) solution contained 145 mM K^+ (70 mM Cl^-).

Results: Upon application of ATP (100 μM) at -60 mV, a large inward whole-cell current activated rapidly and then desensitised in approximately 50% of cells. Interestingly, whole-cell currents appeared to be comprised of several components including an initial rapidly desensitizing current. Furthermore, in outside-out patches, application of external ATP (100 μM) transiently activated flickery single-channel currents (t_{act} ~2 s, t_{des} ~30 s). At -100 mV, the mean single-channel current amplitude (i) and open probability (P_o)* of these channels were -0.59 ± 0.03 pA and 0.63 ± 0.02 (n = 3).

Conclusions: Our result demonstrate that M1 cells express functional ATP-sensitive P2 receptors and, moreover that ATP is able to directly activate channels with properties similar to those of P2X subtypes. Based on these data, we suggest P2X receptors may be key in the regulation of CD solute and water transport.

Functional Coupling between Antinatriuretic Ang II and Natriuretic Bradykinin Signaling Cascades Is Critical for Aldosterone-Independent Regulation of ENaC by Dietary Sodium Intake Oleh Pochynyuk, Mykola Mamenko, Oleg L. Zaika. *Integrative Biology and Pharmacology, University of Texas Health Science Center at Houston, TX.*

Background: It is generally accepted that aldosterone affects activity of the epithelial Na^+ channel (ENaC) in the distal nephron to regulate circulating volume and, consequently blood pressure. However, growing experimental evidence suggest that complementary to aldosterone mechanisms might have a role in regulation of ENaC activity in response to variations in dietary salt intake.

Methods: We used patch clamp electrophysiology in freshly-isolated split-opened murine distal nephrons to test if ENaC can be regulated by systemic salt intake independently of aldosterone.

Results: Inhibition of MR receptors with spironolactone, while decreasing ENaC membrane levels, did not affect regulation of ENaC open probability by dietary sodium. We hypothesized that activation Ang II signaling may contribute to regulation of ENaC by salt intake. Indeed, we found that Ang II in the range from 5 to 500 nM acutely and reversibly increases ENaC Po. Activation of AT1 receptors with subsequent stimulation of NADH oxydase mediated Ang II actions on ENaC. Importantly, saturation of MR status with DOCA treatment did not perturb Ang II regulation of ENaC suggesting that the effect of Ang II is non-redundant. In addition, we found that activation of Ang II cascade further increases ENaC activity via Angiotensin Converting Enzyme (ACE)-dependent mechanism by limiting the inhibitory actions of locally produced Bradykinin (BK). ACE inhibition augmented the inhibitory action of BK on ENaC and caused marked natriuresis in wild type but not in mice lacking BK receptors.

Conclusions: We concluded that the balance between stimulatory Ang II and inhibitory BK cascades allows fine-tuning of ENaC activity during variations in dietary salt independently of aldosterone.

Aldosterone Induces Epigenetic Reprogramming of the αENaC Gene in mIMCD3 Cells Zhiyuan Yu, Qun Kong, Bruce C. Kone. *University of Texas-Houston Medical School.*

Background: Aldosterone increases renal tubular Na^+ reabsorption in part by enhancing α*ENaC* transcription. In addition to known effects of aldo to *trans*-activate α*ENaC* via the mineralocorticoid receptor (MR), we previously reported that α*ENaC* transcription is also governed by an aldosterone-sensitive epigenetic pathway involving histone H3K79 methyltransferase Dot1 and DNA binding protein Af9. The Dot1-Af9 complex associates with and represses basal α*ENaC* transcription in mIMCD3 cells, and aldo releases this repression, increasing αENaC promoter activity and endogenous mRNA levels beginning at 3 h of treatment (J Biol. Chem 284:20917-26, 2009). Determining how genes move through repressed, primed, and active chromatin states is central to understanding transcriptional induction. To understand aldo-induced activation of α*ENaC* transcription, a high-resolution kinetic analysis of aldo-induced changes in the histone code, the recruitment and action of enzymes mediating these changes, and the recruitment and action of MR is needed.

Methods: Time-course ChIP/qPCR assays of the R0 (-988/-713), R1 (-735/-415), R2 (-414/+80), and R3 (-57/+494) subregions of the α*ENaC* promoter from chromatin harvested from mIMCD3 cells in response to 1 μM aldo or vehicle (as a time control) were performed. A common internal genomic fragment was used for normalization.

Results: Under basal conditions, the epigenetic signature of the α*ENaC* promoter included repressive chromatin marks H3K27me3 at R1 and R2, H4K20me3 at R2, and H3K9me3 at R3 (as well as the previously described H3K79 methylation at R0-R3), and occupancy of Dot1, Af9, Sirt1, and Suv39H1. With aldo treatment, Af9 occupancy and H3K79 methylation diminished within 30 min, whereas MR occupancy was first evident at 1 h. Maximal Pol II occupancy, indicative of transcriptional activation, occurred at 1.5 h. In addition, H4K20me3 at R2 and Suv39H1 at R3 decreased while the active chromatin marks H3K36me3, H3K9me1, and H3K4me3 were increased at R1 and R3 during this time frame.

Conclusions: Aldo induces α*ENaC* transcription through an initial, complex reprogramming of the histone code that dismisses the Dot1-Af9 complex to effect de-repression, followed by MR-mediated *trans*-activation of the gene.

An Aldosterone-Regulated NH_2-Terminal Sgk1 Variant with Enhanced Function Is Expressed in the Collecting Duct Christie P. Thomas,[1,2] Nandita S. Raikwar.[1] [1]*Internal Medicine, University of Iowa, Iowa City, IA;* [2]*VAMC, Iowa City, IA.*

Background: Serum and glucocorticoid-regulated kinase 1 (Sgk1), regulates ENaC-mediated Na^+ transport in the distal nephron.

Methods: Sgk1 transcripts were examined in mouse nephron segments and in the collecting duct cell line, $mpkCCD_{c14}$, by qRT-PCR. Sgk1 isoforms were expressed with or without ENaC subunits in $mpkCCD_{c14}$ and FRT epithelia and Na^+ transport measured in Ussing chambers. ENaC surface expression and cleavage were studied in HEK293 cells. Ubiquitination and half-life measurements of Sgk1 isoforms were also studied in HEK293.

Results: Previously, we identified a cell-surface expressed Sgk1 isoform (Sgk1_i2) that stimulates Na^+ transport (AJP 2008, 295: 321-326). We have now identified an aldosterone and insulin-regulated alternate transcript of Sgk1 that is expressed in the native mouse DCT, CNT and CCD and in $mpkCCD_{c14}$. The encoded protein, Sgk_i3 has a variant NH_2-terminus that results in a Sgk1 isoform that is less susceptible to ubiquitination, is more stable and significantly increases Na^+ transport when overexpressed in $mpkCCD_{c14}$ and when co-expressed with ENaC in FRT cells. The increase in Na^+ transport requires an intact kinase domain. Sgk1_i3 increases ENaC cleavage at the cell surface and inhibits the effect of Nedd4-2 to reduce ENaC cleavage, similar to the prototypic Sgk1. Mutation of a conserved polybasic amino acid motif (KKR) in its variant NH_2-terminus converts Sgk1_i3 from a combined nuclear and cytosolic protein to exclusively cytosolic suggesting that the KKR motif may be part of a nuclear localization signal. This KKR motif is also a destabilizing motif; possibly a target for ubiquitination, since mutation of KKR increases the abundance of Sgk1_i3 which correlates with reduced ubiquitination and an increase in the half-life of Sgk1_i3.

Conclusions: In conclusion, we have identified a regulated NH_2-terminal variant of Sgk1 that is expressed in the distal nephron. The encoded protein isoform inhibits Nedd4-2, increases ENaC cleavage and stimulates epithelial Na^+ transport and probably contributes to aldosterone and insulin-stimulated epithelial Na^+ transport in the CNT and CCD.

FR-PO1773

Mechanistic Basis for Specific Activation of SGK1 by mTOR Ming Lu, Jian Wang, Harlan Ives, David Pearce. *Medicine, University of California, San Francisco, CA.*

Background: The serum- and glucocorticoid-induced kinase 1 (SGK1) plays an important role in hormone regulation of ENaC-dependent Na^+ transport. We have previously reported that the mTOR complex-2 (mTORC2) activates ENaC by phosphorylating SGK1. It is, however, unknown which mTORC2 component mediates this interaction, or whether this interaction plays a physiologically relevant role in specific activation of SGK1

Methods: We used the yeast two-hybrid system coupled with random mutagenesis to identify a mutant mSIN1 that does not interact with SGK1.

Results: Expression of the mSIN1 mutant does not restore SGK1 phosphorylation to wild-type levels in mSIN1-deficient murine embryo fibroblasts. Furthermore, in kidney epithelial cells, the mSIN1 mutant has a dominant-negative effect on SGK1 phosphorylation and on SGK1-dependent ENaC-mediated Na^+ transport. Interestingly, the role of mSIN1 to recruit SGK1 to mTOR appears to be specific for SGK1: although mSIN1 is essential for phosphorylation of another mTORC2 substrate, Akt, it does not interact with Akt and its ability to phosphorylate and activate Akt is unaffected by the point mutation that abrogates interaction with SGK1.

Conclusions: These data support the conclusion that mTOR, which regulates a wide array of cellular processes, uses distinct strategies to phosphorylate its various substrates, and suggest a mechanism for specific regulation of ENaC-mediated Na^+ transport without inadvertent effects on unrelated cellular processes.

Role of Sgk2 in Mediating the Regulation of ENaC by Oxygen Russell F. Husted,[1] Rita D. Sigmund,[2] John B. Stokes.[1,2] [1]*Internal Medicine, University of Iowa, Iowa City, IA;* [2]*Internal Medicine, VA Medical Center, Iowa City, IA.*

Background: We have previously demonstrated that changing the ambient oxygen concentration between 1% and 40% has a potent effect on ENaC-mediated Na transport independent of the actions of corticosteroids. This oxygen effect requires hours to become evident, exhibits a clear dose response, and is completely reversible. The purpose of the present experiments was to determine possible molecular mediators of this oxygen effect.

Methods: We used the mouse collecting duct cell line mpkCCD-c14 grown on filters where corticosteroids had been withdrawn for 24 h and measured Na transport by short-circuit current (Isc).

Results: We first investigated the possible role of candidate kinases. At normal oxygen levels inhibitors of ERK1-2 and p38 had minimal effect while inhibitor of JNK reduced Isc by ~50%. However, none of these inhibitors altered the relative effects of 8% or 40% oxygen on Isc. Thus, while JNK may regulate baseline Na transport, it appears not to be involved in the effects of oxygen to regulate ENaC activity. Microarray analysis identified Sgk2 as a possible candidate. Real time PCR demonstrated an increase in Sgk2 mRNA with higher oxygen but no effect of oxygen on Sgk1 or Sgk3 mRNA. Immunoblot demonstrated a similar effect on Sgk2 protein abundance. We constructed Sgk1 and Sgk2 in a tetracycline regulated adenovirus expression system and found that increased expression of Sgk2 had a more potent stimulatory effect on Isc than did Sgk1 at normal oxygen content. Overexpression of Sgk1 did not alter the relative response to changing oxygen. In contrast, overexpression of Sgk2 produced a greater effect at low oxygen and a blunted effect at high oxygen content. Mutation of the analogous phosphorylation site in Sgk2 required for activation by PDK2 (probably mTORC2) greatly blunted the regulatory effect of oxygen.

Conclusions: Regulation of Sgk2 activity has not previously been reported to our knowledge. The results of these studies raise the possibility that Sgk2 plays a role in the regulation of ENaC activity by oxygen.

ENaC Inhibition Stimulates Conductive Cl^- Secretion in the Cortical Collecting Duct Vladimir Pech, Susan M. Wall. *Deparment of Medicine, Emory University School of Medicine, Atlanta, GA.*

Background: In cortical collecting ducts perfused in vitro, Cl^- absorption is reduced when epithelial Na^+ channel inhibitors, such as benzamil, are applied to the luminal fluid. Since ENaC does not transport Cl^-, this study explored the mechanism of benzamil-sensitive Cl^- absorption.

Methods: To do so, Cl^- absorption was measured in CCDs perfused in vitro, taken from mice given aldosterone for 7 days.

Results: Luminal hydrochlorothiazide had no effect on either Cl^- absorption or transepithelial voltage. However, application of benzamil (3 mM) to the luminal fluid reduced Cl^- absorption and transepithelial voltage by ~75% in wild type mice, but had no effect in CCDs from collecting duct-specific ENaC null mice ($Scnn1a^{loxloxcre}$). Eliminating the transepithelial voltage with application of a Na,K-ATPase inhibitor (ouabain) to the bath, also abolished Cl^- absorption, suggesting that benzamil reduces Cl^- absorption by reducing the lumen-negative transepithelial voltage. Benzamil-sensitive Cl^- absorption did not depend on the apical H^+-ATPase or maxi-K^+ channels. In the absence of benzamil, addition of the Cl^- channel inhibitor, DIDS (100 mM), to the luminal fluid had no effect. However, application of DIDS increased Cl^- absorption from 4.3 ± 3.3 to 19.5 ± 4.4 pmol/mm/min ($n=6$, $P < 0.05$) when benzamil was present in the lumen. In addition, with benzamil in the lumen, application of the Na-K-2Cl cotransporter, bumetanide(100 mM) to the bath increased Cl^- absorption from 7.4 ± 3.3 to 16.7 ± 4.9 pmol/mm/min ($n=6$, $P < 0.05$).

Conclusions: 1) in the CCD of aldosterone-treated mice, most Cl^- absorption is benzamil-sensitive, while thiazide-sensitive Cl^- absorption is undetectable and 2) Benzamil applied to the perfusate reduces Cl^- absorption most likely by eliminating the transepithelial voltage, thereby eliminating the driving force for paracellular Cl^- absorption and stimulating conductive Cl^- secretion mediated by an apical Cl^- channel that acts in series with Cl^- uptake across the basolateral membrane mediated by NKCC1.

Preeclampsia Is Associated with Significant Urinary Excretion of Plasmin(ogen) and the Ability of Urine To Activate ENaC In Vitro Kristian B. Buhl,[1] Ulla G. Friis,[1] Bente Jespersen,[2] Per Ovesen,[2] Per Svenningsen,[1] Claus Bistrup,[3] Britta Frederiksen-Møller,[3] Boye Jensen.[1] *[1]University of Southern Denmark, Denmark; [2]Aarhus University Hospital, Denmark; [3]Odense University Hospital, Denmark.*

Background: In patients with nephrotic syndrome, plasminogen is filtered from plasma to pre-urine and activated. Plasmin can proteolytically activate ENaC by cleavage of the γ-subunit, leading to pathophysiological sodium reabsorption.

It was hypothesized that excretion of plasmin(ogen) and the ability of urine to stimulate ENaC activity is a feature of preeclampsia.

Methods: In a cross-sectional study, urine samples were obtained from 16 preeclamptic patients (PE) and 17 normotensive, non-proteinuric pregnant women matched on age and gestational age (Ctrl). Urine was analysed for plasminogen, creatinin, albumin and proteolytic activity. ENaC current after exposure to urine was monitored in mouse cortical collecting duct cells (M1) by whole cell patch clamp.

Results: Urine plasmin(ogen)-creatinine ratio was elevated significantly in PE compared to Ctrl. (geometric mean: 1.7×10^{-4} vs. 3.3×10^{-6}, $p<0.0001$). A significant positive correlation was found in the PE group between urinary plasmin(ogen) and diastolic blood pressure ($p= 0.05$). In the PE-group, proteolytic activity was detected at 75 kD by gelatin zymography in 9 of 13 compared to 1 of 13 in Ctrl. Western blotting of urine yielded results compatible with presence of both plasminogen and plasmin in PE samples. Whole cell patch clamp on M1 cells showed significant increases in current when M1 cells were exposed to urine from PE ($172.6\% \pm 51.4\%$, $n=6$, $p = 0.0002$). The ability of the PE samples to evoke current was abolished by amiloride (2 μM), α_2-antiplasmin (1 μM) and by boiling of the urine samples prior to cell exposure.

Conclusions: Preelampsia is associated with significant urinary excretion of plasmin(ogen) and activation of ENaC by urine. Urinary plasminogen is significantly correlated to blood pressure. We speculate that pathophysiological activation of ENaC by urinary plasmin may contribute to hypertension and edema in preeclampsia.

FR-PO1777

Urinary Content of Plasmin(ogen) and Activation of ENaC Current by Urine Resides during Remission of idiopathic Nephrotic Syndrome Kristian B. Buhl,[1] Rene Frydensbjerg Andersen,[2] Ulla G. Friis,[1] Per Svenningsen,[1] Boye Jensen,[1] Soren Rittig.[2] *[1]University of Southern Denmark, Denmark; [2]Aarhus University Hospital, Denmark.*

Background: In nephrotic syndrome (NS), data show glomerular filtration of plasminogen to pre-urine and activation to plasmin. Urine plasmin activates the epithelial Na^+ channel (ENaC) in vitro. It was hypothesized that this mechanism is causal for NaCl retention and therefore that plasmin and the ability of urine to activate ENaC disappears in the remission phase of nephrotic syndrome.

Methods: Spot urine samples from 20 children with active idiopathic NS were collected and compared to urine samples obtained after remission in the same patients. Urine samples were analyzed for plasmin and plasminogen concentration (ELISA) and urinary protease activity (zymography). Ability of urine to evoke ENaC currents were assessed by whole cell patch clamp using a murine cortical collecting duct cell line (M1).

Results: 20 patients (7 girls) mean age 9.1 ± 3.2 yrs were included. Urine plasmin(ogen) concentration normalized to urine creatinin concentration was found significantly differently in the active phase of NS in comparison to remission by paired t-test ($p<0.0001$, geometric mean: 2244 μg/g vs. 83 μg/g). Gelatin Zymography showed protease activity in urine in 10 of 17 patients in active phase compared to 3 of 17 patients at remission. Western blotting analysis of urine from active phase of NS showed results compatible with the presence of both plasmin and plasminogen whereas at remission, 10 out of 10 tested urine samples were negative. Urine from the active phase of NS evoked a significant increase in ENaC current in M1-cells ($201\% \pm 31\%$, $p<0.006$, $n=6$) that was significantly larger than current evoked by a urine sample from the same individual in the remission phase ($p<0.0006$). Addition of amiloride (2 μmol/L) to urine samples from patients in active phase abolished inward currents.

Conclusions: The parallel observation of remission and normalisation of urine plasmin excretion and proteolytic activity is compatible with a plasma origin of plasmin in urine and a causal role in edema. Further studies should test this by intervention.

Proteinuria Induces Increased Insulin- and IGF1-Receptor Signalling, a Mechanism of ENaC-Mediated Volume Retention Franziska Theilig,[1] Christoph Geers,[1] Daniela Corinne Spohr,[1] Anne Enke,[1] Harm Peters.[2] *[1]Department of Medicine, Institute of Anatomy, Fribourg, Switzerland; [2]Institute of Nephrology, Berlin, Germany.*

Background: Proteinuria is a symptom of many renal glomerular diseases. It is associated with signs of volume retention such as edema formation or hypertension. In the collecting duct a dysregulation of ENaC is assumed to be causative and hormonal activation of aldosterone and vasopressin was excluded.

Therefore, we hypothesized an activation of the insulin- and IGF-receptor signalling to account for the volume retention in proteinuric kidney diseases.

Methods: For the induction of an experimental glomerulonephritis (GN; type Thy1) and puromycin-induced nephritic syndrome (PAN) Wistar rats were injected either with OX-7, puromycin or vehicle. After 6 days, kidneys were prepared for histochemical or biochemical analysis.

Results: Urinary excretion of insulin (control 2.19 ± 0.5; GN 25.1 ± 9.9 und PAN 18.6 ± 6.4 ng/ 24h) and IGF-1 (control 11.9 ± 1.7; GN 264.6 ± 65.5 und PAN 431.9 ± 58.24 ng/ 24h) were strongly increased. Insulin- and IGF-1-R were localized to the apical and basolateral membrane of the collecting duct. Proteinuria induced an increased phosphorylation of the apical insulin/IGF-1 receptor. Insulin and IGF-1 induced a "priming effect" of their respective receptors as determined by cell surface biotinylation experiments and confocal microscopy of mpkCCD cells. An activation of the insulin/ IGF-1R induced signalling cascade with phosphorylation of PDK1, Akt, WNK1, sGK1, Nedd4-2 and consecutive increased ENaC expression was observed upon insulin/ IGF-1 mediated apical stimulation of mpkCCD cells as well as in GN and PAN.

Conclusions: In summary, our results show that proteinuria activated the apical insulin/ IGF-1R pathway and may therefore be an additional mechanism for ENaC mediated volume retention in proteinuric kidney diseases.

FR-PO1779

Nephron Expression and Distribution of the Plasminogen Receptor, PLG-R_{KT}, and Colocalization with ENaC and uPAR, in Murine Kidney Samir Nangia,[1] Hongdong Bai,[1] William B. Kiosses,[2] Kevin W. Chen,[1] Volker Vallon,[1] Lindsey A. Miles,[2] Robert J. Parmer.[1] *[1]University of California, San Diego, and VA San Diego Healthcare System, San Diego, CA; [2]Scripps Research Institute, La Jolla, CA.*

Background: Recent studies suggest a key role for the plasminogen (PLG) activation system in the proteolytic processing and activation of ENaC, providing an important mechanism for the Na^+ retention associated with nephrotic syndrome, in which increased PLG concentrations are present in urine. We recently identified a novel transmembrane PLG receptor, PLG-R_{KT}, which markedly enhances cell surface activation of PLG to the active protease plasmin. Here, we investigated the expression, distribution, and cellular localization of PLG-R_{KT} in murine kidney, and performed quantitative colocalization studies of PLG-R_{KT} and the urokinase receptor (uPAR, another key component of the PLG activation system), with ENaC.

Methods: C57Bl6 mice were perfused *in situ* with 4% paraformaldehyde. Kidneys were fixed, placed through sucrose gradients and frozen in OCT. Sections were immunostained with antisera specific for PLG-R_{KT}, uPAR, and γENaC, followed by fluorescent secondary antibody, and examined using high resolution laser scanning confocal microscopy.

Results: PLG-R_{KT} was prominently expressed in proximal and distal nephron segments, particularly in the distal tubule and collecting duct (as revealed by co-staining with antisera to the sodium chloride co-transporter and aquaporin 2). PLG-R_{KT} was observed primarily on the apical surface, with some labeling also in a punctate distribution in the cytoplasm, in a pattern similar to that observed for γENaC. uPAR (a GPI-linked membrane protein) was primarily observed in the distal nephron, and was almost exclusively on the apical surface. Quantitative analyses of merged images showed substantial apical colocalization of PLG-R_{KT} with ENaC (70.1±1%, n=507 cells), and uPAR with ENaC (62±1%, n=314 cells).

Conclusions: These results demonstrate that PLG-R_{KT}, uPAR, and ENaC are co-localized on the apical surface in the distal nephron, and are present in an orientation to promote PLG activation and ENaC processing.

FR-PO1780

PAR2 Controls the Activity and Expression of Electroneutral Thiazide-Sensitive Sodium Transport in Collecting Duct and Blood Pressure Luciana Morla, Gaëlle Brideau, Lydie Cheval, Gilles Crambert, Suresh Krishna Ramakrishnan, Alain Doucet. *UMRS 872 team 3, UPMC Univ Paris 06 and INSERM and CNRS, Paris, France.*

Background: We previously showed that PAR2 activation increases sodium absorption in cortical collecting ducts (CCD). Therefore, we evaluated whether it participates in the maintenance of blood pressure.

Methods: For this purpose, we compared blood pressure and sodium handling in PAR2$^{-/-}$ and wild type (WT) mice under basal state and sodium depletion *in vivo* and *in vitro* microperfused CCDs.

Results: Under basal state, PAR2$^{-/-}$ mice displayed normal sodium excretion and blood pressure. During the first five days of sodium depletion, PAR2$^{-/-}$ mice showed a blunted ability to maximally decrease their urinary excretion of sodium, as compared to WT mice. This inappropriate ability to conserve sodium was associated with decreased systolic blood pressure (15-20 mmHg) in PAR2$^{-/-}$ mice whereas WT mice maintained a normal blood pressure.

CCDs from WT and PAR2$^{-/-}$ mice fed a normal diet displayed no sodium transport when perfused *in vitro*. However, activation of PAR2 by trypsin or a specific agonist peptide increased electroneutral, thiazide-sensitive sodium reabsorption in WT but not PAR2$^{-/-}$ mice. Sodium depletion induced both electrogenic amiloride-sensitive and electroneutral thiazide-sensitive sodium transport in CCDs of WT mice, but exclusively the electrogenic component in PAR2$^{-/-}$ mice. Thus, PAR2 not only stimulates electroneutral reabsorption of sodium in the CCD, but it is also responsible for the induction of this pathway observed in response to sodium depletion.

Conclusions: In conclusion, through its actions on electroneutral sodium transport, PAR2 participates to the maintenance of blood pressure during sodium depletion.

FR-PO1781

Reduced Anti-Natriuretic Response to Insulin and Benzamil in Mice Lacking Insulin Receptors in the Collecting Duct Lijun Li, Radha Mayuri Garikepati, Carolyn M. Ecelbarger. *Department of Medicine, Georgetown University, Washington, DC.*

Background: The epithelial sodium channel (ENaC) has been shown to be upregulated by insulin in a variety of cell systems and in perfused tubules, but whether circulating insulin plays a role in day-to-day sodium balance is unclear.

Methods: To address this, the IR was selectively knocked out from the collecting duct using mice with Cre recombinase driven by the aquaporin-2 promoter. Natriuretic responses to insulin, dextrose in saline, and select sodium transporter and channel antagonists were studied in both male (M) and female (F) knockout (KO) and wild-type (WT) littermates (3-4 months old).

Results: There were no differences in body weight (bw), basic renal function, or kidney size due to genotype in either sex, with M mice about 5 grams heavier than F. Insulin (0.5 U/kg bw) or vehicle was administered intraperitoneally, and urine collected in metabolic cages for 4 hours. The anti-natriuretic response to insulin was significantly blunted in the KO mice: (μmol Na^+/25g bw/4hr): 5.3 ± 1.6, 13.6 ± 2.7, 8.7 ± 2.5, and 12.4 ± 2.7 for MWT, MKO, FWT, and FKO, respectively ($p = 0.02$ for genotype). Sex differences in this response were not observed. To determine whether reduced basal ENaC activity might play a role in this response, mice were injected with benzamil, ENaC antagonist (1.4 mg/kg bw). KO mice had a significantly blunted diuretic response suggesting reduced basal activity of ENaC in these mice (μl/25g bw/4hr): 399 ± 59, 341 ± 78, 445 ± 75, and 225 ± 30 for MWT, MKO, FWT, and FKO, respectively ($p = 0.04$ for genotype). Sodium excretion trended toward being lower as well in this test in KO, but wasn't quite significant ($p = 0.13$). In contrast, diuretic and natriuretic responses to hydrochlorothiazide (NaCl-cotransporter antagonist) were not affected by genotype, but significantly higher in females.

Conclusions: Our findings suggest that insulin, via its own receptor, is important in renal sodium handling by the collecting duct via activation of ENaC. Fluctuations in circulating insulin levels, therefore, due to diet, disease, or therapy, may be expected to alter sodium handling independently of the renin-angiotensin-aldosterone system.

FR-PO1782

Mechanism of the Epithelial Na+ Channel (ENaC) Regulation by Insulin Tengis S. Pavlov,[1] Vladislav Levchenko,[1] Carolyn M. Ecelbarger,[2] Alexander Staruschenko.[1] *[1]Physiology, Medical College of Wisconsin, Milwaukee, WI; [2]Medicine, Georgetown University, Washington, DC.*

Background: Sodium reabsorption via the epithelial Na^+ channel (ENaC) in the aldosterone-sensitive distal nephron (ASDN) plays a central role in body fluid volume regulation. Insulin is recognized as a powerful regulator of ENaC in the collecting duct.

Methods: To study mechanisms of ENaC regulation by insulin, we generated insulin receptor knockout (IR-KO) mice targeted specifically to the collecting duct principal cells using Cre-lox mediated recombination. Mice with loxP sites flanking the IR gene were crossed with mice possessing Cre-recombinase driven by the AQP2-promoter.

Results: After one week of sodium-deficient diet the IR-KO mice demonstrated significantly lower ENaC activity compared to their wild type littermates as was demonstrated by cell attached patch clamp measurements in freshly isolated split opened collecting duct. Acute insulin application in such experiments revealed that loss of insulin reception prevented increase of ENaC activity which was observed in wild type mice. Immunohistochemical and western-blot assays demonstrated that total abundance of all three ENaC subunits in the kidney cortex were not different between WT and IR-KO mice. Thus, these results suggest that insulin via IR increases ENaC activity affecting the channel open probability (Po). To further determine mechanism of insulin's action on ENaC, we used immortalized mpkCCD$_{c14}$ principal cells. Insulin rapidly increased amiloride-sensitive transepithelial flux in mpkCCD$_{c14}$ cells with the EC_{50}=12.2±1.7nM. Pretreatment of the mpkCCD$_{c14}$ cells with PI3-kinase or mTOR inhibitors LY294002 or PP242, respectively precluded the effect of insulin.

Conclusions: Thus, we propose that insulin is a key regulator of ENaC activity and its effects are mediated via PI3-kinase and mTOR signaling.

FR-PO1783

Effect of Formate on Flow-Dependent Transport of Sodium, Bicarbonate and Chloride in Proximal Tubule Zhaopeng Du,[1] Nanami Gotoh,[1] Sheldon Weinbaum,[2] Alan Mark Weinstein,[3] Tong Wang.[1] *[1]C. & M. Physiology, Yale University, School of Medicine, New Haven, CT; [2]Biomedical Engineering, City College of New York, New York, NY; [3]Physiology and Biophysics, Weill Medical College of Cornell University, New York, NY.*

Background: Glomerulotubular balance (GTB) refers to the nearly proportional change in salt and water reabsorption in proximal tubules with variation in GFR. We have previously demonstrated that axial flow impacts proximal reabsorption of $Na^+$and HCO_3^- by modulating both NHE3 and H-ATPase activity. In this study we investigated whether Cl^- absorption is also impacted by axial flow in the proximal tubule.

Methods: Mouse proximal tubules were perfused in vitro at low (5nl/min) and high (20 nl/min) perfusion rates in the absence and presence of 0.5mM of formate to activate the Cl^-/formate-exchanger. The fluid (J_v) and HCO_3^- (J_{HCO3}) absorption were measured by the changes of ^{3}H-Inulin and total CO_2 concentrations in the original and collected fluid, and the J_{Na} was estimated from the change of J_v and the assumption of isotonic transport. The change in J_{Cl} was estimated as the difference between J_{Na} and J_{HCO3}.

Results: Similar to our previous report, a 53% increase of fluid and Na^+ and doubling of HCO_3^- absorption were observed when the flow rate was increased from 5 to 20 nl/min. Flow did not affect Cl^- absorption, as J_{Cl} was 47.8 and 40.5 pmole/min/mm at low and high flow rates, respectively. Addition of formate significantly increased both Na^+ and HCO_3^- absorption with a stronger increment in Cl^-, but the percentage of increment of transport activity by formate was similar at both low and high flow rates. J_{Na}, J_{HCO3} and J_{Cl} increased by 43%, 39% and 50% and by 42%, 39% and 51% at the low and high flow rate, respectively. Specifically, in the presence of formate, J_{Cl} was 71.4 and 61.3 pmol/min/mm ($P>0.05$) at low and high flow rates.

Conclusions: These results indicate that Cl^- absorption is not impacted by axial flow, and that the absence of a flow effect persists in the presence of formate. They suggest that there is unlikely to be a flow-dependent change in luminal membrane density of the Cl^-/formate-exchanger.

FR-PO1784

Adenosine Receptors Modulate Sodium Uptake in Human Renal Proximal Tubule Cells Earl H. Rudolph, Christopher S. Wilcox, William J. Welch. *Medicine/Nephrology, Georgetown University, Washington, DC.*

Background: Adenosine (Ado) generated in renal proximal tubule cells (RPTCs) acts on local receptors to mediate sodium (Na^+) reabsorption. Inhibition of Ado type 1 receptors (A_1-AR) leads to natriuresis and diuresis, primarily due to its effects in the PT, whereas the effects of inhibition of type 2A receptors (A_{2A}-AR) are unknown.

Methods: To explore the role of Ado in RPTCs, we tested the effects of A_1-AR and A_{2A}-AR inhibition and stimulation on $^{22}Na^+$ uptake in cultured human RPTCs (HK-2 cells). We hypothesized that Ado signals through A_1-AR and A_{2A}-AR to modulate the activity of the Na^+-hydrogen exchanger 3 (NHE3), the major Na^+ reabsorption pathway in RPTCs.

Results: As expected, inhibition of NHE3 with S1611 (10^{-5}M) reduced ^{22}Na uptake by ~60-65% vs. control (Control: 4678±358 vs S-1611: 1772±448 cpm, p<0.001). The A_1-AR antagonist PSB-36 (10^{-8} M) reduced $^{22}Na^+$ uptake by ~20% vs. control (Control: 4678±358 vs PSB: 3707±302 cpm, p<0.001). PSB had no additional effect on $^{22}Na^+$ uptake in the presence of S-1661 vs. NHE3 inhibition alone. Ado deaminase (AD, 5U/mL), which metabolizes endogenous Ado and thereby attenuates AR signaling, inhibited $^{22}Na^+$ uptake by ~20-25% vs. control (Control: 4678±358 vs AD: 3601±424 cpm, p<0.005). Addition of the A_1-AR agonist CHA (10^{-6}M) in the presence of AD restored $^{22}Na^+$ uptake vs. AD alone (CHA+AD: 4689±279 vs. AD: 3601±424 cpm, p<0.005). However, CHA had no additional effect on $^{22}Na^+$ uptake in the presence of S-1611. The A_{2A}-AR antagonist ZM241385 (10^{-8}M) had no effect on $^{22}Na^+$ uptake, with or without inhibition of NHE3. Similarly, the A_{2A}-AR agonist CGS (10^{-8}M) in the presence of AD had no effect on $^{22}Na^+$ uptake, with or without NHE3 inhibition.

Conclusions: In summary, inhibition of A_1-AR decreased $^{22}Na^+$ uptake and stimulation of A_1-AR reduced $^{22}Na^+$ uptake in RPTCs and both actions were attenuated by simultaneous NHE3 blockade. These results suggest that Ado acts on A_1-ARs through signaling pathways that inhibit or promote NHE3 activity. However, neither inhibition nor stimulation of A_{2A}-AR had an effect on $^{22}Na^+$ uptake, either in the presence or absence of NHE3 inhibition, suggesting A_{2A}-AR does not modulate Na^+ uptake in this model.

MPGES-1-Derived PGE2 Mediates Dehydration Natriuresis Zhanjun Jia,[1,2] Gang Liu,[1,2] Tianxin Yang.[1,2] *[1]Internal Medicine, University of Utah, Salt Lake City, UT; [2]Internal Medicine, Veterans Affairs Medical Center, Salt Lake City, UT.*

Background: Dehydration natriuresis is an important physiological response, aiming to reduce the plasma Na^+ and maintain normal plasma osmolality. PGE2 is a natriuretic factor whose production is elevated after water deprivation.The goal of this study was to investigate the role of mPGES-1 in dehydration natriuresis.

Methods: mPGES-1 WT and KO mice were subjected to the 24-h water deprivation (WD).

Results: After 24-h WD, WT mice exhibited a significant increase in 24-h urinary Na^+ excretion (159.2 ± 21.1 vs. 231.2 ± 24.9 μmol/24hl, p<0.01), accompanied with normal plasma Na^+ concentration and osmolality. In contrast, WD-induced elevation of urinary Na^+ excretion was completely abolished in KO mice (152.6 ± 17.3 vs. 128.6 ± 25.9 μmol/24h p>0.05), in parallel with trend increases in plasma Na+ concentration (139.2±1.5 vs. 142.2±1.4 mmol/L, p=0.06) and osmolality (278.4±2.26 vs. 284.0±2.34 mOsm/kgH2O, p=0.051). By qRT-PCR, renal medullary COX-2 mRNA in dehydrated WT mice was upregulated by 2.5 folds, contrasting to unaltered renal mRNA expression of COX-1 and mPGES-1. WD induced 1.8-fold increase in urinary PGE2 output and 1.6-fold increase in PGE2 content in the renal medulla but not the renal cortex of WT mice, both of which were completely abolished in Ko mice. In response to WD, WT mice exhibited a 20% increase in urinary nitrate/nitrite output (p<0.05) and a 2.6-fold increase of urinary cGMP (p<0.01), both of which was completely blocked in the KO mice. By qRT-PCR, the natriuretic EP1 and EP3 subtypes in the renal medulla but not renal cortex were upregulated by 1.5-fold and 1.7-fold, respectively, following WD. In primary IMCD cells EP3 mRNA was elevated by hypertonicity at 540 mOsm/kg H20, irrespective of the type of solutes, whereas the elevation of EP1 mRNA was dependent on the solutes with the stimulation by NaCl, Na-gluconate, but not Cl^- or mannitol.

Conclusions: We conclude: 1) mPGES-1-derived PGE2 contributes to dehydration natriuresis likely via NO/cGMP pathway; 2) EP1 and EP3 in renal collecting cells may distinctively involved in natriuretic effect of PGE2 during water deprivation.

EP1 Receptors Mediate Renal Compensatory Response to Thiazolidinedione-Induced Fluid Retention Via NO/cGMP Zhanjun Jia,[1,2] Tianxin Yang.[1,2] *[1]Internal Medicine, University of Utah; [2]Internal Medicine, VA Medical Center.*

Background: In vitro microperfusion demonstrated the natriuretic property of EP1 receptors but its in vivo action is poorly characterized. This study was to examine the role of EP1 in natriuretic response to rosiglitazone (Rosi)-induced fluid retention.

Methods: WT mice were treated with vehicle or EP1 antagonist SC51322 by minipump and fed a diet incorporated with or without Rosi (320 mg/kg diet).

Results: A 2-week Rosi treatment induced 2-fold increase of urinary PGE2 output, accompanied by 4.2-fold and 2.5-fold increases in renal cortical but not medullary mRNA expression of EP1 and EP2, respectively, contrasting to unaltered expression of EP3 and EP4 in either kidney regions. Rosi treated mice exhibited increased urinary Na^+ excretion (Rosi:1.2±0.06 mmol/24h vs Cont: 0.78±0.14 mmol/24h, p<0.05) and reduced net Na accumulation (intake-excretion: Rosi 0.248±0.043 mmol/24h vs Cont 0.433±0.09mmol/24h, p<0.05), both of which were completely blocked by EP1 antagonism (Na^+excretion:0.756±0.075 mmol/24h, p<0.05 vs Rosi group; Na^+ intake-excretion: 0.399±0.014, p<0.05 vs Rosi group). The changes in 24-h urine volume and water balance followed the same pattern as Na^+. Rosi treatment significantly decreased Hct (Rosi: 47.2±1.4% vs Cont 51.8±0.9%, p<0.05) and this decrease was greater in Rosi+SC51322 group(42.2±1.4%, p<0.05 vs Rosi group), indicating accelerated plasma volume expansion. qRT-PCR showed widespread downregulation of all Na^+ transporters examined, including NHE3, NKCC2, NCC, α-Na-K-ATPase and ENaC subunits in Rosi mice. Interestingly, EP1 antagonism restored the levels of NHE3 and NCC but not other Na^+ transporters. Rosi treatment markedly elevated the urinary output of nitrate/nitrite (Rosi: 323.5±24.5 nmol/24h vs Cont: 94.4±23.2 nmol/24h, p<0.05) and cGMP (Rosi: 10.2±3.1 nmol/24h vs Cont: 3.1±0.77 nmol/24h, p<0.05), both of which were significantly blocked by EP1 antagonism (nitrate/nitrite:163.3±51.2 nmol/24h, p<0.05 vs. Rosi group; cGMP: 4.0±0.54 nmol/24h, p<0.05 vs Rosi group).

Conclusions: Taken together, these data suggest renal PGE2/EP1 pathway play an important role in mitigating Rosi-induced plasma volume expansion via NO/cGMP.

Sodium Delivery and ENaC Regulate Collecting Duct Endothelin Production Donald E. Kohan, Meghana Pandit, Brianna Lyon-Roberts. *Division of Nephrology, University of Utah Health Sciences Center, Salt Lake City, UT.*

Background: Collecting duct (CD) endothelin-1 (ET-1) is an autocrine inhibitor of CD Na reabsorption. Salt loading increases CD ET-1; the mechanisms transducing this effect are poorly understood. Tubule fluid flow increases in response to Na loading, hence we studied flow modulation of CD ET-1. We have previously reported that flow increases mpkCCD cell ET-1 mRNA content via intracellular Ca, PLC and PKC.

Methods: We now extend these studies in MPK cells to examine how flow modulates CD ET-1. MPK cell ET-1 mRNA was assessed at 2 dyne/cm2 for 2 hr using various agents.

Results: Increasing perfusate osmolality to 450 mOsm/L (from 300 mOsm/L) with NaCl, but not mannitol, increased ET-1 mRNA response to flow by 75%. Increasing osmolality with Na acetate, but not choline chloride, increased ET-1 mRNA by 85%, indicating Na-, but not Cl-, dependence. Amiloride (1 μM) or benzamil (0.2 μM) markedly reduced flow-stimulated ET-1 mRNA, indicating ENaC-dependence. Two days of aldosterone increased the flow response by 95%; amiloride reduced the aldosterone response by 75%. Aprotonin reduced flow-stimulated ET-1 mRNA content by 80%. We then examined Ca entry pathways (primarily apical) known to exist in CD. Removal of primary cilia (chloral hydrate or NH4SO4) did not alter the flow response. Blockade (RN1734) or stimulation (La or Gd) of TRPV4 did not affect the flow response, nor did nifedipine. Inhibition of TRPC3/6 channels with SKF96365, BTP2 or Pyr3 modestly reduced the flow response. Blockade of Na/Ca exchange with SEA0400 had no effect on the flow response.

Conclusions: In summary, flow-stimulated CD ET-1 production appears to be mediated in large part by Na delivery whose detection is critically dependent upon ENaC. How this leads to alterations in intracellular Ca signaling remains to be fully determined. These data describe a novel pathway wherein CD Na delivery per se increases CD ET-1 production, thereby potentially down-regulating Na-stimulated ENaC-mediated Na reabsorption. Such a system may be important in natriuretic states wherein diminished CD Na reabsorption is desirable.

Mice with the XX Sex Chromosomal Complement Have a Differential Natriuretic Response to Aldosterone Plus High-NaCl Diet as Compared to XY Lijun Li, Radha Mayuri Garikepati, Carolyn M. Ecelbarger. *Department of Medicine, Georgetown University, Washington, DC.*

Background: Young females (F), on average, have lower blood pressure (BP) than young males (M), in a variety of species. The mechanisms underlying these sex differences are not fully understood but may involve sex steroid and sex chromosomal complement (SCC) influences on sodium handling.

Methods: Utilizing the unique mouse model in which Sry (male sex-determining gene) was translocated from the Y chromosome to an autosome, we evaluated the independent influences of sex (M vs. F) and sex chromosomal complement (XX vs. XY) on natriuretic responses to aldosterone plus high-NaCl diet. Mice of 4 genotypes: 1) XX-F, 2) XY-F 3) XX-M, and 4) XY-M were gonadectomized to remove masking effects of sex steroids. After 2 weeks, they were placed on a low-NaCl diet (0.085%) for 2 days, and then osmotic minipumps were implanted to infuse aldosterone (40 mg/40 g•bw/d). After 4 days, all mice were switched to a high-NaCl diet (3%) for 3-additional days. 24-hr urine was collected. Mice consumed diet and drank water *ad libitum*.

Results: No significant differences in body weight or weight change were observed. By day 2 of high-NaCl diet, mice of the XX SCC demonstrated a significantly more robust aldosterone escape, as evident by higher urine sodium excretion (mmol Na^+/40 g•bw/d): 3.5 ± 0.9 (XX-F), 1.5 ± 0.2 (XY-F), 2.1 ± 0.3 (XX-M), and 1.5 ± 0.4 (XY-M), p = 0.028 for SCC. This significantly increased excretion of sodium in the XX SCC was maintained on day 3 of high-NaCl diet (p = 0.031 for genotype). Interestingly, potassium excretion was also significantly increased in the XX SCC on day 3 (p = 0.045).

Conclusions: These results suggest either: 1) XX SCC are more aldosterone sensitive, leading to early sodium retention necessitating greater pressure natriuresis or, 2) XX SCC have a greater efficiency of escape mechanisms relative to XY. Studies to evaluate BP in this model are currently ongoing. Overall, these studies highlight important differences due to SCC in renal sodium handling in response to high-NaCl diet with aldosterone infusion. This findings may be particularly relevant in the absence of sex steroids, e.g., post-menopausally.

Crosstalk between Kidney and Heart Angiotensin II Contributes to Diabetic Cardiomyopathy through Volume Expansion and Overload Takahiro Masuda, Shigeaki Muto, Eiji Kusano. *Division of Nephrology, Department of Medicine, Jichi Medical University, Tochigi, Japan.*

Background: Chronic kidney disease, including diabetic nephropathy, is a risk factor for cardiovascular disease. In diabetes, kidney and heart angiotensin II (Ang II) play a critical role in each organ damage; however, it is unclear how crosstalk between them is involved in the pathogenesis of diabetic cardiomyopathy (DCM).

Methods: We used male Spontaneously Diabetic Torii (SDT) rats (a novel non-obese human type 2 diabetes model) treated without and with either olmesartan medoxomil (Olm) (an Ang II receptor blocker) or insulin for 16 weeks after diabetes onset. Systolic blood pressure, echocardiographic findings, blood and urinary biochemical findings, and histological findings in left ventricular (LV) and kidney tissues were compared among the groups.

Results: In SDT rats, kidney and heart Ang II, but not circulating Ang II, increased and colocalized with aquaporin 1 (a proximal tubule marker) and cardiac myosin (a cardiomyocyte marker), respectively. SDT rats showed LV chamber dilatation, LV hypertrophy and increases in plasma atrial natriuretic peptide (a plasma volume marker) and tubular Na^+ reabsorption without hypertension. The expression of aquaporin 1 and Na^+-H^+ exchanger 3, both of which contribute to proximal tubule fluid reabsorption, was upregulated in the SDT rat kidney cortex. In SDT rats, cardiomyocyte hypertrophy, interstitial fibrosis and overexpression of Ang II and atrial natriuretic peptide were restricted to the LV subendocardium, which is more susceptible to local environmental changes than is the subepicardium. These events (except the hyperglycemia) were reversed by Olm.; insulin abolished them all.

Conclusions: We conclude that volume expansion via the stimulatory effect of Ang II overproduced in proximal tubules on the tubules' Na^+ reabsorption induces Ang II upregulation in LV subendocardial cardiomyocytes as volume overload, leading to DCM. Therefore, crosstalk between kidney and heart Ang II, which involves the downstream processes of persistent hyperglycemia, contributes to DCM through volume expansion and overload.

Decreased Na-K-ATPase Maximal Activity and Expression in Angiotensin II-Induced Hypertension Agustin Gonzalez-Vicente, Jeffrey L. Garvin. *Hypertension and Vascular Research Division, Henry Ford Health System, Detroit, MI.*

Background: Thick ascending limbs (TALs) reabsorb 25% to 30% of the total filtered NaCl load. NaCl enters TAL cells via NKCC2 and exits via basolateral Na-K-ATPase. We have shown an increase in TAL NaCl reabsorption in Angiotensin II (AngII) induced hypertension. However the transporters affected in this model are not known. Thus we hypothesize that in AngII-induced hypertension Na-K-ATPase activity is enhanced.

Methods: we infused rats with 200ng/kg/min AngII or vehicle for 7 days. Direct femoral mean arterial blood pressure (MABP) was measured. TAL suspensions were obtained and Na-K-ATPase activity measured in permeabilized tubule fragments. Na-K-ATPase expression was analyzed in TAL lysates by Western blots using an anti α1-subunit antibody. We used ^{3}H-Ouabain binding to measure the number of Na-K-ATPases in the plasma membrane.

Results: AngII increased MABP by 20 ± 5 mmHg, (116 ± 4 mmHg, n=10 vs 137 ± 3 mmHg, n=11, $p < 0.001$). Contrary to our hypothesis in AngII-induced hypertension TAL total Na-K-ATPase activity (membrane + intracellular) was decreased by 13% (1.55 ± 0.05 vs 1.35 ± 0.04 mmol PO4/μg protein/min, $p < 0.005$, n=12). We also found a 16 ± 4 % ($p < 0.01$, n=4) decrease in Na-K-ATPase expression. There were no significant differences in the k½ for Na (7.5 ± 0.2 vs 7.4 ± 0.4 mM n=5) or K (1.9 ± 0.1 vs 1.8 ± 0.1 mM, n=7). Despite decreased total activity and expression, we found no differences in the number of pumps located in the membrane (6.5 ± 0.7 x109 vs 6.1 ± 0.8 x109 units/μg protein, n=6).

Conclusions: 1) in contrast to the increase in Na transport, total Na-K-ATPase activity is decreased in AngII-induced hypertension possibly due to decreased expression; 2) changes in enzymatic parameters can not explain the decrease in activity; 3) the increase in NaCl reabsorption that occurs in AngII-induced hypertension must be due to increases in apical Na entry; 4) since total expression is decreased without changes in the number of Na-K-ATPases in the membrane, AngII-induced hypertension may enhance trafficking.

FR-PO1791

Effect of Chronic Tempol on Sodium Transporter Regulation in Sprague Dawley Rats Fed Control Diet Mien T.X. Nguyen, Donna Lee, Nicholas K. Fletcher, Muhammad Madkour, Alicia A. McDonough. *Keck School of Medicine of USC, Los Angeles, CA.*

Background: Both Ang II, which is anti-natriuretic, and high salt diet, which is natriuretic, increase reactive oxygen species (ROS) generation. ROS increases Na+ reabsorption in perfused TALH. Scavenging ROS with Tempol, a superoxide dismutase mimetic, reverses the effects of ROS in the TALH (Ortiz,2002). In contrast, scavenging ROS with Tempol doubles Na+ reabsorption in proximal tubule of Spontaneously Hypertensive Rats (SHR)(Panico,2009). This study aimed to examine effects of Tempol on urinary electrolytes and renal Na transporter abundance and phosphorylation in Sprague Dawley rats.

Methods: Rats fed a normal diet (0.74%NaCl, 2%KCl) were given drinking water without (C, n=5) or with 4mM Tempol (T, n=4) for 2 weeks. Urine was collected overnight in metabolic cages. NHE3, NKCC and NCC abundance and phosphorylation were analyzed in homogenates of renal cortex by immunoblot.

Results: Compared to C, T group had: 38% lower rate of weight gain/wk, 25% lower urine volume (UV), 15% lower UosmV, 30% lower UNa+V, unchanged UK+V and decreased UNa/K ratio (all $p<0.03$). Proximal tubule (PT) NHE3 abundance did not change, NHE3pS552 increased 55% and NHE3p/NHE3total ratio increased 45%, a molecular marker for depressed NHE3 activity (both $p <0.03$). Cortical NKCC and NKCCpT96,T101 both tended to increase (ns) and DCT NCC increased 30% ($p=0.01$) in T treated vs. C.

Conclusions: These results are consistent with effects of Tempol in normal rats to: 1) decrease food and water intake (based on decreased output), 2) decrease PT Na+ reabsorption (in contrast to reports in SHR), 3) increase DCT Na+ reabsorption. We conclude that scavenging basal levels of ROS in control animals significantly alters renal Na+ transporter regulation in a reciprocal manner in PT and DCT.

FR-PO1792

Cellular and Subcellular Aspects of Renal Vasopressin V2 Receptor Distribution Adelina Stoessel,[1] Turgay Saritas,[1] Luca Rampoldi,[2] Sebastian C. Bachmann,[1] Kerim Mutig.[1] *[1]Anatomy, Charite Universitätsmedizin, Berlin, Germany; [2]Molecular Genetics of Renal Disorders Unit Dibit, San Raffaele Scientific Institute, Mailand, Italy.*

Background: Vasopressin (AVP) regulates salt and water transport in renal epithelia, chiefly via vasopressin V2 receptors (V2R). Previous studies of the segment- and cell-type-related aspects of V2R abundance and subcellular distribution produced in part controversial results which may be due to restricted affinities and limited availability of specific antibodies. This study aimed to present a high-resolution analysis of cellular and subcellular V2R distribution in mammalian kidney epithelia.

Methods: A specific anti-V2R antibody was generated and characterized. Renal distribution of V2R was studied using confocal microscopy. Basolateral and luminal subcellular aspects were resolved using immunogold labeling of V2R on kidney sections and confocal evaluation of cultured thick ascending limb (TAL) cells transfected with GFP-V2R.

Results: Application of our anti-V2R antibody on rat, mouse, and human kidney sections produced comparably strong signals in TAL, distal convoluted tubule, and in the principal cells of the connecting tubule and collecting duct as identified using specific markers for the indicated renal tubules. Abundance of the receptor in macula densa (MD) cells was low to absent. No signals were detected in glomeruli, proximal tubules or vascular elements. Confocal evaluation of kidney sections and cultured TAL cells transfected with GFP-V2R revealed no significant co-localization of V2R with luminal proteins, such as Na^+,K^+,$2Cl^-$- cotransporter type 2, Tamm-Horsfall protein, or aquaporin 2, suggesting basolateral distribution of the receptor. Electron microscopic analysis confirmed the predominant basolateral distribution of V2R.

Conclusions: This study provides an extensive analysis of cellular and subcellular V2R distribution in rat, mouse, and human kidney epithelia. Low abundance of the receptor in MD cells may be related to their specific role for TGF.

FR-PO1793

Rho-Kinase Pathway Activated in HIV-Associated Nephropathy Jin Judy Song,[1] Rungwasee Rattanavich,[2] Mohammad Husain,[2] Ashwani Malhotra,[2] Pravin C. Singhal.[2] *[1]Department of Medicine, St. Luke's Roosevelt Hospital Center, New York City, NY; [2]Feinstein Institute for Medical Research, North Shore LIJ Health System, Great Neck, NY.*

Background: Epithelial mesenchymal transition (EMT) plays an important role in the progression of renal interstitial tubular fibrosis. EMT has been shown to contribute to the manifestation of the proliferative phenotype in HIV-associated nephropathy (HIVAN) (Am J Physiol 2010). Activation of Rho A/Rho kinase is one of the major signaling pathways involved in EMT. The inhibition of Rho kinase has been shown to reduce the EMT and renal fibrosis in different animal models. We hypothesized that Rho kinase signaling pathway is contributing to occurrence of EMT in HIVAN. In the present study, we examined the role of Rho kinase in HIVAN.

Methods: Kidneys were harvested from age (4 weeks old) and sex matched control and Tg26 mice. Renal cortical sections were immunolabled for Rho kinase and alpha-SMA (a marker of EMT). To establish a temporal and spatial relationship between Rho kinase and alpha-SMA, serial sections of renal cortical sections of Tg26 mice were labeled either

for Rho kinase or alpha-SMA. Immunoblots were prepared from renal tissues of control and Tg26 mices and probed for Rho kinase. In *in vitro* studies, human tubular cells (HK2) were transduced with either empty vector (EV/HK2) or NL4-3 (HIV/HK2). Immunoblots of EV/HK2s and HIV/HK2 were probed for Rho-Kinase and associated down stream signal- phos-MYPT1.

Results: Tubular cells in Tg26 mice displayed enhanced expression of both Rho kinase and alpha-SMA when compared with control mice. Immunolabling studies revealed spatial relationship between the expression of Rho kinase and alpha-SMA in tubular cells. In *in vitro* studies, HIV/HK2 also showed enhanced expression of Rho kinase. Moreover, HIV/HK2s displayed enhanced expression of phos-MYPT1.

Conclusions: •These findings indicate that Rho kinase is activated in tubular cells in HIVAN.

FR-PO1794

SIRT1/PGC-1α Activation Protects Against Aldosterone-Induced Podocyte Injury Via the Amelioration of Mitochondrial Dysfunction Aihua Zhang, Songming Huang, Guixia Ding. *Department of Nephrology, Nanjing Children's Hospital Affiliated to Nanjing Medical University, Nanjing, Jiangsu, China.*

Background: Podocyte injury causes proteinuria and is found in many glomerular diseases. Mitochondria maintain podocyte energy homeostasis, and mitochondrial dysfunction (MtD) is an early event in podocyte injury. This study investigated whether the transcriptional coactivator, peroxisome proliferator activated receptor-g coactivator 1α (PGC-1α), a major regulator of oxidative metabolism and mitochondrial function, prevented podocyte damage by improving MtD.

Methods: MPC5 conditionally immortalized mouse podocyte clonal cells (kindly provided by Peter Mundel at Mount Sinai School of Medicine) were cultured. C57BL/6J mice had osmotic minipumps implanted subcutaneously. Pumps delivered a continuous infusion of aldosterone (0.15 μg/h). MtD was assessed by mitochondrial membrane potential (MMP), mtDNA copy number, ATP content, and ROS production. Podocyte damage was assessed by apoptosis, nephrin and podocin expression.

Results: Aldosterone (Aldo) decreased PGC-1α expression and induced MtD and podocyte injury in dose- and time-dependent manners. Endogenous PGC-1α suppression by RNAi induced podocyte MtD and apoptosis. Increased PGC-1α levels in podocytes by transfection with a PGC-1α vector prevented Aldo-induced MtD and inhibited injury. The protective effects of PGC-1α overexpression were not observed when a PGC-1α T177A S538A mutant vector was used. *SIRT1* (silent mating type information regulation 2 homolog 1), a gene upstream of PGC-1α, was also investigated. We confirmed that SIRT1 overexpression restored Aldo-induced MtD and podocyte injury by upregulating PGC-1α at both the transcriptional and posttranslational levels. Finally, we found that resveratrol (RSV), a SIRT1 activator, attenuated Aldo-induced MtD and podocyte injury *in vitro* and in Aldo-infused mice *in vivo*.

Conclusions: PGC-1α is important in maintaining normal mitochondrial function, and SIRT1/PGC-1α activation protected podocytes from Aldo-induced MtD and injury. SIRT1 activators, such as RSV, may be useful therapeutically for glomerular diseases to promote and maintain PGC-1α expression and mitochondrial function.

Disparate Effects of Ang II during the Initiation and Progression of HIV-Associated Nephropathy (HIVAN) Divya Salhan,[1] Dileep Kumar,[1] Guohua Ding,[2] Praveen N. Chander,[3] Pravin C. Singhal.[1] *[1]Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY; [2]Medicine, Renmin Hospital of Wuhan University, Wuhan, Hubei, China; [3]Pathology, New York Medical College, Valhalla, NY, China.*

Background: Ang II may contribute to the progression of HIVAN through its hemodynamic effects or its direct effects. We evaluated the role of Ang II in the initiation and progression of HIVAN in genetically engineered HIVAN mice (Tg26) with variable copies of angiotensinogen (agt).

Methods: Tg26 mice with 2, 3, and 4 copies of Agt were evaluated for expression of AT1 and AT2 receptors during embryogenesis (E13, E15, and E18) and after birth, on day 1 and day 10 by immunohistochemical, in situ hybridization, and confocal microscopy. In addition, aging Tg 26 mice with various copy numbers of Agt were evaluated for severity of proteinuria, BUN, renal lesions, collagen deposition, blood pressure and arteriosclerosis, renal tissue mRNA for PAI-1 at 4, 9, 12 and 16 weeks (n=5).

Results: During embryogenesis and on days 1 and 10, renal cells showed greater expression of AT2 receptors when compared to AT1 receptors. Both tubular cells and podocytes showed temporal and spatial relationship between AT1 and AT2 receptors. Mice with 4 Agt copies showed lower blood pressure (mean 110/80 mm Hg) at 4 and 8 wks when compared to mice with two Agt copies (mean 140/90 mm Hg). Mice with 4 Agt copies showed higher blood pressure at 16 wks. Four wks old mice with 4 Agt copies displayed attenuated expression of PAI-1 when compared to age-matched mice with 2 Agt copies; whereas, 16 wks old mice with 4 Agt copies showed 3-fold greater PAI-1 expression than age-matched mice with 2 Agt copies. Tg26 mice (2 Agt copies) aged to nine weeks developed renal lesions that were more severe than those seen in age-matched Tg26 mice with 3 or 4 Agt copies. However, 16 wks old mice with 4 copies of Agt, displayed more advanced renal lesions when compared to wild type Tg26 mice with 2 Agt copies.

Conclusions: We conclude that higher Agt copies-induced protective effect during the initiation of HIVAN may be mediated through the temporo-spatial expression of AT1 and AT2 receptors during embryogenesis and post-natal period.

FR-PO1796

Telmisartan Improves Spatial Memory Dysfunction through Reduction of Cerebral Oxidative Stress in Experimental Uremic Mice Kiichiro Fujisaki, Toshiaki Nakano, Masatomo Taniguchi, Kazuhiko Tsuruya. *Department of Medical and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

Background: Advanced chronic renal failure (CRF) is associated with the brain dysfunction generally referred to as uremic encephalopathy. Although we previously showed an increased oxidative stress in the brain of uremic rodents, a detailed association of oxidative stress with cognitive impairment remains to be elucidated. Recently, antioxidants have been shown to play a neuroprotective role and blockade of renin angiotensin system has been reported to ameliorate brain infarction through reduction of oxidative stress in the brain.

Methods: We investigated the effect of telmisartan (Tel), an angiotensin II type-1 receptor blocker (ARB), against uremia-induced cognitive dysfunction and oxidative stress in mice brain. CRF was induced in male C57BL/6 mice using unilateral nephrectomy and 2/3 electrocoagulation of renal cortex. 8 weeks old mice were divided into four groups: control mice orally administered normal water (CON-NW, n=8), control mice treated with Tel (CON-Tel, n=8), CRF mice orally administered normal water (CRF-NW, n=8), CRF mice treated with Tel (CRF-Tel, n=8). In the radial arm water maze (RAWM) test performed after 8 weeks, we trained all groups for initial four days to memorize water maze and examined on the fifth day. We sacrificed the mice and examined the content of malondialdehyde (MDA), a product of lipid peroxidation, in the brain specimens.

Results: The errors in RAWM test were more frequent in CRF-NW mice than in the control mice, whereas those in CRF-Tel mice were comparable to the controls. The accumulation of MDA was increased in CRF-NW mice, but not in CRF-Tel mice.

	CON-NW	CON-Tel	CRF-NW	CRF-Tel
Blood urea nitrogen (mg/dl)	25 ± 1.8	29 ± 1.8	69 ± 3.9*	68 ± 4.6*
The number of error in RAWM test	1.8 ± 0.64	1.9 ± 0.44	3.9 ± 0.57*♦	1.6 ± 0.50

*p < 0.05 vs. CON-NW and CON-Tel, ♦p < 0.05 vs. CRF-Tel, mean ± SEM.

Conclusions: The present study is the first report that Tel inhibited cerebral oxidative stress and improved memory dysfunction in the uremic mice. It is concluded that Tel has the potential to protect against neuronal cell damage by uremia.

FR-PO1797

Effects of Combined ARB and PPARγ Agonist To Treat Established Glomerulosclerosis in 5/6 Nephrectomized Rats Keizo Matsushita, Li-Jun Ma, Haichun Yang, Agnes B. Fogo. *Department of Pathology, Vanderbilt University Medical Center, Nashville, TN.*

Background: We previously observed that PPARγ agonist can attenuate glomerulosclerosis in rats, with specific protection of podocytes. Azilsartan medoxomil (AZL) is a potent new ARB. We now assessed effects of combination therapy with AZL and pioglitazone on established glomerulosclerosis.

Methods: Sprague Dawley male rats underwent 5/6 nephrectomy (5/6Nx). Body weight (BW), systolic blood pressure (SBP) and urinary protein (UP) were measured at intervals. In pilot studies, AZL in varying doses was given to 5/6Nx rats starting at time of surgery. AZL 3 mg/kg q.d. was effective in controlling SBP (147.3±2.7 vs VEH 199.7±6.1 mmHg at wk12), decreasing UP (309±35 vs VEH 594±92 mg/d at wk12) and sclerosis (GS, 0-4 scale, 0.29±0.06 with preemptive AZL vs 0.96±0.21 in VEH at wk12). Additional 5/6Nx rats were untreated until wk8, then underwent renal biopsy and were randomized to groups with equal starting moderate GS, and treated with AZL (3 mg/kg q.d., n=6), pioglitazone (2.5 mg/kg q.d.; PIO; n=7), combination (AZL+PIO; n=7), or vehicle (VEH; n=7) for 4 wks.

Results: In rats with established sclerosis, SBP, UP and GS were equal in all groups at wk8 by study design (194.4±5.0 mmHg, 254.6±14.9 mg/24hr and 0.84±0.10, respectively). AZL alone from wk8 to 12 prevented increased SBP (195.5±9.1 at wk12), in contrast to further hypertension in VEH (222.0±11.6 at wk12). AZL+PIO significantly decreased SBP (173.4±7.6 at wk12, p<0.05 vs VEH). There was one death in VEH from wk8 to 12, and none in treatment groups. UP at wk12 was not different amongst groups. Sclerosis progressed in VEH from biopsy to autopsy (0.82±0.28 to 1.67±0.35). AZL alone or PIO alone both ameliorated GS at wk12 (1.47±0.42 and 1.36±0.30, respectively). Combination AZL+PIO GS markedly reduced sclerosis at wk12 to 0.70±0.23 (p<0.05 vs VEH). Podocyte number (WT-1/glomerulus) in VEH was 9.6±0.9, and AZL+PIO increased podocyte number to 12.1±0.7 (p<0.05 vs VEH).

Conclusions: Azilsartan is highly effective in primary prevention of hypertension and sclerosis. In combination with pioglitazone, there is enhanced benefit in established sclerosis, linked to podocyte preservation.

Immune Complexes from Patients with IgA Nephropathy Containing Galactose-Deficient IgA1 and Anti-glycan Antibodies Induce Protein-kinase Signaling and Proliferation in Cultured Human Mesangial Cells Zhi Qiang Huang,[1] Joshua Anderson,[1] Stacy D. Hall,[1] Timothy D. Rohrbach,[1] Rhubell T. Brown,[1] Bruce A. Julian,[1] Christopher D. Willey,[1] Jan Novak.[1] *[1]University of Alabama at Birmingham, AL; [2].*

Background: Circulating immune complexes (CIC) in patients with IgA nephropathy (IgAN) consist of galactose-deficient IgA1 (Gd-IgA1) and anti-glycan antibodies. Several *in vitro* studies have shown that these CIC are pathogenic in that they activate mesangial cells (MC) and induce cellular proliferation.

Methods: Using sera of patients with IgAN, we fractionated CIC by size-exclusion chromatography. Cultured primary human MC were stimulated with CIC, samples collected at various time points, and analyzed by SDS-PAGE/Western blotting with anti-phospho-tyrosine (P-Y) antibody. Sera depleted of IgA-containing CIC served as negative control. Maximal changes in P-Y phosphorylation in MC were detected 5 min after stimulation with CIC. These samples were further analyzed using PamStation® 12 high-content peptide substrate microarray to profile global tyrosine kinase (TK) activity (kinomic profiling) to identify CIC-stimulated pathways.

Results: Results showed that CIC increased P-Y of multiple proteins in MC by 3-42%. Kinomic profiling showed that CIC activated multiple TK-mediated signaling pathways, including PDGF signaling and anti-apoptosis processes. To validate these results, similar experiments were performed with engineered immune complexes (EIC) formed *in vitro* from Gd-IgA1 myeloma protein and a recombinant human IgG specific for Gd-IgA1. The EIC increased phosphorylation of proteins in MC by 5-41%. PamStation® kinomic profiling indicated that EIC activated TK in a fashion similar to that for native CIC.

Conclusions: In summary, Gd-IgA1-containing complexes, CIC and EIC, activated multiple signaling pathways in MC and led to cellular proliferation. Importantly, EIC may provide an excellent substitute for native CIC in the future IgAN studies and may be used to develop animal models more closely reflecting human disease.

Protein-kinase Inhibitors Can Block Cellular Proliferation and Signaling Induced in Cultured Human Mesangial Cells by Immune Complexes from Patients with IgA Nephropathy Zhi Qiang Huang, Joshua Anderson, Timothy D. Rohrbach, Stacy D. Hall, Rhubell T. Brown, Bruce A. Julian, Christopher D. Willey, Jan Novak. *University of Alabama at Birmingham, AL.*

Background: IgA1-containing circulating immune complexes (CIC) isolated from sera of patients with IgA nephropathy (IgAN) stimulate proliferation of mesangial cells (MC) *in vitro*. Here, we studied cellular proliferation and signal transduction induced by CIC in cultured primary human MC and the potential blocking effects of tyrosine-kinase inhibitors (TKI).

Methods: CIC were isolated from sera of patients with IgAN by size-exclusion chromatography. Sera depleted of IgA-containing CIC served as negative control. MC stimulated with CIC were analyzed by Western blotting with anti-phospho-tyrosine (P-Y) antibody and by PamStation®12 high-content peptide substrate microarray to profile global tyrosine kinase activity (kinomic profiling) to identify the pertinent signaling pathways. TKIs, dasatinib and sorafenib (50 nM), were tested in assays of cell proliferation and signaling. Cell proliferation was measured as ^{3}H-thymidine incorporation; phosphorylation was assessed by Western blotting with anti-P-Y antibody after MC were incubated with CIC with or without inhibitors.

Results: CIC increased MC proliferation 7-fold compared to the baseline. Dasatinib and sorafenib inhibited the induced MC proliferation by 86% and 19%, respectively. The inhibition of proliferation was reflected by decreased P-Y signaling on Western blots. CIC enhanced P-Y of proteins from MC by 19-67%, based on densitometric analysis. Dasatinib and sorafenib inhibited phosphorylation induced by CIC by 26-64% and by 0-20%, respectively. Kinomic profiling using PamStation®12 showed that CIC increased P-Y of multiple proteins, including those involved in PDGF signaling and in anti-apoptotic processes. Dasatinib significantly blocked CIC-induced P-Y of these proteins, whereas sorafenib was ineffective.

Conclusions: In summary, CIC-induced MC proliferation was mediated by tyrosine-kinase signaling and a TKI can block MC proliferation and signaling, thus raising novel possibilities for potential new options for therapy of IgAN.

Quantitative Analysis of O-Glycosylation of IgA Hinge Portion (HP) in IgA Nephropathy (IgAN) Patients and Its Responsiveness to the Therapy of Tonsillectomy Combined with Corticosteroid IV (TLX+S) Hirotsugu Iwatani,[1] Yasuyuki Nagasawa,[1] Takahiro Inoue,[2] Yoshiyasu Ueda,[1] Ryohei Yamamoto,[1] Maki Shinzawa,[1] Yoshitsugu Obi,[1] Junya Teranishi,[1] Toshihiro Ishigami,[1] Hideki Iijima,[2] Yoshinao Wada,[3] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Gastroenterology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [3]Osaka MCHRI, Izumi, Osaka, Japan.*

Background: Several patterns of sugar chain attached to Ser/Thr residue of IgA1 HP constitute O-glycosylation. The component sugars are N-acetylgalactosamine (GalNAc), galactose (Gal) and sialic acid. Although its qualitative analyses in IgAN patients have been performed and aberrant glycosylation has been already reported, neither its quantitative analysis itself nor its clinical significance has been reported.

Methods: The fully glycosylated form of human IgA1 is as follows; the sugar adjacent to the Ser/Thr residue is GalNAc which is connected to Gal, and sialic acids are attached to GalNAc and Gal. But there are a variety of glycosylated forms of IgA in one individual. We analyzed the serum IgA glycosylation from IgAN patients and control using MALDI-TOF-MS. We calculated the number of GalNAc and Gal at HP and the ratio of Gal to GalNAc. We also analyzed the serum IgA glycosylation of the IgAN patients before and after the therapy of TLX+S.

Results: The ratio of IgA with 5 GalNAc to that with 4 GalNAc in HP and the average number of Gal joined to one GalNAc in HP (Gal/GalNAc) are significantly decreased in patients with IgAN (n=9) compared to healthy control (n=30). In cases of patients with IgAN undergoing TLX+S, the number of GalNAc per HP significantly increased from 4.2 ± 0.085 at pretreatment to 4.4 ± 0.11 at 46 ± 9.5 months post tonsillectomy (p= 0.02). The number of Gal per HP or the ratio of Gal/GalNAc did not change significantly. In remission cases, all patients exhibited the increase of the number of GalNAc per HP.

Conclusions: The O-glycosylation of IgA in patients with IgAN seems to be deeply involved with the pathogenesis of the disease. It can be recovered by the therapy of TLX+S.

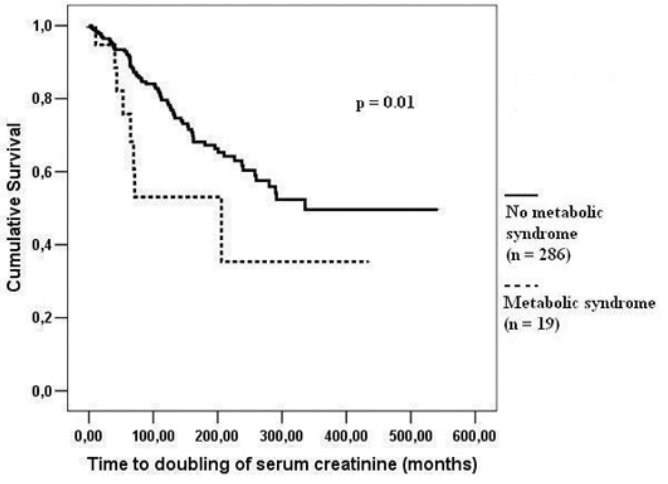
Metabolic Syndrome and Progression of IgA Nephropathy Tibor Vas,[1] Csaba P. Kovesdy,[2] Istvan Kesoi,[1] Balazs Sagi,[1] Istvan Wittmann,[1] Tibor Kovacs,[1] Judit Nagy.[1] *[1]Nephrology Center and 2nd Department of Internal Medicine, Faculty of Medicine, University of Pécs, Hungary; [2]Division of Nephrology, University of Virginia, Charlottesville, VA.*

Background: The components of the metabolic syndrome are major cardiovascular risk factors and the metabolic syndrome itself is associated with a modest but independent and additive risk of new-onset chronic kidney disease (CKD). The purpose of this study is to determine whether there are differences in the progression of IgA nephropathy (IgAN) according to the presence of metabolic syndrome at the diagnosis of IgAN.

Methods: Three hundred and five IgAN patients (19 with metabolic syndrome and 286 without at the diagnosis of the CKD, mean follow-up 142.3 months) were analyzed. Metabolic syndrome was defined on the basis of the modified WHO criteria. End points for renal outcome were doubling of serum creatinine or reaching of end-stage renal disease (serum creatinine >500 umol/l or initiation of dialysis treatment or transplantation).

Results: IgAN patients with metabolic syndrome were significantly older (46.9±15.2 yr), had significantly lower eGFR (54±21 ml/min/1.73m2) than IgAN patients without metabolic syndrome (34.8±13.1 yr, 81±30 ml/min/1,73m2, p<0.001 each). Patients with metabolic syndrome had a significantly lower mean survival time to reach the doubling of serum creatinine than patients without metabolic syndrome (215 months vs 346 months, p=0.01) (Figure).

Conclusions: Metabolic syndrome is associated with faster deterioration of renal function in patients with IgAN. Therefore, the early diagnosis and appropriate treatment of metabolic syndrome may be beneficial in the prevention of progression of IgAN.



FR-PO1802

Metformin Increases Renal Medullary Interstitial Cell Apoptosis In Vitro and In Vivo Youfei Guan,[1,2] Qifei Han,[1] Xiaoyan Zhang.[1] *[1]Physiology and Pathophysiology, Peking University Health Science Center, Beijing, China; [2]Diabetes Center, Peking University, Beijing, China.*

Background: Metformin is the most commonly used pharmacological therapy for type 2 diabetes worldwide. It improves glycemic control in type 2 diabetic patients mainly via the activation of AMP-activated protein kinase (AMPK). AMPK is a Ser/Thr protein kinase acting as a sensor of cellular energy status and is abundantly expressed in the kidney, where it plays an important role in regulating a variety of physiological and pathological processes including ion transport, glomerular and medullary cell function and diabetic nephropathy. We aimed to examine the effect of metformin on the survival of renal medullary interstitial cells (RMICs) under hyperosmotic conditions both in vitro and in vivo. AMPK activity was decreased in RMICs under the hypertonic condition within 12 hr and then gradually returned to the baseline level. Metformin activated AMPK and markedly increased hypertonicity-induced RMIC apoptosis. Similarly, AICAR and A-769662, two selective AMPK activators, or a constitutively active AMPKα construct resulted in a significant increase in apoptosis of RMICs. AMPK activation was associated with the suppression of hypertonicity-induced NFκB nuclear translocation and activation of the cytoprotective cyclooxygenase-2 (COX-2). AMPK activation also resulted in a marked reduction in ROS generation and nuclear expression of tonicity-responsive enhancer binding protein (TonEBP), which prevented up-regulation of osmoprotective genes in hypertonicity-treated RMICs. In vivo study using normal C57Bl/6 mice with water deprivation further demonstrated massive apoptosis of RMICs after treatment with metformin and two other AMPK activators (AICAR and A-769662). Furthermore, treatment of type 2 diabetic db/db mice with AMPK activators including metformin caused a marked increase in RMICs' apoptosis under both normal and dehydration conditions. Taken together, these results identify AMPK as a critical factor involved in the maintenance of RMIC viability in type 2 diabetes and raise safety concerns for metformin in diabetic patients with dehydration.

Decreased Expression of PGC-1α in Skeletal Muscle May Contribute to Protein-Energy Wasting in CKD: Role of Glucocorticoids Russ Price,[1] Bin Zheng,[1] Jennifer L. Gooch,[1,2] Xiaonan H. Wang.[1] *[1]Renal Division, Emory University, Atlanta, GA; [2]Atlanta VA Medical Center, Decatur, GA.*

Background: Accelerated muscle proteolysis contributes to the protein-energy wasting that occurs during CKD and diabetes. PGC-1α is a transcription coactivator that integrates energy metabolism. In muscle, PGC-1α antagonizes the FOXO transcription factors which induce components of proteolytic systems. Previously, we demonstrated that diabetes decreases PGC-1α mRNA as well as calcineurin (Cn)/MEF2/NFAT signaling in rodent muscle; these pathways are implicated in the regulation of PGC-1α transcription. Presently, we tested whether similar changes occur in muscle of CKD mice.

Methods: CKD was induced in mice by partial nephrectomy; controls underwent sham operations. The mice were pair-fed and sacrificed approximately 3 weeks later. mRNAs were measured by qRT-PCR. PGC-1α transcription was evaluated in L6 muscle cells transfected with a PGC-1α-promoter luciferase reporter gene (PGC-1α-Luc).

Results: PGC-1α mRNA was decreased 88±2% (P<0.05) in gastrocnemius muscle of CKD vs controls. The transcriptional activities of MEF2 and NFAT were evaluated by measuring the mRNA levels of their respective gene targets, MRF4 and MCIP1.4 in muscle. CKD decreased MRF4 mRNA by 57±8% and MCIP1.4 mRNA by 43±12% (P<0.05). Since glucocorticoids are necessary for protein wasting in CKD, we tested whether treatment of L6 muscle cells with dexamethasone (DEX; 100 nm, 48 h) affected PGC-1α expression and Cn/MEF2/NFAT signaling. DEX decreased PGC-1α, MRF4 and MCIP1.4 mRNAs by 61±8%, 46±4% and 40±11%, respectively (P<0.05). The decrease in PGC-1α mRNA was due, at least in part, to suppression of transcription because DEX reduced luciferase activity by 30±4% (P<0.05) in muscle cells transfected with PGC-1α-Luc. Importantly, co-expression of constitutively active Cn with PGC-1α-Luc increased luciferase activity 94±20% (P<0.05).

Conclusions: These data indicate that glucocorticoids reduce Cn/MEF2/NFAT signaling and PGC-1α expression in muscle which could lead to higher FOXO activity and accelerated proteolysis. If unchecked, the responses would contribute to the protein-energy wasting associated with CKD.

FR-PO1804

Dysfunction in Renal Protein Handling in Rats Fed a High Fat Diet Deanne H. Hryciw, Esther Grinfeld, Adam M. Miller, Kayte A. Jenkin, Michael L. Mathai, Andrew J. McAinch. *School of Biomedical and Health Sciences, Victoria University, Melbourne, Victoria, Australia.*

Background: Obesity is frequently associated with chronic kidney disease. The earliest marker of chronic kidney disease is microalbuminuria, with an association between the severity of obesity and the magnitude of microalbuminuria. Albumin uptake is processed by a macromolecular complex in the proximal tubules, via interactions with megalin. The molecular mechanism linking obesity and albuminuria is yet to be elucidated, however reduced processing of albumin by the macromolecular complex contributes to the excessive excretion of albumin in the urine. We investigated changes to the mRNA and protein of the macromolecular complex in rats fed a high fat diet, compared to control.

