Results: Before treatment, the P/C and serum albumin levels of the patients ranged from 3.7 to 15.9 g/g and from 1.6 to 3.4 mg/dl, respectively. Although no patient showed a decrease in the P/C during mizoribine monotherapy, all patients showed a decrease in the P/C with time during combination therapy. At 1, 3, and 9 months after combination therapy, a P/C of <1.0 was observed in 17%, 25%, 75% of the patients, respectively. By month 12, the P/C decreased to <0.4 g/g in 10 of 12 patients, and the remaining 2 patients showed a P/C of 1.1 and 1.4 g/g; in addition, the serum albumin levels increased to >3.5 g/dl in 9 of 12 patients.

Conclusions: The addition of prednisone after an initial treatment with mizoribine alone can have beneficial effects in all IMN patients with nephrotic syndrome. The risks associated with immunotherapy can be decreased by initially using mizoribine alone, which acts as a base for establishing therapy, followed by low-dose prednisone.

SA-PO2886

Fabry Disease in Shanghai --A Survey from Chinese Single Center Zhaohui Wang, Xiaoxia Pan, Hong Ren, Wen Zhang, Nan Chen. *Nephrology, Ruijin Hospital, Shanghai, China.*

Background: Fabry disease is an X-linked lysosomal storage disease with morbility of 1/40,000 in male newborns. The deficiency of lysosomal hydrolase a-galactosidase A (a-Gal A) leads to accumulation of globotriaosylceramide in multiple organs including kidney, skin, cornea and heart which results in variable clinical manifestations.

Methods: Since 2002, 39 families of Fabry disease have been recruited in Nephrology Department of Ruijin hospital in Shanghai, China. 207 related family members have been screened and 85 living patients have been diagnosed finally from 18 provinces in China. 39 hemizygotes and 46 heterozygotes were identified in all pedigrees. Among 39 probands, 31 were male and 8 were female with average age of 29.7 ys and 22 cases were biopsy-proven. Clinical manifestations varied from cerebovascular disease(5%), angiokeratoma(26%), renal insufficiency(28%), hypo-/anhidrosis(38%), acroparesthesia(38%), left ventricular hypertrophy(49%) , ophthalmological lesion(51%) and proteinuria(79%). 32 probands including 7 females and 25 males had renal lesions. 31/32 probands had proteinuria including 2 nephrotic syndrome. 8/32 (25%) patients present microscopic hematuria. 11/32 (34.4%) suffered from renal insufficiency including 5 ESRD.

Results: Almost all the main diagnostic technologies of Fabry disease have been set up in our department such as renal pathology, enzyme activity measurement with both peripheral leukocytes and dried blood spots sampled in filter paper and gene analysis. we screened 1544 hemodialysis (HD) patients and 118 peritoneal dialysis (PD) patients using enzymatic measurement and identified 1 male from HD and PD patients, respectively.

Conclusions: By gene sequencing 18 mutations which included 12 novel ones comprised of 13 missense mutations, 2 nonsense mutations, 1 splicing mutation and a single nucleotide deletion, a gross deletion.

SA-PO2887

Albumin Excretion Fraction for Monitoring Proteinuria When Protein Plasma Level Is Manipulated Gianluigi Ardissino, Francesca Tel, Alice Monzani, Sara Testa, Fabio Paglialonga, Alberto Edefonti. *Pediatric Nephrology Unit, Fondazione Ca' Granda Osp Maggiore Policlinico, Milano, Jamaica.*

Background: Urinary protein/creatinine ratio (uPr/uCr) or protein excretion rate are the most common indicators for monitoring nephrotic syndrome and the efficacy of treatments. However, these indicators are very much influenced by changes in plasma protein level induced by plasma or albumin infusion as well as by plasmaexchange (PEX). In these conditions, it becomes difficult to detect improvement, as a response to treatment, since the increase in plasma protein per se causes an increase in proteinuria.

As an example, in a 12 yo boy with clinically stable FSGS without specific treatment but weekly albumin infusion, uPr/uCr was 15, 95 and 34 at baseline, 1 hr and 24 hrs after albumin infusion, respectively.

In the present paper we explore the working hypothesis that albumin excretion fraction (FeAlb) is more accurate for measuring proteinuria whenever plasma protein level is manipulated.

Methods: A 19 yo girl with FSGS unresponsive to standard treatment (steroids, tacrolimus) was addressed to high volume PEX with albumin solution 4.5 gr/dL (thrice weekly).

Results: Following the first few sessions of PEX, uPr/uCr ratio increased (from 11 to 15) as a consequence of the increase in plasma protein level induced by PEX itself. Following are the basic laboratory before, during and after the PEX treatment. After the 3rd PEX the efficacy of the treatment was clearly detected by FeAlb but not by uPr/uCr (line 4 in table).

Day	sAlbumin	uPr/uCr	FeAlb
0 (Baseline)	1.7	11.3	8.9
6 (PEX 2)	2.5	14.9	10.8
7 (PEX 3)	2.7	15.0	8.2
11 (PEX 4)	2.4	11.3	4.8
14 (PEX 5)	2.9	7.7	2.7
20 (PEX 6)	3.1	8.9	2.4
26	2.9	4.4	1.3

Conclusions: In conclusion in selected conditions (whenever plasma protein level is manipulated), FeAlb seems a better indicator of protein loss than protein excretion rate or uPr/uCr. More studies are needed to test its efficacy

SA-PO2888

Low Glomerular Density with Glomerulomegaly Characterizes Renal Biopsies of Obesity-Related Glomerulopathy Nobuo Tsuboi, Go Kanzaki, Yasunori Utsunomiya, Tetsuya Kawamura, Tatsuo Hosoya. *Division of Kidney and Hypertension, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan.*

Background: Obesity-related glomerulopathy (ORG) is a secondary form of glomerular disease that may occur in individuals with obesity. It is histologically characterized by a marked glomerulomegaly closely related to glomerular hyperfiltration. However, there is likely to be factors other than obesity that contribute to the development of this renal complication since only a minority of obese individuals actually manifests renal injury. This study examined the glomerular density (GD; non-sclerotic glomerular number/renal cortical area of biopsy) in ORG to determine if the difference in the glomerular number is associated with the pathogenesis.

Methods: Obesity and overweight were defined as BMI≥30 and 25≤BMI<30kg/m^2, respectively. ORG was morphologically defined as obesity-associated glomerulomegaly with or without FSGS lesions. Patients with any evidence of other renal diseases or eGFR<60 ml/min/1.73m^2 at biopsy were excluded. The GD and the glomerular volume were measured using a computed imaging analyzer.

Results: The distribution of the GD in the biopsies of ORG was extremely low (1.7±0.6/mm^2, n=20). This was quite different than the widely-distributed GD in biopsies of kidney transplantation donors (3.1±1.0/mm^2 , n=20). However, an analysis of autopsy cases without renal diseases showed that the distribution of the GD in overweight (2.9±0.7/mm^2, n=15) or obese (3.1±1.1 x$10^6\mu m^3$, n=8) subjects was similar to that in the non-obese subjects (3.1±0.6 x$10^6\mu m^3$, n=25). The biopsies of patients with ORG showed marked glomerulomegaly (6.3±1.8 x$10^6\mu m^3$) compared with those of kidney transplantation donors (2.4±0.6 x$10^6\mu m^3$). However, only a modest increase in glomerular size was found in the overweight (3.8±1.5x$10^6\mu m^3$) or obese (3.7±1.5x$10^6\mu m^3$) autopsy kidneys without renal diseases. The comparison of the GD in the normotensive ORG patients and hypertensive ORG patients did not show significant difference.

Conclusions: Kidneys with a low GD may be a potential characteristic of individuals who are susceptible to obesity-induced glomerular enlargement and subsequent renal injury.

SA-PO2889

Influence of a Functional Polymorphism of Aldosterone Synthase Gene on Membranous Nephropathy Christos Bantis, Peter J. Heering, Nicoletta-Maria Kouri, Maria Stangou, Christina Schwandt, Nicola Kuhr, Lars C. Rump, Katrin Ivens. *Department of Nephrology, Heinrich-Heine University, Düsseldorf, Germany.*

Background: The C-344T polymorphism of the aldosterone synthase gene was associated with serum aldosterone levels and the development of arterial hypertension. In the present study we evaluated its influence on primary membranous nephropathy.

Methods: Fifty-nine patients with biopsy-proven primary membranous nephropathy were followed up for 8.0 ± 11.8 years. Patients were classified according to their slope of reciprocal serum creatinine (≥ or < -0.1 dl*mg-1 *year-1) into groups A (slow progressors, n=42) and B (fast progressors, n=17). One hundred healthy volunteers were analysed as controls. Aldosterone synthase gene C-344T polymorphism was determined by PCR amplification in all patients and controls. Serum aldosterone levels were determined by ELISA in 57 patients with chronic glomerulonephritis.

Results: Aldosterone synthase gene C-344T polymorphism influenced the serum aldosterone levels (CC/CT: 106.8 ± 70.4, TT: 243.2 ± 323 pg/ml, p<0.05). The genotype frequencies were similar in patients and control subjects (ns). Age, renal function, proteinuria and blood pressure did not differ significantly at the time of renal biopsy between patients with different genotypes (ns). The genotype distribution was similar patients in group A (CC/CT: 71.4%, TT: 28.6%) and to group B (CC/CT: 76.5%, TT: 23.5%, ns). Furthermore, there was no significant difference regarding the actual rate of progression in patients with different genotypes (CC/CT genotypes: -0.099 ± 0.151, TT: -0.050 ± 0.066 dl*mg-1 *year-1; ns). Aldosterone synthase C-344T polymorphism had also no impact on the kidney survival rate in the Kaplan Meier analysis (ns).

Conclusions: Our results indicate that the functional aldosterone synthase gene C-344T polymorphism does not influence the clinical course of membranous nephropathy.

Abstract Withdrawn

SA-PO2891

Effect of the Initial Type of Hemodialysis Access Planned in the Elderly on Mortality Outcomes Ranil N. Desilva, Bhanu K. Patibandla, Yael Vin, Akshita Narra, Alexander S. Goldfarb-Rumyantzev. *Division of Nephrology, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA.*

Background: Patients with fistulas that are functional at the time of hemodialyis initiation are known to have superior survival compared to those with grafts and catheters. Because some of the AV fistulas and AV grafts fail to be functional at the time of dialysis start, we measured outcomes associated with the type of access first placed in preparation for hemodialysis (as opposed to the access used at hemodialysis initiation) in the elderly population.

Methods: We included incident hemodialysis patients who started dialysis from 2005 to 2008, ≥67 years of age, from the United States Renal Data System. Medicare Claims from 2003-2008 were used to identify placement of the first vascular access. Primary variable of interest was the type of vascular access first placed (i.e., fistula, graft, or central catheter), with primary outcome of all-cause mortality (time to death) measured from the first out-patient hemodialysis. Data analyzed using Cox regression model adjusted for age, sex, race, co-morbidity index, BMI, cause of ESRD, and diabetic status.

Results: 115,425 subjects were identified with first access placed being AV fistulas (n=21,436), AV grafts (n=3,472), and catheters (n= 90,517). Significant mortality benefit was found in those with fistula or graft placed as a first vascular access compared to those with catheters [HR 0.506, p<0.001 and HR 0.562, p<0.001 respectively]. Cohort was then stratified by age into three groups: 67-79, 80-89, and ≥90. Each of these three groups demonstrated statistically significant benefit from initial placement of an AV fistula or AV graft compared to catheter: for AVF [HR 0.506 (p<0.001), HR 0.527 (p<0.001), and HR 0.509 (p<0.001), respectively for each age group] and for AVG [HR 0.562 (p<0.001), HR 0.513 (p<0.001), and HR 0.522 (p=0.0013), respectively for each age group].

Conclusions: First access placed in an elderly prospective hemodialysis patient being an AV fistula or AV graft is associated with better mortality outcomes compared to catheters.

SA-PO2892

Effect of the Initial Type of Hemodialysis Access Used in the Elderly on Mortality Outcomes Ranil N. Desilva, Gurprataap Singh Sandhu, Jalaj Garg, Alexander S. Goldfarb-Rumyantzev. *Division of Nephrology, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA.*

Background: Though the "fistula first" initiative is intended to be applied across all population subgroups, we hypothesized that certain subpopulations (i.e., elderly and those with greater co-morbidity) might not benefit from it.

Methods: Study cohort included incident hemodialysis patients from 2005 to 2007 ≥70 years old, derived from the United States Renal Data System. Primary variable of interest was the type of vascular access used at first outpatient hemodialysis (i.e., fistula, graft, or central catheter), with primary outcome of all-cause mortality (time to death measured from the first out-patient hemdialysis).

Results: Of the 82,202 elderly patients, 82.2% were dialyzed initially by catheter, 13.5% by AV fistula, and 4.2% by AV graft. Cohort was stratified by age (70-79, 80-89, and ≥90). Each of these age groups demonstrated a survival benefit with use of an AV fistula compared to catheter [HR 0.56 (p<0.001), HR 0.55 (p<0.001), and HR 0.69 (p=0.007) respectively]. The cohort was further sub-stratified based on specific co-morbidities: those ≥90 lost significant benefit of a fistula compared to a catheter if history of malignancy (HR 0.45, p=0.182), peripheral vascular disease (HR 0.70, p=0.350) or diabetes (HR 0.67, p=0.146) was also present. Comparing graft to a catheter, both groups 70-79 and 80-89 had significant benefit compared to catheter (HR 0.73, p<0.001 and HR 0.74, p<0.001 respectively). However, significance was lost in those ≥90 (HR 0.83 p=0.354). Graft use, in 80-89 years old with a history of malignancy or peripheral vascular disease also did not reach significant benefit compared to a catheter (HR 0.88, p=0.423 and HR 0.85 p=0.221 respectively).

Conclusions: While fistulas and grafts are generally advantageous to survival, there are subgroups of hemodialysis patients (≥90 years old with peripheral vascular disease, malignancy, or diabetes), where their use may not be of clear benefit compared to catheters.

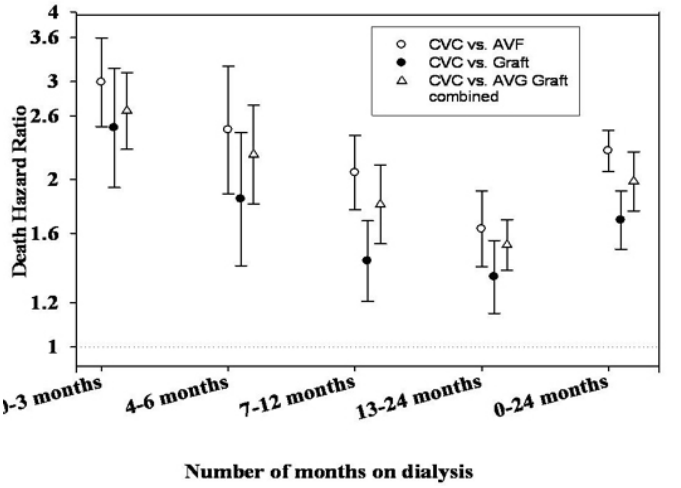
SA-PO2893

Vascular Access Type and Early Death in the First Two Years of Hemodialysis Treatment Lilia R. Lukowsky,[1,2] Leeka I. Kheifets,[2] Onyebuchi A. Arah,[2] Allen R. Nissenson,[3] Kamyar Kalantar-Zadeh.[1,2] *[1]Harold Simmons Center, Torrance, CA; [2]UCLA School of Public Health, Los Angeles, CA; [3]DaVita Inc., Denver, CO.*

Background: Mortality is exceptionally high during the first year of hemodialysis treatment. There are limited data about the role of dialysis access type in early mortality of hemodialysis patients. We hypothesized that central venous catheter (CVC) is associated with stronger death risk in the first several months of dialysis therapy initiation.

Methods: We identified 18,707 incident MHD patients, who had started MHD treatment from the first week of therapy in a DaVita clinic (prior to Gambro acquisition) between 7/1/2001 and 6/30/2006. We calculated the risk of death at the time periods of 0-3, 4-6, 7-12, and 13-24 months after starting of dialysis therapy comparing patients with CVC to those with different types of vascular access.

Results: The incident MHD patients had a mean age of 63±15 years and included 45% women, 24% African Americans and 14% Hispanics. Use of CVC was associated with increased mortality during all time periods, but the death hazard ratio was even higher during the first 3 months of the therapy (2.7 [95% CL: 2.3-3.1]) compared to all other types of vascular access; it was 3.0 (2.5-3.6) compared to arteriovenous fistula (AVF) and 2.5 (1.9-3.2) compared to graft.



Conclusions: Among incident MHD patients, mortality hazard was almost 3 fold higher for patients with CVC compared to patients with AVF. Examining interventions to reduce use of CVC at the start of dialysis therapy and its impact on survival are indicated.

SA-PO2894

The Effect on Cardiac Function of AVF Flow in Hemodialysis Patients Misaki Moriishi,[1] Hideki Kawanishi.[2] *[1]Internal Medicine, Tsuchiya general hospital, Hiroshima, Japan; [2]Surgery, Tsuchiya general hospital, Hiroshima, Japan.*

Background: Cardiac failure is majority of deaths in hemodialysis patients. Some studies demonstrated that increase of the blood flow by AVF flow might cause left ventricle overload, resulting left ventricular failure. This study was to evaluate if AVF flow contributes to an increase in left ventricular mass (LVM).

Methods: 43 hemodialysis patients with ejection fraction (EF) more than 50% who had first AVF access created, entered the study. All were performed echo cardiography prior to AVF access creation and again at 12, 24 months post-hemodialysis initiation. Blood flow of brachial artery (BA Flow) as AVF blood flow was measured by echography prior hemodialysis initiation and again at 12, 24 months post-hemodialysis induced. Date were analysed usig Student's t-test, correlation coefficients and regression.

Results: The mean BA Flow was 420.1±175.6 mL/min prior hemodialysis initiation, and increased to 486.5±233.2 mL/min at 24 months post-hemodialysis initiation (p<0.01). The mean LVM was not changed at 24 months post-hemodialysis initiation(prior : 251.6±69.2 g , post-24 months 232.±84.3 g). BA Flow at 24 months did not correlate with percent change in LVM. Percent change in LVM correlated with percent change in percent change in EF.

Conclusions: Our study shows that blood flow of AVF had not a effect on left ventricular mass in hemodialysis patients with normal cardiac function.

SA-PO2895

Effect of the "Fistula First" Paradigm on the Population Attributable Fraction (PAF) for Mortality from Vascular Access (VA) in the Australian and New Zealand (ANZ) Hemodialysis (HD) Population Mark R. Marshall,[1] Stephen P. McDonald,[2] Peter G. Kerr,[3] Kevan R. Polkinghorne.[3] *[1]Department of Renal Medicine, Counties Manukau District Health Board, Auckland, New Zealand; [2]Australia and New Zealand Dialysis and Transplant Registry (ANZDATA), Adelaide, Australia; [3]Department of Nephrology and School of Medicine, Monash Medical Centre and Univeristy, Clayton, Australia.*

Background: Arteriovenous fistulas (AVFs) are associated with lower mortality than arteriovenous grafts (AVGs) and central venous catheters (CVCs). The "Fistula First" paradigm emphasizes the need to increase use of AVFs. We determined the PAF for mortality attributable to AVGs and CVCs pre and post "Fistula First" in prevalent stable HD patients in ANZ.

Methods: Using the ANZDATA Registry, we included all adults commencing renal replacement therapy (RRT) between 1999-2007 and on HD at 1 year post-RRT inception. We defined the primary exposure as VA recorded in the next ANZDATA survey. We

categorized patients into eras (1999-2002, 2003-7). The primary outcome was death. We used Cox regression with shared frailty by hospital, to determine PAF attributable to AVGs and CVCs in each era adjusting for baseline characteristics.

Results: We analyzed 1936 deaths in 5079 pts (18502 pt-years) from 70 hospitals. Compared to 1999-2002, there was a lower prevalence of AVGs but a higher prevalence of CVCs in 2003-2007. Adjusting for age, sex, ethnicity, late referral, eGFR at RRT inception, BMI, flux, HD time & dose, primary renal disease, diabetes and co-morbidity, the HR for death (relative to AVFs) was 1.64 (1.41-1.90) for AVGs and 1.78 (1.10-2.87) for CVCs. 354 of the deaths (PAF 18.3%) were attributable to VA other than AVFs:

	Pre "Fistula First" (1999-2002)		Post "Fistula First" (2003-2007)	
	n (%)	PAF (95% CI)	n (%)	PAF (95% CI)
All pts	2423	-	2656	-
AVF	1,737 (71.6)	-	1909 (71.9)	-
AVG	268 (11.1)	6.3% (4.1% - 8.4%)	203 (7.64)	4.6% (3% - 6.2%)
CVC	418 (17.25)	11.9% (4% - 19.2%)	544 (20.48)	13.9% (4.6% - 22.3%)

Conclusions: The lower PAF due to less AVGs post "Fistula First" has been offset by the higher PAF due to more CVCs. We suggest a complementary paradigm of "Line Last", and re-emphasize establishing AVFs before HD inception to avoid ongoing CVC use.

Funding: Government Support - Non-U.S.

SA-PO2896

Haemodialysis (HD) Via a Functioning Native Arteriovenous Fistula (AVF) Is Associated with a Lower Erythropoietin (EPO) Requirement in Camparison to HD Via a Central Venous Catheter (CVC) Muhammad Umair Sharif,[1] David Lappin,[2] Donal N. Reddan.[2] *[1]Nephrology, Mayo General Hospital, Castlebar, Ireland; [2]Nephrology, University College Hospital, Galway, Ireland.*

Background: EPO use is a significant cost in patients requiring long-term haemodialysis (HD). Higher doses of EPO are known to be an independent predictor of mortality & morbidity in this patient population. Due to difficulties in obtaining and maintaining a functioning native AVF many patients in our HD centre dialyse using a CVC. In this study, we examined the relative amount of EPO use in HD patients dialysing either via an AVF or CVC.

Methods: EPO requirement for 53 maintenance HD patients was calculated & then matched with their dialysis access, whether native AVF or CVC. The following conversion factors were applied when converting other forms of EPO to similar dose equivalents of epoetin alpha or beta.

Epoetin = Epoetin alpha = Epoetin beta

1 mg of Darbepoetin (Aranesp) = 200 units of Epoetin

1 microgram Methoxy polyethylene glycol-epoetin beta (MIRCERA) = 200 units of Epoetin

Results: In our study patients with a native AVF required an average of 7919 Units of Epoetin/week as compared to patients dialysing via a CVC who required an average of 10125 units of Epoetin /week.

	AVF	CVC
Age	55+_27	62+_28
No. of Patients	32	21
Hemoglobin	11.1+_2.1	11.6+_2.7
Average EPO Requirement/ Week/Patient	7919 Units	10125 Units

Conclusions: HD via a functioning native AVF, in comparison to HD via a CVC, results in significant cost savings of approximately 72 euros per patient per month or 850 euros per patient per year.

SA-PO2897

Non-Programmed Vascular Access Is Associated with Greater Mortality in Patients Who Return to Hemodialysis with a Failing Renal Graft Gustavo Laham, Carlos H. Diaz, Gervasio Soler Pujol, Mario Davalos, Ana M. Cusumano, Antonio R. Vilches. *Nephrology Section, Department of Medicine, CEMIC, Buenos Aires, Argentina.*

Background: There is an increasing number of Pts entering dialysis because of a failing graft. Although the use of a catheter for vascular access (VA) in Pts entering a hemodialysis program (HD) is associated with increased mortality it is not known whether this association also holds in the case of failed renal transplants (Tx). The purpose of our study was to assess the relationship between the type of VA and mortality in Tx patients re-entering our HD program.

Methods: Between 1/1995 and 05/2010, 131 incident Pts started HD after a failed Tx. The cohort was divided into 2 groups according to the type of VA: 1) Planned VA (PVA), A-V fistula or a graft; and 2) Unplanned VA (UPVA), (catheter). Pts were censored at the time of re-transplantation or loss of follow up (FU). Co-morbid conditions were weighted using Khan's index based on age, presence of diabetes and organ-specific conditions. Cox regression analysis was used to establish mortality predictors and Kaplan-Meir's method for survival comparisons.

Results: Mean age was 44 years; 67.9% were males and median follow up was 52 months, IQR 14-105. Median Tx survival was 106 months, IQR 62-162, and the serum creatinine at the start of HD was 6.2 mg/dl +/- 2.4. 48/131 Pts (36.6%) died during FU.There were significant differences in age ($p<0.04$), Khan index ($p<0.008$), time on HD after re-started on the program ($p<0.0001$), and survival when the PVA (n=82) and UPVA (n=49) groups were compared. Mortality was 26.8% and 54.2 5%, respectively, Log Rank test $p<0.0001$. Multivariate Cox regression analysis showed that catheter use was independently associated with a greater mortality after adjusting for the other variables also associated with mortality in this cohort, such as Khan Index and donor type; Odds ratio 6.5; 95%; Confidence Interval 2.9-14.

Conclusions: In this retrospective study patients entering our institutional hemodialysis program after a failed renal Tx using a catheter, as opposed to a previously fashioned permanent access, showed a greater all cause mortality.

SA-PO2898

Hemodialysis Vascular Access Patency: Results from a Single Centre Initiative Janet Lynn Graham, Peter Magner, Swapnil Hiremath. *Division of Nephrology, Ottawa Hospital, Ottawa, ON, Canada.*

Background: Guidelines recommend the arteriovenous (AV) fistula as the vascular access of choice. The data on patency rates is from studies done over two decades ago; since then the hemodialysis population has changed with increasing proportion of older patients with diabetes and vascular comorbidities. At our academic centre, we have an active vascular access monitoring program, comprising of regular access flow surveillance, weekly rounds with interventional radiology +/- vascular surgeons and early intervention. The aim of our study was to examine the patency rates of AV access with this system of active surveillance.

Methods: This was a retrospective cohort study examining all patients who had creation of a vascular access at our centre over the period 2003 to 2010. Data was abstracted from our administrative database. Access survival was calculated as time from access placement to abandonment, including intervening manipulations (surgical or endovascular). Intervention-free access survival was measured as the time from access placement to any intervention designed to maintain or re-establish access patency. Kaplan-Meier survival analysis and the life table method were used to calculate access patency rates.

Results: 1064 patients, with 62% men with a mean age of 63 +/- 18 years had a first vascular accesses created over the period of study, with 960 AV fistula and 104 grafts. 319 accesses failed over the period of study with thrombosis being the commonest cause (68.5%). The median survival for fistula at 6.21 years was much longer than grafts at 1.05 years. 175 patients had a 2nd attempt at a vascular access (81% fistula, 17% graft), 35 patients had a 3rd access (83% fistula, 17% graft) and 5 patients had a 4th vascular access (all fistula). 482 patients (45%) required at least one intervention to assist in maintaining patency, an angioplasty being the commonest intervention (418/482, 87%). The intervention-free survival of the vascular accesses was also higher for fistula (4.4 years) compared to grafts (0.58 years).

Conclusions: A system of active vascular access surveillance results in a high access survival rate despite the increasing vascular comorbidity burden in the hemodialysis population.

Who Is Eligible for a Fistula? A Survey of Vascular Surgeons Andra Nica,[1] Charmaine E. Lok,[2] Timmy C. Lee,[3] Jeremy R. Harris,[1] Michele H. Mokrzycki,[4] Ivan D. Maya,[5] Miguel A. Vazquez,[6] Louise M. Moist.[1] *[1]London Health Sciences Center -Victoria Hospital, London, ON, Canada; [2]University of Toronto, ON, Canada; [3]University of Cincinnati, OH; [4]Albert Einstein College of Medicine, NY; [5]University of Alabama, AL; [6]UT Southwestern Medical Center, TX.*

Background: The arteriovenous fistula (AVF) is the recommended vascular access (VA). Currently there are no criteria to determine which patients are eligible for an AVF.

Methods: We conducted an international survey of VA surgeons to assess the patient, vessel and process considered to decide the type of VA created, as well as contraindications and barriers to VA.

Results: The 131 responses had marked variability in the pre-operative assessment of patients. We found variability in the minimum vein diameter that surgeons consider for AVF creation. In general, surgeons accept a smaller cephalic vein, but require a larger basilic vein for a basilic vein transposition. The use of venous duplex ultrasound mapping is done in 70-90% of patients regardless of age, gender or co-morbidities. There was significant variability in its influence on the final VA decision.

Patient co-morbidities were the biggest deterrent for fistula creation, while a history of one failed VA increased the use of grafts rather than AVFs.

Absolute contraindications to a permanent VA were patient life expectancy less than 1 year, left ventricular ejection fraction (LVEF) <15%, and dementia. No absolute contraindications were indicated by 40% of surgeons. Figure 1 shows perceived barriers to the creation and use of an AVF.

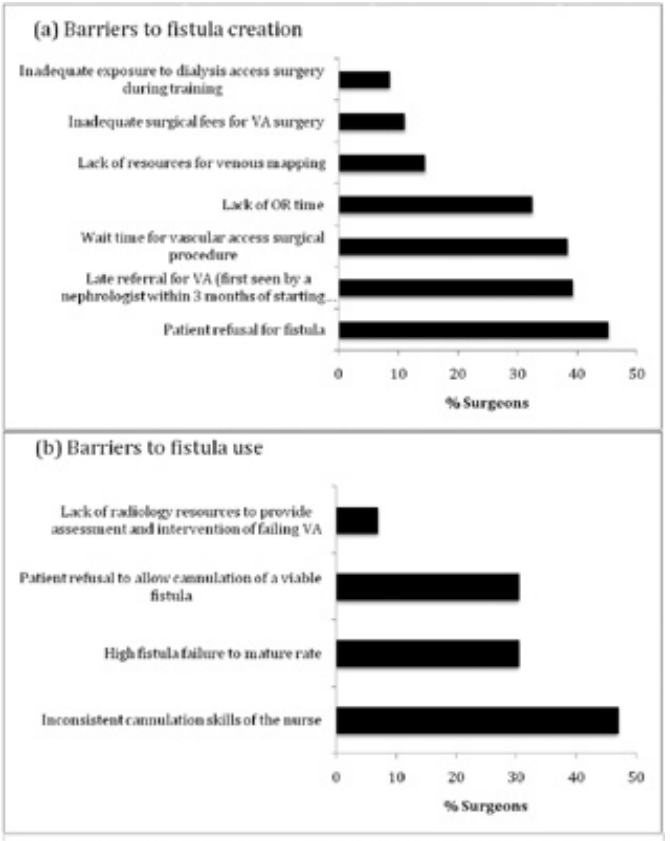

Figure 1. (a) Perceived barriers to establishing a mature AVF. (b). Perceived barriers to use of a created AVF

Conclusions: This study demonstrates great variability in the pre-operative assessment of patients, and in the criteria used to determine which type of VA a patient receives. Establishing guidelines for VA access eligibility is an important future step in optimizing patient care.

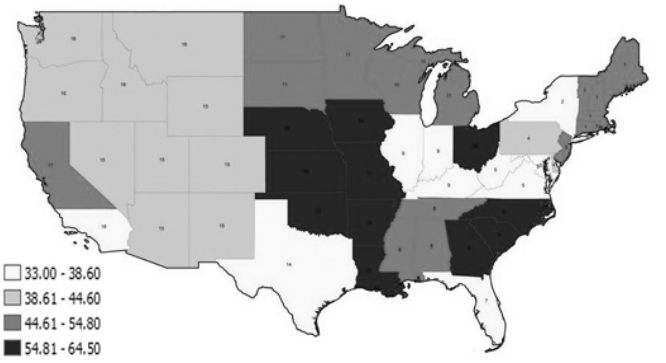
SA-PO2900

Surgical Specialist Practice Pattern Variation in AVF Placement across ESRD Networks for Late Stage CKD and ESRD Medicare Patients Edwin D. Huff, Sumit Mohan, William M. McClellan, The FFBI Data Committee. *Fistula First Breakthrough Initiative.*

Background: Given variation in practice patterns in many areas of medical care we inquired into the possible existence of similar variation among specialists treating ESRD patients. If specialists of fistula placements can be distinguished within ESRD Networks, it may be possible to increase referrals for such placements and increase fistula placement rates.

Methods: We reviewed over 600,000 part B Medicare claims for late stage CKD and ESRD patients who had hemodialysis access placements and/or access related diagnostic, maintenance or revision procedures during 2009.

Results: The variation in the ratio of surgeon AVF placement procedures over all procedures done by surgeons is over 2.5, from 13.4% to 34.1%. Which physician specialists are doing more AVF placements than others? General surgeons do 46% of all AVFs, followed by vascular surgeons, who do 38%. NW variation revealed rates from 33% to 64% done by general surgeons (See display), and rates from 20% to 54% done by vascular surgeons across regions. What variation exists in the availability of surgical specialists who perform permanent access placements across ESRD Networks? The presence of Ambulatory surgeons and Physician Assistants doing AVF procedures varies considerably with more of these specialties active in rural western regions.



Conclusions: What surgical specialists do varies considerably across the 18 ESRD Networks. Practice patterns and concentration within a practice vary over two fold within the same surgical specialty depending on regional distinctions.

Arteriovenous Fistula for the 80 Years and Older Patients on Hemodialysis: Is it Worth It? Annie-Claire Nadeau-Fredette, Remi Goupil, Bernard Montreuil, Annie Carignan, Martine Leblanc. *Hôpital Maisonneuve-Rosemont, Université de Montréal.*

Background: Over the last years, the proportion of patients older than 80 years with end-stage renal disease has been constantly growing. Arteriovenous fistula (AVF) is known as the best vascular access in hemodialysis (HD) population but the evidence for its added value is lacking for older patients. We evaluated patients aged 80 years and older (>80 yo), in whom a new AVF had been installed and compared their outcome to a group of HD patients between 50 and 60 years.

Methods: For both groups, we identified every new vascular access (AVF and central venous catheter [CVC]) created or installed between June 2005 and June 2008. We collected demographic and clinical data as well as radiological and surgical interventions from June 2005 to April 2010. We calculated primary failure rates (AVF never used after 6 months from creation), primary patency (intervention-free survival) and secondary patency (survival until definitive failure) durations for every new AVF.

Results: In our study, 55 and 57 patients had a new vascular access (AVF or CVC) in the 50 to 60 yo and > 80 yo groups respectively. Among these, 41 and 26 were new AVF in the younger and older groups. As recognized in the literature, primary failure was significantly more frequent in the older group than in the younger group (40% vs 17%, p =0.0449). When excluding primary failure, the primary patency was not significantly different in both groups (median 8 vs 16 months, p=0.32). However, the secondary patency was significantly shorter for the older group (p=0.04). During the 58 months of observation, the mortality rate was 24% in the 50 to 60 yo group while it was 54% for the > 80 yo patients. Among the younger group, the presence of an AVF was associated with a significant lower rate of mortality (12% vs 43% p=0.008) but not in the older group (46% vs 60%, p=0.28).

Conclusions: In conclusion, knowing the advantages of AVFs in the HD population and keeping in mind the similar primary patency duration shown here between the older and younger groups, patients of 80 yo should probably be considered just as younger patients for AVF creation for hemodialysis.

SA-PO2902

Hemodialysis Patients' Preference for Thigh Grafts – A Cross-Sectional Survey Zulqarnain Abro,[1] Sunanda J. Ram,[1] Neville R. Dossabhoy.[1,2] *[1]Nephrology, LSUHSC, Shreveport, LA; [2]Nephrology, VA Medical Center, Shreveport, LA.*

Background: Recent studies have shown that survival and complication rates of thigh grafts are similar to or better than those of arm grafts and fistulas. However, there is little information in the literature regarding patients' preference for thigh grafts.

Methods: This IRB-approved cross-sectional survey was conducted on patients currently on hemodialysis (n=159), who were queried regarding their preference for access location (arm access *vs.* thigh graft) and details of their dialysis access history. Data on age, race, gender and educational level was collected. Data is presented as means or percentages and analyzed using unpaired t test or chi square test. Significance set at P< 0.05.

Results: 93% were African American, 52% were female, 94% had been on dialysis ≥1 year. Most patients (79%) had completed high school or higher education. Most patients' current access was arm fistula (54%), followed by catheter (30%) and arm graft (13%). Only 3% had thigh grafts currently; 5.7% had previously had thigh grafts. Overall, 90% patients preferred arm accesses, but 10% said they would go for a thigh graft if there was no arm site available. The patients' preference for access location was not influenced by their level of education, nor by a prior history of placement of arm access. Patients' age, gender, particular dialysis unit and dialysis vintage did not seem to influence patient preference.

Those patients with a current (3.1%) or prior thigh graft (5.7%) were more likely to prefer a thigh graft for their next access, when compared to those without (P<0.05). However, even in this subset, the majority still preferred arm access (approximately 60% to 40%).

Conclusions: The likelihood of preference for placement of a thigh graft is increased by patients having a current or prior thigh graft - apparently influenced by possibly favorable

experience with thigh grafts. Other demographic factors and dialysis history seemed not to influence patient preference. As thigh grafts are a better option than tunneled dialysis catheters in patients who have exhausted all arm access sites, more efforts at educating patients on their benefits in this setting are warranted.

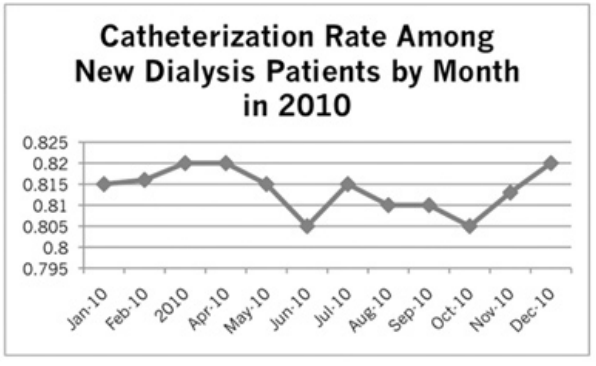
SA-PO2903

Contemporary Assessment of Incident Dialysis Patients Starting Dialysis with Catheters through 2010 Vincent Mor,[1] Franklin W. Maddux,[2] Mahesh Krishnan.[3] *[1]Brown Center for Gerontology & Health Care Research; [2]Fresenius Medical Care; [3]DaVita, Denver, CO.*

Background: The Performance Excellence and Accountability in Kidney Care (PEAK) initiative is a program sponsored by Kidney Care Partners. Its goal is to reduce first year patient mortality by 20% from 2007 to 2012. Since catheterization at dialysis initiated is associated with infections, we examined changes in incident patient vascular access for first outpatient dialysis sessions among new ESRD patients.

Methods: In order to get the most recent data, we used the Renal Management Information System (REMIS) available under a Data Use Agreement from CMS through December 2010. Beginning dates of entry of patients (from Medical Evidence form 2728), Patient demographic and clinical characteristics (2728/Patient Master file), and Date of death (From Patient Master file, Form 2746, Social Security Master Death File (SSMDF)) were obtained. Initial vascular access type was obtained through December 2010 from the completed 2728 forms for all new entrants initiating dialysis.

Results: The percentage of patients dialyzing with catheters as their primary access on first date of dialysis is recorded below.



Conclusions: Through 2010, over 80% of incident patients were documented to dialyze via a catheter on their first dialysis session. This was in spite of significant improvements in prevalent catheter rates as a result of efforts such as the Fistula First Breakthrough Initiative. While some of these patients may be dialyzing with a catheter as a temporary bridge access while a permanent access matures, their risks of infectious complications are directly correlated to catheter days. These data suggest that additional effort is needed to improve incident vascular access placement with sufficient time for maturation as a means to reduce a measure of incident patient risk.

SA-PO2904

Differences in Vascular Access Use in Incident U.S. Hemodialysis Patients – Ethnic Disparities in the Optimal Delivery of Timely Nephrology Care Maria Cristina Arce, Aya Alice Mitani, Benjamin A. Goldstein, Wolfgang C. Winkelmayer. *Division of Nephrology, Stanford University, Palo Alto, CA.*

Background: Hispanics are the largest and fastest-growing minority in the U.S. and comprised 16.3% of the US population in 2010. Hispanics are at double the risk of end-stage renal disease (ESRD) compared with non-Hispanics. Numerous studies have demonstrated the poor access to health care and the low quality of the care received among Hispanic individuals; yet, relatively little is known about the preparation of Hispanic patients with progressive CKD for dialysis. We used a contemporary national dataset to investigate any differences by Hispanic ethnicity in the rate of incident arteriovenous access.

Methods: We used data from the Medical Evidence Report form CMS-2728-U3 (version 06/04) for the ascertainment of all patient characteristics and outcomes. All adult patients who initiated hemodialysis (HD) between 7/1/2005 and 12/31/08 were evaluated. Incident arteriovenous vascular access use was considered present if either an arteriovenous fistula (AVF) or graft (AVG) was noted. We used a log binomial model with state as a random effect to estimate crude and adjusted prevalence ratios (PR).

Results: Among 321,996 U.S. patients initiating HD, 13.1% were Hispanic. Fewer Hispanics than non-Hispanics received > 6 months of pre-dialysis nephrology care (40.1% vs. 45.5%). Use of incident AVF/AVG was reported in 14.5% of Hispanic and 17.6% in non-Hispanic patients. The unadjusted PR was 0.82 (95% CI: 0.80-0.84) indicating that Hispanics were 18% less likely to use AVF/AVG for their first HD session. Adjustment for age, gender, race, BMI, comorbidities, enrollment to Medicaid, and unemployment status attenuated the PR to 0.87 (95% CI: 0.85-0.90). After further adjustment for predialysis nephrology care, the PR was further attenuated to 0.95 (95% CI: 0.92-0.97).

Conclusions: Hispanics are less likely to use arteriovenous vascular access during the initiation of hemodialysis. While differences in clinical and socioeconomic characteristics explained some of the difference, access to adequate predialysis nephrology care explained more than half of the underuse of these more desirable access options.

SA-PO2905

Effect of Interventions in Hemodialysis Outcomes with Clinical Coordinated Care Model in Renal Therapy Service Colombia Network Angela S. Rivera. *Medical Director, Baxter, Bogota, Cundinamarca, Colombia.*

Background: Renal Therapy services (RTS) is a network of renal units in Colombia with national coverage in 49 renal unitswith a Clinical Coordinated Care Model focused on clinical quality assurance process (standardized clinical protocols, ongoing education and training), internal national and regional clinical audits for protocol compliance, disease management (anemia, hypertension, diabetes, nutrition, mineral & bone disorder, hepatitis B vaccination and Dialysis management including in center hemodialysis with single use dialyzers) and quality standards adherence monitored by nephrologists and nurses

Methods: A retrospective analysis of hemodialysis prevalent patients older than 18 years was performed from 2006 to 2010. There were analyzed trend of achievement of standards: Kt/V sp, hemoglobin, vascular access, adverse patient's occurrences (including clotted dialyzer rate) and outcomes as mortality rate. The data collection was made from clinical record.

The interventions implemented were:

On-site nephrologists

Monthly comprehensive evaluation by nephrologists

Dedicated and trained professional nurses to hemodialysis

Attention by nutrition, psychology and social work according to risk

Intensive and continuing education program in vascular access care for nurses

Strengthening quality process and define key performance indicators of care vascular access including monthly reports

Results: 23058 HD patients were attended. Mean age was 59.9 years, 38,5% were female and 34,95% were diabetic. Annual mortality rate decreased from 15.18% to 12.67%

Hemodialysis Standards Achievement

Standard (proportion of patients)	2006	2007	2008	2009	2010
Hb>=11gr%	58.7	52.8	52.8	74.4	75.5
Sp Kt/v >=1.2	79.8	80.2	84.2	88.8	91.4
Proportion Native AVF %	53	66	70	73.9	75
Adverse patient's occurrences (rate per 1000 sessions)	3.89	2.38	1.93	1.4	1.14
Clotted dialyzer (rate per 1000 sessions)	1.37	1.02	0.63	0.47	0.38

Standards Achievement Trend

Conclusions: The comprehensive model of RTS implemented in Colombia has resulted in consistently improvement of achievement of dialysis standards and a trend of reduction of mortality rate during 5 years of implementation

SA-PO2906

Can a Nephrology Service Protect the Veins of Hospitalized Patients? Rita L. McGill, Jessica G. Lucas, Tomoki Tsukahara, Richard J. Marcus. *Division of Nephrology, West Penn Allegheny Health System, Pittsburgh, PA.*

Background: Patients with CKD should have no PICC lines or IV lines in their non-dominant arms. A prior survey of vein protection practices in our hospital suggested potential for improvement. Effects of a year-long educational initiative to improve compliance by increasing Nephrologist awareness of these guidelines were assessed, compared to prior results.

Methods: Estimated GFR (eGFR) was assessed on all hospital patients on a single day. Patients with eGFR <60 were examined for the locations of all intravenous devices and limb protection bracelets. Device rates were compared from before (2010) and after (2011) the initiative.

Results: For 415/420 patients, eGFR could be determined; 107 (26%) had eGFR<60. 41 had eGFR between 45-59, 29 had eGFR 30-44, and 37 had eGFR<30, of whom 15/37 were dialyzing. CKD rates differed widely within the hospital, present in more than 50% of patients in medical and thoracic ICU's and stepdown units, but <10% in Neurological, Neurosurgical, and Orthopedic areas. Med-Surg, Cardiology, and Oncology had CKD rates of 20-40%.

Limb protection bracelets were found on 19 patients, which represented a 9% improvement in the protection rate. 53% of dialysis patients had bracelets, and 10-12% of all other CKD groups. One PICC line and one peripheral IV were found in bracelet-protected arms. Among the 88/107 patients without protection bracelets, 86 had some IV device, of which 5 were central lines.

Unprotected CKD Patients (N=88)

	2010	2011
non-dominant PICC	12%	13%
dominant PICC	18%	16%
non-dominant IV	40%	41%
dominant IV	28%	38%

Conclusions: Raising awareness of vein protection among nephrologists resulted in a modest increase in the placement of limb bracelets, particularly among patients already on dialysis, but did not reduce the rate of PICC placement or prevent invasion of non-dominant arms in patients with CKD stages 3-5. Our results suggest that other factors may influence choice and placement of vascular access devices, which are now virtually universal in inpatients. Effective measures to protect veins in CKD must involve multiple stakeholders in the hospital community.

SA-PO2907

Fistula First Breakthrough Initiative (FFBI): Lessons about AVF Prevalence Goals Andrew D. Howard,[1,4] Robin S. Howard,[2] Stuart Goldstein,[4] Klemens B. Meyer.[3,4] *[1]Metropolitan Nephrology Asso, Alexandria, VA; [2]Clinical Investigation, Walter Reed Army Medical Center, Washington, DC; [3]Tufts Medical Center, Boston, MA; [4]Forum of ESRD Networks, Richmond, VA.*

Background: FFBI is a successful quality improvement collaboration between the Centers for Medicare & Medicaid Services (CMS) and ESRD Networks (NW). In 2005, CMS set a 2009 prevalent national arteriovenous fistula (pAVF) goal of 66%. 13/18 Networks failed to meet their individual 2009 pAVF goals. The Forum of ESRD NW analyzed these outcomes and proposed alternative approaches to goal-setting.

Methods: In 2006, CMS defined the Annual Improvement Target for each NW as (66%-NW's March pAVF rate) x 20%; with a maximum rate 4%, minimum 1%. We proposed a regression model based on 2004-09 data, relating pAVF changes to an annual average of each NW's pAVF rate, and compared model predictions to actual 2010 and 2011 pAVF changes for each of the 18 NW. Differences between achieved pAVF rates and model predictions vs CMS targets were compared using the Wilcoxon signed ranks test.

Results: The 2009 likelihood of failure was associated with pAVF rate. The CMS formula favored NW with pAVF ≥50% ($p<0.001$,Fisher's exact test): 12 NW with March 2008 pAVF rates <50% were unable to meet goal, and the 5 NW with pAVF rates >50% met their goals. The CMS formula assumes linear improvement, but the data suggest non-linear pAVF change. For 2010-11, the non-linear model more accurately predicted 26 of 36 pAVF rates (72%) than did the CMS formula ($p<0.001$, Wilcoxon signed ranks test).

Conclusions: CMS goals are based on March data only and do not reflect NW differences in prevalent and incident AVF rates, and in the number, demographics and characteristics of patients served. We suggest a more robust methodology using all data. Vascular access may become the next measure in the CMS Quality Incentive Program, and can be expected to incorporate goals for chronic venous catheters and pAVF rates for both facilities and NWs. We propose an adaptive approach to goal-setting, similar to that described by the FDA with reference to clinical trials, which includes prospectively planned opportunities for modification of one or more specified goals based on periodic analysis of data.

SA-PO2908

Reasons for Unavailability of AV Fistula at the Initiation of Hemodialysis in Pakistan Syed Rizwan Bokhari, Hafiz I. Ahmad. *Department of Nephrology, Allama Iqbal Medical College/Jinnah Hospital, Lahore, Pakistan.*

Background: Chronic kidney disease (CKD) is a challenging condition in the developing countries such as Pakistan. In our set up a great majority of patients presenting with CKD does not have an arteriovenous fistula (AVF) at the time of initiation of dialysis.

Methods: In this study, we investigated the reasons for unavailability of an AVF. One hundred consecutive CKD patients presenting for chronic hemodialysis through outpatients and emergency department during a period of three months (March to May, 2011) were included in this study. Patients were interviewed according to a standardized questionnaire.

Results: The demographic characteristics revealed that 52 were males (52%), with mean age 34.2 years. None of the patients had an AVF at the time of initiation of hemodialysis. 36% had received the advice to get AVF but refused the surgery. 31% were not aware of their pre-existing renal disease. Although 17% had prior knowledge of their kidney disease they were not referred to a nephrologist or a surgeon. 8% did not have the availability of surgeons trained in vascular access creation. 7% mentioned poverty/lack of resources. 6% had unsuccessful AVF surgery. Only 2% presented with presumed ARF. They received dialysis through temporary catheter and did not get AVF for 3 months in hope of recovery.

Conclusions: The two most frequent reasons for unavailability of AVF were the refusal to get permanent vascular access and the presence of advanced CKD (stage 5) without having a prior knowledge of renal disease. Both are modifiable risk factors and highlight the issue of lack of public awareness and health education and underscore the importance of robust efforts on part of medical community and health authorities to educate the masses about kidney diseases.

SA-PO2909

Variability in Vascular Access Management for Canadian Home Hemodialysis Patients Undergoing Intensive Hemodialysis Deborah Lynn Zimmerman,[1] Robert P. Pauly,[2] Paul Komenda.[3] *[1]Medicine, University of Ottawa, ON, Canada; [2]Medicine, University of Alberta, Edmonton, AB, Canada; [3]Medicine, University of Manitoba, Winnipeg, MB, Canada.*

Background: Despite growing interest in intensive hemodialysis (HD) (more frequent and/or longer), there is little published information on how to establish and maintain an intensive HD program. The purpose of this study was to survey Canadian nephrologists responsible for intensive HD to describe practice patterns.

Methods: Survey development was completed with the assistance of physician and allied health experts in intensive home HD. The survey underwent several iterations based on reviews of the expert panel prior to a face-to-face meeting with the physician experts before final instrument changes were made. The survey was completed on line. This abstract summarizes vascular access practice patterns.

Results: Of the 19 physicians contacted, 17 participated in survey development and provided program information. The preferred vascular access is the AVF in 14/16 programs. Lack of an AVF (6/16) might delay training but would not prevent training for any intensive HD program. The majority of programs are using the buttonhole technique for AVF needling (8, 100% of patients; 3, 81-99%; 4, 61-80%; 1, 21-40%; 1, 1-20%). One set of buttonholes is usually developed during training (12/17) but most programs have had to establish new buttonholes post training (14/16). Steel needles are used in 14/16 programs; 2/16 programs use angiocatheters. Routine monitoring of access flow is not done by the majority of programs. For patients on nocturnal HD, the majority of patients with an AVF or AVG use single needle HD in 3 and 5 programs respectively. For patients with CVCs, 5 programs do not have patients use any type of safety 'connectology'; 6 use lockboxes and 11 are using devices like the TEGO. Locking solutions were heparin and citrate for 6 and 11 programs respectively.

Conclusions: There is substantial variability among vascular access type, cannulation approaches, and utilization of access safety devices in Canadian home HD programs. Such variability may, in part, explain perceived differences in access complication rates, but further prospective study is necessary.

SA-PO2910

Early Versus Late Arteriovenous Fistula Placement and Use in the First Year after an Acute Inpatient Start of Chronic Hemodialysis Stacy L. Andersen,[1] Yue-Fang Chang,[3] Patricia A. Seddon,[1] Susan C. Martin,[2] Kevin Ho.[1] *[1]Renal Electrolyte Division, University of Pittsburgh Medical Center, PA; [2]Donald D. Wolff, Jr. Center for Quality Improvement and Innovation, University of Pittsburgh Medical Center, PA; [3]University of Pittsburgh, PA.*

Background: Tunneled dialysis catheter (TDC) conversion to an AV fistula in incident hemodialysis (HD) is associated with a 30+% decrease in first-year mortality risk. But early AV fistula or graft (AVF/G) placement may not necessarily lead to successful use.

Methods: We studied if early AVF/G placement in adult incident HD inpatients is associated with less TDC use in the first 365 days (d) of outpatient HD. 84 such patients were discharged over 26 months(m) to 8 clinics affiliated with our academic hospital and transplant center. 30 had Early AVF/G, placed ≤90d after inpatient HD began; and 40 had Late AVF/G, placed >90d. 14 patients with <90d HD were excluded. To gauge AVF/G placement and function, we compared outpatient mean HD_{TDC} (HD_{TDC} = total HD treatments via TDC/total HD treatments) at 3, 6, and 12m for Early vs. Late AVF/G.

Results: 46% of patients (mean age 55 years) had diabetes, 36% were female; 16% had PD just before HD, and 19% had a failing renal allograft. 26% had other non-renal transplants. For 89% of patients, HD began via TDC, 10d (median) before hospital discharge. Those who eventually had an AVF/G placed took 101d (median) to do so. Of 59 non-ESRD patients, only 3 became dialysis-independent by 90d (5.1%); not one had prior CKD. Early AVF/G resulted in a mean HD_{TDC} = 57% from 3 to 6 m (n=29), compared with a HD_{TDC} = 91% for Late AVF/G (n=38) ($p=0.0004$). From 6 to 12 m, the HD_{TDC} for Early AVF/G was 33% (n=28) versus 74% for Late AVF/G (n=33) ($p=0.0004$). Early AVF/G is associated with progressively less TDC use. However, we were not able to correlate differences between Early and Late AVF/G HD_{TDC} with differences in hospital days or mortality.

Conclusions: Early AVF/G placement even in incident HD inpatients is associated with earlier AVF/G function and less TDC use in the first year of HD, providing a basis for inpatient vascular access planning.

SA-PO2911

Central Venous Catheter (CVC) Incidence at Hemodialysis Initiation: Is It the Right Metric for Provider Quality of Care? Karthik K. Tennankore, Steven D. Soroka, Bryce A. Kiberd. *Medicine, Dalhousie University, Halifax, NS, Canada.*

Background: High CVC rates for incident dialysis patients may indicate indicate poor quality of provider care. Nurse lead multi-disciplinary kidney clinics might reduce CVC starts.

Methods: We studied consecutive incident ESRD patients (hemo, PD and pre-emptive transplantation) over 36 months at a single center. Patients were excluded if their first presentation was to hospital with AKI.

Results: There are 3 nurse practitioners (NP) and 9 nephrologists (NEPH) involved with CKD multi-disciplinary clinic patients. NPs were less likely to start hemopatients

with a CVC (51% [20/39]) compared to NEPHs (65% [104/160]). However NPs were more likely (p=0.004) to see patients followed for greater than 2 years (80%) compared to physicians (62%) and 35 of the 36 CKD patients referred late (<0.5 year) were seen only by NEPHs. In a logistic model, the only predictor of CVC start was time of referral, not provider type. Patients referred <0.5 years were 8.3 (OR, 95% CI 3.1-23) more likely to start with a CVC.

Figure 1 shows the difference in CVC vs fistula rates considering hemodialysis alone. Rates among the 3 NPs differed (NP1 had highest and NP2 the lowest CVC rate) whereas the rates for the 2 selected NEPHs were similar and high. However figure 2 shows that when PD starts and pre-emptive transplants are included, all NPs were equivalent but the 2 physicians differed. NP1 and NEPH 8 had high pre-emptive transplant and peritoneal dialysis rates but only 40% of their starts were with a CVC when considering all patients.

Figure 1

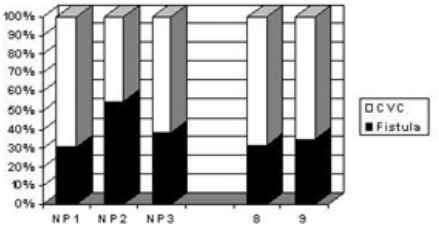

Figure 2

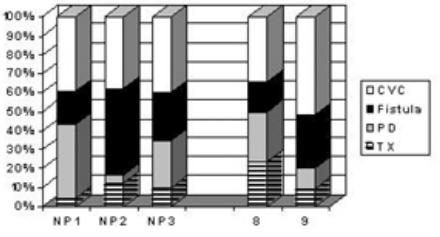

Conclusions: Since pre-emptive transplant and PD is a priority for some providers, CVC rates for incident hemodialysis patients may not truly reflect quality of provider care. After taking into account pre-dialysis provider exposure time, there is no difference in CVC rates for NPs versus NEPH care.

SA-PO2912

Reducing Catheter Prevalence in a Dialysis Population by Using Early Intervention with a Multi-Disciplinary Vascular Access Team Vandana Niyyar, Jack Work, Jyothishree R. Pinnaka, Pankaj Manocha, James L. Bailey. *Nephrology/Internal Medicine, Emory University, Atlanta, GA.*

Background: Strategies to decrease central venous catheter (CVC) prevalence are required to minimize the complications associated with vascular access. Supported by an Emory University FAME grant, we implemented an aggressive approach to decrease the CVC prevalence in an inner-city Emory dialysis unit, by using a multidisciplinary vascular access team (VAT) including a nephrologist, an interventional nephrologist, a vascular surgeon and an access coordinator.

Methods: Of the 104 patients dialyzing at the start of the protocol, 42 patients had a CVC as their only access. Weekly access rounds were conducted by the interventional nephrologist and the access coordinator. A detailed vascular access history was obtained on all CVC-dependent patients, including venous mapping, as well as location and dates of prior accesses. This information was recorded in a catheter tracking spreadsheet and was used in monthly vascular access rounds with the entire team, which formulated long term plans for proposed future accesses. Every attempt was made to ensure placement of arteriovenous fistula (AVF). In those patients in whom an AVF was not possible due to poor vasculature, partial success was achieved by placing an arteriovenous graft (AVG).

Results: During the 9 month follow up (104 total patients, 42 CVC's); 11 were converted to functional AVF (success), 10 were converted to functional AVG (partial success), 5 patients have both a catheter and a permanent access in the process of maturation, and 9 are currently not candidates (comorbid conditions, illegal immigrants and patient refusal). There has been an attrition of 7 patients (1 died, 3 changed clinics and 3 recovered renal function). Thus the intervention was successful in decreasing CVC prevalence in this cohort from 40% to 14%.

Conclusions: Though there are multiple barriers (lack of patient education, transportation constraints resulting in missed appointments, failed access surgeries, multiple comorbidities), an aggressive, multidisciplinary approach is successful in decreasing CVC prevalence in an inner-city dialysis population.

Funding: Private Foundation Support

SA-PO2913

Nephrologist Care for 12 Months or More Increases Hemodialysis Initiation with Permanent Vascular Access Daijo Inaguma,[1] Masato Ikeda,[2] Nobuhiko Joki,[2] Takashi Shigematsu.[2] *[1]Nephrology, Nagoya Daini Red Cross Hospital, Nagoya, Aichi, Japan; [2]Nephrology, Study Group for Assessing Initiation of Renal Replacement Therapy, Tokyo, Japan.*

Background: The objective of this study was to evaluate the effect of early referral (ER) to nephrologists on the type of vascular access (VA) . In patients who have been followed by nephrologists for less than 3 months, management before the initiation of hemodialysis(HD) is often insufficient and urgent initiation of HD is often necessary; therefore, patients in this study were limited to those who had been followed for at least 3 months by nephrologists.

Methods: 940 patients at 9 institutions were enrolled in the study. The study was a retrospective observational study. We defined the ER group as patients followed up by nephrologists for at least 12 months, the late referral (LR) group as followed between 3 and 12 months, and the type of VA available was compared between the groups.

Results: ER was found to be significantly associated with the availability of a permanent VA at the time of initiation of HD (OR, 1.705; p=0.001). A multivariate analysis also revealed ER to be significantly associated with the availability of a permanent VA.

Logistic regression analysis of initiation of hemodialysis with permanent VA

Variables	95%CI	OR	p value
Crude			
ER	1.244-2.337	1.705	0.001
Model 1			
ER	1.241-2.354	1.709	0.001
Age (/1year)	0.980-1.001	0.991	0.084
Male gender	0.822-1.504	1.112	0.491
Model 2			
ER	1.058-2.153	1.509	0.023
Age (/1year)	0.981-1.006	0.994	0.303

ER early referral, GFR glomelular filtration rate, ESA erythropoiesis stimulating agent, GFR glomerular filtration rate

Conclusions: ER is advantageous for increasing the likelihood of availability of a permanent VA even after patients who had been followed up for less than 3 months by nephrologists were excluded.

SA-PO2914

Low Renal Recovery in Inpatients Starting Hemodialysis and Transitioning to Outpatient Dialysis: Prior Chronic Kidney Disease and Vascular Access Planning Stacy L. Andersen,[1] Yue-Fang Chang,[3] Patricia A. Seddon,[1] Susan C. Martin,[2] Kevin Ho.[1] *[1]Renal Electrolyte Division, University of Pittsburgh Medical Center, PA; [2]Donald D. Wolff, Jr. Center for Quality Improvement and Innovation, University of Pittsburgh Medical Center, PA; [3]University of Pittsburgh, PA.*

Background: 81% of our local incident outpatient hemodialysis (HD) actually begins in hospital, yet little is known about renal recovery and vascular access (VA) planning for incident HD inpatients who then start outpatient HD. It is difficult to know which incident HD inpatients will need chronic HD and benefit from early VA planning.

Methods: We examined renal recovery (dialysis independence by 90d), AVF/G placement, and pre-ESRD renal care in 84 adult incident HD inpatients discharged from our tertiary care and transplant center to 8 affiliated HD units over 26 months (m). Inpatients were on HD neither at hospital admission nor in the preceding 12m. We defined Early AVF/G as access placement ≤90d and Late AVF/G as >90d after inpatient HD began. We calculated the Early Access Rate (EAR=Early AVF/G patients/All AVF/G patients) for each CKD stage.

Results: Of 59 non-ESRD incident HD inpatients discharged to outpatient HD, only 3 (5.1%) had renal recovery. All 48 patients with prior CKD remained dialysis-dependent at 3m: 1 CKD1, 7 CKD3A, 14 CKD3B, 19 CKD4, 7 CKD5. 5 patients had no CKD data. Of 6 patients with no prior CKD, 2 recovered. 89% of patients began HD via a TDC. Those without prior AVF/G who got one had it after 101d (median). 79% of CKD4 patients had prior renal care (mean=254d) with EAR=53%; 86% of CKD5 had renal care (mean=286d) with EAR=33%. 43% of CKD3B and 29% of CKD3A patients had renal care (mean=274d and 291d) with EAR=33% and 29%. For 15 ESRD patients with a failing renal graft, EAR=57%; and for 10 PD patients, EAR=50%. 95% of CKD3 patients had ≥1 and 53% ≥2 of the following: DM, age 65, AKI in the past 12m, or tacrolimus use.

Conclusions: Given these low renal recovery rates, CKD status may help to predict which incident HD inpatients will require chronic HD post-discharge and benefit from inpatient VA planning.

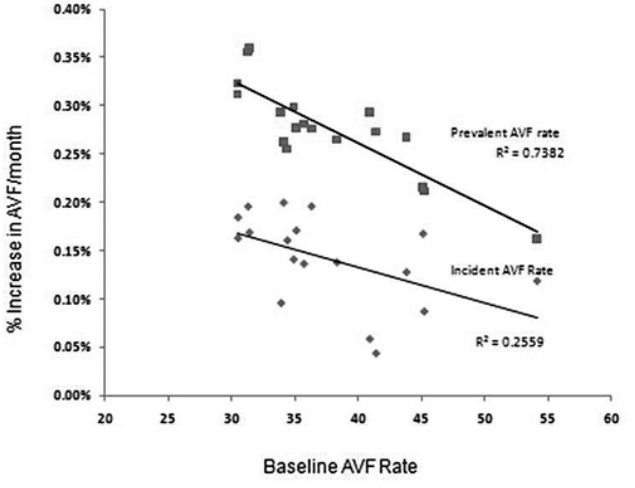
SA-PO2915

Geographic Variability in Rate of Improvement in Incident and Prevalent AVF Is Not Strongly Correlated Sumit Mohan, Edwin D. Huff, William M. McClellan, The FFBI Data Committee. *Fistula First Breakthrough Initiative.*

Background: Substantial regional variation in the rate of change of incident and prevalent AVF at the start of hemodialysis is noted in the United States. This report examines the degree to which the improvement in incident and prevalent AVF use are similar and correlate to the baseline AVF prevalence.

Methods: ESRD Networks collect a census of the vascular access currently in use of each patient within all treatment centers within their region. The date that hemodialysis for ESRD began is also recorded. We defined a patient as incident during the 91 days after the start of treatment and prevalent otherwise. Data aggregated at the network levels was used to calculate slopes of change in prevalent and incident AVF for the period from March 2007 to February 2011. The recorded AVF rates for March 2007 were taken as baseline AVF rate.

Results: Incident and prevalent mean (SD) and median rates for all Networks were 0.0578% /month (0.02), 0.0586% /month and 0.277% /month (0.05) and 0.277% /month (Figure). Network incident and prevalent AVF slopes were modestly correlated (Pearson correlation=0.2875). The Figure shows that the rates of incident and prevalent AVF improvement were inversely associated with baseline AVF rate.



Conclusions: Incident and prevalent AVF rates increased in all networks, with the largest increases in AVF prevalence occurring in networks with the lowest baseline AVF rates.

SA-PO2916

The Majority of Autogenous Dialysis Access (AVF) Is Now Constructed with Advanced Surgical Techniques Michael P. Lilly,[1,2] Janet R. Lynch,[1] Nancy Jean Carlson,[2] Edwin D. Huff.[2] *[1]Mid-Atlantic Renal Coalition (NW 5), Richmond, VA; [2]Fistula First Breakthrough Initiative (FFBI) Data Committee, IPRO ESRD Network of NY, Lake Success, NY.*

Background: Concept 5 of the FFBI Change Package urges surgeons to "utilize current techniques for AVF placement including vein transposition." While there has been a progressive increase in the proportion of AVF construction among incident and prevalent HD patients, there are few data to show the contribution of changes in surgical practice to this result.

Methods: We reviewed CY 2009 claims submitted to the Centers for Medicare and Medicaid Services (CMS) for primary hemodialysis (HD) access procedures performed in NW5. Data were grouped by self-designated CMS surgical specialty codes (General Surgery 2 [GS], Thoracic Surgery 33 [TS] & Vascular Surgery 76+77[VS]) and primary access procedures were grouped into direct AVF (36821), complex AVF (36818, 36819, 36820, 36825) and AVG (36830).

Results: In CY 2009, 4747 long-term surgical HD accesses were constructed in NW5. Self-designated VS performed 62% of cases, and GS performed nearly one third. Surgeons constructed autogenous AVFs in 64% of cases and complex AVFs accounted for 52% of all AVFs. Although direct AVF as a proportion of all access was similar among GS and VS, the ratio of complex AVF to all AVF was higher among GS.

Procedure Description	GS	VS	TS	Total #	%
# HD primary access	1538	2955	264	4757	
% HD primary access	32.3%	62.1%	5.6%		
Direct AVF	480 (32%)	920 (31%)	67 (25%)	1467	30.8%
Complex AVF	596 (39%)	886 (30%)	90 (34%)	1572	33.1%
AVG	462 (30%)	1149 (39%)	107 (41%)	1718	36.1%
Complex AVF/ all AVF	55.4%	49.1%	57.3%	51.7%	

Conclusions: Although construction of AVG remains high, these data clearly show significant adoption of advanced AVF construction techniques by surgeons in NW5 and that these approaches contributed significantly to the rate of AVF construction in NW5. Subspecialty contributions must be interpreted with caution since this is a self-designated parameter. Claims data provide no information regarding the eventual maturation or function of these accesses. Regardless, these data support the success of the "spread" methodology of the FFBI as regards surgical practice.

Funding: Other U.S. Government Support

SA-PO2917

Starting Long-Term Hemodialysis with an Arterio-Venous Fistula: The Importance of a Formal Patient-Based Chronic Kidney Disease Course Kumar Pannagasayanam Dinesh, Jose A. Morfin, Andrew I. Chin. *Division of Nephrology, University of California, Davis School of Medicine, Sacramento, CA.*

Background: Starting long-term hemodialysis (HD) with an arterio-venous fistula (AVF) is critically important, but most patients in this country start with a catheter. We analyzed data from our renal clinics to determine which factors were signficant in predicting the initiation of HD with an AVF or having an AVF placed.

Methods: CQI data of all new patient HD starts within an urban academic medical center over a 12 month period were examined. We eliminated patients who had no prior renal care or were not seen in our Nephrology clinics. Data analyzed included: demographics, insurance, med history, creatinine levels, number of clinic visits, documents of physician counselling, Chronic Kidney Disease (CKD) education course participation, access vein mapping, and placement of AV shunt. Binary Logistic Regression modeling was used to find significant associations.

Results: 110 patients were started on HD. We excluded (67%) those who had no prior renal care, were seen in other clinics, or were prevalent to HD. 37 patients (33%) were cared for in our Nephrology clinics prior to HD - these were the subjects of our analyses. 10 patients initiated HD with an AVF. In 27 patients who started with a catheter, 6 had AVF's in place but not ready to use. Binary logistic regression for *start of HD with AVF* showed that attending our CKD education course was significantly associated with that outcome (0.021, 0.001 to 0.51; p=0.018). When we analyzed for the outcome of *having any AVF placed prior to HD*, regardless of whether it was used or not, having attended the CKD education course was also favorably associated (0.02, 0.00 to 0.86; p=0.042).

Conclusions: A large percentage of patients who started long-term HD presented with no prior renal care and started HD with a catheter. Of patients who were seen in the Nephrology clinics, those who had participated in a formal CKD education course that is led by a team consisting of an experienced Renal nurse specialist, an Access nurse coordinator and a Renal dietician, were more likely to have an AVF in place at the start of HD *and* to initiate HD with an AVF.

SA-PO2918

Patients with Cardiac Failure and Female Gender Is Most Likely To Start Hemodialysis Using a Double Lumen Catheter Eirini Grapsa,[1] Anna Vourliotou,[2] Paraskevi Tseke,[1] Chrisoula Pipili,[1] Konstantinos Pantelias,[1] Edmond Deda,[1] Spiridon Moutafis,[2] Helen Tzanatos.[1] *[1]Nephrology, Aretaieion University Hospital, Athens, Greece; [2]Renal Unit, Henry Dunant Hospital, Athens, Greece.*

Background: Vascular access is the key step for a successful hemodialysis (HD) treatment. Early Nephrologists referral provide better options for a long term HD vascular access. Despite this important issue, a number of patients are without a permanent vascular access at HD initiation. The aim of the study was to assess whether age, gender and primary renal disease associate with differences in the type of first vascular access placement.

Methods: We reviewed the records of 145 patients on HD 44 female and 101 male with mean age 64±14.5 on HD for 46.9±41.2 months (range 1-252). The primary renal diseases were diabetes, (23.4%), hypertention (17.2%.) glomerulonephritis (25.7%), cardiac failure (6.9%) and others (26.8%).

Results: Double lumen catheter and arteriovenous fistula was the first vascular access in 109 (75%) and 35 patients (24) patients respectively. Graft was the first vascular access in 1 patient (0.5%). Arteriovenous fistula was the fist choice for 29.7% of the male patients and 9% of the female. Double lumen catheter was the first choice for 70.3% of the male (subclavian 50.5%, femoral 4.95% , and jugular 14.85%) and 86.4% of the female (subclavian 75%, femoral 2.3%, and jugular 9.1%) (p=0.04). Double lumen catheter was the first choice for the 79.7% of the patients older than 65 years old of age and 70.4% for the patients <65 years old (p=0.19). Double lumen catheter was the first choice for all the patients with cardiac failure as primary cause of renal disease.

Conclusions: Double lumen catheter was the first vascular access for the majority of our patients, probably due to late Nephrologists referral. Cardiac failure as primary cause of renal disease, Female gender, but not the age seems to influence this choice.

SA-PO2919

A Randomized, Controlled, Prospective, Double-Blinded Trial Investigating the Prevention of Catheter-Caused Infections Via a Coating Containing Bismuth Alexander Gontcharov,[1] Marc De Almeida,[1] Heike B. Lebsanft,[2] Birgit Doris Bader,[1] Karsten Schlieps,[1] Werner Beck,[2] Christiane M. Erley.[1] *[1]Nephrology, St. Joseph Krankenhaus (Hospital), Berlin, Germany; [2]Gambro Medical & Safety Office, Gambro Dialysatoren GmbH, Hechingen, Germany.*

Background: Hemodialysis (HD) catheter-related bacteremia is a major cause of increased morbidity and mortality of patients with acute renal failure (ARF) and chronic renal failure (CRF).

Methods: We conducted a randomized, controlled, prospective, double-blind clinical study investigating the efficacy of a new non tunnelled HD-catheter with a surface coating containing bismuth in patients in need of temporary short-term vascular access. Implanted was a standard catheter (GamCath™, SC) or a bismuth-containing surface coated catheter (GamCath™ Dolphin® Protect, BCC) both with identical standard design. After removal of the catheter due to medical indication, both arterial and venous lumina were rinsed and the fluid cultured for detection of bacterial colony-forming units (CFU). The catheter tip was placed in a tube containing sterile saline, ultrasonicated for 2 min at 35 kHz and shaken at 300 rpm for 10 min The filtrate was assayed for colonization.

Results: 88 patients received a catheter. 76 suffered from ARF, 12 from CRF (the catheter was implanted due to initiation of HD or shunt dysfunction). 58 (66%) catheters were removed due to no further need. 5 SC and 3 BCC were removed after assumed infection. The time to catheter removal for any reason was shorter for SC with a mean dwell time of 13 days vs 21 days for BCC.

Bacterial colonization over cut off 100 CFU/mL was not different, both for collected catheter tips as well as for rinsing fluids. However, 19 (50%) of collected SC were not colonized vs 23 (59%) of BCC. Mean predialytic CRP was significantly lower for BCC treatments (p<0,001) and procalcitonin values tended to be lower for BSC treatments. The last CRP value during catheter dwell time of each patient was significantly lower for BCC treatments (p<0,034).

Conclusions: Surface modification with bismuth film offers a new promising alternative to reduce HD catheter-related septicaemia in patients who need temporary non-tunnelled central venous catheters.

SA-PO2920

Prevention of Tunneled Cuffed Hemodialysis (HD) Catheter-Related Thrombosis and Bacteremia by the TEGO® Connector: A Monocentric Randomized Controlled Study Florence Bonkain,[1] Judith Racape,[1] Isabelle Goncalvez,[1] Micheline Moerman,[1] Olivier Denis,[2] Nadia Gammar,[1] Karine Gastaldello,[1] Joelle L. Nortier.[1] *[1]Nephrology, Erasme Hospital, Université Libre de Bruxelles, Brussels, Belgium; [2]Microbiology, Erasme Hospital, Université Libre de Bruxelles, Brussels, Belgium.*

Background: The TEGO® connector (ICU Medical) is a closed positive pressure system for tunneled cuffed catheter (TCC) attached on each hub flushed with 0.9% NaCl, and used during 3 consecutive HD sessions. We conducted a randomized controlled trial, approved by our Ethical Committee, comparing the incidence of TCC-related thrombosis and bacteremia in patients carrying a TEGO® connector *vs* controls receiving trisodium citrate 46.7 % as locking solution (Citralock®).

Methods: All adult HD patients of our Unit, prevalent or incident, were included, except those with a mature AV fistula and with a dysfunctional TCC (mean blood flow < 250 ml/min). The primary combined outcome was the incidence of thrombotic complications (defined by the need of a fibrinolytic agent and/or a mean blood flow < 250 ml/min during 2 consecutive HD sessions) and TCC-bloodstream infections (defined by positive blood cultures). Patients who developed TCC thrombosis or bacteremia were censured. The time period of TCC use was calculated and the incidence of complications was expressed per 1,000 TCC days.

Results: Sixty-six patients were followed during 9,194 days. Baseline characteristics were similar in both groups. The combined primary outcome was not significantly different in the TEGO® group *vs* in controls (3.15 *vs* 4.36 /1,000 TCC days, p=0.34). TCC-thrombosis rates were equivalent (2.96 *vs* 3.15 /1,000 TCC days, p=0.87). Only 6 TCC-bacteremia episodes were identified, 1 in the TEGO® group (0.19 *vs* 1.2 / 1,000 TCC days, p=0.06). The annual cost of the TEGO® procedure was significantly lower than the Citralock® one (560 *vs* 1,086 $ per patient).

Conclusions: This study confirms the non-inferiority of the TEGO® connector in preventing TCC-related complications compared to citrate locking solution. Strict nursing procedures and TCC hub manipulations can explain our low bacteremia rate. The TEGO® connector seems to be a promising and attractive device.

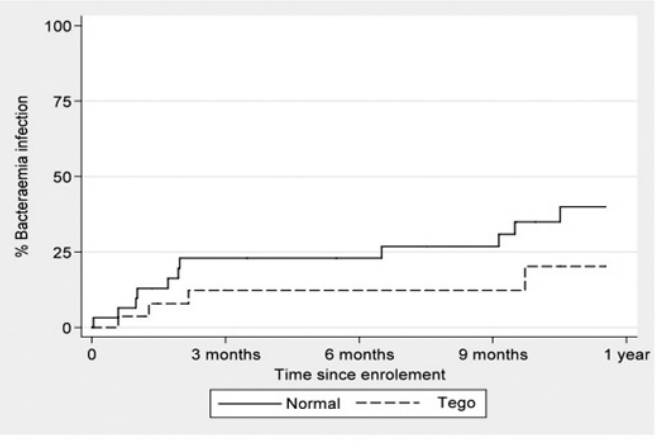
SA-PO2921

Randomised Control Trial Comparing Bacteraemia Rates in Closed Luer Lock Access Devices (TEGO) with Standard Access Devices in the Outpatient Haemodialysis Setting Frank J. O Brien, Claire Kennedy, Peter J. Conlon. *Department of Nephrology, Beaumont Hospital, Dublin, Ireland.*

Background: Catheter related bloodstream infections (CRBSI) are the second commonest cause of death in haemodialysis patients. Patients with permanent indwelling catheters have a 50% higher risk per year of developing systemic sepsis compared to patients with arteriovenous fistulae. The international rates of CRBSI's are 2.5-5 episodes per one hundred catheter days. This study hypothesizes that reduced handling of central catheters will reduce rates of CRBSI

Methods: A randomised controlled trial is being conducted from April 2010 to March 2012. This compares CRBSI rates in patients who have closed luer lock access devices (TEGO) placed at the end of their central catheters to those patients receiving current gold standard central catheter access techniques as per the current Beaumont Hospital protocol. All patients attending out patient haemodialysis units at Beaumont Hospital are eligible for inclusion in the study. This study highlights interim results at twelve months.

Results: 58 patients were recruited in the first twelve months, 27 in the TEGO group and 31 in the control group. 36 patients completed follow up at month 12. 11 episodes of CRBSI were noted in the control group, and four in the TEGO group, (p=0.159)



p=0.159

Conclusions: Preliminary twelve month follow up data on the use of closed luer lock access devices in reducing CRBSI shows a reduction in episodes of infection, but was not statistically significant. There was no difference in flow rates or thrombosis rates between the groups

SA-PO2922

TEGO® Connectors Reduce Heparin Use without Affecting Blood Flow Rate Compared to Traditional Central Venous Catheter Locks Mahesh Krishnan, Tracy Jack Mayne, Carol Farthing, Shaun S. Collard, Allen R. Nissenson. *DaVita Inc, Denver, CO.*

Background: The TEGO® Connector is a heparin-free device developed to reduce catheter-related infections and clots associated with central venous catheters (CVCs). We compared the efficacy and cost effectiveness of the TEGO Connectors and saline CVC locks to traditional heparin CVC locks, and compared both to the costs of using rt-PA.

Methods: We conducted a pre/post study comparing conversion from traditional CVC locks to TEGO Connectors in hemodialysis patients. The pre-period was defined as 90 days before, and the post-period 90 days after TEGO Connector conversion. Outcomes included monthly blood flow rate and heparin use (efficacy analysis); and cost of heparin, connectors, syringes, activase, sodium citrate, medication and equipment (cost analysis). Both CVC locks and TEGO Connector costs were compared to the cost of using rt-PA.

Results: Blood flow rate remained unchanged over the course of the evaluation period (Table). Total heparin use decreased nearly 2000 units 3 months after TEGO conversion. The 6-month cost of traditional locks + caps + heparin + syringes was $127.92 per CVC patient compared to $111.54 for TEGO Connectors. Both are significantly less than rt-PA ($1834).

Blood Flow Rate and Heparin Use (before and after conversion to TEGO Connectors)

Variable	Days Prior to Conversion			Days After Conversion to TEGO Connectors		
	90-61	60-31	30-01	01-30	31-60	61-90
# Facilities	225	230	234	234	233	232
# Patients	2,040	2,302	2,656	2,656	2,447	2,256
Blood Flow Rate (mL/min) Mean ± SD	348.3 ± 41.5	348.2 ± 42.6	346.7 ± 40.3	345.5 ± 40.7	343.1 ± 41.4	341.4 ± 41.1
Total Heparin Units / Treatment	6,177	6,782	7,798	6,691	4,931	4,240

Note: the observed periods pivot around the date the dialysis facility switched to TEGO Connectors.

Conclusions: Use of TEGO Connectors decreased heparin use without affecting blood flow rate at a lower monthly cost. Cost of both TEGO and saline CVC locks were significantly lower than use of rt-PA. TEGO Connectors are a viable and cost-effective alternative to traditional locks.

Funding: Clinical Revenue Support

SA-PO2923

Comparison of Trisodium Citrate and Heparin as Catheter Locking Solution in Hemodialysis without Anticoagulant Xiaolei Chen, Ping Fu. *Department of Nephrology, West China Hospital, Sichuan University, Chengdu, Sichuan, China.*

Background: Bleeding complications are common in hemodialysis patients, especially for those with high risk. To prevent the hemorragic events, adjustment for the anticoagulant in catheter locking solution should be considered.Because of the property of local antigulation, trisodium citrate has recently become an ideal capping solution for hemodialysis.

Methods: The efficacy of different locking solutions were prospectively explored in a randomized, controlled, single blind trial. All enrolled patients used temporary central venous catheter as dialysis access. They were prescribed no-anticoagulant hemodialysis due to hemorrage tendency. These patients were randomly assigned to three groups according to the locking solution: Group A (routine heparin,4168U/ml),Group B (low heparin, 2084U/ml),Group C (4% trisodium citrate). The incidence of bleeding, index of coagulation function and catheter patency during one observational period were evaluated. The observational period indicated the interval between two consecutive hemodialysis sessions. Prothrobin time(PT) , activated partial thromboplastin time (APTT) were determined at 0.5 hour, 2 hour and 24 hour after the catheter locking procedure.

Results: Ninety patients were enrolled and thirty in each group. There were no significant differences in patient and catheter characteristics on inclusion. Both PT and APTT prolonged distinctly at 0.5 hour and 2h after the locking in Group A ($P<0.01$), then regressd to normal at 24h. In Group B, just APTT at 0.5h prolonged significantly ($P<0.05$) and it had quickly reversed to normal at 2h. No significant changes on coagulation index were observed in Group C. During the observational period, six hemorragic cases occurred in Group A (20%), just one in Group B (3.3%) and no bleeding in Group C. The incidence is apparently higher in Group A($P<0.05$). Besides, two cases of minor catheter clotting were observed in Group B.

Conclusions: To prevent post-hemodialysis bleeding, adjustment for the concentration or type of the locking antigulant should be considerd. Due to the better outcomes of local antigulation, trisodium citrate can be advocated as a safe and less expensive alternatinve to heparin.

SA-PO2924

Peripherally Inserted Central Catheters Use in Patients with Acute and Chronic Kidney Disease: Single Center Experience Mireille El Ters,[#1] Andrew D. Rule,[#1] Amy Mahon,[#2] Bernice (Bonnie) M. Jenson,[#1] Amy W. Williams,[#1] Sanjay Misra,[#2] Robert C. Albright,[#1] Sandra J. Taler,[#1] Marie C. Hogan.[#1] *[1]Div of Nephrology, Mayo Clinic; [2]Dept of Radiology, Mayo Clinic, Rochester, MN.*

Background: Peripherally inserted central catheter(PICC) use has increased significantly due to many perceived advantages in acutely ill patients.Their potential to cause central venous thrombosis/stenosis led to efforts to limit their use in the CKD population.We implemented a new PICC line orderset in our institution in 2010 listing elevated creatinine (↑sCr) as relative contraindication for PICC placement and studied the impact of changes to this orderset before & after on physician prescribing patterns of PICCs at our center.

Methods: In a cross-sectional study, the medical records of a total of 550 patients undergoing PICC placement (equally divided before and after revised orderset implementation) were reviewed to determine sCr levels at the time of PICC request.The PICC RN is required to contact ordering physician to discuss contraindications before proceeding. Acute kidney injury (AKI) was defined as ↑sCr of 25% from baseline at the time of the PICC placement and CKD defined as ↑sCr ≥1.3mg/dL in women and ≥1.5mg/dL in men.

Results: Of 275 patients undergoing PICC placement before the orderset change, 52 met the criteria for ↑sCr (18.9%). After the revised orderset was implemented of 275 individuals 66 met the criteria for ↑sCr (26.4%). The percentage of patients with CKD in the sample prior to orderset implementation was 18/275(6.5 %)& increased to 36/275 (13.1 %). No statistically significant difference was noted between the two samples both for ↑sCr & CKD (p:0.145 and 0.09 respectively).

Conclusions: Despite efforts to increase awareness of the risks associated with PICC use in the CKD population, this venous access continues to be used frequently due to its ease and convenience. In fact we observed an increasing trend toward more CKD patients among those receiving PICC lines even after listing it as a relative contraindication.Effective processes should be developed to promote alternative venous access in our CKD population, including small bore internal jugular access, in order to preserve future venous access.

SA-PO2925

Improvements in Clinical and Operational Outcomes for a Cohort of Patients Converted from Central Venous Catheter Access Andrew Glowalla, Andrew Barba, Randy Smith, Chan Basho, Abbe Volz. *DaVita Inc, Denver, CO.*

Background: Improvements in mortality and morbidity related to the reduction of central venous catheters (CVCs) in end-stage renal disease (ESRD) patients have been reported, however, little has been described regarding improvements in surrogate biochemical outcomes and operational parameters. Given the economic incentives associated with the new ESRD bundled payment system, improvements in operational and surrogate biochemical outcomes may be an important ancillary driver to CVC reduction efforts.

Methods: We assessed operational and biochemical outcomes of patients after implementation of a CVC reduction program called Cathaway™ which significantly reduced CVC rates from 2008 to present. Data from 6 months pre and post CVC conversion were assessed in a cohort of patients who converted from CVCs between October 2008 and June 2010 (n=3235). The analysis had 2 components, (i) impact on relevant clinical parameters including albumin, Kt/V, hemoglobin (Hb), and average blood flow rate (BFR) and (ii) impact on operational dialysis parameters including heparin use, tissue plasminogen activator (tPA) use, and missed treatments. Three month averages for the cohort from months -6 to -4 were compared to months +4 to +6.

Results: Improvements were noted in most of the clinical parameters including an improvement in BFR. These clinical improvements were achieved with more efficient resource utilization, specifically heparin and tPA (Table).

Parameter	Months -6 to -4	Months +4 to +6	P-value	% Change
Albumin (mg/dL)	3.67±0.45	3.86±0.38	<0.0001	5.2%
Kt/V	1.61±0.39	1.70±0.34	<0.0001	5.6%
Hb (mg/dL)	11.63±1.08	11.59±0.87	0.10 (NS)	(0.34%)
BFR	359±41	414±51	<0.0001	15.3%
Heparin (U/tx)	11.44±6.02	4.92±2.70	<0.0001	(57.0%)
tPA (mg/tx)	0.072±0.24	0.0051±0.073	<0.0001	(92.9%)
Missed tx/month	0.92±1.72	0.85±1.66	0.10 (NS)	(7.6%)

Conclusions: We demonstrate that tangible benefits exist both in terms of patient outcomes and operational parameters with the successful conversion of patients from CVCs as a method of vascular access. These findings add to the compelling rationale for continuing to reduce the prevalence of CVC access in ESRD patients.

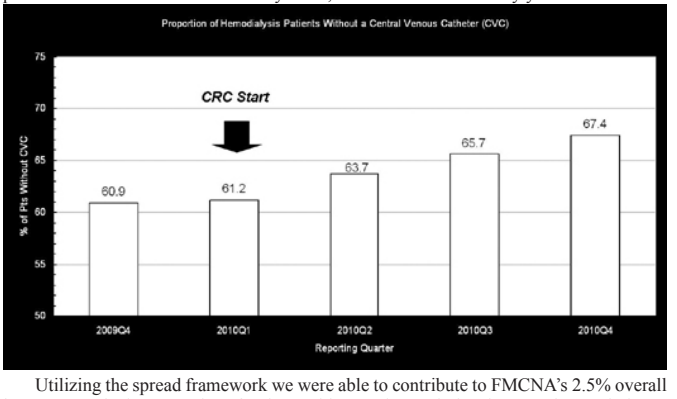
SA-PO2926

Outcomes from a Multi-Center Catheter Reduction Collaborative Program Alex J. Rosenblum, Eduardo K. Lacson, Shu-Fang Lin, Jill A. Hall, Raymond M. Hakim. *Fresenius Medical Care, North America, Waltham, MA.*

Background: In 2010, Fresenius Medical Care, North America (FMCNA) implemented a pilot Catheter Reduction Collaborative (CRC) based on the Institute for Healthcare Improvement (IHI) Framework for Spread Model to reduce prevalent hemodialysis catheter rates.

Methods: Medical Directors and their facility team from high-catheter facilities were invited to participate in the CRC. They were expected to adopt and implement a list of ten clinical and operational "best practices" and engage in six months of peer to peer learning meetings and calls. The proportion of patients dialyzing without a central venous catheter (CVC) was tracked. Overall rates of positive blood cultures are also being collected.

Results: 164 facilities volunteered to participate. The group improved percentage of patients without a catheter in 2010 by 6.2%, from 61.2% to 67.4% by year-end.



Utilizing the spread framework we were able to contribute to FMCNA's 2.5% overall improvement in the proportion of patients without catheters during the same time period. Top 5 best practices according to CRC participants included: 1) Physicians taking accountability and asserting leadership, 2) Use of a chronic kidney disease education program, 3) Selective referral to surgeons with best outcomes and timely appointments, 4) Use of vascular access manager/champion, and 5) Documented catheter removal plan. Preliminary trends from ongoing analyses show a decline in positive blood cultures.

Conclusions: Our CRC experience demonstrated that the IHI spread model with utilization of "best practices" along with ongoing facilitation and peer-to-peer sharing can effectively reduce catheter rates. Reduction in CVC may have contributed to early observations of declining rates of bloodstream infections.

SA-PO2927

Accuracy of Blood Culture Results from the Hemodialysis Circulation Based on Guidelines for Diagnosing Catheter-Related Blood Stream Infections Friederike S. Quittnat Pelletier, Mohammad Z.H. Joarder, Charmaine E. Lok. *Toronto General Hospital, Toronto, ON, Canada.*

Background: Most hemodialysis (HD) units diagnose HD catheter-related bloodstream infections (CRBSI) by obtaining blood cultures (BC) from the HD bloodline concurrent with clinical exclusion of other sources of infections.

The recently updated guidelines from the Infectious Diseases Society of America (IDSA) recommend making the diagnosis of CRBSI by cultivating the same organism from a peripheral vein and from the catheter hub meeting criteria of differential time to positivity. The IDSA criteria for CRBSI have not been validated in HD patients.

Our hypothesis is that a BC taken from a peripheral vein during HD will yield the same result as a BC taken from the dialysis circulation or the catheter hub.

We further hypothesize that obtaining peripheral vein BC will be challenging (<50%) and may limit application of IDSA guidelines.

Methods: Four adult sets of BC (from a peripheral vein, from both catheter hubs and from the dialysis line) were obtained from patients who were suspected to have a CRBSI. Data was collected on the challenges of obtaining peripheral BC.

Results: To date, 40 patients who presented with signs and symptoms of CRBSI have been enrolled in this study. Bacteremia was found in 45% of these patients and all BC consistently grew the same bacteria from all culture sites. In 55% with undetectable bacteremia, all BC were negative for bacterial growth.

Peripheral vein BC were obtained in 77.5% of the suspected CRBSI. 28.6% had > 1 attempt before successful blood flow; 10% required a second nurse to obtain the peripheral blood. 1 Patient refused peripheral blood sample drawing, and in one case the blood sample did not yield the appropriate amount for a BC set due to collapsing peripheral veins.

Conclusions: More than ¾ of HD patients had successful peripheral vein BC drawn. 100% of organisms identified in peripheral vein samples were identical to those obtained from the dialysis bloodline, suggesting that the current standard of practice of obtaining BC from the HD bloodline concurrent with clinical exclusion of any other sources of infections is a valid method of diagnosing CRBSI.

Attributed Mortality of Catheter Use in Incident Dialysis Patients: The Impact of an Acute Dialysis Start Karthik K. Tennankore, Steven D. Soroka, Bryce A. Kiberd. *Nephrology, Dalhousie University, Halifax, NS, Canada.*

Background: Central venous catheter (CVC) use as incident dialysis access is associated with mortality. However, some patients unexpectedly progress to end stage renal disease prior to reaching a GFR at which one would expect to establish alternative access. The purpose of this study was to identify the impact of this "acute start" on attributed CVC mortality.

Methods: We studied 406 incident dialysis patients from 1/2006 to 12/2009. Patients were classified as "acute start" if the MDRD eGFR was >25 ml/min/1.73 m2[/sup], ≤3 months prior to dialysis initiation and declined after an acute event (n= 48). RPGN/myeloma patients without prior GFR measurements were also included (n= 10). All remaining patients were classified as "CKD start" (n=348).

Results: 58.7, 23.6 and 17.7% of patients initiated dialysis with a CVC, fistula and peritoneal dialysis catheter, respectively. 81 patients (20%) were referred late (within 90 days of dialysis start). At 2 years, there were 103 deaths. The mortality of acute start patients was significantly higher than CKD start patients (figure 1, p<0.001). In a univariate Cox survival analysis, acute start (HR 3.44, p<0.001), CVC use (HR 1.88, p=0.004), and late referral (HR 2.52, p<0.001) were associated with mortality. Adjusting for age, gender, Charlson Comorbidity Index and albumin, only acute start remained associated with mortality (HR 2.50, 95% CI 1.57-3.99, p<0.001). Restricting the analysis to CKD start patients on hemodialysis (n = 276), CVCs were not associated with mortality (HR 0.86, 95% CI 0.49-1.53, p=0.614).

Conclusions: A significant proportion of early dialysis mortality occurs after an "acute start". Most of this mortality is related to the acute event itself, as opposed to CVC use or late referral. Dialysis registry analyses may overestimate attributed CVC mortality without considering the impact of an "acute start".

Catheter Related Infections with Sodium Citrate 4% Locks Compared to Heparin Locks in Hemodialysis Patients Calantha K. Yon, Eva Wong, Chai L. Low. *Pharmacy Services, VA San Diego Healthcare System, San Diego, CA.*

Background: This open, prospective cohort study aims to evaluate the difference in the incidence of catheter related infections (CRI) with sodium citrate 4% compared to heparin 5,000 units/ml as a catheter locking solution in hemodialysis (HD) patients. Secondary outcomes include hospitalization, mortality, and catheter patency.

Methods: The use of citrate locks were compared to a historical control using heparin locks before September 2009. Medical records of chronic HD patients with permanent catheters between the periods of July 2008 - July 2009 and September 2009 - December 2010 were reviewed. CRI incidence was calculated as the number of infections per total number of catheter days. Pertinent information on patient medical history, thrombosis, infections, hospitalization, and mortality were collected.

Results: Mean age was above 60 years, and more than 90% of the patients were male in both groups. The major causes for ESRD were diabetes and hypertension in the 2 cohorts. A total of 412 and 441 patient-months were included in the heparin and citrate groups respectively. There were 22 CRIs with heparin and 11 CRIs with citrate (p = 0.013). CRI for heparin was 1.76 infections per 1,000 catheter days compared to 0.82 infections per 1,000 catheter days in the citrate group. Hospitalization occurred in 17 of the 22 CRIs in the heparin group and 9 of 11 CRIs in the citrate group (p = 0.086). The heparin group had 41 incidents of thrombosis compared to 40 in the citrate group (p = 0.69). CRI and thrombosis led to catheter exchange or removal in 36 cases in the heparin group and 18 cases in the citrate group (p = 0.09). There was no statistical difference in 6-month mortality from CRI between the treatment groups (p = 0.27).

Conclusions: This study showed a statistically significant difference in the incidence of CRI using sodium citrate versus heparin as a locking solution. Sodium citrate is also as effective as heparin as an antithrombotic agent. Secondary outcomes were also comparable between sodium citrate and heparin. Results of this study support the use of sodium citrate as an alternative to heparin for the maintenance of catheter patency and prevention of CRI.

Hypertonic Trisodium Citrate Induces Protein Precipitation in Hemodialysis Catheters Gernot Schilcher,[1] Hubert Scharnagl,[2] Joerg H. Horina,[1] Werner Ribitsch,[1] Alexander R. Rosenkranz,[1] Tatjana Stojakovic,[2] Hans D. Polaschegg.[1] *[1]Department of Internal Medicine, Division of Nephrology and Hemodialysis, Medical University of Graz, Graz, Austria; [2]Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University of Graz, Graz, Austria.*

Background: Between haemodialysis treatments catheters are locked with a locking anticoagulant. Because of its antimicrobial properties hypertonic trisodium citrate has become popular. This solution is not only spilled when injected, but is in part exchanged against whole blood due to its high density. Plasma proteins are therefore exposed to hypertonic trisodium citrate.

Methods: In vitro, whole blood and trisodium citrate (concentrations ranging from 4.7 to 46.7%) mixtures were used to assess protein precipitation. In vivo, listed filling volumes of hemodialysis catheters locked with trisodium citrate 4% (n=10) or 46.7% (n=10) were aspirated and then analyzed for protein precipitation.

Results: During in-vitro tests with hypertonic trisodium citrate protein precipitation was observed at concentrations exceeding 12%. When catheter locks were aspirated in-vivo, precipitated protein could only be separated and analysed in catheters locked with 46.7%. The main constituent was albumin.

Literature search revealed data confirming precipitation of proteins by different salts. 'Salting out of plasma proteins by sodiumcitrate' has become a common method for serum protein purification since the 19th century. Nevertheless, none of these papers has considered its relevance with respect to clinical application in hemodialysis patients.

Conclusions: Hypertonic trisodium citrate lock solution is exchanged against whole blood even up to the highest point in the catheter. During this process plasma proteins come into contact with hypertonic citrate and subsequently precipitate. Therefore, hypertonic trisodium citrate lock solutions are potentially dangerous and may be the underlying cause for reported embolic complications in patients with central venous catheters. Based on our findings we suggest that only commercially available trisodium citrate 4 % lock solution can be used safely.

SA-PO2931

Gentamicin Catheter Locks: Trends and Markers for Development of Resistance and Clinical Outcomes in One Urban Outpatient Dialysis Center Sudhir B. Vyakaranam,[1] Heather Duncan,[1,2] Karthikeyan Meganathan,[3] Kotagal Shashi Kant.[1,2] *[1]Int Med, Div Neph & HTN, Univ Cincinnati Coll Med, Cincinnati, OH; [2]DCI, Cincinnati, OH; [3]Public Health Science, Univ Cincinnati, Cincinnati, OH.*

Background: Catheter Related Bacteremia (CRB) and associated deep infections remain the second leading cause of hospitalization and mortality for patients dialyzing with tunneled catheters (TC). Antibiotic catheter lock solutions (CLS) reliably reduce CRBs. Several studies report development of resistance to gentamicin (GR). To address these concerns we examined CLS (gent 2.7mg/mL heparin) use in one large urban dialysis facility

Methods: We identified all TC patients over a three year period. Demographics, labs, ESA use and positive blood cultures were reviewed. Unlike in some past reports, ALL inpatient and outpatient CRBs were identified.

Results: There were a total of 27 separate CRBs- below 1.2 CRB per 1000 catheter days in each period of the study. There were three "deep" infections: endocarditis (period 2) and septic arthritis and osteomyelitis (period 3). Patients with and without CRBs are compared in Table 1; Diabetes was more prevalent in the group of patients who did get a CRB.

Comparison of no CRB patients with CRB patients

measure (sd)	no CRB	CRB
% Male	61	50
% Black	91	90
% diabetic	46	75*
Age (yrs)	56.9 (14.1)	57.3 (9.0)
ESRD Vintage (yrs)	4.4 (5.8)	2.9 (4.0)
avg monthly EPO/kg	124.2 (113.1)	104.1 (86.5)
Albumin	3.7 (0.4)	3.6 (0.5)
Hemoglobin	11.4 (0.7)	10.9 (1.5)
Kt/V	1.6 (0.3)	1.5 (0.3)

Fisher's exact p<0.05

There were 9 instances of GR in the three years. Mean days of exposure to the CLS prior to GR was 611; the earliest this appeared was 211 days. In no instance did the patient who had GR require gent for treatment of an infection. No patients with GR have died as a result of infection with a GR organism, with more than 37000 catheter days in approximately 200 patients. No increasing temporal trend for GR was obvious.

Conclusions: The practice of Gent CLS in this institution has been associated with a stable, low CRB rate, and no apparent increase in GR; in contrast to the study of Landry et al (2010). Continued study and observation is warranted for this important issue.

SA-PO2932

Comparative Evaluation of Shower-Washing Technique and Aseptic Technique for Exit-Site Care of Tunneled Cuffed Venous Catheters Nami Shibahara,[1] Hiroshi Shibahara,[2] Susumu Takahashi. *[1]Hashimoto Minami Internal Medicine Clinic, Sagamihara, Kanagawa, Japan; [2]Blood Purification Center, Sagamihara Kyodo Hospital, Sagamihara, Kanagawa, Japan.*

Background: We have reported a new care method designed to prevent infection by normalizing the skin condition at the exit site of a tunneled cuffed venous catheter (TCC): the exit site is directly cleaned using a shower without the use of antiseptic. In this study, we compared the shower-washing technique with the aseptic technique for exit-site care of TCC.

Methods: The subjects were 100 hemodialysis patients who had begun to use a TCC in our institutions from January 2005 to January 2010. Fifty subjects used shower-washing technique (Group S) and 50 used the aseptic technique (Group A). The shower-washing technique in Group S involved washing the exit site of the TCC with tap water immediately after TCC insertion and at every dialysis session. Moisture could be wiped away with non-sterile gauze. No antiseptic was applied. The aseptic technique in Group A was a conventional exit-site care method using povidone-iodine. In both groups we evaluated the skin conditions of the exit-site at the time of removal of TCC and the incidence of catheter-related infections, and compared the white blood cell (WBC) count and C-reactive protein (CRP) at the time of insertion with those at the time of removal of TCC.

Results: No significant difference was observed in the skin conditions of the exit site at the time of removal of TCC. Two exit-site infections (ESIs) and two catheter-related blood stream infections (CRBSIs) occurred in Group S, and three ESIs and two CRBSIs in Group A. There was no significant difference in WBC count and CRP between the time of insertion and at removal of TCC in both groups.

Conclusions: The shower-washing technique for exit-site care of TCC is simple, effective and as safe as the aseptic technique. Future studies are needed to compare these approaches in a larger number of subjects.

SA-PO2933

Comparative Evaluation of Tensile Strength between Cuff and Catheter of Soft Cell and Another Type of Tunneled Cuffed Catheter Hiroshi Shibahara,[1] Nami Shibahara,[2] Susumu Takahashi. *[1]Blood Purification Center, Sagamihara Kyodo Hospital, Sagamihara, Kanagawa, Japan; [2]Hashimoto Minami Internal Medicine Clinic, Sagamihara, Kanagawa, Japan.*

Background: A characteristic of tunneled cuffed venous catheters (TCC) is that the cuff promotes tissue in-growth, providing a barrier against infection and anchoring the catheter. However, we have reported 16 cases of catheter malfunction of a Soft Cell (Bard Access Systems, Salt Lake City, UT, USA), due to a poor connection between the cuff and the catheter since December 2008 (*Ther Apher Dial* 2011;15:213-215). Therefore, we evaluated the tensile strength (TS) between the cuff and the catheter in Soft Cells with a similar expiration date to those associated with malfunction (Group SC-1), Soft Cells with a later expiration date (Group SC-2), and another type of TCCs (Group SP).

Methods: Group SC-1 consisted of Soft Cells with an expiration date before February 2012; Group SC-2, Soft Cells with an expiration date after March 2012; and Group SP, Split Caths (Medcomp, Harleysville, PA, USA). TS between the cuff and the catheter of 10 unused TCC in each of the three groups was measured using a Universal Testing Machine (Imada Seisakusho Co., Ltd., Aichi, Japan) at a crosshead speed of 200 mm/min and a grip distance of 30 mm.

Results: Mean TS between the cuff and the catheter was 34.0±14.7 N in Group SC-1, 67.2±13.3 N in Group SC-2, and 56.0±11.1 N in Group SP. TS in Group SC-1 was significantly lower than that in Groups SC-2 and SP ($p<0.01$, $p<0.01$), without a significant difference in TS between groups SC-2 and SP.

Conclusions: It was revealed that the connection between the cuff and the catheter was poorer in Group SC-1, which might have been one of the reasons for catheter malfunction in 16 Soft Cells we experienced. It is of great concern that TS between the cuff and the catheter of Soft Cell significantly differed according to the expiration date. Currently, TS between the cuff and the catheter of TCC is determined by each manufacturer voluntarily. In order to ensure safe use of TCCs, it is necessary to establish an international standard.

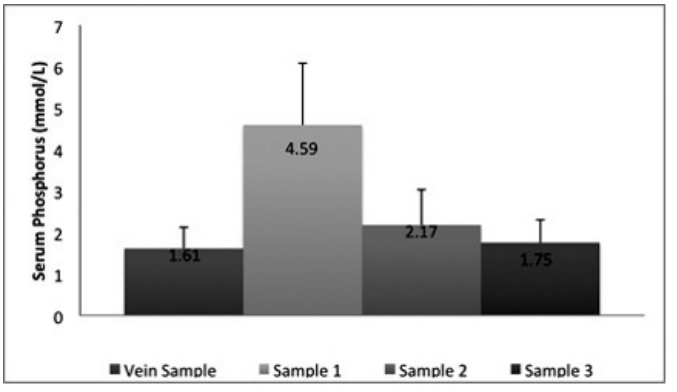
SA-PO2934

Use of Alteplase in Dialysis Catheters May Lead to Hyperphosphatemia Overtreatment Dimitrios Anestis Moutzouris, Panoraia Papadopoulou, Sotiris Mikros, Alexandra Fatourou, Fotios Makris. *Nephrology, "Mesogeios" Satellite Dialysis Unit, Palaio Faliro, Athens, Attica, Greece.*

Background: In dialysis catheters, heparin is usually used as locking solution with alteplase being administered in malfunctioning catheters. According to Clinical and Laboratory Standards Institute, when drawing blood from a vascular access device, after flushing, the first 5ml of blood or five times the dead space should be discarded. We aimed to investigate whether alteplase as locking solution can be the cause of increased serum phosphorus.

Methods: We examined serum phosphorus in 27 dialysis patients with catheters, with alteplase as locking solution. We used four blood samples: one sample was drawn from a peripheral vein before session (Vein Sample); the second sample was drawn from the arterial port after 4ml of blood was discarded (Sample 1); the third sample after 5ml was discarded (Sample 2) and the fourth after 7ml was discarded (Sample 3).

Results: The mean age of patients was 73.4 ± 11.3 years. There were significant differences regarding serum phosphorus among Vein Sample and Samples 1,2 and 3. Whereas the difference between Vein Sample and Sample 1 was anticipated (alteplase contains phosphoric acid), differences remained significant after 5ml or even 7ml of blood was discarded.



Columns represent mean serum phosphorus in the four samples (mmol/L). There were significant differences between Venous Sample and Sample 1 ($p=0.004$), Venous Sample and Sample 2 ($p<0.0001$), Venous sample and Sample 3 ($p<0.001$). Bars represent standard deviation.

Conclusions: Alteplase as locking solution may increase serum phosphorus. Even moderate increases of serum phosphorus might be due to blood contamination with alteplase. Specific guidelines should be established to address blood sampling. We recommend that at least 7ml of blood should be discarded before sampling to avoid spurious hyperphosphatemia.

SA-PO2935

Citrate (46%) Based Catheterlock Solution Reduces the Incidence of Catheter Related Sepsis in Dialysis Patients as Compared to Heparin, but Might Induce a Change in Pathogens Hans S. Brink,[1] Anniek Brink,[1] Ron M.G. Hendrix.[2] *[1]Internal Medicine, Medisch Spectrum Twente, Enschede, Netherlands; [2]Laboratorium voor Microbiologie Twente Achterhoek, Enschede, Netherlands.*

Background: Catheter related sepsis is a major cause of morbidity and mortality in haemodialysis patients. Citrate-based catheter lock solutions were reported to reduce its incidence.

Methods: We tested the effect of citrate (46%) on 7 species of pathogenic bacteria, using the Kirby-Bauer method. All tunnelled dialysis catheters used in our centre from 1-1-2000 until 7-1-2009 were reviewed. Episodes of sepsis were identified and responsible microorganisms were recorded. On 10-1-2003 citrate replaced heparin as a catheter lock solution. The incidence of sepsis before and after this switch was calculated. Sepsis free survival of the catheters was compared using Kaplan Meijer analysis.

Results: In vitro, citrate was bactericidal for Staph. aureus and S. pneumoniae. Enterococci and Gram-negative species were not affected. 438 tunnelled dialysis catheters in 330 patients were studied. Heparin was used in 175 catheters; citrate in 263 catheters. The number of catheter days per catheter in both cohorts was similar. The sepsis rate was

0.60 for heparin and 0.29 per 1000 days for citrate. The Kaplan Meijer analysis showed a statistically significant longer sepsis free survival of the dialysis catheters with citrate than with heparin ($p < 0.05$).While using heparin, 1 out of 20 episodes of catheter related sepsis was caused by Gram negative species. With citrate 3 out of 19 episodes of sepsis were caused by Gram negative species.

Conclusions: In our dialysis centre the rate of catheter related sepsis is low. After the switch to citrate as a catheter lock solution it further decreased. However, we also observed a change in the pathogens causing catheter related sepsis. Our data support the view that prevention of catheter related sepsis is not primarily dependent on the catheterlock solution. The effect of citrate is not due to its bactericidal effect. The shift in pathogens causing catheter related sepsis indicates the need for close surveillance in order to adjust primary treatment for catheter related sepsis.

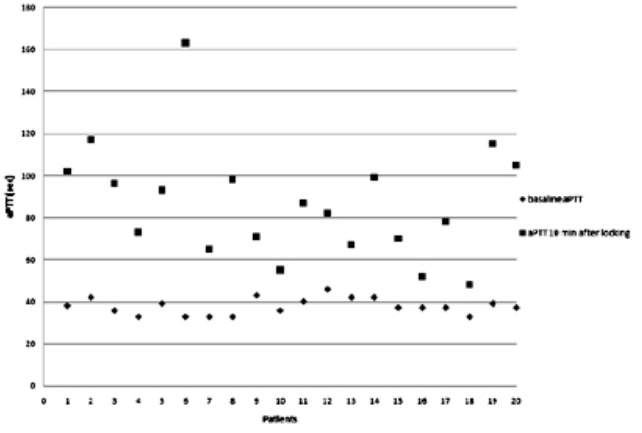
SA-PO2936

Systemic Anticoagulation as a Result of Heparin Locking of Temporary Hemodialysis Catheters Liza Di Monte,[1] Pablo Martin Jimenez,[1] Aldo J. Peixoto,[2] Marcelo Orias.[1] *[1]Sanatorio Allende, Argentina; [2]Yale University.*

Background: Bleeding is an important problem in critically ill patients with AKI. Temporary hemodialysis (HD) catheters require locking with heparin to maintain patency. In permanent tunelled catheters, there is evidence that heparin leaks into the circulation in concentrations that are high enough to produce anticoagulation. Impact of heparin locking on systemic coagulation has not been tested with temporary catheters.

Methods: We performed a prospective study of 20 patients requiring HD, and used a 11 Fr, 20 cm double lumen temporary catheter (Balton Co., Warsaw, Poland). Catheters were locked using unfractionated heparin 5,000 U/ml according to manufacturer's instructions. We obtained peripheral blood draws before catheter use for HD and 10 minutes after the catheter was locked post-HD. HD was performed without heparin. Coagulation parameters measured included activated partial thromboplastin time (aPTT), prothrombin time (PT) and platelet count.

Results: We recruited 17 men and 3 women aged 60±16 years (range 21-85). All patients had normal baseline coagulation parameters. Baseline aPTT was 38 ±3.8 seconds, whereas the mean aPTT 10 min after locking was 87±27 seconds. All patients had an increase in aPTT; the average increase was 130% from baseline ($p< 0.01$). Three of the 20 patients had bleeding complications in the 24h period following testing. All 3 had post-locking aPTT levels >100 seconds. Patients with femoral catheters were associated with significantly higher post-lock aPTT levels as compared with jugular catheters despite identical catheter size and heparin dose.



Conclusions: Temporary double lumen catheter locking with heparin increases aPTT to levels capable of inducing systemic anticoagulation . This must be considered an important risk factor for bleeding in patients undergoing HD through a catheter in the acute setting.

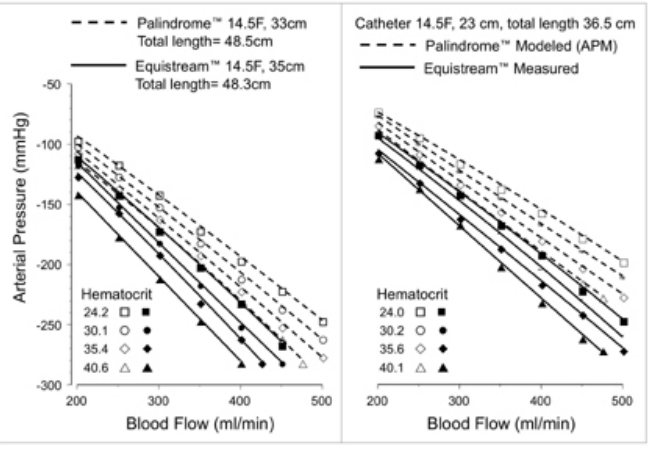
Mathematical Modeling of *In Vitro* Data Provides an Accurate Method for Comparing the Performance of Dialysis Catheters Stanley Frinak, Anatole Besarab, Lalathaksha Murthy Kumbar, Jerry Yee. *Nephrology and Hypertension, Henry Ford Hospital, Detroit, MI.*

Background: Patient outcomes depend on catheter blood flow rate (Qb); therefore a method is needed to compare catheter performance since they vary in length and design. Modeling of *in vitro* data was used to calculate negative arterial pressure (AP) at any Qb or hematocrit (HCT), allowing comparison of catheters from different manufacturers.

Methods: Palindrome™ (PAL) (19, 33, 55 cm, 14.5 F) and Equistream™ (EQ) (23, 27, 35, 42 cm, 14.5 F) catheters were evaluated in an *in vitro* dialysis circuit. Blood was adjusted to HCTs of 40%, 35%, 30%, 24% using plasma. Height difference (ΔH) from AP transducer to reservoir blood level was -24cm. AP was recorded at each HCT starting at a Qb of 200 ml/min and increased by 50 ml/min until 500 ml/min. Total catheter length (TL) was recorded. Data was analyzed using multiple nonlinear regression (DataFit). EQ 23cm data was used in the PAL AP model (APM) to calculate AP at each Qb and HCT. Mean difference EQ AP - PAL APM was calculated at Qb = 200 to 500 ml/min for all TLs and HCTs.

Results: TLs were PAL (33.8, 48.5, 70.1 cm) and EQ (36.5, 40.7, 48.3, 55.8 cm). HCTs for all data were 24.2±0.1 (N=46), 30.2±0.1 (45), 35.4±0.3 (38), and 40.4±0.2 (36). Modeling of PAL data gave $APM = 0.00001(TL)^{0.57536}Qb^2 - 0.10262(TL)^{0.57536}(HCT^2 + 0.00796\ HCT + 0.49958)Qb - (\Delta H)(0.0518\ HCT + 0.74232)$ with R^2=0.989. Measured AP for PAL 33cm and EQ 35 cm are shown in Fig. left. EQ (23cm) measured AP and PAL values from APM are shown in Fig. right. Mean difference EQ AP - PAL APM for Qb = 200, 300, 400 and 500 was -25±4 (N=14), -33±6 (14), -46±7 (14), and -55±10 (5).

Conclusions: For all Qb and HCT values, EQ catheters had greater negative APs than PAL. Modeling of *in vitro* data provides an accurate method for comparison of catheter performance regardless of variations in catheter length and design.



SA-PO2938

***Staphylococcus Aureus* Invasive Infections and Vascular Access in a Hospital Setting: A Retrospective Database Analysis** Mário Raimundo, Fernando Neves, Antonio Gomes da Costa. *Nephrology and Renal Transplantation, Hospital de Santa Maria, Lisbon, Portugal.*

Background: *Staphylococcus aureus* (SA) is the most frequent bacteria responsible for bacteriemia in End-Stage Renal Disease (ESRD) patients undergoing hemodialysis (HD). In this group of patients vascular access type is the main risk factor for bacteriemia, hospitalization related to infection and mortality. Our aim was to evaluate the incidence and mortality of SA infection in patients treated with extracorporeal depuration techniques in a hospital unit and its relationship with the type of vascular access.

Methods: We retrospectively analyzed the databases of the hemodialysis and bacteriology departments of Hospital de Santa Maria (Lisbon) for a two-year period.

Results: There were a total of 511 SA invasive infections in the entire hospital, of which 40% were methicilin-resistant species. Patients who needed extracorporeal depuration techniques contributed to 25% of these infections. Eigthy percent of these had a central venous catheter (CVC) as vascular access, while less than 10% had an arterio-venous fistula (AVF). Infection rates (n/1000 dialysis treatments) in patients who needed extracorporeal depuration techniques were: overall 5.6; AVF 1.44; short-term CVC 7.94 (OR compared to AVF: 5.57 [2.81-11.02], $p<0.0005$); tunelized CVC 6.78 (OR compared to AVF: 4.75, [2.39-9.41], $p<0.0005$); PTFE grafts 9.44 (OR compared to AVF: 6.63, [3.006-14.40], $p<0.0005$). The overall SA invasive infection mortality in patients who needed extracorporeal depuration techniques was 32% (40% with methicilin-resistant species). There were no differences in mortality between the types of vascular access once the infection was established.

Conclusions: ESRD patients undergoing HD are a group at risk for SA invasive infections and its incidence is directly related to the type of vascular access. Strategies for solving this problem should focus on prevention, including early referral of ESRD patients to the Nephrologist and adoption of strict hygienic and barrier measures.

SA-PO2939

Impact of Co-Morbidity and Type of Access on Subsequent Hospitalisation Following a Bacteraemic Episode – Observational Study in a Hemodialysis Cohort Manivarma Kamalanathan, Josie Murphy, Subash Somalanka, Maggi Steele, David Makanjuola. *Nephrology, St. Helier Hospital, Surrey, United Kingdom.*

Background: Patients on hemodialysis (HD) are at risk of bacteraemia and this is a major cause of morbidity and mortality. The type of dialysis access is a major factor, with HD lines being more likely to become infected than AV fistulae. Co-morbidities may increase the risk of hospitalisation, and the length of stay (LOS) in hospital.

Objective: To assess the effect of a bacteraemic episode on morbidity (as defined by the need for hospitalisation), and to see whether this is influenced by the type of HD access or co-morbidity in HD patients.

Methods: Data were obtained on patients who had HD in 2009. We studied two groups - those who experienced a bacteraemia in 2009 (group A) and patients who did not (group B). Data on the source of the infection, HD access at the time of infection, Davis co-morbidity score, and diabetes status were analysed, as was the total in-patient days in the 12 months following the bacteraemic episode.

Results: 720 patients were included in the study. 61(8.5%) in group A and 659 (91.5%) in group B. 243 (34%) patients were diabetic, 30 (49%) in group A, and 213 (30%) in group B. In group A, 66% were dialysing via a line, and 34% were dialysing through an AVF. Mortality within 12 months: group A - 16 (26%), group B - 88 (13.3%). Co-morbidity scores were similar in both groups.

Hospitalisations: group A - 92% , group B - 50%. Average LOS - group A - 40.9 days, group B - 9.4 days.

Conclusions: Morbidity was higher in the subsequent 12 months in patients who had a bacteraemia, as compared with those who did not. The LOS in hospital was also greater in group A especially in diabetics. Patients in group A were more likely to be dialysing via lines. Co-morbidities were similar in both groups, but diabetics had an increased risk of bacteraemia and re-admissions.

Costs of treating bacteraemias, and the increased LOS in hospital add to the financial burden on the health service. One modifiable risk factor is the type of HD access, and we feel our study adds weight to the need to reduce the number of patients on HD via lines.

SA-PO2940

Factors Associated with Bacterial Endocarditis in Dialysis Patients Darren Green, Paul Dunne, Philip A. Kalra. *Department of Renal Medicine, Salford Royal Hospital, United Kingdom.*

Background: Following a cluster of sub-acute bacterial endocarditis (SBE) in a nephrology unit, we reviewed who was most at risk.

Methods: Most SBE patients were on hemodialysis via a catheter. We reviewed data from the prospectively collected audit of tunneled dialysis catheters inserted at this centre. We hypothesised that those most at risk had underlying structural heart disease or immunosuppression.

Results: 13 patients were treated for SBE over 2 years.

Table 1. Characteristics of SBE in dialysis patients

	Age	Organism	Vegetation	Duke	Access	Complication	Pre-existing valve changes
1	67	Staph Aureus	AV	Yes	Temporary	None	Metallic AVR
2	72	Culture -ve	AV	No	Tunneled	Death	No
3	60	Culture -ve	No	Yes	Tunneled	Death	MR MS AR
4	58	Culture -ve	No	Yes	AVF	Death	No
5	74	Enterococcus	AV	Yes	Tunneled	Death	MR MS AR
6	49	Staph Aureus	MV	Yes	Tunneled	Death	No
7	68	Staph Aureus	AV MV	Yes	Tunneled	MR AR	Unk
8	82	Pseudomonas	AV	Yes	Tunneled	Death	No
9	70	Staph Aureus	MV	Yes	Tunneled	MVR	No
10	63	Pseudomonas	MV	Yes	Tunneled	Embolic CVA	MR
11	78	Staph Aureus	MV	Yes	Tunneled	MVR	MR
12	64	Staph Aureus	MV	Yes	Tenckhoff	Embolic CVA	MR
13	57	Coag -ve staph	MV	Yes	Tunneled	Embolic CVA	MR

12 cases met Duke criteria. There was no difference in age, gender, diabetes, BMI or immunosupression between SBE and non-SBE cases. There were 156 tunneled catheters over 2 years. 9 of 34 patients (26.5%) with a previous catheter associated bacteremia developed SBE. Of the 156 tunneled catheter patients, 109 had a previous echocardiogram. 5 of 8 patients with underlying mitral regurgitation (MR) who had a previous catheter-related bacteremia developed SBE. This compared with 4 of 26 patients without MR (63% vs 15%, p=0.064). In total, 5 of 30 people with underlying moderate or severe MR developed SBE compared with 4 of 79 of people with no or mild MR (17% vs 5%, p=0.049).

Conclusions: More than half of dialysis patients who develop SBE die as a result. Tunneled catheters, previous bacteremia and MR appear to be associated with developing SBE. Screening for mitral valve disease may be worthwhile in dialysis patients, as such patients may need to undergo line removal in cases of bacteraemia, and be prioritized for vascular access surgery.

Abstract Withdrawn

SA-PO2942

The Risk of Peritonitis after Exit Site Infection in Peritoneal Dialysis: A Contemporary Analysis Alissa Lloyd,[1] Sharon Nessim,[2] Leigh Anne Shafer,[1] Jeffrey Perl,[3] Mauro Verrelli,[1] Claudio Rigatto,[1] Paul Komenda,[1] Manish M. Sood.[1] *[1]Medicine, University of Manitoba, Winnipeg, MB, Canada; [2]Medicine, McGill University, Montreal, QC, Canada; [3]Medicine, University of Toronto, ON, Canada.*

Background: Peritonitis remains a leading cause of morbidity and technique failure among Peritoneal Dialysis (PD) patients. It is generally accepted that the development of PD catheter exit site infections (ESIs) may directly lead to peritonitis with the same organism, however, the evidence to support this conclusion is limited.

Methods: The cohort consisted of 991 incident adult patients (≥ 18 years of age) residing in the province of Manitoba, Canada who received PD during the period from 2000-2009. 975 (98%) of patients were included where complete data was available. All ESIs were treated with oral or local antibiotics. Patients who experienced an ESI were matched by time on dialysis to those with no ESI and the probability of subsequent peritonitis was determined using generalized estimating equations (GEE) at 3, 6, and 9 months.

Results: There were a total of 1,002 ESIs and 1,228 episodes of peritonitis among 692 individuals. Nine hundred and forty-seven matched pairs were analyzed. Patients with an ESI and peritonitis on the same day were excluded. When the organisms were classified as gram positive, gram negative, culture negative or fungal, the risk of peritonitis following ESI with the same class of organism was significantly increased at 3, 6, and 9 month intervals post-ESI (3 mths: 2.02 CI 1.18-3.48, 6 mths: OR 1.81 CI 1.20-2.75, 9 mths: 1.84 CI 1.30-2.64). When individual organisms were examined, the risk of peritonitis due to *Staphylococcus aureus* or *Pseudomonas* species was significantly increased up to 9 month post-ESI due to the same organism. In all analyses, the effects persisted after adjustment for diabetes, Aboriginal status and gender.

Conclusions: Patients with one or more ESI had an increased likelihood of developing peritonitis following the ESI. This increased risk occurred despite antibiotic treatment of the ESI suggesting biofilm formation, occult tunnel infection or poor technique.

SA-PO2943

Left Atrial Enlargement Is Associated with a Rapid Decline in Residual Renal Function in ESRD Patients on Peritoneal Dialysis Seung Jun Kim, Mi Jung Lee, Dong Ho Shin, Dong Eun Yoo, Hyung Jung Oh, Seung Hyeok Han, Tae-Hyun Yoo, Shin-Wook Kang. *Dept. of Int. Medicine, College of Medicine, BK 21, SBSI, Yonsei Univ., Seoul, Korea.*

Background: Left atrial volume index(LAVI) has been considered an indicator of diastolic dysfunction and an independent predictor of mortality in patients with end-stage renal disease(ESRD). Residual renal function(RRF) has also been recognized as a significant predictor of morbidity and mortality in these patients. However, little is known on the relationship between LA enlargement(LAE) and the changes in RRF in ESRD patients. Therefore, we conducted this prospective observational study to investigate the impact of LAVI on the decline in RRF in ESRD patients on peritoneal dialysis(PD).

Methods: One hundred and twenty-one incident PD patients were included. Within 2 months after PD initiation, LAE was determined by echocardiography and RRF by 24-hour urine collection. Subsequently, RRF was measured every 6 months. Patients were divided into 2 groups according to the presence of LAE(LAVI >32 ml/m^2), and the clinical and laboratory data, including the rates of decline in RRF, were compared between the two groups.

Results: Patients with LAE tended to have higher baseline RRF, but RRF at 24-month was significantly lower in patients with LAE(P=0.014). The overall rates of decline in RRF were significantly greater in patients with LAE compared to those without LAE(-0.17±0.18 vs. -0.07±0.16 ml/min/month/1.73m^2, P=0.002). Moreover, there was a significant inverse correlation between the slope of the decline in RRF and LAVI(P=0.036). Simple linear regression analysis revealed that male gender, diabetes, higher body mass index and baseline RRF, and enlarged LA were associated with a rapid decline in RRF. In multiple linear regression analysis adjusted for other risk factors, LAVI was found as an independent determinant of the rates of decline in RRF(β =-0.026, P=0.018) along with diabetes(β=-0.513, P=0.016) and baseline RRF(β=-0.129, P<0.001).

Conclusions: This study shows that a higher LAVI is independently associated with a more rapid decline in RRF in ESRD patients on PD, suggesting that volume and pressure control may help to preserve RRF in these patients.

SA-PO2944

Automated Wearable Artificial Kidney (AWAK): Feasibility of Removing Protein-Bound Toxins Martin Roberts,[1-3] John F. Collins,[4] Marjorie Wai Yin Foo,[5] Siti Noor Huda,[5] Christian G. Bluchel,[6] David B. Lee.[1-3] *[1]VAGLA Healthcare System, Los Angeles, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]AWAK Technologies, Singapore; [4]Auckland City Hospital, Auckland, New Zealand; [5]Renal Medicine, Singapore General Hospital, Singapore; [6]Temasek Engineering School, Temasek Polytechnic, Singapore.*

Background: Current dialytic modalities do not remove protein-bound (P-B) uremic toxins. Using digoxin as a surrogate P-B uremic toxin, we examined whether our peritoneal dialysis (PD)-based AWAK removes this ligand from spent peritoneal dialysate (SPDs).

Methods: From a CAPD patient taking 62.5 µg of digoxin orally every other day, the SPDs drained from an overnight dwell contained a [digoxin] and [protein] concentrations (per L) of 0.5 µg and 0.82 g, respectively. This SPDs was flowed through (single-pass) a miniature AWAK sorbent cartridge (SC), 1/30 in size and content of a regular SC and at a proportionately reduced dialysate flow rate of 200 mL/h.

Results: [Digoxin] dropped to undetectable levels (<0.2 µg/L) in the first effluent emerging from the SC and remained undetectable through a 6-hour study. Initial effluent [protein] dropped to 0.49 g/L, but returned to its pre-SC levels within 15 min and thereafter. These observations were duplicated in 3 additional studies using synthetic SPDs with the addition (to each L) of 6 µg digoxin and 1 g bovine serum albumin. Thus, the SC has the capacity to clear digoxin at a concentration 10-fold higher than that encountered in the SPDs of the patient treated with digoxin. At our projected dialysate flow rate of 1 – 4 L/h using AWAK, 144 – 576 µg of digoxin could be removed daily. Of the 3 sorbents in the SC, digoxin removal was accomplished mostly by the activated carbon with some contributions from zirconium phosphate and none by the hydrated zirconium oxide.

Conclusions: Our results indicate that the AWAK SC removes the protein-bound ligand, digoxin, but does not remove dialysate protein and thus has the potential of removing protein-bound uremic toxins. The toxin-free protein is returned to the patient where it can bind more toxins.

SA-PO2945

Predictors of Peritoneal Dialysis (PD) Failure in Incident U.S. Patients Jenny Shen, Aya Alice Mitani, Benjamin A. Goldstein, Wolfgang C. Winkelmayer. *Stanford University, Palo Alto, CA.*

Background: Switching from PD to hemodialysis (HD) is undesirable, due to complications from temporary vascular access, disruption of daily routine, and higher costs. Little is known about the role social factors play in technique failure.

Methods: We identified and followed for 5 yrs a U.S. cohort of 1588 patients who initiated PD (1996-97). Modality failure was defined as any switch from PD to HD. Follow-up was censored at transplantation, death, loss to follow-up. We used Cox regression to examine associations among sociodemographic, medical, and healthcare related factors and the outcome. We estimated hazard ratios (HR) with 95% confidence intervals (CI).

Results: In a multivariate analysis, female sex (HR=0.78; 95%CI: 0.66-0.92) and older age (per 10 yrs; HR=0.89; 95%CI: 0.83-0.96) were associated with lower risks of technique failure. Coronary artery disease (HR=1.38; 95%CI: 1.15-1.65), heart failure (HR=2.20; 95%CI: 1.01-4.77), and receiving Medicaid (HR=1.50; 95%CI: 1.23-1.82) were associated with higher risks of failure. Subjects who completed high school were more likely to fail than those who did not complete high school (HR=1.33; 95%CI: 1.08-1.62). Separated, divorced, and widowed subjects also had a higher risk of failure than married subjects (HR=1.30; 95%CI: 1.03-1.60). Virtually all other levels of employment had a greater risk of failure than those who worked full time (Table 1). In an analysis restricted to subjects who had pre-dialysis care information, early referral to a nephrologist (> 3 months) and the primary decision maker of dialysis modality (physician vs. patient vs. shared) were not significantly associated with technique failure.

Adjusted hazard ratio for technique failure by level of employment

Level of Employment	Hazard ratio (95% confidence interval)
Full Time	1.0
Part Time	1.51 (1.05-2.17)
Homemaker	1.53 (1.07-2.20)
Retired	2.01 (1.52-2.65)
Unemployed	1.30 (0.94-1.81)
Disabled	1.50 (1.16-1.95)
Other	1.41 (1.02-1.95)

Conclusions: Our study confirms that in addition to demographic and medical factors, several social factors are also associated with technique failure. They emphasize the importance of social and financial support in maintaining peritoneal dialysis.

Understanding the Variability in Ultrafiltration Obtained with Icodextrin – From Theory To Bedside Zanzhe Yu,[1,2] Mark Lambie,[1,2] Simon J. Davies.[1,2] *[1]Department of Nephrology, University Hospital of North Staffordshire, Stoke on Trent, Staffordshire, United Kingdom; [2]Institute of Science and Technology in Medicine, Stoke on Trent, Staffordshire, United Kingdom.*

Background: There is considerable between patient variability in ultrafiltration (UF) obtained with icodextrin (ICO) that is not fully understood. Modelling of individual patients using the 3-pore model suggests that both hydrostatic and oncotic pressure differences as well as membrane characteristics need to be considered. The purpose of this study was to elucidate clinical predictors of the variability in UF including indirect measures of these additional factors.

Methods: Net UF obtained during ICO dwell was recorded as well as membrane characteristics and clinical factors every 6 monthly. Multi-level analysis was used to identify the predictor of UF taking account of within subject correlations.

Results: 690 dwells in 202 patients were analysed, among which 280 were CAPD (typically 9 hours overnight dwell), 289 APD long day exchanges (typically 15 hours), and 126 in APD patients using an additional day-time exchange (typically 9 hours day time dwell). In multi-level mixed linear modelling, on CAPD predicted 160mls more UF compared with APD, no matter 9 hours or 15 hours. High input volume (2.5L) was related to an 111mls less UF compared with 2L. The UF negatively correlated to time on PD therapy and serum albumin. D/P creatinine, UF capacity (UF in PET) and BMI contributed positively to UF.

Conclusions: These observations fit with the theoretical modelling. They confirm the impact of membrane characteristics on UF that fast transport status and better UF capacity indicate more UF and prolonged time on PD decreases UF. They also clarify that factors which are likely to affect the oncotic pressure gradient (plasma albumin) and hydrostatic pressure gradient (input volume, patient position, BMI and gender) are more important than the dwell length in explaining UF variability. These observations have clear implications for dialysis prescription.

Stability and Maintenance of Hemoglobin Levels with a Once Monthly Subcutaneous Administration of CERA in Chronic Kidney Disease Patients on Peritoneal Dialysis: The MISTRAL Study Raymond Azar,[1] Jean-Philippe Ryckelynck,[2] Philippe Rieu,[3] Pierre Yves Durand,[4] Bertrand Morel,[5] Robert Milongo,[6] Ali Aizel,[7] David Pau,[8] Christian Verger.[9] *[1]CH Dunkerque; [2]CHRU Caen; [3]CHU Reims; [4]CH Quimper; [5]CH Chambery; [6]Agduc Grenoble; [7]Aurar Reunion; [8]Roche, Neuilly sur Seine; [9]CH Pontoise, France.*

Background: Maintaining the stability of hemoglobin (Hb) level is a major goal of anemia treatment. The new European recommendations (ERBP 2009) indicate that Hb level should be in the target range of 11-12 g/dl without intentionally exceeding 13 g/dL. CERA, continuous erythropoietin receptor activator, corrects anemia and maintains the stability of Hb level with a once monthly administration. This French multicenter clinical trial aims to provide more data about CERA in peritoneal dialysis (PD).

Methods: Patients (pts) without any absolute iron deficiency and stable with darbepoetin alfa, epoetin alfa or beta, received subcutaneous once monthly CERA during 44 weeks. The dose of CERA was adjusted to maintain the Hb level within a range of ± 1 g/dl and in the target range 10-12 g/dL. The primary endpoint was the proportion of pts maintaining Hb level within [10–12] g/dL during the evaluation period (weeks 16, 20 and 24).

Results: 95 PD patients (men: 60%) were analyzed (age: 67±16 years). Main etiologies of chronic kidney disease were hypertension (32%), glomerular diseases (22%) and diabetes (20%). Mean duration of dialysis was 2.4±3.1 years. At baseline, mean dose of previous ESA was 3903±2502 IU/week. Mean Hb level was 11.3±0.6 g/dL at baseline and 11.6±1.0 g/dL during the evaluation period. 51% of pts were within [10-12] g/dL during the evaluation period and 71% of pts were within the target range newly recommended by the ERBP 2009. 74% of pts had a variation of Hb ≤1 g/dL since baseline or their Hb between 10-12 g/dL during the evaluation period. Mean monthly dose of CERA was 133±30 µg at baseline and 127±76 µg after 6 months. 71 serious adverse events were reported in 47 pts (49%) and none were related to CERA.

Conclusions: A once monthly administration of CERA is safe and effective in maintaining the stability of Hb level in PD patients.

Further Development of an Efficient Dialysate Delivery Protocol for Application in a Peritoneal Dialysis-Based Automated Wearable Artificial Kidney (AWAK) Marjorie Wai Yin Foo,[1] John F. Collins,[2] Martin Roberts,[3-5] Siti Noor Huda,[1] Christian G. Bluchel,[6] Kok-Seng Wong,[1] David B. Lee.[3-5] *[1]Renal Medicine, Singapore General Hospital, Singapore; [2]Auckland City Hospital, Auckland, New Zealand; [3]VAGLA Healthcare System, Los Angeles, CA; [4]David Geffen School of Medicine at UCLA, Los Angeles, CA; [5]AWAK Technologies, Singapore; [6]Temasek Engineering School, Temasek Polytechnic, Singapore.*

Background: We have reported high dialysate (D) flow rate (FR, 4 L/h), using tidal PD (TPD) with low tidal volume (TV) and reserve volume (RV). We now report solute exchanges and ultrafiltration (UF) at several D FRs.

Methods: 5-hour TPD (TV 250, RV 500 mL) was conducted in 4 high transporters (HiT) and 4 low transporters (LoT), using Baxter Home Choice system and pH neutralized Dianeal 1.5%. Clearance (mL/min) for urea nitrogen (Cun), creatinine (Ccr), phosphorus (Cp) and beta-2 microglobulin (Cβ); glucose uptake (G-uptake, g/5h); and UF (mL/5h) were measured in each subject at D FR of 1, 2, 3 or 4 L/h, respectively.

Results: 1.Cun is FR-dependent (FR-D) and not membrane-dependent (M-D), i.e., similar C between HiT and LoT. Calculated Kt/V range is 2.5-4.3. 2.Ccr, Cp and Cβ are M-D and relatively FR-independent. Extrapolated peritoneal Cp (L/week/1.73m2) were 64 (at 1L/h, HiT & LoT) and 111 (HiT) and 95 (LoT) at 4L/h. 3. G-uptake was both FR-D and M-D and varied from 106-190 g/day. 4.UF in LoT is higher (500-690 vs 200-580 mL/5h in HiT) and is relatively FR-independent; while UF in HiT is FR-D.

D FR	1 (HiT/LoT)	2 (HiT/LoT)	3 (HiT/LoT)	4 (HiT/LoT)
Cun	8.8/9.7	12.4/12.2	14.5/12.8	15.2/15.5
Ccr	6.2 /6.1	8.4 /7.1	9.5 /7.5	9.3 /8.1
Cp	4.2/4.1	5.4 /4.8	5.7 /4.8	6.8/5.6
Cβ	1.2/0.9	1.6 /0.8	1.8/0.8	1.4/0.9
G-uptake	22.0/21.5	30.4/27.1	35.9/32.2	39.5/36.7
UF	200/500	320/620	480/550	580/690

Conclusions: 1.Dialysis adequacy is maintained with FR as low as 1L/h. A lower FR and lighter sorbent cartridge may be used during day time and a higher FR, heavier cartridge for night time. 2.Adequate UF is obtained at all FRs in both HiT and LoT using only 1.5% D. G-uptake, compared to CAPD (100-150 g/d) is not excessive. 3. Cp exceeds those reported (CJASN, 6:591. 2011) for CAPD, 43/34 (HiT/LoT), and APD, 44/28.

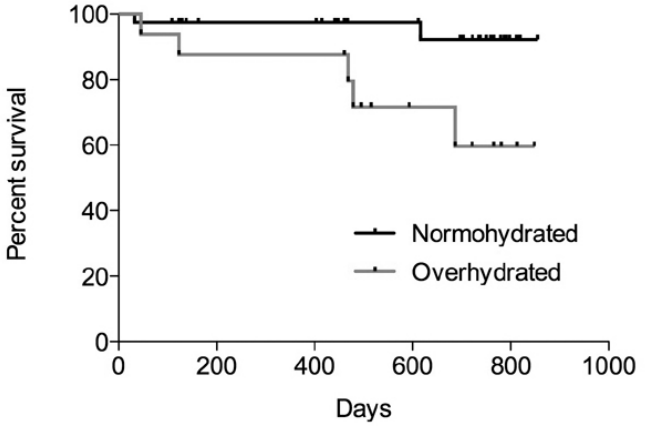
SA-PO2949

The Mortality Risk of Overhydration in Peritoneal Dialysis Lars Kihm, Joerg Seckinger, Christian Morath, Claudia Sommerer, Martin G. Zeier, Vedat Schwenger. *Nephrology, University of Heidelberg, Germany.*

Background: Maintaining euvolemia is an important goal in peritoneal dialysis (PD) patients. Adequate assessment of volume status in clinical practice is difficult. A new multifrequency bioimpedance tool has recently been validated for volume assessment. In a longitudinal observation, we evaluated the association of hypervolemia on cardiac biomarkers, morbidity and mortality in PD patients.

Methods: In 54 PD patients Body Composition Monitoring (BCM; Fresenius Medical Care, Bad Homburg, Germany) and measurement of plasma troponine T (cTNT) and N-terminal-pro brain natriuretic peptide (NT-proBNP) was performed. Clinical overhydration was defined as an overhydration-to-extracellular water ratio of >0.15. Mortality was assessed over a follow-up period of 24 months.

Results: Clinical overhydration was found in 29.6% of the PD patients. Patients with overhydration had significantly higher cTNT and NT-proBNP levels compared to euvolaemic patients (cTNT median 0.089 ng/mL, interquartile range 0.041-0.140 vs. 0.028 ng/mL, 0.010-0.067; p<0,001; NT-proBNP median 13976 pg/mL, interquartile range 4336-31095 vs. 2266 pg/mL, 361-9510; p<0,001). Chronic PD patients with clinical overhydration >0.15, cTNT >0,049 ng/mL and NT-proBNP >7266 pg/mL were more likely to die in the follow-up period.



Conclusions: Although much clinical attention is paid to volume status, almost one third of PD patients still have clinically relevant volume overload. Overhydration assessed by BCM, increased NT-proBNP and cTNT are strongly associated with adverse outcome in PD patients, and are useful tools for risk stratification.

SA-PO2950

A Reduced Ultrafiltration Rate in Children Undergoing Peritoneal Dialysis and a History of Peritonitis Depends on a High Intraperitoneal Pressure Rainer Buescher, Anja K. Büscher, Anika Von Gliszczynski, Peter F. Hoyer. *Pediatrics II, Pediatric Nephrology, University of Duisburg-Essen, Essen, Germany.*

Background: The adequacy and efficiency of peritoneal dialysis (PD) treatment in children is a dynamic process and depends on the administered intraperitoneal volume (IPV), dwell times, intraperitoneal pressure (IPP) and maintenance of peritoneal function following complications such as episodes of peritonitis. While optimal IPP-ranges are well defined for pediatric and adult PD patients under stable clinical conditions, little is known about changes of IPP and ultrafiltration rate (UFR) in children following one or more episodes of peritonitis.

Methods: IPP was measured in 19 children (10 males and 9 females, mean age 12.0 ± 1.8 years (range 2 - 18 years), mean weight 31.4 ± 19.4 kg, (range 8.1 - 60.2 kg) as standard procedure every six months and in addition one month following each peritonitis. Seventeen patients were on automated pertitoneal dialysis (APD) and two on continuous ambulatory peritoneal dialysis (CAPD). All children underwent one (n=14), two (n=3) or three (n=2) episodes of peritonitis. Patients were stratified into two groups according to their initial IPP pressure (IPP < 10 cm H_2O, n = 11 and IPP > 10 cm H_2O, n = 8) and UFR was monitored.

Results: Mean initial IPV was 959.7 ± 281.4 ml/m² BSA, mean UFR prior to the first peritonitis 620.8 ± 335.6 ml/m²BSA/24 h and mean IPP for an inflow volume of 0 ml was 9.1 ± 4.3 cm H_2O. IPP increased lineary by 1.8 ± 0.5 cm H_2O when the IPV was increased by 250 ml/m²BSA. One month after the first peritonitis, UFR did significantly drop in those patients with an initial IPP > 10 cm H_2O (IPP: < 10 cm H_2O: 657.3 ± 253.1 ml/m²BSA/24h vs. IPP > 10 cm H_2O: 364.6 ± 307.7 ml/m²BSA/24h; $p = 0.036$). Hernias were not observed within the study population.

Conclusions: We observed a drop of UFR after one peritonitis in those patients who already presented with a high IPP. Whether this effect is due to a irrversible fibrotic remodeling of the peritoneum or a transient phenomenon needs to be investigated in future studies.

SA-PO2951

Post-Implantation Abdominal X-Ray Parameters Can Predict Functional Catheter Problems in Peritoneal Dialysis Bert Bammens, Domien Peeters, Yves Vanrenterghem. *Nephrology, Dialysis and Renal Transplantation, University Hospitals Leuven, Leuven, Belgium.*

Background: Adequate peritoneal access is a prerequisite for good peritoneal dialysis (PD) treatment. Functional catheter problems constitute a major challenge for every PD program.

Methods: We reviewed the files of patients who received a PD catheter between 01/2005 and 08/2010. Only swan neck double cuffed curled catheters (SWAN NECK™ Missouri) were used and all were placed by open surgical technique. The "internal memory" of these catheters requires two features to be taken into account for good function: (1) swan neck angle and (2) correct inclination of catheter through the abdominal wall. Based on plain abdominal X-ray post-implantation, we defined the following categories: swan neck angle in PA view (<45°, 45-90° or >90°), inclination of catheter through abdominal wall in lateral view (angle between intramural part of catheter with imaginary horizontal line <30° or ≥30°). In addition, we evaluated the position of the internal cuff relative to the spine (L1-2, L3-4 or lower) and the position of the pigtail (hypogastric, umbilical or subcostal zone) in PA view. Endpoints: occurrence of clinically overt functional catheter problems and need for surgical reintervention.

Results: 110 patients (64 male, mean age 56±16 years) were studied. During follow-up (till October 2010), there was at least one documented episode of mechanical catheter dysfunction in 42 patients (38%). 21 patients (19%) needed surgical repositioning of the catheter. Swan neck angle (larger vs. smaller angle, HR 1.58 [1.10-2.28]) and inclination through abdominal wall (<30° vs. ≥30°, HR 3.99 [2.15-7.40]) were associated with clinically overt functional catheter problems. The inclination through abdominal wall (<30° vs. ≥30°, HR 2.80 [1.18-6.60]) was associated with need for surgical reintervention.

Conclusions: Respecting the so-called "internal catheter memory" is of utmost importance to avoid functional PD catheter problems. Plain abdominal X-ray post-implantation is an easy tool to evaluate these parameters and may serve for educational and internal audit purposes.

SA-PO2952

Different Influence of Peritoneal Dialysis Duration on Outcome of Peritonitis between First and Successive Episode Peritonitis Rong Xu, Yanjun Li, Jie Dong. *Institute of Nephrology, Peking University.*

Background: The leading cause for patients dropout from long-term PD therapy is peritonitis. We aim to explore whether there is difference between first and successive episode peritonitis in the influence of peritoneal dialysis duration on outcome of peritonitis.

Methods: A total of 248 episodes of peritonitis (124 first-episodes and 124 successive-episodes) were observed between 1st January 2008 and 30th April 2011. In first-episodes and successive-episodes respectively, patients were divided into "shorter duration" group and "longer duration" group according to the median of PD duration when peritonitis occurred. The baseline demographic data and latest biochemical parameters measured no more than 3 months before the peritonitis were recorded. Multivariate logistic regression analysis was used to find the predictor of peritonitis outcome.

Results: Both in first-episodes and successive-episodes, the age, serum albumin, hemoglobin, total Kt/v, bacterial distribution, dialysate white cell count on 3rd and 5th day were no different between "shorter duration" group and "longer duration" group, although the latter had more or marginally more female, less diabetes patients and lower residual renal function. "Longer duration" group had similar peritonitis dropout rate in first episode but higher dropout rate in successive episode than "shorter duration" group. Longer PD duration was independent predictor for outcome of successive-episode peritonitis (adjusted OR 6.80, 95% CI 1.36-33.96, p=0.02) but not for outcome of first-episode peritonitis.

Conclusions: Compared with peritonitis occurred at shorter PD duration, peritonitis occurred at longer PD duration had similar outcome in first-episode peritonitis, but poor outcome in successive episodes, which couldn't be explained by difference in demographic characteristics and biochemical parameters.

SA-PO2953

Evaluation of Diverticular Diseases by Computed Tomography Is Useful for Selection of Peritoneal Dialysis Modality and Asymptomatic Diverticulosis Is Not a Risk Factor for Peritonitis Yasuhiko Ito, Susumu Toda, Masashi Mizuno, Yasuhiro Suzuki, Isao Ito, Hideki Hiramatsu, Takenori Ozaki, Waichi Sato, Naotake Tsuboi, Shoichi Maruyama, Enyu Imai, Seiichi Matsuo. *Nephrology and Renal Replacement Therapy, Nagoya University, Nagoya, Japan.*

Background: Colonic diverticulitis is an important cause of polymicrobial peritonitis, which requires surgical treatment and cessation of peritoneal dialysis (PD). The aim of this study was to examine whether plain abdominal computed tomography (CT) is useful for evaluating colonic diverticulosis at renal replacement therapy (RRT) modality selection and to explore whether colonic diverticulosis is a risk factor for enteric peritonitis.

Methods: Subjects were 137 consecutive chronic kidney disease patients (stage 4 or 5) who were candidates for PD from February 2005 to November 2009. Abdominal CT without contrast media was performed in all PD candidates. Average individual peritonitis rate, enteric peritonitis rate, and cumulative survival and technical failure survival rate were assessed.

Results: Diverticula of the colon were detected by plain CT in 57 cases (41.6%). The number of diverticula tended to increase with age. The most common site of involvement of diverticulosis was the ascending colon (70.1%). In patients treated with PD, the incidence of peritonitis was higher in patients with diverticulosis than in those without diverticulosis (p=0.004). However, only one episode of enteric peritonitis was observed among patients with diverticulosis. The cumulative survival and technical failure survival rate was not different between the diverticulosis-positive and -negative groups. PD was not selected in 4 cases due to a high frequency of diverticula with episodes of abdominal pain. Two of these 4 cases developed severe diverticulitis with peritonitis and underwent resection of the colon.

Conclusions: Our study suggests that plain CT examination is useful for detecting diverticulosis at modality selection for RRT. Silent diverticulosis is not a risk factor for peritonitis. PD may be contraindicated in cases having frequent diverticulosis with episodes of lower abdominal pain.

SA-PO2954

The Use of Tidal Peritoneal Dialysis in Northern Ireland and the Effect on Residual Renal Function Agnes Masengu,[1] Ronan Cunningham,[2] Robert Mullan.[2] *[1]Nephrology, Belfast City Hospital, Belfast, United Kingdom; [2]Nephrology, Antrim Area Hospital, Antrim, United Kingdom.*

Background: In Northern Ireland (NI) there has been a steady increase in the percentage of patients performing automated peritoneal dialysis (APD). As a consequence of this more patients are being placed on tidal peritoneal dialysis (TPD), meaning that only a certain percentage of dialysis fluid is drained after each cycle. The aims of this study were to review the indications and prescription practices for TPD and determine if any important patient associations exist.

Methods: All NI patients on APD in December 2010 with at least one previous PD adequacy test had relevant data collected from clinical notes and electonic records. A questionnaire concerning TPD prescription and monitoring was also sent to each PD nurse specialist. Statistical analysis was performed using GraphPad Prism version 5.

Results: Of the 54 APD patients identified 93% were receiving TPD. In 68% the indication for TPD was to alleviate pain during drainage. All PD nurses reported prescribing TPD with no direct input from the patient's supervising nephrologist. There appeared to be a regional variation as to how the patient's dialysis prescription was altered after the initiation of TPD, with only some nursing staff making adjustments to account for alterations in dialysis dwell time that can occur with TPD. No association was detected between the amount of TPD prescribed versus membrane transporter status and dialysis adequacy. However there was a significant association between TPD and residual renal function (RRF). Patients on <75% TPD (i.e. >25% dialysis fluid not drained after each cycle) had a higher residual urine output compared to patients on >75% TPD (mean RRF 1530 mls +/- 222 mls vs 922.5 mls +/-112 mls respectively, p=0.02).

Conclusions: The vast majority of APD patients are now prescribed TPD by nursing staff mainly to alleviate drainage pain. Theoretically TPD may alter solute clearance but this was not demonstrated in our study. The amount of TPD prescribed did have a significant effect on urine output and therefore raises the intriguing possibility that TPD plays a role in the preservation of RRF, the mechanism for which remains unclear.

SA-PO2955

Characteristics of Eosinophilic Peritonitis in 19 Children Receiving Peritoneal Dialysis Masako Ikemiyagi, Yuko Hamasaki, Takeshi Yamada, Riku Hamada, Tomoyuki Sakai, Kenji Ishikura, Hiroshi Hataya, Masataka Honda. *Nephrology, Tokyo metropolitan Children's Medical Center, Fuchu, Tokyo, Japan.*

Background: Peritonitis is a common, yet potentially serious complication in patients who are receiving peritoneal dialysis (PD). Eosinophilic peritonitis (EP) is usually benign and often resolves without intervention. It is essential to distinguish EP from bacterial and fungal peritonitis to avoid unnecessary treatments. We retrospectively analyzed children with EP to better characterize the condition.

Methods: EP was defined as >100 white cells per milliliter of dialysate effluent, of which eosinophils constitute >10% of the all white cells.

Results: Between January 2000 and April 2011, 72 children commenced PD. During follow-up, we identified 27 episodes of EP in 19 children (median 2.7 years). One child had 4 episodes, which was the maximum. The study group comprised 11 boys and 8 girls, with a median age of 3.0 years (4 months-13 years). The median interval from the initiation of PD to the first episode was 12 days (0-232 days). The median leukocyte count of the dialysate was 640/μl, and the eosinophil count was 287/μl. The median leukocyte count of peripheral blood was 7554/μl, the median eosinophil count was 554 /μl, and the CRP concentration was 0.2 mg/ml. Twenty-four episodes of EP resolved without antibiotics, and 3 were treated until effluent cultures became negative. Four episodes were associated with physical symptoms (fever, 2 episodes; abdominal pain, 2 episodes). Other episodes were unassociated with physical symptoms. Seventeen of the 27 episodes were associated with mechanical trauma: 11, involved catheter intervention; 5, omental resection; and 1, herniorrhaphy. Five episodes were associated with intraperitoneal administration of antibiotics. Eighty-nine percent of episodes occurred within 14 days after the apparent cause of EP.

Conclusions: EP has an excellent prognosis even in children who are receiving PD. Among the 27 episodes, 24 resolved spontaneously within 1 week. The possibility of EP should be considered in children who present with cloudy dialysate within 14 days after mechanical trauma, even in the absence of physical symptoms.

SA-PO2956

Peritoneal Dialysis Is a Good Option for Patients with Polycystic Kidney Disease Patients Ana M. Tato,[1] Jose Portoles,[2] Paula López,[2] Maria Rosario Llopez Carratala,[2] Maite Rivera.[3] *[1]Nephrology, Hospital Universitario Fundacion Alcorcon, Alcorcon, Madrid, Spain; [2]Nephrology, Hospital Puerta de Hierrro, Majadahonda, Madrid, Spain; [3]Nephrology, Hospital Ramón y Cajal, Madrid, Spain.*

Background: Polycystic kidney disease (PKD) is considered a partial contraindication for peritoneal dialysis (PD) because of concern about hernias and peritonitis eventually would end in technique failure.

Methods: Multicentre observational study of patients starting PD between 2003 and 2007 and follow them up to January 2010.

Outcomes: Patient survival, technique survival; peritonitis rate.

Results: The PD-centre-group's data base (GCDP) includes 882 incident patients (2003-07) from 19 public hospitals. Patients are free to choose the renal replacement therapy, and they mainly opt for hemodialysis (HD) (regional- registry-data: 83.6% HD, 14.9% PD, and 1.5% pre-emptive-transplantation) . PKD patients seem to prefer PD rather than HD (12% vs 7.5%). They are younger and have less morbidity than nonPKD patients. Although the tranfer rate to hemodialysis is similar in both goups, in PKD patiens is more often due to abdominal space related complications. Evolution of PKD patients vs nonPKD patients is summarized in table 1.

	PKD	no PKD	p
Age (yr)	51.7	55.7	0.05<
Charlson index	3.9	5.5	0.05<
RRF (ml/min)	7.1	7.5	0.001<
Diabetes (%)	2.1	24.7	0.001<
KT/V	2.64	2.68	ns
CCr (l/w)	96.1	94.5	ns
Hb(g/dl)	12.7	12.1	ns
TAS mm Hg	126	135	0.05<
TAD	79.5	79.3	ns
peritonitis/yr	0.48	0.58	ns
mortality rate (%)	1.19	6.47	0.008
Hospital admisions (%)	0.46	0.62	0.02
transplant rate (%)	32.1	19.3	0.001<
transfer toHD	8.3	9.2	ns

Conclusions: In our cohort PD is a feasible kidney replacement therapy for most patients with PKD. Their peritonitis rate and technique survival is similar to those of non PKD patients.

SA-PO2957

Improved Technique Survival in Automated Peritoneal Dialysis (APD) Patients Compared to Continuous Ambulatory Peritoneal Dialysis (CAPD) Patients during the Initial 2 Years of Therapy Andrew C. Hayes, Kenneth Story, Steven Guest, Ira D. Davis. *Medical Products, Baxter Healthcare Corporation, McGaw Park, IL.*

Background: Peritoneal dialysis (PD) is an effective therapy for ESRD, with two modes: APD (Automated PD) and CAPD (Continuous ambulatory PD). Mujais et al (KI 70:S21-S26, 2006) assessed a patient cohort of initiating PD therapy between 2000 -2003, determining that technique success was higher for APD. This current study evaluates five subsequent years, evaluating cause for patients leaving PD therapy during the initial 24 months.

Methods: Baxter's U.S. database of PD patient starts from 2004-2008 was reviewed. Demographic data is limited to age, sex, diabetes. Patient status after 24 months was determined; 4 cause codes for leaving PD therapy were available: Transplant; Change to competitive PD product; Transfer to HD; other. The probability of leaving Baxter PD products was computed for both APD and CAPD patients. Hazard ratios were also computed comparing APD and CAPD patients for the risk of leaving Baxter PD products.

Results: A total of 35,968 patients initiated APD; 9,054 initiated CAPD. The APD population was younger (55.6 vs. 56.5), more likely to be male (55.8% vs. 51.0%), but less likely to be diabetic (41.2% vs. 42.0%). Of patients on PD therapy for at least 90 days, by 24 months, 51.7% of the APD patients were no longer performing APD versus 59.1% of those from the CAPD group (p<0.001). Median time to leaving Baxter PD products was 56.2 (APD) months vs. 48.7 (CAPD) months- difference of 7.5 months, p-value <0.0001, from Log Rank test. The hazard ratio comparing APD and CAPD patients for the risk of leaving Baxter PD products, after accounting for age, gender and diabetic status, was 0.872.

Conclusions: There is a 7.4% difference in 2 year technique survival between the CAPD and APD cohorts. Patient groups appear similar based on demographics (age, sex, diabetes, transplant rates), suggesting other factors led to the difference. It is postulated that CAPD, despite being a simpler, non-automated procedure, requires greater patient competencies such as performing four-times daily compared to APD with one start plus one end technique each day.

SA-PO2958

Diastolic Dysfunction as a Cause of Rapid Decline of Residual Renal Function in Patients with Peritoneal Dialysis Jwa-Kyung Kim, Jung-Woo Noh, Ja-Ryong Koo, Young Rim Song. *Department of Internal Medicine & Kidney Research Institute, Hallym University Medical Center, Korea.*

Background: Diastolic dysfunction is frequently observed in dialyzed patients; however, the significance of diastolic dysfunction has not been clearly determined. We evaluated whether diastolic dysfunction could influence the rate of RRF loss in 82 ESRD patients starting peritoneal dialysis.

Methods: This study performed at the Hallym University Hospital between April 2005 and March 2009, and subjects with pre-existing systolic dysfunction were excluded. Timed urine collections were performed at baseline (within 1 month of start) and at 6-month intervals thereafter. Loss of renal function was defined as urine output less than 200mL/day.

Results: The mean follow-up period was 22.9±7.3 months. The median slope of RRF decline was -0.07mL/minute/month/1.73m^2 and the rate was significantly faster in diabetes compared to that of non-diabetes (-0.085 vs. -0.049). Multivariate analysis showed that the rate of RRF loss had the highest correlation with diabetes (r=-0.314, p=0.004), followed by LAVI (left atrial volume index) (r=-0.276, p=0.015), increasing aging (r=-0.256, p=0.020), LV hypertrophy (r=-0.236, p=0.032) and E/E' ratio (early peak transmitral inflow velocity to peak mitral annulus velocity) (r=-0.221, p=0.048). Forty-five patients (54.9%) with fast RRF decline (<-0.07mL/minute/month/1.73m^2) had higher prevalence of diabetes (68.9%) and showed significantly elevated baseline LAVI, LAD (left atrial diameter) and E/E' ratio (p<0.05). However, LV ejection fraction and other laboratory parameters were comparable between the two groups. In unadjusted logistic regression, the presence of diabetes (OR 4.15 95%CI 1.65-10.44), baseline RRF (OR 0.57 95%CI 0.39-0.82), LAVI ≥32 mL/m^2 (OR 3.94 95%CI 1.52-10.21) and eccentric LV hypertrophy (OR 5.50 95%CI 1.26-23.94) was closely associated with the increased risk of accelerated loss of RRF. After adjustment for other clinical variables, LAVI ≥32 mL/m^2 was an independent predictor for RRF loss.

Conclusions: In conclusion, left ventricular diastolic dysfunction could be the main determinant for loss of RRF in ESRD patients starting peritoneal dialysis.

SA-PO2959

Good Glycemic Control Is Associated with Better Survival in Diabetic Patients on Peritoneal Dialysis Dong Eun Yoo,[1] Tae Ik Chang,[2] Mi Jung Lee,[1] Dong Ho Shin,[1] Seung Jun Kim,[1] Hyung Jung Oh,[1] Seung Hyeok Han,[1] Tae-Hyun Yoo,[1] Shin-Wook Kang.[1] *[1]Dept. of Int. Medicine, College of Medicine, BK21, SBSI, Yonsei Univ., Seoul, Korea; [2]Dept. of Int. Medicine, NHIC Ilsan Hospital, Goyang, Korea.*

Background: Previous studies have demonstrated that strict glycemic control was associated with slow progression of diabetic nephropathy, and with higher survival rates in diabetic patients on hemodialysis. However, the impact of glycemic control on the outcome of patients with diabetes(DM) on peritoneal dialysis(PD) has largely been unexplored. This prospective observational study was undertaken to clarify whether good glycemic control is associated with a better outcome in DM patients on PD.

Methods: We conducted a prospective observational study, in which 140 DM patients who started PD between Jan 2001 and Dec 2008 were recruited. Patients were divided into tertiles according to the means of quarterly HbA1C levels measured during the first year after the initiation of PD. Demographic and laboratory data were compared among the 3 groups. In addition, the associations between HbA1C levels and all-cause and cardiovascular mortalities were determined using Cox proportional hazards models.

Results: The mean age was 58.7 years, 59.3% were male, and the mean follow-up duration was 3.5 years. The mean HbA1C levels were 6.3±0.3, 7.1±0.3, and 8.5±1.1% in the 1st, 2nd, and 3rd tertiles, respectively. Compared to the 1st tertile, the overall mortality rates were higher in the 2nd tertile(HR, 2.70; 95% CI, 0.65-11.13; p=0.170) and significantly higher in the 3rd tertile(HR, 8.78; 95% CI, 1.92-40.13; p=0.005), after adjusting confounding factors(p for trend=0.015). Cardiovascular mortality, however, did not differ significantly among the tertiles. In contrast, non-cardiovascular deaths, most of which were caused by infection, were more frequent in the 2nd tertile(HR, 4.23; 95% CI, 0.45-40.01; p=0.208) and significantly more frequent in the 3rd tertile(HR, 27.05; 95% CI, 2.61-280.96; p=0.006) than the 1st tertile(p for trend=0.007).

Conclusions: Poor glycemic control is associated with high mortality rates in DM patients on PD, suggesting that better glycemic control may improve the outcomes of these patients.

SA-PO2960

Predictive Value of Red Blood Cell Distribution Width on Overall Mortality in ESRD Patients on Peritoneal Dialysis Shin-Wook Kang, Mi Jung Lee, Dong Ho Shin, Seung Jun Kim, Dong Eun Yoo, Hyung Jung Oh, Seung Hyeok Han, Tae-Hyun Yoo. *Dept. of Int. Medicine, Collge of Medicine, BK21, SBSI, Yonsei Univ., Seoul, Korea.*

Background: Red blood cell distribution width (RDW) has been found to be independently associated with adverse outcomes in patients with coronary heart disease. Although increased RDW levels are frequently observed in patients with end-stage renal disease, little is known on the relationship between RDW and outcomes in this population. This study was conducted to determine whether RDW values are associated with mortality in peritoneal dialysis(PD) patients.

Methods: We included 197 incident PD patients and classified into 2 groups according to the RDW levels at 3-month, and clinical and laboratory data, echocardiographic findings, and overall and cardiovascular mortalities were compared between the two groups. Cox proportional hazard analysis was performed to determine the independent prognostic power for overall mortality of RDW, and Kaplan-Meier curves were constructed to compare the differences in overall and cardiovascular mortalities between the two groups.

Results: The mean age was 55 years, 58.4% were male, and 51 patients(25.8%) had RDW above the upper limit of normal value(>14.5%). Patients with high RDW (H group) were significantly older (P<0.01) and had significantly more comorbidities (P<0.05) than patients with normal RDW(N group). The proportion of male patients was significantly higher, and serum albumin and total cholesterol concentrations were significantly lower in the H group (P<0.05). In addition, LVMI, LAVI, RVP, and E/E' were significantly higher in the H group compared to the N group (P<0.01). In contrast, there were no significant differences in Hb levels, iron profiles, and LVEF between the two groups. Both overall and cardiovascular mortality rates were also significantly higher in the H group compared to the N group (P<0.01). Cox proportional hazard analysis revealed that RDW was a significant independent predictor of overall mortality even after adjusting for other risk factors (HR, 1.29; 95% CI, 1.07-2.45; P<0.05).

Conclusions: This study shows that RDW provides a meaningful prognostic value on overall mortality in incident PD patients.

SA-PO2961

Statins Decrease Small, Dense Low-Density Lipoprotein in Patients Undergoing Peritoneal Dialysis Anna Clementi, Jeong Chul Kim, Matteo Floris, Dinna N. Cruz, Francesco Garzotto, Monica Zanella, Federico Nalesso, Alessandra Brendolan, Claudio Ronco. *Nephrology, St Bortolo Hosp, Vicenza, Italy.*

Background: Cardiovascular (CV) disease is a major cause of mortality among hemodialysis (HD) and peritoneal dialysis (PD) patients, and dyslipidemia plays an important role in its pathogenesis. Small dense LDL (sd-LDL) have been recently highlighted as an emerging CV risk factor. PD patients exhibit a more abnormal lipid profile than HD patients, likely due to peritoneal dialysate. Statins are able to decrease all LDL subclasses levels, but it is not known whether they can influence the proportion of sd- LDL. Few studies have been performed in HD patients and none in PD patients. We compared the lipid profile and the effect of statins on it in HD and PD patients.

Methods: We enrolled 101 and 79 patients undergoing HD and PD at St Bortolo Hospital in Vicenza. The mean age of HD and PD patients was 66±13.9 and 58±15.9 (yr). Men were 67.3% and 59.5% in the 2 groups. 83.2% of HD and 81% of PD patients had hypertension. 27.7% of HD and 19% of PD patients were diabetic. We divided HD and PD patients into 2 groups according to statin therapy.

Sd-LDL was measured by LDL-EX "SEIKEN" homogeneous Assay on ADVIA 2400 Clin Chemistry Syst. SPSS software version 17 was used for statistical analysis.

Results: HD patients presented lower levels of total cholesterol (TC)(p=0.001), triglyceride (p=0.007), LDL-C (p=0.001), Apo-B (p=0.001), absolute amount of sd-LDL and their proportion (p=0.001). Among HD patients the statin group presented lower levels of TC (p=0.002), LDL-C (p=0.002), HDL-C (p=0.001), Apo-AI (p=0.009), Apo-B (p=0.006). No differences in terms of sd-LDL and their proportion (p=0.058, p=0.745). Among PD patients the statin group presented lower levels of TC (p=0.011), LDL-C (p=0.01), Apo-B (p=0.001), absolute amount and proportion of sd-LDL (p=0.013, p=0.036).

Conclusions: Our study suggests that statins may reduce the absolute amount and the proportion of sd-LDL in patients with a more abnormal lipid profile, such as PD patient. Statins do not alter sd-LDL levels in HD patients due to the higher number of patients with hypertension and diabetes, which can influence their generation.

SA-PO2962

Left Atrium Volume Index as Useful Predictor for Decline of Residual Kidney Function in Peritoneal Dialysis Patients Takeshi Yokoyama,[1] Katsuomi Matsui,[1] Tsutomu Sakurada,[2] Yugo Shibagaki,[2] Yusuke Konno,[1] Takashi Yasuda,[2] Kenjiro Kimura.[2] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, Kawasaki Municipal Tama Hospital, Kawasaki, Kanagawa, Japan; [2]Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Kanagawa, Japan.*

Background: Preservation of residual kidney function (RKF) has been recognized as an independent predictor of survival in peritoneal dialysis (PD) patients. Although heart failure is known to associate with decline of RKF, little is known which parameters of ultrasound cardiography (UCG) are helpful to predict decline of RKF.

The aim of present study is to clarify the relationship between the rate of decline of RKF and the parameters of UCG.

Methods: UCG was performed in 15 PD patients at the initiation of PD, the following parameters such as left atrial dimension (LAD), left atrial volume index (LAVi), left ventricular end-diastolic dimension (LVDd), left ventricular internal dimension in systolic (LVDs) and left ventricular mass index (LVMi) were measured. We calculated RKF as the half of the sum of weekly urea and creatinine clearances normalized to 1.73m^2 BSA, and defined the rate of decline of RKF as [(the latest RKF - intial RKF) / duration of PD]. We examined the correlations between the rate of decline of RKF and the parameters of UCG.

Results: Average RKF at the initiation of PD was 36.11 ± 19.14 L/week/1.73m^2 and average rate of decline of RKF was -0.16 ± 2.07 L/week/1.73m^2/month. Rate of decline of RKF was significant correlated with LAD (r = -0.546), LVDd (r = -0.544), LVMi (r =

-0.562) and LAVi (r = -0.649). Multiple regression analysis revealed that only LAVi was an independent predictor for decline of RKF.

Conclusions: Among the parameters of UCG, LAVi was the most useful predictor of a decline of RKF in PD patients.

SA-PO2963

Use of Dressing with Polyurethane Absorptive Foam with Chlorhexidine Gluconate (BIOPATCH®) To Reduce Exit-Site Infection and Peritonitis in Patients Undergoing Peritoneal Dialysis

Bhrigu Raj Sood, Inaam Mohammed, Maggi Steele. *South West Thames Renal Unit, Epsom and St Helier NHS Trust, Carshalton, Surrey, United Kingdom.*

Background: Peritoneal dialysis (PD) catheter insertion related infections cause significant morbidity and often force the removal of the catheter.

Aim of this study was to find the difference in incidence of exit site infections (ESI) and peritonitis in patients who had PD catheter inserted a year before (1/5/06 to 30/4/07) and after (1/5/07 to 30/4/08) introduction of regular use of Chlorhexidine Gluconate containing foam patch dressing Biopatch.

Methods: We gathered data on 59 patients who had a PD catheter inserted over a year before introduction of Biopatch and 70 patients who had PD catheter inserted over a year afterwards. Our practice is to use Biopatch dressing at the time of catheter insertion and change it weekly for 6 weeks. Data was recorded on ESI, tunnel infection,PD peritonitis, catheter loss and mortality during first 12 weeks after catheter insertion.

Results: 17 patients could not complete the study period in pre-Biopatch group (3-died, 8 - catheter malfunction, 1 - transplant, 2 - transferred out & 2 - lost due to infection).

10 patients could not complete the study period in post-Biopatch group (2-died, 5-catheter malfunction, 1-transferred out & 1 -lost due to infection).

Incidence of infection leading to catheter loss was not statistically different in 2 groups. (p=0.11)

ALL INFECTION EPISODES:

	0-7 days	8-28 days	29-42 days	42-84 days	TOTAL
PRE BIOPATCH	1 (1.7%)	4 (6.8%)	1 (1.7%)	5 (8.5%)	11 (18.6%)
POST BIOPATCH	0 (0%)	5 (7.1%)	1 (1.4%)	7 (10%)	13 (18.6%)
					p = 0.12

ESI

	0-7 days	8-28 days	29-42 days	42-84 days	Total
PRE BIOPATCH	1 (1.7%)	4 (6.8%)	1 (1.7%)	3(5.1%)	9(15.3%)
POST BIOPATCH	0 (0%)	5 (7.1%)	0 (0%)	6 (8.6%)	11(15.3%)
				p = 0.025	p = 0.12

PD peritonitis

	0-7 days	8-28 days	29-42 days	42-84 days	Total
PRE BIOPATCH	0	1 (1.7%)	0	2 (3.4%)	3 (5.1%)
POST BIOPATCH	0	0	1 (1.4%)	0	1 (1.4%)
				p = 0.044	p = 0.066

Conclusions: Introduction of Biopatch made no difference to overall incidence of exit site infection or PD peritonitis in first 12 weeks after PD catheter insertion. However, there was increased incidence of ESI in post Biopatch group after stopping Biopatch application (42 to 84 days after insertion) (p= 0.025). On the other hand incidence of Peritonitis was higher in pre-Biopatch group in period between 42 and 84 days after catheter insertion (p=0.044).

SA-PO2964

Urgent Peritoneal Dialysis Start for Late Referred End-Stage Renal Disease Patients – Single Center Experience

Ewa Wojtaszek,[1] Agnieszka Grzejszczak,[1] Stanislaw Niemczyk,[1,2] Grzegorz Ostrowski,[1] Joanna Matuszkiewicz-Rowinska.[1] *[1]Nephrology, Dialysis & Internal Diseases, Medical University of Warsaw, Warsaw, Poland; [2]Nephrology, Military Medical Institute, Warsaw, Poland.*

Background: Despite improvement in the predialysis care, still 30–50% of the ESRD pts start dialysis urgently via acute central venous catheter. There is some positive experience with acute start on chronic peritoneal dialysis (PD) right after catheter implantation by open surgery. The aim of the study was to assess the impact of unplanned PD start on the outcomes and PD related complications.

Methods: This is a retrospective study of incident ESRD pts treated by PD at our center between Jan 2005 and Dec 2010. Tenckhoff catheter was inserted via open surgery. PD initiated < 9 days after catheter implantation was referred as an acute start. The groups of planned and unplanned start were compared for the outcomes and PD related complications.

Results: From 82 pts, aged 52±17 years, 21 (26%) started PD urgently (12 h overnight APD + dry day, dwell volume 1L). They had lower eGFR (6.4±3.3 vs 8.6±3.1ml/min, p<0.01), lower Hb(9.5±1.3 vs 10.5±1.3g/dL, p<0.01), and serum albumin (3.3±0,4 vs 3.5±0.5 g/dL, p<0.05), and the same Charlson Comorbidity Index (6±3). The pts were observed for 1621 pts-months, median follow-up was 16 (1-61) months. A percent of early (first 2 weeks) mechanical complications was slightly but not significantly higher in the unplanned pts with bleeding in 5 (24%) vs 3 (5%) pts, and leakage in 3 pts (14%) vs none (p=0.09). There was no exit site infection nor peritonitis. Late mechanical complications occurred in 3 (15%) of unplanned pts (leakage in 1, hernia in 2) and 10 (18%) of planned pts (leakage in 4, hernia in 7); p=0.9. PD catheter migration was noted in 1 (5%) urgent and 9 (15%) elective started pts; p=0.2. The incidence of peritonitis was 1/44 pts-months in the unplanned and 1/48 pts-months in the planned group; p=0.6. At the end of follow-up 43% of unplanned and 39% planned pts continued PD; 24% vs 28% were transplanted, 5% vs 21% moved to HD, and 28% vs 12% died; p=0.5.

Conclusions: The PD can be a safe alternative to HD in acute start allowing to avoid a temporary cannulation of large veins.

SA-PO2965

Does the Glomerular Filtration Rate at Initiation of Peritoneal Dialysis Affect the Nutritional Status and Survival of Patients?

Narayan Prasad. *Nephrology, SGPGIMS, Lucknow, UP, India.*

Background: The effect of initial GFR on clinical outcomes on follow-up in Indian PD patients has not been studied.We aimed to study the effect of baseline GFR on nutrition status and survival of PD patients.

Methods: We included 342 **PD** patients (age 51.5±14 yrs,250 male,179 diabetics) and followed for 21.6±14.4 patient-months. Nutrition status of patients was assessed by anthropometry, biochemical parameters, diet-diary and Subjective Global Assessment(SGA). GFR was calculated by using Cockcroft-Gault (CG) formula.Patients were classified into 3 groups(grp): Grp1: GFR<5ml/min, Grp II GFR 5-10 ml/min and Grp III GFR >10ml/min. The clinical outcome and nutritionparameters at basline and follow up were compared between three groups

Results: The variables between 3 grp are shown in the table.

Table 1:various parameters in three different groups

variables	Group 1	Group 2	Group 3	P value
Kt/V Urea	1.79 ±0.41	1.89 ±0.46	1.91 ±0.44	0.76
CrCl (L/week)	63.09 ±19.25	65.1±17.14	69.46±23.54	0.94
D/P Cr	0.67±0.10	0.70 ±0.11	0.69±0.11	0.58
Age (Years)	56.3±14.4	51.8±15.2	49.6±16.3	0.05
S. Albumin(g/dl)	3.0±0.67	3.20±0.5	3.5±0.5	0.04
SGA score	3.5±1.4	4.4±1.6	4.4 ±1.7	0.01
NRI score	86.7±11.5	90.1±7.6	91.3 ±9.1	0.02
Energy(Kcal/Kg/day)	17.9±5.8	19.0 ±6.5	19.1± 6.1	0.66
Protein (g/Kg/day)	0.77±0.30	0.81±0.29	0.84 ±0.27	0.53

D/P cr, dialysate/plasma ctreatinine ratio at 4 hours; NRI,Nutritional risk index;CrCl,creatinine clearance

The median survival (patient-months) in grp I [20 (95% CI 15.5-24.5)] was inferior to Grp II [45.3(95% CI 36.0-54.6) and Grp III [59 (95% CI 18.5-99.5, p-0.001)].The risk ratio of death in Grp I was higher than grp II [OR=2.2(95% CI 1.5-3.1), p<0.001] and grp III [OR 4.7 (95% CI 2.8-8.2), p<0.001] patients.The risk ratio of malnutrition was also higher in grp I compared to grp II [OR=1.3(95% CI 1.2-1.4) p=0.008] and grp III [OR=1.3 (95%CI 1.2-1.6), p=0.003] patients. There was a ↓ in serum albumin in grp I (-0.08±0.59) and ↑ in Grp II (0.06±60.46) and grp III (0.99±0.44). There was a significant ↑ in mean SGA score in grp III (0.66±0.94) compared to grp II (-0.12±0.88) and grp I (-0.41±0.49) patients.

Conclusions: Initial GFR is an important factor to affect the nutrition status and survival of PD patients.

SA-PO2966

Assessment of Hydration State in Peritoneal Dialysis Patients by Two Different Bioimpedance Methods-Body Composition Monitor and Calf Bioimpedance

Ismail Kocyigit, Ozturk Ates, Havva Cilan, Nilüfer Oguzhan, Murat H. Sipahioglu, Bulent Tokgoz, Oktay Oymak, Cengiz Utas. *Nephrology, Erciyes University, Kayseri, Turkey.*

Background: Our aims were to evaluate hydration state in peritoneal dialysis (PD) patients using body composition monitor (BCM) and calf bioimpedance (cBI), and compare both methods.

Methods: 58 PD patients studied. Overhydration (OH) was measured by BCM device (normal limits:-1.1 to1L). Patients were assigned to normo and hypervolemic groups according to OH value. Normalized calf resistivity (nRho) was calculated from resistance at 5 Khz using cBI. The mean value of 3 BP measured at different time on study day were used.

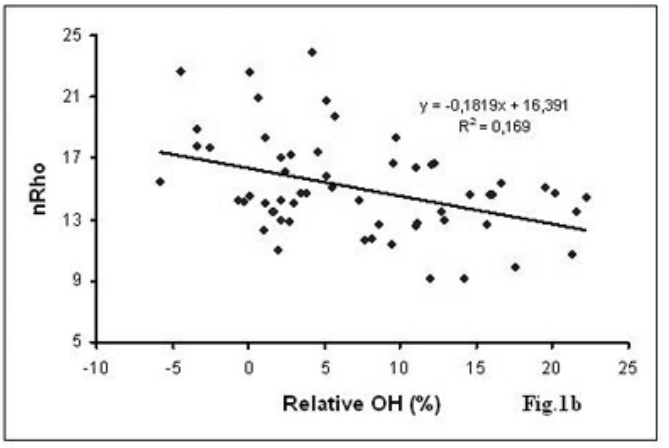
Results: Mean age was 47.2±0.12, 41 (70.7%) male. Clinical characteristics of OH groups were given in the table.

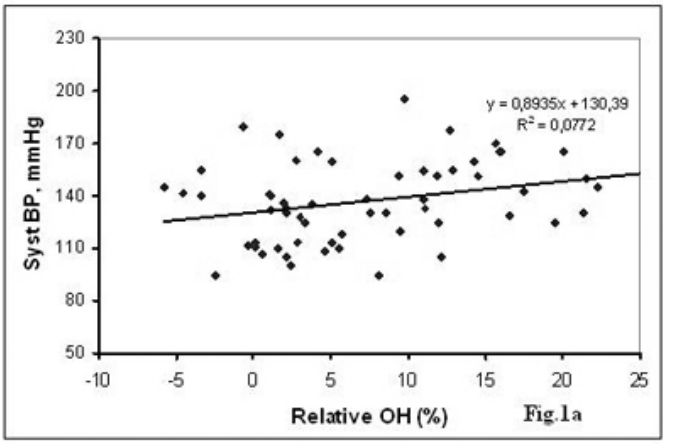
Table 1. Clinical Characteristics of Patients Grouped by BCM Data

Parameters	Hypervolemic (n=24)	Normovolemic (n:34)	P value
Age	51,9±14,9	44.0±12.6	0.034
OH (L)	2,58±0,92	0,312±0,45	0,001
nRho	13.7±2.4	16.0±3.3	0.005
eGFR (mL/min)	4.2±3.9	3.0±3.8	0.270
D/P creatinine	0.69±0.17	0.66±0.11	0.530
No.of antihypertensive	1.54±1.06	0.97±0.93	0.035
Edema + pts (n, %)	11 (45.8%)	6 (17.6%)	0.042

Frequency of edema, Anti-HT drug use were significantly higher in hypervolemic group. nRho was lower in hypervolemic group.Sys BP showed a significant correlation with Relative OH % (OH/ECV), but not with nRho (Figure 1a.)

There was an inverse relation between rel.OH and nRho (p=0.001 r:-0.41) (Fig1b).





28 of the patients who have been using anti-HT drugs didn't have edema. Of these 28 patients, 11 had hypervolemia (OH>1.1 L). In a sub-group analysis of these 28 pts, nRho was lower in hypervolemics (14.8±1.9 vs 16.1±3.4 p=0.517)

Conclusions: In PD patients, BCM may become a benefit tool to evaluate hydration state and determine occult hypervolemia. There was a moderate inverse correlation between BCM and cBIS techniques in terms of assesment of hydration state.

SA-PO2967

Effect of Intra-Peritoneal Dialysate on Evaluation of Volume Status by Bioelectrical Impedance Analysis in the Peritoneal Dialysis Patients Jung-Ju Seo,[1,2] Jang-Hee Cho,[1,2] Mi-Kyung Jin,[1,2] Owen Kwon,[1,2] Kyung-Deuk Hong,[1,2] Ji-Young Choi,[1,2] Se-Hee Yoon,[1,2] Sun-Hee Park,[1,2] Chan-Duck Kim,[1,2] Yong-Lim Kim.[1,2] *[1]Department of Internal Medicine, Kyungpook National University Hospital, Dague, Republic of Korea; [2]Clinical Research Center for End Stage Renal Disease, Republic of Korea.*

Background: Direct segmental multi-frequency bioelectrical impedance analysis (DSM-BIA) has been proposed as a tool for adequate assessment of fluid status in continuous ambulatory peritoneal dialysis (CAPD) patients.

Methods: We examined the influence of intra-peritoneal dialysate on total body water (TBW) and the accuracy of DSM-BIA to estimate TBW. We measured the change of TBW by DSM-BIA ($TBW_{DSM-BIA}$) and compared $TBW_{DSM-BIA}$ with TBW by the Watson formula (TBW_{Watson}) under influence of dialysate in 55 CAPD patients.

Results: After infusion of dialysate, $TBW_{DSM-BIA}$, the index of hydration (TBW/weight(BW), %), and obesity (fat mass(FM)/BW, %) were significantly increased ($p < 0.001$), but the index of edema (extracellular fluid(ECF)/TBW) was not changed. $TBW_{DSM-BIA}$ had fairly strong correlation with TBW_{Watson} before and after infusing dialysate ($r = 0.940$ or 0.946, $p < 0.001$), but $TBW_{DSM-BIA}$ was overestimated versus TBW_{Watson} ($p < 0.001$). The difference between two methods was correlated with index of hydration ($r = 0.529$ or 0.542, $p < 0.001$) and obesity ($r = -0.515$ or -0.538, $p < 0.001$).

Conclusions: The dialysate influences the evaluation of $TBW_{DSM-BIA}$, however, we were able to use the edema index to evaluate fluid status of CAPD patients without the effect of dialysate. DSM-BIA overestimated TBW in hydrated patients and underestimated it in obese patients when compared with the Watson formula.

SA-PO2968

Better Technique Survival with an Alternative Treatment Strategy of PD Related Peritonitis Wim Rüger,[1] Pieter M. Ter Wee.[1] *[1]Nephrology, VU University Medical Center, Amsterdam, Netherlands; [2]Nephrology, University Medical Center, Utrecht, Netherlands.*

Background: ISPD PD-related infections recommendations suggest catheter removal in refractory, relapsing and enteric peritonitis. We compared the outcomes of all PD-peritonitis episodes (1998-2008) treated with different treatment strategies in two university hospitals.

Methods: *Hospital 1:* Initial treatment: intraperitoneal (i.p.) rifampicin and gentamicin, if need be adapted to culture results. Decision to remove PD-catheter guided by ISPD recommendations.

Hospital 2: Patients ≤50 yrs: i.p.cephalotin; Patients >50 yrs: considered at risk for enteral peritonitis. Assuming that PD hinders omental sealing of (micro)perforations, PD was discontinued and meropenem given intravenously and intracatheter. In cases of enteric peritonitis continued for 1 week, then restart of PD with 1 week i.p. meropenem. If cultures yielded non-enteral organisms, PD was resumed with appropriate i.p. antibiotics. Fungal peritonitis was treated with i.p. fluconazol, oral flucytosine and intracatheter amphotericin B. Enteral or fungal peritonitis were no indication for catheter removal.

Results: 323 peritonitis episodes in *Hospital 1* and 251 in *Hospital 2*. Patient and peritonitis episode characteristics were similar. Fungal episodes occurred in 7.4% vs. 3.2%.

Antibiotics alone resulted in cure in 79.9% of episodes in *Hospital 1* vs. 92.8% in *Hospital 2*. PD-catheter removed in 16.7% vs. 2.4% of episodes. Recuperation after catheter removal in 11.4% vs. 1.6%, with patient returning to PD in 3.4% vs. 0.0%, permanently switching to HD in 8.0% vs. 1.6% of episodes. Technique survival thus was 83.3% vs. 92.8% (OR 2.60; 95%CI 1.48-4.56).

Respectively in 5.0% and 0.8% of episodes patients died despite catheter removal and in 3.7% vs. 4.8% with catheter in place. Patient survival thus was 91.3% vs. 94.4% (OR 1.61; 95%CI 0.83-3.10).

Conclusions: A peritonitis treatment strategy with interrupting PD, intravenous and intracatheter meropenem, tailored to patient age and causative micro-organism and particular fungal peritonitis treatment resulted in better PD-technique survival than a strategy consisting of intraperitoneal antibiotics and catheter removal according to ISPD-recommendations.

SA-PO2969

Outcomes of Peritonitis in Incident Peritoneal Dialysis Patients Eduardo K. Lacson, Nien-Chen Li, Raymond M. Hakim, J. Michael Lazarus, Franklin W. Maddux, Joseph P. Pulliam. *Fresenius Medical Care, North America, Waltham, MA.*

Background: We evaluated the incidence and outcomes of peritonitis among peritoneal dialysis (PD) patients who begin home dialysis within 90-days of first (ever) dialysis.

Methods: All 1,984 incident PD patients admitted to Fresenius Medical Care North America facilities from January 1 to December 31, 2009 were followed for one year from their first home PD treatment. We tracked patients that developed peritonitis and investigated outcomes within 30 and 90 days thereafter.

Results: 557 patients (28.1%) developed peritonitis over a median time of 123 days (139±98 days). Compared to patients without peritonitis, mean ages were similar (56.8 vs. 56.3 years, p=0.58), male gender (59.1% vs. 55.2%, p=0.11), white race (69.1% vs 76.7%, p=0.001), diabetes (53.7% vs 53.5% p=0.93), mean BMI (33.3 vs 31.9, p<0.05, medians 30.5 vs 29.3). Overall technique failure rate in patients who had peritonitis was 28.4% compared to patients who did not have peritonitis at 18.4% (p<0.0001). Subsequent hospitalization rates were higher for peritonitis patients as well (72% vs. 52.7%, p<0.0001). Odds ratios for technique failure and hospitalization for patients with peritonitis were 2.31 and 1.75, both p<0.0001. Within 30 days following diagnosis of peritonitis, 140 were hospitalized (25.1%), 43 switched to HD (7.7%) and 5 died (0.9%). One patient who died and 22 that switched to HD did so post-hospitalization. Among 43 patients that switched to HD, only 8 returned to PD and 2 of them eventually had multiple modality switches and were on HD at year-end. By 90 days of diagnosis, 189 were hospitalized (33.9%), 89 switched to HD (16.0%) and 11 died (2.0%). Among 89 patients that switched to HD, only a total of 13 patients returned to PD including the same 2 patients having multiple modality switches as noted above.

Conclusions: Peritonitis episodes were associated with increased hospitalization and technique failure among incident PD patients within 30 and 90 days of the event. Further research is needed to determine interventions that can decrease peritonitis rates in this population.

SA-PO2970

Development and Evaluation of a Novel Semi-Long Peritoneal Dialysis Catheter for Upper Abdominal Exit-Sites Narutoshi Kabashima,[1] Tetsu Miyamoto,[2] Akihiro Kuma,[2] Nana Ishimatsu,[2] Yumi Furuno,[2] Kaori Kanegae,[1] Ryota Serino,[2] Yutaka Otsuji,[2] Masahito Tamura.[1] *[1]Kidney Center, University Hospital of Environmental and Occupational Health, Kitakyushu, Japan; [2]Second Department of Internal Medicine, University Hospital of Environmental and Occupational Health, Kitakyushu, Japan.*

Background: Conventional Swan-Neck peritoneal dialysis catheters (PDC, 43.5cm) have been hitherto used in Japan. Recently several ultra long PDC (80 cm) designed for the presternal or upper abdominal exit-site were established to avoid infectious complications. However, it is not easy to handle these long catheters at the PDC implantation procedure. Furthermore, the problem of dislocation and omental wrapping remain unsolved.

Methods: We developed a newly designed Flexible-Neck semi-long PDC (JBS-2) to reduce the incidence of catheter-related problems including dislocations and omental wrappings. JBS-2 consists of 65 cm of lengths (5 mm of diameter) with 34 smaller side-holes (0.5 mm) on the four longitudinal slit lines. The tube around the peritoneal cuff (8.0 cm between the peritoneal and subcutaneous cuffs) was thickened and reinforced to prevent dislocation. We implanted JBS-2 for 16 patients and assessed implantation procedure and inflow-/outflow- time with 1500 ml of peritoneal dialysis fluid (PDF). The incidence of dislocation and omental wrapping were also recorded.

Results: Owing to the length of PDC, JBS-2 made the implantation technique easier than the ultra long catheters. We could provide upper abdominal exit (UAE) without cutting PDC. It took 7.5 minutes of mean inflow time and 15 minutes of mean outflow time. No omental wrapping and no PDC dislocation has been observed in patients with JBS-2.

Conclusions: Our newly developed PDC (JBS-2) was appropriate for UAE without catheter-related problems including dislocations, omental wrappings and inflow-/outflow-delays.

SA-PO2971

Patient Recruitment to Home Hemodialysis (HHD) in Canada Robert P. Pauly,[1] Paul Komenda,[2] Deborah Lynn Zimmerman.[3] *[1]University of Alberta, Canada; [2]University of Manitoba, Canada; [3]University of Ottawa, Canada.*

Background: There is growing interest in HHD though little is published on establishing and maintaining an HHD program. Canada is a recognized leader in HHD delivery and the purpose of this study was to leverage Canadian expertise and survey HHD programs nationwide to describe practice patterns in a variety of domains. The current abstract focuses on patient recruitment to HHD.

Methods: A comprehensive questionnaire of HHD practice patterns was developed by an expert panel with input from allied health services and underwent multiple modifications. It was distributed and completed online between July and December 2010; data reflect practices during this time period.

Results: Seventeen of 19 (89%) programs responded. Thirteen of 17 (76%) have a specific recruitment strategy including special modality education classes (11/17 – 65%), a designated modality educator (12/17 – 71%), posters advertising HHD (11/17 – 65%), an information video on HHD (10/17 – 59%), discussion of potential HHD patients at patient care rounds (12/17 – 71%), and active recruitment of failing peritoneal dialysis patients (14/17 – 82%). Many programs restrict HHD access to patients expected to remain on HHD for at least 6 months (12/17 – 71%) or at least 12 months (6/17 – 35%), while other programs have no such policy and will train patients even if they are expected to exit the program sooner (eg. for planned living donor transplantation). Ten of 17 programs (59%) mandate an HHD assistant for selected patients; all programs allow family members to act as HHD helpers, and 4 of these 10 (40%) allow paid assistants. Ten of 17 (59%) estimate that <10% of pre-dialysis clinic patients choose HHD as their initial modality and 13/17 (76%) estimate <10% of unplanned (precipitated) dialysis starts will choose HHD.

Conclusions: Most Canadian renal programs use specific strategies to encourage uptake of HHD, though the majority of patients originate from the prevalent ESRD population. There is greater variability in policy concerning the need for HHD assistants and the minimum length of time a patient is expected to remain on HHD. Sharing successful recruitment strategies may facilitate increased uptake.

SA-PO2972

Comparison of Percutaneous and Open Surgical Techniques for First-Time Peritoneal Dialysis Catheter Placement in the Unbreached Peritoneum Samar A. Medani, Wael F. Hussein, Mohamed Shantier, Catherine A. Wall, George Mellotte. *Nephrology, Adelaide & Meath Hospital, Dublin, Ireland.*

Background: The percutaneous seldinger method of peritoneal dialysis catheter (PDC) insertion has gained favour over recent years whereas traditionally it was reserved for patients unfit for general anaesthesia. This blind technique is believed to be less safe in patients with previous abdominal surgery therefore a criticism of this method is selection bias. In those with no history of abdominal surgery the optimal method of insertion has not been established.

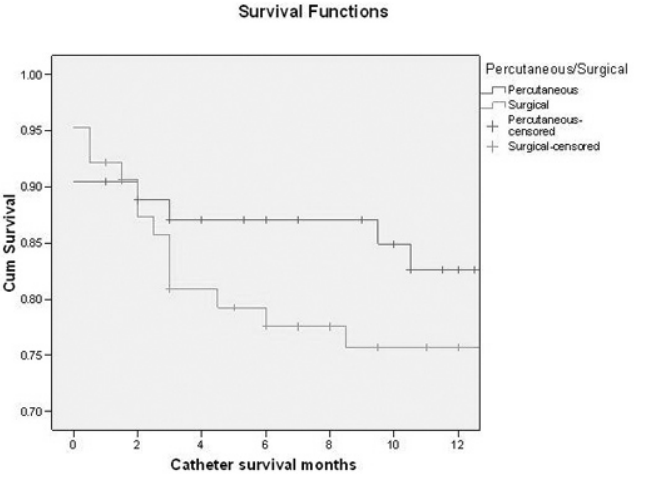
Methods: We retrospectively compared the outcomes of first-time percutaneous (group P) and surgical (group S) PDC placements in our centre between January 2003 and April 2010 in patients without a history of abdominal surgery. We reviewed outcomes and complications of PDCs until April 2011. Kaplan Meier curves were generated to represent technical survival of catheters for the first 12 months after insertion.

Results: 64 percutaneous and 63 surgical catheter insertions were analysed. PDC related complications are shown.

Complications of PDC insertions

Complications	Group S	Group P	P value
Peritonitis (patient-months per episode)	17.2	20	0.66
Exit leak	4 (6.3%)	10 (15.9%)	0.15
Poor initial drainage	7 (10.9%)	6 (9.5%)	0.34
Secondary drainage failure	12 (18.8%)	5 (7.9%)	0.09

There were no differences between the two groups in peritonitis rates, leaks, poor initial drainage and secondary drainage failure. Technical survival for group P catheters compared favourably with group S (P=0.35).



Conclusions: Our results emphasise the success and safety of percutaneous PDC insertion in experienced hands. Technical survival and complication rates were comparable with the surgical technique in this cohort of patients without previous abdominal surgery. The percutaneous technique offers the advantage of ease of insertion and can be done as a day case procedure.

SA-PO2973

Peritoneal Dialysis in Patients with Cancer; the Experience of One Centre in the United Kingdom Harsha Wodeyar Kagodu Surendranath, Muhammad Imran, Gordon M. Bell, Hameed Anijeet, Pearl Pai. *Nephrology, Royal Liverpool University Hospital, Liverpool, Merseyside, United Kingdom.*

Background: Peritoneal dialysis (PD) is often regarded as an inferior modality of renal replacement despite many advances in PD technology and solution formulation. There is also concern whether cancer patients should access chronic dialysis therapy. We report our experience of cancer patients on PD over the last 7 years in a well established PD unit in the north-west of England.

Methods: We reviewed the data of our PD population and the clinical details of those suffering from malignant disease. Our PD programme (n=80) includes 8 patients suffering from malignant disease in the last 7 years. Their details are below:

Age/Gender	Renal Diagnosis	Malignancy (diagnosis year)	PD vintage (months)	Current status
25/Female	Drug induced renal failure	Neuroectodermal tumour (2007)	17	Not on dialysis due to sufficient renal recovery
54/Female	Obstructive uropathy	Endometrial (2010)	26	Still on PD
62/Female	Membranous glomerulonephritis	Breast and bladder (2010)	8	Still on PD
40/Female	Diabetic nephropathy	Malignant melanoma with lymphnode metastasis (2005)	24	Still on PD
65/Female	Myeloma kidney	Multiple Myeloma (2007)	18	Deceased
70/Female	Myeloma kidney	Multiple Myeloma (2005)	24	Deceased
20/Male	IgA nephropathy	Osteosarcoma with lung metastasis (2004)	24	Deceased
54/Male	Myeloma kidney	Multiple Myeloma (2009)	15	Deceased

Results: Our cohort had good nutritional status (mean albumin= 38.5 g/L and range=37 to 45 g/L) and positive feedback with no patient withdrawal from treatment during the study period.

Conclusions: Many of these PD patients with cancer will never be on transplant waiting lists. In the United Kingdom, the use of a cycler (automated PD) frees restrictions and allows the patients to dialyse at their home. The quality of dialysis and life of cancer patients on PD would appear to be just as good as in non-cancer patients.

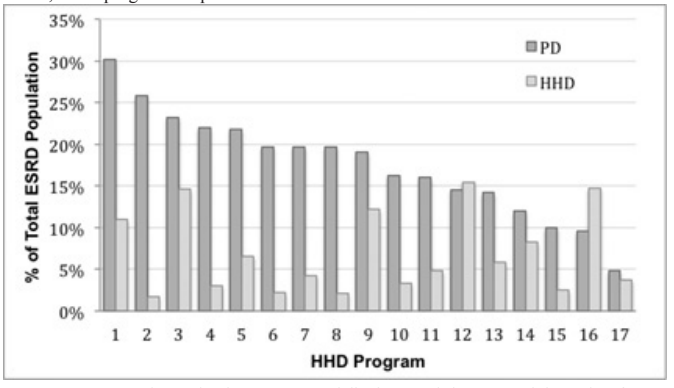
SA-PO2974

Home Hemodialysis (HHD) and Peritoneal Dialysis (PD) in Canada: The Status of Co-Existing Home Therapies in 2010 Robert P. Pauly,[1] Paul Komenda,[2] Deborah Lynn Zimmerman.[3] *[1]University of Alberta, Canada; [2]University of Manitoba, Canada; [3]University of Ottawa, Canada.*

Background: Canada has historically treated a relatively high proportion of ESRD patients with PD. Canada is also a leader in the delivery of HHD, particularly with respect to nocturnal hemodialysis (NHD), short-daily hemodialysis (SDHD), and variations on these prescriptions. Uncertain is the extent to which these two home modalities can successfully co-exist in individual renal programs.

Methods: Between Jul and Dec 2010, 19 dialysis programs (14 university-based centers and 5 community centres known to provide all options of home dialysis therapies) were surveyed to determine the relative proportion of HHD and PD.

Results: Seventeen of 19 programs responded. Uptake of home therapies (HHD and PD) averaged 24.8±7.2% (range 9-41%) of prevalent ESRD patients; the balance was conventional thrice weekly in-centre or satellite HD. One of 17 (6%) programs had a combined HHD and PD population ≥40%, 4 of 17 (24%) had a combined home therapies proportion ≥30%, and 15 of 17 (88%) had a combined population ≥20%. Of patients receiving HHD, the median proportion (and range) receiving some form of NHD (6-8 hours on ≥3 nights per week) was 74% (24-94%), while a median of 4% (0-41%) received SDHD (1.5-3 hours on 6-7 days per week); non-NHD, non-SDHD dialysis prescriptions were also common in the home setting. Program 1 (graph) represents a suburban community dialysis centre, while program 3 represents an urban academic centre.



Conclusions: The predominant HHD modality in Canada is NHD. High uptake of HHD does not necessarily equate to poor PD prevalence; in fact, several programs with HHD uptake >10% also have high PD uptake suggesting that both home dialysis paradigms can successfully co-exist in both academic and nonacademic, urban and suburban settings.

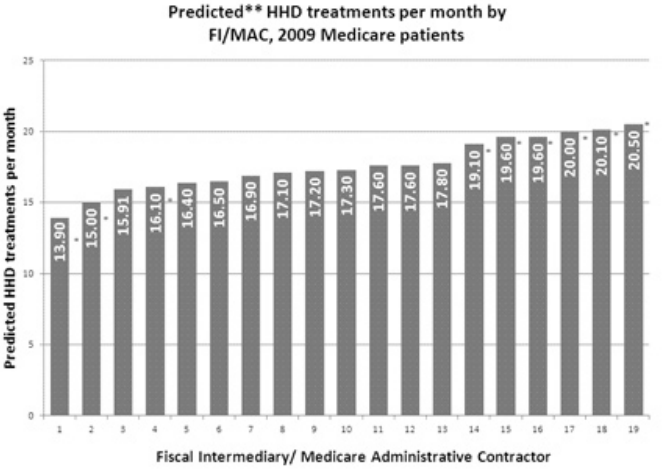
SA-PO2975

Frequency of Payments for More Than Thrice Weekly Dialysis for Home Hemodialysis (HHD) Richard Hirth,[1] Kathryn Sleeman,[1] John R.C. Wheeler,[1] Marc Turenne,[2] Wei Zhang,[1] Adam S. Wilk,[1] Joseph M. Messana.[1] *[1]Kidney Epidemiology & Cost Center, University of Michigan; [2]Arbor Research.*

Background: The limitation to three paid dialysis treatments weekly has been cited as a barrier to the diffusion of HHD, which is often performed on a daily basis. However, the regional fiscal intermediaries (FIs) and Medicare Administrative Contractors (MACs) that pay Medicare claims can authorize the payment of additional treatments based on medical necessity. It is unknown how often additional payments have been authorized and how this varies across FIs/MACs.

Methods: We identified all Medicare HHD patients in 2009 by FI/MAC. The average HHD patient had 17.3 paid treatments per month vs. 11.6 for In-center HD patients. Ordinary Least Square regression was used to define the association between HHD patient treatments per month and individual FIs/MACs active in 2009, adjusting for patient age, race, BMI and an extensive list of Medicare Claims derived comorbidities ,. FI/MACs with fewer than 100 HHD patient months were excluded.

Results: Most FIs/MACs already paid for more than the standard three weekly treatments for HHD in 2009. In addition, we observed substantial variation in average number of paid HHD treatments per month across the 19 FIs/MACs.



n=38,209 HHD patient months. * p<0.0001 vs FI/MAC#10. **OLS with patient HHD treatments/mo. as dependent variable and FI/MAC as independent variables, adjusted for patient demographics, and an extensive comorbidity list.. R. Sq. 0.246

Conclusions: Results of regression analysis suggest that only some of this variation in HHD treatment frequency is predicted by demographics and patient comorbidities. The FI or MAC responsible for administering dialysis facility claims is an independent predictor of number of paid HHD sessions, potentially contributing significantly to the variation in HHD practice.

Funding: Other U.S. Government Support

SA-PO2976

Survival of Patients Receiving Home Daily Hemodialysis: A Multinational Cohort Study Rita Suri,[1] Lihua Li,[1] Robert M. Lindsay,[1] Amit X. Garg,[1] Louise M. Moist,[1] Peter Austin,[2] Cécile Couchoud,[3] Ronald L. Pisoni,[4] Bruce M. Robinson,[4] Meaghan S. Cuerden,[1] Gihad E. Nesrallah.[1] *[1]U Western Ontario; [2]ICES; [3]Biomedicine Agency; [4]Arbor Research.*

Background: Increasing hemodialysis (HD) frequency from 3 to 6 times per week improves left ventricular mass and quality of life, but effects on survival are unknown.

Methods: We identified 177 patients from France, the US, and Canada in the International Quotidian Dialysis Registry, who received home daily HD ≥5 times/wk from 2001-2010. Using propensity-score based matching techniques, we matched 106 of these patients to 240 contemporaneous patients receiving in-center conventional, 3 times weekly HD in the Dialysis Outcomes and Practice Patterns Study. HD session times were <5 hrs. We compared mortality rates between groups using Cox proportional hazards regression. Because the proportional hazards assumption was not met, we divided the followup time into fixed periods and calculated hazard ratios (HR) for each.

Results: The daily group received 5.6±0.5 sessions/wk. Mean weekly treatment time was 16.1±4.8hrs (daily gp) and 11.5±1.3hrs (conv gp). After matching, there were no significant differences in baseline characteristics between groups, except more daily patients had fistulae (68%vs.55%), while more conventional patients had grafts (19%vs.5%). Mean age was 53±14, 71% were male, 32% had diabetes. During 668 patient-yrs, 59/346 patients died. There was a trend toward higher risk of death with home daily HD until 1 yr, after which time the risk was less than with in-center conventional HD.

HR of Death with Home Daily HD

Period	3ms	6ms	12ms	24ms	36ms
HR(95%CI)	2.0(1.0-4.2)	1.2(0.6-2.1)	0.67(0.3-1.3)	0.37(0.2-0.9)	0.27(0.1-0.8)

Conclusions: Compared to in-center conventional HD, the risk of death associated with home daily HD changed over time. Despite rigorous matching, it is possible that our results are affected by indication bias as we did not know reasons for daily HD initiation in this retrospective cohort. Previous studies have had similar limitations. As large RCTs of daily HD have not been feasible, well-conducted prospective studies are needed to better assess the effects of daily HD on survival.

SA-PO2977

Daily Hemodialysis (DHD) Improves Overall Quality of Life (QOL) and Physical Intimacy: Interim Results from the FREEDOM Study Michael A. Kraus,[1] Fredric O. Finkelstein,[2] Rachid Daoui,[3] Janice P. Lea,[4] Yoojin Lee,[5] Brigitte Schiller,[6] Isaac Teitelbaum,[7] Bertrand L. Jaber.[5] *[1]IU, IN; [2]Yale, CT; [3]Rubin, NY; [4]Emory, GA; [5]Tufts, MA; [6]Satellite, CA; [7]U Colorado, CO.*

Background: The FREEDOM study, an ongoing prospective cohort study investigating the clinical and economic benefits of DHD, has demonstrated improvements in various QOL measures following initiation of DHD, including SF-36, depressive symptoms, post-dialysis recovery time, sleep and restless leg symptoms.

Methods: In this *a priori* planned interim analysis, results of the following 3 special study questions (SSQ) from the QOL survey are reported on a 10-point Likert scale (0=worst, 10=best) for the Per Protocol (PP) and Intention-To-Treat (ITT) populations:

1) Considering all aspects of your life, physical, emotional, spiritual, and financial, how would you rate your overall QOL?

2) How satisfied are you with your degree of physical intimacy over the last 4 weeks?

3) If you were given a choice of changing back to the previous regimen you were receiving prior to DHD, how likely would you be to change? (0=extremely likely, 10=strongly opposed)

Results: Of the 299 enrolled pts, 165 completed 12-month f/u. Mean age was 53 yrs, 65% were male, 70% white, 58% used an AVF, 45% had diabetes and 26% CHF. Mean estimates (with 95% CI) of the PP analysis are shown below:

SSQ	Baseline score[1,2]	Month-4 score[1,3]	Month-12 score[2,3]	Global P value
Overall QOL	6.4 (6.0, 6.7)	7.3 (7.0, 7.6)	7.0 (6.6, 7.4)	<0.0001
Physical Intimacy	4.9 (4.3, 5.5)	6.1 (5.5, 6.7)	5.7 (5.1, 6.3)	0.0005
Likelihood of returning to prior dialysis regimen	8.1 (7.6, 8.7)	9.1 (8.7, 9.5)	9.1 (8.7, 9.5)	0.002

[1]All baseline vs. month-4 p≤0.003, [2]All baseline vs. month-12 p≤0.03, [3]All month-4 vs. 12 p>0.05 by ANOVA with Bonferroni correction.

Conclusions: In summary, pts initiating DHD reported sig. improvements in overall QOL and phys. intimacy at 4 & 12 mths. The ITT analyses demonstrated similar results. In the PP analysis, pts initiating DHD were clearly motivated and unlikely to consider returning to prior dialysis modality over 12 mths. These results support previous analyses demonstrating the QOL benefits of DHD.

Continual Improvement in Anemia Control beyond 1 Year of Nocturnal Home Hemodialysis with an Alternate Night Schedule Hon-Lok Tang,[1] Samuel K.S. Fung,[1] Ho Sing Joseph Wong,[2] Clara Poon,[1] Kwok Hong Chu,[1] William Lee,[1] Au Cheuk,[1] Ka Fai Yim,[1] Ka-Foon Chau,[2] Matthew K.L. Tong.[1] *[1]Division of Nephrology, Department of Medicine and Geriatrics, Princess Margaret Hospital, Hong Kong, China; [2]Renal Unit, Department of Medicine, Queen Elizabeth Hospital, Hong Kong, China.*

Background: Nocturnal home hemodialysis (NHHD) offers superior uremia clearance in patients with ESRD. This increased clearance is associated with a rise in hemoglobin (Hb) and reduction of erythropoietin (EPO) requirement, possibly by removing toxins that inhibit erythropoiesis. We previously demonstrated improvement in anemia and reduction of EPO requirement after 1 year of NHHD. This study aims to investigate whether these benefits will extend beyond 1 year of NHHD treatment.

Methods: Forty-three consecutive patients were started on NHHD in 2 dialysis centers between 2006 and 2011 with an alternate night schedule for 6-9 hours (3.5x/week). Hb, EPO dose, weekly spKt/V, iron saturation and serum ferritin at baseline before NHHD, at 12 and 24 month were retrospectively reviewed.

Results: Sixteen patients had completed NHHD for 24 months. Results were:

	Hb,g/dL (n=16)	P value	EPO dose,U/kg/week (n=15)*	P value
Baseline vs 24month	9.4±1.5 vs 11.8±2.6	<0.01	116.9±45.1 vs 40.6±40.2	<0.01
Baseline vs 12month	9.4±1.5 vs 11.5±2.0	<0.01	116.9±45.1 vs 62.6±57.5	<0.01
12month vs 24month	11.5±2.0 vs 11.8±2.6	0.552	62.6±57.5 vs 40.6±40.2	<0.05

* 1 patient did not require EPO at baseline

Hb increased significantly at 12 month and maintained at 24 month. However, the EPO dose requirement continued to decrease beyond 12 month with dosage significantly lower at 24 month. Five patients (33%) were able to be taken off EPO. Two of them stopped EPO beyond 12 month: 1 at 20 month and 1 at 24 month. Weekly spKt/V increased from 3.60±0.91 at baseline to 9.86±3.98 at 24 month (p<0.001, n=16). Iron indexes remained unchanged. Iron saturation was 27±10% at baseline vs 28±8% at 24 month (p=0.798, n=15) and serum ferrritin 805±586 pmol/L vs 586±428 pmol/L at 24 month (p=0.140, n=15).

Conclusions: Enhanced uremia clearance in NHHD results in continual improvement in anemia control with reduction of EPO requirement or cessation of EPO therapy beyond 1 year of NHHD treatment.

SA-PO2979

Effect of Frequent or Extended Thrice-Weekly Hemodialysis on Cardiac and Blood Pressure (BP) Parameters: A Meta-Analysis Paweena Susantitaphong, Ioannis Koulouridis, Nicolaos E. Madias, Bertrand L. Jaber. *Medicine, St. Elizabeth's Medical Center, Boston, MA.*

Background: Left ventricular hypertrophy is a risk factor for cardiovascular mortality in patients with chronic kidney failure. We conducted a meta-analysis to examine the effects of frequent (>3 sessions) or extended (>4 hours) thrice-weekly HD on cardiac and BP parameters.

Methods: Sources used to identify eligible studies included MEDLINE, Clinicaltrials.gov, and the Cochrane Central Register of Trials. We selected randomized controlled trials and single-arm studies, which included within patient comparisons, and examined the efficacy of frequent or extended thrice-weekly HD on cardiac parameters measured by echocardiography or MRI, and BP parameters. Random-effects model meta-analyses were used to compute changes in the outcomes of interest.

Results: 46 single-arm studies (1,159 pts) and 2 randomized controlled trials (296 pts) were identified. In an analysis of 23 study arms that assessed LVMI, frequent or extended thrice-weekly HD resulted in a significant improvement in LVMI (-32.8 g/m^2, 95% CI -41.4,-24.2, P<0.001). However, the test for heterogeneity was significant (I^2=82%; P<0.001). A similar but less pronounced net improvement in LVMI was observed in the 2 randomized trials (-7.4 g/m^2, 95% CI -11.2,-3.6, P<0.001). Other cardiac parameters displayed similar improvements, including LVM, LVSD, LVEDD, LVPW, IVS, LAEDD, and LVEF (Table).

Summary effect on other cardiac and BP parameters

Outcomes	Change (95%CI)
LVM (g)	-64.0 (-95.3,-32.6)
LVSD (mm)	-3.9 (-6.2,-1.5)
LVEDD (mm)	-4.3 (-5.7,-3.0)
LVPW (mm)	-1.1 (-1.6,-0.7)
IVS (mm)	-1.7 (-2.1,-1.3)
LAEDD (mm)	-3.8 (-6.2,-1.3)
LVEF (%)	5.4 (1.3,9.5)
SBP (mmHg)	-14.0 (-17.1,-11.0)
DBP (mmHg)	-7.0 (-9.0,-5.0)
MAP (mmHg)	-11.6 (-13.5,-9.6)
Anti-hypertensive drugs (No.)	-0.8 (-1.2,-0.5)

Finally, there was a significant decrease in SBP, DBP, MAP, and mean number of anti-hypertensive drugs (Table), and 54% of pts discontinued anti-hypertensive drugs.

Conclusions: Conversion from conventional thrice-weekly to frequent or extended thrice-weekly HD is associated with an improvement in LVMI and other cardiac and BP parameters, which may have a potential longterm cardiovascular benefit.

SA-PO2980

Nephrocystin-4 Is a Negative Regulator of Hippo Signaling Sandra Habbig,[1,2] Malte P. Bartram,[1] Roman-Ulrich Mueller,[1] Ricarda Schwarz,[1] Max C. Liebau,[1,2] Thomas Benzing,[1] Bernhard Schermer.[1] *[1]Renal Division, Department of Medicine and Center for Molecular Medicine Cologne, University of Cologne, Germany; [2]Department of Pediatrics, University of Cologne.*

Background: Nephronophthisis (NPH) is the most common genetic cause for endstage renal disease in children and adolescents. NPH is characterized by renal fibrosis and cyst formation, however in contrast to ADPKD the size of the kidneys is normal or even reduced. Although 11 different disease causing genes have been identified recently, there is only little known about the function of the related NPH-proteins (NPHP1-11).