Methods: 18 male Sprague-Dawley rats were fed either a control chow diet (4%) or a high fat diet (22%) for 12 weeks. At weeks 3, 6 and 10, 24 hour urine samples were collected and analysed for sodium, albumin and protein content. Kidneys were excised from animals at week 12. mRNA and protein was extracted, and the levels of megalin, NHE3, ClC-5, NHERF1 and NHERF2 were assessed by real time PCR and Western blot analysis, respectively.

Results: Compared to control, rats fed a high fat diet had a significant increase in body weight. At weeks 3, 6, and 10, there was a significant increase in urinary albumin excretion in rats fed a high fat diet, however the protein in the urine was only significantly increased at week 10. Sodium secretion in rats fed a high fat diet was significantly decreased at 10 weeks. Analysis of the expression of megalin, NHE3, ClC-5, NHERF1 and NHERF2 mRNA indicated no significant difference between control and high fat fed animals. Importantly, the level of NHE3 protein was altered in rats fed a high fat diet which may account for the changes in sodium excretion.

Conclusions: Therefore, in rats fed a high fat diet, there is an increase in renal albumin and protein secretion, and a reduction in sodium secretion. Significantly, albuminuria was shown to precede proteinuria in this model of obesity. This may be due to the altered expression of components of the megalin macromolecular complex observed in these rats.

Endogenous PPAR Agonist Nitro-Oleic Acid Protects Against Adriamycin-Induced Nephropathy in Mice Shanshan Liu,[1,2] Zhanjun Jia,[1,2] Tianxin Yang.[1,2] *[1]Internal Medicine, University of Utah; [2]VA Medical Center.*

Background: Adriamycin (ADR) is an anthracycline antibiotic utilized in antitumor therapy but its clinical use is frequently impeded by renal toxic effects. Nitroalkene derivatives of nitro-oleic acid (OA-NO2) are endogenous lipid products with novel signaling properties, particularly the activation of PPARγ. Our previous studies demonstrated renoprotective action of OA-NO2 in various mouse models of acute and chronic renal injuries. The present study was undertaken to examine the possible role of OA-NO2 in a mouse model of ADR nephropathy.

Methods: BABL/c mice were pretreated for 2 days with OA-NO2 at 5mg/kg/day via osmotic mini-pump, followed by a single injection of vehicle or adriamycin (10mg/kg) via tail vein. Albuminuria and renal function were analyzed at 1 wk of ADR treatment.

Results: ADR mice developed prominent albuminuria (ADR: 508.9±48.5ug/24h vs. Cont: 42.4±7.1ug/24h, p<0.01), hypoalbuminemia (ADR: 0.28±0.08g/dl vs. Cont: 1.01±0.15g/dl, p<0.01), and hyperlipidemia (triglyceride, ADR: 396.2±70.9mg/dl vs. Cont: 61.41±2.7mg/dl, p<0.01), with 90% of the mice in this group having severe ascites. In contrast, the ADR+OA-NO2 group showed less levels of albuminuria (342.4±33.3ug/24h, p<0.01 vs. ADR), hypoalbuminuria (0.58±0.13g/dl, p<0.01 vs. ADR) and hyperlipidemia (212.7±39.2mg/dl, p<0.05 vs. ADR) than ADR group; only 20% of ADR+OA-NO2 mice had mild ascites. The urine thiobarbituric acid-reactive substances (TBARS) significantly increased in ADR group mice (ADR: 0.98±0.1pmol/24h vs. Cont: 0.5±0.07pmol/24h, P<0.05), and this increase was attenuated in the ADR+OA-NO2 group (0.7±0.07pmol/24h, P<0.05 vs. ADR). Kidney histology by PAS staining revealed increased mesangial matrix and mesangial cells in glomeruli, narrow Bowman's capsule, and a large number of protein casts in the tubules. In contrast, these pathological changes were significantly improved in ADR + OA-NO2 group.

Conclusions: Together, these findings suggest a novel therapeutic potential of OA-NO2 in adriamycin nephropathy.

FR-PO1806

Urinary α-1 Microglobulin Is a Stronger Predictor of Glomerular Filtration Rate Than Urinary Albumin in Patients with Diabetic Nephropathy

Rosemary E. Nwoko,[1] Nick Voskoboev,[2] Mykola V. Tsapenko,[1] Timothy M. Borland,[2] Andrew D. Rule,[1] John C. Lieske.[1] *[1]Nephrology, Mayo Clinic, Rochester, MN; [2]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN.*

Background: Urinary albumin excretion is a strong predictor of diabetic nephropathy progression, which presumably reflects abnormal glomerular filtration. In the current study, we evaluated whether measurement of a low molecular weight protein (LMWP, α-1 microglobulin, α1m) or a high MWP IgG is a stronger predictor of GFR.

Methods: A cross-sectional cohort of 114 diabetic patients evaluated in the Mayo Nephrology Clinic were recruited for the study. Random urine samples were obtained for measurement of albumin (Roche immunoturbidometric assay), creatinine, α1m (Siemens nephelometric assay), IgG (ALPCO ELISA), and total protein. Recent serum creatinine, 24-hour albumin and total protein, and other demographic data were abstracted from the chart.

Results: Urinary albumin correlated strongly with urinary total protein (r^2=0.89). Urinary α1m also correlated with urinary total protein (r^2=0.75) and urinary albumin (r^2=0.73). IgG correlated weakly with urinary total protein (r^2 = 0.19). Urinary albumin correlated weakly with GFR (r^2= -0.04). However, urinary α1m had a much stronger correlation with GFR (r^2 = -0.34), while urinary IgG correlated only weakly with GFR (r^2= -0.23). In multivariate analysis, adjusting for comorbidities (hypertension, hyperlipidemia, CAD) and medication use (ACE inhibitors and ARBs), only urinary α1m remained a predictor of GFR (p= 0.018). In a similar model, both urinary urinary α1m (p= 0.0003) and urinary albumin (p= 0.0001) were significant predictors of urinary total protein.

Conclusions: Urinary excretion of α1m is a good indicator of GFR in patients with established diabetic nephropathy, perhaps due to progressive tubulointerstitial disease and proximal tubular dysfunction. Further investigation in longitudinal or prospective cohorts will be necessary to determine if increases in urinary α1m or IgG predict future decline in GFR or carry other prognostic value.

FR-PO1807

The Role of Salt Inducible Kinase in Sodium Retention in the Proximal Tubule

Sonia Saad, Dania Yaghobian, Carol A. Pollock. *Medicine, Kolling Institute, Sydney, NSW, Australia.*

Background: Renal angiotensin II (Ang II) expression is increased in diabetic nephropathy leading to salt retention. Similarly, the peroxisome proliferator activated receptor (PPARγ) pioglitazone, used therapeutically in the treatment of patients with Type 2 diabetes to achieve glyaemic control, also results in excessive sodium reabsorption with salt and water rentention being a limiting side effect to clinical use. We have previously demonstrated that both AngII and pioglitazone increase sodium reabsorption in renal proximal tubular cells (PTC) through increased expression of the sodium hydrogen exchanger 3 (NHE3). Salt inducible kinases (SIK) are members of the AMP-activated protein kinase (AMPK) family. Their levels are regulated by an increase in salt intake and increased SIK1 expression is linked to high blood pressure. The role of SIK1 and 2 in the proximal tube is not known.

Methods: PTCs were exposed to pioglitazone (3μM) or Ang II (100 nM) for 24, 48 or 72 hrs, SIK 1 and 2 mRNA levels were determined by real time PCR. SIK1 and 2 localisation, in the presence and absence of either pioglitazone or AngII, were determined by confocal microscopy. The effect of increasing PPARγ on SIK 1 and 2 expression was determined by Western blot following PPARγ over-expression. The levels of SIK1 and 2 in hypertensive mRen2 rat kidney was determined using immunohistochemistry.

Results: Exposure of PTCs to either AngII or pioglitazone not only increased SIK 1 and 2 in a time dependent matter (P<0.05) but also increased shuffling of SIK1 and 2 from the nucleus to the cytoplasm, reflecting activation. Over-expression of PPARγ increased SIK1 and SIK2 protein levels. Both SIK 1 and 2 were abundantly expressed in hypertensive Ren-2 rats compared to control.

Conclusions: Our data suggest that SIK 1 and 2 are expressed in the proximal tubule and their levels are increased and activated in the presence of both AngII and Pioglitazone. We have additionally demonstrated that SIK1 and 2 are over-expressed in the renal tubules of hypertensive Ren-2 rats. This finding suggests a role of SIK in sodium retention which may be exacerbated in diabetes and further increased by PPARγ agonists.

FR-PO1808

Glomerulosclerosis (GS) in the Rat Diet Induced Obesity (DIO) Model Correlates with Endothelial Dysfunction but Not Renal Hyperperfusion/ Hypertrophy

Aaron Polichnowski,[1] Hector Licea-Vargas,[1] Jianrui Long,[3] Maria M. Picken,[2] Geoffrey A. Williamson,[3] Anil K. Bidani,[1] Karen A. Griffin.[1] *[1]Medicine, Hines VA Hosp and Loyola Univ Chicago, Hines, IL; [2]Pathology, Loyola University Chicago, Maywood, IL; [3]Electrical and Computer Engineering, Illinois Institute of Technology, Chicago, IL.*

Background: Hemodynamic and metabolic pathways have been incriminated in the pathogenesis of GS in obesity models. Yet, minimal GS is seen after 12 wks of DIO. The present studies investigated if significant GS develops after a longer follow-up in the DIO model and the role of hemodynamic mechanisms in its pathogenesis.

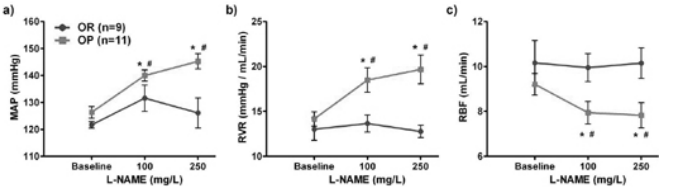
Methods: Obesity prone (OP) and obesity resistant (OR) rats (6-8 wks, Charles River) were placed on a moderately high fat (MHF) diet and BP was monitored radiotelemetrically until ~36 wks of age before sacrifice for histopathology. Additional OP and OR rats were instrumented with a BP radiotransmitter and renal blood flow (RBF) probe (Transonic) at ~20 wks of age before the development of renal injury. After 5-7 days, BP & RBF were recorded (2-4h) in conscious rats at baseline and during escalating doses of L-NAME (100 and 250 mg/L; drinking water) to assess transfer functions and endothelial reserve.

Results: OP but not OR developed modest hypertension, significant proteinuria and GS but not renal hypertrophy.

	BW (grams)	KW (grams)	SBP (mmHg)	Proteinuria (mg/day)	GS (%)
OR (n=8)	588.4 ± 17.7	2.4 ± 0.1	127.5 ± 1.7	12.0 ± 1.4	0.4 ± 0.2
OP (n=10)	699.1 ± 18.9 *	2.4 ± 0.1	142.2 ± 3.0 *	62.4 ± 12.2 *	7.7 ± 1.4 *

mean±SE, * p < 0.05

Fig. 1a-c: MAP, renal vascular resistance (RVR) and RBF were not significantly different at ~20 wks in OP vs. OR rats. L-NAME increased BP & RVR and reduced RBF only in OP rats (*p<0.05 vs baseline; #p<0.05 vs OR)



Conclusions: The mechanism(s) by which endothelial dysfunction leads to GS in DIO models remain to be defined.

FR-PO1809

CKD-Induced Glucocorticoid Production Suppresses Muscle Satellite Cell Function and Stimulates Myostatin Expression Contributing to Atrophy

Liping Zhang,[1] Yanlan Dong,[1] William E. Mitch.[1] *[1]Nephrology Division, Baylor College of Medicine, Houston, TX; [2]; [3].*

Background: We find that chronic kidney disease (CKD) impairs muscle stem or satellite cell function (JASN, 2010). The mechanism for this finding is unclear. We examined if glucocorticoids (GC) suppress satellite cell function because CKD induces GC production and GC are required to stimulate muscle wasting.

Methods: C57/BL6 mice were given physiologic levels of GC (dexamethasone or Dex: 2 μg/100 g/day for 10 days). We measured body and muscle weights and the expression of myogenic genes by satellite cells. Satellite cell function was also analyzed using the standard technique, cardiotoxin (CTX) injection into muscle.

Results: Dex reduced both body and muscle weights vs control values (mice injected with PBS). In gastrocnemius muscles of Dex-treated mice, there was decreased expression of myogenic genes, MyoD, myogenin and Myf-5, indicating impaired satellite cell function. We examined how Dex influences satellite cell activation *in vivo* using the standard CTX method and monitoring muscle regeneration. At 3 days after injury, Dex suppressed Brdu incorporation and myogenin expression indicating impaired proliferation and delayed satellite cell differentiation. At day 5, the newly formed myofibers (detected by their central nuclei) were fewer; after one month, new myofibers in Dex-treated mice were smaller vs those in control mice. Dex also impaired satellite cell function directly: isolated myofibers from gastrocnemius muscles that were cultured on matrigel plates with/without Dex, more satellite cells migrated away from myofibers and proliferated compared to results with Dex. Dex also increased myostatin expression *in vivo* and *in vitro* (cultured C2C12 muscle cells), indicating that the mechanism impairing satellite cell function involves stimulation of myostatin by GC. Indeed, inhibition of the function of myostatin with a myostatin peptibody in Dex-treated mice improved satellite cell proliferation and differentiation and muscle regeneration.

Conclusions: CKD induced GC production upregulates myostatin in satellite cells, suppressing their function, contributing to muscle atrophy.

Activated Prorenin and (Pro)renin Receptor Are Up-Regukated in Glomeruli of Diabetic Nephropathy and IgA Nephropathy Using Renal Biopsy Specimen

Koji Ogata,[1] Yoshiko Shimamura,[1] Kosuke Inoue,[1] Toru Kagawa,[1] Akira Nishiyama,[3] Yoshio Terada.[1] *[1]Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi University, Kohasu, Oko-cho, Nankoku, Kochi, Japan; [2]Endocrinology, Tokyo Women's Medical University, Tokyo, Japan; [3]Pharmacology, Kagawa Medical School, Kagawa University, Kagawa, Japan.*

Background: Activated prorenin plays a key role in the regulation of the tissue renin-angiotensin system (RAS), and a direct renin inhibitor has been reported to reduce proteinuria in diabetic nephropathy through inhibiting the tissue RAS. However, little information is available regarding the localization of activated prorenin and (pro)renin receptor (P)RR in human kidney under pathophysiological conditions.We examined the localization of activated prorenin and (P)RR in kidney biopsy specimens of the patients with IgA nephropathy, diabetic nephropathy, and minimal change nephropathy using parts of renal biopsy specimens.

Methods: This study was approved by Kochi Medical School review boards. The antiserum against activated prorenin was raised in a rabbit by injecting the peptide fragment corresponding to the gate region of human prorenin. Immunohistochemical analyses were performed by confocal microscopy.

Results: We analyzed 21 renal biopsy specimens (n=7 IgA nephropathy, n=6 diabetic nephropathy, n=8 mininal change). Immunohistochemistry with the anti-(P)RR antibody showed positive immunostaining in mesangial area in 14 patients (n=5/7 IgA nephropathy, n=6/6 diabetic nephropathy, n=3/8 mininal change). We also observed positive immunostaining for activated prorenin in podocyte area in 12 patients (n=4/7 IgA nephropathy, n=6/6 diabetic nephropathy, n=2/8 mininal change). These were no significant staining for activated prorenin in endothelial cell in glomeruli. These findings indicate that activated prorenin and (P)RR are up-regulated in mesangial area in diabetic nephropathy and IgA nephropathy, suggesting that activated prorenin and (P)RR may contribute to the pathophysiology of glomerulonephritis.

Conclusions: Activated prorenin and (P)RR are up-regulated in mesangial area and podocyte in diabetic nephropathy and IgA nephropathy, and may contribute to the pathophysiology of these nephropathy.

FR-PO1811

The VEGF Receptor Blocker, Sunitinib (SU), Promotes Glomerular Microthrombosis and Aggravates Segmental Sclerosis in the Remnant Kidney (Nx) Model Flavia G. Machado, Patricia Semedo Kuriki, Clarice K. Fujihara, Camilla Fanelli, Simone R. Costa, Cristiene Okabe, Claudia R. Sena, Grasiela P. Barlette, Vivian L. Viana, Denise M. Malheiros, Niels O.S. Camara, Roberto Zatz. *Univ Sao Paulo, Brazil.*

Background: We showed previously that treatment with SU, used as an antiangiogenic agent, did not influence interstitial capillary density (ICD) in Nx, suggesting that the rate of new vessel formation is not increased in this model. However, SU treatment aggravated glomerulosclerosis (GS). We now investigated whether the latter effect might involve podocyte (POD) injury and/or formation of microthrombi (MT).

Methods: Adult male Munich-Wistar rats underwent Nx and were immediately assigned to Groups Nx+V (vehicle) or Nx+SU (SU, 4 mg/Kg/d). Forty five days later, % GS, % glomerular MT(%GMT), % cortical interstitium (%INT), % glomerular endothelial area (%GE), ICD (capillary profiles/mm^2), glomerular volume (V_G, x 10^{6}μm^3), % glomerular zonula occludens 1 area (%ZO1) and the number of POD per glomerular tuft (POD/G) were assessed in 10 NX+V and 10 Nx+SU rats. Fourteen sham-operated rats receiving vehicle (S+V) or SU (S+SU) were also studied. Results (Mean±SE, ^{a}p<0.05 vs. respective S, ^{b}p<0.05 vs. respective untreated):

Results:

	%GS	%GE	%GMT	%ZO1	POD/G	%INT	ICD
S+V	0±0	53±3	0±0	84±3	16±1	0.1±0.1	609±42
S+SU	0±0	55±3	1±1	85±1	16±1	0.1±0.1	609±30
Nx+V	7±2^a	40±3^a	2±1^a	68±3^a	13±1	2.5±0.4^a	356±39^a
Nx+SU	22±4^{ab}	38±2^a	7±3^{ab}	61±5^a	13±1	3.1±0.4^a	298±33^a

In addition, SU treatment significantly raised serum creatinine in Nx (1.5±0.1 in Nx+SU vs. 1.2±0.1 in Nx+V). SU promoted no glomerular or interstitial change in S, but markedly exacerbated GS in Nx. This effect could not be explained by a reduction in the number of POD or endothelial cells, or by a functional change of POD. However, SU-treated Nx exhibited a marked increase in the frequency of MT, the organization of which may have been the basis for the observed worsening of GS.

Conclusions: Chronic VEGF inhibition can promote glomerular endothelial injury in previously compromised kidneys. However, the antiangiogenic effect of VEGF inhibition may have little influence on glomerular and interstitial injury in the Nx model.

Curcumin Prevents CKD in 5/6 Nephrectomized Rats by Blocking LPS Secretion Siddhartha S. Ghosh, George Bassam Saffouri, Domenic A. Sica, Shobha Ghosh, Todd W. Gehr. *Int Medicine/Nephrology, VCU, Richmond, VA.*

Background: Bacterial lipopolysaccharide (LPS), a known mediator of inflammation is elevated in the circulation of inflammatory disorders such as chronic kidney disease (CKD). This increase in circulatory LPS has been suggested to be due to paracellular transport of bacterial LPS from the gut. Orally acting antibacterial agents by changing gut microbiota can cause decrease LPS translocation. Curcumin which has anti-inflammatory and antibacterial properties ameliorates inflammatory disorders such as CKD. We speculated that one of the mechanisms by which curcumin can decrease inflammation and slow renal failure progression is by decreasing the circulatory content of LPS.

Methods: CKD was induced in Sprague-Dawley rats by 5/6 nephrectomy. 18 Nx animals were divided into untreated (Nx), and curcumin-treated (Cur) groups. The Cur treatment (75 mg/kg) was carried out for 10-weeks and results were compared with Nx and sham-operated animals (SH). Before sacrificing, 4 animals from each group were given thioglycollate (ip) and macrophages (MO) harvested 72 hours later. Proteinuria and creatinine was used as measures of renal function. Lipooxygenase (LO) and cyclooxygenase (COX-2) were measured by western Blot.

Results: As previously observed there was significant improvement in proteinuria and creatinine in Cur treated animals. Plasma LPS concentration in the Nx cohort was (3.3±0.72 EU/ml) significantly higher than in SH (1.1±0.14 EU/ml; p<0.001) and was reduced by Cur treatment (2.1±0.6 EU/ml; p<0.05). Macrophage infiltration is a common phenomenon in CKD and LPS is known to stimulate inflammatory biomolecules such as TNFα, COX-2 and 5 (LO) in macrophages. Compared to SH; macrophages from Nx cohort had a 4 fold higher TNFα mRNA,; 2.3 fold higher LO (p<0.05) and 4 fold higher COX-2 (p<0.01). Compared to the Nx cohort, TNF, LO, and COX-2 were significantly lower in curcumin treated animals (p<0.05).

Conclusions: We reason that the antibacterial aspects of curcumin reduces parcellular transport of LPS and lowers inflammatory marker burden. These findings suggest that paracellular intestinal transport of LPS may play an important role in inflammatory disease states, such as CKD.

FR-PO1813

Adenine-Induced Chronic Kidney Disease: Less Is Best for Equivalence to Human Disease Vishal Diwan,[1] Glenda C. Gobe,[2] Lindsay Brown.[3] *[1]Sch of Biomedical Sciences, Univ of Queensland, Brisbane, Queensland, Australia; [2]Sch of Medicine, Univ of Queensland, Brisbane, Queensland, Australia; [3]Dept of Biological and Physical Sciences, Univ of Southern Queensland, Toowoomba, Queensland, Australia.*

Background: Animal models of chronic kidney disease (CKD), which mimic the insidious development of CKD in humans, are limited. Adenine diet offers an accepted model of CKD pathogenesis but the rapid development from 0.75% adenine can detract from applicability to human CKD. This project aimed to investigate low dose, prolonged, adenine diet in rats as a model of human CKD.

Methods: Male Wistar rats were given 0.25% or 0.75% adenine in comparison with a normal powdered chow (PC) as control (N=12 per group; 300±30g initial body weight), over 16 weeks. We studied: rate of development of CKD; morphometry for glomerular and tubular damage, fibrosis and infiltration/activation of macrophages and myofibroblasts; Western blots for oxidative stress (HO-1), inflammation (TNF-α) and fibrosis (TGF-β); and renal function as blood urea nitrogen (BUN), plasma creatinine (PCr), and their clearances.

Results: 0.75% adenine diet induced renal failure quickly over 4 weeks with approximately 10-fold increase in PCr, marked renal edema, loss of body mass, and the animals were moribund at 4 weeks. In comparison, 0.25% adenine diet induced CKD more slowly, similar to prolonged development in humans. At 16 weeks, in comparison with PC diet, the 0.25% diet induced only moderate loss of body weight, significantly increased % renal fibrosis (35.6±2.8 vs 4.8±0.48), marked tubular atrophy, >10-fold increased macrophage and activated myofibroblast numbers and increased expression of HO-1, TNF-α and TGF-β (all p<0.05). Functionally, 0.25% vs PC diet caused increased BUN (56.5±5.4 vs 6.2±0.6mmol/L) and PCr (267.9±22.9 vs 41.9±2.8μg/L), and decreased BUN clearance (526.7±22.9 vs 753.9±71.2mg/dL/hr) and PCr clearance (380±33 vs 2220±57mg/dL/hr) (both p<0.05).

Conclusions: Development of CKD occurred successfully over 16 weeks with 0.25% adenine diet, with many of the characteristics of human CKD replicated. The slower development of CKD using this model will better allow analysis of modulation of the CKD characteristics with new therapies.

Salutary Effect of a Novel Glutathione Precursor on Chronic Progressive Tubulointerstitial Nephropath Nosratola D. Vaziri,[1] Jun Yuan,[1] Susanne B. Nicholas,[2] Albert B. Crum,[3] Keith C. Norris.[2] *[1]Medicine/Nephrology, University of Califronia, Irviine, CA; [2]Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]ProImmune Company, L.L.C., Rhinebeck, NY.*

Background: Oxidative stress and inflammation play a critical part in the development and progression of CKD. Oxidative stress in CKD is associated with depletion of glutathione (GSH) which is the most abundant and potent intracellular antioxidant. Degradation of GSH by digestive enzymes precludes its use by oral supplementation. Oral administration of F1, a GSH precursor containing cystine as a cysteine carrier has been shown to restore tissue GHS. We tested the hypothesis that GSH repletion with F1 may attenuate oxidative stress, inflammation and severity of CKD in rats with adenine-induced tubulointerstitial nephropathy.

Methods: Male SD rats were randomized to the control (fed regular rat chow), CKD (fed chow containing 0.7% adenine for 2 weeks), and F1-treated CKD (fed chow containing 0.7% adenine for 2 wks during which they received F1, 0.5 g/Kg/day) groups. They were then placed on regular diet and monitored for 2 weeks, after which they were euthanized.

Results: Consumption of 0.7% adenine-containing diet resulted in severe swelling, discoloration and deformation of the kidney, massive interstitial inflammation, heavy tubular and glomerular damage, impaired urinary concentrating capacity, marked elevation of plasma urea and creatinine and severe anemia. Concurrent treatment with F1 significantly attenuated interstitial inflammation, tubular and glomerular injury, renal dysfunction, and anemia in this model.

Conclusions: Administration of the novel glutathione precursor, F1, results in marked attenuation of kidney tissue damage and inflammation in the animal model of severe progressive chronic interstitial nephropathy. Further studies are planned to determine the effect of this intervention in other models of acute and chronic kidney diseases.

Indoxyl Sulfate Causes Accumulation of Uremic Toxins through Down-Regulation of SLCO4C1 Transporter Yasutoshi Akiyama,[1] Yoichi Takeuchi,[1] Eikan Mishima,[1] Takehiro Suzuki,[1] Sadayoshi Ito,[1] Takaaki Abe.[2,3] *[1]Division of Nephrology, Endocrinology and Vascular Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Division of Medical Science, Tohoku University Graduate School of Biomedical Engineering, Sendai, Japan; [3]Department of Clinical Biology and Hormonal Regulation, Tohoku University Graduate School of Medicine, Sendai, Japan.*

Background: With the progression of CKD, various uremic toxins accumulate, subsequently causing renal damage and hypertension. Recently, we have revealed that human kidney-specific organic anion transporter SLCO4C1 excretes uremic toxins, resulting in the reduction of blood pressure and renal inflammation (PNAS 2004, JASN2009). However, in the renal failure, the SLCO4C1 expression level is decreased. So far, the down-regulation mechanism of renal transporters in the renal failure has not been clarified.

Methods: Toxic potentials of various uremic toxins identified by our capillary electrophoresis-based MS analysis (HTN Res 2010) were examined at the translational and transcriptional levels in vitro and in vivo.

Results: Among the compounds tested (18 compounds), indoxyl sulfate (IS) decreased the human SLCO4C1 mRNA level in a dose-dependent manner. Because of the existence of GATA sequence at the 5' UTR of human SLCO4C1, we examined the correlation of SLCO4C1 with GATA transcriptional factors. The mRNA expression level of GATA3 was increased by IS in contrast to down-regulation of SLCO4C1. In the human kidney cells, over-expression of GATA3 significantly inhibited the expression level of SLCO4C1 and conversely, knockdown of GATA3 increased SLCO4C1 expression. GATA-inhibitor K-7174 completely canceled the effects of IS. In 5/6 nephrectomized rats, treatment with oral absorbent AST-120 significantly decreased plasma IS level and conversely increased the renal SLCO4C1.

Conclusions: The accumulation of IS in the renal failure decreases human SLCO4C1 through GATA transcriptional pathway. This down-regulation of SLCO4C1 further causes the rise of uremic toxin levels and subsequently, exacerbates the renal function. Thus, the usage of AST-120 to reduce IS level is a new aspect for treating CKD patients.

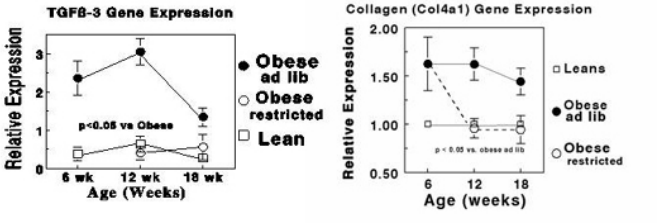
FR-PO1816

Food Limitation Reverses Increased Collagen Type 4 α1 Gene Expression (Col4a1) in the Obese Zucker Rat Bayard C. Carlson,[1] Leah B. Callahan,[1,2] David A. Maddox.[1] *[1]Sioux Falls VA Healthcare System, Sioux Falls, SD; [2]Avera Research Institute.*

Background: Obesity is closely linked to hypertension, Type II diabetes, and hypercholesterolemia, which are among the leading causes of kidney failure. Obese Zucker rats at 6, 12, and 18 weeks of age over-express transforming growth factor beta-3 (TGF- β3) compared to their lean littermates. This effect is prevented by food restriction which also prevents kidney damage. TGF- β3 belongs to a pro-collagen generation pathway leading to kidney damage. We examined the effects of food restriction on Col4a1 gene expression in the obese rat.

Methods: Six week-old obese Zucker rats were fed *ad libitum* or restricted in food intake to that consumed by lean Zucker rats, then tested at 6, 12, and 18 weeks of age. The animals were anesthetized, and their kidneys perfusion-fixed (RNA*Later*™). Tissue mRNA was extracted and quantified from the kidney cortex, converted to cDNA, then run on custom RT-PCR arrays (SABiosciences). Values are mean ± SE.

Results: Previously we found that TGF-β3 gene expression was increased in 6, 12, and 18 week-old obese animals compared to lean. Food restriction reduced TGF-β3 expression to control at 12 and 18 weeks (left panel). Col4a1 gene expression was also significantly increased at 6, 12, and 18 weeks of age in obese animals compared to controls. Food limitation prevented these changes (right panel).



Conclusions: Similar to that seen for TGF-β3, gene expression of Col4a1 in the obese rat was elevated at 6 weeks of age. Food restriction in obese rats beginning at 6 weeks of age led to a significant drop in gene expression levels of Col4a1 by 12 weeks. These data suggest that elevations in the expression of TGF-β3 and Col4a1 are important initiating events leading to kidney damage in these animals. The contents do not present the views of the Department of Veterans Affairs or the United States Government.

FR-PO1817

Renoprotective Effects of Astragaloside IV Synergizes with Ferulic Acid in Rats with 5/6 Nephrectomy Liqiang Meng, Lei Qu, Jiawei Tang, Xiaomei Li. *Renal Division, Department of Medicine, Peking University First Hospital.*

Background: Astragaloside IV (AS-IV) and Ferulic acid (FA) are two major active constituents of Chinese herbs *Astragali* and *Angelicae*, which could alleviate renal tubulointerstitial fibrosis. This study was to investigate whether AS-IV and FA could retard the progression of chronic renal failure in rats with 5/6 Nephrectomy (Nx).

Methods: The Sprague-Dawley rats were randomly divided into sham, Nx, Nx+FA (FA 12mg/kg/d), Nx+AS-IV (AS-IV 20.4mg/kg/d) and Nx+AF (FA 12mg/kg/d, AS-IV 20.4mg/kg/d). After therapy for 2, 4, 8 and 12 weeks, the tail-cuff blood pressure, serum creatinine (Scr), 24 hour protein excretion rate, semiquantitatively evaluated for glomerulosclerosis, tubulointerstitial lesion and vascular damage in PAS stained tissue sections were evaluated.

Results: The blood pressure was significantly increased in Nx group compared with sham group at 4th,8th and 12th week. Compared with the Nx group, blood pressure was reduced in AF-treated group at 4th week (113±4/84±2mmHg vs 139±9/104±19mmHg, P<0.01), and in the three groups with therapies at 8th week (FA: 127±9/96±8mmHg, AS: 115±7/83±7mmHg, AF: 111±12/77±10mmHg, vs Nx:152±9/100±15mmHg, P<0.001). But there was no statistical difference in groups with therapies at 12th week. Scr and proteinuria were gradually increased in the Nx group compared with sham group (P<0.05). After treatment with AF, Scr was decreased at 4th week (42.3±4.5μmol/L vs 55.4±4.7μmol/L, P<0.05), 8th week (47.3±1.2μmol/L vs 58.0±0.0μmol/L, P<0.05) and 12th week (60.3±4.6μmol/L vs 80.2±9.5μmol/L, P<0.05). The similar effect on Scr was shown in the groups treated with AS-IV or FA. The proteinuria was decreased after AS-IV and/or FA at 4th, 8th and 12th week. The pathological injury in kidney was significantly exacerbated from 4th week in the Nx group, and alleviated after treated by AS-IV, FA and AF characterized by total injury index reduced to 83%, 85% and 79% at 12th week, respectively.

Conclusions: AS-IV and/or FA therapy retarded the progression of renal failure in rats with 5/6 Nephrectomy via effective control of hypertension and proteinuria, and the synergistic effect of AS-IV and FA was more effective than AS-IV or FA alone.

Urinary Levels of Angiopoietin-Like 4 in Pediatric Steroid Sensitive Nephrotic Syndrome Support a Possible Role in Proteinuria Michael R. Bennett, Nuntawan Piyaphanee, Prasad Devarajan. *Cincinnati Children's Hospital Medical Center.*

Background: Idiopathic nephrotic syndrome (NS) is the most common glomerular disorder of childhood. Roughly 90% of children under 10 years of age with nephrotic syndrome have minimal change disease (MCD), which is typically responsive to steroid treatment (SSNS). While some structural proteins in the glomerulus have been found that may contribute filtration problems in MCD, many of the disease mechanisms remain unknown. Recent studies in animal models of SSNS suggest a role for podocyte excreted angiopoietin-like 4 protein (ANGPTNL4)in modulating proteinuria in this disease. We set out to determine if urinary levels of ANGPTNL4 were elevated in pediatric patients with SSNS with active proteinuria.

Methods: Urine and clinical data were collected from patients at Cincinnati Children's recently diagnosed with active nephrotic syndrome and healthy controls. Patients with a history of gross hematuria, active/recurrent UTI or nephrotic syndrome secondary to systemic disease were excluded. ANGPTNL4 was measured using a commercially available ELISA. Median ANGPTNL4 levels were calculated and subjected to Kruskal-Wallis One Way Analysis of Variance on Ranks and Dunn's multiple comparison test.

Results: This study included three groups: biopsy-proven FSGS and steroid resistant clinical course-SRNS (n=14), steroid sensitive clinical course-SSNS (n=14), and normal controls (n=10). SSNS was divided into relapse (active nephrotic grade proteinuria; n=7) and remission (n=7). Median ANGPTNL4 levels were significantly (p=0.001) higher in SSNS-relapse (22.2 ng/ml; IQR 1.9-69) vs SSNS-remission (0.0 ng/ml; IQR 0.0-0.6). While median ANGPTNL4 levels were 16 fold higher in SSNS-relapse than SRNS (1.4 ng/ml; IQR 0.4-11.7), it failed to reach significance (p=0.06). ANGPTNL4 was undetectable in healthy control urine.

Conclusions: Significantly increased ANGPTNL4 in urine from pediatric patients with active SSNS vs those in remission is consistent with the animal findings that this protein may be involved in the genesis of proteinuria in this disease. Urinary ANGPTNL4 may serve as a non-invasive biomarker to differentiate between SSNS-relapse and SRNS.

FR-PO1819

Knockout of α2A-Adrenoceptors Delay Progression of Chronic Kidney Disease Henning Hoch, Johannes Stegbauer, Sebastian Alexander Potthoff, Eva Koenigshausen, Lars C. Rump, Oliver Vonend. *Department of Nephrology, Medical Faculty, Heinrich Heine University, Duesseldorf, Germany.*

Background: Chronic kidney disease (CKD) is a major health issue. Investigations were carried out to analyse the function of α2A-adrenergic receptor (AR) for progression of CKD. The α2A-AR is known as main regulator of presynaptic noradrenaline release.

Methods: A murine knockout model (KO) with deletion of α2A-AR was used and compared to its wild-type (WT). Experimental renal failure was induced by subtotal nephrectomy (SNX). Kidneys of WT and KO mice were isolated perfused for evaluation of presynpatic noradrenaline release and angiotensin II pressor response.

Results: In kidneys of KO mice presynaptic noradrenaline release after renal nerve stimulation was significantly higher than in WT mice. After SNX WT and KO mice developed albuminuria which was surprisingly significant higher in WT mice. Kaplan-Meier survival analysis revealed a diminished mortality of KO mice. In isolated perfused kidneys the α2-agonist UK14,304 showed a facilitatory effect on angiotensin II-induced vasoconstriction. In addition, UK14.304 induced a concentration- and time-dependent phosphorylation of extracellular signal-regulated-kinases ERK1/2 in α2A-AR transfected HEK 293T-cell.

Conclusions: The presented data confirms the noradrenaline release regulating effect of presynaptic α2A-adrenergic receptors. Moreover, our data reveal a major role of postsynaptic α2A-adrenergic receptors regulating vascular tone for progression of CKD. The cell culture experiments might hint to an ERK1/2 dependent pathway which could explain the effect of catecholamines modulating fibrotic or inflammatory processes in CKD.

FR-PO1820

Renoprotective Effects of Nicorandil in the Rat Remnant Kidney Model Yoshifuru Tamura, Carlos Alberto Roncal-Jimenez, Christopher J. Rivard, Katsuyuki Tanabe, Wataru Kitagawa, Richard J. Johnson, Takahiko Nakagawa. *Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO.*

Background: Nicorandil has been used to treat patients with ischemic heart disease. Interestingly recent literatures have documented that nicorandil exhibits the protective effects in the acute renal disease in rodents, including acute kidney injury and glomerulonephritis. We hypothesized that nicorandil also exhibits beneficial effects in the chronic renal disease. In order to test our hypothesis, nicorandil was administered in the rat remnant kidney (RK) model. We also examined if nicorandil could be more potent with angiotensin converting enzyme inhibitor (ACEI) in chronic renal disease.

Methods: RK rats were divided into five groups: Sham operated rats (SHAM, n = 7), Untreated remnant kidney rats (RK, n = 7), RK rats treated with Enalapril 5 mg/kg/day (ENAL, n = 7), RK rats treated with low dose Nicorandil 3 mg/kg/day (L-NICO, n = 7), RK rats treated with high dose Nicorandil 30 mg/kg/day (H-NICO, n = 7). Twelve weeks later, the rats were sacrificed.

Results: Enalapril significantly reduced blood pressure (108 ± 2 vs. 147 ± 2 mmHg, $p<0.05$). Nicorandil at high dose tended to reduce blood pressure (136 ± 6 mmHg, $p = 0.11$), while low dose had no effect on it (153 ± 0 mmHg) at 12 weeks. Urine albumin excretion was significantly ameliorated by nicorandil as well as enalapril compared with that in RK (1.66 ± 0.5 in H-NICO, 7.98 ± 3.0 in L-NICO, 0.28 ± 0.2 in ENAL vs. 14.5 ± 5.4 mg/day in RK) at 9 weeks. Interestingly, the preventive effect of L-NICO on albuminuria could be independent of blood pressure. In histology, the development of glomerular sclerosis was significantly attenuated in the group H-NICO and ENAL compared with non-treated RK.

Conclusions: High dose of nicorandil prevents the progression of chronic renal disease as potently as enalapril. Low dose nicorandil may also reduce proteinuria independently of blood pressure. These findings suggest that nicorandil could be a therapeutic option for chronic renal disease.

FR-PO1821

Prolactin Receptor was Up-Regulated in the Proximal Tubules of the Kidney in the Cardio-Renal Syndrome Model Mice Yohei Tsuchida, Yoshikatsu Kaneko, Akihiko Saito, Tadashi Yamamoto, Ichiei Narita. *Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata City, Niigata Prefecture, Japan.*

Background: Many epidemiological investigations revealed the interaction between dysfunctions of kidney and cardiac. These pathological states were recently recognized as cardio-renal syndrome (CRS). However, the precise pathogenesis and the physiological mechanisms of CRS are to yet be elucidated. Hence the aim of our study was to investigate the molecular mechanisms of the development of CRS by generating the CRS model mice.

Methods: We generated CRS model mice by the combination of uninephrectomy (Nx) and abdominal aorta banding (Ab), which caused mild decrease of cardiac function through the continuous pressure load. To evaluate cardiac and renal function, we measured ejection fraction (EF) by echocardiogram and serum cystatin C level by ELISA, respectively. Comprehensive gene expression analysis in the kidney of the CRS model mice, comparing those in the kidney of the mice treated with Nx alone, was conducted using DNA array.

Results: In CRS mice, serum cystatin C level as significantly higher and EF was lower compared with those in the control mice with Nx alone 6 weeks after Nx. DNA array analysis revealed that prolactin receptor (Prlr) gene expression was enhanced in CRS mice kidney compared with that in Nx mice. Real-time RT PCR using mRNA purified from the kidney showed that Prlr gene expression was significantly increased in both Ab and CRS mice. Gene expression levels of several alternative Na^+ channels were not affected by Ab and Nx. *In situ* hybridization study in the fixed kidney tissue demonstrated that the gene expression of prlr was distributed in the proximal tubules along the border between the cortex and the medulla. Serum prolactin (Prl) level was not affected by Ab or Nx.

Conclusions: We newly generated CRS model mice and discovered that prlr expression was up-regulated in the proximal tubules of the kidney in these model mice. Prl may act as a natriuretic hormone by inhibiting proximal tubular Na^+ / K^+-ATPase activity, and the diuresis might be accelerated by up-regulation of the prlr in CRS.

FR-PO1822

Hypoalbuminemia and microRNAs in Chronic Kidney Disease Carmen Josefina Mora,[1] Diego Julio Arenas,[2] Carmen María del Prado,[1] Teresa Renata Romero,[1] Virgilia Soto,[3] Marcela Avila.[1] *[1]UIMEN, CMN SXXI IMSS, Mexico, DF, Mexico; [2]UIMGH, CMN SXXI IMSS, Mexico, DF, Mexico; [3]S. Patologia, H Cardiol, Mexico, DF, Mexico.*

Background: AIbumin synthesis is controled by positive and negative transcription factors. Its transcript translation regulation by microRNAs (miRNAs) is unknown.

The aim was to investigate the relationship between albumin synthesis and a miRNAs profile in a CKD mice model.

Methods: Four mice groups were formed: CKD group, induced with Nx 5/6, Inflammation group (I) induced with E. coli, LPS, food restriction group 50%, (FR), and control group (C). The animals were sacrificed after eight weeks of treatment; total-blood samples and liver were extracted, and plasma creatinine, albumin, and total proteins were measured. Total RNA was extracted from liver for Albumin mRNA measurement in RT-PCR. miRNAs were obtained for miRNAs microarrays. Gene target prediction was made with "miRANDA" database. Liver histological analysis was made to corroborate fibrosis development.

Results: Plasma albumin was different in CKD (1.59 g/dL, $p<0.016$) and I groups (1.68 g/dL, $p<0.009$) from C group (1.80 g/dL). The albumin transcript level was diminished in the CKD (12.30 UR $p<0.009$) and I (11.99 UR, $p<0.005$) groups regarding C group (17.51 UR); FR group (11.66 UR $p<0.006$) had the lowest albumin mRNA level. Liver fibrosis in pixeles was: in I group (58.63 ± 6.04, $p<0.001$), followed by CKD group (55.56 ± 4.03, $p<0.001$) and FR group (24.38 ± 5.61, $p<0.001$), and C group (1.78 ± 0.75). The obtained miRNAs profile, showed 74 miRNAs differentially expressed (-2< Z Score >2).Four sub-expressed miRNAs (miR21, miR30b, miR350 and 376A), had CEBP β as gene target predicted. Other miRNAs target genes predicted, involve structural, and inflammation genes

Conclusions: We found miRNAs related with extracellular matrix genes, and with CEBP β which is a negative transcription factor in albumin transcription. It might be that CEBP is up-regulated by down-expressed miRNAs, promoting transcription suppression of albumin. The heterogeneity of miRNAs differential expression and the gene targets diversity, show that the albumin synthesis regulation in CKD involves several mechanisms

Globotriaoxylceramide (GB3)-Induced Endothelial-to-Mesenchymal Transition as a New Mechanism of Renal Progression in Fabry Disease Mina Yu,[1] Yang-Hee Jang,[1] Jin Ok Choi,[2] Sung Cheol Jung,[2] Duk-Hee Kang.[1] *[1]Nephrology, Ewha Womans University School of Medicine, Seoul, Korea; [2]Biochemistry, Ewha Womans University School of Medicine, Seoul, Korea.*

Background: The lysosomal storage disorder Fabry disease is characterized by excessive globotriaosylceramide (Gb3) accumulation in major organs such as kidney. Defective lysosomal alpha-galactosidase A (Gla) is responsible for excessive Gb3 accumulation, and vascular endothelium is one of the sensitive cells to the effects of Gb3 accumulation. Although renal fibrosis is known to be associated with Fabry disease, it is not known whether it plays any roles in the development of organ damage in Fabry disease or whether Gb3 per se is related to renal progression. Recent data suggest that endothelial-to-mesenchymal transition (endo-MT), which is characterized by the loss of endothelial cell markers and an acquisition of mesenchymal cell markers, is a potential mechanism of renal fibrosis.

Methods: We investigated whether Fabry kidney showed an evidence of endo-MT and whether Gb3 induced endo-MT in cultured human endothelial cells.

Results: Double immunofluorescence staining of CD31 (FITC) and α-SMA (cy3) in the kidney of animal model of Fabry disease, Gla deficient mice, showed a decreased microvascular endothelial staining both in glomerular and peritubular capillaries compared to wild type mice with an appearance of α-SMA (+) and CD31 (+) endothelial cells. Treatment of Fabry mice with of recombinant adeno-associated virus (rAAV) vector encoding alpha-Gal A cDNA (rAAV2/8-hAGA) resulted in the clearance of accumulated Gb3 in kidney with concomitant elevation of alpha-Gal A enzyme activity. rAAV2/8-hAGA therapy also ameliorated endo-MT of glomerular and peritubular capillary endothelial cells. Stimulation of HUVEC with Gb3 (0.1-10 uM) and lyso-Gb3 (10uM) down-regulated the expression of CD31 with an up-regulation of α-SMA from 48 hours in a dose-dependent and time-dependent manner. Blocking of Gla using siRNA and Gb3 after siRNA decreased the expression of CD31 and increased α-SMA expression.

Conclusions: These finding suggest that Gb3-induced endo-MT is one of the mechanisms of nephropathy in Fabry disease.

Correlation of HIF-1 α and Twist in the Proximal Tubular Epithelial Cells of Hypoxia Kidney Diseases Shiren Sun, Rui Du. *Deparment of Nephrology, Xijing Hospital, FMMU, Xi'an, China.*

Background: Our previous studies indicate that the Twist plays an important role in the development of hypoxia-induced tubular epithelial-mesenchymal transition and kidney fibrosis. However, the expression of Twist in the human kidney and its mechanisms are not well known.

Methods: Twist expression was examined by Immunohistochemistry (IHC) study, and consecutive slides were stained for HIF-1α and E-cadhrein. Immunostaining was

evaluated in a blinded manner. A 0–3 relative scale was used to grade the amount of immunostaining: 0, <5% staining; 1+, 5–25% staining; 2+, 25–50% immunostaining; 3+, >50% immunostaining.

Results: Twist was predominantly located in the nuclear of renal tubular epithelial cells from CKD patients including diabetic nephropathy (DN), FSGS, immunoglobulin (Ig) A nephropathy, hypertensive nephrosclerosis, tubulointerstitial nephritis that had different degrees of chronic hypoxia. While little positive staining for Twist was found in the renal tubules of normal kidneys (Twist score of <2), prominent Twist staining (>25% of all cells positive) was found in 48 of 74 patients with CKD (Twist score of ≥2+, P = 0.018 compared with normal controls, when grouped by score of ≥2+ or <2+; Fisher's exact test;). Positive HIF-1α was observed in nuclear in 62.2% (46/74) of CKD kidney tissues, which was closely associated with Twist (P= 0.000). Loss or reduced expression of E-cadherin was observed in 70.83% (34/48) Twist-positive tubular epithelial cells, but only in 26.9% (7/26) of Twist-negative tumors (P =0.000), which was significantly associated with higher levels of Twist in all kidney tissues from CKD patients. Using linear regression, we found a positive linear correlation between active Twist and tubulointerstitial fibrosis in the biopsy samples (r=0.57, P= 0.000).

Conclusions: We found that in the human kidney activated Twist is expressed in a wide range of renal diseases, which was correlated with HIF-1α activation, E-cadherin suppression and tubulointerstitial fibrosis. Our findings could indicate that Twist activation might represent a common downstream pathway for hypoxia-induced tubulointerstitial fibrosis.

FR-PO1825

Assessment of Erythropoietin Effects in the Progression of Experimental Chronic Kidney Disease Fernando Felippe Carvalho, Vicente de Paulo Castro Teixeira, Waldemar S. Almeida, Nestor Schor. *Nephrology, Federal University of São Paulo, São Paulo, Brazil.*

Background: Erythropoietin (EPO) has been used primarily to treat anemia caused by chronic kidney disease. Recent studies have shown a renoprotective EPO effect in ischemic kidney diseases. The mechanisms of renoprotection include antiapoptotic effects and stimulation of endothelial progenitor cells. Thus, the aim of this study is to evaluate the influence of EPO on progression of kidney disease in experimental chronic kidney disease

Methods: Male Wistar rats weighing 280-300g underwent 5/6 nephrectomy and were divided into two groups: (NX) only nephrectomized(n=6) and (NX-EPO) nephrectomized(n=6) and treated with a weekly dose of erythropoietin(250UI/kg/ip).

All animals were sacrificed 8 weeks after surgery. Hematocrit, serum creatinine, proteinuria, indirect blood pressure measurement, glomerular score and tubular lesion were assessed.

Results: The NX-EPO group showed significant improvement in serum creatinine (NX 1.6 ± 0.4 versus NX-EPO 0.8 ± 0.1, P ≤ 0.001) and protein/urine creatinine ratio (NX 11.2 ± 6.0 versus NX-EPO 4.1 ± 2.2, P = 0.021). Preliminary results suggest an improvement in glomerular score and tubular lesion in animals that received EPO.

There were no significant differences in hematocrit and blood pressure between the two groups

Conclusions: Our study suggests a beneficial effect of EPO in the model of progression of experimental chronic renal disease reflected by the improvement of serum creatinine, attenuation of proteinuria and a lower glomerular lesion score, regardless of its effect on the hematocrit and blood pressure.

FR-PO1826

IL-6 Alters Glomerular Structure and Function and Influences Renal Development Mukut Sharma,[1] Jianping Zhou,[1] Madhulika Sharma,[2] Ram Sharma,[1] Ellen T. McCarthy,[2] Jean-Francois Gauchat.[3] *[1]Nephrology Research, KC VA Medical Ctr, Kansas City, MO; [2]Kidney Institute, KUMC, Kansas City, KS; [3]Pharmacology, University of Montreal, QC, Canada.*

Background: Systemic inflammation is a characteristic of obesity, diabetes and hypertension (the metabolic syndrome). Increased levels of the inflammatory cytokine IL-6 in obese mothers may influence renal development, function and susceptibility to disease in the offspring. The role of IL-6 family cytokines in glomerular function and pathophysiology is not known. We hypothesize that IL-6 alters glomerular filtration barrier structure and function and influences renal development.

Methods: 1. Isolated rat glomeruli were incubated for 15 min with IL-6 (0.01-10 ng/mL) and glomerular albumin permeability (P_{alb}) was determined using an *in vitro* assay .

2. Immortalized murine podocytes were incubated with IL-6 (1 ng/mL) for 15 minutes and total and phosphorylated Akt and ERK1/2 were determined by Western blotting.

3. Metanephroi from embryonic mouse kidneys were incubated with IL-6 (10 pg/mL) for 3 days starting at ED13.5. Tissue growth was measured daily using Image J software (NIH) and branching morphogenesis was studied using immunostaining for cytokeratin.

Results: 1. IL-6 increased P_{alb} within 15 min in a dose-dependent manner (10 pg/mL, $P<0.05$ vs. control; 1 ng/mL, $P<0.001$).

2. IL-6 decreased phosphorylation of ERK at 10 pg/mL (<50%) and 1 ng/mL (>50%) within 15 minutes. IL-6 did not alter phosphorylation of Akt.

3. IL-6 (10 pg/mL) resulted in 20% less growth of metanephroi and altered immunostaining for cytokeratin compared to the untreated control.

Conclusions: Physiologically relevant concentrations of IL-6: 1) alter glomerular filtration barrier function as evidenced by increased P_{alb}, 2) alter podocyte signaling via the MAPK/ERK pathway as evidenced by decreased phospho-ERK, and 3) impacts kidney growth and development as evidenced by growth restriction and altered cytokeratin distribution. We conclude that IL-6 may play multiple important roles in glomerular structure and function. Further studies will determine the role of IL-6 in the onset and progression of glomerular dysfunction in CKD.

Albumin Endocytosis Inhibits Autophagy in Proximal Tubular Epithelial Cells Andrea Havasi, Jonathan M. Gall, Zhiyong Wang, Steven C. Borkan, John H. Schwartz. *Department of Medicine, Boston University Medical Center, Boston, MA.*

Background: Proteinuria is associated with progressive chronic kidney disease. It is well known that exposure of proximal tubular epithelial cells (PTEC) to large amounts of albumin leads to the development of tubular atrophy and fibrosis. However, the possible pathogenic role of albumin in this process has not been fully elucidated. To address this issue, we examined the effect of albumin exposure on autophagy and lysosomal function in cultured primary PTEC.

We show that albumin exposure, mimicking nephrotic glomerular filtrate, causes both lysosomal dysfunction and decreased autophagy. In primary mouse tubular cells, albumin exposure decreased LC3-I to LC3-II conversion in a concentration-dependent manner. Similar results were obtained using either recombinant human albumin or fatty acid free bovine albumin. In the presence of bafilomycin, an H+-ATPase inhibitor, autophagic flux was shown to be inversely related to albumin concentration. In addition, albumin treatment decreased the number of autophagosomes (AP) both in normal media (basal autophagy) and in starved cells (induced autophagy). Albumin exposure over 3-5 days markedly reduced the number of AP, suggesting that prolonged albumin exposure blocks AP formation. After a brief exposure of up to 48 hr, albumin caused marked AP enlargement, suggesting that albumin inhibits fusion of AP with lysosomes without impairing the maturation of small, punctate autophagosomes into larger ones. Normal lysosomal function is required for clearance of AP, hence lysosomal pH and enzyme activity were examined. Albumin exposure increased lysosomal pH and decreased lysosomal enzyme activity in PTEC, suggesting that autophagy inhibition might be the result of lysosomal dysfunction.

Taken together, these data show that albumin overload compromises autophagic and lysosomal function that could lead to cell toxicity. Therapy directed at rescuing autophagy during proteinuric states might be a rational approach for preventing or slowing the progression of chronic kidney disease.

Uremia-Induced Cardiac Activity Modifications: A Uremic Rabbit Model Emiliana Ferramosca,[1] Cristiana Corsi,[2] Eleonora Grandi,[2] Luciano Pisoni,[3] Ilaria Rivolta,[4] Boris Dalpozzo,[3] Stefano Severi,[2] Antonio Santoro.[1] *[1]Malpighi Nephrology, S.Orsola-Malpighi Hosp, Bologna, Italy; [2]DEIS, Bologna Univ, BO, Italy; [3]Veterinary Med., Bologna Univ, BO, Italy; [4]Experimental Med., Bicocca Univ, Milano, Italy.*

Background: Cardiovascular disease is the main cause of death in ESRD patients. Besides the increased arrhythmic events, a larger dispersion in the QT interval duration has also been described. The reasons explaining these alterations in the ventricular repolarization are still poorly understood.

So, the cellular mechanisms underlying electrocardiographic and hemodynamic alterations is of great interest.

Methods: We present a set up of an animal model of uremic cardiomiopathy, the cardiac morphological and functional evaluation, and the electrophysiological properties at the single cell level. We set up a rabbit uremic model obtained by partial resection of renal parenchima. Echocardiographic evaluation of the morphology and hemodynamic parameters revealed the onset of left ventricular (LV) hypertrophy. The action potential of ventricular cardiomyocytes was recorded through whole-cell patch clamp technique in current clamp mode and its duration at the 90% of repolarization (APD90) was assessed.

Results: Plasmatic levels of urea, creatinine and K+ increased 2.6 fold, 5 fold and 20%, respectively.

Ecocardiographically, the thickness of posterior wall increased from 3.3 cm up to 6 cm at the end of the diastolic phase and from 4 cm up to 7.2 cm at the end of the systolic phase, while the thickening of the intraventricular septum was 0.07 cm before the surgery and became 0.17 cm after the development of the uremic state. The LV mass grew from 3.9 g to 7.7 g.

Cardiomyocytes isolated form the LV were paced at 2Hz while perfused with a solution with typical post-dialisys plasma electrolyte concentrations. APD90 decreased by 26% compared to that measured on the same cardiomyocytes perfused with a solution mimicking the electrolyte concentrations in the uremic plasma.

Conclusions: Uremic rabbit may represent a useful model for a deeper understanding of the cellular ionic mechanisms underlying uremia-associated cardiac function alterations and for the development of potential therapeutical strategies.

FR-PO1829

Genetic Analysis of Mesangial Matrix Expansion in Aging Mice and Identification of Far2 as a Candidate Gene Gerda A. Noordmans,[1] Yuan Huang,[1] Kenneth A. Walsh,[2] Susan Marie Sheehan,[2] Jan-Luuk Hillebrands,[1] Peter Heeringa,[1] Harry Van Goor,[1] Ron Korstanje.[2] *[1]Pathology and Medical Biology, University Medical Center Groningen, Netherlands; [2]The Jackson Laboratory, Bar Harbor, ME.*

Background: Aging of the kidney is associated with glomerular mesangial matrix expansion (MME). To unravel the mechanism of aging it is important to identify genes involved in this process. Identifying aging-associated genes might help design novel therapeutic modalities in order to prevent histological changes like MME and to reduce the decline of renal function.

Methods: Glomerular structural changes in the aged kidney of 26 mouse inbred strains (www.jax.org/phenome) were characterized in male mice at 20 months of age in PAS stained sections. Haplotype Association Mapping (HAM) was used to determine genetic loci associated with the presence of MME.

Results: Thirteen out of 26 strains showed MME. HAM showed a peak on chromosome 6 and the only gene found within this 200Kb haplotype block is *Far2*. The strains with MME revealed to have a 9bp indel in the 5'UTR of *Far2*, which is absent in most of the strains without MME. RT-PCR showed a 2-fold increase in the expression of *Far2* in the strains with MME compared to strains without.

Conclusions: Our study found an association between *Far2* expression and glomerular mesangial matrix expansion. *Far2* catalyzes the reduction of fatty acyl-CoA to fatty alcohols, the precursors of platelet activating factor (PAF). PAF is shown in vitro in human and rat mesangial cells to increase the expression of the mesangial matrix. Our data suggests that *Far2* plays an important role in renal aging.

Biomarker of Irreversible Glomerular Injury – A Metabolomic Analysis Experimental Glomerulonephritis Kyoung Hee Han,[1] Bora Kim,[2] Se Eun Lee,[1] Seong Heon Kim,[1] Yo Han Ahn,[3] Hee Gyung Kang,[1] Hae Il Cheong,[1] Joo-Youn Cho,[2] IL-Soo Ha.[1] *[1]Department of Pediatrics, Seoul National University Children's Hospital, Seoul, Republic of Korea; [2]Department of Clinical Pharmacology, Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Department of Pediatrics, Center for Pediatric Oncology, National Cancer Center, Goyang, Republic of Korea.*

Background: Some injuries of the kidney recover completely but many other diseases are not completely reversible and progress to chronic kidney diseases(CKD). While complex network of cellular and molecular events have been known to be involved in the pathophysiological mechanism of CKD, the diverging point between the reversals versus progression and the triggering event of the progression are still unknown. An indicator that predicts progression or regression of injuries is not yet available. To understand the different mechanisms between the reversible and irreversible kidney diseases and to search for biomarkers predicting the prognosis, a metabolomic analysis was applied in comparison of acute and chronic experimental nephritis model.

Methods: Urine samples were collected on day 0, 7, and 14 from rats that were treated with anti-Thy 1 MoAb(OX-7) with or without heminephrectomy. Samples were analyzed by ultra-performance liquid chromatography coupled with Synapt Q-TOF mass spectrometry(Waters, USA). Multivariate analysis was performed on 2597 positive ion markers and 7537 negative ion markers using SIMCA-P(ver. 12.0).

Results: A total of 4 peaks in Electrospray Ionization(ESI)+ and 5 peaks in ESI- were detected after peak alignment. Principal components analysis(PCA) revealed that the chronic and acute nephritis models had two discrete phenotypes and orthogonal partial least squares discriminate analysis(OPLS-DA) showed direction of the time trends was different between these two models. Candidates of biomarkers for chronic nephritis were searched from the human metabolome database(HMDB) and confirmed by tandem mass spectrometry of authentic compounds.

Conclusions: These results suggested that metabolomic analysis could provide insights into mechanism of disease progression and biomarkers for early diagnosis of chronic nephritis.

FR-PO1831

PDGF-C Neutralization Protects Collagen 4A3 Deficient Alport Mice from the Development of Renal Fibrosis Claudia R.C. van Roeyen,[1] Ana Kaitovic,[1] Peter Boor,[1] Ina V. Martin,[1] Stephanie Zok,[1] Ulf P.E. Eriksson,[2] Jurgen Floege,[1] Oliver Gross,[3] Tammo Ostendorf,[1] Frank Eitner.[1] *[1]Nephrology, RWTH Aachen, Aachen, Germany; [2]Karolinska Institute, Stockholm, Sweden; [3]Nephrology&Rheumatology, University Medicine Göttingen, Göttingen, Germany.*

Background: PDGF-C is upregulated at sites of renal fibrosis. Reduced renal fibrosis has been demonstrated following neutralization of PDGF-C in mice with ureteral obstruction. We now studied the role of PDGF-C antagonism or deficiency in collagen 4A3 deficient ("Alport") mice, which serve as a model for progressive renal fibrosis.

Methods: Alport mice were crossbred with PDGF-C deficient mice (n=15) and analyzed at 10 weeks of age. In a second experiment, Alport mice (n=24) were treated with neutralizing anti-PDGF-C antibody or control IgG from week 6 until sacrifice at week 9. We analyzed renal function, histological damage and renal inflammation.

Results: PDGF-C deficient Alport mice developed less renal injury: significantly less glomerular injury (76% reduction of glomeruli containing extracapillary proliferates; 65% reduction of glomerular fibrin deposition) and significantly less cortical inflammation (90% reduction of CCL2 mRNA, 80% reduction of CCL5 mRNA). Treatment with neutralizing anti-PDGF-C antibody resulted in significantly less renal injury in 9 week old mice: better renal function (58% reduction of serum urea), less glomerular injury (87% reduction of glomeruli containing extracapillary proliferates), less cortical matrix accumulation (63% reduction of fibronectin, 62% reduction of collagen type I), and less cortical inflammation (73% reduction of CCL2 mRNA, 63% reduction of CCL5 mRNA, 94% reduction of infiltrating macrophages).

Conclusions: In conclusion, both PDGF-C deficiency as well as PDGF-C antagonism significantly reduced the development of progressive renal fibrosis in collagen 4A3 deficient mice. These potent antifibrotic effects of PDGF-C neutralization in an animal model that closely resembles all features of progressive human glomerular diseases make PDGF-C a prime target for the treatment of progressive human renal fibrosis.

FR-PO1832

Gadolinium-Based Magnetic Resonance Imaging (MRI) Contrast Leads to Organ-Specific Fibrosis Associated with Fibrocyte Accumulation in a Rodent Model of Nephrogenic Systemic Fibrosis Brent Wagner,[1,2] Seema S. Ahuja,[1,2] Jeffrey L. Barnes.[1,2] *[1]South Texas Veterans Health Care System, San Antonio, TX; [2]Department of Medicine, University of Texas Health Science Center at San Antonio, TX.*

Background: Nephrogenic systemic fibrosis (NSF) is associated with gadolinium-based MRI contrast exposure in the setting of acute or chronic renal compromise. Given its systemic nature, it has been proposed that circulating fibrocytes mediate the disease. A study was conducted to determine if bone marrow-derived cells are involved in mediating dermal fibrosis in a rodent model of NSF.

Methods: Lethally-irradiated rats s/p 5/6 nephrectomy were used, salvage bone marrow transplant from human placental alkaline phosphatase- (hPAP-) expressing donors. Animals were treated with gadodiamide contrast (Omniscan, 2.5 mmol/kg IP) for 4 weeks or an equivalent volume of normal saline.

Results: Within the 4th week of treatment, contrast-treated animals demonstrated subtle signs of stress (e.g., perioribital porphyrin staining and muzzle swelling). Dermal cellularity in the contrast-treated group was greater than control. Skin from the contrast-treated group demonstrated greater hPAP expression, which co-localized with α-smooth muscle actin-positive stress fibers. These cells were also pro-collagen I+. The donor cells were also CD34+. Heart and liver tissues demonstrated subtle histological differences, yet the latter was characterized by increased fibronectin on immunoblot. Contrast-treated animals demonstrated greater dihydroethidium in the dermis. Skin demonstrated greater NADPH oxidase 4 (Nox4) by immunoblot.

Conclusions: The animal model demonstrates that a radio-sensitive bone marrow-derived cell population is increased in the dermis of MRI contrast-treated rodents. The expression of α-smooth muscle actin, pro-collagen I, and CD34 are consistent with fibrocytes mediating the disease. Further elucidation of the mechanisms of MRI contrast-induced fibrosis may aid in discovering therapies to this devastating disease.

Bone Marrow-Derived Cells Play a Major Role in Unilateral Ureteral Obstruction-Induced Kidney Fibrosis Hee-Seong Jang, Jee In Kim, Kwon Moo Park. *Department of Anatomy, Kyungpook National University School of Medicine, Daegu, Korea.*

Background: Interstitial fibrosis is a hallmark of chronic renal failure. Increased fibroblast induces the accumulation of extracellular matrix proteins in the interstitium leading to kidney fibrosis. However, the origin of these cells contributing to the fibrosis has not been defined yet. In the present study we investigated the role of bone marrow-derived cells in the fibrosis induced by ureteral obstruction in mice.

Methods: Bone marrow cells collected from eGFP transgenic mice were transplanted into lethally irradiated mice which are produced by same strain with eGFP mice. 8 weeks after bone marrow transplantation the chimeric mice were subjected to unilateral ureteral obstruction (UUO). 1, 3 and 12 days after UUO kidneys were harvested and used for further experiments including immunostaining against GFP, fibroblast specific protein-1 (FSP-1), collagen III, and proliferating cell nuclear antigen (PCNA).

Results: UUO resulted in gradual increases of GFP-positive cell number in the interstitium and expansion of interstitial area overtime. Over 80% of interstitial cells were GFP-positive cells at 12 days after UUO. Over 90% of GFP-positive cells in the interstitium expressed FSP-1 at 12 days after UUO. Collagen III also expressed in the GFP-positive cells. 49% and 55% of interstitial PCNA-positive cells were GFP-positive cells 3 and 12 days after UUO, respectively. Some of GFP-positive cells were dividing. Cells presenting weaker GFP signal expressed stronger FSP-1 and collagen III. It suggests that infiltrated cells into the injured kidney may differentiate into fibrogenic cells.

Conclusions: Bone marrow-derived cells play as major contributor in UUO-induced kidney fibrosis via infiltration, accumulation into injured site, and subsequent proliferation and differentiation into fibroblasts.

FR-PO1834

Bone Marrow-Derived Macrophage Myofibroblast Transition (MMT) Is a Previously Unrecognized Major Pathway in Renal Fibrosis Shuang Wang,[1] Yee-Yung Ng,[2] Xiao Ru Huang,[1] Hui Y. Lan.[1] *[1]Departments Of Chemical Pathology, and Medicine & Therapeutics, and Li Ka Shing Institute of Health Sciences, Chinese University of Hong Kong, Shatin, NT, Hong Kong; [2]Division of Nephrology, Veterans General Hospital-Taipei, National Yang-Ming University, Taipei, Taiwan.*

Background: Myofibroblast is a key cell type in renal fibrosis. However, the origin of myofibroblasts during renal fibrosis remain largely debated. The present study tested the hypothesis that bone marrow (BM)-derived macrophage myofibroblast transition (MMT) may be a key pathway leading to renal fibrosis in patients with CKD and in a mouse model of UUO.

Methods: We first determined MMT in renal biopsies from patients with CKD. Then the critical role of BM-derived cells and MMT in renal fibrosis were examined in three mouse models of UUO: 1) BM deletion followed with/without GFP^+BM, GFP^+Smad3^+, GFP^+Smad3^- BM transplantation or; 2) GFP-BM chimeric mice; 3) mice with inducible macrophage deletion (lysM-Cre/DTR). MMT was determined by confocal microscopy and flow cytometry with α-$SMA^+CD68^+/CD11b^+$.

Results: Surprisingly, in CKD patients, upto 70% of α-SMA^+ myofibroblasts were of macrophage phenotype (α-SMA^+CD68^+), contributing to renal fibrosis and fibro-cellular crescents. In mouse models of UUO, irradiative deletion of BM prevented tubulointerstitial fibrosis including α-SMA^+ cells and collagen I/III accumulation, which was restored by GFP-BM transplantation. By confocal microscope and flow cytometry, 70-80% of α-SMA^+ myofibroblasts were $GFP^+F4/80^+$, indicating that BM-derived MMT ($GFP^+\alpha$-$SMA^+F4/80^+$) is a major pathway of myofibroblast origin during renal fibrosis. This was confirmed by the finding that conditional deletion of macrophages largely reduced MMT (60-70%↓) and renal fibrosis after UUO. Moreover, MMT was TGF-β/Smad3-dependent because BM transfusion with GFP^+Smad^+, but not GFP^+Smad3^-, restored MMT and renal fibrosis.

Conclusions: BM-derived macrophage myofibroblast transition (MMT) is a major pathway of myofibroblast origin during renal fibrosis. TGFβ/Smad3 may play an important role in MMT.

Funding: Government Support - Non-U.S.

FR-PO1835

Smad3 Regulates Bone Marrow-Derived Fibroblast Precursors in Renal Fibrosis Jiyuan Chen, Song-Chang Lin, William E. Mitch, Yanlin Wang. *Medicine-Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Progressive renal fibrosis is the final common manifestation of chronic kidney disease resulting in irreversible loss of kidney parenchyma and renal function. Activated fibroblasts play a critical role in the pathogenesis of renal fibrosis. Their origin remains controversial. We and others have recently shown that bone marrow-derived fibroblast precursors termed fibrocytes migrate into the kidney and contribute to renal fibrosis. However, the molecular mechanisms that are responsible for the recruitment and maturation of bone marrow-derived fibroblast precursors in the kidney are not fully understood. Since TGF-beat1/Smad3 signaling has been shown to play an important role in the pathogenesis of kidney fibrosis, we investigated the role of Smad3 in the recruitment and maturation of bone marrow-derived fibroblast precursors in the kidney in a murine model of renal fibrosis.

Methods: Wild type (WT) and Smad3 knockout (Smad3-KO) mice were subjected to unilateral ureteral obstruction and maintained for up to 2 weeks.

Results: Bone marrow-derived fibroblast precursors, identified as cells positive for both CD45 and vimentin were accumulated in obstructed kidneys of WT mice in response to obstructive injury, which were significantly reduced in obstructed kidneys of Smad3-KO mice. Furthermore, the number of bone marrow-derived myofibroblasts that are positive for both CD45 and α-SMA were significantly decreased in obstructed kidneys of Smad3-KO mice compared with WT mice. Immunohistochemical studies and Western blot analysis revealed that the levels of type I collage, fibronectin, and α-SMA were significantly increased in obstructed kidneys of WT mice . In contrast, all of these parameters were dramatically attenuated in obstructed kidneys of Smad3-KO mice.

Conclusions: These data indicate that Smad3 plays a significant role in the recruitment and maturation of bone marrow-derived fibroblast precursors during the pathogenesis of renal fibrosis.

CTP-499, a Novel Drug for the Potential Treatment of Chronic Kidney Disease, Has Anti-Fibrotic, Anti-Inflammatory, and Anti-Oxidative Activities with *In Vivo* Efficacy Ara Aslanian, Kristine Hogan, Shixin Qin, Julie Fields Liu, Changfu Cheng, Gary W. Bridson, Philip B. Graham, Roger Tung, Lijun Wu. *Concert Pharmaceuticals, Lexington, MA.*

Background: Chronic Kidney Disease (CKD) is a complex, multifactorial disease in which renal function is chronically compromised. Decreased glomerular filtration due to dysregulated extracellular matrix (ECM) deposition is a hallmark of progressive CKD. However, oxidative imbalance and inflammation are now increasingly recognized as major pathogenic mechanisms in CKD. Here, we show that CTP-499, a novel, deuterated analog of 1-((S)-5-hydroxyhexyl)-3,7-dimethylxanthine (HDX), the active M1 metabolite of pentoxifylline, exhibits efficacy in key cellular pathological mechanisms involved in CKD and in a rat model of diabetic nephropathy.

Methods: To assess the efficacy of CTP-499 *in vitro*, cells were challenged with various stimuli to induce pro-fibrotic gene expression, inflammatory response, and oxidative stress. To establish the efficacy of CTP-499 in an *in vivo* model of diabetic nephropathy, STZ-treated rats were dosed with CTP-499 for seven weeks and markers of disease progression were measured.

Results: CTP-499 demonstrated anti-fibrogenic, anti-inflammatory and anti-oxidative activities in a series of *in vitro* experiments. In a rat model of diabetic nephropathy, CTP-499 treatment resulted in significantly decreased kidney weights, a trend towards lower albuminuria, and significantly reduced cytokine levels compared to vehicle controls.

Conclusions: In summary, CTP-499 exhibits significant biological activities in multiple inter-related pathological mechanisms that contribute to kidney dysfunction. These data support our continued interest in CTP-499 as a novel compound for the potential treatment of CKD.

FR-PO1837

Thymosin β4 Augmentation of Fibrosis Is Dependent on PAI-1 Yiqin Zuo,[1] Sebastian Alexander Potthoff,[2] Haichun Yang,[1] Li-Jun Ma,[1] Agnes B. Fogo.[1] *[1]Pathology, Vanderbilt University, Nashville, TN; [2]Nephrology, University of Duesseldorf, Germany.*

Background: Thymosin β4 (Tβ4), a G-actin sequestering protein, is degraded by prolyl oligopeptidase (POP) to Ac-SDKP. Our previous study shows that inhibition of POP shifted the balance of Tβ4 and Ac-SDKP and exacerbated tubulointerstitial fibrosis induced by unilateral ureteral obstruction (UUO) in wild type (WT) mice. Both transforming growth factor β (TGF-β) and plasminogen activator inhibitor 1 (PAI-1) pathways promote fibrosis. We now investigated whether PAI-1 deficiency affects fibrosis. We further examined the effects of augmenting Tβ4 in PAI-1-/- mice.

Methods: WT or PAI-1-/- C57BL6 male mice underwent UUO and were sacrificed 5 days and 14 days after UUO. At day 5, there were two groups: WT with or without Tβ4+POP inhibitor. At day 14, there were three groups: WT without treatment, PAI-1-/- with and without Tβ4+POP inhibitor.

Results: Tubulointerstitial fibrosis, assessed by polarized Sirius red morphometry, was increased similarly in WT vs. PAI-1-/- after 14 days of UUO (3.01±0.13 vs. 3.02±0.45%) compared to non-obstructed kidneys (0.33±0.02%). Tβ4+POP inhibitor treatment resulted in enhanced fibrosis in WT mice at day 5 after UUO (WT with treatment 1.75±0.06% vs WT no treatment 1.50±0.04%, $p<0.05$) with more TGF-β1 and fewer infiltrating macrophages. In contrast, PAI-1-/- mice even at day 14 after UUO showed no increase in fibrosis in response to Tβ4+POP inhibitor administration (2.74±0.09 vs. 3.02±0.45%, p NS). Phosphorylated Smad2, an indicator of TGF-β1 activation, was similarly increased in all UUO kidneys at day 14 compared to non-obstructed kidneys. Infiltrating macrophages were similar in WT vs. PAI-1-/- (3.05±0.64 vs.2.54±0.38% F4/80 positive area), and were not increased in PAI-1-/- by adding Tβ4+POP inhibitor (2.85±0.18%).

Conclusions: We conclude that PAI-1-/- mice are not protected from UUO-induced tubulointerstitial fibrosis, and unlike WT mice, do not show enhanced fibrosis when Tβ4 is increased. Thus, Tβ4 in combination with POP inhibitor enhances fibrosis in WT mice, and this effect is dependent on the presence of PAI-1.

Long-Term Administration of a Novel Glutathione Precursor Attenuates Age-Related Oxidative Stress and Kidney Damage Xin J. Zhou,[1] Indrani Sinha-Hikim,[3] Ting Ye,[1] Dinesh Rakheja,[1] Albert B. Crum,[2] Keith C. Norris,[3] Nosratola D. Vaziri.[4] *[1]pathology, UT Southwestern Medical Center, Dallas, TX; [2]Proimmune, Rhinebeck, NY; [3]Medicine, Charles Drew University, Los Angeles, CA; [4]Medicine, UC Irvine, Irvine, CA.*

Background: Oxidative stress (OS) plays a key role in the pathogenesis of renal senescence. Glutathione (GSH) is the most abundant and potent endogenous antioxidant whose tissue contents can be exhausted by OS and its deficiency can cause/intensify OS. The present study was undertaken to examine the effect of long-term oral administration of a novel GSH precursor, F1 (a compound containing cystine as the carrier of cysteine), on the aging kidney.

Methods: Eighteen-month old male B6 mice were randomized to groups fed regular diet or diet containing F1 (0.5 g/Kg/day) for six months. Young adult (2 month old) mice consuming regular diet served as controls. Animals were then euthanized and kidneys were harvested and processed for histological examination, measurement of of markers of OS, and expression of key molecules involved in the redox and inflammatory pathways.

Results: Compared to the young mice, kidneys in the untreated aged mice showed marked GSH depletion, mesangial matrix expansion, focal tubular atrophy, interstitial fibrosis and patchy interstitial inflammation. This was associated with accumulation of TBARs, upregulation of MPO, and down-regulation of GSH peroxidase (GPX), PPARγ, SIRT1, and catalytic and modifier subunits of glutamate cysteine ligase (GCL). Treatment with F1 restored renal tissue GSH content and attenuated age-related histological abnormalities. This was accompanied by amelioration of OS, reduction in MPO abundance and partial or complete restoration of GPX, PPARγ, SIRT1, and GCL expression. Despite OS, which should have evoked activation of Nrf2, its nuclear content was unchanged reflecting impaired response to oxidative stress in the aged mice. Amelioration of OS with F1 administration was associated with the maintenance of Nrf2 activity in the kidneys of the aged mice.

Conclusions: These findings illustrate the efficacy of F1 in mitigating age-associated oxidative stress and renal injury in this model.

Disrupted TGF-β Receptor II Abrogates Smad3-Mediated Renal Fibrosis but Exaggerates Inflammatory Response In Vivo and In Vitro Xiaoming Meng, Xiao Ru Huang, Jun Xiao, Haiyong Chen, Hui Y. Lan. *Department of Medicine and Therapeutics and Li Ka Shing Institute of Health Sciences, Chinese University of Hong Kong, Shatin, NT, Hong Kong, China.*

Background: It is well known that TGF-β1 plays distinct roles in fibrosis and inflammation. The present study tested the hypothesis that TGF-β1 may signal through its receptor II to exert the diverse effects on renal fibrosis and inflammation in vivo and in vitro.

Methods: The hypothesis was examined in vivo in a mouse model of unilateral ureteral obstructive (UUO) nephropathy induced in TGFRII (RII) conditional knockout mice (KspCre/RII$^{f/f}$) in which RII was deleted specifically from the kidney tubular epithelial cells and in vitro in primary kidney fibroblasts and NRK52E cell line where the RII was deleted by adenovirus Cre or by overexpressing dominant negative RII (DNRII).

Results: Disrupted RII from the kidney as well as from kidney fibroblasts substantially inhibited fibrogenesis including collagen and fibronectin expression (50% ↓) and α-SMA+ myofibroblasts accumulation (approximately 20% ↓) in the UUO kidney and in TGF-β1-stimulated kidney fibroblasts. These changes were associated with significant reduction of TGF-β1($p<0.05$) and CTGF ($p<0.01$) and deactivation of Smad3 signaling (80%↓). In contrast, deletion of RII enhanced inflammatory response as demonstrated by up-regulation of IL-1β, TNFα (20%↑) in the UUO kidney and in IL-1β-stimulated DNRII-NRK52E cells. Further studies revealed that enhanced renal inflammation in the UUO kidney and cells with conditional deletion of RII was associated with a further increase in activation of NF-κB signaling.

Conclusions: In conclusion, TGF-β1 may signal through its RII to exert its diverse role in causing renal fibrosis while inhibiting renal inflammation under pathophysiological conditions.

Suramin: A Novel Treatment for Chronic Kidney Disease Shougang Zhuang.[1,2] [1]*Department of Medicine, Brown University School of Medicine, Providence, RI;* [2]*Department of Nephrology, Tongji University Shanghai East Hospital, Shanghai, China.*

Background: Current drug discovery efforts for fighting renal fibrosis are largely focused on compounds that are specific for a particular receptor or protein kinase. Since renal fibrogenesis is associated with increased production of multiple cytokines/growth factors, inhibitors with broad specificity might offer improved therepautic benefit in fibrotic diseases of the kidney. We here assessed the therapeutic effect of suramin, an FDA approved drug for treating selected malignancies, on the activation of renal interstitial fibroblasts and the development and progression of renal fibrosis in animal models of chronic kidney injury.