Here we report that NPHP4 negatively regulates Hippo signaling. The Hippo pathway has recently emerged as a potent regulator of cell proliferation and organ size. NPHP4 directly interacts with LATS1, the central kinase of the pathway, and prevents the inactivation of the downstream effectors YAP and TAZ. In the presence of NPHP4, TAZ is released from 14-3-3 binding and translocates to the nucleus thereby promoting TAZ/TEAD-dependent pro-proliferative transcriptional activity. Consistently, knockdown of NPHP4 results in reduced transcription of TAZ/TEAD target genes and diminishes cell proliferation in human kidney epithelial cells and several tumour cell lines. Currently, we are investigating the influence of other nephrocystins on Hippo signaling.

Our data suggest that NPHP4 promotes cell proliferation through the control of Hippo signaling. Loss of NPHP4 in NPH patients might result in hyperactive Hippo signaling and reduced pro-proliferative transcriptional activity. These changes might be critical in the pathogenesis of NPH characterized by small-sized kidneys and atrophic tubular epithelium. In contrast, loss of Hippo signaling activity might be associated with polycystic kidney diseases characterized by massive proliferation such as ADPKD.

3-D-Spheroid Defects in NPHP Knockdown Cells Are Rescued by the Somatostatin Agonist Octreotide Amiya K. Ghosh,[1] Toby W. Hurd,[1] Friedhelm Hildebrandt.[1,2] *[1]Department of Pediatrics, University of Michigan, Ann Arbor, MI; [2]Howard Hughes Medical Institute, University of Michigan, Ann Arbor, MI.*

Background: Ciliopathies are a clinically and genetically heterogeneous group of diseases that exhibit shared clinical phenotypes, including renal cysts, retinal degeneration, mental retardation and obesity. Nephronophthisis (NPHP) is one such ciliopathy characterized by kidney cysts at the cortico-medullary border. Among the 10 different disease-causing genes (*NPHP1-NPHP10*), mutations in *NPHP3, NPHP6* or *NPHP8* cause the ciliopathy variants of NPHP, Joubert syndrome and Meckel Syndrome.

In this study we hypothesized that loss of function of *NPHP3, NPHP6* or *NPHP8* leads to morphological defects in a 3-dimentional (3-D) renal cell (IMCD3) culture model by either lack of cilia formation and/or cell polarity defects.

Methods: Stable shRNA knockdown cells of *NPHP3, NPHP6* and *NPHP8* were generated using a retroviral transduction method. Knockdown cell lines were examined in 3-D spheroid culture followed by rhodamine-phalloidin staining to assess spheroid architecture.

Results: We observed significantly higher percentages of abnormal spheroids for all three stable cell lines (NPHP3; 72%, NPHP6; 80% and NPHP8; 50%) compared to control shRNA cells (25%). Recent studies indicated that the somatostatin receptor agonist octreotide decreased cAMP level and inhibited cysts formation in PKD model systems. In our study, we observed that treatment of knockdown spheroids with octreotide (2mM) reduced the percentage of abnormal spheroids to 30% (*NPHP3*), 36% (*NPHP6*), and (*NPHP8*) 35% (*NPHP8*) respectively, whereas vehicle control abnormal spheroids were 66% (*NPHP3*), 91% (*NPHP6*), 60% (*NPHP8*).

Conclusions: This study reveals that the lack of NPHP3, NHPH6 or NPHP8 leads to cell polarity defects resulting in spheroid abnormalities which can be rescued by inhibiting cAMP levels with octreotide treatment. Our study confirms that manipulation of cAMP-pathway could be one of the therapeutic approaches in treating patients with kidney cysts.

Ciliated Cell-Type Specific Functions of Cep290/NPHP6 Christina Austin,[1] Iain A. Drummond.[1,2] *[1]Department of Genetics, Harvard Medical School, Boston, MA; [2]Nephrology Division, Massachusetts General Hospital, Charlestown, MA.*

Background: Mutations in the centrosomal protein Nephrocystin 6 (NPHP6/Cep290) are implicated in a broad spectrum of genetic disorders featuring polycystic kidneys in addition to pleiotropic ciliopathy phenotypes. A recent study finds that Chlamydomonas reinhardtii Cep290 mutants have truncated cilia with abnormal protein content, which was attributed to defective protein gating at the basal body transition zone. Nevertheless, cilia structural defects have not been observed in vertebrate models of Cep290 loss of function.

Methods: We set out to determine whether the Cep290 protein is, in fact, required for vertebrate ciliogenesis using the zebrafish Danio rerio as a model system particularly amenable to the study of cilia in vivo. Cilia of the photoreceptors, pronephros, and Kupffer's vesicle (KV) were characterized after disruption of Cep290 expression by injection of antisense morpholino oligonucleotides.

Results: In contrast to IFT protein mutants, we find that a subset of single cilia, which includes sensory cilia, are truncated in Cep290 morphants, while the length of motile, multiciliated bundles is unchanged. Despite the apparent restriction of cilia structural changes to singly ciliated cells, immunostaining with anti-zebrafish Cep290 antibody revealed that the protein localizes to the basal bodies of all ciliated cell types in the zebrafish embryo. Furthermore, immunoelectron microscopy demonstrated that Cep290 localization is not restricted to the transition zone but also accumulates on the basal body and ciliary rootlet, implying that Cep290 may play roles independent of protein entry into the cilium.

Conclusions: In summary, we have characterized a vertebrate Cep290 loss-of-function model that implicates the basal body-localized protein, Cep290, in the structural maintenance of a select class of cilia.

Abelson Helper Integration Site-1 Knockdown in Zebrafish Models the Ciliopathy Joubert Syndrome and Is Associated with Altered Left-Right Axis Determination Roslyn Jane Simms, Lorraine Eley, Ann Marie Hynes, Colin Miles, Bill Chaudhry, John A. Sayer. *Nephrology, Institute of Genetic Medicine, International Centre for Life, Newcastle upon Tyne, United Kingdom.*

Background: Joubert syndrome and related disorders (JSRD) are autosomal recessive cerebello-oculo-renal syndromes, associated with cystic kidney disease such as nephronopthisis (NPHP) in over 20% of cases. Mutations in *Abelson helper integration site-1* (*AHI1*) are a leading cause of JSRD and similar to all other cystic kidney diseases, the protein product is expressed in the primary cilium/basal body. We were interested in evaluating the effect of *ahi1* knockdown on cilia in zebrafish (ZF) models of JSRD.

Methods: Antisense morpholino oligonucleotides (MO) designed to block ZF *ahi1* were injected into *cldnb*-lyn-GFP and *cmcl2*-GFP transgenic ZF embryos. *Cldnb-lyn*-GFP embryos were fixed at 8-10 somites for Kupffer's vesicle (KV) analysis and 72-96 hours post fertilisation (hpf) to evaluate for pronephric cysts and neuromasts of the posterior lateral line (PLL). Following immunofluorescence using anti-acetylated tubulin, cilia were studied. Left-right patterning (initiated and regulated by KV) was assessed by scoring cardiac looping in *cmcl2*-GFP embryos at 48-56 hpf.

Results: *ahi1* knockdown in ZF causes abnormal development of KV with an absence of cilia in 92% of embryos. Cardiac looping was reversed in 68% of a*hi1* injected embryos and there was a reduction in the number of neuromasts in the PLL, with loss of kinocilia. *ahi1* morphants display ciliopathy phenotypes including: curved body axis; hydrocephalus; developmental retinal and rudimentary ear anomalies. Cilia remain present in the distal pronephros, however there is dilatation of the cloaca in a*hi1* morphants.

Conclusions: In ZF models of human JSRD, a*hi1* knockdown is associated with several developmental cilial defects and subsequent aberrant organogenesis. The loss of cilia from KV and reduced formation of neuromasts and kinocilia in the PLL, suggests a role for *ahi1* in both ciliogenesis and planar cell polarity signalling.

SA-PO2984

The Deglutamylase ccp5 Is Essential for the Structural and Functional Integrity of Zebrafish Pronephric Cilia Narendra H. Pathak,[1] Christina Austin,[2] Iain A. Drummond.[1,2] *[1]Nephrology Division, Massachusetts General Hospital, Charlestown, MA; [2]Department of Genetics, Harvard Medical School, Boston, MA; [3]Department of Pathology, Massachusetts General Hospital, Charlestown, MA.*

Background: Cilia are microtubule-based organelles that mediate diverse functions in kidney epithelial cells and other organs. Ciliary axonemal microtubules are rich in posttranslational tubulin polymodifications, glutamylation and glycylation. Glutamylation is required for interactions of microtubules with their associated proteins. The equilibrium in microtubule glutamylation levels is dynamically maintained by opposing activities of Ttll (glutamylating) and recently discovered Ccp (deglutamylating) enzymes. Hypo as well as hyper glutamylation of axonemal microtubules disrupts structural integrity and motility of cilia. Our earlier work has highlighted an essential role for the glutamylating enzymes, Ttlls 1, 3 and 6 in cilia. However little is known about deglutamylases that function in cilia.

Methods: ccp5 expression was assessed by in situ hybridization. Morpholino knockdown of ccp5 was conducted in zebrafish embryos and larvae and effects on axoneme glutamylation and cystic phenotypes in ccp5 MO and fleer mutants were examined using confocal immunofluorescence and histology.

Results: We show here that the deglutamylase encoded by ccp5 is expressed in ciliated tissues and that its inactivation in wildtype zebrafish produces characteristic ciliopathic phenotypes and structurally defective B-tubules in microtubules of the ciliary axoneme. Our earlier work identified a role for the zebrafish TPR repeat protein Fleer in regulation of cilia tubulin glutamylation and glycylation. Interestingly, we show that knockdown of ccp5 in the fleer mutant partially restores glutamylation to otherwise hypoglutamylated axonemes and mitigates the severity of pronephric cysts.

Conclusions: Ccp5 is an essential regulator of axoneme tubulin glutamylation. Rescue of tubulin glutamylation and suppression of cyst formation by ccp5 knockdown in fleer mutants suggests that the Fleer protein may act as a negative regulator of Ccp5.

SA-PO2985

The Centriolar Satelite Protein Wtip Regulates Cilia Mediated Processes by Modulating Non-Canonical Wnt Signaling Tomoko Obara. *Cell Biology, University of Oklahoma Health Science Center, Oklahoma City, OK.*

Background: Defects in cilia and basal bodies/centrosomes are linked to human cystic kidney diseases (ciliopathies). However, pathological mechanisms leading to kidney cyst formation still remain unknown and no effective treatments are available.

Methods: We and others established zebrafish as a powerful model system to study the physiological roles of cilia, basal bodies/centrosomes related human ciliopathies genes in vivo.

Results: During our studies, we unexpectedly discovered that zebrafish Wtip protein localizes to the basal bodies/centrosomes. However, the precise in vivo function of the Wtip is still unknown. The wtip gene knock down in zebrafish resulted in pronephric cyst accompanied with cloaca occlusion, hydrocephalus, body axis curvature, and heart edema, a phenotype similar to pkd2 knockdown related to human ciliopathies. These phenotypes were specific since they could be completely rescued by co-injection of zebrafish wtip mRNA. We also showed that early defects in wtip knockdown could be explained by mitotic defects including centrosome, spindle formation and centrosome migration to the apical cell surface. Moreover, we discovered that phenotype caused by loss of Wtip implies a possible involvement of Wtip in planar cell polarity (PCP) modulating non-canonical Wnt signaling. Wtip is required to maintain PCP and cilia protein trafficking defects for both Polycystin-2 and Ift88 by interacting with core PCP Vangl2. To further understand the function of Wtip in zebrafish embryos, we performed a yeast two-hybrid screening with full-length zebrafish wtip as a bait and identified zebrafish lats2. Lats2 is a Serine/threonine-protein kinase, which is part of the Hippo signaling pathway. Intriguingly, our preliminary data showed that knockdown of lats2 in zebrafish resulted in same phenotypes as that seen in the wtip knockdown.

Conclusions: Based on our preliminary data, we hypothesized that Wtip is a new player in ciliopathies, which interacts with Lats2 and regulates PCP and cilia protein trafficking by interacting with core PCP Vangl2. Our studies in zebrafish demonstrated for the first time in a non-mammalian vertebrate the function of Wtip as a model of ciliopathies.

The von Hippel-Lindau Tumor Suppressor Is Required for Proximal Tubule/Glomerulus Integrity during Zebrafish Development and Regulates Renal Endosomal Trafficking Rachel H. Giles,[1,2] Ellen Van Rooijen,[2,3] Ive Logister,[2,3] Emile E. Voest,[2] Stefan Schulte-Merker.[3] *[1]Nephrology and Hypertension, University Medical Center Utrecht, Netherlands; [2]Medical Oncology, University Medical Center Utrecht, Netherlands; [3]Hubrecht Institute, Utrecht, Netherlands.*

Background: The von Hippel-Lindau (VHL) tumor suppressor gene is commonly mutated in hereditary and sporadic clear cell renal cell carcinoma (ccRCC).

Methods: We generated two stable zebrafish lines with null alleles of vhl and no detectable protein. Because the pronephros is externally visible in transparent zebrafish embryos, we could observe transformative events in situ over time. Analysis of the kidney phenotype was performed by immunohistochemistry, confocal microscopy in living fish and electronic microscopy. Human cell cultures from VHL-/- renal cell carcinoma and epithelial renal cells knocking down endogenous VHL by siRNA were recapitulated the in vivo phenotype.

Results: Here, we report that loss of vhl in zebrafish embryos results in severe pronephric abnormalities. In vhl mutants the glomerulus is enlarged, the Bowman space is widened and dilated cxcr4a-positive capillary loops are observed. While siblings exhibit a single layer of cuboidal cells comprising the proximal tubule, vhl-/- tubule cells are irregular with a alveolar appearance. Ultrastructural analysis revealed that mutant cells accumulate excessive amounts of vesicles that are variable in size and electron density. Since glomerular filtration and endocytosis in vhl-/- proximal tubule cells is not impaired, this might reflect a defect in exocytosis. VEGF receptor inhibition confirms that neovascularization of the vhl-/- proximal tubule does not obviously contribute to the aberrant cell morphology. Live cell imaging and vesicle tracking experiments suggest that human kidney epithelial cells lacking VHL, either derived from a renal cell carcinoma or upon acute siRNA or shRNA knock-down of VHL likewise accumulate Rab5, Rab7 and Rab11 endosomes and demonstrate defective transport.

Conclusions: Our data indicate that vhl is required to maintain pronephric tubule and glomerulus integrity during zebrafish development possibly through endosome homeostasis.

SA-PO2987

Functional Analysis of Renal Ciliopathy Disease Alleles in 3D Spheroid Culture Rachel H. Giles,[1] Liyun Sang,[2] Peter K. Jackson.[2] *[1]Nephrology and Hypertension, University Medical Center Utrecht, Netherlands; [2]Cell Regulation, Genentech, South San Francisco, CA.*

Background: Renal cystic diseases such as Bardet-Biedl, nephronophthisis (NPHP), Joubert, and Meckel-Gruber syndromes are phenotypically and genetically overlapping diseases displaying variable mental retardation, blindness, cerebellar ataxia, and renal anomalies. Genes known to be mutated in these disorders often code for proteins associated with cilia and/or basal bodies.

Methods: Standard 2D immunofluorescence often does not reveal clear effects on renal cilia when we reduced cellular levels of a panel of 21 ciliopathy-associated proteins by siRNA knockdown, which were validated by qPCR. To improve the sensitivity of our readout we generated a more physiological setting by growing siRNA-treated murine IMCD cells in a 3D matrix consisting of matrigel and collagen.

Results: We observe reduced apical-basal polarity, lumen irregularities, and small but significant changes in cilia numbers or length, depending on the target. Reconstitution experiments with a subset of the proteins using siRNA-insensitive alleles confirmed specificity of the effects in all cases tested. Live cell imaging of the vasopressin receptor in these 3D spheroids reveals functional transport of AQ2 to the apical membrane upon exposure to arginine vasopressin. Furthermore, IMCD3 stable lines expressing ciliary GFP- or RFP-labeled serotonin receptor 5-HT6 grown in 3D spheroids revealed ciliary dynamics including rubbing, membrane shedding, and extended contact with debris in the lumen. Chimeric GFP- and RFP-spheroids can be generated such that one cell type has been treated with siRNA, but is surrounded by wild-type sister cells. We demonstrate this principle by evaluating the cell-autonomous effects of siRNA of Nphp1, Nphp2, Bbs1, Bbs2, Kif3A, or Mks1 with real-time imaging of 3D spheroid cultures.

Conclusions: We conclude that this assay is a robust and sensitive read-out for loss of function or hypomorph mutations involving ciliopathy disease alleles.

Kinesin Family Member 12 Localizes to Primary Apical Cilium and Correlates with Structural and Developmental Expression Patterns of Key Cystogenic Genes Michal Mrug,[1] Bruce Aronow,[2] Lisa M. Guay-Woodford.[1] *[1]University of Alabama at Birmingham, AL; [2]Cincinnati Children's Hospital, Cincinnati, OH.*

Background: We have mapped a major modifier of polycystic kidney disease (Mpkd) interval to mouse chromosome (Chr) 4 using a large [C57BL/6J (B6)-*Cys1*$^{cpk/+}$ x CAST/Ei] F1 intercross and determined that this interval contains at least three individual loci that modulate progression of cystic kidney disease (*Mpkd1-3*).

Methods: To validate cystogenesis-promoting effects of the *Mpkd1-3* loci, we crossed B6-*Cys1*$^{cpk/+}$ mice with congenic mouse lines carrying either the entire CAST/Ei-derived *Mpkd1-3* interval or its *Mpkd1-2* segment on a B6 background. Resulting positional candidate genes for these loci were further evaluated using analyses based on gene and protein molecular features, mouse strain SNP haplotypes, mutational analyses, NIDDK GUDMAP developing kidney gene expression atlas profiling, and candidate gene product immunolocalization.

Results: CAST/Ei-derived *Mpkd1-3* and a *Mpkd1-2* intervals strongly modified cystic disease progression. Relative strength of independent dominant cystogenic effects associated with CAST/Ei-derived *Mpkd1-2* interval allowed the use of congenic recombinants to fine map the *Mpkd2* locus to <14 Mbp interval with 69 RefSeq genes. Among them, 32 were expressed in kidney and liver. Of these, 16 contained non-synonymous single nucleotide polymorphisms. The latter subset included *Kif12*. Among the positional *Mpkd2* candidates only *Kif12* contained an apparently functional coding variation (a B6-associated deletion in catalytic domain of kinesin motor). In addition, only *Kif12*-encoded protein, kinesin family member 12, was present in polycystin-1 positive urinary exosome-like vesicles together with proteins encoded by *Cys1*, *Pkhd1* and *Pkd2*. Moreover, we have demonstrated that like most cystogenic proteins kinesin family member 12 localizes to primary apical cilium. Finally, we have shown that *Kif12* expression correlates with developmental and structural distribution profiles of *Cys1*, *Pkhd1* and *Hnf1b*.

Conclusions: Taken together, the above data point to *Kif12* (*Mpkd2*) as a novel component of a pathway capable of modifying the severity of recessive polycystic kidney disease.

Renal Epithelial Cells Lacking Primary Cilia Have Reduced Sensitivity to a Hyperosmolal Microenvironment Bradley P. Dixon, Brian J. Siroky, Lu Lu, John J. Bissler. *Division of Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Defects in primary cilia have been linked to cystic kidney diseases, and may play a role in certain cancers. Recent evidence suggests that cilia sense changes in osmolality through activation of transient receptor potential vanilloid (TRPV) channels. Activation of TRPV1, a sensor of hyperosmolality, also activates the ATM-chk2-p53 DNA damage response pathway, causing cell cycle checkpoint activation and arrest. Defective cilia may therefore lead to aberrant cellular responses to osmotic stress in the hyperosmolal renal microenvironment. We sought to characterize the effects of gradual adaptation to hyperosmolal microenvironments in renal epithelial cells that either have, or lack, functional cilia.

Methods: The 176-5 renal epithelial cell line contains a floxed Kif3a gene (a kinesin motor required for ciliogenesis) and a tamoxifen-inducible Cre recombinase, and was cultured both without tamoxifen, and with tamoxifen to conditionally delete Kif3a (176-5Δ cells). These cells were gradually adapted to 450mOsm/kg and 600mOsm/kg with NaCl or urea, or maintained under control conditions. Cell proliferation was measured by crystal violet DNA binding assay. Activation of signaling pathways was measured by western blot.

Results: Cilia-proficient 176-5 cells experienced arrest of cell proliferation upon adaptation to hyperosmolal NaCl or urea, whereas cilia-deficient 176-5Δ cells continued to proliferate in spite of hyperosmolal adaptation. Expression of PCNA, a marker of cell proliferation, was unchanged in osmotically adapted 176-5Δ cells, whereas 176-5 cells demonstrated a reduction in PCNA under hyperosmolal conditions. Interestingly, activation of p53 was not present in either cell following adaptation to hyperosmolal conditions.

Conclusions: These results indicate that cilia are required for reduction in cell proliferation following adaptation to hyperosmolal conditions, and this reduction appears to be ATM-independent. Further studies are needed to determine the role TRPV1 plays in the transduction of the hyperosmolal microenvironment to cell cycle arrest.

Loss of the Primary Cilia Leads to Elevated Activity of the Disintegrin Metalloenzyme ADAM17 Monika Gooz, May Y. Amria, Yujing Dang, Binlin Song, P. Darwin Bell. *Medicine, Medical University of South Carolina, Charleston, SC.*

Background: Epidermal growth factor receptor (EGFR)-dependent signaling pathways are among the most important regulatory circuits that induce and maintain cellular proliferation. In polycystic kidney disease (PKD) abnormal expression\function of EGFR and its substrate growth factors have been described. Since ADAM17 is the main sheddase enzyme responsible for activation of EGFR ligands, we investigated whether primary cilia dysfunction leads to increased ADAM17 activity, which in turn maintains an autocrine signaling loop resulting in the proliferative phenotype found in PKD.

Methods: We used a tamoxifen-inducible Cre recombinant adult mouse model of autosomal recessive PKD that had the conditional floxed allele for the *Ift88*/*Tg737* gene, a component of the primary cilia.

Results: We observed significant cyst development in cilia (-) animals compared to cilia (+) animals. There were no significant differences in overall ADAM17 expression using whole kidney lysates from cilia (+) compared to cilia (-) mice by Western blot. However, using immunohistology, there was intense ADAM17 staining in the epithelium that lined cystic structures in cilia (-) mice. This staining was localized mainly to the apical surface of these cells. In cilia (+) kidneys, ADAM17 staining was distributed more evenly across apical and basolateral membranes of epithelial cells. Interestingly, we observed strong ADAM17 staining in the primary cilia. Since cyst development is localized mainly to the collecting duct, we next used the cilia (-) and cilia (+) collecting duct cell lines PCDNA and BAP2 originating from the orpk mouse (*Itf88* hypomorph) to compare ADAM17 activity. Using a fluorogenic substrate we observed increased ADAM17 activity in cilia (-) cells. Phorbol ester (PMA) treatment elevated ADAM17 activity by 2-fold in cilia (+) cells but, interestingly, PMA-induced ADAM17 activity was attenuated in cilia (-) cells.

Conclusions: We conclude that in PKD, ciliary dysfunction induces localized ADAM17 activity in the kidney, resulting in continued up-regulation of EGFR activity and maintenance of the proliferative phenotype of cystic epithelium.

Expression Patterns of Joubert Syndrome Genes during Development Ann Marie Hynes, Yuzhu Cheng, Jennifer Whitehead, Lorraine Eley, Roslyn Jane Simms, Colin Miles, Susan Lindsay, John A. Sayer. *Institute of Genetic Medicine, Newcastle University, Newcastle upon Tyne, Tyne and Wear, United Kingdom.*

Background: Joubert syndrome (JBTS) is an inherited ciliopathy leading to a cerebellar-retinal-renal syndrome. Recent genetic advances have allowed positional cloning and identification of several JBTS genes. AHI1 encodes Jouberin and CEP290 (alias NPHP6) encodes nephrocystin-6. Mutations in AHI1 account for ~12% of patients with JBTS and mutations in CEP290 account for ~7% of patients with JBTS.

Methods: Using human embryonic and fetal tissue from the MRC/Wellcome Trust-funded Human Developmental Biology Resource (www.hdbr.org), we reveal an early

onset neuronal / retinal / renal expression pattern for AHI1 and CEP290 which persists throughout development.

The expression profile of CEP290 during development was compared directly to that of Cep290 by making use of a β-geo reporter gene, being placed under transcriptional control in Cep290+/LacZ transgenic mice. X-gal staining of tissue in adult and embryos was performed.

Results: AHI1 and CEP290 expression was abundant in the developing forebrain, especially the ventricular zone and in the neural retina and throughout the developing hindbrain.

AHI1 and CEP290 expression during human nephrogenesis revealed that AHI1 and CEP290 transcripts are abundant in both the developing mesonephros and metanephros. Developing glomeruli, tubules and collecting ducts strongly expressed AHI1 and CEP290.

In Cep290+/- animals, specific X-gal staining representative of Cep290 expression was observed in the brain, retina, nasal epithelium and renal tissues.

Conclusions: These data support a role for AHI1 and CEP290 in multiple organs throughout development and explain the wide phenotypic spectrum of JBTS secondary to AHI1 and CEP290 mutations in man.

α-actinin4 Localizes to the Basal Body in Collecting Duct Cells Robert J. Kolb,[1] P. Darwin Bell.[2] *[1]Pediatrics, Medical University of South Carolina, Charleston, SC; [2]Medicine, Medical University of South Carolina, Charleston, SC.*

Background: Primary cilia are microtubule projections from basal body anchored below the surface of renal cells. Evidence suggests cilia along the nephron function as a flow sensor. Cilia signaling events are associated with the cell cycle and growth, events leading to the development of a polarized apical and basolateral membrane through the organization of the cytoskelton Numerous reports suggest a link between dysfunctional cilia of the collecting duct and Polycystic Kidney Disease.

Methods: Coimmunoprecipitation experiments with a specific antibody to γ-tubulin, a basal body component, helped identify potentially novel basal body components. To monitor changes in BB composition in a PKD cell model, Western Blot analysis was used to to determine cellular expression of proteins known to localize to the basal body in comparison to our candidate proteins in CD cell lines with normal length cilia and in a cell line with stunted cilia. We confirmed potential changes in localization and expression of these basal body proteins by immunofluorescence in both cell types.

Results: We provide novel evidence for α-actinin4 localization to the basal body in normal collecting duct cells. Coimmunopreciption of γ-tubulin revealed α-actinin4 and acetylated α-tubulin are in a complex. To determine if α-actinin4 was bound to a bona fide ciliary protein, a polaris antibody was used. This result shows acetylated α-tubulin but not α-actinin4 binds to polaris. Immunofluorescent labeling of the basal body revealed colocalization of α-actinin4 and acetylated α-tubulin, confirming our co-IP study.

Conclusions: Our data suggests α-actinin4 binds to the basal body but not to the protein polaris. To our knowledge, this is the first report of α-actinin4 binding to basal bodies belonging to non-motile cilia. Our current hypothesis is α-actinin4 links the sub-apical actin ring to the microtubule cytoskelton and the basal body. Considering the role for calcium in cilia signaling events, plus membrane vessicle trafficking and insertion, the calcium binding protein α-actinin4 is a potential candidate for future studies on cellular differentiation, cilia and PKD.

PAR6γ, a New Interaction Partner of PLCε1/NPHS3, Is Required for Renal Glomerulogenesis in Zebrafish Embryos Weibin Zhou,[1] Shazia Ashraf,[1] Friedhelm Hildebrandt.[1,2] *[1]Pediatrics and Human Genetics, University of Michigan, Ann Arbor, MI; [2]Howard Hughes Medical Institute.*

Background: Steroid resistant nephrotic syndrome (NS) is a malfunction of the kidney glomerular filter that leads to proteinuria, hypoalbuminemia, edema, and renal failure. Mutations in the *phospholipase C epsilon 1* (*PLCE1*) have been associated with SRNS manifesting diffuse mesangial sclerosis (DMS) and focal segmental glomerulosclerosis (FSGS). To understand the pathogenic role of PLCE1 in NS, we have identified a number of new interaction partners of PLCE1, including PAR6 through proteomic analyses following GST pulldown.

Methods: To test whether PAR6γ plays a role in normal glomerular development, we characterized a zebrafish mutant of *pard6gb*, which contains a non-sense mutation at AA position 63 in the zebrafish ortholog of PAR6gb (2). The mutated protein partially lacks the PB1 domain (aPKC-interating) and completely deletes the C domain (cdc42-interating) and the PDZ domain (Par3-interacting).

Results: Using a transgenic zebrafish line expressing GFP under the control of zebrafish podocin promoter, we showed by confocal microscopy that the pronephric glomeruli in pard6gb$^{-/-}$ embryos are morphologically abnormal. Examination of the developing glomeruli using *podocin* and *wt1a* as markers revealed that the developing primordia in pard6gb$^{-/-}$ embryos failed to reach the midline of the embryo during the morphogenesis of the pronephric glomeruli.

Conclusions: Our study of the loss-of-function *pard6gb* mutant in zebrafish demonstrated that PAR6gb plays an essential role in normal glomerular development. Given its interaction with PLCE1, loss of cell polarity may be underlying the DMS phenotypes that result from loss of PLCE1 function.

Generation and Analyses of AQP11 BAC Transgenic Mice Yuichi Inoue,[1] Eisei Sohara,[1] Katsuki Kobayashi,[2] Tatemitsu Rai,[1] Kenichi Ishibashi,[3] Sei Sasaki,[1] Shinichi Uchida.[1] *[1]Nephrology, Tokyo Medical and Dental University, Bunkyoku, Tokyo, Japan; [2]Division of Molecular Genetics, Clinical Research Center, Chiba-East National Hospital, Chiba, Japan; [3]Medical Physiology, Meiji Pharmaceutical University, Kiyose, Tokyo, Japan.*

Background: Aquaporin 11 (AQP11) belongs to superaquaporins since it has Asn-Pro-Cys (NPC) motif instead of the typical NPA motif. We previously reported that the disruption of AQP11 gene in mice resulted in polycystic kidneys following vaculolization of the proximal tubular cells. However, mechanism of the cyst formation and the vaculolization has not yet been clarified partly because of lack of an antibody good for detecting endogenous AQP11 in mouse tissues.

Methods: To enable the analyses of AQP11 in mice at the protein level, we decided to generate AQP11 BAC transgenic mice that expresses AQP11 tagged with 3xHA sequences at its N-terminus. By injecting the transgene containing whole exons of mouse AQP11 with its promoter region into fertilized eggs of C57BL/6J mice, we could obtain seven lines of transgenic mice with different copy numbers.

Results: In two lines carrying three and ten copies of the transgene respectively, we first performed immunofluorescence in the kidney, and found that 3xHA-AQP11 was mainly localized in the cytoplasm of proximal tubules. Double immunofluorescence with organelle markers revealed that 3xHA-AQP11 was partially co-localized with KDEL, an ER marker, suggesting that AQP11 is an aquaporin of intracellular organelles. In addition to kidney, we investigated the expression of AQP11 in other organs. Immunoblots of various mouse organs with anti-HA antibody revealed a single 27kDa band in brain, liver, and testis, which is consistent with the previous Northern blot of AQP11. Moreover, we detected abundant 3xHA-AQP11 in thymus, spleen, stomach, small intestine and colon, which has not been identified before.

Conclusions: Thus, we clarified in vivo intracellular localization and tissue distribution of AQP11. The AQP11 transgenic mice will be a useful tool to clarify the physiological role of AQP11 as well as the pathogenesis of polycystic kidney in the AQP11 knockout mice.

CFTR Is Highly Expressed in the Cyst-Lininng Epithelial Cells of the AQP11 Knockout Mouse Kidney Katsuki Kobayashi,[1] Shinichi Uchida,[2] Sei Sasaki.[2] *[1]Division of Molecular Genetics, Clinical Research Center, Chiba-East National Hospital, Chiba City, Chiba, Japan; [2]Department of Nephrology, Tokyo Medical and Dental University, Bunkyo-ku, Tokyo, Japan.*

Background: AQP11 knockout mouse suffers from polycystic kidney disease and dies of end-stage renal failure at the weaning stage of the neonatal development. A large number of studies have established that the aberrant cell proliferation of the cyst epithelial cells and the abnormal secretion of fluid into the cyst cavity are the essential mechanisms of the cyst formation and growth in the polycystic kidney disease. We have previously reported that cell proliferation induced by ER stress is involved in the cystogenesis of the AQP11 knockout mouse. In this study we examined the cystic fibrosis transmembrane conductance regulator (CFTR) Cl^- channel, supposed to be the channel playing the central role in the fluid secretion, in the AQP11-null mouse kidney.

Methods: To elucidate the expression we stained the wild-type mouse and AQP11 knockout mouse kidneys with the anti-CFTR antibody, produced in rabbit, affinity-isolated (HPA021939, Sigma-Aldrich, St. Louis, MO). For the functional test we subcutaneously administered the CFTR inhibitor (CFTR(inh)-172, Sigma-Aldrich, St. Louis, MO) to the AQP11-deficient mouse for one week starting at the postnatal day 14 (5 mg/kg of body weight/day).

Results: Immunohistochemistry using the specific antibody against the CFTR protein displayed that CFTR was expressed in the proximal tubule cells deeply located in the cortex of the wild type mouse and in the mutant mouse CFTR was markedly expressed in the cyst-lining epithelial cells. This result prompted us to administer the CFTR inhibitor to AQP11 knockout mouse in order to investigate its effect on the cyst growth. Subcutaneous administration of the CFTR inhibitor, however, produced no significant effect on the cyst growth in the AQP11 knockout mouse.

Conclusions: These results collectively suggest that CFTR could function as the main channel via which chloride ion is secreted into the cyst cavity in the AQP11 knockout mouse, but further experiments are needed to determine its significance in the cystogenensis.

P-Glycoprotein Expression and Function in Cystinotic Proximal Tubular Cells Elena N. Levtchenko,[1] Karen Peeters,[1] Martijn J. Wilmer,[2] Rosalinde Masereeuw.[2] *[1]Dept of Pediatric Nephrology/Laboratory for Pediatrics, KULeuven, Leuven, Belgium; [2]Dept. of Pharmacology and Toxicology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.*

Background: P-glycoprotein (P-gp) is an ATP-dependent organic cation transporter localized on the apical membrane of the proximal tubules, that plays a role in the efflux of endogenous waste products and xenobiotics into urine. Studies in mice deficient for P-gp showed proximal tubular dysfunction and ATP deficiency combined with swollen mitochondria, resembling the phenotype of patients with cystinosis. We now have investigated whether the proximal tubular efflux transporter P-gp is affected in cystinosis.

Methods: We used conditionally immortalized (ci) proximal tubular cells (ciPTEC) obtained from urine from cystinotic patients and controls. ciPTEC were cultured to determine P-gp expression by Western blot and P-gp gene expression was assessed by qPCR. P-gp-mediated transport was measured by using the fluorescent P-gp substrate calcein in the presence and absence of the P-gp-inhibitor PSC833. Additionally, the effect of the cystine depleting drug cysteamine on transport activity was determined by the calcein-assay.

Results: The activity of P-pg, in presence or absence of PSC833, in control cell lines is comparable to the activity in cell lines of cystinotic patients. Cysteamine depletes cystine acculumation in cystinotic cell lines and had a stimulatory effect on P-gp activity. PO_4 uptake was determined in cystinotic and control ciPTEC and was decreased in cystinotic cells. The uptake was sodium-dependent and in the majority of the cells and conditions tested, both PSC833 and cysteamine (pre)incubation resulted in significant decreased uptake of phosphate.

Conclusions: Inhibition of P-gp activity in ciPTEC resulted in decreased uptake of phosphate comparable to the phenotype of P-gp deficient mice and to that of patients with cystinosis. Although cysteamine depleted cystine accumulation in cystinotic cells and increased P-gp activity, it inhibited phosphate uptake in ciPTEC. This observation is compatible to the persistence of renal Fanconi syndrome in vivo under cysteamine therapy and requires further study.

SA-PO2997

Pathology and Clinical Manifestations in Patients with Uremic Tumoral Calcinosis Undergoing Hemodialysis Rikako Hiramatsu, Keiichi Sumida, Masayuki Yamanouchi, Yoshifumi Ubara. *Nephrology Center, Toranomon Hospital, Tokyo, Minato-ku, Japan.*

Background: Uremic tumoral calcinosis (UTC) is a rare complication in patients undergoing hemodialysis (HD) and its clinical manifestations are poorly understood. This study aimed to elucidate clinical manifestations and pathological features in cases with UTC.

Methods: The subjects were 8 HD patients (1 male and 7 females; age, 41 - 75 years) with UTC, who visited our hospital between 1999 and 2011. HD duration was 6 years or shorter in 87.5%.

Results: Calcification was observed in about 75% of large joints, such as hips, wrist and shoulders. Mean serum adjusted Ca and P were 10.7±0.6 mg/dl and 7.0±1.1 mg/dl, and the mean Ca x P was 72± 11.7 mg^2/dl^2. Mean serum CRP was 1.46 ± 2.1 mg/dl. Intact-PTH (iPTH) was 247±325 pg/ml, and iPTH higher than 500 pg/ml (high iPTH) was observed in 37.5% suggesting secondary hyperparathyroidism, while low iPTH (iPTH < 100 pg/ml) was seen in 37.5%. All cases with high iPTH showed positive CRP. The aortic calcification index (ACI) was 16.7% on average and 0% in three cases with high iPTH. In cases with high iPTH, parathyroidectomy with Ca x P control eliminated UTC and CRP became negative. Biopsy was performed in all cases of UTC and only calcium depositions were observed in 75%, while the remaining two cases showed ectopic bone tissue with positive CRP and fibrous bone. Of the 5 cases undergoing right iliac bone biopsy, there were 2 high iPTH cases with osteitis and 3 low iPTH cases with adynamic bone.

Conclusions: UTC was observed around large joints in cases with short HD duration and high Ca x P with hyperphosphatemia. Parathyroid hyperfunction may contribute to large UTC, while hypoparathyroidism may lead to small UTC.Serum CRP was positive in cases with secondary hyperparathyroidism, which suggested that tumoral calcinosis induced an inflammatory reaction that in turn led to ectopic bone formation. Vascular calcification was mild and not always present in UTC. It is conceivable that different onset mechanisms and factors other than Ca x P and iPTH are involved in UTC.

SA-PO2998

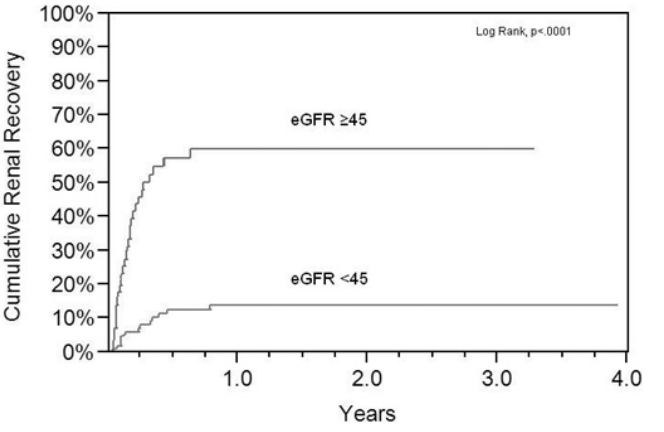
Recovery of Renal Function in Incident Hemodialysis Patients Initiating Dialysis Therapy in the Hospital Sanjay Chaudhary, LaTonya J. Hickson, Andrew D. Rule, John J. Dillon, Robert C. Albright, Amy W. Williams. *Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Patients initiating renal replacement therapy (RRT) may have acute or chronic renal failure. The rate at which renal function recovers in patients dismissed to a chronic hemodialysis unit following RRT initiation in the hospital is not well known.

Objective: To determine rate and clinical predictors of renal recovery in incident hemodialysis patients beginning RRT in the hospital and continuing chronic outpatient therapy.

Methods: Incident hemodialysis patients initiating RRT in a tertiary care setting from 2007-2009 were included in the study and followed for recovery of renal function with complete discontinuation of dialysis.

Results: Of 173 incident patients: mean age 64 years, 64% males, 87% Caucasian, 51% diabetic, 47% coronary artery disease (CAD), 47% congestive heart failure (CHF). Baseline estimated GFR (eGFR) was 34±33 ml/min with eGFR≥45 in 36%. Over a mean period of 1.1±1.1 years, 46 recovered renal function. Kaplan-Meier estimate of cumulative renal recovery rate at 6 months was 27%. Baseline eGFR (HR=1.01 per ml/min, CI 1.01-1.02, p<.0001) was a strong positive predictor of renal recovery. eGFR≥45 was also associated with renal recovery, HR=6.3, CI 3.4-12.6, p<0.0001 (see figure). Also in univariate analysis, diabetes (HR=0.56, CI 0.30-0.998, p=0.049), CAD (HR=0.54, CI 0.29-0.98, p=0.044) and CHF (HR=0.40, CI 0.21-0.75, p=0.003) were negative predictors of renal recovery. In multivariate analysis, only eGFR was associated with renal recovery (HR=1.01, CI 1.00-1.02, p=0.001), while diabetes, CAD, and CHF were not.



Conclusions: Recovery of renal function in the chronic hemodialysis unit setting following dialysis initiation in the hospital is not infrequent. Patients with normal to even moderately impaired function at baseline are more likely to recover.

SA-PO2999

Long Term Use of Trisodium Citrate for Regional Anticoagulation in Chronic Intermittent Hemodialysis in Patients with Risk of Bleeding Birgit Doris Bader, Anna Weber, Christiane M. Erley. *Department of Medicine II, St. Joseph Hospital Berlin-Tempelhof, Berlin, Germany.*

Background: Hemodialysis patients suffer often from bleeding complications. Their management is difficult. Frequently the bleeding is associated with heparin anticoagulation during dialysis treatment. An alternative to heparin is the regional citrate anticoagulation (RCA), described first in 1961 and in wider clinical use since 1983. Normally RCA is used in short term and in continuous renal replacement therapy. This retrospective study documents the chronic use of RCA (trisodium citrate) in intermittent hemodialysis.

Methods: 6 patients (5 women, 1 man; aged 46-80 years) with bleeding complications were followed up from 12/2008 over 10-28 months. They received >1000 intermittent hemodialysis treatments with RCA. Initially the patients got a trisodium citrate 4% solution by an infusion rate of 250-280 ml/min with a blood flow of 200-350 ml/min, since 09/2010 a trisodium citrate 30% solution was used (infusion rates of 50-70 ml/min with a blood flow of 200-250 ml/min). Citrate flow was adapted to achieve post-filter ionized calcium of 0.5-0.7 mmol/L. Calcium substitution was adapted to maintain the patients' serum calcium levels within the physiological range. Low calcium dialysis fluid (1.00 – 1.25 mmol/L) was used.

Results: Within the extracorporal blood circuit a successful regional anticoagulation was achieved while the coagulation of all 6 patients remained within physiological ranges. Only one patient showed clotting problems with RCA, solved by increasing the citrate dose and changing the filter from high to low flux. Adverse events didn't occur, safety laboratory measurements stayed within normal ranges. In all 6 patients the bleeding complications decreased or stopped during dialysis with RCA. The rate of transfusion was reduced markedly.

Conclusions: The long term use of trisodium citrate (4% or 30%) for regional anticoagulation in chronic intermittent hemodialysis in patients with risk of bleeding is feasible, safe and effective.

SA-PO3000

A Quality Audit Analysis of Hemodialysis Circuit Clotting in an Inpatient Dialysis Unit Merfake Semret,[1] Mary Ann Ryan,[2] Robert C. Albright,[1] John J. Dillon,[1] Sandra J. Taler,[1] Marie C. Hogan.[1] *[1]Nephrology Division, Dept of Internal Medicine; [2]Dept of Nursing, Mayo Clinic, Rochester, MN.*

Background: Quality of delivery of inpatient hemodialysis (HD) in the acutely ill patient has received little attention & no clinical performance measure guidelines exist. HD circuit clotting has adverse effects on the process and quality of dialysis. Past studies reveal clotting can occur in up to a quarter of heparin-free dialysis treatments. The purpose of this audit was to evaluate HD circuit clotting rates in acutely hospitalized patients, & to determine if heparin use rates could be safely increased.

Methods: We audited heparin use & dialyzer clotting rate during HD before & following a practice intervention in an inpatient dialysis unit. The intervention was to notify nephrologist to prescribe heparin on all dialysis patients, if not contraindicated. The dialysis unit was located in a 1500 bed acute surgical & medical hospital which runs >6000 HD treatments yearly. All non-ICU inpatient HD runs were included. Clotting and heparin use rates were recorded for 2 weeks pre-intervention & 4 weeks post intervention & medical records reviewed.

Results: Of 178 pre-intervention HD treatments, 111 (62%) were in a non ICU setting. Heparin was used in 17 (15%) these HD treatments. Clotting of the HD circuit occurred in 12 (10.8%) treatments. Of those whose HD circuit clotted, 58% were on chronic HD, 83% had a tunneled dialysis catheter & 42% had a documented reason for not using heparin. Of the 549 post intervention HD treatments, 317 (58%) were in a non ICU setting. Heparin use increased to 23.2% (p=0.08) & HD circuit clotting decreased to 2.2% (p=0.0005) of treatments.

Conclusions: At our center, heparin use in acutely ill surgical & medical inpatients in the sampled cohort was low & dialyzer clotting rates were higher than anticipated. We demonstrated that heparin prescribing can be modified when the prescribing nephrologist is made aware of the extent of the problem of HD clotting rates in their patients. Following this quality intervention, we increased heparin prescribing rates without negative effects and further audits are ongoing.

SA-PO3001

Heparin-Free Hemodialysis: A Multi-Center, Prospective, Randomized, Crossover Study between Two Hemodialyzers VIE Versus EVODIAL Mohamed Shariful Islam,[1] Zarih A. Hassan,[2] Olivier Moranne,[1] Sandor Vido,[1] Mohamed Berrada,[1] David Verhelst,[2] Patrick Donnadieu,[2] Vincent L.M. Esnault.[1] *[1]Nephrology, CHU, Nice; [2]CH, Avignon, France.*

Background: Several strategies of Heparin-free hemodialysis (HFH) were performed in patients with high risk bleeding problems. In this study, we tested the non-inferiority of the hemodialyzer VIE (vitamin E coated) having anti-oxidative and anti-thrombotic activities compared with EVODIAL (heparin coated) having anti clotting properties in a HFH strategy.

Methods: (NCT01221337): 32 patients aged 68±18, with well functioning fistulas or long-term catheters and no major hemodynamic or inflammatory disorders, were assigned to be dialyzed in random order with VIE or EVODIAL. The two study periods consisted of 4 hemodialysis (HD) sessions of 4-hours, separated by a washout period of two HD sessions with the patient's usual hemodialyzer. During each study period, the usual heparin dose was reduced to 50% for the 1st HD session, to 25% for the 2nd, followed by 2 successive HFH sessions. The primary endpoint was the success rate with no clotting event leading to a premature end of the HD session. Secondary endpoints included total HD duration without clotting, the number of saline flashes, the bubble trap and the hemodialyzer restitution qualities (1-4 grades), eKt/V (Daugirdas) and hemoglobin levels.

Results: The success rate with VIE (81 %) was not inferior to EVODIAL (78 %, p = NS). Restitution quality was better with VIE compared to EVODIAL (p = 0,002).

Secondary endpoints		VIE	EVODIAL	P
Total HD duration without clotting (min/patient)		900	907	NS
Saline flash (number)		0.31±0.68	0.26±0.67	NS
Blood flow rate (ml/min)		340±26	344±23	NS
End Transmembrane pressure (mmHg)		23.5±20	24.2±21	NS
Kt/V		1.48±0.3	1.43±0.3	0.07
Hemoglobin level (g/dL)		11.2±1.4	11.2±1.5	NS
Bubble trap quality	1	34(28)	32(27)	
n (%)	2	19(16)	26(22)	
	3	63(52)	57(47)	
	4	5(4)	5(4)	NS
Hemodialyzer restitution quality	1	25(21)	2(2)	
n (%)	2	72(59)	30(25)	
	3	22(18)	83(67)	
	4	2(2)	5(4)	0.002

Conclusions: Both VIE and EVODIAL permitted to perform 4-hour HD sessions with reduced dose or no heparin. As the mechanisms of clot prevention are different with these two hemodialyzers, further large-scale studies are required.

Funding: Pharmaceutical Company Support

SA-PO3002

Effects of Hydration Status and Relative Blood Volume Changes on Peripheral Skin Blood Flow during Hemodialysis Sylvie Sulkova, Roman Safranek, Michaela Kubisova, Lydia Habanova, Petr Moucka, Erik Mistrik, Katerina Petranova, Lubos Sobotka. *Department of Nephrology, Gerontology and Metabolic Care, Medical Faculty and Teaching Hospital, Hradec Kralove, Czech Republic.*

Background: In chronic hemodialysis patients, disorders of perfusion of peripheral tissues are very common, clinically important and may for example aggravate healing of frequent skin defects. The aim of our study was to investigate effect of hemodialysis procedure (HD) on peripheral skin blood flow.

Methods: Forty-one clinically and hemodynamically stable hemodialysis patients (22 males, 19 females, 64 (29-84) years) underwent routine HD (4h isotermic HD, low-flux dialyzer FX10 1.8m^2, QB 300ml/min, ultrafiltration to "dry weight" set by clinician). Skin blood flow was measured noninvasively at 1-1.5mm depth on the principle of backscattered light from moving red blood cells using Laser Doppler Line Scanner. Skin blood flow was estimated on hands and feet in every patient before HD, at 30, 90, 240min of HD, and 30 min postHD. Using Crit-line we assessed relative blood volume changes during HD. Bioimpedance spectroscopy (Body Composition Monitor) was used to assess hydration status.

Results: Skin perfusion progressively declined during HD ($p<0.001$), being decreased by 39% in toes, and 35% in fingers at the end of HD. 30 minutes after the end of HD, skin perfusion was still decreased; by 35 and 30% in toes and fingers, respectively. Skin perfusion decreased in patients with observed either decrease or increase in blood pressure during HD. Lower hydration at the end of HD was associated with more pronounced decrease in peripheral perfusion (correlation coefficient 0.51-0.65 for different areas of perfusion measurement).

Conclusions: HD significantly reduces peripheral skin blood flow. Drop in peripheral perfusion is dependent on relative blood volume decrease during HD and hydration status. Change in blood pressure during HD cannot be used as a simple tool to assess peripheral perfusion.

SA-PO3003

Serum Sodium Concentration and Interdialytic Weight Gain in a Cohort of Hemodialysis Patients Prince Mohan, Lingpin Hung, Sayed Husain, Manaf Alroumoh, Gabriel EL-Kass, Marilyn Galler, Chaim Charytan, Bruce S. Spinowitz. *Nephrology, New York Hospital Queens, Flushing, NY.*

Background: Patients on hemodialysis (HD) have high rates of cardiovascular mortality and morbidity. Important risk factors include hypertension and fluid retention, measured as interdialytic weight gain (IDWG). This study aimed to describe the distribution of pre-dialysis serum sodium(SS) concentrations and to investigate the relationships between SS and IDWG.

Methods: This retrospective analysis determined the relationship with monthly SS levels and 48 hour subsequent IDWG. We reviewed the records of 260 patients on HD over a period of 12 months. IDWG, SS concentration, age and gender were tabulated. The mixed procedure method in SAS was utilized with a mixed effect model to capture the individual differences, and the fixed effect model to see the relationship between SS and IDWG.

Results: 260 patients, 106 male and 154 female, with total of 5054 dialysis sessions in 12 months period were analyzed. Average SS for the group was 137.2 + 2.1 and average IDWG was 2.42 + 1.42 KG. Data showed that IDWG and SS level are inversely related to each other in the entire male cohort. Subgroup analysis shows a significant relationship in all patients >80 years. SS expressed as mean mEq/L + SD and IDWG as mean Kg+ SD.

table1

	<60 Years	60-70 Years	71-80 Years	>80 Years
Female	Na 137.5±2.7 IDWG 2.42±1.08 P= 0.293	Na 137.3±2.8 IDWG 2.25±0.92 P = 0.904	Na 136.2±3.6 IDWG 1.80±0.95 P = 0.759	Na 137.5±3.5 IDWG 1.63±0.80 P = 0.011
Male	Na 137.0±2.5 IDWG 3.23±1.21 P = 0.800	Na 137.4±3.1IDWG 2.87±1.18 P = 0.318	Na 136.7±3.3 IDWG 2.53± 0.99 P = 0.130	Na 137.8± 2.7 IDWG 2.09±0.84 P = 0.003

Conclusions: For a given patient, a decreasing sodium level is predictive of a greater subsequent IDWG. This is most prominent in male patients and in all patients above the age of 80. This finding, if confirmed, will have implications for guiding patient treatment and dietary counseling. Further evaluation as to mechanism is needed.

SA-PO3004

Dialysate Sodium and Mortality in Hemodialysis Finnian R. McCausland, Steven M. Brunelli, Sushrut S. Waikar. *Renal Division, Brigham and Women's Hospital, Boston, MA.*

Background: Dialysate sodium concentration has increased over many years in response to controlled ultrafiltration and shorter treatment times. However, higher dialysate sodium has been associated with increased thirst, weight gain and higher blood pressure. The relationship between dialysate sodium and outcome, and influence on serum sodium, has not yet been thoroughly investigated.

Methods: We studied a cohort of 2272 subjects from a medium-sized dialysis provider. Available data included demographic, laboratory and clinical parameters, detailed information of the dialysis prescription and 2.5 year follow-up for all subjects. Patterns of dialysate sodium prescription were examined within and between centers. Cox regression models, stratified on clinical center, were used to compare all-cause mortality according to dialysate sodium concentrations. Interaction was examined for in relation to serum sodium, inter-dialytic weight gain and pre-dialysis systolic blood pressure.

Results: The mean pre-dialysis serum sodium was 136.1mmol/L, without significant difference across dialysate sodium concentrations. There was evidence for interaction between serum and dialysate sodium and their relationship with all-cause mortality (p=0.04). The hazard ratio for death for higher dialysate sodium (>140mmol/L or sodium modeling) versus lower dialysate sodium (≤140mmol/L) was 1.05 (0.85, 1.30) at serum sodium of 134mmol/L; 1.15 (0.94, 1.40) at serum sodium of 136mmol/L; and 1.26 (1.01, 1.58) at serum sodium of 138mmol/L.

Conclusions: The dialysate sodium varies within and between centers; does not appear to effect the pre-dialysis serum sodium concentration; but has a variable relationship with mortality, according to the pre-dialysis serum sodium. Future research should focus on changes in total body sodium during hemodialysis and potential biological mechanisms for it's association with mortality.

The Effect of Isonatremic Sodium Dialysate Prescription in Conventional In-Center Hemodialysis Patients: A Case Series Rohini Arramreddy,[1,2] Sumi J. Sun,[2] Jair Munoz Mendoza,[1,2] Glenn M. Chertow,[1,2] Brigitte Schiller.[1,2] *[1]Medicine, Division of Nephrology, Stanford University, School of Medicine, Stanford, CA; [2]Medical Affairs, Satellite Healthcare, Inc., San Jose, CA.*

Background: Recent studies have focused on the association between sodium (Na^+) dialysate prescriptions and interdialytic weight gain (IDWG). We report on a case series of 13 patients undergoing thrice weekly, conventional, in-center hemodialysis with an individualized, isonatremic dialysate prescription.

Methods: Isonatremia was achieved in all patients through a stepwise weekly reduction of the standard Na^+ dialysate prescription (140 mEq/L) by 2mEq/L until reaching a Na^+ gradient of -2 mEq/L (Na^+ dialysate minus average plasma Na^+ over the preceding 3 months). Dialysis logs from six consecutive treatments with the two different Na^+ prescriptions (standard and isonatremic) were reviewed. Changes were assessed for the following measures: interdialytic weight gain corrected for dry weight (IDWG%), blood pressure, and proportion of treatments with cramps, hypotension (drop in systolic blood pressure > 30 mmHg) and hypotension requiring intervention.

Results: The average age of the patients was 62 years; 10 of 13 were male. The pre-dialysis plasma Na^+ concentration ranged from 132 to 141 mEq/L. The mean pre-dialysis plasma Na^+ was unchanged (135.5 ± 3.7 mEq/L vs. 134.9 ± 3.9 mEq/L; p=0.3) but the mean post-HD plasma Na^+ concentration was significantly reduced (137 ± 3.1 mEq/L vs. 134.3 ± 3.4 mEq/L; p=0.03). IDWG% was decreased with isonatremic dialysate (3.4 ± 1.6% vs. 2.5 ± 1.0%; p=0.003) without affecting pre- or post-HD blood pressure (all p>0.05). No significant changes in the proportion of treatments with cramps (6% vs. 13%), hypotension (62% vs. 65%) or hypotension requiring an intervention (29% vs. 33%) were noted.

Conclusions: Individualized isonatremic dialysate prescriptions reduced IDWG without increasing the incidence of cramps or hypotension.

SA-PO3006

Interaction of Potassium, Sodium with Higher Magnesium Dialysate on Muscle Cramps in Chronic Hemodialysis Patients Sudhir Movva, Patrick Gerard Lynch, Nand K. Wadhwa. *Nephrology, Stony Brook University, Stony Brook, NY.*

Background: We reported an inverse relationship between predialysis serum magnesium (Mg) and muscle cramps in chronic hemodialysis (HD) patients (JASN 21:436A, 2010). The interaction of potassium and sodium with different dialysate Mg concentrations and muscle cramps in ESRD patients is scarce.

Methods: 62 ESRD patients (Mean age 60, range 25-87 years; 36 males, 26 females) on HD were studied. The patients were hemodialyzed initially with a dialysate Mg of 0.75 mEq/L and then with a dialysate Mg of 1.00 mEq/L. The patients received HD with each dialysate for at least 3 months. Monthly pre-HD laboratory data, before and after the change in dialysate Mg, were used for analysis. A single nephrology fellow conducted an in-person questionnaire on 62 patients twice. The severity of cramps was evaluated on a 0-10 scale, with 10 rated as maximal severity. We analyzed the frequency of muscle cramps in patients with serum potassium of <4 mEq/L or ≥4 mEq/L and serum sodium of <135 mEq/L or ≥135 mEq/L before and after change in dialysate Mg.

Results: 48 out of the total 62 ESRD patients had muscle cramps with dialysate Mg of 0.75 mEq/L, vs only 35 had muscle cramps with dialysate Mg of 1.00 mEq/L (χ^2=6.16, p =0.01). The frequency of muscle cramps significantly decreased with higher dialysate Mg (1.00 mEq/L) in patients with serum potassium of ≥4 mEq/L (χ^2= 4.74, p=0.02) or serum sodium of ≥135 mEq/L (χ^2= 4.59, p=0.03). The frequency of muscle cramps were not significantly decreased in patients with serum potassium of <4 mEq/L or serum sodium of <135 mEq/L with higher dialysate Mg.

Data are summarized below (mean ± SD)

Variable	Dialysate Mg 0.75 mEq/L	Dialysate Mg 1.00 mEq/L	p value
Cramp severity	5.36±3.63	3.95±3.93	0.004
Serum Magnesium mg/dL	1.89±0.26	2.15±0.31	0.002
Serum Potassium mEq/L	4.97±0.81	4.99±0.75	NS
Serum Sodium mEq/L	138.32±3.47	137.24±3.34	0.02

Conclusions: These results suggest that frequency of muscle cramps, when hemodialyzed with dialysate Mg concentration of 1.00 mEq/L, decreased significanly in ESRD patients with relatively higher serum potassium or sodium level. Further studies are needed to understand this interaction.

SA-PO3007

Fluid Distribution in the Chest and Calf in Hemodialysis Patients Samer Rateb Abbas,[1,2] Fansan Zhu,[1] Stephan Thijssen,[1] Rakesh Malhotra,[1] Peter Kotanko,[1] Nathan W. Levin.[1] *[1]Nephrology, RRI, NY; [2]Nephrology, BIMC, NY.*

Background: Knowledge of body fluid status is essential in the management of hemodialysis (HD), but excess fluid volume may not be uniformly distributed in the body. This study compares fluid removal from the chest and calf during HD.

Methods: Chronic HD patients were studied pre- and post-HD after the long (LINT) and short (SINT) interdialytic interval using 2 bioimpedance techniques, the ZOE fluid status monitor (NMT) for chest impedance (Zo), and Hydra 4200 for calf bioimpedance spectroscopy (cBIS) (Xitron Technologies). Calf and chest resistivities were determined and normalized to body mass index (ρ_{Ncalf}, ρ_{Nchest}).

Results: We studied 15 patients. During HD weight decreased in both LINT and SINT groups, the decrease was greater in LINT than SINT (LINT: -2.9±1.3; SINT -2.1±1.3: P<0.01). In LINT, ρ_{Ncalf} , chest Zo, and ρ_{Nchest} increased during HD.

		LINT			SINT	
	Pre HD	Post HD	P	Pre HD	Post HD	P
Weight, kg	94.2±23.6	91.3±22.9	<0.001	93.0±23.5	90.9±22.6	<0.001
cBIS_R, Ω	30.7±6.0	38.3±8.3	<0.001	32.1±8.3	39.6±9.1	<0.001
ρN_cBIS, [Ωm³/kg]/100	10.9±2.5	13.1±3.2	<0.001	11.5±3.5	13.7±3.6	<0.001
ZOE_Zo, Ω	21.9±2.8	24.2±3.3	<0.01	23.6±3.8	24.7±3.6	NS
ρN_ZOE, [Ωm³/kg]/100	28.0±8.8	31.9±10.8	<0.01	31.7±11.3	33.5±12.2	NS

In SINT, ρ_{Ncalf} increased but Zo and ρ_{Nchest} did not. Although pre-HD weight was lower after SINT (LINT: 94.2±23.6 kg; SINT 93.0±23.5 kg), no differences in pre-HD calf or chest measurements were observed between LINT and SINT.

Conclusions: Intradialytic fluid removal can be detected by both calf and chest bioimpedance measurements after the long interdialytic period, but after the short dialysis interval, calf BIS is more sensitive than chest impedance measurements in detecting fluid volume changes. Pre-HD ρ_N did not differ significantly between LINT and SINT, suggesting that measurement variability is too high to detect a significant effect of a 1.2 kg average weight reduction in a sample of 15 subjects. These findings indicate that the calf is the preferable location for measuring intradialytic body fluid volume changes.

SA-PO3008

Effect of Lowering Dialysate Temperature in Chronic Hemodialysis: A Systematic Review and a Meta-Analysis Reem Mustafa,[1] Fadi Bdair,[2] Elie Akl,[1,2] Gihad E. Nesrallah,[1,4,5] Amit X. Garg,[1,4] Holger Schunemann.[1,3] *[1]Department of Clinical Epidemiology & Biostatistics, McMaster University, Hamilton, ON, Canada; [2]Department of Medicine, State University of New York at Buffalo, Buffalo, NY; [3]Department of Medicine, McMaster University, Hamilton, ON, Canada; [4]Department of Medicine, University of Western Ontario, London, ON, Canada; [5]Department of Nephrology, Humber River Regional Hospital, Toronto, ON, Canada.*

Background: Lowering dialysate temperature may improve outcomes for patients undergoing maintenance chronic hemodialysis.

Objectives: To evaluate the effect of cooling dialysate compared to normal temperature dialysate on important outcomes in chronic hemodialysis patients

Methods: We searched the Cochrane Central Register of Controlled Trials, OVID MEDLINE, EMBASE and Pubmed (from inception to January 2011). We included all prospective randomized controlled trials that evaluated the effect of any method of cooling dialysate in adult patients receiving chronic hemodialysis. Two authors independently assessed trial quality and extracted data in duplicate. The GRADE methodology was followed to assess bias in individual studies and across studies for each outcome. We pooled data using a random effects model. We measured heterogeneity using the $\chi 2$ and I2 statistics. We registered this systematic review at PROSPERO: International prospective register of systematic reviews. 2011 (CRD420111104)

Results: We included twenty-six cross-over studies. Cool dialysis significantly reduced the rate of intradialytic hypotension (IDH) by 70% (95% CI 49%-89%; I2 =0%). Also it significantly increased mean arterial pressure (MAP) 14 mm Hg (95% CI 10 -18 mm Hg; I2 =89%).

Conclusions: Limitations: The overall quality of studies was poor. The effect on symptoms of discomfort were poorly studied. None of the studies reported long-term patient important outcomes

Cooling dialysate is an effective intervention to reduce IDH and to increase MAP in chronic hemodialysis patients. The effect on symptoms of discomfort were poorly studied. High quality, large, multicenter studies with long follow up are needed to assess the effect of cool dialysis on long-term patient important outcome.

SA-PO3009

Intradialytic Hypotension (IH): Variation in Dialysis Facilities Jeffrey J. Sands,[1] Len A. Usvyat,[2] Sandi Moore,[1] Mary T. Sullivan,[2] Jonathan H. Segal,[3] Paul M. Zabetakis,[1,2] Jose A. Diaz-Buxo.[1] *[1]Fresenius Medical Care NA; [2]Renal Research Institute; [3]U Michigan.*

Background: Intradialytic hypotension (IH) occurs in 10-30% of HD treatments (Tx) but is not routinely reported or aggregated to facilitate evaluation and prevention.

Methods: We studied IH (systolic blood pressure (SBP) < 90mmHg and decreased >30mmHg from Tx maximum) in 313 HD patients, (2788 Tx) in 4 facilities in an ongoing Quality Improvement Initiative. Blood pressure was captured by machine download and IH risk factors assessed by logistic regression.

Results: Patients are 58.1% white, 39.0% black, 52.7% diabetic, 62.0% AVF; 19.8% catheter, mean age 60.9±15.7 years, vintage 3.7±3.8 years. Mean pre-HD SBP is 138.8±22.1 mmHg, EDW 83.8±25.2 kg, Albumin 3.9±0.4 g/dL and Na gradient (dialysate-patient Na)-1.3±2.8 mEq/L. IH was common (20.8% Tx) and highly variable by patient (0 to 100% Tx), facility (5.3% to 27.4% Tx) and Tx date (0% to 43% Tx). 43.4% of patients had ≥1 IH (facility range: 8.6% to 86.3%) and 10.5% (facility range: 3.4% to 15.7%) had IH on ≥50% of Tx.

	Odds Ratio	95% CI		p-value
Vintage (yrs)	1.051	1.017	1.087	0.003
Pre-HD SBP (mmHg)	0.976	0.972	0.980	<0.0001
Male	0.349	0.279	0.436	<0.0001
Age (yrs)	1.030	1.021	1.038	<0.0001
Race (white)	1.256	0.997	1.583	0.054
Diabetes	1.314	1.037	1.666	0.024
Ultrafiltration (UFV) (L)	1.599	1.425	1.795	<0.0001
Shift (Mid)	1.078	0.806	1.442	0.614
Shift (PM)	0.800	0.564	1.136	0.212
Tx T,Th,Sat	1.122	0.793	1.587	0.515
Catheter	0.889	0.671	1.177	0.412
BMI (kg/m)²	1.001	0.989	1.013	0.883
Albumin (g/dL)	1.864	1.275	2.723	0.001
Dialysate-patient Na (mEq/L)	0.990	0.939	1.044	0.707
Post Weigh -EDW (kg)	1.112	1.059	1.116	<0.0001
Clinic 1	0.748	0.577	0.970	0.028
Clinic 2	0.448	0.259	0.773	0.004
Clinic 3	0.181	0.070	0.469	<0.001

Reference: black; female; non-diabetic; AM shift; M W F; AVF/AVG; Tx in clinic 4

Conclusions: IH is common and highly variable by patient and facility. Increased risk of IH was associated with older age, diabetes, higher UFV, albumin and post HD weight-EDW difference, lower pre-HD SBP and being dialyzed in clinic 4. Additional evaluation of facility practice patterns and modifiable risk factors is needed to decrease the frequency of IH.

SA-PO3010

Dialysate Calcium Concentration and Intradialysis Hemodynamic Stability Carlo Basile, Pasquale Libutti, Francesco Casucci, Piero Lisi, Carlo Lomonte. *Division of Nephrology, Miulli General Hospital, Acquaviva delle Fonti, Italy.*

Background: The interplay of correct sodium (Na+), potassium (K+) and total calcium (tCa) mass balances (respectively, Na+MB, K+MB and tCaMB) with adequate ultrafiltration volumes (V_{UF}) is crucial for the hemodynamic stability during hemodialysis (HD). This study was aimed to investigate the effects that three dialysate tCa concentrations (1.25, 1.375 and 1.50 mmol/l) may exert on the latter.

Methods: Twenty-two stable anuric uremic patients underwent three 4h-bicarbonate HD sessions, each with one of the three dialysate tCa concentrations. V_{UF} and dialysate Na+, K+ and bicarbonate concentrations were prescribed to be the same (respectively, 140, 2.0 and 35 mmol/l). Hourly measurements of plasma water (pw) ionized Ca (Ca++), Na+ and K+, blood pH and bicarbonate concentrations were effected. tCaMBs, Na+MBs and K+MBs were measured from the dialysate side (GENIUS batch dialysis system, FMC, Germany). Intradialysis systolic, diastolic and mean arterial pressure (SBP, DBP and MAP, respectively) and heart rate (HR) trends were analyzed.

Results: A statistically significant difference was observed among the mean hourly pwCa++ concentrations, being significantly higher with a dialysate tCa concentration of 1.50 ($P < 0.0001$). Mean tCaMBs were positive (diffusion gradient from the dialysate to the patient), being more and more higher by increasing dialysate tCa concentrations (+ 75 ± 122 mg, + 182 ± 125 mg, + 293 ± 228 mg, respectively) ($P < 0.0005$). No statistically significant difference was observed when comparing pw concentrations of Na+ and K+, blood pH and bicarbonate levels during the three different sessions (repeated measures ANOVA stratified for treatments). Mean Na+MBs and K+MBs were not statistically significantly different among the three treatments. No statistically significant difference was observed when comparing SBP, DBP, MAP and HR during the three different sessions (repeated measures ANOVA stratified for treatments).

Conclusions: These highly controlled experiments show that hemodynamic stability does not appear to be statistically significantly influenced by any specific dialysate tCa concentration in this peculiar subset of patients.

SA-PO3011

The Effect of Pneumatic Compression Devices on Hemodynamic Parameters in Hemodialysis Patients: A Randomized Crossover Trial Davina J. Tai, Sofia B. Ahmed, Brenda Hemmelgarn, Jennifer M. MacRae. *University of Calgary.*

Background: Intradialytic hypotension (IDH) is the most common complication of chronic hemodialysis (HD) therapy, leading to increased morbidity and mortality. The pathophysiology of IDH is multifactorial and poorly understood. Studies have shown that central blood volume (CBV) is maintained in stable HD patients. Pneumatic compression devices (PCDs) are thought to improve venous return by preventing pooling of blood in the lower extremities. Thus, PCDs could potentially improve CBV and intradialytic blood pressure (BP) in HD patients.

Methods: We performed a randomized, two-period crossover trial to determine the effect of PCDs, compared with control, on central blood volume (CBV) in HD patients. Patients on intermittent HD ≥ 3 times per week for ≥ 3 months were eligible for study inclusion. The study period consisted of 2 consecutive mid-week HD sessions. Patients were randomized to begin with either 1 mid-week HD session with PCDs (the intervention), or 1 mid-week HD session without PCDs (the control), stratified by whether or not they were IDH-prone.

Results: 51 patients (75% male, 49% diabetic) with a mean age of 65 ± 14 years and mean HD vintage of 44 ± 37 months were randomized. Forty-six patients completed the study. During HD, the mean change in CBV in the control and intervention sessions was -0.077L vs -0.085L ($p=0.78$). Similarly, comparing control and intervention sessions, there were no differences in change in cardiac output (-0.49L/min vs -0.63L/min, $p=0.78$) and systemic vascular resistance (+1.55 mmHg/L/min vs +1.30 mmHg/L/min, $p=0.67$). Post HD systolic blood pressures (SBP) and minimum intradialytic SBPs were similar in the control and intervention sessions [(126 mmHg vs 128 mmHg, $p=0.08$), and (112 mmHg vs 108.5 mmHg, $p=0.19$), respectively].

Conclusions: Compared with standard of care, PCDs have no effect on hemodynamic parameters, including CBV, during HD. Further studies are required to better understand the physiological and hemodynamic changes in patients during HD, so that superior preventative strategies for IDH can be uncovered.

SA-PO3012

The Use of Crit-Line® To Monitor and Quantify Fluid Removal Rates in Dialysis Patients during a Baseline Observational Period Linda H. Ficociello,[1] Len A. Usvyat,[2] Michael Black,[1] Patrice B. Taylor,[2] Heather J. Ansede,[2] Kay D. Cuaton-Maier,[2] Antoinette M. Ordish,[2] Paul Balter,[2] Paul M. Zabetakis,[2] Claudy Mullon,[1] Jose A. Diaz-Buxo.[1] *[1]Fresenius Medical Care-NA, Waltham, MA; [2]Renal Research Institute (RRI), New York, NY.*

Background: Real-time blood volume (BV) monitoring during hemodialysis sessions (HD) using a Crit-Line® Blood Volume Monitor may help to quantify fluid removal for better fluid management.

Methods: As part of a quality improvement project, two RRI clinics monitored BV changes via Crit-Line during an observational period in 88 HDD-CKD patients. Crit-line monitors reporting BV changes every 1 minute were installed at all 14 stations in one center and 10 randomly selected stations in the second center. Patients with BV decreases of ≥ 3%/hour (hr) were considered to have an adequate fluid removal rate, patients with BV decrease of <3%/hr and BV decrease by HD end of ≥8% had a slower removal rate/hr but adequate BV decrease by HD end, and patients with BV decrease <3%/hr and a BV decrease <8% by HD end were considered to have inadequate fluid removal rates.

Results: On average, patients were 60 years old with a vintage of 4 years and HD time of 223 minutes. 66% of patients had a BV decrease of <3%/hr and <8% by HD end, 20% had a BV decrease of <3%/hr, but ≥8% by HD end, and 14% BV decreases ≥3%/hr. A BV decrease of <3%/hr and <8% by HD end was associated with documented hypertension (86%) or fluid overload/CHF (40%) when compared to patients with more adequate fluid removal. The amount of fluid removed during HD was highest for those with ≥3%/hr BV decrease and lowest for those with <3%/hr and <8% by HD end. The difference between post-treatment weight (Wt) and estimated dry Wt was similar between groups.

Conclusions: Monitoring of real-time BV changes using Crit-Line may be used to better determine appropriate fluid removal and develop new algorithms for fluid management.

Characteristic	BV decrease <3%/hr, <8% by HD end (n=58, 66%)	BV decrease <3%/hr, ≥8% by HD end (n=18, 20%)	BV decrease ≥3%/hr (n=12, 14%)	pvalue
Pre-Post HD Wt (kg)	-2.1	-2.8	-4.0	0.005
Post HD - Estimated Dry Wt (kg)	0.22	0.03	-0.10	0.37
% Hypertension	86	67	67	0.10

Continuous Recording Reveals Extreme Blood-Pressure Variability in Nominally Stable Dialysis Scott Wilson, Gavin J. Becker. *Royal Melbourne Hospital, Australia.*

Background: The prediction and avoidance of haemodynamic instability during haemodialysis (HD) is important to minimize circulatory stress and maintain efficacy. Intradialytic hypo- or hypertension is defined as a symptomatic change in systolic blood pressure (SBP) of ≥20 mmHg and associated with increased mortality and morbidity. In clinical practice, intradialytic blood pressure records are used to adjust HD, ultrafiltration, and antihypertensive prescription. Clinicians assume this record captures a true haemodynamic profile and the descriptor "stable dialysis" is routinely drawn from such observation. We sought to investigate the actual SBP variability during HD using continuous recordings and compare these with standard clinical measures and changes in relative blood-volume (RBV).

Methods: Continuous measure of SBP by plethysmograph using the Finometer system and RBV were recorded in 6 "stable" midweek HD outpatients. In parallel, 5 arm-cuff SBP measures were made by HD staff blind to the continuous record. Time-series data from beat-to-beat recording (~17,000 data points/HD) was analysed using a heart-rate dependent median-hybrid filter.

Results: Concordance between the plethysmograph and simultaneous arm measures of SBP was excellent (mean difference <5mmHg). The time-series record revealed a slow increase in SBP through HD with a mean change from start (127mmHg) to end (167mmHg) of 40mmHg. Continuous recordings revealed significant asymptomatic fluctuations in SBP that weren't associated with variation in RBV. The mean difference between minimum (94mmHg) and maximum (199mmHg) SBP during HD was 105mmHg. SBP was beyond 2 standard deviations from baseline for an average of 18% of HD time, typically in the hypertensive range. Among the 6 dialyses only a single symptomatic event was observed.

Conclusions: Clinically silent SBP variability during "stable" HD is common and unrecognised. Such variation might be relevant to dialytic efficiency, interdialytic blood pressure control and long-term cardiovascular outcomes.

Effect of Oxygen Therapy on Hemodynamic Stability during Hemodialysis with Continuous Blood Volume and O2 Saturation Monitoring Nupur Jhawar, Kiran M. Goli, Paul F. Visintainer, Jason D. Cooney, Joy Whitbeck, Michael J. Germain. *Baystate Medical Center/Tufts University School of Medicine., Springfield, MA.*

Background: Intradialytic hypotension (IDH) is the most common complication of hemodialysis (HD). The effects of oxygen administration on IDH during HD are currently unknown. To address this question, a randomized-controlled clinical trial (RCT) of the effects of oxygen(O2) administration on hemodynamic stability during HD is planned. Prior to initiating the clinical trial, we present results of a preliminary pilot study.

Methods: This pilot study was a non-randomized, prospective and two group study that included 24 patients receiving HD in a inpatient HD unit with either an AV fistula or a venous catheter. The study compared hemodynamic stability in 12 patients receiving 2 liters of O2 via nasal cannula during HD to 12 patients not receiving O2 during HD. BP was recorded every 30 minutes. RBV, Hct and O2 saturation were recorded continuously by Crit-line III monitor.

Results: Results showed that O2 administration during HD significantly stabilized systolic blood pressure (SBP) over time (average change in SBP = 1.10 mmHg every 30 minutes) compared to the placebo group (average change in SBP = -1.62 mmHg; p = 0.037). Furthermore, O2 administration resulted in substantially lower variability in the individual readings in the treatment group compared to the placebo group (SD_{tx} = 8.9 v. SD_{pbo} = 17.2; p < 0.001), suggesting that O2 may stabilize SBP over time during HD.

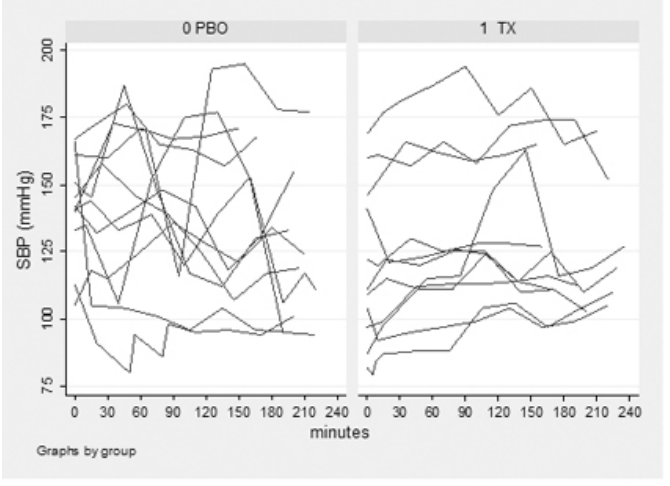

Figure 1. Oxygen administration resulted in substantially lower variability in the individual readings of SBP in the treatment group compared to the placebo group (p < 0.001), suggesting that oxygen may stabilize SBP over time during HD. 0 PBO refers to the placebo group. 1 TX refers to the treatment group. SBP refers to systolic blood pressure.

Finally, log-RBV slope showed a significantly steeper decline compared with placebo (average change in log-RBV every 30 minutes for treatment vs. placebo: -0.018 vs. -0.013, p = 0.005).

Conclusions: Greater hemodynamic stability and fewer episodes of IDH are achieved in the treatment group compared to the control group. These results need to be validated in a subsequent RCT.

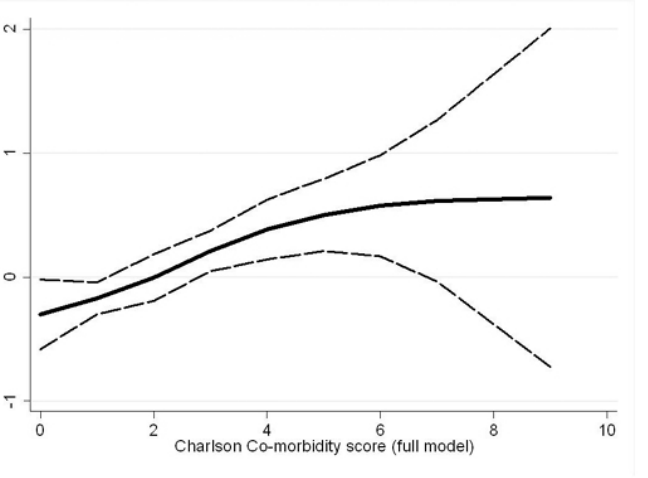
SA-PO3015

Mortality-Predictability of Charlson Comorbidity Score in Maintenance Hemodialysis Patients and the Role of Race Usama Feroze,[1] Miklos Z. Molnar,[1] Ramanath B. Dukkipati,[2] Csaba P. Kovesdy,[3] Allen R. Nissenson,[4] Keith C. Norris,[2] Joel D. Kopple,[2] Kamyar Kalantar-Zadeh.[1,2] *[1]Harold Simmons Center, Torrance, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Salem VA Medical Center, Salem, VA; [4]DaVita, Inc, Denver, CO.*

Background: The Charlson co-morbidity index (CCI) is a commonly used scale for assessing morbidity. Maintenance hemodialysis dialysis (MHD) patients (pts) are a unique cohort with significant cardiovascular risk & marked variations in mortality characteristics by race/ethnicity.

Methods: A 6-year cohort of 893 MHD pts was examined for an association between a modified (without age and kidney disease) CCI (mCCI) & mortality.

Results: Pts were 53±15 years old(mean±SD), and included 47% women, 31% African-Americans & 55% diabetics. In our fully adjusted model, 2nd (mCCI: 1-2), 3rd (mCCI=3), and 4th (mCCI: 4-9) quartiles compared to 1st (mCCI=0) quartiles showed death hazard ratios (HR) (and 95% confidence intervals) of 1.43(0.92-2.23), 1.70(1.06-2.72), and 2.33(1.43-3.78), respectively.



The mCCI was a significant mortality predictor either in non-African Americans(1.40 {1.29-1.51}) or in African Americans(1.12 {1.01-1.23}) in our unadjusted model. After adjustment for nutritional and inflammation markers, mCCI was a significant mortality predictor in non-African Americans(1.27{1.12-1.44}), but not in African Americans(1.07 {0.94-1.21}).

Conclusions: The mCCI is a robust and linear predictor of mortality in MHD pts, in particular in non-African Americans. The mCCI scale for co-morbidities does not appear to be a significant factor for mortality risk in African American MHD pts after adjusting for nutritional & inflammatory markers. Studies to examine race-specific comorbidity scales as effective predictors for mortality risk in dialysis populations are warranted.

Associations of the Malnutrition-Inflammation Score with Depressive Symptoms and Kidney-Disease Targeted Health-Related Quality of Life Measures in a Brazilian Sample of Hemodialysis Patients Gustavo Behrens Pinto, Luiz Fernando Catto, Larissa Moura Silva, Raissa Araujo, Rafaela Lima, Camila Joau, Marcelio Piccolo, Gildete Barreto Lopes, Antonio Alberto Lopes. *Núcleo de Epidemiologia Clínica do Hospital Universitário Professor Edgard Santos, Universidade Federal da Bahia.*

Background: The malnutrition-inflammation score (MIS) has been largely used to evaluate nutritional status in maintenance dialysis (MHD) patients. There is a lack of studies, however, to assess associations of the MIS with kidney-disease targeted health-related quality of life (KDT-HRQOL) measures and depression symptoms in MHD patients. This study assessed associations of MIS with scores of KDT-HRQOL and depressive symptoms in MHD patients.

Methods: Cross-sectional study of 632 prevalent MHD patients enrolled in the Prospective Study of the Prognosis of Chronic Hemodialysis Patients (PROHEMO) developed in Salvador, Brazil. MIS≥6 defined worse nutrition status. The Kidney Disease Quality of Life Short-Form was used to determine scores (range: 0 to 100) for the eleven KDT-HRQOL scales. The Center for Epidemiological Studies Depression scale was used for depression symptoms scores (range: 0-60). Linear regression with adjustments for numerous covariates were used to determine differences in scores of HRQOL and depression symptoms by MIS categories.

Results: Patients with MIS≥6 (compared with MIS<6) were found to have significantly (P<0.05) lower adjusted scores for the following KDT-HRQOL: symptoms/problems (difference=-5.35), effects of kidney disease (difference=-4.28), burden of kidney disease (difference=-6.45), cognitive function (difference=-4.87), social interaction (difference=-4.37) and sleep (difference=-4.08). Depression symptoms scores were significantly (P<0.05) higher for patients with MIS ≥6. Gastrointestinal symptoms and functional capacity were the MIS components more strongly associated with poorer HRQOL and higher depression symptoms.

Conclusions: The data suggest that MHD patients with higher MIS have clinically significantly lower scores for several HRQOL components (both generic and kidney-disease targeted) and higher probability of depression.

SA-PO3017

Depression and Its Management in Maintenance Haemodialysis Patients Marguerite McCloskey, Ronan Cunningham, Robert Mullan, Agnes Masengu, Camille Harron. *Renal Unit, Antrim Area Hospital, Antrim, Northern Ireland, United Kingdom.*

Background: The purpose of this audit was to determine the prevalence of depression within our haemodialysis population and review treatment strategies in accordance with National Institute of Clinical Excellence (NICE) guidance.

Methods: A total of 126 haemodialysis patients (71 male, 55 female, median age 66.9) were asked to complete a voluntary depression questionnaire, namely the patient health questionnaire 9 (PHQ-9), which has been validated for use by general practitioners.

We also identified those patients on antidepressant medication using our computerised database.

Results: 76.2% (96/126) completed the questionnaire, 15.9% (20/126) refused, 0.8% (1/126) were unable to complete secondary to language barrier, and 6.3% (8/126) were unable to complete secondary to cognitive impairment. 42.7% (41/96) were identified as being depressed. 29.2% (28/96) were classified as mildly depressed, 35.7% (10/28) of whom were on an antidepressant. 8.3% (8/96) were classified as moderately depressed, 25% (2/8) of whom were on an antidepressant. 4.2% (4/96) were classified as moderately severely depressed, 75% (3/4) of whom were on an antidepressant, and one patient was classified as severely depressed and was already on an antidepressant.

32.5% (41/126) were already on an antidepressant at the time of assessment, 80.5% (33/41) of whom were on a serotonin selective reuptake inhibitor (SSRI), 12.2% (5/41) were on amytriptyline, 4.9% (2/41) were on mirtazepine, and 2.4% (1/41) were on a selective noradrenaline reuptake inhibitor (SNRI).

Conclusions: Depression is common in the haemodialysis population and the majority of those with moderately severe and severe symptoms were appropriately on medication. The majority of those treated were on low dose SSRIs. Those who were mildly/moderately depressed did not appear to be identified and treated for depressive symptoms as readily.

This audit also highlights the use of antidepressant medication in this population group, and the difficulties in management that may be related to side effects.

The results were reviewed and consideration made to the use of alternative approaches, such as counselling and art therapy.

SA-PO3018

Buddhist Intrahemodialytic-Insight Meditation Improves Depression in Hemodialysis Patients Kriengsak Vareesangthip. *Renal Division, Department of Medicine, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand.*

Background: End stage renal disease (ESRD) patients can be lived longer with renal replacement therapy, including hemodialysis, continuous ambulatory peritoneal dialysis and kidney transplantation. Living on hemodialysis is a perpetual challenge, due to the demanding treatment schedule, dietary restrictions, and changes in function. The life expectancy of dialysis patients is 1/3 to 1/6 that of general population. Depression has long been identified as the primary mental health problem of patients with ESRD. It has been clearly shown that Buddhist meditation can improve the depression state of chronic illness patients. We, therefore, hypothesized that buddhist intradialytic-Insight Meditation for 10 weeks could calm down the severity of depression in hemodialysis patients.

Methods: Twenty stable hemodialysis patients who have been dialysed three times a week and all have Kt/V > 1.2. All patients were trained to practice Insight Meditation schedule in the term of Anapanasati during hemodialysis for 30 minutes in each hemodialysis session for 10 weeks. The severity of depression was assessed at pre and post period of insight meditation schedule by using Thai Depression Inventory. The Thai Depression Inventory was developed as a self-rating instrument for measuring the severity of depression. The scale was tested with the Hamilton Rating Scale for Depression.

Results: The depression score in hemodialysed patients was significant improved after practicing the buddhist insight meditation (pre and post depression score, 15.0 ± 7.2 vs. 10.3 ± 7.8, p = 0.01).

Conclusions: The buddhist insight meditation can be used to improve the depression and would provide good quality of life in hemodialysis patients.

SA-PO3019

Anxiety during Dialysis in Maintenance Dialysis (MD) Patients: A Highly Prevalent Co-Morbidity Usama Feroze,[1,2] David J. Martin,[1,3] Astrid Reina-Patton,[1,3] Jun Chul Kim,[1,2] Kamyar Kalantar-Zadeh,[1,2,3,4] Joel D. Kopple.[1,2,3,4] *[1]Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA; [2]Harold Simmons Center for Chronic Disease Research and Epidemiology, Torrance, CA; [3]David Geffen School of Medicine at UCLA, Los Angeles, CA; [4]UCLA School of Public Health, Los Angeles, CA.*

Background: Maintenance dialysis (MD) patients have a high prevalence of anxiety and depression. We have begun to study the frequency of anxiety episodes related to regular dialysis sessions and factors which may engender anxiety in MD patients.

Methods: 170 patients, 155 undergoing Maintenance hemodialysis (MHD)patients and 15 undergoing chronic peritoneal dialysis, were examined.Inclusion criteria included dialysis vintage of at least six months.Patients completed the Beck Anxiety Inventory and Beck Depression Inventory and questionnaires that examined their feelings of anxiety related to individual dialysis sessions.

Results: Patients' age was 56±SD 16 years, dialysis vintage, 55±48 months, 46% were female. Anxiety and depression were found in 53% and 36 % of patients, respectively. Patients frequently experienced episodes of anxiety associated with a number of the events that commonly occur in dialysis centers. As examples, 30% of MHD patients described moderate to extreme anxiety when they come for their regular MHD sessions, 24% showed moderate to extreme anxiety when a new or unknown staff person connected them to the dialyzer machine, and 18% reported moderate to extreme anxiety if the alarm sounded on the dialysis machine while they were undergoing dialysis.

Anxiety Level

Activity	None	Mild	Moderate	Quite a Bit	Extreme
Coming for a MHD treatment	50%	20%	13%	9%	8%
Connected to dialyzer by a new person	51%	25%	8%	6%	10%
Alarm sounds on dialysis machine	59%	23%	8%	6%	4%

Conclusions: Our study indicates that even well-established MD patients become anxious, often substantially so, in response to a number of the events that they commonly experience in during a chronic hemodialysis treatment. Research to examine the causes and methods of prevention and treatment of these anxieties would seem to be strongly indicated.

SA-PO3020

Recovery after a Hemodialysis Session: Associations with Patient's Characteristics, Quality of Life and Depression Symptoms in a Sample of Brazilian Patients Camila Joau, Marcelio Piccolo, Raissa Araujo, Larissa Moura Silva, Gustavo Behrens Pinto, Luiz Fernando Catto, Rafaela Lima, Gildete Barreto Lopes, Antonio Alberto Lopes. *Núcleo de Epidemiologia Clínica e Medicina Baseada em Evidências, Universidade Federal da Bahia, Salvador, BA, Brazil.*

Background: Many patients do not feel well after a hemodialysis (HD) session and need some time to recover. The study investigated associations of recovery after a HD session with patient's characteristics, health-related quality of life (HRQOL) and depression symptoms.

Methods: Cross-sectional study of 718 patients enrolled in the ongoing Prospective Study of the Prognosis of Hemodialysis Patients (PROHEMO) in Salvador, Brazil. The SF-36 was used to determine HRQOL scores for physical component summary (PCS) and mental component summary (MCS). The Center for Epidemiologic Studies Depression (CESD) scale was used for depression symptoms. Multivariable logistic regression was used to identify characteristics associated with recovery after HD and multivariable linear regression to estimate differences in scores with adjustments for age, gender, vintage, Kt/V, vascular access, albumin, creatinine, hemoglobin, diabetes, heart failure, cerebrovascular disease, peripheral vascular disease and intra-HD hypotension requiring IV saline.

Results: Approximately 30% of the patients (213/718) reported some time to recover after a HD session. Intra-HD hypotension was the variable more strongly associated with higher odds of reporting some time to recover (adjusted odds ratio=2.68, P=0.003). Compared with patients who reported feeling well after a HD session, those who reported some time to recover had significantly lower PCS score (adjusted difference (AD)= -4.77), lower MCS score (AD= -4.48) and higher CESD score (AD= +4.66); each P<0.001.

Conclusions: The results suggest that patients experiencing intra-HD hypotension are more likely to need some time to recover after a HD session, independently of age, Kt/V and comorbidities. It is also suggested that patients who need some time to recover have, in general, poorer HRQOL and higher depression probability, independently of intra-HD hypotension and numerous other covariates.

SA-PO3021

Under-Recognised and Undertreated? Symptoms in Haemodialysis Patients Catherine Susanna Vinen,[1] Chris Jones,[1] Kate A. Shepherd,[2] Heather Jane Brown,[3] Katherine Bristowe,[2] Beverley Matthews,[4] Donal O'Donoghue,[5] Fliss E. Murtagh.[2] *[1]King's College Hospital, London, United Kingdom; [2]King's College London, United Kingdom; [3]Guy's and St Thomas', United Kingdom; [4]NHS Kidney Care, London, United Kingdom; [5]Department of Health, United Kingdom.*

Background: Symptoms in haemodialysis patients are under-researched and under –treated. We identified the prevalence and severity of key symptoms using a validated assessment tool.

Methods: We undertook a cross-sectional study of haemodialysis patients in 2 UK renal units. We used the patient-reported Palliative Outcome Scale (POS-S renal) – a symptom module adapted for renal patients to capture prevalence and severity of 17 physical and psychological symptoms.

Results: 330 patients were included, mean age 61 years (range 22-89), mean time on dialysis 4.3 years (range 0–31 years). Most prevalent symptoms were: weakness (79%), pain (69%), poor mobility (66%), pruritis (63%), insomnia (61%) and dyspnoea (57%). 33% of all participants had moderate and 19% had severe/overwhelming weakness, 30% had moderate and 17% severe/overwhelming pain, and 29% had moderate and 20% severe/overwhelming poor mobility The mean global symptom score was 14/68 (range 0-56). There was no correlation between global symptom score and: age, dialysis vintage, gender, or ethnic group. Diabetes mellitus (as primary cause of end-stage kidney disease) was associated with significantly higher global symptom score compared to reno-vascular disease (17.4 vs 11.9, p=0.01). Analysis of symptoms by age tertiles (22-57, 58-72, 73-89 years)

showed insomnia was more common and decreased mobility less common in the youngest age group (p=0.01 & p<0.001, respectively). Global symptom score showed significant but weak negative correlation with urea reduction ratio (coeff -0.13, p=0.016).

Conclusions: Data reveal symptoms are highly prevalent among dialysis patients. Global symptom score does not correlate with age or dialysis vintage, and specific symptoms are more prevalent in certain age and diagnostic groups. Aggressive symptom management will improve quality of life and could be targeted by age and diagnostic group.

This work is part of a project led by NHS Kidney Care.

SA-PO3022

Daytime Intradialytic Sleep, Nocturnal Sleep, and Mortality Risk among Hemodialysis Patients in the CDS Nancy G. Kutner,[1] Rebecca H. Zhang,[1] Kirsten L. Johansen,[1,2] Donald L. Bliwise.[1] *[1]USRDS Rehabilitation/QoL Special Studies Center, Emory University, Atlanta, GA; [2]Nephrology Section, San Francisco VA Medical Center, San Francisco, CA.*

Background: Increased sleepiness during HD may reflect treatment-induced alterations in arousal status and/or thermoregulatory processes (*Sleep* 23:887-891, 2000). We explored intradialytic sleep, nighttime sleep, and survival among HD participants in the Comprehensive Dialysis Study (CDS).

Methods: Incident dialysis patients aged >18 from 296 randomly selected clinics were surveyed. 1,439 HD patients reported how long they typically dozed off/slept during HD, usual nighttime sleep hours, and trouble with waking up at night (nocturnal sleep fragmentation). These variables, and age, gender, race, education, employment status, diabetes, cardiovascular comorbidity, BMI, early nephrology care, SF-12 PCS score, and reported RLS, were included in a Cox proportional hazards model predicting mortality from dialysis start date to September 30, 2009. Patients were censored at change to PD or transplant.

Results: Younger age and diabetes were associated with greater doze/sleep time. 684 patients (47.5%) slept 6 or fewer hours at night, and 755 patients (52.5%) slept >6 hours at night. More patients who slept 6 or fewer hours reported always/sometimes experiencing nocturnal sleep fragmentation (73% vs. 47%; p < 0.0001), and they reported more intradialytic doze/sleep time than patients who slept >6 hours at night (0.97 [0.94] vs. 0.85 [0.90] hour; p = 0.01). In the multivariable Cox model, mortality risk increased as HD doze/sleep time increased among patients with 6 or fewer nighttime sleep hours (HR 1.23 [95% CI 1.06-1.44]; p = 0.008), but among patients with >6 hours nighttime sleep, greater HD doze/sleep time was not associated with increased mortality risk (HR 1.02 [95% CI 0.86-1.20]; p = 0.85).

Conclusions: Consistent with evidence that subjective sleepiness increases during HD treatment, intradialytic sleep was common. Patient and treatment factors that may be associated with different intradialytic sleep and nighttime sleep quantity/quality patterns may have important clinical implications.

SA-PO3023

John Henryism Active Coping, Perceived Health, and Depression Symptoms in Brazilian Hemodialysis Patients: The PROHEMO Study Gildete Barreto Lopes,[1] Carolina Cartaxo Penalva,[2] Marcelio Piccolo,[1] Camila Joau,[1] Sherman A. James,[3] Antonio Alberto Lopes.[1] *[1]Universidade Federal da Bahia (UFBA), Brazil; [2]Clinica NEPHRON; [3]Duke University.*

Background: John Henryism refers to a strong behavioral predisposition to actively cope with difficult psychosocial stressors. It is measured by the 12 item John Henryism Active Coping Scale (JHAC). Sample JHAC questions are: 1) In the past, even when things got really tough, I never lost sight of my goals; 2) Once I make up my mind to do something, I stay with it until the job is completely done. Persons who score high on the JHAC believe they can overcome difficult problems through determination and hard work. This study assessed if JHAC scores were associated with perceived general health (HRQOL) and depressive symptoms in maintenance hemodialysis (MHD) patients.

Methods: Cross-sectional analyses were conducted on 585 patients from phase II of the PROHEMO Study developed in Salvador, Brazil. John Henryism was assessed by the scores of the 12-item JHAC (range 12-60). The SF-36 was used to determine general health score (range 0-100); and the Center for Epidemiologic Studies Depression (CESD) scale to depression symptoms score (range 0-60). Linear regression was used to test associations of JHAC score above the median with general health and depression symptoms scores, adjusting for several sociodemographic, treatment and comorbid factors.

Results: Mean age was 48.29±13.66 yr, 61.3% males, 19.4% diabetics and 88.5% non-whites. Median JHAC=52. Patients with JHAC score above the median had higher mean general health score (difference= +6.36 points, P=0.002) and lower mean depressive symptoms score (difference= -2.43, P=0.013). The differences in scores after adjustments for covariates were +6.75 (P=0.002) for general health and -2.55 (P=0.011) for depression symptoms. Similar patterns of associations were observed by subgroups of age (<60 and ≥60 yr), race, gender and diabetic status.

Conclusions: These results suggest that MHD patients with high JHAC scores are more likely to report better general health and lower depression symptoms than patients with low JHAC scores, independently of sociodemographic factors and comorbidities.

Funding: Government Support - Non-U.S.

SA-PO3024

Predictive Characteristics of Successful Hemodialysis Patient Survival in the First 120 Days of Treatment Len A. Usvyat, Penny Faith Palmiero, Lizette Borges, Lisa A. Pacelli, Mary T. Sullivan, Paul Balter, Peter Kotanko, Paul M. Zabetakis. *Renal Research Institute, NY, NY.*

Background: In 2007, mortality rate in the first 3 months of dialysis was more than double compared to the overall annual mortality rate of 19% of prevalent hemodialysis patients (pts) [USRDS]. We aim to understand some of the specific factors that impact success during this period of care.

Methods: We reviewed data of all HD pts who were admitted to the RRI clinics within 30 days from their first date of dialysis b-n 2001 and 2010. Survival was assessed in the end of the incident dialysis period at 120 days.

2 analyses were conducted:

--Analysis 1 (pre-dialysis "PRE-D" factors) looked at success factors at the initiation of dialysis

--Analysis 2 (incident dialysis "INC-D" factors) looked at success factors present at the end of the incident period

Cox proportional hazards models were constructed for PRE-D and INC-D adjusted for: gender, race, ethnicity, age, comorbid conditions, facility effect, access type, BMI, presence of cardiac medication [beta blockers, ACEs, ARBs] and nutritional supplements, EPO dose, blood pressure, albumin, online clearance [OLC], neutrophil to lymphocyte ratio [NLR] and target weight.

Results: We analyzed data of 11,727 pts for PRE-D.

Table 1 summarizes the outcomes of Cox models for PRE-D and INC-D. Only significant predictors are shown (p<0.05). Other covariates described above were not significant.

PRE-D

Associated with better outcomes	Associated with poorer outcomes
Higher systolic blood pressure: 1% greater chance of survival for every 1 extra mmHg of BP	Being Male: 26% greater risk of death
Higher diastolic blood pressure: 1% greater chance of survival for every 1 extra mmHg of BP	Higher Age: 3.6% greater risk of death for every 1 year of age
	Presence of catheter as first access: 158% greater risk of death
	Presence of the following co-morbids: hepatitis and history of myocardial infraction suggest poorer survival
	Higher EPO dose: 2.5% greater risk of death for every 1000 additional units of EPO
	Larger size: 0.8% greater risk of death for every 1 unit of BMI

INC-D

Associated with better outcomes	Associated with poorer outcomes
Higher systolic blood pressure: 1% greater chance of survival for every 1 extra mmHg of BP	Higher Age: 2.7% greater risk of death for every 1 year of age
Higher diastolic blood pressure: 4% greater chance of survival for every 1 extra mmHg of BP	Presence of catheter as the access at the end of 120 days (or death): 251% greater risk of death
Higher albumin: 63% greater chance of survival for every 1 g/dL higher albumin	Higher neutrophil lymphocyte ratio (NLR): 0.3% greater risk of death for every 1 unit increase in NLR
Higher online clearance (LOC): 56% greater chance of survival for every 1 unit higher OLC	Presence of the following co-morbids: hepatitis suggest poorer survival
Presence of cardio-protective drugs: 30% greater chance of survival for patients who are on cardio-protective therapy	

Conclusions: Incident success as measured by survival in the first 120 days of dialysis is being closely watched for all dialysis patients. We observed that the following were associated with improved survival: AVG/AVF, higher blood pressure, utilization of cardio-protective drugs, and higher online clearance. Factors associated with poorer outcomes are lower albumin, higher NLR, being male, higher age, higher EPO dose, and various comorbid conditions.

SA-PO3025

The Effect of the Bundled Payment System on the Utilization of Erythropoiesis Stimulating Agent Therapy Mahmoud T. El-Khatib,[1,2] Heather Duncan,[1,2] Kotagal Shashi Kant.[1,2] *[1]Int Med, Div Neph and HTN, University of Cincinnati Coll Med, Cincinnati, OH; [2]DCI, Cincinnati, OH.*

Background: In 2011, CMS implemented a "Bundled" payment system, in which dialysis treatment payments include dialysis procedures and drug therapies. It is widely believed that this system will change treatment practices, especially dosing of ESA, the most expensive drug therapy. To decrease ESA usage, changes in IV iron use and route of ESA administration were implemented. The aim of the study is to assess effectiveness and consequences for patients.

Methods: Records for 90 patients from a single dialysis unit were examined. Period A (July 2010) and Period B (April 2011) were compared as 2 months with complete data for the measures of interest, and stable "before" and "after" time points. The changes to ESA management included: brands of IV iron, ESA route and frequency. The level of ferritin at which IV iron was stopped increased to 1200 ng/mL, while TSAT limit remained at 50%, and hemoglobin (Hb) target remained 10-12 g/dL.We examined ESA and IV iron dosing, Hb, Ferritin, and TSAT. Paired T and Wilcoxin Signed Rank Tests were used for analysis.

Results: In comparing Period A to Period B, ESA dose decreased, but IV iron doses did not change. Hb and TSAT remained the same. Ferritin levels were significantly higher after the change in IV iron product used.

ESA dosing and outcomes

Measure mean (sem)	Period A	Period B
Hb g/dL	11.0 (0.12)	11.2 (0.11)
TSAT %	28.1 (1.47)	27.3 (1.35)
Ferritin ng/mL	958.9 (200.67)	1157.0* (165.59)
ESA units per week per kg	177.5 (13.53)	126.0* (5.72)
IV iron mg per month	175.6 (21.74)	214.9 (27.0)

* p<.01

Conclusions: The strategies implemented in the dialysis unit successfully decreased ESA use and thus expense, yet maintained Hb level within target. IV iron dosing and TSAT remained the same, yet ferritin levels increased. It is difficult to identify if one factor (brand of IV iron, IV vs. SC dosing, better dosing protocols) boosted cost-effectiveness more than another, but the combined effect appears beneficial. Because of the limitation of the short period of observation, we will continue to monitor this strategy and the possible long-term effects of these increased ferritin levels.

SA-PO3026

Drop-Out Rates in Home Hemodialysis (HHD): Understanding the Challenges Rohini Arramreddy,[1,2] Sumi J. Sun,[2] Brigitte Schiller.[1,2] *[1]Medicine, Division of Nephrology, Stanford University, School of Medicine, Stanford, CA; [2]Medical Clinical Affairs, Satellite Healthcare, Inc., San Jose, CA.*

Background: Advanced technology has led to the re-emergence of HHD in the US. However, more frequent dialysis schedules may limit acceptance of HHD due to the increased burden of therapy on patient and/or partner. Limited data exist on modality failure with HHD. We report HHD drop-out rates from a dialysis provider with dedicated home training centers caring for about 200 HHD patients.

Methods: We performed a retrospective analysis of patients undergoing HHD with the NxStage System One (NxStage Medical Inc., Lawrence, MA) who dropped out during a 3 year period (2008-2010) to further understand reasons for drop out.

Results: The annual drop-out rate for HHD patients was 48% over the 3 years. 186 events of discontinuation were noted in a total of 182 patients. Reasons are shown below.

Transferred to center hemodialysis (CHD)	n = 84 (45%)
Died	n = 31 (17%)
Transplanted	n = 34 (18%)
Transferred to peritoneal dialysis	n = 15 (8%)
Transferred to another home program	n = 13 (7%)
Failed to complete training	n = 9 (5%)

Reasons for modality switch to CHD were documented for 72/84 (86%) events; 12 were unknown. Primary reason for modality switch to CHD was found to be "burn-out" in 34 patients (47%). Either HHD became overwhelming, strained the patient-partner relationship or resulted in care partner's fatigue. Medical, non-dialysis related reasons caused drop-out in 16 patients (22%), while access issues were responsible in 12 patients (17%). Acute medical issues of the care partner resulted in 4 patients (6%) transferring to CHD. Lack of access to a home dialysis provider after moving resulted in 4 patients (6%) changing to CHD. Non-adherence and lifestyle issues resulted in transfer of 2 patients (3%).One third of the transfer to CHD occurred within the first 90 days after starting HHD.

Conclusions: Drop-out rate in HHD was found to be substantial and caused by a variety of reasons. The primary cause was the perceived burden of HHD and subsequent fatigue of both patient and partner. The impact of close attention to possible "burn-out" symptoms and respite care options needs to be evaluated.

SA-PO3027

Which Dialysis Facilities Chose to Transition into the Expanded Prospective Payment System (PPS)? Implications for Access to Care Richard Hirth,[1] Tammie A. Nahra,[1] Marc Turenne,[2] John R.C. Wheeler,[1] Joseph M. Messana.[1] *[1]Kidney Epidemiology & Cost Center, Univ. of MI; [2]Arbor Research.*

Background: January 1, 2011, Medicare implemented an expanded PPS under which drugs and tests formerly billed on a fee-for-service basis were added to a bundle of dialysis-related services. Dialysis facilities were given the opportunity to transition into the new payment system over 4 years. Those choosing to transition have payments based 75% on prior system ,and 25% on the expanded PPS in 2011, with an increasing percentage based on the PPS until the phase-in is complete in 2014.

Methods: We examined determinants of facilities' choice to transition rather than going directly to the PPS.

Large-dialysis organizations (LDOs) did not opt for the transition. Our analysis focused on non-LDO facilities, 22.3% of which opted for the transition. We estimated a logit model predicting the choice to transition.

Results: Opting for the transition was predicted by being hospital-based (vs. free-standing; adjusted odds ratio (AOR)=1.88), % Black patients (AOR 1.08 per 10% increase), and being in certain Census regions. Membership in a regional chain (vs. independent; AOR 0.36) and having >5% of patients on peritoneal dialysis (PD) (AOR 0.67) predicted lower likelihood of choosing the transition. Facility size, rural location, % pediatric, or having an exception to the prior payment system did not significantly predict the choice to transition.

Conclusions: Overall, a minority of facilities opted for the transitional payment, suggesting that they anticipate being worse off financially under the new system. Knowing which types of facilities were most likely to choose the transition can serve as an early warning system to identify possible access to care barriers (e.g., for Black patients) or financial challenges (e.g., for hospital-based or independent facilities), allowing CMS and others to monitor facility closures and other measures of access to high quality care. Even though LDOs entered the new payment system as a block, monitoring could extend to LDO facilities with similar characteristics. The lower likelihood of opting for the transition by PD facilities suggests that the PPS may be favorable to home dialysis.

SA-PO3028

Economic Impact of Reduced HBV Testing among Hemodialysis Patients in the New Environment of Bundling: Results of a Study of De Novo HBV Infection Rates in a Mayo Clinic Hemodialysis Population – A Call for Changes in Current US CDC Guidelines on HBV Testing Protocols Macaulay A. Onuigbo,[1,2] Nnonyelum T. Onuigbo.[3] *[1]College of Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology/Hypertension/Transplant, Mayo Clinic Health System, Eau Claire, WI; [3]Information Technology, NT Systems, Eau Claire, WI.*

Background: Hepatitis B Virus (HBV) infection is a serious public health issue. Hemodialysis (HD) exposes ESRD patients to significantly higher HBV risks. Therefore, current US CDC guidelines call for monthly HBsAg tests for all HD patients. The charge to Medicare per HBsAg test is about $100 per patient per month. In the new environment of Medicare Bundling, this is unwise and wasteful if the de novo HBV infection is rare.

The aim of this study is to determine de novo HBV infection rates among HD patients in a Mayo Clinic HD population between July 2000 to July 2010.

Methods: A retrospective analysis of electronic databases of all relevant HBV serology and clinical data from patients attending five Mayo Clinic HD units between July 2000 and July 2010 was carried out to identify de novo HBV infection.

Results: A total of 965 HD patients were studied. There was one de novo HBV infection - a case incidence rate of 0.1%. He was a 54-year old Caucasian male with a known history of IV drug abuse, and previous hepatitis C carrier. Transient asymptomatic Recombinant post-vaccination HBsAgenemia (false positive HBsAg) was identified in another patient, two days following an Engerix B HBV booster vaccination.

Conclusions: Our study demonstrated that de novo HBV infection among HD patients in the US is very rare. We recommend 3-monthly HBsAg testing for all HD patients, but to continue current monthly testing for IV drug users and other high-risk groups. There exists no solid evidence-base for the efficacy of monthly HBsAg testing. At the national level, with over 500,000 HD patients, this would translate to a mind-boggling $40 billion annual savings in Medicare charges. The US CDC current guidelines on HBV serology testing among US HD patients, last revised in 2001, are outdated, and must be revised to fall in line with current clinical realities on the ground.

SA-PO3029

Overview of Regular Hemodialysis Treatment in China Guangyan Cai,[1] Dong Zhang,[1] Xiang-Mei Chen.[1] *[1]Nephrology, PLA Genaral Hospital, State Key Laboratory of Kidney Disease, Beijing, China; [2]Nephrology, PLA Genaral Hospital, State Key Laboratory of Kidney Disease, Beijing, China.*

Background: The China Renal Data System (CRDS) is built to understand the situation of hemodialysis in China.

Methods: The data system collected information of dialysis center, dialysis equipment, demographic and treatment of hemodialysis.

Results: There were 3583 hemodialysis centers in China registered in CRDS. The total number of hemodialysis patients at the end of 2010 was 221 628. The mean age of patients was 53 and the male to female ratio was 1.44:1. The mean duration of hemodialysis was 3.03 years. Primary diseases were primary glomerular diseases (58.76%), diabetic nephropathy (16.83%), hypertensive nephropathy (10.7%), polycystic kidney disease (3.54%), renal calculus (2.39%) and others (7.78%). The standard-achieving rate of blood pressure in predialysis (<=140/90 mmHg) was 39.08%. The average dose of erythropoietin was 7498.33IU/week and the standard-achieving rate of hemoglobin in predialysis (>=110g/L) was 18.56%. The level of serum calcium was 2.1 to 2.37mmol/L in 36.73 percent of patients. There were 13.08% patients whose serum phosphorus was 1.13 to 1.78mmol/L. The standard-achieving rate of calcium-phosphorus product (<55%) was 51.08%. There were 24.22% patients whose serum phosphorus was 1.13 to 1.78mmol/L. The HBsAg positive rate was 7.81% and the HCV antibody positive rate was 33.64%.

The new hemodialysis patients in 2010 was 58732. The mean age was 52.18 and the male to female ratio was 1.5:1. The diseases were primary glomerular diseases (55.74%), diabetic nephropathy (17.29%), hypertensive nephropathy (9.62%), renal calculus (2.96%), polycystic kidney disease (2.67%) and others (4.36%). 6424 hemodialysis patients died in 2010, the mean age was 59. The mean duration of hemodialysis was 3.4 years. The causes of death were cardiovascular events (45.78%), cerebrovascular events (18.05%), infection (7.37%). In 2010, 1137 hemodialysis patients received kidney transplant treatment, and 653 patients changed to peritoneal dialysis.

Conclusions: This is the first survey on the treatment of hemodialysis in China. We have had an overview of situation of hemodialysis in China.

The Changing Pattern of Primary Renal Disease in the Haemodialysis Population: A Forty Year Retrospective Review Siddhesh Mukund Prabhavalkar, Aisling E. Courtney. *Nephrology, Belfast City Hospital, Belfast, United Kingdom.*

Background: There is established geographical variation in the epidemiology of primary renal disease worldwide, but less is known about the temporal change in patterns of primary renal diagnoses over time. The aim of this study is to identify the variation in the pattern of primary renal diagnoses among incident chronic haemodialysis (HD) patients over last four decades.

Methods: All 4142 patients that were established on the chronic haemodialysis programme in Northern Ireland (NI) between 1970 and 2009 were included in this study. Clinical data was obtained from a prospectively recorded database. Each patient had a primary renal diagnosis classified according to the European Dialysis and Transplant Association (EDTA) coding system. The study period was divided into four decades: A (1970-79), B (1980-89), C (1990-99), and D (2000-09) in order to assess the change in patterns over time. Statistical analysis was performed using SPSS software and Cochran-Armitage Chi-square test was used for analysing trends.

Results: The greatest change was the proportion of people with diabetic nephropathy (type 1 diabetes rising from 0% in the 1970s to 9.5% in 2000s, $p<0.001$ and type 2 diabetes from 0.5% to 9.4%, $p<0.001$). There was also significant increases in the number of patients with chronic renal failure of unknown aetiology (from 17.8% to 29.1%, $p<0.001$), and renovascular disease (from 2.7% to 10.6%, $p=0.003$).

Conversely, there was a significant decrease in the proportion of patients with non-IgA glomerulonephritis (37% to 5.7%, $p<0.001$), interstitial nephritis (25.6% to 13.7%, $p<0.001$), and congenital nephropathy (2.3% to 0.8%, $p<0.001$).

Conclusions: There has been a significant change in the primary renal disease diagnosis in the HD population over past 40 years. The reasons for this are probably multifactorial including restricted acceptance policies in the early dialysis era, and advances in the management of diabetes mellitus and cardiovascular disease with increased numbers surviving to reach end-stage kidney disease. This is of relevance in planning HD provision in the future.

SA-PO3031

Emergent Support for Dialysis Patients Evacuated from the Northeast Japan Earthquake Disaster-Lesson from Previous Earthquakes Junichiro J. Kazama, Yoshikatsu Kaneko, Noriaki Iino, Shin Goto, Ichiei Narita. *Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: Dialysis patients need to receive regular hemodialysis therapy, which requires a large amount of water and electricity supply. Therefore, they have less chance to survive under disastrous condition. In 2004 and 2007, magnitude 6.8 earthquakes attacked Niigata, a prefecture located at northwest coast of mainland Japan. One of the earthquakes even caused a minor accident in a nuclear power plant. We have overcome the crises by sending patients from destroyed dialysis facilities to unaffected ones.

Results: A magnitude 9.0 earthquake and subsequent tsunami struck northeast mainland of Japan on March 11, 2011. Dialysis patients had to evacuate from the affected area, because water and electricity supplies were severely destroyed. Within a week from the earthquake, Niigata University Hospital and its related facilities accepted 181 of those evacuated dialysis patients. None of them brought their own medical records. Upon arriving at Niigata, they immediately received triage decision by expert nephrologists, and those who diagnosed as in critical condition immediately received emergent hemodialysis. Severely exhausted patients were directly admitted to hospitals. Some of patients received decontamination before the hemodialysis session, because they had been exposed by radioactive substances by the Fukushima-Daiichi nuclear power plant accident. The incoming patients were given tags recording their name, age, blood access side, and dry weight, so that all the medical staff could view and share basic information regarding large numbers of first-time visiting patients in the dialysis facilities. Thus, the emergent rescue and subsequent maintenance hemodialysis therapies were successfully performed without any remarkable troubles.

Conclusions: The experience of previous two earthquakes was definitely helpful when we accepted evacuated hemodialysis patients on this present great disaster. The concrete plans for saving hemodialysis patients under disastrous conditions must be drawn up before it comes into reality.

SA-PO3032

Aggravation of Blood Pressure Control in Patients with CKD5D after the March 11, 2011 Disaster in Japan and Its Potential Therapeutic Role as an α-Blocker Yoshihiro Tani, Kimio Watanabe, Yuki Kusano, Kenichi Tanaka, Yoshimitsu Hayashi, Koichi Asahi, Masaaki Nakayama, Tsuyoshi Watanabe. *Nephrology and Hypertension, Fukushima Medical University, Fukushima, Japan.*

Background: Control of blood pressure (BP) is aggravated by natural disasters such as earthquakes and it usually resolves within 4 weeks to the basal level. We examined the time course of BP variation and its influencing factors in patients with CKD 5D in areas of Japan affected by the earthquake that occurred on March 11, 2011.

Methods: We recruited 98 patients on regular hemodialysis (HD) from 3 HD centers in the Fukushima City area between February 28 and April 9, 2011. The profiles of the patients were as follows: mean age, 64.8 ± 13.9 years; male, 63%; HD vintage, 9.5 ± 12.6 years. The patients were administered with the following anti-hypertensive agents: calcium-channel blockers, 62.2%; ARB, 64.3%; ACE-I, 25.5%; diuretics, 27.6%; α-blockers, 29.6%; β-blockers, 21.4%; and DRI, 12.2%. Systolic and diastolic BP, heart rate (HR) and body weight (BW) at 4 weeks after the earthquake were retrospectively determined from medical records.

Results: Predialysis systolic and diastolic BP did not significantly change during the study period despite a significant reduction in increases in BW between dialysis sessions during the first week. However, postdialysis systolic and diastolic BP were significantly elevated (both $P < 0.01$; one-way repeated measures ANOVA), whereas HR and postdialysis BW did not change. The BP elevation after dialysis was sustained for 4 weeks even after correcting for the dry weight of each patient. Multiple logistic regression analysis revealed that α-blockers comprised the only independent factor for better post-dialysis blood pressure during the survey period: e.g., systolic and diastolic BP at week 4: OR, 0.25 (95%CI, 0.09 - 0.73) and 0.27, (0.07 - 0.65), respectively.

Conclusions: Blood pressure was aggravated at 4 weeks after the earthquake in patients with CKD 5D, and α-blockers comprised an independent influential factor for better BP. These findings indicate that α-blockers play a role in aggravated BP control after natural disasters in patients with CKD.

SA-PO3033

Advantage of HD/PD Combination Therapy in Disaster: Lessons from the Experience of the Japan Earthquake and the Fukushima Nuclear Accident Keita Kimura,[1] Makoto Ogura,[1] Akihiko Hamaguchi,[1] Tatsuo Hosoya,[1] Hiroyuki Terawaki,[1] Yasuo Kimura.[2] *[1]Division of Kidney and Hypertension, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan; [2]Shinkasiwa Clinic, Chiba, Japan.*

Background: The HD (hemodialysis) / PD (peritoneal dialysis) combination therapy, which comprises five or six days of PD combined with one HD session per week, is performed in Japan to better control body fluid and remove solute. After the Japan earthquake and the Fukushima nuclear accident, medical resources for dialysis therapy were temporarily limited because of many transferred patients from the destroyed area to our hospital, shortage of a dialyzer and dialysate and failure of power supply. In addition, dialysis patients had difficulty in visiting the hospital because of transportation systems failure. In such extraordinary situations, in Kashiwa Hospital of Jikei University School of Medicine, ten patients on the combination therapy were obliged to stop HD session for two weeks. To evaluate the safety and validity of it, we assessed the condition of the patients before and after the earthquake.

Methods: Respiratory condition, body weight gain, blood urea nitrogen, creatinine and potassium level were evaluated before and after the earthquake at the beginning of each HD sessions.

Results: After the earthquake, ten patients visited the hospital two weeks after the last HD session skipping one HD session. No one showed symptom of respiratory failure after the earthquake. Body weight gain(2.0±0.6 vs1.9±0.5% of dry weight), blood urea nitrogen (55.9±10.8 vs 59.1±18.4 mg/dl), creatinine (14.9±2.1 vs 16.2±2.6 mg/dl) and potassium (4.6±0.8 vs 4.6±0.6 mEq/l) level were not significantly different before and after the earthquake.

Conclusions: The HD/PD combination therapy is a modality which allows patient to choose from both PD and HD after disaster safely depending on the situation. This is a large merit of the HD/PD combination therapy.

SA-PO3034

Gene Therapy with Indoleamine 2,3-dioxygenase Ameliorates Development of Chronic Rejection Changes in the Rat Allotransplantation Diana Vavrincova-Yaghi,[1] Maria Sandovici,[1] Marc Seelen,[2] Harry Van Goor,[3] Robert H. Henning,[1] L.E. Deelman.[1] *[1]Dep. of Clinical Pharmacology, UMCG, Groningen, Netherlands; [2]Dep. of Internal Medicine, UMCG, Groningen, Netherlands; [3]Dep. of Pathology and Medical Biology, UMCG, Groningen, Netherlands.*

Background: Chronic transplant dysfunction (CTD) is the primary reason for late allograft loss in kidney transplantation. Because there is no effective treatment available, improvement of long-term graft survival remains the major challenge in the kidney transplantation field. Indoleamine 2, 3-dioxygenase (IDO) is crucially involved in foeto-maternal tolerance, and prevents allograft rejection. In our previous experiment, we showed that gene therapy with IDO inhibits acute rejection of renal allograft. The aim of current experiment is to show whether IDO is also able to improve CTD.

Methods: Kidney transplantation was performed in a rat Dark-Agouti (DA) to Wistar-Furth (WF) CTD model. RGD modified adenovirus carrying IDO gene (RGD-AdTIDO, n=4) or RGD modified adenovirus carrying gene for GFP (RGD-AdTL, n=4) were injected into the renal artery of the donor kidney before transplantation. Recipients were immunosuppressed with cyclosporine for 10 days. After 10 days, the contra lateral kidney was removed. Body weight, serum creatinine and blood pressure (BP) were measured and 24 hour urine was collected every two weeks. Rats were sacrificed after 12 weeks.

Results: Local gene therapy with IDO significantly improved body weight during the whole experiment in comparison with RGD-AdTL treated rats. It also decreased elevated plasma creatinine (40 ± 4.8 μmol/l) compared to treatment with RGD-AdTL (55 ± 8.5 μmol/l, 12nd week) and elevated proteinuria (10.3 ± 3.1 mg/24 h for RGD-AdTIDO and 32.2 ± 9.3 mg/24 h for RGD-AdTL, 12nd week). The therapy did not affect blood pressure, except for the second week (121 ± 5 mmHg for RGD-AdTIDO and 144 ± 4 mmHg for RGD-AdTL). Moreover, IDO therapy significantly decreased the incidence of focal glomerulosclerosis (10.5 ± 1.5 %) compared to AdTL therapy (33.1 ± 3.37 %).

Conclusions: Here we show for first time the beneficial effect of local IDO gene therapy in a model of CTD.

SA-PO3035

Y-box Protein-1 Induces Collagen I Production in Mesangial Cells Following CsA Treatment Lydia Hanßen,[1] Bjoern C. Frye,[1] Tammo Ostendorf,[1] Christina Alidousty,[1] Sonja Djudjaj,[1,2] Peter Boor,[1] Thomas Rauen,[1] Jurgen Floege,[1] Peter R. Mertens,[2] Ute Raffetseder.[1] *[1]Department of Clinical Immunology and Nephrology, University Hospital RWTH Aachen, Aachen, Germany; [2]Department of Renal Medicine and Hypertonia, University Hospital Magdeburg, Magdeburg, Germany.*

Background: The immunosuppressants cyclosporine A (CsA) and tacrolimus (Tac) are part of the standard therapy to prevent allograft transplant rejection, however they can cause tubulointerstitial/mesangial fibrosis. The fibrogenic effect of these calcineurin inhibitors (CNIs) is induced amongst others by transforming growth factor (TGF)-β with reactive oxygen species (ROS) as mediators..

Methods: The YB-1 content of CsA and Tac treated rat mesangial cells (rMCs) was determined via immunoblot. YB-1 was immunoprecipitated from cytoplasm of CsA-challenged rMCs and coprecipitated mRNA was detected by RT-PCR. *In vivo* experiment was performed in C57BL/6 mice (single dose CsA s.c., 100 mg/kg).

Results: We investigated the role of Y-box-binding protein-1 (YB-1), a highly conserved transcription and translation factor, in the CNI-triggered renal fibrogenesis. Upon treatment with therapeutic relevant doses of CsA and Tac, the intracellular content of YB-1 protein rose up to 10-fold in rMCs depending on time and dose. Both hindering translation through cycloheximide as well as blocking the ERK/Akt phosphorylation pathways prevented CsA-triggered YB-1 activation in contrast to inhibition of transcription via actinomycin D. Furthermore, degradation rate of YB-1 protein was significantly reduced in response to CsA. Thus, rapid accumulation of YB-1 following CsA-challenge is due to translation of YB-1 mRNA stores and enhanced protein stability. ROS, especially hydrogen peroxide, mediate YB-1 upregulation under CsA. Notably, this process is independent of TGF-b. The enhanced expression of collagen I (Col I) in rMCs following CsA application is caused by mRNA-stabilization due to physical interaction with YB-1 protein and consequently, absent in YB-1-depleted cells. The CsA-induced accumulation of YB-1 in the mesangium could be confirmed *in vivo*.

Conclusions: YB-1 induces profibrotic effects of CNI in the kidney via regulation of Col I translation.

SA-PO3036

Tacrolimus Induces a Myofibroblast-Like Phenotype in Human Kidney Fibroblasts by Ligand-Independent Activation of TGF-Beta Receptor Christian Koppelstaetter,[1] Susie-Jane Noppert,[1] Gerhard A. Mueller,[3] Michael Rudnicki,[1] Herbert Schramek,[1] Gert J. Mayer.[1] *[1]Department of Internal Medicine VI, Nephrology and Hypertension, Medical University of Innsbruck, Austria; [2]Department of Internal Medicine I, Clinical Immunology and Infectious Diseases, Medical University of Innsbruck, Austria; [3]Nephrology & Rheumatology Medical Center, Georg-August University Goettingen, Germany.*

Background: TGF-b is considered a strong inducer of renal interstitial fibrosis, which is a dominant factor in long-term outcome of kidney transplant recipients. Here we demonstrate the TGF-b-like effects of tacrolimus on kidney fibroblasts *in vitro* and the modulatory effect of NAD(P)H-oxidase 4 on this process.

Methods: The human renal fibroblast cell line TK-173 was treated with varying doses of tacrolimus (FK506, Prograf®) for three days. mRNA expression levels for NAD(P)H-oxidase 4, transgelin (a myofibroblast marker), TGF-b1, tropomyosin 1, and the collagen chain alpha-1(V) were determined by real-time qPCR. NOX4 protein expression and intracellular peroxide concentration were also determined.

Results: Tacrolimus-treated renal fibroblasts showed increased expression of NOX4, transgelin, tropomyosin 1, TGF-b1, and collagen mRNA. NOX4 up-regulation lead to a 20 % (max.) increase in intracellular hydrogen peroxide levels. TGF-b1 treatment duplicated the effects of tacrolimus. Specific inhibition of the TGF-b pathway repressed the effects of both tacrolimus and TGF-b1. Neutralization of extracellular TGF-b by specific antibodies almost completely abolished the reaction to TGF-b1, but left the response to tacrolimus unchanged. Si-RNA mediated knock-down of NOX4 had no effect on the tacrolimus-induced effects.

Conclusions: Tacrolimus at low nanomolar concentrations had TGF-b-like effects on cultured human renal fibroblasts. The binding of tacrolimus to FK506 binding protein 12 (FKBP12) leads to increased TGF-b receptor activity, even in the complete absence of ligand. This effect was sufficient to induce a myofibroblast-like phenotype and might thereby contribute to the induction of interstitial fibrosis in immunosuppressed kidney transplant patients.

SA-PO3037

Protection from Kidney Injury during Hibernation Is Associated with Increased Expression of X-Linked Inhibitor of Apoptosis Proteins (XIAP) Alkesh Jani, Swati Jain, Kameswaran Ravichandran, Charles L. Edelstein. *U of Colorado.*

Background: The 13-lined ground squirrel is a hibernating mammal that cycles through alternating phases of extreme cold ischemia (CI) for several days during torpor (T) followed by re-warming during interbout arousal (IBA). Hibernation is a natural model of DGF as evidenced by repeated prolonged CI during T followed by warm reperfusion during IBA. We hypothesized that hibernating squirrel kidneys are protected from apoptosis and necrosis.

Methods: Kidneys of C57BL6 mice and 1-2 year old summer (S), IBA and T squirrels were perfused with cold UW solution. The contralateral right kidney was immediately used as a control and the left kidney was stored in UW for 72 hours. Caspase-3/7 activity was measured using the fluorescent substrate DEVD-AMC. Apoptotic cells and the % of tubules displaying BBI were counted and scored by a pathologist. XIAP was detected by immunoblot and quantitated by densitometry.

Results: Tubular apoptosis, Brush Border Injury (BBI) and caspase-3 activity were significantly increased in mice vs. squirrels. To investigate the mechanism of protection against apoptosis in hibernating squirrels kidneys, we examined the protein expression of X-linked inhibitor of apoptosis proteins (XIAP). XIAP is a naturally occurring inhibitor of caspase-3. XIAP was significantly increased in hibernating squirrel kidneys, especially during IBA, whereas it was undetectable in mouse kidneys.

Table 1

Stage	Caspase-3 activity (nmol/min/mg)	Apoptosis (cells/hpf)	BBI score	XIAP protein
S (0 hr)	14	0.2	0	++
S (72 hr)	27	0.1	< 10%	++
T (0 hr)	6.5	0.1	0	+
T (72 hr)	13.6	0.0	0	+
IBA (0 hr)	23	0.1	<10%	+++
IBA (72 hr)	51	0	< 10 %	+++
Mouse (0 hr)	0	0	0	ND
Mouse (72 hr)	800*	1*	> 50%*	ND

n = 3; * p <0.05 vs mouse 0 hr, S, LT, IBA. ND = not detected.

Conclusions: Protection against CI in hibernating squirrel kidneys is associated with increases of XIAP. Mouse kidneys that are not protected against CI have undetectable XIAP. IBA kidneys that are most susceptible to CI and WR have the highest levels of XIAP.

Funding: NIDDK Support

SA-PO3038

Indoleamine 2,3-dioxygenase Inhibition Improves Renal Blood Flow Following 30 Minutes of Ischemia Todd D. Merchen,[1] John R. Gardner,[1] Rachel Harbarger,[1] A. Mellor,[1] James J. Wynn,[1] N. Stanley Nahman,[2,3] David M. Pollock.[1] *[1]Surgery, Georgia Health Sciences University, Augusta, GA; [2]Medicine, Georgia Health Sciences University, Augusta, GA; [3]Medicine, Charlie Norwood VAMC, Augusta, GA.*

Background: Ischemia reperfusion injury (IRI) is associated with delayed function and chronic allograft injury after renal transplant. Indoleamine 1, 2-dioxygenase (IDO) is an immunodulatory enzyme that mediates degradation of tryptophan. In a mouse renal ischemia model, IDO inhibition with 1-methyl-D-tryptophan (1-MT) improved serum creatinine (Cr) and decreased tubular epithelial cell apoptosis. To assess whether IDO improves post ischemia hemodynamics, we measured bilateral renal blood flow (RBF) in a rat ischemia model.

Methods: Three groups of SD rats (N=5) had bilateral renal artery probe placement and 1 hr of recovery. Shams (S) then had 30 mins of observation. Control (C) and 1-MT treated had 30 mins of renal artery clamp time, followed by 1 hr of recovery (POST). All rats then underwent recovery of serum and kidneys. 1-MT were pre-treated with 140 mg/kg of 1-MT 24 hrs prior to surgery and 1 hr prior to clamping.

Results: The serum kynurenine/tryptophan ratio was significantly reduced by 1-MT (0.052±.01 vs 0.103±.01uM, mean±SEM for 1-MT vs C, $p < 0.05$) indicating suppression of IDO. There were no differences in mean arterial pressure (101±2.1, 104±5, and 106±2.7mmHg, for S, C and 1-MT) or pre-ischemia renal blood flow (PRE RBF) (9±0.7, 11±0.7, and 14.4±1 ml/min for and 1-MT). However, 1-MT had significantly higher POST RBF: 11.6±1 vs 7.5±0.6 ml/min for 1-MT vs C ($p < 0.05$). Also, recovery of RBF in 1-MT was significantly increased: 83.2±3.5 vs 68.2±2.8% of PRE RBF levels for 1-MT vs C ($p < 0.05$). No differences were noted in post ischemia serum Cr(1.22±0.15, 1.21±0.10,1.21±0.04 mg/dl for S, C and 1-MT). These data suggest that IDO inhibition with 1-MT prior to renal artery cross clamping improves RBF 1 hr post ischemia.

Conclusions: IDO inhibition with 1-MT may help preserve renal function via an improvement in post ischemia hemodynamics. These findings also suggest that IDO may be a useful target to protect donor kidneys from the effects of IRI.

SA-PO3039

Early Outcome in Renal Transplantation Using Size Mismatched Recipients and Donors – A Porcine Experimental Model Tashi Chhoden,[1] Kristian Ravlo,[1] Peter Søndergaard,[1] Niels Secher,[2] Anna Krarup Keller,[4] Michael Pedersen,[3] Ulla Moeldrup,[5] Ernst Oeyvind Oestraat,[5] Rikke Norregaard,[4] Henrik Birn,[1] Bente Jespersen.[1] *[1]Department of Renal Medicine, Aarhus University Hospital, Aarhus, Denmark; [2]Department of Anaesthesiology, Aarhus, Denmark; [3]MR Research Center, Aarhus, Denmark; [4]Inst. of Clinical Medicine, Aarhus, Denmark; [5]Dept. of Urology, Aarhus, Denmark.*

Background: Transplantation of a kidney from a large donor to a small recipient, as in pediatric transplantation, is associated with marginal renal blood flow, shut down of GFR and risk of thrombosis. To study the mechanisms regulating early graft function we established a porcine model of size mismatched renal transplantation. GFR, renal blood flow (RBF) and markers of kidney injury were studied within 10 h after transplantation.

Methods: After induction of brain death, kidneys were removed from 60 kg donor pigs and kept in cold storage for 22h until transplanted into small (15 kg, n= 8) or size-matched (60 kg, n=8) recipients. The first 10 h after transplantation we measured GFR as urinary clearance of 51Cr-EDTA with constant infusion, RBF by MRI-technique, urinary NGAL-excretion by ELISA, and renal expression of hemeoxygenase (HO)-1 by qRT-PCR.

Results: In small recipients mean GFR was reduced within 30 min after reperfusion compared to size-matched recipients. This was associated with a significant reduction in medullary(M)-RBF, which decreased steadily up to 9 h after reperfusion. No difference was observed in cortical RBF. While no significant difference was observed in urinary NGAL excretion, increased HO-1 mRNA levels were observed in the cortex of small recipients compared to size-matched recipients.

Conclusions: After transplantation of kidneys from large donors to small recipients in a model with high risk of delayed graft function, a very early reduction in GFR was observed when compared to size matched recipients. This may in part be due to a reduction in M-RBF, although other mechanisms are likely to be involved as M-RBF continued to decrease while GFR remained stable. Increased expression of HO-1 in kidney cortex may reflect ischemic injury, although cortical RBF was not reduced in the small recipients.

SA-PO3040

Association of Transforming Growth Factor-beta (*TGF*-β) Gene Polymorphism with Acute Rejection in Korean Kidney Transplantation Recipients Hyun Ju Kim, Tae Hee Kim, Sunwoo Kang. *Department of Nephrology, College of Medicine, Pusan Paik Hospital, Pusan.*

Background: Acute renal graft rejection influences the results of kidney transplantation. Acute rejection (AR) is mainly caused by T-cell immune responses activated by cytokines, included transforming growth factor-β (*TGF*-β). *TGF*-β inhibits the inflammatory response of T helper cells. Recent investigations based on epidemiologic and genetic studies have defined several single nucleotide polymorphisms (SNPs) in regulatory sequences of cytokines have been associated with allograft survival. In this study, we examined whether polymorphisms of the TGF-β gene were associated with susceptibility to kidney transplantation rejection.

Methods: A total of 342 patients who had received kidney transplants were included. We extracted genomic DNA from blood samples and amplified the genomic DNA using the primers for each SNP. Three SNPs of *TGF*-β gene were genotyped from genomic DNA with direct sequencing. We analyzed 3 SNPs of *TGF*-β gene (rs2228048, rs764522, rs3087465).

Results: Acute rejection developed in 62 patients (18%). There is no significant differences in age, sex, number of HLA mismatches, cause of renal failure, immunosuppressant regimen between the AR and non-AR group. The one SNP (rs3087465) of the *TGF*-β gene were significantly associated with the fewer episode of acute rejection in the recessive model (odds ratio 0.0 ; 95% confidence interval 0.00-NA, P=0.042).

Conclusions: Our results show that one *TGF*-β gene polymorphism was associated with acute rejection in Korean kidney transplantation recipients.

SA-PO3041

Investigating the Mechanisms That Prevent Antibody-Mediated Injury in Patients with Donor-Specific Anti-HLA Antibodies by Microarrays Nicole A. Hayde,[1] Yi Bao,[2] Robert Brent Calder,[3] Bin Ye,[3] Enver Akalin.[2] *[1]Pediatric Nephrology; [2]Einstein/Montefiore Kidney Transplant Program; [3]Computational Genomics Facility, Albert Einstein College of Medicine, Bronx, NY.*

Background: Although, most patients with donor-specific anti-HLA antibodies (DSA) develope acute or chronic antibody-mediated rejection (AMR), some demonstrate normal allograft biopsies. We aimed to investigate the mechanisms involved in protection of the allograft from antibody-mediated injury by microarrays.

Methods: We retrospectively reviewed biopsies of 221 patients performed in 2009 and 2010. The gene expression profiles of transplant kidney biopsies were studied by Affymetrix HuGene 1.0 ST expression arrays.

Results: 77 patients had DSAs at the time of the biopsy and 43 showed antibody-mediated injury (9 acute, 34 chronic AMR) and 24 were normal or demonstrated minimal injury. There was no difference in frequency or mean fluoresence intensity (MFI) values of DSAs between 2 groups. 12 chronic AMR samples and 5 with minimal injury were available for microarray analysis and demonstrated differential gene expression profiles, mostly related to immune responses. 16 of the top 50 differentially expressed genes were non-coding RNAs. Gene set enrichment analysis using Pathogenesis Based Transcripts created by Edmonton Group demonstrated cAMR biopsies had upregulated interferon-gamma-dependent rejection-induced ($p<0.01$) and cytotoxic T cell associated transcripts ($p=0.03$).

	Normal or Minimal Allograft Injury (n=24)	Antibody-mediated injury (n=43)	p-value
Age	47 (33-62)	45 (30-52)	0.51
Male sex (%)	58	56	0.84
African-American Race (%)	38	37	0.98
Deceased-donor transplant (%)	71	67	0.77
Previous transplant (%)	17	12	0.56
Time to biopsy (days)	118 (56-500)	1110 (447-2483)	< 0.001
Class I DSA (%)	67	74	0.5
Class II DSA (%)	46	63	0.18
Median Peak Class I DSA MFI	2334 (2041-4196)	3560 (2437-5245)	0.22
Median Peak Class II DSA MFI	7704 (1675-12279)	4980 (1904-8524)	0.62

Conclusions: The strength of DSAs could not determine the development of antibody-mediated injury. Microarray analysis of biopsy samples suggested that the control of immune response for prevention of antibody-mediated injury may be mediated through non-coding RNAs.

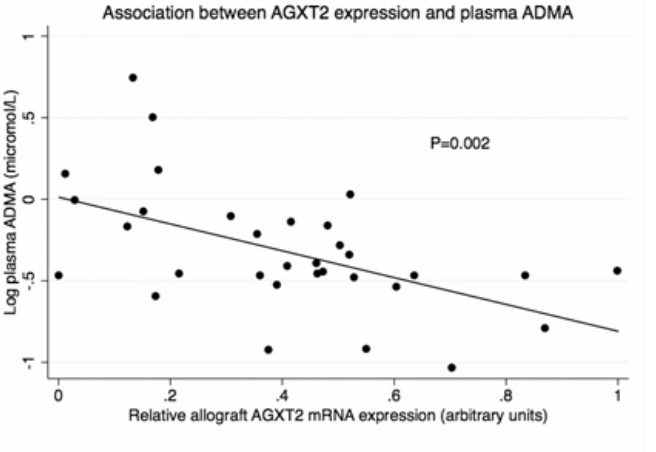
SA-PO3042

Allograft Expression of Alanine Glyoxylate Aminotransferase-2 in Protocol Biopsies Is Associated with Asymmetric Dimethylarginine Levels and Rate of Decline of Renal Function Ben Caplin,[1] Dorothea Nitsch,[2] Valeria Mas,[3] Jill T. Norman,[1] James M. Leiper,[4] David C. Wheeler.[1] *[1]UCL Medical School; [2]London School of Hygiene and Tropical Medicine; [3]Virginia Commonwealth University; [4]MRC Clinical Sciences Centre.*

Background: Asymmetric dimethylarginine (ADMA), inhibits nitric oxide synthesis, is metabolised by dimethylarginine dimethylaminohydrolase-1 (DDAH1) and alanine glyoxylate aminotransferase-2 (AGXT2), and is raised in kidney transplant reicipients. DDAH1 has been reported to influence decline in kidney function so we investigated the association between allograft AGXT2 gene expression, change in glomerular filtration rate (eGFR) and ADMA levels in renal transplant patients.

Methods: AGXT2 and DDAH1 mRNA were quantified by RTqPCR in 3-month protocol biopsies and plasma ADMA measured by LCMS. Associations between gene expression and decline in renal function were examined using a multilevel model of eGFR over the next year.

Results: Normalised mRNA levels were generated for 36 first kidney transplants, mean eGFR 52.9mL/min/1.73m^2 at biopsy. AGXT2 and DDAH1 expression were correlated. AGXT2 levels were inversely associated with plasma ADMA (Figure) and this persisted after adjustment for DDAH1 expression and eGFR. There was also a strong association between AGXT2 mRNA and eGFR decline: -0.17mL/min/1.73m^2/week (95% CI -0.32 to -0.02) for allograft AGXT2 expression above versus below the median (adjusted for donor and recipient age, sex and ethnicity and DDAH1 expression).



Conclusions: Independent replication of these observations is being pursued in a US cohort but these data raise the possibility that renal AGXT2 regulates plasma ADMA in transplant recipients. Taken with data on DDAH1 these findings suggest increased renal methylarginine metabolism associates with early decline in allograft function and that AGXT2 may be a potential therapeutic target.

Renal Transplant Genome Wide Association Study (GWAS) Demonstrates Genetic Indicator of Long-Term Allograft Function/Survival Paul J. Phelan,[1] Robert P. O'Brien,[2] Judith Conroy,[3] Sean Ennis,[3] Mary T. Keogan,[4] Gianpiero Cavalleri,[2] Susan Jennings,[4] Derk O'Neill,[4] Peter J. Conlon.[1] *[1]Nephrology and Transplantation, Beaumont Hospital, Dublin, Ireland; [2]Molecular and Cellular Therapeutics, Royal College of Surgeons of Ireland, Dublin, Ireland; [3]School of Medicine and Medical Science, University College Dublin, Dublin, Ireland; [4]Histocompatibility and Immunogenetics, Beaumont Hospital, Dublin, Ireland.*

Background: Genetic interaction between donor and recipient genomes in renal transplantation is known to contribute to allograft rejection and overall outcome, although the nature of the genetic component remains largely uncharacterized. In this study we aimed to examine genetic variation in the recipient genome, with respect to allograft function at 5 years, as a pilot study to a wider donor/recipient genome-wide association study (GWAS).

Methods: We performed GWAS on a primary cohort of 326 Irish transplant recipients using the Illumina 610-Quad chip. Patients were first time, kidney-only, deceased donor transplants between 1993 and 2002. All patients were on calcineurin inhibitor based immunosuppression.

Results: Using linear regression, we found a significant signal (p=6.9 x 10-08) in Chromosme 14 in the TRA locus (TRA@) with respect to allograft function at 5 years post transplantation, as measured by serum creatinine. Serum creatinine at 5 years showed a statistically significant difference between genotypes (p=0.0006; mean 153.3 µmol/L V. 255.5 µmol/L). The TRA locus codes for T cell receptor alpha chains which have a key function in immune recognition.

Conclusions: These findings are interesting given our relatively small yet homogenous patient population and the potential biological mechanism at play. It emphasizes the importance of studying genetic variation in transplant outcome. We aim to investigate this further by replication in a new recipient cohort.

SA-PO3044

Renal Allograft Biopsies Classified as AIN Display a CTL Molecular Signature Michelle L. Lubetzky, Darshana Dadhania, Janani Rangaswami, Thangamani Muthukumar, Kenar D. Jhaveri, Surya V. Seshan, Manikkam Suthanthiran. *Nephrology, Cornell University, NY, NY.*

Background: The molecular signature of post transplant allergic interstitial nephritis (AIN) has not been well described. Characterized by prominent eosinophils on biopsy, it is also known to share pathologic features with acute rejection (AR).

Methods: We identified 19 biopsies classified by pathology as AIN from a cohort of 512 for-cause biopsies from Jan 2008 to Feb 2011 (3.7%). From this cohort 8 patients had urinary specimens available for gene expression profiling. Immunohisotchemical staining (IHC) was done on corresponding biopsy specimens. We compared these urinary profiles and IHC to 5 patients with AR.

Results: Table 1 shows patient characteristics and treatments. Urinary profiling for Granzyme B (GB) revealed evidence of cytotoxic T cell response similar to that in AR (Figure 1A). IHC demonstrated significant staining for GB positive T cells (range of 5%-35%) in both AIN and AR biopsy groups (P=0.28). Graft survival was better when AIN occurred early in the post transplant course (<1 month, n=13) as compared with late (n=6), P=0.005, Figure 1B.

Table 1 AIN Patient Characteristics and Treatment Course (n=19)

Days post transplant	27 (5-3643)
Common offending agents	Bactrim (n=11), PPI (n=6)
Cre at biopsy (mean±SD)	2.99±1.88
% Peripheral Eosinophilia (mean±SD)	4.64±0.03
Eosinophils on biopsy	89% (17/19)
Treatment with Steroids (oral or IV Pulse)	89% (17/19)
Treatment by withdrawal of offending agent	100% (19/19)
Response to Therapy (return of cre to within 15% of baseline at 4 weeks)	79% (15/19)
Graft Loss	26% (5/19)

Figure 1A

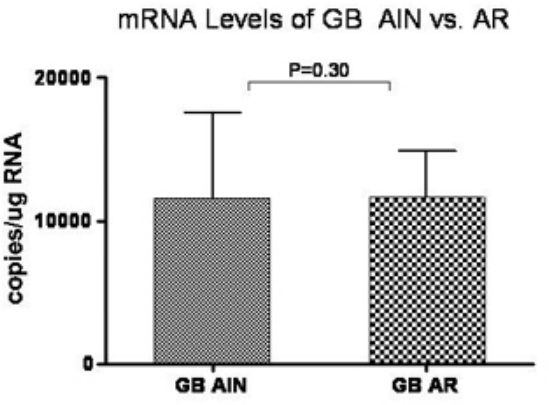

Figure 1 B

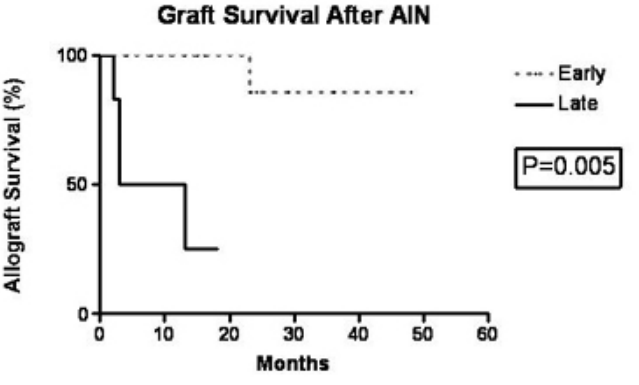

Conclusions: Our data suggests that AIN is associated with heightened expression of cytotoxic attack molecules similar to that seen in AR. The molecular response seen may have implications for the management of AIN.

SA-PO3045

KIM-1 Expression in Pre-Transplant Donor Kidney Biopsies as a Predictor of 1 Year Post Transplant Renal Function and Incidence of Acute Rejection Dwight M. Matthew,[1] Rachel E. Musial,[2] Sandeep Aggarwal,[1] Suganthi Soundararajan,[2] Gregory Malat,[3] Karthik M. Ranganna.[1] *[1]Nephrology, Drexel University College of Medicine, Philadelphia, PA; [2]Pathology, Drexel University College of Medicine, Philadelphia, PA; [3]Pharmacy, Hahnemann University Hospital, Philadelphia, PA.*

Background: Kidney injury molecule-1 (KIM-1), a type 1 transmembrane glycoprotein, is believed to be a specific histological biomarker for the diagnosis of early kidney allograft injury. However, its usefulness as a predictor of allograft function is uncertain.

Methods: The purpose of our study is to evaluate KIM-1 expression in pre-transplant donor biopsies as a predictor of 1 year post transplant renal function and acute rejection in the immediate post transplant period. In this study we included 44 patients who underwent deceased-donor kidney transplant from May 2008 to April 2010. We stained pre-transplant donor wedge biopsies for KIM-1 using immunohistochemistry.

Results: 23 out of 44 patients who had pre-transplant wedge biopsy for KIM-1 had a 1 month post transplant biopsy. Two out of 13 KIM-1 negative patients had evidence of acute rejection in 1 month post transplant biopsy while, 1 out 10 KIM-1 positive patients had acute rejection. The difference was not statistically significant (p=0.696). The 1 year post transplant eGFR (by MDRD) was 59.4 ±20.2 in KIM-1 positive and 60.5±23.7 in KIM-1 negative groups respectively (p=0.880).

	Biopsy 1 Month Post Transplant		
Donor Wedge Biopsies	AR	IFTA 0-2	IFTA 2-4
Positive KIM-1 staining: Total - 10 patients	1/10	9/10	1/10
Negative KIM-1 staining: Total - 13 patients	2/13	11/13	2/13

IFTA: Interstitial Fibrosis and Tubular Atrophy;

AR: Acute Rejection (both cellular and anti-body mediated)

Conclusions: Our results suggest that KIM-1 positivity in pre-transplant biopsies did not influence the 1 year post transplant renal function in patients who receive a deceased donor renal allograft. KIM-1 positivity did not predict an increased risk of developing acute rejection in the immediate post transplant period. The IFTA score, a marker of chronic allograft nephropathy, was also not different between the two groups.

SA-PO3046

Glomerular mRNA Expression of Pro- and Antithrombotic Factors in Thrombotic Microangiopathy in Renal Transplants Clemens L. Bockmeyer,[1] Putri Andina Agustian,[1] Svjetlana Lovric,[2] Anke Schwarz,[2] Mario Schiffer,[2] Maximilian Ernst Daemmrich,[1] Friedrich Modde,[1] Thorsten Feldkamp,[4] Udo Vester,[3] Verena Broecker,[1] Jan U. Becker.[1] *[1]Institute of Pathology, Hannover Medical School, Germany; [2]Clinic for Nephrology and Hypertension, Hannover Medical School, Germany; [3]Clinic for Pediatrics II, University Hospital Essen, Germany; [4]Clinic for Nephrology, University Hospital Essen, Germany.*

Background: Thrombotic microangiopathy (TMA) occurs in renal transplants as recurrent TMA or as de novo TMA with the two subforms CNI-toxicity TMA (CNI-TMA) and acute humoral rejection TMA (AHR-TMA). Since little is known about the contribution of the renal microvessels to thrombus formation, we analyzed the glomerular expression of pro- and antithrombotic genes.

Methods: Biopsies from 17 patients with TMA after transplantation (12 de novo and 5 recurrent TMA) were compared to 8 transplant biopsies without signs of TMA or humoral rejection. RNA was isolated from microdissected glomeruli of paraffin-embedded biopsies. The relative expressions of ADAMTS13, von Willebrand Factor (VWF), PAI-1, tPA, uPA, membrane cofactor protein (MCP), tissue factor and thrombomodulin were determined by quantitative RT-PCR after preamplification.

Results: Glomerular ADAMTS13 was higher in recurrent TMA and lower in de novo TMA compared to controls. Glomerular tPA was lower in de novo TMA, CNI-TMA and AHR-TMA compared to controls. Glomerular uPA was higher in recurrent and de novo TMA compared to the controls. Glomerular PAI-1 was higher in recurrent TMA, de novo TMA and AHR-TMA compared to controls. Glomerular MCP was higher in recurrent and de novo TMA than in controls. VWF, tissue factor and thrombomodulin were not found to be different between the cohorts.

Conclusions: These data provide insight into the contribution of the glomerular capillary bed to microthrombus formation in renal transplants. While all TMA forms seem to share partial defects in fibrinolysis and compensatory upregulation of MCP, different etiologies are reflected in differential expression of ADAMTS13. The increase of glomerular ADAMTS13 expression in recurrent and decrease in de novo TMA could be diagnostically and therapeutically relevant.

SA-PO3047

The Impact of Living Kidney Donation on Peripheral Blood Micro-RNAs Sophie Domhan,[1] Claudia Sommerer,[1] Martin G. Zeier,[1] Amir Abdollahi.[2] *[1]Medicine/Nephrology, University of Heidelberg Medical School, Heidelberg, Germany; [2]Radiation Oncology, University of Heidelberg Medical School, Germany.*

Background: The molecular effects of kidney donation by living donors are poorly investigated. Micro-RNAs (miRs) are considered as the masterregulators of transcriptome. We aimed to detect differential expression of peripheral blood microRNAs (miRs) as the function of unilateral nephrectomy in living donors.

Methods: So far, 16 patients consented to participate in this study. Whole blood total RNA including miRs were collected prior and post nephrectomy using PAXgene tubes. MiR isolation was performed using Qiagen's PAXgene Blood miRNA Kit and the QIAcube system. RNA quality control and quantitation was performed using total- and small RNA Agilent Chips (Bioanalyzer, Agilent) and NanoDrop spectrophotometer. Genome-wide miR profiling was performed with 12 samples representing 6 patients using Illumina's microRNA DASL assay. Clustering and statistics were performed using SUMO software package.

Results: We found 39 unique miRs to be differentially regulated post nephrectomy ($p<0.01$).The prevailing pattern was downregulation of miRs post nephrectomy (25 miRs) as compared to upregulation (14 miRs). In addition the extent of regulation was stronger among downregulated miRs. Given the inhibitory function of miRs on post/transcriptional regulation, our data suggest a global activation of the trancriptome via downregulation of miRs in response to nephrectomy. Interestingly, we found an enrichment of certain miR families among the downregulated miRs e.g., miR18a/18b, miR20/20* or miR27a/27b. Real-time quantitative RT-PCR using Taqman probes are performed to confirm the regulation of miRs in the entire collective. We further attempt to correlate the miR expression with renal function, urinary protein excretion and development of hypertension in kidney donors.

Conclusions: Our data demonstrate the feasibility of peripheral blood based miRNAs as sentinel organ to detect nephrectomy related effects in living kidney donors. This promising data might be instrumental towards identifying kidney donors at risk for post-nephrectomy associated deteriorations of health status via novel blood miR based biomarkers.

SA-PO3048

Urinary Angiotensin-Converting Enzyme 2 (ACE2) Is Increased in Renal Transplant Recipients Fengxia Xiao, Joe A. Zimpelmann, Valerie Catherine Cronin, Dean Fergusson, Greg A. Knoll, Kevin D. Burns. *Kidney Research Centre, Division of Nephrology, Dept. of Medicine, Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada.*

Background: Angiotensin-converting enzyme 2 (ACE2) is highly expressed in the kidney, and may protect against kidney disease progression by degrading angiotensin (Ang) II to Ang-(1-7). ACE2 has been identified in human urine, and may be shed from tubular epithelial cells, where it is localized to the apical membrane. We tested the hypothesis that urinary ACE2 is increased in renal transplant recipients.

Methods: Spot urine samples were collected from healthy subjects (C: age: 43.6 yrs, eGFR 81.0 mls/min, urine alb/Cr 9.3±1.9 μg/mg, n=50), renal transplant recipients without albuminuria (Tx: age: 52.3 yrs, 30% diabetic, eGFR 48.6 mls/min, urine alb/Cr 5.3±0.6 μg/mg, n=50), and renal transplant patients with significant albuminuria (Tx+A: age 52.0 yrs, 48% diabetic, eGFR 49.5 mls/min, urine alb/Cr 246.8±33.1 μg/mg, n=50). No subjects were being treated with inhibitors of the renin-angiotensin system.

Results: Levels of urinary ACE2 mRNA did not differ amongst the 3 groups, while ACE mRNA was increased in Tx+A, compared to C ($p<0.03$). In contrast, urinary ACE2 activity was significantly increased in both groups of renal transplant recipients, compared to healthy subjects (C: 2.35±0.32 vs Tx: 5.94±0.82 vs Tx+A: 6.01±1.39 pg eq/mg Cr x 10^5; $p<0.03$ vs C), while ACE activity did not differ amongst the groups. By immunoblot, ACE2 was detected in urine specimens as a protein of ~120 kDa, with a smaller band at ~ 90 kDa. Transplant patients had significantly higher levels of urinary ACE2 protein on blot analysis, compared to controls ($p<0.04$). Urinary levels of Ang-(1-7) were significantly increased in transplant patients (C: 0.55±0.14 vs Tx: 1.38±0.25 vs Tx+A: 1.33±0.24 ng/mg Cr; n=50, $p<0.04$ vs C).

Conclusions: These data indicate that urinary ACE2 protein is increased in renal transplant recipients, independent of albuminuria. The higher urinary levels of Ang-(1-7) in these subjects suggest increased cleavage of Ang II by urinary ACE2 in this setting. Although its source is unclear, urinary ACE2 may be a marker of renal injury in transplant recipients.

SA-PO3049

Effect of Immunosuppressive Drugs on DNA Repair in Human Peripheral Mononuclear Blood Cells Uzi Gafter,[1,2] Michal Herman-Edelstein,[1,2] Yaacov Ori,[1,2] Tsipora Malachi.[1] *[1]Nephrology and Hypertension, Rabin Medical Center, Petah Tikva, Israel; [2]Sackler School of Medcine, Tel Aviv University, Tel Aviv, Israel.*

Background: Cancer is a major cause of mortality among transplant recipients. Immunosuppressive treatment is one of the modifiable factors contributing to this phenomenon. Cyclosporine treatment in kidney transplant recipients was associated with reduced UV-induced DNA repair by peripheral blood mononuclear cells (PBMC) and increased cancer rate.

Aim: To investigate the effect of currently used immunosuppressive drugs on DNA repair.

Methods: H_2O_2-induced DNA repair by human PBMC was tested in-vitro in the presence of cyclosporine, tacrolimus, mycophenolic acid (MPA), sirolimus and everolimus at low to high non-toxic concentrations. The effect of combination therapy at maintenance levels was also tested.

Results: Cyclosporine and tacrolimus suppressed DNA repair throughout the tested dose range. In contrast, MPA, sirolimuis and everolimus did so only at the high doses. Maintenance doses of a combination of tacrolimus and MPA, the most frequent treatment regimen, reduced DNA repair, while MPA with sirolimus or everolimus did not.

Conclusions: Regarding risk of post-transplant malignancy, long-term treatment with mycophenolate mofetil or mycophenolate sodium combined with an mTOR inhibitor could be the treatment of choice.

SA-PO3050

Urinary Biomarkers in Cyclosporine A-Induced Nephrotoxicity Carla P. Carlos,[1] Nathalia M. Sonehara,[2] Sonia M. Oliani,[2] Emmanuel A. Burdmann.[1,3] *[1]Sao Jose do Rio Preto Medical School; [2]IBILCE, UNESP; [3]University of Sao Paulo Medical School, Brazil.*

Background: The aim of this study was to assess potential urinary biomarkers (Elisa assays) for cyclosporine A (CsA)-induced acute and chronic renal injury and compare them to renal tissue immunohistochemistry markers.

Methods: Male rats on low salt-diet (n=6/group) were studied 7, 14 and 21 d after CsA (15 mg/kg/day) or vehicle (V) treatment.

Results: CsA increased urinary fibronectin (ng/mL) after 7 (40.7±10.4 vs. 17.8±3.8 in V, mean ± SD) and 14 d of treatment (33.4±7.9 vs. 24.8±4.9 in V, $p<0.05$). Urinary TNF-alpha (pg/ml) presented the same pattern: 866±535 in CsA vs. 159±184 in V at day 7 and 836±243 in CsA vs. 401±349 in V at day 14, $p<0.05$. CsA increased urinary TGF-beta after 21d (746±1097 vs. 88±40 in V, $p<0.05$). CsA treatment increased urinary osteopontin (ng/ml) after 14 (404±73 vs. 167±99 in V) and 21d (467±139 vs. 120±59 in V, $p<0.01$). CsA increased urinary KIM-1 (pg/ml) in all periods: 1134±47 vs. 184±82 in V at day 7; 1152±50 vs. 264±87 in V at day 14 and 1013±186 vs. 372±224 in V at day 21, $p<0.01$). Renal immunohistochemistry showed an increased ED-1 infiltration (positive cells) in

CsA-treated rats at 14 (3.9±2.4 vs. 0.5±0.5 in V) and 21 d (15.4±13.1 vs. 0.8±0.8 in V, p<0.05). In the same way, increased tubulointerstitial alpha-actin expression (densitometry, arbitrary units) was observed in CsA groups after 14 (113±27 vs. 80±6 in V, p<0.05) and 21 d (142±16 vs. 69±10 in V, p<0.0001). Vimentin expression was increased only in CsA 21d (158±18 vs. 61±17 in V, p<0.0001), as well as periglomerular alpha-actin (145±12 vs. 70±11 in V, p<0.0001). Collagen IV expression was increased in all CsA-treated groups (137±10 vs. 88±10 in V at 7d, p<0.0001; 133±11 vs. 108±12 in V at 14d, p<0.01 and 135±7 vs. 111±17 in V at 21d, p<0.05).

Conclusions: We conclude that urinary fibronectin and TNF-alpha were indicators of the early phase of CsA-induced nephrotoxicity and urinary TGF-beta and osteopontin were observed in the later phase of the lesion. Urinary KIM-1 was elevated in all nephrotoxicity stages, suggesting that tubular damage is a continuous process during CsA exposure. Financial support: FAPESP 09/17100-2 and CNPq 150954/2009-3.

Funding: Government Support - Non-U.S.

SA-PO3051

Urinary NGAL Allows for Differential Diagnosis of Acute Kidney Injury in Renal Allograft Recipients Martina Guthoff,[1] Stephan Kemmner,[1] Silvio Nadalin,[2] Hans-Ulrich Haering,[1] Nils Heyne.[1] *[1]Dept. of Endocrinology and Diabetes, Angiology, Nephrology and Clinical Chemistry, University of Tuebingen, Germany; [2]Dept. of General, Visceral and Transplantation Surgery, University of Tuebingen, Germany.*

Background: Neutrophil gelatinase-associated lipocalin (NGAL) regulates growth and differentiation in renal epithelia. In the absence of systemic inflammation (SIRS), urinary NGAL is of renal origin and an early and specific marker of acute kidney injury. Here, we demonstrate urinary NGAL at respective cut-off to accurately predict acute rejection among other causes of acute kidney injury in renal allograft recipients.

Methods: Spot urine specimen were prospectively assessed in 182 consecutive renal allograft recipients on maintenance immunosuppression upon presentation at our outpatient clinic. Samples were blinded and NGAL concentrations determined by ELISA. Patient data were classed according to allograft function and AKIN criteria into stable allograft function or acute kidney injury (AKI) and according to underlying condition into control, chronic allograft nephropathy (IFTA), bacterial- or viral infection, allograft rejection or other.

Results: In stable allograft recipients, median urinary NGAL [interquartile range] was 6.9 [3 - 13] ng/ml, or 10.8 [5 - 27] µg/g creatinine. A moderate increase was seen in IFTA, CMV and BKV infection. Urinary tract infection was associated with a significant increase in urinary NGAL, yet highest values were observed in acute allograft rejection. With a cutoff at 30 ng/ml, urinary NGAL discerned stable allograft function from AKI. At cutoff 100 ng/ml, elevated urinary NGAL accurately predicted acute allograft rejection within our cohort (AUC-ROC 0.98, sensitivity 1.0, specificity 0.93), even in the presence of urinary tract infection.

Conclusions: Urinary NGAL, at respective cutoff, accurately predicted acute allograft rejection among all other causes of acute kidney injury in kidney transplant recipients. As a readily available parameter, urinary NGAL facilitates to quickly delineate the pathogenesis of renal functional deterioration in allograft recipients presenting with a rise in serum creatinine.

SA-PO3052

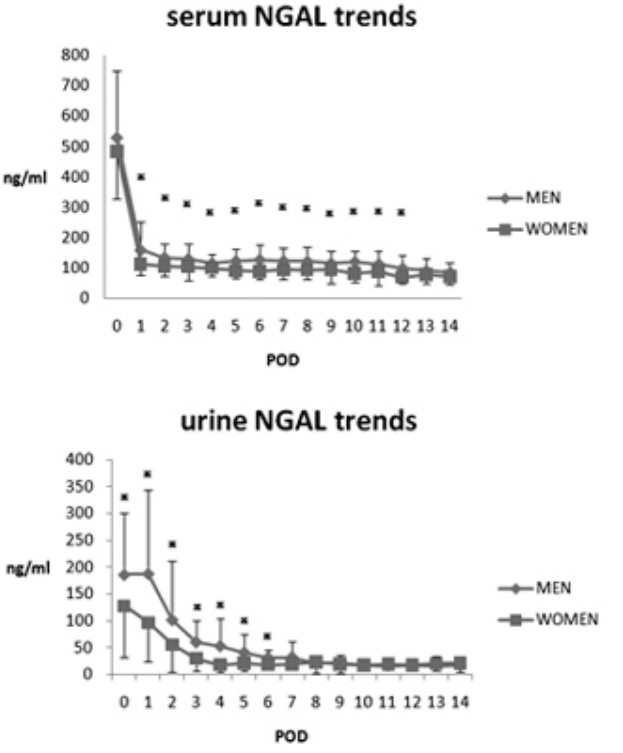
NGAL Trends in Living Donated Kidney Transplant Recipients during the Postoperative Period: Gender Differences Junko Kohei, Kosaku Nitta, Ken Tsuchiya, Takumi Yoshida, Michihiro Mitobe, Hidekazu Sugiura, Shunji Shiohira. *Fourth Department of Internal Medicine, Kidney Center, Shinjuku, Tokyo, Japan.*

Background: Neutrophil gelatinase-associated lipocalin (N-GAL) variations have previously been associated with acute kidney injury in postoperative period, and there are some reports about the NGAL trends after kidney transplantation. However gender difference in the NGAL trends after living donated kidney transplant recipients has not been studied in depth. This study's objective is to examine the gender differences in the NGAL trends during recovery after surgery.

Methods: We included only adult recipients undergoing living donated kidney transplantation. For NGAL detection the serum and urine samples were collected everyday after operation. The samples were analyzed using an immunoassay (ARCHITECT).

Results: In the results, 38 male cases and 20 female cases without delayed graft function were examined (mean age of male was 47±15, female was 47±13). In the results the male was changing highly intentionally rather than the females in the both serum NGAL and urine NGAL level. Gender difference in the urine NGAL trends became less clear on the POD7, in the serum NGAL, it was on the POD13 similarly.

[figure1]



Conclusions: This is a first report of gender differences in the serum and urine NGAL trends in the recovery process after renal transplantation. Renal dysfunction after kidney transplantation is difficult to diagnose with only serum creatinine, therefore using of the biomarker is expected as auxiliary diagnosis. This research has a high possibility of helping to diagnose delayed graft function in the postoperative early stage.

SA-PO3053

Peripheral Blood CD19+ Lymphocytes Predict Kidney Allograft Interstitial Fibrosis and Tubular Atrophy on 1-Year Protocol Biopsies Karlo M. Mihovilovic,[1] Stela B. Bulimbasic,[2] Zoran S. Siftar,[3] Danica Galesic Ljubanovic,[2] Mladen Knotek.[1] *[1]Department of Medicine, University of Zagreb Medical School, Clinical Hospital Merkur, Zagreb, HR, Croatia; [2]Department of Pathology, University of Zagreb Medical School, Clinical Hospital Dubrava, Zagreb, HR, Croatia; [3]Department of Clinical Chemistry, Clinical Hospital Merkur, Zagreb, Croatia.*

Background: Noninvasive tests of cellular or humoral immunity may be helpful in prediction of late kidney allograft function and progression of chronic histology changes. Aim of this study was to assess whether specific subset of peripheral blood lymphocytes could predict 1-year renal function and renal histology changes over 1 year.

Methods: A cohort of 46 kidney transplant patients was analyzed. Immunophenotyping of peripheral blood lymphocytes (CD4, CD8, CD127, CD25 and CD19) was done by flow cytometry at kidney transplantation. Protocol kidney biopsies were done on day 0 and at 1 year after transplant and were scored according to the Banff 07 classification. Δci, Δct and Δah were calculated by subtracting 0 scores from 1 year scores. Univariate and multiple regression analyses were done to test correlations.

Results: In a univariate analysis recipient and donor age were positively correlated with 1-year Δci, Δct and Δah. The number of CD19+ and CD8+ cells was negatively correlated with 1-year Δci, Δct and Δah. Δah was also in a positive correlation with CD4/CD8 ratio. In a multiple regression analysis Δci (b=-0,54 ± 0.20, p=0,007) and Δct (b=-0,50 ± 0,20, p=0,018) were independently associated only with number of CD19+ lymphocytes. Δah remained significantly correlated only with value of CD4/CD8 (b=0,50 ± 0,17, p=0,007). In a univariate analysis 1-year creatinine clearence was negatively correlated with recipient and donor age and positively with CD19+ and CD8+ lymphocyte counts. However, recipient and donor age were the only variables that remained significantly correlated with 1-year kidney function in multiple regression analysis.

Conclusions: CD19+ cells in peripheral blood may be a useful biomarker for prediction of 1-year kidney allograft histology changes. Higher CD19+ cell count at kidney transplantation may be associated with slower progression of IF/TA.

Funding: Government Support - Non-U.S.

SA-PO3054

The Clinical and Molecular Significance of Glomerular C4d Staining Nicole A. Hayde,[1] Yi Bao,[2] Robert Brent Calder,[3] Bin Ye,[3] Enver Akalin.[2] *[1]Pediatric Nephrology; [2]Einstein/Montefiore Kidney Transplant Program; [3]Computational Genomics Facility, Albert Einstein College of Medicine, Bronx, NY.*

Background: Diffuse C4d staining, defined as involving more than 50% of the peritubular capillaries (PTC), is accepted as a footprint of antibody-mediated rejection (AMR). However, the clinical and molecular significance of isolated glomerular C4d staining is not known.

Methods: We retrospectively reviewed biopsies of 221 patients performed in 2009 and 2010. The gene expression profiles of transplant kidney biopsies were studied by Affymetrix HuGene 1.0 ST expression arrays.

Results: 115 biopsies (52%) were C4d negative, 40 (18.1%) were PTC C4d+ (22 diffuse and 18 focal) and 66 (29.9%) were isolated focal glomerular C4d+. While positive PTC C4d staining is significantly associated with acute or chronic AMR, circulating DSAs and higher class I DSA MFI values, higher spot urine protein/creatinine ratio, there were no statistical significant differences between isolated glomerular C4d+ patients compared to C4d negative patients. Comparison of gene expression profiles of 12 chronic AMR biopsies to 6 isolated glomerular C4d+ biopsies without DSAs and 4 with DSAs, revealed 2630 and 717 differentially expressed genes, respectively ($p < 0.01$), where 618 genes were mutual in both comparison. Differentially expressed genes were mostly related to cellular immune response activation in chronic AMR.

	C4d neg (n=115)	Isolated Glomerular C4d+ (n=66)	PTC C4d+	p-value

Peak Class I DSA MFI	2882 (1980-5551)	3603 (2041-7266)	5106 (3622-8034)	0.05
Peak Class II DSA MFI	4596 (1904-73170	3603 (2041-7266)	5106 (3622-8034)	0.16
Pathologic diagnosis (%)				< 0.001
Acute cellular rejection	7	3	2	
Acute AMR	0	0	15	
Chronic AMR/TGP	19	18	65	
Serum creatinine (mg/dL)	2.5	2.5	2.5	
Spot urine pr/cr	0.3 (0.1-1.2)	0.4 (0.1-1.2)	1.1 (0.2-2.4)	0.04
History of Previous Tx (%)	9	15	10	0.4

Conclusions: Isolated glomerular C4d staining does not have clinical significance and the gene expression profiles do not demonstrate immune activation.

SA-PO3055

Proximal Tubular Expression of Activated Ask1 Is Up-Regulated in Recipients with Early New-Onset Diabetes, Pre-Existing Diabetes Mellitus, and Impaired Fasting Glucose Post-Renal Transplantation Zoltan G. Laszik,[1] Sindhu Chandran,[2] David G. Breckenridge,[3] Flavio G. Vincenti.[2] *[1]Department of Pathology, University of California San Francisco, San Francisco, CA; [2]Division of Nephrology, University of California San Francisco, San Francisco, CA; [3]Gilead Sciences, Palo Alto, CA.*

Background: Apoptosis signal-regulating kinase 1 (ASK1) activates c-Jun N-terminal kinase and p38 in response to various stimuli such as oxidative stress and cytokines. Activation of ASK1 results in diverse cellular reactions including cell differentiation, inflammation, and apoptosis. New-onset diabetes after transplantation (NODAT) is an independent risk factor for graft loss of unclear etiology. The aim of our study was to assess the proximal tubular expression of activated Thr845 autophosphorylated ASK1 (pASK1) in 6-month post-transplantation biopsies with normal morphology of recipients with NODAT, pre-existing type 2 diabetes mellitus (DM), or impaired fasting glucose (IFG).

Methods: Renal transplant recipients with NODAT, pre-existing type 2 DM, and IFG who underwent a 6-month surveillance biopsy at UCSF were identified. Quantitative immunofluorescence analysis of pASK1 expression was compared in groups of recipients with NODAT (n=6), pre-existing type 2 DM (n=9), IFG (n=9), or non-diabetic recipients (n=7). ImageJ software was used to quantify nuclear expression of pASK1 in the proximal tubules as visualized by double pASK1 and Lotus stain on frozen sections.

Results: pASK1 nuclear expression in the proximal tubules was significantly up-regulated in recipients with NODAT (0.0930 +/-0.046, p=0.0001), pre-existing type 2 DM (0.0937 +/-0.050, p=0.0001), and those with IFG (0.0721 +/-0.035, p=0.0006) compared to non-diabetic recipients (0.0333 +/-0.023). No significant differences were detected between recipients with NODAT and those with pre-existing type 2 DM (p=0.48) and IFG (p=0.086).

Conclusions: Increased nuclear expression of pASK1 in the proximal tubules in 6 month surveillance biopsies of recipients with NODAT, pre-existing type 2 DM and IFG indicates a potential role of ASK1 in the pathogenesis of graft dysfunction in the diabetic milieu.

Significance of Isolated Intimal Arteritis (v1) in Kidney Transplants: A Multicenter Observational Study Banu Sis, S. Bagnasco, Belinda Lategan, Mark Haas, Parmjeet S. Randhawa, Lynn D. Cornell, A. Magil, A. Herzenberg, Ian W. Gibson, Philip F. Halloran, Edward S. Kraus. *University of Alberta.*

Background: Microarray studies of biopsies from kidney transplants identified few isolated v-lesions (intimal arteritis) with no/minimal tubulointerstitial inflammation and low T cell transcripts, questioning whether these cases reflect true rejection (AJT 2007:7:2712-22).

We investigated the clinical significance of isolated v1 lesions in 266 conventional kidney transplants performed between 1999 and 2010 in seven transplant centers in North America.

Methods: We studied clinical parameters and graft survival (median follow-up after biopsy 44 months) in 100 isolated v1 biopsies (v1 and i<2 and t<2; group 1), in comparison to 90 biopsies with v1 plus high tubulointerstitial inflammation (v1 and i≥2 and t≥2; group 2) and 91 biopsies with v0 with minimal tubulointerstitial inflammation (v0 and i<2 and t<2; group 3). Biopsies with C4d positivity or biopsies from ABOi or cross-match positive kidneys were excluded. In selection of controls, no clinical parameter was matched (not to introduce bias). The biopsies were reviewed by a central pathology committee.

Results: The median post transplant time was 29 days in isolated v1, 33 days in group 2, and 21 days in group 3 biopsies (p>0.05). Indication for biopsies differed among groups: delayed or slow graft function triggered biopsies in 24% of isolated v1 group, but was uncommon in control groups (5% in group 2, 11% in group 3) (p<0.05). Serum creatinine at biopsy, 1 month and 6 month post biopsy did not differ among groups (p>0.05). Graft survival also did not differ among groups.

Conclusions: We conclude that, 1) isolated v1 biopsies are seen early and associated with increased delayed graft function; 2) v1 with or without high tubulointerstitial inflammation is not related to increased graft failure compared to v0. Thus, isolated v1 lesions, after the exclusion of antibody-mediated rejection, are of two types: T cell-mediated rejection and endothelial injury, and have no independent prognostic significance following anti-rejection treatment.

SA-PO3057

Pharmacodynamic Immune Monitoring in Pediatric Renal Allograft Recipients – Analysis of NFAT-Regulated Gene Expression and Immuknow® Yo Han Ahn,[1] Kyoung Hee Han,[2] Se Eun Lee,[2] Seong Heon Kim,[2] IL-Soo Ha,[2] Hae Il Cheong,[2] Hee Gyung Kang.[2] *[1]Center for Pediatric Oncology, National Cancer Center, Goyang, Republic of Korea; [2]Department of Pediatrics, Seoul National University Children's Hospital, Seoul, Republic of Korea.*

Background: Introduction of calcineurin inhibitor (CNI) as immunosuppressant has markedly improved the outcome of kidney transplantation. While therapeutic drug monitoring (TDM) is used to adjust the dosage of CNI, some patients, especially children, still suffer from rejection or infection and CNI toxicity. This study was to assess the adequacy of immunosuppression using pharmacodynamic monitoring.

Methods: Pharmacodynamic monitoring was done for 37 pediatric kidney allograft recipients. Expression of nuclear factor of activated T lymphocytes (NFAT)-regulated genes in patients' mononuclear cells was measured after activation, by qPCR of IL-2, IFN-g, and GM-CSF before (trough) and 1.5hr (peak) after ingestion of tacrolimus and the residual gene expression (RGE) was calculated. Global immune response was assessed by Cylex-ImmuKnow® assay. Trough and peak levels of tacrolimus were measured and clinical findings of rejection episodes and infectious complications were reviewed retrospectively.

Results: REG of IFN-γ and mean REG of the three NFAT-regulated genes showed negative correlation with tacrolimus peak levels. In patients with acute rejection episodes, REGs of IL-2 (35 ± 9 vs. 18 ± 24%) and IFN-γ (97 ± 58 vs. 40 ± 20%) were higher and tacrolimus peak levels were lower (15.3 ± 5.4 vs. 8.4 ± 3.0 ng/ml), compared to those in children without rejection. REG of GM-CSF (28 ± 33 vs. 47 ± 21%) was lower and tacrolimus trough level was higher (5.2 ± 1.8 vs. 4.0 ± 2.1 ng/ml) in patients with infectiouscomplication than in those without infectious complications. On the other hand, immune response measured by ImmuKnow® was not correlated with tacrolimus levels or clinical manifestations.

Conclusions: REG of NFAT-regulated genes showed correlation with clinical manifestation of under- or over-suppression of immune function in pediatric kidney allograft recipients. Further studies are required to assess whether pharmacodynamic monitoring as such would be more relevant than TDM.

SA-PO3058

Subclinical Rejection Management and Transplanted Kidney Function in Children Undergoing Kidney Transplantation Yuko Hamasaki,[1] Masaki Muramatsu,[2] Riku Hamada,[1] Tomoyuki Sakai,[1] Kenji Ishikura,[1] Hiroshi Hataya,[1] Hiroyuki Satoh,[2] Seiichirou Shishido,[3] Masataka Honda.[1] *[1]Nephrology, Tokyo Metropolitan Children's Medical Center, Fuchu, Tokyo, Japan; [2]Urology, Tokyo Metropolitan Children's Medical Center, Fuchu, Tokyo, Japan; [3]Pediatric Nephrology, Toho University Omori Medical Center, Ota-ku, Tokyo, Japan.*

Background: The introduction of basiliximab and other chimeric monoclonal antibodies has decreased the incidence of early clinical rejection after transplantation. However, subclinical rejection may occur, and its treatment remains controversial.

Methods: We analyzed 81 children (45 boys) without clinical rejection after ABO-compatible living donor kidney transplantation. Their mean age was 8.5 years. Routine kidney biopsies were performed 4 months and 1 year after transplantation. Histopathological findings were evaluated according to the Banff classification (2007). Borderline (BL) or severer changes were defined as subclinical rejection. Rejection was treated by methylprednisolone or deoxyspergualin. Kidney function was assessed on the basis of glomerular filtration rates (GFR), calculated with the Schwartz formula. Changes in histopathological findings and transplanted kidney function at 1 year were examined according to the presence or absence of treatment 4 months after transplantation.

Results: Histopathological examination 4 months after transplantation showed BL in 42 patients (51.9%) and acute T cell-mediated rejection of grade IA or higher (AR) in 13 (16.0%). Anti-rejection therapy was given to 6 patients with BL and all patients with AR. Histopathological findings at 1 year were normal in 5 and BL in 1 of the 6 patients with BL who received therapy. The GFR improved slightly from 73.9 ± 9.5 mL/min at 4 months to 77.8 ± 9.6 mL/min at 1 year. In 8 of the 13 patients with AR, histopathological findings at 1 year were BL. Among the patients with BL untreated 4 months after transplantation, histopathological findings at 1 year were BL in 22 (61.1%) and AR in 8 (22.2%). The GFR decreased significantly from 80.0 ± 13.3 mL/min to 77.0 ± 14.4 mL/min ($p<0.05$).

Conclusions: BL or severer subclinical rejection should be treated to improve outcomes after kidney transplantation.

SA-PO3059

Effect of Treatment of Subclinical Borderline Rejection on Early Renal Allograft Function Grace Chabala Chibesakunda,[1] Ignatius Yun-Sang Tang,[1] Suman Setty,[2] Sanjeev Akkina.[1] *[1]Medicine, University of Illinois at Chicago, IL; [2]Pathology, University of Illinois at Chicago, IL.*

Background: The management of subclinical borderline rejection on protocol biopsy and its impact on renal allograft function is unclear. We evaluated the effects of two treatment strategies on early allograft function

Methods: All patients who underwent protocol biopsy within the first year of transplant were evaluated. Patients with subclinical borderline rejection were divided into two groups according to their treatment. Group 1 received methyprednisolone 1500 mg over two to three days and an increase in baseline immunosuppresion while Group 2 was treated with an increase in baseline immunosuppresion only. The baseline demographics, renal allograft function as assessed by MDRD eGFR at baseline, time of biopsy and 1, 3, and 6 months after treatment were evaluated. The change in eGFR from the time of biopsy at 1, 3, and 6 months after treatment was compared between the two groups.

Results: Twenty three patients had subclinical acute cellular rejection: Banff 1A (3), Banff 1B (2) and borderline rejection (18). There were 7 patients in Group 1 and 11 in Group 2. Group 1 had a lower eGFR than Group 2 at the time of biopsy (42.4+/- 13.3 vs. 63.4 +/- 22.5 mL/min/1/73m^2, p = 0.041).The eGFR at the time of biopsy and at 1, 3 and 6 months after treatment are shown in the table. There was a greater percent improvement in eGFR at one month in Group 1 than Group2 (134.2% +/- 33.8 vs. 103.1%+/-18.9, p = 0.027) but there was no difference between the two groups at 3 and 6 months.

Renal Allograft Function

	Group 1 (n =7)	Group 2 (n =11)	
Time	eGFR mL/min/1.73m²		P Value
At Biopsy	42.4±13.2	63.4±22.4	0.04
1 Month	55.7±18.8	60.2±21.8	0.67
3 Months	48.3±21.8	63.0±25.4	0.21
6 Months	47.8±18.7	76.0±27.6	0.05

Conclusions: In patients with subclinical borderline rejection, steroid treatment resulted in improvement of 1- month eGFR. However there was no difference at 3 and 6 months. Further studies are needed to assess the impact of steroid treatment on long term graft function

Funding: NIDDK Support

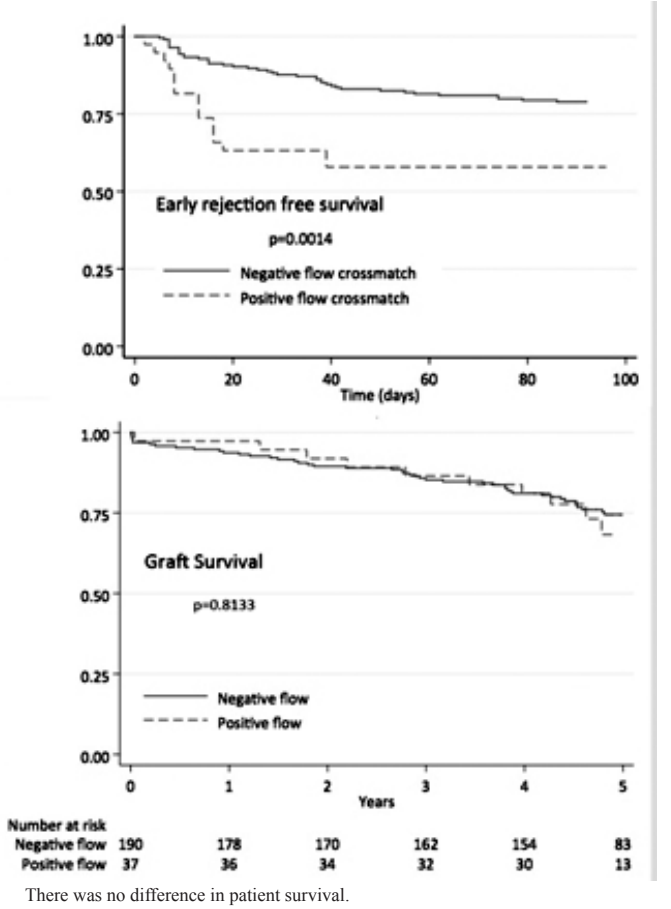
SA-PO3060

The Impact of a Positive Flow Cytometric Crossmatch on Long-Term Outcomes Following Deceased Donor Renal Transplant Geoffrey K. Dube, Sumit Mohan, David J. Cohen. *Medicine, Columbia University Medical Center, New York, NY.*

Background: Flow crossmatch (FCM) is often done at the time of deceased donor renal transplant (DDRT), and a positive FCM may be used either to exclude the recipient from receiving that transplant or to alter post-transplant management. Data are conflicting regarding whether a positive FCM at the time of DDRT is associated with an increased risk of acute rejection or graft loss. We analyzed the effect of a positive FXM at the time of DDRT on long-term outcomes.

Methods: We reviewed all adult recipients of a DDRT who were transplanted at a single center from 1/01/05-1/31/07. All patients had a FCM performed. 233 patients were transplanted, 38 had a positive FCM. All patients were on a rapid steroid withdrawal protocol. Maintenance immunosuppression consisted of tacrolimus and mycophenolate. All patients received induction therapy.

Results: Recipient demographics are shown in table 1. Rejection-free survival and graft-survival are shown in figure 1.



There was no difference in patient survival.

	Positive FCM (n=38)	Negative FCM (n=195)	p-value
Mean follow up (yrs)	4.27	4.35	NS
Age (yrs)	45.3	52.4	0.001
% female	42.1	45.1	NS
% African-American	23.7	31.8	NS
% diabetes	13.2	29.2	0.04
% retransplant	34.2	17.2	0.018
% thymoglobulin	77.8	92.1	0.044
% delayed graft function	42.1	48.2	NS
% ECD	18.4	30.2	NS
Cold ischemia (hrs)	30.5	31.6	NS
Creatinine 1-yr	1.8	1.8	NS
Creatinine 2-yrs	1.74	1.73	NS
Creatinine 3-yrs	1.61	1.74	NS

Conclusions: A positive FCM at the time of DDRT is associated with an increased risk of acute rejection. Despite a higher rate of acute rejection, especially in the first month post-transplant, there is no difference in patient survival, graft survival, or renal function at 3 years. A pre-tranplant positive FCM should not be used to exclude patients from receiving a DDRT.

SA-PO3061

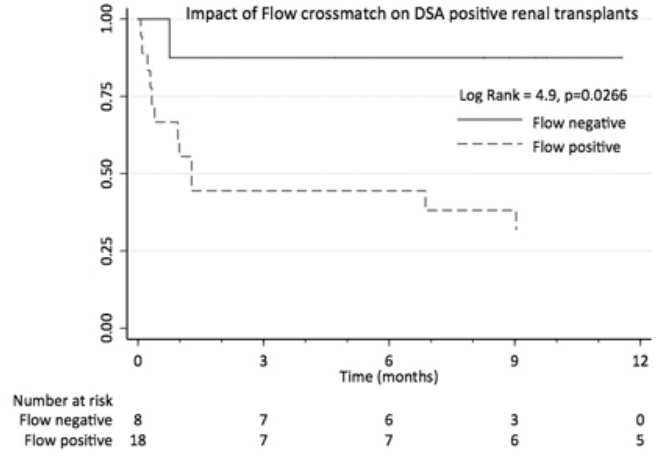
Flow Crossmatch Is a Better Predictor in Patients with Preformed Donor Specific Antibodies Demetra Tsapepas, Amudha Palanisamy, Sumit Mohan, Elena Rodica Vasilescu, Russell J. Crew, Bekir Tanriover, Geoffrey K. Dube, Nicole M. Ali, Lloyd Ratner, David J. Cohen. *Columbia University.*

Background: The impact of flow crossmatch results on transplant outcomes remains unclear, particularly in patients with donor specific antibodies (DSA). We attempt to determine if patients with a positive flow crossmatch (flow-xm) were more likely to have acute rejections than those who had a negative flow-xm despite the presence of DSA.

Methods: We performed a retrospective review of all adult DDRT recipients from 1/2009-12/2010. All patients had a negative CDC crossmatch at the time of transplantation and had solid phase assay measurement of HLA antibodies. A flow-xm was subsequently done if HLA antibodies (donor specific or otherwise) were detected by Luminex. We identified 26 patients with DSA who did not receive any additional treatment other than our standard induction regimen at the time of transplantation followed by our steroid free immunosuppression protocol of tacrolimus and mpa. In this cohort, 18 had a positive flow-xm and 8 had a negative flow-xm.

Results: Patients with positive flow-xm had a similar age (50.9 ± 14 v 57.5 ± 12.9, p=0.27), gender distribution (female 62.5 v 37.5%, p=0.35), race (white 50 v 62.5%, p=0.27) prevalence of pts with previous transplants (50 v 50%, p=ns) and cold ischemia time (28.2 ± 10.1 v 30.9 ± 9.6, p=0.55) to patients with a negative flow-xm. All patients with a negative flow-xm had MFI < 4500 by luminex. Patients with positive flow-xm have a significantly

higher risk of rejection (14.3 v 62.5%) and the 6 cases of early antibody mediated rejection (AMR) seen in our cohort were all present in the positive flow-xm group.



Conclusions: Among patients with preformed DSA, the presence of a positive flow-xm appears to predict a significantly higher risk of early acute rejection and in particular acute AMR.

SA-PO3062

Pre-Transplant Immunologic Risk Assessment in Patients with Donor-Specific Anti-HLA Antibodies Kwaku Marfo, Min Ling, Daniel G. Glicklich, Graciela De Boccardo, Enver Akalin. *Einstein/Montefiore Kidney Transplant Program, Bronx, NY.*

Background: We developed an algorithm for pretransplant immunologic risk assessment based on mean fluorescence intensity (MFI) values of Luminex single antigen beads and channel shift values of flow-cytometry cross-match results in patients with donor-specific anti-HLA antibodies (DSA) to decrease antibody-mediated rejection (AMR), which has been reported as 30-40%.

Methods: Patients' Anti-HLA antibodies with MFI values more than 5,000 were reported to UNET as unacceptable antigens. Kidney transplants were performed only if the MFI values of DSAs were less than 5,000 and flow T and B cell cross-match channel shift values were less than 150 and 250, respectively. Patients received anti-thymocyte globulin induction and IVIG (2 gram/kg) induction treatment.

Results: Cohort of 22 patients with pre-transplant DSAs received a transplant with this protocol. There were 15 female, 7 male, 15 African-American, 17 deceased-donor and 5 living-donor recipients with a median age of 50. 12 patients had class I, 8 class II, 2 both class I and II DSAs with a mean number of DSAs 1.68 ± 0.72, DSA MFI 3766 ± 3752, and peak Luminex PRA 70 ± 30 prior to transplant. During a mean follow-up of 373 ± 225 days, patient and graft survival was 95% (one patient died due to cardiovascular disease with a functioning allograft). 16 patients underwent 22 clinically indicated kidney biopsies and 2 showed (9%) AMR (both responded to treatment) and there was no acute cellular rejection or transplant glomerulopathy. 8 patients (36%) lost their DSAs during follow-up and the remaining patients' DSA MFI was 3471 ± 4783 at the last clinic visit. Patients have stable kidney function with a median serum creatinine level of 1.25 mg/dL. Patients were screened monthly for BK viremia and 2 patients (9%) developed BK viremia without polyoma nephropathy.

Conclusions: We demonstrate that pretransplant immunologic risk assessment based on MFI values of Luminex single antigen beads and channel shift values of flow-cytometry cross-match and transplant with anti-thymocyte globulin and IVIG significantly decreases AMR rates in kidney transplant recipients with DSAs.

SA-PO3063

The Effectiveness of Rituximab/Intravenous Immunoglobulin Therapy with Chronic Active Antibody Mediated Rejection in Renal Transplant Recipients Yu Ah Hong, Hyun Gyung Kim, In O Sun, Sun Ryoung Choi, Hoon Suk Park, Byung Ha Chung, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang. *Nephrology, Internal Medicine, Seoul St. Mary's Hospital, Seoul, Republic of Korea.*

Background: Chronic active antibody mediated rejection (cAMR) is one of the causes of chronic allograft kidney dysfunction. Until now, there is no established treatment protocol of cAMR. We report on our experience of a combination of rituximab and intravenous immunoglobulin (IVIG) treatment in patients with cAMR.

Methods: Six renal transplant recipients who showed progressive deterioration of graft function were included. The diagnosis of cAMR was confirmed with graft biopsy based on Banff' 05 classification. The patients received single dose of rituximab (375mg/m^2), followed by intravenous immunoglobulin (0.4g/Kg) once daily for 4 days. Steroid pulse was given concurrently at first 3 days. Human leukocyte antigen-donor specific antibodies (DSA) were detected by Luminex solid-phase assays before and after 2 weeks. The effect of a combination of rituximab and IVIG was assessed by graft function, amount of proteinuria, and titer of DSAs. The responder group was defined as glomeular filtration rate improved or stabilized after treatment.

Results: The response rate was 50% (3/6). GFR increased or maintained in three patients after Rituximab/IVIG treatment, but three patients did not respond to therapy. One patient of responder group showed a marked reduction of proteinuria after treatment. But, amount of proteinuria increased in all three non-responders. Follow up donor specific antibodies after treatment were checked in two responder patients. DSA titer dropped significantly in response to the therapy in one patient, whereas unchanged donor specific antibody titer was observed the other patients.

Non-responders had the high degree of transplant glomerulopathy, severely deteriorated allograft function, and heavy proteinuria at the time of diagnosis of cAMR. They had a longer duration of post-transplant time in comparison with responder patients. The treatment regimen was well tolerated.

Conclusions: A combination of Rituximab and IVIG may be effective for the treatment of cAMR at earlier stage.

SA-PO3064

Treatment of Vascular Rejection with ATG by CD3 Monitored Dosing Is Safe and Effective in Renal Transplantation Scott R. Henderson, Lucy A. Galloway, Robert Vaughan, David S. Game. *Nephrology & Transplantation, Guy's Hospital, London, United Kingdom.*

Background: Acute vascular rejection carries a poor prognosis for graft survival and proposed treatments have been associated with morbidity and mortality. Reports of ATG to treat vascular rejection are prior to the routine use of anti-CD25 antibody induction and include steroid resistant rejection. ATG dose guiding is most often performed according to total white cell count. We use ATG as first line treatment for Banff acute T cell mediated rejection type 2 and adjust dose according to CD3 count. This study reviews the efficacy and safety of this approach.

Methods: All patients treated at our centre with ATG between 2007 and 2009 were reviewed.

Results: 16 kidney transplant recipients and 4 simultaneous kidney-pancreas transplant recipients received ATG. 15 cases were classified as Banff 2A and 5 cases as 2B. Humoral component to the rejection was noted in 4/20. 17/20 patients received anti-CD25 antibody induction and all were receiving calcineurin inhibition, mycophenolate mofetil and prednisolone during acute rejection. 11/16 kidney transplant recipients had baseline immunosuppression switched from ciclosporin to tacrolimus; all other patients continued on tacrolimus. After an average of 642 days follow-up, 3 patients lost their grafts (average 8 months; 2/3 had persistent humoral component treated with plasma exchange and IVIg) and 1 patient died with a functioning graft. The mean creatinine censored for graft survival was 151 umol/l (n=17, SEM 44), representing an average 37% improvement from pre-treatment creatinine in patients not requiring pre-treatment dialysis (n=15). Bacterial infection was uncommon (n=1) although 6 patients were treated empirically for bacterial chest infections. CMV viraemia was common (n=12) and often within 1 week (n=7). There were no reports of fungal infection or malignancy.

Conclusions: ATG treatment for Banff type 2 acute cellular rejection in the modern era of immunosuppression is effective and safe when dose adjusted for CD3 count. CMV viraemia is common early after ATG treatment if a CMV surveillance strategy is used. A randomised controlled trial is required to further confirm the efficacy of this approach.

SA-PO3065

Evolving Therapies for Antibody Mediated Rejection: Is Bortezomib Better Than Rituximab? Michelle L. Lubetzky, Jennifer K. Walker, Marie Matignon, Choli Hartono, Thangamani Muthukumar, Surya V. Seshan, Manikkam Suthanthiran, Darshana Dadhania. *Nephrology, Cornell University, NY, NY.*

Background: It is not known if addition of Rituximab (Ritux) or Bortexomib (Bort) therapy (Rx) has added value in treating ABMR. We compared outcomes of ABMR in 26 renal allograft recipients treated with Ritux (n=11) or Bort (n=15) based Rx.

Methods: We reviewed for-cause renal allograft biopsies from 1/08 to 3/11. Inclusion criteria were ABMR by Banff'07, presence of DSA, and use of Bort or Ritux as a key component of Rx. Primary endpoint was response to Rx (return of Cre to within 15% of baseline at 4 wks). Secondary endpoints were reduction in DSA, proteinuria, and graft survival.

Results: Table 1 shows baseline data and details of ABMR. Response to Rx at 6 mths was 54% vs. 71% in Ritux and Bort groups, respectively. Bort was associated with a greater reduction in Class I DSA and proteinuria in patients with >1g/day of protein at time of ABMR diagnosis (Fig 1). 6 mth graft survival was 73% & 93% in Ritux and Bort groups respectively.

	Ritux	Bort	P
Post transplant days (median)	779 (26-2889)	38 (3-1853)	0.03
Biopsy Creatinine (mg/dl) (mean±SD)	3.55±2.2	3.92±2.8	0.94
Biopsy Protein (g/d) (mean±SD)	2.13±2.4	1.84±1.9	0.98
Rx IVIG ±TPE	73%	100%	0.06
Rx r-ATG	55%	73%	0.68
Response to Therapy	55%	73%	0.41
Post Rx Creatinine (3mths, mg/dl) (mean±SD)	2.9±1.9	2.1±1.1	0.23
Reduction of Class I iDSA	11.3±19.6% (n=3)	83.0±21.9% (n=9)	0.02
Reduction of Class II iDSA	14.2±15.0% (n=6)	38.2±34.5% (n=10)	0.43
Post Rx Proteinuria (3-6mths, g/day) (mean±SD)	7.3±11.4	1.29±1.7	0.05
6 month graft suvival	73%	92%	0.28

Figure 1A

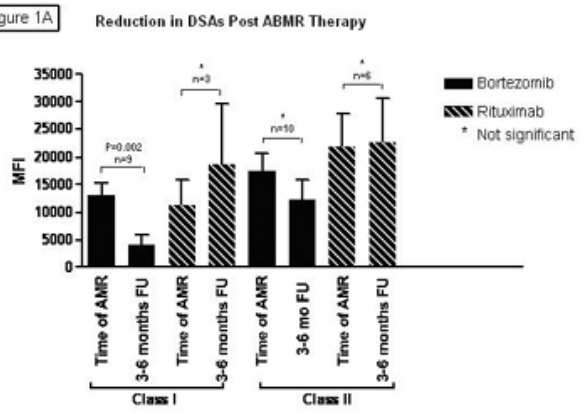


Figure 1B

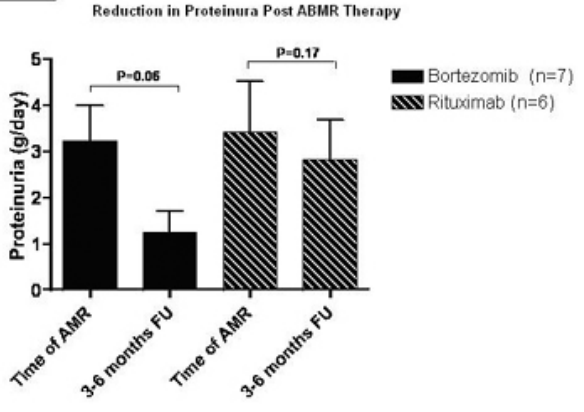


Conclusions: Bort was associated with a higher rate of ABMR reversal and significantly greater reductions in DSA and proteinuria compared to Ritux. Validation of our observations favoring Bort over Ritux may help develop a standardized protocol for ABMR.

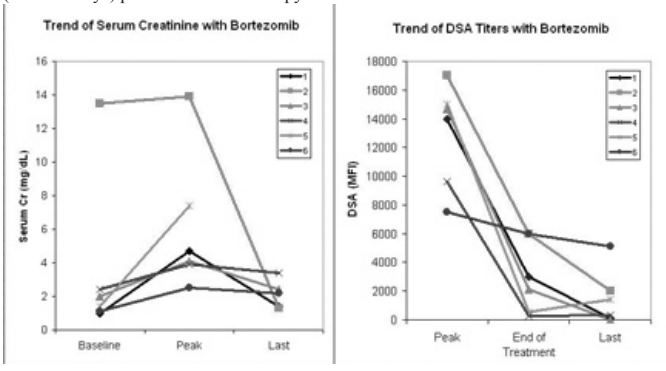
SA-PO3066

Treatment of Antibody Mediated Rejection in Kidney Transplantation: A Single Center Experience with a Bortezomib-Based Regimen Swati Arora,[1] Janice G. Nigos,[1] Parineesha Nath,[1] Ngoc L. Thai,[2] Akhtar Khan,[2] Kusum B. Tom,[2] Richard J. Marcus,[1] Sabiha M. Hussain,[1] Tina Y. Ko,[1] Rita L. McGill,[1] Kalathil K. Sureshkumar.[1] *[1]Nephrology and Hypertension, Allegheny General Hospital; [2]Abdominal Transplantation, Allegheny General Hospital, Pittsburgh, PA.*

Background: Antibody mediated rejection (AMR) following kidney transplantation (KTx) responds poorly to conventional anti-rejection therapies. The proteasome inhibitor bortezomib has activity against mature plasma cells that produce damaging donor-specific antibodies (DSA). We present our experience of using a bortezomib-based regimen in patients with severe AMR.

Methods: A retrospective chart review was performed on patients with biopsy proven AMR after KTx at our institution over 12-months. Diagnosis of AMR was made on the basis of positive peritubular capillary C4d staining along with either histological evidence of acute rejection or positive DSA titers. Treatment for AMR included plasmapheresis (1- 1.5 Volume), IVIG (cumulative dose of 1-2 g/kg), steroids, single dose rituximab (375 mg/m^2) along with bortezomib (1.3 mg/m^2) on days 1, 4, 8 and 11.

Results: AMR was diagnosed in 6 patients, aged 43±13 years, with PRA range 0-80%, and 4±1 HLA mismatches. There were 5 females, 2/6 had living donors, 5/6 had first KTx, 4/6 had alemtuzumab and 2/6 had rabbit-antithymocyte globulin induction; all were maintained on a tacrolimus/MMF/early steroid withdrawal protocol. Figure 1 shows serum creatinine and DSA titer trends. Five patients responded to treatment; one (#5) became dialysis dependent. Responders had stable kidney function during the follow-up (223±143days) post-bortezomib therapy.



Conclusions: This series demonstrates effectiveness of a bortezomib-based regimen in achieving reduction of DSA titers and stabilizing allograft function in patients experiencing severe AMR following kidney transplantation.

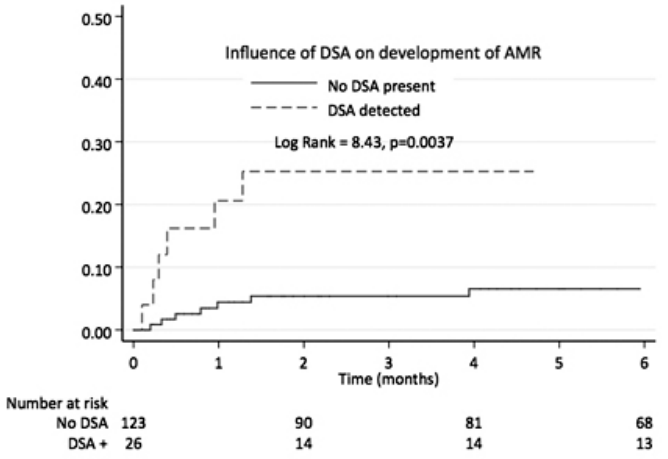
SA-PO3067

Presence of Donor Specific Antibodies Increases the Risk of Antibody Mediated Rejection Amudha Palanisamy, Demetra Tsapepas, Sumit Mohan, Bekir Tanriover, Russell J. Crew, Geoffrey K. Dube, Nicole M. Ali, Lloyd Ratner, David J. Cohen, Elena Rodica Vasilescu. *Columbia University.*

Background: The introduction of solid phase methods provides increased sensitivity and specificity for the detection of HLA antibodies. The clinical impact of the detection of preformed donor specific antibodies (DSA)on early rejections is unclear.

Methods: We performed a retrospective review of all adult DDRT recipients at our center from 1/2009 to 12/2010. All patients had a negative CDC crossmatch at the time of transplantation and had solid phase assay measurement of HLA antibodies. A flow crossmatch was subsequently done if HLA antibodies (donor specific or otherwise) were detected by luminex. We identified 149 patients with a negative flow crossmatch, 26 had DSA by Luminex and received no additional treatment other than our standard induction regimen at the time of transplantation followed by our steroid free immunosuppression protocol of tacrolimus and mycophenolic acid.

Results: In our cohort, patients with DSA were of similar age (53±13.8 v 55.8±14.1 yrs, p=0.35) and cold ischemia time (28.9±9.8 v 29.6±9.8, p=0.75) but were more frequently female (61.5 v 32.3%, p=0.005) and had a previous transplant (50 v 17%, p<0.001) than patients without DSA. Overall rejection rates (cellular and AMR) rates were higher in pts with DSA (50% v 22.6%, p=0.004) as were rates of antibody mediated rejection (23.1 v 6.5%, p=0.004). Additionally, the lowest MFI of preformed DSA among pts experiencing AMR was 6200.



Conclusions: Our center data demonstrates a higher overall risk of rejections and specifically a higher risk of antibody mediated rejections in patients with preformed DSA.

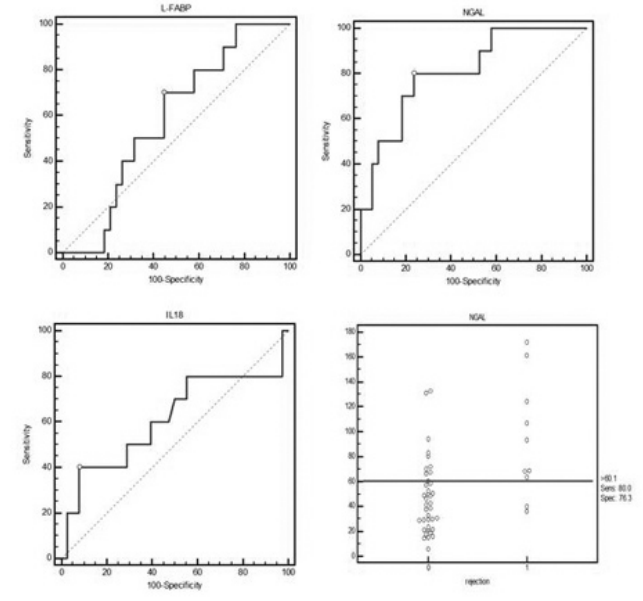
SA-PO3068

Neutrophil Gelatinase-Associated Lipocalin Is Most Sensitive to the Acute Rejection after Living Donated Kidney Transplantation Junko Kohei, Kosaku Nitta, Ken Tsuchiya, Takumi Yoshida, Michihiro Mitobe, Hidekazu Sugiura, Shunji Shiohira. *Fourth Department of Internal Medicine, Kidney Center, Shinjuku, Tokyo, Japan.*

Background: Delayed graft function (DGF) after kidney transplantation is difficult to diagnose with only serum creatinine, therefore using of the biomarker is expected as auxiliary diagnosis. Identification and validation of biomarkers of kidney injury has currently reported in this area. We hypothesized that these markers predicted rejection after living donated kidney transplantation.

Methods: This study was prospective, single-center study of living-donor kidney transplant patients to evaluate urinary NGAL, L-FABP and IL-18 including consecutive 48 (male=32) patients. We collected serial urine samples of 3 days after transplantation and analyzed using an immunoassay (ARCHITECT) for NGAL and standard commercial ELISA kits for LFABP and IL18. For diagnostic sensitivity of these biomarkers, receiver operating characteristic curve (ROC) was plotted and area under the curve (AUC) was calculated to quantify the accuracy of the parameter.

Results: Ten cases were clinically diagnosed or noted by biopsy as acute rejection and DGF was not observed in other 38 cases. NGAL was the most sensitive to detect an acute rejection in these markers. The best cut-off value of NGAL was 60.1ng/ml, with an Area under the ROC curve of 0.811 (95% CI 0.671-0.909). AUC of L-FABP, IL-18 were 0.584 (95% CI 0.433-0.725), 0.612 (95% CI 0.460-0.749).



Conclusions: Current methods for predicting graft recovery after kidney transplantation are not reliable. This research has a high possibility of helping to diagnose rejection in the postoperative early stage.

SA-PO3069

Correlation of Pretransplant Trough Tacrolimus Level with Early Acute Rejection in Live Donor Renal Transplantation Kalpesh D. Gohel, Umapati Hegde, Sishir D. Gang, Mohan M. Rajapurkar. *Department of Nephrology, Muljibhai Patel Urological Hospital Society for Research in Nephro-Urology, Nadiad, Gujarat, India.*

Background: The risk of acute rejection is greater in the first week post transplant and progressively decreases after the first month. Thus, the concentration of immunosuppression must be maximal initially and tapered during subsequent months.The information of pretransplant administration of immunosuppression and acute rejection is minimal. So we aimed the present study to assess the correlation of baseline pretransplant trough tacrolimus level with early rejection.

Methods: We prospectively analyzed the trough tacrolimus level on pretransplant day of 179 patients transplanted from September 2007 to September 2009. We divided them into three groups according to the trough levels: Group I - < 5 ng/ml (n=34), Group II - 5-15 ng/ml(n=112) and Group III - 15ng/ml(n=33). Their demography, rejections, NOD, infections and biopsy proven CNI toxicity were studied.

Results: Their demography was comparable.Incidence of biopsy proven acute rejections were highest in the Group I and lowest in the Group III. Incidence of post transplant infection, new onset diabetes were comparable. Incidence of biopsy proven CNI toxicity was higher from group I to Group III.

Table.1 Results

Parameters	Group I (Tac Level< 5)	Group II (Tac Level 5-15)	Group III (Tac Level >15)
Mean Age (years)	49.06 + 10.15	47.38 + 9.6	49.42 + 10.2
Gender Male: Female	24:10	94:18	27:6
Relation: Related	28	76	22
Relation: Other than related	6	36	11
Donor Age	49.05 + 10.15	47.7 + 10.14	46.42 + 10.2
Induction	15 (44.1%)	35 (31.2%)	17(51.5%)
Anti proliferative -Azathioprine: MMF	20:14	50:62	11:22
Biopsy proven CNI toxicity	2(5.8%)	9(8%)	5(15%)
New Onset Diabetes	17(50%)	42(37.5%)	14(42.4%)
Rejection Episodes	12(35.3%)	27(24.1%)	05(15.2%)
Banff > 2 A	3	8	0
Post Tx Infections	12(35.3%)	33(29.5%)	15(45.4%)
Graft Survival % (1 year)	97.1	98.2	100

Tac level - Tacrolimus trough level expressed in ng/ml, CNI - calcineurine inhibitor

Conclusions: Incidences as well as severity of early rejection reduces as the pretransplant trough level increases. We did not encounter any higher grade TIR or antibody mediated rejection when trough level was > 15 ng/ml.

SA-PO3070

Assessment of Renal Allograft Fibrosis by Transient Elastography: Possibilities and Limitations Claudia Sommerer,[1] Michael Scharf,[1] Christoph Seitz,[1] Gunda Millonig,[2] Sebastian Mueller,[2] Martin G. Zeier.[1] *[1]Nephrology, University Hospital Heidelberg, Heidelberg, Germany; [2]Internal Medicine, Salem Medical Center, Heidelberg, Germany.*

Background: Chronic allograft dysfunction remains the major reason for late allograft loss. To date renal biopsy has been the only option for an early diagnosis. Throughout the last couple of years Transient Elastography (TE) has become a valid non-invasive alternative for diagnosing hepatic fibrosis. The purpose of the present study was to evaluate the possibility of identifying renal allograft fibrosis by using TE as well as analyzing its inherent limitations.

Methods: The tissue stiffness of 164 patients with renal allograft was measured twice, at the pole and the pars media of the allograft, using TE (FibroScan®). Clinical and anatomical data were collected for each patient.

Results: The measurement was successful in 310 out of 328 cases (94.5%). The mean elasticity was 34.8 ± 19.6 kPa and 33.6 ± 19.1 kPa for the pole and pars media respectively. There was no evidence for a correlation between allograft elasticity and renal function (estimated glomerular filtration rate: $r_{sp\text{-}Pole}$: -0.02; $p_{\text{-}Pol}$: 0.76 and $r_{sp\text{-}PM}$:-0.03; $p_{\text{-}PM}$: 0.68). Body-mass-index (BMI) and distance between skin and allograft have an impact on the success rate of the examination (BMI: $r_{sp\text{-}Pol}$: -0.31; $p_{\text{-}Pol}$: < 0.001 and $r_{sp\text{-}PM}$:-0.27; $p_{\text{-}PM}$: <0,001; distance: $r_{sp\text{-}Pol}$: -0.50; $p_{\text{-}Pol}$: < 0.001 and $r_{sp\text{-}PM}$:-0.56; $p_{\text{-}PM}$: <0.001). Sonographic proof of peri- or intrarenal accumulated fluid (cysts, lymphoceles) was accompanied by a drop in the success rate of 12.2% at the pole and 17.3% at the pars media.

Conclusions: Altogether using TE for the examination of renal allografts might be possible. Taking into account certain confounders, TE gains clinical significance. A requirement for a broader application, however, is the implementation of several technical modifications.

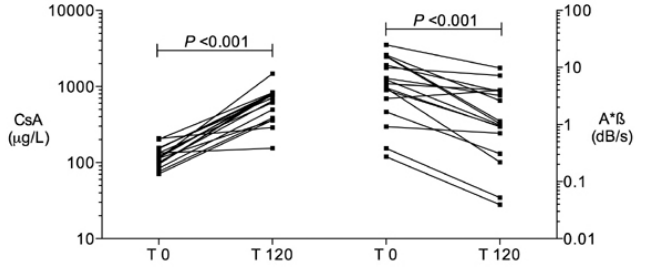
SA-PO3071

Acute Effects of Cyclosporine A on Kidney Allograft Microperfusion Visualized by Contrast-Enhanced Sonography Lars Kihm, Joerg Seckinger, Christian Morath, Martin G. Zeier, Vedat Schwenger. *Nephrology, University of Heidelberg, Germany.*

Background: Cyclosporine A (CsA) induces detrimental vascular remodeling, which is a leading cause of chronic allograft failure. Real-time contrast-enhanced sonography (CES) is a relatively new technique in providing quantitative information on microvascular tissue perfusion in kidney allografts in more detail. The purpose of the study is to assess acute effects of CsA to kidney allograft perfusion.

Methods: In an explorative single-center clinical trial, renal parenchymal tissue perfusion of 17 stable kidney allograft recipients was evaluated with CES prior to and two hours after the intake of CsA. In addition to laboratory and clinical parameters, Doppler indices and estimated glomerular filtration rate were measured.

Results: Systolic and diastolic blood pressure and color Doppler indices (RI and PI) did not significantly differ prior to and after the administration of CsA. There was a significant decrease of renal blood flow two hours after the intake of CsA compared to baseline. Kidney allograft microperfusion was reduced by 5.27 ± 4.08 dB/s.



Furthermore, there was a significant correlation between renal blood flow obtained prior to CsA administration and kidney function.

Conclusions: Acute effects of CsA on kidney allograft microperfusion visualized by CES revealed a 54 % reduction 2 h after the intake of CsA. Kidney allograft microperfusion correlates with kidney allograft function.

SA-PO3072

Combination of Blood Oxygen Level-Dependent Magnetic Resonance Imaging and Doppler Ultrasonography in Prediction of Acute Renal Rejection Ying Xu, Fei Han, Jianghua Chen. *Kidney Disease Center, First affiliated hospital, Zhejiang University, Hangzhou, Zhejiang, China.*

Background: Our previous study has shown that blood oxygen level-dependent magnetic resonance imaging (BOLD MRI) could discriminate between acute rejection (AR) and acute tubular necrosis. Other studies have demonstrated that Doppler ultrasonography could predict renal allograft outcome. This study aims to establish a mathematic model for predicting AR through the analysis of the data obtained from the imaging modalities.

Methods: 103 patients took BOLD MRI and Doppler ultrasound within 6 months after transplantation. 82 patients with normal functioning grafts took the examinations within 3 weeks post-surgery, 21 patients with biopsy-proven AR took the examination within 6 days before or after biopsy. Four parameters were recorded: medullary R2* value (MR2*), cortical R2* value (CR2*), segmental arterial resistance index (RI) and segmental arterial pulsatility index (PI). Support Vector Machine (SVM) was applied to separating the 4-dimensional data set (CR2*, MR2*, RI and PI) into two categories, AR and normal. A SVM model was tuned with 3-fold cross validation, the parameters were regularized to calibrate the classification and improve the training accuracy, which is the ratio of number of correct classification/total number of training samples.

Results: After performing the 3-fold cross validation, the average SVM accuracy on training data was 100%, which means the sensitivity and specificity are 100%, and the average training accuracy (MR2*+CR2*, MR2*+RI, MR2*+PI, CR2*+RI, CR2*+PI, RI+PI) was respectively 74%, 79.10%, 81.60%, 79.10%, 81.60%. After training the SVM model, a kernel function was produced for prediction. Due to the over-fitting of the classifier, the average test accuracy (the ratio of number of correct classification using the trained kernel function/total number of test samples) for four parameters is not high enough (around 65%) for AR.

Conclusions: The combination of BOLD-MRI and Doppler ultrasonography could be useful for the prediction of AR posttransplant by the SVM model and kernel method, larger sample should be tested to verify the accuracy, sensitivity and specificity of this mathematic model.

SA-PO3073

Clinical Usefulness of 3-Dimension Computed Tomography Angiography for Detection of Transplant Renal Artery Stenosis In O Sun, Yu Ah Hong, Hyun Gyung Kim, Hoon Suk Park, Sun Ryoung Choi, Byung Ha Chung, Bumsoon Choi, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang. *Division of Nephrology, Department of Internal Medicine, Catholic University of Korea, Seoul, Republic of Korea.*

Background: The aim of this study is to evaluate whether 3-Dimension computed tomography angiography (3D-CTA) is useful to detect transplant renal artery stenosis (TRAS).

Methods: In our transplant center, 9 of 514 (1.8 %) renal transplant recipients were diagnosed with TRAS according to renal angiography from 2004 to 2010. These patients received color doppler ultrasonography (CDU) and 3D-CTA ahead of renal angiography. A usefulness of 3D-CTA was compared to CDU on the basis of angiography. To investigate the safety of 3D-CTA, estimated GFR (eGFR) were measured before and after the 3D-CTA examinations.

Results: The patients included six men and three women, 27-56 years old (mean age, 43). The TRAS occurred from 2.6 to 24 months after transplantation (average 9.6 months). The median eGFR was 72.4 ml/min/1.73m^2 (range, 57-92). Three out of the nine patients diagnosed with TRAS were not detected by CDU. Two of them had TRAS with end-to-side (ES) arterial anastomosis, in which it can be difficult to detect the stenosis by CDU compared with the cases of EE. That is because the PSV at the stenosis in ES could be lower than that in EE due to anatomic and hemodynamic differences. However, 3D-CTA detected the significant stenosis in all patients with TRAS. Moreover, the stenotic area in 3D-CTA was similar to that of renal angiography (69.2±8.0 vs 69.5±6.5, p=0.88). There was no difference in eGFR before and after 3D-CTA examinations (77 ± 13.2 vs. 72 ± 14.1 ml/min/1.73 m^2, p = 0.54). All nine patients with TRAS were treated successfully by percutaneous transluminal renal angioplasty (PTA). After PTA, allograft function (72 ± 14.1 vs. 80 ± 11.0 ml/min/1.73 m^2, p = 0.028) and hypertension (mean arterial pressure, 111 ± 10.1 vs 98± 7.0, p = 0.011) improved.

Conclusions: The 3D-CTA is effective and safe method to screen the renal artery stenosis in renal transplant recipients with eGFR > 60 ml/min/1.73 m^2.

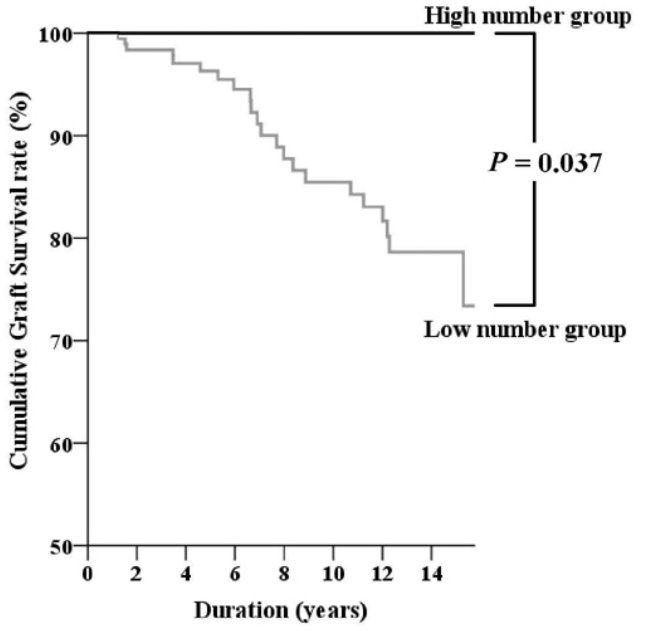
SA-PO3074

Combined Effect of Recipient's and Donor's Matrix Metalloproteinase Gene Polymorphisms on the Process of Kidney Aging after Kidney Transplantation Seung Seok Han,[1] Seung Hee Yang,[1] Jin Suk Han,[1] Suhnggwon Kim,[1] Yon Su Kim.[1,2] *[1]Internal Medicine, Seoul National University College of Medicine, Seoul, Korea; [2]Clinical Research Center for End Stage Renal Disease, Seoul, Korea.*

Background: The process of kidney aging is different in each individual, but the factors in the variation are largely unknown. Matrix metallopeptidase (MMP) 7 and 20 genes are associated with kidney aging, and thus we assessed the correlation between the MMP gene polymorphisms (rs880197 in MMP 7 (A > T) and rs1711437 in MMP 20 (G > A) and transplant outcomes in 235 recipients.

Methods: The transplant outcomes were assessed according to the number of A alleles combining those from both the recipient and the donor: the high-number group of A alleles (≥ 3) and the low-number group (< 3).

Results: During the follow-up period (mean 92.3 months), the high-number group of MMP 7 had a lower risk of chronic tubulointerstitial lesion than the low-number group (P = 0.015), while the high-number group of MMP 20 had greater risks of chronic tubulointerstitial lesion (P = 0.055) and glomerulonephritis (P = 0.025) than the low-number group. However, in the long-term (after 9 years of transplantation), the high-number group of MMP 20 had a greater transplant function (eGFR) than the low-number group.The high-number groups of MMP 20 showed a trend toward better graft survival rate than the low-number groups, especially when we analyzed the recipients who were followed for more than 1 year (P = 0.037).



Conclusions: The polymorphism of MMP 7 and 20 genes may be a surrogate marker that may be used to predict the long-term outcome after kidney transplantation.

SA-PO3075

Genetic Polymorphisms of Interleukines Associated with PTDM in Korean Renal Allograft Recipients Yang Gyun Kim,[1] Sang-Ho Lee,[1] Chun-Gyoo Ihm,[1] Tae Won Lee,[1] Kyung-Hwan Jeong,[1] Ju-Young Moon,[1] Sul-Ra Lee,[1] Eun Young Kim,[1] Yeong Hoon Kim,[2] Sunwoo Kang.[2] *[1]Nephrology, Kyung Hee University College of Medicine, Seoul, Republic of Korea; [2]Nephrology, Inje University Paik Hospital, Busan, Republic of Korea.*

Background: Posttransplantation diabetes mellitus (PTDM) is a serious metabolic complication after renal transplantation. Although β-cell dysfunction is considered the main contributing factor for the development of PTDM, precise pathogenesis was not identified. There are several studies about various cytokines that induce inflammation and destruction of islet beta cells in diabetes mellitus. But there is rare study about the cytokines associated with β-cell dysfunction in PTDM. So, was examined the association between PTDM and 18 single nucleotide polymorphisms (SNPs) located within the genes of 10 interleukines or their receptors, which were related to diabetes mellitus in Korean renal allograft recipients.

Methods: A total of 305 renal transplants recipients between 2000 and 2009 were included at 3 transplants centers, without a history of diabetes. We analyzed the association between the PTDM development and the 18 IL genes.

Results: The prevalence of PTDM was 18% (52/305 patients). Patients with PTDM group were older than those in non-PTDM (44.91±1.33 vs 38.34±0.71, p<0.001) Ten SNPs in five genes were significantly associated with PTDM development after adjusting with age, sex : IL1B (rs3136558), IL4 (rs2243250, rs2070874), IL7R (rs1494558, rs2172749) ,IL17R (rs2229151, rs4819554), IL17RB (rs1043261, rs1025689, rs3733075). Among haplotypes, the frequency of GGT in IL7R gene and TT in IL2 gene were significantly different between the patients with PTDM and those without PTDM. (p=0.044, 0.041,respectively)

Conclusions: These data suggest that genomic variations in IL1B, IL4, IL7R, IL17R and IL17RB are significantly associated with PTDM in Korea. Especially, significant variations of IL7R and IL17R, which was recently reported to be associated with type 1 DM, could elucidate the pathogenesis of PTDM in renal transplant recipients.

SA-PO3076

Significant Associations between Angiotensin Converting Enzyme and Angiotensinogen Genes Polymorphisms and Post Transplantational Diabetes Mellitus in Renal Allograft Recipients Sul-Ra Lee,[1] Kyung-Hwan Jeong,[1] Yang Gyun Kim,[2] Ju-Young Moon,[2] Sang-Ho Lee,[2] Chun-Gyoo Ihm,[1] Tae Won Lee.[1] *[1]Division of Nephrology, School of Medicine, Kyung Hee University, Seoul, Korea; [2]Kohwang Medical Research Institute, School of Medicine, Kyung Hee University, Sroul, Korea.*

Background: Post-transplant diabetes mellitus (PTDM) is a frequent and serious complication after kidney transplantation. Genetic polymorphisms of the angiotensin-converting enzyme (ACE) and angiotensinogen (AGT) genes have been reported to be related to diabetes mellitus and insulin sensitivity. But the role of these genes on the development of PTDM is not known. For this purpose, we investigated the association of polymorphisms in the genes for ACE and AGT genes with development of PTDM in Korean patients who had undergone renal transplants.

Methods: A total of 312 patients who had received kidney transplants without a prior history of diabetes were included. One ACE SNP (rs4291 in promoter –262) and two AGT SNPs (rs 699 in inton_1 and rs 4762 in intron 2) were genotyped from genomic DNA with direct sequencing.

Results: Of 312 patients, PTDM developed in 56 patients (17.9%). Patients in the PTDM group were older than those in the non- PTDM group (43.18±9.51years vs. 36.75±11.58). There were significant difference between two subjects in the percentage of tacrolimus use (n=18 vs. n=76; p=0.01).

Of three SNPs, the rs699 in intron_1 of the *AGT* gene was significantly associated with the development of PTDM in the codominant 1 (p = 0.009) and dominant models (p = 0.02).

In haplotypes of the rs699 in intron-1 of AGT gene, the frequency of the TCA haplotype was significantly higher in patients with PTDM than in those without PTDM.

Conclusions: AGT gene rs699 polymorphisms may act as genetic markers for the development of PTDM. Angiotensinogen may help identify patients who are at risk for PTDM. The exact molecular mechanisms still need to be clarified.

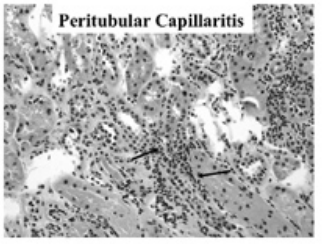
SA-PO3077

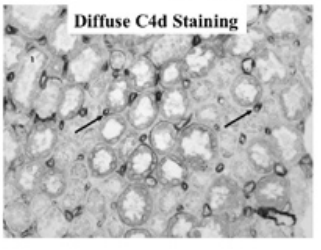
Concurrent Peritubular Capillary C4d Staining and BK Virus Nephropathy: Long-Term Outcomes Vijay Vidyasagar, Sanjeev R. Shah, Maha A. Mohamed, Brenda L. Muth, Jose R. Torrealba, John D. Pirsch, Dixon Kaufman, Hans Sollinger, Arjang Djamali. *Medicine and Surgery, UW-SMPH, Madison, WI.*

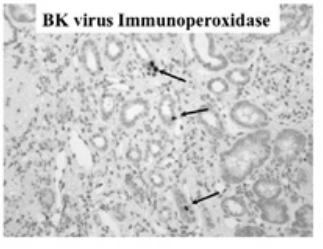
Background: BK virus nephropathy (BKVN) results from over-immunosuppression while peritubular capillary deposition of C4d is associated with under-immunosuppression. There is a paucity of information on long-term outcomes in patients who present with concurrent BKVN and C4d staining.

Methods: In a retrospective analyses of 69 consecutive kidney allograft recipients with biopsy confirmed BKVN between 2005 and 2011, we examined patient and graft outcomes in the presence or absence of peritubular capillary C4d staining (focal or diffuse). BKVN alone was treated with a reduction in immunosuppression ± cidofovir and IVIG while combined BKVN and C4d staining was treated with a reduction in immunosuppression + IVIG ± plasma exchange.

Results: There were 57 (82.6%) patients with BKVN alone and 12 (17.3%) patients with concurrent BKVN and focal or diffuse C4 staining.







The majority of patients were male (76%). Mean age at biopsy was 46.8 years. Mean follow-up after biopsy was 5.6 years. There were 6 deaths (8.7%) and 17 graft losses (24.6%). These differences were not statistically significant between the 2 groups. Similarly, there was no significant difference between Scr levels at biopsy and last follow-up suggesting that concurrent C4d staining in patients with BKVN is not associated with worse outcomes.

	C4d (+)	C4d (-)	p
N	12	57	
Age at Bx	42	47	0.19
Follow-up interval (m)	50	71	0.24
Scr at Bx	2.73	2.67	0.73
Last Scr	3.38	3.38	0.98
Patient Death	0	6	0.54
Graft Loss	4	13	0.68

Conclusions: These studies demonstrate that

(1) approximately 1/4 of allografts with BKVN may be lost within 5.6 years of diagnosis

(2) concurrent BKVN and peritubular C4d is not an uncommon feature on biopsy samples (17%)

(3) the presence of C4d is not a predictor of worse outcomes in patients with BKVN

SA-PO3078

Urinary Haufen Testing for Diagnosing Polyomavirus Nephropathy & Assessing Intrarenal Viral Load Levels: Comparative Analysis with Current Screening Tests Harsharan Singh,[1] Tomasz Kozlowski,[2] Vimal K. Derebail,[3] Volker Nickeleit.[1] *[1]Div. of Nephropathology, University of North Carolina, Chapel Hill, NC; [2]Transplant and Abdominal Surgery, University of North Carolina, Chapel Hill, NC; [3]Div. of Nephrology, University of North Carolina, Chapel Hill, NC.*

Background: PVN, a common complication post-renal-transplant, has an incidence of 4% (BANFF-PVN working group). Early non-invasive diagnosis facilitates patient management and graft survival. We developed a new qualitative test to detect three-dimensional viral casts, called "Haufen", in voided urine samples to accurately diagnose PVN and previously reported that urinary Haufen shedding is tightly correlated with PVN (positive and negative predictive values >95%). Hypothesis: The degree of urine Haufen shedding most accurately reflects extent of intrarenal PVN and can help distinguish PVN disease stage A (early) from stages B and C.

Methods: Quantitative analysis of urine Haufen shedding (#Haufen/mL urine), quantitative PCR assays on serum/urine,and urine decoy cells on 40 samples from 31 patients with concurrent biopsy proven PVN. Comparative analysis with biopsy findings (PVN disease stage, #cells/tubules expressing viruses (manual & morphometric counts, i.e.SV40-T, capsid proteins). Statistical analysis using Kruskal Wallis testing with ties.

Results: A) PVN disease stage: Only Haufen shedding showed a statistically significant difference between PVN stage A versus B or C ($p<0.0001$). Neither degree of viremia or viruria predicted any disease stage. B) Degree of intrarenal polyomavirus replication: Only Haufen shedding accurately reflected extent of polyomavirus replication in renal tubules, i.e.correlated with number of virus expressing cells or tubules. No significant correlation was found between degree of viremia and viruria.

Conclusions: Compared to other common laboratory tests, only quantitation of urinary Haufen shedding is an accurate reflection of the intrarenal burden of polyomavirus and can help predict PVN disease stages. This observation makes "Haufen-testing" the most accurate non-invasive technique not only to initially diagnose PVN but to also monitor therapeutic effects during follow-up.

SA-PO3079

Center-Specific Plasma BK Virus Levels in the Presumptive Diagnosis of BK Virus Allograft Nephropathy Amit Arora,[1] Sanjeev Akkina,[1] Suman Setty,[2] Shrihari Kadkol,[2] Ignatius Yun-Sang Tang.[1] *[1]Medicine, University of Illinois at Chicago, IL; [2]Pathology, University of Illinois at Chicago, IL.*

Background: The KDIGO clinical practice guidelines for the care of kidney transplant recipients suggest a threshold plasma BK virus (BKV) PCR level of >10,000 copies/ml for presumptive diagnosis of BKV allograft nephropathy (BKVAN). Determination of BK viremia by real time PCR varies with the methodology, the target gene (VP-1, 2, 3 or large T antigen) and the primers used. We evaluated the performance of an in-house developed PCR assay in the diagnosis of BKVAN.

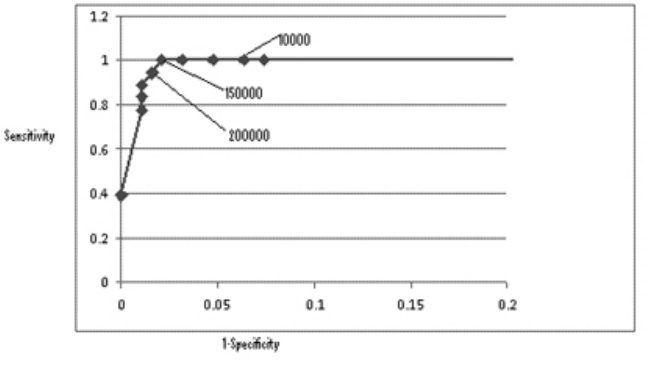
Methods: All transplant recipients with renal allograft biopsies and plasma BK virus PCR measurements during 2010 were evaluated. Viremia was measured using a primer set against the large T antigen. BKVAN was diagnosed with cytopathic changes and positive SV40 immunohistochemical stain. The sensitivity, specificity, positive and negative predictive values, positive likelihood ratio, and ROC curve were computed.

Results: Two hundred eighteen transplant recipients were evaluated: 39 had BK viremia and 18 were diagnosed with BKVAN. The performance characteristics are shown in Table.

Performance Characteristics

Plasma BKV (copies/ml)	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	+Likelihood ratio
10000	100	93.7	60	100	15.9
50000	100	96.8	75	100	31.3
100000	100	96.8	75	100	31.3
150000	100	97.9	81.8	100	47.6
200000	94	98.4	85	99.5	58.8

The ROC analysis is depicted in Figure.



Compared to a plasma BKV PCR of 10,000 copies/ml, values between 50,000 and 150,000 copies/ml were associated with better positive predictive value and positive likelihood ratio.

Conclusions: The plasma BKV PCR levels for presumptive diagnosis of BKVAN should be validated for each individual assay. Nephrologists caring for transplant recipients should be aware of the differences in the performance of BKV PCR assays to optimize management.

Funding: NIDDK Support

SA-PO3080

Impact of Polyoma Virus in Blood Only Taken at Week 6 after Kidney Transplantation on Inflammation and Fibrosis/Atrophy in Biopsies Taken at Week 52 Willy Aasebo. *Akershus University Hospital.*

Background: Polyoma virus associated nephropathy (PVAN) is associated with graft loss due to fibrosis in kidney transplant recipients and is defined as the presents of BK virus (BKv) in biopsies. The aim of this study is to assess if early presence of BKv in blood only, PVAN excluded, affects histological markers of inflammation and fibrosis after one year.

Methods: Protocol biopsies were taken at weeks 6 and 52 in patiens transplanted during 2009. BKv-PCR was measured in weeks 10 and 52. Biopsies were stained for BKv if BKv-PCR in blood was positive, or if any histological or clinical suspicion of PVAN were present. Recipients with PVAN at week 6 were excluded.

Immunosuppressive treatment consisted of induction therapy with Basiliximab (two doses), thereafter calcineunone inhibitor, mycophenolate and steroids.

Results: After excluding 3 patients with PVAN at week 6, 156 patients were included.

At week 6 BKv were positive in 14 patients (9%), of whom 7 (50%) had BKv-PCR >5 x 10^3 copies/ml (median: 1.8 x 10^4 copies/ml).

At one year 12 recipients had positive BKv (8%), of whom 6 (50%) had >5 x 10^3 copies/ml.

Four patients were BKv positive both at week 6 and week 52.

Inflammation, fibrosis and graft function at one year according to Polyoma in blood at 6 weeks.

	Polyoma neg	Polyoma pos	P	BKv >5000	P
	N = 157	N = 14		N = 7	(neg vs.>5000)

Tubulitis	0.50 (0.80)	0.92 (0.86)	0.074	1.00 (1.10)	0.061
Interst fibrosis	0.81 (0.63)	0.93 (0.83)	0.53	0.71 (0.76)	0.76
Tub atrophy	0.99 (0.59)	1.12 (0.86)	0.41	0.86 (0.69)	0.62
Creatinine (µmol/l)	116 (44)	103 (29)	0.27	98 (14)	0.33
Prot/Creat (mg/mmol)	27 (79)	21 (40)	0.95	30 (54)	0.89

Mean (SD)

The 4 recipients with BKv positive at both week 6 and 52 had mean interstitial fibrosis of 0.5, tubular atrophy of 0.75, tubulitis: 1.00 and interst. inflam: 1.00. Mean creatinine was 95 µmol/l (SD 13.2) and Prot/creat 8,5 mg/mmol (12.8) (NS vs. one positive BKv).

Conclusions: The presence of BKv in blood only early after transplantation does not increase fibrosis/atrophy one year after transplantation.

However, they had a tendency towards increased inflammation, especially in patients with BKv-PCR >5 x 10^3 and in patients with viremia both early and at one year.

SA-PO3081

Incidence of BK Virus Infection in Renal Transplant Recipients Induced with Alemtuzumab Versus Anti-Thymocyte Globulin Shahrouz Shadrou,[1] Bishal B. Rawal,[1] Kevin C. Roe,[1] Riaz Ali Shah,[2] Tadahiro Uemura,[2] Nasrollah Ghahramani.[1] *[1]Nephrology, Penn State Hershey Medical Center, Hershey, PA; [2]Transplant surgery, Penn State Hershey Medical Center, Hershey, PA.*

Background: BK virus associated nephropathy (BKVAN) is a major cause of graft failure. Treatment with lymphocyte depleting agents has been associated with increased incidence of BKVAN. Our primary aim was to compare the incidence of BK virus infection in renal transplant recipients based on the type of initial induction agent.

Methods: In a retrospective case-control study, 99 patients who underwent kidney alone transplant at our center between 8/2006 and 6/2010 were selected. We compared the incidence of BK virus infection in the first year among the alemtuzumab (AL) (n=50) and anti-thymocye globulin (ATG) groups (n=49). Maintenance immunosuppression for the AL group was steroid-free; for the ATG group, a 6-month steroid taper was used. Both groups also received tacrolimus and mycophenolate mofetil.

Results: In the AL group, 19 (38%) had living donors, 37 (74%) were Caucasian, 27 (54%) were male and age range was 53.6 ± 15.7. In the ATG group, 23 (46.9%) had living donors, 40(81.6%) were Caucasian, 34(69.3%) were male and age range was 49.4 ± 16.1.

The incidence of elevated BK PCR (>4000 copies) within the first year was not statistically different between the AL (n=12) and ATG (n=10) groups. Biopsy proven BKVAN was also not significantly different (AL: 2 patients; ATG: 4 patients). The incidence of biopsy proven acute rejection (AR) was not statistically different between the groups (AL: 21 episodes in 16 patients; ATG: 26 episodes in 18 patients). However, the mean time of onset of AR was significantly delayed in the AL group compared with the ATG group (157± 125 days vs. 73 ± 82 days; p=0.01).

Conclusions: Incidence of BKVAN and elevation of BK PCR is similar in induction with alemtuzumab and ATG. The incidence of acute rejection is similar between the two groups, but occurs later with alemtuzumab induction.

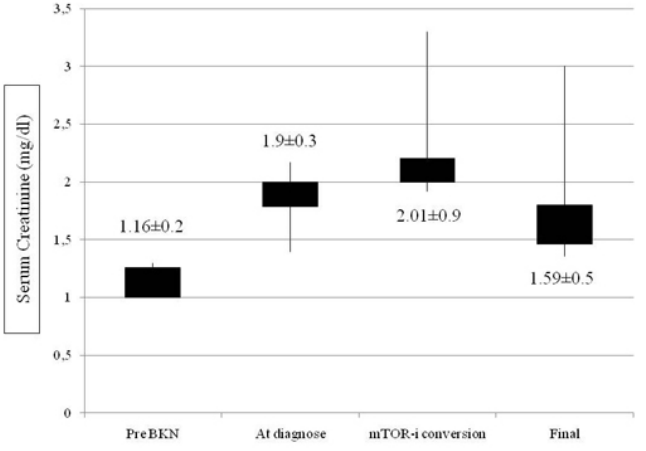
SA-PO3082

Successful Evolution of BK Virus Nephropathy Treated with Everolimus-Based Immunosuppression Natalia I. Polanco Fernandez, Laura Garcia-Puente Suarez, Esther Gonzalez Monte, Enrique Morales, Ignacio Bengoa, Jose M. Morales, Manuel Praga, Amado Andres. *Nephrology, H. U. 12 de Octubre, Madrid, Spain.*

Background: The incidence of renal allograft dysfunction due to BK virus nephropathy (BKVN) has increased over the last decade.Over the last few years mTOR-inhibitors (mTOR-i) have gained strength as a plausible treatment option.Based on this data, we initiated in 2007 an anticalcineurinic-free regime based on Everolimus (EVE) conversion protocol in patients with BKVN.Aims of the study were to evaluate renal allograft survival and BK viral load after conversion.

Methods: Diagnostic criteria for BKVN were:biopsy proven infection and/or positive serum viral load≥10000 copies demonstrated by PCR on at least two consecutive measurements.Of the 647 renal transplants done in our center between 2007 and 2010, 13 cases of BKVN were diagnosed.

Results: Of the 13 BKVN diagnosed cases, 8(4m/4f, aged 34.7±13.3 years) were converted to EVE-based regime, being the rest excluded because of proteinuria >0.8 gr/d.Follow up was 25±7 months.Maintenance immunosuppressive therapy consisted of tacrolimus(T), mycophenolate mofetil(MMF) and corticosteroids. Post-transplant renal function was optimal achieving a serum creatinine (sCr) of 1.16±0.2 mg/dl. Evolution is shown in the figure.



Treatment with MMF was stopped in all the patients and conversion from T to EVE was performed.Renal function improved in all the patients and the viral load became negative in 6 of them and diminished over 80% in the other two.None of them developed acute rejection after conversion to EVE.At the end of follow-up all renal allografts were functioning and viral load was under 10000 BK copies in every case.

Conclusions: BKVN treatment is still controversial. Our data suggest that treatment with mTOR-i could provide additional benefits in selected patients, preserving renal allograft function and lowering BK viral load.

SA-PO3083

Obstructive Uropathy May Be a Risk Factor for Polyomavirus Progression in Pediatric Kidney Transplant Recipients Debora Matossian, Farah N. Ali, Richard A. Cohn, Craig B. Langman. *Pediatric Kidney Disease, Childrens Memorial Hospital, McGaw Medical Center, Feinberg School of Medicine, Northwestern University, Chicago, IL.*

Background: Polyomavirus–associated nephropathy (BKVN) is recognized increasingly as a disease that may lead to progressive allograft dysfunction in pediatric kidney transplant (KTX) recipients. Published pediatric surveys reveal an incidence of BK-viruria from 18%-33%, BK-viremia 6%-16%, and BKVN 2%-8%.

The purpose of the study is identify patients with a KTX who have BK viruria, and evaluate for predictive risk factors for progression to BK viremia.

Methods: Retrospective chart review was performed of pediatric KTX recipients from January 2005 - December 2009. Analysis used unpaired t-test for normally distributed data, Mann-Whitney rank sum test for data not normally distributed, and Fisher exact test for qualitative data.

Results: 93 patients received a KTX in the 5 year period. 22 patients developed viruria (24%) and 12 of the latter group developed viremia (13% of total KTX). One patient with BK viremia had confirmed BKVN. No patient had graft loss due to BK disease during this period. Obstructive uropathy (OU) was the cause of end stage kidney disease in 22% of our total KTX population. 24% of such patients developed viremia, while only 7/71 patients (9.7%) of patients without OU had BK viremia (p=0.001). In patients who developed viruria but not viremia (n= 10), BK presented later in the transplant course (median 13.5 vs. 6 months post-KTX), in a higher proportion of preemptive KTX (50% vs.17%), in those with living donors (60 % vs. 33%) and in those with a younger age at the time KTX (median 6.5 vs. 13 years).

Conclusions: We found expected rates of viruria, viremia, and BKVN. However, BK viremia was more frequent in patients with obstructive uropathy. This supports the "two-hit" hypothesis in which immunosuppression and viral reactivation alone are insufficient to lead to BKVN; a damaged uroepithelium from a high-pressure system may be the predisposing factor. Ideal KTX scenarios (living donor, preemptive KTX, and younger age) favored resolution of viruria, decreased progression to viremia and consequently, a lower risk of BKVN.

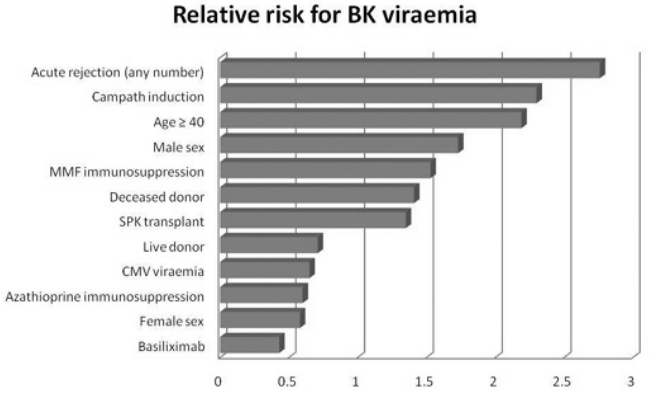
SA-PO3084

Risk Stratification To Improve Screening for BK Viraemia and Nephropathy in Kidney Transplant Recipients Vivian W. Yiu, Rui Gao, Miriam Rose Berry, Yisu Yisu Gu, Afzal N. Chaudhry, Sharon Mulroy. *Nephrology, Addenbrookes Hospital, Cambridge, United Kingdom.*

Background: BK viraemia occurs in 10-15% patients after renal transplantation. It can lead to graft dysfunction and loss, hence an effective screening programme can lead to early treatment and better outcomes. A screening protocol was introduced at our hospital in 2009 and we report on a risk stratification strategy developed after an audit of compliance.

Methods: A database was set up to collect data on all patients receiving a kidney transplant or simultaneous kidney-pancreas (SPK) transplant from May 2009 to January 2011. Data were collected from electronic and paper records.

Results: Acute rejection is the most predictive factor for developing subsequent BK viraemia, with a relative risk (RR) of 2.76. There was no significant association between the severity of the histological grade of acute rejection with BK viraemia. Other significant risk factors include Campath induction (RR=2.30), age ≥40 years (RR= 2.19), male gender (RR= 1.73), the use of Mycophenolate mofetil (MMF) in immunosuppression regimes (RR= 1.53), a deceased donor (RR= 1.41) and receiving a SPK transplant (RR= 1.35). Factors associated with lower risk of viraemia include Basiliximab induction (RR=0.43), the incidence of CMV viraemia (RR=0.65), use of Azathioprine (RR= 0.6) and female gender (RR=0.58).



Conclusions: Patients with more risk factors for BK viraemia should be screened more intensely in order to identify viraemia early and allow prompt treatment. SPK patients (receiving Campath and MMF) and those treated for acute rejection should prompt more frequent screening. We propose to develop a scoring system based upon these risk factors to streamline the screening protocol and target monitoring more effectively.

SA-PO3085

Factors Influencing the Course of Polyoma BK-Virus Nephropathy after Renal Transplantation Anke Schwarz,[1] Albrecht Heim,[2] Theodor Framke,[3] Hermann G. Haller.[1] *[1]Medicine, Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Virology, Hannover Medical School, Hannover, Germany; [3]Statistics, Hannover Medical School, Hannover, Germany.*

Background: The course of polyoma BK-virus nephropathy (BKVN) is still difficult to predict.

Methods: We evaluated factors influencing renal function and viral clearing during BKV infection.

Results: BKVN was diagnosed in 46 patients since 2008 by routinely done quantitative PCR (qPCR) and SV40 staining in all biopsies (done by protocol 6/ 12/ 26 weeks post-transplantation and for cause at any time). Either immunosuppression was generally reduced (calcineurin inhibitor=CNI by 30%, mycophenolate-mofetil=MMF by 30 to 50%, n=23), or CNI was switched primarily to mTOR inhibitor (n=7), or CNI was switched to mTOR inhibitor as a secondary step in case of delayed viral clearing (n=16). The influence of dichotomous variables on the response variables eGFR (≥0 or <0) and the time in weeks for qPCR reduction by 1 log (≤13 or >13 weeks) were measured as well as that of continuous variables. Tacrolimus (65%) and cyclosporine treatment (35%) always was combined with MMF and steroids. - 15% of cases suffered graft failure after 30±13 weeks. eGFR was stable or increased in 63% and decreased in 37%. BKV viral clearing was fast in 54% (reduction by 1 log ≤13 weeks) and slow in 46% (>13 weeks). Fast viral clearing was associated with stable or increasing eGFR (84%) compared to slow viral clearing (33%; p=0.001). Univariate logistic regression revealed that factors with a negative influence on renal function and viral reduction time were maximal viral load, tacrolimus treatment and late diagnosis by biopsy for cause. Using multiple logistic regressions, maximal viral load was the most important factor. In Cox regression analysis defining viral reduction by 1 log as event, tacrolimus compared to cyclosporine had a delaying influence on viral

reduction. In 88% of patients with delayed viral clearing the switch of CNI to mTOR inhibitor effected viral reduction.

Conclusions: We conclude that maximal viral load, tacrolimus treatment, and late diagnosis are influencing renal function and viral reduction time; and viral reduction time is important for renal function.

SA-PO3086

A Vitamin D Metabolism Signature Predictive of BK Viremia and Acute Rejection: Implications for Vitamin D Repletion John R. Lee, Thangamani Muthukumar, Darshana Dadhania, Jun B. Lee, Manikkam Suthanthiran. *Nephrology and Hypertension, Weill Cornell Medical College, New York, NY.*

Background: Vitamin D may play a crucial role in the regulation of the immune system. In this study, we examined whether levels of 25-hydroxyvitamin D (25-Vit D) or 25-dihydroxyvitamin D (1,25(OH)2 Vit D) are associated with allograft dysfunction, BK viremia (BKV), or acute rejection (AR).

Methods: We identified 171 renal transplant recipients who had both 25-Vit D and 1,25(OH)2 Vit D measured within the first 3 months of transplantation. We examined whether levels of 25-Vit D or 1,25(OH)2 Vit D were associated with serum creatinine (Cr), with AR, or with BKV during 24 month follow up.

Results: The high 25-Vit D group (≥35ng/ml,n=26) was associated with significantly worse allograft function at 24 months than the low 25-Vit D group (<35ng/mL,n=145)(Cr 2.10 mg/dL vs. 1.59 mg/dL,p=.049). As a possible explanation, the high 25-Vit D group was associated with more BKV than the low 25-Vit D group (30.8% vs. 11.7%, p=.029);Cox Proportion Hazard model revealed a high 25-Vit D level as an independent risk factor for BKV (HR=3.1,p=.019)(Fig 1A). Interestingly, treatment with a 25-Vit D analog was an independent risk factor for BKV (HR=11.4,p =.019).

The low 1,25(OH)2 Vit D group (<29pg/ml,n=119) was associated with significantly worse allograft function at 24 months than the high 1,25(OH)2 Vit D group (≥29pg/ml,n=52) (Cr 1.80 mg/dL vs. 1.37 mg/dL,p=.035). As a possible explanation, the low 1,25(OH)2 Vit D group was associated with more AR than the high 1,25(OH)2 Vit D group (16.8% vs. 5.8%,p=.055). Cox Proportion Hazard model showed that a low 1,25(OH)2 Vit D level was an independent risk factor for AR (HR=3.89,p=.040)(Fig 1B).

Figure 1A: Cox Proportion Hazard Model for BK Viremia

	B	SE	HR	p
HIGH 25-Vit D	**1.13**	**0.48**	**3.10**	**0.019**
High Risk Tx	0.36	0.52	1.44	0.483
Deceased Donor Tx	0.19	0.42	1.20	0.661
Sex (F)	-0.22	0.44	0.81	0.622
Race (AA)	-0.22	0.58	0.80	0.706
Tx 25-Vit D analog	**2.43**	**1.03**	**11.36**	**0.019**

Figure 1B: Cox Proportion Hazard Model for Acute Rejection

	B	SE	HR	p
LOW 1,25(OH)2 Vit D	**1.36**	**0.66**	**3.89**	**0.040**
High Risk Tx	1.21	0.52	3.34	0.020
Deceased Donor Tx	0.35	0.45	1.42	0.442
Sex (F)	0.41	0.46	1.51	0.368
Race (AA)	-0.76	0.64	0.47	0.230
Tx 1,25(OH)2 Vit D analog	-0.02	0.44	0.98	0.963

Conclusions: We have identified that a high 25-Vit D level is an independent risk factor for BKV whereas a low 1,25(OH)2 Vit D level is an independent risk factor for AR.

SA-PO3087

Polyoma Virus in Patients Admitted for Indication Biopsy Long Time after Kidney Transplantation Willy Aasebo. *Akershus University Hospital, Norway.*

Background: Once Polyoma virus associated nephropathy (PVAN) is established long-term graft outcome is poor due to development of graft fibrosis. PVAN is probably related to use and dosages of immunosuppressive drugs. The aim of this report is to find out how Polyoma virus affects kidney grafts in patients that were transplanted several years ago and were using maintenance immunosuppressive treatment (low or standard dosages).

Methods: All kidney recipients that were transplanted >12 months before they were admitted to indication biopsies during the years 2008, 2009 and 2010 were included. Biopsies were graded according to Banff criteria.

PVAN was defined as the presence of BK virus (BKv) in biopsies.

Results: A total of 308 kidney transplant recipients were included. Median time after transplantation was 66 months (range: 13 - 415 months).

Nine recipients (2.9 %) had detectable Polyoma virus in blood (all had BKv), of whom 5 had PVAN (1.6%).

Five patients had BKv-PCR >5.0 x 10^3 copies/ml (1.6 %)(median: 5.3 x 10^5. Range: 8.2 x 10^3 - 8.2 x 10^7), of whom 4 (80%) had PVAN. One recipient had PVAN with 2,1 X 10^2 copies/ml.

Inflammation, fibrosis and graft function in recipients transplanted >12 months before biopsy.

	Polyoma neg	Polyoma pos	P	BKv-PCR >5000	P
	N = 299	N = 9		N = 5	neg vs. BKv >5000
Interst fibrosis	1.66 (0.94)	1.89 (0.78)	0.48	2.00 (071)	0.42
Tubular atrophy	1.69 (0.90)	1.78 (0.67)	0.77	1.80 (0.45)	0.78
Interst inflam	0.68 (0.93)	1.25 (0.71)	0.089	1.40 (0.89)	0.095
Tubulitis	0.69 (0.81)	1.33 (0.71)	0.019	1.60 (0.55)	0.016
Creatinine (μμmol/l)	215.1 (85.7)	212.8 (114.2)	0.95	199.3 (25.9)	0.71
Prot/Creat (mg/mmol)	122.7 (188.6)	140.4 (286.3)	0.81	31.3 (28.5)	0.41

Mean (SD)

Conclusions: PVAN is rare in kidney recipients with "old" transplants (1,6%). However, 80% of the recipients with BKv-PCR in blood >5.0 X 10^3 had PVAN.

Recipients with polyoma viremia had more tubulitis, and a tendency towards more interstitial inflammation compared to other patients with indication biopsies and they had considerable amount of interstitial fibrosis and tubular atrophy.

SA-PO3088

A Systematic Review and Meta-Analysis of Prophylactic *Versus* Pre-Emptive Approach for Preventing Cytomegalovirus (CMV) Infection in Renal Transplant Recipients Bishal B. Rawal,[1] Shahrouz Shadrou,[1] Feroz Abubacker,[2] Nasrollah Ghahramani.[1] *[1]Nephrology, Penn State Hershey Medical Center, Hershey, PA; [2]Internal Medicine, York Hospital, York, PA.*

Background: In kidney transplant (KT) recipients, CMV infection poses significant morbidity and mortality. Both prophylactic and pre-emptive approaches for preventing CMV infection have been utilized.

Methods: We conducted a systematic review and meta-analysis comparing the effectiveness of routine prophylaxis vs. pre-emptive treatment for preventing CMV disease after KT. Combining 4 comprehensive search themes (CMV, renal transplant, prophylaxis, pre-emptive), we searched MEDLINE, EMBASE, ISI Web of Science, and Cochrane Central Register from inception through January 2011. We also evaluated studies referenced in review articles and abstracts from meetings of major nephrology and transplant societies (2009-2011). Two authors independently extracted data and assessed methodological criteria. The primary outcome was the pooled estimate of the odds ratio (OR) of developing CMV infection. Secondary outcomes included OR of acute rejection (AR), OR of graft loss and OR of death within first year of KT. Comprehensive Meta-analysis V2 software was used for data analysis.

Results: Analysis of 9 randomized controlled trials (893 patients; Ganciclovir=5, Valganciclovir=4) with CMV infection as an outcome revealed the OR of CMV infection to be 0.34 [0.25-0.46, 95% CI, p=0.008] for the prophylactic vs. the pre-emptive groups. The risks of AR (7 studies; OR 0.65 [0.34-1.23, 95% CI, p=0.12]), graft loss (7 studies; OR 0.52 [0.34-1.12; p=0.32] and mortality (6 studies; OR 0.84 [0.62-1.23; p=0.23]) were similar between the two groups.

Conclusions: Prophylactic approach is superior to pre-emptive approach in preventing CMV infection within the first year of kidney transplant. There is no significant difference in the risk of developing AR, graft loss and mortality with either approach.

SA-PO3089

Trimethoprim/Sulfamethoxazole vs. Atovaquone Prophylaxis: Respective Roles in Risk of Urinary Tract Infection Post-Kidney Transplantation Gaurav Gupta,[1] Dionissios Neofytos,[2] Kavita M. Kakkad,[1] Robert Avery Montgomery,[3] Edward S. Kraus,[1] Nada Alachkar.[1] *[1]Division of Nephrology, Johns Hopkins Hospital; [2]Division of Infectious Diseases, Johns Hopkins Hospital; [3]Division of Transplant Surgery, Johns Hopkins Hospital, Baltimore, MD.*

Background: Primary prophylaxis with trimethoprim/sulfamethoxazole (TMP/SMX) for *Pneumocystis carinii* is administered for the first six months post-kidney transplant (KTx). In some patients, TMP/SMX may be substituted to an alternative agent (AA; e.g. atovaquone) due to allergy, cytopenias etc. At our center we do not provide additional antibiotic coverage for urinary tract infection (UTI) prophylaxis to these patients. We hypothesized that TMP/SMX administration during first 6 months post-KTx may decrease the rate of UTIs.

Methods: All adult KTx recipients transplanted between 01/09 and 06/10 were identified. UTIs up till 6 months post-KTx were reviewed. UTI was defined as either, a positive urine culture for a pathogen at >10^4 colonies/mL with urinalysis (UA) positive for >5 WBCs/HPF and/or nitrite and leukocyte esterase; or a pathogen at >10^5 colonies/mL, regardless of UA.

Results: 65% (209/323) received TMP/SMX and 35% (114/323) received an AA. Overall, 22%(72/323) patients had at least one UTI. Patients with UTI were more likely to be female (53% vs. 35%; p=0.01) and diabetic (36% vs. 14%; p<0.01). Compared to TMP/SMX group (37/209; 18%), a greater number of patients on AA (35/114; 31%) developed UTI (p=0.01). This association was preserved on multivariate analysis(RR=0.45, p=0.005) after controlling for age, gender and diabetes. TMP/SMX group did not differ from AA group in terms of presence of ureteric stent or urinary tract obstruction at time of UTI. Most UTIs (50/72; 69%) were caused by the Enterobacteriaceae, of which, most were resistant to TMP/SMX (72%).

Conclusions: KTx patients who received prophylaxis with an AA had a higher incidence of UTIs within 6 months post-KTx, compared to those on TMP/SMX. Further studies will define which patients might benefit from additional UTI prophylaxis and the effect of UTI prevention on allograft function.

SA-PO3090

Acute Tubular Necrosis (ATN) on Implant Biopsy of Living Kidney Donors Is Associated with Lower Recipient Graft Function Amr El Toukhy, Richard A. Fatica, Milen Amde, Emilio D. Poggio, Titte Srinivas. *Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH.*

Background: Donor kidneys removed by laparoscopy may exhibit slow graft function likely reflecting acute kidney injury. This acute kidney injury may manifest in implant kidney biopsies (ImBx) as histologic acute tubular necrosis (ATN). We examined the association between histologic ATN in IMBx and recipient graft function

Methods: We studied relationships between IMBx ATN, metabolic syndrome (MS) and 1 yr recipient eGFR (CKD-EPI equation) by multiple linear regression in 161 living donor-recipient pairs transplanted 2005-09. In a logistic model we studied associations of IMBx ATN and the proportion of patients with eGFR<45 ml/min/1.73 m². (MS: BMI>25, SBP >130 mm Hg, Triglyceride >150, Low HDL/sex and FBS>100mg/dl)

Results: ATN was observed 21.4 % of ImBx. Donor factors associated with increased incidence of IMBx ATN were 1) Donor MS: Of those with IMBx ATN 21.2 % % (7/33) had MS vs. 6.5 % (8/124) of those with no IMBx ATN; p=.01) and 2) Donor uric acid levels, (p=0.05). Donor age, gender and race were not significantly related to IMBx ATN. Overall, adjusted transplanted iothalamate GFR (donor GFR x Proportion of total kidney volume transplanted and adjusted for recipient BSA) averaged 53.2 ml/min/1.73m²(sd 11.86) and mean recipient eGFR at 1 year was 55.23 ml/min/1.73m² (sd 17.5). Recipient eGFR at 1 year was 56.5 ml/min/1.73m² for recipients with IMBx ATN vs 49.7 ml/min/1.73m² (p= 0.010) in those with no ATN by univariable analysis.

In a multivariable linear regression model, IMBx ATN was a significant correlate of 1 yr recipient eGFR.

Table

Parameter	Value mL/min/1.73 m²	p-value
Intercept	48.5	<0.0001
No IMBx ATN	3.34	0.0361
No acute rejection	2.7	0.0264
Recipient Age/yr	-0.24	0.0160
Donor age	-0.32	0.0008
Donor Race (Black)	-0.74	0.0160
Donor Sex (Male)	-0.74	0.6428

Conclusions: ATN in the implant biopsy is associated with a significantly lower 1 year recipient eGFR . The impact of IMBx ATN on recipent eGFR is similar in to that of acute rejection. Minimal surgical manipulation is thus desirable to reduce IMBx ATN. The long-term impact of IMBx ATN on transplant outcomes merits further study.

SA-PO3091

Thymoglobulin Attenuates Renal Ischemia Reperfusion Injury Prabir Roy-Chaudhury, Yang Wang, Kamyar A. Zahedi, Meenakshi J. Mistry, Virgilius Cornea, Manoocher Soleimani. *Division of Nephrology and Hypertension, University of Cincinnati, OH.*

Background: Ischemia reperfusion injury (IRI) resulting in delayed graft function (DGF) is an important cause of morbidity in renal allograft recipients. Despite its clinical significance there are no effective interventions for the prevention of renal allograft IRI. Thymoglobulin (Thymo) is a potent T cell depleting polyclonal antibody which also reduces the expression of adhesion molecules which play an important role in the causation of renal IRI. The aim of the current study, was to assess the role of a murine surrogate of Thymo (rabbit anti-mouse thymocyte globulin), in attenuating renal IRI in a mouse model of bilateral renal artery ligation.

Methods: 20 C57Bl/6 mice were administered either mouse Thymo (T) 500 mcg IV through the tail vein, control mouse IgG (I) in a similar dose, or no therapy (C = Control); 30 minutes prior to clamping the renal arteries bilaterally (for 30 minutes). Animals were sacrificed at the 24 hr, 3d and 14d time points. Both kidneys were assessed for changes of acute tubular necrosis (tubular dilation, cast formation, brush border loss, necrosis and epithelial vacuolization) using a semi-quantitative scoring scale from 0 to 3+ (0 = normal, 1+ = <25% renal parenchyma involved, 2+ = 25-50%, 3+ = > 50%). An ANOVA test was used for the statistical analysis.

Results: Table 1 describes the composite injury score for the three groups. Note the significant reductions in histologic injury (at both early and late time points) in animals treated with mouse Thymo as compared to controls, and also in most cases IgG.

Conclusions: Our experience suggests that murine Thymo might have important beneficial effects in the setting of mouse renal IRI. Further clinical studies are needed to ascertain whether Thymo should be preferentially used prior to clinical reperfusion in renal transplant patients at increased risk of DGF.

Composite Injury Score

Time	Control (C)	Mouse IgG (I)	Mouse Thymo. (T)
24 Hrs	1.5+/-0.3	1.0+/-0.3	0.17+/-0.2*#
3 Days	2.0+/-0.6	0.25+/-0.25*	0.25+/-0.25*
14 Days	1.75+/-0.5	1.75+/-0.5	0*#

*=p<0.05 compared to Control; #=p<0.05 compared to IgG

Funding: Pharmaceutical Company Support

SA-PO3092

Serum Erythropoietin-Levels of Deceased Organ Donors Are Predictive of Delayed Graft Function after Renal Transplantation Teresa Kauke,[4,5] Thomas Breidenbach,[6] Detlef Boesebeck,[6] Ulf Schoenermarck,[1] Bernhard Banas,[2] Manfred J. Stangl,[4] Peter Schnuelle,[3] Bernhard K. Krämer,[3] Michael Fischereder.[1] *[1]Nephrology, Klinikum der LMU, Munich, Germany; [2]Nephrology, Universityhospital, Regensburg, Germany; [3]Nephrology, UMMH, Mannheim, Germany; [4]Surgery, Klinikum der LMU, Munich, Germany; [5]Laboratory of Immunogenetics, Klinikum der LMU, Munich, Germany; [6]DSO, Munich, Germany.*

Background: Delayed graft function (DGF) affects acute and long-term function of renal transplantats. As experimental data suggest a benefit from epoetin (EPO) administration to the donor, we examined the effect of endogenous donor EPO (dEPO) levels on DGF incidence.

Methods: We examined dEPO levels in 55 deceased organ donors. DGF was defined as the need for ≥ dialysis treatment during the first week post transplantation. Demographic data, DGF incidence and transplant function were obtained from the patient record.

Results: Mean donor age was 52.9 years (SD ± 16.0), median donor age was 53.0 years (range 15 – 83), 20 donors were 60 years or older. Mean recipient age was 50.7 years (± 12.3). Mean dEPO level was 57.8 mU/ml (± 86.4), median dEPO level was 33.7 mU/ml (range 4.6 – 502). DGF was significantly less in recipients with dEPO > 70 mU/ml than in recipients with dEPO < 70 ng/ml, i.e. 1 of 16 vs. 23 of 58 patients (p=0.038). Recipients of dEPO > 70 mU/ml kidneys required on average 0.3 dialysis treatments (± 1.0) vs. 2.7 dialysis treatments for patients with dEPO < 70 mU/ml (p=0.0447). dEPO > 70 mU/ml resulted in serum-creatinine of 1.7 mg/dl (± 0.4) vs. 2.4 mg/dl (± 1.9; p=0.14) on day 28 and shorter hospitalization 22.7 days (± 6.4) vs. 29.0 days (± 12.8; p=0.0809). Cold ischemia time, donor and recipient age, PRA and immunosuppressive regimens were not different for dEPO< 70 or > 70 mU/ml.

Conclusions: dEPO levels < 70 mU/ml have a sensitivity of 95% for prediction of DGF with a specificity of 30%. The negative predictive value of dEPO > 70 mU/ml for DGF is 93.8%.

dEPO levels > 70 mU/ml appear protective in deceased kidney donors and allow prediction of DGF. Modification of dEPO levels to reduce DGF deserves further study.

SA-PO3093

Comparison of Chronic Kidney Disease Complications Management in Kidney Transplanted and Non-Transplanted Patients Saleh Kaysi, Julien Aniort, Carole Philipponnet, Patrice M. Deteix, Anne-Elisabeth Heng. *Nephrology, CHU Gabreil Montpied, Clermont-Ferrand, France.*

Background: Chronic kidney disease (CKD) complications are common in kidney transplanted patients (KT). We compared retrospectively the management of CKD complications according to the K/DOQI guidelines in KT and non-transplanted CKD patients (NT).

Methods: Files of all KT and NT patients with CKD stages 4 and 5 (GFR obtained by MDRD equation) seen in consultations in the department of nephrology at the University Hospital of Clermont-Ferrand between May 2009 and June 2010 were screened. Inclusion criteria were; more than 6 months of follow up, and a complete file concerning the data being collected. Exclusion criteria were; admission to the hospital or the emergency or infection in the 3 months before data collection date, cancer or primary hyperparathyroidism. The proportion of patients who achieved K/DOQI guidelines was analyzed (*: p<0.05).

Results: 58 KT were compared to 85 NT CKD patients matched by CKD stage (age 57y±13* vs 67y±17, diabetes: 21 vs 27%, GFR: 21.3±6* vs 18.3±6 ml/min respectively). Results after data analyzing (mean ± standard derivation) and proportions of patients achieving K/DOQI guidelines targets are shown in the following table 1.

	KT n=58	KDOQI %	NT n=85	KDOQI %
Hemoglobin (g/dl)	10,9 ± 1,3	41% *	11,6 1,5	51%
Ferritin (ng/ml)	225 [62-1650]	80% *	121[31-593]	52%
Cholesterol (g/l)	1,97 ± 0,4	35% *	1,94 ±0,28	60%
LDL (g/l)	1,1 ± 0,24	38% *	0,99 ± 0,25	64%
Ca (mmol/l)	2,3 ± 0,14	67% *	2,22 ± 0,17	60%
Ph (mmol/l)	1,3 ±0,32	79% *	1,43 ± 0,32	62%
PTH (ng/ml)	156 ± 108	50% *	140 ± 144	65%
Vit D (ng/ml)	20 ± 11	35% *	17 ± 10	20%
Albumin (g/l)	35 ± 5	22%	22%	22%
sBP (mmHg)	135 ± 20	52% *	140 ± 20	41%

table 1

Conclusions: More attention has to be given to achieve a better control of anemia, dyslipidemia and hyperparathyroidism in KT CKD patients. Immunosuppressive treatment, inflammation, weight gain, may explain the difference of CKD complications management observed between the KT and NT patients.

Prospective studies are needed to confirm the beneficial effect of treating CKD complications on graft function and patient outcomes

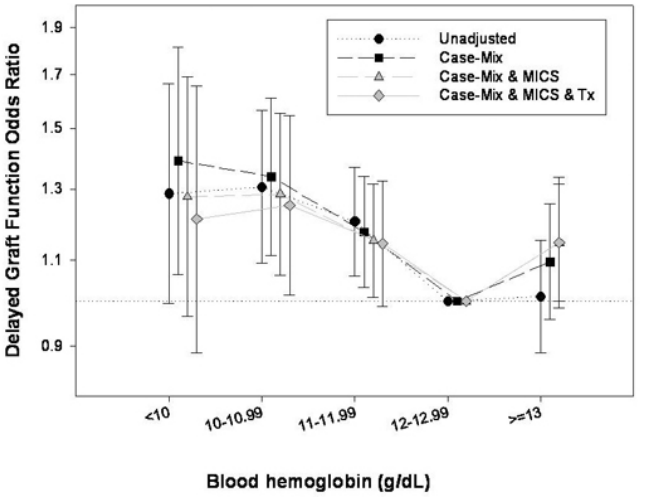
Associations of Pre-Transplant Hemoglobin and Iron Deficiency with Post-Transplant Delayed Graft Function in Kidney Transplant Recipients Miklos Z. Molnar,[1,2] Csaba P. Kovesdy,[3] Laszlo Rosivall,[2] Suphamai Bunnapradist,[4] Junichi Hoshino,[1] Elani Streja,[1] Mahesh Krishnan,[5] Kamyar Kalantar-Zadeh.[1,4] *[1]Harold Simmons Center, Torrance, CA; [2]Semmelweis University, Budapest, Hungary; [3]Salem VA Medical Center, Salem, VA; [4]David Geffen School of Medicine at UCLA, Los Angeles, CA; [5]DaVita, Inc, Denver, CO.*

Background: Delayed graft function(DGF) complicates kidney allograft outcomes in the immediate post-transplantation period. We hypothesized that in hemodialysis patients (pts) more severe anemia & iron deficiency are associated with higher risk of DGF.

Methods: Linking 5-year hemodialysis pts data of a large dialysis organization to the Scientific Registry of Transplant Recipients, we identified 11836 hemodialysis pts. Using logistic regression analyses we examined the association between pre-transplant parameters and post-transplant DGF.

Results: Pts were 49±14(mean±SD) years old and included 38% women, 27% Blacks and 26% diabetics. Compared to pre-transplant hemoglobin of 12-<13 g/dL, there was 25% higher risk of DGF with blood hemoglobin 10-<11 g/dL (OR=1.25;95%CI: 1.01-1.55), whereas blood hemoglobin ≥13 g/dL exhibited 15% higher risk of DGF (OR=1.15;95%CI: 0.98-1.34).



After adjustment for confounders, no association was found between iron parameters & DGF.

Association hemoglobin, iron parameters and DGF

	Unadjusted	Case-mix adjusted	Case-mix&MICS adjusted	Case-mix&MICS&Transplant adjusted
	OR (95% CI)	OR (95% CI)	OR (95% CI)	OR (95% CI)
Hb (+1 g/dL increase)	0.62 (0.40-0.96)	0.51 (0.33-0.79)	0.55 (0.35-0.86)	0.58 (0.35-0.96)
Serum ferritin (+100 ng/mL increase)	1.05 (1.03-1.06)	1.02 (1.01-1.04)	1.02 (1.00-1.03)	1.01 (0.99-1.03)
Iron saturation ratio (+10 increase)	1.47 (1.05-2.06)	1.38 (0.98-1.94)	1.39 (0.98-1.97)	1.39 (0.97-2.00)

Conclusions: Pre-transplant either high or low blood hemoglobin but not iron markers are associated with higher risk of DGF.

SA-PO3095

Associations of Pre-Transplant Anemia Management with Post-Transplant Delayed Graft Function in Kidney Transplant Recipients Miklos Z. Molnar,[1,2] Csaba P. Kovesdy,[3] Junichi Hoshino,[4] Suphamai Bunnapradist,[5] Laszlo Rosivall,[2] Elani Streja,[1] Mahesh Krishnan,[6] Kamyar Kalantar-Zadeh.[1,4,5] *[1]Harold Simmons Center, Torrance, CA; [2]Semmelweis University, Budapest, Hungary; [3]Salem VA Medical Center, Salem, VA; [4]UCLA School of Public Health, Los Angeles, CA; [5]David Geffen School of Medicine at UCLA, Los Angeles, CA; [6]DaVita, Inc, Denver, CO.*

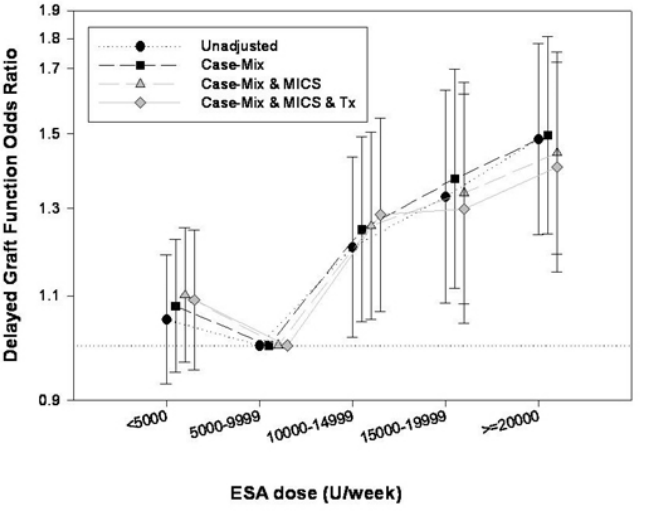
Background: Delayed graft function (DGF) is an important complication in early post-transplant period. We hypothesized that in hemodialysis patients the requirement for higher doses of erythropoietin stimulating agents (ESA) or blood transfusions prior to transplantation is associated with higher risk of DGF.

Methods: Linking 5-year hemodialysis patient data of a large dialysis organization to the Scientific Registry of Transplant Recipients, we identified 11,836 hemodialysis patients. Using logistic regression analyses we examined the association between pre-transplant anemia management and post-transplant DGF.

Results: Patients were 49±14 (mean±SD) years old and included 38% women, 27% Blacks and 26% diabetics. After adjusting for relevant covariates, pre-transplant blood transfusion was associated with 33% higher DGF risk (odds Ratio [OR]=1.33; 95% confidence interval[CI]: 1.19-1.48).

	Unadjusted	Case-mix adjusted	Case-mix & MICS adjusted	Fully adjusted
	OR (95% CI)	OR (95% CI)	OR (95% CI)	OR (95% CI)
Pretransplant transfusion	1.30 (1.18-1.44)	1.29 (1.16-1.43)	1.31 (1.18-1.45)	1.33 (1.19-1.48)
ESA dose (+5000 units/wk increase)	1.07 (1.04-1.10)	1.07 (1.03-1.10)	1.05 (1.02-1.09)	1.05 (1.02-1.09)

Each 5000 U/week increase of pre-transplant ESA dose was associated with 5% higher DGF (OR=1.05; 95%CI: 1.02-1.09).



Conclusions: Pre-transplant blood transfusion and higher ESA dose are associated with higher risk of DGF.

SA-PO3096

Alemtuzamab Induction and Tacrolimus Monotherapy Maintenance Eliminates Cellular Rejection in Kidney Allografts: Five Year Follow Up Milap Pokharel, Prajwol R. Pant, Michael C. Chobanian. *Medicine, Dartmouth Medical School, Hanover, NH.*

Background: Alemtuzumab is increasingly used as induction therapy for renal transplants to minimize post transplant immunosuppression. Biopsy confirmed acute rejection (BCAR) has been shown to be less frequent with alemtuzumab compared to conventional induction therapies and standard immunosuppressive regimens. We investigated the rate of BCAR in patients receiving alemtuzumab induction followed by tacrolimus monotherapy and compared the results to those receiving alternative induction and maintenance therapies.

Methods: We retrospectively reviewed data from all kidney transplant recipients between 1992 and 2010 with BCAR. Demographics, type of kidney transplant, type and cause of rejection, graft survival and patient survival times were determined.

Results: 647 renal transplants were performed, 345 patients in the pre and 302 patients in the post alemtuzumab era. 36 patients had 44 episodes of BCAR, 32 (9.3%) were pre and 12 (3.9%) were post alemtuzumab. Mean age was 34.2 years, 56.8% were male and 91.7% were Caucasians. 16 (36.3%) rejected allografts were from living and 28 (63.4%) were from deceased donors. Of the pre alemtuzumab rejections, 13 (40.6%) were antibody mediated (AMR) while 19 (59.4%) were ACR. In the post alemtuzumab era, 5 (41.7%) were AMR and 7 (58.3%) were ACR. No patients in the post alemtuzumab era died at the end of the study period, whereas 5 year survival rate was 93.7% for patients in the pre alemtuzumab era. Mean time of graft survival was 3.7 versus 10.6 months in the pre vs post alemtuzumab group. Incidence of both ACR and AMR were significantly lower in patients who received alemtuzumab induction (9.3% vs 3.9%). Of the 7 cases of ACR in the post alemtuzumab era, 5 had non compliance to medications and 2 were taking cyclosporine, prednisone, and MMF, not tacrolimus monotherapy.

Conclusions: Alemtuzumab induction plus tacrolimus monotherapy maintenance eliminates ACR up to 5 yrs post kidney transplant in compliant patients. Alemtuzamab induction appears to confer greater longevity in both patients and grafts undergoing rejections than other induction modalities.

SA-PO3097

Acute Rejection and Long Term Graft Survival in Renal Transplant Recipients Using Campath 1-H Induction Mekdess Abebe, Diane Triolo, Heesuck Suh, Frank Darras, Mersema Abate, Edward P. Nord. *Nephrology and Transplantation, SUNY Stony Brook, Stony Brook, NY.*

Background: Acute rejection (AR) remains a determinant of long term graft survival.

Methods: We report on the AR rate and its impact on long term graft survival following alemtuzumab (campath-1H) induction (30 mg) and rapid steroid withdrawal (methylprednisolone 500 mg , 250 mg, and 125 mg on days 1-3 respectively) in 487 consecutive renal transplant patients from July 2003 through January 2011. Maintenance immunosuppression consisted of tacrolimus and mycophenolate mofetil with target level of 8-10 ng/ml and 1.5-3.0 ng/ml respectively. A renal biopsy was prompted by an unexplained rise in serum creatinine.

Results: AR was biopsy proven in 55/487 (11.3%) patients and an additional 10 patients had borderline changes (see table). By Banff criteria, 31 (6.4%) showed acute cellular rejection (ACR), 16 (3.3%) showed acute humoral rejection (AHR), and 8 (1.6%) displayed both ACR and AHR. The mean age of these 65 patients was 53 ± 14 yrs, 35 (54%) were male, 19 (29%) were African American, 11(17%) were Hispanic, 48 (74%) received a deceased donor kidney, and 14 (21%) were retransplants. AHR was treated with plasmapharesis, IVIG and rituximab and ACR with steroid and/or thymoglobulin or OKT3. Mean follow up was 43 ± 22 months post AR.

Banff category	ACR (Type 4)	AHR (Type 2)	ACR+AHR	Borderline
Number of patients(%)	31 (6.4%)	16 (3.3%)	8 (1.6%)	10 (2.1%)
PRA (%), (mean±SD)	10 ± 26	56 ± 44	41 ± 46	28 ± 44
HLA match (mean±SD)	2.4 ± 2.4	1.1 ± 1.2	1.8 ± 0.8	1.1 ± 1.6
Days to AR(mean±SD)	209 ± 172	15 ± 23	221± 269	385 ± 300
Outcome				
Graft survival	18	10	4	9
Dialysis dependent	13	6	4	1
Death	4	2	0	2

At 43 ± 22 months post AR patient survival was 88% (57/65) and graft survival was 63% (41/66), with a mean serum creatinine of 2.1 ± 0.97 mg/dL. Eight of 65 patients died, 4 with a functioning graft. The cause of death was sepsis 3, CAD 2, PTLD 1, lung cancer 1, and stroke 1.

Conclusions: 1. Using campath-1H induction the incidence of ACR was 6.4%, AHR 3.3% and ACR+AHR 1.6%. **2.** AHR occurs at an earlier time point than ACR or ACR+AHR and is associated with a better outcome.

SA-PO3098

Independent Predictors of Renal Allograft Failure in Patients with Acute Antibody-Mediated Rejection Marie Matignon, Thangamani Muthukumar, Michelle L. Lubetzky, Darshana Dadhania, Surya V. Seshan, Manikkam Suthanthiran, Choli Hartono. *Cornell University.*

Background: The impact of co-existing histological findings in renal allograft biopsies showing acute antibody-mediated rejection (AMR) on graft outcome has not been well defined.

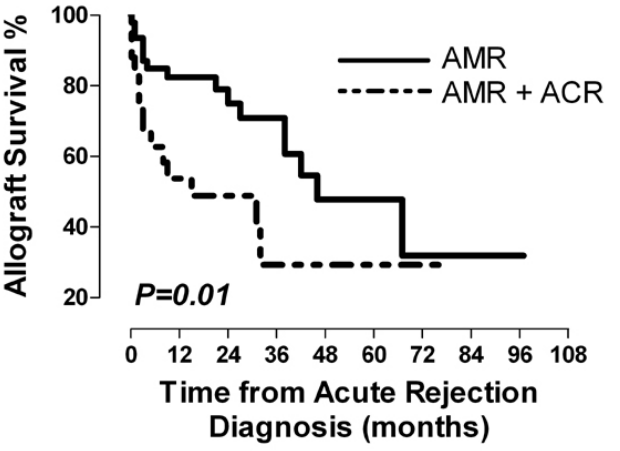
Methods: We reviewed all for-cause kidney allograft biopsies between 12/2003 and 12/2010. We identified AMR as defined by Banff 2009. Primary outcome was graft loss. Significant baseline variables were entered into a Cox model to identify independent predictors of outcome. Robustness of the model was verified by analysis with a logistic model.

Results: 76 of 1386 (5.5%) kidney recipients had AMR. Median follow up was 21(0-97) months (mo) after diagnosis. 31 (40%)lost their graft, 48% of them within 3 mo of AMR.

Concomitant acute cellular rejection (c-ACR) on biopsy and eGFR at the time of AMR were the only predictors of graft loss. 26 (34%) of the 76 with AMR had c-ACR.

	Cox Model for Graft Loss After AMR			**Logistic Regression Model for Graft Loss at 1-year After AMR**		
VARIABLE	**Hazard Ratio**	**95%CI**	**P**	**Odds Ratio**	**95%CI**	**P**
Concomitant ACR	2.7	1.2 to 6.3	0.02	5.1	1.02 to 25.6	0.04
eGFR at AMR	0.95	0.92 to 0.99	0.016	0.93	0.86 to 0.99	0.03

Median graft survival for AMR with c-ACR was 15 mo (vs. 46 mo for AMR alone) from the diagnosis of rejection.



These predictors were independent of (i) time to AMR, (ii) presence of concomitant (a) chronic active AMR, (b) IF/TA, (c) g/ptc inflammation, (d) arteriolar hyalinosis, and (iii) addition of (a) Rituximab, (b) anti-thymocyte globulin or (c) bortezomib for the treatment of AMR, to the standard treatment (steroids, plasmapheresis or intravenous immunoglobulin).

By logistic regression, the same two variables predicted graft loss at 1-year after AMR.

Conclusions: In biopsies showing AMR, the concomitant presence of ACR, independent of any other allograft pathology or rejection therapy, is a risk factor for graft loss.

SA-PO3099

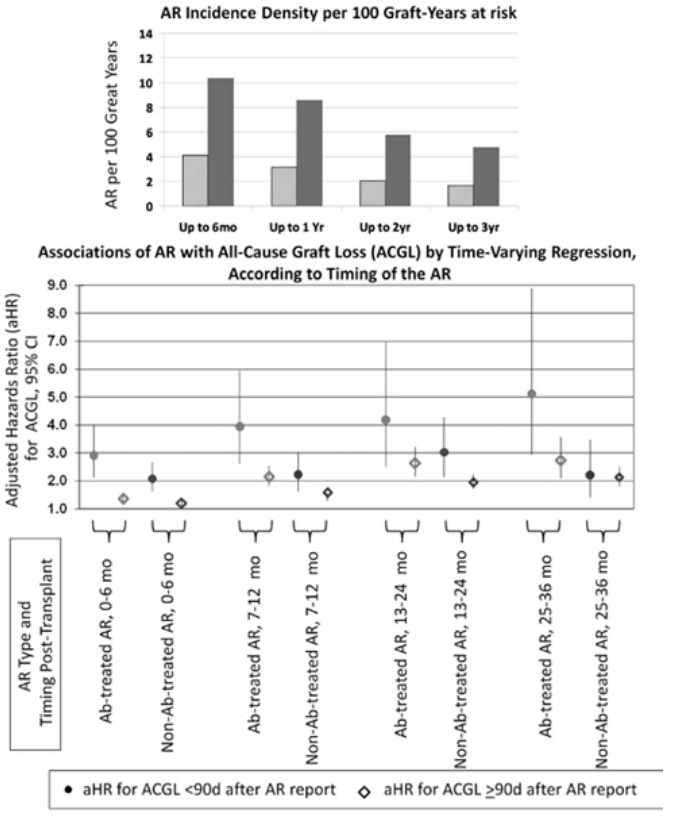
The Outcomes of Acute Rejection in Contemporary Kidney Transplantation: Importance of Timing and Risk Window Krista L. Lentine,[1] Adrian Gheorghian,[1] Gilbert Litalien,[2] Anupama Kalsekar,[2] Mark Schnitzler.[1] *[1]Saint Louis Univ; [2]Bristol-Myers Squibb.*

Background: We examined the frequency of acute rejection (AR) in contemporary U.S. kidney transplantation (KT) and the clinical impact of AR based on: 1) AR timing after KT, 2) risk period after the AR event.

Methods: Data for Medicare-insured KT recipients in 2000-2007 (n=44,831) were drawn from the USRDS. AR events were ascertained from OPTN reports covering 0-6, 7-12, 13-24, and 25-36 mo post-transplant. AR was classified as antibody-treated AR (Ab-AR) or other management (non-Ab-AR). Associations of AR with subsequent all-cause graft loss (adjusted hazards ratio, aHR) were estimated with time-varying Cox regression. Risk associated with AR was partitioned within the first 90d after AR or ≥90d after the AR events. Covariates included factors in the UNOS Kidney Allocation Review Committee survival model.

Results: AR was more common when evaluated early after KT (e.g., within 6 mo or 1yr) compared to over longer intervals. Non-Ab-treated AR was more than twice as common as Ab-treated AR by period and donor type. In time-varying multivariate regression, development of Ab-AR predicted greater risk of graft loss than non-Ab-AR.

The aHR for graft loss from Ab-AR increased with later timing of AR after transplant, while risk associated with non-Ab AR peaked for events reported in mo 13-24 after KT. Regardless of the diagnosis time, the relative risk of graft loss was higher in the first 90d after a given AR report compared to beyond 90d.



Conclusions: While AR after KT is less common than in the past, AR is associated with increased graft loss risk when it occurs. AR events recognized later after transplant have more serious graft loss implications, especially within the first 90d following an AR event. This observation may reflect reduced monitoring, delays in diagnosis, or clinico-pathological features of late AR.

SA-PO3100

Posttransplant Glomerulonephritis; Incidence and Impact on Graft Outcome

Jung Nam An,[1] Jung Pyo Lee,[2] Yun Kyu Oh,[2] Yon Su Kim,[1] Chun Soo Lim.[2] *[1]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea; [2]Department of Internal Medicine, Seoul National University Boramae Medical Center, Seoul, Korea.*

Background: Recently, the significance of posttransplant glomerulonephritis (PTGN) is revisited as it may induce the allograft failure. The purpose of this study is to identify the incidence of PTGN and the association between PTGN and allograft failure, and to analyze the risk factors of PTGN.

Methods: In this cohort study, among 910 Korean patients who underwent renal transplantation from 1995 to 2009, a total of 681 patients were enrolled, excluding patients under age 18 and received second or multi-organ transplantation. The medical records were reviewed.

Results: During the follow-up period, a total of 70 patients (10.3%) were diagnosed as PTGN. The incidence increased with time after transplantation, from 10.7% at 5year to 18% at 10year. PTGN was diagnosed in 14.6% of biopsy-proven or clinically diagnosed chronic GN, compared to 10.6% in unknown etiology group, and 4.1% in other etiology group such as diabetes and hypertension. In patients with PTGN, allograft survival rate was significantly decreased (p<0.001). As PTGN developed, the incidence of graft failure increased 3.86 times (95%CI 1.67-8.93), and in case of occurrence of both acute rejection and PTGN, the odds ratio (OR) of graft failure was 7.03 (95%CI 2.93-16.89) after adjusting for other risk factors. In univariate analysis for probability of PTGN, underlying diseases, era of transplantation, preemptive transplantation, and the use of tacrolimus and simulect were significant risk factors. However, donor type, timing difference of referral, and HLA antigen mismatch were not associated. In addition, through multivariate analysis, the use of tacrolimus (OR 2.44, 95%CI 1.49-4.00, p<0.001) and basiliximab (OR 2.29, 95%CI 1.36-3.87, p=0.002) increased the development of PTGN significantly.

Conclusions: The development of PTGN was strongly associated with the poor kidney allograft survival. Therefore, the main focus should aim for the management of recurrent or de-novo GN after kidney transplantation.

SA-PO3101

Rituximab in Pediatric Recurrent Focal Segmental Glomerulosclerosis

Juhi Kumar,[1] Ibrahim F. Shatat,[4] Amy L. Skversky,[3] Eduardo M. Perelstein,[1] Valerie L. Johnson,[1] Shefali Mahesh.[2] *[1]Pediatrics, Weill Cornell Medical Center, New York, NY; [2]Pediatrics, Akron Childrens Hospital, Akron, OH; [3]Pediatrics, Children's Hospital at Montefiore, Bronx, NY; [4]Pediatrics, MUSC Children's Hospital, Charleston, SC.*

Background: FSGS recurs in 35-50% of allografts. Plasmapheresis (TPE) has been one of the mainstays of treatment but results are variable. Rituximab (RTX), a anti CD20 antibody is being used for its treatment but pediatric experience is very limited.

Methods: We report 8 cases of recurrent FSGS treated with Rituximab.

Results: See Table 1 for details.

8 children, age range 7 to 17 years had recurrence of FSGS within 2 weeks after transplant. All were on TPE for an average of 7 days to 5 years with persistent nephrotic range proteinuria. They received 1 to 4 doses of RTX.

Complete response, urine protein creatinine (u p/c) ratio < 0.2 was seen in 2/8 patients. Partial decrease in u p/c ratio was seen in 3/8 patients. 3 patients had no response. Those who responded did so within the first month of RTX.

One patient received RTX for biopsy proven severe recurrence with allograft dysfunction requiring hemodialysis. Proteinuria diminished and serum creatinine improved significantly post RTX. The patient developed severe respiratory failure 4 weeks post Rituximab and died. No infectious agent was identified on bronchoscopy. Autopsy revealed thrombotic microangiopathy in multiple organs.

One patient developed CNS malignancy 2 years post Rituximab and one had ATN after receiving Rituximab.

Table 1

	Age/Sex/ Race	Transplant Type	Pre Transplant Pheresis	Nephrectomy	CD19%pre/ post	Scr pre/post	Urine P/C pre/post
Case 1	15/m/w	LRD	y	n	23/0	1.2/0.9	2.3/1.2
Case 2	12/m/w	DD	y	n	17/0	1.25/1.13	8.1/3.3
Case 3	8/m/b	LURD	n	n	11/0	0.74/1.24	4.4/7.5
Case 4	16/m/b	LURD	y	n	67/0	4.22/1.57	5/2.2
Case 5	17/f/w	DD	n	u/l	12/1	2.2/2.8	10/8
Case 6	14/f/w	LRD	n	n	-/0	1.8/1.7	25/21
Case 7	7/m/w	LRD	y	y, b/l	1.2/0.5	1/0.8	23/0.1
Case 8	15/m/w	LRD	y	y, b/l	1/0	1.2/1.0	4.19/0.14

Post :1 mo after RTX

Conclusions: Rituximab can be used as a treatment for recurrent FSGS. Efficacy is variable. Larger multicenter studies are needed to prove its sustained efficacy in those who respond. Long term follow up is required to monitor for adverse effects.

SA-PO3102

Successful Treatment of Recurrent Focal Segmental Glomerulosclerosis after Kidney Transplantation Results in Recovery of Podocyte Injury

Kavita M. Kakkad,[1] Michelle M. Estrella,[1] Rachel Marino,[2] Hamid Rabb,[1] Nada Alachkar.[1] *[1]Nephrology, Johns Hopkins University, Baltimore, MD; [2]Surgery, Johns Hopkins University.*

Background: Focal segmental glomerulosclerosis (FSGS) commonly recurs after kidney transplantation (Tx). We describe the clinical course of individuals with recurrent FSGS treated with plasmapheresis (PP)±rituximab.

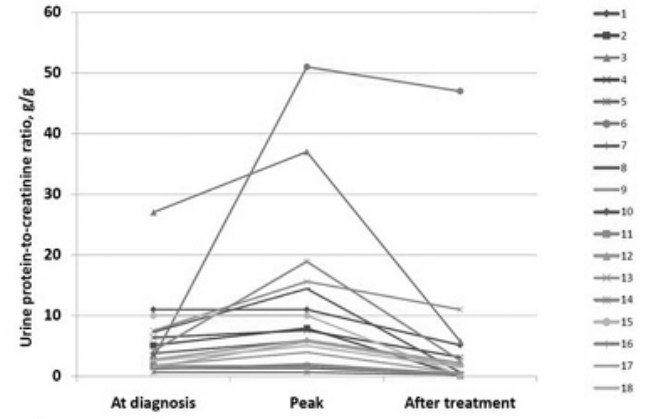
Methods: Eighteen patients with recurrent FSGS after Tx between 2005 and 2011 were followed for up to 2 years. All received PP (median 19 exchanges [IQR: 10-24]); 8 who were refractory to PP received 1 dose of rituximab. 17 patients underwent kidney biopsy (Bx) at the time of recurrence and at least 1 Bx after treatment. Response to therapy was defined by the decline in proteinuria to sub-nephrotic range or complete resolution.

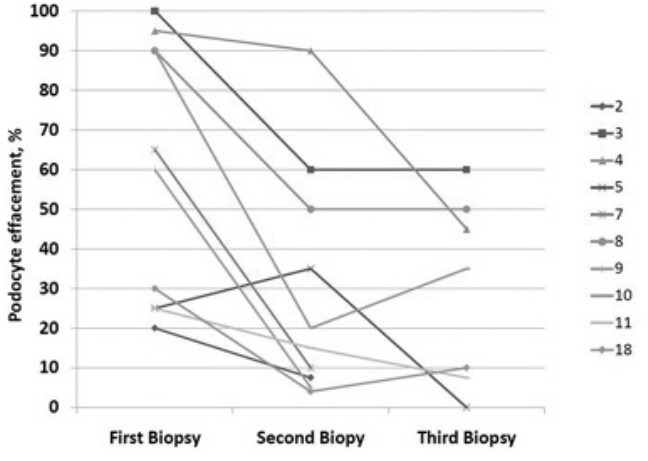
Results: Clinical characteristics are shown in the table.

Clinical Characteristics

Mean age at Txp, y(SD)	41(13)
Black, %	55
Male, %	55
Mean years on dilaysis, y(SD)	2.8(3.1)
Per Txp Nephrectomy, %	28
Tx Type, %	
Deceased	44
Living related	28
Living unrelated	28
Serum Cr at recurrence mg/dl, mean(SD)	2.7(1.7)
Pr/Cr at recurrence g/g, mean(SD)	5.5(6.2)

Median time to recurrence was 20 days (IQR 5-90) after Tx. On initial Bx, individuals had variable degree of podocyte effacement (PE) on EM; only 2 had FSGS changes on light microscopy (LM). Mean serum creatinine improved from 2.7 to 2 mg/dL (P=0.07) and mean urine protein/creatinine ratio (Pr/Cr) declined from 11.7 (peak) to 4.9 g/g (P<0.01) after treatment. Receipt of rituximab improved Pr/Cr by a mean of 3.3 g/g (P=0.03). 10 patients had improvement in PE after treatment; 8 of whom did not develop FSGS changes on LM and 2 had persistent changes. Treatment Failure did not result in improvement of PE (7 patients).





Conclusions: Decreased proteinuria was accompanied by improvement in podocyte effacement in patients treated with PP ± rituximab for recurrent FSGS after Tx.

SA-PO3103

High-Dose Corticosteroid Therapy (HDCS) for Recurrent idiopathic Membranous Nephropathy (IMN) after Renal Transplantation Maria Lopez Picasso,[1] Esther Gonzalez Monte,[2] Alberto De Lorenzo,[2] Maria Moya,[1] Laura Garcia-Puente Suarez,[2] Jose M. Morales,[2] Amado Andres,[2] Manuel Praga.[2] *[1]Nephrology, H.U. La Princesa, Madrid, Spain; [2]Nephrology, H. U. 12 de Octubre, Madrid, Spain.*

Background: IMN can recur in 40% of renal allografts or appear de novo. Corticosteroids as a single therapy for IMN is not recommended.No studies have been performed in IMN recurring or presenting de novo after renal transplantation.We observed a beneficial effect of HDCS in transplant patients with renal biopsy showed an IMN.In this study, we collect our experience with HDCS in IMN of renal transplant patients.

Methods: Single-center,observational study of patients with biopsy-proven IMN after renal transplantation.Patients were divided into two groups according to whether they received HDCS in addition to their immunosuppressive regimen(group 1) or not(group 2).

Results: Twenty-one patients(66.7% male, mean age 51.3 ± 13.3 years)were collected.47.6% were HCV+.

Fourteen patients (group 1) received HDCS, 6 of them with oral steroids (0.7 mg/kg/day) and 8 with intravenous pulses (mean dose 1,25gr).Seven patients (group 2) received no corticosteroid treatment. The baseline characteristics, clinical presentation and outcome are summarized in the table.

Characteristics and outcome of group 1 vs group 2

	Group 1 (HDCS) (14p)	Group 2 (7p)	p
Age (years)	49,3±12	52,7±7,6	NS
Time from Tx to diagnosis (months)	39,3±32,2	35,5±23	NS
sCr at diagnosis (mg/dl)	1,4±0,3	1,7±0,46	NS
eGFR at diagnosis (ml/min)	46,9±17,4	42,5±24,4	NS
Proteinuria at diagnosis (gr/d)	9,1±4,6	6,2±5,1	0,06
Patients receiving CSA or TAC at the time of diagnosis (%)	100	100	NS
Patients receiving ACEI / ARB(%)	100	42,8	0,006
Patients with CR or PR (%)	12(85,7)	2(28,6)	0,009
Time to reach complete or partial remission (months)	5±3,4	12±3	0,001
Final sCr (mg/dl)	1,8±0,9	3,2±2	0,04
Final proteinuria (gr/d)	2,1(r0,1-10)	5,9(r0,2-20)	NS

Group 1 patients achieved a higher rate of complete (CR) or partial (PR) remission, as compared to those of group 2 (85.7 vs 28.6%). Final sCr was significantly better among group1.

Conclusions: A majority of patients with recurrent or de novo IMN achieved CR or PR of nephrotic syndrome after receiving oral or i.v. high-dose corticosteroid therapy.

SA-PO3104

The Graft Outcome of HLA Non-Mismatch Kidney Transplantation; the Impact of Recurrent Glomerulonephritis and Rejection Hee Jung Jeon,[1] Ran-Hui Cha,[2,3] Jung Nam An,[1] Jung Pyo Lee,[3,4] Curie Ahn,[1] Suhnggwon Kim,[1] Yon Su Kim.[1,3] *[1]Department of Internal Medicine, Seoul National University College of Medicine, Korea; [2]Department of Internal Medicine, National Medical Center, Korea; [3]Clinical Research Center for End Stage Renal Disease, Korea; [4]Department of Internal Medicine, Boramae Hospital, Korea.*

Background: Although histocompatibility leukocyte antigen (HLA)-identical renal transplantation reveals superior graft outcome, the graft survival has not been indefinite. Original disease recurrence and effect of acute rejection (AR) may preclude indefinite survival. Here, we analyzed the factors that affected the graft outcomes in HLA non-mismatch condition.

Methods: We have studied the effect of recurrent glomerulonephritis (GN) and AR on graft outcomes in HLA non-mismatch (n=122), 3-4 mismatch (n=317), and 5-6-mismatch (n=102) renal allograft of Seoul National University Hospital. And 41% patients had GN as underlying disease.

Results: Overall graft survival was 93.4% at 5 years, 83.3% at 10 years, and 55.5% at 20 years. Surprisingly, HLA compatibility did not affect the graft survival (0 vs. 3-4 vs. 5-6 mismatch; 92.8% vs. 92.7% vs. 95.8% at 5 years, 82.5% vs. 77.6% vs. 88.9% at 10 years, 42.0% vs. 73.1% vs. 37.2% at 20 years, respectively, p=0.602). In GN subgroup, male recipients (p=0.041), acute rejection (p=0.001), and recurrent GN (p=0.003) were the risk factors for graft loss, whereas living donor graft showed the protective effect (p=0.029). The acute rejection was more prevalent as more HLA incompatibility [0 (ref.) < 3-4 < 5-6 mismatch; p=0.047 and p=0.014]. But the recurrence of GN showed the opposite trend, i.e., the less HLA mismatch, the more recurrence of GN [0 (ref.) > 3-4 > 5-6 mismatch; p=0.106 and p=0.022]. Furthermore, the graft loss due to recurrent GN was significant in HLA non-mismatch group compared with 3-4 mismatch group (p=0.047).

Conclusions: Although HLA non-mismatch group experienced less AR, the graft survival was not different from others, which was mainly due to the recurrence of underlying disease. Therefore, the main focus should aim for the management of recurrence, especially in HLA-identical renal transplantation.

SA-PO3105

Proteinuria as a Marker of Renal Injury in Children after Kidney Transplantation Tanya E. Pereira, Jayanthi Chandar, Chryso P. Katsoufis, Wacharee Seeherunvong, Carolyn L. Abitbol, Michael Freundlich, Gaston E. Zilleruelo. *Division of Pediatric Nephrology, Department of Pediatrics, University of Miami, Miller School of Medicine, FL.*

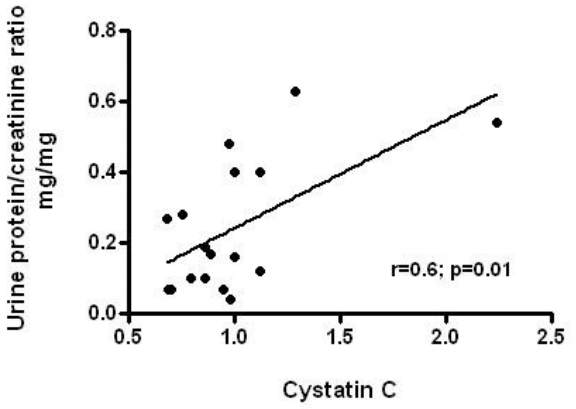
Background: Acute kidney injury occurs at the time of kidney transplantation as a consequence of ischemia-reperfusion injury.

The purpose of this study is to sequentially and quantitatively measure proteinuria in children with kidney transplants and assess the correlation between cystatin C and proteinuria at the end of the first post-transplant year.

Methods: The cohort consists of 25 children with kidney transplants followed at the University of Miami between the years 2008 to 2010. Proteinuria was assessed by urine protein/creatinine (Upr/cr -mg/mg) ratio at 2 days, 1 week, 1 month and 1 year post-transplant. Comparisons were made between living donor (LD) and deceased donor (DD) transplants. Children with FSGS were analyzed separately.

Results: The mean age was 12± 4.9 years with 11 males. Seventeen of 25 had DD.transplants. At one month post-transplant, there was a significant decrease in proteinuria in both DD and LD. The urine pr/cr ratio was 1.35±1.45, 0.27±0.16, 0.19± 0.17 in DD versus 0.2 ± 0.5, 0.38± 0.5 and 0.27± 0.16 in LD at 1 week, 1 month and 1 year post-transplant respectively. Those with FSGS had a mean urine pr/cr ratio of 8.3±6.4 versus those without

FSGS who had a pr/cr ratio of 1.6± 1.5 2 at 2 days post transplant (p< 0.02). Forty percent of the initial proteinuria consisted of albumin. There was a significant correlation between cyststain C and urine pr/cr ratio at the end of the first post- transplant year.



Conclusions: Proteinuria is a useful marker of post-transplant renal injury, and when used in conjunction with serum cystatin c is a good predictor of renal parenchymal integrity. Sequential assessment of urine pr/cr ratio helps determine recovery from acute kidney injury.

SA-PO3106

Altered mTOR Pathway in Glomerular Epithelial Cells May Not Be Associated with Proteinuria Ping L. Zhang, Wei Li. *Department of Anatomic Pathology, William Beaumont Hosptial, Royal Oak, MI.*

Background: Several studies report that transplant patients treated with Sirolimus, an inhibitor of mammalian target of rapamycin pathway (mTOR), have a high chance to develop a reversible proteinuria. In this study, we evaluated phosphorylated (p) form of mTOR and its downstream signals 70S6K and 4EBP in glomerular epithelium in both native and transplant biopsies from patients with proteinuria, and correlated the expression of these markers with proteinuria levels.

Methods: The first study included 17 control cases, 18 focal segmental glomerulosclerosis (FSGS) and 22 immune complex mediated glomerulopathy (ICMGN). The second study consisted of 30 unremarkable control kidney sections (removed for renal tumors), 30 transplant cases with Sirolimus treatment (Siro), 59 cases with both Sirolimus and Cyclosporine therapy (Siro+Cyclo) and 39 transplant cases with only cyclosporine treatment (Cyclo). All sections were stained for p-mTOR, p-p70S6K and p-4EBP. Nuclear staining was assessed and categorized into four grades: 0 - 3+ based on intensity of staining in proximal tubules (PT), glomerular parietal epithelium (PE) and visceral epithelium (VE).

Results: In the first study, nephrotic range of proteinuria was found in FSGS and IMCMG groups. In the second study, proteinuria was significantly higher in Siro and Siro+Cyclo groups than Cyclo group. In both native and transplant biopsies, study groups all showed 1- 2 fold higher staining for all 3 markers in PT, PE and VE when compared to controls. In both studies, proteinuria was not associated with expression of any marker in any location but the proteinuria was significantly associated with interstitial fibrosis in the transplant study. Expression of p-70S6K in proximal tubules was significantly related to either serum creatinine (native study) or acute cellular rejection (transplant study).

Conclusions: Our data demonstrated a low activity of mTOR pathway in PT, PE and VE in control kidneys. The extent of proteinuria was not significantly associated glomerular expression of the mTOR pathway activity in both native and transplant studies, as activated mTOR pathway in glomerular epithelium appeared related to the high mTOR pathway activity in the PT.

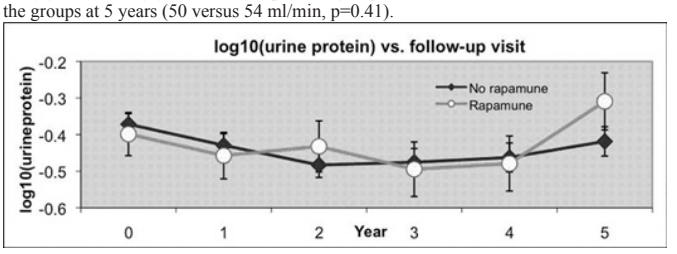
De Novo Rapamune Use Is Not Associated with the Development of Proteinuria Allyson Hart,[1] Liangxing Zou,[2] James Hodges,[2] Hassan N. Ibrahim.[1] *[1]Medicine - Division of Renal Diseases and Hypertension, University of Minnesota, Minneapolis, MN; [2]Coordinating Center for Biometric Research - Biostatistics, University of Minnesota, Minneapolis, MN.*

Background: Rapamune has been associated with the development of proteinuria when used to replace calcineurin inhibitors for allograft dysfunction. The long-term effect of de novo Rapamune use on proteinuria is less well studied. We evaluated the effects of Rapamune use on proteinuria and GFR in kidney transplant recipients followed up for five years.

Methods: 153 kidney transplant recipients in the Angiotensin II Blockade for Chronic Allograft Nephropathy trial (NCT00067990) received Rapamune plus CNI (n=29) or Cellcept plus CNI (n=124). Iothalamate GFR and 24-hour urine albumin and protein were obtained at baseline and annually for 5 years. Statistical analyses used mixed linear models with a random effect for subjects and AR(1) errors within subject, and adjusted for age, sex, donor source, episodes of acute rejection, and systolic blood pressure.

Results: The Rapamune group was 44% female; mean age was 49 and 75% were live donor recipients. The non-Rapamune group did not differ with respect to sex, age, donor source, or systolic blood pressure at any follow-up time. GFR was higher at baseline in the Rapamune group (54 vs. 65 ml/min, p=0.002). At annual follow-up visits, GFR, proteinuria, albuminuria, and systolic blood pressure did not differ between Rapamune and non-Rapamune groups. At 5 years, adjusted mean urine protein in the Rapamune group was 0.5 g/g versus 0.4 g/g in the non-Rapamune group (P=0.21). GFR did not differ between the groups at 5 years (50 versus 54 ml/min, p=0.41).



Conclusions: De novo Rapamune use was not associated with increased proteinuria or a difference in measured GFR. The noted association of Rapamune with proteinuria may be due to the removal of the vasoconstrictive effects of CNIs.

Safety and Efficacy of Administering the Maximal Dose of Candesartan in Renal Transplant Recipients Noritaka Kawada,[1] Toshiki Moriyama,[2] Masayoshi Okumi,[3] Naotsugu Ichimaru,[3] Harumi Kitamura,[1] Jun-Ya Kaimori,[1] Norio Nonomura,[3] Shiro Takahara,[4] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Div. of Nephrol, Osaka Univ. Graduate School of Med., Suita, Osaka, Japan; [2]Health Care Center, Osaka university, Suita, Osaka, Japan; [3]Dep. of Urology, Osaka Univ. Graduate School of Med., Suita, Osaka, Japan; [4]Advanced Technology for Transplantation, Osaka Univ. Graduate School of Med., Suita, Osaka, Japan.*

Background: The regular dose of angiotensin II type-1 receptor blocker (ARB) used in renal transplant patients for hypertension is shown to be safe and effective. However, information on the appropriate dosing of ARB in renal transplant patients is limited. We evaluate the efficacy and safety of the maximal dose of candesartan administered to renal transplant patients.

Methods: Sixty-nine recipients were enrolled in this study. Patients were divided into three groups based on the basal dose of candesartan, patients not taking candesartan (Group A), taking low to medium dose candesartan (2-4mg/day; Group B), and taking high dose candesartan (8mg/day; Group C). During the course of the study, patients were treated with a gradual increase of candesartan to a final dose of 12 mg/day. Physiological and biochemical parameters were acquired before and after the twelve-month study period.

Results: Ninety-one percent of patients succeeded in continuing their administration of candesartan for one year and 75% tolerated the administration of the maximal dose of candesartan. Significant differences in proteinuria, albuminuria, serum creatinine, and eGFR level among the groups were detected. In group A, candesartan reduced systolic blood pressure, decreased the levels of proteinuria, albuminuria, eGFR, and hemoglobin and increased plasma potassium, creatinine level, and plasma renin activity.

Conclusions: Gradual increase of ARB to its maximal dose in renal transplant patients is safe when carefully monitored. We could demonstrate the impact of maximal RAS blockade on both proteinuria and albuminuria, which indicates the need for future, long-term randomized prospective trials to further establish the impact of maximal RAS blockade on renal and cardiovascular protection in transplant patients.

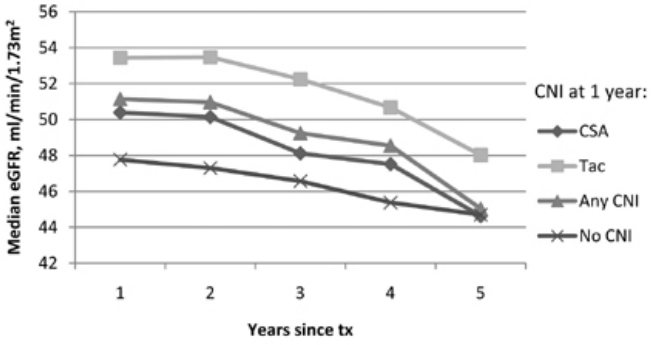
Estimated Glomerular Filtration Rate during Years 1 to 5 Post-Transplant by CNI Use, Data from the Patient Outcomes in Renal Transplant (PORT) International Data Collaboration Jon J. Snyder,[1] Melissa Skeans,[1] Ajay K. Israni,[1,2] Gilbert Litalien,[3] Bertram L. Kasiske.[1,2] *[1]Chronic Disease Research Group, Minneapolis, MN; [2]Hennepin County Medical Center, Minneapolis, MN; [3]Bristol-Myers Squibb, New Haven, CT.*

Background: Serum creatinine-based estimation of glomerular filtration rate (eGFR) is the standard marker for monitoring graft function. Monitoring changes in eGFR can aid clinicians in anticipating long-term prognoses.

Methods: We explored the association between MDRD eGFR during years 1 through 5 post-transplant and CNI use at 1 year post-transplant to see if differences were evident by CNI and would aid inference based on eGFR measurements. We studied 7,594 patients from 11 transplant centers in the Patient Outcomes in Renal Transplantation (PORT) international database transplanted 1999-2006 whose allografts survived 1 year post-transplant. Patients who returned to dialysis were assumed to have an eGFR of 0 from the time of graft failure until the earliest of death, loss-to-follow-up, or end of study.

Results: Use of any CNI at 1 year post transplant was reported for 88% of patients. Cyclosporine (CSA) was more common, reported in 56% of patients; Tacroliumus (Tac) was reported in 28% of patients. Median eGFR for was highest in Tac users at every post-transplant time point, from 53.5-48.0 ml/min/1.73 m2 in years 1 to 5 (Figure). Median eGFR in CSA users was 3-4 ml/min/1.73 m2 lower than in Tac users (p<0.001), and 3-6 ml/min/1.73 m2 lower in people in whom no CNI was reported (p<0.001). Median eGFR declined over time in all groups, regardless of CNI use or type of CNI.



Conclusions: In summary, median eGFR between years 1 and 5 post-transplant was highest in patients who were on Tac 12-months post-transplant; however, median eGFR declined over time in all groups.

SA-PO3110

Over Ten Years Kidney Graft Survival Determinants Anabela Malho, Jorge Malheiro, Isabel Fonseca, La Salete Martins, Sofia Pedroso, Manuela Almeida, Leonidio Dias, Antonio Andresen Henriques, António Manuel Nunes Cabrita. *Serviço de Nefrologia, Hospital Santo António, Porto, Portugal.*

Background: Kidney graft survival has been mainly evaluated using an up to 10-years threshold. Instead, in this study our aim was to evaluate predictive variables that impact long term kidney graft survival (≥10 years).

Methods: We analyzed data from 996 kidney transplants performed between 1983 and the end of June 2000. Inclusion criteria: graft survival > 3 months and patient survival > 1 year post-transplant (PT). Exclusion criteria: simultaneous multiple grafts recipients. We enrolled 892 patients in our analysis: 638 patients with functioning graft at 10-years PT and 254 patients with graft failure at 10-years PT (considering patient death with a functioning graft <10 years PT as graft failure). Between groups comparisons were done using Mann-Whitney and chi-square test. To determine independent predictive variables for long-term graft survival a multivariate-adjusted logistic regression was performed.

Results: Patients with long-term graft survival had significant lower donor age, 12-month PT creatinine, HLA-B mismatches, panel of reactive antibodies (PRA) level (<30%) and number of transfusions (<3); higher frequency of immediate graft function, absence of acute rejections (AR) episodes, positive CMV IgG and induction with anti-thymocyte immunoglobulin (ATG). Significant predictors of long term graft survival were 12-month PT creatinine (OR=0.26, P<0.001), donor age (OR=0.98, P=0.004), time on dialysis (OR=0.93, P=0.044), recipient positive CMV IgG (OR=1.59, P=0.040), absence of AR episodes (OR=1.57, P=0.047), 0 to 1 HLA-B mismatch (OR=1.80, P=0.004) and recipients male gender (OR=1.84, P=0.005). Recipients age at transplant, number of transfusions (< vs ≥ 3), PRA level (< vs ≥ 30%), immediate graft function and induction with ATG were not significant predictors.

Conclusions: Recipient gender, IgG CMV status, dialysis vintage, absence of AR episodes, lower number of HLA-B mismatches and donor age were all significant predictors, while a lower 12-month PT creatinine remained the stronger determinant for long term kidney graft survival.

SA-PO3111

Favorable Effect of Systemic Insulin Delivery on Lipid Profiles in Simultaneous Kidney Pancreas Transplantation George A. Osuchukwu,[1] Ijeoma C. Nwelue,[1] Bruns A. Watts,[1] Tina Kochar,[1] Horacio E. Adrogue.[2] *[1]Department of Nephrology and Hypertension, University of Texas Medical Branch, Galveston, TX; [2]Methodist J.C Walter Jr Transplant Center, Department of Internal Medicine Methodist Hospital, Houston, TX.*

Background: Simultaneous kidney pancreas transplant (SPK-t) is the treatment of choice for carefully selected patients with diabetes mellitus and end stage renal disease. Due to the ease of the surgery a systemic delivery of the exocrine drainage is favored. Systemic insulin delivery in SPK-t has been demonstrated to lead to hyperinsulinism. Hyperinsulinism and insulin resistance in other populations are associated with an unfavourable lipid profile, one factor in their overall cardiovascular risk profile. Here we examine the effect of a systemic delivery of insulin on lipid profile in SPK-t patients.

Methods: Fasting glucose, insulin, c-peptide and lipid profile levels were obtained from 27 (SPK-t) patients with systemic exocrine drainage during routine post transplantation follow up. Homeostasis model of Assessment 2 calculations were used to estimate the beta cell secretory capacity HOMA-B, insulin resistance HOMA-IR and insulin sensitivity HOMA-S. The Fasting lipid profile of SPK-t patients was compared to 53 age, sex and immunosupresion protocol matched nondiabetic kidney transplant (K-t) patients using the unpaired student's t-test.

Results: HOMA scores for the SPK-t group were (mean ± SD): HOMA-B 203 ± 54, HOMA-IR 2.5 ± 1.2 and HOMA-S 48.8 ± 21. These results suggest hyperinsulinism, insulin resistance and an increased beta cell mass, which are consistent with previous studies. The SPK-t group had a lower total cholesterol (155 ± 31 SPK-t vs 183 ± 36 K-t; p< 0.0001), lower LDL (89.3 ± 27 vs. 105.5 ± 30.4 ; p<0.01) and a higher HDL (50.6 ± 10.7 vs. 40.6 ± 10.2 ; p<0.01) levels than the K-t group, indicating a more favorable lipid profile in SPK-t than in K-t.

Conclusions: Previous studies have shown that Systemic delivery of insulin is associated with hyperinsulinism and insulin resistance in SPK –t. Our findings show that this type of hyperinsulinism, due to a systemic delivery of insulin in SPK-t patients is associated with a significantly more favorable lipid profile.

SA-PO3112

Anemia in Adult Renal Allograft Recipients: Prevalence and Predictors Jorge Malheiro, La Salete Martins, Isabel Fonseca, Manuela Almeida, Josefina Santos Lascasas, Antonio Andresen Henriques, António Manuel Nunes Cabrita. *Nephrology Unit, CH Porto, Porto, Portugal.*

Background: Posttransplantation anemia (PTA) is multifactorial. Besides being associated with kidney dysfunction, other factors play a role, namely immunosuppressant regimens (IsR). Our purpose was to investigate an adult kidney graft recipient's population to elucidate the prevalence of PTA and its predictors.

Methods: Clinical data recorded throughout 2010 of adult kidney graft recipients with > 1-year postengraftment and no use of erythropoiesis stimulating agents was randomly selected from our unit, weighted for gender, age and time since transplantation (TsT). We aimed to examine clinical characteristics of the enrolled population and determine the prevalence of PTA. Multivariate adjusted linear regression was undertaken to detect hemoglobin (Hb) predictors: age, gender, estimated glomerular filtration rate (eGFR) by MDRD equation, log-body mass index (BMI), diabetic status, log-ferritin, log-transferrin saturation and serum albumin, mycophenolate mofetil (MMF), azathioprine (AZA), calcineurin inhibitor (CNI) and angiotensin converting enzyme inhibitors (ACEI) use. WHO anemia criteria were employed.

Results: A total of 302 (119 females) patients were studied with a mean age of 49.6±13.4 years, a median TsT of 7.6 years and a mean eGFR of 51.9±18.5 ml/min. The prevalence of anemia was 39.4% with a mean Hb of 13.2±1.6 g/dl. CNI was used in 97.7% and 77.8% took prednisolone (all with ≤10 mg). The most common IsR were CNI plus MMF (73.5%), CNI plus AZA (10.6%) and CNI alone (11.9%). No significant difference in Hb was found between these regimens. Multivariate adjusted linear regression (R^2=0.41) showed as significant predictors of lower Hb: female gender (*P*<0.001); lower eGFR (*P*<0.001), log-BMI (*P*=0.01), albumin (*P*= 0.02), log-transferrin saturation (*P*=0.01); higher log-ferritin (*P*=0.03); MMF (*P*=0.002) and ACEI (*P*=0.01) use.

Conclusions: Prevalence of PTA was high. Expectable demographical (gender) and clinical (eGFR) variables were strong predictors of Hb. Inflammation markers (lower albumin, higher ferritin) and drugs with reported negative effect in erythropoiesis (MMF and ACEI) were also associated with lower Hb.

SA-PO3113

Undiagnosed Glucose Metabolism Disorders in Dialysis Patients: An Analysis Using Oral Glucose Tolerance Tests in German Dialysis Centers Bernhard K. Krämer,[1] Bernhard Banas,[2] Miriam C. Banas,[2] Bernd Krüger.[1] *[1]Medizinische Klinik V, Mannheim University Hospital, Mannheim, Germany; [2]Nephrology, Regensburg University Hospital, Regensburg, Germany.*

Background: Post-transplant diabetes mellitus (PTDM) or new-onset diabetes mellitus (NODM) after renal transplantation is considered a major health threat for renal transplant recipients, that goes along with decreased patient and graft survival.

Methods: Screening for undiagnosed diabetes mellitus was done with the use of oral glucose tolerance test (oGTT) in 4 dialysis centers in Germany according to ADA criteria. Impaired glucose metabolism disorders were defined as a fasting glucose level ≥ 100 - 125 mg/dL (impaired fasting Glucose IFG) and/or a 2 h glucose level 140-199 mg/dL (impaired glucose tolerance IGT). Overt diabetes mellitus was defined as a fasting glucose level ≥ 126 mg/dL and/or a 2 h glucose level ≥ 200 mg/dL.

Results: 237 adult hemodialysis patients were considered for inclusion in this trial. 91 patients (=38.4%), that were known to be diabetic were excluded from the trial leaving 146 non-diabetics. Since oGTT was not performed in 40 of these nondiabetics due to refusal to participate or inability to give informed consent or to participate or nonadherence, 106 patients underwent oGTT. From these 106 patients, 12.3% had an abnormal fasting glucose (≥ 100 and < 126 mg/dL), 18.9% had an impaired glucose tolerance (2 h glucose level ≥ 140 and < 200 mg/dL), and 9.4% had overt diabetes mellitus.

Conclusions: There is a considerable number of undiagnosed glucose metabolism disorders including overt diabetes mellitus in German hemodialysis patients. These patients may (eronneously) be classified as PTDM or NODM after renal transplantation.

SA-PO3114

Risk Factors for Vitamin D Deficiency Post Transplant and Role in PTH Regulation Temitope Ojo,[1] Priyanka Jain,[1] Carmen Castaneda-Sceppa,[2] Vaidyanathapura S. Balakrishnan,[1] Madhumathi Rao.[1] *[1]Nephrology, Tufts Medical Center, Boston, MA; [2]Health Sciences, Northeastern University, Boston, MA.*

Background: 25-OH Vitamin D (VitD) deficiency is common in kidney transplant (KTX) recipients, secondary to insufficient intake and sun exposure, and increased catabolism by medications and FGF-23 hypersecretion. We examined risk factors for VitD deficiency and its association with PTH levels post-transplant.

Methods: In 106 clinically stable KTX recipients enrolled between 6 months and 5 years from transplant,VitD levels were measured by liquid chromatography and tandem mass spectroscopy.Intact PTH in serum was measured by non-competitive chemiluminescent immunoassay and intact FGF-23in plasma by ELISA (Immutopics, San Clemente, CA).

Results: The mean (SD) age was 47(11) years, 63% were male and 12% African American; 54% had CKD stage 1T and 2T, 41% stage 3T and 5% stage 4T; 62% had low VitD levels, 73% had hypophosphatemia, and 66% had elevated PTH levels. VitD levels were lower in African American subjects and within the first year from transplant; higher levels were seen after pre-emptive transplantation, and subjects with lower eGFR and using of VitD supplements. A significant inverse correlation was seen between PTH and VitD levels (r=-0.31; p=0.001). Indeed, PTH levels did not vary with eGFR or serum calcium, suggesting impaired normal feedback regulation. Median (95% CI) PTH levels were higher by 0.85(0.74-0.98) pg/mL for a 10ng/mL lower VitD level (p=0.04). Higher PTH levels were associated with longer duration on dialysis pre-transplant (mean, 95%CI: 56, 39-81 pg/mL among pre-emptive transplant, 85, 61-119 pg/mL with up to 3 years of dialysis, and 145, 106-199 pg/mL with > 3 years of dialysis pre-transplant; p<0.001). VitD supplementation was used in 62% of the study population; however, 45% of individuals with low VitD were not receiving supplementation.

Conclusions: In summary, low VitD levels are common after transplantation, likely secondary to depletion while on dialysis and could potentially play a role in PTH elevation after transplant. Pre-transplant repletion may be a relevant therapeutic option for post-transplant mineral bone disorder.

SA-PO3115

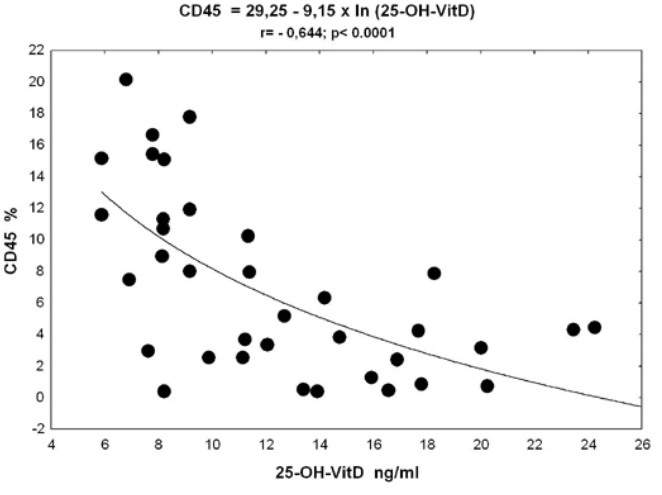
Mineral Metabolism, Parenchymal Calcification and Inflammatory Indices in Kidney Transplant Biopsies Ofelia Jercan, Carlo Maria Alfieri, Donata Cresseri, Gabriella Moroni, Maria Teresa Gandolfo, Maria Daniela Croci, Maria Pia Rastaldi, Piergiorgio Messa. *Nephrology and Dialysis, IRCCS Fondazione Ca' Granda Ospedale Policlinico, Milan, Italy.*

Background: Some studies suggested that parenchymal calcifications (PC), inflammation (I), epithelial-mesenchymal transition (EMT) and fibrosis (F) might contribute to chronic graft dysfunction in transplanted kidneys (KTx). A role for mineral metabolism (MM) derangement in these pathologic changes has been suggested. The aims of our study were to evaluate: a) the relationships between MM and PC, I, EMT and F indices in KTx biopsies (Bx) ; b) their possible relationship with graft outcome.

Methods: In the Bx of 87 KTx pts (46 M; aged 48 ±12 yrs), stainings for leukocytes (CD45: I marker), vimentin (EMT marker), alizarin red (PC marker), and Sirius red (F marker) were quantitatively evaluated by electronic image analysis on 20 low power fields (% of the total area). PC was estimated as present (+) or absent (-). MM (PTH, Ca, phosphate), biochemical and clinical parameters were recorded at Bx and 1 year after Bx. 25-(OH)-VitD levels were assessed in 35 patients.

Results: In the 76% of PC+ Bx, I and EMT markers were lower than in PC- (4.8±6.54 vs 8.6±7.3 % p=0.03; 7.75±5.1 vs 10.5±6.09 p=0.05, resp). MM parameters were not related with either PC or any other marker.

I and EMT were negatively related with MDRD (p=0.007, p=0.01 respectively). A neg correlation was found between 25OH-VitD and both I (p=0.0002)[figure 1] and EMT (p=0.01), but not with MDRD.



In the 14 patients restarting dialysis during the follow-up, I (12.91±7.9 vs 7.0±6.8 % p=0.004) and EMT were significantly higher(12.6±7.0 vs 9.3±5.6 % p=0.05).

Conclusions: Our results suggest: a) CD45 and Vimentin as good prognostic markers of graft outcome; b) no major effects of MM parameters on injury markers, apart from a possible protective role for VitD status.

SA-PO3116

Correlates of FGF23 Levels in a Population of Stable Kidney Transplant Recipients with Hypovitaminosis D and Hyperparathyroidism Mariana S. Markell, Sima Terebelo. *Medicine, SUNY Downstate Medical Center, Brooklyn, NY.*

Background: FGF-23 interacts with Vitamin D and parathyroid metabolism in a complex fashion that has not been fully delineated, resulting in conflicting results when patients with CKD are studied. FGF23 is elevated early post-transplant but has not been carefully studied at longer time periods.

Methods: 41 stable kidney transplant recipients (KTRs) with hyperparathyroidism and hypovitaminosis D were studied. Patients were not receiving supplementation with any form of vitamin D. Full length FGF23 was measured by ELISA.

Results: The population included 22 men (51%), 34 Blacks (83%), mean age 49.2±13.5; 55.5±47 months since last transplant, creatinine 1.5±0.4 mg/dl, phosphorus, 2.97±0.56, magnesium, 1.72±0.3, 25-OH Vit D 16.2±0.7, 1,25 (OH)2 vit D3, 49.1±18.2, PTH, 187±78.3, GFR by MDRD, 56.9±19.2 m;/min (range 21.7-103.4 ml/min). The mean FGF23 value was 103.6±64.8 pg/ml (range 33.8-388.6 pg/ml). 90% of the patients had FGF23 levels > 55 pg/ml. FGF-23 levels positively correlated with gender p=.039, r=.324, months since last transplant, r=.322, p=.045, BUN r=0.484, p=0.001, creatinine r=0.369, p=.017, serum phosphorus r=.428, p=.006, and serum magnesium r=.374, p=.016. FGF-23 levels correlated inversely with 1,25 vit D r=-.351, p=.026, and GFR by MDRD r= -.469, p=.002, although 1,25 Vit D levels did not correlate with GFR. By T-test Black pts had lower FGF23 values than Non-black, mean 94.3 pg/ml vs. 148.7 pg/ml, p=.042 although GFR by MDRD did not differ. There were no correlations between FGF-23 and age, tacrolimus dosage or level, prednisone daily dose, diuretic use, BP, calcium level, 25-OH vitamin D level, or PTH.

Conclusions: 1) FGF23 maintains an inverse relationship with 1,25 Vitamin D in the pts with Vitamin D deficiency despite elevated PTH levels and abnormal kidney function, suggesting that FGF23 may be more important in regulating 1,25 Vit D than PTH in this setting . 2) Black pts have lower FGF23 levels than Non-Blacks despite similar GFR, 3) FGF23 maintains a strong correlation with gender, GFR by MDRD, PO4, Mg++ and time since transplant, but as these factors are interrelated, a larger population will be needed to examine independent relationships.

SA-PO3117

Serum Adipokines and Coronary Artery Calcification in Renal Transplant Recipients with Metabolic Syndrome Kuo-Hsiung Shu,[1,4] I-Chen Tsai,[2] Hao-Chung Ho,[3] Chi-Hung Cheng,[1,4] Ming-Ju Wu,[1,4] Cheng-Hsu Chen,[1] Tung-Min Yu,[1] Ya-Wen Chuang,[1] Shih-Tin Huang.[1] *[1]Div. of Nephrology, Dept. of Medicine, Taichung Veterans General Hospital, Taichung, Taiwan; [2]Radiology, Taichung Veterans General Hospital, Taichung, Taiwan; [3]Div. of Urology, Dept. of Surgery, Taichung Veterans General Hospital, Taichung, Taiwan; [4]School of Medicine, Chung-Shan Medical University, Taichung, Taiwan.*

Background: Renal transplant (RTX) recipients are associated with several metabolic disorders, of which metabolic syndrome (MetS) is relatively common. The current study aims at elucidation of the alterations of adipokines in RTX patients with MetS.

Methods: A cross-sectional study was carried out in our prevalent RTX patients. A modified Asian version of the ATP III criteria was adopted for the definition of MetS, in which the abdominal obesity was defined as a waist circumference >90 cm for male and >80 cm for female. Fasting blood samples were obtained for adiponectin, leptin and resistin by using commercial available ELISA kits. A multidetector computed tomography was performed to access coronary artery calcium score (CACS).

Results: A total of 271 RTX patients (male:female=133:138) were enrolled for the study. MetS was diagnosed in 72 (26.6%). MetS patients tend to be older (54.8±9.6 vs 51.4±13.4, p=0.055), had higher body mass index (26.1±3.9 vs 27.4±51.0, p<0.0001), serum creatinine (1.61±0.74 vs 1.41±0.55 mg/dl, p=0.009), hemoglobin A1c (6.84±1.44 vs 6.03±4.38% p<0.0001), CACS (848.9±1224.9 vs 286.4±720.7, p=0.016) and number of antihypertensive agents used (1.69±0.97 vs 0.82±1.02, p<0.0001). There was no significant difference in terms of gender, age and drugs used for immunosuppression. MetS patients had significantly lower serum adiponectin level (21.8±13.9 vs 28.7±18.7 mg/ml, p=0.002), higher leptin level (29.6±24.3 vs 15.5±20.0 ng/ml, p<0.0001) but comparable resistin level (2.6±1.7 vs 2.6±2.1 ng/ml, p=0.364).

Conclusions: RTX recipients with MetS were associated with alterations of adipokines that favor the development of atherosclerosis. Together with the finding of a significantly higher CACS, these patients are at high risk of acquiring coronary artery disease.

Value of Adenosine Stress Cardiac Magnetic Resonance Imaging for Coronary Artery Disease Screening before Renal Transplantation Francois Glowacki,[1] Alexandra Botte,[1] Sébastien Homs,[1] Marco Midulla,[2] Christian Noël,[1] Jean-Paul Beregi.[2, 3] *[1]Nephrology, University Hospital, Lille, France; [2]Radiology, University Hospital, Lille, France; [3]Radiology, University Hospital, Nimes, France.*

Background: Coronary heart disease remains a major cause of morbidity and mortality after renal transplantation, also some practice guidelines recommend to evaluate ischemic heart disease before renal transplantation. We studied cardiac stress-magnetic resonance imaging (MRI) in this indication.

Methods: Candidates for kidney transplantation with risk factors for coronary disease underwent a cardiac stress-MRI scan (injection of gadoterate and coronary stress induced by adenosine). When the MRI scan revealed positive results, a coronary angiography was carried out. The incidence of major cardiovascular events and gadoterate toxicity were recorded during follow-up.

Results: Since January 2008, 114 patients have undergone a cardiac stress-MRI scan. These patients had an average of 2.7±1.4 cardiovascular risk factors (age 55.6±10.4 years, diabetes: 35.1 %). Coronary lesions were suspected on 22 MRI scans and confirmed in 85 % by systematic coronary angiography. Thus, we diagnosed 9.4% of coronary disease in patients with no previous history of coronary artery disease, leading to specific treatment. In the population, sensitivity of cardiac MRI was 89.5 % and specificity 62.5 %. During follow-up (1.67±0.7 years), 35 patients received a kidney transplant and 5 patients had a major cardiac event. Negative predictive value of cardiac MRI for major coronary events is 96.7 %. No patient developed nephrogenic systemic fibrosis.

Conclusions: With its high negative predictive value, stress-cardiac MRI appears to be a valuable tool for excluding ischemic heart disease before kidney transplantation.

Risks of Death and Graft Failure Following Percutaneous Compared with Surgical Coronary Revascularization in Renal Transplant Patients David M. Charytan,[1] Yang Qiu,[2] Shuling Li,[2] Charles A. Herzog.[2] *[1]Medicine, Brigham and Women's Hospital, Boston, MA; [2]CVSSC, USRDS, Minneapolis, MN.*

Background: Surgical (CABG) or percutaneous (PCI) intervention may precipitate graft failure (GF) in patients with renal transplants, but reliable data on the absolute and relative risks of death and GF following PCI and CABG are unavailable.

Methods: Renal transplant patients undergoing PCI (3,531) or CABG (1,003) were identified using the USRDS. Comorbidity adjusted Cox models were used to assess the risks of death and non-fatal GF.

Results: Age race and sex were similarly distributed in the PCI and CABG groups. In the PCI group, 36% received bare metal stents, 36% received drug eluting stents, and 17% had intervention on ≥ 2 vessels. Internal mammary grafts were used in 84% of CABG patients, 95% had ≥2 vessels bypassed, and 83% had on-pump procedures. In-hospital death (2.3% vs. 5.3%) was more frequent after CABG. Overall survival was non-significantly lower with CABG (HR 1.14, P=0.05) in crude models [figure 1], but revascularization type was not associated with overall survival after adjustment for comorbidities (HR 0.89, P=0.12). At 3 years, freedom from non-fatal GF was lower with CABG vs. PCI (83% vs. 85%). However, the difference in non-fatal GF did not achieve significance in crude (P=0.09) or adjusted models (P=0.72). The risk of GF was not different following off-pump vs. on-pump CABG (HR 0.78, P=0.34).

Conclusions: CABG does not appear to be associated with improved survival compared with PCI in the renal transplant population. Non-fatal GF occurs more frequently following CABG, but the risk of non-fatal GF is similar with both PCI vs. CABG and off-pump vs. on-pump CABG following adjustment for baseline comorbidity.

Renal Cell Carcinoma in Allograft Kidneys: Use of Short Tandem Repeat Analysis To Determine Donor Origin of Cancer Kumarpal C. Shrishrimal, Eric P. Cohen, Ehab R. Saad, Lauren N. Parsons, Min Le, Alexander C. Mackinnon. *Medical College of Wisconsin.*

Background: Kidney transplant recipients have a high risk for renal cell carcinoma (RCC) in their native kidneys. We describe 3 cases of RCC in allograft kidneys. Short tandem repeat (STR) DNA was used to determine donor origin of the RCC.

Methods: RCC tissue was obtained in all cases. Donor DNA was obtained from cancer-free regions of the kidney (cases 1 and 2); Donor DNA was not available for case 3. Host DNA was obtained from fresh leukocytes (cases 1 and 3) or a non-cancerous lymph node (case 2). Penta C and Penta D genotypes were determined using GeneMapper.

Renal Cell Carcinoma in Allograft Kidneys

Case	Age at Transplant (years)	Time to cancer (years)	Histology of RCC	RCC recurrence
1	31	15	Clear Cell	None
2	54	8	Clear Cell	None
3	16	19	Clear Cell & Papillary	6 years with metastases

Results: Penta C and Penta D alleles were robustly amplified in all samples. Each case had two or more informative Penta C or Penta D alleles. In the two cases with donor DNA samples (cases 1 and 2), the Penta C and Penta D alleles from the cancer exactly matched the Penta C and Penta D alleles derived from the uninvolved donor kidney. Furthermore, one or more Penta C or Penta D alleles from the host were absent from the cancer. This shows that the cancer DNA is donor-derived, being genetically identical to the donor DNA. In case 3 donor DNA was not available for analysis, so cancer and host alleles were compared. In this instance, none of the Penta D alleles matched in the two specimens, and each specimen had a unique Penta C allele indicating that the cancer is genetically distinct from the host.

Conclusions: Determination of tumor cell origin is potentially significant for treating metastatic cancers, as in case 3. Reduction of immunosuppression may cause cancer rejection for cancers derived from the donor. But host derived cancers would not respond to reduction of immunosuppression. The Penta C and Penta D method is informative of sample identity over 99% of the time. Our data show that STR analysis is a simple strategy to determine donor versus recipient origin of cancers in kidney transplant patients.

SA-PO3121

Clinical Features and Outcomes of Tuberculosis among Kidney Tranplant Recipients in Brazil: A Report of the Last Decade Igor Marques,[1] Renato Antunes Caires,[2] Victor Sato,[2] Lilian P.F. Carmo,[1] Gustavo Ferreira,[1] Ligia C. Pierrotti.[1] *[1]Renal Transplant Service, University of Sao Paulo School of Medicine, SP, Brazil; [2]Nephrology Division, University of Sao Paulo School of Medicine, SP, Brazil.*

Background: It is necessary to clarify the incidence of tuberculosis (TB) among kidney transplant recipients (KTR) as well as changes in the chronology, clinical presentation and prognosis of the disease, especially in highly endemic areas, in order to develop prophylaxis strategies.

Methods: Retrospective single-center observational study involving all cases of TB that occurred in KTR between 2000 and 2010 confirmed by culture, isolation of *M. tuberculosis* DNA by polymerase chain reaction or histopathology, according to WHO criteria.

Results: Among the 1549 kidney transplantations performed during the study period, 43 (2.8%) developed TB, with an incidence of 803 cases per 10^5 patients per year, which was very higher than in general population in Brazil (45 cases per 10^5 inhabitants per year; RR 17.8). Of the TB cases, 84% occurred within the first 2 years posttransplant, and 72% were pulmonary forms. Previous TB infection was present in 3 (7%) patients. No chemoprophylaxis was applied. The most common symptoms were fever (79%), cough (35%) and dyspnea (16%). Time elapsed from the onset of symptoms to the start of treatment was 28 days (range, 2 - 138 days). Median length of antituberculous therapy was 196 days. Immunosuppressive therapy was reduced in 15 (35%) patients and incidence of acute rejection was higher in TB than in non-TB group (44% vs. 28%, p=0.03, respectively). Crude mortality was 14%, and attributable mortality was 12%. Ten year death-censored graft survival (44.3% vs. 56.3%, p=0.64) and patient survival (69.1% vs. 72.4%, p=0.67) were similar between TB and non-TB groups, respectively.

Conclusions: Kidney transplantation increases the risk of TB. Symptoms of infection are often attenuated, leading to delayed diagnosis. TB-attributable mortality is still high. Clinicians should consider chemoprophylaxis for high risk patients, as the residents of endemic areas. However, randomized controlled trials are needed to confirm the benefits of such approach.

SA-PO3122

The Effect of Interferon Therapy on HLA Alloantibodies in Waitlisted Patients with Hepatitis C Infection Yasmin G. Brahmbhatt, Bernd Schroppel, Michele Witlieb, Vinay Nair. *Kidney Transplantation, Mount Sinai Medical Center, NY, NY.*

Background: Interferon (IFN) therapy is recommended for dialysis patients with chronic hepatitis C (HCV) awaiting kidney transplantation. IFN is known to cause autoimmunity and increase alloimmunity. We aimed to examine the effect of IFN on HLA antibodies (Ab) in waitlisted chronic HCV patients.

Methods: All current kidney waitlisted patients and patients that received a kidney transplant from 1/2008 to 1/2011 were screened for HCV serostatus. Patients with a positive HCV pcr and pre-existing HLA antibodies determined by Luminex single antigen (LSA) beads were considered for study. Patients without LSA testing 3 months to 12 months apart were excluded. We identified 2 groups of patient, those treated with IFN (treatment group) and those not treated (control group) in-between LSA testing. Antibody strength (Ab) was quantified by mean fluorescence intensity (MFI). We used a threshold of 10,000 MFI to determine cPRA

Results: We identified 7 patients who were treated with IFN and 23 patients who were not IFN treated that had 2 sets of LSA testing. In the treatment group 3 patients had a prior kidney transplant of which 1 had the graft present at time of IFN. In the control group, 3 patients had a prior transplant of which 2 had the graft present at the time of LSA testing.

43% (3/7) IFN treated patients and 26% (6/23) of patients in the control group had a significant rise in median MFI (p= 0.64, Fishers exact test). The median change in MFI was 239 (IQR -377 to 2053) in the IFN group and 4 (IQR -3226 to 940) in the control group. The change in Ab strength was not significantly different between groups (p=0.14, Mann-Whitney test). Class I and class II Ab strength was not significantly different between groups. The median cPRA (MFI >10,000) was 94% (range 0-100) in the IFN group and did not change after IFN therapy (median cPRA 94% pre-IFN vs. 94% post-IFN).

Conclusions: Compared to a matched control group IFN did not change the strength or breadth of preexisting HLA antibodies. Our data suggests that the decision to treat chronic HCV with IFN should not be altered out of concern for increasing sensitization in kidney transplant waitlisted patients.

SA-PO3123

Tacrolimus Percent Coefficient of Variation as a Superior Marker of Late Acute Rejection Associated with Nonadherence in Adolescent Renal Transplant Recipients Hilda E. Fernandez, Robert B. Ettenger, Eileen W. Tsai. *Pediatric Nephrology, UCLA, Los Angeles, CA.*

Background: We have previously shown that tacrolimus (TAC) percent coefficient of variation (CV%) is a superior marker compared to TAC standard deviation (SD) for detecting the likelihood of acute rejection (rej) associated with medication nonadherence (NA) in pediatric renal transplantation (Tx). We aimed to identify a significant threshold and time interval for which TAC CV% is predictive of late acute rej associated with NA in adolescents.

Methods: TAC SD and CV% were measured in 31 adolescents (ages 11-21) who underwent Tx from 2004 - 2008. Patients were maintained on immunosuppression with TAC and MMF ± steroids. All rej was confirmed by biopsy (Bx). Bxs were classified by Banff 2007 criteria. SD and CV% was calculated from trough TAC levels over various time intervals post-Tx. Receiver operator curve (ROC) analysis was used to analyze TAC CV% values.

Results: We found that the significant time interval for TAC CV% measurement was 6 mos prior to the first rej or, in non-rejectors, 6 mos prior to the last clinic follow-up. TAC CV% was higher in rejectors vs. non-rejectors (58.2% vs. 26.9%, p = 0.021).

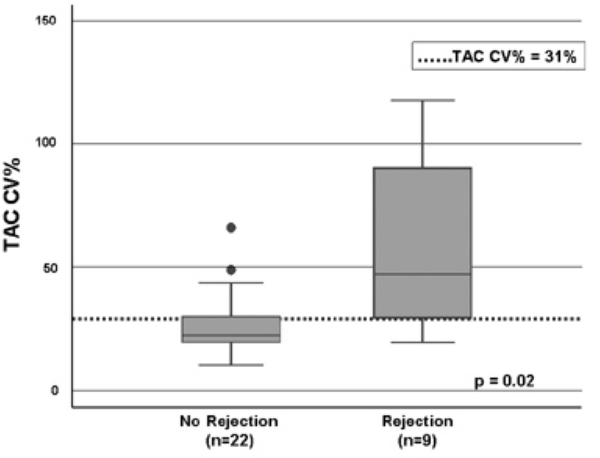

Figure 1: TAC CV% by rejection status 6 months prior to last clinical follow-up or biopsy-proven rejection.

The mean TAC SD was not different (2.52 vs. 1.79, p = 0.098). Using ROC analysis with an AUC of 0.77, TAC CV% > 31% had an OR=6.8 (p=0.04).

Conclusions: TAC CV% is superior to TAC SD in detecting late acute rej 6 months prior to allograft rej. This is the first time that a clinically relevant TAC CV% of > 31% has been demonstrated to be associated with an increased risk of allograft rej. Frequent monitoring with TAC CV% for adolescents may decrease acute rej due to medication NA in adolescent Tx recipients.

Cardio-Renal Interaction in Living Kidney Donors: Correlation between Glomerulosclerosis in 0-Hour Biopsy and Left Ventricular Mass Index (LVMI) Naoki Haruyama,[1] Akihiro Tsuchimoto,[1] Toshiaki Nakano,[1] Masatomo Taniguchi,[1] Hidehisa Kitada,[2] Kazuhiko Tsuruya,[1] Takanari Kitazono.[1] *[1]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Department of Surgery and Oncology, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

Background: Although living kidney donors are almost normal healthy individuals, the "0-hour" biopsy from them often reveal glomerulosclerosis (GS) to various degrees. Recently, cardiorenal interaction has been a major clinical implication and it is well known about high prevalence of left ventricular hypertrophy (LVH) in CKD patients. However, this interaction in the subjects with GS despite normal kidney function has not been previously reported.

Methods: We examined the association between the proportion of GS (%GS) in the 0-hour biopsy and LVMI determined by the echocardiogram before surgery. In the 206 subjects who donated a kidney in our hospital from March 2006 to May 2011, 50 donors were excluded because of lack of clinical data or inadequate kidney samples (less than 10 glomeruli). We divided the remaining 156 donors into the three groups according to %GS; the subjects without GS (Group I, n=41), the subjects with %GS of 0.1~9.9% (Group II, n=58), and the subjects with %GS above 10% (Group III, n=57). We compared baseline characteristics and LVMI among the groups. Moreover, we investigated correlation between %GS and LVMI by multivariate analysis. Data are expressed as mean ± SD.

Results: LVMI in Group III was significantly higher than those in the other two groups (80 ± 3, 81 ± 3, and 91 ± 3 g/m^2 in Group I, II, and III, respectively; $p < 0.05$). The multivariate linear regression analysis showed that %GS was significantly associated with LVMI even after adjusting for the other confounders like age, renal function, and hypertension (standardized $\beta = 0.16$, $p < 0.05$).

Conclusions: In the present study, the association between GS and LVMI was observed in the living kidney donors. This association was independent of blood pressure, renal function and age, suggesting that cardio-renal interaction might exist even before renal function declines.

SA-PO3125

Expression of FGF23/KLOTHO System in Human Vascular Tissue Javier Donate,[3] Mercedes Muros,[2] Carmen Mora,[2] Violeta Cazaña,[2] Javier García-Pérez,[1] Rafael Martinez Sanz,[4] Juan F. Navarro Gonzalez.[1,2] *[1]Nephrology, University Hospital Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain; [2]Clinical Biochemistry, University Hospital Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain; [3]Research Unit, University Hospital Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain; [4]Cardiac Surgery, Hospital Universitario de Canarias, La Laguna, Spain.*

Background: Fibroblast growth factor (FGF)-23 levels have been independently associated with impaired vasoreactivity and increased arterial stiffness, as well as cardiovascular events and mortality, whereas a protective function of KLOTHO against endothelial dysfunction has been reported, suggesting the potential participation of FGF23-KLOTHO axis in human vascular pathophysiology. Since expression of members of the FGF23-KLOTHO system in human vascular tissue remains unproved, we aimed to study the expression of FGF23, FGF receptors (FGFR) and KLOTHO in human aorta.

Methods: Thoracic aorta specimens from 44 patients with coronary artery disease who underwent elective coronary artery bypass surgery were tested for expression of FGF23-KLOTHO system, including FGF receptors.

Results: Expression of KLOTHO (mean expression level 4.85±5.43, arbitrary units) and two of the three cognate FGFR (FGFR-1 and -3) were detected and confirmed by RT-PCR, sequencing and qRT-PCR. However, expression of FGF23 and FGFR4 was not observed. We also detected the expression of membrane–anchored A Desintegrin and Metalloproteinases (ADAM)-17, the enzyme responsible for the shedding of KLOTHO from the cell surface, and the anti-inflammatory cytokine interleukin (IL)-10. Interestingly, there was a direct association between the KLOTHO mRNA expression levels and those of ADAM-17 and IL-10 (r=0.54, $P<0.001$; r=0.51, $P<0.01$, respectively).

Conclusions: Human vascular tissue expresses members of the FGF23-KLOTHO system, indicating that it can be a direct target organ for FGF23. These findings suggest a putative role of FGF23-KLOTHO axis in human vascular pathophysiology and cardiovascular disease.

SA-PO3126

Niacin Protects Against Renal but Aggravates Cardiac Damage in Rats with the Metabolic Syndrome Praveen N. Chander,[1] Youn-Jung Kang,[2] Charles T. Stier.[2] *[1]Pathology, New York Medical College, Valhalla, NY; [2]Pharmacology, New York Medical College, Valhalla, NY.*

Background: Studies were conducted to examine the end-organ protective effects of niacin in obese spontaneously hypertensive rats (SHROB/cp); a model of the metabolic syndrome.

Methods: Animals were chronically treated with either a low dose (1% in chow; n=5) or a high dose (5% in chow; n=5) of niacin starting at 7.14 weeks of age. SHROB/cp (n=9) and lean hypertensive control animals (SHROB/Kol) received Purina 5008 chow to which no niacin was added. Urinary protein excretion and pretermial systolic blood pressure (SBP) were measured and the animals sacrificed at 15 weeks of age. Hearts and kidneys were harvested for histology.

Results:

	SHROB/kol	SHROB/cp	SHROB/cp & Low Niacin	SHROB/cp & HighNiacin
SBP (mm Hg)	215±4	200±2**	185±4**††	193±4*
UPE (mg/day)	20±2	221±21**	158±25**†	48±12††
Insulin (ng/mL)	7.6±1.8	64.0±7.4**	60.9±3.5**	29.8±7.4*††♠♠
FSGS (%)	0.8±0.3	12.4±3.3**	6.9±1.4	1.3±0.4††
Cardiac infarcts (#)	0.9±0.4	17.9±3.3**	35.6±5.8**†	12.4±3.0*♠

*P<0.05, **P<0.01 v SHROB/kol; † P<0.05, †† P<0.01 v SHROB/cp; ♠ P<0.05, ♠♠ P<0.01 v SHROB/cp low niacin

SBP was slightly but significantly lower in SHROB/cp vs SHROB/Kol and was not affected by niacin treatment. Consistent with the metabolic syndrome, SHROB/cp showed hyperinsulinemia which was lowered by high dose but not low dose niacin. However, both dose levels of niacin significantly decreased urinary protein excretion and the degree of focal segmental glomerular sclerosis (FSGS) in SHROB/cp. Despite lower SBP in SHROB/cp, these animals had significantly more myocardial microinfarcts frequently undergoing organization. Additionally, there were hypereosinophillic myocardial fibers suggesting ongoing acute necrosis in a few animals. Unlike kidney damage, cardiac injury was not reduced by niacin treatment and, with low dose niacin, was instead significantly increased.

Conclusions: These results suggest that 1) cardiac and renal damage in SHROB/cp are independent of hypertension; the latter considered secondary to hyperperfusion injury of the metabolic syndrome and 2) niacin causes target-organ protection in the kidney, but may further aggravate cardiac injury.

Loss of TDAG51 Inhibits Vascular Medial Calcification Induced by High Doses of 1,25 Dihydroxycholecalciferol Imtisal Al-Bondokji, Jeffrey G. Dickhout, Alistair J. Ingram, Joan C. Krepinsky, Richard Austin. *Medicine, McMaster University, Hamilton, ON, Canada.*

Background: Vascular calcification (VC) is a progressive disorder that increases stiffening in the aorta and large capacitative arteries. This process is associated with uraemia produced by end stage renal disease (ESRD) and increases the cardiovascular morbidity and mortality in these patients. However, the underlying molecular mechanism of vascular calcification in uraemia remains unclear. We hypothesized that an imbalance between genes that promote and inhibit osteoblast differentiation drives this process. Thus, we tested the effects of T-cell death associated gene 51 (TDAG51), a novel osteoblast differentiation promoting gene, which modulates and induces smooth muscle cell calcification and differentiation to osteoblast-like cell phenotype.

Methods: We induced vascular medial calcification in mice by administration of super-physiological doses of 1,25 dihydroxycholecalciferol (Vitamin D_3). This VC model increases bone resorption leading to elevated plasma Ca^{2+} and PO_4 levels inducing genes that promote osteoblast differentiation and calcification. C57BL/6 and TDAG51 knockout male mice (8 weeks of age) were administered subcutaneous injection of Vitamin D_3 (50,000IU) for three consecutive days. Four days post-treatment, tissues were harvested for protein and mRNA analysis.

Results: Our results indicate C57BL/6 male mice receiving Vitamin D_3 had increased TDAG51 mRNA and protein levels in the aorta. TDAG51 knockout mice aorta and aortic smooth muscle cells (ASMC) have significantly less Ca^{2+} deposition/mg protein, reduced mineralization observed by von Kossa, xylenol orange staining and decreased alkaline phosphatase activity. Furthermore, peroxisome proliferator-activated receptor (PPAR) gamma mRNA and protein levels are up-regulated in TDAG51$^{-/-}$ ASMC, whereas osteoblast differentiation marker RUNX2/Cbfa1, Osterix, and phospho-SMAD 1/5 are down-regulated.

Conclusions: This data suggests, the loss of TDAG51 gene may confer resistance to smooth muscle calcification and differentiation to an osteoblast-like phenotype, thereby decreasing the risk of cardiovascular disease in ESRD.

SA-PO3128

The Interaction of Uraemic Toxins and Endothelial Progenitor Cells in the Progression of Cardiovascular Disease Shaundeep Sen,[1,2,3] Claudine Sharon Bonder,[1,3] Stephen P. McDonald.[1,2] *[1]Department of Medicine, University of Adelaide, Adelaide, South Australia, Australia; [2]Central & Northern Adelaide Renal & Transplantation Service, Royal Adelaide Hospital, Adelaide, South Australia, Australia; [3]Division of Human Immunology, Centre for Cancer Biology, SA Pathology, Adelaide, South Australia, Australia.*

Background: Bone marrow (BM) derived endothelial progenitor cells (EPC) have a role in both blood vessel formation and regulation of function. How EPCs are affected by uraemic toxins p-cresol (PC) and indoxyl sulfate (IS), and how this relates to cardiovascular disease (CVD) risk is not clear.

Methods: Peripheral blood (PB) concentrations of EPCs, IS and PC were measured in control (Cx), haemodialysis (HDx) and kidney transplant (KTx) subjects, and compared to markers of CVD. In vitro, functional assays were performed on cultured HUVEC and EPC in the setting of increasing physiological concentrations of PC and IS.

Results: PB EPC concentration (% of mononuclear cells, MNCs) was decreased in KTx (0.006±0.006%, 95%CI) and HDx (0.006±0.005) compared to Cx (0.03±0.02, n=9/group, $p<0.01$). Both PC sulfate (Cx 2.1±0.8mg/L, HDx 23.6±12.4, KTx 3.6±2.5) and IS (Cx 1.9±1.7mg/L, HDx 60±26, KTx 1.9±1.3) were increased in HDx ($p<0.001$). There was no association between EPC and toxin concentrations (p=ns). Low EPC counts were associated with history of CVD (p=0.002). Carotid intima medial thickness, aortic pulse wave velocity and augmentation index did not correlate with toxin or EPC concentration.

In vitro, PC inhibited tube-forming capacity of HUVEC (n=5, one-way ANOVA $p<0.01$), with no benefit of addition of EPC (n=5, p=ns). Increased IS concentration inhibited HUVEC tube formation (n=5, $p<0.05$), however EPC addition prevented IS reduction in HUVEC tubes (n=4, p=ns). No difference was seen in EPC migration with toxins. Vascular cell adhesion molecule-1 expression increased on HUVEC with increased PC/IS concentration ($p<0.05$), but with no effect of EPC addition.

Conclusions: EPC PB concentration does not correlate with toxin concentration, however reduced EPC function, as shown in vitro to PC and IS, may be more clinically relevant.

SA-PO3129

Effect of Different Vitamin D Receptor Activators on Left Ventricular Hypertrophy and Myocardial Fibrosis in Subtotal Nephrectomised Rats
Sara Panizo,[1] Sara Barrio-Vazquez,[1] Natalia Carrillo-Lopez,[1] Amalia Fernandez-Vazquez,[2] Socorro Braga,[3] Ana Rodriguez-Rebollar,[1] Manuel Naves,[1] Jorge B. Cannata-Andia.[1] *[1]Bone and Mineral Research Unit, Hospital Universitario Central de Asturias. Instituto Reina Sofía de Investigación. REDinREN del ISCIII. Universidad de Oviedo, Oviedo, Asturias, Spain; [2]Pathological Anatomy Unit, Centro Médico de Asturias, Oviedo, Asturias, Spain; [3]Biochemistry Unit, Hospital Universitario Central de Asturias, Oviedo, Asturias, Spain.*

Background: Observational data suggest that increased survival in CKD patients treated with vitamin D receptor activators (VDRAs) could be in part due to their positive cardiac effect. The aim of this study was to analyze the effect of different VDRAs on left ventricular hypertrophy (LVH) and myocardial fibrosis in uremic rats.

Methods: Rats (n=22) with 7/8 nephrectomy were treated with equivalent doses of VDRAs (calcitriol 10 ng/kg/day, alfacalcidol 20 ng/kg/day and paricalcitol 30 ng/kg/day, 5 days per week) for 4 weeks. Placebo (n=7) and Sham (n=7) groups were included for comparison. Blood and tissues were collected at sacrifice. Histological and molecular parameters of LVH and fibrosis were evaluated.

Results: All VDRAs prevented LVH, the values of heart/body weight ratio, wall and septum thickness and cardiomyocites size were similar to those observed in the Sham group. In addition, all VDRAs showed a significant decrease in atrial and brain natriuretic peptides (ANP and BNP) expression and they were able to decrease the phosphorilation of ERK 1/2, this effect was more marked in the paricalcitol group. Paricalcitol was the only VDRA able to reduce myocardial fibrosis compared to Placebo (2.6±0.6 % vs. 10.5±3.0 %, p=0.027) (Masson staining), showing similar values than the Sham group (2.8±1.1 %). Paricalcitol and alfacalcidol reduced collagen I expression, but only paricalcitol showed significant increases of collagenase MMP1 expression, a finding that suggest a high rate of collagen degradation.

Conclusions: In summary, the use of VDRAs prevents LVH in uremic rats. Paricalcitol was the most effective preventing myocardial fibrosis.

Differential Expression of MicroRNA-126 Contributes to Renal Microvascular Heterogeneity in VCAM-1 Protein Expression in Inflammation
Coen van Solingen,[2,3] Sigridur Anna Asgeirsdottir,[1] Neng Fisheri Kurniati,[1] Peter Heeringa,[1] J. Kamps,[1] Peter Zwiers,[1] Ton J. Rabelink,[2,3] Anton Jan Van Zonneveld,[2,3] Grietje Molema.[1] *[1]Department of Pathology & Medical Biology, UMCG, Groningen, Netherlands; [2]Department of Nephrology, LUMC, Leiden, Netherlands; [3]Einthoven Laboratory for Experimental Vascular Medicine, LUMC, Leiden, Netherlands.*

Background: Endothelial cells (EC) in different microvascular segments of the kidney have different functions and exhibit differential responsiveness to disease stimuli. Microvascular-segment specific responses to anti-glomerular basement membrane (anti-GBM) glomerulonephritis (GN)-induction as well as TNF-α, LPS, and anti-MPO induced GN showed that glomerular E-selectin expression was transcriptionally regulated. In contrast, VCAM-1 mRNA expression was highly increased in both arterioles and glomeruli, while the protein was only expressed to a limited extent in the glomerular compartment suggesting post-transcriptional regulation.

Methods: To assess a role for microRNA-126 (miR-126) in microvascular-segment specific regulation of VCAM-1 we employed mouse models of inflammation and isolated seven hundred glomeruli and arteriolar vascular segments and quantified both the expression of mRNAs and miR-126. Using an antagomir we silenced miR-126 in mice to identify the role of this miR in regional VCAM-1 expression.

Results: We validated the regulation of VCAM-1 by miR-126 in glomerular EC *in vitro*. In mice with experimental anti-GBM glomerulonephritis VCAM-1 mRNA expression was highly increased in both arterioles and glomeruli, while VCAM-1 protein was expressed to a limited extent in the glomeruli. These high VCAM-1 mRNA - low VCAM-1 protein levels were associated with high local miR-126 levels. *In vivo* silencing of miR-126 unleashed VCAM-1 protein expression in the glomerular EC upon inflammatory challenge with TNF-α. Heterogenic expression of the transcription factor Ets-1 with preferential expression in the glomerular compartment likely underlies the spatial expression pattern of miR-126.

Conclusions: These data imply that miR-126 has a major role in the segmental, heterogenic response of microvascular EC to systemic inflammatory stimuli.

Uremia Regulates Tissue Factor Stability and Ubiquitylation and Predisposes to Stent Thrombosis
Vipul C. Chitalia,[1,2] Sowmya Shivanna,[1,2] Jordi Martu,[1,4] Merche Balcells,[1,4] Irene Bosch,[1] Kumaran Kolandaivelu,[1,3] Elazer Edelman.[1,3] *[1]Harvard-MIT Division of Health Science and Technology, Massachusetts Institute of Technology, Cambridge, MA; [2]Renal Section, Department of Medicine, Boston Medical Center, Boston University School of Medicine, Boston, MA; [3]Cardiovascular Division, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [4]Biological Engineering Department, Institut Químic de Sarrià, Universitat Ramon Llull, Barcelona, Spain.*

Background: Coronary stent thrombosis (ST) is a fatal complication that occurs in 1.3% of patients and results in 50% mortality. CRF has emerged as one of the strongest predictors with a 6-fold higher risk. Tissue factor (TF) is a crucial mediator of injury-related thrombosis. We investigated effects and mechanism of uremic serum and solutes on thrombosis and TF regulation.

Methods: Pooled sera from 23 ESRD patients and healthy individuals were used. As a model of the de-endothelialitzed, post-interventional state, we exposed primary human vascular smooth muscle cells (vSMC) pretreated with uremic or control sera in an ex vivo flow-loop system. TF abundance, activity and mRNA in vSMC were examined. vSMCs were treated with individual uremic solutes at a concentration observed in ESRD patients.

Results: vSMCs pretreated with uremic serum showed significantly greater clot formation in flow-loop model. Uremic serum induced higher TF expression and activity in vSMCs. This effect was partially recapitulated by isolated uremic solutes including indole-3-acetic acid (IA), indoxyl sulfate (IS) and uric acid (UA). We further demonstrate that TF is ubiquitylated at baseline and IA and IS significantly prolong TF half-life by reducing its ubiquitylation. Consistently, vSMCs treated with IA, IS and UA were more thrombogenic in flow-loop model.

Conclusions: Uremia significantly increases thrombogenicty by unpregulating TF in vSMCs. Uremic solutes partially account for this via regulating TF stability by decreasing ubiquitylation. Together, these data demonstrate for the first time, the importance of post- translational regulation of TF in uremia and provides a mechanistic link between uremia and ST.

Calcineurin Inhibitors Stimulate MAPK Signaling in Endothelial Cells: Implications for Novel Therapeutics
Craig Bryan Woda,[1,2] Sarah Bruneau,[1,2] Jennifer Jardine,[1,2] David M. Briscoe.[1,2] *[1]Nephrology, Children's Hospital Boston, Boston, MA; [2]Pediatrics, Harvard Medical School, Boston, MA.*

Background: The calcineurin inhibitors (CNI), cyclosporine A (CsA) and FK506, are potent immunosuppressive agents used to treat a broad range of renal diseases. While the rationale for these strategies is based on their ability to inhibit lymphocyte activation, we propose that these agents alter additional molecular signals in non-immune cells that serve to attenuate progression of the underlying disease process. We recently observed that CNIs have effects on the activity of Ras family GTPases within vascular endothelial cells (EC). Here, we tested the hypothesis that the pro-activational effects of CNIs in EC involve Raf/MAPK and/or PI-3K/Akt signaling.

Methods: Purified human EC (HUVEC) were cultured in the absence or presence of CsA or FK506 (1 to 1000ng/ml), and the temporal phosphorylation of Akt, mTOR, p70S6K and p44/42 were evaluated by Western blot analysis.

Results: In multiple experiments, we found little effect of each CNI on the activity of the PI-3K/Akt signaling pathway, but we consistently found a marked increase in the expression of phospho-p44/42 after ~ 2.5hrs of treatment. We also assessed the interaction between each CNI and VEGF, which is known to induce activity of these intracellular signals. VEGF (5-20ng/ml) enhanced MAPK activity; and we found that CNIs have an additive effect to further augment expression of phospho-p44/42 in EC. Finally, to determine the functional implications of these observations, HUVEC were cultured with CsA (0.1-1μg/ml) or FK506 (0.01-1μg/ml) +/- VEGF for 72hrs and the degree of proliferation was assessed by 3[H]-thymidine incorporation. CNIs alone were found to augment EC proliferation from basal levels, but were potent to augment the VEGF-induced proliferative response.

Conclusions: Collectively, these observations demonstrate that CNIs have direct and/or indirect effects on the activation of the MAPK intracellular signaling pathway in ECs. Our studies have implications for therapeutic uses of CNIs to promote vasculoprotection or vascular repair; and they provide insight into how these agents may protect against immune-mediated renal injury.

Neurohumoral and Renal Mechanisms in the Pathogenesis of Hypertension in Polycystic Kidney Disease Benjamin F. Wyse,[1] Joanne Harrison,[2] Jacqueline K. Phillips.[1] *[1]Australian School of Advanced Medicine, Macquarie University, Sydney, NSW, Australia; [2]School of Veterinary and Biomedical Sciences, Murdoch University, Perth, WA, Australia.*

Background: Hypertension is a common presenting factor in polycystic kidney disease (PKD) patients prior to the onset of renal failure. Neurohumoral systems such as the sympathetic nervous system (SNS) and renin angiotensin system (RAS) are key regulators of blood pressure and may contribute to hypertension in these patients. We have shown that AngII levels and PRA are reduced in the Lewis Polycystic Kidney (LPK) model of PKD at 12 wks of age. In this study we examined AngII at different ages, and baseline levels of SNS activation by determination of circulating catecholamines. Activation of an intra-renal RAS as a local mediator of hypertension was assessed by renal RAS gene expression.

Methods: LPK & age matched Lewis controls were assessed at 6, 10 and 16 wks old. Systolic blood pressure was measured via tail cuff and upon euthanasia, serum collected. Kidneys were collected for quantitative RT-PCR for RAS genes (angiotensinogen, renin, angiotensin converting enzyme (ACE) I/II and the ATR1A. Plasma AngII levels were determined by radioimmunoassay and catecholamines by HPLC.

Results: In LPK of all age groups, intra-renal expression of RAS genes were greater in the LPK ($p<0.05$, n=32). ATR1A receptor and ACE displayed 8 fold increases, whilst ACE2, Renin and Angio displayed 2, 4 and 6 fold increases, respectively, in comparison to Lewis. Ang II levels were decreased in the LPK across all ages groups (LPK = 24.1 v Lewis = 54pg/mL) whilst catecholamine levels were greater for noradrenaline (4.9 v. 0.54nmol/mL) & adrenaline (4.7 v. 0.87nmol/mL) in 10 wk old LPK ($p<0.05$).

Conclusions: Increased expression of intra-renal RAS genes, in concert with a concomitant decrease in serum AngII levels provide evidence for intra-renal RAS as a local mechanism driving hypertension in PKD. However, increased circulating catecholamines suggest an additive role for the SNS, which in addition to direct vascular effects may modulate RAS gene expression in the kidney.

SA-PO3134

Impact of Vitamin D on Cachexia, Cardiovascular Disease and Mortality in Chronic Kidney Disease Robert H. Mak,[1] Wai W. Cheung,[1] Yusu Gu,[2] Nancy Dalton,[2] Erika Alvarez,[2] Kirk L. Peterson.[2] *[1]Pediatrics, University of California San Diego, La Jolla, CA; [2]Medicine, Cardiovascular Institute, La Jolla, CA.*

Background: Patients with chronic kidney disease (CKD) have increased mortality and morbidity. Known risk factors include vitamin D insufficiency, cardiovascular (CV) disease, and cachexia. We studied the effect of vitamin D supplementation on nutrition, CV system, and mortality in a mouse model of CKD.

Methods: 9-month old c57BL/6J mice underwent 5/6 nephrectomy (N). We previously showed decreased serum levels of 25-VitD and 1,25-VitD in N mice. N mice received 25-VitD (N-25VitD) (0.08mg/kg, ip, 3x/week), paracalcitol (N-PC) (0.15mg/kg, ip, 3x/week) or vehicle (N-V). Sham-operated mice received vehicle (S-V). N-V mice were fed ad libitum. S-V, N-25VitD, N-PC mice were pair-fed to N-V mice. The study period was 90 days.

Results: Serum BUN and creatinine was significantly higher in N-V, N-25VitD and N-PC compared with S-V mice ($p<0.01$). The mortality rate in N-V mice (57.5%) was significantly higher than N-25VitD (40.0%) or N-PC (30.0%) mice. N-25VitD and N-PC mice gained more weight than N-V mice ($p<0.01$) despite equal food consumption. Basal metabolic rate was significantly higher in N-V compared with N-VitD25 and N-PC mice ($p<0.01$). N-V mice lost lean body mass and fat mass whereas N-25VitD and N-PC mice gained lean body mass and fat mass. Muscle strength was assessed. Rotarod activity and grip strength were significantly improved in N-25VitD, N-PC compared with N-V mice ($p<0.001$). The mean systolic blood pressure in N/V was significantly higher than S-V, N-25VitD or N-PC (145.7±8.2 mmHg vs 99.8±3.7 mmHg, 113.5±5.6 mmHg and 123.2±3.5 mmHg, respectively, $p<0.001$) mice. Left ventricular mass adjusted for body weight was significantly elevated in N-V mice than S-V, N-25VitD and N-PC (26.4±7.8 mg/10g vs 20.9±3.1 mg/10g, 23.4±2.1 mg/10g and 21.6±3.2 mg/10g, respectively, $p<0.01$).

Conclusions: 25-VitD and PC ameliorated cachexia, muscle wasting, hypertension, left ventricular hypertrophy and mortality in mice with CKD. Correction of vitamin D insufficiency is important in preventing nutritional and CV complications of CKD, leading to improvement in survival.

SA-PO3135

Direct Renin Inhibitor Is Better Than Angiotensin II Receptor Blocker for Intrarenal Arterioles Kazushige Nakanishi,[1] Yohko Nagai,[1,2] Nobuaki Yamanaka.[2] *[1]Department of General Medicine and Emergency Care, Faculty of Medicine,Toho University, Tokyo, Japan; [2]Tokyo Kidney Research Institute, Tokyo, Japan.*

Background: We have reported that long-term administration of angiotensin II receptor blockers (ARBs) on rats induced unusual proliferative changes of smooth muscle cells (SMCs) in renal afferent arteriolar walls, and the changes were suspected to be induced by the overproduction of renin in JG cells. We examined the effect of the long-term administration of a direct renin inhibitor (DRI) on intrarenal arterioles in spontaneous hypertensive rats (SHR).

Methods: Sixteen 6-week-old male SHR were divided into the following three groups: DRI group (n=5) fed a standard diet containing aliskiren 30mg/kg/day, ARB group (n=6) fed a standard diet containing varsartan 10mg/kg/day, and control group (n=5) fed a standard diet, respectively. Blood pressure and proteinuria were measured every three weeks. After 12 weeks, blood samples were drawn; afterward, lightmicroscopic, electronmicroscopic and immonohistochemical examinations were performed.

Results: Blood pressure in the DRI group and the control group was significantly high compared to the ARB group (188.4±4.2, 185.8±19.3, 124.5±7.3mmHg, respectively).. Remarkable proliferative changes in the afferent arteriolar SMCs were more frequently observed in the ARB group than in the control group (48.9%±6.7% versus 5.1%±2.9% of total observed arterioles in each rat, p=0.0061), but the SMC changes were rarely seen in the DRI group. In the DRI group, glomerular abnormalities and tubulointerstitial changes were very mild. Urinary protein excretion significantly decreased in the DRI group (11.0±3.6mg/day) compared to the ARB group and the control group (30.1±7.6 and 37.5±8.5mg/day, p=0.0487 and p=0.0043, respectively). The serum creatinine level was higher in the DRI group than in the control group (0.46±0.40 versus 0.16±0.03mg/dl, p=0.0158).

Conclusions: The long-term ARB administration induces unusual proliferative changes of SMCs in afferent arterioles; however, DRI does not induce such proliferative changes in SHR. It is indicated that DRI is better than ARB for intrarenal arterioles to suppress the renin-angiotensin system.

SA-PO3136

Chronic Kidney Disease in a Rat Model Modifies Tissue Concentrations of Vitamin K Kristin M. McCabe,[1] Xueyan Fu,[2] Michael A. Adams,[1] Rachel M. Holden.[1] *[1]Queen's University, Kingston, ON, Canada; [2]Tufts University, Boston, MA.*

Background: Patients with chronic kidney disease (CKD) develop vascular calcification (VC) and serum phosphorus is considered a putative signalling molecule in this process. Matrix-Gla protein (MGP) is a vitamin-K dependent protein that inhibits calcification. The major form of vitamin K consumed in the diet and preferentially found in the liver is Phylloquinone (K1). Menaquinone-4 (MK-4), although present in the diet in small quantities, is preferentially found in extra-hepatic tissues. In the present study we assessed tissue concentrations of K1 and MK-4 in the presence of CKD.

Methods: Sprague Dawley rats were fed a diet containing either 0.25% adenine (CKD; n=24) or 0% adenine (control; n=18), both diets containing high phosphate (1%) and low vitamin K1 (0.2 mg/kg) for 7 weeks. Kidney function was assessed by measuring serum creatinine. The concentrations of K1 and MK-4 in tissue and serum were determined by reversed phase HPLC and expressed relative to wet weight.

Results: Serum creatinine was elevated in the CKD group (352 ± 107 μM) compared to controls (50 ± 10 μM, $p<0.001$). CKD animals had significantly higher levels of K1 in the serum (1.4±0.1 vs 0.7±0.5 pmol/g, p=0.019) and lower levels in the liver (33.6±20 vs 57.3±31pmol/g, $p<0.001$) compared to control animals. The kidney medulla in CKD animals had significantly higher MK-4 levels (58.3±21 vs 36.9±8.8 pmol/g, $p<0.001$) and lower K1 levels (5.4±0.4 vs 11.2±8.8 pmol/g, p=0.015) compared to controls. The thoracic aorta accumulated MK-4 and K1 in CKD animals (104.5±46.3 and 152.3±234.9 pmol/g, n=9). MK-4 concentration in the thoracic aorta had a positive correlation with serum phosphorus ($r^2= 0.8$, p=0.001).

Conclusions: These results indicate that CKD modifies tissue concentrations of K1 and MK-4 under low dietary conditions. The presence of CKD attenuates K1 storage in the liver but enhances MK-4 accumulation in non-hepatic tissues. In the thoracic aorta, we found a significant correlation between serum phosphorus and MK-4. We hypothesize that there are, as yet undefined, factors associated with CKD that increase peripheral conversion of K1 to MK-4.

SA-PO3137

Lipopolysaccharide and TNF-α Aggravate Calcification in Vascular Smooth Muscle Cells by High Inorganic Phosphate and High Calcium Concentration Media Matsuhiko Hayashi,[1] Ichiro Takamatsu,[1] Chihiro Horimai,[1] Tadashi Yoshida,[1] Toshifumi Wakamatsu.[2] *[1]Apheresis and Dialysis Center, Keio University, School of Medicine, Shinjuku-ku, Tokyo, Japan; [2]Institute of Molecular Design, Bunkyo-ku, Tokyo, Japan.*

Background: Uremia and disturbances in calcium/phosphate metabolism induce vascular calcification (VC), which contributes to cardiovascular diseases in the patients on chronic hemodialysis (HD), and inflammation also plays important roles in VC. To examine the roles of pro-inflammatory factors, TNF-α and lipopolysaccharide (LPS), which are related to chronic inflammation in HD patients, we performed the in vitro studies with cultured human vascular smooth muscle cells (VSMC).

Methods: VSMC was cultured in control (C, phosphate concentration; Pi 1.0 mM, calcium concentration; Ca 1.8 mM), high inorganic phosphate (HPi, Pi 3.6 mM, Ca 1.8 mM), and high calcium (HCa, Pi 1.0 mM, Ca 3.6 mM) media. After 7 to 10 days of cell culture, calcium contents of the cells were measured and RNA was extracted for real time PCR.

Results: HPi and HCa media significantly increased calcium contents of VSMC, and TNF-α (50 ng/ml) and LPS (500ng/ml) further increased calcium contents in either HPi (2.25 and 2.31 fold increases, respectively) or HCa (1.92 and 1.27 fold increases, respectively), significantly, as previously reported for TNF-α. Since recent reports suggested involvement of endochondral transformation in vascular calcification by uremia, mRNA expressions of BMP2, an osteoblast marker, and RUNX3/cbfa3, a chondrocyte marker, were determined by real-time PCR, showing that TNF-α and LPS significantly increased BMP2 but not RUNX3/cbfa3. Furthermore, we examined roles of nuclear factor κB (NFκB), which plays key roles in inflammation and bone metabolism, by specific inhibitor for IKKβ activation, IMD-0354, and inhibition of NFκB activation by IMD-0354 did not prevent VSMC calcification by either TNF-α or LPS.

Conclusions: TNF-α and LPS aggravate VC, involving osteoblastic but not chondrocytic transformation via NFκB-independent pathway. Since LPS is often contaminated in water for dialysate, it is suggested that water purification is important to prevent progression of VC in the patients on chronic HD.

Funding: Government Support - Non-U.S.

SA-PO3138

(Pro)renin Receptor-Like Immunoreactivity in Patients with Chronic Renal Failure Kazuhito Totsune,[1] Takuo Hirose,[2] Nobuyoshi Mori,[3] Hirohito Metoki,[4] Kei Asayama,[2] Masahiro Kikuya,[2] Osamu Murakami,[5] Yutaka Imai,[2] Kazuhiro Takahashi.[6] *[1]Faculty of Synthetic, Tohoku Fukushi University, Sendai, Japan; [2]Planning for Drug Development and Clinical Evaluation, Tohoku Univ Grad Sch of Pharm Sci and Med; [3]Department of Internal Medicine and Rehabilitation, Tohoku Univ Grad Sch of Med; [4]Obstetrics and Gynecology, Tohoku Univ Grad Sch of Med; [5]Department of Medicine, Tohoku Univ Grad Sch of Med; [6]Endocrinology and Applied Med Sci, Tohoku Univ Grad Sch of Med, Sendai, Japan.*

Background: (Pro)renin receptor ((P)RR) is a new member of the renin-angiotensin system. The presence of soluble type of (P)RR with 28 kDa has been reported in the human and rat blood. However, the characteristics of the soluble type of (P)RR in the plasma are unclear to date.

Methods: We therefore examined the (P)RR-like immunoreactivity ((P)RR-LI) in the human plasma by a specific enzyme immunoassay (EIA) which we newly developed, and Western blot analysis. The antiserum against (P)RR was raised in a rabbit by injecting the peptide fragment of human (P)RR corresponding to 224-237 amino acid (human (P)$RR_{224-237}$) conjugated with bovine serum albumin. The EIA has a sensitivity limit of 7.8 fmol/tube and no cross-reactivity to other peptides tested such as endothelin-1 and urotensin II. 50 µl of plasma was directly assayed. Plasma (P)RR-LI levels were measured in 51 hemodialysis patients.

Results: In the EIA, a 2-fold dilution curve of human plasma paralleled with a standard curve. (P)RR-LI levels were significantly elevated during HD session by 1.2-fold ($p<0.001$ by paired t-test). Western blot analysis showed a band with a size over 100 kDa, but no band at the position of 28 kDa, where a previously reported soluble type of (P)RR was found. In contrast, rat plasma showed a 28 kDa band in addition to a band over 100 kDa.

Conclusions: The present study has shown for the first time the changes of (P)RR-LI levels in human plasma and that the major component of (P)RR-LI has a higher molecular size, possibly an assembly of several (P)RR molecules. Our results suggest that (P)RR-LI may act as a circulating receptor and play an important role in the cardiovascular regulation of renal failure patients.

SA-PO3139

Effect of Lower Calcium Dialysate on Laboratory Parameters in Chronic Kidney Disease Associated Mineral and Bone Disorder (CKD-MBD) Anip Bansal,[1] Gagangeet S. Sandhu,[1] Rohit Chitale,[2] Rushi K. Nayak,[1] Shriharsha Kallahalli,[1] James P. Jones,[1] Ira S. Meisels.[1] *[1]Nephrology, St. Luke's-Roosevelt Hospital Center, Columbia University College of Physicians and Surgeons, New York, NY; [2]International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Background: Increased vascular calcification is a concern as a risk factor for cardiovascular disease in patients with ESRD. The incidence of vascular calcification may be decreased by use of a lower dialysate calcium(Ca). However, this effect may be mitigated by increased use of Ca based phosphate binders and increased requirement for active Vitamin D analogues(VDA).

Methods: We retrospectively reviewed the charts of 141 eligible patients who were changed from a higher to a lower Ca dialysate and who were on maintenance hemodialysis (HD) for at least 3 or more months to determine the effect of lower Ca dialysate (2.25 mEq/L) on biochemical variables associated with CKD-MBD and on the use of phosphate binders and VDAs. Student paired t-test was used.

Results: There was a statistically significant decrease in the mean serum Ca and an increase in the mean serum P. The change did not lead to a statistically significant difference in the mean serum intact PTH or Ca-P product, nor in requirement of calcium-based phosphate binders (CPB), non-calcium based phosphate binders, or VDAs.

Table 1

	High Ca Dialysate (2.50 mEq/L)	Low Ca dialysate (2.25 mEq/L)	Mean difference	P value
Total Serum Ca (mEq/L)	9.26±0.06	8.97±0.06	0.29±0.08	<0.0001
Serum P (mg/dL)	5.04±0.12	5.48±0.14	0.44±0.14	0.002
Ca-P product	46.36±1.19	48.88±1.33	2.52±1.35	0.06
Intact PTH	514.95±45.17	567.49±46.58	52.54±38.69	0.18
Paricalcitol dose per HD (mcg)	4.68±0.25	4.91±0.26	0.23±0.27	0.39
No. of Ca acetate pills per meal	0.49±0.08	0.45±0.08	0.05±0.09	0.58
No. of sevelamer pills per meal	1.62±0.14	1.78±0.14	0.16±0.13	0.21

Comparison of mean values of biochemical variables and drug dosage with high vs. lower Ca dialysate

Conclusions: The use of lower Ca dialysate in maintenance hemodialysis patients leads to reduction in mean serum Ca concentrations without significantly increasing requirement for VDAs and CPBs. The long term impact of this intervention needs further study.

SA-PO3140

The Effect of Kidney Function on Intimal Neovascularization and Intraplaque Hemorrhage in Coronary Atherosclerosis: The Hisayama Study Toshiaki Nakano,[1,2] Toshiharu Ninomiya,[1] Kazuhiko Tsuruya,[1] Yutaka Kiyohara,[3] Takanari Kitazono.[1] *[1]Department of Medicine and Clinical Science, Kyushu University, Fukuoka, Japan; [2]Pathophysiological and Experimental Pathology, Kyushu University, Fukuoka, Japan; [3]Department of Environmental Medicine, Kyushu University, Fukuoka, Japan.*

Background: People with chronic kidney disease (CKD) are at the increased risk of coronary heart disease. The aim of this study is to investigate the relationships of CKD with neovascularization and intraplaque hemorrhage in coronary atherosclerosis.

Methods: We randomly selected 126 subjects from 844 consecutive autopsy samples of residents of the town of Hisayama, Japan and examined the relationship of estimated glomerular filtration rate (eGFR) with the severity of coronary atherosclerosis. The subjects were classified into four categories based on eGFR. We estimated the numbers of intimal neovascularization and intraplaque hemorrhages in the vessels. The expressions of oxidized low-density lipoprotein (oxLDL) and vascular endothelial growth factor (VEGF) in the vessels were examined immunohistochemically.

Results: Lower eGFR was associated with increased numbers of neovascularization (10.7, 11.8, 18.7, and 23.5 per vessel by eGFR levels) and intraplaque hemorrhages. The positive areas of oxLDL and VEGF increased significantly with reducing eGFR levels. Likewise, the positive areas of oxLDL and VEGF were correlated significantly with the numbers of neovascularization and intraplaque hemorrhages (all $p<0.01$).

Conclusions: People with CKD have higher risks of intimal neovascularization and intraplaque hemorrhage in coronary arteries. Greater expressions of oxLDL and VEGF may be attributed to neovascularization and consequent intraplaque hemorrhage in coronary atherosclerosis.

High Concentration Ucid Acid Trigger Oxidative Stress in Endothelial Cell Via Aldose Reductase Pathway Di Wu, Zhiyong Huang, Quan Hong, Liyuan Wang, Shaoyuan Cui. *Department of Nephrology, Chinese General Hospital of PLA, State Key Laboratory of Kidney Diease, Beijing, China.*

Background: Hyperuricemia is an independent risk factor for cardiovascular and kidney disease. Uric acid is an antioxidant but high level uric acid(UA) become a prooxidant. In this study, we tried to what causes the switch.

Results: The human umbilical vein endothelial cell line (HUVEC) were cultured with 600µmol/L UA and no UA was added in the control group. Using stable isotope labeling by amino acids in cell culture (SILAC) combined with liquid chromatography-mass spectrometry, we selected 39 proteins with significant difference. Two interesting proteins relating to oxidative stress, increased aldose reductase (AR) and decreased mitochondrial superoxide dismutase (Mn-SOD), attracted our attention.

We detected the changes of total ROS and its components (O2•-, H_2O_2, $1O_2$, •OH) by laser scanning confocal microscope. The total intracellular ROS, O2•- and H_2O_2 was upregulated, but 1O2, and•OH was decreased, which suggested that high UA level keeps parts of its antioxidant property but lose the capability of decreasing the O2•- and / or H_2O_2. Because the O2•- quickly transforms to H_2O the H_2O_2 might be the major contributor of UA-mediated endothelial dysfunction. The supernatant NO level significantly upregulated but it may be a sign of inflammation. Removing the H_2O_2 with catalase can attenuate the injury.

When the HUVEC were pretreated with AR inhibitor, the intracellular total ROS, as well as the NO level significantly decreased compared with the high level UA group. The AR inhibitor also inhibited the NADPH oxidase (NOX) activation which suggested that high level UA may activate the AR pathway first, then increase the generation of ROS by NOX, finally promote the inflammatory response.To verify the results in vivo, hyperuricemia mouse model was established in male C57B6 mice. After given the AR inhibitor or PEG-SOD, the endothelium function recovered.

Conclusions: Our results demonstrated that high level UA actives the AR then increase the H_2O_2 level which causing endothelial dysfunction. But UA keeps its capability of decreasing other ROS components.

PUB001

Modulation of Tubular Cell Injury by Mesenchymal Stromal Bone Marrow Cells in a Single Kidney Partial Protection Model Dileep Kumar, Kang Cheng, Partab Rai, Rivka Lederman, Mohammad Husain, Ashwani Malhotra, Pravin C. Singhal. *Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY.*

Background: Cisplatimum has been demonstrated to induce acute tubular necrosis both in human and animal experimental models. Mesenchymal stromal bone marrow cells (MS-BMCs) have been demonstrated to provide cytoprotection by the modulation of cytokine production in several cytotoxic models. In the present study, we evaluated the effectof MS-BMCs on cisplatinum -induced tubular cell injury.

Methods: MS-BMCs were harvested from bone marrows of mice and their profile was characterized. Mice in groups of six were administered either buffer (group A), cisplatinum alone (group B, 12.5 mg/Kg, intraperitoneal), intracapsular instillation of MS-BMCs in left kidney 24 hours prior to cisplatinum administration (group C). All mice were sacrificed on day 3; urine and blood samples were collected for BUN and albumin: creatinine ratio. Kidneys were harvested for renal histology and TUNEL staining. Immunohistochemical studies were carried out to study interstitial inflammatory milieu. In parallel sets of experiments, conditioned media of MS-BMC was collected. The effect of conditioned media of MS-BMC was evaluated on cisplatinum-induced tubular cell apoptosis in in vitro studies.

Results: Group B mice showed elevated BUN when compared to group A mice (84.5 ± 12 vs. 40.9 ± 2 mg/dl, P<0.5). However, group C mice displayed only mild elevation of BUN (56.3 ± 4 mg/dl). Group C (5,495 ± 716 mg/gm creatinine) mice displayed decrease (P<0.05) in albumin: creatinine ratio vs. Group B (9,615 ± 2306 mg/gm creatinine) mice. Left kidneys from the group C displayed decreased number for TUNEL +ve tubular cells when compared to the contralateral kidneys of the same group and kidneys from the group B. In in vitro studies, conditioned media from MS-BMC provided partial protection to tubular cells against cisplatinum-induced injury

Conclusions: These findings indicate that MS-BMCs provide protection from injurious effect of cisplatinum by modulating apoptotic signaling in renal cells.

PUB002

Erythropoietin Effects on Renal Ischemia/Reperfusion Injury Vitor Maciel de Sousa Pinto, Vicente de Paulo Castro Teixeira, Waldemar S. Almeida, Elisa M.S Higa, Nestor Schor. *Medicine - Division of Nephrology, Universidade Federal de São Paulo- Escola Paulista de Medicina, São Paulo, Brazil.*

Background: Recently has been suggested a protective action of rHuEPO (recombinant human erythropoietin) in ischemia/reperfusion (I/R) injury in several tissues, including the kidney. However, the mechanism of action of rHuEPO in the model of ischemia/reperfusion AKI is not clear. We evaluated the effects of rHuEPO in rats subjected to I/R and the potential role of rHuEPO in the inflammatory process as a consequent reaction of the injury.

Methods: Males wistar rats received i.v. infusion of a high dose of rHuEPO (3,000UI/kg) or saline 15 minutes prior the bilateral clamping of renal artery during 45 minutes. Serum creatinine (sCr), urea (sUr) and nitric oxide (sNO) levels were evaluated before and up to 24, 48 and 72 h after I/R injury. Tissue samples were evaluated after 72 h I /R via a semi-quantitative scale.

Results: After 24h and 48h sUr from saline group increased more than the rHuEPO group, and sCr, sNO did not change up to 72h. However, a striking differences were observed with the histological evaluation since rHuEPO (N=8) group I/R presented a significantly less tubular damage (TD) in comparison to saline group (N=5); p<0.05. Data are expressed as distribution frequency of renal TD severity score. Scores: 0= until 10%; 1= 10 to 25%; 2= 25 to 50%; 3= 50 to 75%; 4= above 75%. The group rHuEPO had predominance in low scores, while the group saline had predominance in high scores.

Histology - Tubular damage

Group	Score 0	Score 1	Score 2	Score 3	Score 4
Sham	100%	0	0	0	0
Saline	0	0	20%	20%	60%
rHuEPO	0	25%	50%	25%	0

Conclusions: Our preliminary results suggest that administration of rHuEPO as a single and high dose before the onset of I/R produced a significant reduction in tubular injury. Further studies are underway in order to identifying mechanisms involved in this mechanism.

PUB003

Podocyte, a Type of Newly Discovered Target Cell for Aristolochic Acid in Aristolochic Acid Nephropathy Xueqin Bian, Junwei Yang, Chunsun Dai. *Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical University, Nanjing, Jinagsu, China.*

Background: Aristolochic acid nephropathy (AAN), a rapidly progressive tubulo-interstitial nephropathy, is manifested as proteinuria in most of the cases. Whether Aristolochic acid (AA) can directly impair podocyte, one of the most important parts of glomerular filtration barrier, remains completely unknown. Here we reported that Aristolochic acid could direct damage podocyte and lead to albuminuria in mice.

Results: In this study, to induce AAN, we injected male ICR/CD-1 mice intraperitoneally with AA (6mg/kg) twice during the first week. Mice were sacrificed at day 3, 7 and 30 after first injection and urine and kidney samples were collected at each time point respectively. At day 3 after AA injection, all of the mice developed apparently albuminuria according to urinary protein SDS-PAGE gel electrophoresis and albumin ELISA assay. Immunofluorescent staining results showed that nephrin staining pattern was changed from linear to granular. Both Wilms tumor 1 (WT1) and podocin expression level in isolated glomeruli were suppressed significantly compared to those in control. In cultured mouse podocytes, AA could dose-dependently induce cell death and F-actin distribution alteration, from initial trabs-shape to surrounding along the cell membrane.

Conclusions: In conclusion, AA can directly induce podocyte damage and albuminuria, which provides a new aspect for the therapy of AA nephropathy.

Baselining Drug-Induced Kidney Injury Urinary Biomarkers in Rats within an Automated Blood Sampling and Telemetry System Yafei Chen, Harriet Kamendi, David Brott, Patricia Bentley, Herbert Barthlow, James Fikes, Lewis B. Kinter, Russell Bialecki. *Global Safety Assessment, AstraZeneca Pharmaceuticals, Wilmington, DE.*

Background: Drug-induced kidney injury (DIKI) is routinely monitored in preclinical safety testing using clinical chemistry, urinalysis and histopathology. However, limitations with these traditional approaches are increasingly recognized, especially for prediction of DIKI in early drug discovery. Nephron site specific DIKI biomarkers recently have shown better sensitivity and specificity than regulatory standards (serum creatinine and blood urea nitrogen) for detection or prediction of kidney injury following acute drug exposure in rats. However, baseline values for these biomarkers under normal physiological conditions are not well described.

Methods: In this study, we evaluated eight urinary biomarkers (αGST, GSTYb1, albumin, clusterin, KIM-1, RPA-1, lipocalin and osteopontin) from rats in an integrated automated blood sampling and telemetry (ABST) system for DIKI detection (Kamendi, et al. J. Pharmacol Toxicol Methods. 62(1):30-9, 2010). To establish the reference range for these DIKI biomarkers, urine samples were collected overnight (16-18 hrs) from surgically cannulated and telemetered control animals (n≥4 rats/study, 8 studies) within ABST system using a quantitative urine collection unit.

Results: Urine basal levels of DIKI biomarkers were measured using Multiplex Meso Scale Discovery® assay kits. Baseline values were determined for all biomarkers and normalized to urinary creatinine (biomarker/creatinine: α-GST, 25.4±6.3; GSTYb1, 7.7±1.6; Clusterin, 2.8±0.4; Albumin, 3.5±0.4; KIM-1, 0.15±0.03; Lipocalin, 0.3±0.1; Osteopontin, 0.9±0.3; RPA-1, 0.3±0.03).

Conclusions: These preliminary baseline findings provide valuable background information on DIKI urinary biomarkers for subsequent qualification and validation studies using benchmark compounds within ABST platform.

PUB005

The Change of Urinary Kidney Injury Molecule-1 after Cardiac Catheterization in Children with Congenital Heart Disease Min Hyun Cho. *Pediatrics, Kyungpook National University Hospital, Daegu, Korea.*

Background: Contrast-induced nephropathy (CIN) is an important cause of acute kidney injury (AKI) in hospitalized patients. The aim of this study was to investigate the frequency of CIN caused by the contrast material used for cardiac catheterization in pediatric patients with congenital heart disease, and to evaluate the clinical usefulness of the Kidney Injury Molecule-1 (KIM-1) for detecting AKI in pediatric group.

Methods: A variety of clinical findings were analyzed in 26 children that received cardiac catheterization for congenital heart disease; including the amount of contrast agent used and the level of serum creatinine before and after the catheterization. No patient had a prior history of renal disease. In addition, the level of urine KIM-1 was evaluated and compared as a biomarker for AKI, by ELISA, before and after catheterization.

Results: The mean age of the patients was 7.1 years and the male: female ratio was 12:14. Although only one patient had cyanosis caused by pulmonary atresia (oxygen saturation 89%), the others had no cyanosis or congestive heart failure. Ultravist®, a low osmolar dye, was used as the contrast media in all 26 cases; the amount of contrast agent used was on average 31.2±16.7 mL (2.5±2.8 mL/kg of weight). The levels of serum creatinine were checked before, 6h, and 24h after catheterization and showed little change within the normal range as: 0.4±0.19, 0.41±0.19, 0.41±0.22 mg/dL, respectively. However, the average levels of the urine KIM-1 evaluated before, at 6h and 24h after catheterization were: 70.94±80.83, 78.33±52.5, and 107.98±94.2 pg/mL respectively, showing a progressive increase after catheterization. There was significant difference between the level of KIM-1 before and at 24h after catheterization.

Conclusions: Although typical CIN may be rare, contrast agents are a potential cause of AKI in children with congenital heart disease. Further long-term prospective research is needed.

PUB006

Acyclovir Induced Rhabdomyolysis Vince Faridani, Adil Akthar, Ahmed M. Awad. *Nephrology, University of Missouri - Kansas City, Kansas City, MO.*

Background: Acyclovir is an acyclic guanosine analogue used in the treatment of herpes simplex virus and varicella-zoster virus. Although generally well tolerated, usage of acyclovir may be complicated by development of acute renal failure (ARF) in select patients. The following case demonstrates a rare example of ARF secondary to acyclovir-induced rhabdomyolysis.

Case: A 29 year old female with a known history of Type I Diabetes and ESRD on peritoneal dialysis presented to the hospital with altered mental status, weakness, and vomiting. Four days prior she was started on oral acyclovir therapy for treatment of genital herpes. Upon initial presentation, afebrile, vital signs stable. Physical examination revealed the patient to be alert but not orientated x 0, no focal neurological deficits. Initial evaluation, CT head was negative for acute injury and lumbar puncture revealed CSF to be normal. Laboratory studies revealed Na 122, K 3.7, BUN 101, Creatinine 12.3, and Phosphorus 11.2, creatine kinase (CK) 20,199. Serological work and HIV viral load was negative. The patient was immediately discontinued from her acyclovir, given IV fluids, and underwent emergent dialysis for two consecutive days given her acute on chronic renal failure, altered mental status, and elevated CK. Nearly 48 hours later her CK decreased and menation returned to baseline. Hemodialysis was discontinued and she resumed her peritoneal dialysis.

Discussion:

The mechanism of acyclovir-induced ARF classically involves the administration of intravenous acyclovir leading to precipitation of crystals within the nephron tubules and renal parenchyma. However, the above case highlights a different physiologic mechanism whereby oral acyclovir can lead to reversible rhabdomyolysis-induced uremic encephalopathy and oliguric acute kidney injury. Clinicians should also be aware that acyclovir-related ARF can occur with lower doses of oral therapy as well as rapid IV infusions. This consideration is especially important when dealing with patients who have underlying chronic kidney disease as seen here. These patients warrant lower doses of acyclovir treatment given their greater predisposition to renal damage.

PUB007

Effects of Pretreatment with High Doses of Methylprednisolone (MP) on Renal Ischemia/Reperfusion (I/R) Injury Ida M. Fernandes,[1] Gloria Mendes,[1] Emmanuel A. Burdmann.[1,2] *[1]Medical School of Sao Jose do Rio Preto, Sao Paulo, Brazil; [2]University of Sao Paulo Medical School, Brazil.*

Background: Renal ischemia is the most important cause of acute kidney injury.

Methods: To assess a possible protective role of MP in renal I/R male rats were treated with MP 30mg/kg or saline (S) iv 1 h before 30 min renal ischemia (RI). They were divided into 3 groups (n=8 each): sham control (C, sham surgery, no RI), I/R (saline infusion before RI), and MP (MP infusion before RI). Inulin clearance (GFR, ml/min/100g), sodium fractional excretion (FENa, %), urinary volume, osmolality and renal histological analysis were assessed 2 d after I/R. Immunohistochemical staining was performed to measure macrophages (ED-1 positive cells), neutrophils (No), and lymphocytes (Lo) and nuclear factor-kappa- B (NFκ-B), scored according to the extent of tubulointerstitial (TI) immunostaining in the cortex and outer medulla (OM) areas. Results are mean±SD (ANOVA, followed by Bonferroni test, $p<0.05$).

Results: GFR was 0.92±0.3 in MP, 0.90±0.3ml in C, and 0.47±0.2 in I/R ($p<0.05$ vs. MP and C). FENa was similar in the MP (0.19) and C groups (0.35), and higher in the I/R group (0.57, $p<0.05$ vs. MP and C). Urinary volume and osmolality were similar among the 3 groups. Acute epithelial degenerative changes and tubular dilatation were significantly more intense in the I/R group than the MP and C groups, with focal acute tubular necrosis. TI staining for Lo was significantly higher in I/R as compared to the C and MP groups in the cortex (14.4±3 vs. 6.7±1 and 5.3±1.6, respectively, $p<0.05$ I/R vs C and MP) and OM areas (10.6±3 vs. 4.3±1 and 3.7±0.6, $p<0.05$ I/R vs. C and MP). Similar results were seem for OM staining of ED1 (9.8±3 in I/R vs. 4.6±1 in C and 4.1±2 in MP, $p<0.05$) and No (3.1±2 in I/R vs. 1.1±0.3 in C and 1.4±1 in MP, $p<0.05$). NFκ-B staining was more intense in the OM of I/R compared with the C and the MP (0.6±0.3 in I/R vs. 0.03±0.03 in C and 0.1±0.1 in MP, $p<0.05$).

Conclusions: Pretreatment with high doses of MP conferred striking protection against renal I/R. This effect is probably related to the modulation of I/R-induced inflammatory mechanisms by MP.

PUB008

Acute Kidney Injury Associated with Intravenous Vancomycin Administration Carlos R. Franco-Palacios,[1] Qi Qian.[1] *[1]Nephrology, Mayo Clinic; [2]Nephrology, Mayo Clinic.*

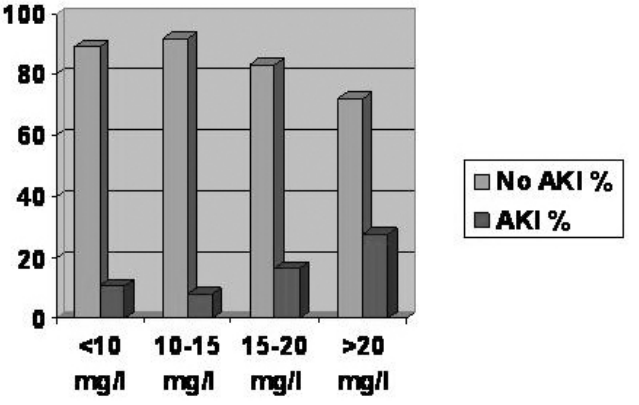
Background: Studies suggest an association of vancomycin and nephrotoxicity. The temporal relationship between the two remains unclear.

Methods: Retrospective study to determine the relationship between incidence of AKI and IV vancomycin. 547 patients with trough vancomycin level in our institution in 2009 were selected,428 were entered for analysis after excluding chronic dialysis patients, patients less than 18years, and patients with incomplete clinical data. Serum Cr levels before, during and after vancomycin treatment were examined.

Results: Baseline patient characteristics: Mean (SEM) age 59.7-±18.1, 56.7 % male, baseline serum Cr 0.92±0.53, diabetes 27.5%, hypertension 50.4%, CHF 17%, ICU admission 50.4%, pressor use 24.5%, aminoglycoside use 5.8%, loop diuretics 48.3%, thiazide diuretics 10.3%.

56 patients (13%) developed AKI. AKI patients had higher trough vancomycin level, 16.1±6.5 vs 13.1±5.7 (P=0.02); higher baseline Cr 1.32±1.05 vs 0.86±0.37 (P=0.02); more ICU admission (66% vs 47.5% P = 0.009), more vasopressor use (40% vs19.9%, P=0.009).

Higher vancomycin trough levels were associated with AKI incidence.



In multivariate regression analysis Vancomycin trough level remained an independent predictor for AKI (**Table 1**). After adjusting for NSAIDs, ACEI/ARBs, diuretics and aminoglycoside use, Vancomycin remained associated with AKI. (OR=1.06, 95% CI 1.01-1.10, p=0.01).

Table1. Predictors of AKI.

Variable	Odds Ratio (95% CI)	P value
Vancomycin trough level (mg/l)	1.05 (1.002, 1.10)	0.03
Hypotension	1.45 (1.12, 2.08)	0.01
CHF	1.08 (0.76, 1.63)	0.67
Baseline serum creatinine (mg/dl)	2.54 (1.47, 4.62)	0.001
HTN	1.14 (0.89, 1.66)	0.41
DM	0.94 (0.69, 1.37)	0.74

Longer duration was associated with a higher incidence of AKI (P=0.02), after adjusting all potential confounding factors.

Conclusions: High dosage and long-duration vancomycin use is an independent risk factor for AKI.

PUB009

Longitudinal Changes in Biomarkers Associated with Acute Kidney Injury in Rats Treated with Doxorubicin or Cisplatin for 15 Days Ryan M. Fryer, Suzanne Nodop Mazurek, James D. Smith, Rong Rhonda Chen, Akalushi C. Muthukumarana, Amy Hudak, Anthony Mineo, Kathleen A. Lincoln, Franklin D. Pack, Paul Harrison, Jonathan Phillips. *Boehringer-Ingelheim Pharmaceuticals Inc.*

Background: Numerous biomarkers of AKI have been proposed in pre-clinical research and some validated for clinical use.

Methods: We report temporal changes in functional and tissue-injury urinary biomarkers of AKI in rats treated weekly for 15D with doxorubicin (5 or 10 mg/kg i.v.) with confirmed renal pathology; the 10 mg/kg group was sacrificed at D11.

Results: Creatinine clearance (CrCL; D7, D15) was unaffected at D7 but was reduced at D15 (5 mg/kg). Albuminuria (mg Alb/Cr) was first detected on D4 at 10 mg/kg (0.29 *vs.* 0.02 in veh); at 5 mg/kg the onset of albuminuria was delayed (D7; 0.49 *vs.* 0.02) and peaked at D15 (34.79 *vs.* 0.03). Other functional biomarkers, including total protein, β_2 microglobulin, Cystatin C, and RBP4 generally increased in parallel with, but not before, that of albumin. Tissue-injury leakage biomarkers such as β-NAG increased on D7 at 10 mg/kg (0.09 *vs.* 0.05) and peaked at D11 (0.25 *vs.* 0.02) whereas values were not increased until D15 at 5 mg/kg (0.12 *vs.* 0.05); RPA-1 increased in both groups immediately before study-end. However, other putative leakage biomarkers including GST-α and GST-μ were unaffected; urinary LDH, γGT, ALP, and ALT were also unaffected although urinary AST increased in parallel with that of β-NAG. As expected, tissue-injury response biomarkers including clusterin and NGAL tended to increase slightly later than the functional biomarkers. Interestingly, KIM-1 increased only immediately before study-end and not to a magnitude typically observed with classic tubular toxicity.

Conclusions: Results suggest that renal damage was primarily glomerular leading to secondary protein overload in the tubules. While many of the biomarkers could be detected prior to changes in CrCL, none demonstrated the ability for earlier detection than more classically-accepted endpoints of AKI (e.g. albumin). A separate study in rats treated for 15D with Cisplatin that elicits direct tubular injury was in-progress at the time of abstract submission and will also be presented.

PUB010

The Role and Mechanism of CHOP in Inflammation Induced by Hypoxia Reoxygenation in Renal Tubular Epithelial Cells Yani He, Yuna Tong, Wei-Wei Zhang, Jurong Yang, BenGang Huo. *Department of Nephrology, Daping Hospital, the Third Military Medical University, Chongqing, China.*

Background: Inflammation is the key pathophysiology basis in the development of acute kidney injury. Our study focuses on the role and mechanism of CHOP in inflammation induced by hypoxia reoxygenation in renal tubular epithelial cells.

Methods: Rat renal tubular epithelial cells (NRK-52E) were exposed to hypoxia for 4 hours and subsequently reoxygenation for 1, 3, 6, 12 and 24 hours, respectively. LDH in culture supernatant was detected with automatic biochemistry analyzer. ELISA was adopted to evaluate the level of IL-1β. RT-PCR and Western blot were applied to detect the expression of GRP78, CHOP, caspase-11, caspase-1 and IL-1β. Double immunofluorescent staining was performed to study the expression of CHOP and caspase-11.

Results: LDH leakage and the expression of IL-1β in culture supernatant were increased after H/R. H/R induced the expression of mRNAs and proteins of GRP78, CHOP, caspase-11, caspase-1 and IL-1β. Immunofluorescent study showed that most CHOP nuclear positive NRK-52E cells were co-stained with caspase-11 positive in cytoplasm. LDH, IL-1β in supernatant and caspase-11, active caspase-1, active IL-1β were decreased after knockdown of CHOP in NRK-52E cells by siRNA at H/R12h.

Conclusions: Our results indicated that H/R can activate ERS and CHOP to amplify inflammation cascade in renal tubular epithelial cells. CHOP-caspase pathway may regulate IL-1β activation in H/R induced inflammation in renal tubular epithelial cells, which may be an important mechanism of acute ischemic renal injury.

PUB011

Preconsultation Evaluation and Outcome in Acute Kidney Injury Patients

Naing L. Htike, Adeel A. Siddiqui, Geoffrey S. Teehan, Robert L. Benz. *Nephrology, Lankenau Medical Center and LIMR, Wynnewood, PA.*

Background: Upon renal consultation for Acute Kidney Injury (AKI), diagnostic data such as urine creatinine/lytes and urinalyses (UA) are often not available. We compared outcomes among those who did or did not have preconsult urine dx'ic studies (UDS).

Methods: Six month retrospective cohort study of AKI in a community teaching hospital. We defined AKI as creatinine >/= 0.3 mg/dl vs. baseline. Those with at least UA performed were Grp 1, and those without UA were Grp 2. Fisher's Exact Test and T-Test were employed.

Results: 116 patient charts were reviewed (Grp 1: N = 67, Grp 2: N = 49). The groups did not differ with respect to overall comorbidities (P = NS). There was a higher likelihood of having a full set of UDS in Grp 1 vs. Grp 2 (P = 0.001). Twice as many patients had renal imaging in Grp 1 (28%) vs. Grp 2 (14%) (P = 0.11). At least a doubling of baseline serum creatinine occurred in 41% of the cohort (48% in Grp 1 vs. 33% Grp 2) (P = 0.13). Death and the need for renal replacement therapy (RRT) occured more in Grp 1 (3% vs. 0% and 6% vs. 2%) but did not reach statistical significance (P = 0.5, 0.39). Returned to baseline creatinine was similar between groups (P = 0.62).

Characteristics and Outcomes

N = 116	Grp 1 (UA); n=67 (58%)	Grp 2 (non-UA); n=49 (42%)
Age (yr)	26-97	41-97
Female	31 (46%)	24 (49%)
Hispanic	0	2 (4%)
White	30 (45%)	23 (47%)
Black	37 (55%)	23 (45%)
CKD	47 (70%)	41 (84%)
HTN	61 (91%)	45 (92%)
DM	31 (46%)	28 (57%)
CAD	20 (30%)	30 (61%)
Primary called nephrologist	34 (51%)	15 (32%)
ICU	12 (18%)	10 (20%)
FeUr/ FeNa	36 (54%)	0
Renal Imaging	19 (28%)	7 (14%)
Cr doubled fr. Bl	32 (48%)	16 (33%)
ATN	16 (24%)	9 (18%)
RRT	4 (6%)	1 (2%)
Death	2 (3%)	0
Discharge Cr (P = 0.84)		
At Bl	14 (21%)	10 (20%)
<0.3mg/dl above Bl	24 (36%)	22 (45%)

Cr = Serum Creatinine; Bl = Baseline

Conclusions: While we support obtaining UDS prior to renal consultation, this study of 116 patients could not support the hypothesis that such studies preconsultation resulted in improved outcome vs. obtaining them upon consultation. We are unaware of evidence based studies showing otherwise. A larger study is indicated to verify whether preconsult UDS, while empirically making sense, actually alters outcomes.

PUB012

Acute Kidney Injury in Sepsis Is More Influenced by Shock, Than by Sepsis

Karin Janssen van Doorn,[1] Hilde Jansens,[2] Vanessa De Wit,[3] Philippe Jorens.[4] *[1]Nephrol-Hypert, Univ Hosp Antwerp; [2]Microbiology, Univ Hosp Antwerp; [3]i-ICT, Biomina, Univ Hosp Antwerp, Univ of Antwerp; [4]ICU, Univ Hosp Antwerp, Edegem, Belgium.*

Background: AKI can be defined by the RIFLE-classification with 3 different severity stages: Risk (R), Injury (I) or Failure (F). In this retrospective single centre study we looked for the influence of sepsis and hemodynamic instability on the evolution of AKI and the need for hemodialysis (HD).

Methods: For a 19 mo period, 82 pts with blood-cultures positive for pathogenic bacteria were evaluated. AKI was assessed starting from 1 day before blood-cultures were taken, until the end of the ICU stay. Pts with pre-existing renal failure were excluded. Pts were divided in the groups with stage R, I or F. The influence of the duration of (severe) hypotension (mean blood pressure <65 mmHg regardless of vasopressor necessity or dose) was evaluated on the evolution for AKI. Pts were evaluated for demographic and infectious parameters; SAPS 3 was used as predictor of the disease severity.

Results: Equal age, gender and diabetes distribution was present in the groups with or without HD. Infectious parameters were not significantly different. Pts requiring HD were sicker (higher SAPS score), needed higher doses of vasopressors and had a higher mortality rate.

Characteristics (mean)	HD	No-HD	P value HD vs No-HD
Number (n)	33	49	
Outcome (mortality)	78.8%	34.7%	<0.0001*
Days in ICU since positive blood culture	7.5	1	=0.0125*
SAPS 3-score	66.6	57.4	=0.0055*
Cumulative vasopressor load (y/day)	17.7	2.44	<0.0001*

*p<0.05 is considered significant

Multiple regression showed the influence of the hemodynamic parameters on the tendency to develop stage R, I or F. Within each stage the duration of hypotension was highly predictive for the occurrence of AKI (p=0,01 for stage I, p<0001 for stage R and F).

Conclusions: Critically ill pts with AKI due to sepsis have a worse outcome when they need HD. In pts requiring HD, a significantly higher percentage also needed vasopressors. The increasing need for vasopressors and the duration of hypotension (septic shock) are, besides changes in serum creatinine and/or changes in urinary output (RIFLE criteria), important as determinants for stage R and F.

PUB013

Metformin Reduces Renal Proximal Tubule Epithelial Cell Detachment Due to Ischemia by Maintaining Actin Stress Fiber Structure

Justin Sean Johnson,[2] Simon J. Atkinson.[1, 2] *[1]Dept of Biology, Indiana University Purdue University Indianapolis, Indianapolis, IN; [2]Dept of Biochemistry and Molecular Biology, Indiana University School of Medicine, Indianapolis, IN.*

Background: Interruption of bloodflow to the kidney can cause ischemic damage, potentially including detachment of proximal tubule epithelial cells from the basement membrane, which leads to loss of resorptive surface area as well as tubule obstruction. Prior studies of drugs for preventing ischemic damage have focused on inflammation, but it is possible that preventing cell detachment may also provide effective protection. Metformin is a safe, inexpensive and widely used diabetes drug that we have found enhances *in vitro* renal epithelial cell attachment during ischemia.

Methods: Cultured murine S3 proximal tubule epithelial cells were used for all experiments. A previously established *in vitro* protocol of nucleotide triphosphate depletion ("depletion") was used to simulate ischemia. Cells were placed in glucose-free media and treated with Antimycin A, an inhibitor of oxidative phosphorylation, for 30 minutes. Metformin treatment was 1 uM concentration for four hours prior to depletion. Detached cells were counted with a hemocytometer. Total protein was measured using bicinchoninic acid assay. Phosphonucleotide ratios were calculated using high-performance liquid chromatography. Cell structures were examined via confocal microscopy.

Results: Cells treated with metformin prior to depletion had no significant difference in phosphonucleotide ratios from depleted control cells. Metformin-treated renal epithelial cells had higher protein concentration than depleted controls, and fewer detached cells were counted in cultures treated with metformin prior to depletion. When visualized microscopically, individual metformin-treated cells showed more basal F-actin than untreated control cells, although the F-actin did not have the appearance of normal stress fibers.

Conclusions: Metformin enables individual renal epithelial cells to remain attached to substrate during depletion by enabling individual epithelial cells to retain basal F-actin structures, unlike cells that are not treated with metformin.

Differentiation, Division and Proliferation of Cultured Mesenchymal Stem Cells under Acute Kidney Injury Microenvironment

Nanmei Liu, Weiwei Wang, Jinyuan Zhang. *Division of Nephrology, Jimin Hospital, Shanghai, China.*

Background: To establish acute kidney ischemia-reperfusion(I/R) injury model of mice, make kidney homogenate with renal cortex, culture mouse mesenchymal stem cells(mMSCs) with kidney homogenate,observe mMSCs' differentiation and replication.

Methods: To make acute kidney injury(AKI) mice models by clamping bilateral renal pedicles 30 minutes and reopening 30 minutes. Then immediately drew both renal cortex to make I/R kidney homogenate supernatant. C57BL/6 mice's mMSCs had been successfully isolated by Percoll density gradient centrifugation and adherence cultivation, surface markers were identified by flow cytometry. Then P3-mMSCs were treated with different group: Control group(low glucose DMEM medium with 10% fetal bovine serum);Intervention group(low glucose DMEM medium with 10% fetal bovine serum plus I/R kidney homogenate supernatant).Each group was incubated for 1d,3d,5d,7d. Use inverted microscope to observe morphological changes of these cells, ultrastructure changes were observed by transmission electron microscope. Cytokeratin-18 was detected by flow cytometry.Proliferation of mMSCs was detected by CCK-8, apoptosis was detected by TUNEL.

Results: The cells that we got highly expressed CD29,CD44,lowly expressed CD34,CD45.Compared with the control group, the cells of intervention group present oval shape, short fusiform on the third day, round shape, oval shape, short-pang fusiform on the seventh day. At the same time, it appeared much rough endoplasmic, lysosome, mitochondria.There was trace expression of CK18 in control group, after intervention of

I/R kidney homogenate supernatant,the expression rate increased significantly. The I/R kidney homogenate supernatant could alleviate the proliferation ability of mMSCs, while the apoptoic percentage increased significantly(P<0.01).

Conclusions: The simulation AKI microenvironment can induce mMSCs partially to transfer to renal tubular epithelial-shaping cells. But this kind of microenvironment can also make mMSCs' apoptosis, weaken their proliferation ability, as a result, decreased the number of mMSCs that can transdifferentiation.It may be that renal repair ability of MSCs'transplantation is limited.

PUB015

Hypokalemia in Adult Patients with Acute Kidney Injury Due to Severe Leptospirosis: Association with Patient Characteristics and Case-Fatality Rate Marcelo Lopes,[1] Daniela Lopes,[1] Antonio Alberto Lopes.[2] *[1]Escola Paulista de Medicina, Universidade Federal de São Paulo, São Paulo, SP, Brazil; [2]Núcleo de Epidemiologia Clínica e Medicina Baseada em Evidências, Universidade Federal da Bahia, Salvador, BA, Brazil.*

Background: The acute kidney injury due to leptospirosis is characterized by a predisposition to hypokalemia presumably due to an inhibition of Na, K-ATPase activity in proximal tubule. The study investigated patient characteristics associated with hypokalemia, i.e., serum potassium (sK) <3.5 mEq/L, and associations of hypokalemia with the case-fatality rate of leptospirosis.

Methods: A prospective study of 253 patients hospitalized with leptospirosis. All patients reached ≥26 points in the WHO probability score for leptospirosis and had a positive macroscopic agglutination test or a microscopic agglutination test (MAT) for leptospirosis. Results of serum potassium (sK) and other laboratory exams were obtained at admission.

Results: Mean age was 35.5±13.4 yr, 89.7% males, all patients were icteric. The distribution by sK concentration was 64.4% for <3.5 mEq/L, 34.8% for 3.5-5.5 mEq/L and 0.8% for >5.5 mEq/L. Compared with sK ≥3.5 mEqL, patients with sK <3.5 mEq/L had significanly (P<0.05) lower means of age (32.37±11.38 vs 38.10±14.47 yr), serum creatinine (4.14±1.77 vs 4.96±2.42 mg/dL), serum urea (167.40±97.23 vs 202.56±129.76 mg/dL) and serum sodium (132.59±5.95 vs 134.94±6.23 mEq/L) The frequency of non-oliguric (urinary output≥500 ml/dia) patients was 85.5% for sK <3.5 mEq/L and 72.2% for sK ≥3.5 mEq/L (P=0.021). The case fatality rate of leptospirosis was 4.5% in patients with sK<3.5 mEq/L and 12.2% with sK≥3.5 mEq/L (P=0.046). The association between sK and case fatality rate was virtually eliminated after logistic regression adjustment for age, renal function and urinary output by (odds ratio=0.80; P=0.768).

Conclusions: More than half of leptospirosis patients had hypokalemia (sK <3.5 mEqL). Results indicate that leptospirosis patients with hypokalemia are more often younger and non-oliguric. The case fatality rate of leptospirosis was lower for patients with sK<3.5 mEq/L, a finding explained by the younger age, better renal function and higher urinary output.

PUB016

AMPK Signaling in Wound Healing of High Glucose Treated Renal Proximal Tubular Cells Jianping Peng, Zheng Dong. *Department of Cellular Biology and Anatomy, Georgia Health Sciences University and Charlie Norwood VA Medical Center, Augusta, GA.*

Background: Recovery from acute kidney injury (AKI) is harder and slower in the patients with chronic kidney diseases including diabetic nephropathy, leading to higher risk of progression to end stage renal disease and higher mortality. We hypothesize that the diminished recovery is related to impaired wound healing capacity in kidney tissues of these patients.

Methods: We used a scratch wound healing model to examine the effect of high glucose in cultured renal proximal tubular cells. The cells were cultured for two weeks in media with 5.5 mM glucose, 30 mM glucose, or 30 mM mannitol, followed by scratch wounding.

Results: It was shown that wound healing was significantly slower in high glucose conditioned cells. To explore the signaling pathway, we initially focused on AMPK signaling pathway. It was shown that phosphorylated AMPK (p-AMPK) was significantly higher in high glucose conditioned cells. Following scratch wounding, p-AMPK increased in both low and high glucose cells. Pharmacologic activation of AMPK with metformin inhibited wound healing in low glucose and mannitol treated cells, but the inhibitory effect was markedly lower in high glucose RPTC cells.

Conclusions: These results suggest that up-regulation of AMPK signaling may contribute to the defective wound healing in high glucose treated renal cells and hyperglycemic tissues.

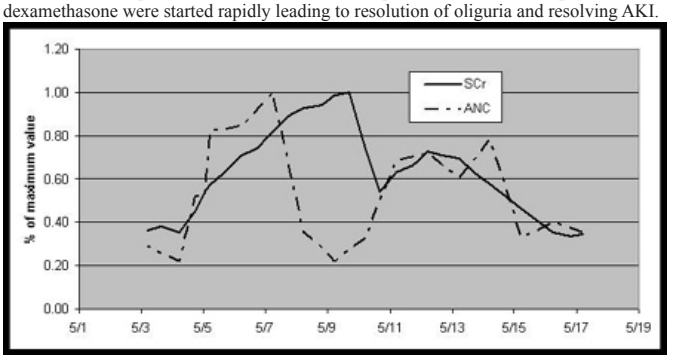
PUB017

Acute Kidney Injury Associated with Retinoic Acid Syndrome Jason Prosek, Udayan Y. Bhatt. *Division of Nephrology, Ohio State University, Columbus, OH.*

Background: Acute promyelocytic leukemia (APL), a variant of AML, has a high rate of mortality. Untreated, survival is less than one month. Treatment with all-trans-retinoic acid (ATRA) and arsenic trioxide (ATO) induces a complete remission in 85% of cases. These agents therapeutically induce a sudden increase in differentiated myelocytes and neutrophils. This rapid maturation is accompanied by increased expression of Cathepsin G, the adhesion molecule LFA-1, and in growth factors IL-1b, TNF-a, and IL-6. This pro-inflammatory environment may result in retinoic acid syndrome (RAS). This potentially fatal complication occurs in approximately 25% of patients receiving ATRA/ATO. Clinical findings include capillary leak, pulmonary infiltrates, hypotension and fever. It is typically treated with dexamethasone. Renal involvement with RAS has not been fully described. We describe a patient whose first manifestation of RAS was AKI in the absence of hypotension and responded quickly with steroid therapy.

Results: The patient is an elderly female who began ATRA/ATO for APL. She developed oliguria with AKI and coarse granular casts on the fifth day of ATO therapy which coincided with a rapid increase in her absolute neutrophil count (ANC). Therapeutic doses of dexamethasone were started rapidly leading to resolution of oliguria and resolving AKI.



Conclusions: We previously described AKI complicating bone marrow engraftment. This is believed to be related to tubulitis during the pro-inflammatory period. Also, RAS has been described to include organ infiltration with newly maturated leukocytes. Similarly, the AKI in this report presented as oliguric ATN following a rise in ANC and resolved with dexamethasone treatment. We hypothesize that direct tubulitis from neutrophil migration and cytokine release into the renal parenchyma may be an important cause of reversible AKI during RAS, supporting the need for prompt therapy.

PUB018

Polymyxin: Renewed Antibiotic and the Old Nephrotoxicity Maria De Fatima Vattimo,[1] Cassiane Dezoti Fonseca,[1] Mirian Watanabe,[1] Fernanda Teixeira Borges.[2] *[1]School of Nursing, University of Sao Paulo, SP, Brazil; [2]Nephrology Division, Federal University of Sao Paulo, Sao Paulo, SP, Brazil.*

Background: Polymyxin (Pmx) is a polypeptide cationic antibiotic with activity against multidrug resistant gram-negative bacteria and it re-emerged in clinical practice to be used in immunessupressed patients. Its nephrotoxicity consists of direct damage to the renal tubules, with the consequent release of reactive oxygen species (ROS) and inflammatory processes. The present study investigated the renoprotective effect of heme oxygenase -1 (HO-1) against toxicity caused by PmxB in rats.