Methods: Unilateral ureteral obstruction and remnant kidney models were used.

Results: In a model of unilateral ureteral obstruction (UUO), administration of a single dose of suramin (20 mg/kg) immediately after injury prevented the onset of renal fibrosis as shown by abolishing expression of fibronectin, suppressing expression of alpha-SMA and type I collagen and reducing deposition of extracellular matrix proteins. In a rat model of remnant kidney disease, suramin also prevented progressive renal injury as demonstrated by inhibiting the rise of 24 hour-proteinuria and serum creatinine, preserving renal tissue architecture and preventing glomerular and tubulointerstitial damage. Furthermore, delayed administration of suramin starting at day 3 of obstruction completely blocked further increase in expression of type 1 collagen and fibronectin and largely suppressed expression of alpha-SMA in both treatment groups. UUO injury or renal ablation induced phosphorylation of epidermal growth factor receptor and platelet derived growth factor receptor and several signaling molecules including Smad-3, STAT3 and ERK1/2 that are associated with renal fibrogenesis. Suramin treatment completely blocked phosphorylation of all these molecules in the injured kidney and also repressed expression of multiple cytokines and decreased leukocyte infiltration to the interstitium.

Conclusions: These findings indicate that suramin is a potent anti-fibrotic agent and may have therapeutic potential in treating patients with CKD.

Lipocalin-Type PGD2 Synthase (L-PGDS) Play a Key Role in Kidney Interstitial Fibrosis Via the Activation of Th2-Dominant Inflammatory Response Hideyuki Ito,[1,2] Motoaki Sano,[2] Yasunori Utsunomiya,[1] Keiichi Fukuda,[2] Tatsuo Hosoya.[1] [1]*Division of Kidney and Hypertension, Jikei University School of Medicine, Minato-ku, Tokyo, Japan;* [2]*Division of Cardiology, Keio University School of Medicine, Shinjuku-ku, Tokyo, Japan.*

Background: L-PGDS, which was identified as an enzyme responsible for PGD2 biosynthesis, is expressed in the kidney. It has reported that urinary L-PGDS excretion increased in diabetic nephropathy and hypertensive nephrosclerosis. However, the pathophysiological role of PGD2 biosynthesis in the kidney is still unknown.

Methods: We examined the interaction of kidney expression of L-PGDS and tissue injury in an animal model of unilateral ureteral obstruction (UUO).

Results: L-PGDS expression was induced in cortex after 3days of UUO and continued to increase thereafter. Tubular-epithelial de novo synthesis of L-PGDS was also demonstrated by in situ hybridization. Of note, the interstitial collagen deposition and mRNA expression of collagen-I was less in the UUO-kidneys of L-PGDS knockout (LKO) mice compared to those of wild-type (WT) mice. In addition, the number of infiltrating CD4+ T cells, not macrophages, was significantly decreased in LKO mice. Intracellular staining in the kidney revealed that the infiltration of IL-4 producing Th2 cells, but of IFN-γ producing Th1 cells, was reduced in LKO mice. CRTH2, which is one of the PGD2 receptors, is expressed on Th2 cells and mediates Th2-cytokine production. CRTH2-KO mice showed lower expression levels of IL-4 and IL-13 in the UUO-kidneys. Interestingly, UUO-induced interstitial fibrosis was markedly reduced in CRTH2-KO mice. In the further support to these notes, both IL-4-KO and IL-13-KO mice reduced the degree of UUO-induced interstitial fibrosis compared to WT mice. Furthermore, administration of CRTH2 antagonist, CAY10471, following UUO attenuated the progression of interstitial fibrosis.

Conclusions: L-PGDS is de novo synthesized in tubular epithelium of the obstructed kidneys and contributes to the progression of interstitial fibrosis via the activation of Th2 cells. Blockade of CRTH2-signalings is a promising strategy to attenuate the tubulointerstitial fibrosis via inhibition of Th2-dominant inflammatory response.

FR-PO1842

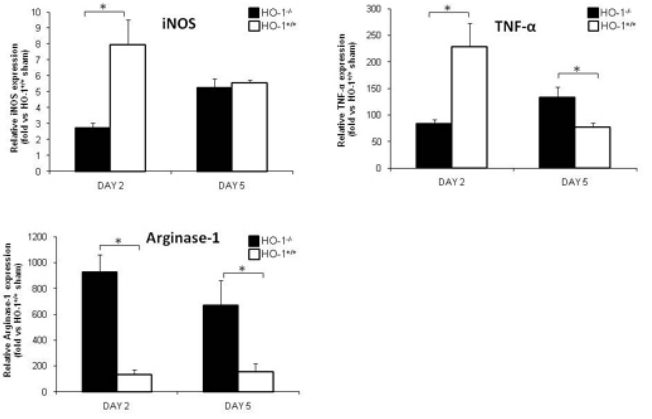
Regulation of Macrophage Polarization by Heme Oxygenase-1 in Renal Fibrosis Abolfazl Zarjou,[1] Anjana Perianayagam,[2] Subhashini Bolisetty,[1] Anupam Agarwal.[1] [1]*Medicine, Nephrology, University of Alabama at Birmingham;* [2]*Medicine, Nephrology, University of Arkansas.*

Background: Heme oxygenase-1 (HO-1) is known to modulate innate and adaptive immune responses. We previously showed that there is increased renal fibrosis following unilateral ureteral obstruction (UUO) in HO-1 deficient (HO-1$^{-/-}$) mice compared to HO-1$^{+/+}$ mice. Macrophages play an essential role in such fibrosis. The M1 (classically activated) macrophages predominate during early phases of kidney injury and inflammation, whereas M2 (alternatively activated) macrophages predominate at later time points and promote cellular repair and fibrosis. The purpose of this study was to determine the effect of HO-1 on the distribution of renal macrophage subtypes following UUO.

Methods: Renal macrophage infiltration and polarization was investigated at 2 and 5 days following UUO in HO-1$^{+/+}$ and HO-1$^{-/-}$ kidneys using flow cytometry and real time-PCR.

Results: A significantly higher number of macrophages were detected in HO-1$^{-/-}$ kidneys at 48h post UUO. Following isolation of CD11b^{+} (a macrophage marker) population from UUO kidneys, we performed real time-PCR evaluation of M1 (iNOS and TNFα) and M2 (Arginase-1) markers (Figure 1). As expected, the M1 subpopulation in HO-1$^{+/+}$ kidneys was higher at 2 days while the predominant inflammatory cells were M2 macrophages at 5 days post UUO. Although there were no significant differences in sham animals, polarization was dysregulated in HO-1$^{-/-}$ mice that underwent UUO. The M2 macrophages were the most abundant inflammatory cells at 2 days in HO-1$^{-/-}$ kidneys and M1 macrophages were significantly increased only 5 days post UUO (*$P < 0.05$).

Figure 1



Conclusions: Our findings elucidate the key role of HO-1 in macrophage polarization and suggest that modulation of HO-1 expression in inflammatory disorders has the potential as a novel therapeutic modality.

Inflammation Exacerbates the Progression of Vascular Calcification in Hemodialysis Patients through the Disruption of LDL Receptor Pathway
Jing Liu, Kun Ling Ma, Min Gao, Xiaoliang Zhang, Bi-Cheng Liu. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiangsu Province, China.*

Background: Chronic microinflammation in hemodialysis patients played crucial roles in the progression of vascular calcification (VC). Our previous studies *in vivo* and *in vitro* demonstrated that inflammation accelerated the progression of atherosclerosis (AS) via the dysregulation of low density lipoprotein receptor (LDLr) pathway. This study was to investigate whether LDLr pathway is involved in the progression of VC under inflammatory stress.

Methods: Twenty-eight hemodialysis patients receiving arteriovenostomy were divided into two groups by the plasma level of C-reactive protein: Control (n=14), inflamed group (n=14). Hematoxylin-eosin staining and alizarin red S staining were respectively used to check foam cell formation and VC using tissues surgically removed from radial artery. Immunohistochemistry and immunofluorescent staining were used to check protein expressions related with intracellular cholesterol trafficking and VC.

Results: There was parallel change for increased foam cell formation and significant VC in continous cross-sections of radial arteries in inflamed group compared to control, which were correlated with the increasing protein expressions of LDLr, bone morphogenetic proteins-2 (BMP-2) and collagen I respectively. Confocal microscopy observation showed that inflammation enhanced the protein expressions of alkaline phosphatase, and reduced the protein expression of alpha-smooth muscle actin, contributing to the phenotype conversion of vascular smooth muscle cells in calcified vessels from the fibroblastic to the osteogenic, which was one of the main cell components involved in VC. Further analysis showed that the dysregulation of LDLr pathway induced by inflammation was significantly associated with the enhanced expression of BMP-2 and collagen I.

Conclusions: Our study firstly demonstrated that inflammation accelerated the progression of VC in hemodialysis patients through the disruption of LDLr pathway, suggesting a new potential mechanism involved both in the progression of VC and AS.

M2 Macrophages Contribute to Kidney Repair Via Promoting Degradation of Extracelluar Matrix through Legumain
Xiaoyue Tan, Min Xiong. *Pathology, School of Medicine, Tianjin, China.*

Background: Studies have suggested that the switch of macrophage phenotype from M1 to M2 regulates the kidney injury and repair. In this study, we investigated that the role of Legumain in the mechanism underlying the renal beneficial effect of M2 macrophage.

Methods: Adult male C57 mice underwent Recovery unilateral ureteral obstruction (R-UUO). Liposome cholodronate (LC) was used to deplete the macrophages. LC/control liposome was administrated either before the operation or at the time when recovery. 20 mice were randomly divided into 4 groups: LC before operation; Control liposome before operation; LC recovery; Control liposome recovery (n=5). Macrophage and Legumain expression were identified by Immunofluorescence staining ; FACS analysis further evaluated the phenotype of Macrophage. Legumain expression was confirmed via Western blot. *In vitro* experiments were performed in co-culture system of M2 macrophage and HK-2 cells. HK-2 cell were treated with or without 5 ng/ml TGF-beta1. Degradation of Fibronectin and Collagen I in the condition medium were measured via western blots. Legumain inhibitor was usd to evaluate the effect of legumain. IP assay were performed to evaluate the possible interaction between legumain and extracellular matrix.

Results: Compared with control liposome recovery group, depletion of macrophage at the time of UUO recovery increased extracellular matrix deposition and the legumain expression was inhibited in LC recovery group with the depletion of M2 macrophage. Result of immunofluorescence staining and FACS analysis showed the M2 macrophages were the major source of legumain in the process of kidney repair. *In vitro* experiment showed that co-culture with M2 macrophage promoted the degradation of Fibronetin and collagen I while small inhibitor of Legumain blocked this effect. IP assay confirmed the interaction between legumain and two major extracellular matrix components, Fibronectin and Collagen I.

Conclusions: Our results suggest that M2 macrophages exhibit protective effect on the kidney recovery from fibrosis. The underlying mechanism is most likely related with inducing expression of legumain thus promoting the degradation of extracellular matrix.

PBI-4050, a Novel Orally Active Anti-Inflammatory/Anti-Fibrotic Agent, Reduces Fibrosis and Sclerosis in 5/6 Nephrectomized Rats
Lyne Gagnon, François Sarra-Bournet, Brigitte Grouix, André Doucet, Valérie Perron, Jean-Simon Duceppe, Abdallah Ezzitouni, Boulos Zacharie, Christopher Penney, Pierre Laurin. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: PBI-4050 is a novel first-in-class, orally active low molecular weight compound which displays anti-inflammatory/anti-fibrotic activities via a novel mechanism of action. The aim of this study was to investigate the effect of PBI-4050 on 5/6 nephrectomized rats.

Methods: Wistar rats were partially nephrectomized (2/3 of the left kidney) on day 0. On day 7 the right kidney was removed. Oral treatment with PBI-4050 (200 mg/kg, once a day) or vehicle was initiated at day 21. GFR was measured at day 21 and assessed every 3 weeks up to day 190 at which time the animals were sacrificed.

Results: Treatment with PBI-4050 resulted in a significant improvement (up to three fold relative to control) in GFR as demonstrated by an increase in creatinine clearance. Histological lesion scores of kidney were also significantly ($p<0.05$) reduced in PBI-4050-treated rats (2.7 ± 1.5) compared to control (3.9 ± 1.4), as determined by HPE, PAS and Masson's trichrome staining. Tubulo-interstitial fibrosis and sclerosis were significantly ($p<0.05$) reduced by treatment with PBI-4050. Also, a reduction in blood pressure was observed in PBI-4050-treated rats. Furthermore, oral treatment with PBI-4050 induced a significant reduction of urine MCP-1 level in treated 5/6 nephrectomized rats. This reduction correlates with GFR improvement and inhibition of fibrosis observed in PBI-4050-treated rats, indicating that PBI-4050 delays disease progression.

Conclusions: Taken together, these results suggest that PBI-4050 offers the potential as a novel therapy for chronic kidney disease by reduction of fibrosis and sclerosis.

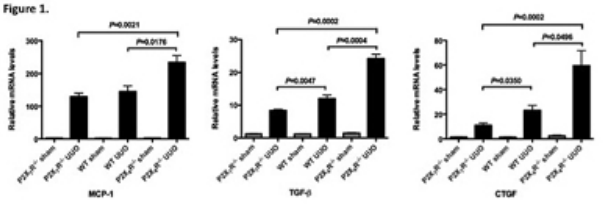
FR-PO1846

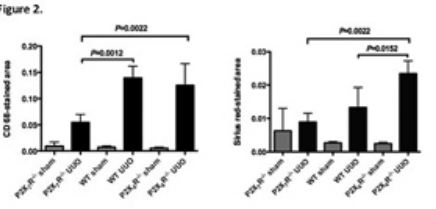
Deficiency of P2X4 Receptor May Promote Renal Fibrosis in a Mouse Model of Unilateral Ureteral Obstruction
Min Jeong Kim,[1] Reiko Hewitt,[1] Jennifer Smith,[1] Robert J. Unwin,[2] Frederick W.K. Tam.[1] *[1]Kidney and Transplant Institute, Imperial College London, United Kingdom; [2]Centre for Nephrology, University College London, United Kingdom.*

Background: Among the seven mammalian P2X receptors, P2X7 (P2X7R) has been shown to have pro-inflammatory effects in two models of renal injury: nephrotoxic nephritis and unilateral ureteral obstruction (UUO). P2X4 (P2X4R) is a related receptor with similarities to P2X7R; it is adjacent on the same chromosome, but has a wider tissue distribution. We compared the function of these receptors in the UUO model using knockout (KO) mice.

Methods: Ten to 12-week-old male P2X4R-/-, P2X7R-/- (a model expressing a novel splice variant of P2X7R) - gifts from GSK - and WT mice were subjected to either UUO or sham operation. Kidney samples taken at day 7 or day 14 were evaluated for MCP-1, TGF-β and CTGF expression by qPCR; macrophage infiltration and collagen deposition were assessed by immunostaining for CD68 and staining for picrosirius red (SR).

Results: On day 7 after UUO there were no significant differences in mRNA expression of MCP-1, TGF-β and CTGF, or CD68+ staining (P2X7R-/-, WT or P2X4R-/-); however, SR staining was significantly greater in P2X4R-/- compared with P2X7R-/-. By day 14 mRNA expression of MCP-1, TGF-β and CTGF was significantly higher in P2X4R-/- compared with P2X7R-/- and WT (Fig 1); CD68+ staining was significantly greater in both P2X4R-/- and WT compared with P2X7R-/-; SR staining was significantly greater in P2X4R-/- compared with P2X7R-/- and WT (Fig 2).





Conclusions: These findings suggest: (1) that P2X4R deficiency increases renal fibrosis in UUO; (2) that the reduced inflammation and fibrosis in another P2X7R KO model is consistent with previous findings, and that there is no functional role for the P2X7R splice variant in UUO.

FR-PO1847

Accelerated Tubulointerstitial Alterations Induced by Unilateral Ureteral Obstruction in Mice Lacking Vasohibin-1 Hiroyuki Watatani,[1] Yohei Maeshima,[1] Daisuke Saito,[1] Hiroko Yamasaki,[1] Masaru Kinomura,[1] Norikazu Hinamoto,[1] Haruyo Ujike,[1] Hitoshi Sugiyama,[1] Hikaru Sonoda,[2] Yasufumi Sato,[3] Hirofumi Makino.[1] *[1]Dept. of Medicine and Clinical Science, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [2]Discovery Research Laboratories, Shionogi & Co., Ltd., Settsu, Osaka, Japan; [3]Dept. of Vascular Biology, Institute of Development, Aging and Cancer, Tohoku Univ, Sendai, Miyagi, Japan.*

Background: Tubulointerstitial injuries are crucial histological alterations predicting deterioration of renal function in chronic kidney disease. Vasohibin-1(VASH-1), serves as a negative feedback regulator of angiogenesis as well as a maturation factor of neovessels by inducing pericyte attachment. We previously reported the protective role of Vasohibin-1 in diabetic nephropathy, but its role on tubulointerstitial injuries remains to be elucidated. In the present study, we aimed to evaluate the potential role of endogenous VASH-1 to regulate tubulointerstitial alterations in a mouse unilateral ureteral obstruction (UUO) model.

Methods: UUO was induced in female VASH-1 heterozygous knockout mice (VASH1+/-) or wild-type (VASH1+/+) littermates (C57/BL6J background). Mice were sacrificed on Day 3 or 7 after inducing UUO and the obstructed kidneys (OBK) were obtained.

Results: Glomerular or tubulointerstitial alterations were not observed in the kidneys of sham-operated VASH1+/- mice. Interstitial fibrosis, accumulation of type I and III collagen and F4/80+ monocytes/ macrophages in the OBK on Day 7 after inducing UUO were significantly accelerated in VASH1+/- mice compared with VASH1+/+ mice. Increase in the levels of transforming growth factor (TGF)-beta1 (immunoblot) and the number of interstitial fibroblast specific protein (FSP)1+ cells in the OBK were significantly aggravated in VASH1+/- mice compared with the wild-type mice.

Conclusions: These results suggest that endogenous VASH-1 may play a role in suppressing tubulointerstitial alterations induced by UUO via regulating inflammation and fibrosis, thus implicating its potential use to serve as a novel therapeutic reagent for renal disorders.

FR-PO1848

S1PR3 Is Pivotal Factor in Fibrosis in the Kidney Shunji Shiohira,[1] Takumi Yoshida,[1, 2] Junko Kohei,[1] Hidekazu Sugiura,[1] Michihiro Mitobe,[1] Kosaku Nitta,[1] Ken Tsuchiya.[1] *[1]Department of Medicine IV, Tokyo Women's Medical University, Shinjuku, Tokyo, Japan; [2]Internal Medicine, Yoshida Medical Clinic, Suginami, Tokyo, Japan.*

Background: The major sphingolipid metabolite, sphingosine-1-phosphate (S1P), is now attractive mediator of renal fibrosis. In our past report, S1P induced fibrosis *in vitro* in normal rat kidney interstitial fibroblast cells (NRK-49F). S1P is likely to have potentiality to mediate directly renal fibrotic processs in addition to via inflammaroy pathway. On the other hand, S1P is known to have unique tissue distribution of the receptor subtypes and the differing signaling pathways resulting from S1P receptor (S1PR) subtype activation. In our past study, NRK-49F showed mRNA expressions of S1PR 1, 2, 3 and 5, but not 4.And FTY720 inhibited fibrosis induced by S1P. FTY720 is S1PR 1,3,4,5 antagonist. S1PR 1 is mostly related with inflammatory pathway and S1PR 5 is involved in the regulation of nervous system. Thus, these results suggest that S1PR 3 is likely to play main role in renal fibrosis.

In this study, the role of S1P as a migratory mediator and which subtype of S1PR was related to fibrosis in the kidney were investigated in NRK-49F.

Methods: NRK-49F were stimulated with S1P and the expressions (mRNA/western blotting) of a-SMA, E-cadherin, collagen type 1 (COL1), collagen type 4 (COL4), TIMP1 and PAI1 were examined. The morphological changes of the NRK-49F after stimulation by S1P were examined. Increased migration of the cells was evaluated by the cell count within a field of view. And these examinations were adapted to siRNA (S1PR3) model.

Results: S1P stimulated fibrosis of NRK-49F in a dose- and time-dependent manner, and induced fibrotic transformation of the NRK-49F. Increase in a-SMA, COL1, COL4, TIMP1 and PAI1 expressions and decrease in E-cadherin expression were observed in the S1P-stimulated cells. Treatment of S1P-induced morphological changes (elongation of the cell shape with spindle-like extension, increased migration) in NRK-49F. In the presence of siRNA, fibrotic changes induced by S1P were suppressed.

Conclusions: In conclusion, S1P is a novel fibrotic mediator in the kidney, and S1PR3 is pivotal factor in fibrosis.

FR-PO1849

BMP2 Induces a Pro-Fibrotic Phenotype in Adult Renal Progenitor Cells (ARPCs) through Nox4 Activation in Transplant Recipients with Delayed Graft Function (DGF) S. Simone,[1] M. Cariello,[1] C. Cosola,[1] Antonia Loverre,[1] F. Rascio,[1] Fabio Sallustio,[1] Loreto Gesualdo,[1] Francesco Paolo Schena,[1] G. Grandaliano,[2] G. Pertosa.[1] *[1]Dept. of Emergency and Organ Transplantation, University Aldo Moro, Bari, Italy; [2]Dept. of Biomedical Sciences, University of Foggia, Italy.*

Background: ARPCs contribute to repair featuring acute kidney injury (AKI). Bone morphogenetic proteins (BMPs) regulate differentiation, modeling and regeneration in several tissues. Aim of the study was to evaluate the biological actions of BMP2 in ARPCs.

Methods: BMP2/BMP2 Receptors (BMP-R) gene (RT-PCR) and protein (ELISA/ immunoblotting) expression was evaluated in ARPCs isolated from adult human kidney (magnetic cell sorting). Intracellular reactive oxygen species (ROS) generation was measured by 2',7'DCF. Nox4 protein expression was studied by immunoblotting. BMP2, CD133, a-SMA and Nox4 protein expression was evaluated in renal biopsies of patients (pts, n=10) with DGF by confocal microscopy.

Results: BMP2 was expressed by ARPCs in adult human kidney and was upregulated in vivo after DGF (p=.02). ARPCs expressed type I and II BMP-R. ARPCs treated with BPM2 induced ROS production (basal 36.2±15.3 Arbitrary Unit (AU); BMP2 15' 65.5±17.8 AU, p=.03), NADPH oxidase activity (basal 86.5±38.2 AU; BMP2 15' 212±75.4 AU, p=.01) and Nox4 protein expression (p=.03). In vivo, Nox4 was localized in BMP2+CD133+cells at the tubular level after DGF. BMP2 incubation induced a-SMA (basal .3±.1 AU; BMP2 .8±.2 AU, p=.02), collagen-I (p=.03) and fibronectin (p=.04) protein expression in ARPCs. a-SMA colocalized with CD133 in vivo after DGF. H2O2 induced a-SMA expression in ARPCs (basal 1.0±.2 AU; H2O2 2.6±.8 AU, p=.03), while N-acetyl-cysteine inhibited BMP2-induced a-SMA expression (BMP-2 2.2±.6; BMP2+NAC 1.3±.4 fold change, p=.04). Nox4 silencing (siRNA) abolished BMP2-induced NADPH oxidase activation and myofibroblastic induction (p=.01).

Conclusions: In conclusion: a) ARPCs express BMP2; b) this expression is increased in pts with DGF; c) BMP2 may induce the commitment of ARPCs towards a myofibroblast phenotype; d) this profibrotic effect is mediated by Nox4 activation suggesting a novel mechanism linking DGF with progressive graft damage

FR-PO1850

RGS2, a Regulator of G Protein Signaling 2, Is Essential for the Prevention of Renal Fibrosis Induced by Unilateral Ureteral Obstruction Hee-Seong Jang, Jee In Kim, Kwon Moo Park. *Department of Anatomy, Kyungpook National University, Daegu, Korea.*

Background: A regulator of G protein signaling 2 (RGS2) is the most potent negative regulator of angiotensin II (AngII) type 1 receptor (AT1R), which is well-known contributor in the progression of chronic kidney disease. However, the role of RGS2 in kidney fibrosis remains to be defined. Here, we investigated the role of RGS2 in renal interstitial fibrosis following unilateral ureteral obstruction (UUO).

Methods: RGS2 deficient (RGS2-/-) and wild type (RGS2+/+) mice were subjected to UUO or sham-operation and kidneys were harvested at 3 and 5 days after operation. Expressions of RGS2 mRNA and protein were determined by RT-PCR and Western blot analysis, respectively. AT1R, AngII type 2 receptor (AT2R) and α- smooth muscle actin (α-SMA) expressions, and collagen deposition were evaluated by Western blot analysis and trichrome staining.

Results: UUO elevated the levels of RGS2 mRNA and protein along with increased expression of α-SMA and collagen deposition in the kidney. AT1R and AT2R expressions also significantly increased in the kidney after UUO. RGS2 gene deletion accelerated the kidney fibrosis with increase in the expression of α-SMA and collagen deposition. UUO-induced increase of AT1R expression was greater in the kidney of RGS2-/- mice than in those of RGS2+/+ mice and AT2R was vice versa. Well known downstream effector of AT1R such as PAI-1 and phosphorylated-ERK (p-ERK) were also greater in the kidney of RGS2-/- than in those of RGS2+/+ mice.

Conclusions: Our findings suggest that RGS2 prevents the progression of UUO-induced renal fibrosis through inhibition of AT1R.

A Synthetic Serine Protease Inhibitor Camostat Mesilate Attenuates Renal Interstitial Fibrosis in Rats Jun Morinaga,[1] Yutaka Kakizoe,[1] Taku Miyoshi,[1] Tomoaki Onoue,[1] Teruhiko Mizumoto,[1] Manabu Hayata,[1] Kohei Uchimura,[1] Naoki Shiraishi,[1] Masataka Adachi,[1] Sakai Yoshiki,[2] Kimio Tomita,[1] Kenichiro Kitamura.[1] *[1]Department of Nephrology, Faculty of Life Sciences, Kumamoto University, Kumamoto, Japan; [2]Ono Pharmaceutical Co., Ltd, Osaka, Japan.*

Background: Interstitial fibrosis is an important common pathway to end stage renal disease. It has been shown that serine proteases such as plasmin and thrombin have important roles in the pathogenesis of fibrosis. Therefore, we hypothesized that orally active serine protease inhibitor camostat mesilate (CM; FOY 305) can improve renal fibrosis.

Methods: In vivo, we investigated the effect of CM on unilateral ureteral obstruction (UUO) model. Sprague-Dawly rats were divided into three groups: Sham, UUO placebo, UUO CM (7mg/day). Rats were sacrificed after 2 weeks from UUO treatment. In vitro, we investigated the effect of CM on TGF-β1 signaling. Rat kidney fibroblasts (NRK cells) were divided into three groups: Control, TGF-β1+vehicle, TGF-β1+CM. After incubation in serum free medium for overnight, NRK cells were premedicated by CM or vehicle. Then, active TGF-β1 was administered to the NRK cells. Cells were harvested with time.

Results: In vivo, renal collagen I and III mRNA expression, percentage of sirius red positive area, hydroxyproline content, αSMA mRNA expression and its protein quantity was increased by UUO treatment. Administration of CM attenuated these fibrotic changes. Active TGF-β1 concentration of the kidney, phosphorylation of smad2 and ERK were increased by UUO, and significantly ameliorated by CM induction. Matrix metalloproteinase (MMP) -2 activity was increased by UUO, and ameliorated by CM administration. In vitro, mRNA expression of PAI-I, αSMA, CTGF, and protein quantity of αSMA, collagen I were increased by TGF-β1 treatment. Phosphorylation of ERK and smad2 were increased by TGF-β1 treatment. Administration of CM significantly ameliorated these changes.

Conclusions: CM attenuated renal interstitial fibrosis in UUO rats, probably through the inhibition of activating process of TGF-β1 by serine proteases. And more, in vitro study suggested that CM directly inhibited TGF-β1 signaling.

FR-PO1852

Silencing of Pericyte MicroRNA-132 Reduces Renal Fibrosis and Is Associated with Altered Sirt1 Expression Roel Bijkerk,[1,2] Ton J. Rabelink,[1] Benjamin D. Humphreys,[2] Anton Jan Van Zonneveld.[1] *[1]Nephrology, Leiden University Medical Center, Leiden, Netherlands; [2]Renal Division, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.*

Background: Lineage analysis has shown that during nephrogenesis, FoxD1-positive mesenchymal cells give rise to adult interstitial pericytes. These FoxD1-derivative interstitial cells expand and differentiate into smooth muscle actin (α-SMA) positive myofibroblasts during renal fibrosis, accounting for a large majority of myofibroblasts, which are responsible for scar formation in fibrotic kidney disease. MicroRNAs (miRNAs) involved in this differentiation could serve as a target to decrease myofibroblast formation in fibrotic kidney disease.

Methods: Fibrosis was induced in FoxD1-GC;Z/Red mice by unilateral ureteric obstruction (UUO) and FoxD1-derivative interstitial cells (dsRed positive) were isolated using FACS sorting. To identify differentially expressed microRNAs we profiled these specific cell populations in UUO vs. healthy controls. To investigate the role of miRNA-132 *in vivo* in renal fibrosis we injected antagomirs i.v. to silence its function in the UUO model. Mice were sacrificed both 5 and 10 days after surgery.

Results: miR-132 was amongst the most highly up regulated microRNAs in the FoxD1-derivative interstitial cells in the fibrotic kidney. Blocking the function of miR-132 with antagomir-132 in the UUO model resulted in an almost 20% decrease in collagen deposition after 10 days as compared to scramblemir controls, as determined by Sirius Red staining. In addition, immunohistochemical analyses show that the number of interstitial α-SMA positive cells, representing the myofibroblast population, is decreased by 25%. Western blot analyses showed a two fold reduction in the expression of α-SMA. This protection from a fibrotic phenotype is associated with a 3-fold reduction in the expression of the NAD-dependent deacetylase Sirt-1.

Conclusions: Silencing miR-132 protects against the development of renal fibrosis and is associated with strongly altered Sirt-1 levels.

FR-PO1853

In Tubulointerstitial Inflammation of the Kidney Notch3 Receptors Play a Non-Redundant Profibrogenic Role Sonja Djudjaj,[1,2] Christos Chatziantoniou,[3] Ute Raffetseder,[1] Dominique Guerrot,[3] Peter Boor,[1] Tammo Ostendorf,[1] Jurgen Floege,[1] Clemens D. Cohen,[4] Peter R. Mertens.[2] *[1]Department of Nephrology & Immunology, University Hospital RWTH Aachen, Germany; [2]Department of Nephrology & Hypertension, Otto-von-Guericke University, Magdeburg, Germany; [3]INSERM U702, Hospital Tenon, Paris, France; [4]Division of Nephrology & Institute of Physiology, University Zürich, Switzerland.*

Background: Tubulointerstitial fibrosis is the final common pathway in chronic kidney diseases. Recent studies link Notch receptor expression with kidney damage and scarring. We performed in vitro and in vivo experiments to analyze the participation of Notch3 receptors in the inflammatory response and tissue fibrosis.

Methods: Primary human mesangial cells were challenged with TGF-β and analyzed for Notch receptor expression. We extended our studies to an in vivo model of tubulointerstitial fibrosis: unilateral ureteral obstruction was performed with 20 week-old females. The right ureter of C57Bl6 and Notch3 -/- mice was ligated for 5 and 14 days, respectively. Kidneys were harvested for qRT-PCR and immunohistochemical analyses.

Furthermore qRT-PCR for Notch receptor and ligands was performed in human renal biopsies collected by the European Renal cDNA Bank.

Results: TGF-β challenge increased Notch1 and Notch3 receptor expression/activation at protein and mRNA levels within 30 minutes in hMC.

The expression of Notch3 mRNA and protein was significantly increased in the obstructed kidneys of C57Bl6 mice as compared with contralateral kidneys (6- and 3.8-fold at 5 and 14 days of UUO). Furthermore, analysis of renal tissue on day 5 showed that in comparison with wild type animals Notch3 -/- mice had fewer activated myofibroblasts (αSMA:-48%), markedly less matrix deposition (Sirius Red:-70%, collagen I:-73%, collagen III:-69%), tubular cell loss and infiltration of inflammatory cells (F4/80 staining:-95%). Upregulated Notch3 transcripts were also found in various inflammatory glomerular and tubulointerstitial human kidney diseases.

Conclusions: Upregulation of Notch3 receptor expression is a prerequisite for key events in fibrosing kidney diseases. The receptor may be a novel target for therapeutic intervention.

FR-PO1854

Oral Treatment with a Novel First-in-Class Anti-Fibrotic Compound, PBI-4419, Delays Tubulo-Interstitial Fibrosis and Sclerosis in 5/6 Nephrectomized Rats Lyne Gagnon, Lilianne Geerts, André Doucet, François Sarra-Bournet, Shaun Abbott, Jean-François Bienvenu, Jean-Simon Duceppe, Boulos Zacharie, Christopher Penney, Pierre Laurin, Brigitte Grouix. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: Recently, we discovered a novel, first-in-class, orally active low molecular weight compound which displays anti-inflammatory and anti-fibrotic activities via a new mechanism of action. The aim of this study was to investigate the effect of this first-in-class compound PBI-4419 on 5/6 nephrectomized rats.

Methods: Male Wistar rats were partially nephrectomized (2/3 of the left kidney) on day 0. On day 7 the right kidney was removed. Treatment with vehicle or PBI-4419 (10 and 50 mg/kg, oral once a day) was from day 1 through day 125. GFR was measured at day 21 and assessed every 3 weeks up to day 126 and animals were sacrificed at day 133. Serum urea and creatinine were also assessed every 3 weeks.

Results: Treatment with PBI-4419 increased survival. Rats treated with PBI-4419 demonstrated lower serum urea and creatinine levels than control. A significant GFR improvement (threefold increase) was also observed in PBI-4419-treated rats. Histological lesion scores of kidney were also reduced in PBI-4419-treated rats, as determined by HPE, PAS and Masson's trichrome staining. Tubulo-interstitial fibrosis and sclerosis were significantly ($p<0.05$) reduced by treatment with PBI-4419. Furthermore, oral treatment with PBI-4419 induces a significant reduction of urine MCP-1 level. This reduction correlates with GFR improvement and inhibition of fibrosis observed in PBI-4419-treated rats, indicating that PBI-4419 delays disease progression. 5/6 Nephrectomized rats showed an increase in TGFβ and CTGF mRNA expression in the kidney. Treatment with PBI-4419 gave a significant reduction of the expression of TGFβ (37%, $p=0.002$) and CTGF (30%, $p< 0.0001$) in the kidney.

Conclusions: Taken together, these results suggest that PBI-4419 offers the potential as a novel therapy for chronic kidney diseases by prevention or reduction of fibrosis and sclerosis.

Kinin B1- and Angiotensin1-Receptor Antagonists Display Comparable Curative Antifibrotic Effects in an Accelerated Model of Renal Fibrosis Antoine Huart,[2] Julie Klein,[1,3] Julien Gonzalez,[1,3] Eric Neau,[1,3] Benedicte Buffin-Meyer,[1,3] David Ribes,[2] Joost Schanstra,[1,3] Jean-Loup Bascands.[1,3] *[1]Inserm U1048, Toulouse, France; [2]Department of Nephrology, CHU-Rangueil, Toulouse, France; [3]Université Toulouse III Paul-Sabatier, Toulouse, France.*

Background: Renal tubulointerstitial fibrosis is the pathological hallmark of chronic kidney disease. Currently, inhibitors of the renin angiotensin system (RAS) remain the sole therapy in humans displaying antifibrotic effects. Therefore new antifibrotic drugs are needed and should be evaluated in combination with RAS inhibitors. We have recently reported that delayed treatment with a kinin B1 receptor antagonist (B1Ra) reduced renal fibrosis in the unilateral ureteral obstruction (UUO) model. The usefulness of new drugs also resides in outperforming the gold standards and being potentially additive or complementary to existing therapies. For this reason we compared the efficacy of a B1Ra with that of an angiotensin type 1 receptor antagonist (AT1a) in a curative model of UUO and determined whether bi-therapy presented higher efficacy than any of the drugs alone.

Methods: Treatments with the AT1 (Valsartan-TAREG) and B1 (SSR240612) receptors antagonists were started 3 days after UUO surgery and continued throughout the time (8 days) of obstruction. A control group received only the vehicle.

Results: Delayed B1Ra treatment was as efficient as the gold-standard AT1a treatment. However bitherapy did not improve the antifibrotic effects. We sought for the reason of the absence of this additive effect by studying the modifications of a panel of genes involved in the fibrotic process. We observed that at the gene expression level the drugs exhibited clear differences in their efficacy to down regulate the different players in fibrosis that, however, in this severe model did not result in improved reduction of fibrosis at the protein level.

Conclusions: As the B1R is induced specifically in the diseased organ and thus potentially displays low side effects, it might be an interesting alternative in cases where AT1a are not effective.

FR-PO1856

Age Affects Kidney Remodeling in Response to Ureteral Obstruction Lucas Falke,[1] Amelie Dendooven,[1] Roel Broekhuizen,[1] Reinout Stoop,[2] Jaap A. Joles,[3] Tri Q. Nguyen,[1] Roel Goldschmeding.[1] *[1]Pathology, University Medical Center, Utrecht, Netherlands; [2]Metabolic Health Research, TNO, Leiden, Netherlands; [3]Nephrology and Hypertension, University Medical Center, Utrecht, Netherlands.*

Background: Tubulointerstitial fibrosis (TI) is the final common pathway for all CKD leading to ESRD. CKD incidence increases with age in humans. However, for most experimental studies, young mice are used, and little is known about possible effects of aging on renal matrix biology in the TI compartment.

Methods: Unilateral ureteral obstruction (UUO) was performed in young (16wks; n=5) and old (48wks; n=5) C57Bl6 mice. Structural damage was scored after 14 days on PAS-stained slides. Gene expression was assessed by qPCR. Hydroxyproline and proline were measured by HPLC (hyp/proline ratio). Contralateral kidneys were used as an internal control.

Results: Old mice had 1.2-fold more tubular atrophy ($p=0.02$) and 2-fold more dilation ($p=0.02$) in the obstructed kidney than young mice. Contralateral non-obstructed kidneys in old mice tended to have lower 'baseline' hyp/proline ratio than in young mice, which, after UUO also increased 30% less in old than in young kidneys ($p=0.03$). Accordingly, COL1A2 mRNA was induced in obstructed kidneys in both young and old mice (12-fold, $p<0.0001$), but tended to be lower (1.6-fold, $p=0.07$) in obstructed kidneys of old vs. young mice, while collagenase MMP1/13 mRNA was decreased similarly in old and young obstructed kidneys (2.4-fold, $p<0.001$). In response to injury, BMP6 mRNA was decreased in young (1.9-fold, $p=0.03$), but not old mice after UUO, while decrease of BMP7 (4-fold, $p=0.01$), and increase of TGFβ (4-fold, $p=0.03$) and CTGF mRNA (1.7-fold, $p=0.04$) by UUO were not affected by age.

Conclusions: We conclude that age affects renal response to UUO. The more severe tubular atrophy and dilation upon obstruction might reflect decreased resistance to stretching due to differences in matrix remodeling in old kidneys. The latter might involve preserved BMP6 expression.

FR-PO1857

Silencing Ki-Ras with Antisense Oligonucleotides Reduces Renal Fibrosis in Unilateral Ureteric Obstruction but Does Not Affect Wound Healing Lucy Jade Newbury,[1] Jia-Hui Wang,[1] A. S. Knisely,[2] Bruce M. Hendry,[1] Claire C. Sharpe.[1] *[1]Renal Medicine, King's College London, United Kingdom; [2]Institute of Liver Studies, King's College London, United Kingdom.*

Background: Pathogenic fibrosis in the kidney is thought to occur via many different signaling pathways, many of which converge on Ras GTPases. Work in our laboratory has highlighted that the Ki-Ras isoform is important in renal fibrosis. In this project we used antisense oligonucleotides (ASO) to silence Ki-Ras expression to prevent fibrosis in a unilateral ureteric obstruction (UUO) model and assessed the effects on surgical wound healing.

Methods: Male Adult Wistar rats underwent unilateral ureteric ligation. The treatment group (n=7) received 12.5mg/kg ASO in saline subcutaneously on alternate days for 16 days. The control group (n=7) received saline alone. Obstructed kidney, contralateral kidney, liver, heart, and wound tissues were fixed in formalin at sacrifice (day 16). Microscopy of sections stained with H&E and Picro-Mallory Trichrome techniques allowed assessment of fibrosis and inflammation whilst an ASO-specific antibody was used to visualize tissue ASO accumulation. Anti-aquaporin 1 immunostaining was used to identify proximal tubular cells whilst anti-aquaporin 2 marked collecting ducts.

Results: In ASO-treated rats, ASO accumulated in all examined tissues, including surgical wounds. In obstructed kidneys ASO were seen primarily in proximal tubules and the interstitium of obstructed kidneys; they was absent from collecting ducts. Silencing Ki-Ras expression markedly reduced fibrosis in the obstructed kidneys. No difference between ASO-treated and vehicle only-treated rats was identified in inflammation or fibrosis at healing wounds.

Conclusions: Subcutaneously administered ASO are deposited in multiple tissues around the body. Although Ki-Ras ASO can prevent pathological renal fibrosis it does not inhibit normal wound healing, which permits the inference that fibro-inflammatory change in UUO and in wound healing operate via different mechanisms. Ki-Ras ASO use in clinical settings may not be contraindicated by wound-healing concerns.

FR-PO1858

Hyaluronan Synthase 1 Gene Expression Modulates Fibroblast Phenotype Timothy Bowen,[1,2] Rachel D. Neville,[1,2] John Martin,[1,2] Robert Steadman,[1,2] Aled O. Phillips.[1,2] *[1]Institute of Nephrology, Cardiff University School of Medicine, Cardiff, United Kingdom; [2]Cardiff Institute of Tissue Engineering and Repair, Cardiff University, Cardiff, United Kingdom.*

Background: To identify the processes underlying scar-free healing we are using donor-matched primary human dermal (DFs) and oral mucosal fibroblasts (OFs) as models of scarring and non-scarring fibroblast phenotypes, respectively. Dermal and oral mucosal wounds heal via inflammation, proliferation and extracellular matrix (ECM) remodelling. However, OF-mediated wound healing lacks scar formation, occurring more rapidly via increased migration, experimental wound repopulation and ECM reorganization.

ECM glycosaminoglycan hyaluronan (HA) is synthesised by the HA synthase (HAS) enzymes, encoded by genes HAS1-3. Transcriptional induction of HAS1 in DF by pro-inflammatory cytokine interleukin (IL)-1β up-regulates HA synthesis and alters cell migration. Fibrotic mediator transforming growth factor (TGF)-β1 also stimulates HAS1 mRNA synthesis in DF, driving differentiation to a myofibroblastic phenotype. Neither quiescent nor cytokine-treated OFs express HAS1, and these cells do not differentiate in response to TGF-β1. We describe here studies on the effect of modulation of HAS1 expression on DF and OF phenotype.

Methods: We used 5'-RACE to identify the HAS1 transcription start site. Selected transcription factor mRNAs were then subjected to small interfering (si)RNA knockdown. siRNA knockdown of HAS1 and HAS2 open reading frames (ORFs) was also carried out, together with forced expression of these ORFs.

Results: siRNA knockdown in DFs showed that HAS1 induction by IL-1β was Sp3-dependent, while TGF-β1 up-regulated HAS1 mRNA synthesis specifically via Smad3. Forced HAS1 ORF expression in OFs drove up-regulated transcription of alpha-smooth muscle actin (α-SMA), a key marker of fibroblast-to-myofibroblast transition. Further analyses in DF, following siRNA knockdown of HAS1 and / or HAS2, showed that visible α-SMA was absent only when siRNAs to both isoforms were used.

Conclusions: Our data provide evidence of synergy in the function of HAS1 and HAS2 in fibroblast phenotypic plasticity, with HAS1 facilitating differentiation to a myofibroblastic phenotype.

FR-PO1859

Regulation and Function of Hyaluronan Synthase 2-Antisense 1 Noncoding RNA, HAS2-AS1 Timothy Bowen,[1,2] Daryn R. Michael,[1,2] James Edward Redman,[3] Abdalsamed Altaher,[1] John Martin,[1,2] Aled O. Phillips.[1,2] *[1]Institute of Nephrology, Cardiff University School of Medicine, Cardiff, United Kingdom; [2]Cardiff Institute of Tissue Engineering and Repair, Cardiff University, Cardiff, United Kingdom; [3]School of Chemistry, Cardiff University, Cardiff, United Kingdom.*

Background: Noncoding (nc)RNAs are emerging rapidly both as novel regulators of gene expression and potential therapeutic targets. Glycosaminoglycan hyaluronan (HA) is a ubiquitous extracellular matrix component that is synthesised by the HA synthase (HAS) enzymes. HA synthesis and pericellular assembly drive the differentiation of renal proximal tubular epithelial cells (PTCs) and fibroblasts to a pro-fibrotic, myofibroblastic phenotype. HAS2 gene expression is essential to this process, and HAS2-antisense 1 (HAS2-AS1) is a natural antisense for the HAS2 gene that down-regulates HAS2 transcription and HA synthesis in osteosarcoma cells. We have recently shown that HAS2-AS1 transcriptional induction facilitates HAS2 expression in PTCs. In the present investigation we investigated HAS2-AS1 and HAS2 expression in fibroblasts as well as the mechanism of HAS2-AS1:HAS2 ncRNA:mRNA interaction in PTCs.

Methods: We used RT-qPCR and siRNA knockdown to analyse HAS2-AS1 and HAS2 expression in fibroblasts. HAS2-AS1 ncRNA and HAS2 mRNA secondary structures were investigated in silico to verify the thermodynamic feasibility of heterodimer formation. Minimum free energy and partition function calculations were performed using the Vienna suite of programs. Analysis of ncRNA:mRNA duplex location in PTCs was carried out using endpoint RT-PCR.

Results: Our data showed coordinated expression of HAS2-AS1 and HAS2 in fibroblasts, supporting our previous analyses in PTCs. The thermodynamic feasibility of HAS2-AS1/HAS2 heterodimer formation was demonstrated, and locus-specific cytoplasmic double-stranded RNA was detected.

Conclusions: We provide evidence that the interaction between HAS2 mRNA and HAS2-AS1 ncRNA stabilises and/or augments HAS2 expression via cytoplasmic duplex formation. Our results emphasise the potential of modulating antisense RNA expression to regulate both HAS2-driven HA synthesis, and the downstream myofibroblastic conversion of PTCs and fibroblasts.

FR-PO1860

The Senescence of Renal Tubular Epithelial Cells Correlates with Tubulointerstitial Fibrosis in Immunoglobulin A Nephropathy Yani He, Jun Liu, Jurong Yang, Wei-Wei Zhang, Lirong Lin, BenGang Huo, Jun Zhan. *Department of Nephrology, Daping Hospital, the Third Military Medical University, Chongqing, China.*

Background: Tubulointerstitial fibrosis (TIF) is the key pathophysiology basis in the development of immunoglobulin A nephropathy (IgAN). Here we report our studies on the relationship between the senescence of RTECs and TIF in IgAN.

Methods: Patients with IgAN were initially classified according to Lee's classification method. With immunohistochemical staining, the expression of Col III and fibronectin (FN) in tubulointerstitium were examined, and expression of p16, p21, cyclin D1 in RTECs were examined, also positive staining of SA-β-gal in RTECs was evaluated. Immunohistochemical staining in serial sections was also performed to examine the expression of p16, p21, cyclin D1 and FN in IgAN with Lee's Grade V. Correlation analysis show the expression of Col III, FN and positive staining of SA-β-gal in RTECs.

Results: With the increased level of Lee's IgAN grades, positive staining of SA-β-gal and the nuclear positive expression of p16 and p21 were progressively increased ($P < 0.01$), which was consistent with the increased expression of Col III and FN in tubulointerstitium; while the expression of cyclin D1 was significantly decreased ($P < 0.01$). Immunohistochemical staining in serial sections in Lee's Grade V IgAN showed that the increased p16 and p21 in RTEC associated with elevated FN expression in tubulointerstitium, whereas the expression of cyclin D1 notably decreased. Correlation analysis suggested that positive staining of SA-β-gal in RTECs presented significant positive correlation with the expression of Col III and FN in tubulointerstitium ($r=0.665$, $r=0.682$, $P < 0.01$).

Conclusions: Our results revealed that the senescence of RTECs tightly links with TIF in IgAN, which is the possible underlying mechanism response for the progression of TIF in IgAN.

FR-PO1861

Increased Expression of Intranuclear Matrix Metalloproteinase 9 in Atrophic Renal Tubules Is Associated with Renal Fibrosis Jen-Pi Tsai,[1,2] Jong-Da Lian,[2,3] Horng-Rong Chang.[2,3] *[1]Department of Nephrology, Buddhist Dalin Tzu Chi General Hospital, Chiayi, Taiwan; [2]Institute of Medicine, Chung Shan Medical University, Taichung, Taiwan; [3]Division of Nephrology, Department of Internal Medicine, Chung Shan Medical University Hospital, Taichung, Taiwan.*

Background: Reduced turnover of extracellular matrix has a role in renal fibrosis. Matrix metalloproteinase (MMP) is associated with many glomerular diseases, but the histological association of MMP and human renal fibrosis is unclear.

Methods: We studied the role of MMP-9 in the pathogenesis of renal fibrosis in 46 patients who received nephrectomies by immunohistochemical analysis of renal expression

of MMP-9 in nephrectomized kidneys, and determination of the association of renal expression of MMP-9 and renal fibrosis. MMP-9 expression in individual renal components and fibrosis was graded as high or low based on MMP-9 staining and fibrotic scores.

Results: Patients with high interstitial fibrosis scores (IFS) and glomerular fibrosis scores (GFS) had significantly higher serum creatinine, lower estimated glomerular filtration rate (eGFR), and were more likely to have chronic kidney disease (CKD) and urothelial cell carcinoma. Univariate analysis showed that IFS and GFS were negatively associated with normal and atrophic tubular cytoplasmic MMP-9 expression and IFS was positively correlated with atrophic tubular nuclear MMP-9 expression. Multivariate stepwise regression indicated that MMP-9 expression in atrophic tubular nuclei ($r = 0.315$, $p = 0.013$) was an independent predictor of IFS, and that MMP-9 expression in normal tubular cytoplasm ($r = - 0.483$, $p < 0.001$) was an independent predictor of GFS.

Conclusions: Our results indicate that renal fibrosis is associated with a decline of MMP-9 expression in the cytoplasm of normal tubular cells and increased expression of MMP-9 in the nuclei of tubular atrophic renal tubules. We postulate that increased intranuclear MMP-9 expression may reflect intranuclear gelatinase proteolysis, play a role in oxidative DNA damage by cleaving nuclear matrix proteins (PARP-1 and/or XRCC1), and contribute to cell death and fibrosis.

HIV-1 Promotes Renal Tubular Epithelial Cell Protein Synthesis: Role of mTOR Pathway Shabina Rehman,[1] Mohammad Husain,[1] B. S. Kasinath,[2] Ashwani Malhotra,[1] Pravin C. Singhal.[1] *[1]Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY; [2]Medicine, University of Texas Health Science Center, San Antonio, TX.*

Background: Tubular cell HIV-infection has been reported to manifest in the form of cellular hypertrophy. The mammalian target of rapamycin (mTOR) has been considered to be a central pathway of protein synthesis. In the present study, we evaluated the role of the mTOR pathway in the HIV-induced tubular cell protein synthesis and hypertrophy.

Methods: Mouse proximal tubular epithelial cells (MPTECs) were transduced with either gag/pol-deleted NL4-3 (HIV/MPTEC) or empty vector (Vector/MPTEC). Vector/MPTECs and HIV/MPTECs were evaluated for DNA synthesis by BrdU labeling and for protein synthesis by immunoblotting for β-laminin and fibronection. Immunoblots prepared from vector/MPTECs and HIV/MPTECs were probed for phosphorylation of mTOR, p70S6 kinase and associated down stream molecules (eEF2, eIF4B and 4EBP-1). We also evaluated the effect of rapamycin on HIV-induced tubular cell mTOR activation and associated downstream signaling. In addition, we studied the effect of mTOR inhibition on HIV-induced tubular cell protein synthesis. In vivo studies, tubular cell mTOR activation was also examined.

Results: HIV/MPTECs showed enhanced ($P<0.01$) production of β-laminin and fibronection in addition to increased ($P<0.01$) protein content per cell. Analysis of mTOR revealed increased expression of phospho (p)-mTOR in HIV/MPTECs when compared to vector/MPTECs. Further downstream analysis of mTOR pathway revealed enhanced ($P<0.01$) phosphorylation of p70S6 kinase and associated diminished phosphorylation of eEF2 in HIV/MPTECs; moreover, HIV/MPTECs displayed enhanced phosphorylation of eIF4B and 4EBP-1. Rapamycin not only attenuated ($P<0.01$) phosphorylation of p70S6 kinase and associated down stream signaling in HIV/ MPTECs but also inhibited HIV-1 induced tubular cell protein synthesis. In in vivo studies, renal cortical sections from HIVTg mice and HIVAN patients showed enhanced tubular cell phosphorylation of mTOR.

Conclusions: The mTOR pathway activation in HIV-expressing tubular cells results in increased protein synthesis and cellular hypertrophy.

Matrix Metalloproteinase-7 as a Surrogate Marker Predicts Renal Wnt/β-Catenin Signaling in Progressive Chronic Kidney Diseases Weichun He, Roderick J. Tan, Yingjian Li, Dan Wang, Youhua Liu. *Department of Pathology, University of Pittsburgh, PA.*

Background: Matrix metalloproteinase-7 (MMP-7) is a secreted, zinc and calcium dependent endopeptidase that cleaves a variety of extracellular matrix components and other substrates. In this study, we investigated MMP-7 regulation in progressive chronic kidney diseases and delineated its relation to renal Wnt/β-catenin signaling. In mouse model of obstructive nephropathy, both MMP-7 mRNA and protein were upregulated in a time-dependent manner. Induction of MMP-7 mRNA and protein was also found in adriamycin nephropathy. The pattern and extent of MMP-7 induction were closely correlated with an increased Wnt/β-catenin signaling in these models. Activation of β-catenin through ectopic expression of Wnt1 gene *in vivo* promoted MMP-7 expression, whereas delivery of endogenous Wnt antagonist Dickkopf-1 gene abolished its induction. MMP-7 protein was detectable in urine and its urinary levels correlated with renal Wnt/β-catenin activity. Pharmacologic blockade of Wnt/β-catenin signaling by paricalcitol also inhibited MMP-7 expression in diseased kidneys and its excretion to urine. *In vitro*, β-catenin activation induced MMP-7 expression and secretion, and promoted the occupancy of T cell factor to the MMP-7 promoter in kidney epithelial cells, as shown by ChIP assay. MMP-7 expression was also induced, and correlated with an increased β-catenin, in human kidney biopsies from patients with various nephropathies. These results suggest that MMP-7 level could serve as a surrogate marker for predicting renal Wnt/β-catenin activity, thereby monitoring the progression of renal fibrotic lesions.

Albumin Caused the Activation of NLRP3 in Proximal Tubule Cells Dan Liu, Linli Lv, Bi-Cheng Liu. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiangsu, China.*

Background: Proteinuria is considered to play a central role in the pathogenesis of progressive renal dysfunction, especially, in the renal tubulointerstitial inflammation and fibrosis. Recent studies have indicated that NLRP3 inflammasome is a key platform for the formation of inflammation, it is thereby interesting to understand the potential influence of albuminuria on the expression of NLRP3 inflammasome in kidney tubular cells. In this study, we firstly investigated whether albumin would induce the activation of NLRP3 inflammasome in tubular epithelial cells.

Methods: Proximal tubule cell (HK-2) was cultured and stimulated with different concentrations (2.5 mg/ml, 5 mg/ml, 10mg/ml) of Bovine Serum Albumin (BSA). The expression of mRNA for NLRP-3, caspase-1, IL-1beta and IL-18 was detected by Real time PCR. Immunohistochemistry and immunofluorescence was applied to detect the expression of NLRP3 in cytoplasm of HK-2 cells. The secreted IL-1beta and IL-18 in the supernatant from cell culture was determined by ELISA.

Results: After the 10 mg/ml BSA stimulation, real time RT-PCR analysis revealed the increasing expression of mRNA of NLRP3, caspase-1 and IL-1beta compared with control group. Study by immunohistochemistry and immumofluorescence showed that the expression of NLRP-3 was significantly increased in cytoplasm. Furthermore, it was shown that secretion of IL-1beta and IL-18 in supernatant significantly increased when HK2 cells exposed to the treatment of BSA stimulation ($P<0.05$).

Conclusions: Our study firstly demonstrated that albumin would cause the activation of NLRP-3 in proximal tubular cells, which provide a novel insight about the albuminuria in inducing tubulointerstitial inflammation and subsequent fibrosis.

Core Fucosylaion of Megalin Is Required for Albumin Binding and Endocytosis in HK-2 Cells Hong Li Lin, Wang Da Peng, Zheng Mei Jie, Yan Ling Sun, Hua Xie. *First Affiliated Hospital of Dalian Medical University.*

Background: Proteinuria is an independent risk factor leading to end-stage renal failure. Over-reabsorption of filtered proteins has been proved to trigger interstitial inflammation and fibrosis in glomerular disease. Megalin, an endocytic receptor expressed on the renal tubular brush border, is responsible for albumin reabsorption. It has been reported that megalin was a glycoprotein and there was amount of core fucose structure in megalin. In this study, we investigated the role of core fucose of megalin which catalysed by its specific transferring enzyme FUT8 in albumin overloading injury in human renal proximal tubular epithelial cells lines (HK-2)

Methods: An albumin overload cell mode was induced by adding 10mg/mL BSA in HK-2 cells. FUT8siRNA or FUT8 full length cDNA vector was transiently transfected into HK-2 cells respectively. The spatial relationship in localization between megalin and core fucose was examined by double immunostaining. BSA binding and endocytosis was determined by flow-cytometry and laser scanning confocal microscope. Expression of megalin protein and core fucose of megalin were detected by immunoprecipitation and lectin blotting. Furthermore,we detected the expression of MCP-1 and RANTES to investigate the effect of core fucosylaion of megalin on the inflammation iuduced by BSA in HK-2 cells.

Results: BSA binding and endocytosis was in a time- and dose-dependent manner in HK-2 cells after BSA administration. Core fucosylation of megalin was inhibited by FUT8siRNA and up-regulated by FUT8 full length cDNA. Our data firstly showed that megalin was modified by core fucosylation, and furthermore the core fucosylation of megalin was essential for its binding and endocytosis of albumin in HK-2 cells .Incubation with BSA led to a significant increase of MCP-1 and RANTES in HK-2 cells. Reducing expression of core glycosylation of megalin markedly decreased expression of MCP-1 and RANTES.

Conclusions: Core fucosylaion of megalin was required for albumin binding and endocytosis. Reducing expression of core glycosylation of megalin markedly decreased expression of inflammation factors in HK-2 cells induced by albumin overload.

Oncostatin M Is a Novel Inhibitor of TGF-β1-Induced CTGF Expression in Human Proximal Tubular Cells Markus Pirklbauer, Rita Sarkozi, Christine M. Hauser, Susie-Jane Noppert, Andreas Kronbichler, Viktoria Maria Haller, Gert J. Mayer, Herbert Schramek. *Department of Internal Medicine IV, Nephrology and Hypertension, Innsbruck Medical University, Innsbruck, Austria.*

Background: Matricellular proteins (MP) such as connective tissue growth factor (CTGF), thrombospondin-1 (TSP-1), tenascin-C (TNC), and SPARC (secreted protein, acidic and rich in cystein) have been implicated in the development of tubulointerstitial lesions in human and experimental diabetic nephropathy. This study investigated potential anti-fibrotic effects of the cytokine oncostatin M (OSM) in human proximal tubular cells (hPTC), particularly with regard to inhibition of pro-fibrotic events mediated by transforming growth factor-β1 (TGF-β1).

Methods: Cell culture, Western blot, real-time PCR.

Results: In quiescent hPTC 10 ng/ml OSM diminished TGF-β1-induced expression of the transcriptional EMT mediator FoxC2. Real-time PCR analysis revealed time-dependent induction of CTGF, TSP-1, TNC, and SPARC in hPTC stimulated with TGF-β1 (10 ng/

ml). While TGF-β1-mediated induction of TNC, TSP-1, and SPARC was highest after 24 h, strongest stimulation of CTGF mRNA and protein was detected after 3 h and 6 h, respectively. Exposure to OSM attenuated basal and TGF-β1-induced expression of the four MPs regardless of the sequence of ligand administration. OSMs inhibitory effect on TGF-β1-induced CTGF mRNA expression was effective after 2 h and not affected by inhibition of DNA methylation. OSM resulted in rapid and sustained phosphorylation of Stat1 and Stat3 and a transient phosphorylation of Smad2/3 in contrast to TGF-β1, which demonstrated a gradually building phosphorylation of Smad2/3 and a brief phosphorylation of Smad1/5/8.

Conclusions: In hPTC OSM is a potent inhibitor of basal and TGF-β1-induced CTGF, TSP-1, TNC, and SPARC mRNA expression. Utilising receptor-blocking molecules we found the inhibitory effect of OSM on TGF-β1-induced CTGF mRNA expression occurs independently of Smad2/3 signaling and present evidence that this effect may be partially driven by OSM receptor-mediated Stat1 and/or Stat3 signaling pathways. Thereby providing a mechanism whereby OSM can contribute to tubulointerstitial protection.

HSP27 Inhibits Renal Fibrogenesis Via Stabilization of Membrane-Bound E-Cadherin Aparna Vidyasagar, Shannon Reese, Lingjin Huang, Jose R. Torrealba, Lynn M. Jacobson, William F. Swain, Arjang Djamali. *Medicine and Surgery, UW-SMPH, Madison, WI.*

Background: We hypothesized that HSP27, a small stress response protein, protects the kidney from tubulointerstitial fibrosis in obstructive nephropathy.

Methods: To test this hypothesis we assessed HSP27 expression in human kidneys with ureteropelvic junction (UPJ) obstruction. Next, we generated transgenic mice that specifically overexpress human HSP27 in renal tubules under a kidney androgen protein promoter, and investigated the effects of HSP27 on epithelial-to-mesenchymal transition (EMT) and tubulointerstitial fibrosis following unilateral ureteral obstruction (UUO). We confirmed our findings in the in vitro model of TGF-β-induced EMT in NRK52E cells.

Results: There was a significant increase in tubular HSP27 in human kidneys with UPJ obstruction, supporting the clinical importance of these studies (Fig 1)

Figure 1. Tubular Hsp27 was increased in kidneys with UPJ obstruction

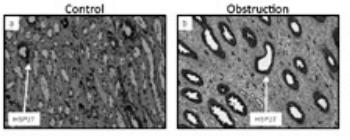

Figure 2. Hsp27 was increased after UUO in Transgenic Mice

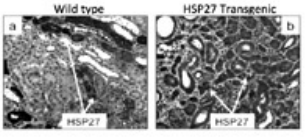

Figure 3. E-cadherin and beta-catenin remained at the cell membrane in HSP27 transgenic mice

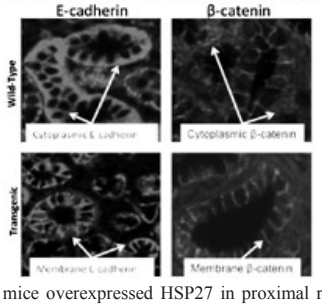

HSP27 transgenic mice overexpressed HSP27 in proximal renal tubular epithelial cells after UUO (Fig 2). HSP27 upregulation was associated with decreased fibrosis as evidenced by significant reduction in trichrome staining and decreased oxidative stress (OS) measured by HNE and nitrotyrosine western blots. Notably, E-cadherin and β-catenin were preserved at the cell membrane of tubular cells in transgenic mice undergoing UUO (Fig 3). These studies were confirmed in vitro, where human HSP27 transfection preserved E-cadherin and β-catenin at the cell membrane of rat tubular epithelial cells during TGF-β-induced EMT.

Conclusions: Our studies demonstrate that HSP27 overexpression in renal tubular epithelial cells is associated with reduced fibrogenesis and OS after UUO. The inhibitory effects of HSP27 on fibrogenesis may be mediated via stabilization of the E-cadherin-β-catenin complex at the cell membrane. The molecular mechanisms that regulate HSP27-E-cadherin interactions need to be determined.

Matrix Metalloproteinases-2 Was Involved in the Development of Renal Interstitial Fibrosis through Tubular Epithelial-to-Mesenchymal Transition Xuanyi Du,[1] Akira Shimizu,[1] Yukinari Masuda,[1] Akiko Mii.[2] *[1]Analytic Human Pathology, Nippon Medical School, Tokyo, Japan; [2]Internal Medicine (Division of Neurology, Nephrology, and Reumatology), Nippon Medical School, Tokyo, Japan.*

Background: Renal fibrosis is common characteristic findings of the progressive renal diseases. Matrix metalloproteinases (MMPs) is involved in the epithelial-to-mesenchymal transition (EMT). We investigated the role of MMP-2 and the effect of inhibition of MMPs on the development of renal fibrosis.

Methods: Renal fibrosis was induced in MMP-2 wild type (MMP-2+/+) mice by unilateral ureteral obstruction (UUO). Renal histology, EMT-associated molecules, and activity of MMP-2 and MMP-9 were examined during the development of interstitial fibrosis. Renal fibrosis using UUO was also induced in MMP-2 deficient (MMP-2-/-) and MMP-2+/+ mice treated with inhibitor of MMPs (minocycline; 150 mg/kg body wt/day).

Results: In MMP-2+/+ mice, MMP-2 and MMP-9 expressed on the dilated or atrophic damaged tubules, and their activities increased in a time-dependent manner at days 3 to 14 after UUO. At day 14, interstitial fibrosis developed with the deposition of type I and type III collagens, new expression of mesenchymal phenotypes (S100A4, vimentin, αSMA, and HSP-47) in damaged tubular epithelial cells, and F4/80+ macrophage infiltration. In the fibrotic kidneys, EMT-associated molecules (TGF-b1, smad, ILK, and snail) were up-regulated. In contrast, the kidneys of MMP-2-/- mice and MMP-2+/+ mice treated with minocycline showed reduction of renal fibrosis with decreased expression of mesenchymal phenotypes of tubular epithelial cells, inhibition of the up-rugulated EMT-associated molecules, and suppression of macrophage infiltration.

Conclusions: We conclude that MMP-2 play a pathogenic role in the progression of renal interstitial fibrosis, possibly through inducing EMT and macrophage infiltration. Inhibition of MMPs may provide a novel therapeutic advantages aimed at attenuating progressive renal diseases.

FR-PO1869

Targeted Inhibition of NF-κB Activation in Tubular Epithelia Protects Mice Against Renal Fibrogenesis Following Nephrotoxic Serum Nephritis (NTN) Tsutomu Inoue,[1] Matsuhiko Hayashi,[2] Hiromichi Suzuki,[1] Hirokazu Okada.[1] *[1]Nephrology, Saitama Medical University, Irumagun, Saitama, Japan; [2]Apheresis and Dialysis Center, Keio University School of Medicine, Shinjuku-ku, Tokyo, Japan.*

Background: Although it is well known that NF-κB is involved in renal fibrogenesis following NTN, the relative role of NF-κB activation in tubular epithelia is unclear.

Methods: Two lines of transgenic (tg) mice were used. IκB-dominant negative (IκBdN) tg mice that carry the IκBdN gene (IκBdN gene product inhibits NF-κB activation *in vivo*; JASN 21:2047-2052, 2010) separated from a universal CAG promoter by a floxed STOP sequence were crossed with γGT.Cre tg mice that express Cre recombinase in tubular epithelia. Male, 6-8 week-old, double-tg mice (γGT.Cre;IκBdN) and wild-type mice were then challenged with NTN. Inflammation/Fibrosis-related parameters in the kidneys were determined by real-time RT-PCR and immunohistochemistry.

Results: Either urinary protein excretion or glomerular damage such as crescent formation was significantly increased at the similar degree in the γGT.Cre;IκBdN and wild-type mice with Day14 NTN. In contrast, the number of p-p65^{+} nuclei was significantly lower in tubular epithelia in the NTN kidneys of the γGT.Cre;IκBdN mice due to tubular epithelium-specific induction of the IκBdN gene, compared to those of the wild-type mice ($p<0.05$). In contrast, F4/80^{+} monocyte infiltration and matrix deposition by Masson's trichrome staining in peritubular interstitium were significantly decreased in the NTN kidneys of the γGT.Cre;IκBdN mice, compared to those of the wild-type mice ($p<0.05$). Levels of mRNAs encoding KIM-1, MCP-1, PAI-1, and fibronectin-EIIIA were also significantly decreased in the NTN kidneys of the γGT.Cre;IκBdN mice, compared to those of the wile-type mice ($p<0.05$).

Conclusions: Targeted expression of IκBdN in tubular epithelia provides evidence of the critical role of NF-κB activation in tubular epithelia in proinflammatory cell recruitment and subsequent fibrogenesis in the NTN kidneys.

Adenovirus Mediated Gene Transfer of Gremlin1 to the Peritoneal Membrane Is Associated with Epithelial Proliferation and Cellular Transition Simon P. Curran,[1] Imad U. Siddique,[2] Peter Margetts.[2] *[1]Medicine, University of Toronto, ON, Canada; [2]Medicine, McMaster University, Hamilton, ON, Canada.*

Background: Gremlin1 (grem1) is a bone morphogenetic protein (BMP) antagonist that displays increased expression in models of fibrosis, including diabetic nephropathy. Grem1 expression is associated with epithelial to mesenchymal transition (EMT) due to reduced BMP-7 signaling. Grem1 has also been identified as an agonist of vascular endothelial growth factor receptor 2. EMT and angiogenesis are important processes leading to peritoneal membrane injury and alteration in solute transport properties for patients on peritoneal dialysis (PD) therapy.

Methods: C57Bl/6 mice received an intraperitoneal injection of an adenovirus vector encoding grem1 or control adenovirus (AdDL). Grem1 was delivered at $1.5x10^{8}$ pfu (AdGrem1(low dose)) or $3x10^{8}$ pfu (AdGrem1(high dose)). As a positive control for fibrosis, we treated animals with an adenovirus expressing active transforming growth factor β (AdTGFβ). Animals were sacrificed 7, 14 and 21 days after infection.

Results: mRNA was extracted from peritoneal tissues. Gene expression for grem1 was increased in both low dose and high dose AdGrem1 animals. On histology, we observed epithelial proliferation and increased submesothelial thickening, most prominent in the high dose group. Compared with AdTGFβ1 treated mice, the thickened submesothelium zone in AdGre1 treated animals demonstrated little collagen accumulation on trichrome stain. This was confirmed by PCR. AdGrem1 did not induce significant collagen gene expression. AdGrem1 did increase α-smooth muscle actin and decreased E-Cadherin gene expression, suggestive of an EMT process.

Conclusions: Grem1, by inhibiting BMP-7, appears to cause EMT and epithelial proliferation without strong evidence of fibrosis. The clinical importance of Grem1 in peritoneal dialysis patients is unknown.

The Spectrin-Based Cytoskeleton Organizes Differential Functional Domains along the Mouse Nephron Gilbert W. Moeckel, Michael C. Stankewich. *Pathology, Yale University School of Medicine, New Haven, CT.*

Background: The spectrin-based cytoskeleton lines the intracellular side of membranes of many cell types, forming a molecular scaffold that links the actin cytoskeleton to many membrane-spanning proteins either directly or through its partner, ankyrin. Seven spectrin genes and three ankyrin genes (spectrin αI/αII; βI-βV and ankyrins I (R), II (B) & III (G) are known in vertebrates.

Methods: Their expression profiles were investigated using RT-PCR/ q-PCR/Western analysis/immuo-fluorecence and electron microscopy in the mouse kidney.

Results: mRNA for seven of the ten-spectrin/ankyrin genes is found (all except for αI, βIV and βV spectrin). αII/βII are the most abundant spectrin transcripts and Ank3 (G) is the most abundant ankyrin. βII spectrin is predominantly expressed together with αII spectrin in the proximal tubules at the basolateral membrane and in coated vesicles near the lateral and apical membrane, while βIII spectrin is expressed in distal segments of the kidney. AnkyrinB is predominantly found in the thick loop of Henle and the distal convoluted tubule, while AnkyrinG reactivity is observed in most renal tubules. In the glomerulus, αII/βII/βIII spectrins and ankyrinB are found in podocytes and capillary endothelial cells.

Conclusions: Together, the full repertoire of spectrin and ankyrin genes provide a membrane scaffold for apical and basolateral surfaces and for vesicular structures in both the proximal and distal renal tubules. We propose that the distinct distribution of spectrin and ankyrin proteins to intracellular, lateral or apical membrane domains suggest their involvement in the cellular location and properties of receptors, ion channels and transporters in kidney cells.

Mouse Renal Fibrosis after Unilateral Ureteral Obstruction Is Reduced by Klotho Protein Overexpression through Wnt Signaling Inhibition Minoru Satoh, Tamaki Sasaki, Naoki Kashihara. *Department of Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: Wnt proteins play important roles in regulating cell differentiation, proliferation, and polarity. Increased Wnt signaling is implicated in many fibrotic diseases including obstructive nephropathy. Blockade of Wnt/β-catenin signaling may offer a novel therapeutic approach to renal fibrosis. Klotho, characterized as an anti-aging gene, is reported to function as a secreted Wnt antagonist. The Wnt-klotho interaction results in suppression of Wnt biological activity. Here we explored the possibility that klotho protein could improve renal fibrosis by inhibition of Wnt signaling.

Methods: Unilateral ureteral obstruction (UUO) performed in transgenic mice overexpressing the alpha-klotho gene under control of human elongation factor 1 alpha promoter (KLTG; C57BL/6 background) and in C57BL/6 mice (WT) was studied after 14 days. In some WT, plasmid encoding mouse klotho (pCAGGS-KL) was transferred into skeletal muscle by electroporation. Wnt/β-catenin signaling activation was examined by crossing with BAT-LacZ mice overexpressing the β-galactosidase gene under control of seven repeat T cell factor/lymphoid enhancer-binding factor 1 promoter.

Results: In WT, UUO led to increased extracellular matrix deposition and tubulointerstitial fibrosis, and significantly decreased wet weight of the obstructed kidney compared with sham-operated kidney. In KLTG and pCAGGS-KL, however, there was markedly less extracellular matrix deposition compared to WT mice. At 7 days post-UUO, Wnt/β-catenin signaling activation was activated in the tubulointerstitium in WT but less so in KLTG. Expression of Wnt/β-catenin target genes was increased in WT and reduced in KLTG and pCAGGS-KL. Expression of connective tissue growth factor, transforming growth factor-β1, and type III collagen post-UUO was decreased in KLTG and pCAGGS-KL compared to WT. KLTG also showed less progression of epithelial to mesenchymal transition compared to WT post-UUO, as evidenced by reduced amounts of alpha-smooth muscle actin.

Conclusions: Klotho protein is a critical negative regulator of Wnt signaling and plays negative regulating roles in renal fibrosis after UUO.

FR-PO1873

Tubulointerstitial De Novo Expression of the α8 Integrin Chain Attenuates Tubulointerstitial Fibrosis after Unilateral Ureteral Obstruction (UUO) Andrea Hartner,[1] Nada Cordasic,[2] Carlos Menendez-Castro,[1] Bernd Klanke,[2] Wolfgang Rascher,[1] Karl F. Hilgers.[2] *[1]Department for Pediatrics and Adolescent Medicine, University Hospital of Erlangen, Erlangen, Germany; [2]Department of Nephrology and Hypertension, University Hospital of Erlangen, Erlangen, Germany.*

Background: In the normal kidney, the α8 integrin chain is expressed only on mesangial and vascular smooth muscle cells. α8 integrin ligates several matrix molecules including fibronectin (FN), osteopontin (OPN) and fibrillin-1 (FB1). Recently, we detected de novo expression of α8 integrin on epithelial cells in the wall of renal cysts. We hypothesized that the α8 integrin chain is induced in dedifferentiating tubular epithelia and that binding to its ligands adds to the fibrotic response in the tubulointerstitium after UUO.

Methods: Rats underwent right UUO or sham operation for 4, 7 or 14 days. mRNA expression of α8 integrin and its ligands was evaluated by real-time PCR. The localization of α8 integrin and its ligands was determined by immunoflourescence. UUO was also induced in α8 integrin-deficient mice. Blood pressure and renal function was measured and tubulointerstitial (TI) damage was quantified in renal sections.

Results: The α8 integrin chain was induced 10fold after 7 days of UUO and an induction of the ligands FN (4fold), OPN (20fold) and FB1 (70fold) was observed. α8 integrin was localized to some cytokeratin-positive, but also to vimentin-positive dedifferentiating epithelial cells and to TI fibroblasts; and was detected adjacent to FN, OPN and FB1 positive extracellular matrix. Lack of α8 integrin led to more severe TI damage after UUO compared to controls. Blood pressure, albumin excretion and creatinine clearance, however, were not different in α8 integrin-deficient and wildtype mice after 7 days of UUO.

Conclusions: We conclude that the expression of the α8 integrin chain and its ligands is strongly induced in UUO. Moreover, a colocalization of α8 integrin with its ligands in the tubulointerstitium was observed. Mice lacking the α8 integrin chain are more susceptible to TI damage than wildtypes. Thus, interactions of α8 integrin with its ligands seem to be relevant for the development or progression of TI fibrosis in UUO.

FR-PO1874

Role of Heme Oxygenase-1 in Mediating Epithelial-to-Mesenchymal Transition of Peritoneal Mesothelium Jongho Shin,[1] Jinuk Jeong,[1] Kitae Bang,[1] Jo Seong-Min,[1] Chang Nam Kim.[2] *[1]Department of Internal Medicine, Eulji University of Medicine, Daejeon, Korea; [2]Department of Surgery, Eulji University of Medicine, Daejeon, Korea.*

Background: Epithelial-to-mesenchymal transition (EMT) or mesothelial-to-mesenchymal transition of peritoneal mesothelial cells has been regarded as an early mechanism of peritoneal fibrosis. The effects of HO-1 expression on Epithelial-to-mesenchymal transition , which plays a critical role in the development of peritoneal membrane fibrosis, are unknown and its roles in peritoneal fibrosis has not been studied, yet.

Methods: We treated the human peritoneal mesothelial cells(HPMCs) with high glucose solution, HO-1 inducer(hemin, 10μmol/l) and HO-1 antagonist(SnPPIX, 10 μmol/l). To further investigate the pure effect of HO-1 on EMT of mesothelium, Gene transfer of recombinant Adenovirus-harboring human HO-1(Adv-HO-1 Gene) to HPMCs was done.

Results: Exposure of HPMCs to HG solution (30, 60, and 120 mM D-glucose) for 2 to 7 d increased the expression of mesenchymal markers such as α-smooth muscle actin(α-SMA) and vimentin, associated with an decrease in the expression of epithelial markers, E-cadherin. HO-1 protein expression was decreased in the same situation. Treatment of HPMCs with HO-1 inducer, hemin (2.5, 5, 10, and 20 mM) showed a dosage-dependent amelioration of HG induced changes in markers of EMT with increase of expression of HO-1. Treatment of HPMCs with HO-1 antagonist(SnPPIX, 10 μmol/l) simultaneously with HG or after the treatment of HO-1 inducer reversed the effect of HO-1 inducer. Adenovirus-harboring human HO-1 (Adv- HO-1) gene transfer resulted in a significant increase in HO-1 expression and ameliorated HG-induced changes in expression of E-cadherin, α-SMA, vimentin. Consistent with the protein data, HO-1 treatment resulted in an amelioration of HG-induced changes in *mRNA* of those markers.

Conclusions: Taken together, our results suggest that HO-1 has a critical role in the modulation of peritoneal fibrosis, and, more important, the suppression of EMT. Modulation of EMT, a major contributor to peritoneal fibrosis, through the HO-1 pathway may provide a means for novel therapeutic interventions aimed at progressive peritoneal diseases.

FR-PO1875

Altered Podocyte Integrins and Cytoskeleton in *Col4a3*$^{-/-}$ Alport Mice Brooke M. Steenhard,[1] Kathryn S. Isom,[1] Larysa Stroganova,[1] Adrian T. Zelenchuk,[1] Patricia St. John,[1] Billy G. Hudson,[2] Roberto M. Vanacore,[2] Dale R. Abrahamson.[1] *[1]Anatomy and Cell Biology and the Kidney Institute, University of Kansas Medical Center, Kansas City, KS; [2]Medicine, Vanderbilt University Medical Center, Nashville, TN.*

Background: The Alport mouse harbors a deletion of the *Col4a3* gene, resulting in an absence of the α3(IV) α4(IV) α5(IV) collagen heterotrimer in the mature glomerular basement membrane (GBM), recapitulating many aspects of human Alport disease. Glomeruli in *Col4a3* mutants retain the infantile collagen IV network of α1(IV) and α2(IV) chains, progressively deteriorate, and kidneys become massively proteinuric. Here, we studied how glomeruli of Alport mice respond to the incorrect GBM collagen IV network.

Methods: Glomeruli from Alport and wildtype littermates were purified, protein digests from each were fluorescently labeled with spectrally distinct dyes (Cy3 and Cy5), combined, and separated by two dimensional gel electrophoresis (DIGE) (n=3). Differentially expressed peptides ($p<0.05$) were robotically picked for MALDI-TOF mass spectroscopy for protein identification. We also designed PCR primers to assess mRNA changes, and carried out quantitative immunofluorescence microscopy.

Results: Among the most significantly upregulated proteins identified in Alport glomeruli by DIGE, qPCR, and quantitative immunfluorescence were the intermediate filament protein vimentin and the actin-associated protein tropomyosin. Overexpression of both occurred specifically in Alport podocytes. Reasoning that an Alport GBM lacking the α3(IV), α4(IV), α5(IV) collagen IV network affected the podocyte cytoskeleton through

integrins, we quantified integrin mRNA and protein abundance. Significant mRNA increases were seen for integrin α3 and integrin β1. In contrast, glomerular immunofluorescence signals for both integrin α1 and integrin α3 were significantly upregulated in Alport podocytes whereas integrin α2 and integrin β1 were unchanged.

Conclusions: We conclude that the Alport GBM alters the normal expression and distribution pattern of podocyte integrins, which in turn may lead to cytoskeletal reorganization and other signaling events important for pathogenesis of the disease.

Funding: NIDDK Support

FR-PO1876

Prevention of Cyclosporin A-Induced Fibronectin Synthesis by Simvastatin in Rat Mesangial Cells Chong Myung Kang, Joon-Sung Park, Chang Hwa Lee, Gheun-Ho Kim. *Internal Medicine, Hanyang University Hospital, Seoul, Korea.*

Background: Cyclosporin A(CsA) is an effective immunosuppressant for prevention of rejection after kidney transplantation. CsA has nephrotoxicity leading to chronic allograft nephropathy and renal fibrosis. Simvastatin improves hypercholesterolemia after renal transplantation and preserves structures and functions of glomeruli. But, it is not well known how simvastatin acts on CsA induced fibronectin synthesis. We studied to investigate the effect of simvastatin(simva) on Smad pathway, which is the key pathway of CsA induced fibronectin synthesis in rat mesangial cells(RMCs).

Methods: Transforming growth factor-β1 (TGF-β1) was induced by CsA cultured RMCs. Optimal concentration and time of CsA were measured according to its concentration (0.1 ~ 10 μM) and TGF-β1 expression time (1~72 h) measured by ELISA. All RMCs were divided into six experimental goups: control, CsA (1 μM) alone, simva (1 μM) alone, simva 0.1 μM pretreatment plus CsA 1 μM, simva 1 μM pretreatment plus CsA 1 μM, and simva 10 μM pretreatment plus CsA 1 μM. The level of cytokines such as phosphorylated Smad3 (phospho-Smad3), Smad7 and fibronectin proteins were measured by semiquantitative immunoblotting.

Results: TGF-β1 expression was maximally increased at 1 μM dose of CsA, 24h after CsA treatment. After treatment with CsA alone, the level of TGF-β1 expression significantly increased (3.995 ± 1.272-fold, p=0.0035). Phospho-Smad3 expression and fibronectin production significantly increased after CsA treatment (2.900 ± 0.053-fold, p=0.006, 1.812 ± 0.223-fold, p=0.0085). When all the groups treated with CsA and simva were compared with those treated with CsA alone, phospho-Smad3 expression (p = 0.0010, 0.0001, 0.0003) and fibronectin production (p = 0.0064, 0.0005, 0.0002) significantly decreased. But, in simva 10 μM pretreatment CsA 1 μM group, the level of Smad7 expression was significantly increased compared with control (p=0.0316).

Conclusions: This study demonstrates that simvastatin may ameliorate CsA-induced fibronectin synthesis by modulating the TGF-β1/Smad pathway in RMCs. These results suggest that simvastatin may inhibit the development of nephrosclerosis and subsequent chronic CsA nephropathy.

FR-PO1877

Parathyroid Hormone Induces Endothelial-to-Mesenchymal Transition in Human Aortic Endothelial Cells Min Wu, Rining Tang, Linli Lv, Kun Ling Ma, Bi-Cheng Liu. *Institute of Nephrology, Zhongda Hospital, Southeast University Medical School, Nanjing, Jiangsu Province, China.*

Background: Cardiovascular disease (CVD) is the leading cause of death among patients with end-stage renal disease (ESRD). Recent studies have suggested that highly secreted parathyroid hormone (PTH) might be involved in the development of uremic vascular impairment. However, the underline mechanism has not been well understood. Our previous study have showed that endothelial-mesenchymal transition (EndMT) involves in the cardiac fibrosis. In this study, we addressed the question of whether PTH as an inducer of EndMT, and subsequently contributes to the vascular sclerosis in ESRD.

Methods: Primary human aortic endothelial cells (HAECs) between passage 3 to 5 were stimulated with 10^{-11} to 10^{-7} mol/L PTH. Pathological changes were examined by confocal microscopy for co-expression of endothelium marker (CD31) and fibroblast markers (FSP1 and α-SMA). The mRNA and protein expressions of CD31, FSP1 and α-SMA were detected by real-time PCR and western blot. Cellular ultrastructure was observed with electron microscopy.

Results: CD31 has been found to be expressed in HAECs and its mRNA and protein levels were inhibited by increasing concentrations of PTH (P<0.05). Besides, the expression of FSP1 and α-SMA upon the treatment with PTH were significantly increased in dose-dependent manners compared with control (P<0.05). Double staining indicated that a co-expression of CD31 and FSP1 when HAECs were exposed to PTH, and some cells acquired spindle-shaped morphologies accompanying with a loss of CD31 staining. Ultrastrctural investigation showed HAECs incubated with PTH (10^{-7} mol/L) have an increasing roughed endoplasmic reticulum.

Conclusions: We firstly demonstrated that PTH could stimulate HAECs developing phenotypic changes as EndMT, which may provide a novel insight that secondary hyperparathyroidism being involved in the vascular sclerosis in CKD.

FR-PO1878

Serum Galectin-3 and Leucocyte-Endothelial Adherence Are Increased in a Murine Model of Chronic Uremia Andrew Duncan Stewart Findlay, Julius Edward Kieswich, Magdi Yaqoob. *William Harvey Research Institute, Barts and the London, Queen Mary's School of Medicine and Dentistry, London, United Kingdom.*

Background: Galectin -3 is a galactoside binding protein with diverse roles including leucocyte adhesion with unknown roles in chronic uremia. Intravital microscopy visualises leucocyte-endothelial interactions in post-capillary venules *in vivo*.

We measured serum Galectin-3 levels in an adenine diet model of chronic uremia. We then established the feasibility of intravital microscopy in this model and described endothelial-leucocyte interactions.

Methods: Male c57bl6 wild-type mice were fed 0.25% adenine diet for 4 weeks after which intravital microscopy was performed.

The cremaster muscle was isolated and placed over a plexi-glass stage perfused with bicarbonate buffered saline. The muscle was placed under a microscope and transilluminated. After a 30 min stablisation period leucocyte rolling velocity, flux, adhesion and transmigration was recorded in 3-5 vessels per mouse for off-line analysis.

Serum Galectin-3 was subsequently measured by ELISA in sham and adenine diet uremic mice

Results: Serum Galectin-3 was significantly raised in uremic mice compared to sham mice (60.35ng/ml vs 34.23ng/ml, p=0.0303)

The uremic mice had significantly more leucocyte adherence to endothelium but equivalent levels of leucocyte flux, rolling velocity and transmigration.

Leucocyte Interactions with Endothelium Uremic (Adenine diet) vs Sham

	Adenine Diet (n=5)	Sham Diet (n=6)	p-value
Urea mmol/l	37.4	9.8	
Leucocyte Flux (per min)	12.4	13.2	p=0.9269
Leucocyte Velocity (μm/s)	42.3	65.6	p=0.4205
Leucocyte Adherence (per100μm)	9.7	4	p=0.0043
Leucocyte Transmigration(per 100x50μm ²)	1.2	0.6	p=0.0814

Values shown Mean

Conclusions: Serum Galectin -3 is raised in the adenine diet chronic uremic mouse model. The same model also demonstrated significantly more adherent leucocytes to endothelium. This could represent a mechanism of inflammatory uremic microvascular dysfunction. We intend to persue the significance of Galectin-3 on leucocyte-endothelial interactions in uremia with Galectin-3 knockout mice.

Our results demonstrate intravital microscopy is a feasible technique to gain novel insights into uremic microvascular dysfunction.

FR-PO1879

Continuous Rituximab Therapy for Antineutrophil Cytoplasmic Antibody-Associated Vasculitis John Niles, Karen A. Laliberte. *Renal, Massachusetts General Hospital, Boston, MA.*

Background: We identified 68 patients with AAV who were initiated on continuous B-cell depletion treatment with rituximab prior to 5/6/2009.

Patients: The average age was 56.5. 39 patients had PR3 and 33 patients had MPO. Patients were followed for a total of over 2448 patient months.

Treatment: Most patients received 2 or 4 doses of rituximab to start and then one dose every 4 months. Other medications were initially continued, but then tapered slowly with the goal of coming off all other immunosuppression.

Results: All patients entered complete remission except for the patient with acute airway obstruction. Medications were slowly weaned off in most patients. 6 patients had major relapses (BVAS-WG >/= 3). All were in the setting of weaning of their other medications. All were with positive ANCA titers. In only one, did the ANCA titer rise significantly with the flare. 5 patients developed late onset neutropenia. One developed bacteremia. IgG levels gradually fell in most patients, ultimately leading to discontinuation of therapy in 2 patients. 4 patients died. One patient died of disease related sudden airway obstruction (36 yo). One died of lung ca (71 yo), and one of aortic stenosis (90 yo). An additional patient died of acute disease related lung injury (90 yo), 21 months after stopping all therapy.

Conclusion: Continuous rituximab therapy was associated with a high rate of remission, ongoing disease control and facilitated the withdrawal/weaning of other immunosuppressive medications and was associated with a low rate of relapses and complications. Routine monitoring for late onset neutropenia, on maintenance rituximab dosing, should become a standard of care. More data is needed about the delayed adverse effects of rituximab.

We declare no potential conflicts of interest.

FR-PO1880

Soluble fms-Like Tyrosine Kinase 1 (sFLT) Correlates with Proteinuria in ANCA-Associated Vasculitis and Declines during Immunosuppressive Treatment Svjetlana Lovric,[1] Torsten Kirsch,[1] Anna Bertram,[1] Hermann G. Haller,[1] Marion Haubitz.[2] *[1]Nephrology and Hypertension, Medical School Hannover, Hannover, Germany; [2]Division of Nephrology, Klinkum Fulda, Fulda, Germany.*

Background: Fms-like tyrosine kinase-1 (FLT1) is one of major receptors for the vascular endothelial growth factor (VEGF). Its soluble form (sFLT1) may act as decoy receptor for VEGF in the circulation thereby reducing VEGF bioavailability. Hence, increased levels of sFLT1 may cause inactivation of VEGF and therefore leads to endothelial dysfunction.

Elevated serum levels of sFLT1 have been found in sepsis and preeclampsia and correlated with disease severity. In ANCA-associated vasculitis higher VEGF levels have been reported in patients with major disease activity compared to those with minor activity. The present study was therefore intended to determine the role of sFLT1 serum level in ANCA-associated vasculitis.

Methods: Plasma sFLT1 levels were measured with a commercially available ELISA in patients with ANCA-associated vasculitis at initial diagnosis and after 1, 3, 6 and 12 months (n=38). Disease activity was assessed in accordance with the Birmingham Vasculitis Activity Score (BVAS). Proteinuria, BVAS, C-reactive protein, creatinine and ANCA titres were recorded at baseline and during follow-up.

Results: In patients with active ANCA- associated vasculitis median levels of sFLT1 are elevated (108 (96.5- 165.5) pg/mL, $p < 0.05$) compared to healthy controls (86 (71.88-100.5) pg/mL). sFLT1 correlates with proteinuria ($r=0.5$, $p <0.01$), disease activity (BVAS) ($r= 0.6$, $p<0.05$) and CRP levels levels ($r=0.6$, $p< 0.05$) in active vasculitis patients. Compared to those without activity median level of sFLT1 were increased ($p<0.05$) and declined during follow-up.

Conclusions: sFLT1 serum level correlate with proteinuria in severe ANCA-associated vasculitis. sFLT1 is elevated before treatment and declines during immunosuppressive therapy. We therefore conclude that sFLT1 may act as a robust marker for disease activity.

FR-PO1881

Long-Term Observation of Clinicopathological Characteristics and Outcome of Japanese Patients with Pauci-Immune Crescentic Glomerulonephritis Kiyoki Kitagawa,[#1] Yasuyuki Shinozaki,[#2] Tadashi Toyama,[#2] Shinji Kitajima,[#2] Akinori Hara,[#2] Kengo Furuichi,[#1] Shuichi Kaneko,[#2] Takashi Wada.[#3] *[1]Division of Blood Purification, Kanazawa University Hospital, Kanazawa, Japan; [2]Department of Disease Control and Homeostasis, Kanazawa University, Kanazawa, Japan; [3]Department of Laboratory Medicine, Kanazawa University, Kanazawa, Japan.*

Background: Clinicopathological characteristics and outcome of Japanese patients with pauci-immune crescentic glomerulonephriris (CreGN) are presumed to vary among periods. We examined characteristics and outcome of patients with CreGN according to the periods.

Methods: From 1968 to 2010, a total of 100 patients who were diagnosed as CreGN by renal biopsy in Kanazawa University Hospital and Kanazawa collaborative group was examined in this study. All cases were divided into group I (1968-1988, 18 cases, mean age 52.9±3.7, female 6, male 12), group II (1989-2001, 37 cases, mean age 66.4±2.5, female 21, male 16) and group III (2002-2010, 45 cases, mean age 67.5±1.5, female 24, male 21).

Results: Mean follow-up period was 1367±130 days. Neither blood pressure, the degree of hematuria, renal function nor titer of ANCA had statistical difference among three groups. On the other hand, the degree of proteinuria was reduced in group II and III compared with group I. The rate of total and fibrous crescentic formation was significantly lower in group III (total crescent : group I 82.9±3.8%, group II 60.6±4.7%, Group III 48.9±4.3%, fibrocellular and fibrous crescent : group I 46.9±4.0%, group II 34.8±3.5%, group III 22.8±3.7%, $p<0.05$). Furthermore, 1- and 5-year renal and patient survival rate improved significantly in group III compared with group I and II (One-year renal survival rate: group I 50%, group II 75%, group III 89%. 5-year renal survival rate: group I 22%, group II 56%, group III 75%. One-year patient survival rate: group I 67%, group II 81%, group III 95%. 5-year patient survival rate: group I 33%, group II 65%, group III 76%).

Conclusions: In conclusion, the patients with CreGN were diagnosed at early phase of crescentic formation and outcome was improved in recent years.

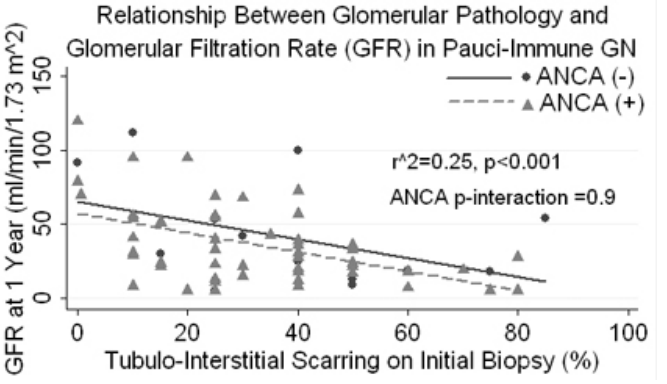
FR-PO1882

ANCA Negative Pauci-Immune Glomerulonephritis in a U.S. Cohort John Havill, Michael Kuperman, Abigail Thompson, Duvuru Geetha, Stephen M. Sozio. *Johns Hopkins Medical Institutions, Baltimore, MD.*

Background: ANCA antibodies are thought to play an important role in the pathogenesis of ANCA associated vasculitis. The lack of ANCA antibodies may indicate a variation in clinical presentation and outcomes of this disease.

Methods: We identified 78 patients from the Johns Hopkins Renal Pathology database between 1995 and 2008 with the diagnosis of pauci-immune glomerulonephritis (GN). Comparing ANCA negative and positive patients, we examined demographics, histological features at presentation, and subsequent treatment and correlated this with renal function at presentation and follow-up. Renal histology was reviewed by a pathologist blinded to clinical data.

Results: 60 patients had positive ANCA serology, and 18 were ANCA negative. At presentation, overall mean age was 54 years, 49% male, 77% Caucasian, and mean Birmingham Vasculitis Score of 8; these were similar between ANCA negative and positive patients. Overall mean eGFR at presentation was 32.5 ml/min/1.73 m^2 with 37% requiring acute hemodialysis; there was a trend toward more renal severity in the ANCA negative group which did not reach statistical significance ($p=0.07$ and 0.2 respectively). Long-term renal function was similar between ANCA negative and positive patients, with mean overall eGFR at one year 39.8 ml/min/1.73 m^2, $p=0.7$. Tubulo-interstitial scarring was a good negative predictor of eGFR at 1 year in both groups (Figure). There were similar relationships between predictors of eGFR at 1 year between ANCA negative and positive patients.



Conclusions: Ours is the first USA based study to compare patients with ANCA negative and positive serology, and we showed these two groups had similar demographics, presentation, and outcomes in our 13 year experience. Percentage of tubulo-interstitial scarring was a strong negative, graded predictor of renal outcomes at 1 year for both groups.

FR-PO1883

Persistent or New Onset Microscopic Hematuria in Vasculitis Patients in Remission: Findings on Renal Biopsy Duvuru Geetha, John Havill, Michael Kuperman. *Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Hematuria is considered a sign of active disease in patients with small vessel vasculitis requiring aggressive immunosuppressive therapy. In patients who are in apparent clinical remission, the presence of persistent or new onset microscopic hematuria after completion of induction therapy and years after completion of induction and maintenance therapy may be due to active renal vasculitis, chronic and healed vasculitis or other glomerular pathology

Methods: We identified 78 patients from the Johns Hopkins Renal Pathology database between 1995 and 2008 with the diagnosis of pauci-immune glomerulonephritis (GN). Among these 78 patients, we indentified patients who were in apparent clinical remission and underwent a renal biopsy for evaluation of persistent or new onset microscopic hematuria. Renal histology was reviewed by a pathologist blinded to clinical data.

Results: 8 patients with small vessel vasculitis, 7 ANCA positive and 1 ANCA negative underwent a renal biopsy at variable time periods after remission of vasculitis (6 months to 14 years) for persistent microscopic hematuria (n=5) or new onset microscopic hematuria (n=3). All patients were in apparent clinical remission at the time of renal biopsy. Of the three patients presenting with new onset hematuria, two patients had crescentic IgA nephropathy and one patient had healed crescentic pauci-immune glomerulonephritis with fibrous crescents. Of the five patients with persistent hematuria, two patients had arteriosclerosis with no evidence of active vasculitis, two had focal segmental glomerulosclerosis and no signs of active vasculitis and one had global and segmental glomerulosclerosis.

Conclusions: Microscopic hematuria in patients with renal vasculitis otherwise in remission could represent chronic glomerular injury from prior episode of vasculitis or may represent new glomerular pathology. We conclude that patients with small vessel vasculitis who are in apparent clinical remission presenting with persistent or new onset microscopic hematuria should undergo renal biopsy prior to escalation of immunosuppressive therapy.

FR-PO1884

Long-Term Outcome of Severe Alveolar Haemorrhage in Small Vessel Vasculitis: A Retrospective Cohort Study Alina L. Casian,[2] Zdenka Hruskova,[1] Pavel Konopásek,[1] Vladimir Tesar,[1] David R.W. Jayne.[2] *[1]Dpt of Nephrology, First Faculty of Medicine, Charles University, Prague, Czech Republic; [2]Vasculitis and Lupus Clinic, Addenbrooke's Hospital, Cambridge, United Kingdom.*

Background: Alveolar haemorrhage (AH) is an important manifestation of small vessel vasculitis (SVV) and the most common vasculitic cause of early death. We describe the characteristics and long-term outcome of severe AH due to SVV from two European centres.

Methods: A retrospective analysis of hospital notes on 867 patients with SVV presenting between 1990 and 2011. AH was defined as the presence of bilateral alveolar infiltrates on radiological imaging without an alternative explanation plus at least one of

the following: haemoptysis, increased CO diffusing capacity, bronchoscopic evidence of haemorrhage, or an unexplained drop in haemoglobin >2g/dL. AH was considered severe if either hypoxia or the need for blood transfusions were recorded.

Results: 59 patients (M/F 36/23; median age 58 [18-81] years) were identified. Most (89.8%) were diagnosed with ANCA-associated vasculitis, six with anti-GBM disease. PR3-ANCA was positive in 38 (64.4%), MPO-ANCA in 15 (25.4%, p<0.05 for MPO vs PR3-ANCA), and anti-GBM in 9 patients (3 were also ANCA-positive). AH was the first disease manifestation in 54/59 (91.5%). Invasive assisted ventilation was required in 24 patients (40.7%). Renal involvement was present in 57 (96.6%), 33 (55.9%) required dialysis. Forty-six (78.0%) were treated with plasma exchange (PE). At 6 months, 50/59 (84.7%) were alive, six died of active refractory vasculitis and 3 of infection. The mean follow-up was 50 months when 37 (62.7%) were alive. Mortality was higher in those requiring dialysis at entry (48.5 vs. 23.1%, p<0.05). No significant difference in mortality was found between PE and no-PE (39.1 vs. 30.8%, p=0.3).

Conclusions: Severe AH was more commonly associated with PR3- than MPO-ANCA or anti-GBM and strongly correlated with renal vasculitis. Current treatment of severe AH with combined immunosuppression (with or without PE) helps to overcome the acute period in most patients but long-term mortality remains high. Concurrent renal failure was associated with worse outcome. *Supported by ERA-EDTA Fellowship.*

FR-PO1885

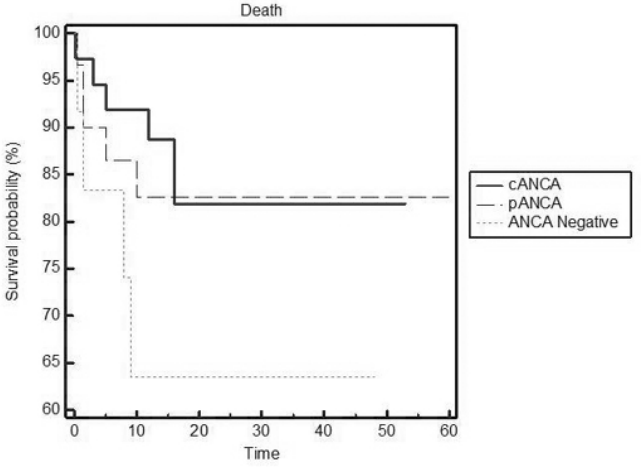
Outcomes of Renal Vasculitis in Preston, UK: 2005-2010 Cheralathan Arunachalam, Olumide Ogundare, Harish B. Shetty. *Department of Renal Medicine, Royal Preston Hospital, Lancashire Teaching Hospitals, Preston, United Kingdom.*

Background: We report outcomes of renal vasculitis in a group of patients treated with standard induction therapy containing pulse cyclophosphamide plus prednisolone followed by Azathioprine and prednisolone for maintenance treatment

Methods: All new patients diagnosed with renal vasculitis at our centre from 2005 until 2010 were evaluated from presentation until last visit or death

Results: 79 patients received standard treatment. Median age was 63 ± 14 years. 36 (45%) patients were PR3- ANCA positive, 31(40%) MPO-ANCA positive and 12 (15%) were ANCA negative. Presenting Creatinine(Cr) was 448±392 mmol/l and mean follow up period was 26 ±13 months. All patients started on pulse intravenous (i.v) cyclophosphamide dose as per the Cyclops protocol. 30% patients received oral pulses later during induction while the rest continued with iv pulse. Patients with presenting serum Cr >500 and or pulmonary haemorrhage received seven plasma exchanges in addition. 15% patients had pulmonary haemorrhage and 39% received plasma exchange.

28 (35%) patients needed renal replacement therapy (RRT) at diagnosis. Of these 28 patients, 10 died, 12 recovered renal function and 6 patients were RRT dependent. Overall 8 (10%) patients reached end stage renal disease (ESRD) and 15 (19%) died. At 2 years, 85% of survivors were dialysis independent. In the ANCA positive group, 1 year and 5 year survival rates were 88% and 82% respectively.



PR3 or MPO ANCA did not influence the major outcomes. ANCA negative patients had a higher mortality rate at 25%. 12% patients developed life threatening infections. We noted a low relapse rate at 13 % and less cumulative cyclophosphamide dose, 5414±2642gm.

Conclusions: In renal vasculitis with less cumulative dose of cyclophosphamide we report survival rates comparable to other treatment regimes and a low relapse rate.

FR-PO1886

Increased Incidence of Venous Thromboembolism in ANCA Associated Vasculitis Sehrash Noor, Issaam Oozeerally, Olumide Ogundare, Ajay Prabhakar Dhaygude. *Renal Medicine, Royal Preston Hospital, Preston, United Kingdom.*

Background: ANCA associated systemic vasculitis (AASV) is a heterogeneous chronic inflammatory relapsing autoimmune disease. Dutch and American studies have suggested that there is an increased incidence (1.8 to 7 per 100 person-years) of venous thromboembolism (VTE) in AASV. Recently it has been shown that there is an increased prevelance of anti-plasminogen antibodies and also anti tissue plasminogen activator antibodies in AASV patients and these antibodies were associated with increased severity of renal involvement .In this retrospective study we analysed incidence of VTE in 165 British patients with AASV and compared it with incidence of VTE in the general population.

Methods: Retrospective analysis of case records of 165 patients with AASV was performed to identify patients with evidence of VTE (deep vein thrombosis and/ or pulmonary embolism).

Results: One hundred sixty-five patients were followed for 3.35 person-years. Seventeen patients experienced 19 events of VTE; three of these events predated the diagnosis of AASV by at least 12 months and were consequently excluded. The overall incidence of VTE in AASV was 2.9 events per 100 person years. Nine patients had active vasculitis and one patient was in partial remission at the time of diagnosis of VTE. VTE occurred between 0 months to 95 months from the diagnosis or relapse of AASV but 10 out of 16 VTE occurred within 6 months of active disease. Age at the time of diagnosis of vasculitis was slightly higher (65.8 years) in patients with VTE; compared with non VTE patients (59.9years). Nine patients with VTE were PR-3 positive.

Conclusions: This study has confirmed previous published findings of increased incidence of VTE in AASV in British population. In general population incidence of VTE is 0.05 per 100 person years but the risk increases with age to 0.2 per 100 person years for age group of 70-79 years. Increased incidence is likely to be multifactorial, related to inflammation, endothelial dysfunction, pro-coagulant state, presence of anti plasminogen antibodies in AASV and chemotherapy. This study has strengthened the association between AASV and VTE and may help the clinicians treating AASV.

FR-PO1887

Serum Polyclonal Free Light Chain Levels in Patients with Vasculitis Lakhvir Assi,[1] Andrew McClean,[2] Gemma Webb,[1] Lorraine Harper,[2] Colin A. Hutchison.[2] *[1]The Binding Site Group Ltd, United Kingdom; [2]Renal Institute of Birmingham, United Kingdom.*

Background: Serum concentrations of polyclonal free light chains (FLCs) have been shown to be elevated in autoimmune conditions (Sjogrens syndrome and systemic lupus erythematosus). In these diseases, FLCs correlated with disease activity and clinical outcomes. The purpose of this study was to evaluate FLCs in patients with vasculitis and to determine if their levels correlated with established markers of disease activity.

Methods: 42 patients were assessed; their average age was 55years and median GFR was 36ml/min/1.73m2. 38% were female and 90% were white. The following laboratory assessments were made at presentation: FLCs (Freelite™ assay, normal range: κ: 3.3-19.4mg/L, λ: 5.71-26.3mg/L), high sensitivity CRP (hsCRP), cystatin C (cys C) and immunoglobulins (Igs). One month follow up (FU) samples were also analysed (N=38). Patients predominately received induction therapy consisting of steroids and cyclophosphamide.

Results: Total FLCs (TFLCs) were elevated in the cohort (median: 39.2mg/L, range 3.75-343.5mg/L).

Disease	N=42	TFLCS (mg/L) median	TFLCs/cys C median
Wegeners granulomatosus	23	36.9	18.8
Churg strauss	2	49.4	39.3
ANCA associated vasculitis	2	72.6	25.4
ANCA -ve vasculitis	2	33.7	20.1
Microscopic polyangitis	10	71.9	32.4
Other	3	51.9	41.9

To determine rates of FLC production, TFLCs were corrected for renal function using cys C (TFLCs/cys C median: 19.7mg/L, range: 4.6-94.6mg/L). There was a weak association between TFLCs and total Igs (GAM): Spearman r=0.32, p=0.04; significance increased when TFLCs/cys C were correlated with Igs (r=0.72, p<0.001). TFLCs also correlated with CRP (r=0.47, p=0.002) although there was no association with autoantibodies (MPO/PR3) (r=0.09, p=0.59). TFLCs increased with decreasing GFR (p<0.03) and increasing age (p=0.01). TFLCs were higher at baseline: 39.21mg/L vs 26.3mg/ml (p=0.007). When analysing patient outcome, there was no difference between TFLCs in patients admitted to hospital over 12 months (p=0.39), nor was there a difference in patients who had suffered an infection (p=0.88).

Conclusions: Further FU samples will be analysed to further elucidate the role of TFLCs in vasculitis.

Funding: Pharmaceutical Company Support

FR-PO1888

Clinical Outcomes of Japanese Myeloperoxidase (MPO) Anti-Neutrophil Cytoplasmic Antibody (ANCA) Related Nephritis: Significance of Initial Renal Death for Survival Kimio Watanabe, Yoshihiro Tani, Kenichi Tanaka, Yoshimitsu Hayashi, Koichi Asahi, Masaaki Nakayama, Tsuyoshi Watanabe. *Nephrology and Hypertension, Fukushima Medical University School of Medicine, Fukushima, Japan.*

Background: MPO-ANCA related vasculitis constitutes 60% of the rapidly progressive glomerulonephritis that occurs among Japanese. The reported 1-year survival rate of such patients is >80%, but the long-term prognosis remains unknown. Therefore, we investigated the prognosis and the clinical factors affecting the survival of patients with MPO-ANCA related nephritis.

Methods: We retrospectively investigated 44 patients (female, n = 26; mean age, 70.2 ±11.4 y) who were diagnosed with MPO-ANCA related nephritis between 2000 and 2010 at our hospital.

Results: The serum creatinine value was 3.7 ± 2.6 mg/dL, the MPO-ANCA titer was 568 ± 731 EU and the Birmingham Vasculitis Activity Score (BVAS) was 17.1 ± 4.4. At the initial therapy, 38 (86.4%) patients achieved remission (non-renal death group: NRD), whereas the remaining 6 (13.6%) did not and required permanent dialysis therapy (renal death group: RD). After 8 weeks of initial prednisolone therapy, six patients relapsed and four developed kidney failure progression in the NRD group, whereas two patients relapsed in the RD group. Eleven (25.0%; NRD, n = 5; RD, n = 6) patients died during a mean observation period of 36.6 ± 33.7 months due to infection (n = 4), recurrent vasculitis (n = 4), cancer (n = 1) and other causes. The 1-and 2-year survival rates were 100.0% and 96.3%, respectively, in the NRD group and 33.3% and 0.0%, respectively, in the RD group. Multiple logistic analysis revealed that renal death at the initial phase was the only significant risk factor for all-cause death (OR, 29.0; 2.4 - 351.8), BVAS at the initial visit for the relapse (OR, 1.52; 1.09 - 2.14) and BVAS at week 4 for death (OR, 2.33; 1.02 - 5.37).

Conclusions: Renal death at the initial phase was a powerful risk factor for all-cause death in patients with MPO-ANCA related nephritis. Patients at high risk of recurrence and death could be stratified according to BVAS during initial therapy.

FR-PO1889

Outcomes of Two Different Cyclophosphamide Regimes for Treatment of ANCA Associated Vasculitis Issaam Oozeerally,[1] Ajay Prabhakar Dhaygude,[1] Edmond O'Riordan.[2] *[1]Renal Medicine, Royal Preston Hospital, Preston, United Kingdom; [2]Renal Medicine, Salford Royal Hospital, Salford, United Kingdom.*

Background: Cyclophosphamide (Cyp) treatment has transformed ANCA associated systemic vasculitis (AASV) from a potentially fatal condition to a chronic remitting, relapsing disease though it is associated with significant mortality and morbidity. Recently published meta-analysis of outcome of 535 AASV patients from four different clinical trials suggested that 48% of the mortality was due to infections in the first year and 19% mortality due to active vasculitis. RAVE and RITUXIVAS trials showed that Cyp. therapy is as effective as Rituximab therapy in majority of the patients. Pulsed arm of CYCLOPS trial protocol recommends 10 pulses of cyp given over 6 months, initially at 2 weekly and subsequently 3weekly intervals. Lupus nephritis regimes consists of 6 pulses given at monthly intervals. In North-west of England, clinicians have used these two regimes for the treatment of AASV and in this retrospective study we analysed the outcomes of these two different regimes.

Methods: Data was collected for 103 AASV patients treated with pulse cyp, regarding cumulative cyp dose, rate of major infections, rate of relapses and renal outcomes. All the patients had at least 2 years follow up.

Results: Seventy-nine patients were treated with CYCLOPS protocol and 24 patients were treated with monthly (lupus nephritis) protocol. Cumulative cyp dose was high in CYCLOPS regime (7.14 grams) compared to monthly regime (4.63 grams). Outcomes are presented in Table-1

Table-1:Outcomes of the two different regimes

Outcomes	**Monthly Cyp 24 patients**	**CYCLOPS Cyp 79 patients**	**p Value**
Infections	7 (29.3%)	29 (36.7)	0.3
Relapses	4 (16.7%)	28 (35.4%)	0.04
Reduction in Creatinine	21.4%	46.5%	0.0001

Conclusions: These results suggests that- CYCLOPS regimes is associated with-

1] Higher cumulative dose

2] Significant improvement in renal function

3] Increased rate of infections though statistically not significant.

Limitations:

1]Retrospective study.

2] Small sample size for monthly regime patients which may explain the lower rate of relapse in this group in spite of low cumulative dose of Cyp.

FR-PO1890

Outcome of Anti GBM Disease: A Single Center Review Arvind Ponnusamy, Edmond O'Riordan. *Renal, Salford Royal NHS Trust Foundation, United Kingdom.*

Background: The incidence of anti-GBM disease is reported to be 0.5 per million per annum. It is associated with significant morbidity and mortality.

Methods: We retrospectively reviewed the case notes of all the patients(n= 19) who were diagnosed with anti-GBM disease over a period of 10 years (1999 – 2009). Creatinine and presence of 100% crescents at presentation were co-related to outcome (End stage Renal Disease and Death)

Results: The average age at diagnosis was 61 with bimodal peaks at decade 30-40 and those over 60 years of age. Male to female ratio was 10:9.18 out of the 19 had a serum creatinine above 500 umol/l (5.6 mg/dl). 7 (36.84%) of them were dialysis dependent at presentation. Only 2 had clinical and radiological evidence of pulmonary haemorrhage. 4 (22.2%) patients were 'double positive' for pANCA (MPO) & anti GBM. Renal biopsy was performed in 14 patients (73.7%) 7 of those had crescentic glomerulonephritis in 100% of glomeruli seen. At 6 months 15 patients (78.9%) were dialysis dependent, 4 patients were dialysis independent with a mean creatinine of 265umol/l (3 mg/dl)+[/underline]117 (1.3). At last follow up mortality was 52.63%. Causes for death include pulmonary haemorrhage, sepsis, and cardiac related. The mortality figures were better for patients who were double positive for anti GBM and pANCA compared to patients who had positive anti GBM and negative ANCA (25% vs 60%)

Outcome according to serum creatinine and crescents at presentation:

Serum creatinine at presentation	Number of patients	Renal survival at 6 months (%)	Patient survival at last follow up
<500 umol/l (5.6mg/dl)	1	1 (100)	1 (100)
>500 umol/l (5.6mg/dl)	18	3 (16.67)	8 (44.44)

Renal biopsy	Number of patients	Renal survival at 6 months (%)	Patient survival at last follow up (%)
less than 100%	7	2 (28.57)	4 (57.14)
Cresentic GN (100%)	7	0 (0)	4 (57.14)

Conclusions: Our data confirms previous studies in which creatinine more than 500umol/l and presence of 100% crescent were associated high mortality and poor renal survival. Patients with double-positive (ANCA and anti GBM) appear to have better patient survival rate although the renal survival appear to be same in both between the double positive group and anti GBM group. Only 16% of our patients with creatinine >500 had renal survival at 6 months underlining the potential risk-benefit balance of aggressive therapy in this group

FR-PO1891

Anti-Glomerular Basement Membrane Disease; a Review of the Experience in an Irish Centre over 21 Years Yvonne C. Ryan,[1] Thomas J. McEnery,[1] Mary T. Keogan,[1] Peter J. Conlon,[1] Anthony M. Dorman,[1] Mark Donald Denton.[1] *[1]Nephrology, Beaumont Hospital, Dublin, Ireland; [2]Histopathology, Beaumont Hospital, Dublin, Ireland.*

Background: We present a series of 64 patients with anti-GBM disease managed at Beaumont Hospital in Dublin, Ireland.

Methods: The biopsy records from January 1st 1990 to April 1st 2011 were reviewed and patients with biopsy proven anti-GBM disease identified. Patients with anti-GBM who did not get a renal biopsy were identified using a database of immunology sera. We conducted a chart review to ascertain demographic data, presenting features, anti-GBM titre, treatment, renal replacement therapy and outcome. Statistical package used was Stata (version 10, College Station, Texas).

Results: 56% of patients were female. The mean age of males and females was 46 and 54 years respectively. 17% had concurrently positive ANCA at presentation. 22% had lung involvement. The mean anti-GBM titre was 265 iu/ml, ref <10iu/ml (range 0-1000) and 26% patients were anuric at presentation. 62/64 patients had a renal biopsy. Mean crescents on biopsy 80% (SD 27), mean percentage fibrosis was 52% (SD 30). Three patients (4.7%) died during the initial admission.

Patient survival was 78%, 67%, 60% and 46% at 1, 5, 10 and 15 years respectively. Age at presentation HR 1.09 (CI 1.04-1.44) and log serum creatinine at presentation HR 5.59 (CI 1.81-17.25) were significantly associated with survival. The renal survival was 26%, 21%, 16% and 16% at 1, 5, 10 and 15 years respectively. Four patients had recurrence within 1 year of presentation (2 lung involvement, 2 renal involvement). One patient had a renal recurrence 9 years after initial presentation. Thirty two percent of patients had at least one renal allograft during the study period. None had recurrent disease post-transplant. Two patients had anti-GBM disease on biopsy for work up of microscopic haematuria with normal creatinine and no lung disease. Neither progressed.

Conclusions: This is a large series of anti-GBM disease with long term follow up. This series emphasises the devastating consequences of anti-GBM disease on patient and renal survival. We also describe an indolent form of anti-GBM disease which is not well understood.

FR-PO1892

Laser Capture Microdissection (LCM) Followed by Tissue Proteomics Identifies Differences in Protein Expression in Biopsies from Class IV and V Lupus Nephritis (LN) Brad H. Rovin,[1] Samir Parikh,[1] Michael A. Freitas,[3] Anjali A. Satoskar,[2] John P. Shapiro,[3] Tibor Nadasdy,[2] Lee A. Hebert.[1] *[1]Internal Medicine, Ohio State University; [2]Pathology, Ohio State University; [3]Molecular Virology, Immunology and Medical Genetics, Ohio State University.*

Background: We postulated LCM of kidney biopsies followed by proteomics of the captured tissues can identify disease-specific protein expression that will inform diagnostic biomarker development and provide a better understanding of disease pathogenesis.

Methods: To test this hypothesis, LCM was used to isolate glomeruli or tubulointerstitium from baseline transplant biopsies (control, n=3), Class IV (n=3) and V (n=2) LN biopsies. Tissue was digested, mass analyzed with an LTQ Orbitrap XL mass spectrometer, and proteins identified using MassMatrix. For each protein, peptide spectral counts reflect abundance. Differences in spectral counts were compared by the G-test to determine significant differences in abundance (G-score >5).

Results: Class IV and V LN glomeruli showed 91 and 26 differentially-expressed proteins respectively, compared to control, while Class IV and V LN interstitium showed 164 and 144 differentially-expressed proteins. Direct comparison of Class IV and V glomeruli showed 38 differentially-expressed proteins, while direct comparison of Class IV and V interstitium showed 56 differentially-expressed proteins. Glomerular and interstitial proteins mainly restricted to either Class IV or V LN are shown in the Table, with average spectral counts and G-scores (G).

0p7	IV	V	G	Interstitial Proteins	IV	V	G
Exostosin-1	0	13	8	Uromodulin	2	24	23
Exostosin-2	0	29	23	Glutathione S-transferase	23	1	15
C1Q	24	0	10	Dipeptidase-1	19	0	12
Complement 8	0	16	10	Fibrinogen	18	0	11
IFN-induced GTP-Binding Protein	27	5	6	IFN-induced GTP-Binding Protein	13	0	7

Conclusions: These data demonstrate that LCM/proteomics identify tissue compartment specific, differentially-expressed proteins in kidney biopsies of glomerular diseases. This can focus diagnostic biomarker development to increase probability of success. Differentially expressed proteins can also provide clues as to the pathogenesis of different types of GN.

FR-PO1893

The Impact of Partial Remission on Renal and Patient's Survival in Severe Lupus Nephritis

Mamdouh N. Albaqumi, Lutfi Alkorbi, Dania Alkhafaji. *KFSHRC, Riyadh, Saudi Arabia.*

Background: Few studies have addressed the value of partial remission on long term renal and patient's survival. In this study, we describe the effect of partial remission (PR) in comparison to complete remission (CR), and treatment failure (TF) on long term renal outcome in a cohort of patients with severe lupus nephritis.

Methods: We retrospectively reviewed our patient's archived files and identified all patients with the diagnosis of lupus nephritis from 2003 until 2008. All renal biopsies were reviewed blindly and reclassified according to ISN/RPS 2003 classifications.

Results: A total of 63 patients with Lupus Nephritis class IV were identified. 31 patients (49%) achieved PR, while 13 (21%) patients had CR, and 19 (30%) patients had TF. Serum creatinine at presentation was higher in patients with TF (178.0 ± 126.0 umol/L) compared to PR (128.4 ± 97.0 umol/L), however, when GFR is estimated, there was no statistical difference between PR and TF groups at presentation (PR: 94.4 ± 84.5 ml/min, TF: 57.8 ± 39.3 ml/min, P= 0.117) . proteinuria was also similar between PR and TF groups (PR:4.9 ± 3.9 mg/24hr, TF: 5.4 ± 4.9 mg/24hr, P= 0.126). Renal survival over the next four years was significantly higher in the CR and PR groups compared to TF (CR: 77% PR: 55%, TF: 29%. P= 0.033).

Conclusions: Despite having a similar GFR and proteinuria at presentation to TF, PR group had a better renal survival in four years, highlighting the favorable impact of partial remission in severe lupus nephritis.

FR-PO1894

Efficacy and Safety of Double Filtration Plasmapheresis Therapy in Severe Lupus Nephritis

Hai-Tao Zhang, Wei-Xin Hu, Zheng-Zhao Liu, Ying-Hua Chen, Dehua Gong, Daxi Ji, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.*

Background: To investigate the clinical efficacy and safety of double filtration plasmapheresis (DFPP) accompanied with corticosteroid in patients with severe lupus nephritis(LN).

Methods: 8 patients (5 females and 3 males, average age 23.9±10.3) with severe LN including class IV (n=5),III,V+IV and V+IIIl were studied. Among them, 7 cases showed rapidly progressive glomerulonephritis(RPGN) with elevated serum creatinine(SCr) (3.9±2.8mg/dl), and 3 of them needed renal replacement therapy. DFPP was performed with two-fold plasma volume on each session using membrane type plasma component separator (EC50W and EC20W, Asahi Kasei Kuraray, Japan).

Results: ***1)Clinical efficacy*** DFPP treated 2.8 times(2~3)for each patient. SLE-DAI was reduced significantly from 18.9±3.3 to 10.5±0.9 (P<0.01)and SCr decreased from 3.9±2.8 to 2.3±2.2mg/dl (P=0.13)after DEPP. 2 patients got off dialysis by 1 and 2 weeks, respectively. ***2)Immunologic parameters*** Serum IgG decreased from 10.3±5.4 to 4.8±3.1g/L(P<0.01). The titers of anti-dsDNA and anti C1q antibody were significantly declined after DFPP, while the levels of complement C3 and C4 had no change. ***3)Improvements of vascular endothelial cell function*** Increases of circulating endothelial cell_(CEC) number and vascular cell adhesion molecule (VCAM) were observed in 6 out of the 7 patients with RPGN, and elevation of thrombomodulin level was found in 5 cases before therapy. After DFPP, CEC count was decreased in 4 cases, VCAM and thrombomodulin levels were lowered in 5 and 3 patients, respectively. ***4)Follow up study*** 8 patients were followed up for 2~16 months(4.3±4.9). 5 patients achieved complete remission, and 2 had partial remission. 5***)Adverse effect*** 1 patient showed transient hypotension at the beginning of DFPP.

Conclusions: DFPP can rapidly and effectively clear autoantibodies in severe LN, thus improving renal function and protecting the endothelial cells. DFPP accompanied with corticosteroid is an effective therapeutic method for LN.

FR-PO1895

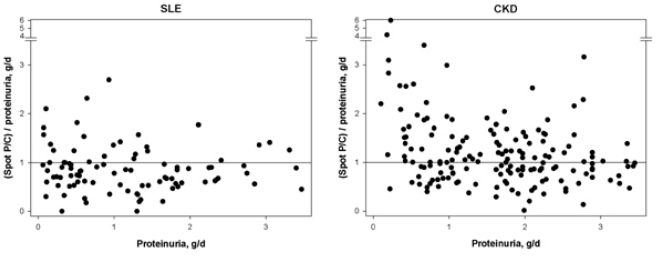
Random Spot Urine P/C Ratio Is Unreliable in Estimating 24-h Proteinuria Magnitude in Both SLE GN Patients and CKD Patients, However the Type of Inaccuracy Is Different between These Conditions

Ganesh B. Shidham, Daniel J. Birmingham, Brad H. Rovin, Lee A. Hebert. *Internal Medicine/ Nephrology, Ohio State University Medical Center, Columbus, OH.*

Background: We have previously shown that random spot P/C ratio (spot P/C) is highly inaccurate in estimating 24-h proteinuria in individual SLE GN patients (pts), particularly in the sub-nephrotic range. Here we extend this work to CKD pts and compare the results to those of SLE GN pts.

Methods: For the SLE GN analysis, we added a third cohort to our two previously reported cohorts. The individual data were obtained from our own database and from a previously published work. For the CKD analysis we identified from the published literature three CKD studies of spot P/C and 24-h proteinuria in which the data were presented on linear plots. The individual data were extracted by computer graphic analysis. For all the data, only those with sub-nephrotic proteinuria (< 3.5 g/d), the most common level of proteinuria encountered clinically, are included in this analysis.

Results: The SLE GN pts (N = 93) showed a mean (spot P/C)/(24-h proteinuria) ratio of 0.86 ± 0.48 (p < 0.001 compared to 1.0). The CKD pts (N = 162) showed a mean (spot P/C)/(24-h proteinuria) of 1.21 (p = 0.021) compared to 1.0. The difference in the ratios was significant (p < 0.0001). The figure below shows a calibration plot of the individual data.



Conclusions: Spot P/C is unreliable in estimating 24-h proteinuria in the sub-nephrotic range. In addition, in SLE GN it tends to underestimate and in CKD it tends to overestimate 24-h proteinuria. The mechanism and pathophysiologic significance of this difference is unclear.

FR-PO1896

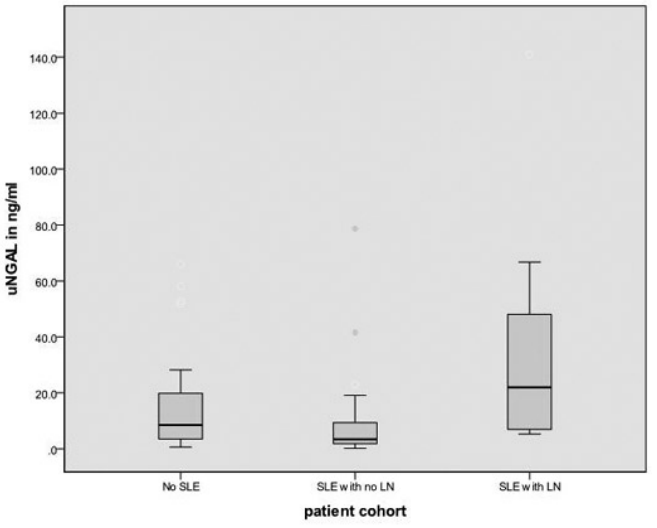
Urine Neutrophil Gelatinase Associated Lipocalin Is Increased during Active Lupus Nephritis

Li Ping Tan, Soo Kun Lim, Tee Chau Keng, Yip-Boon Chong, Wan Ahmad Hafiz Wan Md Adnan, Kok Peng Ng. *Department of Medicine, Division of Nephrology, University of Malaya Medical Center, Kuala Lumpur, Wilayah Persekutuan, Malaysia.*

Background: Urine Neutrophil Gelatinase Associated Lipocalin (NGAL) is a novel marker of acute kidney injury. While it's expression is upregulated chiefly in response to ischemic reperfusion injury, it can also be produced by glomerular mesangial cells and inflammatory cells. Patients with systemic lupus erythematosus (SLE) are often complicated by lupus nephritis, during which the glomeruli can be infiltrated by inflammatory cells. We postulate that urine NGAL levels will rise in patients with active lupus nephritis (LN).

Methods: A cross sectional study was performed over a period of 8 months. Urine NGAL levels were compared between patients with biopsy proven active ILN and SLE patients without LN. Normal healthy volunteers served as a negative control group. Patients were excluded if they had a glomerular filtration rate of <30ml/min/1.73m2.

Results: A total of 72 subjects were recruited. 12 with biopsy proven active lupus nephritis (LN), 27 with SLE but without LN and 33 healthy controls. 67% of the LN group had WHO Class IV disease. Mean GFR was similar in all 3 groups. Patients with LN had significantly higher levels of urine NGAL (median 21.95 ng/ml IQR 6.35- 52.2) compared to SLE patients without LN (median 3.4 ng/ml IQR 1.75 – 10.8)(p<0.01) and the healthy individuals (median 8.5 ng/ml IQR 3.5 – 20.4) (p<0.05). Correcting for the serum creatinine also produced similar results. With the exception of ESR (r=0.268 p<0.05), no correlation was found betweem urine NGAL levels and activity markers of LN.



Conclusions: Urine NGAL is raised in active LN. Urine NGAL may be a promising biomarker in the detection of active LN. Further studies need to be done on larger sample sizes to verify these findings.

Effect of N-acetylcysteine on Proteinuria, Parameters of Oxidative Stress and Markers of Kidney Damage in Patients with Lupus Nephropathy

Marta Jagodzinska, Jolanta Fijalkowska-Morawska, Michal P. Nowicki. *Dept. Nephrology, Hypertension and Kidney Transplantation, Medical University, Lodz, Poland.*

Background: Excessive generation of reactive oxygen species modulates expression of inflammatory chemokines thereby inducing tissue damage in autoimmune diseases. Patients with lupus nephritis present impaired oxidative stress status even without clinical signs of renal activity. N-acetylcysteine (NAC) has a strong antioxidant activity. The aim was to evaluate the effect of NAC treatment on proteinuria and serum markers of oxidative stress and kidney injury in patients with lupus nephritis.

Methods: In a cross-over placebo-controlled study 14 patients (3M, 11F; mean age 35±8 years) with diagnosis of lupus nephritis (class II,III or IV, mean time from diagnosis 8.5±4.2 years) with stable serum creatinine (1.1±0.4mg/dl) and persistent low-range proteinuria 480±550 mg/l were randomly assigned to two 3-month treatment periods with 2 week wash-out. During the active treatment phase the patients received NAC 600 mg per day. Most patients were on stable low doses of steroids (n=12) and azathioprine (n=3) or mycophenolate mofetil (n=2).

Results: The treatment with NAC caused a significant decrease of proteinuria. hsCRP tended to decrease after NAC (p=0.07). None of other biomarkers of lupus nephritis activity (C3, C4 and monocyte chemoattractant protein-1 – MCP-1) changed significantly during the treatment. While serum cystatin C remained unchanged there was a tendency of neutrophil gelatinase-associated lipocalin (NGAL) to decrease during the treatment (p=0.08).

	baseline	active treatment phase (NAC)	control phase
proteinuria [mg/l]	524±627	309±471 (p=0.02 vs baseline)	376±474
hsCRP [ug/ml]	4.0±2.3	3.3±1.9	5.1±2.6
C3 [g/l]	0.89±0.26	0.86±0.31	0.94±0.25
C4 [g/l]	0.25±0.3	0.18±0.09	0.18±0.09
MCP1- [pg/ml]	936.9±641.4	829.4±502.3	663.5±302.5
cystatin C [ng/ml]	1534.6±515.7	1345.7±462.1	1399.9±463.4
NGAL [ng/ml]	103.3±57.3	86.7±49.0	110.8±60.4

Conclusions: In this small pilot study the treatment of clinically stable lupus nephritis patients with NAC led to a decrease of proteinuria but showed neither renoprotective effect nor any significant influence on serum markers of disease activity and oxidative stress.

FR-PO1898

Complement Activation in Ten Patients with C3 Glomerulonephritis without MPGN

Xiao-Juan Yu, Gang Liu, Ming-Hui Zhao. *Renal Division, Peking University First Hospital, Beijing, China.*

Background: Complement activation is the key pathogenetic factor in C3 glomerulonephritis (C3GN) without membranoproliferative glomerulonephritis (MPGN). It has been well accepted that the alternative pathway possibly plays an important role in it, but the classic pathway is not involved, and involvement of the lectin pathway is still unknown.

Methods: From January 1999 to June 2010 in Renal Division, Peking University First Hospital, ten biopsies were consistent with the definition of C3GN without MPGN (isolated mesangial C3c deposition in the absence of IgG, IgA, IgM and C1q by immunofluorescene). Concentration of plasma C4a, factor B, Ba, C3, C3a and C5a was detected by ELISA. Glomerular C4d and MAC were detected by immunohistochemistry.

Results: The concentration of plasma complement in patients with C3GN without MPGN was shown in table 1.

Table 1

	C3GN without MPGN	Normal controls	t/z	P
C4a(ug/ml)	11.73±7.23	1.96±0.78	4.052	0.004
Factor B(ug/ml)	6.78±0.53	12.07±7.02	-2.374	0.041
Ba(ng/ml)	1149.0±543.2	403.2±108.4	4.102	0.003
C3(g/L)	0.84±0.41	0.80±0.23	0.406	0.684
C3a(ug/ml)	2.61±2.30	0.12±0.06	3.257	0.012
C5a(ng/ml)	24.87±26.79	8.59±6.98	2.262	0.024

	Proteinuria (g/ d)	Plasma creatinine (umol/L)
C4a(ug/ml)	r= 0.015 P=0.969	r= 0.084 P=0.829
Ba(ng/ml)	r= 0.706 P=0.033	r= 0.193 P=0.619
C3a(ug/ml)	r= 0.437 P=0.239	r=-0.017 P=0.966
C5a(ng/ml)	r=-0.127 P=0.744	r=-0.209 P=0.590

The analysis between concentration of plasma complement and proteinuria, plasma creatinine was shown in table1.Glomerular C4d was positive in 8 biopsies in mesangial areas and glomerular capillary wall, and negative in 2 biopsies. MAC was detected in 8 biopsies in a mesangial pattern and negative in 2 biopsies(one patient was negative for C4d, and the other one was positive for C4d).

Conclusions: Alternative pathway in circulation might play an important role in the pathogenesis of C3GN without MPGN. There might also be complement activation via both the lectin and alternative pathway in glomeruli, which needs further investigations.

FR-PO1899

The Terminal Complement Complex (TCC) – A Potential Biomarker for Disease Activity in Patients with Membranoproliferative Glomerulonephritis

Magdalena Riedl,[1] Alejandra Rosales,[1] Verena Jeller Jeller,[1] Johannes Hofer,[1] Udmila Podracka,[2] Christoph Rudin,[3] Henry Fehrenbach,[4] Heiko Billing,[5] Reinhard Würzner,[1] Therese C. Jungraithmayr.[1] *[1]Medical University, Innsbruck, Austria; [2]University Children's Hospital, Kosice, Slovakia (Slovak Republic); [3]University Children's Hospital, Basel, Switzerland; [4]Children's Hospital, Memmingen, Germany; [5]University Children's Hospital, Heidelberg, Germany.*

Background: The role of complement (C) in membranoproliferative glomerulonephritis (MPGN) has been investigated in more detail lately. Mutations in C regulator genes, antibodies against C proteins and a common persistent hypocomplementemia (low C3) in many patients support the role of C in the pathogenesis. No biomarker for monitoring disease activity is available yet.

Methods: Here we present data on the concentration of the soluble terminal complement complex (TCC, sC5b-9) in 11 pediatric patients with MPGN. Seven patients were classified as MPGN type I and 4 as DDD (MPGN II) by their renal biopsies, 6/11 were tested positive for C3NeF. In 3 patients multiple tests were performed. 98 healthy adult blood donors were used as controls. The measurement of the TCC, generated as a potentially lytic end product of C activation, was performed by a sandwich ELISA technique. Mann-Whitney-U-test was used for statistical evaluation.

Results: Patients with MPGN showed a statistically significant higher TCC concentration in plasma (3.9 ± 3.0µg/ml vs 1.5 ± 1.2µg/ml, p<0.01) than controls. Patients with an active disease (hematuria, gross proteinuria, arterial hypertension) had a significant increased TCC value (4.8 ± 3.3 µg/ml) compared to patients in remission (1.9 ± 0.6 µg/ml, p<0.03). No significant difference of C3 levels during active disease (37.2 ± 16.1mg/dl) and patients in remission (30.0 ± 14.7mg/dl, p=0.15) was discovered.

Conclusions: This work emphasises the role of C activation in DDD as well as in MPGN I. Thus, complement inhibition therapies targeting the terminal C cascade, such as Eculizumab, should also be considered in patients with MPGN and elevated TCC. The TCC concentration may represent a good biomarker for monitoring disease activity in patients with MPGN.

Membranoproliferative Glomerulonephritis and Mixed Cryoglobulinemia after Hepatitis C Virus Infection Secondary to Glomerular NS3 Viral Antigen Deposits

Stanislas Bataille, Bertrand Dussol. *Nephrology, Hôpital de la Conception, Marseille, France.*

Background: Hepatitis C virus infection is the main etiology of type I membranoproliferative glomerulonephritis. We report on three cases of type I membranoproliferative glomerulonephritis associated with type II cryoglobulin in patients with hepatitis C virus (HCV) antibodies but with a negative viral load.

Methods: We searched for occult HCV infection in B cells or kidney glomeruli using PCR assays and immuohistochemistry.

Results: Hepatitis C virus infection-associated lymphoma was excluded by computed tomodensitometry, bone marrow phenotyping and histology but indirect features of B cell proliferation were present in the three patients. Using ultrasensitive PCR assays, we did not evidence occult hepatitis C infection in peripheral blood mononuclear and bone marrow cells, and in the cryoprecipitates but found HCV-NS3 antigen the kidney in the patient tested using immunohistochemisty 6years after viral PCR was negative. Liver tissue specimens were not available. Remission occurred spontaneously in one patient and after rituximab treatment in one patient. The third patient was lost for follow up.

Conclusions: Persistence of viral antigen HCV-NS3 at least in kidney, even many years after HCV PCR is negative, may explain immunological stimulation and persistence of cryoglobulinemia with a predominant renal clinical expression.

FR-PO1901

Eculizumab for Dense Deposit Disease (DDD) and C3 Glomerulonephritis (C3GN) Andrew S. Bomback,[1] Jai Radhakrishnan,[1] Pietro A. Canetta,[1] Yuzhou Zhang,[2] Carla Nishimura,[2] Nicole Meyer,[2] Kathy Frees,[2] Michael Jones,[2] Richard J. Smith,[2] Gerald B. Appel.[1] *[1]Columbia University; [2]University of Iowa.*

Background: The principle immune defect in DDD and C3GN is excessive alternative complement activation. Eculizumab, a monoclonal Ab to C5 that prevents formation of the membrane attack complex, may provide targeted therapy for DDD and C3GN.

Methods: We present a 6-month interim analysis of an open label, proof-of-concept efficacy/safety study of eculizumab in DDD or C3GN (NCT01221181). Six pts are treated with eculizumab 1200 mg IV every other week for 1 yr. All had proteinuria ≥1 g/day and/or AKI (serum creatinine ≥150% baseline) at enrollment. All underwent biopsy at enrollment and will have repeat biopsies at 1 yr. Additional testing included: mutation screening of CFH, CFI, MCP, CFB, CFHR5 and THBD; autoAb screening for C3 nephritic factors and factor H autoAbs; and functional analysis of complement activity.

Results: We enrolled 3 pts with DDD (2 native, 1 recurrent) and 3 pts with C3GN (1 native, 2 recurrent). One pt (DDD) carried a CFH mutation; 4 pts were C3Nef(+) (2 DDD, 2 C3GN); and 2 pts (1 DDD, 1 C3GN) had elevated sMAC. Total complement levels declined to 0-1 CAE units by week 4 in 5/6 pts (in 1 pt, level was 4 CAE units by week 8). At 6 mos, two pts with AKI (native DDD and recurrent C3GN) had sustained improvements in creatinine (2.1→1.4 and 2.0→1.5 mg/dl, respectively) with consistently low proteinuria. Three other pts (recurrent DDD, native C3GN, and recurrent C3GN) had significant declines in proteinuria (10579→1417, 2279→520, and 4455→2441 mg/g, respectively) with rising serum albumin (2.9→4.1, 3.2→3.9, and 3.4→4.2 g/dl, respectively) and stable creatinine. One pt (native DDD) had no improvement in creatinine or proteinuria. Response to therapy was associated with normalization of sMAC. No C3Nef(+) pt has become C3Nef(-). No adverse events have been reported.

Conclusions: Eculizumab is well-tolerated in pts with DDD and C3GN. Interim results at 6 mos suggest effective inhibition of the terminal complement cascade. For most pts, a clinical response was observed. Laboratory and repeat biopsy data at 12 mos will be done to validate these preliminary results.

FR-PO1902

Successful Treatment of Membranoproliferative Glomerulonephritis Type I with Monoclonal Anti C5 Antibody (Eculizumab) Arnaud Garnier,[1] Anne Modesto,[2] Stephanie Tellier,[1] Flavio Bandin,[1] Stéphane Decramer.[1] *[1]Pediatric Nephrology Unit, Hopital des Enfants, CHU Purpan, Toulouse, France; [2]Division of Anatomic Pathology, Hôpital Rangueil, CHU Rangueil, Toulouse, France.*

Background: Membranoproliferative glomerulonephritis (MPGN) is a heterogeneous group of nephropathy, characterized on histology by mesangial hypercellularity with increased matrix, splitting of the glomerular basement membrane and different pattern of deposit (type I, II and III). MPGN type I represent less than 5% of primary glomerulonephritides and can be related to complement dysregulation.

Results: We report the case of a 7 years old boy referred to our unit for nephrotic syndrome with hematuria. Renal biopsy displayed classical MPGN type I with subendothelial deposits of C3, C1q, IgG and IgM. Serum C3 level was low (0.11g/L) and a C3 nephritic factor (C3NF) was present. No mutation was found in the complement alternative pathway factors H and I. A 6 months course of oral steroids together with angiotensin converting enzyme inhibitor (ACEi) and angiotensin II receptor blocker (ARB) did not improve proteinuria. After 3 years of sustained nephrotic syndrome, glomerular filtration rate (GFR) slowly decreased and a second renal biopsy was performed. Histological and immunological findings were similar to the first biopsy with global sclerosis concerning 20% of the glomeruli. Low serum C3 level and C3NF were still present. A second course of steroids together with the maintenance of the ACEi and ARB did not succeed to reduce proteinuria. After tetravalent meningococcal vaccine and initiation of prophylactic penicillin V therapy, treatment with the anti C5 monoclonal antibody eculizumab was initiated as follows: 900mg once a week for 4 weeks, then 1200mg every 2 weeks. 3 months after the beginning of treatment, proteinuria is nearly normal (0.2g per 24h) with normal GFR and albuminemia (35g/L).

Conclusions: This is the first report of successful treatment of MPGN type I with eculizumab, a monoclonal anti C5 antibody that blocks the terminal complement activation. In primary MGPN, dysregulation of complement activation is a frequent feature, and the treatment with eculizumab should be discussed in the most severe forms.

FR-PO1903

Lymphangiogenesis and Tertiary Lymphoid Neogenesis in Progression of IgA Nephropathy Guangchang Pei, Rui Zeng, Min Han, Lily Liu, Gang Xu. *Devision of Nephrology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, wuhan, Hubei, China.*

Background: The lymphangiogenesis and formation of tertiary lymphoid organs in renal interstitium have been previously identified in human chronic renal diseases and in human kidney transplants. However, they are not specially described in IgA nephropathy(IgAN). In this prospective study, the lymphangiogenesis and lymphoid neogenesis process and the prognosis of IgAN were evaluated.

Methods: 176 patients with biopsy-proven IgAN were selected. We graded renal biopsy specimens according to the classification of Haas. We assessed tubular lesions, interstitial fibrosis and abnormalities of the arteriolar wall by a semi-quantitative scoring system. The presence of lymphatic vessels, macrophages, dendritic cells and lymphocytes was examined by IHC.

Results: Lymphatic vessels density(LVD) in renal interstitium inversely correlated with the severity of tubular lesions and interstitial fibrosis according to Haas grades. It was also significantly associated with the amount of infiltrating macrophages, dendritic cells, lymphocytes and tertiary lymphoid organs. LVD and tertiary lymphoid organs density in renal interstitium were significantly associated with the renal function. The higher the LVD and tertiary lymphoid organs density, the higher the serum creatinine at the time of biopsy and 12 months after biopsy. The more remarkable discovery was both of the lymphangiogenesis and lymphoid neogenesis correlate with vasculopathy. Lymphangiogenesis and lymphoid neogenesis were found frequently adjacent to the vascular lesion. LVD was higher in IgAN patients with severe arterial lesions and hyaline changes (43.92mm^{-2}) than in IgAN patients who had mild / moderate arterial lesions. (20.92 mm^{-2}, p=0.000358)

Conclusions: Lymphangiogenesis and formation of tertiary lymphoid organs in renal interstitium reflected the renal activity state of chronic inflammatory and they were associated with the IgAN progression. Lymphangiogenesis participated in formation of tertiary lymphoid organs in renal interstitium.Vasculopathy might play a part in lymphangiogenesis and formation of tertiary lymphoid organs in renal interstitium of IgAN patient.

FR-PO1904

Novel Diagnostic Approach for IgA Nephropathy Hiroyuki Yanagawa,[1] Hitoshi Suzuki,[1] Yusuke Suzuki,[1] Keiichi Matsuzaki,[1] Satoshi Horikoshi,[1] Jan Novak,[2] Yasuhiko Tomino.[1] *[1]Division of Nephrology, Department of Internal Medicine, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Dapartment of Microbiology, University of Alabama at Birmingham, AL.*

Background: Galactose-deficient IgA1 (Gd-IgA1) is found in elevated amounts in the circulation and in the mesangial deposits of patients with IgA nephropathy (IgAN). Moreover, serum levels of Gd-IgA1-specific antibodies, responsible for the formation of immune complexes (IC) with Gd-IgA1, are also elevated in IgAN. However, due to the clinical heterogeneity of IgAN, there is no biomarker to replace the diagnostic renal biopsy.

Methods: A cross-sectional study was performed using serum samples collected from 2006 to 2010 at the time of renal biopsy from 121 patients with IgAN and 73 patients with other renal diseases, such as lupus nephritis, diabetic nephropathy, and membranous nephropathy. We measured serum IgA, IgA-IgG IC, Gd-IgA1 and Gd-IgA1-specific IgA by ELISA to assess whether these biomarkers can be used for diagnosis of IgAN. ELISA data from healthy volunteers (n=74) were used to establish baseline for each assay and calculate quantitative scores for each biomarker for IgAN patients and disease controls by principal component analysis using JMP software.

Results: Serum levels of IgA, Gd-IgA1, IgA-IgG IC and Gd-IgA1-specific IgA were elevated in IgAN patients compared with disease controls (P<0.0001) and healthy controls (P<0.0001). However, no biomarker alone could effectively differentiate IgAN from disease controls, due to the overlapping values for these markers in many IgAN patients and disease controls. To test a combination of these four biomarkers as a potential differential diagnostic method for IgAN, these four biomarkers were quantitated and combined by principal component analysis based on data from healthy volunteers. This scoring system showed high sensitivity and specificity of 75% and 81%, respectively.

Conclusions: Our results suggest that serum Gd-IgA1, Gd-IgA1-specific antibodies and IC might be may be useful as combined disease specific biomarkers of IgAN. This novel quantitative scoring system can be used to complement renal biopsy in the diagnosis of IgAN.

FR-PO1905

Beneficial Effect of Steroids and Immunosuppressants in the Treatment of IgA Nephropathy May Be Due to Modifying Local Production or Activation of Multiple Cytokines Maria Stangou,[1] Aikaterini A. Papagianni,[1] Christos Bantis,[1] Maria Skoularopoulou,[1] Afroditi Pantzaki,[2] Nicoletta-Maria Kouri,[3] George Efstratiades,[1] Demitrios Memmos.[1] *[1]Department of Nephrology, Aristotle University of Thessaloniki, Hippokration Hospital, Thessaloniki, Greece; [2]Department of Pathology, Hippokration Hospital, Thessaloniki, Greece; [3]Department of Biochemistry, Hippokration Hospital, Thessaloniki, Greece.*

Background: Steroids and immunosuppressants can reduce proteinuria and delay progression of renal function in IgAN, possibly by interfering with local cytokines, which lead to inflammation and fibrosis.

Methods: Histology in 53 IgAN patients [M/F 35/18 age 40.5yrs (17-65)] was evaluated by Oxford classification system and renal biopsies were classified as MEST score (Mesangial, Endocapillary hypercellularity, Segmental glomerulosclerosis, Tubular atrophy) 1, 2, and 3. IL-1β, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12, INF-γ, MCP-1, MIP-1β, TNF-α were measured by multiplex cytokine assay in first morning urine samples at day of renal biopsy. Steroids±azathiopine were introduced in 18/53 proteinuric patients, while 35/53 were treated with angiotensin inhibitors (RAASi)±fish oils(FO).

Results: Screat1 at time of diagnosis correlated with proteinuria (p=0.02), MEST score (0.0001) and urinary levels of IL-1β, IL-2 and MCP-1 (p=0.04, p=0.03 and p=0.04 respectively). At the end of follow up [5.5 (1-12years)], Screat2 was increased significantly in RAASi+FO (from 1.6±0.9 to 3.3±3.7mg/dl, p=0.004) and remained stable in steroids±aza treated patients.

In RAASi+FO patients, Screat2 at the end of follow up had positive correlation with MEST score (p=0.006), IL-1β (p=0.007), IL-2 (p=0.01), IL-6 (p=0.02), IL-10 (p=0.04), IL-12 (p=0.01) and MCP-1 (p=0.03) urinary levels. In steroids±aza patients, the only parameters correlated with Screat2 were IL-1β (p=0.01), IL-6 (p=0.01) and MCP-1 (p=0.01).

Conclusions: In conclusion, several cytokines are excreted in the urine of patients with IgAN, and their levels predict outcome of the disease. Treatment with steroids+aza seems to have a beneficial effect in renal function outcome, and this is probably due to their influence in local cytokine production or activation.

FR-PO1906

Clinical Features and Long-Term Outcomes of Nephrotic Syndrome in Patients with IgA Nephropathy Hyung Jung Oh, Dong Eun Yoo, Seung Jun Kim, Seung Hyeok Han, Tae-Hyun Yoo, Shin-Wook Kang. *Dept. of Int. Medicine, College of Medicine, BK21, SBSI, Yonsei Univ., Seoul, Korea.*

Background: Nephrotic syndrome(NS) is a rare manifestation of IgA nephropathy(IgAN), which has been reported to behave similarly as minimal change disease. Accordingly, glucocorticoids have been frequently prescribed in IgAN patients with NS. In contrast, a recent study demonstrated that spontaneous remission(SR) of NS was commonly observed in these patients. This study was conducted to investigate the clinical features and long-term outcomes of NS in patients with IgAN.

Methods: A total of 1,076 patients with biopsy-proven IgAN were included from 4 centers in Korea. The primary outcome was regarded as doubling of the baseline serum Cr, and the secondary outcomes as ESRD or death. Cox regression analysis was performed to identify independent risk factors for the development of primary and secondary endpoints and to evaluate the predictive factors of the occurrence of SR.

Results: Among 100 patients(10.2%), who presented with NS, glucocorticoids were prescribed in 65(65.0%). Complete remission(CR), partial remission(PR), and no response(NR) were observed in 48.0%, 32.0%, and 20.0%, respectively. During the median follow-up of 44.0 months, 24 patients(24.0%) in the NS group reached the primary endpoint compared to 63(7.2%) in the non-NS group(P<0.001). Compared to the CR group, the risk for attaining the primary endpoint was significantly higher in the PR(HR, 14.49; 95% CI, 1.14-183.7; P=0.039) and the NR groups(HR, 215.97; 95% CI, 15.63-2983.6; P<0.001). Among patients with NS, 24(24.0%) underwent SR. Multivariate Cox regression analysis revealed that a >50% decrease in proteinuria within 3 months after the onset of NS, serum Cr≤1.2 mg/dL, and female gender were associated with a significantly increased likelihood of SR. None of these patients reached the primary endpoint, and they had fewer relapses during follow-up.

Conclusions: This study shows the prognosis of NS in patients with IgAN is not favorable unless CR or PR is achieved. In addition, SR occurs more frequently in patients with preserved renal function and a prompt decrease in proteinuria after the onset of NS, and these patients have excellent outcomes.

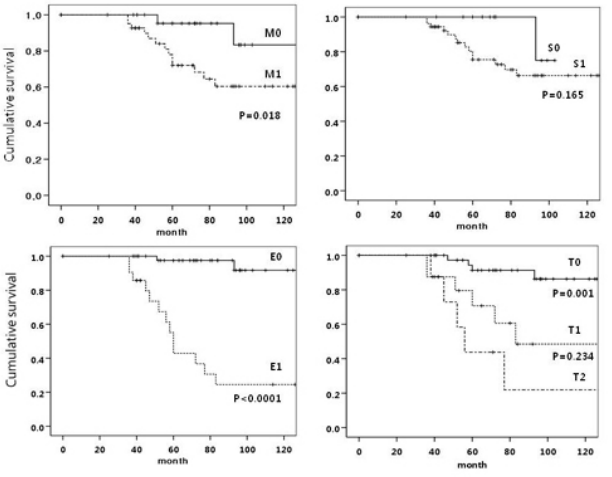
FR-PO1907

Validation of the Oxford Classification of IgA Nephropathy in Korean Adults Soon Hyo Kwon,[2] So-Young Jin.[1] *[1]Department of Pathology, Soon Chun Hyang Univiersity Hospital, Seoul, Korea; [2]Department of Internal Medicine, Soon Chun Hyang University Hospital, Korea.*

Background: The recently published Oxford classification of IgA neuropathy (IgAN) proposed a split system for histologic grading based on prognostic pathologic features. The new classification system must be validated in different cohorts. We investigated whether these pathologic features are applicable in the adult Korean population.

Methods: One hundred seven adult Korean patients with IgAN were analyzed with the Oxford classification system at Soon Chun Hyang University Hospital, Seoul, Korea. Renal biopsies from all patients were scored by a pathologist who was blinded to the clinical data for pathological variables. Inclusion criteria were age greater than 18 years and at least 36 months follow-up. We excluded cases with secondary IgAN, diabetic nephropathy combined other glomerulopathies, less than 36 months of follow-up, and rapidly progressing cases.

Results: The median age of patients was 34 years (range, 27–45 years). Mean arterial blood hypertension (MAP) was 97±10 mmHg at the time of biopsy. The median follow-up period was 85 months (range, 60–114 months). Kaplan-Meier analysis showed significant prognostic prediction with M, E, and T lesions.



E and T lesions also revealed prognostic prediction in the Cox proportional hazards regression analysis.

Cox regression analyses between pathologic features and a 50% delcine in eGFR: univariatie and multivariate pathologic determinants

	Univaritate hazard ratio (95% CI),p	Multivariate hazard ratio	
E0	1	E0	1
E1	12.61(2.47-64.35),p=0.002	E1	12.21(2.23-66.71),p=0.004
T0	1	T0	1
T1	3.60 (0.87–14.81), p=0.75	T1+T2	3.58 (1.03–12.40), p=0.044
T2	14.01 (1.61–121.74) p=0.017		

a: One pathologic feature + mean arterial pressure, proteinuria, and eGFR

Conclusions: In the Oxford classification of IgAN, E and T lesions predict renal outcome in Korean adults after taking clinical variables into account.

FR-PO1908

Long-Term Outcome of Biopsy-Proven IgA Nephropathy Presenting with Mild Proteinuria and or Isolated Microhematuria. A Multicenter Study Eduardo Gutierrez,[1] Isabel Zamora,[2] Teresa Olea,[3] Sara Jiménez álvaro,[4] Carmen Bernis,[5] Manuel Praga.[6] *[1]Nephrology Department, Hospital 12 de Octubre; [2]Nephrology Department, Hospital La Fe; [3]Nephrology Department, Hospital La Paz; [4]Nephrology Department, Hospital Ramon y Cajal; [5]Nephrology Department, Hospital La Princesa; [6]Nephrology Department, Grupo de Estudio de las Enfermedades Glomerulares, Spain.*

Background: Renal biopsies are rarely performed in patients presenting with mild proteinuria and/or isolated microhematuria. Clinical information about long-term outcomes of IgA nephropathy (IgAN) presenting with such benign manifestations is very scarce.

Methods: Retrospective and multicenter study to collect patients with biopsy-proven IgAN who presented at renal biopsy a normal renal function, microhematuria and proteinuria lower than 0.5 g/d.primary endpoint was renal survival, defined as an increase >50% or >100% of baseline serum creatinine (sCr).Secondary endpoints were the occurrence of remission, the development of >1 gr/d proteinuria and the development of ESRD. Thebiopsies were classified according to the new Oxford Classification.

Results: 141 patients were collected.Mean follow-up was 108 months.Clinical characteristics at baseline were:63.4% males, age 23,7±14,8 yr, sCr 0,8±0,2 mg/dl and a median proteinuria of 0.2 gr.Renal biopsies showed mesangial proliferation in 32.6% of patients, focal and segmental glomerulosclerosis in 15.6% ,and endocapillary proliferation in 8.5%.No patient received any immunosuppressive treatment.59 patients were treated with ACEI/ARB during follow-up.Renal survival (> 50% sCr) was 96,2% and 93,6% after 10 and 15 yr,and 97.6% at both 10 and 15 yr when it was defined by >100% sCr increase.Only 6 patients (4.2%) had a e-GFR <60 ml/m and none reached ESRD.Remission was observed in 37.6% and proteinuria increased to >1g/d in only 6 patients (4.2%).By multivariate analysis only age (HR 1,1;95% CI 1,01-1,3;p 0,03) and FSGS lesions in renal biopsy (HR 10,3, CI: 0,9-120; p 0,04) were significant risk factors for renal survival .

Conclusions: Long-term renal outcomes in patients with benign clinical presentations are excellent.Spontaneous clinical remission occurred in more than a third of patients.

FR-PO1909

Down-Regulated Peripheral Lymphocyte miR-155 Is Related to IgA Nephropathy Wei Qin, Mian Wei, Ping Fu. *Division of Nephrology, Department of Medicine, West China Hospital, Sichuan University, Chengdu, Sichuan, China.*

Background: MicroRNA-155 (miR-155) is a very important immune regulatory factor, which involved in the lymphocyte homeostasis and adjusting of multiple immune related genes. Immune abnormalities, such as lymphocytes dysfunctions and impaired

homeostasis, are key pathogenesis of IgA nephropathy (IgAN). Therefore, we studied the expression level of miR-155 in the peripheral lymphocytes of IgAN.

Methods: Forty biopsy-proven IgAN patients and 15 unrelated healthy controls were included. Expression of miRNAs in peripheral lymphocyte was first determined using Exiqon microRNA microarray in 3 IgAN patients and 3 healthy controls. Realtime RT-PCR of miR-155 was performed. The expression level of Foxp3, a regulator of miR-155, was also measured. Correlation between miR-155 and Foxp3 expression level as well as clinical indexes was analyzed.