Methods: Adult male Wistar rats, 250-300g, were submitted to the following treatments: Control, PmxB (rats that received 40,000 U/kg/day PmxB, i.p., for 5 successive days); PmxB preconditioning rats received HO-inducer or HO-inhibitor. Renal function (Jaffe method), urinary peroxides (FOX-2), renal tissue thiols, catalase activity, urinary TBARS and renal tissue histology (interstitial area fraction, IAF)were analyzed in vivo.

Results:

Table1: Renal function, oxidative profile and IAF.

Group (n)	crCl/100g (ml/min)	UP (nmol/g Creatinine)	Thiols (nmol / mg total protein)	CA (noml/ H2O2 / mg total protein)	TBARS (nmol/g creatinine)	IAF (%)
Control (6)	0.70±0.08	5.0±1.3	28.9±6.1	5.6±1.2	34.4±12.0	7.5±0.5
PmxB	0.30±0.33a	35.6±9.9a	15.7±1.3	1.2±0.4	98.1±35.7a	10,0±1.0a
PmxB+Hemin (6)	0.50±0.10ab	10.7±2.0b	28.0±11.9	3.4±1.0	46.6±7.9b	8.7±0.5
PmxB+ZnPP (6)	0.28±0.14ac	24.4±12.5ac	21.0±9.4	1.4±0.3	60.0±22.6b	10.4±1,.a

Results are reported as the mean ± standard deviation. a p < 0.05 vs Control. b p < 0.05 vs PmxB. c p < 0.05 vs PmxB + Hemin.

Conclusions: The disturbances in renal function, oxidative stress, tubular necrosis confirmed the nephrotoxicity of PmxB. The protective antioxidant role of the heme oxygenase inducer contributed to the amelioration of renal function and histology after PmxB treatment, suggesting that the heme oxigenase system can be involved in this model of acute kidney injury.

PUB019

Clinical Characteristics and Risk Factors of Acute Kidney Injury in Patients with Acute Alcohol Intoxication Yu-Seon Yun,[1] Hyun Gyung Kim,[2] Young Ok Kim,[1] Jihan Yu.[1] *[1]Nephrology, Uijeongbu St. Mary's Hospital, Geumo-dong, Uijeongbu-si, Gyeonggi-do, Korea; [2]Nephrology, Seoul St. Mary's Hospital, Banpo-dong, Seocho-gu, Seoul, Korea.*

Background: Acute alcohol intoxication (AAI) causes various complications such as electrolyte imbalance, alcoholic ketoacidosis (AKA), rhabdomyolysis, and acute kidney injury (AKI). This study was performed to evaluate the clinical course and prognostic factors of patients with AKI due to AAI.

Methods: We retrospectively evaluated the medical records of 371 patients with AAI between January 2004 and May 2010 in our institute. We investigated the incidence and clinical courses of AKI and compared the clinical findings, laboratory results, morbidity and mortality rate between AKI and normal kidney function (NKF) groups.

Results: Of the total 371 patients with AAI, AKI occurred in 107 patients (28.8%). The peak serum creatinine level in AKI was 2.9±1.9 mg/dL. Thirteen of the 107 patients (12.1%) received renal replacement therapy. AKI group had higher incidence of decreased mentality (29.0% vs 16.3%, p=0.006), dyspnea (11.2% vs 1.9%, p=0.029), and hypotension (66.0% vs 41.7%, p<0.001), and lower incidence of gastrointestinal bleeding (22.4% vs 34.8%, p=0.019), compared to NKF group. The AKI group also had higher incidence of ketoacidosis (78.5% vs 28.8%, p<0.001), rhabdomyolysis (19.6% vs 4.2%, p<0.001), and pneumonia (22.4% vs 8.0%, p<0.001), and the independent risk factors of AKI were ketoacidosis (OR 4.484, 95% CI 1.498-13.416, p=0.007) and increased serum osmolality (OR 3.792, 95% CI 1.280-11.232, p=0.016). The length of ICU stay was longer (7.4 ± 10.8 vs 4.1 ± 6.1 days, p=0.003) and the mortality rate was higher (17.8% vs 2.3%, p<0.001) in AKI group. multivariate analysis confirmed that AKI, increased serum CPK level and pulmonary edema were independent predictors of mortality.

Conclusions: This study demonstrated that incidence of AKI in patients with AAI was 28.8%, and the independent risk factors of AKI were ketoacidosis and increased serum osmolality. AKI was associated with high morbidity and mortality, so in patients with AAI, early aggressive management is needed to prevent AKI in high risk patients.

PUB020

The Influence of Age on the Effect of Dietary Supplementation with Reduced Glutathione (GSH) on GSH Levels in Mitochondria from Rat Kidney Cortex and Medulla

Marianna J. Zamlauski-Tucker, William C. Lorson, Bingwei Ye. *Department of Physiology & Health Science, Ball State University, Muncie, IN.*

Background: The purpose of dietary supplementation with antioxidants is to provide protection from oxidative stress inside cells by increasing the level of GSH, the principal antioxidant found in cells. A previous study reported that mitochondrial GSH levels in kidneys from old rats, but not young rats, increased following exogenous dietary supplementation with the antioxidant alpha lipoic acid. The present study was undertaken to determine whether rat age affects the influence of exogenous supplementation with GSH on cytosolic and mitochondrial GSH levels in kidney cortex and medulla.

Methods: Young (i.e., 3 months of age) and Old (i.e., 22 months of age) female Lewis rats were given GSH (250 mg/Kg body wt) via intraperitoneal injection for one week. Age-matched control rats were not given any exogenous supplementation. The kidneys were harvested at the end of the treatment period and separated into cortical and medullary sections. The sections were then further separated into cytosolic and mitochondrial fractions by differential centrifugation. GSH levels in the fractions were measured using a spectrophotometric assay. There were 4 to 6 rats in each group, and statistical comparisons between similar aged rats were done using a Student's t test.

Results: There was a significant increase in mitochondrial and cytosolic GSH levels in kidney cortex and medulla from both Young and Old rats.

		Young			Old	
		Control	Experimental		Control	Experimental
Cytosol						
umol/g kid wet wt	Cortex	5.7±0.3	8.3±0.5*		5.8±0.2	8.7±0.8*
	Medulla	3.5±0.1	6.0±0.9*		3.0±0.1	4.5±0.5*
Mitochondria						
nmol/g kid wet wt	Cortex	122±2	196±12*		139±3	164±5*
	Medulla	116±5	156±12*		141±4	155±3*

All data expressed as X +/- SEM. * significantly different from age-matched Control.

Conclusions: Age does not affect the increase in mitochondrial or cytosolic GSH levels in rat kidneys observed with exogenous dietary supplementation with GSH.

PUB021

Transfusion Related Acute Kidney Injury: Result of a Prospective Cohort Study

Ladan Zand,[1] Rodrigo Cartin-Ceba,[2] Kianoush Banaei-Kashani.[1 and 2] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Pulmonary and Critical Care, Mayo Clinic, Rochester, MN.*

Background: Acute kidney injury (AKI) occurs in up to two third of intensive care unit (ICU) patients. It has been shown that blood product transfusion increases risk of acute lung injury (TRALI). Considering strong association between ALI and AKI, we evaluated the association between transfusion and AKI in ICU patients.

Methods: We performed a retrospective analysis of a prospectively collected cohort of consecutive adults (>18 years of age) who were admitted to the ICU and received blood product transfusion from March 2004 to December 2005. We excluded those who developed AKI prior to receiving transfusion or who were on chronic hemodialysis at time of admission.

Results: A total of 127 patients met the inclusion criteria. The median age was 64 (IQR, 53-77), 65 were male (51%). A total of 49 (38%) patients developed AKI based on the AKIN criteria. In univariate analysis, there was no statistical significant difference in development of AKI based on the type of blood product that the patients received (cryoprecipitate, packed red blood cells, platelets or fresh frozen plasma). After adjustment for age, gender, baseline creatinine and presence of shock upon ICU admission, the transfusion of blood products was not independently associated with development of AKI (Odds ratio 1.06, 95% CI 0.95-1.18, p=0.25).

Conclusions: In a cohort of heterogenous group of ICU patient who received blood product transfusion, there was no increased risk of AKI as it is defined by AKIN criteria. However, this study does not rule out that subtle kidney injury might be detected with more sensitive novel biomarkers.

PUB022

Renoprotective Effects of Long Term Oral Nicotine in a Rat Model of Proteinuria

Pramod Kumar Agarwal,[1] Jacob Van den Born,[2] Harry Van Goor,[3] Gerjan Navis,[2] Reinold O.B. Gans,[1] Stephan J.L. Bakker.[1] *[1]Internal Medicine; [2]Nephrology; [3]Pathology, University Medical Center Groningen, Groningen, Netherlands.*

Background: Many proteinuric renal diseases are accompanied by renal inflammation. Reduction of inflammation might be crucial for long term preservation of renal function. Nicotine is known to have anti-inflammatory properties. A potential anti-inflammatory role of oral nicotine in proteinuric renal diseases is not known yet. Therefore we evaluated the effects of oral nicotine in a rat model of proteinuria-induced renal inflammation.

Methods: 24 wk old spontaneously proteinuric male Munich-Wistar-Fromter rats (n=40) were used. Four groups (n=10 each) were given either no (placebo), 20 (N20), 60 (N60) or 100 (N100) mg/l nicotine in drinking water, till 52 weeks of age. Body weight, blood pressure and water intake were measured weekly. Collection of blood and 24h urine were performed at baseline and monthly thereafter. At 52 weeks, histology and mRNA expression of inflammatory markers were assessed in renal tissue. ANOVA followed by Tukey post-hoc test was performed.

Results: Nicotine treatment in N60 and N100 vs placebo improved creatinine clearance (ml/min) (0.72±0.06, 0.71±0.05 vs 0.43±0.06 resp., both p<0.05) and reduced glomerulosclerosis score (scale of 0 till 400) (49±8, 54±12 vs 108±16 resp., both p<0.05). Percentage area of ED-1 positive macrophages (0.29±0.07, 0.28±0.06 vs 0.72±0.14 resp., both p<0.01) and myofibroblasts (0.68±0.19, 0.89±0.26 vs 2.1±0.60 resp., both p<0.01) were also reduced in N60 and N100 vs placebo. Nicotine treatment in N60 and N100 vs placebo furthermore reduced mRNA of MCP-1 (0.60±0.15, 0.63±0.08 vs 1.10±0.12 resp., both p<0.01) and VCAM-1 (0.66±0.12, 0.70±0.11 vs 1.10±0.16 resp., both p<0.05). Results of N20 did not differ from placebo. Other physiological parameters were similar among the groups throughout the experiment.

Conclusions: Long term oral nicotine is renoprotective by reducing renal inflammation and glomerulosclerosis in a rat model of proteinuria. We suggest to evaluate cholinergic agonists as a potential therapeutic option for treating proteinuric /inflammatory kidney diseases.

A Novel U-STAT3-Dependent Regulation of TGFβ1-Induced Renal Tubular Epithelial-Mesenchymal Transition by Chronic Nicotine Exposure

Istvan Arany,[1] Dustin Reed,[1] Samira C. Grifoni,[2] George W. Booz,[3] Luis A. Juncos.[2,4] *[1]Pediatrics, University of Mississippi Medical Center, Jackson, MS; [2]Physiology and Biophysics, University of Mississippi Medical Center, Jackson, MS; [3]Pharmacology and Toxicology, University of Mississippi Medical Center, Jackson, MS; [4]Medicine, University of Mississippi Medical Center, Jackson, MS.*

Background: Smoking-associated damage of renal proximal tubules may contribute to tubulointerstitial injury and progression to chronic renal disease. Epithelial-mesenchymal-transition (EMT) could be mediated by the tobacco smoke component nicotine (NIC). We previously found that chronic exposure to NIC exacerbates severity of acute renal ischemic injury (AKI) in mice. Since STAT3 may be involved in interstitial fibrosis we tested the hypothesis that chronic NIC may augment renal tubular EMT in a STAT3-dependent manner.

Methods: Kidneys from postischemic (24 hours) mice were analyzed for pro-fibrotic markers (αSMA, TGFβ1) and STAT3 activation. Cultured renal proximal tubule cells (LLC-PK1) were used to study effects of chronic NIC treatment as well as STAT3 activation on TGFβ1-mediated tubular EMT.

Results: Renal TGFβ1 content as well as αSMA expression were augmented in the ischemic kidneys upon chronic NIC exposure. AKI-induced tyrosine phosphorylation of STAT3 (pTyrSTAT3) was attenuated while expression of unphosphorylated STAT3 (U-STAT3) was increased by NIC exposure. TGFβ1 treatment significantly increased αSMA expression and activity of the αSMA promoter along with concomitant F-actin reorganization in LLC-PK1 cells that were further enhanced by chronic NIC pretreatment. Adenoviral infection of LLC-PK1 cells with a U-STAT3 mimetic dramatically amplified both TGFβ1- and NIC+TGFβ1-induced αSMA expression and promoter activity.

Conclusions: Our results reveal a novel, U-STAT3-dependent mechanism that mediates a sustained αSMA transcription that is related to remodeling in the kidney. Hence, chronic NIC exposure may facilitate progression of AKI to CKD by sustained upregulation of αSMA transcription via a novel U-STAT3-dependent transcriptional pathway.

PUB024

Lower Blood Pressure and Better Renal Function Despite Reduced Nephron Numbers in Caspase-3 Deficient Mice Midori Awazu,[1] Yoshifumi Yamaguchi,[2] Masayuki Miura,[2] Mariko Hida.[1] *[1]Department of Pediatrics, School of Medicine, Keio University, Tokyo, Japan; [2]Department of Genetics, Graduate School of Pharmaceutical Sciences, The University of Tokyo, Tokyo, Japan.*

Background: Pharmacological blockade of caspase-3 in organ-cultured metanephroi inhibits nephron formation and ureteric bud branching. In the present study, we examined whether caspase-3 deficiency leads to low nephron number *in vivo*, and if so, whether it results in elevated blood pressure and compromised renal function.

Methods: Homozygous caspase-3-deficient mice (Casp3-/-) were examined in comparison with heterozygous mice (Casp3+/-) and wild type mice (WT).

Results: The glomerular number, counted at 3 weeks postnatally using the acid maceration technique, was significantly reduced in Casp3-/- (n=7) compared with Casp+/- (n=8) (10127±357 vs 14174±314 per kidney). The body weight (11.1±1.1 vs 13.3±0.4 g) and kidney weight (143±13 vs 160±4 mg) were numerically lower in Casp3-/-. We next examined the consequences of low nephron number at 8 months of age. Since there was no difference between Casp+/- and WT in all parameters examined, data were combined. As shown in the Table, blood pressure measured by tail-cuff methods, urine protein/creatinine ratio, serum creatinine, and blood urea nitrogen were significantly lower in Casp3-/- compared with Casp3+/- and WT. Body weight and urine creatinine excretion were not different between the two groups.

Blood pressure and renal function

	Casp3+/- and WT (n=6)	Casp3-/- (n=4)
Blood pressure mmHg	111±1/77±2	87±7*/57±3*
Urine protein/creatinine ratio	11.4±1.7	3.0±0.8*
Serum creatinine mg/dl	0.78±0.07	0.23±0.03*
Blood urea nitrogen mg/dl	35.9±0.9	27.3±3.0*
Body weight g	29.9±0.9	28.0±1.0
Urine creatinine excretion mg/day	0.23±0.04	0.17±0.03

*, P<0.05 vs Casp+/- and WT

Conclusions: Caspase-3 deficiency reduces nephron number but prevents high blood pressure and renal function deterioration in later life. The mechanisms remain to be determined but may be related to apoptosis, cell motility, differentiation, or proliferation, functions associated with caspase-3. Superior renal function despite low nephron number indicates a possibility of a novel approach for prevention of chronic kidney disease.

PUB025

Role of Cdc42 Interacting Protein-4 in TGF-β1-Induced Epithelial-Mesenchymal Transition of Renal Proximal Tubular Epithelial Cells Shoujun Bai, Rui Zeng, Chuou Xu, Qiaodan Zhou, Gang Xu. *Division of Nephrology, Department of Internal Medicine, Tongji Hospital, Tongji Medical College, HUST, Wuhan, Hubei, China.*

Background: Cdc42 interacting protein-4 (CIP4) is a membrane-binding protein which plays a key role in cancer cell invasion. The migration and invasion of cancer cells is a process analogous to that observed during epithelial-mesenchymal transition (EMT). In kidneys, EMT promotes the pathogenesis of renal fibrosis. Thus, the role of CIP4 in EMT and renal fibrosis was explored.

Methods: Western blotting and Immunofluorescence analysis for CIP4, E-cadherin and α-SMA; Immunohistochemistry and Masson staining for Rat kidney tissue

Results: The expression of CIP4 was increased in the tubular epithelia of 5/6-nephrectomized rats and in TGF-β1 treated HK-2 cells. Endogenous CIP4 had a polarized distribution at the cell surface of HK-2 cells. After TGF-β1 treatment, the CIP4 expression was gradually increased and migrated to the cytoplasm, and simultaneously the cells was confirmed to induce EMT by morphological change, loss of E-cadherin and gain in α-SMA expression. Overexpression of CIP4 promoted similar characteristics of EMT. Using small interfering RNA (siRNA) to knockdown CIP4, we demonstrated the reversed EMT.

Conclusions: Taken together, our results indicate the importance of CIP4 as a downstream target of TGF-β1 signal in the development and progression of renal fibrosis, and thus suggest that this is a novel therapeutic target for the treatment of renal fibrosis.

PUB026

In Vitro Study To Evaluate the Effect of Fructose Induced Metabolic Syndrome and Chronic Kidney Disease on Bone Marrow Mesenchymal Stem Cells Proliferation Potential Anna Bajek,[1] Mariusz Flisinski,[2] Andrzej Brymora,[2] Arkadiusz Jundzill,[1] Pawel Strozecki,[2] Tomasz Drewa,[1,3] Jacek Manitius.[2] *[1]Tissue Engineering Department, Nicolaus Copernicus University, Bydgoszcz, Poland; [2]Nephrology, Hypertension and Internal Diseases, Nicolaus Copernicus University, Bydgoszcz, Poland; [3]Urologic Oncology, Oncology Center, Bydgoszcz, Poland.*

Background: Fructose consumption deranges many metabolic processes and contributes to development of metabolic syndrome (MS).MS and direct effect of consumed fructose modulate function of many organs and cells. The aim of study was to evaluate the high- fructose intake on proliferation capacity of Bone Marrow Mesenchymal Stem Cells (MSCs) in rats with surgically induced CKD.

Methods: Male Wistar rats were divided into groups: control (CON) (n=12) was sham-operated, CKD ½ (n=12) - uninephrectomy; CKD 5/6 (n=12) uninephrectomy plus 1/3 of contra-lateral kidney cortex mass resection. Rats received regular diet containing <3% of fructose – F3; 60% fructose diet (Harlan Teklad) – F60 or regular diet with 10% solution of fructose in drinking water – F10. After 8 weeks creatinine in serum were measured and MSCs were isolated from femur. Cells were cultivated in Dulbecco's modified essential medium supplemented with 10% of fetal bovine serum. Cultures were observed for six passages. MSCs were counted with trypan blue test.

Results: We indicate statistically significant relationship between increasing fructose content in diet and deteriorating renal function. The number of MSCs are presented as mean ± SD (x10^3) in table 1.

Table 1

Diet	F3	F10	F60	p - ANOVA
CON	39.9±6.8	22±7.8	16.2±11.5	<0,01
CKD1/2	30.2±19.5	25.5±11.2	10.1±9.8	<0,05
CKD5/6	33.3±9.6	27.2±8.4	36.5±9.5	NS
p - ANOVA	NS	NS	<0,01	

Increasing fructose consumption was associated with continuous fall of capacity of MSCs to proliferate in CON and CKD1/2. But opposite tendency was observed in CKD 5/6 fed with F60.

Conclusions: Our study suggest that high fructose intake may adversely affect proliferation capacity of MSCs in healthy and CKD rats. But further study is demanded to elucidate whether fructose affects MSCs function directly or indirectly eg.: hyperuricemia or metabolic syndrome.

Epithelial-to-Mesenchymal Transition was Induced by Indoxyl Sulfate in Rat Kidneys and Human Proximal Tubular Cells Dilinaer Bolati, Hidehisa Shimizu, Toshimitsu Niwa. *Advanced Medicine for Uremia, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Indoxyl sulfate (IS) is a uremic toxin that accelerates the progression of chronic kidney disease (CKD). Hypertension is a consequence of renal disease and one of the most important risk factors for progressive CKD. This study aimed to determine if IS induces epithelial-to-mesenchymal transition (EMT) in the kidneys of hypertensive rats, and human cultured proximal tubular cells (HK-2).

Methods: EMT was evaluated by immunohistochemistry, reverse transcription-polymerase chain reaction (RT-PCR) and immunoblotting of the epithelial makers E-cadherin and zonula occludens-1 (ZO-1), and the mesenchymal maker a-smooth muscle actin (a-SMA) in rat kidneys and HK-2 cells. The rat groups consisted of (1) Dahl salt-resistant normotensive rats (DN), (2) Dahl salt-resistant normotensive indoxyl sulfate-administered rats (DN + IS), (3) Dahl salt-sensitive hypertensive rats (DH), and (4) Dahl salt-sensitive hypertensive indoxyl sulfate-administered rats (DH + IS). HK-2 cells were incubated with or without IS (250 mM).

Results: In the kidneys, DH rats showed reduced expression of E-cadherin and ZO-1, and enhanced expression of a-SMA compared with DN rats. Further, IS-administered rats, DN+IS and DH+IS rats, showed reduced expression of E-cadherin and ZO-1, and enhanced expression of a-SMA compared with DN and DH rats, respectively. IS-treated HK-2 cells showed reduced expression of E-cadherin and ZO-1, and enhanced expression of a-SMA compared with untreated cells.

Conclusions: IS induced EMT in the kidneys of hypertensive as well as normotensive rats, and in HK-2 cells accompanied by reduced expression of E-cadherin and ZO-1, and enhanced expression of a-SMA. IS-induced EMT might be involved in the progression of CKD.

PUB028

AST-120 Ameliorates Kidney Fibrosis by Inhibiting Epithelial-to-Mesenchymal Transition in CKD Rats Dilinaer Bolati, Hidehisa Shimizu, Toshimitsu Niwa. *Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Indoxyl sulfate (IS), a uremic toxin, is a risk factor for progression of chronic kidney disease (CKD). AST-120 reduces serum IS, and delays the progression of CKD. This study aimed to examine if AST-120 inhibits epithelial-to-mesenchymal transition (EMT) in the kidneys of CKD rats.

Methods: CKD rats were produced by 5/6-nephrectomy, and divided into 2 groups: (1) CKD rats and (2) AST-120-treated CKD rats at a dose of 4 g/kg body weight/day. After 16 weeks, their kidneys were excised for histological and immunohistochemical analysis. EMT was evaluated by immunohistochemistry of zonula occludens (ZO-1), an epithelial marker, and a-smooth muscle actin (a-SMA), a mesenchymal marker. Interstitial fibrosis was evaluated by Masson's trichrome (MT) staining.

Results: CKD rats showed reduced expression of ZO-1, and enhanced expression of a-SMA as compared with normal rats. Administration of AST-120 to CKD rats increased expression of ZO-1, and decreased expression of a-SMA. Further, CKD rats showed enhanced extent of interstitial fibrosis as compared with normal rats. Administration of AST-120 to CKD rats ameliorated interstitial fibrosis.

Conclusions: AST-120 inhibited EMT, and ameliorated fibrosis in the kidneys of CKD rats.

Effect of Iron Chelator, Deferiprone, on the Progression of Chronic Kidney Disease in Mouse Model Chhanda X. Bose,[1] Neriman Gokden,[2] Sudhir V. Shah,[1] Sundararaman Swaminathan.[1] *[1]Nephrology, University of Arkansas for Medical Sciences and Central Arkansas VA Medical Center, Little Rock, AR; [2]Pathology, University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: There are no effective treatments for halting progression of chronic kidney disease (CKD). Catalytic iron capable of catalyzing free radical reactions has been implicated in tissue injury in various organ systems. We examined the effect of deferiprone, an oral iron chelator in a mouse model of CKD.

Methods: We utilized one 5/6 nephrectomy mice for our studies. After one week of 5/6 nephrectomy mice developed renal insufficiency with serum creatinine values of 0.49±0.0.02 mg/dl compared to sham operated controls (0.11±0.04). Average body weights were 25.72±0.13 g (sham) and 20.632±0.66 g (CKD). The CKD Mice were divided in to two groups with similar serum creatinine and body weights. Deferiprone was started at 125 mg/kg body weight in one group of CKD mice in drinking water and continued up to 12 weeks (n=7). Sham (n=5) and CKD groups (n=12) were given water. At 13 weeks, serum creatinine levels were significantly ($p>0.05$), lower in treated group of mice than CKD group, 0.58±0.08 and 0.38±0.025 mg/dl respectively. Histopathological changes in kidneys were evaluated and a quantitative scoring system was employed to account for histological changes. Scoring and validation was done by an expert kidney pathologist in a blinded manner. Sham operated controls showed no pathologic changes. CKD Kidneys showed interstitial fibrosis and tubular atrophy (Average score, 13.5±5.83%), interstitial inflammation (6.571±2.04%) and global sclerosis (3.875±2.08%). In contrast, these pathological changes were significantly attenuated in the kidneys of deferiprone treated mice. The average score was for interstitial fibrosis and tubular atrophy (6.66±1.1), interstitial inflammation (1) and global sclerosis (0.5±0.29).

Conclusions: Our preliminary data suggest a role of iron in the progression of CKD.

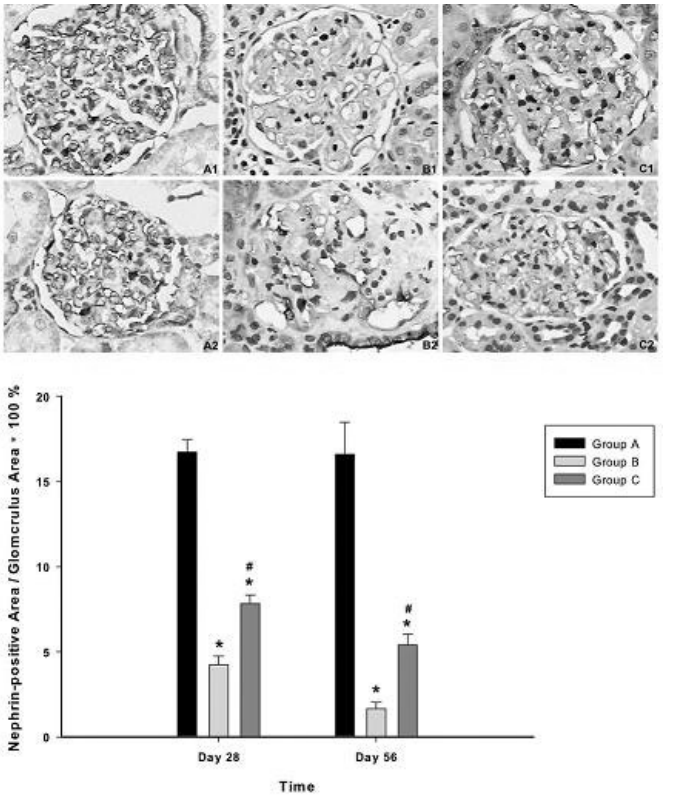
Effect of Shen-Qi-Di-Huang Decoction on Reducing Proteinuria by Preserving Nephrin in Adriamycin-Induced Nephropathy Rats Hongyu Chen,[1] Qin Zhu.[2] *[1]Department of Nephrology, Hangzhou Hospital of Traditional Chinese Medicine, Hangzhou, Zhejiang, China; [2]Department of Nephrology, Hangzhou Hospital of Traditional Chinese Medicine, Hangzhou, Zhejiang, China.*

Background: The aim of this study is to investigate the effect of Shen-qi-di-huang decoction on reducing proteinuria and to discuss the mechanism of its action in Adriamycin (ADR)-induced nephropathy rats.

Methods: The rats were randomly divided into three groups (n=12 each group): normal control (group A); ADR model control (group B); ADR + Shen-qi-di-huang decoction (group C). In group B and C, the rats were intravenously injected with ADR (6.5mg/kg). The rats in group C were orally administrated with Shen-qi-di-huang decoction after the injection of ADR. On day 7, 14, 28, 56 after ADR injection, 24h urine protein was detected. On day 28, 56 after ADR injection, ALB, ALT, serum creatinine (Scr) and BUN were examined. The morphological changes of the kidneys were observed by light microscope and electron microscope on day 28, 56 after ADR injection. The expression of nephrin was determined by immunohistochemistry and RT-PCR on day 28, 56 after ADR injection.

Results: Compared with group B, 24h urine protein and Scr decreased in group C on day 56 ($P<0.05$). The expression of nephrin determined by immunohistochemistry and RT-PCR increased in group C on day 28, 56 ($P<0.05$). The morphology observed by light microscope and electron microscope improved in group C on day 28, 56.



Conclusions: Shen-qi-di-huang decoction decreases proteinuria, protects kidney function, and ameliorates histopathology in ADR-induced rats by preserving nephrin expression.

PUB032

The Epithelial-to-Mesenchymal Transition and ECM Accumulation of Human Peritoneal Mesothelial Cell in Response to LDL and Glucose In Vitro Yanhui Fang, Limeng Chen, Xuewang Li. *Department of Nephrology, Chinese Academy of Medical Science & Peking Union Medical College Hospital, Beijing, China.*

Background: Human Peritoneal mesothelial cells(HPMCs) play an important role in fibrogenesis and vasculopathy that underlie peritoneal membrane dysfunction. New and extensively studied aspects of peritoneal mesothelial cell biology include epithelial-to-mesenchymal transition (EMT) and cellular senescence.The objective of this study was to investigate the effect of LDL on EMT and ECM accumulation in HPMCs and study the role of the LDL receptor and PPARγsignaling pathway in these processes.

Methods: After co-cultured with the LDL for 24h, the LDL receptor was observed to expression on the cell membrane of HPMCs by immuno-fluorescence method. HPMCs morphological and cytoplasm immuno-fluorescence intensity of α-SMA changes were observed after stimulated with different concentration of LDL (0, 25, 50, 100μg/ml).PPARγ mRNA and protein expression were detected by realtime-PCR and Western blot.

Results: Oil red staining results showed that LDL could be up-taken into the cells and abolished by LDL receptor blocker. The increasing expression of α-SMA mRNA and protein, lower expression of E-cadherin mRNA were showed in HG + LDL group(glucose 120mmol/l, LDL 100μg/ml). ELISA assay showed that the COL-I protein was significantly increased. The difference COL-I and FNmRNA expression was not observed with or without LDL by realtime-PCR. The plasminogen inhibitor (PAI-1) mRNA and protein level of the cell culture supernatant of HG+LDL group were significantly increased than the control.HG+LDL significantly increased the expression of PPARγ mRNA. Added different concentrations of GW9662 (5μg/ml, 10μg/ml), a kind of PPARγ ligand blocker, the effects of HG+LDL showed above were abolished partly.

Conclusions: Human peritoneal mesothelial cells could uptake LDL into cells via LDL receptor. The PPARγ signaling pathway may be play a role in these processes of HPMCs EMT and ECM accumulation induced by LDL in the context of high glucose.

PUB033

New Applications of the Mouse Electrocautery Model of Chronic Kidney Disease Raymonde Gagnon. *Internal Medicine, Division of Nephrology, McGill University Health Centre, Montreal, QC, Canada.*

Background: Arteriosclerotic vascular disease and vascular calcifications are common manifestations of chronic kidney disease (CKD) in man.

Methods: A model of CKD induced surgically in the mouse was described in 1983 (the model requires 2 surgical procedures i.e. electrocautery-induced damage to the surface of the right kidney followed by left nephrectomy 2 weeks later). The right kidney was chosen to undergo electrocautery-induced surface damage because it lies lower than the left kidney in the abdominal cavity (due to the presence of the liver) and therefore its entire surface is better visualized during the induction of the electrocautery-induced damage. Of note, this first surgical step is an essentially bloodless procedure which is another important consideration in young mice with a small blood volume. In this surgical model, the depth of the electrocautery-induced surface damage to the right kidney determines the degree of renal impairment observed following the left nephrectomy performed 2 weeks later i.e. mild, moderate or severe CKD. An interval of 2 weeks between the 2 surgical procedures is required to allow sufficient time for edema resorption and tissue regeneration to take place following the electrocautery-induced damage to the right renal parenchyma.

Results: During the initial 20 years following its description, this mouse model was used successfully in experiments conducted in genetically defined inbred mice only (usually young female mice of the C57BL/6 strain). Since the availability of knockout mice, the mouse electrocautery model of CKD has been used successfully to increase our understanding of the cellular and biochemical contributors to various serious vascular conditions observed in man with CKD i.e. arteriosclerosis and vascular calcifications.

Conclusions: It is impossible to predict at the outset the nature of the main future applications of a novel animal model. In the case of the mouse electrocautery model of CKD, the recent availability of genetically-modified mouse strains has contributed to make this animal model of CKD a prime model for research in vascular complications of CKD more than 2 decades after its original description.

PUB034

Inulin Immunoassay for Kidney Function Ernest V. Groman, Dennis E. Vaccaro, Christopher P. Reinhardt, James S. Weinberg. *BioPAL.*

Background: The absence of a widely accepted method to measure GFR in animal models, human research and clinical practice has had profoundly negative effects on developing methods and drugs for treating kidney disease, accurately assessing kidney transplant recipients and donors, calibrating drug dosing in the young and elderly, minimizing nephrotoxicity in the drug development process, and accurately assessing nephrotoxicity in the clinical setting. To correct this deficiency we have developed a sensitive, specific ELISA for inulin.

Methods: NZW rabbits were injected with inulin conjugate and responded with high titer anti-inulin antiserum. ELISA components include an inulin-coated-microtiter plate, inulin standards, inulin in sodium chloride, anti-inulin polyclonal antiserum, and HRP-goat anti-rabbit antiserum. The assay is completed in 70 minutes.

Results: Anti-inulin antiserum binds to polyfructans with a degree of polymerization greater than 4. The antibody has exquisite specificity, does not bind to fructose, glucose or glucose polymers, or other disaccharides and polysaccharides. The sensitivity of the assay is 10ng inulin/mL. The concentration required to inhibit 50% of the maximum signal is about 100ng inulin/mL. Reproducibility measurements for inulin in rat or human serum had CVs of less than 12%. Spike and recovery experiments gave recovery values between 85% and 112%. The sensitivity of the antiserum allows inulin doses 10 to 100 times lower than doses used in previously reported GFR protocols. A correlation coefficient between the inulin immunoassay and a fluorescent inulin assay in human serum of 0.98 was obtained. The high sensitivity of the anti-inulin antiserum allowed the detection of dietary inulin in human urine.

Conclusions: Inulin is widely used in foods, has beneficial effects on cancer treatment in animal models, and is the gold standard for assessing kidney function. Nutritional dogma regarding dietary inulin states that inulin is not absorbed from the gastrointestinal tract into blood; all dietary inulin is quantitatively eliminated in the feces. Demonstration that this dogma is not true may have significant implications for nephrology, gastroenterology, cancer therapy, nutritional studies, and food chemistry.

PUB035

Microarray Analysis of Gene Expression Profiles in Rat Kidney Fibroblasts Exposed to Advanced Lycation End Products Xuezhu Li,[1] Shougang Zhuang,[1,2] Haidong Yan.[1] *[1]Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai; [2]Department of Medicine, Brown University School of Medicine, Providence, RI.*

Background: Diabetic nephropathy (DN) is the most important cause of end-stage renal disease worldwide, and renal interstitial fibroblasts play a critical role in the development of diabetic nephropathy. Although advanced glycation end products (AGEs) have been showed to contribute to renal fibroblast activation and proliferation, mechanisms involved remain incompletely understood.

Methods: In this study, we examined the profile of gene expression in normal rat kidney fibroblast (NRK-49F) cells exposed to AGEs, and assessed the effect of ginkgo biloba extract (EGb), an antioxidant, on this response by using microarray analysis. Biological functions of the differentially expressed genes were analyzed using Gene Ontology (GO), and the up-regulated or down-regulated genes were further validated using real time-PCR.

Results: Compared with non-treated NRK-49F cells, 61 genes were up-regulated and 67 genes were down-regulated in cells exposed to AGEs. GO analysis showed that these differentially expressed genes were primarily related to the regulation of the biosynthetic and protein kinase activity, cell proliferation, gene transcription, cell cycle, apoptosis as well as cellular response to reactive oxygen species. Treatment with EGb dramatically altered expression of some genes including transforming growth factor-beta1, monocyte chemotactic protein-1, angiopoietin-1, superoxidase dismutase, matrix Gla protein, G protein-coupled receptor and inhibitor protein-kappa B. The real time-PCR results were consistent with the results obtained using gene chip analysis. AGEs exposure resulted in changes of multiple genes in NRK-49F cells, and EGb treatment altered the profile of gene expression.

Conclusions: These results lay the groundwork for further identification of novel molecules involved in the pathogenesis of diabetic nephropathy and elucidation of mechanisms of anti-fibrotic therapies in DN and other fibrotic kidney diseases.

Use of ACEI/ARB in Diabetic Patients with Late Stage Chronic Kidney Disease (CKD) Reduces the Risk for Mortality and Progression to Dialysis Jia-Sin Liu,[1] Ta-Wei Hsu,[2] Yu-Kang Chang,[1] Chih-Cheng Hsu,[1] Der-Cherng Tarng.[3] *[1]Institute of Population Health Sciences, NHRI, Miaoli County, Taiwan; [2]Division of Nephrology, Department of Internal Medicine, National Yang-Ming University Hospital, Yilan, Taiwan; [3]Department and Institute of Physiology, National Yang-Ming University, Taipei, Taiwan.*

Background: Whether the use of ACEI/ARB in diabetic patients with late stage CKD could reduce the risk for ESRD and/or mortality, since this issue lock of population-based evidence.

Methods: We conducted a nationwide, prospective cohort study in Taiwan using the national insurance database. There were 10,619 diabetic patients with CKD and the eGFR less than 12 ml/min/1.73m^2 at the beginning of the study in 2000-2005. All patients never staring dialysis before the recruitment were followed up until December 31, 2007. Cox proportional hazards model was applied to analyze the risk for progression to dialysis and/or death.

Results: The cohort had mean age of 65 years, 51% of female, 91% of hypertension prevalence. The median follow-up period was 4 years. In the first 2 years of follow up, 60% and more of the patients progressed to ESRD necessitating dialysis therapy. After adjustment for age, gender and hypertension, ACEI/ARB nonuser had higher risk for progression to dialysis and/or death than ACEI/ARB user with a hazard ratio of 1.26 (95% CI: 1.21-1.31, P <0.001).

PUB037

Glomerular and Interstitial Injury and Effect of Losartan (L) Treatment in Adenine-Induced Chronic Kidney Disease (CKD) Cristiene Okabe, Denise M. Malheiros, Flavia G. Machado, Simone R. Costa, Camilla Fanelli, Claudia R. Sena, Grasiela P. Barlette, Vivian L. Viana, Niels O.S. Camara, Roberto Zatz, Clarice K. Fujihara. *Univ Sao Paulo.*

Background: Chronic oral adenine (ADE) promotes interstitial (INT) inflammation due to tubular obstruction, being used as a model of CKD. We investigated whether ADE-induced CKD: 1. still progresses after ADE is discontinued. 2. responds to treatment with L, known to ameliorate CKD progression.

Methods: Adult male Munich-Wistar rats received ADE in the chow, at 0.75% for 1 week, then at 0.53% for 2 weeks. Two weeks after ADE was ceased, tail-cuff pressure (TCP, mmHg), albuminuria (ALB, mg/d), serum creatinine (S_{cr}, mg/dL), glomerular volume (V_G, x 10^6 μm^3), % glomerular luminal area (%Lum), tubulointerstitial macrophage density (MØ, cells/mm^2, and % cortical INT (%INT) were measured in 5 rats, used as pretreatment controls (Group ADE_{prc}). The remaining rats were divided into groups ADE+V, untreated, and ADE+L, receiving oral L, 50 mg/kg/d, and followed for an additional 3 months. Age-matched normal controls (C) were also studied. Results (Mean±SE, ^{a}p<0.05 vs. C, ^{b}p<0.05 vs. ADE_{prc}, ^{c}p<0.05 vs. ADE):

Results:

	TCP	ALB	S_{cr}	V_G	%Lum	MØ	%INT
C	136±1	5±1	0.6±0.1	0.96±0.1	28.6±1.9	18±2	1±1
ADE_{pre}	145±4	4±1	1.4±0.1[a]	0.58±0.1[a]	27.8±2.1	196±18[a]	29±1[a]
ADE+V	194±3[ab]	14±5[ab]	1.3±0.2[a]	0.60±0.1[a]	21.3±1.0[ab]	179±33[a]	19±2[ab]
ADE+L	139±3[c]	4±1[c]	1.2±0.1[a]	0.54±0.1[a]	23.9±1.1	214±22[a]	18±3[ab]

Group ADEpre showed marked S_{cr} elevation, along with INT expansion and MØ infiltration. Although glomerulosclerosis was not observed, V_G was markedly reduced. Three months later, ALB and hypertension were associated with persistence of glomerular hypotrophy, now with partial loop collapse. INT expansion, but not MØ, regressed, in all likelihood due to partial release of tubular obstruction, suggested by a linear correlation between %INT and the number of crystals. L treatment normalized TCP and ALB, but failed to ameliorate any of the structural abnormalities.

Conclusions: ADE-induced INT expansion is only partially reversible after ADE cessation, while other parameters of renal injury persist, responding poorly to L. Further studies will clarify the injurious mechanisms involved in this model.

Renal Parenchymal Thickness and Maximum Interpolar Diameter in Ultrasound Investigation of Patients with Chronic Kidney Disease Roberto Palumbo,[1] Annalisa Noce,[2] Fulvio Fiorini,[3] Olga Durante,[2] Nicola Di Daniele.[2] *[1]Nephrolgy and Dialysis Unit, S. Eugenio Hospital, Rome, Italy; [2]Internal Medicine Department, Tor Vergata University, Rome, Italy; [3]Nephrology and Dialysis Unit, S. Maria della Misericordia Hospital, Rovigo, Italy.*

Background: To investigate the relationship between renal dimensions on US, i.e. renal parenchymal thickness (PT) and maximum interpolar diameter (MD) and GFR in chronic kidney disease.

Methods: Four-hundred seventy–one Caucasian subjects (235 males and 236 females, aged 60.54±9.80 years) with no history of nephropathy were investigated. An Esaote MyLab 70 X-vision gold (Esaote spa, Genoa, Italy) US system with a multi-frequence 2,5-5MHz curved-array transducer was used. Serum creatinine was dosed 30 days before and after US, with no variation between the two determinations. GFR was calculated in all subjects by Cockroft-Gault (CG), MDRD and CKD-EPI formulas, separately. According to GFR subjects were stratified into 1). controls (GFR>90ml/min/m^2, 111 subjects); 2). CKD St. II (GFR 60-90ml/min/m^2, 180 patients); 3). CKD St. III (GFR <60ml/min/m^2, 180 patients).

Results: There was no relationship between serum creatinine and renal MD or PT either in controls and in CKD patients. Conversely, there was a significant difference in renal PT among controls compared to CKD St. II and III patients ($p<0.0001$). Also, there was a significant difference in renal PT among CKD ST. II patients compared to CKD St. III (16,53±1,28 vs. 15,23±1,23mm, $p<0,0001$). A renal PT ≤15mm is always significantly related to a reduced GFR regardless the formula employed.

Conclusions: Our results suggest that renal PT rather than MD may be related to GFR in CKD patients.

PUB039

Impact of High-Fructose Feeding on Pancreatic Islets Insulin Secretion in Experimental Model of Chronic Kidney Disease (CKD) in Rats Marta Pokrywczynska,[1,] Arkadiusz Jundzill,[1,5] Mariusz Flisinski,[4] Andrzej Brymora,[4] Aleksander Deptula,[2] Magdalena Bodnar,[3] Tomasz Kloskowski,[1] Sandra Krzyzanowska,[1] Pawel Strozecki,[4] Andrzej Marszalek,[3] Eugenia Gospodarek,[2] Tomasz Drewa,[1] Jacek Manitius.[4] *[1]Tissue Engineering Department, Nicolaus Copernicus University, Bydgoszcz, Poland; [2]Microbiology, Nicolaus Copernicus University, Bydgoszcz, Poland; [3]Clinical Pathomorphology, Nicolaus Copernicus University, Bydgoszcz, Poland; [4]Nephrology, Hypertension and Internal Diseases, Nicolaus Copernicus University, Bydgoszcz, Poland; [5]General, Vascular and Endocrinology Surgery, Nicolaus Copernicus University, Bygoszcz, Poland.*

Background: The aim of the study was to evaluate the impact of fructose intake on insulin islets *in vitro* secretion in rats with CKD

Methods: Rats were divided into groups (each n=12): CON was sham-operated, CKD½ - uninephrectomy; CKD5/6 uninephrectomy + 1/3 of contraletral kidney cortex mass resection. Animals from each groups were further assigned to 3 different diets protocol: regular diet (RD), RD with 10% solution of fructose in drinking water - F10, 60% fructose diet – F60. After 8 weeks glucose, insulin and creatinine were measured. The pancreas islets were evaluated in *in vitro* static glucose insulin stimulation test (IST). Pancreatic tissue was stained for collagen formation.

Results: Glucose did not differ significantly between groups. Serum insulin and IST test are presented in table 1.

	CON	CKD1/2	CKD5/6	P
Diet	Insulin[ng/ml]	Insulin[ng/ml]	Insulin[ng/ml]	
RD	4,07±1,86	4,02±1,99	4,81±1,83	NS
F10	4,61±1,5	6,0±1,73	6,89±1,15	NS
F60	5,59±0,75	5,03±2,05	3,48±2,01	< 0,05
P	NS	NS	< 0,01	
	IST	IST	IST	
RD	0,63±0,33	0,19±0,07	3,89±4,73	NS
F10	0,46±0,17	1,80±2,11	4,76±3,15	<0,05
F60	2,24±3,08	1,46±1,78	0,98±1,18	NS
P	NS	NS	NS	

Mean±SD

These results confirmed that 10% fructose could stimulate while 60% fructose down-regulate pancreas islet insulin *in vitro* secretion in CKD rats. Extensive collagen formation was observed in CKD 5/6 and F60 group.

Conclusions: Our results suggest that overfiding with fructose may tremendous influence on insulin in vitro secretion in very advanced CKD but clinical meaning of this finding need further study.

HIV Enhances Tubular Cell Angiotensinogen Expression and Angiotensin II Production through Phosphorylation of p66ShcA Divya Salhan,[1] Himanshu Vashistha,[2] Shabina Rehman,[1] Mohammad Husain,[1] Ashwani Malhotra,[1] Leonard G. Meggs,[2] Pravin C. Singhal.[1] *[1]Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY; [2]Medicine, Ochsner Clinic, New Orleans, LA.*

Background: Renin angiotensin system (RAS) has been demonstrated to play an important role in the development of HIV-associated nephropathy (HIVAN). Moreover, modalities which either inhibit the production or block the effect of Ang II have been demonstrated to retard the progresson of HIVAN. We recently demonstrated that HIV also enhances phosphorylation of p66ShcA in kidney cells (J BC 284:16648-58, 2009). We hypothesized that HIV would enhance renal cell angiotensin (Ang) II production through phsophorylation of p66ShcA.

Methods: To have an in vitro model of tubular cell HIV infection, human tubular cells (HK2) were transduced with either vector only or HIV (NL4-3) constructs. Vector/HK2s and HIV/HK2s were incubated in serum-free media (SFM) for 24 hours and lysates were prepared for protein electrophoresis. Western studies were conducted for protein expression for phospho-p66ShcA, total p66ShcA, and angiotensinogen (Agt). Ang II ELISA was carried out on cells prepared under similar conditions. To establish a causal relationship between Agt and p66ShcA, EV/HK2s and HIV/HK2s were transduced with mu36-p66ShcA and then evaluated for Agt expression. Similarly, p66ShcA silenced tubualr cells (siRNA-p66ShcA/HK2s) were assayed for Agt expression.

Results: HIV/HK2s displayed 2.5 fold increased ($P<0.01$) expression of Agt when compared with EV/HK2s. Similarly, HIV/HK2 showed 3-fold increased ($P<0.01$) Ang II production when compared to EV/HK2s. HIV/HK2s also displayed increased ($P<0.01$) expression of phospho-p66ShcA vs EV/HK2s. On the other hand, mu36-p66ShcA transduced HK2s showed diminished expression of Agt. Similarly, si-RNA-p66ShcA/HK2 showed diminished Agt expression.

Conclusions: These findings indicated HIV-induced phosphorylation of p66ShcA promotes RAS activation in tubular cells. The present study provides an insight into the RAS activation in HIVAN patients.

HIV-Associated Nephropathy: Role of Angiotensin Type 2 Receptor (AT_2R) Divya Salhan,[1] Rungwasee Rattanavich,[1] Subani Maheshwari,[1] Madhuri Adabala,[1] Mohammad Husain,[1] Ashwani Malhotra,[1] Guohua Ding,[2] Praveen N. Chander,[3] Pravin C. Singhal.[1] *[1]Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY; [2]Medicine, Renmin Hospital of Wuhan University, Wuhan, Hubei, China; [3]Pathology, New York Medical College, Valhalla, NY.*

Background: Activation of AT_1R and AT_2R contributes to opposite outcomes in several kidney disease models. AT_1R has been demonstrated to play a role in the progression of HIV-associated nephropathy (HIVAN). We evaluated the role of AT_2R in a mouse model of HIVAN (Tg26).

Methods: Age and sex matched control (FVB/N) and Tg26 mice aged 4, 8, and 16 weeks (n=4) were studied for renal tissue expression of AT1R and AT2R (Protocol A). In protocol B, 4 weeks old Tg26 mice were treated with either saline, telmisartan (TEL, TAT1 blocker), PD123319 (PD, AT_2R blocker), or TEL + PD for two weeks. Renal tissues and cells were evaluated or renal molecular and biomarkers.

Results: Renal tissue expression of AT2R was lower in Tg26 mice when compared with control mice. Eight weeks old Tg26 mice displayed HIVAN phenotype in the form glomerulosclerosis and formation of microcysts. TEL-receiving Tg26 (TRTg) displayed less advanced glomerular and tubular lesions when compared with saline-receiving Tg26 (SRTg). Although renal tissues of SRTgs displayed diminished expression of both AT_1R and

AT_2R when compared with saline-receiving FVB/N mice (SRF), but diminution in AT_2R expression was more pronounced. On the other hand, TRTgs displayed enhanced renal tissue AT_2R expression. Diminution of renal tissue AT_2R expression was associated with advanced renal lesions in SRTgs; whereas, upregulation of AT_2R expression in TRTgs was associated with attenuated renal lesions. PD-receiving Tg 26 mice (PDRTg) did not show any alteration in the course of HIVAN; whereas, PD + TEL-receiving Tg26 (PD-TRTg) showed worsening of renal lesions when compared with TRTgs. Interestingly, plasma as well as renal tissues of Tg26 mice displayed enhanced expression of Ang III, a metabolite of Ang II and a ligand of AT_2R.

Conclusions: These findings suggest that in TRTgs, besides AT_1R blockade, enhanced renal tissue AT_2R expression might have contributed to slowed progression of HIVAN.

Novel Experimental Model of CKD with Uremia in Mice: Involvement of Inflammatory Mechanisms

Alexandre Santana,[1] Humberto Dellê,[1] Cleonice Silva,[1] Sergio Catanozi,[2] Sabrina Degaspari,[3] Cristoforo Scavone,[3] Paula Blanco,[4] Irene L. Noronha,[1] Kim Solez.[4] *[1]Nephrology, Univ Sao Paulo, Brazil; [2]Lipids, Univ Sao Paulo, Brazil; [3]Pharmacology, Univ Sao Paulo, Brazil; [4]Pathology, Univ Alberta, Canada.*

Background: Dietary adenine leads to the accumulation of 2.8-dihydroxyadenine in the kidney and causes progressive renal dysfunction that resembles stage CKD with uremic manifestations. Here, we developed this model of CKD in mice and analyzed the role of inflammatory mechanisms using thalidomide (Thalid) as an anti-inflammatory drug.

Methods: CKD was induced in C57/BL-6 mice (n=48) by adenine-containing diet for 6 weeks. Mice were divided into 3 groups: **Control**, receiving normal diet, **Adenine**, receiving adenine to develop CKD, and **Adenine+Thalid**, Adenine mice treated with Thalid. The following parameters were analyzed: biochemical, histological, and IL-1β, TNF-α, IL-6 serum and kidney mRNA levels (real time PCR).

Results: Adenine-fed mice developed CKD and resulted in significantly higher serum urea and creatinine levels compared with controls. Histological analyses showed dilated tubules, loss of tubular epithelial cells, crystalline deposits in tubular lumens, cortical scarring, and macrophage infiltration ($Mac\text{-}2^+$) in the renal tissue of Adenine mice. A significant increase of serum and relative mRNA levels of IL-1β, TNF-α and IL-6 was observed in mice with CKD. Thalidomide treatment significantly reduced all these parameters.

Parameters	Control	Adenine	Adenine+Thalid
Urea(mg/dl)	46.0±3.3	287±10.2#	102±3.9#*
Creatinine(mg/dl)	0.34±0.0	0.87±0.03#	0.50±0.03#*
Serum IL-1β(pg/ml)	13.2±5.1	57.8±23.5#	7.2±3.0#*
Serum TNF-α(pg/ml)	0.8±0.1	21.9±8.0#	1.3±0.5#*
Serum IL-6(pg/ml)	14.0±4.3	145.8±19.7#	4.8±2.7#*
$Mac\text{-}2^+$(cells/mm^2)	1.28±0.4	228.1±5.2#	104.7±6.4#*
IL-1β(mRNA level)	1.0±0.2	16.4±0.7#	5.0±0.7#*
TNF-α(mRNA level)	1.0±0.3	24.2±0.8#	15.8±0.3#*
IL-6(mRNA level)	1.0±0.7	24.7±1.0#	9.0±0.5#*

#p<0.05 vs Control; *p<0.05 vs Adenine

Conclusions: Dietary adenine caused advanced CKD in mice, providing a useful experimental model to study changes associated with uremia. Although crystalline precipitates in tubular lumens are a major change observed in this model, inflammatory mediated mechanisms play an important role.

PUB044

Intra-Renal Angiotensin System Activation, Oxidative Stress, Inflammation and Impaired Nrf2 Activity in the Progression of Focal Glomerulosclerosis

Tadashi Sato,[1] Nosratola D. Vaziri.[2] *[1]Pediatrics, N.H.O. Ureshino Medical Center, Ureshino-City, Saga, Japan; [2]Medicine, Physiology and Biophysics Division of Nephrology and Hypertension Schools of Medicine & Biological Sciences University of California, Irvine, CA; [3]Universitario, Universidad del Zulia and Instituto de Investigaciones Biomédicas, Maracaibo, Venezuela.*

Background: The Imai rat is a model of spontaneous focal glomerulosclerosis (FGS) which leads to heavy proteinuria, hyperlipidemia and progressive renal failure. Treatment with AT-1 blockers (ARB) ameliorates proteinuria, hyperlipidemia, and nephropathy in this model. We hypothesized that progressive nephropathy in the Imai rat is accompanied by oxidative stress, inflammation and impaired activity of the nuclear factor-erythroid-2-related factor 2 (Nrf2), the master regulator of genes encoding antioxidant molecules activation and that amelioration of nephropathy with AT1 receptor blockade in this model may be associated with the reversal of these abnormalities.

Methods: Ten week-old Imai rats were randomized to the ARB-treated (olmesartan, 10 mg/kg/day) or vehicle-treated groups. Sprague-Dawley rats served as controls.

Results: At 34 weeks of age Imai rats showed heavy proteinuria, glomerulosclerosis and tubulointerstitial inflammation, increased number of angiotensin II expressing cells and AT1 and AT2 receptor expression, up regulation of NAD(P)H oxidase and inflammatory mediators, activation of nuclear factor kappa B (NF-kB) and reduction of Nrf2 activity and expression of its downstream gene products in the renal cortex. ARB therapy prevented nephropathy, suppressed oxidative stress and inflammation and restored Nrf2 activation and expression of the antioxidant enzymes.

Conclusions: These abnormalities are accompanied by activation of intra-renal angiotensin system and can be prevented by ARB administration.

PUB045

Is Decrease Rate in ANCA Titer a Predictor of the Inopportunity Infection?

Oonishi Takahiro. *Nephrology, Yamada Red Cross Hospital, Ise, Mie, Japan.*

Background: Without therpy renal vasuculitis in ANCA vasculitides will usually progress end-stage renal disease. The toxicity of high corticosteroid doses and immunosuppressive agent has been accepted to achieve this aim. Consequently elderly patients have a higher rate of severe infection and infective death. We found that some patients who had immunosuppresion treatment occurred infection disease, their ANCA titer was rapidly decrease .we hypothesized that ANCA titer is used to the incident of infectious disease.

Methods: We evaluated 10 (male:11 female:9 mean age:73.8) MPO-ANCA-associated vasculitis presenting with rapidly progressive glomerulonephritis undergoing steroid and immunosuppressive agent therapy in 2008-2010. We measured ANCA titers before treatment and after 2 months later.

We calculated the ANCA decrease rate. We defined rapidly decrease ANCA titers group (RD-ANCA) that more than 90% reduction in ANCA titers between before and after 2 months. And we examined in RD-ANCA group (n= 10) and non-RD group (n=10) about Creatinine, hemogulobin,infectous disease event and death.

Results: RD group are no difference in age, ANCA titer. albumin,and Hb. However significant difference in Cr (4.25mg/dl vs 2.38mg/dal, p =0.005) between RD group and NRD group. 3 patients had pnumonia due to cytomegalovirus and 2 patients died. They were all RD group.

Conclusions: In our study, Rapidly decrease ANCA titer might be related to opportunity infection disease. Their renal function were decreased before immunosuppuresive therapy. We suggest that ANCA titer is not only RPGN acitivity but also immune compromised condition.

PUB046

Inhibition of Obesity-Related Lomerulopathy by Grape Seed Roanthocyanidin Extract

Jinhua Tang,[1] Shougang Zhuang,[1,2] Haidong Yan.[1] *[1]Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China; [2]Department of Medicine, Brown University School of Medicine, Providence, RI.*

Background: Obesity-related glomerulopathy (ORG) is increasingly a cause of end-stage renal disease, and there is no effective treatment. It has been reported that oxidative stress may play a primary role in the pathogenesis of ORG. and grape seed proanthocyanidin extract (GSPE), an antioxidant agent, provides superior antioxidant efficacy. However, the therapeutic effect of GSPE on ORG has not yet been investigated.

Methods: In this study, we examined the effect of GSPE on ORG and explored mechanisms involved in a rat model of ORG. A rat model of ORG was established by feeding adult Sprague-Dawley (SD) rats with high-fat diet for 24 weeks. GSPE (200mg/kg) was then given daily for 12 weeks. Serum biochemical and oxidation indexes, urinary protein, renal pathology, and expression of UCP2, a candidate gene of obesity, were assessed.

Results: Our results showed that the body weight, body mass index, and 24-hour urinary protein were increased in rats with ORG. Administration of GSPE significantly reduced those parameters. Rats with ORG had increased serum cholesterol and low-density lipoprotein cholesterol (LDL-C) and decreased HDL-C. GSPE treatment reversed these responses. Compared with normal control group, there were increased serum levels of oxidant MD and decreased antioxidant enzyme, GSH-Px, in ORG group. GSPE treatment resulted in an increase in GSH-Px and decrease in serum oxidant malondialdehyde. Pathological analysis showed obesity-associated glomerulomegaly and increased mesangial matrix and glomerular sclerosis in rats with ORG. All those pathological changes were attenuated in animal subjected to GSPE treatment. Further, renal gene expression of mitochondrial uncoupling protein-2 (UCP2) was increased in rats with ORG and declined after GESP treatment.

Conclusions: These data indicate that development of ORG is associated with increased oxidative stress. Antioxidant GSPE supplementation can prevent obesity, ameliorate renal damage and reduce proteinuria. Thus, GSPE holds a therapeutic potential for treatment of ORG.

Erythropoietin Inhibited Complement 3-Mediated Renal Tubular Epithelial to Mesenchymal Transition

Jian-Xin Wan, Feng-Xia Zhang. *Nephrology, First Affiliated Hospital of Fujian Medical University, Fuzhou, China.*

Background: Our previous research had suggested that complement 3 (C3) involved in renal tubular epithelial to mesenchymal transition (EMT). Sun showed erythropoietin (EPO) could decrease renal fibrosis in mice with ureteral obstruction through inhibiting TGF-β induced EMT. This study should investigate EPO inhibit C3-mediatiated renal tubular EMT.

Methods: HK-2 cells were cultured respectively as follows: Control group, 10U/ml EPO group, 3ng/ml TGF-β1 group, 3ng/ml TGF-β1 + 10U/ml EPO group, 0.1μM C3a group and 10U/ml EPO + 0.1μM C3a group. Expressions of α-SMA, E-cadherin and C3 mRNA and protein of HK-2 cells was respectively detected by RT-PCR, western blot and cell immunofluorescence. And then model of UUO rats was established. Experimental animals were randomly divided into four groups: Control group (sham operation group), UUO group, UUO rats treated with low-dosage EPO (100U/Kg EPO) and with high-dosage EPO (1000U/Kg EPO). EPO was injected in intraperitoneal every other day from 3th to 14th day after estibilished UUO. All experimental rats were executed after anesthesia in

the 14th day after estibilished UUO. Morphological changes of renal tissue by HE stain, collagen deposition by Masson trichrome stain, expressions of α-SMA, E-cadherin and C3 by immunohistochemical stain were observed.

Results: The expression of α-SMA mRNA and protein had increased, the expression of E-cadherin mRNA and protein had decreased, the expression of complement 3 had increased after HK-2 cells stimulating with C3a or TGFβ1. After HK-2 cells stimulating with C3a or TGFβ1 combining with EPO, the expressions of α-SMA, E-cadherin and C3 mRNA and protein had occurred conspicuous changing (P<0.05). The expressions of α-SMA of UUO rats was significantly increased, and the expression of E-cadherin of UUO rats was significantly reduced. Simultaneously expressions of C3 of UUO rats was significantly reduced. After UUO rats treated with EPO, the expressions of α-SMA was significantly reduced, and the expression of E-cadherin was significantly increased. and the expressions of C3 was significantly increased.

Conclusions: EPO can inhibit C3-mediated renal tubular epithelial to mesenchymal transition.

PUB048

Generation of a Renal Fibroblast Cell Line To Study Modulation of Mineralocorticoid Receptor Hong Wang, Cheng-Kon Shih, Steven S. Pullen. *Cardiometabolic Diseases Research, Boehringer Ingelheim Parmaceuticals, Ridegfield, CT.*

Background: The renal protection provided by mineralocorticoid receptor (MR) antagonists has been ascribed to the blockage pro-inflammatory and pro-fibrotic genes in non-epithelial cells in the kidney. The NRK49F rat cell line is derived from kidney tubular fibroblasts and thus represents a renal non-epithelial cell type which is potentially suitable for in vitro studies. However, these cells were not responsive to aldosterone at physiological concentrations in preliminary studies, suggesting a lack of MR expression which was confirmed by RT-PCR quantification.

Methods: Cloned NRK49F cell lines stably expressing rat MR were generated for cellular studies. Expression was confirmed by RT-PCR quantification. A panel of genes previously described to be regulated by MR including PAI-1, Col1a1, Col4a1, OPN, and ORM-1 were quantified to characterize the response of the stable cell lines to aldosterone. Subsequently, the effect of the MR antagonist Spironolactore on the response of the cells was determined.

Results: Of the genes studied, ORM-1 was the most highly regulated in response to aldosterone. Using cell lines that express different levels of MR, it was demonstrated that the level of ORM-1 induction by aldosterone correlated with MR expression. Aldosterone induced ORM-1 expression was demonstrated to be inhibited by spironolactone in a dose responsive manner.

Conclusions: An aldosterone responsive, stably transfected rat kidney fibroblast cell line was generated and characterized. This cell line will be useful for further studies to investigate the effect of MR antagonism in fibroblast cells.

Prolonged Hypertension and Renal Impairment in Old Age of Neonatally Overfed Rats Hyung Eun Yim, Kee Hwan Yoo, Seong Woo Nam, In Sun Bae, Joo Won Lee. *Pediatrics, Korea University Medical Center, Seoul, Republic of Korea.*

Background: Neonatal growth plays a key role in "developmentally programmed" adult diseases. The objective was to evaluate the long-term influence of early postnatal overnutrition on the renal pathophysiological changes in aging rats.

Methods: Three or 10 male pups per mother were assigned to either the small litter (SL) or normal litter (NL) control groups during the first 21 days of life. The effects of early postnatal nutrition excess on body weight, blood pressure, blood glucose, and renal changes were determined at 12 months.

Results: Pups in the SL group weighed more than controls between 4 days and 6 months of age ($P < 0.05$). However, there was no difference of body weights between the two groups at 12 months. In the SL group, at 12 months of age, systolic blood pressure levels were higher than those of the controls ($P < 0.05$). The numbers of ED-1 positive macrophages and cortical apoptotic cells increased in the SL group ($P < 0.05$). The index scores for glomerulosclerosis and tubulointerstitial fibrosis were also increased in the SL group ($P < 0.05$). Immunoblotting and immunohistochemistry showed that intra-renal renin expression was decreased in the SL group ($P < 0.05$). However, angiotensin II type 1 receptor (AT1), AT2, matrix metalloproteinase-9, plasminogen activator inhibitor-1, tumor necrosis factor-α, and osteopontin expressions were unaffected in the SL group.

Conclusions: Our data suggests that early postnatal overfeeding increases systolic blood pressure, cortical macrophage infiltration and apoptosis, glomerulosclerosis, and tubulointerstitial fibrosis and suppresses intra-renal renin in aging male rats. Early postnatal overnutrition even following an appropriate birth weight can have long-term renal sequelae in late adulthood.

PUB050

Cell Surface Biliverdin Reductase Help To Sustain E-Cadherin Expression Level in Proximal Renal Tubular Cell Rui Zeng, Guangchang Pei, Qiaodan Zhou, Min Han, Gang Xu. *Division of Nephrology, Department of Internal Medicine, Tongji Hospital, Tongji Medical College,HUST, Wuhan, Hubei, China.*

Background: Biliverdin reductase(BVR) was solely considered as a reductase that catalyzes biliverdin to bilirudin. Recent studies reveal that BVR functions as a serine/threonine/tyrosine kinase, a transcription factor, or an antioxidant. BVR can be induced by reactive oxygen species(ROS) and was identified to have PKB/Akt-like activity.

Methods: We detected expression of BVR,HIF1α,E-cadherin,CD34,P-AKT,Snail expression in a 5/6 nephrectomized rats model and renal biopsy specimens from patients with sclerosing glomerulonephritis or obstructive nephropathy. Nomal kidney tiusse and uninjured areas of pathologic specimens were used as control. We also examined the BVR expression in HKC and NRK52E cell in normoxic and hypoxia conditions.

Results: In normoxic renal sections of rats or human beings, BVR expressed cell surface of tight junction and basolateral membrane of proximal renal tubular cell, the expression of HIF1α,P-AKT,Snail tubules in normal rats was bare. In fibrotic kidney from either rats or human beings, along with a discrease of CD34 and E-cadherin and an increase of HIF1α, P-AKT,Snail, BVR is located in cytoplasm and nuclear in the renal epithelia, and the distribution patterns of HIF1α and BVR were highly congruent in the renal tubules on serial sections. The phenomenon of BVR transferred from cell surface to cytoplasm and nuclear was also confirmed in cell line. In hypoxia conditions, BVR which transferred into nuclear activated AKT and Snail,then reduced the expression of E-cadherin.When BVR in cytoplasm and nuclear was downreglated by SiRNA, E-cadherin restored to a level near to the normoxic condition.

Conclusions: Our findings suggest that BVR on cell surface play a role in sustaining E-cadherin expression level in proximal renal tubular cell.

PUB051

Conditional Knockout of E-Cadherin in Renal Proximal Tubular Epithelial Cells Aggravates Kidney Fibrosis in Murine Model of Unilateral Ureteral Obstruction (UUO) Guoping Zheng,[1] So Ra Lee,[1] Jianlin Zhang,[1] Tim Tzu-Ting Hsu,[1] Thian Kui Tan,[1] Ye Zhao,[1] David A.F. Loebel,[2] Isabelle Rubera,[3] Michel Tauc,[3] Ya Wang,[1] Qi Cao,[1] Yiping Wang,[1] Patrick P.l. Tam,[2] David C. Harris.[1] *[1]Centre for Transplantation and Renal Research, Westmead Millennium Institute, University of Sydney, Australia; [2]Children's Medical Research Institute, Australia; [3]University of Nice-Sophia Antipolis, France.*

Background: Epithelial-mesenchymal transition (EMT) has been proven to play an important role in kidney fibrosis. E-cadherin was found not only to be a cell adhesion molecule, but may also be involved actively in signal transduction in EMT. Our previous study showed that disruption of E-cadherin by MMPs caused EMT where E-cadherin passes on extra-cellular signals to nucleus through β-catenin and slug in murine models of kidney fibrosis. This study is to examine the critical role of E-cadherin in renal tubular EMT using a novel conditional knockout of E-cadherin in mouse proximal tubular epithelial cells (PTEC).

Methods: Conditional knockout of E-cadherin in PTEC was generated by crossing cdh1flox/flox mice sequentially with CMV Cre, Sglt2Cre mice and then backcrossed to cdh1flox/flox mice. UUO was performed to the knockout and control mice. Primary culture of PTEC from knockout mice was treated with TGF-β1 (3ng/ml) to examine the role of E-cadherin in EMT in vitro.

Results: Depletion of E-cadherin in PTEC did not result in histological changes to proximal tubules under light-microscope. However, an upregulation of α3 integrin was found in PTEC.There were no significant changes to other adhesion molecules such as ZO-1. Kidney fibrosis after UUO was worse in conditional knockout mice compared to control mice demonstrated by Gomori Trichrome and Sirius red staining, and by immunohistological staining of α-SMA. EMT was significantly up-regulated in proximal tubular cells from E-cadherin conditional knockout mice compared to control.

Conclusions: Conditional depletion of E-cadherin in proximal tubule does not directly cause kidney fibrosis, but aggravates kidney fibrosis in mouse UUO model, likely through increased level of α3 integrin and EMT in PTEC upon stimulation.

PUB052

Uric Acid Induces Renal Inflammation Via Activating Tubular NF-kB Signaling Pathway Yang Zhou, Chunsun Dai, Junwei Yang. *Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical University, Nanjing, Jiangsu, China.*

Background: Renal Inflammation is a pathologic feature of hyperuricemia in clinical settings. However, the underlying mechanisms remain unknown.

Results: Here, we found a significantly increased T cells and macrophages infiltration in kidneys from mice with hyperuricemia. This increased inflammatory cell infiltration was accompanied by upregulated kidney TNF-a, MCP-1 and RANTES expression. Immunohistochemical staining showed that the induction of RANTES was primarily localized to tubular epithelial cells, suggesting that tubular cells may play a role in uric acid-induced renal inflammation. Evidences of uric acid-induced NF-kB signaling activation were obtained *in vivo*. In cultured rat renal tubular epithelial cells (NRK-52E), uric acid treatment could induce TNF-a, MCP-1 and RANTES mRNA as well as RANTES protein

expression. Moreover, uric acid-induced TNF-a, MCP-1 and RANTES expression were largely abolished by a specific NF-kB signaling inhibitor, SN 50.

Conclusions: Taken together, these results suggest that tubular cell NF-kB signaling activation may play an important role in uric acid-induced renal inflammation.

PUB053

Diabetes and High Protein Concentrations Alter Nrf2 Phosphorylation in Renal Tubule Cells Michelle T. Barati, Susan M. Isaacs, Jon B. Klein. *Nephrology, University of Louisville, KY.*

Background: Renal tubule cell exposure to high glucose and protein concentrations in diabetes increases formation of reactive oxygen species (ROS). A cellular mechanism to alleviate oxidative stress is activation of the transcription factor, nuclear factor erythroid-derived 2-related factor 2 (Nrf2). Nrf2 expression increases in glomeruli of diabetic patients and diabetic rat kidneys, suggesting a compensatory response to oxidative stress, yet the effect of diabetes on Nrf2 in tubules is not clear. The goal of this study was to define Nrf2 regulation in cortical renal tubules of diabetic mice and proximal tubule cells exposed to high protein concentrations.

Methods: Cortical tubules were isolated from 3 and 7 month old OVE26 diabetic and FVB non-diabetic mice and Nrf2 expression analyzed by immunoblotting (IB). Phospho-Ser40 Nrf2 (P-Nrf2) was analyzed by immunohistochemistry of mouse kidney sections with image analysis of cortical regions. Serine 40 Nrf2 phosphorylation occurs during its activation and nuclear import. For *in vitro* studies, proximal tubules cells (HK2) were treated with 1mg/ml human serum albumin (HSA) for various time points and cell extracts fractionated to determine total and P-Nrf2 in the cytosol and nuclei by IB.

Results: Total Nrf2 expression was not different between isolated tubules of 3 and 7 month old diabetic and non-diabetic mice. Nuclear P-Nrf2 was decreased in cortical tubules of 7 month old mice compared to 3 month old mice within the same group. Furthermore, cortical tubules of 7 month old diabetic mice had less nuclear P-Nrf2 compared to age-matched non-diabetic mice. HSA increased P-Nrf2 and Nrf2 nuclear import in HK2 cells, suggesting activation.

Conclusions: Together, decreased P-Nrf2 in cortical tubules of older mice with unaltered Nrf2 protein expression suggests dysregulation of this compensatory mechanism with age. Additional attenuation of this system in the older diabetic mice may be a mechanism to exacerbate oxidative stress. The ability of HK2 cells to activate Nrf2 following HSA exposure alone, suggests that additional factors in the diabetic milieu may be responsible for decreased nuclear Nrf2 localization in tubules of older diabetic mice.

Diabetic Nephropathy in FVB/NJ Akita Mice: Temporal Pattern of Kidney Injury and Urinary Nephrin Excretion Jae-Hyung Chang,[1] Susan B. Gurley,[2] Robert F. Spurney.[2] *[1]Duke University, Durham, NC; [2]Duke University and Durham VAMC, Durham, NC.*

Background: Glomerular podocytes are terminally differentiated cells with little potential for proliferation. As a result, a sufficient loss of podocytes may lead to instability of the glomerular tuft and glomerulosclerosis. Increasing evidence suggests that a decrease in the number of glomerular podocytes is a characteristic feature of both animals and humans with diabetic kidney disease. Early detection of podocyte injury before podocyte loss might permit intensification of medical therapies to delay or prevent diabetic nephropathy (DN). In this regard, the podocyte protein nephrin can be detected in urine of both animals and patients with diabetes mellitus, perhaps reflecting early podocyte damage. In the present study, we investigated the relationship between hyperglycemia, podocyte number and apoptosis, albuminuria and urinary nephrin excretion during the course of renal disease in a genetic model of type 1 diabetes (FVB/NJ Akita mice).

Methods: Akita mice have phenotypic characteristics useful for studying the mechanisms of DN in humans including sustained hyperglycemia, progressive albuminuria and mesangial matrix expansion. The goal of this study was to examine the role of urinary nephrin excretion as an early marker of diabetic kidney injury.

Results: In 4-week old male Akita mice, the onset of hyperglycemia was accompanied by increased podocyte apoptosis and enhanced excretion of nephrin in urine before the development of albuminuria. After 4 weeks of age, Akita mice developed albuminuria, which increased progressively over time. By 20 weeks of age, Akita mice developed a 10-fold increase in albuminuria and a decrease in the number of glomerular podocytes. Urinary nephrin excretion was also significantly increased at 16 and 20 weeks of age and correlated with the urinary albumin excretion rate.

Conclusions: In summary, enhanced urinary nephrin excretion was associated with podocyte apoptosis in normoalbuminuric 4-week old diabetic mice as well as increased albuminuria in older diabetic animals. These data suggest that urinary nephrin excretion may be a useful marker of early glomerular injury in diabetes mellitus.

Astragalus Modulates Advanced Glycation End Products-Induced Microinflammation of Macrophage Yong Gu,[1,2] Qiaojing Qin,[1] Jianying Niu.[1] *[1]Division of Nephrology, Fifth People's Hospital of Shanghai, Fudan University, Shanghai, China; [2]Division of Nephrology, Huashan Hospital, Fudan University, Shanghai, China.*

Background: Microinflammation induced by advanced glycation end products (AGEs)-activated macrophages is a cardinal mechanism in diabetic nephropathy(DN). Adverse effects from immunosuppressant limit immunosuppressive therapy apply for microflammation in DN. Astragalus is an herb and possess bidirectional immunological regulation properties in many diseases. So we evaluate the effects and mechanism of astagalus on macrophage secretion of the inflammatory cytokines, IL-1β and TNF-α, in AGEs and normal vitro environment to determine the value of astragalus treatment in DN.

Methods: The viability of Ana-1 murine macrophages on treatment with various concentrations of astragalus or AGEs was evaluated by MTT method. The cells were treated with astragalus, and/or AGEs, and receptor for advanced glycation end products (RAGE) antibody, and scavenger receptor A (SR-A) antibody. The cells were pretreated with RAGE or SR-A antibody for 1h before astragalus addition and were pretreated with astragalus for 1h before AGEs addition. The protein secretion of TNF-α and IL-1β was measured by ELISA and mRNA expression by RT-PCR. The activity of nuclear factor (NF)-κB was assayed using EMSA. The expression of Phospho-P38 mitogen-activated protein kinase (MAPK) was assessed by western blotting.

Results: We not found astragalus cytotoxicity in macrophage. Astragalus increased the protein secretion and mRNA expression of IL-1β and TNF-α and suppressed the AGEs-stimulated expression of IL-1β and TNF-α in macrophage. All the effects were seemed to occur via activation or inhibition NF-κB and Phospho-P38 MAPK pathway. Additionally, RAGE or SR-A antibody did not affect the secretion of IL-1β and TNF-α induced by astragalus in macrophage significantly.

Conclusions: Base on these data, we suggested that astragalus may decrease AGEs-stimulated microinflammation in macrophage while maintaining macrophage benefit of body protection. Astragalus may be efficacious and promising remedy in the microinflammation treatment of DN. The effects of astragalus on macrophage may associate multi-targets but the special receptor.

PUB056

Chondrogenic Phenotypic Change Contribute to the Irreversible Progression of the Diabetic Nephropathy Seiji Kishi, Hideharu Abe, Tatsuya Tominaga, Kojiro Nagai, Toshio Doi. *Nephrology, Univ of Tokushima, Tokushima, Japan.*

Background: We reported that BMP4 -Smad1 signaling pathway played a critical role for mesangial expansion and phenotypic alteration in diabetic nephropathy (DN) and Sox9 was also involved in the glomerulosclerosis. We hypothesized that MCs acquire a chondrocyte-like phenotype which was mediated by BMP signaling pathway and SOX9 during glomerulosclerosis progression.

Methods: Cell Culture, Alcian blue staining or immunocytochemistry, Transient transfection of MCs, Western blotting, Histological Examination, Animals; #transgenic mouse expressing inducible nitric oxide synthase under control of insulin promoter (iNOS Tgm) #BMP4 knock-in transgenic mice(BMP4 Tgm)

Results: MCs showed chondrogenic potential in a micromass culture and BMP4 induced the expressions of chondrocyte markers (SOX9 and COL2) in MCs.

AGEs induced the expression of chondrocyte markers downstream of BMP4-Smad1 signaling pathway in MCs. In addition, hypoxia also induced the expression of BMP4, HIF1α, and chondrocyte markers. Overexpression of SOX9 caused ectopic expression of proteoglycans and COL2 in MCs.Furthermore, overexpression of Smad1 induced expressions of chondrocyte markers. Dorsomorphin inhibited these inductions.

By using iNOS Tgm which exhibited severe DN, glomerular expressions of HIF1α,BMP4, and chondrocyte markers were observed.SOX9 was partially colocalized with HIF-1 and BMP4.

BMP4 Tgm showed not only similar pathological lesions to DN, but also the induction of chondrocyte markers in the sclerotic lesions.

Conclusions: Chondrogenic potential of MCs provide new aspects in the progression of glomerular injury. BMP4-Smad1 signaling and SOX9 are candidate regulators of phenotypic change in DN. Chondrocytes are the only cells found in cartilage, an avascular and hypoxic mesenchymal tissue. Therefore, it makes sense that this transdifferentiation of MCs is an adaptation to chronic pathological hypoxia but cartilage related ECM production caused irreversible structural change. HIF-1, which are known to be upstream molecules of SOX9, also have important an influence on the phenotypic change of MC in DN.

Reduced Beta Cell Mass and Function by High Glucose Feeding in Rats Anil K. Mandal,[5812] Linda M. Hiebert.[0980] *[1]Dept of Medicine, Univ of Florida, Gainesville, FL; [2]Veterinary Biomedical Science, Univ of Saskatchewan, Saskatoon, SK, Canada.*

Background: People with high normal blood glucose double the risk of diabetes (DM). We asked; does overeating reduce beta cell (BC) mass or function, causing DM? We designed an experiment to answer the question.

Methods: Wistar rats 250 g treated with 25% glucose (G) in water for 2 weeks (wk.) (G), then tap water (W) for 2 wk. (GW), G and N insulin (I) 2-4 units s.c. daily for 2 wk. (GI), then W for 2 wk. (GIW). Control given W for 2 and 4 wk. (C). Samples for G and creatinine (cr) drawn prior to treating, and at 2 wk. for groups GW and GIW. Samples for G, cr and I drawn from abdominal aorta at end of experiment (2 wk. for C, G, GI and 4 wk. for C, GW and GIW). Islet tissue extracted from pancreas and fixed for immunohistochemical staining (IHC). IHC staining run on Bond II immunostainer using guinea pig antiswine insulin primary antibody (1:150) and biotinylated rabbit antiguinea pig secondary antibody (1:100; both DAKO). 5 slides (C, G, GW, GI, GIW, 2 sections/slide) imaged on Olympus BX61 microscope using a Q Imaging Retega 4000R color camera and Velocity software. IHC stain area measured and lighter stained BC selected using intensity segmentation. BC areas measured and results pasted to a spreadsheet where the % of BC area to whole IHC area computed. Also computed sum, mean and standard deviation of each of the 5 ratios (IHC/BC) for each slide. Serum G and cr measured by standard procedures, I measured by ELISA (Mercodia). Mean ± SEM of data in all groups analyzed.

Results: G in G group (290.52 ± 23.22 mg/dL) was higher than C (196.9 ± 29.1 mg/dL, p=0.023) and GW (203.4 ± 20.5 mg/dL, p=0.014). IHC/BC ratio mean ± SD in G (5.83 ± 1.03) and GW (6.29 ± 1.54) was higher than C (3.74 ± 0.77). IHC/BC ratio in GIW (4.26 ± 0.84) was lower than GW. Significant reduction of BC mass was noted in all treated groups compared to C. I (ug/L) was higher in both G (2.89 ± 0.72) and GI (3.95 ± 0.84) groups, compared to C but two wk. W lowered I to control levels (GW 0.24 ± 0.04, GIW 0.41 ± 0.17). No difference in cr levels among groups.

Conclusions: G feeding reduces BC mass. Study highlights that overeating may shrink BC mass and cause DM in humans.

Effectiveness and Safety of Bicarbonate in the Prevention of Contrast Induced Nephropathies in Chronic Nephropathic Diabetic Patients Undergoing to Interventional Radiology of the Lower Limbs Filippo Mariano,[1] Luca Monge,[2] Valter Verna,[3] Mario Boffano,[2] Giorgio Triolo.[1] *[1]Dpt of Medicine Area, Nephrology and Dialysis Unit, CTO Hospital, Turin, Italy; [2]Dpt of Medicine Area, Diabetology Unit, CTO Hospital, Turin, Italy; [3]Dpt of Radiology, CTO Hospital, Turin, Italy.*

Background: The risk score for contrast-induced acute nephropathy (CI-AKI) can increase up to 50% in patients with chronic nephropathy and diabetes mellitus. The purpose of this study is to evaluate the effectiveness and the tolerability of a bicarbonate protocol infusion (BPI) in chronic nephropathic diabetics submitted to interventional radiology (IR) for lower limb revascularization, by comparing the incidence of CI-AKI with the pre-procedure risk score.

Methods: 98 diabetic chronic nephropathic patients (68M/30F, age 73.4±9.7 years old (average ± SD)) were prospectively studied between January 2010 and January 2011 for lower limb revascularization. Patients were treated as prophylaxis with BPI 1.4% (1ml/Kg/hour bw for 180' pre procedure followed in post procedure of 1ml/Kg/hour bw for 6 hours) and e n-Acetilcisteina per os (600 mg 2 times a day the day before and the day of the exam). The CI-AKI has been defined with a serum creatinine increase of 0.5 mg/dl or of 25% with respect to the basal value (post procedural control at 24-48 hours) and risk score of CI-AKI was calculated according to Mehran

Results: The average eGFR of nephropathic patients stage >=2 K-DOQI and not in dialysis (n 62, formula CKD-EPI) has been of 56.1.2±16.5 in the pre procedure and 62.5.2±20.2 ml/min/1.73 m^2 in the post procedure (pre vs. post procedure p 0.003). The average volume of contrast medium has been of 96.1±30.0 ml. Face to an average global score of risk of CI-AKI of 17.6% and of dialysis of 0.5%, the real incidence of CI-AKI with BPI has been of 6.4%. No hypervolemic complications or significant electrolytic alterations were observed. In patients with advanced nephropathy (level IV-V K-DOQI) no cases of CI-AKI were registered.

Conclusions: These results indicate that the applied BPI is an effective and safe measure for CI-AKI prevention in nephropathic diabetic patients submitted to IR for lower limbs revascularization.

PUB059

Oxidative Stress in the Kidneys of the Fetus and Pre-Adolescent Offspring of Diabetic Rats Arwa Nada,[1,4] Lawrence Fordjour,[2] Charles Cai,[2] Dharmendra Kumar,[2] Morris J. Schoeneman,[1] Anil K. Mongia,[1] Bandana Paudyal,[1] Kelly Benedict,[1] Gloria Valencia,[2] Jacob Aranda,[2] Kay Beharry.[3] *[1]Department of Pediatrics, Division of Nephrology, SUNY Downstate Medical Center, Brooklyn, NY; [2]Department of Pediatrics. Division of Neonatology, SUNY Downstate Medical Center, Brooklyn, NY; [3]Department of Pediatrics. Division of Neonatology, University of California Irvine Medical Center, Orange, CA; [4]Department of Pediatrics, Division of Nephrology, Alexandria University Children's Hospoital, Alexandria, Egypt.*

Background: Oxidative stress (OS) plays an important role in the development of fetal complications of diabetic pregnancies. This role is not well studied in the kidney of embryos and offspring of diabetic mothers.

Methods: Objectives:To determine the effect of DM on OS in the kidneys of fetuses and the pre-adolescent offspring of diabetic mothers.

Results: Fetuses at embryonic age 20 (E20) and adolescent pups at postnatal age 14 (P14) were studied: 1) Non-diabetic, non-treated (E20-CTL); 2) diabetic, non-treated (E20-DNT); 3) diabetic insulin-treated (E20-DIT); 4) P14-CTL; and 5) P14-DIT. Prior to mating, DM was induced in rats using streptozocin (65 mg/kg IV). Once DM was confirmed , either insulin or placebo pellets subcutaneously were started. Markers of OS (8-isoprostane); DNA damage (OHdG); reactive oxygen species (H_2O_2); antioxidant activity (SOD, GPX, and catalase); and genes regulating OS were studied.

Results: Markers of OS had significant higher concentration in the kidney samples of E20NT group , 8-iso-PGF2a (P< 0.001), and 8-OHdG (P<0.01). E20IT group showed significant higher concentration of SOD (P<0.001). E20NT group showed upregulation of the gene expression of the antioxidative enzymes. E20IT group showed downregulation of gene expression of the antioxidative enzymes.P14-IT group showed upregulation of the gene expression of the antioxidative enzymes.

Conclusions: DM increases the oxidative stress in the kidneys of embryos and offspring of diabetic mothers. This effect extends to the postnatal period. These findings may suggest long term effect of diabetes on the kidneys of children of diabetic mothers, and their need to antioxidant therapy.

High Glucose Induces Human Glomerular Endothelial-to-Mesenchymal Transition by RhoA Activation Hui Peng, Yuanqing Li, Canming Li, Cheng Wang, Pengli Luo, Tan-Qi Lou. *Division of Nephrology, Department of Internal Medicine, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China.*

Background: Emerging evidence suggests that endothelial-to-mesenchymal transition (EndMT) contributes to kidney fibrosis including STZ-induced diabetic nephropathy (DN). Researches including us have showed that hyperglycemia plays an important role in the development and progression of DN. Our aim is to investigate whether high glucose induces EndMT in glomerular endothelial cells through RhoA activation.

Methods: Primary human glomerular endothelial cells (hGEnCs) were exposed for 24 hours to culture medium containing: (1) no additions (control), (2) high glucose medium 1 (HG1, 15mM), (3) high glucose medium 2 (HG2, 30mM), (4) high glucose medium2 with ROCK1 inhibitor Y27632 (1mM), (5) mannital control. Immunofluorescent staining was performed to detect the expression of CD31, fibroblast specific protein-1 (FSP-1), and α -smooth muscle actin (α-SMA) in hGEnCs of different groups. Phenotypic changes of hGEnCs were observed using phase contrast microscope. Protein and mRNA expression of FSP-1, α-SMA and CD31 were measured by Western blotting and real-time PCR respectively. RhoA activity was detected by pull-down assay.

Results: It was showed hGEnCs changed their phenotype from cobble-like to fibroblast-like cells in high glucose, which did not happen in mannitol control groups. It also showed that α-SMA with CD31 double positive percentage was significantly increased in HG groups with a dose dependent manner when comparing with control group and mannitol group. However when pre-incubated with ROCK1 inhibitor Y27632 in high glucose, α-SMA with CD31 double positive stained cells did not increase (P<0.05, n=3). Real-time PCR and Western blotting results indicated FSP-1 and α-SMA mRNA and protein significantly increased in HG group compared with control group and mannitol group, but not in Y27632 group (P<0.05, n=3). RhoA activity was significantly increased in HG group compared with control group (P<0.01, n=3).

Conclusions: Our results indicate that high glucose may contribute to the EndMT of glomerular endothelial cells through RhoA signaling pathway.

PUB061

Value of the Neutrophil to Lymphocyte Ratio as a Predictive Tool of Worsening Renal Function in Diabetic Population Jennifer Ross, Morton J. Kleiner, Suzanne E. El Sayegh. *Nephrology, Staten Island University Hospital, Staten Island, NY.*

Background: The role of inflammation and inflammatory cytokines in diabetic nephropathy was studied over the last few years. Neutrophil to lymphocyte ratio rather than other white cell parameters was found to be a useful inflammatory marker which predicts adverse outcomes in acute and chronic medical and surgical conditions. Nevertheless, the use of Neutrophil to lymphocyte ratio (NLR) as an inflammatory marker for diabetic nephropathy has not been elucidated.

Methods: A338 diabetic patients were followed at our clinic between 2007 and 2009. The variables were total WBC, neutrophil, lymphocyte, monocyte and NLR, serum levels (creatinine, BUN, hemoglobin, hemoglobin A1C, LDL, and HDL), urine albumin creatinine ratio and GFR. Demographic variables (race, gender, age and BMI), presence of risk factors (e.g. hypertension, smoking, CAD, CHF) and medication were retrieved for each patient index. We arranged our patients into tertiles according to the initial NLR. Dropping of GFR ≥ 12 over a 3 year follow-up period with the last GFR ≤ 60 was considered a positive primary endpoint.

Results: The lowest NLR tertile had fewer patients (2.7%) with primary outcome(i.e. worsening renal functions) compared to middle and highest NLR tertile, which had more patients with primary outcomes (8.7% and 11.5% respectively) with a significant P value 0.01. Higher prevalence of stage ≥ 3 of CKD was found in higher two NLR tertiles(32% and 25%) versus 12% in the lowest NLR tertile group.

Conclusions: NLR as an inflammatory marker predicted the worsening of the renal function in the diabetic population. Further studies over a longer follow-up period are needed to confirm this result

PUB062

Urine pH as a Predictor of Developing Type 2 Diabetes Majed Samarneh, Morton J. Kleiner, Suzanne E. El Sayegh. *Nephrology, Staten Island University Hospital, Staten Island, NY.*

Background: The role of urine pH in predicting the risk for developing diabetes mellitus remains unclear. We hypothesize that as urine pH increases, the risk of developing diabetes mellitus decreases.

Methods: We performed a retrospective cohort study of patients admitted to Staten Island University Hospital during the period from June 2008 to June 2009. Patients with conditions that are known to influence the urine pH were excluded: CKD (defined as GFR< 60 for over 3 months), urinary tract infection, acute kidney injury, and chronic indwelling bladder catheter.

Results: The final study cohort included 92 subjects who had an appropriate database to use the Atlanta diabetes risk prediction model for estimation of the diabetes risk score. Urine pH was inversely correlated with the diabetes risk prediction score but this was not statistically significant (r= -0.14, p=0.20). Univariate analysis showed that BMI ≥ 30 kg/m^2 was associated with a lower urine pH but this was not statistically significant. There was no association between urine pH and hypertension, low HDL or elevated TG. Our study had a few limitations.

Conclusions: First, it is a retrospective cohort and we have no long term follow-up on the patients to determine the exact incidence of diabetes in the population. Another limitation is the limited number of participants in the final cohort. Moreover, we have not validated the accuracy of a urine dip in calculating the urine pH for this study. Our study is the first to study the relationship between urine pH as a marker of insulin resistance and the risk of developing diabetes. We found an inverse relationship between urine pH and the risk of developing diabetes although not statistically significant. We also found an inverse correlation between BMI and urine pH, similar to the existing literature. Urine pH is a promising marker of insulin resistance. Further studies are necessary to determine whether urine pH is a true predictor of diabetes mellitus. If validated, urine pH has the potential to become one of the screening tools for diabetes in the primary care setting.

PUB063

Renal Function in Diabetic eNOS Knockout Mice Assessed by Dynamic ^{99m}Tc-MAG3 SPECT Imaging Mohammed Noor Tantawy,[1] Rosie T. Jiang,[2] Keiko Takahashi,[2] Christopher Chad Quarles,[1] Raymond C. Harris,[2] Takamune Takahashi.[2] *[1]Vanderbilt University Institute of Imaging Science, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: Endothelial dysfunction is a hallmark of diabetic vascular complications. Recent studies have shown that deficiency of endothelial nitric oxide synthase (eNOS) significantly advances diabetic renal injury in mice. The finding indicates a crucial role of eNOS in the pathogenesis of diabetic kidney disease. However, the underlying mechanisms are incompletely understood. In this study, we assessed renal function in diabetic eNOS knockout mice using ^{99m}Tc-MAG3 SPECT imaging.

Methods: Diabetes was induced in C57BL6 strain eNOS knockout (eNOSKO) and wild type males (n=5 per group) at the age of 8 wks by multiple low-dose STZ injections (50 mg/kg, i.p., 5 days). Citrate buffer-injected eNOSKO and wild type males (n=5 per group) were used as non-diabetic controls. Renal function was assessed by planar dynamic mode ^{99m}Tc-MAG3 NanoSPECT imaging [~37 MBq, retroorbital injection, 30min scan] at 6 and 14 wks post STZ injection. Time-activity curves (TACs) of each kidney were recorded over the duration of the scans. Renal perfusion was assessed by the peak activity, time-to-peak (TTP), and the slope of first influx (RBF).

Results: At 6 wks post STZ injection, the perfusion parameters (peak activity, TTP, and RBF) showed no differences among the four groups of mice. However, all diabetic eNOSKO mice showed a remarkable delay in renal ^{99m}Tc-MAG3 clearance, indicating impaired tubular function, while other groups of mice did not. At 14 wks post STZ injection, significant differences were also not observed in the perfusion parameters among the four groups of mice. Surprisingly, delayed ^{99m}Tc-MAG3 clearance was not observed in diabetic eNOSKO mice at this time point.

Conclusions: In STZ-eNOSKO (C57BL6) model, eNOS deficiency causes acute tubular dysfunction in the setting of diabetes. However, this disorder is restored in the following period. Significant changes in renal perfusion are not observed by ^{99m}Tc-MAG3 scintigraphy in STZ-eNOS KO mice up to 14 wks post STZ injection. Further follow-up study is currently underway.

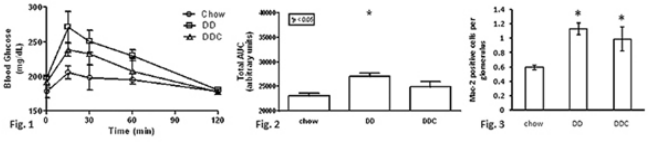
A Murine Model of Diet-Induced Insulin Resistance and Metabolic Syndrome Tomasz A. Wietecha,[1] Jinkyu Kim,[2] Antonio Haw Sta. Teresa,[2] Kelly L. Hudkins,[1] Ewa M. Skarbek,[1] Takahisa Kobayashi,[1] Bardia Askari,[1] Kevin D. O'Brien,[2] Charles E. Alpers.[1] *[1]Pathology, UW, Seattle, WA; [2]Cardiology, UW, Seattle, WA.*

Background: BTBR is an inbred mouse strain that is susceptible to development of diabetes and advanced complications including diabetic nephropathy(DN) (JASN. 2010; 21:1533), particularly in the presence of the leptin-deficiency mutation (*ob/ob*). Wild-type BTBR mice are not hyperglycemic on Chow diet, but have insulin resistance (high insulin levels). We sought to determine whether dietary modification could induce diabetes and DN in the presence of an intact leptin/leptin receptor axis. At 4 weeks of age, female BTBR mice were assigned to Chow, DD (diet high in fat and refined sugar) or DDC (DD diet with 0.15% cholesterol) groups. Oral glucose tolerance tests (OGTT) were performed at Baseline and after 8 and 16 weeks on diet, when all mice (n=7/group) were sacrificed. At 8 and 16 weeks, both DD and DDC groups had significantly impaired glucose responses, consistent with increased insulin resistance, represented as total area under the curve (Fig. 1, 2), but no significant increases in fasting glucose. Body weights were modestly increased in DD and DDC mice at 16 weeks. Histologically, a significantly increased glomerular influx of Mac-2 positive cells (monocytes) was detected in both DD and DDC compared to Chow group (1.1 and 1.0 vs. 0.6 Mac-2 positive cells per glom respectively, P<0.05, Fig.3). In all groups, there was no significant glomerular hypertrophy, mesangial expansion, glomerular cell activation or proliferation. Increased proteinuria in DD and DDC diet groups did not achieve significance. These results characterize early inflammatory changes of glomeruli in diet-induced insulin resistance and metabolic syndrome, which may be a first step towards development of structurally advanced DN.



PUB065

ACE2 Deficiency Is Not Sufficient To Aggravate Kidney Damage in Diabetic Mice on a C57BL Genetic Background Resistant to Kidney Disease Jan A. Wysocki,[1] Susan B. Gurley,[2] Minghao Ye,[1] Yashpal S. Kanwar,[1] Thomas M. Coffman,[2] Daniel Batlle.[1] *[1]Division of Nephrology & Hypertension, Northwestern University, Chicago, IL; [2]Duke University Medical Center, Durham, NC.*

Background: Angiotensin II overactivity is believed to be a major factor in diabetic kidney injury. ACE2 is an enzyme highly expressed in the kidney that dissipates Ang II and its expression has been shown to be altered in diabetic mouse models. We reasoned that ACE2 deficiency especially in the context of diabetes could lead to local Ang II overactivity due to a decreased Ang II degradation causing increased kidney damage.

Methods: We compared male WT and ACE2 KO mice (ace2$^{+/y}$ and ace2$^{-/y}$, respectively) on C57BL6/J background which were rendered diabetic using low (5x40mg/kg at week 0 and 7 of diabetes) and high-dose STZ (2x150mg/kg).

Results: ACE2 deficiency alone was not associated with albuminuria or any gross pathological kidney changes except for a mild mesangial expansion in glomeruli from ace2$^{-/y}$ mice as compared to WT (0.49±0.05 vs. 0.24±0.07, respectively, p<0.05). After low-dose STZ, mesangial score was about equally increased in ace2$^{-/y}$ or ace2$^{+/y}$ mice (0.74±0.08 vs. 0.78±0.08, respectively). Because low dose STZ did not cause albuminuria in either of the groups despite severe hyperglycemia, we used high dose STZ. High dose STZ was associated with a significant increase in albumin/creatinine ratio (ACR) in both groups. Initially, ACR was higher in ace2$^{-/y}$ than in ace2$^{+/y}$ mice but the trend was abolished later on. Mesangial score in STZ-treated ace2$^{-/y}$ mice was higher than in ace2$^{+/y}$ mice (0.89±0.29 vs. 0.56±0.13, respectively) but the difference was not statistically significant. Other indicators of kidney injury, such as glomerular fibronectin and MCP-1 staining as well as collagen expression were equally increased in diabetic ace2$^{-/y}$ and ace2$^{+/y}$ mice.

Conclusions: Genetic ACE2 ablation in itself does not accelerate STZ-induced diabetic injury in mice on the C57BL background and further demonstrates the resistance of this strain to chronic kidney injury. Studies in more injury-prone genetic backgrounds are needed to better understand the role of ACE2 in diabetic kidney disease.

PUB066

Urinary ACE2 as a Biological Marker of ACE2 Activity Jan A. Wysocki, Minghao Ye, Laura Garcia-Halpin, Daniel Batlle. *Division of Nephrology & Hypertension, Northwestern University, Chicago, IL.*

Background: Urine is an easily accessible biological fluid that, as it is formed, stays in a direct contact to kidney apical membranes from which proteins are instantly shed. We have shown that ACE-related carboxypeptidase (ACE2) is excreted in the urine in large quantity particularly in diabetic mice. Here we describe a method of distinguishing between ACE2-deficient and ACE2-replete mice using a simple, single-step approach that detects urinary enzymatic activity of a protein such as ACE2 which is expressed abundantly in the apical membrane of renal epithelial cells.

Methods: The procedure is based on a cleavage of an ACE2-specific fluorogenic substrate, Mca-APK-Dnp. Four uL of urine sample was used in two reaction wells (2 uL/per well) where one of wells constituted a blank containing a specific ACE2 inhibitor, MLN-4760 (10^{-5}M).

Results: Using purified recombinant mouse ACE2 it was established that the linear detection range of the assay captures ACE2 protein levels of normal mouse urines. To further validate the method we used WT mice carrying two alleles of the ace2 gene (ace2$^{+/y}$), ACE2 KO mice (ace2$^{-/-}$ or ace2$^{-/y}$) as well as heterozygous (HT) mice carrying only one allele of the ace2 gene (ace2$^{+/-}$) that exhibit an intermediate ACE2 phenotype between WT and KO. The results obtained by measuring urinary ACE2 activity, were confronted with the results of ACE2 expression in post-mortem kidney tissue. In urines from ACE2KO (n=45) the assay yielded median value of -0.05 (range -0.17 - 0.30), in HT mice (n=23) 1.22 (range 0.51-2.14) and in WT (n=29) 4.11 (range 1.55-8.3) providing an excellent discrimination between ACE2-replete and ACE2-deficient mice.

Conclusions: Measuring urinary enzymatic activity of proteins such as ACE2 which normally are expressed in kidney apical membranes provides a convenient tool for identification of mice with deficiency of the enzyme in question or its over-expression.

Using sensitive assays to measure urinary enzyme activity can be useful for non-invasive phenotyping and determining successfulness of time-restricted kidney-specific gene knock-out or over-expression attempts.

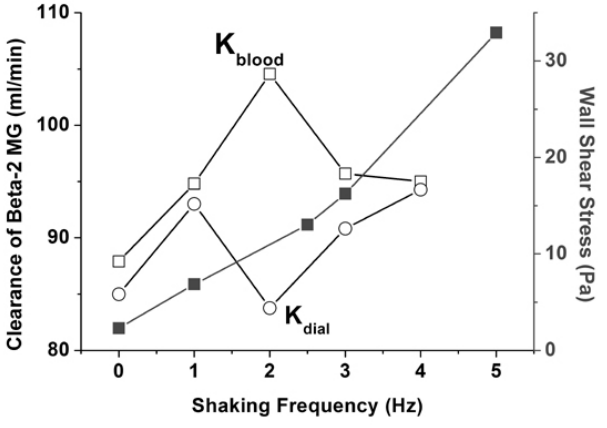
Enhancement of Beta-2 Microglobulin Clearance by Shaking Hemodialyzer: Numerical and Experimental Studies Jeong Chul Kim,[1,2] Francesco Garzotto,[1] Mauro Neri,[1,2] Massimo de Cal,[1] Dinna N. Cruz,[1,2] Alessandra Brendolan,[1] Claudio Ronco,[1,2] Federico Nalesso.[1] *[1]Department of Nephrology, San Bortolo Hospital, Vicenza, Italy; [2]International Renal Research Institute Vicenza, Italy.*

Background: Clearances of middle-molecular-weight solutes in hemodialysis are limited by blood-membrane interaction such as protein gel layer and concentration polarization. To increase the clearances of middle molecules, shaking hemodialyzer can be useful because it increases wall shear stress at the surfaces of dialysis membrane and reduce resistances layers. We numerically predicted the effects of hemodialyzer shaking on hemodynamics inside hollow fiber and experimentally measured clearances of solutes at different shaking conditions.

Methods: Using a numerical package we analyzed hemodynamics of single hollow fiber according to the shaking profiles (longitudinal, transverse and rotational directions). To validate numerical model we developed a dialyzer shaking instrument and measured clearances of urea and beta-2 microglobulin in blood side and dialysate side and calculated mass balance errors.

Results: Numerical results showed that transverse shaking is optimal for clinical application because it provide uniform enhancement of effective blood flow rate and wall shear stress during the hemodialyzer shaking. These hemodynamic parameters were linearly proportional to the vibration amplitude or frequency. In experimental results, the effects of hemodialyzer shaking were negligible in urea diffusion while beta-2 microglobulin clearance increased with shaking hemodialyzer. However, the linear relationship between shaking parameters and beta-2 microglobulin clearance was not observed.



Conclusions: Shaking hemodialyzer could improve middle-molecular-weight solute clearances during hemodialysis.

PUB068

Profiling Cardiovascular Phenotype by Continuous Measurement Using FIR Median-Hybrid Preprocessing Scott Wilson, Gavin J. Becker. *Royal Melbourne Hospital, Australia.*

Results: The prediction and avoidance of significant haemodynamic instability during haemodialysis (HD) is a challenge in clinical monitoring. A 'normal' response to HD, and subsequently pathological variants, is not described. It is likely that particularly complex patterns are missed by routine arm-cuff measurement. Haemodynamic parameters would be ideally captured by continuous recording and trend-based analysis; however monitoring typical HD creates a massive data-set, typically yielding over 16,000 samples per session. Standard hardware and software can find usefully manipulating such a data load difficult. Separately, the sensitivity of research devices can create signal distortion and measurement artifacts when used in the clinical HD setting, obscuring true trend signals. Preprocessing is an attractive solution to these problems. Using real patient plethysmography data (Blood Pressure, Heart Rate, Peripheral Resistance) collected during HD treatments we have experimented with single and bidirectional, linear and nonlinear algorithms to reduce artifact whilst preserving the edges and direction of the underlying trends and subtrends. Linear temporal filters perform poorly through delay and sustained signal distortions depending upon the length of the observational window. Increasing filter complexity requires predefined assumptions about the character and quality of the underlying dataset. Single filter processes are inflexible and behave inconsistently across different haemodynamic parameters and individual patients. They do not alleviate the computational load of a large dataset.

We report the design and first known application of a 5 window Heart-Rate Dependent Finite-Impulse-Response Median Hybrid Filter (FirMHF) algorithm to cardiovascular monitoring. This filter reduces measurement artifact and preserves signal edge to create a robust time-series estimate of haemodynamic variables. No predefined tolerance thresholds or assumptions about the original dataset are required. The character of the physiologic trend is retained for analysis whilst the data-point burden is condensed to approximately 15% of the original continuous sample.

Relationship between Fluid Overload and Serum Sodium Concentration in Hemodialysis Patients Fansan Zhu,[1] Li Liu,[1,2] Jochen G. Raimann,[1] Peter Kotanko,[1] Stephan Thijssen,[1] Nathan W. Levin.[1] *[1]Renal Research Institute, New York, NY; [2]Dept. of Nephrology, Peking University, Beijing, China.*

Background: It has been proposed that fluid overload may be the cause of low serum sodium concentration [Na+] in hemodialysis (HD) patients. The aim of this study was to investigate the relationship of changes in [Na+] and fluid status in chronic HD patients.

Methods: In HD patients post HD weight was gradually reduced until dry weight as defined by calf bioimpedance spectroscopy (DW_{cBIS}) was reached.(Zhu, Physiol Meas 2008). Body weight (Wt), serum [Na+], and normalized calf resistivity (nRho; using Hydra 4200, Xitron Technologies) were measured pre and post HD at baseline (BL) and at DW_{cBIS}, respectively.

Results: From BL to DW_{cBIS} pre and post HD Wt decreased and nRho increased significantly. Serum [Na+] increased from pre to post HD both at BL and DW_{cBIS}, however, pre-HD serum [Na+] did not change between BL and DW_{cBIS} (Table 1).

Table 1

	Wt [kg]	nRho [Ω*m³/kg]/100	[Na+] [g/ml]
BL Pre HD	76.4±16.8**¤	14.9±2.8**¤	136.9±5.8*
BL Post HD	73.8±16.4¤	18.5±3.8¤	139.1±4.9
DW Pre HD	74.4±16.7**	17.1±3.2**	136.6±5.4**
DW Post HD	72.0±16.3	22.4±4.5	138.5±5

* and ** represent difference between pre and post HD.¤ represents difference between BL and DW (DWcBIS)

Conclusions: In this prospective study pre HD serum [Na+] was not affected by achieving dry weight. This finding argues against the notion that low pre-HD serum Na+ is due to fluid overload.

Iron and Ultrasound--A Case Report of High Ferritin Levels and Increased Renal Echogenicity James Paul Rogers,[1] Pran M. Kar,[2] Kevin B. Patel,[3] Sunny Kar.[4] *[1]Operative IT, Inc., Kennewick, WA; [2]Orlando Nephrology, Orlando, FL; [3]Florida State University; [4]LECOM, Bradenton, FL.*

Background: The lack of ionizing radiation in ultrasound imaging has made it a powerful yet safe diagnostic tool. When interpreting renal ultrasound images, echogenicity of the cortex and medulla has been used to identify changes in kidney function. In fact, where chronic kidney disease is concerned, a quantification of echogenicity has been suggested as a means of more accurately identifying abnormalities. But what happens when ferritin levels are high, such as in patients with hemochromatosis? What affect does this have on the echogenicity of a patient's organs? These cases bring to light the possibility that high ferritin levels can confound interpretations of renal ultrasound images by increasing the kidney's echogenicity.

Methods: Patient records were retrospectively examined for patients who presented with an acute kidney injury, increased kidney echogenicity on ultrasound, and high ferritin levels.

Results: Two patients in this case study displayed increased renal echogenicity and concomitantly high ferritin levels. Our first patient's acute kidney injury was probably medicinally induced. Therefore, the increased renal echogenicity observed was not expected. In our second patient, a renal ultrasound changed from a highly echogenic cortex to a normal cortex within ten days. This was also unexpected. Furthermore, she had normal renal function prior to her second admission. Therefore, it is worth considering that high ferritin levels contributed to the renal echogenicity we observed in both patients.

Conclusions: We postulate that high ferritin concentrations in the kidneys, as indicated by high serum ferritin levels, may contribute to increased renal echogenicity. Therefore, when ferritin levels are high, we advise caution when interpreting echogenic changes in renal ultrasounds as evidence of chronic disease.

PUB071

Reversion of High Glucose-Induced EMT in HPMC by the SARA/SBD Fusion Protein Containing Protein Transduction Domain Huang Chen,[1] Rui Du.[2] *[1]Nephrology, Xijing Hospital, Xi'an, China; [2]FMMU, Xi'an, China.*

Background: In this study, we constructed a SARA peptide aptamer based on the sequence of SBD(SARA/SBD). The recombinant SARA/SBD fused with a protein transduction domain (PTD-SARA) was cloned. We express and purify the PTD-SARA/SBD fusion protein in prokaryotic cells and determine its effect on the epithelial-to-mesenchymal transition of human peritoneal mesothelial cells treated with high glucose and possible mechanisms.

Methods: PTD-SARA/SBD gene was cloned into prokaryotic expression vector pET-44a(+) with His tag. Then the constructed recombinant plasmid was transformed to E.coli BL21 for expression under induction of IPTG. The expressed product was purified by Ni^{2+}-NTA affinity chromatography and identified by SDS-PAGE and Western

blot; Immunocytochemistry methods was used to test the transmembrane efficiency and colocalization of the fusion protein with Smad2 which was one of factors in TGF-β_1 signal transduction pathway in HPMC. Western Blot was used to test the level of E-cadherin, α-SMA, Smad2/3 and pSmad2/3 protein in HPMC to confirm whether the recombinant fusion protein can inhibit the epithelial-to-mesenchymal transition of HPMC treated with high glucose and its possible mechanisms.

Results: The PTD-SARA/SBD fusion protein was expressed and purified using the methods of genetic engineering. It was indicated that the expressed product contained 20% of total somatic protein and existed in a soluble form. The purity quotient was beyond 95% after being purified by Ni^{2+}-NTA affinity chromatography. The results of function experiments indicated that the PTD-SARA/SBD fusion protein could transduce into HPMC efficiently which mainly located in nucleolus and could colocalize with Smad2. The fusion protein could increase the level of E-cadherin protein and decrease the level of α-SMA protein in HPMC treated with high glucose. It could decrease the level of pSmad2 protein, which had no effect on the Smad3 phosphorylation level.

Conclusions: PTD-SARA/SBD fusion protein could prevent the epithelial-to-mesenchymal transition of HPMC treated with high glucose. The possible mechanism was that the fusion protein could prevent the phosphorylation of Smad2.

PUB072

Short-Term Impact of Sevelamer Hydrochloride on Hyperphosphatemia in Chinese Patients on Maintenance Hemodialysis Therapy Yi Fang, Jianzhou Zou, Jie Teng, Xiaoyan Zhang, Xiaoqiang Ding. *Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China.*

Background: This open-lable, self-control study was aimed to evaluate the safety and efficacy of Sevelamer Hydrochloride in treating Chinese maintenance hemodialysis (MHD) patients with hyperphosphemia.

Methods: Phosphate binders were discontinued during a two-week washout period. Patients whose serum phosphorus was more than 1.78mmol/L after two-week washout period were eligible for treatment. The dose could be adjusted every two weeks as necessary to achieve serum phosphorus control. Sevelamer Hydrochloride was administered to 138 MHD patients for 10 weeks and a second two-week washout period followed.

Results: 111 of the 138 patients fulfilled the whole 14-week study. Mean serum phosphorus and calcium-phosphate products started to declined after two-week Sevelamer Hydrochloride treatment. By the end of 10-week sevelamer hydrochloride treatment, mean serum level of phosphorus (1.85±0.5 *vs* 2.57±0.54mmol/L, p<0.01), calcium-phosphate product (4.16±1.72 *vs* 5.79±1.50 $mmol^2/L^2$, p<0.01) and low density lipoprotein (1.64 ±0.76 *vs* 2.31±0.87 mmol/L, p<0.01) were significantly lowered while the adjusted serum level of calcium and serum intact parathyroid hormone kept steady. Both serum phosphorus and calcium-phosphrus increased after the second washout period, but the levels were still lower than their pre-treatment ones (2.26±0.71vs 2.57±0.54 mmol/L; 5.12±1.63 vs 5.79±1.50 $mmol^2/L^2$, p<0.01). Of the 138 patients involved, 214 cases in 106 patients and 121 cases in 121 patients were reported as adverse events and adverse drug reaction respectively. Gastrointestinal symptoms, of which most were mild or moderate, happened to 68.12% patients.

Conclusions: Sevelamer Hydrochloride can control serum phosphorus and reduce the level of calcium-phosphorus product and cholesterol. Slight gastrointestinal symptoms like constipation were common during the treatment.

PUB073

Facility-Level Phosphorus (P) Control of Peritoneal Dialysis Patients in a Large Dialysis Organization Jamie Heise,[1] Kamyar Kalantar-Zadeh,[2] John Brian Copley,[1] Moshe Fridman,[3] Rajnish Mehrotra.[2] *[1]Medical Affairs, Shire Pharmaceuticals, Chesterbrook, PA; [2]Medicine, Harbor-UCLA Medical Center, Torrance, CA; [3]Statistics, AMF Consulting, Los Angeles, CA.*

Background: Increased serum P is a robust predictor of all-cause and cardiovascular mortality in dialysis patients. Though P control in the last decade has improved overall, performance varies widely among facilities.

Methods: 10, 177 patients treated with peritoneal dialysis in January of 2011 were selected for the study and aggregated by facility. The facilities with at least 5 patients (N=480) were then ranked by the proportion of patients with serum P < 5.5 mg/dl for the calendar month. The top and bottom 5% of facilities were compared for the achievement of targets for other laboratory measures (calcium, Ca; parathyroid hormone, PTH, and albumin), P-binder and vitamin D use, geographic region, and use of a central pharmacy.

Results: For the population studied, 67% of peritoneal dialysis patients achieved serum P < 5.5 mg/dl. The top 5% of facilities (n=24) treated 306 patients and bottom 5% (n=31) treated 248 patients. P control was achieved in 97% of patients of top-performing facilities compared to 34% of the bottom-ranked facilities. There was no significant difference in the proportion of patients achieving targets for serum albumin (< 3.5 g.dl; 69% vs. 73%, p=0.416), and calcium (< 9.5 mg/dl; 98% vs, 94%, p < 0.089) but top-performing facilities were more likely to achieve the PTH target (150-600 pg/ml; 75% vs. 60%, p=0.0004). Furthermore, top-performing facilities were less likely to use combinations of P-binders (7% vs. 22%; p=0.002). There was no significant difference in use of other P-binders, oral vitamin D or cinacalcet use, or use of a central pharmacy between the top and bottom 5% of facilities.

Conclusions: Despite a high overall rate of P control, there appears to be a unit level treatment or demographic difference which affects the proportion of patients with serum P < 5.5 mg/dl at a facility level. Identifying practice patterns that allow a larger proportion of patients to achieve P control has the potential of further improving outcomes.

PUB074

Oxalate Nephropathy Leading to End Stage Renal Disease after Gastric Bypass Surgery Ghaziuddin Qadri, Manish K. Saha, Tarek Hamieh, Vishal Sagar. *Regions Hospital, St. Paul, MN.*

Background: 52-year-old Caucasian female with history of DM-2, hypertension (HTN), Roux-en-Y gastric bypass (RYGB) 2 years ago, CKD stage 1-2, attributed to HTN and DM, was admitted with worsening renal function. She had no symptoms of uremia. Vital signs were normal. Trace pedal edema was noted. Renal chemistry showed BUN 56 mg/dl, creatinine(Cr) of 4.5 mg/dl, eGFR 10.9 ml/min/1.73m2, K+ 3.6 mmol/L and bicarbonate of 18 mmol/L. Urine analysis showed 27 RBCs/hpf and TP/Cr ratio was 0.7. Serological workup and renal ultrasound was normal. Hemodialysis(HD) was initiated for chemical exchange and improvement of platelet function prior to kidney biopsy. Biopsy showed calcium oxalate deposits within the tubules, early diabetic nephropathy and mild arterial thickening. Immunoflouresence was negative. Plasma oxalate level was 17 uM/L (ref <1.8 mmol/L), urine oxalate of 44.6 mg/specimen (ref 9.7-40.5 mg/spec), oxalic acid/cr ratio of 53.2 mg/g (ref 1.6-37). 72 hr fecal fat was 8g (Ref 2-7 g). She was diagnosed with oxalate nephropathy secondary to RYGB. Patient was continued on HD and started on low oxalate and fat diet and calcium carbonate, as an oxalate binder. She was later switched to home HD six times a week to maintain a plasma oxalate level less than 30 uM/L and referred for a kidney transplant.

Conclusions: Hyperoxaluria and oxalate nephropathy are an uncommon complication after RYGB. RYGB results in fat malabsorption thereby leading to more calcium binding to free fatty acids. This results in an increased quantity of oxalate, not bound to calcium, but free and readily absorbed causing increased calcium oxalate in the serum and hyperoxaluria. Patients may benefit from low oxalate diet, low fat diet and calcium supplement, but oftentimes, patients may progress to becoming HD dependent. Patients, who have undergone RYGB, especially in the setting of CKD, as in our patient, may be at increased risk of worsening renal function due to oxalate deposition. They should be closely monitored for oxalate nephropathy and counseled to follow strict dietary regimen. While those contemplating RYGB procedures may need to be screened and informed of this unfortunate complication.

PUB075

Rationale and Design of an Open-Label, Randomised, Active-Controlled Phase 3 Study Evaluating the Management of Hyperphosphatemia with PA21 in Dialysis Patients James A. Tumlin,[1] Edward M.F. Chong,[2] Sylvain Gaillard,[3] Jurgen Floege.[4] *[1]Southeast Renal Research Institute University of Tennessee, USA; [2]Vifor Pharma, Canada; [3]Vifor Pharma – Vifor (International) Inc, Switzerland; [4]Medizinische Klinik II, Aachen, Germany.*

Background: Hyperphosphatemia is a common and serious complication in patients with chronic kidney disease (CKD), and can usually not be satisfactorily controlled by dietary restriction and hemodialysis, thus necessitating pharmacologic phosphate binders. Currently available phosphate binders have limitations in regard to efficacy, safety, tolerability, pill burden and/or patient adherence that impact their effectiveness. Vifor Pharma is developing a new calcium-free, iron-based phosphate binder, PA21, for therapeutic use in the management of hyperphosphatemia. A Phase 2 study demonstrated that PA21 is effective and safe in lowering serum phosphorus (P) with a lower pill burden than most currently available phosphate binders.

Methods: The PA21 study is a randomized, active-controlled, two-stage, re-randomization, Phase 3 study designed to investigate the efficacy and safety of PA21 in lowering and maintaining serum P levels in patients with CKD on dialysis. The study population will consist of 640 subjects with hyperphosphatemia (serum P ≥6.0 mg/dL after washout). Other study endpoints include the assessment of biochemical markers of bone resorption and formation, FGF-23, and patient preference and satisfaction assessments. Subjects will be randomized 2:1 to PA21 or sevelamer carbonate (SevCa) for 24 weeks, followed by a 3-week superiority assessment of PA21 (maintenance dose) versus low-dose PA21 in a pool of 100 subjects from the PA21 treatment arm. Doses of PA21 or SevCa will be adjusted based on serum P levels and per-protocol specified guidelines to reach and maintain serum P levels between 2.5 to 5.5 mg/dl.

Results: Recruitment is currently taking place at 200 sites worldwide.

Conclusions: The study will provide robust evidence regarding the efficacy and safety of PA21 with 1 pill per meal (2-3 pills daily) in treating hyperphosphatemia in adult patients with CKD on dialysis.

PUB076

Bone Tissue Evaluation by Bone Morphology Measurements in Type 1 Diabetes Patients with a History of Dialysis for 10 Years or Longer Rikako Hiramatsu, Keiichi Sumida, Masayuki Yamanouchi, Yoshifumi Ubara. *Kidney Center, Toranomon Hospital, Tokyo, Minato-kku, Japan.*

Background: Since the prognosis of diabetes patients undergoing dialysis is poor, little is known of bone disease in diabetes patients undergoing long-term dialysis. We therefore investigated the influence of long-term dialysis on bone disease in diabetic patients.

Methods: Six patients with type 1 diabetes mellitus who had been on hemodialysis for over 10 years and had undergone bone biopsy at our hospital between 2000 and 2011 were enrolled. There were 3 men and 3 women aged 48.7 ± 8.4 (42-58) years who had been on dialysis for 13.1 ± 4.9 (10 to 22) years. The duration of diabetes was 28.7 ± 10.8 (12 to 42) years. Right iliac bone biopsy was performed after tetracycline labeling.

Results: Laboratory tests revealed: serum intact PTH, 816.0 ± 160.4 pg/ml (247.0 to 1268.0); serum ALP, 413 ± 150 IU/l; adjusted serum Ca, 10.1 ± 2.2 mg/dl; and serum P, 6.2 ± 2.1 mg/dl. Bone histomorphometric measurements were: OB/BV (osteoid volume), 9.96 ± 5.92%; ES/BS (eroded surface), 23.50 ± 9.09%, Fb.V/TV (fibrosis volume), 1.39 ± 1.92%; mineral apposition rate (MAR), 0.82 ± 0.28 μm/day; and BFR/BS (bone surface-referent bone formation rate), 0.024 ± 0.02 (mm^3/mm^2/year). Three patients had osteitis fibrosa, two showed mixed bone disease (osteitis fibrosa plus osteomalacia), and one only had mild changes.

Conclusions: Since the report by Pei et al. in 1995, diabetes mellitus has been considered to show a close relation with low turnover bone disease, including adynamic bone. They studied diabetic patients with a dialysis period of less than 5 years. However, in Japan where renal transplantation from cadaver donors is uncommon, some diabetic patients remain on hemodialysis for longer than 10 years due to progress in dialysis technology. High turnover bone disease such as osteitis fibrosa will develop in diabetic patients receiving hemodialysis for over 10 years, as well as in non-diabetic patients.

Uremic Toxins Exacerbate Bone Mechanical Property in Chronic Kidney Disease Yoshiko Iwasaki,[1] Junichiro J. Kazama,[2] Hideyuki Yamato,[3] Masafumi Fukagawa.[4] *[1]Health Sciences, Oita University of Nursing and Health Sciences, Oita, Japan; [2]Division of Blood Purification Therapy, Niigata University Medical and Dental Hospital, Niigata, Japan; [3]Biomedical Research Laboratory, Kureha Corporation, Shinjuku, Tokyo, Japan; [4]Division of Nephrology, Endocrinology, and Metabolism, Tokai University School of Medicine, Isehara, Kanagawa, Japan.*

Background: Chronic kidney disease (CKD) patients are associated with greater fracture risk than general population, while the reason remains obscure. Bone quality is a prescribe factor of bone strength. Bone quality is consisted of several components including bone chemical composition. We previously revealed that cortical bones from CKD rats showed decreased mechanical property and altered chemical composition, and moreover changes of these parameters were dependent on kidney function. Thus we conducted an in vivo study to elucidate whether uremic toxins affect bone fragility.

Methods: CKD rat were divided into two groups; those administered oral charcoal absorbent which decreases the circulating levels of uremic toxins (CKD-AST), and those received vehicle (CKD-V). The Control group underwent sham operation.

Results: Storage modules in the CKD-V group were significantly less than those in the Control group, indicating decreased mechanical strength in the uremic cortical bone. However, the levels were maintained in the CKD-AST group. The raman spectroscopic analyses revealed that mineral matrix ratio, physiological collagen crosslinks and the ratio of carboxymethyl lysine (CML) were increased while crystallinity was decreased in the CKD-V group. These parameters were comparable between the CKD-AST and the Control groups. Serum parameters were comparable between the CKD-AST and the CKD-V groups except the indoxyl sulfate level, which is surrogate marker of uremic toxins, was significantly higher in the CKD-V group. Multiple regression analysis revealed that physiological collagen crosslink and the ratio of CML were independently associated with storage modulus.

Conclusions: In conclusion, accumulated uremic toxins are quite likely candidate for those deteriorate bone mechanical property through changing the chemical composition in CKD.

PUB078

Bone Turnover Markers in Haemodialysis Patients with Chronic Liver Disease Guillaume Jean, Charles Chazot. *Hemodialyse, NEPHROCARE, Tassin, France.*

Background: In chronic kidney disease (CKD) patients, bone turnover (BT) diagnosis remains challenging for nephrologists. Because it is an invasive procedure, bone biopsy cannot be performed as a routine examination. Furthermore, it is well recognized that the serum level of parathyroid hormone (PTH) is not a reliable bone turnover marker (BTM). The Kidney Disease: Improving Global Outcomes (KDIGO) foundation recommends regular sampling of BTMs such as total alkaline phosphatases (t-ALP) and bone-specific alkaline phosphatase (b-ALP) in the case of patients with liver diseases (LDs). Bone-collagen peptides such as beta-Cross-Laps (CTX) are not recommended by the KDIGO.

Methods: Between March 2004 and March 2011, all HD prevalent patients in our centre were examined for chronic LD and included in the study after at least 3 months of dialysis. Serum iPTH levels and t-ALP levels were assessed every month. B-ALP and CTX levels were assessed at least every 6 months. Linear regression between t-ALP, b-ALP, PTH, and CTX values and between CTX and Kt/V was performed.

Results: 76 prevalent HD patients (335 blood samples) with different LDs were examined: 42% were women, with a mean age of 68 ± 12 years and on dialysis for 61 ± 86 months, and 55% were diabetic, with dialysis schedule varying from 3 × 4 to 3 × 8 hours.

Linear regression showed that b-ALP (mean 28.1 ± 23 μg/l) and t-ALP (431 ± 300 U/l) levels were closely related (r^2: 0.6; $p < 0.0001$), even when the serum PTH level was <250 pg/ml (r^2: 0.56; $p < 0.001$). The b-ALP/t-ALP ratio was 0.07 ± 0.12 (range: 0.02–0.2) and correlated poorly with PTH levels (r^2: 0.03; $p = 0.01$). Both b-ALP and t-ALP levels correlated with PTH levels (233 ± 183 pg/ml); CTX levels (2.2 ± 1.2 μg/l) correlated better with PTH levels (r^2: 0.3; $p < 0.001$) and were not influenced by Kt/V or dialysis session time, even though CTXs are eliminated by dialysis. Owing to accumulation of CTXs between dialysis sessions, normal CTX values in HD patients were 4 to 5 times higher than in patients with normal renal function.

Conclusions: The bone specificity of b-ALP appears insufficient for the diagnosis of BT in the case of patients with LDs. In such cases, CTX appears to be more reliable and is independent of liver function.

PUB079

The Mechanism of Bone and Joint Pain in Chronic Hemodialysis Patients Ikuto Masakane. *Dialaysis Center, Yabuki Shima Clinic, Yamagata, Japan.*

Background: The recent concern for evaluating dialysis quality is how to relieve dialysis patients of their dialysis related symptoms, reflecting the increase of elder patients and long-dialyzed patients. The most frequent complaint of chronic hemodialysis patients is bone and joint pain, and it consists of many causes not only in dialysis patients but also in general population. In the current study, we evaluated the pathogenesis of bone and joint pain in dialysis patients.

Methods: We have performed a comprehensive survey for dialysis related symptoms twice a year, and bone and joint pain is the most frequent one prior to other typical uremic symptoms. In Jan. 2011, a further survey for bone and joint pain was performed in 301 chronic dialysis patients. The demographic data and the exact data about their pains, such as the region, degree and existence of bone deformity were collected. The demographic data and blood chemistry data were compared using t-test and Chi-square test for the pain on lumber supine, knee joint and shoulder joint.

Results: Ninety one patients (31%) had more than moderate bone and joint pain. The most frequently injured joints were lumber supine (84%), knee joint (66%) and shoulder joint (48%). The significant factors for lumber supine pain were the past history of lumbago and high level of serum parathyroid hormone. The significant factors for knee joint pain were sex, age and high level of serum parathyroid hormone. The significant factors for shoulder pain were dialysis vintage, history of the operation of carpal tunnel syndrome.

Conclusions: Based on the results of the current study, we hypothesized of two main mechanisms in the pathogenesis of bone and joint pain in chronic dialysis patients. The first mechanism is the deterioration in bone strength against the gravity and it appears as the pain on lumber supine and knee joint. This kind of pain could be worsened by secondary hyperparathyroidism. The second is the concomitant of dialysis related amyloidosis which damages the smooth movement of tendons in many joints, and it clearly appears as shoulder pain. In conclusion the protection of secondary hyperparathyroidism and dialysis related amyloidosis is essential to relieve dialysis patients of bone and joint pains.

PUB080

Oral Calcitriol Versus Intravenous Vitamin D Analogues in the Treatment of Secondary Hyperparathyroidism Sandeep Aggarwal, Ellie Kelepouris, Irfan Ahmed, Ami Patel. *Nephrology, Drexel University College of Medicine, Philadelphia, PA.*

Background: With the move toward bundled payment for dialysis to include injectable medications, alternative agents are being considered to save cost without impairing outcome in the treatment of secondary hyperparathyroidism.

Methods: We conducted a retrospective study of a single inner city dialysis unit where a cohort of dialysis patients with Medicare insurance were converted from intravenous vitamin D analogues (paricalcitol or doxercalciferol) to oral calcitriol. We investigated the differences in calcium, phosphorus, and intact parathyroid hormone (iPTH) levels before and after implementation of calcitriol therapy. A total of 52 dialysis patients were analyzed for serum calcium, phosphorus, and iPTH levels prior to calcitriol initiation and 8-12 weeks post calcitriol initiation. Equivalent doses of oral calcitriol were calculated using KDOQI guidelines.

Results: There was no significant difference in calcium and phosphorus levels detected after switching to calcitriol. The oral calcitriol dosage was significantly lower compared to the calculated equivalent doses of doxecalciferol or paricalcitol. The intact PTH levels were higher after introduction of calcitriol but did not reach statistical significance. Preliminary data suggested significant per patient cost reduction with conversion to calcitriol. The incidence of hypercalcemia(>10.2 mg/dl) was 7% in intravenous group and 9% in oral group.

Results

	Ave.	STDEV	95% CI	p
Pre PTH pg/ml	348.19	236.15	348.19±78.05	0.568
Post PTH	379.02	275.10	379.02±73.12	
Pre Phos mg/dl	5.53	1.76	5.53±0.51	0.981
Post Phos	5.52	1.68	5.52±0.47	
Pre Calcium mg/dl	9.24	0.75	9.24±0.23	0.723
Post Calcium	9.29	0.77	9.29±0.21	
Calcitriol Dose mg	4.09	3.11	4.09±1.05	0.0098
Pre Calcitriol (Dose equiv)	6.20	4.59	6.20±1.19	

Conclusions: Oral calcitriol is equivalent to injectable vitamin D analogues in the treatment of secondary hyperparathyroidism.

PUB081

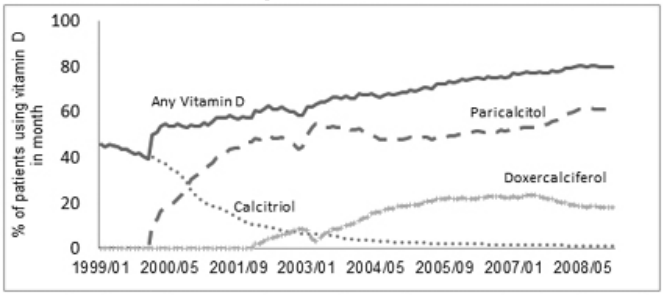
Trends in Intravenous Vitamin D Use among Dialysis Patients in the United States (1999-2008) Anne C. Beaubrun, Abhijit V. Kshirsagar, Lily Wang, M. Alan Brookhart. *University of North Carolina, Chapel Hill, NC.*

Background: Injectable vitamin D agents are commonly used to manage renal osteodystrophy in the dialysis population. Yet, there is little data documenting the temporal variability and patterns of use of these agents. We sought to to describe patient- and facility-level utilization patterns of vitamin D formulations (calcitriol, paricalcitol, doxercalciferol) in the US hemodialysis population.

Methods: We studied adult patients in the United States Renal Data System (USRDS) between January1999 and December 2008 with Medicare as a primary payer and who initiated dialysis at least 90 days prior to the month being investigated. Monthly percentages of patients treated with any vitamin D and each type of formulation were tabulated.

Results: We identified 140,790 dialysis patients in January 1999 and the number of eligible patients steadily increased to 214,113 in December 2008. Between 1999 and 2008, vitamin D use steadily increased with the exception of a slight decrease in use in the latter half of 1999. The use of calcitriol has declined since 1999, going from being administered in 44% of patients in January 1999 to 1.1% in December 2008. Paricalcitol is now the overwhelmingly preferred formulation. Doxercalciferol use in the dialysis cohort began in 2002, steadily increased and has begun to slightly decline since 2007. As of 2008, approximately 80% of the USRDS population used any vitamin D formulation.

Conclusions: Vitamin D use has increased and parallels the rise in use of paricalcitol and doxercalciferol. Furthermore, there is variation in formulation choice. Given the known pharmacologic differences in the vitamin D formulations, future research should focus on identifying the reasons for differences in vitamin D use, and, whether the variation in vitamin D use differentially affects patient outcomes.



PUB082

Switching Haemodialysis Patients from Oral to Intravenous Vitamin D May Not Improve Adherence to Prescribed Medication Alison Brown,[1] Claire Jackson,[2] James Shawcross,[1] George Hartley.[1] *[1]Renal Unit, Freeman Hospital, Newcastle upon Tyne, Tyne and Wear, United Kingdom; [2]Medical School, University of Newcastle upon Tyne, Newcastle upon Tyne, Tyne and Wear, United Kingdom.*

Background: Achievement of recommended calcium, phosphate and parathyroid hormone (PTH) levels in haemodialysis (HD) patients remains a significant challenge. Our 260 HD patients are reviewed by renal dieticians who prescribe and adjust phosphate binders, and clinicians who adjust Vitamin D (Vit D) dose; medication is then dispensed in primary care. Our unit results in the UK Renal Registry compare well with the rest of the UK. However, compliance with prescribed medication remains variable. We change patients from oral self-administered Vit D to intravenous (IV) given on HD when control or compliance is poor. We describe the results of audit of bone chemistry and compliance with oral and IV Vit D.

Methods: Our local protocol based on KDOQI and UK Renal Association recommendations targets these predialysis levels :

PTH 120-540 ng/l, Adjusted calcium 2.20-2.50 mmol/l, Phosphate 1.10-1.70 mmol/l

We reviewed predialysis serum PTH, adjusted calcium and phosphate levels, and Vitamin D analogue prescription in all established HD patients during December 2010.

Results: Complete data was available for 222 of 260 patients. Only 10.8% had results within target for all parameters

Of 138 patients receiving Vit D, 55% had levels within target range for PTH, 48% for calcium and 44% for phosphate

Of 84 patients not prescribed Vit D, 55% had levels within target for PTH, 45% for calcium and 43% for phosphate

36% of all patients were taking oral Vit D doses different to that recorded in hospital notes

Only 70% of IV Vit D doses were adminstered as prescribed

Conclusions: Although achieved bone chemistry compares well with other UK renal units, 36% of oral and 30% of IV doses of Vit D differed from the recommended dose in our HD patients ; giving poorly controlled or compliant patients IV Vit D did not significantly improve compliance with medication.

Our study highlights the importance of documenting Vit D medication accurately to ensure alterations are appropriate. Future introduction of electronic and patient-held records may help to achieve this.

PUB083

Long-Term Skeletal Health and Integrity in Renal Transplant Patients – Are we Measuring the Right Parameters? Nihil Chitalia,[1] Sharon Frame,[1] Ana Sofia Rocha,[2] David Goldsmith.[1] *[1]Nephrology and Transplantation, Guy's and St. Thomas' Hospital NHS trust, London, United Kingdom; [2]Renal Medicine, St. George's Hospital NHS trust, London, United Kingdom.*

Background: As the success of kidney engraftment improves, there is a progressively larger cohort of renal transplant patients surviving a long time. We established a specialized multidisciplinary clinic to focus on best management of these patients' multiple medical issues. It is well-known that bone and mineral metabolism (CKD-MBD) parameters are abnormal after renal transplantation, but long-term data are scarcer, particularly with reference to bone mineral density as measured by DEXA scans

Methods: We took 151 well, ambulant renal transplant patients who were transplanted for more than 10 years and examined their CKD-MBD parameters and DEXA scans in detail

Results: The findings are summarized in Table 1.

Table 1: Demographic, biochemical and bone mineral density categories on DEXA scan in ambulant transplant recipients on long term follow-up (n=151)

Variable	Mean±SD or percentages
Age *(yrs)*	54±12
Gender (% Males)	62
Months post transplant (median±IQR)	207±126
eGFR *(ml/min/1.73m2)*	49±20
Haemoglobin (gm%)	12.8±1.5
Serum Calcium *(mmol/L)*	2.4±0.15
Serum Phosphate *(mmol/L)*	1.04±0.25
Serum Alkaline Phosphatase *(U/L)*	77±30
Serum PTH pmol/L	94±67
Serum 25 Hydroxy Vitamin D (nmol/L)	48±31
Vitamin D Deficient <37.5 nmo/L Vitamin D insufficient 37.5-75 nmol/L	59(39.1%) 58(38.4%)
Vitamin D sufficient >75 nmol/L	34(22.5%)
% on Steroids	77(51%)
% on Bisphosphonates	17(11%)
% on Vitamin D or Calcium supplements	26(17%)
BMD Category	
Normal	65(43%)
Osteopenia	65(43%)
Osteoporosis	20(14%)

Diagnosis of osteoporosis based on the National Osteoporosis foundation guidelines 2008.

On bivariate correlations between bone biochemistry and T-scores on DEXA scanning, serum calcium showed a negative correlation with T-score at neck of femur (NOF)(r=-0.296, p=0.002), whereas serum PTH showed a positive correlation with t-score at NOF (r=0.324, p=0.01). Serum 25 hydroxy vitamin D did not show a significant correlation with T-scores at any sites on DEXA scanning.

Conclusions: In a selected ambulant population of long-term renal transplant survivors, there were only 8% of patients with normal serum calcium, phosphate, PTH and 25(OH) ≥75nmol/L. Vitamin D deficiency and abnormal BMD indicative of osteopenia or osteoporosis is common in transplant recipients but did not seem to correlate with the usual biochemical parameters typically measured in patients on clinic visits. There is a need for further research into novel biomarkers and longitudinal study data.

PUB084

Effectiveness of a MG-Based Phosphate (P) Binder on the Development of Vascular Calcifications (VC) in Uremic Rats Tineke De Schutter,[1] Ellen Neven,[1] Geert J. Behets,[1] Mirjam Peter,[2] Sonja Steppan,[2] Jutta Passlick-Deetjen,[3] Patrick C. D'Haese.[1] *[1]Laboratory of Pathophysiology, University of Antwerp, Antwerp, Belgium; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]Nephrology, University of Dusseldorf, Germany.*

Background: Ca-based P-binders are widely used to control hyperphosphatemia, however go along with hypercalcemia and accelerated progression of VC. We compared the effect of 2 doses of the Mg-based P-binder CaMg (2/3 Ca-acetate and 1/3 Mg-carbonate, Osvaren®) to that of sevelamer carbonate (sev) on the development of VC in rats with CRF.

Methods: 56 male rats were divided in 4 groups: Vehicle (Veh), 375mg/kg CaMg, 750mg/kg CaMg, 750mg/kg sev. CRF was induced by feeding 0.75% adenine (AD)-2.5% protein diet for 4 wks. After 1 wk of CRF, rats were gavaged with P-binders or Veh (7d/wk) until sacrifice at wk 6.

Results: Renal function was sign. impaired after 4 wks of AD-treatment and comparable in all groups. Veh-treated CRF rats developed severe hyperphosphatemia which was well controlled in the groups receiving P-binders particularly those receiving CaMg even at the lowest dose (Cmax Serum P: Veh: 20.3 - CaMg375: 11.5 - CaMg750: 9.9 - sev: 16.3mg/dl). AUC0-6wks of serum Ca did not differ sign. between groups. Serum Mg AUC0-6wks dose-dependently increased in CaMg treated groups (Veh: 15.0 - sevelamer: 16.0 - CaMg375: 20.8 - CaMg750: 27.16 mg.wk/L). Induction of CRF went along with a sign. increase in serum PTH. Treatment with CaMg dose-dependently prevented this increase whilst sev did not. Based on tissue Ca measurements, aortas of CaMg treated rats were sign. less calcified compared to Veh. Sev had no sign. effect on aortic calcifications although a clear reducing trend was seen. In contrast, calcifications in A. femoralis and A. carotis were sign. reduced by sev and showed a clear trend for CaMg, indicating a possibly different mechanism of calcification in these arteries. Results were confirmed on Von Kossa stained sections, showing that both CaMg and sev sign. reduced the area% calcification in the aorta.

Conclusions: Treatment with the Mg-based P-binder CaMg effectively controlled serum P and PTH levels resulting in reduced aortic calcifications in uremic rats.

Chronic Kidney Disease-Mineral and Bone Disorder in a Cohort of Internal Inpatients: A Prospective Analysis

Claudia Friedl,[1] Alexander R. Rosenkranz,[1] Astrid Fahrleitner-Pammer.[2] *[1]Department of Internal Medicine, Division of Nephrology and Hemodialysis, Graz, Austria; [2]Department of Internal Medicine, Division of Endocrinology and Metabolism, Austria.*

Background: Patients with chronic kidney disease (CKD) are at excess risk of cardiovascular morbidity and mortality. Abnormalities of parameters related to bone and mineral metabolism are common in CKD patients. Aim of the present study was the determination of prevalence of CKD-MBD in inpatients at a general internal ward.

Methods: In a prospective analysis (November 2008 - February 2009) eGFR and serum levels of phosphate (P), calcium (Ca), parathyroid hormone (PTH) and 25-hydroxyvitamin D (25(OH)D) were measured from 238 patients who were admitted to a general internal medical ward. Patients with acute renal failure (n=3) and those who were on dialysis (n=7) were excluded.

Results: The patient population consisted of 228 patients (110 women) with a median age of 76 years (20-99); women were significant older than men ($p<0.001$). The median eGFR of the patients was 60.7 ml/min/1.73m² (10.4-171.9), no gender-specific difference was detectable. The overall prevalence of CKD (eGFR<60) was 49.1%. There was a significant correlation between eGFR and P ($r=-0.307$; $p<0.001$) and PTH ($r=-0.395$; $p<0.001$). eGFR was not associated with Ca and 25(OH)D. Compared to individuals with eGFR≥60, CKD patients were significant older [80 (37-99) vs. 67 (20-97)], showed higher P [3.24 mg/dl (1.36-6.56) vs. 2.97 (1.40-3.46)] and higher PTH levels [64.2 pg/ml (13.9-260.8) vs. 38.2 (15.8-264.0)]; ($p<0.001$). A significantly higher proportion of subjects with CKD had PTH levels >65 (23% vs. 12%; $p<0.001$). The overall prevalence of hypovitaminosis D (25(OH)D <30 ng/ml) was high (83.8%), but there was no significant difference of 25(OH)D levels between the CKD and non CKD group.

Conclusions: 50% of the acutely admitted patients had an eGFR<60 ml. Patients with CKD had higher P and PTH levels compared with those with an eGFR ≥ 60. There was a high overall prevalence of low 25(OH)D levels, however no association was found between renal function and hypovitaminosis D. The data indicate that CKD per se may not be a risk factor for developing vitamin D deficiency.

PUB086

Single-Dose Pharmacokinetics and Tolerability of Paricalcitol Capsules in Pediatric Subjects with Moderate to Severe Chronic Kidney Disease

Tushar Garimella, Samina Khan, Cheri Enders Klein. *Abbott Laboratories, Abbott Park, IL.*

Background: Paricalcitol (Zemplar) is a selective vitamin D receptor activator approved in adults for the prevention and treatment of secondary hyperparathyroidism associated with chronic kidney disease (CKD). The pharmacokinetics, safety and tolerability of single doses of paricalcitol capsules were evaluated in pediatric subjects with CKD stage 3 and 4 to support dose selection for a clinical study in similar population to study the effect of paraicalcitol on treatment of secondary hyperparathyroidism (SHPT).

Methods: This was an open-label, single oral dose study in pediatric subjects aged 10 to 16 years. Following a 3 mcg dose of paricalcitol, sequential blood samples were collected for 48 hours and pharmacokinetic parameters were determined using noncompartmental methods. Safety was assessed by adverse event monitoring, vital signs, physical examinations, ECGs and laboratory assessments.

Results: Six subjects with CKD Stage 3 (age range 10-16 years and body weight range 36-108 kg) and five subjects with CKD Stage 4 (age range 11-16 years and body weight range 37-62 kg) received study drug. Mean paricalcitol C_{max} was 0.12 ng/mL and 0.14 ng/mL and mean AUC was 2.6 ng*hr/mL and 3.2 ng*hr/mL in the Stage 3 and 4 subjects, respectively. After normalizing for dose and body weight the mean C_{max} and AUC in pediatric Stage 3-4 subjects were 18% and 13-15% lower, respectively, than adults with CKD The harmonic mean half-life of paricalcitol was 13.4 and 16.1 hours after single doses in subjects with CKD Stages 3 and 4, respectively. Overall no adverse events were reported to be related to study drug and no safety concerns were encountered in the single dose study.

Conclusions: The pharmacokinetics of paricalcitol were similar in pediatric subjects with CKD Stages 3 and 4 after single oral doses and appear to be similar to those in adults with CKD Stages 3 and 4 when corrected for dose and body weight. The pharmacokinetic data from these subjects was used to select a 1 mcg TIW dose for a clinical study in CKD stage 3 and 4 pediatric subjects with SHPT.

Prevalence and Factors Associated with Vitamin D Insufficiency/Deficiency in Dialysis Patients: Results of the French National Observatory for Mineral and Bone Metabolism

Guillaume Jean,[1] Hubert Roth,[2] Tilman B. Drueke,[3] Gerard M. London,[4] Thierry P. Hannedouche,[5] Jean-Louis Bouchet,[6] Denis Fouque.[7] *[1]NEPHROCARE, Tassin, France; [2]CRNH, Grenoble, France; [3]INSERM, Amiens, France; [4]Hôpital Manhes, Fleury Merogis, France; [5]Hôpital Civil, Strasbourg, France; [6]CTMR Saint Augustin, Bordeaux, France; [7]Hôpital E. Herriot, Lyon, France.*

Background: Vitamin D insufficiency/deficiency is very common in dialysis patients and has been associated with a less favourable survival rate.

The aim of this study was to analyse the prevalence and the factors associated with vitamin D deficiency in patients on maintenance dialysis.

Methods: Using October 2010 baseline data from a national, prospective observational study evaluating the management of mineral metabolism abnormalities in patients who were on haemodialysis for less than 12 months and not taking nutritional vitamin D, we have compared those with a serum 25-hydroxy vitamin D (25-D) < 75 nmol/l with those ≥75 nmol/l.

Results: Of 3,808 patients, 2,380 (62.5%) were tested for serum 25-D, mean age was 68.3 ± 15.5 years and 37.6% were female. Average serum 25-D was 64.3 ± 42.4 nmol/l. Among the subset of patients who were not treated with nutritional vitamin D (n=928), serum 25-D was associated with the following factors.

Table 1

Patients not treated with nutritional vitamin D	25-D < 75 nmol/l n= 672	25-D ≥ 75 nmol/l n= 256
Age (years)	68.6 ± 15.5	67.6 ± 16.3
BMI kg/m²	25.7 ± 6.0	24.6 ± 5.0 *
Kt/V	1.26 ± 0.30	1.33 ± 0.30 **
Ca mmol/l	2.20 ± 0.19	2.22 ± 0.18
P mmol/l	1.60 ± 0.58	1.56 ± 0.51
iPTH pg/ml°	236 [120-416]	193 [93-337] **
Albumin g/l	34.7 ± 5.1	36.3 ± 5.4 ***
Hemoglobin g/l	111 ± 15	113 ± 15 *
Diabetes	37.4%	31.3%
Vasc. Calcifications	40.0%	34.8%

° Median [Q1-Q3], *P < 0.05, **P < 0.01, ***P < 0.001, Chi² or t-test.

No other clinical, biochemical or therapeutic factor was significantly associated with vitamin D deficiency.

Conclusions: Vitamin D insufficiency/deficiency frequently occurs in patients on maintenance dialysis. Factors associated with this insufficiency include larger BMI, low Kt/V, albumin, haemoglobin and high iPTH.

Prevalence and Factors Associated with Vitamin D Insuffciency/Deficiency in Non Dialysed Chronic Kidney Disease Patients: Results of the French National Observatory for Mineral and Bone Metalolism

Guillaume Jean,[1] Hubert Roth,[2] Tilman B. Drueke,[3] Gerard M. London,[4] Thierry P. Hannedouche,[5] Jean-Louis Bouchet,[6] Denis Fouque.[7] *[1]NEPHROCARE, Tassin, France; [2]CRNH Rhône Alpes, Grenoble, France; [3]INSERM, Amiens, France; [4]Hôpital Manhes, Fleury Merogis, France; [5]Hôpital Civil, Strasbourg, France; [6]CTMR Saint Augustin, Bordeaux, France; [7]Hopital E. Herriot, Lyon, France.*

Background: Vitamin D insufficiency/deficiency is frequently observed in CKD patients and has been associated with a more rapid CKD progression and reduced survival rate. We report the prevalence and the factors associated with vitamin D deficiency in CKD stage 4-5.

Methods: Using October 2010 baseline data from a national, prospective observational study evaluating the management of mineral metabolism abnormalities in CKD patients with eGFR < 60 ml/min/1,73m² and not taking nutritional vitamin D, we have compared those with serum 25-hydroxy vitamin D (25-D) < 75 nmol/l with those ≥75 nmol/l.

Results: Among a total of 876 patients, 585 (67%) were tested for serum 25-D, mean eGFR 21 ±7 ml/min/1,73m² and 41% were female. Average serum 25-D was 62.9 ±40.4 nmol/l. 67.2% had a serum 25-D < 75 nmol/l. Among the subset of patients who were not treated with nutritional vitamin D (n=200), serum 25-D was associated with the following factors.

Table 1

Patients not treated with nutritional vitamin D	25-D < 75 nmol/l n= 142	25-D ≥ 75 nmol/l n= 58
Diabetes	43.7%	25.9% *
Previous CV history	64.1%	46.6% *
Age (years)	72.5 ± 12.5	68.6 ± 15.3
BMI kg/m²	27.9 ± 6.3	25.4 ± 4.5 *
iPTH pg/ml °	156 [82-246]	120 [65-210]
Albumin g/l	38.9 ± 4.5	39.3 ± 4.5
CRP mg/l °	5 [2-15]	2 [1-5] **

° Median [Q1-Q3], *P < 0.05, **P < 0.01, chi² or t-test.

Discussion: A multivariate analysis is pending to further identify independent risk factors.

Conclusions: Vitamin D insufficiency/deficiency is widely prevalent in the majority of patients with stage 4-5 CKD. Factors associated with vitamin D deficiency include diabetes, previous cardiovascular history, larger BMI and inflammation. The potential benefits of nutritional vitamin D supplementation need to be examined prospectively.

Low 25-hydroxyvitamin D Levels Are Associated with an Increased Risk of Sepsis in a Large Managed Care Organization

Anna Jeanette Jovanovich,[1] Michel B. Chonchol,[1] Shailendra Sharma,[1] Kim McFann,[1] Sidney N. Thornton,[2] Jessica B. Kendrick,[1] John R. Holmen. *[1]Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]Intermountain Healthcare, Salt Lake City, UT.*

Background: Vitamin D is an important mediator of immune function and vitamin D deficiency may play an important role in the development of infections, which is the second cause of death in ESRD patients. We hypothesized that patients with vitamin D deficiency would have an increased risk of sepsis admissions.

Methods: We conducted a population-based cohort study of adult patients requiring hospitalization for sepsis who had vitamin D levels measured 3 to 15 months prior to sepsis admission. Vitamin D was evaluated as a continuous variable and a categorical predictor (< 15 ng/mL vs. higher). The primary outcome of interest was sepsis admissions identified through ICD9 codes. Patients admitted with sepsis were matched 1:1 with controls on age, sex, race and season. Conditional multivariate logistic regression was used to evaluate if low vitamin D levels were associated with an increased risk of sepsis admission.

Results: We identified 211 individuals with sepsis and 211 matched controls. The mean (SD) age of the participants was 65±14 years, 59% were female and 91% were Caucasian. Compared to controls, patients with a sepsis admission had a significantly higher percentage of diabetes (46.0% vs. 30.3 %; p=0.0009) and chronic kidney disease (36.0% vs. 21.8%; p=0.001). Mean (SD) levels of 25(OH)D were lower in patients with sepsis than controls (28.8 ±16 vs. 32.1 ± 17 ng/mL p=0.046). After adjustment for diabetes, renal disease and peripheral vascular disease higher 25(OH)D levels were protective for sepsis (OR 0.99, 95% CI 0.98-0.995; p=0.0006). Similarly, when evaluated as a categorical predictor, vitamin D levels < 15 ng/mL vs. higher (adjusted OR 2.20, 95% CI 1.41-3.50; p=0.0006) were strongly associated with a two-fold increased odds of sepsis admissions.

Conclusions: Vitamin D deficiency is associated with an increased risk of sepsis hospitalizations. Clinical trials are needed to evaluate whether vitamin D_3 supplementation can reduce the risk of sepsis in patients with and without CKD.

PUB090

Trends in Demographic and Abnormalities in Bone Mineral Metabolism Parameters in Incidents Dialysis Patients between 2009-2011. Evidence for Vitamin D Deficiency

Achour Laradi,[1] Francois Babinet,[2] Alain Cremault.[3] *[1]Nephrologie-Dialyse, ECHO-PSSM, Le Mans, France; [2]Nephrologie-Dialyse, ECHO-PSSM, Le Mans, France; [3]Nephrologie-Dialyse, ECHO-PSSM, Le Mans, France.*

Background: The prevalence of elderly treated patients (pts) on hemodialysis (HD) has been increasing steadily..The.Phosphocalcic disorders(PCD) have not been studied in these pts.

Methods: A single cohort retrospective database analysis of 24 incidents (HD pts) in 2009 and 2011 was performed.Information on demographics, laboratory data and treatments were abstracted from medical records.

Results: Mean age: 77.7 year, mean plasma albumin value was 34.8 gr/L . CRP mean value was 6.8 mg/L. The mean P value was 1.5 mmol/L .The mean value of Ca was 2.15 mmol/L. Mean iPTH was 337.3pg/mL with 68.2% of pts having iPTH between 134 pg/mLand 603pg/L . iPTH was in 13 % > 603 pg/mL.

The 25(OH)D level (ng/mL) was < 30 ng/mL in 70 % of pts with a mean value of 24.1 ng/mL.

Treatments :36.4 % of pts were having Calcium with a mean dose of 1.16 gr of calcium acetate , 22.7 % of pts were receiving sevelamer with an average dose of 1.60 gr /day , 18.2 % were treated by Cinacalcet with an average daily dose of 30 mg.90.9 % of pts were supplemented with oral vitamin D 3 (cholecalciferol) with mainly an average dose of 75 µg once a week or for a few 2.5 mg (100 000 UI) once a month .18.2 % of pts were treated by an active vitamin D (IV or per os)with an average weekly dose of 1.56 µg.

Discussion: vitamin D deficiency increases in the elderly HD pts with a low 25(OH) D. Treatment strategies have been focused, until recently , on suppression of the parathyroid ‘s glands activity. But an associated age-related decline in iPTH can lead to adynamic bone disease ,these pts being already in a state of low bone remodeling.

Conclusions: Our study highlights the changing presentation of PCD and the adjustements of the treatment practices with a necessary use of vitamin D analogs which are low costs with a lack of side effects.Further studies are mandatory to evaluate the benefits on relevant patient outcomes.

PUB091

Cholecalciferol Is More Efficient Than Ergocalciferol in Normalizing 25OH Levels in Prevalent Hemodialysis Patients

Herve Maheut,[1] Eric Canivet,[2] Khaled Gaha,[1] Pierre Clavel,[2] Isabelle Kazes,[1] Andreea Petrache,[2] Philippe Rieu.[1] *[1]Nephrology, CHU Reims, Reims, France; [2]ARPDD, Reims, France.*

Background: Hemodialysis patients(hd) have low levels of 25(OH)vitamin D and supplementation with ergocalciferol(ergo)D2 or cholecalciferol(chole)D3 is recommended. We have previously shown that a 3 months supplementation with a 600000 IU cumulative dose of ergo failed to normalize 25(OH)D plasma levels in 40% of hd. However chole might be more efficient than ergo.

Methods: Six months, prospective, non randomized open-study was conducted in a cohort of 97 unselected prevalent hd from 2 large in-center french facilities with different modalities of supplementation. Patients were divided in 2 monthly oral treatment groups: in group1 hd received 200000IU of ergo, in group2 hd received 200000IU of chole. Plasma levels of 25(OH)D(normal 30 µg/l)and parathormone(PTH) were measured at baseline, month 3 and month 6. Total calcemia(Ca) and phosphatemia were measured monthly from baseline to month 6. Pre defined exclusion criteria at entry and per study were: native vitamin D supplementation less than 6 months before inclusion, Ca>2,65 mmol/l on 2 consecutive dosages and 25(OH)D plasma level>100 µg/l.

Results:

Baseline characteristics and evolution of biologic parameters

	Group 1 (ergo)(n=69)	Group 2 (chole)(n=29)
Age (years)	69,1	74,7
HD duration(months)	55,6 (53,6)	70,2 (66,7)
Baseline25(OH) D(mcg/l)	19,9(7,6)	18,0(6,5)
Baseline Ca(mmol/l)	2,16(0,1)	2,2(0,15)
Baseline Phosphatemia(mmol/l)	1,66(0,51)	1,36(0,55)
Baseline PTH(pg/ml)	437(351)	405(346)
25(OH)D M3** (mcg/l)	29,5(10,2)	41,6(17,3)
Ca M3**(mmol/l)	2,18(0,20)	2,30(0,13)
Phosphatemia M3(mmol/l)	1,57(0,50)	1,43(0,57)
PTH M3(pg/ml)	376(322)	428(357)
25(OH) D M6**(mcg/l)	32,5(11,7)	44,3(13,6)
Ca M6*(mmol/l)	2,18(0,19)	2,28(0,15)
Phosphatemia M6(mmol/l)	1,61(0,58)	1,49(0,53)
PTH M6(pg/ml)	386(374)	418(418)

results are expressed by means (SD) * p<0,05 ** p<0,001

At month 6, 25(OH)D was>30µg/l in 82,8% of group2 hd and in 56,5% of group1 hd (p=0,01). No significant episod of hypercalcemia nor toxic 25(OH)D levels were observed.

Conclusions: Chole is more effective than ergo in normalizing 25(OH)D in hd. Modalities of long term supplementation remain to be established.

PUB092

Efficacy and Safety of Paricalcitol Dosing Regimens for Subjects on Hemodialysis in China

Jia Qi Qian,[1] Hong Li Lin,[2] Gengru Jiang,[3] Nan Chen,[3] Xueqing Yu,[4] Li Zuo,[5] Mei Wang,[5] Xue-Wang Li,[6] Changying Xing,[7] Zhaoxing Huang,[8] Liqiu Liu,[9] Michael Amdahl,[10] Samina Khan.[10] *[1]Jiatong U; [2]Dalian U; [3]Shanghai Jiatong U; [4]Sun Yat-sen U, ; [5]Peking U; [6]Peking Med; [7]Nanjing U; [8]Wenzhou Med; [9]Qingdao U; [10]Abbott.*

Background: In China there is a growing prevalence of hemodialysis (HD) subjects with secondary hyperparathyroidism (SHPT). The study aim was to evaluate the safety and efficacy of paricalcitol a selective vitamin D receptor (VDR) activator for reduction of intact parathyroid (iPTH) levels in HD subjects.

Methods: In this randomized, multi-center, single-blind study 216 subjects received dosing regimens based on EU (iPTH/80) or US (0.04µg/kg) package inserts (PI) of paricalcitol over 12 weeks. Primary efficacy analysis evaluated non-inferiority of EU compared to US PI in proportion of subjects achieving at least 2 consecutive ≥30% decreases from baseline iPTH. Secondary analyses evaluated the proportion achieving KDOQI (150-300pg/mL) and KDIGO (130-585 pg/mL) recommended iPTH ranges incidence of hypercalcemia (at least 2 consecutive Ca>11.0mg/dL) and changes from baseline iPTH to each post-baseline visit.

Results: A higher proportion (88.6%) of subjects initiated at iPTH/80 achieved at least 2 consecutive ≥30% decreases in baseline iPTH than subjects receiving 0.04µg/kg (55.9%). A comparable proportion treated with both regimens achieved KDOQI (17.6% EU and 19.4% US) and KDIGO (59.3% EU and 54.6% US) recommended iPTH ranges. Repeated measures analysis showed significantly greater mean reduction from baseline iPTH (p<0.001) in subjects receiving iPTH/80 compared to subjects receiving 0.04µg/kg. Overall, treatment with iPTH/80 and 0.04µg/kg dosing presented a low incidence of hypercalcemia (1 of 216).

Conclusions: Paricalcitol dosing of iPTH/80 (EU) demonstrated superiority over 0.04µg/kg (US) in achieving ≥30% reductions from baseline iPTH levels. However, both regimens were comparable in achieving KDOQI and KDIGO recommended iPTH ranges with low risk of hypercalcemia. Paricalcitol represents a potentially beneficial treatment option for subjects with SHPT on HD in China.

PUB093

Ergocalciferol (ergo) Therapy in Calcidiol Deficient Hemodialysis (HD) Patients on Therapeutic Doses of Paricalcitol Does Not Decrease Cytokine Release in Peripheral Blood Mononuclear Cells

Vidya M. Raj Krishnamurthy,[2] Srinivasan Beddhu,[1,2] Tom H. Greene,[1,2] Guo Wei,[2] Yuxia He,[1] Huan Li,[1,2] Alfred K. Cheung,[1,2] Christi M. Terry.[1,2] *[1]VA; [2]Univ Utah.*

Background: Vitamin D possesses immuno-regulatory activities such as inhibiting nuclear factor-κB activity, increasing IL-10 production and decreasing IL-6 and TNF-α production. It is unclear whether additional therapy with ergo in those with calcidiol deficiency would inhibit cytokine release by peripheral blood mononuclear cells (PBMC) and thus have beneficial anti-inflammatory effects in this population.

Methods: We conducted a randomized double blind cross-over trial of ergo vs placebo in 24 HD patients treated with therapeutic doses of paricalcitol with iPTH range between 150-600 pg/ml but with plasma 25(OH) vitamin D levels <30 ng/ml and high sensitivity C-reactive protein (hs-CRP) >3mg/L. 24 HD participants were randomly assigned to ergo 50,000 U/week vs. placebo for 12 wks, followed by 4 wk washout and cross-over for 12 wks. Blood was collected at baseline and wks 12, 16 and 28. PBMC were obtained using standard Ficoll-Paque isolation then incubated for 24 h plus or minus 10 ng/ml LPS, in media with 10% patient serum. Cytokine release to media was tested (ELISA).

Results: The test population demographics were 59 ± 13 yrs, 42% men, 80% Caucasian, 67% diabetic and the average duration of ESRD was 3.7±4.6 years. Ergo treatment significantly increased plasma 25(OH) vitamin D levels (p<0.001). Table 1 shows the difference between pre and post ergo vs placebo treatment in LPS-induced release of IL-6 or TNF from PBMC.

Difference in pre and post ergo vs the pre and post placebo treatment

	Mean(95%CI)	p value
Plasma 25(OH) vitamin D ng/ml	17.5(9.3-25.7)	<0.001
IL6* pg/ml	1.00(0.53-1.90)	1.00
TNF-α * pg/ml	0.93(0.61-1.42)	0.74

*LPS stimulated release from PBMCs; IL6 and TNFα are log transformed

Conclusions: Ergo treatment of HD patients increases 25(OH) vitamin D levels but had no significant effect on PBMC response to LPS treatment in vitro. These results suggest that ergo treatment will not decrease inflammation in this patient population.

PUB094

The Effect of Cholecalciferol Supplementation on Physical Function and Health Related Quality of Life in 25 Hydroxy Vitamin D Insufficient Hemodialysis Population

Wilner Samson,[1] Sharad Sathyan,[2] Anne M. Kenny.[3] *[1]Nephrology, University of Connecticut School of Medicine, Farmington, CT; [2]Nephrology, Cornell School of Medicine, New York, NY; [3]University of Connecticut Health Center, Farmington, CT.*

Background: To determine the effects of Vitamin D supplementation on physical performance and health-related quality of life in a hemodialysis population

Methods: Subjects were followed for 4 weeks without treatment (as a control period), then were supplemented with 3000 IU cholecalciferol (vitamin D3) for 8 weeks. The following tests were performed at -4 weeks, baseline, 4 and 8 weeks post-supplementation: 25-hydroxyvitamin D (25OHD); parathyroid hormone (PTH); physical assessment including 6 minute walk,handgrip strength and Short Physical Performance Battery (SPPB); health questionnaires including cognitive screen, activities and instrumental activities of daily living, SF-36 and Geriatric Depression Scale.

Results: 30 subjects (mean age 64 + 16 years; 18 men/ 12women; 57% Caucasian) had 25 OHD levels of 19.9 + 7.7ng/dl. Twenty-four subjects (80%) had 25 OHD less than 30 ng/dl. Sixty-five percent of participants reported general health to be fair or poor. While 25 OHD increased significantly to 26.5+8.9 after supplementation, there were no changes in physical performance or health related quality of life.

Conclusions: Our data confirms that 25 OHD insufficiency is widely prevalent in the ESRD population. Further, health-related quality of life is rated below good in a majority of the patients. Modest cholecalciferol supplementation was able to increase 25OHD levels, but a significant portion of patients remained below 35 ng/dl, a level required to benefit many health outcomes including physical performance, suggesting a need for higher doses of cholecalciferol. We found no significant change in physical performance or quality of life. Further work will be required to address the appropriate dose of cholecalciferol to obtain sufficient 25OHD levels and whether physical performance or quality of life improve with supplementation in ESRD patients.

Cinacalcet Hydrochloride Prohibits Bone Mineral Density Loss in Dailysis Patients

Megumi Sato,[1] Masanor Jotoku,[2] Yuzuru Sato,[2] Ryota Ikee,[3] Masataka Tsunoda,[4] Naomi Sasaki,[5] Nobuo Hashimoto.[5] *[1]Department of Nephrology, Jinzonaika Megumi Clinic, Sapporo, Hokkaido, Japan; [2]Department of Internal Medicine, Sato Junkankikanaika, Matsuyama, Ehime, Japan; [3]Department of Nephrology and Dialysis, H.N.Medic Kitahiroshima, Kitahiroshima, Hokkaido, Japan; [4]Department of Nephrology and Dialysis, H.N.Medic Sapporo-Higashi, Sapporo, Hokkaido, Japan; [5]Department of Nephrology and Dialysis, H.N.Medic, Sapporo, Hokkaido, Japan.*

Background: In dialysis patients, bone mineral density(BMD) loosing is closely related not only to the progress of chronic kidney disease-mineral bone disorder(CKD-MBD) but also to the patient mortality.In this study we evaluated whether Cinacalcet hydrochloride (CH) is effective in keeping BMD or not.

Methods: We selected 106 patients from the consecutive 152 chronic hemodialysis patients for the current study.The inclusion criterion of the patients was that their %BMD was more than 80%.106 patients were divided into the following 3 groups by the medication for secondary hyperparathyroidism (2HPT).

Group A: intra-venous vitamin D administration (i.v. VD)+CH

Group B: i.v. VD

Group C: oral VD administration

We compared the changes in %BMD, intact-PTH (iPTH) and bone alkaline phosphate (BAP) among 3 groups 6 months and 18 months after the administration of CH.

Results: i-PTH when CH before started in group A was 450.3±266.1 pg/mL, then it was significantly reduced after CH started.%BMD was significantly reduced Group B and C but did not change in Group A.The mean values in iPTH and BAP 6 months and 18 months of each group were not significantly different (Table 1).

Parameters of each group

	%BMD		i-PTH			BAP	
Group	6 months	18 months	pre-CH	6 months	18 months	6 months	18 months
A	97.7±9.0	96.7±7.9	450.3±266.1	170.0±104.5	138.4±34.5	20.6±3.0	22.5±10.7
B	97.9±11.5*	96.3±12.3*	blank	130.2±57.4	141.3±69.5	24.8±12.9	25.1±11.3
C	102.8±11.9**	101.2±12.7**	blank	85.1±61.6	105.3±65.6	25.1±10.7	27.2±11.0

*,**p<0.01

Conclusions: In Group A, using CH together with i.v.VD has the possibility of prohibiting the decrease of the bone mineral density .And it seemed that it was preferable to use CH with i.v. VD as much as possible before the %BMD falls below 80%.

PUB096

Hipovitaminosis D in Macroalbuminuric Diabetic Nephropathy

Silvia M. Titan,[1] Márcia Silva Queiroz,[2] Maria Alice Muniz Domingos,[1] Vanda Jorgetti,[1] Rui Toledo Barros,[1] Rosa M. Moyses,[1] Roberto Zatz.[1] *[1]Nephrology Division, Hospital das Clínicas, Sao Paulo University Medical School, Sao Paulo, Brazil; [2]Endocrinology Division, Hospital das Clínicas, Sao Paulo University Medical School, Sao Paulo, Brazil.*

Background: The frequency of hypovitaminosis D in CKD patients is very high, although causal mechanisms are still unclear. In this study, we analyzed the frequency and predictors of hypovitaminosis D in diabetic nephropathy (DN) patients.

Methods: Data on 56 DN patients with proteinuria and class III CKD was collected from 2005-07. Mann-Whitney and chi-square tests were used; linear and logistic regression models were built for 25OH-vitamin D (25vitD).

Results: Mean 25vitD was 21,9 ng/mL(±10,1), with 84% of patients presenting a 25vitD <30 ng/mL. When patients were classified according to median 25vitD, those with <21 ng/mL presented lower creatinine clearance, hemoglobin, serum albumin and calcium, and higher proteinuria, serum phosphorus, urinary MCP-1, urinary VEGF and serum MCP-1. In linear regression, adjustment for creatinine clearance left only proteinuria, serum albumin and serum MCP-1 as significant predictors of 25vitD. However, further adjustment for age, sex and creatinine clearance left only proteinuria (B-1,24; 95%CI-2,26/-0,22; p=0,02) and serum MCP-1 (B-0,02; 95%CI-0,04/-0,01; p=0,002) as independent predictors. In the logistic regression model adjusted for creatinine clearance, both proteinuria and serum MCP-1 were independently related to the risk of lower 25vitD.

Logistic regression models on the risk of having 25OH-vitaminD < 21 ng/mL in DN patients.

	OR	Lower 95% CI	Upper 95% CI	p
Univariate models				
Estimated creatinine clearance (CG; ml/min/1,73m2)	0,97	0,94	1,00	0,05
24 proteinuria (g/d/1,73m2)	1,45	1,12	1,88	0,01
Serum MCP-1 (pg/mL)	1,01	1,00	1,01	0,01
Multivariate model				
Estimated creatinine clearance (CG; ml/min/1,73m2)	0,97	0,95	1,00	0,10
24 proteinuria (g/d/1,73m2)	1,31	1,01	1,70	0,04
Serum MCP-1 (pg/mL)	1,01	1,00	1,01	0,03

Conclusions: Hypovitaminosis D is extremely frequent in macroalbuminuric DN patients. While creatinine clearance may not be a major determinant of 25vitD, proteinuria and systemic inflammation were importantly associated to the risk of low 25vitD in our study.

PUB097

Oral Cholecalciferol Therapy in Prevalent Hemodialysis Patients: A Randomized Placebo Controlled Pilot Study Karen To, Azim S. Gangji, Trevor J. Wilkieson, Cathy Z. Kotsamanes, Catherine M. Clase. *Medicine, McMaster University, Hamilton, ON, Canada.*

Background: Vitamin D is a prohormone that is activated in the liver and kidney. Besides the kidney, other tissues express 1α-hydroxylase. This local autocrine/paracrine activity is important for health maintenance and relies on adequate 25(OH)D levels. Objectives: To investigate the effects of cholecalciferol (D3) compared with placebo on i) serum 25(OH)D, calcitriol, parathyroid hormone (PTH), inflammatory and bone turnover markers; ii) blood pressure (BP); iii) the use of erythropoesis stimulating agents (ESA).

Methods: We conducted a randomized controlled pilot study of 20 prevalent adult in-center hemodialysis (HD) participants whom we assigned, using concealed randomization, to receive 50,000 IU of D3 or identical-appearing placebo weekly for 12 weeks. Health care providers, participants, and research staff were masked to allocation. The primary outcome was the change in 25(OH)D between baseline and week 12. We measured other laboratory outcomes at the same time points, and calcium and phosphorus every two weeks. We assessed BP as the mean of pre- and post-dialysis and collected information on medication use. Analysis was done according to the intention-to-treat principle. Unpaired t tests were used to assess differences between mean baseline and week 12 blood work results. Chi-squared tests were used to compare categorical variables between groups.

Results: Mean serum 25(OH)D levels of both groups were similar at baseline [14.7±6.1 (D3) versus 13.2±8.1 ng/ml (placebo);p=0.63], consistent with insufficiency.

The mean difference (week 12 minus baseline) in 25(OH)D levels were 25.1±14.3 and -1.2±3.7 ng/ml in the D3 and placebo groups, respectively (p<0.001). There were no differences in the change in calcitriol, PTH, ALP, CRP, ESR, ferritin, Alb levels between treatment groups. There were no differences between treatment groups in the mean change of BP, or in haemoglobin:ESA ratio. There were no episodes of hypercalcaemia (≥11 mg/dL). Episodes of hyperphosphatemia (≥9.3 mg/dL) were comparable between groups [n=2 (D3) versus n=3 (placebo); p>0.99].

Conclusions: Weekly D3 was effective in correcting the vitamin D status in HD participants.

PUB098

Vitamin D Deficiency in Renal Transplantation Kristin Vibeke Veighey,[1] David C. Wheeler,[1] Mark Harber,[2] Anne B. Dawnay,[5] Francis Lam,[5] Martyn Egerton,[3] Aliyye Karasu,[4] John Cunningham.[1] *[1]UCL Centre for Nephrology; [2]Royal Free Hampstead NHS Trust; [3]Epsom & St Helier University Hospitals NHS Trust; [4]Anthony Nolan Trust; [5]UCL Hospital.*

Background: Animal studies have demonstrated a reduction in ischaemia-reperfusion (IR) injury following systemic administration of vitamin D. Vitamin D deficiency is endemic renal patients. We postulated that patients deficient in 25-hydroxyvitamin D (25OHD) and/or 1,25-dihydroxyvitamin (1,25OH2D) D might have poorer cardiac and endothelial function, greater IR injury at transplantation, and increased fibrosis on protocol biopsies.

Methods: 103 patients transplanted from 2008-2011 had protocol biopsies at 6(t6)/56 weeks(t56) and had stored serum from the time of transplantation. The population was 53.40% White, 22.33% Black, 14.56% Asian, 2.91% Mixed and 6.80% Other. None received supplemental vitamin D.

Serum 25OHD and 1,25OH2D were quantified by mass spectrometry (25OH D2/D3 by LC-MS/MS (Inter-assay CV <10%); 1,25OH2D by enzymeimmunoassay (IDS)).

Fibrosis on protocol biopsies was quantified using a validated index of chronic damage (ICD) score(%) (Mean inter-observer difference 1.0(CI 0.94-1.06)).

Results: In our cohort, 20(19.42%) were deficient(<25nmol/l), 57(55.34%) insufficient(25-75nmol/l), and 26(25.24%) replete (>75nmol/l) in vitamin D. 60% of Asian patients were deficient. In 97(94.17%), D2 was below the assay range.

62 patients (60.19%) were deficient and 41(39.81%) were replete(40-150pmol/l) in 1,25-dihydroxyvitamin D. 80% of Asian patients were deficient. 25-hydroxyvitamin D levels did not predict 1,25-dihydroxyvitamin D levels in many cases - 67.86% of those replete in the former were deficient in the latter.

Linear regression was used to assess associations between 1,25-dihydroxy-/25-hydroxy-vitamin D levels and ICD at t6 and t56. Despite adjustment for cold ischaemic time, donor age and recipient diabetes, there was no association between either measure and ICD at t6/t56.

Conclusions: Only 25% of this population was vitamin D replete at transplantation. The prevalence of deficiency amongst Asian patients was 60%. D2 status had little bearing on overall D status. There was no association between vitamin D status and chronic damage on protocol biopsies.

PUB099

RAAS Blockade Abrogates the Effect of Parathyroidectomy on Renal Hemodynamics Liesbeth Viaene, Kathleen Claes, Bjorn K.I. Meijers, Pieter Evenepoel. *Nephrology, University Hospital, Leuven, Belgium.*

Background: Acute renal dysfunction is a common, although not universal finding after parathyroidectomy (PTX). Available experimental evidence points to a hemodynamic mechanism mediated at least partly by changes in the renin angiotensin aldosterone system (RAAS). In animal studies, parathyroid hormone (PTH) and calcium modify plasma renin activity. Supportive clinical evidence, however, is lacking.

Methods: We performed a prospective interventional study in renal transplant recipients with persistent hyperparathyroidism and hypercalcemia (NCT00452049). 16 patients (5 female, age 53±11 y) were enrolled of whom 10 were treated with RAAS blockade therapy at the time on inclusion. Mineral metabolism parameters (including PTH, FGF-23 and calcitriol) and renal hemodynamics (inulin and para-aminohippurate (PAH) clearances) were assessed before and after PTX.

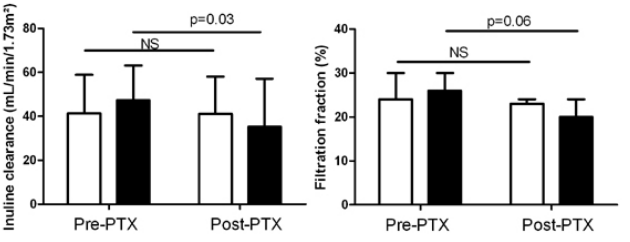
Results: PTH and calcium levels significantly decreased after PTX.

Evolution of parameters of mineral metabolism after PTX

	Pre-PTX	Post-PTX	p
Calcium (mg/dL)	10.9	8.9	0.0005
Phoshorus (mg/dL)	2.1	3.1	0.0005
PTH (ng/L)	98.9	4.8	0.0005
Calcitriol (ng/l)	55.1	50.5	0.6

Median values are shown

Inulin clearances (GFR) decreased whereas PAH-clearances (Renal Blood Flow) remained unchanged. Filtered fraction tended to decrease after PTX (p=0.07). Subgroup analysis in patients with and without RAAS blockade therapy revealed changes in renal hemodynamics in patients free of RAAS blockade only, despite similar PTH and calcium levels and similar calcitriol exposure pre- and post PTX.



Inuline and filtration fraction in patients free (black bars) and on (white bars) RAAS blockade before and after PTX.

Conclusions: GFR and filtered fraction (tend to) decrease after PTX. RAAS blockade abrogates the effect of PTX on renal hemodynamics. Our data support the thesis that PTH and calcium affect renal hemodynamics through modulation of the RAAS.

PUB100

Markedly Suppressed Parathyroid Levels in Bedridden Diabetic Patients Compared to Ambulatory Diabetic Patients on Dialysis Michael Yudd, Gabriela Wojnarska-Alvarez, Payam Benson, Parin M. Makadia, Albert Siu, Filberto D. Kelly, Shivangi Patel. *Renal Section, Veterans Affairs New Jersey Health Care System, East Orange, NJ.*

Background: Suppressed PTH levels in ESRD are noted in diabetics and the elderly, and are associated with Malnutrition- Inflammation Complex (MIC) surrogates.

Methods: We evaluated our clinical impression that sick bedridden patients had makedly depressed PTH levels. All patients in a single hemodialysis unit were divided into 3 groups: ambulatory(n=30), bedridden for at least 3 months (n=10), and wheel-chair bound (n=10). Demographic, clinical, and treatment parameters of renal bone disease were compared in the bedridden patients to the ambulatory ones. Since 90% of our bedridden patients were diabetic, we then compared these to the 14 diabetic ambulatory patients.

Results: Serum intact PTH was much lower in the bedridden patients compared to the ambulatory ones: 81.7 +/- 57.37 vs. 410.0 +/- 281.32 pg/ml (p = 0.008). This difference persisted when the diabetic bedridden pts were compared to the ambulatory diabetics: 68.7 +/- 42.3 vs. 394.4 +/- 348.5 pg/ml (p= 0.011).

There were no differences between the groups in age or dialysis vintage.

Serum albumin was much lower, and dropping over the past year in the bedridden group compared to the ambulatory (2.89 +/- 0.78 vs. 3.83 +/- 0.35 g/dl ,p = 0.0001). No differences in corrected serum calcium or phosphorus.Review of bone-related medications showed that this PTH suppression was not iatrogenic.

Review showed that most of the bedridden patients had higher PTH levels when they were ambulatory.

Conclusions: 1. Bedridden pts on hemodialysis, who were mainly diabetic, have markedly suppressed intact PTH levels, compared to ambulatory diabetic pts. This was associated with low albumin levels. It was not associated with higher calcium or phosphorus levels, or due to oversuppression by medications.

2. Before becoming bedridden, when the patients were ambulatory, PTH levels tended to be much higher.

3. The cause of this PTH suppression was not investigated. With the association of hypoalbuminemia, factors associated with the Malnutrition- Inflammation Complex may play a role. Immobilization may be a factor.

PUB101

Vitamin D Deficiency Is Associated with Poor Response to Active Hepatitis B Immunisation in Patients with Chronic Kidney Disease Emanuel Zitt,[1,2] Hannelore Sprenger-Maehr,[1,2] Florian Knoll,[1] Ulrich Neyer,[1,2] Karl Lhotta.[1,2] *[1]Department of Nephrology and Dialysis, Academic Teaching Hospital Feldkirch, Feldkirch, Austria; [2]Vorarlberg Institute for Vascular Investigation and Treatment (VIVIT), Academic Teaching Hospital Feldkirch, Feldkirch, Austria.*

Background: Vitamin D deficiency is highly prevalent in patients suffering from chronic kidney disease. At present it is not known whether this condition is a cause of the poor response to hepatitis B vaccination in these patients.

Methods: We performed a retrospective analysis of 200 patients with chronic kidney disease, who had undergone hepatitis B vaccination with three to four 40 µg recombinant hepatitis B vaccine doses. Anti-HBs antibody titers and vitamin D (25(OH)D) levels were measured by chemiluminescence immunoassays.

Results: Vitamin D deficiency with serum levels <10 ng/mL was found in 35.5% of patients. These patients had a lower seroconversion rate than did patients with levels ≥10 ng/mL (45 *vs* 64%; P=0.011) and their mean antibody titres were lower (215±706 vs 476±1583 IU/L). Non-responders had lower 25(OH)D concentrations than did responders (12.9±6.5 vs 15.1±7.4 ng/mL; P=0.034). In a multiple logistic regression analysis vitamin D deficiency (OR 0.532; P=0.043) and diabetes (OR 0.493; P=0.035) remained independent and significant negative predictors of seroconversion.

Conclusions: In patients with chronic kidney disease severe deficiency of vitamin D is associated with a poor antibody formation upon hepatitis B vaccination. Vitamin D supplementation might be useful in improving response to immunisation.

PUB102

Platelet Reactivity in Erythropoietin (EPO) Treated Long-Term Hemodialysis Patients Pravin Bhat, Angella Brown, Reisha Twanna Browne, Melissa Rampal, Anna Babinska, Moro O. Salifu. *Medicine, Division of Nephrology, SUNY Downstate Medical Center, Brooklyn, NY.*

Background: Recombinant human erythropoietin (EPO) is widely used for the therapy of anemia of chronic kidney disease (CKD) however its use has been associated with increased cardiovascular mortality. The mechanisms underlying excess cardiovascular mortality with use of EPO in CKD are poorly understood. We hypothesize that given the 70% homology between erythropoietin and thrombopoietin, the administration of exogenous EPO could induce increased platelet reactivity via direct platelet stimulation by EPO.

Methods: Using washed isolated platelets obtained predialysis from 20 hemodialysis (HD) patients with no history of antiplatelet or antihistamine ingestion, we evaluated platelet aggregation using a Chronolog-Lumi impedance aggregometer model 560-CA, after exposure of platelets to 0.5 mcg/ml and 1mcg/ml final concentrations of collagen. All patients were on dialysis for at least 3 months and received EPO three times a week on dialysis. Ten healthy donors served as controls. Platelet aggregation was measured as amplitude (Amp, Ohms) and Slope (Ohms/s). Data are presented as mean±SEM. Mann-Whitney U Test was used to compare differences in aggregation parameters between patients and controls.

Results: At 0.5 mcg/ml of collagen exposure, the Amp (53.93±3.9 vs. 34.4±10.1, p=0.059) and Slope (35.5±2.6 vs. 22.7±6.0, p=0.049) of aggregation was significantly higher in HD patients compared with Controls. At 1 mcg/ml of collagen exposure, the Amp (55.6±4.0 vs.25.0±12.6, p=0.099) and Slope (34.9±9.2 vs. 17.0±8.6, p=0.029) of aggregation was significantly higher in HD patients compared with Controls. There was no significant dose response relationship.

Conclusions: EPO-treated HD patients had increased platelets reactivity ex vivo compared to control healthy subjects. Direct stimulation of platelets by EPO independent of dose may generate a chronic low grade platelet activation state and may explain the excess cardiovascular mortality associated with ESA therapy in CKD. Further studies are needed to elucidate the effect of EPO on platelet function.

PUB103

Effect of Recombinant Human Erythropoiesis-Stimulating Agent on In Vitro Platelet Reactivity in Healthy Subjects Pravin Bhat, Reisha Twanna Browne, Melissa Rampal, Angella Brown, Thin Maw, Anna Babinska, Moro O. Salifu. *Medicine, Division of Nephrology, SUNY Downstate Medical Center, Brooklyn, NY.*

Background: Erythropoietin (EPO) use has been associated with increased cardiovascular mortality via unknown mechanisms. We hypothesize that given the 70% homology between erythropoietin and thrombopoietin, exogenous erythropoietin could induce increased platelet reactivity via direct platelet stimulation.

Methods: Isolated platelet aggregation, measured as amplitude (Amp, Ohms) and Slope (Ohms/s) was tested at time zero and at 4 hours of incubation in 23 healthy donors using three final concentrations of darbepoetin; low (81ng/ml), intermediate (108.8 ng/ml) and high (249.6 ng/ml). Paired sample t-test was used to compare the means ±SEM between darbepoetin-treated and untreated platelets.

Results: At time Zero, the Amp of aggregation was significantly higher at low (42.3±4.0, p=0.003), intermediate (46.8±3.7, p=0.001) and high (46.2±4.1, p=0.002) darbepoetin-treated compared to control (untreated) platelets (29.9±4.2). The Slope, representative of the speed of the aggregation curve, was significantly higher at low (24.6±2.3, p=0.001) and intermediate (25.2±1.7, p=0.002) darbepoetin-treated compared to control (untreated) platelets (17.8±2.2). At 4 hours incubation, the Amp of aggregation was significantly higher at low (41.3±3.0, p=0.001), intermediate (34.5±4.0, p=0.001) and high (30.6±4.2, p=0.013) darbepoetin-treated compared to control (untreated) platelets (21.2±3.2). The Slope was significantly higher at low (28.4±2.5, p=0.001) and intermediate years (20.2±2.3, p=0.029) darbepoetin-treated compared to control (untreated) platelets (16.36±2.3). There was no significant difference in Amp or Slope between low, intermediate and high darbepoetin treatments at zero or 4 hours.

Conclusions: Darbepoetin-treated platelets had increased platelet reactivity in vitro compared to untreated platelets but a dose response relationship was not observed. Direct stimulation of platelets by EPO independent of dose may explain the excess cardiovascular mortality associated with EPO therapy in CKD. Ex vivo platelet function studies are needed to validate these findings.

PUB104

Microarray Analysis of Genes Expressed by Glomerular Parietal Epithelial Cells Takamoto Ohse,[1] Jeffrey W. Pippin,[2] Ron D. Krofft,[2] Alice M. Chang,[2] Stuart J. Shankland.[2] *[1]Division of Nephrology and Endocrinology, University of Tokyo Graduate Medical School, Japan; [2]Division of Nephrology, University of Washington, Seattle, WA.*

Background: Glomerular parietal epithelial cells (PECs) are squamous epithelial cells which form a monolayer on the urinary side of Bowman's capsule of the glomerulus. Unlike other glomerular cells, very little is known about the normal protein expression profile of PECs. In this study differential microarray analysis was performed on RNA from capsulated (PECs present) and de-capsulated (PECs absent) rat glomeruli in order to determine which genes are constitutively expressed by PECs.

Methods: Two types of rat glomeruli, capsulated and de-capsulated ones, were isolated with the newly developed modified sieving technique and mRNAs extracted from these two fractions were compared with microarray. The levels of highly expressed genes were then verified by PCR and immunohistochemistry.

Results: Two types of analysis were pursued. First, we identified 20 genes considered highly expressed (defined as > 2 fold increase in capsulated glomeruli compared to de-capsulated glomeruli). The mRNA expression for 15 of these was verified in a cultured mouse PEC cell line. Based on the difference in expression level between PEC cells and mouse cortex, the highest expressing 5 genes in PECs were PKHD1, Aldh1a1, CDH6, FRAS1 and PAX8. Their expression was confirmed at the protein level. In the second analysis, mRNA expression was verified with Human Protein Atlas. Among 148 genes which is expressed in capsulated glomeruli with more than 2 fold difference with de-capsulated glomeruli, we found the 26 genes were included in Human Protein Atlas. Finally, we had 14 genes which were expressed in PECs in glomeruli and not expressed in glomerular tuft.

Conclusions: By microarray analysis, 29 genes were detected to be expressed in PECs, and 5 of them were verified their expression in PECs with immunohistochemistry. While none of these proteins were exclusively expressed by PECs within the kidney, these genes should serve to expand our understanding of the role and function(s) of PECs during health and disease.

Disrupted Autophagosomal Traffic Enhances Tubular Cell HIV Replication: Role of Nef Divya Salhan, Shabina Rehman, Ashwani Malhotra, Pravin C. Singhal, Mohammad Husain. *Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY.*

Background: Tubular cells have been considered to serve as reservoir for HIV in kidney. HIV-Nef has been demonstrated to modulate endosomal traffic in macrophages. Recently, the role of endosomes has been highlighted in HIV replication. We asked whether Nef has the potential to enhance HIV replication in human tubular cells.

Methods: To develop productive HIV infection in tubular cells, HK2 (human tubular cells) were co-cultivated with infected lymphocytes for 72 hours. Subsequently, tubular cells were extensively, washed and evaluated for Gag expression by real time PCR. To determine the role of Nef in HIV replication, HK2 cells were transfected with Nef +ve (Nef+/HK2) or Nef-ve (Nef-/HK2) constructs, followed by co-cultivation with HIV infected lymphocytes for 24 hours. Subsequently, Nef(+)/HK2 and Nef(-)/HK2 were evaluated for the quantification of Gag expression. To determine the role of autophagy in Nef induced HIV replication, cells were prepared under similar conditions and then treated with or without rapamycin (100 nM) during co-cultivation studies. To determine the mechanism involved, HK2s, Nef(+)/HK2s, Nef(-)/HK2s, and Bafilomycin/NH4Cl-treated HK2s (positive control) were immunolabled for LC3-2 (as a marker of autophagosome). To quantify the number of autolysosomes (autophagosome fused with lysososomes), double labeling for LC3-2 and lysosome tracker was carried out.

Results: Nef(+)/HK2 cells displayed enhanced HIV replication when compared to Nef(-)/HK2s. However, rapamycin decreased HIV reoplication in Nef(+)/HK2. Interestingly, Nef(+)/HK2s also showed enhanced number of autophagosomes and diminished number of autolysosomes when compared with Nef(-)/HK2. On the other hand, rapamycin treated cells displayed enhanced numbers of autolysosomes.

Conclusions: These findings indicate that Nef enhances tubular cell HIV replication by accumulation of autophagosomes through inhibiton of autophagy by disruption of fusion of autophagosomes to lysosomes.

Tubular Expression of the Facilitative Glucose Transporter GLUT1 in Normal Human Kidney Pamela J. Fall,[2] Rokshana R. Thanadar,[2] Saadia A. Khan,[2] Sitharam C. Nandigam,[2] Rajendra Chalasani,[2] John White,[2] Muralidharan Jagadeesan,[1,2] Charles W. Heilig,[3] N. Stanley Nahman.[1,2] *[1]Medicine, Charlie Norwood VAMC, Augusta, GA; [2]Medicine, Georgia Health Sciences University, Augusta, GA; [3]Medicine, University of Florida COM Jacksonville, FL.*

Background: We showed that tubular GLUT1 expression was increased in chronic allograft nephropathy (CAN) (*J Invst Med* 59:532). In that report, ~ 41% of CAN kidney tubules expressed GLUT-1, whereas ~ 24% of tubules from normals (NL) were GLUT1(+). Due to the potential pro-sclerotic effects of increased GLUT1 we reasoned that a more qualitative assessment of GLUT1 expression from normal kidney was warranted.

Methods: We scored tubular GLUT1 staining from NL from the previous report. 10 random fields were examined by 3 readers. Each GLUT1(+) tubule was scored from 1 to 4, with 4 exhibiting the strongest staining. A GLUT1 expression score was calculated (100 to 400). NL were from the normal portion of renal cell carcinoma nephrectomy specimens.

Results: Four kidneys were reviewed. 177 fields with 7196 tubules were scored. The mean percent of GLUT1(+) tubules was 0.03±0.02, 73.5±1.5, 19.7±1.3, and 6.7±0.8 % for scores of 1, 2, 3, and 4, respectively (mean±SEM, $p < 0.05$, ANOVA), implicating that the majority of tubular GLUT1 was minimal (2+). To gauge these findings against CAN kidneys, we scored 22 fields (787 tubules) from JPEGs of CAN sections. When compared to NL, CAN had a lower percent of grade 2 tubules (61.3±4.4 vs 73.5±1.5 % for CAN vs NL, respectively, $p < 0.05$) and a higher percent of grade 4 tubules (14.8±2.2 vs 6.7±0.8 for CAN vs NL, respectively, $p< 0.05$). When assessing GLUT1 expression score, CAN showed greater GLUT1 staining (254±5.7 vs 233±2.0 for CAN vs NL, $p<0.05$).

Conclusions: There are low levels of constitutive GLUT1 staining in normal human kidney, which would be expected for ongoing metabolism of glucose in the resting state. CAN may increase tubular GLUT1 expression, however it is unclear if the increase is pathologic or adaptive.

5-HT1F Receptor Agonist-Mediated Mitochondrial Biogenesis *In Vitro* and *In Vivo* Sara M. Garrett. *Biomedical Sciences, Medical University of South Carolina, Charleston, SC.*

Background: Recovery from renal cell injury requires the biogenesis of mitochondria. Studies by Xu *et al.* (2007) showed that the kidney expresses several 5-hydroxytryptamine (5-HT) receptors and we have shown that the 5-HT2 receptor agonist DOI stimulates mitochondrial biogenesis in renal proximal tubule cells (RPTC). The goal of these studies was to further explore 5-HT receptors in RPTC mitochondrial biogenesis.

Methods: Immunoblot and qPCR analyses revealed 5-HT1F receptor expression in rabbit RPTC.

Results: A mitochondrial biogenesis assay that incorporates FCCP-induced uncoupled oxygen consumption rate (OCR) and a Seahorse Biosciences analyzer demonstrated that two 5HT1F receptor agonists, LY334370 and LY344864, increased uncoupled OCR at 1 nM & 10 nM, and at 10 nM & 100 nM respectively. The increase in uncoupled OCR was not sensitive to pertussis toxin, suggesting that the signaling of 5HTR1F-agonist-mediated mitochondrial biogenesis is not through Gi/o-coupling and inhibition of adenylyl cyclase. Both agonists increased the mitochondrial proteins ATP synthase β, Cox1, and NDUFB8 at 24 h. In murine kidney tissue, mitochondrial copy number and PGC1α and Cox1 transcript levels increased in response to LY334370.

Conclusions: In summary, the 5-HT1F receptor agonists LY334370 and LY344864 induce mitochondrial biogenesis.

PUB108

The Expression of Barx2 and K-Cadherin in Human Proximal Tubule Cells Nileshkumar Shah,[1] Iain Macphee,[2] Mark Edward Dockrell.[1] *[1]SWT Institute for Renal Research, London, United Kingdom; [2]St George's University of London, London, United Kingdom.*

Background: K-cadherin (Cdh6) is the predominant cadherin expressed in the human proximal tubule and we have previously demonstrated its expression is lost in diabetic nephropathy (ASN 2010), however nothing is known about the cellular mechanisms regulating Cdh6 expression in the kidney. In a series of ovarian cancer cell lines, Cdh6 expression showed a significant direct correlation with Barx2 expression. Barx2 is a homeobox protein transcription factor that can mediate a number of signaling cascades including Ras/Raf dependent transcription. Hence we have investigated whether Barx2 might regulate Cdh6 expression in human proximal tubule epithelial cells (PTEC).

Methods: Cdh6 and Barx2 expression was investigated in 3 cell types, primary human PTEC, and two transformed human PTEC cell lines, HK-2 and HKC8, by Western blot and qPCR. Barx2 expression was suppressed using RNAi and over expression achieved using Barx2-Cherry Red expression vector.

Results: Barx2 mRNA was detectable in all 3 cell lines and its expression (by qPCR) correlated with the Cdh6; Primary cells > HK2>HKC8.

Following treatment with TGFβ1 mRNA levels of Barx2 dropped rapidly, again in a pattern similar to that seen for Cdh6.

However, treatment of primary PTEC with siRNA targeting Barx2 did not reduce Cdh6 expression and over expression of Barx2 did not increase Cdh6 mRNA expression in HKC8 cells.

Conclusions: In conclusion, we have demonstrated for the first time that human PTEC express the transcription factor Barx2 and that its expression is regulated by TGFβ1, but we do not have any evidence to support the regulation of Cdh6 (K-cadherin) expression by Barx2 in these cells. We have investigated alternative regulatory pathways in a separate abstract as we believe that understanding the regulation of Cdh6 in the human proximal tubule has genuine relevance to the development of human renal disease. The role of Barx2 remains undefined

Connective Tissue Growth Factor Activation of Intracellular Signaling in Human Podocytes in Culture Simon K. Winn,[1] Felicia Heidebrecht,[1] Irbaz Isaac Badshah,[1] Jochen Reiser,[2] Mysore Keshavmurthy Phanish,[1] Mark Edward Dockrell.[1] *[1]SWT Institute for Renal Research, London, United Kingdom; [2]Nephrology and Hypertension, University of Miami, FL.*

Background: CTGF is expressed in mesangial cells and podocytes in diabetic nephropathy. In animal models an early increase in expression in podocytes is followed by an increase in parietal epithelial and mesangial cells. Altering CTGF expression in podocytes results in a change in podocyte number and increased albuminuria; whether this is through autocrine or paracrine effects has not been defined. Consequently, we investigated the effect of CTGF on human podocytes in the absence of other cell types.

Methods: Expression of CTGF responsive receptor TrkA was demonstrated by immunofluorescence. Cells also demonstrated punctate staining for CTGF consistent with localization in intracellular vesicles. Activation of TrkA causes phosphorylation of Erk5, hence expression of Erk5 in these cells was confirmed. As the C-terminal module of CTGF (cCTGF) is believed to be the region that binds to TrkA activating Erk5 we incubated cells in the presence of full length recombinant human CTGF (flCTGF) from human renal cells and cCTGF, PeproTech Ltd.

Results: Challenge with cCTGF or flCTGF (60 min, 37°) did not increase phospho-Erk5.

flCTGF but not cCTGF resulted in increased phospho-p38 and phospho-Smad2&3. (No phospho-Smad2/3 was detectable in control cells).

The fact that flCTGF but not cCTGF caused Smad activation suggested potentiating of sub-threshold levels of TGFβ1, as TGFβ is believed to bind to the N-terminal of CTGF. We tested this by blocking the activity of the TGFβ type I receptor Alk5 which prevented flCTGF-induced signaling as did a TGFβ neutralising antibody

We confirmed flCTGF binding to TGFβ1 by plasmon surface resonance. Interestingly, we were also able to demonstrate binding of cCTGF with TGFβ1; in the light of the result above this would not appear to cause an increase in TGFβ1-mediated effects.

Conclusions: We conclude that human podocytes in culture produce sub-threshold concentrations of TGFβ1 and the presence of exogenous CTGF results in TGFβ1 signaling; although we can not exclude the possibility that CTGF activates latent TGFβ.

PUB110

Ouabain-Activated c-Src as a Potential Biomarker for Salt-Sensitivity Yanling Yan,[1] Vinai Kumar Katragadda,[1] Chiamaka Mbaso,[1] Deepak K. Malhotra,[1] Zi-Jian Xie,[2,1] Basil Akpunonu,[1] Joseph I. Shapiro,[1,2] Jiang Liu.[1] *[1]Medicine, University of Toledo College of Medicine, OH; [2]Pharmacology and Physiology, University of Toledo College of Medicine, OH.*

Background: The relationship between dietary sodium, salt sensitivity and blood pressure (BP) is well established. Excessive dietary sodium intake significantly contributes to the development of resistant hypertension and tends to be more pronounced in typical salt-sensitive subgroup (the 2008 AHA Scientific Statement). The current methods for assessment of salt sensitivity are largely depended on patients' compliance. A simple rapid in vitro test without salt intervention would be desired.

Circulating ouabain is significantly increased under conditions such as high salt diet and renal insufficiency, as well as in a large portion (about 70-80%) of essential hypertensive patients. Accumulated data suggest that Ouabain is involved in regulation of BP and renal sodium handling.

Through ligand-modulated Na/K-ATPase/c-Src signaling, we recently demonstrated that impaired or attenuated renal proximal tubular ouabain-Na/K-ATPase/c-Src signaling contributes to salt-sensitivity and salt-sensitive hypertension, by affecting renal sodium excretion. Furthermore, ouabain-activated Na/K-ATPase signaling is not tissue-specific which broadenes the choice of sampling. We found that ouabain can activate c-Src in renal proximal tubules, cardiac and skin fibroblasts, and mononuclear white blood cells (mWBCs, lymphocytes and monocytes) in Dahl salt-resistant, but not in salt-sensitive rats ($n=3$-8, $p<0.05$ or $p<0.01$). In isolated mWBCs from Dahl rats fed with low salt diet, ouabain stimulated c-Src activation in the salt-resistant rats, which was not seen or in a much less degree in the salt-sensitive rats (with ouabain as low as 1nM for 15min, $n=8$ per group per strain, $p<0.01$). In healthy normotensive volunteers, ouabain significantly activated c-Src in a dose-dependent manner (with ouabain as low as 1nM for 15min, $n=5$, $p<0.01$). c-Src activation is the proximal step in ouabain-induced Na/K-ATPase signaling and endocytosis, and may serve as a biomarker for salt sensitivity.

PUB111

Tubulointerstitial Nephritis and Uveitis in an Elderly Female Krishna M. Baradhi, Jeffrey D. Clement. *Nephrology, Brown University, Providence, RI.*

Background: Tubulointerstitial nephritis and uveitis (TINU) is an unusual oculorenal syndrome that is often under recognized in clinical practice. Dobrin et al. first described TINU syndrome in 1975 and since then, more than 150 cases have been reported.Most patients with TINU are adolescents and young women, with a median age of 15 years. It has also been reported in adults, albeit rarely in the elderly.

Methods: We briefly report a 71 year old female with Tubulointerstitial nephritis and uveitis.

Results: A 71year old female presented with eight weeks history of intermittent nausea, vomiting, fatigue, fever and anorexia. Work up revealed a creatinine of 11 mg/dl and further evaluation revealed sterile pyuria and tubular proteinuria. Serological studies in the form of ANA, ANCA, complement and protein electrophoresis were negative. Renal biopsy showed acute interstitial nephritis (AIN) with no evidence of glomerular disease. Initially etiology of AIN was unclear and patient responded to steroids with improvement in renal function. Four months later, patient presented with bilateral anterior uveitis, thus leading to a diagnosis of TINU. Uveitis responded to topical steroids.

Conclusions: TINU is a rare clinical entity characterized by interstitial nephritis and uveitis usually observed in children and young adults. The present case demonstrates that this entity may also occur in the elderly,in fact our case represents one of the oldest reported in the literature. TINU remains a diagnosis of exclusion and high degree of suspicion is essential as uveitis may precede, be concurrent or present after nephritis. The pathogenesis remains elusive though delayed-type hyper- sensitivity and suppressed cell-mediated immunity with a pre- dominance of lymphocytes have been advocated. Renal disease in patients with TINU is usually self-limited with steroids reserved for patients with progressive renal insufficiency. The optimal management of the patient with uveitis requires early referral to ophthalmologist.

PUB112

Natural History of Iron Chelation Toxicity in Patients with Thalassaemia in Oman Sunil Bhandari,[1] Shahina F. Daar,[2] Vinodh Kumar Panjwani.[2] *[1]Renal Medicine, Hull & East Yorkshire Hospitals NHS Trust & Hull York Medical School, Hull, East Yorkshire, United Kingdom; [2]College of Medicine and Health Sciences, Sultan Qaboos University Hospital, Muscat, Oman.*

Background: Chelation therapy is essential in Thalassaemia to avoid iron overload related toxicity. Chelation related toxicity/adverse effects including agranulocytosis, liver and renal dysfunction may occur. This study assessed the prevalence of iron chelator related side affects in thalassaemics exposed to Deferasirox (DFX).

Methods: A retrospective assessment of the prevalence of chelator related side affects of DFX was performed. Case notes and databases were interrogated.

Results: 70 patients, mean age 20±1y, were studied. At DFX initiation, 65 had been on deferiprone (DFP) + deferoxamine (DFO); 2 DFO only, 3 DFP only. 35 had compliance issues with DFO. 4 had agranulocytosis with DFP necessitating drug discontinuation. No patient had pre-existing renal disease or hypertension. 6 had NIDDM and 2 IDDM.

During mean follow-up of 16months, 6 patients had rashes and 6 had gastrointestinal upset. DFX was discontinued in 15 patients: 2 generally unwell, 1 severe diarrhoea, 2 high transaminases. 3 converted to DFO+DFP as DFX was not biochemically effective. DFX therapy was stopped in 7 patients because of persistently raised serum creatinine. 8 further patients had a successful dose reduction of DFX. Creatinine at baseline was 39±1.2µmol/L, rising to a peak of 61.2±5.6 ($p<0.001$). Diabetic patients had a 54% mean peak rise in creatinine. 5 of 7 others failed re-challenge with a reduced DFX dose.

Changes in serum ferritin did not correlate with a rise in creatinine. No correlation of renal function with cardiac T2* or liverT2* was observed. Cardiac MRI T2* remained stable ($p=0.4$), while liver MRI T2* ($p=0.013$) improved with DFX therapy.

Conclusions: Transient and potentially progressive renal dysfunction occur in patients exposed to DFX, especially diabetic thalassaemic patients. Haemodynamic, pre-renal hypovolaemia from diarrhoea and direct tubular toxicity related to DFX or its effects may be responsible. Further studies are required. Monitoring of renal function and flexibility of use of chelators may avoid short and long term renal toxicity.

PUB113

Contrast-Enhanced Computed Tomography and Acute Kidney Injury in Patients with Severe Acute Pancreatitis Yuan Han Chen, Xinling Liang, Fen Jiang, Wei Shi. *Division of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.*

Background: To study the relation between contrast-enhanced computed tomography (CECT) and acute kidney injury (AKI) in patients with severe acute pancreatitis (SAP).

Methods: Eighty-four SAP cases without surgery from January 2005 to January 2011 were retrospectively reviewed. SAP was diagnosed by an Acute Physiology and Chronic Health Evaluation (APACHE) II score ≥ 8 and AKI was diagnosed by RIFLE criteria for acute renal failure.

Results: AKI incidence in the patients with CECT and without CECT was 30.6% versus 15.6%, respectively ($P=0.090$). In the APACHE II score ≥ 15 subgroup analysis, the patients with CECT had a higher AKI incidence than those without CECT (71.4% versus 35.7%, respectively, $P=0.026$). After being adjusted by the APACHE II score, CECT was a risk factor for AKI (odds ratio 1.247, 95% confidence interval 1.195-1.387). In the patients with APACHE II score ≥ 15, CECT increased the risk for AKI (odds ratio 4.292, 95% confidence interval 3.101-5.087).

Conclusions: CECT is a potential risk factor for AKI in SAP patients, especially in more severe cases.

PUB114

Etiologies, Clinical Characteristics and Outcomes of Anuric Acute Kidney Injury Hye Min Choi, Eunjung Cho, Jae-Won Lee, Sang-Kyung Jo, Won-Yong Cho, Hyoung-Kyu Kim. *Nephrology, Korea University Hospital, Seoul, Republic of Korea.*

Background: Acute kidney injury (AKI) could be clinically described as oliguric (<400ml urine volume/24hr), nonoliguric (≥400ml), or anuric (<100ml). Anuric AKI is uncommon and has been known to occur from either complete ureteral obstruction or a major vascular event such as bilateral renal infarction or cortical necrosis. However most anuric AKI were known through sporadic case reports and there are limited data regarding to the epidemiology or outcomes. We purposed to examine the causes, clinical characteristics and outcomes of recent anuric AKI cases and compare those with non-anuric AKI.

Methods: This was a prospective cohort study. We enrolled anuric AKI patients who were admitted or referred to the Nephrology division between 2009 and 2010 if they showed anuria in the initial period of AKI despite maximum dose of diuretic challenge. Age- and gender-matched non-anuric AKI patients who required RRT were also enrolled.

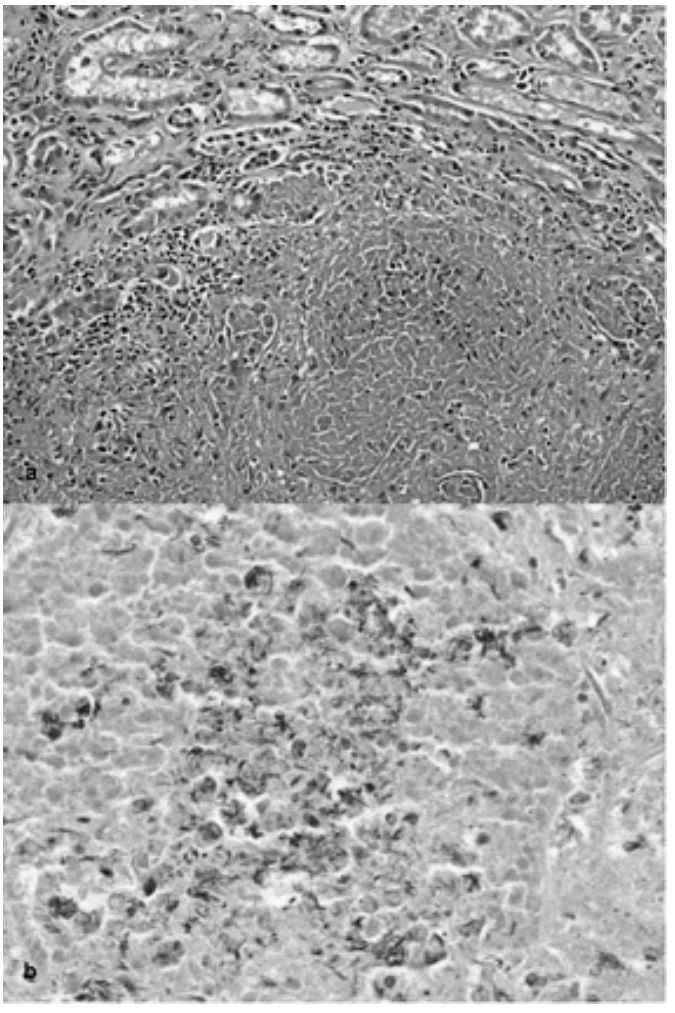
Results: Total 21 patients presented anuric AKI and the etiologies were postoperative (38.1%), sepsis (33.3%), rhabdomyolysis, ATIN, severe vasculitis and unknown. The most common cause of non-anuric AKI (n=46) was sepsis (52.1%). CKD prevalence was significantly higher in anuric compared to non-anuric group and interestingly, prevalence of malignancy was significantly much higher in anuric patients. Although CRRT requirement, duration of ICU stay, vasopressor requirement and in- hospital mortality were not different between the two groups, chronic dialysis dependence was more frequently observed in anuric group. In multivariate logistic regression analysis, the presence of anuria as well as older age, non-septic as the cause of AKI, were independent predictors of RRT dependence among AKI patients who received RRT.

Conclusions: Etiologies of anuric AKI are thought to have been changed from the past. Postoperative and sepsis were the most common causes of anuric AKI in our study. Co-morbidities with CKD and malignancy were more common in anuric patients, and anuric AKI also seems to be more commonly associated with non-recovery of renal function after episode of AKI.

PUB115

Renal Tuberculosis without Pyuria – A Fatal Case Report Paul J. Der Mesropian,[1] Snezana H. Mijovic-Das,[2] Jabulani Sidile.[1] *[1]Internal Medicine, Albany Medical Center, Albany, NY; [2]Nephrology, Albany Medical Center, Albany, NY.*

Background: Genitourinary tuberculosis is a considerably rare occurrence in developed countries, comprising only 6% of extrapulmonary cases of tuberculosis (TB) in the U.S. We report the case of fulminant miliary TB with extensive renal involvement that was diagnosed post-mortem in a 42-year-old male who presented with immunocompromise of unclear etiology, dysuria, microscopic hematuria, and sterile urine without pyuria. The kidneys were involved by a necrotizing granulomatous process (figure 1a) with AFB stain of the renal parenchyma showing numerous mycobacteria (figure 1b). The absence of pyuria, which is seen in almost all patients, makes this an atypical case of a rare disease. In fact, up to 20% of patients do not have any leukocytes in the urine. In spite of aggressive treatment with antituberculous agents, the patient succumbed to this rapidly progressing infection.



PUB116

Low 25-hydroxyvitamin D Levels Are Not Associated with an Increased Risk of Acute Kidney Injury Anna Jeanette Jovanovich,[1] Michel B. Chonchol,[1] Shailendra Sharma,[1] Kim McFann,[1] Sidney N. Thornton,[2] Jessica B. Kendrick,[1] John R. Holmen. *[1]Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]Intermountain Health Care, Salt Lake City, UT.*

Background: Low 25-hydroxyvitamin D (25(OH)D) levels are associated with chronic kidney disease (CKD) but it is unknown if low 25(OH)D levels are a risk factor for acute kidney injury (AKI).

Methods: We conducted a population-based cohort study of adult patients with no history of CKD who developed AKI requiring hospitalization and had serum 25(OH)D measured 3 to 15 months prior to sepsis admission. Vitamin D was evaluated as a continuous variable and a categorical predictor (< 15 ng/mL vs. higher). AKI was defined by the RIFLE classification, which requires at least a 50% increase in serum creatinine. Cases of AKI were matched 1:1 with controls on age, sex, race and season. Conditional multivariate logistic regression analysis was used to evaluate if 25(OH)D levels were associated with an increased odds of AKI.