Results: microRNA microarray indicated that the expression level of miR-155 in IgAN patients was dramatically lower than that in normal control (2.12 vs 3.21), which was confirmed by realtime RT-PCR examination (IgAN 0.19±0.07 vs Control 0.74±0.22, p=0.003). Further study showed that baseline proteinuria (24 hour quantification) and hematuria (RBC per high power view) level was significantly correlated to the miR-155 expression level (proteinuria: r=-0.490, p=0.007, hematuria: r=-0.648, p<0.001). Significantly correlation between miR-155 and Foxp3 expression level was also noticed. However, no apparent correlation was observed in baseline serum creatinine level, serum albumin level, serum IgA concentration as well as pathological grade (Lee's).

Conclusions: Remarkable lower expression of miR-155 in peripheral lymphocytes was observed in IgA nephropathy patients, which was significantly correlated with severity of proteinuria, hematuria and Foxp3 expression level. These results suggested that miR-155 might play important roles in the pathophysiology of IgAN.

FR-PO1910

Urinary Proteome Analysis by MALDI-TOF-MS with Magnetic Beads Can Identify the Pathologic Presentation of Clinical Early IgA Nephropathy
Qiang He, Lina Shao, Jianghua Chen. *Kidney Disease Center, First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China.*

Background: To test if pathologic presentation of early IgA nephropathy could be identified by proteomic patterns in the urine from patients using surface-enhanced laser desorption/ionization time-of-flight mass spectrometry (SELDI-TOF-MS) protein chip array technology.

Methods: Total 56 patients with IgA nephropathy were included in this study, with 23 patients having severe pathologic presentation, and the other 33 having mild ones. The control group is 14 normal subjects. The urinary proteomic spectra from those three groups were generated by MALDI-TOF-MS with weak cationic exchange magnetic beads. The total experiment data was handled by the Zhejiang University ProteinChip Data Analysis System.

Results: The urine protein/peptide spectra patterns were established to distinguished severe IgA nephropathy from the mild IgA nephropathy group and the normal group. Several potential biomarkers were found and the diagnostic system distinguished the severe IgA nephropathy from the mild IgA nephropathy with a sensitivity of 90.48% and a specificity of 96.77%.

Conclusions: Using MALDI-TOF-MS with magnetic beads to detect urine proteomic patterns shows great potential in identifying early IgA nephropathy with different pathologic prognosis.

FR-PO1911

Evaluation of Serial Serum Levels of IgA-IgG Immune Complexes Prior To Diagnosis of IgA Nephropathy
Stephen W. Olson,[1] Hitoshi Suzuki,[2] Rhubell T. Brown,[2] Zina Moldoveanu,[2] Kevin C. Abbott,[1] Jan Novak,[2] Bruce A. Julian.[2] *[1]Nephrology Department, Walter Reed Army Medical Center, Washington, DC; [2]Nephrology Department, University of Alabama at Birmingham, AL.*

Background: Galactose-deficient IgA1 (Gd-IgA1) kidney deposits in IgA nephropathy (IgAN) are likely derived from IgA-containing circulating immune-complexes (IgA-IgG IC). There is no previous study of the presence or levels of circulating IgA-containing IC prior to the biopsy diagnosis of IgAN.

Methods: We compared serial serum levels of IgA-IgG IC preceding diagnosis in 6 patients with biopsy-proven IgAN to the levels in 18 healthy age-, sex-, race-, and age-of-serum-sample-matched healthy controls (HC) using the Department of Defense Serum Repository. IgAN cases had a 25-100% elevation in serum creatinine from baseline, 1-3 g/d proteinuria, or moderate tubulointerstitial disease without crescents on biopsy at the time of diagnosis. IgA-IgG IC were detected by cross-capture ELISA.

Results: IgAN patients had higher mean IgA-IgG IC level compared to HC at less than 500 days prior to diagnosis (0.86 vs. 0.66 OD units; p=0.03) but not greater than 500 days prior to biopsy diagnosis (0.84 vs. 0.75 OD units; p=0.16). More IgAN patients had multiple longitudinal serum samples with IgA-IgG IC level greater than 0.58 OD units than did matching HC (100% vs. 50%; p=0.05).

Conclusions: IgAN cases had a higher average circulating level of IgA-IgG IC prior to diagnosis compared to matching HC. Multiple serial circulating levels of IgA-IgG IC greater than 0.58 OD were associated with the future diagnosis of IgAN. Serial measurements of circulating levels of IgA-IgG IC may improve the prospects for a serologic non-invasive diagnosis of IgAN.

***ACE* Insertion/Deletion (I/D) Polymorphism Predicts Renoprotective Effectiveness of Renin-Angiotensin System Brockade (RASb), along with Progression, in IgA Nephropathy (IgAN)**
Junya Teranishi,[1] Ryohei Yamamoto,[1] Yasuyuki Nagasawa,[1] Tatsuya Shoji,[2] Takuya Uehata,[1] Noriyuki Okada,[2] Atsushi Yamauchi,[3] Yoshiharu Tsubakihara,[2] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Kidney Disease and Hypertension, Osaka General Medical Center, Osaka, Japan; [3]Nephrology, Osaka Rosai Hospital, Sakai, Osaka, Japan.*

Background: Although many studies identified multiple gene polymorphisms as genetic prognostic factors of IgAN, little information is available about genetic predictors of renoprotective effectiveness of RASb.

Methods: The present multicenter longitudinal study included 257 IgAN patients, who participated in our previous study PREDICT-IgAN. To identify genetic predictors of progression in IgAN, we assessed the association between progression (50% increase in serum creatinine at renal biopsy) and RAS-related gene polymorphisms (*ACE* I/D, *AT1R* A1166C, *AGT* M235T and *CYP2C9* A1075C), in multivariate Cox proportional-hazards (CPH) models. To indentify renoprotective effectiveness of RASb in IgAN, effect modifications between RASb and the gene polymorphisms were assessed in multivariate CPH models. P for interaction <0.10 was regarded as statistically significant. As sensitivity analysis, we also assessed these associations with the slope of eGFR during the observational period in multivariate linear regression (LR) models.

Results: During median 10.2 (interquartile range 6.7 - 13.4) yr of the observational period, 50.2% received RAS inhibitors and 27.6% developed progression. Among 4 gene polymorphisms, only *ACE* I/D predicted progression (DD vs. non-DD, hazard ratio (HR) 1.82 [95%CI 1.04 - 3.18]) and also effectiveness of RASb (P for interaction (*ACE* I/D * RASb) = 0.066)). HR of DD patients with RASb was remarkably lower than DD patients without RASb, whereas not in non-DD patients (non-DD without RASb as a reference; non-DD with RASb, 1.48 [0.78 - 2.79]; DD without RASb, 2.96 [1.42 - 6.15]; DD with RASb, 1.38 [0.50 - 3.80]). Multivariate LR models also ascertained the results described above.

Conclusions: *ACE* I/D polymorphism predicts renoprotective effectiveness of RASb, besides progression, in IgAN.

A Nationwide Questionnaire on Treatments for IgA Nephropathy in Japan
Keiichi Matsuzaki,[1,5] Yusuke Suzuki,[1,5] Junichirou Nakata,[1,5] Naoko Sakamoto,[2,5] Satoshi Horikoshi,[1,5] Tetsuya Kawamura,[3,5] Seiichi Matsuo,[4,5] Yasuhiko Tomino.[1,5] *[1]Division of Nephrology, Depertment of Internal Medicine, Juntendo Faculty of Medicine, Tokyo, Japan; [2]National Research Institute for Child Health & Development, Tokyo, Japan; [3]Jikei University School of Medicine, Tokyo, Japan; [4]Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan; [5]Progressive Renal Diseases Research, Research on Intractable Disease, from the Ministry of Health, Labour and Welfare of Japan, Japan.*

Background: Since annual check-ups with urinalysis are routine patients with various stages of IgA nephropathy (IgAN) are managed in Japan. A wide variety of treatments for IgAN including tonsillectomy with steroid pulse therapy (TSP) is performed because there is no single clear treatment approach to all IgAN. The objective of the present study was to investigate the current status of treatments for IgAN in Japan via Progressive Renal Diseases Research, Research on intractable disease, from the Ministry of Health, Labour and Welfare of Japan.

Methods: The nation wide questionnaire survey was conducted in 1,194 teaching hospitals by the Japanese Society of Nephrology in 2008.

Results: Answers from 376 hospitals (31.4%) showed that TSP was performed in 223 hospitals (59.3%). The histological severity and levels of urinary protein excretion (73.5%) were the most cited indications for TSP. Patterns of steroid pulse therapy in TSP were mainly grouped as follows: 1) three times in three consecutive weeks (47.8%) and 2) three times every two months (18.9%). No major differences were found in clinical efficacy between the two groups. The rate of clinical remission by TSP, a condition with no continuing or transient abnormalities in urinalysis was better than that for steroid pulse therapy alone in each hospital. Combination therapy with corticosteroids, immunosuppressants and anticoagulants/antiplatelet agents was performed in about 70% of pediatric departments. Renin-angiotensin system inhibitors (RAS-I) and antiplatelet agents were used in most hospitals.

Conclusions: Besides popular treatments such as RAS-I and antiplatelet agents, TSP is a current treatment for IgAN mainly with two different patterns of steroid pulse therapy in Japan.

FR-PO1914

Mesangial IgG Deposition Is Not Associated with Outcome in Pediatric IgA Nephropathy
Margaret Colleen Hastings,[1,2] Kim R. McGlothan,[2] Theodore Matthew Eison,[1] Noel Delos Santos,[1] Bettina H. Ault,[1] Robert J. Wyatt.[1] *[1]Pediatrics, University of Tennessee Health Sciences Center, Memphis, TN; [2]Medicine, University of Tennessee Health Sciences Center, Memphis, TN.*

Background: Anti-glycan IgG antibodies to *N*-acetylgalactosamine have been implicated in the pathogenesis of IgA nephropathy (IgAN) [PMID 19478457]. However, many patients with IgAN do not have IgG in their glomerular deposits, suggesting different

pathogenic mechanisms in those patients. Recent analysis of data from Oxford classification cohort (OCC) suggested that the presence of IgG in mesangial deposits is associated with progression to end stage kidney disease (ESKD) in children and adults with IgAN [PMID 21273233]. The purpose of this study was to determine whether the presence of IgG deposits associates with progression to ESKD in the Le Bonheur Children's Hospital (LBCH) IgAN cohort.

Methods: Renal biopsy reports with immunofluorescence data for IgA, IgG and IgM were available for 99 patients diagnosed with IgAN prior to age 18 at LBCH in Memphis, TN since 1974. Kaplan-Meier curves were generated using SAS v9.2. P-values of <0.05 were considered statistically significant.

Results: This cohort included 1 Native American, 2 Asians, 23 African Americans, and 73 Caucasians with a mean age of 10.6 ± 4.0 years at time of diagnosis and a median length of follow up of 5.4 (IQR 2.0 - 15.0) years. Male:Female ratio was 70:29. Twelve patients reached the endpoint of ESKD, defined as date of initiation of chronic dialysis or primary renal transplantation. Overall kidney survival was 92%, 86%, and 83% at 5, 10, and 15 years, respectively. IgA was the only immunoglobulin in 33%, occurred in combination with IgG in 51%, and with IgM in 36%. For those with IgG deposition, survival was 92%, 83% and 83% and without IgG was 91%, 83% and 83% at 5, 10, and 15 years. For those with IgM deposition, survival was 89%, 79%, and 79% and without IgM was 93%, 88%, and 84%. Kidney survival did not differ based upon gender or race.

Conclusions: Survival data from the LBCH IgA cohort does not support the suggestion based upon the OCC that the presence of IgG in glomerular deposits is a risk factor for progression to ESKD.

FR-PO1915

Elevated Soluble Flt-1 Was Associated with Clinical and Pathological Severity in IgAN Patients Li Zhu,[1,2] Sufang Shi,[1,2] Lijun Liu,[1,2] Jicheng Lv,[1,2] Hong Zhang.[1,2] *[1]Renal Division, Peking University First Hospital, Beijing, China; [2]Peking University Institute of Nephrology, Beijing, China.*

Background: Patients with IgA nephropathy often displayed vascular injury, such as clinical hypertension and histological arteriolar hyaline and arterial intimal thickening. Till today, factors for vascular injury in IgAN patients remain incompletely understood. Soluble Flt-1 is a splice variant of VEGF receptor. For lacking of trans-membrane and cytoplasmic domains, sFlt-1 can bind and sequester VEGF to act as a VEGF antagonist. High levels of sFlt-1 were reported in many diseases with proteinuria and hypertension symptoms, including preeclampsia and essential hypertension. Recently, CKD patients were also reported to have elevated sFlt-1, indicating its involvement in kidney disease. In the present study, we investigated the effect of sFlt-1 in IgAN.

Methods: A total of 122 individuals (100 IgAN patients and 22 healthy volunteers) were enrolled. Clinical manifestations at the time of renal biopsy and pathological characteristics were collected from the clinical record. Plasma sFlt-1 levels were determined using commercial ELISA kits.

Results: Plasma sFlt-1 level were significantly elevated in IgAN (patients Vs controls: 101.06±24.84 Vs 79.73±18.85 pg/ml, p<0.001). Furthermore, IgAN patients with hypertension showed significant higher plasma sVCAM-1 levels than those without (106.68±28.30 Vs 96.27±20.54 pg/ml, p=0.029), although IgAN patients, with or without hypertension, presented with higher plasma sFlt-1 levels than controls (p<0.001 & p=0.006), indicating the correlation between sFlt-1 and clinical phenotype of hypertension in IgAN patients. Similar correlation was also found about the phenotype of proteinuria. IgAN patients with proteinuria more than 1g/d, showed significant elevated sFlt-1 to those with less than 1g/d (p=0.025). According to the pathological lesions, IgAN patients were grossly grouped to five groups. Interestingly, we can find the gradually elevated sFlt-1 level from mild to severe pathological group.

Conclusions: Elevated sFlt-1 was associated with hypertension, proteinuria phenotype and pathological severity in IgAN patients, which indicated the involvement of sFlt-1 in IgAN.

Funding: Government Support - Non-U.S.

FR-PO1916

IgA Nephropathy: A Long Term Follow-Up of 132 Cases Doloretta Piras, Patrizia Melis, Maura Conti, Riccardo Cao, Andrea Angioi, Antonello Pani. *Nefrologia e Dialisi, Azienda Ospedaliera Brotzu, Cagliari, Italy.*

Background: Since the beginning of the 1990s our medical practitioners have extensively prescribed angiotensin-converting enzyme inhibitors for patients with mild IgA nephropathy (IgAN) and steroids for those with severe IgAN. The purpose of this retrospective study was to analyze the probability of renal survival in medical practice and to study risk factors for kidney disease progression in a cohort of patients with IgAN.

Methods: We included 132 patients with primary biopsy proven IgAN first diagnosed between 1987 and 2008 in our department. They were observed for an average of 8,4 years (0,14-23,2). 89 patients had been followed up in our centre; 43 were found through databases or telephonic interview. The primary endpoint was the achievement of a glomerular filtration rate (GFR)<15 ml/min or end-stage renal disease (ESRD). Renal survival was estimated using Kaplan Meier plots, logrank test and Cox proportional-hazard models.

Results: At diagnosis, GFR was less than 60 ml/min in 45,1% of patients. The renal survival rate following biopsy at 5th, 10th,15th, and 22nd year was respectively 85% (95% confidence intervals, CI 78-91%), 67% (CI, 58-77%), 50% (CI, 39-63%), and 37%(CI, 20-69%). Univariate analysis showed that patients who had hypertension, proteinuria, and GFR<60 ml/min were associated with poor prognosis. Age, sex, and macroscopic hematuria at initial presentation did not influence prognosis. We created several models of multivariate analysis, each of which included 4 variables (44 events). Hazard ratio of the final model were: 2.6 (CI 1.21-5.6;p=0.014) for patients with hypertension; 1.27 (CI 1.12-1.46;p=0.0002) for each increase of proteinuria of 1 g/day; 0.98 (CI 0.97-0.99;p=0.006) for each increase of eGFR of 1 ml/min.

Conclusions: In medical practice, renal survival rate was poor despite therapy. This is partially explained by lead-time bias: as a matter of fact diagnosis was made when renal function was impaired in nearly half of patients. Moreover, "real" population is more heterogeneous and complex than cohorts enrolled in randomized controlled trial. Patients with renal impairment, hypertension and proteinuria had the highest risk for disease progression.

FR-PO1917

Treatment of Early Immunoglobulin A Nephropathy by Angiotensin Converting Enzyme Inhibitor – A Randomized Controlled Trial Philip K.T. Li,[1,2] Cheuk-Chun Szeto.[1] *[1]Department of Medicine & Therapeutics, Chinese University of Hong Kong, Shatin, Hong Kong; [2]Department of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, Hong Kong.*

Background: The treatment of IgA nephropathy with normal renal function and minimal proteinuria is unknown.

Methods: We randomly assigned 60 patients with IgA nephropathy, proteinuria <0.5 g/day, normal blood pressure and renal function, to ramipril 2.5 mg daily or no treatment. Patients were followed for 5 years for the development of hypertension, proteinuria, or impaired renal function.

Results: The blood pressure of the treatment group was marginally lower than the control group throughout the study period. At 60 months, the event-free survival was similar between the treatment and control group (81.1% and 70.5% respectively, p = 0.3). Similarly, the proteinuria-free survival was 82.9% and 79.3% for the treatment and control groups, respectively (p = 0.6); hypertension-free survival was 86.4% and 79.3% (p = 0.2). None of the patient developed impaired renal function. In general, the study medication was well tolerated, although 2 patients needed to stop prematurely because of cough and dizziness.

Conclusions: For IgA nephropathy patients with minimal proteinuria, blood pressure and normal renal function, treatment with ACE inhibitor does not offer any benefit.

FR-PO1918

Clinical Characteristics and Outcome of Patients with Diffuse Crescentic IgA Nephropathy Yihe Yang, Jicheng Lv, Lijun Liu, Min Chen, Zhao Cui, Sufang Shi, Yuqing Chen, Ming-Hui Zhao, Hong Zhang. *Renal Division, Department of Medicine, Peking University First Hospital, Peking University Institute of Nephrology, Beijing, China.*

Background: Guidelines recommended immunosuppressive therapy for crescentic IgA nephropathy (IgAN). However, the response to such treatment and clinical outcomes were still unclear.

Methods: In this study, 52 patients with diffuse crescentic IgAN(crescent affected>50% glomeruli) were collected and followed up at least 12 months. Crescentic glomerulonephritis due to anti-GBM disease (n=38) and ANCA associated systemic vasculitis (AASV, n=44) served as controls. Logistic regression was used to assess the outcome of all patients with ESKD as the end-point.

Results: Mean initial serum creatinine(SCr) was 413.0±304.7μmol/L and percentage of crescents was 68.5%±15.4%. Cumulative renal survival rate was 59.6%, 53.8% and 31.1% at 1st, 3rd and 5th year. On multivariate Cox analysis, initial SCr was the only independent risk factor of ESKD. Cumulative probability of ESKD at one year by initial SCr fitted an "S" shape curve. Risk of ESKD was relative low when SCr < 360μmol/L (<21.1 %), then grew rapidly with the increase of SCr. While for those with initial Scr >599μmol/L, none recovered from dialysis. This S shape curve was similar to that observed in anti-GBM disease, while it was not observed in AASV.

Conclusions:

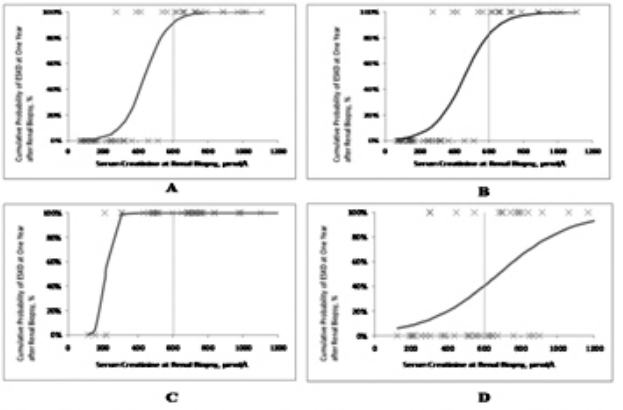

Figure 1: Logistic curve of crescentic IgAN, anti-GBM disease and AASV
Red line: Logistic curve of each disease
Green line: Scr=599 μ mol/L
Blue cross: renal survival at one year after renal biopsy. 0% means the patient did not reach ESKD, 100% means the patient had reached ESKD.
A: Logistic curve of crescentic IgAN fitted an S shape. For patients with Scr<360 μ mol/L, cumulative probability of ESKD was lower than 21.1%. None of the patients with Scr>599 μ mol/L recovered.
B: Similar result was observed in patients with crescentic IgAN received immunosuppressive therapy.
C: Logistic curve of anti-GBM disease fitted an S shape.
D: Logistic curve of AASV. We did not observe such an S shape.

Conclusions: Serum creatinine at presentation was the strongest predictor for ESKD in patients with crescentic IgAN. Patients should receive immunosuppressive therapy as early as initial presentation (SCr < 360μmol/L) at an early stage. Patients with initial renal function severe impairment (Scr >600μmol/L) seldom recover even after aggressive immunosuppressive therapy.

FR-PO1919

The Association of Complement 3 (C3) and Proteinuria in IgA Nephropathy Tsuyoshi Miyagi, Kentaro Kohagura, Yusuke Ohya, Kunitoshi Iseki. *Department of Cardiovascular Medicine, Nephrology and Neurology, University of the Ryukyus, Nishihara-cho, Okinawa, Japan.*

Background: Adipocytokine such as Complement 3 (C3) is associated with metabolic abnormality. However, the roles of C3 in the association with the metabolic marker and proteinuria are not clear. Moreover, its relationship in IgA nephropathy (IgAN) has not been investigated.

Methods: We examined 142 patients with IgAN (54% male) and analyzed clinical and pathological markers among tertile of C3 by sex.

Results: The mean (SD) age were 36.3 (16.3) years, amount of urine protein (UP) 1.1 (1.0) g/gCr, and eGFR 88.5 (12) ml/min/1.73 m^2, C3 88.8 (26) mg/dl. Although the mean age, eGFR, histological change were similar among both sexes, UP was significantly higher in women than in men (1.2 v.s. 0.8 g/gCr, P <0.025). In both sexes, the higher the tertiles of C3 and triglyceride (TG) increased. In the 3rd tertile of C3, TG was significantly higher than that of the 1st tertile and highest proteinuria and percentage of crescent in biopsy specimen was observed in women. Multiple logistic analysis adjusted for age, eGFR, percentage of crescent showed that the 2nd and 3rd tertiles of C3 were significantly associated with higher risk for the presence of above the mean value of UP than that of the lowest tertile only in women. The adjusted odds ratios (95% CI) were 6.0 (1.3 to 28.7) and 7.3 (1.6 to 33.7), respectively.

Conclusions: In conclusion, increased level of C3 was associated with higher UP only in women among IgAN patients. The present study suggested the clinical significance of C3 among patients with IgAN. Reasons of gender difference remained speculative.

FR-PO1920

Henoch-Schonlein Purpura Nephritis in Older Adults Hiroyuki Ueda, Yoichi Miyazaki, Yasunori Utsunomiya, Tetsuya Kawamura, Tatsuo Hosoya. *Division of Kidney and Hypertension, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan.*

Background: Whereas Henoch-Schonlein purpura nephritis (HSPN) has been extensively studied in children, its natural history in adults, especially elderly patients, is not fully understood. We have analyzed 15 individuals with biopsy-proven HSPN ≥ 50 years of age to clarify the clinical characteristics in this group.

Methods: Patients older than 50 years (older adults, OA) at the time of biopsy were compared with those from 18 to 50 year of age (younger adults, YA) in regard to clinical and pathological features, and outcome of treatment. All patients showed typical renal histology consistent with HSP (predominant IgA mesangial deposits) associated with palpable purpura.

Results: Of 23 patients included, 8 were classified in YA (age at diagnosis: 29.2 ± 9.4 years) and 15 in OA (age at diagnosis: 67.3 ± 8.5 years), with an overall follow-up duration of 32.69 ± 28.69 months. OA had a higher prevalence of complications (e.g., diabetes mellitus, hypertension, atrial fibrillation and malignancy) than YA at presentation. OA was likely to develop rapidly progressive glomerulonephritis (33.3%) and nephrotic syndrome (40.0%) at presentation. Histologically, in OA, cellular and fibrocellular crescents (18.33% vs. 6.66%), interstitial fibrosis and tubular atrophy (20.0% vs. 5.0%), and arteriosclerosis (1.28 vs. 0.0) were seen in a great degree than in YA. More than 70% of patients in both groups received corticosteroid. Finally, renal damage improved in most case of both groups at last visit. However, adverse events including severe infection and cardiovascular events occurred more frequently in OA than YA leading to four deaths in OA group.

Conclusions: HSP in OA is characterized by severe renal involvement, and is susceptible to treatment-related adverse events. Adjustment of treatment regimens is necessary in this age group to reduce the risk of adverse events.

FR-PO1921

Henoch-Schönlein Purpura Nephritis: Comparison of Two Therapies (azathioprine vs Mycophenolate) and it´s Effect on the Urinary Excretion of MCP-1 Yolanda Fuentes, Saul Valverde, Ana M. Hernández, Lourdes M. Ortiz, Mara Medeiros. *Hospital Infantil de México Federico Gómez, Mexico.*

Background: Renal expression of MCP-1 promotes infiltration of monocytes and macrophages in Henoch-Schönlein Purpura Nephritis (HSPN). There is no consensus in the treatment of severe forms of HSPN. Azathioprine (AZA) has proved an effective drug. There is litlle experience using mycophenolate (MMF). Primary outcome is to compare the effectivness of theese drugs in the remission of proteinuria, excretion of MCP-1 and regressions of the histologic lesions in children with HSPN.

Methods: Prospective, randomized, open trial in children with renal biopsy proven HSPN. Two treatment groups: I. Oral prednisone + AZA and II. Oral prednisone + MMF. Monthly visits for serum creatinine, proteinuria, liver function test, urine MCP-1 by ELISA. Renal biopsies and immunohistochemistry with CD68 at baseline and 12 months after treatment. SPSS v16 was used for statistical analysis. We present the preliminary results of 22 patients.

Results: Median age of 7 years (4 - 11 years). 15 males. Hematuria and no nephrotic protienuria was present in 11 patients (50%), 10 patients (45%) had nephrotic syndrome. Mean 12 hour proteinuria in all patients were 89.27 ± 94.1 mg/sqmeter/hour, mean urine MCP-1 was 919 ± 1149.94.1 pg/ mL. Twelve patients (54%) had class III lesion and CD68 was positive in 56% of the glomerulus at baseline in renal biopsies. Ten patients received AZA and twelve patients received MMF. After one year of treatment only 8 patients had remission of proteinuria in the AZA group; all patients in the MMF group had remission of proteinuria without significant statistical difference. In both groups urine MCP-1 decreased. In renal biopsies 5 patients in the AZA group presented regression of the initial histologic lesion vs eigth patients in the MMF group without statistical difference between tehm. There was also a reduction in CD68 on glomerulus of 35%.

Conclusions: There are more remissions of proteinuria and in the histologic lesions in MMF grup, the difference is not statistically significant. More patients and prolonged follow up is needed.

FR-PO1922

The Soluble VEGF Receptor sFLT-1 Correlates with Inflammation but Not Glomerular Filtration Rate or Proteinuria in Patients with Acute Glomerulonephritis Anna Bertram, Svjetlana Lovric, Hermann G. Haller, Marion Haubitz, Torsten Kirsch. *Nephrology, Hannover Medical School.*

Background: The soluble vascular endothelial growth facter (VEGF) receptor Fms-like tyrosine kinase-1 (sFLT-1) is known to bind and sequester VEGF in the circulation, thereby antagonizing its regulatory function on endothelial integrity. Elevated levels of sFLT-1 cause endothelial dysfunction and enhanced proteinuria. Furthermore, elevated sFLT-1 levels have been found in patients with chronic kidney disease, where they were correlated with impaired renal function and proteinuria. This study aimed to determine sFLT-1 levels in patients with acute kidney disease and to correlate them with parameters of kidney function and inflammation.

Methods: Plasma levels of sFLT-1 were assessed using a commercially available ELISA in patients with clinically active membranous glomerulonephritis (N = 18), clinically active ANCA associated pauci-immune glomerulonephritis (N = 14), or healthy subjects as a control (N = 18). Serum creatinine, serum C-reactive protein (CRP) and serum cholesterol levels, blood cell counts and proteinuria were examined at the same time. Glomerular filtration rate was estimated using the CKD-EPI formula.

Results: Mean plasma levels of sFLT-1 were significantly elevated in patients with active membranous glomerulonephritis (104.2 ± 5.2 pg/mL, p = 0.028) and ANCA-associated pauci-immune glomerulonephritis (121.7 ± 15.0 pg/mL, p = 0.025) compared to healthy subjects (88.1 ± 4.7 pg/mL). This increase significantly correlated with parameters of inflammation, i.e. white blood cell counts (r = 0.578, p = 0.001) and CRP levels (r = 0.518, p = 0.002). Different to previous findings in chronic kidney disease, sFLT-1 levels did not correlate with glomerular filtration rate (r = -0.244, p = 0.179) and proteinuria (r = 0.122, p = 0,63).

Conclusions: In contrast to chronic kidney disease, sFLT-1 levels do not correlate with renal function in clinically active glomerulonephritis. In these forms of acute kidney disease, sFLT-1 seems to be a marker for inflammatory processes rather than renal function.

FR-PO1923

Impact of a Functional Polymorphism of Vascular Endothelial Growth Factor (VEGF) Gene on Primary Glomerulonephritis Christos Bantis, Peter J. Heering, Nicoletta-Maria Kouri, Maria Stangou, Christina Schwandt, Nicola Kuhr, Lars C. Rump, Katrin Ivens. *Department of Nephrology, Heinrich-Heine University, Düsseldorf, Germany.*

Background: Vascular endothelial growth factor (VEGF)regulates endothelial cell proliferation and participates in interstitial remodelling. In the kidney, VEGF is mainly expressed by podocytes. We evaluated the influence of C-2578A polymorphism, located in the promoter of the VEGF gene, on primary glomerulonephritis.

Methods: We studied 284 patients with biopsy proven primary glomerulonephritis (IgA nephropathy: n=143, focal segmental glomerulosclerosis: n=82, membranous glomerulonephritis: n=59) followed up for 7.0 ± 5.7 years. According to the slope of reciprocal serum creatinine (≥or< -0.1 dl * mg-1 * year-1) group A (slow progressors, n=192) and group B (fast progressors, n=92) were defined. One hundred volunteers were analysed as controls. The biopsies of 156 patients were analysed by the same pathologist. VEGF polymorphism was determined by PCR. VEGF serum levels were determined by ELISA in 105 patients with chronic kidney disease.

Results: VEGF serum levels correlated to the C-2578A genotype: CC/CA: 396 ± 251, AA: 558 ± 425 pg/ml (p=0.018). The genotype frequencies were similar in patients and controls (ns). The initial renal function correlated to the degree of glomerular sclerosis (r=0.520, p<0.001), tubulointerstitial fibrosis (r=0.557, p<0.001) and arteriosclerosis (r=0.469, p<0.001). The percentage of sclerosed glomeruli was higher in group B (44.0 ± 31.1% vs 32.9 ± 28.7% in group A, p=0.051) as was the degree of tubulointerstitial fibrosis (34.1 ± 26.3% vs 24.7 ± 20.2% in group A, p=0.043). There was no significant difference regarding the histological parameters between patients with different genotypes (ns). VEGF gene polymorphism influenced the progression as shown by the genotype distribution in group A (CC/CA: 70.3%, AA: 29.7%) compared to group B (CC/CA: 81.5%, AA: 18.5%, p=0.05). There was also a significant difference in the actual rate of progression (CC/CA genotypes: -0.160 ± 0.417, AA: -0.085 ± 0.132 dl*mg-1 *year-1; p=0.021).

Conclusions: The functional VEGF C-2578A polymorphism is a progression marker in primary glomerulonephritis.

FR-PO1924

Acute Manifestation and 1-Year Follow-Up of a Big Cohort of Patients with Atypical Hemolytic Uremic Syndrome (aHUS) Magdalena Riedl,[1] Johannes Hofer,[1] Alejandra Rosales,[1] Reinhard Würzner,[1] Therese C. Jungraithmayr.[1,2] *[1]Pediatrics, Medical University, Innsbruck, Austria; [2]Gemeinschaft für Pädiatrische Nephrologie (GPN).*

Background: The atypical HUS is a form of thrombotic microangiopathy. Dysfunction of complement proteins are associated with the pathogenesis of the disease. Long-term prognosis is poor.

Methods: Since 2002 the HUSnet Registry investigates the role of complement in aHUS and collects clinical data on long-term outcome. Here we present data of 116 aHUS patients at diagnosis and the 1 year follow-up of 72 patients.

Results: During acute phase the hemoglobin value dropped to 6.03±1.4 mg/dl, the platelet count to 51.3±43.8x109 and mean creatinine was elevated to 4.8±3.5mg/dl. Oliguria/anuria was seen in 59% (mean duration: 13±15 days) of patients. Dialysis was performed in 66% (mean duration: 26±44 days) of patients, of which 30% required chronic dialysis. Arterial hypertension was seen in 79%. Other organ involvement was reported as follows: GI (44%), CNS (28%), cardiac (12%) and pancreas (8%). Treatment of first episode included plasma infusions (PI, 42%) and plasma exchange (PE, 50%). PT was initiated in patients with a higher rate of CNS involvement (p<0.05, X^2) and a tendency towards an increased need for dialysis (p=0.057, X^2).HUS recurrences were reported in 68% (mean 2.6±2.2) of the patients. The first recurrence occurred in median after 4.5 months (range 1-26 months).

One year after diagnosis arterial hypertension was seen in 65%, dialysis in 33% and chronic renal insufficiency in 13% of patients. 51% of the patients had a normal renal function. Two patients died within the first year, due to cardiopulmonary insufficiency. CNS sequel was reported in 1 patient. Patients treated with plasma therapy (PT) showed comparable outcomes to patients without PT after 1 year as measured by the incidence of hypertension, kidney function, CNS sequel and recurrences.

Conclusions: In the acute phase aHUS presents as a multisystem disorder, but in the long term impaired renal function is the main concern. PT is considered as first line treatment, it was especially used in severe cases. Outcome after 1 year was comparable between patients with vs without PT.

FR-PO1925

Transcianocobalamin C Deficiency: A Common Cause of Neonatal Thrombotic Mycroangiopathy Gianluigi Ardissino,[1] Francesca Tel,[1] Sara Testa,[1] Fabio Paglialonga,[1] Cristina Felice Civitillo,[1] Francesca Menni,[2] Marta Cerutti,[2] Gabriella Chiarelli,[2] Lorenza Pugni,[3] Fabio Mosca,[3] Alice Monzani.[1] *[1]Pediatric Nephrology Unit, Fondazione Ca'Granda Osp. Maggiore Policlinico, Milano, Italy; [2]Dept. of Pediatrics, Fondazione Ca' Granda Osp. Maggiore Policlinico, Milano, Italy; [3]Neonatal Intensive Care Unit, Fondazione Ca' Granda Osp. Maggiore Policlinico, Milano, Italy.*

Background: Thrombotic mycroangiopathy (TMA) in neonates is extremely rare but when it occurs, transcianocobalamin C deficiency should be suspected.

Methods: We reported 4 cases admitted in our hospital over the past five months.

Results: In all cases symptoms started very early in life with feeding difficulties, failure to thrive and severe hypotonia. In one case left ventricular dilatation had been detected antenatally.

Hereafter, we report the main clinical characteristics of patients at onset.

Patients' characteristics

	SP	MP	DC	MD
Age (days)	21	30	21	19
Weight (Kg)	2.79	3.38	3.30	3.49
PLT (10^3/mm^3)	142	76	120	32
Hb (g/dl)	6.5	7.3	7.8	9.0
LDH (IU/l)	768	911	1101	818
Haptoglobin (mg/dl)	<20	<20	<20	<20
Homocysteine (µmol/l)	17	36	28	>50
sCr (mg/dl)	0.7	0.4	0.6	0.3
uPr/uCr	2.0	10.3	3.8	n.a.
uHb	++++	++	++	+++

uPr/uCr: urinary protein over creatinine ratio - n.a.: not available

The finding of hypomethioninemia, homocystinuria and methylmalonic aciduria led to the diagnosis of methylmalonic acidemia with homocystinuria. Intravenous hydroxocobalamin, oral betain and folic acid were immediately started. During the course of the disease, the first 3 patients developed AKI stage F pRIFLE criteria). Remission of TMA and the recovery of kidney failure took place within next 10 days. Presently, at a mean age of 6 months, all four children are alive and well.

Conclusions: The described "cluster" of TMA due to transcianocobalamin C deficiency, points out that this disease might be a lot more common than diagnosed. Whenever neonatal TMA is detected homocysteinemia should be determined and the disease ruled out. We expect that this report will contribute to an increased awareness regarding this disease among pediatric nephrologists.

FR-PO1926

Mass Spectrometry as a Novel Method for Detection of Podocyturia in Preeclampsia Iasmina Craici,[1] Steven Wagner,[1] Stephen T. Turner,[1] Joseph P. Grande,[2] Vesna D. Garovic.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN.*

Background: Increasing evidence suggests that podocyturia may serve as both a reliable diagnostic tool for preeclampsia and as a marker of active disease in proteinuric renal diseases. Reservations exist regarding both the research and clinical utilities of the current method to detect podocyturia, mainly due to its technical complexity, time commitment, and the level of expertise required for interpretation of the results.

Methods: The aim of this study was to develop a new technique for the identification of urinary podocytes based on the detection of podocyte specific tryptic peptides by liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS), which will provide an operator-independent and highly reproducible method. Urine samples collected within 24 hours prior to delivery were centrifuged. One half of the sediment was cultured for 24-hours and then stained with podocin antibody followed by a FITC-labeled secondary antibody to identify viable podocytes. The second half of the pellet was solubilized, digested and analyzed by LC-MS/MS using an internal standard.

Results: We have recruited 12 patients with preeclampsia and 6 patients with HELLP. The diagnosis of preeclampsia was confirmed by the presence of hypertension (>140/90 mm Hg) and proteinuria >0.3 g/24 hour. The diagnosis of HELLP was confirmed based on the accepted clinical criteria of Hemolysis, Elevated Liver enzymes, and Low Platelet count. The presence of podocytes was confirmed in all patients by the podocyte culture method. With the LC-MS/MS technology, we documented the presence of a podocin-specific tryptic peptide in all samples.

Conclusions: LC-MS/MS technology may facilitate the use of podocyturia, as confirmed by the presence of podocyte-specific proteins in the urine, both as a diagnostic test and as a research tool in studying renal injury in human disease and animal models of preeclampsia. In addition, if validated in preeclamptic patients, this technology may be used in future studies to assess both disease activity and response to treatment in a variety of proteinuric renal diseases.

FR-PO1927

Renal Outcome in Patients Presenting with Dialysis Dependent ANCA Associated Vasculitis Treated with Pulsed Intravenous Cyclophosphamide
Ruth J. Pepper,[1] Dimitrios Chanouzas,[2] Alina L. Casian,[3] Michael Walsh,[4] Ruth M. Tarzi,[5] Mark Little,[1] Charles D. Pusey,[5] Lorraine Harper,[2] Alan D. Salama.[1]
[1]UCL; [2]Birmingham University Hospital; [3]Addenbrookes Hospital Cambridge; [4]McMaster; [5]Imperial College London.

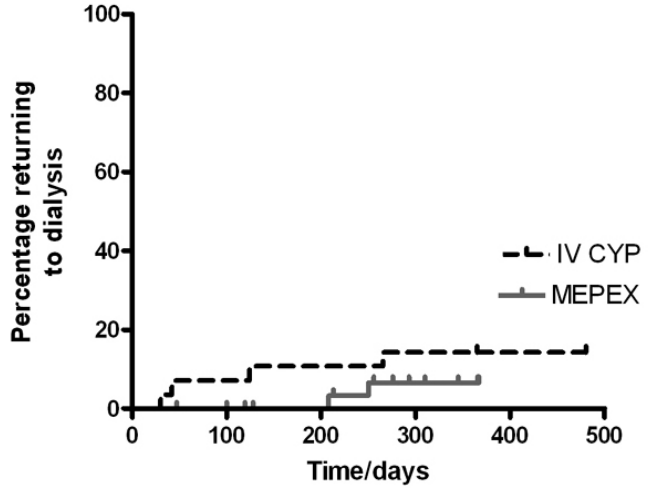
Background: Oral cyclophosphamide (CYP) is the standard of care for patients with severe renal failure (SCr>500 µmol/l) secondary to ANCA associated vasculitis (AAV), while pulsed IV CYP is beneficial for those with less severe disease and induces less toxicity.

Methods: We retrospectively analysed patients with AAV requiring dialysis, who presented between 2005-10 at 2 renal units. All patients were treated with plasma exchange, steroids and IV CYP. We assessed the rate of dialysis independence, as well as the adverse effects of CYP.

Results: Forty-one patients included, 27 male. Mean age 59.7 years. 20 patients MPO-ANCA, 19 PR3-ANCA, 1 ANCA negative, 1 positive for both. 13 patients had concurrent pulmonary haemorrhage. Median number of plasma exchanges 7 (range 2-14); median number of CYP doses 6 (range 1-10) total mean dose 4.75g. Median number of HD days 14 days (range 3-120 days).

12 patients remained dialysis dependent from the time of presentation, including 3 patients who died. 29 patients initially recovered function. 4 patients returned to HD, median time 83 days (range 30 to 265 days). 12 patients had leucopenia, transient in 7. 4 patients relapsed in the 1st 12 months.

At 3 months, 3 dead, 26 patients HD free with 12 on HD (63.4% alive and HD free). At 1 year, 59% patients alive and HD free. This is comparable with the MEPEX study which used oral CYP, in which 52% of patients reaching 1 year were alive and HD free (p=0.58, log rank test).



Conclusions: IV CYP is an effective alternative to oral CYP in dialysis dependent AAV,and results in an equivalent clinical response .

A Candidate Gene Approach to Genetic Contributors to Development of IgA Nephropathy
Ryohei Yamamoto,[1] Yasuyuki Nagasawa,[1] Tatsuya Shoji,[2] Tetsuya Kaneko,[2] Kazunori Inoue,[1] Hirotsugu Iwatani,[1] Enyu Imai,[1] Atsushi Yamauchi,[3] Yoshiharu Tsubakihara,[2] Hiromi Rakugi,[1] Yoshitaka Isaka.[1]
[1]Department of Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Department of Kidney Disease and Hypertension, Osaka General Medical Center, Osaka, Japan; [3]Department of Nephrology, Osaka Rosai Hospital, Sakai, Osaka, Japan.

Background: Genetic factors contributing to development of IgA nephropathy remains to be elucidated.

Methods: Present multicenter cross-sectional case-control study measured genotype frequencies of 65 atherosclerotic disease-related gene polymorphisms in 230 Japanese patients with IgA nephropathy and 262 apparently healthy volunteers with estimated glomerular filtration rate (eGFR) ≥60 mL/min/1.73m^2 and negative or trace for proteinuria and hematuria by dipstick test (non-chronic kidney disease (CKD) participants). Clinical characteristics at kidney biopsy of patients with IgA nephropathy and those at the study recruitment of non-CKD participants were included as covariates in multivariate logistic regression models.

Results: Among 31 gene polymorphisms with ≥5% of minor genotype in non-CKD participants, methionine synthase *MTR* A2756G (D919G) was significantly associated with IgA nephropathy using χ^2 test even after controlling for family-wise error rate by the method of Bonferroni (P = 0.044). A multivariate non-conditional logistic regression model identified *MTR* A2756G as a significant contributor of IgA nephropathy (2756AG and GG vs. AA, odds ratio 0.42 [95%CI 0.25 - 0.69] and 0.21 [0.06 - 0.68], $P_{trend} < 0.001$). After each patient with IgA nephropathy was randomly matched to a non-CKD participant on age (±5 years), gender, mean arterial pressure (±5 mmHg), and eGFR (±5 mL/min/1.73m^2), a multivariate conditional logistic regression model also verified their significant association (0.42 [0.18 - 1.00] and 0.09 [0.01 - 0.73], $P_{trend} = 0.004$). *MTR* A2756G was not associated with slope of eGFR (mL/min/1.73m^2/year) in 230 patients with IgA nephropathy.

Conclusions: Methionine synthase *MTR* A2756G was associated with development, not progression, of IgA nephropathy.

FR-PO1929

Characteristics of Patients with Systemic Lupus Erythematosus Admitted to the Intensive Care Unit
Partha Das, Scott R. Henderson, Maria Ostermann.
Department of Nephrology and Transplantation, Guy's and St Thomas' Hospitals NHS Foundation Trust, London, United Kingdom.

Background: Systemic Lupus Erythematosus (SLE) is a multisystem inflammatory disorder associated with significant morbidity and mortality. Affected patients may become critically ill as a complication of disease or treatment. Our aim was to describe the epidemiology and characteristics of SLE patients admitted to the Intensive Care Unit (ICU) in a tertiary teaching hospital.

Methods: Retrospective review of the medical notes of all SLE patients admitted to ICU between 2008-2011 detailing emographics, disease duration and previous treatments alongside reason for ICU admission, APACHE and SOFA scores, level of organ support, immunosuppression and patient mortality.

Results: 25 patients were admitted (88% female; mean age 47±16.8 years). 11 patients were Caucasian, 10 were black and 4 were from other ethnic groups. The most common reasons for admission to ICU were infection (48%), respiratory failure (32%) and renal failure (24%). 64% of patients had been treated with immunosuppression prior to admission (steroids 64%, mycophenolate mofetil 20%) in the preceding 3 months. 44% of patients needed mechanical ventilation, 56% had renal replacement therapy and 76% were treated with antimicrobial therapy. Mean length of stay in ICU was 8.8 days ± 10.1 with a mean hospital length of stay of 30.7 days ± 26.3. 16% died in ICU due to overwhelming sepsis. Among ICU survivors, 1 year survival was 100%.

Conclusions: Infection was the most common reason for admission to ICU. The majority of this group had already been on immunosuppression. Despite a high need for organ support and health care resources, ICU mortality was 16%. The most common cause of death was overwhelming sepsis. 1 year outcome of ICU survivors was excellent.

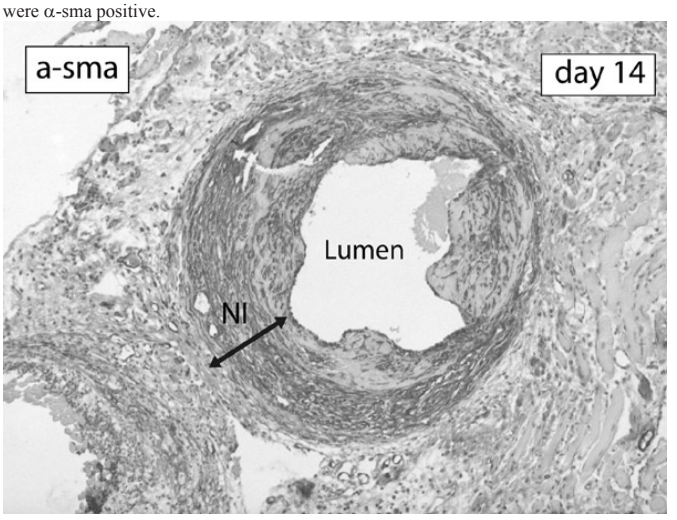
FR-PO1930

A Novel Murine Model of Arteriovenous Fistula Failure
ChunYu Wong,[1] Margreet De Vries,[2] Anton Jan Van Zonneveld,[1] Ton J. Rabelink,[1] Paul Quax,[2] Joris I. Rotmans.[1] *[1]Nephrology, LUMC, Leiden, Netherlands; [2]Surgery, LUMC, Leiden, Netherlands.*

Background: The arteriovenous fistula (AVF) still suffers from a high number of failures caused by insufficient remodeling and neointimal hyperplasia. We developed a mouse model of AVF-failure to unravel the underlying pathophysiology. Since the hemodynamic profile including flow turbulence is an important determinant for the vascular response to fistula insertion, we configured the AVF in an end-to-side manner similar to what is frequently performed in humans.

Methods: AVFs were created by connecting the end of the external jugular vein to the side of the common carotid artery using interrupted 10.0 sutures. Animals were sacrificed at 14 or 28 days. AVFs were processed for histological analysis and sections were stained for hematoxillin, Phloxin and Saffron (HPS), Weigert's Elastin staining and α-smooth muscle actin (α-sma).

Results: At day 14 and 28 after surgery, vessel size increased 20-fold and 32-fold respectively when compared to control veins. Progressive venous neointima formation was observed. At day 14, a luminal stenosis of 65% was observed and at 28 days this number increased to 75%. The majority of the cells that were present in the neointima were α-sma positive.



α-sma staining of venous outflowtract; [NI] neointima

Conclusions: The AVF-model, which resembles the AVF configuration most frequently used in humans, shows that despite substantial outward remodeling, progressive stenotic lesions develop as a result of rapid neointimal hyperplasia in the venous outflow tract. Similar to failed human AVFs, the neointimal hyperplasia is mainly composed of α -sma positive cells. These lesions make this model suitable for intervention studies using e.g. genetically modified mice. We conclude that this murine AVF-model is a good addition to the AVF animal model arsenal.

FR-PO1931

The Effect of Temporal Variation in Wall Shear Stress on the Remodeling of Arteriovenous Fistulae Ehsan Rajabi-Jaghargh,[1] Prabir Roy-Chaudhury,[2] Yang Wang,[2] Kyuran Ann Choe,[2] Paul Succop,[2] Rupak Banerjee.[1] *[1]CEAS-Schl Dynamic Systems, University of Cincinnati, OH; [2]Dialysis Vascular Access Research Group, Division of Nephrology, University of Cincinnati, OH.*

Background: Non-maturation of arteriovenous fistulae (AVF) is in many ways the "Achilles Heel" of hemodialysis. The surgical configuration of the AVF and the subsequent wall shear stress (WSS) are key players in the remodeling of the AVF. This study aimed to investigate the temporal effect of WSS on the maturation of AVFs created in two different configurations.

Methods: AVFs were created between the femoral artery and vein of three pigs in a curved (n=3) and straight (n=3) configuration. Reconstructed geometry of the AVF obtained from CT-scans and flow data from Doppler ultrasound were utilized to numerically evaluate WSS at 2D (D: days), 7D, and 28D post-surgery. Time dependent WSS-area data was regressed using a random effects model: Area = $\beta 0 + \beta 1 time + \beta 2 \Delta WSS/\Delta time$, where βi and Δ were the regression coefficients and the gradient, respectively. A p-value < 0.05 indicated statistical significance.

Results: For the curved AVF, the slope of temporal gradient of WSS (-0.019) had a statistically significant effect (p = 0.022) on the dilation of the vein, while it was not significant for the maturation of the straight AVF (p = 0.53). Also, time had a positive effect ($\beta 1 = 0.337$) on the maturation of the curved AVF (p < 0.05), while it had a negative effect ($\beta 1 = -0.071$) for the straight AVF (p < 0.05).

Conclusions: Our results document a temporal linkage between an increase in diameter and a decrease in WSS in the curved AVF, with an opposite interaction in the straight AVF. Creation of an AVF in a surgical configuration which results in a favorable linkage between WSS and diameter could result in a significant improvement in AVF patency rates.

	Straight Fistula		Curved Fistula

Treatment with Recombinant Human Type 1 Pancreatic Elastase (PRT-201) Does Not Alter the Safety of Angioplasty in a Porcine Arteriovenous Graft Model Dirk M. Hentschel,[1] Steven K. Burke.[2] *[1]Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Proteon Therapeutics, Waltham, MA.*

Background: PRT-201 is being developed as a treatment for newly created arteriovenous grafts (AVGs) and fistulas to promote access patency. It is not known if degrading elastin fibers in the access outflow vein impacts the safety of subsequent angioplasty procedures.

Methods: Eleven male Yorkshire swine underwent bilateral femoral artery to vein ePTFE grafts insertion (Bard Carboflo 4-6 mm taper) followed by application of PRT-201 6 mg (n=11) or vehicle (n=11) to the external surface of the venous anastomosis and outflow vein. Acute effects were measured using digital photography. At 28 days, AVGs underwent angiography, measurement of graft blood flow (Transonic ReoCath), and angioplasty (Bard Conquest 8mm x 4cm). The animals were euthanized and anastomoses/veins were excised for histology.

Results: Two animals were euthanized early: one due to intestinal torsion, the other due to bilateral AVG occlusion. PRT-201 treated vessels (n=11) increased in diameter by 12 ±14% (p=0.01). In the nine animals surviving to Day 28, 17 of the 18 AVGs had some anastomotic and venous stenosis, one was occluded. Stenosis was > 50% for 5 of 8 PRT-201 and 6 of 9 of vehicle. In this study there were no significant differences in average and minimum lumen diameters and blood flow. Angioplasty was successful in all cases resulting in significant increases in lumen diameter and blood flow. The pressures required to efface stenoses were similar between PRT-201 (10.5±2.6 atm) and vehicle (10.2±3.1 atm). No venous ruptures were documented even after a final inflation of 20atm held for 30sec. Histopathology of the excised veins/anastomoses demonstrated elastin degradation by PRT-201 and a trend to increased mean vein (+18%) and lumen (+26%) areas and decreased mean neointimal area (-25%) for PRT-201 vs. vehicle. There was no apparent adverse effect of PRT-201 with respect to fibrosis, endothelialization, inflammation, and wound healing.

Conclusions: In comparison to vehicle, PRT-201 applied to the venous anastomosis and outflow vein immediately following AVG creation did not impair the safety of subsequent angioplasty.

Prospective Clinical Investigation of Vascular Structural and Functional Changes Following Hemodialysis Vascular Access Surgery Andrea Remuzzi,[1,2] Anna Caroli,[1] Marko Malovrh,[5] Katia Passera,[1] Luca Antiga,[1] Stefano Rota,[3] Giuseppe Remuzzi,[1,3] Aron Bode,[4] Jan Tordoir.[4] *[1]Mario Negri Institute, Bergamo; [2]Univ. of Bergamo, Italy; [3]Ospedali Riuniti di Bergamo, Italy; [4]Maastricht Univ. Hospital, Netherlands; [5]Univ. Medical Center Liubljana, Slovenia.*

Background: Vascular access (VA) complications represent a major cause of morbidity and hospitalization in hemodialysis (HD) patients and are the major limitation of HD treatment. The ARCH project (EU FP7-ICT) aims to computational modelling tools for surgical planning of VA. These tools are developed using ultrasound (US) measurements and multi-scale computational model of blood flow (BF). Given the high inter-subject variability, the modelling tools must be patient-specific and need calibration and validation using clinical data.

Methods: To this purpose, a prospective observational clinical study has been conducted to collect anatomic, physiologic and clinical data to quantify structural-functional relation between patient vasculature and and its changes after surgery. 93 consecutive patients with ESRD awaiting VA creation have been enrolled in the study (63/30 M/F, age 62Y [18-85]). Pre- and post-operative clinical data and US measurements have been collected for a two years period.

Results: Mean artery diameter in distal (radial artery, RA) and proximal (brachial artery BA) VA and BF before (V0) and after surgery (V1-V4) are as follows.

Visit	time	N	RA Diam mm	RA BF ml/min	N	BA Diam mm	BA BF ml/min
V0	0	52	2.7±0.6	39±33	37	4.2±0.8	89±45
V1	1d	42	3.6±0.9	549±418	22	4.6±0.8	890±554
V2	1w	41	4.0±1.0	676±430	32	4.7±0.7	1288±606
V3	6w	41	4.4±1.1	933±472	28	5.0±0.8	1760±629
V4	>8w	32	4.5±1.1	1057±437	23	5.4±1.0	2229±985

Data are mean+SD. All patients in V4 were on HD treatment.

A large variability in both arterial size and BF was observed during VA maturation. As expected, larger changes in artery diameter were observed in distal than in proximal VA while BF increase was higher in proximal as compared to distal VA.

Conclusions: The clinical data set obtained is currently used to calibrate the model and to simulate BF before and after surgery to investigate major determinants of BF in VA and to predict flow related VA complications.

FR-PO1934

Computational Model for Simulation of Vascular Adaptation Following Hemodialysis Vascular Access Surgery Andrea Remuzzi,[1,2] Simone Manini,[1] Katia Passera,[1] Lorenzo Botti,[1] Wouter Huberts,[3] Luca Antiga.[1] *[1]Mario Negri Institute, Bergamo, Italy; [2]Univ. of Bergamo, Italy; [3]Eindhoven Univ. of Technology, Netherlands.*

Background: Up to 50% of surgical procedures for autologous vascular access (VA) in hemodialysis (HD) patients result in inadequate increase in blood flow volume (BFV). The required increase in BFV after arteriovenous anastomosis of native vessels depends on the ability of the vasculature to dilate and remodel. These changes ultimately determine VA maturation and subsequent use for HD treatment. We have previously reported changes in radial artery (RA) diameter and BFV over time after end-to-end distal fistula creation in 28 ESRD patients. The aim of the present study was to use these data to develop and validate a 1-D computational model of arterial and venous circulation able to simulate changes in vessel diameter in response to surgically induced increase in BFV.

Methods: Blood vessel dimensions and elastic properties have been assumed according to a set of rules defined for generation of patient-specific vascular network models that are dependent on gender, age and body surface area. Arterial and venous diameters, as well as BFV, have been calculated before and after VA creation by assuming constant peak wall shear stress in the arm vasculature.

Results: The best comparison between experimental measurements and computed results of RA diameter and BFV during VA maturation was obtained for a reference arterial peak wall shear stress of 40 dynes/cm2. These results are as follows.

	Time (days)	t=0	t=10	t=40	t=100
RA diameter (mm)	Measurements	2.4	3.7	4.1	4.4
	Computed results	2.5	3.1	4.0	4.3
RA blood flow (ml/min)	Measurements	18	329	476	584
	Computed results	18	380	480	578

t = 0, before surgery. Values are mean of 28 patients.

These results show that the computational model has the ability to accurately simulate flow induced vascular dilatation and the BFV increase in arterial and venous segments that develop with time after VA surgery.

Conclusions: The use of this modelling approach to simulate vascular changes responsible for VA maturation may allow more accurate planning of vascular surgery with the aim to ameliorate surgery outcomes and to increase the rate of VA maturation.

Hemodialysis Treatment Factors Associated with Outcomes of Arteriovenous Fistula: International Comparison between Facilities Using Data from the Dialysis Outcomes and Practice Patterns Study (DOPPS) Manabu Asano,[1] Jyothi R. Thumma,[2] Kenichi Oguchi,[1] Tadao Akizawa,[3] Ronald L. Pisoni,[2] Takashi Akiba,[4] Kiyoshi Kurokawa,[5] Akira Saito.[6] *[1]Renal Unit, Ikegami General Hospital, Tokyo, Japan; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Division of Nephrology, Showa University, Tokyo, Japan; [4]Tokyo Women's Medical University, Tokyo, Japan; [5]National Graduate Institute for Policy Studies, Tokyo, Japan; [6]Tokai University School of Medicine, Isehara, Japan.*

Background: Various factors have been supposed to associate with the fate of vascular access. Our objective was to clarify the relationship between the dialysis treatment factors and AVF patency across the three regions of Japan, North America (North Am) and Europe/Australia/New Zealand (EUR/ANZ).

Methods: Analyses included 1,288 incident hemodialysis patients on dialysis [[] le[]]7 days and using an AVF at DOPPS II and III entry and 1,046 prevalent patients (on dialysis > 7 days at study entry) who used a new AVF created during study observation for hemodialysis and for which the date of first AVF use was reported. The association of AVF survival with predictable factors (patient characteristics and treatment factors) were compared by the three regions using Cox regression models.

Results: A meaningful relationship appeared to exist between higher rates of primary/final AVF failure and prior catheter use (primary: HR 1.27, 95%CI 1.03-1.57, final: HR 1.38, 95%CI 0.98-1.92). Facilities having higher median blood flow rate (mBFR) were seen to consistently display substantially higher rates of final AVF failure (HR=1.22, 95% CI 1.06-1.40). mBFR varied greatly by region: North Am (mBFR=400 mL/min, IQR=360-448), EUR/ANZ (mBFR=300 mL/min, IQR=300-343), Japan (mBFR= 200 mL/min, IQR=180-200). Analysis not adjusted for mBFR showed higher rate of primary/final AVF failure in North Am (primary: HR 2.14, 95%CI 1.47-3.12, final: HR 2.76, 95%CI 1.34-5.69) and EUR/ANZ (primary: HR 1.75, 95%CI 1.27-2.41, final: HR 2.13, 95%CI 1.13-4.03) relative to Japan.

Conclusions: Of all considered factors, first catheter use and median blood flow rate during hemodialysis only had a significant association with primary/final AVF failure.

FR-PO1936

Causes and Consequences of Arteriovenous Access Failure in Hemodialysis Patients: A Prospective Cohort Study Gurbey Ocak,[1] Joris I. Rotmans,[2] Carla Y. Vossen,[1] Frits R. Rosendaal,[1,3] Raymond T. Krediet,[4] Elisabeth W. Boeschoten,[5] Friedo W. Dekker,[1] Marion Verduijn.[1] *[1]Department of Clinical Epidemiology, Leiden University Medical Center; [2]Department of Nephrology, Leiden University Medical Center; [3]Department of Thrombosis and Haemostasis, Leiden University Medical Center; [4]Department of Nephrology, Academic Medical Center; [5]Hans Mak Institute Naarden, Netherlands.*

Background: Arteriovenous access dysfunction is an important cause of morbidity in patients receiving hemodialysis treatment. The aim of this study was to investigate causes and consequences of loss of primary functional patency within two years in a large Dutch cohort of incident hemodialysis patients.

Methods: We followed 919 incident hemodialysis patients with a functional arteriovenous access, and calculated hazard ratios (HRs) for putative risk factors of primary functional patency using Cox regression. Furthermore, HRs were calculated using time-dependent Cox regression to study the effect of primary functional patency loss on two-year all-cause, cardiovascular (CV), and non-CV mortality.

Results: Age ≥65 years (HR 2.2; 95%CI 1.8-2.8), female sex (HR 1.3; 95% CI 1.1-1.6), CV disease (HR 1.9; 95% CI 1.5-2.4), diabetes mellitus (HR 1.7; 95% CI 1.3-2.1), prior catheter use (HR 1.6; 95% CI 1.3-1.9), albumin (lowest versus highest tertile, HR 1.4; 95% CI 1.1-1.8), high-sensitivity C-reactive protein (hsCRP) (highest versus lowest tertile, HR 1.7; 95% CI 1.2-2.6), and fetuin-A (lowest versus highest tertile HR 2.6; 95% CI 1.7-4.1) were associated with primary functional patency loss after adjustment. Primary functional patency loss was associated with a 2.3-fold (95% CI 1.5-3.5) increased two-year all-cause mortality risk, an 1.6-fold (95% CI 0.9-3.0) increased two-year CV mortality risk, and a 3.1-fold (95% CI 1.7-5.8) two-year non-CV mortality risk after adjustment.

Conclusions: Increased age, female sex, cardiovascular disease, diabetes mellitus, prior catheter use, albumin, hsCRP, and fetuin-A were associated with primary functional patency loss. Primary functional patency loss appears a serious condition with a marked effect on survival.

FR-PO1937

Hypercalcemia as a Risk Factor for Vascular Access Failure in Chronic Hemodialysis Patients Myung Jin Choi,[1] Jong-Woo Yoon,[1] Ja-Ryong Koo,[1] Jung-Woo Noh,[1] Eun Young No,[2] Hyun Ok Kim,[2] Man Gyu Lee.[2] *[1]Department of Internal Medicine, Hallym Research Institute, Collage of Medicine, Hallym University, Chuncheon, Republic of Korea; [2]Dialysis Center, Chuncheon Sacred Heart Hospital, Chuncheon, Republic of Korea.*

Background: Chronic kidney disease-mineral bone disorder (CKD-MBD) is known to be an important risk factor for cardiovascular morbidity and mortality. However, it is not known whether vascular access outcomes in hemodialysis (HD) patients are associated with CKD-MBD. We evaluated the relationship between CKD-MBD and vascular access failure in HD patients.

Methods: Sixty patients (age 57 ± 11 years, male 55%, diabetes 43%, arteriovenous fistula 88%, HD duration 59 ± 50 months) who underwent HD for at least 3 months were enrolled. Vascular access failure was defined as thrombosis or hemodynamically significant stenosis requiring intervention. During 2 year follow-up period, the effects of each components of CKD-MBD (mean value of monthly measured corrected calcium, phosphorus and quaterly measured intact parathyroid hormone) on vascular access failure were retrospectively evaluated using Cox proportional hazards regression analysis.

Results: During follow-up periods, the incidence of vascular access failure was 46.7 % (n=28). Among components of CKD-MBD, only corrected calcium level was a significant risk factor for vascular access failure in univariate Cox analysis. Lower serum albumin, hemoglobin and higher predialysis systolic blood pressure (SBP) were also significant risk factors in univariate analysis. After adjustment for dialysis access type, diabetes, aspirin ingestion, serum albumin and predialysis SBP, corrected calcium (hazard ratio, 1.96; 95% confidence interval, 1.038-3.703; p = 0.038) and hemoglobin (hazard ratio, 0.472; 95% confidence interval, 0.230-0.967; p = 0.040) were significant independent risks of the development of vascular access failure.

Conclusions: Higher level of serum calcium was associated with higher incidence of vascular access failure. Calcium loading in CKD-MBD could be a major risk factor of vascular access failure in HD patients.

FR-PO1938

Isometric Handgrip Exercises Improve Success Rates in Arteriovenous Fistula (AVF) Placement in Unsuitable Candidates Alice L. Uy,[1] Christina M. Yuan,[1] Rahul Jindal,[2] Frank P. Hurst.[1] *[1]Medicine (Nephrology), Walter Reed Army Medical Center, Washington, DC; [2]Surgery (Organ Transplant), Walter Reed Army Medical Center, Washington, DC.*

Background: Incident AVF rates remain low. AVF placement is often not attempted because of small vein diameter. We postulated that isometric handgrip exercises would increase forearm vein diameter and allow successful AVF creation in patients who would otherwise receive a synthetic graft.

Methods: Adult subjects without prior vascular access (eGFR< 25; cephalic vein < 2.5mm) were prospectively enrolled. They performed daily handgrip exercises in the preferred access arm (EA), with the non-exercised arm (NEA) as control. Adherence was assessed by exercise logs and grip strength. Vein diameter was measured at baseline, 4 and 8 weeks by duplex ultrasound by the same technician. Primary endpoint was the mean increase in vein diameter (EA vs. NEA). Secondary endpoints were vein diameter increase from baseline, successful AVF placement and maturation.

Results: 16 subjects (7 male and 9 female, median age 77) were enrolled. At present, 11 completed the study. EA grip strength increased significantly. For the primary endpoint, mean vein increase in the EA v. NEA in the distal and proximal veins were 0.31mm v. 0.69mm (p=0.235) and 0.44mm v. 0.66mm (p=0.614) respectively, with a greater increase in NEA. For the secondary endpoints, at 0 to 4 weeks all vein diameters increased significantly. Distal EA veins increased from 1.57mm to 2.14mm and proximal veins increased from 2.23mm to 2.91mm. In the NEA, distal veins increased from 1.58mm to 2.42mm and proximal veins increased from 2.24mm to 3.09mm. Over 90% (10 of 11) of patients achieved at least one vein diameter > 2.5mm at 4 weeks. 3 patients received a successful placement of AVF.

Conclusions: Our data suggested that isometric handgrip exercises resulted in significant increase of cephalic vein diameter with 4 weeks of exercise, in both EA and NEA and may allow AVF creation in those previously not suitable for primary AVF.

The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, the Department of Defense, or the United States government.

FR-PO1939

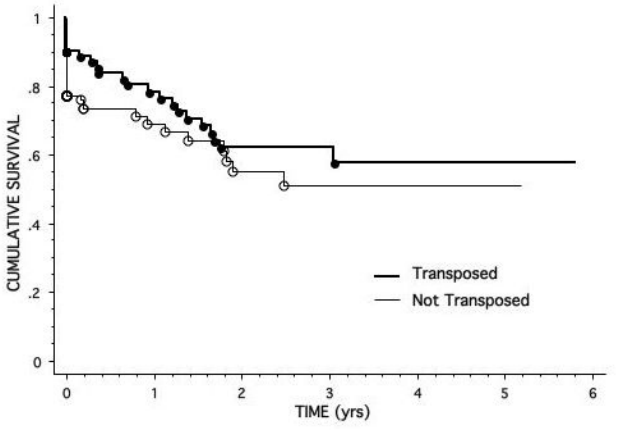
Transposed Brachio-Basilic Fistulae Have Long-Term Survival Comparable to Non-Transposed Arm Fistulae Renu Gupta, Peter Van, Neville R. Dossabhoy.

Background: Transposed brachial-basilic fistulae (TBBF) are not the first choice for all dialysis patients, but may be an attractive option in those patients who cannot get a radio-cephalic or brachio-cephalic fistula (non-transposed, NT). They are a better option than arteriovenous grafts in many respects. However, studies on transposed fistulae are limited. In this study we compared the maturation and survival of TBBF and NT fistulae.

Methods: Our prospective, computerized clinical database was queried retrospectively to identify the clinical outcomes of all upper extremity (UE) fistulae placed at our VA hospital over a 6-year period (2005-10) in CKD and ESRD patients. Patient demographics and comorbid conditions were noted. Primary end points of this study were failure of

maturation and failure of the fistula. Proportions were compared by chi square test. Kaplan-Meier survival curves were also plotted.

Results: 180 UE fistulae were placed in the 6 year period: 81 were transposed (TBBF), 99 non-transposed (NT). Mean age at placement 63 years. African American 64%, Male 99%, Diabetics 61%, HTN 99%, CVD 54%. Patients were already ESRD in 83% cases. Failure of maturation was noted in 9.8% in TBBF and 18.8% in NT group (P=0.11). Fistula failure was 22.5% for TBBF, and 12.2% for NT group (P=0.09). Cumulative survival was 76% and 62% at 1 and 2 yrs for TBBF; and 69% and 55% respectively for NT. The figure shows the Kaplan-Meier survival curves for the two groups (P=0.27).



Conclusions: Transposed brachial-basilic fistulae in our study had an overall survival that was comparable to non-transposed UE fistulae. This study confirms that TBBF remains a viable option in patients who have lost options for non-transposed fistulae.

FR-PO1940

Impact of Past Peripherally Inserted Central Catheters on Prevalence of Functioning Arterio-Venous Fistula in an Outpatient Hemodialysis Unit – Single Center Study Mireille El Ters,[#1] Andrew D. Rule,[#1] Bernice (Bonnie) M. Jenson,[#1] Amy Mahon,[#2] Sanjay Misra,[#2] Robert C. Albright,[#1] Amy W. Williams,[#1] Sandra J. Taler,[#1] Marie C. Hogan.[#1] *[1]Div of Nephrology, Mayo Clinic; [2]Dept of Radiology, Mayo Clinic, Rochester, MN.*

Background: Practice guidelines recommend native arteriovenous fistula (AVF)as the hemodialysis (HD) vascular access of choice. One barrier to successful AVF function is prior central or peripheral venous injury/thrombosis.The impact of prior peripherally inserted central catheter(PICC) on AVF patency among chronic hemodialysis patients has not been systematically examined.

Methods: Medical records of all end stage renal disease (ESRD)patients undergoing HD in the Mayo Clinic HD network and receiving their care in our medical system(n=205) were examined. Baseline characteristics (age, gender, race,history of diabetes, congestive heart failure, peripheral vascular disease & coronary artery disease) & history of PICC line placement were obtained. Patients were considered cases if they did not have a functioning AVF & controls if they did. Those who had PICC placed after AVF creation were excluded. Likelihood of functioning AVF with past history of a PICC was assessed using logistic regression models, with & without adjustment for other clinical characteristics.

Results: Of 205 ESRD patients, 90 did not have functioning AVF. Mean ± SD age was 69 ± 16, 57% were male, 86% caucasian, 56% diabetic, 24% had peripheral vascular disease, and 55% had coronary disease. History of PICC was present in 41% (37/90) of the ESRD patients without a functioning AVF compared to only 14% (16/115) of the ESRD patients with a functioning AVF(OR=4.3, p<0.001).This association increased after adjustment for age, gender & race (OR=4.7, p<0.001),& increased further with additional adjustment for DM, peripheral vascular disease,coronary disease & heart failure (OR=5.5, p<0.001).

Conclusions: Prior PICC placement is an important predictor of lack of functioning AVF even after adjustment for traditional risk factors. More studies are needed to determine whether this association is due to direct venous injury following PICC placement, as its use continues to grow due to perceived convenience and cost-effectiveness.

FR-PO1941

Ipsilateral Dialysis Catheter Use Is Associated with Decreased Long-Term Vascular Access Survival Roman A. Shingarev, Michael Allon. *Department of Medicine, Division of Nephrology, University of Alabama at Birmingham, AL.*

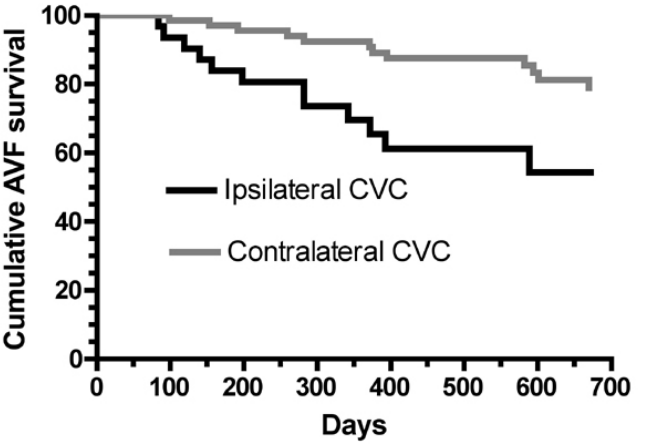
Background: Central venous catheters (CVC) are frequently used for hemodialysis (HD) access while patients await arteriovenous fistula (AVF) or graft (AVG) placement and maturation. CVC may result in central vein stenosis, which could adversely affect vascular access outcomes. We compared the vascular access outcomes in patients with an ipsilateral vs contralateral CVC in place.

Methods: We retrospectively queried a prospective, computerized vascular access database to identify 322 patients who initiated HD with a CVC and had no prior access surgery. Of 233 pts who subsequently received an AVF, 69 had an ipsilateral CVC and 164 a contraleral CVC. Of 89 pts who received an AVG, 27 had an ipsilateral CVC and 62 a contralateral CVC. We calculated primary access failure and cumulative access survival for each subgroup.

Results: Among pts receiving an AVF, primary failure was similar in those with ipsilateral and contralateral CVC, but cumulative survival was inferior in those with an ipsilateral CVC (Table, Figure). Likewise, among pts receiving an AVG, primary failure was similar, but cumulative survival tended to be lower in those with ipsilateral CVC (Table).

Vascular access outcomes in pts with ipsilateral and contralateral CVC

Outcome	Ipsi CVC	Contra CVC	HR	95% CI	p-value
AVF prim fail	50%	53%	0.94	0.70-1.26	0.69
AVF cum surv	54% at 2 yr	74% at 2 yr	2.48	1.33-7.33	0.009
AVG prim fail	35%	38%	0.92	0.49-1.73	0.80
AVG cum surv	22% at 2 yr	58% at 2 yr	2.04	0.92-5.38	0.07



Conclusions: The primary failure rate of AVF and AVG is not affected by the presence of an ipsilateral CVC. However, cumulative AVF and AVG survival is inferior in pts with prior ipsilateral CVC. Avoidance of ipsilateral CVC may improve long-term vascular access survival.

FR-PO1942

Clinical Determinants of Arteriovenous Fistula Patency, Primary Failure and Longevity in Hemodialysis Patients Srikanth Kunaparaju, Kambiz Kalantarinia. *Nephrology, University of Virginia, Charlottesville, VA.*

Background: Arteriovenous fistulae(AVF) are considered the preferred vascular access(VA). Complications such as primary failure and thrombosis have been barriers in achieving higher AVF rates. In this study in addition to the effect of traditional risk factors, we looked at local factors such as the effect of hemodialysis facility or surgeons' expertise on their outcomes.

Methods: Electronic Medical Records are used for collecting patient demographic, co morbidy and VA related data. The main outcomes studied were overall patency, primary failure(PF) and longevity of AVF. Univariate analyses and multivariate analysis in three different models was performed.

Results: From 695 VA, 428 AVF were studied. Mean age was 60.7 years, 35% females and 55% African American. Patency: Was 70%. The rate was higher for the expert surgeon (76% vs. 67%, p = 0.046) and for those with an AVF as their first VA ever (84% vs. 42%, p<0.0001). In multivariate analysis, hypertension (OR 2.1, 95% CI 1.1 – 4.2), first VA ever (OR 13.1, 95% CI 6.7 – 25.7), expert surgeon (OR 2.4, 95% CI 1.2 – 0.84) and HD facility were associated with higher patency. AVF-PF: 18% had PF and was significantly higher for those created after initiation of HD (20.9% vs.11.8%, p = 0.02) and those with multiple accesses (30.3% vs. 11.9%, p <0.0001).In multivariate analysis, multiple accesses & male gender were associated with better outcomes. Longevity: Median was 16 m. Longevity was lower for women(12.5 vs. 17 mo., p =0.05), those placed after HD initiation (20.8 vs. 33.8 mo., p <0.0001), upperarm AVF (21.8 vs. 32.8 mo., p = 0.01), and those with at least one other HDVA compared to those with first HDVA (16.0 vs. 29.0 mo., p <0.0001). In the multivariate analysis, gender and HD facility were the only associated factors.

Conclusions: Hypertension, first access ever, expert surgeon and HD facility were associated with higher AVF patency. For AVF-PF, male gender and first access ever were significantly associated with better outcomes. First access ever, forearm location and HD facility were significantly associated with longer AVF life span. A history of multiple access surgeries was negatively associated with all three outcomes.

FR-PO1943

Plasma 25-Vitamin D, 1,25-Vitamin D, Parathyroid Hormone (iPTH), and Fibroblast Growth Factor 23 (FGF23) Levels Do Not Predict Vascular Access Thrombosis Shailendra Sharma,[1] Michel B. Chonchol,[1] James S. Kaufman,[2] Alfred K. Cheung,[3,4] Jessica B. Kendrick.[1] *[1]University of Colorado Denver; [2]VA Boston Healthcare System, Boston; [3]VASLCHCS; [4]University of Utah.*

Background: Assessment of risk factors for vascular access failure may provide insight into therapeutic targets for stenosis and thrombosis. Aim of the study was to evaluate the associations of abnormalities of mineral metabolism with vascular access thrombosis in patients requiring hemodialysis.

Methods: We investigate the longitudinal association between 25-vitamin D, 1,25-vitamin D, iPTH and FGF23 levels with vascular access thrombosis in 654 patients requiring hemodialysis, aged, 67± 12 years who participated in a randomized clinical trial evaluating the effects of folic acid and B vitamins on death in subjects requiring dialysis. Thrombosis events were collected only for vascular accesses that were actually being used for dialysis and did not include events that occurred before dialysis initiation or that resulted in failure of access maturation. We used Cox proportional-hazards models to examine the association between abnormalities of mineral metabolism levels with vascular access thrombosis.

Results: Participants had a mean age of 60±11 years and median dialysis vintage of 1.4 years.Vascular access thrombosis occurred in 73 of the 336 patients (22%) with fistulae and 101 of the 221 patients (46%) with grafts at baseline. Increasing log for 1,25D levels (HR 0.77; 95% CI 0.40-1.47; p=0.43) and increasing log FGF23 levels (1.03; 95% CI 0.79-1.34;p=0.82) were not associated with vascular access thrombosis in unadjusted analyses. In multivariate analyses including all predictor variables, age, gender, race, smoking, BMI, treatment assignment, hypertension, diabetes and serum calcium and phosphate levels the associations between log 1,25-vitamin D, land log FGF23 were not significant (p>0.05 for each). Increasing log 25-vitamin D and iPTH were not associated with vascular access thrombosis in unadjusted and adjusted analyses.

Conclusions: In patients requiring hemodialysis, plasma levels of 25-vitamin D, 1,25-vitamin D, iPTH and FGF23 were not independently associated with vascular access thrombosis.

Erythropoietin Use Is Associated with Increased and ACE-Inhibitor Use Is Associated with Decreased Risk for Failure of Primary Arteriovenous Hemodialysis Fistulae Sylvia Stracke,[1] Lena Hoven,[2] Friedlinde Ernst,[1] Christian Aymanns,[1] Frieder Keller.[2] *[1]Nephrology, University Medicine Greifswald, Greifswald, Germany; [2]Nephrology, University Hospital Ulm, Ulm, Germany.*

Background: Hemodialysis treatment requires a well-functioning vascular access. Access patency is limited by the development of venous intimal hyperplasia, which predisposes to fistula stenosis and subsequent thrombosis. We prospectively followed 100 consecutive patientes receiving a primary arteriovenous hemodialysis fistula.