Results: We identified 51 patients with AKI and 51 matched controls. The mean (SD) age of the participants was 61 ± 18 years, 59% were female and 98% were Caucasian. Compared to patients without AKI, patients with AKI had a higher prevalence of diabetes (46.0% vs. 30.3%; p=0.0009) and chronic kidney disease (36.0% vs. 21.8%; p=0.001). There was no statistical difference between patients with and without AKI on mean (SD) 25(OH)D levels (28.8 ± 17 vs. 32.4 ± 13 ng/mL; p=0.099). After adjustment for diabetes, renal disease and peripheral vascular disease, 25(OH)D levels were not associated with AKI (OR 0.996, 95% CI 0.98-1.01; p=0.57). Similarly, when evaluated as a categorical predictor, vitamin D levels < 15 ng/mL vs. higher (OR 1.91, 95% CI 0.76-4.79; p=0.16), there was no association between vitamin D deficiency and AKI cases.

Conclusions: In this population-based cohort, low 25(OH)D levels are not associated with AKI. Larger studies are needed to evaluate whether vitamin D deficiency is a risk factor for AKI.

PUB117

Bilateral Emphysematous Pyelonephritis- A Rare But Serious Disease Praveen Kandula, Sanjiv Anand. *Nephrology, Indiana University School of Medicine, Indianapolis, IN.*

Background: A 24 year old male with history of diabetes and poly substance abuse was admitted to the hospital with diabetic ketoacidosis and acute renal failure. He had no known history of renal insufficiency and was found to have a creatinine of 3.2 on admission. His urinalysis revealed 115 WBC, bacteria, positive leukocyte esterase and nitrites. He was treated aggressively with volume repletion, insulin and broad spectrum antibiotics. A CT scan of abdomen was done on day#2 and revealed bilateral emphysematous pyelonephritis [Figure 1 and 2). Patient was also found to have severe thrombocytopenia, elevated INR, GI bleed and E.Coli bacteremia. He was deemed not to be a surgical candidate for bilateral nephrostomies as treatment of his pyelonephrtis due to his coagulopathy and comorbid illnesses. Patient's renal failure worsened and was put on continuous veno-venous hemofiltration. He succumbed to his illness 21 days later.

Conclusions: Bilateral emphysematous pyelonephritis is a rare but severe illness associated with >40% mortality in the absence of surgical intervention. Early and aggressive intervention is needed. In significantly ill patients physicians should be more aware of this entity.

PUB118

Hyperhomocysteinemia Is Independently Associated with the Risk of Contrast-Induced Nephropathy in Patients Undergoing Percutaneous Coronary Intervention Seung Jun Kim, Mi Jung Lee, Dong Ho Shin, Dong Eun Yoo, Hyung Jung Oh, Seung Hyeok Han, Tae-Hyun Yoo, Shin-Wook Kang. *Dept. of Int. Medicine, College of Medicine, BK21, SBSI, Yonsei Univ., Seoul, Korea.*

Background: Endothelial dysfunction and oxidative stress have been considered to be responsible for the vascular damage in hyperhomocysteinemia as well as the development of contrast-induced nephropathy (CIN). To date, however, little is known on the relationship between hyperhomocysteinemia and CIN. This observational cohort study was conducted to investigate whether hyperhomocysteinemia was independently associated with CIN in patients undergoing percutaneous coronary intervention (PCI).

Methods: A total of 572 patients, who underwent PCI at Severance Cardiovascular Hospital, Seoul, Korea, were included. CIN was defined as absolute ≥ 0.5 mg/dl or relative ≥ 25% increase in serum creatinine levels at 48 hour after the procedure. Patients were divided into 2 groups; patients with and without CIN, and the clinical and laboratory data, and echocardiographic findings were compared between the two groups.

Results: Sixty-nine patients (12.1%) developed CIN after PCI. Patients with CIN were significantly older and had a higher prevalence of diabetes. Moreover, acute myocardial infarction, three vessel coronary artery disease, and the use of intra aortic balloon pump were significantly more prevalent in patients with CIN. Plasma glucose and homocysteine levels (16.9±4.9 vs. 13.5±4.2 μmol/L, p<0.001) were also significantly higher in patients with CIN compared to those without CIN. In multiple logistic regression analysis, hyperhomocysteinemia was an independent risk factor for CIN [per 1 SD change in plasma homocysteine levels (4.44 μmol/L); OR, 1.70; 95% CI, 1.07-2.71, p=0.025] even after adjusting for other major risk factors.

Conclusions: Hyperhomocysteinemia is independently associated with the risk for CIN in patients undergoing PCI, suggesting that measurement of plasma homocysteine levels may aid in the risk stratification for the development of CIN in patients undergoing PCI.

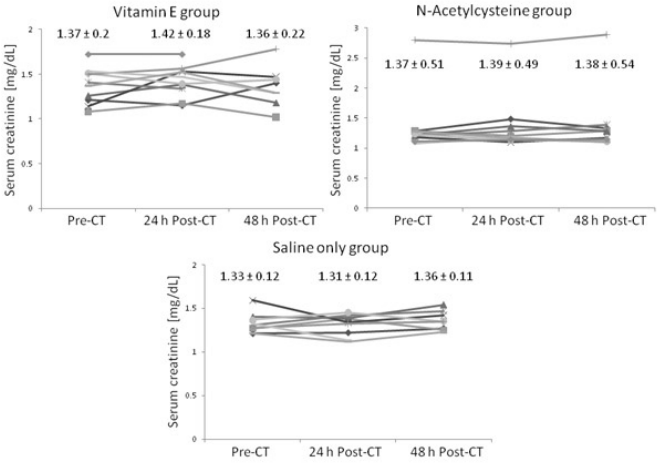
PUB119

Efficacy of Vitamin E and N-Acetylcysteine To Prevent Radiocontrast Induced Acute Kidney Injury in Patients with Chronic Kidney Disease: A Randomized Controlled Trial Thomas M. Kitzler,[1] Aala Jaberi,[1] Gerald Sendlhofer,[2] Peter H. Rehak,[2] Christian Binder,[4] Rudolf Stacher,[4] Peter Kotanko.[5] *[1]Department of Medicine, McGill University, Montreal, QC, Canada; [2]Medical University of Graz, Graz, Styria, Austria; [3]Krankenhaus der Barmherzigen Brueder Graz, Graz, Styria, Austria; [4]Renal Research Institute, New York, NY.*

Background: Contrast induced acute kidney injury (CIAKI) is a leading cause of hospital-acquired acute kidney injury, with patients suffering from chronic kidney disease (CKD) at particularly high risk. This trial tested the hypothesis that vitamin E or N-acetylcysteine improved renal outcomes following radiocontrast administration in CKD patients.

Methods: This single-center, prospective, double-blind, double dummy, placebo-controlled, randomized, parallel clinical trial enrolled patients with CKD who underwent elective computer tomography (CT) with administration of radiocontrast agents. Patients were randomized to receive either vitamin E (2160 mg i.v.) or N-acetylcysteine (4800 mg p.o) in addition to saline (1 mL/kg/h over 24 h), or saline alone. CIAKI was defined as a rise in serum creatinine > 25% within 96 h after CT. Primary and secondary outcomes were 24 h change of serum creatinine and measured creatinine clearance, respectively.

Results: Thirty patients (CKD stages 1 to 4; mean age 74.6 years; 17 F, 30% diabetics; all Caucasians) were enrolled; 1 patient was excluded after randomization because of protocol violation. No patient developed CIAKI. There was no significant difference in serum creatinine change between the three study arms.



In secondary analysis, creatinine clearance did not differ between the groups.

Conclusions: Vitamin E and NAC in addition to saline did not demonstrate a beneficial preventive effect on kidney function when compared to saline administration only.

PUB120

Role of Novel Biomarkers for Early Detection of Acute Kidney Injury Following Gadolinium-Based Contrast Agents Administration Louis-Philippe Laurin, Jean-François Naud, François Leblond, Vincent Pichette, Martine Leblanc. *Nephrology, Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada.*

Background: Gadolinium-based contrast agents have been originally used in patients with severe renal dysfunction instead of iodinated contrast media due to their presumed non-nephrotoxicity. However, several cases of systemic nephrogenic fibrosis have been reported afterwards in patients with renal insufficiency. Cases of acute kidney injury associated with gadolinium-based media in patients with normal renal function have also been published recently, rising concerns about their potential nephrotoxicity.

Methods: We studied four novel biomarkers of acute kidney injury: interleukin 18 (IL-18), N-acetyl-{beta}-d-glucosaminidase (NAG), neutrophil gelatinase-associated lipocalin (NGAL) and Cystatin C in 12 volunteers with normal renal function after the intravenous administration of a gadolinium-based contrast agent. Urinary and serum levels of biomarkers were analyzed at 0, 3 h and 24 h following injection.

Results: All urinary biomarkers were normalized for creatinine concentration. Baseline levels of urinary IL-18 were highly variable between patients (0 to 42.5 pg per mmol of creatinine). IL-18 urinary concentration was significantly increased at 3 h (0.5 to 59.2 pg/mmol; $p<0.01$) and 24 h (0.4 to 51.3 pg/mmol; $p<0.05$) in most studied patients. Similarly, urinary NAG levels were higher at 3 h compared to baseline levels (0.0 to 18.7 IU/mmol before gadolinium injection and 0.9 to 24.0 IU/mmol at 3 h; $p<0.001$). However, impact of gadolinium injection on NAG levels was no longer measurable at 24 h. Some patients also showed a significant increase of urinary NGAL (baseline at 0.9 to 7.8 ng/mmol) at 3 h (1.4 to 19.1 ng/mmol; $p<0.05$) and 24 h (1.3 to 28.7 ng/mmol; $p<0.05$). No difference in serum levels of Cystatin C and NGAL was observed following gadolinium administration compared to baseline levels.

Conclusions: Gadolinium-based contrast agents may induce a transient kidney injury shortly after their administration. These results provide new insights about the potential nephrotoxicity of gadolinium contrast media.

PUB121

Statin Initiation for the Prevention of Post-Surgical Acute Kidney Injury J. Bradley Layton, Abhijit V. Kshirsagar, M. Alan Brookhart. *UNC, Chapel Hill, NC.*

Background: Previous studies suggest preoperative statins reduce the occurrence of acute kidney injury (AKI) following coronary artery bypass graft (CABG). Yet it is unclear whether the findings result from a direct, protective effect of statins or are a result of immeasurable differences in patient characteristics among long-term users of statins.

Methods: Hospitalized CABG patients' statin use was assessed in Thomson Reuters' MarketScan Commercial Claims and Encounters database based on pharmacy dispensing prior to CABG. To reduce confounding by adherence and behavioral factors, only new statin users (initiating a statin ≤20 days before CABG) and never statin users and were included. Prevalent statin users were excluded, as were those with ESRD or AKI at baseline. AKI was identified from diagnosis codes in the 15 days post-CABG. Indicators of cardiovascular disease (CVD) management, disease severity, and acute CVD events were assessed in the 6 months prior to CABG. Logistic regression estimated the effect of statins on post-CABG AKI. An additional analysis restricted to CABG patients without recent myocardial infarction or unstable angina to better reflect planned surgeries where physicians are able to make medication prophylaxis decisions.

Results: When examining the new users of the medication in the immediate perioperative period, our results are consistent with a protective effect of statin initiation on post-CABG AKI, particularly in non-emergency CABG. This finding should be interpreted cautiously, as statin initiation may serve as a proxy for unmeasured health-seeking behaviors, disease characteristics, adherence, and other factors which cannot be fully controlled in observational analyses.

Conclusions: When examining the new users of the medication in the immediate perioperative period, our results are consistent with a protective effect of statin initiation on post-CABG AKI, particularly in non-emergency CABG. This finding should be interpreted cautiously, as statin initiation may be a proxy for unmeasured health-seeking behaviors, disease characteristics, adherence, and other factors which cannot be fully controlled in observational analyses.

PUB122

Incidence, Prognosis and Risk Factors in Hospitalized Acute Kidney Injury Defined by AKIN Renhua Lu, Yucheng Yan, Jiayuan Gao, Liu Shang, Zhaohui Ni, Jia Qi Qian. *Renal Division, Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China.*

Background: AKIN has been proposed as a consensus definition of Acute Kidney Injury(AKI) . The aim of this study is to investigate the incidence, prognosis and related risk factors in hospitalized AKI defined by AKIN to help clinicians better understand and prevent AKI.

Methods: All hospitalized patients during Jan. to Dec. 2009 were screened by Lab Administration Network. Study Cohort by AKIN. Patients' clinical data including etiology, distribution characteristics and prognosis were retrospectively collected. Logistic regression analysis was used to investigate the risk factors of prognosis.

Results: As a result, 934 patients were enrolled. The incidence of AKI in hospitalized patients was 2.14%. The comprised rate of AKI was 65.8%, 25.1% and 9.1% for Stage I, II and III respectively. The ratio of male to female was 1.88:1. The average age was (60.82±16.94) years old. 331(35.4%) patients with AKI were distributed in Intern Medicine Department while 63.4% patients in Surgical Department and 1.2% in Obstetric and Gynecologic Department. Analyzing the cause of AKI, ATN accounted for 52.0%, followed by 44.7% of renal parenchyma AKI and 3.3% of Post-AKI The mortality of AKI in hospitalized patients was 23.6%, and the rate of renal lose was 65.7%. Multivariate logistic regression analysis showed that age(OR=1.327,95%CI:1.067-1.649), renal injury drugs (OR=3.050, 95%CI: 2.023 -4.598), hypotension(OR=5.584,95%CI:2.713-11.496), oliguria (OR=4.083,95%CI: 2.586-6.447), rising amplitude of serum creatinine (OR=1.712,95%CI:1.371-2.138) and RRT(OR=3.208, 95%CI:1.365-7.537) were independent risk factors for patients death.

Conclusions: In conclusion, AKI is one of the most common clinical syndrome in hospitalized patients. The most common reasons for hospitalized AKI are pre-AKI and ATN. The mortality of AKI in hospitalized patients was high. Age, drugs, hypotension, oliguria, rising amplitude of serum creatinine and RRT were independent risk factors of patient death.

PUB123

A Case of Auto-PEEP Induced Acute Kidney Injury Dwight M. Matthew, Karthik M. Ranganna. *Nephrology, Drexel University College of Medicine, Philadelphia, PA.*

Background: Acute kidney injury (AKI)is common among critically ill patients and results in increased mortality in this population. However, PEEP (positive end-expiratory pressure) as a cause of AKI has never been reported. We present a rare case of auto-PEEP induced AKI.

Results: A 57 year old African American male with a past medical history of hypertension and α1-anti-trypsin deficiency was admitted for a 2 day history of progressive shortness of breath. He was initially treated with steroids and bronchodilators for a COPD flare. Day 2, his respiratory status declined necessitating intubation and mechanical ventilation. A CT angiogram performed was unremarkable for pulmonary embolism.

His urine output was 50-75cc/hr on day 2 and declined to 5-10cc/hr on day 3. His serum bun/creatinine were as follows: day 1: 7/0.73, day 2: 9/0.83 and day 3: 37/2.22. His physical examination on day 3 was pertinent for bilateral wheezes and a distended, firm, tender abdomen. A non-contrast CT abdomen showed no acute pathology. Renal ultrasound revealed kidneys normal in size and echogenicity with a collapsed bladder. His urine analysis and sediment were unremarkable.

Day 4, his urine output was 0-5cc/hr, his bun/creatinine peaked at 67/3.37 and respiratory status further declined. He was noted to have significant auto-PEEP and increasing difficulty to oxygenate. His bladder pressure was measured at 30 mmHg. He then received the neuromuscular blocking agent cisatracurium (Nimbex) after other methods to remedy his auto-PEEP proved futile.

Within the first three hours of paralysis, his urine output was 300cc then continued at 100-200 cc/hr for the next 24hrs. His abdomen was no longer firm or distended on examination. A repeat bladder pressure was 5 mmHg. Day 5 his serum bun/creatinine were 64/2.87 and over the next 5 days trended to his baseline.

Conclusions: Literature addressing PEEP as a cause for IAH is very sparse. However, Verzilli and colleagues demonstrated that PEEP can have a significant impact on IAH. Acute kidney injury in the ICU can often be multifactorial. However, the rapid return of renal function after effective treatment of auto-PEEP indicates the crucial role that IAH, as a result of auto-PEEP, played in this case.

PUB124

Reno-Prevention: A New Concept for Re-Engineering of Nephrology Practice: An Economic Impact and Patient Outcome Analysis of Two Hypothetical Patient Scenarios in the CCU

Macaulay A. Onuigbo,[1,2] Nnonyelum T. Onuigbo.[3] *[1]College of Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, WI; [3]Information Technology, NTEC Solutions LLC, Eau Claire, WI.*

Background: The impact of AKI on CKD progression remains uncertain. Common but untested opinion assumes that AKI in CKD is short-lived with little sequele. Ishani et al. demonstrated that 25.2% of Medicare ESRD patients all had prior AKI. Menon et al. showed that ESRD in the elderly was often precipitated by AKI. We described the new syndrome of rapid onset end-stage renal disease (SORO-ESRD) in 2010 where ESRD was a continuum of the AKI. We continue to call for more preventative measures to limit AKI (Reno-prevention, RP). We compare healthcare value outcomes with/without RP strategies (RPS).

Methods: Two similar hypothetical patients with symptomatic CAD get elective cardiac catheterization (CC)and CABG procedures, one with, and one without RPS.

Results: A more aggressive fluid repletion and one week withholding of ACEI in patient A allowed for discharge after 6 days. Patient B was continued on lisinopril 40 mg QD through CC and CABG, experienced prolonged peri-operative hypotension (POH), suffered severe oliguric AKI and needed daily RRT x 6. Kidney function improved; discharged on day 20.

Total hospital charges - \$68,580 (A) versus \$154,650 (B). 20 liters of colloid for prevention of POH in patient A, an additional hospital charge of \$2,000, was a huge return on investment (ROI).

PATIENT	ADMISSION SERUM CREATININE (mg/dL)	NUMBER OF RRT SESSIONS	LOS (DAYS)	WBC GIVEN	DISCHARGE SERUM CREATININE (mg/dL)	NUMBER OF DAYS ON THE VENT	COST OF RRT (CVVHD) ($)	COST OF VENT DAYS ($)	TOTAL CHARGES ($)
A	1.6	0	6	1	1.1	3	0	35,000	68,580
B	1.6	6	20	3	2.2	8	11,050	100,000	154,650

Conclusions: We posit that RPS in cardiac surgery patients (and other critically ill patients) - withholding nephrotoxics including RAAS blockers and avoiding POH, improves patient/renal outcomes, lessens AKI, lessens SORO-ESRD, and produces massive dollar savings. Our call for more RPS would constitute major rethinking and practice re-engineering in current nephrology practice.

PUB125

Influence of Diastolic Blood Pressure and Fluid Removal during Intermittent Hemodialysis on Incomplete Acute Kidney Injury Recovery

Milan M. Radovic,[1,2] Jelena Pavlovic.[1] *[1]Clinic of Nephrology, Clinical Center of Serbia, Belgrade, Serbia; [2]University of Belgrade, School of Medicine, Belgrade, Serbia.*

Background: Fluid overload and its removal during intemittent hemodialsyis (IHD) are independent risk factors for mortality in patients with acute kidney injury (AKI). Impact of such an event on incomplete AKI recovery has not been elucidated.

Methods: Retrospective, observational, single centre study (2000–2008) was undertaken in 386 patients (age 52.1±16.4 years, 279 male), treated by hemodialysis because AKI stage 3. Patients were assigned to one out of 4 groups according to in-hospital outcome: 1=no AKI recovery and death (N=152, 39.4%), 2=AKI recovery but death (N=5, 1.3%), 3=incomplete AKI recovery and survival (N=26, 6.7%), 4=complete recovery and survival (N=203, 52.6%, p <0.001). Individual severity score (ISS), age (ANOVA and post test), frequencies of comorbidities, systolic (Δsbp) and diastolic blood pressure (Δdbp) changes during IHD and ultrafiltration rate were compared between groups. Cox proportion hazard model was calculated.

Results: Patients in group 1 were older than groups 3 (p=0.023) and 4 (p=0.002), and had greater ISS than group 3 (p<0.001). Group 1 had significantly greater fall in Δsbp (6.323, 95% CI 0.745–4.856) fall during IHD than groups 3 (Δsbp 2.088, CI 0.8216–0.489) and 4 (Δsbp 2.745,CI 0.469–1.823; both p<0.001). Group 1 had greater Δdbp (3.462, CI 0.582 – 2.323) fall during IHD than group 3 (Δdbp 1.661, CI 0.517–0.644; both p=0.114) and group 4 (Δdbp 1.391, CI 0.310-0.783, p<0.001). Average ultrafiltration rates were similar (p=0.074). Cox regression model (p<0.001) showed significant influence of hypertension (OR 1.88, CI 1.087–3.251, p=0.024), neoplasia (OR 1.698, CI 1.136–2.537, p=0.01), cardiovascular disease (OR 6.617, CI 4.129–10.603), liver disease (OR 12.238, CI 6.284 – 21.948) and preexisting renal disease (OR 0.245, CI 0.155-0.386, all p<0.001) on incomplete ARF recovery.

Conclusions: Preventing significant dbp fall during IHD in patients with hypertension, cardiovascular disease, neoplasia and preexisting renal disease may influence risk for incomplete recovery of patients with AKI stage 3.

PUB126

Correlation of Neutrophil Gelatinase-Associated Lipocalin with Renal Function and Proteinuria in Patients with Chronic Kidney Diseases

Xuan Shi, Xiaoliang Zhang, Bi-Cheng Liu. *Institute of Nephrology, Zhongda Hospital, Southeast University School of Medicine, Nanjing, Jiangsu Province, China.*

Background: Neutrophil gelatinase-associated lipocalin (NGAL) represents a novel biomarker for early detection of acute kidney injury. Recent studies have noticed the change of NGAL in some kind of chronic kidney disease (CKD) whereas the exact role of NGAL in evaluation of CKD is unknown. The aim of this study was to investigate plasma and urine NGAL (pNGAL and uNGAL) in a cohort of CKD patients in order to verify its relationship with the severity of renal impairment and proteinuria.

Methods: 100 CKD outpatients from Zhongda Hospital, who were verified at stable disease status, were recruited into this study. The random plasma and urine specimens were obtained from the eligible subjects for NGAL determination. 24-hour urine samples were collected for proteinuria measurement. Clinical data including serum creatinine (CR), eGFR and cause of CKD etc. were collected for analyzing correlation of NGAL with renal function and proteinuria.

Results: Both pNGAL and uNGAL were significantly higher than those in healthy control. Inverse correlation of eGFR with pNGAL and uNGAL were observed in all CKD patients. This relationship was also observed in subgroups with different range of proteinuria or causes. Using eGFR as a dependent variable in a multivariate model, the relationship of CR with pNGAL and uNGAL remained significant. In proteinuric patients, positive correlation of proteinuria with pNGAL and uNGAL was observed, and this relationship still existed in subgroups with different range of renal function or causes. Using pNGAL or uNGAL as dependent variables in a multivariate model, the relationship of pNGAL with eGFR remained significant in subgroups with different causes. In patients with diabetic nephropathy and chronic glomerulonephritis, uNGAL positively correlated with protienuria and eGFR, whereas only the relationship of uNGAL with protienuria remained significant in patients with hypertensive nephropathy.

Conclusions: Both pNGAL and uNGAL are significantly correlated with eGFR and proteinuria in patients with CKD. This suggests NGAL may be used as a biomarker to predict the development of CKD.

PUB127

Coexistence of ANCA-Associated Glomerulonephritis and Anti-Phospholipase A_2 Receptor Antibody Positive Membranous Nephropathy

Sheena Surindran,[1] Rivka Ayalon,[3] Laurence H. Beck,[3] David J. Salant,[3] Laura M.C. Barisoni,[2] Edward Y. Skolnik,[1] Lada Beara Lasic.[1] *[1]Department of Medicine, Division of Nephrology, New York University Medical Center, New York, NY; [2]Department of Pathology, New York University Medical Center, New York, NY; [3]Department of Medicine, Division of Nephrology, Boston University Medical Center, Boston, MA.*

Background: The etiologies of idiopathic membranous nephropathy (IMN) and anti neutrophil cytoplasmic antibody (ANCA)-associated glomerulonephritis (GN) have recently been identified. Antibodies to myeloperoxidase (MPO) and PR3 have been demonstrated to mediate ANCA-associated disease. For membranous nephropathy, antibodies to the podocyte-expressed phospholipase A_2 receptor (anti-PLA_2R) are highly associated with disease activity and have been reported in at least 70% of patients with IMN.

Methods: We now present a case of a 56 year old male with one year history of hypertension, leg edema, and proteinuria, who presented with advanced renal failure and was found to have both ANCA-associated GN and IMN on kidney biopsy.

Results: Consistent with the idea that this is due to the chance occurrence of two independent diseases, we found both anti-MPO and anti-PLA_2R antibodies in the patient's sera. Treatment with methylprednisolone, plasmapheresis, and cyclophosphamide resulted in the improvement in kidney function and proteinuria, together with the simultaneous decrease in both autoantibodies.

Conclusions: This is the first demonstration of two pathogenic antibodies giving rise to ANCA-associated GN and IMN in the same patient. It confirms the importance of classifying disease based upon the underlying mechanism, in addition to renal histopathology, to both optimize therapy and predict prognosis. Serial monitoring of changes in titers of these disease-associated antibodies, together with clinical response, should provide valuable insight into assessing response to treatment and predicting recurrent disease.

PUB128

Therapeutic Hypothermia and Prevention of Acute Kidney Injury: A Meta-Analysis of Randomized Controlled Trials Paweena Susantitaphong,[1] Mansour Alfayez,[1] Abraham Cohen-Bucay,[1] Ethan M. Balk,[2] Bertrand L. Jaber.[1] *[1]Medicine, St. Elizabeth's Medical Center, Boston, MA; [2]Center for Clinical Evidence Synthesis, Tufts Clinical and Translational Science Institute, Tufts University, Boston, MA.*

Background: Therapeutic hypothermia has been shown to reduce neurological morbidity and mortality in the setting of out-of-hospital cardiac arrest and may be beneficial following brain injury and cardiopulmonary bypass. We conducted a systematic review to ascertain the effect of therapeutic hypothermia on development of acute kidney injury (AKI) and mortality.

Methods: We searched for randomized controlled trials in MEDLINE through February 2011. We included trials comparing hypothermia to normothermia that reported on the incidence of AKI, dialysis requirement, changes in serum creatinine and mortality. We performed Peto fixed-effect and random-effects model meta-analyses, and meta-regressions.

Results: Nineteen trials (2,218 patients) were included; in the normothermia group, the weighted incidence of AKI was 4.2%, dialysis requirement 3.7%, and mortality 10.8%. By meta-analysis, hypothermia was not associated with a significant decrease in the incidence of AKI (OR 1.01, 95% CI 0.68, 1.51; P = 0.95) or dialysis requirement (OR 0.81; 95% CI 0.30, 2.19; P = 0.68); however, by meta-regression, a lower target cooling temperature was associated with a lower incidence of AKI (P = 0.01). Hypothermia was associated with a 31% lower odds of mortality (OR 0.69; 95% CI 0.51, 0.92; P = 0.01).

Conclusions: Therapeutic hypothermia has no impact on the incidence of AKI or dialysis requirement, but is associated with lower mortality in the included trials. Different definitions of AKI and different rates of AKI and mortality in trials together with concerns about the optimal target cooling temperature preclude definitive conclusions.

PUB129

Epidemiology and Outcome of Acute Kidney Injury after Cardiac Surgery in China Jie Teng,[1] Yi Fang,[1] Jianzhou Zou,[1] Chunsheng Wang,[2] Xiaoqiang Ding.[1] *[1]Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China; [2]Cardiac Surgery, Zhongshan Hospital, Fudan University, Shanghai, China.*

Background: The aim of this study was to analyze the incidence of AKI and its risk factors after open heart surgery.

Methods: 4007 patients who underwent cardiac surgery from April 2009 to April 2011 were involved. Demographic characteristics, laboratory exam, types of surgeries and clinical outcomes were recorded.

Results: Of the 4007cases, valve surgery occupies the largest proportion (n=2090, 52.16%), followed by coronary artery bypass graft (CABG) surgery (n=695, 17.34%), congenital heart surgery (n=461,11.5%), combined surgery (n=352, 8.7%, aorta surgery (n=238, 5.9%), others (n=134, 3.3%), and orthotopic cardiac transplantation (n=37, 0.9%). AKI was defined and classified by RIFLE criteria. The overall incidence of AKI was 31.2% (n=1250), RIFLE-R 78.4% (n=837), RIFLE-I 8.4% (n=90), and RIFLE-F 13.2% (n=141). The incidence of AKI requiring replacement treatment (AKI-RT) was 2.6% (n=104). The overall hospital mortality was 1.9%. In-hospital mortality of AKI-RT group was up to 38.5%. Length of stay, ICU time, age, body mass index (BMI), basic Scr and NYHA degree were all significantly higher in AKI group than in non-AKI group. CPB time and aortic cross-clamp time of AKI group were longer than non-AKI group, and AKI group use more vasoactive drugs postoperative. The incidence of AKI was 73% after cardiac transplantation, 58% after CABG and valve combined surgery, 52% after aorta surgery, 14% after congenital heart surgery. Hospital mortality after cardiac transplantation was the highest one as 18.9%.

Conclusions: The pattern of AKI after cardiac surgery in out population was different from that in developed countries, reflected in the larger proportion of valve and aorta surgery.

PUB130

Manifestation of IgA Nephropathy by Acute Kidney Injury in Warfarin Overdose Patient Anton Y. Verbine.[1] *[1]Nephrology, St Michael's Hospital, Toronto, ON, Canada; [2]Dept of Pathology, St Michael's Hospital, Toronto, ON, Canada.*

Background: We report a biopsy-proven case of glomerular hematuria leading to acute kidney injury (AKI) with newly diagnosed IgA nephropathy in patient supra-therapeutic on warfarin. There is increased body of evidence that tubular obstruction with RBC casts can be rare but serious complication of warfarin therapy, and can lead to acute tubular necrosis (ATN).

Methods: Clinical and pathological findings are presented, available evidence on combination of warfarin anticoagulation, glomerular hematuria and AKI are discussed.

Results: 62 y.o. F was admitted to hospital with clinically worse congestive heart failure and diagnosed with pulmonary edema and new AKI. She had gross hematuria without dysuria for 3 days prior to admission. There was no previous history of hematuria, renal colic or known kidney disease. Patient was on warfarin for atrial fibrillation and previous deep venous thrombosis.

On physical exam patient was anuric and appeared hypervolemic. Admission Cr was 8.4 mg/dL (compared to 1.14 mg/dL 2 weeks prior) K 7.3 mEq/L ,Hb 98, INR on presentation 6.91. Urine dipstick grossly positive for blood and protein, microscopy showed abundant erythrocytes with rare heme-granular casts. After correction of INR with prothrombin complex concentrate temporary hemodialysis line was inserted and acute hemodialysis initiated.

Kidney biopsy demonstrated mesangial hypercellularity with early crescents, mild interstitial fibrosis. Some tubules contain red blood cell casts with evidence of ATN. Immunofluorescence shows mesangial deposits of IgA and C3.

Patient was treated with pulse steroids and cyclophosphamide and became dialysis -independent in 3 month with CKD 4.

Conclusions: AKI can be an uncommon complication combination of two common conditions combined- IgA nephropathy and anticoagulation with warfarin. Macrohematuria in patient with INR prolongation deserve serious clinical attention, and IgA nephropathy with AKI should be in differential diagnosis. In general, clinical outcomes are unfavorable. Unusual feature of our case is no previous history of hematuria and new diagnosis of IgA nephropathy.

PUB131

Early Identification of Leptospirosis as a Important Cause of Acute Kidney Injury in Taiwan: A Case Control Analysis Huang-Yu Yang,[1, 2] Chan-Yu Lin.[1] *[1]Nephrology, Chang-Gung Memorial Hospital, Taipei, Taiwan; [2]Johns Hopkins, Baltimore.*

Background: Leptospirosis, caused by the pathogenic spirochete leptospira, is the most wide spread zoonosis throughout the world.

Methods: From September 2000 to March 2006, surveillance of 455 multiple organ dysfunction syndrome patients with unclear cause or clinical suspicion of leptospirosis was performed. Diagnosis was confirmed by microscopic agglutination test or isolation. Cases were classified as excluded based on confirmed etiology other than leptospirosis or negative paired serologic test. Rapid serology tests have been applied for screening. The difference between the confirmed and excluded cases was compared by the Student t test. Statistically significant presentations of leptospirosis were tested using logistic-regression models. The relationship between delayed antibiotics treatment and days in hospital were examined by regression analysis.

Results: Forty-two patients were confirmed as leptospirosis which accounted for 9.2% of total patients with multiple organ dysfunction syndrome. Forty-nine excluded cases were identified for a case-control analysis for clinical distinction. The most common presentations of leptospirosis are fever (97.6%), acute kidney injury (85.7%), and jaundice (61.9%). The leptospirosis group showed lower urine specific gravity (cutoff value: 1.0145) and enlarged kidney size (cutoff value: 11.05 cm) as compared with the excluded cases by multivariate logistics regression. Delayed antibiotics administration prolongs the duration of hospitalization (R Square: .486, P< .01). No mortality has been found in the leptospirosis group after initiation in 2003 of rapid IgM serology assay which showed considerably high sensitivity and specificity.

Conclusions: Leptospirosis accounts for a salient cause of multiple organ dysfunctions in Taiwan. Early awareness of leptospirosis by distinct presentations, followed by prompt antibiotics therapy can dramatically save the patients. The easy-performed rapid IgM serology assay is suitable as a rapid screening test for the diagnosis of leptospirosis.

PUB132

Monocyte ADAM17 Content Correlates with the Neovascularization of the Carotid Adventitia and with Intima Media Thickness in Normal Individuals with No Risk Factor for Atheromatous Disease M. Vittoria Arcidiacono,[1] Teresa Vidal,[2] Didac Mauricio,[3] Elvira Fernandez,[4] Adriana S. Dusso.[1] *[1]Experimental Nephrology, IRBLLEIDA, Lleida, Spain; [2]UDETMA, Hospital Arnau de Vilanova, Lleida, Spain; [3]Endocrinology Dept., Hospital Arnau de Vilanova, Lleida, Spain; [4]Nephrology Dept., Hospital Arnau de Vilanova, Lleida, Spain.*

Background: Cardiovascular (CV) disease is the leading cause of mortality in chronic kidney disease (CKD) patients. A challenge for nephrologists is to develop accurate non invasive tools for the early identification of subclinical CV disease. We focussed on ADAM17 as an early marker because mild elevations in the activity of this enzyme in peripheral blood monocytes-macrophages (PBMM) associates with a high risk for CV mortality in normal individuals. Furthermore, ADAM17 plays a key role in the development of neovascularization, inflammatory lesions in the arterial wall, and foam cell formation.

Methods: We studied the association between ADAM17 content in PBMM and both the degree of neovascularization [vasa vasorum density (VV)] of the adventicia and carotid intima media thickness (CIMT) because neovascularization is shown to precede the arterial inflammatory/atheromatous damage that leads to increases in CIMT. We examined 43 normal individuals, 51% men, average age 46 years old (Age range 30-70) with none of the classical risk factors for atheromatous or CV disease.

Results: PBMM ADAM 17 correlated positively with VV content in the carotid adventicia ($r=0.43$ $p<0.005$; $n=42$) at all ages for both genders. Importantly, PBMM ADAM17 correlated with the CIMT only in the age range 41 to 50 ($r=0.71$, $p<0.005$, $n=15$), which precedes the highest increases not only in CIMT, but also in serum cholesterol and in blood pressure (two well known risk factors for the progression of vascular lesions) that occur in the age range 50-60.

Conclusions: PBMM ADAM17 content appears to contribute to the initiation of both neovascularization and the subclinical inflammatory/atheromatous lesion leading to increases in CIMT thereby providing a novel and highly sensitive diagnostic tool for subclinical atheromatous disease.

PUB134

Prevalence of Aspirin Resistance in Chronic Kidney Disease Patients Isabelle Ayoub, Abdallah Sassine Geara, Suzanne E. El Sayegh. *Nephrology, Staten Island University Hospital, Staten Island, NY.*

Background: Aspirin resistance is a new concern with a prevalence of 28% in the population with cardiovascular diseases without a history of CKD. In the hemodialysis population this prevalence was observed to be 34.7%. Aspirin is prescribed frequently in Chronic Kidney Disease (CKD) patients for primary and secondary prevention of cardiovascular diseases. The aim of this study was to determine the prevalence of aspirin resistance in patients with CKD.

Methods: In a cross-sectional study, we measured platelets reactivity in CKD patients on aspirin therapy. A total of 19 patients with CKD stage III and IV were evaluated in this study. The resistance to aspirin was assessed by evaluating the Aspirin Reaction Units (ARU) using platelet function analyzer-100 (VerifyNow Aspirin®). Aspirin resistance is defined as ARU > 550. The control group was a cohort of patients with cardiovascular diseases on aspirin but without CKD.

Results: In the nineteen CKD patients on aspirin the mean ARU was 425.2 compared to 468.03 in the hundred patients in control group ($p<0.003$). The control group was found to have 10% aspirin resistance with ARU >550.

Conclusions: We were able to conclude that our patient with CKD stage III and IV do not have characteristic findings of aspirin resistance by testing ARU. Although our sample size was small this information is helpful as these patients carry a high degree of cardiovascular risk.

PUB135

Presence of Anemia and Its Therapeutic Management in Patients with Chronic Kidney Disease Stages 3, 4 and 5 Not on Dialysis at Nephrology Units in Catalonia (The MICENAS I Study) Aleix Cases,[1] Alberto M. Martinez-Castelao,[2] Joan Fort,[3] Jordi Bonal,[4] J.M. Galceran,[5] J. V. Torregrossa.[1] *[1]Nephrology and Transplantation Unit, Hospital Clínic, Barcelona, Spain; [2]Nephrology Unit, Hospital de Bellvitge, Barcelona, Spain; [3]Nephrology Unit, Hospital Vall d'Hebron, Barcelona, Spain; [4]Nephrology Unit, Hospital Germans Trias i Pujol, Badalona, Barcelona, Spain; [5]Nephrology Unit, Fundación Althaia, Manresa, Barcelona, Spain.*

Background: Anemia prevalence and its therapeutic approach in patients with CKD stage 3-5 not on dialysis in Catalonia in usual clinical practice conditions are unknown.

Methods: Cross-sectional study conducted in nephrology units in Catalonia, study approved by an Ethical Committee. Patients aged ≥18 years, diagnosed with CKD stages 3, 4 and 5 not on dialysis, with Hb measurement in the previous 2 months and give their informed consent were consecutively recruited. Anemia defined as Hb<13.5 g/dL in men, Hb<12.0 g/dL in women or receiving ESA.

Results: A total of 22 investigators recruited 531 patients, of which 504 were valid for analysis. 56.4% of patients were men; mean age: 67.8±15.5 years. Regarding CKD Stage, 61.5% of patients were in stage 3 (3a: 23.0%, 3b: 38.5%), 30.2% stage 4 and 8.3% stage 5. 58.5% of patients had anemia (stage 3a:35.3% and 3b:52.1%; stage 4:73,7%; stage 5:97,6%) showing a higher prevalence in more advanced stages. 40.5% received treatment for anemia at the time of the visit, the percentage of treated patients were 16.7%, 31.3%, 58.2% and 85.7% in Stage 3a, 3b, 4 and 5 respectively ($p<0.05$). 66.0% received iron; 14.5% folic acid; 10.0% vitamin B12 and 54.5% were treated with ESA. ESA therapy was more frequent in stage 5 (Stage 3a: 26.3%, stage 3b: 36.7%, stage 4: 61.2%, stage 5:83.3%; $p<0.001$). Darbepoetin alfa was the ESA most frequently prescribed (62.5%), mainly administered every 2 weeks; followed by methoxy polyethylene glycol-epoetin beta (30.4%) administered on a monthly basis, with a median monthly dose of 80 and 75 µg, respectively, both subcutaneously.

Conclusions: More than half of patients in stages 3, 4 and 5 not on dialysis attended in nephrology units of Catalonia had anemia and stage 5 patients were the ones who received more anemia therapy.

PUB136

Prospective Observational Multicenter Study To Evaluate the Effectiveness and Safety of MIRCERA® in Patients with Anemia Secondary to Chronic Kidney Disease. MINERVA Study Aleix Cases,[1] Jose Portoles,[2] J. Calls,[3] Alberto M. Martinez-Castelao,[4] Domingo Sanchez-Guisande,[5] Alfonso Segarra.[6] *[1]H. Clínic, Spain; [2]H. Puerta de Hierro, Spain; [3]H. Manacor, Spain; [4]H. Bellvitge, Spain; [5]H. Barbanza, Spain; [6]H. Vall d'Hebron, Spain.*

Background: Once-monthly dosing of MIRCERA® provides stable and sustained hemoglobin (Hb) levels in CKD patients. This study aimed to evaluate the effectiveness and safety of once-monthly MIRCERA® in patients with CKD stages 3-5 on pre-dialysis or receiving hemodialysis (HD) in routine clinical practice

Methods: Multicenter prospective observational study. An interim analysis at 6-months follow-up is presented. Data were collected from patients receiving MIRCERA® (at least one month of treatment at baseline visit) to correct anemia or as conversion treatment

Results: A total of 243 patients were evaluated: 55% male; age: 71±15years. Diabetic nephropathy was the most frequent etiology of CKD (27%). Naïve and converted patients: 51% and 49% respectively. 64% were on predialysis and 36% on HD. Out of converted patients 73% had previously received epoetin beta and 27% darbepoetin alfa; mean weekly doses 6,762±6,259.7IU and 38.8±32.4µg respectively. Mean Hb levels at the initiation of MIRCERA® and after 6 months of study were 10±1.1g/dL and 11.6±1.1g/dL in naïve patients. Mean Hb levels at baseline and after 6 months were 11.5±1.1g/dL and 11.4±1.2g/dL in converted patients. There were not significant differences in Hb levels between groups. Mean doses of MIRCERA® at the beginning of treatment and 6 months after study initiation were 117±104µg/month and 122±90µg/month in naïve patients and 118±72.9µg/month and 141±103.9µg/month in converted patients with no significant differences between both groups. 94% and 75% of naïve and converted patients did not require any dosage adjustment. None of the patients experienced MIRCERA®-related adverse events

Conclusions: The preliminary results of this interim analysis suggest that MIRCERA® is effective and safe for anemia correction and Hb level maintenance in CDK patients not on dialysis and on HD in routine clinical practice. These results support the data obtained in previous phase III/IV clinical trials.

Obesity Is Associated with Proximal Tubular Hypertrophy Avry Chagnac,[1,2] Ana Tovar,[4] Yaacov Ori,[1,2] Michal Herman-Edelstein,[1] Boris Zingerman,[1] Sydney Benshetrit,[3] Uzi Gafter.[1,2] *[1]Nephrology, Rabin Medical Center, Petah Tikva, Israel; [2]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel; [3]Nephrology, Meir Hospital, Kfar Saba, Israel; [4]Pathology, Rabin Medical Center, Petah Tikva, Israel.*

Background: Obesity and Diabetes mellitus are associated with glomerular hyperfiltration and glomerular hypertrophy. Data in diabetic rats suggest that tubular hypertrophy and increased proximal sodium reabsorption may play a role in the pathogenesis of glomerular hyperfiltration. Proximal tubular sodium reabsorption is increased in obesity. No studies in obese animals and humans have yet shown that the volume of tubules is increased in obesity.

The aim of the present study is to estimate the volume of the proximal tubules in obese subjects and to determine whether tubules undergo cellular hyperplasia.

Methods: Seven obese (BMI>30) and 6 lean subjects (BMI<25) participated in the study. Subjects had undergone a kidney biopsy for renal abnormalities. Inclusion criteria were normal GFR or mild chronic renal insufficiency and no or mild chronic interstitial fibrosis. Stained sections were retrospectively examined on light microscope. All available glomerular profiles and 15 randomly chosen proximal tubular profiles were photographed at x200 and x400 magnification respectively. The cross sectional area of these structures was estimated using a grid. The number of proximal tubular cells was estimated by counting the number of nuclei per tubular section.

Results:

	Obese	Lean	P
Age (yrs)	56±11	25±6	<0.0005
BMI	40±7	21±3	significant per definition
S creat (mg/dl)	1.3±0.5	0.8±0.2	<0.05
Proteinuria (g/d)	3.2 (0.2-7.6)	1.1 (0-3.8)	NS
Fasting blood glucose (mg/dl)	104±9	87±4	<0.005
Hba1c (%)	5.95±0.3	NA	

Cross sectional area of the proximal tubules was 35% higher in the obese as compared to the lean group ($P<0.002$). Glomerular cross sectional area was 106% higher in the obese as compared to the lean subjects ($P<0.004$). The number of nuclei profiles/proximal tubule profile was similar.

Conclusions: Obesity is associated with increased proximal tubular volume, without tubular cell proliferation. These data suggest that the increased tubular volume is due to cellular hypertrophy and not hyperplasia.

PUB138

Plasma Fluorescent Oxidation Products and Risk of Chronic Kidney Disease Jing Chen,[1] Tianying Wu,[2] L. Lee Hamm,[1] Islam Enver Khan,[1] Arnold B. Alper,[1] Grace Browne,[1] Chung-Shiuan Chen,[1] Yanxi Liu,[1] Katherine T. Mills,[1] Chuan He,[1] Md Mahfuzur Rahman,[1] Stephanie E. Rogers,[3] Joseph Tarsia,[1] Kamal Ramesh Shah,[1] Eric E. Simon,[1] Myra A. Kleinpeter,[1] Jiang He.[1] *[1]Tulane University; [2]University of Cincinnati Medical Center; [3]University of California, San Francisco.*

Background: A few clinical studies have reported increased oxidative stress in patients with end-stage kidney disease. Plasma fluorescent oxidation product (FLOP) is a stable and easily measured biomarker of oxidative stress. However, its association with risk of chronic kidney disease (CKD) has not been studied.

Methods: We examined the association of FLOP and risk of CKD in 201 CKD patients and 201 controls without CKD from the community. CKD was defined as estimated glomerular filtration rate (eGFR) <60 ml/min/1.73m² or presence of albuminuria.

Results: Compared to controls, patients with CKD were older (56 vs. 53 yrs), more likely to be male (55% vs. 45%), less likely to have graduated from high school (59% vs. 82%), or consume alcohol (28% vs. 59%). Race and cigarette smoking were comparable between CKD patients and controls. Mean systolic blood pressure (132 vs. 122 mmHg), body mass index (32 vs. 29 kg/m²), fasting glucose (120 vs. 103 mg/dL), history of hypertension (88% vs. 24%), history of diabetes (49% vs. 6%), and cardiovascular disease (44% vs. 7%) were higher while LDL cholesterol (102 vs. 118 mg/dL) was lower

in CKD patients than in controls. After adjustment for the above risk factors, the median inter-quartile range (IQR) of FLOP was significantly higher in patients with CKD than in controls [46.19 fluorescent intensity (FI)/mL (IQR, 31.35-61.04) vs. 15.49 FI/mL (IRQ, 1.01-29.97), p=0.013]. Compared with those with a FLOP level below the 75th percentile, participants with a FLOP level above the 75th percentile had a 15.4-fold increased odds (95% CI, 6.2-38.2) of CKD after adjustment for co-variables.

Conclusions: These data indicate that an elevated FLOP level is associated with risk of CKD. Furthermore, our study findings support the notion that oxidative stress is involved in the pathogenesis of CKD.

Efficacy and Safety of Valsartan in Hypertensive Patients with Albuminuria in China Xiaoqiang Ding, Xiaoyan Zhang. *Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China.*

Background: There is limited study to demonstrate efficacy of ARB in albuminuria reduction in Chinese hypertensive patients with albuminuria.The objective of this observational study was to evaluate the safety and efficacy of valsartan in Chinese hypertensive patients with albuminuria whose blood pressure was not adequately controlled in a real-world setting.

Methods: This is an observational, open-label study. Chinese hypertensive patients with albuminuria(range for 30~1000mg/24h or UACR 30-1000mg/g Cr) whose blood pressure was not controlled received valsartan 80-160mg and were observed for 12 weeks.

Results: Significant reduction of mean sitting systolic blood pressure (MSSBP) and mean sitting diastolic blood pressure (MSDBP) from baseline at each visit were observed in the intent-to-treat (ITT) population(n=1180). General BP controlled rate in ITT population at end of week 12 was 73.2%. Besides, at end of week 12, mean albuminuria reduction rate of those patients who repeated urine albumin level test(n=904) was 33.7%. 18.9% (171 of 904) of these patients have returned to normal albuminuria and the rate of normalization was higher in diabetes patients than in non DM patients. 37.6% (340 of 904) of patients have gained over 50% reduction of albuminuria, and the rate of >50% reduction of albuminuria is also higher in diabetes patients than in non DM patients (41.7% vs 33.8%, p=0.016). The total incidence of adverse events was 4.7% in safety population. There were no investigator drug related serious adverse events reported in the study.

Conclusions: This is the first large sample size observational study to demonstrate ARB's effect in albuminuria reduction in Chinese hypertensive patients with albuminuria. Valsartan is efficacious, well tolerated and devoid of any serious adverse events both in BP reduction and in albuminuria reduction in Chinese real-world setting. Besides, valsartan may reduce more albuminria in diabetes patients than non diabetes patients.

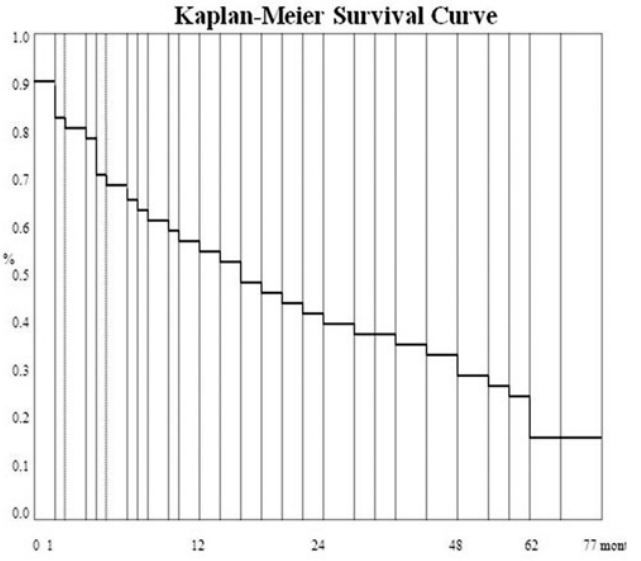
PUB141

Cardiorenal Syndrome Type 4 (crs 4) Associated with Anemia: Long Term Survival Analysis Matteo Floris,[1] Anna Clementi,[2] Dinna N. Cruz,[2] Antonello Pani.[1] *[1]G Brotzu Hosp, Cagliari, Italy; [2]S. Bortolo Hosp, Vicenza, Italy.*

Background: In Cardiorenal Syndrome type 4(CRS4)CKD is responsible for heart failure.Anemia is a complication of both conditions and is associated with an increased risk of mortality,but the possible correlation between the clinical outcome and the hemoglobin(Hb)levels still remains unclear.We analyzed the prevalence of the association between CRS4 and anemia in our hospital and the effect of the severity of anemia on long-term survival

Methods: Among all the patients admitted to our department from Jan 2001 to Jan 2008(n = 7768)we selected those who met the following criteria upon admission:signs and symptoms of systolic heart failure,left ventricular ejection fraction<40%,GFR MDRD<60 ml/min,Hb <13.5in males and <12.0in females.76 patients(0.97%)met the inclusion criteria.The primary outcome was all cause mortality and all patients were followed up for at least 18 months after discharge.Patients were stratified according to Hb levels into three groups(1,2,3)homogeneous for sex, age and comorbidities (1=Hb≥10.5, 2=Hb<9 and>10.5, 3=Hb≤9 g/dl).Univariate survival analysis were performed using Kaplan-Meier estimation and long-rank tests

Results: The overall survival is shown in the figure



60 months survival was 15%, 26%, and 18% in groups 1, 2, and 3, respectively.The difference between the survival curves in the 3 groups was not statistically significant(Log Rank Test=0.13).

Conclusions: Considering that limited data are available in this field we found that the association between CRS4 and anemia was characterized by severe prognosis.We have not observed a significant correlation between the severity of anemia and mortality risk, probably because of the elderly age of patients and the presence of comorbidities. Further studies are necessary to better understand the overall burden of disease, for a risk stratification and design of potential targets for intervention.

PUB142

Umbilical Hernia in Patients with Autosomal Dominant Polycystic Kidney Disease Yoshinari Hattori, Tatsuya Suwabe, Keiichi Sumida, Rikako Hiramatsu, Masayuki Yamanouchi, Noriko Hayami, Junichi Hoshino, Yoshifumi Ubara. *Toranomon Hospital, Nephrology Center, Kajigaya, Kanagawa, Japan.*

Background: Patients with autosomal dominant polycystic kidney disease (ADPKD) are known to have a high prevalence of abdominal wall complications such as umbilical hernia due to increased intra-abdominal pressure because of severe nephromegaly and/or hepatomegaly. However, the actual frequency has not yet been reported.

Methods: We performed transcatheter arterial embolization (TAE) for ADPKD patients who chose this option to alleviate compression symptoms related to kidney and/or liver enlargement. The frequency of umbilical hernia (apparent in the standing position) was evaluated retrospectively.

Results: Out of 497 patients receiving TAE, 159 patients were diagnosed as having umbilical hernia (31.9%) (64 men and 95 women). Their mean age was 55.3+/-8.5 years. Out of these 159 patients, hepatomegaly was dominant in 38% (n=60), nephromegaly was dominant in 54% (n=86), and both were similar in 8% (n=13). After abdominal distension was improved by TAE, umbilical hernia improved partially. Surgery for the hernia was performed successfully in five patients.

Conclusions: Although umbilical hernia is a potentially serious complication in patients with ADPKD, TAE may provide therapeutic improvement by reducing the intra-abdominal pressure.

Neurocognitive and Social-Behavioral Functioning of Preschool Children with Mild to Moderate CKD Stephen R. Hooper,[1] Arlene C. Gerson,[2] Robert W. Butler,[3] Susan R. Mendley,[4] S. Shinnar,[5] Marc Lande,[6] Debbie S. Gipson,[7] Matthew Matheson,[8] Marjolaine M. Limbos,[9] Bradley A. Warady,[10] Susan L. Furth.[11] *[1]UNC, Chapel Hill, NC; [2]JHMI, Baltimore, MD; [3]OHSU, Portland, OR; [4]U Maryland, Baltimore, MD; [5]Albert Einstein, New York, NY; [6]U Rochester, Rochester, NY; [7]U Michigan, Ann Arbor, MI; [8]JHSPH, Baltimore, MD; [9]BC Children's Hospital, Vancouver, BC, Canada; [10]Mercy Children's Hospital, Kansas City, KS; [11]CHOP, Philadelphia, PA.*

Background: Few studies have examined the neurocognitive and social-behavioral functioning of preschool children with CKD. We used baseline data to describe the CKiD preschool sample, and to identify disease-specific factors for impaired function in this sample.

Methods: Subjects included 95 children, 12 mos. to 5.9 yrs. (median = 3.9 yrs), with a median iohexol or estimated GFR of 44.7 ml/min/per 1.73m^2. In addition to level of function and percent of subjects 1 SD or more below the test mean, multiple regression examined the associations between biomarkers of CKD (i/eGFR, anemia, hypertension, seizures, low birthweight), and IQ, attention, and parent ratings of adaptive behavior, social-emotional, and executive functions.

Results: Scores for all measures fell in the average range; however, 28% had low IQ, 30% executive dysfunction, 21% attention variability, and 36% adaptive behavior problems. None of the biomarkers were significantly associated with measures of attention, executive function, or social-behavioral functioning, but presence of seizures ($p<.03$), low birth weight ($p<.02$), and maternal eduation ($p<.02$) were related to low IQ, and presence of seizures ($p<.008$) was related to low adaptive behavior ratings.

Conclusions: Although when compared to normative expectations an increased number of preschoolers with CKD had low IQ, executive dysfunction, inattention, and low adaptive behavior, only the presence of seizures and low birthweight were related to IQ and adaptive behavior. These findings support ongoing neurodevelopmental surveillance of young children with CKD, particularly with respect to disease progression.

PUB144

Daptomycin Plus Ampicillin for Enterococcal Endocarditis in a Patient at Higher Risk for Gentamicin Nephrotoxicity Oscar A. Iznaola,[1] Matthew M. Goodwin,[2] Miguel A. Sierra-Hoffmann,[1] John Mohr.[2] *[1]Nephrology, Citizens Medical Center, Victoria, TX; [2]Cubist Pharmaceuticals; [3]Infectious Disease, Citizens Medical Center, Victoria, Tx.*

Background: Nephrotoxicity is one of the most important adverse events and therapeutic limitations of gentamicin. We present a case of a patient with CKD stage 4 , and enterococcus faecalis bioprosthetic valve endocarditis, treated with daptomycin plus amplicillin, instead of ampicillin plus gentamicin, the accepted standard of care.

Case report: An 83 year-old female, with history of CKD Stage 4, DM2, HTN, aortic bioprosthetic valve replacement, and permanent pacemaker was admitted with low grade fever and positive blood cultures for E. faecalis susceptible to ampicillin. The admitting physician thought the source of the infection was from an infected toe. The patient received levofloxacin IV for a total of 15 days and discharged. After the completion of this treatment, repeated blood cultures showed persistent E.faecalis. The patient was readmitted to the hospital and a transesophageal echocardiogram (TEE) showed small vegetations in the aortic valve. Ampicillin plus gentamicin were discussed, with consideration of gentamicin nephrotoxicity given the patient's baseline eGFR of 25 ml/min. Alternatively, a non-standard treatment for enterococcal endocarditis was proposed to the patient with daptomycin 400 mg (6 mg/kg) IV q 48 hrs plus ampicillin 2 gr bid. The patient decided to opt for daptomycin + ampicillin therapy for 6 weeks. Two weeks after completion of treatment, a set of blood cultures came back negative without any changes in her baseline renal function.

Conclusions: Gentamicin nephrotoxicity can reach 10-25% of treated patients. In enterococcal endocarditis, ampicillin plus gentamycin is the standard of care for 6 weeks. Here we show that the alternative daptomycin plus ampicillin, a non-standard option negativized the blood cultures 2 weeks after the completion of treatment without worsening the patient's eGFR. To our knowledge, this is the first publication showing the possible benefits of daptomycin plus ampicillin for enterococcal endocarditis in patients at high risk for gentamicin nephrotoxicity.

PUB145

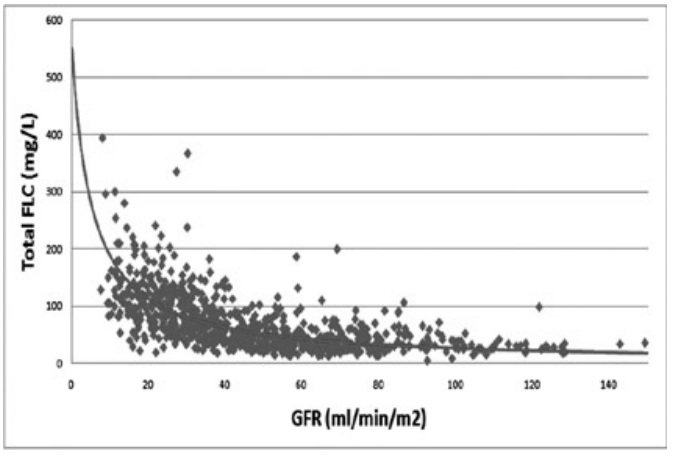
Determining Serum Polyclonal Free Light Production Rates: A Mathematical Model Richard T. Keir,[1] Neil D. Evans,[1] Anne Bevins,[2] Maarten W. Taal,[4] Colin A. Hutchison.[3] *[1]University of Warwick, United Kingdom; [2]The Binding Site Group Ltd, Birmingham, United Kingdom; [3]Renal Unit, University Hospital Birmingham, United Kingdom; [4]Nephrology, Derby Royal Infirmary, Derby, United Kingdom.*

Background: Serum concentrations of polyclonal free light chains (FLC) are determined by the activity of the adaptive immune system and when raised they independently predict adverse clinical outcomes in renal and general populations. However their absolute serum levels are also influenced by renal function. A method for determining the underlying FLC production rate independently of renal function is required.

Methods: Steady state analysis was performed on a 2 compartment mathematical model to generate a relationship between FLC production rates, total serum FLC levels and estimated GFR, namely:

$eProduction = a\text{Serum}\ (b + c\text{GFR})$

where a,b and c are constants derived from the model parameters, which include reticuloendothelial clearance, body volumes and the inter-compartmental transfer rates.



The derived production rates for kappa and lambda FLCs were 0.330 g/day and 0.178 g/day respectively.

Results: This equation was applied to data sets from two CKD cohorts. The first cohort was recruited from tertiary care nephrology clinics with moderate to advanced CKD (median GFR 29mls/min/1.73m$^{2)}$. The second cohort was recruited from a primary care with CKD stage 3 (GFR 53mL/min/1.73m^2). The work determined that FLC production rates were significantly raised in both cohorts. In each group 55% and 43% of patients, respectively, had FLC production rates more than twice normal.

Conclusions: In conclusion, we have developed a mathematical method whereby the production rate of FLCs can be determined from the absolute serum FLC level and estimated GFRs. The intention is that this new tool can be assessed in clinical studies as the role of serum FLCs is further evaluated as a prognostic marker in CKD.

PUB146

Is the Uremic Foot a Burning Emergency? Antonia Lopez,[100191] Marcora Mandreoli,[100191] Tommaso Bianchi,[100191] Maria Letizia Soverini,[100191] Juri Piattoni,[100191] Annalisa Zuccejlli,[100191] Antonio Santoro.[100191] *[1]Unit of Nephrology Dialysis Hypertension, Policlinico S Orsola Malpighi; [2]Dermatology, Local Health Unit.*

Background: Chronic Kidney Disease (CKD) is an independent risk factor for developing/worsening of wounds and the increasing risk correlates with decline of renal function. With the advent of hemodialysis, the life expectancy of these patients (pts) has improved, giving time for suffering all the consequences too.

Aim: We want to evaluate if an organized foot care team in an Hemodialysis Unit, transforming an "hard to heal" in an healing wound, can save limbs, reduce mortality, improve quality of life. We report our experience of a Dialysis Unit.

Methods: In the last year, over 83 dialysis pts, 25.3% was treated for 'hard-to-heal' wounds. The mean age was 75, the mean dialytic age 3.8 years; 41% were diabetic. The team was composed from a nephrologist, a dermatologist specialized in wound-care and three dedicated nurses of our Dialysis Unit, with an expertise in this field. The pathway required a dedicated nurse, personalized medication outline, all during the dialysis session without other hospital access of the patient.

Results: After a mean of 17 topical medications/pts and 1.5 months for each case, 13 cycles of systemic antibiotics, 2 cycles of VAC-therapy, we achieve wound healing in 77,5% of treated cases. **Comments**: Lower limb lesions and diabetic foot are well known complications in diabetic pts. However, in hemodialysis population the prevalence of uremic foot is scarcely recognized, despite, nearly 25% of dialysis pts exhibited peripheric arteriopathy (PAD). Moreover, current guidelines on foot care should recognize CKD-5d as an indipendent risk factor for foot disease.

Conclusions: Our initial experience demonstrated that a "task force" expressly dedicated to the care of wounds in the setting of Hemodialysis Unit, may contribute to change the overwhelming course of foot lesions in CKD-5d pts and underlie the clinical weight of uremic foot on the quality of life of uremic pts. Our experience is in accord to some studies reporting that structured clinical pathways and a dedicated team are associated with a decreased lenght of stay and in-hospital complications, thus reducing in-hospital costs.

PUB147

Association between Chronic Kidney Disease and Abnormal Ankle Brachial Index Fukun Niu,[1,2] Luxia Zhang,[1] Xingyu Wang,[3] Lisheng Liu,[3] Haiyan Wang.[1] *[1]Institute of Nephrology and Division of Nephrology, Peking University First Hospital, Beijing, China; [2]Nephrology and Rheumatology, First Affiliated Hospital of Zhengzhou University, Zheng Zhou, Henan, China; [3]Beijing Hypertension League, Beijing, China.*

Background: Both low and high ankle-brachial index (ABI) has been reported to be independently associated with increased risk of cardiovascular disease and mortality. However, it is not clear whether chronic kidney disease (CKD) is associated with abnormal ABI.

Methods: This prospective cohort study included 1189 community-based participants from Beijing, China. Among them, 928 participants (78.0%) had complete data of kidney damage and ABI, and were therefore included in the present study. ABI was categorized as low ABI (< 1.00), normal ABI (1.00 – 1.30), and high ABI (>1.30) . Urinary albumin-to-creatinine ratio(ACR) and eGFR were assessed at baseline, and ABI was measured after a median of 6 years of follow-up. All participants had estimated glomerular filtration rate (eGFR) above 30mL/min/1.73m2 . Multivariable logistic regression was used to evaluate the association between CKD and abnormal ABI.

Results: The average age was 59.1±9.1 years and 45.6% were males. Among 63 participants with CKD defined by the presence of eGFR<60mL/min/1.73m2 or albuminuria, the prevalence of low ABI was significantly higher than those among participants without CKD (30.2% vs15.2%, P<0.01). After adjusting for potential confounders including eGFR, ACR was independently associated with increased risk of low ABI. For every 10 mg/g increase of ACR, the odds ratio(OR) for low ABI was 1.06 [95%CI, 1.02–1.11]. However, baseline eGFR was not significantly associated with low ABI. Among 151 participants with low ABI, 122 of them (80.8%) did not have self-reported history of cardiovascular disease. Indicators of kidney damage were not associated with high ABI in both univariate and multivariate analysis.

Conclusions: Albuminuria is independently associated with low ABI among a Chinese population with normal or mildly impaired renal function.

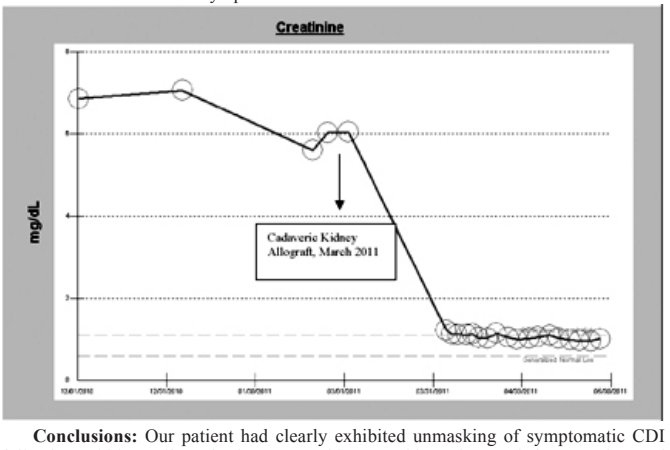
Relapsing Central Diabetes Insipidus Following Renal Transplantation in an ADPKD ESRD Patient Macaulay A. Onuigbo.[1,2] *[1]College of Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, WI.*

Background: A 59 year old Caucasian female with ESRD from ADPKD had in 2008 developed symptoms of central diabetes insipidus (CDI) following intracranial hemorrhage which were subsequently controlled with oral desmopressin. The behavior of her CDI after a successful kidney transplant had long been a subject of much speculation.

Methods: Case Report

Results: The patient had remained on HD between 2008 and 2011, serum creatinine about 7 mg/dL. In September 2009, 24-hour urine volume was 1,430 ml. She had a left elective nephrectomy in August 2010, as part of pre-transplant work up; subsequently she made less urine. She received a cadaveric renal allograft transplant in March 2011. Desmopressin was withheld post-operatively. Graft function was excellent; serum creatinine 1.2 mg/dL; on cellcept and prograf. She presented to our Transplant Office in April 2011, concerned about increasing urinary frequency, polyuria, nocturia 6x/night, and disabling thirst. Post-renal transplantation CDI exacerbation was diagnosed. Blood was sent out for a vasopressin (AVP) level. She was immediately restarted on PO desmopressin, 0.1 mg QHS. 24-hour urine volume was 3,700 ml; measured creatinine clearance 65 ml/min (Figure). Plasma AVP was not measurable. After six days, she reported no improvement in symptoms and the dose was raised to 0.2 mg QHS. She improved to 2x/night nocturia and resolution of the other symptoms.



Conclusions: Our patient had clearly exhibited unmasking of symptomatic CDI following a kidney allograft placement. This unmasking of pre-existing CDI in renal allograft recipients following kidney transplantation has been the subject of a few published case reports. Our patient, we submit, should have been maintained on pre-transplant oral desmopressin regimen post-transplantation, with the dose titrated as indicated, and not simply withheld.

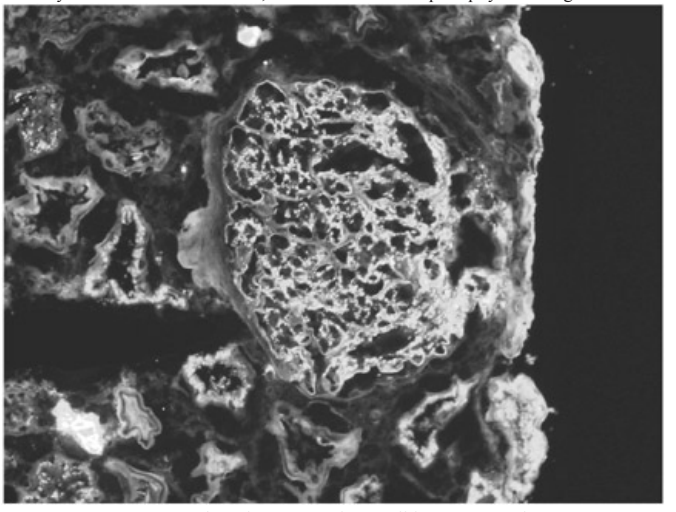
PUB150

IgA-Dominant Post-Infectious Glomerulonephritis – An Unrecognized Cause of Reversible Acute Kidney Injury in a Diabetic CKD Patient Macaulay A. Onuigbo,[1,2] Samih H. Nasr.[3] *[1]College of Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, WI; [3]Pathology, Mayo Clinic, Rochester, MN.*

Background: According to Nasr et al, postinfectious glomerulonephritis (PIGN) is primarily a childhood disease, and follows URI or impetigo; its occurrence in adults is not well characterized. Immunocompromise is common; commonly diabetes or malignancy. Common infection site was skin; common causative agent staphylococcus. IgA-dominant PIGN (IgA-PIGN), a distinct subgroup, constituted 17% of cases. We report an unusual case of adult IgA-PIGN.

Methods: Case Report

Results: A 55-year old type 2 diabetic male patient presented in January 2011 with glomerulonephritis, vomiting and increased serum creatinine of 2.5 mg/dL up from 1.4. Immunologic work up for secondary GN was negative. IF staining for IgA in kidney biopsy showed coarsely granular mesangial and GBM positivity, the typical "starry sky" pattern of acute PIGN. This diagnosis triggered a search for recent infection(s). It turned out that in mid-November 2010, the patient broke his left humerus after a fall and had developed intergluteal pressure ulcers, treated with topical clotrimazole and Bactrim. Examination confirmed healed inter-gluteal ulcers. Dicloxacillin, 250 mg 4x/day for 10 days led to falling serum creatinine from a peak of 4.36 mg/dL. Hypotension from carbegoline interrupted AKI recovery. After it was discontinued, serum creatinine fell promptly to 1.5 mg/dL.



Conclusions: Our patient demonstrated reversible AKI secondary to IgA-PIGN. Lessons learnt include that kidney biopsy should be considered in undiagnosed diabetic AKI, that long after the triggering infection(s), AKI from IgA-PIGN remains potentially reversible with anti-staph therapy, and we submit that in diabetics with unexplained AKI, a trial course of anti-staph therapy may be warranted.

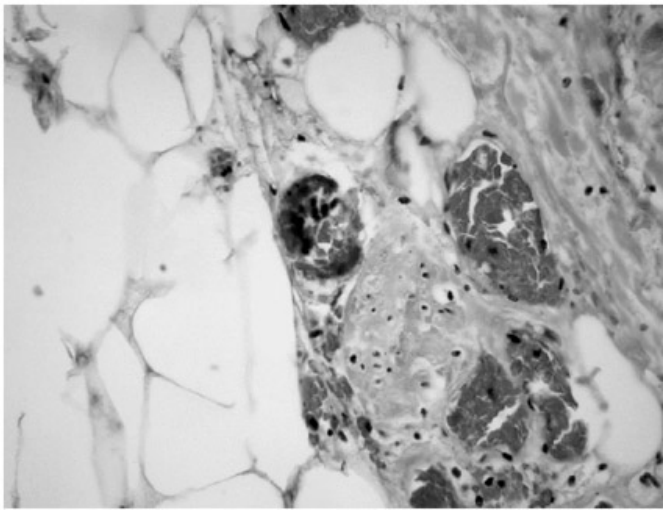
PUB151

Cutaneous Capillary Calciphylaxis – A New Variant of Calciphylaxis in End Stage Renal Disease Macaulay A. Onuigbo,[1,2] Scott A. Martin.[3] *[1]College of Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, WI; [3]Pathology, Mayo Clinic Health System, Eau Claire, WI.*

Background: Calciphylaxis is a rare, usually fatal vasculopathic disorder of cutaneous iscemia/necrosis with calcification in small- and medium-sized venules/arterioles, mostly in ESRD. It has been reported infrequently among patients on warfarin. Warfarin-induced skin necrosis (WISN) and calciphylaxis can mimic each other. Typically, WISN occurs soon after drug initiation. We encountered an unusual spreading cutaneous condition in an ESRD patient also on warfarin.

Methods: Case Report

Results: A 61-year old diabetic male patient on HD for ESRD presented in March 2011 with a painless abdominal "mass". Initial diagnosis was lipoma. A surgical evaluation with ultrasound examination and biopsy suggested panniculitis; he did not improve after oral antibiotics. The lesions spread locally with increasing pain and blue-violet discoloration of the overlying skin. Calciphylaxis versus hematoma were considered. By early April, he reported "spreading" to the thighs; was admitted, started on IV antibiotics, and atypical WISN was now entertained. Warfarin was discontinued; IV heparin and IV vitamin K started. Review of ultrasound images revealed no dystrophic calcifications. He never recovered and expired. Autopsy revealed cutaneous ulceration and necrosis, mural calcification of subcutaneous capillaries, without intravascular thrombin formation, consistent with calciphylaxis.



Conclusions: Our patient demonstrated the well acknowledged diagnostic dilemma of differentiating between calciphylaxis and WISN in an ESRD patient on warfarin. Regardless of morphology, absent radiologic findings, normal PTH and concurrent warfarin, calciphylaxis must be considered in the differential diagnosis of painful, necrotic lesions occurring in the setting of ESRD.

PUB152

The Factors Associated with the Beneficial Effect of Angiotensin Receptor Blocker on Glomerular Filtration Rate and Albuminuria among Hypertensive Patients Gen Ouchi, Kentaro Kohagura, Atsushi Sakima, Kunitoshi Iseki, Yusuke Ohya. *Department of Cardiovascular Medicine, Nephrology and Neurology, Faculty of Medicine, and Dialysis Unit, University of the Ryukyus, Nishiharacho, Okinawa, Japan.*

Background: Benefit of angiotensin II receptor blocker (ARB) on estimated glomerular filtration rate (eGFR) has been reported, but not all hypertensive patients. However, the factors related to improving eGFR and decreasing albuminuria is not clear in these patients.

Methods: We conducted retrospective cohort study in hypertensive patients (N=90, 37% male) who had more than two data for eGFR and albuminuria from 2008 to 2010. We compared these data between baseline and the last visit data (mean observation period 21 months)

Results: At baseline, the mean age were 66 years, blood pressure (BP) 130/75 mmHg, eGFR 65 ml/min/1.73 m^2, albuminuria (uAlb) 124 mg/gCr, and uric acid 5.9 mg/dl. BP had not changed between the study periods. There were elevated eGFR in 44 patients (49%) and decreased uAlb in 47 patients (52%). Changes in eGFR was negatively correlated with the changes in serum uric acid (r=-0.31, p=0.003) and was not correlated with the changes in uAlb. Changes in uAlb were positively correlated with the changes in BP, serum glucose, and body mass index (BMI). Logistic analysis showed that decrease in serum uric acid was significantly associated with elevation of eGFR; age-adjusted odds ratios (95% CI) was 3.80 (1.78-8.13). While, the changes in BMI and serum glucose were significantly associated with the decreased in uAlb; age-adjusted odds ratios (95% CI) were 1.55 (1.02-2.37) for BMI and 1.02 (1.00-1.04) for serum glucose, respectively.

Conclusions: In conclusion, decrease in uric acid was associated with elevation of eGFR, while decreases in BMI and serum glucose were associated with the decrease in uAlb. Results suggest that the factors associated with the beneficial effect of ARB might be different between eGFR and uAlb.

PUB153

Low Protein Supplemented Diet in Chronic Kidney Diseases: Are They Feasible? Giorgina B. Piccoli, Federica N. Vigotti, Martina Ferraresi, Valentina Consiglio, Stefania Scognamiglio. *Nephrology and Dialysis, San Luigi Hospital - University of Turin, Orbassano, Torino, Italy.*

Background: The criticisms on the early start of dialysis, the increase in old patients with poor dialysis survival and the budget constrains have renovated interest in low protein diets, not only for slowing the progression of CKD, but also as "metabolic stabilisers", prolonging the pre dialysis care.

Low protein diets are often considered as hardly feasible in the clinical practice.

Aim of the present study was to identify the clinical profile of patients successfully treated by a vegetarian low protein diet, defining success as >6 months of diet.

Methods: Prospective analysis, December 2007-April 2011, since the start of a new Nephrology Unit. A schema of vegetarian low protein diet was proposed for progressive CKD stages 3-5 and/or refractory proteinuria: Proteins 0.6 g/Kg/day; ketoacids and aminoacid supplements 1 pill every 8- 10 Kg, 1-3 free meals/week, according to clinical situation and personal needs, monthly follow-up, the simplified "non weighted" schema was based upon allowed and forbidden foods.

To identify patients with high probability pf success (>6 months diet) the following covariates were considered: age, sex, creatinine, GFR, proteinuria, educational level.

Results: Out of over 2000 patients evaluated, 129 started the diet. The population was heterogeneous; at start: median age 67 years (20-89); creatinine 3.6 mg/dL (0.9-16); proteinuria 1.5 g/day (0.1-18), GFR 20 mL/min (3-92). Educational level was the Italian standard(University in 12%). Diabetes and/or hypertension accounted for half of the nephropathies; 22/129 displayed no comorbidity.

At April 2011, 53 patients were on the diet, 35 discontiued it, 8 died, 33 started dialysis. The main side effect was poor enteric tolerance.

No correlation with functional data at start of treatment, educational level, age and compliance was found. In the subset with >6 months of follow-up, no patient developed clinical malnutrition, weight loss or hypercalcemia.

Conclusions: Vegetarian, supplemented low protein diets are feasible in a heterogeneous, non selected CKD population. A one-month trial may help identifying patients who may benefit from the diet.

PUB154

Depressive Symptoms Impact on Quality of Life and Cognitive Function of Elderly Patients Undergoing Chronic Hemodialysis Carmen B. Tzanno-Martins,[1] Geison Stein Meirelles Ramos,[2] Fernanda Ribeiro Nisihara,[3] Elzo R. Junior,[3] João Paulo L.B. Martins.[1] *[1]CINE - Integrate Center of Dialysis, Guarulhos, São Paulo, Brazil; [2]Home Dialysis Center, São Paulo, Brazil; [3]Renal Class, São Paulo, Brazil.*

Background: To assess the impact of depressive symptoms on quality of life and cognitive function in elderly patients undergoing chronic hemodialysis (HD) through the application of specific test for depression: Beck Depression Inventory (BECK), a test for cognitive assessment: Modified Mini-Mental State Examination (3MS) and Kidney Disease Quality of Life-short form (KDQOL-sf).

Methods: We selected 159 patients on hemodialysis and apply the BECK, 3MS and KDQOL. We evaluated demographic data, presence of depressive symptoms, quality of life and cognitive function

Results: Patients were divided into two groups: Group I: <60 years (n=85) and group II: >60 years (n=74). In group I, median time was 12.4 years, 43/85 (50,5%) were females, 50/85 (58,8%) were married, 9/85 (10,5%) were divorced or widowed and 26/85 (30,5%) were single. In group II, median time of HD was 8 years, 37/74 (47,3%) were females, 50/74 (67,5%) were married, 17/74 (22,9%) were divorced or widowed, and 7/74 (9.4%) were single. Comparing Beck Inventory with 3MS, we obtained the following results: group I, 27/85 (31,7%) had depressive symptoms, of these 7/27 (25,9%) had cognitive impairment. In Group II, 29/74 (39,1%) had depressive symptoms, of these 16/29 (55,2%) had cognitive impairment. BECK compared with who had a median scale score below 50 or above in KDQOL-sf, we obtained the following results: group I, 27/85 (31,7%) had depressive symptoms; of these 15/27 (55,5%) had scores <50. In group II, 29/74, depressive symptoms, these 17/29 (58.6%) had <50.

Conclusions: We found that depressive symptoms correlate with cognitive impairment only in group II. However the quality of life is impaired in both groups with depressive symptoms, regardless of age.

We can conclude that the presence of depressive symptoms alters the quality of life in patients with chronic kidney disease in HD, and that the cognitive impairment in this population relates more with age than with presence of depressive symptoms.

PUB155

Greater Incidence of Dental Disease and Oral Health Hygiene after Survey in Single Center of Chronic Kidney Disease Clinic Program in Thailand Manoch Rattanasompattikul.[1] *[1]Medicine Division, Medical Department, Golden Jubilee Medical Center, Mahidol University, Nakhon Pathom, Thailand; [2]Oral Medicine and Periodontics, Faculty of Dentistry, Mahidol University, Bangkok, Thailand.*

Background: Limited data exist about the effect of chronic kidney disease (CKD) on dental health problem, especially in Asian population. Thus, oral infection and inflammation should be early investigated in all uremic patients.

Methods: This cross-sectional study was conducted in CKD clinic program after National Security Policy for improvement CKD care. We divided one hundred and twenty eight patients into different stages: late-stage (GFR <30ml/min/1.73m2), moderate-stage (GFR 30-59ml/min/1.73m2) and early-stage (GFR 60-90 ml/min/1.73m2) (N = 34 vs. 44 vs. 50). Data from medical records, clinical oral examination, radiologic studies for detection of dental caries and carotid calcification, saliva parameter, and yeast culture were collected and statistically analyzed among these CKD groups.

Results: Of 128 CKD patients, 94 (73.4%) were men. Age range was between 30-86 years, with an average of 61.0 ± 10.9 years. Common etiologies of CKD in this study were hypertension (26.6%) and DM type 2 (16.4%). %HbA1c was not different among the groups (p = 0.39). The most prevalent oral health problem in CKD patients was periodontitis (65.3%) followed by gingivitis (29.4%) but no difference among groups was observed in periodontal health. In late-stage CKD had less dental caries index when compared with early-stage CKD (5±4.8 vs. 8±5.5; -5.6 to -0.9, $p < 0.05$) and was correlation with increasing growth of saliva culture for S. mutans culture in early-stage CKD ($p < 0.05$). Although DMFT index was not significantly different, it showed tendency greater in early CKD group (22±6.3 vs. 19± 9.3, p=0.19). Candida significantly grew with deterioration of GFR when adjusted with HbA1C ($p < 0.05$).

Conclusions: Our data indicate that a single center experienced. Early stage had more dental health problems than late-stage CKD. High prevalent of periodontitis was observed in CKD patients. Routine dental examination and proper preventive dental care were suggested in CKD patients, especially in early stage of CKD.

PUB156

The Role of CXCL12 (SDF-1α) in the Uremic Endothelial Dysfunction Vanessa Ribeiro,[1] Liandra Kondrat,[1] Geison Tiberá,[1] Simone Cristina Mikosz Goncalves,[2] Sérgio Elias Gardano Bucharles,[2] Roberto Pecoits-Filho,[2] Andréa Marques Stinghen.[1] *[1]Basic Pathology Department, Universidade Federal do Paraná, Curitiba, Paraná, Brazil; [2]Center for Health and Biological Sciences, Pontificia Universidade Catolica do Paraná, Curitiba, Paraná, Brazil.*

Background: Endothelial dysfunction play a key role in the pathogenesis of cardiovascular disease (CVD) related to chronic kidney disease (CKD). The exact mechanism by which uremic toxicity leads to endothelial dysfunction is still poorly understood. CXCL12 (SDF-1α) is a pleitropic chemokine over expressed in inflamed and injured organs, capable of mobilizing cells to the site of injury where it can support tissue repair and regeneration. In this study we investigate the plasmatic associations between systemic inflammation, endothelial dysfunction and CXCL12, in hemodialysis (HD) patients.

Methods: Plasma samples were collected from HD patients. The systemic inflammation was assessed by high-sensitivity C-reactive protein (hsCRP) and interleukine-6 (IL-6) using an automated immunoturbidimetric and ELISA assay respectively. Endothelial dysfunction (IL-8) and CXCL12 levels were investigated by ELISA.

Results: Twenty-six patients (17±3 months on HD), 52±2 years old, 38% males, 11% diabetics) were included. The mean plasma concentrations of hsCRP, IL-6, IL-8, and CXCL12 were respectively 4,9±4,8 mg/mL, 6,76±8,1 pg/mL, 128,2±206,2 pg/mL, and 2313,01±1458,1 pg/mL. There was a positive correlation between hsCRP and IL-6 (ρ=0,57, P<0,005) and CXCL12 and IL-8 (ρ=0,4294, P<0,05).

Conclusions: Our data demonstrate that chemotaxis-related factors such as CXCL12 and IL-8 are increased and correlated in HD patients. These occurs in parallel with systemic inflammation. It is also well known that these chemokines are responsible to mobilized undifferentiated cells to the injured organs. We suggest that increased levels of CXCL12 and IL-8 found in these patients could reflect an activated repair system which hypothetically would be a way of measuring the extent of cardiovascular damage caused by uremic toxicity.

PUB157

Evaluation of Efficacy of Lanthanum Carbonate (Fosrenol) in Patients with Calciphylaxis: A Novel Pilot Study Olatokunbo O. Shobande, Micah R. Chan. *Nephrology, University of Wisconsin, Madison, WI.*

Background: Calciphylaxis is a rare and debilitating vasculopathy seen primarily in patients with end stage renal disease (ESRD). The proposed mechanism of injury of vascular calcification involves hyperphosphatemia, elevated serum PTH, and hypercalcemia. Lanthanum carbonate is a potent non-aluminum, non-calcium phosphate binder that was approved for the treatment of hyperphosphatemia in patients with ESRD.

Methods: We have designed a multi-center open-label uncontrolled pilot study in collaboration with Wisconsin Network for Health Research (WinHR) to determine the efficacy of Lanthanum carbonate in the treatment of calciphylaxis. Twelve ESRD patients will be recruited from multiple dialysis centers and clinics around Wisconsin over a period of 21 months. Patients enrolled will have a baseline physical exam, recent dermatology consult with biopsy-proven calciphylaxis skin lesions, and photograph of the skin lesions. Laboratory parameters measured will include intact PTH, phosphorus, calcium, and albumin. Lanthanum will be administered orally in a dose of 1500-3750mg daily in divided doses with meals over a 12-week period. Dose escalation will be utilized to a target dose of 3750mg daily over a 4-week period. Patients will be evaluated monthly to determine clinical response and followed for a period of 3 months for the remainder of the 21-month recruitment and treatment period. Primary endpoints will be resolution of skin lesions, while secondary endpoints will be serum levels of calcium, phosphorus, and intact PTH.

Results: Three patients are currently enrolled in our study. After 8 weeks of treatment, there are noticeable improvements of their skin lesions.

Conclusions: Lanthanum carbonate is a novel, potential treatment modality for patients with calciphylaxis.

Self Reported Quality of Life by EQ5D in Chronic Kidney Disease Stephanie J. Stringer,[1,2] Mary Dutton,[1] Paul Cockwell.[1,2] *[1]Renal Unit, University Hospital Birmingham, United Kingdom; [2]University of Birmingham, United Kingdom.*

Background: Patients with CKD have reduced quality of life (QoL), however many instruments used to measure QoL are too detailed for use in routine clinical practice. The EQ5D (EuroQoL) health status assessment is a simple and robust questionnaire that has been validated in non-CKD populations and can be used in a routine clinical setting. In this study we utilised EQ5D to assess QoL in patients with progressive CKD

Methods: The Renal Insufficiency In Secondary Care (RIISC) study is a prospective cohort study of patients with progressive CKD. Patients undergo a detailed social and bio-clinical assessment including self assessment of QoL by EQ5D and questions relating to educational attainment and employment.

Results: To date 100 patients have been recruited: 61% were men; 70% were white and 15% Black and South-Asian respectively; mean age was 61.3 years (SD 18.1). 44% of the cohort had no qualifications and 15% were educated to university level. 35% were unemployed, 35% were retired and 30% were in employment. 20% of those employed were in unskilled occupations, 23% were in managerial or professional occupations. 51 % reported mobility problems, 9% could not self care and 52% could not carry out usual activities of daily living. 57% reported experiencing at least moderate pain and 30% reported anxiety and/or depression. The mean self rated health score was 63.5/100 (SD 20.9) and was associated with mobility ($p = 0.012$), inability to carry out usual activities ($p = 0.016$) and the presence of anxiety or depression ($p = 0.02$).There was no significant association with co-morbid load, number of medications taken, educational attainment and employment status.

Conclusions: In people with progressive CKD, EQ5D represents a simple scoring system for self reported QoL. Self rated health is a major determinant of mobility, ability to carry out usual activities and anxiety and/or depression. These findings indicate that self related health assessment by EQ5D in progressive CKD can identify key QoL indicators. This has implication for utilising social and cognitive interventions in people with CKD.

PUB159

Multiple Measures of Neuronal Membrane Excitability from Chronic Kidney Disease to Renal Transplantation Matthew R. Todd,[1] Juan Mason,[1] Christopher E.G. Moore.[2] *[1]Wessex Renal & Transplant Service, Queen Alexandra Hospital, Portsmouth, Hampshire, United Kingdom; [2]Department of Clinical Neurophysiology, Queen Alexandra Hospital, Portsmouth, Hampshire, United Kingdom.*

Background: Uremic neuropathy is common in Chronic Kidney Disease (CKD). Traditional nerve conduction studies (NCS) correlate poorly with clinical neuropathy and only slowly and partially resolve after the initiation of Renal Replacement Therapy (RRT). These changes are associated with histological features suggesting structural and cytoskeletal changes. Novel electrophysiological tests can show changes in neuronal membrane function after a single dialysis session (Krishnan et al., 2005), but have not been reported in pre-RRT CKD or after transplantation.

Methods: We used multiple measures of excitability as described by Kiernan et al. (2000) to demonstrate peripheral nerve function in a patient being worked up for a living-related pre-emptive renal transplant. These techniques have been validated for longitudinal measurement by University College Dublin (data presented to the British Society of Clinical Neurophysiology, March 2011). Measures were taken at 8 months and 1 day pre-transplant, and 22 hours and 4 months post-transplant. NCS were also performed at each visit.

Results: NCS showed a mild symmetrical sensorimotor neuropathy which did not change significantly over the 12 months. Membrane function, as measured by threshold electrotonus and recovery cycle, was significantly impaired at 8 months pre-transplant and progressed by the day of transplant. Within 22 hours of transplantation membrane function had normalized, and continued improvement was shown at 4 months post-transplant.

Conclusions: Rapid changes in neuronal membrane function imply a uremic toxin or toxins are responsible for nerve dysfunction in CKD, and that these toxins are readily removed by RRT. The changes seen are reminiscent of chronically depolarized neurons, e.g. in hyperkalemia. These techniques could be used in a hypothesis-generation study to investigate factors associated with progression of neuronal dysfunction, and lead to better understanding and prevention of the neurological complications of CKD.

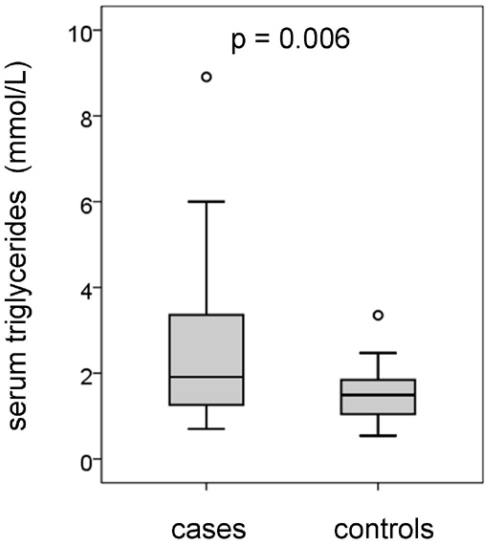
PUB160

High Triglyceride Levels Are Associated with Pancreatitis in Patients with End Stage Renal Disease Fiona S. Turkes,[1] Nadey S. Hakim,[2] Damien Ashby.[2] *[1]Imperial College School of Medicine, London, United Kingdom; [2]Imperial College Kidney and Transplant Institute, Hammersmith Hospital, London, United Kingdom.*

Background: Acute pancreatitis has been found to occur more frequently in renal patients than in the general population however the cause remains unclear.

Methods: This was a retrospective case control study. Data was collected from patients on renal replacement therapy (RRT) with a previous admission for acute pancreatitis without known cause such as stones or alcohol. For each case, 2 controls were selected matched for age, sex and modality.

Results: We identified 16 patients (aged 38-85, 8 male) who were admitted with acute pancreatitis of unknown cause. Compared to controls, cases tended towards a longer period on RRT (9.6+/-10.7 vs 5.2+/-4.8 years, p=0.051) and in the 6 months prior to admission had higher average levels of triglycerides (2.7+/-2.3 vs 1.5+/-0.6mmol/L, p=0.006) and CRP (47+/-88 vs 11+/-18mg/L, p=0.033). Cases did not have grossly lipaemic serum, and triglyceride levels were all below that generally thought to cause pancreatitis (10mmol/L).



Defining a poor outcome group as those patients who died or required ITU support during the same admission (n=7), the only clinical parameter associated with poor outcome was CT severity criteria (Balthazar score 3.1+/-2.4 vs 1.0+/-1.2, p=0.039). Co-morbidity and medication use were not risk factors for acute pancreatitis or related to prognosis. Of the 12 survivors, during an average follow up of 26 months, 3 died, and 4 of the remaining 9 had recurrent episodes of pancreatitis.

Conclusions: Duration of RRT and a high serum triglyceride level are risk factors for acute pancreatitis in renal patients. This illness has a high mortality and many of the survivors have recurrent episodes.

PUB161

Age Interference on Quality of Life of Patients Undergoing Chronic Hemodialysis Carmen B. Tzanno-Martins,[3] Fernanda Ribeiro Nisihara,[1] Geison Stein Meirelles Ramos,[2] Elzo R. Junior,[1] João Paulo L.B. Martins,[2] Paul Clesca Troconis.[1] *[1]Renal Class, São Paulo, Brazil; [2]Home Dyalisis, São Paulo, Brazil; [3]Centro Integrado de Nefrologia, Brazil.*

Background: To assess quality of life through self-administered KDQOL-sf (Kidney Disease Quality of Life – short form) by patients on hemodialysis (HD) classified according to age.

Methods: We randomly selected 159 patients with chronic kidney disease (CKD) on hemodialysis and applied the KDQOL-sf between February 2010 and March 2011. We evaluated the quality of life based on scores below or above 50, on all scales, according to age < 60 years (n = 85) and > 60 years (n = 74).

Results: We analyzed the KDQOL-sf according to age. In patients aged 60 years or more, the scales in which they had poorer quality of life were: physical function 47/85 (55.3%), CKD burden 46/85 (54.1%), professional role 57/85 (67.1%) and sexual function 47/85 (55.3%). In patients younger than 60 years, the scales with poorer quality of life were: physical functioning 47/74 (62.2%), physical function 51/74 (68.9%), general health 38/74 (51.3 %), energy / fatigue 45/74 (60.8%), burden of CKD 56/74 (75.7%), professional role 49/74 (66.2%) and sexual function 60/74 (81.1 %).

Conclusions: We found that the quality of life in patients aged 60 years or more is below the 50 score on the following scales: physical function, CKD burden, professional role and sexual function. In patients younger than 60 years, the scales showed lower scores were: physical functioning, physical role, general health, energy / fatigue, burden of CKD, professional role and sexual function. While patients younger than 60 years have a quality of life decrease in 4 scales, patients with more than 60 years have worsened in 7 scales, with significant worsening of sexual function and energy / fatigue. We conclude that the quality of life is more impaired in the elderly undergoing HD.

PUB162

Role of Gender and Disabilities in the Development of Depressive Symptoms in Elderly Patients under Hemodialysis Carmen B. Tzanno-Martins,[1] Geison Stein Meirelles Ramos,[2] Fernanda Ribeiro Nisihara,[3] João Paulo L.B. Martins,[1] Paul Clesca Troconis,[3] Elzo R. Junior.[3] *[1]CINE - Integrate Center of Dialysis, Guarulhos, São Paulo, Brazil; [2]Home Dialysis Center, São Paulo, Brazil; [3]Renal Class, São Paulo, Brazil.*

Background: This study aims to measure the quality of life and depressive symptoms of hemodialysis patients over 60 years old, using KDQOL-sf and Beck Depression Inventory

Methods: We randomly selected 142 patients, 71 (50%) of them were males

We also analyzed separately patients with physical disabilities

We applied the KDQOL-sf test, and a screening test for depression (BDI), only in the group over 60 years. Aiming more specific ratings, for interpreting the results, we select only the item "emotional function" in KDQOL-sf

Results: We obtained 47.9% (68/142) patients above 60 years. Among them, 31 were female (45.6%).

We found a frequency of depressive symptoms in the group of female patients 13/31 (41.9%). In male, there was 14/37 (37,8%).

Concerning "emotional function", we found higher frequency of sub-standard results in the female group, 16/31 (51.6%), while the male population had rates below the standard in 14/37 (37.8%).

The presence of physical disability in females was 29% (9/31).

When the female population was evaluated separately (9/15), 4 of them (66.6%) had scores at BDI that suggested depression. Same number and same percentage rated lower than expected at KDQOL, concerning "emotional function".

When the male population (6/15) was isolated under the same conditions, 5 of them (83.34%) showed signs of depression as 6 (100%) rated lower than expected at "emotional function".

Among the female population with depressive symptoms 30.7% (4/13) showed physical disability. In male population we found 35.7%.

Associating variables disability and below expected results using KDQOL, we observed a statistically significant association in men (p=0.04), but not in women.

Conclusions: Age increases prevalence of depressive symptoms. The presence of physical disability was higher in patients with depressive symptoms, regardless of gender. However, the presence of physical disability seems to be a determining factor for the onset of depressive symptoms, especially in males

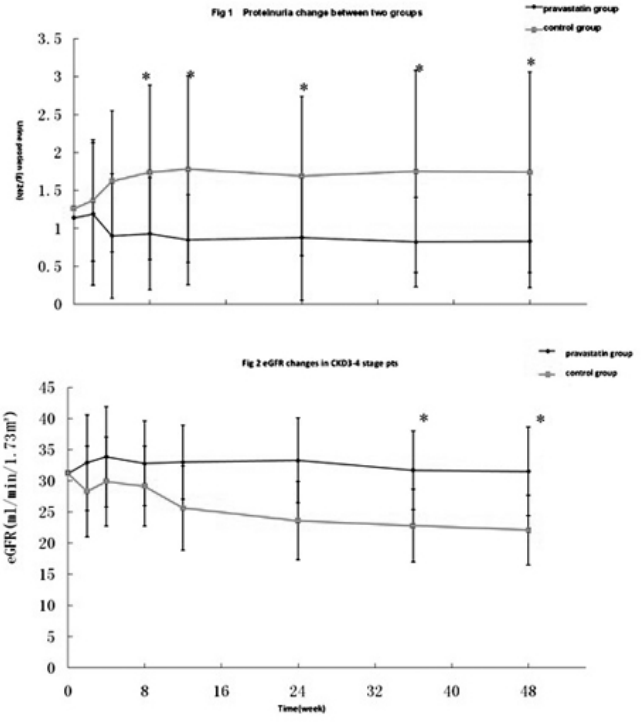
PUB163

Pravastatin Inhibition in Progression of CKD Qin Wang, Liang Ma, Shan Mou, Beili Shi, Minxia Zhu, Liou Cao, Leyi Gu, Zhaohui Ni. *Renal Division, Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China.*

Background: Lowering low-density lipoprotein (LDL) cholesterol with statin has been shown to reduce the incidence of atherosclerotic events in many diseases, but it remains uncertain whether it is of benefit among people with chronic kidney disease (CKD).

Methods: Patients with CKD who were classified based on an estimated glomerular filtration rate (eGFR) ≥15 mL/min/1.73m² and urine protein between 1 to 3.5g/day were randomized in a ratio of 1:1 to pravastatin 20mg daily versus matching placebo. The key outcome was double of serum creatinine, end-stage renal disease and atherosclerotic events, defined as the combination of myocardial infarction, coronary death, ischemic stroke, or any revascularization procedure in one-year follow-up.

Results: Totally 43 CKD pts were randomized (mean age 58 years, 46.5% male), among which 15% had diabetes mellitus, one fifth had hypertension, and 2% had cadiovascular disease. Compared with placebo group, allocation to pravastatin was not associated with any excess of myopathy, hepatic toxicity, or biliary complications. Serum cholesterol(4.25±0.23mmol/L vs 5.33±0.41mmol/L,P<0.01), triglyceride(1.33±0.29mmol/L vs 1.84±0.44mmol/L,P<0.05) and LDL(2.61±0.70mmol/L vs 3.57±0.76mmol/L,P<0.05) was lower in pravastatin group. Proteinuria start to decrease in pravastatin group at 8 week, and continue to the end of the year.



There are no significant differences in alteration of eGFR. but it was likely to slow down in pravastatin group[figure2]. 2 pts occurred CVD events in pravastatin group and 5 pts in control group. Cards-Mai's survival curve showed significant differences between two groups.

Conclusions: Pravastatin can safely adjust the lipid metabolism, reduce proteinuria and CVD risk in CKD patients. It was likely to slow down kidney disease in patients whose eGFR is between 15 to 60 mL/min/1.73m^2.

PUB164

Increasing the Dose of Lanthanum Carbonate Results in Better Serum Phosphorus Control Rosamund Wilson,[1] Lynne Poole.[2] *[1]Spica Consultants, Marlborough, United Kingdom; [2]Shire Pharmaceuticals, Basingstoke, United Kingdom.*

Background: Controlling serum phosphorus to recommended target levels is challenging. Patients should be treated with the appropriate dose of phosphate binder titrated to achieve these target levels.

Methods: To investigate whether patients had better control of serum phosphorus on a dose of 3000 mg/day of lanthanum carbonate compared with lower doses, data were analysed from a randomized controlled study conducted in Europe. After randomization, patients entered a titration phase of 5 weeks during which doses were titrated to achieve phosphorus control (≤ 5.6 mg/dL). After the titration period, patients who had achieved control continued into a 20-week maintenance phase. Data from patients randomized to the lanthanum carbonate arm, who started the maintenance period on a dose < 3000 mg/day and during the maintenance period increased their dose to 3000 mg/day, were analysed to evaluate whether increasing the dose to 3000 mg/day had a positive effect on serum phosphorus levels.

Results: Thirty-five patients started the maintenance period on 1500 or 2250 mg/day of lanthanum carbonate and had their dose increased to 3000 mg/day during this period. On average these patients had serum phosphorus levels approximately 0.6 mg/dL lower on 3000 mg/day of lanthanum carbonate compared with doses ≤ 2250 mg/day. Sixty-six percent of patients had better phosphorus control on 3000 mg than on lower doses.

Conclusions: Increasing the dose of phosphate binders may improve phosphorus control. This *post hoc* exploratory analysis suggests that increasing the dose of lanthanum carbonate to 3000 mg/day results in positive effects on serum phosphorus levels and may improve the percentage of patients achieving target levels. Lanthanum carbonate has been shown to be well tolerated when given at doses up to 4500 mg/day in patients with CKD receiving hemodialysis.

PUB165

Glomerular Filtration Rate Using 2 Different Methods and Albumin Creatinine Ratio in the Irish Population Gemma M. Browne,[1] Joseph A. Eustace,[2] Ivan J. Perry.[1] *[1]Department of Epidemiology and Public Health, University College Cork, Cork, Ireland; [2]Department of Nephrology, Cork University Hospital, Cork, Ireland.*

Background: This study describes stages of estimated glomerular filtration rate (eGFR) and albumin creatinine ratio (ACR) in Ireland. At present the MDRD equation is used in clinical practice to estimate renal function. This is the first population based estimate in Ireland.

Methods: A population-based cross-sectional study of adults was conducted using data from the 2007 Survey of Lifestyle, Attitudes and Nutrition (SLAN). A representative sample of 1,207 adults aged 45 and over, underwent a comprehensive physical examination including serum and urinalysis. Demographically this sample was similar to 2006 national census data. Using regression equations recalibrated MDRD and CKD-EPI, eGFR was calculated from a single serum creatinine. Spot Urine Albumin Creatinine ratio (ACR mg/g) was measured

Results: eGFR <60 ml/min/1.73 m^2 based on the CKD EPI regression equation occurred in 12.1% (95%CI 10.3-14%). ACR >30mg/g occurred in 13.2% (95%CI 11.2-15.2%). ACR >30mg/g varied from 11.1% in GFR Stage 1 to 100% in GFR stage 4-5. Using the MDRD regression equation, more subjects were categorised as eGFR<60, and similarly more subjects were described as GFR Stage 2 compared to GFR Stage 1 (Table 1). Younger and female subjects were more likely to be categorised as a lower GFR using the MDRD equation.

Prevalence of GFR Stages (G1-5) by CKD EPI & MDRD

	ALL N=1160* (95%CI)	
GFR STAGES	CKD EPI	MDRD
G1	33.2% (30.9, 36.3%)	19.2% (17, 21.5%)
G2	54.22% (51.4, 57.1%)	65.5% (62.8, 68.3%)
G3A	9.22% (7.6, 10.9%)	11.98% (10.1, 13.9%)
G3B	2.5% (1.6, 3.4%)	2.84% (1.9, 3.8%)
G4-5	0.43% (0.05, 0.8%)	0.43% (0.05, 0.8%)

*Subjects with an available serum creatinine

Conclusions: Lower estimates of GFR, which may be dependent on the method of estimation, can impact on the individual. In laboratories in Ireland and in the UK, the MDRD regression equation has widespread use. The CKD-EPI formula results in higher estimated GFR especially in younger and female subjects. Albuminuria, as an additional measure of cardiovascular risk, is prevalent in this population.

PUB166

Prevalence of Albuminuria in Polish Elderly Population (The Polsenior Study) Jerzy Chudek,[1,2] Katarzyna Wieczorowska-Tobis,[3] Andrzej Wiecek.[1] *[1]Department of Nephrology Endocrinology and Metabolic Diseases, Medical University of Silesia; [2]Department of Pathophysiology, Medical University of Silesia; [3]Department of Geriatric Medicine and Gerontology, Poznan University of Medical Sciences.*

Background: Albuminuria is used as a screening tool for detection of chronic kidney disease (CKD) in epidemiological studies. Therefore, the aim of this study was to assess albumin excretion, in addition to serum creatinine concentration, in a representative group of Polish elderly population.

Methods: The study was carried out as a part of the nationwide PolSenior project in the population of randomly selected 4,979 people aged 65 and older (2,567 males and 2,412 females) using the national PESEL database (the National Electronic System of Population Records). Data concerning the prevalence of arterial hypertension, diabetes, kidney stones, refractory urinary tract infections, prostate diseases were collected. Urinary albumin and creatinine concentrations were assessed in 3792 of 3915 obtained urine samples. Microalbuminuria was scored as an albumin to creatinine ratio of 17-250 mg/g in men and 25-355 mg/g in women. Higher albumin excretion was scored as a macroalbuminuria. eGFR was estimated according to CKD-EPI formula, based on serum creatinine concentration.

Results: Micro- and macroalbuminuria were found in 2150 (56.7%) and 652 (17.2%) urine samples, respectively. The prevalence of participants with microalbuminuria was similar in all examined age categories (varied from 55.3% to 60.1%), while the prevalence of macroalbuminuria was significantly increasing with age from 10.14% in subjects aged 65-69 to 29.04% in those aged 90 and older. In consequence, the percentage of subjects with albumin excretion within the normal range was diminishing from 29.8% in the age group 65-69 yrs. to 14.42% in the age group 90 and older. Surprisingly enough , a substantial percentage of subjects with normal range of albumin excretion showed eGFR below 60 ml/min/1.73m^2 (from 9.5% aged 65-69 to 48.0% aged 90 and older.

Conclusions: In Polish elderly population the prevalence of normal range albumin excretion is declining with aging. Albuminuria should not be used as a screening tool of CKDin elderly subjects.

PUB167

Performance of Serum Cystatin C Versus Serum Creatinine as a Marker of Glomerular Filtration Rate Referred for Inulin Renal Clearance Masaru Horio,[1] Enyu Imai,[2] Yoshinari Yasuda,[2] Tsuyoshi Watanabe,[3] Seiichi Matsuo.[1] *[1]Functional Diagnostic Science, Osaka University Graduate School of Medicine, Osaka, Japan; [2]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [3]Third Department of Medicine, Fukushima Medical University, Fukushima, Japan.*

Background: Serum cystatin c was recently proposed as an alternative marker of GFR. Better performance of cystatin C compared with creatinine has been suggested. However, detailed studies are limited. We evaluated the performance of cystatin C as a GFR marker.

Methods: GFR was measured by inulin clearance in 763 Japanese subjects. Factors other than GFR influencing serum cystatin C or serum creatinine were analyzed by multivariate analyses. Correlations between GFR and 1/cystatin C or 1/creatinine were evaluated in subjects stratified by gender and age groups with 18-39, 40-59, and 60-79 y.o.

Results: After adjustment for GFR, value of serum creatinine was 25.2% lower in female than male, and was decreased 5.2% every 20 years of age. Serum cystatin C was 8.2% lowerin female than in male, and was not significantly changed with aging. Creatinine but not cystatin c was significantly affected by body weight, height and body mass index after adjustment for GFR, gender and age. Correlation coefficient between GFR and 1/cystatin C was significantly higher than that of 1/creatinine in total subjects (0.866 and 0.810, respectively, $p<0.001$) and consistently higher in subjects stratified by gender and all age groups although not reaching statistical significance. Unlike serum creatinine, serum cystatin C did not increase in association with reduction of GFR in subjects with very low GFR. Regression line of 1/cystatin C against GFR showed a significantly negative intercept of about -8ml/min/1.73m^2

Conclusions: Age, gender, body weight, height and BMI had smaller effect on serum level of cystatin C than that of creatinine. Reciprocal cystatin C had a better correlation with GFR than reciprocal creatinine, suggesting a superior GFR marker. On the other hand, cystatin C appeared to have an apparent non-renal elimination that could affect the performance as the marker of GFR.

PUB168

Performance of GFR Estimation Equations in the Elderly Harbir Singh Kohli,[1] Ashesh Dhungana,[1] B.R. Mittal.[2] *[1]Nephrology, Post Graduate Institute of Medical Education and Research; [2]Nuclear Medicine, Post Graduate Institute of Medical Education and Research, Chandigarh, India.*

Background: It is important to know the glomerular filtration rate (GFR) in elderly population for staging of chronic kidney disease (CKD) and also for drug dosing. GFR can be estimated from e GFR equations and from creatinine clearance (Cr Cl) by estimating 24 hour urinary creatinine. Which one is an accurate reflection of true GFR is controversial.

Methods: A total of 51 elderly patients with serum creatinine up to 3.5 mg/dl were included. GFR was measured in all with Tc-99m DTPA plasma sample method which was considered the standard GFR (DTPA GFR) and with 4 GFR estimating equations: Cockroft-Gault (CG), Cockroft-Gault adjusted for body surface area (CG-BSA), 4 variable MDRD (4MDRD) and 6 variable MDRD (6MDRD) equations. Cr Cl was also calculated. Pearson's correlation coefficient was used to compare the correlation of equations with DTPA GFR. Bland and Altman plots were derived for each method of GFR measurement to estimate agreement with DTPA GFR results. Limits of agreement were calculated as mean ± 2SE for each pair. The accuracy was calculated as percentage of estimated GFR lying within 10%, 30% and 50% of measured GFR.

Results: The mean age was 70.14 ± 4.6 years (65-80), mean DTPA GFR was 65.42 ± 26.28 ml/min/1.73m^2 (23-147). Of 51, 23 were in CKD 3, 17 in CKD 2 stages. Overall correlation of 6MDRD was the highest (r- 0.714) followed by 4MDRD (r- 0.706), CG-BSA (r- 0.635) Cr Cl (r- 0.608), and CG (r- 0.542). On Bland and Altman plots, mean bias was least and limits of agreement narrowest with 6MDRD (-2.8 ± 2.7) followed by 4MDRD (-3.7±2.8), Cr Cl (-9.6 ± 3.2), CG- BSA (-10.6± 2.9), and CG (-11.3 ± 3.3). The accuracy of 6MDRD (33%, 77% and 94% accuracy at 10, 30 and 50 percent respectively) was the best followed by 4 MDRD (28%, 71% and 92% accuracy at 10, 30 and 50 percent respectively) and CG- BSA (22%, 67% and 90% accuracy at 10, 30 and 50%). The accuracy of CG and Cr Cl was low.

Conclusions: 6MDRD equation was found to be superior in terms of correlation, bias, and accuracy, and can be used as a good surrogate for actual GFR in the elderly. This requires validation in a larger population.

Improved GFR Estimation by BP Neural Network Xun Liu,[1,2] Xiaoming Wu,[2] Ningshan Li,[2] Tan-Qi Lou.[1] *[1]Department of Internal Medicine, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China; [2]College of Biology Engineering, South China University of Technology, Guangzhou, Guangdong, China.*

Background: Chronic kidney disease (CKD) is a growing health problem that needs to be addressed. This paper attempts to develop and validate a GFR-estimating model using BP neural network.

Methods: 831 Chinese patients with CKD enrolled, of whom 562 were randomly selected as the training data set; the remaining 269 patients constituted the internal validation data set. Additional 349 patients were included in the external validation data set. Serum creatinine (SC) was determined enzymatically. The ^{99m}Tc-DTPA-GFR was used as the reference GFR (sGFR). The input layer of the BP network consisted of seven units, the patients' records of serum SC, albumin, urea, age, sex, height and weight. The output layer consisted of only one unit representing sGFR. Average sGFR was 46.1±27.0 (3.3-130.1) ml/min/1.73 m^2 in the training data set, 44.2±28.0 (4.4-137.6) ml/min/1.73 m^2 in the internal validation data set and 49.1±26.6 (2.8-122.9) ml/min/1.73 m^2 in the external validation data set. The Cockcroft-Gault-equation, reexpressed 6-variable MDRD equation, reexpressed 4-variable MDRD equation and BP network were compared in both two validation data sets.

Results: In both two validation data sets, bland-Altman analysis demonstrated that BP network was better than the other equations. Only the precision of the BP network exceeded the prior acceptable tolerances defined as 60 ml/min/1.73 m^2. The slope of the regression line estimated by the BP network was smaller than those of the other equations**.** Differences as well as the accuracy with a deviation less than 30% from the sGFR of the BP network were significantly better than those of the other equations. When compared the internal validation data set with external validation data set, the bias as well as accuracy of eGFR estimated by BP network were not statistically significant.

Conclusions: Our data indicated this BP network model is suitable for the specific Chinese population tested. Relevant procedures are being developed to facilitate the validation of the model.

Is the GFR Estimation Equation in Japan and China Useful in Elderly Chinese Patients with Chronic Kidney Disease? Xun Liu, Cailian Cheng, Tan-Qi Lou. *Division of Nephrology, Department of Internal Medicine, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China.*

Background: China faces an aging crisis. Recently, some modified glomerular filtration rate (GFR) estimating equations had been established in Japan and China. In this study, we sought to evaluate the applicability of these formulas in elderly Chinese patients with CKD.

Methods: 332 patients enrolled. Serum creatinine (SC) was determined enzymatically. The ^{99m}Tc-DTPA-GFR was used as the standard GFR (sGFR). The mean age was 69.8±6.7 years (range, 60-93 years). The mean sGFR was 39.7±21.6 ml/min/1.73 m^2 (range, 23.7-116.6 ml/min/1.73 m^2). The reexpressed 4-variable MDRD equation, Chinese-equation and new Japanese equation were tested. The performance of estimated GFR (eGFR) was compared with sGFR in various stages of CKD.

Results: Median of difference ranged from -9.79 ml/min/1.73 m^2 to 6.81 ml/min/1.73 m^2. Median percents of the absolute difference ranged from 25.38% to 38.04%. Accuracy with a deviation less than 15% ranged from 20.5% to 28.9%. Accuracy with a deviation less than 30% ranged from 38.9% to 55.4%. Accuracy with a deviation less than 50% ranged from 64.5% to 77.7%. CKD stage misclassification ranged from 42.2% to 57.5%. However accuracies with a deviation less than 30% of all the equations were less than 70%. When the overall performance as well as bias and accuracy were compared in different stages of CKD, GFR estimated by reexpressed 4-variable MDRD equation showed promising results.

Conclusions: When SC was measured by the enzymatic method, GFR estimation equation in Japan and China showed great bias in elderly Chinese patients with CKD. Further improved equations are needed. If conditions are not available, reexpressed 4-variable MDRD equation may be more accurate to assess GFR in elderly Chinese CKD patients.

PUB171

Chronic Kidney Disease Prevalance in Primary Care – Missing Cases Donal O'Donoghue,[1] Beverley Matthews,[2] Stephen Green.[2] *[1]Salford Royal Foundation NHS Trust; [2]NHS Kidney Care.*

Background: The aims of this study were:

to compare QOF reported CKD prevalence and Public Health (PH) estimated prevalence,

to identify the extent of under-diagnosis; and

to aid commissioners and primary care in improving ascertainment.

Methods: The prevalence of Chronic Kidney Disease in people aged 18 years plus in Primary Care is reported annually through the Quality and Outcomes Framework (QOF). The East Midlands Regional Public Health Observatory has used the NEOERICA study to model estimated CKD Prevalence, nationally, at SHA and PCT levels. The gap in % prevalence and the estimated "missing people" have been calculated by subtracting the QOF results from the PH estimates.

Results:

CKD Prevalence (%)

People with CKD	QOF Reported	PH Estimated	% Identified	QOF Reported	PH Estimated	Missing People
England	4.3%	8.8%	48%	1,817,871	3,770,267	1,952,396
East Midlands	5.3%	9.0%	59%	189,602	322,613	133,011
East Of England	4.3%	9.3%	46%	199,106	430,491	231,385
London	2.7%	6.8%	40%	181,575	456,593	275,018
North East	5.0%	9.1%	55%	105,248	191,117	85,869
North West	4.5%	9.0%	51%	258,350	510,800	252,450
South Central	3.9%	8.6%	46%	131,577	287,963	156,386
South East Coast	4.4%	9.8%	45%	158,367	351,237	192,870
South West	4.7%	10.1%	47%	202,428	433,033	230,605
West Midlands	4.5%	9.1%	49%	200,056	406,096	206,040
Yorkshire & Humber	4.6%	8.8%	52%	191,562	371,729	180,167
PCT - High	7.4%	8.2%	90%	15,939	17,634	1,695
PCT - Low	1.4%	5.9%	23%	2,769	12,096	9,327

Conclusions: The key findings from this assessment show that:

CKD Prevalence as reported through QOF has increased from 3% in 2006/7, 3.7% in 2007/8, 4.1% in 2008/9 to 4.3% in 2009/10.

However, compared with Public Health estimated prevalence of 8.8% for England, national ascertainment is still only 48% of expected prevalence.

At SHA level in 2009/10, ascertainment ranges from 40% of estimated prevalence in London to 59% of estimated prevalence in East Midlands.

At PCT level, the range is even wider, with the PCT with the lowest estimated ascertainment reporting 27% of expected prevalence and the PCT with the highest reporting 90% of estimated.

Overall, there is an estimated 1.95 million people with undiagnosed CKD and not being treated and at risk of faster disease progression, emergency admission and poor outcomes.

PUB172

Pregnancy in Chronic Kidney Diseases and Chronic Kidney Diseases in Pregnancy: Outcome in 188 Singleton Pregnancies with Renal Involvement

Giorgina B. Piccoli,[1] Rossella Attini,[2] Silvia Parisi,[2] Valentina Consiglio,[1] Stefania Scognamiglio,[1] Federica N. Vigotti,[1] Martina Ferraresi,[1] Piero Gaglioti.[2] *[1]Nephrology and Dialysis, San Luigi Hospital - University of Turin, Orbassano (TO), Italy; [2]Materno-Foetal Unit, S. Anna Hospital - University of Turin, Torino, Italy.*

Background: The relationship between pregnancy and CKD is complex, entangled and difficult to explore.

The present study was aimed at assessing pregnancy outcomes in a large cohort of CKD women followed in a tertiary care Center where a conjunct Outpatient Unit is run by Nephrologists and Obstetricians.

Methods: Prospective, Singel Center, observational study. In 2000-2011 262 pregnancies in 235 women were referred. The results were compared with a cohort of "low-risk" pregnancies, followed in the same setting. PE patients were not referred unless there was the need for a differential diagnosis with CKD. The following data were gathered: age, parity, educational level, CKD (cause and stage); acute kidney disease, creatinine, GFR, proteinuria, arterial pressure, delivery (week, caesarian, need for intensive care, weight and entile of the newborn, major clinical problems).

Results: The prevalence of early CKD stages is high (192 in stage 1; 44 in stage 2; 20 in stage 3; 4 in stages 4-5, 2 not yet classified), underlining the importance in the of the wider population of early CKD stages; the prevalence of 24 proteinuria <0.3 g was 66%; 0.3-1 g 18%; 1-3 g 9% and over 3 grams per day 6% (2/262 not yet classified: prevalence 1%).

Diagnoses are related with referral patterns. Glomerular diseases are the most frequent diagnoses in patients who are first diagnosed CKD in pregnancy, urological disorders are the frequently known but overlooked.

188 singleton deliveries were observed, 167 in stages 1-2; the prevalence of preterm delivery (<37th week) was 21% and of "early" preterm (<34th week) was 15%, significantly higher then prevalence recorded in control group (>37 weeks:5%). Caesarean section: 91/188 singleton deliveries (48.4%)versus 25%.

Conclusions: CKD is a risk factor for pregnancy related morbidity, since the early stages; pregnancy is a valuable occasion for early CKD diagnosis.

Funding: Government Support - Non-U.S.

PUB173

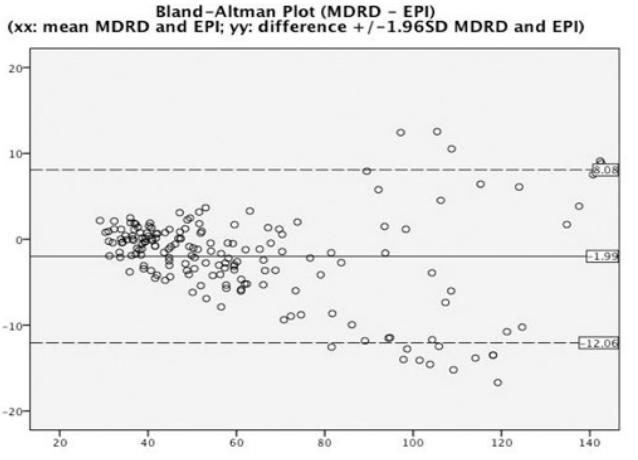
MDRD or EPI Equations for Estimating Glomerular Filtration Rate (GFR) in a Stage 1-3 CKD Population: Any Relevant Differences?

Hugo Mário Silva, Pedro Francisco Azevedo, Jorge Malheiro, Maria Joao Carvalho Azevedo Rocha, Josefina Santos Lascasas, António Manuel Nunes Cabrita. *Nephrology Department, CHP - HSA, Porto, Portugal.*

Background: MDRD equation is considered accurate for estimated GFR <60 ml/min. The new equation EPI was developed to enable a better performance for GFR ≥60 ml/min. Our aims were to understand the difference of estimated GFR using MDRD or EPI equations for stage 3 CKD.

Methods: We randomly selected 175 patients from our clinic with stage 1-3 CKD and stable kidney function. Serum creatinine (SCR) was measured by an IDMS traceable method. We compared eGFR by each formula using Wilcoxon paired samples test. Prevalence of stage 3 CKD was compared by McNemar's χ^2 test. Agreement between equations in categorizing patients in stage 3 versus stage 1-2 CKD was evaluated by Kappa statistics. Pearson correlation was determined between the difference between formulas (calculated as MDRD_GFR minus EPI_GFR for each paired estimates) and age, SCR and MDRD_GFR.

Results: Patients enrolled were mainly old (median age, 66 years), with a high prevalence of stage 3 CKD (by MDRD and EPI formulas 65.7% and 59.4% respectively, *P*=0.003), median MDRD_GFR of 52.3 ml/min and EPI_GFR of 52.2 ml/min. Estimated GFR by each equation were significantly different (P<0.001) but Kappa statistics showed a good agreement (K=0.84). The string of the differences between formulas correlated significantly with age (r=-0.30, *P*=0.02), SCR (r=-0.48, *P*<0.001) and MDRD_GFR (r=0.60, *P*<0.001). Bland-Altman analysis between formulas is plotted in Figure 1.



Conclusions: Estimated GFR varied significantly between equations, with noticeable lower EPI_GFR in younger and with lower SCR patients. However, a significantly lower prevalence of stage 3 CKD by the EPI equation was shown. In patients with mild kidney dysfunction, EPI_GFR estimates seemed more accurate, permitting a more adequate CKD staging.

PUB174

Profile of Chronic Kidney Disease Practice in Queensland, Australia – CKD. QLD Phase 2 Survey

Sree Krishna Venuthurupalli,[1,4] Anne Salisbury,[3] Wendy E. Hoy,[3] Helen G. Healy,[2] Robert G. Fassett.[2,4] *[1]Renal Medicine, Toowoomba Hospital, Toowoomba, Queensland, Australia; [2]Renal Medicine, Royal Brisbane & Women's Hospital, Brisbane, Queensland, Australia; [3]Centre for Chronic Disease, University of Queensland, Brisbane, Queensland, Australia; [4]School of Medicine, University of Queensland, Brisbane, Queensland, Australia.*

Background: Chronic kidney disease (CKD) management is evolving from doctor and hospital centric models towards nurse practitioner (NP) led multidisciplinary community models of care. We assessed CKD practice management in Queensland, Australia, which has a multiethnic population of 4.47 million.

Methods: Profile of CKD management was undertaken using a web-based questionnaire (Survey-monkey) completed by senior medical and nursing staff across all public renal units in Queensland, Australia.

Results: The response rate was 100% with participation of all clinics in the survey. The majority of CKD practice was hospital based (85%) with community CKD clinics available in major cities only. Total number of patients followed in all public CKD clinics was 11668, exceeding the number (10,469) estimated during the first CKD site profiling 12-months previously.

The majority of patients (90%) were seen by a nephrologist, as most clinics were hospital based, while 5 NPs using the NP model seeing the rest. Numbers of indigenous CKD patients varied according to location, ranging from 0 to 40%. Indigenous staff were available in 50% of units surveyed and there was a high level (88%) of cultural awareness and training.

Patient follow up was based on CKD stage and co-morbidities, and ranged between intervals of 6-weeks to 1-year. Allied health professionals were available in all clinics, with 80% of patients seen by a dietician and follow-up was according to need. The multi-disciplinary care model including pharmacist, psychologist, social worker and podiatrist was being implemented in all units, but variably limited by resources.

Conclusions: CKD management has become a major focus of renal services in Queensland Health with almost 12,000 patients to care for, with increasing numbers as new referrals are seen regularly. Community based services and NP models are increasingly explored for CKD service delivery.

PUB175

Evaluation of Polyclonal Free Light Chains in Chronic Kidney Disease Stage 3 Lakhvir Assi,[1] Natasha J. McIntyre,[2] Colin A. Hutchison,[3] Philip Young,[1] Richard Hughes,[1] Stephanie J. Stringer,[3] Richard J. Fluck,[2] Chris W. McIntyre,[2] Paul Cockwell,[3] Maarten W. Taal.[2] *[1]The Binding Site Group Ltd, United Kingdom; [2]Royal Derby Hospital, United Kingdom; [3]Renal Institute of Birmingham, United Kingdom.*

Background: Polyclonal free light chains (FLCs) are elevated in patients with kidney impairment and serve as an independent risk factor for renal progression in patients with advanced chronic kidney disease (CKD). The aim of this study was to assess serum (S) and urine (U) FLCs in CKD stage 3 patients, in relation to their disease status.

Methods: 1741 patients were recruited from primary care practices. Subjects were predominantly white (98%) and female (60%) with an average age of 73 years. 17% had diabetes. The median eGFR was 53ml/min/1.73m2. FLCs were measured in the S and U using the Freelite™ assay. SFLCs (Sκ, Sλ) were compared to established normal ranges (Sκ: 3.3-19.4mg/L, Sλ.: 5.71-26.3mg/L,). UFLCs (Uκ and Uλ) and Ucreatinine values were obtained from healthy volunteers (Table).

Results: Median Sκ 19mg/L (4-181mg/L) and Sλ 17mg/L (2-74mg/L) concentrations were elevated, in the CKD population. Multivariable linear regression identified several factors as independent determinants of SFLCs including eGFR, UACR, albumin and cholesterol. UFLCs corrected using Ucreatinine (κCR and λCR, mg/mmol) were also elevated (Table). UFLCs and FLCs/CR were further increased in patients with albuminuria (Table). κCR and λCR correlated significantly with ACR (r=0.38 and r=0.47 respectively). Of the CKD patients with an abnormal ACR, 59% had abnormal UFLCs. 43% patients with a normal ACR had abnormal UFLCs, indicating UFLCs are an earlier indicator of renal damage.

Conclusions: The clinical relevance of these observations will be determined as the population is prospectively followed up.

PUB176

Is Glycosylated Hemoglobin a Predictor for Onset of Diabetes Mellitus in Chronic Kidney Disease? Eleni Chelioti, Sotiris Mikros, Evagelia Chrisanthopoulou, Thnasis Georgiou, Maria Sotiraki, Theodora Fragou, Maria Tsilivigou, Gabriel Papadakis. *Dept. of Nephrology and Renal Unit, General Hospital of Piraeus, Athens, Greece.*

Background: Glycosylated hemoglobin (HbA1c) is a powerful predictor of future cardiovascular events in diabetic patients with chronic kidney disease (CKD). The optimal target for glycemic control has not been established in these patients. However, few studies have found that HbA1c maybe related to manifestation of diabetes mellitus (DM) in patients with CKD. Aim of this study was to evaluate the association between HbA1c and onset of DM in non-diabetic patients (DP) on stage 3 and 4 of CKD.

Methods: A retrospective study was performed in Outpatient Clinic. Participants were 121 non-DP on stage 3 and 4 of CKD (51,2% men, age range 29 to 97 years, mean duration 12 months). Fasting glucose levels (FGL), HbA1c and serum creatinine (SCr) were evaluated at time 0 and after 12 months (time 1) in patients with stable renal function. They were separated in 2 groups according to the initial HbA1c and FGL: normal (HbA1c < 5,7%, FGL<100 mg/dl) and prediabetics (HbA1c > 5,7%, FGL > 100 mg/dl).

Results: Of the 121 patients, mean HbA1c was 5,99% at time 0 and 5,78% at time 1. Mean FGL were 105,6 mg/dl at time 0 and 104,7 mg/dl at time 1. Mean SCr did not change significantly at time 0 and 1. Normal patients (HbA1c < 5,7%)presented a statistically significant increase in HbA1c levels during the study year (p=0,04). The same applies to patients with normal FGL (<100 mg/dl). Their FGL were significantly higher after one year (p=0,013). However, mean FGL and HbA1c levels remained below 100 mg/dl and 5,7% respectively. For the group of patients with baseline HbA1c and FGL suggestive of prediabetes there was no significant difference after a year of observation.

Conclusions: In non-DP with stage 3 and 4 of CKD, HbA1c and FGL cannot be used as predictors for the onset of DM while their renal function remains stable. Only in normal patients did we notice a significant deterioration of HbA1c and FGL, but always within normal levels. Finally, the stability of renal function in these patients contributes to their stability in terms of glycemic control.

PUB177

The Chronic Kidney Disease Prognosis Consortium (CKD-PC): A Global, Collaborative, Individual Participant Data Meta-Analysis (for CKD-PC Collaborators) Josef Coresh, Kunihiro Matsushita, Shoshana Ballew, Brad C. Astor, Mark Woodward, Brenda Hemmelgarn, Adeera Levin, Chi Pang Wen, Paul E. de Jong, Ron T. Gansevoort, Andrew S. Levey. *Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Background: The Chronic Kidney Disease Prognosis Consortium (CKD-PC) was established in 2009 and currently consists of 46 cohorts from 17 countries of North America, Europe, Asia, and Oceania. The consortium conducts complex individual participant data meta-analyses with the goal of providing comprehensive evidence regarding CKD prognosis.

Methods: The consortium governance includes a steering committee, operations committee, and data coordinating center (DCC). Cohorts can join the consortium at any time following operating principles posted at www.jhsph.edu/ckdpc. Each cohort opts in or out for each proposed manuscript. Statistical code for each manuscript is written by the DCC, distributed to participating cohorts, and shared publicly on the website for each manuscript. Piece-wise linear spline models allow a detailed examination of the dose-response association between eGFR and albuminuria with outcomes (mortality, cardiovascular disease, ESRD, AKI, and progression of CKD) and can be pooled across cohorts using the variance-covariance matrix of the regression coefficients.

Results: The consortium includes cohorts representing general (24 cohorts), high risk (10 cohorts), and CKD (12 cohorts) populations including over 1.5 million participants. CKD-PC published four meta-analysis manuscripts in 2010 (phase 1), with seven meta-analyses to be completed in 2011 (phase 2) and meta-analyses of individual risk and definitions of CKD-progression in 2012 (phase 3). Forty-three cohorts from phase 1 opted in for phase 2 analyses and three new cohorts joined. Authorship includes ~15 authors and ~100-200 collaborators per paper.

Conclusions: CKD-PC has established a productive model allowing flexible collaborative meta-analyses. Distribution of statistical code allows inclusion of cohorts which cannot share the raw data due to legal/administrative constraints.

PUB178

Single Center Experience with Rituximab: Indications, Use, and Response in Pediatric Patients Roshan P. George, Leonard C. Hymes, Rochelle Schmidt, Sandra Amaral. *Pediatric Nephrology, Emory University and Children's Healthcare of Atlanta, Atlanta, GA.*

Background: Rituximab is an anti-CD20 monoclonal antibody, initially approved for use in Non-Hodgkin's Lymphoma. It is frequently used off-label for various other conditions, including renal diseases. There is scant knowledge about response to rituximab use in pediatric patients for these renal conditions.

Methods: We performed a retrospective cohort study of the indications, use and response to rituximab within our nephrology center in the Southeastern US. We included all patients who received rituximab from January 2003 to May 2011 for any indication.

Results: 39 patients received rituximab. 9 patients had renal transplants with rejection unresponsive to other therapies. 9 patients had EBV infection and post-transplant lymphoproliferative disease (PTLD). 15 patients had lupus nephritis; 14 (93%) had either class IV, V or a combination of these. 6 patients had other conditions, including 4 with nephrotic syndrome, and 1 each with Wegener's Granulomatosis and Thrombotic Thrombocytopenic Purpura (TTP). Among transplant patients, rejection improved significantly in 4 of 9 cases (44%) with resolution in 11%. All 9 PTLD patients responded with complete resolution of disease. Among the 15 lupus patients, 4 had clinical and serologic response, 4 had partial response with improved hypocomplementemia but residual significant proteinuria. These 8 patients received 2 or more doses. None of the patients with other conditions showed a response. 18 (46%) experienced adverse effects including 4 with anaphylaxis requiring aborting the dose. 3 had minor infusion reactions. 3 (33%) of the transplant patients with PTLD had persistent hypogammaglobulinemia requiring monthly IVIG. 3 patients had altered mental status, 3-30 days following rituximab dose.

Conclusions: In our single center, rituximab was most effective for PTLD with heterogeneous responses in patients with renal transplant rejection, lupus nephritis and other conditions. There was a high incidence of adverse events (46%). These results emphasize that rituximab should be used with caution and more research is needed to discover optimal therapies for these challenging renal conditions.

PUB179

Combined Impact of Anemia, Hepcidin-25 and Proteinuria on Early Mortality in Cancer Patients Masaki Hara,[1,2] Minoru Ando,[1,2] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Department of Nephrology, Tokyo Metropolitan Komagome Hospital, Tokyo, Bunkyo-ku, Japan; [2]Department IV of Internal Medicine, Tokyo Women's Medical University, Tokyo, Shinjuku-ku, Japan.*

Background: Anemia of chronic disease (ACD) occurs in patients with either cancer or kidney disease or both. Hepcidin-25 is a key player in the pathologic state of ACD. We examined associations among hepcidin-25, proteinuria and mortality in cancer patients.

Methods: Two-year prospective cohort study was conducted in a total of 55 cancer patients receiving chemotherapy. Underlying malignancies included malignant lymphoma (47%), gastric cancer (25%), and other cancers (28%). Serum hepcidin-25 level was measured by liquid chromatography mass spectrometry. Proteinuria was defined as a dipstick

test ≥±. Anemia was defined as Hb <10 g/dl. Cumulative survival rate was analyzed using Kaplan-Meier curves with stratification by median value of serum hepcidin-25 (25.1 ng/ml), proteinuria, or anemia. Multivariate Cox proportional hazards analysis, adjusted for age, gender, performance status and estimated GFR, was used to calculate mortality HR for the combined effect of such 3 markers on mortality. 'Score 1' was assigned to each marker.

Results: Mean hepcidin-25 level was 46.7±48.8 ng/ml, which was nearly 2-fold greater than the reference value(22.2±12.3 ng/ml). Cumulative survival rate was significantly lower in the high hepcidin-25, proteinuria (+) or anemia (+) group than in each corresponding opposite. Multivariate analysis showed that the HR (95% CI) was 27.8 (6.27-155.2) for patients with 3 points; 4.0 (1.26-19.4) for those with 2 points; and 1.6 (0.53-7.19) for those with 1 point, as compared to the reference patients with neither of them.

Figure1-a; 2-year Survival curves stratified by each factors

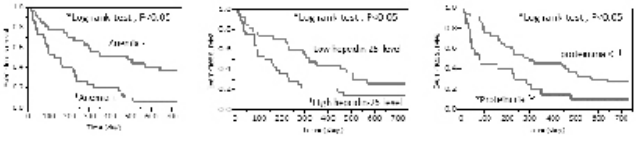

Figure1-b; The combined impact of anemia, hepcidin-25 and proteinuria for mortality

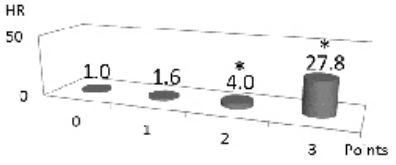

Conclusions: High hepcidin-25 may be a novel predictor for early mortality in cancer patients receiving chemotherapy. Adding either anemia or proteinuria or both to hepcidin-25 increases its predictive power.

PUB180

Serum Uric Acid as a Marker of Mortality in an Elderly Patients Cohort

Manuel M. Heras, María José Fernández-Reyes, Rosa Sanchez, Alvaro Molina, Astrid Rodriguez, Fernando Alvarez-Ude. *Nephrology, General Hospital, Segovia, Spain.*

Background: There is growing evidence of the role of serum uric acid (SUA) as a risk factor for cardiovascular and renal disease. We analyze the association between baseline SUA and overall mortality in elderly patients followed prospectively for 5 years

Methods: 80 clinically stable patients, median age 83 years (range 69-97), 31.3% men, 35% diabetic, 83% hypertensives, recruited in Geriatrics and Nephrology consultations between January-April 2006, were followed for 5 years. Predictive variables were: baseline SAU and plasma creatinine; estimated glomerular filtration rate (GFR) (abbreviated MDRD formula); recorded age, gender, baseline comorbidity (Charlson index), cardiovascular individualized treatment and mortality. Statistical analysis: SPSS15.0.

Results: Baseline SUA was normally distributed and its median was 5.85 mg/dl. We found not significant differences in levels of SUA by gender, diabetes mellitus, hypertension, diuretic use, heart failure (HF), peripheral arterial disease or stroke. Patients with an history of HF had significantly higher SUA (7.00 ± 1.74 vs. 5.90 ± 1.71, P = 0.031). 41 deaths occured during follow-up (15 men and 26 women): 15 general deterioration, 8 infections, 4 stroke, 4 tumors, 3 cardiovascular disease, 2 fractures and 5 unknown. The table shows how patients with SUA higher than the median had significantly lower GFR and higher mortality at 5 years.

Comparison of variables between groups according to SUA median

	Group 1: SUA < 5,85;N=40	Group 2: SUA>5,85;N=40	P
Baseline SUA (mg/dl)	4,77 ± 0,86	7,45 ± 1,27	0,000
Creatinine (mg/dl)	1,15 ± 0,45	1,46 ± 0,51	0,005
MDRD (ml/min/1.73m2)	56,94±15	45,60± 16	0,001
Age, years	81,55±6	83,42±6	N. S.
Sex (male/female)	10/30	15/25	N. S.
Charlson	1,62±1	1,97±1,29	N. S.
Mortality at 5 years	32,5%	70%	0,001

In logistic regression analysis for overall mortality (independent variables: age, gender, Charlson Index, history of HF, SUA, creatinine and GFR), only age (HR:1.14, 1.04-1.025, P=0.004) and SUA levels (HR:1.92, 1.28-2.88, P=0.002) were independently associated with mortality.

Conclusions: In our study, levels of SUA are shown as independent risk factor for mortality in elderly patients.

PUB181

Better Outcomes of Chronic Kidney Disease (CKD) Patients in Okinawa, Japan: Single Renal Clinic Report Okinawa Tokuyama Clinic Epidemiology and Nephrology Study (OCEANS)

Kunitoshi Iseki.[2] *[1]Internal Medicine, Tokuyama Clinic, Urasoe, Okinawa, Japan; [2]Dialysis Unit, University Hospital of the Ryukyus, Nishihara, Okinawa, Japan.*

Background: The purpose of the study is to examine the outcomes of the registered patients in single renal clinic in Okinawa, Japan. Tokuyama clinic is one of the referral centers taking care of CKD patients in Urasoe City which the population is about 110,000. All the members of general practitioners in the city are cooperative with the support of the Urasoe Medical Association. Medical records are filed to the registry database of Okinawa Tokuyama Clinic Epidemiology and Nephrology Study (OCEANS).

Methods: The registration period was from April 2004 to March 2008, 4 years, and followed up until March 2011. Serum creatinine was measured in 3,141 patients during the study period. Among them, a total of 1,962 (62.4%) patients were followed until events such as death and dialysis program or followed regularly, at least more than 3 months. Others (N=1,179) were not followed regularly as 1) visited simple medical reasons such as health-check, Cold, gastro-intestinal problems and miscellaneous reasons (N=661), moved outside to other area (36), transferred to other hospitals and hospitalization (307), and unknown (175). Serum creatinine was measured using the enzymatic method and the GFR was estimated by the formula of the Japanese Society of Nephrology.

Results: Baseline characteristics of the study cohort (N=1,962) were men (58.2%), mean (SD) age of 55.0 (15.4) years, systolic blood pressure 131.3 (23.1) mmHg, diastolic blood pressure 78.3 (13.6) mmHg, proteinuria 20.1%, serum creatinine 0.95 (0.89) mg/dl, and eGFR 71.4 (25.0) ml/min/1.73m^2. The distribution of eGFR was <15 in 2.9%, 15 to 29 in 3.5%, 30 to 59 in 21.6%, 60 and over in 72.0%. During the follow-up period, 69 patients entered dialysis program (3.5% of the total) and 33 patients (1.7%) died. None were entered dialysis program among those referred at eGFR>;;;45 ml/min/1.73m^2.

Conclusions: Based on our observation, early referral from general practitioners, eGFR>45 ml/min/1.73m^2 is warranted for the reduction of ESRD.

Determinants of Vitamin D Deficiency in Korean Adult: Kidney Function and Other Factors

Yun Jung Oh,[1] Hajeong Lee,[1] Jung Pyo Lee,[1,2] Chun Soo Lim,[2] Yon Su Kim,[1] Dong Ki Kim.[1] *[1]Internal Medicine, Seoul National University College of Medicine, Seoul, Korea; [2]Internal Medicine, Seoul National University Boramae Medical Center, Seoul, Korea.*

Background: Vitamin D deficiency has been associated with increased cardiovascular risk, mortality and progression of various chronic diseases including chronic kidney disease (CKD). But, there is limited information about the other factors interacting with the kidney function regarding vitamin D deficiency.

Methods: We examined the association between vitamin D deficiency and CKD by analyzing the data from the Fourth Korea National Health and Nutrition Examination Surveys 2008, consisted of 6529 adults aged 20 years or older. Vitamin D deficiency was defined as a serum 25-hydroxyvitamin D (25(OH)D)≤20 ng/ml, and the kidney function was estimated by the equation of Modification of Diet in Renal Disease equation.

Results: The overall prevalence rate of vitamin D deficiency was 54.3%, and the mean value of vitamin D showed a tendency of increase in proportion to age from twenties to sixties, pointing out that 25(OH)D level was lowest in the most young-aged group. Though there was a significant positive correlation between 25(OH)D level and GFR in multiple linear regression models, there was no significant difference in prevalence of vitamin D deficiency between two groups divided by GFR level of less or greater than 60 ml/min/1.73m^2. However, the prevalence of vitamin D deficiency at GFR level of less than 45 ml/min/1.73m^2 was higher than the other, even after adjustment for age, sex, smoking, residential region (urban/rural area), physical activity (regular exercise and walking), other medical co-morbidities; odds ratio: 2.040; 95% confidential interval: 1.096-3.799; p=0.025. In general adults population, vitamin D deficiency was significantly more common among those who were female, young aged, urban resident, seldom exercise, anemic, having proteinuria, and also with renal impairment.

Conclusions: Decreased renal function and young aged urban female resident are the prominent predictors of vitamin D deficiency. Based on the above data, the longitudinal observation for the association between vitamin D deficiency and clinical outcome should be studied.

PUB183

Evidence of the Syndrome of Rapid Onset End-Stage Renal Disease (SORO-ESRD) in the Acute Kidney Injury (AKI) Literature – Preventable Causes of AKI and SORO-ESRD – A Call for Re-Engineering of Nephrology Practice Paradigms

Macaulay A. Onuigbo,[1,2] Nnonyelum T. Onuigbo.[3] *[1]College of Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, WI; [3]Information Technology, NTEC Solutions, Eau Claire, WI.*

Background: We published the first report of the previously unrecognized syndrome of rapid-onset end-stage renal disease (SORO-ESRD) in 2010. We investigated the AKI literature to ascertain to what extent this syndrome may have been reported in the past without acknowledging its uniqueness.

Methods: We reviewed the AKI literature for SORO-ESRD as defined by sudden unanticipated AKI requiring RRT and quickly terminating in irreversible ESRD.

Results: The AKI reports revealing SORO-ESRD appear below. The 15 reports spanning the world, 20-1095 patients each, age 39-65 years, published from 1975-2010, demonstrated SORO-ESRD rates from 1%-85%. AKI was commonly caused by hypovolemia/hypotension, infections/sepsis, and nephrotoxics - radiocontrast, NSAIDs, aminoglycosides and ACEIs/ARBs.

Results of Literature Review Revealing SORO-ESRD from AKI Studies From Around the World

(Authors Publication, Year)	Country	Number of AKI patients	Mean age (Years)	Number of AKI patients that received RRT (%)	Number with SORO-ESRD	SORO-ESRD rate (%)	RAAS Blockade Implicated in AKI	Common Causes of AKI

Ozturk et al Ren Fail, 2007	Turkey	192	56		18	9	+	Acute Tubular Necrosis, Acute Glomerulonephritis, Nephrotoxics including ACEI/ARB in 10 patients
Al-Azzam et al Ren Fail, 2008	Jordan	111		20 (18)	4	4	+	Dehydration, Sepsis, Nephrotoxics as NSAIDs, Contrast, ACE Inhibitors
Kelly/Dominguez AJN, 2010	USA	20			17	85		Not Available

Conclusions: Not surprisingly, at least to us, several published AKI reports dating back to 1975 had demonstrated SORO-ESRD. This has substantiated our hypothesis that SORO-ESRD is prevalent worldwide. The human body is a complex adaptive system (CAS), so small changes can lead to huge effects; thus AKI can lead to irreversible ESRD, fairly quickly. The studies incriminated the same preventable causes of AKI. Reno-prevention, a new concept that we reported in the QJM in 2009, measures to prevent AKI, would benefit CKD patients everywhere. Note worthily, Merino et al in 1975 who described irreversible post-operative ESRD in older CKD patients following AKI from hypotension, with or without septicemia, had asked the rhetorical question whether indeed this should not represent a new syndrome. Now we know - the rest of the story. It is SORO-ESRD.

PUB184

Outcomes of Valvular Heart Surgery in Patients with Chronic Kidney Disease Almothana Shanaah,[1] Eleanor D. Lederer,[1, 2] Ihab Hamzeh,[1, 2] Michael E. Brier.[1, 2] *[1]Medicine, University of Louisville, KY; [2]Medicine, Robley Rex Veterans Affairs Medical Center, Louisville, KY.*

Background: Few studies have focused on the surgical outcome of patients with chronic kidney disease (CKD) undergoing valvular heart surgery. Furthermore, the optimal choice of valve type in this population remains unknown (ACC/AHA guidelines). A previous report showed that mortality was lower in patients undergoing aortic valve replacement (AVR) with mechanical vs. tissue valve in general VA population. The purpose of this study is to examine short-term and long-term outcomes in CKD patients undergoing cardiac valve surgery at our VA.

Methods: A retrospective review of patients with chronic kidney disease undergoing valve replacement from January 2000 through December 2010 at Robley Rex Veterans Affairs Hospital. ICD-9 and CPT codes were used to identify patients from electronic medical records. Outcomes were compared using Pearson chi-square.

Results: A total of 16 patients met the selection criteria for inclusion in this study. The average age at time of surgery was 68 years. The majority of patients were white (75%). The average body mass index was 28.6 kg/m^2. The prevalence of hypertension, diabetes mellitus and cerebrovascular accidents was 88%, 75% and 31%, respectively. Most patients (81%) had CKD-III, while 19% had end stage renal disease requiring hemodialysis. 63% underwent concomitant coronary artery bypass surgery. 9 underwent AVR, 5 underwent MVR and 2 underwent combined valve replacement. 19% or 3/16 received mechanical heart valves while 81% received tissue heart valves. Overall mortality was 5/16, 2 with mechanical valves and 3 with tissue valves. Six month mortality was 19%, one of three with mechanical valve and two of thirteen with tissue valve (p=0.49). Two mechanical valves, but no tissue valves, developed perivalvular regurgitation.

Conclusions: The mortality rate after valvular heart replacement surgery is similar to the previously reported mortality rate in general VA patients. While the small sample size precludes a definitive conclusion, these results suggest that bioprosthetic valves may provide a survival advantage in CKD population.

PUB185

Epidemiology of Chronic Kidney Disease: Results from a Polycentric Community Based Population of Middle-Older Aged Adults in Shanghai, China Yi Wang,[1] Shougang Zhuang,[1,2] Haidong Yan.[1] *[1]Department of Nephrology, Tongji University Affilated Shanghai East Hospital, Shanghai, China; [2]Department of Medicine, Brown University School of Medicine, Providence, RI.*

Background: The purpose of this study is to investigate the prevalence, awareness and the risk factors of chronic kidney disease (CKD) among community adult population in Pudong New Area, Shanghai, China.

Methods: 2000 adult residents (≥45 years old) from Pudong New Area were randomly selected to answer a questionnaire and to receive health examinations from July 2006 to October 2009. The morning spot urine dipstick test was used to evaluate proteinuria, creatinine and hematuria. Urine protein to creatinine ratio ≥ 30 mg/g and urine red blood cells>3 /Hp were considered abnormal. The association of kidney damage indicators including age, gender, hypertension, diabetes mellitus, smoking, income, education, cholesterol, triglyceride, body mass index and waist-to-hip ratio were assessed as well. The Chinese improved abbreviated MDRD equation was applied to estimate the glomerular filtration rate (eGFR, abnormal: <60ml/min^{-1}(1.73m^2)). A SPSS13.5 statistical software was used for statistical analysis.

Results: 1905 residents with complete data were enrolled in the study, with mean age 59.02±9.42 years old. After the adjustment of age and gender components, the prevalence of albuminuria, hematuria and the reduced renal function was 12.5% (95%CI:10.5%–13.5%), 7.90% (95%CI:6.7%-9.1%), and 1.9% (95%CI:1.7%-2.1%), respectively. Approximately 13.2% subjects had at least one indicator of kidney damage. Age, hypertension, diabetes mellitus and hyperuricemia were independently associated with CKD.

Conclusions: The prevalence of CKD in adult residents (≥45 years old) from Pudong New Area in Shanghai is 13.2%, and the awareness is 20.9%. The independent risk factors associated with CKD include age, triglyceride, hypertension, diabetes mellitus and hyperuricemia.

Regional CKD Medical Network System, OCKD-NET: Design and Method of Prospective Cohort Study of Japanese CKD Patients Hiroko Yamasaki,[1] Yohei Maeshima,[1] Norikazu Hinamoto,[1] Daisuke Saito,[1] Hiroyuki Watatani,[1] Haruyo Ujike,[1] Shinji Kitamura,[1] Hitoshi Sugiyama,[2] Hirofumi Makino.[1] *[1]Medicine and Clinical Science, Okayama Univ. Graduate School of Medicine, Okayama, Japan; [2]Center for Chronic Kidney Disease and Peritoneal Dialysis, Okayama Univ. Graduate School of Medicine, Okayama, Japan.*

Background: The continuous increase of patients requiring dialysis therapy is a major clinical and socioeconomical issue. Effective management of CKD patients requires association between nephrologists and primary care physicians (PCPs). Okayama city CKD Network (OCKD-NET) was established in 2007. Six referral hospitals with nephrologists and 115 PCPs in Okayama city have registered. Prospective cohort study within OCKD-NET was designed to identify risk factors for progression of CKD and cardiovascular disease (CVD).

Methods: CKD patients, aged ≥ 20 yrs, attending to the PCPs are enrolled. Clinical information on age, gender, blood pressure (BP), proteinuria and eGFR will be collected annually, up to 5 yrs. Progression of CKD stage, annual decline of eGFR, CVD event and initiation of dialysis therapy will be assessed. The outcome between groups of CKD patients attending to 1) PCPs and 2) both PCPs and nephrologists will be compared. Study protocol was approved by the ethical review committee of our university.

Results: A total of 111 Japanese CKD patients were enrolled until May, 2011. In Group 1 (n=17), mean age was 79 yr, 33% were male and mean eGFR was 32 ml/min per 1.73m2 at enrollment. In Group 2 (n=94), mean age was 67, 64% were male and mean eGFR was 41. Overall, 48% had hypertension, 22% had diabetes, 43% were at CKD stage 3, 32% were at CKD stage 4, and 48% had proteinuria. Lower eGFR was associated with older age (P<0.001), proteinuria (P<0.01) and complication of Diabetes (P=0.03). Proteinuria was significantly greater in diabetic group compared with non-diabetic group (P<0.01).

Conclusions: OCKD-NET was established to facilitate regional CKD medical association. Long-term follow-up will provide critical insights into potential risk factors of CKD and CVD progression, leading to the establishment of an effective CKD care system.

PUB187

Cost of Treatment Schemes of Intra-Venous Iron in CKD Patients with Iron Deficiency Anaemia: A Patient Record Study Patricia R. Blank,[1] Thomas D. Szucs.[2] *[1]Institute of Social and Preventive Medicine, University of Zurich, Switzerland; [2]Institute of Pharmaceutical Medicine, University of Basel, Basel, Switzerland.*

Background: Iron deficiency (ID) and anaemia in chronic kidney deficient (CKD) patients can be treated by erythropoiesis-stimulating agents (ESAs) or intravenous (i.v.) iron. This study assessed costs of treating CKD patients with i.v. iron based on record data.

Methods: Nephrologists (5 EU countries) completed questionnaires on anaemic CKD patients seen within 3 months (Aug-Sept 2010). Demographics and iron parameters were recorded at initiation and last visit of ID treatment (n=1143). Administration and drug costs were identified from a Swiss payer perspective.

Results: Mean dosage was 583mg i.v. (n=428) and 11604mg oral iron (n=467). respectively. ESA dose was not measured (n=425). Treatment costs are shown in Tab.

Table 1. Treatment scheme and costs (EUR) per single dose and over survey group (rounded values)

	Ferric Gluconat (n=23)	Iron dextran (n=20)	Iron sucrose (n=244)	Ferric carboxymaltose (n=251)
Mean total dose given (mg)	305	1000	482	692
Number of session needed	3.7	1.6	2.4	2.5
Infusion administration scheme as per approved label	62.5mg per 10min	1134 mg in 7h	200 mg in 30min	500-1000 mg in up to 15min
Administration type	65% infusion, 35% injection**	Infusion	80% infusion, 20% injection**	65% infusion, 35% injection *
Costs of administration (EUR)	164	594	149	128
Costs of total i.v. iron (EUR)	35	205	110	193
Total costs (EUR)	199	799	259	321

*push injection with max. 200mg; ** slow injection with max 200mg

HB levels for iron sucrose or ferric carboxymaltose (FCM) were 9.3g/dl (standard deviation (SD) 1.1) or 9.4g/dl (SD 1.3) at initiation and 10.9g/dl (SD 1.2) or 11.5g/dl (SD: 1.4) at last visit, respectively. ESA patients had levels of 9.3g/dl (SD: 1.5; initiation) and 11.0g/dl (SD: 1.6; last visit).

Conclusions: This survey identified practice related treatment schedules in CKD patients with ID. The i.v. iron group achieved similar HB levels compared to ESA. Due to methodological limitations, it was not possible to assess data on treatment duration or the superiority of a therapy. I.v. iron might be a clinically and economically viable alternative to expensive ESAs in CKD patients.

Automated Reporting of Estimated Glomerular Filtration Rate Varies among Veterans Affairs Laboratories Rasheeda K. Hall,[2] Bradley G. Hammill,[2] George L. Jackson,[1,2] Virginia Wang,[1,2] Matthew L. Maciejewski,[1,2] Uptal D. Patel.[2] *[1]VA Health Services Research & Development; [2]Duke University, Durham, NC.*

Background: The prevalence of CKD among veterans is increasing, and to facilitate earlier detection of CKD, clinical practice guidelines have recommended automated reporting of eGFR by clinical laboratories. We sought to better understand the diffusion of this innovation within the Veterans Health Administration (VHA) by evaluating time to adoption of eGFR reporting at individual VHA facilities and associations between adoption and site-specific organizational characteristics.

Methods: Using VHA laboratory data, we estimated time to adoption from the date VHA delivered a mandate for eGFR reporting (July 2004). For each medical facility with a laboratory (n= 135), adoption was defined by the presence of an associated eGFR for at least 1% of creatinine values. VHA facilities were classified by adoption status, and adopters were further divided into 3 categories (early-, mid-, and late-adopters) based on tertiles of time to adoption. Then, we compared organizational characteristics between facilities with bivariate analyses.

Results: By September 2009, 109 (81%) facilities adopted eGFR reporting while 26 (19%) facilities had not. Time to adoption varied widely with range, 0.2 to 4.3 years, and median of 1.8 (IQR 2.2) years. Comparing facilities by adoption status, dialysis units were only present among adopters (59%)($p<0.05$). Among adopters, there were no significant differences in organizational characteristics.

Conclusions: Despite a uniform mandate to adopt this laboratory reporting innovation, 1 in 5 facilities did not adopt eGFR reporting and among those who did, time to adoption varied widely. These findings suggest that adoption may be due to availability of local resources (e.g., dialysis units). Still, reasons for the wide range in adoption remain unclear, but may be the result of local decision-making between clinical and information technology administrators. With the emergence of newer eGFR equations to improve CKD detection, our findings should be considered prior to future rollouts of other laboratory reporting innovations to promote more uniform and timely adoption.

PUB189

Trial Announcement: Vitamin K2 To Slow Vascular Calcification in Hemodialysis Patients, "VitaVasK" Thilo Krueger,[1] Georg Schlieper,[1] Mario Cozzolino,[2] Johannes Jacobi,[3] Ralf-Dieter Hilgers,[11] Michel Y. Jadoul,[4] Markus Ketteler,[5] Tom Cornelis,[6] Lars C. Rump,[7] Peter Stenvinkel,[8] Andrzej Wiecek,[9] Ralf Westenfeld,[10] Leon J. Schurgers,[12] Jurgen Floege.[1] *[1]Nephrology, University Clinic Aachen, Aachen, Germany; [2]Renal Division, University of Milan, Milan, Italy; [3]Nephrology, University of Erlangen Nuremberg, Erlangen, Germany; [4]Nephrology, University of Louvain, Brussels, Belgium; [5]Nephrology, Coburg Hospital, Coburg, Germany; [6]Nephrology, University Hospital Maastricht, Maastricht, Netherlands; [7]Nephrology, University Duesseldorf, Duesseldorf, Germany; [8]Renal Medicine, Karolinska Institute Stockholm, Stockholm, Sweden; [9]Nephrology, University of Katowice, Poland; [10]Cardiology, University Duesseldorf, Duesseldorf, Germany; [11]Medical Statistics, University Clinic Aachen, Aachen, Germany; [12]CARIM, University Maastricht, Maastricht, Netherlands.*

Background: Patients on hemodialysis (HD) exhibit an increased cardiovascular mortality associated with vascular calcification (VC). Matrix Gla protein (MGP) is a powerful vascular wall-based inhibitor of VC. MGP needs activation by vitamin K-dependent carboxylation.

The ERA/EDTA sponsored VitaVasK study will be the first clinical trial in HD patients to target the progression of VC using dietary vitamin K-containing supplements. VitaVasK is a randomized, double-blind, placebo-controlled trial with parallel groups. Participants are recruited from nine European nephrology centers. Multislice spiral computed tomography (MSCT) will be used to screen for coronary artery calcification (CAC). Stable HD patients with CAC scores >100 will be randomized to a daily oral supplementation of vitamin K2 (n=178) or placebo (n=178) for 18 months. Primary outcomes will be attenuation of progression of coronary and aortal calcification at 12 and 18 months using volume scores determined by MSCT. Secondary outcomes will be regression of VC, attenuation of progression of aortic and mitral valve calcification, major cardiac events, mortality, and change in serum levels of undercarboxylated and carboxylated MGP. Patients will be followed beyond the primary study duration to determine the mortality at three and five years.

CKD.QLD Phase 2 Survey: Risk Factor Modification for Prevention of Chronic Kidney Disease Progression Sree Krishna Venuthurupalli,[1,4] Anne Salisbury,[3] Wendy E. Hoy,[3] Helen G. Healy,[2] Robert G. Fassett.[2,4] *[1]Renal Medicine, Toowoomba Hospital, Toowoomba, Queensland, Australia; [2]Renal Medicine, Royal Brisbane and Women's Hospital, Brisbane, Queensland, Australia; [3]Centre for Chronic Disease, University of Queensland, Brisbane, Queensland, Australia; [4]School of Medicine, University of Queensland, Brisbane, Queensland, Australia.*

Background: Management of traditional risk factors for chronic kidney disease (CKD) progression include antiproteinuria therapy, hypertension and diabetes control, diet, exercise and lipid lowering therapy. We investigated the current clinical practice for prevention of CKD progression in Queensland, Australia.

Methods: Using a web based questionnaire, nephrology medical and nursing staff from each CKD clinic in Queensland were surveyed to assess risk factor modification in CKD management practices.

Results: The participation rate was 100%. Restriction of salt and fats formed the corner stone (80%) of diet modification. Routine protein restriction was not advised. Dietary potassium and phosphate limitations were used as case by case.

Anthropometric measurements included weight (100%), height (81%), body mass index (61%) and waist circumference (10%). An exercise physiologist was not available in all clinics, though physical activity and exercise was routinely recommended.

Angiotensin converting enzyme inhibitors and angiotensin receptor blockers were routinely prescribed for blood pressure reduction and to slow CKD progression. However, combination therapy was only used in 50% of cases, based on level of proteinuria. Lipid lowering therapy was a frequent practice (90%), with use of statins being the main strategy. Interestingly, statins were used with the aim of reducing cardiovascular mortality and morbidity but not to slow CKD progression.

Diabetes control was routine with HbA1C levels used as the main tool for follow up (85%). Patients are screened for vascular complications related to diabetes with annual follow up.

Conclusions: Traditional risk factors management was incorporated in CKD practice across renal units in Queensland, Australia. A longitudinal study in this population will determine the impact of these on CKD progression and cardiovascular events and mortality.

Relationship between Clinicopathological Findings and Renal Outcomes of Diabetic Nephropathy in Type 2 Diabetes Tomoaki Funamoto,[1] Miho Shimizu,[1] Tazuko Ohama,[1] Chikako Nose,[1] Yasuyuki Shinozaki,[1] Shinji Kitajima,[1] Tadashi Toyama,[1] Akinori Hara,[1] Kiyoki Kitagawa,[1] Kengo Furuichi,[1] Shuichi Kaneko,[2] Takashi Wada.[1] *[1]Division of Nephrology, Kanazawa University Hospital, Kanazawa, Ishikawa, Japan; [2]Department of Disease Control and Homeostasis, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa, Ishikawa, Japan.*

Background: The purpose of the present study was to evaluate the relationship between clinicopathological findings and renal outcomes of diabetic nephropathy in Japanese patients with type 2 diabetes.

Methods: Two hundred and sixty, biopsy-proven type 2 diabetic patients with diabetic nephropathy (164 males and 96 females) were examined. Observation period was 7.9±6.5 years. Renal outcomes were assessed by requirement for dialysis or 50% reduction of estimated glomerular filtlation rate (eGFR). For presumption of clinicopathological factors that affected renal outcomes, multivariate analysis by the Cox proportional hazards model was employed.

Results: The number of cases of normal albuminuria or urinary protein (-) or (±), microalbuminuria or urinary protein (+), and overt nephropathy were 47, 50 and 163 respectively. 2) Seventeen patients (36.2%) with normal albuminuria or urinary protein (-) or (±), 21 patients (42%) with microalbuminuria or urinary protein (+), and 116 patients (71%) with overt nephropathy were under 60ml/min/1.73m^2 of eGFR. 3) In patients with microalbuminuria and overt nephropathy, renal outcomes were good in patients with over eGFR values of 45 ml/min/1.73m^2. 4) Higher albuminuria was the most important clinical factor for poor renal outcomes. Lower eGFR was an independent risk factor for renal outcomes in patients with overt nephropathy. Pathological factors for poor renal outcomes were nodular lesions and interstitial fibrosis in microalbuminuria patients, while those were atherosclerosis, exudative lesions, and nodular lesions in overt nephropathy patients.

Conclusions: Our observations suggest that development of albuminuria play an important role for renal outcomes of diabetic nephropathy in type 2 diabetes. Lower eGFR was an independent risk factor in renal outcomes among patients with overt nephropathy.

PUB192

Low 25-hydroxyvitamin D Levels Are Associated with an Increased Risk of Non-Alcoholic Fatty Liver Disease (NAFLD) in a Large Managed Care Organization Anna Jeanette Jovanovich,[1] Giovanni Targher,[2] Jessica B. Kendrick,[1] Shailendra Sharma,[1] Kim McFann,[1] Sidney N. Thornton,[3] Michel B. Chonchol,[1] John R. Holmen. *[1]Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]Section of Endocrinology, Department of Medicine, University Hospital, Verona, Italy; [3]Intermountain Health Care, Salt Lake City, UT.*

Background: To explore associations between serum 25-hydroxyvitamin D levels and NAFLD.

Methods: We conducted a population-based cohort study of adult patients with NAFLD who had vitamin D levels measured 3 to 15 months prior to diagnosis of NAFLD. Vitamin D was evaluated as a continuous variable and a categorical predictor (< 15 ng/mL vs. higher). The primary outcome of interest was diagnosis of NAFLD identified through ICD9 codes and sex-specific elevation in liver function tests. Patients with a history of alcoholic liver disease were excluded from the analyses. Patients with NAFLD were matched 1:1 with controls on age, sex, race and season. Conditional multivariate logistic regression was used to evaluate if low vitamin D levels were associated with an increased risk of NAFLD.

Results: We identified 607 individuals with NAFLD and 607 matched controls. The mean (SD) age of the participants was 56±14 years, 74% were female and 90% were Caucasian. Compared to controls, patients with NAFLD had a significantly higher body mass index (31±17 vs. 28 ±14 Kg/m2; p<0.0001), and higher percentage of diabetes (36.0% vs. 30.0 %; p<0.0001). Mean (SD) levels of 25(OH)D were lower in patients with NAFLD than controls (30 ± 7 vs. 34 ± 8 ng/mL p=0.0003). After adjustment for BMI, diabetes, chronic kidney disease and peripheral vascular disease higher 25(OH)D levels were protective for NAFLD (OR 0.97, 95% CI 0.97-0.98; p<0.0001). Similarly, when evaluated as a categorical predictor, vitamin D levels < 15 ng/mL vs. higher (adjusted OR 1.98, 95% CI 1.33-2.97; p=0.0008) were strongly associated with almost a two-fold increased odds of NAFLD.

Conclusions: Vitamin D deficiency is associated with an increased risk of NAFLD. Clinical trials are needed to evaluate whether vitamin D_3 supplementation can reduce the risk of NAFLD in patients with and without CKD.

PUB193

Effects of Dual Blockade of the Renin Angiotensin System in Diabetic Kidney Disease: A Systematic Review and Meta-Analysis Jacqueline Pham,[1] Brian P. Schmitt,[2] David J. Leehey.[1] *[1]Renal and Hypertension, Edward Hines Jr. VA Medical Center, Hines, IL; [2]Edward Hines Jr. VA Medical Center, Hines, IL.*

Background: There is much evidence to support a renoprotective effect of inhibitors of the renin- angiotensin system in diabetic kidney disease. However, it remains unclear whether dual renin- angiotensin system blockade has additional benefits in this population and whether any benefits outweigh the risks.

Methods: *Study Design:* Systematic review and meta-analysis

Setting and Population: Diabetic patients with overt proteinuria

Selection Criteria for Studies: Randomized, controlled, parallel or crossover design studies

Intervention: Combination renin-angiotensin system blockade vs. monotherapy

Outcomes: The primary outcome measure was the post-treatment difference in proteinuria with combination therapy versus monotherapy. Secondary outcomes included percent change in proteinuria, changes in systolic blood pressure, glomerular filtration rate, and serum potassium, and incidence of hyperkalemia. Sensitivity analyses that evaluated differences in outcome based on study quality (assessed by Jadad scores), baseline systolic blood pressure, and drug types and doses were conducted.

Results: There was significantly less proteinuria (by 334 mg/24 hr) after treatment with combination therapy vs. monotherapy. Systolic blood pressure (BP) after treatment with combination therapy vs. monotherapy was significantly lower (by 4.1 mmHg). However, clinically significant hyperkalemia was 3.5-fold more common with dual blockade. Sensitivity analyses did not identify subgroup differences that altered these findings.

Conclusions: Dual renin-angiotensin system blockade in patients with diabetic kidney disease reduces proteinuria and BP but is associated with a higher incidence of clinically significant hyperkalemia. Further studies assessing long-term outcomes are needed to weigh the benefits versus risks of combination renin-angiotensin system inhibitor therapy.

PUB194

Effect of Blockers of the Renin-Angiotensin System on Renal Tissue Oxygenation in Type 2 Diabetics as Measured by BOLD-MRI Menno Pruijm, Lucie Hofmann, Anne Zanchi, Marc P. Maillard, Valentina Forni, Meryll Cassat, Grégoire Wuerzner, Bruno Vogt, Michel Burnier. *Nephrology, Centre Hospitalier Universitaire Vaudois, Lausanne, VD, Switzerland.*

Background: Previous studies have shown that acute intake of certain drugs alters renal tissue oxygenation, and animal studies suggest that blockers of the renin-angiotensin system might exert their renoprotective effect by correcting diabetes-induced renal hypoxia.

The objective of this study was to investigate the chronic effect of the ATII- type 1 receptor blocker (ARB) candesartan, compared to the ACE-inhibitor (ACEI) enalapril on renal tissue oxygenation in type 2 diabetics with microalbuminuria and/or hypertension, using blood oxygenation level-dependent magnetic resonance imaging (BOLD-MRI).

Methods: After a wash out period, ten patients (aged 63.8±8.4 y, BMI 35.0±3.0, 30% women) underwent BOLD-MRI at baseline, after one month of enalapril (20mg/day), and after one month of candesartan (16 mg/day). BOLD-MRI was performed before and after intravenous administration of furosemide.

Four coronal slices were selected, and a modified MEDIC sequence was used to acquire T2* weighted images. The mean R2* values (=1/T2*) were calculated, a low R2* indicating a high tissue oxygenation.

Results: Baseline characteristics and their changes are shown in table 1. The mean cortical and medullary R2* did not differ significantly between groups (ANOVA, p=0.88 and 0.24). Furosemide did not change cortical R2*, and decreased medullary R2* to a similar extent in all groups (mean decrease 7.51±2.17 s^{-1}).

	Baseline	Candesartan	Enalapril
SBP (mmHg)	135.4 (10.2)	132.4 (12.2)	132.4 (10.5)
DBP (mmHg)	74.4 (14.6)	72.4 (9.2)	73.0 (10.3)
Creatinine (µmol/l)	86 (67-186)	89 (58-210)	89 (64-202)
Clearance (ml/min)	105.4 (48.7)	99.8 (30.8)	99.6 (36.2)
Urinary sodium (mmol/24h)	198.6 (23.6)	185.0 (51.7)	174.0 (46.9)
HbA1c (%)	7.60 (0.9)	7.47 (1.07)	7.45 (0.8)
Medullary R2* (1/s)	28.5 (1.3)	27.9 (1.6)	29.1 (1.6)
Cortical R2* (1/s)	17.8 (1.5)	17.8 (1.4)	18.1 (1.7)

Values are shown as mean±SD, or median (min-max), as appropriate

Conclusions: At the current stage, chronic intake of ACEI or ARB does not seem to alter renal tissue oxygenation measured by BOLD-MRI in type 2 diabetics.

PUB195

Design and Rationale for a Randomized, Double-Blind, Placebo-Controlled Phase 2 Study To Evaluate the Safety and Efficacy of CTP-499 in Patients with Diabetic Nephropathy James Shipley, LuAnn A. Sabounjian, Virginia Braman, Dolly A. Parasrampuria, Lijun Wu, David J. Turnquist, Philip B. Graham. *Concert Pharmaceuticals, Lexington, MA.*

Background: CTP-499 is a deuterium-containing analog of 1-((S)-5-hydroxyhexyl)-3,7-dimethylxanthine (HDX), an active metabolite of pentoxifylline (PTX). Small published clinical trials with PTX have shown evidence of beneficial effects in CKD patients. CTP-499 is being investigated as a novel treatment for diabetic nephropathy and

is expected to be additive to RAS blockade. Deuterium is a safe, naturally-occurring, non-radioactive isotope of hydrogen. Selective incorporation of deuterium does not appear to alter the binding, potency or selectivity, but in select cases may provide beneficial effects on compound metabolism. In vitro and ex vivo studies have shown CTP-499 possesses anti-inflammatory, anti-fibrotic and anti-oxidative properties, making it potentially useful in slowing the progression of DN. In rats with streptozotocin-induced diabetes, CTP-499 reduced urinary protein excretion and improved other renal function markers.

Methods: Design: Approximately 170 patients with type 2 diabetic nephropathy, macroalbuminuria (UACR ≥400 mg/g) and an eGFR ≥25 mL/min/1.73m2 (MDRD), who are receiving concomitant ACEi and/or ARB therapy, will be enrolled at approx. 30 US centers. After a 4-8 week stabilization period, during which BP will be managed to a target of <145/90 mmHg, patients will be randomized (1:1) to receive 24 weeks of treatment with CTP-499 600 mg bid (600 mg qd for the first 2 weeks), or placebo. UACR will be assessed monthly using the geometric mean of 3 consecutive first morning voids. eGFR will be determined at each visit along with a biomarker panel incl. cytokines and markers of fibrosis and kidney function. Plasma conc. of CTP-499/metabolites will be assessed monthly. In a subset of patients, 24h plasma and urine conc-time profiles will be obtained after 1st and last doses.

Results: Primary Endpoint: UACR change from pre-treatment baseline to post-treatment using a longitudinal model with data from weeks 16, 20, and 24.

Conclusions: Study enrollment is expected to begin in late 2011; top-line data are expected in 2013.

Funding: Pharmaceutical Company Support

PUB196

A Systematic Review and Meta-Analysis: Impacts of Albuminuria and Low GFR on Renal Failure, Cardiovascular Death, or Mortality in Patients with Diabetic Nephropathy Tadashi Toyama,[1] Kengo Furuichi,[1] Toshiharu Ninomiya,[2] Shuichi Kaneko,[3] Takashi Wada.[1] *[1]Division of Nephrology, Kanazawa University Hospital, Kanazawa, Japan; [2]Department of Nephrology, Hypertension,and Strokology, Kyushu University Hospital, Fukuoka, Japan; [3]Department of Disease Control and Homeostasis, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa, Japan.*

Background: The relationships between albuminuria and complications of diabetes mellitus have been reported. However consistency and strength of these evidences have not been cleared so far. In this study, we explored the impacts of albuminuria on renal failure, cardiovascular death, and all-cause mortality in diabetes mellitus.

Methods: Relevant studies were identified from MEDLINE, EMBASE, and CINAHL by using relevant text words and medical subject headings that includes all keywords related to "diabetes mellitus," "renal failure," "cardiovascular diseases," and "mortality." The literature search and data extraction was conducted for three endpoints (renal failure, cardiovascular death, all-cause mortality) by two independent researchers. The extracted estimates were combined using a random-effects model.

Results: The literature search yielded 6546 articles, of which 328 papers were reviewed in full. In diabetic patients, the presence of microalbuminuria is associated with an approximate 3.5-fold increase in risk of renal failure (relative risk 3.52, 95% CI 2.04-6.05). And there are the same trends in cardiovascular death (relative risk 1.90, 95% CI 1.56-2.32), and all-cause mortality (relative risk 1.62, 95% CI 1.45-1.82). In addition, there are significant trends towards greater effects with macroalbuminuria in each outcome.

Conclusions: These findings suggest that microalbuminuria and macroalbuminuria are risk factors for renal failure, cardiovascular mortality, and all-cause mortality in diabetic patients. Individual patient data meta-analysis is needed in the future.

PUB197

Clinical and Histological Features of Patients with IgA Nephropathy Who Have Attained Stable Clinical Remission Lasting Longer Than 5 Years Alessandro Amore,[1] Roberta Camilla,[1] Laura Morando,[1] Rachele Gallo,[1] Licia Peruzzi,[1] Cristiana Rollino,[2] Raffaella Cravero,[4] Marco Quaglia,[5] Loredana Colla,[6] Gianna Mazzucco,[6] Rosanna Coppo.[1] *[1]Nephrology, Dialysis, Transplant, R. Margherita H., Turin, Italy; [2]Nephrology and Dialysis, G. Bosco H., Turin, Italy; [3]Nephrology, University of Turin, Italy; [4]Nephrology, Infermi H, Biella, Italy; [5]Nephrology, East Piedmont University, Novara, Italy; [6]Biomedical Science and Human Oncology, University of Turin, Italy.*

Background: IgA nephropathy (IgAN) progresses to ESRD in 30% of cases within 20 years, but some patients have a long-lasting clinical remission. Little attention has been devoted to them.

Methods: This retrospective study enrolled IgAN patients who showed for more than 5 years a stable remission defined as absence/trace of hematuria (Hb-/+ or < 5 RBC/hpmf),absence/trace of proteinuria (< 250 mg/day or uP/uCr < 0.2),stable renal function (loss of eGFR <1 ml/min/1.73m2/year)and normal BP with/without RAAS inhibition.

Results: Entering criteria were fulfilled by 51/320 patients.They were followed for 15±7.2 years from onset to December 2010. Median age at onset was 25 y(7-65); 61% had history of gross hematuria; e-GFR was 106±25(60-159) ml/min/1.73m2 and uP/uCr 1.1±.5 (0.01-14).

Renal biopsies were reviewed according to Oxford classification for IgAN. Treatments included steroids in 14 cases(3-9 i.v. MP pulses or oral for 6-8 months), oral cyclophosphamide for 8 weeks in 2 cases, ACE-inhibitors/ARB in 24.The median time from renal biopsy to remission was 24 months (IQ range 6-48). In subgroups of patients presenting with clinical or histological risk factors for progression, time to remission resulted longer in proteinuric cases.

Factors affecting time to remission

	N of cases	Time to remission, months (median - IQ range)
proteinuria > 1 (uP/uCr)	18	30 (6-57)
hematuria Hb > ++	43	24 (6-48)
eGFR < 90 ml/min/1.73m2	14	24 (12-57)
MEST > M0E0S0T0	22	24 (6-60)

Conclusions: A subset of patients with IgAN can enter a long-lasting clinical remission even when presenting clinical or histological risk factors at renal biopsy. These patients are good candidate for genetic and biomarker investigations to be compared with progressive cases.

PUB198

Dense Deposit Disease Associated with a CFH Gene Mutation, CFH Autoantibodies and C3 Nephritic Factor: What Is Responsible? Gianluigi Ardissino,[1] Francesca Tel,[1] Nicolò Borsa,[2] Richard J. Smith,[3] Yuzhou Zhang,[3] Silvana Tedeschi,[2] Stefania Salardi,[2] Sara Testa,[1] Alberto Edefonti.[1] *[1]Ped Nephrol Unit, Fondazione IRCCS Osp. Maggiore Policlinico, Milano, Italy; [2]Lab. Medical Genetics, Fondazione IRCCS Osp. Maggiore Policlinico, Milano, Italy; [3]Molecular Otolaryngology and Renal Research Laboratories, Departments of Pediatrics and Medicine, Divisions of Nephrology, University of Iowa, Iowa City, IA.*

Background: DDD is a rare disease leading to ESRD ~50% of pts < than 10 yrs of age at diagnosis. The pathophysiology of DDD is the uncontrolled activation of the alternative pathway (AP) of complement cascade. AP dysregulation can be caused by mutations in *CFH* and antibodies to complement proteins such as factor H (FHAA) and C3 convertase (C3 nephritic factor, C3Nef).

Methods: We report a 9-yr-old boy who developed DDD and was found to have a CFH mutation, FHAA and C3Nefs.

Results: This child presented with occasional macrohematuria, persistent microhematuria, proteinuria and hypocomplementemia. A renal biopsy showed DDD with endo-extracapillary proliferation (10%). Over a 2 yrs period, he was treated with 4 cycles (x 3) of methylprednisolone followed by oral prednisone. uPr/uCr temporarily normalized and sC3 levels increased. Additional studies identified a novel heterozygous *CFH* variant as well as FHAA and C3Nefs. Steroid treatment was stopped and plasma exchange (PEX) with fresh frozen plasma (FFP) was initiated, followed by weekly FFP infusions over a period of 3 months. This treatment led to a stable reduction in FHAA with normalization of sC3 and uPr/uCr ratio for as long as 5 mos, after which FHAA increased, proteinuria recurred and sC3 levels dropped. A single PEX followed by weekly infusions of FFP was temporary effective in lowering FHAA but uPr/uCr did not improve. The addition of mycofenolate mofetil (MMF) was ineffective.

Time (d)		FHAA (IU)	C3 (mg/dl)	uPr/uCr
0	Baseline pre-PEX	>100	42	1.75
0	Post-PEX	6	80	0.36
10	FFP	13	75	0.38
45	FFP	8.7	97	0.3
162	NO TX	100	9	0.9
204	FFP	3.4	19	1.9
232	MMF	3.5	18	2
262	MMF	11	18	3.1

Conclusions: Herein we share this unique case of DDD where several possible causes of the disease coexist and the response to different treatment modalities.

PUB199

Necrotizing Crescentic Glomerulonephritis Complicating Membranous Nephropathy: A Rare Coexistence Syed N. Babar, Richard A. Sherman. *Nephrology, Robert Wood Johnson University Hospital, New Brunswick, NJ.*

Background: Membranous glomerulonephritis (MG) is among the most common causes of nephrotic syndrome in adults. The majority of MG cases represent primary or idiopathic disease, whereas the remaining cases represent secondary forms related to infection, drugs and malignancy. Necrotizing crescentic glomerulonephritis (NCGN) is characterized by glomerular necrosis and crescent formation. One half of NCGN is associated with SLE, Goodpasture's or Wegener's while the other half is idiopathic. We present a case demonstrating the rare coexistence of MG and NCGN.

Methods: A 38 year old male with biopsy proven MG maintained initially on prednisone, and then mycophenolate mofetil and later cyclosporine was noted to have worsening lower extremity swelling and fatigue two years after his diagnosis. Labs revealed worsening nephrotic range proteinuria and azotemia along with positive p-ANCA and MPO Abs. Serologies for lupus and anti-GBM disease were negative. Repeat renal biopsy revealed NCGN superimposed on MG with segmental and global sclerosis. Aggressive salvage therapy with pulse methylprednisolone and IV cyclophosphamide failed to improve renal function. Four months after starting hemodialysis he received a kidney transplant. A year and a half post-transplant, he remains stable with a creatinine of 1.5 mg/dl.

Results: The concurrence of MG and NCGN is a rare phenomenon with only a handful of reported cases. The presence of fibrinoid necrosis and crescent formation in the setting of membranous nephropathy may be seen in lupus nephritis, anti-GBM disease, or ANCA-associated RPGN. Renal biopsy is required to make the diagnosis and treatment typically involves pulse steroids with cyclophosphamide. The outcomes vary and generally correlate with the percentage of globally sclerotic glomeruli seen on the biopsy. The manifestation of both membranous nephropathy and necrotizing crescentic glomerulonephritis likely represents a coincidental happening given their distinct pathogenesis.

Conclusions: Unexpected or sudden worsening of proteinuria and renal function in patients with established glomerular disease should prompt consideration of a superimposed renal lesion.

PUB200

Validation of Histology Classification of ANCA Associated Vasculitis and Patient Outcomes Sophie Louise Bennett,[1] Ajay Prabhakar Dhaygude.[1] [1]*Renal Medicine, Royal Preston Hospital, Preston, United Kingdom;* [2]*Histopathology, Royal Preston Hospital, Preston, United Kingdom.*

Background: Recently published meta-analysis of outcome 535 ANCA associated systemic vasculitis (AASV) patients from four different clinical trials suggested that 48% of the mortality was due to infections in the first year and 19% mortality due to active vasculitis. Validation of Berden histological classification of AASV in 100 patients demonstrated good correlation with histology class of AASV and renal outcomes at 1 and five years and is likely to be a valuable tool to guide therapy of AASV. In this study we validated this classification in 35 patients with renal vasculitis.

Methods: We retrospectively classified all kidney biopsies of newly diagnosed patients with small vessel vasculitis who presented between 1/1/2003 and 31/12/2005. Data was collected regarding their ANCA serology, overall survival and renal survival.

Results: Thirty-five patients were analysed. Fifteen patients were cANCA positive, 13 patients were pANCA positive and seven patients were ANCA negative. Average creatinine at the time of diagnosis was 535.97 mmol/lr and average creatinine at the time of last follow up was 253.08 mmol/lr. Outcomes are presented in table-1

Table-1: Outcome of patients with renal vasculitis.

Histology Class	Average Diagnosis Creatinine (mmol/lr)	Average Follow up Creatinine (mmol/lr)	Patient survival	Renal survival	Reduction in creatinine
Crescentic (11)	543	208	10 (90.9%)	8 (72.7%)	61.7%
Focal (14)	378	239	12 (85.7)	13 (92.8%)	36.8%
Mixed (8)	648	285	3 (37.5)	8 (100%)	56%
Sclerotic (2)	1151	800	1 (50%)	1 (50%)	30.5%

Conclusions: These results suggests that patients with

1] Patients with crescentic class of renal vasculitis have most improvement in their renal function.

2] Patients with mixed lesions had poor patient survival

3] Patients with sclerotic lesions have poor patient and renal survival

Limitations: Small sample size and retrospective study.

PUB201

Membranoproliferative Glomerulonephritis with IgMk Deposits in an Anti-HCV Positive Patient with Concurrent Small B-Cell Lymphoproliferative Disease Eleni Chelioti, Sotiris Mikros, Evagelia Chrisanthopoulou, Maria Tsilivigou, Gabriel Papadakis. *Dept. of Nephrology and Renal Unit, General Hospital of Piraeus, Athens, Greece.*

Background: Hepatitis C(HCV) infection has been associated with Membranoproliferative Glomerulonephritis(MPGN),usually in the context of type II cryoglobulinemia with polyclonal IgG and monoclonal IgM precipitates. On the other hand, MPGN has been reported as the most frequent histological diagnosis of renal involvement in the context of B-cell lymphoproliferative diseases. Renal complications of malignant IgM-secreting proliferations are rare, the most common cause being Waldenstrom's Macroglobulinemia,but small B-cell non-Hodgkin and Marginal Zone Lymphoma are also reported occasionally.

Methods: We report the case of a 50-year-old male with history of alcohol and IV drug abuse,chronic HCV infection and renal failure of undetermined origin who presented in the emergency department with uremic symptomatology. The patient was dyspnoeic, hypertensive, without peripheral oedemes, with metabolic acidosis, hyperkalemia, hyperphosphatemia, hypoalbuminemia, anemia, thrombocytopenia and severe renal failure with signs of glomerular involvement(urine red blood cells=40–60/HPF,24-hour urine proteins=3.06g).

Results: The clinical and laboratory findings on admission necessitated the immediate start of dialysis.The imaging exploration revealed hepatosplenomegaly and normal sized kidneys with high echogenicity. There was no clinical or radiological sign of lymph node involvement.Laboratory analyses suggested monoclonal IgM+κ gammopathy,present in serum and urine immunofixation,type I cryoglobulinemia and low C4 complement levels. After clinical stabilization and restoration of anemia and thrombocytopenia,a bone marrow biopsy was performed,suggestive of a small B-cell lymphoproliferative disorder. A renal biopsy revealed a MPGN with IgMκ deposition and lymphocyte infiltration of the interstitium.

Conclusions: The rapidly deteriorating renal function in the context of nephrotic syndrome and emergence of MPGN secondary to IgMκ deposits and monoclonal gammopathy by B-cell lymphoproliferative disorder is a rare diagnosis.In similar cases, renal biopsy is a powerful diagnostic tool.

PUB202

Study of Malignancy and Chronic Infections in Patients with Biopsy Proven Membranous Nephropathy Marie B. Condon, Tom Cairns, Megan Griffith. *Imperial College NHS Trust, United Kingdom.*

Background: Membranous nephropathy (MN) is a common cause of nephrotic syndrome in adults. Most cases of MN are idiopathic, however historical studies have shown MN can also occur in association with malignancy or chronic infections. This study investigated the prevalence of these secondary causes of MN in all patients presenting to this institution with nephrotic syndrome (NS) as a consequence of MN from March 2008.

Methods: Forty-one pts presented with biopsy proven MN, 24 male, 17 female. 37 de novo presentations and 4 relapses of NS, at median time of 6 years post 1st presentation (3-18). The median age was 54 yrs (25-80), 10/41 were aged >60. 18 Caucasian, 18 Asian and 5 African/Caribbean. Blood was tested for hepatitis B, C and HIV. Pts were screened for malignancy with CT chest/abdomen/pelvis, prostate specific antigen in males and underwent endoscopic investigations if any gastro-intestinal symptoms were present.

Results: Three pts had asymptomatic chronic infections; 1 Hep B, 1 HIV and 1 pulmonary TB detected on CT scan. 2/41(5%) had solid tumours. Pt 1 (male, 74 yrs) had an asymptomatic lung malignancy, detected on CT scan. Pt 2 (male, 72 yrs) a colonic adenocarcinoma on colonoscopy performed for bowel symptoms. Both pts were presenting with a relapse of nephrotic syndrome due to MN; pt 1, 18 years after the initial diagnosis (treated with IV cyclophosphamide); pt 2, 3 years after initial diagnosis (treated with Rituximab, Mycophenolate Mofetil and Tacrolimus).

Conclusions: This prevalence of malignancy in this study is lower (5%) than some previous reports (7-16% in all patients with MN and >50% in pts >60 yrs.) Interestingly the 2 cases of malignancy in our study were in pts presenting with a relapse of their MN. Others have reported an increase in malignancy in pts with MN in the years post presentation. The contribution of malignancy to the pathogenesis of MN and the role of immunosuppressive treatment for MN in the development of malignancy is not yet clearly defined. Surveillance is required not only at diagnosis but also during follow up. The association of MN with infection and malignancy needs to be taken into account when considering treatment with immunosuppressive therapy.

PUB203

A European Network for IgA Nephropathy Focused on the Validation of the Oxford Clinico-Pathology Classification Rosanna Coppo, Laura Morando, John Feehally, H. Terence Cook, Stephan Troyanov, Daniel C. Cattran, Ian Roberts. *for the VALIGA European Immunonephrology working group, R. Margherita H.*

Background: A recent publication from an International Consensus - based on a retrospective analysis of 265 patients with IgA Nephropathy (IgAN) from 4 continents - focused on prognostic information provided by renal biopsy. According to this Oxford Classification of IgAN, mesangial hypercellularity, segmental glomerulosclerosis, endocapillary hypercellularity and tubular atrophy/interstitial fibrosis predict renal outcome independently from all clinical indicators at the time of biopsy and during follow up (KI 2009;76:534-45; and 2009;76:546-56). The number of patients and their heterogeneous origin indicated a need for validation studies involving large cohorts of patients. Some validation studies have now been published, but these are of limited size (273 cases in a Korean study, 187 in a study from USA).

Methods: To validate the Oxford classification in Europe,the ERA-EDTA scientific community was invited to participate in this study, as a new model for researches needing large integration and collaboration, aiming to enrol at least 500 European patients with IgAN.

Results: We have presently enrolled 674 IgAN patients with long follow-up or rapidly progressive course from 29 nephrology and renal pathology centers in 10 European Countries: Italy (14 centers); Spain (3 centers); Turkey, Greece, Sweden Netherlands(2 centers each); Germany, Croatia, Czech Republic, Poland (1 Center each). Renal biopsies have been scored by the local pathologist and are under central review in Oxford, UK. Clinical data at renal biopsy and during follow-up were provided by local nephrologists to the Coordinating Center, 481 further cases are being checked for completeness of clinical data and their biopsies are under review.

Conclusions: Networking is the only possible way to obtain sufficient case enrolment in studies of rare rare conditions, such as glomerular disease. This European Network, now established, is open to further research opportunities, for example genetic studies, and the development of clinical trials. This presentation at the ASN is aimed at encouraging future scientific networks.

PUB204

Epidemiology of Patients with Pulmonary Haemorrhage from Anti-Neutrophil Cytoplasmic Antibody Associated Vasculitis Admitted to the Intensive Care Unit Partha Das, Scott R. Henderson, Maria Ostermann. *Department of Nephrology and Transplantation, Guy's & St Thomas' Hospitals NHS Foundation Trust, London, United Kingdom.*

Background: Anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitides are associated with significant morbidity and mortality despite advances in diagnosis and immunosuppressive treatment. Pulmonary haemorrhage is a much feared and life-threatening manifestation of the disease and may lead to admission to the Intensive Care Unit (ICU). Our aim was to describe the epidemiology of patients with pulmonary haemorrhage admitted to the ICU in a tertiary care teaching hospital.

Methods: A retrospective case note review was performed on all patients with pulmonary haemorrhage due to new or previously diagnosed ANCA associated vasculitis admitted to ICU between 2008 - 2011 for pulmonary haemorrhage. Demographics, disease duration and previous treatments were recorded alongside reason for ICU admission, APACHE II and SOFA scores, level of organ support, immunosuppression and patient mortality.

Results: 11 patients (9 men, mean age 56.2 years ± 16.1, 10 Caucasian, 1 mixed race) were admitted to the ICU with pulmonary haemorrhage. This was thefirst presentation for 8 patients. Proteinase 3 (PR3) ANCA was positive in 8 patients, myeloperoxidase (MPO) ANCA in 1 patient, and 2 patients had no detectable ANCA. 45% of patients had received immunosuppressive treatment prior to admission in the preceding 3 months. Patients were managed by a multidisciplinary team. 63% of patients had invasive ventilation, 54% had renal replacement therapy, and 54% were treated for sepsis. 8 patients (72.7%) received steroids and cyclophosphamide treatment and 7 patients (63%) had plasmapheresis.

Mean length of stay in ICU was 13 days ±10.5 and in hospital 29 days ±20 days. 2 patients (18%) died in ICU due to bowel ischaemia. 1-year mortality of ICU survivors was 100%.

Conclusions: Outcome of patients with vasculitis associated pulmonary haemorrhage in ICU is good, even when significant organ support, immunosuppressive therapy and plasma exchange are required.

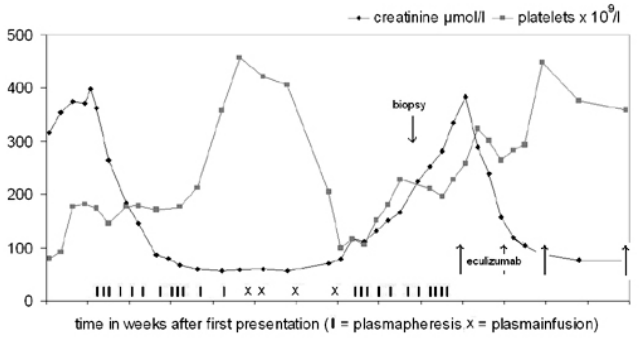
PUB205

Child with Plasma Resistant Atypical HUS Escaped End Stage Renal Failure by Eculizumab Therapy Eiske Dorresteijn,[1] Nicole Van De Kar,[2] Karlien Cransberg.[1] [1]*Pediatric Nephrology, Erasmusmc-Sophia, Rotterdam;* [2]*Pediatric Nephrology, UMC-St.Radboud, Nijmegen.*

Background: Recently, eculizumab, a humanized monoclonal antibody against C5 that blocks the terminal complement pathway, is reported to be effective in the treatment of atypical haemolytic uremic syndrome (aHUS).

Methods: We report the successful treatment of plasma resistant aHUS with eculizumab.

Results: A 6-year-old girl developed aHUS with severe renal insufficiency and hypertension. Plasmapheresis was immediately started, after which serum creatinine levels returned to almost normal after 3 weeks. Then, however, aHUS recurred shortly after an upper respiratory tract infection with influenza B virus. Her platelet count normalised after immediate intensive plasmapheresis, but the renal failure progressed, necessitating dialysis. C3 and C4 serum complement levels at the first presentation were normal, but C3d was elevated by 4.4%. Complement factors H, I, B, C3 or MCP showed no mutations. No other possible cause of aHUS was found. As end stage renal failure rapidly developed despite aggressive plasma therapy, plasmapheresis was stopped and treatment with eculizumab was initiated. Thereupon the girl's renal function promptly improved; after 8 weeks' therapy the estimated creatinine clearance had increased from 12 to 70 ml/min.1.73m^2. The multiple anti hypertensive treatment could be tapered to monotherapy with ACE inhibition. Four months after initiating eculizumab treatment, her renal function was stable at an estimated creatinine clearance of 85 ml/min.1.73m^2 with therapy every other week.



Conclusions: This case of aHUS shows that timely started, intensified plasmapheresis restored the haematological parameters, but could not restore kidney function. However, the change to eculizumab improved kidney function without the need of dialysis. Treatment with complement inhibitors might well be promising for patients with aHUS.

PUB206

Case Report: Thrombotic Thrombocytopenic Purpura (TTP) like Syndrome in the Setting of Systemic Lupus Erythematosus (SLE) Vince Faridani, Adil Akthar, Ahmed M. Awad. *Nephrology, University of Missouri - Kansas City, Kansas City, MO.*

Background: We report a unique case of a patient with SLE , manifesting as acute renal failure, thrombocytopenia, and altered mental status. TTP-Like Syndrome may present with a myriad of symptoms and laboratory abnormalities. This case highlights the diagnostic challenges raised by the occurrence of microangiopathic hemolysis in the setting of multi-organ involvement in a patient with underlying SLE.

Case: A 42-year-old African American female with a history of hypertension and systemic lupus erythematous presented with altered mental status, renal failure, and thrombocytopenia. Vitals signs revealed blood pressure of 161/113, pulse rate 153, respiratory rate 36, saturation 92% on 4 liters of nasal cannula. On examination, crackles present at both lung bases bilaterally, 3+ pitting edema in lower extremities. Notable laboratory studies were hemoglobin 9.2, wbc 11.2, platelets 138, BUN 37, creatinine 2.6. CT of the head revealed no acute processes. Echocardiography revealed an EF 10-15% with global LV-hypokinesis. Lab studies showed low complement levels, a positive dsDNA antibody screen. Dialysis was initiated in addition to 5 rounds of plasmapharesis, 1gm of methylprednisone for 3 days, and mycophenolate mofetil. Renal biopsy showed thrombotic microangiopathy with secondary segmental sclerosis and mild interstitial fibrosis and no evidence of lupus nephritis. On day 8, repeat echo showed ejection fraction of 35%, a lower serum creatinine, urine output improved and dialysis was ceased.

Discussion:

This case highlights the diagnostic challenge raised by the occurrence of microangiopathic changes in the setting of multiorgan involvement in patients with underlying SLE. Microangiopathic changes can be caused by active SLE, malignant hypertension, antiphopholipid syndrome, TTP; differentiation between these syndromes is difficult given their numerous overlapping clinical and laboratory features. Prompt institution of aggressive blood pressure control, plasma exchange, corticosteroids should be instituted within 24hrs of presentation as delay in treatment initiation may increase treatment failure.

PUB207

Microscopic Polyangiitis: Case Report in Coexistence with Systemic Lupus Erythematosus Nephritis Vince Faridani, Ahmed M. Awad, Adil Akthar. *Nephrology, University of Missouri - Kansas City, Kansas City, MO.*

Background: We report a unique case of microscopic polyangiitis (MPA) manifesting as a renal-pulmonary syndrome in the setting of systemic lupus erythematosus (SLE) nephritis.

Case:

A 66-year-old female with a history of biopsy confirmed Class III SLE nephritis, presented with shortness of breath. On examination, right lower extremity revealed a 5x8 cm erythematous, painful, palpable purpura. Notable serum studies were creatinine 1.84 mg/dL, Hb 12.8 g/dl. Urinalysis was positive for a large amount of blood. CT chest demonstrated patchy bilateral infiltrates. Bronchoscopy showed diffuse alveolar hemorrhage and endoscopy revealed diffuse erosive gastritis. Immune serology was negative for anti-GBM, anti-dsDNA, but positive for ANA, with a pANCA, and myeloperoxidase 100 units (0-9 units). She underwent 11 consecutive treatments of plasma exchange along with 1 gram IV cyclophosphamide and 1 gram daily methylprednisolone and made a full recovery.

Discussion:

This is the first reported case of MPA in the setting of established SLE nephritis. Our case exemplifies the importance of a methodical approach to an extensive list of differential diagnoses. The main clinic clues to the alternative diagnosis of renal-pulmonary syndrome were diffuse alveolar hemorrhage and erosive gastritis. A positive pANCA and high anti-MPO titers without upper respiratory involvement strongly supports our diagnosis.

PUB208

Systemic Lupus Erythematous Masking Pre-Eclampsia Vince Faridani, Ahmed M. Awad, Adil Akthar. *Nephrology, University of Missouri - Kansas City, Kansas City, MO.*

Background: Systemic lupus erythematous (SLE) is one of the most common autoimmune disorders that affect women during their childbearing years. We report a unique case of pregnancy induced SLE nephritis presenting as pre-eclampsia.

Case:

A 27-year-old African American woman, with no previous medical illnesses presents seven days status post cesarian section at 29 weeks of gestation due to worsening pre-eclampsia. She was admitted with shortness of breath and uncontrolled hypertension. Vitals, blood pressure 173/123, pulse rate 106, oxygenation 92% on 2 liters nasal cannula. Physical exam revealed, diffuse scattered rhonchi bilaterally, 2+ lower extremity edema bilaterally. Labs revealed, hemoglobin 7.2, hematocrit 22, WBC 15, Platelets 619, creatinine 1.4, albumin 1.4, positive ANA, normal C3 and C4 level, all other serologies were negative. Urine analysis was positive for RBC 12, moderate hemoglobin, protein > 300. CT chest done was suggestive of pulmonary hemorrhage which was confirmed by bronchoscopy. Percutaneous renal biopsy showed type V lupus nephritis, diffuse proliferative and membranous lupus nephritis. She was treated with methylpredisolone 1 gram for 3 days, followed by oral prednisone and mycophenolate mofetil. The patient was followed up at 2 months and 4 months at which time her creatinine returned to her baseline and she was asymptomatic.

Discussion:

Pregnancies for patients with lupus have a greater risk of fetal loss, pre-eclampsia, intrauterine growth retardation, and neonatal lupus syndrome. Thus, it is important to do a thorough assessment in patients with new onset of gestational proteinuria not to delay diagnosis. The patients course was consistent with preeclampsia and the renal biopsy confirmed the diagnosis of lupus which explained her multisystemic involvement. Clinicians should be cautious and consider SLE nephritis when treating pre-eclampsia whom present with new onset proteinuira and hypertension.

PUB209

Procalcitonin – A Good Predictor for Persisting Kidney Damage in Patients with Goodpasture's Syndrome? Susanne V. Fleig, Jan T. Kielstein. *Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.*

Background: Autoantibodies to the NC-1 domain of the type IV collagen's α3 chain are the pathogenetic basis for anti glomerular basement membrane (GBM) disease, otherwise known as Goodpasture's syndrome. It involves both the kidneys and lungs to varying degrees. Prediction of renal outcome in the phase of acute presentation of disease is difficult. Procalcitonin (PCT) has been proposed as a parameter of potential prognostic value. Based on a small group of patients (n=7), high procalcitonin (PCT) had been proposed as a predictor of poor renal outcome.

Methods: We report on a case demonstrating a severe manifestation of Goodpasture's syndrome, in which a high PCT on admission was fortunately not associated with detrimental renal outcome.

Results: Apart from dialysis, high intensity immunosuppressive therapy was begun immediately after admission in spite of high PCT. Our patient recovered to full renal function and remains free of symptoms after two years of follow-up. In contrast, a further three cases observed during 2010 presenting with acute renal failure and low procalcitonin remained dialysis dependent.

Conclusions: Our data do not confirm the notion that high procalcitonin is a good prognostic factor for renal outcome in Goodpasture's syndrome. Causal immunosuppressive therapy should not be delayed because of high PCT.

PUB210

Neurohumoral Control of Sodium Excretion in Nephrotic Syndrome (NS): A Case Report Musab S. Hommos, William G. Haynes, Bradley S. Dixon. *Int Med, U Iowa & VAMC, Iowa City, IA.*

Background: The importance of aldosterone (ALDO) and the sympathetic nervous system (SNS) in mediating sodium retention in NS has been questioned.

Methods: A 63 y/o woman, healthy except for hypertension treated with metoprolol and lisinopril, presented with renal salt wasting despite nephrotic range proteinuria (NP) from membranous nephropathy. Serial clinical exams and lab tests were performed. Autonomic function was assessed by respiratory variation in heart rate (RVHR) and by changes in BP and pulse with the valsalva maneuver and orthostasis.

Results: Two months earlier she had acute bronchitis requiring ibuprofen for chest pain. She subsequently developed incapacitating orthostatic hypotension, requiring recurrent admissions for intravenous saline during which NP was discovered. On transfer to us she had no edema and jugular venous pressure was undetectable. She was too dizzy to sit or stand. Her urine protein/creatinine ratio=8.3 gr/gr. Plasma creatinine=1.0 mg/dl and BUN=22 mg/dl. Serum electrolytes were normal. After 2 liters of intravenous saline she felt better. No further saline was administered and a day later she had recurrent orthostatic hypotension and tachycardia (supine BP 134/85, pulse 80/min; standing BP 117/77, pulse 125/min) with a urine sodium of 91 mEq/L. Plasma ALDO was undetectable and renin=0.6 ng/ml/hr. Treatment with florinef and oral salt led to edema, supine BP=160/110 and urine protein/creatinine ratio=25.3 gr/gr and was stopped. Cyclosporine with a burst and taper of prednisone led to complete remission of her proteinuria, which has not recurred. Following remission, she continued to have profound orthostatic hypotension but without tachycardia and persistent hyporeninemic hypoaldosteronism (24 hour urine ALDO=undetectable). Autonomic function testing including RVHR and valsalva confirmed primary autonomic failure (PAF) with severe sympathetic dysfunction and partially preserved parasympathetic function.

Conclusions: This patient developed PAF (possibly from a viral infection) with associated hyporeninemic hypoaldosteronism and renal salt wasting despite the presence of NP from membranous GN. Hence, ALDO and the SNS are required for the renal sodium retention of NS.

PUB211

Complete Remission Is Severe Lupus Nephritis: Assessing the Rate of Loss in Proteinuria Stephen M. Korbet, Edmund J. Lewis, The Collaborative Study Group. *Internal Medicine, Rush University Medical Center, Chicago, IL.*

Background: The prognosis of severe lupus nephritis (SLN) is improved in pts attaining a complete remission (CR). The time to remission ranges from 10-16 mos with many pts not attaining a CR until after 12 mos. We assess whether the rate of loss of proteinuria (UPro) at 3 and 6 mos is predictive of a CR in SLN pts.

Methods: We studied the 86 adult pts in the previously reported trial of plasmapheresis in SLN (NEJM 1992). All pts had ISN/RPS class IV ± class V lesions. All pts received prednisone and oral cyclophosphamide and 40 pts received plasmapheresis. A CR was defined by a serum creatinine (SCr) of ≤ 1.4 mg/dL and UPro (g/d) of ≤0.33. The change in UPro from baseline in g/d per week was determined at 3 and 6 months.

Results: CR was attained in 37 pts (44%) by 16±14 mos. The level of UPro at baseline was similar in CR and No Remission (NR) pts (5.5 vs. 6.4 g/d). CR pts had a lower SCr (1.2 vs. 2.4, P <0.0001). At 3 mos UPro decreased in CR pts by 2.3 g/d but increased by 0.19 g/d in NR pts (P-0.01) and at 6 mos UPro decreased by 4.1 vs. 1.8 g/d (P=0.006). The rate of change of UPro in CR vs. NR pts at 3 mos was (-)0.259 vs. (+)0.033 g/d/wk (P=0.01) and at 6 mos was (-)0.224 vs. (-)0.107 g/d/wk (P=0.01). The time to a CR was ≤12 mos in 19 pts and >12 mos in 18 pts. The baseline SCr was similar but the UPro was lower in pts with CR in ≤12 mos (3.9±2.7 vs. 7.2±3.0 g/d, P =0.001). The proportion of pts with MGN was similar (16% vs. 22%). At 3 mos the UPro decreased by 2.0 vs. 2.6 g/d in CR ≤12 vs. >12 mos pts (P=NS), and at 6 mos the UPro had decreased by 3.4 vs. 4.8 g/d (P=NS). The rate of change in UPro in CR ≤12 vs. >12 mos pts at 3 mos ((-)0.236 vs. (-)0.214 g/d/wk) and 6 mos ((-)0.214 vs. (-)0.235 g/d/wk) was similar (P=NS). Additionally, the rate of change in UPro at 3 and 6 mos was similar within each group.

Conclusions: The rate of change in proteinuria is significantly greater at 3 and 6 months in pts attaining a CR relative to NR pts. In pts attaining a CR at >12 mos the rate of change in UPro was similar to that in pts with CR in ≤12 mos. Thus, the rate of loss of UPro at 3 and 6 mos may help in predicting which pts will attain a CR.

PUB212

Renal Biopsy Patterns in an Urban Immigrant Population Kayode C. Lawrence, Salwa Rhazouani, Saad A. Bhatti, Sudhanshu Jain, George N. Coritsidis. *Nephrology, Elmhurst Hospital Center, Elmhurst, NY.*

Background: The types and incidence of glomerular diseases vary worldwide. Elmhurst and Queens Hospital Centers (QHN) are public hospitals located in Queens, New York, the most ethnically diverse county in the United States. We were interested in reviewing the pattern of glomerular pathology presenting to our centers from various immigrant population..

Methods: 222 patients had kidney biopsies between 2001 and 2010. 74 patients were removed from the final analysis due to incomplete data, 14 patients due to non glomerular pathology.

Data reviewed included sex, age, proteinuria, estimation of glomerular filtration rate (eGFR) at time of biopsy, this was further divided by areas of origin into Caribbean, Subcontinent Asia (India, Pakistan, Bangladesh, Nepal), Far Asia (China, Tibet, Hong Kong, Philippines, Korea, Indonesia) South and Central America.

Statistical analysis was done using analysis of variance

Results: Baseline characteristics was statistically similar in all groups.

Origin	South America	Central America	Caribbean	Subcontinent Asia	Far Asia	Total
Number	45	30	22	22	15	134
*Age	46±2.1	37±2.4	43±2.9	39±2.4	43±4.1	42±1.0
Sex (Male)	58%	37%	41%	55%	63%	51%
*Proteinuria (g/day)	7.9±2.5	6±0.8	8.1±1.7	5.7±0.8	5.4±1.5	6.6±1.0
*eGFR (mdrd ml/min)	66±9.2	66±5.5	64±8.5	67±8.9	43±8.0	61±3.1
* Serum albumin (g/dl)	2.5±0.1	2.8±0.3	2.3±0.2	2.7±0.3	2.4±0.3	2.5±0.1
African ancestry **	8	3	40	0	0	10
Lupus**	33	10	27	14	33	23
IgA**	9	20	9	18	27	16
Membranous**	13	14	27	14	13	16
Minimal change**	2	10	9	9	7	7
FSGS**	13	10	5	23	7	12

*= Mean ± SEM,** percent

Within the immigrant groups lupus continued to be the most common diagnosis, IgA was highest in far asians, while focal segmental glomerulosclerosis (FSGS) was increased in subcontinental asians. Despite 40% African ancestry within the caribbean populace FSGS was only seen in 5%.

Conclusions: Over all expected global trends were found in our population. Increased FSGS in subcontinent Asians and not caribbeans is surprising and suggests possible geographical and environmental influences in glomerular pathology that go beyond genetics.

FSGS incidence was surprisingly high among patients from subcontinent Asia.

PUB213

A Fascinating Case of Vasculitis with Mixed ANA and P-ANCA Seropositivity Sunggeun Lee, Marie-Alex Michel. *Medicine, Woodhull Medical Center, Brooklyn, NY.*

Background: To present a case of RPGN type 3 with SLE features

Methods: The patient's medical chart was reviewed to obtain the clinical course/relevant laboratory/ancillary work-up/pathology/interventions.

Results: A 60 y/o female with no past medical history who initially presented to clinic complaining of multiple joint pain. She has been using NSAIDs. The out-patient work up demonstrated Cr 1.6 ANA (+) 502, anti-SSA (+). ESR 77. normal.complements

UA: 3+ protein, 3+ heme

1 month later, the patient presented to the ER with painless hematuria and was found to have H/H 6.2/ 19.7 BUN 82 Cr 8.9

Renal U/S demonstrated large kidneys,14cm with increased cortical echogenicity

Prednisone 100mg/d and HD were started

Kidney biopsy: 25 out of 45 glomeruli showed complete obliteration with sclerosis and fibrous crescents. No immune deposits. The finding was compatible with pauci-immune GN.

Subsequently P-ANCA was (+) and C3 low

During the hospital course, patient was found to have aortic aneurysm (5.1 cm), NSTEMI , DVT , Pericardial effusion,VRE bacteremia,clostridium difficile, sepsis.

On day 31, she received pulse cytoxan and methylprednisolone.

On day 45, she was off the dialysis for 2 weeks maintaining her Cr around 3.5. HD was restarted after she developed generalized rash, edema and sepsis. Therefore, subsequent pulse cytoxan was held.

Patient had RPGN III with P-ANCA vasculitis featuring medium and large vessel involvement with NSTEMI and thoracic aortic aneurysm. In addition, she had strong clinical features of SLE: polyarthritis, pericarditis, pleuritis, anemia, ANA(+). The kidney biopsy revealed pauci-immune GN with crescents without IC deposits. She originally responded to pulse therapy. Subsequently septic course prevented further immunosupression, she became HD dependent.

Conclusions: P-ANCA RPGN can be present with SLE concurrently. This mixed seropositivity should be further investigated. Multiple cases have been reported in the literatures. Since RPGN progresses rapidly, it is important to be aggressive in diagnosing and treating. Sometimes initial symptom can be non-specific like arthritis or painless hematuria, which is why it is paramount for clinicians to always suspect RPGN in a setting as such.

Clinicopathological Findings, Long-Term Mortality and Renal Outcome in Japanese Patients with Idiopathic Focal Segmental Glomerulosclerosis

Taito Miyake,[1] Shinji Kitajima,[1] Yasuyuki Shinozaki,[1] Tadashi Toyama,[1] Akinori Hara,[1] Kiyoki Kitagawa,[1] Kengo Furuichi,[1] Hitoshi Yokoyama,[2] Shuichi Kaneko,[3] Takashi Wada.[1] *[1]Division of Nephrology, Kanazawa University Hospital, Kanazawa, Ishikawa, Japan; [2]Division of Nephrology, Kanazawa Medical University Hospital, Uchinada, Ishikawa, Japan; [3]Department of Disease Control and Homeostasis, Kanazawa University, Kanazawa, Ishikawa, Japan.*

Background: The 20-years renal survival of idiopathic focal segmental glomerulosclerosis (iFSGS) was reported around 30% in Japan. In this study, we examined clinicopathological findings, long-term mortality and renal outcome of iFSGS.

Methods: Forty seven Japanese patients (34 males and 13 females; mean age 39.0 years, mean time of follow-up was 96.0 months) with biopsy proven iFSGS from 1961 to 2010 in Kanazawa University Hospital were examined in this study. The patients were followed for more than one year, or until renal or patient death. Clinicopathological findings were evaluated for renal and patient death.

Results: Twelve renal death (25.5%, 9 males and 3 females) and 12 patient death (25.5%, 9 males and 3 females) were observed. Age of onset was higher in the group of patient death. The percentage of nephrotic syndrome out of all patients was 95.7%. Thirty out of 45 nephrotic syndrome patients (66.7%) achieved complete remission (CR) or incomplete remission I (ICRI) (proteinurea < 1 g/day) after initial treatment within 6 months, and only one renal death was observed. We treated 46 patients with corticosteroids, and 28 patients with additional immunosuppressive drugs (cyclophosphamide, 36%; cyclosporine, 64%). Sixteen out of 18 patients with additional cyclosporine treatment were achieved CR or ICRI, and only one renal death was observed. Regarding pathological findings, percentage of glomerulosclerosis was higher in group of renal death. The pathologic variants were as follows; Perihilar, 13%; Cellular, 13%; Tip, 36%; and not other specified (NOS), 38%. Five renal deaths were observed in 6 patients with perihilar variant.