Methods: At the time of fistula creation, a 5 mm segment of the future shunt vein was removed and examined by histology and histomorphometry. Intima-to-media ratio (IMR) and intimal thickness indices (ITI) were documented. Clinical data were followed for at least one year.

Results: 31 patients showed histologically normal vessel walls (IMR 0.3 ± 0.15; ITI 0.13 ± 0.05). These patients were 70 ys old (range 24-85 ys), 29% were female. The other 69 patients showed intimal hyperplasia with a significantly increased IMR (1.2 ± 1.04; ITI 0.35 ± 0.22; both p<0,001); median age was 67 ys (range 19-86 ys); 29% females. Intimal hyperplasia was seen in 66% of lower arm veins and in 87% of upper arm veins. In 31 cases, stenoses that needed intervention were seen. Stenoses developed at a median of 9.7 mo after operation. Patency of fistulae was 60% after 6 mo, 57% after 9 mo and 56% after 12 mo. Intimal hyperplasia did not predict the development of stenosis, nor did the localization of fistula, sex, age, comorbidities, hyperparathyroidism, CRP or Hb levels. In a cox regression model, we found a hazard ratio (HR) of 8.3 for the use of erythropoietin (p=0.04), HR of 5.3 for comorbid peripheral arterial disease (p=0.009), HR of 2.5 for comorbid coronary artery disease (p=0.03) and HR of 0.2 for the use of ACE-inhibitors (p=0.02).

Conclusions: The patency rate in our 100 primary arteriovenous hemodialysis fistulae of 56% after 12 months is in accordance with the literature. Erythropoietin use was associated with an increased and ACE-inhibitor use with a decreased fistula failure rate in the first twelve months after fistula creation in our cohort.

Vein Mapping by Angiography: Findings That Prevent Arterio-Venous Fistula Maturation Zahidul H. Mondal, Candace D. Grant, Mary C. Mallappallil, Fasika M. Tedla, Moro O. Salifu. *Internal Medicine, Division of Nephrology, SUNY HSCB Downstate, Brooklyn, NY.*

Background: Vein mapping is recommended prior to creation of Arterio-Venous Fistula (AVF) in hemodialysis (HD) patients. While ultrasound is sometimes used, it may not be sensitive to the presence of accessory veins and central vein (CV) stenosis that may interfere with AVF maturation. We analyzed results of preoperative vascular imaging with angiography (ANGIO) in 178 HD patients.

Methods: Bilateral ANGIO was performed on 178 patients using 15-20 ml of contrast by our interventional nephrologists. Data were retrospectively abstracted to identify (i) luminal diameter (LD) and (ii) presence of accessory branches in right (R) and left (L) radiocephalic (RC), elbow-cephalic (EC) and elbow-basilic(EB) veins. Presence or absence of CV stenosis was also documented. Veins with LD ≥2.5mm were considered usable. Statistical comparisons were made with chi-square or t-test as appropriate.

Results: Mean age was 57±16[SD] years (range: 18-94), and HD vintage ranged from 0 to >5years. 87% of patients were hypertensive; 53% were diabetic; 49% were men, and most were African American. Only 21/178 (12%) of RRC veins were usable and of these 7/21 (33%) had branches; on the L side, only 12/178 (9.6%) were usable, of which 4/12 (18%) had branches. 42/178 (24%) of REC veins were usable, and 5/42 (12%) had branches; on the L, 39/178 (22%) were usable, while 6/39 (15.4%) had branches. Among the REB veins, 80/175 (45%) were usable, of which 5/80 (6.3%) had branches; on the L, 97/178 (54.5%) were usable, but 11/97 (11%) had branches. CVs were visualized in 96.6%, showing stenosis in 6% of patients. Diabetes was evenly distributed in all categories; patients with usable veins were significantly younger (mean age difference 6-12 years, p<0.05).

Conclusions: ANGIO detected branch-veins in 9.3-33% (average 13%) of usable veins, and central stenosis in 6% of patients --findings less likely to be detected with ultrasound. Usable veins were less likely to be identified in the forearm or in older individuals. These findings underscore the need for vein-preservation strategies in patients with chronic kidney diasease.

FR-PO1946

Arteriovenous Anastomosis Creation Using the Optiflow Anastomotic Connector Lajos Matyas, Istvan Mogan, Adrian Ebner, Mark Mantell, Roberto Manson, Eric Chemla, Sandip Mitra, Milind Nikam, Afshin Tavakoli, Prabir Roy-Chaudhury. *Bioconnect Systems, PA.*

Background: Early arteriovenous fistula (AVF) maturation failure is a major clinical problem. AV fistula failure is frequently preceded by the occurrence of aggressive stenosis in the perianastomotic (PA) region. The Optiflow™ implant device is designed to protect the PA region from the development of stenosis and improve AVF hemodynamics. Clinical data for patients treated with the Optiflow™ was collected and analyzed in order to evaluate safety and clinical performance.

Methods: End to side AVF were created with a novel anastomotic device (Optiflow™). The study population included fifty three patients treated in Paraguay, Hungary, Greece, and the United Kingdom. Forty seven patients were evaluable for patency (5 were lost due to immediate technical failures and 1 patient due to a cardiac event). Unassisted primary patency was evaluated in two different study groups with follow-up time points of 42 (n=10) and 90 days (n=38) respectively. The safety endpoint was freedom from serious adverse events (SAE's) and unanticipated adverse device events (UADE's) during the follow-up period.

Results: Of the 47 patients, 47% were male and 39% were diabetic. Table 1 describes the study results at different time points. Aside from the technical failures, there were no device related SAE's or UADE's.

Study Results

14d Primary Patency	42d Primary Patency	90d Primary Patency	42d ultrasound Vein Size (mm)
100%	91%	82%	6.6 +/- 2.2

Conclusions: The results from the interim data support the safety and effectiveness of the Optiflow™. The 82% unassisted primary patency rate at 90 days for Optiflow™ is favorable when compared to published unassisted primary patency rates of 70% (Falk, 2006) for sutured AVF. Additionally, 42 day ultrasound follow-up performed on 31 patients demonstrated an average vein diameter of 6.6mm. These initial results suggest that the Optiflow™ could potentially play an important role in enhancing AVF maturation.

The Optiflow™ received the CE mark in August 2010.

Far Infrared (FIR) Therapy – An Effective Treatment for AV Fistula Maturation and Maintenance Iain Moore, Jennifer H. Adam, Debbie Sweeney, Jonathan Murray, Sean Fenwick, Saeed Ahmed. *Renal Unit, City Hospitals Sunderland, Sunderland, United Kingdom.*

Background: Having a functioning arterio-venous fistula (AVF) placed in a timely manner before commencement of haemodialysis (HD) is associated with reduction in patient morbidity, mortality and length of hospital stay. UK renal units are now focused on achieving better than 85% incidence of permanent vascular access rates in their HD population. At the renal unit in Sunderland, we have been using Far Infrared (FIR) therapy to improve our vascular access outcomes since December 2008.

Methods: FIR therapy involves a non-invasive 40 minute heat treatment onto the AVF area. This induces expression of endothelial Heme Oxygenase-1, reducing monocyte adhesions in the endothelium cells, thus inhibiting inflammatory responses that cause further endothelial injury.

From July to December 2010, we used FIR therapy to help maintain AVF function by treating haematomas and pain on needling in our HD unit.

We then extended our FIR therapy usage to the pre-dialysis population, treating patients immediately after AVF formation. We assessed AVF function by Doppler ultrasound.

Results: In one 6 month period, from July to December 2010, 88 HD patients benefited from the use of FIR therapy. 257 individual sessions were completed (median FIR sessions 2, range 1-5).

14/17 patients had improvement of pain score on AVF needling. 23/34 needle-site haematomas resolved more quickly and had improved pain scores compared with those not using FIR therapy.

15/20 AVFs matured with demonstrably better blood flow rates on Doppler, including patients with previous AVF maturation failure.

Conclusions: Currently, we are using FIR therapy across all our HD units as well as on the renal ward. We have instituted a twice weekly, nurse-led Heat Treatment clinic on our Ambulatory Care unit for all patients with new AVFs.

We have found FIR therapy to be of use in AVF maturation, particularly in patients with challenging access, as well as in treatment of haematoma formation and those with AVF pain during HD. We believe FIR therapy offers our patients improved access function, more comfortable treatment provision and decreased access-related morbidity and mortality.

FR-PO1948

Outcomes of Partial Aneurysmectomy in Managing Aneurysm-Associated Complications of Hemodialysis Arteriovenous Fistulae Ammar Almehmi, Shouwen Wang. *Interventional Nephrology, University of Arizona- AKDHC, Phoenix, AZ.*

Background: Fistula aneurysm formations are frequently encountered and their associated complications may affect the viability and function of dialysis vascular access. The key feature of aneurysm-associated complications is that the diseased tissues usually involve only part of the aneurysm, which provides a localized target for intervention. The aim of this study is to describe a targeted approach, "partial aneurysmectomy", for treating these complications and to assess its effects on fistula patency rate.

Methods: This study included 36 dialysis patients who presented with aneurysm-associated complications. All procedures were performed under conscious sedation in an outpatient ambulatory surgery center. Partial aneurysmectomy involved the resection of the diseased skin and aneurysm wall followed by suture repair of the fistula wall and the overlying skin. Kaplan-Meier survival analysis was utilized to calculate the aneurysm intervention-free patency and fistula primary patency rates.

Results: Of the 36 patients: 20 (56%) were males, mean patient age was 54.5±14.6 years, 15 (42%) were diabetics, 35 (97%) were hypertensive, 26 (72%) had upper arm fistula and 10 (28%) had forearm fistula. The average age of the fistula was 72.8±39.5 months. The indications for partial aneurysmectomy were: active bleeding (14%), skin scab or necrosis with fistula defect in imminent danger of bleeding (33%), skin necrosis/erosion (28%), and thin-walled aneurysm in danger of rupture (25%). The procedure was successful in all cases and the patients continued dialysis therapy using their fistulae. The patency rates at 6 months were: 97% for the aneurysm intervention-free patency, 64% for the fistula primary patency, and 97% for the fistula primary-assisted patency.

Conclusions: Partial aneurysmectomy is a simple, safe, and effective intervention for managing aneurysm-associated complications and preserving dialysis fistulae. Further studies with long term follow up are needed to validate the results of this targeted approach.

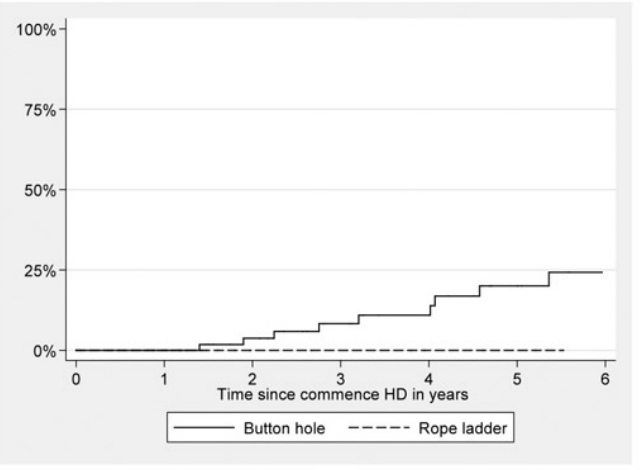
FR-PO1949

Arterio-Venous Fistula Buttonhole Cannulation Technique: A Review of Infectious Complications Frank J. O Brien, Hong Kuan Kok, Peter J. Conlon. *Department of Nephrology, Beaumont Hospital, Dublin, Ireland.*

Background: There are two main methods of arterio-venous fistula (AVF) access; 'buttonhole' cannulation technique and 'rope-ladder' cannulation technique. Several small-scale international studies have hypothesized that the buttonhole technique is associated with increased rates of fistula infection. This study aims to examine this hypothesis.

Methods: A retrospective review of all patients attending a large out patient haemodialysis clinic was performed. Data was collected on cannulation modality, infection rates, organisms grown in the microbiology laboratory, complications of infection, and time on haemodialysis.

Results: 135 patients were noted to undergo haemodialysis via an AVF, 74 in the buttonhole group and 61 in the rope-ladder group. Nine episodes of clinically significant bacteraemia were noted in the buttonhole group.



p=0.02

This equates to a rate of 0.22 bacteraemia events per 100 patient dialysis months. These were attributed to AVF cellulitis. There were no episodes of bacteraemia in the rope ladder group.

8 infections were due to methicillin-sensitive staphylococcus aureus (MSSA); one was secondary to staphylococcus epidermidis infection. Three patients with MSSA bacteraemia subsequently developed infective endocarditis as a complication. Five patients who developed bacteraemia events were undergoing home haemodialysis.

Conclusions: This study highlights the infectious complications associated with buttonhole cannulation techniques. All organisms isolated in our cohort are known skin colonisers. The reason for the increased rates of infection is unclear; however as this is a relatively new technique, further patient and nursing education may help reduce infectious complications. This has particular implications for patient education and training in those doing home haemodialysis, as these patients self needle their fistulae.

FR-PO1950

Buttonhole Versus Sharp Needle Cannulation: Clinical Outcomes in a Home Haemodialysis Cohort Christopher A. Muir,[1] Sradha S. Kotwal,[2] Carmel M. Hawley,[4] Martin P. Gallagher,[2,3] Paul Snelling,[3] Meg J. Jardine.[2,3] *[1]University of Sydney, Australia; [2]The George Institute for Global Health, Sydney, Australia; [3]Statewide Renal Services, Sydney, Australia; [4]Princess Alexandra Hospital, Brisbane, Australia.*

Background: Buttonhole (BH) cannulation is increasingly popular within home haemodialysis (HHD) programs, although recent reports have raised concern about associated infection rates.

Methods: A retrospective review was conducted of consecutive HHD patients dialysing via an arteriovenous fistula (AVF) from training commencement between 01/01/2003 and 31/12/2009 until cessation of HHD, death or 31/12/2010. Co-primary outcomes were systemic access infections (culture-positive infections attributed to dialysis access) and surgical access interventions (AVF surgical intervention or abandonment). Secondary outcomes included all access infections, initial HHD training time, and total staff time requirement (number of days of training, home visits and returns to the unit for dialysis). Incidence-rate ratios (IRR) by cannulation method were calculated using Poisson regression clustered by patient.

Results: There were 35 access infections (9.30/1000 AVF months [AVFmths]), including 17 systemic infections (4.52/1000AVFmths), in 90 patients followed for 3765 AVFmths. BH was associated with a non-significantly higher rate of systemic access infections (IRR 2.71; 95% CI 0.66-11.09; p=0.17) and a significantly higher all-access infection rate (IRR 3.85 (1.66-12.77); p=0.03, absolute increase 8.6 (3.3-13.8) infections/1000AVFmths) compared with sharpneedle cannulation (SN). Surgical access interventions were not different for BH compared with SN (IRR 1.08; 95% CI 0.33-3.55; p=0.90). Adjustment for age and diabetes did not alter the results. BH was associated with longer initial training (mean 51 vs. 41 training days, p=0.01) and increased staff time requirements (1 encounter/13.2 days followup (BH) vs 1 encounter/19.0 days (SN), p<0.001).

Conclusions: In a single unit, BH cannulation was associated with increased rates of infectious events and prolonged initial and ongoing staff support compared with SN. There was no reduction in the requirement for surgical access interventions.

FR-PO1951

Multiple Specialists Perform Percutaneous Hemodialysis (HD) Access Interventions Michael P. Lilly,[1] Nancy Jean Carlson,[2] Janet R. Lynch,[1] Edwin D. Huff.[2] *[1]Mid-Atlantic Renal Coalition (NW5), Richmond, VA; [2]Fistula First Breakthrough Initiative (FFBI) Data Committee, IPRO ERSD Network of NY, Lake Success, NY.*

Background: Interventions to improve maturation or prolong the function of HD access are common. Interventional radiologists (IR) have traditionally done these services in hospitals. Recently, internists/interventional nephrologists (IN) and access surgeons (AS) have begun to perform these access salvage procedures. The extent of this shift in practice is not well documented.

Methods: We reviewed CY 2009 claims submitted to the Centers for Medicare & Medicaid Services (CMS) for dialysis-related access procedures done in NW5. We grouped practitioners by self-designated CMS specialty codes: AS (gen surg 2, thorac surg 33, vasc surg 76+77), IN (int med 11, nephrology 39) and IR (diagnostic radiol 30, interventional radiol 94). We grouped procedures by CPT code: fistulography (36145), percutaneous (precut) interventions (angioplasty 35476, G0392, G0393; and percut thrombectomy 36870), tunneled catheter (HD cath) placement (36558), HD cath exchange (36581), AVF or AVG construction (36818, 36819, 36820, 36821, 36825, 36830) and open thrombectomy/ revision (36831, 36832, 36833, 36834, 37607).

Results: Fistulograms and percut interventions accounted for 67.1% of procedures. IR performed the greatest share of these procedures, but 54% were performed by AS and IN. AS did nearly all open procedures and placed the most of HD caths, while IR or IN did most HD cath exchanges.

Procedure grouping	Surgeons	%	Internists	%	Radiologists	%	Total
Fistulogram	3369	28.6	2951	25.1	5458	46.3	11778
Percut Interventions	3890	23.0	5309	31.4	7714	45.6	16913
Insert HD cath	3138	56.1	441	7.9	2012	36.0	5591
Exchange HD cath	513	27.3	598	31.8	767	40.8	1878
AVF/AVG Construction	4757	99.7	14	0.3	0	0.0	4771
Open AVF/ AVG Revisions	1789	98.6	17	0.9	8	0.4	1814

Conclusions: Changing practice patterns influence the methods used to modify practice behavior. FFBI has focused its efforts on AVF construction on surgeons who still perform nearly all such procedures. Efforts to enhance AVF maturation rates and prolong AVF function must be directed to a broader range of physicians.

Funding: Other U.S. Government Support

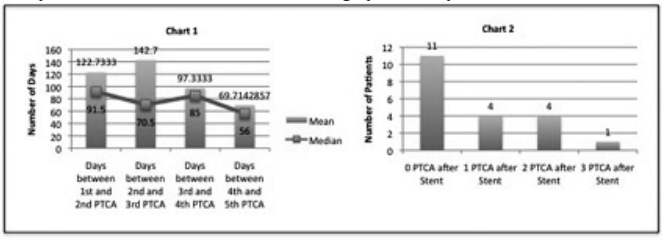
FR-PO1952

Cephalic Vein Arch Stenosis with and without Stent Placement in Hemodialysis Patients Ramanath B. Dukkipati,[1] Luani Lee,[1] Raahil Kajani,[1] Kamyar Kalantar-Zadeh,[1] Naveen K. Atray.[2] *[1]Nephrology, Harbor-UCLA Medical Center, Torrance, CA; [2]Nephrology, Capital Nephrology Associates, Sacramento, CA.*

Background: Cephalic vein arch (CVA) stenosis is a common feature leading to dysfunction and/or failure of brachial artery to cephalic vein fistula. The value and timing of percutaneous transluminal angioplasty (PTA) versus placement of a stent in management of CVA stenosis is not known.

Methods: We examined the risk of recurrence of CVA stenosis after PTA or after stent placement determined by angiography of the involved upper extremity over time in a contemporary cohort of MHD patients treated from March 2008 through May 2011.

Results: We retrospectively identified 45 MHD patients with evidence of CVA stenosis on elective angiograms. The median number of days until another PTA was required decreased (see chart). An association was found between the number of angioplasties and a decreasing median number of days between each subsequent PTA. However, the median number of days between stent placement and the subsequent PTA was much greater (152 days) than the median number of days between the first two angioplasties of a patient who did not have a stent placed. An association was found between increased patency and stent placement. Of the 20 patients who had stents placed, the mean number of angioplasties required after stent placement was 0.75. Of the 25 patients who did not have a stent placed, the mean number of total angioplasties required was 2.76. An association was found between stent placement and a decreased number of angioplasties required.



Conclusions: PTA seems to hasten the recurrence of CVA stenosis. Compared to PTA alone the placement of intravascular stent shows a trend towards a prolonged patency of the CVA. Clinical trials with a larger sample size will better elucidate the value and timing of PTA versus stent placement in CVA stenosis.

FR-PO1953

Cardiac Rhythm Devices and Arteriovenous Access Dysfunction in Hemodialyzed Patients: Experience in a Single Urban Vascular Access Center Brinda Desiraju, Neal Mittman. *Brooklyn Vascular Access, Heights Nephrology Medical Group, Brooklyn, NY.*

Background: Recent attention has been focused on the incidence of hemoaccess-related complications with cardiac rhythm devices (CRD) in hemodialyzed pts. Cardiac co-morbidities are common, and the use of CRD in this population has increased in recent years. The use of contralateral vessels is generally recommended, but the concomitant use of central venous dialysis catheters (CVC) and the presence of unrecognized or developing central venous stenosis and occlusion can complicate this option.

Methods: Retrospective chart review identified forty-three patients with arteriovenous hemoaccess and indwelling cardiac rhythm devices (CRD) referred to our access center for evaluation.

Results: Reasons for referral included arm swelling in 38%, increased venous pressure 14%, thrombosed access 14%, decreased access flows 8%, and prolonged post-dialysis bleeding 6%. Thirty pts had AV fistulae (14 forearm, 16 upper arm) and twenty had AV grafts (5 forearm, 15 upper arm), seven with a second access after prior access losses. CRD were ipsilateral in 21 pts, all of whom had angiographic evidence of central vein stenosis or occlusion, and 71% were symptomatic (arm swelling). Four with ipsilateral fistula received contralateral access, of which two had recurrent arm swelling. CRD were contralateral in 29 pts, of whom 23 (79%) had central vein stenosis or occlusion. Of these 23, 30% had arm swelling, 39% had prolonged bleeding or high venous pressures, and 22% presented with access thrombosis. Arm swelling was more common in pts with upper arm accesses. Fourteen pts had concomitant CVC during a visit.

Conclusions: Pts with ipsilateral CRD are at greater risk of developing symptomatic central vein stenosis. However, a substantial number of pts with contralateral CRD developed symptoms requiring intervention and even access failure. Alternative approaches, including the use of epicardial leads, subcutaneous implantable cardioverter-defibrillators or of peritoneal dialysis have been suggested, but a re-evaluation of the risk-benefit ratio and indications for CRD in this population is in order.

Funding: Clinical Revenue Support

FR-PO1954

Pacemakers & Implantable Cardiverter-Defibrillators in Hemodialysis Patients: Prevalence and Relationship to Ipsilateral and Contralateral Arteriovenous Access Interventions Theodore F. Saad. *Nephrology, Christiana Care Health System, Newark, DE.*

Background: Cardiac rhythm management devices (CRMD), including pacemakers & implantable cardioverter-defibrillators are commonly used for treatment of rhythm disorders in HD patients. CRMD leads may induce central vein stenosis resulting in venous hypertension with ipsilateral arteriovenous (AV) access.

Methods: We surveyed all chronic HD patients in our practice & retrospectively reviewed procedure records to determine the presence of CRMD and the effect of CRMD leads on intervention rates. The study cohort included 1233 HD patients from Jan-Mar, 2011. Data collected included demographics, type & side of AV access & CRMD, dates of access interventions, & sites of lesions treated in the access circuit. Interventions were classified as being performed anywhere in the access circuit & in central veins related to CRMD leads. Rates of intervention were calculated by dividing the number of interventions by the number of access-years (AY) using the current AV access & CRMD.

Results: HD access was a fistula in 767 (62.1%); graft in 271 (21.9%); catheter in 195 (15.8%). 127 patients had a CRMD; ICD's in 69 (5.6%) and pacemakers in 58 (4.7%). Mean age of patients with a CRMD was 72 years, 79 male and 48 female. All CRMD leads were inserted via subclavian or cephalic vein; there were no jugular, femoral, or epicardial leads. 93/127 (73.2%) had left-sided & 34/127 (26.8%) had right-sided leads. Six patients with contralateral access and CRMD had failed previous ipsilateral access due to CRMD-related stenosis. No patient with either ipsilateral or contralateral access was found to have significant SVC stenosis. Rates of interventions are shown in the table:

Rates of Intervention

	Contralateral	Ipsilateral
Number of Patients	80	47
Total Access Years	133.7	109.5
Access Circuit Interventions	204 (1.50/AY)	168 (1.53/AY)
CRMD lead-related interventions	0	66 (0.60/AY)

Conclusions: Prevalence of CRMDs in these chronic HD patients is 10.3%. Access circuit intervention rates were similar for CRMD ipsilateral and contralateral to the AV access; CRMD-lead related interventions were more frequent in the ipsilateral group. SVC stenosis was not demonstrated in any patient.

FR-PO1955

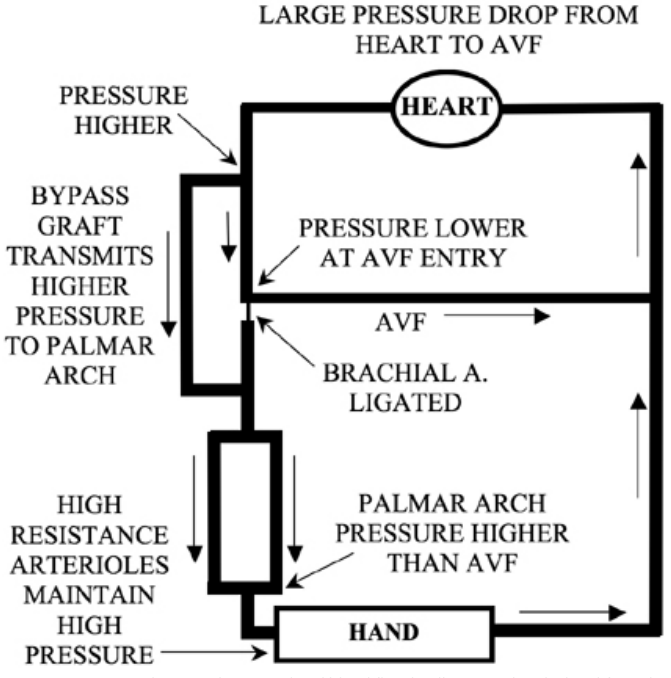
Mathematical Model Explains Why DRIL Procedure Is Effective in Treating Hand Ischemia in Brachiocephalic Fistula William D. Paulson,[1] James J. Wynn,[1] Jan Malik,[2] Vladimir Tuka,[2] Tushar J. Vachharajani,[3] Todd D. Merchen,[1] Steven A. Jones.[4] *[1]Georgia Health Sci. Univ., Augusta, GA; [2]Charles Univ., Prague, Czech Republic; [3]Wake Forest Univ. School of Med., Winston-Salem, NC; [4]Louisiana Tech Univ., Ruston, LA.*

Background: The high flow brachiocephalic fistula (AVF) may be complicated by hand ischemia. The DRIL procedure increases blood flow to the hand by anastomosing a bypass graft to the brachial artery above and below the AVF anastomosis; the brachial

artery distal to the AVF is ligated. Although it is widely accepted that DRIL is effective, there is no consensus on its mechanism.

Methods: We used a mathematical model of the AVF to study effect of DRIL on hand arterial pressure and blood flow. Equations from the engineering literature were used to predict circuit pressures and flow.

Results: The AVF is a high flow shunt with a large drop in pressure by the time brachial artery flow reaches the AVF. This pressure drop reduces hand flow. In the DRIL, the proximal anastomosis of the bypass graft is placed upstream to the AVF where pressure is higher than at the AVF. This higher pressure is transmitted to the hand, which increases hand flow. The narrower the brachial artery, the greater the pressure drop in the artery; this effect is offset by placing the proximal bypass anastomosis further upstream where pressure is higher. The bypass graft and hand are part of a high resistance circuit that is controlled by arteriolar resistances. Pressure is high in this circuit with a minimal drop until the arterioles are crossed.



Conclusions: The DRIL increases hand blood flow by disconnecting the hand from the low pressure AVF circuit and connecting it to the proximal brachial artery where pressures are higher. The model explains why the DRIL is effective, and shows how to optimize application of the DRIL in individual patients with hand ischemia.

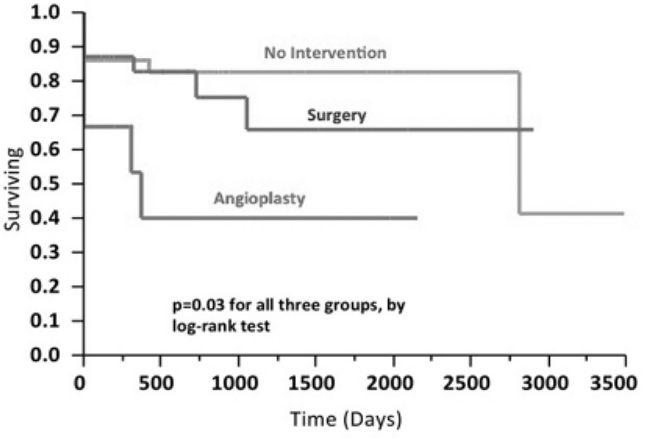
FR-PO1956

Prolonged Cumulative Survival in Fistulas with Surgical Interventions To Promote Maturation Compared to Endovascular Interventions Timmy C. Lee,[1,2] Arshdeep Tindni,[1] Prabir Roy-Chaudhury.[1,2] *[1]Internal Medicine, University of Cincinnati, OH; [2]Dialysis Vascular Access Research Group, Cincinnati, OH.*

Background: Due to high primary failure rates, arteriovenous fistulas (AVF) frequently require either endovascular or surgical interventions to promote maturation (defined as the ability of an AVF to support hemodialysis). The objective of this study was to compare the impact of surgical versus endovascular interventions to promote AVF maturation on cumulative AVF survival.

Methods: We evaluated 89 patients with new AVF placement from a Veterans Affairs patient population. We calculated and compared cumulative survival between AVFs requiring no intervention, and surgery or endovascular intervention to promote AVF maturation.

Results: Among the 89 patients with new AVF placement, 46 AVFs required intervention to promote maturation (31 surgical and 15 endovascular). One year cumulative survival was 86% vs 83% vs 40% for no intervention vs. surgery vs. angioplasty, respectively. Cumulative survival was worse in angioplasty group compared to the no intervention and surgery groups (p=0.03).



Cumulative survival was longer in AVFs receiving surgical intervention compared to angioplasty to promote AVF maturation (p=0.05).

Conclusions: In AVFs that required interventions to promote maturation, AVFs with surgical intervention had longer cumulative survival compared to AVFs treated with endovascular intervention. AVFs with surgical intervention to promote maturation had similar one-year cumulative survival to those AVF that did not require intervention to promote maturation. Our results emphasize the huge need in this area for hard scientific data (from large clinical trials evaluating biology of vascular injury and vascular access outcomes) that could be used to guide clinical practice.

Reversible Endovascular Occlusion with Thermo-Sensible Polymer LeGoo® in Arterovenous Fistula Confection Roberto Palumbo,[1] Michele Ferrannini,[1] Annalisa Noce,[2] Simone Manca di Villahermosa,[2] Fulvio Fiorini,[3] Mariapaola Canale,[2] Nicola Di Daniele.[2] *[1]Nephrology and Dialysis Department, S.Eugenio Hospital, Rome, Italy; [2]Nephrology and Dialysis Unit, Tor Vergata University, Rome, Italy; [3]Nephrology and Dialysis Unit, S.Maria della Misericordia Hospital, Rovigo, Italy.*

Background: The temporary interruption of blood flow, using clamps or rubber loops stretching or kinking vessels, is necessary in the confection of arterovenous fistula (AVF). However the vascular trauma may jeopardize the outcome of the procedure. LeGoo® (Pluromed, Woburn, MA), a thermosensitive polymer, is a viscous liquid at room temperatures and changes into a firm occlusive plug instantaneously when exposed to body temperatures. We report five cases of AVF construction using LeGoo® to temporary interrupt the arterial and vein blood flow.

Methods: Five uremic patients (4 male, 1 female) were submitted to AVF construction.

Patients submitted to AVF construction

M/F, age	AVF	Artery caliber (mm)	Renal disease
M, 78	Right radio-cephalic AVF	2.1	hypertension
M, 81	Left radio-cephalic AVF	1.9	hypertension
M, 68	Left radio-cephalic AVF	2.2	ADPKD
F, 72	Left proximal foream AVF	2.1	unknow
M, 84	Left proximal foream AVF	2.4	diabetes

carhacteristics of patients and surgical approach

LeGoo® were employed to occlude the vein and the arteries without clamps or loops. After completing the anastomosis, we employed cold saline on the outer vascular wall to make fluid the polymer.

Results: We obtained a rapid, safety and prolonged emostasis. LeGoo® application is simple and effective. In all cases, the application of cold saline on the outer vascular wall just after completing the anastomosis, made the polymer fluid and promptly cleared by the re-established blood flow.

Conclusions: LeGoo® allows effective hemostasis in distal and proximalized AVF surgery; its use is simple and safe and gives the advantages of a temporary complete, highly selective, non-traumatic, totally reversible endovascular occlusion.

FR-PO1958

Pilot Study Evaluating the Safety and Efficacy of Drug Eluting Balloons in the Treatment of Recurring Shunt Stenosis Deborah Weiss,[1] Beata Lux,[2] Birgit Doris Bader,[1] Christiane M. Erley.[1] *[1]Nephrology, St. Joseph Hospital, Berlin, Germany; [2]Radiology, St. Joseph Hospital, Berlin, Germany.*

Background: With a rising number of HD-patients of an continually increasing age, the percutaneous transluminal angioplasty (PTA) as a treatment option for insufficient dialysis shunts is gaining importance. Though many PTAs are successfull, there remain patients, who suffer from a recurring shunt stenosis. Drug eluting balloons (DEB) could provide a feasible alternative to the standard balloons; even more so since the use of drug

eluting stents in these venous vessels have been considered too problematic by most interventionalists.

Methods: We undertook a pilot study applying new drug eluting balloons (IN.PACT Admiral=DEB coated with paclitaxel, made by KRAUTH cardiovascular GmbH) in patients with recurring shunt stenosis

Results: 11 patients with recurring shunt stenosis were treated with the DEB between 9/2009-12/2009. 1 patient had an AV-fistula, 2 a fistula which had already been corrected by the implantation of a short synthetic graft, and 8 had always had a synthetic graft. All patients had a type III-stenosis, in addition to that 6 patients a type II-stenosis and two patients had a type I-stenosis and a type IV-stenosis, respectively. Apart from 1 patient who took only phenprocoumon all patients were on acetylsalicylic acid, 2 patients received clopidogrel on top, 1 patient phenprocoumon on typ and 1 patient switched to ASS/Dipiridamol. 9 patients underwent a further PTA during the next 4 months. Only one re-stenosis seemed to have developed more slowly. We found, though, that not during all the procedures the special positioning device protecting the paclitaxel-coat hat been used. In the following two years, no apparent increase of restenosis rate, shunt aneurysm or other-possibly procedure related- adverse events have been observed. 2 patients died due to unrelated causes (1 breast cancer, 1 myocardial infarction).

Conclusions: The use of DEB during PTA in shunt stenosis is not primarily associated with a higher rate of complications. The benefit for the patients, especially the prevention of recurring shunt stenosis by using these balloons should be the aim of further investigations.

FR-PO1959

A New Prosthetic Graft (RAPIDAX™) for Arteriovenous Access and Early Cannulation: A Single Center Experience Concetta Gangemi,[1] Marta Proglio,[1] Maria Firpo,[2] Michele Giuseppe Messa,[1] Vittorio Ortalda,[1] Antonio Lupo.[1] *[1]Division of Clinical Nephrology, AOUI, Verona, Italy; [2]Division of Vascular Surgery, AOUI, Verona, Italy.*

Background: The AV prosthetic graft is indicated whenever there is a recurrent failure of the native access or the venous bed is not suitable. The main advantage in the use of vascular prosthetic graft is the faster healing time compared to a native fistula, an avarage of 2-3 weeks. In particular, the new ePTFE graft (Rapidax™; Vascutek-Terumo, Renfrewshire, Scotland, UK) thanks to its trilaminar conformation with an elastomer, allows an early cannulation (until 24 hours) and reduces time of bleeding, limiting HD catheter use.

Methods: In the Division of Clinical Nephrology of Verona, a vascular access with Rapidax™ graft was carried out in seven patients. The graft efficacy, patency and post-operative complications were evaluated. Six-month to eighteen-month follow-up data are presented.

Results: in six patients successful first cannulation was achieved within 48 hours, with a mean of 21,7 hours; just one graft was used after 1 week, because the patient had already a HD catheter. At six months graft patency was 100% in all patients. The primary efficacy was evaluated by the eKt/V at three months: mean value was 1.41; at six month 1.58. The mean blood flow at first use was 200 ml/min, at one month 300 ml/min. Time of bleeding was normal. Only one patient had an acute thrombosis 2 hours after graft implantation. Although the small number of patients, no pseudoaneurysm nor loss of graft occurred, even in the one case at eighteen-month follow-up.

Conclusions: this kind of graft permits an early cannulation, reducing the use of HD catheter, preventing also pseudoaneurysm and seroma formation. New ePTFE graft can be a good alternative to long term HD catheter in patients who cannot receive an autologous graft.

FR-PO1960

The Safety and Efficacy of Bedside Tunneled Catheter Removal by Physician-in-Training in an Academic Teaching Setting Vikram R. Beemidi,[1] Naseem A. Qureshi,[1] Albert W. Dreisbach,[1] Eva Csongradi,[2,3] Luis A. Juncos,[1] Tibor Fulop.[1] *[1]Department of Medicine, University of Mississippi Medical Center, Jackson, MS; [2]Department of Medicine, 1st University of Debrecen, Hungary; [3]Department of Physiology & Biophysics, University of Mississippi Medical Center, Jackson, MS.*

Background: Anecdotal experience suggests that procedural aspects of Nephrology training may be endangered. Safety and efficacy of bedside removal of tunneled dialysis catheter (TDC) is relatively little studied in a purely training setting.

Methods: We performed a retrospective cohort review of our consecutive 3-year experience (01/2007 - 12/2009) with bedside TDC removal at the University of Mississippi Renal Fellowship Program. We collected data on patients and procedure-related variables, success and complications rates. The study was reviewed and approved by the University of Mississippi Human Research Office. Data was analyzed with PAWS Statistics 18.

Results: During the index period, we had 55 inpatient TDC removals at bedside under supervision in our teaching log. Of these, 50 (90.9%) were accomplished by Nephrology Fellows with Attending's supervision and the rest of them with Attending/Medical Resident team. 36 (65.5%) TDC was removed from right internal jugular (IJ), 14 (25.5%) from left IJ, and 5 (9.1%) from femoral vein location. Indication at the time of removal included bacteremia in 36.4%, fever in 41.8%, or clinical sepsis with hemodynamic instability or with respiratory failure in 20%. Only 1 complication was observed with prolonged local bleeding, controlled with local pressure.

Conclusions: Our results suggest that bedside removal of TDC is a safe and effective procedure and should be part of competent Nephrology Fellowship Training.

Physical Examination of Dysfunctional Arteriovenous Fistulae by Non-Interventionalists: A Skill Worth Teaching Luis Coentrao,[1] Manuel Pestana,[1] Bernardo Faria.[2] *[1]Nephrology Research and Development Unit, Hospital S. Joao, Faculty of Medicine University of Porto, Portugal; [2]Nephrology Department, Hospital S. Teotónio, Viseu.*

Background: Physical examination of arteriovenous fistulae (AVF) has recently emerged as an important element in the detection of stenotic lesions. This study examines the accuracy of physical examination in the assessment of AVF dysfunction by non-interventionalists, in comparison with angiography.

Methods: A prospective observational blinded study was performed among 177 haemodialysis patients with AVF dysfunction consecutively referred to our centre for an angiography procedure. Eleven referring general nephrologists completed a form reporting the physical examination findings regarding their patients' AVFs. Before angiography examination was carried out, a trained nephrology resident performed a physical examination in all the cases. Angiography of the AVFs was then performed by an interventionalist. Cohen's κ value was used as the measurement of the level of agreement beyond chance between the diagnosis made on physical examination and angiography.

Results: There was a moderate agreement beyond chance between the general nephrologists' physical examination and angiography in the detection of AVF inflow problems (κ = 0.49), outflow problems (κ = 0.58) and thrombosis (κ = 0.52). On the other hand, physical examination performed by the trained nephrology resident strongly agreed with angiography in the detection of AVF inflow problems (κ = 0.84), outflow problems (κ = 0.92), and thrombosis (κ = 0.98). The agreement between physical examination and angiography in the detection of coexisting AVF inflow-outflow problems was poor for the general nephrologists and moderate for the trained nephrology resident (κ = 0.14 vs. κ = 0.55, respectively).

Conclusions: Physical examination may provide an accurate means of diagnosis of AVF dysfunction. Theoretical and hands-on training in physical examination of dysfunctional AVFs should be provided for nephrologists in-training and for the dialysis staff.

Utility of Non-Invasive Arteriovenous Access Monitoring in Children Isa F. Ashoor, Elizabeth Hughson, Michael J. Somers. *Nephrology, Children's Hospital Boston and Harvard Medical School, Boston, MA.*

Background: Limited data exist regarding the use and efficacy of ultrasound dilution monitoring (UDM) as a technique to assess arteriovenous (AV) access patency and reduce AV access complications in children.

Methods: We studied all permanent AV access pts in our pediatric dialysis unit by monthly UDM between 2009-2011. Fistulagrams were prompted by UDM for flow rate <600 ml/min or >20% drop from baseline. Rates of AV access complication (thrombosis, hospitalization, temporary access placement) during the UDM period were compared to baseline rates manifested in the 2 years prior. To account for differences in length of time on HD, rates were determined for individual pts in both groups based on episode count relative to months on HD.

Results: No differences existed between the UDM (n=16) and baseline (n=14) groups with regards to age, gender, weight or age at ESRD diagnosis. In the UDM group (50% boys; median age at ESRD diagnosis 15 yo; median weight 51 kg; median AV access age 12 mos), 162 UD measurements were obtained over median follow-up of 5 mos (range 1-29 mos). Rates of access-related complications (hospitalization, new access formation, or temporary access placement) fell from 4 events/100 pt-mos at baseline to 2.5/100 pt-mos with UDM. Mean rate of thromboses in the UDM group (3.5/ 100 pt-mos on HD) was significantly lower than the baseline group (13.5/ 100 pt-mos on HD) ($p<0.04$). Within the UDM group, mean blood flow rate was lower in AV accesses that went on to thrombose compared to those without thrombosis (1203 ml/min/1.73m2 vs. 1683, $p <0.0001$). In the UDM group, 29 fistulagrams were done, 18 prompted by decreased UDM flow. 55% had hemodynamically significant stenoses requiring angioplasty +/- stenting. UDM was 94% sensitive and 77% specific in detecting hemodynamically significant stenoses with positive and negative predictive values of 83% and 91% respectively.

Conclusions: We conclude that in children on dialysis UDM: 1) reduces adverse outcomes requiring emergent intervention; 2) detects evolving hemodynamically significant stenoses; 3) reduces thrombosis rates in permanent AV access; and 4) has high sensitivity and predictive values as a screening tool.

FR-PO1963

Mapping Segmental AVF Pressure & Resistance with the BlueDop Imager David H. King,[1] Graeme Taylor, Mo Al-Qaisi, Sumith C. Abeygunasekara,[1] Anthony Chan,[1] Yiannis Panayiotopoulos,[3] Abdelgalil Abdelrahman Ali.[1] *[1]Renal Unit, Broomfield Hospital, Chelmsford, Essex, United Kingdom; [2]Department of Physics, Guy's and St Thomas Hospital Trust, London, United Kingdom; [3]Department of Surgery, Broomfield Hospital, Chelmsford, Essex, United Kingdom.*

Background: A novel device 'BlueDop Imager' uses an IP protected method to estimate mean arterial pressure at multiple locations within the body

Methods: Data values are derived from the incident pressure and resultant blood flow wave. An algorithm gives mean pressure.Incident data is derived from an arm BP.

The resultant flow wave is displayed on a pc which processes Bluetooth audio transmitted from the Doppler probe and video from a webcam.

Aims: Correlate venous needle pressure(pump off) with BlueDop pressure:Analyse pressure gradients in AVF:Video imaging of probe position makes fluid resistance per centimeter of blood vessel possible.

Results: After nominal correction for CVP(6mmHg)the following pressures were obtained from 14 AVF patients: Needle = 38.4+/-14.8mmHg, BlueDop = 37.4+/-9.9mmHg,corr coeff =0.48. Pressure gradients recorded from 41 AVF (49 gradients), indicate an axillary artery pressure minimum of 40mmHg, (Fig 1a).KEY:failing AVF-black arrow,narrowed AVF-grey,normal AVF=white (true pressure=40+CVP). This may be the first indication of a control loop mediated by the central venous system, effectively protecting the truncal arteries from ischaemia.(Fig 1b) shows probe position plus pressure image.A single flow entry can generate a resistance map.

Conclusions: Averaged BlueDop and direct needle pressure data agree. Labile CVP may be a confounding factor, principally affecting the correlation coefficient at low pressures: A previously unsuspected vasoactive venous control loop has been identified: Fluid resistance per centimetre of blood vessel can be computed non invasively.

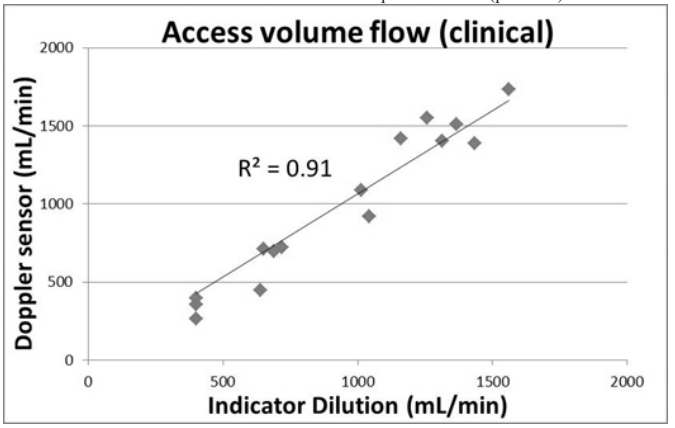
Doppler Smart-Sensor for Vascular Access Monitoring William Weitzel,[1] Grant H. Kruger,[1] Brian Thelen,[2] Benjamin Walter Koziol,[2] Benjamin Carpenter,[1] Mainak Mitra,[1] Leo Koziol,[1] David E. Conway,[1] Christopher R. Diroff,[1] Andre Preston,[1] Doug Swaney,[1] Dae Woo Park,[1] Robert Dodde.[1] *[1]Medicine and Engineering, University of Michigan, Ann Arbor, MI; [2]Michigan Technical Research Institute, Ann Arbor, MI.*

Background: Monthly access flow monitoring strategies aiming to reduce morbidity, cost, and improve access decision making have been met with mixed results. We hypothesize that flow measurements monitored throughout every dialysis with functional regression modeling for each patient will allow improved access decision making and reduce costs.

Methods: To investigate this hypothesis we developed a low-cost, low-profile, compact Doppler smart-sensor system with scalable modular hardware and software architecture that can be integrated into the dialysis clinic for continuous patient monitoring. Laboratory testing was conducted using a pulsatile pump (simulating patient access flow) and blood mimicking fluid through phantoms with mock dialysis pump to assess the spectral velocity profile for linearity and determine optimal digital signal processing strategies for access flow ranges from 0 to 2000 ml/min. The prototype was evaluated clinically for performance using indicator dilution measurements as reference measurements.

Results: Laboratory testing showed the Doppler smart-sensor velocities were linearly related to the vascular access phantom volume flow with an R-squared of 0.988 ($p < 0.01$). Clinical comparison of the optimized Doppler digital signal processing model with indicator dilution measurements was correlated with an R-squared of 0.91 ($p < 0.01$).



Conclusions: We conclude it is feasible to obtain accurate flow measurements in the laboratory and clinical setting using this Doppler smart-sensor. Functional regression data analysis is in progress preparing to test this device and monitoring strategy in an upcoming prospective study.

The Importance of the Presence of Reverse Color Flow and Collapsibility in Doppler Ultrasound Examination To Evaluate Central Venous Stenosis

Hoon Suk Park, Yu Ah Hong, Sun Ryoung Choi, In O Sun, Byung Ha Chung, Bumsoon Choi, Young Ok Kim, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim. *Division of Nephrology, Department of Internal Medicine, Catholic University of Korea, Seoul, Republic of Korea.*

Background: The absence of variation in venous diameter or flow pattern during respiration in doppler ultrasound(DU) examination is known as a useful clue to predict central venous stenosis(CVS). However, the variation in venoous diameter or flow pattern during respiration may exist in the cases of CVS. There may be the findings that subclavian vein isn't collapsed when pressed with the probe or the significant amount of reverse color flow exists during expiration in the cases of CVS. We performed this study how exactly DU detect CVS with these additional findings.

Methods: Flow patterns in the both pulsewave and color modes, collapsibility at distal subclavian vein in 2D mode were analyzed in 28 patients. Sixteen patients on chronic hemodialysis underwent subsequently substraction angiography for the evaluation of CVS while the other 12 patients underwent subsequently conventional venography for the creation of access. We define the case with CVS in DU examination that satisfies all of the findings including the variations in venous diameter and flow pattern exist during respiration, venous collapse exsits when pressed with the probe and the significant amount of reverse color flow during respiration doesn't exist. The image findings between DU and substraction angiography or conventional venography were compared.

Results: Kappa between DU and angiography was 0.593(p=0.001). Positive predictive value was 55%, negative predictive value was 100%, sensitivity was 100% and specificity was 77%.

Comparison of DU with angiography

	No stenosis in angiography(N)	Stenosis in angiography(N)	Total(N)
Unsuspicious stenosis in DU(N)	17	0	17
Suspicious stenosis in DU(N)	5	6	11
Total(N)	22	6	28

N: numbers

Conclusions: DU examination with our additional criteria showed favorable power to screen the cases wih possibility of CVS. Therefore, DU can screen asymptomatic patients on hemodialysis with CVS and also detect CVS more efficiently if used with venography prior to access creation.

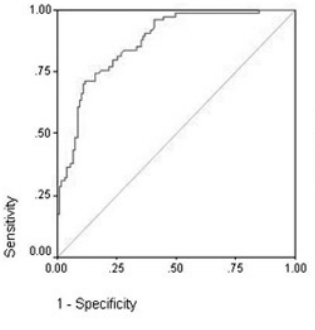
FR-PO1966

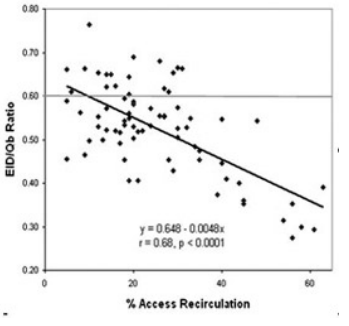
Using Effective Ionic Dialysance/Blood Flow Rate Ratio To Detect Access Recirculation in Hemodialysis Catheters Jennifer Tan,[1] Sumit Mohan,[2] David B. DaRocha-Afodu,[1] Leroy Herbert,[1] Herman L. Anderson,[1] Jen-Tse Cheng.[1] *[1]Div. of Nephrology, Harlem Hospital, NY, NY; [2]Div. of Nephrology, Columbia University Medical Center, NY, NY.*

Background: Vascular catheter use for dialysis remains highly prevalent. Access recirculation is a complication of catheter use and adversely impacts dialysis delivery. We previously reported the utility of effective ionic dialysance(EID)/blood flow rate(Qb) ratio in identifying significant(≥5%) access recirculation (sAR) in AV fistulas. We now present data from 63 patients (59% men, age 53±15.5 yrs, 1.9±2.6 yrs on HD), receiving HD via catheters (86% tunneled catheters, 75±79.8 days of catheter use).

Methods: EID and Qb were measured by Diascan® incorporated in the Gambro Phoenix® HD system during dialysis. Access recirculation was measured at least once monthly by saline dilution technique using Transonic HD-02 monitor.

Results: Among 193 HD sessions when simultaneous measurements of EID, Qb, and access recirculation were performed, we identified 74 instances of sAR. Temporary catheters were associated with a greater incidence of sAR than tunneled catheters(66.7% vs 35.4%, *p=0.019*), as were femoral catheters when compared to IJ catheters(60.9% vs 31.2%, *p=0.002*). No significant difference was seen in the duration of catheter use, yrs on dialysis, and Qb in patients with and without sAR. Patients with sAR had significantly lower EID(191.2±45.9 vs 252.2±35.7ml/min, *p<0.0001*) and demonstrated a significant inverse relationship between the EID/Qb ratio and access recirculation. The area under the ROC curve for EID/Qb was 0.87 and demonstrated a sensitivity of 76% and specificity of 78% at an EID/Qb ratio of 0.60. The highest Youden index was seen at a ratio of 0.58.





Conclusions: Our data show the usefulness of the EID/Qb ratio as an indicator of sAR in dialysis catheters and identifies the practical threshold value for detecting sAR to be an EID/Qb of <60%.

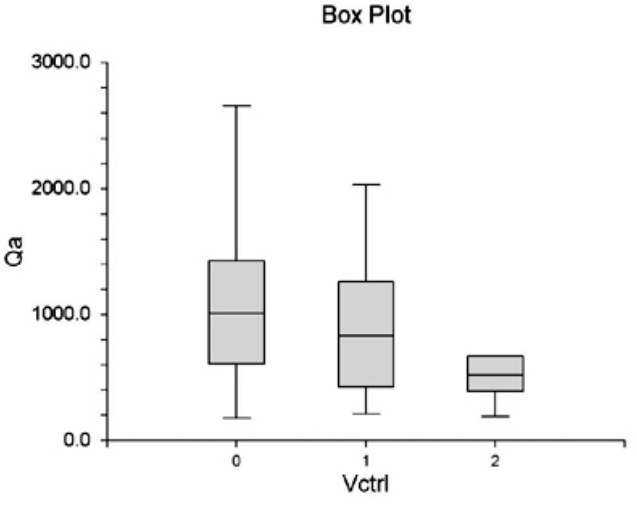
FR-PO1967

Validation of a New Fistula (AVF) Monitoring System by Time Pattern Data Analysis Compared to the Ultrasound Dilution Method (US) in Hemodialysis Patients (HD Pts) Massimo Adorati Menegato. *San Antonio's Hospital, San Daniele, Italy.*

Background: Evaluation of vascular access blood flow (Qa) by US represents the diagnosis gold standard for AVF malfunctions. Unfortunately, US requires sufficient distance between the needles, a dedicated disposable, is time consuming and has a not well-defined Qa threshold. We compared the accuracy of AVF monitoring by US and a new tool (Vascontrol, VCtrl), analyzing the time pattern of parameters, such as arterial and venous pressures (AP, VP), iDy, blood flow (Qb) and Hb.

Methods: We prospectively evaluated 21 HD pts (age 72±18 yrs) with native AVF (thrice-weekly dialysis schedule) for 17 months. The VCtrl approach is based on a supervised learning of a Dynamic Bayesian Networks (DBN) for classifying the dialysis sessions according to a medical risk score (0=good, 1=alert, 2=failed). The DBN system, evaluating the trend of dialytic parameters, calculated a score of AVF status. US test was performed monthly (score 0 Qa≥1000, 1 1000>Qa>600; 2 Qa≤600ml/min).

Results: We assessed 223 AVF monitoring by both US and VCtrl. A significant correlation between VCtrl scores and Qa was found and three different Qa cluster were identified (570±250 vs. 855±196 vs. 1163±50 ml/min, p<0.05 fig.1).



Sexteen angiographies were performed in 12 pts classified by a US score 2, showing 9 stenosis in 8 pts. VCtrl predicted, considering as positive score 1+2, AVF stenosis in 3/9 resulting in a sensitivity of 33.3% and a specificity of 90.4% (Chi^2 test, p=0.023), while US showed a sensitivity of 100% and a specificity of 71.7% (p<0.00005).

Conclusions: US monitoring system confirmed its own validity in AVF stenosis diagnosis, but it requires montly evaluation and presents a relative low specificity, leading in unsuitable angiography prescription. VCtrl seems to be more specific, but it requires further adjustments to increase its sensitivity.

FR-PO1968

Vascular Access Flow Monitoring in Clinical Practice during Maintenance Hemodialysis Improves Graft Survival Eng Kuang Lim,[1] Hui-Lin Choong,[2,3] Manish Kaushik,[2] Soh Theresa,[3] Lay Kwee Chin.[3] *[1]Renal Unit, Department of Medicine, Khoo Teck Puat Hospital, Singapore; [2]Renal Medicine, Singapore General Hospital, Singapore; [3]Kidney Dialysis Foundation, Singapore.*

Background: Ultrasound dilution measurement is one of KDOQI's recommended tools for vascular access surveillance in maintenance hemodialysis (MHD). We studied arteriovenous grafts (AVG) survival after applying this tool in routine clinical practice.

Methods: A retrospective survey of MHD patients using AVG as vascular access in 3 hemodialysis centers was carried out. Data from patients followed up by a single nephrology unit was analyzed. Vascular Access Surveillance (VAS) by ultrasound dilution flow monitoring using the Transonic system (Transonic Inc. Ithaca, NY) had been introduced since 2001. Flow-related problems (AVG flow < 600 ml/min or thrombosis) were promptly referred back to the parent unit for assessment and intervention. The data were divided and analyzed according to 3 study phases: I- Pre-VAS (1997-2000), II-Early VAS (2001-2003) and III-Established VAS (2004-2007).

Results: A total of 119 AVGs were followed in 42 patients (Phase I-16, II-27 and III-40). Etiology of ESRD was Chronic Glomerulonephritis 21 [50%], Diabetic Nephropathy 6 [14.3%], and Lupus Nephritis 4 [9.5%]. There was significant difference in age(I-42.4±9.6yrs, II-46.5±10.5, III-48.8±7.6, p =0.043). There were no significant differences in gender distribution, diabetic and cardiovascular status. Graft loss from thrombosis occurred as follows: Phase I-38, Phase II-29, Phase III-13 events per 100 patient-years. Cox regression survival analysis unadjusted and adjusted for age (using Phase I as reference) showed that AVG survival was significantly better for Phase III (HR 0.35, 95% CI 0.16-0.79, P=0.01 and HR 0.34, 95% CI 0.15 - 0.76, P<0.01 respectively) but not Phase II (HR 0.82, 95% CI 0.37-1.80,P=0.61 and HR 0.73, 95% CI 0.33 - 1.62, P = 0.44 respectively).

Conclusions: Vascular access flow surveillance in maintenance haemodialysis was associated with improved AVG survival despite increasing age of the studied population. There was probably a transition phase after the introduction of access flow monitoring before gains were obvious.

FR-PO1969

How To Measure the Access Flow Volume by Doppler Ultrasound in the Cases of Anatomical Variation and Comparison It with Ultrasound Dilution Technique Hoon Suk Park, Sun Ryoung Choi, In O Sun, Byung Ha Chung, Bumsoon Choi, Young Ok Kim, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim. *Division of Nephrology, Department of Internal Medicine, Catholic University of Korea, Seoul, Republic of Korea.*

Background: In previous studies, comparing doppler ultrasound(DU) with ultrasound dilution technique(UDT) in measuring intra-access flow volume(Qac), Qac by DU was measured at brachial artery or basilic vein at upper arm to avoid anatomical variation that may cause inaccuracy of the measurement. In practice, the sites where the needles are insertetd are different from these sites mostly. We performed this study to investigate how to measure Qac by DU between the needling sites in the cases of anatomical variation and how consistent it is with Qac by UDT.

Methods: We measured Qac by DU only between needling sites in the cases without anatomical variation. But, in the cases with accessory vein or aneurysmal change, we measured Qac at the two needling sites separately and calculate mean of them instead of measuring between the needling sites. Eighty seven Qac were measured in this way by DU and compared it with the Qac by UDT. We also compared the differences of Qac(ΔQac) between these two methods with regard to access location(lower arm VS upper arm), access type(fistula VS graft) and the presence of anatomical variation.

Results: Mean of the Qac measurements in this way by doppler ultrasound was 955.1±569.1ml/min and mean of the Qac measurements by UDT was 1040.4±713.6ml/min. The correlation coefficient(γ) between the two methods was 0.829(p<0.05). ΔQac(expressed by mean±standard deviation) were compared with regard to acecess location, access type and the presence of anatomical variation and there were no differences in ΔQac according to the groups.

Comparison of ΔQac according to the groups

Group comparison	ΔQac(ml/min)	p-value
lower arm VS upper arm	-117.7±436.9 VS -23.5±315.8	0.461
fistula VS graft	-99.3±423.3 VS-48.4±336.4	0.666
presence of anatomical variation VS otherwise	-214±808.46VS-60.4±263.1	0.338

Conclusions: Qac by DU can be measured between or at the needling sites regardless of the presence of anatomical variation, showing the high consistency with the Qac by UDT.

FR-PO1970

Effectiveness of Shower Washing Method without Antiseptics for Exit-Site Care of Noncuffed Hemodialysis Catheters Hiroshi Shibahara,[1] Nami Shibahara,[2] Susumu Takahashi. *[1]Blood Purification Center, Sagamihara Kyodo Hospital, Sagamihara, Kanagawa, Japan; [2]Hashimoto Minami Internal Medicine Clinic, Sagamihara, Kanagawa, Japan.*

Background: To prevent catheter-related infections with noncuffed hemodialysis catheters (NCC), skin disinfection has long been the mainstay of exit-site care. However, we have reported a care method to prevent infection by restoring the normal skin condition at the exit site, consisting of direct shower-washing without antiseptics. The aim of this study was to evaluate this care method for the exit site of NCCs.

Methods: The subjects were 50 hemodialysis patients (male/female, 33/17; mean age, 69.0 ± 13.3 years; diabetes mellitus/non-diabetes mellitus, 26/24) who had begun to use an NCC and gave informed consent to participate in this study at Sagamihara Kyodo Hospital between January 2008 and January 2010. Our method involved washing the exit site of NCC with physiological saline immediately after catheter insertion. Moisture was wiped away with non-sterile gauze. No antiseptic was applied. Shower washing of the exit-site was continued after every dialysis session until NCC removal. We evaluated the skin condition of the exit site, the incidence of catheter-related infection, and blood examination data [white blood cell (WBC) count, C-reactive protein (CRP), interleukin-6 (IL-6), albumin] at the time of insertion and removal of NCC.

Results: No exit site infection was observed. Slight erythema as compared to the normal skin was observed in two subjects. Three NCCs were removed because of catheter-related blood stream infections. These infections improved immediately following replacement of the NCC together with treatment with antibiotics. There were no significant differences in the values of WBC, CRP, IL-6, and albumin between the times of insertion and removal of NCC.

Conclusions: A shower washing method without antiseptics was effective for management of the NCC exit site. Future studies comparing this approach with conventional care methods in a larger number of subjects are needed.

FR-PO1971

Complications of Vascular Access for Haemodialysis and How To Avoid Them Irena Glowinska,[1] Jerzy Glowinski,[2] Jolanta Malyszko,[1] Edyta Zbroch,[1] Michal Mysliwiec.[1] *[1]Department of Nephrology and Transplantology, Medical University, Bialystok, Poland; [2]Department of Vascular Surgery and Transplantology, Medical University, Bialystok, Poland.*

Background: Maintenance of the vascular access continues to be the Achilles' heel of dialysis therapy. Different strategies have been implemented for monitoring and surveillance of the av fistulae. However, there is still much to do in the field of everyday care and basic monitoring.

The aim of the study was to identify causes of fistula losses that might be saved by the interdisciplanary approach to the problem, and proper cooperation between nephrologist, surgeon, nurse and patient.

Methods: Over 500 cases of reoperation and fistula losses out of total 1500 operation of vascular access, performed on patients from 11 dialysis centers, in 10-year period, made by one vascular surgeon were analyzed.

Results: The most common cause of early dysfunction of fistula was maturation failure. Majority were the result of inadequate blood vessels but some of them were caused by patients' non-compliance. Inappropriate cannulation technique of av fistula led to thrombosed aneurysms or hematomas with subsequent fibrosis. A few patients had symptoms of central or peripheral venous hypertension, mostly treated with endovascular procedure. Many patients required trombectomy and only a few underwent reconstruction of still functioning av fistula. Collateral ligation within 1-2 months after primary operation was rarely performed. Six grafts of total over 70 implanted were removed due to infection and 3 due to post-cannulation damage. Two fistulas were ligated due to steal syndrome (both within 2 months after primary procedure).

Conclusions: Proper understanding of the problem by all people involved (nephrologist, dialysis nurse, surgeon and the properly informed patient) could save many of those fistulas losses. Policy Treat the *failing*, not the *failed* arteriovenous fistula should be implemented more often. Clinical examination of arteriovenous fistula and more frequent use of ultrasonography to detect an early failure might give a chance for better survival. A vascular access should stop being a Cinderella and start its life of first-born son.

FR-PO1972

The Outcome of the Primary Dialysis Access and Its Translation in Prevalence Rates in Chronic Hemodialysis Patients Claudia Praehauser,[1] Tobias Breidthardt,[2] Cora Nina Moser-Bucher,[2] Thomas Wolff,[3] Katrin Bächler,[2] Michael Dickenmann,[2] Lorenz Gurke,[3] Michael Mayr.[1,2] *[1]Medical Outpatient Department, University Hospital Basel, Switzerland; [2]Clinic for Transplantation Immunology and Nephrology, University Hospital Basel, Switzerland; [3]Clinic for Transplantation Surgery, University Hospital Basel, Switzerland.*

Background: In chronic hemodialysis, the creation of a native arteriovenous fistula (AVF) as the primary vascular access is recommended because of higher patency rates and fewer access-related complications. The aim of our study was to investigate the long term outcome of the primary access and its impact on prevalence rates.

Methods: We conducted a retrospective analysis of all patients who had a primary dialysis vascular access created from 1995 to 2006. Primary endpoints were the 'primary access failure free survival' defined as the time from creation of the permanent vascular access to its complete loss, and the prevalence rates of the different access types.

Results: 246 patients were included in the study. 211 (86%) received a native arteriovenous fistula (AVF), 16 (6%) a synthetic arteriovenous graft (AVG) and 19 (8%) a permanent tunneled catheter (PC) as the first permanent vascular access. 1, 3 and 5-year primary access failure free survival rates were 72%, 61% and 51%. Primary access failure free survival was significantly worse for female gender (HR 1.96 (CI 1.24-3.12)), peripheral artery disease (PAD) (HR 1.99 (CI 1.16-3.43)), AVG (HR 2.99 (CI 1.57-5.68)) and PC (HR 3.05 (CI 1.32-7.06)). When stratified by gender, AVG and PC were the only significant risk factors in female patients, while in male patients PAD, malignoma and AVG were associated with a poorer outcome. The rate of patients needing a second vascular access was 32% for patients primarily dialysed by AVF, 75% by AVG and 37% by PC. The overall median prevalence was 80% for AVF, 14% for AVG and 6% for PC.

Conclusions: A high rate of primary AVF contributes to a high prevalence rate of AVF, indicating that in most patients the creation of a native AVF also leads to its sustained use. In consequence, the consistent implementation of the vascular access guidelines achieves their goals.

FR-PO1973

Changes in Incident Dialysis Patient Mortality through 2010 Vincent Mor,[1] Franklin W. Maddux,[2] Mahesh Krishnan.[3] *[1]Brown Center for Gerontology & Health Care Research; [2]Fresenius Medical Care; [3]DaVita, Denver, CO.*

Background: The Performance Excellence and Accountability in Kidney Care (PEAK) Campaign is an initiative sponsored by Kidney Care Partners, a organization representing the vast majority of the kidney care community. Its goal is to reduce incident patient mortality by 20% from 2008 through 2012. As part of this program, incident patient mortality was calculated for day 90, day 120 and at one year for all patients entering dialysis.

Methods: In order to get the most recent results, data were obtained from CMS from the Renal Management Information System (REMIS) through December 2010. Beginning dates of entry of patients (from Medical Evidence form 2728), Patient demographic and clinical characteristics (2728/Patient Master file), and Date of death (From Patient Master file, Form 2746 merged with Social Security Master Death File (SSMDF)) were obtained. The 1-year mortality rate, calculated as number of deaths in the first year after dialysis initiation/total number of patient years was calculated. Similar methods were used to calculate the 90 and 120 day mortality rates. Any individual who began dialysis in any given time period January 1, 2007-December 31, 2007 (Cohort 1 - 2007), Jan 1, 2008-December 31, 2008 (Cohort 2 - 2008), January 1, 2009-December 31, 2009 (Cohort 3 - 2009) was included.

Results: Results for each year's 90 day, 120 day, and 1 year mortality rates are displayed below.

	Incident_2007	Incident_2008	Incident_2009
90-day	0.389	0.383	0.372
120-day	0.374	0.369	0.356
1-year	0.267	0.259	0.250

Conclusions: All three measures of incident patient mortality appear to be decreasing. This may be in part due to efforts to reduce catheters and improve the biochemical markers in these patients on the part of nephrologists and dialysis providers. However, other improvements influencing cardiovascular and infectious complications in the general population may also be having an effect. The PEAK Campaign continues to provide insights and interventions to achieve this important goal for the nephrology community and further analysis is required to understand the genesis of these results.

FR-PO1974

Arteriovenous Fistulas Should Really Be the First Choice Joao Albuquerque Goncalves, Rui Alves Filipe, Raquel Chorão, Ernesto F. Rocha. *Nephrology, Hospital Castelo Branco, Castelo Branco, Portugal.*

Background: The survival of hemodialysis (HD) patients (pt) depends on the long-term functioning and patency of the vascular access. The goal of this investigation is to emphasize the use of "Fistula First" guideline in a region of Portugal, checking the reality of long-term HD access patency, comparing arteriovenous fistula (AVF) to graft and its characteristics.

Methods: Retrospective review of all the HD accesses built from Jan 1st 2008 to June 30th 2010 in a region of Portugal. Follow-up until 15th Jan 2011. Pts were categorized according to demographics, co-morbidities, access date, type and location. Follow-up was considered until pt death or permanent access failure. Patency was calculated. Kaplan-Meyer, Cox-regression and Log Rank test used to analyze data with SPSS®. CI - 95% and $p<0.05$ considered. Access endpoints and complications were documented.

Results: The study reviewed 217 accesses in 181 pts, age 72.1+/-15.4 years, 53% male, 41,5% diabetics; 68.2% AVF and 31.8% grafts; 84,3% proximal, 15,7% distal. Median patency time was 18.37 [16.48; 20.26] months (m), 19.96 m for AVF and 12,5 m for grafts, with 37.4% difference of patency time (p=0,01). The femoral graft had an estimated survival time of 6,9m (p=0,03). There were 44,7% access thrombosis - 55% of grafts (n=38) and 39,8% of AVF (n=59). At 6 months there were 76,6% working AVFs and only 66,7% working grafts (p=0,17). At 1 year of follow-up 68,8% of AVF were working versus 55,3% of grafts (p=0,07). At 18 months there was a significant difference between still functioning AVFs -58,9% and functioning grafts-only 31,7% (p=0,008). There was no difference between diabetics and no diabetics, distal and proximal accesses.

Conclusions: Although both AVF and grafts are useful for pts requiring HD, our data shows that fistulas should really come first because of their longer term patency. This study also reveals the extreme importance of a HD access database.

FR-PO1975

Malnutrition-Inflammation Syndrome in Hemodialysis Patients Associated with Vascular Access Luis Alberto Evangelista-Carrillo,[1] Hildelisa Ordaz Solis,[1] Trinidad Orlando Lugo Lopez,[1] Yeny Pescador,[1] Salvador Mendoza Cabrera,[1] Jorge Andrade-Sierra,[1] Enrique Rojas-Campos,[2] Benjamin Gomez-Navarro.[1] *[1]Department of Nephrology, Hospital de Especialidades, IMSS, CMNO, Guadalajara, Jalisco, Mexico; [2]Medical Research Unit in Renal Diseases, IMSS, CMNO, Guadalajara, Jalisco.*

Background: The Malnutrition-Inflammation Complex Syndrome (MICS) is high prevalent in dialysis. The MICS include anorexia, loss of muscular mass, hypoalbuminemia, refractory anemia and atherosclerosis, also increase morbi-mortality. The association between the type of vascular access and MICS was not been evaluated. **Aim:** To determine the association in patients with MICS and type of vascular access.

Methods: Transversal analytic with 78 prevalence hemodialysis patients. All were evaluated for Malnutrition-Inflammation Score (MIS).

Results: Mean age was 42 years, female was 61%, 20% had Diabetes as cause of CKD, 46% had arteriovenous fistula, 61% received 12,000 UI of EPO (erythropoietin) but only 18% were receiving intravenous iron, 42% had >4 pts in MIS. Age, hospitalization times, antihypertensive drugs were significantly higher in patients with >4pts in MIS compare with <4pts. In logistic regression analysis, had >4pts in MIS were predicted by hospitalization times (p=0.02), low Hb (p=0.04), low alkaline phosphatase (p=.01). Other results are shown in Table.

Comparison between types of vascular access

	All n=78	Catheter n=39	Fistula n=39
MIS (pts)	6(±3.2)	6.3(±4)	5.7(±2.4)
Mean age	42(±20)	43 (±22)	41(±18)
Time in dialysis	45(±35)	28(29)	62(32)*
Hb (gr/dl)	9.6(±1.8)	9.3 (±1.7)	9.3 (±1.7)
EPO (UI/week)	9743(±3832)	10564(±2936)	8923(±4444)
EPO index	1143(±411)	1199(±406)	1080(±413)
Ferritin (ng/ml)	503(±624)	394(±499)	608(±718)
Kt/V	1.4 (±0.7)	1.3(±0.6)	1.4(±0.8)
Phosphorus (mg/dl)	5.6(±1.5)	5.2(±1.2)	6(±1.6)*
Alkaline phosphatase	322(±448)	331(±596)	313(±262)
Albumin (gr/dl)	3.9(±0.5)	3.8 (±0.6)	4.1(±0.4)*
CRP (mg/L)	14(±18)	18.6(±23)	10(±11)
PTHi (U)	890(±804)	643(±502)	1112(±955)*
Hospitalization times	1.18	1.77	0.59*

p=<0.05 between catheter and fistula

Conclusions: According to vascular access was not difference in prevalence of MICS. Although, hyporesponsiveness on EPO and hospitalizations were most frequent in catheter group.

FR-PO1976

The Impact of Vascular Micro-Calcification of Radial Artery on Cardiovascular Mortality in Hemodialysis Patients Yu-Seon Yun, Young Ok Kim, Hyun Gyung Kim. *Nephrology Department, Catholic University of Korea, Seoul, Korea.*

Background: Vascular gross calcification by imaging study is common in hemodialysis (HD) patients, and it is a significant predictor for cardiovascular mortality in HD patients. But vascular micro-calcification (VMC) by pathologic study has been rarely reported. Recently, we have reported that VMC is associated with vascular access failure as well as aortic stiffness (2010 ASN). The aim of this study was to determine the impact of VMC of radial artery on cardiovascular mortality in uremic patients receiving vascular access operation.

Methods: One-hundred forty nine HD patients (Mean age; 59.0 ± 13.9 years, Male/Female; 86/63, Percent of diabetes mellitus; 65.8%) receiving vascular access operation were included in this study. During the operation, we obtained partial arterial specimen and performed pathologic examination by von Kossa stain to identify VMC. We investigated cardiovascular mortality for at least 1 year after the operation. Finally we compared clinical and laboratory findings, and cardiovascular mortality between the patients with VMC and those without VCM.

Results: Mean duration of follow-up was 37.8 ± 34.5 months and the incidence of VCM was 38.8% (n=57). Diabetes (OR 4.138, 95% CI 1.631-11.830, p=0.002) and peripheral artery disease (OR 9.958, 95% CI 1.021-1339.97, p=0.048) were independent predictors for VCM. Serum parameters were not significantly related to VMC. During the period of flow up, there were 27 cardiovascular deaths. Kaplan-Meier analysis showed an increased cardiovascular mortality risk (HR 2.613, 95% CI 1.196-5.711, p-value= 0.016) in VMC group, and Cox regression analysis confirmed that VMC was an independent predictor for cardiovascular mortality (HR 2.352, 95% CI 1.087-5.088, p-value= 0.030).

Conclusions: This study demonstrates that VMC is a strong risk factor of cardiovascular mortality in HD patients.

Novel Blood Access for Home Hemodialysis Frank Prosl.[N/A] [1]*Koestenberg, Austria;* [2]*Duxbury, MA.*

Background: HDA is called Achilles Heel of dialysis from poor safety & performance & reliability. We describe a novel Hemodialysis Access (HDA) system which meets critical needs for improved outcomes & helps patients perform home hemodialysis.

Methods: HDA problems spanning 4 decades seemed intractable. Patients report strong dissatisfaction with HDA in several newly published surveys. Patients achieve best QoL with home hemodialysis(HD)which further detracts on HDA performance & safety requirements. Forecasts indicate increasing numbers of HD patients cannot be sustained forcing policy consideration towards patient personal care. Authors performed fundamental analysis of a HDA system seeking to better performance for critical characteristics & added requirements for patient self-accessing. Additional mandate was to satisfy patient's important self-image concerns of HDA & enable easy secure self-accessing.

Results: The approach was to design elements for solving various problems & integrate them into an elegant system. Our HDA system comprises an implantable port, a novel tissue tract construct, new prophylaxis composition & method, new ancillary tools & methods for accessing and forming the engineered tissue tract. Performance benefits include: 1)"Fail-Safe" design from needle & bloodline dislodgement 2) Simple accessing without pain, bleeding, docking mistakes or tissue damage or infection 3) Increased fluid integrity during HD & between times & comprehensive effective prophylaxis 4) Preserved patient self- reliance & self –image, no stigma or loss of arm function & no bleeding 5) Novel engineered tissue tract comprising new etiology and tissue morphology suitable for connector tissue penetration in precise alignment without guessing (i.e., not buttonhole) & 6) Substantial robustness & system life time, low costs.

Conclusions: Test models demonstrate superior safety and ease of patient accessing. Worst case blood loss is limited to volume in the extracorporeal circuit. Air embolism is prevented in case of dislodgement. The system will help attract patients for home HD & remove the major cause of partner burnout. This HDA should help create conditions favoring HD at home.

FR-PO1978

"Hybrid" Graft Reduces Venous Stenosis in a Pig Arteriovenous Graft Model Prabir Roy-Chaudhury,[1] Yang Wang,[1] Meenakshi J. Mistry,[1] Begoña Campos,[1] Timmy C. Lee,[1] Kyuran Ann Choe.[1,2] [1]*Dialysis Vascular Access Research Group, Division of Nephrology and Hypertension, University of Cincinnati, OH;* [2]*Department of Radiology, University of Cincinnati, OH.*

Background: Arteriovenous graft (AVG) stenosis due to neointimal hyperplasia (NH) remains an important cause of hemodialysis vascular access dysfunction. Despite the magnitude of the clinical problem there are currently no effective therapeutic interventions. The "Hybrid" graft (manufactured by WL Gore) is a heparin bonded graft with a nitinol reinforced section (NRS) at the venous end. Insertion of the NRS through a venotomy followed by expansion results in a sutureless end to end anastomosis (see Figure). The biological rationale for the "Hybrid" graft is that the functional end to end anastomosis will optimize hemodynamic profiles resulting in a reduction of NH.

Methods: Standard AVGs and the "Hybrid" grafts were placed between the femoral artery and vein on opposite sides. Animals were auscultated every 3 days to document patency. A 64 slice CT angiogram was performed at 6 weeks to assess for stenoses within the arteriovenous circuit. The maximal degree of stenosis within the access circuit was used for the statistical analysis. A thrombosed graft was considered to constitute a 100% stenosis.

Results: The majority of stenoses in both the control and "Hybrid" arms were at the graft-vein or NRS-vein junction, or within the first 3 cms of downstream vein (in a cranial direction). Control grafts had a mean percentage stenosis+/-SE of 83.3+/-12 % as compared to 45+/-10% for the "Hybrid" grafts (p=0.024;paired t test).

Conclusions: Our results suggest that the "Hybrid" graft reduces venous segment stenosis as compared to control grafts in our pig model of arteriovenous stenosis. Further investigations as to the mechanisms involved are currently ongoing.

Geographic Variation and Trends in Vascular Access-Related Infection Rates in the United States Rajiv Saran, Joseph M. Messana, Erik Roys, N. A. Lueth, Casey Parrotte, T. H. Shearon, John Kalbfleisch. *UM-KECC, Univ. of MI, Ann Arbor, MI.*

Background: The 2011 Dialysis Facility Reports will include information on dialysis access-related infection (ARI) rates for Medicare Hemodialysis (HD) patients for 2007-2010. These metrics were derived from ICD-9 codes for dialysis ARI for HD patients (996.62 - Infection and inflammatory reaction due vascular device, implant and graft) and will help dialysis providers compare their infection rates to national, state, and ESRD Network averages.

Methods: We describe variation in ARI rate across dialysis facilities and geographic regions. ARI rates per 100 patient months were calculated using ICD-9 codes reported in Medicare claims 2007-2010 and data from other national ESRD data. Poisson regression (log link, offset=ln of patient months) was used to assess the association of facility characteristics with infection rates and to establish expected values and standardized infection rates.

Results: Significant facility variation exists in vascular ARI rates across the country. Over the 4 years of observation, these infection rates have significantly declined overall ($p<0.001$ average decrease 0.05). The new measure of vascular ARI rates is strongly correlated with known predictors of infection such as patient age, percent of patients with diabetes, and percent of patients using catheter at those facilities ($p<0.001$). Mortality associations with vascular ARI were completely abrogated by adjustment for percent facility use of catheter as vascular access ($p<0.01$ to $p=0.71$).