Conclusions: The good response of initial treatment within 6 months, and cyclosporine may be favorable prognostic factors.

PUB215

Clinicopathological Study of the Possible Relation between Hepatitis C Virus Infection and Nephrotic Syndrome in Children

Arwa Nada,[1,2] Morris J. Schoeneman,[1] Mona Salem,[3] Dalal Elkaffash,[4] Hanan K. Tawadrous,[1] Mahmoud El-Kersh.[2] *[1]Pediatrics, Division of Nephrology, SUNY Downstate Medical Center, NY; [2]Pediatrics, Division of Nephrology, Alexandria University Children's Hospital, Alexandria, Egypt; [3]Pathology, Alexandria University, Alexandria, Egypt; [4]Clinical Pathology, Alexandria University, Alexandria, Egypt.*

Background: Glomerulonephritis (GN) is one of the major consequences of HCV infection in adults. Neither the course of nephrotic syndrome (NS) in children with HCV infection nor the effect of interferon therapy were studied thoroughly in children.

Objective: To study the possible clinicopathological relation between HCV infection and cases of NS in children who are steroid resistant or dependent

Methods: Sixty children were found to be HCV positive out of 378 who presented with NS between 2004 and 2009 at Alexandria University Children's Hospital, Egypt, 20children were steroid resistant or dependent on high dose corticosteroids. Those twenty patients were subjected to comprehensive biochemical, histological, virological and immunological investigations. RT-PCR to detect HCV RNA was performed in the kidney biopsy. The pattern of steroid responsiveness was studied before and after HCV infection. Interferon and ribavirin therapy was given to 9 children with assessment of proteinuria before and during therapy.

Results: FSGS accounted for 50% of the patients, MPGN accounted for 20%, 5% endocapillary proliferation, 5% minimal change NS, 5% fibrillary glomerulonephritis, 5% mesangioproliferative GN, and 10% inadequate renal biopsies. None of the patients showed clinical or laboratory manifestations of cryoglobulinemia. RT-PCR for HCV RNA was positive in 80% of children. Significant worsening was observed in the pattern of steroid responsiveness after HCV infection (p= 0.001). Significant reduction of proteinuria was observed in the 9 children who received therapy with interferon and ribavirin (p= 0.004).

Conclusions: HCV infection worsens the course of NS in children based on detecting the virus RNA in the renal biopsy, increased steroid requirements after HCV infection and the significant reduction of proteinuria after treatment with interferon and ribavirin.

PUB216

Retrospective Analysis of Enteric Coated Mycophenolate Sodium Therapy in Patients with Adult Primary Nephrotic Syndrome Who Relapsed or Were Resistant to Standard Treatment

Miguel Angel Nadal,[1] Bruno Lococo,[2] Alcira B. Otero.[3] *[1]Nephrology, DAOMI, Caba, Argentina; [2]Nephrology, DIAVERUN, Caba, Argentina; [3]Argentina Medical Department, Novartis SA, Caba, Argentina.*

Background: Mycophenolic acid is an optional treatment of Adult Primary Nephrotic Syndrome relapsant/resistant to standard therapy with Corticosteroids (Cs) and/or alkylating agents (Al). Enteric coated mycophenolate sodium (ecMPS) is a formulation designed to improve gastrointestinal tolerability.

Methods: A retrospective analysis of nephrotic syndrome patients resistant to standard (st) therapy and treated with ecMPS was performed in Argentina. They were 53 patients, 60% males, aged 44 ± 17 years old. Baseline biopsies: Idiopathic membranous nephropathy IMN I: 2 and IMN II-III: 18, membrano proliferative glomerulo nephritis MPGN: 5, focal segmental glomerulosclerosis FSGS: 12, mesangial glomerular disease 1, and Minimal Changes MCD: 9, IgMN: 4, C1qN: 2. Entry criteria: diagnosis of Nephrotic Syndrome (urinary protein ≥ 3g/24hs and serum albumin ≤ 3g/dl) with BP ≤ 140/90 mmHg (under treatment) after relapse or resistance to st therapy (Cs and/or Al). Patients received ecMPS 1440 mg bid during 12 months. Primary endpoint: percentage of patients achieving complete (urinary protein <0.5 g/day and albumin > 3 g/dl) or partial (urinary protein 0.5-3 g/24hs and albumin > 3g/dl) response. Analysis applied consisted of descriptive statistics

Results: Patient effectiveness results are summarized by response to therapy in the table.

Response N (%)	Albumin g/dl		Creatinine mg/dl		Urinary protein (g/24hs)	
	Baseline	Month 12	Baseline	Month 12	Baseline	Month 12
CR: 22 (42)	2.6±2.2	3.8±0.6	1.1±0.4	1.0±0.0	9.5±7.9	0.1±0.0
PR: 11 (20)	2.6±0.8	3.9±0.3	0.9±0.1	1.3±0.9	8.6±5.1	1.5±0.6
NR: 20 (38)	2.4±1.1	3.3±1.2	1.3±0.7	3.3±2.6	7.4±2.3	7.6±3.0

Responders (complete or partial) included: IMN I: 1/2, IMN II-III: 11/18, MPGN: 5/5, FSGS: 7/12, MCD: 4/9, IgMN: 3/4, C1qN: 2/2. Safety findings included five infections: 4 herpes virus and 1 cellulitis; 2 anemia and 5 mild diarrhea episodes.

Conclusions: One year treatment with ecMPS provided a complete or partial response of 33/53 (62%) in patients relapsant/resistant to prior standard therapy including Cs and or AI.

Clinicopathological Analysis of Primary Focal Segmental Glomerulosclerosis in 560 Cases

Hong Ren, Wen Xue, Xiaoxia Pan, Xiao Li, Wen Zhang, Nan Chen. *Department of Nephrology, Ruijin Hospital, Shanghai Jiao Tong University, Shanghai, China.*

Background: To investigate the relationship between clinical and pathological features of primary focal segmental glomerulosclerosis (FSGS) .

Methods: The data of 560 patients diagnosed as primary FSGS from January 2002 to December 2010, excluding secondary FSGS by renal biopsies in Shanghai Ruijin Hospital, were reviewed and analyzed retrospectively.

Results: Of the 560 cases of primary FSGS, 331 were males (55.9%) and 247 females (44.1%). The median age of onset was 41 yrs (ranging 16-79 yrs). The median case history was 6 months (range 2 days to 40 years). Proteinuria (97.7%) was the most common clinical manifestations. However, its severity varies from minor or moderate, that is, 1 g/day to 3.5 g/day the most common (41.2%), followed by nephrotic levels, >3.5g/day (27.7%). Primary FSGS is always accompanied by microscopic haematuria (61.4%) and hypertension (31.4%). The percentage of patients in CKD stages 1~3 was approximately 81.9%. Pathologically, the NOS (not other specified) variant was the most frequent type (91%) .The percentage of patients with glomerular sclerosis grade 1~2 and TIL stage 0~2 was 75.7% and 92.1%, respectively. Patients with renal vascular lesions accounted for 58.2%. The results of immunofluorescent study were negative in 68% of the cases while deposits of IgM (19.1%) and C3 (21.3%) component of complement were seen within the segmental scars. The degree of glomerulosclerosis and tubulointerstitial lesion was positively with serum creatinine (P<0.01) . A positive corelation was also found between glomerulosclerosis and tubulointerstitial lesion (P<0.01). Patients with vascular disease suffered much more severe clinical manifestations and renal pathological changes.

Conclusions: We retrospectively analysed the largest data of clinical and pathological features in 560 primary FSGS. The main clinical manifestation of primary FSGS is proteinuria. In addition, haematuria, hypertension and renal dysfunction are common presenting features. Glomerulosclerosis, tubulointerstitial and renal vascular lesions, which contribute to renal insufficiency, are common when the patients are diagnosed as primary FSGS.

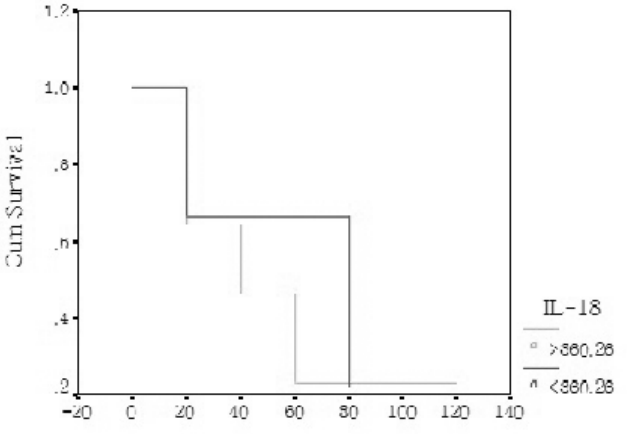
PUB218

Serum Interleukin 18 Levels Are Closely Associated with the Progression of IgA Nephropathy Beili Shi, Minjie Zhou, Liou Cao, Shan Mou, Qin Wang, Ling Wang, Wei Fang, Yucheng Yan, Aiwu Lin, Minfang Zhang, Renhua Lu, Mingli Zhu, Jia Qi Qian. *Renal Division, Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China.*

Background: IgA nephropathy (IgAN) was once thought to be benign but recently found to be slowly progressive. The aim of this research is to investigate the value of serum IL-18, a biomarker for tubule injury, for assessing the disease progression in IgAN patients.

Methods: Serum IL-18 in patients with IgAN and healthy controls were measured by ELISA. Percentage of global glomerular sclerosis (GGS) and extent of tubulointerstitial damage (TID) were semiquantitatively estimated. Deterioration in renal function was defined as a 50% increase of serum creatinine than baseline.

Results: 36 patients (19 females, 37.9±9.7 years) were enrolled and presented with 2.6 (1.7-3.1)g/day proteinuria . Compared with controls, serum IL-18 levels were significantly elevated in IgAN (360.3±25.2 vs 51.2±8.9 pg/ml, P<0.01). Univariate analysis showed that albumin(r=-0.395, P=0.001), proteinuria (r=0.494, P=0.002), Serum creatinie (r=0.61, P<0.001), and eGFR (r=-0.598, P<0.001) were significantly correlated with IL-18 levels. TID scores showed a borderline significance with serum IL-18 levels (r=0.355, P=0.057), whereas GGS did not. During 38 (12-60) months of follow-up, 14 patients (38.89%) had a deteriorated renal function. Spearman correlation analysis showed that baseline IL-18 were correlated with decline of eGFR (r=-0.127, P=0.045). Kaplan-Meier analysis found those who with elevated IL-18 had a poorer renal outcome (P=0.008) and Cox analysis further confirmed that serum IL-18 levels were independent predictor of renal outcome (β=0.984, 95%CI 0.926-1.,042, P<0.001).



Figue 2. IgAN patients with elevated serum IL-18 levels at baseline (>360.26pg/ml) predict renal function deterioration in the follow-up period.

Conclusions: Elevation of serum IL-18 levels may be served as an early biomarker of predicting renal disease progression in patients with IgAN.

PUB219

Intravenous Corticosteroid Pulse Therapy Predicts the Remission of Proteinuria in Patients with Minimal Change Nephrotic Syndrome, along with Serum Creatinine and Age Maki Shinzawa,[1] Ryohei Yamamoto,[1] Yasuyuki Nagasawa,[1] Susumu Oseto,[2] Kakuya Niihata,[3] Yoshitsugu Obi,[1] Megumu Fukunaga,[2] Yoshiharu Tsubakihara,[3] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Internal Medicine, Toyonaka Municipal Hospital, Toyonaka, Osaka, Japan; [3]Nephrology and Hypertension, Osaka General Medical Center, Osaka, Japan.*

Background: Little information is available about predictors of effectiveness of corticosteroid in adult patients with MCNS.

Methods: In the present multicenter retrospective cohort study in 3 major nephrology centers, eligible patients were 75 patients aged ≥15 yr who were diagnosed as new-onset primary MCNS by kidney biopsy between 2000 and 2009. The outcome was time from initiation of corticosteroid to complete remission of proteinuria (CR), defined as urinary protein <0.3g/day, urinary protein/creatinine ratio (UPCR) <0.3, or negative/trace for UP by dipstick. Predictors of CR were identified using log-rank test and multivariate Cox proportional hazard (CPH) models.

Results: Baseline characteristics; age 38 (20-61) yr median (interquartile range), male 45(60%), serum creatinine (Cr) 0.9 (0.7-1.3) mg/dL, UPCR 10.8 (5.8-19.9). No significant difference was observed in baseline characteristics of 26 patients with intravenous methylprednisolone pulse (mPSL) and 49 patients with prednisolone (PSL), except serum albumin (1.7±0.6 vs. 2.0±0.5 g/dL, P=0.015) and UPCR (6.2 (3.5-15.8) vs. 12.9 (8.4-19.9)). During 5.5 (3.0-9.5) yr of observational period, mPSL patients had significantly higher cumulative probability of CR, compared with PSL patients (time to CR, 10 (7-22) vs. 22 (9-44) days, P=0.023 for log-rank test). Use of mPSL (HR 1.93 [95%CI 1.11-3.34], P=0.020) was identified as predictor in multivariate CPH models adjusting for clinically relevant factors, besides age (per 10 yr, 0.84 [0.73-0.96], P=0.012) and log(Cr) (0.22 [0.06-0.73], P=0.013).

Conclusions: The present study, based on one of the largest MCNS cohort in the world, identified intravenous corticosteroid pulse therapy as a predictor of CR in patients with MCNS, along with serum creatinine and age.

PUB220

Treatment of Hepatitis B Associated IgA Nephropathy In O Sun, Yu Ah Hong, Hyun Gyung Kim, Sun Ryoung Choi, Byung Ha Chung, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim, Bumsoon Choi. *Division of Nephrology, Department of Internal Medicine, Catholic University of Korea, Seoul, Republic of Korea.*

Background: A strong association between IgA nephropathy (IgAN) and hepatitis B surface (HBs) antigenemia has been reported in endemic regions. However, there are few data about treatment of HBV-associated IgAN. We describe our experiences about treatment of IgAN with HBsAg.

Methods: From 1996 to 2010, biopsy-proven IgAN was diagnosed in 498 patients and 22 (4.4%) had HBsAg. We evaluated the clinical feature and therapeutic responses of IgAN with HBsAg.

Results: The patients included 16 men and 6 women, with a mean age of 37 years (range, 18-56). All were seropositive for HBsAg, and hepatitis e antigen (HBeAg) or circulating HBV DNA was detected in nine patients (41%). The mean follow-up duration was 77 months (range, 14-160). Out of 22, two patients (9%) developed end-stage renal disease requiring hemodialysis during follow-up. Comparing the patients (N=9) with HBeAg or circulating HBV DNA and those (N=13) without, there were no significant differences in the changes of estimated GFR, urinary protein excretion and renal survival between two groups during follow-up. Six out of nine patients with HBeAg or HBV DNA were treated with anti-viral agents, but the treatment didn't show any benefits on the clinical outcomes in comparison with patients not treated with. Five patients were treated with steroid. Out of 5 with steroid therapy, 2 had HBeAg or HBV DNA, whereas 3 didn't have. During steroid treatment, no hepatic flare occurred in three patients who didn't have HBeAg or HBV DNA despite no anti-viral therapy. But one patient out of 2 with HBV DNA experienced active viral replication when the patient stopped receiving lamivudine during follow-up. On the other hand, one patient who had maintained entecavir consistently had no hepatic flare.

Conclusions: There were no differences of clinical outcomes between the patients with HBeAg or HBV DNA and those without. However, when the patient with HBeAg or HBV DNA should receive immunosuppressant including steroid, it is necessary to combine anti-viral therapy to prevent viral replication.

PUB221

A Case Report of Chronic Osteomyelitis Causing Secondary Renal Amyloidosis Dhwanil Vyas, George George Sunny, Anuja Vyas. *University of Connecticut.*

Background: Secondary Amyloidosis is usually seen in diseases of chronic inflammation such as Rheumatoid Arthritis, Inflammatory Bowel Disease, Bronchiectasis and Familial Mediterranean Fever. It is rarely reported in patients with chronic osteomyelitis.

Results: A 50 year old Hispanic female was admitted for right lower extremity swelling secondary to cellulitis. Her past medical history includes spinal cord tumor resection at the age of 27 years with residual paraplegia. Over past few years, patient developed a sacral decubitus ulcer and chronic osteomyelitis after unsuccessful surgical interventions. The patient also has Type 2 Diabetes Mellitus without known complications.

Her physical examination was significant for right lower extremity cellulitis and paraplegia.

A urinalysis, obtained as a part of routine studies, showed proteinuria. A 24 hour urine sample had 19 grams of protein. Of note, her serum creatinine was within normal range. Work up including Hepatitis panel, ANA, Anti- dsDNA Ab, complement levels, SPEP and UPEP were negative/within normal level. Fundoscopy did not show diabetic retinopathy.

Renal biopsy was obtained. Light microscopy of glomeruli, tubulo-interstitium and the walls of the blood vessels showed signs of Amyloid deposition with positivity to Congo Red and Thioflavine T stains. Immunohistochemical stain for Amyloid AA was positive. Electron microscopy showed matted deposits of randomly oriented, non-branching fibrils consistent with Amyloid material in the mesangium. Diagnosis of Renal Amyloidosis (AA) was made. In this patient, the triggering factor was chronic osteomyelitis.

Patient's renal function kept worsening as we could not treat her underlying osteomyelitis. Patient was placed on hemodialysis within 2 months after the diagnosis of Secondary Renal Amyloidosis was made.

Conclusions: Outcomes in Secondary Amyloidosis usually depend on the control of the underlying disease. There have been case reports of Secondary Amyloidosis caused by osteomyelitis disappearing clinically and pathologically after successful treatment of osteomyelitis. However, if the underlying disease is not treated, the outcome can be detrimental.

PUB222

Mycophenolate Mofetil Rescue Therapy in Primary Glomerulonephritis with Chronic Renal Injury Suya Wang, Xianping Yu, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China.*

Background: The role of mycophenolate mofetil (MMF) in chronic kidney disease (CKD) is not conclusion. MMF may be an effectively therapy for chronic renal injury with active lesions.

Methods: During 2005.2 to 2011.1, 5 patients with CKD-III-IV stage were treated by MMF. Renal biopsy proved the diagnosis were IgA nephropathy (lee IV-Vstage) in 4 cases, and proliferative sclerosis glomerulonephritis in 1 case. The kidney pathological changes in the 5 patients were characterized by glomerular sclerosis by 10.34% to 56.25%, respectively; adhesion of glomeruli and Bowman's capsule in 4 cases; proximal tubular atrophy by 10% to 70%, respectively; 4 patients shown cellular and/or segmental crescent by 6.25%, 6.9%, 17.65%, 25%, respectively, and diffuse mesangial proliferation. The inflammatory cell infiltration in vascular loop cavity were seen in 2 cases; 4 patients presented with tubulitis; multiple foci or diffuse interstitial infiltration of inflammatory cells in all 5 patients, and inflammatory cells in peritubular capillaries cavity were visible in 2 patients. Immunofluorescence IgA and C3 deposited 3-4+ as mass shape in mesangial region in 4 and 5 cases, respectively. According to the renal pathological activity targets, 5 patients were treated with oral MMF (0.75-1.0g/d).

Results: All patients were followed up by 22.7±28.31 (range 4-72) months.The duration of MMF therapy was 6.2± 2.59 (range 3-10) months. The average serum creatinine (Scr) level at renal biopsy was 247.4±62.19 (range 178-322) μmol/L, compared with the last Scr level after treatment (147.6±39.07, range 63-191 μmol/L), P=0.016. The mean eGFR before treatment was 30.17±8.55 (range 23.5-40.3) mL/min/1.73m^2, related to the last eGFR after treatment (53.87±19.36, range 38.98-86.31 mL/min/1.73m^2), P=0.035. The Scr level in 3 patients decreased to normal at 1-3 months after treatment. Scr levels decreased to less than 200 umol /L at 1.5 and 6 months after treatment in the other 2 cases.

Conclusions: This small sample study showed MMF therapy can effectively save kidney function and delay renal failure in primary glomerulonephritis with chronic renal injurry and active lesions.

PUB223

Histopathologic Classification of Glomerular Lesions in ANCA-Associated Glomerulonephritis in Children: A Single Center Experience Adam Weinstein, Swarupa R. Eskapalli, Samuel K. Okoh, Martha L. Graber, Thomas M. Kaneko, Alan R. Schned. *Dartmouth Hitchcock Medical Center, Lebanon, NH.*

Background: There are few reports of outcome of antineutrophil cytoplasmic autoantibody (ANCA)-associated glomerulonephritis (GN) in the pediatric population, in particular regarding the classification schema by Berden et al, which found class an independent predictor of outcome in a cohort of 100 adults.

Methods: We performed a retrospective analysis of all 5 children, age 7 to 13, with ANCA-associated GN at a Northern New England center over the past 10 years. We compared clinical outcomes to Berden's schema that distinguishes between 4 classes of ANCA-associated GN based on the appearance of glomeruli: Focal (F), crescentic (C), mixed (M) and sclerotic (S).

Results: All biopsies were categorized: 3 as class C; 2 as class M; none as class F or S. Biopsies had a mean of 12.4 glomeruli per sample. Patients were followed for 34.4 (7-79) months. 3 of 5 patients were female. All patients received cyclophosphamide and corticosteroids for initial therapy; none received apheresis. Estimated GFR (eGFR) at entry for the class C patients was 21, 24, and 30 mL/min/1.73m^2. These patients responded to treatment with eGFR's of 90, 107, and 115 mL/min/1.73m^2 at most recent follow-up ($p<0.001$). The 2 class M patients presented with eGFRs of 79 and 80. These have decreased to 47 and 66 mL/min/1.73m^2 at last follow-up. None have reached ESRD. One class C patient relapsed after 2 years follow-up. She required acute dialysis, but died from complications of immunosuppression.

Conclusions: We describe a 10 year single center experience of ANCA-associated GN in 5 pediatric patients. Though this is a small sample size, our patients responded as predicted by Berden et al's study and classification scheme. Further, our patients responded similarly to other pediatric cohorts, demonstrating a better prognosis compared to published reports in adults. We conclude that the proposed schema should be studied further in the pediatric population to gauge whether it will be a reliable tool in these patients. Due to small numbers of patients, multicenter collaboration will likely be needed.

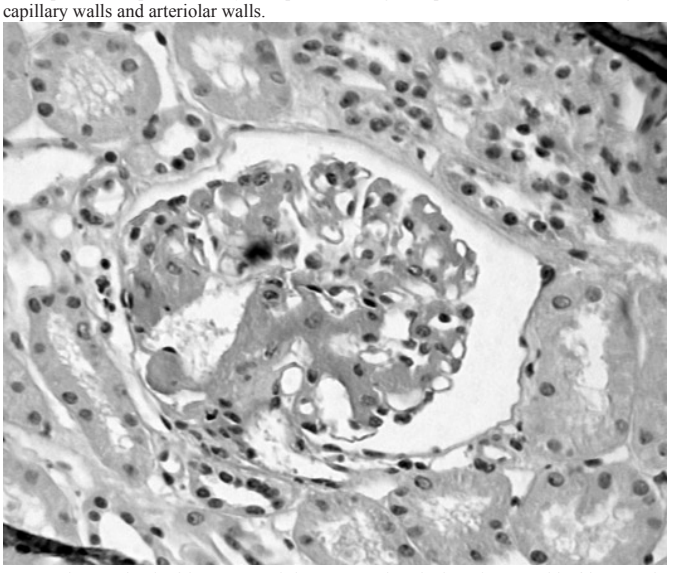
PUB224

AH-Amyloidosis Related to Franklin Disease Elena Zakharova,[1] Ekaterina Stolyarevich.[2] *[1]Nephrology, Clinical City Hospital n.a. S.P. Botkin, Moscow, Russian Federation; [2]City Nephrology Center, Moscow, Russian Federation.*

Background: Firstly described in 1990, AH-amyloidosis is exceptional condition, associated with plasma cell/B-cell lymphoproliferative disorders, with only few cases derived from heavy chains μ and γ thus far reported

Methods: 45 y.o. Caucasian female presented with weakness, night sweats, mild anemia (Hb 10.4 g/dl), proteinuria (1.2 g/day) and splenomegaly. We performed kidney biopsy, serum and urine protein electrophoresis, immunoelectrophoresis, immunofixation electrophoresis, and bone marrow biopsy with immunohistochemical examination

Results: Kidney biopsy revealed no proliferative changes, and showed deposition of eosinophilic, amorphous, weakly PAS-positive, Congo red-positive material in mesangium, capillary walls and arteriolar walls.



Sections stained with Congo red demonstrated typical apple-green birefringence in polarized light. Immunofluorescent study of infixed frozen tissue for IgA, IgM, IgG, C3, C1q, κ and λ proved to be positive only for IgG in mesangial zones, immunohistochemistry on formalin fixed/paraffin embedded tissue with immunoperoxidase staining for amyloid A-protein was negative. Immunochemical study showed presence of paraprotein heavy chain γ both in serum and urine, profound secondary immunodeficiency and glomerular proteinuria. Bone marrow smear found elevated lymphocyte count up to 32%, bone marrow biopsy revealed clusters of CD20+ B-lymphoid cells, and a great number of CD38+, CD138+ plasma cells

Conclusions: Based on clinical presentation with weakness, night sweats, anemia, splenomegaly, and workup showing lymphoplasmacytic infiltration of bone marrow, presence of paraprotein heavy chains γ, secondary immunodeficiency and kidney amyloidosis with positive immunofluorescence for IgG, the patient was diagnosed with Heavy chain disease γ (Franklin disease) with AH-amyloidosis and treated with rituxima b+bortezomib+dexametasone

PUB225

The Safety and Efficacy of Percutaneous Renal Biopsy by Physcian-in-Training in an Acadamic Teaching Setting Bereket Alemu,[1] Mehrdad Hamrahian,[1] Albert W. Dreisbach,[1] Eva Csongradi,[2] Luis A. Juncos,[1,2] Tibor Fulop.[1] *[1]Department of Medicine, University of Mississippi Medical Center, Jackson, MS; [2]Department of Physiology and Biophysics, University of Mississippi Medical Center, Jackson, MS.*

Background: The safety and efficacy of percutaneous renal biopsy (PKB) is relatively little studied in a purely training setting. We performed a retrospective cohort review of our consecutive 3-year renal biopsy experience (01/2007 - 12/2009) at the University of Mississippi Renal Fellowship Program.

Methods: We collected data on numerous baseline and procedure related variables, as well as complication rates. All biopsies were performed exclusively by Renal Fellows under real-time ultrasound (US) visualization within a framework of structured US-PKB training course. Data was analyzed with PAWS Statistics 18 and the results expressed as either percents or means with standard deviation (±SD).

Results: 70 patients underwent PKB during the index period, 50 (71.4%) of native kidneys. Age was 40.4 (±13.7) years, blood pressures 140/84.7 (±20.8/14.6) mmHg and biopsied kidneys measured 11.7 (±1.6) cm. Serum creatinine was 3.16 (±3.09) mg/dL, random urine protein/creatinine ratio 5.22 (±7.16) and urine sediments showed 12.9 (±24.8) RBC and 10.7 (±20.7) WBC/high-power fields. Specimens appeared "Sufficient" in 64 (91.4%), "Borderline" 4 (5.7%) at bedside inspection. We recovered 18.6 (±11.4) glomeruli per procedure (range: 0-72; median 17.5); 2 biopsies (2.8%) remained unsuccessful. There was a very close correlation between preceding history and recovered diagnoses of diabetic changes (r 0.580; $p=1.74\ 10^{-7}$) and lupus nephritis (r 0.847; $p=5.04\ 10^{-20}$). Only 3 specimens returned with "No diagnostic changes". Initial Hemoglobin of 10.7 (±1.8) g/dL dropped by 0.5 (±0.73) after PKB (NS). Three (4.3%) patients needed transfusion; 1 patient experienced persistent urine leakage, but no one needed surgical or radiological intervention or died.

Conclusions: In the setting of well-structured training environment, US guided PKB performed by relatively inexperienced operators in-training is safe and an essential component of fellowship training.

PUB226

Prenatal Ultrasound Prediction of Postnatal Renal Outcome in Fetuses with Renal Abnormalities Gianluigi Ardissino,[1] Simona Boito,[2] Elisa Dusi,[3] Francesca Tel,[1] Sara Testa,[1] Stefano Ghirardello,[3] Fabio Mosca.[3] *[1]Pediatric Nephrology Unit, Fondazione Ca' Granda Osp Maggiore Policlinico, Milano, Italy; [2]Department of Obstetrics and Gynecology 'L. Mangiagalli', Fondazione Ca' Granda Osp Maggiore Policlinico, Milano, Italy; [3]Neonatal Intensive Care Unit, Fondazione Ca' Granda Osp Maggiore Policlinico, Milano, Italy.*

Background: To examine the predictive role on renal function at 6 mos of age, of amniotic fluid (quantitative) and renal echogenicity in fetuses with bilateral renal abnormalities.

Methods: We searched our database and identified all cases of fetal renal abnormalities, normal karyotype and no evidence of other structural defects on ultrasound for which data on post natal renal function were available. Post-natal renal function was classified into 3 severity categories: a. CKD1 b. CKD2-4, c. CKD5.

Results: We identified 29 cases of isolated renal abnormalities in fetuses subsequently born at term of pregnancy (ge] 38 weeks), which were divided into two groups. The first group included 12 cases of obstructive uropathy with bilateral moderate to severe hydronephrosis. The second group included fetuses with PKD (N: 6), ranal dysplasia (N:11). The mean gestational age at the time of the scan was 26.5 (range 14-36) weeks. In all fetuses with obstructive uropathy both amniotic fluid and renal echogenicity were normal and had a normal renal function (CKD1) postnatally. In the second group, 8 patients (47%) were classified as CKD1: 7 (88%) had normal amniotic fluid and 6 cases were associated with hyperechogenic kidneys. Five patients (29%) were classified as CKD2-4; all were characterized by oligo (4) or anhydramnios (1) and hyperechogenic kidneys. In those pts requiring dialysis (CKD5), 3 out of 4 had anhydramnios and the remaining one oligohydramnios. In all of these cases the kidneys were hyperechogenic.

Conclusions: Amniotic fluid production is the main predictive indicator of post-natal renal outcome. The finding of hyperechogenic kidneys with normal amniotic fluid is associated with a normal postnatal renal function at 6 mos of age.

PUB227

Safety and Efficiency of Native Kidney Percutaneous Biopsy Stanislas Bataille,[1] Laurent Daniel,[2] Stephane Burtey.[1] *[1]Nephrology, Hôpital Conception, Marseille, France; [2]Anatomopathology, Hôpital Timone, Marseille, France.*

Background: Renal biopsy (RB) procedures vary among nephrology units. We compared efficacy and complications of different native kidney percutaneous RB procedures.

Methods: RB data from 5 nephrology units (C1 to C5) performed between 2006 and 2010 were recorded: age, gender, number of glomeruli on light microscopy (LM) and immunofluorescence (IF) and serious adverse event.

Results: Before RB, all centers required platelet count, coagulation test and clotting time except in C3 which required no clotting time and C4 which required no platelet count and no clotting time. C1 performed US assessment before RB, C2 and C4 real-time US guidance, C3 and C5 tomodensitometry guidance. C1, C2 and C3 used 14 gauge core cutting needles, C4 and C5 16 gauge.

Data from 943 RB were collected (C1:408; C2:254; C3:81; C4:136; C5:64). Number of failed biopsies, was 48/943(5%) on LM. It was higher in C1 and C3 than in other units ($p<0.001$). Number of failed biopsies on IF was 99/943(10%). It was higher in C3 than in other nephrology units ($p<0.001$). On LM, mean number of glomeruli was 14.2+/-8.6(mean +/-SD). It was higher in C1 and C2 than in C3, C4 and C5 ($p=0.01$). On IF, mean number of glomeruli was 4.4 +/-3.3. It was higher in C1 and C2 than in C3, C4 and C5 ($p<0.001$). In multivariate analysis, the only factor that influenced number of glomeruli was the nephrology unit ($p=0.004$). Complications occurred in 14/943(1.5%) of biopsies with no difference between nephrology units.

Conclusions: Number of failed RB was higher in C1 and C3. In these two units, failed RB are mainly due to the absence of renal core. The absence of kidney sample is certainly due to an imprecise kidney location. Thus, practices could be improved, especially in C1 where no real-time radiological guidance is performed. In C1 and C2, mean number of glomeruli were higher than in other units. These two units which have the higher number of glomeruli are the two units who perform the more RB: experience may be important for efficiency. Technical procedure does not affect the rate of serious complications.

RB is safe. Experience, radiological guidance or core-cutting needle-size could influence quality of RB.

PUB228

Free Light Chains in Urine – An Additional Diagnostic Tool To Detect Cast Nephropathy? Raoul Bergner, Nikolaos Karapanagiotidis, Jochen Breuer, Michael J. Uppenkamp, Martin Hoffmann. *Medizinische Klinik A, Klinikum Ludwigshafen, Ludwigshafen, Germany.*

Background: The examination of free light chains (FLC) in serum is a very useful diagnostic tool in patients with monoclonal light chain (MLC) disease. About 30% of patients with multiple myeloma (MM) have renal involvement at the time of diagnosis increasing to 50% during the course of disease. But different kinds of renal involvement have different prognostic values. Cast nephropathy (CN) usually progresses very rapidly to end stage renal disease. Currently the type of renal involvement can be diagnosed correctly only by kidney biopsy. We investigated if the analysis of FLC in urine may be helpful to predict the type of renal involvement.

Methods: We analysed the excretion of FLC in urine in patients with MLC associated disease who underwent kidney biopsy because of unclear proteinuria or renal insufficiency. Patients were grouped according their histological findings: 1: CN, 2: light chain deposit disease (LCDD), 3: AL amyloidosis (ALA), 4: other renal disease (ORD). Urine FLC was determined by immune electrophoresis and immunoessay.

Results: Kidney biopsies of 94 patients with MM (n=52), B-cell Non Hodgkin lymphoma (B-NHL n=5), AL-amyloidosis (ALA n=15) and monoclonal gammopathy of undeterminated significance (MGUS n=22) were available. The findings in kidney biopsy were CN n=27, LCDD n=6, ALA n=19 and ORD n=42.

If the critical FLC concentration for detecting a CN was defined with >50mg/dl, the sensitivity was 85%, the specificity 79%. With FLC concentration >75mg/dl the sensitivity was 78% the specificity was 85%, respectively. Adjusted to the renal function (FLC x 1/GFR) the sensitivity and specificity was 93% and 87% for a quotient > 2 and 81% and 94% for a quotient >5, respectively.

Conclusions: This data demonstrate that the examination of FLC in urine is helpful to find patients with CN. Patients with LCDD or ALA had significant lower FLC concentrations in urine and better renal function at the time of diagnosis. This might be important in patients who are not eligible for kidney biopsy. Because CN decreases very often rapidly with renal function the correct diagnosis of renal involvement is important for treatment decisions.

PUB229

Renal Function in Myeloma Patients Treated with Ibandronate Raoul Bergner, Jochen Breuer, Nikolaos Karapanagiotidis, Michael J. Uppenkamp, Martin Hoffmann. *Medizinische Klinik A, Klinikum Ludwigshafen, Ludwigshafen, Germany.*

Background: Treatment of myeloma bone disease (MBD) with bisphosphonates (BP) is standard of care. However, renal toxicity due to BP treatment tends to be a major problem in myeloma patients (MP), especially. At highest risk are patients with reduced renal function (RF) and patients who had switched the BP. Toxicity appears typically after few month of BP treatment.

We evaluated the renal safety of ibandronate (IBD) in MP, who were treated with IBD for MBD. The patients were stratified according to pretreatment and kidney function.

Methods: In a prospective noninterventional study (NIS) about safety and efficacy of IBD in breast cancer patients it turned out that MP were also included unintentionally. Out of 3540 documented patients 105 MP were identified. The data from these MP were evaluated separately.

The patients were subdivided in 4 groups according to their RF: GFR >90 (1), 60–90 (2), 30–59 (3) and <30 (4) ml/min. Since pretreatment with other BP could be of influence, patients were analysed according to former pretreatment: no BP, IBD, and other BP. The RF was calculated every month over a period of six month by the MDRD-formula.

Results: 105 patients were available for evaluation. In 99 patients RF was documented over a minimum of 5 months. The initial RF was (1) n=14, (2) n=36, (3) n=38 and (4) n=17, respectively. At baseline there were no differences in RF according to their pretreatment. The IBD dosage was 6 mg in 90% of all infusions, 4 mg in 3,6%, 3 mg in 2% and 2 mg in 4.4%, respectively. The GFR was stable over time in the groups 1-3 and improved significantly in group 4: GFR +15.6 ml/min [95%CI 1.0–32.9];

In 9 patients the treatment was terminated prematurely, due to disease progression (n=3), death due to myeloma during study period (n=3). Two patients were lost by follow up and one patient declined further treatment.

Conclusions: The data of this NIS demonstrate, that there is no evidence for renal toxicity of IBD in MP in all stages of RF. Quite in contrary to previous observations with other BP patients with worse kidney function (stage 4) had a significant improvement of GFR over the study period.

PUB230

The Role of a CT Urogram in a Stone Clinic Farrukh M. Koraishy,[1] Thuy-Trang T. Ngo,[2] Gary M. Israel,[3] Neera K. Dahl.[1] *[1]Internal Medicine, Yale University School of Medicine, New Haven, CT; [2]Internal Medicine, Norwalk Hospital, Norwalk, CT; [3]Diagnostic Radiology, Yale University School of Medicine, New Haven, CT.*

Background: Medullary sponge kidney (MSK) is traditionally diagnosed by intravenous pyelography. When Computed Tomography Urography (CTU) is combined with three-dimensional post-processing using MultiDetector-Row Computed Tomography (MDCT), the diagnosis of MSK can be made with high accuracy.

Methods: Patients with multiple bilateral stones or with a finding of medullary calcinosis were referred for a CTU in addition to standard laboratory testing, and a 24 hour urine collection for evaluation of metabolic risk factors for recurrent stones. A retrospective analysis of the first 16 of these patients is presented. Patients were seen between January 2008 and March 2011 for initial evaluation of stones. Characteristic findings of MSK on CTU included dilatation of the collecting tubules manifested as a papillary "blush", "paintbrush" or "bouquet of flowers" pattern. In addition, medullary calcinosis and medullary cysts were also evaluated. This information was assessed in light of demographic and laboratory data of the patients.

Results: Four patients were diagnosed with MSK based on the characteristic radiologic features seen on the CTU. All 4 of these patients had features of medullary calcinosis, while only three had medullary cysts. Three of the four patients also had features suggestive of distal RTA. Six patients had medullary calcinosis without MSK. 3 of these 6 patients (without MSK) also had features of distal RTA. 2 of 8 patients with features of distal RTA did not have medullary calcinosis or MSK.

Conclusions: CT Urography effectively demonstrates characteristic radiologic findings of MSK and helps distinguish between medullary calcinosis and MSK. Medullary cysts were not seen in all cases of MSK. Most but not all cases of distal RTA were associated with medullary calcinosis.

PUB231

Kidney Cysts in a Patient with Systemic Toxicity from D-Penicillamine Farrukh M. Koraishy,[1] Gary M. Israel,[2] Neera K. Dahl.[1] *[1]Internal Medicine, Yale University, New Haven, CT; [2]Diagnostic Radiology, Yale University, New Haven, CT.*

Background: D- Penicillamine (PCA) has been used for treatment of cystinuria due to its cysteine binding properties. PCA has also been known to cause impaired collagen deposition and dysfunction in the elastic fibers resulting numerous systemic toxicities. Nephrotoxicity reported with PCA is typically a membranous glomerulonephritis. We describe a patient who developed large bilateral kidney cysts during long-term treatment with PCA for cystinuria.

The patient was treated effectively for cystinuria for over 20 years with a PCA dose of 2.0 grams per day His renal function remained normal and he had no proteinuria. In 1999, an Intravenous pyelogram (IVP) with tomography showed normal kidney sizes and no cysts were noted. In 2003, the patient was admitted progressive dyspnea. A CT of the chest and abdomen revealed new, multiple, bilateral cysts in the kidneys. The largest cyst on the right was 11.9 x 8.8 cm, the largest on the left was 8.3 x 5.8 cm. Both kidneys were between 9-10 cm in size. Patient also had a rise in his serum creatinine. PCA was discontinued in 2005 when the patient developed systemic toxicities of PCA including loosening of the skin, keratoconus and popliteal aneurysms. A skin biopsy diagnosed cutix laxa. Other systemic toxicities included cardiomyopathy, restrictive lung disease and thickening of the walls of the esophageous and duodenum. During these 2 years, the size of his kidney cysts had continued to progress and his renal function also worsened. He also developed proteinuria that ranged between 0.5 to 1.0 grams per day.

Since the discontinuation of PCA, the size of his kidney cysts and his renal function has been stable. Other systemic toxicities have also remained stable.

Conclusions: To our knowledge, this is the first report of kidney cysts acquired during PCA therapy. The etiology of cyst formation due to PCA is unknown. The possible mechanisms include the alteration in the connective and elastic fibers of the kidney and the malfunction of the extra-cellular matrix and epithelial cell interactions.

Cystic renal disease should be evaluated in patients treated with PCA.

PUB232

Estimating the Range of Kidney Length in Adults with Normal GFR by Automatically Extracting Data from Dictated Ultrasound Reports Brian J. Lee,[1] Ekamol Tantisattamo.[2] *[1]Nephrology, Kaiser Moanalua; [2]Medicine, University of Hawaii.*

Background: Abnormal kidney size can reflect renal disease. However, normal kidney size is not well-characterized, particularly in the mixed ethnic population in Hawaii. Maximum ultrasound kidney length is the most practical way to estimate kidney size. Ultrasound dictations are unstructured freetext having data that must be extracted manually, and this limits the number of data points available. To analyze the largest possible sample, we create a tool to automatically extract kidney lengths from the ultrasound reports.

Methods: Freetext ultrasound reports were extracted by using natural language processing principles. Programs to download and parse the text and extract data were written in SAS and Excel/VBA to extract the longest kidney length from 45,020 renal and abdominal ultrasound reports from 2002-2010. The top 1% of outliers were manually reviewed. To validate the data extracted from the program, we compared computer-extracted maximum kidney lengths from 500 reports to two independent physicians extracting the same data manually. To determine which ultrasounds were eligible to represent "normal" kidneys, we excluded patients 18 years old, diabetes, HIV, polycystic kidneys, eGFR ≥60 ml/minute/1.73 m^2, kidney or other organ transplant, and abnormal echogenic kidneys.

Results: The computer-extracted data was validated, with no significant difference in human vs computer error rate. Of the 45,020 dictated reports, 4,493 qualified for this study. The maximum kidney length was 11.62 cm (SD 1.09) and 11.18 cm (SD 1.11) in male and female adults, respectively. The kidney length peaked in the 30-39 age group and decreased with increased age. Kidney length was positively correlated with both height and weight.

Conclusions: We created a novel technique to collect and analyze a massive amount of data and characterize the normal range of kidney length within Hawaii population. The maximum kidney length depends on age, gender, height, and weight. Ultrasound kidney length can be used as a diagnostic tool for early detection of renal disease. We plan to examine the use of kidney length as a predictor of risk of progressive loss of kidney function in a future study.

PUB233

Urine Neutrophil Gelatinase-Associated Lipocalin in Early Diagnosis of Urinary Tract Infection in Children Inseok Lim, Do Soo Kim, Hakyoung Kim. *Pediatrics, Chung-Ang University Hospital, Seoul, Korea.*

Background: Neutrophil gelatinase-associated lipocalin (NGAL) is a protein mainly found in activated neutrophils and renal tubular cells. The expression of NGAL can rise 1000-fold in response to renal tubular injury, so that it has been proposed as an early biomarker of acute kidney injury. But, there are a few studies for NGAL level in urinary tract infection (UTI) so far. And result of urine culture that is the most accurate method for diagnosing UTIs may not be available for 2-3days, so a new technique that is swift and as least as accurate would be valuable. The present study assessed whether urine and serum NGAL levels could be an early biomarker of UTI.

Methods: Fifty febrile UTI patients and a control group of 50 febrile non-UTI patients were enrolled. Serum and urine NGALs were quantified using the BioPorto® NGAL enzyme-linked immunosorbent assay within 48 hours after fever onset in both patient groups.

Results: Mean urine NGAL level was significantly higher in UTI patients than in control (49.06 ng/ml vs 12.30 ng/ml, p=0.001). But, there was no significant difference of mean serum NGAL level in the UTI and control groups (116.29 ng/ml vs 101.90 ng/ml, p=0.651). Using 10.4 ng/ml of urine NGAL as the cutoff -value for diagnosis of UTI, sensitivity was 95.8% and specificity was 66.7%.

Conclusions: The results indicate that urine NGAL may be useful for additive marker to urinalysis in the early diagnosis in UTI in children.

PUB234

Baclofen Toxicity in Renal Failure: An Underappreciated Occurrence Julie Ann T. Linatoc, Domenic A. Sica, Daniel E. Carl. *Nephrology, Virginia Commonwealth University, Richmond, VA.*

Background: Baclofen (BA) is used for the treatment of musculoskeletal spasticity and occasionally for hiccups. It is mainly eliminated by renal mechanisms and its half life of 4 to 7 hours in normal subjects, extends to 3 to 4 times higher in patient with advanced chronic kidney disease (CKD). This pattern of drug accumulation puts patients with impaired renal function particularly prone to BA toxicity.

Methods: We report 6 patients with impaired renal function and BA-related toxicity seen at our institution from Oct 2010 to Feb 2011.

Results: These 6 cases all had altered mental status (AMS) as the major presenting symptom following BA administration. In all cases, either conventional hemodialysis or continuous renal replacement therapy (RRT) were used to accelerate BA clearance and where obtained blood levels dropped proportionately. Central nervous system (CNS) symptoms resolved in all patients following initiation of RRT. The time to resolution of BA-related symptoms varied substantially reflective of the known CNS compartmentalization of BA.

Characteristics of 6 Patients with Baclofen Toxicity

	Case 1	Case 2	Case 3	Case 4	Case 5	Case 6
Age (y)/Sex	56/F	49/M	62/M	66/M	52/F	66/M
Renal Function	CKD 4(eGFR 20-25)	AKI	AKI (2 days prior giving BA)	AKI, on HD	ESRD on PD	CKD 3(eGFR 30-35)
Reason for Use	low back pain	spasticity	spasticity	hiccups	spasticity	hiccups
BA dose (mg), cumulative	25	90	10	30	50	10
Duration of use (days)	1	3	1	1	1.5	< 1
Symptoms	coma, respiratory distress	coma, respiratory distress (1 day after onset of AKI)	AMS	AMS, hypotension	AMS	AMS
Intervention	4 hr HD	4 hr HD x 2 days	supportive	CRRT x 24 hr, then switched to HD	4hr HD x 3 days	supportive
Recovery Time	4 hr	48 hr	2.5 days	36 hr	3 days	2 days

Abbreviations: AKI, acute kidney injury; ESRD, end-stage renal disease; HD, hemodialysis; PD, peritoneal dialysis; eGFR, estimated glomerular filtration rate

Conclusions: These cases illustrate the poor knowledge of this drug's pharmacokinetics and its concentration-dependent toxic profile in patients with renal failure. Our institution has now inserted precautionary statements into the usage criteria for BA and a ban on its use at an eGFR below 15 mL/min is under consideration.

PUB235

Awareness of Chronic Kidney Disease and Association with Proteinuria in Japanese General Population Yohei Maeshima,[1] Norikazu Hinamoto,[1] Daisuke Saito,[1] Hiroko Yamasaki,[1] Hiroyuki Watatani,[1] Haruyo Ujike,[1] Masashi Kitagawa,[1] Hitoshi Sugiyama,[1] Yoshinari Yasuda,[2] Tadao Akizawa,[3] Hirofumi Makino.[1] *[1]Medicine and Clinical Science, Okayama Univ. Med. School, Okayama, Japan; [2]Medicine, Univ. of Nagoya, Nagoya, Aichi, Japan; [3]Medicine, Univ. of Showa, Tokyo, Japan.*

Background: In spite of high prevalence of CKD in Japan, majority of CKD patients may not be aware of CKD due to the lack of subjective symptoms, thus leading to the increasing number of patients on dialysis therapy. The aim of the current study is to survey the awareness of CKD in the Japanese general population and to examine association with proteinuria.

Methods: Questionnaire form and urinary dipstick check kit was distributed to participants in the annual meeting of International Rotary 2690th district held in 2010. The questionnaire form of Research program of Ministry of Health, Labour and Welfare was used. The questionnaire included questions on awareness of CKD, self-reported renal function, knowledge questions on diagnosis, risk factors, clinical symptoms and effective life-style modification of CKD, and the degree of proteinuria using urinary check kit.

Results: Of 1238 participants, 505 general population excluding medical professionals were studied. The mean age was 60 years and 95% were male. The awareness of CKD was 30.9%, and complication of hypertension, diabetes mellitus or dyslipidemia (33%) did not affect CKD awareness. In regard to CKD diagnosis, proteinuria (61%) was recognized sufficiently, but eGFR (14%) was poorly recognized. In regard to the symptoms of CKD, hypertension (73%) was recognized sufficiently, but renal anemia (49%) and mineral bone disorder (38%) were poorly recognized. Mild (34.3%) and heavy proteinuria (1.7%) was observed. The degree of actual life-style modification significantly correlated with proteinuria (r=-0.11, P=0.016) and self-reported renal function (r=0.25, P<0.01).

Conclusions: These results suggest that awareness of CKD remains low in Japan, and efforts to improve knowledge of CKD and to promote life-style modification may play important roles in delaying the progression of CKD.

PUB236

Urine Protein-to-Creatinine Ratio Does Not Correlate with 24-H Urine Total Protein Excretion in Nephrotic Proteinuria Nuria Montero,[1] Maria Jose Soler,[1] Maria Jose Pascual,[1] Clara Barrios,[1] Eva Marquez,[1] Eva Rodriguez,[1] Maria Antonia Orfila,[1] Luis Coca,[2] Julio Pascual.[1] *[1]Nephrology, Hospital del Mar., Barcelona, Spain; [2]Laboratori de Referencia de Catalunya.*

Background: Measurement of protein content of a timed 24h urine collection is the definitive method for establishing presence of abnormal proteinuria, however, urine collection is cumbersome. Spot urine protein to creatinine ratio seems to be a reliable diagnostic tool for urine protein measurement. Our aim is to evaluate spot urine protein-to-creatinine ratio compared to 24h urine total protein excretion in different proteinuria ranges.

Methods: Observational, cross-sectional study of 159 consecutive paired determinations of 24h urine total protein excretion and spot urine protein-to-creatinine ratio in renal patients. The strength of the correlation was determined by calculating intraclass correlation coefficient(ICC) and Spearman correlation coefficient(SCC).

Results: Among all groups, ICC was 0.756(CI 95% 0.680-0.816) and SCC was r=0.91(p<0.05). There is an excellent significant correlation between the spot urine protein to creatinine ratio and 24h urine total protein excretion when proteinuria was<3500mg/24h. This correlation decreased when it was<300mg.

TABLE: Intraclass correlation coefficient between spot urine protein to creatinine ratio and 24-h urine total protein excretion

Proteinuria 24h (mg)	< 300	300-3499	≥3500
Number	60	77	22
Intraclass correlation coefficient (Confidence interval 95%)	0.456 (0.230-0.635)	0.656 (0.508-0.766)	0.340 (-0.041-0.650)
Spearman correlation coefficient (r)	0.498	0.828	0.181
p	<0.001	<0.001	0.420

When patients were stratified according to eGFR, the correlations between spot urine protein-to-creatinine ratio and 24h urine total protein excretion were similar between groups.

Conclusions: In summary, a strong correlation is observed between spot urine protein to creatinine ratio and 24h urine total protein excretion when the level of proteinuria is <3500mg/day. In our experience, there is no relevant correlation between spot urine protein to creatinine ratio and 24h urine total protein excretion in nephrotic-range proteinuria. Further studies with larger sample sizes are needed to confirm these results.

PUB237

Impact of Reduced Glomerular Filtration Rate on Japanese Acute Stroke Naoki Nakagawa. *Asahikawa Medical University, Japan.*

Background: Patients with chronic kidney disease (CKD) are at high risk of stroke and other cardiovascular diseases, and recent guidelines for the management of stroke stress the importance of managing such patients. However, the characteristics of the subtypes of stroke that occur in patients with CKD remains to be determined. The present study investigates stroke subtypes in patients with or without CKD using the stroke database at our hospital.

Methods: We analyzed data from 470 (male, 251; mean age, 70.6 y) patients admitted to our hospital with stroke between 2006 and 2010. Relationships between the type of stroke and estimated glomerular filtration rate (eGFR) for Japanese, age, sex, hemoglobin and the presence or absence of various risk factors for arteriosclerosis were investigated.

Results: The type of stroke was transient ischemic attack in 17 patients (4%), lacunar infarction in 40 (9%), atherothrombosis in 30 (6%), cerebral embolism in 129 (27%), unclassified cerebral infarction in 90 (19%), subarachnoid hemorrhage in 41 (9%), and cerebral hemorrhage in 104 (22%). Among the 470 patients, 140 (30%) had CKD with eGFR < 60 mL/min/1.73 m^2. Compared with a group without CKD (mean eGFR 85 mL/min/1.73 m^2), the rate of complications with all risk factors was higher in the CKD group (mean eGFR 46 mL/min/1.73 m^2) with more advanced age (76 vs. 68 years, P < 0.01), atrial fibrillation (31% vs. 15%, P < 0.01) and a history of cardiovascular disease (38% vs. 19%, P < 0.01) being the most prevalent. The prevalence of hypertension tended to be higher in the group with CKD, but the difference did not reach significance (58% vs. 53%). A comparison of stroke subtypes revealed a significantly higher incidence of cardiogenic cerebral embolism (34% vs. 25%, P < 0.05) and a significantly lower incidence of subarachnoid hemorrhage (3.6% vs. 11%, P < 0.01) in the group with, than without CKD.

Conclusions: About 30% of patients with stroke admitted to our hospital had CKD. Those with CKD were older, had a higher prevalence of atrial fibrillation and a significantly higher rate of cardiogenic cerebral embolism. Thus, strict control of blood pressure and prevent the onset of atrial fibrillation should be important to prevent stroke among patients with CKD.

PUB238

Evaluation of Rectus Sheath Hematoma Risk Factors Heena S. Sheth, Hoda Kaldas. *Medicine, UPMC, Pittsburgh, PA.*

Background: The following risk factors for rectus sheath hematoma (RSH) are known: systemic or prophylactic anticoagulation, trauma, abdominal surgery or injections, cough, old age, female gender and pregnancy. Platelet dysfunction associated with kidney disease, administration of antiplatelet agents, steroids, or immunosuppressants may increase the risk of bleeding complications such as RSH. RSH may increase morbidity/mortality, length of stay and readmissions.

Purpose: To evaluate the risk factors for RSH such as Chronic Kidney Disease, antiplatelet therapy, steroids and immunosuppresants.

Methods: The patients who developed RSH during 2006-6/2009 were identified from the CT reports from UPMC MARS data system. Patient charts were reviewed for demographics and risk factors. Descriptive statistics are reported for the risk factors.

Results: The MARS query identified 114RSH CT reports. 12 patients were ineligible : NO RSH (10) and inadequate documentation (2). The 102 patients evaluated, demographics were: 60.8% females, 10.8% AA, mean age 62.6 years (SD 16.9, range18.9-87.6). 6 patients (5.8%) were underweight and 35 (34.3%) obese. 23 (22.5%) were admitted for RSH management. 24 (23.5%) patients had not received any anticoagulation. 60 (58.8%) were on chronic anticoagulation or received anticoagulant treatment in the hospital, 18 (17.7 %) received prophylactic anticoagulant doses. The presenting symptoms were pain, drop in hematocrit, hypotension, or incidentally diagnosed on CT. Among the 42 patients administered prophylactic doses or no anticoagulants; 11 (26%) had CKD stage 4/ 5, 28 (66.6%) were on immunosuppressant, steroids or antiplatelet therapy and 23 (54.7%) had abdominal surgery. RSH treatment was conservative [pain management, transfusion and coagulopathy reversal] in 91 (89 %) and surgical in 11(11%) patients. Mortality was 24.5% (25) and RSH was contributing to death in one patient.

Conclusions: Our study highlights the importance of RSH as a bleeding complication in patients who are on anticoagulation and among those who are not on anticoagulation. High percentage of patients may have platelet dysfunction related to Kidney disease, steroids, immunosuppressants, antiplatelet therapy. These risk factors warrant further exploration in a large sample study.

PUB239

A Systematic Review of Maternal Deaths in Women with Systemic Lupus Erythematosus and Lupus Nephritis Andrew Smyth,[1,2] James Ritchie,[3,4] Clare Tower,[7] Michael Venning,[5] Vesna D. Garovic.[6] *[1]Medicine, National University of Ireland, Galway, Ireland; [2]Nephrology, Galway University Hospitals, Galway, Ireland; [3]Renal Medicine, Salford Royal Hospital, Salford, United Kingdom; [4]Manchester Academic Health Science Centre, University of Manchester, United Kingdom; [5]Manchester Institue of Nephrology & Transplantation, Central Manchester Trust, Manchester, United Kingdom; [6]Nephrology & Hypertension, Mayo Clinic, Rochester, MN; [7]Fetal & Maternal MEdicine, St Mary's Hospital, Manchester, United Kingdom.*

Background: Pregnancies in women with systemic lupus erythematosus (SLE) and lupus nephritis are considered high risk due to high rates of maternal and fetal complications. However, there has not been a formal analysis addressing the issue of maternal deaths in these women. The aim of this study was to perform a systematic literature review of the maternal deaths in women with SLE and lupus nephritis to: (1) identify the main causes of death and (2) discuss possible reasons for these, and strategies that may improve patient care and outcomes.

Methods: We performed an extensive electronic literature search from 1966 to 2009 using online databases (PubMed, Embase, Lilacs, Cochrance Controlled Trials Register, Medline and Science Citation Index). Studies were included if they reported pregnancies in patients with SLE and lupus nephritis with at least one reported death.

Results: We identified eleven studies reporting sixteen deaths in the immediate post-partum period that were attributable to SLE and lupus nephritis. In all cases, death occurred in the setting of active disease, and was attributed either to infection (n=7) or disease activity (n=7). The two remaining deaths were due to pulmonary embolus (n=1) and steroid withdrawal (n=1).

Conclusions: All maternal deaths in patients with SLE and lupus nephritis occurred in those with active disease, with disease activity/complications and infections (mainly opportunistic) being two major causes. The presented evidence further supports timing of pregnancy relative to SLE activity, and judicious use of immunosuppressive agents in pregnant patients.

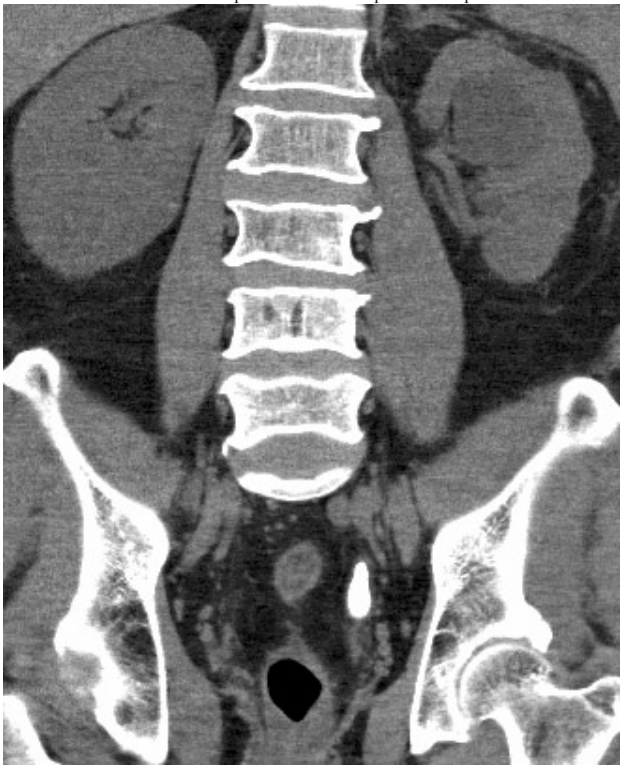
PUB240

Recurrent *Proteus mirabilis* Urinary Tract Infection Presenting with a Large Struvite Stone Ekamol Tantisattamo, Chuong Dinh. *Department of Medicine, University of Hawaii, John A. Burns School of Medicine, Honolulu, HI.*

Background: Urinary tract infection (UTI) is uncommon in adult male, and always results from a complicated UTI. Urease forming bacteria cause the urine to become alkaline, thus leading to favorable conditions for struvite stone formation. We report a case of a man who had recurrent *Proteus mirabilis (P. mirabilis)* UTI and was found to have a large ureterovesical junction (UVJ) struvite stone complicated by severe sepsis and acute kidney injury.

Results: TThe patient is a 59-year-old man with a history of *P. mirabilis* UTI 5 years ago. Urine pH was 8. He was successfully treated with antibiotics but lost to follow up. One day prior to admission, he presented with fevers, chills, and severe sepsis. Abdominal exam was unremarkable. He had no costovertebral angle tenderness. Digital rectal exam showed 5 fingerbreadths nontender prostate gland. His scrotum was erythematous, mildly tender, but with no swelling or penile discharge. He developed acute kidney injury. His serum creatinine was 7.6 mg/dl rising from baseline serum creatinine of 1 mg/dl. Urinalysis showed an alkali urine with pH of 8. Blood and urine cultures grew *P. mirabilis*. Abdominal CT scan revealed a 1.5 * 5 cm left distal ureteric stone extending across the UVJ. He underwent left percutaneous nephrostomy tube placement, and then laser lithotripsy of the left ureteral stone. Stone analysis was consistent with struvite stone. His sepsis ultimately resolved and serum creatinine returned to his baseline.

Conclusions: *P. mirabilis* is a common cause of struvite stone which is difficult to treat medically and needs surgical treatment. Incomplete treatment of *P. mirabilis* can result in progressive struvite stone formation with complications of acute kidney injury and urosepsis. Infected alkaline urine is an important clue to the presence of persistent *P. mirabilis* UTI.



PUB241

Collagen 4-Related Nephropathies: A Series of Patients Treated with ACEi Silvia M. Titan,[1] Helen Takagi,[2] Denise Maria Avancini Costa Malheiros,[3] Benita Schvartsman,[2] Maria Helena Vaisbich.[2] *[1]Nephrology Division, Sao Paulo University Medical School, Sao Paulo, Brazil; [2]Nephrology Division, Instituto da Criança, Sao Paulo University Medical School, Sao Paulo, Brazil; [3]Pathology Division, Sao Paulo University Medical School, Sao Paulo, Brazil.*

Background: Collagen IV-related nephropathies (COLIV) are associated with a high frequency of ESRD. ACEI and ARBs are the only pharmacological measures, but the impact of this treatment remains unclear. In this study, we have analyzed the effect of ACEI in COLIV patients.

Methods: Retrospective data on 19 COLIV patients treated with ACEi was collected. Primary outcome (PO) was defined as an estimated creatinine clearance <60 ml/min/1,73m².

Results: At diagnosis, 70% of cases presented macroalbuminuria, 47% hypertension and 63% hyperfiltration. Figure 1 shows the laboratorial evolution during the first 2 years of treatment, with no significant change in proteinuria.

	ACEi initiation	6 months	12 months	18 months	24 months	p value*
Urea (mg/dL; mean / std)	32,7 (15,6)	32,6 (11,6)	30,3 (13,0)	37,3 (24,7)	43,7 (35,8)	0,1
Creatinine (mg/dL; mean / std)	0,6 (0,2)	0,7 (0,2)	0,7 (0,4)	0,9 (0,9)	1,2 (1,7)	0,004
Estimated creatinine clearance (mL/min/1,73m²; mean / std)	161,3 (52,7)	131,7 (36,8)	149,1 (47,0)	143,5 (63,7)	134,7 (60,6)	0,14
24h proteinuria (mg/kg/d; median, min - max)	25 (5 - 190)	25,3 (5 - 184)	28,9 (5 - 167)	22 (5 - 170)*	27 (4 - 113)*	0,94

* 2 missing values
# Friedman test (pairwise data, non parametric)

During follow-up, 4 patients reached the PO. Table 1 shows that renal function, proteinuria and hypertension were significantly related to the PO.

Clinico-laboratorial features according to PO.

	no-PO (n=15)	PO (n=4)	p
At baseline			
Age (months; mean/std)	117,3 (39,4)	150,3 (37,2)	0,15
Sex (men; n / %)	9 (60)	4 (100)	0,25
Creatinine (mg/dL; mean / std)	0,5 (0,2)	0,8 (0,1)	0,01
Estimated creatinine clearance (ml/min/1,73m2; mean / std)	165,5 (40,6)	118,0 (45,1)	0,06
24h proteinuria (mg/kg/d; median, min - max)	23 (6-87)	172 (40-225)	0,004
Mean ACEi dose (mg/kg/d; mean / std)	0,25 (0,08)	0,18 (0,07)	0,22
Hypertension (n / %)	5 (33,3)	4 (100)	0,03
Abnormalities at optic microscopy (n / %)	4 (30,8)	2 (66,7)	0,52
Follow-up			
Ratio of proteinuria during follow-up (median, min - max)	1,1 (0,25 - 8,3)	0,5 (0,5 - 2,0)	0,60

Conclusions: In our series, no major effect of ACEi on proteinuria could be seen. RCTs are needed to further explore the real impact of ACEi and ARBs in the natural history of COLIV.

PUB242

Is There a Relation between ADPKD and Valvular Heart Disease? Yoshiki Tsuchiya,[1] Yoshifumi Ubara,[2] Tatsuya Suwabe,[2] Keiichi Sumida,[2] Kenmei Takaichi,[2] Masayuki Yamanouchi,[2] Rikako Hiramatsu,[2] Noriko Hayami.[2] *[1]Nephrology Center, Tohkatsu Hospital, Nagareyama, Chiba, Japan; [2]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Kanagawa, Japan.*

Background: Hossack (NEJM 1988) reported that ADPKD has a close relation with valvular heart disease, including mitral valve incompetence. However, Ecder (Nat Rev Nephrol. 2009) argued that there was no significant difference of valvular abnormalities between ADPKD patients and healthy controls, so this issue still remains unclear and further study is needed.

Methods: A retrospective analysis of echocardiographic data was performed with comparison among 4 groups: group 1 (ADPKD patients on hemodialysis, CKD stage 5, n=421), group 2 (ADPKD patients in CKD stage 3, n=49), group 3 (chronic glomerulonephritis patients, mainly IgA nephropathy, on hemodialysis, CKD stage 5, n=60), and group 4 (IgA nephropathy patients with CKD 3, n=70).

Results: In group 1, 48% had mitral incompetence (MI), 29.2% had aortic incompetence (AI), and 41.8% had tricuspid incompetence (TI). The total valvular disease (TVD) rate (MI, A1, and TI) was 77.9%.

Comparison among five groups

	MI	AI	TI	PI	TVD	pericardiac effusion	ejection fruction
GROUP1 ADPKD CKD stage5 (N=421)	48.0%	29.2%	41.8%	20.7%	77.9%	19.2%	67.3 +- 11.0%
GROUP2 ADPKD CKD stage3 (N=49)	20.4%	14.3%	24.5%	57.1%	71.4%	4.1%	70.0 +- 7.7%
GROUP3 CGN CKD stage 5 (N=60)	43.3%	31.7%	61.7%	23.3%	80.0%	10.0%	67.7+- 11.7%
GROUP4 IgAN CKD stage3 (N=70)	22.3%	8.6%	38.6%	47.1%	72.9%	0%	71.6 +- 5.3%

However, the rates of MI, AI, and TI were significantly different (P<0.01) for group 1 vs. group 2 and group 3 vs. group 4.

Conclusions: Patients with ADPKD and CGN (including IgA nephropathy) showed no differences whether they were CKD 3 or CKD 5. However, ADPKD and non-ADPKD patients with CKD3 or 5 showed significant differences. Valvular heart disease may not be characteristic of ADPKD, but could have a close relation with some hemodynamic factors secondary to hemodialysis.

PUB243

The Impact of Gene Polymorphisms of Interleukin-18 (IL-18), Transforming Growth Factor-β (TGF-β) and Vascular Endothelial Growth Factor (VEGF) on Development of IgA Nephropathy or Thin Glomerular Basement Membrane Disease Jang-Hee Cho,[1,2] Hee-Yeon Jung,[1,2] Mi-Kyung Jin,[1,2] Owen Kwon,[1,2] Kyung-Deuk Hong,[1,2] Ji-Young Choi,[1,2] Se-Hee Yoon,[1,2] Sun-Hee Park,[1,2] Yong-Lim Kim,[1,2] Chan-Duck Kim.[1,2] *[1]Internal Medicine, Kyungpook National University Hospital, Daegu, Republic of Korea; [2]Clinical Research Center, End Stage Renal Disease in Korea, CRC for ESRD, Republic of Korea.*

Background: We investigated the effects of gene polymorphisms on the development of IgA nephropathy and thin glomerular basement membrane (GBM) disease by analyzing polymorphisms in the interleukin (IL)-18, transforming growth factor (TGF)-β, and vascular endothelial growth factor (VEGF) genes in Korean patients.

Methods: The study included 146 normal subjects (control group) and biopsy-proven 69 IgA nephropathy and 44 thin GBM disease patients. The gene polymorphisms A-607C and G-137C in *IL18*, C-509T and T869C in *TGFB1*, and C-2578A and C405G in *VEGF* were investigated in DNA extracted from peripheral blood.

Results: The frequencies of the *IL18* -607CC genotype (p=0.002) and the *VEGF* 405GG genotype (p=0.002) were significantly increased in the IgA nephropathy group compared with the control group. No significant differences in genotype frequency were observed between the thin GBM disease and control group. There were no significant differences in genotype and allele frequencies between IgA nephropathy and thin GBM disease groups.

Conclusions: Significant differences of genotype and allele frequencies were observed only between IgA nephropathy and control group. However, because of the small size of the IgA nephropathy and thin GBM group, additional extensive studies are required to clarify the potential role of gene polymorphism to discriminate IgA nephropathy and thin GBM disease.

DNA Methylation and CpG Dinucleotide Frequencies in Promoter Regions of Human Kidney Development Genes Yasunobu Kawata,[1] Walter L. Ruzzo,[2] Karol Bomsztyk.[3] *[1]Department of Medicine, Shimonoseki Municipal Saiseikai Toyoura Hospital, Shimonoseki, Yamaguchi, Japan; [2]Department of Computer Science and Engineering, University of Washington, Seattle, WA; [3]Department of Medicine, University of Washington, Seattle, WA.*

Background: DNA methylation of CpG dinucleotides in genome regulates gene expression. CpG islands are frequently found in gene promoters, but the detailed analysis of these sequences are not known.

Methods: Here, we analyzed sequences from -5kb to +5kb of transcriptional start site (TSS) of human genomic genes by computing CpG dinucleotide frequencies every 500 bps. From Gene Ontology and UCSC website, human genomic genes including kidney development, cell cycle, mitosis, chromatin, extracellular matrix and receptor genes were examined.

Results: This analysis revealed that CpG frequencies flanking TSS regions in genes encoding kidney development, cell cycle, mitosis, chromatin genes are significantly higher than average. The TATA box is a critical promoter element that regulates transcriptional initiation and is located in 10% of all genes. We found that as a whole TATA box-containing promoters have lower CpG frequencies flanking TSS than the average. In contrast, interestingly, 15% of the kidney development genes have promoter TATA boxes associated but with higher CpG frequencies flanking TSS regions. We used GSE17001 of Gene Expession Omnibus datasets in NCBI of the same set of genes of primary human fibroblasts and breast adenocaricinoma cell lines to analyze DNA methylation patterns. This analysis revealed that compared to the average, kidney development genes show higher DNA methylation level in promoter regions but lower methylation levels at TSS. This unique pattern at these genes was not found in the adenocarcinoma cell lines, which show higher methylation level at TSS and lower level at the promoter region. This analysis suggest that regulation of CpG islands methylation flanking TSS is different in kidney development genes than an average gene.

Conclusions: This suggest that renal development may involve transcriptional mechanisms that are unique.

PUB245

^{1}H NMR Spectroscopy Analysis of Metabolites in the Kidneys Provides New insight into Pathophysiological Mechanisms: Applications for Treatment with *Cordyceps sinensis* Fang Zhong, Qiao Zhou, Ying Lu, Xu Hao, Cong Li, Shanmai Guo, Weiming Wang, Nan Chen. *Department of Nephrology, Ruijin Hospital, Shanghai Jiao Tong University, School of Medicine, Shanghai, China.*

Background: The number of patients with chronic kidney disease (CKD) is continuously growing worldwide. Treatment with traditional Chinese medicine might slow the progression of CKD.

Methods: In this study, we evaluated the renal protective effects of the Chinese herb *Cordyceps sinensis* in rats with 5/6 nephrectomy. Male SD mice (weighing 150-200 g) were subjected to 5/6 nephrectomy. The rats were divided into three groups: (a) untreated nephrectomized group (OP group, n=16), (b) oral administration of *Cordyceps sinensis*-treated (4 mg/kg/d) nephrectomized group (CS group, n=16) and (c) sham-operated group (SO group, n=16). The rats were sacrificed at four and eight weeks after 5/6 nephrectomy, and the kidneys, serum and urine were collected for ^{1}H nuclear magnetic resonance (^{1}HNMR) spectral analysis. Multivariate statistical techniques and statistical metabolic correlation comparison analysis were performed to identify metabolic changes in aqueous kidney extracts between these groups.

Results: Significant differences between these groups were discovered in the metabolic profiles of the biofluids and kidney extracts. Pathways including the citrate cycle, branched-chain amino acid metabolism and the metabolites that regulate permeate pressure were disturbed in the OP group compared to the SO group; in addition, these pathways were reversed by *Cordyceps sinensis* treatment. Biochemistry and electron microscopic images verified that *Cordyceps sinensis* has curative effects on chronic renal failure. These results were confirmed by metabonomics results.

Conclusions: Our study demonstrates that *Cordyceps sinensis* has potential curative effects on CKD, and our metabonomics results provided new insight into the mechanism of treatment of this traditional Chinese medicine.

PUB246

Changing Demographics of Autosomal Dominant Polycystic Kidney Disease over Four Decades Imed Helal, Berenice Y. Gitomer, Xiang-Dong Yan, Kim McFann, Godela M. Brosnahan, Robert W. Schrier. *Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO.*

Background: ADPKD is the most life threatening hereditary disease. Over the last four decades there have been considerable improvements in clinical diagnosis and management of patients with ADPKD. The impact of these changes on the overall demographics of the ADPKD patient population is however, unknown. The present study compared the demographics of ADPKD patients who were seen at our ADPKD center from 1961-1992 versus 1993-2007.

Methods: Data was collected from the ADPKD clinical database at the University of Colorado for the first subject visit with full clinical information and patient clinical and demographic information compared for both time intervals. All patients were evaluated during a 2-day in-patient visit at the Clinical Translational Research Center at University of Colorado Hospital.

Results: The results are depicted in the table.

Table 1: Demographics of ADPKD

Parameter	1993-2007	1961-1992	P-value
N	579	281	
Age (years)	41 ± 12	43 ± 13	0.003
Gender: Male/Female	219/360	133/148	0.007
Sysstolic blood pressure (mm Hg)	129 ± 16	142 ± 24	<0.0001
Diastolic blood pressure (mm Hg)	81 (144-37)	92 (160-60)	<0.0001
CrCl (ml/min/1.73m2)	75 ± 35	49 ± 33	<0.0001
Proteinuria (mg/24h)	0.24 (3.31-0.01)	0.81 (5.9-0.04)	<0.0001
ACE/ARB use	275 (34.6%)	25 (3.3%)	<0.0001

While the earlier cohort was somewhat older and had more male patients, it seems unlikely that these demographics alone explain the major differences in blood pressure (BP), kidney function and proteinuria. The improved BP control was accompanied by the increased use of the renin-angiotensin system (RAS) inhibitors.

Conclusions: Over the last 4 decades the demographics of ADPKD have changed in a more favorable manner.

Congenital Heart Disease in Autosomal Dominant Polycystic Kidney Disease
Maria V. Irazabal,[1] Amber Harmon,[1] Heidi M. Connolly,[2] Marie C. Hogan,[1] Jamie L. Sundsbak,[1] Sandro Rossetti,[1] Peter C. Harris,[1] Vicente E. Torres.[1] *[1]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Division of Cardiovascular Diseases, Mayo Clinic, Rochester, MN.*

Background: *Pkd2* and *Pkd1l1*, but not *Pkd1*, are expressed in the embryonic node and required for left-right patterning. Disturbances in embryonic left-right patterning are an important cause of disrupted cardiac development and congenital heart disease (CHD). *Pkd2* and *Pkd1l1* null mice exhibit cardiac septation and outflow tract defects. Although cardiac valvular abnormalities occur with increased frequency in Autosomal Dominant Polycystic Kidney Disease (ADPKD), it is uncertain whether an association between ADPKD and CHD exists.

Methods: To examine this question we reviewed the echocardiogram reports obtained between 1999 and 2010 in ADPKD patients (554 patients).

Results: A diagnosis of CHD (including previous diagnoses, excluding patent foramen ovale and atrial septal aneurysm) was present in 25 patients (4.5 %). Atrial or ventricular septal defect (n=4 or 0.7 %), patent ductus arteriosus (n=1), isolated bicuspid aortic valve (BAV n=9 or 1.6 %), aortic coarctation (n=4 or 0.7 %, 3 with associated BAV), hypoplasia of upper descending thoracic aorta (n=1), left coronary artery to pulmonary artery fistula (n=1), congenital pulmonic stenosis (n=1), Ebstein anomaly (n=1), tetralogy of Fallot (TOF n=1), tricuspid atresia (n=1), and double inlet left ventricle with transposed great vessels and pulmonic stenosis (n=1). Four cases had been referred to our institution for evaluation of CHD; in the remaining the diagnosis of CHD was incidental to evaluation for ADPKD or other conditions. Three additional ADPKD patients with TOF, VSD and isolated left superior vena cava were seen during the same period of time but had no echocardiogram. Genetic studies (in progress) have so far revealed 7 *PKD1*, no *PKD2* mutations, and no mutation detected in one patient.

Conclusions: CHD is rarely associated with ADPKD, but the observed prevalences seem higher than those in the general population 2.9 vs 0.8 % (excluding isolated BAV). Preliminary results do not demonstrate an enrichment of *PKD2* mutations in these patients.

Mutations in KIF7 Link Joubert Syndrome with Sonic Hedgehog Signaling and Microtubule Dynamics
Max C. Liebau,[1,2] Claudia Dafinger,[2,4] Yorck Hellenbroich,[5] Christoph Korenke,[8] Francesca Fabretti,[2,3] Inga Ebermann,[4] Gudrun Nürnberg,[3,6] Thomas Benzing,[2,3] Hanno Jörn Bolz,[4,7] Bernhard Schermer.[2,3] *[1]Department of Pediatrics, University Hospital of Cologne, Cologne, Germany; [2]Department of Medicine and Centre for Molecular Medicine, University Hospital of Cologne, Cologne, Germany; [3]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases, Cologne, Germany; [4]Institute of Human Genetics, University Hospital of Cologne, Cologne, Germany; [5]Institute of Human Genetics, University Hospital of Schleswig-Holstein, Luebeck, Germany; [6]Cologne Center for Genomics and Centre for Molecular Medicine, University of Cologne, Germany; [7]Bioscientia Center for Human Genetics, Ingelheim, Germany; [8]Elisabeth Kinderkrankenhaus, Oldenburg, Germany.*

Background: Joubert syndrome (JBTS) is characterized by a specific brain malformation with various additional pathologies including a nephronophthisis-like cystic renal phenotype in around 25% of the JBTS patients. JBTS can result from mutations in at least 10 different genes and has been linked to dysfunction of primary cilia. We have identified a disease locus, JBTS12, with mutations in the KIF7 gene, a homolog of the Drosophila kinesin Costal2, in a consanguineous JBTS family and subsequently in other JBTS patients. Interestingly, KIF7 is a known regulator of Hedgehog signaling and a putative ciliary motor protein. In human epithelial cells knockdown of KIF7 expression caused defects in cilia formation and induced abnormal centrosomal duplication and fragmentation of the Golgi network. These cellular phenotypes likely result from abnormal tubulin acetylation and microtubular dynamics induced by loss of KIF7 function. Further functional studies concerning the mechanisms involved are ongoing. In summary we suggest that modified microtubule stability and growth direction caused by loss of KIF7 function may be an underlying disease mechanism contributing to JBTS.

PUB249

Mutational Analysis of the TRPC6 Gene in Czech Adult Patients with Steroid-Sensitive and Steroid-Resistant Idiopathic Nephrotic Syndrome
Jana Reiterová,[1] Vladimir Tesar,[1] Jitka Stekrova,[2] Petr Lnenicka.[2] *[1]Department of Nephrology, 1st Medical Faculty and General Teaching Hospital, Charles University, Prague, Czech Republic; [2]Department of Biology and Human Genetics, 1st Medical Faculty and General Teaching Hospital, Charles University, Prague, Czech Republic.*

Background: Focal segmental glomerulosclerosis (FSGS) and minimal change disease (MCD) are frequent causes of nephrotic syndrome (NS). About 50% of patients are resistant to immunosuppresive therapy.TRPC6 mutations are the cause of idiopatic NS in about 2-7 % of steroid-resistant patients. These mutations lead a variable rate of progression to end stage renal disease. The aim of the study was the identification of mutations in adult patients with FSGS/MCD.

Methods: 40 patients (22 females, 18 males) with steroid- resistant FSGS/MCD and 44 patients (22 females, 22 males) with steroid-sensitive FSGS/MCD were studied. Renal biopsy with the histological finding of FSGS/MCD was performed in the years 2004-2008. The mean age of the onset of NS was 39± 20.7 years. Family history for proteinuria was positive in three patients. 300 healthy Czech individuals formed control group with mean age 58.4±19.5 years. High resolution melting method (HRM) was established for all 13 exons and intron-exon boundaries of the TRPC6 gene. Suspected samples were analysed by direct sequencing on ABI Prism 3130 Genetic Analyzer.

Results: No TRPC6 gene mutation was identified. Two polymorphisms were described: in exon 1 C43T (P15S) with prevalence 32.5% of heterozygotes and in exon 4 C1211T (A404V) with prevalence 20% of heterozygotes (resp. 1% of T/T homozygotes) in patients with steroid-resistant FSGS/MCD. The prevalence of heterozygotes in steroid-sensitive patients was 13.9% for C43T polymorphism and 29.5% for C1211T polymorphism. The prevalence of heterozygotes in control group was 16.5% for C43T and 20.5% for C1211T (resp. 2.5% of T/T homozygotes). T allele of C43T polymorphism in exon 1 was significantly more frequent in patients with steroid-resistant FSGS/MCD.

Conclusions: TRPC6 gene mutations are rare causes of FSGS/MCD in adult patients. The C43T polymorphism could have some influence on the therapeutic response and progression of the disease.

PUB250

Ambiguous Genitalia in a Neonate; Cause and Consequence
Sarah Hasham,[1] Tetyana L. Vasylyeva.[1] *[1]Pediatrics, Texas Tech University Health Sciences Center, Amarillo, TX; [2].*

Background: Denys-Drash syndrome (DDS) is a rare disorder consisting of the triad of congenital nephropathy, Wilms tumor, and intersex disorders resulting from mutations in the Wilms tumor suppressor (*WT1*) gene. Worldwide, more than 200 cases of DDS have been reported since 1967 when Denys et al originally described a child with nephropathy, ambiguous genitalia, and Wilms tumor. WT1 gene is thought to have tumor suppressor activity and play an important role in nephrogenesis, genitourinary development, haematopoiesis and sex determination.

Methods: We report a case of DDS in a baby boy who was born with ambiguous genitalia and transferred to our NICU.

Results: He was found to have persistent HTN and proteinuria in the NICU. His kryotype was XY and WT1 gene showed mutation *P.D 396N*: c.1186G>;A consistent with DDS. We followed him in Nephrology clinic for 8 months and his proteinuria reached nephritic range and he became albumin transfusion dependent.

Conclusions: DDS is the result of mutations in the *WT1* gene on chromosome band 11p13. The WT1 protein is a transcription factor predominantly expressed in the embryonic kidneys and gonads. Patients with Denys-Drash syndrome develop early-onset nephrotic syndrome, have a high prevalence of severe hypertension, and experience rapid progression to end-stage renal disease (ESRD). The vast majority of patients with DDS is destined to develop Wilms tumor in the native kidneys and are at significant risk for development of gonadoblastoma in the dysgenetic gonads. DDS therapy includes management of fluid and electrolyte balance, treatment of hypertension, renal replacement therapy for ESRD or after bilateral nephrectomy and renal transplant. DDS and WT1 related syndromes are under recognized. Late diagnosis of DDS may lead to late diagnosis of Wilms' tumor, which is often associated with this syndrome. Diagnosis of WT1 related syndromes and molecular testing for WT1 mutations should be considered in the presence of ambiguous genitalia and hypertension or proteinuria.

PUB251

Genetic Factors in the Development of Primary Chronic Glomerulonephritis
Magdalena Mostowska,[1] Stanislaw Czekalski,[1] Pawel P. Jagodzinski,[2] Andrzej P. Oko.[1] *[1]Department of Nephrology, Transplantology and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland; [2]Department of Biochemistry and Molecular Biology, Poznan University of Medical Sciences, Poznan, Poland.*

Background: Genetic factors can play a significant role in the onset of primary chronic glomeluronephritis (GN). Genes encoding proteins of the renin - angiotensin - aldosterone system (RAAS) are candidate genes for primary chronic GN because of influence on renal function in physiological and pathological conditions. The aim of the study was to evaluate the association of 10 polymorphisms of RAAS genes (ACE rs4646994; AGT rs699; AGTR1 rs5186; ATP6AP2 rs2968917 and rs2971597; CMA1 rs1885108 and rs1956923; CYP11β2 rs1799998; REN rs11571080 and rs2368564) with the risk of primary chronic GN in the Polish population.

Methods: The analysis of selected single nucleotide polymorphisms (SNPs) was conducted in the group of 148 patients from the Polish population with biopsy proven primary chronic GN. Control group consisted of 193 healthy persons matched by sex, age, and place of birth. SNP genotyping was performed using PCR-RFLP (Restriction Fragment Length Polymorphism) or HRM (High - Resolution Melting) analyses.

Results: The significant result was found for the rs1799998 polymorphism of the CYP11β2 gene. Individuals carrying two copies of the rs1799998 C allele has nearly twofold increased risk of primary chronic GN (ORCCvsCT+TT = 1.941; 95%CI: 1.171 - 3.218; p = 0.0095). The genetic variations in ACE (rs4646994), AGT (rs699), AGTR1 (rs5186), ATP6AP2 (rs2968917, rs2971597), CMA1 (rs1885108, rs1956923), REN

(rs11571080, rs2368564) are not associated with the risk of primary chronic GN. Moreover, the gene-by-gene interaction analysis conducted using the Multifactor Dimensionality Reduction approach revealed no significant interactive genetic effect on primary chronic GN occurrence.

Conclusions: Polymorphism rs1799998 of the CYP11β2 gene is associated with primary chronic GN in the group of patients from the Polish population.

PUB252

Acute Caffeine Overdose Requiring Hemodialysis Syed N. Babar, John A. Walker. *Nephrology, Robert Wood Johnson University Hospital, New Brunswickl, NJ.*

Background: Caffeine is commonly consumed by humans in the form of beverages like coffee, tea and soft drinks. In the brain, it acts as an antagonist of adenosine receptors, and with adenosine having vasodilatory properties, it is a common composition of various headache pills. We present a rare case of caffeine intoxication requiring hemodialysis.

Methods: A 40 year old woman was found unresponsive after she had consumed approximately 100 pills of Fioricet (Composition: Caffeine 40 mg, Acetaminophen 325 mg, Butalbital 50 mg). Labs revealed hypokalemia, lactic acidosis, and an elevated serum acetaminophen level. Gastric detoxification was initiated with activated charcoal along with IV N-acetyl cysteine. The patient became agitated and developed seizures. Three hours of emergent hemodialysis was administered empirically. Immediately post dialysis, she responded to her name and the next day was fully awake and oriented. Pre and post hemodialysis serum caffeine levels were 51 and 4 mcg/ml respectively (therapeutic level 5-15 mcg/ml).

Results: In quantities found in most foods and beverages, caffeine is unlikely to cause any acute medical problems. However, its presence in higher concentrations in OTC products like energy drinks, diet aids, analgesics and in prescription medications may be a potential cause for acute toxicity. Average doses may result in feelings of alertness and decreased fatigue, whereas high doses (250-500 mg) results in restlessness, nervousness, insomnia and tremors. Even higher doses can cause a hyperadrenergic syndrome resulting in seizures, cardiovascular instability and altered mental status. Hypokalemia, lactic acidosis, and hyperglycemia are classic features of caffeine overdose.

Treatment of severe acute intoxication is generally supportive and includes providing treatment of the immediate symptoms. However, extracorporeal therapy is indicated for caffeine concentrations of >100 mcg/ml or in patients who develop seizures or arrhythmias regardless of the caffeine concentration.

Conclusions: With the widespread availability and consumption of caffeine, its toxicity, (intentional or unintentional) should be recognized by physicians and appropriate treatment provided in a timely fashion.

PUB253

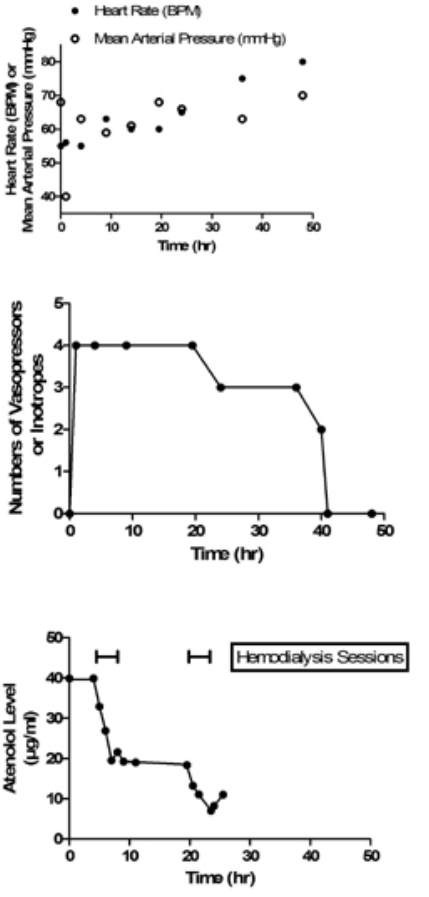
Atenolol Overdose Successfully Treated with Hemodialysis: A Case Report Shih-Han S. Huang, Rita Suri. *Medicine, Nephrology, London Health Sciences Centre, London, ON, Canada.*

Background: Atenolol overdose is common. Because of its hydrophilic characteristic, a few case reports have demonstrated the benefits of hemodialysis treatments. However, the amount of atenolol clearance throughout hemodialysis sessions has not been studied.

Methods: In this case report, a patient with impaired renal function was successful treated with two 5-hour intermittent high-flux high-efficiency hemodialysis therapies after atenolol overdose. Serial atenolol levels were measured during his hemodialysis treatments.Atenolol in plasma was determined using liquid chromatography, tandem mass spectrometry.

Results: We demonstrated an over 50% atenolol reduction after each 5 hours hemodialysis therapy. The parameters for mean arterial blood pressure (mmHg), heart rate (BPM), the numbers of inotropes and vasopressors and the plasma atenolol levels required during the first 48 hours of hospital admission, are presented in Figure 1The zero hour was set at time when the patient first present to emergency room.

Figure 1 A-C. The Recorded Heart Rate (BPM) and Mean Arterial Blood Pressure (mmHg) (Figure 1A), Numbers of Vasopressors and Inotropes Used (Figure 1B), and Atenolol Levels (μg/mL), (Figure 1C) During the First 48 Hours in Our Patient.



Conclusions: Hemodialysis therapy is an effective treatment for atenolol overdose, especially in patients with impaired renal function.

PUB254

Retrospective Comparison of Renal Replacement Therapies (RRT) in Critically Ill Patients with Acute Kidney Injury (AKI): Intermittent Hemodialysis (IHD) vs. Sustained Low Efficiency Daily Dialysis (SLEDD) vs. 24 hrs SLEDD (c-SLEDD) Sudhanshu Jain,[1,2] George N. Coritsidis,[1] Andrew Chao,[1] Yiannis Apergis,[1] Edward T. Zawada.[2] *[1]Elmhurst Hospital Center, Elmhurst, NY; [2]Avera Mckennan Hospital, Sioux Falls, SD.*

Background: Use of SLEDD is steadily increasing in critical care units due to its relative ease of usage and cost effectiveness. Recently there has been interest in its continuous use even though data is lacking

Methods: We reviewed charts for all patients with AKI requiring RRT admitted to ICU (Surgical or medical). Data was collected from 1998-2009 from Elmhurst Hospital Center and Avera Mckennan Hospital. SLEDD modalities were available after 2004. Statistical analysis was done using analysis of variance.

Results: 31 pts (IHD) vs 48 pts (SLEDD) vs 45 pts (c-SLEDD) were compared. There was no significant difference between the groups with the following: age, gender, organ failure rate, diabetes mellitus and cardiac disease history. IHD group had significantly lower rate of sepsis. Vasopressor use (38.7% vs 79.2% vs 77.7%) was significantly higher in both SLEDD modalities as compared to IHD. APACHE II score at admission was significantly lower in SLEDD group where as pre RRT APACHE II scores and organ failure index showed no significant difference. In hospital mortality was significantly higher in SLEDD modality when unadjusted for acuity.

	IHD	SLEDD	c-SLEDD	p
Patients #	31	48	45	
Age	57 ± 3.1	62.6 ± 2.4	60± 2.2	NS
Gender(M)	80.6%	75%	69%	NS
Vasopressor(VP)	38.7%(n=12)	79.2% (n=38)	77.7%(n=35)	<0.0002
Organ Failure	2.26 ± 0.15	2.35 ± 0.15	2.55 ± 0.14	NS
Cardiac Ds Hx	38.7%	27.1%	25%	NS
DM	43.3%	47.9%	40%	NS
Sepsis	25.8%	45.8%	51.1%	0.04
APACHE II(adm)	20.8 ± 1.4	16.8 ± 1.1	21.08 ± 1.4	0.02
APACHE II(preRRT)	26.1 ± 1.4	28.2 ± 0.9	25.1 ± 1.1	NS
Mortality	48.4%	78.8%	57.8%	0.04
Mortality(no VP)	42.1%	40%	20%	0.05
Mortality(w/ VP)	58.3%	79.6%	74.3%	NS

Conclusions: When comparing the three modalities in critically ill patients, mortality was higher in the SLEDD population. This difference disappeared after correcting for acuity and vasopressor (VP) use.

PUB255

Continuous Renal Replacement Therapy with Regional Citrate Anticoagulation Induces a Negative Calcium Balance Victor Sato, Renato Antunes Caires, Igor Marques, Renato Pontelli, Patricia T. Goldenstein, Emmanuel A. Burdmann, Maristela Carvalho Costa, Rosa M.A. Moyses. *Nephrology, University of Sao Paulo School of Medicine, Brazil.*

Background: Continuous Renal Replacement Therapy (CRRT) associated with regional citrate anticoagulation (RCA) is commonly employed in intensive care units, especially in patients with acute kidney injury (AKI), hemodynamic instability and high risk of bleeding. However, this therapy carries the potential risk of negative calcium (Ca) balance associated with a worsening of hemodynamic instability. The aim of the study was to better understand the safety aspects of CRRT with RCA.

Methods: In order to assess the effects of CRRT with RCA in Ca kinetics, 10 continuous venovenous haemodialysis (CVVH) sessions, performed with Ca-free dialysate, were evaluated. The delivered dialysis dose and the blood flow were fixed, and intravenous Ca reposition was titrated based on ionized Ca values.

Results: During therapy, our patients (7 males, 66±11yrs, 6 with AKI) presented a diuresis rate of 0.3L (range, 0; 2.4L). No cardiac arrhythmia neither any circuit clotting was observed during therapy. Biochemical parameters are shown below.

Comparison of biochemical parameters at the baseline and the end

	Baseline	End
Ionized calcium (mg/dL)	4.7±0.4	4.2±0.4*
Phosphate (mg/dL)	5.6±2.6	3.1±0.6*
PTH (pg/mL)	140±110	68±3*

Results are shown as mean ± SD. * p<0.05

Median Ca balance was -372mg (range, -855; 290mg), and was negative in 8 patients. Mean effective ultrafiltration (UF) was 6.3±1.9 L. Ca balance presented a trend toward a negative correlation with UF (R= -0.58: p=0.09). Curiously, despite a negative Ca balance and a decrease in serum Ca, PTH decreased after 24h of CRRT.

Conclusions: In conclusion, this study showed a negative calcium balance in patients submitted to CRRT, which was not accompanied by a compensatory increase in PTH, probably due to the critic clinical status of these patients. These results indicate that Ca should be closely monitored in critically ill patients submitted to CRRT therapy, mainly in those with a high UF rate.

PUB256

Outcomes of Patients with End Stage Renal Disease (ESRD) under Chronic Hemodialysis and Patients without ESRD in Acute Renal Failure Requiring Continuous Renal Replacement Therapy: A Single Center Study Ho Sik Shin, Yeon Soon Jung, Hark Rim, Jin Hee Park, Sung Bin Kim. *Internal Medicine, Kosin University College of Medicine, Busan, Korea.*

Background: The purposes of this study were to compare the survival of conventional hemodialysis (HD) patients with the survival of non-end stage renal disease (ESRD) patients.

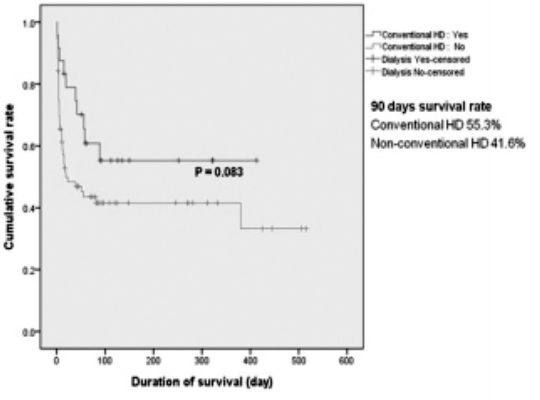
Methods: We evaluated adults (> 18 years) requiring CRRT who were treated in the ICU of Kosin University Gospel Hospital, Busan, Korea from January 1, 2008 to November 30, 2010. A total of 100 (24 ESRD, 76 non-ESRD) patients received CRRT during the study period. Predictors of all-cause death were examined using Kaplan-Meier analysis and Cox proportional hazards analyses in both treatment groups.

Results: For non-ESRD patients, the 90 day survival rate was 41.6 %. For ESRD patients, the 90 day survival rate was 55.3 %. Multivariate Cox proportional hazards analyses demonstrated that conventional HD was not a significant predictor of mortality [hazard ratio (HR) 0.334, 95% confidence interval (CI) 0.063–0.1.763, P = 0.196].

Table 1. Comparison between ESRD Group and Non-ESRD Group

	ESRD (n=24)	Non-ESRD (n=76)	P value
Age, years	53.6 ± 31.6	49.5 ± 28.2	0.324
Admission to CRRT, day	6.4 ± 8.5	8.4 ± 28.7	0.819
APACHE score	89.2 ± 34.9	89.0 ± 32.5	0.982
Medical setting (%)	20 (83.3)	54 (71.1)	0.293
No. of organ failure (range)	1.4 ± 0.8	1.8 ± 0.9	0.131
Serum BUN (mg/dL)	59.2 ± 33.9	53.2 ± 28.5	0.391
Serum creatinine (mg/dL)	6.5 ± 4.0	3.5 ± 2.3	0.002
Leukocyte (× 103/μL)	12.6 ± 5.1	14.6 ± 10.2	0.351
Hemoglobin (g/dL)	10.3 ± 1.7	10.4 ± 2.1	0.701
Platelet (× 103/μL)	126.2 ± 5.5	105.6 ± 82.2	0.534
Serum albumin (g/dL)	2.5 ± 0.6	2.7 ± 0.5	0.179
UFR (mL/kg/hr)	22.4 ± 4.6	21.7 ± 4.4	0.609
Sepsis (%)	12 (50)	48 (63.2)	0.251
Death	10 (41.7)	43 (56.6)	0.202

Fig. 2. Patient survival in conventional hemodialysis group and non-ESRD group



Conclusions: The survival rates of non-ESRD and ESRD patients requiring CRRT did not differ, and conventional HD was not a significant predictor of mortality.

PUB257

The Efficacy of Ferumoxytol in Peritoneal Dialysis Patients Manaf Alroumoh, Farhanah Yousaf, Sayed Husain, Hani Judeh, Prince Mohan, Chaim Charytan, Bruce S. Spinowitz. *Department of Nephrology, New York Hospital Queens, Flushing, NY.*

Background: Iron deficiency is one of the major elements contributing to anemia in CKD patients. Oral iron is often not tolerated and ineffectively absorbed. Intravenous infusion is time consuming and inconvenient in peritoneal dialysis (PD) patients self-treating at home. A new iron preparation , ferumoxytol, which can be administered as a bolus intravenous injection, would allow PD patients to more easily comply with current IV iron dosing regimens. Therefore, we evaluated the effect of ferumoxytol on hemoglobin, hematocrit, ferritin, and iron saturation.

Methods: We reviewed the medical records of PD patients aged ≥ 18 years, who received at least one dose of ferumoxytol between January 2010 and August 2010 at our institution.

Results: 9 males and 8 females, aged 53.5 ± 16.6 years with average weight of 83.94 ± 22.8 kg were included. 15 patients received 2 doses and 2 patients received only 1 dose of ferumoxytol.

table 1

Lab	Baseline	4 Wk Post Feraheme	8 Wk Post Feraheme	12 Wk Post Feraheme	16 Wk Post Feraheme
Hemoglobin (g/dL)	10.4±1.0	11.0±0.9*	11.3±0.9*	11.3±1.0*	10.9±1.2
Hematocrit (%)	32.3±3.9	33.8±3.5*	34.6±3.2*	34.6±3.4*	33.6±3
Ferritin (mg/dL)	279±152	625±248*	743±259*	N/A	640±367*
TSAT (%)	18.1±6.3	37.4±14.7*	36.9±23.7	N/A	32.9±12.9*
Epoetin(U)/ week	39,573	29,764	27,058	27,329*	26,585

*p<0.05 versus baseline

The average time interval between the two doses of ferumoxytol was 6.9 ± 3.6 days. The average intervals between the 2nd dose and subsequent labs were 24.6±11.7 days (Wk 4), 56.1±8.4 days (Wk 8), 87.3±13.6 days (Wk 12), and 116.7±13.8 days (Wk 16). Data presented as mean±SD. Epoetin dose presented as mean.

Conclusions: Ferumoxytol has the expected efficacy of an intravenous iron compound, with improvements in anemia and iron being evident as early as 4 weeks post ferumoxytol. Additionally, significant decrease in monthly epoetin dose was noted at 12 weeks post ferumoxytol dosing. Ferumoxytol is a desirable therapeutic option in peritoneal dialysis patients, who typically visit the clinic at monthly intervals. Alternative iron therapies would require lengthy infusions, or frequent visits to achieve comparable iron delivery.

PUB258

Gender Related Differences in Mortality in Hemodialysis Sonia Maria Holanda Almeida Araujo,[1] Constance Almeida de Alencar Araújo,[1] Nicole Araujo,[2] Andre Pantaroto,[2] Elizabeth De Francesco Daher,[1] Pedro Bruin,[1] Veralice Meireles Sales Bruin.[1] *[1]Medicina, Universidade Federal do Ceara, Fortaleza, Ceara, Brazil; [2]Medicina, Faculdade de Medicina de Jundiai, Jundiai, Sao Paulo, Brazil.*

Background: Long-term prognosis of patients undergoing chronic hemodialysis remains poor. Presently, we hypothesize that factors influencing survival/mortality in hemodialysis are different for each gender.

We aimed to evaluate factors influencing mortality in men and women on chronic hemodialysis.

Methods: All cause mortality was examined in a two-year follow-up study of 400 patients (59% men, mean age 51.6±5.5 years) from three hemodialysis centers. Analyzed factors were age, body mass index, albumin levels, hemoglobin, eKt/V<1.2, ferritin, parathormone<150pg/L, diabetes, stroke, heart failure, hypertension, excessive daytime sleepiness, depressive symptoms (Beck Depression Inventory, BDI), and comorbidity severity (Charlson Comorbidity Index, CCI). Time-dependent Cox regression analysis was performed in all cases and in the cohort grouped by gender.

Results: Two-year mortality was 13.5%. Crude analysis showed that old age, diabetes, stroke, depressive symptoms BDI and CCI scores were associated with all-cause mortality, in all cases. In men, old age, hypoalbuminemia, low hemoglobin, low parathomone, heart failure, excessive daytime sleepiness and comorbidity severity were associated with mortality; in women, old age, diabetes, depressive symptoms and comorbidity severity. In the final model and in all cases, old age and comorbidity severity were associated with increased mortality; in women, comorbidity severity was the determinant of mortality; in men, old age, hypoalbuminemia, low parathormone and excessive daytime sleepiness were determinant of mortality.

Conclusions: Determinants of mortality are specific for each gender in hemodialysis patients. In men, old age, hypoalbuminemia, low parathormone and excessive daytime sleepiness are independent risk factors. These differences must be considered when evaluating effects of therapy.

PUB259

Statins, Vitamin D, Cholesterol in End-Stage Renal Disease Ishir Bhan, Sagar U. Nigwekar, Ravi I. Thadhani. *Department of Medicine, Division of Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Randomized trials of statins in end-stage renal disease (ESRD) have failed to convincingly demonstrate an effect on cardiovascular mortality. However, recent studies in the general population have suggested a possible effect of statins on the metabolism of 25-hydroxyvitamin D (25-OH D). We sought to examine the relationship between statin use, 25-OH D levels, and total cholesterol levels in ERSD.

Methods: We obtained statin usage status, and 25-OH D levels, total cholesterol levels in a subset of patients in the Accelerated Mortality in Renal Replacement (ArMORR, n=10044) cohort of incident hemodialysis patients. We then determined associations between these factors using univariate and multivariate modeling, controlling for potential confounding factors.

Results: 26% of individuals were on statins at baseline. 25-OH D levels were available in 12.3% of subjects. In univariate analysis, there was no association between statin use and 25-OH D levels (p=0.4). However, both statin use and higher 25-OH D levels were associated with lower total cholesterol (Figure 1). In multivariate analysis controlling for age, race, sex, albumin, and season, both statin use (p=0.001) and 25-OH D (p=0.017) continued to be independently associated with lower cholesterol levels. There was no evidence for interaction between the effects of 25-OH D and statins on cholesterol.

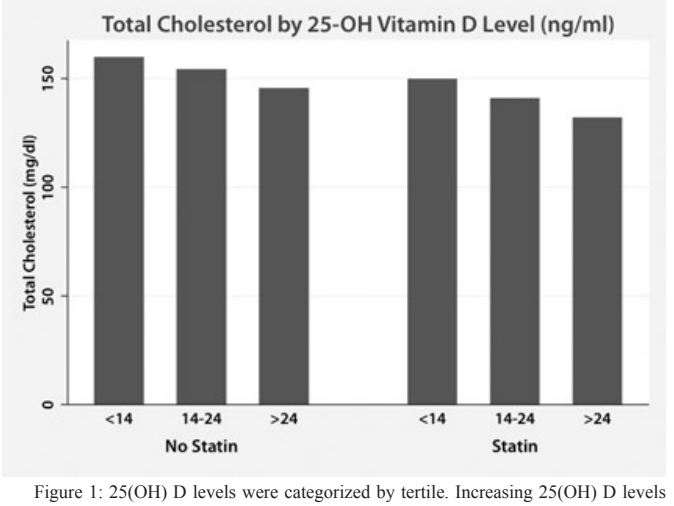

Figure 1: 25(OH) D levels were categorized by tertile. Increasing 25(OH) D levels were associated with lower cholesterol levels among statin users (p=0.003) and non-users (p=0.004). Statin use was also associated with lower total cholesterol (p<0.001).

Conclusions: In patients initiating hemodialysis, both statin use and higher 25-OH D are independently associated with lower total cholesterol levels. Future studies of statins in ESRD should examine the additional value of optimizing vitamin D status.

Frequent Epoetin Alfa Dose Titrations Observed in End-Stage Renal Disease (ESRD) Patients T. Christopher Bond, Steven Wang, Jaime Rubin. *DaVita Clinical Research, Minneapolis, MN.*

Background: There is increasing pressure to maintain hemoglobin (Hb) levels in the range of 10-12 g/dL in U.S. dialysis patients (pts). Physicians use dose titration to attempt to keep patients in Hb range. We sought to characterize EPO dose titrations patterns in patients at a large dialysis organization.

Methods: We examined all EPO doses in patients treated at DaVita dialysis clinics between 1/2009-12/2010. Pts were age ≥18 years, prevalent (>120 days on dialysis), receiving in-center hemodialysis 3 times per week. We segmented EPO utilization into 3 categories. "Dose holds" were defined as ≥3 consecutive sessions with zero EPO dose. "Stable periods" were defined as consecutive doses within 10% of 1st dose in the period, ignoring zero EPO doses lasting <3 consecutive sessions. Non-dose hold and non-stable periods were defined as "transition periods". We defined titrations as absolute differences of ≥ 10% between mean EPO dose in consecutive periods. Dose changes on either end of a dose hold were considered 1 titration if the dose returned to within ±10% of the dose in the period immediately prior to the dose hold; they were considered 2 titrations otherwise. Titration frequency was calculated at the clinic level as the total number of titrations divided by the total number of patient-months.

Results: 84,126 pts from 1,627 clinics met the inclusion criteria; mean per clinic = 52; mean follow up = 15 months. Results show that EPO is titrated 1.1 times per month on average (median = 1.1; SD = 0.25). Only 2% of clinics averaged < 0.6 titrations per patient-month, while majority of clinics (71%) averaged ≥1 titrations per patient-month. Of the observed titrations, there were an equal number of up and down titrations not from/to a dose hold (41%). The remaining titrations were to or from a dose hold.

Conclusions: Results suggest that physicians titrate EPO in ESRD patients very frequently, with the majority of patients receiving at least 1 dose titration per month. Further research is needed to determine if these frequent dose titrations are associated with time in target range.

PUB261

The Effect of Long Acting ESA on Maintaining Stable Hb Levels in Chronic HD Patients; 3 Year Observational Study Christopher Brown, Rupinder Rai, Jennifer Williams, Sadananda V. Aithal, Ashraf I. Mikhail. *ABM ULHB.*

Background: Increasingly, the focus of anaemia management of CKD has shifted from absolute Hb levels to achieving stable Hb with minimal variability. The risk of failing to maintain or overshoot Hb levels in chronic dialysis patients has been a concern with long acting ESA.

We assessed the efficacy of long acting ESA in maintaining Hb levels in chronic HD patients.

Methods: This study used data from 83 patients switched from shorting acting sc epoetin β to CERA. Six months treatment period with epoetin β were compared with upto 3 years treatment with CERA. Hb stability was analysed using Hb levels, number of Hb excursions and residual standard deviation of Hb regression. Two methods of analysis was used to assess Hb stability:

Method 1:- Quantifying excursions of ≥1g/dL outside individual mean Hb levels.

Method 2:- Regressional residual SD, a surrogate marker for Hb stability. RSD has been validated to be one of the best measure of Hb stability.

Treatment approach to iv Iron was not changed throughout the study.

Results: Throughout the observation, ESA dose was modified to maintain the Hb within the target range. During the observation period and due to the publication of large multi-centre studies and regulatory advice, target Hb range was lowered from (10.5 - 12.5) to (10 - 12) g/dL.

6 monthly Hb parameters before and after switch

	Pre-switch (months -6 to -1)	Months 12 to17	Months 18-23	Months 24-29	Months 30-35
Mean Hb	11.8	11.2	11.2	11.2	11.5
Epoetin (IU/wk)	8575				
CERA (mcg/Mth)		212	230	272	260
No. Hb excursions/pt	1.07	0.94	0.95	0.84	0.88
No. low excursions/pt	0.53	0.49	0.44	0.34	0.42
No. high excursion/pt	0.54	0.45	0.51	0.50	0.46
Residual SD	0.7	0.63	0.61	0.60	0.62

Aspiration Hb targets were maintained throughout the observation period. The no. of Hb excursions decreased 1 year post switch; this reduction was maintained throughout the 3 year observation period. The residual SD of Hb (a marker for Hb variability) showed a trend for reduction but did not reach statistical significance.

Conclusions: Long acting ESA therapy can effectively maintain stable Hb in chronic HD patients.

Further analysis of these data assessing the relationship of Hb stability to patient outcomes will be presented.

Funding: Government Support - Non-U.S.

PUB262

Influence of Different Erythropoietin Stimulating Agents on Stability of Hemoglobin Levels in Patients on Maintenance Hemodialysis Maciej Drozdz, Dominik Cieniawski, Karolina Dudek, Maja Koziarz, Sylwester Smialek. *Dept. of Nephrology, Jagiellonian University Collegium Medicum, Cracow, Poland.*

Background: Fluctuations of hemoglobin (Hb) level in dialysed patients leading to changes its concentration outside the target range (10 to 12g/dl) may contribute high cardiovascular mortality in this group. One of the factor affecting these fluctuations might be the choice of erthropoiesis stimulating agent (ESA).

The aim of the study was to find out if using different ESAs - methoxy polyethylene glycol-epoetin β (PEG-epoietin β) and darbepoetin α may affect the stability of Hb level in patients on maintenance hemodialysis.

Methods: The study was composed of 54 (35 M and 19 F) stable hemodialysed patients aged was form 23 to 85 years, mean 57.7 yrs. Time on dialysis was between 16 to 218 months and all of the patients were treated with ESA at least 12 months before beginning of the study. During 12 months of observation Hb level, transferrin saturation and ESA dose were controlled monthly. ESA dose was determined so that Hb level was between 10 to 12g/dl. Only patients, who finished a year of observation were covered in analysis (population per protocol). Before the study patients were randomly (2:1 ratio) assigned to group treated with methoxy PEG-epoetin β (n=36) and group treated with darbepoetin α (n=18).

Results: At the beginning of the study Hb level was: 10.65 vs 11.21g/dl and after 12 months of observation: 10.61 vs 11.6g/dl (no statistically significant difference), respectively. Mean transferrin saturation was 43.9 vs 44.1% and there was no significant difference between groups. During observation in the group treated with methoxy PEG-epoetin β 26.67% of Hb measurements were outside target level. In group treated with darbepoetin α 45.92% of them were outside target level and the difference was statistically significant (Chi^2=12.4; p<0.004). 3.58 changes of methoxy PEG-epoetin β dose and 5.18 changes of darbepoetin α dose was needed during observation, but this difference wasn't statistically significant.

Conclusions: Therapy with methoxy PEG-epoetin β provided better stability of Hb level achieved by lower number of dose changes.

PUB263

Maintenance of Hemoglobin Levels with Once-Monthly C.E.R.A. in Chronic Kidney Disease Patients – Data from the MORAL Study, a Phase IIIb, Single Arm, Open Label Study Neval Duman, Abdullah Uyanik, Abdulkadir Unsal, Siren Sezer, Taner Camsari, Mustafa Cirit, Mehmet Emin Yilmaz, Bulent Altun, Murat Duranay, Alaattin Yildiz, Idris Sahin, Ayhan Dogukan, Sedat Ustundag, Ibrahim Karayaylali, Arzu Kahveci, Sukru Sindel, Yavuz Yenicerioglu, Ahmet Alper Kiykim, Ertugrul Akbas, Fatih Ozdener. *Ankara Univ. School of Med.*

Background: MORAL study was conducted to assess the long term maintenance of hemoglobin (Hb) levels, with once-monthly IV administration of continuous erythropoietin receptor activator (C.E.R.A.) in patients with chronic kidney disease (CKD) previously treated with other erythropoiesis stimulating agents (ESAs) and to evaluate safety and tolerability.

Methods: This study consisted of a 4-week Study Verification Period (SVP), a 16-week Dose Titration Period (DTP), an 8-week Efficacy Evaluation Period (EEP) and a 4-week follow-up period.

Results: Totally 173 patients were screened in the SVP, 132 of which entered the DTP and 107 the EEP. Forty-four patients reported 73 adverse events, 15 of which were serious. Hypertension and bronchitis were the most frequent adverse events reported, occurring in 3.8% and 2.3% of patients, respectively. Two treatment-related serious adverse events were reported and both resolved.

Table 1. Study results

	ITT n=127	PP n=84
Mean (SD) BL Hb concentration g/dL	11.1 (0.56)	11.1 (0.54)
Mean (SD) EEP Hb concentration g/dL	11.3 (1.06)	11.3 (1.07)
Hb concentration ±1 g/dL of baseline & within 10-12 g/dL during EEP n (%)	44 (34.7)	39 (46.4)
Hb concentration 10-12 g/dL during EEP n (%)	65 (51.2)	54 (64.3)
Mean (SD) change in Hb concentration from baseline g/dL	0.29 (1.08)	54 (64.3)
Median time in target range days	38	38

Conclusions: The results of this study further demonstrate that once-monthly C.E.R.A. administration maintains Hb levels within the target range. The data contributes to the clinical efficacy and safety experience of once-monthly C.E.R.A. in clinical practice.

PUB264

Effectiveness and Safety of Methoxy Polyethylene Glycol-Epoetin beta for the Treatment of Anemia in Patients with Chronic Kidney Disease in Hemodialysis (EPOSEM Study) Joan Fort,[1,3] Fernando Marco,[2] Rafael Ramos,[2] Mouhssen El Manouari,[3] Bernat De la Torre,[4] Antoni Pelegri,[3] Jorge Bartolome,[5] Irene Agraz,[1] Daniel Seron.[1] *[1]Nephrology, Vall d'Hebron Hospital, Barcelona, Spain; [2]Nephrology, CD Diaverum Nephros, Barcelona, Spain; [3]Nephrology, CD Diaverum Verge de Montserrat, Barcelona, Spain; [4]Nephrology, Diaverum Clinica E. Rotellar, Barcelona, Spain; [5]Nephrology, Clinica Secretari Coloma, Barcelona, Spain.*

Background: To evaluate the effectiveness of Mircera® in prefilled syringes in the treatment of anemia in patients with chronic kidney disease (CKD) on hemodialysis.

Methods: Multicenter, observational, retrospective study. Included patients aged ≥ 18 y.o. with anemia associated with CKD on hemodialysis (HD), who have begun treatment with Mircera® at least 6 months before and were on hemodialysis 6 months before the start of Mircera®.

Results: A total of 57 patients were included in the analysis (61.4% men and 38.6% women). Mean time on HD was 4.4 years. All patients received previous treatment with an eritrophoietic stimulating agent (ESA) before starting treatment with Mircera® (70.2% epoetin beta, 10.5%epoetin alfa, 24.6% darbepoetin). Average dose of conversion to Mircera® were: 123.7 µg/month (DA 40-80 or 8000-16000 epoetin weekly) 102.8 µg/month for lower doses and 200 µg/month for patients with higher doses being below those recommended in SPC. Median Haemoglobin (Hb) at baseline was 11.2 g/dl, 11.6 g/dl at the start of treatment Mircera® and 11.0 g/dl at follow-up.

19.3% and 15.8% of patients were within the Hb range of 10-12 g/dl (p> 0.05), without differences between the two time periods . No differences either between the percentage of patients with Hb <10 and Hb> 12 g/dl, or between the percentage of patients maintaining Hb between 10-13 g/dl or complications (p> 0.05) during the two treatment periods.

Conclusions: In HD patients the conversion to monthly Mircera from other ESAs is safe and effective, maintaining Hb levels within the desired targets.

PUB265

Hemoglobin Variability in Peritoneal Dialysis Patients Treated with Erythropoiesis Stimulating Agents Ashwani K. Gupta,[1] Sumit Narula,[1] Ramesh Saxena.[2] *[1]Nephrology, University of Florida, Jacksonville, FL; [2]Nephrology, University of Texas Southwestern, Dallas, TX.*

Background: Hemoglobin (Hb) variability and cycling have been documented both in Hemodialysis and Pre-dialysis patients receiving Erythropoiesis stimulating agents(ESA). Increased Hb variability (HbVar) has been linked to greater morbidity and mortality in these populations. Similar data for PD patients is extremely limited. A previous report of 12 PD patients from the Netherlands reported the average amplitude of HbVar to be 3.1 g/dL.

We hypothesized existence of HbVar in PD patients and conducted a pilot study to characterize it.

Methods: A random sample (10%, n=20) of prevalent PD patients at a university based PD program was chosen for analysis. Hb, ESA doses and laboratory parameters were abstracted for a period between September 2009 and February 2011(mean follow up= 14 months). HbVar was examined by calculating the standard deviation of Hb within each subject and across all subjects.

Results: 95% of the observed Hb values varied by upto 2.8g/dL(2SD) from the mean. Table 1 summarizes the study findings. 3 patients (15%) did not require therapy with EPO. HbVar was significantly lower in patients not requiring EPO in comparison to those requiring EPO(0.65 vs 1.4 g/dL, p value<0.001). The mean EPO dose was 12,000 U/wk(Range 1000-54000 U/wk). Mean number of dose chages were 10/pt(range 3-15).

Patient Characteristics and HbVar

Mean(SD)	Hb(g/dL)	Albumin	PTH	Ferretin	Saturation(%)
All Patients(n=19)	11.5(1.7)	3.6(0.6)	433(400)	800(400)	35(18)
No ESA(n=3)	12.9(0.6)				
Recieving EPO(n=14)	11.2(1.4)				

Table 1

Conclusions: This pilot study confirms the existence of HbVar in PD patients. Intercurrent events, varying iron stores and inflammatory mediators have been implicated in HbVar in pre-dialysis and hemodialysis patients. Similar factors may play a role in PD patients. However, significantly greater HbVar in patients treated with ESA suggests a causal role of ESA administration in HbVar. PD patients may benefit from an improved ESA dosing protocol to reduce HbVar. A larger analysis including more patients will be undertaken to confirm these findings. Studies relating HbVar to outcomes are needed in PD patients.

PUB266

Factors Affecting the Levels of Serum Glycated Albumin in Peritoneal Dialysis Patients Ami Hayashi, Yoshitaka Miyaoka, Toshiyuki Nakao. *Nephrology, Shinjuku-ku, Tokyo, Japan.*

Background: Glycated albumin (GA) is an alternative glycemic maker in diabetic hemodialysis patients. However, GA levels may be affected by albumin turnover, independent of glycemic status. We investigated the dialysis-related factors which affect GA levels in peritoneal dialysis (PD) patients.

Methods: The levels of GA, HbA_{1c}, serum glucose, and other clinical variables related to PD, namely, daily peritoneal protein loss (PPL), peritoneal weekly creatinine clearance (pwCcr), and dialysate-to-plasma creatinine ratio (D/Pcr) were measured in 33 stable PD patients (13 diabetic, 20 non-diabetic; age, 59.9 ± 10.5 years; men/women, 25/8; dialysis duration, 44 ± 35 months). The variables for each patient were calculated as the mean values of 3 monthly measurements. The correlations between GA and these variables were examined using the Pearson correlation coefficient and stepwise multivariable regression analysis.

Results: GA, HbA_{1c}, and serum glucose levels were significantly higher in diabetic patients than in non-diabetic patients (diabetic, 17.0% ± 2.91%, 6.4% ± 0.8%, 140 ± 49 mg/dl; non-diabetic, 13.3% ± 1.89%, 5.1% ± 0.3%, 99 ± 11 mg/dl; all, $p < 0.001$). In diabetic patients, a significant correlation was found among serum glucose, HbA_{1c} and GA levels. In non-diabetic patients, a significant correlation was found between pwCcr and GA levels. There were no significant correlations among serum albumin, PPL, D/Pcr, and GA levels in either diabetic or non-diabetic patients. Stepwise multivariable regression analysis showed that serum glucose and pwCcr were significant variables associated with GA levels in all patients (β= 0.69, -0.44, R^2 = 0.72). In the diabetic patients, serum glucose, pwCcr and age were significant variables (β= 0.62, -0.31, -0.42, R^2 = 0.87). In the non-diabetic patients, only pwCcr was a significant variable associated with GA levels (β= -0.64, R^2 =0.41).

Conclusions: GA was affected by pwCcr in both diabetic and non-diabetic PD patients.

PUB267

Injection of Darbepoetin alfa at the Start of a Hemodialysis Session Might Be More Efficient Than Injection at the End of the Session Noritomo Itami. *Kidney Center, Nikko Memorial Hospital, Muroran City, Hokkiado, Japan.*

Background: It has been noted that the injection of darbepoetin alfa(DA) at the end of hemodialysis(HD) was often neglected because of the confusion that can occur at the end of the HD session due to complications such as hypotension, vomiting and cramps. Injection of DA can be performed with more certainty at the start of HD but there is the possibility that an increased dose of DA will be required because of its adherence to the dialysis system's tubing.

Methods: Thirty-eight patients were recruited (M/F Ratio, 20:18; Age: 63.6±10.5yrs; Primary disease: Diabetes(13), Glomerulonephritis(12), Polycystic kidney(3); others(10)). Written informed consent was obtained. At the start of the study, DA treatment was changed from the end of HD (Period I) to the start of HD (Period II). Other anemia treatment was carried out as usual. DA dose was altered biweekly according to our algorithm which was presented at the 52nd Congress of the Japanese Society of Dialysis Therapy. The algorithm maintains a target hemoglobin(Hb) level of 10-12g/dL while keeping the change in Hb to within 0.5g/dL to prevent the occurrence of Hb cycling. After 24 weeks, the average DA dose and clinical parameters were examined.

Results: Hb was unchanged at the end of both periods (Period I: 11.01±0.95g/dL and Period II: 10.91±0.87g/dL, not significant(NS)). Serum ferritin increased (143.9±94ng/mL and 193.2±126.5ng/mL, $p<0.001$) although the number of patients undergoing iron treatment (Period I: 18.8±4.1 and Period II: 16.3±2.4, NS) was unchanged. Average DA dose in Period II was significantly reduced from 18.0±11.6mg/week in Period I to 16.1±10.7mg/week in Period II($p<0.05$). The average fulfillment of target Hb(%) was 69.4±8.4% in Period I and 77.6±4.3% in Period II($p<0.01$). There was no neglection of injections of DA in Period II.

Conclusions: The injection of darbepoetin alfa at the start of an HD session might be more efficient and reliable than injection at the end of the HD session. A multicenter study providing access to more patients and a longer time period is warranted.

PUB268

Poor Performance of Correction Formula for the Prediction of True Hypocalcemia in Dialysis Patients Zainab Khan, Christine A. White, Alexander R. Morton, Rachel M. Holden. *Medicine, Queen's University, Kingston, ON, Canada.*

Background: Abnormalities in serum calcium are frequently encountered in patients receiving dialysis therapy. Total calcium is most frequently measured because of sample handling and cost concerns. Given that the ionized form is biologically active a number of adjustment formulae have been derived to "correct" the total calcium for changes in serum albumin (SA) and phosphorus (P). International guidelines for nephrology recommend that calcium be kept in the normal range reference range and K/DOQI recommends using SA-corrected formulas. We determined the accuracy of noncorrected calcium and 5 published corrected calcium formulae in the identification of abnormal ionized calcium in a cohort of hemodialysis (HD)patients.

Methods: Ionized calcium (iCa), total calcium (tCa), serum albumin (SA), total protein (TP) and phosphorus (P) were measured in HD patients. The accuracy with each each SA and P corrected formulae (Table 1) identified abnormal iCa was determined.

Results: There were 73 HD patients with a mean age of 63 y. There were only 3 cases of hypercalcemia (ica > 1.31 mmol/L). There were 50 cases of hypocalcemia (iCa < 1.19 mmol/L). The mean SA was 35.1. The accuracy of each formula to predict abnormal iCa is demonstrated in the table. Non-corrected tCa identified true hypocalcemia in 38% of cases with minimal improvement achieved with mathematical correction. The single P-corrected formula was least accurate in this sample.

	low ionized Ca	high ionized Ca
	calculated low (%)	calculated high (%)
tCa+0.0176 x (34-SA)	42	33.3
tCa+0.02 x (40-SA)	22	66.7
tCa+(0.015 x (40-SA)+0.07 x (1.5 - P)	24	66.7
tCa+0.01 x (30-SA)	52	33.3
tCa+0.018 x (35-SA)	40	66.7
Uncorrected tCa	38	66.7

Conclusions: There was a high prevalence of hypocalcemia in this cohort of HD patients. In patients with difficult to control hyperparathyroidism, it is important to know that true hypocalcemia is not present particularly when vitamin D analogues and calcimimetics are being used. There is little benefit of SA or P corrected forumulae in identifying true hypocalcemia. Future studies should identify those dialysis patients best monitored by ionized calcium values.

PUB269

The Association of Nutrition with Interdialytic Weight Gain and Depressive Disorder in Hemodialysis Patients Hyun Gyung Kim, Young Ok Kim. *Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea.*

Background: Malnutrition was reported to occur in 23-76% and known as an important predictor of increased mortality in maintenance hemodialysis (HD) patients. This study was performed to evaluate the association of nutrition with interdialytic weight gain (IDWG) and depression in HD patients.

Methods: Sixty-five HD patients for at least 3 months were enrolled. We investigated malnutrition by OSND (Objective score of Nutrition on dialysis) score and depressive disorder by Montgomery depression rating scale and Hamilton depression rating scale. We compared the clinical and biochemical profiles according to the malnutrition.

Results: Mean age of the patients was 55.7 ± 12.6 years and patients with diabetes accounted 55.4%. Mean duration of HD was 36.2 ± 32.0 (4 - 129) months. Depressive disorder was diagnosed in 21 (32.3%), Malnutrition (OSND score < 22) in 24 (36.9%) and large IDWG (>1kg/day) in 40 (61.5%) out of the 65 HD patients. Patients with malnutrition had lower incidence of large IDWG (45.8% vs 70.7%, p=0.046) and depression (19.5% vs 54.1%, p=0.004) than those without. BMI (21.2 ± 3.0 vs 23.4 ± 3.0 kg/m^2 ,p=0.006), TSF (triceps skin fold thickness, 8.8 ± 4.2 vs 15.0 ± 6.2 mm, $p<0.001$), MAC (mid-arm circumference, 23.6 ± 2.7 vs 26.4 ± 3.0 cm, p=0.001), serum albumin (3.6 ± 0.3 vs 3.8 ± 0.2 g/dL, p=0.029) and total cholesterol (142.5 ± 29.2 vs 169.7 ± 31.2 mg/dL, p=0.001) were also lower in patients with malnutrition, compared to the patients without malnutrition. There was no difference in age, gender, diabetes and HD duration between the two groups. In multivariate analysis, Depressive disorder was an independent risk factor for malnutrition.

Conclusions: This study showed that depressive disorder was significantly related to malnutrition in maintenance HD patients. Therefore, we suggest that the depressive disorder may be considered in HD patients at the time of the assessment of nutritional status in maintenance HD patients.

The Factors Affecting Health-Related Quality of Life in Dialysis Patients Owen Kwon,[1,3] Ji-Young Choi,[1,3] Jung-Ju Seo,[1,3] Jang-Hee Cho,[1,3] Mi-Kyung Jin,[1,3] Kyung-Deuk Hong,[1,3] Chung-Hoon Yu,[1,3] Se-Hee Yoon,[1,3] Sun-Hee Park,[1,3] Chan-Duck Kim,[1,3] Ki-Soo Park,[2,3] Yong-Lim Kim.[1,3] *[1]Internal Medicine, Kyungpook National University School of Medicine, Daegu, Korea; [2]Preventive Medicine, Gyeongsang National University School of Medicine, Jinju, Korea; [3]Clinial Research Center for End Stage Renal Disease, Korea.*

Background: To investigate the factors influencing health-related quality of life (HRQOL) in ESRD patients on dialysis, we measured the level of HRQOL.

Methods: The study subjects were 237 patients with ESRD on HD or PD over 6 months in two university hospitals in Korea. Patients completed the Korean version of KDQOL (kidney disease quality of life)-36 with five subscales. Measures of self-efficacy and treatment satisfaction in other studies were translated and modified for this study. Various sociodemographic and clinical variables were also recorded.

Results: The quality of life score were 46.3, 49.2, 67.6, 58.5, and 41.1 in the subscales of physical, mental component, symptoms and problems, effect of kidney disease on daily life, and burden of kidney disease, respectively. Variables associated with better physical component were male gender, lower age, higher educational level, having an occupation, higher self-efficacy, and higher treatment satisfaction; a variable associated with better mental component was male gender; variables associated with better symptoms and problems component were hemodialysis and self efficacy. Burden of kidney disease component was associated with educational level, primary cause of ESRD and self efficacy. Effect of kidney disease component correlated positively with self-efficacy and treatment satisfaction. Multiple linear regression analysis showed that independent variables associated with HRQOL were age, educational level, duration and adequacy of dialysis, primary cause of ESRD, self-efficacy, and treatment satisfaction.

Conclusions: Adequacy of dialysis, self-efficacy and treatment satisfaction were associated with HRQOL in ESRD patients on dialysis. Strategies to increase adequacy of dialysis, self-efficacy and treatment satisfaction may be helpful to enhance the HRQOL in dialysis patients.

PUB271

The Newly Identified Anorexigenic Adipokine Nesfatin-1 in Hemodialysis Patients: Associations with Protein Intake and Body Composition Denise Mafra,[1] Juliana Saldanha,[1] Julie Lobo,[3] Milena Barcza Stockler-Pinto,[3] Viviane Oliveira Leal,[1] Antonio Calixto,[4] Bruno Geloneze,[4] Denis Fouque,[5] Juan J. Carrero.[2] *[1]Clinical Nutrition, Federal University Fluminense, Niteroi, Rio de Janeiro, Brazil; [2]Division of Renal Medicine, Karolinska Institutet, Sweden; [3]Institute of Biophysics Carlos Chagas Filho, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; [4]Laboratory of Investigation on Metabolism and Diabetes, State University of Campinas, Campinas, Brazil; [5]Nephrology, Universite Claude Bernard I - Hôpital Edouard Herriot, Lyon, Rhone, France.*

Background: Nesfatin-1 is a anorexigenic peptide. Anorexia and malnutrition are common features of chronic kidney disease (CKD) that predispose patients to worse outcomes. The aim of this study was to evaluate the plasma nesfatin-1 levels in hemodialysis (HD) patients.

Methods: Twenty five HD patients were studied and compared to 15 healthy subjects matched for body mass index (BMI), % body fat mass (BF) and age. Nesfatin-1 levels were analyzed using ELISA and, leptin levels were measured by a multiplex assay kit manufacture by R&D Systems®. Appetite was measured using a specific questionnaire and food intake were recorded.

Results: Plasma nesfatin-1 levels did not differ between HD patients and healthy subjects.

Clinical and anthropometric characteristics of the HD patients and healthy subjects

Parameters	HD Patients	Healthy Subjects
Age (years)	53.2±11.9	47.9±14.8
BMI (kg/m2)	23.1±2.8	24.9±3.9
Triceps skinfold thickness (mm)	13.1±4.9	15.2±5.9
Body fat (%)	28.6±6.5	29.3±5.2
Leptin (ng/mL)	13.9±21.2*	5.1±4.3
Nesfatin-1 (ng/mL)	0.16±0.07	0.17±0.10

*p<0.05

Nesfatin-1 levels showed significant negative correlations with protein intake (r=-0.42; p=0.03), and positive correlations with BMI (r=0.33; p=0.03), % body fat (r=0.35; p=0.03) and the triceps skinfold thickness (r=0.36; p=0.02). Nesfatin-1 levels also correlated positively with leptin levels (r=0.45; p=0.006).

Conclusions: In conclusion, nesfatin-1 levels did not differ between HD patients and healthy subjects who were matched for BMI, % body fat and age. However, nesfatin-1 correlated with protein intake and body composition.

PUB272

Is Body Mass Index of 23kg/m² a Reliable Marker of Protein-Energy Wasting in Hemodialysis Patients? Denise Mafra,[1] Viviane Oliveira Leal,[1] Cristiane Moraes,[1] Milena Barcza Stockler-Pinto,[2] Julie Lobo,[2] Najla Elias Farage,[3] Denis Fouque.[4] *[1]Clinical Nutrition, Federal University Fluminense (UFF), Niterói, Rio de Janeiro, Brazil; [2]Institute of Biophysic Carlos Chagas Filho, Federal University of Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil; [3]Nutrition, RenalCor Clinic, Rio de Janeiro, Brazil; [4]Nephrology, Université Claude Bernard I, Lyon, Rhône, France.*

Background: There are several parameters that may be indicative of protein-energy wasting (PEW) in hemodialysis (HD) patients and the International Society of Renal Nutrition and Metabolism panel reccomends that a body mass index (BMI) less than 23kg/m² is a marker of PEW. However, BMI can be heavily influenced by fat mass and the adiposity is related to inflammation. Therefore, the adequate cut-off point by BMI remains controversial and this study compared the body composition and inflammatory status of HD patients according to the cut-off of 23kg/m² for BMI.

Methods: Forty seven HD patients (30 men, 11 diabetic, 53.8 ± 12.2 yr, 58.2 ± 50.9 months on dialysis) were studied. Anthropometric data and handgrip strenght (HGS) were evaluated. Inflammatory markers (CRP, TNF-α, leptin and IL-6) were measured.

Results: Nineteen (40.4%) patients presented BMI values < 23kg/m², and leptin levels, midarm muscle circunference and free fat mass (FFM) were significantly lower in these patients when compared to patients with BMI > 23kg/m². However, the prevalence of muscle functional loss was not different between the BMI groups. The percentage of body fat (%BF), fat mass (FM), FM/FFM ratio and waist circumference (WC) were significantly lower in patients with BMI < 23kg/m² but the mean values of %BF did not indicate energy wasting. Patients with BMI > 23kg/m² presented higher prevalency of inflammation and the WC and %BF values were compatible with metabolic derangements associated with obesity. The adiposity parameters were correlated with CRP and leptin.

Conclusions: HD patients with BMI < 23kg/m² did not presented signs of energy wasting while those with BMI > 23kg/m² were more inflammed probably due higher adiposity. Thus, the BMI of 23kg/m² seems not to be a realiable marker of PEW in HD patients.

PUB273

Efficacy of Intradialytic Parenteral Nutrition on the Aminoacid Status: Preliminary Results of a Kinetic Study Elena Mancini, Antonio Santoro. *Nephrology Dialysis Hypertension, Policlinico S.Orsola-Malpighi, Bologna, Italy.*

Background: Intradialytic parenteral nutrition (IDPN) may be useful to contrast malnutrition of hemodialysis (HD) patients. However, it is essential to verify whether IDPN is actually able to draw positively upon metabolism, enriching the aminoacid (AA) status, thereby enhancing protein synthesis.

A kinetic study was planned to evaluate whether IDPN can induce an effective AA gain in the short-run in malnourished HD patients.

Methods: Ten HD patients (3 x week; Bologna Malpighi & Trento Hospitals) with albumin <3.5 gr/dl and pre-albumin < 30 mg/dl for at least one month were studied (low-flux membrane, 240 min/session). After a dialysis study session without IDPN, patients received IDPN for one month (*all-in-one* bag NutriSpecialipid: 625ml, Proteins 35.9 gr, 10 AA: Ser, Pro, Gly, Ala, Val, Met, Leu, Phe, Lys, His). In the first session, as well as after 2 and 4 weeks, we measured the plasma (pre- and post-HD), and dialysate AA concentration (dialysate spilling technique at 120 and 240 min). Albumin, pre-albumin, glucose and lipid metabolism, inflammation indices and blood cell count were also evaluated.

Results: Preliminary results show that even with a low-flux dialyzer and without IDPN infusion an AA loss in dialysate does exist. With the IDPN infusion that loss actually increases (43±13 with IDPN *vs* 23±14mmol/L without IDPN, p<0.001). Nevertheless, after one month IDPN, the pre-dialytic plasma concentration of each infused AA was increased as compared with the basal value (minimum 5.2% for Tyr, maximum 66% for Try), with a mean increment of 36.8%. No derangement was found in glucose and/or lipid metabolism.

Conclusions: In one month of IDPN, a time range that is quite insufficient to induce a clinically relevant change in the nutritional state, a homogeneous growth in the plasma concentration of all the infused AA was evident, however, leading us to hypothesise that the use of IDPN for a longer time-span may actually translate into increased protein synthesis.

PUB274

Stopping of Dialyzer Reuse and Switch to High-Flux Dialyzers Is Associated with Lower ESA Requirement and Better Phosphare Control Andrzej Milkowski,[1] Teresa Rydzynska,[1] Jolanta Malyszko.[2] *[1]Fresenius Nephrocare, Poland; [2]Nephrology, Medical University, Bialystok, Poland.*

Background: Dialyzer reuse is still common practice in some dialysis units. There are three major concerns with reuse: the risk of infection; biochemical and immunologic effects; and loss of performance with impairment in clearance and/or ultrafiltration.

Methods: The aim of our study was to assess the dialysis adequacy, anemia control and use of ESA as well as phosphate control in 68 patients from a single center before and 1 year after stopping of reuse of dialyzers. In addition, together with single use of dialyzers, all the patients were switched to high-flux dialyzers (Fresenius, Germany).

Results: All the parameters are given in the Table 1.

Parameters before and 1 year after stopping of dialyzer reuse

	before	after
Phosphate (mmoL/L)	1.87±0.55	1.73±0.51 *
Urea before HD (mmoL/L)	24.01±6.35	24.24±6.90
Urea after HD (mmoL/L)	7.40±2.41	6.64±2.15
Urea reduction ratio (%)	69.34±6.79	72.54±4.73 ***
Kt/V	1.46±0.54	1.54±0.17
HD time weekly (hours)	11.71±2.27	12.34±1.54 *
ESA weekly dose (IU)	3485±2179	2846±2706 **
ESA dose per kg dry body weight	55.12±38.41	45.42±45.56 **
Serum iron (nmoL/L)	12.07±4.38	13.76±5.99
TSAT (%)	32.34±19.02	34.64±17.77
Iron iv weekly (mg)	54.76±71.84	53.73±67.03
Hb (mg/dL)	10.74±1.66	11.13±1.58 p=0.06

*p<0.05, ** p<0.01. ***p<0.001

One year after switch to single use high flux dialyzers a highly significant rise in urea reduction ratio was observed, together with a tendency to rise in Kt/V. Moreover, use of ESA dropped significantly in the study group with a tendency to higher achieved hemoglobin, whereas the iron supplementation did not change. A significant fall in serum phosphate was also observed.

Conclusions: Single use high-flux dialyzers are more efficient in clearing urea and other molecules. Moreover, after switch amelioration of anemia with lower use of ESA was demonstrated together with better phosphate control. It may be associated with better survival and lower costs. However, further investigation is required to accurately assess the morbidity and mortality associated with reuse or single use as well as cost effectiveness.

PUB275

C-Peptide (CPR) Levels of Diabetic Patients (pts) on Maintenance Hemodialysis (HD) as Compared to Non-DM HD pts Ibuki Moriguchi,[1] Michihito Okubo,[1] Yoko Itoh,[1] Naoyuki Kobayashi,[1] Shokichi Naito,[2] Kei Kobayashi,[2] Yasuo Takeuchi,[2] Kouju Kamata.[2] *[1]Sohbudai Nieren Clinic, Zama, Kanagawa, Japan; [2]Dept. of Internal Med., Kitasato University, Sagamihara, Kanagawa, Japan.*

Background: CPR concentration in HD pts was known to be higher as compared to pts with normal renal function.

The purpose of this study was to investigate the plasma CPR levels in 28 type 2 DM HD pts and to compare them with levels in 57 non-DM HD pts(control). Further, DM HD pts were split into three treatment groups, i.e., 12 pts given insulin, those under diet control only(12pts) and the remaining 4 treated with other anti diabetics. Their respective CPR levels were studied.

Methods: Mean age was 64.3±9.5 (mean ±SD) years in DM pts versus 57.8± 16.0 yrs in non DM. Vintage on HD was 5.1±3.7 yrs (DM) vs. 10.3±8.0 yrs (non-DM). CPR (ng/ml), HbA1c (%) and glycated albumin (GA, %) were measured in pre-and post-HD samples of the first weekly session. Statistical difference between groups was analyzed by Mann-Whitney U test and chi-square test. Correlation coefficient was also calculated.

Results: 1. Pre-HD CPR levels in DM pts was significantly lower than those in non-DM pts (8.59±5.06 vs. 11.68±4.47 p<0.0052). Post-HD CPR levels were significantly lower than pre-HD levels both in DM and non-DM pts (2.74±1.47 vs. 5.44±4.40, p<0.001). CPR in pts on insulin were significantly lower than those in pts on dietary control (pre-HD: 6.01±3.49 vs. 10.70±5.92 p<0.0243; post-HD: 1.97±0.98 vs. 3.24±1.57, p<0.0282)

2. Pre-HD GA as well as HbA1c levels in DM pts were significantly higher than those in non DM pts. Post-HD GA levels were significantly decreased compared with pre-HD levels both in DM and non-DM pts.

3. A significant negative correlation was observed between serum levels of CPR and GA only after HD session both in DM (r=-0.373, p<0.0499) and non-DM pts (r=-0.388, p<0.0003).

These data indicate that DM HD pts may have a lower insulin secretion from their pancreas than that in non DM HD pts. Post-HD decrease in CPR levels might be induced by an effective removal through high-flux membrane used in this study.

Conclusions: Pre-HD CPR level may reflect pancreatic secretion of insulin as well as the effect of disturbed renal disposal.

PUB276

Changes in Cholesterol Related to Dialysis: Magnitude, Impact on Statin Use and Relation of Statin Use to Eythropoetin Requirements Janice G. Nigos, Jeannie P. Co, Barbara A. Clark. *Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA.*

Background: While CKD is associated with abnormailites in lipid profiles and CV risk, hemodialysis (HD) patients may have improved profiles, possibly explaining a lack of proven CV benefit of statins in this population. The purpose of the present study was to determine the magnitude of changes in lipid profiles for individual dialysis patients related to hemo or peritioneal dialysis (PD) and if these changes impacted statin use before and after regular dialysis. In addition, since statins may have pleitropic effects we wanted to see if statin use could be associated with reduced erythropoetin (Epo) requirements in HD patients.

Methods: Retrospective review of 88 charts revealed 35 HD patients and 8 PD patients with enough data to compare from 1 to 3 years before dialysis and after at least 3 months of regular dialysis. Crosssectional comparison was also made of Epo doses in stable iron replete HD pts with (n=30) or without statin use (n=34).

Results: In HD there were reductions in total cholesterol (181 ±8 vs 142±5, p<0.001), LDL (104±6 vs69±4, p<0.001), TG (163±17 vs 117±13, p<0.01), and significant improvements in HDL (44±2 vs 50±2, p<0.05) and serum albumin (3.5±0.1 vs 3.96 ±0.06, p<0.001). Statins were used in 65.7% pre versus 54.3% after. Conversely, In PD, LDL levels increased significantly (103±22 vs 131±28, P<0.05) with no significant changes in the other parameters (TC 183±22vs 208±39; TG 168±51 vs 153±57; HDL 45±19 vs 47±18; albumin 3.8±0.4 vs 3.8±0.4). Statins were used in 50% pre and 62.5% after PD. HD lowers TC, LDL, and TG by about 25%, while in PD, LDL levels rise by 25%. Epo doses were significantly lower with statin use than without (3160±353 vs 5717±664 units/ treatment, p<0.05).

Conclusions: HD is associated with favorable lipid profiles, while profiles worsen with PD. Statin use may be becoming less prevalent in HD patients. Since statins have pleitropic efffects aside from lipid lowering, including possible lower Epo requirements, additional studies of trends in statin use and the clinical impact of this in ESRD are warranted and more study is needed regarding CV outcomes with statin use in the PD population.

PUB277

Changes of Plasma Volume Play a Major Role in Intradialytic Hemoglobin Variations Esteban L. Siga,[1] Raul Coste,[2] Hugo De Palma,[3] Vito Mesina,[4] Mario Galarza,[5] Miguel Fernandez.[6] *[1]Htal Madariaga; [2]Htal Interzonal; [3]Dialysis Azul; [4]Dialysis Tandil; [5]Dialysis Olavarria; [6]CENU Trenque Lauquen, Argentina.*

Background: It is known that ultrafiltration induces cyclic Hemoglobin (Hg) variations, but others factors could also affect Hg level. Therefore, the "true" functional Hg may be different. We studied the role of changes in plasma volume and if choosing functional Hg would modify estimation of ESA needs.

Methods: Multicentric, three phases study. Post minus Pre Dialysis changes of Hg (ΔHg, gr.dl) and body weight (ΔBW, Kg) were measured. Functional Hg was calculated by the average Hg (AVGHg) and by the time-averaged Hg concentration (TACHg, Krisper P et al). Percent changes in relative plasma volume were estimated by Albumin changes (%ΔRPValb, Van Stone J et al).

Results: Phase 1: in 57 Patients (Pts), pairs of Pre and Post samples were measured separately and the repeatability coefficient was 0.29 (Bland and Altman). In the next phases, only Pts with a ΔHg 0.3 were included. Phase 2: Out of 291 Pts, a ΔHg 0.3 was observed in 241: 144 male and 97 female. ΔHg (median 1.1, Interquartile Range: 0.75-1.6) was correlated (r = 0.38, p=0.000) only to ΔBW (median 2.4, IR: 1.8-3.2). Pts of the two upper quartiles of ΔBW showed a ΔHg of 1.41 (95% CI 1.3–1.52). This change was higher than the observed in Pts of the two lower quartiles : 1.05 (95% CI 0.95–1.15, p = 0.000). Phase 3: 76 Pts with ΔBW > 2.5 were studied. %ΔRPValb was 11.4 (95% CI 10.3-12.5). Regression analysis of %ΔHg as outcome and %ΔBW or %ΔRPValb as predictor, estimates a r^2 of 0.16 and 0.41 (p= 0.041), respectively. PreHg level of phase 2 and 3 Pts (total n=312) was significantly lower than AVGHg and TACHg. Both estimations of functional Hg were similar. Of the Pts with ΔBW >2.5 and PreHg between 9-9.9, the AVGHg was ≥10 in 62%. Conversely, odds of getting out of target was high in Pts with PreHg between 11-12 and ΔBW >2.5, since 67% of them showed an AvgHg >12.

Conclusions: i) changes in RPV play a major role in Hg intradialytic variations. ii) ESA dosing in dialysis Pts with more than 2.5 Kg of weight loss should be based on the average of the Hemoglobin levels measured before AND after dialysis.

PUB278

Patterns and Predictors of Blood Transfusion among Hospitalized Hemodialysis Patients Ben C. Wong, Rick Chin, Brenda Hemmelgarn, Pietro Ravani, Robert R. Quinn. *University of Calgary, Calgary, AB, Canada.*

Background: Hospitalized hemodialysis patients may be at increased risk of blood transfusion due to acute illness and relative erythropoietin resistance. The primary objective of this study was to quantify the risk of transfusion in the three months following hospital admission and to identify important baseline predictors.

Methods: Administrative datasets were used to identify adult hemodialysis patients admitted to hospital between September 2004 and March 2008 in Calgary, Canada. Primary clinical data was abstracted from electronic medical records and linked to blood bank records and laboratory holdings. Logistic regression was used to model the risk of transfusion in the three months following admission to hospital and to identify important clinical predictors, accounting for clustering of hospitalizations within individuals.

Results: A total of 475 patients experienced 695 eligible hospital admissions. The risk of blood transfusion was 25% at 3 months. Higher baseline erythropoiesis stimulating agent (ESA) dose was an independent predictor of transfusion risk. The presence of congestive heart failure and a higher baseline hemoglobin level were protective. Of note, there was a significant interaction between baseline hemoglobin level and ESA dose such that, for a given baseline dose of ESA, a 10 unit increase in hemoglobin level was associated with a 1% reduction in transfusion risk. Age, sex, serum albumin, and a medical history of other conditions (ischemic heart disease, diabetes mellitus, peripheral vascular disease, atrial fibrillation, and stroke) were not independently associated with the risk of transfusion.

Conclusions: Among hospitalized, prevalent hemodialysis patients, there was a high risk of blood transfusion in the 3 months following admission. Future work will focus on the impact of changes in ESA dose on transfusion risk in high-risk patients admitted to hospital.

PUB279

Risk Factors of Cardiovascular Events in Peritoneal Dialysis Patients: A Single Center Experience Ana Cabrita,[1] Ana Pinho,[1] Helena Morim Carreira,[2] André Fragoso,[1] Anabela Malho,[1] Idalecio Bernardo,[1] Pedro Neves.[1] *[1]Serviço de Nefrologia, Hospital de Faro, EPE, Faro, Portugal; [2]Public Health Institute, Oporto University, Oporto, Portugal.*

Background: Cardiovascular (CV) disease is the main cause of morbidity and mortality in chronic kidney disease. Several risk factors for CV disease have been described and it is crucial to know their real predictive value. However, the number of studies regarding peritoneal dialysis (PD) patients is scarce.

The aim of our study was to evaluate the predictive factors of cardiovascular events in a sample of PD patients.

Methods: Since 2000 we prospectively followed 105 incident PD patients (mean follow up = 31 months). Data on comorbidities and laboratorial data were collected at the start of PD and the CV events were collected during the follow-up. We defined CV events as one of the following: cardiac event, cerebrovascular event, peripheral vascular event.

Results: We included in our study 105 patients, 57% males, with a mean age of 53 years at the start of PD. During the follow-up period, 36.2% patients had a CV event (1.4 episodes/patient-year). The ocurrence of CV events was significantly associated with all causes of death (p<0.001). The univariate analysis showed an association between CV events and previous hemodialysis treatment, age and C-reactive protein (CRP), albumin and parathyroid hormone levels. After adjusting for potencial confounders (gender, diabetes, hypertension, pulse pressure, peritonitis, treatment with vitamin D), the albumin (hazard ratio (HR)=7.8, 95% CI- 14.4 to 42.8), age at start of PD (HR=1.1, 95% CI- 1.03 to 1.2), male gender (HR=0.2, 95% CI- 0.03 to 0.98), pulse pressure (HR=1.1, 95% CI- 1.01 to 1.12) and CRP (HR=1.1, 95% CI- 1.05 to 1.18) remained as significant predictors of CV events in PD patients.

Conclusions: Patients with higher age at the beginning of PD, with lower levels of albumin, elevated pulse pressure and CRP levels have an increased risk of developing a CV event.

PUB280

Statin Therapy Correlates with Lower Cardiovascular Death, but Not with Lower Cardiovascular Events among Patients on Hemodialysis Edmond Deda,[1] Chrisoula Pipili,[1] Paraskevi Tseke,[1] Konstantinos Pantelias,[1] Petros Korfiatis,[1] Zoi Tegou,[2] Helen Tzanatos,[2] Eirini Grapsa.[1] *[1]Nephrology, Aretaieion University Hospital; [2]Dialysis Unit Specimed, Loutraki, Greece.*

Background: Cardiovascular events are the major cause of death among patients on maintenance hemodialysis. Regulation of cholesterol and triglyceride levels within target goals is paramount. Our purpose was to examine whether statin therapy correlated with evidenced (presence or absence) cardiovascular events among patients receiving hemodialysis.

Methods: A total of 106 patients (32 women and 74 men, aged 66 ± 14 years) on chronic hemodialysis were studied. The lipidemic profile (total cholesterol, LDL-cholesterol, triglycerides) and all the cardiovascular events (acute coronary syndrome, stroke and heart failure) as well as deaths caused from them were recorded within two - year follow up.

Results: Patients on hemodialysis with dyslipidemia showed higher rates of cardiovascular events (20% vs. 2,4%, odds ratio 3.75, p =0.005). Cardiovascular deaths were noted among 41% of patients not receiving treatment for dyslipidemia and only in 22% among them who were under treatment (statins, omega-3 or both) (p = 0.039). Logistic regression analysis showed that patients receiving treatment for dyslipidemia had 60% reduced risk for cardiovascular death compared with patients without treatment (odds ratio = 0.41, p = 0.042).

Conclusions: Patients on chronic hemodialysis present impaired lipid profile. Those received treatment for dyslipidemia presented lower risk for cardiovascular deaths, but not for cardiovascular events.

PUB281

Evolution of Diabetic Patients Older Than 65 Years Starting Hemodialysis. Comparation with Control Group Herrero Juan Carlos. *Nephrology, Hospital Severo Ochoa, Leganes, Madrid, Spain.*

Background: In the last years we have seen a significative increase of patients starting hemodialysis (HD) due to diabetic nephropathy older than 65 years. This patients has more cardiovascular risk factors and morbi-mortality.

Methods: We want study evolution, demographic and clinical characteristics of these patients (Group I) starting HD in our service, versus patients starting HD with similar age and other cause of ESRD (Group II).

Results: Between September-2006 to September-2010, 165 patients incident HD. 68 (41%) patients older than 65 years. Median follow up was 23 months (5-51). Main results shown in the table.

Characteristics	Group I (n=20)	Group II (n=48)	p
Mean age (year)	73,5±4 (65-82)	74,5±6 (65-85)	ns
Males, %	50%	56%	ns
Body Mass Index (kgr/m2) *	24±3	23±3	ns
Charlson Comorbidity Index	8,5±1,4	7,6±2	0,029
Ischemic heart disease (%)	35	15	0,06
Cerebrovascular disease (%)	25	33	ns
Peripheral vascular disease (%)	35	42	ns
Hypertension (%)	95	81	ns
Dyslipidemia (%)	55	40	ns
Hemoglobin >11 gr/dl * (%)	60	64,5	ns
Ferritin levels 100-500 mg/ml * (%)	55	64,5	ns
Serum calcium levels 8,4-9,5 mg/dl * (%)	65	60,4	0,002
Phosphate <5,5 mg/dl * (%)	95	92	ns
PTH levels 150-300 pg/ml * (%)	35	31,5	ns
Albumin >3,5 gr/dl * (%)	40	50	ns
Number Hospitalization Index (NHI)	0,35 (0-1,05)	0,19 (0-0,88)	0,053
Day's Hospitalization Index (DHI)	5,13 (0-23)	2,88 (0-29)	0,034
Death	7 (35%)	22 (46%)	ns
Survival at 12 months	75%	80%	ns
Survival at 36 months	26%	46%	ns
Renal transplant	2 (10%)	4 (8%)	ns

NS, no significant. NHI: number hospitalization / patients / month. DHI: day's hospitalization / patients / month. *: end study level

Cause of death in Group I: 4 due to infection disease, 3 to decline in general status. Main cause in Group II: 6 to decline in general status, 6 for cardiological pathology. In multivariate analysis, survival was significantly influence by DHI (p 0.001, HR 1.26, 95%CI 1.114-1.401).

Conclusions: In conclusion, patients starting HD with diabetic nephropathy older than 65 years have similar survival at 12 months, although less at 36 months, that patient in Group II. The main reason is major comorbidity, in relation with major percentage of ischemic heart disease and peripheral vascular disease, with more number and day's hospitalization index.

PUB282

Audit of the Management of Atrial Fibrillation in Haemodialysis Patients Jonathan Reaney, Cathal L. Steele, Agnes Masengu, Camille Harron, Robert Mullan, Ronan Cunningham. *Department of Nephrology, Antrim Area Hospital, Antrim, United Kingdom.*

Background: The prevalence of atrial fibrillation (AF) in haemodialysis (HD) patients ranges from 7.7% to 27%. A recent study found one-year mortality rates were twice as high in HD patients with AF than in those without. An audit of management of AF in the haemodialysis unit was carried out.

Methods: Baseline electrocardiograms (ECGs) were performed on patients attending for HD sessions and the rhythm analysed by medical staff. In addition, serum samples were analysed for high sensitivity C reactive protein (hsCRP) and high sensitivity Troponin-T (hsTropT). The notes and electronic records of patients identified with AF were reviewed to determine if AF had been previously documented. Patients identified with AF had their CHADS2 stroke risk index score calculated and management reviewed.

Results: ECGs were carried out on 57 dialysis patients. Median age was 73 years, ethnicity 100% Caucasian, female 47.4% (27/57) and diabetic 41.1% (24/57). The incidence of AF on ECG was 10.5% (6/57). No cases of undiagnosed AF were identified. No significant association between the levels of hsCRP and hsTropT and presence of AF was found. In this study, all patients with AF had a CHADS2 score ≥2. Oral anticoagulation therapy is recommended for patients with CHADS2 score ≥2. All patients with AF were on oral antithrombotic agents (Warfarin 3/6, Aspirin 2/6, Clopidogrel 1/1). The presence of AF was not clearly documented in the patient's medical records in 3/6 cases.

Conclusions: Rates of AF in our HD population were similar to rates reported from larger studies. AF in haemodialysis patients carries a significant risk of mortality. All patients identified with AF were receiving oral antithrombotic therapy however little evidence exists for the use of this for AF in this population. HD patients on warfarin have an increased risk of stroke and major haemorrhage. An individual risk stratification with respect to oral antithrombotic agents needs to be performed and documented for each haemodialysis patient with AF.

PUB283

With Increased Inflammation, Fibrinogenolysis May Counterbalance Platelet Hyperactivity in Diabetic Hemo and Peritoneal Dialysis Patients Saila V. Ventrapragada,[1] George P. Bayliss,[2] Bijan Roshan,[1] Ray E. Gleason,[1] Larry A. Weinrauch,[1] John A. D'Elia.[1] *[1]Harvard Medical School, Boston, MA; [2]Brown Medical School, Providence, RI.*

Background: Study subjects with Type1 diabetes (DM) had elevated levels of hemostasis factors [Factor VII (FVII), fibrinogen (fibr), vonWillebrand factor (vWf)], decreased plasminogen activator inhibitor (PAI) levels, accelerated platelet adhesion/aggregation. With intensive treatment over 6-12 months, FVII, fibr, PAI factor levels improved significantly. Follow-up study examined impact of hemostasis, inflammation, oxidative stress on cardiovascular events (CVE) in 124 diabetic study subjects on dialysis (103 HD and 21 PD) vs 26 nondiabetic controls (HD+PD).

Methods: DM + dialysis subjects divided into CVE + history (n= 58) vs CVE– (n=66): CVE + history associated with significantly higher levels of CRP ($p < 0.05$). DM – subjects had significantly higher levels of low MW/fibr and PAI-1 if CVE history +. Dialysis study group data analyzed using platelet activation index: fibrinogen x vWf x p- selectin. Result for DM+ group significantly greater than DM – group ($p< 0.05$). Data analyzed using an index of fibrinogenolysis: low MW/ intact fibr (% degradation) x fibrinolytic activity x 1/PAI-1. Result for DM + group significantly greater than DM – group ($p< 0.05$).

Results: Results at follow up: CVE + DM + study group had significantly higher inflammation index (fibr x interleukin-6 x C-reactive protein) vs CVE – DM + dialysis patients (p= 0.02). Accelerated platelet function and fibrinogenolysis indices didn't discriminate DM + dialysis patients + or – CVE. When CVE free interval analyzed for 150 DM + and – subjects, there was no difference between tertiles for platelet activation index. When CVE free interval analyzed for 150 subjects, tertiles for fibrinogenolysis index reflected more favorable prognosis of DM – (p = 0.04).

Conclusions: DM dialysis patients with CVE on followup had higher inflammation index. Increased fibrinogenolysis may counterbalance accelerated platelet aggregation/adhesion. Impact of fibrinogenolysis on CVE free survival reflects more favorable prognosis of non-diabetic subjects on dialysis.

PUB284

Hemodialysis Induced Bacteremia in Our Dialysis Unit, Where Do We Stand from International Rates? Jafar Al-Said, Aimee Pagaduan, Soni Murdeshwar. *Nephrology and Internal Medicine Department, Bahrain Specialist Hospital.*

Background:

Aim:

(1) Identify the prevalence rate of hemodialysis related bacteremia in our dialysis unit and compare it with published North America data.

(2) Measure the admission rate for hemodialysis related bacteremia and vascular access infection and compare it to USRDS 2010 data.

Methods: In this retrospective observational study we reviewed all our patients' dialysis electronic records over 87 months, from January 2004 through March 2011. Demographic information was collected from the files. The definition used for dialysis related bacteremia is: the combination of clinical symptoms and positive blood culture within one week.

Contaminated blood cultures were excluded. The prevalence rate of dialysis induced bacteremia per 100 patient months and per 1000 hemodialysis sessions were estimated. Admission rates for dialysis related bacteremia and access related infection was measured. Our data was compared to USRDS 2010 and other published North America data.

Results: Total 4,300 hemodialysis sessions were included which were done on 114 patients. Thirteen dialysis related bacteremia were encountered in 7 patients over 87 months. Six of them had cuffed tunneled catheter and one had an AV fistula. Two patients required admission during their bacteremia infection. Sphingomonas paucimobilis was the only organism causing all the infection episodes. This was significantly different from the type of bacteria causing dialysis related infection in other units. The source was found to be the main dialysis water tank.

Table(1): Prevalence of dialysis infection bacteremia in our unit as compared to International data:

Item	Our data	International data	P
Prevalence of Dialysis related bacteremia per 100 patient months	0.02	3.59	0.002
Prevalence of bacteremia per 1000 Hemodialysis procedure.	3.02	3.07	0.9
Prevalence of admission for Hemodialysis related bacteremia per 1000 patient years	0.76	180	0.006
Prevalence of admission for cuffed tunneled access infection per 1000 patient years.	Zero	456	NS

Conclusions: Dialysis related bacteremia per patient in our unit is less than North America data while the prevalence per dialysis session is the same.

We had lower admission rates compared to USRDS 2010.

PUB285

Increasing Mean Body Mass Index among Adults Initiating Treatment for End-Stage Renal Disease, by Diabetes Status, United States, 1996–2008

Nilka Rios Burrows,[1] Israel Hora,[2] Andrew S. Narva,[3] Desmond Williams.[1]
[1]Centers for Disease Control and Prevention, Atlanta, GA; [2]Northrop Grumman, Atlanta, GA; [3]National Institutes of Health, Bethesda, MD.

Background: Diabetes is a major risk factor for end-stage renal disease (ESRD), and high body mass index (BMI) is associated with developing type 2 diabetes. We assessed trends in mean BMI among U.S. adults initiating ESRD treatment.

Methods: Using 1996–2008 data from the U.S. Renal Data System, we obtained mean BMI at initiation of ESRD treatment among people aged ≥18 with diabetes (ESRD-DM) or other conditions (ESRD-OT) listed as the primary diagnosis. Mean BMI was examined by age group. Joinpoint regression was used to analyze trends and calculate an average annual percentage change (AAPC) with 95% confidence interval (CI).

Results: From 1996 to 2008, mean BMI increased among adults initiating treatment for ESRD-DM (from 25.7 to 29.6) and ESRD-OT (from 23.6 to 26.7). Among ESRD-DM incident cases, mean BMI increased from 24.4 to 29.6 (AAPC=1.6% per year, CI=1.5%–1.8%) among those aged 18–44, from 26.8 to 30.6 (1.2%, 1.0%–1.5%) among those aged 45–64, from 25.2 to 29.8 (1.5%, 1.3%–1.7%) among those aged 65–74, and from 23.9 to 27.3 (1.2%, 1.1%–1.3%) among those aged ≥75. Among ESRD-OT incident cases, mean BMI increased from 24.6 to 27.8 (1.0%, 0.8%–1.1%) among those aged 18–44, from 24.6 to 27.9 (1.0%, 0.9%–1.1%) among those aged 45–64, from 23.2 to 26.7 (1.2%, 1.0%–1.3%) among those aged 65–74, and from 22.1 to 24.7 (0.9%, 0.8%–1.0%) among those aged ≥75. Throughout the period, among incident cases aged ≥45, mean BMI was higher among ESRD-DM than among ESRD-OT. From 2005 to 2008, mean BMI was ≥30 among incident ESRD-DM cases aged 45–64.

Conclusions: Mean BMI at initiation of ESRD treatment increased during the study period irrespective of diabetes status. Higher BMI is associated with greater likelihood of survival in the first 12 months of ESRD treatment, but also associated with comorbidities, such as cardiovascular disease (CVD), which could impact survival. Evaluation of the nutritional profile of people preparing for ESRD treatment and reduction of CVD risk factors is important to improve outcomes.

PUB286

Schizophrenia and Schizoaffective Disorder in a Dialysis Population: A Pilot Sample

Joseph Cha,[2] Kruti N. Thakkar,[2] Navin Jaipaul,[1] James I. McMillan.[1]
[1]Nephrology Section, VA Loma Linda Healthcare System, Loma Linda, CA; [2]Department of Internal Medicine, Loma Linda University, Loma Linda, CA.

Background: Schizophrenia (Sp) affects about 1% of the world's population. It complicates the treatment of patients with ESRD, and the stresses of dialysis may exacerbate Sp. We compared the prevalence of Sp and schizoaffective disorder (Sa) in dialysis patients treated in the VA Loma Linda Healthcare System over a 9 year period with that in matched patients without kidney disease in the same system.

Methods: Medical records of all chronic hemodialysis patients in the Loma Linda VA from January 1, 2000 through December 31, 2008 were examined for a diagnosis of Sp or Sa made by a mental health professional. Each ESRD patient was matched with a control by age, race (non-African American vs. African American), sex, and the diagnosis of diabetes and hypertension. Continuous variables were compared using the Student's T-test, and dichotomous variables ware compared using the Chi-squared test.

Results: The 410 patients with ESRD were matched with 407 controls without kidney disease. Three of the ESRD patients had rare characteristics (e.g. female gender, young age) and could not be matched. Of the 817 remaining patients, 197 (24.1%) were African American, 17 (2.1%) female, 770 (94.3%) had hypertension, and 541 (66.2%) had diabetes. The prevalence of Sp/Sa in cases vs. controls was not significantly different, 10 (2.4%) vs. 6 (1.5%) (p = 0.32). Consistent with other published reports, African American race was associated with a higher prevalence of Sp/Sa, 8 of 197 (4.1%) vs. 8 of 620 (1.3%) non-African Americans in our combined population (p = 0.014).

Conclusions: Our control population had a prevalence of Sp/Sa similar to the accepted prevalence of these diseases. The ESRD population showed a trend toward a higher prevalence of Sp/Sa at 2.4%, but in this small population the difference was not significant. If this trend is correct, power analysis based on our findings, assuming an alpha of 5%, would require a sample size of 3000 ESRD patients and their matched controls to have a power of 80% to detect a difference of 1% in the prevalence of Sp/Sa between the two groups.

PUB287

Co-Existence of Peripheral Vascular Disease(PVD) Is Associated with High 5 Yr Mortality in Diabetics on Dialysis

Vinod Sathyanarayana Dibbur,[1] Hasan Haboubi,[1] Christopher Edwards,[1] Ashraf I. Mikhail,[1] Sadananda V. Aithal.[1] *[1]Morriston Hospital, United Kingdom; [2]Morriston Hospital; [3]Morriston Hospital; [4]Morriston Hospital; [5]Morriston Hospital.*

Background: Patients with diabetic nephropathy starting dialysis are at high risk for cardiovascular(CV) events. A 70% 5yr mortality has been reported in them (USRDS data). Data on the influence of glycaemic status on survival in patients on dialysis is conflicting.

We retrospectively looked at the impact of coexistent CV disease and conventional risk factors on 5yr survival in a cohort of 98pts(28 diabetic)who started dialysis in 2005. We audited our management of prevalent diabetic patients on dialysis in 2010.

Methods: Data collected and analysed from the renal data base.

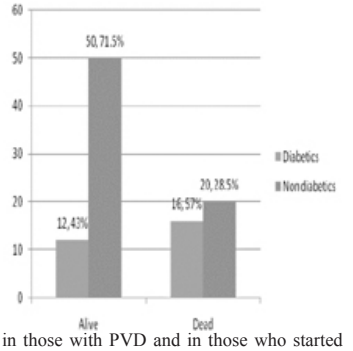
Results: 82.66% of the 98 pts started haemodialysis and 17.34% peritoneal dialysis. 28.6% were diabetic and 71.42% were non diabetics.Ischaemic heart disease IHD(42.85% vs 18.5%)and PVD(25% vs 2.85%)was significantly higher in diabetics.Mean age in both groups was 70yrs.

The 5yr mortality in diabetics was significantly higher when compared to non-diabetics(57%vs28.5%).The median survival in the mortality group was 2years.15.7%of nondiabetics and 10.7%of diabetics were transplanted.

Diabetic mortality data

	Alive	Dead
Age(yrs)	66.3	73.4
HbA1c(%)	6.8	7.5
IHD(%)	58.3	31.2
PVD(%)	8.3	37.5

Diabetic/Non diabetics



5yr mortality in diabetics was higher in those with PVD and in those who started dialysis at a later age.

Audit of 53 prevalent diabetic patients on dialysis in 2010 showed that risk factors were managed satisfactorily [Mean HbA1c(SD)7.2 (1.8),cholesterol 3.68(0.70),predialysis systolic BP(SD)144(22.9),diastolic BP 67.35(11.34) mmHG and CaxPO4 product 3.39(0.81)].75.4% were on antiplatelets,90.6%were non-smokers.

Conclusions: Diabetes is an independent predictor of mortality in patients starting renal replacement therapy. PVD in diabetics worsened survival significantly at 5years. Management of risk factors may not have an impact on survival in patients on dialysis.

PUB288

Views of Renal Healthcare Professionals About the Role of Palliative Care in Patients with End Stage Kidney Disease

Robert G. Fassett,[1] Iain Robertson,[2] Rosalind M. Bull.[3] *[1]Renal Medicine, Royal Brisbane and Women's Hospital and The University of Queensland, Brisbane, Queensland, Australia; [2]Human Life Sciences, University of Tasmania, Launceston, Tasmania, Australia; [3]School of Nursing and Midwifery, University of Tasmania, Launceston, Tasmania, Australia.*

Background: Palliative care is increasingly recognized as an important part of end stage kidney disease (ESKD) care. Health professionals' own beliefs and knowledge about palliative care, death and dying impact on their decision to offer and support palliative care involvement. This study explored the perceptions of renal health professionals regarding palliative care and how this influenced how palliative care was integrated into ESKD patient management. The aim of this study was to identify barriers and facilitators experienced by renal healthcare professionals to incorporating palliative care into ESKD management.

Methods: All renal healthcare professionals in North and Northwest Tasmania were invited to complete a questionnaire exploring their views on the role of palliative care in the management of patients with CKD.

Results: Of 105 surveys distributed 41 were completed (response rate 39%). Health professionals' beliefs that emerged included; Loss of will to live was the greatest influence on dialysis withdrawal. Loss of will to live mainly followed pain and depression. Acute co-morbidity or depression delayed withdrawal of treatment. Malignancy and functional decline influence health professionals and family towards palliation. End of life care should be discussed early at pre-dialysis education, openly, honestly and sensitively with full disclosure by senior renal medical or nursing staff. Final decisions should occur depending on the patient's ongoing condition. The patient should make the decision supported by family.

Conclusions: Renal health professionals believed the patient, with involvement of the family, should make end of life decisions. Preparation should occur at the start of ESKD management with the actual decision made when the patient is ready.

Factors Affecting Quality of Life in Caucasian Octogenarians and Nonagenarians on Dialysis in Southern Indiana – A Cross Sectional Study

Manish Gera, Kumar Gaurav, Raj Jeevan. *Nephrology, Internal Medicine Nephrology INC., Terre Haute, IN.*

Background: The elderly constitute the fastest-growing segment of the ESRD population. The numbers of octogenarians & nonagenarians starting dialysis have more than doubled in the last decade, corresponding to an average annual increase in dialysis initiation of 9.8%. Literature mainly focuses on elderly in general (≥ 65 years). While management is focused on cardiovascular end points, mortality & lab parameters including KT/V, albumin, & mineral bone disorder. There is paucity of literature focusing on patients ≥ 80 years & on their symptomatology. Symptoms affecting quality of life (QOL) may involve HEENT, musculoskeletal or nervous systems. Also, majority of these patients may find it hard to respond to extensive questionnaires used by most studies. Moreover, access to primary care is not readily available in this patient population.

Methods: We performed a cross sectional study to look at the factors affecting QOL in patients ≥ 80 years, in order to provide comprehensive care to this population. Two hundred thirty two (232) patients from 4 outpatient dialysis units in Southern Indiana were screened. Both hemo and peritoneal dialysis patients were included. Patients had to be on dialysis for at least 3 months. Patient with underlying dementia were excluded.

Results: Twenty five (25) (10.7%) met criteria. A simple questionnaire was devised to look at factors that could affect QOL. This included identifying problems related to hearing, vision, dizziness, headache, gait, joint pain, back pain & appetite. Patient's responses were recorded. Management of these symptoms was integrated in care plan along with lab parameters for optimal health care delivery.

Conclusions: 1.Symptoms related to gait, vision, back pain & joint pain predominated in effecting QOL irrespective of modality of dialysis.

2. Patients indicated that dialysis per se did not affect QOL.

3. Symptoms related to volume issues were present in about 10% patients only.

3. We propose, a simplified questionnaire to determine symptoms affecting QOL be integrated in care plan for comprehensive care.

4. Palliative care should be considered when attempt to relieve symptoms is unsuccessful.

PUB290

Achievement of CKD-MBD (Chronic Kidney Disease-Mineral and Bone Disorder) Management with Vitamin D Analogs and Minimal Calcium Load in Patients on Maintenance Hemodialysis

Nobuo Hashimoto,[1] Naomi Sasaki,[1] Masataka Tsunoda,[2] Ryota Ikee,[3] Megumi Sato.[4] *[1]Department of Nephrology and Dialysis, H.N.Medic, Sapporo, Hokkaido, Japan; [2]Department of Nephrology and Dialysis, H.N.Medic Sapporo-Higashi, Sapporo, Hokkaido, Japan; [3]Department of Nephrology and Dialysis, H.N.Medic Kitahiroshima, Sapporo, Hokkaido, Japan; [4]Department of Nephrology, Jinzonaika Megumi Clinic, Sapporo, Hokkaido, Japan.*

Background: CKD-MBD (chronic kidney disease-mineral and bone disorder) is an important issue associated with increased mortality in hemodialysis (HD) patients.We had a strict calcium,phosphorus management and administration in order to actively tried to use vitamin D.

Methods: In 86 patients in our hospital,serum concentrations of calcium, phosphorus, and intact parathyroid hormone (iPTH), administrated dose of calcium carbonate,sevelamer, and vitamin D analogs in 2004, 2006, and 2008 were examined. In addition, the rate of the patients with achievement of Clinical Practice Guideline for the Management of Secondary Hyperparathyroidism in Chronic Dialysis Patients by the Japanese Society for Dialysis Therapy (JSDT guideline) was investigated.

Results: Datas shown in Table1. We were maintaing the value of phosphorus, increased the dose of severamaer without increasing the level of serum calcium. Calcium carbonate was administered in 76.7% of the patients in 2004, and in 33.7% in 2008 ($P < 0.001$). Sevelamer was administered in 34.9% in 2004, and in 82.6% in 2008($P < 0.001$). Vitamin D analogs were administered in 93.0% in 2004, and 100% in 2006 and 2008.

parameters of each year

	in 2004	in 2006	in 2008
Ca(mg/dL)	9.47±0.57*	9.28±0.70*	9.10±0.37*
Ca.Carbonate (g/day)	2.1±0.8**	blank	1.5±0.7**
Severamaer (g/day)	3.4±1.4***	blank	3.5±1.6***

*,**,***:$p<0.001$

Conclusions: In 2004, mean calcium concentration in our hospital was within target range of JSDT guideline, but was mainly dependent on calcium carbonate. We consider that this was fake and fruitless achievement. Subsequent replacement of calcium carbonate with sevelamer successfully resulted in the administration of vitamin D analogs in 100% of the patients.

PUB291

Antithrombotic Therapy and Bleeding in Hospitalized Patients with End-Stage Renal Disease Receiving Hemodialysis

Olayinka O. Holt, Shyan-Yih Chou, Hongbao Ma. *Division of Nephrology & Hypertension, Brookdale University Hospital & Medical Center, Brooklyn, NY.*

Background: In end-staged renal disease (ESRD) patients, use of anticoagulation and antiplatelet agents for cardiovascular disease is common but may increase the risk of major hemorrhage because of uremic platelet dysfunction. The aims of this study were to evaluate transfusion burden and hospital length of stay (LOS) associated with antithrombotic therapy in hemodialysis (HD) patients with ESRD who developed bleeding during hospitalization.

Methods: We analyzed medical records from 151 consecutive HD patients who developed bleeding during hospitalization between January 2008 and June 2010. The patients were stratified into two groups: Group 1 (n=73) were those who received antithrombotic therapy (aspirin, clopidogrel, warfarin, or heparin but exclusive of its use during HD). The antithrombotic therapy followed the practice standard for clinical needs such as prophylaxis against cardiac or venous thrombosis, or after percutaneous coronary intervention. Group 2 (n=78) did not receive antithrombotic therapy.

Results: In the cohort, the age was 62±1 yr (mean±SE), 46% male, and 79 patients received blood transfusion. Similar clinical characteristics were noted in the two groups, including age, gender, race, urea reduction ratio, platelet count, baseline INR, and HD time. In Group 1, the nadir hemoglobin before transfusion was 7.9±0.3, similar to 8.0±0.2 g/dl in Group 2. In Group 1, 48% patients received blood transfusion, similar to 52% in Group 2. In patients who received transfusion, Group 1 received 5.5±0.6 units of blood, similar to 4.7±0.6 units in Group 2. LOS in Group 1 was 11.6±1.0 days, longer than 6.1±0.6 days in Group 2 ($P<0.001$). In a multivariate survival analysis, exposure to antithrombotic agents was associated with longer LOS ($P = 0.0018$); however, blood transfusion as clinically indicated did not affect LOS ($P = 0.38$).

Conclusions: In conclusion, in hospitalized ESRD patients receiving HD, antithrombotic therapy did not adversely affect severity of bleeding or transfusion burden and the significantly increased LOS in patients on antithrombotic therapy was linked to the clinical conditions requiring its use.

Analysis of Factors Associated with Complaints in Patients Treated with Hemodialysis or Hemodilafiltration

Atsuhiro Kanno, Ikuto Masakane, Satoko Ito, Minoru Ito, Kiyotaka Yabuki. *Yabuki Hospital.*

Background: Recently, the growing concern for dialysis is considered to be the increase in the number of aged and long-term patients in Japan. Therefore, the objective of dialysis treatment is not only the longevity of the patients but the improvement of quality of life among them. For that reason, it is essential to determine factors related to these complaints. In our cross-sectional study, we examined the relationship between the severity of the uncomfortable symptoms and various clinical parameters.

Methods: A total of 342 patients performed with chronic maintenance dialysis in our three facilities were participated. Additionally, they were evaluated by the self-rating score questionnaire based on fifth graded face scales from 0 (none) to 4 (very strong) according to the severity. The symptoms were composed of 20 common physical and psychological complaints. Odds ratios for each of moderate to severe (score = 2, 3, 4) or severe (score = 3, 4) levels were calculated using a multiple logistic regression model adjusted for confounding factors including age, gender, time of dialysis, history of diabetes mellitus, Kt/V, normalized protein catabolic rate, body mass index, predialytic values of hemoglobin, albumin, β2-microglobulin, sodium, potassium, phosphate.

Results: Among participants, 146 (42.7%) patients were treated with hemodiafiltration and the overall mean values were 66.7 years for age and the median values were 5.4 years for years of dialysis.The adjusted significant factors for the presence of reduction of blood pressure during dialysis were age (odds ratio [OR] 1.04, P =0.0002), body mass index (OR 1.13, P =0.001) and β2-microglobulin (OR 1.04, P =0.045). Potassium was significantly related to severe disturbance of sleep (OR 0.55, P =0.0014) and constipation (OR 0.65, P =0.018).

Conclusions: In our study, dialysis-related symptoms are significantly associated with various clinical parameters. This comprehensive strategy based on self-assessment of common problems could provide an opportunity for us to revisit the therapeutic modality and ameliorate these symptoms, therefore, it would lead to improve the quality of life among each of the patients.

PUB293

Patients with Type 2 Diabetes Admitted for RRT – Are There Any Differences According to Primary Renal Disease and Referral? Radka Kleckova, Jana Veresova, Petra Ronova, Katarina Nehezova, Ivan Rychlik. *Dialysis Unit, FMC, Prague 10, Czech Republic.*

Background: Late referral of type 2 diabetic(T2D) patients(pts) is well-known risk factor for morbidity/mortality in RRT,but the role of primary renal disease(PRD)is not well determined.

Methods: All T2D pts admitted for hemodialysis(HD) in 3-yrs period were divided according to PRD /1=diabetic nephropathy(DN);2=non-diabetic renal disease(NDRD)/ and referral as early(E)>3months vs.non-referral(N).Selected lab&clinical parameters were compared.

Results: 38 T2D pts entered HD(=34% of all incident pts).50% were diagnosed as DN,while atherosclerotic renal disease represented majority of NDRD.All were managed by diabetologist, but only 68% were referred early.

Starting HD,following parameters differed significantly comparing all groups: E1(n=14):highest 24h proteinuria(PU)(4.8g),GFR (0,138 ml/s),DM vintage(21yrs),insulin th (86%),RAS blockers(86%) and lowest mean age(64yrs); E2(n=12):highest s-albumin(ALB)(34.7g/l),hemoglobin(Hb)(99.9g/l),systolic BP(161mmHg) and lowest smoking(0%),coronary artery dis.(CAD)(33%),peripheral arterial dis.(PAD)(8%),congestive heart failure(CHF)(25%),stroke(CS)(8%); N1(n=5):highest HbA1c(7.2%),CHF(60%)and lowest GFR(0.10ml/s),ALB(27.6g/l); N2(n=7):highest s-creatinine(s-cr)(716 umol/l),mean age (75 yrs) and lowest PU(1,0g),DM vintage(7.3yrs),Hb(88.8g/l).

Comparing groups according to PRD(1 vs.2),significantly differed: s-cr(577/671umol/l), PU(4,5/1,8g), cholesterol(4,5/3,7mmol/l), mean age(64,6/71,3 yrs), DM vintage (19,3/10yrs),insulin(76/5%),RAS blockers(74/53%),smoking(47/18 %),CS (26,3/10,5%)but not CAD,CHF,PAD,while according to referral(E vs.N) these were: PU(3.6/2.0g),ALB(33.9/29.8g/l),s-cr(600/676umol/l),DM vintage(16.8/10.4 yrs),insulin(50/25%),RAS blockers(77/33%),statins(46/25%),CHF(31/50%),PA D(27/42%).

Conclusions: 1/early referral had positive clinical-lab consequences;2/non-referred DN pts had the worst metabolic status,the highest CHF and shortest DM vintage;3/non-referred NDRD had highest prevalence of atherosclerotic complications,while early referred NDRD pts had lowest ones;4/anemia treatment was poor in all groups,while RAS blockers and lipid lowering drugs were used highly in early referrals.

PUB294

Perceived Stress in Chronic Kidney Disease Patients Jennifer Ling, Amy L. Jones, Amir Toussi, Sean Wo, Sarah Ramer, Mark L. Unruh. *University of Pittsburgh School of Medicine, PA.*

Background: Stress has been linked to increased risk of cardiovascular events and insufficient immune response. This study examined the relationship between kidney disease and stress to see whether modifiable risk factors may attenuate it.

Methods: The sample consisted of 88 chronic kidney disease (CKD) and 95 end-stage renal disease (ESRD) patients on dialysis as well as 224 controls from the Sleep-Strategies Concentrating on Risk Evaluations study of sleep and cardiovascular risk. Participants completed the Perceived Stress Scale-4 (PSS4), a 4-item instrument that rates a respondent's stress (maximum score of 16). The PSS4 has been shown to be reliable and valid and has been widely used in studies of chronic illness. Participants' demographics, blood pressure, depression, and objective and subjective sleep quality were also assessed.

Results: The sample (median age 58 years) was 56.3% male and 62.1% white. The mean PSS4 score differed between the control (3.8±2.6), CKD (5.5±2.7) and ESRD patients (5.6±3.5), p<0.001. In a multivariable linear regression adjusted for sex, race, and employment, age (-0.06, 95% CI -0.08, -0.03), CKD (vs. control) (1.19, 95% CI 0.43, 1.95), and ESRD (vs. control) (1.29, 95% CI 0.53, 2.05) independently predicted higher stress. In a second model adjusted for the same covariates as above with depression also entered, age (-0.05, 95% CI -0.07, -0.03), CKD (vs. control) (1.17, 95% CI 0.42, 1.92), ESRD (vs. control) (1.28, 95% CI 0.54, 2.03), and depression (1.18, 95% CI 0.63, 1.72) independently predicted higher stress. In a final model adjusted for the same covariates as in the second model with the Pittsburgh Sleep Quality Index (PSQI) also entered, age (-0.06, 95% CI -0.08, -0.03), CKD (vs. control) (0.99, 95% CI 0.25, 1.75), depression (0.89, 95% CI 0.35, 1.42), and PSQI score (0.18, 95%CI 0.11, 0.25) independently predicted higher stress.

Conclusions: The CKD and ESRD patients had significantly more stress than control patients. Poor sleep quality appears to attenuate the association of ESRD and higher stress. Both depression and sleep quality can potentially be modified as part of interventions to reduce stress in this at-risk population.

The Troponin T Level at Initiation Time of Hemodialysis May Be Considered an Independent Prognostic Factor for All-Cause and Cardiovascular Mortality for a Short Term Shoichi Maruyama, Seiichi Matsuo. *Kidney Internal Medicine, Nagoya University, Nagoya, Aichi, Japan.*

Background: Cardiac troponin T , a useful marker for diagnosing acute myocardial infarction (AMI) in the general population, is significantly higher than the usual cut-off value in many hemodialysis patients without clinically apparent evidence of AMI. The aim of this study was to examine whether the troponin T level at initiation time of hemodialysis is related to the occurence of cardiovascular diseases (CVD) afterwards and short term mortality.

Methods: 170 patients began hemodialysis between January 2006 and November 2008 at our hospital. Among them we examined 124 patients(76 male and 48 female) without ischemic heart disease concurrence. These patients were followed until death or November 2010. We examined 1)the association of troponin T level at initiation time of hemodialysis and other clinical data and 2) occurence of CVD afterwards .

Results: Positive troponin T level was found in 39 of 124 patients. The 74% of this group were diabetes and it were significantly many compared with non DM ($P < 0.01$). On the other hand, patients with diabetes were 29% in a negative group. In addition, the laboratory data were as following: Creatinin 8.67mg/dl (positive group) vs 9.71 (negative group), serum total protein 5.95g/dl vs 6.34, serum Alb was 3.06g/dl vs 3.58 at the beginning time of hemodialysis. These datas were significantly a low tendency in comparison with negative group. ($P < 0.01$) High sensitive CRP was 0.54mg/dl vs 0.31mg/dl(positive group vs negative group). at the beginning time of hemodialysis ($P < 0.05$)

As for the 2-year occurence of CVD were significantly higher in positive group (36%)than in negative group (11%) ($P < 0.01$) and the total mortality was higher in positive group (13%), compared with that of negative group (2%).

Conclusions: The troponin T level at initiation time of hemodialysis may be considered an independent prognostic factor for all-cause and cardiovascular mortality for a short term.

PUB296

Novel Methicillin Resistant S. aureus (MRSA) Reduction Practices in Outpatient Hemodialysis Mark G. Parker,[1] Elisabeth Tillotson,[2] Dottie Lagasse,[2] Rosalie Blenkhorn,[1] Michelle Duval,[1] Nicole Boutet,[1] Ioan Cosma,[1] Bradley N. Doebbeling.[3,4] *[1]Maine Medical Center, Portland, ME; [2]Fresenius Medical Care North America, Westbrook and Biddeford, ME; [3]HSR&D Center, Indianapolis VAMC, Indianapolis, IN; [4]Regenstrief Institute, Indiana University School of Medicine, Indianapolis, IN.*

Background: The MRSA Reduction Collaborative is an AHRQ-funded seven hospital Quality Improvement consortium studying the application of systems improvement and positive deviance to reduce MRSA infection.

Methods: In April, 2010, staff from two southern Maine FMCNA dialysis units and MMC introduced lean methods and social/behavioral change dialogues from positive deviance methods in dialysis to identify effective practice changes for prevention of MRSA transmission. Process measures identified and introduced include new patient and staff infection prevention education strategies, reinforcing staff and patient hand hygiene adherence, standardized communication tools, and dissemination strategies. Patient outcome measures include MRSA infection rates, all bloodstream infection rates, and costs.

Results: In the intervention period to date, practice changes have included improved identification of patients with drug-resistant organism colonization or infections, development of hand hygiene education tools, ongoing random infection control and hand hygiene audits, and improved reporting and planning between inpatient and outpatient dialysis teams. An average 10% reduction in monthly unit supply costs and 2.6% reduction in per treatment costs have been observed.

Conclusions: Our results demonstrate successful application of combined lean manufacturing principles and positive deviance in outpatient dialysis, including quantifiable process improvements to reduce infection transmission. Challenges have included limits in time and human resources in the outpatient dialysis setting available for positive deviance dialogues, as well as coordination of inpatient/outpatient teams across institutions. Interrupted time series analysis of MRSA infection and bloodstream infection rates will be analyzed after completion of intervention and follow-up periods.

PUB297

Hepatitis C Virus Infection among End Stage Renal Disease Population of Guam Saied Safabakhsh, Christina Vasques, Brittany L. Balajadia, Ali H. Ahangari. *Micronesian Institute for Disease Prevention & Research.*

Background: The purpose of this study was to establish the prevalence and incidence of Hepatitis C Virus (HCV) among End Stage Renal Disease (ESRD) population of Guam and whether there was a correlation between HCV infection and cholesterol levels.

Methods: This research was a retrospective study that was conducted at four Hemodialysis (HD) centers on Guam, a total of 341 subjects were screened using electronic medical records and written chart records. Subjects with Hepatitis C were identified and recorded.

Results: 341 ESRD patients participated in this study out of 410 patients in Guam. 23 out of 341 ESRD patients were positive for HCV. Two patients had converted to HCV positivity in 2010. The average cholesterol level was 138 for all non-HCV patients, while the average cholesterol level was 127 for all HCV patients. 197 (62%) of non-HCV patients were on cholesterol reducing agents. 263 (79%) of all patients were diabetics. 19 (7%) of diabetic patients had HCV. 4 (5%) of non-diabetic patients had HCV.

Conclusions: Hepatitis C Virus infection is considered to be one of the factors increasing morbidity and mortality among ESRD patients. Our study shows that the prevalence of HCV among ESRD patients on Guam is significantly lower than in the United States and other countries. Rate of annual conversion to HCV was less than 1%. Although there was no statistically significant difference between the average cholesterol levels of all non-HCV patients and HCV positive (+) patients, knowing that majority (197 or 62%) of non-HCV (+) patients were on cholesterol reducing medication, we can conclude that HCV infection among ESRD patients affects cholesterol synthesis; therefore, reducing their total cholesterol levels. This may play an important factor in management of ESRD patients. Diabetic patients were found to be at higher risk for HCV infection compared to non-diabetic patients.

PUB298

Increase of HCV RNA Levels during Hemodialysis Treatment in Patients with Chronic Hepatitis C Gernot Schilcher,[1] Csilla Putz-Bankuti,[2] Daniel Schneditz,[3] Harald Kessler,[4] Alexander R. Rosenkranz,[1] Rudolf E. Stauber.[2] *[1]Department of Internal Medicine, Division of Nephrology and Hemodialysis, Medical University of Graz, Graz, Austria; [2]Department of Internal Medicine, Division of Gastroenterology and Hepatology, Medical University of Graz, Graz, Austria; [3]Institute of Physiology, Center for Physiological Medicine, Medical University of Graz, Graz, Austria; [4]Institute of Hygiene, Microbiology and Environmental Medicine, Medical University of Graz, Graz, Austria.*

Background: Previous studies suggest a reduction of hepatitis C virus (HCV) viremia by hemodialysis. The aim of this study was to quantify the effect of hemodialysis (HD) and hemodiafiltration (HDF) treatment on HCV RNA levels.

Methods: HD as well as hemodiafiltration (HDF) was delivered to chronic HD patients (n=11). Blood samples were taken before dialysis (t=0 min) and from the arterial and venous line of the extracorporeal circulation during dialysis at times t=30 min and t=180 min for quantitative detection of HCV RNA using real-time PCR.

Results: HCV RNA levels significantly increased during extracorporeal therapy (p<0.001, Tab.1). After 180 minutes and correction for hemoconcentration, HCV RNA levels increased relative (R180) to baseline by 56%. Importantly, no significant differences could be observed between serum samples collected pre and post dialyzer as well as between HD and HDF treatments.

Tab. 1 HCV viral load during extracorporeal blood treatment (N=11, mean ±SD)

	Unit	all	SD	p
HCV RNA_0	10^6 IU/mL	2.88	4.92	
HCV RNA_{30}	10^6 IU/mL	3.44	5.97	
HCV RNA_{180}	10^6 IU/mL	3.61	5.11	<0.001
R_{30}		1.13	0.26	n.s.
R_{180}		1.56	0.89	<0.0001

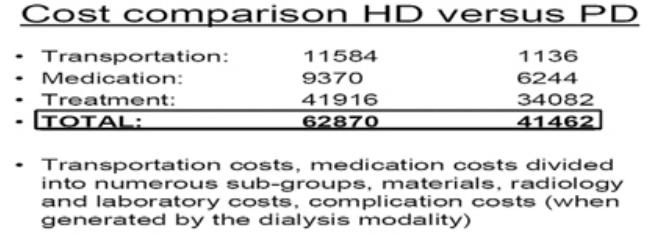
R: HCV RNA level changes relativ to baseline (t=0'), ultrafiltration corrected

Conclusions: Contrary to published data that HCV viremia would be reduced during HD/HDF, a significant increase of HCV RNA was observed after 180 min of treatment. These virological changes could not be explained by HCV RNA absorption on the dialysis membrane, by hemoconcentration or inhibition of real-time PCR due to uremic toxins. After 48 hours of dialysis free time all patients underwent a reduction in viremia by yet unknown mechanisms. Our results also document the importance of timing to collect HCV serum in HD and HDF.

PUB299

Quality of Life in Patients with Various Dialysis Modalities: A Multi-Center, Retrospective Study Klaus Schuster. *Regionalmanagement Mostviertel, Niederösterreichische Landeskliniken-Holding, Amstetten, Austria.*

Background: Public health planning often tries to balance between medical outcomes like survival, etc. and economical/operational reasons. A measurement of quality of life (QuoL)in comparable patients with ESRD seldom is done. Patients with ESRD mainly have 2 options: in-center-dialysis, mainly with hemodialysis (HD), or a home-therapy like peritoneal-dialysis (PD) or home-hemodialysis(HHD). In a recent full-cost analysis we could successfully demonstrate, that treatment at home with PD is obviously cost benficial, but with equal or even better medical outcomes using PD.



Now in a subsequent analysis we did a patient-questionnaire to evaluate the individual QuoL of those patients.

Methods: The questionnaire was completed by 258 patients (62 PD, 196 HD) in 6 dialysis-centres in Lower-Austria, a federal state in Austria. Beside some epidemiological data the questionnaire has three parts, as three different questionnaires are combined. We chose the following surveys: SF-36,an international standard in QuoL-analysis, PLC, a german assessment tool especially for patients with chronic diseases and HADS, the Hospital Anxiety and Depression Scale.

Results: After adjusting age and sex, the results proof our hypothesis, that a home-dialysis-therapy like PD serves the patients better in their subjective self-assessment of various QuoL-aspects. All three parts of the questionnaire show a tendency favouring home-dialysis-therapy, but according to the subscore HADS, the significance is striking.

subscore HADS (points, max. 10)

PD	7.9
HD	6.3

Conclusions: Home-therapy is the choice for patients with ESRD. Not only medical outcomes like better survival and economical/operational (cost saving) reasons, but also the individual self-assessments in QuoL show an advantage for home-dialysis-modalities and so has to be the first choice according to ethics and limited resources.

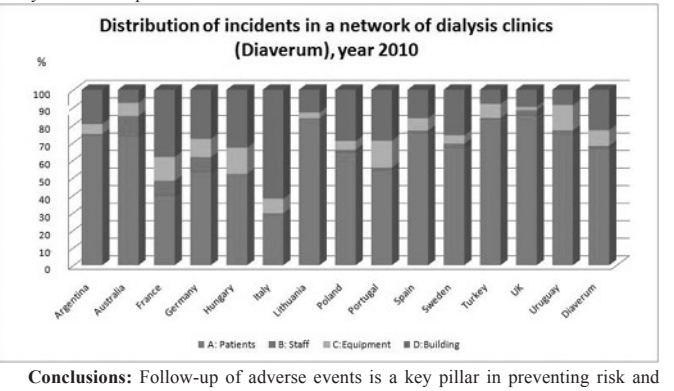
PUB300

Top 5 Incidents in a Worldwide Dialysis Network Paul Stroumza, Jorgen B.A. Hegbrant, Giovanni F.M. Strippoli. *Diaverum, Lund, Sweden.*

Background: The management of adverse events management is a key priority in the overall management policy for quality of care in international dialysis provider groups. Hemodialysis treatments are prone to risks. To our knowledge, a systematic analysis of these incidents in the dialysis world has never been presented. We presents the collection and the analysis of adverse events data for in 2010 in a network of 220 dialysis centers, treating 18,000 patients in Europe, Australia and South America.

Methods: All centers report annualy their incidents through an on-line reporting system. All staff members may report an incident. There are 4 categories of incidents (related to patients, staff, equipment, buildings (fluids, computer, water treatment, other) divided in 49 subgroups. Data on these incidents are presented by monthly analyses with standard descriptive statistics.

Results: In 2010, 25,960 incidents were reported in our organization, with large inter country variability. This is 1.56 incidents per patient per year or 10 per 1000 treatments. The five most common incidents represent 60% of the total. They are, in order: 16% sessions missed-patient did not show up, 15% interruptions of sessions per monitor malfunction, 12% dialyzer and/or blood lines changed due to clotting, 10% vascular access problems, 7% hypotension requiring a filling of more than 300 ml. Distribution of the four groups of incidents were different from country to country; incidents relating to patients were always the most represented.



Conclusions: Follow-up of adverse events is a key pillar in preventing risk and improving the quality of care for dialysis patients. We are implementing a more detailed analysis specially for the first cause: sessions missed; is it voluntary or not? If yes, what about the right for stopping treatment and the physician's responsibility?

PUB301

Characteristics of Bacteremia in Hemodialysis Patients Masashi Suzuki,[1,2] George Seki,[2] Norio Hanafusa,[3] Toshiro Fujita,[2,3] Kyoji Moriya.[1] *[1]Department of Infection Control and Prevention, University of Tokyo Hospital, Bunkyo-ku, Tokyo, Japan; [2]Department of Nephrology and Endocrinology, University of Tokyo Hospital, Bunkyo-ku, Tokyo, Japan; [3]Department of Hemodialysis and Apheresis, University of Tokyo Hospital, Bunkyo-ku, Tokyo, Japan.*

Background: Hemodialysis patients are thought to be immunocompromised. Although infection is the second cause of death in all hemodialysis patients and the first cause of death in patients within one year after initiation of hemodialysis therapy in Japan, the underlying mechanisms are unclear.

Methods: To clarify the characteristics and prognosis of bacteremia, retrospective chart reviews were performed for 850 patients who were admitted to The University of Tokyo Hospital in 2007-2009 and received hemodialysis therapy.

Results: Within 50 cases of bacteremia, the most common types were catheter related infection (20%) and pneumonia (18%), with a substantial portion (22%) unspecified. The common causes of bacteremia were *Staphylococcus aureus* (28%),*Escherichia coli* (10%), *Staphylococcus epidermidis* (8%), *Klebsiella pneumonia*, *Pseudomonas aeruginosa, Candida glabrata* (6%). The frequency of detection was similar to patients who did not receive hemodialysis therapy. Age, types of blood access, catheter, hypertension, cerebrovascular disease, smoking, peripheral vascular disease, serum albumin, hemoglobin, body mass index did not affect the causative organisms. In all hempdialysis patients, the mortality rates within one and three months after bacteremia were 20% and 34%, respectively. These values were even higher (28% and 52%) in a subset of patients who received hemodialysis for less than one year. In these patients, mortality after *S. aureus* bacteremia was extraordinary high (60% and 80% within one and three months, respectively). Mortality was also very high after *Candida glabrata* bacteremia (67% within one and three months).

Conclusions: There was no difference in the cause of bacteremia between hemodialysis and non-hemodialysis patients. Because the bacteremia of *S. aureus* and *Candida glabrata* in the first-year after initiating hemodialysis predicted very bad prognosis, careful observation and intensive care would be required in such cases.

Abstract Withdrawn

PUB303

Patient Characteristics Associated with Dialysis for Veterans with ESRD in VA and Non-VA Settings Virginia Wang,[1,2] Matthew L. Maciejewski,[1,2] Uptal D. Patel,[1,2] Morris Weinberger.[1,2] *[1]HSR&D, Durham VA Med Ctr, Durham, NC; [2]Gen Int Med, Duke Univ Med Ctr, Durham, NC.*

Background: Dialysis is a limited resource within the VA, and growing demand for ESRD care has led VA to purchase dialysis treatment from non-VA providers on a fee for service basis. Decisions about the optimal mix of "making" dialysis in-house or "buying" non-VA services requires an understanding of current users within the VA system. This study examined characteristics of veterans with ESRD who utilized outpatient dialysis in VA and non-VA settings.

Methods: We constructed a cohort of veterans with ESRD in 2 regional networks who received VA-financed outpatient dialysis treatment in 2007-8. Using VA administrative data, we identified veterans who received dialysis in VA; non-VA fee basis; or both settings ("dual users"). We performed bivariate and multinomial probit analysis to identify patient characteristics associated with dialysis setting.

Results: 1,388 veterans received chronic hemodialysis financed by VA: 25% received VA dialysis, 36% used non-VA fee basis dialysis, and 39% were dual users. VA dialysis users were more likely to be non-White, unmarried, sicker, and living closer to VA dialysis units than veterans in non-VA and dual settings (p<.05-.01). After covariate adjustment, non-VA dialysis was positively associated with marital status (p<.05) and negatively associated with comorbidity burden (p<.001). Greater geographical distance to VA dialysis was associated with non-VA and dual dialysis (p<.001). There was regional variation in veterans' use of dual dialysis (p< .001).

Conclusions: A significant proportion of VA-funded dialysis is delivered via fee basis. Non-VA providers benefit from favorable selection of patients, as veterans with lower comorbidity burden are more likely to obtain dialysis outside of VA. With limited service capacity and increasing ESRD prevalence in VA, veterans are likely to continue receiving non-VA dialysis. VA may need to account for selection bias in determining the optimal 1) mix of making vs. buying dialysis services and 2) payment to non-VA dialysis providers. More research is needed to understand the implications on the quality and cost of VA's make-buy decisions.

PUB304

Prosthetic Status and Treatment Needs for Lost Masticatory Function in Hemodialysis Patients Magdalena Wilczynska-Borawska,[2] Jolanta Malyszko,[1] Michal Mysliwiec.[1] *[1]Nephrology, Medical University, Bialystok, Poland; [2]Dentistry, Medical Universiy, Bialystok, Poland.*

Background: Premature loss of permanent teeth leads to stomatognathic system disability, loss of masticatory functions, speech and alterations in face aesthetics. Loss of masticatory function may result in severe malocclusion which, if not treated, may lead to irreversible dysfunction of the whole masticatory system. Premature loss of permanent teeth is a very serious but underrated problem for patients with chronic renal failure.

Methods: The analysis of the degree of loss of masticatory function and number of teeth present for hemodialysis patients, and defining, based on the results, patients' needs for prosthetic treatment, which could restore correct occlusal condition. We studied the total number of teeth and number of teeth separately for upper and lower jaws, 2) the existing prosthetic restorations and 3) the preserved masticatory function in 68 HD patients.

Results: Nearly 70% of tested hemodialysis patients did not have a reconstructed masticatory function. Female patients had less remaining natural teeth in both jaws compared to males and constituted a higher percentage of edentulous patients in the test group. All patients with at least 28 natural teeth with retained occlusal contacts whilst chewing were males (4; 10% males; 5,7% of the whole group). There were 15 edentulous patients: 7 males (10%,) and 8 females (11,5%). More of them had their masticatory functions restored, implementation of prosthetic treatment was needed to a lesser degree. In this group, more extensive restorations like partial, skeletal and complete dentures were observed.

Conclusions: The population of hemodialysis patients from the North East part of Poland are patients with severe stomatognathic system dysfunctions which developed as a result of the loss of physiological function of the masticatory system (more than 20% of patients were edentulous). It is of importance for dentists, as well as nephrologists, to understand the essence of the problem, as the general health of a patient cannot be improved without ensuring functional comfort of such as important system as the masticatory one.

PUB305

A Prospective, Randomized, Multicenter Study Comparing Survival in Subjects Receiving Peritoneal Dialysis or Hemodialysis (SURinD) Xueqing Yu,[1] Anders P. Tranaeus,[2] The SURinD Study Group.[1] *[1]Renal Department, First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [2]Baxter Asia Pacific, Shanghai, China.*

Background: There is currently no consensus on whether peritoneal dialysis (PD) or hemodialysis (HD) is associated with better survival outcomes in patients with end-stage renal disease (ESRD). Results from a pilot study, where 61% of eligible subjects were willing to be randomized to either dialysis modality, suggest that it is feasible to conduct an adequately powered, randomized controlled study to investigate survival outcomes in patients with ESRD receiving PD or HD.

Methods: SURinD is a prospective, randomized, multicenter, open-label study being conducted in China (registered at www.clinicaltrials.gov; sponsor: Baxter Healthcare Corporation). The primary objective is to compare survival in subjects receiving PD or HD; the primary endpoint is the PD/HD mortality hazard ratio (HR). Secondary objectives include a comparison between the two modalities of technique failure, cause of death, residual renal function, erythropoietin-stimulating agent dose, systemic inflammation, quality of life, and safety. Eligible subjects are ≥ 18 years, diagnosed with ESRD (glomerular filtration rate ≤ 15 mL/min/1.73 m² body surface area), and predicted to need dialysis within 10 weeks after the pre-screening period. Approximately 1,370 subjects will be randomized (1:1) to PD or HD (centralized randomization, stratified by investigator site) and followed for up to 5 years. The sample size is based on an overall type I error of 5% and overall power of 80%, and assumes that a non-inferiority margin of 1.25 for the PD/HD mortality HR is clinically relevant. Assessments will be conducted to ensure that internationally accepted standards of care (including adequacy, anemia, calcium, phosphate, and blood pressure) and clinical practice guidelines for dialysis are met for both modalities.

Results: Recruitment will start soon and the final study results are expected in 2017.

Conclusions: This large randomized study will assess whether survival outcomes differ between PD and HD in patients with ESRD, and will provide information on factors that influence modality choice, including quality of life.

PUB306

Female Chinese Hemodialysis Patients with a Better Prognosis Than Man When Treated by the Same Dialysis Parameters Jianzhou Zou, Yi Fang, Jie Teng, Wenlv Lv, Xiaoqiang Ding. *Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China.*

Background: Dialysis dose would be higher in female hemodialysis patients than that in males when treated by the same dialysis parameters. Literatures suggest that greater dialysis dose may significantly benefit women, but not men. So we speculate that prognosis of female hemodialysis patients will be better than that of males.

Methods: All 151 patients were treated by the same dialysis parameters and would be followed up for 30 months or ceased by death, transforming to the other renal replacement therapy, or transferring to other dialysis centers. The demographic datas, laboratory test results and dialysis dose would be collected when the patients enrolled in the cohort study.

Results: During the follow-up, five patients changed to kidney transplant and one to peritoneal dialysis, one patient transferred to the other dialysis center. Among the analyzed 144 patients, almost 45% were females. Thirty one patients died from all causes and the all-cause mortality was 21.53%, Adjusted death rate per 100 patient years was 9.83 by the end of follow-up. The all-cause mortality for male (29.11%) was significantly higher than that for females(12.30%, p<0.05). Adjusted death rate per 100 patient years was 13.82 in males which was higher than that in females (5.27, p<0.05). The level of hemoglobin, white blood cell count and predialysis serum creatinine were significantly higher in males than that in females, but URR and spKt/V were significantly lower in males. When analyzed by Cox proportional hazards regression modeling, we found that for male patients, C-reactive protein, preablumin and iPTH were independent predictors of death; however for the females, the independent predictors of death were C-reactive protein and iPTH.

Conclusions: When treated by the same HD parameters in Chinese patients, the prognosis of females was better than that of males. Meantime, we found that iPTH was associated with mortality in males or females, but the impact was different by gender.

PUB307

Hemodialysis Catheter Adherent to Jugular Vein Solange Bourque. *Nephrology, CHUS, Sherbrooke, QC, Canada.*

Background: Hemodialysis catheters are used in patients without any other possible vascular access. However, they have multiple complications. We present an unusual complication, namely a catheter adherent to the jugular vein.

Methods: A 50 year old man was dialysed with a permanent right jugular tunneled catheter since 1999. He presented his first tunnel infection on July 7th 2010. Infective organism was staphylococcus aureus. At that time, there was a first, unsuccessful attempt to remove the catheter at the dialysis clinic. The patient was sent to radiology for further attempt. Ultrasound showed that the dialysis catheter seemed to be attached to the jugular vein. The surgeon was called in for help but was unable to remove the catheter even with further incision and dissection. It was then decided to proceed to surgical dissection under general anaesthesia. A partial sternotomy had to be done to reach the jugular vein. An incision was made along the jugular vein to retrieve the catheter. This caused a massive

2L bleed with severe hypotension. After hemostasis was completed, the procedure was finished. The patient fully recovered and is now dialysed with a permanent left jugular tunneled catheter.

Results: Ten cases of hemodialysis catheters embedded or adherent to central vein are described in the literature. Clinically, there was either resistance or chest pain while trying to remove the catheter. Every patient needed surgery to try to remove the catheter. Some could not be removed and needed to be ligatured, cut and buried under the fascias. Some catheters were fragmented during the attempt to remove them. The most important risk factor was the length of time since the installation of the catheter, which varied from one and a half to seven years. Other risk factors are the presence of thrombus around the catheter and stenosis of the vessel.

Conclusions: Resistance or chest pain during attempt to remove a hemodialysis catheter should make us think of possible adherence to the blood vessel. There currently aren't any recommendations available about optimal or maximal time for which a catheter can be left in place or if routine investigation such as fluoroscopy or cardiac ultrasound should be done.

PUB308

When To Refer for Vascular Access Fistulogram in Hemodialysis Patients with Decreasing Intra-Access Flow? Sun Ryoung Choi, Hoon Suk Park, In O Sun, Hyun Gyung Kim, Yu Ah Hong, Byung Ha Chung, Bumsoon Choi, Cheol Whee Park, Chul Woo Yang, Young-Soo Song. *Division of Nephrology, Department of Internal Medicine, Catholic University of Korea, Seoul, Republic of Korea.*

Background: Intra-access flow measurement is preferred to surveil vascular access in hemodialysis patients. K/DOQI guidelines emphasized prospective trend analysis of access flow on a monthly basis. They recommend refer for fistulogram if access flow 1,000 ml that has decreased by more than 25% over 4 months in graft, and do not mention about fistula.

Methods: This study was a prospective observational trial. The surveillance used was intra-access flow measured by ultrasound dilution (Transonic HD03 hemodialysis monitor; Transonic Systems, Inc., Ithaca, NY) performed monthly. We defined 25% decrease in Qac compared to that of the last measurement as significant finding and thus performed intervention without follow-up over four months.

Results: Out of total 52 cases, 38 patients were male, mean age 63 years old, 22 (42.3%) diabetics, 38 (73.1%) fistulae, and 37 (71.2%) accesses were on the forearm. At the time of referring for fistulogram, the access flow has been decreased from 816±367 ml/min to 614±312 ml/min in fistulae, and from 1140±448 ml/min to 849±393 ml/min in grafts. The mean decrease in access flow was 30±7% in fistulae and 34±11% in grafts. Significant stenosis was found in 48 cases (94%) on the fistulogram. The result of fistulogram showed outflow stenosis (55%), inflow stenosis including juxta-anastomotic stenosis (36%), accessory vein (3%), and no stenosis (6%). Twenty two percent of patients had increasing venous pressure or negative arterial pressure during dialysis. However, none of the patients showed abnormal physical finding

Conclusions: Our study suggests that the patient should be immediately referred to fistulogram if access flow has decreased more than 25% regardless of access type, absolute value of access flow, or duration of decreased access flow

PUB309

Impact on Autologous Arteriovenous Fistula Aneurysm by Improved Puncture Technique: Centripetal and Exodic Alternate Xia Fu, Wei Shi, Xinling Liang. *Nephrology, Guangdong General Hospital, Guangzhou, Guangdong, China.*

Background: To study the appropriate puncture technique of autologous arteriovenous fistula for reducing the occurrence of aneurysm or avoiding aneurysm increasing.

Methods: 298 maintenance hemodialysis patients with autologous arteriovenous fistula were randomized into 3 groups, respectively punctured by centripetal method, exodic method and alternate ways. Incidence of aneurysm, aneurysm increasing, blood flow and Kt/v were compared among the three groups.

Results: Aneurysm incidence and aneurysm increasing in the centripetal group and the alternate group had no significant difference ($p>0.05$). The incidence and increasing of exodic group was significantly higher than those of centripetal group and alternate group ($p < 0.05$). The values of blood flow and Kt/v in the centripetal group were significantly lower than those in the exodic group and alternate group ($p < 0.05$).

Conclusions: Alternating centripetal and exodic puncture not only guaranteed blood flow but also effectively avoided occurrence or increase of aneurysms of autologous arteriovenous fistula.

PUB310

Evaluation of Intravascular Ultrasound (IVUS) Observations with AVF in Which Intravascular Stents Were Inserted into Their Central Veins Tomonari Ogawa, Tota Kiba, Yuta Kogure, Shimpei Okazaki, Mizuki Iwanaga, Chie Noiri, Akihiko Matsuda, Hajime Hasegawa, Tetsuya Mitarai. *Nephrology and Blood Purification, Saitama Medical Center, Saitama Medical University, Kawagoe, Saitama, Japan.*

Background: In hopes for long-term patency, insertion of intravascular stents into sites of stenosis in the central vein is not a rare case in recent years. Intravascular assessments were conducted before and after treatment on patients with stents placed inside the lesion of the central vein.

Methods: This study is based on 8 cases where intravascular ultrasound (IVUS) analysis was conducted on dialysis patients with AVF and have a stent inserted into sites of venous stenosis in or near their trunk.IVUS was used to measure the vascular diameter and to assess the lumen of the stegnotic site for cases in which central vein stenosis was confirmed through angiography. The vascular diameter was measured again after stent placement. In addition, blood flow was measured before and after treatment using ultrasonography in order to make functional assessments of the stent.

Results: A clear blood clot was found in 2 out of the 8 cases, but not in the other remaining 6 cases. A low echoic area was identified around the blood vessel, and thus a form of exclusion was confirmed in all 8 cases. A Wallstent was placed in patients whose improvement in vascular diameter could not be confirmed using only balloon dilation. An improvement in vascular diameter after Wallstent placement, relative to that before treatment, was observed in all cases. In terms of functional assessment, there was a significant increase in blood flow in the brachial artery before and after treatment.

Conclusions: Stenosis was confirmed through angiography in the patients who received treatment in this study, and exclusion of the stenosis was confirmed through IVUS examinations. A clear morphological improvement was observed as a result of stent insertion in these cases, and an improvement in blood flow was also confirmed through functional assessments. Although there are negative opinions against stent insertion, it could be concluded that this treatment could be effective depending on the morphology of the stenosis.

PUB311

Identifying Factors Associated with Type of Hemodialysis Access: Efforts To Reduce Catheter Rates Maria Aurora C. Posadas, Aleksandra Gmurczyk, Robert M. Rosa, Daniel Batlle, James J. Paparello, Jennifer A. Tuazon, Shubhada N. Ahya. *Department of Medicine - Division of Nephrology and Hypertension, Northwestern Memorial Hospital, Chicago, IL.*

Background: HD catheters are suboptimal due to associated increased infection, morbidity, and mortality. Identifying factors that affect the patients' choice of HD access is valuable to reduce the catheter rate.

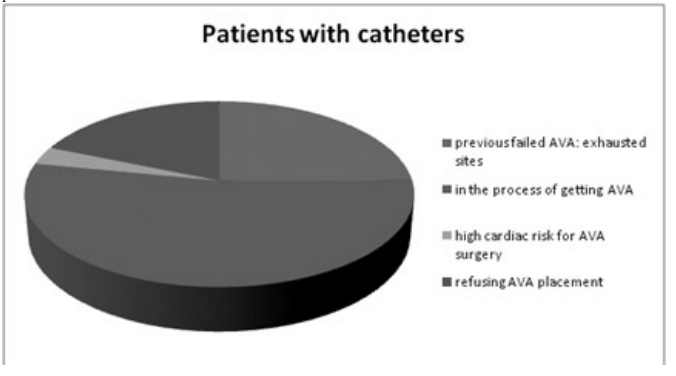
Methods: This is a cross-sectional study of 83 ESRD patients on HD at one outpatient dialysis unit. The subjects were grouped based on HD access type: catheter or arteriovenous access (AVA). T-test was used to look at differences in demographics, presence of pre-dialysis care, health literacy, HD vintage, and labs.

Results: Subjects from both groups were similar. Patients with catheters had shorter HD vintage (P=0.02) and were more likely to have received pre-dialysis care from a nephrologist (P=0.049) compared to patients with AVA.

Demographic Data

Parameters	Catheter	AVA	P-value
no. of subjects	42	41	
gender			0.063
male	14	22	
female	28	19	
received pre-HD care	31	26	0.049s
HD vintage (months)	29	57	0.020s
STOFHLA numeracy	3.3	3.5	0.230
STOFHLA reading comprehension	32.6	33.6	0.328

Nineteen percent of patients with catheters had previous AVA that either had primary non-function or ceased to function and 14% of the patients with catheters refuse AVA placement.



Conclusions: Patients with catheters had shorter mean HD vintage compared to patients with AVA. While patients with catheters were more likely to have received pre-dialysis care compared to patients with AVA, these patients had previous failed AVA, or were undergoing evaluation for AVA placement at the time of the study, were either awaiting kidney transplantation or switching to peritoneal dialysis. More studies need to be done to explore qualitative factors for high catheter rates including patients' refusal for AVA placement.

PUB312

Malfunction of Tunneled Cuffed Venous Catheter with Small Gap between Cuff and Catheter: A Report of Four Cases Nami Shibahara,[1] Hiroshi Shibahara,[2] Susumu Takahashi. *[1]Hashimoto Minami Internal Medicine Clinic, Sagamihara, Kanagawa, Japan; [2]Blood Purification Center, Sagamihara Kyodo Hospital, Sagmihara, Kanagawa, Japan.*

Background: The cuff of a tunneled cuffed venous catheter (TCC) provides a barrier against infection, and firmly anchors the catheter by fixing it to the subcutaneous tissue. However, we experienced four cases of malfunction of a Soft Cell (Bard Access Systems, Salt Lake City, UT, USA), a type of TCC, with a small gap between the cuff and the catheter.

Methods: In case 1 (74-year-old woman), case 3 (95-year-old woman), and case 4 (74-year-old woman), a Soft Cell (12.5 Fr diameter, 19 cm long) was used as a permanent access, while in case 2 (86-year-old woman) a Soft Cell was used as a bridge access for arteriovenous graft failure. The Soft Cell was removed because of tunnel infection at 290 catheter-days in case 1 and at 29 catheter-days in case 2, suspected catheter-related blood stream infection at 513 catheter-days in case 3, and catheter dysfunction at 734 catheter days in case 4.

Results: In all of the removed Soft Cells, the presence of a gap was confirmed by passing a probe through this gap. Sections of formalin-fixed cuffs of these Soft Cells showed that the cuff had detached from the catheter at the part where it was possible to pass a probe, despite the cuff being tightly attached to the adjacent dermal connective tissue with marked foreign body reaction and fibrosis histologically.

Conclusions: In the four cases presented, the cuff was tightly attached to the dermal connective tissue histologically. Even if the cuff were firmly fixed to the subcutaneous tissue, bacteria and foreign substances would have been able to get into the tunnel site through the gap. The gap between the cuff and the catheter, representing a break in the barrier against infection, might have been the cause of the two cases of tunnel infection. Fortunately these patients improved immediately without hospitalization, and all Soft Cells were hardly anchored to the skin. The cause of this malfunction of the Soft Cell is currently being investigated by the manufacturer.

PUB313

An Assessment of International Frequent Hemodialysis Utilization and Practice Patterns: A Collaboration between the Canadian Home Hemodialysis Study Group and Nephrology Now Nathan D. Allen,[1] Daniel Schwartz,[2] Paul Komenda,[1] Deborah Lynn Zimmerman,[3] Robert P. Pauly,[4] Gemini Tanna,[5] Jeffrey Schiff,[5] Manish M. Sood.[1] *[1]Medicine, University of Manitoba, Winnipeg, MB, Canada; [2]Medicine, University of British Columbia, Abbotsford, BC, Canada; [3]Medicine, University of Ottawa, ON, Canada; [4]Medicine, Univeristy of Alberta, Edmonton, AB, Canada; [5]Medicine, University of Toronto, ON, Canada.*

Background: The purpose of our study was to determine influences for the utilization of frequent HD and attitudes regarding initiation of and the evidence for frequent HD.

Methods: An international cohort of subscribers of a nephrology education website (www.nephrologynow.com) was invited to participate in an online survey. Survey questions assessed indications, reasons for withdrawal support of evidence and attitudes towards frequent HD. Frequent dialysis was defined as nocturnal, short daily or long conventional hemodialysis, either in-centre or at home. Variables associated with frequent HD use were determined using multivariate logistic regression analysis.

Results: Our survey had a 40.9% response rate. The final cohort was limited to 311 physicians.125 (40.2%) physicians had patients treated with frequent HD. In the multivariate model, adequate training (OR 2.47 CI 1.25-4.16), government physician reimbursement (OR 2.66, CI 1.11-6.40), higher national health care expenditure and number of ESRD patients per centre were independently associated with frequent HD utilization. Hemodialysis providers with patients on frequent HD were significantly more likely to support the evidence base and less likely to agree with the statements that frequent HD increases fistula/graft thrombosis and is too costly. The most common reasons to initiate frequent HD were driven by patient preference and the desire to improve volume control and global health outcomes

Conclusions: Frequent HD use and support of the evidence vary according to identifiable factors. Interventions and health policy targeting these areas and increased physician education and training in frequent HD modalities may be effective in increasing frequent HD utilization.

PUB314

Recurrent Pancreatitis Associated with Icodextrin Mehrdad Hamrahian, Tibor Fulop, Luis A. Juncos. *Division of Nephrology, University of Mississippi, Jackson, MS.*

Background: Acute pancreatitis is an infrequent condition in peritoneal dialysis (PD) patients; determining its cause can be challenging. We present a patient with recurrent bouts of chemical pancreatitis that appear to be due to icodextrin.

Methods: A 42 year-old diabetic and hypertensive female on PD presented with recurrent pancreatitis. Laboratory studies consistently showed high serum lipase levels, normal peritoneal fluid white blood cell counts of macrophage predominance, and negative cultures (Table 1). Imaging studies were consistent with pancreatitis. The results raised the possibility of chemical pancreatitis, but no clear culprit was identified. Her cycler automated PD dialysate consisted of 2.5% and 4.25% dextrose plus a daytime dwell of icodextrin. A chart review revealed that the patient rapidly improved with admission, despite the lack of specific therapy. The only intervention identified that was consistently instituted during each admission was a change from icodextrin to dextrose in the daytime dwell (due to formulary restrictions). We therefore entertained the possibility that icodextrin was inducing chemical pancreatitis and thus eliminated the icodextrin dwell from her outpatient PD prescription. Removal of icodextrin not only led to a complete resolution of her symptoms, but she did not have any further recurrences.

Admission	1st	2nd	3rd	4th
Lipase/Amylase	2669/-	683→534/17	1266→173/23	931→245/-
WBC/Culture	15-131/∅	22/∅	17/∅	29/∅

Results: Discussion: Icodextrin is an osmotic glucose polymer which is especially useful in patients with high peritoneal membrane transport, because of its limited diffusion across this membrane. While it is usually well-tolerated, it can cause cutaneous allergic reactions, abdominal pain, sterile peritonitis, hyponatremia and decreased plasma amylase activity (with unaltered lipase levels). Our report suggests that it may also cause chemical pancreatitis. This is suggested by the clinical presentation, chronologic relationship and the resolution of symptoms with no further recurrence of episodes upon icodextrin withdrawal.

Conclusions: Chemical pancreatitis should be considered in recurrent unexplained pancreatitis in PD patients when icodextrin is used.

PUB315

Changing Picture in the Microbiology of Peritoneal Dialysis Associated Peritonitis – A Single Center Experience over Almost Three Decades Martin Kimmel, Niko Braun, Mark Dominik Alscher. *Department of Internal Medicine, Division of General Internal Medicine and Nephrology, Robert-Bosch Hospital, Stuttgart, Germany.*

Background: Peritonitis is the most important complications of peritoneal dialysis (PD) and is still a major cause of morbidity and technique failure. In previous reports concerning the microbiology of peritonitis and its characteristics the longest observation period was one decade.

Aim of this retrospective study is to analyze the microbiological spectrum of PD-associated peritonitis from July 1983 over an almost three decade-long period up to December 2010 in a local peritoneal dialysis reference center.

Methods: Retrospective study analyzing >300 peritonitis episodes at a peritoneal dialysis reference center in south Germany. All peritonitis episodes in three timeframes (a-c) were analyzed: a: 1983-1989, b: 1993-2006 and c: 2007-2010. The spectrum of organisms causing PD-associated peritonitis and the antibiotic resistance profiles were assessed for each pathogen.

Results: Organism spectrum: the ratio gram-positive to gram-negative organism is changing: gram-positive organisms are decreasing (a: 74%, b: 66%, c: 66%). Staphylococcus aureus and coagulase-negative Staphylococcus (CoNS) is decreasing, but Methicillin-resistant CoNS is increasing and formerly rare organisms appeared more frequently (e.g. Serratia marcesens or Stenotrophomonas maltophilia). Antibiotic susceptibility: there is an increasing rate of resistant organisms with the need to adapt the initial treatment protocol.

Conclusions: There is a changing picture in the microbiology of peritonitis episodes over almost three decades with an ongoing need to adapt continuously the initial treatment protocol

PUB316

How Home Hemodialysis Programs Deal with the Non-Adherent Patient: A Survey of 17 HHD Programs in Canada Paul Komenda,[1] Deborah Lynn Zimmerman,[2] Robert P. Pauly.[3] *[1]Medicine, Nephrology, University of Manitoba, Winnipeg, MB, Canada; [2]Medicine, Nephrology, University of Ottawa, ON, Canada; [3]Nephrology, Univeristy of Alberta, Edmonton, AB, Canada.*

Background: Despite growing interest in intensive hemodialysis (HD) prescriptions (more frequent and or longer), there is little published information on how to establish and maintain an intensive HD program. The purpose of this study was to survey Canadian nephrologists responsible for intensive HD to describe practice patterns. This abstract pertains to how programs address non-adherence in patients performing independent home hemodialysis.

Methods: A survey was developed and then sent to 19 physician experts to ensure content and face validity. Physicians were encouraged to seek input from allied health team members. The survey was modified based on responses received and then circulated prior to a face-to-face meeting with the same physician experts before final changes to the instrument were made. The survey was completed on line.

Results: Seventeen of 19 (89%) physicians representing individual programs in Canada participated in survey development and provided program information. 11/17 (65%) HHD Medical Directors felt that patients were entitled to make decisions clinicians may deem "unsafe". 12/17 (71%) programs have discontinued HHD therapy to patients against their wishes. Reasons for removing patients from HHD therapy could include missing routine bloodwork (15/17), missing clinic visits (14/17), or not performing routine machine maintenance (12/17).

Conclusions: The majority of HHD programs in Canada communicate that informed patients may be permitted to make their own decisions regarding safety in performing HHD. The majority of these programs however have removed a patient from therapy against the patient's wishes. Consensus guidelines may help guide HHD teams in setting thresholds for involuntarily removing patients from this modality.

PUB317

Training Variability in Home Hemodialysis in Seventeen Canadian HHD Programs: The Case in Favor of Standardization Paul Komenda,[1] Deborah Lynn Zimmerman,[2] Robert P. Pauly.[3] *[1]Medicine, Nephrology, University of Manitoba, Winnipeg, MB, Canada; [2]Medicine, Nephrology, University of Ottawa, ON, Canada; [3]Nephrology, University of Alberta, Edmonton, AB, Canada.*

Background: Despite growing interest in intensive hemodialysis (HD) prescriptions (more frequent and or longer), there is little published information on how to establish and maintain an intensive HD program. The purpose of this study was to survey Canadian nephrologists responsible for intensive HD to describe practice patterns. This abstract addresses practice patterns pertaining to training schedule.

Methods: A survey was developed and then sent to 19 physician experts to ensure content and face validity. Physicians were encouraged to seek input from allied health team members. The survey was modified based on responses received and then circulated prior to a face-to-face meeting with the same physician experts before final changes to the instrument were made. The survey was completed on line.

Results: Seventeen of 19 (89%) physicians representing individual programs in Canada participated in survey development and provided program information. Programs vary in training schedules with 7/17 (41%) training three days per week, 4/17 (23%) four days/week and 6/17 (35%) five days/week. 9/17 programs report a median training time of 5-6 weeks, with 5/17 training for 7-8 weeks. Training more days per week did not always correlate with shorter training duration. 14/17 programs maintain a 1:1 nurse to patient ratio throughout training. Most programs (16/17) generate their own training manual.

Conclusions: Significant heterogeneity exists between Canadian HHD programs in terms of the intensity and duration of training provided to new patients. As up front training represents a significant fixed cost in providing access to this modality, standardized training manuals across centres may augment efficiency in helping new programs to grow quickly and safely.

PUB318

A Flexible Approach to Extended Hours Hemodialysis at Home Rathika Krishnasamy, Carmel M. Hawley, David W. Johnson, David Mudge, Nicole M. Isbel, Scott B. Campbell, Carolyn L. Van Eps. *Department of Nephrology, University of Queensland at Princess Alexandra Hospital, Brisbane, Queensland, Australia.*

Background: Home hemodialysis (HHD) allows greater tailoring of prescription to individual needs both medically and socially. The aim of this survey is to review current dialysis prescription practices of HHD patients and to explore factors involved in their decision making.

Methods: 60 HHD patients from PAH were invited to complete a written survey containing 24 questions in April 2011.The survey covered duration and timing of HHD, patient's health perception, support system and perceived barriers.

Results: 60% of patients responded to the survey. 82% of patients had been on HHD for more than a year. At least 35% of these patients stayed on HHD for more than 5 years.

Duration and Timing of HHD

Variable	HHD(n=35)	Nocturnal HHD (n=21)
Frequency(sessions/week)		
daily	6%	5%
alternate days	57%	67%
< 4 days	37%	28%
Duration(hours/session)		
> 8	20%	28%
6-8	49%	62%
4-6	26%	10%
< 4	5%	0%
Start time		
morning(0400 -1100)	22%	0%
midday and afternoon(1100-1700)	20%	3%
evening(1700-2000)	18%	40%
night(2000-0400)	40%	67%

Nearly 80% of them rated their overall health, mental health and their current dialysis as being good, very good or excellent. 75% of patients felt that doing dialysis at home was both beneficial to their health and their family.70% of patients had a support person during dialysis and mostly were satisfied with the care from the dialysis training centre.

The duration of dialysis was mainly influenced by lifestyle preferences (42%) and advice from the dialysis training centre (39%) rather than work choices (3%) or dietary allowances (10%). The concerns regarding their current dialysis included medical problems (28%), expenses for dialysis (17%), storage space (14%) and maintenance of equipment (14%).20% of patients dropped out from previous nocturnal HHD and reported sleep disturbance as a primary problem. Lifestyle limitation and inability to contact dialysis staff were the concerns raised by patients who declined nocturnal HHD.

Conclusions: This survey suggests that the flexibility of HHD is perceived as highly beneficial for patients and their families. We also identified patients' concerns and barriers towards HHD.

PUB319

The Effect of Newly Developed Semi-Long Peritoneal Dialysis Catheter on the Inflow- and Outflow Time of Peritoneal Dialysis Fluid Akihiro Kuma,[1] Narutoshi Kabashima,[2] Tetsu Miyamoto,[1] Nana Ishimatsu,[1] Yumi Furuno,[1] Kaori Kanegae,[2] Ryota Serino,[1] Masahito Tamura,[2] Yutaka Otsuji.[1] *[1]Second Department of Internal Medicine, University of Occupational and Environmental Health, Kitkakyushu, Japan; [2]Kidney Center, University of Occupational and Environmental Health, Kitakyushu, Japan.*

Background: To reduce the incidence of omental wrapping, we developed a newly designed peritoneal dialysis catheter (PDC) for the upper abdominal exit. This catheter (JBS-2) called "CAVA CATHETER" has smaller end-holes (2.0 mm) and smaller side-holes (0.5 mm) with 4-line slits on the surface to prevent omental entanglement. While JBS-2 could prevent a suction of omental tissue, this catheter could cause an inflow- or outflow-delay of peritoneal dialysis fluid (PDF).

Methods: We provided five different types of catheters according to the existence of slits and size/number of end-hole or side-hole. The effect of JBS-2 (n=5), the five different types of catheters (n=3-6) and conventional Swan Neck catheter (JB5A, n=3) on inflow- and outflow- times were assessed with artificial abdominal cavities.

Results: The mean PDF outflow of the PDC with 2.0 mm of end-hole (JBS-2) was delayed compared to the PDC with 3.0 mm of end-hole (15min 2 sec vs 9 min 33 sec). We observed trivial difference of inflow time between the two types of catheters (8 min 3 sec vs 6 min 9 sec). Meanwhile, the existence of slit, side-hole size/number had no impact on the inflow or outflow time of PDF. It took 8 minutes of mean inflow time with JBS2.

Conclusions: The bag exchange procedure with JBS-2 will finish within 30 min, which is considered to be permissible in clinical settings. The smaller side-holes and slit structure of the PDC may contribute to the lower incidence of catheter-related problems including omental wrapping without a delay of PDF inflow- or outflow- time.

PUB320

First Year Outcomes of Incident Peritoneal Dialysis Patients Eduardo K. Lacson, Nien-Chen Li, Raymond M. Hakim, J. Michael Lazarus, Franklin W. Maddux, Joseph P. Pulliam. *Fresenius Medical Care, North America, Waltham, MA.*

Background: There have been few large multi-center studies on peritoneal dialysis (PD) outcomes in incident dialysis patients. We describe a contemporary cohort of patients starting PD and their outcomes in the first year of therapy.

Methods: All adult (age ≥18 years) patients admitted to Fresenius Medical Care North America facilities between January 1 to December 31, 2009 who initiated PD within their first 90 days were included. Patient follow-up is for one year from their first home PD treatment. We describe the cohort and their outcomes including deaths (with withdrawals), hospitalization, transplants, hospitalization, peritonitis and technique failure rates (a switch from PD to hemodialysis for ≥30 days).

Results: Patients (N=1,960) had mean age of 57.0±14.8 years, BMI was 32.2±12.0 kg/m^2, 56.2% male, 74.7% white, 54.1% diabetic, 3.0% with CHF, 7.1% with PVD, and 3.6% with limb amputation. During follow-up, 136 died (6.9%), 47 withdrew (2.4%), 128 were transplanted (6.5%) and 34 recovered kidney function (1.7%). No patient was lost to follow-up - leaving 1,615 (82.4%) active patients on PD by year-end. The median time to to death/withdrawal was 167 days. Patients stayed on PD until being censored 78.6% of the time while 21.4% switched to HD. The median time to technique failure was 158 days. More than half (57.9%) were hospitalized and 28.2% had at least one episode of peritonitis. Median time to 1st hospitalization was 111 days and to 1st peritonitis episode was 123 days. Overall peritonitis rate was 0.68/24 patient-months.

Conclusions: Four out of 5 patients initiating PD within their first 90 days continue with PD for the first year. 1 of 5 patients who died or were discharged switched to HD beforehand. Causes of high hospitalization and peritonitis rates will need to be explored.

PUB321

Psychological Problems and Nursing Intervention of Patients Undergoing Continuous Ambulatory Peritoneal Dialysis Rong Li. *Deparment of Nephrology, Xijing Hospital, FMMU, Xi'an, China.*

Background: To promote psychological care for patients undergoing the continuing ambulatory peritoneal dialysis(PD), and help patients can cooperate with the medical staff in order to improve dialysis results and quality of patients' life.

Methods: Professional staff provide self-management education, self-care guide and targeted communication for PD patients with different psychological problems, and provide psychological intervention by such means as the combination of individual guidance and group education. Firstly, investigations on PD patients' age, occupation, personality and family background may be carried out and the psychological problems of patients should be confirmed. The specialist, professional nurses and dietitians will provide self-management education and self-care guide for patients and their families by means of lectures, videos, pictures and brochures. Patients club will be established and patients with successful experience in the treatment will be invited to give speeches on successful treatments, Individual guidance and group education will be integrated to achieve better effect.

The nurse staff should encourage patients to face the reality with positive attitude and receive dialysis treatment and therapy. The nurse staff should narrow the mental differences among the patients, establish harmonious relationship among doctors, nurses and patients by individualized services. The nurse staff should detect problems and help resolve the problems timely thereby to effectively improve the PD quality and patients' life quality.

Results: Psychological problems of PD patients are one of the growing concerns of the medical personnel. Active intervention can improve the life of patients and reduce the burden brought to individuals, the families of the patients and the society. So patients are willing to receive psychological care, and the dialysis will have a significant effect, which will improve patents' life significantly.

Conclusions: Psychological care for patients undergoing the long-term dialysis has significant meaning.

PUB322

Percutaneous Versus Surgical Insertion of Peritoneal Dialysis Catheters: Experience of an Irish Center Samar A. Medani, Mohamed Shantier, Wael F. Hussein, Catherine A. Wall, George Mellotte. *Nephrology, Adelaide & Meath Hospital Dublin, Dublin, Co Dublin, Ireland.*

Background: Peritoneal dialysis (PD) is the preferred available option of renal replacement therapy for a growing number of end stage kidney disease patients. A major limiting factor to the successful continuation of PD is long-term viability of the PD catheter (PDC). Percutaneous placement of PDCs is not commonly practiced despite recently published data encouraging use of this technique. Its advantages include faster recovery and avoidance of general anaesthesia.

Methods: We carried out a retrospective analysis of the outcomes of 313 PDC insertions in our centre comparing all percutaneous PDC insertions between July 1998 and April 2010 (group P) with all surgical PDC insertions from January 2003 to April 2010 (group S).

Results: 151 group P and 162 group S catheter insertions were analysed. Significantly more patients in group S had previously undergone abdominal surgery or PDC insertion compared with group P (41.8 % vs 9.3 % and 33.3 % vs 3.3% respectively; P=0.00). There were more exit site leaks in group P than in group S (22.1 % vs 7.4 %; P= 0.00) but no significant differences in peritonitis rates (1 episode per 16.5 catheter months vs 1 episode per 12.5 catheter months; P= 0.36), poor initial drainage (9.9 % vs 11.7 %; P= 0.1) or secondary drainage failure (8.7% vs 13.7 %; P= 0.183). Technical survival at 3 months was significantly better for group P than for group S (86.6 % vs 77 %; P= 0.037) and at 12 months was 77.7 % vs 68.7 % respectively (P= 0.126). No life threatening complications attributable to the insertion of the PDC occurred in either group.

Conclusions: We have demonstrated further encouraging outcomes of percutaneous PDC placement in comparison with the open surgical technique. The percutaneous insertion group were primarily a selected subset of patients without prior abdominal surgery or PDC insertion, therefore limiting this comparability. Studies eliminating these confounding factors are required although local expertise may affect generalisability of results. We recommend formal training of junior nephrologists on this bedside technique, particularly in healthcare systems with limited resources.

PUB323

Medical (Trocar & Cannula Method) Versus Open Surgical Insertion of Peritoneal Dialysis Catheters: A Retrospective Cohort Study Girish S. Namagondlu,[1] Vivian W. Yiu,[2] Thomas F. Hiemstra,[2] Paul F. Williams.[1,2] *[1]Nephrology, Ipswich Hospital, Ipswich, United Kingdom; [2]Nephrology, Addenbrookes Hospital, Cambridge, United Kingdom.*

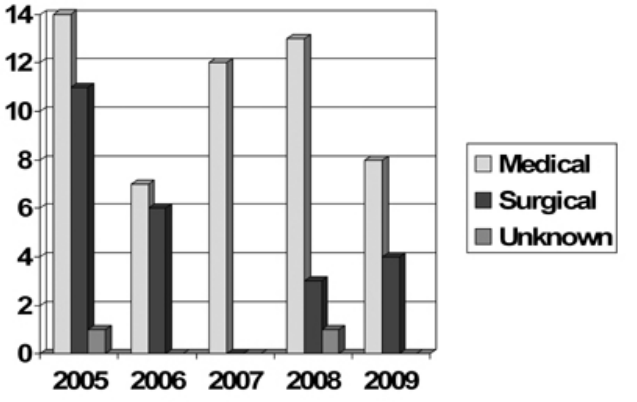
Background: There is little evidence in literature about direct comparison of trocar & cannula method vs open surgical technique for PD catheter insertions. A 5year(Jan 2005 - Dec 2009) retrospective cohort study of medical insertion(MIs) versus surgical insertion(SIs) of PD catheters, was performed at our centre (Ipswich Hospital). Primary end point was catheter patency at 1 year (Censored for death & elective modality switch).

Methods: Data were extracted from an electronic database & patient case records.

Results: We identified 84 catheter insertions in 80 patients during the study period,54/84 (64.2%) were MIs.Age did not differ significantly between groups.More MIs were male (44/54) compared to SIs (10/24, P=0.013).7/24 (29.2%) SIs and 5/54 MIs (9.2% overall) were no longer patent after 12 months(P=0.052).Combined catheter patency at 12 months (censored for death and transplant) was 79.2% (ISPD recommendations suggests >80%).

	MIs	SIs	Unknown	Total
Mean age in years, at the time of catheter insertion	56.5	52.7		58.1
No. of catheter insertions	54(64.2%)	24(28.5%)	6	84
Catheter patency at 1 year(Censored for death and Transplantation)	48(88.8%)	15(62.5%)	2(33.3%)	65(79.2%)
Catheter failure within 1 year	5(9.2%)	7(29.2%)	1	13(16.6%)
Immediate mechanical Complications (< 4 weeks post insertion)	4(7%)	2(8%)		6(7.1%)
Catheter related infections (< 4 weeks post insertion)	0	0		0

Rates of immediate complications (<4 weeks) were similar in both the groups and comparable to ISPD recommendations.



Conclusions: Our data indicates that MIs of PD catheters by trocar & cannula method, are comparable to open SIs in terms of safety and better in efficacy. Strict selection criteria for MIs is required to acheive these results.Our data is comparable to ISPD recommendations 2010.

PUB324

Equipment and Home Requirements for Home Hemodialysis (HHD) among Canadian Renal Programs Robert P. Pauly,[1] Paul Komenda,[2] Deborah Lynn Zimmerman.[3] *[1]University of Alberta, Canada; [2]University of Manitoba, Canada; [3]University of Ottawa, Canada.*

Background: There is growing interest in HHD though little published information on establishing and maintaining an HHD program. The purpose of this study was to survey Canadian HHD programs to describe practice patterns in a variety of domains. The current abstract focuses on equipment and home requirements for HHD.

Methods: A questionnaire was developed by 19 physician experts with input from allied health team members. The instrument underwent multiple modifications to ensure content and face validity, and was completed online between Jul and Dec 2010; data reflect practices during this period.

Results: Seventeen of 19 (89%) programs responded. All programs use conventional HD machines in the home setting. Maintenance of the equipment is provided by the vendor in 6/17 (35%) or by the renal program in 11/17 (65%). Wetness detectors are routinely used around cannulation sites and on the floor beside the HD machine in 14/17 (82%) while 3/17 (18%) use detectors at one site or the other. Centrifuges (for home blood sample preparation) and weigh scales are provided by 14/17 (82%) and 10/17 (59%) of programs respectively. Real-time remote monitoring is performed in a minority of programs (3/17 – 18%). Reasons for denying access to HHD include substandard water (11/17 – 65%), and substandard/ nonmodifiable plumbing (13/17 – 76%) or electrical (11/17 – 65%). Only 2 programs (12%) do not reimburse patients for some or all plumbing/electrical renovations, with 11/15 (73%) covering in excess of $1,500 (CDN) in expenses. Five of 17 (29%) reimburse patients for additional monthly utility costs incurred by dialyzing at home.

Conclusions: Significant heterogeneity exists among Canadian renal programs in terms of delivery of and equipment requirements for HHD. It is unknown whether such differences change patient outcomes or pose potential safety concerns; this will require prospective study.

PUB325

Teaching Home Haemodialysis: An e-Learning Platform Defined by a Multidisciplinary Group in a Series of Brainstorm Sessions Giorgina B. Piccoli,[1] Martina Ferraresi,[1] Federica N. Vigotti,[1] Valentina Consiglio,[1] Stefania Scognamiglio,[1] Franca Giacchino.[2] *[1]Nephrology and Dialysis, San Luigi Hospital - University of Turin, Orbassano, Torino, Italy; [2]Nephrology and Dialysis, Ivrea Hospital, Ivrea, Torino, Italy.*

Background: Home hemodialysis is a hot topic; it conveys self management and empowerment of the patients; lower costs and availability of non conventional, highly efficient techniques. Lack of knowledge and confidence are the main barriers for its wider use.

Aim of this study was to design an e-learning platform, for home dialysis patients and their caregivers, designed by a multdisciplinary group.

Methods: The elements needed were identified in 4 brainstorm sessions, with the participation of a senior engineer, a senior nephrologist, a nephrologist in training, 1-3 dialysis nurses (skilled on home-self care), plus either 1-2 patients/caregivers on home dialysis (5-34 years of experience) or 2 experts in computer programming/communication. At the end of each session, the suggestions were gathered by the two nephrologists, and presented, for approval, at the start of the next session.

Results: The following elements were identified as crucial for a e-learning home support:

1. tutorial (video recording in real time) on the preparation dialysis machine and water treatment, alarms, end of the session, disinfection.
2. lessons: generalities on kidney diseases, indications for dialysis start; other dialysis modalities, transplantation; details on hemodialysis membranes, efficiency and water and biochemical tests, generalities on imaging tests.
3. Kt/V calculation and other formulae (equivalent clearances, BMI, Calcium phosphate balance).
4. videos on different aspects of dialysis and transplantation, including patients' histories
5. laws and legal support.
6. video-calls and video-conferences with the center and the caregivers.

The main patients' request was a high degree of detail, and simple, not oversimplified explanation, and the possibility to directly interact with the Center.

Conclusions: A flexible approach to e-learning and home hemodialysis support, including technical experts, patients and caregivers may help tailoring the programme to the specific needs of each clinical and cultural setting.

PUB326

Non Planned Dialysis and Peritoneal Dialysis Choice Maite Rivera, Antonio Gomis Couto, Nuria Rodriguez Mendiola, Franz Fernandez Rodriguez, Francisco Díaz Crespo, Sara Jiménez álvaro, Robert Marcen-Letosa, Jose L. Teruel, Milagros Fernandez Lucas, Carlos Quereda. *Nephrology, Hospital Universitario Ramón y Cajal, Madrid, Spain.*

Background: The underutilization of Peritoneal Dialysis (PD) as a renal replacement therapy is well known . It has been published that predialysis information about the different modalities of dialysis would increase the patients who chose PD as dialysis treatment. Furthermore, some authors affirm that an unplanned starting of dialysis influences the election of dialysis modality towards Hemodialysis (HD).

Aim: To analyze the patients who started dialysis treatment in a non-scheduled manner in our renal unit during 2010 and what was the treatment modality chosen.

Methods: From January to December 2010, 64 patients started dialysis in our Hospital. 44 patients (69%) started dialysis treatment on a programmed basis and dialysis was unplanned in 20 patients (31%). In those patients acute HD was required through a central venous access for several weeks.

Results: 16 non-programmed patients started HD (80%) while 4 chose PD (20%) despite. They were 18 male and 2 female with a mean age of 61.3±13.2 years (range 37-85 years). Causes of unplanned dialysis were: acute renal failure (n=2), unexpectedly rapid deterioration of end stage renal disease (n=7), late start of dialysis (n=8) and other (n=3).

1 out of 20 non-programmed dialysis patients was prescribed HD because having an impracticable abdomen. Finally, 19 patients chose dialysis modality after being informed of the different dialysis modalities. The reasons why 15 patients chose maintenance HD were: personal preference (n=8), social reasons (n=6), expected short survival (n=1). All 4 patients who chose PD to maintain their independence (n=2) and to continue working (n=2). HD patients were older than patients who chose PD (64.3 vs 49.5 years).

Conclusions: When informed, 20% of patients who started on an unscheduled basis were finally included in PD. Younger patients choose PD over HD in order to maintain their independence. In our experience, unplanned dialysis does not always mean HD.

PUB327

Factors That Influence the Dialysis Modality Choice Maite Rivera, Antonio Gomis Couto, Nuria Rodriguez Mendiola, Francisco Díaz Crespo, Sara Jiménez álvaro, Robert Marcen-Letosa, Jose L. Teruel, Carlos Quereda. *Nephrology Service, Hospital Ramon y Cajal, Madrid, Spain.*

Background: Peritoneal dialysis is an underutilized dialysis technique. The reasons why this occurs are not well known. In this work we analyze the reasons that condition the choice of hemodialysis (HD) or peritoneal dialysis (PD) in incident patients of our hospital during 2010.

Methods: 64 patients started dialysis from January to December 2010 (49 male and 15 female),with a mean age of 58 years (range17-85 years). The most frequent cause of chronic renal failure was diabetic nephropathy (23%). 13 patients had a dysfunctioning graft and were transferred to dialysis (20%). 39 patients (61%) started HD and 25 PD (39%). 44 patients (69%) started dialysis treatment on a programmed basis and dialysis was unplanned in 20 patients (31%). At the start of dialysis 18 (28%) were occupationally active and expressed their desire to keep on working. All patient received information about dialysis modalities.

Results: Treatment modality was a personal choice in 55 patients (86%). The remaining patients could not choose to have a contraindication to any form of dialysis.Of the 55 patients who could choose, 31 chose HD and 24 PD. Patients who chose HD were older (62±16 vs 52±14 years, $p< 0.05$) and had a higher comorbidity Charlson index (6.6±2.6 vs 4.7±2.2, $p<0.01$). The choice of technique was not influenced by patient sex, cause of chronic renal failure, previous failed graft, planned dialysis or time of follow-up in predialysis consulting. PD was chosen by 54% of patients who wished to continue working while only 10% of patients that chose HD wanted to work ($p<0.001$).

Conclusions: In our unit, the dialysis options information program provides 39% of patients began treatment with PD. In our experience, the main factor that influences the choice of PD , mainly in young patients, was the decision to continue working.

PUB328

Effect of Interventions in Peritonitis Rate and Technique Failure in Renal Therapy Service Colombia Network Angela S. Rivera. *Medical, Baxter, Bogota, Colombia.*

Background: Peritonitis and technique failure are the most frequent complications in peritoneal dialysis (PD). Interventions in education and training impact clinical outcomes

Renal Therapy Service (RTS) is a network of renal units in Colombia, with a large PD program (proportion of PD patients 47% and an average of 3515 patients), in 49 clinics with a Clinical Coordinated Care Model focused on quality assurance process (standardized clinical protocols, ongoing education and training), internal national and regional clinical audits (continuous quality improvement) for protocol compliance, disease management (anemia, hypertension, diabetes, nutrition, mineral & bone disorder, hepatitis B vaccination and Dialysis management) and quality standards adherence monitored by nephrologists and nurses.

Methods: A retrospective analysis of peritonitis rate and technique failure trend after care model implementation was performed from 2004 to 2010.

The interventions were:

Monthly comprehensive evaluation by nephrologist and nurse

Attention by nutrition, psychology and social work according to risk

Programmed home visits and prioritized visits according to risk

PD Training for clinical team

Standardized nurse/ patient ratio: 1 / 45

Protocol Standardization for peritonitis prevention: Prophylaxis for exit site infection with antibiotic ointment

Change in antiseptic for cleaning hands and surfaces: Not use of iodinated solutions and introduction of chlorhexadine and glycerinated alcohol

Results: Mean age was 58.4 years, 53.7% were female, 38% were diabetic and 63% has a low socioeconomic level. There was a significant decrease in peritonitis rate from 1 episode each 25.2 to 1 episode each 44.1 patient months in risk (RR 0.55 [0.52 – 0.59], $p< 0.05$) and decrease in technique failure defined as transfer to hemodialysis due to clinical complications from 16.20% to 8.11%(RR 0.52 [0.45- 0.59] $p< 0.05$)

Conclusions: here is an improvement of peritonitis rate and a decrease in PD technique failure after a systematic compliance of protocols and the development of continuous education programs.

PUB329

Pasteurella Multocida Peritonitis in a Peritoneal Dialysis Patient Manish K. Saha,[1] Tarek Hamieh,[1] Vishal Sagar.[2] *[1]Internal Medicine, Regions Hospital, Saint Paul, MN; [2]Nephrology, Regions Hospital, Saint Paul, MN.*

Background: 64 year old male with end stage renal disease on automated peritoneal dialysis(PD) with a cycler at home presented with abdominal pain and vomiting for 1-2 days. He noted that his PD fluid was cloudy a day before presentation. On exam, there was diffuse abdominal tenderness but no evidence of erythema or tenderness over the PD catheter site. Hemogram was unremarkable . Blood cultures were negative. CT scan of abdomen did not show any evidence of bowel perforation or abscess. Initial PD fluid was cloudy and showed 1195 nucleated cell/ul with 91 % of PMNs. Patient was started on intraperitoneal vancomycin and tobramycin after PD fluid was sent for culture for presumed peritonitis. Initial gram stain showed gram negative bacillus and cultures grew Pasteurella multocida. On further review of history, patient disclosed that he had 2 pet cats that had been licking/ biting on his PD tubing while he was on the cycler at night. A diagnosis of pasteurella multocida peritonitis was made and his antibiotic regimen was changed to intraperitoneal ampicilin-sulbactum for 2 weeks with improvement of symptoms. Patient was counseled and educated about pasteurella multocida and routes of transmission prior to discharge. He was also advised to keep cats, cats oral secretions at bay while performing dialysis.

Discussion: Pasteurella multocida is a gram-negative bacilli and is found the oropharyngeal flora of cats and felines. Patients on peritoneal dialysis are at increased risk for peritonitis if PD catheter gets exposed to cats or felines' oral flora. Peritonitis is major cause of mortality and morbidity in PD patients. The usual symptoms are fever, abdominal pain, and cloudy dialysate as in our patient. Since our patient had significant history of

cat's oral secretion exposure to PD catheter, this is a rare form of transmission without PD catheter break or scratches. Increasing awareness through patient education is of utmost importance given the prevalence of patients having animal pets at home.

PUB330

Prevalence and Clinical Relevance of Sick Euthyroid Syndrome in a Peritoneal Dialysis Population Hugo Mário Silva, Joana Tomás, Anabela S. Rodrigues, Maria João Carvalho, António Manuel Nunes Cabrita. *Nephrology, HSA, ICBAS, Portugal.*

Background: Sick euthyroid syndrome (SES) has been linked with severity and outcomes in acute illness, however scarce data is available in dialysis patients.

We aimed to evaluate the prevalence of low T3 syndrome in our peritoneal dialysis population and determine its relation with peritoneal transport rate, peritoneal protein loss, inflammation, nutrition and volume status.

Methods: Cross sectionall design: 56 prevalent patients on PD, aged 57.3 (45.4-68.0) years, 46.4% male, 16.1% diabetics, median Charlson comorbidity score of 5; 28.6% anuric, residual GFR 5.0 (2.7-6.8) mL/min; time on PD 28.6 (11.5-55.4) months.

Prevalence of SES and comparisons between subgroups according to the median T3 value were evaluated. Nutritional and volume parameters were obtained by multifrequency bioimpedance. Serum protein C reactive (PCR), D/P creatinine, protein losses, normalized protein catabolic rate, anemia, albumin and dose of dialysis were also explored. Multinominal linear regression model was applied to determine relevant correlations.

Results: SES was diagnosed in 5.3% of patients. Median plasma free T3 level (FT3) was 2.9mg/dL (2.5-3.1). Lower FT3 group was older (58.7 vs. 48.3 years, P=0.003), had lower albumin (3.6 vs. 3.9 mg/dL, P=0.005) and haemoglobin levels (11.6 vs. 12.5 mg/dL, P=0.028); higher ferritin (540.0 vs. 356.2 mg/dL, P=0.021) and PCR (7.9 vs. 5.0 mg/dL P=0.03); a trend for higher extracellular/intracellular water (ECW/ICW) ratio (0.98 vs. 0.91, P=0.052) was found. No differences were documented in peritoneal transport rate, protein losses or dialysis dose. In a multivariate linear model, entering with age, haemoglobin, PCR, ferritin and ECW/ICW ratio as independent variables only haemoglobin and PCR were able to predict FT3 (Beta + 0.33, P=0.004 ; and Beta - 0.27 P=0.042 respectively).

Conclusions: There was a very low prevalence of SES in our PD population. Thyroid dysfunction was associated with markers of systemic inflammation, volume status and malnutrition, however only hemoglobin and PCR were good predictors of FT3. Longitudinal evaluation of this overlooked parameter might elucidate more its clinical impact on morbidity and mortality.

PUB331

Peritoneal Dialysis Technique Outcome and Associated Risk Factors: A 9-Year Single-Center Study Namita Singh,[1] Ramesh Saxena.[2] *[1]Internal Medicine, JHU/ Sinai Hospital, Baltimore, MD; [2]Internal Medicine, UT Southwestern Medical Center, Dallas, TX.*

Background: To review the peritoneal dialysis (PD) technique outcomes at our center and assess factors affecting the technique survival (TS).

Methods: This is a retrospective study on 315 patients who initiated PD between January 2001 and September 2009 at UT Southwestern/ DaVita PD-Clinic, Dallas. Medical records were reviewed for demographic and clinical information. The primary end point was PD technique failure (TF), defined as discontinuation of PD due to catheter-related, technique-related or other medical/surgical/social complications. TS was analyzed by Kaplan Meier method. Cox proportional hazard regression model was used to identify factors independently associated with TS.

Results: There were 54.6% females, and 42.5% African Americans and 43.2% diabetics in our study population. More than 90% of patients had co-morbidities; and 57.5% had previous abdominal surgery. The mean BMI was 28.6 +/- 13.8 kg/m^2.

Infectious complications included 39.7% peritonitis and 22.9% catheter-related infections. Non-infectious/ mechanical catheter problems were observed in 24.1%. There were total of 203 PD failures, of which 12.8% were due to catheter-related problems and 20.2% due to peritonitis. Poor performance on PD, and medical/ surgical events contributed to 7.4% and 6.9% PD discontinuations, respectively.

Overall PD TS rates at 1, 2 and 3 years were 82.12%, 69.42% and 58.38%, respectively. Two variables significantly affecting TS rates were PD catheter-related non-infectious problem (Hazard ratio 1.812; 95% CI 1.193-2.750), and Diabetes as the etiology of ESRD (Hazard ratio 1.712; 95% CI 1.146-2.556). No significant association was observed between TS and other risk factors including age, BMI, previous abdominal surgeries or infections.

Conclusions: Our study shows 58.4% 3-year PD TS. Diabetes and PD catheter-related non-infectious problems are significantly associated with PD TF. Other factors such as age, gender, race, BMI, previous abdominal surgeries, peritoneal infections or exit-site/ tunnel infections do not affect the PD technique survival and should not be considered barriers to PD initiation.

PUB332

Comparison of Change in the Adequacy of Peritoneal Dialysis over Time in Diabetic and Non-Diabetic Patients – A Single Centre Observational Study Subash Somalanka, Manivarma Kamalanathan, Bhrigu Raj Sood. *South West Thames Renal Unit, Epsom and St Helier NHS Trust, Carshalton, Surrey, United Kingdom.*

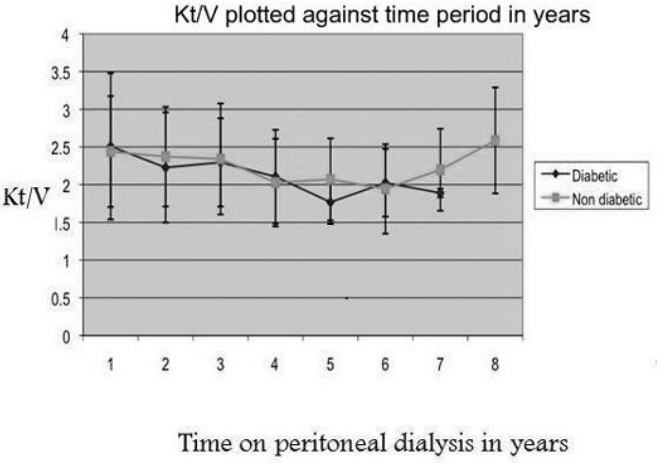
Background: The diabetic patient with end stage renal failure presents many therapeutic challenges, some of which are particularly difficult when peritoneal dialysis is selected as modality for renal replacement. Given the advantages of home based therapy, more patients with diabetes are taking up peritoneal dialysis. We wanted to compare the difference in change of adequacy of peritoneal dialysis over time in patients with and without diabetes undergoing peritoneal dialysis.

Methods: We studied a cohort of peritoneal dialysis patients in our unit. The data of all the patients who are currently on the peritoneal dialysis programme in 2011 was obtained from our renal unit database. We compared the dialysis adequacy between diabetic and non-diabetic patients over the last 8 years. We studied variable including age, sex, diabetes status, modality of PD, and annual Kt/V. The follow up period varied between 2 to 8 years.

Results: A total of 64 patients were identified from the renal unit database who had annual adequacy data. 19 patients had a diagnosis of diabetes and 45 were non-diabetic.

Patient characteristics

	Diabetic	Non-diabetic
N	19	45
Male	8 (42%)	21 (47%)
Female	11 (58%)	24 (53%)
APD	14 (74%)	34 (75%)
CCPD	5 (26%)	11 (25%)



Conclusions: No significant difference was observed in serial change in adequacy of dialysis when compared over time in diabetic and non-diabetic population. This observational study shows that peritoneal dialysis can be used effectively as a form of RRT in diabetic patients.

PUB333

Early Start of Combination Therapy with Hemodialysis and Peritoneal Dialysis Prolongs Survival Term and Reduces Cardiovascular Events in Male Patients Hiromichi Suzuki, Tsuneo Takenaka, Hirokazu Okada, Tsutomu Inoue. *Department of Nephrology, Saitama Medical University, Iruma gun, Saitama, Japan.*

Background: Although peritoneal dialysis (PD) has been proposed as the initial type of dialysis therapy, a majority of patients with end-stage renal disease choose hemodialysis (HD) therapy. Several previous studies comparing survival rates and cardiovascular events between these two therapies have not clearly demonstrated the superiority of one over the other. Recently our data have indicated that renal replacement therapy with a combination of HD and PD prolonged survival rates and reduced cardiovascular events compared with either HD or PD alone. However, combination dialysis therapy is currently not a widely adopted procedure.

Aim: To analyze the efficacy of combination dialysis therapy of PD and HD in patients who were started with PD as the initial dialysis therapy.

Methods: A single center, retrospective cohort study was performed that included 401 patients (female/male: 165/236; age: 61± 12/62 ± 9 years) who started PD as the initial dialysis treatment from 1995 to 2005. Chart and electronic databases were used to obtain information on the course of dialysis therapy including mortality and cardiovascular events.

Results: A total of 103 patients were treated with PD and HD in combination. In 5 years of follow-up after the start of PD, 80 patients died. There were no significant differences in cumulative mortalities between males (49; 20%) and females (31; 18%), and in the cumulative incidence of catheter removals (35 vs. 31%) for various reasons. A significant

difference ($p<0.05$) was seen in the start of hemodialysis between males and females. In male patients on PD, HD therapy was started 24± 16 months after the start of PD. In contrast, in female patients, HD was started 55± 16 months after the start of PD.

Conclusions: Although females have a survival advantage in the general population as well as among dialysis patients, females undergoing PD have a similar mortality to men. The reasons for these findings remain to be explained. However, this analysis suggests that early start of hemodialysis therapy will prolong survival rate in patients on PD, and especially in male patients.

Developing Bioimpedance (BIA) as a Tool for Fluid Management in Peritoneal Dialysis Patients: A Validation Study Boon Kay Tan,[2] Zanzhe Yu,[1] Frauke Wenzelburger,[1] Martin E. Wilkie,[3] Sarah Jenkins,[3] Jia Qi Qian,[4] Zhaohui Ni,[4] Simon J. Davies.[1] *[1]Institute for Science and Technology in Medicine, Keele University, Stoke on Trent, Staffordshire, United Kingdom; [2]Nephrology Department, University Hospital of North Staffordshire, Stoke on Trent, Staffordshire, United Kingdom; [3]Sheffield Kidney Institute, Sheffield, South Yorkshire, United Kingdom; [4]Renal Department, Renji Hospital, Shanghai, China.*

Background: The assessment of fluid status in PD patients using simple clinical parameters is insensitive due to spontaneous body composition changes with time on therapy. We hypothesize regular monitoring of body composition using BIA adds value to the fluid management in PD patients.

Methods: This is an ongoing multi-centre, prospective, randomized study of incident and prevalent PD patients in the UK and China stratified by country and residual renal function >200ml vs <200ml at entry. To detect a between group difference in extracellular fluid volume (ECFv) of 0.8 Kg requires 38 patients per group with 80% power. Following a 2-3 months run in period where fluid status is deemed optimal baseline BIA measurement is obtained in all patients. Measurements are taken in both groups 3 monthly and in addition at any time of clinical need in the active limb where BIA data is available. Interventions can be a combination of advice on dietary salt and fluid intake, increased use of diuretics, hypertonic solutions and icodextrin. Any interventions based on BIA data and their intended effects will be recorded prospectively. This study makes no assumptions as to the ideal desirable fluid status in PD patients at any given time.

Results: The primary outcome is the maintenance of ECFv determined from BIA in the active limb. Other outcome measures are BP, residual urine volume, membrane function, biomarkers and cardiac functions by echocardiography.

Conclusions: Measurement of fluid status in PD is challenging and BIA can be a powerful clinical tool in the routine management of fluid status. This study will give insight and valuable information as to the best application of this technique.

Variability in Water Source and Dialysate Composition for Canadian Intensive Home Hemodialysis Programs Deborah Lynn Zimmerman,[1] Robert P. Pauly,[2] Paul Komenda.[3] *[1]Medicine, University of Ottawa, ON, Canada; [2]Medicine, University of Alberta, Edmonton, AB, Canada; [3]Medicine, University of Manitoba, Winnipeg, MB, Canada.*

Background: Despite growing interest in intensive hemodialysis (HD) prescriptions (more frequent and/or longer), there is little published information on how to establish and maintain an intensive HD program. The purpose of this study was to survey Canadian nephrologists responsible for intensive HD to describe practice patterns.

Methods: A survey was developed with the assistance of 17 physician experts with input from their allied health teams. The survey was modified based on reviews received. The instrument was finalized after a face to face meeting with the expert physician panel. The survey was completed on line. The current abstract addresses water quality and dialysis prescription.

Results: Seventeen of 19 programs contactied participated in survey development and provided information. For water sources, 16 and 6 programs have used well or surface water respectively. Testing for microbial contamination, endotoxin units (EU), organics/inorganics is done by 15, 13, and 13 programs respectively. All programs set a limit of 50 or 100 CFU for the product water. There was more variability in EU limits of < 0.25/ml (3), <1.0/ml (9), <2.0/ml (1) and not measured or not answered (4). Water sampling is variable and done by patients, technicians and/or the equipment manufacturer. For nocturnal HD, starting dialysate prescription was Na (136-140mmol/L), K (2-3mmol/L), HC03 (28-37mmol/L), Ca (1.5-1.75mmol/L), Mg (0.5-0.75mmol/L) and glucose (5.55-11.1mmol/L). Dialysate flow was 150-500mls/min and most programs are using high-flux dialyzers. For short daily HD, variability was also seen in dialysate concentrations except the lowest HC03 was 30mmol/L and Ca was usually 1.25mmol/L. Dialysate flow was 500-800mls/min and all programs used high flux dialyzers.

Conclusions: Despite a long history of intensive HD utilization in Canada, there is tremendous practice variability. Deciphering the results of observational data is made more complicated by these differences in prescription. A lack of published patient outcomes or guidelines for patient management may contribute to variability.

Malnutrition Inflammation Complex Syndrome in Haemodialysis Patients: Assessing the Prevalence and Severity Using Malnutrition Inflammation Score Christopher T. Agbo, Sumith C. Abeygunasekara. *Renal Medicine, Broomfield Hospital NHS, Chelmsford, United Kingdom.*

Background: The combination of inflammation and protein energy malnutrition (PEM) is very common condition among maintenance haemodialysis patients. The term malnutrition-inflammation complex syndrome (MICS) has been widely used to describe this condition and is associated with increased morbidity and mortality in maintenance haemodialysis(MHD) patients. Malnutrition-inflammation score (MIS) is a comprehensive tool for evaluating MICS and there has been recorded correlation between MIS and mortality among haemodialysis patients. In this study, we used MIS to assess the prevalence and severity of MICS in MHD patients.

Methods: Observational cross-sectional study of 139 maintenance haemodialysis patients in our renal unit. The MIS tools was used to evaluate all the patients within the study period, other laboratory parameters such as C-reactive protein (CRP), Haemoglobin(Hb), protein catabolic rate (nPCR), urea reduction ratio were measured.

Analysis of the data was done using SPSS statistical software. Pearson's correlation coefficient was used for selected continuous variables, Spearman's rank correlation used for non-parametric variable.

Results: The mean age was 68.4 +/- 15.1, 68.9% were men and mean duration on dialysis in months was 42.92 +/-51.45 ; mean MIS was 6.17 +/- 3.03; MIS < 3 (3.8%), 3 – 5 (40.6%), 6 – 8 (36.8%), > 8 (18.8%). MIS showed a strong correlation with serum CRP level ($p = 0.014$), Haemoglobin level ($p =0.004$), Age ($p=0.034$) and nPCR ($p=0.039$). This result showed high CRP,low Hb,low nPCR and age were associated with increase morbidity and mortality.

Conclusions: Malnutrition- inflammation score is a powerful tool in assessing the prevalence and severity of MICS. It is useful also in predicting the factors that affect morbidity and mortality in haemodialysis patients such as CRP,Hb,nPCR and age. MIS showed a strong correlation with CRP, haemoglobin, nPCR and age. The entire patients studied had some degree of MICS, the greater the MIS the increased risk of morbidity and mortality. Apart from using the MIS to risk stratify haemodialysis patients, there is need to establish a universal cut off point in order to define MICS.

PUB337

N-acetylcysteine (NAC) Supplemented in the Reinfusate during Acetate-Free Biofiltration (AFB) to Blunt Oxidative Stress Generated during Dialysis (HD) Alessandro Amore, Roberta Camilla, Licia Peruzzi, Roberto Bonaudo, Rosanna Coppo. *Nephrology, Dialysis, Transplant, R. Margherita H., Turin, Italy.*

Background: The oxidative stress (OXS) plays a key role in triggering the dialytic vasculopathy. Bioincompatible reactions during HD amplify the phenomenon. In an in vivo study we showed that NF-kB is activated during HD and it is blunted by i.v. infusion of NAC at the end of HD. We realized that both NF-kB activation during HD and NAC blunting effects were too sharp to be satisfactory, apart from prolonging the time of each HD, not liked by the patients.

We aimed this study to improving a highly biocompatible HD, acetate free biofiltration (AFB), adding NAC to the infusion fluid in order to blunt the OXS generated during HD.

Methods: We performed 8 AFB ex vivo sessions by circulating healthy blood donors 250 ml/min, in AN60-ST dialyzers, using a buffer-free dialysate (Safebag,Hospal) 500 ml/min flow and NaHCO3 reinfusate (Hospasol 145, Hospal) 30 ml/min. Reinfusate was additioned by NAC, 10 mM. NAC SH residues were measured in blood, reinfusate and dialysate at 0, 1, 5, 15 , 30, 60 min by cation exchange chromatography, Biochrom, specific for -SH and S-S residues, after derivatization with Ninhydrin (440 and 570 nm) correcting values for hematocrit.

Results: A SH peak in blood as well as in dialysate was detected. At 5 min after start of dialysis, we added to the recirculating blood Nitroprusside (SNP) 5 µM which, reacting with NAC SH groups,leads to the production of S-S compounds.

The addition of SNP significantly reduced the SH peak, while a peak of S-S appeared indicating a buffering effect on OXS during in vitro HD.

Data, expressed as mM of SH and S-S compounds, are reported in the table.

Table1

Time minutes	1	5	15	30	60
Dialysate effluent SH compounds	5.4±0.68	5.7±0.63	5.6±0.66	5.3±0.07	5.9±0.42
Blood +NAC in reinfusate SH compunds	0.92±0.16	1.13±0.09	1.15±0.05*	1.72±0.01*	0.73±0.11*
Blood+NAC 10mM+ Sodium Nitroprusside 5µM SH compounds		0.77±0.03*	0.78±0.09*	0.71±0.03*	0.73±0.11*
Reinfusate+ SNP 5µM S-S compounds		0.32±0.12	0.45±0.21	0.47±0.18	0.38±0.09

*$p<0.01$ vs blood +NAC in reinfusate

Conclusions: In conclusion, we proved that the addition of NAC to the reinfusate fluid of AFB, can blunt the OXS generated during HD.

PUB338

The Relationship between TRAIL Concentration and Inflammatory Markers Marek Kuzniewski,[1] Danuta Fedak,[2] Dariusz Giza,[1] Pawlica Dorota,[3] Beata Kusnierz-Cabala,[2] Paulina Dumnicka,[3] Bogdan Solnica,[2] Wladyslaw Sulowicz.[1] *[1]Department of Nephrology, Jagiellonian University, Collegium Medicum, Cracow, Poland; [2]Department of Clinical Biochemistry, Jagiellonian University, Collegium Medicum, Cracow, Poland; [3]Department of Medical Diagnostics, Jagiellonian University, Collegium Medicum, Cracow, Poland.*

Background: TRAIL (TNF-related apoptosis-inducing ligand) is a member of TNF ligand superfamily. Five different receptors of TRAIL has been identified. Two receptors containing a death domain (TRAIL-R1 and TRAIL-R2) are capable of rapidly inducing apoptosis. Two decoy receptors (TRAIL-R3 and TRAIL-R4) unable to transducer apoptosis signals but may activate nuclear factor kappa-light-chain enhancer of activated B cells and block apoptosis and osteoprotegerin (OPG)-soluble decoy receptor (TRAIL-R5). TRAIL can activate both apoptotic and anti-apoptotic signals. TRAIL, TRAIL-R2 and OPG are present in human atherosclerotic lesions and their expression levels are higher in vulnerable plaques than in stable ones. Chronic kidney disease is associated with accelerated atherosclerosis and exacerbated but ineffective inflammatory response.

Aim of the study was to investigate the relationship between soluble TRAIL (sTRAIL) and selected markers of inflammation in patients on maintenance hemodialysis.

Methods: Studied group: 76 patients (36 female and 40 male) of average age 60 12 years on maintenance hemodialysis (25 5 months). sTRAIL, IL-6 and IL-8 were determined by ELISA and hsCRP using immuno-nephelometry.

Results: The mean values of TRAIL was 959.6 ± 204.0 pg/ml, hsCRP 11.5 ± 18.8 mg/l, IL-6 6.4 ± 8.7 pg/ml and IL-8 20.0 ± 15.7 pg/ml. The obtained correlations between TRAIL and tested parameters were given in table 1.

Correlations between TRAIL and selected inflammatory parameters

TRAIL			
Parameter	r (Pearson's)	r^2	p
hs-CRP	-0.143050	0.020463	<0.217663
IL-6	-0.275220	0.075746	<0.048301
IL-8	-0.304642	0.092807	<0.015199

Conclusions: Nevertheless we found no correlation between TRAIL and CRP the interrelations between TRAIL and IL-6 and IL-8 indicate that sTRAIL may be considered as is a negative inflammation marker.

PUB339

Clinical Characteristics and Cytokine Expression Profile in Hemodialysis Patients Following Hepatitis B Vaccination Roy Mathew,[1] Darius Mason,[2] Jeffrey S. Kennedy.[3] *[1]Internal Medicine, Stratton VA Medical Center, Albany, NY; [2]Nephrology, Albany College of Pharmacy and Health Sciences, Albany, NY; [3]Department of Health of the State of New York, Wadsworth Laboratories, Albany, NY.*

Background: Hepatitis B vaccine (Hbvax) efficacy is suboptimal in Hemodialysis (HD) patients. We proposed to study the role of inflammation using cytokine profile surrounding vaccination to understand the impact on adaptive immune responses to Hbvax in HD patients.

Methods: Eligibility - HD patients at the Stratton VA Medical Center receiving the EngerixB® (GlaxoSmithKline) Hbvax as a primary or repeat vaccination. Exclusion - Coinfection with HIVor Hepatitis C, acute infection, severe anemia precluding blood draws, <30days vaccination with any agent, inability to give consent. Vaccination series: Day 0, Day 30, Day 60 and day 180. Optimal anti-HepB titer is defined >100 pg/mL. Following informed consent, 50ml of blood was collected at Day 0, 3, 7, 10, 14, 30, 180 following the last vaccination in the series. All bloods were drawn pre-dialysis, mid-week. Cytokine analysis: IL-2, -6, -12, -18, TNF-alpha, IFN-gamma. Descriptive statistics were used to evaluate baseline variables. Repeated measures ANOVA was used to compare change in cytokine following vaccination.

Results: N=13. Mean age 73.9 years, mean duration of dialysis 23 months. 4 of 13 received Hbvax previously. 8 developed optimal response (mean 504 pg/ml), and 5 suboptimal (mean 51 pg/ml). No significant differences were noted between dialysis adequacy, paricalcitol or erythropoietin dose, and 25-OH Vitamin D levels (31.4 ng/ml v 31.8 ng/ml, p>0.05; responder v non-responder). No significant cytokine modulation was noted following vaccination from pre-vaccine levels. Antibody titers dropped an average of 30% from 30 days to 180 days post final booster.

Conclusions: Dialysis patients demonstrate a poor response to Hbvax despite higher dosing, as well as an impaired ability to maintain adequate titers. Vitamin D use or adequate serum levels do not improve ability to respond to Hbvax. Cytokine analysis suggests an inability to modulate inflammatory response to stimulate cellular response to vaccine.

PUB340

Usefulness of Biomarkers of Inflammation in Predicting Subsequent Cardiovascular Events in Diabetic Patients on Renal Replacement Therapy Bijan Roshan, George P. Bayliss, Saila V. Ventrapragada, Ray E. Gleason, Larry A. Weinrauch, John A. D'Elia. *Renal Unit, Joslin Diabetes Center/Harvard Medical School, Boston, MA.*

Background: Biomarkers of inflammation, oxidative stress and hemostasis (BIOMARK) were abnormal in hemodialysis pts, but only levels above vs. below the median of IL-6 and CRP were associated with an increased prevalence of prior CVE. Nevertheless, we hypothesized that BIOMARK levels would predict event-free follow up in stable RRT patients.

Methods: In a prospective study, 177 stable renal failure patients (pts) were followed for 0.04-13.69 years for CE (myocardial infarction, coronary arterial intervention, peripheral arterial bypass or amputation, cerebrovascular accident, or carotid artery intervention). Treatment groups were based on modality at entry into the study. 128 hemodialysis pts (64 male, age 58.1±1, 63 [49%] with prior CE); 22 peritoneal dialysis pts, (12 male, age 49 ± 3, 10 [45%], with prior CE); 27 renal transplant pts (10 male, age 44±1, 13 [48%] with prior CE) were included. Tests of inflammation included: Il-6, CRP, fibrinogen; of hemostasis included: fibrinogen, PAI-1, fibrinolytic activity, vWF, factor VII, p-selectin, viscosity; oxidative stress: Advanced glycated end products and antibody to oxidized LDL. For each, upper vs. lower median and tertiles were compared for evaluation of event free follow up.

Results: Median levels of all BIOMARK were in an abnormal range. 14 tests assessing thrombosis, inflammation and oxidative stress were evaluated for their relationship with subsequent event free survival. When upper vs. lower tertiles and above/below medians were compared for event free survival no BOMARK was related to duration of event free survival.

Conclusions: In clinically stable patients undergoing renal replacement therapy, levels of most biomarkers were not associated with differences in event free survival. The use of BIOMARK for prediction of CVE in stable RRT pts is not supported. Further studies of metabolism of fibrinogen and its relationship to event free survival may be worthwhile.

PUB341

Pre and Post Dialysis Echocardiography Performed by a Nephrologist. A Useful and Accessible Tool for Hemodynamic Evaluation of Chronic Hemodialysis Patients Adriano Luiz Ammirati,[1] Maria C.C. Andreoli,[1] Fellype Barreto,[1] Wercules Antonio De Oliveira,[2] Marcelo Luiz Campos Vieira,[2] Claudio Henrique Fischer,[2] Bento Santos.[1] *[1]Dialysis Unit, Albert Einsten Hospital, Sao Paulo, Brazil; [2]Cardiology, Albert Einsten Hospital, Sao Paulo, Brazil.*

Background: Echocardiographic (ECHO) parameters are useful to evaluate the volume status in hemodialysis (HD) patients. In this work, we studied the feasibility of a handheld ECHO analysis by a nephrologist, and the correlation of different ECHO parameters and hemodynamic and volume status in HD patients

Methods: Subjects were recruited from a single HD clinic and underwent, at the beginning and at the end of a HD section, a focused handheld transthoracic ECHO by a trained nephrologist. The variables measured were fractional shortening; inferior vena cava diameter and inspiratory collapse index (VCCI), mitral inflow early diastolic velocity (E), late diastolic velocity (A), mitral annular early (E') diastolic velocities and TVI (time–velocity integral obtained across the aortic valve). These parameters were compared with pre and post HD arterial blood pressure, blood volume monitoring data (Fresenius 4008®, Germany) and HD ultrafiltration volume (UF).

Results: Eleven patients were enrolled (age=70.5 ±13 yo). The mean UF was 1.43 ± 0.9 kg. Pre and post HD ECHO parameters values were: TVI (15,6 ± 4; 13.7± 4 cm); VCCI (28.9 ±14%; 29.4± 14%), Fractional shortening (33.6 ± 10.5%; 32.4 ± 6%), E/A ratio (0.62±0.2; 0.61 ± 0.2). Of note, VCCI variations were related with UF (r=0.70; p=0.03) and changes in A wave (r=0.73; p=0.04). Additionally, there was a correlation between changes in VCCI and relative plasma volume slope (r=-0.54; p= 0.10). Furthermore, VCCI changes were related with the variation in systolic blood pressure (r=0.78; p=0.02)

Conclusions: ECHO parameters, especially VCCI, were associated with fluid removal and the variation of blood pressure during a HD session. In addition, ECHO method performed by nephrologist is a helpful and feasible tool in evaluation of hemodynamics status and dry weight in HD patients.

PUB342

Combined Ultrafiltration and Plasmaexchange for Patients with Steroid Resistant Nephrotic Syndrome Gianluigi Ardissino,[1] Fabio Paglialonga,[1] Rosalia Viviana Scarfia,[2] Sara Testa,[1] Antonietta Biasuzzi,[1] Maria Elena Albion,[1] Giovanna Bagnaschi,[1] Cristina Felice Civitillo,[1] Francesca Tel.[1] *[1]Pediatric Nephrology Unit, Fondazione Ca' Granda Osp. Maggiore Policlinico, Milano, Italy; [2]Nephrology and Dialysis Unit, AOU Policlinico V. Emanuele, Catania, Italy.*

Background: Plasmaexchange (PEX) is one of the possible treatment strategies for steroid resistant nephrotic syndrome (SRNS), in particular when associated to focal segmental glomerulosclerosis. Most of the patients with SRNS becomes resistant to diuretics and the management of their fluid overload sometimes becomes a major clinical challenge.

Methods: Here we describe our experience with combining ultrafiltration (UF) together with plasmaexchange aimed at removing part of the fluid overload in patients with SRNS undergoing PEX for other indications.

Results: The described procedure was performed in 2 patients, a boy and a girl, 11 and 19 years old, with a baseline body weight of 39 and 80 Kg and an estimated overhydration of 3 and 16 Kg, respectively. The total number of PEX sessions was 7 for the boy and 5 for the girl.

PEX treatment (BM25 device) was performed with a substitution of 150% of plasma volume (10 with albumine in Ringer Lactate, 2 with fresh frozen plasma) in 3-6 hrs. Heparinization schedule was an initial bolus of 40-50U/kg followed by 20U/Kg/hr. On the arterial line, just before the plasmafilter (Gambro PF2000N), a hemofilter (Edwards Lifesciences HF 0.3) was placed, with a single line out for collecting and measuring

ultrafiltrate. The UF volume obtained ranged between 320 and 2800 mL/session (equal to 2 to 7 mL/kg/hr), the Qb was 80-120 ml/min. The UF was well tolerated, hematocrit (monitored by CritLine2000) remained stable during the sessions.

No significant adverse events were observed, except urticarial reactions. Only one session was complicated by increased transmembrane pressure requiring treatment discontinuation.

Conclusions: The combination of UF and PEX is feasible, safe and efficacious and it represents an additional tool whenever fluid removal is necessary in patients unresponsive to diuretics and requiring PEX.

PUB343

The Impact of a Prior History of Cardiovascular Events on Outcomes in Patients on Renal Replacement Therapy George P. Bayliss,[1] Bijan Roshan,[2] Saila V. Ventrapragada,[2] Larry A. Weinrauch,[2] Ray E. Gleason,[2] John A. D'Elia.[2] *[1]Division of Kidney Diseases and Hypertension, Department of Medicine, Alpert Medical School, Brown University, Providence, RI; [2]Joslin Diabetes Center, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA.*

Background: The majority of morbidity and mortality on renal replacement therapy (RRT) is cardiovascular. Prior cardiovascular events (CVE) have an unknown impact in the presence of uremia, however they are considered when important therapeutic decisions are made.

Methods: In a prospective study, 177 stable renal failure patients (pts) were followed for 0.04-13.69 years for CVE (myocardial infarction, coronary arterial intervention, peripheral arterial bypass or amputation, cerebrovascular accident, or carotid artery intervention). Pts group was based on treatment at entry into the study. 128 hemodialysis pts (64 male, age 58.1±1, 63 [49%] with prior CVE); 22 peritoneal dialysis pts, (12 male, age 49 ± 3, 10 [45%], with prior CVE); 27 renal transplant pts (10 male, age 44±1, 13 [48%] with prior CVE).

Results: Clinical endpoints included CVE (total of 61; 29 heart, 27 peripheral vascular, 5 cerebrovascular), and 27 deaths (6 cardiovascular). 38 patients underwent renal transplant. Of 150 pts with diabetes mellitus, 24 of 76 (31.6%) type 1 and 34 of 74 (45.9%) type 2 study subjects experienced a CVE, as opposed to 27 pts without diabetes, 3 had CVE (11.1%), p= 0.043, 0.001. There were no significant differences for median event free follow up between groups defined by the presence vs. absence of prior CVE for either dialytic (2.0 vs. 2.3 yrs) or transplant therapy (2.0 vs. 2.9 yrs) (all p>0.20).

Conclusions: In clinically stable patients undergoing renal replacement therapy, diabetes mellitus is associated with a higher CVE rate such that the presence of prior CVE may not predict future CVE. Clinical decision-making for such pts should not overemphasize the importance of prior cardiovascular morbidity.

PUB345

Responses to Furosemide in Hemodialysis Patients with Residual Renal Function Louis A. Carrera, Maria V. DeVita, Michael F. Michelis. *Department of Nephrology, Lenox Hill Hospital, New York, NY.*

Background: It has been generally accepted that residual renal function provides a contribution to the well-being of end stage renal failure patients. Studies regarding the use of furosemide in peritoneal dialysis patients have shown some benefit, however its role in hemodialysis patients is less well known. We report our experience with the use of furosemide at our outpatient hemodialysis center.

Methods: All patients were screened for residual renal function, which was defined by urine output of > 400 ml over a 24 hour period. From a total of 167 patients, 28 patients met our criteria and 14 patients agreed to participate. For 3 weeks, patients were given either furosemide 100 mg daily if their weight was <80 kg, or 160 mg daily for weight > 80 kg. Baseline and post furosemide measurements were obtained for urine volume, blood pressure (BP), potassium, phosphorous and interdialytic weight gain (IDWG). Twenty-four hour urine collections were obtained commencing on the day preceding the first dialysis session of the week. BP was quantified by using the average of three readings obtained predialysis on the week preceding the use of furosemide and during the last week of the study. The average of three IDWG on the week preceding administration of furosemide and the last week of the study period were used for comparison. The effect of furosemide on these parameters was analyzed using a paired t-test**.** During the study, 3 of the 14 patients were non-responders and were excluded from further analysis.

Results: The mean increase in urine volume was statistically significant at 575 ml (p<0.001). The mean systolic BP decreased 2.72 mmHg (p=0.58) but diastolic BP decreased by 5.45 mmHg (p=0.06), which approached statistical significance. Changes in serum potassium and phosphorus were not statistically significant. Interestingly, IDWG was not significant suggesting that patients were liberalizing fluid intake.

Conclusions: Our study suggests that furosemide is effective in increasing urine output in hemodialysis patients. Furthermore, it may improve diastolic pressure and lessen fluid restriction.

PUB346

Comparison of In-Vitro Metabolism of Medications in Uremic Serum Using Human and Recombinant Hepatic Microsomes Brian S. Decker, Nitesh Thakker, James Slaven, Zhangsheng Yu, Sharon M. Moe, David Jones. *Medicine, Indiana University School of Medicine, Indianapolis, IN.*

Background: Studies have demonstrated that uremia can diminish the hepatic metabolism of medications. Human and recombinant hepatic microsomes are used to evaluate the in-vitro hepatic metabolism of medications. The purpose of this study was to compare the magnitude and variability of the metabolism of medication substrates in uremic serum using human and recombinant hepatic microsomes.

Methods: The medication substrates evaluated for this study were midazolam and dextromethorphan. Uremic serum was obtained at the midpoint of a four hour hemodialysis session from six anuric subjects with end-stage renal disease (ESRD). The control used in each experiment was pooled normal serum obtained from subjects with normal renal function. Midazolam and dextromethorphan were incubated with human liver and recombinant microsomes in normal and uremic serum. Hepatic metabolism by the microsomes was tested according to validated protocols. The analysis of the 1-OH and 4-OH midazolam and dextrorphan metabolites was performed by mass spectrometry. Statistical analyses using Students t-test were then performed to compare the magnitude of metabolite formed from the human and recombinant microsomes. Coefficients of variation were also analyzed to look at variability between the human and recombinant microsomes. All data were normalized with the normal pooled serum values, to control for day-to-day run variation.

Results: There was no statistical difference in the magnitude of the metabolites formed from either human or recombinant liver microsomes. Analysis of metabolism using normalized data found no significant difference between human and recombinant live microsomes in all three outcomes. Without normalization, recombinant microsomes demonstrate significant higher level of activities than human microsomes. There were no significant differences in coefficients of variation within each metabolite.

Conclusions: Human and recombinant microsomes do not differ in the magnitude or variability of metabolites formed when incubated in uremic serum, after normalizing to control for day-to-day run variation.

Urea, Creatinine and β2-Microglobulin Concentrations in Spent Dialysate Measured by Spectrophotometric and Spectrofluorimetric Measurements Carlo Donadio,[1] Dario Calia,[2] Fabio Di Francesco,[2] Silvia Ghimenti,[3] Angeliki Kanaki,[1] Massimo Onor,[3] Danika Tognotti,[1] Roger Fuoco.[2] *[1]Internal Medicine, Nephrology, University of Pisa, Italy; [2]Dept. Chemistry & Industrial Chemistry, University of Pisa, Italy; [3]ICCOM, CNR, Pisa, Italy.*

Background: The aim of this study was to evaluate the possibility to determine the concentration of urea (URE), creatinine (CRE) and ß2-microglobulin (ß2M) by spectrophotometric and spectrofluorimetric measurements in spent dialysate samples during hemodialysis (HD) sessions.

Methods: Eight maintenance HD males patients, 61±17 years, treated with a low-flux polysulfone membrane (4 pts) or a high-flux triacetate membrane (4 pts).

Spent dialysate samples were collected 5, 15, 30, 60, 120, 180, and 240 min after the beginning of HD. URE, CRE and ß2M concentration were determined by standard laboratory methods. The absorbance and the fluorescence spectra of standard solutions of URE, CRE and ß2M were determined to select the best analytical conditions, then samples were analyzed by flow injection in a high pressure liquid chromatograph mounting a spectrophotometric and a spectrofluorimetric detector.

Results: The concentrations of URE, CRE and ß2M in spent dialysate decreased, according to a single exponential function. The spectrometric analyses of the pure compounds showed 1) a peak of maximum absorbance at 235 nm and no fluorescence for CRE; 2) a peak of absorbance at 280 nm and a peak of fluorescence at 340 nm (excitation wavelength 220 nm) for ß2M; 3) neither absorbance nor fluorescence for URE. High correlations were found between concentration and absorbance values: 0.918 for URE (at 280 nm), 0.855 for CRE (at 235 nm), and 0.979 for ß2M (at 235 nm). The correlations between fluorescence and concentration values were definitely lower: 0.675 (URE), 0.621 (CRE), and 0.765 (ß2M).

Conclusions: URE, CRE and ß2M concentrations into spent dialysate strictly correlate with absorbance values. A predominant contribution to the spectrometric signals is linked to undetermined substances, which should be identified, before validating spectrometric analyses in spent dialysate to monitor the removal of toxins and to predict dialytic efficiency.

The Results of Multicenter Study Comparing Effects of Different Renal Replacement Therapy Modalities (Low-Flux Hemodialysis vs. Online Hemodiafiltration) Maciej Drozdz, Wojciech Marcinkowski, Andrzej Milkowski, Teresa Rydzynska, Tomasz Prystacki, Ryszard August, Ewa Benedyk-Lorens, Katarzyna Bladek, Jan Cina, Grazyna Janiszewska, Andrzej Kaczmarek, Teresa Lewinska, Malgorzata Mendel, Mariusz Paszkot, Ewa Trafidlo, Malgorzata Trzciniecka-Kloczkowska. *Fresenius Nephrocare Polska, Poznan, Poland.*

Background: Online hemodiafiltration (online HDF), as compared to low-flux hemodialysis (low-flux HD), is postulated as a superior method of renal replacement therapy (RRT), but the effect of both methods on clinical effects of treatment still remains unclear.

The aim of this multicenter (11 dialysis units) study was to compare the dialysis adequacy, anemia and calcium-phosphate disturbances correction as well as the frequency of intradialytic hypotension (IH) in patient treated with different RRT modalities – HDF vs. low-flux HD.

Methods: The study was composed of 423 patients (171F and 252 M) aged 21 to 87 yrs. (mean 61.6), on RRT for 0.9 do 275 mths. (mean 44.2). 192 (5 dialysis units) patients was treated using online HDF and 231(6 dialysis units) using low-flux HD.

Patients were observed for 24 mths. 274 of them (65%) finished the observation period. Other patients died, were transplanted or transferred to other units. The assessment of biochemical and clinical parameters was performed at the start of the trial and next every year.

Results: All results are shown in table.

The results of tested parameters

Parameter	start	after 12 mths.	after 24 mths.
spKt/V	1.51 vs. 1.16 p<0.0001	1.52 vs. 1.2 p<0.0001	1.54 vs. 1.45 p<0.05
Hb (g/dl)	11.2 vs. 11 p=NS	11.5 vs. 11.1 p<0.05	11.3 vs. 11.2 p=NS
P (mmol/l)	1.57 vs. 1.77 p<0.05	1.69 vs. 1.88, p<0.005	1.5 vs. 1.85 p<0.001
CaxP (mmol2/l2)	3.5 vs. 3.8, p<0.05	3.7 vs. 4.1, p<0.05	3.3 vs. 3.8, p<0.001
SBP (mmHg)	124 vs. 128, p<0.005	123 vs. 130, p<0.005	119 vs. 128, p<0,005
DBP (mmHg)	69 vs. 77, p<0.0001	69 vs. 77, p<0.0001	66 vs. 77, p<0.001
IH episodes (per week)	0.2 vs. 0.5, p<0.01	0.08 vs. 0.4, p<0.005	0.2 vs. 0.4, p<0.05

The erythropoiesis stimulating agents dose did not differ between the groups.

Conclusions: Treatment with online HDF brings important biochemical and hemodynamic benefits for RRT patients.

Comparison of Online Clearance Monitor with Other Blood-Sampling Methods in Hemodialysis Adequacy Evaluating Jiayuan Gao, Renhua Lu, Zhaohui Ni, Jia Qi Qian, Yucheng Yan. *Nephrology, Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China.*

Background: To compare the accuracy of hemodialysis adequacy evaluated by online clearance monitor (OCM) with other blood-sampling methods, using direct dialysate quantification method (DDQ) as a gold standard.

Methods: We included 19 anuric maintenance hemodialysis patients. Drained dialysate samples were collected continuously during the entire therapy by partial dialysate collection method (PDC). Urea nitrogen levels were assessed to calculate Kt/V by DDQ. Blood urea nitrogen (BUN) at the beginning of dialysis, at the end of dialysis and as well as 30 minutes after therapy were measured. Single pool Kt/V (Sp Kt/V) by Daugirdas II formula was calculated. Equilibrated Kt/V (Eq Kt/V) and rate adjusted Kt/V (Ra Kt/V), which seem close to double pool Kt/V, were also employed. OCM Kt/V was provided by OCM module from Fersenius. The value and correlation of Kt/V by different methods were analyzed. Urea distribution volume (Vurea) used in the three formulas internally installed in OCM were compared with the standard Vurea level from DDQ.

Results: As a result, the value of OCM Kt/V, Ra Kt/V and Eq Kt/V were very similar with DDQ Kt/V (1.24±0.24, 1.39±0.24, 1.41±0.27 vs. 1.34±0.26, all P >0.05), while Sp Kt/V was significantly higher than DDQ Kt/V (1.58±0.27 vs. 1.34±0.26, P<0.05). OCM Kt/V, Sp Kt/V, Ra Kt/V or Eq Kt/V was all well correlated with DDQ Kt/V. The relationship between OCM Kt/V and DDQ Kt/V (r= 0.706, P<0.05) was lower than that of Sp Kt/V, Ra Kt/V or Eq Kt/V (R values were 0.901, 0.891, 0.963, separately. all P<0.05). Vurea levels calculated from all three formulas internally installed in OCM were significantly higher than DDQ (P<0.05).

Conclusions: In conclusion, the correlation between OCM Kt/V and DDQ Kt/V was ideal with almost similar value. It can ideally evaluate the actual delivered dialysis dose of hemodialysis patients. The advantage of online quick monitoring implys its further value in application, yet still need more validation.

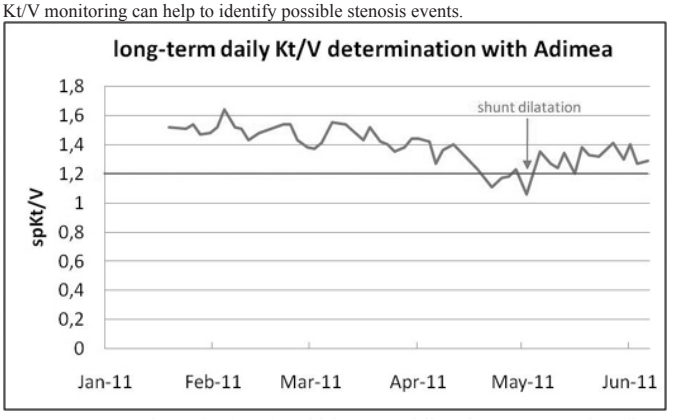
Daily Long-Term Kt/V Determination by Ultraviolet Absorbance (Adimea) in Hemodialysis Helps To Detect Clinical Complications Marten Kelm,[1] Roman Guenthner,[2] Martin Kuhl,[1] Juergen Wagner.[1] *[1]B. Braun Avitum AG, Melsungen, Germany; [2]PHV Dialysezentrum, Melsungen, Germany.*

Background: Online Kt/V-determination with Adimea has become an established measuring principle in regular hemodialysis and has proven its measurement adequacy in various clinical studies (Castellarnau et al., 2010). The aim of this work was to show that daily and long-term Kt/V-measurement with Adimea can lead to the detection of possible events during hemodialysis such as shunt stenosis.

Methods: In this case study, patient data from the PHV Dialysezentrum Melsungen, Germany was analysed.

Results: A case of a 54 year old woman is reported who had chronic bicarbonate hemodialysis 3x per week for nearly 1 year. The patient underwent the third vascular access dilatation due to a shunt stenosis in 05/2011. Before and after this intervention, the patient underwent regular hemodialysis with a Dialog+ machine and daily Kt/V measurements with Adimea. Kt/V data was analysed retrospectively over a period of 5 months to identify a possible change in administered dialysis dose. It can be seen that the Kt/V dose gradually decreases over a period of 7 weeks before the patient was sent to shunt dilatation. Prior to shunt revision, the administered blood flow had to be decreased. After the patient returned from shunt dilatation, the blood flow and Kt/V dose increased and the patient was able to reach the Kt/V target again. This data shows that in patients prone to shunt stenosis, daily Kt/V monitoring can help to identify possible stenosis events.



Conclusions: The results show that with long-term daily Kt/V measurement by Adimea it is possible to detect changes in dialysis efficacy over time and clinical complications such as shunt stenosis.

PUB351

Utility of Multifrequency Bioimpedance Analysis in HD Patients Vijay K. Kher, Salil Jain, Shyam Bihari Bansal, Saurabh Pokhariyal. *Nephrology and Transplant Medicine, Medanta - The Medicity, Gurgaon, Haryana, India.*

Background: Clinically estimating the dry weight (DW) in dialysis pts is subjective & often inaccurate. Several methods used include natriuretic peptides, measurement of IVC diameter and collapsibility on inspiration by ultrasound, intradialytic relative blood volume change and single frequency bioimpedance. These methods suffer from poor specificity . Multifrequency Bioimpedance Spectroscopy (MBIS)to determine TBW & ECV has been validated by applying dilution methods as gold standard.

Aim

To study the utility of MBIS in HD pts in addition to clinical method of assessment of DW.

Methods

A prospective study in prevalent HD pts at a single dialysis centre.

Inclusion Criteria

HD pts on 3/week treatment for 4 hours for more than 3 months, clinically euvolemic.

Exclusion Criteria

Active infection, CHF, Liver disease with ascitis ,Pacemaker/ ICD,Metallic Implants,URR< 60%,Hb <9.0 gm/dl, Albumin < 3.0 gms/dl

20 pts were monitored over 2 week for BP, no.& dosage of antihypertensive drugs, weight & no. of hypotensive episodes during dialysis.

MBIS(Body Composition Monitor BCM-Fresenius) machine was used to assess TBW and ECV. The new calculated DW was obtained from BCM . We tried to achieve this new DW over next 2 weeks and the parameters were reassessed.

Results

20 pts with mean age of 60.25 years ,mean weight of 73.4kgs , median SBP of 145.5 mmHg, median DBP of 75mmHg & average number of anti hypertensive drugs was 1.7. Average Hb, Albumin and URR were 10.82 mg%,3.6 mg/dl and 69.105. All pts were hypertensive , 20% had coronary artery disease and 65%were diabetics . All pts finished the study.

SBP significantly decreased from 145.5 to 131.5 mmHg. DBP decreased from 78 to 75 mmHg (NS). The mean weight decreased significantly from 73.4 to 71.09 kg. Hypotension episodes increased in 35% decreased in 25% and remained constant in 40% cases.

The numbers of antihypertensive drugs reduced in 20% & remained constant in 80% (NS)

Conclusion

This study shows that MBIS is helpful in achieving DW in addition to clinical examination & a longer follow up will demonstrate if it translates into decreasing cardiovascular morbidity & mortality.

PUB352

Dialyzer Reuse in Short Daily Online Hemodiafiltration: Impact on Solutes Extraction Natalia C.V. Melo,[1, 2] Rosa M. Moyses,[1] Manuel C. Castro.[1] *[1]Nephrology Department, University of Sao Paulo School of Medicine, Brazil; [2]CDRB/HRT, Brasilia, Brazil.*

Background: In daily online hemodiafiltration(D-OL-HDF), there are no studies evaluating the impact of dialyzer reuse on solutes extraction.

Methods: 14 patients(47.9±13.5 years) in daily hemodialysis(D-HD) program were included. The impact of high flux dialyzer reuse on solutes extraction in D-OL-HDF sessions was evaluated and compared to that in D-HD.

Results: Directly quantified small solutes total mass removal(MTdq) and clearance(Kdq) were similar when 1st, 7th and 13th dialyzer D-HD uses were compared to D-OL-HDF respective uses. Small solutes MTdq and Kdq were similar among dialyzer uses in D-HD and in D-OL-HDF sessions. β2-microglobulin(β2-m) MTdq and Kdq were greater in D-OL-HDF dialyzer 1st, 7th and 13th uses than in the respective D-HD uses. β2-m MTdq and Kdq were similar among dialyzer uses in D-OL-HDF; but were inferior in 13th D-HD dialyzer use than in 1st and 7th D-HD uses.

Solutes removal in D-HD and D-OL-HDF

	1st D-HD dialyzer use	7th D-HD dialyzer use	13th D-HD dialyzer use	1st D-OL-HDF dialyzer use	7th D-OL-HDF dialyzer use	13th D-OL-HDF dialyzer use

Conclusions: Dialyzer reuse did not impact on solute extraction in D-OL-HDF sessions. β2-m extraction was greater in D-OL-HDF sessions than in D-HD, without differences in other solutes extraction.

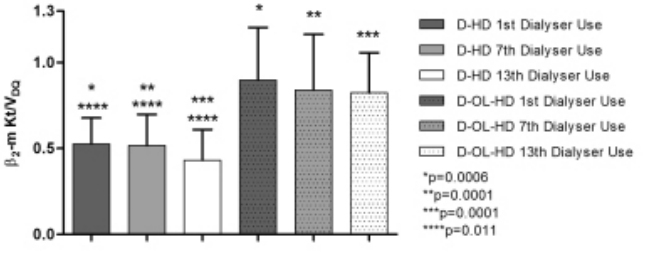
PUB353

High-Flux Polysulfone Dialyzers Reprocessment in Short Daily Online Hemodiafiltration: Impact on Dialysis Dose and β2-Microglobulin Kinetics Natalia C.V. Melo,[1, 2] Rosa M. Moyses,[1] Manuel C. Castro.[1] *[1]Nephrology Department, University of Sao Paulo School of Medicine, Brazil; [2]CDRB/HRT, Brasilia, Brazil.*

Background: In daily online hemodiafiltration(D-OL-HDF), there is a lack of studies evaluating the impact of dialyzer reuse on dialysis dose and β2-microglobulin(β2-m) kinetics.

Methods: 14 patients(47.9±13.5 years) in daily hemodialysis(D-HD) program were included. Impact of high flux polysulfone dialyzer reuse on dialysis dose and β2-m kinetics, in D-OL-HDF sessions, was evaluated and compared to that in D-HD.

Results: Dialysis dose -measured by single-pool Kt/V, equilibrated Kt/V, standard Kt/V and direct dialysis quantification Kt/V (DDQ Kt/V)- was similar when 1st, 7th and 13th dialyzer D-HD uses were compared to 1st, 7th and 13th D-OL-HDF uses, respectively. Additionally, dialysis dose was similar among 1st, 7th and 13th dialyzer uses in D-HD sessions and also in D-OL-HDF sessions. β2-m directly measured Kt/V (Kt/Vdq) was statistically higher in D-OL-HDF dialyzer 1st use(0.90±0.30) than in D-HD dialyzer 1st use (0.53±0.15)(p=0.0006). β2-m Kt/Vdq in D-OL-HDF dialyzer 7th use (0.84±0.32) was superior to that in D-HD dialyzer 7th use (0.52±0.18)(p=0.0001). β2-mKt/Vdq in D-OL-HDF dialyzer 13th use(0.82±0.23) was also superior to that in D-HD 13th dialyzer use (0.43±0.18)(p=0.0001). β2-m Kt/Vdq was decreased in 13th D-HD dialyzer use (0.43±0.18) when compared to 1st (0.53±0.15) and 7th (0.52±0.18) D-HD dialyzer uses (p=0.011). β2-m Kt/Vdq was similar among the 1st, 7th and 13th dialyzer uses in D-OL-HDF sessions.



Conclusions: Polysulfone high flux dialyzer reprocessment did not result in reduction in dialysis offered dose or in β2-m kinetics in D-OL-HDF sessions. There was an increase on the β2-m Kt/Vdq in D-OL-HDF sessions when compared to D-HD sessions, without significant variations in dialysis dose.

PUB354

Differences and Similarities among Daily High Flux Hemodialysis, Online Hemofiltration and Online Hemodiafiltration: A Kinetical Approach Natalia C.V. Melo,[1,2] Rosa M. Moyses,[1] Manuel C. Castro.[1] *[1]Nephrology Department, University of Sao Paulo School of Medicine, Brazil; [2]CDRB/HRT, Brasilia, Brazil.*

Background: There is a lack of studies comparing dialysis dose and solutes removal among short daily high flux hemodialysis(D-HD), short daily online hemofiltration(D-OL-HF) and short daily online hemodiafiltration(D-OL-HDF).

Methods: 14 patients(47.9±13.5 years) in daily hemodialysis(D-HD) program were included. There were collected blood pre, post and in the middle of the sessions and dialisate (partially and homogeneously collected) in two-hour D-HD, pre-dilution D-OL-HF and post-dilution D-OL-HDF sessions.

Results: Dialysis dose measured by direct dialysis quantification Kt/V (DDQ Kt/V) was significantly smaller in D-OL-HF sessions (0.43±0.12) than in D-HD (0.92±0.26) and D-OL-HDF sessions (0.96±0.28)(p=0.0002). Urea directly measured total extracted mass (MTdq) and clearance (Kdq) were smaller in D-OL-HF sessions (14.28±7.73g; 136.4±54.5mL/min) than in D-HD (25.22±6.1g; 262.8±25.4mL/min) and D-OL-HDF(25.68±6.1g; 275.3±35.9mL/min) sessions (p<0.0001). Phosphorus MTdq and Kdq were smaller in D-OL-HF sessions (475.8±169mg; 84.03±28.0mL/min) than in D-HD (810.4±165mg; 149.1±24.0mL/min) and D-OL-HDF(790.7±199mg; 142.0±23.9mL/min) sessions (p<0.0001).). Creatinine MTdq and Kdq were smaller in D-OL-HF sessions (915.0±352mg; 97.84±30.7mL/min) than in D-HD (1523±397mg; 171.9±12.56mL/min) and D-OL-HDF(1512±416mg; 177.0±19.4mL/min) sessions (p<0.0001). Uric Acid MTdq and Kdq were smaller in D-OL-HF sessions (417.5±140mg; 110.4±34.8mL/min) than in D-HD (821.7±158mg; 213.0±26.6mL/min) and D-OL-HDF(748.6±195mg; 205.8±41.6mL/min) sessions (p<0.0001). β2-microglobulin MTdq and Kdq were greater in D-OL-HDF sessions (148.4±43.4mg; 108.0±25.8mL/min) than in D-OL-HF(94.05±45.9mg; 67.62±14.2mL/min) and D-HD(123.1±49.5mg; 62.95±12.1mL/min) sessions (p<0.0001).

Conclusions: Removal of small solutes (urea, phosphorus, creatinine and uric acid) was significantly smaller in pré-dilution D-OL-HF than in D-HD and in post dilution D-OL-HDF sessions, undergone with the same dialyzer type. The removal of β2-microglobulin was greater in D-OL-HDF sessions than in the other studied methods.

PUB355

Viral Serology in Dialyzed Patients Dilip Kumar Pahari. *Nephrology, Medica Super Speciality Hospital, Kolkata, West Bengal, India.*

Background: Hepatitis B and Hepatitis C outbreaks in dialysis units are well known. Contamination from a reprocessed dialyzer often blamed for the increased transmission. We started a new dialysis unit and wanted to study prospectively the incidence and nature of transmission.

Methods: We have 280 patients on maintenance dialysis. We check viral serology(Hepatitis B, Hepatitis C and HIV) for all patients at entry and every 3 months interval (January, May, September,December). 15 Hepatitis B positive patients dialyzed in a separate room with isolated washing area. 13 hepatitis C positive patients dialyzed on machines in a separate room with isolated washing area. Hepatitis B and hepatitis C negative patients are dialyzed in two different rooms with two different washing areas. We have no patients with HIV positive status. We reprocess dialyzers for 240 patients who are Hepatitis B and C negative, and 12 patients use single dialyzers. of the 240 patients, 102 patients who regularly use Erythropoietin, and some of them also have single use dialyzer are dialyzed in a separate room with separate washing area. Patients hepatitis B and hepatitisC negative but depend on transfusion and do not take take Erythropoeitin are dialyzed in forth area. 2 patients of hepatitis B and 3 patients of hepatitis C use single dialyzers. 102 patients (36%) receive EPO during dialysis, rest depend on blood transfusion whenever necessary.

Results: In one year April 2010 to March 2011, 3 (0.01%) patients became Hepatitis C and 2 (0.007%) patients got Hepatitis B positive. No patient acquired HIV infection at any point of time. 2 patients became Hepatitis B positive from non EPO group and 1 from EPO group, and all 2 patients became Hepatitis C positive from Non EPO group. The single patient who became Hepatitis B positive also received multiple transfusions earlier during bladder resection due to transitional cell cancer.

Conclusions: Hepatitis B and Hepatitis C transmission during dialysis is only 0.01% and 0.007% for Hepatitis B and C respectively. The seroconversion is from blood transfusion rather than from dialysis procedure or dialyzer reprocessing if safe practice is followed.

PUB356

"This Is Not Your Father's Dialyzer" – Leukocyte and Platelet Stability Indicate That Newer Dialyzers Are Significantly More Biocompatible Than Previous Dialyzers Norbert Shtaynberg, Morton J. Kleiner, Suzanne E. El Sayegh. *Nephrology, Staten Island University Hospital, Staten Island, NY.*

Background: One factor associated with the poor outcomes with HD patients is the exposure to a foreign membrane. Older membranes were very bioincompatible and increased complement activation, caused leukocytosis by activating circulating factors which caused sequestration of leukocytes (WBC) in the lungs, and activated platelets. Recently, newer membranes have been developed which were designed to be more biocompatible. We investigated what effect these membranes had on platelet levels and white blood cell count.

Methods: 99 maintenance hemodialysis patients with no known systemic or hematologic diseases affecting their platelets or WBC had blood drawn immediately prior to, ninety minutes into, and immediately following their first hemodialysis session of the week. All patients were dialyzed using a Fresenius Medical Care Optiflux polysulfone membrane F160, F180 or F200 (polysulfone synthetic dialyzer membranes, 1.6 m2, 1.8 m2, and 2.0 m2 surface area respectively, electron beam sterilized). WBC and platelet counts were measured from each sample by analysis on a CBC analyzer (Sysmex XT-4000i)

Results: The average age of the patients was 62.7 years; 36 were females and 63 were males. The mean platelet count pre, mid and post dialysis was 193 (SD 74.86), 191 (SD 74.67), and 197 (SD 79.34) TH/mm3 (Fig. 1), showing no statistical difference. The average WBC count pre, mid and post dialysis was 6.84, 6.44, and 6.16 TH/mm3, with a p-value of 0.05, showing a statistically significant, but clinically insignificant, decrease in WBC.

Conclusions: Newer membranes have no significant effect on platelet count, and have a statistically significant, but very minimal effect on leukocytes. This suggests that they are, in fact, more biocompatible than their predecessors and may explain their association with increased survival.

PUB357

Dialysis Patients' Fluid Overload, Antihypertensive Medications and Obesity Mihaly Tapolyai,[1,2] Maria Faludi,[1,2] Virag Reti,[1,2] Zsolt Lengvarszky,[3] Tibor Szarvas,[3] Klara Berta.[1,2] *[1]Dialysis, Semmelweis University, Budapest, Hungary; [2]Dialysis, Fresenius Medical Care, Budapest, Hungary; [3]Mathematics, Louisiana State University Shreveport, Shreveport, LA.*

Background: Overhydration (OH) is both a major etiology of hypertension in hemodialysis patients and a serious risk factor for mortality. We investigated the association of multiple variables and OH.

Methods: This is a cross sectional study of prevalent hemodialysis patients examining the hydrational status with a portable bioimpedance apparatus to measure the degree of hydrational status and comparing these with demographic, dialysis and laboratory data.

Results: We completed our study in 79 patients mean age was 60.7 ±16.9 years, 49.3% men, 30.7% diabetic, vintage: 66.5 ±57.1 months, residual urine output of 442 ±521 mL/day. Patients were overhydrated by 2.6 ±2.4 L and had a percent body fat of 36.4 ±11.6 kg. The average medication count was 2.4 ±1.5 and 45% had diuretics. We found a significant correlation between OH and systolic BP (r^2: 0.152 p: 0.0006), each liter of OH generating 3.6 mmHg. We also found a positive correlation between the use of diuretics and OH (p: 0.003 two tailed Student t test) but no correlation between OH and body weight (r^2: <0.00001 p: 0.99), body mass index (r^2: 0.03), age (r^2: 0.008) and vintage (r^2: 0.002). Every 10% increase in body fat OH decreased by 1.2 L; residual urine output gave no protection from OH (r^2: 0.006) and did not correlate with BP (r^2: 0.0001).

Conclusions: OH is strongly associated with the use of antihypertensive medications and the use of diuretics in this dialysis population. Obesity seems to afford some protection from OH.

PUB358

Rapid Correction of Chronic Metabolic Acidosis in Hemodialysis Olga R. Carmona. *Nephrology Center, University of Uruguay, Montevideo, Uruguay.*

Background: Metabolic Acidosis is associated with chronic renal failure for the incapacity of H+ excretion and the decrease of NH4+ production, besides the increase of protein catabolism and the decrease of protein syntesis.

Methods: 27 Chronic HD patients(mean age 54,55 ± 16,44 years , 44,7%F) were study. Samples for acid base and blood gases analysis were drawn from the arterial side of the a-v fistula at pre, second hour and post HD using a Radiometer Copenhagen 700 and $NaHCO_3$ (39mmol/L) in the dialysate. Measured parameters were: pH,pCO_2, pO_2, SO_2. Calculated parameters were: HCO^-_3,CO_2t, SBE, GAP, p50 (pO2at 50 % Sat.) Student t test was used to evaluate differences between means (p<0,05).

Results: A significant increase of HCO_3-, pH, pCO_2, CO_2t, SBE were observed fundamentally at the second hour. The decrease of GAP in the first two hours was not significant but at the end of HD, increase significatly respect to the second hour. Besides a significant decrease of pO_2 and p50 were produced.

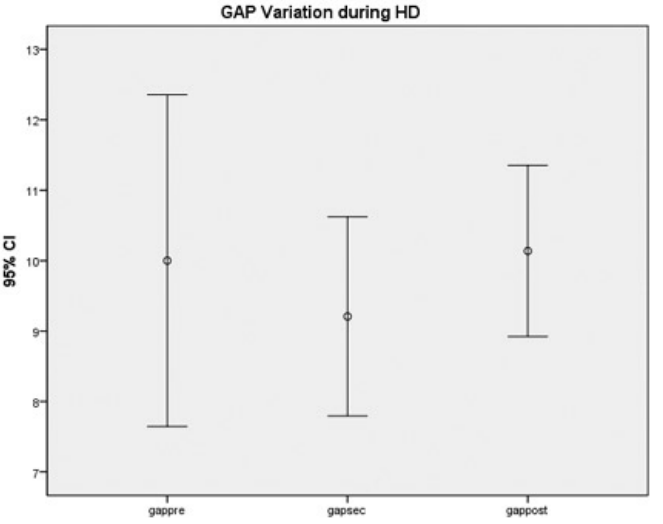
p<0,05



Conclusions: The rapid correction of metabolic acidosis occurred in the first two hours of HD may contribute to the significant decrease of pO2 and the Oxygen delivery to the tissue (↓p50) that may cause increase in intermediates of Krebs acid cycle, with the consequences of a significant increase of anion gap at the end of HD.

PUB359

An Unusual Case of Refractory Hypokalemia Nwamaka Mukoso Osakwe,[1] Rajnish Dhingra,[2] Mohammad G. Saklayen.[3] *[1]Department of Internal Medicine, WSU Boonshoft School of Medicine, Dayton, OH; [2]Department of Internal Medicine, WSU Boonshoft School of Medicine, Dayton, OH; [3]Department of Internal Medicine, WSU Boonshoft School of Medicine, Dayton, OH.*

Background: Extrapituitary causes are identified in 10-15% of patients with Cushing's syndrome. When in excess, cortisol may act as a mineralocorticoid resulting in hypokalemic alkalosis and hypertension. Hypokalemic alkalosis is seen in 74 to 95% of patients with ectopic ACTH secreting syndrome but in fewer than 10% of all patients with Cushing's disease.

Methods: Single Case Report

Results: A 37 year old ten-week pregnant woman was admitted for vomiting, generalized fatigue and weakness since onset of pregnancy. Physical examination revealed BP 117/70mmHg [Normal 70s-80s/50 mmHg] and no evidence of striae or cervico dorsal fat pad. Laboratory data showed severe hypokalemia of 2.0 meq/L, Mg 2.2mg/dl, HCO_3 32meq/L and WBC 16,000. She was commenced on aggressive intravenous and oral repletion of potassium. However, patients' potassium levels remained very low. Three days after admission patient had a missed abortion and her BP was in the 130s/70s.

Laboratory Findings

Lab	Results	Normal Range
Plasma renin assay [ng/ml/hr]	3.6	1.9-3.7
Aldosterone [ng/dL]	4	2-16
Urinary free Cortisol [mcg/24hours]	37,627.2	10-100
Morning cortisol [mcg/dL]	194	6-23
ACTH [pg/ml]	901	9-52
CT abdomen/pelvis	bilateral hypertrophic changes of the adrenal glands without a definite adrenal mass	
PET/CT	mild to moderate uptake in a 2.1cm left mediastinal lesion	

She was transferred to a regional referral hospital for surgical removal of the mediastinal mass and she died from complications of surgery. Final pathology report revealed she had an atypical carcinoid tumor.

Conclusions: This case illustrates the challenges clinicians face in diagnosing ectopic ACTH-secreting tumor and also the pitfalls of fragmented medicine practice. Ectopic ACTH-secreting syndrome can present in several ways ranging from the traditional Cushingoid features (refractory hypertension, diabetes etc) to hypokalemic alkalosis as seen in this patient. In many cases, optimal management is dependent on early localization and surgical resection of the ACTH secreting tumor.

PUB360

Serum Acetone: A Cause of Elevated Serum Osmolal Gap in Wide Anion Gap Metabolic Acidosis Ekamol Tantisattamo, Alexander L. Pan. *Department of Medicine, University of Hawaii, Honolulu, HI.*

Background: Serum osmolal gap is useful to screen for toxic alcohol ingestion in wide anion gap metabolic acidosis (WAGMA). However, often times there is limited history and delay before blood toxic alcohol levels are available. Serum acetone is one of the overlooked

causes of a serum osmolar gap. While awaiting for serum alcohol levels and considering syndromes of toxic alcohol ingestion, checking a serum acetone level may avoid costly and invasive treatments such as fomepizole and hemodialysis.

Results: A 45-year-old male with a history of alcohol abuse and poor oral intake presented with chest pain and nausea. He drank 4 glasses of wine the previous night. There were no visual symptoms. His laboratory data, below, showed a WAGMA with an elevated anion gap of 22 mmol/l and lactic acid of 8.8 mEq/l. Measured and calculated serum osmolality were 301 and 278 mOsm/kg, respectively; resulting in an osmolal gap of 23 mOsm/kg. His alcohol level was negative. Urine sediment showed no crystals. Initially, toxic alcohol ingestion was considered, so was treatment with fomepizole and hemodialysis. However, serum acetone returned elevated at 100 mg/dl, likely explaining of his osmolal gap. Patient responded well to supportive treatment, both anion and osmolal gaps closed with the normalization of his acetone level; and, one week later, both serum methanol and ethylene glycol levels returned negative.

Laboratory data

pH 7.33	Na 134	Blood glucose 150 mg/dl
PaCO2 22	K 4.3	Albumin 4.6 g/dl
PaO2 100	Cl 99	BUN 5
BE -14	HCO3 13	Creatinine 0.8
HCO3 12		
SaO2 97%		

Conclusions: WAGMA and serum osmolal gap in our patient could be the result of high serum acetone levels (likely from starvation ketoacidosis). Alcohol was not a contributor for his anion gap, nor was lactic acid - as it is dissociated at physioligic pH. The below formula calculates acetone's contribution towards the patient's osmolality:

Serum osmolality = 2xNa + (1.15 glucose/18) + BUN/2.8 + ETOH/3.7 + Acetone/5.8

His recalculated osmolality is 297mOsm/kg, resulting in no significant osmolal gap. Therefore, serum acetone should be included in the calculation of serum osmolal gap if the clinical presentation is inconsistent with toxic alcohol ingestion.

PUB361

Differences in Serum Sodium Related to Sex While Patients Grow Older

Noemí Esparza,[1] Cesar Garcia-Canton,[1] Marta Riaño-Ruiz,[2] Santiago Suria,[1] Ana Sánchez Santana,[1] Batista Fatima Garcia,[1] Pablo Marcos Braillard Poccard,[1] Eduardo Baamonde,[3] Maria Dolores Checa.[1] *[1]Nephrology, Hospital Universitario Insular de Gran Canaria, Las Palmas de Gran Canaria, Las Palmas, Spain; [2]Biochemistry, Hospital Universitario Insular de Gran Canaria, Las Palmas de Gran Canaria, Las Palmas, Spain; [3]Centro de Hemodiális Dialsu, Avericum, Santa Brígida, Las Palmas, Spain.*

Background: Elderly patients become more susceptible to clinical complications involving salt and water abnormalities. Both hypernatremia and hyponatremia were reported more frequently in geriatric population and both confer a high risk of death.

Methods: Thanks to the cooperation of the biochemistry service of our hospital, we could use a file with all measurements (n = 27973) including uric acid from June 1 to December 31, 2010. The following determinations were removed from this file: 1182 from measurements without number of clinical history, 1822 from dialysis patients, 300 from the occupational health service, 151 patients under 14 years old and 260 from patients with a transplanted kidney. The determination with a higher uric acid was always chosen, out of the determinations from patients with more than a determination during the semester. In total 15413 patients (7320 women and 8093 men) were left to study.

Results: In 15413 patients studied, 14563 had normal serum sodium (serum sodium > to 135 mmol / l and < to 145 mmol / l), 675 had hyponatremia and 175 had hypernatremia. Women were older than men (56,17 + 17,58 vs 55,25 + 17,10 years, p = 0.01). There were not differences related to age between hyponatremic and hypernatremic patients (63,07 + 17,39 vs 65,54 + 16,63 years) but both were older than normonatremic patients (55,58 + 17,30) (p = 0.000). When performing the Pearson´s correlation for age and serum sodium variables we obtained the results shown in Table 1.

Pearson´s correlations between serum sodium and age in women and in men

	Age (years) (n= 15413 patients)	Age (years) (n = 8093 men)	Age (years) (n = 7320 women)
Serum sodium (mmol/l)	r = 0.26 p = 0.03	r =- 0.36 p = 0.04	r = 0.76 p = 0.000

Conclusions: Serum sodium increases while patients grow older only in women. In men, the serum sodium decreases as age increases.

PUB362

Is Hyponatremia Managed Appropriately in an Academic Tertiary Care Center?

Chelsea Estrada, Navdeep Kaur, Nand K. Wadhwa. *Nephrology, Stony Brook University, Stony Brook, NY.*

Background: Hyponatremia is a common electrolyte abnormality in hospitalized patients and has been shown to be associated with increased morbidity, mortality, length of stay and health care costs. We examined if hyponatremia is appropriately diagnosed and/or treated in an academic tertiary care center.

Methods: We reviewed 415 serial electronic medical records retrospectively on 3 different medical services over a two month period. We collected demographic, diagnostic and therapeutic data on each patient who had hyponatremia (hyponatremia was defined as having 2 or more values of serum sodium (Na)<135 mEq/L). The study was approved by the Stony Brook University IRB.

Results: 48(11.5%) patients (18 females and 30 males with a mean age of 65.8, range 24-97 years) were found to be hyponatremic during their hospitalization. Mean duration of hospital stay was 9.7 days. 8(16.6%) patients had serum Na levels <126 mEq/L, 20(41.6%) with 126-130mEq/L, and 20 (41.6%) with Na levels of 131-134mEq/L. The mean serum Na(133.0±4.0 mEq/L) on discharge was unchanged to admission mean serum Na(133.9±3.9 mEq/L). 17 patients had normal mean serum Na (138.3±2.3 mEq/L) on admission and became hyponatremic (serum Na 128.5±3.8 mEq/L) during their hospital stay. Their mean discharge serum Na (133.0±3.7 mEq/L) was significantly (p= 0.002) lower than admission serum Na. 31 patients were hyponatremic on admission (mean Na 131.5±2.1 mEq/L)and were discharged with mean Na of 133.1±4.3 mEq/L(p=0.02). The mean serum glucose, potassium, bicarbonate and chloride were similar on admission and discharge. Of 48 hyponatremic patients, only 6(12.5%) had serum osmolarity measured,11(22.9%) had urine osmolarity done and 17(35%) had urine electrolytes checked during their hospital stay. Regarding therapy 11(22.9%) were given IV 0.9% NaCl infusion with diuretics simultaneously, and 26(54.1%) were on Na and fluid restricted diet while receiving IV 0.9% NaCl infusion.

Conclusions: The data suggest that hyponatremia was not managed appropriately in majority of patients at the tertiary care institution. Further studies are needed to evaluate the reasons and to assess it's impact on patient care and length of hospital stay.

PUB363

Electrolyte Disorders Following Major Cardiac Surgery in Patients in the ICU

Vijay Lapsia,[1] A. Ahsan Ejaz.[2] *[1]Nephrology, Mount Sinai School of Medicine, New York; [2]Nephrology, University of Florida, Gainesville.*

Background: Electrolyte disorders are an important cause of various complications in the ICU. We studied the incidence of electrolyte abnormalities following major cardiacthoracic surgery (CTS) in patients with renal dysfunction (RD).

Methods: A retrospective review of patients post CTS from 2001 to 2006 with ICU stay of atleast 5 days was performed. Serum levels of creatinine (SCR, mg/dl), sodium, potassium, chloride, calcium, magnesium and phosphate were collected pre-op and 5 consecutive postop days. For each electrolyte, patients with abnormal preop levels were excluded from analysis. RD was defined as SCR>1.4, patients with SCR≤1.4 served as controls. The chi square test was used for statistical analysis.

Results: We included 836 patients; mean age 60 ± 16.7 years, mostly men (64%). Comorbidities included coronary artery disease (55.4%), hypertension (60%), diabetes mellitus (21.8%), CKD (20.1%), COPD (19.3%) and peripheral vascular disease (10.8%). Most surgeries were elective (65.2%). CABG (40.8%) and aortic surgeries (20.9%) were the commonest procedures. The mean length of stay in the ICU was 12.7 ± 16.1 days. Hyperkalemia (44.4% Vs 24.9%), hypercalcemia (14% Vs 6.8%), hypermagnesemia (26.9% Vs 14.8%) and hyperphosphatemia (52.5% Vs 29.1%) were significantly more common in RD (p<0.05). Hypophosphatemia (73.7% Vs 85.5%) and hypocalcemia (69.1% Vs 89.1%) were significantly more common in controls (p<0.05).

Electrolyte abnormalities

	RD	Control
Hyponatremia	190 (34.9%)	34 (27.4%)
Hypernatremia	193 (35.4%)	54 (43.5%)
Hypokalemia	34 (5.6%)	11 (7.2%)
Hyperkalemia*	152 (24.9%)	68 (44.4%)
Hypochloremia	33 (6.4%)	4 (3.3%)
Hyperchloremia*	451 (87.7%)	90 (75.0%)
Hypocalcemia*	447 (81.9%)	94 (69.1%)
Hypercalcemia*	37 (6.8%)	19 (14.0%)
Hypomagnesemia	13 (2.1%)	1 (0.6%)
Hypermagnesemia*	93 (14.9%)	45 (26.9%)
Hypophosphatemia*	288 (85.5%)	87 (73.7%)
Hyperphosphatemia*	98 (29.1%)	62 (52.5%)

*p<0.05

Conclusions: Electrolyte abnormalities are common in the first 5 days following CTS. Patients with RD prior to surgery are at a higher risk for post-op hyperkalemia, hypercalcemia, hypermagnesemia and hyperphosphatemia. Patients with SCR<1.4 were more likely to develop hypophosphatemia and hypocalcemia.

PUB364

An Uncommon Case of Hyponatremia – A Case of Cerebral Salt Wasting

Reginald Ifeanyi Obi, Melanie I. Hames. *Nephrology and Hypertension, East Carolina University, Greenville, NC.*

Background: A 71 year- old female with a history of Stage IIIB Non-small cell adenocarcinoma of the lungs admitted with mental status change and found to have a large solitary left parietooccipital mass consistent with brain metastasis . At presentation, laboratory studies included a serum sodium of 137mEq/L and a serum creatinine of 0.8 mg/dl.

Methods: She subsequently underwent a left parietooccipital craniotomy with total excision of the brain tumor. Five days post-surgery her sodium had decreased to 131mEq/L, and serum creatinine was 0.67 mg/dl. By postoperative day 8, her sodium had decreased further to 129 mEq/L with urine osmolality of 629 mOsmol/kg, serum osmolality of 274 mOsmol/kg, and urine sodium of 88 mEq/L. Nephrology was consulted. The syndrome of inappropriate antidiuretic hormone secretion (SIADH) was suspected and a trial of fluid restriction was implemented. The patient did not respond and had a further drop in serum sodium to 126mEq/L.

Results: Further evaluation revealed evidence of orthostatic hypotension. Cerebral salt wasting was then suspected and she was started on intravenous normal saline and oral salt tablets. Her urine osmolality improved from a high of 707 mOsmol/kg down to 323 mOsmol/kg and her serum sodium trended back up nicely to 135mEq/L upon hospital discharge.

Conclusions: Cerebral salt wasting(CSW) is defined as the renal loss of sodium during intracranial disease leading to hyponatremia and a decrease in extracellular fluid volume. It was first introduced as a concept in 1950 but lost ground to SIADH and only in recent years has it come back in favor as a distinct entity. This case illustrates the challenges of differentiating CSW from SIADH as a cause of hyponatremia. The major difference between them which was exemplified in this case is the presence of a volume depleted state in CSW as opposed to euvolemia or hypervolemia in SIADH. Treatment involves salt and volume repletion using isotonic or hypertonic saline, salt tablets and fludrocortisone. Further research is needed to better define incidence of CSW, identify other disorders that can lead to this and elucidate the mechanism underlying this syndrome.

PUB365

Does Bio-Impedance Analysis Predict Volume Overload States and Clinically Relevant Outcomes in Septic Intensive Care Unit Patients with Acute Kidney Injury? A Prospective Observational Study Bram Rochwerg,[2] Jason H. Cheung,[2] Catherine M. Clase,[1, 2] Scott K. Brimble,[1, 2] Deborah Cook,[1, 2] Peter Margetts,[1, 2] Azim S. Gangji.[1, 2] *[1]Division of Nephrology, St. Joseph's Healthcare, Hamilton, ON, Canada; [2]McMaster University, Hamilton, ON, Canada.*

Background: The initial management of sepsis has been well established through early-goal directed therapy. Beyond the acute setting, persistent hypervolemia results in prolonged ventilation, the need for renal replacement therapy, and increased mortality. Clinical assessment of volume status is limited, however, bio-impedance analysis (BIA) may be a more accurate measure. The use of BIA to assess volume status and prognosis in septic ICU patients is unknown. We hypothesized that the change in BIA vector length (VL) is predictive of ventilator-free days in those have systemic inflammatory response syndrome (SIRS) due to infection.

Methods: A prospective observational study targeting 100 ICU patients. BIA will be measured on ICU admission days 2, 5, 10 and 15. Patients will be followed up for 60 days. Secondary outcomes include mortality, acute kidney injury requiring dialysis, and length of stay in the ICU. A correlation between BIA with known measure of volume status including physical exam, central venous pressure, brain natriuretic peptide and chest radiographs will be completed.

Results: To date, 16 patients have been recruited & enrolment is ongoing. Initial data suggest patients are persistently volume overloaded at both days 2 and 5 (mean VL 188 +/- 26 at day 2 and 174 +/- 20 at day 5). A high correlation existed between edema scores and VL (r = -0.645, p = 0.007); CVP also correlated with VL (r = -0.237, p = 0.376) although this was not significant. Finally, fluid balance between days 2 & 5 correlated inversely with change in VL (r = -0.648, p=0.009).

Conclusions: Septic patients in the ICU are persistently volume overloaded at days 2 and 5 based on BIA measures. VL correlates with known measures of volume status adding to BIA's construct validity. This pilot study has proved to be feasible and may identify BIA as an easy bedside measure to assess ICU patients' volume status. At the current pace, by the fall we will have recruited 50 patients.

PUB366

Wine Potomania Takashi Shinha. *Internal Medicine, Long Island College Hospital, New York, NY.*

Background: Beer potamania caused by excessive alcohol consumption other than beer has rarely been reported. Recongition is particularly important because the patients usually respond quickly to normal saline and therefore they are put at high risk of complications from rapid correction.

Methods: We describe a case of beer potomania caused by wine abuse and analyze the pathophysiology and literature review.

Results: A 47-year-old female with no significant past medical history was admitted to ICU for tonic-clonic seizures. She had a history of wine abuse which constituted her major dietary intake. Her labs revealed serum sodium 120 mEq/L, plasma osmolality 265 mOsm/L, urine osmolality 65 mOsm/L and urine sodium 12 mEq/L. She was started on intravenous normal saline. In a 24-hour period, her sodium went up to 135 mEq/L. The pivotal pathophysiologic mechanism in beer potomania is the minimal intake of solute and the hypoosmolality of beer. This will lead to the inability to excrete sufficient amounts of free water. Wine is as hypotonic as beer. Sodium content of beer is 18 mg per 12 fluid ounce (fl oz) while wine contains 5 mg of sodium per 3.5 fl oz. From our literature review, only 2 cases of beer potomania caused by other alcohol beverages have been reported. One was cider and the other was Japanese rice wine. The consumption of large amounts of hypotonic solution, whether beer or wine, can lead to the dilution of serum sodium. Differentiating beer potomania from other causes of hyponatremia is paramount because the patients usually respond quickly to normal saline and therefore they are put at high risk of complications from rapid correction. In fact, central pontine myelinolysis associated with beer potomania has often been reported. In this case, sodium level was corrected by 15 mEq/L in a 24-hour period only with normal saline infusion. This case re-illustrates the value of controlled correction of hyponatremia in the case of beer potomania because of its rapidity and unpredictability.

Conclusions: Beer potomania should be considered as a cause of hyponatremia in alcohol misusers regardless of the type of alcohol consumed. Extra caution should be exercised because of its rapidity and unpredictability when correcting sodium level.

PUB367

Unsung Hero or Unrecognized Villain: Correction of Hyponatremia with Potassium Lonika Sood,[1] John Kevin Hix,[1,2] Jonathan W. Bress,[1] Richard H. Sterns.[1,2] *[1]Dept. of Medicine, Rochester General Hospital, Rochester, NY; [2]Nephrology Division, University of Rochester School of Medicine and Dentistry, NY.*

Background: An 80 year old female on chlorthalidone and a selective serotonin reuptake inhibitor presented with one week of poor dietary intake and ten pound weight loss. On admission, blood pressure 143/76 mm Hg, SaO2 99% on room air, weight 45.8 kg. Examination was unremarkable except for lethargy. Her serum sodium (sNa) was 110 mEq/L, serum potassium 2.2 mEq/L. She was treated initially with 50 ml of 3% NaCl (25 mEq). Because of a 1.1 L water diuresis, sNa rose by 5 mEq/L, five times the increase predicted by formulas that ignore urine output. A tonicity balance analysis was performed to explain the sNa increase after 3% NaCl during the first 2.5 hours of therapy, using the following equation:

Predicted sNa=
sNa*Total Body Water + (Infused Na + Infused K)=
Total Body Water + Net fluid balance
110 mEq/L*(0.45 L/kg*45.8 kg) + (50 ml*0.513 mEq/mL + 0)
(0.45 L/kg*45.8 kg) – 1.05 L
Predicted sNa = 117 mEq/L (actual = 115 mEq/L)

After the 3% NaCl she was given subcutaneous DDAVP every 8 hours to prevent unintended over-correction of sNa (Am J Kidney Dis. 2010; 56:774-9). In addition she received 60 mEq KCl orally and 60 mEq KCl intravenously as a 400 millimolar solution, and 180 ml 0.9% NaCl (27 mEq). Twenty-four hours after admission her sNa was 121 mEq/L, an 11 mEq/L increase.

Methods: A tonicity balance analysis was performed to explain the additional 6 mEq/L increase in sNa that occurred in response to KCl and a small amount of 0.9% NaCl despite the prevention of excess water losses with DDAVP:

Results: Predicted sNa =
115 mEq/L *(0.45 L/kg*44.8 kg) + (27 mEq + 120 mEq)
(0.45 L/kg*44.8 kg) + 0.172 L
Predicted sNa = 121 mEq/L (actual = 121 mEq/L)

Conclusions: Administration of hypertonic potassium chloride can be substituted for hypertonic saline in the treatment of hyponatremic patients who are also hypokalemic. Because a reversible impairment in water excretion is common in such patients, concurrent administration of DDAVP with KCl is an attractive strategy.

PUB368

Hyponatremia, but Not Hypernatremia, Is Significantly Associated with Rhabdomyolysis in a Burn Population Ian J. Stewart,[1] Molly A. Tilley,[1] Chris A. Gisler,[2] James K. Aden,[3] Evan Renz,[3] Kevin Chung.[3] *[1]Medicine, San Antonio Military Medical Center, San Antonio, TX; [2]Medicine, University of Texas Health Science Center at San Antonio, TX; [3]Burn Center, U. S. Army Institute of Surgical Research, San Antonio, TX.*

Background: Both hypernatremia and hyponatremia have been associated with rhabdomyolysis, correlations based largely on case reports and small series. We sought to examine this relationship in a large population of burn patients, where it has never been reported.

Methods: All admissions to the burn center at our institution from January 2003 to December 2008 were examined. Patents less than 18 years old, those with end stage renal disease, without a measured creatine kinase (CK) or serum sodium (SNa), or who died within 24 hours of admission were excluded from review. Independent variables included age, inhalation injury, percentage total body surface area burned (%TBSA), percentage of full thickness burns, Injury Severity Score (ISS), presence of electrical injury, hyponatremia (SNa less than 130) and hypernatremia (SNa more than 150). These variables were examined via a multiple logistic regression analysis against those with rhabdomyolysis, as defined by a maximum CK level > 5000 Units/L.

Results: In 530 subjects with a mean age of 44±19, average %TBSA of 28±24, and average ISS of 18±15, hypernatremia occurred in 24.0% (n=137) while hyponatremia occurred in 14.2% (n=75) during their admission. The prevalence on rhabdomyolysis was 17.2% (n=91). On multiple logistic regression, presence of electrical injury (OR 17.5, 95% CI 8.8-34.5, p <0.0001) and hyponatremia (OR 3.1, 95% CI 1.7-5.7, p=0.0003) had the greatest correlation with rhabdomyolysis. Hypernatremia (OR 1.1, CI 0.6-2.1, p=0.69) had no effect.

Conclusions: In the burn population, presence of electrical injury as well as hyponatermia, but not hypernatremia, is significantly associated with rhabdomyolysis. The results from this large retrospective review call into question prior assumptions of a relationship between hypernatremia and rhabdomyolysis, specifically in burn patients.

Severe Hypokalemia and Hypomagnesemia in a Patient Presenting with a History of Muscular Dystrophy Heino R. Anto, Rong Rong, Gurjeet Singh Sandhu. *Nephrology, St. John's Episcopal Hospital, New York, NY.*

Background: A 52 year old female from Trinadad presented with acute cholecystitis requiring a cholecystectomy. In Trinadad the patient was diagnosed to have muscular dystrophy since her 30's. Another sibling was also diagnosed with the same muscular condition. On this admission serum potassium was 2.9 mEq/L, serum magnesium 0.8-1

mg/dL. Bun 12 mg/dL , serum creatinine 0.2 mg/dL and CPK of 85 U/L.Two 24 hour urines for calcium ranged from 35 to 100 mg.It was felt that the diagnosis of muscular dystrophy was incorrect and that the patient had Gitleman's syndrome. The patient was treated with spironolactone , KCL, and magnesium oxide . Serum magnesium corrected to 1.8-2 mg/dL and serum potassium is 4-4.8 mEq/L. Gitleman's syndrome must be considered in a patient presenting with generalized muscle weakness associated with severe hypokalemia and hypomagnesemia.

PUB370

High Glucose Modifies NHE Activity in hSGLT1 Transfected Cells Olivia Beloto-Silva, Maria Oliveira-Souza. *Physiology and Biophysics, University of Sao Paulo, SP, Brazil.*

Background: Na^+/glucose co-transporter 1 (SGLT1) is one of the proteins responsible for the glucose transport into the cells. Protein kinase A (PKA) can phosphorylate the *Serine* 418 of the SGLT1 changing its cellular distribution. In addition, high glucose can modulates the activity of the Na^+/H^+ exchange 1 and 3 (NHE1 and 3, respectively) which are important to regulation of intracellular pH (pHi). In this study was investigated if the chronic treatment with high glucose can modulate the intracellular pH recovery rate (dpHi/dt) in Human Embryonic Kidney (HEK-293) cells overexpressed with wild-type human SGLT1 (WT) or transfected with human SGLT1 mutant of S418 to Histidine (S418H).

Methods: The cDNA of WT and S418H were cloned into the expression vector pEGFP-N1. All the recombinants were transfected into HEK-293 cells and the stable transfection was confirmed by Confocal microscopy. The presence of mRNA for a glucose sensor, G-Protein Receptor 1 (GPR1) was investigated by RT-PCR. The HEK-293 cells not-transfected (NT), transfected with WT or S418H grown to confluence in DMEM medium containing glucose 25 mM for 20 days. The dpHi/dt was analyzed by fluorescence microscopy using BCECF-AM fluorescent probe.

Results: The dpHi/dt decreased in WT and S418H when compared with NT cells [0.148±0.02 (n=5); 0.208±0.02 (n=6) and 0.4321±0.02 (n=7), respectively, $p<0.05$]. The addition of H-89 (PKA inhibitor; 10^{-6}M) did not prevent this effect but reduced it partially only in WT [WT: 0.282±0.02 (n=6) and S418H: 0.242±0.02 (n=7), $p<0.05$]. Western blot analysis showed that the chronic treatment increased the NHE1 expression only in WT cells [NT: 0.327±0.046 (n=3); WT: 0.807±0.050 (n=3); S418H: 0.2976±0.030 (n=3), $p<0.05$].

Conclusions: Our results indicate that despite having increased NHE1 expression, the dpHi/dt decreased in WT and S418H cells indicating that in NT cells another NHE isoform could be involved. GPR1 could activate PKA which phosphorylates SGLT1 and NHE1 and modulates differently the activity of these proteins, justifying the reduction on the inhibitory effect on dpHi/dt, observed only in WT.

Dysnatremias in Polytrauma Patients Shilpa Reddy Carlson,[2] George M. Feldman.[1] [1]*Hunter Holmes Mcguire Veterns Affairs Medical Center, Richmond, VA;* [2]*Virginia Commonwealth University.*

Background: Dysnatremias are associated with increased morbidity and mortality. (Waikar, 2009, O'Donoghue, 2009). Mild hyponatremia can cause deficiencies in posture, gait and can cause diminished cognition. (Decaux, 2006). There is a high incidence of hyponatremia in spinal cord patients (Furlan, 2009). Recently, patients with polytrauma, i.e., patients sustaining injuries to multiple body parts, are being treated in VA hospitals and may be at risk of dysnatremia. The aim of this study was to evaluate the incidence of abnormalities in serum sodium concentration (sNa) in a population of polytrauma patients.

Methods: Charts of patients discharged from the Polytrauma Unit at the Richmond VAMC between 12/2007 and 12/2009 were reviewed (n=64). Laboratory records were reviewed retrospectively from the time of injury until discharge. A sNa of less than 135 meq/L was defined as hyponatremia and a sNa above 145 meq/L was defined as hypernatremia

Results: The average age was 30 ± 11.6 years old; 98.4% were male; 10.9% were African American; 1.5% were Hispanic; and 87.5% were caucasian. Intracranial hemorhage occurred in 32% and fracture of cranial/peripheral bones occurred in 41%. Two (2) had been diagnosed with diabetes mellitus, 2 with diabetes insipidus, and 1 with SIADH. None had been diagnosed with adrenal insuffiency, hypothyroidism, congestive heart failure, or cirrhosis. Upon review of the laboratory records 29 patients (45.3%) had had abnormalities of sNa. Of these patients, 10 (34.5%) had hypernatremia only, 11 (37.9%) had hyponatremia only, and 8 (27.6%) had both hypo and hypernatremia during their hospital course. 44.4% of the hypernatremic patients had hypernatremia on their first available sNa determination, and 36.8% of the hyponatremic patients had hyponatremia on their first available sNa determination. At discharge, 94% of the patients with dysnatremia had documented normal sNa.

Conclusions: Polytrauma patients appear to be at high risk of experiencing dysnatremia. It is uncertain whether dysnatremia contribute to the mortality or morbidity of patients with acute polytrauma or whether dysnatremia and associated neurological sequelae delay recovery or prolong hospitalization and rehabilitation.

PUB372

Novel Reconfiguration of the Fractional Excretion of Sodium (FENa) Equation Vernon S. Chiu, Eric J. Bloom, Rasib Raja, Daranee Chewaproug, Saurabh A. Pande, Elio A. Torres, Pankaj Jawa, Sayed A. Kazi, Kawin Tangdhanakanond. *Nephrology, Albert Einstein Medical Center, Philadelphia, PA.*

Background: FENa is calculated when the true volume status of a patient is in question. Creatinine clearance (CrCl) is widely used as an estimate for glomerular filtration rate (GFR) and is part of the FENa formula. CrCl overestimates renal function as creatinine is freely filtered by glomeruli and secreted at the level of the proximal tubules. Urea clearance underestimates GFR since filtered urea is not secreted but reabsorbed in the proximal and distal nephrons. Our aim is to test a potentially more accurate equation for determining FENa, by implementing both creatinine and urea in an attempt to offset the inherent errors of creatinine and urea clearance alone. This should translate to improved volume assessments and medical management.

Methods: All patients seen in consult between 7/1/10 to 12/15/10 with AKI or any stage of CKD. Subjects must have had metabolic panels drawn simultaneously with urinary electrolytes, urea, and creatinine. FENa was calculated using both conventional and modified equations.

Conventional FEna

$$FEna = \frac{(Una) \bullet V}{(Pna) \bullet GFR}$$

Modified FEna

$$FEna = \frac{(Una) \bullet V}{(Pna) \bullet \left[\frac{\left(\frac{(Ucr) \bullet V}{(Pcr)} \right) + \left(\frac{(Uurea) \bullet V}{BUN} \right)}{2} \right]}$$

Results: When using the modified FENa equation, 23 of 26 (88%) subjects had good correlation between conventional and modified FENa.

Conventional vs Modified FENa

Subject	Conventional FEna	Modified FEna
1	0.15	0.22
2	0.22	0.35
3	3.02	2.32
4	0.33	1.6
5	0.24	0.35
6	0.36	0.52
7	1.93	2.86
8	2.17	3.56
9	5.65	6.55
10	4.6	6.16
11	1.79	2.16
12	0.82	1.26
13	1.74	2.72
14	2.8	3.57
15	0.25	0.4
16	0.55	0.79
17	0.33	0.46
18	0.16	0.22
19	0.47	0.74
20	3.11	2.68
21	14.8	16.68
22	3.18	2.11
23	0.97	1.39
24	0.27	0.48
25	0.69	0.93
26	3.3	4.21

Conclusions: The conventional FENa equation may be sufficient to determine an accurate volume status in most clinical scenarios.

PUB373

Normalization of Fractional Excretion of Urate (FEurate) after Correction of Hyponatremia Differentiates SIADH from Cerebral/Renal Salt Wasting (RSW) James Drakakis, Louis J. Imbriano, Nobuyuki (Bill) Miyawaki, Shayan Shirazian, John K. Maesaka. *Division of Nephrology & Hypertension, Winthrop University Hospital, Mineola, NY.*

Background: Differentiating SIADH from RSW has been an unresolved diagnostic conundrum that has important therapeutic consequences, to water-restrict those with SIADH and administer salt and water in RSW.The normalization of a previously elevated FEurate of > 12% to < 10% in SIADH can be contrasted to a persistent elevation in RSW after correction of hyponatremia.We utilize this normalization of FEurate after timely correction of hyponatremia to confirm the diagnosis of SIADH in 2 patients

Results: A 93 year old female presented with a pneumonia and serum sodium (SNa) 115 mmol/L, urine osmolality (Uosm) 336 mosm/kg, urine sodium (UNa) 82 mmol/L and FEurate 18.1%,; her plasma renin was increased and aldosterone decreased on ACE inhibitor. She was treated with intravenous antibiotics and fluid restriction.By the fifth hospital day, SNa increased to 132 mmol/L, FEurate 11.3% and on the sixth day, SNa increased to 136 mmol/L and FEurate now normal at 6.5%.

An 87 year old male with bronchogenic carcinoma was admitted after a fall due to a SNa of 112 mmol/L/L.The Uosm was 547 mosm/kg, UNa 90 mmol/L and FEurate 27.5% with low plasma renin and aldosterone.The initial treatment of isotonic saline, fluid restriction and salt supplementation for probable RSW failed to correct SNa, briefly exhibiting desalination.Isotonic saline was switched to 1.5% hypertonic saline and SNa gradually increased from 131 to 138 mmol/L over two days as FEurate normalized from 27.5 to 8.5%.The normalization of FEurate after correction of hyponatremia in both cases is consistent with SIADH.

Conclusions: A normal FEurate after correction of hyponatremia is consistent with SIADH.This contrasts to a persistently increased FEurate in RSW

Correction of hyponatremia can be achieved gradually with hypertonic saline over several days. Determination of FEurate after correction of hyponatremia can be used to differentiate SIADH from RSW.Normalization of FEurate after correction of hyponatremia by hypertonic saline confirms our notion that saline has a meager effect on FEurate

PUB374

Effect of Angiotensin Converting Enzyme Inhibitors on Serum Potassium Concentrations in Hemodialysis Patients. An Observational Study Ezio Movilli, Corrado Camerini, Paola Gaggia, Roberto Zubani, Giovanni Cancarini. *Division of Nephrology, Spedali Civili and Section of Nephrology, University of Brescia, Brescia, Italy.*

Background: Angiotensin converting enzyme inhibitors (ACEi) are drugs increasingly used in uremic patients (pts). However, their effect on serum potassium concentrations (sK) in pts on chronic hemodialysis (HD) is controversial. Aim of the study: To evaluate sK before and after ACEi therapy.

Methods: From 1-1-2009 to 31-12-2010, 87/206 prevalent HD pts started ACEi therapy. Mean age was 67±14 years, 57/87 were men, dialytic vintage was 6-204months. In the 2 months before (24 HD sessions) and after (24 HD sessions) the start of ACEi, were evaluated in pre dialysis after the long interdialysis interval: sK (mean of 8 determinations) (mmol/L), maximum sK (maximum K value observed during observations) (sKmax; mmol/L), serum sodium (Na; mmol/L), hemoglobin (Hb; g/dL), EPO dose (U/Kg/sett), pre dialysis systolic (SBP: mmHg) and diastolic (DBP: mmHg) blood pressure, body weight (BW; Kg), interdialytic weight gain (IWG; Kg), Kt/V. SBP, DBP, IWG are the mean values of the 24 HD sessions. Duration of HD, blood and dialysate flow rate were kept constant. Data are expressed as mean±SD, t test for paired data was employed. Significant differences were defined as $p<0.05$.

Results: sK increased from 5.0±0.4 mmol/L to 5.7±0.5 mmol/L ($p< 0.0001$). sKmax increased from 5.4±0.5 mmol/L to 6.2±0.6 mmol/L ($p<0.0001$). 7/87 pts reduced the K dialysate concentration. 15/87 pts (18%) stopped ACEi therapy. sK in these pts varied from 5.2±0.3 mmol/L to 6.5±0.2 mmol/L at the moment of suspension ($p<0.0001$). sKmax varied from 5.5±mmol/L to 6.9±0.3 mmol/L at the moment of suspension ($p< 0.0001$). After the suspension of ACEi, sK and sKmax decreased to basal levels within 1 month. There were no significant changes of BW, IWG, SBP, DBP, Na, Hb, EPO dose, Kt/V in both periods.

Conclusions: Treatment with ACEi causes a significant 13% increase of the sK concentrations in chronic HD pts. This fact can lead, in 18% of cases, to the need to stop the drug for sK values greater than 6.5 mmol/L. This suggests caution in the increasingly wider utilization of this class of drugs in HD patients.

PUB375

Hypokalemia in Hospitalizaed Patients Fahad Saeed, Muhammad Omer Toor, Noaman Siddiqi, Digant V. Bhatt, Jae Hyung Cho, Nadia Kousar, Jean L. Holley. *Department of Medicine, University of Illinois at Urbana Champaign, IL.*

Background: Hypokalemia is common in hospitalized patients and can lead to prolonged length of stay and increased mortality. The aim of this study was to assess causes of hypokalemia and the average time taken for repeat potassium (K) orders to be entered in electronic medical records.

Methods: Data of all adult patients (> 18 years) with any low K level (K<3.5 mEq/L) admitted between January 2009 to March 2009 for any reason were reviewed. Average time taken by the treating physicians to order IV or oral K replacement was noted as were any events ascribable to hypokalemia and possible causes of low K.

Results: A total of 375 hypokalemic lab values in 202 patients were analyzed. Severe hypokalemia (K<2.5meq/L) occurred 10 times in six patients (2.7% of all hypokalemic episodes). Average patient age was 60.24±16.81 years and 68.8% of hypokalemic episodes were in women (P=<0.05). Use of loop diuretics (19.2%) was the most common cause of hypokalemia, followed by beta 2 agonists (15.2%), hypomagnesemia (12.0%), steroids (10.7%), insulin (10.1%), diarrhea (9.1%), thiazide diuretics (5.9%), and amphotericin B (5.3%). Use of corticosteroids (40 %) and amphotericin B (40%) were the most common causes of severe hypokalemia. Steroid (13.5 % vs 4.4 %) and amphotericin b (7.3 % vs 0.9 %) usage was more common in women than men who received more loop diuretics than women (23.9% vs 17.3 %). Mean time between low K lab value and orders for repeat K value was 15.41 ±11.4 hours, the longest being for patients on surgical services (21.5± 8.5 hrs vs 15.7±10.2 hrs for patients on medical services, p = <0. 01).

Conclusions: Loop diuretics are the most common cause of hypokalemia in hospitalized patients. Steroids and amphotericin B are associated with severe hypokalemia. Women are more prone to hypokalemia than men despite less frequent diuretic usage. The electronic medical record can be a useful tool in the analysis of causes and management of hypokalemia.

PUB376

Pseudohyponatremia: Not a Diagnosis of the Past Dana F. Work, Ayesa N. Mian, Marc Lande. *Pediatric Nephrology, University of Rochester, NY.*

Background: Pseudohyponatremia, the finding of hyponatremia associated with normal serum osmolality, occurs in disorders with marked elevation of serum lipids or protein. The fraction of water in the serum is thereby reduced, causing an artificially low serum sodium concentration. Low measured sodium values observed in pseudohyponatremia are not clinically relevant. The use of direct potentiometry via ion-selective electrode (ISE) rather than flame photometry for measurement of the serum sodium can avoid artificially low sodium readings.

Methods: Case Report

Results: A 12-mo-old male with Alagille Syndrome was found to have a low serum sodium concentration of 127 mmol/L, but a normal serum osmolality of 284 mOsm/Kg H2O. Total cholesterol was markedly elevated at 1,455 mg/dl, a finding thought to be related to the patient's hepatic disease. The diagnosis of pseudohyponatremia was originally considered, but thought unlikely given the use of ISE measurements in our laboratory. Oral sodium supplementation was initiated. However, analyses of sodium on subsequent blood samples by blood gas analyzer were normal, whereas simultaneous measurements by ISE continued to be low. On further investigation, it was discovered that the ISE analyzer in our laboratory automatically dilutes the serum sample 1:31 prior to direct potentiometry sodium measurement. The dilution step had introduced the potential for pseudohyponatremia, despite the use of ISE technology. By contrast, the blood gas analyzer measures sodium directly, without a dilution step. The diagnosis of pseudohyponatremia was made, and oral sodium supplementation was discontinued.

Conclusions: The diagnosis of pseudohyponatremia was delayed due to the incorrect assumption that the use of ISE measurement of serum sodium precluded that possibility. Commercially available ISE analyzers differ in whether potentiometry is performed on diluted or undiluted serum. This case serves to underscore that clinicians need to know the method used in their laboratory when considering a diagnosis of pseudohyponatremia.

PUB377

Central Diabetes Insipidus and Acute Myeloid Leukemia Solange Bourque. *CHUS.*

Background: Central diabetes insipidus (CDI) can occur in acute myeloid leukemia (AML) by infiltration of the central nervous system (CNS). We present a case of CDI in AML without evidence of CNS involvement.

Methods: A 48 years old woman was treated since 2004 for essential thrombocytosis. She was hospitalised in November 2010 with a diagnosis of AML. At that time her platelet count was 1950 x 10^9/L. Her karyotype showed an inversion of the chromosome 3 (q21q26) without any abnormality of the chromosome 7. In January 2011, while she was receiving her third induction chemotherapy for her AML, she started to urinate more than 20 litres per day. Her natremia was 151 mmol/L, plasmatic osmolarity 311 mosm/L, urinary osmolarity 203 mosm/L, TSH and cortisone levels were normal. DDAVP 4mg IV reduced her diuresis to 5 liters per day and normalised her sodium to 140 mmol/L. Brain MRI was normal; lumbar puncture didn't show any cells.

Results: CDI without CNS involvement is a rare but recognised complication of myelodysplastic syndrome, AML and chronic myeloid leukemia. Most cases are associated with a monosomy of the 7th chromosome. There are also some cases of the 3q21q26 syndrome with or without 7th monosomy. 3q21q26 syndrome implies an inversion, an insertion or a translocation of the chromosome 3. MRI and cerebrospinal fluid are usually normal. Etiology of CDI is unknown. Hypothesis includes infiltration, thrombosis, bleeding or infection too small to be detected without an autopsy. A paraneoplasic factor could also inhibit, degrade or interfere with the formation of arginine vasopressin. Thrombocytosis in 3q21q26 syndrome can also interfere with the level and the function of arginine vasopressin as more than 90% of this hormone circulates with platelets. Nine cases of CDI with 3q21q26 syndrome are described in the litterature. They are usually but not always associated with monosomy 7.

Conclusions: CDI in AML without CNS involvement is rare. It is usually associated with chromosomal abnormalities such as monosomy 7 or 3q21q26 syndrome. It is unknown whether the chromosomal abnormalities cause the CDI or if it is just a marker.

PUB378

Pioglitazone Suppresses Renal Tubular Senescence in Dahl Salt-Sensitive Hypertensive Rats Yuki Kusano, Yoshimitsu Hayashi, Shigeatsu Hashimoto, Kimio Watanabe, Yoshihiro Tani, Kaoru Sakurai, Koichi Asahi, Masaaki Nakayama, Tsuyoshi Watanabe. *Nephrology and Hypertension, Fukushima Medical University, Fukushima, Japan.*

Background: The PPAR-g agonist pioglitazone has several functions including anti-inflammation, anti-oxidative stress and anti-senescence. Increased oxidative stress plays a pivotal role in premature senescence. Dahl salt-sensitive (DSS) rats are characterized by increased oxidative stress in the renal outer medulla caused by salt loading, which results

in chronic tubulointerstitial damage to the kidney. Because pioglitazone protects against aging-related tubular damage in SD rats, we investigated whether it also affects tubular senescence in DSS rats.

Methods: Six-week-old male DSS rats were assigned to either a group fed with 4% salt (high salt [HS] group; n = 10) or a group fed with 4% salt containing 0.005% pioglitazone (HSP group; n = 10). The rats were weighed and blood pressure was regularly measured during the study period. The rats were sacrificed after 12 weeks to examine kidney function, metabolic markers and kidney parameters such as histological changes, positive areas of SA-b-gal (cellular senescence marker) activity and Sirt1 mRNA expression.

Results: Body weight, blood pressure, blood glucose, insulin levels and proteinuria did not significantly differ between the two groups. However, creatinine clearance and serum adiponectin levels significantly differed (HS vs. HSP: 2.34 ± 0.37 vs. 3.60 ± 0.52 mL/min, $p < 0.001$ and 2.32 ± 0.39 vs. 3.78 ± 0.32 mg/mL, $p < 0.001$, respectively). The tubular injury index and positive area of SA-b-gal activity in tubular cells were significantly lower in the HSP group (8.53 ± 3.4 vs. 4.49 ± 3.3, p=0.016 and 11.0 ± 4.1 vs. 4.48 ± 2.0%, $p < 0.001$), whereas Sirt1 mRNA expression in the kidney was significantly higher (1.0 ± 0.4 vs. 1.6 ± 0.4, p=0.012).

Conclusions: Pioglitazone suppressed tubulointerstitial damage and tubular senescence in DSS rats, although it did not confer a benefit in terms of reducing blood pressure, urinary protein and blood glucose levels. Increased levels of serum adiponectin and of Sirt1 mRNA expression in the kidney might be involved in the anti-senescence mechanism of pioglitazone.

PUB379

Serum Protein and Podocin Expression Changes in Living Mouse Glomeruli under the Acute Hypertensive Condition Zilong Li, Juan Wang, Fengxia Yu, Xiaohui Yin, Jun Wang, Hua Zhou, Lining Wang. *Department of Nephrology, First Affiliated Hospital of China Medical University, Shenyang, Liaoning, China.*

Background: The purpose of this study is to visualize topographical serum protein and podocin changes in living mouse glomerular capillary loops (GCL) under various hemodynamic conditions by novel "in vivo cryotechnique"[1, 2].

Methods: "In vivo cryotechnique" group: The "in vivo cryotechnique" was performed on left kidneys of anesthetized C57BL/6 mice, as reported before[3]. **Control group:** the kidney tissues were fixed with the conventional immersion and perfusion preparation methods. Their serial sections were stained and observed by light, confocal laser scanning microscopy[4] and immunoelectron microscopy. The animals were also evaluated for renal podocin mRNA, and protein expression.

Results: By the "in vivo cryotechnique", the distribution of serum proteins: albumin and immunoglobulinG (IgG; Ig kappa light chain and IgG1 heavy chain) were disorder and the immunoreactivity of albumin or Ig kappa light chain was markedly increased and immunolocalized in apical areas of the foot processes and urinary space, not slit-diaphragm, but the podocin expression was seriously decreased under the acute hypertensive condition. The abnormal distribution of serum proteins and podocin was also found in the control group under the normotensive condition was similar to that under the acute hypertensive condition with "in vivo cryotechnique".

Conclusions: These results suggest that the redistribution of serum proteins and podocin was the important factor about proteinuria under the acute hypertensive condition. The "in vivo cryotechnique" followed by freeze-substitution should be a reliable tool to observed the serum or podocyte foot process proteins in situ and capture transient images of functioning glomeruli in living mice. The artifacts seemed to be due to immersion and perfusion fixation procedure.

Characterization of Blood Pressure and Urine Sodium Retention in Mouse Models of Insulin Resistance Robert B. McClellan,[1] Wuxing Dong,[2] Michael Pellizzon,[3] Vivek Bhalla.[2] *[1]Pediatrics, Stanford Univ., Stanford, CA; [2]Medicine, Stanford Univ., Stanford, CA; [3]Research Diets, Inc., New Brunswick, NJ.*

Background: The optimal mouse model for elucidating the role of the kidney in mechanisms of hypertension in diet-induced insulin resistance, obesity, and the metabolic syndrome is unknown.

Methods: At 4 weeks of age, C57BL/6J male mice were fed 10% fat, 45% fat, 60% fat, 30% fructose H2O, or 60% fat plus 30% fructose H2O (n=4/group). At 10 months of age, the diets were supplemented with 4% NaCl. Fasting serum insulin (ELISA), body weight, and systolic BP (tail-cuff) were measured at 1, 2, 6, and 12 months after initiation. Urine sodium excretion rates were measured via calibrated flame photometry. Results are expressed as mean±SEM and p-values< 0.05 were determined by t-tests or ANOVA.

Results: Compared with control mice, fasting serum insulin increased significantly at 2 months in the 45% fat diet (0.57±0.11 ng/mL vs. 1.40±0.29, $p = 0.04$) and at 6 months in the 45%, 60%, and 60% fat/30% fructose diets [1.0 ng/mL vs. 2.9 (p=0.001), 3.0 (p=0.01), and 3.6 (p=0.0006)], respectively. Body weight was also significantly increased in the 45%, 60%, and 60% fat/30% fructose mice compared with control or 30% fructose-fed mice. The mice in all groups maintained similar BP(mean systolic 108.6mmHg±11.9, 106.8mmHg±12.4, 106.7±11.2, 108.3±13.4, and 107.4±11.9). No significant differences in BP were noted after 3 weeks of high-salt food. Urine sodium excretion after initiation of a high-salt diet was significantly higher in control mice vs. other groups (19.26 µmol/12-hrs±2.75 vs.1.76±1.10, 4.22±1.56, 7.32±4.02, and 1.63±1.62, $p<0.007$).

Conclusions: High-fat but not high-fructose med mice develop sustained hyperinsulinemia and weight gain compared with normal fat-fed control mice. Despite defects in urine sodium excretion rates compared with controls, the mice did not develop systolic hypertension with or without high-salt chow. Ongoing radiotelemetry-based measurements may discriminate amongst these mouse models further. High-fat (45% or 60%) fed mice are useful models for insulin resistance, obesity, and decreased urine sodium excretion in male mice.

PUB381

Effect of Tamsulosin on Bladder Microcirculation in a Rat Bladder Outlet Obstruction Model, Evaluated by a Pencil Lens Charge-Coupled Device Microscopy System Hideki Mizuno,[1,2] Tokunori Yamamoto,[1] Yasushi Yoshino,[1] Momokazu Gotoh.[1] *[1]Urology, Graduate School of Medical Sciences, Nagoya University, Nagoya, Aichi, Japan; [2]Urology, National Hospital Organization Nagoya Medical Center, Nagoya, Aichi, Japan.*

Background: To investigate the effect of tamsulosin hydrochloride on blood flow in a submucosal capillary of the bladder (SCB) in a rat bladder outlet obstruction (BOO) model, using a pencil lens charge-coupled device microscopy system (PLCMS).

Methods: BOO was produced in rats by partial ligature of the proximal urethra, which was maintained for 2 weeks. Tamsulosin or saline (control) was subcutaneously administered via an osmotic pump for 2 weeks immediately after the BOO surgery. Using the PLCMS, bladder microcirculation was visualized and quantitatively assessed by measuring the velocity of blood flow in a SCB of the bladder at the two site the base and dome of the bladder. The blood flow in the SCB of the sham-operated rats, the control BOO rats, and the tamsulosin-treated BOO rats were compared.

Results: The blood flow in the SCB was significantly greater at the base than at the dome. The blood flow in the SCB both at the base and the dome was significantly reduced in BOO rats as compared with sham-operated rats, but pretreatment of tamsulosin significantly increased the blood flow in the SCB at both sites in the BOO rats than in the control . The PLCMS imaging morphologically revealed that BOO rats showed chronic ischemic capillary injury and tamsulosin ameliorated it.

Conclusions: The present study suggests that tamsulosin hydrochloride exerts a protective effect on the blood flow in the SCB from ischemic injury following bladder outlet obstruction.

PUB382

The Disturbed Circadian Rhythm and Salt Sensitivity of Blood Pressure in Adriamycin Nephropathy Rats Lijun Mou, Yan Qin, Xuewang Li, Xuemei Li. *Kidney Department, Peking Union Medical College Hospital, Beijing, China.*

Background: Adriamycin Nephropathy rats developed significant proteinuria as an useful mouse model for nephrotic syndrome. In the present study we determined the blood pressure levels, their circadian rhythm, and their regulation by changes in salt intake.

Methods: Circadian characteristics of DBP, HR, PP and locomotor activity were measured in conscious and unrestrained ADR nephropathy rats and age-matched SD control rats by the radiotelemetry system. After baseline studies were obtained, the rats were were provided a high salt diet (8.0%) for a 1-wk period prior to the 3 day telemetry study.

Results: Adriamycin Nephropathy rats demonstrated reversed diurnal rhythms of DBP, and PP compared with SD control rats. However, there is no significant difference in 24-h mean value of MAP or SBP. In ADR nephropathy rats, the circadian rhythm of the urine sodium excretion was also reversed. The RUNa in Dark period was significantly lower than that in the Light period [(14.69 ±3.65)µmol/h v.s (27.66± 5.84)µmol/h, P=0.001] . In the ADR nephropathy rats, the FENa in Dark period was significantly lower than that in the Light period (0.15±0.06 v.s 0.29±0.06,P=0.008) and also significantly lower than that in the Dark period of the control group(0.15±0.06 v.s 0.31±0.19,P=0.05). Both the ADR nephropathy rats and control rats adapted to the high NaCl diet with significant blood pressure elevated($P<0.001$). The control rats maintained the normal BP rhythm and ADR nephropathy rats still presented disturbed BP circadian rhythm after 1week high salt diet.

Conclusions: We concluded that circadian patterns of blood pressure were dramatically altered in ADR nephropathy rats with the disturbed circadian rhythm of the urine sodium excretion and FENa. The ADR nephropathy rats also showed a striking salt sensitivity of blood pressure. So the ADR nephropathy rat was a suitable CKD animal model with disturbed circadian BP rhythm and sodium sensitivity.

PUB383

Indoxyl Sulfate Accelerates Vascular Smooth Muscle Cell Senescence through Oxidative Stress Gulinuer Muteliefu,[1,2] Hidehisa Shimizu,[1] Masahide Takahashi,[2] Toshimitsu Niwa.[1] *[1]Department of Advanced Medicine for Uremia, Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Department of Pathology, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: We previously demonstrated that indoxyl sulfate (IS), a uremic toxin, induced oxidative stress in human aortic smooth muscle cells (HASMCs). This study aimed to clarify whether IS contributes to cellular senescence in cultured HASMCs and the aorta of hypertensive rats.

Methods: The mRNA expression of cyclin-dependent kinase inhibitors, p16 and p21, and tumor suppressor proteins, p53 and pRb, in HASMCs was analyzed by RT-PCR. The protein expression of p53, p21, prelamin A, a senescence marker of VSMCs, and FACE1

(also named Zempste 24) was detected by western blotting. The activity of senescence-associated β-galactosidase (SA β-gal) was evaluated by SA β-gal staining in HASMCs. The expression of prelamin A in the arcuate aorta in rats was examined by immunohistochemical analysis using (1) Dahl salt-resistant normotensive rats (DN), (2) Dahl salt-resistant normotensive IS-administered rats (DN+IS), (3) Dahl salt-resistant hypertensive rats (DH), (4) Dahl salt-resistant hypertensive IS-administered rats (DH+IS).

Results: IS treatment enhanced the mRNA expression of p53 and p21 in a time- and dose-dependent manner, whereas the mRNA expression of p16 and pRb showed no significant change. The IS-induced mRNA expressions of p53 and p21 in HASMCs were suppressed by the addition of N-acetylcysteine (NAC), an antioxidant. IS significantly promoted the protein expression of p53, p21 and SA β-gal activity, and NAC and pifithrin-α, p-nitro (PFTα), a p53 inhibitor, blocked these effects in HASMCs. IS upregulated prelamin A and downregulated FACE1 protein expression, and NAC suppressed these effects in HASMCs. In aorta, DH+IS rats showed significantly increased expression of prelamin A in the cells embedded in the calcification area as compared with DH and DN rats.

Conclusions: IS accelerates cellular senescence through oxidative stress in HASMCs and the aorta of hypertensive rats. Thus, accumulation of IS in blood due to renal dysfunction may be one of the risk factors for vascular senescence in CKD patients.

Effects of Angiotensin II on Vasomotor Function of Pregnant Rats Rosemary E. Nwoko,[1] Iasmina Craici,[1] Steven Wagner,[1] Livius V. d'Uscio,[2] Joseph P. Grande,[1] Zvonimir S. Katusic,[2] Vesna D. Garovic.[1] *[1]Department of Nephrology, Mayo Clinic, Rochester, MN; [2]Department of Anesthesiology, Mayo Clinic, Rochester, MN.*

Background: The mechanism of resistance to the pressor effect of Angiotensin II (Ang II) in pregnancy is not well understood.

Methods: Pregnant and non-pregnant Sprague Dawley rats underwent subcutaneous implantation of Ang II (0.96mg/kg/day) or saline (sham) via osmotic pumps on day 5 of gestation. Animals were then sacrificed on day 19, and vasomotor function was studied in the isolated thoracic aortic rings suspended in organ chambers (37°C; 95% O_2, 5% CO_2).

Results: The contractile effect of KCL (20 mmol) was significantly potentiated in both non-pregnant and pregnant rats treated with Ang II. However, this Ang II-induced potentiation of contractions to KCL was significantly attenuated by pregnancy (p=0.01). Contractions to an alpha1-adrenergic agonist, phenylephrine (10^{-9}-10^{-5} M), were significantly increased in both Ang II treated pregnant and non-pregnant rats (maximal contraction: 78±7% and 71±4%, respectively; P<0.05 vs. sham: 52±5%; n=7). However, the sensitivity to phenylephrine was significantly reduced in Ang II treated pregnant rats (pD_2: 7.03±0.03, P<0.05 vs. Ang II treated non-pregnant rats: 7.44±0.10). We also examined the effect of pregnancy on endothelium-dependent and endothelium-independent relaxations. In the presence of acetylcholine (10^{-9}-10^{-5} M), endothelium-dependent relaxation did not differ between saline and Ang II treated non-pregnant rats (n=7). In contrast, in pregnant animals treated with Ang II, relaxations to acetylcholine were significantly enhanced as compared to sham animals: maximal relaxation: 99±1% vs. 92±3% for saline treated pregnant rats, respectively, P=0.02; (n=7). Endothelium-independent relaxations to nitric oxide-donor, DEA-NONOate (10^{-10}-10^{-5} M) were not significantly different among groups.

Conclusions: Pregnancy may modulate pressor effect of Ang II by: a) attenuating vasoconstrictor effects dependent on depolarization of smooth muscle cells and activation of alpha1-adrenergic receptors, b) by enhancing endothelium-dependent vasodilatation mediated by production and release of nitric oxide.

PUB385

Identifying Adolescents at Risk for High Blood Pressure Eleni Chelioti,[1] Dimitrios Athanasopoulos,[1] Ekaterini Garopoulou,[2] Maria Sotiraki,[1] Theodora Fragou,[1] Thnasis Georgiou,[1] Maria Tsilivigou,[1] Gabriel Papadakis.[1] *[1]Dept. of Nephrology and Renal Unit, General Hospital of Piraeus, Athens, Greece; [2]Dept. of Pediatrics, General Hospital of Kalymnos, Kalymnos, Greece.*

Background: The increased prevalence of childhood obesity and the strong relationship of blood pressure (BP) with the body weight indicate that high blood pressure (HBP) prevalence in adolescents could increase as well. Therefore accurate diagnosis in young people is problematic.Primary objective of the study is to estimate the prevalence of HBP in adolescents of a remote Greek island. Secondary objective is to reveal which factors are associated with HBP.

Methods: A cross sectional study was carried out.Eligible subjects were adolescents aged between 13 to 15 years from a high school of the island of Kalymnos. Somatometrics and BP were measured at the school environment.HBP was defined according to simplified abnormal BP screening table based on the 4th report of National HBP Education Program Working Group in Children and Adolescents. Nutritional status was defined according to International Obesity Task Force.

Results: Participants were 215 adolescents (106 boys and 109 girls). 60 subjects were classified with HBP (27.9%, 95%CI 22.1-34.5%). Significant differences between the two genders were the outschool sport activities (p=0.03), the mean weight (p<0.01), height (p<0.001), systolic and diastolic BP (p<0.001and p=0.01). Statistically significant factors associated positively with HBP were the male gender and the overweight. The adjusted odds ratios of the best fitted model showed that the independent factors associated with HBP were still the male gender and the overweight. Female subjects had 83% lower odd in comparison with male subjects, taking into account other model terms. The odds of subjects with increased body weight were approximately 3 times higher compared to subjects with normal body status, adjusting for other model terms.

Conclusions: A great number of adolescents from the island of Kalymnos are in danger to develop hypertension in adulthood. Both screening of adolescents for HBP and recognition of risk factors for HBP could give us the opportunity for early prevention and intervention of hypertension.

PUB386

Genetic Variants of the Renin Angiotensin System (RAS) and Blood Pressure Response to the RAS Blocking Drugs -A Systematic Review for Pharmacogenomics in the Renin Angiotensin System- Tadashi Konoshita. *Third Department of Internal Medicine, Fukui University School of Medicine, Eiheiji, Fukui, Japan.*

Background: The concept of "pharmacogenomics" promises to offer the ultimate in personalized medicine and the renin-angiotensin system (RAS) is one of the most plausible candidates for this approach in the area of hypertension. For the past two decades, genetic variants of the RAS have been tested for association with blood pressure response, but the results have been inconsistent. The most fundamental concern is thought to be the statistical power. Therefore, we have tried to put together a new systematic review using a database search including only reports with adequate subjects numbers.

Methods: Studies were identified by a PubMed search with condition 1 (("pharmacogenetics"[All Fields] OR "pharmacogenomics"[All Fields]) AND ("renin"[All Fields] OR "ACE"[All Fields] OR "angiotensinogen"[All Fields])) or condition 2 (("genetic variant"[All Fields] OR "polymorphism"[All Fields]) AND ("blood pressure response"[All Fields] OR ("blood pressure responder"[All Fields]) AND "angiotensin"[All Fields]).

Results: Condition 1 identified 136 studies, and condition 2 found 52. Practical clinical implications require detection of a difference in diastolic blood pressure (DBP) of almost 5 mm Hg. Thus, we calculated the necessary sample size, assuming a standard deviation for the DBP of 10 mm Hg with protection against type I error of 5% and 80% of power, and determined that a study required 200 subjects. We therefore adopted studies with about 200 or more subjects. Evaluated genes were ACE, AGT, AT1, AT2, renin (REN) and ACE2. The evaluated drugs were ARB and ACEI. Finally 11 studies were recruited and put together to a new systematic review.

Conclusions: From the results, we were able to draw conclusions with nearly consistent findings that the conventional variants (ACE I/D, AGT M235T, AT1 A1166C and AT2 variant) are not associated with antihypertensive effects by RAS blockade, at least by one individual SNP. By contrast, significant associations have been reported (by one report each) for AGT rs7079, AT1 haplotype, REN, and ACE2. For these variants, further evaluations and confirmation are anticipated.

PUB387

The Impact of Endothelin Receptor Antagonists on Predictors of Mortality in Patients with Heart Failure Natallia Maroz, Amir Kazory. *Nephrology, Hypertension, and Renal Transplantation, University of Florida, Gainesville, FL.*

Background: Elevated blood urea nitrogen (BUN) and decreased level of serum sodium have being consistently shown to predict adverse outcomes in patients with heart failure (HF) both at short and long-term. Endothelin receptor antagonists (ERA) represent an emerging therapeutic option for HF but their impact on mortality is not yet well-known. This study was designed to explore the currently available data on the impact of these agents on predictors of mortality in HF.

Methods: Articles cited in Pub Med database from 1980 to 2011 using key words: "endothelin receptor antagonist" and "heart failure" were searched. Those clinical randomized controlled trials that exclusively included HF population were identified, and relevant articles were selected. The results of these studies were then reviewed and compared with regards to impact on levels of BUN and serum sodium.

Results: A total of 40 relevant articles were identified that used four different ERA agents (tezosentan, erasentan, bosentan, and darusentan,). Twelve randomized, placebo-controlled trials were selected to be included in this study. While 10 studies could not find any significant change in the levels of BUN and serum sodium prior to and after therapy, 2 studies did not report them.

Conclusions: Although there is a promising theoretical basis for the use of ERA in patients with HF, currently available data does not support any beneficial impact on predictors of mortality. Future large-sized trials are needed to further evaluate long-term effects of ERA and their potential impact on patient's outcome.

PUB388

Resistant Hypertension and Vitamin D Deficiency in a Tertiary Care Clinic Alexis Payette, Jean-Philippe Lafrance, Michel Vallee. *Department of Nephrology, HMR, University of Montreal, Montreal, QC, Canada.*

Background: Vitamin D deficiency is thought to play a significant role in cardiovascular disease and hypertension. Suppression of the renin gene could be involved, although the precise mechanisms underlying this association are incompletely understood.

The goal of this study is to evaluate the possible association between vitamin D deficiency and resistant or difficult-to-control hypertension.

Methods: We conducted a retrospective study among patients referred for resistant or difficult-to-control hypertension in a tertiary center in Montreal. We collected the demographic, clinical and laboratory data of 49 patients via review of their medical records.

Blood pressure levels were measured using 24-hour ambulatory blood pressure monitoring (ABPM) which correlates more closely with cardiovascular complications.

A possible association between circulating 25(OH)D concentration and ABPM levels was analyzed in 28 patients.

Results: Up to 65.3% of all patients received three or more antihypertensive drugs and 36.7% also had a 24-hour ABPM average above 130/80 mmHg.

24-hour Ambulatory BP monitoring (mmHg)

Visit Number	Number of measures	Systolic BP	Diastolic BP
1	41	134.6	77.0
2	16	128.3	75.6
3	10	135.9	81.5
Follow-up		Systolic BP variation	Diastolic BP variation
Visit 2 vs1	11	-6.6	-3.5
Visit 3 vs 2	5	-8.6	-4.0
Visit 3 vs 1	7	0.0	+3.7

Among these patients with resistant or difficult-to-control hypertension the mean circulating level of 25(OH)D was 29.7 ng/mL, and was low (<20 ng/mL) in 28.6% of patients. This mean value is similar to that of the general Canadian population which is 27.1 ng/mL.

We did not observe a significant relationship between 25(OH)D circulating level and systolic or diastolic 24-hour average blood pressure in this population.

The majority of patients (73.5%) involved in this study received a final diagnosis of essential hypertension.

Conclusions: We did not observe a significant relationship between circulating levels of 25(OH) vitamin D and blood pressure levels in our population of patients with resistant or difficult-to-control hypertension.

These results suggest that vitamin D deficiency is not a significant factor in the severity of resistant or difficult-to-control hypertension.

PUB389

Blood Pressure Control in Chronic Kidney Disease Hypertensive Patients Using Home Blood Pressure Monitoring Deepali Prasad,[1] Thilagavathi Venkatachalam,[1] Akash Ajmera,[1] Krystal Hunter,[2] Barry Milcarek,[2] Christopher B. McFadden.[1] *[1]Medicine, Cooper University Hospital, Camden, NJ; [2]Cooper Research Institute, Cooper University Hospital, Camden, NJ.*

Background: Home Blood Pressure Monitoring (HBPM) is frequently used by subjects with hypertension. Literature supports its role in predicting cardiovascular risks better than office blood pressure (OBP). Limited information is available about the relationship between use of HBPM and blood pressure control in a population with Chronic Kidney Disease (CKD). We hypothesized that HBPM use in a CKD population would be associated with better blood pressure control as measured by OBP.

Methods: We estimated a sample size of 112 subjects would be needed to show a higher rate of BP control in the HBPM group (one-sided difference) with a power of 80% and a p value of <.05. A significant difference was defined as 20% or more subjects at goal BP (<130 mm SBP and 80 mm DBP). Subjects filled out a survey about their use of HBPM (yes or no) as well as other demographic and medical questions. BP control was determined by clinic BP at time of enrollment.

Results: Preliminary results follow enrollement of 70 subjects (44% male and 56% female). This included 26 HBPM and 44 non HBPM users from 2 Nephrology clinics at Cooper University Hospital. No significant difference in BP control was noted. 42% of subjects with HBPM had controlled BP compared to 45% of non HBPM subjects. No significant difference in mean age (65 years in both groups) or CKD stage between HBPM and non HBPM groups existed. Men were more likely to use HBPM (54%) then women (23%). 50% of Caucasians used HBMP compared to 37% of enrolled African Americans and 27% Hispanics. No difference in education existed between the groups.

Conclusions: A preliminary analysis of our study shows no clear difference between HBPM use or non-use in BP control in this population with CKD. The study has not reached target enrollment. Preliminary enrollment and more severe HTN in the HBPM group are potential explanations for a possible type 2 error. The study is ongoing. A difference in frequency of HBPM use between Caucasians, African-Americans, and Hispanics may exist.

PUB390

Role of Ambulatory Blood Pressure Monitoring as a Predictor of Renal and Cardio-Vascular Endpoints Mihail Ion Soare, Dianne T. Sandy, Mauro Braun, Rute C. Paixao, Umabala Pasupala. *Nephrology and Hypertension, Cleveland Clinic Florida, Weston, FL.*

Background: Ambulatory blood pressure monitoring has traditionally been used to diagnose white coat hypertension and only recently has had a more widespread use. The loss of circadian blood pressure rhythm on ABPM correlates with the presence of obstructive sleep apnea and renal insufficiency and may be a prognostic marker. Our study aimed to determine the prevalence of the different types of hypertension in our clinic population, and whether ABPM was useful as a predictor of renal and cardiovascular outcomes.

Methods: Retrospective chart review done from July 2005 to June 2009. 175 charts were reviewed. 34 patients excluded due to incomplete monitoring (<90 % successful readings). 141 patients included in the final statistical analysis.

BP was classified according to JNC-7 guidelines.Nocturnal dipping status: nocturnal drop in SBP, DBP and heart rate of > 10%. Statistical analysis was performed using the SPSS Statistical Analysis Software.

Results: Mean age: 58 years, 44% male, 70.9% Caucasian. Mean serum creatinine 0.87 mg/dl (range 0.5 -1.7 mg/dl), 15% diabetic. 10% GFR< 60 ml/min, 11% OSA

Primary outcome: the composite outcome of renal (doubling in serum creatinine / reaching ESRD) and cardio-vascular (acute myocardial infarction, acute CHF) endpoints. Mean study follow-up period: 3 years.

Six patients (4.3%) reached the composite outcome. There was a trend towards the composite outcome in patients with isolated systolic HTN and Stage 2 HTN. OSA was associated with the loss of circadian rhythm.(67% vs 31%, p =0.01). The composite outcome was associated with the presence of diabetes, CHF and microalbuminuria

Conclusions: The study shows a trend towards renal and cardiovascular outcomes in patients with isolated systolic hypertension, stage 2 hypertension and loss of circadian rhythm as measured with ABPM. These trends could be confirmed with a larger study population and longer follow up period. Our study showed a strong association of these endpoints in patients with diabetes, CHF and albuminuria. ABPM is useful not only in the diagnosis of hypertension, but can be a valuable prognostic tool.

PUB391

Blood Pressure Measurement in Diabetes – New Techniques and Validity of Current Modalities in Hypertension Diagnostics Simone Theilade, Maria Lajer, Christel Joergensen, Frederik I. Persson, Peter Rossing. *Steno Diabetes Center, Gentofte, Denmark.*

Background: Tonometry is a novel technique for measuring BP. A watch-like device captures radial pulsewave reflection and calculates ambulatory brachial blood pressure (BP). Hypertension (HTN) is often diagnosed by office blood pressure (OBP) rather than ambulatory BP (AMBP). In this study we investigate if tonometry is applicable and reliable, and if OBP is reliable in HTN diagnostics in patients with diabetes.

Methods: In 24 Caucasian diabetic patients we compared tonometric (BPro) to cuff-based (Takeda TM2421) BPs. Patients were seen twice<2 weeks. At visit 1, 15 minutes rest was followed by 3 Takeda BPs and 2 minutes continuous BPro BPs. At both visits AMBP was recorded with BPro.

Another 450 Caucasian type 1 diabetic patients, 262 men(58%), (mean±SD) 55±13years, 261(58%) with albuminuria (>30mg/24h), regularly attending clinical controls were randomly selected for AMBP with BPro. OBP was calculated as the mean of cuff-based BPs at 3 separate office visits<1 year prior to AMBP. AMBP and OBP≥130/80mmHg were classified as HTN. Masked HTN was present with normal OBP and elevated AMBP, and white coat HTN was present with normal AMBP and elevated OBP.

Results: Validation: At visit 1, Takeda BP (mean±SD) was 136±19/72±8mmHg vs. BPro 138±19/78±8mmHg. Visit 1 AMBP was 132±20/76±9mmHg vs. 131±13/75±9mmHg at visit 2. Correlations between Takeda and BPro systolic and diastolic BP were r=0.86 and 0.65, (p<0.001). Mean differences (±SD) between devices were 1.9±10 and 5.5±6.6mmHg for systolic and diastolic BP.

Mean AMBP, day BP, night BP and dipping at the 2 visits were similar (p>0.40).

Evaluation: OBP was 137±14/76±8mmHg vs. AMBP 129±15/75±10mmHg. HTN with both AMBP and OBP was present in 211(47%), 79(18%) had normal BP, 117(26%) had white coat HTN and 43(10%) had masked HTN.

In 65% OBP and AMBP were in concordance. HTN (incl masked, and excl white coat HTN) was seen in 254(57%). In 26% BP was ≥140/90.

Conclusions: In patients with diabetes tonometric and cuff-based BPs are comparable and tonometric AMBPs are reproducible.

In 35% there is discrepancy in HTN diagnosis between AMBP and OBP. In a majority of patients BP is not below target <130/80mmHg.

PUB392

The Association of Renal Arteriolopathy and Proteinuria in Chronic Kidney Disease Kentaro Kohagura,[#1] Tsuyoshi Miyagi,[#1] Yusuke Ohya,[#1] Kunitoshi Iseki.[#2] *[1]Department of Cardiovascular Medicine, Nephrology and Neurology, Faculty of Medicine, University of the Ryukyus, Nishihara-cho, Okinawa, Japan; [2]Dialysis Unit, University of the Ryukyus, Nishihara-cho, Okinawa, Japan; [3]Japan; [4]Japan.*

Background: Preglomerular arteriole has a pivotal role in the regulation of glomerular pressure. Therefore, its damage might be associated with proteinuria by inducing glomerular hypertension. However, an association of renal arteriolopathy with urine protein in patients with chronic kidney disease (CKD) has not been investigated.

Methods: In the present study, we examined the cross-sectional association between the urine protein and renal arteriolar hyalinosis using renal biopsy specimen. Arteriolar hyalinosis was assessed by semi quantitative grading for arterioles among 162 patients with non-nephrotic (serum albumin ≥ 3 g/dl) CKD (mean age, 42 yrs; 52% male).

Results: Hyalinosis was seen in 96 patients. The patients with hyalinosis were older and higher prevalence of hypertension and metabolic disorder compared with the patients without hyalinosis. Among the patients with hyalinosis, max grade of hyalinosis (r=0.37, p=0.0002) in addition to systolic blood pressure (SBP) and metabolic risk factors such as body mass index, triglyceride, and uric acid were significantly correlated with urine protein. On the other hand, SBP was only factor, which correlated with UP among the patients without hyalinosis. Multivariate regression analysis showed that triglyceride (β= 0.31, p= 0.002) and max grade of hyalinosis (β= 0.25, p= 0.01) were independent predictor of the urine protβein among the patients with hyalinosis (R^2=0.30, ANOVA P<0.0001).

Conclusions: In conclusion, significant association between the severity of renal arteriolar hyalinosis and the amount of urine protein was observed among the patients with hyalinosis. Besides primary disease, renal arteriolopathy might be associated with the amount of proteinuria and subsequent progression of CKD.

PUB393

Plasma Desmosine and MMP-2 Levels as Potential Predictors of Arteriovenous Fistula (AVF) Maturation in a Porcine Model Yan-Ting E. Shiu,[1] Huan Li,[1] Sun Hyung Kwon,[2] Alfred K. Cheung.[1,3] *[1]Medicine, Univ. of Utah, SLC, UT; [2]Pharmacology & Toxicology, Univ. of Utah, SLC, UT; [3]Medical Service, VASLCHCS, SLC, UT.*

Background: AVFs for chronic hemodialysis often fail to mature and become usable. The underlying factors that cause maturation failure are not well understood. Elastin and collagen are the major extracellular matrix (ECM) proteins in large vessel walls, whose mechanical properties are dependent on these two proteins, which in turn are regulated by matrix metalloproteinases (MMPs) and tissue inhibitors of metalloproteinases (TIMPs). We postulate that aberrant ECM turnover plays a role in the pathogenesis of AVF maturation failure, and that the plasma levels of desmosine and ICTP (degradation products of elastin and type I collagen, respectively), MMPs and TIMPs reflect ECM turnover of the AVF wall and hence can be used as predictors of AVF maturation.

Methods: We examined plasma MMP-2 and desmosine levels and the AVF maturation outcomes in a porcine AVF model. An AVF was created between the common carotid artery and external jugular vein on one side on each pig; the un-operated contralateral vessels served as controls. Serial plasma MMP-2 and desmosine levels were measured using respective ELISA. The patency, blood flow rate (BFR) and vein diameter (VD) of the AVF were assessed using serial duplex ultrasound.

Results: Compared to the animals with AVF patency at 10 weeks, the animal with occluded AVF before 10 weeks had higher plasma MMP-2 and desmosine concentrations and lower BFR and VD prior to that time point.

Conclusions: These preliminary data support the notion that increased proteolysis activity and elastin degradation in the AVF wall, as reflected by increased plasma MMP-2 and desmosine levels, respectively, are predictive of AVF maturation failure. Work is ongoing to further examine the relationships among vascular wall characteristics, plasma levels of ECM and their regulatory proteins, and AVF maturation outcomes in both experimental animal and clinical settings.

The Role of Vitamin D Supplementation on Aortic Augmentation Index and Pulse Wave Velocity in Healthy Humans Ahmed Abdi Ali, David Donald McTavish Nicholl, Brenda Hemmelgarn, Jennifer M. MacRae, Darlene Y. Sola, Sofia B. Ahmed. *University of Calgary.*

Background: Vitamin D (VD) deficiency is a risk factor for kidney and cardiovascular (CV) disease. Animal studies suggest a role for VD in modulation of the renin-angiotensin system (RAS), though the mechanism in humans is unclear. Arterial stiffness is an important predictor of CV risk in both healthy and chronic kidney disease (CKD) populations. We sought to determine the effect of VD supplementation on arterial stiffness and the RAS, both at baseline and in response to angiotensin II (AngII) challenge, a well-accepted measure of RAS activity, in VD-deficient healthy humans.

Methods: Ten VD-deficient (25(OH)-VD<50nmol/L), normotensive, non-obese, healthy subjects (7 females and 3 males) were studied before and after ingestion of 5000U of VD daily for 28 days. All subjects were studied in a high salt balance state, a state of maximal RAS suppression, and female subjects were studied in the same phase of their menstrual cycle. Arterial stiffness (aortic augmentation index (AIx) and pulse wave velocity (PWV) (brachial, n=9 and femoral, n=1) was measured by tonometry at baseline and in response to AngII infusion (3ng/kg/min x 30 minutes followed by 6ng/kg/min x 30 minutes).

Results: Baseline mean serum 25(OH)-VD levels increased from 51.2±3.8nmol/L to 101.8±9.5nmol/L after VD supplementation (p=0.001). VD supplementation resulted in a non-significant improvement in baseline arterial stiffness (baseline AIx pre- vs. post-VD supplementation, 12.3±3.3% vs. 10.8±4.3%, p=0.6), while the AIx response to AngII challenge increased non-significantly (AIx pre- vs. post-VD supplementation, 11.1±2.2% vs. 12.6±3.8%, p=0.8), consistent with downregulation of RAS activity. In contrast, VD supplementation did not alter the PWV at baseline (p=0.8) or in response to AngII challenge, p =0.058).

Conclusions: VD supplementation may improve arterial stiffness and down-regulate intrinsic vascular RAS activity. Further studies are needed to determine if VD supplementation ultimately decreases CV disease in patients with CKD.

PUB395

The Equilibrium and Dynamic Interactions of Albumin with Anionic Polyions Demonstrate That Charge Selectivity and Electrical Effects of the Glomerular Filter on Albumin Filtration Are Small Wayne Comper. *Exosome Diagnostics Inc, New York, NY.*

Background: Recent studies have suggested that the restricted transport of albumin across the glomerular filter may be due charge repulsion offered by the endothelial cell glycocalyx (charge selectivity) or repulsion offered by an electric field induced through convection across the filter (electrical effects).

Methods: The equilibrium charge and size interaction of albumin with polyanions (charge selectivity) has been accurately studied by a number of techniques including exclusion chromatography and light scattering under physiological conditions. The dynamic interaction of albumin in polyion systems where there is a convection-induced charge separation (electrical) has been studied by sedimentation analysis in the ultracentrifuge.

Results: The equilibrium interaction studies all demonstrated that the interaction of albumin with the polyanion was dominated by size exclusion and that charge interactions were small and would not have a major influence on transglomerular transport. Sedimentation analysis of albumin transport in polyion solutions with induced-charge separation at hydraulic conductivity levels equivalent to physiological GFRs again demonstrates that albumin transport is governed by size exclusion effects and that the electrical effects of induced charge separation were small if not negligible.

Conclusions: The lack of significant charge selectivity and electrical effects clearly reflects the influence of the relatively high ionic strength and screening of charge interactions that occur under physiological conditions. These results also support recent direct measurements of the glomerular sieving coefficient of albumin by 2-photon microscopy to be in the range of 0.01-0.03 as predicted by purely size selectivity transport studies.

PUB396

Mechanisms for the Enhanced Plasma Retention of Albumin and IgG Are Coupled and Renal Centric: Uncoupling and Loss of Enhancement Occurs in Nephrotic States Wayne Comper,[1] Leileata M. Russo,[1] Maria Koltun.[2] *[1]Exosome Diagnostics Inc, New York, NY; [2]Biochemistry, Monash University, Clayton, Victoria, Australia.*

Background: The hypthothesis to be tested here is whether hypoalbuminemia and hypoimmunoglobulinemia are related and whether this relationship is centered at the kidney. The study employs plasma elimination measurements as they offer certain advantages over renal clearance studies particularly in terms of examining the behaviour of high molecular weight proteins

Methods: Plasma elimination rates measured over 24h were determined for tritium-labeled tracers of Ficolls (radii range 3.5-8.5nm), dextrans (5.0-10.5nm), albumin and IgG in healthy control and nephrotic (induced by puromycin aminonucleoside (PA)) Sprague Dawley rats. Nephrotic state resulted in a 1000-fold increase in the urinary excretion of intact albumin and 500- fold increase in intact IgG. Tissue uptake was also measured.

Results: Plasma elimination rate of albumin (n=18) (3.6nm radius) and IgG (n=6) (5.5nm radius) in control rats were coupled as their elimination rates were identical at 0.019±0.003 h^{-1} independent of their size. Their elimination rate was far enhanced as compared to the elimination rates of inert transport markers of equivalent hydrodynamic radius; their elimination rate corresponded to the elimination of a 7.5nm radius Ficoll (n=5) and >10.5nm radius dextran (n=5). The renal centric mechanism of the enhanced plasma elimination was demonstrated in nephrotic states where the increase in the plasma elimination rate for albumin and IgG was equal to the increased quantities of material excreted in the urine. In nephrotic states plasma retention was uncoupled and enhancement destroyed as the plasma elimination of both albumin and IgG was identical to Ficolls with radii of 3.6nm and 5.5nm respectively.

Conclusions: Given recent studies that the glomerular sieving coefficient of albumin is in the range of 0.01-0.03, the present studies indicate that the renal centric mechanism is the albumin retrieval pathway in proximal tubular cells and the retrieval pathway participates in retrieving filtered IgG.

PUB397

Idiopathic Edema (IE) in Patients with Polycystic Ovary Syndrome (PCOS): Importance of Nocturia Sudharani Dikkala,[1] Jonah Feldman,[1] Siham Accacha,[2] Louis J. Imbriano,[1] Nobuyuki (Bill) Miyawaki,[1] Shayan Shirazian,[1] John K. Maesaka.[1] *[1]Department of Medicine, Winthrop University Hospital, Mineola, NY; [2]Department of Pediatrics, Winthrop University Hospital, Mineola, NY.*

Background: IE is characterized by weight gain of more than 2 lbs between 8 AM and 8 PM unrelated to menses in obese women.Nocturia is not included as a feature of IE but is a needed compensation to maintain fluid balance and avert progressive fluid retention.We present 3 cases of IE in patients with PCOS in whom nocturia was prominent

Three female patients, ages 42, 47 and 50 yrs, with PCOS, obesity, type II diabetes mellitus, hypertension, hypercholesterolemia met criteria for IE by daily orthostatic weight gains of 5-8 lbs from 8 AM to 8 PM with bloating, increased abdominal girth, tightening of clothes, 4X nocturia with full bladders and loss of weight gained during the day.Two patients noted edema of hands and face in the morning.Two have glomerular hyperfiltration, 1 obesity-related FSGS by biopsy, 1 gout, sleep apnea and antiphospholipid syndrome with 7 miscarriages, 2 emotional instability.None were on diuretics before development of edema.In 1 patient, while on hydrochlorothiazide, her orthostatic daily weight gains decreased to 3-5 lbs on a 3gm salt diet, 1-2 lbs on a 2gm salt intake and no weight gain and elimination of nocturia on 1gm salt intake.Weight gains were aborted by furosemide on the morning after salt intake exceeded 1gm/day.Successful treatment of her edema led to greater emotional stability

Conclusions: IE may be common in PCOS.Increased vascular permeability appears to be abnormal in IE (edema of hands and face) and accounts for the orthostatic weight gain, nocturia must be an essential feature of IE to prevent continuing fluid retention and weight gain.Salt restriction with judicious use of diuretics can reduce or eliminate fluid retention.Control of fluid retention and understanding the pathophysiology of their disorder in 2 patients led to greater emotional stability.Additional studies must be performed to determine the prevalence of IE in PCOS and effectiveness of judicious use of diuretics and salt restriction in controlling orthostatic fluid retention

PUB398

Hemodynamic and Renal Function in Rats with AngiotensinII-Induced Hypertension Claudia Ferreira-Figueiredo, Maria Oliveira-Souza. *Physiology and Biophysic, University of Sao Paulo, Brazil.*

Background: The angiotensin II (Ang II) has been shown to control glomerular hemodynamic and renal function, including the sodium homeostasis. Thus, this study investigated the renal function and modulation of epithelial transporters of rats with angiotensin-induced hypertension.

Methods: 4-weeks-old male Wistar rats were divided in two groups: Sham or treated with Ang II (200 ng/kg/min) by 15 days, using osmotic minipumps (Alzet). Blood pressure (BP) was monitored weekly by tail cuff plethysmography. Renal plasmatic flow (RPF) and glomerular filtration rate (GFR) were determined by para-aminohippurate sodium (PAH) and inulin clearance. Plasmatic levels of renin were analyzed by Enzime Immunoassay Kit (EIA), Urinary excretion of ions were also analyzed. The expression of renal transporters, Ang II and aldosterone receptors will be analyzed by Western Blot.

Results: Our preliminary results showed that the dose of Ang II used was enought to induce hypertension [114 ± 2,2 (Sham) versus 142 ± 2,66 (Ang II)*p<0,0001]. RPF decreased [12,65 ± 0,55 (Sham) versus 9,80 ±0,44 (Ang II) ml/kg/min p<0,0001]. The GFR decreased [8,8 ± 0,33 (Sham) versus 4,75 ± 0,52 (Ang II) ml/kg/min, p < 0,0001]. The plasma renin level increased [4,54 ± 3,2 (Sham) versus 9,29 ± 1,8 (Ang II) ng/ml]. Urinary Na+ and K+ also decreased in Ang II treated rats. The expression of Na+/H+ exchanger (NHE1) decreased [0,973 ± 0,009 (Sham) versus 0,788 ± 0,04 (Ang II), p<0,001]. The expression of Na+/H+ exchanger (NHE3) did not change [0,911 ± 0,052 (Sham) versus 0,93 ± 0,071 (Ang II)], nephrin did not change [1,19 ± 0,057 (Sham) versus 1,22 ± 0,032 (Ang II)].

Conclusions: Our results suggest that the dose of Ang II (200 ngr / kg/ min) was enough to affect hemodynamic parameters, tubular function and renin plasmatic level. The decrease of RPF and GFR may be involved with the action Ang II intraglomerular The handling ionic by tubule should be evaluate by expression of other transporters.

Arterial Stiffness Is an Independent Determinant of Compensatory Hyperfiltration after Kidney Donation Pierre Fesler, Jean Ribstein, Guilhem Du Cailar, Georges J. Mourad, Albert Mimran. *Department of Internal Medicine and Nephrology, Lapeyronie Hospital, Montpellier, France.*

Background: After kidney donation, the remaining kidney tends to hyperfiltrate thus limiting the initial loss of renal function. However, the potential determinants of this compensative hyperfiltration (CHF) and the possible influence of arterial function are not known.

Methods: In 26 normotensive healthy kidney donors (51 +/- 9 yrs [mean+/-SD], 22 females), glomerular filtration rate (GFR) was measured by the clearance of continuously infused Tc99m-DTPA and timed urine collections at baseline -i.e. before donation- and 1 year after donation. CHF was computed as post-donation GFR minus half of baseline GFR. Arterial function was assessed at baseline through carotido-femoral pulse wave velocity (PWV) and carotid augmentation index (AIx).

Results: After kidney donation, there were no significant changes in blood pressure (BP), but 2 subjects became hypertensive. GFR decreased from 104+/-17 to 71+/-11 mL/min/1.73m² and mean CHF was 19+/-9 mL/min/1.73m². In univariate analysis, CHF was inversely correlated to baseline age (r^2=0.15, p=0.049) and PWV (r^2=0.23, p=0.012), but not mean BP or AIx. In multivariate analysis, CHF remained inversely correlated to PWV (p=0.020), independently of baseline age and mean BP (model r^2=0.54, p=0.002).

Conclusions: In healthy subjects, increased arterial stiffness seems to be associated with a limited magnitude of post-donation hyperfiltration. This could reflect an influence of arterial function on renal reserve, providing further insights into the relationship between macrocirculation and renal microcirculation.

PUB400

Evaluation of Vascular Function in Hemodialysis Patients: Small Artery Elasticity Index (SAE) Correlates with Pulse Wave Velocity (PWV) and Flow Mediated Dilatation (FMD) William D. Paulson,[1,2] John White,[2] David M. Pollock,[2] Jennifer S. Pollock,[2] Allison Dubner,[2] Gaston K. Kapuku.[2] *[1]Charlie Norwood VA Medical Center, Augusta, GA; [2]Georgia Health Sciences University, Augusta, GA.*

Background: Cardiovascular disease is the most important cause of mortality in dialysis patients, and contributes to vascular access failure. Tests of vascular function are important in evaluating and treating these problems, but standard methods such as PWV and FMD may not be fast and easy enough for widespread use. Measurement of arterial elasticity may meet this need since it is fast and easy to apply and has correlated with maturation failure of arteriovenous fistulas (Kheda NDT 2010). We report herein early results from an ongoing study of the correlation of SAE with PWV and FMD.

Methods: Sixteen hemodialysis patients underwent measurement of arterial blood pressure, SAE (HDI/PulseWave System), carotid-femoral PWV (SphygmoCor System), and FMD by standard protocol. SAE is measured by a tonometer that is applied noninvasively to the skin over the radial artery. The HDI device performs pulse contour analysis of the radial artery waveform. We plan to study a total of 60 dialysis patients.

Results: Mean values were generally consistent with arterial dysfunction (high systolic and pulse pressures, low SAE, high PWV, low FMD):

Systolic BP	Pulse Pressure	SAE	PWV	FMD
138.7 mmHg	60.8 mmHg	6.03 ml/mmHg x100	9.48 m/sec	5.31 %

In simple regression analysis, SAE negatively correlated with systolic blood pressure (R^2 = 0.27, P = 0.038) and PWV (R^2 = 0.35, P = 0.027), but did not reach significance with FMD (R^2 = 0.10) in this small initial sample. In multiple regression analysis, SAE correlated with PWV, FMD, and mean arterial pressure (R^2 = 0.80, all P <0.014), indicating that 80% of SAE variation was due to its relation with these 3 variables.

Conclusions: SAE closely correlated with standard measures of vascular function and is fast and easy to apply. These results support the concept that elasticity may be a feasible alternative measure of vascular function in dialysis patients. Further study with a larger number of patients is needed to confirm these promising results.

PUB401

Increased Baroreceptor Sensitivity Predicts Intradialytic Hypertension Dan Sapoznikov, Rebecca Backenroth, Dvora Rubinger. *Nephrology and Hypertension Services, Hadassah University Medical Center, Jerusalem, Israel.*

Background: Autonomic hyperactivity may be involved in the pathogenesis of intradialytic hypertension (HD-H).

Methods: To assess intradialytic changes in autonomic activity in patients without (H (-)) and with (H (+)) intradialytic hypertensive episodes and to identify HD-H predictors, continuous beat to-beat blood pressure and heart rate recordings were performed in 108 patients during 113 hemodialysis sessions without (n=51) and with (n=62) HD-H episodes. HD-H was defined as a period of at least 10 mmHg increase in the systolic blood pressure (SBP) between the start (*Begin*) and the end (*End*) of dialysis, or hypertension resistant to ultrafiltration occurring during or immediately after dialysis. SBP, diastolic blood pressure (DBP), SBP and interbeat intervals (IBI) variability and baroreceptor sensitivity (BRS) in the low frequency (LF) range (LF SBP, LF IBI and LF BRS) were assessed using the complex demodulation method (CDM). LF oscillations are believed to be representative of sympathetic activation.

Results: SBP, IBI, LF SBP, LF IBI and LF BRS at *Begin* and at *End* of HD (median and interquartile range) were:

Table 1.

	SBP (mmHg)	DBP (mmHg)	IBI (msec)	LF SBP (mmHg)	LF IBI (msec)	LF BRS (msec/mmHg)
H(-) *Begin*	139 (42)	69 (19)	802 (198)	1.98 (0.93)	5.39 (4.49)	3.03 (1.95)
H(-) *End*	125 (34)	71(18)	813 (274)	1.95(1.00)	6.01 (6.80)	3.21 (3.20)
p	0.023	0.056	NS	0.051	0.046	0.001
H(+) *Begin*	132 (30)	67 (17)	850 (162)	1.92 (0.64)	6.11 (4.92)	3.62 (2.79)*
H(+) *End*	143 (36)*	76(21)*	878 (175)	1.88 (0.86)	7.16 (5.49)	3.67 (2.67)
p	0.001	0.001	NS	NS	NS	NS

* p <0.05 vs. H (-)

In multivariate analysis, including clinical and CDM data, pre-dialysis LF IBI , LF SBP, LF BRS, age and serum albumin were the main predictors of HD-H.

Conclusions: These results show: 1. H (-) sessions are associated with blood pressure normalization and enhanced IBI variability and BRS. 2. H (+) sessions are associated with increased post dialysis blood pressure. 3. pre-dialysis LF SBP , LF IBI, and LF BRS predict HD-H. Our data suggest that sympathetic activation with enhanced BRS, in concert with clinical factors contribute to HD-H. Intradialytic hypertension has to be further evaluated as a potential cause of interdialytic hypertension.

PUB402

IgA Nephropathy and Alcoholic Cirrhosis Display Common IgA Abnormalities Laureline Berthelot,[1] Emilie Tissandie,[1] Willy Morelle,[2] Eric Daugas,[3] Ivan Cruz Moura,[1] Francois Vrtovsnik,[3] Richard Moreau,[4] Renato C. Monteiro.[1] *[1]INSERM U699, Faculté Xavier Bichat, Paris, France; [2]Unité Mixte de Recherche CNRS/USTL 8576, Université des Sciences et Technologies de Lille, Villeneuve d'Ascq, France; [3]Service de Néphrologie, Hôpital Bichat-Claude Bernard, Paris, France; [4]INSERM U773, Centre de Recherche Biomédicale Bichat-Beaujon CRB3, Paris, France.*

Background: Alcoholic cirrhosis (AC) patients present IgA abnormalities including mesangial IgA deposits. Contrary to primary IgA nephropathy (IgAN), very little is known about IgA1 glycosylation and IgA-circulating immune complexes containing soluble CD89-IgA or IgG-IgA complexes in secondary IgAN which occurs in AC.

Methods: Here, purified IgA1 from serum of 32 patients with compensated or advanced AC were analyzed for O- and N-glycosylation. IgA-IgG and soluble CD89-IgA complexes presence in the sera of AC patients was assessed by ELISA.

Results: Similar to IgAN, galactose deficiency and decreased sialylation of IgA1 were observed in advanced AC. Increased amounts of abnormally O-glycosylated polymeric IgA1 were detected in serum from these patients. Moreover, aberrant IgA1 formed complexes with IgG and soluble CD89 in serum of patients with advanced AC as observed in primary IgAN. However, IgA1 from AC patients exhibited also several modifications of N-glycosylation, not observed in IgA1 from primary IgAN patients. In AC patients with IgAN, IgA deposits were associated with CD71 overexpression in mesangial areas suggesting that CD71 might be involved in deposit formation. Although AC purified IgA1 bound more extensively to human mesangial cells than control IgA1, they differ from primary IgAN by not inducing mesangial cell proliferation.

Conclusions: To conclude, abnormally O-glycosylated IgA1, soluble CD89-IgA and IgA-IgG complexes, features of primary IgAN, are also present in AC and could indicate common environmental factors influencing the development of IgAN.

Transgenic Rat with GEC Targeted HO-1 Overexpression Ling-Mei Chiang,[2] Pu Duann,[1] Elias A. Lianos.[1] *[1]Medicine, Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Pediatrics, Chang-Gung Memorial Hospital, Keelung, Taiwan.*

Background: Induction of heme oxygenase (HO)-1 is a key defense mechanism against oxidative stress. Compared with tubules, glomeruli are refractory to HO-1 upregulation in response to injury. This can be a disadvantage as it may be associated with insufficient production of cytoprotective heme-degradation metabolites. We, therefore, explored whether 1) targeted HO-1 expression can be achieved in glomeruli without altering their physiological integrity and 2) this expression reduces proteinuria in immune injury induced by an anti-glomerular basement membrane (GBM) antibody (Ab). We previously reported generation a transgenic mice mice, pNeph-hHO1, in FVB/N strain with confirmed GEC-targeted HO-1 expression and had shown a reduced proteinuria in both glomerular immune injury and adriamycin glomerulopathy.

Methods: Using Sleeping Beauty(SB) transposon system we subcloned pNeph--FLAG-hHO1 expression cassette between inverted repeats of the transposon vector SB10. We then injected pNeph-FLAG-hHO1 transgene with an mRNA source of SB transposase into newly fertilized Sprague Dawley eggs. This resulted the transposition of the transgene, pNeph-FLAG-hHO-1, and its integration as a single copy unit.

Results: We thus obtained transgenic rats with GEC targeted HO-1 overepression. These rats show no apparent changes in weight, eating habits, fur color or motility. In addition, there is no infertility or deviated Mendelian ratio in offspring. Assessed by electron microscopy revealed no glomeruli microstructure deformity such processes effacement, flattening or microvillus transformation of GEC.

Conclusions: Transgenic rats with GEC targeted HO-1 overexpression could help us study the role of renoprotective HO-1 in the GEC pathobiology.

PUB404

Caspofungin Efficacy in Re-Establishing Chronic Haemodialyzed and Renal Transplant Patient Phagocyte Primary Functions Against Candida albicans and C. glabrata Infections Franca Giacchino,[1] Giuliana Banche,[2] Valeria Allizond,[2] Narcisa Mandras,[2] Giuseppe Garneri,[1] Daniela Scalas,[2] Rosaria Patti,[1] Janira Roana,[2] Chiara Merlino,[2] Vivian Tullio,[2] Anna Maria Cuffini.[2] *[1]Nephrology and Dialysis Unit, Civil Hospital, Ivrea, Turin, Italy; [2]Public Health and Microbiology, University of Turin, Italy.*

Background: Although invasive fungal infections attributed to *Candida spp.*, particularly to *C. albicans,* are prevalent, a tendency of an increasing proportion of *C.* non-*albicans* species has also been reported: the most important species is *C. glabrata.* Due to the impaired phagocyte-dependent host defences, patients with chronic renal failure are more frequently at risk of candidiasis than healthy subjects (HSs). Thus, for candidiasis resolution immunomodulating antifungal drugs may be decisive. This study aimed to evaluate the potential immunomodulating activity exerted by caspofungin on polymorphonuclear cells (PMNs) from haemodialysed patients (HDs) and renal transplant recipients (RTRs), compared with HSs, towards both *C. albicans* and multidrug-resistant *C. glabrata*.

Methods: PMNs were separated from venous blood samples of 66 HDs, 54 RTRs and 30 HSs. The effects of caspofungin on both phagocytosis and intracellular killing by PMNs towards *Candida* spp. were investigated by incubating yeasts and PMNs with caspofungin at MIC values. Drug-free controls were included.

Results: A reduced fungicidal activity towards intracellular *C. albicans* and *C. glabrata*, was detected in HD-PMNs and RTR-PMNs, in comparison with HS-PMNs. This decreased PMN antibacterial activity was re-estabilished by the addition of caspofungin that significantly improved the intracellular killing of HD-PMNs and RTR-PMNs against both *C.albicans* and *C.glabrata*, without affecting phagocytosis.

Conclusions: These data provide confirmation that caspofungin in addition to its antifungal activity possesses immunomodulating properties that make it highly suitable for the treatment of infections caused by both *C. albicans* and multidrug-resistant *C. glabrata* in patients with altered phagocyte-dependent innate immunity which represent a high risk population.

PUB405

Involvement of Anaphylatoxins C3a, C5a in Tubulointerstitial Fibrosis in Rats with Unilateral Ureteral Obstruction Fang Liu, Ping Fu. *Department of Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan Province, China.*

Background: To investigate the role of anaphylatoxins C3a, C5a in tubulointerstitial fibrosis in rats with unilateral ureteral obstruction (UUO) and to clarify the possible mechanism.

Methods: In vivo study, the expressions of C3a, C5a and their receptors C3aR, C5aR (CD88) were detected by immunohistochemistry staining in UUO rats. In vitro study, HK-2 cells were divided into C3a and C5a group which were divided into four subgroups: control group, 10 ng/ml TGF-β1, 50 nmol/L C3a, 50 nmol/L C3a plus 1 μmol/L C3aRA; control group, 10 ng/ml TGF-β1, 50 nmol/L C5a, 50 nmol/L C5a plus 2.5 μmol/L C5aRA. 10 μg/ml TGF-β1 receptor antagonist (TGF-β1RA) was used to investigate the mechanism of C3a- and C5a-induced tubular epithelial-myofibroblast transdifferentiation (TEMT). Electron microscopy was used to observe the morphological changes. Immunocytochemistry staining, real time PCR and Western blot were used to detect the expressions of α-SMA, E-cad, Col-I, C3aR, CD88, CTGF and TGF-β1.

Results: In vivo study, the expressions of C3a/C3aR and C5a/CD88 were detected in tubular epithelial cells 7 days after UUO established, especially in dilated tubules. In vitro study, after HK-2 cells were cultured with C3a and C5a for 72 hr, many cells had strong staining for α-SMA, lost the positive staining of E-cad, and showed a slightly spindle-like shape and loss of microvilli on the cell surface. The expressions of α-SMA, E-cad, Col-I, C3aR, CD88, TGF-β1 and CTGF in C3a- and C5a-treated groups were higher than normal control group ($P < 0.05$). C3aRA and C5aRA inhibited the expressions of α-SMA, Col-I, C3aR, CD88, and up-regulated the expression of E-cad ($P < 0.05$). TGF-β1 and CTGF mRNA expressions induced by C3a and C5a were blocked by TGF-β1RA ($P < 0.05$).

Conclusions: Anaphylatoxins C3a, C5a and their receptors were involved in the early pathophysiologic process of tubulointerstitial fibrosis in rats with UUO by inducing TEMT via the up-regulations of C3aR and CD88 and the activation of TGF-β/CTGF signaling pathway.

PUB406

The Pivotal Role of Midkine in the Pristane-Induced Lupus Nephritis Mice Kayaho Maeda, Tomoki Kosugi, Waichi Sato, Hiroshi Kojima, Yuka Sato, Hiroshi Nagaya, Mayuko Hori, Shoichi Maruyama, Seiichi Matsuo. *Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: The growth factor midkine (MK) exerts pleiotrophic effects such as cell proliferation and migration in various organs. We have previously demonstrated that the major biological activity of MK in the kidneys affects in the progress of ischemic renal injury, diabetes and hypertension. A recent study proposed that inhibition of MK alleviates experimental autoimmune encephalomyelitis through the expansion of $CD4^+CD25^+$ regulatory T cell (Treg) population. However, the precise mechanism remains unclear yet. In order to clarify the molecular mechanism of autoimmune disease, we examined the role of MK in pristane-induced lupus nephritis model.

Methods: Lupus nephritis was induced in MK deficient mice ($Mdk^{-/-}$) or wild-type mice ($Mdk^{+/+}$) with an intraperitoneal injection of pristane (0.5ml/each mice). Mice were measeured on albuminuria and anti-nuclear antibody once a month and sacrificed at 6 months later. Kidney, spleen and lipogranulomas were analyzed.

Results: There was no difference between $Mdk^{+/+}$ and $Mdk^{-/-}$ in serum anti-nuclear antibodies during the experimental period. Albuminuria in $Mdk^{+/+}$ was more than $Mdk^{-/-}$. Histological analysis showed that there were no differences in IgG and C3 depositions of glomeruli, whereas mesangial and endocapillary proliferations were more severe in $Mdk^{+/+}$ mice. Macrophage infiltration in glomeruli was prominent in $Mdk^{+/+}$. By electron microscopy, electron dense deposits were more found in the mesangial area in glomeruli of $Mdk^{+/+}$. Macrophage-related cytokines such as monocyte chemotactic protein-1 were suppressed in the $Mdk^{-/-}$. Serum IL-12, IL-6 and IL-1β levels were higher in $Mdk^{+/+}$, but not IL-10. By flow cytometry analysis, IFN-γ and IL-17A in $Mdk^{+/+}$ spleen are higher than $Mdk^{-/-}$ mice, but not $CD4^+CD25^+$ Treg population and $CD4^+/CD8^+$ T cell ratio in spleen.

Conclusions: MK is involved in the pathogenesis of lupus nephritis through Th1 and Th17 cell activations. This finding opens up new avenues that may facilitate research on the development of therapeutics for SLE.

PUB407

Comparison of Everolimus and Sirolimus on Cyclosporine A-Induced Pancreatic and Renal Injury in Rats ShangGuo Piao, Sunwoo Lim, Byung Ha Chung, In O Sun, Sun Ryoung Choi, Chul Woo Yang. *Internal Medicine, Seoul St. Mary's hospital, The Catholic University of Korea, Seoul, Republic of Korea.*

Background: It is well known that sirolimus (SRL) aggravates cyclosporine A (CsA)-induced renal and pancreatic injury. But**,** the effect of everolimus (EVL) on CsA-induced organ injury is undetermined.This study was conducted to investigate the pharmacologic interaction between EVL and CsA at the blood and tissue level.

Methods: Male Sprague-Dawley (SD) was subcutaneously administrated with CsA (15 mg/kg/day) and EVL or SRL (0.3 mg/kg/day) for 4 weeks. The effect of EVL on CsA-induced nephrotoxicity and pancreatic islet dysfunction was compared with that of co-administered CsA and SRL. To confirm the drug interaction between CsA and EVL or SRL, concentration of each drug was evaluated in the whole blood and tissue samples using liquid chromatography-mass spectrometry.

Results: The EVL or SRL treatment did not cause severe renal injury and pancreatic dysfunction, but combination treatment with CsA aggravated CsA-induced toxicity. Macrophage infiltration, TIF, 8-OHdG excretion were significantly increased in the CsA group compared to the VH group. Addition of EVL or SRL on CsA showed much more aggravation of pancreatic islet dysfunction than CsA group. In whole blood, CsA concentration did not differ among CsA, CsA + EVL, and CsA + SRL groups. In kidney and pancreas tissue, CsA concentration was also not significantly different between the CsA + EVL and the CsA group. However, a surprising higher CsA concentration was detected in the CsA + SRL group in the kidney (2-fold) and pancreas (2.1-fold) compare to the CsA group. There was no difference of concentration of EVL in kidney and pancreas from the CsA + EVL group compared with EVL group . However, concentration of SRL in kidney and pancreas tissues from CsA + SRL was higher than that of SRL group.

Conclusions: EVL aggravates CsA-induced organ injury but pharmacologic interaction between EVL and CsA is less than that of SRL at tissue level. This finding provides a better understanding of difference of EVL and SRL in combined treatment with CsA.

PUB408

Novel Transcription Factors in Regulation of M2 Macrophage Phenotype
Changqi Wang,[1] Qi Cao,[1] Di Yu,[2] Guoping Zheng,[1] Ya Wang,[1] Junyu Lu,[1] Yiping Wang,[1] David C. Harris.[1] *[1]Centre for Transplantation and Renal Research, University of Sydney at Westmead Millennium Institute, Sydney, New South Wales, Australia; [2]Department of Immunology (Clayton), School of Biomedical Sciences, Monash University, Melbourne, Victoria, Australia.*

Background: Macrophages can be classified phenotypically into two main groups, namely classically activated macrophages (M1) and alternatively activated macrophages (M2). M2 macrophages can be polarized further with cytokines into M2a (after exposure to IL4 or IL-13) and M2c (IL-10 or TGFbeta). Previous studies showed that M2a and M2c macrophages have a protective effect in reducing renal injury, and that endogenous macrophages can undergo phenotypic switch in response to microenvironmental stimuli. However, the contribution of transcription factors to M2 macrophage differentiation and phenotypic switching is poorly understood. The aim of this study was to identify key transcription factors involved in M2 macrophage differentiation.

Methods: Peritoneal and bone marrow-derived macrophages were isolated and polarized into M0 (non-activated macrophages), M1, M2a and M2c respectively. Whole genome array analysis was employed to identify transcription factors. Changes in all selected novel genes were validated by real time PCR.

Results: By comparison of differential gene expression, our data showed that several transcription factors were highly upregulated in M2a and M2c. Some of these transcription factors have been associated previously with M2 (Irf4 and Tcfec for M2a; Cebpb for M2c), but some uncharacterized transcription factors (4 with M2a, 3 with M2c) were identified for the first time in this study. In addition, several novel specific surface markers for M2 (3 with M2a; 3 with M2c) were identified.

Conclusions: Several transcription factors involved in M2 macrophage differentiation and M2 specific surface markers have been identified. Gene transfer and gene silencing techniques are currently being employed to demonstrate the possible relevance to M2 differentiation of these newly identified genes. This finding could provide clues for application of M2 macrophages as a therapy for chronic inflammatory diseases, by controlling M2 phenotype.

Influence of the Tariable Domain Glycosylation on Anti-Neutrophil Cytoplasmic Autoantibodies and Anti-Glomerular Basement Membrane Autoantibodies
Peng-Cheng Xu, Xiao-Wei Yang, Zhao Cui, Xiao-Yu Jia, Min Chen, Ming-Hui Zhao. *Renal Division, Department of Medicine, Peking University First Hospital, Institute of Nephrology, Peking University, Beijing, China.*

Background: Pathophysiological significance of variable region of IgG is still unclear by now. The influences of the variable region N-linked oligosaccharides on the antigen binding ability of three kinds of autoantibodies were investigated with Sambucus nigra agglutinin (SNA), which mainly binds to oligosaccharides with terminal α2, 6-linked N-acetylneuraminic acid on the variable region of IgG.

Methods: Twenty-seven patients with serum autoantibodies against myeploperoxidase (MPO, proteinase 3 (PR3), or noncollagenous domain of α3 chain of type IV collagen (α3(IV) NC1) of glomerular basement membrane (GBM) were enrolled. IgG was divided into non-SNA-binding and SNA-binding fractions with SNA affinity chromatography. Antigen-specific IgG were purified with immunoaffinity chromatography.

Results: Variable glycosylation level of total IgG was significantly lower than that of purified anti-MPO antibodies IgG (1.021±0.201 *vs.* 1.434±0.134, P=0.004, expressed by absorbance value 405nm). Variable glycosylation level of total IgG was significantly higher than that of purified anti-GBM antibodies IgG (1.034±0.340 *vs.* 0.734±0.333, P=0.007). The antigen binding level of non-SNA-binding IgG was significantly lower than that of SNA-binding IgG for anti-MPO antibodies (0.572±0.590 *vs.* 0.962±0.670, P<0.001) and anti-PR3 antibodies (0.362±0.530 *vs.* 0.560±0.531, P=0.003), while significantly higher for anti-GBM antibodies (1.301±0.594 *vs.* 1.172±0.583, P=0.044). SNA-binding fraction of anti-MPO and anti-PR3 antibodies-containing IgG could induce higher level of neutrophils respiratory burst than non-SNA-binding fraction.

Conclusions: Variable region glycosylation levels were different among different antigen-specific IgG, and could influence the antigen-binding ability of antigen-specific IgG, which might be dependent on the type of target antigens.