Conclusions: The decreasing trend in vascular ARI is reassuring, but requires continued monitoring. Decreasing use of dialysis catheters should remain a national priority. Our study helps to validate the calculation of infection rates using ICD-9 codes derived from Medicare claims. Lowering the proportion of catheters as vascular access can reduce vascular ARI and potentially mortality resulting therefrom.

Development of an Adult-Like Model of Autosomal Dominant Polycystic Kidney Disease by Manipulating the Timing and Extent of Pkd1 Deletion in a Conditional Knockout Mouse Thomas A. Natoli, Kelly A. Rogers, Laurie A. Smith, Sarah E. Moreno, Nikolay Bukanov, Herve Husson, Oxana Beskrovnaya. *Cell Biology, Genzyme Corp., Framingham, MA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) results from mutations in one of two genes, PKD1 or PKD2. Development of effective therapies to slow cyst growth and preserve renal function requires the use of preclinical models that closely mimic ADPKD. Pkd1 conditional knockout mice have been generated to develop such a model. However, several limitations remain. Conditional inactivation of mouse Pkd1 gene prior to postnatal day 14 leads to aggressive kidney cyst formation within the neonatal period and early death. Deletion after postnatal day 14 leads to cyst formation in adults, but with a very long lag period that is inconvenient for therapeutic testing. We set out to develop a more adult-like model of ADPKD to study molecular pathogenesis and to test potential therapies. Here, we use a tamoxifen-inducible Cre fusion protein and a Pkd1 conditional knockout allele to show that altering the timing of deletion during the first 10 days of life modifies the extent of cystogenesis; deletion on postnatal day 1 gives an aggressive cystic phenotype, while progressively milder cystogenesis is obtained with deletion on days 2, 3, 4, 5 or 8. We further demonstrate that altering the dose of tamoxifen also modifies cystogenesis: using doses of tamoxifen ranging from 10-250 mg/kg delivered at postnatal day 1 produces a dose-dependant PKD phenotype, with lower doses producing fewer kidney cysts, slower decline in renal function and survival up to 6 months of age. Molecular analysis of cystic kidneys reveals changes in a number of signaling pathways, proliferation and apoptosis similar to human ADPKD. The kidneys from these animals also demonstrate signs of fibrosis, which begins after cyst formation. By manipulating the timing and extent of Pkd1 deletion, we have now developed an adult-like model of ADPKD that recapitulates many of the features of human disease and can be used for therapeutic testing.

Treatment of Embryonic Pkd1 Mutant Mice with the HDAC Inhibitor Trichostatin-A Reduces Cyst Growth Carol G. Carlton,[1,2] Binu M. Paul,[1,2] Lynn Magenheimer,[2] Madhulika Sharma,[1,2] Gregory B. Vanden Heuvel.[1,2] *[1]Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS; [2]Kidney Institute, University of Kansas Medical Center, Kansas City, KS.*

Background: Cux1 is a homeobox gene involved in cell cycle regulation and kidney development. Cux1 represses the cyclin kinase inhibitor p27 during early kidney development, promoting cell proliferation in the nephrogenic zone. Promoter reporter analysis of p27 revealed that Cux1 represses p27 in a concentration dependent manner, and chromatin immunoprecipitation showed that Cux1 interacts with the co-repressor Grg4 and the histone deacetylases HDAC1 and HDAC3 on the p27 promoter in vivo. To determine whether HDACs are required for Cux1 repression of p27 we analyzed p27 promoter activity in the presence of the HDAC inhibitor trichostatin A (TSA). TSA treatment completely relieved the repression of p27 by Cux1 and Grg4, demonstrating that Cux1 represses p27 in an HDAC dependent manner. Cux1 is upregulated in the kidneys of both mice and humans with ADPKD. However, Cux1 transgenic mice do not develop cystic kidneys, indicating that upregulation of Cux1 alone is insufficient to develop PKD. Rather, mice carrying both a collecting duct deletion of Pkd1 (Pkd1CD) and a targeted deletion of Cux1 showed that Cux1 is required for cyst growth. Moreover, p27 was upregulated in the cyst lining cells. To begin to test whether HDAC inhibitors could be used to target Cux1 repression of p27 for the treatment of PKD, we treated Pkd1CD mice with TSA or vehicle beginning at embryonic day 10.5 until embryonic day 18.5. Newborn Pkd1CD mice that received vehicle exhibited extensive collecting duct cysts, while newborn Pkd1CD mice that received TSA showed a significant reduction in cysts. Taken together, these results suggest that HDACs are required for cyst growth, and raise the possibility that HDAC inhibitors may be an effective treatment for PKD.

FR-PO1982

Cilia Defects and Polyploidy Linked to Low PC1 Expression in Kidney Epithelia Cells Are Mediated by Increased Expression of Sirt2 and HDAC6 Xia Zhou,[1,2] Lucy X. Fan,[1,2] Wei Liu,[1,2] William E. Sweeney,[1,2] James P. Calvet,[4] Ellis D. Avner,[1,2] Xiaogang Li.[1,2,3] *[1]Children's Research Institute, Children Hospital of Wisconsin, Milwaukee, WI; [2]Pediatrics, Medical College of Wisconsin, Milwaukee, WI; [3]Physiology, Medical College of Wisconsin, Milwaukee, WI; [4]Biochemistry and Molecular Biology, University of Kansas Medical Center, Kansas City, KS.*

Background: The association of PC-1 and PC-2 with the primary cilium has led to the ''primary cilia'' hypothesis in ADPKD. However, how polycystin(s) levels affects ciliogenesis is still unknown.

Results: In this study, we found that HDAC6 and its binding partner, Sirt2 were upregulated in *Pkd1* mutant mouse kidney epithelial (MEK) cells and tissues compared to Pkd1 wild type MEK cells and tissues. To examine the role of HDAC6 and Sirt2 in ciliogenesis we over-expressed either HDAC6 or Sirt2 in mouse inner medullary collecting duct (mIMCD) cells. Over-expression of either HDAC6 or Sirt2 significantly reduced the percentage of cells with cilia. Inhibition of HDAC6 with either trichostatin (TSA), a general HDAC inhibitor, or tubacin, a specific HDAC6 inhibitor, or inhibition of Sirt2 with nicotinamide, prevented cilia disassembly and increased the acetylation of a-tubulin in both Pkd1 wild type and mutant renal epithelia. Nicotinamide treatment also resulted in a significant increase in the percentage of Pkd1 mutant renal epithelial cells that developed cilia. These results suggest that while HDAC6 may regulate cilia assembly and disassembly during the normal cell cycle, Sirt2 levels appear to be critical for ciliogenesis in cystic epithelial cells. In addition, we found that overexpressing Sirt2 but not HDAC6 induced polyploidy and centrosome amplification similar to that found in the Pkd1 knockdown mIMCD cells.

Conclusions: In summary, reduced PC1 levels results in increased HDAC 6 and Sirt2. While HDAC6 is important in cilia assembly and disassembly, Sirt2 plays a central role in cilia development and increased Sirt2 levels lead directly to polyploidy and centrosome amplification. This is the first report that mechanistic links reduced PC1 levels to ciliogenesis, polyploidy and centrosome amplification.

FR-PO1983

The Microtubule-Associated HDAC6 and Sirt2 Regulate Epidermal Growth Factor Receptor (EGFR) Endocytic Trafficking and Degradation Wei Liu,[1,2] Lucy X. Fan,[1,2] Xia Zhou,[1,2] William E. Sweeney,[1,2] Ellis D. Avner,[1,2,3] Xiaogang Li.[1,2,3] *[1]Children's Research Institute; [2]Pediatrics, ; [3]Physiology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Apical mislocalization, over-expression and hyperactivity of the epidermal growth factor family of receptors and ligands (EGFR axis) has been shown to create an autocrine/paracrine loop of aberrant proliferation in human ADPKD epithelia *in vivo* and *in vitro,* as well as in rodent models of ADPKD and ARPKD. However, the mechanism(s) involved in regulating apical EGFR stability and endocytic trafficking in cystic epithelial cells is unknown.

Results: In this study, we present evidence for the first time that both histone deacetylase 6 (HDAC6) and its binding partner, Sirtuin family protein 2 (Sirt2), regulate EGFR degradation and trafficking along microtubules in Pkd1 mutant kidney epithelial cells. HDAC6 and Sirt2, microtubule-associated deacetylases with tubulin deacetylase activity, demonstrate increased expression in Pkd1 mutant mouse embryonic kidney (MEK) cells. We found that targeting HDAC6 or Sirt2 with a general HDAC inhibitor, trichostatin (TSA), a specific HDAC6 inhibitor, tubacin, or a Sirt2 inhibitor, nicotinamide, increased the acetylation and therefore stability of α-tubulin and downregulated the expression of EGFR in Pkd1 mutant kidney epithelial cells. To examine the role of deacetylation on EGFR expression we treated MEK cells with epidermal growth factor (EGF). HDAC6 or Sirt2 was co-localized with EGF induced endocytic EGFR and endosomes, respectively. Within 10 minutes following EGF stimulation of MEK cells there was a random distribution of EGFR that co-localized with early endosomes. Thirty minutes following EGF stimulation, a significant rearrangement of EGFR along microtubules was evident with EGFR co-localized to late endosomes.

Conclusions: These data indicate that the Pkd1 mutation induces upregulation of HDAC6 and Sirt2, leading to increased deacetylation of α-tubulin and therefore decreased degradation and endocytic trafficking of EGFR. Targeting HDAC6 and/or Sirt2 to downregulate EGFR activity may provide a potential therapeutic approach to treat polycystic kidney disease.

FR-PO1984

mTOR Kinase Inhibition in a Model of Polycystic Kidney Disease Atif A. Kidwai,[1] Hyunho Kim,[2] Michael Martin,[3] Yi Liu,[3] Jian Wang,[1] Kevan Shokat,[1] Christian Rommel,[3] Feng Qian,[2] David Pearce.[1] *[1]Division of Nephrology, UCSF, San Francisco, CA; [2]Center for Polycystic Kidney Disease, Johns Hopkins University, Baltimore, MD; [3]Intellikine, La Jolla, CA.*

Background: Polycystic Kidney Disease is a relatively common cause of renal failure with no current acceptable therapies. There has been some success with treating the disease in rodent models with rapamycin, an mTOR inhibitor; however, success in clinical trials has been poor. This may be in part due to the fact that phosphorylation of several mTOR targets is insensitive to rapamycin.

Methods: We examined the effects of a new class of ATP competitive mTOR kinase inhibitors, termed "torkinibs", on mTOR activities, as well as on cyst volume in PKD(V/V) homozygous mutant mice. We treated V/V mutants, heterozygous (V/+), or wild type (+,+) mice from postnatal days 5-11 with oral torkinib or vehicle (n=6 in each group). Mice were sacrificed 2 hrs after their last dose on P11, and kidneys harvested for immunoblot and histologic analysis.

Results: Total body mass and average kidney mass were lower in treated than in untreated mutants (5.42 gms vs 3.34 $p < 0.01$, 301mg +/- 39 to 172mg +/- 43 $p = 0.02$, respectively). The reduction in kidney mass was greater than reduction in body mass, and the combined kidney mass/body mass ratio in the torkinib-treated mutants was significantly lower than in vehicle-treated mice (0.081 +/- 0.012 vs. 0.113 +/- 0.008; $p = 0.02$). In non-mutant mice, body mass was lower in torkinib-treated than in vehicle-treated animals ($p = 0.02$), but there was no difference in kidney mass ($p = 0.22$) or combined kidney mass/body mass ratio ($p=0.5$). Kidney lysates immunoblots were probed with phospho-specific antibodies to assess the phosphorylation status of mTOR targets; mTOR targets had markedly lower phosphorylation in torkinib vs vehicle-treated controls. In preliminary histologic analysis, cyst volume was lower and parenchymal volume greater in torkinib-treated V/V mice than in vehicle treated mice.

Conclusions: These data demonstrate that torkinibs can inhibit mTOR in the kidneys of V/V mice, and suggest that they may have a beneficial effect on cystogenesis in this model of PKD.

Kirsten-Ras GTPase Isoform as a Target in ADPKD Ayesha Irtiza-Ali,[1] Richard N. Sandford,[2] Dorien J.M. Peters,[3] Patricia D. Wilson,[4] Claire C. Sharpe,[1] Bruce M. Hendry.[1] *[1]King's College London; [2]Cambridge University; [3]Leiden Univ Medical Center; [4]University College London.*

Background: Our previous studies show that inhibition of Kirsten (Ki)-Ras GTPase isoform using antisense oligonucleotide (ASO) has marked anti-proliferative and anti-fibrotic effects in different models of proliferative renal disease. Autosomal dominant polycystic kidney disease (ADPKD) is characterized by abnormal cell proliferative responses that lead to cystogenesis and progressive fibrosis, resulting in loss of renal function. Ras-GTPase signalling may be implicated in these processes. We aim to examine this further.

Methods: Renal cystic disease in an orthologous PKD1nl/nl hypomorphic mouse model, bred on a C57B6xCD1 genetic background, was characterized in detail using histochemistry, qPCR and immunoblotting, and compared to wt (n=4/group). We then employed modified ASO technology to study the effect of Ki-Ras inhibition in vitro and in vivo.

Results: PKD1nl/nl kidneys exhibit altered cystic epithelial cell morphology and E-cadherin expression, peri-cystic and interstitial fibrosis, increased tubular and cystic epithelial cell proliferation and phospho-ERK expression, and upregulation of Ras-GTP. Ki-Ras expression is increased by 4-fold in cystic kidney compared to wt ($p=<0.0001$). Two Ki-Ras ASOs each transfected into mIMCD3 cells at a concentration of 100nM cause selective knockdown of Ki-Ras by >80%, and inhibit cell proliferation by 29 and 38% compared to a control ASO ($p=<0.05$). In C57B/6 mice, these ASOs selectively knockdown Ki-Ras in the kidney by 50% ($p=<0.001$), without adverse effect. Antibody detection of ASO localizes distribution to within the tubular epithelia of the proximal and distal nephron.

Conclusions: Our results indicate that Ki-Ras is important in renal epithelial cell proliferative responses, and may be involved in ADPKD pathogenesis. These studies are also the first to demonstrate use of 2 active ASOs in mouse that safely and specifically target Ki-Ras in the kidney, supporting their use for therapeutic study. Our current work investigates the role of Ki-Ras as a potential common link in the abnormal proliferative and fibrogenic responses that occur in ADPKD.

Cell Therapy in Polycystic Kidney Disease Rende Xu, Karen M. Peterson, Peter J. Psaltis, Peter C. Harris, Lilach O. Lerman, Amir Lerman, Martin G. Rodriguez-Porcel. *Department of Internal Medicine, Mayo Clinic, Rochester, MN.*

Background: Polycystic kidney disease (PKD) is the most common genetic renal disease and is characterized by the development of parenchymal cysts and impaired renal vascular and tubular structure and function. In previous studies, cell therapy ameliorated renal dysfunction in a model of chronic renovascular disease. Thus, we hypothesize that cell therapy may ameliorate the renal vascular and tubular dysfunction in PKD**.**

Methods: Bone marrow derived mesenchymal stromal cells (MSCs) ($2.5x10^5$) were transplanted to a rat model of autosomal recessive PKD (ARPKD, n=6) through direct injection into the left renal artery at 6 weeks of age, and compared to wild type. Mean arterial pressure (MAP) was measured via tail-cuff. Fifteen-hour urine collections were performed and kidney volume was measured with High Resolution Ultrasonography (frequency: 30MHz). Renal vascular function was calculated by measuring end-diastolic Doppler flow velocities before and after injection of the endothelial dependent vasodilator Acetylcholine (Ach, 4μg/kg), and expressed as end-diastolic reserve (Baseline/Ach). Measurements were performed at 9 weeks of age.

Results: PKD and controls were similar in body weight (196.8±9.2 vs. 190.3±10.8 grams) and MAP (121.9±9.7 vs. 118.9±11.6 mmHg), while kidney volume was higher in PKD rats compared to wild type (1419.1±176.6 vs. 962.9±90.3 mm^3, $p<0.05$). Compared to controls, PKD rats had lower urinary output and higher end-diastolic reserve, both of which were partially preserved in PKD rats that received MSCs (Figure).

Conclusions: Cell therapy partially restores urinary volume and vascular function in a rat model of ARPKD. While the potential mechanisms of the beneficial effect deserve further study, cell therapies appear as a potential therapeutic intervention in PKD.

Urinary Secretion and Extracellular Aggregation of Mutant Uromodulin Isoforms: New Insight for the Understanding of Uromodulin-Associated Kidney Diseases Pathogenesis Celine Schaeffer,[1,2] Angela Cattaneo,[2] Matteo Trudu,[1,2] Sara Santambrogio,[1,2] Ilenia Bernascone,[1,2] Daniela Francesca Giachino,[3] Gianluca Caridi,[4] Corrado Murtas,[4] Mario De Marchi,[3] Antonio Amoroso,[3] Gian Marco Ghiggeri,[4] Francesco Scolari,[5] Angela Bachi,[2] Luca Rampoldi.[1,2] *[1]Dulbecco Telethon Institute, Milan, Italy; [2]San Raffaele Scientific Institute, Milan, Italy; [3]University of Turin, Italy; [4]G. Gaslini Institute, Genoa, Italy; [5]Montichiari Hospital, Brescia, Italy.*

Background: Uromodulin is the most abundant protein secreted in urine where it is found as high molecular weight polymers. Mutations in uromodulin lead to tubulo-interstitial disorders collectively referred to as uromodulin-associated kidney diseases (UAKD). Previous studies pointed at retention in the endoplasmic reticulum (ER) as a common feature of uromodulin mutant isoforms. In this work, we assessed if mutant protein can partly escape the ER quality control and enter the secretory pathway.

Methods: Our studies were carried out in MDCK cells stably expressing wild type and mutant protein and in a transgenic mouse model for UAKD. Secretion of mutant uromodulin was also assessed by mass spectrometry analysis on urine samples from UAKD patients.

Results: In cellular models, mutant uromodulin could partly reach the plasma membrane where it formed large extracellular aggregates. Interestingly, mutant isoforms co-assembled with wild type protein and exerted a dominant negative effect on polymerisation. This was confirmed in transgenic mice, where mutant uromodulin not only accumulated in the ER of thick ascending limb epithelial cells, but was also found in urine and in large lumenal casts. Notably, urinary excretion of mutant uromodulin was also detected in patients carrying uromodulin mutations (R212C, C256Y, C317Y), supporting the relevance of our findings in UAKD.

Conclusions: These results demonstrate that mutant uromodulin can be trafficked to the cell membrane where its aggregation interferes with the formation of uromodulin matrices and possibly affects the function of other membrane proteins. This suggests a new extracellular gain of function effect of uromodulin mutations that has implications for therapeutic strategies.

Initiation and Progression of Fibrosis in a Pkd1 Hypomorphic Mouse Model of Autosomal Dominant Polycystic Kidney Disease Kandai Nozu,[1,2] William E. Sweeney,[1,2] Dorien J.M. Peters,[4] Ellis D. Avner.[1,2,3] *[1]Children's Research Institute, Children's Hospital of Wisconsin, Milwaukee, WI; [2]Pediatrics, Medical College of Wisconsin, Milwaukee, WI; [3]Physiology, Medical College of Wisconsin, Milwaukee, WI; [4]Human and Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by the development of bilateral fluid filled cysts and intraparenchymal renal fibrosis. The C57Bl6/J-*Pkd1*$^{nl/nl}$ is a mouse model of ADPKD where hypormorphic expression of *Pkd1* results in a model with 2 distinct phases of disease progression. Phase 1 is the formation and growth of cysts followed by phase 2, the development of renal fibrosis.

Methods: We used Masson's trichrome staining, immunohistochemistry (IHC), Western blotting (WB) and quantitative RT-PCR to examine the phenotypic and molecular changes associated with the development of fibrosis in this model.

Results: We chose PN28 as the best time point to examine the molecular changes associated with early stage fibrosis based on the following: 1)Trichrome (+) areas were first evident at PN28; 2) WB revealed initial decreases in ZO-1 and E-cadherin expression: 3) WB demonstrated increases in αSMA; and 4) IHC revealed a layer of αSMA (+) cells beneath the epithelia layer of trichrome (+) cysts. FSP-1 (+) cells within cystic epithelial were very rare and remained rare even at PN56, a point of reduced kidney size due to fibrosis.

Molecular analysis by RT-PCR revealed the earliest changes included statistically increased expression of *Col1A2*, *Col3A1* and *Col5A2.* Changes in the TGFβ/BMP pathway included increased *Bmp1* (7.5 fold), *Tgf*β*2* (17 fold), and *Tgf*β*3* (5 fold). *Bmp7* expression decreased 3 fold while *Tgf*β*1* and *Smad2* remained statistically unchanged. Wnt pathway demonstrated modest increases in *Gsk3*β, *Wnt5a*, *5b* and *Wnt11.* Transcription factors including *Stat3*, *Tcf3*, *Zeb1, Zeb2* and *Twist1* were all significantly increased.

Conclusions: There is no evidence of EMT in this model. Later time point analysis suggest the αSMA (+) layer of cells below the cystic epithelia are myofibroblasts or precursors that trigger fibrotic changes.

Conditional Inactivation of *TGF*β*RI* (*Alk5*) in a *Pkd1*- Deletion Mouse Model for ADPKD Does Not Inhibit Renal Fibrosis Wouter N. Leonhard,[1] Anne Marike Van der Wal,[2] Hester Happe,[1] Martijn H. Breuning,[1] Peter Dijke,[3] Emile De Heer,[2] Dorien J.M. Peters.[1] *[1]Human Genetics; [2]Pathology; [3]Molecular Cell Biology, Leiden University Medical Center, Netherlands.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD), caused by mutations in *PKD1 / 2*, is characterized by progressive cyst formation and renal fibrosis. The latter significantly contributes to loss of kidney function, ultimately leading to end-stage renal failure. Characteristic for fibrosis, our *Pkd1*-deletion models display increased nuclear accumulation of phosphorylated SMAD2 (pSMAD2) and elevated expression

of TGFβ target-genes at advanced PKD and can therefore be used to study therapeutic interventions in order to inhibit fibrosis in PKD.

Methods: Since fibrosis is frequently associated with increased TGFβ signaling, we initially treated mice with a pan-selective neutralizing TGFβ antibody (2G7), but observed no reduction in fibrosis-related parameters. Next, we crossbred our tamoxifen-inducible kidney-specific *Pkd1*-deletion model (cKO) with a mouse in which the type I receptor for TGFβ (*Alk5)* is flanked by Lox P sites. We analyzed tissues by immuno-histology and gene expression by RT-MLPA.

Results: Tamoxifen administration to these double-cKO's disrupted both *Pkd1* and *Alk5* as demonstrated by reduced expression levels of these genes. Double-cKO's developed cystic kidneys within the same time frame as single-cKO's and renal histology appeared not to be different. Of note, also in double-cKO's, nuclear pSMAD2 levels and SMAD signaling-dependent gene expression were elevated at end-stage PKD. These results indicate that initiation of renal fibrosis in PKD does not depend on SMAD signaling via *Alk5* in renal epithelial cells and that alternative signaling pathways have to account for the increased levels of nuclear pSMAD2.

Conclusions: In the present study, loss of *Alk5* in renal epithelial cells did not inhibit renal fibrosis in PKD. It is therefore unlikely that targeting only *Alk5* will be successful to halt fibrosis. We will discuss *in vitro* and *in vivo* data suggesting alternative pathways that can lead to SMAD2 phosphorylation and expression of fibrosis-related genes.

Inhibition of Multidrug Resistance-Associated Proteins Reduce Cystogenesis Via ERK-Dependent Pathway Jong Hoon Park, Eun Sun Chang, Eun Young Park, Kyung Hyun Ryu. *Department of Biological Science, Sookmyung Women's University, Seoul, Korea.*

Background: Increased tubular epithelial cell proliferation is a prerequisite for cyst formation and expansion in autosomal dominant polycystic kidney disease (ADPKD). Multidrug resistance-associated protein-1 (Mrp1) and Mrp3 are members of the subfamily of ABC transporters. They are well known as drug-resistant proteins, and their other functions are mostly unknown.

Methods: To profile the genes related with cystogenesis, we carried out microarray analysis using cortex region of PKD2 transgenic mice kidney. We found Mrp3 is overexpressed on cyst lining cells of PKD2 transgenic mice kidney using immunohistochemistry. Next we performed three-dimensional culture to determine the effect of Mrp3 with MK571.

Results: Mrp1 and Mrp3 were upregulated dramatically in the cystic region. To examine the effects of these multidrug resistant proteins on cystogenesis, we treated MK571 for inhibition of Mrp1/Mrp3 in Mardin-Darby canine kidney (MDCK) cell line. We found treatment of MK571 reduced the volume of cysts ($P < 0.001$) via reduction of MAPK/ERK signaling.

Conclusions: Our results demonstrate that Mrp1 and Mrp3 may drive proliferation signal on cyst lining cells. In conclusion, antagonist of Mrp1 and Mrp3 (MK571) may have therapeutic potential in ADPKD.

FR-PO1991

An Imbalance of Lymphangiogenesis Versus Blood Vessel Angiogenesis in Polycystic Kidney Disease Jennifer L. Huang,[1] Maria Kolatsi-Joannou,[1] Adrian S. Woolf,[2] Paul J.D. Winyard,[1] David A. Long.[1] *[1]Institute of Child Health, University College London, United Kingdom; [2]Developmental and Regenerative Medicine Research Group, University of Manchester, United Kingdom.*

Background: Therapeutic strategies to reduce cystogenesis in polycystic kidney diseases (PKD) directly target epithelial proliferation using rapamycin-like drugs, cyclin-dependent kinase inhibitors and vasopressin receptor blockade. An alternative approach could be to target pathways extrinsic to epithelia themselves, such as microvessels, which may modulate cystogenesis by paracrine signalling, oxygen delivery, and access to inflammatory/immune mediators.

Methods: To begin to examine this possibility, we investigated the expression of molecules associated with blood vessel angiogenesis and lymphangiogenesis in congenital polycystic kidney (*cpk*) mice. In this mutant, renal lesions phenocopy human autosomal recessive PKD.

Results: We measured 88 angiogenic genes using real-time PCR profiling of whole kidneys. In early stages, levels of 7 transcripts were modestly altered in *cpk* mice. At three weeks of age, when there is massive nephromegaly caused by collecting duct cystogenesis, 37 angiogenic genes were deregulated. Notably, levels of *Tgfb2*, a key player in vascular remodelling, were increased versus wild-types at both time-points. With disease progression, *Vegfr1*, *Vegfr2*, *Npr1* and *Hif1a* were downregulated, as was the mature blood endothelial marker *Meca32*. The lymphatic system was examined by real-time PCR and immunohistochemistry. *Podoplanin* and *Lyve-1* were significantly upregulated in *cpk* mice from day 10 after birth and continued to be elevated throughout the later stages of disease. The number of vessels with positive podoplanin staining found between cysts was increased with additional ectopic expression in cyst walls. mRNA levels of *Vegfr3* and *Vegfc*, implicated in lymphangiogenesis, were however not altered in *cpk* mice.

Conclusions: This is the first evidence that the balance between blood angiogenic and lymphatic gene expression are altered in ARPKD. Further research into the functional significance of our novel findings is being conducted and it is hoped that targeting these pathways may attenuate disease progression.

Global Gene Expression Profiling in Kidneys of PPAR-γ Agonist-Treated PCK Rats, an Orthologous Model of Human ARPKD Daisuke Yoshihara,[1 and 2] Masanori Kugita,[1] Hiroki Kurahashi,[2] Miwa Morita,[1] Yoshiyuki Hiki,[3] Tamio Yamaguchi,[1] Harold M. Aukema,[4] Darren P. Wallace,[5] James P. Calvet,[5] Takafumi Toyohara,[6] Takaaki Abe,[6] Shizuko Nagao.[1] *[1]Education and Research Center of Animal Models for Human Diseases, Fujita Health University; [2]Molecular Genetics, ICMS, Fujita Health University; [3]Health Sciences, Fujita Health University, Toyoake, Aichi, Japan; [4]Human Nutritional Sciences, University of Manitoba, Winnipeg, MB, Canada; [5]Kidney Institute, University of Kansas Medical Center, KC, KS; [6]Medical Science, Tohoku University, Sendai, Miyagi, Japan.*

Background: In polycystic kidney disease (PKD), kidney enlargement is caused by aberrant proliferation of tubule epithelial cells leading to the formation of numerous fluid-filled cysts, extensive nephron loss, and interstitial fibrosis. Pioglitazone (PIO), a PPAR-γ agonist, decreased cell proliferation, interstitial fibrosis and inflammation, and ameliorated PKD progression in PCK rats (Yoshihara et al, AJP, 2011).

Methods: To examine the beneficial effects of PIO, we analyzed changes in global gene expression by DNA microarray in PCK rats treated with 10 mg/kg PIO for 16 weeks.

Results: By Gene Set Enrichment Analysis that used 30655 genes showing significant signal, six of 25 canonical pathways identified to be down-regulated by PIO-treatment were related to cell cycle and cell proliferation, including EGF, JNK, GSK3 and PDGF pathways. Of 43,379 probes examined, 49 were altered 2-fold or more in PIO- compared to vehicle-treated kidneys. Their relevant pathways were identified using the Kyoto Encyclopedia of Gene and Genomes database. Two key enzymes in fatty acid metabolism and three proteins related to calcium signaling were in the top 15 genes down-regulated by PIO treatment. Immunohistochemical analysis revealed that the gene product of two of these, stearoyl-CoA desaturase 1 and cholinergic receptor, were highly expressed in PCK kidneys, and decreased by PIO-treatment.

Conclusions: These data show that PIO has effects on the expression of renal genes involved in fatty acid metabolism, cholinergic signaling, cell cycle progression and proliferation.

FR-PO1993

Effects of *Pkd1* Quantitative Differential Expression on Urinary Metabolic Parameters Potentially Involved in ADPKD-Associated Nephrolithiasis Renato Ribeiro Nogueira Ferraz,[1] Jonathan Mackowiak Fonseca,[2] Gregory G. Germino,[3] Luiz F. Onuchic,[2] Ita Pfeferman Heilberg.[1] *[1]Nephrology, Federal University of Sao Paulo, São Paulo, Brazil; [2]Nephrology, University of Sao Paulo School of Medicine, Brazil; [3]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: In order to address whether urinary metabolic abnormalities potentially related to the high prevalence of nephrolithiasis in Autosomal Dominant Polycystic Kidney Disease (ADPKD) are caused by *PKD1* haploinsufficiency or the renal cystic phenotype, urinary lithogenic parameters were determined in non-cystic *Pkd1*-haploinsufficient (*Pkd1*$^{+/-}$) and *Pkd1*-targeted cystic(*Pkd1*$^{cond/cond}$:Bal^{cre}) mice models.

Methods: 24-h urine samples were collected during 3 non-consecutive days from 12 week-old male *Pkd1*$^{+/-}$ (n=12), *Pkd1*$^{+/+}$ controls (n=11), *Pkd1*$^{cond/cond}$:Bal^{cre} cystic (n=17), and *Pkd1*$^{cond/cond}$ non-cystic controls (n=18).

Results: As shown in the table, *Pkd1*$^{+/-}$ showed significantly higher urinary calcium than *Pkd1*$^{+/+}$ (p=0.05), an observation not detected in *Pkd1*$^{cond/cond}$:Bal^{cre}. Sodium and potassium FE% and urinary oxalate were significantly lower in *Pkd1*$^{cond/cond}$:Bal^{cre} vs *Pkd1*$^{cond/cond}$ (p=0.0003, p=0.004 and p=0.003, respectively). Urinary citrate did not differ between test and control groups.

	Pkd1+/+	Pkd1+/-	Pkd1cond/cond	Pkd1cond/cond:BalCre
pH	6.31±0.30	6.52±0.26	6.33±0.38	6.06±0.30
Oxalate (mg/mg creat)	0.16±0.17	0.16±0.10	0.16±0.06	0.10±0.04*
Calcium (mg/mg creat)	0.28±0.17	0.41±0.07*	0.15±0.09	0.15±0.07
Magnesium (mg/mg creat)	1.10±1.23	1.23±0.26	0.63±0.17	0.61±0.11
Citrate (mg/mg creat)	3.1±1.5	4.2±2.0	2.8±1.7	3.2±1.3
Uric Acid (mg/mg creat)	0.39±0.27	0.29±0.15	0.26±0.06	0.22±0.05
Sodium (FE%)	0.75±0.18	0.61±0.20	0.75±0.12	0.59±0.07*
Potassium (FE%)	23.3±5.3	19.8±2.4*	23.4±4.3	19.1±2.9*
Creatinine (mg/L)	35.3±11.7	35.0±8.5	42.5±4.5	45.4±3.6

*statistically different vs respective control; FE% (fractional excretion)

Conclusions: These results did not reproduce the main urinary metabolic pattern reported in ADPKD stone formers. Such findings suggest that more complex mechanisms may lead to the urinary metabolic disturbances associated with nephrolithiasis in ADPKD and evince the limitations of these models to investigate this problem.

FR-PO1994

Acceleration of Smad3 Phosphorylation at Linker Regions Via c-Jun NH2-terminal Kinase (JNK) in Cyst-Lining Epithelial Cells in cpk Mouse, a Model of ARPKD Hironobu Mukaiyama,[1] Koichi Nakanishi,[1] Taketsugu Hama,[1] Hiroko Togawa,[1] Yuko Shima,[1] Masayasu Miyajima,[2] Hisahide Takahashi,[3] Shizuko Nagao,[3] Kazumoto Iijima,[4] Norishige Yoshikawa.[1] *[1]Pediatrics, Wakayama Medical University, Wakayama City, Wakayama, Japan; [2]Laboratory Animal Center, Wakayama Medical University, Wakayama City, Wakayama, Japan; [3]Education and Research Center of Animal Model for Human Disease, Fujita Health University, Toyoake, Aichi, Japan; [4]Pediatrics, Kobe University Graduate School of Medicine, Kobe, Hyogo, Japan.*

Background: Cyst-lining epithelia in PKD is characterized by dedifferentiation and perturbations of polarized phenotype with consequent renal tubular cyst formation and progressive enlargement. Previously, we showed activation of key mediators of EMT, TGF-β/Smad3 pathway in cpk mouse (JASN 21:520A,2010). However, specific mechanisms of this phenotypic alteration during cyst formation remain to be elucidated. TGF-β signaling involves Smad3 phosphorylated at linker regions (pSmad3L) and COOH terminal regions (pSmad3C). Therefore, we examined Smad3 phosphorylation profile in this model.

Methods: Kidneys from 5 male cpk and control mice (each on day 0, 7, 14, 21) were harvested. Formaldehyde fixed, paraffin embedded sections were stained with antibodies to domain-specific phospho-Smad3, TGF-β and JNK. We also evaluated their expressions by western blotting.

Results: pSmad3L expression was increased according to age in cpk, while there was no significant staining of pSmad3L in control. pSmad3L was predominantly expressed in nuclei of tubular epithelia in large cysts, and in cytoplasm and nuclei in small and middle cysts. pSmad3C was expressed in both cpk and control in all age, and expression level showed increased tendency according to age in cpk. TGF-β expression was seen in both cpk and control, and also expression level showed increased tendency according to age in cpk. JNK showed the similar staining pattern to pSmad3L. Western blotting analysis supported the expression profiles in sections. These findings suggest that pSmad3L up-regulated via JNK has a key role in cpk.

Conclusions: The linker phosphorylation of Smad3 may be a key pathophysiology in PKD and a target for a disease-specific intervention.

FR-PO1995

Vitamin D Deficiency Exacerbates Renal and Cardiac Enlargement in Rats with Polycystic Kidney Disease Kristina Gjerdrum Schwensen, David C. Harris, Gopala K. Rangan. *Centre for Transplant and Renal Research, Westmead Millennium Institute and The University of Sydney, Sydney, NSW, Australia.*

Background: Vitamin D promotes cellular differentiation and inhibits proliferation, raising the hypothesis that the deficiency of vitamin D promotes cyst growth in polycystic kidney disease (PKD). Therefore, the aim of this study was to determine the effect of dietary vitamin D deficiency on the progression of kidney enlargement in PKD.

Methods: Male Lewis PKD rats (Phillips et al. Kidney Blood Press Res 30:129, 2007) received either a semi-pure control diet (AIN93G, D+) or AIN93G with no added Vitamin D (D-), from postnatal week (wk) 3, and examined on wk10 and wk20 (n=9 per group).

Results: Serum 25-hydroxy vitamin D in the control diet group was normal (wk10:109±9; wk20:151±27ng/ml; mean±SD) whereas it was severely reduced in the D-deficient group (wk10:7±9; wk20:17±10 ng/ml). Kidney enlargement, as determined by combined right and left kidney weight, was increased in the D-deficient group compared to the control group, at both wk10 (D+ 11.0±2.2; D- 15.7±2.3) and wk20 (D+ 22.6±1.9; D- 25.5±3.6 g;P<0.05). The latter was confirmed by serial assessment of total kidney volume by magnetic resonance imaging. At wk20, urine volume was greater in the D-deficient group (by 33%), as was proteinuria (D+ 372±84; D-696±246 mg/mmol), whereas the corrected serum calcium was reduced (D+ 2.73±0.10; D-2.46±0.23 mmol/L) (all P<0.05). Endogenous creatinine clearance was similar in both groups (wk10: D+3.4±0.5; D- 3.7±0.6; wk20: D+1.0±0.4; D- 0.8±0.4 ml/min/cm^2). Weight gain was greater in the D-deficient group (32% higher compared to the control diet group) as was cardiac enlargement (wk10: D+ 0.90±0.03; D- 1.18±0.03; wk20: D+ 1.21±0.12;D- 1.62±0.11 g) (both P<0.05).

Conclusions: Dietary deficiency of vitamin D worsens renal and cardiac enlargement in PKD. Further studies should define if kidney enlargement is mediated by the direct or indirect effects of vitamin D on cyst growth, and whether this can be attenuated by replacement therapy.

FR-PO1996

A Novel Mouse Mutant for Cystic Kidney Disease and Defects of Planar Cell Polarity Joseph P. Ly,[1] Yoshiro Maezawa,[1] Tuncer Onay,[1] Robert Harrison,[6] Susan E. Quaggin.[1,7,8] *[1]Samuel Lunenfeld Research Institute, Toronto, ON, Canada; [2]University Hospital Aachen, Aachen, Germany; [3]Centre for Modeling Human Disease, Toronto, ON, Canada; [4]Development and Stem Cell Biology Program, Hospital for Sick Children, Toronto, ON, Canada; [5]Departments of Medicine and Molecular Genetics, University of Toronto, ON, Canada; [6]Department of Otolaryngology, Hospital for Sick Children, Toronto, ON, Canada; [7]Nephrology, St. Michael's Hospital, Toronto, ON, Canada; [8]Medicine, University Health Network, Toronto, ON, Canada.*

Background: Cystic kidney diseases represent the primary genetic cause of ESRD in North America, contributing up to 5% of incident cases. The molecular basis of cyst development is complex; recently, defects in planar cell polarity (PCP) have been associated with cyst formation. Here, we describe a new mouse model of cystic kidney disease with evidence for PCP involvement.

Methods: In an autosomal dominant ENU mutagenesis screen, we identified a heritable mouse mutation that causes renal cysts.

Results: Heterozygous mutant mice demonstrate variable and often striking glomerular cysts that can affect up to 100% of glomeruli. At a lower frequency, cysts are identified along the entire nephron. Homozygous mutants die within the first few hours of birth and already exhibit both tubular and glomerular cysts. In addition, homozygotes have "kinked" tails and disoriented inner ear hair cells, phenotypes specific for PCP defects. Furthermore, the loss of one copy of vangl2, a core PCP gene enhances cyst formation in heterozygotes, further substantiating PCP involvement. In addition, there is a trend towards fewer and shorter primary cilia within the renal tubules of the homozygotes. Using SNP analysis, we show that the mutation resides in a 3 MB critical region of chromosome 6 that contains 25 genes, none of which have been associated with cystic disease. Whole-exome next-generation resequencing is currently underway.

Conclusions: Taken together, we report a novel mouse model of renal cysts, which may further elucidate the role of PCP in cystic kidney diseases.

Planar Cell Polarity Dependent Regulation of Kidney Tubule Morphogenesis Roy D. Bayly, Jeffrey D. Axelrod. *Pathology, Stanford University School of Medicine, Stanford, CA.*

Background: Failure of proper kidney tubule development can result in polycystic kidney disease (PKD), one of the most common genetic disorders inherited in humans. Genetic analysis has revealed that many of the causative gene products identified from patients with PKD localize to or interact with components of the primary cilium, but how they regulate kidney tubule morphogenesis is the subject of considerable interest. Recent research suggests that kidney tubule morphogenesis may involve convergent extension movements and oriented cell division, two processes that require input from the planar cell polarity (PCP) pathway in other developmental contexts. However, the interconnectivity between components within the primary cilium, the PCP pathway and the developmental processes that regulate kidney tubule morphogenesis is tenuous.

Methods: Using mouse genetics and confocal microscopy, we have analyzed the requirement of Vangl1 and Vangl2 during the development and morphogenesis of kidney tubules.

Results: We present results that demonstrate a definitive role for Vangl1 and Vangl2, core members of the PCP pathway, during kidney tubule morphogenesis. Specifically, we observe the asymmetric localization of Vangl1, Vangl2, Frizzled3, and Frizzled6 along the proximal-distal axis of kidney tubule cells. We show that these core components are required for molecular asymmetry, for the proper orientation of cells with respect to the tubule axis, and for the regulation of kidney tubule diameter. Surprisingly, we also observe that in Vangl1 and Vangl2 mutant mice, levels of Polycystin-2, a gene product that is mutated in a class of PKD, is reduced in primary cilia, and increased along the apical surface of kidney tubule cells.

Conclusions: Taken together, we show that Vangl1 and Vangl2, core components of the PCP pathway, are critically important in the regulation of kidney tubule morphogenesis due in part to their requirement for the proper ciliary localization of polycystic kidney disease associated gene products, such as Polycystin-2.

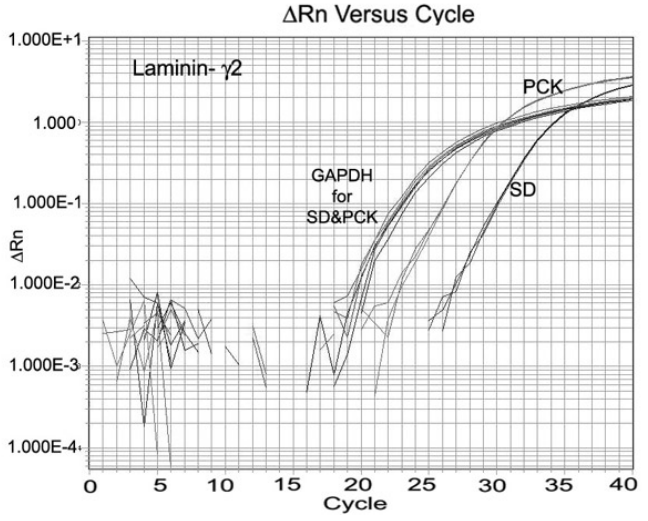
Abnormal Expression and Assembly of Laminin-332 and Laminin-511 in ARPKD Soundarapandian Vijayakumar, Kanchan Parkhi, Jessica Stolar. *Pediatrics, University of Rochester, NY.*

Background: Extracellular matrix abnormalities have been associated with PKD and it is suggested that abnormal upregulation of laminin-332 contributes to ADPKD cystogenesis by inducing proliferation. However, the possible role of aberrant ECM assembly in ARPKD cystogenesis has not yet been investigated. In this study, we addressed this question using PCK rat model of ARPKD and *orpk* cell lines.

Methods: RNA was extracted from 4 adult PCK and control SD rat kidneys and from mutant and rescued orpk cell monolayers. Real-time PCR was performed using Taqman method with GAPDH normalization. For immunoblotting, 300μg of PCK and SD whole

kidney extracts were probed with laminin-γ2 (sc-7652) & laminin γ1 antibodies. Frozen kidney sections were stained with a laminin α5 polyclonal (JH Miner) and a laminin-α3 monoclonal (R&D). Paraffin sections were stained using laminin-γ2 antibody.

Results: Our qPCR results show significant upregulation of laminin-332 chains in PCK kidneys compared to wild-type SD kidneys. Laminin γ2 was upregulated 10 fold, laminin β3 4-fold, and laminin α3, 2-fold.



Immunoblotting confirmed the presence of laminin γ2 in PCK kidneys but not in SD. Immunostaining of frozen and paraffin sections using two different laminin-332 antibodies clearly demonstrated the abnormal expression of laminin-332 in PCK kidney cysts. We also observed a 2 to 4 fold increase in the expression of laminin-332 chains in the cilia defective *orpk* cells. Also, qPCR studies show a modest (1.5-1.8 fold) increase in the expression of laminin-511 chains in PCK kidneys. Preliminary staining results show a weaker laminin α5 staining in PCK cysts but increased staining in nephron tubules.

Conclusions: The abnormal expression and assembly of laminin-332 (and possibly laminin-511) in various ARPKD model systems makes a strong case for further investigation into the role of aberrant laminin assembly in ARPKD cystogenesis.

MicroRNA Regulation of Angiogenesis in Autosomal Dominant Polycystic Kidney Disease Wei Wang, Robert W. Schrier, Berenice Y. Gitomer. *Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO.*

Background: It is apparent that vascular changes including expansion and remodeling must occur in order to support the massive growth of cysts in patients with autosomal dominant polycystic kidney disease (ADPKD). Evidence for angiogenesis in the form of development of a well-defined vascular capsule around human renal cysts in ADPKD supports this tenet. We have previously reported that the circulating levels of angiogenic growth factors including vascular endothelial growth factor are increased in young patients with ADPKD. Hypoxia is a well established stimulus for angiogenic pathways. The growth of renal cysts with attendant compression of the renal vasculature results in ischaemia within the kidney. We hypothesized that microRNAs (miRs) may play a role in up-regulation of angiogensis in the ADPKD kidneys

Methods: Total RNA was extracted from 5 normal and 6 ADPKD kidneys and cDNA prepared. Renal expression of miR-107, miR-126, and miR-132 was measured by quantitative PCR and compared to expression of the housekeeping genes RNU-6 and SNORD 48.

Results: Expression of miR-107 was significantly decreased (P =0.0006) by 19 fold in the ADPKD kidneys compared to control kidney. There was no significant change in miR-126 expression, while variable increase in expression of miR-132 occured (43 fold increase, P = 01.3) in ADPKD kidneys compared to control kidney.

Conclusions: miR-107 has previously been shown to inhibit hypoxia signaling pathways and inhibit tumor angiogenesis, while decreased miR-107 expression increases HIF-1β, hypoxia signaling and angiogenesis. miR-132 has been shown to facilitate pathological angiogenesis by targeting p120RasGAP in the endothelium. Thus, the observed changes in ADPKD kidney are consistent with upregulation of angiogenesis in response to hypoxia.

NDRG1 Gene Is Involved in the Regulation of Cystogenesis in Transgenic Mice Over-Expressing PKD2 Jong Hoon Park,[1] Bo Hye Kim,[1] Eun Young Park,[1,2] Soo Young Choi.[2] *[1]Department of Biological Science, Sookmyung Women's University, Seoul, Korea; [2]Department of Biomedical Sciences, Hallym University, Gangwon-do, Korea.*

Background: N-myc downstream regulated gene 1 (NDRG1) was chosen as a candidate gene as a regulator of cystogenesis. In this study, relation between PKD2 gene and NDRG1 gene on the cyst formation was uncovered.

Methods: Candidate genes controlled by PKD2 were examined by two dimensional electrophoresis (2-DE) using 18month-old transgenic mice and age-matched wild-type mice. Validation of gene expression was performed by analyzing real time RT-PCR and western blot. To elucidate the effect of gene on cystogenesis, MDCK cells were cultured on the collagen.

Results: Increase of NDRG1 gene expression level in the kidney of PKD2 TG mice was confirmed using real time RT-PCR and western blot. Furthermore, immunohistochemistry result showed that NDRG1 protein highly expressed in the cyst lining epithelial cells. The hypothesis that PKD2 gene will regulate the expression of NDRG1 gene might be supported by *in vitro* experiments. NDRG1 knock down suppressed cystogenesis in 3D culture of Madin-Darby canine kidney cells (MDCK). This result indicated that NDRG1 had impact on the cyst formation. Based on the cell proliferation assay and western blot data, NDRG1 over-expression would accelerate the cellular growth in mIMCD-3 cells.

Conclusions: In conclusion, over-expression of PKD2 promotes the expression level of NDRG1 gene product. This causes the increase in cellular proliferation, aggravating cyst formation.

Transgenic Expression of Epitope Tagged Pkd2 from Bacterial Artificial Chromosomes Provide a Model for Structure-Function Studies of Polycystin-2 In Vivo Yiqiang Cai,[1] Ming Ma,[1] Xin Tian,[1] Yuehong Wang,[1] Rachel Gallagher,[1] Sorin V. Fedeles,[1] Stefan Somlo.[1,2] *[1]Internal Medicine, Yale University School of Medicine, New Haven, CT; [2]Genetics, Yale University School of Medicine, New Haven, CT.*

Background: Transgenic mice overexpressing Pkd1 or Pkd2 have been reported to develop renal cystic phenotypes. Our recent studies on dual epitope-tagged Pkd1F/H-BAC mouse lines showed that Bacterial Artificial Chromosome (BAC) transgenic expression of PC1 with eight or less copies of the transgene does not cause cystic phenotypes. This observation suggests that low copy BAC-transgenic mouse models are appropriate for the study of polycystin function.

Methods: We modified a BAC containing Pkd2 by homologous recombination in E. coli to introduce a triple-HA epitope tag before the stop codon in the last exon of Pkd2. Transgenic mouse lines were produced using this Pkd2-BAC and tissues from transgenic progeny were analyzed by immunoblotting and immunofluorescent tissue staining using anti-HA and other cellular marker antibodies.

Results: We obtained transgenic mice expressing COOH-terminal triple-HA tagged PC2 from the Pkd2-BAC transgene. Immunoblotting analysis using anti-HA antibodies showed that transgenic PC2 is expressed in all tissues tested in a pattern and at levels comparable to that of native PC2. Immunofluorescent staining of transgenic PC2 by anti-HA in kidney tissue demonstrated a cytoplasmic staining pattern in vivo. Histological examination of tissues from five-month old kidneys of Pkd2-BAC transgenic mice showed normal tubular structure without microscopic cysts. These observations suggest that the BAC-transgenic HA-tagged PC2 recapitulates the expression pattern of native PC2 in vivo. Studies on subcellular localization of transgenically expressed PC2 are ongoing.

Conclusions: The HA epitope tagged Pkd2-BAC can be further modified with site-specific mutation and transgenic mice produced from these BACs will serve as a platform for studying structure-function relationships in PC2 in vivo.

Dose-Expression of Exogenous Polycystin-2 Can Significantly Ameliorate the Phenotypic Severity of Pkd2 Knock-Out Mice Guanqing Wu.[1] *[1]Medicine, Vanderbilt University, Nashville, TN; [2]State Key Laboratory of Molecular Oncology, Cancer Hospital and Institute, Chinese Academy of Medical Sciences, Beijing, China.*

Background: Loss of polycystin-2 (PC2) in mice (Pkd2-/-) results in total body edema, focal hemorrhage, structural cardiac defects, abnormal left-right axis, hepatorenal and pancreatic cysts, and embryonic lethality. To study PC2 functions in vivo, we have produced a Pkd2 transgenic mouse (Pkd2tg7) to test if ectopic overexpression of Pkd2 is able to rescue its disease phenotypes.

Methods: The full-length hPKD2 ORF cDNA was constructed under the control of a CMV immediate early enhancer, a chicken β-actin promoter, and a rabbit β-globin poly A signal downstream of the native termination codon (pCAGGS expression vector). Four founders (Tg7, 9, 10, 14) were found to overexpress PC2, determined by Western blotting using polyclonal antiserum hPKD2-Cp. We selected Tg7 as our founder (PKD2tg7) because these mice have been most extensively studied.

Results: Using a mating strategy, PKD2tg7 mice were crossmated with Pkd2+/- mice to produce PKD2+/tg7:Pkd2-/- and PKD2tg7/tg7:Pkd2-/- mice. Our results showed that both PKD2+/tg7:Pkd2-/- and PKD2tg7/tg7:Pkd2-/- mice can overcome the embryonic lethality seen in Pkd2-/- mice. However, PKD2+/tg7:Pkd2-/- mice were born at a frequency of 10%, much lower than 21% in Pkd2-/- mice with the double Tg7 alleles (PKD2tg7/tg7:Pkd2-/-). In addition, the PKD2tg7/tg7:Pkd2-/- mice exhibited significantly decreased cystic number and volume in the pancreas, liver and kidneys compared to PKD2+/tg7:Pkd2-/- littermates, suggesting that an increased expression level of PC2 can ameliorate ADPKD disease phenotypes seen in Pkd2-/- mouse models. Kaplan and Meier survival analysis also indicated that the PKD2tg7/tg7:Pkd2-/- mice can survive much longer than the Pkd2-/- mice with a single Tg7 allele.

Conclusions: This finding indicates that the functional restoration of PKD2 gene product can rescue disease phenotypes in Pkd2-/- mice and sufficient expression of PC2 can potentially cure PKD2-mutant ADPKD.

Expression of Bicc1 Protein during the Mouse Development Guanqing Wu.[1] [1]*Medicine, Vanderbilt University, Nashville, TN;* [2]*State Key Laboratory of Molecular Oncology, Cancer Hospital and Institute, Chinese Academy of Medical Sciences, Beijing, China;* [3]*Pathology, Yale University, New Haven, CT.*

Background: *Bicc1* is a mouse homologue of Drosophila *Bicaudal-C* (*dBic-C*). Orthologs of *dBic-C* can be identified in many species, from C.elegans to human being. The *Bicc1*-mutant mouse models, *jcpk* and *bpk*, both exhibit cystic phenotype in the kidney that are very similar to human polycystic kidney disease. Yet, the developmental profiles of Bicc1 protein (Bic-C) in the mammalian system remain uncharacterized.

Methods: We have therefore generated two polyclonal antibodies against different portions of Bic-C to examine its spatial and temporal expression patterns during mouse embryogenesis and organogenesis. Two mouse Bicc1-fusion proteins encoding residues from E61 to A199 (mBic-N), and Q711 to D858 (mBic-C) of Bicc1, were used to produce rabbit polyclonal antisera.

Results: Our study demonstrated that Bic-C can be detected in epithelial cells of the neural tube as early as embryonic day 8.5 (E8.5) and positive staining appeared in the myocardial wall of the heart at E10.5. By E11.5, the immature hepatocytes and epithelial cells of the primordial gut, main bronchi and aorta exhibit positive staining at their cytosol. In the kidneys, Bic-C expression is seen in the epithelia of early ureteric bud and mesonephric tubules, as the bud penetrates into the metanephrogenic mesenchyme during E11.5. Significant staining continues in the renal comma-shaped body and the S-shaped body until E12.5. By 1-month of age, increased Bic-C staining extended to the renal juxta-medullary region. At this stage, no significant staining was seen in the medullary and papillary regions and relatively weak Bic-C staining were present in the cortical region of the kidneys. By co-staining adult kidney with Bic-C antibody and renal tubular segment markers, we found that Bic-C is predominantly stained at proximal convoluted tubules in the kidneys.

Conclusions: These results indicate that Bic-C is developmentally regulated and Bic-C exerts an important role in tubulogenesis and organogenesis during the renal

Targets and Binding Motif of the Polycystic Kidney Disease-Associated RNA Binding Protein BICC1 Iddo Zeev Ben-Dov, Thomas Tuschl. *Laboratory of RNA Molecular Biology, Rockefeller University, New York, NY.*

Background: Mutations in protein bicaudal C homolog 1 (BICC1) have been shown to cause polycystic kidney disease in mice. We aimed to systematically explore the RNA binding characteristics of BICC1 in-vivo.

Methods: BICC1 was cloned from human podocyte cDNA. Photoactivatable ribonucleoside-enhanced crosslinking and immunoprecipitation (PAR-CLIP) was performed on FLAG-BICC1 expressing HEK293 cells. Recovered small RNA was sequenced (Solexa), genome-aligned and annotated.

Results: Two BICC1 splice isoforms were (inadvertently) cloned from human podocyte cDNA (panel A). Upon expression, both showed cytoplasmic localization in HEK293 cells (panel B). Ample in-vivo crosslinking of BICC1 to RNA was noted with or without the photoactivatable nucleoside (panel C). PAR-CLIP evidence for BICC1 crosslinking to mRNA was widespread, and sporadic associations were noticed with noncoding RNA (tRNA, miRNA). High confidence mRNA clusters were >90% exonic (both isoforms). Of these, 59% (isoform 1) and 82% (isoform 2) mapped to 3'UTRs, while 36% and 17% mapped to coding regions, respectively. Isoform 1 and isoform 2 clusters mapped to 5791 and 2853 genes, respectively (panel D). Subjection of these clusters to motif finder algorithms yielded similar results for both isoforms, with TTGACAA as the chief finding (panel E). Using PAR-CLIP data we were able to substantiate and pinpoint a previously suggested association between BICC1 and PKD2 mRNA near a putative miR-17 binding site (panel F).

Conclusions: PAR-CLIP robustly reveals the in-vivo RNA binding characteristics of BICC1. Nucleotide-level information from these experiments can direct further biochemical studies, while transcript-level data may identify targets involved in the pathogenesis of human polycystic kidney disease.

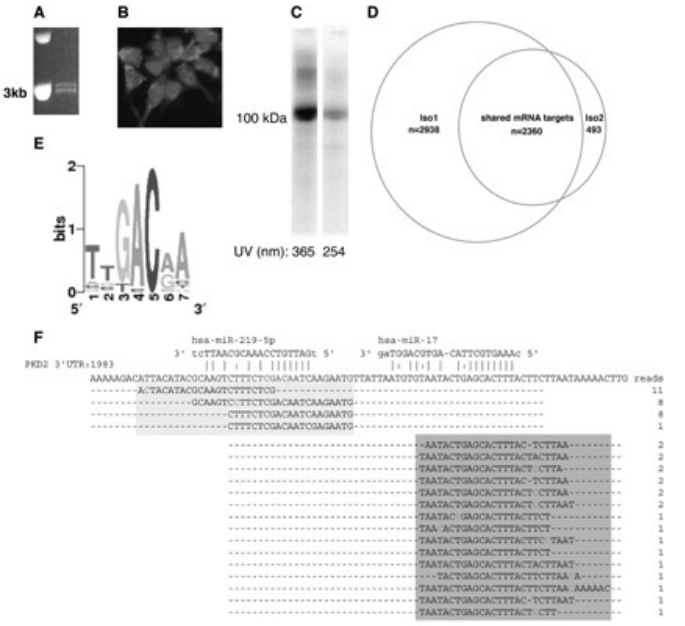

Figure: (A) RT-PCR of the 2 BICC1 isoforms. **(B)** IF staining of FLAG-BICC1 in HEK293 cells. **(C)** SDS gel autoradiography of FLAG IP (RNA is 32P-labeled). **(D)** Venn diagram of isoform 1 and 2 mRNA targets. **(E)** weblogo of the main BICC1 binding motif. **(F)** Example of a BICC1 (isoform 1) PAR-CLIP mRNA cluster aligned with an mRNA cluster from argonaute (AGO) PAR-CLIP experiment. The shown region is within the 3'UTR of the PKD2 gene. The yellow box depicts BICC1 binding reads, while the brown box shows AGO binding reads. Pink 'C's represent PAR-CLIP's crosslinking T->C transition signature. A region similar to the BICC1 binding motif is shown in red. Potential miRNA binding sites are depicted above, with the predominant crosslinked positions in the AGO PAR-CLIP shaded violet.

Tissue Engineering Models for Human ADPKD Wei-Che C. Ko, Balaji Karthick Subramanian, Tessa Desrochers, David Kaplan. *Department of Biomedical Engineering, Tufts University, Medford, MA.*

Background: Modeling cystic diseases in vitro presents a unique challenge as cyst morphogenesis, in addition to complex intercellular interactions, is also governed by synergistic spatial, mechanical and temporal effects. We report the development of kidney-like tissue structures for normal and diseased (cystic) states using commercially available human kidney cells.

Methods: Gene silencing is used to simulate autosomal dominant polycystic kidney disease, as inactivating mutations in polycystins -1 and/or -2 are responsible for the disease in vivo. Our system utilizes extracellular-matrix molecules infused in slow degrading porous silk scaffolds, which provides a 3D microenvironment for proper cell polarization (ECM), while exhibiting structural robustness and tension (silk scaffold).

Results: Our results indicate development of cyst-like structures in a 3D environment, while also demonstrating the respective normal and altered phenotypes concurrent with normal tissue and patient-derived ADPKD tissue. The structural and functional features of kidney-like tissue structures were further characterized based on distribution of E-cadherin, N-cadherin, transport phenomena of 6-carboxyfluorescein, and cell-matrix interactions through integrin signaling.

Conclusions: Importantly, this 3D in vitro model may be further extended via perfusion reactor for long term studies of ADPKD or other renal cystic diseases, and may have beneficial use as a therapeutic drug screening tool.

Lonidamine Reduces Cyst Size in Polycystic Kidney Disease Brenda S. Magenheimer, Shirin Sundar, Sumanth Mulamalla, Monica K. Johnson, Gail Reif, Darren P. Wallace, James P. Calvet. *Kidney Institute, Univ of Kansas Medical Center, Kansas City, KS.*

Background: Currently, there is no effective treatment to slow kidney enlargement in ADPKD. A lead therapeutic compound for ADPKD should effectively block both abnormal cell proliferation and cyst-filling fluid secretion in addition to having favorable safety/toxicity and biodistribution profiles. Lonidamine, an indazole carboxylic acid derivative, was originally developed to inhibit tumor growth. It is approved for the treatment of prostate, breast, and head and neck cancers and is being tested as a combination therapy with other conventional chemotherapeutic agents. Lonidamine inhibits hexokinase activity, which is often important in the anaerobic glycolysis typical of abnormally growing neoplastic cells; and it inhibits CFTR channel activity. We showed that lonidamine inhibits ADPKD cell proliferation with an LD50 of 5.7 μM, as shown by MTT assay; and at 5 μM, lonidamine inhibits forskolin-induced chloride secretion in M-1 cells as measured by short-circuit current in the presence of benzamil.

Methods: Cell culture, organ culture, and mouse models of PKD.

Results: To determine whether lonidamine alters the cyst-forming process in response to cAMP, kidneys from Pkd1 +/+, +/-, and -/- mice were placed in metanephric culture at E15.5 and treated with 100 μM 8-Br-cAMP with or without lonidamine for 4 days. Lonidamine did not appear to be toxic to the kidneys at these doses, yet it significantly inhibited cystic dilation. 2 μM lonidamine was effective in Pkd1 +/- kidneys, essentially preventing cyst formation, while 10 μM lonidamine resulted in dramatic cyst reduction in Pkd1 -/- kidneys. Lonidamine was also shown to significantly inhibit wound closure in a cell motility scratch assay at 25 μM and 50 μM. Cystic Nphp3 (pcy) mice treated with 50 mg/kg lonidamine or vehicle 6 days a week by oral gavage for 8 weeks showed a decrease in kidney weight to body weight ratio and cystic index upon quantification of midsagittal sections. The drug appeared to be well-tolerated.

Conclusions: These studies suggest that lonidamine or its derivatives may be effective therapeutic agents for long-term use in ADPKD.

Therapeutic Potential of Phospholipase D Inhibitor in Autosomal Dominant Polycystic Kidney Disease Yang Liu,[1] Rudolf P. Wuthrich,[1,2] Andreas L. Serra.[1,2] *[1]Institute of Physiology, University of Zürich, Zürich, Switzerland; [2]Division of Nephrology, University Hospital, Zürich, Switzerland.*

Background: The mTOR pathway is activated in tubular epithelial cells lining cysts in animal and human polycystic kidneys. Phospholipase D (PLD) and the metabolite phosphatidic acid (PA) regulate mTOR activity which is competitive with the classic mTORC1 inhibitor rapamycin. We explored novel and highly specific PLD inhibitors as new therapies for PKD.

Methods: The cellular responses and mechanisms to the PLD1/2 inhibitor Honokiol, a natural compound purified from Magnolia, as well as to the highly specific PLD1, PLD2 and dual PLD1/2 inhibitors were evaluated in primary renal tubular epithelial cells either derived from Han:SPRD rats (Cy/+ TECs) or derived from human ADPKD kidney (HAK).

Results: PLD2 inhibitor decreased cell proliferation Cy/+ TECs and HAK more effective compared with either PLD1 inhibitor or dual PLD1/2 inhibitor. Honokiol reduced total cell numbers, cell viability and DNA synthesis of Cy/+ TECs with inducing complete inhibition at 40μM. Cleavage fragments of caspase 3 could be detected. Phosphorylation of PLD1 (PLD1ser561) decreased upon Honokiol treatment in a dose-dependent way. The phosphorylation of the upstream regulators (AktThr308) and downstream effectors of mTORC1 (4EBPThr37/46, S6KThr421/Ser424, S6Ser235/236) was prevented at a concentration of 30μM. Honokiol suppressed phosphorylation of Akt at Ser473 site, the readout of mTORC2 activity. Phosphorylation of the MAPK (ERK1/2Thr202/204) decreased at the concentration of 40μM.

Conclusions: The PLD2 inhibitor halted primary tubular epithelial cell proliferation derived from human and animal polycystic kidneys, at least in part by inducing apoptosis. The signaling through PLD1, mTORC1/2, and MAPK pathways was blocked by Honokiol. PLD2 but not PLD1 controls proliferation of tubular epithelial cells. PLD2 is a critical regulator of mTOR activity which has been largely overlooked in the rapamycin-based treatment strategies in PKD. Targeting PLD may offer a new therapeutic target for PKD.

FR-PO2008

Periostin, a Soluble Extracellular Matrix Molecule, Activates Focal Adhesion Kinase and Cytoskeleton Reorganization of Human ADPKD Cells Gail Reif, Emily Nivens, Cibele S. Pinto, Corey White, Stephen C. Parnell, Maodong Liu, Darren P. Wallace. *Internal Medicine, University of Kansas Medical Center, Kansas City, KS.*

Background: In ADPKD, abnormal cell proliferation, apoptosis and matrix production suggest that cyst epithelial cells are poorly differentiated, possibly involving an aberrant repair mechanism. Periostin, a soluble extracellular matrix (ECM)-related protein involved in tissue development and repair, is highly over expressed in ADPKD cells and accumulates within the matrix adjacent to cysts. Periostin binds α_V-integrins and accelerates ADPKD cell proliferation. Focal adhesions are sites of integrin clustering and formation of protein complexes involved in ECM communication with intracellular signaling molecules including focal adhesion kinase (FAK). Rho and FAK regulate the assembly and disassembly of focal adhesions by activating pathways that lead to actin polymerization and contraction. We hypothesize that periostin signaling at the focal adhesions causes FAK activation and Rho dependent changes in the cytoskeleton and cell adhesions which contribute to a less differentiated phenotype.

Methods: Human ADPKD cells were treated with recombinant 100-250 ng/ml periostin and levels of phosphorylated Rho (P-Rho), Rac (P-Rac) and FAK (P-FAK) were measured by immunoblot analysis. To determine the effect of periostin on the cytoskeleton, actin filaments were stained with Phalloidin-FITC.

Results: Periostin increased P-Rho and P-FAK levels within 30 min; however these increases were transient. By contrast, periostin did not appear to affect Rac phosphorylation within this time period, consistent with reciprocal activation of Rac and Rho during cell migration. Actin staining indicated that periostin caused bundling of actin filaments into stress fibers, whereas FAK inhibition either in the absense or presence of periostin caused broad web-like extensions.

Conclusions: Periostin binding to integrins at focal adhesions causes activation of Rho and FAK, leading to cytoskeletal reorganization. These effects are consistent with periostin-induced changes in cell adhesion which may play a role in aberrant regulation of cell morphogenesis, repair, and matrix deposition.

Ouabain Regulates Expression of Adhesion Proteins and Cell-Cell Interaction in ADPKD Cells Madhulika Sharma,[1] Elsa Bello-Reuss,[2] Gustavo Blanco.[1] *[1]Molecular and Integrative Physiology and Kidney Institute, University of Kansas Medical Center, Kansas City, KS; [2]Internal Medicine, Division of Nephrology and Hypertension, Texas Tech University Health Science Center, Lubbock, TX.*

Background: Epithelial cell proliferation is one of the hallmarks of the development of renal cysts in autosomal dominant polycystic kidney disease (ADPKD). Cell proliferation requires relaxation of the contact between neighboring cells and cell junctions. Cell junction function is controlled by regulation of the expression of adhesion proteins. We have previously shown that the hormone ouabain, at physiological concentrations, stimulates proliferation of cultured human ADPKD cells.

Methods: In this work, we studied the effect of ouabain on adhesion proteins of tight and adherens junctions of ADPKD cells. ADPKD cells were incubated in the absence or presence of 3nM ouabain for 24hrs and the expression levels of a series of adhesion molecules were determined in the whole cells and in plasma membrane fractions by immunoblot and immunocytochemistry.

Results: Ouabain differentially affected tight junction protein expression. While claudin1 and ZO-1 were not significantly modified, occludin amounts were elevated in ouabain-treated ADPKD cells. Ouabain also regulated expression of zonula-adherens proteins in a specific manner, increasing the amounts of vinculin, reducing the levels of E-cadherin and maintaining β-catenin unchanged. In addition, ouabain modulated cell-cell interaction, reducing the ability of ADPKD cells to adhere to each other. In contrast, permeability of ADPKD cell monolayers to dextran showed no significant changes after ouabain treatment.

Conclusions: These results show that in ADPKD cells, ouabain regulates the expression of adhesion proteins in a complex manner to concomitantly favor relaxation of cell-cell junctions while still preserving the permeability of the paracellular pathway of the ADPKD epithelium. These effects are important in contributing to the overall action of ouabain of promoting proliferation of ADPKD cells.

Curcumin Analog 2a Inhibits *In Vitro* Proliferation of Autosomal Dominant Polycystic Kidney Disease Cyst Cells Beatriz Adriana Velez,[1] Laura Parra,[1] Moses Lee,[2] Albert C. Ong,[3] Elsa Bello-Reuss.[1] *[1]Internal Medicine, TTUHSC, Lubbock, TX; [2]Hope College, Holland, MI; [3]Academic Nephrology Unit, University of Sheffield Med School, United Kingdom.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by progressive renal cyst development and destruction of the renal parenchyma conducing to kidney failure. Curcumin inhibits proliferation pathways activated in cancer that are common to ADPKD cyst cells. However no therapeutic levels are achieved by oral administration. Analog 2a, a curcumin derivative lacking glucuronidation sites has improved intestinal absorption and is a more potent cytotoxic agent to cancer cell lines. Thus, it may be of value for treatment of ADPKD. Since cyst cells exhibit proliferative pathways not present in normal kidney cells, Analog 2a may have a predominant inhibitory effect on cyst cell proliferation. We addressed the effects of Analog 2a on proliferation of cyst cells,normal kidney cells and cyst cell lines.

Methods: We used the ADPKD-cyst cell lines OX161 and SKI-001, ADPKD-cyst cells in primary cultures, normal cortical tubule cells in primary cultures, and the normal kidney cell line UCL93/9.Cell survival was measured at concentrations between 0 and 3μM.The half-maximal inhibitory concentrations (IC50) of Analog 2a were determined by data fitting to a 4 parameter logistic curve.

Results: Analog 2a was cytotoxic to cyst cells at lower concentrations than to normal kidney cells with a selectivity index larger than 3. The IC50 (mean ± SD) were: ADPKD cyst-cell lines, 0.98 ± 0.13 μM (n=3); cyst-cell primary cultures, 0.73 ± 0.32 μM (n=4); control cell line, 0.87 μM ± 0.09, not different from cyst cells; normal kidney cell primary cultures were unaffected by Analog 2a at 3 μM. P <0.001 vs cyst cells.

Conclusions: 1. ADPKD cell lines and primary cultures of ADPKD cells have high and similar sensitivities to Analog 2a. 2. Normal kidney cells, in primary cultures, are more resistant than ADPKD cells to Analog 2a. 3. Immortalized cells from normal kidney are sensitive to Analog 2a, and hence are not an appropriate control system. These results indicate that Analog 2a has potential for the treatment of ADPKD.

FR-PO2011

Bidirectional Regulation between Polycystin-2 and Cellular Stress Jungwoo Yang,[1] Qian Wang,[1] Wang Zheng,[1] Carlos Lara,[1] Zuocheng Wang,[1] Guanqing Wu,[2] Xing-Zhen Chen.[1] *[1]Physiol, Univ of Alberta, Edmonton, AB, Canada; [2]Medicine, Vanderbilt Univ, Nashville, TN.*

Background: ADPKD is associated with several cellular abnormalities such as cell over-proliferation and apoptosis. Mutations in polycystin-2 (PC2), a Ca-permeable channel present in the ER membrane, plasma membrane and cilia, account for ~10% of ADPKD cases. How PC2 expression is regulated and how it regulates cell growth remains elusive. We recently reported that PC2 down-regulates cell proliferation and protein synthesis through promoting the phosphorylation of eukaryotic initiation factor eIF2α by kinase PERK.

Results: Here we found that endogenous PC2 protein expression is up-regulated in HEK, HeLa and mouse embryonic fibroblast cells under cellular stress conditions including ER stress, oxidative stress and virus infection-induced stress, which all increase the phosphorylated eIF2α (P-eIF2α). Increased P-eIF2α triggers a number of downstream processes, including global inhibition of translation and proliferation, and regulation of gene expression and apoptosis via translational up-regulation of transcription factor ATF4. Inhibition and stimulation of the activity of protein phosphatase of eIF2α by salubrinal and Gadd34 over-expression respectively up- and down-regulated PC2 expression in cultured cells or live mice. RT-PCR assays indicated that the Pkd2 mRNA level is not affected by stress conditions or P-eIF2α. Further, removal of the 5' upstream ORF (uORF) of Pkd2 mRNA abolishes the regulation of PC2 by P-eIF2α. These data together indicate that P-eIF2α translationally up-regulates PC2 expression through uORF. We found that PC2 binds ER chaperone and ER stress marker GRP-78 and that the binding is substantially reduced during ER stress. In contrast, PC2 also interacted with calnexin, an ER chaperone assisting protein folding, but the binding was increased by ER stress. Finally, using mouse collecting duct cells with Pkd2 knockout and HeLa cells with PC2 knockdown, we found that PC2 is critical for the up-regulation of GRP-78 by ER stress.

Conclusions: In conclusion, PC2 is not only up-regulated by P-eIF2α under stress conditions but is also essential in mediating cellular responses to ER stress.

Endoplasmic Reticulum Stress in the Pathogenesis and Treatment of TSC Renal Cystic Disease

Brian J. Siroky,[1] Hong Yin,[2] Lu Lu,[1] John J. Bissler.[1] *[1]Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Pathology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Tuberous sclerosis complex (TSC) is an inherited tumor predisposition syndrome in which TSC1 or TSC2 mutations lead to deregulated mammalian target of rapamycin complex 1 (mTORC1) signaling. Nearly 50% of TSC patients develop renal cystic disease, and these patients are at the highest risk to progress to end stage renal failure. ER stress can develop in angiomyolipomas and TSC-mutant mouse embryonic fibroblasts due to increased protein translation stemming from constitutive mTORC1 activity. Recent evidence indicates that TSC solid tumors may experience a cytotoxic response to therapies that potentiate ER stress. However, it is not known whether or to what extent ER stress plays a role in TSC renal cystic disease.

Results: Using the EKT2 renal cystic cell line derived from the Eker rat, we found that mTORC1 inhibition (20 nM RAD001, 1hr, 24hr and 72 hr) reduced levels of ER stress markers glucose related protein-78 (GRP78 or BiP), inositol-requiring enzyme-1 (IRE-1), protein kinase-like ER kinase (PERK), and phospho-eIF2α by western blot. In the HK-2 human proximal tubule cell line, RNAi-induced knockdown of TSC2 increased expression of BiP, IRE1α, and CCAAT/enhancer-binding protein homologous protein (CHOP), a pro-apoptotic transcription factor. ER stress exacerbation by proteasome inhibition with MG-132 (1 μM, 24 hr) induced CHOP expression and cleavage of poly (ADP ribose) polymerase (PARP) in EKT2 cells, indicating pro-apoptotic signaling. This effect was attenuated by pre-treatment with an mTORC1 inhibitor (20 nM RAD001, 72 hr). Co-administration of MG-132 with salubrinal (15 μM), an inhibitor of eIF2α phosphatases that can enhance pro-apoptotic functions of eIF2α under ER stress conditions, was synergistic with respect to CHOP induction and PARP cleavage. Finally, we observed BiP positivity by immunohistochemistry in TSC patient renal cystic epithelia.

Conclusions: These findings indicate that the TSC renal cystic epithelium experiences ER stress due to mTORC1 activation, and that ER stress can be targeted therapeutically toward a cytotoxic endpoint.

mTOR Signaling Is Differentially Affected in Human Renal Cells with *PKD1* or *PKD2* Mutations

Djalila Mekahli,[1,3] Geert Bultynck,[1] Albert C. Ong,[2] Ludwig Missiaen,[1] Elena N. Levtchenko,[3] Humbert De Smedt.[1] *[1]Laboratory of Molecular and Cellular Signalling, K.U.Leuven, Leuven, Belgium; [2]Academic Unit of Nephrology, University of Sheffield, United Kingdom; [3]Laboratory of Pediatrics and Department of Pediatrics, K.U.Leuven, Leuven, Belgium.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common monogenic disorder leading to end stage renal disease (ESRD). It is caused by loss-of-function mutations in either *PKD1* (85%) or *PKD2* (15%) genes which encode polycystin-1 (PC1) and -2 (PC2) respectively. Patients with *PKD2* mutation have a milder phenotype and reach ESRD ~20 years later than those with *PKD1* mutation.

Increased activity of mammalian target of rapamycin (mTOR) pathway has been shown in *PKD1* mutants and is implicated in accelerated cell proliferation. Furthermore, it has been demonstrated that rapamycin is highly effective in reducing renal cystogenesis. However, mTOR activity in PC2 mutants has not been studied thus far.

Methods: We developed conditionally immortalized human proximal tubule epithelial cell lines (ciPTEC) from patients with known *PKD1* and *PKD2* mutations and from healthy controls. Also, we generated stable PC1 and PC2 knockdown (KD) cell lines using lentiviral vectors expressing miRNA-based shRNA. In these models we measured the mTORC1 activity (phosphorylated ribosomal protein S6) via Western blotting.

Results: We confirmed in the PC1 KD cell line and in ciPTEC with *PKD1* mutations an upregulation of mTORC1 activity compared with controls (160% vs 100% respectively; p=0.005). In contrast, in the PC2 KD cells and ciPTEC from patients with PKD2 mutations mTORC1 activity was in the range of control cells (80% vs 100% respectively; p=0.350).

Conclusions: This is the first report that highlights an important difference in the underlying molecular mechanism between *PKD1* and *PKD2* mutations. Using human renal cell models of ADPKD, we demonstrate that mTORC1 activity seemed not to be affected by the downregulation of PC2. This might contribute to the milder renal phenotype in these patients. Our data can have important therapeutic implications for selecting patients for treatment with mTOR inhibitors.

Pericystic Matrix Interactions Regulate the Rate of Cystogenesis in Autosomal Dominant Polycystic Kidney Disease

Balaji Karthick Subramanian, Wei-Che C. Ko, David Kaplan. *Department of Biomedical Engineering, Tufts University, Medford, MA.*

Background: Autosomal Dominant Polycystic Kidney Disease remains a major health care concern affecting several thousand patients worldwide. This is in part attributed to the lack of appropriate tissues for research studies and to assess for therapeutic interventions prior to moving to clinical trials.

Methods: Tissue engineering provides novel approaches to the development of 3D in vitro tissue systems. We have developed a model based on tissue engineering principles for the emulation of cystic structures in vitro, with structural and functional features similar to in vivo. The tissue system was developed by culturing normal or polycystin-1 silenced mouse inner medullary collecting duct cells in extracellular matrix molecules infused into 3D porous silk scaffolds. In the system, silk biomaterial scaffolds were used due to the slow degradation, bio-compatibility, ability to maintain structure and transport and can function in perfusion bioreactor systems for sustained time periods.

Results: The results provide evidence for an increased rate of cystogenesis in the disease system, initiated by abnormal pericystic ECM interactions between matrix molecules and integrin subunit proteins. In addition, molecular signaling analysis showed abnormalities in cyclin proteins and cell-cycle progression. Very importantly, we show that inhibiting the pericystic interaction by double silencing the integrin proteins reverses the abnormalities and reduces the rate of cystogenesis and may be considered for ADPKD therapeutic interventions.

Conclusions: We provide evidence for an autocrine signaling involving abnormal matrix interactions, to regulate the rate of cystogenesis and could be targeted for ADPKD therapeutics.