PUB410

Plasma Induces Non-Muscle Myosin Type IIA-Mediated Changes in Neutrophil Migration and Morphology during Phagocytosis
Chen Yu. *Department of Nephrology, East Hospital, Shanghai, China.*

Background: Neutrophils are the primary effector cells in the pathogenesis of transfusion-related organ injury or multiple organ failure (MOF) after blood transfusion. However, the mechanisms underlying the effect of plasma transfusion on neutrophil migration and morphological changes during phagocytosis remain largely unknown.

Methods: We investigated the effect of fresh (one day preparation) and aged (42 day preparation) plasma on neutrophil morphology, migration and phagocytosis. We evaluated the production of reactive oxygen species (ROS) and the expression of non-muscle myosin heavy chain IIA (MYH9) in plasma-treated neutrophils. We used western blots and antibody arrays to evaluate changes in signal transduction pathways in plasma-treated neutrophils.

Results: Aged plasma elicited a stronger oxidative burst in neutrophils when compared with fresh plasma. Antibody arrays showed increased phosphorylation of NF-κB proteins (p105, p50 and Ikk) in plasma-treated neutrophils. The expression of non-muscle myosin IIA (MYH9), a cytoskeleton protein involved in immune cell migration and morphological change, was also significantly upregulated in neutrophils treated with aged plasma. Pretreatment of neutrophils with blebbistatin (a specific type II myosin inhibitor), ascorbic acid (an antioxidant), or staurosporine (a protein tyrosine kinase inhibitor), effectively abrogated the morphological changes, neutrophil migration, and phagocytosis in response to plasma.

Conclusions: Our data provide an insight into the cellular and molecular mechanisms of transfusion-related injury

Key Words: neutrophils, migration, MYH9, NFκ

Activation Markers of Thrombogenesis and Endothelial Dysfunction in End Stage Renal Disease
Vinod K. Bansal,[1] Debra Hoppensteadt,[2] Jawed Fareed.[2] *[1]Nephrology, Loyola University Medical Center; [2]Pathology, Loyola University Medical Center; [3]Thoracic and Cardiovascular Surgery, Loyola University Medical Center.*

Background: The pathogenesis of ESRD is complex involving inflammatory, thrombotic, and calcification processes. Current studies suggest that chronic inflammation is a major risk factor in ESRD. This study profiles markers of inflammation, thrombogenesis, and vascular dysfunction in the ESRD population.

Methods: Samples from 117 ESRD patients over the age of 18 on maintenance hemodialysis for at least 3 months and 50 aged matched control samples obtained from healthy volunteers with no known kidney disease were included in the study. The Randox Evidence Investigator (Antrim, United Kingdom) was used to measure IL-1α, IL-1β, IL-2, IL-4, IL-6, IL-8, IL-10, Vascular Endothelial Growth Factor (VEGF), Interferon-γ (INF-γ), Tumor Necrosis Factor-α (TNF-α), Monocyte Chemotactic Protein-1 (MCP-1), Epidermal Growth Factor (EGF), C-Reactive Protein (CRP), D-Dimer, and Thrombomodulin (TM). Plasminogen Activator Inhibitor -1 (PAI-1) and Asymmetric Dimethylarginine (ADMA) were measured using ELISA kits by Diagnostica Stago (Paris, France) and DLD Diagnostika GmbH (Hamburg, Germany), respectively.

Results: IL-6 levels in ESRD were 4.3 times the controls. VEGF and INF-γ were both elevated at 2.6 times the controls. MCP-1, IL-8, IL-10, EGF, TNF-α, and IL-1α were elevated at 2.0, 1.6, 1.4, 1.4, 1.3, 1.2 times the controls, respectively. IL-4, IL-2, and IL-1 β levels were reduced at 0.9, 0.9, and 0.5 times the controls. TM, CRP, DDMER, PAI-1, and ADMA were increased at 5.9, 4.4, 3.0, 1.4, and 1.6 times the controls, respectively, each demonstrating statistically significant p-values.

Conclusions: The elevation of the interleukins, INF-γ, TNF-α and MCP-1 revealed intense inflammatory activation of leukocytes. The increase in these cytokines also demonstrates the vascular and tissue damage occurs in ESRD. VEGF and EGF are both elevated in the ESRD samples indicating a state of cellular proliferation, possibly in an attempt to replace damaged tissue caused by the heightened inflammatory state. These markers should be evaluated for their role in kidney disease risk stratification and prognosis.

A Mouse Glomerular Epithelial Cell Line with HO-1 Overexpression
Ling-Mei Chiang,[2] Pu Duann.[1] *[1]Medicine, Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Pediatrics, Chang-Gung Memorial Hospital, Keelung, Taiwan.*

Background: The study of cultured glomerular cells has greatly extended our knowledge of the individual cells in the normal and changed glomeruli. Podocytes have primarily been cultured from rat or human glomeruli. But GEC from glomeruli of normal mice, although available, still limited. GEC are terminal differntiated cells thus left only limited replication and proliferation potency. GEC Only limited exception, ie. derived from an immortalized transgenic mice (TsA58), conditional immortal GEC cells are available. Previously we reported a transgenic mice with GEC targeted HO-1 overexpression which show attenuation of proteinuria in GEC injury (Am J Physiol. 297[5]:F1476, 2009). In order to explore the emchanistic role of HO-1 in renoprotection, we generated a GEC cell line from the pNeph-hHO1 tranbsgenic mice.

Methods: Glomeruli are isolated from pNeph-hHO1 transgenic mice by standard differential sieving (80-, 107- and 75- μm) several cell populations were subcloned by the differential speed of growth and subcloning enhanced medium according to previously report (J Cell Physiology 105, 369-378, 1980). Cultured glomeruli was trypsionizd on day 7 and outgrowth cells were subcloned. Several single cell clones were identified and isolated. From these single cells we were able to clone a specific cell types.

Results: The cell with GEC specific surface cilia were further identified for GEC marker C3 (55%) and nephrin (64%) immunohistochemically. The pNeph-hHO1 transgenic mice, as we previously reported, with GEC targeted HO-1 overexpression. The FLAG-Tagged HO-1 was exclusively expressed in GEC with no leakage. This provided us a solid basis to assess FLAG-tagged HO-1 in the newly cloned GEC candidate line(s) and identified

87% FLAG(+) in FACS assay. The homogenous GEC cells are capable to replicated in limited passage, thereby, this newly clone homogenous GEC will preserve its physiological characteristics, with transprotein, FLAG-tagged hHO1, constantly expressed.

Conclusions: This novel GEC cells, with hHO1 over expression will assist future mechanistic studies, supplemental to animal model, of the renoprotective role of HO-1 in GEC injury.

PUB413

Imaging Activation of Complement Sarah De Freitas, Adam Badar, Richard Smith, James Clark, Greg Mullen, Steven H. Sacks. *MRC Centres for Transplantation and Imaging, King's College London, London, United Kingdom.*

Background: Ischemia reperfusion injury (IRI) is an important result of cardiovascular disease as well as impacting on organ transplantation. Complement activation contributes to inflammation and the degree of injury in IRI.

We characterised the first in vitro radiopharmaceutical targeting of activated complement. The SPECT tracer, based on the N-terminal binding domain of endogenous complement receptor 2 (CR2) binds C3d a product of complement activation that remains bound to IRI tissue.

Preliminary imaging studies evaluating the radiotracer in the setting of IRI were done using a mouse myocardial IRI model.

Methods: rCR2 was radiolabelled with [99mTc(CO)3]+ via the engineered C-terminus hexahistidine tag. Serum stability was assessed at 37°C in human and mouse serum and analysed using instant thin layer chromatography and gamma detection via radio TLC scanner. Samples were further analysed using SDS-PAGE followed by autoradiography and densitometry of the protein bands. Induction of IRI was achieved in mice by occluding the left anterior descending coronary artery for 30 min prior to reperfusion. After 24 hr, 100 µL of 1mg/mL rCR2-[99mTc(CO)3]+ at a specific activity of 7 MBq/µg was injected via tail vein and mice imaged 1 hr later using a preclinical SPECT/CT system. Controls included sham operated mice, and injection of a radiolabelled inactive mutant of rCR2 (K41E CR2). Myocardium slices were sectioned for autoradiography and histology (H&E and C3d staining).

Results: After 8hrs serum stability was over 94%. Emission tomography revealed significant uptake in the hearts of mice (n=3) induced with MIRI compared with controls. Autoradiography of heart sections suggested that this was localised to the left ventricle. No activity was detected in control hearts. Histological staining confirmed that C3d was present in areas of tissue damage on myocardial sections, and absent in hearts of control mice.

Conclusions: Initial in vivo evaluation of the rCR2-[99mTc(CO)3]+ SPECT tracer indicates that this has potential as an imaging ligand for delineating the footprint of complement activation in organs affected by IRI.

Adam Badar is joint first author.

PUB414

Repression of Heme Oxygenase(HO)-1 Expression in Glomerular Epithelial Cells (GEC) Maria Detsika,[2] Pu Duann,[1] Elias A. Lianos.[1] *[1]Medicine, RWJ Medical School, New Brunswick, NJ; [2]Thorax Foundation, University of Athens, Medical School, Athens, Greece.*

Background: Of the glomerular cells, the least capable of upregulating HO-1 expression in response to the natural HO-1 substrate/inducer, heme, or to various forms of injury are the GEC (J Lab Clin Med. 147, 150, 2006). While this may be a disadvantage, given the well-established cytoprotective effects of heme degradation products, it may also be justified because production of catalytically active Ferrous iron also occurs following HO-1 induction thus promoting Fenton-type oxidant reactions, i.e. hydroxyl radical formation, in these terminally differentiated cells. Indeed, HO-1 repression does occur in organ injury and was shown to serve as a defense mechanism (Exp Biol Med. 228, 472, 2003). To assess whether GEC do repress HO-1 expression, cultured rat glomeruli were used as a means to obtain a short-term (18h) co-culture of endothelial, mesangial and epithelial cells. In addition, GEC were cultured alone. Both preparations were incubated with heme at concentrations (0, 2.5, 5.0 and 10µM) likely to be encountered in the glomerular milieu following intravascular hemolysis or hematuria. There was a concentration-dependent increase in HO-1 expression (Western blot analysis) in cultured glomeruli. An opposite effect (a concentration-dependent HO-1 decrease) was observed in cultured GEC, indicating a suppressor effect of heme on HO-1 that is apparent in GEC only. We next employed a pNeph-hHO1 transgenic mice in which GEC-targeted hHO-1 expression was achieved as previously described (Am J Physiol. 297[5], F1476, 2009). To upregulate the hHO-1 in GEC, we induced glomerular inflammation by administration of an anti-GBM Antibody to transgenic (Tg) and wild-type (Wt) control mice. While proteinuria was attenuated in Tg mice compared to Wt, this effect was dissipated on day 9 following anti-GBM Ab, and this was associated with a decrease in glomerular hHO-1 levels.

Conclusions: These observations point to the presence of HO-1 repressor mechanisms in GEC that can be activated both by its natural substrate and by proinflammmatory mediators.

PUB415

TNF-α and Tunicamycin Interfered with Glycosylation of Nephrin Protein, Then Resulted in Endoplasmic Reticulum (ER) Stress Shokichi Naito, Tomoko Okamoto, Togo Aoyama, Mariko Kamata, Chikako Okina, Yasuo Takeuchi, Kouju Kamata. *Department of Internal Medicine, Kitasato University School of Medicine, sagamihara, Kanagawa, Japan.*

Background: Accumulation of deglycosylated proteins in ER induces unfolded protein response. However, it is difficult to directly identify these deglycosylated proteins. We have successfully generated antibody against deglycosylated nephrin protein. (Naito et al; Clin Exp Nephrol, 2011, in press) In this study, we investigate ER stress by deglycosylated nephrin protein.

Methods: HEK293-NW cells producing nephrin protein were cultured with 0-10 µg/ml of tunicamycin, an N-linked glycosylation inhibitor, or 0-30 ng/ml of TNF-α for 20 hrs. Cell survivals were evaluated by using Trypan blue dye exclusion test. Then, production of deglycosylated nephrin proteins and expression of GRP78 and calreticulin were analyzed using immunoprecipitation method and western blotting.

Results: Cell death in HEK293-NW cells increased in more than 1 µg/ml of tunicamycin, while did not increase in any dose of TNF-α. Tunicamycin with more than 0.05 µg/ml and TNF-α with more than 0.1 ng/ml induced deglycosylated nephrin proteins in HEK293-NW cells. Tunicamycin with more than 0.5 µg/ml incresed GRP78 and calreticulin in the cells. TNF-α with more than 10 ng/ml increased GRP78 in the cells, and did not increase calreticulin in any dose.

Conclusions: Deglycosylated nephrin proteins induced unfolded protein response in the cells. TNF-α showed a different response compared with it in tunicamycin.

PUB416

Novel Method for Simultaneous Determination of P-cresylsulphate and P-cresylglucuronide: Clinical Data and Pathophysiological Implications Eva Schepers, Natalie Meert, Griet L.R.L. Glorieux, Nathalie Neirynck, Annemieke Dhondt, Raymond C. Vanholder. *Internal Medicine, Nephrology, University Hospital Gent, Gent, Belgium.*

Background: The uremic retention solutes p-cresylsulphate and p-cresylglucuronide, two conjugates of p-cresol, were never determined simultaneously. In the present paper an HPLC method was developed and used to quantify both compounds in parallel in an *in vivo* observational study and their *in vitro* effect was evaluated by flow cytometry.

Methods: P-cresylsulphate and p-cresylglucuronide were determined in serum. For the validation specificity, linearity, recovery, precision and the quantification limit were evaluated. In vivo, concentrations of both compounds were determined in 15 controls and 77 hemodialysis patients, as well as protein binding in the dialyzed group and the reduction ratios during hemodiafiltration. In addition, the i*n vitro* effect of the solutes on leukocyte free radical production at measured concentrations was assessed.

Results: A fast and accurate HPLC method was developed to simultaneously quantify p-cresylsulphate and p-cresylglucuronide. Both conjugates are retained in uremia with a substantially higher total serum p-cresylsulphate in comparison to p-cresylglucuronide (31.4 ± 15.8 vs 7.3 ± 6.5 mg/L) but also a substantial difference in protein binding (92.4 ± 3.0 vs 8.3 ± 4.4 %) and in reduction ratio during post-dilution hemodiafiltration (37.4 ± 7.1 vs 78.6 ± 6.4 %). P-cresylglucuronide *per se* has no effect on leukocyte oxidative burst activity whereas in combination with p-cresylsulphate a synergistic activating effect was observed.

Conclusions: Serum concentrations of p-cresylsulphate and p-cresylglucuronide are elevated in uremia. Both conjugates show a different protein binding, resulting in a different dialytic behavior. Biologically, both conjugates are synergistic in activating leukocytes.

PUB417

Preeclampsia, Hemopexin and Extracellular ATP. Pro-Inflammatory Activation by Hemopexin and Hemopexin-ATP Complexes Floor Spaans, Marijke M. Faas, Chiwan Chiang, Theo Borghuis, Harry Van Goor, Winston W. Bakker. *Department of Pathology and Medical Biology, University Medical Center Groningen, Groningen, Netherlands.*

Background: Preeclampsia (PE) is clinically characterized by hypertension and proteinuria, whereas also activated inflammatory cells in the circulation and altered endothelium is observed. We previously showed that hemopexin (Hx), which is able to down regulate vascular responsiveness to angiotensin II, rises in healthy pregnancy , leading to an expandend vascular bed. In PE this does not occur due to enhanced plasma ATP, which inhibits Hx activity, leading to persisting vascular responsiveness upon angiotensin II and hypertension.

As activated endothelium and monocytes occur in PE and to a lesser extent in normal pregnancy, the question emerged whether Hx, ATP, or Hx inactivated by ATP is associated with the pro-inflammatory status of PE and (to a lesser extent) of normal pregnancy.

Methods: Human monocytes (monomac-6 cell line; $6x10^6$ cells/ml) or confluent human endothelial cells (HUVEC) were stimulated with either LPS (2 µg/ml; positive control), ATP (150 µM), plasma Hx (100µg/ml), Hx-ATP complexes (100µg/ml), or saline (negative control) for 4 hours under standard conditions. Cells were subsequently washed, stained for ICAM-1 and processed for flow cytometry.

Results: In monocytes enhanced ICAM-1 expression was shown after stimulation with Hx-ATP complexes ($p<0.01$) and to a lesser extent after Hx alone ($P<0.05$) as compared with saline stimulation. ATP alone was negative in this respect. In endothelial

cells, ICAM-1 expression was upregulated after stimulation with either Hx or with Hx-ATP complexes as compared with saline stimulation ($p<0.05$). Again ATP alone did not affect ICAM-1 expression.

Conclusions: Endothelial cells are activated by both Hx or HX-ATP complexes equally, whereas monocytes are activated by Hx-ATP complexes and to a lesser extent by Hx. This may reflect the in vivo situation, i.e. enhanced pro-inflammatory stimulation in PE (due to inactivated Hx and enhanced plasma ATP), and moderate stimulation in healthy pregnancy associated with increased plasma Hx activity.

PUB418

Renal Lymphangiogenesis in Experimental Proteinuric Nephropathy Parallels Fibrosis-Development over Time Saleh Yazdani,[1] Menno Hovingh,[1] Maartje C.J. Slagman,[1] Andrea B. Kramer,[1] Klaas A. Sjollema,[3] Gerjan Navis,[1] Harry Van Goor,[2] Jacob Van den Born.[1] *[1]Nephrology, University Medical Center, Groningen, Netherlands; [2]Pathology, University Medical Center, Groningen, Netherlands; [3]Microscopy Center, University Medical Center, Groningen, Netherlands.*

Background: Renal lymphangiogenesis was reported in transplantation and in nephropathies with interstitial fibrosis, mostly cross-sectionally. Proteinuria (UP) is an important cause of progressive renal fibrosis. Whether UP in itself could trigger a renal lymphangiogenic response has not been established, moreover, the temporal relationship between development of fibrosis and lymphangiogenesis is unknown.

Methods: To evaluate the time course of lymph vessel (LV) formation related to UP and morphological damage we studied unilateral adriamycin nephropathy (1.5 mg/kg; left kidney clipped for 12 minutes), UP was measured and rats sacrificed at 6, 12, 18, 24, and 30 weeks after nephrosis induction, and kidneys were harvested (n=6 /time point). LVs were quantified by tissue FAXS/Image J using podoplanin/VEGFR3 IF double staining. Myofibroblasts (α-SMA), collagen III, macrophages (ED1), lymphangiogenic factors VEGF-C and -D and focal glomerulosclerosis were also quantified.

Results: After 6 weeks UP (100-200 mg/24h) was established however without influx of interstitial macrophages, myofibroblasts, collagen III deposition and LV formation. LV density gradually increased over time (18.6 ± 3.4 LV/HPF at 30 wks vs. 4.6 ± 1.5 at 6 wks; $p<0.0001$), especially in fibrotic regions. Increase in LV density was associated with macrophage and myofibroblast numbers, focal glomerulosclerosis and proteinuria (all $p<0.05$). Besides, increase in LV size was observed over time. VEGF-C was expressed by interstitial cells, VEGF-D by tubular epithelium. All parameters remained low in non-adriamycin exposed kidneys.

Conclusions: UP up to week 6 is not associated with renal lymphangiogenesis. However, subsequent chronic proteinuria induces lymphangiogenesis in temporal conjunction with influx of macrophages and myofibroblasts and development of interstitial fibrosis.Whether modulation of lymphangiogenesis may modulate fibrosis development should be subject of future studies.

PUB419

The Prognostic Significance of Crescentic Lesions in IgA Nephropathy Abdulkareem Alsuwaida,[1] Mohammed A. Al-Ghonaim,[1] Hala M. KFoury,[2] Sufia Husain.[2] *[1]Medicine, King Saud University, Riyadh, Saudi Arabia; [2]Pathology, King Saud University, Riyadh, Saudi Arabia.*

Background: Oxford classification of IgA Nephropathy has been developed to predict renal outcome. However, this classification system does not include crescentic lesions. The objectives is of this study is to assess the prognostic significance of crescentic lesion in predicting renal outcome.

Methods: A retrospective review of all biopsied cases of IgA nephropathy from May 1998 to May 2011 was undertaken done at the King Khalid University Hospital, Saudi Arabia. The renal biopsy routine slides were reexamined and clinical and laboratory parameters were also collected. Predictors of worsening of renal function (WRF), which was defined as 50% increment in baseline serum creatinine, were examined.

Results: Among 59 patients included in the study 17 (28.3%) had histological evidence of crescentic lesion. Baseline levels of serum creatinine, but not proteinuria, were significantly higher ($p = 0.01$) in the patients with crescentic, versus patients without crescent (310 umol/l vs. 137 umol/l, respectively). Worsening of renal function was observed in 11 patients (18.3%). The odd ratio of WRF among those with any crescent was 1.37 (CI: 1.02-1.82).

Conclusions: The existence of crescentic lesion is an independent risk factor for WRF among patients with IgA nephropathy. Our data raises the question of whether attempts should be made to incorporate the crescentic lesion into other parameters of Oxford Classifications. This is would allow more precise prediction of renal outcome.

PUB420

Tamm Horsfall Protein Promotes Adherence of Uropathogenic Bacteria to Urinary Catheters James M. Bates, Hajamohideen S. Raffi, Satish Kumar. *Medicine/Nephrology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Catheter associated urinary tract infection (CAUTI) is a common problem. Tamm-Horsfall Protein (THP) is urine's most abundant protein and has been shown to bind to uropathogenic bacteria. We hypothesized that Tamm-Horsfall Protein (THP) may adsorb to the surface of urinary catheters and induce bacterial binding. In this study, we determined the effect of THP on adherence of *Escherichia coli* and *Pseudomonas aeruginosa* (*P. aeruginosa*) to silicone and latex urinary catheters.

Methods: *E. coli* strain UTI89 and *P. aeruginosa* (ATCC 27314) were grown in tryptose broth and brain heart infusion broth, respectively for 24 hours at 37°C with 5 uCi/ml of methyl-^{3}H Thymidine (64 Ci/mmol specific activity). The radiolabelled bacteria were washed in Dulbecco's phosphate buffered saline (DPBS) and resuspended in artificial urine with or without THP. The bacterial solutions were incubated with 1-cm sections of the two types of catheter at 37°C. Three sections were removed from each tube at 1, 6 and 24 hrs, and washed with DPBS. Bacterial binding to the catheter segments was measured by scintillation counting. On days 2, 4 and 7, three sections were removed from each tube, and sonicated in DPBS to dislodge the bacteria from the catheters. The bacteria were quantitated by serial dilution and culture on agar. The data were expressed as the mean ± SE and analyzed with Student's t-test.

Results: *E. coli* adherence (expressed as Log CFU/cm catheter), in the artificial urine with THP, was greater to the silicone catheter at 1 hr (6.25 ± 0.17 vs 5.73 ± 0.01, $P = 0.02$), 6 hr (6.08 ± 0.04 vs 5.67 ± 0.13, $P = 0.02$) and 1 day (6.1 ± 0.02 vs 5.57 ± 0.02, $P = 0.00004$) and to the latex catheter at 6 hr (5.95 ± 0.06 vs 5.68 ± 0.05, $P = 0.01$) than in artificial urine alone. *P. aeruginosa* adherence was more to the latex catheter at 2 days (6.7 ± 0.03 vs 5.57 ± 0.01, $P = 0.0003$) in the artificial urine with THP versus the artificial urine alone.

Conclusions: THP facilitates the binding of *E. coli* to both silicone and latex catheters, and the binding of *P. aeruginosa* to latex catheters. THP may play a role in the pathogenesis of CAUTI.

PUB421

Effect of Pioglitazone in Controlling Proteinuria and Renal Failure in Focal Segmental Glomeruloscelosis Induced by Adriamycin in Male Wistar Rats Pratik Das. *Nephrology, Majula Ben Kidney Hospital, Kolkata, India.*

Background: Focal Segmental Glomerulosclerosis (FSGS) results in impaired renal function and proteinuria. Peroxisome proliferator-activated receptor-gamma (PPAR-γ) modulate angiogenesis and PPAR- γ agonists have been shown to be protective in nondiabetic glomerulosclerosis. This study compares the effects of Pioglitazone and Losartan in controlling progressive renal damage in Doxorubicin- induced FSGS.

Methods: Progressive renal damage was induced with I.V. Doxorubicin (5mg/kg) and baseline serum creatinine and 24-hour urinary protein were estimated. The animals were randomized into 4 treatment groups, each comprising of six animals after proteinuria developed at Day-7.Oral treatment was distilled water (control-C),Losartan 9mg/kg/day(L), Pioglitazone 4mg/kg/day (P) or a combination of L and P(L+P), for 8 weeks.24 hour urinary protein was estimated at 14-day intervals, serum creatinine was estimated at Day-63 and excisional renal biopsy obtained. The pathological changes were estimated using a semi-quantitative histological score.

Results: Proteinuria continued to progress in all groups but the degree of proteinuria varied. At Day-21, 35, 49 and 63, L, P and L+P treated rats had significant reduction in proteinuria.

Proteinuria in 24 hours in different groups after adriamycin treatment

Group No.	Treatment	D-0	D-7	D-21	D-35	D-49	D-63
1	Saline treated control (C)	1.72±0.27	40.58±4.47	78.83±10.81	138±7.75	217.43±33.01	302.17±41.36
2	Losartan (L)	1.69±0.26	25.46±1.02	43.67±2.34*	119.55±4.87	134.5±3.58	150.72±3.25***
3	Pioglitazone (P)	1.76±0.23	37.08±1.56	65.33±2.80	120.7±3.05	147.45±5.46	181.22±7.26**
4	Losartan+ Pioglitazone (L+P)	1.83±0.22	32.03±2.83	39.15±3.25**	91.85±3.58**	135.27±2.87*	140.4±3.31***

* $p<0.05$; ** $p<0.01$; *** $p<0.001$

Doxorubicin caused significant rise in serum creatinine in C rats from D-0 to D-63 . P and L+P treatment caused significant reduction in serum Creatinine. Histological changes reflected the protective nature of both drugs.

Conclusions: Pioglitazone controls the rise in serum creatinine in Doxorubicin -induced glomerulosclerosis. Combining Losartan with Pioglitazone produced greater reduction of proteinuria, serum creatinine and sclerosis.

PUB422

Calcium Oxalate Crystal Deposition Is Associated with Production of More Urinary Osteopontin, Monocyte Chemoattractant Protein-1 and Kidney Injury Molecule Than Hyperoxaluria Alone in an Experimental Rat Model Saeed R. Khan, Aslam Khan. *Pathology, University of Florida, Gainesville, FL.*

Background: Calcium oxalate (CaOx) crystal deposition in the kidneys is associated with renal injury. The cause of injury, oxalate (Ox) or CaOx crystals, has been argued. Since short term experimental hyperoxaluria does not produce CaOx crystal deposition in all the rats, we decided to investigate this issue by comparing renal and urinary changes in hyperoxaluric rats with and without renal CaOx deposits.

Methods: Male Sprague-Dawley rats were fed a diet containing 5% HLP for 28 days. 24 hour urine was collected on days 7, 14, 21 and 28. After that rats were sacrificed and their kidneys processed for various microscopic and molecular investigations.

Results: All rats, with and without renal CaOx crystals on 28th day, significantly increased their urinary Ox by day 7. Those with crystals excreted more Ox. With time however, differences in urinary Ox between the two groups decreased. It was highly significant ($p<0.001$) on day 7, less significant ($P<0.01$) on day 14 and even lesser ($p<0.05$)

on day 21. No statistically significant was seen on day 28, the last day. Urinary citrate and calcium were not significantly affected by hyperoxaluria. Significant increases were seen in urinary excretion of hydrogen peroxide (HP), kidney injury molecule-1 (KIM1), monocyte chemoattractant protein-1 (MCP1) and osteopontin (OPN) by rats with renal crystals than control rats and those without crystals. There was a highly significant increase in renal expression of ED1 and KIM1 as determined by densitometric analyses of western blots.

Conclusions: Increase in urinary excretion of MCP-1 starts as early as day 7 and only by rats with crystal deposits while HP and KIM-1are also increased by day 7 but in both group of rats. Increase in urinary OPN is seen by day 14 in rats with crystals but by 28th day both group of rats showed significant increase in OPN urinary excretion. Results presented here show that both high Ox as well as CaOx crystals are injurious to the kidneys. There are, however subtle differences indicating the possibility that Ox and CaOx crystals trigger different pathways.

p63 Is a Candidate Gene Responsible for Angiotensin II-Induced Glomerular Endothelial Cell Injury in Progressive Glomerulonephritis

Shuji Kondo,[1] Sato Matsuura,[1] Ariunbold Jamba,[1] Maki Urushihara,[1] Yukiko Kinoshita,[1] Toshiaki Tamaki,[1] Tetsuo Morioka,[2] Simon C. Satchell,[3] Peter W. Mathieson,[3] Shoji Kagami.[1] *[1]Department of Pediatrics and Pharmacology, University of Tokushima, Japan; [2]Department of Cellular Physiology, Niigata University, Niigata, Japan; [3]Academic Renal Unit, University of Bristol, Bristol, United Kingdom.*

Background: Angiotensin II (ang II) is a key mediator for development of glomerular hypertension and glomerulosclerosis. Glomerular endothelial cell (GEnC) plays a crucial role in the initiation and progression of glomerulonephritis (GN). However, little is known about gene expression for ang II-induced GEnC injury and its contribution to progression of GN.

Methods: Profiling gene expression of RNAs from immortalized human GEnCs stimulated by ang II (10^{-8}M) for 0, 4, 12, and 24 hours was performed. Progressive GN was induced in rats by injection of anti-Thy-1 antibody and unilateral nephrectomy and was treated with or without ang II receptor blocker (ARB; Valsartan). Gene analyses were performed by using RNAs in isolated glomeruli from control rats, vehicle-, and ARB-treated nephritic rats on day 14. Gene analyses were carried out using whole human genome oligo microarray (Agilent).

Results: Among 41,000 genes of GEnC, ang II upregulated 111 genes more than 1.5-fold during the course of experiments. Nephritic rats showed the increase of 2,632 glomerular genes more than 2-fold compared to control on day 14. ARB treatment attenuated 408 glomerular genes of those upregulated genes to the control level. By comparing 111 transcripts of GEnC with 193 human genes converted from 408 rat genes in GN, p63, which is considered as a cell senescence inducible- and tumor suppressor protein (Nat Cell Biol 11: 1451-1458, 2009), was identified as a candidate gene responsible for development and progression of GN. Finally, western blot and immunostaining showed that the increased level of GEnC-p63 expression was paralleled with progression of GN and was suppressed with ARB treatment.

Conclusions: p63 is a candidate gene responsible for ang II-induced GEnC injury in the development and progression of GN.

PUB424

Inhibition of NFkB Acetylation Improves Kidney Injury in a HIVAN Mouse Model

Ruijie Liu,[1] Yifei Zhong,[2] Peter Y. Chuang,[1] John C. He.[1] *[1]Dept of Medicine, Div of Nephrology, Mount Sinai School of Medicine, New York, NY; [2]Div of Nephrology, Longhua Hospital, University of Chinese Traditional Medicine in Shanghai, Shanghai, China.*

Background: Nuclear factor kappa B (NF-kB) pathway plays a critical role in the pathogenesis of HIV Associated Nephropathy (HIVAN). Activation of the NF-kB pathway is regulated by the acetylation of p65, a subunit of the NF-kB dimer, at the K310 residue by acetyltransferase coactivator p300. The bromodomain (BRD) is a conserved structural module found in many acetyltransferases, including p300, that recognize acetyllysine. Here, we examined whether a bromodomain inhibitor (BRDi) is able to suppress the NF-kB pathway and attenuate kidney injuries in a well-established animal model of HIVAN (Tg26).

Methods: p65 acetylation and NFkB activation in human renal tubular epithelial cells (RTEC) were determined by western blotting and reporter assay, respectively. The expression of NFkB target genes was profiled using microarrays and qRT-PCR arrays. BRDi (0.08mg/kg/day) was given to Tg26 and control littermates by daily gavage for 4 weeks. Renal function and mortality were monitored. Urine, serum, total kidney, and glomeruli were collected. Renal function, proteinuria, renal pathology and acetylation of p65 were determined.

Results: BRDi inhibited the acetylation of p65 (K310) and transcriptional activity of NFkB in human RTEC that were either treated with TNF-alpha or infected by a HIV-pseudotyped virus. Gene expression PCR arrays and microarray studies showed that BRDi treatment inhibited several NFkB-targeted genes related to apoptosis, inflammation, and oxidative stress. BRDi treatment of Tg26 mice significantly lessened proteinuria, improved kidney function, attenuated tubular injury, reduced p65 acetylation, and decreased renal expression of NF-KB target genes.

Conclusions: Our studies demonstrated that the BRDi could be developed as a potential pharmacologic agent for the treatment of patients with HIVAN.

Lack of Flow in Dilated Renal Tubules in Murine Model of HIV-Associated Nephropathy

Olumuyiwa Omolayo, Jeremy S. Leventhal, Michael J. Ross. *Mt Sinai Division of Nephrology, Mt Sinai School of Medicine, New York, NY.*

Background: HIV-associated nephropathy (HIVAN) is the most common cause of end stage renal disease in HIV-infected patients. Histopathologic findings in HIVAN include collapsing glomerulosclerosis and severe tubulointerstitial disease with microcystic dilation of the renal tubules. Severity of tubulointerstitial disease is the best histologic predictor of progression to ESRD in most forms of chronic kidney disease. We therefore hypothesize that in HIVAN, renal tubular obstruction leads to increased intratubular pressure and dilatation resulting in decreased glomerular filtration and glomerular collapse. In these studies, we tested the hypothesis that dilated renal tubules in kidneys of HIV-transgenic mice, which develop a renal phenotype identical to HIVAN, do not have flow.

Methods: We injected HIV-transgenic mice and wild-type mice with 3kDa Texas Red-conjugated dextran which is freely filtered across the glomerulus and large, non-filterable, 500kDa fluoresceinated dextran. Kidneys were then analyzed for presence of fluorescent dextran in tubules, glomeruli and blood vessels. Tubules with preserved flow were detected by the presence of red fluorescence and tubules without red fluorescence were presumed to have no flow. Green fluorescence was used to identify patent blood vessels.

Results: High molecular weight dextran was detected within glomeruli and peritubular capillaries but not within tubules, confirming that it was not filtered by glomeruli. Low molecular weight dextran was detected in cells lining normal-appearing tubules in wild type and HIV-Tg mice but not in dilated tubules in HIV-Tg mice. The pattern of punctate sub-apical fluorescence suggests that the red dextran was localized to endocytic vesicles.

Conclusions: These results suggest that in HIVAN, as tubules become dilated, they lose flow. However, we have not ruled out the possibility that the lack of fluorescence in dilated tubules reflects impaired endocytosis in these cells. Further studies are needed to determine the role of loss of tubular patency in the progression of HIVAN and other chronic kidney diseases.

In-Dwelling Urinary Catheter Reduces the Protective Effect of Tamm-Horsfall Protein Against Urinary Tract Infection

Hajamohideen S. Raffi,[1] James M. Bates,[1] Zoltan G. Laszik,[2] Satish Kumar.[1] *[1]Medicine/Nephrology, University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]Pathology, University of California San Francisco, San Francisco, CA.*

Background: We have demonstrated previously that Tamm-Horsfall Protein-deficient ($THP^{-/-}$) mice, created in our laboratory, have increased susceptibility to experimental urinary tract infection (UTI) when compared to $THP^{+/+}$ mice. In this study we determined if the protective effect of THP against UTI persisted in presence of an in-dwelling urinary catheter.

Methods: Mouse urinary catheters were made from 2 cm. long segments of polyethylene tubing with a spiral portion at one end and a straight portion on the other end. The catheters were mounted on a stylet and introduced trans-urethrally into $THP^{+/+}$ and $THP^{-/-}$ mice (n = 7) under anesthesia, after collecting baseline urine samples. The end of the catheter outside the urethral meatus was trimmed. *E. coli* strain UTI 89 was propagated and a 10 ul aliquot of a suspension containing 1 x 10^8 bacteria /mL was introduced from the side of the indwelling catheter using a Hamilton syringe. The mice were housed in individual cages and allowed to eat and drink ad lib. On days 2 and 7, urine was collected and cultured on EMB agar. The mice were euthanized on Day 8 with CO_2 narcosis. Bladder and kidneys were removed aseptically and divided into two portions. One portion was homogenized and cultured on EMB agar; the other was processed for histological assessment.

Results: Results showed that the number of bacteria excreted in urine and the bacterial loads in bladder and kidneys were not statistically different between $THP^{+/+}$ and $THP^{-/-}$ mice. The number of bacteria bound to the catheter surface was also not statistically different between the two groups.

Conclusions: These findings imply that the protective effect of THP against UTI is lost in presence of an in-dwelling urinary catheter. Restoring the protective effect of THP against UTI in patients with in-dwelling urinary catheters may help reduce the burden of catheter-associated UTI.

Cardiorenal Syndrome Type 1 May Be Immunologically Mediated

Grazia Maria Virzì,[1,3] Massimo de Cal,[1] Chiara Bolin,[2] Dinna N. Cruz,[1,3] Claudio Ronco.[1,3] *[1]Nephrology, S Bortolo Hosp; [2]Internal Medicine, S Bortolo Hosp; [3]IRRIV, Vicenza.*

Background: Cardiorenal syndrome type1 (CRS1) is characterized by acute worsening of cardiac function leading to AKI. CRS1 pathophysiology is complex and unclear.

An alteration of immune response has been postulated as a potential mechanism involved in CRS1, but has not been demonstrated.

The aim of this pilot study was to demonstrate that plasma of pts with CRS1 was able to trigger off a response in monocytes which resulted in apoptosis. In fact, monocytes have a central role in initiation, development and outcome of the immune response.

Methods: In this study, we compared the differential responses of U937 monocytes incubated for 24 hours with plasma (50%) from pts with CRS1, with acute heart failure(HF) and healthy control(CTR), to verify the behaviour of immunologic cells when exposed to the disease environment.

AKI and CRS1 was defined according to the current classification systems.

We evaluated apoptosis by fluorescence microscope (expressing as percent of the total cell population) and Caspase3, that is indispensable for chromatin condensation and DNA fragmentation in apoptosis.

Results: We enrolled 5 CRS1pts (3M/2F; mean age 75±11yrs; mean crea 1,1±0,2mg/dl, mean eGFR 72±13mL/min/1.73m^2), 7 HFpts (7M; 67±10yrs; 1±0,1mg/dl, 85±10mL/min/1.73m^2) and 5CTR (3M/2F; 63±8yrs).

Mean plasma-induced apoptosis in U937 was 28% for CRS1group while it was 16,5% for HF and 4% for CTR, at 24 hours.

Monocytes showed a greater apoptosis when incubated with plasma from CRS1pts compared to other 2groups.

There was marked proapoptotic activity in monocytes incubated with plasma from CRS1pts. In these preliminary results, Caspase3 was elevated: it was higher in CRS1(7,7ng/ml) when compared to HFgroup (5,6ng/ml) and CTR(4,1ng/ml).

It is likely that apoptosis of U937 cells may be due to presence of factors in CRS1 plasma (i.e. cytokines).

Conclusions: This is the first study that demonstrate a higher proapoptotic activity in plasma of CRS1pts. It suggests a possible immune-mediated process in CRS1 pathophysiology. The present study has some limitations: cohorts of pts was small and the paracrine signaling pathways and the factors involved did not analyze.

The Role of Mannan-Binding Lectin Pathway Activation and Interaction with Apoptosis Pathway in the Pathogenesis of Diabetic Nephropathy

Weihua Wu, Songmin Huang, Ping Fu. *Department of Nephrology in Western China Hospital, Sichuan University, Chengdu, Sichuan, China.*

Background: To study the role of MBL pathway activation and downstream mechanisms in experimental STZ-induced diabetic nephropathy.

Methods: Diabetes was induced by a single intravenous injection of streptozotocin dissolved in citrate buffer . The end of 2rd week, 4th week, 6th week and 8th week after modeling were considered as observation time points. With ligation of proximal of abdominal aorta, a catheter was inserted into distal of abdominal aorta. One part of kidney was fixed in 4% paraformaldehyde for 48 hours, and then embedded in paraffin for histological examination and immunohistochemical staining. The other part of kidney were frozen rapidly in lipuid nitrogen used for RT-PCR examine and Western Blotting examine.

Results: (1) the 2th week after modeling, ACR and plasma glucose of DN group were significantly higher than control (P< 0.05), with modeling extended, both 24-h PRO and ACR of DN group were higher than the control; (2) It is showed by immunohistochemistry that MBL-A, MBL-C, NF-KAPPA, MAC and C3 depositions were significantly higher than the control (P <0.05); (3) It was showed by western blotting that MBL-A, MBL-C and MAC deposition than the control (P <0.05). (4) at the end of 2 week after modeling, CD26 and CD91 expression in DN kidney tissue increased at the end of 2th week after the modeling and reached the peak and the end of 8th week, and Western Blotting examine also supported the results.

Conclusions: (1)MBL pathway activation in diabetic nephropathy may be related to inflammation in diabetic nephropathy. (2) MBL possibly through CD26, CD91 and further amplified with the downstream effects; (3) MBL may be involved by identifying apoptotic cells and apoptotic cell clear, and further activation of endoplasmic reticulum stress

Obesity Is Associated with Increase in Glomerular Size in Renal Transplant Recipients

Sanjeev Akkina,[1] Vishal K. Varma,[2] Grace Chabala Chibesakunda,[1] Suman Setty.[2] *[1]Medicine, University of Illinois at Chicago, IL; [2]Pathology, University of illinois at Chicago, IL.*

Background: Obesity-related glomerulomegaly has been well described but little is known about the pathogenesis of the disease. Newly transplanted renal allograft recipients with various body mass index (BMI) and serial protocol biopsies provide a unique opportunity to examine the progression of glomerulomegaly.

Methods: Renal transplant recipients in the first year after transplant with at least 2 protocol biopsies 3-12 months apart (n=37) were studied. Recipient BMI at the time of transplant was noted and individuals were grouped as non-obese (BMI < 30, n=14) or obese (BMI >= 30, n=23). A subset was categorized as normal (<=25, n=8) or morbidly obese (BMI >=35, n=10). Surface area of three to nineteen glomeruli per biopsy was measured using the Aperio software. Only glomeruli with either the vascular or tubular pole present were analyzed. The percentage change between the average glomerular surface area of the paired biopsies was compared using the paired t-test.

Results: The change in surface area over time was as follows: Non-obese, (<=30), n=14, mean change -6.38% +/- 15.9% and Obese, (>30), n=23, mean change 6.0% +/- 25.9% (p=0.1171); Normal (<=25), n=8, mean change -7.46% +/- 12.9% and Obese (>=35), n=10, mean change 14.7%/- 25.4% (p= 0.0403).

Conclusions: Alteration in glomerular surface area is observed in renal transplants. Normal individuals had a reduction in surface area which is contrary to the expected adaptational response due either to early ischemia or immunosuppressive therapy. The extremely obese group developed glomerulomegaly which, though consistent with an adaptational response, is tempered by the same effects as seen in the normal group. The differences in the obese vs. non-obese group, while as not striking, showed the same trend.

Atypical Case of Thrombotic Thrombocytopenic Purpura

Badria M. AlGhaithi,[1] Nasreen H. Mohamed,[2] Christoph Licht.[1] *[1]Division of Nephrology, The Hospital for Sick Children; [2]Pathology, Toronto General Hospital, Toronto, ON, Canada.*

Background: Thrombotic thrombocytopenic purpura (TTP) is a rare thrombotic microangiopathy disorder (TMA), characterized by thrombocytopenia, microangiopathic haemolytic anemia, neurologic abnormalities, renal impairment, and fever. TTP is caused by deficiency of the von Willebrand factor cleaving protease (VWFCP), ADAMTS-13, which cleaves the VWF multimers produced by endothelial cells. In the absence or abnormal ADAMTS-13, ultralarge VWF multimers occur, which bind platelets and promote clot formation. Different from the typical presentation of TTP, we report a case with ADAMTS-13 deficiency who presented with malignant hypertension and progressive kidney failure.

Methods: Retrospective review of the medical record.

Results: A 15 year old girl, presented with a hypertensive crisis (BP 190/110 mmHg) with features of chronic hypertension (i.e. exudative hypertensive retinopathy). Investigations revealed creatinine 191 umol/L, hemoglobin 94 g/L, platelets 113x10^9/L, and signs of hemolysis. Ultrasound demonstrated normal kidneys with no renal artery stenosis. Our impression was atypical hemolytic uremic syndrome (aHUS) and/or TTP. Renal function rapidly deteriorated. Thus, a renal biopsy was performed demonstrating TMA a diagnosis confirmed via repeat biopsy 6 months later. Hence, the patient was commenced on plasmaphersis (TPE) and maintained on intermittent hemodialysis (IHD). While complement work up was normal, ADAMTS-13 activity level was <5% with no mutations or antibodies detected. Recovery of renal function was noted at 6 months; therefore, IHD and TPE were slowly weaned off. Three months later, the patient had a mild disease recurrence coinciding with severe hypertension which was controlled by few sessions of plasma infusions.

Conclusions: This case is remarkable as a hypertensive crisis was the first manifestation of TTP in this female adolescent. Furthermore, ADAMTS-13 activity was only initially decreased but returned to normal upon TPE and remained normal even at the first disease recurrence. While the patient is currently stable off hemodialysis further TTP crises have to be anticipated – a scenario for which we may consider rituximab treatment.

PUB431

The Damage of Glomerular Podocytes and Its Manifestations Resulted from Aristolochic Acid

Hong Cheng, Yi-Pu Chen. *Division of Nephrology, Beijing Anzhen Hospital, Capital Medical University, Beijing, China.*

Background: In our previous research work I found that some patients with acute aristolochic acid nephropathy presented massive proteinuria, so we designed this study to investigate whether aristolochic acid can damage glomerular podocytes and, if so, what are its manifestations?

Methods: Eighteen male SD rats were equally divided into the following 2 groups: model group in which the rats received the extract of *Aristolochia manshuriensis Kom (AmK)* by gavage; control group received tap water only by gavage. 24h urinary protein excretion was measured and urinary protein composition was analyzed with SDS-PAGE electrophoresis at the end of the 1st and 4th week, respectively. At the end of the 4th week, all the rats were sacrificed and their kidney tissue was collected for electron microscopic analysis and laser capture microdissection of glomeruli. The average widths of glomerular foot process were measured by electron microscopy and image analysis. The mRNA expression of nephrin, podocin, CDA2P, podocalyxin and podoplanin in microdissected glomeruli was determined by real time RT-PCR.

Results: At the end of the 4th week, 24h urinary protein excretion in the model group was significantly higher than that in the control group (13.8±2.4mg/d vs 10.4±1.8mg/d, *P*<0.01) and the urinary protein composition in the model group was presented as mixed pattern of glomerular and tubular protein. The segmental effacement of glomerular foot process in the model group was observed, and the average widths of glomerular foot process in the model group were significantly larger than those in the control group (0.36±0.06mm vs 0.26±0.02mm, *P*<0.01). The mRNA expression of nephrin, podocin, CDA2P, podocalyxin and podoplanin in glomeruli was significantly down-regulated in the model group compared with the control group. Their mRNA expression was reduced 34%, 62%, 56%, 50% (*P*<0.01) and 27% (*P*<0.05), respectively.

Conclusions: Aristolochic acid can damage the glomerular podocytes, leading to the down-regulation of nephrin, podocin, CD2AP, podoplanin and podocalyxin mRNA expression in podocytes, the segmental effacement of foot process, and proteinuria.

PUB432

Generation of Heme Oxygenase (HO)-1 Deficient Rats Using Zinc Finger Nuclease (ZFN)-Mediated HO-1 Gene Disruption

Pu Duann, Elias A. Lianos. *Medicine, RWJ Medical School, New Brunswick, NJ.*

Background: We have previously shown that, compared to renal tubules, the ability of rat glomeruli to upregulate the cytoprotective enzyme, HO-1, in response to natural HO-1 inducers or injury is limited, the least capable cell being the terminally differentiated GEC (J Lab Clin Med, 147[3], 150, 2006). Since the role of GEC in regulating glomerular

filtration and permeability to protein can best be studied in the rat, we generated rats with HO-1 gene disruption using a zinc finger nuclease (ZFN)-mediated gene disruption system. The ZFN reagents employed targets the HO-1 sequence 5'-GGT GGC CCA CGC ATA tac ccg cTA CCT GGG TGA CCT CTC AG-3' within Exon 3 of the rat hmox1 gene. Underlined sequences are recognized by the right and left ZFNs, respectively, and are separated by 7-bp spacer sequences where the nuclease domains interact to cause a double strand break. 149 Sprague Dawley (SD) embryos were microinjected with hmox1 specific ZFN messenger RNAs. 78 out of 149 embryos were transferred to pseudopregnant SD females and 18 live pups were obtained. Screening for target gene (hmox1) disruption revealed three distinct founders; HO1-m1, HO1-m2 and HO1-m3. The HO-m3 founder was further characterized and found to contain a 10-bp frameshift deletion. We then obtained a backcross generation (N2) of heterozygotes (hmox+/-) from this founder, with five individual pups inheriting the HO1-m3 frameshift mutation among a litter of eleven. By cross-mating these 5 heterozygotes, we have since obtained a total of 31 N3 pups, of which two were homozygotes (hmox-/-) for the 10 bp frame-shift mutation as confirmed by PCR-based genotyping coupled with Surveyor nuclease mutation detection assay. Further, this mutation was stably heritable and the absence of the hmox1 gene and protein in tissues was validated. The N3 homozygotes are surviving to-date, and this represents a 6% yield that is superior to the one achieved using the sequence-mediated gene disruption approach previously reported in HO-1 knock-out mice (PNAS, 94[20], 10919, 1997; J Clin Invest. 103[8], R23, 1999).

Conclusions: The HO-1 deficient rat can enhance our understanding on the role of HO-1 in nephron physiology.

Angiotensin II Induces Mesangial Cell Apoptosis Via TLR4/MyD88 Pathway

Jinlei Lv,[1] Hong-Bo Xiao,[1] Qinkai Chen,[1] Guohua Ding.[2] *[1]Division of Nephrology, First Affiliated Hospital of NanChang University, NanChang, JiangXi Province, China; [2]Division of Nephrology, Renmin Hospital of Wuhan University, WuHan, HuBei Province, China.*

Background: Angiotensin II(Ang II) could induce mesangial cell(MC) apoptosis both in vivo and in vitro, but the precise mechanisms are far from well understood. Toll-like receptors (TLRs) have been identified to be functional receptors for response to innate immune events and present in the kidney. It is reported recently that Ang II contributes to the TLR4 expression on MC. However, evidence for the role of TLR4 in the Ang II mediated MCs apoptosis and the direct effect of candesartan on TLR4 expression in MCs is paucity. The aims of the present study were to investigate the involvement of TLR4 and its proximal adaptor myeloid differentiation factor 88(MyD88) in Ang II-induced MC early apoptosis and its possible mechanism as well as to examine whether candesartan has direct effects through this pathway.

Methods: MC was cultured in DMEM medium and treated with candesartan and/or Ang II. Apoptosis was determined by Hoechst staining and flow cytometry with annexinV-FITC and propidium iodide. The intracellular formation of reactive oxygen species(ROS) was detected by confocal microscopy with fluorescent probe CM-H2DCFDA. TLR4 and MyD88 mRNA expression were determined by reverse transcription-polymerase chain reaction. TLR4 protein was evaluated by western blotting.

Results: Ang II induces MC oxidative stress and apoptosis in a time-dependent manner. Ang II upregulates TLR4/MyD88 mRNA expression as well as TLR4 protein synthesis significantly,and causes intercellular ROS acumulation, and subsequently apoptosis on MCs. Candesartan inhibits the above effects dramaticly.

Conclusions: These results support our hypotheses firstly that TLR4/MyD88 pathway is involved in the process of Ang II-induced apoptosis through the up-regulation of intracellular ROS formation, candesartan suppresses MC apoptosis via a direct action that depends on this pathway.

Localization of the G-Protein-Coupled Receptor 40 (GPR40) in the Kidney

Seong Kwon Ma,[1 AND 2] Jianchun Chen,[1] Raymond C. Harris,[1] Jian-Kang Chen.[1] *[1]Medicine, Vanderbilt University, Nashville, TN; [2]Internal Medicine, Chonnam National University School of Medicine, Gwangju, Korea.*

Background: GPR40 is a seven transmembrane G protein coupled receptor that is activated by long chain fatty acids. Although GPR40 has been shown to play a role in insulin secretion in pancreatic islets, its role in other organs, including the kidney, is still undetermined. As a first step in understanding potential roles in the kidney, our initial studies were directed at determining the sites of expression along the nephron.

Methods: Expression of GPR40 was determined in male Balb/C mice by semi-quantitative RT-PCR, immunoblotting, and immunohistochemical and double- or triple-labeling immunofluorescent staining with nephron-segment specific markers

Results: Initial experiments detected GPR40 mRNA expression in the kidney. Immunoblotting analysis was used to screen for an antibody specifically recognizing for a single band of GPR40 in the homogenates of renal cortex/the outer stripe of the outer medulla (OSOM). Immunohistochemical staining with the identified specific GPR40 antibody revealed the strongest immunolabeling of GPR40 in the majority of renal tubules in OSOM as well as in a subset of cortical tubules. Double- or triple-labeling immunofluorescent staining confirmed that in the cortex, GPR40 was expressed in the THP-, DBA-, and AQP2-positive tubules, with minimal expression in the LTA-positive tubules. However, in the medulla, GPR40 staining was the highest in the LTA-positive tubules of the OSOM but very weak in the THP-, DBA-, and AQP2-positive tubules. The labeling of GPR40 was also prominent in the calbindin-D28K-positive tubules but still relatively weaker than that in the LTA-positive tubules of the OSOM.

Conclusions: Our studies have determined that in the kidney, GPR40 is expressed at the highest levels in the S3 segment of proximal tubule, with an apparent expression in the distal convoluted tubule, connecting tubule, cortical collecting duct and cortical thick ascending limb.

HIV-Induced Down Regulation of Vitamin D Receptor (VDR) Increases Activation of Renin Angiotensin System in Tubular Cells

Divya Salhan, Shabina Rehman, Ashwani Malhotra, Mohammad Husain, Pravin C. Singhal. *Medicine, North Shore LIJ Hofstra Medical School, Great Neck, NY.*

Background: Renin angiotensin system (RAS) has been demonstrated to play an important role in the development of HIV-associated nephropathy (HIVAN). Vitamin D receptor (VDR) has been reported to be a negative regulator of renin transcription. Since the activation of the RAS plays an important role in the progression of HIVAN, we hypothesized that HIV infection may be activating renal cell RAS by dowreguating renal cell VDR expression.

Methods: To have a model of tubular cell HIV infection, mouse tubular cells (MCT) were transduced with either vector only or HIV (NL4-3) constructs. Vector/MCTs and HIV/MCTs were incubated in serum-free media (SFM) fro 24 hours and then followed by protein and RNA extraction. Immunoblotting and real time PCR studies were conducte for protein and mRNA expression for VDR, angiotensinogen (Agt) and renin. Ang II ELISA was carried out on cells prepared under similar conditions. To establish a causal relationship between VDR and the RAS, MCTs were silenced for VDR by transfection of siRNA-VDR and then evaluated for the RAS activation. To confirm relationship between VDR and the RAS, vector/MCCs and HIV/MCTs were treated with vitamin D2 analogue (calcitriol, 25 nM) for 24 hours and evaluated for VDR expression and the activation of the RAS as mentioned above.

Results: HIV/MCTs showed attenuated ($P<0.05$) expression of VDR when compared to control and vector/MCTs. HIV/MCTs also displayed 2-fold enhanced expression of renin. Moreover, HIV/MCTs showed 2.5 fold increase in Ang II (intracellular) when compared to vector/MCTs. Similarly, siRNA-VDR/MCTs displayed activation of the RAS. On the the other hand, Vitamin D treated HIV/MCTs not only showed upregulation (<$P<0.01$) of VDR but also displayed attenuated ($P<0.01$) expression of renin and reduction ($P<0.01$) in intracellular Ang II production.

Conclusions: These findings indicated HIV-induced VDR down regulation promotes RAS activation in tubular cells. The present study provides a mechanistic insight into the RAS activation in HIVAN patients.

Calcineurin Correlates with Endoplasmic Reticulum (ER) Stress in Podocyte In Vivo and In Vitro

Jianling Tao, Rongrong Hu, Xuemei Li, Hang Li, Xue-Wang Li. *Renal Division, Peking Union Medical College Hospital, Beijing, China.*

Background: Podocyte injury is an early phenomenon in diabetic nephropathy. Saturated free fatty acid palmitate was key in causing insulin resistance by inducing ER stress in pancreatic -cells. Our previous in vitro work showed it can also induce podocyte apoptosis via ER stress. If ER stress with altered calcium homeostasis could activate calcineurin, which mediates dephosphorylation of synaptopodin and disrupts the stabilization of cytoskeleton in podocytes, was explored.

Methods: Six, nine, twelve-week-old male C57BLKS/J db/db mice (n=7) and age-matched db/m control mice (n=5) were studied. Twenty-four hour urine protein output (24UP) were assayed. The intensity of Glucose-regulated protein 78(GRP78), calcineurin was co-localized with synaptopodin in renal samples by immunofluorescence(IF) stain. In podocyte treated by palmitate with or without ursodeoxycholic acid, the changes in protein and mRNA expressions of calcineurin were assayed by western blot and real-time PCR. Calcineurin and synaptopodin were co-localized by IF stain.

Results: 24UP of all studied db/db mice were significantly higher than each age matched control ($p<0.05$), and it was significantly higher in 9w and 12w db/db mice compared with that of 6w db/db mice ($p<0.05$). Confocal microscopy showed steadly increased expression of calcineurin and GRP78 in podocytes only in db/db mice with age increase. Palmitate significantly increased cultured murine podocytes calcineurin protein and mRNA expressions time-dependently when loading 0.5 mM (3h, 5h compared with 0h, $p<0.05$) and dose-dependently when loading 0.25-0.5 mM for 5h (compared with control, $p<0.05$). Addition of 10μM ursodeoxycholic acid inhibited calcineurin increase (compared with palmitate treatment group, $p<0.05$).

Conclusions: There has calcineurin activation at the onset of albuminuria in DN animal model. Calcineurin correlates with ER stress in podocytes induced by palmitate in vitro. The inhibitory effect of ursodeoxycholic acid suggests activation of calcineurin, podocyte injury and consequent proteinuria could be ameliorated by relief of ER stress.

Clinicopathological Features and Treatment Discussion on HBV-Associated Endocapillary Proliferative Glomerulonephritis Jian Chen, Yinghao Yu. *Dept. of Nephrology, Dong Fang Hospital, Fuzhou, Fujian, China.*

Background: To discuss the clinicopathological features and treatment on HBV-associated endocapillary proliferative glomerulonephritis.

Methods: A total of 29387 biopsies were included from Jan. 2001 to Oct. 2009. 25 cases were diagnosed as HBV-associated endocapillary proliferative glomerulonephritis by renal biopsy. 10 cases of relatively comprehensive information have been done a retrospective analysis.

Results: 9 cases of acute nephritic syndrome, 4 cases of gross hematuria and 3 of hypertension among the above 9 cases; 5 cases of Hypoproteinemia, 1 case of NS, 4 of oliguria, 3 of acute kindey injury(AKI), 1 of abnormal liver function. Diffuse endocapillary proliferative and neutrophilic leukocyte infiltration could be seen in the diseased glomeruli;Immunoglobulin like IgG, IgM, IgA and C_3, C_4, C_{1q}, Fib deposited in many parts, in which three cases are of "full house" phenomenon;9 cases of HBsAg deposited in the renal tissue, 3 of HBcAg, 2 of HBsAg and HBcAg, Many of them, clinical symptoms disappeared and renal function recovered ,two of these cases proteinuria turned negative ,two had no change after 16 days on average of treatment in the way of treating as acute nephritis. One patient of NS was treated with Lamivudine (100mg qd) and prednisone (30mg qd) and 26 days later the level of proteinuria went down under the nephrotic level proteinuria; one of AKI with high serum HBV-DNA and abnormal liver function was given treatment of Lamivudine (100mg qd) and HD and 26 days later clinical symptoms disappeared, liver and renal function returned normal and the number of serum HBV-DNA decreased.

Conclusions: The main clinical manifestation of HBV-associated endocapillary proliferative glomerulonephritis is acute nephritic syndrome and is worse to primarily endocapillary proliferative glomerulonephritis.In terms of immunopathology,it is more complicate. The principle of treatment is same as that of acute nephritis. Anti-virus therapy works better. Patients of NS can be treated by anti-virus therapy combined with small dose corticosteroid. But the long-term efficacy needs further observation.

PUB438

Association of Podocytopathy and Proteinuria in Membranous Lupus Nephritis Niraj B. Desai,[1] David J. Cimbaluk,[2] William Whittier,[1] Edmund J. Lewis.[1] *[1]Section of Nephrology, Department of Medicine, Rush University Medical Center, Chicago, IL; [2]Department of Pathology, Rush University Medical Center, Chicago, IL.*

Background: In patients (pts) with lupus nephritis, a wide range of proteinuria exists irrespective of the presence of peripheral or mesangial immune aggregate deposition. Biopsies from pts with membranous lupus nephritis (MLN) often exhibit evidence of glomerular involvement overlapping multiple pathogenetic mechanisms. Podocytopathy in pts with MLN may represent an independent pathogenetic process underlying the development of nephrotic range proteinuria.

Methods: We conducted a retrospective clinicopathologic study of pts with a histologic diagnosis of MLN (WHO Va and Vb, n=20) and proteinuria. The degree of immune aggregate deposition in the capillary walls and mesangium was detailed using fluorescent (FM) and electron microscopy (EM). The degree of glomerular epithelial cell effacement and average foot process width (FPW) was detailed using EM. Baseline and follow-up clinical parameters were collected.

Results: Nine pts had subnephrotic range proteinuria (<3 grams proteinuria/gram creatinine [g/g]) and eleven demonstrated nephrotic range proteinuria (≥3g/g). Mean proteinuria (8.3 +/- 5.1 g/g vs. 1.63 +/- 0.83 g/g, p=0.001) and foot process effacement (88.6 +/- 11% vs. 48.3 +/- 36.1%, p=0.002) and average FPW (1798 +/- 736 nm vs. 1000 +/- 333 nm, p=0.008) was greater in the nephrotic group compared to subnephrotic. All biopsies from nephrotic pts demonstrated at least 75% foot process effacement. There were no other significant histopathologic differences between the groups. The nephrotic pts were younger (31.9 +/- 10.8 vs. 44.2 +/- 11.4 years, p=0.02) and demonstrated a shorter time from diagnosis of lupus to time of biopsy (28.6 +/- 26.2 vs. 106.7 +/- 62.8 months, p= 0.001).

Conclusions: The single distinguishing morphologic feature in pts with MLN and nephrotic range proteinuria was diffuse visceral epithelial cell foot process effacement. No association between immune aggregate burden and proteinuria was observed. We conclude that nephrotic range proteinuria in patients with MLN is likely a manifestation of concomitant podocyopathy.

PUB439

Monoclonal Immunoglobulin Deposition Disease without Evidence of Multiple Myeloma or Extra-Renal Involvement Treated with Bortezomib. Two Pilot Cases and Literature Review Kumar Gaurav, Manish Gera, Raj Jeevan. *Nephrology, Internal Medicine Nephrology Inc., Terre Haute, IN.*

Background: Monoclonal Immunoglobulin Deposition Disease (MIDD) can present pathologically as two broad forms: AL/AH amyloidosis, which usually presents with both renal (nephrotic syndrome) and extrarenal (postural hypotension, diarrhea, CHF) manifestations. Secondly, it may present in form of Light/Heavy Chain Deposition Disease (L/HCDD) which may further manifest as AKI, CKD, tubulointerstitial or nephrotic syndrome and less commonly with extra renal features. Incidence of MM in this patient population is about 10-15%. Data on treatment of these patients is limited. In literature, treatment has ranged from Bone Marrow Transplantation to melphalan, chlorambucil and bortezomib. Usually, these treatment regimens are used in presence of multiple organ involvement or multiple myeloma. Literature on treatment of MIDD limited to renal involvement without any extrarenal manifestations or without MM is very sparse.

Methods: We present 2 such cases of MIDD with renal involvement without extra-renal manifestations and without MM. Review of literature was done.

Results: Case A presented with Nephrotic syndrome (10g/24hrs) without any cardiovascular, liver or bone marrow involvement. Renal biopsy was consistent with AL amyloidosis. Patient was treated with bortezomib and dexamethasone. Proteinuria subsided to 1.5 g/24hrs and remains stable without any other organ involvement at 1 year of follow up. Case B presented with AKI. Diagnsotic workup and renal biopsy was consistent with cast nephropathy and LCDD, which in itself is a relatively rare presentation. Patient's AKI got worse requiring Renal Replacement Therapy (RRT). Simultaneous treatment with bortezomib and dexamethasone was initiated. Patient's renal function subsequently improved without further need for RRT and remains stable at 3 years of follow up without evidence of MM.

Conclusions: 1. Both cases of renal limited MIDD demonstrate reasonable response in terms of renal parameters and future development of MM after treatment with bortezomib.

2. Given the favorable side effect profile, bortezomib may be used as a first line of treatment in such patients.

PUB440

A Rare Case of Podocytic Infolding Glomerulopathy Associated with Multiple Myeloma Makoto Harada, Yasufumi Takahashi, Yuji Kamijo, Makoto Higuchi. *Nephrology Internal Medicine, Shinshu University School of Medicine, Matsumoto, Japan.*

Background: Recently, podocytic infolding glomerulopathy (PIG), newly proposed by Joe *et al*, has attracted considerable attention for its rare pathological changes. The glomerular change is characterized by specific lesions of thickened glomerular basement membrane (GBM), which include microspheres, a microtubular structure, or podocytic infolding. Today, there are only a small number of case reports of PIG, and the clinical features and the developmental process of PIG are still unclear. To accumulate the information about PIG, we report a rare case of PIG with multiple myeloma.

Methods: A 79-year-old male was admitted to our hospital for proteinuria, hypergammaglobulinemia, hypoalbuminemia and kidney dysfunction. The patient did not exhibit any autoimmune abnormality, including anti-nuclear antibody, rheumatoid factor, and hypocomplementemia. However, serum, urine and bone marrow examinations revealed the monoclonal IgG(λ) M protein, bence jones protein, and monoclonal plasma cell proliferation, indicating a diagnosis of multiple myeloma. To determine the cause of kidney dysfunction, we conducted a kidney biopsy.

Results: Light microscopic examination showed glomeruli with irregularly thickened GBM and a bubble-like appearance of the capillary walls. There was no deposition of immunoglobulin, light chain, complement, or amyloid protein. Electron microscopic analysis demonstrated a marked unusual structure, which included podocytic infoldings as well as microspheres, in the irregularly thickened GBM, suggesting PIG. The patient was treated with corticosteroid; however, he died due to severe pulmonary infection 2 months after the introduction of steroid therapy.

Conclusions: Here we report the first rare case of PIG with multiple myeloma. The mechanism underlying the development of PIG is still unclear. Several earlier studies reported the association of autoimmunity, while the current case exhibited an obvious immunoglobulin abnormality. These findings suggest a close relation between the PIG development process and immune system abnormality. Further accumulation of case reports is necessary.

PUB441

Correlation of Chemokine Biomarkers in Urine of Patients with Renal Allograft Rejection Mark J. Lerman,[1] Afzal Nikaein,[2] Brandt Moore,[2] Sandra Hinton,[1] Cindy L. Corpier,[1] Judson M. Hunt.[1] *[1]Transplant Services, Medical City Dallas Hospital, Dallas, TX; [2]Transplant Immunology, Medical City Dallas Hospital, Dallas, TX.*

Background: Diagnosis of acute renal transplant cellular rejection or chronic allograft nephropathy is based on serum creatinine (Cr) and invasive biopsies. However, biopsies do not always show graft injuries due to sample size, or section of biopsies. Urine is produced and excreted by the kidney, and therefore, has the potential to reflect injuries to the renal allograft. We have been interested to investigate the presence of bio-markers in urine of patients with or without acute cellular rejection. The bio-markers studied include osteoprotegerin (OPG), monokine induced by interferon-y (MIG) and interferon-y induced protein of kDa (IP-10). These three biomarkers have been shown to increase in urine of majority of renal allograft recipients undergoing acute cellular rejection or BK viral nephropathy, but not in patients with chronic allograft nephropathy or stable graft function.

Methods: Twenty renal transplant recipients who were biopsied for possible rejection were included. Biopsy results were correlated with serum Cr and clinical symtoms. All biopsies were stained for C4d and BK virus. Serum specimens obtained at the time of biopsies were tested for the presence of HLA antibody by solid phase immunoassays. Urine of patients was obtained at the time of biopsies and biomarkers were quantitated in the urine by solid phase immunoassay using luminex technology.

Results: Eight patients were diagnosed with acute cellular rejection, and one with BK viral nephropathy. Level of all 3 chemokines, IP-10, MIG, and OPG was increased in 6

patients with acute cellular rejection. Level of OPG was increased in all 8 patients with acute cellular rejection. Level of 2 chemokines IP-10 and OPG was increased in the one patient with BK Nephropathy.

Conclusions: This preliminary study shows that quantitation of chemokine biomarkers in the urine of renal allograft recipients may correlate with acute cellular rejection. This noninvasive test may be used for diagnosis of rejection and in some cases would eliminate an invasive test which may cause complications with bleeding and infection.

PUB442

Glomerular Involution: A Special Pattern of Glomerular Injury, Not Limited to Patients with Relapsing Minimal Change Nephrotic Syndrome

Rutger J. Maas,[1] Henry Dijkman,[2] Linda Koster-Kamphuis,[3] Jack F. Wetzels.[1] *[1]Nephrology, Radboud University Nijmegen Medical Center, Netherlands; [2]Pathology, Radboud University Nijmegen Medical Center, Netherlands; [3]Pediatric Nephrology, Radboud University Nijmegen Medical Center, Netherlands.*

Background: Glomerular involution is a special pattern of glomerular injury (Kidney Int 2007;71:44). It is distinct from global glomerulosclerosis, and characterized by a reduction in size, the presence of vital podocytes, parietal epithelial cells and the notable absence of periglomerular fibrosis. Involuted glomeruli were detected in children with frequently relapsing minimal change nephrotic syndrome (MCNS). The percentage ranged from 0-33% and depended on the interval between disease onset and renal biopsy. In the present study, we show that glomerular involution is present in renal biopsies of patients with other proteinuric disorders.

Methods: We identified 4 patients with proteinuria and biopsy reports that suggested the presence of glomerular involution. All slides were reviewed, and evaluated for the presence of involuted glomeruli, based on the abovementioned morphologic criteria.

Results: Patient 1 is a child with a compound heterozygous *NPHS1* mutation, with a spontaneous partial remission, and a 2nd biopsy during relapse. Patient 2 has a membranous nephropathy, with 2nd biopsy during relapse. Patient 3 has a mitochondrial nephropathy with FSGS. Patient 4 has a mesangiocapillary glomerulonephritis, with 2nd biopsy during relapse. Characteristics are in the table. The percentage involuted glomeruli ranged from 5-30%. The identification of involuted glomeruli in adults was hampered by the presence of globally sclerosed glomeruli of other types, with surrounding fibrosis.

Patient	Age at disease onset (yr)	Age at biopsy (yr)	Max. number of glomeruli per section	Glomerular involution (%)
1	0	3.2	30	30
2	44.7	62.2	20	15
3	< 30?	49.4	12	8
4	20.0	29.1	24	5

Conclusions: Glomerular involution is not limited to children with frequently relapsing MCNS. Typically, involuted glomeruli were seen in patients with longstanding, limited proteinuria. Additional studies are needed to determine if involution is a significant cause of nephron depletion in adult proteinuric patients

PUB443

ANCA-Associated Systemic Vasculitis Newly Onset in Maintenance Hemodialysis Patients

Huijuan Mao, Changying Xing. *Department of Nephrology, First Affiliated Hosptial of Nanjing Medical University, Nanjing, Jiangsu Province, China.*

Background: ANCA-associated systemic vasculitis (AASV), newly onset in uremic patients maintaining renal replacement therapy for several years, has not been reported before. Here we reported two cases in order to cause the clinical concerntration.

Methods: The two cases, both of male, aged 76 and 65 years old respectively, who underwent maintenance hemodialysis were retrospectively analyzed with clinical information, including diagnosis, treatment and outcome.

Results: The two patients have both maintaining renal replacement therapy for several years because of IgA nephropathy and chronic interstitial nephritis respectively. But they had cough and asthma several months ago,accompanied by fever,fatigue, anorexia; The chest CT scan showed diffuse lung involved.The treatments such as anti-infection and improving heart function didn't get any effect. Subsequently the 2 patients both had ANCA positive results(MPO and p-ANCA both positive). After steroid and cyclophosphamide treatment, those clinical symptoms were relieved obviously and ANCA examinations were negative several month later.

Conclusions: AASV newly onset in uremic patients is so rare that it is easy to be misdiagnosed and missed diagnosed, especially in the early stage. The importance of ANCA examination in the diagnosis should be paid much attention to uremic patients.

PUB444

Mesangial Hypercellular Infantile Nephrotic Syndrome

Olivera Marsenic, Ajla T. Wasti, Zhongxin Yu, Kevin Couloures, Dwayne D. Henry, Martin A. Turman. *Pediatric Nephrology, Oklahoma University Health Sciences Center, Oklahoma City, OK.*

Background: Infantile nephrotic syndrome (NS) is mainly caused by genetic mutations and has poor treatment response and prognosis. Idiopathic diffuse mesangial hypercellularity (DMH) has a good response to treatment and prognosis. DMH is seen in young children with NS, but has not been reported as cause of infantile NS.

Methods: A nine-month-old girl presented with gross hematuria, edema, hypertension, large proteinuria, decreased renal function and hypoalbuminemia. Tests for secondary (infectious and autoimmune causes, malignancy) and primary etiology were obtained. Renal biopsy was performed.

Results: Investigations for secondary NS were negative. Karyotype was 46 XX. Genetic tests for mutations in PLCE1, LAMB2, WT1, NPHS1, and NPHS2 genes were negative for known disease-causing mutations. Histologic testing showed mesangial expansion primarily by increased mesangial cellularity, and mild mesangial sclerosis. Immunofluorescence was negative. Electron microscopy showed expanded mesangial areas by increased cell number and matrix and extensive effacement of foot processes with podocyte hypertrophy and microvillous transformation of the podocyte cytoplasm. No immune type electron dense deposits were seen. She was treated with steroids and supportive treatments. Her renal function normalized and proteinuria improved over two weeks, with gross hematuria lasting 3 weeks. Steroids did not achieve full remission, and Tacrolimus was initiated. Full remission was then achieved with normal renal function, normal blood pressure and no recurrence during 5-month follow-up period.

Conclusions: We suggest that DMH be included in differential diagnosis of infantile NS. It has good prognosis with good response to immunosuppressive treatment and therefore its recognition is important in order to start treatment. This is contrary to NS due to genetic mutations that comprises majority of cases of NS in first year of life, is resistant to immunosuppressive treatment and treatment attempts are not recommended.

PUB445

The Therapeutic Mechanism of Total Flavonoids of Ajuga on Mesangial Proliferative Glomerulonephritis

Weihua Peng. *Dept. of Nephrology, Fuzhou General Hospital, Nanjing Command PLA, Fuzhou, Fujian, China.*

Background: To observe the mechanism of total flavonoids of Ajuga (TFA) on mesangial proliferative glomerulonephritis,we prepared TFA containing serum in vitro.

Methods: The glomerular mesangial cells(GMC)synchronized in the quiescent culture were divided into different groups.After confounding factor added, the cells and medium were collected in 24h&48h to detect the proliferation of GMC by MTT assay.The expression of type IVcollagen (Col-IV)was observed by ELISA assay.Mitotic cycle ofGMC was detected by flow cytometry in 48h.

Results: After 24h&48h, the cell viability had reached more than 95% in four kinds of concentration of drug-containing serum group, respectively, with no cell toxic evidence. The proliferation of GMC and the expression of Col-IV in TFA-containing serum group at 24h&48h were obviously lower than those in LPS group.When acting on GMC for 48h, the GMC percentage in G_1 phases in TFA-containing serum group was obviously higher than those in LPS group, while lower in S phases.

Table1 The influence of TFA on GMC ($\chi\pm s$)

		IOD of GMC		Col-IV (ng/ml)		Cell phase (%)	
	n	24h	48h	24h	48h	G1	S
normal control group (10% normal rat serum)	6	0.219± 0.025	0.321± 0.020	17.60± 5.83	35.20± 19.58	81.44± 5.31	12.29± 2.20
model control group (LPS 10μg/ml and 10% normal rat serum)	6	0.325± 0.026**	0.598± 0.093**	85.95± 38.77**	140.73± 43.51**	60.88± 6.40**	33.51± 3.42**
10%TFAgroups(10μg/ml LPSand 10% concentration of TFA serum)	6	0.231± 0.028ΔΔ	0.307± 0.011ΔΔ	28.75± 13.04Δ	47.72± 14.89ΔΔ	78.15± 3.10ΔΔ	14.26± 1.74ΔΔ
5%TFAgroups(adding 10μg/ml LPS and 5% concentration of TFA serum)	6	0.262± 0.044Δ	0.388± 0.063*ΔΔ	41.54± 18.41*Δ	74.32± 27.62*Δ	70.38± 3.42**Δ	23.51± 2.39**ΔΔ
2.5%TFAgroups(adding 10μg/ml LPS and 2.5% concentration of TFA serum)	6	0.273± 0.038*Δ	0.441± 0.093*Δ	48.97± 16.98**	93.35± 19.68**Δ	68.32± 4.17**Δ	27.48± 2.45**Δ

Notes:Compared with normal control group*P<0.05,** P <0.01;Compared with model control groupΔP<0.05, ΔΔP <0.01.

Conclusions: The research indicated that the TFA might be related to regulate the expression of cell cycle, decrease the proliferation of GMC and the expression of extracellular matrix.

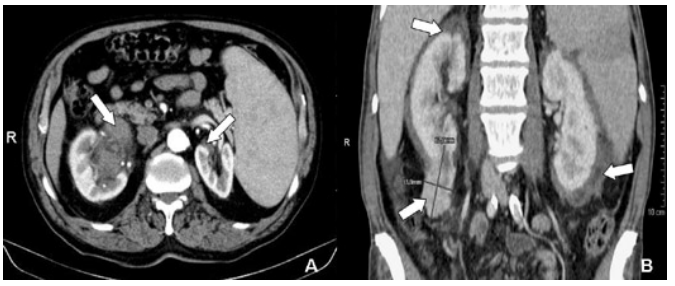
PUB446

Extra Medullary Haematopoiesis in the Kidney: Two Case Reports

Davide Ricci,[1] Marcora Mandreoli,[1] Elena Sabattini,[2] Antonio Santoro.[1] *[1]Nephrology, Dialysis and Hypertension Unit, Policlinico S.Orsola-Malpighi, Bologna, Italy; [2]Hemo-linphopathology Unit, Policlinico S.Orsola-Malpighi, Bologna, Italy.*

Background: The differential diagnosis of renal masses is quite wide and includes tumor, inflammation and various proliferative diseases. Often extramedullary haematopoiesis (EMH) in not considered because the involvement of other parenchymatous organs rather than liver and spleen is rare and there are only sporadic reports concerning kidney.

Methods: Case 1: An eighty-year old patient had a diagnosis of post-polycytemia myelofibrosis. The computed tomography (CT) shows bilateral parapyelic solid renal lesions that can simulate renal carcinoma.



CT guided needle biopsy was then performed. The histological exam showed positive glycophorin cellularity in the erythroid component, positive myeloperoxidases in the myeloid component with negativity for CD34 compatible with extramedullary erythropoiesis.

Case 2: In seventy-nine year old patient with perirenal infiltrating tissue, hepato-splenomegaly and idiopathic myelofibrosis, CT showed bilateral perirenal tissue with modest contrast enhancement (CE) and showed a solid right-inferior polar formation with an intense CE. The CT guided needle-biopsies revealed to the right a clear cell Adeno-Ca, while the bilateral perirenal tissue was an haematopoietic tissue.

Conclusions: Extra medullary haematopoiesis (EMH) in the kidney represents an interesting "speculative challenge" in terms of differential diagnosis in renal masses, tissue biopsy is nullifying. Furthermore the localization of hemopoietic tissue in the kidney, that is not a customary district, raises controversial questions: 1) Does the kidney possess a niche for haematopoietic stam cells (HSCs)? 2) Is the heterotopic haematopoietic tissue a true "station" of hemopoisis or just an aberrant tissue that must be cyto-reduced?

PUB447

Negative Double Stranded DNA and Anti-Smith Antibodies in Severe Lupus Nephritis Gagangeet S. Sandhu,[1] Anip Bansal,[1] Aditi Ranade,[2] James P. Jones.[1] *[1]Nephrology, St. Luke's - Roosevelt Hospital Center, Columbia University College of Physicians & Surgeons, New York, NY; [2]Pathology, St. Luke's - Roosevelt Hospital Center, Columbia University College of Physicians & Surgeons, New York, NY.*

Background: In Systemic lupus erythematosus (SLE) auto-antibodies are generated against a variety of intracellular antigens. Anti-Smith (Sm) and anti-double stranded DNA (dsDNA) antibodies are particularly considered to be nephritogenic. In addition, severe lupus nephritis (LN) may facilitate the process of Anti-Myeloperoxidase (MPO) antibody (p-ANCA) formation by promoting neutrophil degranulation. However, apart from mere seropositivity, ANCAs may have a possible pathogenetic role in LN.

We had a case where the patient had diffuse proliferative "full house" LN with very high serum anti-MPO titers, yet negative ds-DNA and anti-Sm antibodies.

Methods: Review of PubMed literature for cases of lupus nephritis with negative dsDNA antibodies.

Results: Although extremely rare, a few subsets of patients with drug-induced (hydralazine) LN have been described in the literature to have negative dsDNA and anti-Sm antibodies on serological screening. Our patient had no evidence of drug induced LN. On further review, and similar to our case, we found only 6 additional well documented cases of non-drug induced severe LN with negative dsDNA antibodies.

Six cases of non-drug induced lupus nephritis with negative dsDNA antibodies

Number	Age/Sex	Presentation	ANA	ds-DNA	Complements	p-ANCA	Renal Biopsy
1	9/F	Renal Failure	Neg.	Neg.	Normal	N/A	LN type IV
2	8/F	Nephrotic	Neg.	Neg.	Normal	N/A	LN type IV/ V
3	10/F	Nephritic	Neg.	Neg.	Normal	N/A	LN type III
4	10/F	Atypical	Neg	Neg.	Normal	Neg.	LN type III
5	22/F	Renal Failure	1:1286	Neg.	Low	+	LN type IV & ANCA GN
6	50/F	Renal Failure	1:160	Neg.	Low	+	LN type III & ANCA GN
7	29/F	Renal Failure	1:80	Neg.	Low	+	LN type IV/ V

(7) Our patient. Abbreviations: F: female; Neg: Negative; N/A: Not reported; LN: Lupus Nephritis; GN: Glomerulonephritis

Conclusions: Although considered nephritogenic, dsDNA and anti-Sm antibodies may be negative even in patients with severe proliferative LN.

PUB448

Association of Glomerular Podocytopathy and Systemic Lupus Erythematosus Roberto Savio Silva Santos, Daniela Loss Mattedi, Liliany P. Repizo, Lectícia Jorge, Rui Toledo Barros, Viktoria Woronik. *Department of Nephrology, University of Sao Paulo, SP, Brazil.*

Background: The aim of this study was to evaluate the clinicopathologic features of patients with systemic lupus erythematosus and glomerular podocytopathy.

Methods: We performed a retrospective study of 17 patients with SLE diagnosis according of the American Rheumatologic Association, proteinuria and a histologic diagnosis of MCD, mesangial proliferative glomerulonephritis or FSGS.

Results: The baseline clinical characteristics are shown in Table 1.

Clinical Features

Number	17
Age (yr)	34,4(±9,7)
Female	82,4%(14)
Serum Creatinine(mg/dl)	1,3(±0,9)
Albumin(g/dl)	1,8(±0,65)
Proteinuria(g/day)	5(±3,9)
Active urine sediment	35%(6)
C3(mg/dl)	100,5(±46,7)
ANA(>1/80)	88%(15)
Hypertension	41%(7)
Nephrotic Syndrome	88%(15)
Time since SLE diagnosis > 12 months	30,8%(4)

Results of continuous variables are mean SD.

Regarding the histological features: 2 biopsies (11,8%) were normal by light microscopy, 2 (11,8%) demonstrated mesangial proliferation alone, 9 (52,9%) had FSGS and 4 (23,5%) had GESF accompanied by mesangial proliferation. Immunofluorescence showed focal and segmental IgM and/or C3 deposits in 9 biopsies, had only mesangial deposits of IgG, IgM, C3 and C1q and was completely negative in 4 biopsies. The patients were treated with prednisone alone (12) or in association with cyclophosphamide (2), azathioprine (2) or cyclosporine (1). Complete or partial remission occurred 11 patients (65%). At the end of follow-up (82,5 ± 73,9 months) no patient progressed to end stage renal disease (creatinine 0,8 ± 0,16mg/dL; proteinuria 1,2 ± 0,9g/day; serum albumin concentration, 3,6 ± 0,6g/dL). Two patients underwent a second biopsy during nephritic flair and proliferative lupus nephritis was detected. Finally, two patients died from infection complications probably related to the immunosuppressive therapy, one patient received prednisone plus cyclophosphamide and another received prednisone plus azathioprine.

Conclusions: We report 17 cases of patients with SLE and glomerular podocytopathy, that was characterized by nephrotic syndrome, good response to steroid therapy and seems to entail low risk of progression to ESRD.

Funding: Government Support - Non-U.S.

CT Scan Guided Percutaneous Kidney Biopsy Performed by Nephrologists: Description of the Procedure and Outcomes Jinil Yoo,[1] Roger F. Carbajal Mendoza,[2] Nripesh Pradhan,[2] Lin N. Lwin,[1] Hugo J. Villanueva.[1] *[1]Nephrology, Montefiore Medical Center, North Division, Bronx, NY; [2]Renal Service, Metropolitan Hospital Center, New York, NY.*

Background: The real-time ultrasonography has helped nephrologists to obtain adequate kidney tissue with less postbiopsy complications. Currently a CT-guided kidney biopsy is mostly performed by interventional radiologists.

Methods: The Nephrology Division [1] introduced a CT guided percutaneous kidney biopsy with an automated 18-gauge (G) biopsy-cut needle and "matched" 17–G guide-needle in 1999. The biopsies have been performed primarily by nephrology fellows under the supervision of an experienced nephrologist. First, a 17-G guide-needle is introduced and its position in the cortex is confirmed by CT scanning. Then, a 18-G biopsy needle is passed through the guide-needle to obtain 2 cores of tissue, followed by postbiopsy scanning.

Results: During the 11- year period , 107 biopsies in total were performed. 56 out of 107 biopsies were performed on an outpatient (OP) basis (discharged home after 6-hour observation at the ambulatory surgery unit after the procedure) and 51 of 107 were done for in-hospital patients (IP). 107 biopsies in all yielded enough tissues for the light-, immuno-histologic and electron microscopy. 3 out of 107 experienced gross hematuria (2 from IP, 1 from OP), not requiring transfusion, but one from OP required overnight observation. No other significant complications related to the procedure were observed. The average age of the patients: 46 (range of 20 to 87 years), the average counts of glomeruli from each biopsy: 22 (3 to 67 glomeruli) and serum creatinine level: average 3.1 mg /dL (OP: average 2.1 mg /dL with range of 0.6 to 8.4, IP: average 4.2 with range of 0.7 to 12.8 mg/dL).

Conclusions: We believe that a CT-guided percutaneous kidney biopsy technique described above can be performed safely and successfully by nephrologists for diagnostic clarity of more kidney diseases.

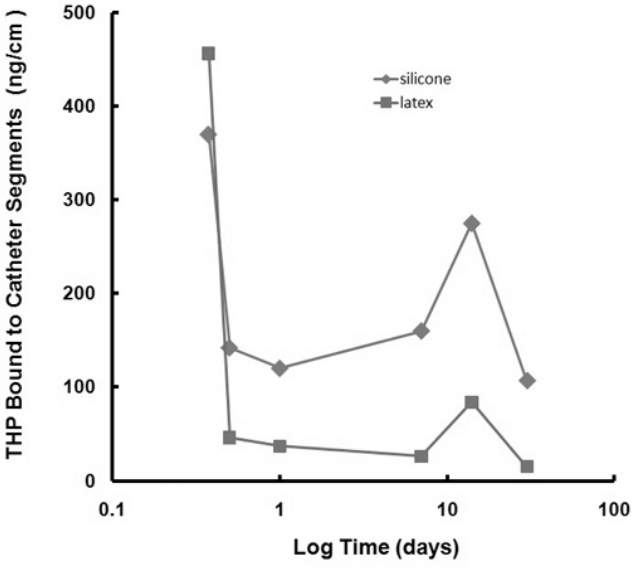
Tamm Horsfall Protein Binds to Urinary Catheters James M. Bates, Hajamohideen S. Raffi, Satish Kumar. *Medicine/Nephrology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Urinary catheters are commonly associated with bacteriuria and frequently with urinary tract infection. Tamm-Horsfall Protein (THP) is urine's most abundant protein and is known to bind to uropathogenic bacteria. We hypothesized that THP may adsorb to the surface of urinary catheters and facilitate bacterial binding. In this study, we determined the adsorption of THP to two common types of catheter in clinical use in the United States.

Methods: Bardex Infection Control (latex) and Lubri-Sil Infection Control (silicone) 20 French catheters were cut into 1-cm segments. The catheter segments were incubated with human urine at 37°C, in sterile, rotating tubes with a daily change of the solutions. Three catheter segments were removed each at 9, 12 and 24 hrs and on days 7, 14 days and 30, and rinsed in PBS. THP bound to the catheter segments was extracted in 0.5 % Triton-X 100/20 mM EDTA/pH 7.5 and quantitated by ELISA.

Results: Both silicone and latex urinary catheters were quickly and equally coated with THP from the first time point at 9 hrs (silicone, 370 ng/cm ± 65 and latex, 456 ± 155 ng/cm). At later time points, more THP was found bound to the silicone catheters than the

latex catheters: 12 hr (142 ng/cm ± 15 vs 46 ± 37 ng/cm, P = 0.001) , day 1 (120 ng/cm ± 4 vs 37 ± 5 ng/cm, P = 0.0001) , day 7 (160 ng/cm ± 33 vs 26 ± 5ng/cm, P = 0.003), day 14 (275 ng/cm ± 41 vs 84 ± 4 ng/cm, P = 0.002) and day 30 (107ng/cm ± 32 vs 15 ± 5 ng/cm, P =0.014). THP binding to urinary catheters increased further after 7 days of incubation.



Conclusions: THP binds to both latex and silicone urinary catheters, and may provide a substrate for bacterial binding. THP binding to urinary catheters begins to increase after 7 days. Catheter removal or change at 7 days may help prevent catheter associated urinary tract infection.

Wnt-7a Counteracts Epithelial to Mesenchymal Transition in Mice of Unilateral Ureteral Obstruction Model Guo-Qin Wang,[1] Pei-Ling Bao,[1] Hong Cheng,[1] Ping Li,[2] Yi-Pu Chen.[1] *[1]Division of Nephrology, Beijing Anzhen Hospital, Capital Medical University, Beijing, China; [2]China-Japan Friendship Hospital, Beijing, China.*

Background: To investigate the protective effect of Wnt protein on renal interstitial fibrosis in unilateral ureteral obstruction(UUO)mice model.

Methods: Eighteen male C57BL/6 mice were randomly divided into 3 groups: sham-operation group, the UUO model group and treatment group; the body weight of mice were measured everyday.All mice were sacrificed at the7th day after the operation.The left kidney was taken for histology evaluation and molecular biology assay. Masson'S stain was performed as an main indicator of interstitial fibrosis. The expressions of vimentin, a-smooth muscle actin(a-SMA), and E-cadherin in renal tissue were detected by immunohistochemistry staining and Western-blot, respectively.

Results: Compared with sham-operation group, body weight of the model group was significantly lower(P<0.05) , and the relative area of interstitial fibrosis was significantly larger(P<0.05) . Furthermore, the expressions of vimentin and a-SMA were significantly up-regulated(P<0.05), and E-cadherins were significantly down-regulated(P<0.05). Compared with model group, all the above-mentioned abnormalities were restored to some extent and showed significant difference (P<0.05) in treatment group.

Conclusions: Wnt protein could decrease the interstitial fibrosis by counteracting epithelial to mesenchymal transition in UUO mice.

Examining the Patient-Centered Decision Making Attributes Towards Blood Transfusion among Individuals with Chronic Kidney Disease Ahmad B. Naim,[1] Danielle Walls,[2] Jan Gollins,[3] Chuck Reynolds.[4] *[1]HECOR, Centocor Ortho Biotech Services, LLC, Horsham, PA; [2]Project Manager, BDJ Solutions, Medford, MA; [3]Principal & Co-founder, Delta Modelling Group, LTD, Mount Prospect, IL; [4]President, Employer Practice, The Benfield Group, St. Louis, MO.*

Background: Examine patient engagement towards blood transfusion among individuals with chronic kidney disease (CKD) currently not on dialysis.

Methods: An online survey was conducted from a nationally representative patient panel in 1Q2011. All respondents were ≥18 years and diagnosed with CKD by a physician. Participants were asked about their blood transfusion history, information seeking behaviors, and knowledge about blood transfusion.

Results: Of 416 respondents: 59%(n=246) female; 40%(n=165) were >65 years. 35%(n=144) had stage4 and 58%(n=240) stage3 CKD. 54%(n=226) were anemic. 43%(n=179) had received blood transfusion, whereas, 57%(n=237) had no transfusions. Among previously transfused, only 50% indicated they shared in treatment decision with their doctor, whereas 40% indicated their doctor or someone else had made the decision for them. Among those who indicated someone else made the decision, 82% indicated that they like to make a shared decision. Among not transfused, only 40% are clear about their treatment choice for blood transfusion and over 75% would like to share decision to have blood transfusion with their doctor. Among not transfused, 30% agree that they are unsure about receiving blood transfusion and less than two-thirds (60%) are likely to stick with their decision to get a blood transfusion. About 39% of not transfused said it is hard to decide if benefits outweigh risks and 38% said that decision is hard for them to make.

Conclusions: There is a substantial lack of patient engagement towards shared-decision making in blood transfusion. Individuals most likely to receive blood transfusion expressed the most uncertainty about their decisions and are least informed about choices, benefits, and risks. These findings suggest that a significant portion of individuals facing a blood transfusion feel disempowered and are interested in engaging in shared-decision making with their physicians.

PUB453

Examining Knowledge and Information Seeking Behaviors Towards Blood Transfusion among Individuals with Chronic Kidney Disease Ahmad B. Naim,[1] Danielle Walls,[2] Jan Gollins,[3] Chuck Reynolds.[4] *[1]HECOR, Centocor Ortho Biotech Services, LLC, Malvern, PA; [2]Project Manager, BDJ Solutions, Medford, MA; [3]Principal & Co-founder, Delta Modelling Group, LTD, Mount Prospect, IL; [4]President, Employer Practice, The Benfield Group, St. Louis, MO.*

Background: Examine knowledge and information seeking behaviors towards blood transfusions among individuals with chronic kidney disease (CKD) currently not on dialysis.

Methods: An online survey was conducted from a nationally representative patient panel in 1Q2011. Respondents were ≥18years and diagnosed with CKD by a physician. Participants were asked about blood transfusion history, information seeking behaviors, and knowledge about blood transfusion.

Results: Of 416 respondents: 59%(n=246) female; 40%(n=165) >65 years; 35%(n=144) had stage4 and 58%(n=240) stage3 CKD. 54%(n=226) were anemic, 43%(n=179) had received blood transfusion, 57%(n=237) had no transfusions. Top 2 sources of information were doctor(93.8%) and Internet(80.5%). Among previously transfused, 62% received right amount of information, 34.6% received too little information, and 3.4% reported receiving too much information. More than 80% of transfused indicated knowing reasons for and benefits of getting a blood transfusion. Less than two-thirds received information about effects, risks, and time it would take; only 26% knew the costs. Over 60% said it is extremely important to know right blood type, screening techniques and quality of blood, and risks of infections. Among previously transfused, only 50% agreed they made an informed choice about receiving blood transfusions. Among previously transfused, 77% agree they knew the benefits vs 49% not transfused. Among previously transfused, 69% agreed they knew the risks of blood transfusion vs 51% with no transfusion history.

Conclusions: Doctor and Internet are primary sources of information about blood transfusions. Gaps in knowledge exist about benefits, risks, and costs of blood transfusions. A significant number feel they need more information about blood transfusion to make an informed choice. Providers should consider adopting shared-decision making with their patients.

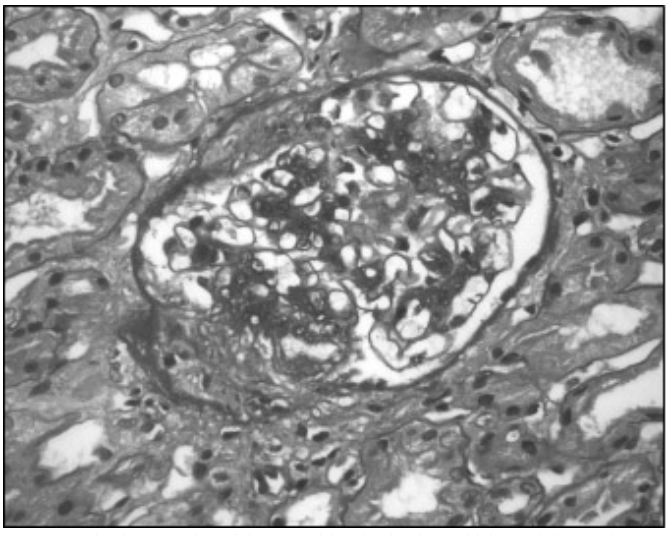
PUB454

Treatment of IgA Myeloma Results in Remission of Henoch-Schonlein Purpura Sandip Sandilya, Coral Parikh, Katherine Rausa, Ladan Golestaneh. *Nephrology, Montefiore Medical Center, Bronx, NY.*

Background: The pathogenesis of IgA nephropathy involves overproduction of IgA and deposition in mesangium, decreased clearance of IgA protein, and inflammatory response to IgA deposition. There are reported cases of the abnormally glycosylated IgA in IgA myeloma.

Methods: We present a patient with recurrent HSP who was diagnosed with IgA-producing myeloma.

Results: A 28 year old man presented with abdominal and joint pain, purpura, recurrent GI bleeds and hematuria over several months. A skin biopsy showed early leukocytoclastic vasculitis with IgA positive immunofluorescence. He was diagnosed with HSP, and flares were managed with high dose steroids. Immunofixation showed an IgA lambda monoclonal protein, and the results of a bone marrow biopsy were consistent with myeloma. His kidney biopsy showed mesangioproliferative glomerulonephritis.



He received two cycles of therapy with velcade, doxorubicin, and dexamethasone, consolidation with cytoxan, and an autologous stem cell transplantation. The patient's hematuria and proteinuria resolved after the stem cell transplant. Subsequent SPEP, quantitative immunoglobulins, and bone marrow biopsy have shown no signs of recurrence of IgA myeloma.

Patient Data

	Before	After
Bone Marrow Biopsy	Hypercellular marrow (60-70%), 20% atypical plasmacytosis consistent with plasma cell myeloma	Normocellular marrow
IgA level	2040 (68-243)	356 (68-423)
Urine Analysis	Total protein 3393 (50-100), RBCs 4261 (0-4)	Total protein 33, RBCs 0

normal values in parentheses

The patient has had no more flares of HSP over the last three years.

Conclusions: Resolution of both HSP and nephropathy are documented after treatment of IgA myeloma with simultaneous reduction in IgA levels. The resolution of nephropathy with treatment of this myeloma argues for overproduction of the IgA subtype as the main pathogenic factor in this case.

PUB455

Lack of Awareness in Future Medical Professionals of Risk of Consuming Hidden Phosphate-Containing Diet Yoshiko Shutto,[1] Michiko Shimada,[1] Hideaki Yamabe,[1] Mohammed S. Razzaque.[2] *[1]Nephrology, Hirosaki University School of Medicine, Hirosaki, Japan; [2]Oral Medicine, Harvard School of Dental Medicine, Boston.*

Background: Hyperphosphatemia is the single most important determinant of mortality in chronic kidney disease (CKD) patients receiving hemodialysis. CKD patients are advised to take low phosphate diet with phosphate lowering drugs. However, phosphate-containing ingredients are widely used as preservative in processed foods/soda drinks, and thereby can affect to total phosphate intake. As patients seek advice from medical professionals on phosphate-containing diet, we conducted a survey to determine the level of awareness in future medical professionals of diet containing artificial phosphate ingredients.

Methods: We randomly selected 190 medical and nursing students (average age: 21.6 years) at Hirosaki University School of Medicine in Japan and asked them to fill out a questionnaire.

Results: While 99% of students are aware of increased sugar-content in soda drinks, only 7% are aware of presence of phosphate (phosphoric acid) in such drinks. Similarly, only 12% of students are aware of presence of phosphate-containing ingredients in processed foods, including burgers/pizzas, etc. More importantly, 68% of the surveyed students are unaware of possible harmful effects of unrestricted consumption of phosphate-containing foods/drinks. Furthermore, 28% of surveyed students consume "fast food" at least once/week, while another 36% take such food once/month. However, after realizing long-term risks of consuming excessive phosphate, 41% of students want to reduce their phosphate-intake by minimizing consumption of fast foods/soda drinks, while another 48% showed interest in getting more information.

Conclusions: The survey highlights two important points: medical/nursing students, the future medical professionals, who will soon assume the role of patient management **1**) are not thoroughly aware of the risk related to prolonged high-phosphate intake; **2**) are not fully aware of the foods/drinks that contain hidden phosphate ingredients. This survey exposes the need for an education initiative to raise the awareness of risk posed by diet with hidden phosphate-containing ingredients.

Interdialytic Weight Gain and Food Intake in Hemodialysis Patients, Users of a Private Clinic in Sao Paulo, Brazil Carmen B. Tzanno-Martins,[12] Camila Machado de Barros,[1] Bárbara Margareth Menardi Biavo,[1] Jacqueline Santos,[1] Elzo R. Junior.[12] *[1]Nephrology, Home Dialysis Center, São Paulo, SP, Brazil; [2]Nephrology, Integrated Center of Nephrology, Guarulhos, São Paulo, Brazil.*

Background: Individuals with chronic kidney disease (CKD) on dialysis treatment can present disorders of nutritional status and inadequate dietary intake. The purpose of this study was to evaluate interdialytic weight gain and food intake in hemodialysis patients, users of a private clinic in Sao Paulo.

Methods: This is a cross-sectional study which evaluated 97 patients. Clinical and socio-demographic data were collected, weight and height were measured and food intake was evaluated by three 24 hour-recalls. Study variables were: pre and post-dialysis weight, interdialytic weight gain, body mass index (BMI), energy intake, carbohydrates, proteins, lipids, sodium, phosphorus and potassium. It was also conducted qualitative analysis of the diet through the consumption of different food groups.

Results: According to BMI, the majority of elderly and adult had normal weight, but the elderly had a higher prevalence of malnutrition (25.0%) compared to younger patients (5.3%). The analysis of interdialytic weight gain showed that 48.5% had adequate weight gain (3 to 5% of "dry weight"), and only 15.5% of subjects had excessive weight gain. The intake of oils, sugar, beans and meat, fish and eggs proved to be excessive. Energy intake, as well as the intake of carbohydrates and lipids, presented below requirements values for most individuals. The consumption of protein and sodium was high for most individuals. Potassium intake was below the recommended values and phosphorus proved to be adequate.

Conclusions: The interdialytic weight gain was adequate in most of the population studied but it was identified inadequate food consumption, characterized by an imbalance of intake of macro and micronutrients. Therefore, it is important for individuals with CKD the adoption of proper diet to maintain their health.

PUB457

Treatment of Late Antibody Mediated Rejection in Kidney Transplant Recipients: The Johns Hopkins Experience Bassam G. Abu Jawdeh,[1] Gaurav Gupta,[1] Robert Avery Montgomery,[2] Brandon L. Trollinger,[3] Edward S. Kraus,[1] Niraj Desai,[2] Nada Alachkar.[1] *[1]Division of Nephrology, Johns Hopkins University; [2]Division of Transplant Surgery, Johns Hopkins University; [3]Department of Pharmacy, Johns Hopkins University, Baltimore, MD.*

Background: Several strategies for treating early antibody mediated rejection (AMR) have been investigated, however, evidence is sparse on the utilization and success of these therapies in late AMR. In this study, we present data from 13 patients who were treated for late AMR at our institution.

Methods: We collected data from 13 patients who developed biopsy-proven AMR after 6 months from the time of transplantation. AMR was defined as having at least two of the following pathologic changes: glomerulitis (g-score), peritubular capillary margination (ptc-score) and C4d staining (C4d-score). All patients had class I and/or class II donor specific antibodies (DSA) and were treated with plasmapheresis followed by low dose Cytogam +/- Rituximab +/- Bortezomib +/- high dose IVIg. 11 patients had at least one follow up allograft biopsy. Parameters followed through and post-treatment were serum creatinine (SCr), estimated GFR (eGFR), DSA levels and histopathologic scores.

Results: The median follow up from the time of biopsy proven AMR was 4 months (range: 1 to 15 months). The mean rate of change in SCr was -0.07 mg/dl/month (range: -0.24 to +0.11 mg/dl/month). The mean change in eGFR since diagnosis of AMR was +0.55 ml/min/1.73m2 (range: -1.71 to +3.33 ml/min/1.73m2). DSA levels of 8 patients, all with class II, did not decrease with treatment; the other 5 patients responded partially, however continued to have low level DSA. Only 2 patients had reduction in their g-scores, 2 in their ptc-scores and 5 in their C4d-scores.

Conclusions: We infer that treatment of late AMR is not associated with significant improvement in SCr, eGFR, DSA levels or histopathologic scores.

PUB458

Nested Case Control Study with Follow up Survey for Polyoma Virus among Kidney Transplant Recipients Ahmed G. Adam,[1] Nagwa Farouk,[1] Mona Salem,[2] Doaa Hashad,[3] Hala S. Elwakil.[1] *[1]Internal Medicine - Nephrology, Dialysis & Transplantation Unit, Faculty of Medicine; [2]Pathology, Faculty of Medicine; [3]Clinical Pathology, Faculty of Medicine, University of Alexandria, Alexandria, Egypt.*

Background: Polyoma virus associated nephropathy is an increasingly recognized cause of graft dysfunction among kidney transplant recipients. It is related somehow to modern potent immunosuppression aimed at reducing acute rejection. Asymptomatic viremia and /or nephritis with or without worsing renal function may be present. Biopsy remains the gold standard for diagnosis. Untreated cases lead to allograft dysfunction or loss. There is no safe and effective antiviral therapy, so prevention based upon a screening and preemptive strategy is superior to an approach that relies upon therapy of established disease

Methods: 74 transplant recipients in University of Alexandria, Egypt were included. Urine decoy cells, PCR for BKV and Biopsy were done. Positive cases of cytology or PCR are followed up within 1-3 months.

Results: 7 +ve for decoy cells (10%), 3 viremia by PCR (4%), only one nephropathy (1.4%) presented with tubulointerstitial nephritis with intranuclear inclusions of Polyoma JC virus rather than BK, CMV or Herpes. Cases with stable renal function and viruria with or without viremia cleared the virus spontaneously during the period of follow up without the need of intervention. A biopsy proven nephropathy and deteriorating graft function lost the graft and was suggestive of JC Nephropathy (the 11th reported so far) rather than BK.

Case #	Decoy cells	PCR	Renal Biopsy
1	+/=	-/-	TIN-Inclusion
2	-/-/-	500/50/0	
3	+/-	30/0	
4	+/-	-/-	
5	+/-	-/-	
6	+/=	-/-	
7	+/-	-/-	
8	+/-	-/-	
9	Inflammtory	45	Rejection

Follow up of Decoy, PCR based on Therapy

Conclusions: The trend in quantitative rather than qualitative PCR for BKV is more important than single value especially when considering therapeutic plane. JC as a cause of nephropathy post transplantation do happen and must be considered as part of Polyoma related nephropathy; however more rare than BKV nephropathy, and possibly more aggressive. Decoy cell, viruria and viremia are neither synonymous nor interchangable and all are necessary for proper management.

PUB459

Therapeutic Options for Recurrent Focal Segmental Glomerulosclerosis after Kidney Transplantation- The Need for Multicenter Trials Vaqar Ahmed, Sarat C. Kuppachi, Beje S. Thomas, Anita Sultan, Maria F. Egidi. *Nephrology, Medical University of South Carolina, Charleston, SC.*

Background: No controlled trials have been performed to address the management of recurrent FSGS post KTX. Most studies reported single center experience with enrollment of few patients and discrepant results. Purpose of the study is to compare our management of recurrent FSGS with other experiences (not shown) and to address the need for collaborative approach.

Methods: Analysis of 7 KTX recipients with recurrent FSGS who received plasmapheresis (PP). Additionally 5 patients received 3 doses of rituximab (RTX) at 375 mg/meter square. Two living donor recipients received PP and RTX pre-KTX.

Results: One patient had complete remission while 3 had partial remission. Mean follow up 463 days. No graft losses or initiation of dialysis.

Table 1: Summarizes patients demographics, treatment of recurrent FSGS and outcomes in our institution.

Induction post Tx	Maintenance IS	Scr at diagnosis of FSGS recurrence	Treatment of recurrence	Proteinuria [in grams] before PP	Proteinuria [in grams] after last PP cycle	Duration of follow up after relapse [days]	Outcome
Thymoglobulin	Prednisone, MMF, Tacrolimus	3.8	PP	9.4	2.4	240	Scr 2.8, PCR 5.71
Thymoglobulin	Prednisone, MMF, Sirolimus	4.3	PP and RTX	5.4	0.79	285	Scr 2.9, PCR 0.8
Basiliximab	Prednisone, MMF, Tacrolimus, Everolimus	4.9	PP and RTX	20	5.8	365	Scr 1.3, PCR 8.6
Daclizumab	Prednisone, MMF, Tacrolimus	1.8	PP and RTX	3.7	3.7	1380	Scr 2.1, PCR 4.8
Thymoglobulin	Prednisone, MMF, Everolimus	1.2	PP and RTX	7.73	3.8	150	Scr 1.4, PCR 4.6
Basiliximab	Prednisone, MMF, Tacrolimus	4.7	PP	4.8	6.7	90	Scr 2.1, PCR 6.7
Daclizumab	Prednisone, MMF, Tacrolimus	1.1	PP and RTX	7.4	4.4	730	Scr 2.1, PCR 4.1

RTX= Rituximab, PP= Plasmapheresis

Conclusions: PP was effective only in temporary reduction of proteinuria. Whether RTX had an impact on patient outcomes could not been established. Multicenter trials are warranted to assess optimal strategies for recurrent FSGS. As RTX seems to have a role in FSGS treatment, question should be arisen about its consideration for an early introduction or perhaps to be used as an induction agent in this patient population.

PUB460

Urinary Tract Infections in Renal Transplant Patients: The Emergence of ESBL Mamdouh N. Albaqumi, Lutfi Alkorbi, Saad Alghamdi. *KFSHRC, Riyadh, Saudi Arabia.*

Background: UTI affects 5%- 36% of kidney transplant patients. The typical organisms causing post-transplant UTI are the enteric gram negative bacilli and enterococci. However, there is an increased rate of ESBL infections among renal transplant patients which might carry a significant morbidity. We report our center experience with UTI and ESBL- UTI impact in renal transplantation

Methods: We retrospectively reviewed electronic data and medical charts of 165 renal transplant patients followed up by nephrology team of KFSH & RC from 2003 until 2007

Results: A total of 165 patients with renal transplant were included in the analysis. 65 out of 165 (39%) patients develop UTI. Median time interval of developing UTI was 8 months. Females tend to develop more UTI as compared to males, 38(62.3%) vs. 23(37.7%) $p<0.05$. The episodes of acute rejection at 1 year were 11 (17.0%) in the UTI group as compared to 22 (22.0%) in the group without UTI with no statistical difference. There was no difference in graft and patient survival between the two groups at 1 and 2 years follow up. Both groups received similar immunosuppression. Among the UTI group, 9 patients (13.8%) were found to have ESBL positive UTI. Upon subgroup analysis of those developing ESBL, we found that the most frequent β-lactamase mediated resistant gram negative enteric bacilli was E. coli 14 (87.5%) followed by Klebsiella pneumonia 2 (12.5%). All patients in ESBL group 9 (100%) had documented recurrent UTI as compared to 40 (71.4%) in the non ESBL UTI group. Univariate analysis of the risk factors for β-lactamase-mediated resistant gram negative bacilli infection, showed that living related donor, recurrent UTI and number of UTI (>3 episodes) were significantly associated with ESBL UTI.

Conclusions: We found that UTI has no significant impact on renal function, graft function, and patient survival in the first two years. In our study 13.8% developed one or more infections due to ESBL producing gram negative bacilli. We found that recurrent UTI and number of UTI (>3 episode) are the most important risk factors for development of ESBL UTI. Efforts should be made to prevent first episode of UTI in this population of patients which might have a positive impact on long term outcome.

PUB461

Transplant Biopsy for the Early Diagnosis of Graft Dysfunction Secondary to Haemolytic Uraemic Syndrome Mansoor N. Ali, Sunil Bhandari. *Renal Medicine, Hull and East Yorkshire Hospitals NHS Trust, Hull, East Yorkshire, United Kingdom.*

Background: Haemolytic uraemic syndrome, either recurrent or de novo is uncommon post transplantation and is usually diagnosed from haematological changes including thrombocytopenia, anaemia and fragments on blood film. Confirmation with the transplant biopsy is helpful.

Methods: We highlight a series of three patients with acute transplant dysfunction which presented without clinical or haematological clues to the aetiology. Subsequent transplant biopsy revealed Haemolytic uremic syndrome (HUS); two of which had HUS as primary renal disease and one had de novo HUS secondary to possible use of tacrolimus therapy

Results: Early transplant biopsy prior to development of classical haematological features of low platelets and fragments should be undertaken to confirm the diagnosis. In this series biopsies were performed early prior to the fall in platelets and appearance of fragments.

Treatment, using plasma exchange and fresh frozen plasma in combination, intravenous immunoglobulin and switching immunosuppression, led to recovery of haematological parameters but salvage of only one graft function. Screening for complement and ADAMT13 mutations were negative.

De novo and recurrent HUS may occur post transplantation. Classical haematological changes of thrombocytopenia, anaemia (microangiopathic haemolytic anaemia) are a late phenomenon, occurring in only 50% of patients.

Conclusions: Transplant biopsy should be considered early to institute early therapy and recovery of haematological parameters and potentially transplant function thereby avoiding toxic therapy and complications.

PUB462

Cutaneous Calciphylaxsis in a Renal Allograft Recipient Amarpali Brar, Carmencita Yudis, Nabil Sumrani, Fasika M. Tedla. *SUNY Downstate Medical Center, Brooklyn, NY.*

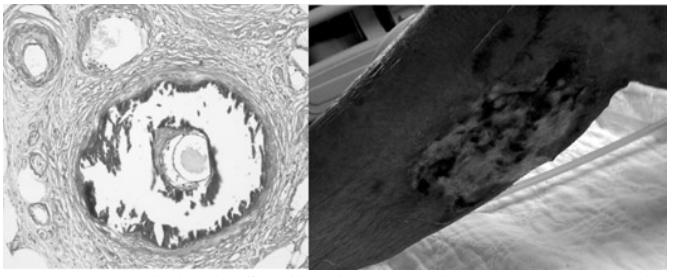
Background: Calcific uremic arteriolopathy is a disease first described in patients on dialysis. It involves calcium deposition in the walls of small and medium sized arteries with consequent ischemic necrosis and gangrene.

Methods: We describe a case of cutaneous calciphylaxsis in a patient with renal allograft transplant.

Results: A 52-year-old African American woman with end stage renal disease due to lupus nephritis who was on hemodialysis for 16 years received a deceased donor kidney transplant in 2002. She received thymoglobulin induction; and tacrolimus and prednisone for maintenance immunosuppresion. Both pre and post transplant serum calcium and phosphorus levels were normal.

Eight years after transplantation, patient was admitted with skin lesions bilaterally on the medial aspect of her thighs. She then had 6 cm X 3cm lesion in left lower extremity after trauma. The lesion was well demarcated, gangrenous in appearance and foul smelling. Peripheral pulses were intact. Laboratory data showed serum creatinine of 2.5 mg/dl, calcium of 8.9 mg/dl, phosphorus of 3.7 mg/dl and PTH of 439 pg/ml which improved over the next two months to 180 pg/ml.

Wound swabs grew Pseudomonas aeruginosa. Intravenous antibiotics were started. A skin biopsy of the lesion confirmed the diagnosis of calciphylaxis.



Later treatment included sodium thiosulfate 25 grams intravenously every other day and cinacalcet 60 mg twice a day.

She was lost to follow up and then returned four months later with worsened leg lesions with purulent discharge. Despite aggressive intervention, patient had multiple episodes of infection at the site of lesions and died due to complications of sepsis.

Conclusions: Calcific uremic arteriolopathy is a rare entity in patients with renal transplant, it is associated with high mortality and an evidence based strategy for management needs to be evaluated.

PUB463

Risk Factors and Outcomes in Renal Transplant Recipients with Hyperuricemia Amarpali Brar, Mary C. Mallappallil, Candace D. Grant, Fasika M. Tedla, Nabil Sumrani, Melissa Rampal, Moro O. Salifu. *SUNY Downstate Medical Center, Brooklyn, NY.*

Background: Hyperuricemia is a common finding post-transplant. However risk factors for development of hyperuricemia and its impact on allograft function remain unclear.

Methods: To determine risk factors for our predominantly African American kidney transplant patients, we analyzed 208 renal transplant recipients in our center from 1998-2007, whose data set for serum uric acid was complete.

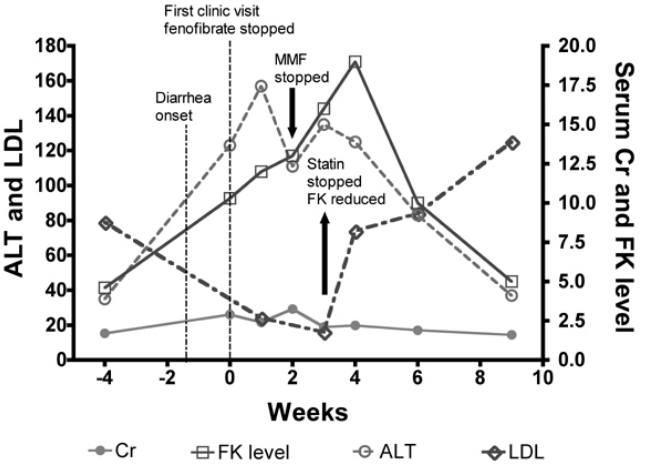
Results: During this period, immunosuppression consisted of antithymocyte globulin induction plus tacrolimus, mycophenolic acid and steroids maintenance immunosuppression. Only 7 patients received cyclosporine. Hyperuricemia was defined as uric acid level over 7 mg/dL. Patients were divided into 2 groups based on their uric acid levels; hyperuricemia (>7mg/dl, 61.5%) and normal (<7mg/dl, 38.5%). Mean age (48.8 13.1 vs. 46.6 14), black race (70.3% vs. 60%), BMI (25.9 5.7 vs. 24.8 4.9), HLA mismatch, tacrolimus levels, cholesterol, donor age, diabetes and race were not significantly different between the groups. Male gender (63.3% vs. 36.3%, p=0.0001) and DGF (18.9% vs. 7.6%, p=0.026) were significantly higher in hyperuricemic patients. Patients with hyperuricemia had significantly higher discharge creatinine (3.2 2.0 vs. 2.3 1.5, p=0.001), 6 weeks creatinine (1.95 1.5 vs. 1.49 0.91, p=0.22), 6 months creatinine (1.6 0.5 vs. 1.3 0.3, p=0.001) and 1 year creatinine (1.6 0.5 vs. 1.2 0.3, 0.001) compared to recipients with uric acid less than 7. However using logistic regression, we did not identify any independent predictors of hyperuricemia in this population. There was also no difference in acute rejection or overall graft survival between the two groups.

Conclusions: Demographics and clinical characteristics did not predict the development of hyperuricemia in this population. Hyperuricemia may be secondary to the high cell turnover in this patient population. This study may be limited by sample size and future studies are needed to elucidate the mechanism of hyperuricemia posttransplant.

PUB464

Mycophenolate Mofetil Induced Duodenal Villous Atrophy in a Renal-Transplant Recipient and Its Effect on Tacrolimus and Lipid Levels Monique E. Cho,[1] Stefanie Glenn,[1] Christine Chris Chamberlain,[2] David Kleiner,[3] Yuen-Yi Hon.[2] *[1]Kidney Disease Branch, NIDDK, NIH, Bethesda, MD; [2]Clinical Center Pharmacy, Clinical Center, NIH, Bethesda, MD; [3]Department of Laboratories, NCI, NIH, Bethesda, MD.*

Background: Mycophenolate mofetil (MMF) commonly causes diarrhea, typically early following drug initiation. We report an atypical case of MMF-associated diarrhea in a 28 year-old kidney transplant recipient, starting after 41 months of maintenance therapy with tacrolimus (FK) and MMF. Infectious etiologies were excluded and the anti-motility agents failed to improve his symptoms. He developed sharp increase in FK levels from 5 to 19 ng/mL, despite having his dose reduced. His LDL decreased from 79 to 16 mg/dL in the setting of stable statin therapy and 4-fold increase in transaminases.



Esophago-gastroduodenoscopic biopsies revealed marked shortening of duodenal villi with repair and regenerative changes, consistent with drug effect and MMF was stopped. Within a few days, his diarrhea improved and completely resolved within 4 weeks. His FK level, lipid profile and transaminases returned to baseline values within 8 weeks. Genotyping revealed that the patient is a homozygous variant for CYP3A5 6986A>G and ABCB1 1236C>T, 2677G>T/A, and 3435C>T, indicating that CYP3A4 is the enzyme primarily involved in drug bioavailability and metabolism. While few case reports have described duodenal villous atrophy with MMF use recently, it is important to consider the effect of intestinal barrier disruption on drug absorption and consequent renal and hepatic toxicities. Possible underlying mechanisms include reduced CYP3A4 expression/activity due to duodenal villi shortening, complex interplay between p-glycoprotein and CYP3A genotype and phenotype, and potential FK-statin interaction.

Clinical Usefulness of BK Virus Monitoring by Plasma BKV Quantitative PCR in Renal Transplant Recipients Byung Ha Chung, Yu Ah Hong, Hyun Gyung Kim, In O Sun, Bumsoon Choi, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang. *Department of Internal Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea.*

Background: Because of the lack of effective therapy for BK virus associated nephropathy (BKVAN), early diagnosis of BKV replication is the basis for the prevention of BKVAN. Present study analyzed the clinical usefulness of BK viremia monitoring by plasma real time PCR to prevent the development of BKVAN.

Methods: First, we compared plasma PCR with urine decoy cell and urine BKV real time PCR (urine PCR) for the diagnosis of BKVAN in comparison. Second, we prospectively monitored plasma PCR at 1, 3, 6, 9, 12 months after kidney transplantation (KT). We analyzed the kinetics of BKV replication and investigated the effectiveness and safety of preemptive immune suppressant (IS) reduction in BKV viremia.

Results: From Oct. 2006 to Oct. 2008, the prevalence of BKVAN was 3.0 % in the study population (6 / 200). The sensitivity and negative predictive value for BKVAN by decoy cell, urine and plasma BKV real time PCR was 100 % respectively. However, plasma BKV real time PCR was superior to urine real time PCR and urine decoy cell in specificity and positive predictive value. In the prospective monitoring of BKV real time PCR, BK viremia developed in 8.3 % (12 / 145) within 1 year after transplantation and the median interval from KT to the development of viremia was 163 days (29 – 685). After reduction of immune suppressant, viremia was successfully cleared out in 91.6 % (11 / 12) and it took 103 days (25 – 254). BKVAN developed in only one patient, who took intensive desensitization before KT because of high grade sensitization and ABO mismatch to donor. In comparison between patients with viremia and without viremia, allograft function and the frequency of acute rejection did not differ significantly up till post-transplant 1 year ($P > 0.05$, respectively).

Conclusions: Plasma PCR is reliable method for the diagnosis of presumptive BKVAN and regular monitoring of it is useful to prevent the development of BKVAN without the risk for acute rejection.

PUB466

Sirolimus-Induced Granulomatous Lung Disease in a Kidney Transplant Recipient Abdelaziz A. Elsanjak, Rishi Raj, Kamonpun Ussavarungsi, Vineeta Sood, Melvin E. Laski. *Internal Medicine, Texas Tech University Health Sciences Center, Lubbock, TX.*

Background: Pulmonary complications of sirolimus immunosuppression include pneumonitis, bronchiolitis obliterans, organizing pneumonia, and alveolar hemorrhage. We here present a case of granulomatous lung disease, a rare side effect of sirolimus treatment.

Methods: Clinical case report and literature review

Results: The patient is 54 year old Hispanic female s/p DDKT for ESRD due to ADPKD. The patient presented with dyspnea, dry cough, fatigue and low grade fever

for two weeks. Her initial regimen included mycophenolate mofetil 750 mg BID, and tacrolimus 3 mg BID, but she had been switched to sirolimus 3 mg daily six weeks earlier because of post transplant DM. CXR showed bilateral infiltrates; WBC was normal. She was treated initially with ceftriaxone, azithromycin, bactrim, and diflucan, but five days later she nonetheless became hypoxic. Blood culture, sputum culture, and fungal and viral serology were negative. Spiral chest CT showed bilateral lower lobe ground glass infiltrates. Bronchoscopy with bronchoalveolar lavage and transbronchial biopsy revealed granulomatous lung disease. Tissue was sent for cytology, AFB, PCP, and fungal and viral culture. No infectious cause was found. Videoassisted thoracoscopy and wedge lung biopsy again demonstrated granulomatous lung disease. Tissue for cytology, AFB, CMV, and PCP again came back negative. Sirolimus induced granulomatous lung disease was suspected. Sirolimus was therefore discontinued and prednisone 60 mg po daily was started. The patient's symptoms subsequently rapidly resolved. A follow up spiral chest CT in two months showed complete resolution of lung infiltrates.

Conclusions: That sirolimus was the cause of the granulomatous lung disease in our patient is based on the occurrence of symptoms after patient was started on sirolimus, the exclusion of other causes, and the resolution of symptoms and infiltrates after discontinuation of sirolimus and treatment with steroids.

Pulmonary granulomas due to sirolimus use are rare but should be included in the differential diagnosis of transplant patients who develop respiratory symptoms and lung granulomas while on sirolimus.

PUB467

De Novo Glomerulonephritis (GN) in Renal Transplants (Tx): Are We Spuriously Counting the Number of Cases of De Novo GN Post Transplant by Presuming Diabetic Nephropathy (DN) as the Cause of End Stage Renal Failure Pre Transplant?

Swarupa R. Eskapalli, Michael C. Chobanian. *Dept. of Medicine and Pediatrics, Dartmouth Medical School, Lebanon, NH.*

Background: De novo and recurrent GN are important causes of renal allograft failure that account for as many as 5-10% of allograft failures.Presumed DN as the cause for ESRD in patients with long standing uncontrolled diabetes mellitus is commonplace. Without a proper diagnosis,recurrent or de novo disease other than DN might either be under or over diagnosed in grafts.

Objective: To determine whether the incidence of presumed DN as the cause of ESRD without a native kidney biopsy prior to renal transplant inadvertently exaggerates or underestimates the diagnosis of de novo GN cases in renal allografts.

Methods: We retrospectively reviewed the charts of Tx patients undergoing 225 renal allograft biopsies performed over a 12 year period at our center from January 1997 to December 2009.The review included determining the biopsy diagnosis of the failing allograft,the etiology of ESRD based upon Form CMS-2728-U3 and whether a native renal biopsy was performed to confirm the cause of ESRD

Results: Among 225 post Tx biopsies reviewed, only 33.3%(n=75) had a native renal biopsy and 66.6%(n=150)had no prior renal biopsy.Of the 150 patients reviewed, 33.3%(n=50) had the diagnosis of presumed DN and were included in analysis.Only 6%(n=3)of those 50 patients had de novo GN diagnosed as the cause of allograft failure without features of DN, whereas 22%(n=11) had DN alone in their post biopsy specimens. The remaining 36 patients had other diagnoses including acute cellular(1%),or antibody mediated(0.6%) rejection, chronic transplant glomerulopathy(0.8%), acute TIN(12%), and CNI toxicity(14%)among others

Conclusions: De novo GN is an infrequent cause of renal allograft failure in patients presumed to have DN as the cause for ESRD.Recurrent DN is the most common form of recurrent disease in transplanted kidneys in our center.The diagnosis of DN as the presumed cause of ESRD does not significantly increase the number of de novo GN cases and thus would not alter the immunosuppressive approach for these transplant recipients because of the risk for recurrent GN.

PUB468

Incidence of Asymptomatic Elevated Uric Acid Levels and Gout after Kidney Transplantation in Inner City African American Patients

Candace D. Grant, Amarpali Brar, Mary C. Mallappallil, Moro O. Salifu. *Nephrology, SUNY Downstate Medical Center, Brooklyn, NY.*

Background: We determined the incidence of clinical gout 652 kidney transplant patients between 1997 to 2010 in a predominantly African American population in the inner city. We found of the 652 patients, serum uric acid levels in 253 patients. Of these 253, 208 had information about serum uric acid and clinical gout. Of the 208 patients, 128 (61.5%) had elevated serum uric acid levels and 80 (38.5%) had normal serum uric acid levels.

In the group with elevated serum uric acid levels (128 patients), 16.4% had gout (HUG) and 83.6% had no clinical gout (HUNG). The large number of patients with elevated serum uric acid without clinical gout (HUNG) could not be explained on the basis of immunosuppression. In the (HUNG) group there was no significant difference in uric acid levels in patients on cyclosporine or those on tacrolimus.

No correlation was found between elevated uric acid levels (HUNG) and the following :age, diabetics as the etiology of kidney failure, gender, race, mycophenolate use, **HLA**, Body Mass Index, serum creatinine levels six months and at one year, serum cholesterol at 6 months or delayed graft function.

The incidence of asymptomatic serum uric acid levels (HUNG) in the African American inner city population is high (16.4%) and the clinical significance of this has to be further studied.

HUG: High Uric acid with Gout

HUNG: High Uric acid No Gout

PUB469

Eculizumab in Acute Recurrence of Thrombotic Microangiopathy Associated with Anti-Phospholipid Antibodies after Renal Transplantation

Karine Hadaya, Pierre-Yves F. Martin. *Nephrology, University Hospital of Geneva, Switzerland.*

Background: Renal thrombotic microangiopathy (TMA) is a severe complication of systemic lupus erythematosus (SLE), associated with the presence of anti-phospholipid antibodies (aPL). In its most fulminant form, TMA leads to a rapid and irreversible end-stage renal failure. Eculizumab, an anti-C5 monoclonal antibody, is the therapy of choice for patients with paroxysmal nocturnal hemoglobinuria and a promising therapy to cure and prevent recurrences of atypical hemolytic uremic syndrome (aHUS).

Methods: We report the case of a 27-year-old woman, with past history of one abortion, which underwent a kidney biopsy for end-stage renal failure.

Results: Severe TMA, complete glomerular scarring and diffuse tubule-interstitial fibrosis were diagnosed. The presence of aPL antibodies (lupus anticoagulant, IgG anti cardiolipin and IgG anti B2 glycoprotein type I), anti-nuclear and anti-nucleosome antibodies at high titer and a reduce level of C3 level was compatible with the diagnosis of fulminant TMA in a SLE patient in presence of aPL. No evidence of genetic or biological abnormalities, similar to those described in aHUS, were detectable. After 10 months of dialysis, the patient underwent living related kidney transplantation. Immunosuppressive therapy was based on rabbit anti-thymocytes globulin induction, mycophenolate mofetil, methylprednisolone and rituximab. The graft produced urine immediately but as serum creatinine remained at 172µmol/L at day 6, a graft biopsy was performed. Isolated diffuse glomerular and arteriolar TMA, C4d negative, was detected. Despite daily plasma exchange, performed from day 7 to 10, the patient developed oligoanuria leading to the administration of weekly eculizumab perfusion under penicillin prophylaxis. Three months post transplant, serum creatinine is 100µmol/L without proteinuria, C3 level is within the normal range and aPL antibodies are undetectable. Graft biopsy revealed complete resolution of TMA without sequel.

Conclusions: This case report demonstrates for the first time the benefit of eculizumab therapy in a fulminant recurrence of TMA related to aPL antibodies and resistant to classical therapy after kidney transplantation.

PUB470

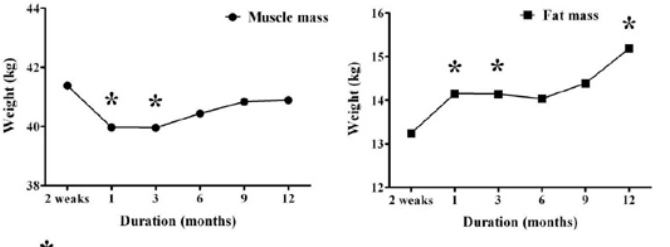
The Effect of Changes of Body Composition on Graft Function after Kidney Transplantation

Seung Seok Han,[1] Curie Ahn,[1] Jin Suk Han,[1] Suhnggwon Kim,[1] Yon Su Kim.[1,2] *[1]Internal Medicine, Seoul National University College of Medicine, Seoul, Korea; [2]Clinical Research Center for End Stage Renal Disease, Korea.*

Background: Kidney transplantation and accompanying medical conditions including immunosuppressive agents may result in the changes of body composition. But the changes and its effects on graft function are not well delineated, especially in Asian recipients. In this study, we prospectively observed the changes of body composition in 50 consecutive kidney recipients and evaluated its effect on graft function.

Methods: A total of 50 Korean recipients (age, 47 ± 11.2 years; living donor, 60%; body mass index, 21.8 ± 2.64 kg/m^2) were enrolled as a prospective cohort. Body composition (muscle and fat mass) was assessed 2 weeks, 1, 3, 6, 9, and 12 months after kidney transplantation by the bioelectrical impedance analysis. Body composition in 2 weeks of transplantation was used as baseline for reducing the effect of excessive water after operation.

Results: All the patients had good graft function during the study period (last serum creatinine (SCr), 1.15 ± 0.28 mg/dL). The muscle mass decreased within 6 months (41.4 to 40.4 kg, $P = 0.056$), but was regained after 6 months. The fat mass continuously increased over time (13.2 to 15.2 kg, $P = 0.004$). The waist circumference had a similar trend to the muscle mass (81.7 to 78.9 cm in 6 months, $P = 0.043$; to 80.5 cm in 1 year, $P = 0.313$).



But BMI did not changed during the study period. High increase group (n = 25) in fat mass showed the trend of higher serum creatinine level than low increase group (n = 25); Δ SCr level (change in SCr between baseline and 1 year) was 0.15 mg/dL in high increase group and 0.01 mg/dL in low increase group, $P = 0.077$.

Conclusions: Body composition in the Asian transplant recipients changes over time and this change is associated with graft function.

PUB471

Proteinuria and the Risk of End Stage Renal Disease in Kidney Transplant Recipients Allyson Hart,[1] Liangxing Zou,[2] James Hodges,[2] Hassan N. Ibrahim.[1] *[1]Medicine - Division of Renal Diseases and Hypertension, University of Minnesota, Minneapolis, MN; [2]Coordinating Center for Biometric Research - Biostatistics, University of Minnesota, Minneapolis, MN.*

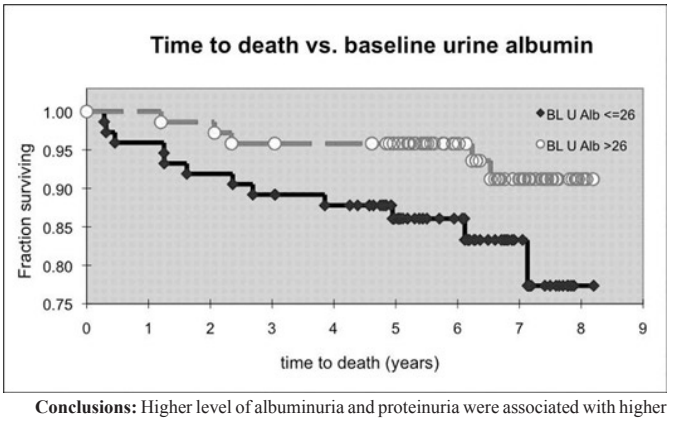
Background: Proteinuria is associated with increased risk of progression to end stage renal disease (ESRD), decreased graft survival, and death. We describe the association between proteinuria, graft survival and all-cause death in a prospective cohort of 153 kidney transplant recipients.

Methods: 153 kidney transplant recipients were followed prospectively with annual 24-hour urine protein and albumin measurements, with the first measurement occurring on average 58 days after transplantation. Analyses of time to death, ESRD, or the first of death or ESRD used Cox regression and Kaplan-Meier estimates.

Results: 19 (12%) of the 153 subjects died and 19 (12%) progressed to ESRD. Median baseline 24-hour urine protein and albumin were 0.34 g/g and 26 mg/g, respectively. Higher urine albumin was associated with higher risk of ESRD, but also with *lower* risk of death. Results were similar for proteinuria. The combined outcome of death or ESRD was not associated with baseline albuminuria or proteinuria. The results did not change notably when adjusted for age, sex, systolic blood pressure, donor source, or presence of acute rejection in the first 3 months after transplantation.

	Hazard Ratio*	(95%CI; p-value)
Outcome	BL Urine Albumin	BL Urine Protein
Death	0.42 (0.22-0.77; p=0.006)	0.38 (0.11-1.30; p=0.12)
ESRD	1.83 (0.91-3.70; p=0.09)	3.68 (1.10-12.3; p=0.034)
Death or ESRD	0.91 (0.55-1.48; p=0.69)	1.27 (0.50-3.20; p=0.62)

* For 10-fold increase in urine albumin or protein



Conclusions: Higher level of albuminuria and proteinuria were associated with higher risk of ESRD but lower risk of death in kidney transplant recipients. This result differs from what has been described in other populations, and needs to be confirmed.

PUB472

Terminal Complement Blockade by Eculizumab Effectively Reverses Recurrent Atypical Hemolytic Uremic Syndrome after Kidney Transplantation Nils Heyne,[1] Marcus Weitz,[2] Martina Guthoff,[1] Mark Dominik Alscher,[3] Hans-Ulrich Haering,[1] Silvio Nadalin.[4] *[1]Dept. of Diabetes and Endocrinology, Angiology, Nephrology and Clinical Chemistry, University of Tuebingen, Germany; [2]Dept. of Pediatrics, University of Tuebingen, Germany; [3]Robert-Bosch Hospital, Stuttgart, Germany; [4]Dept. of General, Visceral and Transplantation Surgery, University of Tuebingen, Germany.*

Background: Recurrence of atypical hemolytic uremic syndrome (aHUS) is frequent after kidney transplantation, limiting transplant options for these patients. The reported incidence of 15 - 90% is largely dependent upon the underlying dysfunction of the complement system. Plasmapheresis is current standard therapy, yet of limited efficacy. The humanized C5b-antibody eculizumab is a novel therapeutic option, blocking terminal complement activation. We report eculizumab to effectively reverse recurrent aHUS in kidney transplantation.

Methods: A 43 year old patient with a history of postpartal aHUS presented for second kidney transplantation. Mutation of complement factor H had been ruled out. On day 7 after transplantation, the patient developed severe recurrent aHUS with systemic hemolysis, thrombopenia and acute kidney injury under calcineurin inhibitor-free immunosuppression. Complement C5b-9 (membrane attack complex, MAC) was highly detectable.

Results: Eculizumab was administeredand continued weekly, with subsequent prolongation of intervals. Hemolysis and thrombopenia ceased quickly and allograft function fully recovered. No unwanted side effects were observed. Under continuous monitoring of SC5b-9, dosing intervals of eculizumab were successively tapered to every other month, currently. 6 months after transplantation, allograft function is excellent with an eGFR of 41 ml/min/1.73 m² (serum creatinine 1.4 mg/dl) and C5b-9 within reference range.

Conclusions: Complement C5b blockade by eculizumab is highly effective in reversing recurrent aHUS in kidney transplantation. Pharmacodynamic monitoring of C5b-9 may guide adaptation of eculizumab dose and interval. As novel treatment option, eculizumab may facilitate access to transplantation for patients with aHUS.

PUB473

Acute Rejections (ARs) Associated with Subsequent or Concurrent Chronic Graft Dysfunction (CGD) in Kidney Transplants (Tx) Ajay K. Israni,[1,4] Robert Leduc,[2] David P. Schladt,[2] William S. Oetting,[3] Pamala A. Jacobson.[3] *[1]Medicine, HCMC, Univ. of MN, Minneapolis, MN; [2]Biostatistics, Univ. of MN, Minneapolis, MN; [3]School of Pharmacy, Univ. of MN, Minneapolis, MN; [4]DeKAF Investigators.*

Background: AR is a risk factor for CGD and allograft failure. However not all ARs lead to CGD. Therefore, we examined the severity of AR and response to AR treatments, for ARs that are association with CGD.

Methods: We enrolled 2,366 at the time of tx between 2006 - 2010. CGD was defined as ≥25% rise in serum creatinine (SCr) after 3 months post-tx, that resulted in a biopsy. The rise in SCr is defined relative to a baseline SCr that was initially set at 3 months post-tx and re-set after AR.

Results: CGD occurred in 366 recipients at 509 (± 387) days from the 3 month baseline. All CGD biopsies had chronic changes. AR was more likely among recipients with CGD than without CGD (p< 0.0001).

AR among recipients with versus without CGD

	Recipients with CGD (n=366)	Recipients without CGD (n=1,970)	p-value
No ARs	171 (46.7%)	1,744 (88.5%)	<0.0001
One AR only	136 (37.2%)	197 (10.0%)	
Two or more ARs	59 (16.1%)	29 (1.5%)	
At least one AR before 3 months post-tx	49 (13.4%)	151 (7.7%)	0.0072
At least one AR after 3 months post-tx*	160 (43.7%)	89 (4.5%)	<0.0001
Characteristics of First AR After 3 months post-tx*			
	Recipients with CGD (n=160)	Recipients without CGD (n=89)	p-value
Biopsy Findings:			
Local pathology C4d positive	60 (42.6%)	19 (33.3%)	0.010
Treatment:			
Steroids only	86 (53.8%)	67 (76.1%)	0.0023
Antibodies only	6 (3.8%)	0	
Steroids & Antibodies	30 (18.8%)	7 (8.0%)	
Steroids then Antibodies	35 (21.9%)	11 (12.5%)	
None	3 (1.2%)	3 (3.4%)	
Response to treatment:			
SCr (in mg/dl) before AR	3.0 ± 2.2	2.0 ± 1.8	0.0004
SCr returned to baseline	22 (15.3%)	27 (32.5%)	<0.0001
SCr partially improved	88 (61.1%)	19 (22.9%)	
No improvement in SCr	34 (23.6%)	37 (44.6%)	

* not including AR after CGD

Even after excluding the 141 (39%) of ARs that occurred concomitantly with CGD, AR was associated with CGD

Conclusions: AR events associated with CGD appear to be different than those without CGD: more often C4d positive, reoccurred frequently, less likely to respond despite more intensive therapy.

PUB474

Prophylactic Ganciclovir for Gastrointestinal Cytomegalovirus Infection in Renal Transplant Recipients Hyun Chul Kim, Eun-Ah Hwang, Sung Bae Park, Seung Yeup Han. *Internal Medicine, Keimyung University School of Medicine, Daegu, Korea.*

Background: Cytomegalovirus(CMV) can cause morbidity in renal transplant recipients, and the gastrointestinal (GI) tract is a major target for CMV disease. Currently, there is no report concerning CMV prophylaxis to prevent GI CMV infection in CMV intermediate-risk patients(R(+) patients). The aim of this study was to evaluate the benefit of ganciclovir prophylaxis on GI CMV infection in R(+) patients.

Methods: In 41 patients who received renal transplantation after January 2009, intravenous ganciclovir(5mg/kg, twice daily) was started for 14days just after transplantation. The historical control group consisted of 45 patients received renal transplantation between January 2007 and December 2008. For evaluating effect of prophylaxis on GI CMV infection, routine endoscopic examination with mucosal biopsy was performed at the time of pretransplantation and then 1,3 and 6 months posttransplant.

Results: The average age of 86 studied patients was 43.7±10.6 (14-63) years and male to female ratio was 1:1.3. 43 (50%) patients received deceased donor transplantation and 84(97.7%) patients were seropositive for CMV IgG at the time of transplantation. The incidence of GI CMV infection was significantly lower in prophylaxis group than in historical control group (24.4% vs. 48.9%, p=0.026). The patient age, numbers of deceased donor and trough levels of tacrolimus at 1, 3months posttransplant were significantly lower in prophylaxis group than those of historical control group. In multivariate analysis for risk factors associated with GI CMV infection, ganciclovir prophylaxis was the only significant risk factor.

Conclusions: Prophylactic treatment with ganciclovir decreased the incidence GI CMV infection in seropositive renal transplant recipients.

PUB475

BKV Infection Stimulates Alloimmune Response in Kidney Transplant Patients Kosuke Masutani,[1] Parmjeet S. Randhawa.[1] *[1]Department of Pathology, University of Pittsburgh Medical Center, PA; [2]Department of Surgery, University of Pittsburgh Medical Center, PA.*

Background: Earlier stages of BK virus infection characterized by asymptomatic viruria are considered to be of no clinical significance.

Methods: To critically examine this widespread assumption, we identified 230 patients with sustained viruria (SVU) in whom multiple samples taken at a median 877 days (24-2739) after onset of viruria showed no progression to viremia or nephropathy.

Results: Compared to no viruria, SVU was associated with greater incidence of T-cell mediated acute rejection (30.9% versus 23.9%), increased number of rejection episodes (0.62 versus 0.33 per patient), and more frequent steroid resistance (36.2 versus 19.6% episodes). Most rejection episodes (52.1%) occurred concurrently with viral excretion, while a minority occurred prior to (7.8%) or after clearance of (40.1%) viruria. Lack of steroid response was seen more frequently in rejection occurring concurrently with viruria (48.6%), compared to rejection prior to onset of (9.1%) or subsequent to clearance of viruria (26.0%). The last serum creatinine, graft loss and death rates were not demonstrably affected.

Conclusions: These observations provide evidence that BKV infection stimulates the alloimmune response in kidney transplant recipients: its effect on development of tolerance deserves further investigation.

PUB476

Collapsing FSGS – A Significant Risk Factor for Allograft Failure Sumit Mohan, Leal C. Herlitz, Nicole M. Ali, Philip Imus, Russell J. Crew, Geoffrey K. Dube, Bekir Tanriover, Michael B. Stokes, Glen S. Markowitz, Vivette D. D'Agati, David J. Cohen, Ali G. Gharavi, Jai Radhakrishnan. *Columbia University.*

Background: Collapsing variant of FSGS (cFSGS) is an uncommon finding in the renal allograft that is associated with a high rate of graft loss (Stokes et al. AJKD 33:658-666, 1999). Transplant patients with cFSGS are a heterogeneous group underscoring the probability of diverse mechanisms leading to this pattern of allograft injury. Cases of cFGSG in allografts have been attributed to recurrent disease, ischemia, chronic allograft nephropathy and viral infections (including parvovirus B19). Literature on cFSGS in allografts is limited to case reports/small series.

Methods: We identified 17 patients (pts) with features of cFSGS on for-cause renal allograft biopsy (2 for DGF, 7 for rising creatinine, 3 for proteinuria, 5 for proteinuria and rising creatinine).

Results: Twelve pts were female(6 black, 6 Hispanic, 4 white) with a mean age of 41.8±9.8 yrs. There were 6 female and 11 male donors (7 white, 4 black, 5 Hispanic donors). Of the 17 pts who developed cFSGS in the allograft, 3 had FSGS as their native renal disease (including 1 pt with cFSGS). Four patients were seropositive for CMV; 2 pts developed CMV disease, 1 was seropositive for parvovirus B19 and 1 developed HIV post-transplant. Additionally, 4 pts had a history of lupus, 3 had prominent microvascular disease and chronic allograft nephropathy and 7 were treated with sirolimus prior to biopsy. Two pts (1 black, 1 white) received organs from the same donor and developed CMV infection after transplantation. Three pts had no identifiable risk factor for developing cFSGS. The diagnosis of cFSGS was made 3.6±4.6 yrs after transplantation with a creatinine of 3.7±1.8mg/dL (range 1.5-7.3 mg/dL) and protein/creatinine ratio of 4±3.5g/g (range 0.3-11.6g/g). Eight pts had nephrotic range proteinuria at the time of biopsy. Median allograft survival after diagnosis was 1.5 yrs (range 0.3–5.8) and appeared to be worse in those with nephrotic range proteinuria.

Conclusions: Collapsing FSGS in renal transplant is an uncommon cause of graft failure that has a poor prognosis when associated with heavy proteinuria.

PUB477

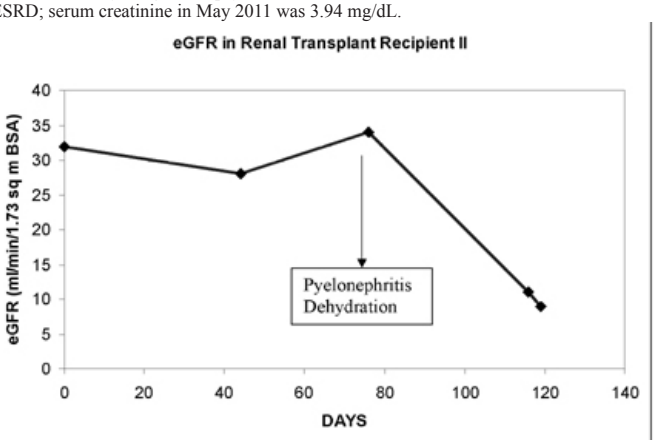
Syndrome of Rapid Onset End-Stage Renal Disease (SORO-ESRD) Described in Two Consecutive Renal Transplant Recipients over a Period of Six Months in a Mayo Clinic Renal Unit Macaulay A. Onuigbo.[1,2] *[1]College of Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, WI.*

Background: We described a new syndrome of rapid onset end-stage renal disease (SORO-ESRD) in CKD patients in 2010. This is the unpredictable and unanticipated accelerated progression from a priori stable CKD to permanent ESRD requiring RRT, after AKI. Whether this syndrome similarly affects renal transplant recipients (RTR) is uncertain and unknown. Recently, over six months, two renal transplant recipients demonstrated SORO-ESRD.

Methods: Case Reports

Results: Patient I is a 56 year old Caucasian female diabetic patient who received a simultaneous pancreas/kidney (SPK) transplant in 1991 for ESRD. Transplant CKD was stable, serum creatinine was 1.8 mg/dL in June 2010. She suffered AKI from pneumonia in July 2010; serum creatinine reached 4.8 mg/dL, requiring RRT for uremic symptoms, oliguria and volume overload. She remains on HD for ESRD; serum creatinine in May 2011 was 3.68 mg/dL.

Patient II, is a Caucasian female type 1diabetic with an SPK transplant in 2000 for ESRD. CKD was stable; serum creatinine was 1.6 mg/dL in November 2010. She developed AKI from pyelonephritis with dehydration; serum creatinine quickly reached 5.16 mg/dL on January 6, 2011, requiring RRT for uremic symptoms, acidosis, oliguria and volume overload. Kidney allograft biopsy revealed acute tubular necrosis. She remains on HD for ESRD; serum creatinine in May 2011 was 3.94 mg/dL.



Conclusions: This is the first report of SORO-ESRD among renal transplant recipients. Multicenter studies are mandated to accurately identify the extent this syndrome contributes to renal allograft losses. More research into reno-prevention strategies in RTR is warranted. This may well call for critical process re-engineering of several current accepted paradigms and norms in transplant nephrology practice.

PUB478

Incidence, Risk Factors and Clinical Characteristics of Delayed Graft Function in Living Donor Renal Transplantation Hoon Suk Park, Yu Ah Hong, Sun Ryoung Choi, In O Sun, Byung Ha Chung, Bumsoon Choi, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang. *Division of Nephrology, Department of Internal Medicine, Catholic University of Korea, Seoul, Republic of Korea.*

Background: Delayed graft function(DGF) is the need for dialysis during the first week even after renal transplantation. DGF can be seen in deceased donor renal transplantation(DDRT) with relatively longer ischemic time. But DGF in living donor renal transplantation(LDRT) is rare, so its incidence and risk factors have not yet been established. We investigated the incidence, risk factors and clinical characteristics of DGF of LDRT for the last 10 years.

Methods: The 429 cases of LDRT for the last 10 years were analyzed. We compared recipent and donor's characteristics, HLA mismatch numbers, the frequency of non-related donors, gender matching status, total ischemic time and graft weight between DGF and non DGF group.We also reviewed the biopsy findings and clinical courses in the cases with DGF.

Results: The incidence of DGF in LDRT is 7/429(1.6%) and is significantly lower than the incidence of DGF in DDRT(13.7%) during the same period($p<0.05$). In univariate analysis, numbers in HLA mismatch were significantly increased in DGF group($4.43>2.88$, $P<0.05$), the frequencies of female recipients and non-related donors were also increased in DGF group($85.7\%>36.5\%$, $P<0.05$). The biopsy findings during DGF were available in six out of seven cases except the one in which exploratory laparotomy was done. Two cases were related to rejection, one case was related to acute pyelonephritis and the other three cases were related to ATN. The shortest duration of dialysis in DGF is just 1 day and the longest one is 97 days, whereas in DDRT, the shortest duration of dialysis in DGF is 1 day and the longest one is 55 days and most of them were within 7 days. The two cases related to rejection resulted in graft failure within three years after transplantation. But the other cases not related to rejection have been followed up with favorable graft function.

Conclusions: We conclude that the strenuous strategies including biopsy should be done when DGF developed in LDRT because DGF related to rejection in LDRT shows poor prognosis.

PUB479

Incidence, Risk Factors and Clinical Characteristics of Recurrent Focal Segmental Glomerular Sclerosis in Adult Renal Transplantation Hoon Suk Park, Yu Ah Hong, Hyun Gyung Kim, Sun Ryoung Choi, In O Sun, Byung Ha Chung, Bumsoon Choi, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang. *Division of Nephrology, Department of Internal Medicine, Catholic University of Korea, Seoul, Republic of Korea.*

Background: Recurrence of Focal segmental glomerular sclerosis(FSGS) is known as being relatively common compared with the recurrence of the other primary diseases in renal transplantation. Furthermore, it's recurrence tends to result in graft failure. We investigated the incidence, risk factors and clinical characteristics of recurrent FSGS in renal transplantation for the last 20 years.

Methods: The cases of which the primary renal diseases were FSGS in renal transplantation were 25 for the last 20 years. We investigated the subtypes of recurrent FSGS(early recurrence or late recurrence) and compared the possible factors that may cause recurrence between the group with recurrence and the other group without recurrence.

Results: The rate of recurrence in FSGS was 40%(10/25). The eight cases recurred early and the other two cases recurred late. There was no variable significantly different between the group with recurrence and the other group without recurrence. Five year graft survival rate(38%) in the group with recurrence was significantly lower than 80% in the other group without recurrence(p=0.01). Univariate Cox regression according to the subgroups showed the only early recurrence influenced the graft survival significantly(p=0.01, 1.91<β<53.49). There were 7 cases in 25 cases with FSGS, who underwent plasmapharesis before transplantation to prevent the recurrence of FSGS or rejection. FSGS recurred in 2 cases out of them. Eight out of 10 patients with the recurrence of FSGS were treated with plasmapharesis. Six cases resulted in graft failure and the one case with the amount of proteinuria less than 1g/day has been closely monitored and the other case with the amount of proteinuria more than 1g/day has been treated with the subsequent plasmapharesis.

Conclusions: We conclude the graft survival in FSGS with recurrence was poor, so the more intensive protocol of plasamapharesis should be done.

PUB480

Successful Use of Plasma Exchange To Prevent Recurrence of Type I Membranoproliferative Glomerulonephritis after Kidney Transplantation: A Case Report Lissa Pipeleers,[1] Jacques Sennesael,[1] Caroline Geers,[3] Robert Hilbrands,[1] Siddhartha Lieten,[1] Christian L. Tielemans,[1] Patrick Stordeur,[2] Karl M. Wissing.[1] *[1]Department.of Nephrology and Hypertension, Universitair Ziekenhuis Brussel, Brussels, Belgium; [2]Immunochemistry Laboratory - Immunobiology Clinic, Erasme Hospital, Brussels, Belgium; [3]Department of Pathology, Universitair Ziekenhuis Brussel, Brussels, Belgium.*

Background: Membranoproliferative glomerulonephritis (MPGN) with constitutional activation of the alternative complement pathway relapses in about 80% of patients with a history of disease recurrence on a previous graft. There is so far no efficient strategy to prevent recurrence.

Methods: Case report on the use of intermittent plasma exchange to prevent recurrence of MPGN in a second kidney transplant, after loss of a previous graft due to disease recurrence.

Results: The 26 year-old patient with end stage renal disease due to MPGN received a first renal transplant in 2007. She developed aggressive disease recurrence with strong mesangial C3 positivity, and electrondense deposits causing rapid graft failure. Activation of the alternative complement pathway (low C3, high C3d and normal C4) was persistent before, during and after transplantation, although the underlying pathogenic mechanism could not be documented by extensive evaluation. After a second kidney transplantation, in January 2011, standard immunosuppression was combined with plasma exchange (40mL/kg body weight per treatment) at decreasing frequency, with a maintenance schedule of 1 exchange every two weeks after the first month. The patient maintained good graft function (creatinine 1.3 mg/dL) without signs of complement activation, microscopic hematuria and proteinuria during the whole follow-up. A protocol biopsy 3 months after transplantation showed no signs of disease recurrence on immunofluorescence and electron microscopy.

Conclusions: Prophylactic plasma exchange might correct the underlying pathogenic mechanism in patients with idiopathic MPGN, thereby preventing complement activation and recurrence of disease after renal transplantation.

PUB481

Erythropoetin Requirements for Anemia in Renal Transplant Recipients Compared to Chronic Kidney Disease Patients Ashish V. Regulagadda, Shirley Shwu-Shiow Chang, Rocco C. Venuto. *Department of Nephrology, University at Buffalo, Buffalo, NY.*

Background: The risk of developing post transplant anemia (PTA) increases as renal function declines. Immunosuppression, infections, and inflammation purportedly increase the risk for PTA and may impair response to erythropoesis-stimulating agents (ESA).

Methods: We compared 39 renal transplant (RT) recipients (26 decreased and 13 living) with PTA to 41 anemic chronic kidney disease (CKD) patients receiving ESAs. All patients had hemoglobin (Hb) less than 11 gm/dl at time of initiation. Exclusion criteria were recent hospitalization and active bleeding. Data collected included age, gender, race, and medication use, specifically renin-angiotensin-aldosterone system (RAAS) blockers, immunosuppressants, prophylactic anti-viral and anti-bacterial agents.

Results: The mean Hb at ESA initiation was similar (9.08 ± 0.79 gm/dl in transplant vs. 9.5 ± 0.81 gm/dl in CKD, p=ns). Deceased RT recipients (Hb 8.95 ± 0.89 gm/dl) tend to be more anemic at baseline than living donor RT recipients (Hb 9.34 ± 0.47gm/dl)(p=0.09). The 30% of RT recipients who were not Caucasian (Hb 8.73 ± 0.75 gm/dl) were more anemic than their Caucasian counterparts (9.23 ± 0.77 gm/dl(p=0.015) despite similar eGFR (p=0.86). Transplant recipients appear to need larger doses of darbepoetin (954.7 ± 1424 mcg) than CKD patients (517.0 ± 502 mcg) (p=0.08) but did not take longer to reach the target 11 gm/dl (mean 2.66 vs. 2.57 months). This was true even though transplant recipients (31.4 ml/min) had eGFRs that were at least as high as their (p=0.84) CKD counterparts (33.4 ml/min). There was no difference in the rate of iron deficiency (defined as Tsat<20% and/or Ferritin <200ng/ml) before ESA initiation. Use of RAAS blockers was lower in RT *vs*. CKD patients (23% *vs. 39*%, p=0.01<XX< b>) respectively.

Conclusions: Renal transplant recipients developed anemia requiring ESA when their eGFRs were at least as high as race and gender matched CKD patients. Transplant recipients did not require significantly higher doses of ESA or take longer to reach target compared to CKD patients.

PUB482

Successful Treatment of Pseudallescheria Boydii Brain Abscesses in a Renal Transplant Recipient Dawinder S. Sohal, Melvin E. Laski, Vineeta Sood. *Internal Medicine/Nephrology, Texas Tech University Health Sceince Center, Lubbock, TX.*

Background: Psuedallescheria boydii (Scedosporium apoiospermum), is a ubiquitous, saprophytic fungus found in still waters. It usually causes skin infections. It can cause CNS infections with high mortality even if diagnosed and treated promptly and may be fatal in immunosuppressed patientsl. Here we present a case demonstrating successful treatment of Pseudallescheria boydii lung infection and brain abscesses in a renal transplant recipient.

Methods: Case report and literature review

Results: A 63 year old woman was hospitalized for altered mental status 6 weeks after kidney transplant. Her post transplant course had been marked by poor diabetes control but no episodes of rejection. Past medical history was positive for DM2, HTN, and Bell's palsy. Immunosuppression included tacrolimus, everolimus, and prednisone. She also took prophylactic TMP/SMX and valganciclovir. After admission, mental status rapidly worsened and respiratory failure developed requiring mechanical ventilation. Brain MRI revealed multiple hypodense ring enhancing lesions with surrounding edema. Chest CT demonstrated a right lower lobe infiltrate. Lab: WBC 7,400, Hct 34%, platelets 134,000, creatinine 0.4 mg/dl. Tacrolimus level was 15.6 ng/ml. Transbronchial biopsy and brain biopsy were both performed within 48 hours.

Brain biopsy revealed fungal abscess, and lung and brain biopsy cultures grew Psuedallescheria boydii. Three brain abscesses were each surgically drained and voriconazole was administered with resulting clinical improvement. The patient was eventually discharged to a rehabilitation facility without neurological impairment.

Conclusions: Pseudallescheria boydii is a neurotrophic pathogen which has been rarely reported to infect immunosuppressed individuals. It is sometimes confused with Aspergillus sp and Fusarium sp on pathology, which may lead to inappropriate treatment with amphotericin. As shown by this case, modification of immune suppression, aggressive drainage of abscesses, and voriconazole therapy may result in cure. Early, accurate diagnosis, aggressive surgical drainage, and specific treatment are necessary.

PUB483

Clinical Characteristics of Renal Cell Carcinoma of Native Kidney in Renal Transplant Recipients In O Sun, Hoon Suk Park, Sun Ryoung Choi, Yu Ah Hong, Hyun Gyung Kim, Byung Ha Chung, Bumsoon Choi, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang. *Division of Nephrology, Department of Internal Medicine, Catholic University of Korea, Seoul, Republic of Korea.*

Background: The aim of this study is to investigate the incidence and clinical characteristics of renal cell carcinoma (RCC) in native kidney of renal transplant recipients

Methods: Between 1991 and 2010, 1425 patients underwent kidney transplantation at our institution. We retrospectively evaluated the clinical features and outcomes of five patients of RCC in the native kidney following transplantation.

Results: The patients included three men and two women, with a mean age of 63 years (range, 52-74). The incidence of RCC was 0.35%. The median interval between renal transplantation and occurrence of RCC was 16.2 years (range, 9 to 20). In our center, all patients with RCC had acquired renal cysts before (N=3) and after renal transplantation (N=2). The mean duration of dialysis was 12 months (range, 2 to 39), and most patients had duration of dialysis within 8 months except one. Four patients were asymptomatic and one patient presented a vague abdominal discomfort. And all patients received standard immunosuppressive treatment at the time of RCC diagnosis. Of the 5 patients, 4 received dual therapy with cyclosporine and prednisolone. And one patient received triple immunosuppression including cyclosporine, azathioprine and prednisolone. The mean tumor size was 3.2 cm (range, 0.5-5.1), and the stage of all RCCs was low grade at diagnosis. Two patients had clear cell carcinoma, another two papillary RCC and the last one multilocular cyst RCC. Radical nephrectomy was performed in all case except one who refused operation. Four patients who received radical nephrectomy showed no evidence of local recurrence or distant metastasis during median follow-up of 2.9 years. However, the patient who didn't have surgical treatment experienced the spinal metastasis of RCC six years later.

Conclusions: Follow-up period seems to be an important factor for development of RCC in renal transplant recipients.

PUB484

Delayed Graft Function Due to Early Onset Renal Transplant Artery Stenosis Si-Yen Tan,[1] David Cumberland,[1] Shahrin Merican,[1] Heinz Regele,[2] Mohan Rao,[3] Tee Chau Keng.[1] *[1]Nephrology, Prince Court Medical Centre, Kuala Lumpur, WP, Malaysia; [2]Department of Pathology, Medical University of Vienna, Austria; [3]Department of Surgery, Queen Elizabeth Hospital, Adelaide, Australia.*

Background: Transplant renal artery stenosis (TRAS) is a late transplant complication which characteristically presents with impaired graft function and hypertension. TRAS is however a rare cause of delayed graft function (DGF).

Methods: We report here 2 cases of DGF due to TRAS.

Results: The first patient had a living related renal transplant with donor renal artery anastomosed end to side into the internal iliac artery. This was complicated by DGF with

poor perfusion on imaging studies. Graft biopsy however confirmed healthy viable kidney and MRA 2 weeks post transplant suggested severe TRAS. Subsequent angioplasty and stenting of TRAS was accompanied by immediate diuresis and full recovery of graft function. The second patient had the donor renal artery anstomosed end to side to the external iliac artery. There was DGF and suspicion for injury to the initima during surgery was confirmed by CT angiogram which showed severe TRAS at the site of anastomosis. Graft biopsy confirmed healthy viable kidney with no evidence for ATN. Angioplasty and stenting of the TRAS was postponed till day 14 post surgery to minimize risk of anastomotic rupture during angioplasty. Angioplasty balloons could be fully inflated at low pressure suggesting a "soft" lesion which reappeared rapidly upon deflation and this was felt to be consistent with an intimal flap. Two stents were implanted in a "double barrel shot gun" fashion over the same lesion with one stent into the renal transplant artery whilst the second stent maintained perfusion downstream into the external iliac artery. This was accompanied by immediate diuresis within hours of stenting and subsequent full recovery of graft function.

Conclusions: Early TRAS post transplant must therefore be considered and excluded as a potential cause of DGF which is amenable to early intervention angiographically. The pathophysiology of early TRAS is likely to be different from the more common later onset TRAS and related to tissue injury during surgical anastomosis.

PUB485

A Case Series of Endothelial Tubuloreticular Inclusions in Transplant Kidney Biopsies Kawin Tangdhanakanond, Daranee Chewaproug, Eric J. Bloom, Rasib Raja. *Department of Nephrology, Albert Einstein Medical Center, Philadelphia, PA.*

Background: Tubuloreticular inclusions (TRIs) are unique subcellular structures that arise from the membranes of the rough endoplasmic reticulum of endothelial cells. TRIs have been associated with viral infections and autoimmune diseases, particularly human immunodeficiency virus (HIV) infection and lupus nephritis, as well as administration of exogenous interferon. However, it is not clear whether some other underlying illnesses or disease processes are associated with TRI expression in transplant kidney biopsies.

Methods: During the three-year period (2008 to 2011), TRIs were observed in five post-transplant kidney biopsies on ultrastructural examination. Donor and recipient records were reviewed for demographics, underlying diseases, and laboratory data including pertinent serologic tests as well as kidney biopsy findings.

Results: All donors and recipients were HIV-negative and had no clinical or serologic evidence of autoimmune diseases. Four of five recipients had hepatitis C virus (HCV) infection. Three out of these four recipients had never received any specific treatment for HCV infection; the other one received pegylated interferon 2 years prior to the kidney transplantation. All recipients were biopsied to evaluate for rejection. Borderline cellular rejection was found in two recipients. A biopsy from another recipient was focally positive for C4d (C4d 1). Biopsies from the other recipients showed no evidence of acute cellular rejection or antibody-mediated change. All recipients were on prednisone, tacrolimus, and mycophenolate as the maintenance immunosuppressive regimen.

Conclusions: Calcineurin inhibitor (CNI), has been demonstrated to increase alpha-interferon expression in patients with HCV infection. All recipients in our study were on CNI as a part of their immunosuppressive medication, and four of them had HCV infection. The TRIs seen in our biopsies may be a result of the HCV infection and/or the elevation of alpha-interferon secondary to CNI therapy; however, larger studies along with alpha- and beta-interferon measurement are necessary for further investigation.

PUB486

Pancreatic Anastomosis Leak 15 Years after Simultaneous Pancreas-Kidney Transplantion from Late-Onset Allograft Cytomegalovirus Duodenal Ulcers Presenting with Gross Hematuria Ekamol Tantisattamo,[1] Roland C.K. Ng,[1] Heath Chung,[1] Manami Okado.[2] *[1]Department of Medicine; [2]Surgery, University of Hawaii.*

Background: Cytomegalovirus (CMV) infection is one of the most important causes of mortality in solid organ transplantation. It is an important cause of hematuria, the most common urological complication in the early post-simultaneous pancreas-kidney (SPK) transplant period. Negative CMV viremia may not correlate with, and delay, diagnosis of tissue invasive disease. We report a case of a man with bladder-drained SPK transplant presenting with recurrent gross hematuria from CMV infected duodenal graft ulcers 15 years after preserved well-functioning grafts.

Results: A 70-year-old male with SPK transplantation in 1995 presented with recurrent gross hematuria for 1 month. Initial cystoscopy revealed bleeding from the duodenovesical orifice, but biopsy was not performed. He was admitted with septic shock and peritonitis from uncontrolled pancreatic ascites leaking from the duodenocystostomy suture line. Continued leakage of pancreatic fluid into the peritoneal cavity necessitated explant of the functioning pancreatic graft. Pathology revealed erosive ulcers at the duodenal graft segment. He also developed acute kidney injury from tacrolimus toxicity; transplant kidney biopsy showed no evidence of rejection. Serum quantitative PCR for CMV and BK virus were negative. The hospital course was complicated by disseminated candidiasis, pulmonary aspergillosis, and *Clostridium difficile* colitis. To reduce immunosuppression, tacrolimus was discontinued. Insulin therapy and intermittent hemodialysis were started. Despite our efforts, he expired due to uncontrolled sepsis. Postmortem duodenal graft staining for CMV was positive, and confirmed the cause of the inciting ulcers.

Conclusions: Early detection of CMV disease even in the late post-transplant period is important especially with recurrent hematuria from duodenal graft ulcers. Even though CMV antigenemia may be negative, tissue biopsy should be obtained with initial cystoscopy. Moreover, presumptive treatment for CMV disease in a SPK recipient presenting with recurrent hematuria should be considered in this at-risk population.

PUB487

Role of Immune Cell Function Assay in Predicting Risk of BK Viremia in Pediatric Renal Transplant Recipients Wee Song Yeo,[1] Yew Weng Perry Lau,[1] Kar Hui Ng,[1,2] Ching Ching Seah,[2] Yiong Huak Chan,[2] Hui Kim Yap.[1,2] *[1]Shaw-NKF Children's Kidney Center, University Children's Medical Institute, National University Health System, Singapore; [2]Pediatrics, Yong Loo Lin School of Medicine, National University of Singapore, Singapore.*

Background: BK virus nephropathy is one of the significant causes of allograft dysfunction and graft loss in renal transplant recipients. Prompt diagnosis and early intervention in terms of immunosuppressant reduction is vital for optimal outcome. This study aims to determine the usefulness of the Cylex®ImmuKnow™ assay, an immune function assay based on measurement of intracellular adenosine triphosphate (ATP) levels, in predicting risk of BK viremia.

Methods: This is a prospective study involving 29 pediatric transplant recipients with 69 concomitant Cylex®ImmuKnow™ assay and plasma BK viral DNA quantification performed over the period from February 2010 to May 2011. BK viremia is defined as plasma viral titre >10,000 copies/ml. Statistical analysis was performed using Student's *t*-test to compare mean ATP values between BK viremic and non-BK viremic patients. Receiver-operating characteristic (ROC) curve analysis was used to determine the ATP threshold that would predict BK viremia.

Results: There were 5 episodes of BK viremia amongst these 29 patients. Mean ATP level was significantly lower during episodes of BK viremia as compared to episodes without BK viremia (213.8±51.6 ng/ml vs 463.2±197.4, respectively, $p<0.001$). Using ROC curve analysis, the area under the ROC curve was 0.93 (95% CI: 0.85 -1.00), and using a threshold ATP level <256.5 ng/ml gave a sensitivity of 80%, specificity of 87.5% for BK viremia. An ATP level <256.5 ng/ml also yielded a positive likelihood ratio of 6.4 (95% CI: 2.9-14.0) for BK viremia.

Conclusions: In conclusion, these results suggest over-immunosuppression as a contributing factor of BK viremia. Our results also suggest that adjustment of immunosuppression therapy towards a target ATP level >256.5 ng/ml may reduce the risk of developing BK viremia. Further prospective studies are, however, required to validate the above findings.

Screening of BK Viraemia and Nephropathy in Kidney Transplant Recipients Vivian W. Yiu, Rui Gao, Miriam Rose Berry, Yisu Yisu Gu, Afzal N. Chaudhry, Sharon Mulroy. *Nephrology, Addenbrookes Hospital, Cambridge, United Kingdom.*

Background: BK viraemia affects 15% of renal transplant recipient (8% develop nephropathy). A protocol to detect and treat BK viraemia was set up in our hospital.We aim to assess the effectiveness of the protocol on BK viraemia and graft outcome.

Methods: A database was set up from electronic and paper records on patients receiving a kidney transplant or simultaneous kidney-pancreas(SPK) graft from May 2009-Jan 2011.

Results: Of 263 transplant recipients,39(14.8%) developed BK viraemia. Baseline demographics of those with viraemia(Gp 1) and those without(Gp 2) were similar. Compliance with screening was 86%. Onset of viraemia was mostly between 5-20 wks. Risk factors for viraemia include Campath induction,a deceased donor, SPK graft, acute rejection(AR) and Mycophenolate(MMF) use. Urine testing was performed in 28% patients and biopsy in 40% patients with a high BK viral load(>10,000copies/ml). Immunosuppression reduction occurred in 50.0% of Gp1. The only additional treatment was Ciprofloxacin, used in 10.2%. 75.0% of Gp1 patients had more intense screening for 6 months after the resolution of viraemia. No patients died or lost their grafts as a result of BKV. Investigations beyond protocol requirements were performed in 19.0%.

Baseline characteristics

	BKV positive (gp 1)	BKV negative (gp 2)
Mean Age (yrs)	52.0	48.8
Gender (M:F)	30:9	143:81
Mean follow up (mths)	12.1	7.8
Kidney graft	31	188
SPK graft	8	34
Deceased donor	31	162
Live donor	8	62
0 AR	23	187
≥1 AR	16	37
Kidney recipients only:		
MMF immunosuppression	20	96
Azathioprine immunosuppression	11	92

Outcomes for Gp1

Mean onset of viraemia(wks)	14.4
Mean length of viraemia(wks)	14.1
BKV PCR>10,000copies/ml	20(51%)
Total biopsied	12(30.7%)
BK nephritis on biopsy	10(25.6%)
Decoy cells in urine	6(15.3%)
Median pre-viraemia creat (µmol/l)	140
Median Post viraemia creat (µmol/l)	144.5

Conclusions: Outcomes for patients with BK viraemia were good.The protocol was refined by reducing excess screening,starting intense screening for patients treated for AR and highlighting need for biopsy in those with high viral loads. Risk stratification can tailor screening for individual patients to improve efficiency and cost.

PUB489

Outcome of Renal Transplantation in Lupus Nephritis — Kuwait Expierience Narayanan Nampoory,[12345] Torkii Al-Otaibi,[12345] Praasad Nair,[12345] Nawas Nawas,[12345] Tarek Saeed,[12345] Medhat Haleem,[12345] Osama Gheith.[12345] *[1]Nephrology, OTC, Kuwait; [2]Nephrology, OTC, Kuwait; [3]Nephrology, OTC; [4]OTC, Kuwait; [5]OTC.*

Background: The major cause of morbidity and mortality in systemic lupus erythematosus (SLE) is Lupus Nephritis (LN). The outcome of renal transplantation in LN is a matter of concern especially with respect to the recurrence of the original disease in the allograft. The objective of this retrospective study is to determine the long term outcome of renal transplantation among lupus patients in Hamed Al-Essa Organ Transplant Centre of Kuwait

Results: Amongst 884 renal transplantations done in our centre between the year 1993 and 2008; 28 candidates (3%) were with LN. The clinical and laboratory data of these patients were reviewed for an average follow up period of six years and compared with age and sex matched controls (90 candidates).

Results: The recurrence of LN in the allograft was observed in 3 cases (10.7%). Serological flares of Lupus activity was noted in 2 patients (7%). The overall patient and graft survival rates on an average 6 years follow up was similar to the control group (100% and 89.3% Vs 100% and 90%). The graft rejection rates were found to be higher in the lupus group than the controls (53% Vs 33%,p<0.05) with the acute cellular rejection rates being significantly higher than the acute antibody mediated rejection (AMR) (35% Vs 24%,p<0.05) respectively. However, the Acute Antibody mediated rejection (AMR) rates were comparable (7.1% Vs 6.6).

Conclusions: The overall outcome of renal transplantation in LN is encouraging, especially with regard to the patient and graft survival rates as well as recurrence of the disease in the allograft.

PUB490

The Key to Successful Renal Transplantation in Patients with Sickle Cell Disease Sana R. Akbar,[1] Sadanand S. Palekar,[1] Ismael Ismael Shaukat,[2] Alice Joy Cohen.[2] *[1]Department of Renal and Pancreas Transplantation, Newark Beth Israel Medical Center, Newark, NJ; [2]Department of Hematology and Oncology, Newark Beth Israel Medical Center, Newark, NJ.*

Background: Renal failure in Sickle Cell Disease (SCD) occurs in 5-18% of patients and is associated with a poor prognosis. Survival of patients on hemodialysis(HD) has been shown to be equivalent to other nondiabetic ESRD patients.

Methods: We review a case in which an elderly patient with ESRD 2°to SCD underwent a successful renal transplant with no morbidity and mortality on follow up.

Results: A 69 year old African American male with SCD, homozygous for hemoglobin (Hb)S,HbF(1.2%) with ESRD on HD for 2 yrs underwent a living unrelated renal transplant. Prior to transplant he received routine HD followed by exchange transfusion with 6 Units of PRBCs to a preoperative hematocrit (HCT)of 30%.The Panel Reactive Antigen was 3% and it was a 2-2-2 mismatch transplant.Induction immunosuppression was with Daclizumab and Solumedrol.There was immediate graft function manifested by a good urine output.The maintenance immunosuppression consisted of Tacrolimus, prednisone and mycophenolate mofetil.He continued to receive simple transfusions post operatively to maintain HbS<30% then every 6 weeks for symptomatic anemia or Hb<6.5g/dl.Hydroxyurea was added to increase HbF levels and reduce transfusion requirement.The patient continues to do well one year post transplant with good allograft function.There have been no hospitalizations, episodes of vaso-occlusive crisis (VOC) or infections.

Conclusions: Sickle cell patients with ESRD rarely receive renal transplantation as a treatment modality.An increase in the frequency of VOC's has been demonstrated in patients who undergo renal transplantation.This appears to be due to increased blood viscosity stemming from endogenous hematopoiesis leading to VOC.To our knowledge,our patient is the oldest successful renal transplant recipient without evidence of VOC postoperatively. We recommend a protocol of pre-transplant exchange transfusion to a goal HCT of 30% with close follow-up of HbS along with concurrent use of Hydroxyurea to increase HbF levels thus reducing the frequency of crisis.

PUB491

Lower Dose of Mycophenolate Mofetil Is Enough for Rituximab Treated Renal Transplant Patients Chung Hee Baek,[1] Kyung Sun Park,[1] Duck Jong Han,[2] Jae Berm Park,[2] Tae Young Kim,[1] Su-Kil Park.[1] *[1]Internal Medicine, Asan Medical Center, Seoul, Republic of Korea; [2]Transplant Surgery, Asan Medical Center, Seoul, Republic of Korea.*

Background: Rituximab, anti-CD 20 antibody, enabled HLA-sensitized and ABO incompatible renal transplantations possible without splenectomy. As rituximab has a good suppressive effect on B lymphocytes, we would like to know the differences of the conventional immunosuppressive regimen without any harmful effect on graft in rituximab-treated patients compared to usual patients.

Methods: We investigated 69 patients who underwent rituximab treated (200 mg or 500 mg) living donor renal transplantation between January 2009 and March 2011 (group 1). The outcomes of seventy-two renal transplant recipients who did not require rituximab were compared as controls (group 2). All patients except 11 patients were treated with a combination of tacrolimus (FK506), mycophenolate mofetil (MMF) and methylprednisolone (mPD) after two doses of basiliximab for induction therapy in group 1.

Results: Graft survival was 98.3% in group 1 and 100% in group 2 (p=0.446). Renal function and incidence of infection including cytomegalovirus and BK virus were not significantly different between the two groups. Acute cellular rejection episodes occurred in 5.2% in group 1 and 9.7% in group 2 (p=0.511). Hyperacute rejection and antibody-mediated rejection episode was absent. The drug levels of FK506 and the doses of mPD after 1 year and 2 years after transplantation showed no difference between the two groups (p=0.237 and 0.625 at 1 year, p=1.000 and 0.667 at 2 years). The required dose of MMF (g/day, mean ± S.D.) was lower in rituximab-treated group post operative 1 month, 3 months, 6 months and 1 year (1.25 ± 0.45 g vs. 1.42 ± 0.39 g at 1 month; p=0.035, 1.15 ± 0.50 g vs. 1.38 ± 0.34 g at 3 months; p=0.006, 1.07 ± 0.51 g vs. 1.30 ± 0.42 g at 6 months; p=0.015, 0.92 ± 0.57 g vs. 1.22 ± 0.42 g at 1 year; p= 0.017).

Conclusions: These results suggest that lower dose of MMF is enough for successful immunosuppressive effect in rituximab-treated renal transplantation.

PUB492

Women Are Extremely Disproportionately Affected by High Panel Reactive Antibody Levels Prior to Kidney Transplantation Anthony J. Bleyer, Patricia L. Adams, Gregory B. Russell. *Nephrology, Wake Forest Medical School, Winston-Salem, NC.*

Background: High panel reactive antibody (PRA) levels are obstacles to kidney transplantation. The epidemiology of high PRA levels has not been well studied.

Methods: Data from the United Network of Organ Sharing on individuals placed on the transplant list for a first kidney transplant were analyzed from 1990 until 2010.

Results: 240,938 individuals between 18 and 60 yrs were placed on the waiting list. Women were 7.5 times(95% CI 6.99-7.94) more likely to have a high PRA (≥85%) than men. Of 7,721 individuals on the waiting list with high PRA levels , 6384 (82.3%) were women. Of 20,180 individuals with a medium PRA (15 to 85%), 13,253 (66%) were women. Table 1 shows the effect of pregnancy on PRA. Findings remained consistent after excluding individuals with sickle cell anemia, lupus, or transfusion history. In a multivariate logistic model with PRA (high vs. medium or low) as the outcome, odds ratios for variables associated with high PRA included gender (2.6 (95%CI 2.3-3.0)), 1 pregnancy vs. 0 (1.96 (1.7-2.3)), 2 pregnancies vs. 0 (2.9 (2.5-3.3)), 3 pregnancies vs. 0 (3.3 (2.9-3.8)), ≥4 pregnancies vs. 0 (3.8 (3.3-4.4)), sickle cell (3.0 (1.6-6.2)) lupus (2.1 (1.9-2.4)), African American race (1.2 (1.1-1.3)). Individuals with a high PRA were 1.8 times as likely not to receive a transplant (51.1% vs 28.5%, p<0.001) and 2.5 times more likely to be removed from the waiting list due to death or worsening health (33.1% vs. 13.6%, p<0.001).

Conclusions: Women are highly disproportionately affected with high PRA prior to kidney transplantation. High PRA individuals are much more likely not to receive a transplant or die while on the transplant list. Women at risk for end-stage kidney disease should be counseled about the effect of pregnancy on future transplant.

Early Versus Late Conversion to Sirolimus from Calcineurin Inhibitor Based Immunosuppression in Adult Kidney Transplant Recipients: A Single Center Retrospective Study Mariann D. Churchwell,[1] Rose Jung,[1] Shobha Ratnam.[2] *[1]Pharmacy Practice, University of Toledo,-College of Medicine, OH; [2]Medicine, University of Toledo-College of Medicine, OH.*

Background: To compare the efficacy and safety of conversion from calcineurin inhibitors in adult kidney transplant recipients to sirolimus as a component of their immunosuppression therapy.

Methods: We conducted a single center retrospective study of adult kidney transplant recipients who received initial immunosuppressive therapy with either cyclosporine (CYA) or tacrolimus (TAC) and were then switched to sirolimus (SIR) after 3-6 months (early conversion) or >6 months (late conversion) or remained on CYA or TAC. Patient

records were reviewed for patient demographics, medications, adverse reactions, graft rejection in addition to serum creatinine, urine protein and triglycerides for up to 5 years post transplant.

Results: We identified 220 adult kidney transplant recipients: CYA (n=73), TAC (n=70) and SIR (n=77) and mycophenolate as part of their immunosuppressive regimen. There was no difference in overall demographics between the three treatment groups. Patients receiving SIR were more likely to also receive HMG CoA Reductase Inhibitor (statin) compared to CYA and TAC patients (p=<0.0001). There was not a statistical difference in graft survival between patients converted from calcineurin inhibitors to SIR either early versus late (p= 0.83). The incidence of transplant rejection was not statistically different between the three groups (p=0.74) nor were the number of transplant failures between the groups (p=0.88). The adverse events included hypertriglyceridemia (p=0.12) and proteinuria (p=0.004) in the SIR converted patients as compared to those remaining on calcineurin inhibitors, but overall did not require a change in their immunosuppressive regimen.

Conclusions: From our single center experience we did not observe a statistical difference in the occurrence of rejection or graft failure in our adult kidney transplant recipients on a calcineurin inhibitor compared with those converted to sirolimus.

PUB494

Association of Marital Status with Access to Renal Transplantation Muhammad W. Khattak,[1] Gurprataap Singh Sandhu,[2] Bhanu K. Patibandla,[2] Akshita Narra,[2] Robert S. Woodward,[3] Alexander S. Goldfarb-Rumyantzev.[2] *[1]Hahnemann University Hospital Drexel University, Philadelphia, PA; [2]Division of Nephrology, Beth Israel Deaconess Medical Center and Harvard Medical Center, Boston, MA; [3]University of New hampshire.*

Background: Disparities in access to renal transplantation have been defined on the basis of age, race, gender and diabetic status. In this report we evaluated the association of marital status with access to renal transplantation.

Methods: We analyzed data from the USRDS. In patients with ESRD aged ≥27 (mean age of first marriage in the US), we analyzed the association of marital status with two outcomes: (1) likelihood of being placed on the waiting list for renal transplantation or first transplant, (2) likelihood of receiving kidney transplant in patients already listed. We analyzed marital status as a categorical variable: (1) not married (including never been married and widowed); (2) divorced or separated; and (3) currently married. Subgroups based on age, race, sex, donor type and diabetic status were also analyzed.

Results: After adjustments for the included independent variables and compared to individuals never married or widowed, those who were divorced/separated (HR 1.55, p < 0.001) and currently married (HR 1.54, p < 0.001) had a higher likelihood of being placed on the transplant waiting list. Once listed, married individuals had higher chances of getting transplanted as well (HR 1.28, p = 0.033). This trend was consistent in most of the subgroups studied.

Conclusions: We demonstrated that being married is associated with better access to renal transplantation compared to those who were never married/widowed.

PUB495

Hypotension Cured by Renal Transplant Sarath Kolluru, M.J. Barchman. *Nephrology and Hypertenstion, East Carolina University, Greenville, NC.*

Background: A 59 year old male with End Stage Renal Disease secondary to polycystic kidney disease who has been on hemodialysis for 5 years presented for deceased donor kidney transplant. Patient had bilateral nephrectomies four years prior due to uncontrolled bilateral flank pain caused by nephromegally. Before the bilateral nephrectomies, patient had a history of hypertension and took the medications of furosemide, diltiazem, and amlodipine.

Methods: At presentation for surgery in November 2006, his blood pressure was 158/92. Ever since the bilateral nephrectomies, patient has had very low blood pressures. The range for his blood pressure in clinic visits and hospital encounters during this time period range from systolic blood pressure of 80-97 and diastolic blood pressure of 52-65. Due to patient's hypotension, he has had multiple arterovenous graft complications including collapse and thrombosis requiring interventions on 5 separate occasions since his nephrectomies. Work up done by his primary nephrologist and ECU Cardiology determined that his hypotension was due to low renin levels. At the time of his renal transplant, patient's arteriovenous graft was nonfunctional and a tunneled catheter was serving as vascular access for hemodialysis.

Results: On presentation for kidney transplantation, his blood pressure was found to be 88/55. Patient claimed to be asymptomatic and denied complaints of lightheadedness, dizziness, weakness or blurry vision. There were no electrolyte abnormalities. The first postoperative day, patient's blood pressure was 107/59. On the sixth postoperative day it was 136/81. Six months after transplant, patient's blood pressure in clinic was 140/71.

Conclusions: Despite being dialysis dependant ESRD, kidneys continue to produce renin contributing to blood pressure. After removal of both kidneys, this patient developed hypotension from renin deficiency. His blood pressure was so low that long term vascular access was unsustainable. After receiving a kidney allograft, his blood pressure rose even prior to initiation of calcineurin inhibitors or any other agents known to cause elevated blood pressure. Normal blood pressure maintenance was reestablished after transplanting a new source of renin production.

PUB496

Affective Disorders among Patients on Different Renal Replacement Therapy Modalities: A Systematic Review Julio Lamprea,[1] Priscilla Auguste,[1] Patti Ephraim,[1] Deidra C. Crews,[1] Johanna Sheu,[1] Temitope Olufade,[1] Tanjala S. Purnell,[1] Raquel Greer,[1] Neil R. Powe,[2] Hamid Rabb,[1] L. Ebony Boulware.[1] *[1]Johns Hopkins Medical Institutions; [2]University of California, San Francisco.*

Background: The relation between patient's use of various renal replacement therapies (RRTs) and their development of affective disorders, has been poorly explored. We performed a systematic review of published studies to identify differences in rates of depressive and anxiety disorders among patients treated with different RRTs.

Methods: We searched Pubmed and performed a hand-bibliographic search to identify studies comparing rates of affective disorders among patients receiving different RRTs (hemodialysis-HD, peritoneal dialysis-PD and renal transplant-TX). Two reviewers abstracted outcome data and assessed article quality. We calculated standardized effect size estimates (cohen's d) of outcomes among patients on different RRTs. We considered effects with a p-value of less than 0.05 statistically significant.

Results: Among 91 studies identified as potentially relevant, 11 studies met the eligibility criteria. All studies had observational (cross-sectional) designs. Most studies reported outcomes based on validated questionnaires. However, no studies reported differences in outcomes while adjusting for potential confounders. A majority of studies (8 of 9) comparing patients on HD to patients on PD demonstrated no significant differences in rates of disorders, while most (5 of 7) studies comparing patients on HD to patients with a TX reported lower rates of disorders among patients on TX.

Table 1. Studies comparing clinical outcomes between RRT treatments

Outcome	Comparison	Number of studies	Treatment favored
Symptoms of anxiety	HD Vs PD	2	1 HD 1 Neither RRT
	HD Vs TX	2	2 TX
	PD Vs TX	1	1 Neither RRT
Symptoms of depression	HD Vs PD	5	5 Neither RRT
	HD Vs TX	4	3 TX 1 Neither RRT
	PD Vs TX	1	1 Neither RRT
Diagnosis of depression	HD Vs PD	2	2 Neither RRT
	HD Vs TX	1	1 Neither RRT

Conclusions: Cross-sectional studies suggest patients receiving transplants may have lower rates of affective disorders compared to patients on hemodialysis.However,the evidence is of variable quality, limiting definitive inferences. Prospective studies with well-balanced treatment groups are needed.

PUB497

Successful Renal Transplantation Despite Preexisting HLA-DQ or -DP Donor Specific Antibodies (DSA) Trung T. Luong,[1] Chantale Lacelle,[2] Bhavna A. Lavingia,[2] Meelie Debroy,[3] Juan Arenas,[3] Christopher Y. Lu.[1] *[1]Division of Nephrology; [2]Department of Pathology; [3]Division of Surgical Transplantation, all from UT Southwestern Medical Center, Dallas, TX.*

Background: The clinical significance of HLA-DQ and -DP DSA detected by single antigen Luminex beads remains unclear. The ability to transplant in the presence of preformed -DQ and -DP DSA may be advantageous for highly sensitized patients, however the risk of rejection versus the increased morbidity and mortality of remaining on the waitlist must be considered.

Methods: We followed 5 patients who received a kidney transplant in the presence of preformed HLA-DQ or -DP DSA from 07/2005 to 10/2010. We monitored their allograft function and DSA level using Luminex single antigen beads (One Lambda).

Results: The characteristics of the 5 kidney recipients transplanted in the presence of preformed HLA-DQ or -DP DSA and a positive B cell (pronase) flow cytometry crossmatch (FCXM) are shown in Table 1. No episodes of rejection were observed and all patients have had good allograft function.

Factors Predicting Graft and Patient Survival in Living Related Kidney Transplantation Pinaki Mukhopadhyay,[1] Manish Rathi,[2] Harbir Singh Kohli,[2] Vivekanand Jha,[2] Vinay Sakhuja.[2] *[1]Nephrology, NRS Medical College, Kolkata, West Bengal, India; [2]Nephrology, PostGraduate Institute of Medical Education and Research, Chandigarh, India.*

Background: Analysis of the factors affecting graft and patient survival in living donor kidney transplantation.

Methods: About 554 transplant recipient from Jan 2002 to Dec 2006 were studied retrospectively. Outcomes measures were overall patient and graft survival. Demographic, laboratory and perioperative variables were analyzed. Multivariate statistical analysis was undertaken using log-rank test and Cox's proportional hazards model.

Results: Of the 554 recipient 86.1% were male and 13.9% were female. The average recipient and donor age was 33.6 ± 10.3 and 42.36 ± 11.27 years. Recipient transplanted among related group76.4% and spouse 23.6% cases. Commonest primary diagnosis of ESRD was chronic glomerulonephritits(78.4%).Overall death censored graft survival at 1, 3 and 5 years were 94%, 90%, 79%. Mean time of graft loss was 33 ± 11.05 months (range 17-56 months). Commonest cause of graft loss was chronic allograft nephropathy (CAN) in 47.8 % . Significant factors predicting graft loss included episodes of rejection ($p < 0.001$), BKV infection ($p < 0.0001$), presence of CAN ($p= 0.06$). Overall patient survival at 1, 3, and 5 year was 92%, 87% and 83% respectively. Mean time to death was 18 ±19.05 months (range 0-76 months). Commonest cause of death was septicemia (66.7%). Significant factors predicting death were elderly recipient (≥ 50 year) ($p = 0.02$), unrelated transplant ($p =0.01$), presence of opportunistic infection ($p = 0.03$), CMV infection ($p < 0.0001$),disseminated fungal infection ($p = 0.002$), presence of multiple co-morbid illness ($p = 0.004$), post transplant hepatitis C infection ($p = 0.05$), pre-transplant diabetes ($p = 0.02$), Post transplant tuberculosis ($p = 0.03$).

Conclusions: Episodes of rejection, BKV infection, and presence of CAN were significant factors negatively impacting graft survival where as elderly age, opportunistic infection, CMV infection, disseminated fungal infection, diabetes, multiple co-morbid illness was independent prognostic factors of patient survival.

PUB499

Kidney Transplant Function after Early Conversion from Tacrolimus to Sirolimus in Mexican Patients Hildelisa Ordaz Solis,[1] M. Cecilia Fernandez-Luna,[1] Trinidad Orlando Lugo Lopez,[1] Benjamin Gomez-Navarro,[1] Alfonso M. Cueto-Manzano.[2] *[1]Nephrology and Organ Transplantation, IMSS, Hospital de Especialidades Centro Médico Nacional de Occidente, Guadalajara, Jalisco, Mexico; [2]Nephrology and Organ Transplantation, IMSS Hospital de Especialidades Centro Médico Naccional de Occidente, Guadalajara, Jalisco, Mali.*

Background: Currently, it is known that calcineurin inhibitor-free immunosuppression is safe after 6 months of kidney transplantation; however, there are few data about its use before that time. ***Aim:*** To evaluate the effect of early conversion from tacrolimus (TAC) to sirolimus (SIR) on graft function of kidney recipients.

Methods: Retrospective cohort of 72 Mexican patients with living-donor kidney transplant who were converted from TAC to SIR before 6 months after transplantation. All patients received prednisone and MMF. Clinical and biochemical variables were evaluated quarterly during 1 year of follow-up. Kidney function was evaluated as estimated glomerular filtration rate by means of the simplified MDRD formula. Urinary protein excretion was evaluated with 24-h collection.

Results: Sixty-one men and 11 women included with 3.7±1.1 months of transplantation at the time of conversion. Fifty-three percent had basiliximab induction. Before conversion, 87% had biopsy indicated by graft dysfunction (all biopsies documented TAC toxicity, additionally, 8% had acute rejection). After conversion, 62% had allograft biopsy showing acute rejection in 25% (80% of the latter diagnosed as borderline). Main results are shown in the table.

RESULTS

	PRECONVERSION	POSTCONVERSION	p
IMC	22.06 ± 3.48	21.93 ± 6.32	0.000
TAS	120 ± 12.7	122 ± 15	0.171
TAD	76 ± 9	75 ± 9	0.448
Leucocytes	7.77 ± 2.93	7.48 ± 2.09	0.277
Lymphocytes	1.99 ± 1.13	2.47 ± 1.27	0.040
Hb	12.8 ± 1.8	13.8 ± 1.8	0.000
Glucose	92.1 ± 17.7	84.2 ± 8.9	0.000
Urea	42.4 ± 19.9	35.5 ± 11.5	0.002
Creatinine	1.5 ± 0.4	1.3 ± 0.3	0.001
Cholesterol	177.5 ± 43.4	195.9 ± 34.5	0.033
Tryglicerides	178 (128 – 217)	173 (139 – 217)	0.606
MDRD	62.07 ± 18.09	71.52 ± 17.57	0.000
Proteinuria	240 (0 – 583)	500 (290 – 665)	0.007

Conclusions: Early conversion of TAC to SIR in patients with kidney transplantation is safe and improved kidney graft function.

PUB500

Expanded Criteria Donor Kidney Transplant Recipients: One Year Analyses from the Mycophenolic Acid Observational Renal Transplant Registry V. Ram Peddi,[1] Kimi Ueda Stevenson,[1] Kevin M. McCague,[2] Anne Wiland.[2] *[1]California Pacific Medical Center; [2]Novartis.*

Background: The Mycophenolic Acid Observational Renal Transplant (MORE) Registry, a prospective study of de novo renal transplant recipients (RTRs) receiving mycophenolic acid (MPA) therapy, is designed to determine effectiveness, tolerability and safety of enteric-coated mycophenolate sodium (EC-MPS) versus mycophenolate mofetil (MMF) regimens. The objective of this analysis was to compare 12-month outcomes in RTRs who received Expanded Criteria Donor (ECD) kidneys to RTRs who received non-ECD kidneys.

Methods: Based on local practices at 40 US sites, outcomes analyzed included: graft survival (GS), patient survival (PS), first biopsy-proven acute rejection (BPAR), adverse event (AE) rates, serum creatinine (SCr) and proportion of RTRs maintained on at least full recommended MPA dose (1.44/2.0 g/day, EC-MPS/MMF). A total of 102 ECD (73 EC-MPS/29 MMF) and 832 non-ECD (557 EC-MPS/275 MMF) RTRs were included.

Results: Donor (60.7 v. 39.0 yrs, $p=<0.01$) and recipient ages were higher (61.6 v. 50.1 yrs, $p=0.03$) in the ECD group. More African American RTRs received ECD kidneys (32.3 v. 23.6%, $p=0.07$). The majority of RTRs received induction therapy (99% ECD, 97% non-ECD), tacrolimus (97% ECD, 96% non-ECD) and steroids (69% ECD, 66% non-ECD) for maintenance therapy. At 1, 3, 6 and 12 months, more non-ECD RTRs received full MPA doses (non-ECD/ ECD: 78.2/ 71.0%, $p=0.12$; 67.4/ 53.6%, $p=0.01$; 51.9/ 42.3%, $p=0.14$; 45.7/41.0%, $p=0.50$). Comparable 12-month effectiveness, tolerability and safety outcomes were achieved in both groups whether they received EC-MPS or MMF. Comparing 12-month outcomes in ECD to non-ECD RTRs regardless of MPA type, BPAR (10.0/9.1%, $p=0.91$), GS (94.5/97.5%, $p=0.08$) and PS (98.8/98.9%) were similar whereas mean SCr (1.75/1.46 mg/dL, $p=<0.01$) was higher in the ECD RTRs. There were no differences in reported AEs (infections including BK and CMV, diabetes, gastrointestinal, neoplasms, hematological) between the groups.

Conclusions: Graft survival and BPAR were similar between RTRs who received ECD and non-ECD kidneys in the short-term. However, as expected, RTRs who received ECD kidneys exhibited higher mean SCrs.

PUB501

Impact of Substance Abuse on Access to Renal Transplantation Gurpratap Singh Sandhu,[1] Muhammad W. Khattak,[2] Bhanu K. Patibandla,[1] Akshita Narra,[1] Martha Pavlakis,[1] Noelle C. Dimitri,[3] Alexander S. Goldfarb-Rumyantzev.[1] *[1]Division of Nephrology, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA; [2]Hahneman Hospital, Drexel University, Philadelphia, PA; [3]Transplant Institute, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: With an ever-increasing demand for kidneys and limited supply pool, it is essential to understand the balance between utility and equity in transplant access. The goal of this project was to evaluate the association between recipient's substance abuse and renal transplant access in patients with end-stage renal disease (ESRD).

Methods: We used data from the United States Renal Data System. The primary variables of interest were abuse of alcohol, tobacco, or illicit drugs based on information from Centers for Medicare & Medicaid Services form 2728. We analyzed three outcomes in Cox model: (1)being placed on the waiting list for renal transplantation or transplanted (whichever occurred first); (2)first transplant in patients who were placed on the waiting list; and (3) graft loss or mortality after transplant. In addition, we performed subgroup analysis based on age, race, sex, diabetic status, and donor type.

Results: We analyzed 1,077,699 patients (age of ESRD onset 62.9±15.5 years, 54.1% males, 64.2% white, and 29.7% African American). When compared with those with no substance abuse, abusing all three substances was associated with reduced transplant

access (hazard ratio 0.39, P<0.001 for wait listing/transplant; hazard ratio 0.67, P=0.019 for transplant). This trend was similar in most subgroups studied.

Conclusions: We demonstrated that patients with ESRD abusing or dependent on tobacco, alcohol, or illicit drugs are less likely to be placed on the waiting list for kidney transplant; and once on the list are less likely to be transplanted. The possible utility justifications for such disparity and potential interventions are discussed.

PUB502

Renal Transplantation from HBs Antigen Positive Donor to Antigen Negative Recipient Immunized with Intradermal Hepatitis B Vaccine: First American Experience Gurmukteshwar Singh, Andrea C. Hsia, Daniel Skiest, Michael J. Germain, Gregory Lee Braden. *Baystate Medical Center/ Tufts University School of Medicine, Springfield, MA.*

Background: The US renal transplant waiting list has 88,972 patients & grows by 4200 every year. Donor pool expansion is imperative to meet the demand-supply mismatch. Inclusion of HBs antigen positive (HBsAg+) donors has been recommended in endemic countries. We present the first American case of a successful HBsAg+ renal transplant into a newly immunized recipient.

Methods: May 2000: A 58 year-old man with mesangiocapillary glomerulonephritis needed pre-emptive renal transplant. His wife was a living unrelated donor match. She had chronic hepatitis B, was HBsAg+ with positive anti-HBc antibody. She had normal liver function & was HBe antigen negative & had undetectable Hepatitis B DNA (HBV DNA).

The recipient (negative for all hepatitis antigens & antibodies) did not mount an antibody response to 3 doses of monthly intramuscular recombinant hepatitis B vaccine (40 mcg). Intra-dermal vaccine was administered (5 mcg) every 2 weeks for 6 months. By the 4th dose, anti-HBs antibody titers reached immune levels (>10 mIU/mL). After the intradermal course, his antibody titer was 160 mIU/mL. This tapered to <10 mIU/mL at 14 months. An intramuscular vaccine booster (40mcg) resulted in an anamnestic response with titer >150 mIU/mL in a month. The patient underwent a successful living-unrelated donor transplant from his wife in August 2002 utilizing prednisone, mycophenolate mofetil & tacrolimus.

Results: Over 9 years, the patient had no evidence of hepatitis B infection. Anti-HBs antibodies slowly declined to 5.8 mIU/mL in May 2011. He has continued to be HBsAg negative with undetectable HBV DNA. Allograft function has been well preserved with a 24 hour creatinine clearance of 78.4 mL/min in December 2010. Immunosuppression was switched to prednisone+ sirolimus 3 years post-transplant.

Conclusions: Our successful long-term experience, using intradermal Hepatitis B vaccination with booster doses led to sustained anti-HBs antibody response allowing transplantation from a HBsAg+ donor. Larger studies are warranted given this strategy's potential to expand the US donor pool.

PUB503

Transient Elastography To Assess Hepatic Fibrosis in Renal Transplant Recipients Claudia Sommerer,[1] Christoph Seitz,[1] Michael Scharf,[1] Gunda Millonig,[2] Martin G. Zeier,[1] Sebastian Mueller.[2] *[1]Nephrology, University Hospital Heidelberg, Heidelberg, Germany; [2]Internal Medicine, Salem Medical Center, Heidelberg, Germany.*

Background: Transient elastography (TE) is a nonivasive, reliable and valide tool for the assessment of hepatic fibrosis. There are some limitations in certain patient groups, for example in patients with ascites or increased central venous pressure. Until now, TE has not been evaluated in renal allograft recipients. We evaluated TE in renal allograft recipients, a patient cohort who often shows hypervolemia and high central venous pressure especially in the early posttransplant period.

Methods: In 109 renal transplant patients liver stiffness measurement (LSM) was performed by transient elastography (TE). The severity of hepatic fibrosis was staged by Forns-Index.

Results: In 91/109 patients (n=29 women, age 47±8 years, 68±59 months post transplantation, BMI 25.5±3.7 kg/m²) it was possible to assess hepatic fibrosis by TE. The mean stiffness was 7.2±3.5 kPa with a mean interquartile range (IQR) of 0.9 kPa. TE and Forns-Indices correlated significantly (p=0.002) with an area under the ROC curve of 0.722. The sensitivity and specificity for detection of fibrosis was 34% and 92% with a cut-off of 8 kPa. Failure of LSM occurred in 61% of the patients with BMI > 28 kg/m². Liver stiffness was significantly higher in the early post-transplant period (p<0.05) indicating significant influence of hypervolemia on the assessment of liver stiffness by TE.

Conclusions: TE might be a rapid, non-invasive tool to assess and identify renal allograft recipients with liver fibrosis. However, several confounders including obesity and hypervolemia leading to increased central venous pressure have to be considered.

PUB504

Management of Transplanted Patients Stage 3B and 4 in France. ANTICIPE Study Paul Stroumza, Malik Touam, Eric Daugas, Georges J. Mourad, Patrick Henri, Bertrand Dussol. *Scientific Council, Amgen, France.*

Background: Describe the follow-up of renal transplanted patients in stage 3b and 4 in France

Methods: During one week of consultations for grafted patients, in a national, prospective and observational study conducted among nephrologists , we recruited 1497 patients. After exclusion of incomplete records or improperly included, we studied 1446 patients. 546 patients with renal insufficiency were on stages 3b and 4 (GFR Cockcroft-Gault).

Results: Age 52,8 + / - 13,8, 60% men, 40% women, weight 70,9kg + / - 14,4, height 167,9 cm + / -9,6, BMI <25kg/cm ²: 53,8% between 25 and 30: 33.6%, Blood pressure 138/78.9 + / -18 and + / -11.3. Initial nephropathy was: Glomerular 1st 26,8%, glomerular 2nd 5,4%, diabetic7,4% , tubulointerstitial 12,4%, vascular 10,1%, polycystic 14,4%, other 11,3% and 12,4% undetermined. Time between transplantation and the study was 1 year to 14.7%, from 2 to 3 years for 24.5%, 4 to 5 years 16.7% ,higher than 10 years to 21.9%. Before the graft: 85.7% were hypertensive, 13.7% diabetics and 69.8% never smokers. In the history, we found 13,4% of ischemic heart disease, 7% heart failure, 3.3% for stroke. 92.1% of patients were on dialysis (HD 85.5%) before transplantation. The average time between first dialysis and transplantation was 3.9 years. The graft is 94,5% of deceased donors, living 4,4%, 1,1% cœur arrested. Only 0.9% of bi-transplantation. HLA mismatch was: 0: 2,6%, 1: 8,9%, 2: 8,9%, 3: 23,9%, 4: 25,8%, 5: 66%, > 5: 6,7%. Cold ischemia was <6 hours: 4,4%,> 24 hours: 21,3%. 23.4% of patients were dialyzed after transplantation. 24.1% had a rejection and 1.9% had more than 2. Among the complications related to transplantation, we have: 33,9% of hospitalized patients over 7 days for infections. The treatment is 65.9% corticosteroids, 87.5%, calcineurin inhibitors 10.8% azathioprine, 73.4%, mycophenolate mofetil, 9,7%, inhibitor of mTOR: another immunosuppressive 1,3 %. Other treatments are: 80% antihypertensive non RAS blockers and 59,5%, blockers, 29,9% ESA, 59.7% statins, 44.1% vitamin D.

Conclusions: Nephrological monitoring of 147 investigators was used to develop this photograph of the transplanted patients stage 3b and 4 .

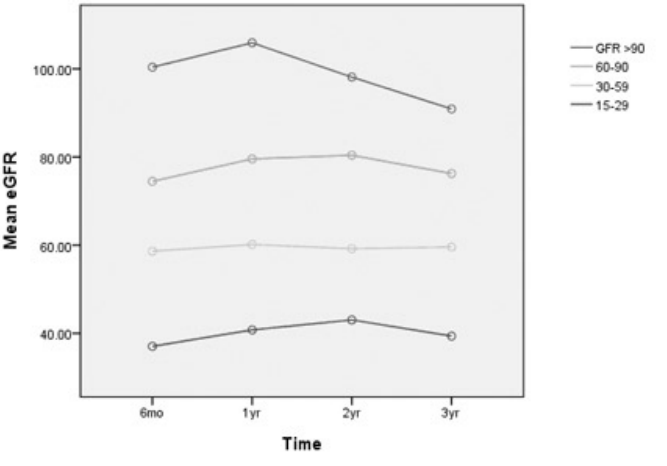
Three-Year Graft Function Is Preserved in the Absence of Rejection or Delayed Graft Function Fasika M. Tedla, Amarpali Brar, Angella Brown, Thin Maw, Subodh J. Saggi, Moro O. Salifu. *Renal Diseases Division, Department of Medicine, SUNY Downstate Medical Center, Brooklyn, NY.*

Background: It is generally accepted that hyperfiltration results in progressive renal damage in native kidneys. Although graft function generally deteriorates over time, the natural course of progression in renal transplant recipients (RTRs) at different levels of renal function has not been studied longitudinally in patients free of acute rejection (AR) or delayed graft function (DGF). We conducted a single-center study of graft function over a three-year period in patients that did not have AR or DGF.

Methods: 275 patients were classified into stages of chronic kidney disease (CKD) based on serum creatinine at six weeks after transplant. Glomerular filtration rate (GFR) was estimated using the abbreviated MDRD formula at 6 weeks (6wk), 6 months (6m), and 1, 2, and 3 years (1yr, 2yr, 3yr). Temporal change in mean eGFR across and within CKD stages was analyzed using repeated-measures ANOVA. CKD stages were compared for other variables by ANOVA, t-test or χ^2 as appropriate.

Results: 123 of 275 RTRs had complete data at 3yr. The mean eGFR of stages 1-4 CKD at 6 weeks were 111, 74, 46 and 21 ml/min. The groups were similar in mean age, hemoglobin, albumin, blood pressure at baseline (6wks) and tacrolimus levels at all time points. There was no significant difference in number of total or HLA DR mismatch, or proportion of African-Americans, retransplants, diabetics, or positive flow-cytometry crossmatches. Female RTRs had higher eGFR than male RTRs at all time points (mean difference 17-21 ml/min, p<0.001). There was no significant change in mean eGFR in each CKD stage over 3 years (p=0.34)



Conclusions: In the absence of AR or DGR, graft function remained stable over three years irrespective of baseline eGFR.

Treatment Strategy for BK Nephropathy in Renal Transplant Recipients: Five Years Follow Up Ying Wang,[1] Mona Razavian,[2] Kate Wyburn,[1] Josette M. Eris,[1] Steven J. Chadban.[1] *[1]Renal Medicine, Royal Prince Alfred Hospital, NSW, Australia; [2]Renal Medicine, Concord Repatriation General Hospital, NSW, Australia.*

Background: BK nephropathy (BKN) is a significant cause of graft loss. There is no single defined treatment algorithm established and usual management consists of a substantial reduction in immunosuppression.

Methods: We retrospectively investigated renal transplant recipients with biopsy proven BKN in our centre from 2003 to 2011. They were followed up over 1-8 years after treatment with a protocol of reduction in immunosuppression and intravenous cidofovir, with or without ciprofloxacin or leflunomide.

Results: 7 cases of BKN were diagnosed with incidence of 1 %.

Demographic characteristics of the patients with BKN

Age&gender	Months post-Tx	Additinal BKN Therapy	Outcome
60M	9	Cipro	Recovery
40M	17	Cipro	Graft loss
81M	16	Cipro	Graft loss
35M	7	No	Recovery
62M	32	LEF&IVIG	Graft loss
53M	2	LEF	Recovery
65M	3	Cipro	Recovery

All were male and 6 had received treatment for acute rejection prior to the diagnosis. The median time to diagnosis was 10 months post transplantation. A reduction in immunosuppression and commencement of cidofovir as an initial treatment strategy were applied to all cases. In addition, 4 patients received ciprofloxacin 250 mg daily concurrently. 2 out of 7 patients were switched from mycophenolate to leflunomide after failure to respond to the initial therapy. 1 patient received intravenous immunoglobulin. The median follow-up was 5.1 years after the treatment. Of 7 patients, 4 showed sustained clinical and virological improvement while 3 incurred graft loss, one due to ongoing BK nephropathy. Two graft losses occurred after a reduction in viral load and initial improvement in graft function: one due to transplant artery thrombosis and one due to rejection following non-adherence to immunosuppression. An overall BK nephropathy related graft loss was 14.3%.

Conclusions: BK nephropathy in renal transplant setting remains a serious complication. Reducing immunosuppression and administration of cidofovir produced sustained remissions for the majority of our cases, however, the optimal therapeutic strategy remains unclear and warrants prospective randomized studies.

A Positive Flow Cross Match in HIV Patients May Not Necessitate Desensitization Sana R. Akbar,[1] Sadanand S. Palekar,[1] Prakash N. Rao,[2] Cecil L. Rhodes.[2] *[1]Department of Renal and Pancreas Transplantation, Newark Beth Israel Medical Center, Newark, NJ; [2]Laboratory Operations and Business Development, NJ Tissue and Organ Sharing Network, New Providence, NJ.*

Background: Renal transplantation in HIV positive patients is becoming common place. Advances in the patho-physiology and treatment of HIV have made it possible for these individuals with end stage renal disease, to undergo successful renal transplantation. Solid phase antibody testing, and donor specific cross-matching by complement dependent cytotoxicity (CDC) and flow cytometry (FCXM) enable the assignment of risk, and determination of the necessity for desensitization therapy with intravenous immunoglobulin or plasmapheresis.

Methods: We would like to report on a series of three HIV positive recipients being evaluated for possible living donor renal transplants.

Results: All three patients had a PRA of < 20%. Solid phase antibody testing revealed the presence of a few HLA antibodies, none of which were donor specific. Upon testing all recipients demonstrated positive T and B cell flow cross-matches with their donors. Positive Flow cytometric auto cross-match testing indicated the presence of auto-antibodies. These results would indicate that the initial donor specific positive flow cytometry cross-matches were caused by auto-antibodies.

Conclusions: Therefore, though the preliminary FCXM made these 3 patients appear to be incompatible with their donors, the autocross match revealed otherwise. Our study would suggest that the presence of positive donor specific flow cross-match in HIV positive recipients should not automatically impute a high risk situation requiring desensitization protocols. These patients can indeed be successfully transplanted without the need for desensitization.

Effective Therapy for Resistant Acute Antibody-Mediated Rejection: Case Report and Review of Literature Narayanan Nampoory,[12345] Torkii Al-Otaibi,[12345] Osama Gheith,[12345] Medhat Haleem,[12345] Praasad Nair.[12345] *[1]OTC , Kuwait; [2]OTC , Kuwait; [3].*

Background: In an effort to reduce the long-term toxicities of immunosuppressant drugs, corticosteroid and calcineurin inhibitor (CNI) sparing immunosuppression protocols have become increasingly popular in managing kidney transplant recipients. The most vexing clinical condition caused by antibodies in organ transplants is antibody-mediated rejection.Limitations of the current AMR therapies include (1) AMR reversal tends to be gradual than prompt, (2) expense, (3) rejection reversal rates below 80%,(4) common appearance of chronic rejection after AMR treatment, and (5) long-term persistence of donor specific antibodies after therapy. Since these limitations may be due to the lack of effects on mature plasma cells, bortezomib's effects on mature plasma cells may represent a quantum advance in anti-humoral therapy.

The initial experience described herein represented the first clinical use of bortezomib as an anti-humoral agent in renal allograft recipients in Kuwait. We aimed to present 2 cases with resistant acute antibody mediated rejection to the standard therapies, and were managed successfully with bortezomib therapy.

Methods: Therefore, we were confronted by two cases of resistant acute antibody mediated rejection with mild chronic changes. The available therapies for antibody mediated rejection lack direct effects on the major antibody producing cell (the mature plasma cell).

Results: Although B lymphocyte specificity has been provided with rituximab, yet it does not deplete plasmablasts or mature plasma cells, which represent the major source of antibody production [(4)]. Each case was managed by one cycle of bortezomib with partial response and satisfactory 1-year graft survival in spite of sustained anti-HLA antibodies.

Conclusions: Immunosuppression minimization carried risk of resistant acute antibody mediated rejection and renal grafts can be rescued by earlier bortezomib use especially in the absence of chronic changes.