Reduced Proteoglycans in the Kidney Causes Both Tubule and Glomerular Abnormalities

Myron Hinsdale,[1,3] Eduard Condac,[1] Beatrix Ferencz,[1] Florea Lupu,[2] Robert Silasi-Mansat.[2] *[1]Physiological Sciences, Oklahoma State University, Stillwater, OK; [2]Program of Cardiovascular Biology Research, Oklahoma Research Foundation, Oklahoma City, OK; [3]Department of Cell Biology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Most cells produce some form of proteoglycan(s). The initial assembly of proteoglycans on the core protein requires the transfer of a xylose to a designated serine. The enzyme responsible for this is xylosyltransferase and exists in two isoforms. Xylosyltransferase 2 (XylT2) is ubiquitously expressed in many organs suggesting a significant role of XylT2 dependent proteoglycans in those organs. In our XylT2 knock out mice (Xylt2-/- mice), considerable XylT activity remains in the kidney due to the remaining XylT1 activity. However, despite this remaining activity, considerable renal abnormalities occur including glomerular basement membrane changes, fibrosis, and tubule dilation. Functionally these changes result in increased blood urea nitrogen, proteinuria, and, in a few mice, renal failure. Our previous findings in Xylt2-/- mice has established that proteoglycans are important in cyst development in the liver. The additional findings in the kidney indicate that reduced glycosaminoglycan assembly onto core proteins due to XylT2 deficiency has a pathologic impact as well. Seventy percent of PKD patients develop liver cysts as well as renal cysts. Overall our findings suggest that reduced proteoglycans may have a genetic modifying role in inherited polycystic kidney disease (PKD) the fourth leading cause of renal failure in the United States. PKD patients that develop proteinuria have a much poorer long term prognosis. Since the cause of the proteinuria in PKD patients is unclear, there is no specific therapeutic intervention. Our analyses in the Xylt2-/- mice suggest that one source of the proteinuria is reduced renal proteoglycans.

Methods: PAGE, electron microscopy, Immunohistochemistry, water deprivation test, glycosaminoglycan measurements

A Metabolomic Approach Reveals a Metabolic Switch in PKD

Isaline Rowe,[1] Valeria Ulisse,[1] Valeria Mannella,[2] Marco Chiaravalli,[1] Giovanna Musco,[2] Alessandra Boletta.[1] *[1]Genetics and Cell Biology, Dulbecco Telethon Institut-San Raffaele Scientific Institute, Milan, Lo, Italy; [2]Translational Genomics and Bioinformatics, Dulbecco Telethon Institut- San Raffaele Scientific Institute, Milan, Lo, Italy.*

Background: Polycystin-1 (PC-1), the product of the PKD1 gene, mutated in most cases of Autosomal Dominant Polycystic Kidney Disease (ADPKD), is a very large plasma membrane receptor. It has been described to regulate several cell signaling pathways, in

particular the mTORC1 and Akt pathways, major actors in energy sensing and cellular metabolism regulation.

Results: To investigate the role of PC-1 in regulating metabolism, we performed metabolomic profiling of the extracellular medium of Pkd1-/- and Pkd1+/+ MEF (murine embryonic fibroblast) cells. NMR Spectra were superimposed and have shown differences between Pkd1-/- and Pkd1+/+ cells. In particular, Pkd1-/- cells presented an increase in glucose uptake and lactate production, suggesting an increased anaerobic glycolysis (Warburg's effect).

Consistent with this, intracellular ATP content was enhanced in the mutant cells compared to the wt cells. Measure of the mitochondrial potential has shown that it was normal in Pkd1-/- cells. There was no increased ATP anymore in Pkd1-/- cells compared to the Pkd1+/+ cells after glucose starvation showing that ATP content was esclusively caused by an increased glycolysis. In line with these results, Pkd1-/- cells were hypersensitive to glucose deprivation, with a rapamycin sensitive increased apoptosis. In the same conditions, autophagy was induced in Pkd1+/+ cells as expected while Pkd1-/- cells failed to undergo autophagy in line with the increased mTORC1 activity in these cells. Next we monitored the activation of the energy sensor AMPK which was downregulated in Pkd1-/- cells. Next, we looked if a similar glycolytic switch could be detected in vivo, we found that ATP content was increased and AMPK downregulated in the cystic kidneys of a Pkd1flox/-:Ksp-Cre mouse model. Preliminary results suggest an increase in glucose uptake in these kidneys in vivo.

Conclusions: Our data uncover a previously unrecognized role for the Pkd1 gene in regulation of cellular energy balance.

FR-PO2017

Renal and Cardiovascular Phenotypes in Mice with Pkd$^{+/-}$ Mice: Evidence for Nephrogenic Diabetes Insipidus and Impaired Urine Acidification but Normal Glomerular Filtration Rate (GFR) Leonidas Tsiokas,[1] Bonnie Eby,[2] Alexander Lau,[2] Uzma I. Hajiyani,[2] Meghan Pantalia,[2] Chris Skaggs,[2] Becky Pennington,[2] Pedro Lozano,[2] Kai Lau.[2] *[1]Cell Biology, University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: *Pkd2*$^{+/-}$mice have shortened survivals despite normal BUN & sparse renal cysts in 30% of them. But renal functions in sex- & age-matched mice have not been carefully studied. Abnormal intracellular Ca regulation & lower basal [Ca]i in VSMC are implicated to reduce longevity. *Pkd1*$^{+/-}$mice have endothelial dysfunctions, hypertension, & SIADH, attributed to lower basal [Ca]i, but if *Pkd2*$^{+/-}$mice have similar defects is unclear.

Methods: We tested if renal & cardiovascular phenotypes exist in male *Pkd2*$^{+/-}$mice by measuring tubular functions & GFR [serum creatinine (cre) & clearance (C) by HPLC], abdominal cysts & heart functions by echo, blood pressure (BP) & endothelial function.

Results: Cardiac systolic & diastolic functions were normal in *Pkd2*$^{+/-}$mice at 9 & 15 mon. Direct carotid BP & aortic relaxations were normal at 20 mon. Liver cysts were multiple on echo in 50% at 15 mon, 80% at 18 mon & 100% by 20 mon. Renal cysts were absent except in 1 mouse. Serum cre & Ccre were similar at 8, 11, 15 & 19 mon. At 9 mon, increase in urine osm from dehydration tended to be smaller in *Pkd2*$^{+/-}$mice. By 11 mon, they were polyuric by 20%. Dehydration x 8 h produced similar osm (in mOsm/kg) in serum (299 vs 295) & urine (2,201 vs 1,887). Increases in urine osm elicited by 4 more h of dehydration, however, were blunted by 57 % in *Pkd2*$^{+/-}$mice (657 vs. 1,515), despite similar serum osm (319 vs. 318). Vasopressin elicited 63% smaller rise in urine osm (822 vs. 2,252) despite similar serum osm. pH in urine under oil from 12-20th h of fast was higher in *Pkd2*$^{+/-}$mice (5.5 vs. 4.4).

Conclusions: 1. Contrary to liver, renal cysts are rare & GFR is normal even at 20 mon. 2. Unlike *Pkd1*$^{+/-}$mice, male *Pkd2*$^{+/-}$mice have no cardiovascular phenotypes. 3. They have impaired acidification & partial nephrogenic diabetes insipidus vs. SIADH in *Pkd1*$^{+/-}$mice. These differences may explain the milder diseases in man.

Diabetes Accelerates Cystogenesis and Results in Glomerular and Tubular Damage in the Adult Conditional ift88 Knockout Mouse P. Darwin Bell, Kelli Margot Sas, May Y. Amria, Monika Gooz. *Medicine/Nephrology, Medical University of South Carolina, Charleston, SC.*

Background: Diabetes, the leading cause of end stage renal disease, results in structural and functional hypertrophy in the kidney. We have previously found that renal hypertrophy accelerates cystogenesis following deletion of cilia in the adult mouse. The goal of this study was to determine if the presence of diabetes would modify the time course and degree of cyst formation in the adult mouse with deletion of cilia.

Methods: To examine the role of cilia in diabetes, we utilized a conditional floxed allele for the *ift88/Tg737* gene to produce cilia (+) or cilia (-) adult mice. Mice were administered streptozotocin at 50 mg/kg for 5 days to induce diabetes. After 6 weeks, mice underwent MRI to determine cystic burden and kidneys were removed after 6 or 12 weeks for histological analysis.

Results: Blood glucose concentrations were elevated but not significantly different between groups. MRI and histological analyses identified accelerated cystogenesis mainly in the glomeruli and collecting ducts of diabetic cilia (-) mice. Additionally, diabetic cilia (-) mice exhibited abnormalities in non-cystic regions with signs of tubular stress and glomerular disease, as evidenced by primitive renal tubules, mesangial expansion, and prominent podocytes. These abnormalities did not occur in cilia (+) mice. There was also a marked increase in lymphocytic infiltration and enhanced mTOR, AKT, and B-catenin signaling, as well as decreased E-cadherin and RKIP expression in kidneys from the diabetic cilia (-) mice.

Conclusions: Diabetes may be a significant risk factor for accelerated cyst formation and renal failure in PKD, and cilia may be reno-protective in diabetes.

FR-PO2019

Projection Structure of the Polycystin-1 Membrane Domains Brian D. Adair. *Massachusetts General Hospital and Harvard Medical School, Charlestown, MA.*

Background: In the majority of cases, polycystic kidney disease arises from a mutation in either of the genes PKD1 or PKD2. PKD2 encodes a nonspecific cation channel (polycystin-2 or PC-2) which possesses six transmembrane spans and is believed to act as a tetramer. In contrast, PKD1 encodes an extremely large membrane protein (polycystin-1 or PC-1) with eleven transmembrane domains and an extensive extracellular N-terminal region possessing numerous structural motifs for binding cell matrix and membrane proteins. The two proteins interact in vivo and are believed to participate in the same signaling pathway with PC-1 modulating the channel activity of PC-2. The nature of the interaction remains elusive, although the region of PC-1 containing the six terminal transmembrane spans shows sequence homology with the transmembrane region of PC-2.

Methods: A region of the PKD1 gene encoding the eleven transmembrane domains has been cloned and expressed in the yeast Pichia pastoris. The construct begins at the GPS domain prior to the first transmembrane span and includes the complete cytosolic C-terminal domain. The recombinant protein forms 2D crystalline arrays in membranes. Electron crystallography has been employed determine the projection structure of the membrane embedded protein.

Results: The 2D crystals have a plane group symmetry of p4 with unit cell parameters a=b=159 Å and γ=90°. The projection structure derived from electron crystallography reveals that the unit cell is composed of four PC-1 dimers related by four-fold rotation symmetry. The dimers are closely associated with direct, protein-protein interactions, while the packing between dimers in the unit cell is much looser with the dimers clearly separated by lipid molecules.

Conclusions: The sequence homology between the transmembrane domains of PC-2 and the terminal transmembrane domains of PC-1 had suggested that the latter might form an equivalent, tetrameric channel. The structure reveals that this is not the case and PC-1 cannot form a channel on its own. However, the dimeric organization suggests that PC-1 might form a heterotetrameric channel with the homologous domains of PC-2, where opposed dimers of PC-1 and PC-2 would form a pseudo four-fold channel.

FR-PO2020

Mitochondrial Defects and Lifespan Extension in Yeast Model of XPNPEP3 Deletion John F. O'Toole, Erine M. Stames. *Case Western Reserve University, Cleveland, OH.*

Background: *XPNPEP3* is a nuclear gene that encodes a mitochondrial aminopeptidase and mutations have been identified in individuals with heritable kidney failure with tubular atrophy and interstitial fibrosis. The *Saccharomyces cerevisiae* ortholog, *ICP55*, localizes to mitochondria and stabilizes its target proteins. Thus, we used yeast as a genetic model of *XPNPEP3*/*ICP55* deletion to elucidate the underlying mechanisms of tubular atrophy observed in patients.

Methods: Yeast strains were generated with PCR based homologous recombination and grown using standard culture media and conditions. Oxygen consumption was measured with a Clarke-type oxygen electrode. Chronological lifespan (CLS) and resistance to H_2O_2 were determined with trypan blue staining and plating serial dilutions. Reactive oxygen species (ROS) were measured with dihydroethidium staining and flow cytometry.

Results: *ICP55* deletion strains are viable and respiratory competent. Growth in glucose media is comparable to parental strains, but mitochondrial oxygen consumption is significantly decreased. As mitochondrial defects often lead to decrements in lifespan we examined CLS. Surprisingly, *ICP55* deletion increased the CLS. Since TOR1 is known to affect mitochondrial respiration and lifespan, we treated deletion strains with rapamycin, which restored the mitochondrial oxygen consumption to wild-type levels. Deletion of *TOR1* also increased the CLS, but interestingly, combined deletion of *TOR1* and *ICP55* increased CLS additively, suggesting independent mechanisms of CLS extension. Deletion strains were also more resistant to H_2O_2 treatment than parental strains and had lower levels of ROS.

Conclusions: These results suggest that deletion of *XPNPEP3*/*ICP55* results in mitochondrial stress possibly related to dysregulation of mitochondrial protein degradation pathways. The stress response pathways activated in the yeast model may include TOR1 activation, but the resistance to oxidative stress and CLS extension likely occurs through mechanisms that are independent of that observed with *TOR1* deletion. Further characterization of yeast mitochondrial stress pathways should define mechanisms underlying the renal tubular atrophy and interstitial fibrosis observed in patients.

Lymphocyte Subpopulations during Hemodialysis and Hemodiafiltration
Detlef H. Krieter,[1] Sebastian Seidel,[1] Karin Merget,[2] Horst-Dieter Lemke,[2,3] Christoph Wanner.[1] *[1]Nephrology, University Hospital, Würzburg; [2]EXcorLab GmbH, Obernburg; [3]Membrana GmbH, Wuppertal, Germany.*

Background: Lymphocytes are central to the adaptive immune response and their function is impaired in maintenance dialysis patients increasing the susceptibility to infection. The effects of different dialysis modes on the course of lymphocyte subpopulations are largely unknown.

Methods: In a prospective, randomized, controlled, cross-over trial, 10 maintenance dialysis patients were subjected to 4 weeks of each low-flux HD (LF-HD), high-flux HD (HF-HD), low- and high-efficiency postdilution hemodiafiltration (Lo-HDF and Hi-HDF, resp.). Identical, highly biocompatible synthetic dialysis membrane materials and ultrapure dialysate were used in all treatment forms (LF-HD, PUREMA® L, 1.8 m^2; HF-HD, Lo-HDF and Hi-HDF, PUREMA® H, 1.9 m^2). Counts of total lymphocytes and lymphocyte subsets (T-lymphocytes ($CD3^+$), T-inducer cells ($CD3^+/CD4^+$), cytotoxic T-cells ($CD3^+/CD8^+$), B-lymphocytes ($CD45^+/CD19^+/CD3^-$), natural killer cells ($CD45^+/CD16^+ 56^+/CD3^-$)) were determined during individual treatments as well as at baseline and at the end of each 4-week period.

Results: At 10 min, total lymphocytes (between 79±12% (LF-HD; $P<0.05$) to 89±11% (HF-HD) of baseline), $CD3^+$ (86±11% (LF-HD; $P<0.05$) to 99±9% (HF-HD) of baseline), $CD3^+/CD4^+$ (91±10% (LF-HD; $P<0.05$) to 104±11% (HF-HD) of baseline), $CD3^+/CD8^+$ (76±16% (LF-HD; $P<0.05$) to 89±15% (HF-HD) of baseline) and $CD45^+/CD19^+/CD3^-$ (82±17% (LF-HD; $P<0.05$) to 90±14% (Hi-HDF) of baseline) cells had only slightly and mostly temporarily decreased. In contrast, $CD45^+/CD16^+ 56^+/CD3^-$ cells steeply and, similar to the course of $CD3^+/CD8^+$ cells, permanently dropped to between 51±14% (LF-HD) to 63±16% (Lo-HDF) of baseline ($P<0.01$). No differences between treatment modes and the predialysis cell counts at baseline and at the end of the 4-week periods were observed.

Conclusions: Different to other lymphocyte subpopulations, $CD45^+/CD16^+ 56^+/CD3^-$ cells are strongly activated during extracorporeal dialysis procedures. Enhanced convective toxin removal, such as in HDF, has no additional effect on the biological behavior of lymphocytes.

FR-PO2022

In Acidotic Hemodialysis (HD) Patients, High Dialysate Bicarbonate Concentration Corrects Pre-HD Acidosis but Induces Post-HD Metabolic Alkalosis and Alkalemia Associated with Attenuated Increase in pCO_2
David Tovbin,[1] Shimon Storch,[4] Lone Solling Avnon,[2] Amir Abd Elkadir,[3] Moshe Zlotnik.[1] *[1]Nephrology; [2]Pulmonary, Soroka Medical Center; [3]Bio-engineering, Ben-Guriun University of the Negev, Beer-Sheva; [4]Nephrology, Bnai-Zion Medical Center, Haifa, Israel.*

Background: Acidosis is a common severe problem in HD patients. K/DOQI guideline of pre-HD serum bicarbonate (BIC) level (SBIC) > 22 mEq/L is probably insufficient and frequently not achieved on routinely used dialysate BIC concentration (DBIC) of 33-34 mEq/L. We hypothesized that high DBIC (HDBIC) can correct pre-HD acidosis but may induce intra-dialytic metabolic alkalosis/alkalemia, or due to increased BIC buffering and CO_2 production, severe hypercapnia in pulmonary problems or apneic sleep episodes during HD. This study aimed to assess effects of high (40 mEq/L) vs low (33-34 mEq/L) DBIC on SBIC, pCO2 and pH levels during HD.

Methods: In a prospective bi-center study, 19 chronic HD patients with peripheral access were assessed for consecutive 3-week periods on LDBIC and afterwards HDBIC. Arterial blood gases and electrolytes were assessed once weekly at start, middle and end of first weekly HD, and data after equilibration (3rd week assessment) presented.

Results: Pre-HD SBIC was <22 mEq/L on LDBIC in 11 patients (acidotic-A) and increased in them by HDBIC to 26.6 mEq/L inducing intra-dialytic metabolic alkalosis /alkalemia (post-HD SBIC 35.3 mEq/L, pH 7.52) resembling the non-acidotic patients. On HDBIC, pre-HD SBIC correlated in all patients and in A with post-HD pCO2 ($r=0.47$, $p<0.05$, $r=0.73$, $p<0.05$, respectively) and in A with mid-end HD pCO_2 change ($r=0.7$,$p<0.05$). In A, when pre-HD pCO2 ≤44 mm Hg , it increased at mid-HD (37.5 to 41.5 mm Hg, $p<0.01$) but subsequently partially decreased post-HD (38.5 mm Hg, $p<0.05$) (overall-$p<0.01$).

Hypercapnia >55 mm HG occurred only once.

Conclusions: HDBIC corrected acidosis but induced intra-dialytic metabolic alkalosis/alkalemia, associated in the more acidotic patients with lower pCO_2 post-HD and sometimes even its' partial decrease toward end-HD. To moderate intra-dialytic metabolic alkalosis/alkalemia we suggest gradual individualized increase in DBIC in acidotic HD patients.

FR-PO2023

Role of Advanced Oxidative Protein Products in Breaking Peripheral Th17/Treg Balance in Patients on Maintenance Hemodialysis
Hualin Qi,[1] Shougang Zhuang,[1,2] Haidong Yan.[1] *[1]Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai; [2]Department of Medicine, Brown University School of Medicine, Providence.*

Background: CD4+CD25+ regulatory T (Treg) cells and Th17 cells, subsets of T-helper cells, have been reported to play important roles in peripheral immunity, and their imbalance leads to the development of tissue inflammation and autoimmune diseases. In this study, we investigated the association between levels of serum advanced oxidation protein products (AOPPs) and atherosclerosis and the effect of AOPPs on the Th17/Treg balance in patients on maintenance hemodialysis (MHD).

Methods: 57 consecutive MHD patients and 24 healthy volunteers were included. Common carotid artery intima-medial thickness (CCA-IMT) and carotid plaques (CPs) were determined with non-invasive high-resolution B-mode ultrasonography. Peripheral blood mononuclear cells (PBMCs) collected from atherosclerotic cardiovascular disease (ASCVD), non-ASCVD and healthy volunteers were incubated with AOPPs *in vitro*, and the frequency of Treg and Th17 cells was measured using flow cytometry.

Results: Serum levels of AOPPs were higher in patients with MHD as compared to those in healthy controls. Patients with CPs and ASCVD also showed higher levels of AOPPs as compared with patients without CPs and ASCVD. Serum levels of AOPPs were strongly associated with CRP and CCA-IMT, positively correlated with the Th17 cells frequency and serum IL-17 levels, and negatively correlated with the Treg cells frequency, serum IL-10 and TGF-β1 levels. *In vitro* incubation of PBMC from controls with AOPPs resulted in a significant reduction of Treg cells and elevation of Th17 cells. There were significant changes in the number of Treg and Th17 cells by AOPPs in ASCVD compared to non-ASCVD and healthy controls groups.

Conclusions: Treg and Th17 cells from ASCVD patients were more susceptible to AOPPs-mediated alterations. Increased AOPPs have an effect on Th17/Treg imbalance, pormote the micro-inflammatory state, and may ultimately contribute to the occurrence of ASCVD in MHD patients.

Tinzaparin for Anticoagulation in Haemodialysis (HD); a Simple Dosing Algorithm Which Is Safe and Efficacious
Christopher J. Kirwan, Neil Ashman, Zahid Farooq Baig. *Royal London Hospital, United Kingdom.*

Background: Bleeding complications when using heparin, essential as anticoagulation during HD, are common. Low molecular weight heparins (LMWH) have reduced their frequency. An iv bolus Tinzaparin (TP), has a 1/2life of 4 hrs in controls but this is longer in renal failure pts allowing potentially dangerous latent anticoagulation. Plasma anti Xa activity (anti-fXa) is used as a surrogate marker for TP activity. TP can be an effective anticoagulation during HD but dosing regimens vary & end HD anti-fXa has not been fully assessed. We studied anti-fXa in pts receiving TP from a fixed dose HD protocol, assessing efficacy & safety aiming to standardise anticoagulation

Methods: Anti-fXa measured during HD in consecutive pts on a single HD unit. 2500,3500 or 4500iu of TP was given based on length of HD and prior coagulation events. Anti-fXa was measured at T0,0.5,1,2hrs & at the end of HD. Anti-fXa<0.2 is considered therapeutically inert. Efficacy & safety data was collected from 5 HD sessions spanning the study day

Results: 43pts on HD (3.5 or 4hrs), had anti Xa profiling. 19,18 & 6pts received 2500, 3500 & 4500iu of TP respectively. 21pts had 3.5hrs HD; 13 received 2500iu, 6/3500iu & 2/4500iu of TP. No pt had detectable anti-fXa at T0. Pts receiving 3500iu weighed more than those for 2500iu (69v56kg; $p<0.005$) & the greater the dose/kg the higher the peak anti-fXa ($p<0.01$). Dose/kg did not predict end HD anti-fXa ($p=0.07$). Higher TP doses correlated to peak anti-fXa ($p<0.05$). 15pts had anti-fXa >0.2 at the end of HD, 5/19 (2500iu), 8/18 (3500iu) & 4/6 (4500iu). Across 260 HD sessions (52 pts) mean AVF compression time post HD was 9 mins & there were 4 incidents of minor bleeding & 1 clotted circuit

Conclusions: Wt based dosing of TP in HD does not add to safety & efficacy of anticoagulation. Higher doses lead to higher peaks & end HD anti-fXa. Adequate anticoagulation can be achieved with a fixed dose of TP in most cases. A higher TP dose causes a significant anti-fXa at the end of HD. We recommend starting TP at 2500iu, increasing to 3500iu if there are signs of circuit coagulation. A single anti-fXa level should be measured at the end of HD guiding dose, if there is a coagulation concern

FR-PO2025

Pharmacokinetics of the Direct Renin Inhibitor Aliskiren in Patients with End-Stage Renal Disease Undergoing Hemodialysis
Dmytro Khadzhynov,[1] Torsten Slowinski,[1] Ina Lieker,[1] Diego Albrecht,[2] Henk Johan Streefkerk,[2] Sam Rebello,[3] Harm Peters.[1] *[1]Department of Nephrology, Charite Campus Mitte, Charite Universitätsmedizin, Berlin, Germany; [2]Novartis Institutes for BioMedical Research, Novartis Campus, Basel, Switzerland; [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ.*

Background: Aliskiren represents a new class of orally active direct renin inhibitors and is approved for the treatment of hypertension. The present study compares the pharmacokinetics, safety and tolerability of a single dose of aliskiren in patients with End Stage Renal Disease (ESRD) on hemodialysis (HD)in comparison to matched healthy subjects.

Methods: This open-label, single-sequence study enrolled 6 male ESRD patients undergoing chronic HD and 6 healthy, age and body-weight matched volunteers without HD treatment. The ESRD patients underwent two treatment periods (Period 1: single oral dose of aliskiren 300mg 24 h after the last HD session and 48 h before the next HD session; and Period 2: single oral dose of aliskiren 300mg 1 h before the HD session) with a wash out period of >10 days between them. HD treatment lasted 4 h (blood flow 300ml/min, dialysate flow 500ml/min). Blood and dialysis samples were taken for up to 96 h post-dose to determine plasma concentrations of aliskiren. The healthy subjects received one oral dose of aliskiren 300mg and 96 h plasma pharmacokinetics was determined.

Results: In both treatment protocols, dialysis clearance was low (1-2% of oral clearance) and not significantly altered by timing of dialysis. Fraction of aliskiren eliminated by HD was <0.2% in both settings. Compared to the healthy subjects, administration of 300 mg aliskiren was associated with an increase in AUC (+61%,2031±737ng*h/mL)

and Cmax (+17%,279±203ng/mL) in ESRD patients receiving HD at 48 h and increase in AUC (+42%,1776±1149ng*h/mL) and decrease in Cmax (-16%,200±321ng/mL) in those receiving HD at 1 hr.

Conclusions: Only a minor faction of aliskiren is eliminated by an intermittent HD. The aliskiren exposure is not significantly different in ESRD patients receiving a single oral dose of 300 mg either at 1 h or 48 h before HD. No severe adverse reactions occurred in this study.

Effective Elimination of Dabigatran with Haemodialysis: A Phase I Single Centre Study in Patients with End-Stage Renal Disease Harm Peters,[1] Dmytro Khadzhynov,[1] Frank-Dietrich H. Wagner,[2] Stephan Formella,[3] Viktoria Moschetti,[3] Andreas Clemens.[3] *[1]Nephrology, Charité, Campus Mitte, Berlin, Germany; [2]Charité Research Organisation GmbH, Berlin, Germany; [3]Boehringer Ingelheim Pharma GmbH Co. KG, Ingelheim, Germany.*

Background: Dabigatran etexilate (DE) is the pro-drug of dabigatran (D), a synthetic low molecular weight orally active reversible direct thrombin inhibitor. DE is approved for the prevention of stroke and systemic embolism in patients with atrial fibrillation and for the primary prevention of thromboembolic events in the orthopaedic setting. A specific antidote for D has been recently preclinically identified and is not yet available for clinical use in patients. Haemodialysis may be a measure in emergency situations requiring fast elimination of D.

Methods: Dialysis modalities (catheter setting, blood flow rate of 200 ml/min, dialysate flow rate of 700 ml/min) are thought to apply for the majority of patients anticoagulated with DE and having a normal renal function. Six patients with end-stage renal disease (ESRD) received DE once daily over 3 days to achieve steady state (Day 1: 150 mg; Day 2: 110 mg; Day 3: 75 mg).

Results: Plasma trough concentrations at Day 3 were 146±58.1 ng/ml and increased to peak concentrations of 176±60 ng/ml 2 h following the final dose of 75 mg. Dialysis was started 8 following the last dose to await absorption and distribution of the drug (D=150±58.9 ng/ml). After the 4-h dialysis, plasma concentrations had dropped sharply to approx. one half (76±48 ng/ml). The extraction ratio calculated from blood entering and leaving the dialyser was 81.3±2.0%. The rebound after stopping dialysis was minor representing a 10% increase in plasma concentration.

Conclusions: The high dialysis extraction ratio of 81.3% in patients with ESRD and the minor rebound of plasma concentration after dialysis indicate that haemodialysis is an efficient method to remove D from the body. Four-hour dialysis under normal blood flow conditions eliminated about 50% of D. Elimination rates with a high blood flow rate of 400 ml/min will be reported in an updated version of this abstract. Haemodialysis can be employed as an effective measure to eliminate D in emergency situations.

FR-PO2027

A Multi-Center, Prospective, Open-Label, 8-Week Study To Investigate the Efficacy, Safety and Pharmacodynamics of Certoparin for Anticoagulation during Maintenance Hemodialysis – The MEMBRANE Study Detlef H. Krieter,[1] Oliver Dorsch,[2] Horst-Dieter Lemke,[3] Nima Melzer,[4] Christian Sieder,[4] Peter Bramlage,[5] Job Harenberg.[6] *[1]Nephrology, University Hospital, Würzburg; [2]KfH Renal Center, Kronach; [3]EXcorLab, Obernburg, Germany; [4]Novartis Pharma, Nuremberg, Germany; [5]Cardiovasc. Pharmacology and Epidemiology, Mahlow; [6]Clin. Pharmacology, Univ. of Heidelberg, Mannheim, Germany.*

Background: Anticoagulation is a prerequisite for hemodialysis (HD) to prevent clotting in the extracorporeal circuit. We provide efficacy, safety and pharmacodynamic data on the LMWH certoparin.

Methods: Multicenter, open-label, prospective, 8-week trial in patients (pts) undergoing HD receiving a single dose of 3,000 IU certoparin i.v. at 2-3 sessions per week. Additional titration steps and continuous infusion were allowed.

Results: Of 109 pts enrolled (median 71 (range 26-90) years; mean body weight 82.5±18.3 kg; dialysis duration 265±29 min), 106 pts were available for efficacy analyses. The primary endpoint (% of unsatisfactory HD results at week 8 due to clotting or bleeding) was met in 1.9% (n=2) of patients (95%CI 0.23-6.65); no major bleeding. 1.9% of pts experienced clinically relevant clotting in blood lines/bubble catcher and 2.8% in the dialyzer at week 8. 15.7±14.3% of the dialysis filters' visual surface area showed reddish fibers. 40.4% of pts (n=44) had prolonged shunt compression times at least once (overall 82 cases in 2724 dialyses (3.0%)). 8.3% had at least one minor and none had major bleeding. 85.3% had adverse events, 9.2% were serious; in 29.4% drug-relation was suspected. At baseline, week 4 and 8 in subgroups of pts (n=12, 12 and 36) receiving median doses of 3000 (range 3000–3000), 3000 (2400–6000) and 4200 (3000–6600) IU, plasma aXa levels (C) were determined (geometric mean [95%CI]): C2h was 0.24 [0.21-0.27], 0.33 [0.27-0.40] and 0.38 [0.33-0.45] aXa IU/ml, C48h was 0.01 [0.01-0.02] aXa IU at all visits (below detection limit in 50, 66.7 and 82.4%). At baseline and week 4, the area under curve AUC0-48h was 2.66 [2.19-3.24] and 3.66 [3.00-4.45] aXa IU*h/ml.

Conclusions: Certoparin appears to be safe and effective for anticoagulation in patients undergoing maintenance HD.

Asymmetric Dimethylarginine Removal in a Hemodiafiltration-Adsorption Technique: Comparison with Bicarbonate Dialyis and Hemodiafiltration Antonino Sidoti,[1] Marina Biagioli,[1] Donella Borracelli,[1] Luisa Sereni,[2] Céline Piekarski,[2] Giuseppe Palladino.[2] *[1]Nephrology, Poggibonsi, Italy; [2]Bellco, Mirandola, Italy.*

Background: Asymmetric dimethylarginine (ADMA) whose plasma levels increase with worsening of kidney failure is a strong independent mortality predictor in ESRD. A large effort to understand which is best dialysis technique to remove it, has not achieved definitive results. A significant protein binding could affect ADMA dialysance.

Methods: SUPRA provides separately, in the same device, hemofiltration, diffusion and adsorption with a 0.7sm super high-flux polyphenilene membrane 43000 D cut–off, a diffusive membrane 1.7sm low-flux polyphenilene and a styrenic resins cartridge to regenerate by adsorption ultrafiltrate for so called endogenous reinfusion.

We studied four patients, three men and a woman, mean age 68.5±15.5, dialytic age 243±119 mo.s, none with residual renal function, each had a 240' SUPRA, on-line Hemodiafiltration(HDF)1.8 sm Polysulfone(PS) hi-flux and bicarbonate dialysis (BD) 1.8 sm PS low-flux treatment as first session of the week. Blood flow was 330±35 ml/min, infusion liters were 13.0±1.9 on SUPRA and 12.9 ±1.29 on HDF. We used ADMA ELISA on plasma samples obtained at 0' and 240'.

Results: ADMA at 0' and 240' were 1.192±0.48 and 0.27±0.09 for SUPRA,1.7±0.355 and 0.625±0.075 for BD, 0.945±0.063 and 0.497±0.063 for HDF. Reduction Ratio Percentage(RR) was 75.9±6.14 for SUPRA, 62.5±5.57 for BD, 47±8.2 for HDF. Differences by pairs were from start to end 0.917±0.418(CI95% 0.25-1.58) p=0.022 for SUPRA, 1.075±0.321(CI 95% 0.56-1.58) p=0.007 for BD, 0.447±0.099 for HDF(CI 95% 0.28-0.60) p=0.003. A two way ANOVA indicate a significant effect due to techniques [F=44.1; p<.001].

Conclusions: SUPRA demostrated a better RR than BD and HDF most likely due to its ability to ultrafiltrate a proportion of plasma protein (e.g. albumin 6g) during each treatment. Substances bound to proteins but also present in plasma water are liable to adsorption during the passage through the cartridge before ultrafiltrate returns to the patient. Further studies are needed to elucidate effectiveness of this technique in a long follow up i.e. in lowering in a permanent way ADMA levels.

FR-PO2029

A Blood Flow – Dialysate Flow Ratio Maintains Dialysis Adequacy While Reducing the Quantity of Dialysate Used Per Treatment Linda H. Ficociello, Norma J. Ofsthun, J. Michael Lazarus, Claudy Mullon, Jose A. Diaz-Buxo. *Fresenius Medical Care - NA, Waltham, MA.*

Background: It has been proposed that a blood flow - dialysate flow ratio instead of a fixed dialysate flow would optimize clearance. Fresenius Medical Care NA (FMC-NA) 2008® K and T dialysis machines have an AutoFlow Dialysate Flow feature where dialysate flow is set to either 1.5 or 2.0 times blood flow. Additionally, Autoflow reduces flow rate to 300 ml/min when in idle mode to reduce waste.

Methods: 53,597 patients converted to either AutoFlow 1.5 or 2.0 and had at least 2 measurements of adequacy before switching and at least 2 after the switch. Change in dialysate flow prescription was not allowed during this time.

Results: Of the 31,851 patients who switched from their prescriptive dialysate flow (median =800 ml/min) to Autoflow 1.5, the percentage of patients achieving a mean eKt/V of 1.2 or greater increased by 3% (from 85 to 88%). Of the 21,746 patients who switched from their prescriptive dialysate flow (median =800 ml/min) to Autoflow 2.0, the percentage of patients achieving a mean eKt/V of 1.2 or greater increased by 4% (from 85 to 89%). Comparing before and after eKt/V for each patient, we find a small but statistically significant improvement in patients switched to Autoflow 1.5 (mean increase = 0.3, p<0.0001) and Autoflow 2.0 (mean increase = 0.4, p<0.0001). Average gallons of dialysate per patient dropped by 3 gallons before and after Autoflow use (from 42 to 39 gallons per patient) not including the reduction of dialysate wasted when in idle mode.

Conclusions: The use of Autoflow reduces the amount of dialysate used in each hemodialysis treatment without reducing adequacy of treatment.

Phosphate Handling by the Kidney in Patients with End-Stage Renal Failure on Hemodialysis Hideaki Iwasawa, Yoshitaka Miyaoka, Ami Hayashi, Toshiyuki Nakao. *Department of Nephrology, Tokyo Medical University, Shinjyuku-ku, Tokyo, Japan.*

Background: Not a few patients with end-stage renal failure on dialysis therapy have residual renal function which plays a significant role on the removal of retained fluids and solutes even after the initiation of dialysis. However, little is known about the excretion mechanism of fluids and solute by end-stage kidneys, such as by those with a glomerulur filtration rate (GFR) of less than 10 ml/min. Thus, we investigated how phosphate is handled and excreted by the end-stage kidneys in hemodialysis patients.

Methods: We studied 67 patients with a urinary output less than 100 ml/day among 189 consecutive chronic hemodialysis patients from 2008 to 2010. Blood specimens were obtained at the start of hemodialysis on the first session of the week, and we measured the serum concentrations of phosphate, calcium, urea nitrogen, creatinine intact PTH and FGF-23. We also collected 24-hour urinary specimens and measured the urinary concentrations of phosphate, calcium, urea nitrogen and creatinine. GFR was calculated from the mean values of creatinine clearance and urea clearance as (Ccr + Curea)/2 based on 24-hour urine collection.

Results: The mean urine volume (UV) and GFR were 1184.9±548.4 ml/day and 3.11±1.94 ml/min, respectively. The mean serum phosphate (sP) and urine phosphate (uP) concentrations and the amount of 24-hour urinary phosphate excretion (PE) were 5.7±1.2 mg/dl, 16.8±6.3 mg/dl and 200.2±122.7mg/day, respectively. sP significantly correlated with uP (r=0.358, p=0.012), but not with PE. The mean maximal tubular reabsorption threshold of phosphate was 2.0±0.9 mg/dl, which correlated with sP (r=0.306, p=0.012), but not with both uP and PE. PE strongly correlated with GFR (r=0.838, p<0.0001) and UV (r=0.791, p<0.0001), and significantly correlated with intact PTH (r=0.533, p<0.0001) and FGF-23, but not with sP.

Conclusions: The daily urinary excretion amount of phosphate by end-stage kidneys in hemodialysis patients mainly depends on GFR. The action of phosphaturic hormones on the kidney remains, even if the GFR is less than 10 ml/min.

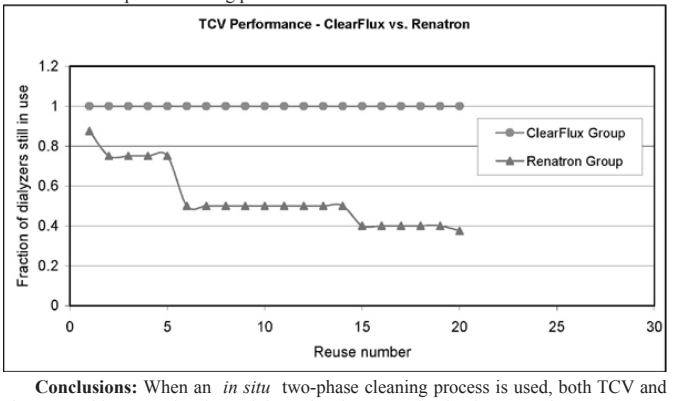
FR-PO2031

Impact of *In Situ* Two-Phase Cleaning on Dialyzer Reuse – Total Cell Volume (TCV) and Middle Molecule Clearance Mohamed E. Labib,[1] Joseph John Murawski,[1] Yacoob Tabani,[1] Dharmeshkumar M. Kanani,[2] Andrew L. Zydney,[2] Toros Kapoian,[3] Richard A. Ward.[4] *[1]Novaflux Technologies, Princeton, NJ; [2]Pennsylvania State University, University Park, PA; [3]Robert Wood Johnson Medical School, New Brunswick, NJ; [4]University of Louisville, KY.*

Background: Reprocessing of dialyzers with peracetic acid has the advantage of easy management of the disinfection solution. However, the clearance of higher molecular weight solutes can markedly decrease after only a small number of reuses and is not reflected in a change in total cell volume (TCV). To address this problem, we studied the effects of an *in situ* two-phase cleaning process (ClearFlux ™ Dialyzer Reprocessing System) on the maintenance of TCV and on the clearance of various molecular weight dextrans under reuse conditions.

Methods: Gambro Polyflux® 21R, Fresenius F80A and Fresenius Optiflux® F200B dialyzers were used for up to 20 treatments, reprocessed using the ClearFlux ™ or conventional peracetic acid reprocessing.

Results: The fraction of dialyzers meeting the criterion for continued use (TCV > 80% of initial value) is shown in the figure. After 20 reuses with the ClearFlux ™, all dialyzers were still usable with TCV > 80% (mean 100% ± 3% SD), while only 40% of those dialyzers treated with conventional processing met the criterion. After 7 patient reuses, clearance of a 10 kDa dextran probe (beta-2 microglobulin = 11.8 kDa) was reduced by 78% in dialyzers with conventional peracetic acid processing, but was unchanged from baseline values with the *in situ* two-phase cleaning process.



Conclusions: When an *in situ* two-phase cleaning process is used, both TCV and clearance of larger molecular weight molecules are maintained to a much greater extent than when using conventional peracetic acid reprocessing.

FR-PO2032

Multi-State Modelling of Serum Albumin and B2-Microglobulin in Hemodialysis Patients Christos Argyropoulos, Maria-Eleni Roumelioti, Mark L. Unruh, Khaled Abdel-Kader. *Renal and Electrolyte, University of Pittsburgh, PA.*

Background: B2-Microglobulin (B2M)and serum albumin (SA) have emerged as predictors of survival in hemodialysis (HD) patients (pts), yet the joint utility of these markers remains unexplored. We examine SA/B2M as determinants of transitory states of health and predictors of mortality in HD pts.

Methods: Prevalent HD pts enrolled in the HEMODIALYSIS (HEMO) trial receiving High Flux dialysis. Panel data of B2M/SA were used to define a Multi-State Model (MSM) of 9 health states by cross classifying patients according to tertiles (Lower, Middle, Upper) of (B2M,SA). We examined instantaneous transitions among these states and relative risk of death with Markov models.

Results: 902 pts out of 1846 initial study participants had available information for MSM. Pt demographics were as follows: age 57.6 ±14, 56.5% women, 63.2% African Americans, 44.7% diabetics SA(nephelometric) and B2M tertiles were L: <3.43, M: 3.43-3.74, U: >3.74 and L: <29.1, M: 29.1-36.6, U: >36.6 respectively. Estimated hazard rates among states are shown in Fig(top), so that patients in state 1 (L B2M and SA) were twice (0.43/0.26) as likely to move to state 4 (L B2M and M SA) than state 2 (M B2M and L SA). Hazard ratios (HR) of death relative to the "best" state 7 (L B2M and H SA) are tabulated below.

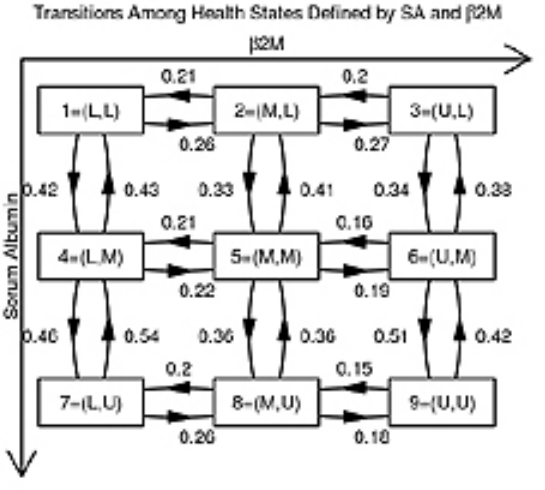
Hazard Rate of Death from Health States Relative to State 7 (L B2M, U SA)

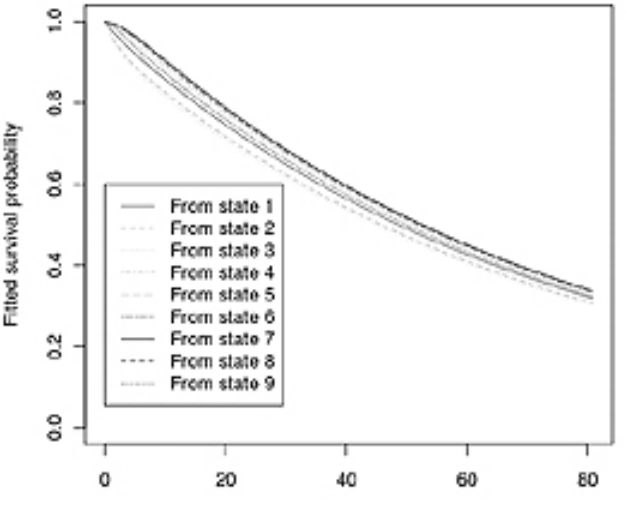
State	HR
1	8.1
2	19.4*
3	16.1*
4	2.3
5	2.0
6	1.8
8	1.7
9	2.4

*p<0.05

For all B2M tertiles, the HR of death appears to worsen with decreasing SA values and the risk was particularly high for pts at the lowest tertile of SA.

Survival estimates from the various states are shown in Fig(bottom).





Conclusions: Joint monitoring of SA and B2M offers a simple clinical rule to identify HD pts with very high risk of death. Future studies should determine optimal management strategies to reduce this risk.

FR-PO2033

Sorbent Dialysis: Results of Eight Real World Water Samples James M. Zacharias,[1] Edwin B. Toffelmire,[2,3] Stephen Merchant.[4] *[1]Department of Medicine, University of Manitoba, Winnipeg, MB, Canada; [2]Department of Medicine, Queen's University, Kingston, ON, Canada; [3]Fresenius Medical Care, Toronto, ON, Canada; [4]SORB Technology Inc, Oklahoma, OK.*

Background: Sorbent dialysis has been used for over 30 years, but use has fallen. Newer Sorbent systems have been developed and would be ideal for use in remote areas with poor access to sufficient quantity/quality water. This study analyzed dialysate quality generated by the sorbent cartridge from water samples from 8 remote sites.

Methods: Tap water was taken from 8 remote Canadian sites. These samples were used to prime HISORB®+ cartridges and perform a mock dialysis with the Fresenius 2008 Sorbent System. Analysis of trace minerals was performed. Paired T-Tests and X^2 analysis were used to analyze the results.

Results: Source water failed to meet ANSI/AAMI Standards for dialysate in 22.6% (38/168) prior to treatment with the sorbent cartridge, but only failed to meet ANSI/AAMI standards in 1.4% (2/144) ($p<0001$) instances. One of these results was with SO_4 which is not well removed by the sorbent cartridge and another was with aluminum which was only 0.002 mg/L above AAMI standards of 0.01 mg/L during the prime. Results are shown in table 1.

Source water and post sorbent cartridge treatment mineral comparison

Mineral	Pre(mg/L)	Pre +/- SD	Post (mg/L)	Post +/- SD	P
Cu	0.09	0.1	0.006	0.002	0.1
SO4	161	141	70	133	0.03
N	0.25	0.1	0.2	0.0004	0.2
Al	0.8	0.2	0.009	0.002	0.3
Ba	0.02	0.03	0.001	0.00003	0.051
Ca	60	42	30	0.02	0.08
As	0.002	0.001	0.002	0.000001	0.4
Mg	38	33	0.6	0.9	0.01
Zn	0.04	0.04	0.009	0.01	0.053
F	0.3	0.02	0.1	0.004	0.08

Reductions were seen with all minerals, but due to small sample size and high variability significant reductions were only seen with SO_4 and Mg. Concentrations for the following minerals were below ANSI/AAMI guidelines and below detection limit and therefore statistical analysis was not performed. (Cd, Sb, Tl, Pb, Ag, Be, Se, Hg, Cr) Mineral concentration was stable during the remainder of a 4 hour treatment.

Conclusions: Dialysis using samples from 8 remote Canadian sites showed that the sorbent cartridge is able to remove excess trace minerals and provide ANSI/AAMI quality dialysate from a variety of real world sources.

Kinetics of Fibroblast Growth Factor 23, Parathyroid Hormone, and Calcium in Hemodialysis Bernhard O. Bielesz, Manfred Hecking, Max Plischke, Gere Sunder-Plassmann. *Nephrology, Medical University of Vienna, Vienna, Austria.*

Background: Fibroblast Growth Factor 23 (FGF23) is rising in the progression of chronic kidney disease. Dialysis induced changes of blood urea nitrogen, calcium, phosphate, β2-microglobulin, and PTH have been studied extensively. Fewer data are available on the kinetics of FGF23 with either minor increases but also decreases reported during a dialysis session.

Methods: 19 adult patients (mean age: 58 yr, range: 26-80 yr) on maintenance hemodialysis not on cinacalcet or any active Vitamin D agent for at least 2 months were selected for determination of serum calcium, phosphate, blood urea nitrogen, β2-microglobulin, PTH (Roche), and intact FGF23 (Kainos). 4 samples per patient and session were drawn at initiation, 1, 2, and 3 hours of dialysis. 11 patients were treated with dialysate calcium of 1,25 mM (6 HDF, 5 HD) and 8 patients with 1,5 mM (4 HDF,4 HD).

Results: PTH showed a decline in the high calcium group (0 hrs 230,98 pg/ml vs. 3 hrs 100,65 pg/ml; p=0,0057) whereas there was no significant change albeit trend to an increase in the low calcium group (0 hrs 336,45 pg/ml vs. 3 hrs 460,46 pg/ml). PTH changes differed in the high vs. low calcium group (-130,33 pg/ml vs. 124,01 pg/ml, respectively; p=0,0383). Correspondingly, serum calcium increased in the high calcium group (0 hrs 2,14 mM vs. 3 hrs 2,35 mM; p=0,0160) whereas it was virtually unchanged in the low calcium group. Changes in serum calcium were significantly different in the high compared to the low calcium group (0,21 mM vs. -0,04 mM, respectively; p=0,0077). Ln(FGF23) dropped significantly in the whole study population (0 hrs vs. 3 hrs, p=0,0009) but was not affected by dialysate calcium. Blood urea nitrogen, phosphate, and β2-microglobulin showed expected and significant decreases over the course of dialysis, which did not differ with respect to dialysate calcium.

Conclusions: PTH and serum calcium were differentially regulated by dialysate calcium content. FGF23 decreased during dialysis but was unaffected by different dialysate calcium concentrations.

FR-PO2035

Exhaled Breath Analysis of Patients with End Stage Renal Disease Using Selected Ion Flow Tube Mass Spectrometry (SIFT-MS) Sevag Demirjian,[1] Kelly Marie Paschke,[2] Riana E. Naude,[1] Leslie Leonard,[1] David E. Grove,[2] Alquam Mashir,[2] Malina Kate Storer,[3] Robert J. Heyka,[1] Raed A. Dweik.[4] *[1]Nephrology, Cleveland Clinic, Cleveland, OH; [2]Pathobiology, Cleveland Clinic, Cleveland, OH; [3]Syft Technologies Ltd., Christchurch, New Zealand; [4]Pulmonary, Allergy, and Critical Care Medicine, Cleveland Clinic, Cleveland, OH.*

Background: End stage renal disease (ESRD) is characterized by the accumulation of numerous compounds, many of which may have adverse biologic effects (uremic toxins). Exhaled breath analysis is a non-invasive method which can measure volatile uremic markers and/or their metabolites. Our aim was to measure the concentration of volatile organic compounds in the breath before and after intermittent hemodialysis (IHD).

Methods: We analyzed the exhaled breath using selected ion flow tube mass spectrometry (SIFT-MS). Pre- and post-IHD comparisons were made using dependent t-test analysis.

Results: Pre- and post-IHD exhaled breath was analyzed in 59 individual ESRD subjects in a single outpatient dialysis unit. Post-IHD exhaled breath concentration was significantly lower for ammonia, acetaldehyde, dimethylsulfide, carbon disulfide, ethanol, 2-propanol, benzene, pentane and higher for isoprene.

Exhaled breath analysis before and after dialysis:

Compound (ppb)	Pre-dialysis (mean ± SD)	Post-dialysis (mean ± SD)	P-value
Ammonia	189±205	117±62	0.001
Trimethylamine	24±43	15±11	0.1
Triethylamine	1.2±1.8	0.8±0.2	0.1
Acetaldehyde±	147±172	90±84	0.0003
Dimethylsulfide	4.6±2.4	3.2±1.8	0.0001
Carbon disulfide	5.2±6.7	3.3±3.2	0.007
Ethanol	720±412	839±527	0.03
2-Propanol	266±160	204±106	0.002
Isoprene	34±18	46±33	0.002
Benzene	6.6±2.5	5.6±1.6	0.0001
Pentane	36±46	22±11	0.02

ppb, parts per billion; SD, standard deviation

Conclusions: Exhaled breath analysis provides a non-invasive method to measure markers of uremia, and their clearance during IHD. Further investigation is needed to examine the agreement between changes of these compounds in exhaled breath and established measures of dialysis adequacy.

Funding: Clinical Revenue Support

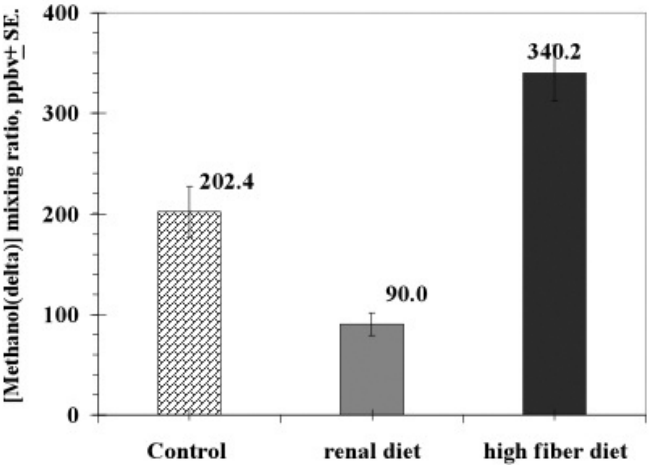
Effect of Hemodialysis and Diet on the Exhaled Breath Methanol in Patients with ESRD Hyun Ji Julie Lee,[2] Madeleine V. Pahl,[1] Nosratola D. Vaziri,[1] Donald R. Blake.[2] *[1]Nephrology and Hypertension, University of California, Irvine, CA; [2]Chemistry, University of California, Irvine, CA.*

Background: While the effect of ESRD and dialysis on solute composition is well known, little is known on their effect on the chemical contents of breath. Methanol is the gaseous byproduct of the breakdown of un-absorbable complex carbohydrates by the gut microbiome. Strict dietary restrictions results in an unintended reduction of dietary fibers in ESRD patients. This can reduce production of methanol by the gut microbiome and curtail its appearance in the exhaled breath. Therefore, we investigated the inter- and intra-dialytic changes in the breath methanol levels in a group of hemodialysis patients (HD).

Methods: Ten patients with ESRD were studied during HD at 3- and 2-day-inter-dialytic intervals. Ten normal subjects served as controls. On each occasion, 20 breath and 18 room air samples were collected and analyzed on a unique six column/detector gas chromatography system.

Results: Seven ESRD patients consuming the prescribed renal diet had lower methanol concentration (90 ±29 ppbv) than three ESRD patients consuming a high fiber diet (340 ± 48 ppbv, $P< 0.0006$) and the ten controls consuming unrestricted diets (202 ± 80 ppbv, $P< 0.001$).



HD resulted in a significant (60 ± 12 %) fall in breath methanol concentration which paralleled the fall in serum urea concentration (70 ± 6 %). The average pre-dialysis methanol concentration was slightly higher at the 3-day than the 2-day inter-dialytic interval.

Conclusions: Dietary restriction of fruits and vegetables aimed at limiting potassium intake results in diminished methanol production by the gut microbial flora in ESRD patients. Perhaps methanol is a reliable breath biomarker to monitor individuals' daily fiber intake. Breath methanol concentration is dramatically reduced by HD due to its efficient removal.

Serum Soluble Alupha-Klotho Levels in Haemodialysis Patients Tanaka Kenji,[1] Yoko Oyama.[2] *[1]Suiyukai, Kashihar, Nara, Japan; [2]Laboratory and Vascular Medicine, Kagoshima University Graduate School, Kagoshima, Japan.*

Background: Alpha-Klotho (αKl) is a cell surface protein with an extracellular domain that can be released as a cleavage product: soluble-type αKl (sαKl). αKl regulates calcium and phosphate homeostasis. Phenotypes of αKl deficiency resemble clinical features of aging and chronic haemodialysis (HD) patients. So we hypothesized that low levels of sαKl might be related to abnormality of mineral metabolism and vascular calcification in HD patients. The aims of this study were to measure serum sαKl levels in HD patients, and to determine correlation with indices of mineral metabolism, age, HD vintage, and coronary artery calcification (CAC).

Methods: A total of 57 patients, 25 males and 32 females, undergoing maintenance HD were investigated. Their mean age was 69.3 ±11.1 years (range from 50 to 75 years). The mean duration of HD was 196.8 ±101.7 months (range from 34 to 397 months). Blood samples were taken from the arteriovenous fistula before HD on the first dialysis day of the week. Serum sαKl levels were assayed using by ELISA methods (soluble α-Klotho ELISA Kit). Serum levels of intact fibroblast growth factor 23 (FGF23) were measured by ELISA methods (FGF-23 ELISA Kit). Kidney size and CAC score were evaluated by multidetector-row CT.

Results: The serum sαKl level was 742.8 ±280.1 pg/ml, the serum level of FGF23 was 7495.1 ±9800.1 pg/ml, CAC score was 1482 ±1577 in HD patients. The serum sαKl level was not significantly lower than that in healthy controls (n=16, aged 69.3 ±11.1 years) (665.3 ±260.7 pg/ml). In HD patients, no significant correlations were found between serum sαKl levels and calcium ion, inorganic phosphate, intact PTH, 1,25 dihydroxyvitamin D, intact FGF 23, age, but strong correlations were found between serum sαKl levels and HD vintage (P<0.003). The serum sαKl levels was not correlated with CAC score (P= 0.115).

Conclusions: The serum sαKl level in chronic HD patients could be found to be compatible to that in age matched healthy controls and to correlate strongly with HD vintage. Although, underlying mechanisms by which circulating levels of sαKl are maintained in long-term HD patients are unknown, we believe that it deserve of further investigation.

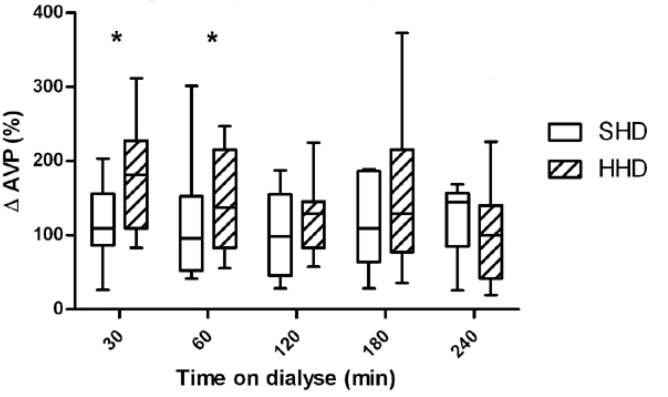
FR-PO2038

Vasopressin Release Is Enhanced by Hemocontrol Biofeedback and Could Contribute to Better Hemodynamic Stability during Hemodialysis Esmée M. Ettema,[1] Johanna J. Kuipers,[2] Henk Groen,[3] Ido P. Kema,[4] Ralf Westerhuis,[2] Paul E. de Jong,[1] Casper F. Franssen.[1] *[1]Nephrology; [2]Dialysis Center Groningen; [3]Epidemiology; [4]Laboratory Medicine, University Medical Center Groningen, Netherlands.*

Background: Hemodialysis (HD) with Hemocontrol biofeedback (HHD) is associated with improved hemodynamic stability compared with standard HD (SHD). Although this beneficial effect of HHD is generally explained by its effect on blood volume (BV), the actual BV change during the second half of HD is comparable between HHD and SHD. Therefore, other factors than BV preservation must play a role. Since HHD is associated with higher initial dialysate sodium concentrations and ultrafiltration rate, we studied whether the beneficial effect of HHD on hemodynamic stability may be explained by increased release of the vasoconstrictor arginine vasopressin (AVP).

Methods: Fifteen HD patients underwent SHD and HHD in random order. All other treatment factors were identical. Plasma levels of AVP and hemodynamic parameters were measured pre-HD and at 30, 60, 180 and 240 min HD.

Results: Median (IQR) pre-HD AVP levels did not differ between SHD (0.94 pg/ml; 0.62-2.10) and HHD (1.0 pg/ml; 0.84-1.60). The Figures shows the percentage change of AVP during HD. AVP levels did not change significantly during SHD whereas AVP levels rose significantly (p<0.01) at 30 min of HHD compared with pre-HD levels. AVP levels were significantly higher at 30 and 60 min of HHD than SHD. Dialysis hypotension occurred significantly less frequent during HHD than during SHD.



Conclusions: HHD is associated with higher AVP levels compared with SHD. The enhanced AVP release with HHD likely contributes to the lower frequency of dialysis hypotension by stimulating plasma refill and facilitating fluid removal during the first part of the HD session, permitting lower ultrafiltration rates during the remainder of the HD session.

FR-PO2039

Prevalance of High Predialysis Serum Bicarbonate and Its Effect on Biochemical Parameters in Maintenance Hemodialysis Patients Kawin Tangdhanakanond, Daranee Chewaproug, Eric J. Bloom, Rasib Raja. *Department of Nephrology, Albert Einstein Medical Center, Philadelphia, PA.*

Background: Due to the routine use of high-bicarbonate dialysate bath, metabolic alkalosis occurs in hemodialysis patients. Some studies suggest that metabolic alkalosis could be detrimental due to its association with various metabolic derangements, e.g., low serum ionized calcium, hypophosphatemia, and hypokalemia, but there is limited data on these parameters in hemodialysis patients.

Methods: We conducted a retrospective study to assess the prevalence of high predialysis serum bicarbonate and its effect on biochemical parameters on 94 hemodialysis patients at an outpatient hemodialysis unit. All patients received hemodialysis 3 times a week with 35 mmol/L bicarbonate bath. We stratified patients into 2 groups based on predialysis serum bicarbonate: the higher bicarbonate group (bicarbonate ≥28 mmol/L, n=25) and the lower bicarbonate group (bicarbonate <28 mmol/L, n=69). Demographic and laboratory data including serum potassium, phosphorus, total calcium, as well as anion gap were analyzed.

Results: Of 94 patients, 51 (54.26%) and 25 (26.60%) patients had predialysis serum bicarbonate ≥26 mmol/L and ≥28 mmol/L, respectively. The higher bicarbonate group (bicarbonate ≥28 mmol/L) was found to have lower mean serum potassium (mmol/L) (4.56 ± 0.73, 5.01 ± 0.99, p=.041), lower mean serum phosphate (mg/dL) (4.61 ± 1.33, 5.56 ± 1.60, p=.01), and lower mean anion gap (mmol/L) (13.84 ± 2.49, 15.41 ± 2.66, p=.012). Other parameters including serum total calcium, alkaline phosphatase, intact parathyroid hormone, albumin, prealbumin, magnesium, iron studies, vitamin B12, folic acid, lipid profiles, urea reduction ratio, and Kt/V were not statistically different between the 2 groups. Mean C-reactive protein (mg/L) was lower in the higher bicarbonate group but not statistically significant (17.33 ± 29.42, 29.39 ± 69.02, p=.30).

Conclusions: In contrast to some pre-existing data, our study demonstrated more favorable biochemical parameters in hemodialysis patients with higher predialysis serum bicarbonate. A future large randomized control trial looking at hard clinical endpoints is warranted.

FR-PO2040

Management of Anemia with CERA in Routine Clinical Practice: Results around 6 Months of the HORTENSIA Study in Hemodialysis David Verhelst,[1] Sébastien Koné,[2] Michel R. Godin.[3] *[1]CH Avignon; [2]Roche, Neuilly sur Seine; [3]CHU Rouen.*

Background: Correction and stability of hemoglobin (Hb) level is a major goal of anemia treatment. CERA, continuous erythropoietin receptor activator, corrects anemia and maintains the stability of Hb level with a once monthly administration. This French non interventional study is conducted to describe in routine clinical practice the management of anemia with CERA in dialysis.

Methods: HORTENSIA is a one-year prospective study conducted in 112 dialysis centers between 2010 and 2011. Eligible patients (pts) were on dialysis for more than 3 months, treated or not with erythropoiesis stimulating agent (ESA) and initiating CERA

at baseline. Primary endpoint was the proportion of patients with Hb level within [10–12] g/dL around the 6th month (M6) of treatment with CERA.

Results: 372 hemodialysis pts (men: 59%) were analyzed (age: 66±15 years). Median duration of dialysis was 4.3 years. 63% of pts were treated in heavy center. Mean Kt/V was 1.5±0.3. At baseline, 4% of pts were ESA-naive and 96% previously treated : 53% with darbepoetin alfa, 34% with epoetin beta and 13% with epoetin alfa. Mean dose was 39±37 µg/week for darbepoetin α and 9033±7212 IU/week for epoetins. 70% of pts had an adequate iron status. Mean Hb level was 11.3±1.2 g/dL at baseline and 11.3±1.1 g/dL around M6. 64% of pts had Hb level within [10-12] g/dL around M6 and 84% within [10-13] g/dL. 78% of pts had a variation of Hb ≤ 1 g/dL from baseline or Hb within [10-12] g/dL around M6. Mean monthly dose of CERA was 136±76 µg at baseline and 141±91 µg around M6. 18 pts (4.8%) had a total of 20 adverse drug reaction (ADR). The most common ADR was the decreased number of platelets/thrombocytopenia in 7 pts (1.9%). Other ADR were uncommonly reported with a frequency <1%. 6 ADR led to treatment modification or discontinuation. 3 pts (<1%) had a serious ADR (ischemic stroke, allergic reaction, thrombosis of the fistula).

Conclusions: A once monthly administration of CERA can maintain stable the Hb level in hemodialysis patients.

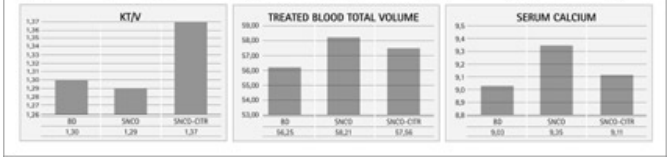
Improving the Dialysis Efficacy in Single Needle by Using Citrasate®: Preliminary Data Roberto Ervo, Sandro Angeletti, Tosca Turrini Dertenois. *Nephrology and Dialysis, Bordighera Hospital, Ventimiglia, Italy.*

Background: The dialysis population shows a growing age, with an increase in clinical problems as malnutrition and cardiovascular diseases. The mortality risks are: ageing, cardiovascular diseases, diabetes, caloric-protein malnutrition and a low serum albumin. Moreover, in those patients the vascular access problems sometimes make it difficult to perform double needle HD, with a serious risk for the dialysis efficacy.

Methods: During a short observational pilot cross over study on 6 patients, we have tested an innovative single needle system where the two pumps run continuously with no interruption of the flux to the dialyser (SNCO - Cross Over B. Braun). The study design shifts patients from standard dialysis (2 months), to SNCO with standard concentrates (3 months), and last to SNCO-CITR with dialysate containing very low acetate (0,3 mmol/l) and 0,8 mmol/l of citrate (Citrasate®) (10 months). The aim was to evaluate the dialysis adequacy (Kt/V, URR, Treated blood volume) with respect to double needle therapies (BD) and in accordance with the KDOQI standards. Furthermore, the evaluation analyzed whether the presence of citrate improved the Kt/V without any change in calcium needs.

Results: Despite the limited number of patients, as indicated in the table below, the three groups are comparable, both as for exchanges (treated blood volume) and Kt/V

	BD		SNCO		SNCO-CITR	
	AVERAGE	ST_DEV	AVERAGE	ST_DEV	AVERAGE	ST_DEV
Kt/V	1,30	0,22	1,29	0,22	1,37	0,19
URR	0,67	0,03	0,66	0,05	0,68	0,05
Nitrogen pre	169,38	59,65	165,75	60,80	146,79	52,62
Nitrogen post	58,13	22,0	60,88	31,63	48,86	26,45
Creat pre	8,71	0,92	9,32	1,84	12,95	10,49
Calcium	9,03	0,7	9,35	1,05	9,11	1,09
B_M	35,91	14,35	33,54	21,30	37,19	16,83
Hb	10,84	0,89	10,38	1,19	11,03	0,72
Htc	35,96	3,98	34,25	4,70	36,52	2,23
Blood Volume	56,25	6,98	58,21	11,93	57,56	5,82
Qb	259,88	11,43	273,13	15,76	260,65	6,04



Conclusions: The SNCO can represent a valid alternative for elderly, diabetic patients and for those with vascular problems who require the native AV fistula preservation over the time or have no chance to use double needle mode and/or a central venous catheter. Citrasate® was introduced to observe whether an increase in the dialysis efficiency may take place due to the higher fibres patency. The study has shown this trend with no significant incidence of the patients' calcium balance.

FR-PO2042

A Potential Use of Polyclonal Free Light Chain Levels for Monitoring in a Chronic Dialysis Population Bertrand Gondouin,[1] Juergen E. Scherberich,[2] Anne Bevins,[3] Paul Cockwell,[1] Colin A. Hutchison.[1] *[1]Renal Unit, University Hospital Birmingham, Birmingham, United Kingdom; [2]Department of Nephrology, Ludwig-Maximilians-University Hospital, Munich, Germany; [3]The Binding site Ltd, Birmingham, United Kingdom.*

Background: Polyclonal free immunoglobulin light chains (FLCs) are uremic toxins. With two isotypes, kappa and lambda, FLCs provide a potential method for the measurement of middle molecular weight uremic toxins (MW 22.5 and 45kDa respectively). The purpose of this study was to determine if FLC levels in a chronic dialysis population are determined by treatment variables and residual renal function (RRF).

Methods: Serum concentrations of polyclonal FLCs were measured in two stable chronic dialysis populations, pre and post dialysis. Levels were compared for different treatment modalities and RRF (>500ml/d).

Results: 112 patients were recruited, 60 were anuric. In both populations anuric patients had higher total FLC levels than those patients with RRF (See table).

	Centre 1	Centre 2
All Patients	316.1 (18.76-738.5)	202,7 (85.1-448)
Anuric	349.3 (125-597)	223 (85.1-448)
RRF	285.6 (18.76-738.5)	153.9 (131.6-322)
P value (anuric vs. RRF)	<0.05	<0.02

Serum total FLC concentrations (mg/L) [Median(range)]

HDF resulted in greater percentage reduction in FLCs compared with regular hemodialysis: 61% [range 43-81] and 39% [14-70], respectively P<0.001.

Patients at the two centres were comparable in terms of age, sex, vascular access, but patients from centre 1 had higher CRP (7.55mg/L [0.12-170]) and FLC levels (316.1mg/L [18.76-738.5]) compared with those from centre 2: 0.7mg/L [0.3-6.6] and 202,7 mg/L [85,1-448.0] respectively (both: P<0.0001).

CRP did not correlate with the serum FLC levels. There was no difference in CRP levels between anuric and RRF patients.

There was no correlation between the amount of FLC removed during the dialysis session and the ultrafiltration rate used.

Conclusions: In conclusion, this study demonstrates polyclonal FLC levels are significantly influenced by both RRF and the dialysis modality used, they could therefore potentially provide a simple target for monitoring 'difficult to remove' middle molecular weight uremic toxins in chronic dialysis populations.

FR-PO2043

Limitations of Serum Cystatin C as Estimate of Residual Renal Function in End-Stage Renal Failure Enric Vilar,[1,2] Capella Boltiador,[1] Ashwini Machado,[1] Adie Viljoen,[1] David Wellsted,[2] Andrew Garrett,[2] Ken Farrington.[1,2] *[1]Lister Hospital, Stevenage, United Kingdom; [2]University of Hertfordshire, Hatfield, United Kingdom.*

Background: Residual renal function (RRF) is inconvenient to measure in HD. Following an HD session, levels of Cystatin C, an alternative marker of GFR, plateau by 24h post dialysis. This suggests that pre-dialysis levels may be a useful marker of RRF in HD.We explored the relationship between serum cystatin C and RRF to determine whether pre-dialysis cystatin C predicts RRF.Additionally, we explored the use of cystatin C as a marker of dialysis adequacy.

Methods: We prospectively analysed serum taken pre- and post- dialysis over two consecutive sessions in 343 patients on high-flux HD or haemodiafiltration. Analyses were performed for urea, creatinine and cystatin C. GFR was measured using body surface area-adjusted mean creatinine and urea clearance from timed urine collections. The relationship of cystatin C to RRF and Kt/V_{urea} was analysed.

Results: GFR ranged from 0-17ml/min/1.73m²BSA. 1/(pre-HD cystatin C levels) had a linear relationship with GFR. For GFR<10ml/min variance increased, with 1/cystatin C explaining only 53% of GFR variance. Inter-dialytic cystatin C rise was inversely related to GFR, explaining 41% of its variance. To investigate poor level of agreement between 1/cystatin C and GFR, we studied pre-dialysis cystatin C in patients without RRF. In this group, cystatin C level (equal to the ratio of generation rate to non-renal clearance) was 6.1mg/L with a wide standard deviation (0.7mg/L), and had no relationship with body size parameters, age and sex. Cystatin C reduction ratio had different linear relationships with Kt/V_{urea} in high-flux HD and HDF(r^2 0.52 and 0.50). A Kt/V_{urea} of 1.2 corresponded to a reduction ratio of 0.46 and 0.53 in high-flux HD and HDF respectively.

Conclusions: Pre-dialysis cystatin C levels have limited usefulness for RRF estimation in patients with GFR<10ml/min due to variation in the generation to non-renal clearance ratio.We were unable to identify parameters which would improve prediction of GFR with cystatin C. Cystatin C reduction ratio correlates with Kt/V_{urea} and may be useful as a marker of middle molecule clearance.

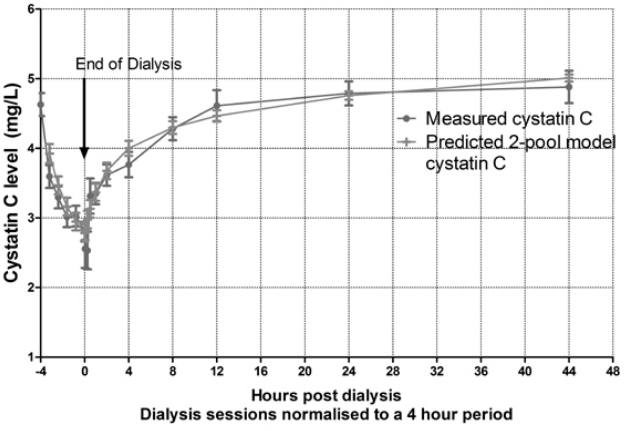
FR-PO2044

Removal Kinetics of Cystatin C during High-Flux Hemodialysis and Hemodiafiltration Enric Vilar,[1,2] Capella Boltiador,[1] Ashwini Machado,[1] Adie Viljoen,[1] Andrew Garrett,[2] David Wellsted,[2] Ken Farrington.[1,2] *[1]Lister Renal Unit, Stevenage, United Kingdom; [2]University of Hertfordshire, Hatfield, United Kingdom.*

Background: Cystatin C has been proposed as a potential alternative marker of GFR since levels correlate more closely than with creatinine. Its 13kDa size allows removal by high-flux dialysis membranes. Serum levels may be useful in estimating residual renal function without the need for urine collection.We studied removal and rebound kinetics of cystatin C during high-flux HD and haemodiafiltration. Using a two-pool computer model, we studied whether serum cystatin C levels are predictable and can be used to determine residual renal function without the need for urine collection.

Methods: We selected 25 patients undergoing high-flux HD or hemodiafiltration. We prospectively collected serum samples at intervals during dialysis and the inter-dialytic period for up to 48 hours. Serum was analysed for urea, creatinine, cystatin C and β2-microglobulin. Cystatin C was measured using an immunoassay. Glomerular filtration rate was measured using mean urea and creatinine clearance.

Results: The mean reduction ratio for each molecule was urea 63%, creatinine 58%, β2-microglobulin 51%, cystatin C 40%. Rebound kinetics differed for all molecules. Cystatin C and β2-microglobulin demonstrated similar kinetics, with 2 hours post-HD levels rebounding to 48% and 38% respectively. A two-pool model demonstrated close goodness-of-fit to actual cystatin C levels, with a median standard deviation of 0.26mg/L between the model and cystatin C data.



Conclusions: Cystatin C levels may be estimated with reasonable accuracy using a two-pool kinetic model. Parameters estimated from this model (internal mass-transfer coefficient, generation rate, non-renal clearance) will allow this model to be tested for prediction of residual renal function in a large dataset.

FR-PO2045

The Difference in Metabolites Disturbance between High-Flux and Low-Flux Hemodialysis: A Metabonomic Study Jiayuan Gao,[1] Zhaohui Ni,[1] Renhua Lu,[1] Jia Qi Qian,[1] Yucheng Yan.[1] *[1]Department of Nephrology, Ren Ji Hospital of Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]School of Pharmacy, Shanghai Jiao Tong University, Shanghai, China.*

Background: Using GC-TOF-MS metabonomic approach, We try to obtain the difference metabolites profiles in both drained dialysate and plasma and analyze the difference in metabolites disturbance between high flux and low flux hemodialysis.

Methods: 25 anuric patients on low flux maintenance hemodialysis and 25 paired high flux dialysis patients were included, Drained dialysate, pre-dialysis and post-dialysis plasma were collected. The concentration of metabolites in drained dialysate and the reduction ratio (RR) in plasma between high flux and low flux were compared to identify different metabolites.

Results: 10 metabolites concentration showed significant differences in drained dialysate between high and low flux dialysis patients, which were tryptophan, Alpha-Ketoisovaleric acid, Gamma-Aminobutyric acid (GABA), Benzoic acid, Ketoleucine, Succinic acid, Palmitic acid, P-Hydroxyphenylacetic acid, Indoleacetic acid and 3-Aminoisobutanoic acid. The concentration of all 10 metabolites was higher in high flux group than low flux group. While in plasma, the RR of 10 metabolites showed significant differences between high and low flux, of which 8 metabolites were higher in high flux group than low flux group, including Alpha-Ketoisovaleric acid, GABA, Allantoin, Citric acid, 4-Hydroxy-L-proline, P-Hydroxyphenylacetic acid, Hippuric acid and Alpha-Tocopherol. Surprisingly, the RR value of Ketoleucine was negative in high flux group but positive in low flux group. On the contrary, the RR value of Hypoxanthine was positive in high flux group but negative in low flux group.

Conclusions: Different metabolites exist in drained dialysis, and metabolites disturbances are different between high flux and low flux hemodialysis patients. Difference in fatty acid metabolism between high flux and low flux exists. Difference might exist in Xanthine metabolism between high and low flux.

Funding: Government Support - Non-U.S.

FR-PO2046

Dialyzer AN69ST – A Valid Alternative in Patients with Hemorrhagic Risk? Mário Raimundo, Catarina Calado Teixeira, Edgar A.F. de Almeida, Antonio Gomes da Costa. *Nephrology and Renal Transplantation, Hospital de Santa Maria, Lisbon, Portugal.*

Background: Heparinization of the extra-corporeal circuit (ECC) during hemodialysis (HD) is unadvisable in patients with hemorrhagic risk. Usually pre-dialyzer saline flushes are employed, which carry potential disadvantages. Polyethylenimine coated polyacrylonitrile dialyzers (AN69ST), which promote heparin adsorption, allow heparin-free HD and obviate the need of frequent saline flushes providing the priming is performed with a heparinized solution. Our aim was to evaluate if systemic anticoagulation occurs with this procedure and compare the efficacy of the AN69ST with a polysulphone (PS) dialyzer with similar characteristics.

Methods: Prospective, open-label, cross-over study. We examined 31 patients during 2 mid-week HD sessions with the AN69ST and the PS dialyzer (without systemic heparinization and with saline flushes). Plasma anti-Xa activity, activated partial thromboplastin time (aPTT), prothrombin time (PT) and urea were determined prior to HD, at 60 and 240min and 180min after HD. A semi-quantitative evaluation of dialyzer clotting was performed at the end of HD.

Results: We found a statistically significant increase in anti-Xa activity at 60min compared to baseline (mean 0,044±0,079 vs 0,025±0,059; p<0,001), which disappeared at the end of the session (mean 0,032±0,049; p=0,145) with the AN69ST. There was no difference in TP and aPTT, although there was a trend to increased PT at 60min (12,63s±4,08 vs 12,43s±3,61s; p=0,061). No differences in anti-Xa or coagulation times were found with the PS dialyzer and it was associated with better dialytic efficacy (URR 73,22±7,67% vs 67,15±11,1%; p=0,01) despite a trend to higher dialyzer clotting in a 0-4 semi-quantitative evaluation (2,29±1,20 vs 1,57±1,08; p=0,065).

Conclusions: The AN69ST dialyzer primed with a heparinized solution is associated with a low-grade and short-lived systemic anticoagulation effect, without significant repercussion in standard coagulation times. The clinical significance of this effect in patients with hemorrhagic risk still needs to be clarified, although the lack of relevant clinical benefit (i.e. improved dialytic efficacy) and higher price may hamper its routine use.

FR-PO2047

Utility of Procalcitonin in Delineating Sepsis in Patients on Haemodialysis Arghya Majumdar,[AMRI] Mukesh Kochar.[AMRI] *[1]Nephrology, AMRI Hospital, Kolkata, India; [2]Nephrology, AMRI Hospital, Kolkata, India.*

Background: Few studies have suggested that procalcitonin (PCT) levels may be elevated in haemodialysis patients in the absence of sepsis. Therefore there is uncertaainity regarding it's utility in diagnosing bacterial sepsis in these patients.

Objectives: To determine the baseline levels of PCT in haemodialysis patients without sepsis and the accuracy of PCT in diagnosing sepsis in these patients.
